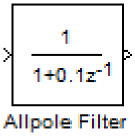
Allpole Filter

Model allpole filters

Library

Filtering / Filter Implementations

dsparch4



Description

The Allpole Filter block independently filters each channel of the input signal with the specified allpole filter. The block can implement static filters with fixed coefficients, as well as time-varying filters with coefficients that change over time. You can tune the coefficients of a static filter during simulation.

This block filters each channel of the input signal independently over time. The **Input processing** parameter allows you to specify whether the block treats each element of the input as an independent channel (sample-based processing), or each column of the input as an independent channel (frame-based processing).

This block supports the Simulink® state logging feature. See “States” in the *Simulink User's Guide* for more information.

Filter Structure Support

You can change the filter structure implemented with the Allpole Filter block by selecting one of the following from the **Filter structure** parameter:

- `Direct form`
- `Direct form transposed`
- `Lattice AR`

Specifying Initial States

The Allpole Filter block initializes the internal filter states to zero by default, which has the same effect as assuming that past inputs and outputs are zero. You can optionally use the **Initial states** parameter to specify nonzero initial conditions for the filter delays.

To determine the number of initial states you must specify and how to specify them, see the table on valid initial states. The **Initial states** parameter can take one of the forms described in the next table.

Valid Initial States

Initial Condition	Description
Scalar	The block initializes all delay elements in the filter to the scalar value.
Vector or matrix (for applying different delay elements to each channel)	Each vector or matrix element specifies a unique initial condition for a corresponding delay element in a corresponding channel: • The vector length equals the product of the number of input channels and the number of delay elements in the filter, `#_of_filter_coeffs-1` (or `#_of_reflection_coeffs` for `Lattice AR`). • The matrix must have the same number of rows as the number of delay elements in the filter, `#_of_filter_coeffs-1` (`#_of_reflection_coeffs` for `Lattice AR`), and must have one column for each channel of the input signal.

Data Type Support

The Allpole Filter block accepts and outputs real and complex signals of any numeric data type supported by Simulink. The block supports the same types for the coefficients.

The following diagrams show the filter structure and the data types used within the Allpole Filter block for fixed-point signals.

Direct Form

You cannot specify the state data type on the block mask for this structure because the output states have the same data types as the output.

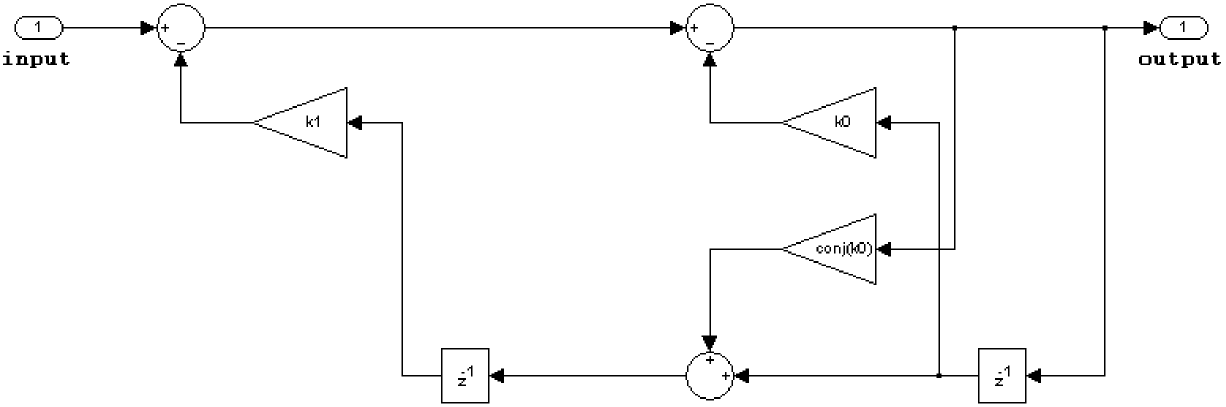
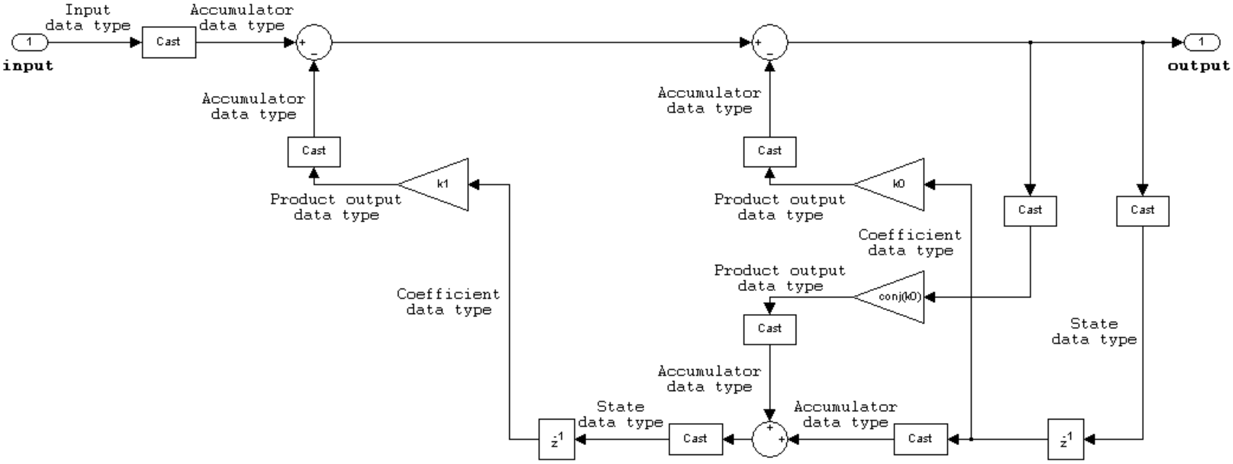
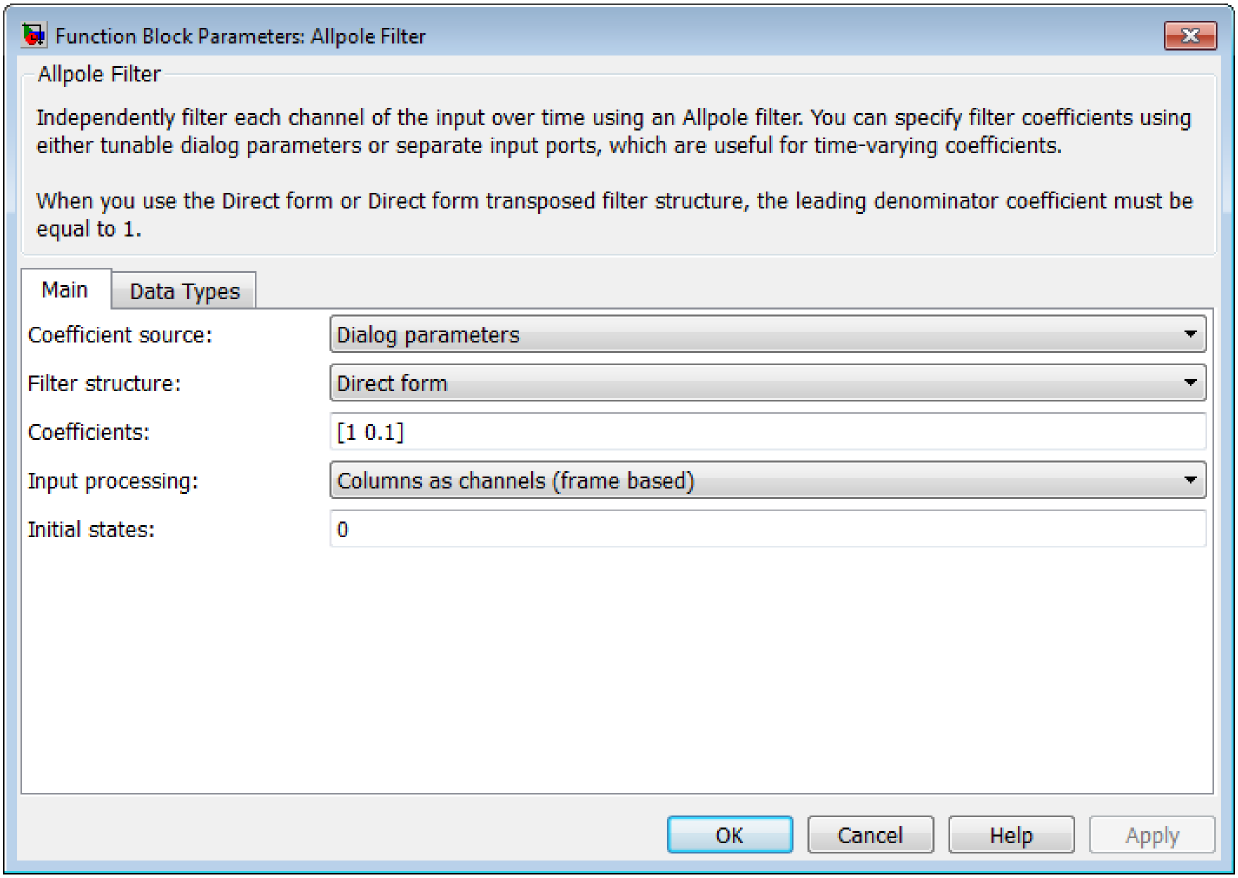
Lattice AR





Parameters and Dialog Box

The **Main** pane of the Allpole Filter block dialog box appears as follows.



Allpole Filter

Independently filter each channel of the input over time using an Allpole filter. You can specify filter coefficients using either tunable dialog parameters or separate input ports, which are useful for time-varying coefficients.

When you use the Direct form or Direct form transposed filter structure, the leading denominator coefficient must be equal to 1.

Coefficient source: Dialog parameters

Filter structure: Direct form

Coefficients: [1 0.1]

Input processing: Columns as channels (frame based)

Initial states: 0

Coefficient source

Select whether you want to specify the filter coefficients on the block mask or through an input port.

Filter structure

Select the filter structure you want the block to implement. You can select `Direct form`, `Direct form transposed`, or `Lattice AR`.

Coefficients

Specify the row vector of coefficients of the filter's transfer function.

This parameter is visible only when you set the **Coefficient source** to `Dialog parameters`.

Input processing

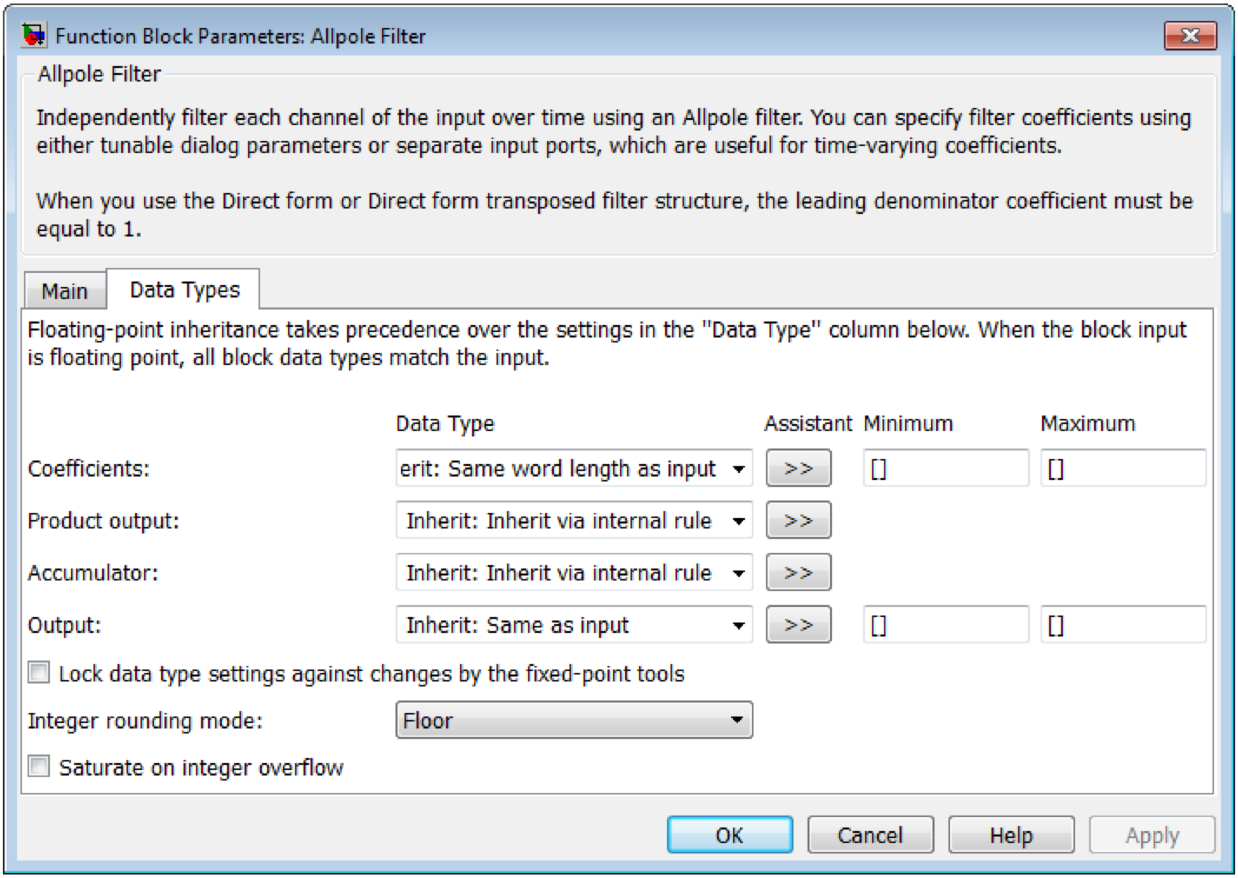
Specify whether the block performs sample- or frame-based processing. You can select one of the following options:

- `Elements as channels (sample based)` — Treat each element of the input as an independent channel (sample-based processing).
- `Columns as channels (frame based)` — Treat each column of the input as an independent channel (frame-based processing).

Initial states

Specify the initial conditions of the filter states. To learn how to specify initial states, see "Specifying Initial States" on page 1-3.

The **Data Types** pane of the Allpole Filter block dialog box appears as follows.



Allpole Filter

Independently filter each channel of the input over time using an Allpole filter. You can specify filter coefficients using either tunable dialog parameters or separate input ports, which are useful for time-varying coefficients.

When you use the Direct form or Direct form transposed filter structure, the leading denominator coefficient must be equal to 1.

Floating-point inheritance takes precedence over the settings in the "Data Type" column below. When the block input is floating point, all block data types match the input.

	Data Type	Assistant	Minimum	Maximum
Coefficients:	erit: Same word length as input	>>	[]	[]
Product output:	Inherit: Inherit via internal rule	>>		
Accumulator:	Inherit: Inherit via internal rule	>>		
Output:	Inherit: Same as input	>>	[]	[]

□ Lock data type settings against changes by the fixed-point tools

Integer rounding mode: Floor

□ Saturate on integer overflow

Coefficients

Specify the coefficient data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same word length as input`
- A built-in integer, for example, `int8`
- A data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Coefficient** parameter.

See “Specify Data Types Using Data Type Assistant” for more information.

Coefficients minimum

Specify the minimum value that a filter coefficient should have. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Check Parameter Values”)
- Automatic scaling of fixed-point data types

Coefficients maximum

Specify the maximum value that a filter coefficient should have. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Check Parameter Values”)
- Automatic scaling of fixed-point data types

Product output

Specify the product output data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`
- A built-in data type, for example, `int8`
- A data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Product output** parameter.

See “Specify Data Types Using Data Type Assistant” for more information.

Accumulator

Specify the accumulator data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`

- A built-in data type, for example, `int8`
- A data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Accumulator** parameter.

See “Specify Data Types Using Data Type Assistant” for more information.

State

Specify the state data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as accumulator`
- A built-in integer, for example, `int8`
- A data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

This parameter is only visible when the selected filter structure is `Lattice MA`.

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **State** parameter.

See “Specify Data Types Using Data Type Assistant” for more information.

Output

Specify the output data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as accumulator`
- A built-in data type, for example, `int8`
- A data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Output** parameter.

See “Specify Block Output Data Types” in the “Simulink User's Guide” for more information.

Output minimum

Specify the minimum value that the block should output. The default value is [ ] (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see "Signal Ranges")
- Automatic scaling of fixed-point data types

Output maximum

Specify the maximum value that the block should output. The default value is [ ] (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see "Signal Ranges")
- Automatic scaling of fixed-point data types

Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

Integer rounding mode

Specify the rounding mode for fixed-point operations.

Saturate on integer overflow

Action	Reasons for Taking This Action	What Happens for Overflows	Example
Select this check box.	Your model has possible overflow and you want explicit saturation protection in the generated code.	Overflows saturate to either the minimum or maximum value that the data type can represent.	An overflow associated with a signed 8-bit integer can saturate to -128 or 127.
Do not select this check box.	You want to optimize efficiency of your generated code. You want to avoid overspecifying how a block handles out-of-range signals. For more information, see "Checking for Signal Range Errors".	Overflows wrap to the appropriate value that is representable by the data type.	The number 130 does not fit in a signed 8-bit integer and wraps to -126.

When you select this check box, saturation applies to every internal operation on the block, not just the output or result. In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Supported Data Types

- Double-precision floating point
- Single-precision floating point
- Fixed point
- 8-, 16-, and 32-bit integers

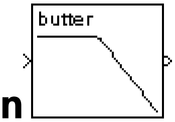
Analog Filter Design

Design and implement analog filters

Library

Filtering / Filter Implementations

`dsparch4`



Description

The Analog Filter Design block designs and implements a Butterworth, Chebyshev type I, Chebyshev type II, or elliptic filter in a highpass, lowpass, bandpass, or bandstop configuration.

The input must be a sample-based, continuous-time, real-valued, scalar signal.

The design and band configuration of the filter are selected from the **Design method** and **Filter type** pop-up menus in the dialog box. For each combination of design method and band configuration, an appropriate set of secondary parameters is displayed.

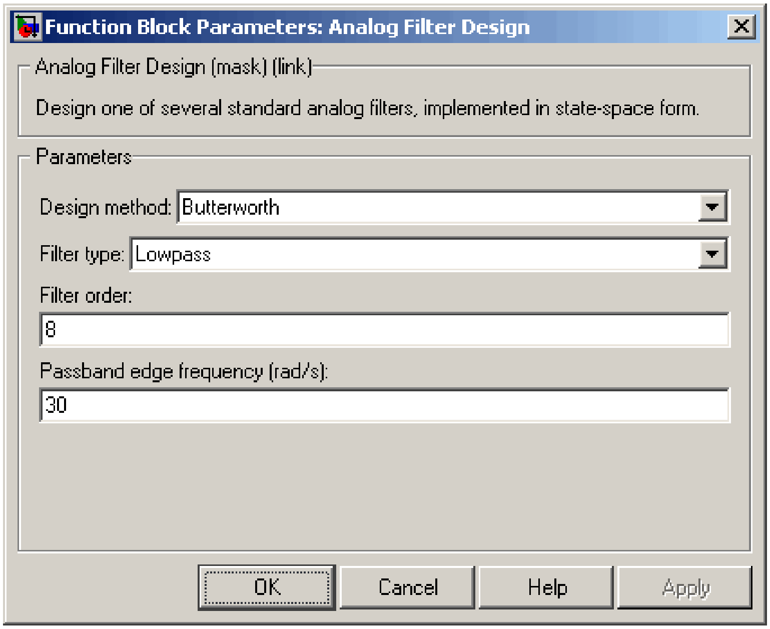
Filter Design	Description
`Butterworth`	The magnitude response of a Butterworth filter is maximally flat in the passband and monotonic overall.
`Chebyshev type I`	The magnitude response of a Chebyshev type I filter is equiripple in the passband and monotonic in the stopband.
`Chebyshev type II`	The magnitude response of a Chebyshev type II filter is monotonic in the passband and equiripple in the stopband.
`Elliptic`	The magnitude response of an elliptic filter is equiripple in both the passband and the stopband.

The following table lists the available parameters for each design/band combination. For lowpass and highpass band configurations, these parameters include the passband edge frequency Ω_p, the stopband edge frequency Ω_s, the passband ripple R_p, and the stopband attenuation R_s. For bandpass and bandstop configurations, the parameters include the lower and upper passband edge frequencies, Ω_p1 and Ω_p2, the lower and upper stopband edge frequencies, Ω_s1 and Ω_s2, the passband ripple R_p, and the stopband attenuation R_s. Frequency values are in rad/s, and ripple and attenuation values are in dB.

	Lowpass	Highpass	Bandpass	Bandstop
Butterworth	Order, Ω_p	Order, Ω_p	Order, Ω_p1, Ω_p2	Order, Ω_p1, Ω_p2
Chebyshev Type I	Order, Ω_p, R_p	Order, Ω_p, R_p	Order, Ω_p1, Ω_p2, R_p	Order, Ω_p1, Ω_p2, R_p
Chebyshev Type II	Order, Ω_s, R_s	Order, Ω_s, R_s	Order, Ω_s1, Ω_s2, R_s	Order, Ω_s1, Ω_s2, R_s
Elliptic	Order, Ω_p, R_p, R_s	Order, Ω_p, R_p, R_s	Order, Ω_p1, Ω_p2, R_p, R_s	Order, Ω_p1, Ω_p2, R_p, R_s

The analog filters are designed using the filter design commands in Signal Processing Toolbox™ software's `buttap`, `cheb1ap`, `cheb2ap`, and `ellipap` functions, and are implemented in state-space form. Filters of order 8 or less are implemented in controller canonical form for improved efficiency.

Dialog Box



Function Block Parameters: Analog Filter Design

Analog Filter Design (mask) (link)

Design one of several standard analog filters, implemented in state-space form.

Parameters

Design method: Butterworth

Filter type: Lowpass

Filter order: 8

Passband edge frequency (rad/s): 30

The parameters displayed in the dialog box vary for different design/band combinations. Only some of the parameters listed below are visible in the dialog box at any one time.

Design method

The filter design method: `Butterworth`, `Chebyshev type I`, `Chebyshev type II`, or `Elliptic`. “Tunable”.

Filter type

The type of filter to design: `Lowpass`, `Highpass`, `Bandpass`, or `Bandstop`. “Tunable”.

Filter order

The order of the filter, for lowpass and highpass configurations. For bandpass and bandstop configurations, the order of the final filter is *twice* this value.

Passband edge frequency

The passband edge frequency, in rad/s, for the highpass and lowpass configurations of the Butterworth, Chebyshev type I, and elliptic designs. “Tunable”.

Lower passband edge frequency

The lower passband frequency, in rad/s, for the bandpass and bandstop configurations of the Butterworth, Chebyshev type I, and elliptic designs. “Tunable”.

Upper passband edge frequency

The upper passband frequency, in rad/s, for the bandpass and bandstop configurations of the Butterworth, Chebyshev type I, or elliptic designs. “Tunable”.

Stopband edge frequency

The stopband edge frequency, in rad/s, for the highpass and lowpass band configurations of the Chebyshev type II design. “Tunable”.

Lower stopband edge frequency

The lower stopband edge frequency, in rad/s, for the bandpass and bandstop configurations of the Chebyshev type II design. “Tunable”.

Upper stopband edge frequency

The upper stopband edge frequency, in rad/s, for the bandpass and bandstop filter configurations of the Chebyshev type II design. “Tunable”.

Passband ripple in dB

The passband ripple, in dB, for the Chebyshev Type I and elliptic designs. “Tunable”.

Stopband attenuation in dB

The stopband attenuation, in dB, for the Chebyshev Type II and elliptic designs. “Tunable”.

Analytic Signal

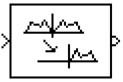
Compute analytic signals of discrete-time inputs

Library

Transforms

`dspxfrm3`

Description



The Analytic Signal block computes the complex analytic signal corresponding to each channel of the real M-by-N input, u

$$y = u + jH\{u\}$$

where $j = \sqrt{-1}$ and $H\{\}$ denotes the Hilbert transform. The real part of the output in each channel is a replica of the real input in that channel; the imaginary part is the Hilbert transform of the input. In the frequency domain, the Fourier transform of the analytic signal doubles the positive frequency content of the original signal while zeroing-out negative frequencies and retaining the DC component.

The block computes the Hilbert transform using an equiripple FIR filter with the order specified by the **Filter order** parameter, n. The linear phase filter is designed using the Remez exchange algorithm, and imposes a delay of $n/2$ on the input samples.

The output has the same dimensions as the input.

Frame-Based Processing

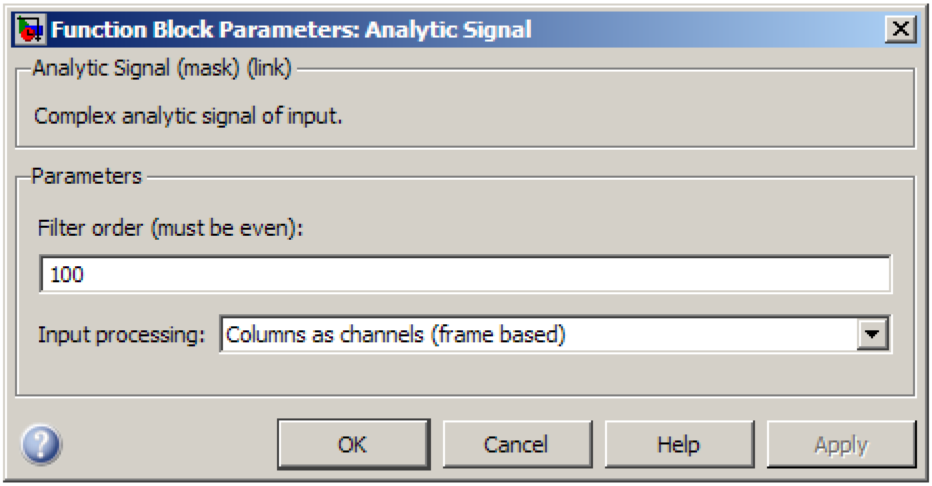
When you set the **Input processing** parameter to `Columns as channels (frame based)`, the block performs frame-based processing. In this mode, the block treats an

M-by-*N* matrix input as *N* independent channels containing *M* sequential time samples. The block computes the analytic signal for each channel over time.

Sample-Based Processing

When you set the **Input processing** parameter to `Elements as channels (sample based)`, the block performs sample-based processing. In this mode, the block treats an *M*-by-*N* matrix input as *M***N* independent channels and computes the analytic signal for each channel (matrix element) over time.

Dialog Box



Function Block Parameters: Analytic Signal

Analytic Signal (mask) (link)

Complex analytic signal of input.

Parameters

Filter order (must be even): 100

Input processing: Columns as channels (frame based)

Filter order

The length of the FIR filter used to compute the Hilbert transform.

Input processing

Specify how the block should process the input. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` — When you select this option, the block treats each column of the input as a separate channel.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

Note: The `Inherited (this choice will be removed - see release notes)` option will be removed in a future release. See “Frame-Based Processing” in the *DSP System Toolbox™ Release Notes* for more information.

Supported Data Types

- Double-precision floating point
- Single-precision floating point

Arbitrary Response Filter

Design arbitrary response filter

Library

Filtering / Filter Designs

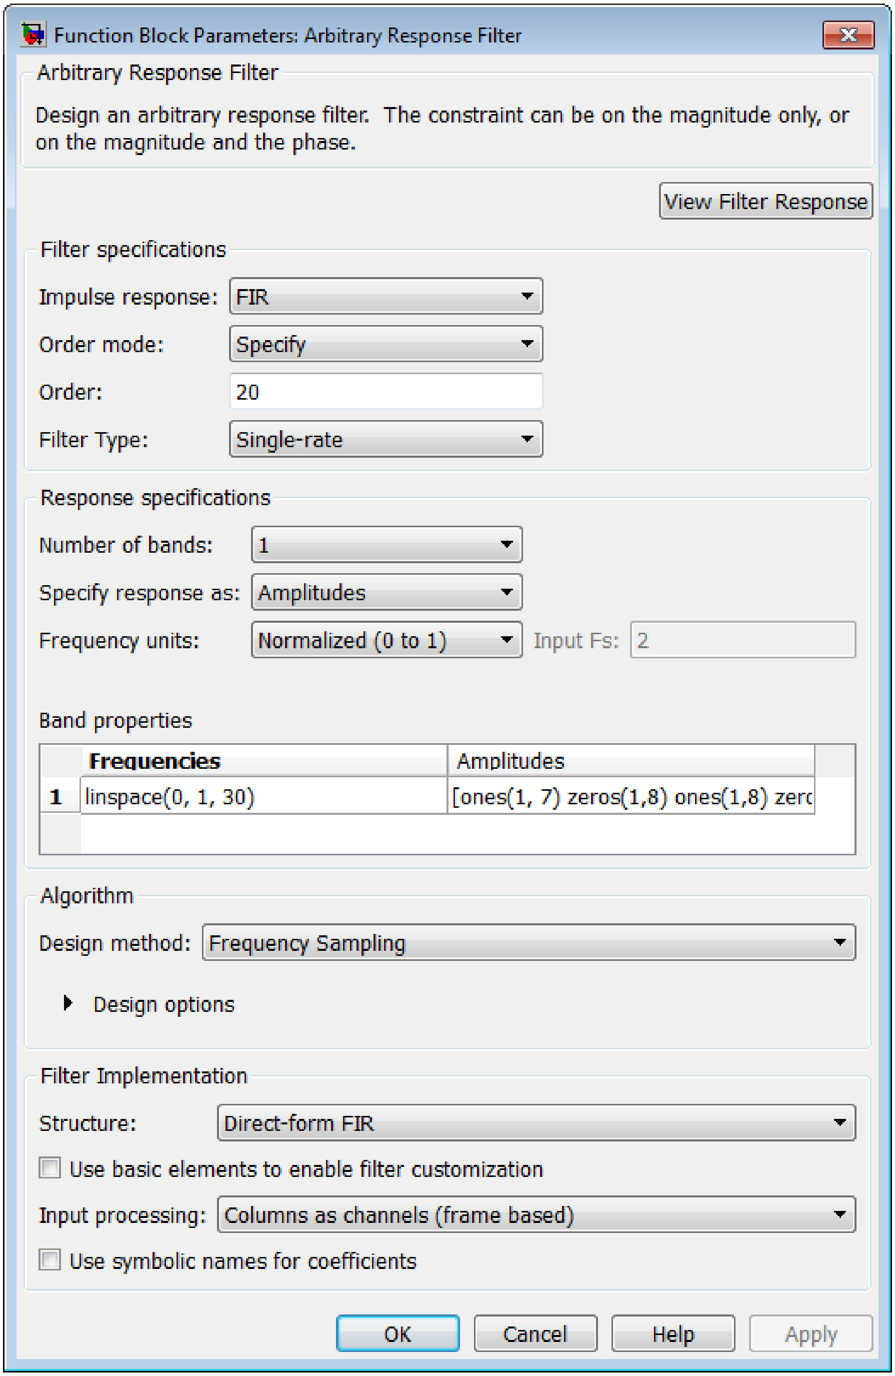
`dspfdesign`

Description

This block brings the filter design capabilities of the “`filterbuilder`” function to the Simulink environment.

Dialog Box

See “Arbitrary Response Filter Design Dialog Box — Main Pane” for more information about the parameters of this block. The **Data Types** and **Code Generation** panes are not available for blocks in the DSP System Toolbox Filter Designs library.



Function Block Parameters: Arbitrary Response Filter

Arbitrary Response Filter

Design an arbitrary response filter. The constraint can be on the magnitude only, or on the magnitude and the phase.

Filter specifications

Impulse response: FIR

Order mode: Specify

Order: 20

Filter Type: Single-rate

Response specifications

Number of bands: 1

Specify response as: Amplitudes

Frequency units: Normalized (0 to 1)

Input Fs: 2

Band properties

	Frequencies	Amplitudes
1	linspace(0, 1, 30)	[ones(1, 7) zeros(1,8) ones(1,8) zerc

Algorithm

Design method: Frequency Sampling

Filter Implementation

Structure: Direct-form FIR

□ Use basic elements to enable filter customization

Input processing: Columns as channels (frame based)

□ Use symbolic names for coefficients

View filter response

This button opens the Filter Visualization Tool (`fvtool`) from the Signal Processing Toolbox product. You can use the tool to display:

- Magnitude response, phase response, and group delay in the frequency domain.
- Impulse response and step response in the time domain.
- Pole-zero information.

The tool also helps you evaluate filter performance by providing information about filter order, stability, and phase linearity. For more information on FVTool, see the Signal Processing Toolbox documentation.

Filter Specifications

In this group, you specify your filter format, such as the impulse response and the filter order.

Impulse response

Select either `FIR` or `IIR` from the drop down list, where `FIR` is the default. When you choose an impulse response, the design methods and structures you can use to implement your filter change accordingly.

Order mode

Select `Minimum` or `Specify` from the drop-down list. Selecting `Specify` enables the **Order** option so you can enter the filter order. When you set the **Impulse response** to `IIR`, you can specify different numerator and denominator orders. To specify a different denominator order, you must select the **Denominator order** check box.

Order

Enter the order for FIR filter, or the order of the numerator for the IIR filter.

Denominator order

Select the check box and enter the denominator order. This option is enabled only if `IIR` is selected for **Impulse response**.

Filter type

This option is available for FIR filters only. Select `Single-rate`, `Decimator`, `Interpolator`, or `Sample-rate converter`. Your choice determines the type of filter as well as the design methods and structures that are available to implement your filter. By default, the block specifies a single-rate filter.

- Selecting `Decimator` or `Interpolator` activates the **Decimation Factor** or the **Interpolation Factor** options respectively.
- Selecting `Sample-rate converter` activates both factors.

Decimation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to `Decimator` or `Sample-rate converter`. The default value is 2.

Interpolation Factor

Enter the interpolation factor. This option is enabled only if the **Filter type** is set to `Interpolator` or `Sample-rate converter`. The default value is 2.

Response Specification

Number of Bands

Select the number of bands in the filter. Multiband design is available for both FIR and IIR filters.

Specify response as

Specify the response as `Amplitudes`, `Magnitudes and phases`, `Frequency response`, or `Group delay`. `Group delay` is only available for IIR designs.

Frequency units

Specify frequency units as either `Normalized`, which means normalized by the input sampling frequency, or select from `Hz`, `kHz`, `MHz`, or `GHz`.

Input Fs

Enter the input sampling frequency in the units specified in the **Frequency units** drop-down list. When you select the frequency units, this option is available.

Band Properties

These properties are modified automatically depending on the response chosen in the **Specify response as** drop-down list. Two or three columns are presented for input. The first column is always Frequencies. The other columns are Amplitudes, Magnitudes, Phases, or Frequency Response. Enter the corresponding vectors of values for each column.

- **Frequencies** and **Amplitudes** — These columns are presented for input if the response chosen in the **Specify response as** drop-down list is `Amplitudes`.

- **Frequencies**, **Magnitudes**, and **Phases** — These columns are presented for input if the response chosen in the **Specify response as** drop-down list is `Magnitudes and phases`.
- **Frequencies** and **Frequency response** — These columns are presented for input if the response chosen in the **Specify response as** drop-down list is `Frequency response`.

Algorithm

Design Method

Select the design method for the filter. Different methods are enabled depending on the defining parameters entered in the previous sections.

Design Options

The options for each design are specific for each design method. This section does not present all of the available options for all designs and design methods. There are many more that you encounter as you select different design methods and filter specifications.

- **Window** — Replace the square brackets with the name of a `window` function or function handle. For example, `hamming` or `@hamming`. If the window function takes parameters other than the length, use a cell array. For example, `{‘kaiser’,3.5}` or `{@chebwin,60}`.
- **Density factor** — Valid when the **Design method** is `Equiripple`. Density factor controls the density of the frequency grid over which the design method optimization evaluates your filter response function. The number of equally spaced points in the grid is the value you enter for **Density factor** times (filter order + 1).

  Increasing the value creates a filter that more closely approximates an ideal equiripple filter but increases the time required to design the filter. The default value of 16 represents a reasonable trade-off between the accurate approximation to the ideal filter and the time to design the filter.
- **Phase constraint** — Valid when the **Design method** is `Equiripple`, you have the DSP System Toolbox installed, and **Specify response as** is set to `Amplitudes`. Choose one of `Linear`, `Minimum`, or `Maximum`.
- **Weights** — Valid when the **Design method** is `Equiripple`. Uses the weights in **Weights** to weight the error for a single-band design. If you have multiple

frequency bands, the **Weights** design option changes to **B1 Weights**, **B2 Weights** to designate the separate bands.

Filter Implementation

Structure

Select the structure for the filter, available for the corresponding design method.

Use basic elements to enable filter customization

Select this check box to implement the filter as a subsystem of basic Simulink blocks. Clear the check box to implement the filter as a high-level subsystem. By default, this check box is cleared.

The high-level implementation provides better compatibility across various filter structures, especially filters that would contain algebraic loops when constructed using basic elements. On the other hand, using basic elements enables the following optimization parameters:

- **Optimize for zero gains** — Terminate chains that contain Gain blocks with a gain of zero.
- **Optimize for unit gains** — Remove Gain blocks that scale by a factor of one.
- **Optimize for delay chains** — Substitute delay chains made up of *n* unit delays with a single delay by *n*.
- **Optimize for negative gains** — Use subtraction in Sum blocks instead of negative gains in Gain blocks.

Optimize for unit-scale values

Select this check box to scale unit gains between sections in SOS filters. This parameter is available only for SOS filters.

Input processing

Specify how the block should process the input. The available options may vary depending on he settings of the **Filter Structure** and **Use basic elements for filter customization** parameters. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` — When you select this option, the block treats each column of the input as a separate channel.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

Note: The `Inherited (this choice will be removed — see release notes)` option will be removed in a future release. See "Frame-Based Processing" in the *DSP System Toolbox Release Notes* for more information.

Rate options

When the **Filter type** parameter specifies a multirate filter, select the rate processing rule for the block from following options:

- `Enforce single-rate processing` — When you select this option, the block maintains the sample rate of the input.
- `Allow multirate processing` — When you select this option, the block adjusts the rate at the output to accommodate an increased or reduced number of samples. To select this option, you must set the **Input processing** parameter to `Elements as channels (sample based)`.

Use symbolic names for coefficients

Select this check box to enable the specification of coefficients using MATLAB® variables. The available coefficient names differ depending on the filter structure. Using symbolic names allows tuning of filter coefficients in generated code. By default, this check box is cleared.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point
Output	• Double-precision floating point • Single-precision floating point

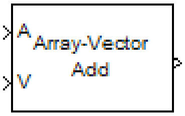
Array-Vector Add

Add vector to array along specified dimension

Library

Math Functions / Matrices and Linear Algebra / Matrix Operations

`dspmtrx3`



Description

The Array-Vector Add block adds the values in the specified dimension of the N-dimensional input array *A* to the values in the input vector *V*.

The length of the input *V* must be the same as the length of the specified dimension of *A*. The Array-Vector Add block adds each element of *V* to the corresponding element along that dimension of *A*.

Consider a 3-dimensional *M*-by-*N*-by-*P* input array *A(i,j,k)* and a *N*-by-1 input vector *V*. When the **Add along dimension** parameter is set to 2, the output of the block *Y(i,j,k)* is

$$Y(i,j,k) = A(i,j,k) + V(j)$$

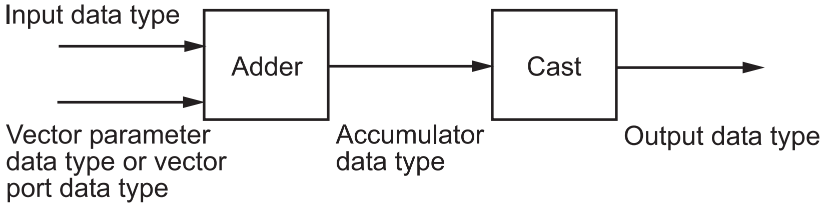
where

$$1 \le i \le M$$
$$1 \le j \le N$$
$$1 \le k \le P$$

The output of the Array-Vector Add block is the same size as the input array, *A*. This block accepts real and complex floating-point and fixed-point inputs.

Fixed-Point Data Types

The following diagram shows the data types used within the Array-Vector Add block for fixed-point signals.

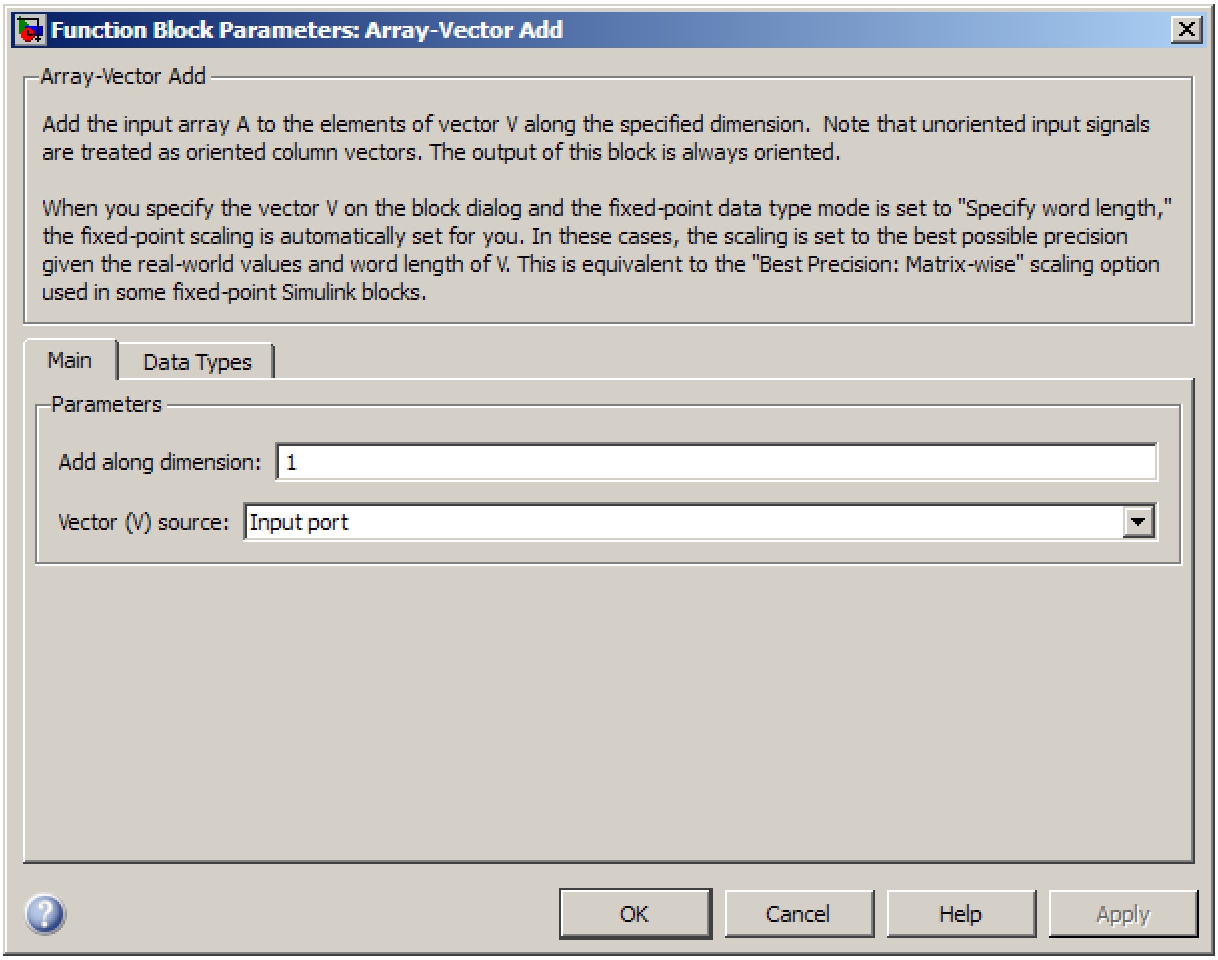


When you specify the vector *V* on the **Main** pane of the block mask, you must specify the data type and scaling properties of its elements in the **Vector (V)** parameter on the **Data Types** tab. When the vector comes in through the block port, its elements inherit their data type and scaling from the driving block.

You can set the vector, accumulator, and output data types in the block dialog as discussed below.

Dialog Box

The **Main** pane of the Array-Vector Add block dialog appears as follows.



Function Block Parameters: Array-Vector Add

Array-Vector Add

Add the input array A to the elements of vector V along the specified dimension. Note that unoriented input signals are treated as oriented column vectors. The output of this block is always oriented.

When you specify the vector V on the block dialog and the fixed-point data type mode is set to "Specify word length," the fixed-point scaling is automatically set for you. In these cases, the scaling is set to the best possible precision given the real-world values and word length of V. This is equivalent to the "Best Precision: Matrix-wise" scaling option used in some fixed-point Simulink blocks.

Parameters

Add along dimension: 1

Vector (V) source: Input port

Add along dimension

Specify the dimension along which to add the input array *A* to the elements of vector *V*.

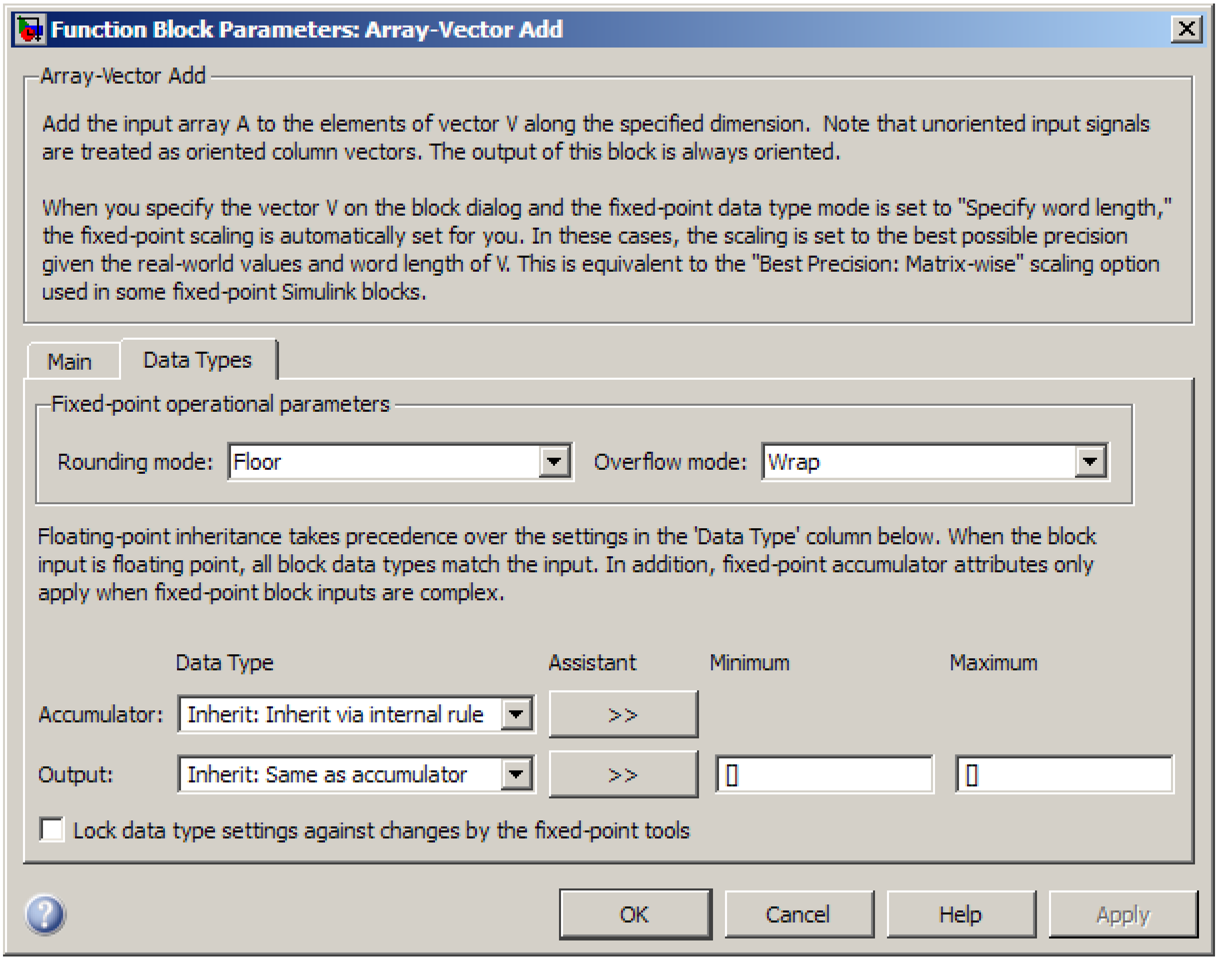
Vector (V) source

Specify the source of the vector, *V*. The vector can come from the `Input port` or from a `Dialog parameter`.

Vector (V)

Specify the vector, *V*. This parameter is visible only when you select `Dialog parameter` for the **Vector (V) source** parameter.

The **Data Types** pane of the Array-Vector Add block dialog appears as follows.



Function Block Parameters: Array-Vector Add

Array-Vector Add

Add the input array A to the elements of vector V along the specified dimension. Note that unoriented input signals are treated as oriented column vectors. The output of this block is always oriented.

When you specify the vector V on the block dialog and the fixed-point data type mode is set to "Specify word length," the fixed-point scaling is automatically set for you. In these cases, the scaling is set to the best possible precision given the real-world values and word length of V. This is equivalent to the "Best Precision: Matrix-wise" scaling option used in some fixed-point Simulink blocks.

Fixed-point operational parameters

Rounding mode: Floor

Overflow mode: Wrap

Floating-point inheritance takes precedence over the settings in the 'Data Type' column below. When the block input is floating point, all block data types match the input. In addition, fixed-point accumulator attributes only apply when fixed-point block inputs are complex.

	Data Type	Assistant	Minimum	Maximum
Accumulator:	Inherit: Inherit via internal rule	>>		
Output:	Inherit: Same as accumulator	>>	[]	[]

□ Lock data type settings against changes by the fixed-point tools

Note: Floating-point inheritance takes precedence over the data type settings defined on this pane. When inputs are floating point, the block ignores these settings, and all internal data types are floating point.

Rounding mode

Select the “rounding mode” for fixed-point operations. If Accumulator Data Type is Inherit: Inherit via internal rule and Output Data Type is Inherit: Same as accumulator, the value of Rounding mode does not affect the numerical results.

Note: The **Rounding mode** and **Overflow mode** settings have no effect on numerical results when both of the following conditions exist:

- **Accumulator data type** is `Inherit: Inherit via internal rule`
- **Output data type** is `Inherit: Same as accumulator`

With these data type settings, the block is effectively operating in full precision mode.

Overflow mode

Select the “overflow mode” for fixed-point operations.

Vector (V)

Use this parameter to specify the word and fraction lengths for the elements of the vector, *V*. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Same word length as input`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Accumulator data type** parameter.

See “Specify Data Types Using Data Type Assistant” in “Simulink User's Guide” for more information.

Note The **Vector (V)** parameter on the **Data Types** pane is only visible when you select `Dialog parameter` for the **Vector (V) source** parameter on the **Main** pane of the block mask. When the vector comes in through the block's input port, the data type and scaling of its elements are inherited from the driving block.

Accumulator data type

Specify the accumulator data type. See “Fixed-Point Data Types” on page 1-32 for illustrations depicting the use of the accumulator data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Accumulator data type** parameter.

See “Specify Data Types Using Data Type Assistant” in “Simulink User's Guide” for more information.

Output data type

Specify the output data type. See “Fixed-Point Data Types” on page 1-32 for illustrations depicting the use of the output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as accumulator`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Specify Block Output Data Types” in “Simulink User's Guide” for more information.

Minimum

Specify the minimum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges”)
- Automatic scaling of fixed-point data types

Maximum

Specify the maximum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges”)

- Automatic scaling of fixed-point data types

Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

Supported Data Types

Port	Supported Data Types
A	• Double-precision floating point • Single-precision floating point • Fixed point (signed only) • 8-, 16-, and 32-bit signed integers
V	• Double-precision floating point • Single-precision floating point • Fixed point (signed only) • 8-, 16-, and 32-bit signed integers
Output	• Double-precision floating point • Single-precision floating point • Fixed point (signed only) • 8-, 16-, and 32-bit signed integers

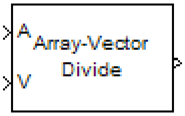
Array-Vector Divide

Divide array by vector along specified dimension

Library

Math Functions / Matrices and Linear Algebra / Matrix Operations

`dspmtrx3`



Description

The Array-Vector Divide block divides the values in the specified dimension of the N-dimensional input array *A* by the values in the input vector *V*.

The length of the input *V* must be the same as the length of the specified dimension of *A*. The Array-Vector Divide block divides each element of *V* by the corresponding element along that dimension of *A*.

Consider a 3-dimensional *M*-by-*N*-by-*P* input array *A(i,j,k)* and a *N*-by-1 input vector *V*. When the **Divide along dimension** parameter is set to 2, the output of the block *Y(i,j,k)* is

$$Y(i,j,k) = \frac{A(i,j,k)}{V(j)}$$

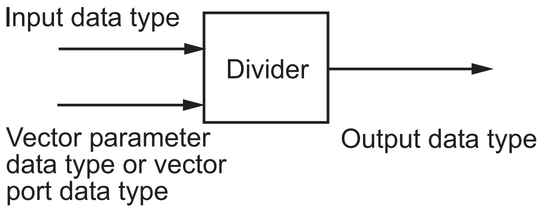
where

$$1 \le i \le M$$
$$1 \le j \le N$$
$$1 \le k \le P$$

The output of the Array-Vector Divide block is the same size as the input array, *A*. This block accepts real and complex floating-point and fixed-point input arrays, and real floating-point and fixed-point input vectors.

Fixed-Point Data Types

The following diagram shows the data types used within the Array-Vector Divide block for fixed-point signals.

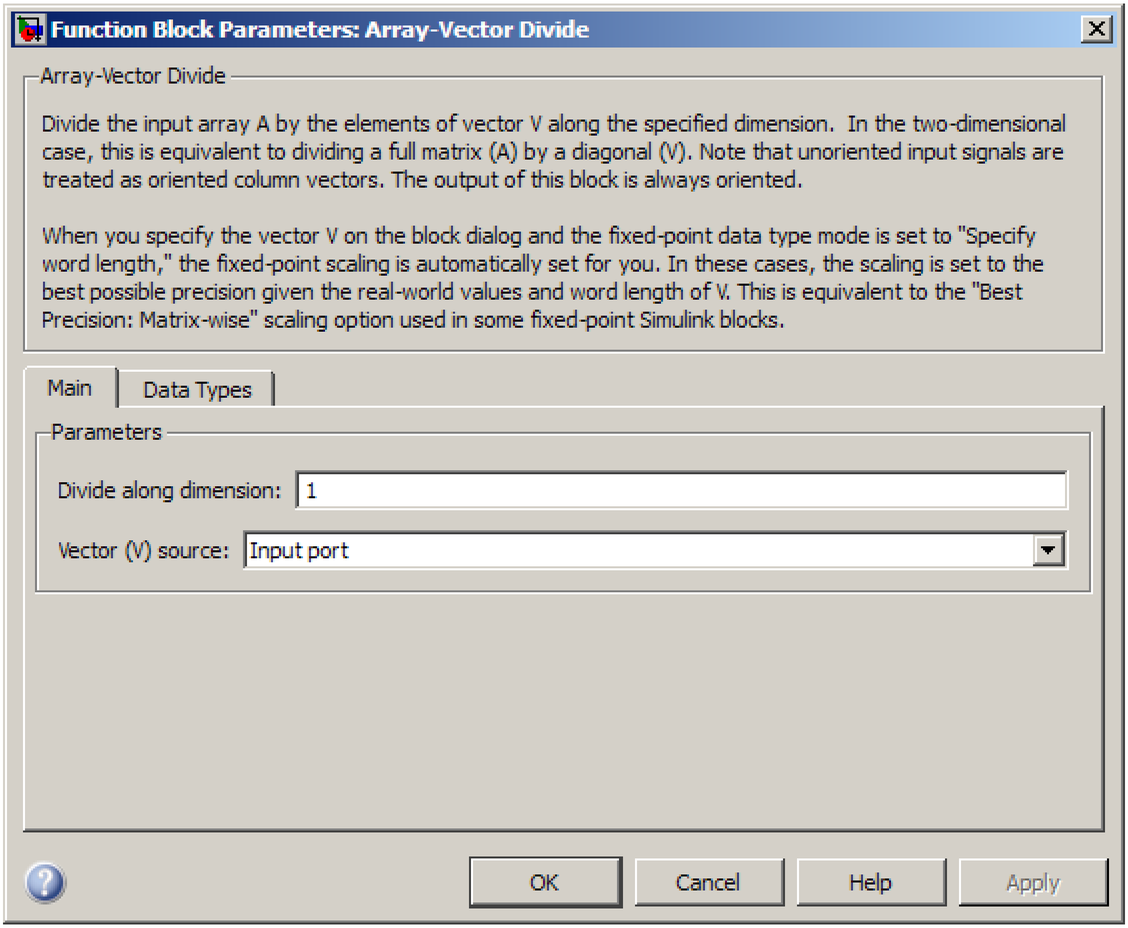


When you specify the vector *V* on the **Main** pane of the block mask, you must specify the data type and scaling properties of its elements in the **Vector (V)** parameter on the **Data Types** tab. When the vector comes in through the block port, its elements inherit their data type and scaling from the driving block.

You can set the vector and output data types in the block dialog as discussed below.

Dialog Box

The **Main** pane of the Array-Vector Divide block dialog appears as follows.



Function Block Parameters: Array-Vector Divide

Array-Vector Divide

Divide the input array A by the elements of vector V along the specified dimension. In the two-dimensional case, this is equivalent to dividing a full matrix (A) by a diagonal (V). Note that unoriented input signals are treated as oriented column vectors. The output of this block is always oriented.

When you specify the vector V on the block dialog and the fixed-point data type mode is set to "Specify word length," the fixed-point scaling is automatically set for you. In these cases, the scaling is set to the best possible precision given the real-world values and word length of V. This is equivalent to the "Best Precision: Matrix-wise" scaling option used in some fixed-point Simulink blocks.

Parameters

Divide along dimension: 1

Vector (V) source: Input port

Divide along dimension

Specify the dimension along which to divide the input array *A* by the elements of vector *V*.

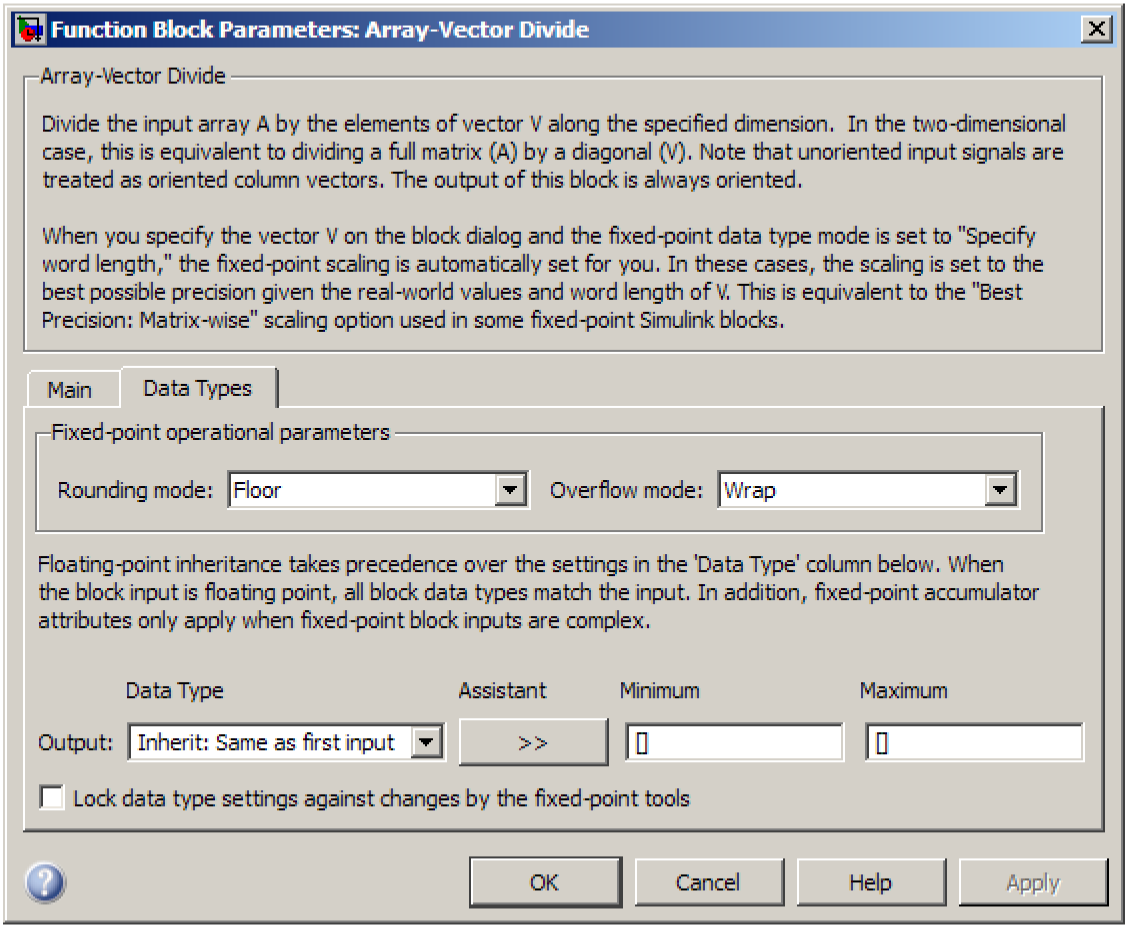
Vector (V) source

Specify the source of the vector, *V*. The vector can come from the `Input port` or from a `Dialog parameter`.

Vector (V)

Specify the vector, *V*. This parameter is visible only when you select `Dialog parameter` for the **Vector (V) source** parameter.

The **Data Types** pane of the Array-Vector Divide block dialog appears as follows.



Array-Vector Divide

Divide the input array A by the elements of vector V along the specified dimension. In the two-dimensional case, this is equivalent to dividing a full matrix (A) by a diagonal (V). Note that unoriented input signals are treated as oriented column vectors. The output of this block is always oriented.

When you specify the vector V on the block dialog and the fixed-point data type mode is set to "Specify word length," the fixed-point scaling is automatically set for you. In these cases, the scaling is set to the best possible precision given the real-world values and word length of V. This is equivalent to the "Best Precision: Matrix-wise" scaling option used in some fixed-point Simulink blocks.

Fixed-point operational parameters

Rounding mode: Floor

Overflow mode: Wrap

Floating-point inheritance takes precedence over the settings in the 'Data Type' column below. When the block input is floating point, all block data types match the input. In addition, fixed-point accumulator attributes only apply when fixed-point block inputs are complex.

	Data Type	Assistant	Minimum	Maximum
Output:	Inherit: Same as first input	>>	[]	[]

□ Lock data type settings against changes by the fixed-point tools

Note: Floating-point inheritance takes precedence over the data type settings defined on this pane. When inputs are floating point, the block ignores these settings, and all internal data types are floating point.

Rounding mode

Select the “rounding mode” for fixed-point operations.

Overflow mode

Select the “overflow mode” for fixed-point operations.

Vector (V)

Use this parameter to specify the word and fraction lengths for the elements of the vector, *V*. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Same word length as input`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Accumulator data type** parameter.

See “Specify Data Types Using Data Type Assistant” in “Simulink User's Guide” for more information.

Note The **Vector (V)** parameter on the **Data Types** pane is only visible when you select `Dialog parameter` for the **Vector (V) source** parameter on the **Main** pane of the block mask. When the vector comes in through the block's input port, the data type and scaling of its elements are inherited from the driving block.

Output data type

Specify the output data type. See “Fixed-Point Data Types” on page 1-39 for illustrations depicting the use of the output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as first input`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Specify Block Output Data Types” in “Simulink User's Guide” for more information.

Minimum

Specify the minimum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges”)
- Automatic scaling of fixed-point data types

Maximum

Specify the maximum value that the block should output. The default value is [ ] (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges”)
- Automatic scaling of fixed-point data types

Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

Supported Data Types

Port	Supported Data Types
A	• Double-precision floating point • Single-precision floating point • Fixed point (signed only) • 8-, 16-, and 32-bit signed integers
V	• Double-precision floating point • Single-precision floating point • Fixed point (signed only) • 8-, 16-, and 32-bit signed integers
Output	• Double-precision floating point • Single-precision floating point • Fixed point (signed only) • 8-, 16-, and 32-bit signed integers

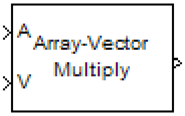
Array-Vector Multiply

Multiply array by vector along specified dimension

Library

Math Functions / Matrices and Linear Algebra / Matrix Operations

`dspmtrx3`



Description

The Array-Vector Multiply block multiplies the values in the specified dimension of the N-dimensional input array *A* by the values in the input vector *V*.

The length of the input *V* must be the same as the length of the specified dimension of *A*. The Array-Vector Multiply block multiplies each element of *V* by the corresponding element along that dimension of *A*.

Consider a 3-dimensional *M*-by-*N*-by-*P* input array *A(i,j,k)* and a *N*-by-1 input vector *V*. When the **Multiply along dimension** parameter is set to 2, the output of the block *Y(i,j,k)* is

$$Y(i, j,k) = A(i,j,k) * V(j)$$

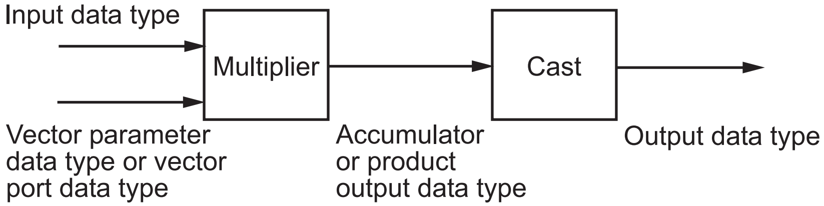
where

$$1 \le i \le M$$
$$1 \le j \le N$$
$$1 \le k \le P$$

The output of the Array-Vector Multiply block is the same size as the input array, *A*. This block accepts real and complex floating-point and fixed-point inputs.

Fixed-Point Data Types

The following diagram shows the data types used within the Array-Vector Multiply block for fixed-point signals.



Input data type
Multiplier
Cast
Vector parameter data type or vector port data type
Accumulator or product output data type
Output data type

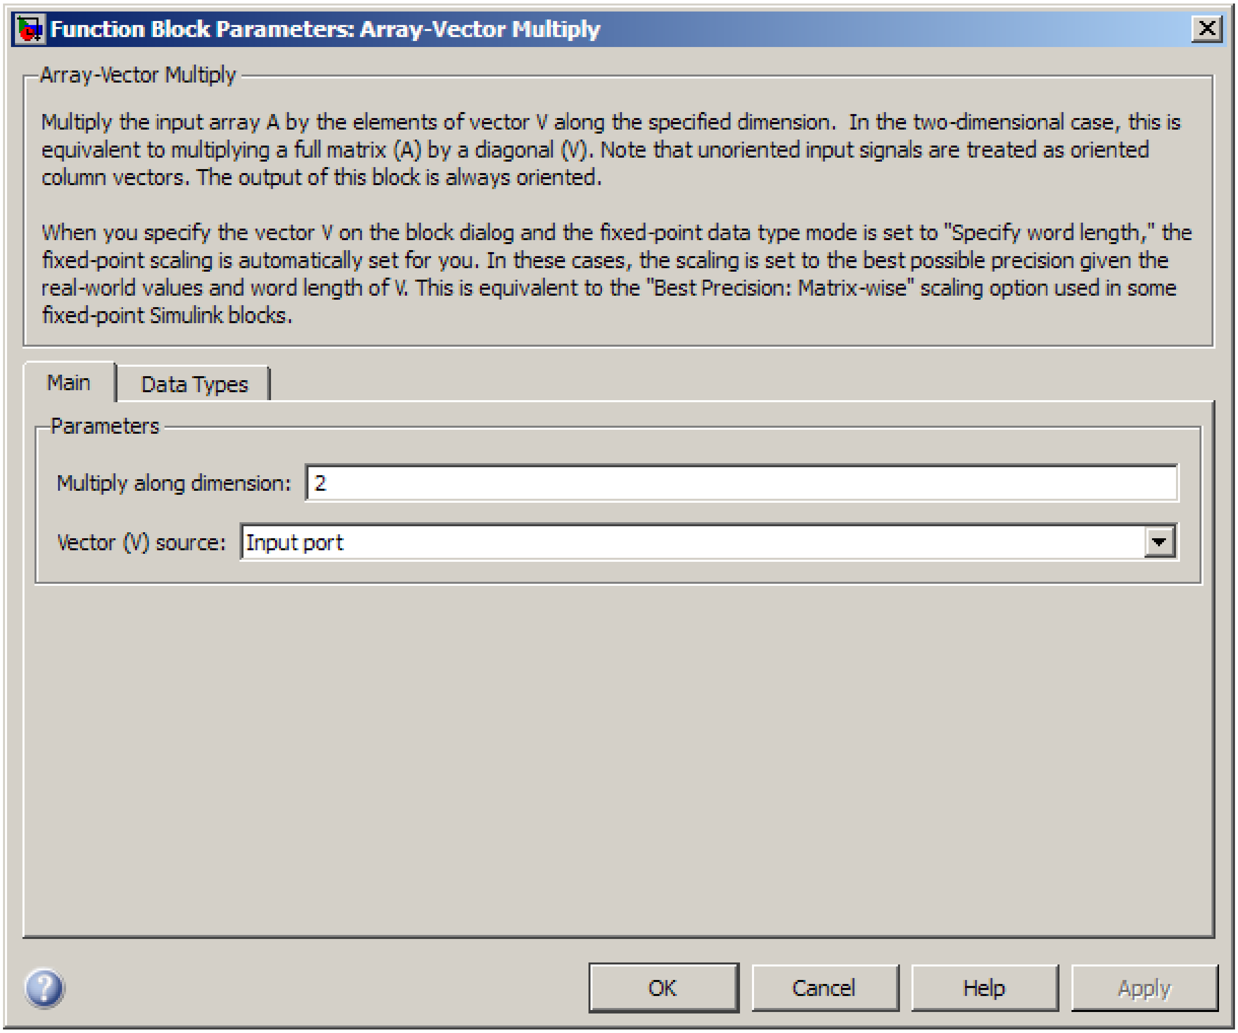
When you specify the vector *V* on the **Main** pane of the block mask, you must specify the data type and scaling properties of its elements in the **Vector (V)** parameter on the **Data Types** tab. When the vector comes in through the block port, its elements inherit their data type and scaling from the driving block.

The output of the multiplier is in the product output data type when at least one of the inputs to the multiplier is real. When both of the inputs to the multiplier are complex, the result of the multiplication is in the accumulator data type. For details on the complex multiplication performed, see “Multiplication Data Types”.

You can set the vector, accumulator, product output, and output data types in the block dialog as discussed below.

Dialog Box

The **Main** pane of the Array-Vector Multiply block dialog appears as follows.



Function Block Parameters: Array-Vector Multiply

Array-Vector Multiply

Multiply the input array A by the elements of vector V along the specified dimension. In the two-dimensional case, this is equivalent to multiplying a full matrix (A) by a diagonal (V). Note that unoriented input signals are treated as oriented column vectors. The output of this block is always oriented.

When you specify the vector V on the block dialog and the fixed-point data type mode is set to "Specify word length," the fixed-point scaling is automatically set for you. In these cases, the scaling is set to the best possible precision given the real-world values and word length of V. This is equivalent to the "Best Precision: Matrix-wise" scaling option used in some fixed-point Simulink blocks.

Parameters

Multiply along dimension: 2

Vector (V) source: Input port

Multiply along dimension

Specify the dimension along which to multiply the input array *A* by the elements of vector *V*.

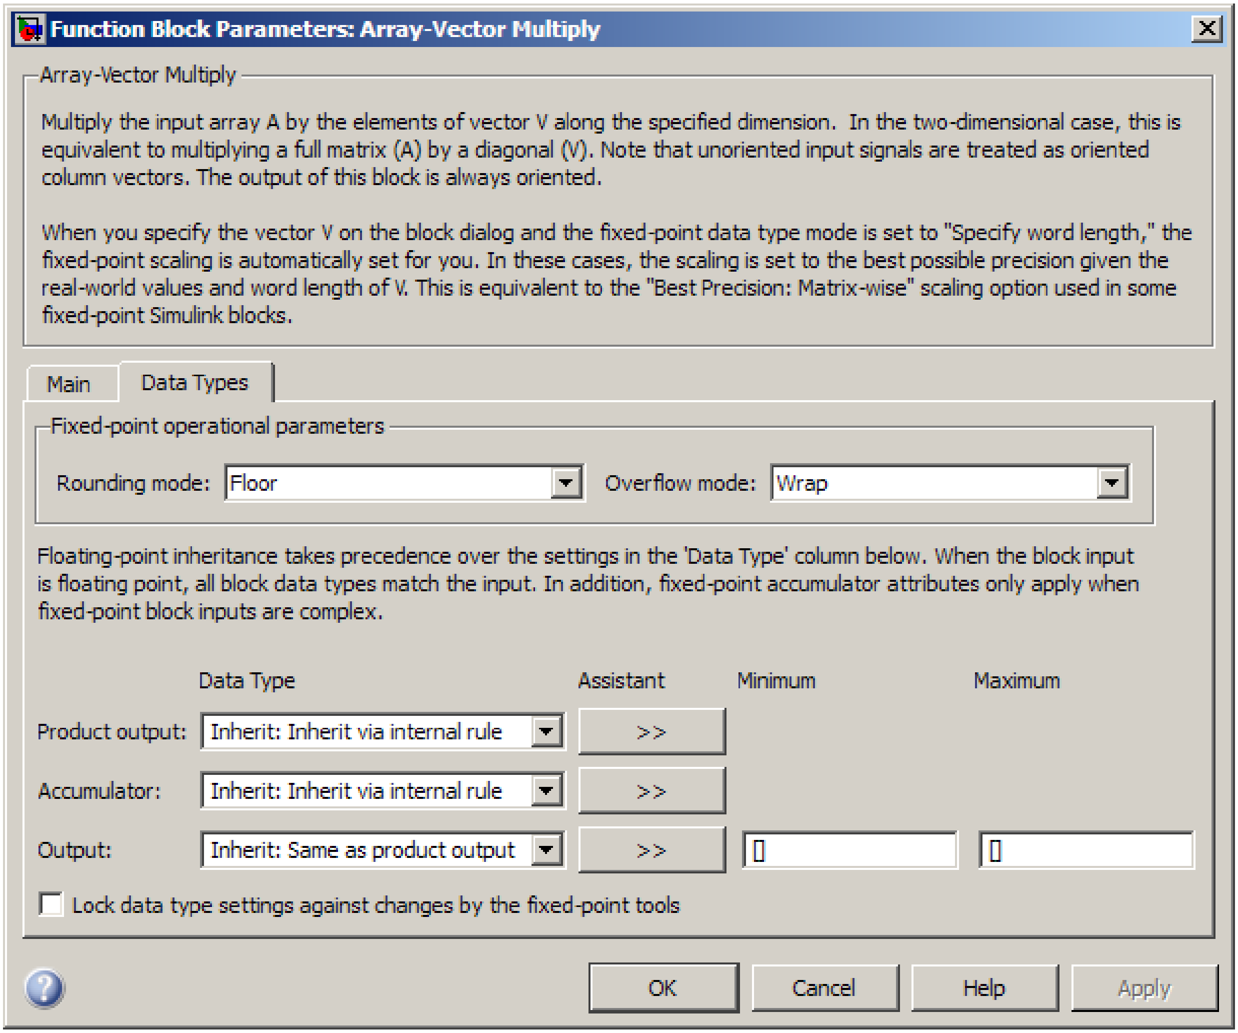
Vector (V) source

Specify the source of the vector, *V*. The vector can come from the `Input port` or from a `Dialog parameter`.

Vector (V)

Specify the vector, *V*. This parameter is visible only when you select `Dialog parameter` for the **Vector (V) source** parameter.

The **Data Types** pane of the Array-Vector Multiply block dialog appears as follows.



Function Block Parameters: Array-Vector Multiply

Array-Vector Multiply

Multiply the input array A by the elements of vector V along the specified dimension. In the two-dimensional case, this is equivalent to multiplying a full matrix (A) by a diagonal (V). Note that unoriented input signals are treated as oriented column vectors. The output of this block is always oriented.

When you specify the vector V on the block dialog and the fixed-point data type mode is set to "Specify word length," the fixed-point scaling is automatically set for you. In these cases, the scaling is set to the best possible precision given the real-world values and word length of V. This is equivalent to the "Best Precision: Matrix-wise" scaling option used in some fixed-point Simulink blocks.

Main | Data Types

Fixed-point operational parameters

Rounding mode: Floor   Overflow mode: Wrap

Floating-point inheritance takes precedence over the settings in the 'Data Type' column below. When the block input is floating point, all block data types match the input. In addition, fixed-point accumulator attributes only apply when fixed-point block inputs are complex.

	Data Type	Assistant	Minimum	Maximum

Vector (V)

Use this parameter to specify the word and fraction lengths for the elements of the vector, *V*. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Same word length as input`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Accumulator data type** parameter.

See “Specify Data Types Using Data Type Assistant” in “Simulink User's Guide” for more information.

Note The **Vector (V)** parameter on the **Data Types** pane is only visible when you select `Dialog parameter` for the **Vector (V) source** parameter on the **Main** pane of the block mask. When the vector comes in through the block's input port, the data type and scaling of its elements are inherited from the driving block.

Product output data type

Specify the product output data type. See “Fixed-Point Data Types” on page 1-46 and “Multiplication Data Types” for illustrations depicting the use of the product output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Product output data type** parameter.

See “Specify Data Types Using Data Type Assistant” in “Simulink User's Guide” for more information.

Accumulator data type

Specify the accumulator data type. See “Fixed-Point Data Types” on page 1-46 for illustrations depicting the use of the accumulator data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Accumulator data type** parameter.

See “Specify Data Types Using Data Type Assistant” in “Simulink User's Guide” for more information.

Output data type

Specify the output data type. See “Fixed-Point Data Types” on page 1-46 for illustrations depicting the use of the output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as product output`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Specify Block Output Data Types” in “Simulink User's Guide” for more information.

Minimum

Specify the minimum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges”)

- Automatic scaling of fixed-point data types

Maximum

Specify the maximum value that the block should output. The default value is [ ] (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see "Signal Ranges")
- Automatic scaling of fixed-point data types

Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

Supported Data Types

Port	Supported Data Types
A	• Double-precision floating point • Single-precision floating point • Fixed point (signed only) • 8-, 16-, and 32-bit signed integers
V	• Double-precision floating point • Single-precision floating point • Fixed point (signed only) • 8-, 16-, and 32-bit signed integers

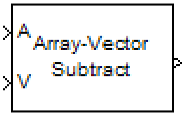
Array-Vector Subtract

Subtract vector from array along specified dimension

Library

Math Functions / Matrices and Linear Algebra / Matrix Operations

`dspmtrx3`



Description

The Array-Vector Subtract block subtracts the values in the input vector *V* from the values in the specified dimension of the N-dimensional input array *A*.

The length of the input *V* must be the same as the length of the specified dimension of *A*. The Array-Vector Subtract block subtracts each element of *V* from the corresponding element along that dimension of *A*.

Consider a 3-dimensional *M*-by-*N*-by-*P* input array *A(i,j,k)* and a *N*-by-1 input vector *V*. When the **Subtract along dimension** parameter is set to `2`, the output of the block *Y(i,j,k)* is

$$Y(i,j,k) = A(i,j,k) - V(j)$$

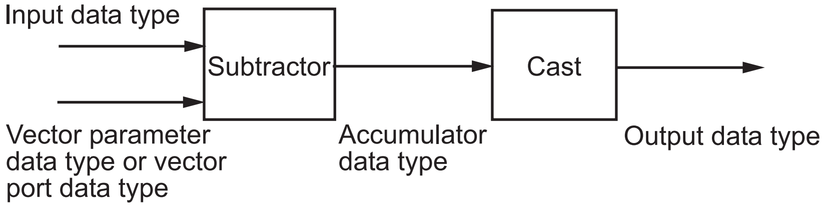
where

$$1 \le i \le M$$
$$1 \le j \le N$$
$$1 \le k \le P$$

The output of the Array-Vector Subtract block is the same size as the input array, *A*. This block accepts real and complex floating-point and fixed-point inputs.

Fixed-Point Data Types

The following diagram shows the data types used within the Array-Vector Subtract block for fixed-point signals.



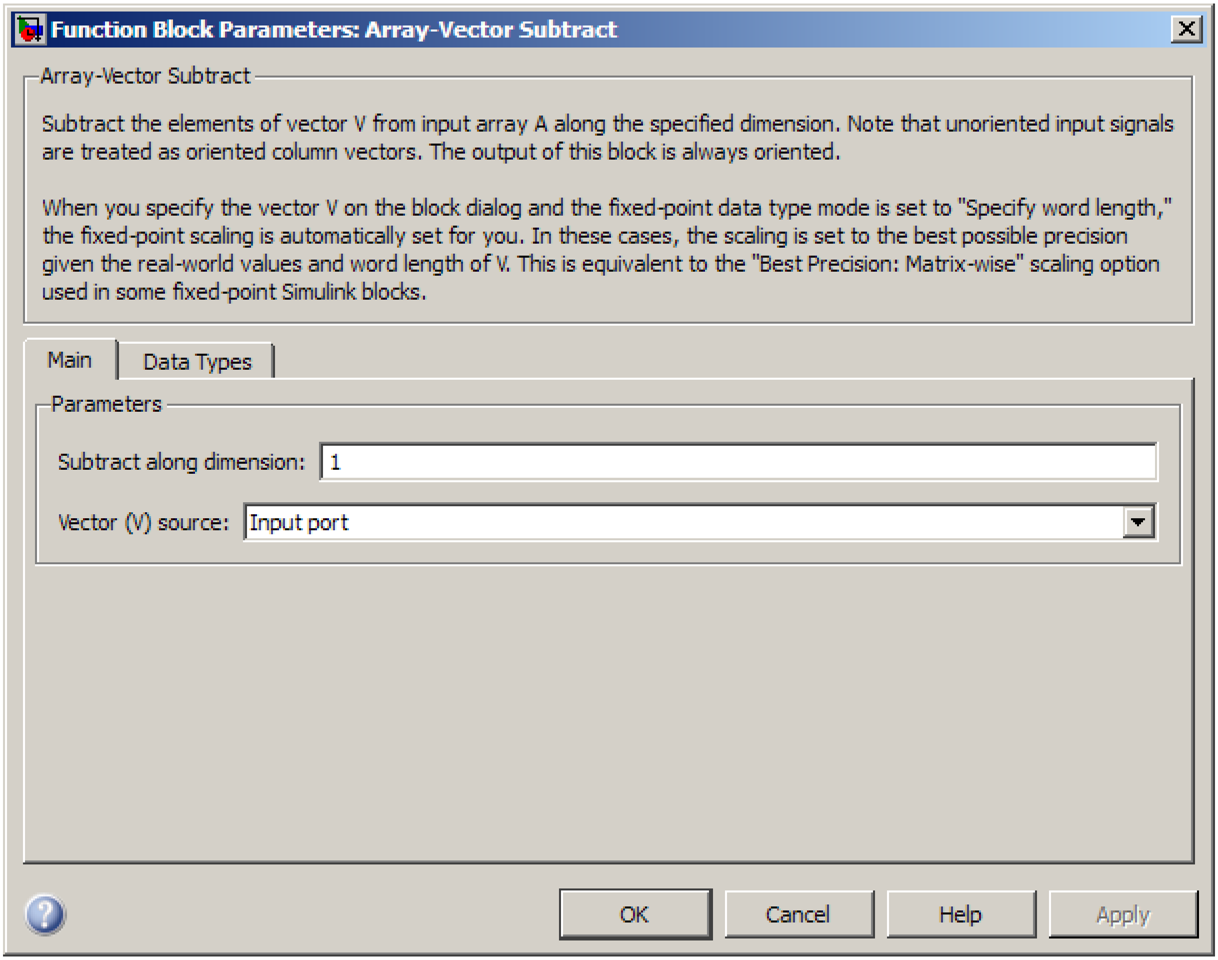
When you specify the vector *V* on the **Main** pane of the block mask, you must specify the data type and scaling properties of its elements in the **Vector (V)** parameter on the **Data Types** tab. When the vector comes in through the block port, its elements inherit their data type and scaling from the driving block.

The output of the subtractor is in the accumulator data type.

You can set the vector, accumulator, and output data types in the block dialog as discussed below.

Dialog Box

The **Main** pane of the Array-Vector Subtract block dialog appears as follows.



Function Block Parameters: Array-Vector Subtract

Array-Vector Subtract

Subtract the elements of vector V from input array A along the specified dimension. Note that unoriented input signals are treated as oriented column vectors. The output of this block is always oriented.

When you specify the vector V on the block dialog and the fixed-point data type mode is set to "Specify word length," the fixed-point scaling is automatically set for you. In these cases, the scaling is set to the best possible precision given the real-world values and word length of V. This is equivalent to the "Best Precision: Matrix-wise" scaling option used in some fixed-point Simulink blocks.

Main | Data Types

Parameters

Subtract along dimension: 1

Vector (V) source: Input port

Subtract along dimension

Specify the dimension along which to subtract the elements of vector *V* from the input array *A*.

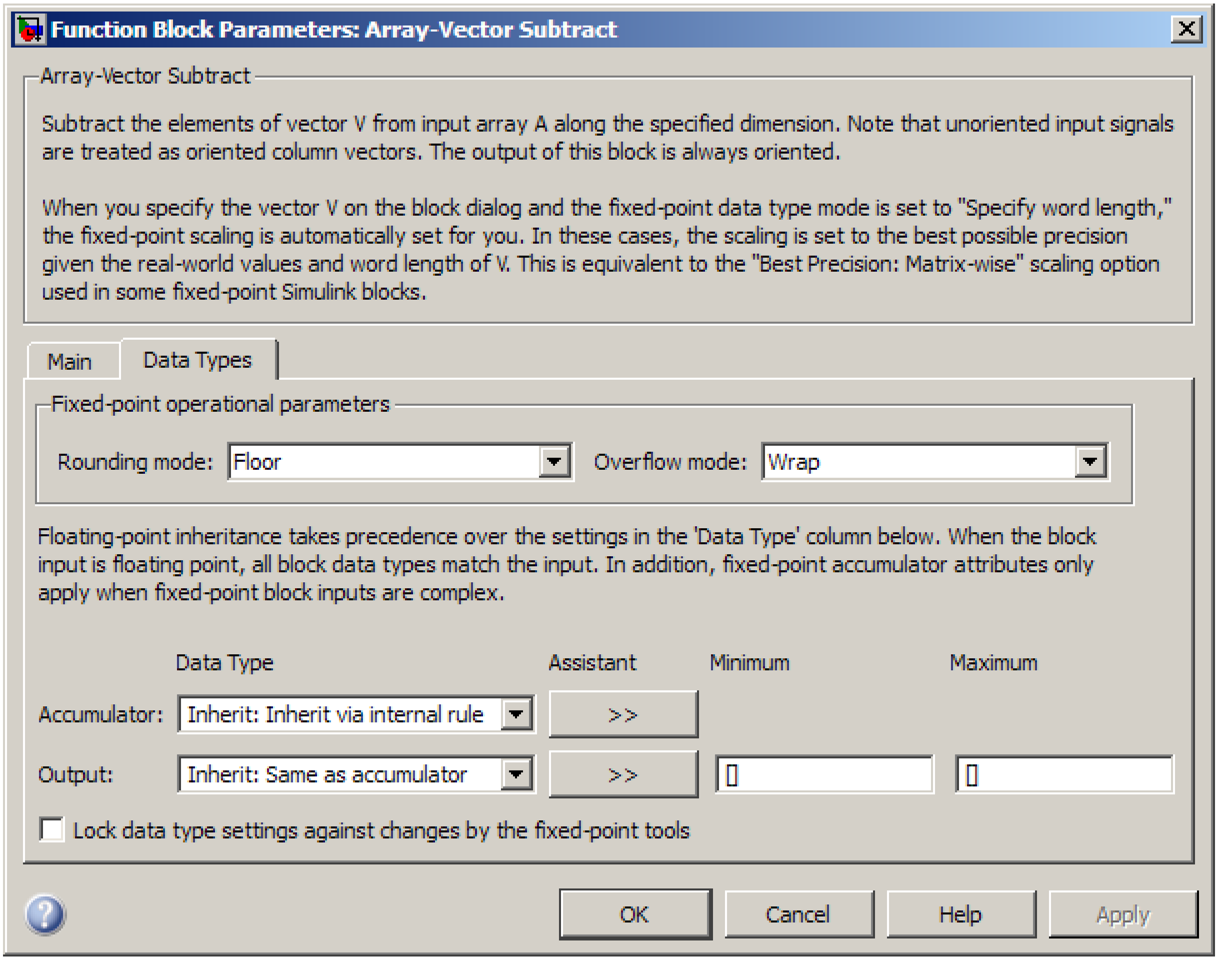
Vector (V) source

Specify the source of the vector, *V*. The vector can come from the `Input port` or from a `Dialog parameter`.

Vector (V)

Specify the vector, *V*. This parameter is visible only when you select `Dialog parameter` for the **Vector (V) source** parameter.

The **Data Types** pane of the Array-Vector Subtract block dialog appears as follows.



Array-Vector Subtract

Subtract the elements of vector V from input array A along the specified dimension. Note that unoriented input signals are treated as oriented column vectors. The output of this block is always oriented.

When you specify the vector V on the block dialog and the fixed-point data type mode is set to "Specify word length," the fixed-point scaling is automatically set for you. In these cases, the scaling is set to the best possible precision given the real-world values and word length of V. This is equivalent to the "Best Precision: Matrix-wise" scaling option used in some fixed-point Simulink blocks.

Fixed-point operational parameters

Rounding mode: Floor

Overflow mode: Wrap

Floating-point inheritance takes precedence over the settings in the 'Data Type' column below. When the block input is floating point, all block data types match the input. In addition, fixed-point accumulator attributes only apply when fixed-point block inputs are complex.

	Data Type	Assistant	Minimum	Maximum
Accumulator:	Inherit: Inherit via internal rule	>>

☐ Lock data type settings against changes by the fixed-point tools

Note: Floating-point inheritance takes precedence over the data type settings defined on this pane. When inputs are floating point, the block ignores these settings, and all internal data types are floating point.

Rounding mode

Select the “rounding mode” for fixed-point operations.

Note: The **Rounding mode** and **Overflow mode** settings have no effect on numerical results when both of the following conditions exist:

- **Accumulator data type** is `Inherit: Inherit via internal rule`
- **Output data type** is `Inherit: Same as accumulator`

With these data type settings, the block is effectively operating in full precision mode.

Overflow mode

Select the “overflow mode” for fixed-point operations.

Vector (V)

Use this parameter to specify the word and fraction lengths for the elements of the vector, *V*. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Same word length as input`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Accumulator data type** parameter.

See “Specify Data Types Using Data Type Assistant” in “Simulink User's Guide” for more information.

Note The **Vector (V)** parameter on the **Data Types** pane is only visible when you select `Dialog parameter` for the **Vector (V) source** parameter on the **Main** pane of the block mask. When the vector comes in through the block's input port, the data type and scaling of its elements are inherited from the driving block.

Accumulator data type

Specify the accumulator data type. See “Fixed-Point Data Types” on page 1-54 for illustrations depicting the use of the accumulator data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Accumulator data type** parameter.

See “Specify Data Types Using Data Type Assistant” in “Simulink User's Guide” for more information.

Output data type

Specify the output data type. See “Fixed-Point Data Types” on page 1-54 for illustrations depicting the use of the output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as accumulator`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Specify Block Output Data Types” in “Simulink User's Guide” for more information.

Minimum

Specify the minimum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges”)
- Automatic scaling of fixed-point data types

Maximum

Specify the maximum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges”)
- Automatic scaling of fixed-point data types

Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

Supported Data Types

Port	Supported Data Types
A	• Double-precision floating point • Single-precision floating point • Fixed point (signed only) • 8-, 16-, and 32-bit signed integers
V	• Double-precision floating point • Single-precision floating point • Fixed point (signed only) • 8-, 16-, and 32-bit signed integers
Output	• Double-precision floating point • Single-precision floating point • Fixed point (signed only) • 8-, 16-, and 32-bit signed integers

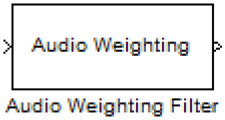
Audio Weighting Filter

Design audio weighting filter

Library

Filtering / Filter Designs

`dspfdesign`

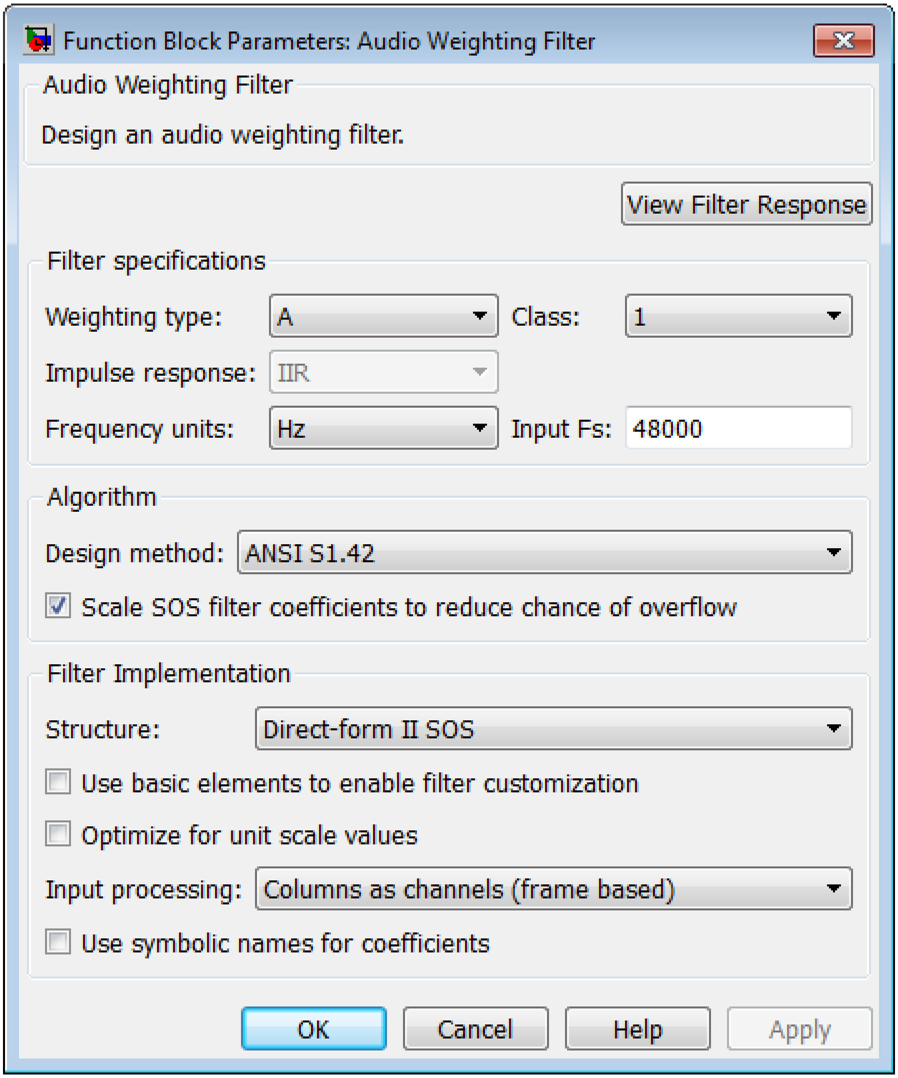


Description

This block brings the filter design capabilities of the “`filterbuilder`” function to the Simulink environment.

Dialog Box

See “Audio Weighting Filter Design Dialog Box — Main Pane” for more information about the parameters of this block. The **Data Types** and **Code** panes are not available for blocks in the DSP System Toolbox Filter Designs library.



Function Block Parameters: Audio Weighting Filter

Audio Weighting Filter

Design an audio weighting filter.

Filter specifications

Weighting type: A

Class: 1

Impulse response: IIR

Frequency units: Hz

Input Fs: 48000

Algorithm

Design method: ANSI S1.42

☑ Scale SOS filter coefficients to reduce chance of overflow

Filter Implementation

Structure: Direct-form II SOS

□ Use basic elements to enable filter customization

□ Optimize for unit scale values

Input processing: Columns as channels (frame based)

□ Use symbolic names for coefficients

View Filter Response

This button opens the Filter Visualization Tool (`fvtool`) from the Signal Processing Toolbox product. You can use the tool to display:

- Magnitude response, phase response, and group delay in the frequency domain.

- Impulse response and step response in the time domain.
- Pole-zero information.

The tool also helps you evaluate filter performance by providing information about filter order, stability, and phase linearity. For more information on FVTool, see the Signal Processing Toolbox documentation.

Filter Specifications

In this group, you specify your filter format, such as the impulse response and the filter order.

Weighting type

The weighting type defines the frequency response of the filter. The valid weighting types for this filter are `A`, `C` , `C-message`, `ITU-R 468–4`, and `ITU-T 0.41`. For definitions of the available weighting types, see the `fdesign.audioweighting` reference page.

Class

The filter class describes the frequency-dependent tolerances specified in the relevant standards [1], [2]. There are two possible class values: `1` and `2`. Class 1 weighting filters have stricter tolerances than class 2 filters. The filter class value does not affect the design. The class value is only used to provide a specification mask in `fvtool` for the analysis of the filter design. The default value of this parameter is `1`.

The filter class is only applicable for `A` weighting and `C` weighting filters.

Impulse response

Specify the impulse response type as one of `IIR` or `FIR`. For A, C , C-message, and ITU-R 468–4 filter, `IIR` is the only option. For a ITU-T 0.41 weighting filter, `FIR` is the only option.

Frequency units

Specify the frequency units as Hertz (Hz), kilohertz (kHz), megahertz (MHz), or gigahertz (GHz). Normalized frequency designs are not supported for audio weighting filters. The default value of this parameter is `Hz`.

Input Fs

Specify the input sampling frequency. The units correspond to the setting of the **Frequency units** parameter.

Algorithm

Design Method

Valid design methods depend on the weighting type. For type A and C weighting filters, the only valid design type is `ANSI S1.42`. This is an IIR design method that follows ANSI standard S1.42–2001. For a C message filter, the only valid design method is `Bell 41009`, which is an IIR design method following the Bell System Technical Reference PUB 41009. For a ITU-R 468–4 weighting filter, you can design an IIR or FIR filter. If you choose an IIR design, the design method is `IIR least p-norm`. If you choose an FIR design, the design method choices are `Equirriple` or `Frequency Sampling`. For an ITU-T 0.41 weighting filter, the available FIR design methods are `Equirriple` or `Frequency Sampling`.

Scale SOS filter coefficients to reduce chance of overflow

Selecting this parameter directs the design to scale the filter coefficients to reduce the chances that the inputs or calculations in the filter overflow and exceed the representable range of the filter. Clearing this option removes the scaling. This parameter applies only to IIR filters.

Filter Implementation

Structure

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. For audio weighting IIR filter designs, you can choose direct form I or II biquad (SOS). You can also choose to implement these structures in transposed form.

For FIR designs, you can choose a direct form, direct-form transposed, direct-form symmetric, or direct-form asymmetric structure.

Use basic elements to enable filter customization

Select this check box to implement the filter as a subsystem of basic Simulink blocks. Clear the check box to implement the filter as a high-level subsystem. By default, this check box is cleared.

The high-level implementation provides better compatibility across various filter structures, especially filters that would contain algebraic loops when constructed using basic elements. On the other hand, using basic elements enables the following optimization parameters:

- **Optimize for zero gains** — Terminate chains that contain Gain blocks with a gain of zero.
- **Optimize for unit gains** — Remove Gain blocks that scale by a factor of one.
- **Optimize for delay chains** — Substitute delay chains made up of *n* unit delays with a single delay by *n*.
- **Optimize for negative gains** — Use subtraction in Sum blocks instead of negative gains in Gain blocks.

Optimize for unit-scale values

Select this check box to scale unit gains between sections in SOS filters. This parameter is available only for SOS filters.

Input processing

Specify how the block should process the input. The available options may vary depending on he settings of the **Filter Structure** and **Use basic elements for filter customization** parameters. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` — When you select this option, the block treats each column of the input as a separate channel.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

For more information about sample- and frame-based processing, see “Sample- and Frame-Based Concepts”.

Use symbolic names for coefficients

Select this check box to enable the specification of coefficients using MATLAB variables. The available coefficient names differ depending on the filter structure. Using symbolic names allows tuning of filter coefficients in generated code. By default, this check box is cleared.

How To

- Audio Weighting Filters Example

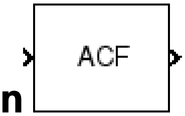
Autocorrelation

Autocorrelation of vector or matrix input

Library

Statistics

`dspstat3`



Description

The Autocorrelation block computes the autocorrelation along the first dimension of an N-D input array. The block accepts fixed-point signals when you set the **Computation domain** to `Time`.

When the input to the Autocorrelation block is an *M*-by-*N* matrix *u*, the output, *y*, is an (*l*+1)-by-*N* matrix whose *j*th column has elements

$$y_{i,j} = \sum_{k=0}^{M-l-1} u^*_{k,j} u_{(k+i),j} \qquad 0 \le i \le l$$

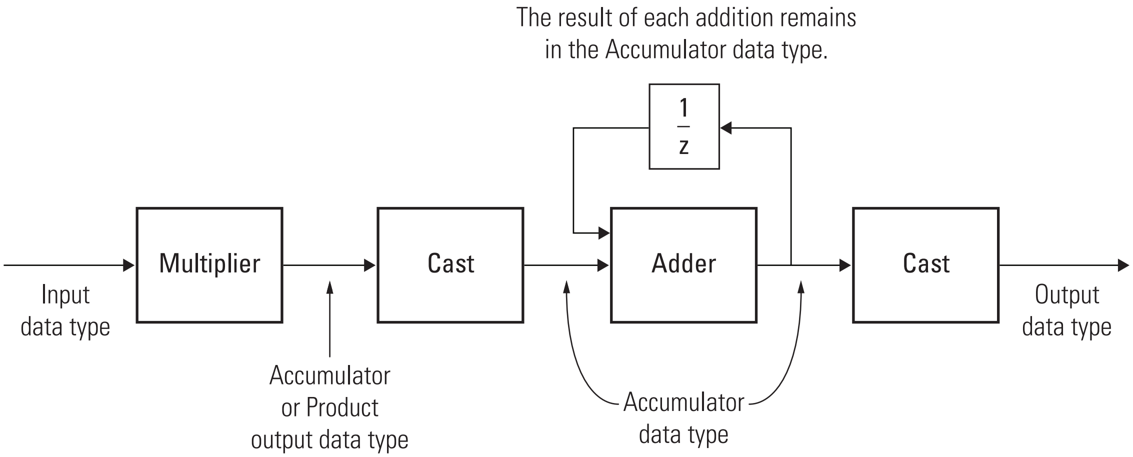
where * denotes the complex conjugate, and *l* represents the maximum lag. $y_{0,j}$ is the zero-lag element in the *j*th column. When you select **Compute all non-negative lags**, *l*=*M*–1. Otherwise, *l* is the nonnegative integer value you specify for the **Maximum non-negative lag (less than input length)** parameter.

Similarly, for an N-D input array, the block outputs an N-D array, where the size of the first dimension is *l*+1, and the sizes of all other dimensions match those of the input array. For example, when the input is an *M*-by-*N*-by-*P* array, the Autocorrelation block outputs an (*l*+1)-by-*N*-by-*P* array.

Fixed-Point Data Types

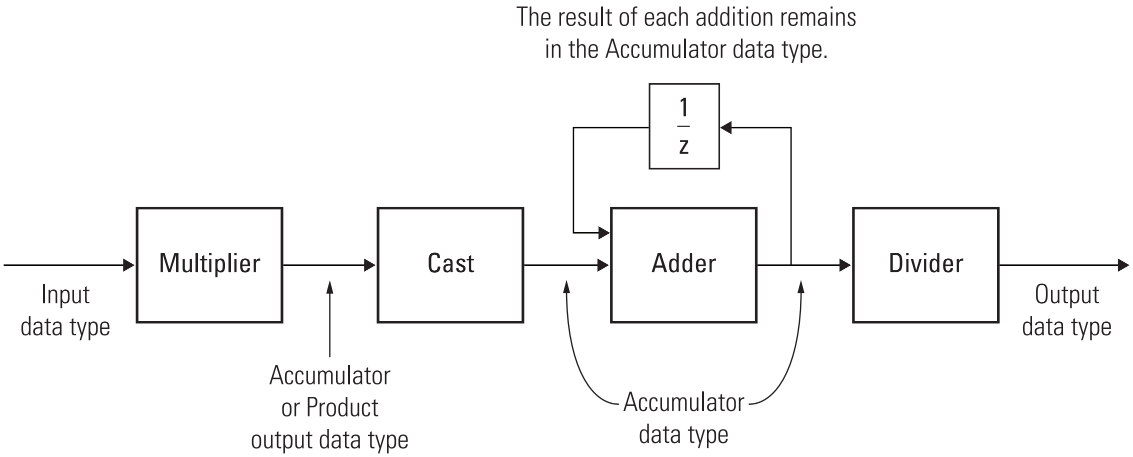
The following diagrams show the data types used within the Autocorrelation block for fixed-point signals (time domain only).

Signal flow when Scaling is "None"



The result of each addition remains in the Accumulator data type.
1/z
Multiplier
Cast
Adder
Cast
Input data type
Accumulator or Product output data type
Accumulator data type
Output data type

Signal flow when Scaling is other than "None"



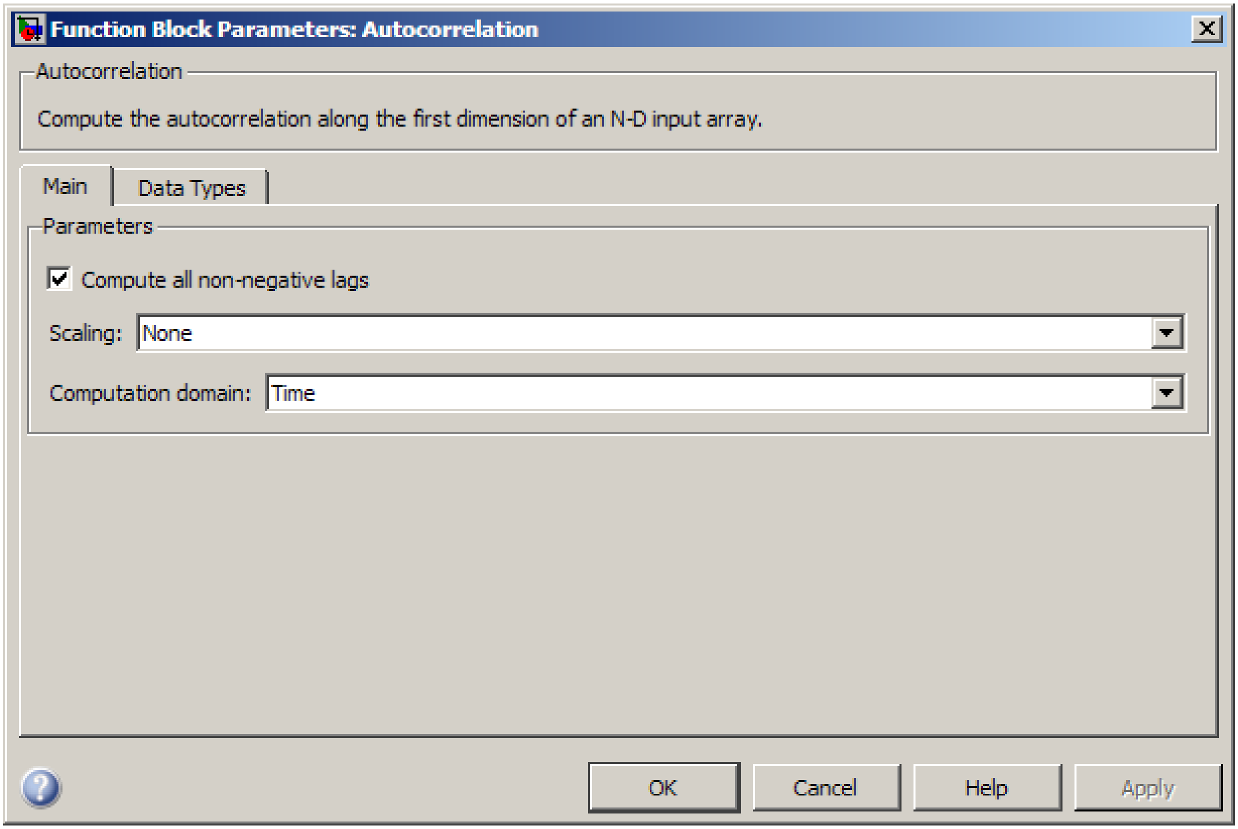
The result of each addition remains in the Accumulator data type.
1/z
Multiplier
Cast
Adder
Divider
Input data type
Accumulator or Product output data type
Accumulator data type
Output data type

You can set the product output, accumulator, and output data types on the **Data Types** pane of the block dialog as discussed in the next section.

The output of the multiplier is in the product output data type when the input is real. When the input is complex, the result of the multiplication is in the accumulator data type. For details on the complex multiplication performed, see “Multiplication Data Types”.

Dialog Box

The **Main** pane of the Autocorrelation block dialog appears as follows.



Autocorrelation

Compute the autocorrelation along the first dimension of an N-D input array.

Parameters

☑ Compute all non-negative lags

Scaling: None

Computation domain: Time

Compute all non-negative lags

When you select this check box, the block computes the autocorrelation over all nonnegative lags in the range [0, `length(input)-1`]. When you clear the check box, the block computes the autocorrelation using lags in the range [0, *l*], where *l* is the value you specify for the **Maximum non-negative lag (less than input length)** parameter.

Maximum non-negative lag (less than input length)

Specify the maximum positive lag, *l*, for the autocorrelation. This parameter is available only when you clear the **Compute all non-negative lags** check box.

Scaling

This parameter controls the scaling that the block applies to the output. The following options are available:

- `None` — Generates the raw autocorrelation $y_{i,j}$ without normalization.
- `Biased` — Generates the biased estimate of the autocorrelation.

$$y_{i,j}^{biased} = \frac{y_{i,j}}{M}$$

- `Unbiased` — Generates the unbiased estimate of the autocorrelation.

$$y_{i,j}^{unbiased} = \frac{y_{i,j}}{M-i}$$

- `Unity at zero-lag` — Normalizes the estimate of the autocorrelation for each channel so that the zero-lag sum is identically 1.

$$y_{0,j} = 1$$

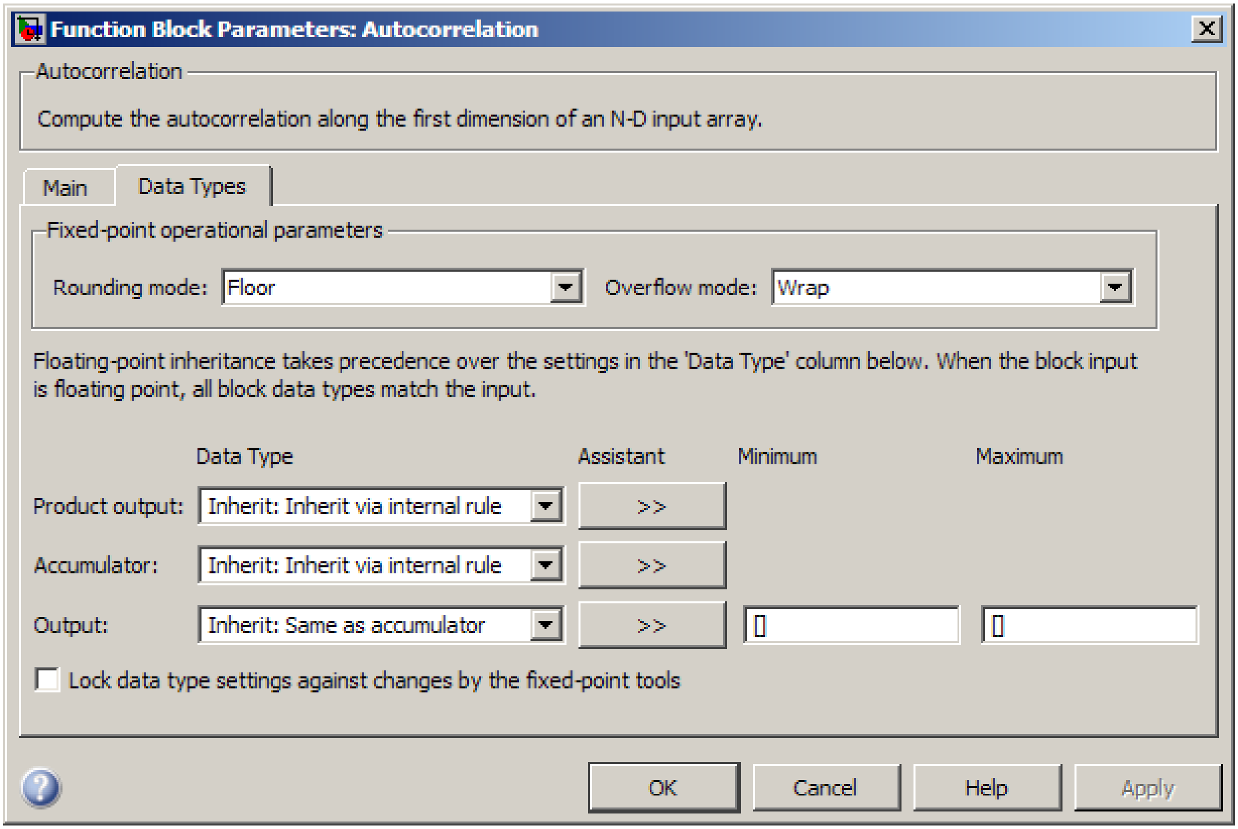
Computation domain

This parameter sets the domain in which the block computes convolutions to one of the following settings:

- `Time` — Computes in the time domain, which minimizes memory use
- `Frequency` — Computes in the frequency domain, which might require fewer computations than computing in the time domain, depending on the input length

Note This parameter must be set to `Time` for fixed-point signals.

The **Data Types** pane of the Autocorrelation block dialog appears as follows.



Function Block Parameters: Autocorrelation

Autocorrelation

Compute the autocorrelation along the first dimension of an N-D input array.

Fixed-point operational parameters

Rounding mode: Floor

Overflow mode: Wrap

Floating-point inheritance takes precedence over the settings in the 'Data Type' column below. When the block input is floating point, all block data types match the input.

	Data Type	Assistant	Minimum	Maximum
Product output:	Inherit: Inherit via internal rule	>>		
Accumulator:	Inherit: Inherit via internal rule	>>		
Output:	Inherit: Same as accumulator	>>	[]	[]

□ Lock data type settings against changes by the fixed-point tools

Note Fixed-point signals are only supported for the time domain. To use the parameters on this pane, make sure `Time` is selected for the **Computation domain** parameter on the **Main** pane.

Rounding mode

Select the “rounding mode” for fixed-point operations.

Note: The **Rounding mode** and **Overflow mode** settings have no effect on numerical results when all the following conditions exist:

- **Product output data type** is `Inherit: Inherit via internal rule`
- **Accumulator data type** is `Inherit: Inherit via internal rule`
- **Output data type** is `Inherit: Same as accumulator`

With these data type settings, the block is effectively operating in full precision mode.

Overflow mode

Select the “overflow mode” for fixed-point operations.

Product output data type

Specify the product output data type. See “Fixed-Point Data Types” on page 1-66 and “Multiplication Data Types” for illustrations depicting the use of the product output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`
- An expression that evaluates to a valid data type, for example, `fixdt([],16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Product output data type** parameter.

See “Specify Data Types Using Data Type Assistant” in “Simulink User's Guide” for more information.

Accumulator data type

Specify the accumulator data type. See “Fixed-Point Data Types” on page 1-66 for illustrations depicting the use of the accumulator data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`
- An expression that evaluates to a valid data type, for example, `fixdt([],16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Accumulator data type** parameter.

See “Specify Data Types Using Data Type Assistant” in “Simulink User's Guide” for more information.

Output data type

Specify the output data type. See "Fixed-Point Data Types" on page 1-66 for illustrations depicting the use of the output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as accumulator`
- An expression that evaluates to a valid data type, for example, `fixdt([],16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See "Specify Block Output Data Types" in "Simulink User's Guide" for more information.

Minimum

Specify the minimum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see "Signal Ranges")
- Automatic scaling of fixed-point data types

Maximum

Specify the maximum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see "Signal Ranges")
- Automatic scaling of fixed-point data types

Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned)

Port	Supported Data Types
	• 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Output	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers

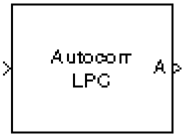
Autocorrelation LPC

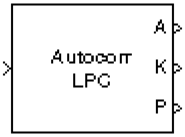
Determine coefficients of Nth-order forward linear predictors

Library

Estimation / Linear Prediction

`dsplp`





Description

The Autocorrelation LPC block determines the coefficients of an *N-step forward linear predictor* for the time-series in each length-M input channel, u, by minimizing the prediction error in the least squares sense. A linear predictor is an FIR filter that predicts the next value in a sequence from the present and past inputs. This technique has applications in filter design, speech coding, spectral analysis, and system identification.

The Autocorrelation LPC block can output the prediction error for each channel as polynomial coefficients, reflection coefficients, or both. It can also output the prediction error power for each channel. The input u can be a scalar, unoriented vector, column vector, sample-based row vector, or a matrix. Frame-based row vectors are not valid inputs. The block treats all M-by-N matrix inputs as N channels of length M.

When you select **Inherit prediction order from input dimensions**, the prediction order, N, is inherited from the input dimensions. Otherwise, you can use the **Prediction order** parameter to specify the value of N. Note that N must be a scalar with a value less than the length of the input channels or the block produces an error.

When **Output(s)** is set to A, port A is enabled. For each channel, port A outputs an (N+1)-by-1 column vector, $a = [1\ a_2\ a_3\ \ldots\ a_{N+1}]^T$, containing the coefficients of an Nth-order moving average (MA) linear process that predicts the next value, $\hat{u}_{M+1}$, in the input time-series.

$$\hat{u}_{M+1} = -(a_2 u_M) - (a_3 u_{M-1}) - \ldots - (a_{N+1} u_{M-N+1})$$

When **Output(s)** is set to K, port K is enabled. For each channel, port K outputs a length-N column vector whose elements are the prediction error reflection coefficients. When **Output(s)** is set to A and K, both port A and K are enabled, and each port outputs its respective set of prediction coefficients for each channel.

When you select **Output prediction error power (P)**, port P is enabled. The prediction error power is output at port P as a vector whose length is the number of input channels.

Algorithm

The Autocorrelation LPC block computes the least squares solution to

$$\min_{i \in \Re^n} \|U\tilde{a} - b\|$$

where $\|\cdot\|$ indicates the 2-norm and

$$U = \begin{bmatrix} u_1 & 0 & \cdots & 0 \\ u_2 & u_1 & \ddots & \vdots \\ \vdots & u_2 & \ddots & 0 \\ \vdots & \vdots & \ddots & u_1 \\ \vdots & \vdots & \vdots & u_2 \\ \vdots & \vdots & \vdots & \vdots \\ u_M & \vdots & \vdots & \vdots \\ 0 & \ddots & \vdots & \vdots \\ \vdots & \ddots & \ddots & \vdots \\ 0 & \cdots & 0 & u_M \end{bmatrix}, \tilde{a} = \begin{bmatrix} a_2 \\ \vdots \\ a_n + 1 \end{bmatrix}, b = \begin{bmatrix} u_2 \\ u_3 \\ \vdots \\ u_M \\ 0 \\ \vdots \\ 0 \end{bmatrix}$$

Solving the least squares problem via the normal equations

$$U^*U\tilde{a} = U^*b$$

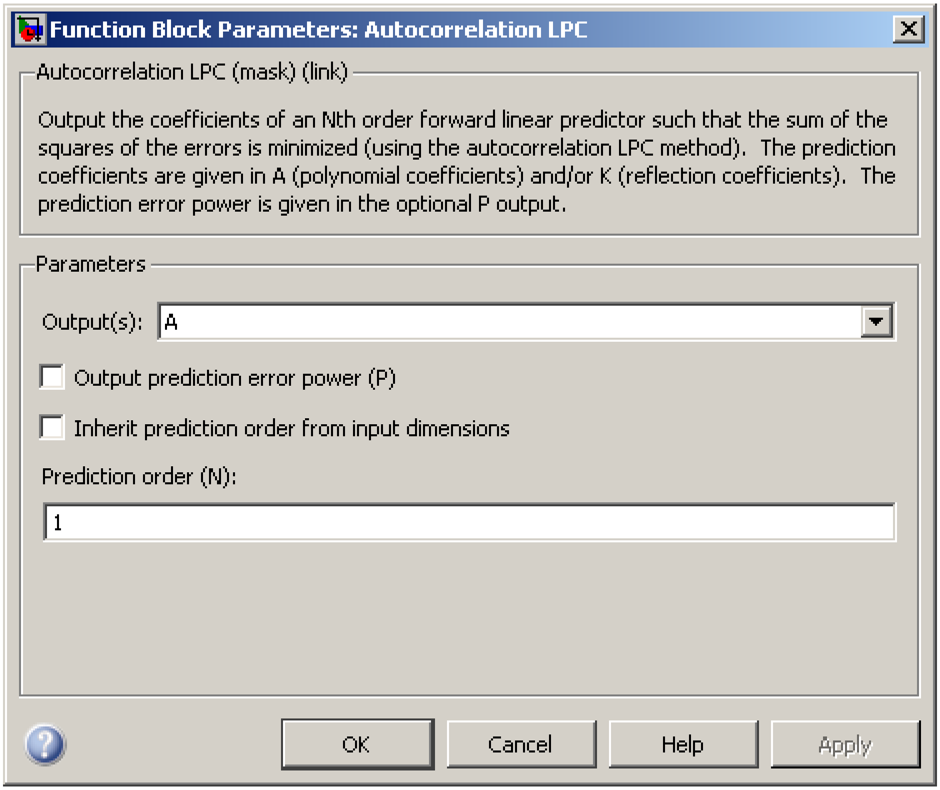
leads to the system of equations

$$\begin{bmatrix} r_1 & r_2^* & \cdots & r_n^* \\ r_2 & r_1 & \ddots & \vdots \\ \vdots & \ddots & \ddots & r_2^* \\ r_n & \cdots & r_2 & r_1 \end{bmatrix} \begin{bmatrix} a_2 \\ a_3 \\ \vdots \\ a_{n+1} \end{bmatrix} = \begin{bmatrix} -r_2 \\ -r_3 \\ \vdots \\ -r_{n+1} \end{bmatrix}$$

where $r = [r_1\ r_2\ r_3\ \ldots\ r_{n+1}]^T$ is an autocorrelation estimate for u computed using the Autocorrelation block, and * indicates the complex conjugate transpose. The normal equations are solved in $O(n^2)$ operations by the Levinson-Durbin block.

Note that the solution to the LPC problem is very closely related to the Yule-Walker AR method of spectral estimation. In that context, the normal equations above are referred to as the Yule-Walker AR equations.

Dialog Box



Function Block Parameters: Autocorrelation LPC

Autocorrelation LPC (mask) (link)

Output the coefficients of an Nth order forward linear predictor such that the sum of the squares of the errors is minimized (using the autocorrelation LPC method). The prediction coefficients are given in A (polynomial coefficients) and/or K (reflection coefficients). The prediction error power is given in the optional P output.

Parameters

Output(s): A

□ Output prediction error power (P)

□ Inherit prediction order from input dimensions

Prediction order (N):

1

Output(s)

The type of prediction coefficients output by the block. The block can output polynomial coefficients (A), reflection coefficients (K), or both (A and K).

Output prediction error power (P)

When selected, enables port P, which outputs the output prediction error power.

Inherit prediction order from input dimensions

When selected, the block inherits the prediction order from the input dimensions.

Prediction order (N)

Specify the prediction order, *N*, which must be a scalar. This parameter is disabled when you select the **Inherit prediction order from input dimensions** parameter.

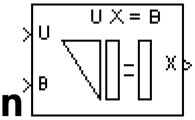
Backward Substitution

Solve *UX*=*B* for *X* when *U* is upper triangular matrix

Library

Math Functions / Matrices and Linear Algebra / Linear System Solvers

`dspsolvers`



Description

The Backward Substitution block solves the linear system *UX*=*B* by simple backward substitution of variables, where:

- *U* is the upper triangular *M*-by-*M* matrix input to the U port.
- *B* is the *M*-by-*N* matrix input to the B port.

The *M*-by-*N* output matrix *X* is the solution of the equations. The block does not check the rank of the inputs.

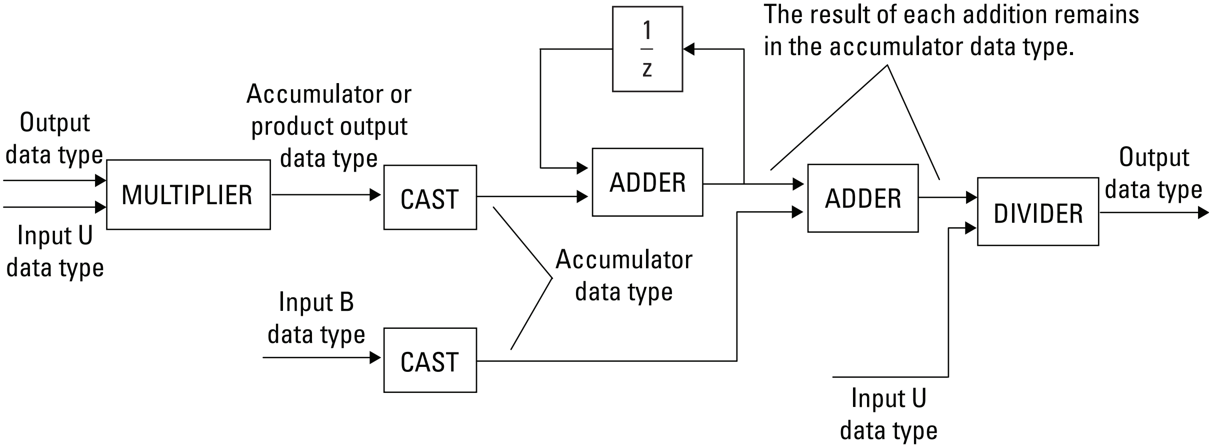
The block uses only the elements in the *upper triangle* of input *U* and ignores the lower elements. When you select the **Input U is unit-upper triangular** check box, the block assumes the elements on the diagonal of *U* are 1s. This is useful when matrix *U* is the result of another operation, such as an LDL decomposition, that uses the diagonal elements to represent the *D* matrix.

The block treats a length-*M* vector input at port B as an *M*-by-1 matrix.

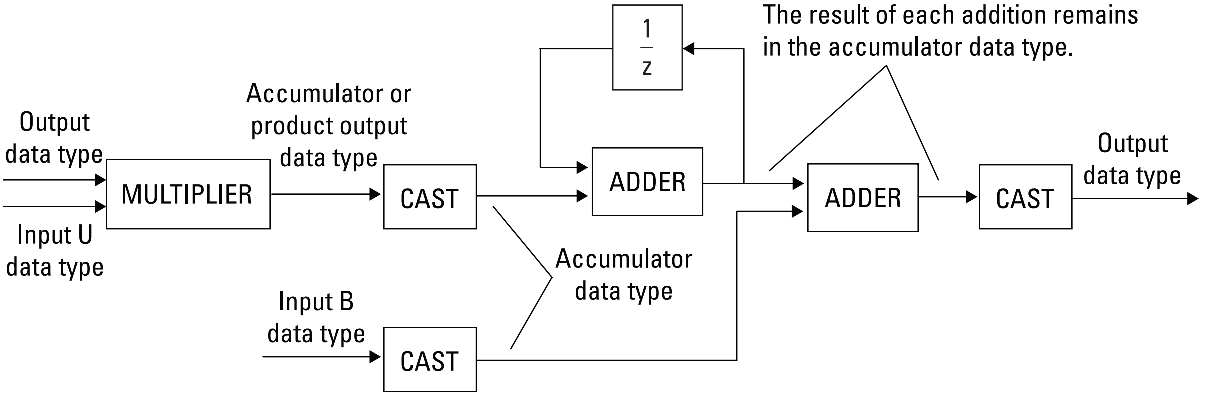
Fixed-Point Data Types

The following diagram shows the data types used within the Backward Substitution block for fixed-point signals.

When input U is not unit-upper triangular:



When input U is unit-upper triangular:

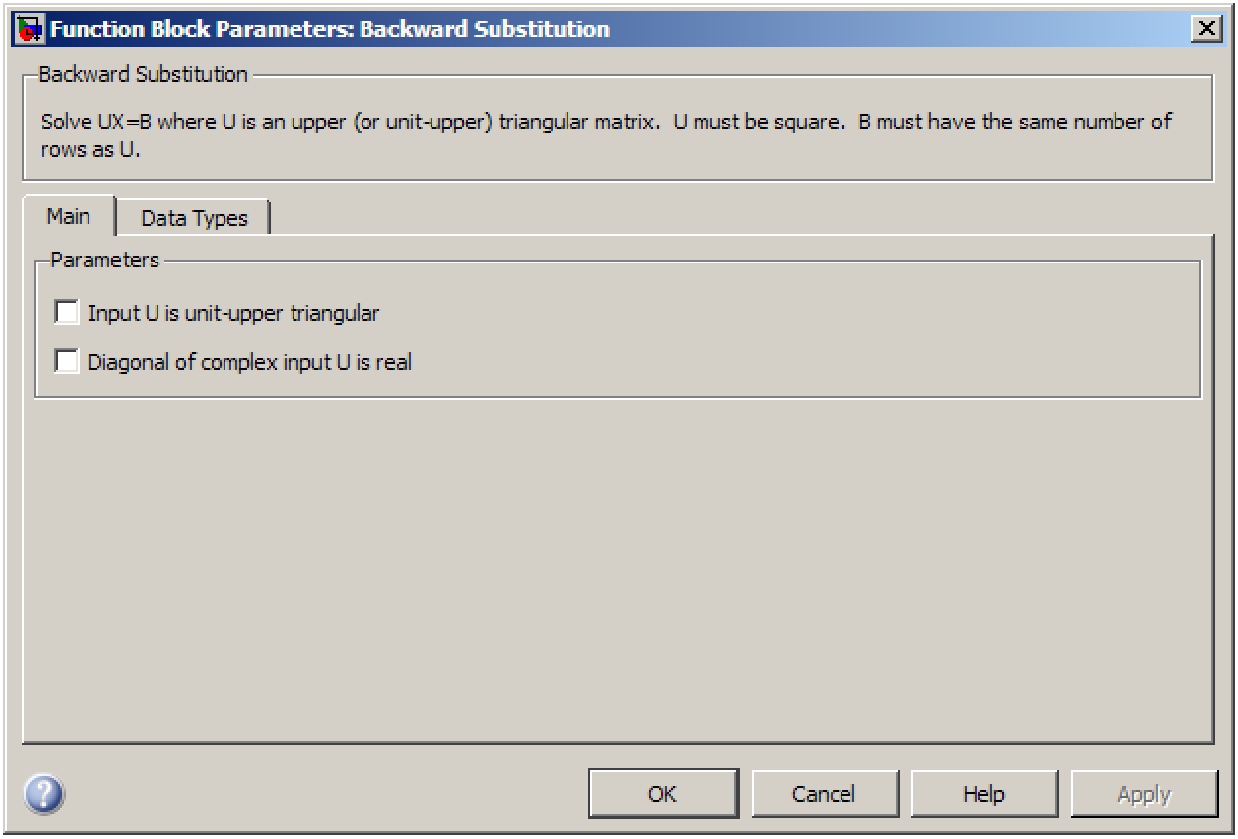


You can set the product output, accumulator, and output data types in the block dialog as discussed in the following section.

The output of the multiplier is in the product output data type when the input is real. When the input is complex, the result of the multiplication is in the accumulator data type. For details on the complex multiplication performed, see “Multiplication Data Types”.

Dialog Box

The **Main** pane of the Backward Substitution block dialog box appears as follows.



Backward Substitution

Solve UX=B where U is an upper (or unit-upper) triangular matrix. U must be square. B must have the same number of rows as U.

Parameters

□ Input U is unit-upper triangular

□ Diagonal of complex input U is real

Input U is unit-upper triangular

Select this check box only when all elements on the diagonal of *U* have a value of 1. When you do so, the block optimizes its behavior by skipping an unnecessary divide operation.

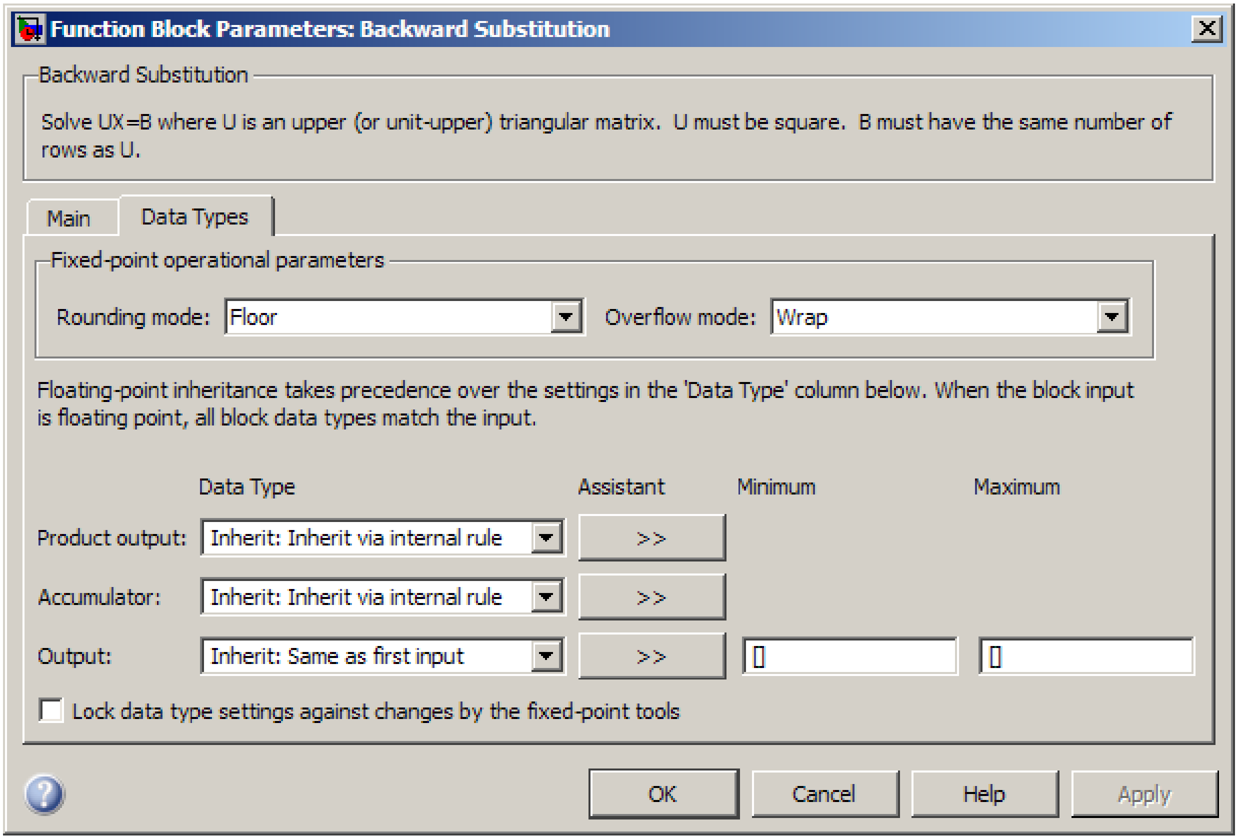
Do not select this check box if there are any elements on the diagonal of *U* that do not have a value of 1. When you clear the **Input U is unit-upper triangular** check box, the block always performs the necessary divide operation.

Diagonal of complex input U is real

Select to optimize simulation speed when the diagonal elements of complex input U are real. This parameter is only visible when **Input U is unit-upper triangular** is not selected.

Note: When U is a complex fixed-point signal, you must select either **Input U is unit-upper triangular** or **Diagonal of complex input U is real**. In such a case, any imaginary part of the diagonal of U is ignored.

The **Data Types** pane of the Backward Substitution block dialog appears as follows.



Function Block Parameters: Backward Substitution

Backward Substitution

Solve UX=B where U is an upper (or unit-upper) triangular matrix. U must be square. B must have the same number of rows as U.

Fixed-point operational parameters

Rounding mode: Floor

Overflow mode: Wrap

Floating-point inheritance takes precedence over the settings in the 'Data Type' column below. When the block input is floating point, all block data types match the input.

	Data Type	Assistant	Minimum	Maximum
Product output:	Inherit: Inherit via internal rule	>>		
Accumulator:	Inherit: Inherit via internal rule	>>		
Output:	Inherit: Same as first input	>>	[]	[]

□ Lock data type settings against changes by the fixed-point tools

Note: Floating-point inheritance takes precedence over the data type settings defined on this pane. When inputs are floating point, the block ignores these settings, and all internal data types are floating point.

Rounding mode

Select the "rounding mode" for fixed-point operations.

Overflow mode

Select the "overflow mode" for fixed-point operations.

Product output data type

Specify the product output data type. See “Fixed-Point Data Types” on page 1-79 and “Multiplication Data Types” for illustrations depicting the use of the product output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Product output data type** parameter.

See “Specify Data Types Using Data Type Assistant” in “Simulink User's Guide” for more information.

Accumulator data type

Specify the accumulator data type. See “Fixed-Point Data Types” on page 1-79 for illustrations depicting the use of the accumulator data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Accumulator data type** parameter.

See “Specify Data Types Using Data Type Assistant” in “Simulink User's Guide” for more information.

Output data type

Specify the output data type. See “Fixed-Point Data Types” on page 1-79 for illustrations depicting the use of the output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as first input`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Specify Block Output Data Types” in “Simulink User's Guide” for more information.

Minimum

Specify the minimum value that the block should output. The default value is [ ] (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges”)
- Automatic scaling of fixed-point data types

Maximum

Specify the maximum value that the block should output. The default value is [ ] (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges”)
- Automatic scaling of fixed-point data types

Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

Supported Data Types

Port	Supported Data Types
U	• Double-precision floating point • Single-precision floating point • Fixed point (signed only) • 8-, 16-, and 32-bit signed integers
B	• Double-precision floating point • Single-precision floating point • Fixed point (signed only) • 8-, 16-, and 32-bit signed integers
X	• Double-precision floating point • Single-precision floating point • Fixed point (signed only)

Bandpass Filter

Design bandpass filter

Library

Filtering / Filter Designs

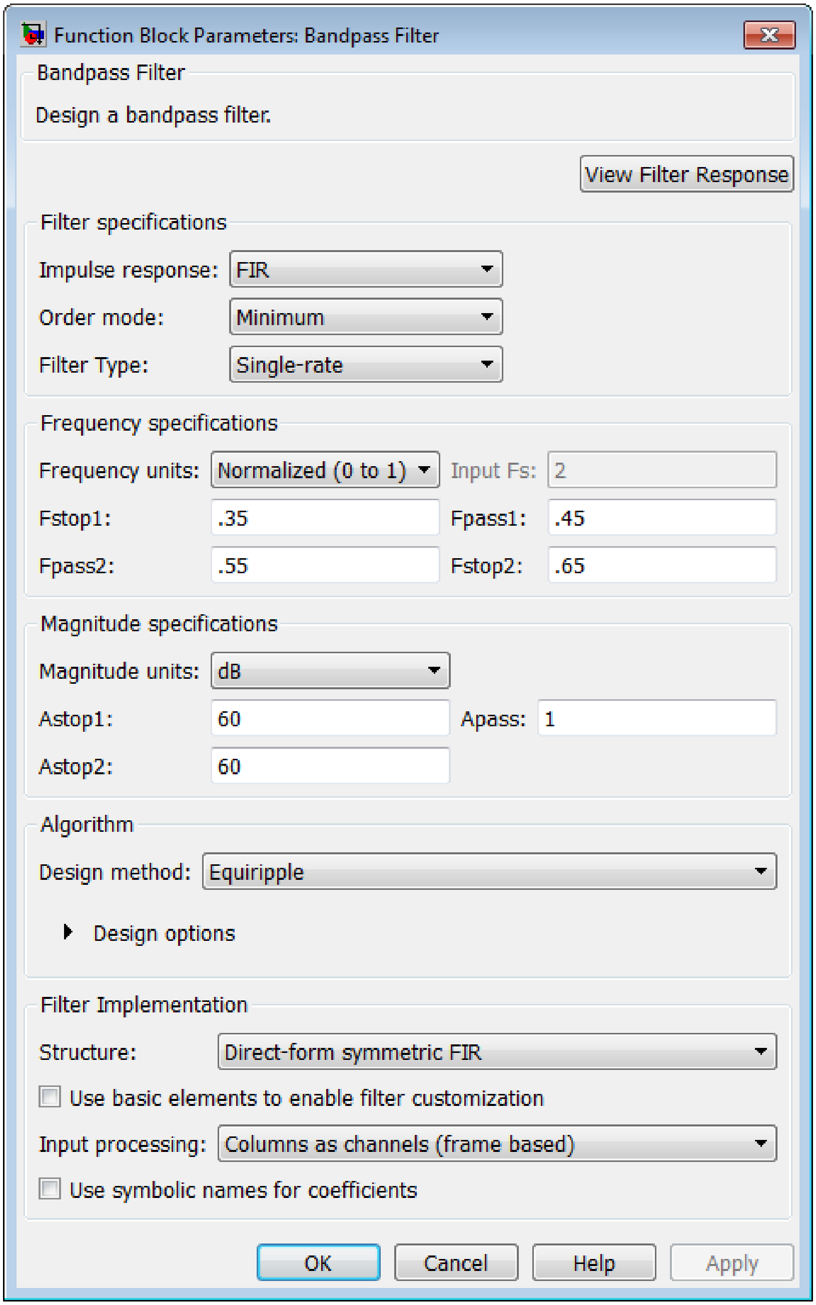
`dspfdesign`

Description

This block brings the filter design capabilities of the “`filterbuilder`” function to the Simulink environment.

Dialog Box

See “Bandpass Filter Design Dialog Box — Main Pane” for more information about the parameters of this block. The **Data Types** and **Code Generation** panes are not available for blocks in the DSP System Toolbox Filter Designs library.



Function Block Parameters: Bandpass Filter

Bandpass Filter

Design a bandpass filter.

Filter specifications

Impulse response: FIR

Order mode: Minimum

Filter Type: Single-rate

Frequency specifications

Frequency units: Normalized (0 to 1) Input Fs: 2

Fstop1: .35 Fpass1: .45

Fpass2: .55 Fstop2: .65

Magnitude specifications

Magnitude units: dB

Astop1: 60 Apass: 1

Astop2: 60

Algorithm

Design method: Equiripple

▸ Design options

Filter Implementation

Structure: Direct-form symmetric FIR

□ Use basic elements to enable filter customization

Input processing: Columns as channels (frame based)

□ Use symbolic names for coefficients

View filter response

This button opens the Filter Visualization Tool (`fvtool`) from the Signal Processing Toolbox product. You can use the tool to display:

- Magnitude response, phase response, and group delay in the frequency domain.
- Impulse response and step response in the time domain.
- Pole-zero information.

The tool also helps you evaluate filter performance by providing information about filter order, stability, and phase linearity. For more information on FVTool, see the Signal Processing Toolbox documentation.

Filter Specifications

In this group, you specify your filter format, such as the impulse response and the filter order.

Impulse response

Select either `FIR` or `IIR` from the drop-down list. `FIR` is the default. When you choose an impulse response, the design methods and structures you can use to implement your filter change accordingly.

Note: The design methods and structures for FIR filters are not the same as the methods and structures for IIR filters.

Order mode

Select `Minimum` (the default) or `Specify`. Selecting `Specify` enables the **Order** option so you can enter the filter order. When you set the **Impulse response** to `IIR`, you can specify different numerator and denominator orders. To specify a different denominator order, you must select the **Denominator order** check box.

Order

Enter the filter order. This option is enabled only if you set the **Order mode** to `Specify`.

Denominator order

Select this check box to specify a different denominator order. This option is enabled only if you set the **Impulse response** to `IIR` and the **Order mode** to `Specify`.

Filter type

Select `Single-rate`, `Decimator`, `Interpolator`, or `Sample-rate converter`. Your choice determines the type of filter as well as the design methods and structures that are available to implement your filter. By default, the block specifies a single-rate filter.

- Selecting `Decimator` or `Interpolator` activates the **Decimation Factor** or the **Interpolation Factor** options respectively.
- Selecting `Sample-rate converter` activates both factors.

Decimation Factor

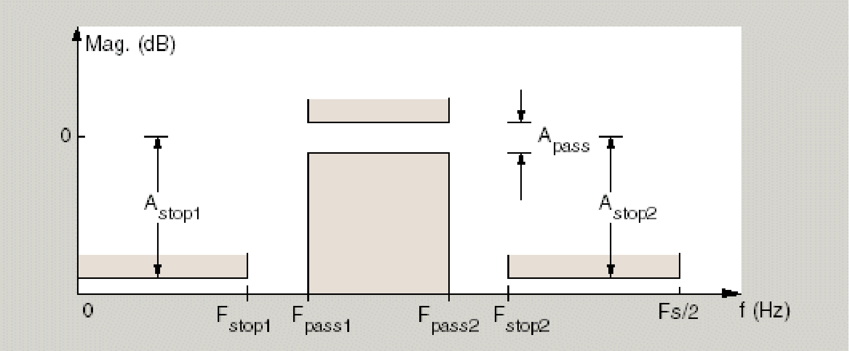
Enter the decimation factor. This option is enabled only if the **Filter type** is set to `Decimator` or `Sample-rate converter`. The default value is 2.

Interpolation Factor

Enter the interpolation factor. This option is enabled only if the **Filter type** is set to `Interpolator` or `Sample-rate converter`. The default value is 2.

Frequency Specifications

The parameters in this group allow you to specify your filter response curve. Graphically, the filter specifications look similar to those shown in the following figure.



In the figure, regions between specification values such as Fstop1 and Fpass1 represent transition regions where the filter response is not constrained.

Frequency constraints

When **Order mode** is `Specify`, select the filter features that the block uses to define the frequency response characteristics. The list contains the following options, when available for the filter specifications.

- `Passband and stopband edges` — Define the filter by specifying the frequencies for the edges for the stop- and passbands.
- `Passband edges` — For IIR filters, define the filter by specifying frequencies for the edges of the passband.
- `Stopband edges` — For IIR filters, define the filter by specifying frequencies for the edges of the stopbands.
- `3 dB points` — For IIR filters, define the filter response by specifying the locations of the 3 dB points. The 3 dB point is the frequency for the point three decibels below the passband value.
- `3 dB points and passband width` — For IIR filters, define the filter by specifying frequencies for the 3 dB points in the filter response and the width of the passband.
- `3 dB points and stopband widths` — For IIR filters, define the filter by specifying frequencies for the 3 dB points in the filter response and the width of the stopband.
- `6 dB points` — For FIR filters, define the filter response by specifying the locations of the 6 dB points. The 6 dB point is the frequency for the point six decibels below the passband value.

Frequency units

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select `Normalized (0–1)` to enter frequencies in normalized form. This behavior is the default. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—`Hz`, `kHz`, `MHz`, or `GHz`. Selecting one of the unit options enables the **Input Fs** parameter.

Input Fs

Fs, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available when you select one of the frequency options from the **Frequency units** list.

Fstop1

Enter the frequency at the edge of the end of the first stopband. Specify the value in either normalized frequency units or the absolute units you select in **Frequency units**.

Fpass1

Enter the frequency at the edge of the start of the passband. Specify the value in either normalized frequency units or the absolute units you selected for **Frequency units**.

Fpass2

Enter the frequency at the edge of the end of the passband. Specify the value in either normalized frequency units or the absolute units you select in **Frequency units**.

Fstop2

Enter the frequency at the edge of the start of the second stopband. Specify the value in either normalized frequency units or the absolute units you select in **Frequency units**.

F3dB1

When **Frequency constraints** is `3 dB points`, `3 dB points and passband width`, or `3 dB points and stopband width`, specify the lower-frequency 3 dB point.

F3dB2

When **Frequency constraints** is `3 dB points`, `3 dB points and passband width`, or `3 dB points and stopband width`, specify the higher-frequency 3 dB point.

F6dB1

When **Frequency constraints** is `6 dB points`, specify the lower-frequency 6 dB point.

F6dB2

When **Frequency constraints** is `6 dB points`, specify the higher-frequency 6 dB point.

Passband width

When **Frequency constraints** is `3 dB points and passband width`, specify the width of the passband, in units corresponding to the **Frequency units** parameter.

Stopband width

When **Frequency constraints** is `3 dB points and stopband width`, specify the width of the stopband, in units corresponding to the **Frequency units** parameter.

Magnitude Specifications

Parameters in this group specify the filter response in the passbands and stopbands.

Magnitude constraints

This option is only available when you specify the order of your filter design. The options for **Magnitude constraints** depend on the value of the **Frequency constraints**. When you set the **Frequency constraints** parameter to `Unconstrained`, **Magnitude constraints** must also be set to `Unconstrained`. When **Frequency constraints** is not set to `Unconstrained`, some combination of the following options will be available for the **Magnitude constraints** parameter: `Unconstrained`, `Passband ripple`, `Passband ripple and stopband attenuation` or `Stopband attenuation`.

Magnitude units

Specify the units for any parameter you provide in magnitude specifications.

From the drop-down list, select one of the following options:

- `Linear` — Specify the magnitude in linear units.
- `dB` — Specify the magnitude in dB (decibels). This is the default setting.
- `Squared` — Specify the magnitude in squared units.

Astop1

Enter the filter attenuation in the first stopband in the units you choose for **Magnitude units**, either linear or decibels.

Apass

Enter the filter ripple allowed in the passband in the units you choose for **Magnitude units**, either linear or decibels.

Astop2

Enter the filter attenuation in the second stopband in the units you choose for **Magnitude units**, either linear or decibels.

Algorithm

The parameters in this group allow you to specify the design method and structure of your filter.

Design Method

Lists the design methods available for the frequency and magnitude specifications you entered. When you change the specifications for a filter, such as changing the impulse response, the methods available to design filters changes as well. The default IIR design method is usually Butterworth, and the default FIR method is `Equiripple`.

Scale SOS filter coefficients to reduce chance of overflow

Selecting this parameter directs the design to scale the filter coefficients to reduce the chances that the inputs or calculations in the filter overflow and exceed the representable range of the filter. Clearing this option removes the scaling. This parameter applies only to IIR filters.

Design Options

The options for each design are specific for each design method. This section does not present all of the available options for all designs and design methods. There are many more that you encounter as you select different design methods and filter specifications. The following options represent some of the most common ones available.

Density factor

Density factor controls the density of the frequency grid over which the design method optimization evaluates your filter response function. The number of equally spaced points in the grid is the value you enter for **Density factor** times (filter order + 1).

Increasing the value creates a filter that more closely approximates an ideal equiripple filter but increases the time required to design the filter. The default value of 20 represents a reasonable trade between the accurate approximation to the ideal filter and the time to design the filter.

Phase constraint

Specify the phase constraint of the filter as `Linear`, `Maximum`, or `Minimum`.

Minimum order

When you select this parameter, the design method determines and design the minimum order filter to meet your specifications. Some filters do not provide this parameter. Select `Any`, `Even`, or `Odd` from the drop-down list to direct the design to be any minimum order, or minimum even order, or minimum odd order.

Match Exactly

Specifies that the resulting filter design matches either the passband or stopband or both bands when you select `passband` or `stopband` or `both` from the drop-down list.

Minimum order

When you select this parameter, the design method determines and design the minimum order filter to meet your specifications. Some filters do not provide this parameter. Select `Any`, `Even`, or `Odd` from the drop-down list to direct the design to be any minimum order, or minimum even order, or minimum odd order.

Note: Generally, **Minimum order** designs are not available for IIR filters.

Filter Implementation

Structure

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. By default, FIR filters use direct-form structure, and IIR filters use direct-form II filters with SOS.

Use basic elements to enable filter customization

Select this check box to implement the filter as a subsystem of basic Simulink blocks. Clear the check box to implement the filter as a high-level subsystem. By default, this check box is cleared.

The high-level implementation provides better compatibility across various filter structures, especially filters that would contain algebraic loops when constructed using basic elements. On the other hand, using basic elements enables the following optimization parameters:

- **Optimize for zero gains** — Terminate chains that contain Gain blocks with a gain of zero.
- **Optimize for unit gains** — Remove Gain blocks that scale by a factor of one.
- **Optimize for delay chains** — Substitute delay chains made up of *n* unit delays with a single delay by *n*.
- **Optimize for negative gains** — Use subtraction in Sum blocks instead of negative gains in Gain blocks.

Optimize for unit-scale values

Select this check box to scale unit gains between sections in SOS filters. This parameter is available only for SOS filters.

Input processing

Specify how the block should process the input. The available options may vary depending on he settings of the **Filter Structure** and **Use basic elements for filter customization** parameters. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` — When you select this option, the block treats each column of the input as a separate channel.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

Note: The `Inherited (this choice will be removed — see release notes)` option will be removed in a future release. See "Frame-Based Processing" in the *DSP System Toolbox Release Notes* for more information.

Rate options

When the **Filter type** parameter specifies a multirate filter, select the rate processing rule for the block from following options:

- `Enforce single-rate processing` — When you select this option, the block maintains the sample rate of the input.
- `Allow multirate processing` — When you select this option, the block adjusts the rate at the output to accommodate an increased or reduced number of samples. To select this option, you must set the **Input processing** parameter to `Elements as channels (sample based)`.

Use symbolic names for coefficients

Select this check box to enable the specification of coefficients using MATLAB variables. The available coefficient names differ depending on the filter structure. Using symbolic names allows tuning of filter coefficients in generated code. By default, this check box is cleared.

View filter response

This button opens the Filter Visualization Tool (`fvtool`) from the Signal Processing Toolbox product. You can use the tool to display:

- Magnitude response, phase response, and group delay in the frequency domain.
- Impulse response and step response in the time domain.
- Pole-zero information.

The tool also helps you evaluate filter performance by providing information about filter order, stability, and phase linearity. For more information on FVTool, see the Signal Processing Toolbox documentation.

Filter Specifications

In this group, you specify your filter format, such as the impulse response and the filter order.

Impulse response

Select either `FIR` or `IIR` from the drop-down list. `FIR` is the default. When you choose an impulse response, the design methods and structures you can use to implement your filter change accordingly.

Note: The design methods and structures for FIR filters are not the same as the methods and structures for IIR filters.

Order mode

Select `Minimum` (the default) or `Specify`. Selecting `Specify` enables the **Order** option so you can enter the filter order. When you set the **Impulse response** to `IIR`, you can specify different numerator and denominator orders. To specify a different denominator order, you must select the **Denominator order** check box.

Order

Enter the filter order. This option is enabled only if you set the **Order mode** to `Specify`.

Denominator order

Select this check box to specify a different denominator order. This option is enabled only if you set the **Impulse response** to `IIR` and the **Order mode** to `Specify`.

Filter type

Select Single-rate, Decimator, Interpolator, or Sample-rate converter. Your choice determines the type of filter as well as the design methods and structures that are available to implement your filter. By default, the block specifies a single-rate filter.

- Selecting Decimator or Interpolator activates the **Decimation Factor** or the **Interpolation Factor** options respectively.
- Selecting Sample-rate converter activates both factors.

Decimation Factor

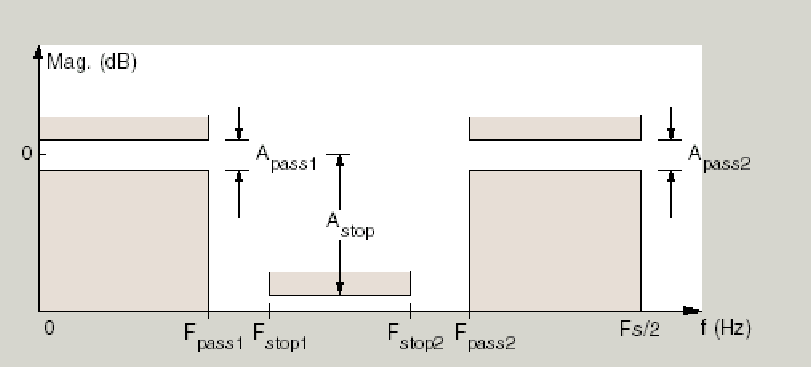
Enter the decimation factor. This option is enabled only if the **Filter type** is set to Decimator or Sample-rate converter. The default value is 2.

Interpolation Factor

Enter the interpolation factor. This option is enabled only if the **Filter type** is set to Interpolator or Sample-rate converter. The default value is 2.

Frequency Specifications

The parameters in this group allow you to specify your filter response curve. Graphically, the filter specifications look similar to those shown in the following figure.



Frequency constraints

When **Order mode** is Specify, select the filter features that the block uses to define the frequency response characteristics. The list contains the following options, when available for the filter specifications.

- `Passband and stopband edges` — Define the filter by specifying the frequencies for the edges for the stop- and passbands.
- `Passband edges` — For IIR filters, define the filter by specifying frequencies for the edges of the passband.
- `Stopband edges` — For IIR filters, define the filter by specifying frequencies for the edges of the stopbands.
- `3 dB points` — For IIR filters, define the filter response by specifying the locations of the 3 dB points. The 3 dB point is the frequency for the point three decibels below the passband value.
- `3 dB points and passband width` — For IIR filters, define the filter by specifying frequencies for the 3 dB points in the filter response and the width of the passband.
- `3 dB points and stopband widths` — For IIR filters, define the filter by specifying frequencies for the 3 dB points in the filter response and the width of the stopband.
- `6 dB points` — For FIR filters, define the filter response by specifying the locations of the 6 dB points. The 6 dB point is the frequency for the point six decibels below the passband value.

Frequency units

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select `Normalized (0–1)` to enter frequencies in normalized form. This behavior is the default. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—`Hz`, `kHz`, `MHz`, or `GHz`. Selecting one of the unit options enables the **Input Fs** parameter.

Input Fs

Fs, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available when you select one of the frequency options from the **Frequency units** list.

Output Fs

When you design an interpolator, Fs represents the sampling frequency at the filter output rather than the filter input. This option is available only when you set **Filter type** is `interpolator`.

Fpass1

Enter the frequency at the edge of the end of the first passband. Specify the value in either normalized frequency units or the absolute units you select in **Frequency units**.

Fstop1

Enter the frequency at the edge of the start of the stopband. Specify the value in either normalized frequency units or the absolute units you select in **Frequency units**.

Fstop2

Enter the frequency at the edge of the end of the stopband. Specify the value in either normalized frequency units or the absolute units you select in **Frequency units**.

Fpass2

Enter the frequency at the edge of the start of the second passband. Specify the value in either normalized frequency units or the absolute units you select in **Frequency units**.

F3dB1

When **Frequency constraints** is `3 dB points`, `3 dB points and passband width`, or `3 dB points and stopband width`, specify the lower-frequency 3 dB point.

F3dB2

When **Frequency constraints** is `3 dB points`, `3 dB points and passband width`, or `3 dB points and stopband width`, specify the higher-frequency 3 dB point.

F6dB1

When **Frequency constraints** is `6 dB points`, specify the lower-frequency 6 dB point.

F6dB2

When **Frequency constraints** is `6 dB points`, specify the higher-frequency 6 dB point.

Passband width

When **Frequency constraints** is `3 dB points and passband width`, specify the width of the passband, in units corresponding to the **Frequency units** parameter.

Stopband width

When **Frequency constraints** is `3 dB points and stopband width`, specify the width of the stopband, in units corresponding to the **Frequency units** parameter.

Magnitude Specifications

Parameters in this group specify the filter response in the passbands and stopbands.

Magnitude constraints

This option is only available when you specify the order of your filter design. The options for **Magnitude constraints** depend on the value of the **Frequency constraints**. Depending on the value of the **Frequency constraints** parameter, some combination of the following options will be available for the **Magnitude constraints** parameter: `Unconstrained`, `Passband ripple and stopband attenuation`, or `Constrained bands`.

Magnitude units

Specify the units for any parameter you provide in magnitude specifications. From the drop-down list, select one of the following options:

- `Linear` — Specify the magnitude in linear units.
- `dB` — Specify the magnitude in decibels (default).
- `Squared` — Specify the magnitude in squared units.

Apass1

Enter the filter ripple allowed in the first passband in the units you choose for **Magnitude units**, either linear or decibels.

Astop

Enter the filter attenuation in the stopband in the units you choose for **Magnitude units**, either linear or decibels

Apass2

Enter the filter ripple allowed in the second passband in the units you choose for **Magnitude units**, either linear or decibels

Algorithm

The parameters in this group allow you to specify the design method and structure of your filter.

Design Method

Lists the design methods available for the frequency and magnitude specifications you entered. When you change the specifications for a filter, such as changing the impulse response, the methods available to design filters changes as well. The default IIR design method is usually Butterworth, and the default FIR method is `Equiripple`.

Scale SOS filter coefficients to reduce chance of overflow

Selecting this parameter directs the design to scale the filter coefficients to reduce the chances that the inputs or calculations in the filter overflow and exceed the representable range of the filter. Clearing this option removes the scaling. This parameter applies only to IIR filters.

Design Options

The options for each design are specific for each design method. This section does not present all of the available options for all designs and design methods. There are many more that you encounter as you select different design methods and filter specifications. The following options represent some of the most common ones available.

Density factor

Density factor controls the density of the frequency grid over which the design method optimization evaluates your filter response function. The number of equally spaced points in the grid is the value you enter for **Density factor** times (filter order + 1).

Increasing the value creates a filter that more closely approximates an ideal equiripple filter but increases the time required to design the filter. The default value of 20 represents a reasonable trade between the accurate approximation to the ideal filter and the time to design the filter.

Phase constraint

Specify the phase constraint of the filter as `Linear`, `Maximum`, or `Minimum`.

Minimum order

When you select this parameter, the design method determines and design the minimum order filter to meet your specifications. Some filters do not provide this parameter. Select `Any`, `Even`, or `Odd` from the drop-down list to direct the design to be any minimum order, or minimum even order, or minimum odd order.

Match Exactly

Specifies that the resulting filter design matches either the passband or stopband or both bands when you select `passband` or `stopband` or `both` from the drop-down list.

Filter Implementation

Structure

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. By default, FIR filters use direct-form structure, and IIR filters use direct-form II filters with SOS.

Use basic elements to enable filter customization

Select this check box to implement the filter as a subsystem of basic Simulink blocks. Clear the check box to implement the filter as a high-level subsystem. By default, this check box is cleared.

The high-level implementation provides better compatibility across various filter structures, especially filters that would contain algebraic loops when constructed using basic elements. On the other hand, using basic elements enables the following optimization parameters:

- **Optimize for zero gains** — Terminate chains that contain Gain blocks with a gain of zero.
- **Optimize for unit gains** — Remove Gain blocks that scale by a factor of one.
- **Optimize for delay chains** — Substitute delay chains made up of *n* unit delays with a single delay by *n*.
- **Optimize for negative gains** — Use subtraction in Sum blocks instead of negative gains in Gain blocks.

Optimize for unit-scale values

Select this check box to scale unit gains between sections in SOS filters. This parameter is available only for SOS filters.

Input processing

Specify how the block should process the input. The available options may vary depending on he settings of the **Filter Structure** and **Use basic elements for filter customization** parameters. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` — When you select this option, the block treats each column of the input as a separate channel.

- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

Note: The `Inherited (this choice will be removed — see release notes)` option will be removed in a future release. See “Frame-Based Processing” in the *DSP System Toolbox Release Notes* for more information.

Rate options

When the **Filter type** parameter specifies a multirate filter, select the rate processing rule for the block from following options:

- `Enforce single-rate processing` — When you select this option, the block maintains the sample rate of the input.
- `Allow multirate processing` — When you select this option, the block adjusts the rate at the output to accommodate an increased or reduced number of samples. To select this option, you must set the **Input processing** parameter to `Elements as channels (sample based)`.

Use symbolic names for coefficients

Select this check box to enable the specification of coefficients using MATLAB variables. The available coefficient names differ depending on the filter structure. Using symbolic names allows tuning of filter coefficients in generated code. By default, this check box is cleared.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point
Output	• Double-precision floating point • Single-precision floating point

Biquad Filter

Model biquadratic IIR (SOS) filters

Library

Filtering / Filter Implementations

`dsparch4`

Description

The Biquad Filter block independently filters each channel of the input signal with the specified biquadratic IIR filter. When you specify the filter coefficients in the dialog box, the block implements static filters with fixed coefficients. When you provide the filter coefficients through an input port, you can tune the coefficients during simulation.

The block filters an M-by-N input matrix as follows:

- When you set the **Input processing** parameter to `Columns as channels (frame based)`, the block treats each column as a separate channel. In this mode, the block creates M instances of the same filter, each with its own independent state buffer. Each of the M filters process N input samples at every Simulink time step.
- When you set the **Input processing** parameter to `Elements as channels (sample based)`, the block treats each element as a separate channel. In this mode, the block creates $M*N$ instances of the same filter, each with its own independent state buffer. Each filter processes one input sample at every Simulink time step.

This block supports variable-size input. This means that while the block is simulating, the frame size (number of rows) can change. The output dimensions always equal those of the input signal. The outputs of this block numerically match the outputs of the `dfilt` object.

The Biquad Filter block supports the Simulink state logging feature. See “States” in the *Simulink User's Guide* for more information.

Coefficient Source and Filter Structures

The Biquad Filter block can operate in three different modes. Select the mode in the **Coefficient source** group box.

- If you select **Dialog parameters**, you enter information about the filter such as structure and coefficients in the block mask. In this mode, you can choose the following filter structures in the **Filter structure** parameter:
  - `Direct form I`
  - `Direct form I transposed`
  - `Direct form II`
  - `Direct form II transposed`
- If you select **Input port(s)**, you enter information about the filter structure in the block mask using the **Filter structure** parameter, but the filter coefficients come into the block via input ports. The following additional ports appear on the block icon:
  - `Num` — numerator coefficients
  - `Den` — denominator coefficients
  - `g` — scale values

  `Num` must be a 3–by–N numeric matrix, `Den` must be a 2–by–N numeric matrix, and `g` must be a 1–by–(N+1) numeric vector, where N is the number of biquad filter sections. The object assumes the first denominator coefficients of each section to be 1. This configuration is applicable when the `SOSMatrixSource` property is 'Input port' and the `ScaleValuesInputPort` property is true. The reason you would need to specify `Num` and `Den` instead of the `SOSMatrix`, is that in Fixed-Point operation, the numerators and denominators can have different fraction lengths. Therefor there is a need to be able to pass the data of the numerator with a different fixed-point type as that of the denominator.
- If you select **Discrete-time filter object (DFILT)**, you specify the filter using a `dfilt` object. This block supports the following `dfilt` structures:
  - `dfilt.df1sos`
  - `dfilt.df1tsos`
  - `dfilt.df2sos`
  - `dfilt.df2tsos`

Specifying the SOS Matrix and Scale Values

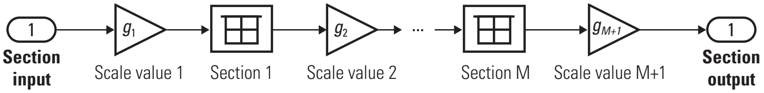
The **SOS matrix (Mx6)** is an *M*-by-6 matrix, where *M* is the number of sections in the second-order section filter. Each row of the SOS matrix contains the numerator and denominator coefficients (b_{ik} and a_{ik}) of the corresponding section in the filter.

$$\begin{bmatrix} b_{01} & b_{11} & b_{21} & a_{01} & a_{11} & a_{21} \\ b_{02} & b_{12} & b_{22} & a_{02} & a_{12} & a_{22} \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\ b_{0M} & b_{1M} & b_{2M} & a_{0M} & a_{1M} & a_{2M} \end{bmatrix}$$

You can use the `ss2sos` and `tf2sos` functions from Signal Processing Toolbox software to convert a state-space or transfer function description of your filter into the second-order section description used by this block.

The **Scale values** parameter specifies the scale values the block uses between each SOS section. You can specify a real-valued scalar or a vector of length *M*+**1**.

- If you enter a scalar, the value specifies the gain value before the first section of the second-order filter. The rest of the gain values default to `1`.
- If you enter a vector of *M*+1 values, each value specifies a separate section of the filter. For example, the first element is the first gain value, the second element is the second gain value, and so on.



Select the **Optimize unity scale values** check box to optimize your simulation when one or more scale values equal 1. Selecting this option removes the unity gains so that the values are treated like Simulink lines or wires. In some fixed-point cases when there are unity scale values, selecting this parameter also omits certain casts. Refer to “Filter Structure Diagrams” on page 1-127 for more information.

Specifying Initial Conditions

The Biquad Filter block initializes the internal filter states to zero by default. You can optionally use the **Initial conditions** or **Initial conditions on zeros side** and **Initial**

conditions on poles side parameters to specify nonzero initial states for the filter delays.

To determine the number of initial conditions you must specify and how to specify them, see the following table on valid initial conditions.

Valid Initial Conditions

Initial Condition	Description
Scalar	The block initializes all delay elements in the filter to the scalar value.
Vector or matrix (for applying different delay elements to each channel)	Each vector or matrix element specifies a unique initial condition for a corresponding delay element in a corresponding channel. Where *M* is the number of sections and *N* is the number of input channels: • The vector length must equal the number of delay elements in the filter, *M**2. • The matrix must have the same number of rows as the number of delay elements in the filter, (*M**2)**N*. The matrix must also have one column for each channel of the input signal.

Fixed-Point Data Types

See the "Filter Structure Diagrams" on page 1-127 section for diagrams showing the data types the biquad filter block uses when processing fixed-point signals.

Examples

Open an example model by typing `ex_biquad_filter_ref` at the MATLAB command line.

Dialog Box

Coefficient Source

The Biquad Filter block can operate in three different modes. Select the mode in the **Coefficient source** group box.

- If you select **Dialog parameters**, you enter information about the filter such as structure and coefficients in the block mask. In this mode, you can choose the following filter structures in the **Filter structure** parameter:

  - `Direct form I`
  - `Direct form I transposed`
  - `Direct form II`
  - `Direct form II transposed`

- If you select **Input port(s)**, you enter information about the filter structure in the block mask using the **Filter structure** parameter, but the filter coefficients come into the block via input ports. The following additional ports appear on the block icon:

  - `Num` — numerator coefficients
  - `Den` — denominator coefficients
  - `g` — scale values

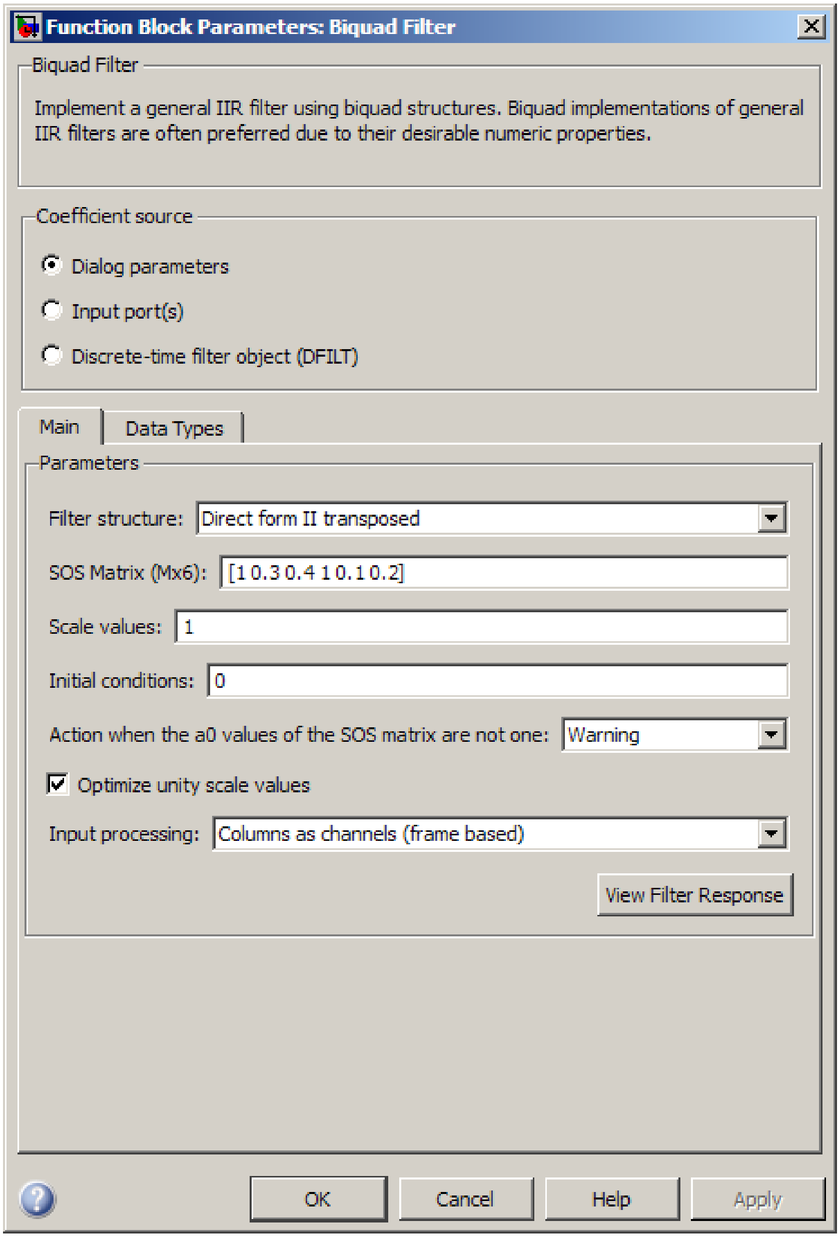
  `Num` must be a 3–by–N numeric matrix, `Den` must be a 2–by–N numeric matrix, and `g` must be a 1–by–(N+1) numeric vector, where N is the number of biquad filter sections. The object assumes the first denominator coefficients of each section to be 1. This configuration is applicable when the `SOSMatrixSource` property is 'Input port' and the `ScaleValuesInputPort` property is true. The reason you would need to specify `Num` and `Den` instead of the `SOSMatrix`, is that in Fixed-Point operation, the numerators and denominators can have different fraction lengths. Therefor there is a need to be able to pass the data of the numerator with a different fixed-point type as that of the denominator.

- If you select **Discrete-time filter object (DFILT)**, you specify the filter using a `dfilt` object. This block supports the following `dfilt` structures:

  - `dfilt.df1sos`
  - `dfilt.df1tsos`
  - `dfilt.df2sos`
  - `dfilt.df2tsos`

Specify Filter Characteristics in Dialog

The **Main** pane of the Biquad Filter block dialog appears as follows when **Dialog parameters** is selected in the **Coefficient source** group box.



Function Block Parameters: Biquad Filter

Biquad Filter

Implement a general IIR filter using biquad structures. Biquad implementations of general IIR filters are often preferred due to their desirable numeric properties.

Coefficient source

● Dialog parameters

○ Input port(s)

○ Discrete-time filter object (DFILT)

Parameters

Filter structure: Direct form II transposed

SOS Matrix (Mx6): [1 0.3 0.4 1 0.1 0.2]

Scale values: 1

Initial conditions: 0

Action when the a0 values of the SOS matrix are not one: Warning

☑ Optimize unity scale values

Input processing: Columns as channels (frame based)

Filter structure

Select the filter structure.

This parameter is only visible when **Dialog parameters** or **Input port(s)** is selected.

SOS Matrix

Specify an M-by-6 matrix, where M is the number of sections in the second-order section filter. Each row of the SOS matrix contains the numerator and denominator coefficients (b_{ik} and a_{ik}) of the corresponding section in the filter.

$$\begin{bmatrix} b_{01} & b_{11} & b_{21} & a_{01} & a_{11} & a_{21} \\ b_{02} & b_{12} & b_{22} & a_{02} & a_{12} & a_{22} \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\ b_{0M} & b_{1M} & b_{2M} & a_{0M} & a_{1M} & a_{2M} \end{bmatrix}$$

This parameter is only visible when **Dialog parameters** is selected.

Scale values

The **Scale values** parameter specifies the scalar or vector of M+1 scale values to be used between SOS sections.

- When you enter a scalar, the value specifies the gain value before the first section of the second-order filter. The rest of the gain values default to 1.
- When you enter a vector of M+1 values, each value specifies a separate section of the filter. For example, the first element is the first gain value, the second element is the second gain value, and so on.

  This parameter is only visible when **Dialog parameters** is selected.

Initial conditions

Specify the initial conditions of the filter states. To learn how to specify initial conditions, see “Specifying Initial Conditions” on page 1-110.

This parameter is only visible when **Dialog parameters** or **Input port(s)** is selected and the filter structure is `Direct form II` or `Direct form II transposed`.

Initial conditions on zeros side

Specify the initial conditions for the filter states on the side of the filter structure with the zeros (b_0, b_1,b_2, ...); see the next diagram.

This parameter is only visible when **Dialog parameters** or **Input port(s)** is selected and the filter structure is `Direct form I` or `Direct form I transposed`. To learn how to specify initial conditions, see"Specifying Initial Conditions" on page 1-110.

Initial conditions on poles side

Specify the initial conditions for the filter states on the side of the filter structure with the poles (a_0, a_1,a_2, ...); see the next diagram.

This parameter is only visible when **Dialog parameters** or **Input port(s)** is selected and the filter structure is `Direct form I` or `Direct form I transposed`. To learn how to specify initial conditions, see "Specifying Initial Conditions" on page 1-110.

Action when the a0 values of the SOS matrix are not one

Specify the action the block should perform when the SOS matrix a_{0j} values do not equal one; `None`, `Error`, or `Warn`.

This parameter is only visible when **Dialog parameters** is selected.

Optimize unity scale values

Select this check box to optimize your simulation when one or more scale values equal 1. Selecting this option removes the unity gains so that the values are treated like Simulink lines or wires. In some fixed-point cases when there are unity scale values, selecting this parameter also omits certain casts. Refer to “Filter Structure Diagrams” on page 1-127 for more information.

This parameter is only visible when **Dialog parameters** is selected.

Input processing

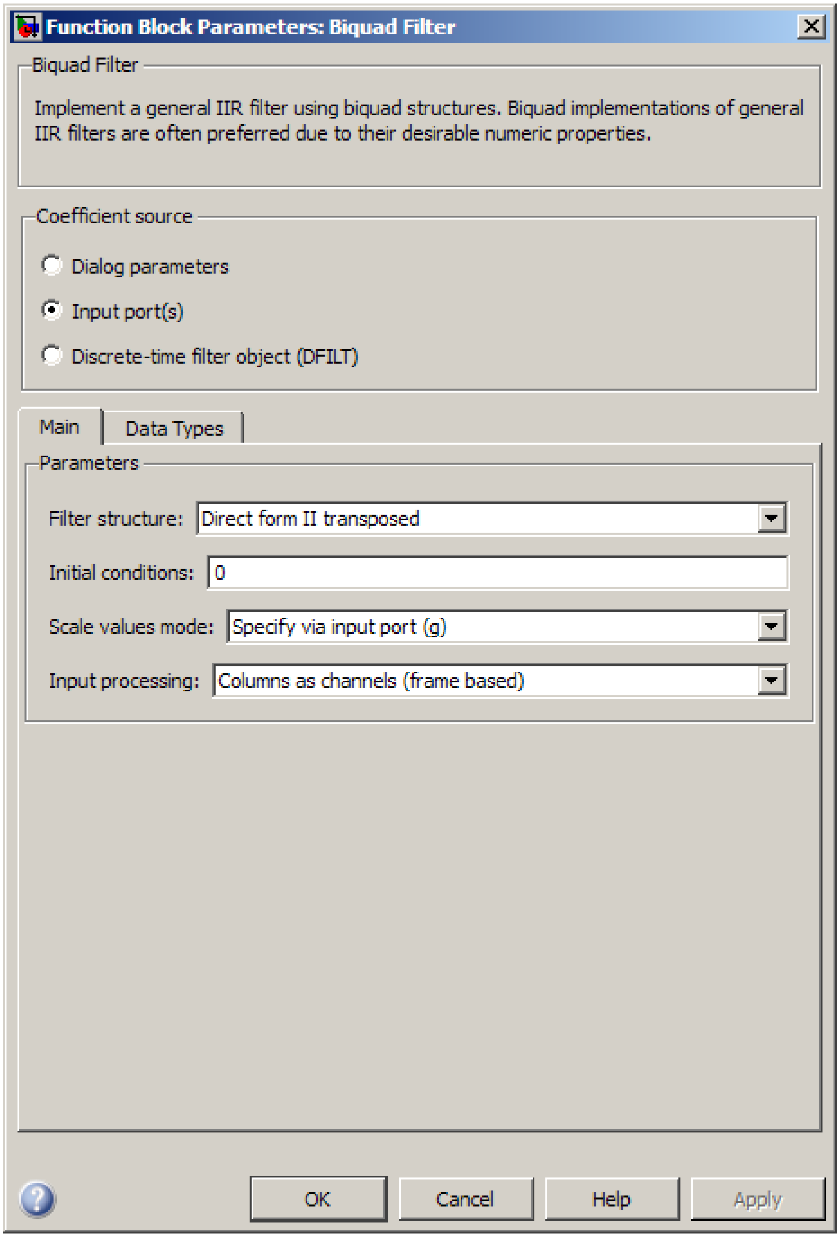
Specify how the block should process the input. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` — When you select this option, the block treats each column of the input as a separate channel.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

Note: The `Inherited (this choice will be removed - see release notes)` option will be removed in a future release. See “Frame-Based Processing” in the *DSP System Toolbox Release Notes* for more information.

Specify Filter Characteristics via Input Port

The **Main** pane of the Biquad Filter block dialog appears as follows when **Input port(s)** is selected in the **Coefficient source** group box.



Function Block Parameters: Biquad Filter

Biquad Filter

Implement a general IIR filter using biquad structures. Biquad implementations of general IIR filters are often preferred due to their desirable numeric properties.

Coefficient source

○ Dialog parameters

● Input port(s)

○ Discrete-time filter object (DFILT)

Parameters

Filter structure: Direct form II transposed

Initial conditions: 0

Scale values mode: Specify via input port (g)

Input processing: Columns as channels (frame based)

Filter structure

Select the filter structure.

This parameter is only visible when **Dialog parameters** or **Input port(s)** is selected.

Initial conditions

Specify the initial conditions of the filter states. To learn how to specify initial conditions, see "Specifying Initial Conditions" on page 1-110.

This parameter is only visible when **Dialog parameters** or **Input port(s)** is selected and the filter structure is `Direct form II` or `Direct form II transposed`.

Initial conditions on zeros side

Specify the initial conditions for the filter states on the side of the filter structure with the zeros (b_0, b_1,b_2, ...); see the next diagram.

This parameter is only visible when **Dialog parameters** or **Input port(s)** is selected and the filter structure is `Direct form I` or `Direct form I transposed`. To learn how to specify initial conditions, see "Specifying Initial Conditions" on page 1-110.

Initial conditions on poles side

Specify the initial conditions for the filter states on the side of the filter structure with the poles (a_0, a_1,a_2, ...); see the next diagram.

This parameter is only visible when **Dialog parameters** or **Input port(s)** is selected and the filter structure is `Direct form I` or `Direct form I transposed`. To learn how to specify initial conditions, see "Specifying Initial Conditions" on page 1-110.

Initial conditions on poles side go here.

Scale values mode

Choose how to specify the scale values to use between filter sections. When you select `Specify via input port (g)`, you enter the scale values as a 2-D vector at port g. When you select `Assume all are unity and optimize`, all scale values are removed and treated like Simulink lines or wires.

This parameter is only visible when **Input port(s)** is selected.

Input processing

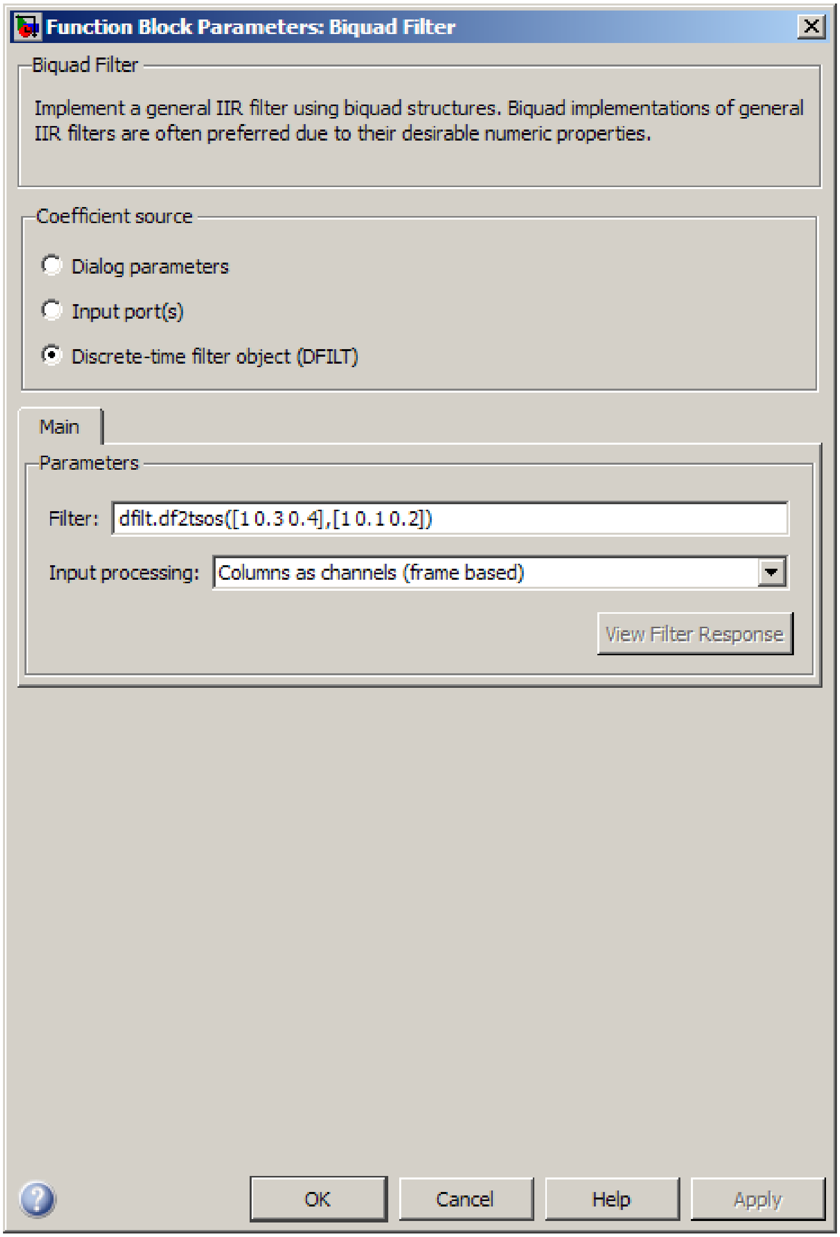
Specify how the block should process the input. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` — When you select this option, the block treats each column of the input as a separate channel.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

Note: The `Inherited (this choice will be removed - see release notes)` option will be removed in a future release. See "Frame-Based Processing" in the *DSP System Toolbox Release Notes* for more information.

Specify Discrete-Time Filter Object

The **Main** pane of the Biquad Filter block dialog appears as follows when **Discrete-time filter object (DFILT)** is selected in the **Coefficient source** group box.



Function Block Parameters: Biquad Filter

Biquad Filter

Implement a general IIR filter using biquad structures. Biquad implementations of general IIR filters are often preferred due to their desirable numeric properties.

Coefficient source

○ Dialog parameters

○ Input port(s)

● Discrete-time filter object (DFILT)

Main

Parameters

Filter: dfilt.df2tsos([1 0.3 0.4],[1 0.1 0.2])

Input processing: Columns as channels (frame based)

Filter

Specify the discrete-time filter object (`dfilt`) that you would like the block to implement. You can do so in one of three ways:

- You can fully specify the `dfilt` object in the block mask.
- You can enter the variable name of a `dfilt` object that is defined in any workspace.
- You can enter a variable name for a `dfilt` object that is not yet defined.

For more information on creating `dfilt` objects, see the `dfilt` reference page.

View filter response

This button opens the Filter Visualization Tool (`fvtool`) from the Signal Processing Toolbox product and displays the filter response of the `dfilt` object specified in the **Discrete-time filter object (DFILT)** parameter. For more information on FVTool, see the Signal Processing Toolbox documentation.

Note: If you specify a filter in the **Discrete-time filter object (DFILT)** parameter, you must click the **Apply** button to apply the filter before using the **View filter response** button.

Input processing

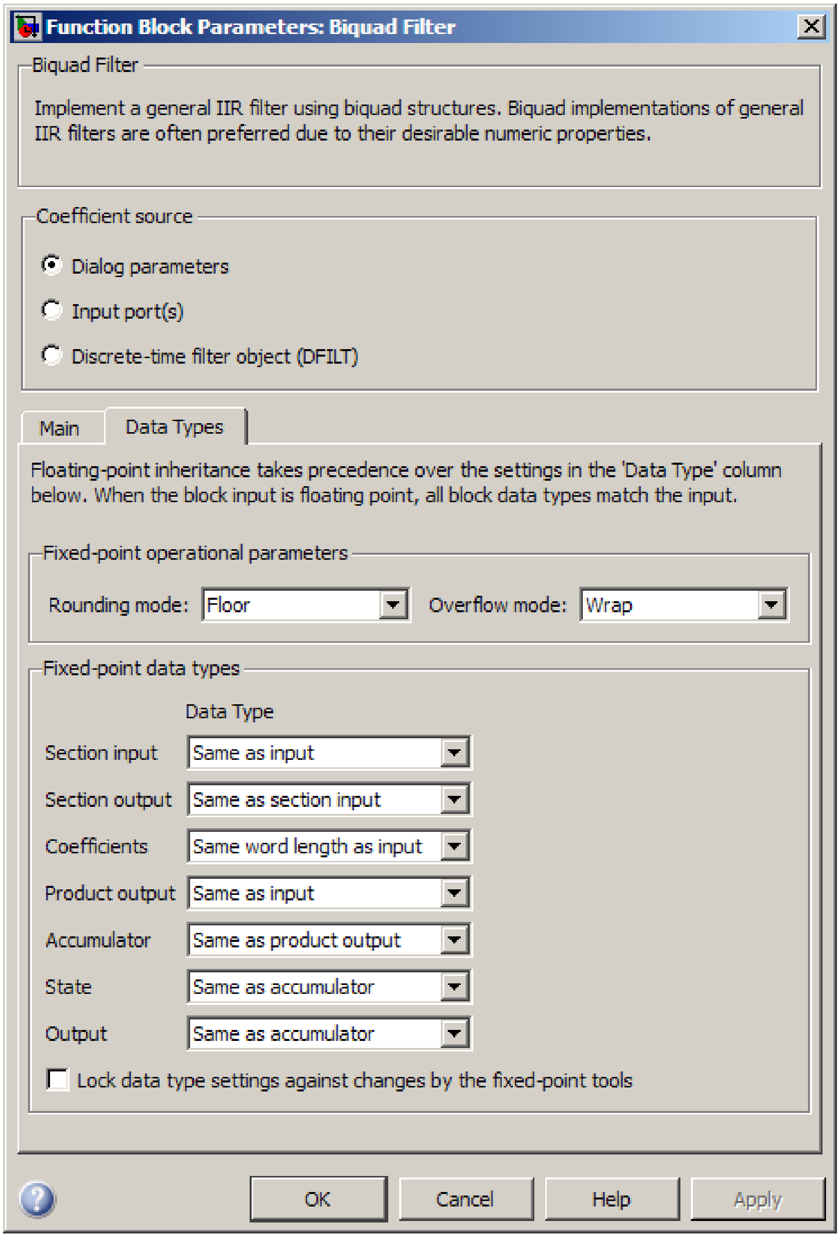
Specify how the block should process the input. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` — When you select this option, the block treats each column of the input as a separate channel.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

Note: The `Inherited (this choice will be removed - see release notes)` option will be removed in a future release. See "Frame-Based Processing" in the *DSP System Toolbox Release Notes* for more information.

Specify Fixed-Point Parameters

The **Data Types** pane of the Biquad Filter block dialog appears as follows. This pane only appears when **Dialog parameters** or **Input port(s)** is selected in the **Coefficient source** group box.



Function Block Parameters: Biquad Filter

Biquad Filter

Implement a general IIR filter using biquad structures. Biquad implementations of general IIR filters are often preferred due to their desirable numeric properties.

Coefficient source

● Dialog parameters

○ Input port(s)

○ Discrete-time filter object (DFILT)

Floating-point inheritance takes precedence over the settings in the 'Data Type' column below. When the block input is floating point, all block data types match the input.

Fixed-point operational parameters

Rounding mode: Floor   Overflow mode: Wrap

Fixed-point data types

	Data Type
Section input	Same as input
Section output	Same as section input
Coefficients	Same word length as input
Product output	Same as input
Accumulator	Same as product output
State	Same as accumulator
Output	Same as accumulator

□ Lock data type settings against changes by the fixed-point tools

Rounding mode

Select the "rounding mode" for fixed-point operations. The filter coefficients do not obey this parameter; instead, they always round to `Nearest`.

Overflow mode

Select the "overflow mode" for fixed-point operations. The filter coefficients do not obey this parameter; instead, they are always saturated.

Multiplicand

Choose how you specify the word length and the fraction length of the multiplicand data type of a `Direct form I transposed` filter structure. See "Fixed-Point Data Types" on page 1-111 and the "Direct Form I Transposed" on page 1-129 filter structure diagram for illustrations depicting the use of the multiplicand data type in this block.

This parameter is only visible when the **Filter structure** parameter is set to `Direct form I transposed`.

- When you select `Same as output`, these characteristics match those of the output of the block.
- When you select `Binary point scaling`, you can enter the word length and the fraction length of the product output, in bits.
- When you select `Slope and bias scaling`, you can enter the word length, in bits, and the slope of the product output. This block requires power-of-two slope and a bias of zero.

Section input

Choose how you specify the word length and the fraction length of the fixed-point data type going into each section of a biquadratic filter. See "Fixed-Point Data Types" on page 1-111 for illustrations depicting the use of the section input data type in this block.

- When you select `Same as input`, these characteristics match those of the input to the block.
- When you select `Binary point scaling`, you can enter the word and fraction lengths of the section input and output, in bits.
- When you select `Slope and bias scaling`, you can enter the word lengths, in bits, and the slopes of the section input and output. This block requires power-of-two slope and a bias of zero.

Section output

Choose how you specify the word length and the fraction length of the fixed-point data type coming out of each section of a biquadratic filter. See “Fixed-Point Data Types” on page 1-111 for illustrations depicting the use of the section input data type in this block.

- When you select `Same as input`, these characteristics match those of the input to the block.
- When you select `Binary point scaling`, you can enter the word and fraction lengths of the section input and output, in bits.
- When you select `Slope and bias scaling`, you can enter the word lengths, in bits, and the slopes of the section input and output. This block requires power-of-two slope and a bias of zero.

Coefficients

Choose how you specify the word length and the fraction length of the filter coefficients (numerator, denominator, and scale value) when **Dialog parameters** is selected in the **Coefficient source** group box. See “Fixed-Point Data Types” on page 1-111 for illustrations depicting the use of the coefficient data types in this block:

- When you select `Same word length as input`, the word length of the filter coefficients match that of the input to the block. In this mode, the block automatically sets the fraction length of the coefficients to the binary-point only scaling that provides you with the best precision possible given the value and word length of the coefficients.
- When you select `Specify word length`, you can enter the word length of the coefficients, in bits. In this mode, the block automatically sets the fraction length of the coefficients to the binary-point only scaling that provides you with the best precision possible given the value and word length of the coefficients.
- When you select `Binary point scaling`, you can enter the word length and the fraction length of the coefficients, in bits. If applicable, you can enter separate fraction lengths for the numerator and denominator coefficients.
- When you select `Slope and bias scaling`, you can enter the word length, in bits, and the slope of the coefficients. If applicable, you can enter separate slopes for the numerator and denominator coefficients. This block requires power-of-two slope and a bias of zero.
- The filter coefficients do not obey the **Rounding mode** and the **Overflow mode** parameters; instead, they are always saturated and rounded to `Nearest`.

Product output

Use this parameter to specify how you would like to designate the product output word and fraction lengths. See “Fixed-Point Data Types” on page 1-111 and “Multiplication Data Types” for illustrations depicting the use of the product output data type in this block:

- When you select `Same as input`, these characteristics match those of the input to the block.
- When you select `Binary point scaling`, you can enter the word length and the fraction length of the product output, in bits.
- When you select `Slope and bias scaling`, you can enter the word length, in bits, and the slope of the product output. This block requires power-of-two slope and a bias of zero.

Accumulator

Use this parameter to specify how you would like to designate the accumulator word and fraction lengths. See “Fixed-Point Data Types” on page 1-111 and “Multiplication Data Types” for illustrations depicting the use of the accumulator data type in this block:

- When you select `Same as input`, these characteristics match those of the input to the block.
- When you select `Same as product output`, these characteristics match those of the product output.
- When you select `Binary point scaling`, you can enter the word length and the fraction length of the accumulator, in bits.
- When you select `Slope and bias scaling`, you can enter the word length, in bits, and the slope of the accumulator. This block requires power-of-two slope and a bias of zero.

State

Use this parameter to specify how you would like to designate the state word and fraction lengths when **Dialog parameters** is selected in the **Coefficient source** group box. See “Fixed-Point Data Types” on page 1-111 for illustrations depicting the use of the state data type in this block.

This parameter is not visible for `Direct form I` and `Direct form I transposed filter` structures.

- When you select `Same as input`, these characteristics match those of the input to the block.

- When you select `Same as accumulator`, these characteristics match those of the accumulator.
- When you select `Binary point scaling`, you can enter the word length and the fraction length of the accumulator, in bits.
- When you select `Slope and bias scaling`, you can enter the word length, in bits, and the slope of the accumulator. This block requires power-of-two slope and a bias of zero.

Output

Choose how you specify the output word length and fraction length. See "Fixed-Point Data Types" on page 1-111 for illustrations depicting the use of the output data type in this block.

- When you select `Same as input`, these characteristics match those of the input to the block.
- When you select `Same as accumulator`, these characteristics match those of the accumulator.
- When you select `Binary point scaling`, you can enter the word length and the fraction length of the output, in bits.
- When you select `Slope and bias scaling`, you can enter the word length, in bits, and the slope of the output. This block requires power-of-two slope and a bias of zero.

Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

Filter Structure Diagrams

The diagrams in the following sections show the filter structures supported by the Biquad Filter block. They also show the data types used in the filter structures for fixed-point signals. You can set the data types shown in these diagrams in the block dialog box. This is discussed in "Dialog Box" on page 1-111.

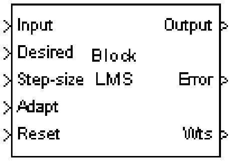
Block LMS Filter

Compute output, error, and weights using LMS adaptive algorithm

Library

Filtering / Adaptive Filters

`dspadpt3`



Block LMS Filter

Description

The Block LMS Filter block implements an adaptive least mean-square (LMS) filter, where the adaptation of filter weights occurs once for every block of samples. The block estimates the filter weights, or coefficients, needed to minimize the error, $e(n)$, between the output signal, $y(n)$, and the desired signal, $d(n)$. Connect the signal you want to filter to the Input port. The input signal can be a scalar or a column vector. Connect the signal you want to model to the `Desired` port. The desired signal must have the same data type, complexity, and dimensions as the input signal. The `Output` port outputs the filtered input signal. The `Error` port outputs the result of subtracting the output signal from the desired signal.

The block calculates the filter weights using the Block LMS adaptive filter algorithm. This algorithm is defined by the following equations.

$$
\begin{aligned}
n &= kN + i \\
y(n) &= \mathbf{w}^T(k-1)\mathbf{u}(n) \\
e(n) &= d(n) - y(n) \\
\mathbf{w}(k) &= \mathbf{w}(k-1) + f(\mathbf{u}(n), e(n), \mu)
\end{aligned}
$$

The weight update function for the Block LMS adaptive filter algorithm is defined as

$$f(\mathbf{u}(n), e(n), \mu) = \mu \sum_{i=0}^{N-1} \mathbf{u}^*(kN+i)e(kN+i)$$

The variables are as follows.

Variable	Description
n	The current time index
i	The iteration variable in each block, $0 \le i \le N-1$
k	The block number
N	The block size
$\mathbf{u}(n)$	The vector of buffered input samples at step n
$\mathbf{w}(n)$	The vector of filter-tap estimates at step n
$y(n)$	The filtered output at step n
$e(n)$	The estimation error at time n
$d(n)$	The desired response at time n
μ	The adaptation step size

Use the **Filter length** parameter to specify the length of the filter weights vector.

The **Block size** parameter determines how many samples of the input signal are acquired before the filter weights are updated. The number of rows in the input must be an integer multiple of the **Block size** parameter.

The adaptation **Step-size (mu)** parameter corresponds to μ in the equations. You can either specify a step-size using the input port, Step-size, or enter a value in the Block Parameters: Block LMS Filter dialog box.

Use the **Leakage factor (0 to 1)** parameter to specify the leakage factor, $0 < 1 - \mu\alpha \le 1$, in the leaky LMS algorithm shown below.

$$\mathbf{w}(k) = (1 - \mu\alpha)\mathbf{w}(k-1) + f(\mathbf{u}(n), e(n), \mu)$$

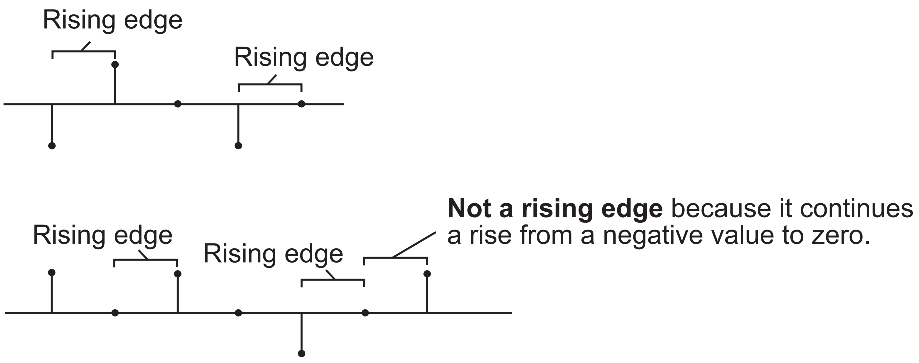
Enter the initial filter weights as a vector or a scalar in the **Initial value of filter weights** text box. When you enter a scalar, the block uses the scalar value to create a vector of filter weights. This vector has length equal to the filter length and all of its values are equal to the scalar value

When you select the **Adapt port** check box, an `Adapt` port appears on the block. When the input to this port is greater than zero, the block continuously updates the filter weights. When the input to this port is zero, the filter weights remain at their current values.

When you want to reset the value of the filter weights to their initial values, use the **Reset input** parameter. The block resets the filter weights whenever a reset event is detected at the Reset port. The reset signal rate must be the same rate as the data signal input.

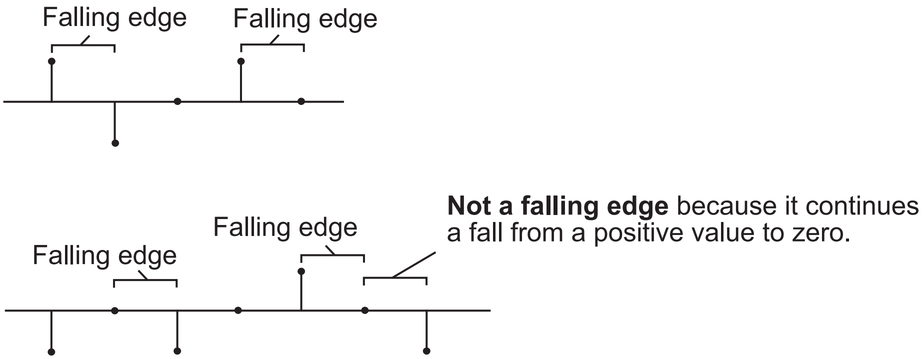
From the **Reset input** list, select `None` to disable the Reset port. To enable the Reset port, select one of the following from the **Reset input** list:

- `Rising edge` — Triggers a reset operation when the Reset input does one of the following:
  - Rises from a negative value to a positive value or zero
  - Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero (see the following figure).



Rising edge
Rising edge
Rising edge
Rising edge
Not a rising edge because it continues a rise from a negative value to zero.

- `Falling edge` — Triggers a reset operation when the Reset input does one of the following:
  - Falls from a positive value to a negative value or zero
  - Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero (see the following figure)

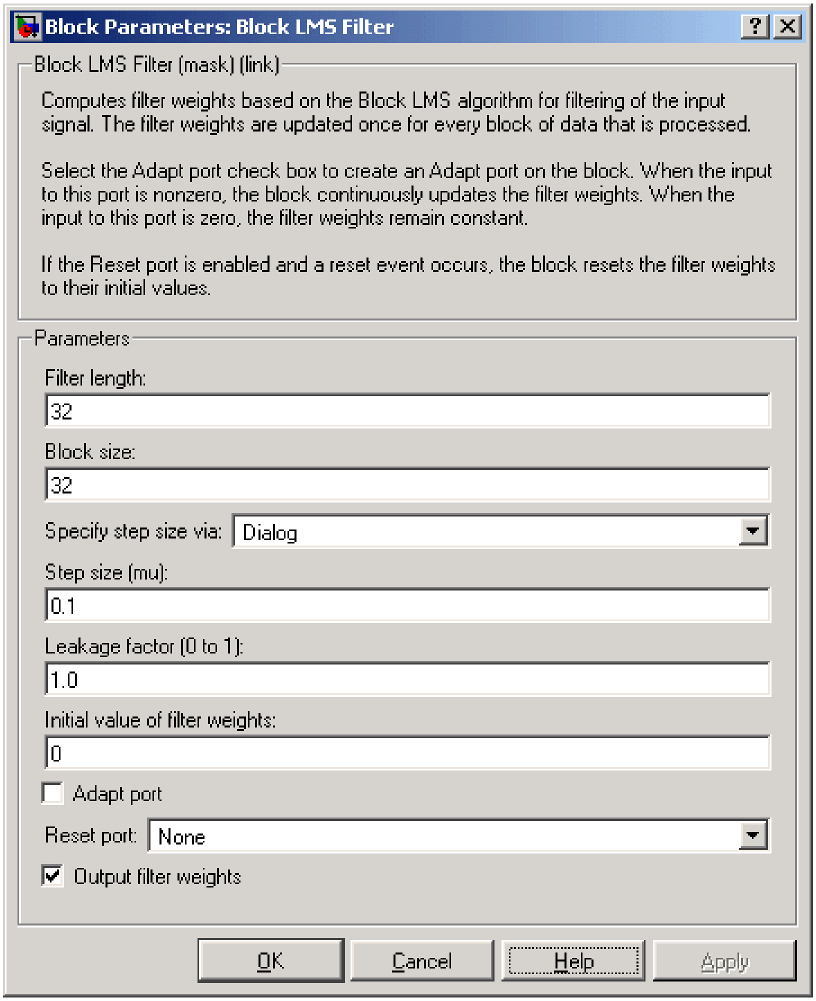


Falling edge
Falling edge
Falling edge
Falling edge
Not a falling edge because it continues a fall from a positive value to zero.

- `Either edge` — Triggers a reset operation when the Reset input is a `Rising edge` or `Falling edge` (as described above)
- `Non-zero sample` — Triggers a reset operation at each sample time that the Reset input is not zero

Select the **Output filter weights** check box to create a `Wts` port on the block. For each iteration, the block outputs the current updated filter weights from this port.

Dialog Box



Block Parameters: Block LMS Filter

Block LMS Filter (mask) (link)

Computes filter weights based on the Block LMS algorithm for filtering of the input signal. The filter weights are updated once for every block of data that is processed.

Select the Adapt port check box to create an Adapt port on the block. When the input to this port is nonzero, the block continuously updates the filter weights. When the input to this port is zero, the filter weights remain constant.

If the Reset port is enabled and a reset event occurs, the block resets the filter weights to their initial values.

Parameters

Filter length: 32

Block size: 32

Specify step size via: Dialog

Step size (mu): 0.1

Leakage factor (0 to 1): 1.0

Initial value of filter weights: 0

□ Adapt port

Reset port: None

☑ Output filter weights

Filter length

Enter the length of the FIR filter weights vector.

Block size

Enter the number of samples to acquire before the filter weights are updated. The number of rows in the input must be an integer multiple of the **Block size**.

Specify step-size via

Select `Dialog` to enter a value for mu in the Block parameters: LMS Filter dialog box. Select `Input port` to specify mu using the Step-size input port.

Step-size (mu)

Enter the step-size. “Tunable”.

Leakage factor (0 to 1)

Enter the leakage factor, $0 < 1 - \mu\alpha \leq 1$. “Tunable”.

Initial value of filter weights

Specify the initial values of the FIR filter weights.

Adapt port

Select this check box to enable the Adapt input port.

Reset port

Select this check box to enable the Reset input port.

Output filter weights

Select this check box to export the filter weights from the Wts port.

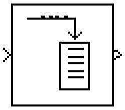
Buffer

Buffer input sequence to smaller or larger frame size

Library

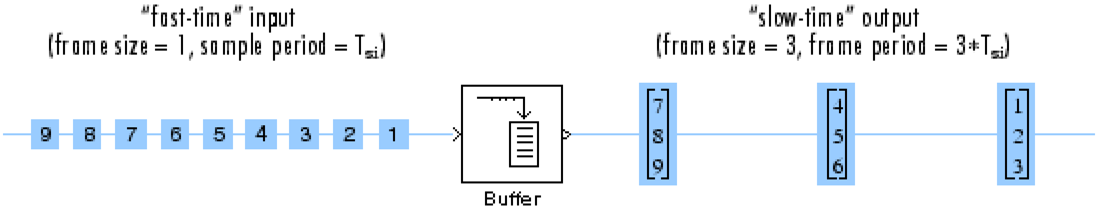
Signal Management / Buffers

`dspbuff3`



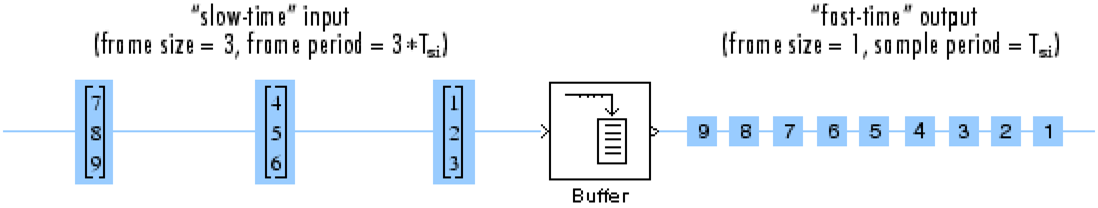
Description

The Buffer block always performs frame-based processing. The block redistributes the data in each column of the input to produce an output with a different frame size. Buffering a signal to a larger frame size yields an output with a *slower* frame rate than the input. For example, consider the following illustration for scalar input.



"fast-time" input
(frame size = 1, sample period = T_si)
9
8
7
6
5
4
3
2
1
Buffer
"slow-time" output
(frame size = 3, frame period = 3*T_si)
[7 8 9]
[4 5 6]
[1 2 3]

Buffering a signal to a smaller frame size yields an output with a *faster* frame rate than the input. For example, consider the following illustration of scalar output.



"slow-time" input
(frame size = 3, frame period = 3*T_si)
[7 8 9]
[4 5 6]
[1 2 3]
Buffer
"fast-time" output
(frame size = 1, sample period = T_si)
9
8
7
6
5
4
3
2
1

The block coordinates the output *frame size* and *frame rate* of nonoverlapping buffers such that the sample period of the signal is the same at both the input and output: $T_{so} = T_{si}$.

This block supports triggered subsystems when the block input and output rates are the same.

Buffering Single Channel Signals

The following table shows the output dimensions of the Buffer block when the input is a single-channel signal. M_o is the value of the **Output buffer size** parameter.

Input Dimensions	Output Dimensions
1-by-1 (scalar)	M_o-by-1
M_i-by-1 (column vector)	M_o-by-1

The input frame period is $M_i \cdot T_{si}$, where M_i is the input frame size and T_{si} is the input sample period. The output frame period is $(M_o - L)T_{si}$, where L is the value of the **Buffer overlap** parameter and T_{si} is the input sample period. When you set the **Buffer overlap** parameter to $M_o - 1$, the output frame period equals the input sample period.

Buffering Multichannel Signals

The following table shows the output dimensions of the Buffer block when the input is a multichannel signal. M_o is the value of the **Output buffer size** parameter and can be greater or less than the input frame size, M_i. The block buffers each of the N input channels independently.

Input Dimensions	Output Dimensions
1-by-N (row vector)	M_o-by-N
M_i-by-N (matrix)	M_o-by-N

The input frame period is $M_i \cdot T_{si}$, where M_i is the input frame size and T_{si} is the input sample period. The output frame period is $(M_o - L)T_{si}$, which equals the sequence sample period when the **Buffer overlap** is $M_o - 1$. Thus, the output sample period is related to the input sample period by

$$T_{so} = \frac{(M_o - L)T_{si}}{M_i}$$

Buffering with Overlap or Underlap

The **Buffer overlap** parameter, L, specifies the amount of overlap or underlap in each successive output frame. To overlap the data in the buffer, specify a value of L in the range $0 \le L < M_o$, where M_o is the value of the **Output buffer size** parameter. The block takes L samples (rows) from the current output and repeats them in the next output. In cases of overlap, the block acquires $M_o - L$ *new* input samples before propagating the buffered data to the output.

When $L < 0$, you are buffering the signal with underlap. The block discards L input samples after the buffer fills and outputs the buffer with period $(M_o - L)T_{si}$, which is longer than in the zero-overlap case.

The output frame period is $(M_o - L)T_{si}$, which equals the input sequence sample period, T_{si}, when the **Buffer overlap** is $M_o - 1$.

Latency

Zero-tasking latency means that the first input sample, received at $t = 0$, appears as the first output sample. In the Simulink single-tasking mode, the Buffer block has zero-tasking latency for the following special cases:

- Scalar input and output ($M_o = M_i = 1$) with zero or negative **Buffer overlap** ($L \le 0$)
- Input frame size is an integer multiple of the output frame size

  $$M_i = kM_o$$

  where k is an integer with zero **Buffer overlap** ($L = 0$); notable cases of this include

  - Any input frame size M_i with scalar output ($M_o = 1$) and zero **Buffer overlap** ($L = 0$)
  - Equal input and output frame sizes ($M_o = M_i$) with zero **Buffer overlap** ($L = 0$)

For all cases of single-tasking operation other than those listed above, the Buffer block's buffer is initialized to the value(s) specified by the **Initial conditions** parameter. The block reads from this buffer to generate the first D output samples, where

$$D = \begin{cases} M_o + L & (L \geq 0) \\ M_o & (L < 0) \end{cases}$$

The dimensions of the **Initial conditions** parameter depend on the **Buffer overlap**, L, and whether the input is single-channel or multichannel:

- When $L \neq 0$, the **Initial conditions** parameter must be a scalar.
- When $L = 0$, the **Initial conditions** parameter can be a scalar, or it can be a vector with the following constraints:
  - For single-channel inputs, the **Initial conditions** parameter can be a vector of length M_o if M_i is 1, or a vector of length M_i if M_o is 1.
  - For multichannel inputs, the **Initial conditions** parameter can be a vector of length M_o * N if M_i is 1, or a vector of length M_i * N if M_o is 1.

For all *multitasking* operations, use the `rebuffer_delay` function to compute the exact delay, in samples, that the Buffer block introduces for a given combination of buffer size and buffer overlap.

For general buffering between arbitrary frame sizes, the **Initial conditions** parameter must be a scalar value, which is then repeated across all elements of the initial output(s). However, in the special case where the input is a 1-by-N row vector, and the output of the block is an M_o-by-N matrix, **Initial conditions** can be

- An M_o-by-N matrix
- A length-M_o vector to be repeated across all columns of the initial output(s)
- A scalar to be repeated across all elements of the initial output(s)

In the special case where the output is a 1-by-N row vector, which is the result of unbuffering an M_i-by-N matrix, the **Initial conditions** can be

- A vector containing M_i samples to output sequentially for each channel during the first M_i sample times
- A scalar to be repeated across all elements of the initial output(s)

Note For more information on latency and the Simulink tasking modes, see "Excess Algorithmic Delay (Tasking Latency)" and "Scheduling " in the *Simulink Coder™ User's Guide*.

Behavior in Enabled Subsystems

The Buffer block cannot be used in an enabled subsystem under the following conditions:

- In a multirate multitasking environment
- When the **Buffer overlap** parameter is set to a negative value

The Buffer block has an internal reservoir that temporarily stores data. When the Buffer block is used in an enabled subsystem, there is the possibility that the reservoir can overrun or underrun. The block implements safeguards against these occurrences.

Overrun occurs when more data enters into the buffer than it can hold. For example, consider buffering a scalar input to a frame of size three with a buffer that accepts input every second and outputs every three seconds. If you place this buffer inside an enabled subsystem that is disabled every three seconds at t = 3s, t = 6s, and so on, the buffer accumulates data in its internal reservoir without being able to empty it. This condition results in overrun.

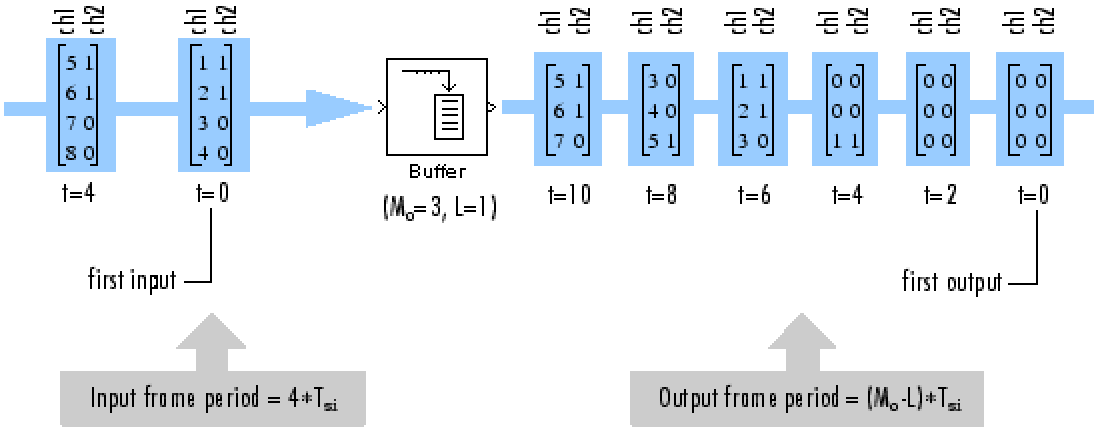
Underrun occurs when the buffer runs out of data to output. For example, again consider buffering a scalar input to a frame size of three with a buffer that accepts input every second and outputs every three seconds. If you place this buffer inside an enabled subsystem that is disabled at t = 10s, t = 11s, t = 13s, t = 14s, t = 16s, and t = 17s, its internal reservoir becomes drained, and there is no data to output at t = 18s. This condition results in underrun.

To protect from overrun and underrun, the Buffer block keeps a record of the amount of data in its internal reservoir. When the Buffer block reads data, the amount of data in its reservoir goes up. When data is output from the Buffer block, the amount of data in its reservoir goes down. To protect from overrun, the oldest samples in the reservoir are discarded whenever amount of data in the reservoir is larger than the actual buffer size. To protect from underrun, the most recent samples are repeated whenever an output is due and there is no data in the reservoir.

Examples

Buffering a two-channel input with overlap

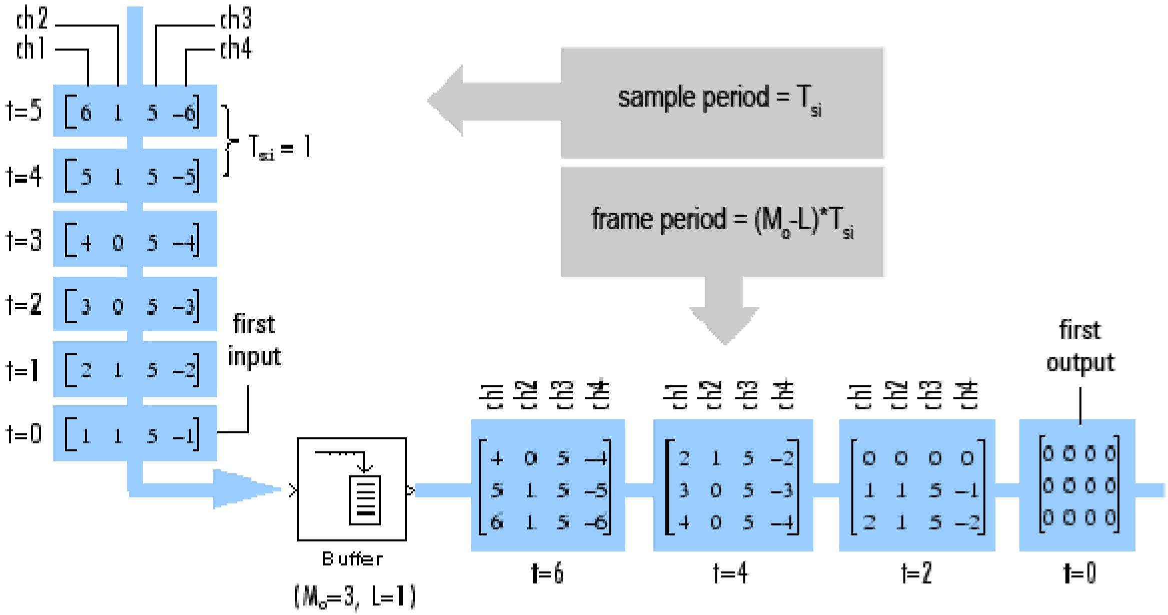
The ex_buffer_tut4 model buffers a two-channel input using an **Output buffer size** of three and a **Buffer overlap** of one. The following diagram illustrates the inputs and outputs of the Buffer block.



Notice that the output is delayed by eight samples. This is latency occurs because of the parameter settings in this model, and because the model is running in Simulink multitasking mode. The first eight output samples therefore adopt the value specified for the **Initial conditions** parameter, which in this case is set to zero. You can use the `rebuffer_delay` function to determine the latency of the Buffer block for any combination of frame size and overlap values.

Buffering a four-channel input with overlap

The ex_buffer_tut3 buffers a four-channel input using a **Output buffer size** of three and a **Buffer overlap** of one. The following diagram illustrates the inputs and outputs of the Buffer block.



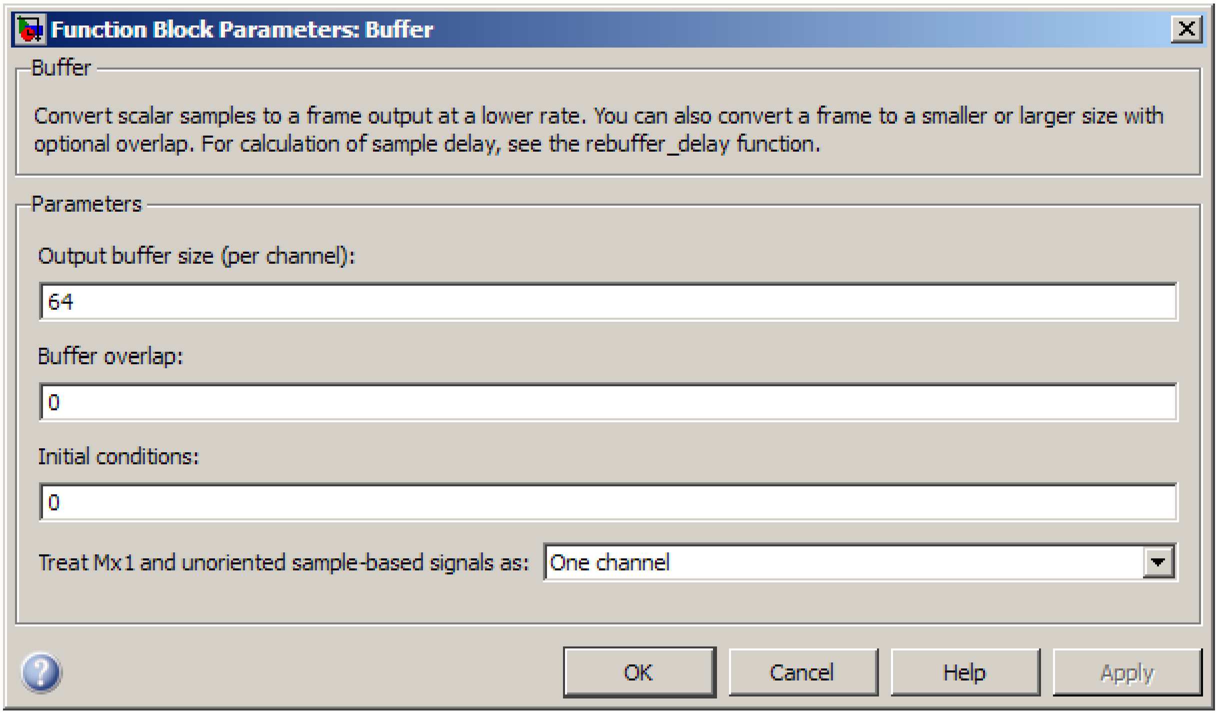
Notice that the input vectors do not begin appearing at the output until the second row of the second matrix. This is due to latency in the Buffer block. The first output matrix (all zeros in this example) reflects the value of the **Initial conditions** parameter, while the first row of zeros in the second output is a result of the one-sample overlap between consecutive output frames.

You can use the `rebuffer_delay` function with a frame size of 1 to precisely compute the delay (in samples). For the previous example,

```
d = rebuffer_delay(1,3,1)
d =
     4
```

This agrees with the four samples of delay (zeros) per channel shown in the previous figure.

Dialog Box



Function Block Parameters: Buffer

Buffer

Convert scalar samples to a frame output at a lower rate. You can also convert a frame to a smaller or larger size with optional overlap. For calculation of sample delay, see the rebuffer_delay function.

Parameters

Output buffer size (per channel): 64

Buffer overlap: 0

Initial conditions: 0

Treat Mx1 and unoriented sample-based signals as: One channel

Output buffer size

Specify the number of consecutive samples, M_o, from each channel to buffer into the output frame.

Buffer overlap

Specify the number of samples, L, by which consecutive output frames overlap.

Initial conditions

Specify the value of the block's initial output for cases of nonzero latency; a scalar, vector, or matrix.

Treat Mx1 and unoriented sample-based signals as

Specify how the block treats sample-based M-by-1 column vectors and unoriented sample-based vectors of length M. You can select one of the following options:

- `One channel` — When you select this option, the block treats M-by-1 and unoriented sample-based inputs as a column vector (one channel). In this mode, the output of the block is an M_o-by-1 column vector, where M_o is the **Output buffer size**.
- `M channels (this choice will be removed – see release notes)` — When you select this option, the block treats M-by-1 and unoriented sample-based inputs as a 1-by-M row vector. Because the block always does frame-based processing, the block interprets the 1-by-M row vector as M individual channels. In this mode, the output of the block is an M_o-by-M matrix, where M_o is the **Output buffer size**, and M is the length of the sample-based input vector.

Note: This parameter will be removed in a future release. At that time, the Buffer block will always perform frame-based processing.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point • Fixed point • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Output	• Double-precision floating point • Single-precision floating point • Fixed point • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers

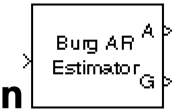
Burg AR Estimator

Compute estimate of autoregressive (AR) model parameters using Burg method

Library

Estimation / Parametric Estimation

`dspparest3`



Description

The Burg AR Estimator block uses the Burg method to fit an autoregressive (AR) model to the input data by minimizing (least squares) the forward and backward prediction errors while constraining the AR parameters to satisfy the Levinson-Durbin recursion.

The input is a sample-based vector (row, column, or 1-D) or frame-based vector (column only) representing a frame of consecutive time samples from a single-channel signal, which is assumed to be the output of an AR system driven by white noise. The block computes the normalized estimate of the AR system parameters, *A*(*z*), independently for each successive input frame.

$$H(z) = \frac{G}{A(z)} = \frac{G}{1 + a(2)z^{-1} + \ldots + a(p+1)z^{-p}}$$

When you select the **Inherit estimation order from input dimensions** parameter, the order, *p*, of the all-pole model is one less that the length of the input vector. Otherwise, the order is the value specified by the **Estimation order** parameter.

The **Output(s)** parameter allows you to select between two realizations of the AR process:

- A — The top output, *A*, is a column vector of length *p*+1 with the same frame status as the input, and contains the normalized estimate of the AR model polynomial coefficients in descending powers of *z*.

```
[1 a(2) ... a(p+1)]
```

- `K` — The top output, K, is a column vector of length p with the same frame status as the input, and contains the reflection coefficients (which are a secondary result of the Levinson recursion).
- `A and K` — The block outputs both realizations.

The scalar gain, G, is provided at the bottom output (`G`).

The following table compares the features of the Burg AR Estimator block to the Covariance AR Estimator, Modified Covariance AR Estimator, and Yule-Walker AR Estimator blocks.

	Burg AR Estimator	**Covariance AR Estimator**	**Modified Covariance AR Estimator**	**Yule-Walker AR Estimator**
`Characteristics`	Does not apply window to data	Does not apply window to data	Does not apply window to data	Applies window to data
	Minimizes the forward and backward prediction errors in the least squares sense, with the AR coefficients constrained to satisfy the L-D recursion	Minimizes the forward prediction error in the least squares sense	Minimizes the forward and backward prediction errors in the least squares sense	Minimizes the forward prediction error in the least squares sense (also called “autocorrelation method”)
`Advantages`	Always produces a stable model			Always produces a stable model
`Disadvantages`		May produce unstable models	May produce unstable models	Performs relatively poorly for short data records

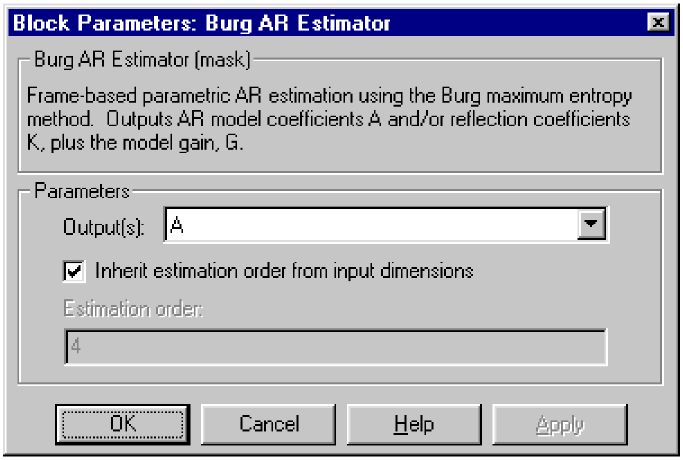
				positive-definite, hence nonsingular

Dialog Box



Block Parameters: Burg AR Estimator

Burg AR Estimator (mask)

Frame-based parametric AR estimation using the Burg maximum entropy method. Outputs AR model coefficients A and/or reflection coefficients K, plus the model gain, G.

Parameters

Output(s): A

☑ Inherit estimation order from input dimensions

Estimation order: 4

Output(s)

The realization to output, model coefficients, reflection coefficients, or both.

Inherit estimation order from input dimensions

When selected, sets the estimation order p to one less than the length of the input vector.

Estimation order

The order of the AR model, p. This parameter is enabled when you do not select **Inherit estimation order from input dimensions**.

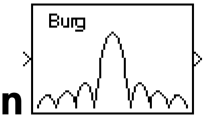
Burg Method

Power spectral density estimate using Burg method

Library

Estimation / Power Spectrum Estimation

`dspspect3`



Description

The Burg Method block estimates the power spectral density (PSD) of the input frame using the Burg method. This method fits an autoregressive (AR) model to the signal by minimizing (least squares) the forward and backward prediction errors. Such minimization occurs with the AR parameters constrained to satisfy the Levinson-Durbin recursion.

The input is a sample-based vector (row, column, or 1-D) or frame-based vector (column only). This input represents a frame of consecutive time samples from a single-channel signal. The block outputs a column vector containing the estimate of the power spectral density of the signal at N_{fft} equally spaced frequency points. The frequency points are in the range $[0,F_s)$, where F_s is the sampling frequency of the signal.

When you select the **Inherit estimation order from input dimensions** parameter, the order of the all-pole model is one less than the input frame size. Otherwise, the **Estimation order** parameter specifies the order. The block computes the spectrum from the FFT of the estimated AR model parameters.

Selecting the **Inherit FFT length from estimation order** parameter specifies that N_{fft} is one greater than the estimation order. Clearing the **Inherit FFT length from estimation order** check box, allows you to use the **FFT length** parameter to specify N_{fft} as a power of 2. The block zero-pads or wraps the input to N_{fft} before computing the FFT. The output is always sample based.

When you select the **Inherit sample time from input** check box, the block computes the frequency data from the sample period of the input signal. For the block to produce valid output, the following conditions must hold:

- The input to the block is the original signal, with no samples added or deleted (by insertion of zeros, for example).
- The sample period of the time-domain signal in the simulation equals the sample period of the original time series.

If these conditions do not hold, clear the **Inherit sample time from input** check box. You can then specify a sample time using the **Sample time of original time series** parameter.

The Burg Method and Yule-Walker Method blocks return similar results for large frame sizes. The following table compares the features of the Burg Method block to the Covariance Method, Modified Covariance Method, and Yule-Walker Method blocks.

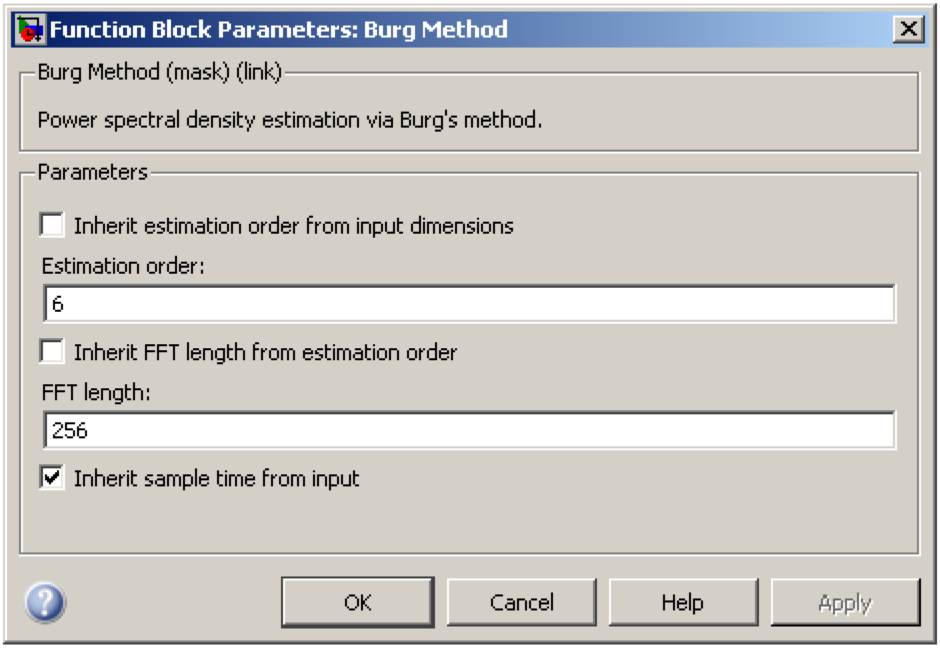
	Burg	Covariance	Modified Covariance	Yule-Walker
Characteristics	Does not apply window to data	Does not apply window to data	Does not apply window to data	Applies window to data
	Minimizes the forward and backward prediction errors in the least squares sense, with the AR coefficients constrained to satisfy the L-D recursion	Minimizes the forward prediction error in the least squares sense	Minimizes the forward and backward prediction errors in the least squares sense	Minimizes the forward prediction error in the least squares sense (also called *autocorrelation method*)
Advantages	High resolution for short data records	Better resolution than Y-W for short data records (more accurate estimates)	High resolution for short data records	Performs as well as other methods for large data records
	Always produces a stable model	Able to extract frequencies from	Able to extract frequencies from	Always produces a stable model

	Burg	Covariance	Modified Covariance	Yule-Walker
		data consisting of p or more pure sinusoids	data consisting of p or more pure sinusoids	
			Does not suffer spectral line-splitting	
Disadvantages	Peak locations highly dependent on initial phase	May produce unstable models	May produce unstable models	Performs relatively poorly for short data records
	May suffer spectral line-splitting for sinusoids in noise, or when order is very large	Frequency bias for estimates of sinusoids in noise	Peak locations slightly dependent on initial phase	Frequency bias for estimates of sinusoids in noise
	Frequency bias for estimates of sinusoids in noise		Minor frequency bias for estimates of sinusoids in noise	
Conditions for Nonsingularity		Order must be less than or equal to half the input frame size	Order must be less than or equal to 2/3 the input frame size	Because of the biased estimate, the autocorrelation matrix is guaranteed to be positive-definite, hence nonsingular

Examples

The dspsacomp example compares the Burg method with several other spectral estimation methods.

Dialog Box



Function Block Parameters: Burg Method

Burg Method (mask) (link)

Power spectral density estimation via Burg's method.

Parameters

□ Inherit estimation order from input dimensions

Estimation order:

6

□ Inherit FFT length from estimation order

FFT length:

256

☑ Inherit sample time from input

Inherit estimation order from input dimensions

Selecting this check box sets the estimation order to one less than the length of the input vector.

Estimation order

The order of the AR model. This parameter becomes visible only when you clear the **Inherit estimation order from input dimensions** check box.

Inherit FFT length from estimation order

When selected, the FFT length is one greater than the estimation order. To specify the number of points on which to perform the FFT, clear the **Inherit FFT length from estimation order** check box. You can then specify a power-of-two FFT length using the **FFT length** parameter.

FFT length

Enter the number of data points on which to perform the FFT, N_{fft}. When N_{fft} is larger than the input frame size, the block zero-pads each frame as needed. When

N_{fft} is smaller than the input frame size, the block wraps each frame as needed. This parameter becomes visible only when you clear the **Inherit FFT length from input dimensions** check box.

Inherit sample time from input

If you select the **Inherit sample time from input** check box, the block computes the frequency data from the sample period of the input signal. For the block to produce valid output, the following conditions must hold:

- The input to the block is the original signal, with no samples added or deleted (by insertion of zeros, for example).
- The sample period of the time-domain signal in the simulation equals the sample period of the original time series.

If these conditions do not hold, clear the **Inherit sample time from input** check box. You can then specify a sample time using the **Sample time of original time series** parameter.

Sample time of original time series

Specify the sample time of the original time-domain signal. This parameter becomes visible only when you clear the **Inherit sample time from input** check box.

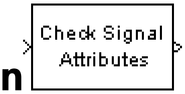
Check Signal Attributes

Error when input signal does or does not match selected attributes exactly

Library

Signal Management / Signal Attributes

`dspsigattribs`



Description

The Check Signal Attributes block terminates the simulation with an error when the input characteristics differ from the characteristics you specify in the block parameters.

When you set **Error when input** to `Does not match attributes exactly`, the block generates an error when the input fails to match *any* of the specified attributes. Only signals that possess *all* of the specified attributes propagate to the output unaltered and do not cause the block to generate an error.

When you set **Error when input** to `Matches attributes exactly`, the block generates an error only when the input possesses *all* specified attributes. Signals that do not possess *all* of the specified attributes propagate to the output unaltered, and do not cause the block to generate an error.

Signal Attributes

The Check Signal Attributes block can test for up to five different signal attributes, as specified by the following parameters. When you select `Ignore` for any parameter, the block does not check the signal for the corresponding attribute. For example, when you set **Complexity** to `Ignore`, neither real nor complex inputs cause the block to generate an error. The attributes are:

- **Complexity**

  Check whether the input is real or complex. You can display this information in a model by attaching a Probe block with **Probe complex signal** selected.

Alternatively, you can select **Port Data Types** from the **Display** > **Signals & Ports** menu.

- **Frame status**

  Check whether the signal is frame based or sample based. The Simulink environment displays sample-based signals using a single line and frame-based signals using a double line.

- **Dimensionality**

  Check the dimensionality of the input for compliance or noncompliance with the attributes in the subordinate **Dimension** menu. See the following table. *M* and *N* are positive integers unless otherwise indicated.

Dimensions	Is...	Is not...
1-D	1-D vector, 1-D scalar	*M*-by-*N* matrix, 1-by-*N* matrix (row vector), *M*-by-1 matrix (column vector), 1-by-1 matrix (2-D scalar)
2-D	*M*-by-*N* matrix, 1-by-*N* matrix (row vector), *M*-by-1 matrix (column vector), 1-by-1 matrix (2-D scalar)	1-D vector, 1-D scalar
Scalar (1-D or 2-D)	1-D scalar, 1-by-1 matrix (2-D scalar)	1-D vector with length>1, *M*-by-*N* matrix with *M*>1 and/or *N*>1
Vector (1-D or 2-D)	1-D vector, 1-D scalar, 1-by-*N* matrix (row vector), *M*-by-1 matrix (column vector), 1-by-1 matrix (2-D scalar) Vector (1-D or 2-D) or scalar	*M*-by-*N* matrix with *M*>1 and *N*>1
Row Vector (2-D)	1-by-*N* matrix (row vector), 1-by-1 matrix (2-D scalar) Row vector (2-D) or scalar	1-D vector, 1-D scalar, *M*-by-*N* matrix with *M*>1
Column Vector (2-D)	*M*-by-1 matrix (column vector), 1-by-1 matrix (2-D scalar) Column vector (2-D) or scalar	1-D vector, 1-D scalar, *M*-by-*N* matrix with *N*>1
Full matrix	*M*-by-*N* matrix with *M*>1 and *N*>1	1-D vector,

Dimensions	Is...	Is not...
		1-D scalar, 1-by-*N* matrix (row vector), *M*-by-1 matrix (column vector), 1-by-1 matrix (2-D scalar)
Square matrix	*M*-by-*N* matrix with *M*=*N*, 1-D scalar, 1-by-1 matrix (2-D scalar	*M*-by-*N* matrix with *M*≠*N*, 1-D vector, 1-by-*N* matrix (row vector), *M*-by-1 matrix (column vector)

When you select **Signal Dimensions** from the **Display** > **Signals & Ports** menu, Simulink displays the size of a 1-D vector signal as an unbracketed integer, and displays the dimension of a 2-D signal as a pair of bracketed integers, `[MxN]`. Simulink *does not display* any size information for a 1-D or 2-D scalar signal. You can also display dimension information for a signal in a model by attaching a Probe block with **Probe signal dimensions** selected.

- **Data type**

  Check the signal data type for compliance `(Is...)` or noncompliance `(Is not...)` with the attributes in the subordinate **General data type** menu. See the following table. You can individually select any of the specific data types listed in the `(Is...)` column from the subordinate **Specific data type** menu.

General Data Type	Is...	Is not...
Boolean	`boolean`	`single, double, uint8, int8, uint16, int16, uint32, int32`, fixed point, enumerated
Enumerated	A user-defined enumerated data type. See "Data Types" in the Simulink documentation.	`boolean, single, double, uint8, int8, uint16, int16, uint32, int32`, fixed point
Floating point	`single, double`	`boolean, uint8, int8, uint16, int16, uint32, int32`, fixed point, enumerated

General Data Type	Is...	Is not...
Floating point or Boolean	`single, double, boolean`	`uint8, int8, uint16, int16, uint32, int32`, fixed point, enumerated
Fixed point	fixed point, `uint8, int8, uint16, int16, uint32, int32`	`boolean, single, double`, enumerated

Integer	Signed integer
	`int8`, `int16`, `int32`
	Unsigned integer
	`uint8`, `uint16`, `uint32`
		`boolean, single, double`, fixed point, enumerated

To display data type information, in your model window, from the **Display** menu, point to **Signals & Ports** and select **Port Data Types**.

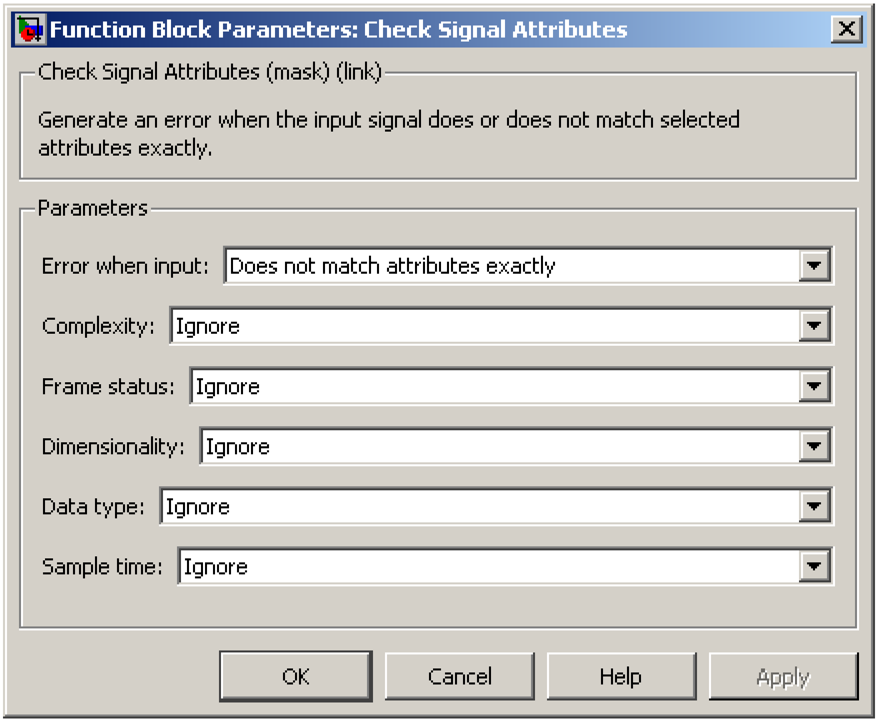
- **Sample time**

  Check whether the signal is discrete time or continuous time. When you select **Colors** from the **Display** > **Sample Time** menu, Simulink displays continuous-time signal lines in black or grey and discrete-time signal lines in colors corresponding to the relative rate.

  When you attach a Probe block with **Probe sample time** enabled to a continuous-time signal, the block icon displays the string `Ts:[0 To]`, where `To` is the sample time offset. Valid values of `To` for continuous-time signals are `0` and `1`. When `To` is `0`, updates occur at every major and minor time step. When `To` is `1`, updates occur only at major time steps and the sample time is *fixed in minor time step*.

  When you attach a Probe block with **Probe sample time** enabled to a discrete-time signal, the block icon displays the string `Ts:[Ts To]` for sample-based signals, and `Tf:[Tf To]` for frame-based signals. `Ts` and `Tf` are the positive sample period and frame period, respectively. `To` is the offset, such that 0 ≤ *`offset`* < *`period`*. Frame-based signals are almost always discrete time.

Dialog Box



Function Block Parameters: Check Signal Attributes

Check Signal Attributes (mask) (link)

Generate an error when the input signal does or does not match selected attributes exactly.

Parameters

Error when input: Does not match attributes exactly

Complexity: Ignore

Frame status: Ignore

Dimensionality: Ignore

Data type: Ignore

Sample time: Ignore

Error when input

Specify whether the block generates an error when the input *does* or *does not* possess *all* of the required attributes.

Complexity

Specify the complexity for which you want to check the input, `Real` or `Complex`. When you select `Ignore` from the list, the block does not check the complexity of the input.

Frame status

Specify the frame status for which you want to check the input, `Sample-based` or `Frame-based`. When you select `Ignore` from the list, the block does not check the frame status of the input.

Dimensionality

Specify whether you want to check the input for compliance or noncompliance with the attributes in the subordinate **Dimensions** menu. When you select `Ignore` from the list, the block does not check the dimensionality of the input.

Dimensions

Specify the dimensions for which you want to check the input. This parameter is only visible when you set the **Dimensionality** parameter to `Is...` or `Is not...`.

Data type

Specifies whether you want to check the input for compliance or noncompliance with the attributes in the subordinate **General data type** menu. When you select `Ignore` from the list, the block does not check the input data type.

General data type

Specify the general data type for which you want to check the input. This parameter is only visible when you set the **Data type** to `Is...` or `Is not...`.

Specific floating-point

Specify the floating-point data type for which you want to check the input. This parameter is only visible when you set the **General data type** to `Floating-point` or `Floating-point or boolean`.

Specific fixed-point

Specify the fixed-point data type for which you want to check the input. This parameter is only visible when you set the **General data type** to `Fixed-point`.

Specific integer

Specify the integer data type for which you want to check the input. This parameter is only visible when you set the **General data type** to `Integer`.

Sample time

Specify the sample time for which you want to check the input, `Discrete` or `Continuous`. When you select `Ignore` from the list, the block does not check the sample time of the input.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point

Port	Supported Data Types
	• Fixed point (signed and unsigned) • Boolean • 8, 16, and 32-bit signed integers • 8, 16, and 32-bit unsigned integers • Enumerated
Output	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8, 16, and 32-bit signed integers • 8, 16, and 32-bit unsigned integers • Enumerated

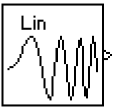
Chirp

Generate swept-frequency cosine (chirp) signal

Library

Sources

`dspsrcs4`



Description

The Chirp block outputs a swept-frequency cosine (chirp) signal with unity amplitude and continuous phase. To specify the desired output chirp signal, you must define its instantaneous frequency function, also known as the output frequency sweep. The frequency sweep can be linear, quadratic, or logarithmic, and repeats once every **Sweep time** by default. See other sections of this reference page for more details about the block.

Variables Used in This Reference Page

f_0	**Initial frequency** parameter (Hz)
$f_i(t_g)$	**Target frequency** parameter (Hz)
t_g	**Target time** parameter (seconds)
T_{sw}	**Sweep time** parameter (seconds)
ϕ_0	**Initial phase** parameter (radians)
$\psi(t)$	Phase of the chirp signal (radians)
$f_i(t)$	User-specified output instantaneous frequency function (Hz); user-specified sweep
$f_{i(actual)}(t)$	Actual output instantaneous frequency function (Hz); actual output sweep
$y_{chirp}(t)$	Output chirp function

Setting the Output Frame Status

Use **Samples per frame** parameter to set the block's output frame status, as summarized in the following table. The **Sample time** parameter sets the sample time of both sample- and frame-based outputs.

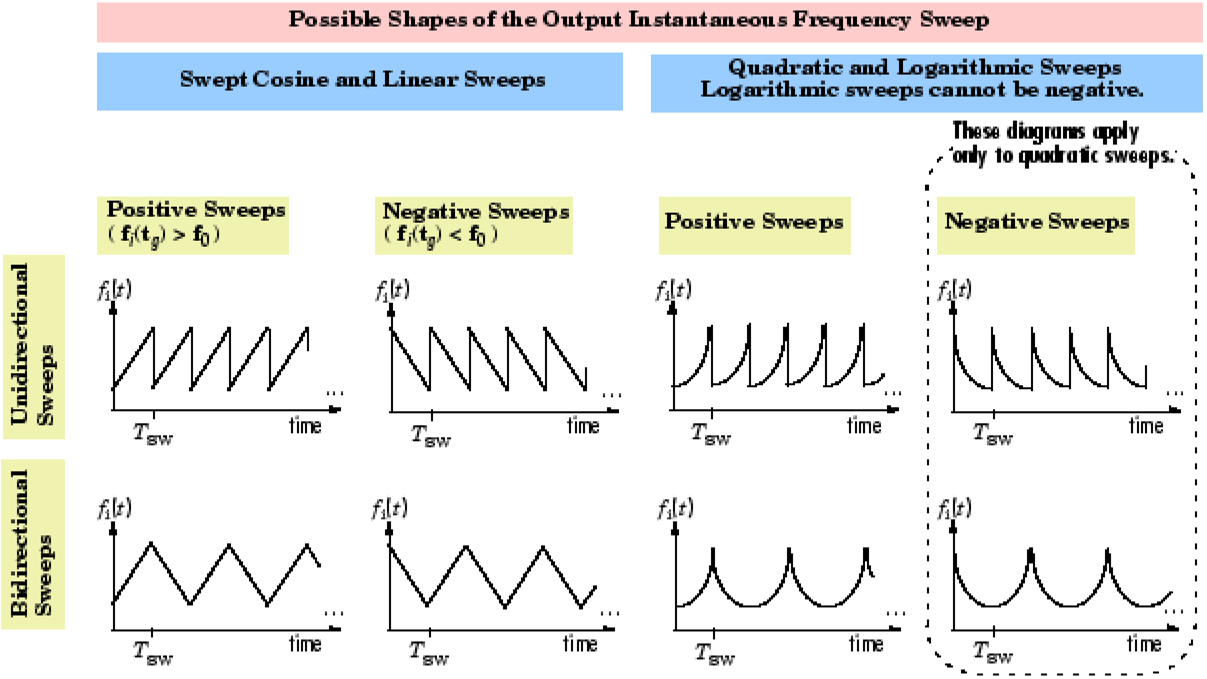
Setting of Samples Per Frame Parameter	Output Frame Status
1	Sample based
n (any integer greater than 1)	Frame based, frame size n

Shaping the Frequency Sweep by Setting Frequency Sweep and Sweep Mode

The basic shape of the output instantaneous frequency sweep, $f_i(t)$, is set by the **Frequency sweep** and **Sweep mode** parameters, described in the following table.

Parameters for Setting Sweep Shape	Possible Setting	Parameter Description
Frequency sweep	Linear Quadratic Logarithmic Swept cosine	Determines whether the sweep frequencies vary linearly, quadratically, or logarithmically. Linear and swept cosine sweeps both vary linearly.
Sweep mode	Unidirectional Bidirectional	Determines whether the sweep is unidirectional or bidirectional. For details, see "Unidirectional and Bidirectional Sweep Modes" on page 1-173

The following diagram illustrates the possible shapes of the frequency sweep that you can obtain by setting the **Frequency sweep** and **Sweep mode** parameters.



Possible Shapes of the Output Instantaneous Frequency Sweep
Swept Cosine and Linear Sweeps
Quadratic and Logarithmic Sweeps
Logarithmic sweeps cannot be negative.
These diagrams apply only to quadratic sweeps.
Positive Sweeps ($f_i(t_g) > f_0$)
Negative Sweeps ($f_i(t_g) < f_0$)
Positive Sweeps
Negative Sweeps
Unidirectional Sweeps
Bidirectional Sweeps
$f_i(t)$
T_{sw}
time
...

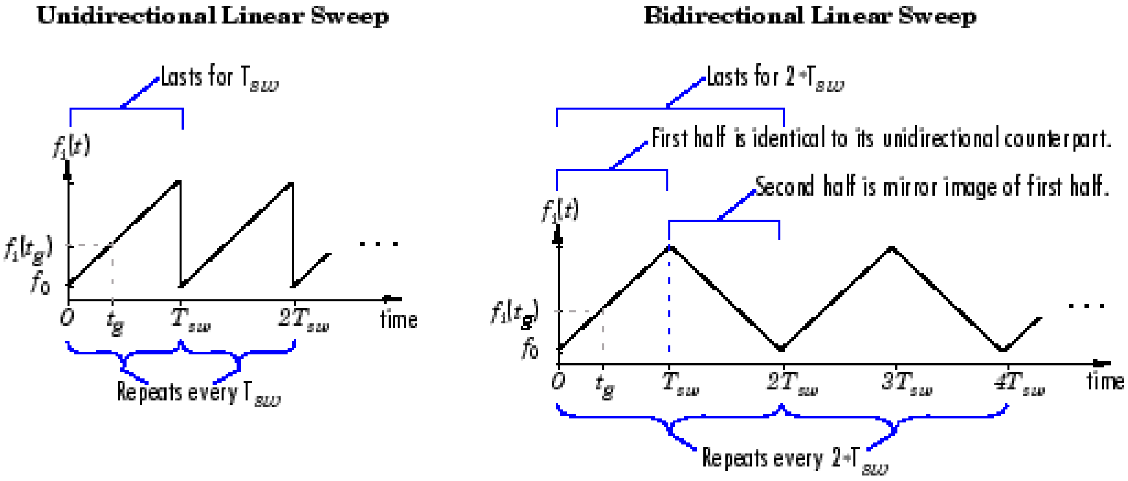
For information on how to set the frequency values in your sweep, see “Setting Instantaneous Frequency Sweep Values” on page 1-174.

Unidirectional and Bidirectional Sweep Modes

The **Sweep mode** parameter determines whether your sweep is unidirectional or bidirectional, which affects the shape of your output frequency sweep (see “Shaping the Frequency Sweep by Setting Frequency Sweep and Sweep Mode” on page 1-171). The following table describes the characteristics of unidirectional and bidirectional sweeps.

Sweep Mode Parameter Settings	Sweep Characteristics
`Unidirectional`	• Lasts for one **Sweep time**, T_{sw} • Repeats once every T_{sw}
`Bidirectional`	• Lasts for twice the **Sweep time**, $2*T_{sw}$ • Repeats once every $2*T_{sw}$ • First half is identical to its unidirectional counterpart. • Second half is a mirror image of the first half.

The following diagram illustrates a linear sweep in both sweep modes. For information on setting the frequency values in your sweep, see “Setting Instantaneous Frequency Sweep Values” on page 1-174.



Setting Instantaneous Frequency Sweep Values

Set the following parameters to tune the frequency values of your output frequency sweep.

- **Initial frequency** (Hz), f_0
- **Target frequency** (Hz), $f_i(t_g)$
- **Target time** (seconds), t_g

The following table summarizes the sweep values at specific times for all **Frequency sweep** settings. For information on the formulas used to compute sweep values at other times, see "Block Computation Methods" on page 1-174.

Instantaneous Frequency Sweep Values

Frequency Sweep	Sweep Value at $t = 0$	Sweep Value at $t = t_g$	Time when Sweep Value Is Target Frequency, $f_i(t_g)$
Linear	f_0	$f_i(t_g)$	t_g
Quadratic	f_0	$f_i(t_g)$	t_g
Logarithmic	f_0	$f_i(t_g)$	t_g
Swept cosine	f_0	$2f_i(t_g) - f_0$	$t_g/2$

Block Computation Methods

The Chirp block uses one of two formulas to compute the block output, depending on the **Frequency Sweep** parameter setting. For details, see the following sections:

- "Equations for Output Computation" on page 1-174
- "Output Computation Method for Linear, Quadratic, and Logarithmic Frequency Sweeps" on page 1-176
- "Output Computation Method for Swept Cosine Frequency Sweep" on page 1-176

Equations for Output Computation

The following table shows the equations used by the block to compute the user-specified output frequency sweep, $f_i(t)$, the block output, $y_{chirp}(t)$, and the actual output frequency sweep, $f_{i(actual)}(t)$. The only time the user-specified sweep is not the actual output sweep is when the **Frequency sweep** parameter is set to `Swept cosine`.

Note The following equations apply only to unidirectional sweeps in which $f_i(0) < f_i(t_g)$. To derive equations for other cases, you might find it helpful to examine the following table and the diagram in "Shaping the Frequency Sweep by Setting Frequency Sweep and Sweep Mode" on page 1-171.

The table below contains the following variables:

- $f_\mathrm{i}(t)$ — the user-specified frequency sweep
- $f_{i(actual)}(t)$ — the actual output frequency sweep, usually equal to $f_i(t)$
- $y(t)$ — the Chirp block output
- $\psi(t)$ — the phase of the chirp signal, where $\psi(0) = 0$, and $2\pi f_i(t)$ is the derivative of the phase

$$f_i(t) = \frac{1}{2\pi} \cdot \frac{d\psi(t)}{dt}$$

- ϕ_0 — the **Initial phase** parameter value, where $y_{chirp}(0) = \cos(\phi_0)$

Equations Used by the Chirp Block for Unidirectional Positive Sweeps

Frequency Sweep	Block Output Chirp Signal	User-Specified Frequency Sweep, $f_i(t)$	β	Actual Frequency Sweep, $f_{i(actual)}(t)$
`Linear`	$y(t) = \cos(\psi(t) + \phi_0)$	$f_i(t) = f_0 + \beta t$	$\beta = \dfrac{f_i(t_g) - f_0}{t_g}$	$f_{i(actual)}{}^{(t)} = f_i{}^{(t)}$
`Quadratic`	Same as `Linear`	$f_i(t) = f_0 + \beta t^2$	$\beta = \dfrac{f_i(t_g) - f_0}{t_g^2}$	$f_{i(actual)}{}^{(t)} = f_i{}^{(t)}$
`Logarithmic`	Same as `Linear`	$F_i(t) = f_0 \left(\dfrac{f_i\left(t_g\right)}{f_0} \right)^{\frac{t}{t_g}}$	N/A	$f_{i(actual)}(t) = f_i(t)$

Frequency Sweep	Block Output Chirp Signal	User-Specified Frequency Sweep, $f_i(t)$	β	Actual Frequency Sweep, $f_{i(actual)}(t)$
		Where $f_i(t_g) > f_0 > 0$		
`Swept cosine`	$y(t) = \cos(2\pi f_i(t)t + \phi_0)$	Same as `Linear`	Same as `Linear`	$f_{i(actual)}(t) = f_i(t) + \beta t$

Output Computation Method for Linear, Quadratic, and Logarithmic Frequency Sweeps

The derivative of the phase of a chirp function gives the instantaneous frequency of the chirp function. The Chirp block uses this principle to calculate the chirp output when the **Frequency Sweep** parameter is set to `Linear`, `Quadratic`, or `Logarithmic`.

$$y_{chirp}(t) = \cos(\psi(t) + \phi_0)$$

Linear, quadratic, or logarithmic chirp signal with phase $\psi(t)$

$$f_i(t) = \frac{1}{2\pi} \cdot \frac{d\psi(t)}{dt}$$

Phase derivative is instantaneous frequency

For instance, if you want a chirp signal with a linear instantaneous frequency sweep, you should set the **Frequency Sweep** parameter to `Linear`, and tune the linear sweep values by setting other parameters appropriately. The block outputs a chirp signal, the phase derivative of which is the specified linear sweep. This ensures that the instantaneous frequency of the output is the linear sweep you desired. For equations describing the linear, quadratic, and logarithmic sweeps, see “Equations for Output Computation” on page 1-174.

Output Computation Method for Swept Cosine Frequency Sweep

To generate the swept cosine chirp signal, the block sets the swept cosine chirp output as follows.

$$y_{chirp}(t) = \cos(\psi(t) + \phi_0) = \cos(2\pi f_i(t)t + \phi_0)$$

Swept cosine chirp output (Instantaneous frequency equation, shown above, does not hold.)

Note that the instantaneous frequency equation, shown above, does not hold for the swept cosine chirp, so the user-defined frequency sweep, $f_i(t)$, is not the actual output frequency sweep, $f_{i(actual)}(t)$, of the swept cosine chirp. Thus, the swept cosine output might not behave as you expect. To learn more about swept cosine chirp behavior, see “Cautions Regarding the Swept Cosine Sweep” on page 1-177 and “Equations for Output Computation” on page 1-174.

Cautions Regarding the Swept Cosine Sweep

When you want a linearly swept chirp signal, we recommend you use a linear frequency sweep. Though a swept cosine frequency sweep also yields a linearly swept chirp signal, the output might have unexpected frequency content. For details, see the following two sections.

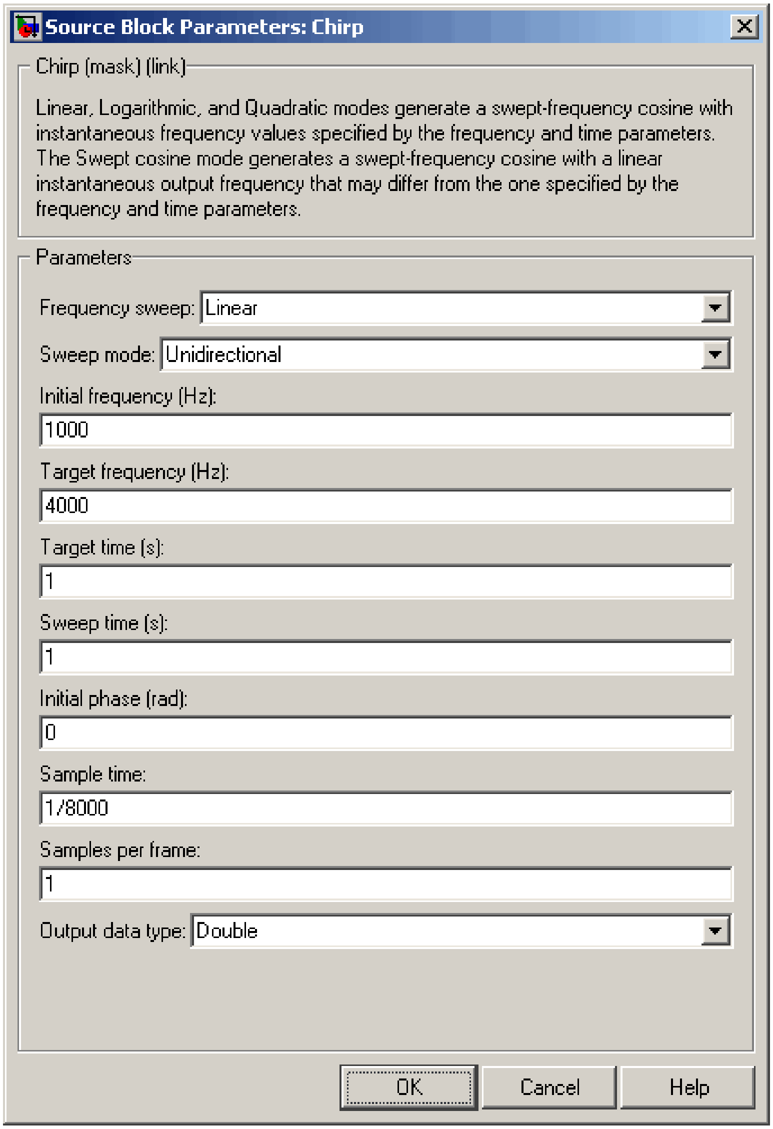
Swept Cosine Instantaneous Output Frequency at the Target Time is not the Target Frequency

The swept cosine sweep value at the **Target time** is not necessarily the **Target frequency**. This is because the user-specified sweep is not the actual frequency sweep of the swept cosine output, as noted in “Output Computation Method for Swept Cosine Frequency Sweep” on page 1-176. See the table Instantaneous Frequency Sweep Values for the actual value of the swept cosine sweep at the **Target time**.

Swept Cosine Output Frequency Content May Greatly Exceed Frequencies in the Sweep

In **Swept cosine** mode, you should not set the parameters so that $1/T$sw is very large compared to the values of the **Initial frequency** and **Target frequency** parameters. In such cases, the actual frequency content of the swept cosine sweep might be closer to $1/T$sw, far exceeding the **Initial frequency** and **Target frequency** parameter values.

Dialog Box



Source Block Parameters: Chirp

Chirp (mask) (link)

Linear, Logarithmic, and Quadratic modes generate a swept-frequency cosine with instantaneous frequency values specified by the frequency and time parameters. The Swept cosine mode generates a swept-frequency cosine with a linear instantaneous output frequency that may differ from the one specified by the frequency and time parameters.

Parameters

Frequency sweep: Linear

Sweep mode: Unidirectional

Initial frequency (Hz): 1000

Target frequency (Hz): 4000

Target time (s): 1

Sweep time (s): 1

Initial phase (rad): 0

Sample time: 1/8000

Samples per frame: 1

Output data type: Double

Frequency sweep

The type of output instantaneous frequency sweep, $f_i(t)$: `Linear`, `Logarithmic`, `Quadratic`, or `Swept cosine`.

Sweep mode

The directionality of the chirp signal: `Unidirectional` or `Bidirectional`.

Initial frequency (Hz)

For `Linear`, `Quadratic`, and `Swept cosine` sweeps, the initial frequency, f_0, of the output chirp signal. For `Logarithmic` sweeps, **Initial frequency** is one less than the actual initial frequency of the sweep. Also, when the sweep is `Logarithmic`, you must set the **Initial frequency** to be less than the **Target frequency**. "Tunable".

Target frequency (Hz)

For `Linear`, `Quadratic`, and `Logarithmic` sweeps, the instantaneous frequency, $f_i(t_g)$, of the output at the **Target time**, t_g. For a `Swept cosine` sweep, **Target frequency** is the instantaneous frequency of the output at half the **Target time**, $t_g/2$. When **Frequency sweep** is `Logarithmic`, you must set the **Target frequency** to be greater than the **Initial frequency**. "Tunable".

Target time (s)

For `Linear`, `Quadratic`, and `Logarithmic` sweeps, the time, t_g, at which the **Target frequency**, $f_i(t_g)$, is reached by the sweep. For a `Swept cosine` sweep, **Target time** is the time at which the sweep reaches $2f_i(t_g)$ - f_0. You must set **Target time** to be *no greater than* **Sweep time** , $T_{sw} \geq t_g$. "Tunable".

Sweep time (s)

In `Unidirectional` **Sweep mode**, the **Sweep time**, T_{sw}, is the period of the output frequency sweep. In `Bidirectional` **Sweep mode**, the **Sweep time** is half the period of the output frequency sweep. You must set **Sweep time** to be no less than **Target time**, $T_{sw} \geq t_g$. "Tunable".

Initial phase (rad)

The phase, ϕ_0 , of the cosine output at t=0; $y_{chirp}(t) = \cos(\phi_0)$. "Tunable".

Sample time

The sample period, T_s, of the output. The output frame period is M_o*T_s.

Samples per frame

The number of samples, M_o, to buffer into each output frame. When the value of this parameter is 1, the block outputs a sample-based signal.

Output data type

The data type of the output, single-precision or double-precision.

Examples

The first few examples demonstrate how to use the Chirp block's main parameters, how to view the output in the time domain, and how to view the output spectrogram:

- “Example 1: Setting a Final Frequency Value for Unidirectional Sweeps” on page 1-180
- “Example 2: Bidirectional Sweeps” on page 1-183
- “Example 3: When Sweep Time is Greater Than Target Time” on page 1-184

Examples 4 and 5 illustrate Chirp block settings that might produce unexpected outputs:

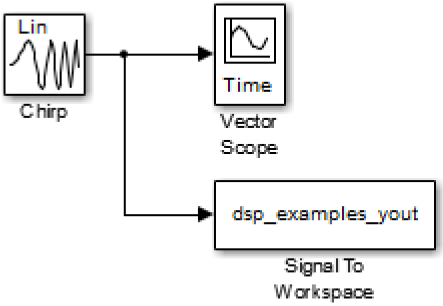
- “Example 4: Output Sweep with Negative Frequencies” on page 1-186
- “Example 5: Output Sweep with Frequencies Greater Than Half the Sampling Frequency” on page 1-187

Example 1: Setting a Final Frequency Value for Unidirectional Sweeps

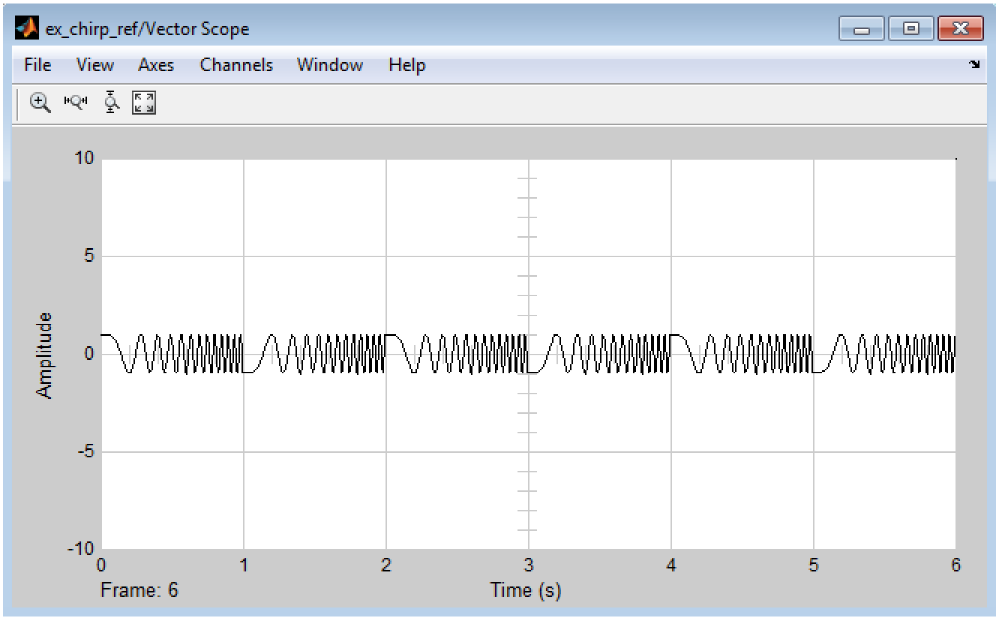
Often times, you might want a unidirectional sweep for which you know the initial and final frequency values. You can specify the final frequency of a unidirectional sweep by setting **Target time** equal to **Sweep time**, in which case the **Target frequency** becomes the final frequency in the sweep. The following model demonstrates this method.

This technique might not work for swept cosine sweeps. For details, see “Cautions Regarding the Swept Cosine Sweep” on page 1-177.

Open the Example 1 model by typing ex_chirp_ref at the MATLAB command line. You can also rebuild the model yourself; see the following list for model parameter settings (leave unlisted parameters in their default states).

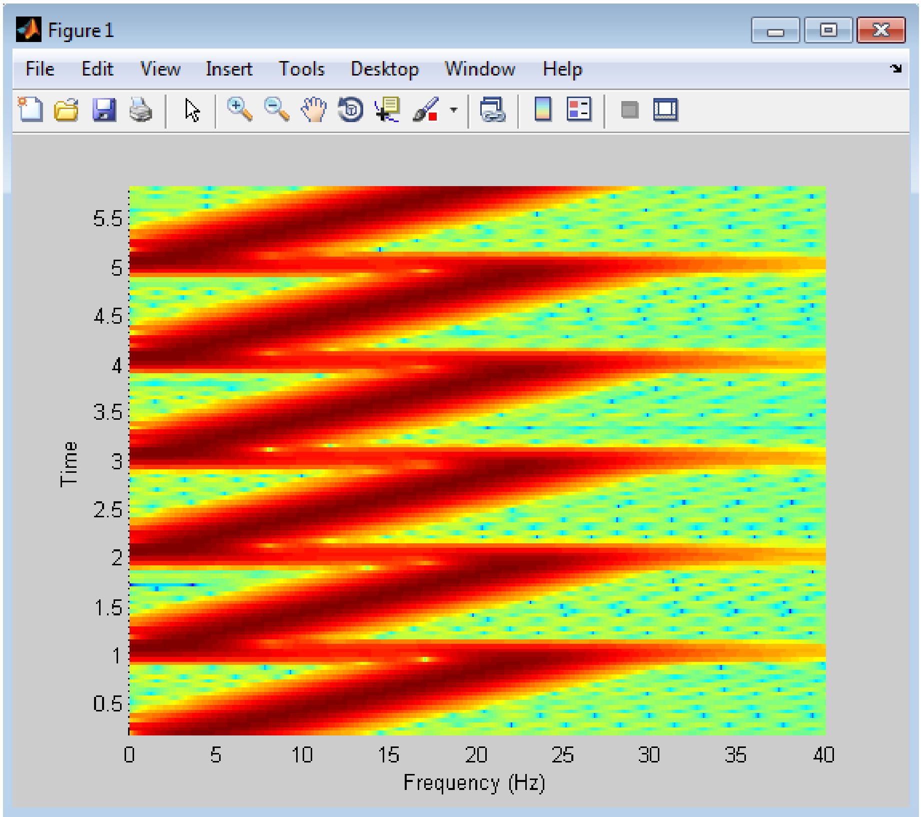


Since **Target time** is set to equal **Sweep time** (1 second), the **Target frequency** (25 Hz) is the final frequency of the unidirectional sweep. Run your model to see the time domain output:



Type the following command to view the chirp output spectrogram:

```
spectrogram(dsp_examples_yout,hamming(128),...
      110,[0:.01:40],400)
```



Chirp Block Parameters for Example 1	
Frequency sweep	`Linear`
Sweep mode	`Unidirectional`
Initial frequency	0
Target frequency	25
Target time	1
Sweep time	1
Initial phase	0
Sample time	1/400
Samples per frame	400

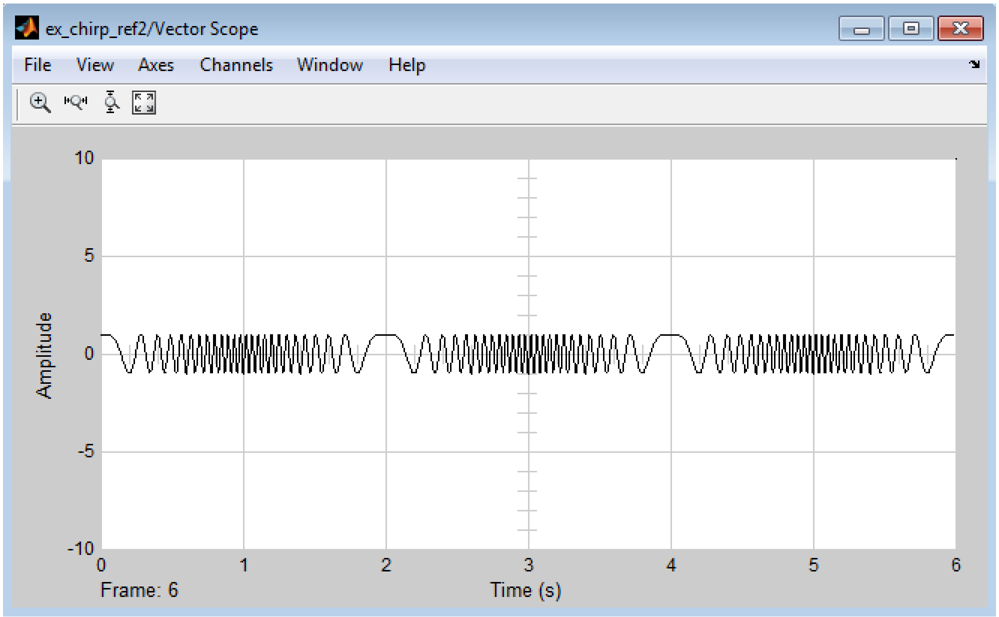
Vector Scope Block Parameters for Example 1	
Input domain	`Time`
Time display span	6
Signal To Workspace Block Parameters for Example 1	
Variable name	`dsp_examples_yout`
Configuration Dialog Parameters for Example 1	
Stop time	5

Example 2: Bidirectional Sweeps

Change the **Sweep mode** parameter in the Example 1 model to `Bidirectional`, and leave all other parameters the same to view the following bidirectional chirp. Note that in the bidirectional sweep, the period of the sweep is twice the **Sweep time** (2 seconds), whereas it was one **Sweep time** (1 second) for the unidirectional sweep in Example 1.

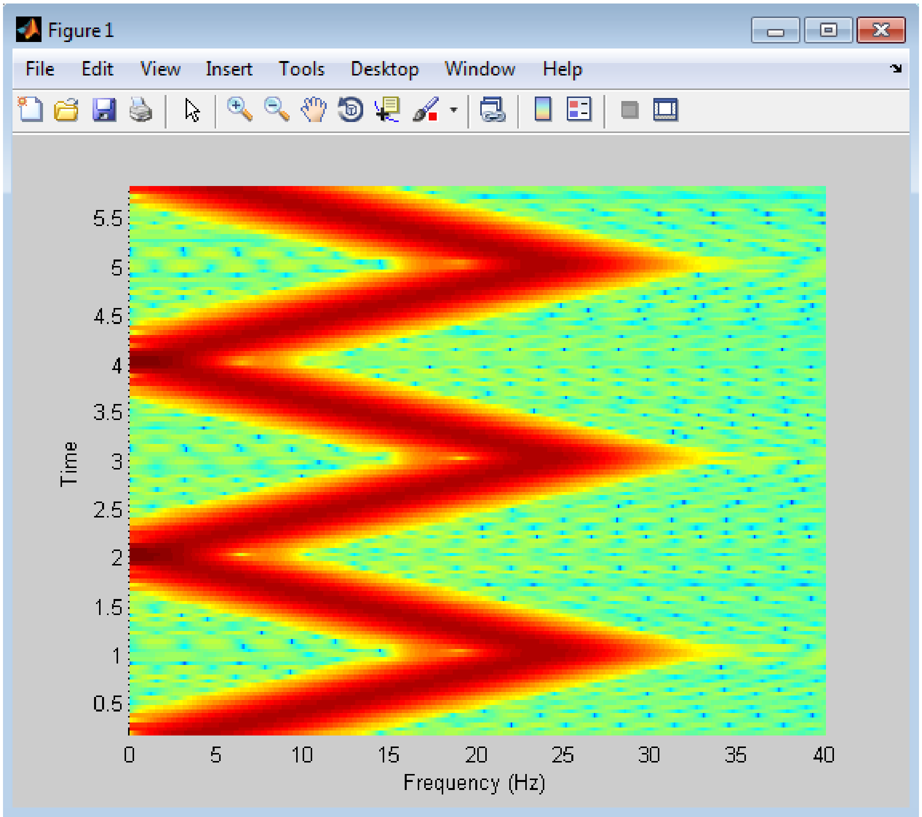
Open the Example 2 model by typing `ex_chirp_ref2` at the MATLAB command line.

Run your model to see the time domain output:



Type the following command to view the chirp output spectrogram:

```
spectrogram(dsp_examples_yout,hamming(128),...
      110,[0:.01:40],400)
```



Example 3: When Sweep Time is Greater Than Target Time

Setting **Sweep time** to `1.5` and leaving the rest of the parameters as in the Example 1 model gives the following output. The sweep still reaches the **Target frequency** (25 Hz) at the **Target time** (1 second), but since **Sweep time** is greater than **Target time**, the sweep continues on its linear path until one **Sweep time** (1.5 seconds) is traversed.

Unexpected behavior might arise when you set **Sweep time** greater than **Target time**; see “Example 4: Output Sweep with Negative Frequencies” on page 1-186 for details.

Open the Example 3 model by typing `ex_chirp_ref3` at the MATLAB command line.

Run your model to see the time domain output:

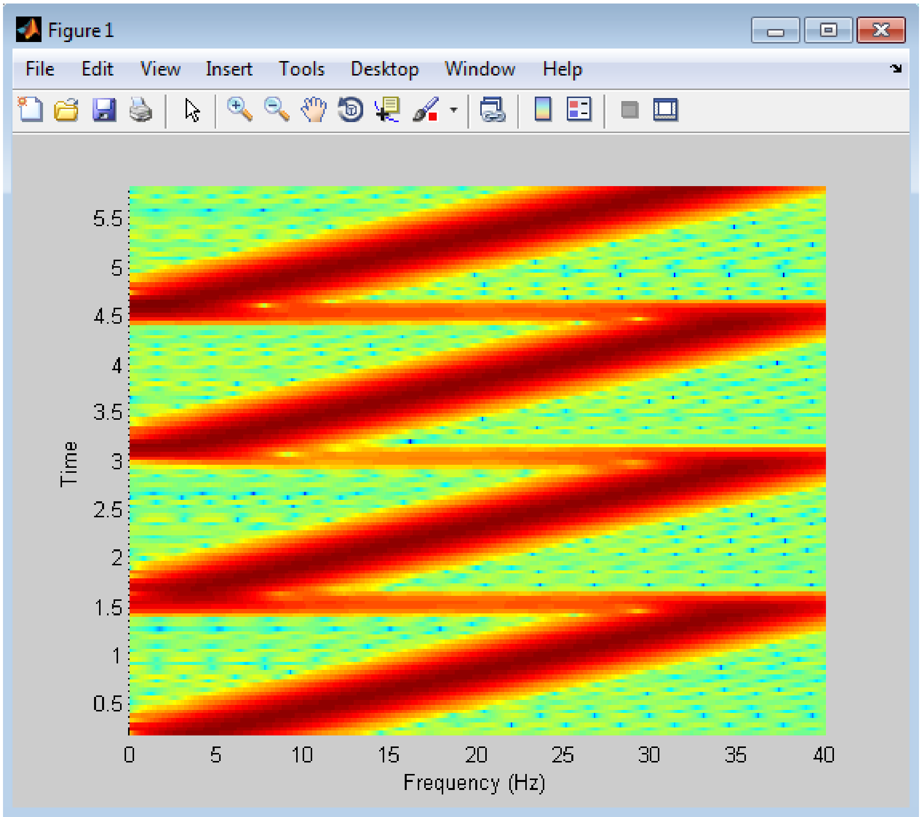
Time (s)

Type the following command to view the chirp output spectrogram:

```
spectrogram(dsp_examples_yout,hamming(128),...
      110,[0:.01:40],400)
```

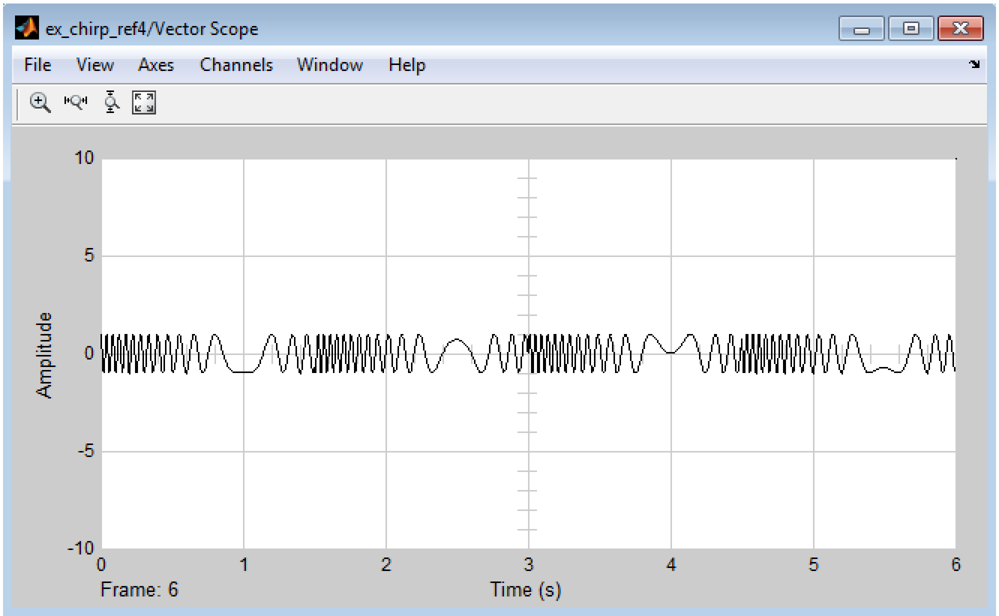


Example 4: Output Sweep with Negative Frequencies

Modify the Example 1 model by changing **Sweep time** to `1.5`, **Initial frequency** to `25`, and **Target frequency** to `0`. *The output chirp of this example might not behave as you expect* because the sweep contains negative frequencies between 1 and 1.5 seconds. The sweep reaches the **Target frequency** of 0 Hz at one second, then continues on its negative slope, taking on negative frequency values until it traverses one **Sweep time** (1.5 seconds).

Open the Example 4 model by typing `ex_chirp_ref4` at the MATLAB command line.

Run your model to see the time domain output:

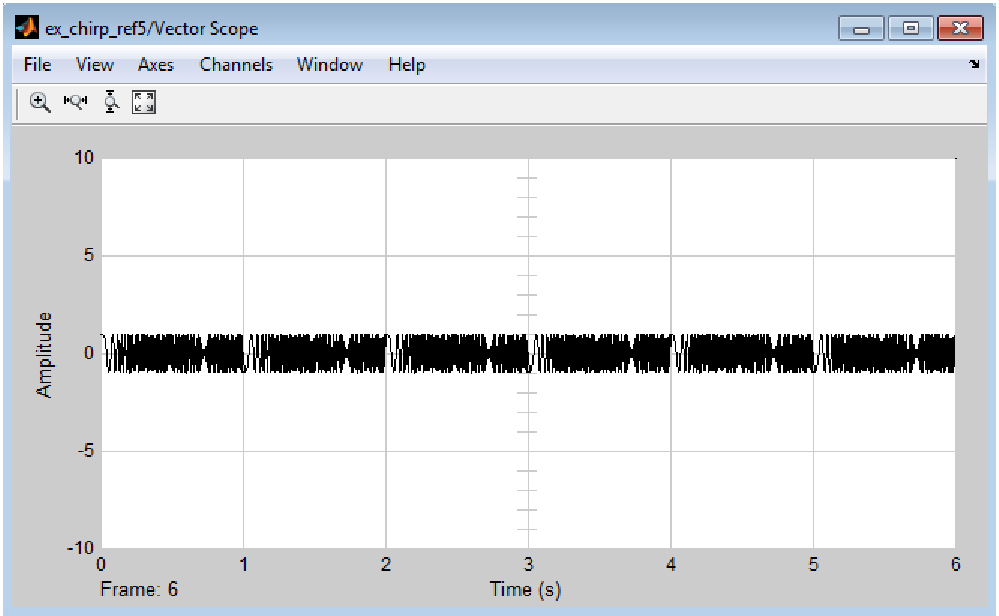


Example 5: Output Sweep with Frequencies Greater Than Half the Sampling Frequency

Modify the Example 1 model by changing the **Target frequency** parameter to `275`. *The output chirp of this model might not behave as you expect* because the sweep contains frequencies greater than half the sampling frequency (`200` Hz), which causes aliasing. If you unexpectedly get a chirp output with a spectrogram resembling the one following, your chirp's sweep might contain frequencies greater than half the sampling frequency.

Open the Example 5 model by typing `ex_chirp_ref5` at the MATLAB command line.

Run your model to see the time domain output:



Type the following command to view the chirp output spectrogram:

```
spectrogram(dsp_examples_yout,hamming(64),...
       60,256,400)
```

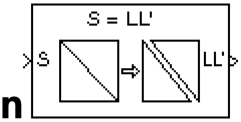
Cholesky Factorization

Factor square Hermitian positive definite matrix into triangular components

Library

Math Functions / Matrices and Linear Algebra / Matrix Factorizations

`dspfactors`



Description

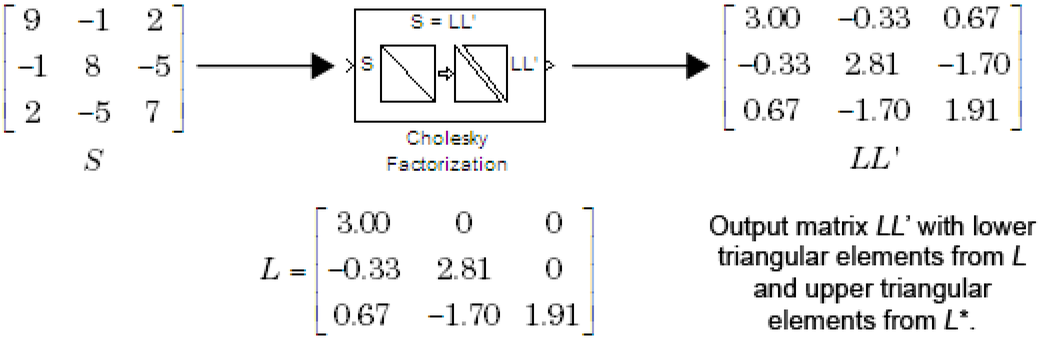
The Cholesky Factorization block uniquely factors the square Hermitian positive definite input matrix S as

$$S = LL^*$$

where L is a lower triangular square matrix with positive diagonal elements and L^* is the Hermitian (complex conjugate) transpose of L. The block outputs a matrix with lower triangle elements from L and upper triangle elements from L^*. The output is not in the same form as the output of the MATLAB `chol` function. In order to convert the output of the Cholesky Factorization block to the MATLAB form, use the following equation:

```
R = triu(LL');
```

Here, `LL'` is the output of the Cholesky Factorization block. Due to roundoff error, these equations do not produce a result that is exactly the same as the MATLAB result.



Output matrix *LL'* with lower triangular elements from *L* and upper triangular elements from *L**.

Block Output Composed of L and L*

Input Requirements for Valid Output

The block output is valid only when its input has the following characteristics:

- Hermitian — The block does *not* check whether the input is Hermitian; it uses only the diagonal and upper triangle of the input to compute the output.
- Real-valued diagonal entries — The block disregards any imaginary component of the input's diagonal entries.
- Positive definite — Set the block to notify you when the input is not positive definite as described in “Response to Nonpositive Definite Input” on page 1-192.

Response to Nonpositive Definite Input

To generate a valid output, the block algorithm requires a positive definite input (see “Input Requirements for Valid Output” on page 1-192). Set the **Non-positive definite input** parameter to determine how the block responds to a nonpositive definite input:

- `Ignore` — Proceed with the computation and *do not* issue an alert. The output is *not* a valid factorization. A partial factorization will be present in the upper left corner of the output.
- `Warning` — Display a warning message in the MATLAB Command Window, and continue the simulation. The output is *not* a valid factorization. A partial factorization will be present in the upper left corner of the output.

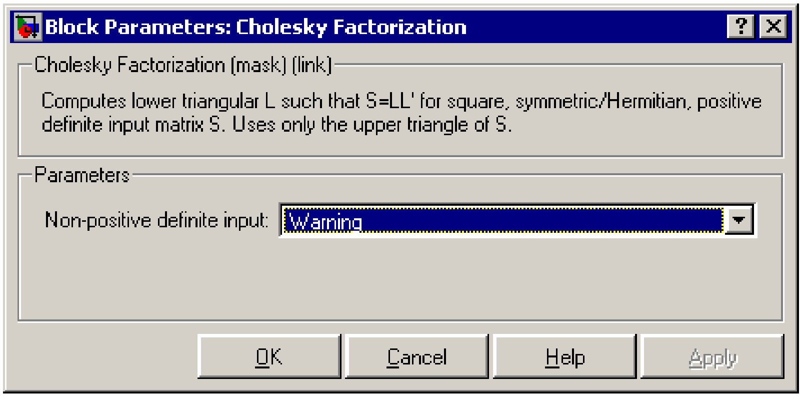
- `Error` — Display an error dialog and terminate the simulation.

Note The **Non-positive definite input** parameter is a diagnostic parameter. Like all diagnostic parameters on the Configuration Parameters dialog box, it is set to `Ignore` in the code generated for this block by Simulink Coder code generation software.

Performance Comparisons with Other Blocks

Note that L and L^* share the same diagonal in the output matrix. Cholesky factorization requires half the computation of Gaussian elimination (LU decomposition), and is always stable.

Dialog Box



Block Parameters: Cholesky Factorization

Cholesky Factorization (mask) (link)

Computes lower triangular L such that S=LL' for square, symmetric/Hermitian, positive definite input matrix S. Uses only the upper triangle of S.

Parameters

Non-positive definite input: Warning

Non-positive definite input

Response to nonpositive definite matrix inputs: `Ignore`, `Warning`, or `Error`. See "Response to Nonpositive Definite Input" on page 1-192.

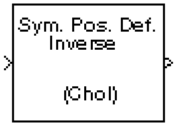
Cholesky Inverse

Compute inverse of Hermitian positive definite matrix using Cholesky factorization

Library

Math Functions / Matrices and Linear Algebra / Matrix Inverses

`dspinverses`



Description

The Cholesky Inverse block computes the inverse of the Hermitian positive definite input matrix S by performing Cholesky factorization.

$$S^{-1} = (LL^{*})^{-1}$$

L is a lower triangular square matrix with positive diagonal elements and L^{*} is the Hermitian (complex conjugate) transpose of L. Only the diagonal and upper triangle of the input matrix are used, and any imaginary component of the diagonal entries is disregarded. Cholesky factorization requires half the computation of Gaussian elimination (LU decomposition), and is always stable.

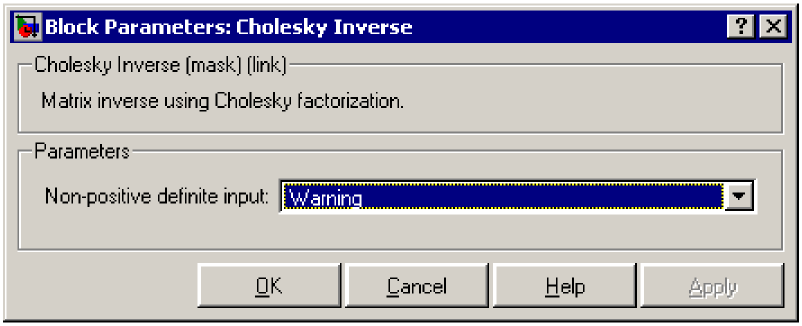
Response to Nonpositive Definite Input

The algorithm requires that the input be Hermitian positive definite. When the input is not positive definite, the block reacts with the behavior specified by the **Non-positive definite input** parameter. The following options are available:

- `Ignore` — Proceed with the computation and *do not* issue an alert. The output is *not* a valid inverse.
- `Warning` — Display a warning message in the MATLAB Command Window, and continue the simulation. The output is *not* a valid inverse.
- `Error` — Display an error dialog box and terminate the simulation.

Note The **Non-positive definite input** parameter is a diagnostic parameter. Like all diagnostic parameters on the Configuration Parameters dialog box, it is set to `Ignore` in the code generated for this block by Simulink Coder code generation software.

Dialog Box



Block Parameters: Cholesky Inverse

Cholesky Inverse (mask) (link)

Matrix inverse using Cholesky factorization.

Parameters

Cholesky Solver

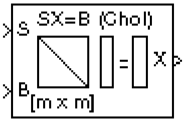
Solve *S*X=*B* for X when *S* is square Hermitian positive definite matrix

Library

Math Functions / Matrices and Linear Algebra / Linear System Solvers

`dspsolvers`

Description



The Cholesky Solver block solves the linear system *S*X=*B* by applying Cholesky factorization to input matrix at the `S` port, which must be square (*M*-by-*M*) and Hermitian positive definite. Only the diagonal and upper triangle of the matrix are used, and any imaginary component of the diagonal entries is disregarded. The input to the `B` port is the right side *M*-by-*N* matrix, *B*. The *M*-by-*N* output matrix X is the unique solution of the equations.

A length-*M* vector input for right side *B* is treated as an *M*-by-1 matrix.

Response to Nonpositive Definite Input

When the input is not positive definite, the block reacts with the behavior specified by the **Non-positive definite input** parameter. The following options are available:

- `Ignore` — Proceed with the computation and *do not* issue an alert. The output is *not* a valid solution.
- `Warning` — Proceed with the computation and display a warning message in the MATLAB Command Window. The output is *not* a valid solution.
- `Error` — Display an error dialog box and terminate the simulation.

Note The **Non-positive definite input** parameter is a diagnostic parameter. Like all diagnostic parameters on the Configuration Parameters dialog box, it is set to `Ignore` in the code generated for this block by Simulink Coder code generation software.

Algorithm

Cholesky factorization uniquely factors the Hermitian positive definite input matrix S as

$$S = LL^*$$

where L is a lower triangular square matrix with positive diagonal elements.

The equation $SX=B$ then becomes

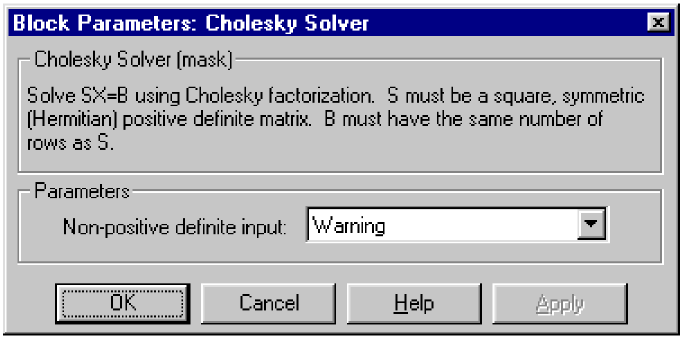
$$LL^*X = B$$

which is solved for X by making the substitution $Y = L^*X$, and solving the following two triangular systems by forward and backward substitution, respectively.

$$LY = B$$

$$L^*X = Y$$

Dialog Box



Block Parameters: Cholesky Solver

Cholesky Solver (mask)

Solve SX=B using Cholesky factorization. S must be a square, symmetric (Hermitian) positive definite matrix. B must have the same number of rows as S.

Parameters

Non-positive definite input: Warning

Non-positive definite input

Response to nonpositive definite matrix inputs: `Ignore`, `Warning`, or `Error`. See "Response to Nonpositive Definite Input" on page 1-198.

- Magnitude response, phase response, and group delay in the frequency domain.
- Impulse response and step response in the time domain.
- Pole-zero information.

The tool also helps you evaluate filter performance by providing information about filter order, stability, and phase linearity. For more information on FVTool, see the Signal Processing Toolbox documentation.

In its normal mode of operation, the CIC Compensator block allows the adder's numbers to wrap around. The Fixed-Point infrastructure then causes warnings to appear on the command line.

Filter Specifications

In this group, you specify your filter format, such as the filter order mode and the filter type.

Filter order mode

Select either `Minimum` (the default) or `Specify` from the drop-down list. Selecting `Specify` enables the **Order** option (see the following sections) so you can enter the filter order.

Filter type

Select `Single-rate`, `Decimator`, `Interpolator`, or `Sample-rate converter`. Your choice determines the type of filter as well as the design methods and structures that are available to implement your filter. By default, the block specifies a single-rate filter.

- Selecting `Decimator` or `Interpolator` activates the **Decimation Factor** or the **Interpolation Factor** options respectively.
- Selecting `Sample-rate converter` activates both factors.

Order

Enter the filter order. This option is enabled only if `Specify` was selected for **Filter order mode**.

Decimation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to `Decimator` or `Sample-rate converter`. The default value is 2.

Interpolation Factor

Enter the interpolation factor. This option is enabled only if the **Filter type** is set to `Interpolator` or `Sample-rate converter`. The default value is 2.

Number of CIC sections

Specify the number of sections in the CIC filter for which you are designing this compensator. Select the number of sections from the drop-down list or enter the number.

Differential Delay

Specify the differential delay of your target CIC filter. The default value is `1`. Most CIC filters use 1 or 2.

Frequency Specifications

The parameters in this group allow you to specify your filter response curve.

Frequency Specifications

Frequency units

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select `Normalized (0–1)` to enter frequencies in normalized form. This behavior is the default. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—`Hz`, `kHz`, `MHz`, or `GHz`. Selecting one of the unit options enables the **Input Fs** parameter.

Input Fs

Fs, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available when you select one of the frequency options from the **Frequency units** list.

Output Fs

Fs, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter output. When you provide an output sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available only when you design interpolators.

Fpass

Enter the frequency at the end of the passband. Specify the value in either normalized frequency units or the absolute units you select in **Frequency units**.

Fstop

Enter the frequency at the start of the stopband. Specify the value in either normalized frequency units or the absolute units you select in **Frequency units**.

Magnitude Specifications

Parameters in this group specify the filter response in the passbands and stopbands.

Magnitude units

Specify the units for any parameter you provide in magnitude specifications. From the drop-down list, select one of the following options:

- `Linear` — Specify the magnitude in linear units.
- `dB` — Specify the magnitude in decibels (default).
- `Squared` — Specify the magnitude in squared units.

Apass

Enter the filter ripple allowed in the passband in the units you choose for **Magnitude units**, either linear or decibels

Algorithm

The parameters in this group allow you to specify the design method and structure of your filter.

Design Method

Lists the design methods available for the frequency and magnitude specifications you entered. When you change the specifications for a filter, such as changing the impulse response, the methods available to design filters changes as well. The default method is `Equiripple`.

Design Options

The options for each design are specific for each design method. This section does not present all of the available options for all designs and design methods. There are many more that you encounter as you select different design methods and filter specifications. The following options represent some of the most common ones available.

Density factor

Density factor controls the density of the frequency grid over which the design method optimization evaluates your filter response function. The number of equally spaced points in the grid is the value you enter for **Density factor** times (filter order + 1).

Increasing the value creates a filter that more closely approximates an ideal equiripple filter but increases the time required to design the filter. The default value of 20 represents a reasonable trade between the accurate approximation to the ideal filter and the time to design the filter.

Phase constraint

Specify the phase constraint of the filter as `Linear`, `Maximum`, or `Minimum`.

Minimum order

When you select this parameter, the design method determines and design the minimum order filter to meet your specifications. Some filters do not provide this parameter. Select `Any`, `Even`, or `Odd` from the drop-down list to direct the design to be any minimum order, or minimum even order, or minimum odd order.

Match Exactly

Specifies that the resulting filter design matches either the passband or stopband or both bands when you select `passband` or `stopband` or `both` from the drop-down list.

Stopband Shape

Stopband shape lets you specify how the stopband changes with increasing frequency. Choose one of the following options:

- `Flat` — Specifies that the stopband is flat. The attenuation does not change as the frequency increases.
- `Linear` — Specifies that the stopband attenuation changes linearly as the frequency increases. Change the slope of the stopband by setting **Stopband decay**.
- `1/f` — Specifies that the stopband attenuation changes exponentially as the frequency increases, where `f` is the frequency. Set the power (exponent) for the decay in **Stopband decay**.

Stopband Decay

When you set Stopband shape, Stopband decay specifies the amount of decay applied to the stopband. the following conditions apply to Stopband decay based on the value of Stopband Shape:

- When you set **Stopband shape** to `Flat`, **Stopband decay** has no affect on the stopband.
- When you set **Stopband shape** to `Linear`, enter the slope of the stopband in units of dB/rad/s. The block applies that slope to the stopband.
- When you set **Stopband shape** to `1/f`, enter a value for the exponent *n* in the relation $(1/f)^n$ to define the stopband decay. The block applies the $(1/f)^n$ relation to the stopband to result in an exponentially decreasing stopband attenuation.

Filter Implementation

Structure

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. By default, the filter uses direct-form structure.

Use basic elements to enable filter customization

Select this check box to implement the filter as a subsystem of basic Simulink blocks. Clear the check box to implement the filter as a high-level subsystem. By default, this check box is cleared.

The high-level implementation provides better compatibility across various filter structures, especially filters that would contain algebraic loops when constructed using basic elements. On the other hand, using basic elements enables the following optimization parameters:

- **Optimize for zero gains** — Terminate chains that contain Gain blocks with a gain of zero.
- **Optimize for unit gains** — Remove Gain blocks that scale by a factor of one.
- **Optimize for delay chains** — Substitute delay chains made up of *n* unit delays with a single delay by *n*.
- **Optimize for negative gains** — Use subtraction in Sum blocks instead of negative gains in Gain blocks.

Input processing

Specify how the block should process the input. The available options may vary depending on he settings of the **Filter Structure** and **Use basic elements for filter customization** parameters. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` — When you select this option, the block treats each column of the input as a separate channel.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

Note: The `Inherited (this choice will be removed — see release notes)` option will be removed in a future release. See "Frame-Based Processing" in the *DSP System Toolbox Release Notes* for more information.

Rate options

When the **Filter type** parameter specifies a multirate filter, select the rate processing rule for the block from following options:

- `Enforce single-rate processing` — When you select this option, the block maintains the sample rate of the input.
- `Allow multirate processing` — When you select this option, the block adjusts the rate at the output to accommodate an increased or reduced number of samples. To select this option, you must set the **Input processing** parameter to `Elements as channels (sample based)`.

Use symbolic names for coefficients

Select this check box to enable the specification of coefficients using MATLAB variables. The available coefficient names differ depending on the filter structure. Using symbolic names allows tuning of filter coefficients in generated code. By default, this check box is cleared.

Supported Data Types

Port	Supported Data Types
Output	• Double-precision floating point • Single-precision floating point

CIC Decimation

Decimate signal using Cascaded Integrator-Comb filter

Library

Filtering / Multirate Filters

`dspmlti4`

Description

The CIC Decimation block performs a sample rate decrease (decimation) on an input signal by an integer factor. Cascaded Integrator-Comb (CIC) filters are a class of linear phase FIR filters comprised of a comb part and an integrator part.

The transfer function of a CIC decimator filter is

$$H(z) = H_I{}^N(z)H_c{}^N(z) = \frac{\left(1 - z^{-RM}\right)^N}{\left(1 - z^{-1}\right)^N} = \left[\sum_{k=0}^{RM-1} z^{-k}\right]^N$$

where

- H_I is the transfer function of the integrator part of the filter.
- H_C is the transfer function of the comb part of the filter.
- N is the number of sections. The number of sections in a CIC filter is defined as the number of sections in either the comb part *or* the integrator part of the filter. This value does not represent the total number of sections throughout the entire filter.
- R is the decimation factor.
- M is the differential delay.

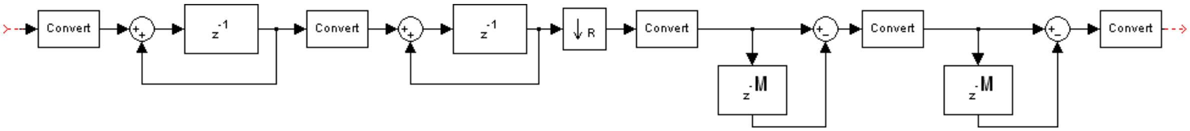
The CIC Decimation block requires a Fixed-Point Designer™ license.

The block supports real and complex fixed-point inputs. In its normal mode of operation, the CIC Decimation block allows the adder's numeric values to overflow and wrap around [1] [3]. The Fixed-Point infrastructure then causes overflow warnings to appear on the command line. This overflow is of no consequence.

CIC Filter Structure

The filter structures supported by the CIC Decimation and CIC Interpolation blocks exactly match those created by the "mfilt.cicdecim" and "mfilt.cicinterp" objects. You can create an `mfilt` object in any workspace and specify that object in the **Multirate filter variable** parameter of this block. Alternatively, you can set the **Coefficient source** to **Dialog parameters** and specify information about the CIC filter using the available block dialog parameters.

You can use this block to create the following CIC filter structure. This decimator has a latency of *N*, where *N* is the number of sections in either the comb or the integrator part of the filter.



Examples

See GSM Digital Down Converter for an example using the CIC Decimation block.

Dialog Box

Coefficient Source

The CIC Decimation block can operate in two different modes. Select the mode in the **Coefficient source** group box. If you select

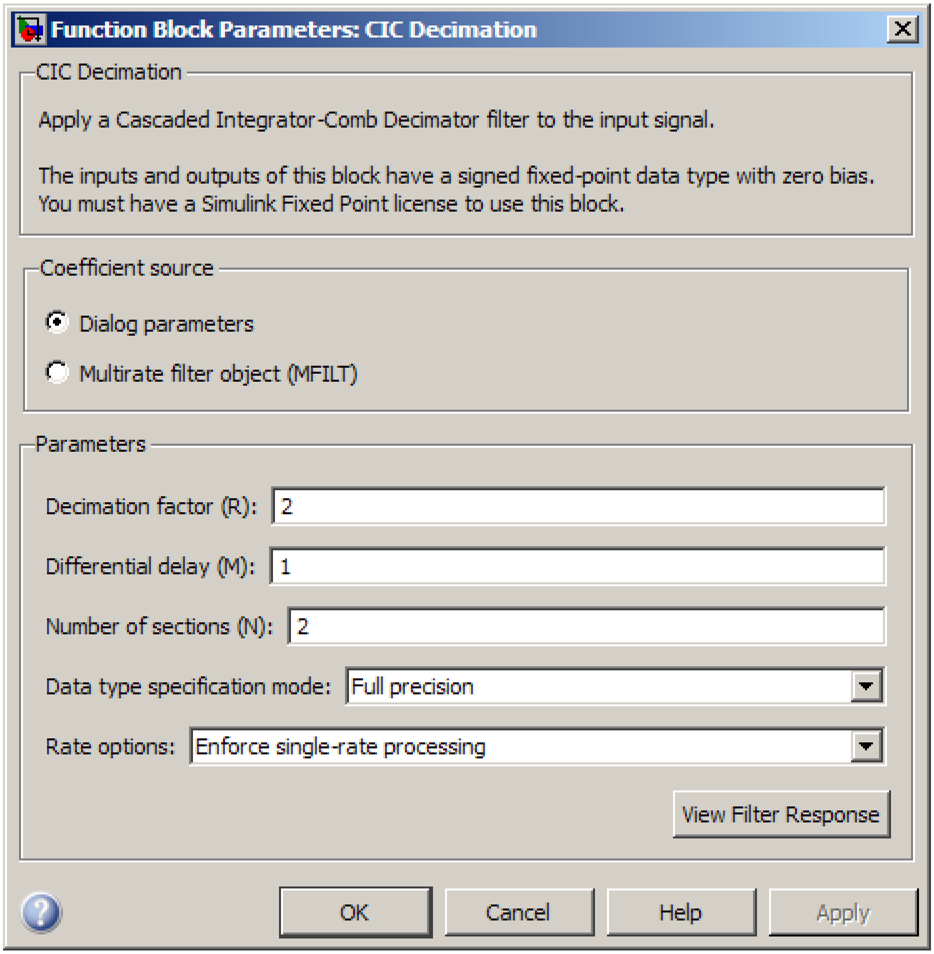
- **Dialog parameters**, you enter information about the filter such as structure and coefficients in the block mask.
- **Multirate filter object (MFILT)**, you specify the filter using an `mfilt` object.

Different items appear on the CIC Decimation block dialog depending on whether you select **Dialog parameters** or **Multirate filter object (MFILT)** in the **Coefficient source** group box. See the following sections for details:

- "Specify Filter Characteristics in Dialog" on page 1-212
- "Specify Multirate Filter Object" on page 1-216

Specify Filter Characteristics in Dialog

The **Main** pane of the CIC Decimation block dialog appears as follows when you select **Dialog parameters** in the **Coefficient source** group box.



Function Block Parameters: CIC Decimation

CIC Decimation

Apply a Cascaded Integrator-Comb Decimator filter to the input signal.

The inputs and outputs of this block have a signed fixed-point data type with zero bias. You must have a Simulink Fixed Point license to use this block.

Coefficient source

● Dialog parameters

○ Multirate filter object (MFILT)

Parameters

Decimation factor (R): 2

Differential delay (M): 1

Number of sections (N): 2

Data type specification mode: Full precision

Rate options: Enforce single-rate processing

Decimation factor (R)

Specify the decimation factor of the filter.

Differential delay (M)

Specify the differential delay of the comb part of the filter, `M`, as shown in the diagram in “CIC Filter Structure” on page 1-211.

Number of sections (N)

Specify the number of filter sections. The number you specify determines the number of sections in either the comb part of the filter or the integrator part of the filter.

This value does not represent the total number of sections in the comb and integrator parts combined.

Data type specification mode

Choose how you specify the fixed-point word length and fraction length of the filter sections and/or output.

- `Full precision` — In this mode, the word and fraction lengths of the filter sections and outputs are automatically selected for you. All word lengths are set to

  $$\text{word length} = \text{ceil}(N * \log_2(M * R)) + I$$

  where

  - I = input word length
  - M = differential delay
  - N = number of sections
  - R = decimation factor

  All fraction lengths are set to the input fraction length.
- `Minimum section word lengths` — In this mode, you specify the word length of the filter output in the **Output word length** parameter. The block automatically selects the word lengths of the filter sections and all fraction lengths such that each of the section word lengths is as small as possible. The precision of each filter section is less than in `Full precision` mode, but the range of each section is preserved.
- `Specify word lengths` — In this mode you specify the word lengths of the filter sections and output in the **Section word lengths** and **Output word length** parameters. The block automatically selects fraction lengths for the filter sections and output such that the range of each section is preserved when the least significant bits are discarded.
- `Binary point scaling` — In this mode you fully specify the word and fraction lengths of the filter sections and output in the **Section word lengths**, **Section fraction lengths**, **Output word length**, and **Output fraction length** parameters.

Section word lengths

Specify the word length, in bits, of the filter sections.

This parameter is only visible if `Specify word lengths` or `Binary point scaling` is selected for the **Data type specification mode** parameter.

Section fraction lengths

Specify the fraction length of the filter sections.

This parameter is only visible if `Binary point scaling` is selected for the **Data type specification mode** parameter.

Output word length

Specify the word length, in bits, of the filter output.

This parameter is only visible if you select `Minimum section word lengths`, `Specify word lengths`, or `Binary point scaling` for the **Data type specification mode** parameter.

Output fraction length

Specify the fraction length of the filter output.

This parameter is only visible if `Binary point scaling` is selected for the **Data type specification mode** parameter.

Rate options

Specify the rate processing rule for the block. You can select one of the following options:

- `Enforce single-rate processing` — When you select this option, the block performs frame-based processing and produces an output that has the same sample rate as the input. To decimate the signal while maintaining the input sample rate, the block decreases the output frame size. In this mode, the input column size must be a multiple of the decimation factor, `R`.
- `Allow multirate processing` — When you select this option, the block performs sample-based processing. In this mode, the block produces an output with a sample rate that is `R` times slower than the input sample rate.

Note: The option `Inherit from input (this choice will be removed - see release notes)` will be removed in a future release. See “Frame-Based Processing” in the *DSP System Toolbox Release Notes* for more information.

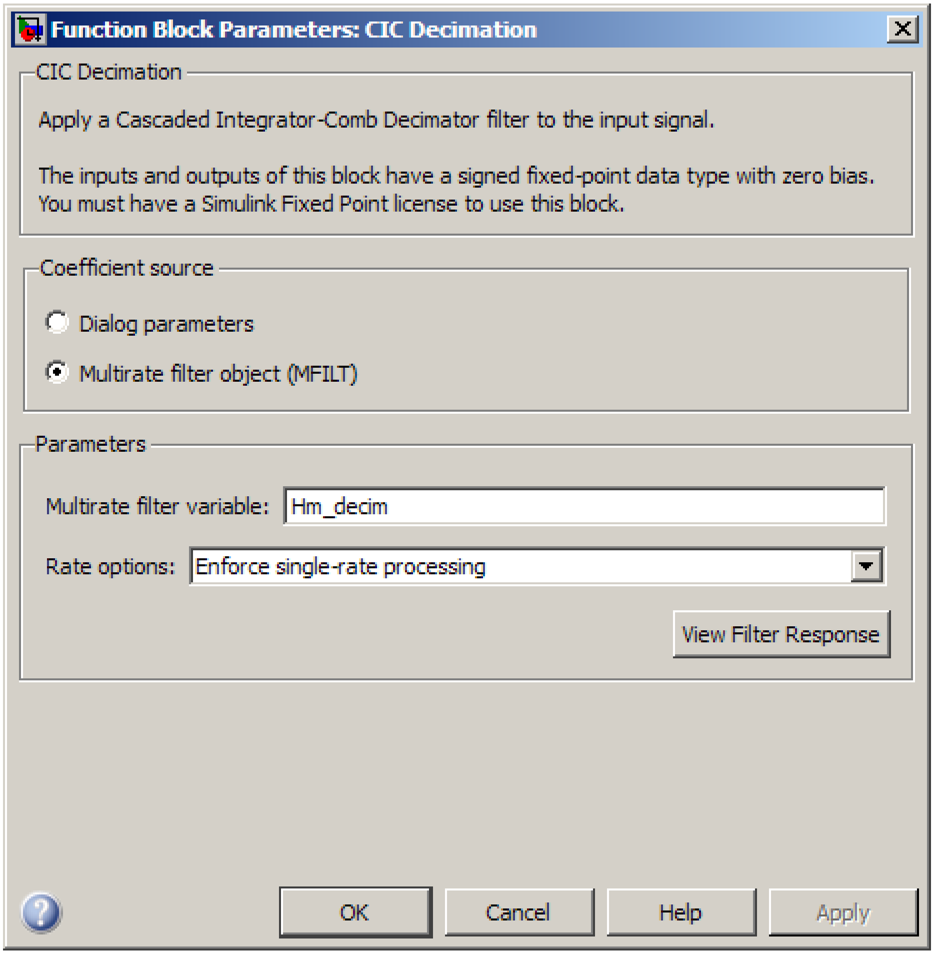
View filter response

This button opens the Filter Visualization Tool (`fvtool`) from the Signal Processing Toolbox product and displays the filter response of the filter defined in the block. For more information on FVTool, see the Signal Processing Toolbox documentation.

Note: If you specify an `mfilt` object in the **Multirate filter variable** parameter, you must click the **Apply** button to apply the filter before using the **View filter response** button.

Specify Multirate Filter Object

The **Main** pane of the CIC Decimation block dialog appears as follows when you select **Multirate filter object (MFILT)** in the **Coefficient source** group box.



Function Block Parameters: CIC Decimation

CIC Decimation

Apply a Cascaded Integrator-Comb Decimator filter to the input signal.

The inputs and outputs of this block have a signed fixed-point data type with zero bias. You must have a Simulink Fixed Point license to use this block.

Coefficient source

○ Dialog parameters

● Multirate filter object (MFILT)

Parameters

Multirate filter variable: Hm_decim

Rate options: Enforce single-rate processing

Multirate filter variable

Specify the multirate filter object (`mfilt`) that you would like the block to implement. You can specify the `mfilt` object in one of three ways:

- You can fully specify the `mfilt` object in the block mask.
- You can enter the variable name of a `mfilt` object that is defined in any workspace.
- You can enter a variable name for a `mfilt` object that is not yet defined, as shown in the default value.

For more information on creating `mfilt` objects, see the `mfilt` function reference page.

Rate options

Specify the rate processing rule for the block. You can select one of the following options:

- `Enforce single-rate processing` — When you select this option, the block performs frame-based processing and produces an output that has the same sample rate as the input. To decimate the signal while maintaining the input sample rate, the block decreases the output frame size. In this mode, the input column size must be a multiple of the decimation factor, `R`.
- `Allow multirate processing` — When you select this option, the block performs sample-based processing and produces an output with a sample rate that is `R` times slower than the input sample rate.

Note: The option `Inherit from input (this choice will be removed - see release notes)` will be removed in a future release. See "Frame-Based Processing" in the *DSP System Toolbox Release Notes* for more information.

View filter response

This button opens the Filter Visualization Tool (`fvtool`) from the Signal Processing Toolbox product and displays the filter response of the `mfilt` object specified in the **Multirate filter variable** parameter. For more information on FVTool, see the Signal Processing Toolbox documentation.

Note: If you specify an `mfilt` object in the **Multirate filter variable** parameter, you must click the **Apply** button to apply the filter before using the **View filter response** button.

HDL Code Generation

This block supports HDL code generation using HDL Coder. HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic. For more information on implementations, properties, and restrictions for HDL code generation, see CIC Decimation.

View filter response

This button opens the Filter Visualization Tool (`fvtool`) from the Signal Processing Toolbox product. You can use the tool to display:

- Magnitude response, phase response, and group delay in the frequency domain.
- Impulse response and step response in the time domain.
- Pole-zero information.

The tool also helps you evaluate filter performance by providing information about filter order, stability, and phase linearity. For more information on FVTool, see the Signal Processing Toolbox documentation.

In its normal mode of operation, the CIC Filter block allows the adder's numbers to wrap around. The Fixed-Point infrastructure then causes warnings to appear on the command line.

Filter Specifications

In this group, you specify your CIC filter format, such as the filter type and the differential delay.

Filter type

Select whether your filter will be a `decimator` or an `interpolator`. Your choice determines the type of filter and the design methods and structures that are available to implement your filter. Selecting `decimator` or `interpolator` activates the **Factor** option. When you design an interpolator, you enable the **Output Fs** parameter.

When you design either a decimator or interpolator, the resulting filter is a CIC filter that decimates or interpolates your input signal.

Differential delay

Specify the differential delay of your CIC filter as an integer value greater than or equal to 1. The default value is 1. The differential delay changes the shape, number, and location of nulls in the filter response. Increasing the differential delay increases the sharpness of the nulls and the response between the nulls. In practice, differential delay values of 1 or 2 are the most common.

Factor

Specify the decimation or interpolation factor for your filter as an integer value greater than or equal to 1. The default value is 2.

Frequency units

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select `Normalized (0–1)` to enter frequencies in normalized form. This behavior is the default. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—Hz, kHz, MHz, or GHz. Selecting one of the unit options enables the **Input Fs** parameter.

Input Fs

Fs, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available when you select one of the frequency options from the **Frequency units** list.

Output Fs

Fs, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter output. When you provide an output sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available only when you design interpolators.

Fpass

Enter the frequency at the end of the passband. Specify the value in either normalized frequency units or the absolute units you select in **Frequency units**.

Magnitude units

Specify the units for any parameter you provide in magnitude specifications. From the drop-down list, select one of the following options:

- Linear — Specify the magnitude in linear units.
- dB — Specify the magnitude in decibels (default).
- Squared — Specify the magnitude in squared units.

Astop

Enter the filter attenuation in the stopband in the units you choose for **Magnitude units**, either linear or decibels.

Filter Implementation

Use basic elements to enable filter customization

Select this check box to implement the filter as a subsystem of basic Simulink blocks. Clear the check box to implement the filter as a high-level subsystem. By default, this check box is cleared.

The high-level implementation provides better compatibility across various filter structures, especially filters that would contain algebraic loops when constructed using basic elements.

Rate options

When the **Filter type** parameter specifies a multirate filter, select the rate processing rule for the block from following options:

- `Enforce single-rate processing` — When you select this option, the block maintains the sample rate of the input.
- `Allow multirate processing` — When you select this option, the block adjusts the rate at the output to accommodate an increased or reduced number of samples. To select this option, you must set the **Input processing** parameter to `Elements as channels (sample based)`.

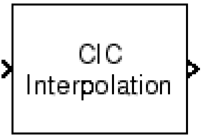
CIC Interpolation

Interpolate signal using Cascaded Integrator-Comb filter

Library

Filtering / Multirate Filters

`dspmlti4`



Description

The CIC Interpolation block performs a sample rate increase (interpolation) on an input signal by an integer factor. Cascaded Integrator-Comb (CIC) filters are a class of linear phase FIR filters that consist of a comb part and an integrator part.

The transfer function of a CIC interpolator filter is

$$H(z) = {H_I}^N(z){H_C}^N(z) = \frac{(1 - z^{-RM})^N}{(1 - z^{-1})^N} = \left[\sum_{k=0}^{RM-1} z^{-k}\right]^N$$

where

- H_I is the transfer function of the integrator part of the filter.
- H_C is the transfer function of the comb part of the filter.
- N is the number of sections. The number of sections in a CIC filter is defined as the number of sections in either the comb part *or* the integrator part of the filter. This value does not represent the total number of sections throughout the entire filter.
- R is the interpolation factor.
- M is the differential delay.

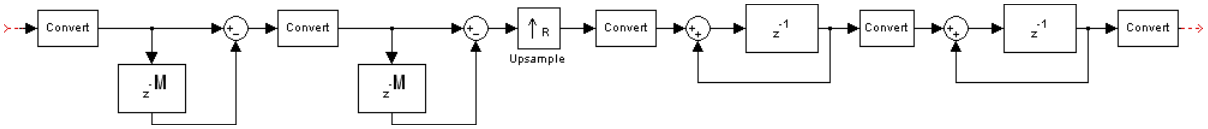
The CIC Interpolation block requires a Fixed-Point Designer license.

The block supports real and complex fixed-point inputs. In its normal mode of operation, the CIC Interpolation block allows the adder's numeric values to overflow and wrap around [1] [3]. The Fixed-Point infrastructure then causes overflow warnings to appear on the command line. This overflow is of no consequence.

CIC Filter Structure

The filter structures supported by the CIC Interpolation and CIC Decimation blocks exactly match those created by the "mfilt.cicinterp" and "mfilt.cicdecim" objects. You can create an `mfilt` object in any workspace and specify that object in the **Multirate filter variable** parameter of this block. Alternatively, you can set the **Coefficient source** to **Dialog parameters** and specify information about the CIC filter using the available block dialog parameters.

You can use this block to create the following CIC filter structure. This interpolator has a latency of *N*, where *N* is the number of sections in either the comb or the integrator part of the filter.



Dialog Box

Coefficient Source

The CIC Interpolation block can operate in two different modes. Select the mode in the **Coefficient source** group box. If you select:

- **Dialog parameters**, you enter information about the filter such as structure and coefficients in the block mask
- **Multirate filter object (MFILT)**, you specify the filter using an `mfilt` object.

Different items appear on the CIC Interpolation block dialog depending on whether you select **Dialog parameters** or **Multirate filter object (MFILT)** in the **Coefficient source** group box. See the following sections for details:

- “Specify Filter Characteristics in Dialog” on page 1-229

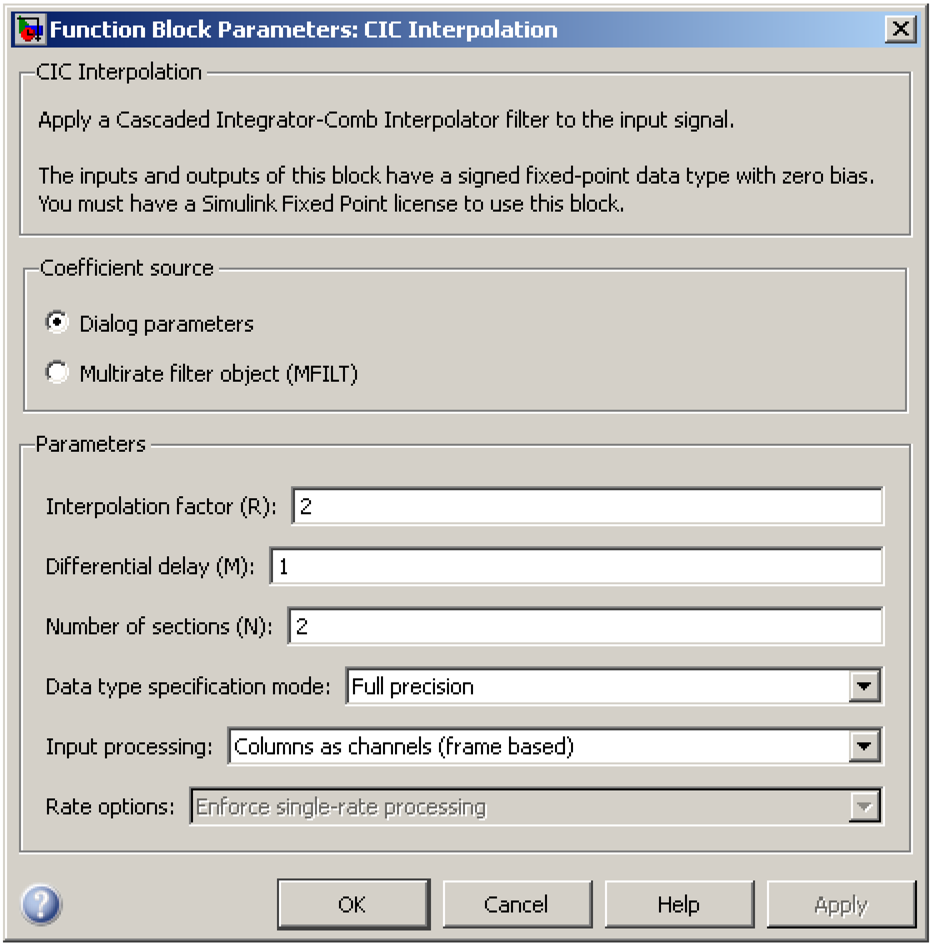
Specify Filter Characteristics in Dialog

The **Main** pane of the CIC Interpolation block dialog appears as follows when you select **Dialog parameters** in the **Coefficient source** group box.



Function Block Parameters: CIC Interpolation

CIC Interpolation

Apply a Cascaded Integrator-Comb Interpolator filter to the input signal.

The inputs and outputs of this block have a signed fixed-point data type with zero bias. You must have a Simulink Fixed Point license to use this block.

Coefficient source

● Dialog parameters

○ Multirate filter object (MFILT)

Parameters

Interpolation factor (R): 2

Differential delay (M): 1

Number of sections (N): 2

Data type specification mode: Full precision

Input processing: Columns as channels (frame based)

Rate options: Enforce single-rate processing

Interpolation factor (R)

Specify the interpolation factor of the filter.

Differential delay (M)

Specify the differential delay of the comb portion of the filter, `M`, as shown in the diagram in "CIC Filter Structure" on page 1-228.

Number of sections (N)

Specify the number of filter sections. The number you specify determines the number of sections in either the comb part of the filter or in the integrator part of the filter. This value does not represent the total number of sections in the comb and integrator parts combined.

Data type specification mode

Choose how you specify the fixed-point word length and fraction length of the filter sections and/or output.

- `Full precision` — In this mode, the word and fraction lengths of the filter sections and outputs are automatically selected for you. The output and last section word lengths are set to

$$\text{word length} = \text{ceil}(\log_2(\frac{(R * M)^N}{R})) + I$$

  where

  - I = input word length
  - M = differential delay
  - N = number of sections
  - R = interpolation factor

  The other section word lengths are set is such a way as to accommodate the bit growth, as described in Hogenauer's paper [1]. All fraction lengths are set to the input fraction length.

- `Minimum section word lengths` — In this mode, you specify the word length of the filter output in the **Output word length** parameter. The word lengths of the filter sections are set in the same way as in `Full precision` mode.

  The section fraction lengths are set to the input fraction length. The output fraction length is set to the input fraction length minus the difference between the last section and output word lengths.

- `Specify word lengths` — In this mode you specify the word lengths of the filter sections and output in the **Section word lengths** and **Output word length** parameters. The fraction lengths of the filter sections are set such that the spread between word length and fraction length is the same as in full-precision mode. The output fraction length is set to the input fraction length minus the difference between the last section and output word lengths.
- `Binary point scaling` — In this mode you fully specify the word and fraction lengths of the filter sections and output in the **Section word lengths**, **Section fraction lengths**, **Output word length**, and **Output fraction length** parameters.

Section word lengths

Specify the word length, in bits, of the filter sections.

This parameter is only visible if you select `Specify word lengths` or `Binary point scaling` for the **Data type specification mode** parameter.

Section fraction lengths

Specify the fraction length of the filter sections.

This parameter is only visible if you select `Binary point scaling` for the **Data type specification mode** parameter.

Output word length

Specify the word length, in bits, of the filter output.

This parameter is only visible if you select `Minimum section word lengths`, `Specify word lengths` or `Binary point scaling` for the **Data type specification mode** parameter.

Output fraction length

Specify the fraction length of the filter output.

This parameter is only visible if you select `Binary point scaling` for the **Data type specification mode** parameter.

Input processing

Specify how the block should process the input. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` — When you select this option, the block treats each column of the input as a separate channel. In this mode, the block always performs single-rate processing.

- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel. In this mode, the input to the block must be a scalar or a vector. You can use the **Rate options** parameter to specify whether the block performs single-rate or multirate processing.

Note: The option `Inherit from input (this choice will be removed - see release notes)` will be removed in a future release. See "Frame-Based Processing" in the *DSP System Toolbox Release Notes* for more information.

Rate options

Specify the rate processing rule for the block. You can select one of the following options:

- `Enforce single-rate processing` — When you select this option, the block maintains the sample rate of the input.
- `Allow multirate processing` — When you select this option, the block produces an output with a sample rate that is `R` times faster than the input sample rate. To select this option, you must set the **Input processing** parameter to `Elements as channels (sample based)`.

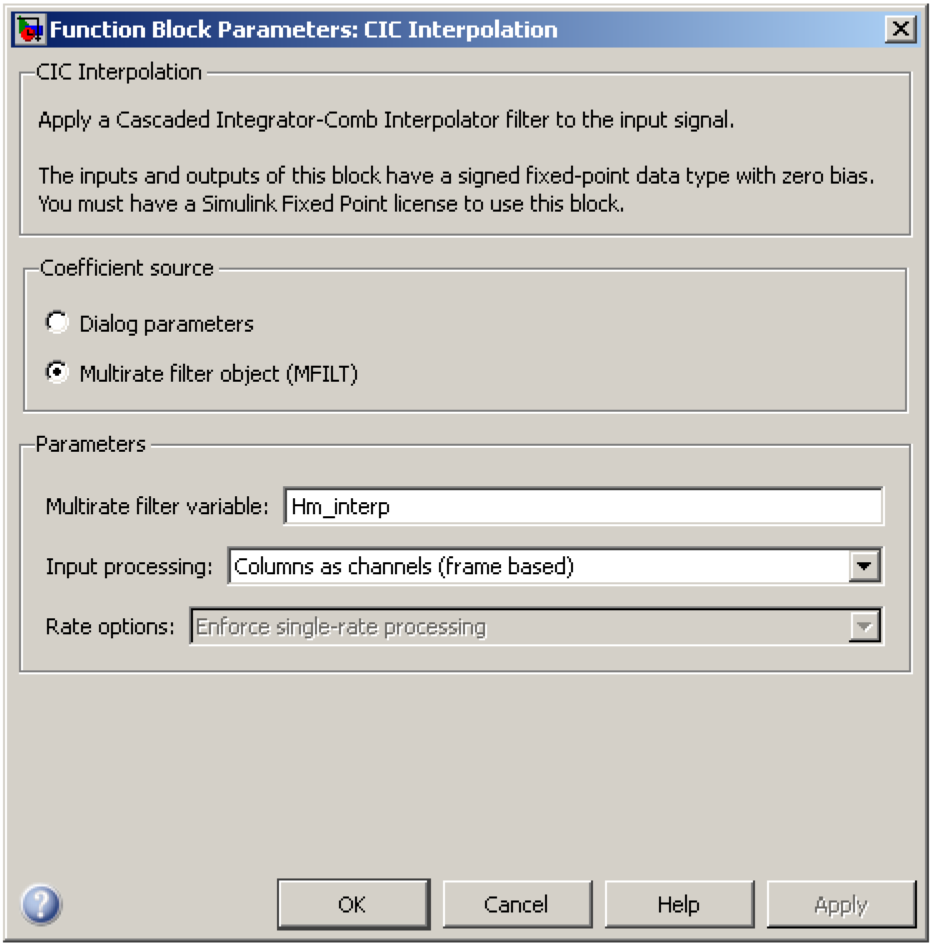
View filter response

This button opens the Filter Visualization Tool (`fvtool`) from the Signal Processing Toolbox product. The tool then displays the filter response of the `mfilt` object specified in the **Multirate filter variable** parameter. For more information on FVTool, see the Signal Processing Toolbox documentation.

Note: If you specify an `mfilt` object in the **Multirate filter variable** parameter, you must click the **Apply** button to apply the filter before using the **View filter response** button.

Specify Multirate Filter Object

The **Main** pane of the CIC Interpolation block dialog appears as follows when you specify **Multirate filter object (MFILT)** in the **Coefficient source** group box.



Function Block Parameters: CIC Interpolation

CIC Interpolation

Apply a Cascaded Integrator-Comb Interpolator filter to the input signal.

The inputs and outputs of this block have a signed fixed-point data type with zero bias. You must have a Simulink Fixed Point license to use this block.

Coefficient source

○ Dialog parameters

● Multirate filter object (MFILT)

Parameters

Multirate filter variable: Hm_interp

Input processing: Columns as channels (frame based)

Rate options: Enforce single-rate processing

Multirate filter variable

Specify the multirate filter object (`mfilt`) that you want the block to implement. You can specify the `mfilt` object in one of three ways:

- You can fully specify the `mfilt` object in the block mask.
- You can enter the variable name of a `mfilt` object that is defined in any workspace.
- You can enter a variable name for a `mfilt` object that is not yet defined, as shown in the default value.

For more information on creating `mfilt` objects, see the `mfilt` function reference page.

Input processing

Specify how the block should process the input. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` — When you select this option, the block treats each column of the input as a separate channel. In this mode, the block always performs single-rate processing.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel. In this mode, the input to the block must be a scalar or a vector. You can use the **Rate options** parameter to specify whether the block performs single-rate or multirate processing.

Note: The option `Inherit from input (this choice will be removed - see release notes)` will be removed in a future release. See "Frame-Based Processing" in the *DSP System Toolbox Release Notes* for more information.

Rate options

Specify the rate processing rule for the block. You can select one of the following options:

- `Enforce single-rate processing` — When you select this option, the block maintains the sample rate of the input.
- `Allow multirate processing` — When you select this option, the block produces an output with a sample rate that is `R` times faster than the input sample rate. To select this option, you must set the **Input processing** parameter to `Elements as channels (sample based)`.

View filter response

This button opens the Filter Visualization Tool (`fvtool`) from the Signal Processing Toolbox product. The tool then displays the filter response of the `mfilt` object specified in the **Multirate filter variable** parameter. For more information on FVTool, see the Signal Processing Toolbox documentation.

Note: If you specify an `mfilt` object in the **Multirate filter variable** parameter, you must click the **Apply** button to apply the filter before using the **View filter response** button.

HDL Code Generation

This block supports HDL code generation using HDL Coder. HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic. For more information on implementations, properties, and restrictions for HDL code generation, see CIC Interpolation in the HDL Coder documentation.

Comb Filter

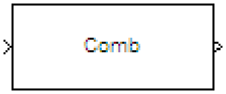
Design comb Filter

Library

Filtering / Filter Designs

`dspfdesign`

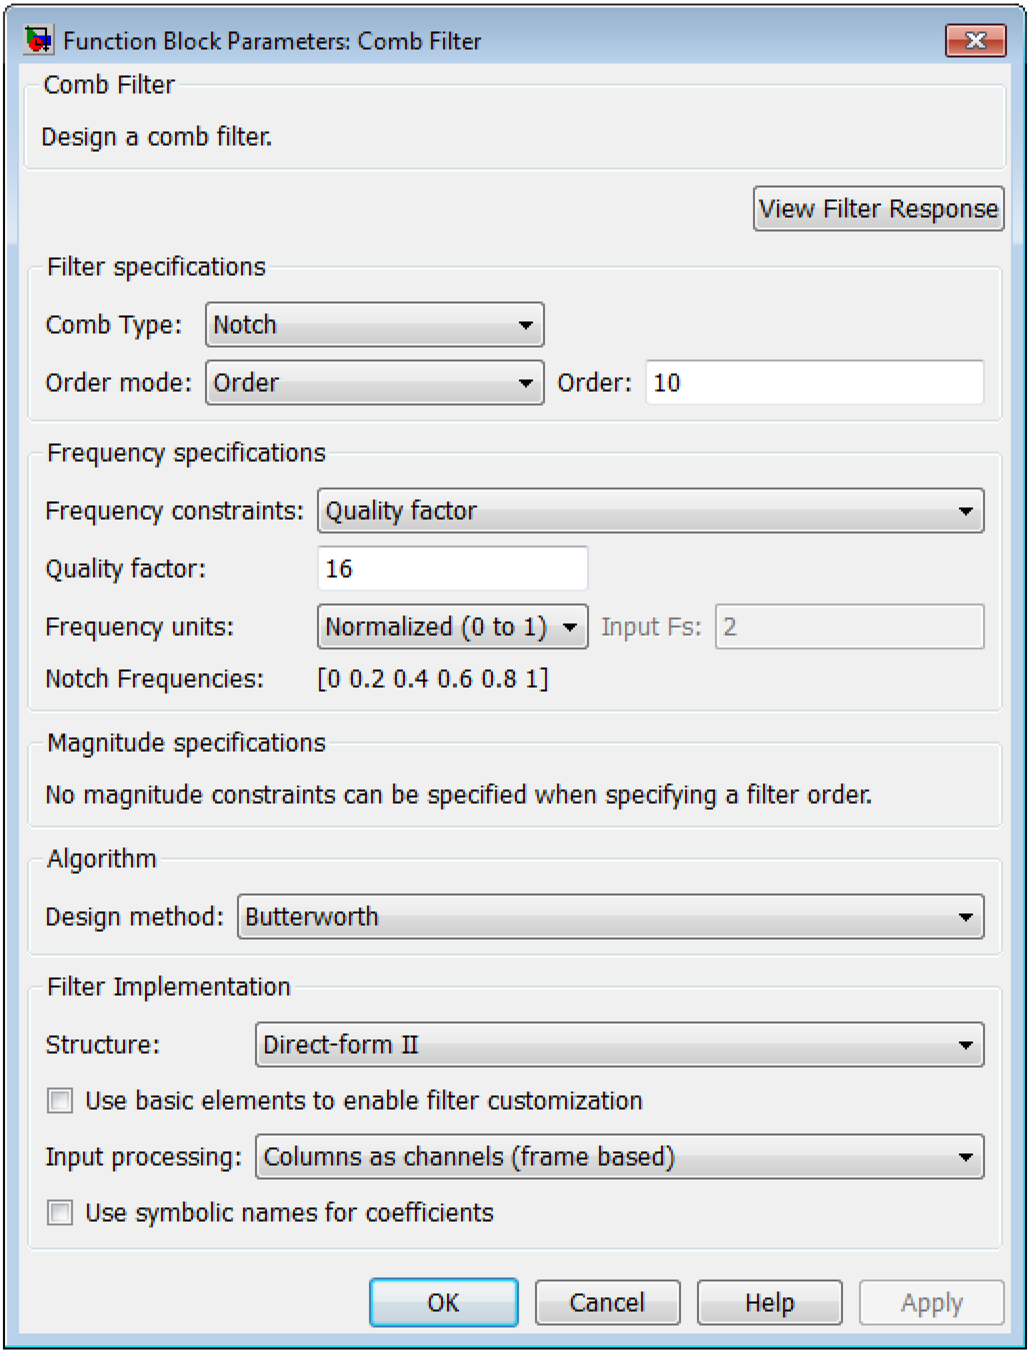
Description



This block brings the filter design capabilities of the “`filterbuilder`” function to the Simulink environment.

Dialog Box

See “Comb Filter Design Dialog Box—Main Pane” for more information about the parameters of this block. The **Data Types** and **Code Generation** panes are not available for blocks in the DSP System Toolbox Filter Designs library.



Function Block Parameters: Comb Filter

Comb Filter

Design a comb filter.

Filter specifications

Comb Type: Notch

Order mode: Order   Order: 10

Frequency specifications

Frequency constraints: Quality factor

Quality factor: 16

Frequency units: Normalized (0 to 1)   Input Fs: 2

Notch Frequencies: [0 0.2 0.4 0.6 0.8 1]

Magnitude specifications

No magnitude constraints can be specified when specifying a filter order.

Algorithm

Design method: Butterworth

Filter Implementation

Structure: Direct-form II

□ Use basic elements to enable filter customization

Input processing: Columns as channels (frame based)

□ Use symbolic names for coefficients

View filter response

This button opens the Filter Visualization Tool (`fvtool`) from the Signal Processing Toolbox product. You can use the tool to display:

- Magnitude response, phase response, and group delay in the frequency domain.
- Impulse response and step response in the time domain.
- Pole-zero information.

The tool also helps you evaluate filter performance by providing information about filter order, stability, and phase linearity. For more information on FVTool, see the Signal Processing Toolbox documentation.

Filter Specifications

In this group, you specify the type of comb filter and the number of peaks or notches.

Comb Type

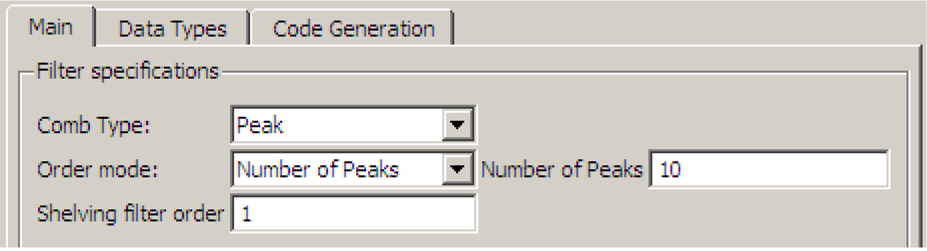
Select either `Notch` or `Peak` from the drop-down list. `Notch` creates a comb filter that attenuates a set of harmonically related frequencies. `Peak` creates a comb filter that amplifies a set of harmonically related frequencies.

Order mode

Select either `Order` or `Number of Peaks/Notches` from the drop-down menu.

Select `Order` to enter the desired filter order in the dialog box. The comb filter has notches or peaks at increments of 2/`Order` in normalized frequency units.

Select `Number of Peaks` or `Number of Notches` to specify the number of peaks or notches and the `Shelving filter order`.



Comb Type: Peak

Order mode: Number of Peaks

Number of Peaks 10

Shelving filter order 1

Shelving filter order

The `Shelving filter order` is a positive integer that determines the sharpness of the peaks or notches. Larger values result in sharper peaks or notches.

Frequency specifications

In this group, you specify the frequency constraints and frequency units.

Frequency specifications

Select either `Quality factor` or `Bandwidth`.

`Quality factor` is the ratio of the center frequency of the peak or notch to the bandwidth calculated at the –3 dB point.

`Bandwidth` specifies the bandwidth of the peak or notch. By default the bandwidth is measured at the –3 dB point. For example, setting the bandwidth equal to 0.1 results in 3 dB frequencies at normalized frequencies 0.05 above and below the center frequency of the peak or notch.

Frequency Units

Specify the frequency units. The default is normalized frequency. Choosing an option in Hz enables the **Input Fs** dialog box.

Magnitude specifications

Specify the units for the magnitude specification and the gain at which the bandwidth is measured. This menu is disabled if you specify a filter order. Select one of the following magnitude units from the drop down list:

- `dB` — Specify the magnitude in decibels (default).
- `Squared` — Specify the magnitude in squared units.

Bandwidth gain — Specify the gain at which the bandwidth is measured. The default is –3 dB.

Algorithm

The parameters in this group allow you to specify the design method and structure of your filter.

Design Method

The IIR Butterworth design is the only option for peaking or notching comb filters.

Filter Implementation

Structure

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter.

Use basic elements to enable filter customization

Select this check box to implement the filter as a subsystem of basic Simulink blocks. Clear the check box to implement the filter as a high-level subsystem. By default, this check box is cleared.

The high-level implementation provides better compatibility across various filter structures, especially filters that would contain algebraic loops when constructed using basic elements. On the other hand, using basic elements enables the following optimization parameters:

- **Optimize for zero gains** — Terminate chains that contain Gain blocks with a gain of zero.
- **Optimize for unit gains** — Remove Gain blocks that scale by a factor of one.
- **Optimize for delay chains** — Substitute delay chains made up of *n* unit delays with a single delay by *n*.
- **Optimize for negative gains** — Use subtraction in Sum blocks instead of negative gains in Gain blocks.

Optimize for unit-scale values

Select this check box to scale unit gains between sections in SOS filters. This parameter is available only for SOS filters.

Input processing

Specify how the block should process the input. The available options may vary depending on he settings of the **Filter Structure** and **Use basic elements for filter customization** parameters. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` — When you select this option, the block treats each column of the input as a separate channel.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

Note: The `Inherited (this choice will be removed — see release notes)` option will be removed in a future release. See "Frame-Based Processing" in the *DSP System Toolbox Release Notes* for more information.

Rate options

When the **Filter type** parameter specifies a multirate filter, select the rate processing rule for the block from following options:

- `Enforce single-rate processing` — When you select this option, the block maintains the sample rate of the input.
- `Allow multirate processing` — When you select this option, the block adjusts the rate at the output to accommodate an increased or reduced number of samples. To select this option, you must set the **Input processing** parameter to `Elements as channels (sample based)`.

Use symbolic names for coefficients

Select this check box to enable the specification of coefficients using MATLAB variables. The available coefficient names differ depending on the filter structure. Using symbolic names allows tuning of filter coefficients in generated code. By default, this check box is cleared.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point
Output	• Double-precision floating point • Single-precision floating point

Complex Cepstrum

Compute complex cepstrum of input

Library

Transforms

```
dspxfrm3
```

Description

The Complex Cepstrum block computes the complex cepstrum of each column in the real-valued M-by-N input matrix, u. The block treats each column of the input as an independent channel containing M consecutive samples. The block does not accept complex-valued inputs.

The input is altered by the application of a linear phase term so that there is no phase discontinuity at $\pm\pi$ radians. That is, each input channel is independently zero padded and circularly shifted to have zero phase at π radians.

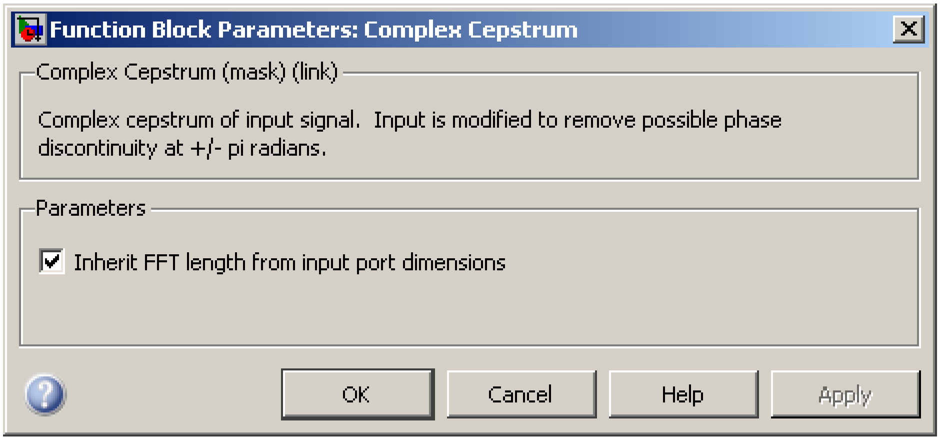
The output is a real M_o-by-N matrix, where M_o is specified by the **FFT length** parameter. Each output column contains the length-M_o complex cepstrum of the corresponding input column.

```
y = cceps(u,Mo)     % Equivalent MATLAB code
```

When you select the **Inherit FFT length from input port dimensions** check box, the output frame size matches the input frame size (M_o=M). In this case, the block processes *sample-based* length-M row vector inputs as a single channel (that is, as an M-by-1 column vector), and returns the result as a length-M column vector. The block *always* processes unoriented vector inputs as a single channel, and returns the result as a length-M column vector.

The output port rate is the same as the input port rate.

Dialog Box



Function Block Parameters: Complex Cepstrum

Complex Cepstrum (mask) (link)

Complex cepstrum of input signal. Input is modified to remove possible phase discontinuity at +/- pi radians.

Parameters

☑ Inherit FFT length from input port dimensions

Inherit FFT length from input port dimensions

When you select this check box, the output frame size matches the input frame size.

FFT length

The number of frequency points at which to compute the FFT, which is also the output frame size, M_o. This parameter is visible only when you clear the **Inherit FFT length from input port dimensions** check box.

Supported Data Types

- Double-precision floating point
- Single-precision floating point

Complex Exponential

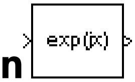
Compute complex exponential function

Library

Math Functions / Math Operations

`dspmathops`

Description

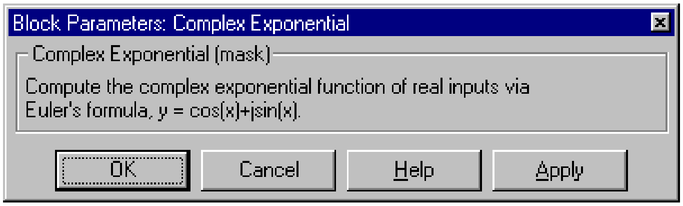


The Complex Exponential block computes the complex exponential function for each element of the real input, u.

$$y = e^{ju} = \cos u + j\sin u$$

where $j = \sqrt{-1}$. The output is complex and the same size as the input.

Dialog Box



Block Parameters: Complex Exponential

Complex Exponential (mask)

Compute the complex exponential function of real inputs via
Euler's formula, y = cos(x)+jsin(x).

Supported Data Types

- Double-precision floating point

- Single-precision floating point

Constant

Generate constant value

Library

Sources

`dspsrcs4`

Description

The Constant block is an implementation of the Simulink Constant block. See Constant for more information.

HDL Code Generation

This block supports HDL code generation using HDL Coder. HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic. For more information on implementations, properties, and restrictions for HDL code generation, see Constant.

Constant Diagonal Matrix

Generate square, diagonal matrix

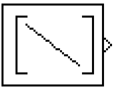
Library

- Sources

  dspsrcs4
- Math Functions / Matrices and Linear Algebra / Matrix Operations

  dspmtrx3

Description

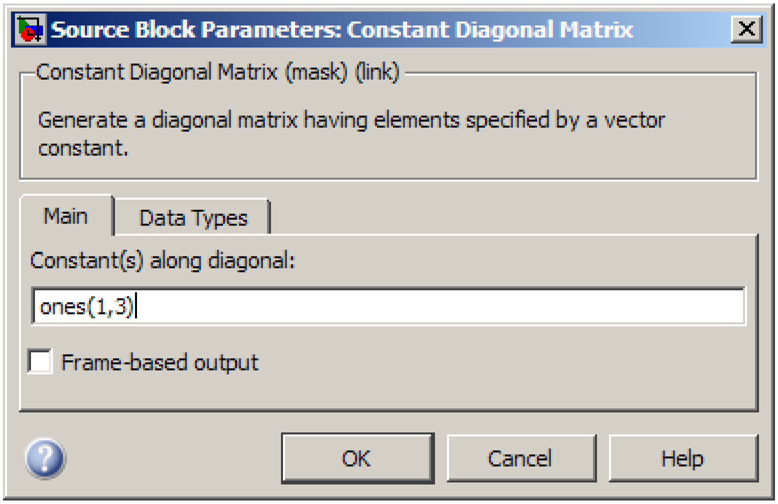


The Constant Diagonal Matrix block outputs a square diagonal matrix constant. The **Constant along diagonal** parameter determines the values along the matrix diagonal. This parameter can be a scalar to be repeated for all elements along the diagonal, or a vector containing the values of the diagonal elements. To generate the identity matrix, set the **Constant along diagonal** to 1, or use the Identity Matrix block.

The output is frame based when you select the **Frame-based output** check box; otherwise, the output is sample based.

Dialog Box

The **Main** pane of the Constant Diagonal Matrix block dialog appears as follows.



Source Block Parameters: Constant Diagonal Matrix

Constant Diagonal Matrix (mask) (link)

Generate a diagonal matrix having elements specified by a vector constant.

Constant(s) along diagonal: ones(1,3)

□ Frame-based output

Constant(s) along diagonal

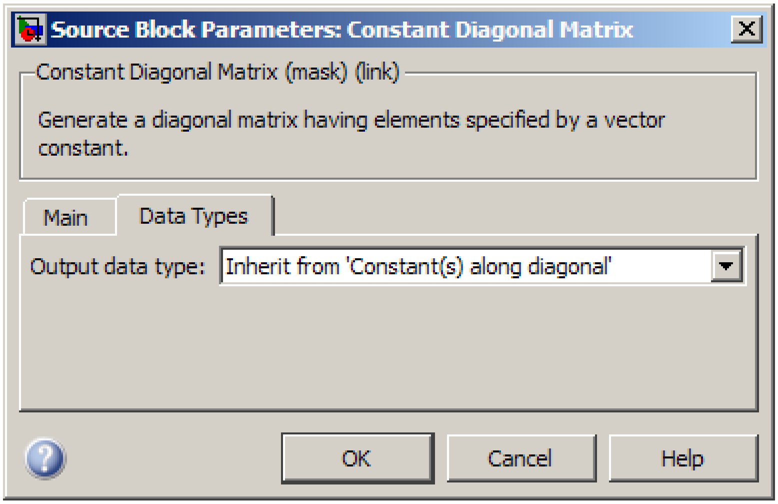
Specify the values of the elements along the diagonal. You can input a scalar or a vector. “Tunable”.

When you specify any data type information in this field, it is overridden by the value of the **Output data type** parameter on the **Data Types** pane, unless you select `Inherit from 'Constant(s) along diagonal'`.

Frame-based output

Select to cause the output of the block to be frame based. Otherwise, the output is sample based.

The **Data Types** pane of the Constant Diagonal Matrix block dialog appears as follows.



Source Block Parameters: Constant Diagonal Matrix

Constant Diagonal Matrix (mask) (link)

Generate a diagonal matrix having elements specified by a vector constant.

Output data type: Inherit from 'Constant(s) along diagonal'

Output data type

Specify the output data type in one of the following ways:

- Choose one of the built-in data types from the list.
- Choose `Fixed-point` to specify the output data type and scaling in the **Signed**, **Word length**, **Set fraction length in output to,** and **Fraction length** parameters.
- Choose `User-defined` to specify the output data type and scaling in the **User-defined data type**, **Set fraction length in output to,** and **Fraction length** parameters.
- Choose `Inherit from 'Constant(s) along diagonal'` to set the output data type and scaling to match the values of the **Constant(s) along diagonal** parameter on the **Main** pane.
- Choose `Inherit via back propagation` to set the output data type and scaling to match the next block downstream.

The value of this parameter overrides any data type information specified in the **Constant(s) along diagonal** parameter on the **Main** pane, except when you select `Inherit from 'Constant(s) along diagonal'`.

Signed

Select to output a signed fixed-point signal. Otherwise, the signal is unsigned. This parameter is only visible when you select `Fixed-point` for the **Output data type** parameter.

Word length

Specify the word length, in bits, of the fixed-point output data type. This parameter is only visible when you select `Fixed-point` for the **Output data type** parameter.

User-defined data type

Specify any built-in or fixed-point data type. You can specify fixed-point data types using the following Fixed-Point Designer functions: `sfix`, `ufix`, `sint`, `uint`, `sfrac`, and `ufrac`. This parameter is only visible when you select `User-defined` for the **Output data type** parameter.

Set fraction length in output to

Specify the scaling of the fixed-point output by either of the following two methods:

- Choose `Best precision` to have the output scaling automatically set such that the output signal has the best possible precision.
- Choose `User-defined` to specify the output scaling in the **Fraction length** parameter.

This parameter is only visible when you select `Fixed-point` for the **Output data type** parameter, or when you select `User-defined` and the specified output data type is a fixed-point data type.

Fraction length

For fixed-point output data types, specify the number of fractional bits, or bits to the right of the binary point. This parameter is only visible when you select `Fixed-point` or `User-defined` for the **Output data type** parameter and `User-defined` for the **Set fraction length in output to** parameter.

Supported Data Types

- Double-precision floating point
- Single-precision floating point
- Fixed point
- 8-, 16-, and 32-bit signed integers
- 8-, 16-, and 32-bit unsigned integers

See Also

`diag`	MATLAB

Constant Ramp

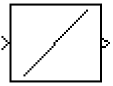
Generate ramp signal with length based on input dimensions

Library

Signal Operations

`dspsigops`

Description



The Constant Ramp block generates the constant ramp signal

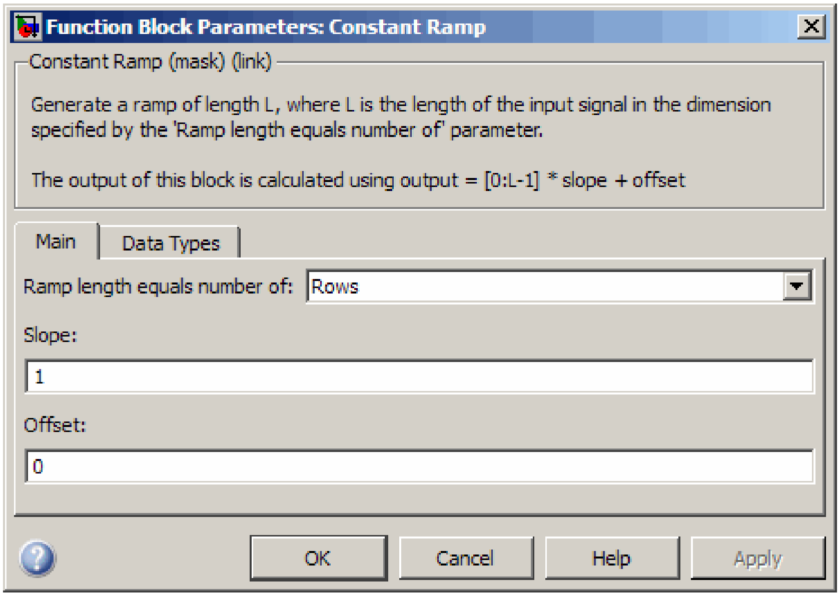
```
y = (0:L-1)*m + b
```

where *m* is the slope specified by the scalar **Slope** parameter, and *b* is the *y*-intercept specified by the scalar **Offset** parameter.

For an unoriented vector input, *L* is equal to the length of the input vector. For an N-D input array, the length *L* of the output ramp is equal to the length of the input in the dimension specified by the **Ramp length equals number of** or **Dimension** parameter. The output, *y*, is always an unoriented vector.

Dialog Box

The **Main** pane of the Constant Ramp block dialog appears as follows.



Function Block Parameters: Constant Ramp

Constant Ramp (mask) (link)

Generate a ramp of length L, where L is the length of the input signal in the dimension specified by the 'Ramp length equals number of' parameter.

The output of this block is calculated using output = [0:L-1] * slope + offset

Main | Data Types

Ramp length equals number of: Rows

Slope: 1

Offset: 0

Ramp length equals number of

Specify whether the length of the output ramp is the number of rows, number of columns, or the length of the specified dimension of the input.

Dimension

Specify the one-based dimension of the input array that determines the length of the output ramp.

This parameter is only visible when you select `Elements in specified dimension` for the **Ramp length equals number of** parameter.

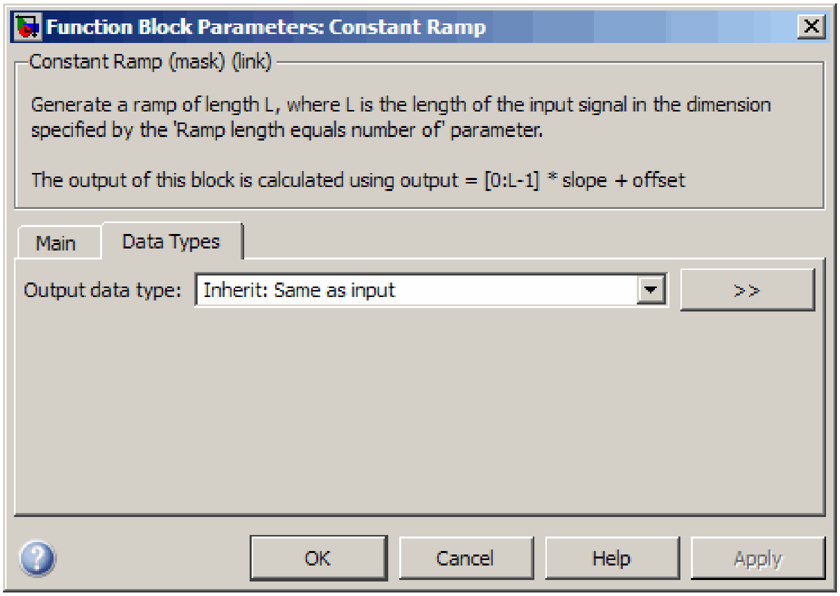
Slope

Specify the scalar slope of the ramp.

Offset

Specify the scalar *y*-intercept of the ramp.

The **Data Types** pane of the Constant Ramp block dialog appears as follows.



Function Block Parameters: Constant Ramp

Constant Ramp (mask) (link)

Generate a ramp of length L, where L is the length of the input signal in the dimension specified by the 'Ramp length equals number of' parameter.

The output of this block is calculated using output = [0:L-1] * slope + offset

Output data type: Inherit: Same as input

Output data type

Specify the output data type for this block. You can select one of the following:

- A rule that inherits a data type, for example, `Inherit: Same as input`.
- A built in data type, such as `double`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Specify Block Output Data Types” in “Simulink User's Guide” for more information.

Supported Data Types

- Double-precision floating point
- Single-precision floating point

- Fixed point
- 8-, 16-, and 32-bit signed integers
- 8-, 16-, and 32-bit unsigned integers

This block differs from other DSP System Toolbox blocks in that unless you choose `Same as input` for the **Output data type** parameter, the data types of the input and the output do not need to be the same.

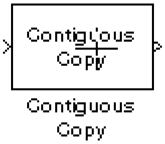
Contiguous Copy (Obsolete)

Create discontiguous input in contiguous block of memory

Library

`dspobslib`



Description

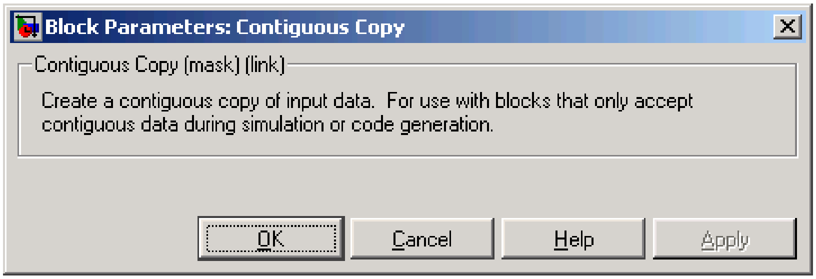
Note The Contiguous Copy block is still supported but is likely to be obsoleted in a future release.

The Contiguous Copy block copies the input to a contiguous block of memory, and passes this new copy to the output. The output is identical to the input, but is guaranteed to reside in a contiguous section of memory.

Because Simulink software employs an efficient copy-by-reference method for propagating data in a model, some operations produce outputs with discontiguous memory locations.

Although this does not present a problem during simulation, blocks linked to versions of DSP Blockset prior to 4.0 may require contiguous inputs for code generation with the Simulink Coder product. When such blocks are used in a model intended for code generation, they should be preceded by the Contiguous Copy block to ensure that their inputs are contiguous.

Dialog Box



Block Parameters: Contiguous Copy

Contiguous Copy (mask) (link)

Create a contiguous copy of input data. For use with blocks that only accept contiguous data during simulation or code generation.

Supported Data Types

- Double-precision floating point
- Single-precision floating point
- Fixed point
- Boolean
- 8-, 16-, and 32-bit signed integers
- 8-, 16-, and 32-bit unsigned integers

Convert 1-D to 2-D

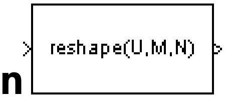
Reshape 1-D or 2-D input to 2-D matrix with specified dimensions

Library

Signal Management / Signal Attributes

`dspsigattribs`

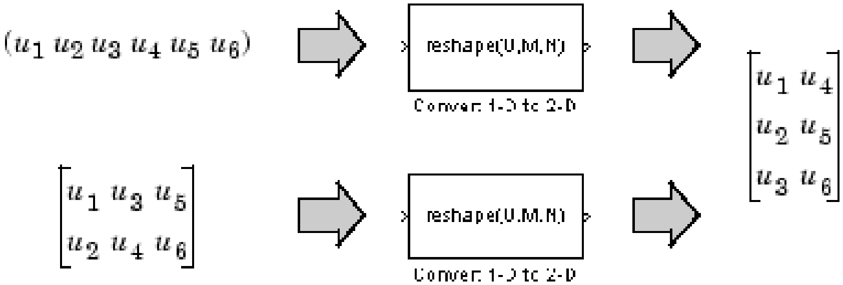
Description



The Convert 1-D to 2-D block reshapes a length-M_i 1-D vector or an M_i-by-N_i matrix to an M_o-by-N_o matrix, where M_o is specified by the **Number of output rows** parameter, and N_o is specified by the **Number of output columns** parameter.

```
y = reshape(u,Mo,No)       % Equivalent MATLAB code
```

The input is reshaped *columnwise*, as shown in the two cases below. The length-6 vector and the 2-by-3 matrix are both reshaped to the same 3-by-2 output matrix.

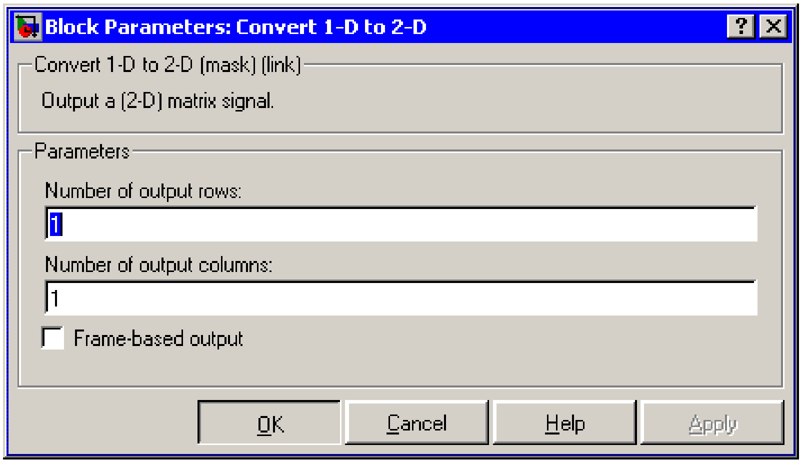


$(u_1\ u_2\ u_3\ u_4\ u_5\ u_6)$
reshape(U,M,N)
Convert 1-D to 2-D
$\begin{bmatrix} u_1 & u_3 & u_5 \\ u_2 & u_4 & u_6 \end{bmatrix}$
reshape(U,M,N)
Convert 1-D to 2-D
$\begin{bmatrix} u_1 & u_4 \\ u_2 & u_5 \\ u_3 & u_6 \end{bmatrix}$

An error is generated when $(M_o{*}N_o) \neq (M_i{*}N_i)$. That is, the total number of input elements must be conserved in the output.

The output is frame based when you select the **Frame-based output** check box; otherwise, the output is sample based.

Dialog Box



Block Parameters: Convert 1-D to 2-D

Convert 1-D to 2-D (mask) (link)

Output a (2-D) matrix signal.

Parameters

Number of output rows: 1

Number of output columns: 1

□ Frame-based output

Number of output rows

The number of rows, M_o, in the output matrix.

Number of output columns

The number of rows, N_o, in the output matrix.

Frame-based output

Creates a frame-based output when selected.

HDL Code Generation

This block supports HDL code generation using HDL Coder. HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic. For more information on implementations, properties, and restrictions for HDL code generation, see Convert 1-D to 2-D in the HDL Coder documentation.

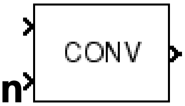
Convolution

Convolution of two inputs

Library

Signal Operations

`dspsigops`



Description

The Convolution block convolves the first dimension of an N-D input array *u*, with the first dimension of an N-D input array *v*. The block can also independently convolve a column vector with the first-dimension of an N-D input array.

Convolution with DSP System Toolbox Blocks

The general equation for convolution is

$$y(k) = \sum_{n} u(n-k)h(k)$$

There are two DSP System Toolbox blocks that can be used for this purpose:

- Convolution
- Discrete FIR Filter

The Convolution block assumes that all of *u* and *h* are available at each Simulink time step, and computes the entire convolution at every one.

The Discrete FIR Filter block can be used for convolving signals in situations where all of *h* is available at each time step, but *u* is a sequence that comes in over the life of the simulation. When you use the Discrete FIR Filter block, the convolution is computed only once.

Use the following questions to help you determine which block best fits your needs:

Question	Answer	Recommended Block(s)
How many convolutions do you intend to perform?	Many convolutions, one at each time step	• Convolution block
	One convolution over the life of the simulation	• Convolution block • Discrete FIR Filter block
How long are your input sequences?	Both sequences have a finite length	• Convolution block • Discrete FIR Filter block
	One sequence has an infinite (not predetermined) length	• Discrete FIR Filter block
How many of the inputs are scalar streams?	None	• Convolution block • Discrete FIR Filter block
	One or both	• Buffer block followed by the Convolution block • Discrete FIR Filter block

Convolving Two N-D Arrays

The block always computes the convolution of two N-D input arrays along the first dimension. When both inputs are N-D arrays, the size of their first dimension can differ, but the size of all other dimensions must be equal. For example, when u is an M_u-by-N-by-P array, and v is an M_v-by-N-by-P array, the output is an (M_u+M_v-1)-by-N-by-P array.

When the input to the Convolution block is a M_u-by-N matrix u and an M_v-by-N matrix v, the output, y, is a (M_u+M_v-1)-by-N matrix whose jth column has the following elements

$$y_{i,j} = \sum_{k=0}^{\max(M_u,M_v)-1} u_{k,j} v_{(i-k),j} \quad 0 \le i \le (M_u + M_v - 2)$$

Inputs u and v are zero when indexed outside of their valid ranges. When both inputs are real, the output is real; when one or both inputs are complex, the output is complex.

Convolving a Column Vector with an N-D Array

When one input is a column vector and the other is an N-D array, the block independently convolves the vector with the first dimension of the N-D input array. For example, when *u* is a M_u-by-1 column vector and *v* is an M_v-by-*N* matrix, the output is an (M_u+M_v–1)-by-*N* matrix whose *j*th column has the following elements

$$y_{i,j} = \sum_{k=0}^{\max(M_u,M_v)-1} u_k v_{(i-k),j} \quad 0 \le i \le (M_u + M_v - 2)$$

Convolving Two Column Vectors

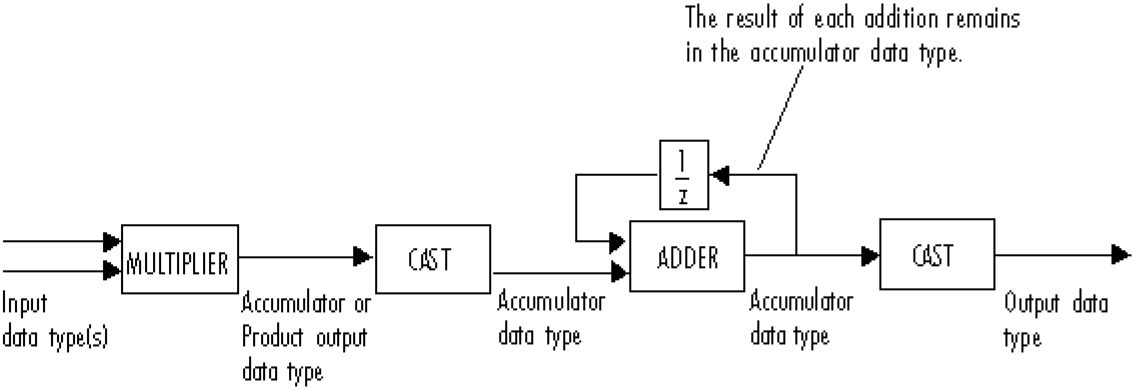
The Convolution block also accepts two column vector inputs. When *u* and *v* are column vectors with lengths M_u and M_v, the Convolution block performs the vector convolution

$$y_i = \sum_{k=0}^{\max(M_u,M_v)-1} u_k v_{(i-k)} \quad 0 \le i \le (M_u + M_v - 2)$$

The output is a (M_u+M_v–1)-by-1 column vector.

Fixed-Point Data Types

The following diagram shows the data types used within the Convolution block for fixed-point signals (time domain only).



The result of each addition remains
in the accumulator data type.
1/z
MULTIPLIER
CAST

CAST
Input data type(s)
Accumulator or Product output data type
Accumulator data type
Accumulator data type
Output data type

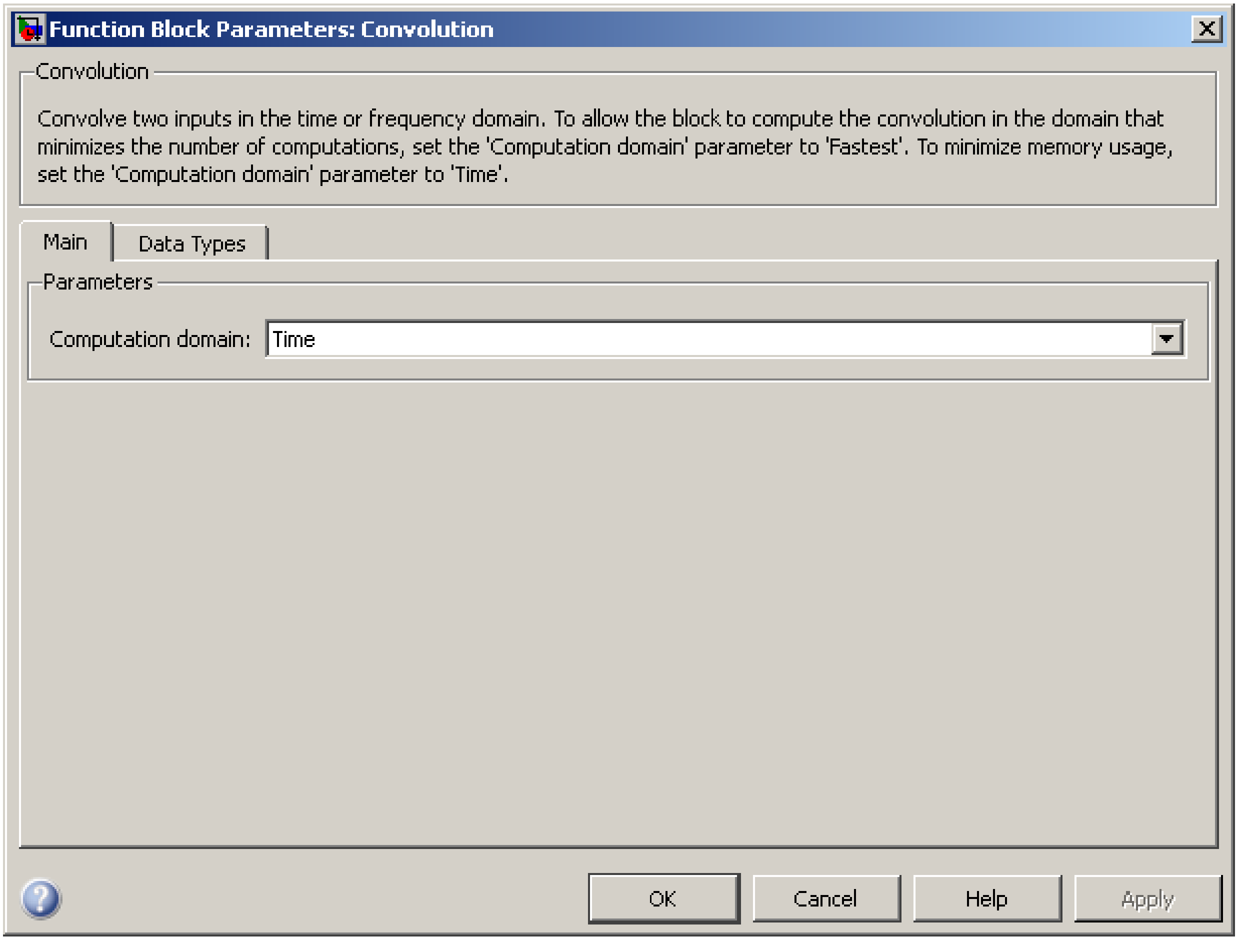
You can set the product output, accumulator, and output data types in the block dialog as discussed in the next section.

The output of the multiplier is in the product output data type when the input is real. When the input is complex, the result of the multiplication is in the accumulator data type. For details on the complex multiplication performed, see “Multiplication Data Types”.

Note: When one or both of the inputs are signed fixed-point signals, all internal block data types are signed fixed point. The internal block data types are unsigned fixed point only when *both* inputs are unsigned fixed-point signals.

Dialog Box

The **Main** pane of the Convolution block dialog appears as follows.



Convolution

Convolve two inputs in the time or frequency domain. To allow the block to compute the convolution in the domain that minimizes the number of computations, set the 'Computation domain' parameter to 'Fastest'. To minimize memory usage, set the 'Computation domain' parameter to 'Time'.

Parameters

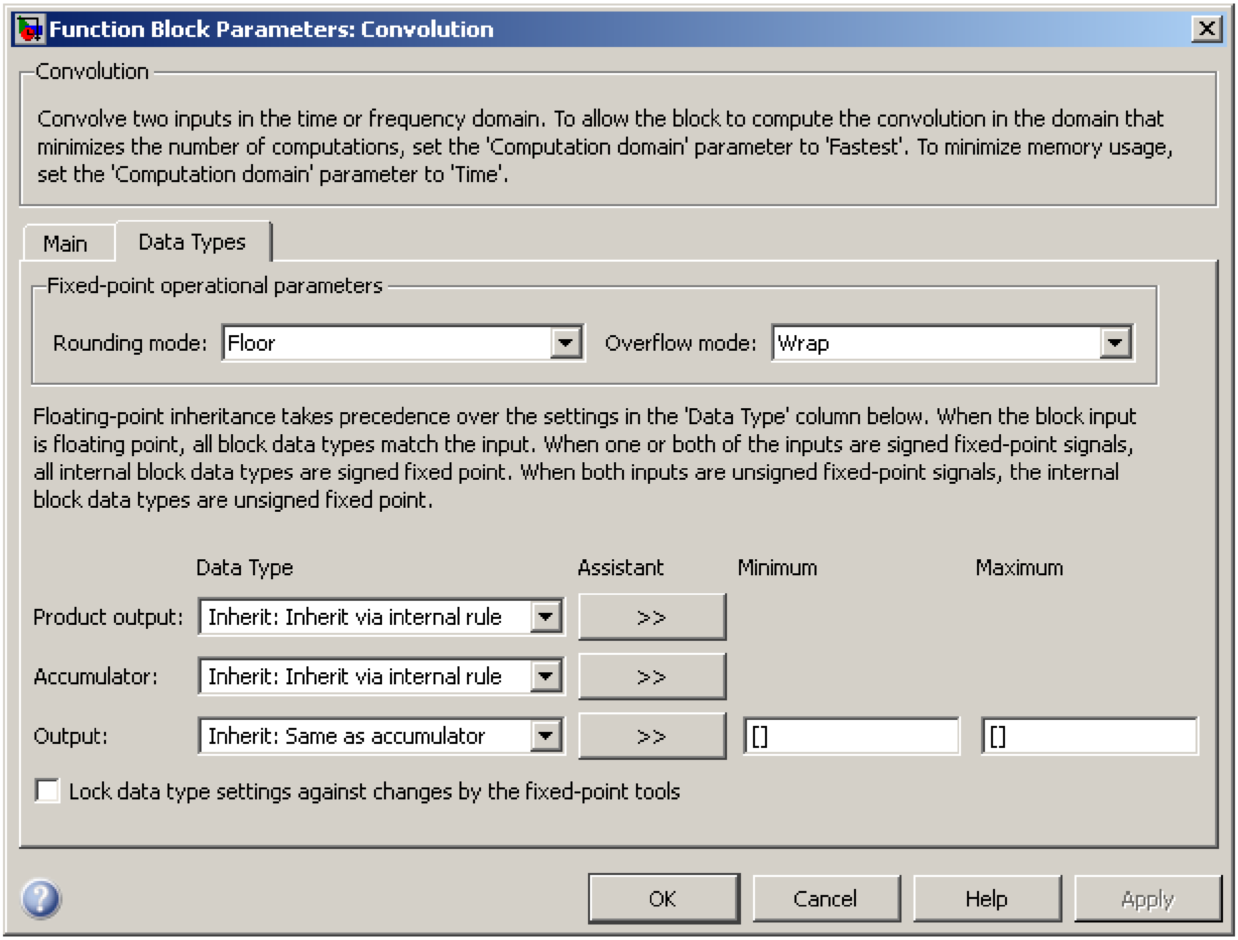
Computation domain: Time

Computation domain

Set the domain in which the block computes convolutions:

- `Time` — The block computes in the time domain, which minimizes memory use.
- `Frequency` — The block computes in the frequency domain, which might require fewer computations than computing in the time domain, depending on the input length.
- `Fastest` — The block computes in the domain, which minimizes the number of computations.

The **Data Types** pane of the Convolution block dialog appears as follows.



Function Block Parameters: Convolution

Convolution

Convolve two inputs in the time or frequency domain. To allow the block to compute the convolution in the domain that minimizes the number of computations, set the 'Computation domain' parameter to 'Fastest'. To minimize memory usage, set the 'Computation domain' parameter to 'Time'.

Fixed-point operational parameters

Rounding mode: Floor   Overflow mode: Wrap

Floating-point inheritance takes precedence over the settings in the 'Data Type' column below. When the block input is floating point, all block data types match the input. When one or both of the inputs are signed fixed-point signals, all internal block data types are signed fixed point. When both inputs are unsigned fixed-point signals, the internal block data types are unsigned fixed point.

	Data Type	Assistant	Minimum	Maximum
Product output:	Inherit: Inherit via internal rule	>>		
Accumulator:	Inherit: Inherit via internal rule	>>		
Output:	Inherit: Same as accumulator	>>	[]	[]

□ Lock data type settings against changes by the fixed-point tools

Note: Fixed-point signals are only supported for the time domain. To use the parameters on this pane, make sure `Time` is selected for the **Computation domain** parameter on the **Main** pane.

Rounding mode

Select the “rounding mode” for fixed-point operations.

Note: The **Rounding mode** and **Overflow mode** settings have no effect on numerical results when all the following conditions exist:

- **Product output data type** is `Inherit: Inherit via internal rule`
- **Accumulator data type** is `Inherit: Inherit via internal rule`
- **Output data type** is `Inherit: Same as accumulator`

With these data type settings, the block is effectively operating in full precision mode.

Overflow mode

Select the "overflow mode" for fixed-point operations.

Product output data type

Specify the product output data type. See "Fixed-Point Data Types" on page 1-266 and "Multiplication Data Types" for illustrations depicting the use of the product output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`
- An expression that evaluates to a valid data type, for example, `fixdt([],16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Product output data type** parameter.

See "Specify Data Types Using Data Type Assistant" in "Simulink User's Guide" for more information.

Accumulator data type

Specify the accumulator data type. See "Fixed-Point Data Types" on page 1-266 for illustrations depicting the use of the accumulator data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`
- An expression that evaluates to a valid data type, for example, `fixdt([],16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Accumulator data type** parameter.

See “Specify Data Types Using Data Type Assistant” in “Simulink User's Guide” for more information.

Output data type

Specify the output data type. See “Fixed-Point Data Types” on page 1-266 for illustrations depicting the use of the output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as accumulator`
- An expression that evaluates to a valid data type, for example, `fixdt([],16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Specify Block Output Data Types” in “Simulink User's Guide” for more information.

Minimum

Specify the minimum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges”)
- Automatic scaling of fixed-point data types

Maximum

Specify the maximum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges”)
- Automatic scaling of fixed-point data types

Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point

Port	Supported Data Types
	• Single-precision floating point • Fixed point (signed and unsigned) • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Output	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers

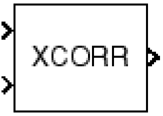
Correlation

Cross-correlation of two inputs

Library

Statistics

`dspstat3`



Description

The Correlation block computes the cross-correlation of two N-D input arrays. The block computes the correlation column-wise, so both inputs must have the same number of columns. If one input is a column vector and the other is an N-D array, the Correlation block computes the cross-correlation of the vector with each column of the N-D array.

Correlating Two N-D Arrays

When the input to the Correlation block is an M_u-by-N input matrix u and an M_v-by-N matrix v, the output, y, is a (M_u+M_v–1)-by-N matrix whose jth column has elements

$$y_{uv(i,j)} = \sum_{k=0}^{\max(M_u,M_v)-1} u_{k,j} v^{*}_{(k-i),j} \qquad 0 \le i < M_v$$

$$y_{uv(i,j)} = y^{*}_{vu(-i,j)} \qquad -M_u < i < 0$$

where * denotes the complex conjugate. Inputs u and v are zero when indexed outside of their valid ranges. When both inputs are real, the output is real; when one or both inputs are complex, the output is complex.

Correlating a Column Vector with an N-D Array

When one input is a column vector and the other is an N-D array, the Correlation block independently cross-correlates the input vector with each column of the N-D array. For example, when u is a M_u-by-1 column vector and v is an M_v-by-N matrix, the output is an (M_u+M_v-1)-by-N matrix whose jth column has elements

$$y_{uv(i,j)} = \sum_{k=0}^{\max(M_u,M_v)-1} u_k \overset{*}{v}_{(k-i),j} \qquad 0 \le i < M_v$$

$$y_{uv(i,j)} = \overset{*}{y}_{vu(-i,j)} \qquad -M_u < i < 0$$

Correlating Two Column Vectors

The Correlation block also accepts two column vector inputs. When u and v are column vectors with lengths M_u and M_v, the Correlation block performs the vector cross-correlation according to the following equation:

$$y_{uv(i)} = \sum_{k=0}^{\max(M_u,M_v)-1} u_k \overset{*}{v}_{(k-i)} \qquad 0 \le i < M_v$$

$$y_{uv(i)} = \overset{*}{y}_{vu(-i)} \qquad -M_u < i < 0$$

The output is a $(M_u+M_\mathrm{v}-1)$-by-1 column vector.

Fixed-Point Data Types

Rounding mode

Select the “rounding mode” for fixed-point operations.

Note: The **Rounding mode** and **Overflow mode** settings have no effect on numerical results when all the following conditions exist:

- **Product output data type** is `Inherit: Inherit via internal rule`
- **Accumulator data type** is `Inherit: Inherit via internal rule`
- **Output data type** is `Inherit: Same as accumulator`

With these data type settings, the block is effectively operating in full precision mode.

Overflow mode

Select the “overflow mode” for fixed-point operations.

Product output data type

Specify the product output data type. See “Fixed-Point Data Types” on page 1-274 and “Multiplication Data Types” for illustrations depicting the use of the product output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`
- An expression that evaluates to a valid data type, for example, `fixdt([],16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Product output data type** parameter.

See “Specify Data Types Using Data Type Assistant” in “Simulink User's Guide” for more information.

Accumulator data type

Specify the accumulator data type. See “Fixed-Point Data Types” on page 1-274 for illustrations depicting the use of the accumulator data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`

- An expression that evaluates to a valid data type, for example, `fixdt([],16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Accumulator data type** parameter.

See “Specify Data Types Using Data Type Assistant” in “Simulink User's Guide” for more information.

Output data type

Specify the output data type. See “Fixed-Point Data Types” on page 1-274 for illustrations depicting the use of the output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as accumulator`
- An expression that evaluates to a valid data type, for example, `fixdt([],16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Specify Block Output Data Types” in “Simulink User's Guide” for more information.

Minimum

Specify the minimum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges”)
- Automatic scaling of fixed-point data types

Maximum

Specify the maximum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges”)
- Automatic scaling of fixed-point data types

Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Output	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers

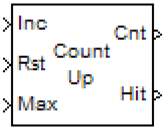
Counter

Count up or down through specified range of numbers

Library

Signal Management / Switches and Counters

`dspswit3`



Description

The Counter block counts up or down through a specified range of numbers. The block enables the Inc (increment) port when you set the **Count direction** parameter to `Up`. When you set the **Count direction** parameter to `Down`, the block enables the Dec (decrement) port. If you set the **Count event** parameter to `Free running`, the block disables the Inc or Dec port, and counts at a constant time interval. For all other settings of the **Count event** parameter, the block increments or decrements the counter each time a trigger event occurs at the Inc or Dec input port. When a trigger event occurs at the optional Rst port, the block resets the counter to its initial state.

The Counter block accepts single-channel inputs. The Inc and Dec ports accept real-valued scalars or vectors. If the input to the Inc or Dec port is a vector, the block treats the vector as a frame. The Rst port only accepts real-valued scalars. The Rst port must have the same port sample time as the Inc or Dec input port. If you enable the optional Max input port, you must provide an unsigned integer input that the **Count data type** can represent.

See the following topics for more information:

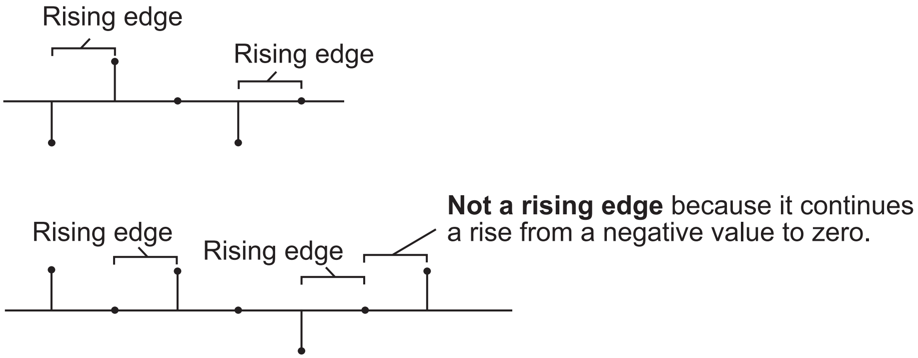
- "Setting the Count Event Parameter" on page 1-282
- "Setting the Counter Size and Initial Count Parameters" on page 1-283
- "Scalar Input Operation" on page 1-284

- "Vector Input Operation" on page 1-285
- "Free-Running Operation" on page 1-285

Setting the Count Event Parameter

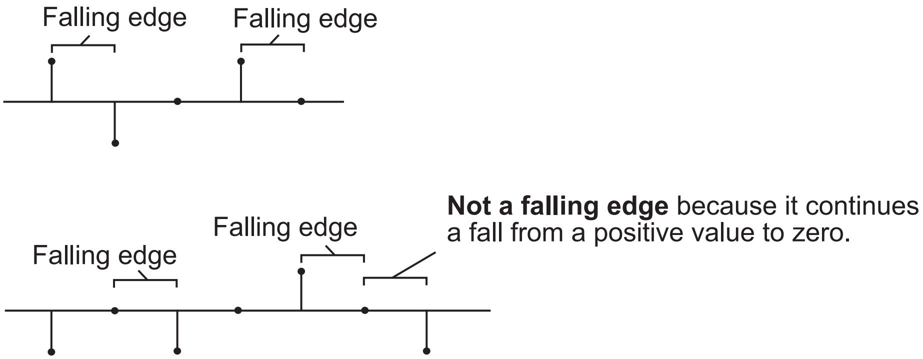
Specify the trigger event for the Inc/Dec and Rst ports by setting the **Count event** parameter to one of the following values:

- `Rising edge` — Triggers a count or reset operation when the input to the Inc/Dec or Rst port behaves in one of the following ways:
  - Rises from a negative value to a positive value or zero.
  - Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero (see the following figure).



Rising edge
Rising edge
Rising edge
Rising edge
Not a rising edge because it continues a rise from a negative value to zero.

- `Falling edge` — Triggers a count or reset operation when the input to the Inc/Dec or Rst port behaves in one of the following ways:
  - Falls from a positive value to a negative value or zero.
  - Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero (see the following figure).



Falling edge
Falling edge
Falling edge
Falling edge
Not a falling edge because it continues
a fall from a positive value to zero.

- `Either edge` — Triggers a count or reset operation when the input to the Inc/Dec or Rst port is a `Rising edge` or `Falling edge`.
- `Non-zero sample` — Triggers a count or reset operation at each sample time when the input to the Inc/Dec or Rst port is not zero.
- `Free running` — Disables the Inc/Dec port and enables the **Samples per output frame** and **Sample time** block parameters. The block increments or decrements the counter at a constant interval, T_s, which you specify using the **Sample time** parameter. For more information, see “Free-Running Operation” on page 1-285. In this mode, the block resets the counter whenever it receives a non-zero sample at the Rst port.

Setting the Counter Size and Initial Count Parameters

At the start of the simulation, the block sets the counter to the value you specify in the **Initial count** parameter. The **Initial count** can be any unsigned integer in the range defined by the **Counter size** parameter.

The **Counter size** parameter allows you to specify the range of integer values the block counts through. When the block counts through the entire counter range, the next time a trigger event occurs at the Inc/Dec port, the block resets the counter as follows:

- When you set the **Count direction** parameter to `Up` and the counter reaches the upper-limit of the counter range, the block restarts the counter at zero.
- When you set the **Count direction** parameter to `Down` and the counter reaches zero, the block restarts the counter at the upper-limit of the counter range.

You can set the **Counter size** parameter to one of the following options:

- 8 bits — Specifies a counter with a range of 0 to 255.
- 16 bits — Specifies a counter with a range of 0 to 65535.
- 32 bits — Specifies a counter with a range of 0 to **2^{32}–1**.
- User defined — Enables the **Maximum count** parameter, which allows you to specify the upper-count limit as any arbitrary unsigned integer that the **Count data type** can represent. The counter values range from 0 to the value of the **Maximum count** parameter.
- Specify via input port — Enables the Max input port, which allows you to specify the upper-count limit as any arbitrary unsigned integer that the **Count data type** can represent. The counter values range from 0 to the value you specify as an input to the Max port.

Scalar Input Operation

When you set the **Count direction** parameter to Up, a trigger event at the Inc (increment) input port causes the block to increase the counter by one. Assuming no reset events occur, the block continues increasing the counter value when triggered, until the counter value reaches the upper-count limit. The next time a trigger event occurs at the Inc port, the block restarts the counter at 0 and resumes increasing the counter by one for each subsequent trigger event at the Inc port.

When you set the **Count direction** parameter to Down, a trigger event at the Dec (decrement) input port causes the block to decrease the counter by one. Assuming no reset events occur, the block continues decreasing the counter value when triggered until the counter value reaches zero. The next time a trigger event occurs at the Dec port, the block restarts the counter at the upper-count limit and resumes decreasing the counter by one for each subsequent trigger event at the Dec port.

Between triggering events, the block holds the output at its most recent value. The block resets the counter to its initial state when the trigger event specified by the **Count event** parameter occurs at the optional Rst input port. When the Inc/Dec and Rst ports receive trigger events simultaneously, the block first resets the counter, and then increments or decrements the counter appropriately. If you do not need to reset the counter during simulation, you can disable the Rst port by clearing the **Reset input** check box.

The **Output** parameter allows you to specify which values the block outputs.

- `Count` enables a Cnt output port on the block, which provides the current value of the counter as a scalar value. The Cnt output port has the same port sample time as the Inc/Dec input port.
- `Hit` enables a Hit output port on the block. The Hit port produces zeros while the value of the counter does not equal any of the integers you specify for the **Hit values** parameter. You can specify an integer or a vector of integers for the **Hit values** parameter. When the counter value does equal one or more of the values you specify for the **Hit values** parameter, the block outputs a value of `1` at the Hit output port. The Hit output port has the same port sample time as the Inc/Dec input port.
- `Count and Hit` enables both the Cnt and Hit output ports.

Vector Input Operation

The block treats vector inputs to the Inc/Dec port as a frame. Vector operation is the same as scalar operation, except that the block increments or decrements the counter by the total number of trigger events contained in the Inc/Dec input vector. Thus, the counter may change multiple times during the processing of a single Inc/Dec input vector.

When the block has a Hit port, the block outputs a value of `1` if any of the **Hit values** match any of the counter values during the processing of the Inc/Dec input vector.

When a trigger event splits across two consecutive vectors, that event is counted in the vector that contains the conclusion of the event. When the Rst port receives a trigger event at the same time as the Inc/Dec port, the block first resets the counter. The block then increments or decrements the counter by the number of trigger events contained in the Inc/Dec input vector.

When the input to the Inc/Dec port is a length *N* vector, the port sample time of the Inc/Dec input port is equal to the frame period of the input, or *N* times the sample time of the input signal. The port sample time of the Cnt and Hit output ports equals that of the Inc/Dec input port.

Free-Running Operation

The block operates in free-running mode when you select `Free running` for the **Count event** parameter.

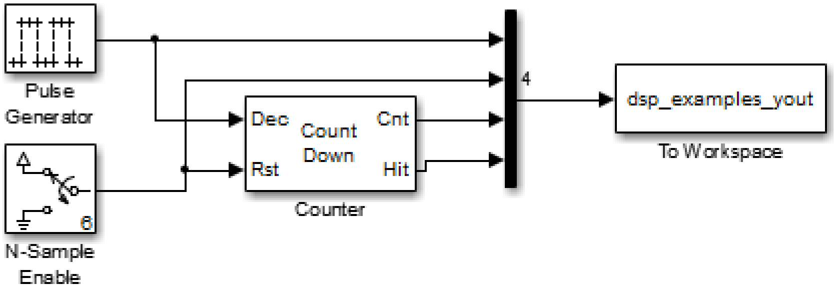
The Inc/Dec input port is disabled in this mode, and the block simply increments or decrements the counter at the constant interval, T_s, which you specify using the **Sample time** parameter.

In this mode, the Rst port always behaves as if the **Count event** parameter were set to `Non-zero sample`. Thus, the block triggers a reset event at each sample time that the Rst input is not zero.

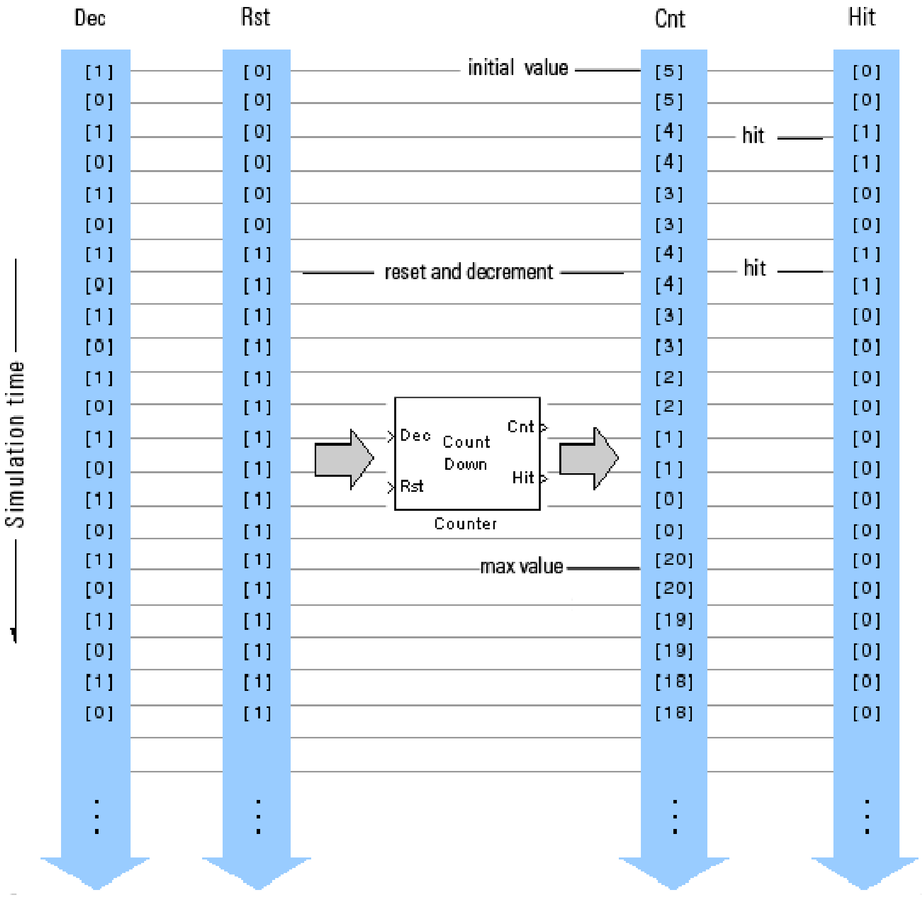
In this mode, the Cnt output is an M-by-`1` vector containing the count value at each of M consecutive sample times, where M is the value you specify for the **Samples per output frame** parameter. The Hit output is an M-by-`1` vector containing the hit status (`0` or `1`) at each of those M consecutive sample times. Both the Cnt and Hit output ports have a port sample time of $M*T_s$.

Examples

In the following model, ex_counter_ref, the Simulink Pulse Generator block drives the Dec port of the Counter block, and the N-Sample Enable block triggers the Rst port. All inputs to and outputs from the Counter block are multiplexed into a single To Workspace block using a 4-port Mux block.



The following figure shows the first 22 samples of the model's four-column output, `yout`.



Dec	Rst	Cnt	Hit
[1]	[0]	[5]	[0]
[0]	[0]	[5]	[0]

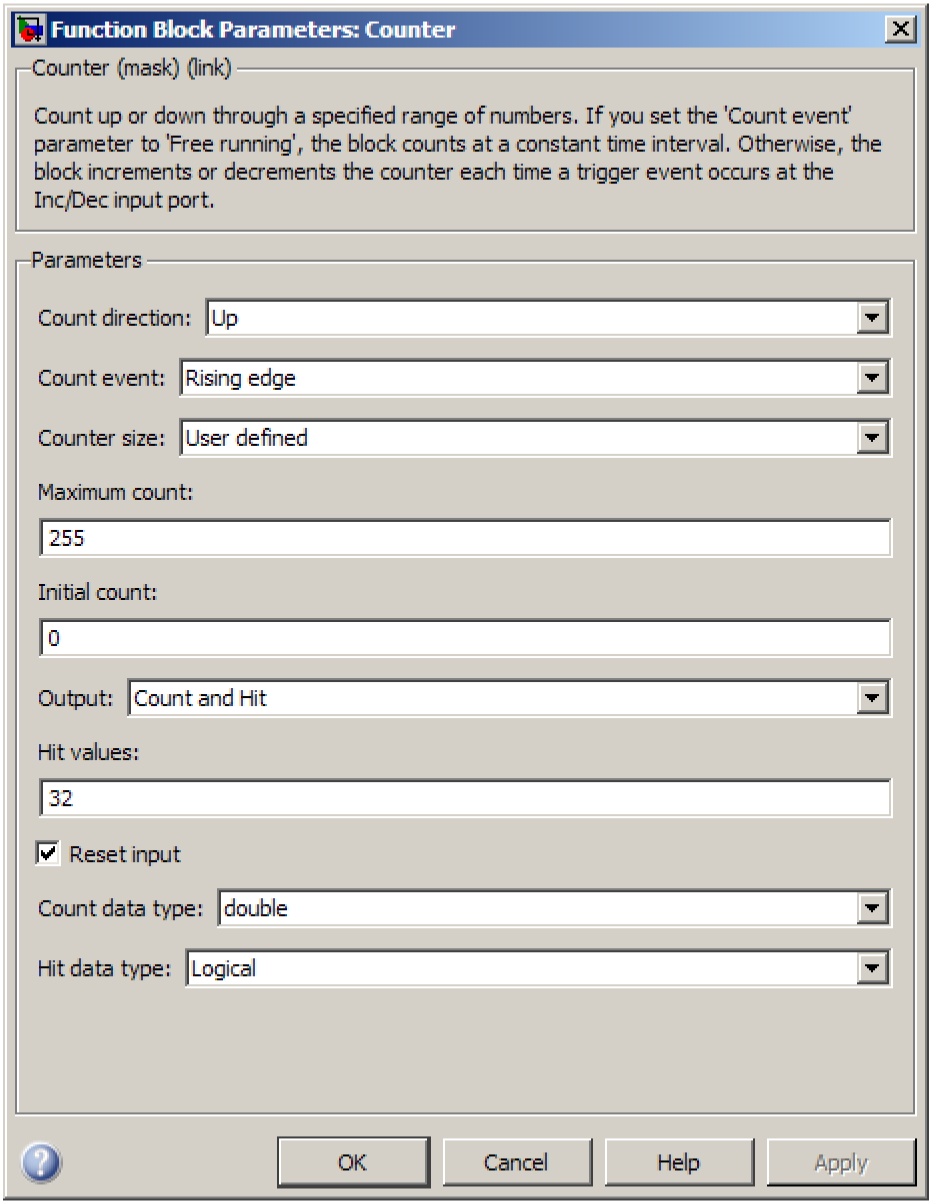
⋮	⋮	⋮	⋮

You can see that the seventh input sample to both the Dec and Rst ports of the Counter block represent trigger events (rising edges). When this occurs, the block first resets the counter to its initial value of 5, and then immediately decrements the counter to 4. When the counter reaches its minimum value of 0, the block restarts the counter at its maximum value of 20 the next time a trigger event occurs at the Dec port.

Dialog Box



Function Block Parameters: Counter

Counter (mask) (link)

Count up or down through a specified range of numbers. If you set the 'Count event' parameter to 'Free running', the block counts at a constant time interval. Otherwise, the block increments or decrements the counter each time a trigger event occurs at the Inc/Dec input port.

Parameters

Count direction: Up

Count event: Rising edge

Counter size: User defined

Maximum count:

255

Initial count:

0

Output: Count and Hit

Hit values:

32

☑ Reset input

Count data type: double

Hit data type: Logical

Count direction

Specify whether to count `Up` or `Down`. The port label on the block icon changes to Inc (increment) or Dec (decrement) based on the value of this parameter.

- When you set the **Count direction** parameter to `Up` and the counter reaches the upper-limit of the counter range, the block restarts the counter at zero the next time a trigger event occurs at the Inc port.
- When you set the **Count direction** parameter to `Down` and the counter reaches zero, the block restarts the counter at the upper-limit of the counter range the next time a trigger event occurs at the Dec port.

This parameter is “tunable” in Simulink Normal mode.

Count event

Specify the type of event that triggers the block to increment, decrement, or reset the counter when received at the Inc/Dec or Rst ports. When you set this parameter to `Free running`, the block disables the Inc/Dec port and counts at the constant interval specified by the **Sample time** parameter. For more information on all the possible settings of this parameter, see “Setting the Count Event Parameter” on page 1-282.

Counter size

Specify the range of integer values the block counts through. For more information about the valid values of this parameter, see “Setting the Counter Size and Initial Count Parameters” on page 1-283.

Maximum count

Specify the maximum value of the counter as any unsigned integer representable by the data type you specify for the **Counter data type** parameter. This parameter appears only when you set the **Counter size** parameter to `User defined`. “Tunable” in Simulink Normal mode.

Initial count

Specify the initial value of the counter. The block uses the initial value of the counter at the start of simulation and resets the counter back to that initial value each time a trigger event occurs at the Rst port. “Tunable”.

Output

Select the output ports to enable. You can choose to enable the `Count`, `Hit`, or `Count and Hit` ports.

Hit values

Specify an integer or vector of integers whose occurrence in the count should be flagged by a `1` at the (optional) Hit output port. This parameter appears only when you set the **Output** parameter to `Hit` or `Count and Hit`. “Tunable”.

Reset input

Select this check box to enable the Rst input port. When you enable the Rst port, the block resets the counter to its initial value each time a trigger event occurs at the Rst port. To specify the type of event that triggers a reset of the counter, set the **Count event** parameter. When you clear the **Reset input** check box, you cannot reset the counter during simulation.

Samples per output frame

Specify the number of samples, *M*, in each output vector. This parameter appears only when you set the **Count event** parameter to `Free running`.

Sample time

Specify the constant interval, T_s, at which the block increments or decrements the counter when in free-running mode. For example, to have the block increment the counter every `5` seconds, set the **Count direction** parameter to `Up`, the **Count event** parameter to `Free running`, and specify a value of `5` for the **Sample time** parameter. In free running mode, the sample time of the output ports is always $M*T_s$.

This parameter appears only when you set the **Count event** parameter to `Free running`.

Count data type

Specify the data type of the output at the Cnt port. This parameter appears only when you set the **Output** parameter to `Count` or `Count and Hit`.

Hit data type

Specify the data type of the output at the Hit port. This parameter appears only when you set the **Output** parameter to `Hit` or set it to `Count and Hit` with the **Count data type** parameter set to `Double`.

Supported Data Types

Port	Supported Data Types

Covariance AR Estimator

Compute estimate of autoregressive (AR) model parameters using covariance method

Library

Estimation / Parametric Estimation

`dspparest3`

Cov AR
Estimator
A
G

Description

The Covariance AR Estimator block uses the covariance method to fit an autoregressive (AR) model to the input data. This method minimizes the forward prediction error in the least squares sense.

The input is a sample-based vector (row, column, or 1-D) or frame-based vector (column only) representing a frame of consecutive time samples from a single-channel signal, which is assumed to be the output of an AR system driven by white noise. The block computes the normalized estimate of the AR system parameters, $A(z)$, independently for each successive input frame.

$$H(z) = \frac{G}{A(z)} = \frac{G}{1 + a(2)z^{-1} + \ldots + a(p+1)z^{-p}}$$

The order, p, of the all-pole model is specified by the **Estimation order** parameter. To guarantee a valid output, you must set the **Estimation order** parameter to be less than or equal to half the input vector length.

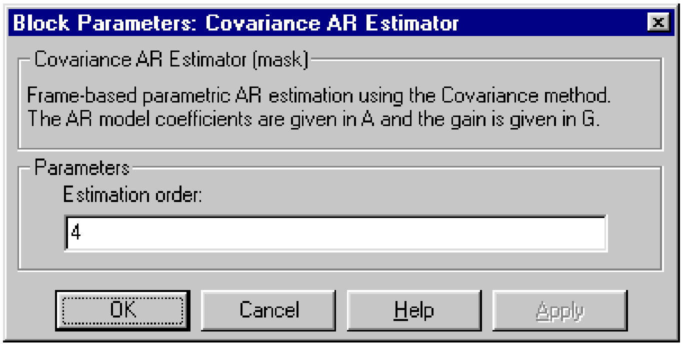
The top output, A, is a column vector of length p+1 with the same frame status as the input, and contains the normalized estimate of the AR model coefficients in descending powers of z.

```
[1 a(2) ... a(p+1)]
```

The scalar gain, G, is provided at the bottom output (G).

See the Burg AR Estimator block reference page for a comparison of the Burg AR Estimator, Covariance AR Estimator, Modified Covariance AR Estimator, and Yule-Walker AR Estimator blocks.

Dialog Box



Block Parameters: Covariance AR Estimator

Covariance AR Estimator (mask)

Frame-based parametric AR estimation using the Covariance method.
The AR model coefficients are given in A and the gain is given in G.

Parameters

Estimation order: 4

Estimation order

The order of the AR model, *p*. To guarantee a nonsingular output, you must set *p* to be less than or equal to half the input length. Otherwise, the output might be singular.

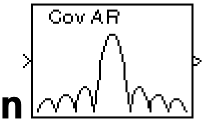
Covariance Method

Power spectral density estimate using covariance method

Library

Estimation / Power Spectrum Estimation

`dspspect3`



Description

The Covariance Method block estimates the power spectral density (PSD) of the input using the covariance method. This method fits an autoregressive (AR) model to the signal by minimizing the forward prediction error in the least squares sense. The **Estimation order** parameter specifies the order of the all-pole model. The block computes the spectrum from the FFT of the estimated AR model parameters. To guarantee a valid output, the **Estimation order** parameter must be less than or equal to half the input vector length.

The input is a sample-based vector (row, column, or 1-D) or frame-based vector (column only). It represents a frame of consecutive time samples from a single-channel signal. The block outputs a column vector containing the estimate of the power spectral density of the signal at N_{fft} equally spaced frequency points. The frequency points are in the range $[0,F_s)$, where F_s is the sampling frequency of the signal.

Selecting **Inherit FFT length from estimation order**, specifies that N_{fft} is one greater than the estimation order. Clearing the **Inherit FFT length from estimation order** check box allows you to use the **FFT length** parameter to specify N_{fft} as a power of 2. The block zero-pads or wraps the input to N_{fft} before computing the FFT. The output is always sample based.

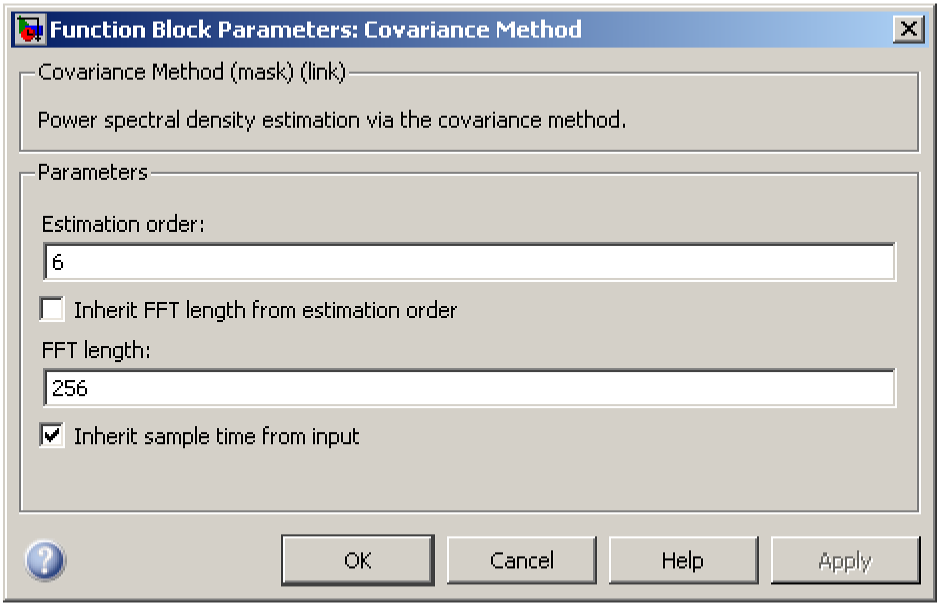
When you select the **Inherit sample time from input** check box, the block computes the frequency data from the sample period of the input signal. For the block to produce valid output, the following conditions must hold:

- The input to the block is the original signal, with no samples added or deleted (by insertion of zeros, for example).
- The sample period of the time-domain signal in the simulation equals the sample period of the original time series.

If these conditions do not hold, clear the **Inherit sample time from input** check box. You can then specify a sample time using the **Sample time of original time series** parameter.

See the Burg Method block reference for a comparison of the Burg Method, Covariance Method, Modified Covariance Method, and Yule-Walker Method blocks.

Dialog Box



Function Block Parameters: Covariance Method

Covariance Method (mask) (link)

Power spectral density estimation via the covariance method.

Parameters

Estimation order: 6

□ Inherit FFT length from estimation order

FFT length: 256

☑ Inherit sample time from input

Estimation order

The order of the AR model. To guarantee a nonsingular output, the value of this parameter must be less than or equal to half the input length.

Inherit FFT length from estimation order

When selected, this option specifies that the FFT length is one greater than the estimation order.

FFT length

Enter the number of data points on which to perform the FFT, N_{fft}. When N_{fft} is larger than the input frame size, the block zero-pads each frame as needed. When N_{fft} is smaller than the input frame size, the block wraps each frame as needed. This parameter becomes visible only when you clear the **Inherit FFT length from estimation order** check box.

Inherit sample time from input

When you select the **Inherit sample time from input** check box, the block computes the frequency data from the sample period of the input signal. For the block to produce valid output, the following conditions must hold:

- The input to the block is the original signal, with no samples added or deleted (by insertion of zeros, for example).
- The sample period of the time-domain signal in the simulation equals the sample period of the original time series.

If these conditions do not hold, clear the **Inherit sample time from input** check box. You can then specify a sample time using the **Sample time of original time series** parameter.

Sample time of original time series

Specify the sample time of the original time-domain signal. This parameter becomes visible only when you clear the **Inherit sample time from input** check box.

Cumulative Product

Cumulative product of channel, column, or row elements

Library

Math Functions / Math Operations

`dspmathops`

Running
Product

In
Rst
Running
Product

Description

The Cumulative Product block computes the cumulative product along the specified dimension of the input or across time (running product).

The input can be a vector or matrix. The output always has the same dimensions, rate, data type, and complexity as the input.

Input and Output Characteristics

Valid Input

The Cumulative Product block accepts vector or matrix inputs containing real or complex values.

Valid Reset Signal

The optional reset port, `Rst`, accepts scalar values, which can be any built-in Simulink data type including `boolean`. The rate of the input to the Rst port must be the same or slower than that of the input data signal. The sample time of the input to the Rst port must be a positive integer multiple of the input sample time.

Output Characteristics

The output always has the same dimensions, rate, data type, and complexity as the data signal input.

Computing the Running Product Along Channels of the Input

When you set the **Multiply input along** parameter to `Channels (running product)`, the block computes the cumulative product of the elements in each input channel. The running product of the current input takes into account the running product of all previous inputs. In this mode, you must also specify a value for the **Input processing** parameter. When you set the **Input processing** parameter to `Columns as channels (frame based)`, the block computes the running product along each column of the current input. When you set the **Input processing** parameter to `Elements as channels (sample based)`, the block computes a running product for each element of the input across time. See the following sections for more information:

-
-
-

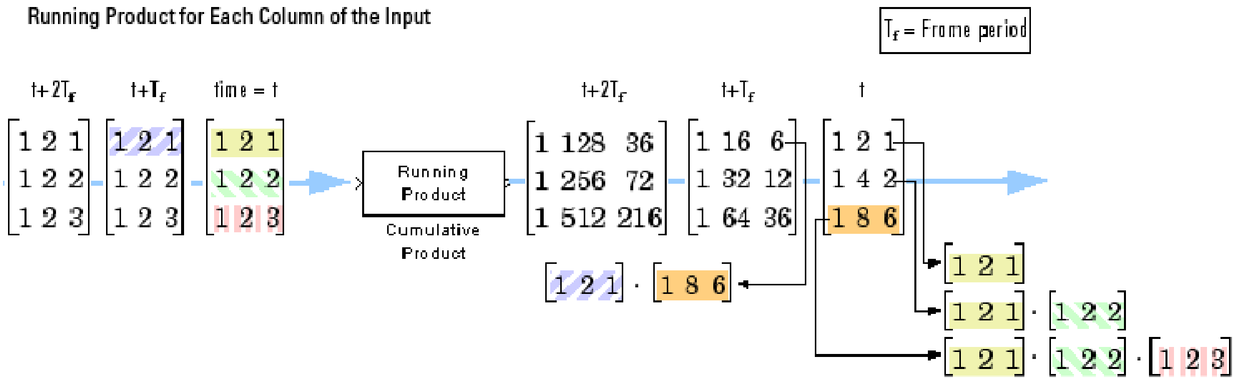
Computing the Running Product for Each Column of the Input

When you set the **Input processing** parameter to `Columns as channels (frame based)`, the block treats each input column as an independent channel. As the following figure and equation illustrate, the output has the following characteristics:

- The first row of the first output is the same as the first row of the first input.
- The first row of each subsequent output is the element-wise product of the first row of the current input (time *t*), and the last row of the previous output (time t - T_f, where T_f is the frame period).
- The output has the same size, dimension, data type, and complexity as the input.

Given an *M*-by-*N* matrix input, *u*, the output, *y*, is an *M*-by-*N* matrix whose first row has elements

$$y_{1,j}(t) = u_{1,j}(t) \cdot y_{M,j}\left(t - T_f\right)$$



Computing the Running Product for Each Element of the Input

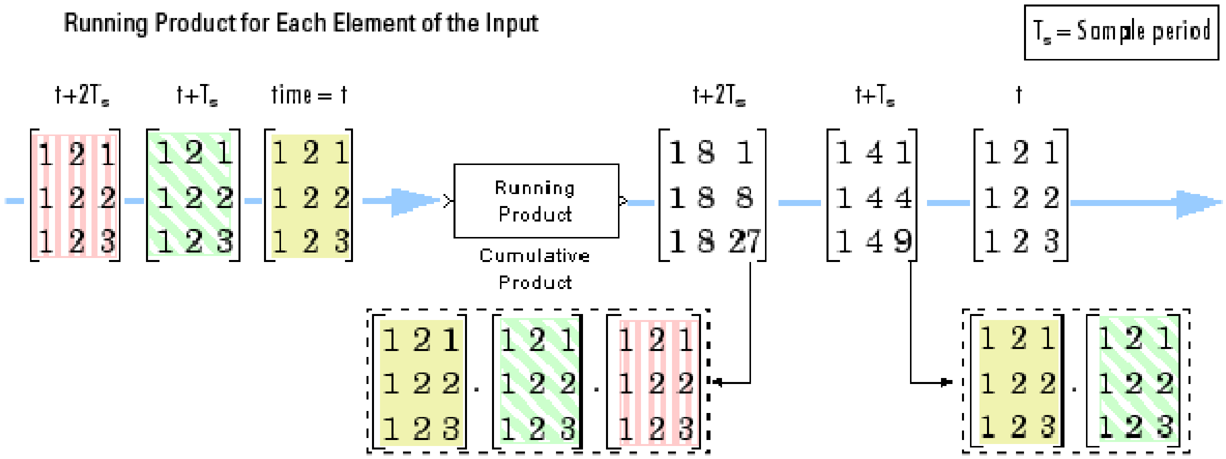
When you set the **Input processing** parameter to `Elements as channels (sample based)`, the block treats each element of the input matrix as an independent channel. As the following figure and equation illustrate, the output has the following characteristics:

- The first output is the same as the first input.
- Each subsequent output is the element-wise product of the current input (time *t*) and the previous output (time t - T_s, where T_s is the sample period).
- The output has the same size, dimension, data type, and complexity as the input.

Given an *M*-by-*N* matrix input, *u*, the output, *y*, is an *M*-by-*N* matrix with the elements

$$y_{i,j}(t) = u_{i,j}(t) \cdot y_{i,j}(t - T_s) \quad \begin{array}{l} 1 \le i \le M \\ 1 \le j \le N \end{array}$$

For convenience, the block treats length-*M* unoriented vector inputs as *M*-by-1 column vectors when multiplying along channels. In such cases, the output is a length-*M* unoriented vector.



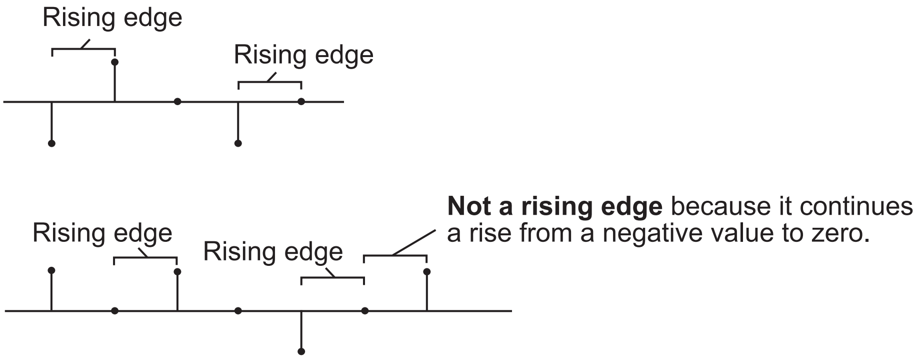
Resetting the Running Product

When you are computing the running product, you can configure the block to reset the running product whenever it detects a reset event at the optional `Rst` port. The rate of the input to the Rst port must be the same or slower than that of the input data signal. The sample time of the input to the Rst port must be a positive integer multiple of the input sample time. The input to the `Rst` port can be of the Boolean data type.

If a reset event occurs while the block is performing sample-based processing, the block initializes the current output to the values of the current input. If a reset event occurs while the block is performing frame-based processing, the block initializes the first row of the current output to the values in the first row of the current input.

The **Reset port** parameter specifies the reset event, which can be one of the following:

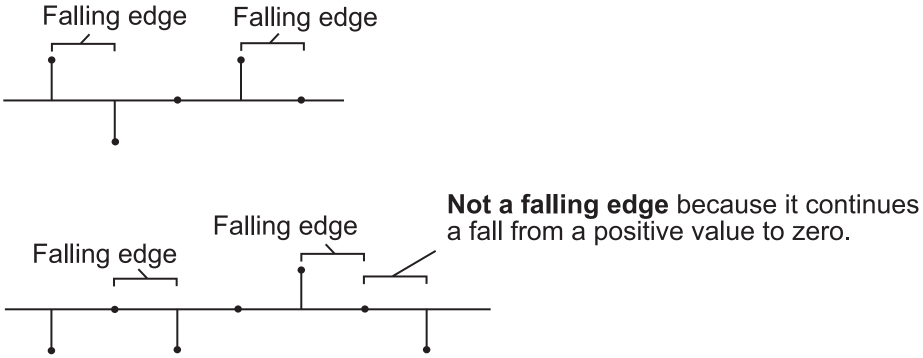
- `None` disables the `Rst` port.
- `Rising edge` — Triggers a reset operation when the `Rst` input does one of the following:
  - Rises from a negative value to a positive value or zero
  - Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero (see the following figure)



Rising edge
Rising edge
Rising edge
Rising edge
Not a rising edge because it continues
a rise from a negative value to zero.

- `Falling edge` — Triggers a reset operation when the `Rst` input does one of the following:

  - Falls from a positive value to a negative value or zero
  - Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero (see the following figure)



Falling edge
Falling edge
Falling edge
Falling edge
Not a falling edge because it continues
a fall from a positive value to zero.

- `Either edge` — Triggers a reset operation when the `Rst` input is a `Rising edge` or `Falling edge` (as described above)
- `Non-zero sample` — Triggers a reset operation at each sample time that the `Rst` input is not zero

Note: When you run simulations in Simulink `MultiTasking` mode, reset signals have a one-sample latency. Thus, when the block detects a reset event, a one-sample delay occurs at the reset port rate before the block applies the reset. For more information on latency and the Simulink tasking modes, see "Excess Algorithmic Delay (Tasking Latency)" and "Scheduling " in the *Simulink Coder User's Guide*.

Multiplying Along Columns

When you set the **Multiply input along** parameter to `Columns`, the block computes the cumulative product of each column of the input. In this mode, the current cumulative product is independent of the cumulative products of previous inputs.

```
y = cumprod(u)      % Equivalent MATLAB code
```

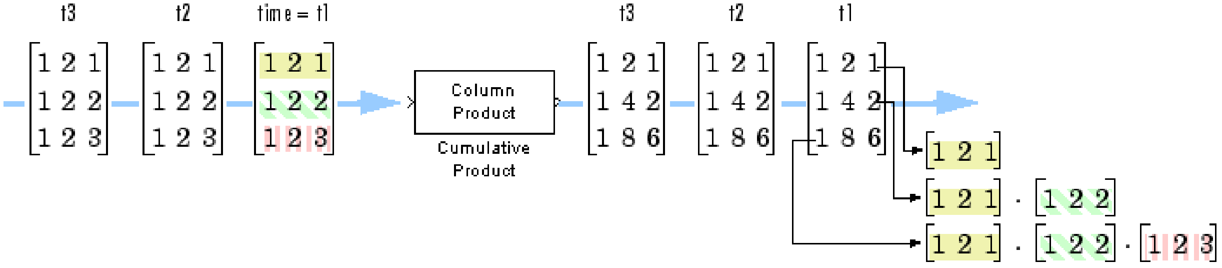
The output has the same size, dimension, data type, and complexity as the input. The *m*th output row is the element-wise product of the first *m* input rows.

Given an *M*-by-*N* input, *u*, the output, *y*, is an *M*-by-*N* matrix whose *j*th column has elements

$$y_{i,j} = \prod_{k=1}^{i} u_{k,j} \qquad 1 \le i \le M$$

When multiplying along columns, the block treats length-*M* unoriented vector inputs as *M*-by-1 column vectors.

Product Along Columns



Multiplying Along Rows

When you set the **Multiply input along** parameter to `Rows`, the block computes the cumulative product of the row elements. In this mode, the current cumulative product is independent of the cumulative products of previous inputs.

```
y = cumprod(u,2)      % Equivalent MATLAB code
```

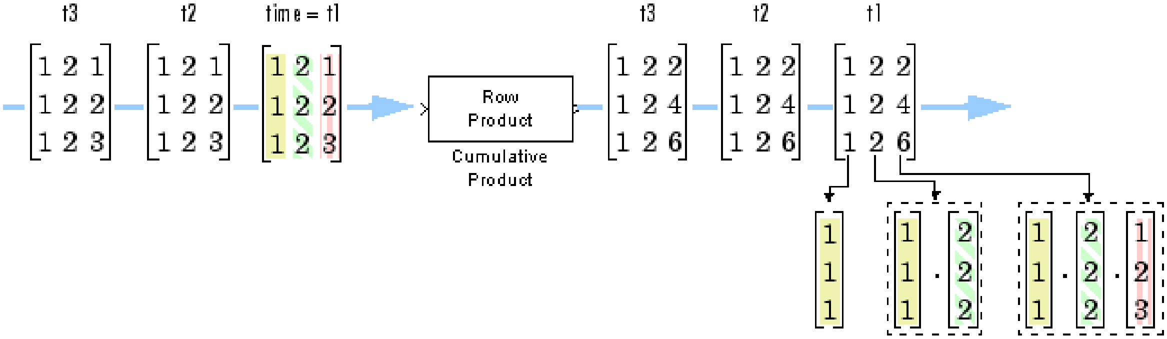
The output has the same size, dimension, and data type as the input. The *n*th output column is the element-wise product of the first *n* input columns.

Given an *M*-by-*N* matrix input, *u*, the output, *y*, is an *M*-by-*N* matrix whose *i*th row has elements

$$y_{i,j} = \prod_{k=1}^{j} u_{i,k} \qquad 1 \le j \le N$$

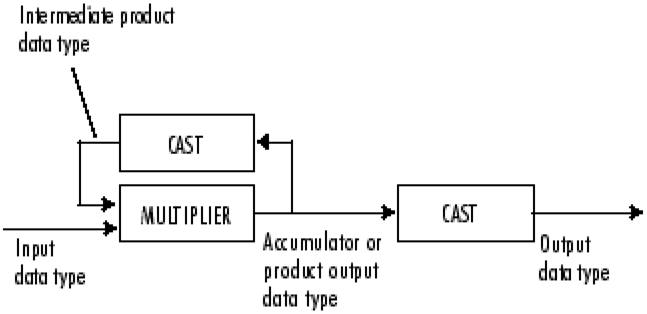
When you multiply along rows, the block treats length-*N* unoriented vector inputs as 1-by-*N* row vectors.

Product Along Rows



Fixed-Point Data Types

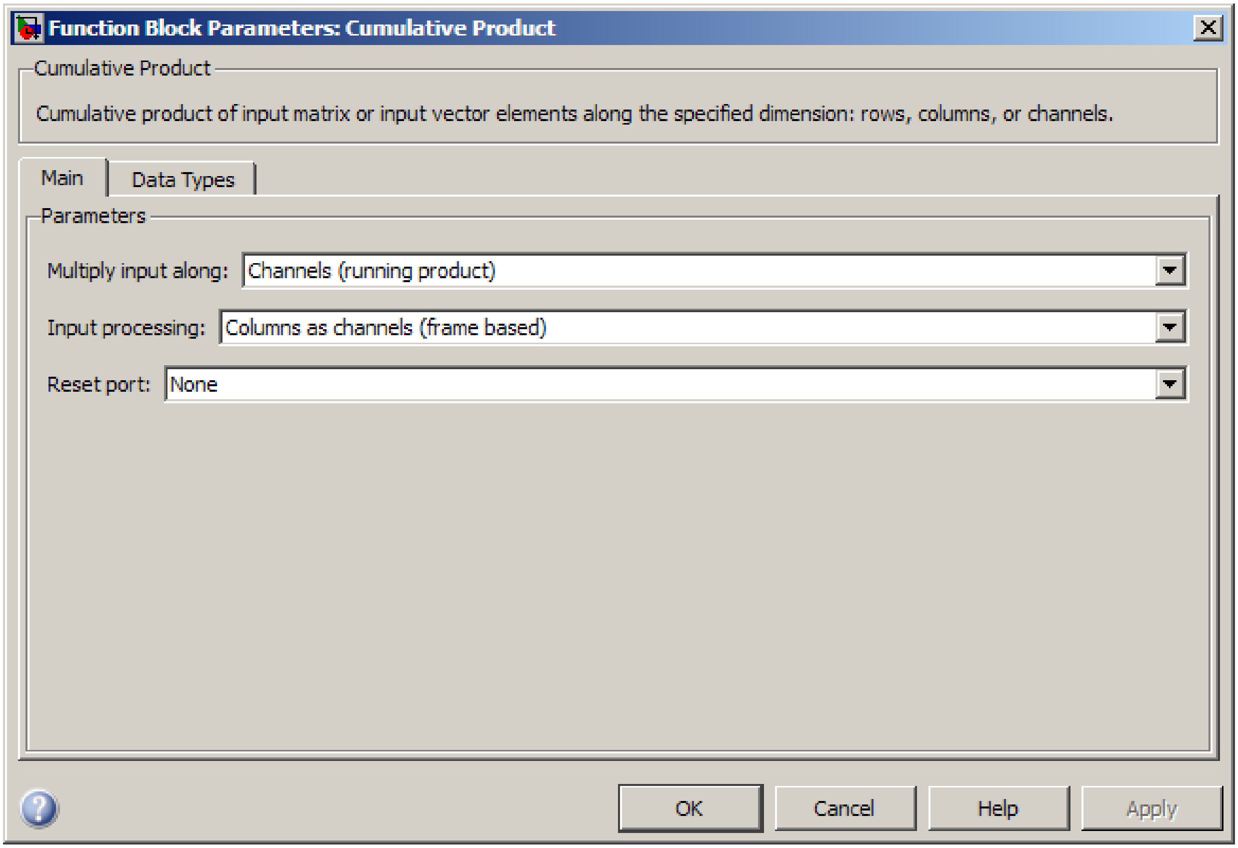
The following diagram shows the data types used within the Cumulative Product block for fixed-point signals.



The output of the multiplier is in the product output data type when at least one of the inputs to the multiplier is real. When both of the inputs to the multiplier are complex, the result of the multiplication is in the accumulator data type. For details on the complex multiplication performed, see “Multiplication Data Types”. You can set the accumulator, product output, intermediate product, and output data types in the block dialog as discussed in “Dialog Box” on page 1-308.

Dialog Box

The **Main** pane of the Cumulative Product block dialog appears as follows.



Function Block Parameters: Cumulative Product

Cumulative Product

Cumulative product of input matrix or input vector elements along the specified dimension: rows, columns, or channels.

Parameters

Multiply input along: Channels (running product)

Input processing: Columns as channels (frame based)

Reset port: None

Multiply input along

Specify the dimension along which to compute the cumulative product. You can choose to multiply along `Channels (running product)`, `Columns`, or `Rows`. For more information, see the following sections:

- "Computing the Running Product Along Channels of the Input" on page 1-302
- "Multiplying Along Columns" on page 1-306
- "Multiplying Along Rows" on page 1-306

Input processing

Specify how the block should process the input when computing the running product along the channels of the input. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` — When you select this option, the block treats each column of the input as a separate channel.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

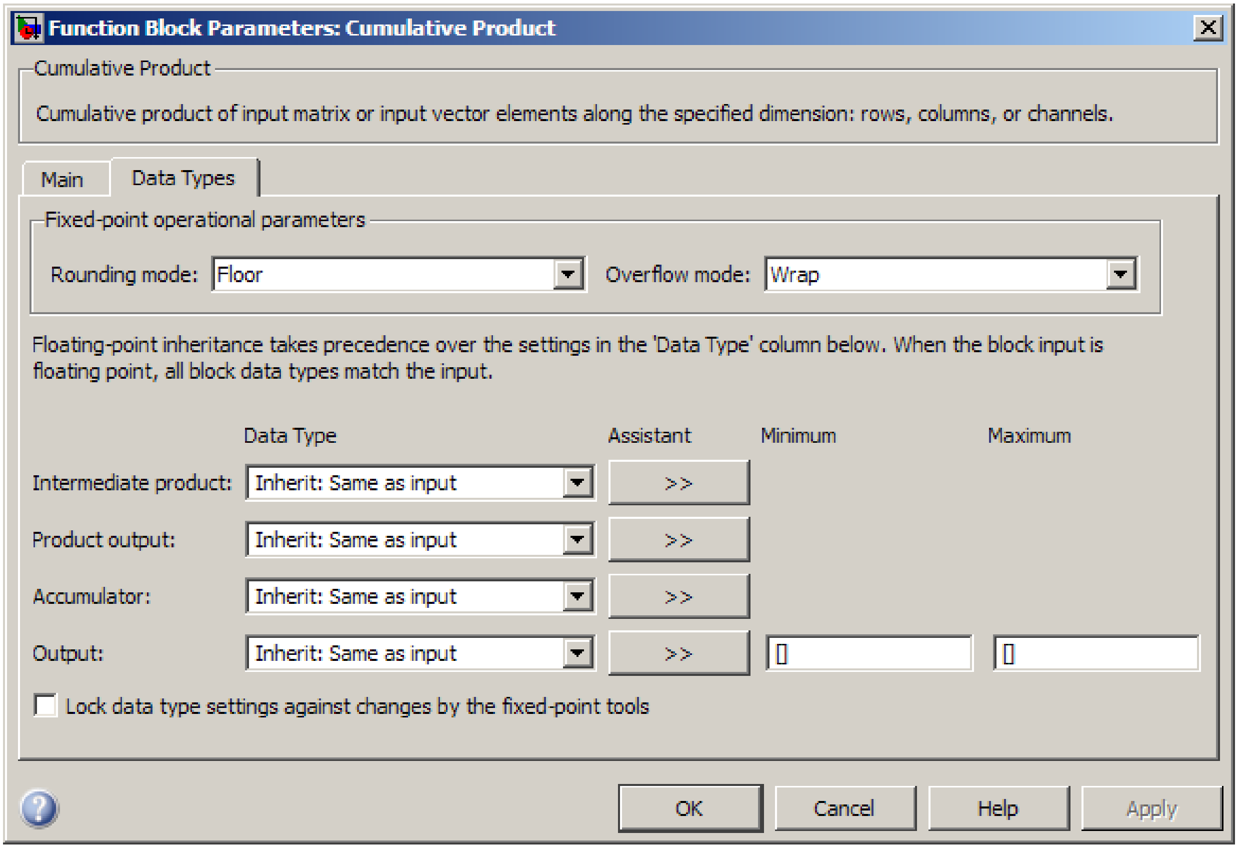
Note: The option `Inherit from input (this choice will be removed - see release notes)` will be removed in a future release. See "Frame-Based Processing" in the *DSP System Toolbox Release Notes* for more information.

This parameter is available only when you set the **Multiply input along** parameter to `Channels (running product)`.

Reset port

Determines the reset event that causes the block to reset the product along channels. The rate of the input to the Rst port must be the same or slower than that of the input data signal. The sample time of the input to the Rst port must be a positive integer multiple of the input sample time. This parameter appears only when you set the **Multiply input along** parameter to `Channels (running product)`. For more information, see .

The **Data Types** pane of the Cumulative Product block dialog appears as follows.



Function Block Parameters: Cumulative Product

Cumulative Product

Cumulative product of input matrix or input vector elements along the specified dimension: rows, columns, or channels.

Fixed-point operational parameters

Rounding mode: Floor

Overflow mode: Wrap

Floating-point inheritance takes precedence over the settings in the 'Data Type' column below. When the block input is floating point, all block data types match the input.

	Data Type	Assistant	Minimum	Maximum
Intermediate product:	Inherit: Same as input	>>		
Product output:	Inherit: Same as input	>>		
Accumulator:	Inherit: Same as input	>>		
Output:	Inherit: Same as input	>>	[]	[]

□ Lock data type settings against changes by the fixed-point tools

Note: Floating-point inheritance takes precedence over the data type settings defined on this pane. When inputs are floating point, the block ignores these settings, and all internal data types are floating point.

Rounding mode

Select the “rounding mode” for fixed-point operations.

Overflow mode

Select the “overflow mode” for fixed-point operations.

Intermediate product

Specify the intermediate product data type. As shown in “Fixed-Point Data Types” on page 1-307, the output of the multiplier is cast to the intermediate product data type before the next element of the input is multiplied into it. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as input`
- An expression that evaluates to a valid data type, for example, `fixdt([],16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Product output data type** parameter.

See “Specify Data Types Using Data Type Assistant” in “Simulink User's Guide” for more information.

Product output data type

Specify the product output data type. See “Fixed-Point Data Types” on page 1-307 and “Multiplication Data Types” for illustrations depicting the use of the product output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as input`
- An expression that evaluates to a valid data type, for example, `fixdt([],16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Product output data type** parameter.

See “Specify Data Types Using Data Type Assistant” in “Simulink User's Guide” for more information.

Accumulator data type

Specify the accumulator data type. See “Fixed-Point Data Types” on page 1-307 for illustrations depicting the use of the accumulator data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Same as input`
- An expression that evaluates to a valid data type, for example, `fixdt([],16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Accumulator data type** parameter.

See “Specify Data Types Using Data Type Assistant” in “Simulink User's Guide” for more information.

Output data type

Specify the output data type. See “Fixed-Point Data Types” on page 1-307 for illustrations depicting the use of the output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as input`
- An expression that evaluates to a valid data type, for example, `fixdt([],16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Specify Block Output Data Types” in “Simulink User's Guide” for more information.

Minimum

Specify the minimum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges”)
- Automatic scaling of fixed-point data types

Maximum

Specify the maximum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges”)
- Automatic scaling of fixed-point data types

Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

Supported Data Types

Input and Output Ports	Supported Data Types
Data input port, `In`	• Double-precision floating point • Single-precision floating point

Input and Output Ports	Supported Data Types
	• Fixed point • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Reset input port, `Rst`	All built-in Simulink data types: • Double-precision floating point • Single-precision floating point • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Output port	• Double-precision floating point • Single-precision floating point • Fixed point • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers

See Also

Cumulative Sum	DSP System Toolbox
Matrix Product	DSP System Toolbox
`cumprod`	MATLAB

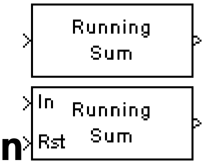
Cumulative Sum

Cumulative sum of channel, column, or row elements

Library

Math Functions / Math Operations

`dspmathops`



Description

The Cumulative Sum block computes the cumulative sum along the specified dimension of the input or across time (running sum).

The inputs can be a vector or a matrix. The output always has the same dimensions, rate, data type, and complexity as the input.

Input and Output Characteristics

Valid Input

The Cumulative Sum block accepts vector or matrix inputs containing real or complex values.

Valid Reset Signal

The optional reset port, `Rst`, accepts scalar values, which can be any built-in Simulink data type including `boolean`. The rate of the input to the Rst port must be the same or slower than that of the input data signal. The sample time of the input to the Rst port must be a positive integer multiple of the input sample time.

Output Characteristics

The output always has the same dimensions, rate, data type, and complexity as the data signal input.

Computing the Running Sum Along Channels of the Input

When you set the **Sum input along** parameter to `Channels (running sum)`, the block computes the cumulative sum of the elements in each input channel. The running sum of the current input takes into account the running sum of all previous inputs. In this mode, you must also specify a value for the **Input processing** parameter. When you set the **Input processing** parameter to `Columns as channels (frame based)`, the block computes the running sum along each column of the current input. When you set the **Input processing** parameter to `Elements as channels (sample based)`, the block computes a running sum for each element of the input across time. See the following sections for more information:

-
-
-

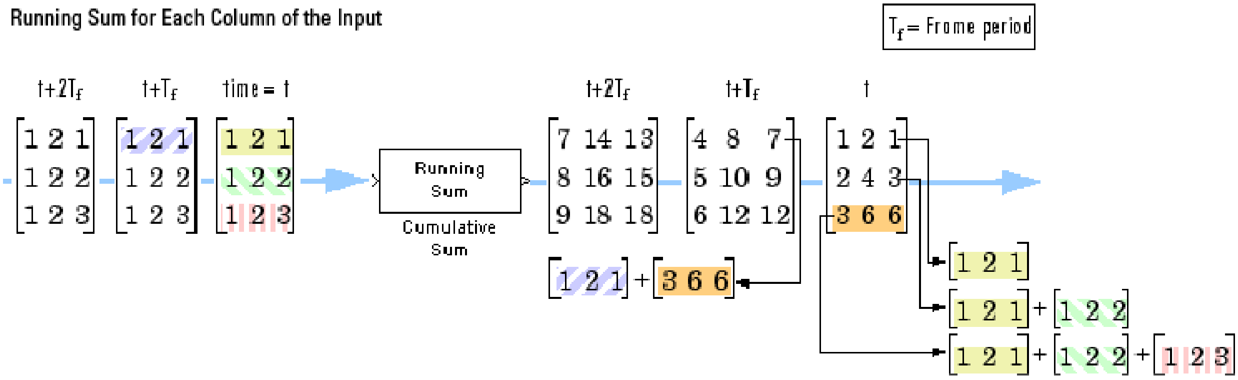
Computing the Running Sum for Each Column of the Input

When you set the **Input processing** parameter to `Columns as channels (frame based)`, the block treats each input column as an independent channel. As the following figure and equation illustrate, the output has the following characteristics:

- The first row of the first output is the same as the first row of the first input.
- The first row of each subsequent output is the sum of the first row of the current input (time *t*), and the last row of the previous output (time t - T_f, where T_f is the frame period).
- The output has the same size, dimension, data type, and complexity as the input.

Given an *M*-by-*N* matrix input, *u*, the output, *y*, is an *M*-by-*N* matrix whose first row has elements

$$y_{1,j}(t) = u_{1,j}(t) + y_{M,j}(t - T_f)$$



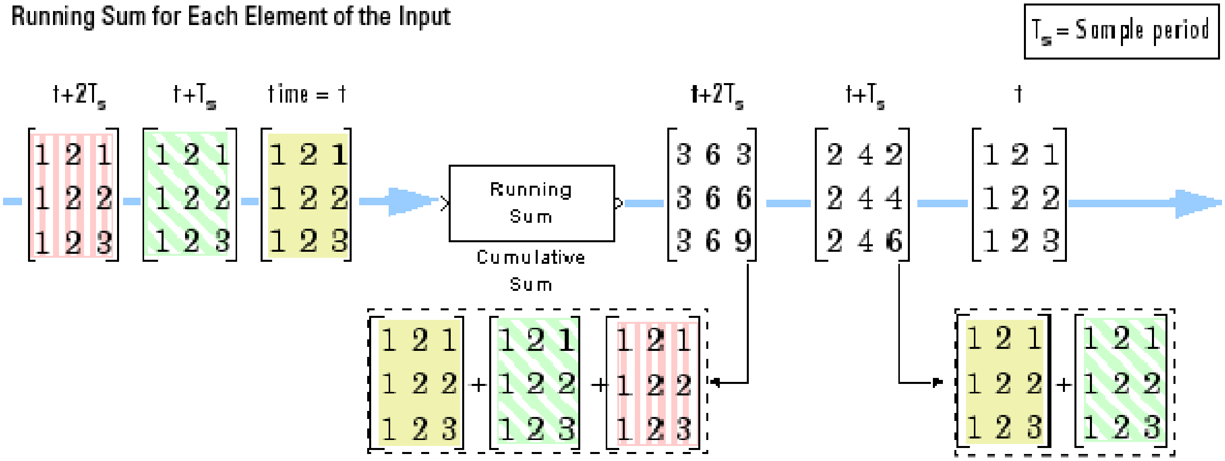
Computing the Running Sum for Each Element of the Input

When you set the **Input processing** parameter to `Elements as channels (sample based)`, the block treats each element of the input matrix as an independent channel. As the following figure and equation illustrate, the output has the following characteristics:

- The first output is the same as the first input.
- Each subsequent output is the sum of the current input (time *t*) and the previous output (time *t* - T_s, where T_s is the sample period).
- The output has the same size, dimension, data type, and complexity as the input.

Given an *M*-by-*N* matrix input, *u*, the output, *y*, is an *M*-by-*N* matrix with the elements

$$y_{i,j}(t) = u_{i,j}(t) + y_{i,j}(t - T_s) \qquad \begin{array}{l} 1 \le i \le M \\ 1 \le j \le N \end{array}$$



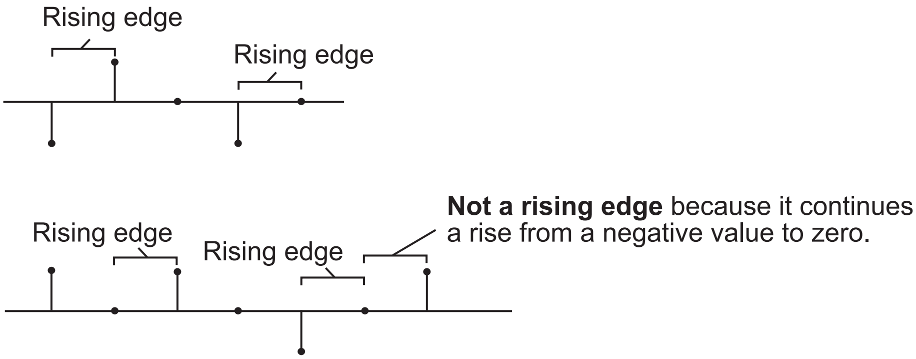
Resetting the Running Sum

When you are computing the running sum, you can configure the block to reset the running sum whenever it detects a reset event at the optional `Rst` port. The rate of the input to the Rst port must be the same or slower than that of the input data signal. The sample time of the input to the Rst port must be a positive integer multiple of the input sample time. The reset sample time must be a positive integer multiple of the input sample time. The input to the `Rst` port can be of the `boolean` data type.

If a reset event occurs while the block is performing sample-based processing, the block initializes the current output to the values of the current input. If a reset event occurs while the block is performing frame-based processing, the block initializes the first row of the current output to the values in the first row of the current input.

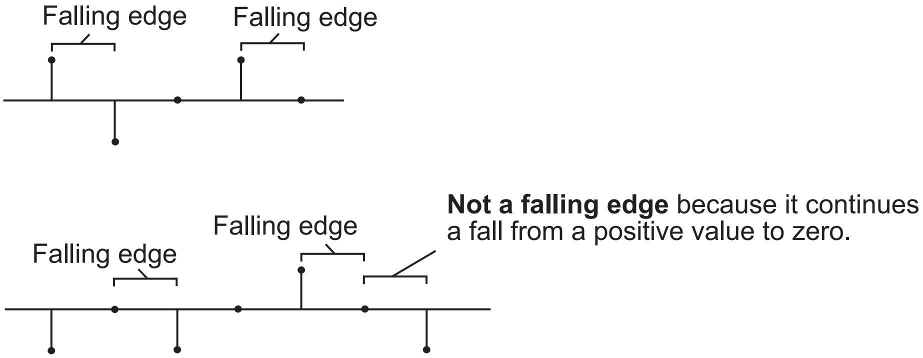
The **Reset port** parameter specifies the reset event, which can be one of the following:

- `None` disables the `Rst` port.
- `Rising edge` — Triggers a reset operation when the `Rst` input does one of the following:
  - Rises from a negative value to a positive value or zero
  - Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero (see the following figure)



Rising edge
Rising edge
Rising edge
Rising edge
Not a rising edge because it continues a rise from a negative value to zero.

- `Falling edge` — Triggers a reset operation when the `Rst` input does one of the following:
  - Falls from a positive value to a negative value or zero
  - Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero (see the following figure)



Falling edge
Falling edge
Falling edge
Falling edge
Not a falling edge because it continues a fall from a positive value to zero.

- `Either edge` — Triggers a reset operation when the `Rst` input is a `Rising edge` or `Falling edge` (as described above)
- `Non-zero sample` — Triggers a reset operation at each sample time that the `Rst` input is not zero

Note: When you run simulations in the Simulink `MultiTasking` mode, reset signals have a one-sample latency. Thus, when the block detects a reset event, a one-sample delay occurs at the reset port rate before the block applies the reset. For more information on latency and the Simulink tasking modes, see "Excess Algorithmic Delay (Tasking Latency)" and the topic on "models with multiple sample rates" in the Simulink Coder documentation.

Summing Along Columns

When you set the **Sum input along** parameter to `Columns`, the block computes the cumulative sum of each column of the input. In this mode, the current cumulative sum is independent of the cumulative sums of previous inputs.

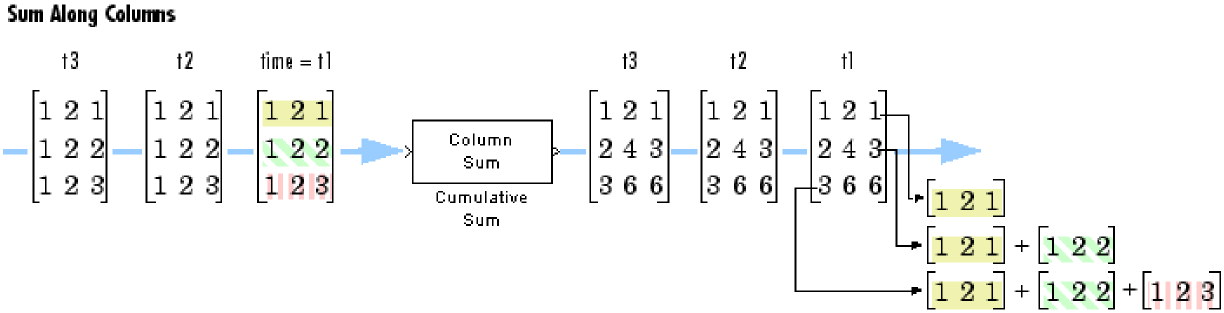
```
y = cumsum(u)      % Equivalent MATLAB code
```

The output has the same size, dimension, data type, and complexity as the input. The *m*th output row is the sum of the first *m* input rows.

Given an *M*-by-*N* input, *u*, the output, *y*, is an *M*-by-*N* matrix whose *j*th column has elements

$$y_{i,j} = \sum_{k=1}^{j} u_{k,j} \qquad 1 \le i \le M$$

The block treats length-*M* unoriented vector inputs as *M*-by-1 column vectors when summing along columns.



Summing Along Rows

When you set the **Sum input along** parameter to `Rows`, the block computes the cumulative sum of the row elements. In this mode, the current cumulative sum is independent of the cumulative sums of previous inputs.

```
y = cumsum(u,2)      % Equivalent MATLAB code
```

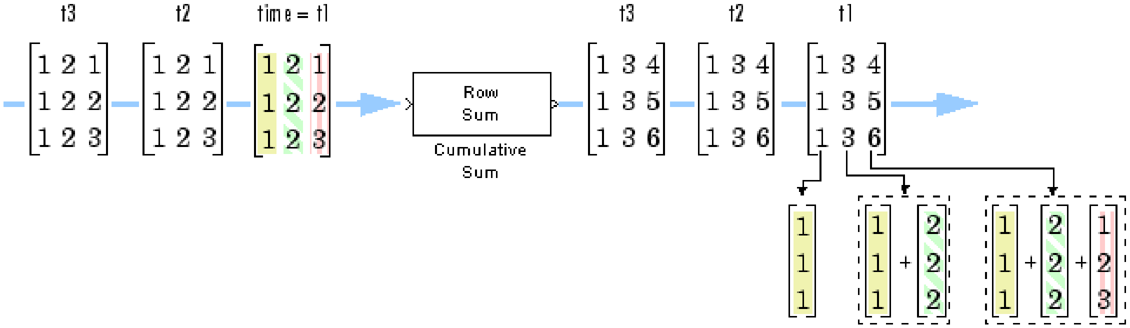
The output has the same size, dimension, and data type as the input. The *n*th output column is the sum of the first *n* input columns.

Given an *M*-by-*N* input, *u*, the output, *y*, is an *M*-by-*N* matrix whose *i*th row has elements

$$y_{i,j} = \sum_{k=1}^{j} u_{i,k} \qquad 1 \le j \le N$$

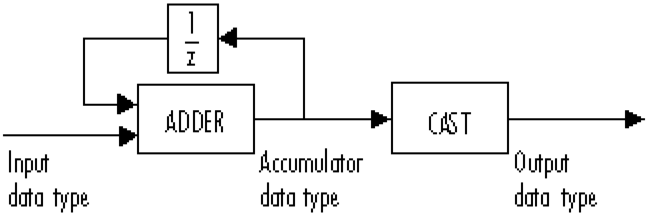
When you sum along rows, the block treats length-*N* unoriented vector inputs as 1-by-*N* row vectors.

Sum Along Rows



Fixed-Point Data Types

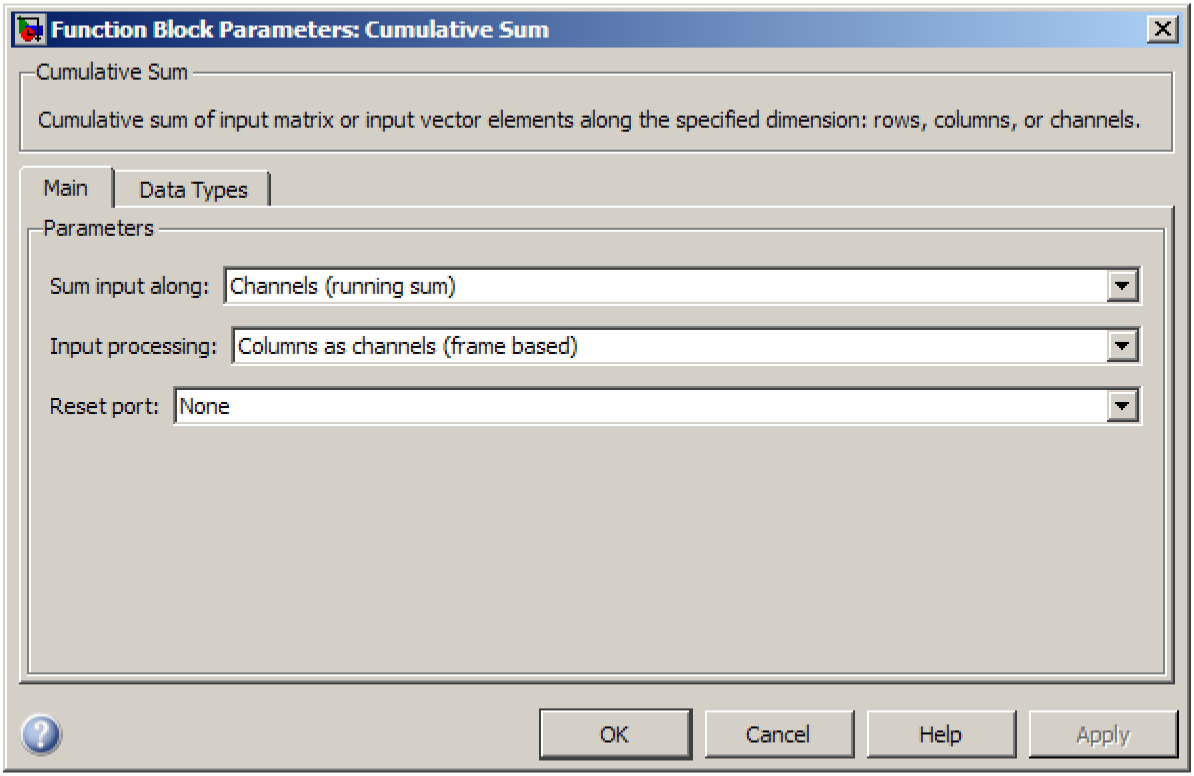
The following diagram shows the data types used within the Cumulative Sum block for fixed-point signals.



You can set the accumulator and output data types in the block dialog as discussed in “Dialog Box” on page 1-322.

Dialog Box

The **Main** pane of the Cumulative Sum block dialog appears as follows.



Function Block Parameters: Cumulative Sum

Cumulative Sum

Cumulative sum of input matrix or input vector elements along the specified dimension: rows, columns, or channels.

Sum input along: Channels (running sum)

Input processing: Columns as channels (frame based)

Reset port: None

Sum input along

Specify the dimension along which to compute the cumulative summations. You can choose to sum along `Channels (running sum)`, `Columns`, or `Rows`. For more information, see the following sections:

- "Computing the Running Sum Along Channels of the Input" on page 1-316
- "Summing Along Columns" on page 1-320
- "Summing Along Rows" on page 1-321

Input processing

Specify how the block should process the input when computing the running sum along the channels of the input. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` — When you select this option, the block treats each column of the input as a separate channel.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

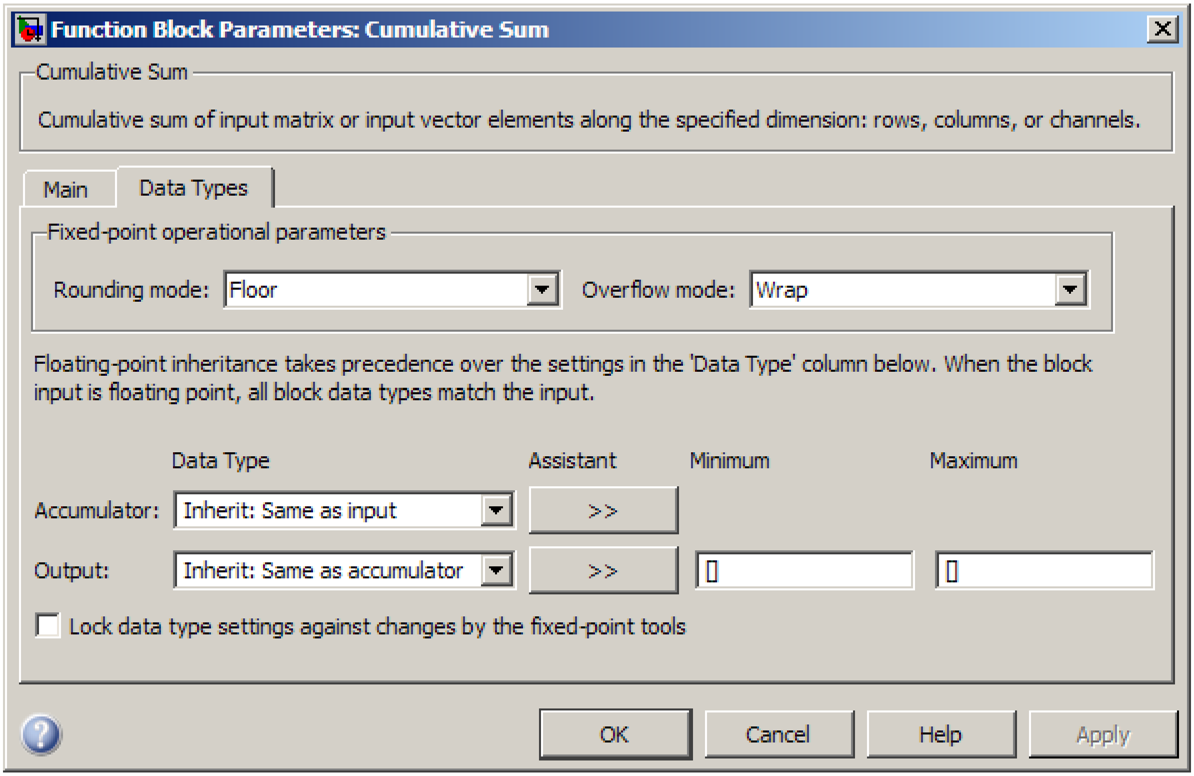
Note: The option `Inherit from input (this choice will be removed - see release notes)` will be removed in a future release. See "Frame-Based Processing" in the *DSP System Toolbox Release Notes* for more information.

This parameter is available only when you set the **Sum input along** parameter to `Channels (running sum)`.

Reset port

Determines the reset event that causes the block to reset the sum along channels. The rate of the input to the Rst port must be the same or slower than that of the input data signal. The sample time of the input to the Rst port must be a positive integer multiple of the input sample time. This parameter appears only when you set the **Sum input along** parameter to `Channels (running sum)`. For more information, see .

The **Data Types** pane of the Cumulative Sum block dialog appears as follows.



Function Block Parameters: Cumulative Sum

Cumulative Sum

Cumulative sum of input matrix or input vector elements along the specified dimension: rows, columns, or channels.

Fixed-point operational parameters

Rounding mode: Floor   Overflow mode: Wrap

Floating-point inheritance takes precedence over the settings in the 'Data Type' column below. When the block input is floating point, all block data types match the input.

	Data Type	Assistant	Minimum	Maximum
Accumulator:	Inherit: Same as input	>>		
Output:	Inherit: Same as accumulator	>>	[]	[]

□ Lock data type settings against changes by the fixed-point tools

Note: Floating-point inheritance takes precedence over the data type settings defined on this pane. When inputs are floating point, the block ignores these settings, and all internal data types are floating point.

Rounding mode

Select the “rounding mode” for fixed-point operations.

Overflow mode

Select the “overflow mode” for fixed-point operations.

Accumulator data type

Specify the accumulator data type. See “Fixed-Point Data Types” on page 1-321 for illustrations depicting the use of the accumulator data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Same as input`
- An expression that evaluates to a valid data type, for example, `fixdt([],16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Accumulator data type** parameter.

See “Specify Data Types Using Data Type Assistant” in “Simulink User's Guide” for more information.

Output data type

Specify the output data type. See “Fixed-Point Data Types” on page 1-321 for illustrations depicting the use of the output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as accumulator`
- An expression that evaluates to a valid data type, for example, `fixdt([],16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Specify Block Output Data Types” in “Simulink User's Guide” for more information.

Minimum

Specify the minimum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges”)
- Automatic scaling of fixed-point data types

Maximum

Specify the maximum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges”)
- Automatic scaling of fixed-point data types

Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

Supported Data Types

Input and Output Ports	Supported Data Types
Data input port, `In`	• Double-precision floating point • Single-precision floating point • Fixed point • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Reset input port, `Rst`	All built-in Simulink data types: • Double-precision floating point • Single-precision floating point • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Output port	• Double-precision floating point • Single-precision floating point • Fixed point • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers

Data Type Conversion

Convert input signal to specified data type

Library

Signal Management / Signal Attributes

`dspsigattribs`

Description

The Data Type Conversion block is an implementation of the Simulink Data Type Conversion block. See Data Type Conversion for more information.

HDL Code Generation

This block supports HDL code generation using HDL Coder. HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic. For more information on implementations, properties, and restrictions for HDL code generation, see Data Type Conversion.

dB Conversion

Convert magnitude data to decibels (dB or dBm)

Library

Math Functions / Math Operations

dspmathops

Description

The dB Conversion block converts a linearly scaled power or amplitude input to dB or dBm. The reference power is 1 Watt for conversions to dB and 1 mWatt for conversions to dBm. The **Input signal** parameter specifies whether the input is a power signal or a voltage signal, and the **Convert to** parameter controls the scaling of the output. When selected, the **Add eps to input to protect against "log(0) = -inf"** parameter adds a value of `eps` to all power and voltage inputs. When this option is not enabled, zero-valued inputs produce `-inf` at the output.

The output is the same size as the input.

Power Inputs

Select `Power` as the **Input signal** parameter when the input, `u`, is a real, nonnegative, power signal (units of watts). When the **Convert to** parameter is set to `dB`, the block performs the dB conversion

```
y = 10*log10(u)       % Equivalent MATLAB code
```

When the **Convert to** parameter is set to `dBm`, the block performs the dBm conversion

```
y = 10*log10(u) + 30
```

The dBm conversion is equivalent to performing the dB operation *after* converting the input to milliwatts.

Voltage Inputs

Select `Amplitude` as the **Input signal** parameter when the input, `u`, is a real voltage signal (units of volts). The block uses the scale factor specified in ohms by the **Load resistance** parameter, `R`, to convert the voltage input to units of power (watts) before converting to dB or dBm.

When the **Convert to** parameter is set to `dB`, the block performs the dB conversion

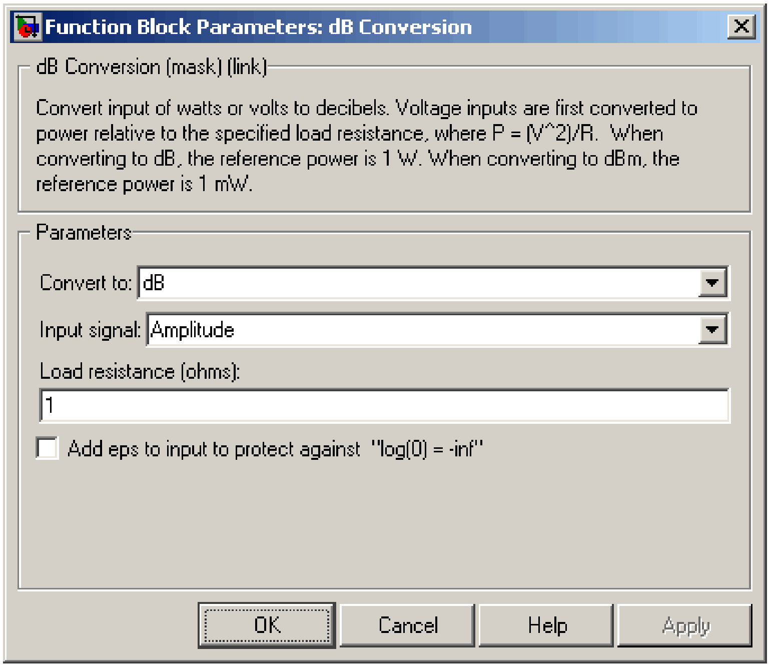
```
y = 10*log10(abs(u)^2/R)
```

When the **Convert to** parameter is set to `dBm`, the block performs the dBm conversion

```
y = 10*log10(abs(u)^2/R) + 30
```

The dBm conversion is equivalent to performing the dB operation *after* converting the `(abs(u)^2/R)` result to milliwatts.

Dialog Box



Function Block Parameters: dB Conversion

dB Conversion (mask) (link)

Convert input of watts or volts to decibels. Voltage inputs are first converted to power relative to the specified load resistance, where P = (V^2)/R. When converting to dB, the reference power is 1 W. When converting to dBm, the reference power is 1 mW.

Parameters

Convert to: dB

Input signal: Amplitude

Load resistance (ohms):

1

□ Add eps to input to protect against "log(0) = -inf"

Convert to

The logarithmic scaling to which the input is converted, `dB` or `dBm`. The reference power is 1 W for conversions to dB and 1 mW for conversions to dBm. “Tunable”.

Input signal

The type of input signal, `Power` or `Amplitude`.

Load resistance

The scale factor used to convert voltage inputs to units of power. “Tunable”.

Add eps to input to protect against “log(0) = -inf”

When selected, adds `eps` to all input values (power or voltage). “Tunable”.

Supported Data Types

- Double-precision floating point
- Single-precision floating point

`log10`	MATLAB

dB Gain

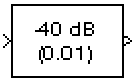
Apply decibel gain

Library

Math Functions / Math Operations

`dspmathops`

Description



The dB Gain block multiplies the input by the decibel values specified in the **Gain** parameter. For an *M*-by-*N* input matrix *u* with elements u_{ij}, the **Gain** parameter can be a real *M*-by-*N* matrix with elements g_{ij} to be multiplied element-wise with the input, or a real scalar.

$$y_{ij} = 10u_{ij}^{(g_{ij}/k)}$$

The value of *k* is 10 for power signals (select `Power` as the **Input signal** parameter) and 20 for voltage signals (select `Amplitude` as the **Input signal** parameter).

The value of the equivalent linear gain

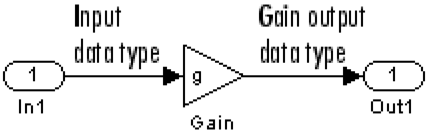
$$g_{ij}^{lin} = 10^{(g_{ij}/k)}$$

is displayed in the block icon below the dB gain value. The output is the same size as the input.

The dB Gain block supports real and complex floating-point and fixed-point data types.

Fixed-Point Data Types

The following diagram shows the data types used within the dB Gain subsystem block for fixed-point signals.

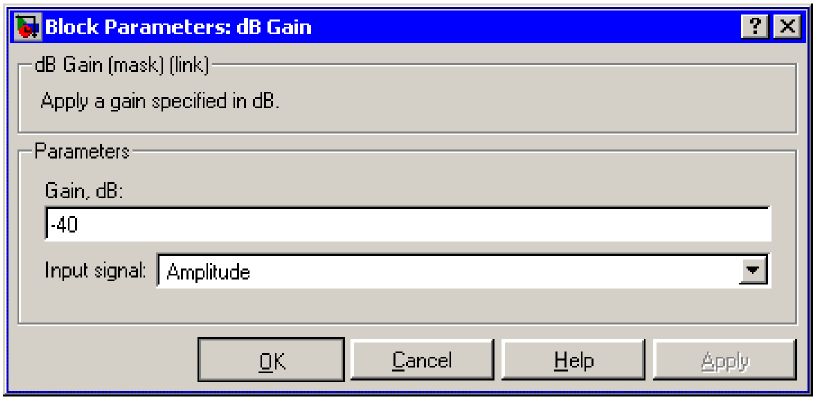


The settings for the fixed-point parameters of the Gain block in the diagram above are as follows:

- Integer rounding mode: `Floor`
- Saturate on integer overflow — unselected
- Parameter data type mode — `Inherit via internal rule`
- Output data type mode — `Inherit via internal rule`

See the Gain reference page for more information.

Dialog Box



Block Parameters: dB Gain

dB Gain (mask) (link)

Apply a gain specified in dB.

Parameters

Gain, dB: -40

Input signal: Amplitude

Gain

The dB gain to apply to the input, a scalar or a real M-by-N matrix. “Tunable”.

Input signal

The type of input signal: `Power` or `Amplitude`. “Tunable”.

Note: This block does not support tunability in generated code.

Supported Data Types

- Double-precision floating point
- Single-precision floating point
- Fixed point (signed and unsigned)
- 8-, 16-, and 32-bit signed integers
- 8-, 16-, and 32-bit unsigned integers

DCT

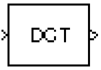
Discrete cosine transform (DCT) of input

Library

Transforms

dspxfrm3

Description



The DCT block computes the unitary discrete cosine transform (DCT) of each channel in the *M*-by-*N* input matrix, *u*.

```
y = dct(u)     % Equivalent MATLAB code
```

When the input is a sample-based row vector, the DCT block computes the discrete cosine transform across the vector dimension of the input. For all other N-D input arrays, the block computes the DCT across the first dimension. The size of the first dimension (frame size), must be a power of two. To work with other frame sizes, use the Pad block to pad or truncate the frame size to a power-of-two length.

When the input to the DCT block is an *M*-by-*N* matrix, the block treats each input column as an independent channel containing *M* consecutive samples. The block outputs an *M*-by-*N* matrix whose *l*th column contains the length-*M* DCT of the corresponding input column.

$$y(k,l) = w(k)\sum_{m=1}^{M} u(m,l)\cos\frac{\pi(2m-1)(k-1)}{2M}, \quad k = 1,\ldots,M$$

where

$$w(k) = \begin{cases} \dfrac{1}{\sqrt{M}}, & k = 1 \\ \sqrt{\dfrac{2}{M}}, & 2 \le k \le M \end{cases}$$

The **Sine and cosine computation** parameter determines how the block computes the necessary sine and cosine values. This parameter has two settings, each with its advantages and disadvantages, as described in the following table.

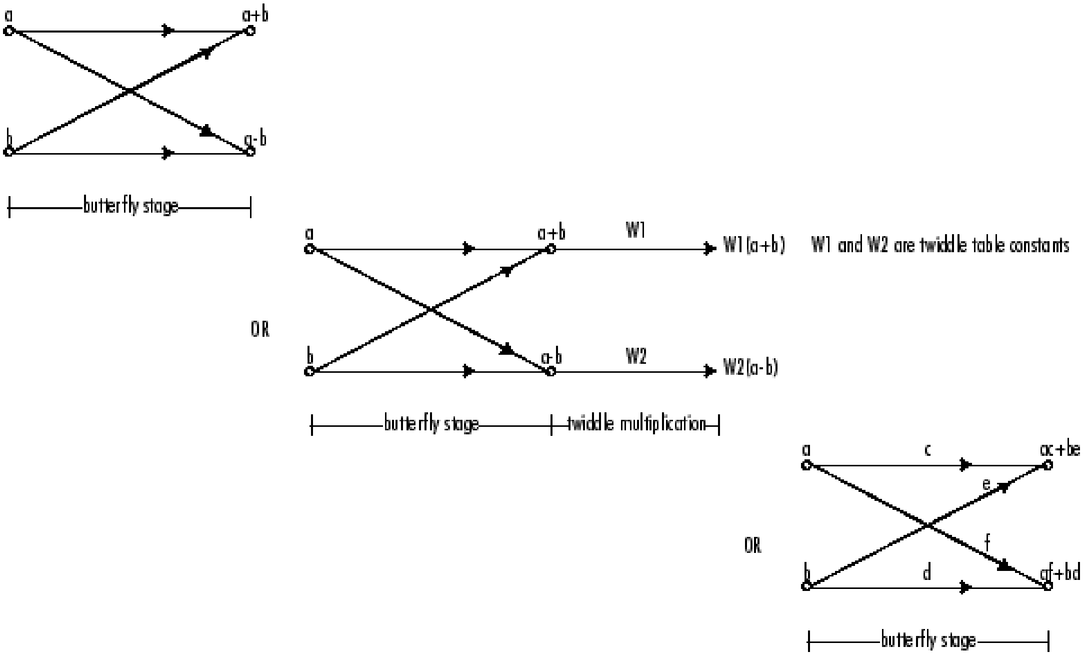
Sine and Cosine Computation Parameter Setting	Sine and Cosine Computation Method	Effect on Block Performance
`Table lookup`	The block computes and stores the trigonometric values before the simulation starts, and retrieves them during the simulation. When you generate code from the block, the processor running the generated code stores the trigonometric values computed by the block in a speed-optimized table, and retrieves the values during code execution.	The block usually runs much more quickly, but requires extra memory for storing the precomputed trigonometric values.
`Trigonometric fcn`	The block computes sine and cosine values during the simulation. When you generate code from the block, the processor running the generated code computes the sine and cosine values while the code runs.	The block usually runs more slowly, but does not need extra data memory. For code generation, the block requires a support library to emulate the trigonometric functions, increasing the size of the generated code.

This block supports Simulink virtual buses.

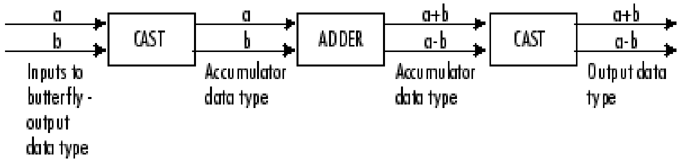
Fixed-Point Data Types

The following diagrams show the data types used within the DCT block for fixed-point signals. You can set the sine table, accumulator, product output, and output data types displayed in the diagrams in the DCT block dialog as discussed in “Dialog Box” on page 1-337.

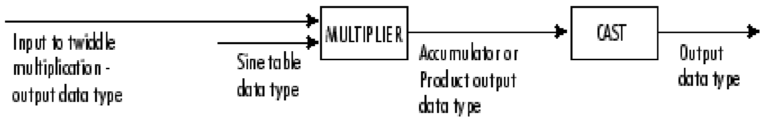
Inputs to the DCT block are first cast to the output data type and stored in the output buffer. Each butterfly stage processes signals in the accumulator data type, with the final output of the butterfly being cast back into the output data type.



Butterfly Stage Data Types



Twiddle Multiplication Data Types



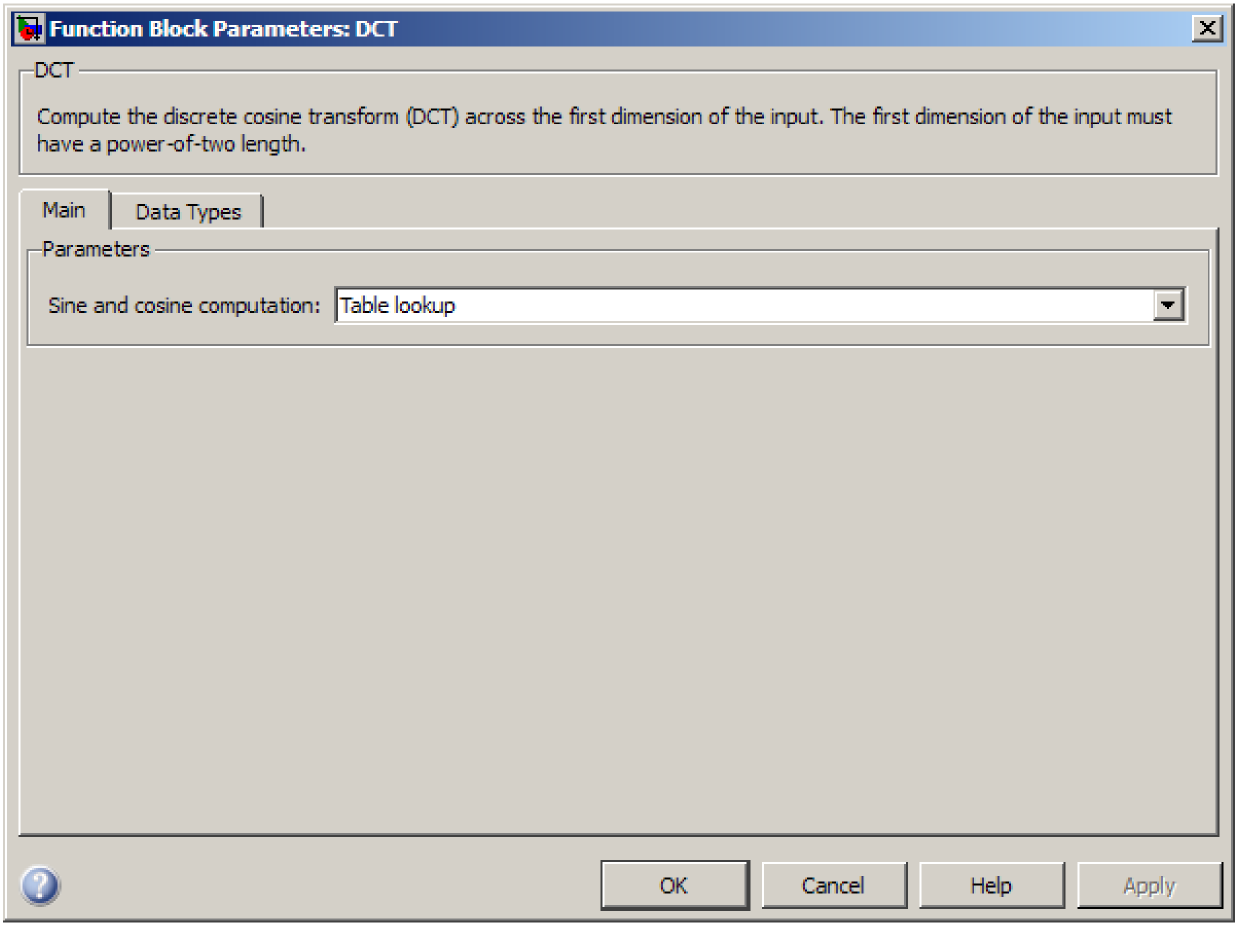
Input to twiddle multiplication - output data type
Sine table data type
MULTIPLIER
Accumulator or Product output data type
CAST
Output data type

The output of the multiplier is in the product output data type when at least one of the inputs to the multiplier is real. When both of the inputs to the multiplier are complex, the result of the multiplication is in the accumulator data type. For details on the complex multiplication performed, see “Multiplication Data Types”.

Note: When the block input is fixed point, all internal data types are signed fixed point.

Dialog Box

The **Main** pane of the DCT block dialog appears as follows.



Function Block Parameters: DCT

DCT

Compute the discrete cosine transform (DCT) across the first dimension of the input. The first dimension of the input must have a power-of-two length.

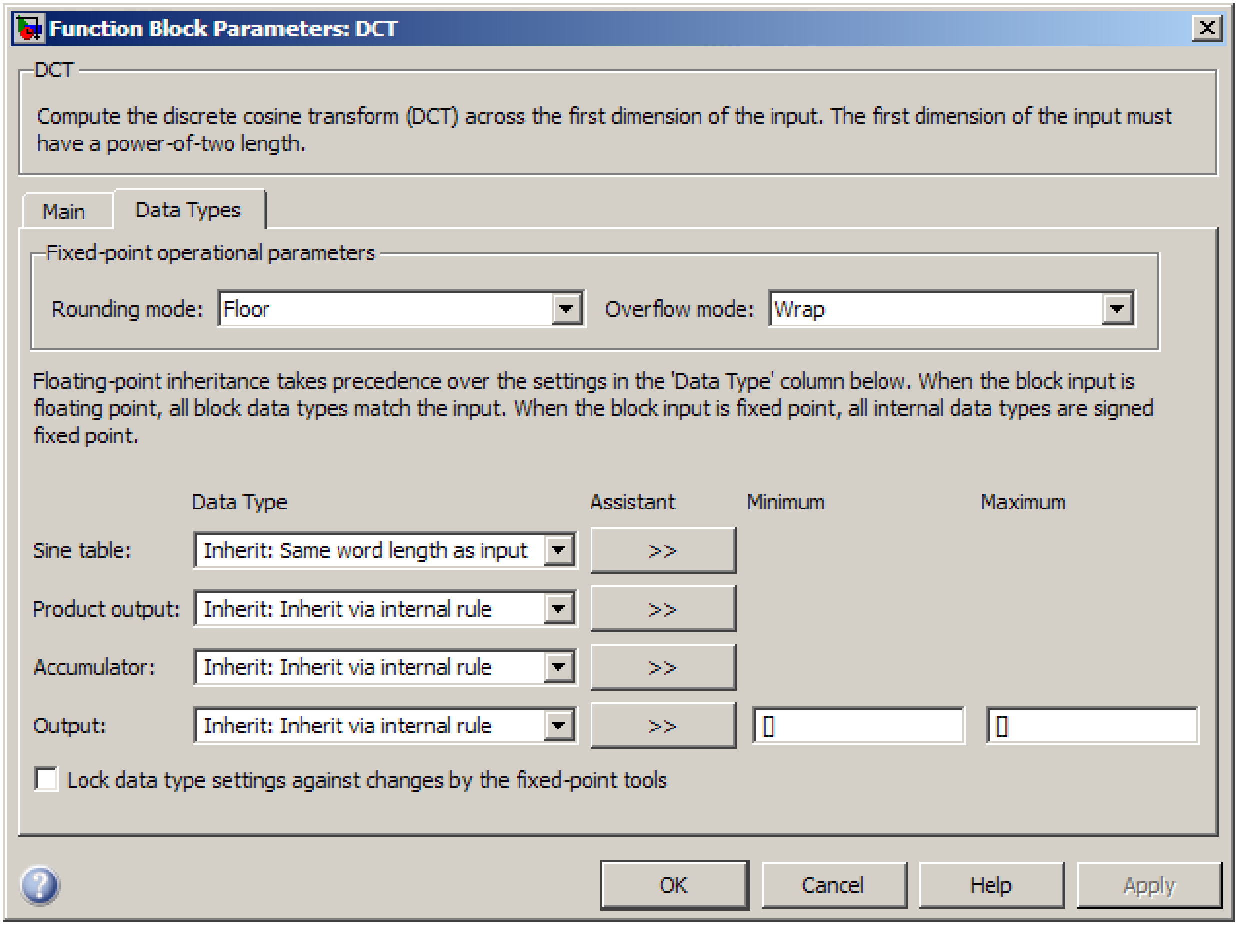
Parameters

Sine and cosine computation: Table lookup

Sine and cosine computation

Sets the block to compute sines and cosines by either looking up sine and cosine values in a speed-optimized table (`Table lookup`), or by making sine and cosine function calls (`Trigonometric fcn`). See the table in the “Description ” section.

The **Data Types** pane of the DCT block dialog appears as follows.



Function Block Parameters: DCT

DCT

Compute the discrete cosine transform (DCT) across the first dimension of the input. The first dimension of the input must have a power-of-two length.

Fixed-point operational parameters

Rounding mode: Floor

Overflow mode: Wrap

Floating-point inheritance takes precedence over the settings in the 'Data Type' column below. When the block input is floating point, all block data types match the input. When the block input is fixed point, all internal data types are signed fixed point.

	Data Type	Assistant	Minimum	Maximum
Sine table:	Inherit: Same word length as input	>>		
Product output:	Inherit: Inherit via internal rule	>>		
Accumulator:	Inherit: Inherit via internal rule	>>		
Output:	Inherit: Inherit via internal rule	>>	[]	[]

□ Lock data type settings against changes by the fixed-point tools

Rounding mode

Select the “rounding mode” for fixed-point operations. The sine table values do not obey this parameter; they always round to `Nearest`.

Overflow mode

Select the “overflow mode” for fixed-point operations. The sine table values do not obey this parameter; instead, they are always saturated.

Sine table data type

Choose how you specify the word length of the values of the sine table. The fraction length of the sine table values always equals the word length minus one. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Same word length as input`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16)`

The sine table values do not obey the **Rounding mode** and **Overflow mode** parameters; instead, they are always saturated and rounded to `Nearest`.

Product output data type

Specify the product output data type. See “Fixed-Point Data Types” on page 1-335 and “Multiplication Data Types” for illustrations depicting the use of the product output data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Product output data type** parameter.

See “Specify Data Types Using Data Type Assistant” in “Simulink User's Guide” for more information.

Accumulator data type

Specify the accumulator data type. See “Fixed-Point Data Types” on page 1-335 for illustrations depicting the use of the accumulator data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Accumulator data type** parameter.

See “Specify Data Types Using Data Type Assistant” in “Simulink User's Guide” for more information.

Output data type

Specify the output data type. See “Fixed-Point Data Types” on page 1-335 for illustrations depicting the use of the output data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`.

  When you select `Inherit: Inherit via internal rule`, the block calculates the output word length and fraction length automatically. The internal rule first calculates an ideal output word length and fraction length using the following equations:

$$WL_{ideal\ output} = WL_{input} + floor(\log_2(DCT\ length - 1)) + 1$$

$$FL_{ideal\ output} = FL_{input}$$

  Using these ideal results, the internal rule then selects word lengths and fraction lengths that are appropriate for your hardware. For more information, see “Inherit via Internal Rule”.
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Specify Block Output Data Types” in “Simulink User's Guide” for more information.

Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Output	• Double-precision floating point • Single-precision floating point • Fixed point (signed only) • 8-, 16-, and 32-bit signed integers

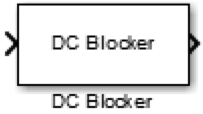
DC Blocker

Block DC component

Library

Signal Operations

`dspsigops`

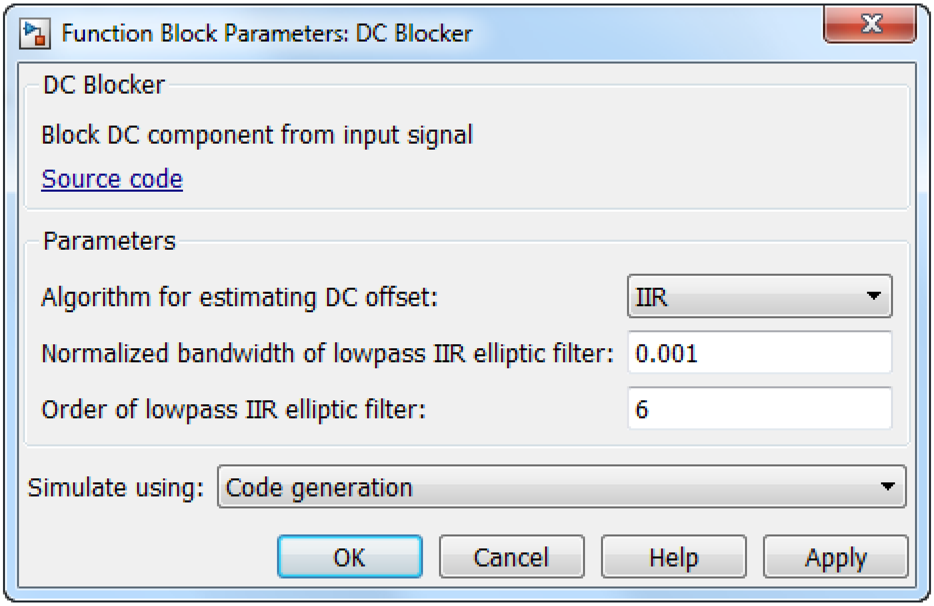


Description

The DC Blocker block removes the DC component of the input signal.

Dialog Box

The DC Blocker dialog box changes based on how the DC offset is estimated. The dialog box for the `IIR` method is shown below.



Function Block Parameters: DC Blocker

DC Blocker

Block DC component from input signal

Source code

Parameters

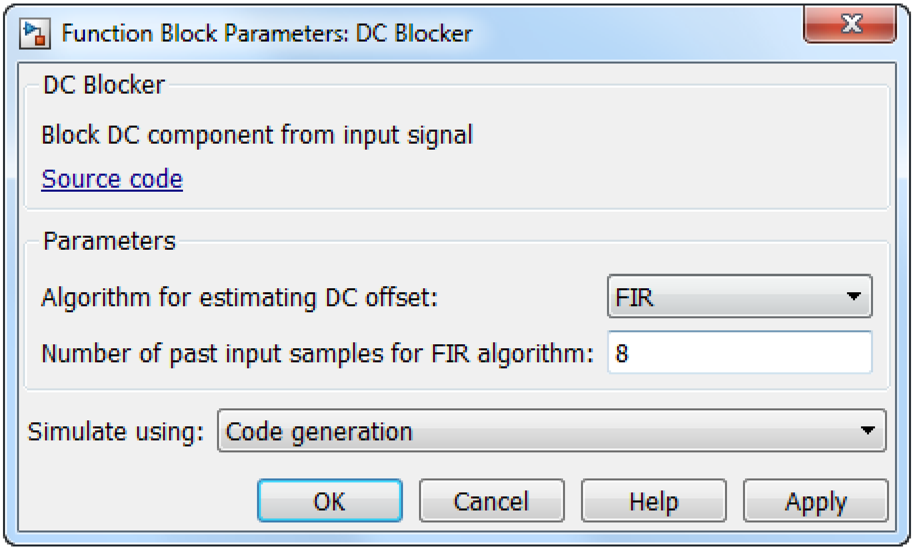
Algorithm for estimating DC offset: IIR

Normalized bandwidth of lowpass IIR elliptic filter: 0.001

Order of lowpass IIR elliptic filter: 6

Simulate using: Code generation

The dialog box for the `FIR` method is shown below.



Function Block Parameters: DC Blocker

DC Blocker

Block DC component from input signal

Source code

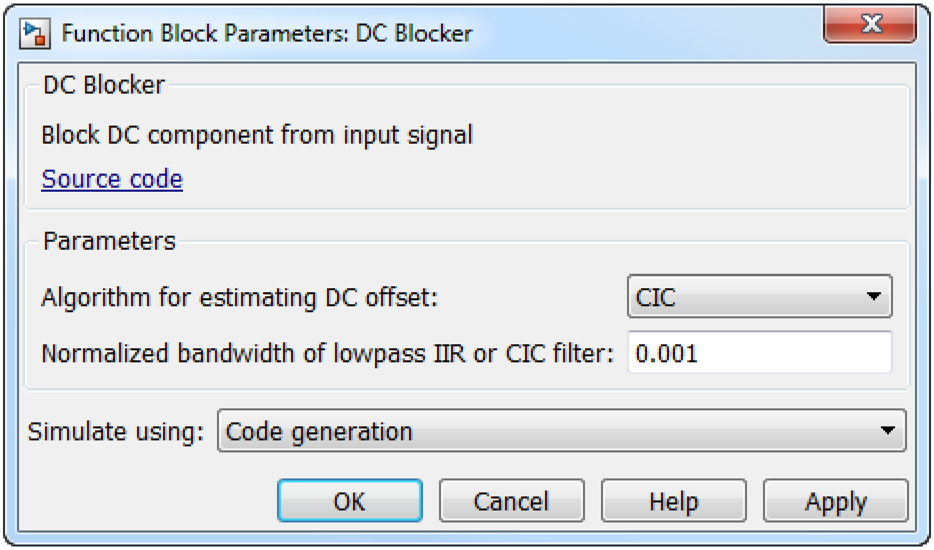
Parameters

Algorithm for estimating DC offset: FIR

Number of past input samples for FIR algorithm: 8

Simulate using: Code generation

The dialog box for the `CIC` method is shown below.



Function Block Parameters: DC Blocker

DC Blocker

Block DC component from input signal

Source code

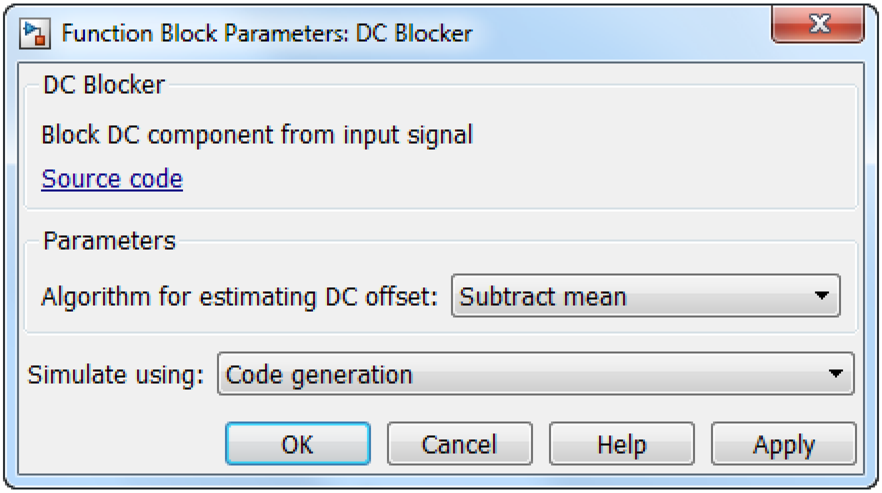
Parameters

Algorithm for estimating DC offset: CIC

Normalized bandwidth of lowpass IIR or CIC filter: 0.001

Simulate using: Code generation

The dialog box for the `Subtract mean` method is shown below.



Function Block Parameters: DC Blocker

DC Blocker

Block DC component from input signal

Source code

Parameters

Algorithm for estimating DC offset: Subtract mean

Simulate using: Code generation

Algorithm for estimating DC offset

Specify the algorithm used for estimating the DC offset. Select from the following:

- `IIR` uses a recursive estimate based on a narrow, lowpass elliptic filter. This algorithm typically uses less memory than FIR and is more efficient.
- `FIR` uses a nonrecursive, moving-average estimate. This algorithm typically uses more memory than IIR and is less efficient.
- `CIC` uses a lowpass filter that does not employ any multipliers. If the algorithm is `CIC`, then fixed-point data must be input to the DC Blocker.
- `Subtract mean` computes the mean of the signal and subtracts it from the input.

Normalized bandwidth of lowpass IIR or CIC filter

Specify the normalized filter bandwidth as a real scalar greater than 0 and less than 1. The DC Blocker uses this parameter only when the estimation algorithm is set to `IIR` or `CIC`.

Order of lowpass IIR elliptic filter

Specify the filter order as an integer greater than 3. The DC Blocker uses this parameter only when the estimation algorithm is set to `IIR`.

Number of past input samples for FIR algorithm

Specify, as a positive integer, the number of samples to use when the estimation algorithm is set to `FIR`.

Simulate using

Select the simulation type from the following:

- `Code generation`
- `Interpreted execution`

Examples

Use DC Blocker to Remove DC Component of Signal

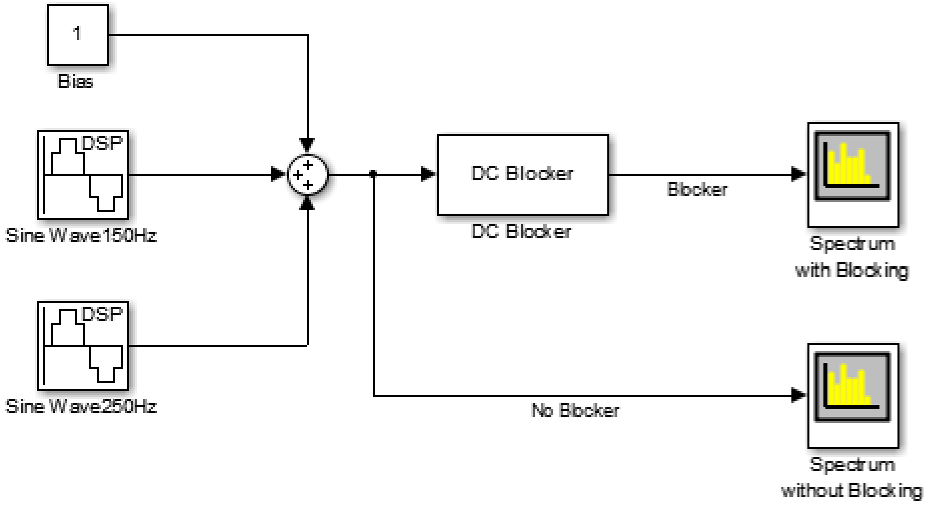
This example shows how to use the DC Blocker to remove the DC component of a signal.

Load the DC Blocker example, ex_dc_blocker, from the MATLAB command prompt.

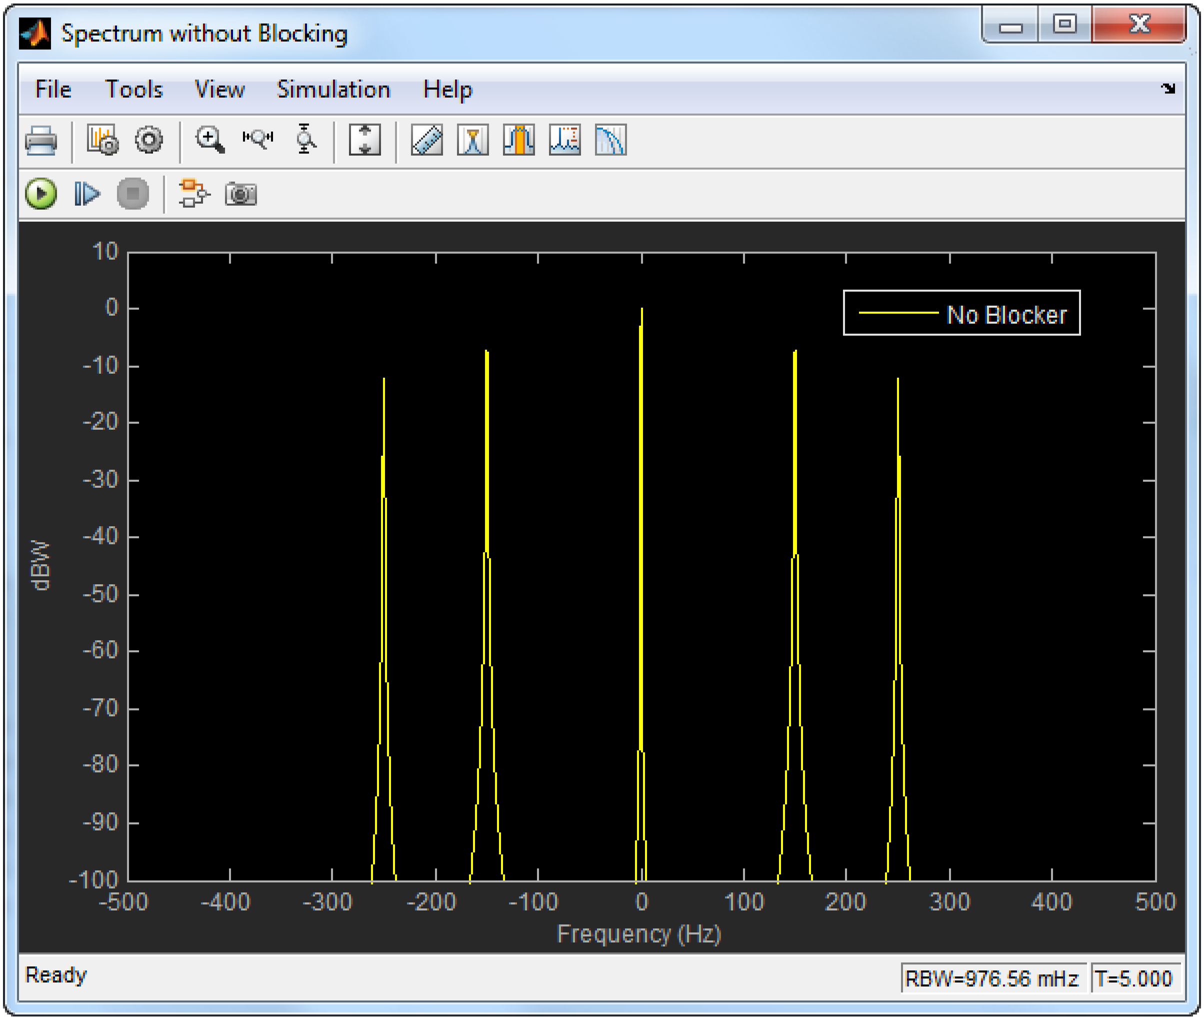
```
ex_dc_blocker
```

The spectral output from the DC Blocker is displayed in Spectrum with Blocking, while the spectrum of the input signal is displayed in Spectrum without Blocking.

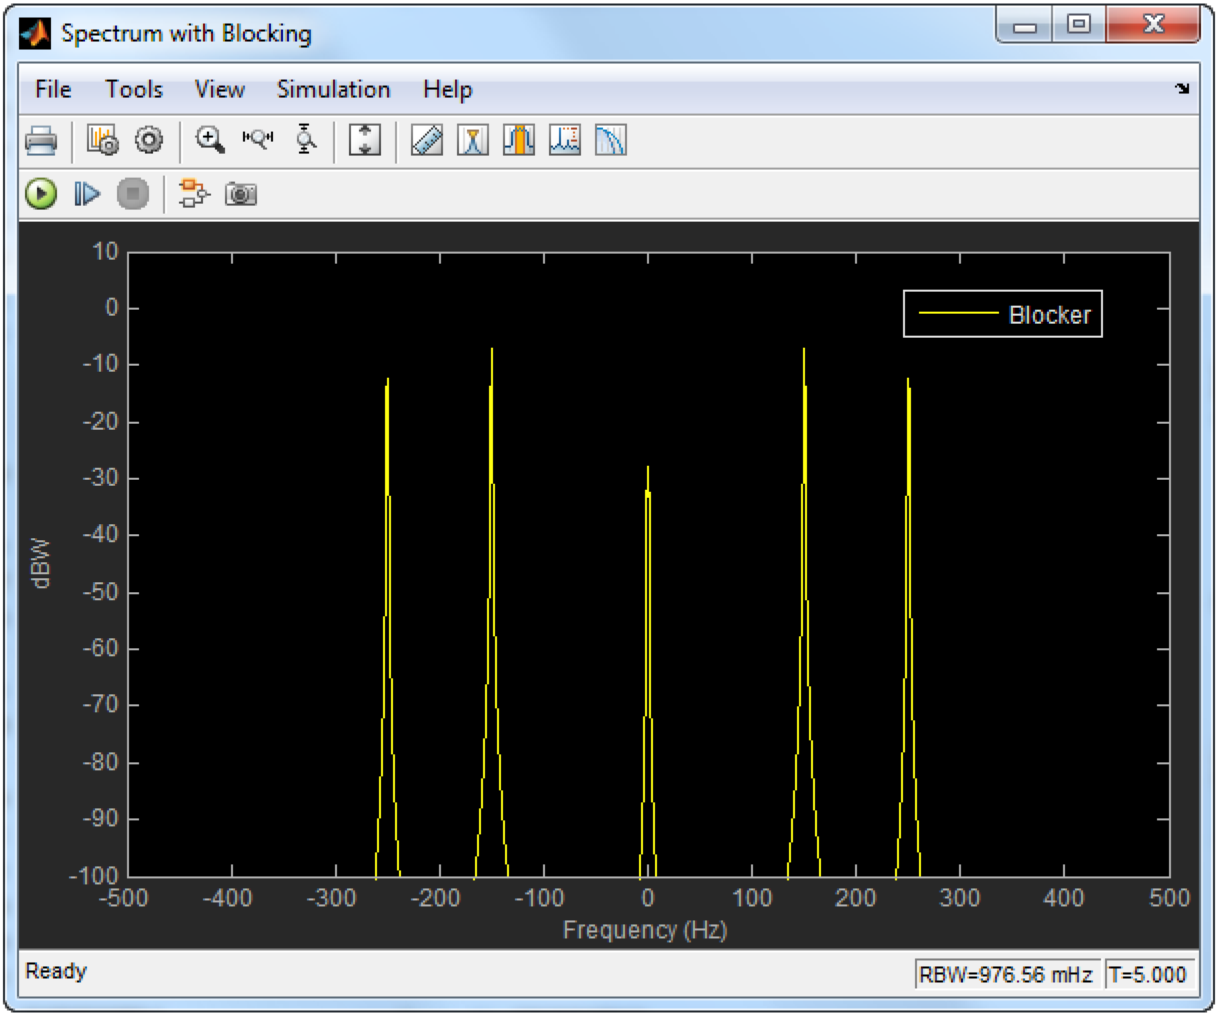
The two sine wave sources are set to use 1000 samples per frame because the `Subtract mean` estimation algorithm requires a statistically significant number of samples to calculate a valid mean.



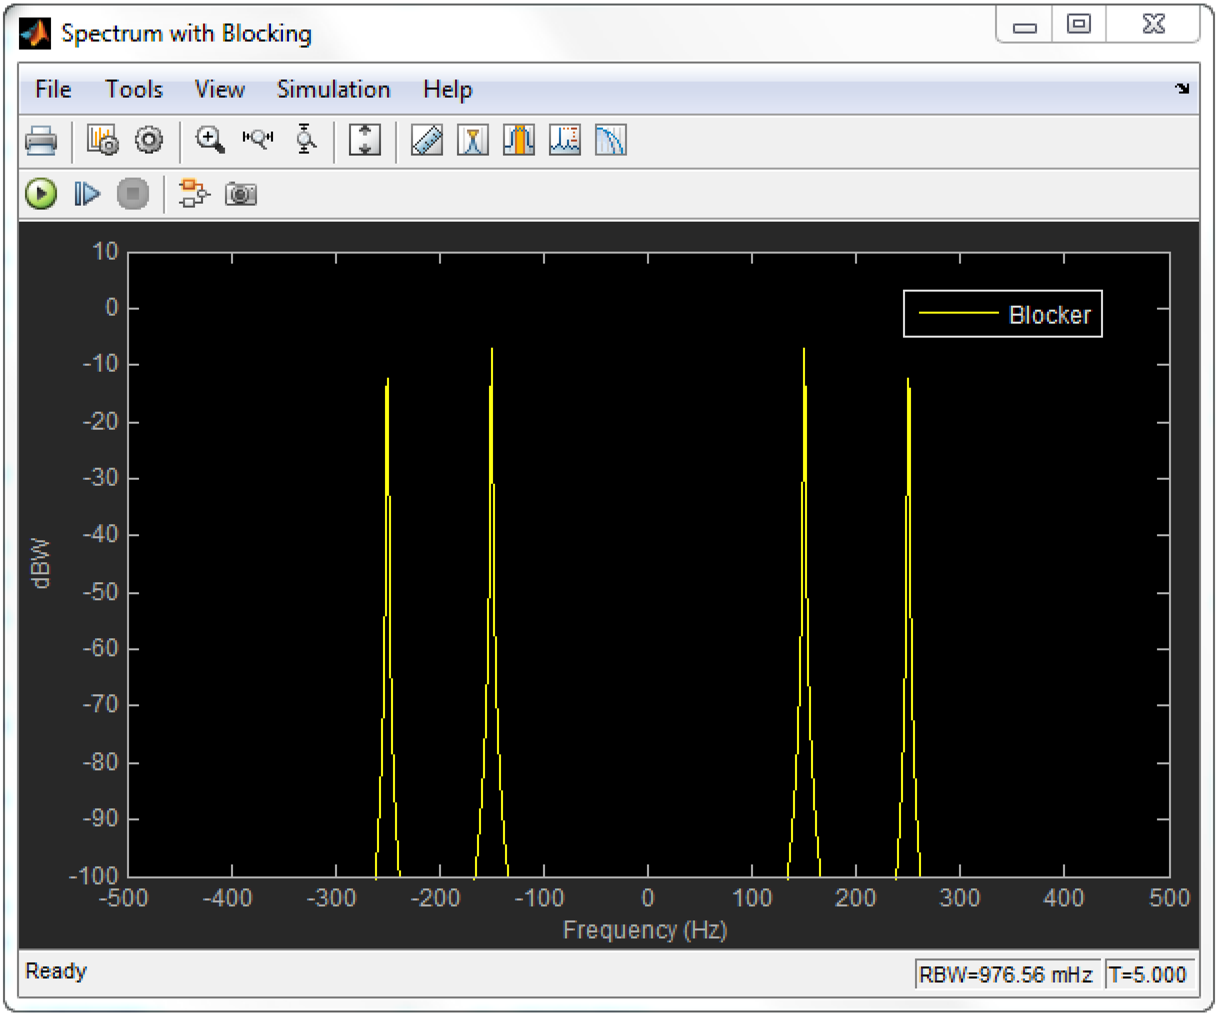
In the model, run the simulation. The spectrum of the input signal shows tones at 150 Hz and 250 Hz and a significant (0 dBW) DC component.



Using the default `IIR` setting for the DC Blocker estimation algorithm, the tones at 150 Hz and 250 Hz are unaffected while the DC component has been attenuated by 30 dB.



Select the DC Blocker block by double-clicking on it and change the algorithm type from `IIR` to `Subtract mean`. Rerun the simulation. The spectral output from the DC Blocker shows that the `Subtract mean` estimation method results in a DC component of less than −100 dBW.



Try all three estimation methods. Modify the `IIR` and `FIR` parameters to illustrate the performance of the DC Blocker using the various estimation techniques.

DC Blocker with Fixed Point Data

This example shows how to use the DC Blocker to remove a DC offset from fixed point data.

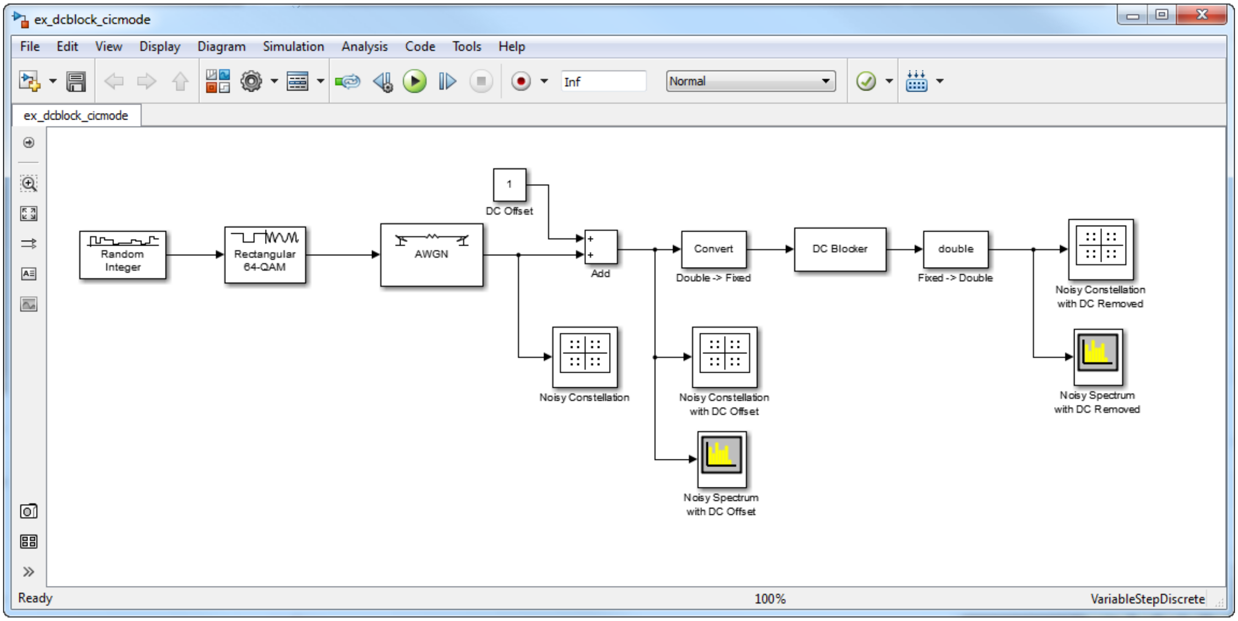
Load the DC Blocker example, ex_dcblock_cicmode, from the MATLAB command prompt.

```
ex_dcblock_cicmode
```

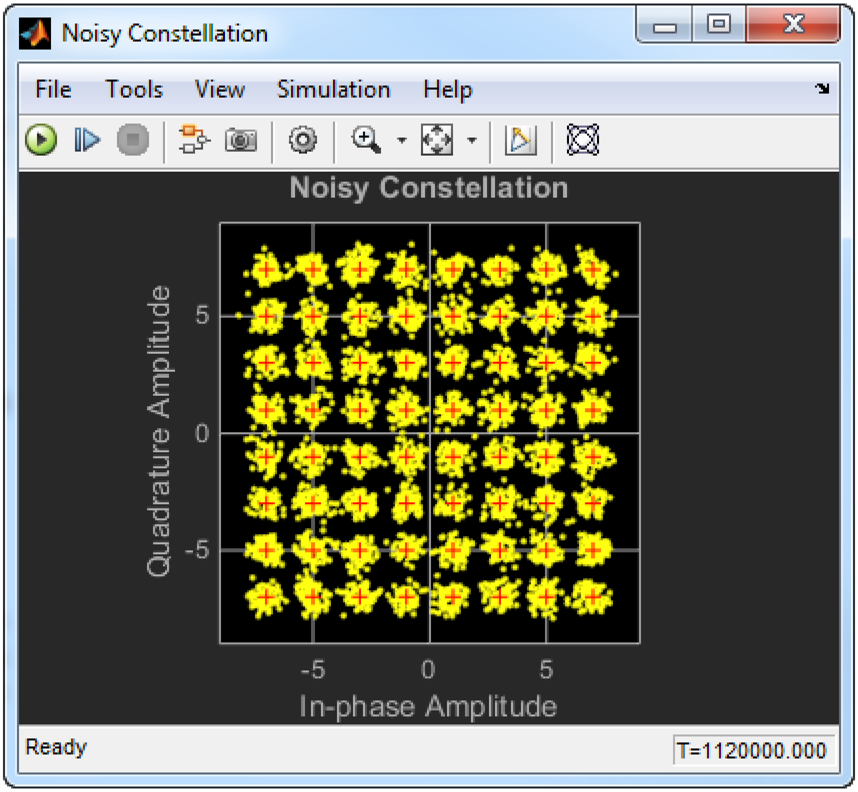
In the model:

- 64-QAM data passes through an AWGN channel.
- A DC offset of 1 is added to the signal .
- The Double -> Fixed block converts the data to 16-bit fixed point.
- The fixed-point data passes through the DC Blocker, which has the CIC algorithm selected, to remove the DC offset.
- The Fixed -> Double block converts the data back to floating point.

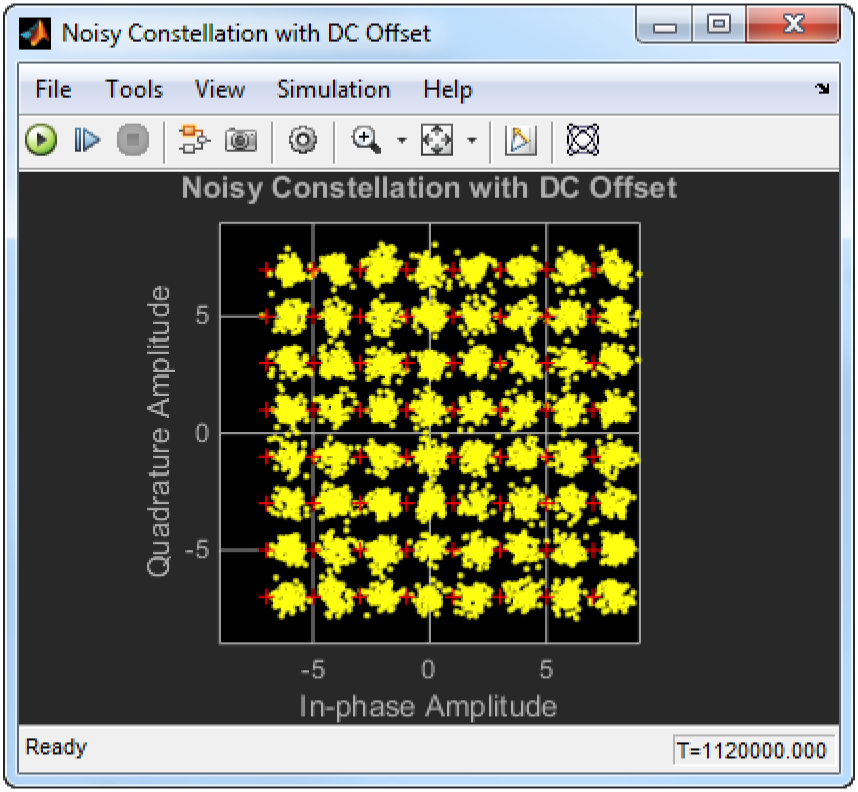
Constellation diagrams and spectrum analyzers are used to show the improvements from the DC Blocker.



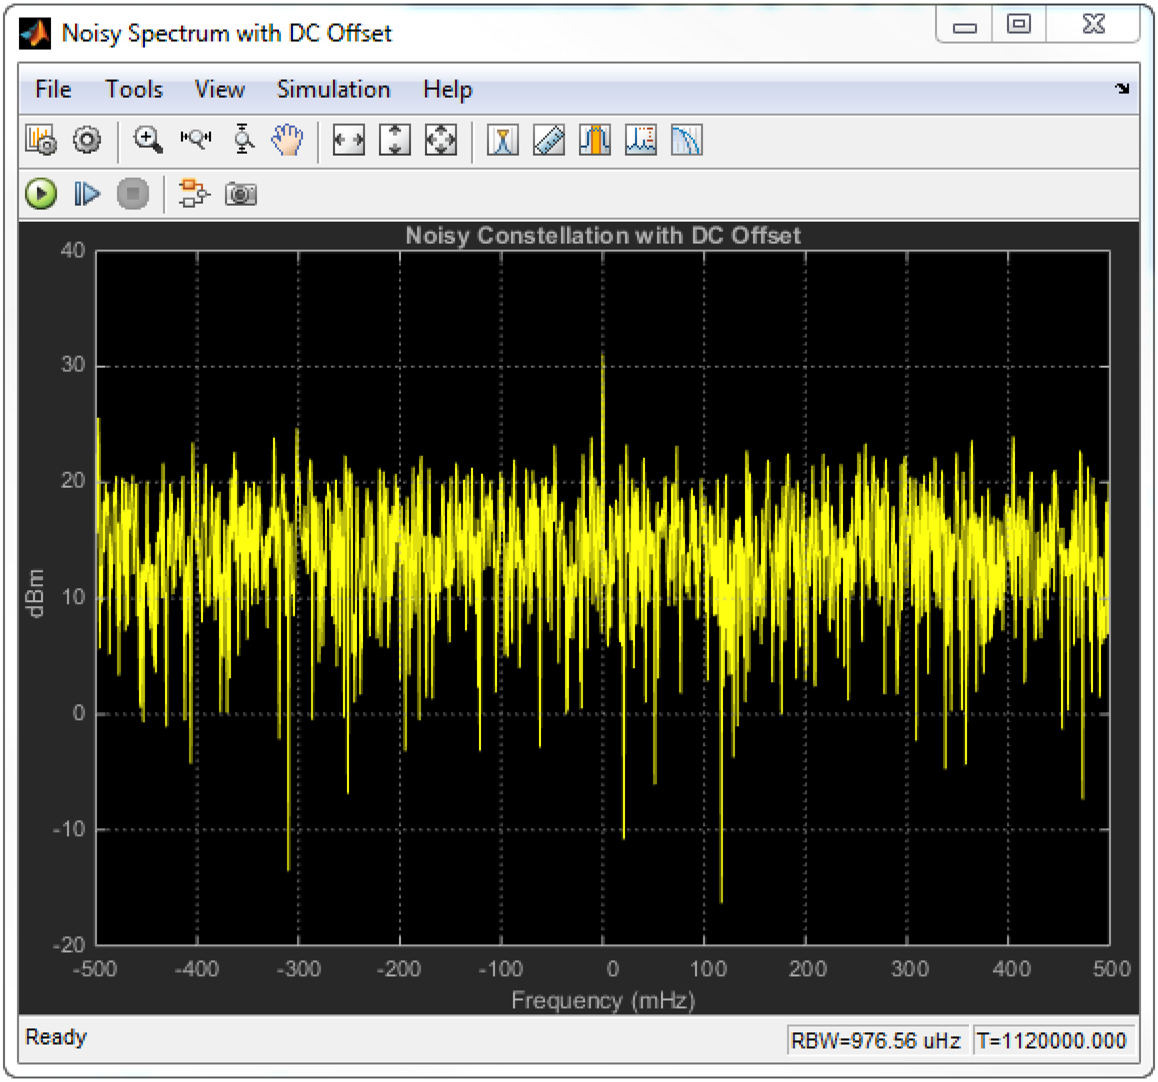
Run the simulation. The first constellation diagram, Noisy Constellation, shows a 64-QAM signal with white noise.



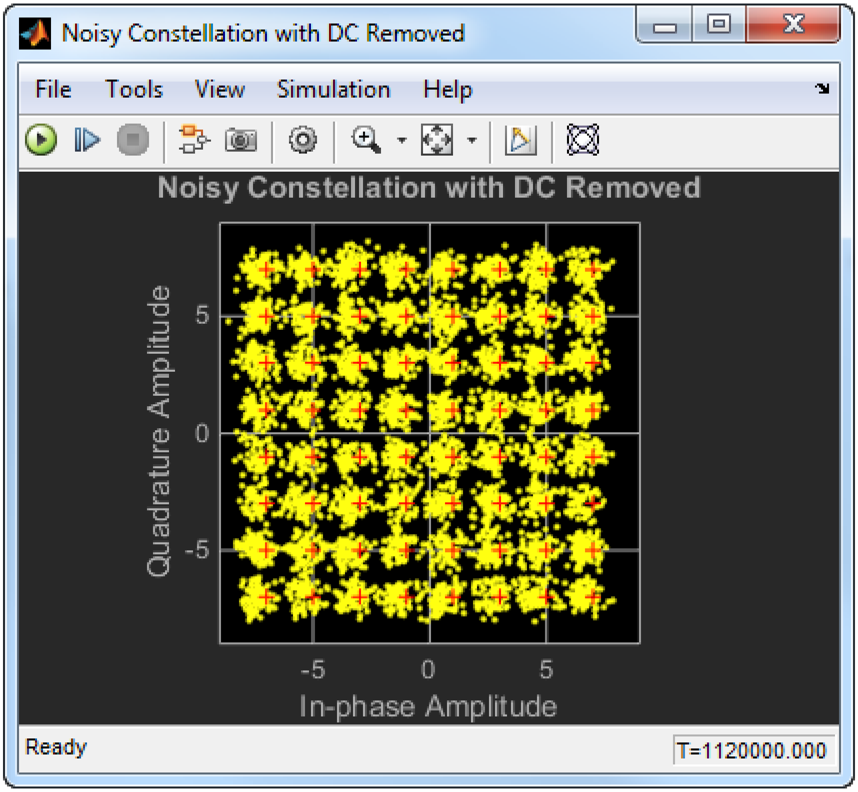
Observe the constellation diagram of the signal after the DC offset of 1 has been applied. The signal, represented by the yellow data points, has shifted one unit to the right.



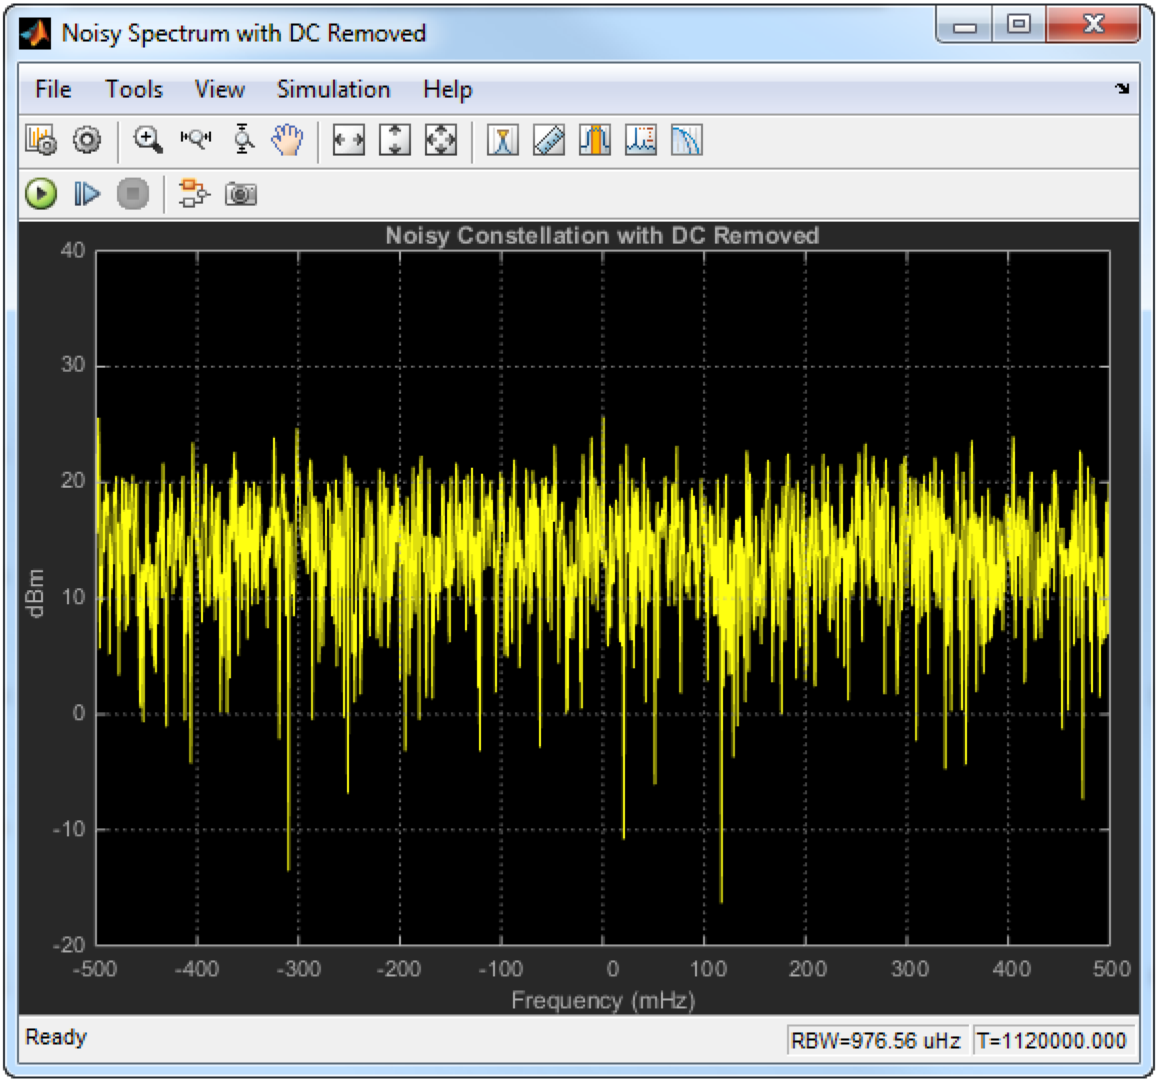
Look at the spectrum of the noisy signal with the DC offset. Notice that the signal has a peak at 0 Hz.



Observe the noisy constellation after the DC offset is removed. The signal has shifted back to the left so that the data clusters are aligned with their corresponding reference points.



Observe the spectrum of the noisy signal after the DC Blocker removes the offset. The spectral peak at 0 Hz has been removed.



RBW=976.56 uHz T=1120000.000

To visualize the efficiency of the DC Blocker under different conditions, try changing the DC offset or the **Normalized bandwidth of lowpass IIR or CIC filter** parameter.

Algorithms

This block implements the algorithm, inputs, and outputs described on the `dsp.DCBlocker` reference page. The object properties correspond to the block parameters.

HDL Code Generation

This block supports HDL code generation using HDL Coder. HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic. For more information on implementations, properties, and restrictions for HDL code generation, see DC Blocker.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point • Fixed point (signed) • 8-, 16-, and 32-bit signed integers
Output	• Double-precision floating point • Single-precision floating point • Fixed point (signed) • 8-, 16-, and 32-bit signed integers

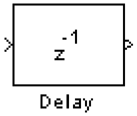
Delay

Delay discrete-time input by specified number of samples or frames

Library

Signal Operations

`dspsigops`



Description

Note: Certain features of this block will be removed in a future release. See “Functionality being removed or replaced for blocks and System objects”.

The Delay block delays a discrete-time input by the number of samples or frames specified in the **Delay units** and **Delay** parameters. The **Delay** value must be an integer value greater than or equal to zero. When you enter a value of zero for the **Delay** parameter, any initial conditions you might have entered have no effect on the output.

The Delay block allows you to set the initial conditions of the signal that is being delayed. The initial conditions must be numeric.

Frame-Based Processing

When you set the **Input processing** parameter to `Columns as channels (frame based)`, the block treats each column of the M-by-N input matrix as an independent channel. The block delays each channel of the input as specified by the **Delay** parameter.

The **Delay** parameter can be a scalar integer by which the block equally delays all channels or a vector whose length is equal to the number of channels.

There are four different choices for initial conditions. The initial conditions can be the same or different for each channel. They can also be constant or varying along each channel. See the “Frame-Based Processing Examples” on page 1-361 section for more information.

Sample-Based Processing

When you set the **Input processing** parameter to `Elements as channels (sample based)`, the block treats each element of the N-D input array as an independent channel. Thus, the total number of channels in the input is equal to the product of the input dimensions. The dimension of the output is the same as that of the input.

The **Delay** parameter can be a scalar integer by which to equally delay all channels or an N-D array of the same dimensions as the input array, containing nonnegative integers that specify the number of sample intervals to delay each channel of the input.

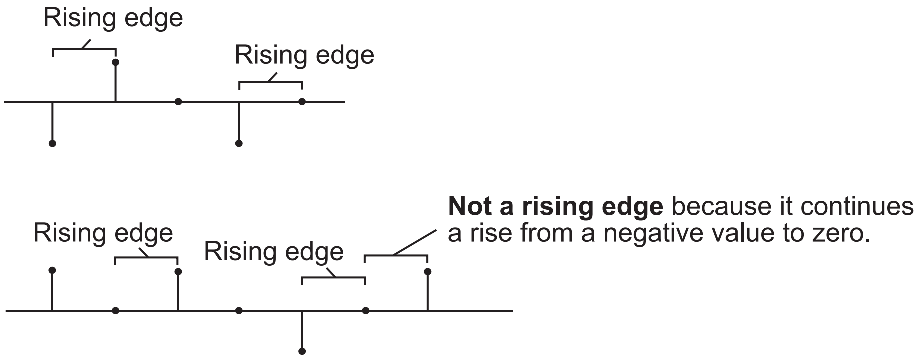
There are four different choices for initial conditions. The initial conditions can be the same or different for each channel. They can also be the same or different within a channel. See the “Sample-Based Processing Examples” on page 1-365 section for more information.

Resetting the Delay

The Delay block resets the delay whenever it detects a reset event at the optional `Rst` port. The reset sample time must be a positive integer multiple of the input sample time.

The reset event is specified by the **Reset port** parameter, and can be one of the following:

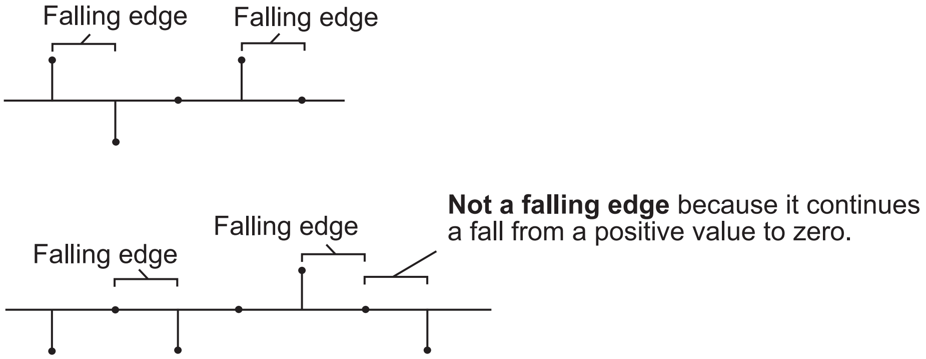
- `None` disables the `Rst` port.
- `Rising edge` triggers a reset operation when the `Rst` input does one of the following:
  - Rises from a negative value to a positive value or zero
  - Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero (see the following figure)



Rising edge
Rising edge
Rising edge
Rising edge
Not a rising edge because it continues a rise from a negative value to zero.

- `Falling edge` triggers a reset operation when the `Rst` input does one of the following:

  - Falls from a positive value to a negative value or zero
  - Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero (see the following figure)



Falling edge
Falling edge
Falling edge
Falling edge
Not a falling edge because it continues a fall from a positive value to zero.

- `Either edge` triggers a reset operation when the `Rst` input is `Rising edge` or `Falling edge` (as described earlier).
- `Non-zero sample` triggers a reset operation at each sample time that the `Rst` input is not zero.

Note When running simulations in the Simulink MultiTasking mode, reset signals have a one-sample latency. Therefore, when the block detects a reset event, there is a one-sample delay at the reset port rate before the block applies the reset. For more information on latency and the Simulink tasking modes, see “Excess Algorithmic Delay (Tasking Latency)” and “Scheduling ” in the *Simulink Coder User's Guide*.

This block supports Simulink virtual buses.

Examples

Frame-Based Processing Examples

There are four different choices for initial conditions. The initial conditions can be the same or different for each channel. They can also be constant or varying along each channel. The next sections describe the behavior of the block for each of these four cases:

- “Case 1 — Use the Same Initial Conditions for Each Channel and Within a Channel” on page 1-361
- “Case 2 — Use Different Initial Conditions for Each Channel and the Same Initial Conditions Within a Channel” on page 1-362
- “Case 3 — Use the Same Initial Conditions for Each Channel and Different Initial Conditions Within a Channel” on page 1-363
- “Case 4 — Use Different Initial Conditions for Each Channel and Within a Channel” on page 1-364

Case 1 — Use the Same Initial Conditions for Each Channel and Within a Channel

Enter a scalar value for the initial conditions. This value is used as the constant initial condition value for each of the channels.

For example, suppose your input is a matrix and you set the **Input processing** parameter to `Columns as channels (frame based)`.

$$\begin{bmatrix}1&1&1\\2&2&2\\3&3&3\end{bmatrix},\begin{bmatrix}4&4&4\\5&5&5\\6&6&6\end{bmatrix},\begin{bmatrix}7&7&7\\8&8&8\\9&9&9\end{bmatrix},\ldots$$

You want the initial conditions of your three-channel signal to be identical and zero for the first frame:

1 Set the **Delay (frames)** parameter to `1`.
2 Clear the **Specify different initial conditions for each channel** and the **Specify different initial conditions within a channel** check boxes.
3 Set the **Initial conditions** parameter to a scalar value of `0`.

   The output of the delay block is

$$\begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}, \begin{bmatrix} 1 & 1 & 1 \\ 2 & 2 & 2 \\ 3 & 3 & 3 \end{bmatrix}, \begin{bmatrix} 4 & 4 & 4 \\ 5 & 5 & 5 \\ 6 & 6 & 6 \end{bmatrix}, \begin{bmatrix} 7 & 7 & 7 \\ 8 & 8 & 8 \\ 9 & 9 & 9 \end{bmatrix}, \ldots$$

   `0`, the scalar initial condition value, is used across the channels and within the channels for the first frame. This frame is the output at sample time zero.

Case 2 — Use Different Initial Conditions for Each Channel and the Same Initial Conditions Within a Channel

The initial conditions must be a vector of length N, where $N \geq 1$. N is also equal to the number of channels in your signal. These initial condition values are used as the constant initial condition value for each of the channels.

For example, suppose your input is a matrix and you set the **Input processing** parameter to `Columns as channels (frame based)`.

$$\begin{bmatrix} 1 & 1 & 1 \\ 2 & 2 & 2 \\ 3 & 3 & 3 \end{bmatrix}, \begin{bmatrix} 4 & 4 & 4 \\ 5 & 5 & 5 \\ 6 & 6 & 6 \end{bmatrix}, \begin{bmatrix} 7 & 7 & 7 \\ 8 & 8 & 8 \\ 9 & 9 & 9 \end{bmatrix}, \ldots$$

You want the initial conditions of your three-channel signal to be `[0 10 20]` for the first frame:

1 Set the **Delay (frames)** parameter to `1`.
2 Select the **Specify different initial conditions for each channel** check box.
3 Clear the **Specify different initial conditions within a channel** check box.

4. Set the **Initial conditions** parameter to `[0 10 20]`.

   The output of the delay block is

$$\begin{bmatrix} 0 & 10 & 20 \\ 0 & 10 & 20 \\ 0 & 10 & 20 \end{bmatrix}, \begin{bmatrix} 1 & 1 & 1 \\ 2 & 2 & 2 \\ 3 & 3 & 3 \end{bmatrix}, \begin{bmatrix} 4 & 4 & 4 \\ 5 & 5 & 5 \\ 6 & 6 & 6 \end{bmatrix}, \begin{bmatrix} 7 & 7 & 7 \\ 8 & 8 & 8 \\ 9 & 9 & 9 \end{bmatrix}, \ldots$$

   The initial condition vector expands to create the frame that is output at sample time zero. Different initial conditions are used for each channel, but the same initial condition value is used with a channel.

Case 3 — Use the Same Initial Conditions for Each Channel and Different Initial Conditions Within a Channel

In this case, the **Delay** parameter can be a scalar integer by which to equally delay all channels or a vector whose length is equal to the number of channels. All the values of this vector must be equal.

Enter the initial conditions as a vector. These values are used as the initial condition value along each of the channels to be delayed. The initial condition vector must have length equal to the value of the **Delay (frames)** parameter multiplied by the frame length. For example, if you want to delay your signal by two frames with frame length two and an initial condition value of 3, enter your initial condition vector as `[3 3 3 3]`.

For example, suppose your input is a matrix and you set the **Input processing** parameter to `Columns as channels (frame based)`.

$$\begin{bmatrix} 1 & 1 & 1 \\ 2 & 2 & 2 \\ 3 & 3 & 3 \end{bmatrix}, \begin{bmatrix} 4 & 4 & 4 \\ 5 & 5 & 5 \\ 6 & 6 & 6 \end{bmatrix}, \begin{bmatrix} 7 & 7 & 7 \\ 8 & 8 & 8 \\ 9 & 9 & 9 \end{bmatrix}, \ldots$$

You want the initial conditions of your three-channel signal to be the same along each of the channels to be delayed:

1. Set the **Delay (frame)** parameter to `1`.
2. Clear the **Specify different initial conditions for each channel** check box.

3 Select the **Specify different initial conditions within a channel** check box.

4 Set the **Initial conditions** parameter to `[10 20 30]`.

The output of the delay block is

$$\begin{bmatrix}10 & 10 & 10\\20 & 20 & 20\\30 & 30 & 30\end{bmatrix},\begin{bmatrix}1 & 1 & 1\\2 & 2 & 2\\3 & 3 & 3\end{bmatrix},\begin{bmatrix}4 & 4 & 4\\5 & 5 & 5\\6 & 6 & 6\end{bmatrix},\begin{bmatrix}7 & 7 & 7\\8 & 8 & 8\\9 & 9 & 9\end{bmatrix},\ldots$$

The initial condition vector defines the initial condition values within each of the three channels. The same initial conditions are used for each channel, but different initial condition values are used with a channel.

Case 4 — Use Different Initial Conditions for Each Channel and Within a Channel

Enter a cell array for your initial condition values. Or, when you have a scalar delay value, you can enter the initial conditions as a matrix.

For example, suppose your input is a matrix and you set the **Input processing** parameter to `Columns as channels (frame based)`.

$$\begin{bmatrix}1 & 1 & 1\\2 & 2 & 2\\3 & 3 & 3\end{bmatrix},\begin{bmatrix}4 & 4 & 4\\5 & 5 & 5\\6 & 6 & 6\end{bmatrix},\begin{bmatrix}7 & 7 & 7\\8 & 8 & 8\\9 & 9 & 9\end{bmatrix},\ldots$$

You want the initial conditions of your three-channel signal to be different for each channel and along each channel.

1 Set the **Delay (frames)** parameter to `1`.

2 Select the **Specify different initial conditions for each channel** and the **Specify different initial conditions within a channel** check boxes.

3 Set the **Initial conditions** parameter to either `[10 20 30; 40 50 60; 70 80 90]` or `{[10 40 70];[20 50 80];[30 60 90]}`. Each cell of the cell array represents the delay along one channel.

Regardless of whether you use a matrix or cell array, the output of the delay block is

$$\begin{bmatrix} 10 & 20 & 30 \\ 40 & 50 & 60 \\ 70 & 80 & 90 \end{bmatrix}, \begin{bmatrix} 1 & 1 & 1 \\ 2 & 2 & 2 \\ 3 & 3 & 3 \end{bmatrix}, \begin{bmatrix} 4 & 4 & 4 \\ 5 & 5 & 5 \\ 6 & 6 & 6 \end{bmatrix}, \begin{bmatrix} 7 & 7 & 7 \\ 8 & 8 & 8 \\ 9 & 9 & 9 \end{bmatrix} \ldots$$

The initial condition matrix is the output at sample time zero. The elements of the initial condition cell array define the initial condition values within each channel. The first element, a vector, represents the initial conditions within channel 1. The second element, a vector, represents the initial conditions within channel 2, and so on. Different initial conditions are used for each channel and within the channels.

Sample-Based Processing Examples

There are four different choices for initial conditions. The initial conditions can be the same or different for each channel. They can also be the same or different along each channel. The next sections describe the behavior of the block for each of these four cases:

- "Case 1 — Use the Same Initial Conditions for Each Channel and Within a Channel" on page 1-365
- "Case 2 — Use Different Initial Conditions for Each Channel and the Same Initial Conditions Within a Channel" on page 1-366
- "Case 3 — Use the Same Initial Conditions for Each Channel and Different Initial Conditions Within a Channel" on page 1-367
- "Case 4 — Use Different Initial Conditions for Each Channel and Within a Channel" on page 1-368

Case 1 — Use the Same Initial Conditions for Each Channel and Within a Channel

Enter a scalar value for the initial conditions. This value is used as the constant initial condition value for each of the channels.

For example, suppose your input is a matrix and you set the **Input processing** parameter to `Elements as channels (sample based)`.

$$\begin{bmatrix} 1 & 1 \\ 1 & 1 \end{bmatrix}, \begin{bmatrix} 2 & 2 \\ 2 & 2 \end{bmatrix}, \begin{bmatrix} 3 & 3 \\ 3 & 3 \end{bmatrix}, \ldots$$

You want the initial conditions of your four-channel signal to be identical and zero for the first two samples:

1 Set the **Delay (samples)** parameter to `2`.
2 Clear the **Specify different initial conditions for each channel** and **Specify different initial conditions within a channel** check boxes.
3 Set the **Initial conditions** parameter to a scalar value of `0`.

The output of the delay block is

$$\begin{bmatrix}0 & 0\\0 & 0\end{bmatrix},\begin{bmatrix}0 & 0\\0 & 0\end{bmatrix},\begin{bmatrix}1 & 1\\1 & 1\end{bmatrix},\begin{bmatrix}2 & 2\\2 & 2\end{bmatrix},\begin{bmatrix}3 & 3\\3 & 3\end{bmatrix},\ldots$$

`0`, the scalar initial condition value, is used for each channel and within the channels. It is the output at sample time zero and sample time one.

Case 2 — Use Different Initial Conditions for Each Channel and the Same Initial Conditions Within a Channel

The initial conditions must be an N-D array for N-D input. The initial conditions must have the same dimensions as the input data. These initial condition values are used as the constant initial condition value for each of the channels.

For example, suppose your input is a matrix and you set the **Input processing** parameter to `Elements as channels (sample based)`.

$$\begin{bmatrix}1 & 1\\1 & 1\end{bmatrix},\begin{bmatrix}2 & 2\\2 & 2\end{bmatrix},\begin{bmatrix}3 & 3\\3 & 3\end{bmatrix},\ldots$$

You want the initial conditions of your four-channel signal to be

$$\begin{bmatrix}7 & 9\\11 & 13\end{bmatrix}$$

for the first two samples:

1 Set the **Delay (samples)** parameter to `2`.
2 Select the **Specify different initial conditions for each channel** check box.

3. Clear the **Specify different initial conditions within a channel** check box.
4. Set the **Initial conditions** parameter to `[7 9; 11 13]`.

   The output of the delay block is

   $$\begin{bmatrix} 7 & 9 \\ 11 & 13 \end{bmatrix}, \begin{bmatrix} 7 & 9 \\ 11 & 13 \end{bmatrix}, \begin{bmatrix} 1 & 1 \\ 1 & 1 \end{bmatrix}, \begin{bmatrix} 2 & 2 \\ 2 & 2 \end{bmatrix}, \begin{bmatrix} 3 & 3 \\ 3 & 3 \end{bmatrix}, \ldots$$

   The initial condition matrix is the output at sample time zero and sample time one. Different initial conditions are used for each channel; the same initial condition value is used within a channel.

Case 3 — Use the Same Initial Conditions for Each Channel and Different Initial Conditions Within a Channel

In this case, for N-D sample-based inputs, the initial conditions parameter must be a vector whose length is equal to the delay value, specified by the **Delay** parameter. The values in this vector are used as the initial condition values along each of the channels to be delayed.

For example, suppose your input is a matrix and you set the **Input processing** parameter to `Elements as channels (sample based)`.

$$\begin{bmatrix} 1 & 1 \\ 1 & 1 \end{bmatrix}, \begin{bmatrix} 2 & 2 \\ 2 & 2 \end{bmatrix}, \begin{bmatrix} 3 & 3 \\ 3 & 3 \end{bmatrix}, \ldots$$

You want the initial conditions of your four channel signal to be the same along each of the channels to be delayed:

1. Set the **Delay (samples)** parameter to `2`.
2. Clear the **Specify different initial conditions for each channel** check box.
3. Select the **Specify different initial conditions within a channel** check box.
4. Set the **Initial conditions** parameter to `[10 20]`.

   The output of the delay block is

   $$\begin{bmatrix} 10 & 10 \\ 10 & 10 \end{bmatrix}, \begin{bmatrix} 20 & 20 \\ 20 & 20 \end{bmatrix}, \begin{bmatrix} 1 & 1 \\ 1 & 1 \end{bmatrix}, \begin{bmatrix} 2 & 2 \\ 2 & 2 \end{bmatrix}, \begin{bmatrix} 3 & 3 \\ 3 & 3 \end{bmatrix}, \ldots$$

The first element of the initial conditions vector is the output, for all channels, at sample time zero. The second element of the initial conditions vector is the output, for all channels, at sample time one. The same initial conditions are used for each channel, but different initial condition values are used within a channel.

Case 4 — Use Different Initial Conditions for Each Channel and Within a Channel

Enter a cell array for your initial condition values. The cell array must be the same size as your input signal. Each cell of the cell array represents the delay values for one channel, and must be a vector of size equal to the delay value. If you have a vector or scalar input and a scalar delay value, you can enter the initial conditions as a matrix.

For example, suppose your input is a matrix and you set the **Input processing** parameter to `Elements as channels (sample based)`.

$$[1\ \ 1],\ \ [2\ \ 2],\ \ [3\ \ 3],\ldots$$

You want the initial conditions of your two channel signal to be different for each channel and along each channel:

1. Set the **Delay (samples)** parameter to `2`.
2. Select the **Specify different initial conditions for each channel** and **Specify different initial conditions within a channel** check boxes.
3. Set the **Initial conditions** parameter to `[10 20; 30 40]`.

   The output of the delay block is

   $$[10\ \ 20],\ \ [30\ \ 40],\ \ [1\ \ 1],\ \ [2\ \ 2]\ldots$$

   The first row of the initial conditions vector is the output at sample time zero. The second row of the initial conditions vector is the output at sample time one. Different initial conditions are used for each channel and within the channels.

In addition, suppose your input is a matrix and you set the **Input processing** parameter to `Elements as channels (sample based)`.

$$\begin{bmatrix}1 & 1\\1 & 1\end{bmatrix}, \begin{bmatrix}2 & 2\\2 & 2\end{bmatrix}, \begin{bmatrix}3 & 3\\3 & 3\end{bmatrix}, \ldots$$

You want the initial conditions of your two-channel signal to be different for each channel and along each channel:

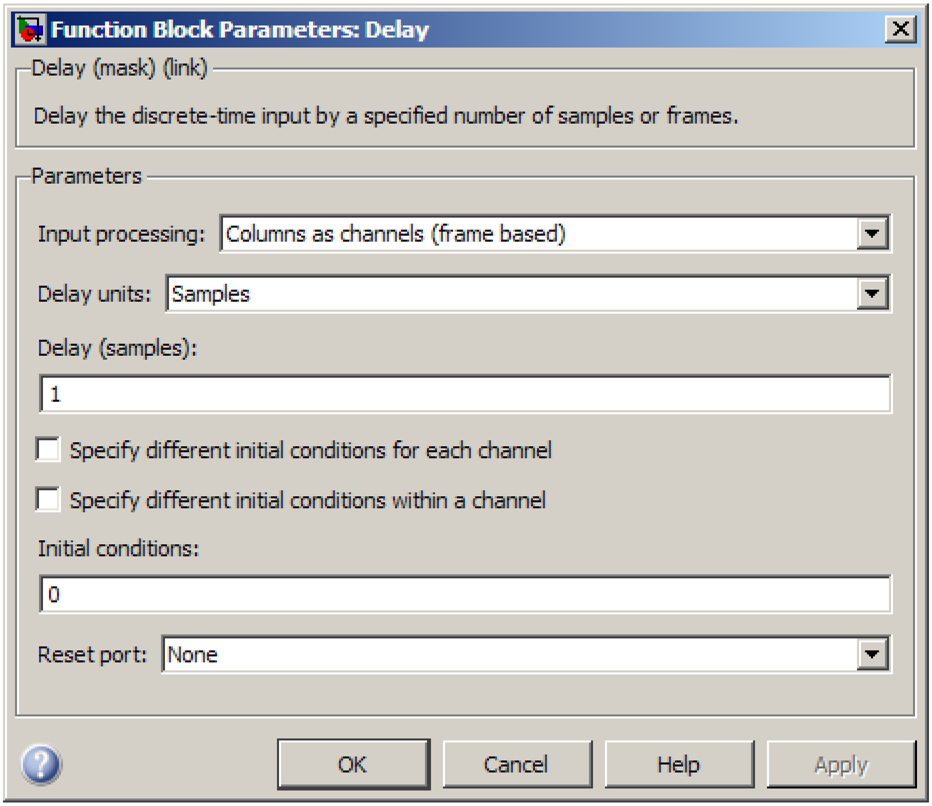
1. Set the **Delay (samples)** parameter to `2`.
2. Select the **Specify different initial conditions for each channel** and the **Specify different initial conditions within a channel** check boxes.
3. Set the **Initial conditions** parameter to `{[11 15] [12 16]; [13 17] [14 18]}`. The dimensions of the cell array match the dimensions of the input. Also, each element of the cell array represents the initial conditions within one channel.

   The output of the delay block is

$$\begin{bmatrix}11 & 12\\13 & 14\end{bmatrix}, \begin{bmatrix}15 & 16\\17 & 18\end{bmatrix}, \begin{bmatrix}1 & 1\\1 & 1\end{bmatrix}, \begin{bmatrix}2 & 2\\2 & 2\end{bmatrix}, \ldots$$

   Each element of the cell array represents the initial conditions within a channel. The first element, a vector, represents the initial conditions within channel 1. The second element, a vector, represents the initial conditions within channel 2, and so on. Different initial conditions are used for each channel and within the channels.

Dialog Box



Function Block Parameters: Delay

Delay (mask) (link)

Delay the discrete-time input by a specified number of samples or frames.

Parameters

Input processing: Columns as channels (frame based)

Delay units: Samples

Delay (samples):

1

□ Specify different initial conditions for each channel

□ Specify different initial conditions within a channel

Initial conditions:

0

Reset port: None

Input processing

Specify how the block should process the input. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` — When you select this option, the block treats each column of the input as a separate channel.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

Note: The option `Inherit from input (this choice will be removed - see release notes)` will be removed in a future release. See “Frame-Based Processing” in the *DSP System Toolbox Release Notes* for more information.

Delay units

Select whether you want to delay your input by a specified number of `Samples` or `Frames`. This parameter appears only when you set the **Input processing** parameter to `Columns as channels (frame based)`.

Delay (samples) or Delay (frames)

See “Sample-Based Processing” on page 1-359 and “Frame-Based Processing” on page 1-358 for a description of what format to use for each configuration of the block dialog.

Specify different initial conditions for each channel

Select this check box when you want the initial conditions to vary across the channels. When you do not select this check box, the initial conditions are the same across the channels.

Specify different initial conditions within a channel

Select this check box when you want the initial conditions to vary within the channels. When you do not select this check box, the initial conditions are the same within the channels.

Initial conditions

Enter a scalar, vector, matrix, or cell array of initial condition values, depending on your choice for the **Specify different initial conditions for each channel** and **Specify different initial conditions within a channel** check boxes. See “Sample-Based Processing” on page 1-359 and “Frame-Based Processing” on page 1-358 for a description of what format to use for each configuration of the block dialog.

Reset port

Determines the reset event that causes the block to reset the delay. For more information, see “Resetting the Delay” on page 1-359.

HDL Code Generation

This block supports HDL code generation using HDL Coder. HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

For more information on implementations, properties, and restrictions for HDL code generation, see Delay.

Supported Data Types

- Double-precision floating point
- Single-precision floating point
- Fixed point (signed and unsigned)
- Boolean
- 8-, 16-, and 32-bit signed integers
- 8-, 16-, and 32-bit unsigned integers

`dsp.Delay` | Unit Delay | Variable Fractional Delay | Variable Integer Delay

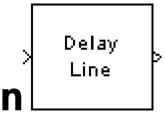
Delay Line

Rebuffer sequence of inputs

Library

Signal Management / Buffers

`dspbuff3`



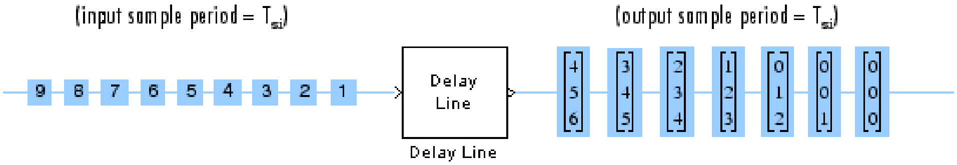
Description

The Delay Line block rebuffers a sequence of M_i-by-N matrix inputs into a sequence of M_o-by-N matrix outputs, where M_o is the output frame size you specify in the **Delay line size** parameter. Depending on whether M_o is greater than, less than, or equal to the input frame size, M_i, the output frames can be underlapped or overlapped. The block always performs frame-based processing and rebuffers each of the N input channels independently.

When $M_o > M_i$, the output frame overlap is the difference between the output and input frame size, M_o-M_i. When $M_o < M_i$, the output is underlapped; the Delay Line block discards the first M_i-M_o samples of each input frame so that only the last M_o samples are buffered into the corresponding output frame. When $M_o = M_i$, the output data is identical to the input data, but is delayed by the latency of the block. Due to the block's latency, the outputs are always delayed by one frame, the entries of which you specify in the **Initial conditions** parameter (see “Initial Conditions” on page 1-374).

The output frame period is equal to the input frame period (T_{fo}=T_{fi}). The output sample period, T_{so}, is therefore equal to T_{fi}/M_o, or equivalently, $T_{si}(M_i/M_o)$

In the most typical use, each output differs from the preceding output by only one sample, as illustrated below for scalar input.



(input sample period = T_{si})
(output sample period = T_{si})

Delay Line
Delay Line

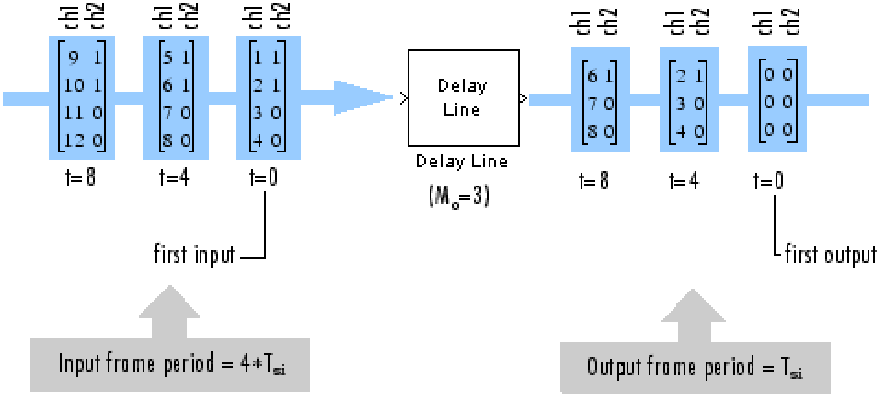
Note that the first output of the block in the example above is all zeros; this is because the **Initial Conditions** parameter is set to zero.

Initial Conditions

The Delay Line block's buffer is initialized to the value specified by the **Initial conditions** parameter. The block outputs this buffer at the first simulation step (*t*=0). When the block's output is a vector, the **Initial conditions** can be a vector of the same size, or a scalar value to be repeated across all elements of the initial output. When the block's output is a matrix, the **Initial conditions** can be a matrix of the same size, a vector (of length equal to the number of matrix rows) to be repeated across all columns of the initial output, or a scalar to be repeated across all elements of the initial output.

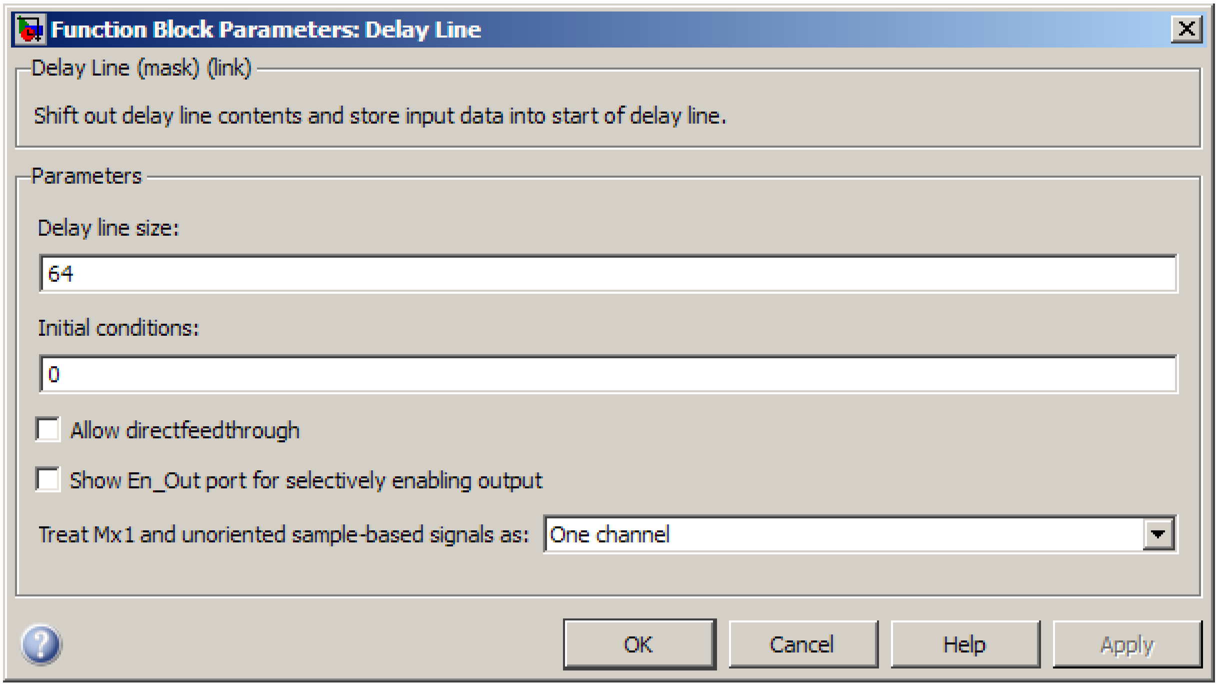
Examples

In the following ex_delayline_ref2 model, the block rebuffers a two-channel input with a **Delay line size** of 3.



The first output frame in this example is due to the latency of the Delay Line block; it is all zeros because the **Initial conditions** parameter is set to zero. Because the input frame size of 4 is larger than the output frame size of 3, only the last three samples in each input frame are propagated to the corresponding output frame. The frame periods of the input and output are the same, and the output sample period is $T_{si}(M_i/M_o)$, or 4/3 the input sample period.

Dialog Box



Function Block Parameters: Delay Line

Delay Line (mask) (link)

Shift out delay line contents and store input data into start of delay line.

Parameters

Delay line size:

64

Initial conditions:

0

□ Allow directfeedthrough

□ Show En_Out port for selectively enabling output

Treat Mx1 and unoriented sample-based signals as: One channel

Delay line size

Specify the number of rows in output matrix, M_o.

Initial conditions

Specify the value of the block's initial output. When the block outputs a vector, the **Initial conditions** can be a vector of the same size, or a scalar value to be repeated across all elements of the initial output. When the block outputs a matrix, the **Initial conditions** can be a matrix of the same size, a vector (of length equal to the number of matrix rows) to be repeated across all columns of the initial output, or a scalar to be repeated across all elements of the initial output.

Allow direct feedthrough

When you select this check box, the input data is not delayed by an extra frame before it is available at the output buffer. Instead, the input data is available immediately at the output port of the block.

Show En_Out port for selectively enabling output

When you select this check box, the En_Out port appears on the block icon. This block uses a circular buffer internally even though the output is linear. This means that for valid output, data from the circular buffer has to be linearized. The En_Out port determines whether or not a valid output needs to be computed based on the value of its `Boolean` input. If the input value to the En_Out port is `1`, the block output is linearized, and thus is valid. Otherwise, the output is not linearized, and is invalid. This allows the block to be more efficient when the tapped Delay Line's output is not required at each sample time.

Note that when the input value to the En_Out port is `0`, the block can give different results depending on the state of the model. The results can appear to match valid results or can be invalid, and they cannot be predicted. You should ignore the block output in all cases when the input to the En_Out port is `0`.

Hold previous value when the output is disabled

This parameter only appears and applies when the **Show En_Out port for selectively enabling output** parameter is selected. Use this parameter to specify the block output at those time steps when the internal state buffer is not being linearized to output valid data.

When you do not select this check box, the block memory is free to be used by other parts of the model, and the signal on the output port is invalid. When you select this check box, the most recent valid value is held on the output port, and slightly more memory is used by the block.

Treat Mx1 and unoriented sample-based signals as

Specify how the block treats sample-based *M*-by-1 column vectors and unoriented sample-based vectors of length *M*. You can select one of the following options:

- `One channel` — When you select this option, the block treats *M*-by-1 and unoriented sample-based inputs as a column vector (one channel).
- `M channels (this choice will be removed — see release notes)` — When you select this option, the block treats *M*-by-1 and unoriented sample-based inputs as a 1-by-*M* row vector. Because the block always does frame-based processing, the block interprets the 1-by-*M* row vector as *M* individual channels.

Note: This parameter will be removed in a future release. At that time, the Delay Line block will always perform frame-based processing.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Output	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers

Detrend

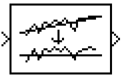
Remove linear trend from vectors

Library

Statistics

`dspstat3`

Description



The Detrend block removes a linear trend from the length-M input vector, u, by subtracting the straight line that best fits the data in the least squares sense.

The least squares line, $\hat{u} = ax + b$, is the line with parameters a and b that minimizes the quantity

$$\sum_{i=1}^{M}(u_i - u_i)^2$$

for M evenly-spaced values of x, where u_i is the ith element in the input vector. The output, $y = u\text{-}\hat{u}$, is always an M-by-1 column vector.

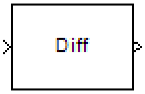
Difference

Compute element-to-element difference along specified dimension of input

Library

Math Functions / Math Operations

`dspmathops`



Description

The Difference block computes the difference between adjacent elements in rows, columns, or a specified dimension of the input array `u`. You can configure the block to compute the difference only within the current input, or across consecutive inputs (running difference).

Basic Operation

When you set the **Running difference** parameter to `No`, the block computes the difference between adjacent elements in the specified dimension of the current input. In this mode, the block can compute the difference along the columns, rows, or a specified dimension of the input.

Columnwise Differencing

When you set the **Difference along** parameter to `Columns`, the block computes differences between adjacent elements in each column of the input.

```
y = diff(u)      % Equivalent MATLAB code
```

For M-by-N inputs, the output is an (M-1)-by-N matrix whose jth column has the following elements:

$$y_{i,j} = u_{i+1,j} - u_{i,j} \quad 1 \le i \le (M-1)$$

Rowwise Differencing

When you set the **Difference along** parameter to `Rows`, the block computes differences between adjacent elements in each row of the input.

```
y = diff(u,[],2)      % Equivalent MATLAB code
```

The output is an *M*-by-(*N*-1) matrix whose *i*th row has the following elements:

$$y_{i,j} = u_{i,j+1} - u_{i,j} \quad 1 \le j \le (N-1)$$

Differencing Along Arbitrary Dimensions

When you set the **Difference along** parameter to `Specified dimension`, the behavior of the block is an extension of the rowwise differencing described earlier. The block computes differences between adjacent elements along the dimension you specify in the **Dimension** parameter.

```
y = diff(u,[],d) % Equivalent MATLAB code where d is the dimension
```

The output is an array whose length in the specified dimension is one less than that of the input, and whose lengths in other dimensions are unchanged. For example, consider an *M*-by-*N*-by-*P*-by-*R* input array with elements *u(i,j,k,l)* and assume that **Dimension** is `3`. The output of the block is an *M*-by-*N*-by-(*P*–1)-by-*R* array with the following elements:

$$y_{i,j,k,l} = u_{i,j,k+1,l} - u_{i,j,k,l} \quad 1 \le k \le (P-1)$$

Running Operation

When you set the **Running difference** parameter to `Yes`, the block computes the running difference along the columns of the input.

For an *M*-by-*N* input matrix, the output is an *M*-by-*N* matrix whose *j*th column has the following elements:

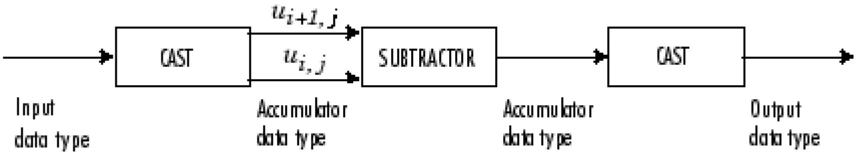
$$y_{i,j} = u_{i+1,j} - u_{i,j} \quad 2 \le i \le (M-1)$$

In running mode, the first element of the output for each column is the first input element minus the last input element of the previous frame. For the first frame, the block subtracts zero from the first input element.

$$y_{1,j}(t) = u_{1,j}(t) - u_{M,j}(t - T_f)$$

Fixed-Point Data Types

The following diagram shows the data types used within the Difference block for fixed-point signals.

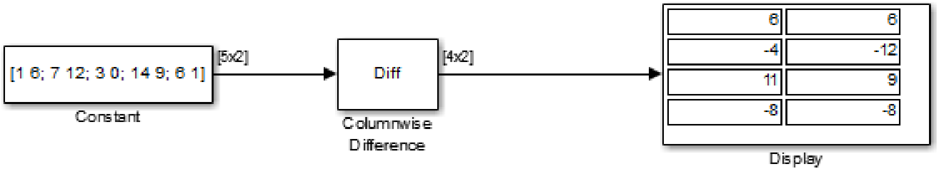


You can set the accumulator and output data types in the block dialog as discussed in “Dialog Box” on page 1-383 .

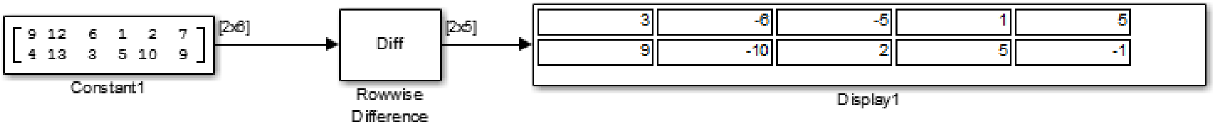
Examples

For an example showing the modes of the Difference block, open ex_difference.

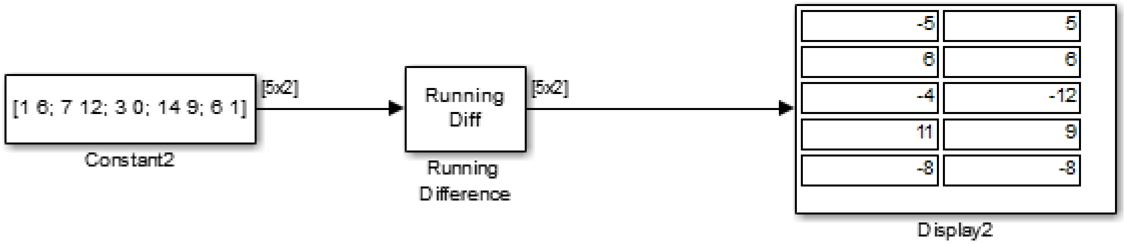
The following figure shows the output of the block when it is differencing along columns in nonrunning mode.



The following figure shows the output of the block when it is differencing along rows in nonrunning mode.

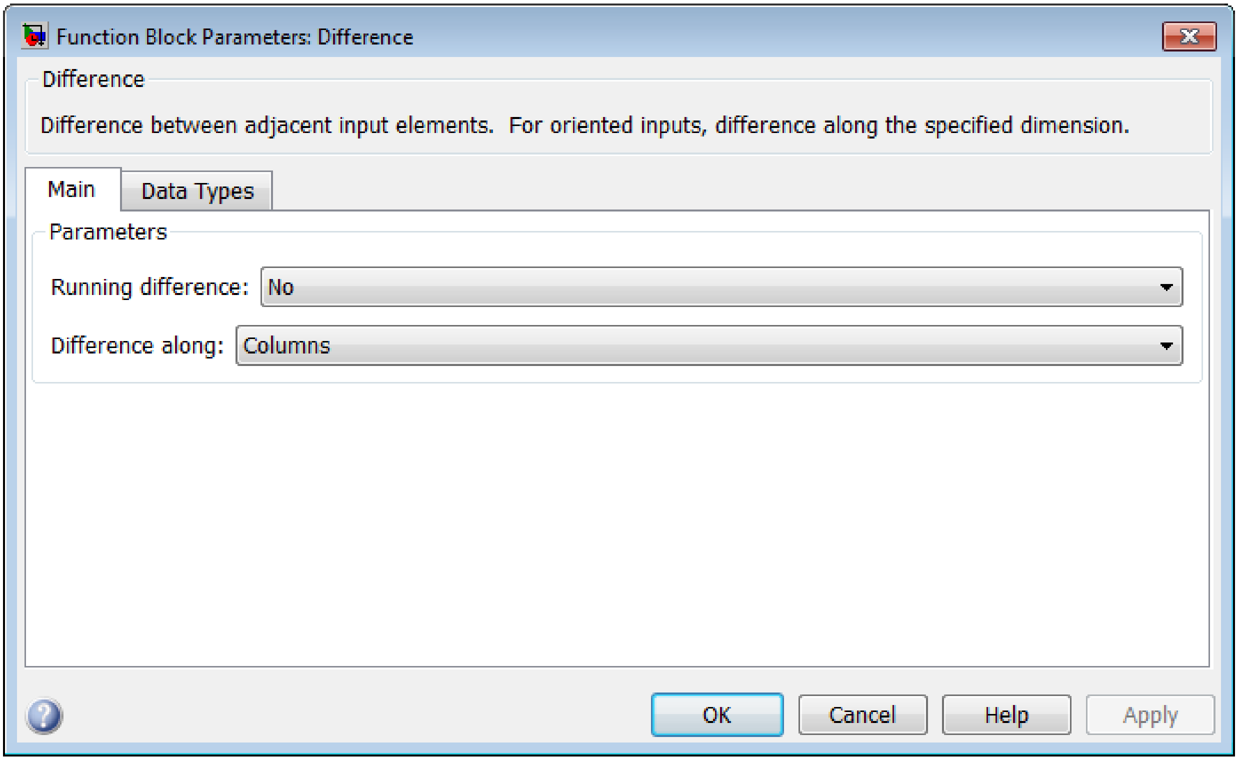


The following figure shows the second frame of block output when the block is computing the running difference.



Dialog Box

The **Main** pane of the Difference block appears as follows.



Function Block Parameters: Difference

Difference

Difference between adjacent input elements. For oriented inputs, difference along the specified dimension.

Parameters

Running difference: No

Difference along: Columns

Running difference

Specify whether or not the block computes a running difference. When you select `No`, the block computes the difference between adjacent elements in the current input. When you select `Yes`, the block computes the running difference across consecutive inputs. In running mode, the block always computes the difference along the columns of the input. See "Running Operation" on page 1-381 for more information.

Note: The `Inherit from input (this choice will be removed - see release notes)` option will be removed in a future release. See "Difference Block Changes" in the *DSP System Toolbox Release Notes* for more information.

Difference along

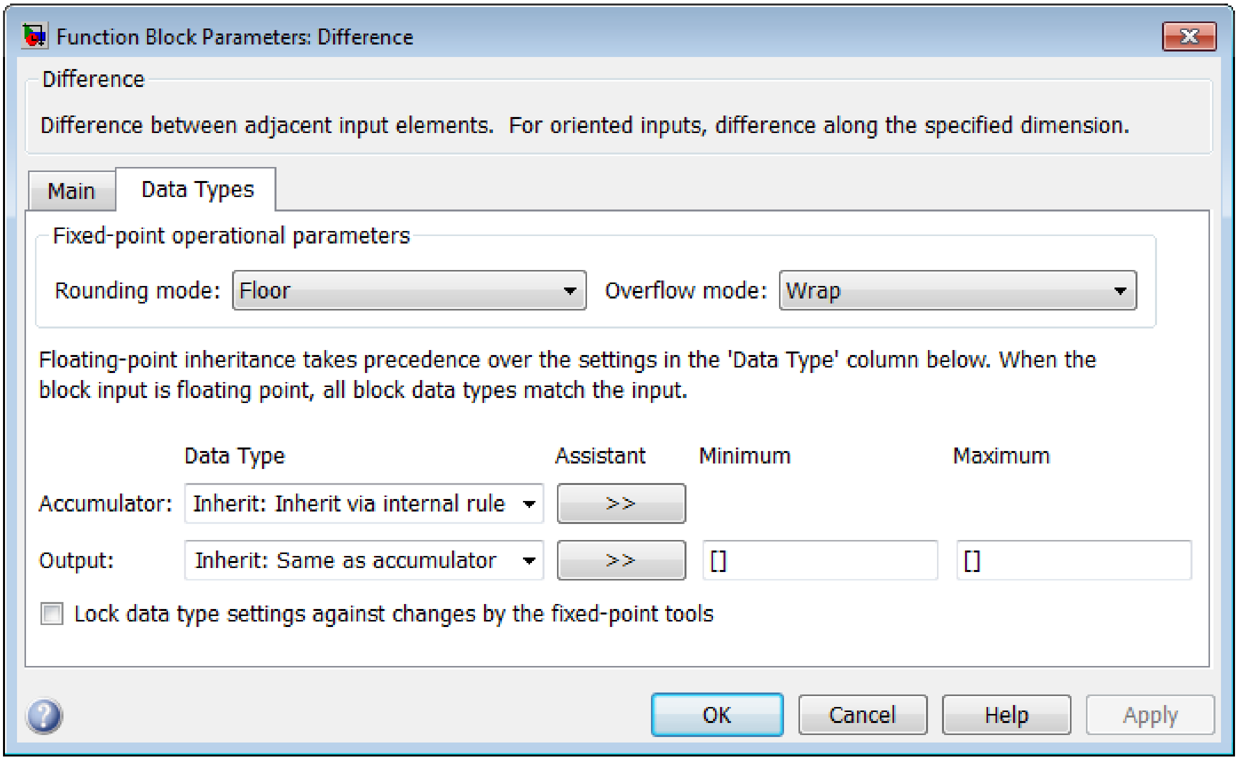
Specify whether the block computes the difference along the columns, rows, or specified dimension of the input.

Dimension

Specify the one-based dimension along which to compute element-to-element differences.

This parameter is only visible when you select `Specified dimension` for the **Difference along** parameter.

The **Data Types** pane of the Difference block appears as follows.



Function Block Parameters: Difference

Difference

Difference between adjacent input elements. For oriented inputs, difference along the specified dimension.

Fixed-point operational parameters

Rounding mode: Floor

Overflow mode: Wrap

Floating-point inheritance takes precedence over the settings in the 'Data Type' column below. When the block input is floating point, all block data types match the input.

	Data Type	Assistant	Minimum	Maximum
Accumulator:	Inherit: Inherit via internal rule	>>		
Output:	Inherit: Same as accumulator	>>	[]	[]

□ Lock data type settings against changes by the fixed-point tools

Note: Floating-point inheritance takes precedence over the data type settings defined on this pane. When inputs are floating point, the block ignores these settings, and all internal data types are floating point.

Rounding mode

Select the “rounding mode” for fixed-point operations.

Overflow mode

Select the “overflow mode” for fixed-point operations.

Accumulator data type

Specify the accumulator data type. See “Fixed-Point Data Types” on page 1-382 for illustrations depicting the use of the accumulator data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`
- An expression that evaluates to a valid data type, for example, `fixdt([],16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Accumulator data type** parameter.

See “Specify Data Types Using Data Type Assistant” in “Simulink User's Guide” for more information.

Output data type

Specify the output data type. See “Fixed-Point Data Types” on page 1-382 for illustrations depicting the use of the output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as accumulator`
- An expression that evaluates to a valid data type, for example, `fixdt([],16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Specify Block Output Data Types” in “Simulink User's Guide” for more information.

Minimum

Specify the minimum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges”)
- Automatic scaling of fixed-point data types

Maximum

Specify the maximum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges”)
- Automatic scaling of fixed-point data types

Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point • Fixed point • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Output	• Double-precision floating point • Single-precision floating point • Fixed point • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers

Differentiator Filter

Design differentiator filter

Library

Filtering / Filter Designs

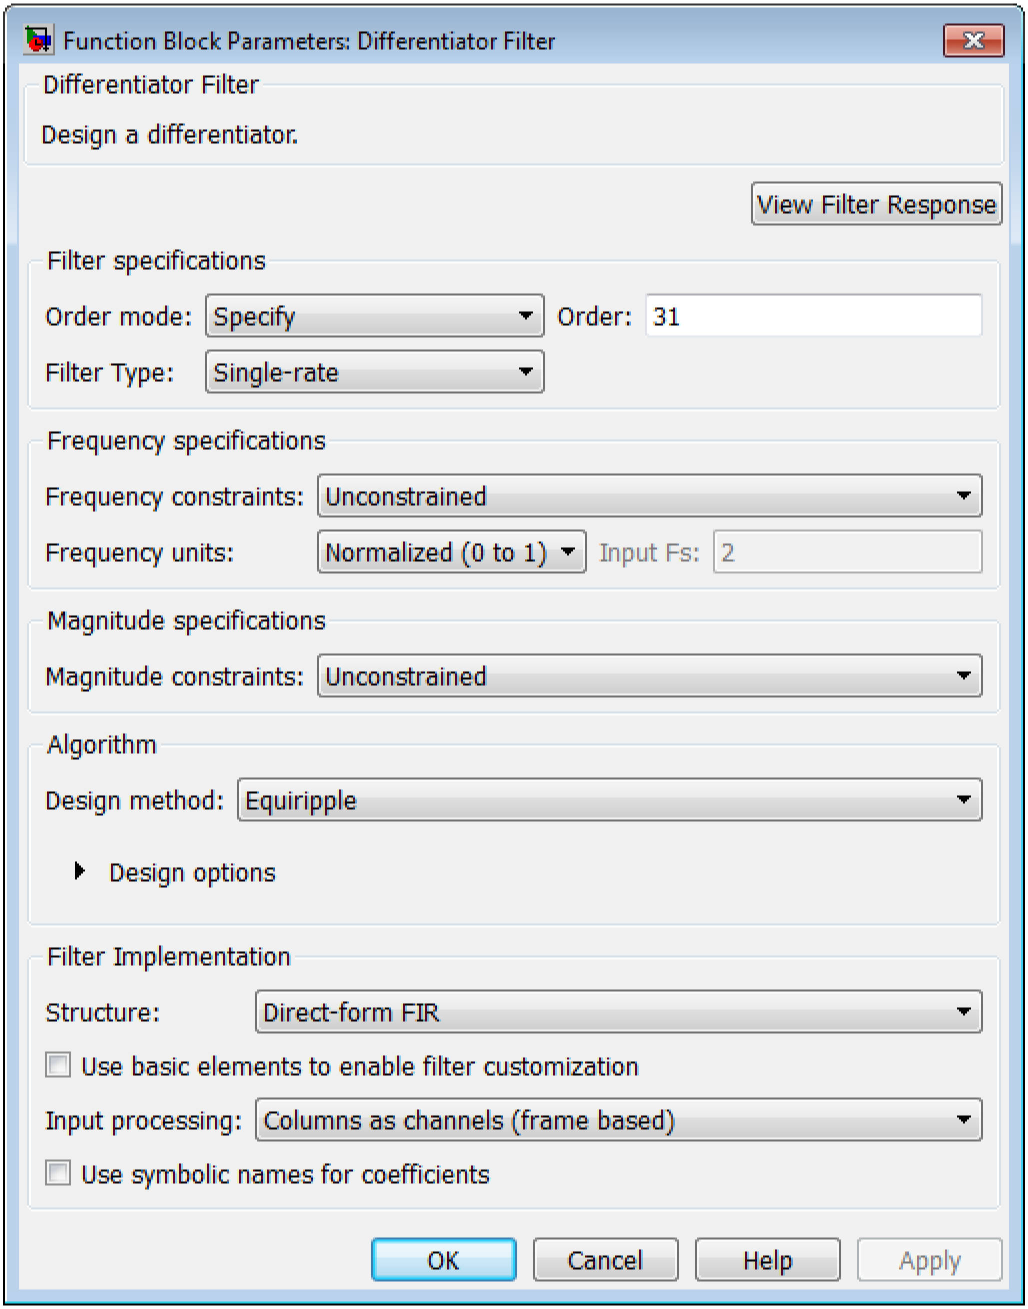
`dspfdesign`

Description

This block brings the filter design capabilities of the “`filterbuilder`” function to the Simulink environment.

Dialog Box

See “Differentiator Filter Design Dialog Box — Main Pane” for more information about the parameters of this block. The **Data Types** and **Code Generation** panes are not available for blocks in the DSP System Toolbox Filter Designs library.



Function Block Parameters: Differentiator Filter

Differentiator Filter

Design a differentiator.

Filter specifications

Order mode: Specify

Order: 31

Filter Type: Single-rate

Frequency specifications

Frequency constraints: Unconstrained

Frequency units: Normalized (0 to 1)

Input Fs: 2

Magnitude specifications

Magnitude constraints: Unconstrained

Algorithm

Design method: Equiripple

Filter Implementation

Structure: Direct-form FIR

□ Use basic elements to enable filter customization

Input processing: Columns as channels (frame based)

□ Use symbolic names for coefficients

View filter response

This button opens the Filter Visualization Tool (`fvtool`) from the Signal Processing Toolbox product. You can use the tool to display:

- Magnitude response, phase response, and group delay in the frequency domain.
- Impulse response and step response in the time domain.
- Pole-zero information.

The tool also helps you evaluate filter performance by providing information about filter order, stability, and phase linearity. For more information on FVTool, see the Signal Processing Toolbox documentation.

Filter Specifications

Order mode

Select either `Minimum` or `Specify` (the default). Selecting `Specify` enables the **Order** option so you can enter the filter order.

Order

Enter the filter order. This option is enabled only if you set the **Order mode** to `Specify`. The default order is 31.

Filter type

Select `Single-rate`, `Decimator`, `Interpolator`, or `Sample-rate converter`. Your choice determines the type of filter as well as the design methods and structures that are available to implement your filter. By default, the block specifies a single-rate filter.

- Selecting `Decimator` or `Interpolator` activates the **Decimation Factor** or the **Interpolation Factor** options respectively.
- Selecting `Sample-rate converter` activates both factors.

Decimation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to `Decimator` or `Sample-rate converter`. The default value is 2.

Interpolation Factor

Enter the interpolation factor. This option is enabled only if the **Filter type** is set to `Interpolator` or `Sample-rate converter`. The default value is 2.

Frequency Specifications

The parameters in this group allow you to specify your filter response curve.

Frequency constraints

This option is only available when you specify the order of the filter design. Supported options are `Unconstrained` and `Passband edge and stopband edge`.

Frequency units

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select `Normalized (0—1)` to enter frequencies in normalized form. This behavior is the default. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—`Hz`, `kHz`, `MHz`, or `GHz`. Selecting one of the unit options enables the **Input Fs** parameter.

Input Fs

Fs, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available when you select one of the frequency options from the **Frequency units** list.

Fpass

Enter the frequency at the end of the passband. Specify the value in either normalized frequency units or the absolute units you select in **Frequency units**.

Fstop

Enter the frequency at the start of the stopband. Specify the value in either normalized frequency units or the absolute units you select in **Frequency units**.

Magnitude Specifications

Parameters in this group specify the filter response in the passbands and stopbands. These parameters are only available for minimum-order designs.

Magnitude constraints

This option is only available when you specify the order of your filter design. The available **Magnitude constraints** depend on the value of the **Frequency constraints** parameter. When you set the **Frequency constraints** parameter to `Unconstrained`, the **Magnitude constraints** parameter must also be `Unconstrained`. When you set the **Frequency constraints** parameter to

`Passband edge and stopband edge`, the **Magnitude constraints** parameter can be `Unconstrained`, `Passband ripple`, or `Stopband attenuation`.

Magnitude units

Specify the units for any parameter you provide in magnitude specifications. From the drop-down list, select one of the following options:

- `Linear` — Specify the magnitude in linear units.
- `dB` — Specify the magnitude in decibels (default).
- `Squared` — Specify the magnitude in squared units.

Apass

Enter the filter ripple allowed in the passband in the units you choose for **Magnitude units**, either linear or decibels.

Astop2

Enter the filter attenuation in the second stopband in the units you choose for **Magnitude units**, either linear or decibels.

Algorithm

The parameters in this group allow you to specify the design method and structure of your filter.

Design Method

Lists the design methods available for the frequency and magnitude specifications you entered. When you change the specifications for a filter, such as changing the impulse response, the methods available to design filters changes as well.

Design Options

The options for each design are specific for each design method. This section does not present all of the available options for all designs and design methods. There are many more that you encounter as you select different design methods and filter specifications. The following options represent some of the most common ones available.

Density factor

Density factor controls the density of the frequency grid over which the design method optimization evaluates your filter response function. The number of equally spaced points in the grid is the value you enter for **Density factor** times (filter order + 1).

Increasing the value creates a filter that more closely approximates an ideal equiripple filter but increases the time required to design the filter. The default value of 20 represents a reasonable trade between the accurate approximation to the ideal filter and the time to design the filter.

Wpass

Passband weight. This option is only available for a specified-order design when **Frequency constraints** is equal to `Passband edge and stopband edge` and the **Design method** is `Equiripple`.

Wstop

Stopband weight. This option is only available for a specified-order design when **Frequency constraints** is equal to `Passband edge and stopband edge` and the **Design method** is `Equiripple`.

Filter Implementation

Structure

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. By default, FIR filters use direct-form structure.

Use basic elements to enable filter customization

Select this check box to implement the filter as a subsystem of basic Simulink blocks. Clear the check box to implement the filter as a high-level subsystem. By default, this check box is cleared.

The high-level implementation provides better compatibility across various filter structures, especially filters that would contain algebraic loops when constructed using basic elements. On the other hand, using basic elements enables the following optimization parameters:

- **Optimize for zero gains** — Terminate chains that contain Gain blocks with a gain of zero.
- **Optimize for unit gains** — Remove Gain blocks that scale by a factor of one.
- **Optimize for delay chains** — Substitute delay chains made up of *n* unit delays with a single delay by *n*.
- **Optimize for negative gains** — Use subtraction in Sum blocks instead of negative gains in Gain blocks.

Input processing

Specify how the block should process the input. The available options may vary depending on he settings of the **Filter Structure** and **Use basic elements for filter customization** parameters. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` — When you select this option, the block treats each column of the input as a separate channel.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

Note: The `Inherited (this choice will be removed — see release notes)` option will be removed in a future release. See "Frame-Based Processing" in the *DSP System Toolbox Release Notes* for more information.

Rate options

When the **Filter type** parameter specifies a multirate filter, select the rate processing rule for the block from following options:

- `Enforce single-rate processing` — When you select this option, the block maintains the sample rate of the input.
- `Allow multirate processing` — When you select this option, the block adjusts the rate at the output to accommodate an increased or reduced number of samples. To select this option, you must set the **Input processing** parameter to `Elements as channels (sample based)`.

Use symbolic names for coefficients

Select this check box to enable the specification of coefficients using MATLAB variables. The available coefficient names differ depending on the filter structure. Using symbolic names allows tuning of filter coefficients in generated code. By default, this check box is cleared.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point

Port	Supported Data Types
Output	• Double-precision floating point • Single-precision floating point

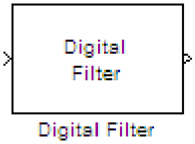
Digital Filter (Obsolete)

Filter each channel of input over time using static or time-varying digital filter implementations

Library

Filtering / Filter Implementations

`dsparch4`



Description

Note: Use of Digital Filter block in future releases is not recommended. Existing instances will continue to operate, but certain functionality will be disabled. See "Functionality being removed or replaced for blocks and System objects". We strongly recommend using one of Discrete FIR Filter, Discrete Filter, Biquad Filter, or Allpole Filter in new designs.

You can use the Digital Filter block to efficiently implement a floating-point or fixed-point filter for which you know the coefficients, or that is already defined in a `dfilt` object. The block independently filters each channel of the input signal with a specified digital IIR or FIR filter. The block can implement *static filters* with fixed coefficients, as well as *time-varying filters* with coefficients that change over time. You can tune the coefficients of a static filter during simulation.

This block filters each channel of the input signal independently over time. You must set the **Input processing** parameter to specify how the block interprets the input signal. You can select one of the following options:

- `Columns as channels (frame based)` — When you select this option, the block treats each column of the input as an independent channel.

- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as an individual channel.

The output dimensions always match those of the input signal. The outputs of this block numerically match the outputs of the Digital Filter Design block and of the `dfilt` object.

Note: The Digital Filter block has direct feedthrough, so if you connect the output of this block back to its input you get an algebraic loop. For more information on direct feedthrough and algebraic loops, see "Algebraic Loops" in the Simulink documentation.

Sections of This Reference Page

Coefficient Source

The Digital Filter block can operate in three different modes. Select the mode in the **Coefficient source** group box.

- **Dialog parameters** Enter information about the filter such as structure and coefficients in the block mask.
- **Input port(s)** Enter the filter structure in the block mask, and the filter coefficients come in through one or more block ports. This mode is useful for specifying time-varying filters.
- **Discrete-time filter object (DFILT)** Specify the filter using a `dfilt` object.

Supported Filter Structures

When you select **Discrete-time filter object (DFILT)**, the following `dfilt` structures are supported:

- `dfilt.df1`
- `dfilt.df1t`
- `dfilt.df2`
- `dfilt.df2t`
- `dfilt.df1sos`
- `dfilt.df1tsos`
- `dfilt.df2sos`
- `dfilt.df2tsos`
- `dfilt.dffir`
- `dfilt.dffirt`
- `dfilt.dfsymfir`
- `dfilt.dfasymfir`
- `dfilt.latticear`
- `dfilt.latticemamin`

When you select **Dialog parameters** or **Input port(s)**, the list of filter structures offered in the **Filter structure** parameter depends on whether you set the **Transfer function type** to `IIR (poles & zeros)`, `IIR (all poles)`, or `FIR (all zeros)`, as summarized in the following table.

Note Each structure listed in the table below supports both fixed-point and floating-point signals.

The table also shows the vector or matrix of filter coefficients you must provide for each filter structure.

Filter Structures and Filter Coefficients

Transfer Function Type	Supported Filter Structures	Filter Coefficient Specification
IIR (poles & zeros)	Direct form I Direct form I transposed Direct form II Direct form II transposed	• Numerator coefficients vector [b0, b1, b2, ..., bn] • Denominator coefficients vector [a0, a1, a2, ..., am] See "Special Consideration for the Leading Denominator Coefficient".
	Biquadratic direct form I (SOS) Biquadratic direct form I transposed (SOS) Biquadratic direct form II (SOS) Biquadratic direct form II transposed (SOS)	• *M*-by-6 second-order section (SOS) matrix. • Scale values
IIR (all poles)	Direct form Direct form transposed	Denominator coefficients vector [a0, a1, a2, ..., am] See "Special Consideration for the Leading Denominator Coefficient".
	Lattice AR	Reflection coefficients vector [k1, k2, ..., kn]
FIR (all zeros)	Direct form Direct form symmetric Direct form antisymmetric Direct form transposed	Numerator coefficients vector [b0, b1, b2, ..., bn]
	Lattice MA	Reflection coefficients vector [k1, k2, ..., kn]

Special Considerations for the Leading Denominator Coefficient

In some cases, the Digital Filter block requires the leading denominator coefficient (a_0) to be 1. This requirement applies under the following conditions:

- The Digital Filter block is operating in a fixed-point mode. The block operates in a fixed-point mode when at least one of the following statements is true:
  - The input to the Digital Filter block has a fixed-point or integer data type.
  - The **Fixed-point instrumentation mode** parameter under **Analysis > Fixed Point Tool** has a setting of `Minimums, maximums and overflows`.
- The **Coefficient source** has a setting of `Dialog` or `Input port(s)`.

Note: If you are working in one of the fixed-point situations described in the previous bullet, and the **Coefficient source** is set to `Input port(s)`, you must select the **First denominator coefficient = 1, remove a0 term in the structure** check box.

- The **Transfer function type** and **Filter structure** parameters are set to one of the combinations described in the following table.

Transfer function type	Filter structure
IIR (poles & zeros)	`Direct form I`
	`Direct form I transposed`
	`Direct form II`
	`Direct form II transposed`
IIR (all poles)	`Direct form`
	`Direct form transposed`

The Digital Filter block produces an error if you use it in one of the these configurations and your leading denominator coefficient (a_0) does not equal 1. To resolve the error, set your leading denominator coefficient to 1 by scaling all numerator and denominator coefficients by a factor of a_0.

Specifying Initial Conditions

In **Dialog parameters** and **Input port(s)** modes, the block initializes the internal filter states to zero by default, which is equivalent to assuming past inputs and outputs are zero. You can optionally use the **Initial conditions** parameter to specify nonzero initial conditions for the filter delays.

To determine the number of initial condition values you must specify, and how to specify them, see the following table on Valid Initial Conditions and Number of Delay Elements (Filter States). The **Initial conditions** parameter can take one of four forms as described in the following table.

Valid Initial Conditions

Initial Condition	Examples	Description
Scalar	5 Each delay element for each channel is set to 5.	The block initializes all delay elements in the filter to the scalar value.
Vector (for applying the same delay elements to each channel)	For a filter with two delay elements: [d_1 d_2] The delay elements for all channels are d1 and d2.	Each vector element specifies a unique initial condition for a corresponding delay element. The block applies the same vector of initial conditions to each channel of the input signal. The vector length must equal the number of delay elements in the filter (specified in the table Number of Delay Elements (Filter States)).
Vector or matrix (for applying different delay elements to each channel)	For a 3-channel input signal and a filter with two delay elements: [d_1 d_2 D_1 D_2 d_1 d_2] or $\begin{bmatrix} d_1 & D_1 & d_1 \\ d_2 & D_2 & d_2 \end{bmatrix}$ • The delay elements for channel 1 are d_1 and d_2. • The delay elements for channel 2 are D_1 and D_2. • The delay elements for channel 3 are $d_1$and d_2.	Each vector or matrix element specifies a unique initial condition for a corresponding delay element in a corresponding channel: • The vector length must be equal to the product of the number of input channels and the number of delay elements in the filter (specified in the table Number of Delay Elements (Filter States)). • The matrix must have the same number of rows as the number of delay elements in the filter (specified in the table Number of Delay Elements (Filter States)), and must have one column for each channel of the input signal.

Initial Condition	Examples	Description
Empty matrix	[ ] Each delay element for each channel is set to 0.	The empty matrix, [], is equivalent to setting the **Initial conditions** parameter to the scalar value 0.

The number of delay elements (filter states) per input channel depends on the filter structure, as indicated in the following table.

Number of Delay Elements (Filter States)

Filter Structure	Number of Delay Elements per Channel

`Direct form`
`Direct form transposed`
`Direct form symmetric`
`Direct form antisymmetric`
	`#_of_filter_coeffs-1`

`Direct form I`
`Direct form I transposed`
	• `#_of_zeros-1`
	• `#_of_poles-1`

`Direct form II`
`Direct form II transposed`
	`max(#_of_zeros, #_of_poles)-1`

`Biquadratic direct form I (SOS)`
`Biquadratic direct form I transposed (SOS)`
`Biquadratic direct form II (SOS)`
`Biquadratic direct form II transposed (SOS)`
	`2 * #_of_filter_sections`

`Lattice AR`
`Lattice MA`
	`#_of_reflection_coeffs`

State Logging

Simulink enables you to log the states in your model to the MATLAB workspace. The following table indicates which filter structures of the Digital Filter block support the Simulink state logging feature. See “States” in the Simulink User's Guide documentation for more information.

Transfer Function Type	Filter Structure	State Logging Supported
IIR (poles & zeros)	`Direct form I`	No
	`Direct form I transposed`	Yes
	`Direct form II`	No
	`Direct form II transposed`	Yes
	`Biquadratic direct form I (SOS)`	Yes
	`Biquadratic direct form I transposed (SOS)`	Yes
	`Biquadratic direct form II (SOS)`	Yes
	`Biquadratic direct form II transposed (SOS)`	Yes
IIR (all poles)	`Direct form`	No
	`Direct form transposed`	Yes
	`Lattice AR`	Yes
FIR (all zeros)	`Direct form`	No
	`Direct form symmetric`	No
	`Direct form antisymmetric`	No
	`Direct form transposed`	Yes
	`Lattice MA`	Yes

Fixed-Point Data Types

All structures supported by the Digital Filter block support fixed-point data types. You can specify intermediate fixed-point data types for quantities such as the coefficients, accumulator, and product output for each filter structure. See “Filter Structure Diagrams” on page 1-418 for diagrams depicting the use of these intermediate fixed-point data types in each filter structure.

Dialog Box

Coefficient Source

The Digital Filter block can operate in three different modes. Select the mode in the **Coefficient source** group box.

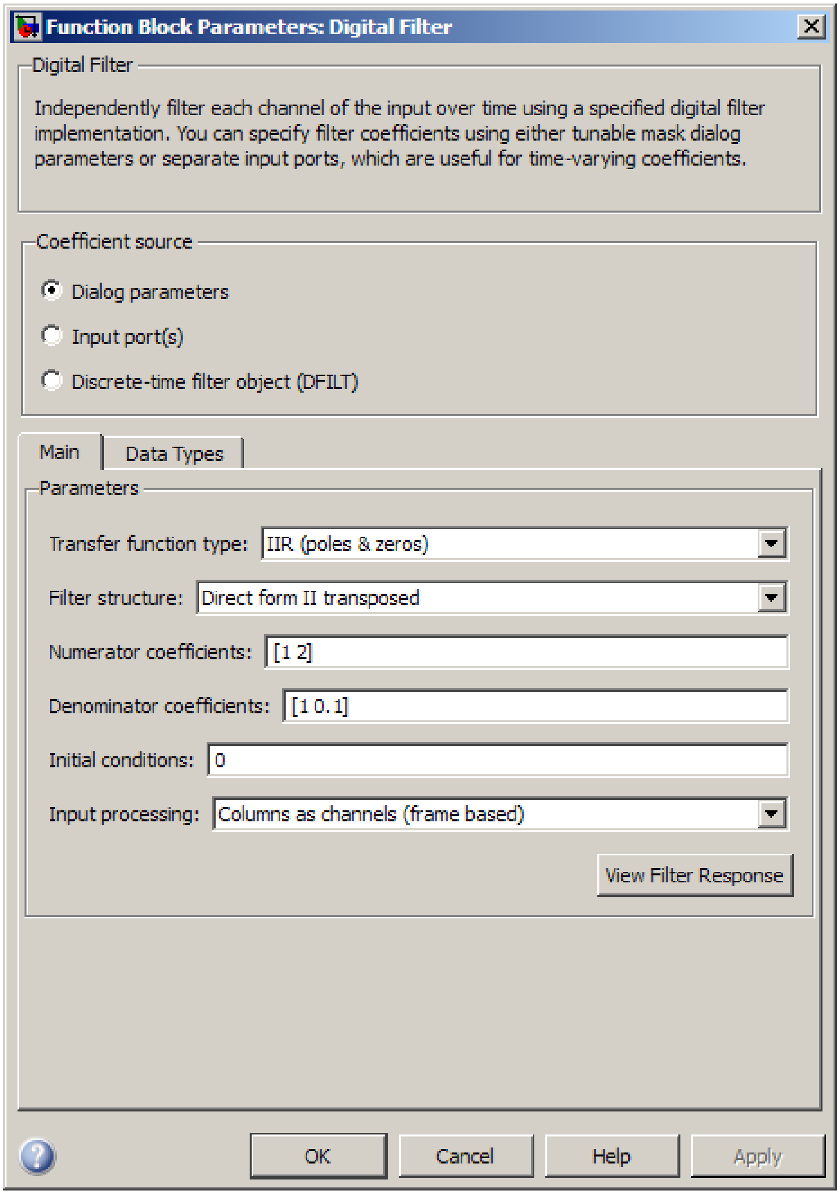
- **Dialog parameters** Enter information about the filter such as structure and coefficients in the block mask.
- **Input port(s)** Enter the filter structure in the block mask, and the filter coefficients come in through one or more block ports. This mode is useful for specifying time-varying filters.
- **Discrete-time filter object (DFILT)** Specify the filter using a `dfilt` object.

Different items appear on the Digital Filter block dialog depending on whether you select **Dialog parameters**, **Input port(s)**, or **Discrete-time filter object (DFILT)** in the **Coefficient source** group box. See the following sections for details:

- "Specify Filter Characteristics in Dialog and/or Through Input Ports" on page 1-404
- "Specify Discrete-Time Filter Object" on page 1-414

Specify Filter Characteristics in Dialog and/or Through Input Ports

The **Main** pane of the Digital Filter block dialog appears as follows when **Dialog parameters** is specified in the **Coefficient source** group box. The parameters below can appear when **Dialog parameters** or **Input port(s)** is selected, as noted.



Function Block Parameters: Digital Filter

Digital Filter

Independently filter each channel of the input over time using a specified digital filter implementation. You can specify filter coefficients using either tunable mask dialog parameters or separate input ports, which are useful for time-varying coefficients.

Coefficient source

- ● Dialog parameters
- ○ Input port(s)
- ○ Discrete-time filter object (DFILT)

Parameters

Transfer function type: IIR (poles & zeros)

Filter structure: Direct form II transposed

Numerator coefficients: [1 2]

Denominator coefficients: [1 0.1]

Initial conditions: 0

Input processing: Columns as channels (frame based)

Transfer function type

Select the type of transfer function of the filter; `IIR (poles & zeros)`, `IIR (all poles)`, or `FIR (all zeros)`. See "Supported Filter Structures" on page 1-398 for more information.

Filter structure

Select the filter structure. The selection of available structures varies depending the setting of the **Transfer function type** parameter. See "Supported Filter Structures" on page 1-398 for more information.

Numerator coefficients

Specify the vector of numerator coefficients of the filter's transfer function.

This parameter is only visible when **Dialog parameters** is selected *and* when the selected filter structure lends itself to specification with numerator coefficients. "Tunable".

Denominator coefficients

Specify the vector of denominator coefficients of the filter's transfer function.

In some cases, the leading denominator coefficient (a0) must be 1. See "Special Consideration for the Leading Denominator Coefficient" for more information.

This parameter is only visible when **Dialog parameters** is selected *and* when the selected filter structure lends itself to specification with denominator coefficients. "Tunable".

Reflection coefficients

Specify the vector of reflection coefficients of the filter's transfer function.

This parameter is only visible when **Dialog parameters** is selected *and* when the selected filter structure lends itself to specification with reflection coefficients. "Tunable".

SOS matrix (Mx6)

Specify an *M*-by-6 *SOS matrix* containing coefficients of a second-order section (SOS) filter, where *M* is the number of sections. You can use the `ss2sos` and `tf2sos` functions from Signal Processing Toolbox software to check whether your SOS matrix is valid.

This parameter is only visible when **Dialog parameters** is selected *and* when the selected filter structure is biquadratic. "Tunable".

Scale values

Specify the scale values to be applied before and after each section of a biquadratic filter.

- If you specify a scalar, that value is applied before the first filter section. The rest of the scale values are set to 1.
- You can also specify a vector with $M + 1$ elements, assigning a different value to each scale. See “Filter Structure Diagrams” on page 1-418 for diagrams depicting the use of scale values in biquadratic filter structures.

This parameter is only visible when **Dialog parameters** is selected *and* when the selected filter structure is biquadratic. “Tunable”.

First denominator coefficient = 1, remove a0 term in the structure

Select this parameter to reduce the number of computations the block must make to produce the output by omitting the `1 / a`$_0$ term in the filter structure. The block output is invalid if you select this parameter when the first denominator filter coefficient is *not* always 1 for your time-varying filter.

This parameter is only enabled when the **Input port(s)** is selected *and* when the selected filter structure lends itself to this specification.

Coefficient update rate

Specify how often the block updates time-varying filters; once per sample or once per frame.

This parameter appears only when the following conditions are met:

- You specify **Input port(s)** in the Coefficient source group box.
- You set the **Input processing** parameter to `Columns as channels (frame based)`.

Initial conditions

Specify the initial conditions of the filter states. To learn how to specify initial conditions, see “Specifying Initial Conditions” on page 1-400.

Initial conditions on zeros side

(Not shown in dialog above.) Specify the initial conditions for the filter states on the side of the filter structure with the zeros (b_0, b_1,b_2, ...); see the diagram below.

This parameter is enabled only when the filter has both poles and zeros, *and* when you select a structure such as direct form I, which has separate filter states corresponding to the poles (a_k) and zeros (b_k). To learn how to specify initial conditions, see “Specifying Initial Conditions” on page 1-400.

Initial conditions on poles side

(Not shown in dialog above). Specify the initial conditions for the filter states on the side of the filter structure with the poles (a_0, a_1,a_2, ...); see the diagram below.

This parameter is enabled only when the filter has both poles and zeros, *and* when you select a structure such as direct form I, which has separate filter states corresponding to the poles (a_k) and zeros (b_k). To learn how to specify initial conditions, see “Specifying Initial Conditions” on page 1-400.

Input processing

Specify how the block should process the input. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` — When you select this option, the block treats each column of the input as a separate channel.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

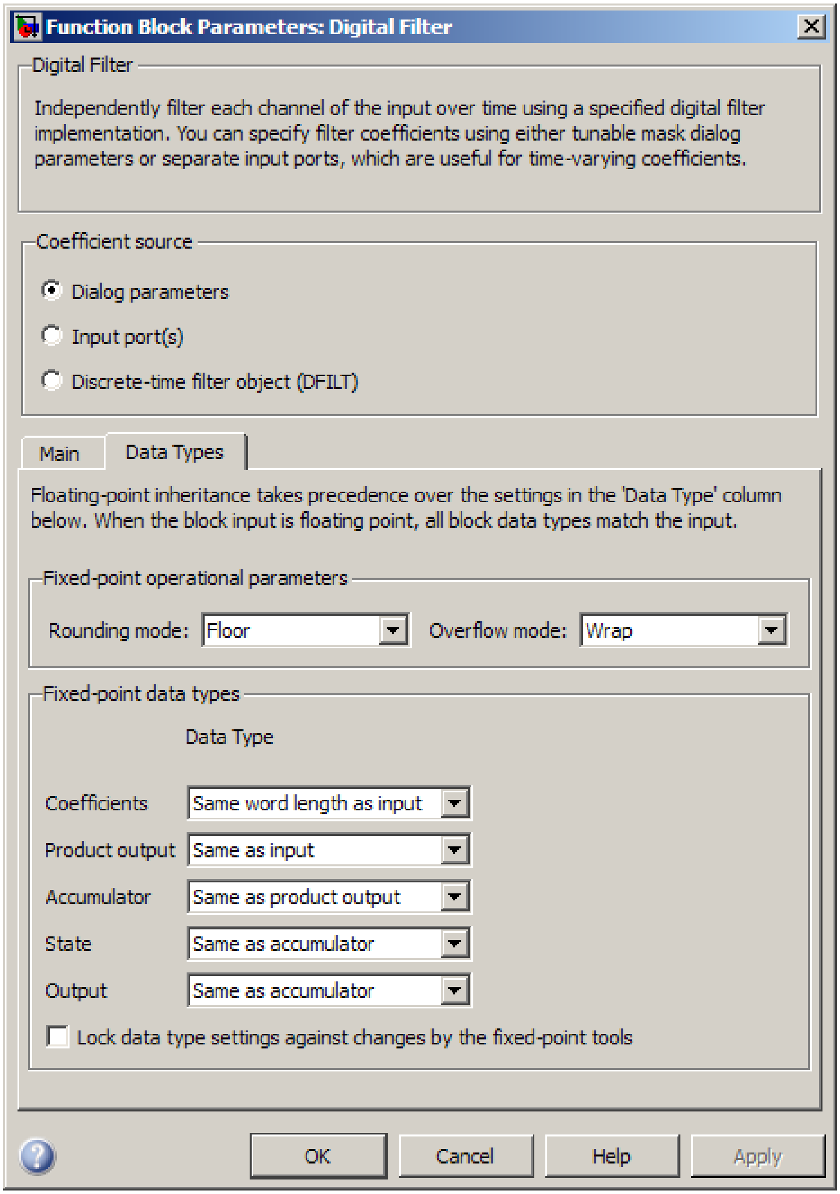
Note: The `Inherited (this choice will be removed - see release notes)` option will be removed in a future release. See “Frame-Based Processing” in the *DSP System Toolbox Release Notes* for more information.

View filter response

This button opens the Filter Visualization Tool (`fvtool`) from the Signal Processing Toolbox product and displays the filter response of the filter defined by the block. For more information on FVTool, see the Signal Processing Toolbox documentation.

Note: If you specify a filter in the **Filter** parameter, you must click the **Apply** button to apply the filter before using the **View filter response** button.

The **Data Types** pane of the Digital Filter block dialog appears as follows when **Dialog parameters** is specified in the **Coefficient source** group box. The parameters below can appear when **Dialog parameters** or **Input port(s)** is selected, depending on the filter structure and whether the coefficients are being entered via ports or on the block mask.



Function Block Parameters: Digital Filter

Digital Filter

Independently filter each channel of the input over time using a specified digital filter implementation. You can specify filter coefficients using either tunable mask dialog parameters or separate input ports, which are useful for time-varying coefficients.

Coefficient source

● Dialog parameters

○ Input port(s)

○ Discrete-time filter object (DFILT)

Floating-point inheritance takes precedence over the settings in the 'Data Type' column below. When the block input is floating point, all block data types match the input.

Fixed-point operational parameters

Rounding mode: Floor

Overflow mode: Wrap

Fixed-point data types

	Data Type
Coefficients	Same word length as input
Product output	Same as input
Accumulator	Same as product output
State	Same as accumulator
Output	Same as accumulator

□ Lock data type settings against changes by the fixed-point tools

Rounding mode

Select the “rounding mode” for fixed-point operations. The filter coefficients do not obey this parameter; they always round to `Nearest`.

Overflow mode

Select the “overflow mode” for fixed-point operations. The filter coefficients do not obey this parameter; they are always saturated.

Section I/O

Choose how you specify the word length and the fraction length of the fixed-point data type going into and coming out of each section of a biquadratic filter. See “Filter Structure Diagrams” on page 1-418 for illustrations depicting the use of the section I/O data type in this block.

This parameter is only visible when the selected filter structure is biquadratic:

- When you select `Same as input`, these characteristics match those of the input to the block.
- When you select `Binary point scaling`, you can enter the word and fraction lengths of the section input and output, in bits.
- When you select `Slope and bias scaling`, you can enter the word lengths, in bits, and the slopes of the section input and output. This block requires power-of-two slope and a bias of zero.

Tap sum

Choose how you specify the word length and the fraction length of the tap sum data type of a direct form symmetric or direct form antisymmetric filter. See “Filter Structure Diagrams” on page 1-418 for illustrations depicting the use of the tap sum data type in this block.

This parameter is only visible when the selected filter structure is either `Direct form symmetric` or `Direct form antisymmetric`:

- When you select `Same as input`, these characteristics match those of the input to the block.
- When you select `Binary point scaling`, you can enter the word length and the fraction length of the tap sum accumulator, in bits.
- When you select `Slope and bias scaling`, you can enter the word length, in bits, and the slope of the tap sum accumulator. This block requires power-of-two slope and a bias of zero.

Multiplicand

Choose how you specify the word length and the fraction length of the multiplicand data type of a direct form I transposed or biquadratic direct form I transposed filter. See "Filter Structure Diagrams" on page 1-418 for illustrations depicting the use of the multiplicand data type in this block.

This parameter is only visible when the selected filter structure is either `Direct form I transposed` or `Biquad direct form I transposed (SOS)`:

- When you select `Same as output`, these characteristics match those of the output to the block.
- When you select `Binary point scaling`, you can enter the word length and the fraction length of the multiplicand data type, in bits.
- When you select `Slope and bias scaling`, you can enter the word length, in bits, and the slope of the multiplicand data type. This block requires power-of-two slope and a bias of zero.

Coefficients

Choose how you specify the word length and the fraction length of the filter coefficients (numerator and/or denominator). See "Filter Structure Diagrams" on page 1-418 for illustrations depicting the use of the coefficient data types in this block:

- When you select `Same word length as input`, the word length of the filter coefficients match that of the input to the block. In this mode, the fraction length of the coefficients is automatically set to the binary-point only scaling that provides you with the best precision possible given the value and word length of the coefficients.
- When you select `Specify word length`, you can enter the word length of the coefficients, in bits. In this mode, the fraction length of the coefficients is automatically set to the binary-point only scaling that provides you with the best precision possible given the value and word length of the coefficients.
- When you select `Binary point scaling`, you can enter the word length and the fraction length of the coefficients, in bits. If applicable, you can enter separate fraction lengths for the numerator and denominator coefficients.
- When you select `Slope and bias scaling`, you can enter the word length, in bits, and the slope of the coefficients. If applicable, you can enter separate slopes for the numerator and denominator coefficients. This block requires power-of-two slope and a bias of zero.

- The filter coefficients do not obey the **Rounding mode** and the **Overflow mode** parameters; they are always saturated and rounded to `Nearest`.

Product output

Use this parameter to specify how you would like to designate the product output word and fraction lengths. See “Filter Structure Diagrams” on page 1-418 and “Multiplication Data Types” for illustrations depicting the use of the product output data type in this block:

- When you select `Same as input`, these characteristics match those of the input to the block.
- When you select `Binary point scaling`, you can enter the word length and the fraction length of the product output, in bits.
- When you select `Slope and bias scaling`, you can enter the word length, in bits, and the slope of the product output. This block requires power-of-two slope and a bias of zero.

Accumulator

Use this parameter to specify how you would like to designate the accumulator word and fraction lengths. See “Filter Structure Diagrams” on page 1-418 and “Multiplication Data Types” for illustrations depicting the use of the accumulator data type in this block:

- When you select `Same as input`, these characteristics match those of the input to the block.
- When you select `Same as product output`, these characteristics match those of the product output.
- When you select `Binary point scaling`, you can enter the word length and the fraction length of the accumulator, in bits.
- When you select `Slope and bias scaling`, you can enter the word length, in bits, and the slope of the accumulator. This block requires power-of-two slope and a bias of zero.

State

Use this parameter to specify how you would like to designate the state word and fraction lengths. See “Filter Structure Diagrams” on page 1-418 for illustrations depicting the use of the state data type in this block.

This parameter is not visible for direct form and direct form I filter structures.

- When you select `Same as input`, these characteristics match those of the input to the block.
- When you select `Same as accumulator`, these characteristics match those of the accumulator.
- When you select `Binary point scaling`, you can enter the word length and the fraction length of the accumulator, in bits.
- When you select `Slope and bias scaling`, you can enter the word length, in bits, and the slope of the accumulator. This block requires power-of-two slope and a bias of zero.

Output

Choose how you specify the output word length and fraction length:

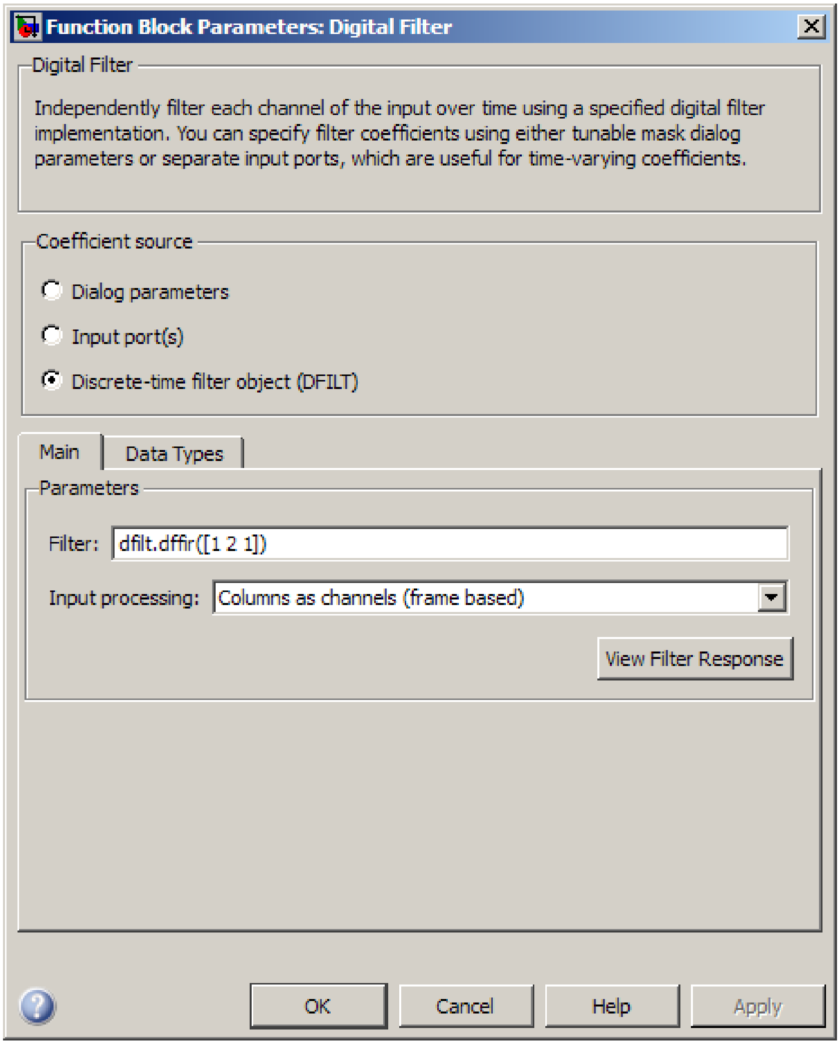
- When you select `Same as input`, these characteristics match those of the input to the block.
- When you select `Same as accumulator`, these characteristics match those of the accumulator.
- When you select `Binary point scaling`, you can enter the word length and the fraction length of the output, in bits.
- When you select `Slope and bias scaling`, you can enter the word length, in bits, and the slope of the output. This block requires power-of-two slope and a bias of zero.

Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

Specify Discrete-Time Filter Object

The **Main** pane of the Digital Filter block dialog appears as follows when **Discrete-time filter object (DFILT)** is specified in the **Coefficient source** group box.



Function Block Parameters: Digital Filter

Digital Filter

Independently filter each channel of the input over time using a specified digital filter implementation. You can specify filter coefficients using either tunable mask dialog parameters or separate input ports, which are useful for time-varying coefficients.

Coefficient source

○ Dialog parameters

○ Input port(s)

● Discrete-time filter object (DFILT)

Parameters

Filter: dfilt.dffir([1 2 1])

Input processing: Columns as channels (frame based)

Filter

Specify the discrete-time filter object (`dfilt`) that you would like the block to implement. You can do this in one of three ways:

- You can fully specify the `dfilt` object in the block mask, as shown in the default value.

- You can enter the variable name of a `dfilt` object that is defined in any workspace.
- You can enter a variable name for a `dfilt` object that is not yet defined.

Input processing

Specify how the block should process the input. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` — When you select this option, the block treats each column of the input as a separate channel.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

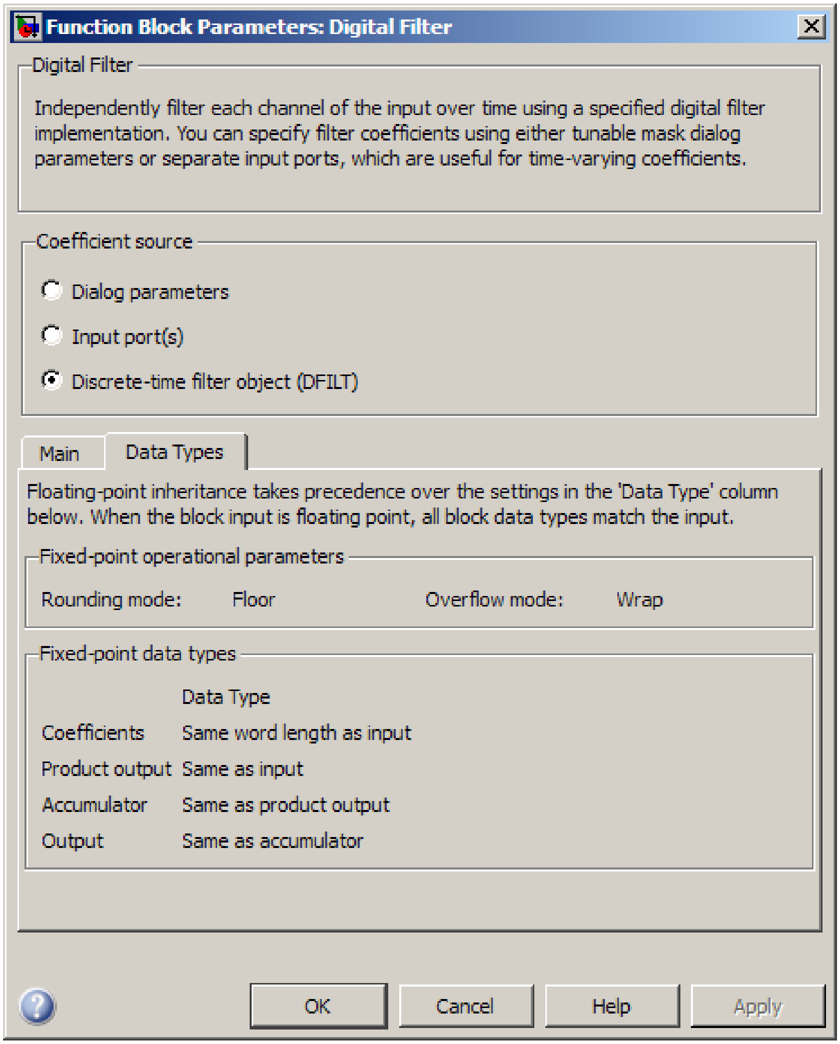
Note: The `Inherited (this choice will be removed - see release notes)` option will be removed in a future release. See "Frame-Based Processing" in the *DSP System Toolbox Release Notes* for more information.

View filter response

This button opens the Filter Visualization Tool (`fvtool`) from the Signal Processing Toolbox product and displays the filter response of the `dfilt` object specified in the **Filter** parameter. For more information on FVTool, see the Signal Processing Toolbox documentation.

Note: If you specify a filter in the **Filter** parameter, you must click the **Apply** button to apply the filter before using the **View filter response** button.

The **Data Types** pane of the Digital Filter block dialog appears as follows when **Discrete-time filter object (DFILT)** is specified in the **Coefficient source** group box.



Function Block Parameters: Digital Filter

Digital Filter

Independently filter each channel of the input over time using a specified digital filter implementation. You can specify filter coefficients using either tunable mask dialog parameters or separate input ports, which are useful for time-varying coefficients.

Coefficient source

○ Dialog parameters

○ Input port(s)

● Discrete-time filter object (DFILT)

Floating-point inheritance takes precedence over the settings in the 'Data Type' column below. When the block input is floating point, all block data types match the input.

Fixed-point operational parameters

Rounding mode: Floor   Overflow mode: Wrap

Fixed-point data types

	Data Type
Coefficients	Same word length as input
Product output	Same as input
Accumulator	Same as product output
Output	Same as accumulator

The fixed-point settings of the filter object specified on the **Main** pane are displayed on the **Data Types** pane. You cannot change these settings directly on the block mask. To change the fixed-point settings you must edit the filter object directly.

For more information on discrete-time filter objects, see the `dfilt` reference page.

Filter Structure Diagrams

The diagrams in the following sections show the filter structures supported by the Digital Filter block. They also show the data types used in the filter structures for fixed-point signals. You can set the coefficient, output, accumulator, product output, and state data types shown in these diagrams in the block dialog. This is discussed in “Dialog Box” on page 1-404.

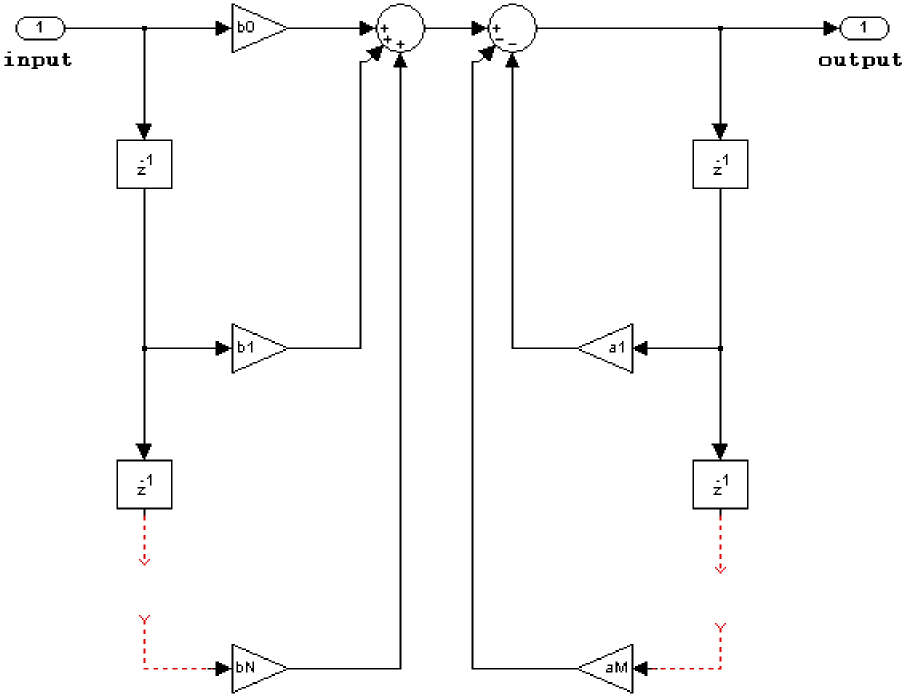
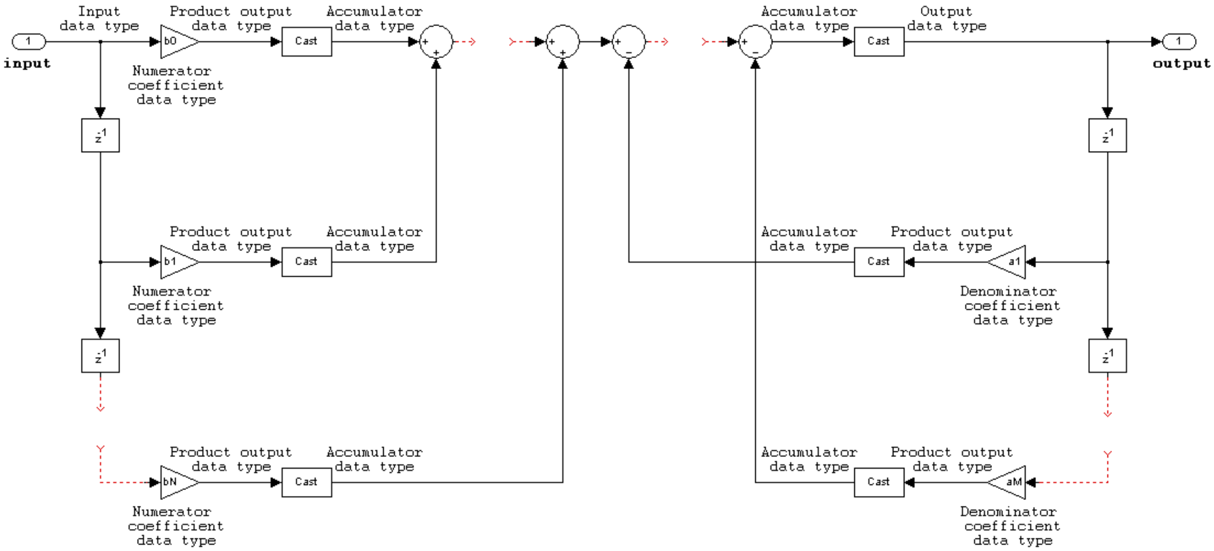
IIR direct form I



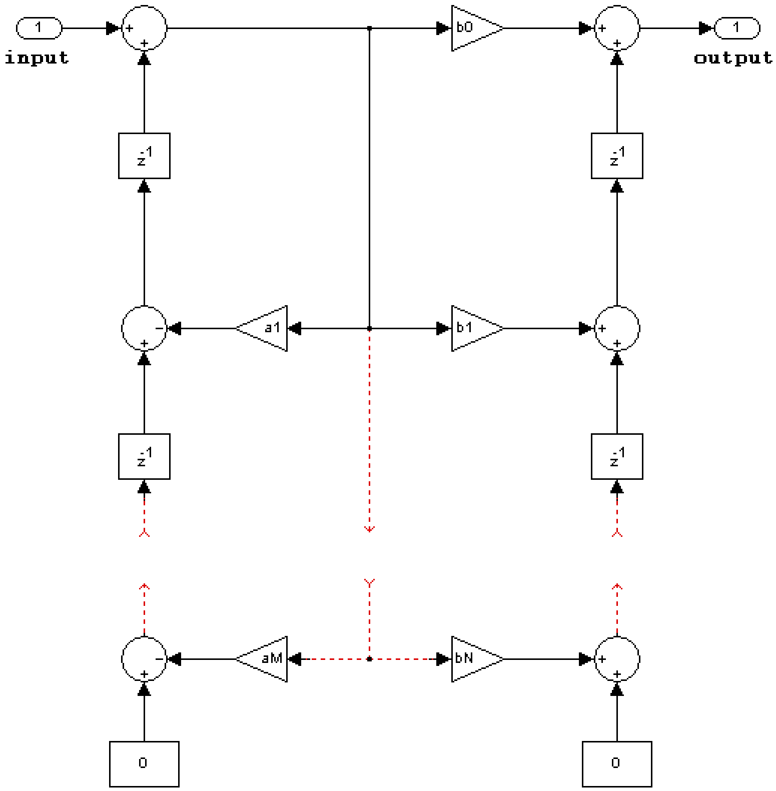
The following constraints are applicable when processing a fixed-point signal with this filter structure:

- Inputs can be real or complex.
- Numerator and denominator coefficients can be real or complex.
- Numerator and denominator coefficients must be the same complexity as each other.
  - When the numerator and denominator coefficients are specified via input ports and have different complexities from each other, you get an error.
  - When the numerator and denominator coefficients are specified in the dialog and have different complexities from each other, the block does not error, but instead processes the filter as if two sets of complex coefficients are provided. The coefficient set that is real-valued is treated as if it is a complex vector with zero-valued imaginary parts.

- Numerator and denominator coefficients must have the same word length. They can have different fraction lengths.
- The State data type cannot be specified on the block mask for this structure, because the input and output states have the same data types as the input and output buffers.



IIR direct form I transposed

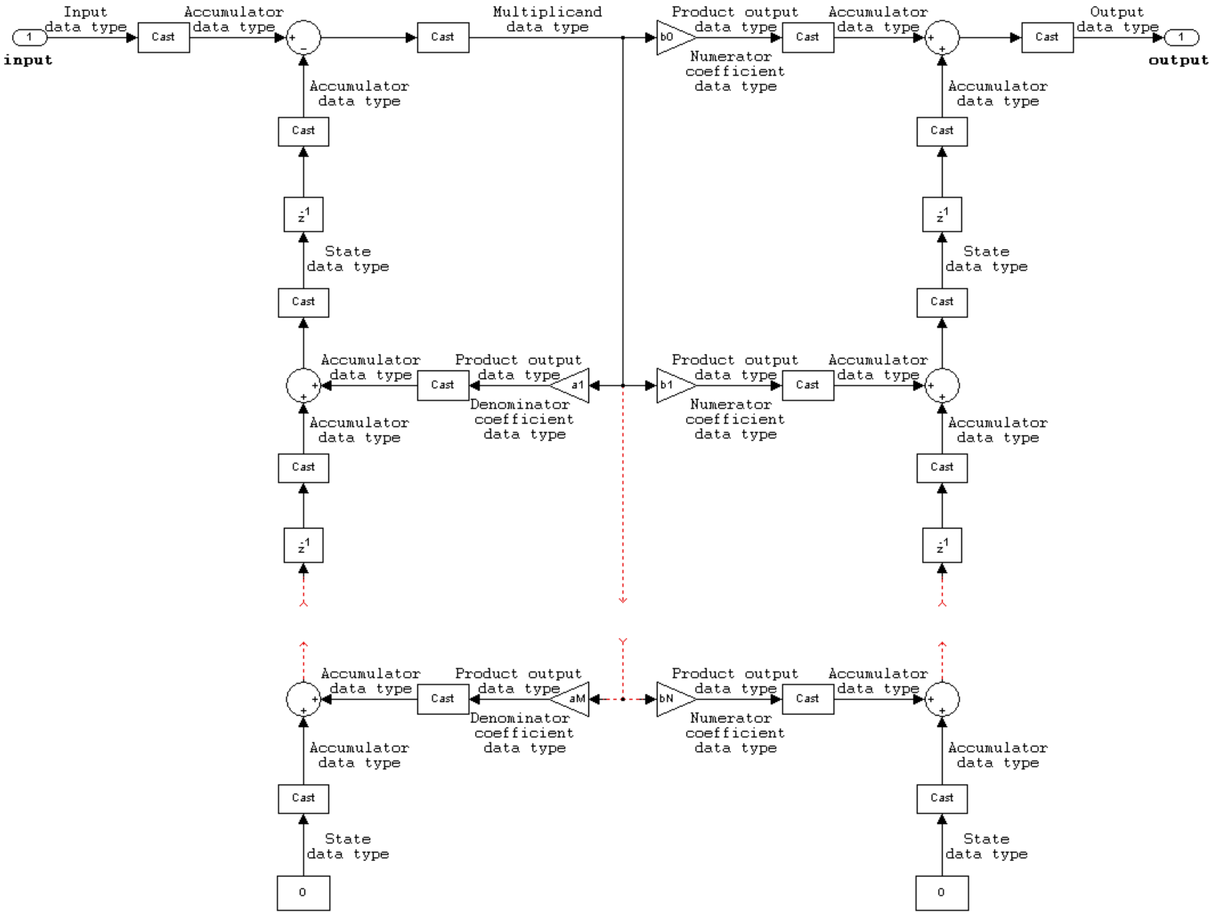


The following constraints are applicable when processing a fixed-point signal with this filter structure:

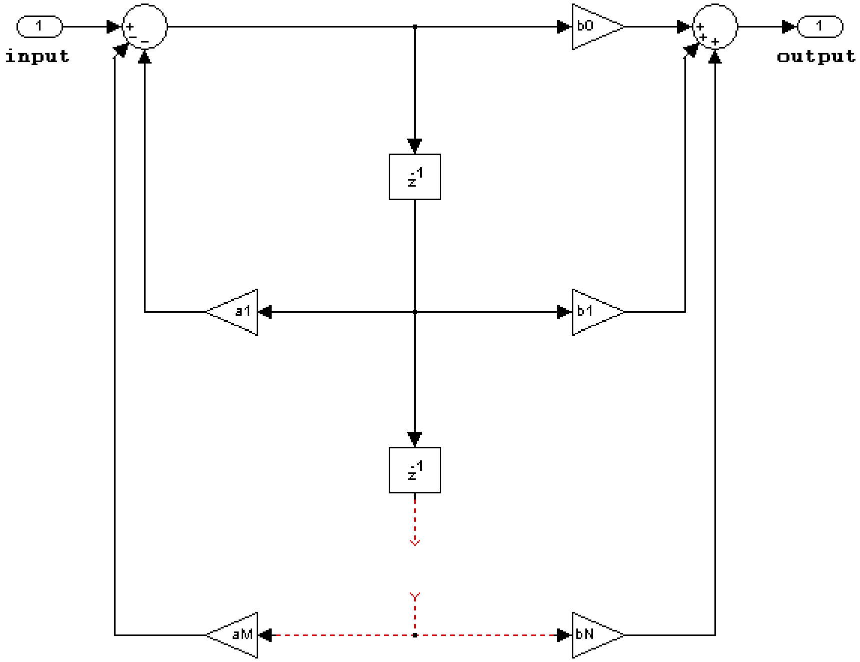
- Inputs can be real or complex.
- Numerator and denominator coefficients can be real or complex.
- Numerator and denominator coefficients must be the same complexity as each other.
  - When the numerator and denominator coefficients are specified via input ports and have different complexities from each other, you get an error.
  - When the numerator and denominator coefficients are specified in the dialog and have different complexities from each other, the block does not error, but

instead processes the filter as if two sets of complex coefficients are provided. The coefficient set that is real-valued is treated as if it is a complex vector with zero-valued imaginary parts.

- States are complex when either the input or the coefficients are complex.
- Numerator and denominator coefficients must have the same word length. They can have different fraction lengths.



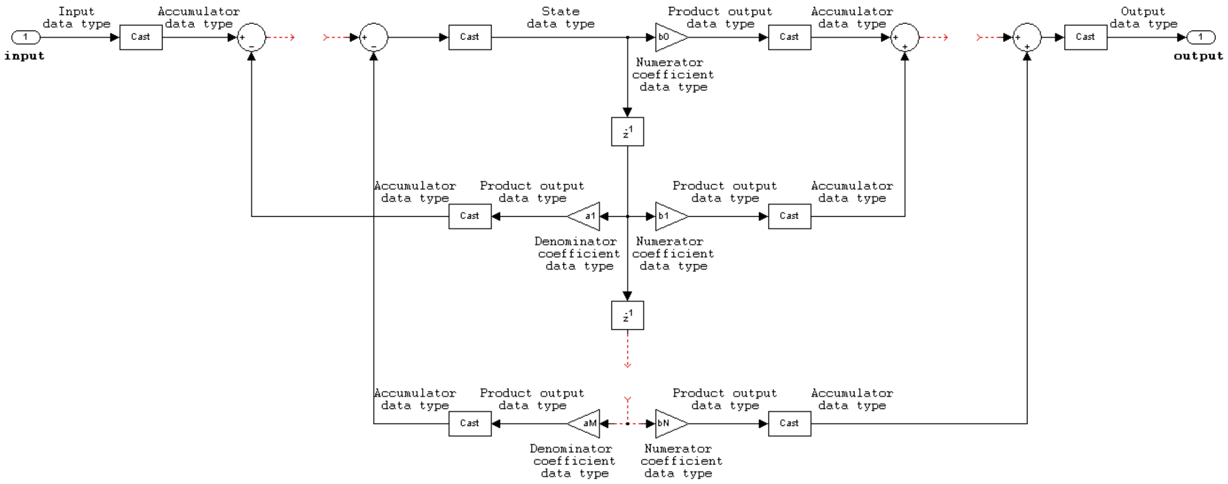
IIR direct form II



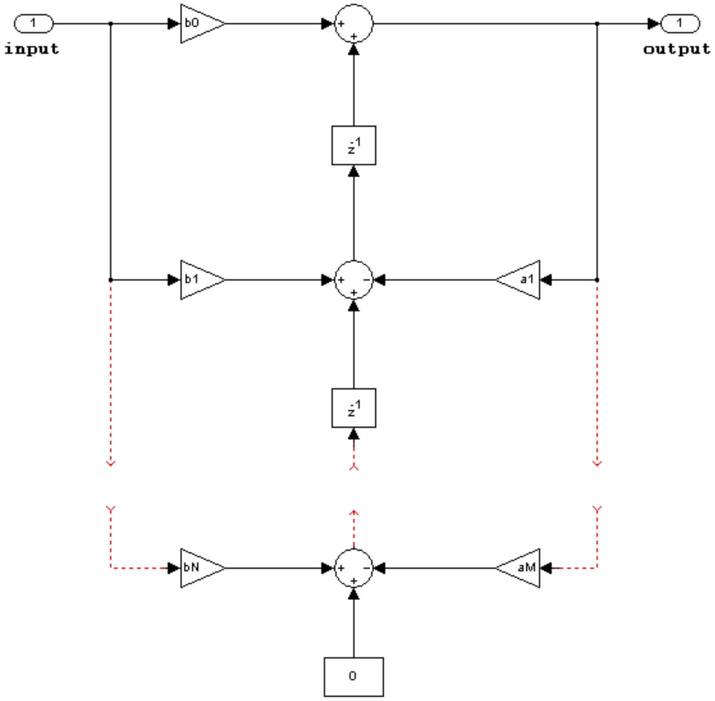
The following constraints are applicable when processing a fixed-point signal with this filter structure:

- Inputs can be real or complex.
- Numerator and denominator coefficients can be real or complex.
- Numerator and denominator coefficients must be the same complexity as each other.
    - When the numerator and denominator coefficients are specified via input ports and have different complexities from each other, you get an error.
    - When the numerator and denominator coefficients are specified in the dialog and have different complexities from each other, the block does not error, but instead processes the filter as if two sets of complex coefficients are provided. The coefficient set that is real-valued is treated as if it is a complex vector with zero-valued imaginary parts.
- States are complex when either the inputs or the coefficients are complex.

- Numerator and denominator coefficients must have the same word length. They can have different fraction lengths.



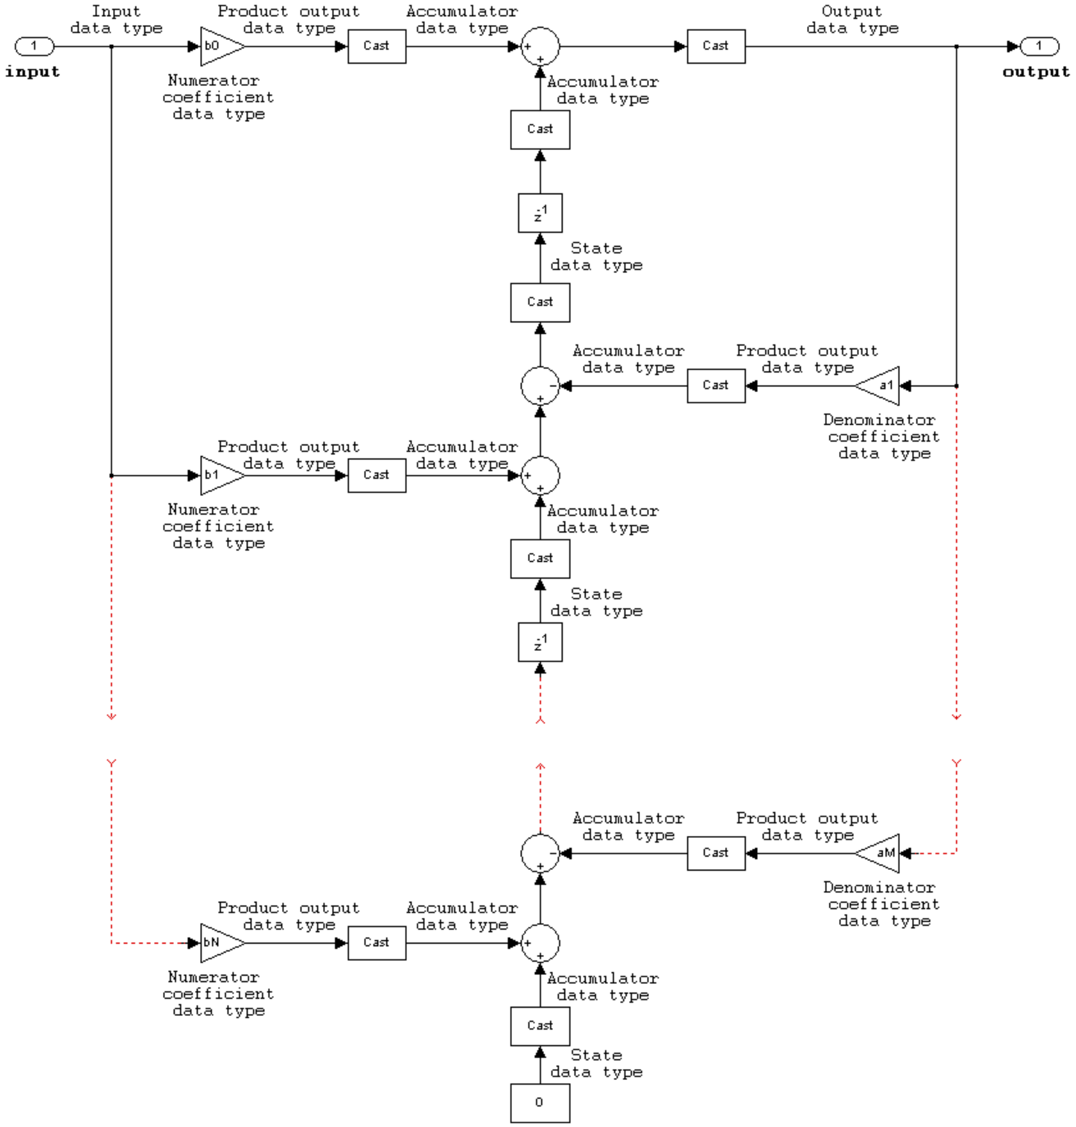
IIR direct form II transposed



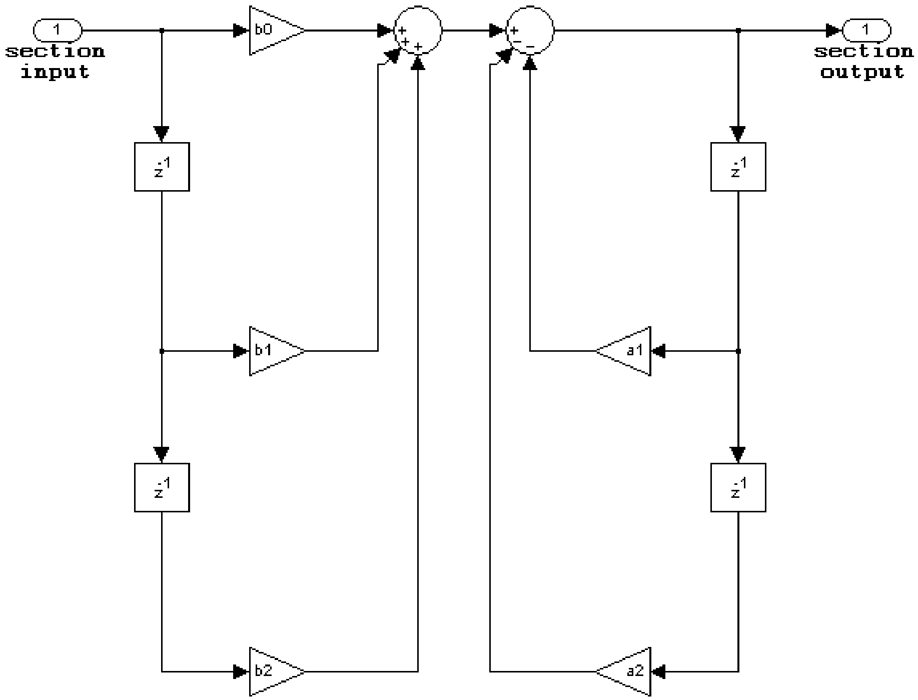
The following constraints are applicable when processing a fixed-point signal with this filter structure:

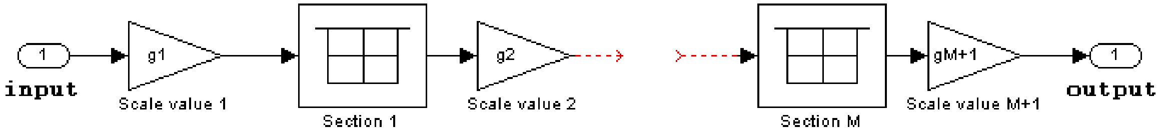
- Inputs can be real or complex.
- Numerator and denominator coefficients can be real or complex.
- Numerator and denominator coefficients must be the same complexity as each other.
  - When the numerator and denominator coefficients are specified via input ports and have different complexities from each other, you get an error.
  - When the numerator and denominator coefficients are specified in the dialog and have different complexities from each other, the block does not error, but instead processes the filter as if two sets of complex coefficients are provided. The coefficient set that is real-valued is treated as if it is a complex vector with zero-valued imaginary parts.

- States are complex when either the inputs or the coefficients are complex.
- Numerator and denominator coefficients must have the same word length. They can have different fraction lengths.



IIR biquadratic direct form I



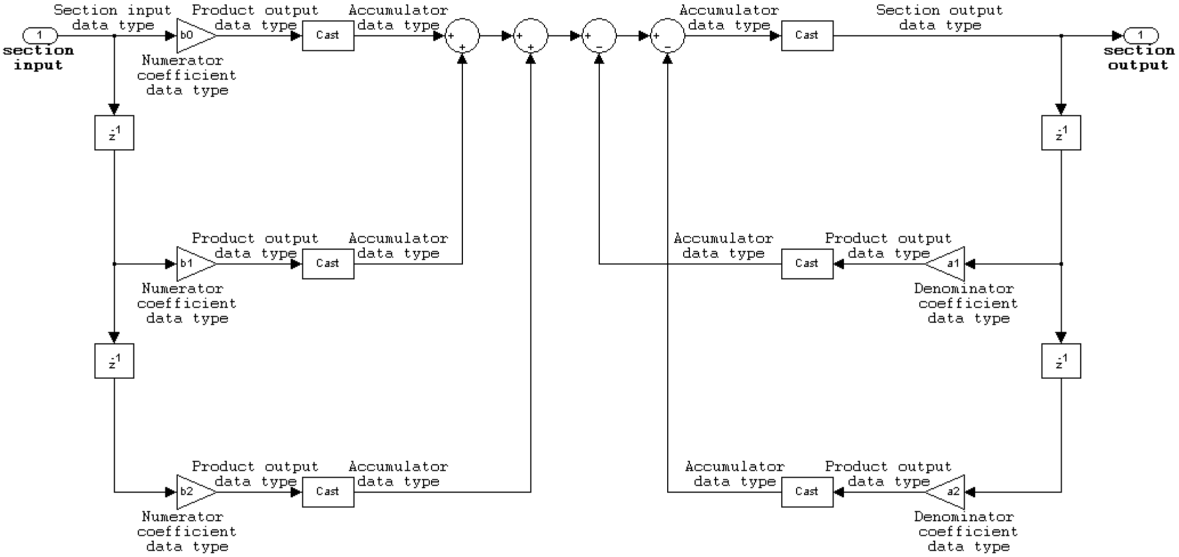


The following constraints are applicable when processing a fixed-point signal with this filter structure:

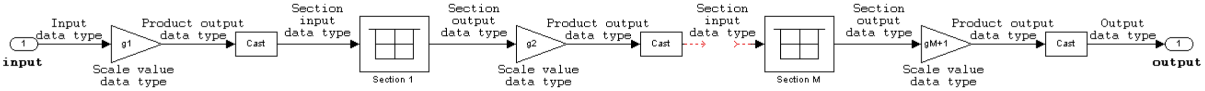
- Inputs and coefficients can be real or complex.
- Numerator and denominator coefficients can be real or complex.
- Specify the coefficients by a *M*-by-6 matrix in the block mask. You cannot specify coefficients by input ports for this filter structure.

- When the a0 element of any row is not equal to one, that row is normalized by a0 prior to filtering.
- States are complex when either the inputs or the coefficients are complex.
- You cannot specify the state data type on the block mask for this structure, because the input and output states have the same data types as the input.
- Scale values must have the same complexity as the coefficient SOS matrix.
- The scale value parameter must be a scalar or a vector of length *M*+1, where *M* is the number of sections.
- The **Section I/O** parameter determines the data type for the section input and output data types. The section input and stage output data type must have the same word length but can have different fraction lengths.

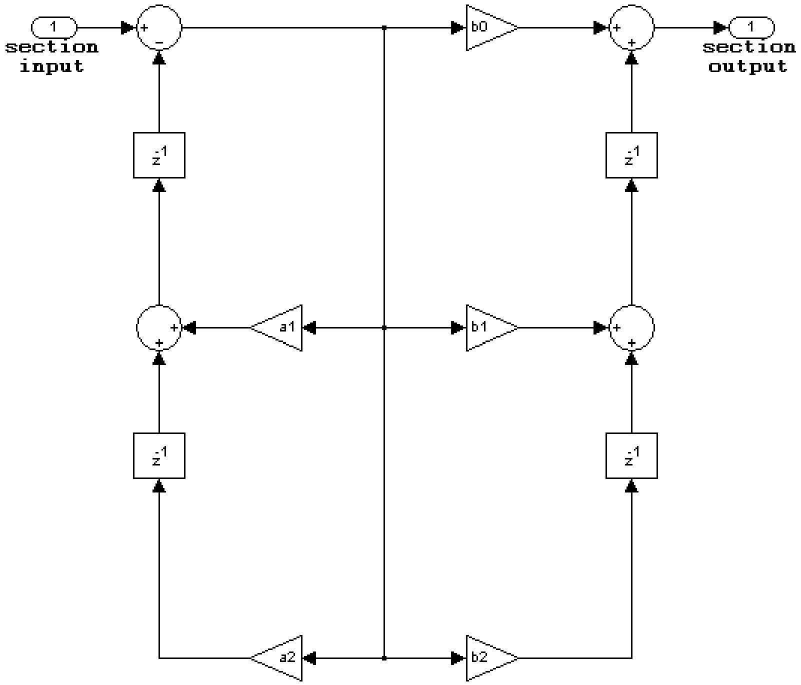
The following diagram shows the data types for one section of the filter.

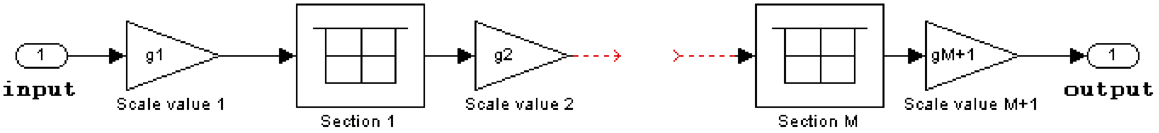


The following diagram shows the data types between filter sections.



IIR biquadratic direct form I transposed



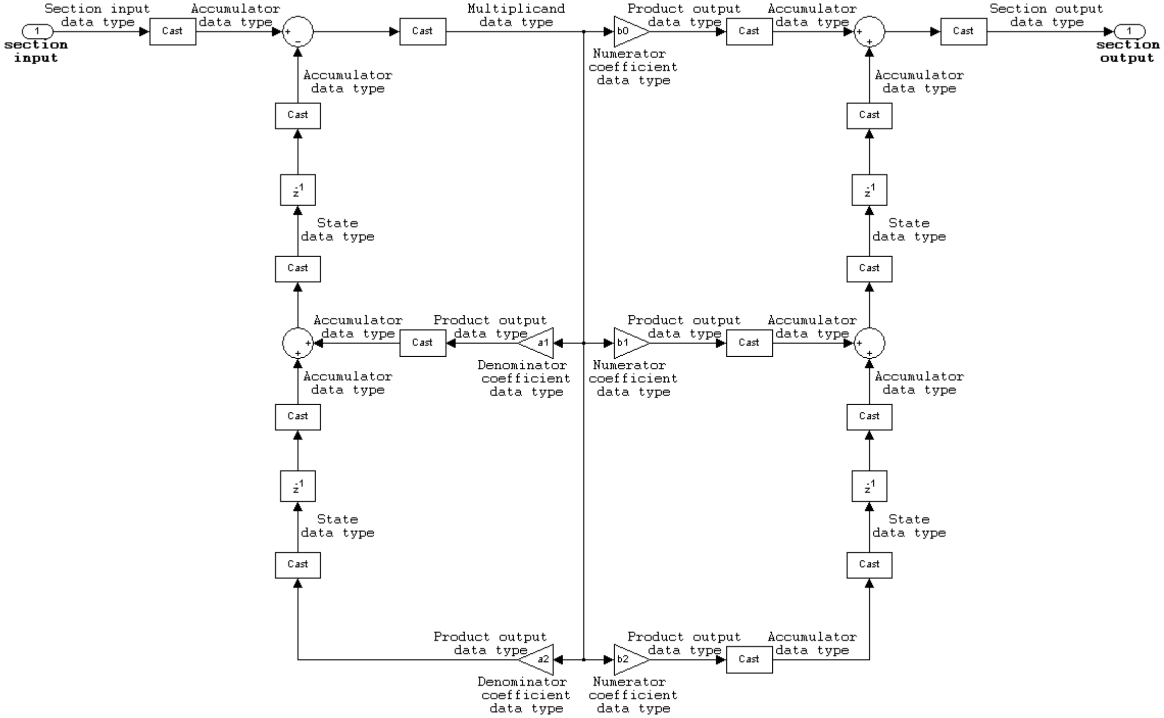


The following constraints are applicable when processing a fixed-point signal with this filter structure:

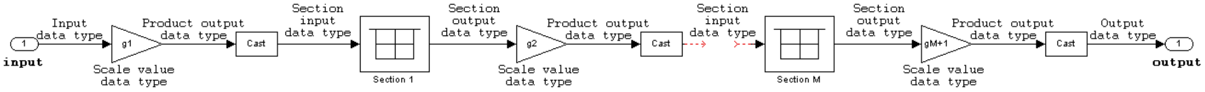
- Inputs and coefficients can be real or complex.
- Numerator and denominator coefficients can be real or complex.
- Specify the coefficients by a *M*-by-6 matrix in the block mask. You cannot specify coefficients by input ports for this filter structure.
- When the a0 element of any row is not equal to one, that row is normalized by a0 prior to filtering.

- States are complex when either the inputs or the coefficients are complex.
- Scale values must have the same complexity as the coefficient SOS matrix.
- The scale value parameter must be a scalar or a vector of length *M*+1, where *M* is the number of sections.
- The **Section I/O** parameter determines the data type for the section input and output data types. The section input and section output data type must have the same word length but can have different fraction lengths.

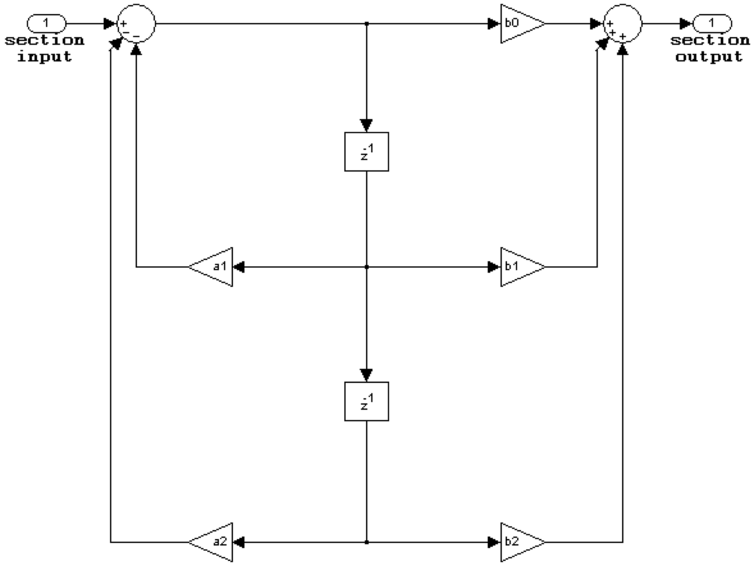
The following diagram shows the data types for one section of the filter.

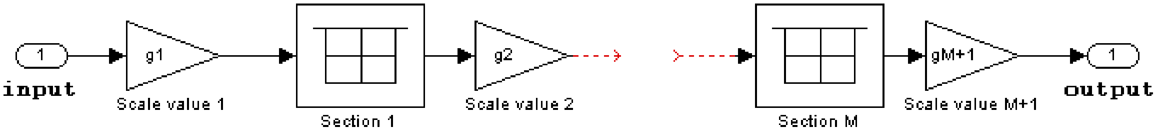


The following diagram shows the data types between filter sections.



IIR biquadratic direct form II



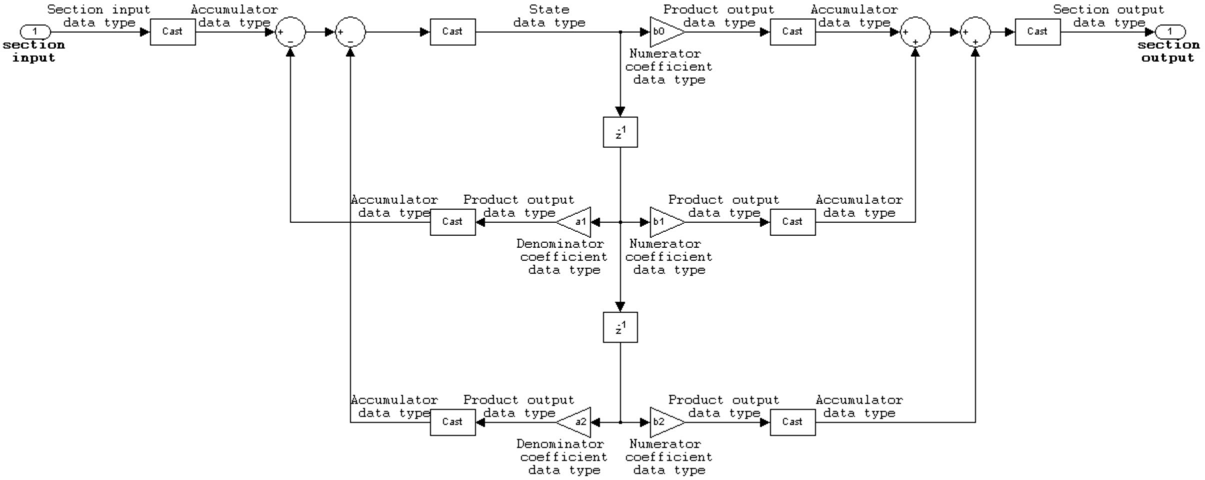


The following constraints are applicable when processing a fixed-point signal with this filter structure:

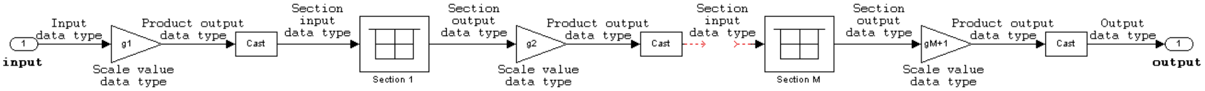
- Inputs and coefficients can be real or complex.
- Numerator and denominator coefficients can be real or complex.
- Specify the coefficients by a *M*-by-6 matrix in the block mask. You cannot specify coefficients by input ports for this filter structure.
- When the a0 element of any row is not equal to one, that row is normalized by a0 prior to filtering.
- States are complex when either the inputs or the coefficients are complex.
- Scale values must have the same complexity as the coefficient SOS matrix.

- The scale value parameter must be a scalar or a vector of length *M*+1, where *M* is the number of sections.
- The **Section I/O** parameter determines the data type for the section input and output data types. The section input and section output data type must have the same word length but can have different fraction lengths.

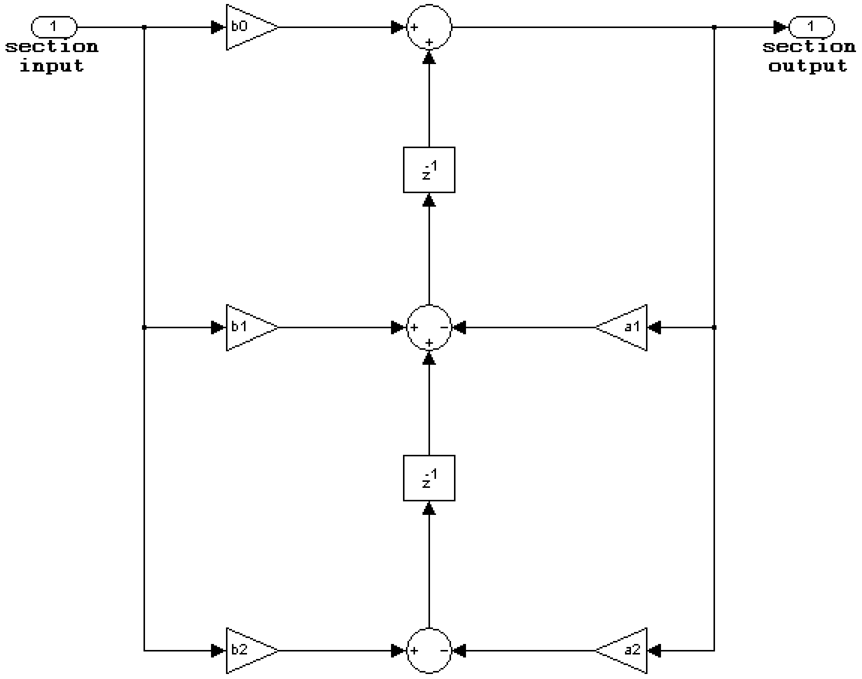
The following diagram shows the data types for one section of the filter.

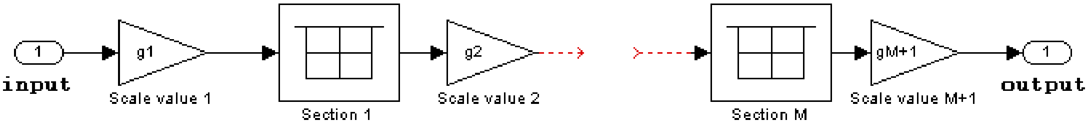


The following diagram shows the data types between filter sections.



IIR biquadratic direct form II transposed



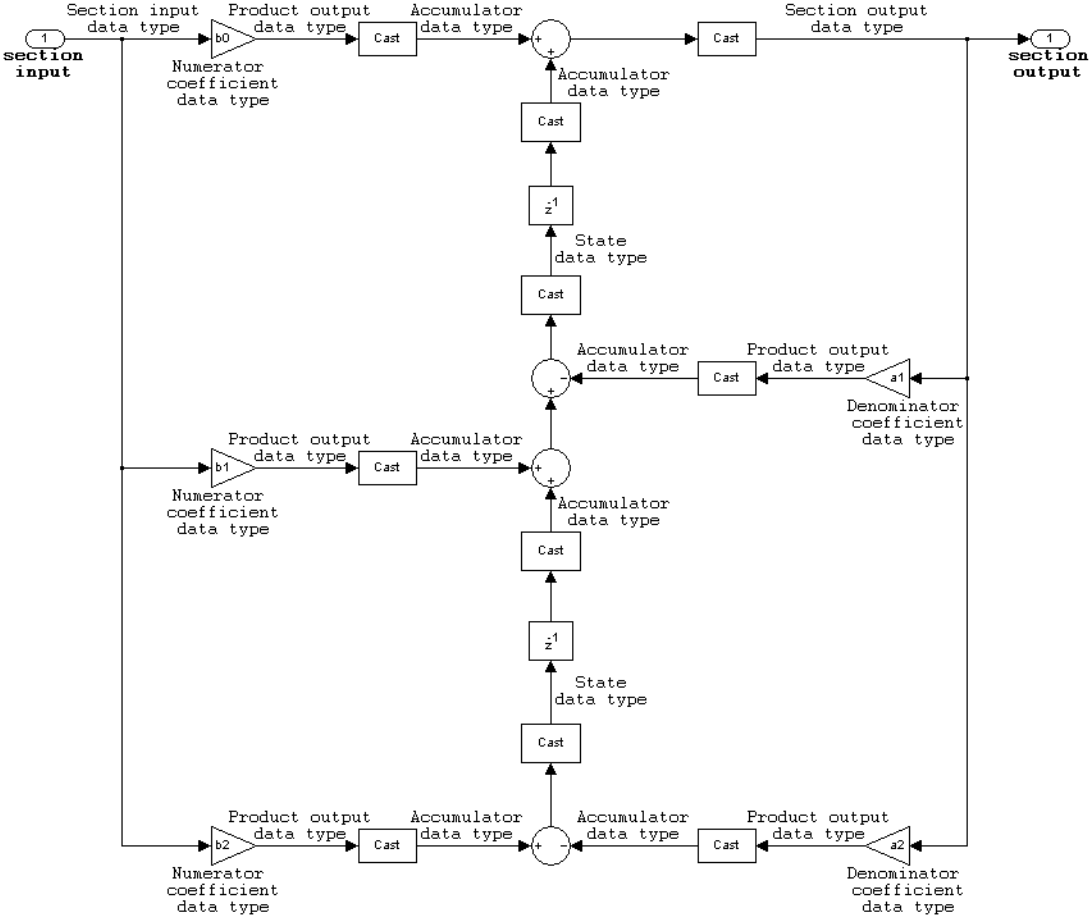


The following constraints are applicable when processing a fixed-point signal with this filter structure:

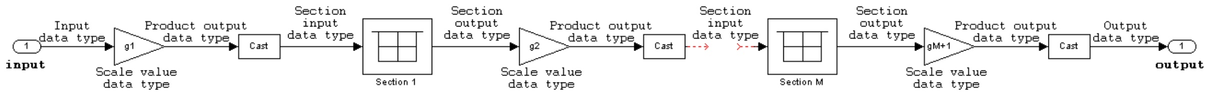
- Inputs and coefficients can be real or complex.
- Numerator and denominator coefficients can be real or complex.
- Specify the coefficients by a *M*-by-6 matrix in the block mask. You cannot specify coefficients by input ports for this filter structure.
- When the a0 element of any row is not equal to one, that row is normalized by a0 prior to filtering.
- States are complex when either the inputs or the coefficients are complex.

- Scale values must have the same complexity as the coefficient SOS matrix.
- The scale value parameter must be a scalar or a vector of length *M*+1, where *M* is the number of sections.
- The **Section I/O** parameter determines the data type for the section input and output data types. The section input and section output data type must have the same word length but can have different fraction lengths.

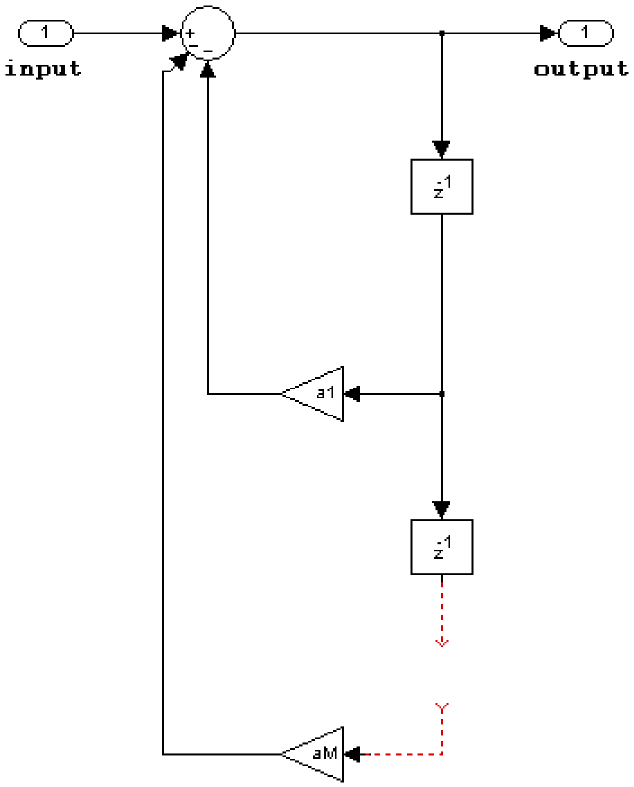
The following diagram shows the data types for one section of the filter.



The following diagram shows the data types between filter sections.



IIR (all poles) direct form



The following constraints are applicable when processing a fixed-point signal with this filter structure:

- Inputs and coefficients can be real or complex.
- Denominator coefficients can be real or complex.
- You cannot specify the state data type on the block mask for this structure, because the input and output states have the same data types as the input.

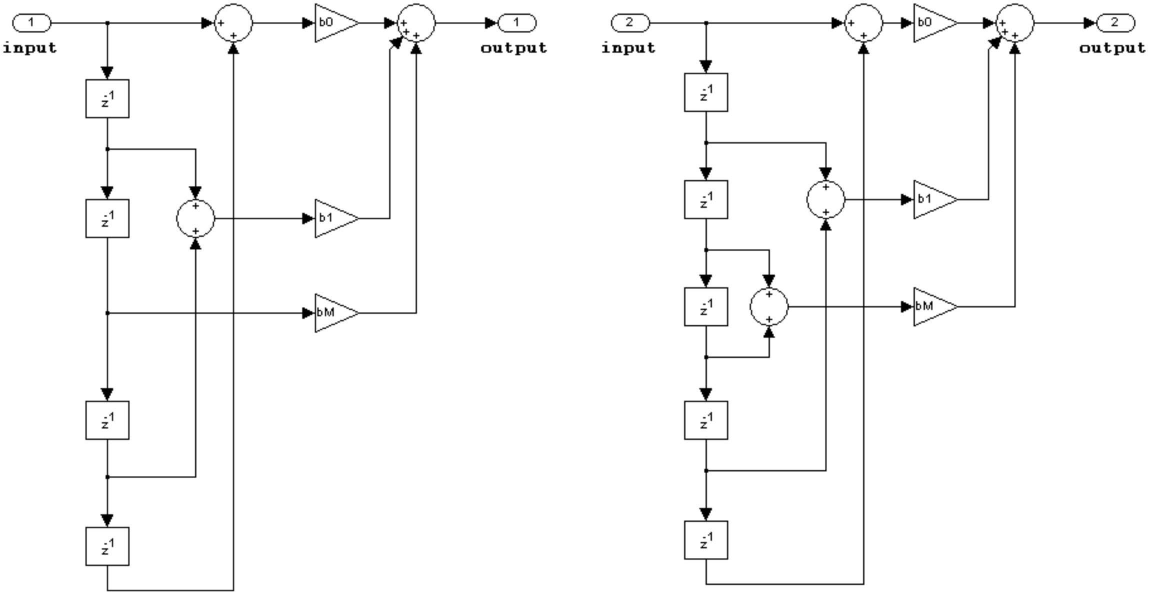
FIR (all zeros) direct form symmetric

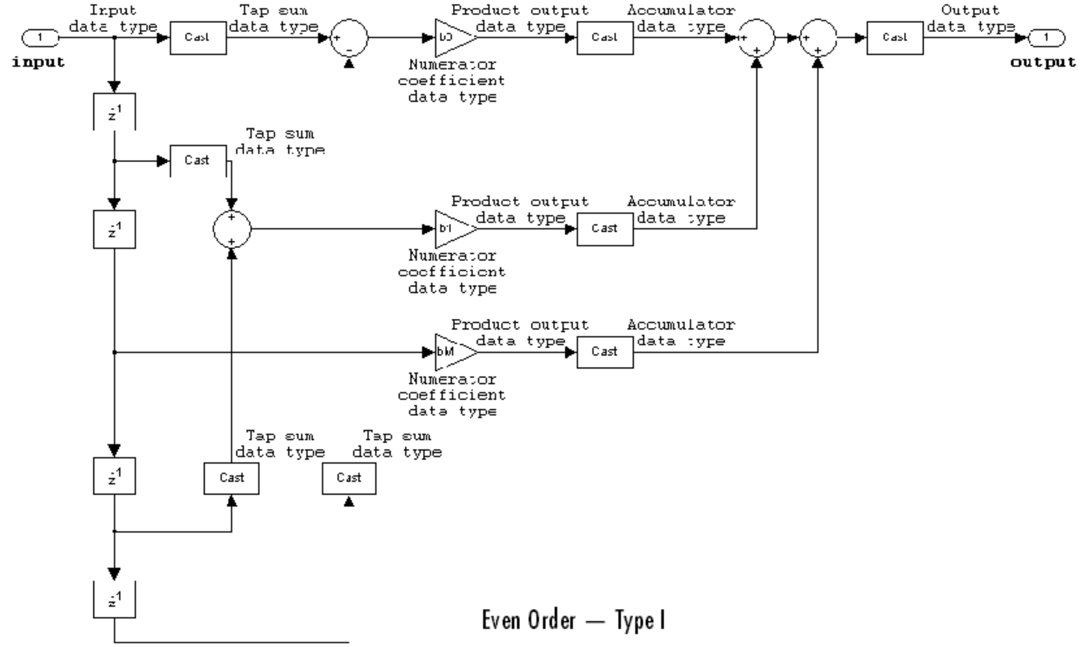


Even Order — Type I

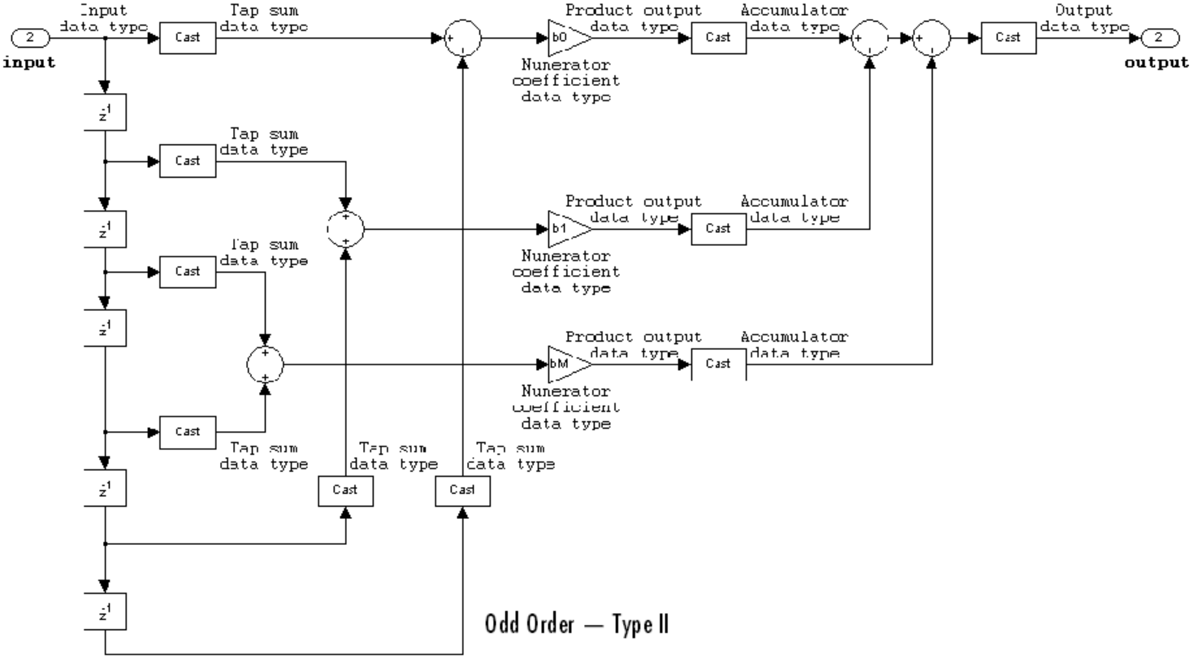
Odd Order — Type II

The following constraints are applicable when processing a fixed-point signal with this filter structure:

- Inputs can be real or complex.
- Numerator coefficients can be real or complex.
- You cannot specify the state data type on the block mask for this structure, because the input and output states have the same data types as the input.
- It is assumed that the filter coefficients are symmetric. Only the first half of the coefficients are used for filtering.
- The **Tap Sum** parameter determines the data type the filter uses when it sums the inputs prior to multiplication by the coefficients.

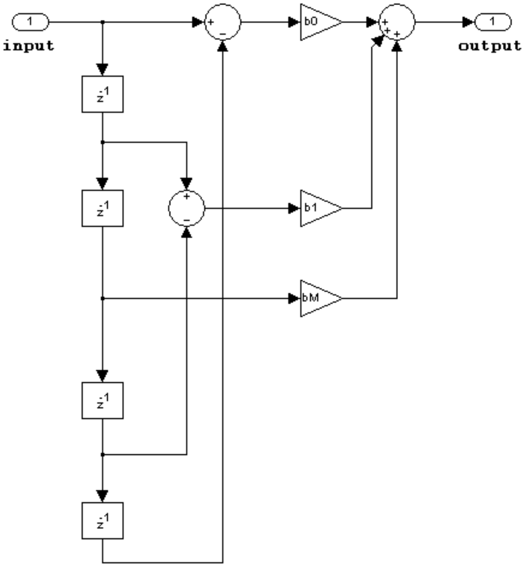


Even Order — Type I

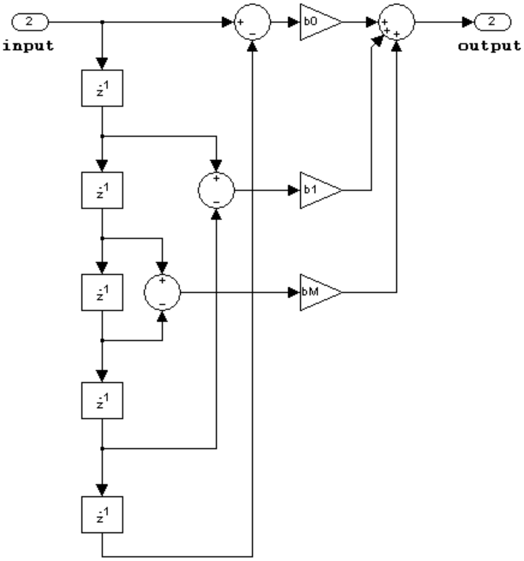


Odd Order — Type II

FIR (all zeros) direct form antisymmetric



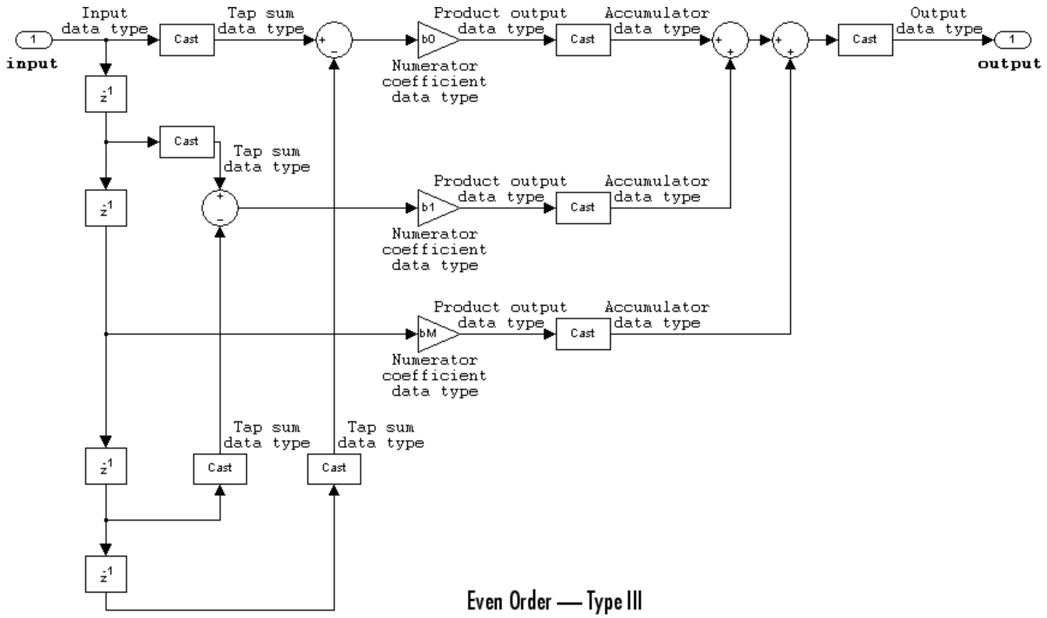
Even Order — Type III



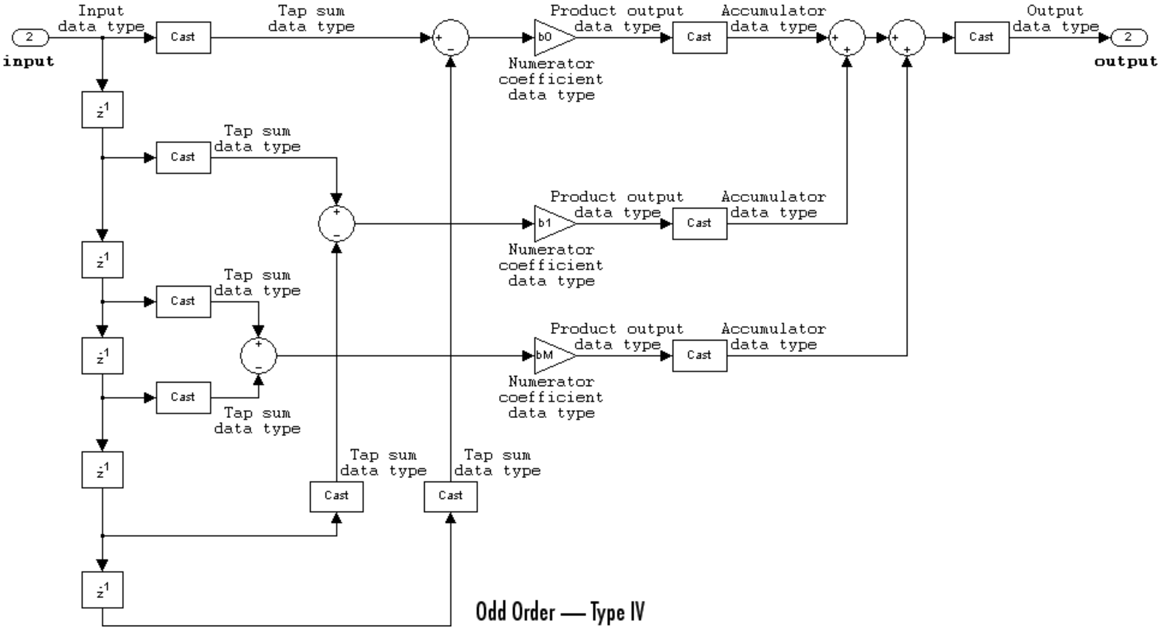
Odd Order — Type IV

The following constraints are applicable when processing a fixed-point signal with this filter structure:

- Inputs can be real or complex.
- Numerator coefficients can be real or complex.
- You cannot specify the state data type on the block mask for this structure, because the input and output states have the same data types as the input.
- It is assumed that the filter coefficients are antisymmetric. Only the first half of the coefficients are used for filtering.
- The **Tap Sum** parameter determines the data type the filter uses when it sums the inputs prior to multiplication by the coefficients.



Even Order — Type III



Odd Order — Type IV

FIR (all zeros) direct form transposed

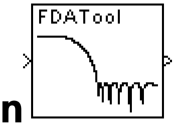
Digital Filter Design

Design and implement digital FIR and IIR filters

Library

Filtering / Filter Implementations

`dsparch4`



Description

Note: Use this block to design, analyze, and efficiently implement floating-point filters. The following blocks also implement digital filters, but serve slightly different purposes:

- Discrete FIR Filter and Biquad Filter— Use to efficiently implement floating-point or fixed-point filters that you have already designed. These blocks provide the same exact filter implementation as the Digital Filter Design block.

- Filter Realization Wizard — Use to implement floating-point or fixed-point filters built from Sum, Gain, and Unit Delay blocks. You can either design the filter within this block, or import the coefficients of a filter that you designed elsewhere.

The Digital Filter Design block implements a digital FIR or IIR filter that you design using the Filter Design and Analysis Tool (`fdatool`) GUI. This block provides the same filter implementation as the Discrete FIR Filter or Biquad Filter blocks.

You must specify whether the block performs “frame-based” or “sample-based” processing on the input by setting the **Input processing** parameter. The block applies the specified filter to each channel of a discrete-time input signal, and outputs the result. The outputs of the block numerically match the outputs of the Discrete FIR Filter or Biquad Filter block, the MATLAB `filter` function, and the DSP System Toolbox `filter` function.

The sampling frequency, Fs, that you specify in the FDATool GUI should be identical to the sampling frequency of the input to the Digital Filter Design block. When the sampling frequencies do not match, the Digital Filter Design block returns a warning message and inherits the sampling frequency of the input block.

Designing the Filter

Double-click the Digital Filter Design block to open FDATool. Use FDATool to design or import a digital FIR or IIR filter. To learn how to design filters with this block and FDATool, see the following topics:

- “Digital Filter Design Block”
- `fdatool` reference page

Tuning the Filter During Simulation

You can tune the filter specifications in FDATool during simulations as long as your changes do not modify the filter length or filter order. The filter updates as soon as you apply any filter changes in FDATool.

Examples

See the “Digital Filter Design Block” section in the DSP System Toolbox documentation.

Discrete Impulse

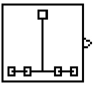
Generate discrete impulse

Library

Sources

`dspsrcs4`

Description



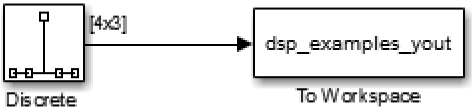
The Discrete Impulse block generates an impulse (the value `1`) at output sample `D+1`, where `D` is specified by the **Delay** parameter (`D` ≥`0`). All output samples preceding and following sample `D+1` are zero.

When `D` is a length-N vector, the block generates an M-by-N matrix output representing N distinct channels, where frame size M is specified by the **Samples per frame** parameter. The impulse for the `i`th channel appears at sample `D(i)+1`. For M=1, the output is sample based; otherwise, the output is frame based.

The **Sample time** parameter value, T_s, specifies the output signal sample period. The resulting frame period is $M*T_s$.

Examples

Construct the model below.



Configure the Discrete Impulse block to generate a frame-based three-channel output of type `double`, with impulses at samples 1, 4, and 6 of channels 1, 2, and 3, respectively. Use a sample period of 0.25 and a frame size of 4. The corresponding settings should be as follows:

- **Delay** = `[0 3 5]`
- **Sample time** = `0.25`
- **Samples per frame** = `4`
- **Output data type** = `double`

Run the model and look at the output, `dsp_examples_yout`. The first few samples of each channel are shown below.

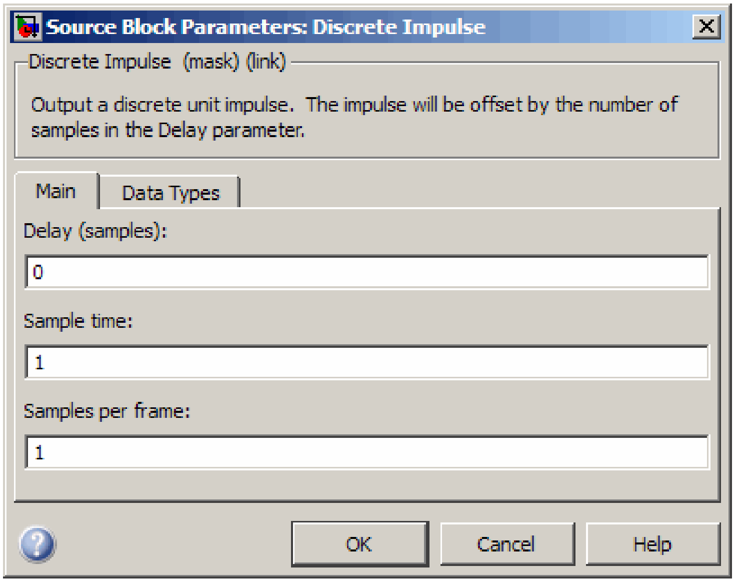
```
dsp_examples_yout(1:10,:)

ans =
     1     0     0
     0     0     0
     0     0     0
     0     1     0
     0     0     0
     0     0     1
     0     0     0
     0     0     0
     0     0     0
     0     0     0
```

The block generates an impulse at sample 1 of channel 1 (first column), at sample 4 of channel 2 (second column), and at sample 6 of channel 3 (third column).

Dialog Box

The **Main** pane of the Discrete Impulse block dialog appears as follows.



Source Block Parameters: Discrete Impulse

Discrete Impulse (mask) (link)

Output a discrete unit impulse. The impulse will be offset by the number of samples in the Delay parameter.

Delay (samples): 0

Sample time: 1

Samples per frame: 1

Delay

The number of zero-valued output samples, `D`, preceding the impulse. A length-N vector specifies an N-channel output.

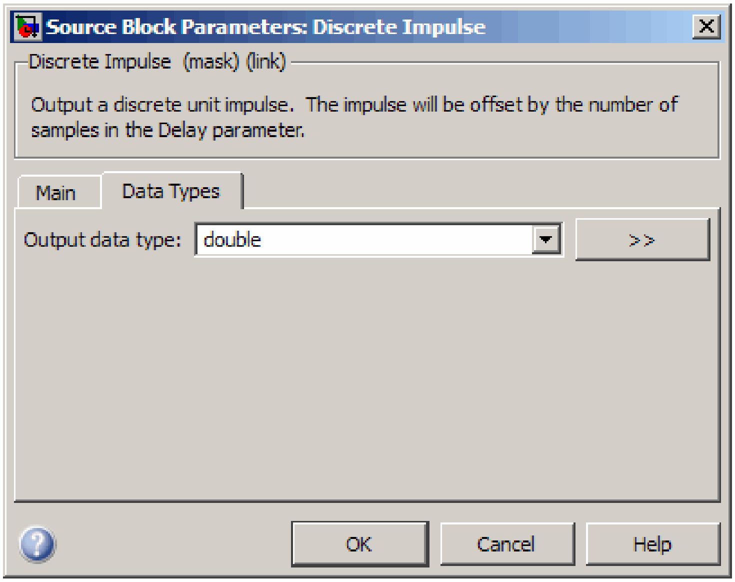
Sample time

The sample period, T_s, of the output signal. The output frame period is $M*T_s$.

Samples per frame

The number of samples, M, in each output frame. When the value of this parameter is `1`, the block outputs a sample-based signal.

The **Data Types** pane of the Discrete Impulse block dialog appears as follows.



Source Block Parameters: Discrete Impulse
Discrete Impulse (mask) (link)
Main

Help

Output a discrete unit impulse. The impulse will be offset by the number of samples in the Delay parameter.

Output data type: double

Output data type

Specify the output data type for this block. You can select one of the following:

- A rule that inherits a data type, for example, `Inherit: Inherit via back propagation`. When you select this option, the output data type and scaling matches that of the next downstream block.
- A built in data type, such as `double`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Specify Block Output Data Types” in “Simulink User's Guide” for more information.

Supported Data Types

- Double-precision floating point

Discrete Transfer Function Estimator

Compute estimate of frequency-domain transfer function of system

Library

Estimation / Power Spectrum Estimation

`dspspect3`

x
y
Discrete
Transfer Function
Estimator
H

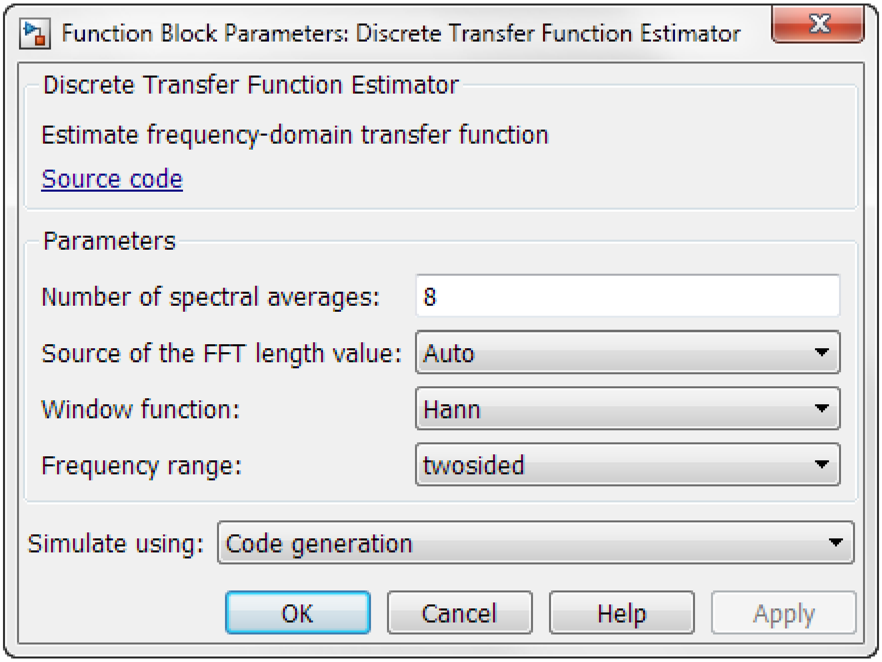
Description

The Discrete Transfer Function Estimator block estimates the frequency-domain transfer function of a system using the Welch algorithm and the Periodogram method.

The block takes two inputs, x and y. x is the system input signal and y is the system output signal. x and y must have the same dimensions. For 2D inputs, the block treats each column as an independent channel. The first dimension is the length of the channel. The second dimension is the number of channels. The block treats 1D inputs as one channel. The sample rate of the block is equal to $1/T$. T is the sample time of the inputs to the block.

The block first applies a window function to the two inputs, x and y, and then scales them by the window power. It takes the FFT of each signal, calling them X and Y. The block calculates P_{xx} which is the square magnitude of the FFT, X. The block then calculates P_{yx} which is X multiplied by the conjugate of Y. The output transfer function estimate, H, is calculated by dividing P_{yx} by P_{xx}.

Dialog Box



Function Block Parameters: Discrete Transfer Function Estimator

Discrete Transfer Function Estimator

Estimate frequency-domain transfer function

Source code

Parameters

Number of spectral averages: 8

Source of the FFT length value: Auto

Window function: Hann

Frequency range: twosided

Simulate using: Code generation

Parameters

Number of spectral averages

Specify the number of spectral averages. The Transfer Function Estimator block computes the current estimate by averaging the last *N* estimates. *N* is the number of spectral averages. It can be any positive integer scalar, and the default is 8.

Source of the FFT length value

Specify the source of the FFT length value. It can be one of `Auto` (default) or `Property`. When the source of the FFT length is set to `Auto`, the Transfer Function Estimator block sets the FFT length to the input frame size. When the source of the FFT length is set to `Property`, you specify the FFT length in the **FFT length** parameter.

FFT length

Specify the length of the FFT that the Transfer Function Estimator block uses to compute spectral estimates. It can be any positive integer scalar, and the default is 128.

Window function

Specify a window function for the Transfer Function Estimator block. Possible values are:

- `Hann` (default)
- `Rectangular`
- `Chebyshev`
- `Flat Top`
- `Hamming`
- `Kaiser`

Sidelobe attenuation of window

Specify the sidelobe attenuation of the window. It can be any real positive scalar value in decibels (dB).

Note: This parameter is visible only when **Window function** is set to `Kaiser` or `Chebyshev`.

Frequency range

Specify the frequency range of the transfer function estimate.

- `twosided` (default)

  When you set the frequency range to `twosided`, the Transfer Function Estimator block computes the two-sided transfer function of the real or complex input signals, *x* and *y*.
- `onesided`

  When you set the frequency range to `onesided`, the Transfer Function Estimator block computes the one-sided transfer function of real input signals, *x* and *y*.
- `centered`

When you set the frequency range to `centered`, the Transfer Function Estimator block computes the centered two-sided transfer function of the real or complex input signals, x and y.

Simulate Using

Choose whether you want to simulate using `Code generation` or `Interpreted execution`.

The **Simulate using** field determines the type of simulation to run. When `Code generation` is selected, the model simulates with generated C code. When `Interpreted execution` is selected, the model simulates using pre-compiled MATLAB code.

Supported Data Types

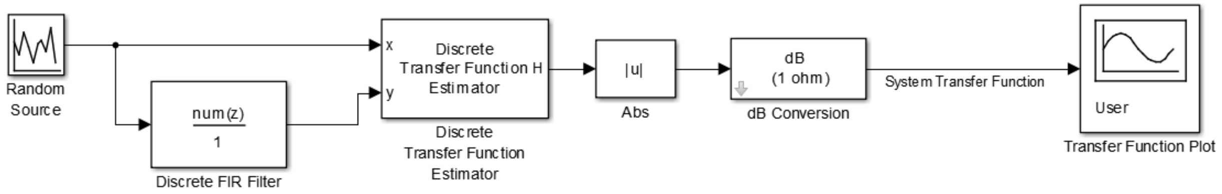
The Discrete Transfer Function Estimator block supports real and complex inputs.

Port	Supported Data Type
x	• Double-precision floating point • Single-precision floating point
y	• Double-precision floating point • Single-precision floating point
Output, H	• Double-precision floating point • Single-precision floating point

Examples

This example shows how to use the Discrete Transfer Function Estimator block to estimate the frequency-domain transfer function of a system.

The Random Source block represents the system input signal. The sample rate of the system input is 44.1 KHz. The Random Source input passes through a low-pass filter with a normalized cutoff frequency of 0.3. The filtered signal represents the system output signal. Because the Discrete Transfer Function Estimator block outputs complex values, take the magnitude of the output to see a plot of the transfer function estimate.



The transfer function plot displays the system transfer function, a low-pass filter that matches the frequency response of the Discrete FIR Filter block.

Downsample

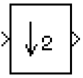
Resample input at lower rate by deleting samples

Library

Signal Operations

`dspsigops`

Description



The Downsample block decreases the sampling rate of the input by deleting samples. When the block performs frame-based processing, it resamples the data in each column of the M_i-by-N input matrix independently. When the block performs sample-based processing, it treats each element of the input as a separate channel and resamples each channel of the input array across time. The resample rate is K times lower than the input sample rate, where K is the integer you specify for the **Downsample factor** parameter. The Downsample block resamples the input by discarding K–1 consecutive samples following each sample that is passed through to the output.

The **Sample offset** parameter delays the output samples by an integer number of sample periods, D, where $0 \leq D \leq (K–1)$, so that any of the K possible output phases can be selected. For example, when you downsample the sequence 1, 2, 3, ... by a factor of 4, you can select from the following four phases.

Input Sequence	Sample Offset, D	Output Sequence (K=4)
`1,2,3,...`	0	`1,5,9,13,17,21,25,29,...`
`1,2,3,...`	1	`0,2,6,10,14,18,22,26,...`
`1,2,3,...`	2	`0,3,7,11,15,19,23,27,...`
`1,2,3,...`	3	`0,4,8,12,16,20,24,28,...`

The initial zero in each of the latter three output sequences in the table is a result of the default zero **Initial conditions** parameter setting for this example. See "Latency" on page 1-467 for more information on the **Initial conditions** parameter.

This block supports triggered subsystems when you set the **Rate options** parameter to `Enforce single-rate processing`.

Sample-Based Processing

When you set the **Input processing** parameter to `Elements as channels (sample based)`, the input can be an N-D array. The Downsample block treats each element of the input as a separate channel, and resamples each channel of the input over time. The block downsamples the input array by discarding K–1 samples following each sample that it passes through to the output. The input and output sizes of the Downsample block are identical.

The **Rate options** parameter specifies how the block adjusts the rate at the output to accommodate the reduced number of samples. There are two available options:

- `Allow multirate processing`

  When you select `Allow multirate processing`, the sample period of the output is K times longer than the input sample period ($T_{so} = KT_{si}$).

- `Enforce single-rate processing`

  When you select `Enforce single-rate processing`, the block forces the output sample rate to match the input sample rate ($T_{so} = T_{si}$) by repeating every Kth input sample K times at the output. In this mode, the behavior of the block is similar to the operation of a Sample and Hold block with a repeating trigger event of period KT_{si}.

Frame-Based Processing

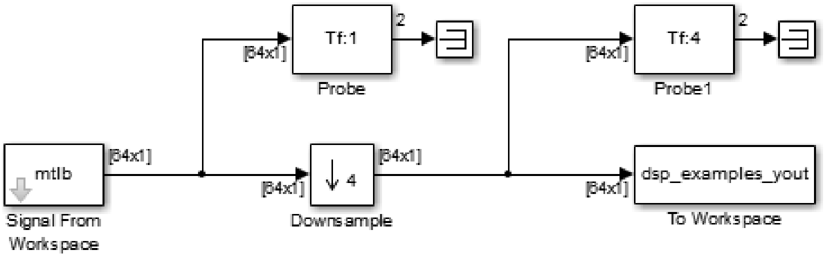
When you set the **Input processing** parameter to `Columns as channels (frame based)`, the block treats each of the N input columns as an individual channel containing M_i sequential time samples. The block downsamples each channel independently by discarding K–1 rows of the input matrix following each row that it passes through to the output.

The **Rate options** parameter specifies how the block adjusts the rate at the output to accommodate the reduced number of samples. There are two available options:

- `Allow multirate processing`

  The block generates the output at the slower (downsampled) rate by using a proportionally longer frame *period* at the output port than at the input port. For downsampling by a factor of K, the output frame period is K times longer than the input frame period ($T_{fo} = KT_{fi}$), but the input and output frame sizes are equal.

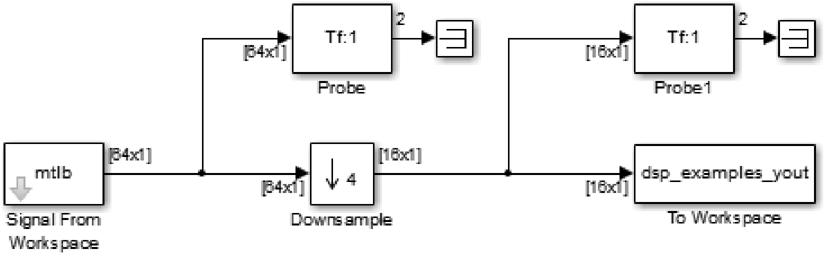
The ex_downsample_ref1 model shows a single-channel input with a frame period of 1 second being downsampled by a factor of 4 to a frame period of 4 seconds. The input and output frame sizes are identical.



- `Enforce single rate processing`

  The block generates the output at the slower (downsampled) rate using a proportionally smaller frame *size* than the input. For downsampling by a factor of K, the output frame size is K times smaller than the input frame size ($M_o = M_i/K$), but the input and output frame rates are equal.

  The ex_downsample_ref2 model shows a single-channel input with a frame size of 64 being downsampled by a factor of 4 to a frame size of 16. The input and output frame rates are identical.



Latency

The Downsample block has *zero-tasking latency* in the following cases:

- The **Downsample factor** parameter, K, is `1`.
- The **Input processing** parameter is set to `Columns as channels (frame based)` and the **Rate options** parameter is set to `Enforce single-rate processing`.
- The **Input processing** parameter is set to `Columns as channels (frame based)` and the input frame size is equal to one.
- The **Input processing** parameter is set to `Elements as channels (sample based)`, and **Sample offset** parameter, D, is `0`.

Zero-tasking latency means that the block propagates input sample D+1 (received at t=0) as the first output sample, followed by input sample D+1+K, input sample D+1+2K, and so on. When there is zero-tasking latency, the block ignores the value of the **Initial conditions** parameter.

In all other cases, the latency is nonzero:

- When the **Input processing** parameter is set to `Elements as channels (sample based)`, the latency is one sample.
- When the **Input processing** parameter is set to `Columns as channels (frame based)` and the input frame size is greater than one, the latency is one frame.

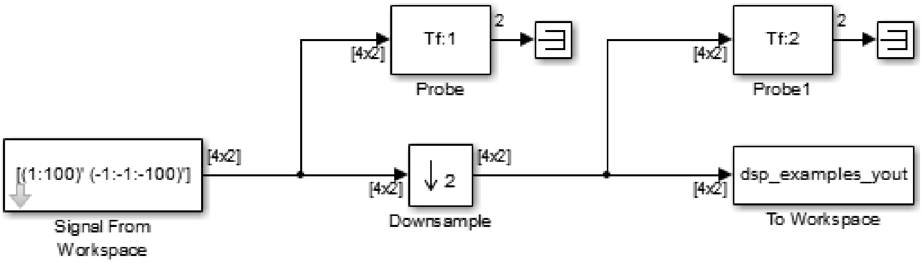
In all cases of *one-sample latency*, the initial condition for each channel appears as the first output sample. Input sample D+1 appears as the second output sample for each channel, followed by input sample D+1+K, input sample D+1+2K, and so on. The **Initial conditions** parameter can be an array of the same size as the input, or a scalar to be applied to all signal channels.

In all cases of *one-frame latency*, the M_i rows of the initial condition matrix appear in sequence as the first M_i output rows. Input sample D+1 (i.e, row D+1 of the input matrix) appears in the output as sample M_i+1, followed by input sample D+1+K, input sample D+1+2K, and so on. The **Initial conditions** value can be an M_i-by-N matrix containing one value for each channel, or a scalar to be repeated across all elements of the M_i-by-N matrix. See the following example for an illustration of this case.

Note For more information on latency and the Simulink tasking modes, see “Excess Algorithmic Delay (Tasking Latency)” and “Scheduling ” in the *Simulink Coder User's Guide*.

Examples

Open the ex_downsample_ref3 model.

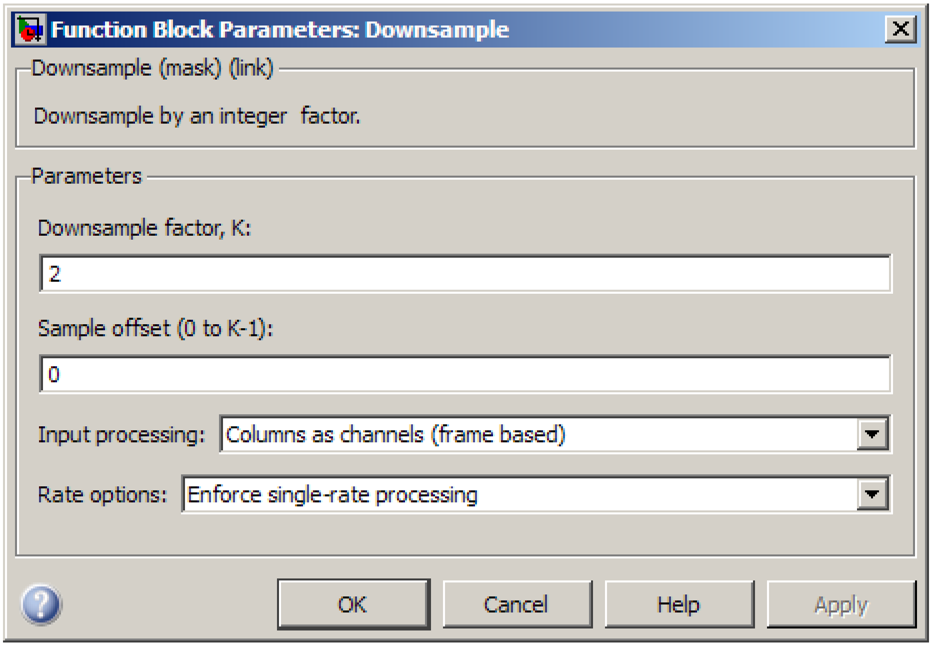


Run the model and look at the output, `yout`. The first few samples of each channel are as follows:

```
yout =
    11    -11
    12    -12
    13    -13
    14    -14
     2     -2
     4     -4
     6     -6
     8     -8
    10    -10
    12    -12
    14    -14
```

You can see from the two Probe blocks that there are at least two distinct frame rates in this model. Because you ran this model in multirate, multitasking mode, the first row of the initial condition matrix appears as the first output sample, followed by the other three initial condition rows. The second row of the first input matrix (row D+1, where D is the **Sample offset**) appears in the output as sample 5 (sample M_i+1, where M_i is the input frame size).

Dialog Box



Function Block Parameters: Downsample

Downsample (mask) (link)

Downsample by an integer factor.

Parameters

Downsample factor, K: 2

Sample offset (0 to K-1): 0

Input processing: Columns as channels (frame based)

Rate options: Enforce single-rate processing

Downsample factor

The integer factor, *K*, by which to decrease the input sample rate.

Sample offset

The sample offset, *D*, which must be an integer in the range [0, *K*–1].

Input processing

Specify how the block should process the input. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` — When you select this option, the block treats each column of the input as a separate channel. See "Frame-Based Processing" on page 1-466 for more information
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel. See "Sample-Based Processing" on page 1-466 for more information.

Note: The `Inherited (this choice will be removed - see release notes)` option will be removed in a future release.

Rate options

Specify the method by which the block should downsample the input. You can select one of the following options:

- `Enforce single-rate processing` — When you select this option, the block maintains the input sample rate.
- `Allow multirate processing` — When you select this option, the block downsamples the signal such that the output sample rate is *K* times slower than the input sample rate.

Initial conditions

The value with which the block is initialized for cases of nonzero latency. You can specify a scalar, or an array of the same size as the input. This parameter appears only when you set the **Rate options** parameter to `Allow multirate processing`.

HDL Code Generation

This block supports HDL code generation using HDL Coder. HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic. For more information on implementations, properties, and restrictions for HDL code generation, see Downsample.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers

Port	Supported Data Types
Output	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers

DSP Constant (Obsolete)

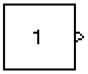
Generate discrete- or continuous-time constant signal

Library

Sources

`dspobslib`

Description



Note The DSP Constant block is still supported but is likely to be obsoleted in a future release. We strongly recommend replacing this block with the Constant block.

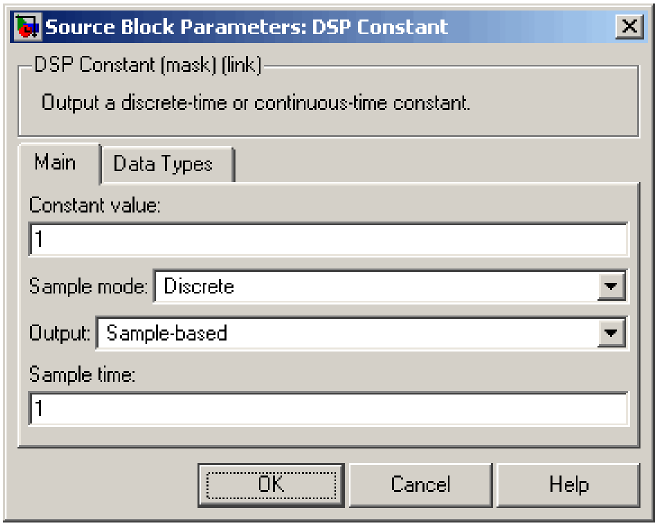
The DSP Constant block generates a signal whose value remains constant throughout the simulation. The **Constant value** parameter specifies the constant to output, and can be any valid MATLAB expression that evaluates to a scalar, vector, or matrix.

When **Sample mode** is set to `Continuous`, the output is a continuous-time signal. When **Sample mode** is set to `Discrete`, the **Sample time** parameter is visible, and the signal has the discrete output period specified by the **Sample time** parameter.

You can set the output signal to `Frame-based`, `Sample-based`, or `Sample-based (interpret vectors as 1-D)` with the **Output** parameter.

Dialog Box

The **Main** pane of the DSP Constant block dialog box appears as follows.



Source Block Parameters: DSP Constant

DSP Constant (mask) (link)

Output a discrete-time or continuous-time constant.

Constant value: 1

Sample mode: Discrete

Output: Sample-based

Sample time: 1

Constant value

Specify the constant to generate. This parameter is “Tunable”; values entered here can be tuned, but their dimensions must remain fixed.

When you specify any data type information in this field, it is overridden by the value of the **Output data type** parameter in the **Data Types** pane, unless you select `Inherit from 'Constant value'`.

Sample mode

Specify the sample mode of the output, `Discrete` for a discrete-time signal or `Continuous` for a continuous-time signal.

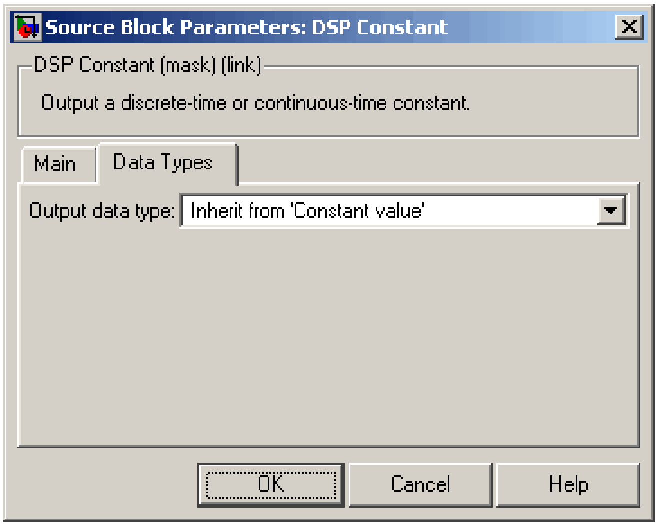
Output

Specify whether the output is `Sample-based (interpret vectors as 1-D)`, `Sample-based`, or `Frame-based`. When you select `Sample-based` and the output is a vector, its dimension is constrained to match the **Constant value** dimension (row or column). When you select `Sample-based (interpret vectors as 1-D)`, however, the output has no specified dimensionality.

Sample time

Specify the discrete sample period for sample-based outputs. When you select `Frame-based` for the **Output** parameter, this parameter is named **Frame period**, and is the discrete frame period for the frame-based output. This parameter is only visible when you select `Discrete` for the **Sample mode** parameter.

The **Data Types** pane of the DSP Constant block dialog box appears as follows.



Source Block Parameters: DSP Constant

DSP Constant (mask) (link)

Output a discrete-time or continuous-time constant.

Output data type: Inherit from 'Constant value'

Output data type

Specify the output data type in one of the following ways:

- Choose one of the built-in data types from the list.
- Choose `Fixed-point` to specify the output data type and scaling in the **Signed**, **Word length**, **Set fraction length in output to**, and **Fraction length** parameters.
- Choose `User-defined` to specify the output data type and scaling in the **User-defined data type**, **Set fraction length in output to,** and **Fraction length** parameters.
- Choose `Inherit from 'Constant value'` to set the output data type and scaling to match the values of the **Constant value** parameter in the **Main** pane.
- Choose `Inherit via back propagation` to set the output data type and scaling to match the following block.

The value of this parameter overrides any data type information specified in the **Constant value** parameter in the **Main** pane, except when you select `Inherit from 'Constant value'`.

Signed

Select to output a signed fixed-point signal. Otherwise, the signal is unsigned. This parameter is only visible when you select `Fixed-point` for the **Output data type** parameter.

Word length

Specify the word length, in bits, of the fixed-point output data type. This parameter is only visible when you select `Fixed-point` for the **Output data type** parameter.

User-defined data type

Specify any built-in or fixed-point data type. You can specify fixed-point data types using the following Fixed-Point Designer functions: `sfix`, `ufix`, `sint`, `uint`, `sfrac`, and `ufrac`. This parameter is only visible when you select `User-defined` for the **Output data type** parameter.

Set fraction length in output to

Specify the scaling of the fixed-point output by either of the following two methods:

- Choose `Best precision` to have the output scaling automatically set such that the output signal has the best possible precision.
- Choose `User-defined` to specify the output scaling in the **Fraction length** parameter.

This parameter is only visible when you select `Fixed-point` for the **Output data type** parameter, or when you select `User-defined` and the specified output data type is a fixed-point data type.

Fraction length

For fixed-point output data types, specify the number of fractional bits, or bits to the right of the binary point. This parameter is only visible when you select `Fixed-point` or `User-defined` for the **Output data type** parameter and `User-defined` for the **Set fraction length in output to** parameter.

Supported Data Types

- Double-precision floating point
- Single-precision floating point
- Fixed point
- Boolean
- 8-, 16-, and 32-bit signed integers

- 8-, 16-, and 32-bit unsigned integers

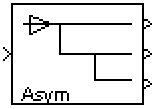
DWT

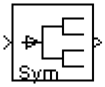
Discrete wavelet transform (DWT) of input or decompose signals into subbands with smaller bandwidths and slower sample rates

Library

Transforms

dspxfrm3





Description

The DWT block is the same as the Dyadic Analysis Filter Bank block in the Multirate Filters library, but with different default settings. See the Dyadic Analysis Filter Bank block reference page for more information.

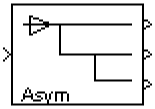
Dyadic Analysis Filter Bank

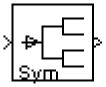
Decompose signals into subbands with smaller bandwidths and slower sample rates or compute discrete wavelet transform (DWT)

Library

Filtering / Multirate Filters

`dspmlti4`





Description

Note: This block always interprets input signals as frames. The frame size of the input signal must be a multiple of 2^n, where n is the value of the **Number of levels** parameter. The block decomposes the input signal into either n+1 or 2^n subbands. To decompose signals with a frame size that is not a multiple of 2^n, use the Two-Channel Analysis Subband Filter block. (You can connect multiple copies of the Two-Channel Analysis Subband Filter block to create a multilevel dyadic analysis filter bank.)

You can configure this block to compute the Discrete Wavelet Transform (DWT) or decompose a broadband signal into a collection of subbands with smaller bandwidths and slower sample rates. The block uses a series of highpass and lowpass FIR filters to repeatedly divide the input frequency range, as illustrated in “Wavelet Filter Banks” on page 1-483 (the Asymmetric one).

You can specify the filter bank's highpass and lowpass filters by providing vectors of filter coefficients. You can do so directly on the block mask, or, if you have a Wavelet Toolbox™ license, you can specify wavelet-based filters by selecting a wavelet from the

Filter parameter. You must set the filter bank structure to asymmetric or symmetric, and specify the number of levels in the filter bank.

For the same input, the DWT configuration of this block does not produce the same results as the Wavelet Toolbox `dwt` function. Because DSP System Toolbox is designed for real-time implementation and Wavelet Toolbox is designed for analysis, the products handle boundary conditions and filter states differently. To make the output of the `dwt` function match the DWT output of this block, complete the following steps:

1. Set the boundary condition of the `dwt` function to zero-padding. To do so, type `dwtmode('zpd')` at the MATLAB command line.
2. To match the latency of the block (implemented using FIR filters), add zeros to the input of the `dwt` function. The number of zeros you add must be equal to the half-length of the filter.

Input Requirements

- Input must be a vector or matrix.
- The input frame size must be a multiple of 2^n, where n is the number of filter bank levels. For example, a frame size of 16 would be appropriate for a three-level tree (16 is a multiple of 2^3).
- The block always treats input signals as frames and operates along the columns.

For an illustration of why the above input requirements exist, see the figure Outputs of a 3-Level Asymmetric Dyadic Analysis Filter Bank.

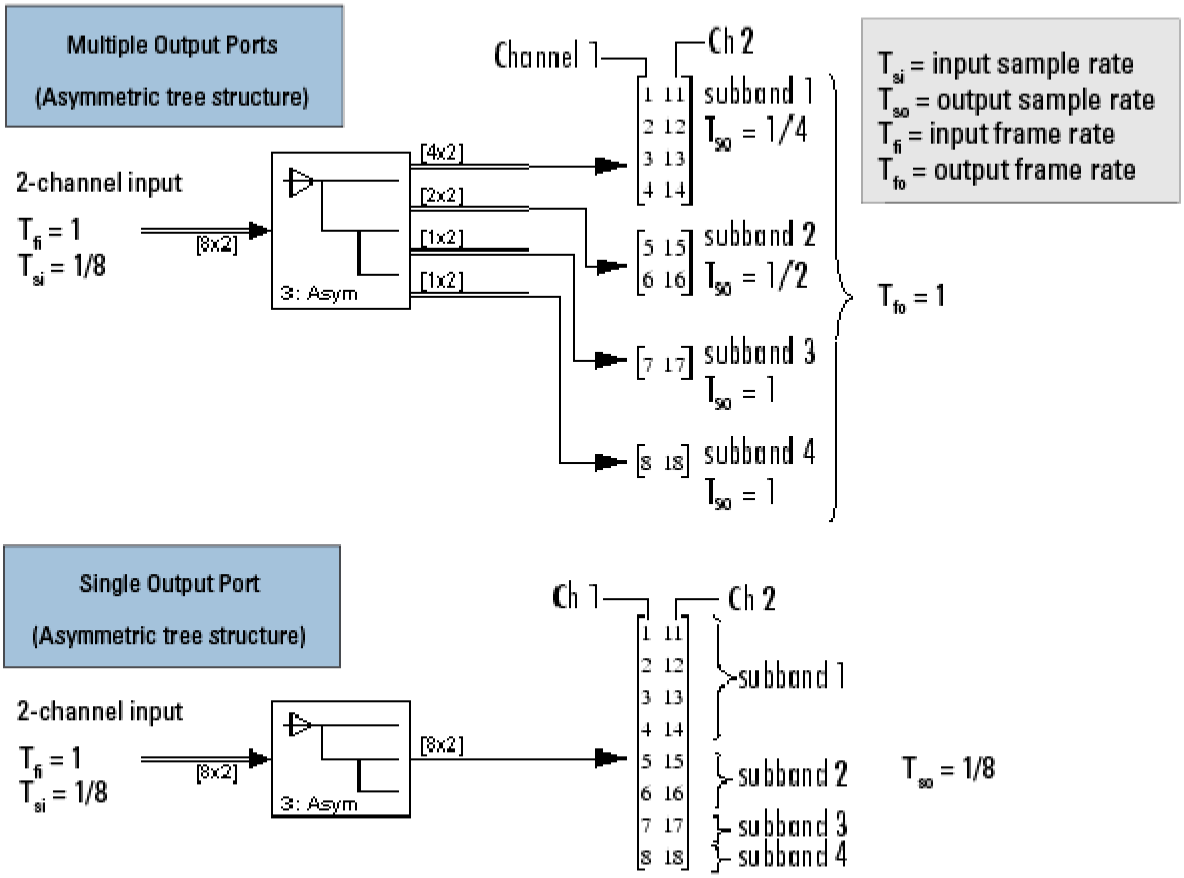
Output Characteristics

The output characteristics vary depending on the block's parameter settings, as summarized in the following list and figure:

- **Number of levels** parameter set to n
- **Tree structure** parameter setting:
  - `Asymmetric` — Block produces n+1 output subbands
  - `Symmetric` — Block produces 2^n output subbands
- **Output** parameter setting can be `Multiple ports` or `Single port`. When you set the **Output** parameter to `Single port`, the block outputs one vector or matrix of

concatenated subbands. The following figure illustrates the difference between the two settings for a 3-level asymmetric dyadic analysis filter bank. For an explanation of the illustrated output characteristics, see the table Output Characteristics for an n-Level Dyadic Analysis Filter Bank.

For more information about the filter bank levels and structures, see "Dyadic Analysis Filter Banks".



Outputs of a 3-Level Asymmetric Dyadic Analysis Filter Bank

The following table summarizes the different output characteristics of the block when it is set to output from single or multiple ports.

Output Characteristics for an n-Level Dyadic Analysis Filter Bank

	Single Output Port	Multiple Output Ports
Output Description	Block concatenates all the subbands into one vector or matrix, and outputs the concatenated subbands from a single output port. Each output column contains subbands of the corresponding input channel.	Block outputs each subband from a separate output port. The topmost port outputs the subband with the highest frequencies. Each output column contains a subband for the corresponding input channel.
Output Frame Rate	*Not applicable*	Same as input frame rate (However, the output frame sizes can vary, so the output sample rates can vary.)
Output Dimensions (Frame Size)	Same number of rows and columns as the input.	The output has the same number of columns as the input. The number of output rows is the output frame size. For an input with frame size M_i output y_k has frame size $M_{o,k}$: • `Symmetric` — All outputs have the frame size, $M_\mathrm{i} / 2^n$. • `Asymmetric` — The frame size of each output (except the last) is half that of the output from the previous level. The outputs from the last two output ports have the same frame size since they originate from the same level in the filter bank. $M_{o,k} = \begin{cases} M_i / 2^k & (1 \le k \le n) \\ M_i / 2^n & (k = n+1) \end{cases}$
Output Sample Rate	Same as input sample rate.	Though the outputs have the same frame rate as the input, they have different frame sizes than the input. Thus, the output sample rates, F_{so}, k, are different from the input sample rate, F_{si}:

	Single Output Port	Multiple Output Ports
		- `Symmetric` — All outputs have the sample rate $F_{si} / 2^n$. - `Asymmetric` — $$F_{so,k} = \begin{cases} F_{si}/2^k & (1 \le k \le n) \\ F_{si}/2^n & (k = n+1) \end{cases}$$

Wavelet Filter Banks

- "Filter Banks"

Filter Bank Filters

You must specify the highpass and lowpass filters in the filter bank by setting the **Filter** parameter to one of the following options:

- `User defined` — Allows you to explicitly specify the filters with two vectors of filter coefficients in the **Lowpass FIR filter coefficients** and **Highpass FIR filter coefficients** parameters. The block uses the same lowpass and highpass filters throughout the filter bank. The two filters should be halfband filters, where each filter passes the frequency band that the other filter stops.
- Wavelet such as `Biorthogonal` or `Daubechies` — The block uses the specified wavelet to construct the lowpass and highpass filters using the Wavelet Toolbox `wfilters` function. Depending on the wavelet, the block might enable either the **Wavelet order** or **Filter order [synthesis / analysis]** parameter. (The latter parameter allows you to specify different wavelet orders for the analysis and synthesis filter stages.) You must have a Wavelet Toolbox license to use wavelets.

Specifying Filters with the Filter Parameter and Related Parameters

Filter	Sample Setting for Related Filter Specification Parameters	Corresponding Wavelet Function Syntax
User-defined	Filters based on Daubechies wavelets with wavelet order `3`: - **Lowpass FIR filter coefficients** `=`	None

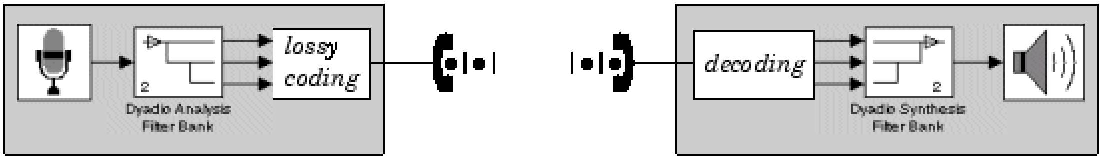
Filter	Sample Setting for Related Filter Specification Parameters	Corresponding Wavelet Function Syntax
	`[0.0352 -0.0854 -0.1350 0.4599 0.8069 0.3327]` • **Highpass FIR filter coefficients** = `[-0.3327 0.8069 -0.4599 -0.1350 0.0854 0.0352]`	
Haar	None	`wfilters('haar')`
Daubechies	**Wavelet order** = 4	`wfilters('db4')`
Symlets	**Wavelet order** = 3	`wfilters('sym3')`
Coiflets	**Wavelet order** = 1	`wfilters('coif1')`
Biorthogonal	**Filter order [synthesis / analysis]** = [3/1]	`wfilters('bior3.1')`
Reverse Biorthogonal	**Filter order [synthesis / analysis]** = [3/1]	`wfilters('rbio3.1')`
Discrete Meyer	None	`wfilters('dmey')`

Examples

Wavelets

The primary application for dyadic analysis filter banks and dyadic synthesis filter banks is coding for data compression using wavelets.

At the transmitting end, the output of the dyadic analysis filter bank is fed to a lossy compression scheme, which typically assigns the number of bits for each filter bank output in proportion to the relative energy in that frequency band. This represents the more powerful signal components by a greater number of bits than the less powerful signal components.



At the receiving end, the transmission is decoded and fed to a dyadic synthesis filter bank to reconstruct the original signal. The filter coefficients of the complementary analysis and synthesis stages are designed to cancel aliasing introduced by the filtering and resampling.

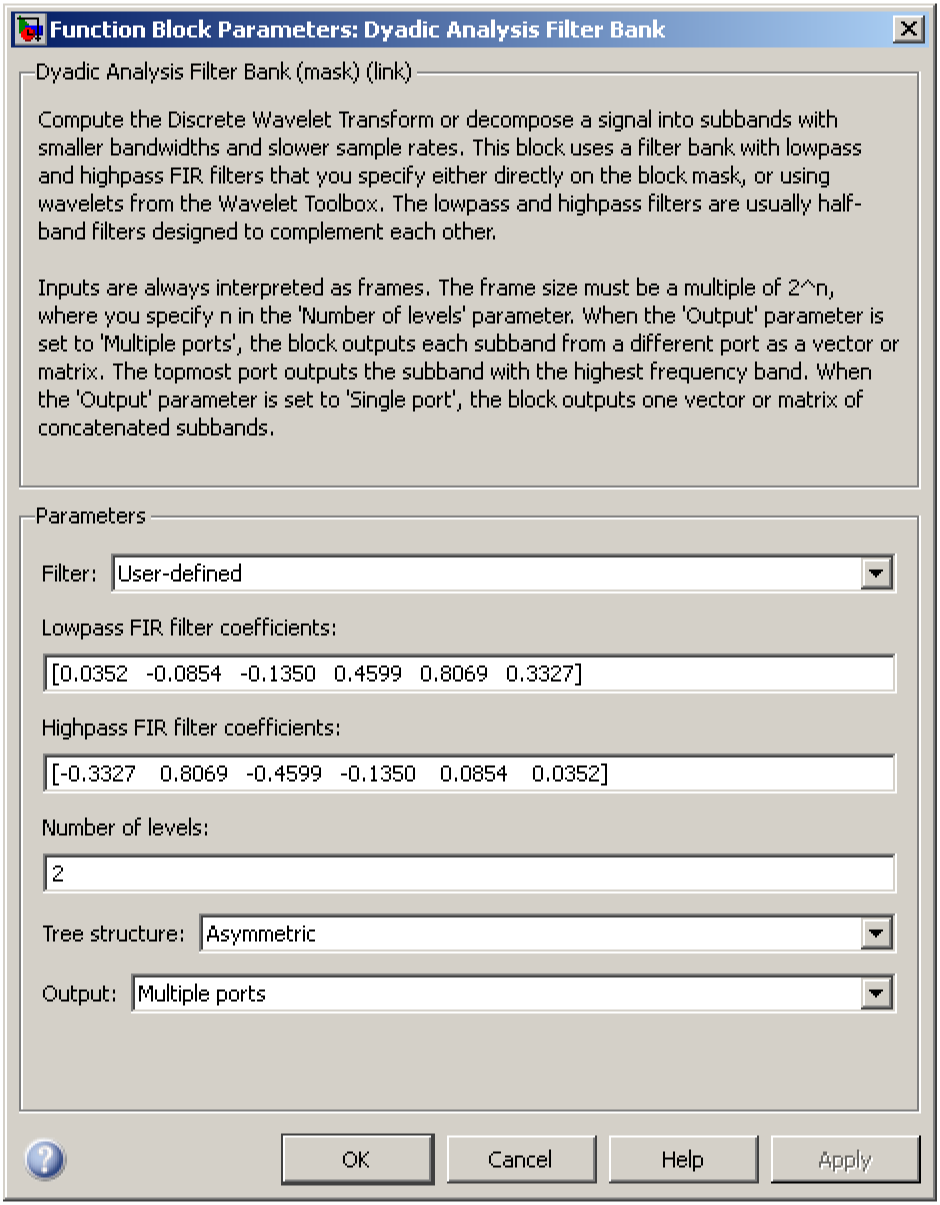
See “Calculate Channel Latencies Required for Wavelet Reconstruction” for an example using the Dyadic Analysis and Dyadic Synthesis Filter Bank blocks.

Examples

See the floating-point frame-based version of the DSP System Toolbox Wavelet Reconstruction and Noise Reduction example, which uses the Dyadic Analysis Filter Bank and Dyadic Synthesis Filter Bank blocks.

Dialog Box

The parameters displayed in the block dialog vary depending on the setting of the **Filter** parameter. Only some of the parameters described below are visible in the dialog box at any one time.



Function Block Parameters: Dyadic Analysis Filter Bank

Dyadic Analysis Filter Bank (mask) (link)

Compute the Discrete Wavelet Transform or decompose a signal into subbands with smaller bandwidths and slower sample rates. This block uses a filter bank with lowpass and highpass FIR filters that you specify either directly on the block mask, or using wavelets from the Wavelet Toolbox. The lowpass and highpass filters are usually half-band filters designed to complement each other.

Inputs are always interpreted as frames. The frame size must be a multiple of 2^n, where you specify n in the 'Number of levels' parameter. When the 'Output' parameter is set to 'Multiple ports', the block outputs each subband from a different port as a vector or matrix. The topmost port outputs the subband with the highest frequency band. When the 'Output' parameter is set to 'Single port', the block outputs one vector or matrix of concatenated subbands.

Parameters

Filter: User-defined

Lowpass FIR filter coefficients:

[0.0352 -0.0854 -0.1350 0.4599 0.8069 0.3327]

Highpass FIR filter coefficients:

[-0.3327 0.8069 -0.4599 -0.1350 0.0854 0.0352]

Number of levels:

2

Tree structure: Asymmetric

Output: Multiple ports

Filter

The type of filter used to determine the high- and low-pass FIR filters in the filter bank:

Select `User defined` to explicitly specify the filter coefficients in the **Lowpass FIR filter coefficients** and **Highpass FIR filter coefficients** parameters.

Select a wavelet such as `Biorthogonal` or `Daubechies` to specify a wavelet-based filter. The block uses the Wavelet Toolbox `wfilters` function to construct the filters. Extra parameters such as **Wavelet order** or **Filter order [synthesis / analysis]** might become enabled. For a list of the supported wavelets, see Specifying Filters with the Filter Parameter and Related Parameters.

Lowpass FIR filter coefficients

A vector of filter coefficients (descending powers of *z*) that specifies coefficients used by all the lowpass filters in the filter bank. This parameter is enabled when you set **Filter** to `User defined`. The lowpass filter should be a half-band filter that passes the frequency band stopped by the filter specified in the **Highpass FIR filter coefficients** parameter. The default values of this parameter specify a filter based on a Daubechies wavelet with wavelet order `3`.

Highpass FIR filter coefficients

A vector of filter coefficients (descending powers of *z*) that specifies coefficients used by all the highpass filters in the filter bank. This parameter is enabled when you set **Filter** to `User defined`. The highpass filter should be a half-band filter that passes the frequency band stopped by the filter specified in the **Lowpass FIR filter coefficients** parameter. The default values of this parameter specify a filter based on a Daubechies wavelet with wavelet order `3`.

Wavelet order

The order of the wavelet selected in the **Filter** parameter. This parameter is enabled only when you set **Filter** to certain types of wavelets, as shown in the Specifying Filters with the Filter Parameter and Related Parameters table.

Filter order [synthesis / analysis]

The order of the wavelet for the synthesis and analysis filter stages. For example, when you set the **Filter** parameter to `Biorthogonal` and set the **Filter order [synthesis / analysis]** parameter to `[2 / 6]`, the block calls the `wfilters` function with input argument `'bior2.6'`. This parameter is enabled only when you set **Filter** to certain types of wavelets, as shown in Specifying Filters with the Filter Parameter and Related Parameters.

Number of levels

The number of filter bank levels. An *n*-level asymmetric structure has *n*+1 outputs, and an *n*-level symmetric structure has 2^n outputs, as shown in “Wavelet Filter Banks” on page 1-483. The block's icon changes depending on the value of this parameter.

The default setting of this parameter is `2`.

Tree structure

The structure of the filter bank: `Asymmetric`, or `Symmetric`. See “Wavelet Filter Banks” on page 1-483.

The default setting of this parameter is `Asymmetric` for the Dyadic Analysis Filter Bank block, and `Symmetric` for the DWT block.

Output

Set to `Multiple ports` to output each output subband on a separate port (the topmost port outputs the subband with the highest frequency band). Set to `Single port` to concatenate the subbands into one vector or matrix and output the concatenated subbands on a single port. For more information, see “Output Characteristics” on page 1-480.

The default setting of this parameter is `Multiple ports` for the Dyadic Analysis Filter Bank block, and `Single port` for the DWT block.

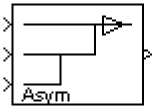
Dyadic Synthesis Filter Bank

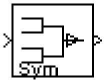
Reconstruct signals from subbands with smaller bandwidths and slower sample rates or compute inverse discrete wavelet transform (IDWT)

Library

Filtering / Multirate Filters

`dspmlti4`





Description

Note This block always does frame-based processing, and its inputs must be of certain sizes. To use input subbands that do not fit the criteria of this block, use the Two-Channel Synthesis Subband Filter block. (You can connect multiple copies of the Two-Channel Synthesis Subband Filter block to create a multilevel dyadic synthesis filter bank.)

You can configure this block to compute the inverse discrete wavelet transform (IDWT) or reconstruct a signal from subbands with smaller bandwidths and slower sample rates. When the block computes the inverse discrete wavelet transform (IDWT) of the input, the output has the same dimensions as the input. Each column of the output is the IDWT of the corresponding input column. When reconstructing a signal, the block uses a series of highpass and lowpass FIR filters to reconstruct the signal from the input subbands, as illustrated in “Wavelet Filter Banks” on page 1-494 (the Asymmetric one). The reconstructed signal has a wider bandwidth and faster sample rate than the input subbands.

You can specify the filter bank's highpass and lowpass filters by providing vectors of filter coefficients. You can do so directly on the block mask, or, if you have a Wavelet

Toolbox license, you can specify wavelet-based filters by selecting a wavelet from the **Filter** parameter. You must set the filter bank structure to asymmetric or symmetric, and specify the number of levels in the filter bank.

When you set the **Input** parameter to `Multiple ports`, you must provide each subband to the block through a different input port as a vector or matrix. You should input the highest frequency band through the topmost port. When you set the **Input** parameter to `Single port`, the block input must be a vector or matrix of concatenated subbands.

Note To use a dyadic synthesis filter bank to perfectly reconstruct the output of a dyadic analysis filter bank, the number of levels and tree structures of both filter banks *must* be the same. In addition, the filters in the synthesis filter bank *must* be designed to perfectly reconstruct the outputs of the analysis filter bank. Otherwise, the reconstruction is not perfect.

This block automatically computes wavelet-based perfect reconstruction filters when the wavelet selection in the **Filter** parameter of this block is the *same* as the **Filter** parameter setting of the corresponding Dyadic Analysis Filter Bank block. The use of wavelets requires a Wavelet Toolbox license. To learn how to design your own perfect reconstruction filters, see “References” on page 1-499.

Input Requirements

The inputs to this block are usually the outputs of a Dyadic Analysis Filter Bank block. Since the Dyadic Analysis Filter Bank block can output from either a single port or multiple ports, the Dyadic Synthesis Filter Bank block accepts inputs to either a single port or multiple ports.

The **Input** parameter sets whether the block accepts inputs from a single port or multiple ports, and thus determines the input requirements, as summarized in the following lists and figure.

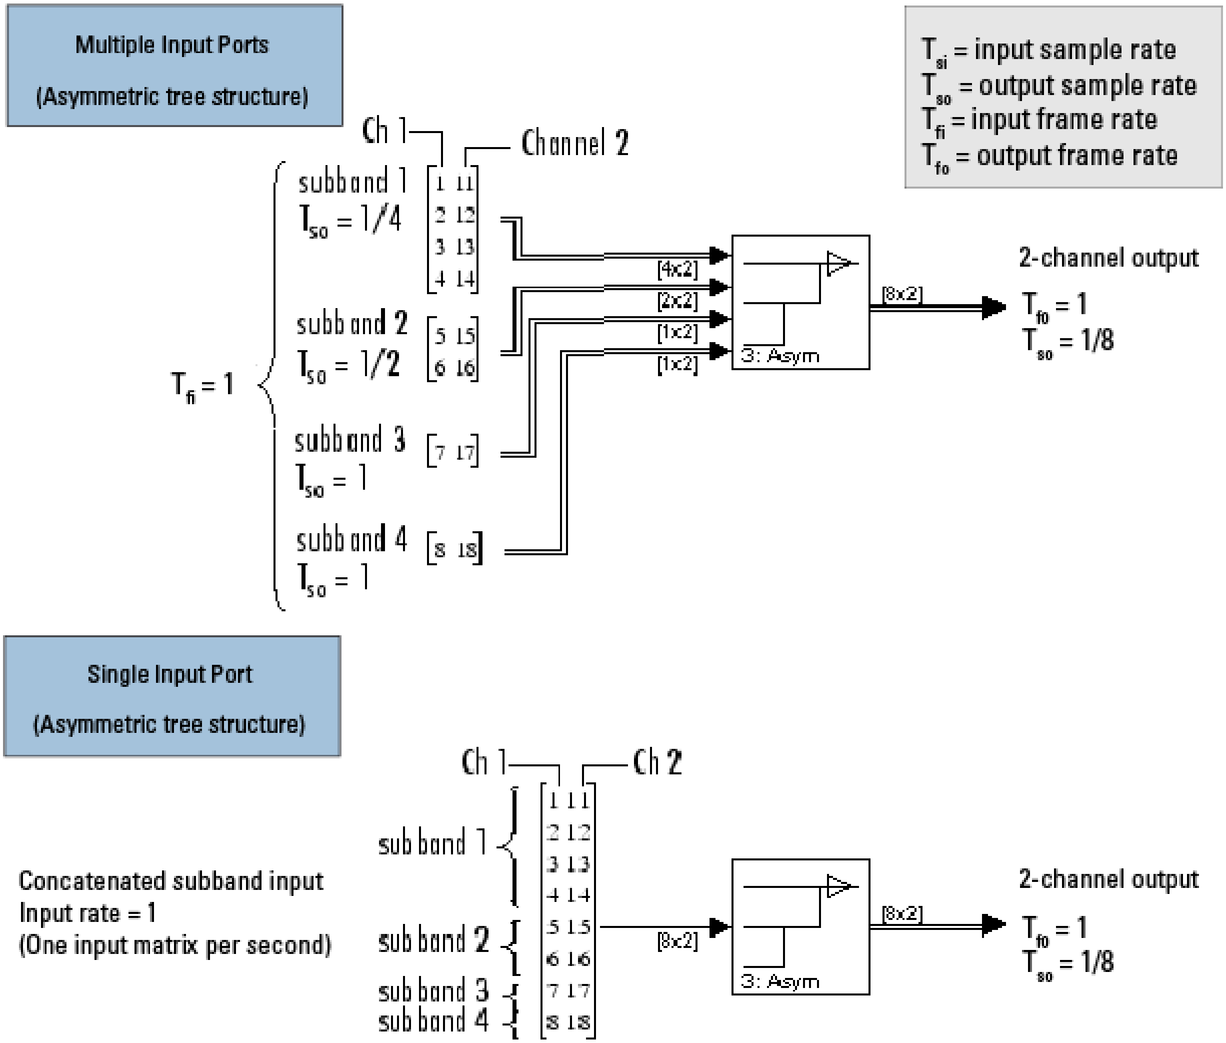
Note: Any output of a Dyadic Analysis Filter Bank block whose parameter settings match the corresponding settings of this block is a valid input to this block. For example, the setting of the Dyadic Analysis Filter Bank block parameter, **Output**, must be the same as this block's **Input** parameter (`Single port` or `Multiple ports`).

Valid Inputs for Input Set to Single Port

- Inputs must be vectors or matrices of concatenated subbands. The block always interprets the inputs as sample based.
- Each input column contains the subbands for an independent signal.
- Upper input rows contain the high-frequency subbands, and the lower rows contain the low-frequency subbands.

Valid Inputs for Input Set to Multiple Ports

- Each subband must be provided as a vector or matrix to separate block input ports. The block always interprets the inputs as frame based.
- The columns of each input contains a subband for an independent signal.
- The input to the topmost input port is the subband containing the highest frequencies, and the input to the bottommost port is the subband containing the lowest frequencies.



Valid Inputs to a 3-Level Asymmetric Dyadic Synthesis Filter Bank

For general information about the filter banks, see “Dyadic Synthesis Filter Banks”.

Output Characteristics

The following table summarizes the output characteristics for both types of inputs. For an illustration of why the output characteristics exist, see the figure Valid Inputs to a 3-Level Asymmetric Dyadic Synthesis Filter Bank.

	Input = Multiple ports	Input = Single port (Concatenated Subband Inputs)
Output Frame Rate	Same as the input frame rate.	Same as the input rate (the rate of the concatenated subband inputs).
Output Frame Dimensions	• The output has the same number of columns as the inputs. • The number of output rows depends on the tree structure of the filter bank: • **Asymmetric** — The number of output rows is twice the number of rows in the input to the topmost input port. • **Symmetric** — The number of output rows is the product of the number of input ports and the number of rows in an input to any input port.	The output has the same number of rows and columns as the input.

For general information about the filter banks, see “Dyadic Synthesis Filter Banks”.

Wavelet Filter Banks

- “Filter Banks”

Filter Bank Filters

You must specify the highpass and lowpass filters in the filter bank by setting the **Filter** parameter to one of the following options:

- `User defined` — Allows you to explicitly specify the filters with two vectors of filter coefficients in the **Lowpass FIR filter coefficients** and **Highpass FIR filter**

coefficients parameters. The block uses the same lowpass and highpass filters throughout the filter bank. The two filters should be halfband filters, where each filter passes the frequency band that the other filter stops. To use this block to perfectly reconstruct a signal decomposed by a Dyadic Analysis Filter Bank block, the filters in this block *must* be designed to perfectly reconstruct the outputs of the analysis filter bank. To learn how to design your own perfect reconstruction filters, see "References" on page 1-499.

- Wavelet such as `Biorthogonal` or `Daubechies` — The block uses the specified wavelet to construct the lowpass and highpass filters using the Wavelet Toolbox function `wfilters`. Depending on the wavelet, the block might enable either the **Wavelet order** or **Filter order [synthesis / analysis]** parameter. (The latter parameter allows you to specify different wavelet orders for the analysis and synthesis filter stages.) To use this block to reconstruct a signal decomposed by a Dyadic Analysis Filter Bank block, you must set both blocks to use the same wavelets with the same order. You must have a Wavelet Toolbox license to use wavelets.

Specifying Filters with the Filter Parameter and Related Parameters

Filter	Sample Setting for Related Filter Specification Parameters	Corresponding Wavelet Function Syntax
User-defined	Filters based on Daubechies wavelets with wavelet order 3: • **Lowpass FIR filter coefficients** = `[0.0352 -0.0854 -0.1350 0.4599 0.8069 0.3327]` • **Highpass FIR filter coefficients** = `[-0.3327 0.8069 -0.4599 -0.1350 0.0854 0.0352]`	None
Haar	None	`wfilters('haar')`

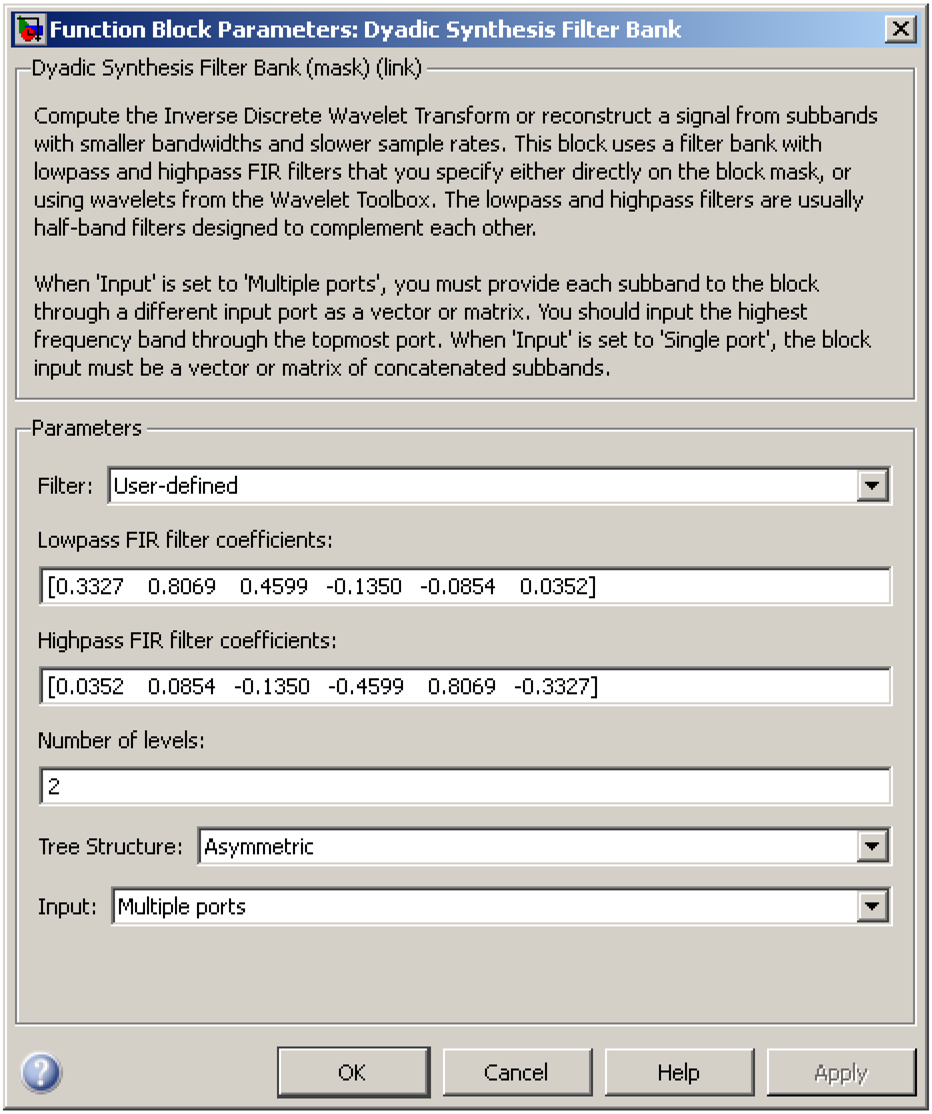
Discrete Meyer	None	`wfilters('dmey')`

Examples

See “Examples” on page 1-484 on the Dyadic Analysis Filter Bank block reference page.

Dialog Box

The parameters displayed in the block dialog vary depending on the setting of the **Filter** parameter. Only some of the parameters described below are visible in the dialog box at any one time.



Function Block Parameters: Dyadic Synthesis Filter Bank

Dyadic Synthesis Filter Bank (mask) (link)

Compute the Inverse Discrete Wavelet Transform or reconstruct a signal from subbands with smaller bandwidths and slower sample rates. This block uses a filter bank with lowpass and highpass FIR filters that you specify either directly on the block mask, or using wavelets from the Wavelet Toolbox. The lowpass and highpass filters are usually half-band filters designed to complement each other.

When 'Input' is set to 'Multiple ports', you must provide each subband to the block through a different input port as a vector or matrix. You should input the highest frequency band through the topmost port. When 'Input' is set to 'Single port', the block input must be a vector or matrix of concatenated subbands.

Parameters

Filter: User-defined

Lowpass FIR filter coefficients:

[0.3327   0.8069   0.4599 -0.1350 -0.0854   0.0352]

Highpass FIR filter coefficients:

[0.0352   0.0854 -0.1350 -0.4599   0.8069 -0.3327]

Number of levels:

2

Tree Structure: Asymmetric

Input: Multiple ports

Note To use this block to reconstruct a signal decomposed by a Dyadic Analysis Filter Bank block, all the parameters in this block must be the same as the corresponding parameters in the Dyadic Analysis Filter Bank block (except the **Lowpass FIR filter**

coefficients and **Highpass FIR filter coefficients**; see the descriptions of these parameters).

Filter

The type of filter used to determine the high- and low-pass FIR filters in the filter bank:

- Select `User defined` to explicitly specify the filter coefficients in the **Lowpass FIR filter coefficients** and **Highpass FIR filter coefficients** parameters.
- Select a wavelet such as `Biorthogonal` or `Daubechies` to specify a wavelet-based filter. The block uses the Wavelet Toolbox `wfilters` function to construct the filters. Extra parameters such as **Wavelet order** or **Filter order [synthesis / analysis]** might become enabled. For a list of the supported wavelets, see the table Specifying Filters with the Filter Parameter and Related Parameters.

Lowpass FIR filter coefficients

A vector of filter coefficients (descending powers of *z*) that specifies coefficients used by all the lowpass filters in the filter bank. This parameter is enabled when you set **Filter** to `User defined`. The lowpass filter should be a half-band filter that passes the frequency band stopped by the filter specified in the **Highpass FIR filter coefficients** parameter. To perfectly reconstruct a signal decomposed by the Dyadic Analysis Filter Bank, the filters in this block *must* be designed to perfectly reconstruct the outputs of the analysis filter bank. Otherwise, the reconstruction is not perfect. The default values of this parameter specify a perfect reconstruction filter for the default settings of the Dyadic Analysis Filter Bank (based on a Daubechies wavelet with wavelet order `3`).

Highpass FIR filter coefficients

A vector of filter coefficients (descending powers of *z*) that specifies coefficients used by all the highpass filters in the filter bank. This parameter is enabled when you set **Filter** to `User defined`. The highpass filter should be a half-band filter that passes the frequency band stopped by the filter specified in the **Lowpass FIR filter coefficients** parameter. To perfectly reconstruct a signal decomposed by the Dyadic Analysis Filter Bank, the filters in this block *must* be designed to perfectly reconstruct the outputs of the analysis filter bank. Otherwise, the reconstruction is not perfect. The default values of this parameter specify a perfect reconstruction filter for the default settings of the Dyadic Analysis Filter Bank (based on a Daubechies wavelet with wavelet order `3`).

Wavelet order

The order of the wavelet selected in the **Filter** parameter. This parameter is enabled only when you set **Filter** to certain types of wavelets, as shown in the table Specifying Filters with the Filter Parameter and Related Parameters.

Filter order [synthesis / analysis]

The order of the wavelet for the synthesis and analysis filter stages. For example, when you set the **Filter** parameter to **Biorthogonal** and set the **Filter order [synthesis / analysis]** parameter to `[2 / 6]`, the block calls the `wfilters` function with input argument `'bior2.6'`. This parameter is enabled only when you set **Filter** to certain types of wavelets, as shown in Specifying Filters with the Filter Parameter and Related Parameters.

Number of levels

The number of filter bank levels. An *n*-level asymmetric structure has *n*+1 inputs, and an *n*-level symmetric structure has 2^n inputs, as shown in "Wavelet Filter Banks" on page 1-494.

The default setting of this parameter is `2`.

Tree structure

The structure of the filter bank: `Asymmetric`, or `Symmetric`. See "Wavelet Filter Banks" on page 1-494.

The default setting of this parameter is `Asymmetric` for the Dyadic Synthesis Filter Bank block, and `Symmetric` for the IDWT block.

Input

Set to `Multiple ports` to accept each input subband at a separate port (the topmost port accepts the subband with the highest frequency band). Set to `Single port` to accept one vector or matrix of concatenated subbands at a single port. For more information, see "Input Requirements" on page 1-491.

The default setting of this parameter is `Multiple ports` for the Dyadic Synthesis Filter Bank block, and `Single port` for the IDWT block.

Edge Detector

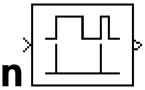
Detect transition from zero to nonzero value

Library

Signal Management / Switches and Counters

`dspswit3`

Description

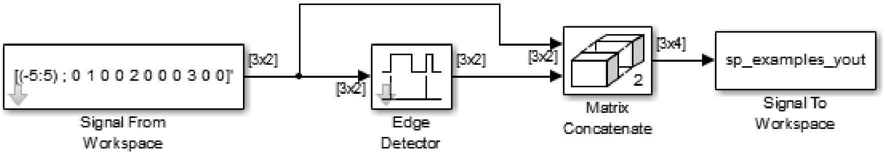


The Edge Detector block generates an impulse (the value 1) in a given output channel when the corresponding channel of the input transitions from zero to a nonzero value. When the input does not transition from zero to a nonzero value, the block generates a zero in the corresponding output channel.

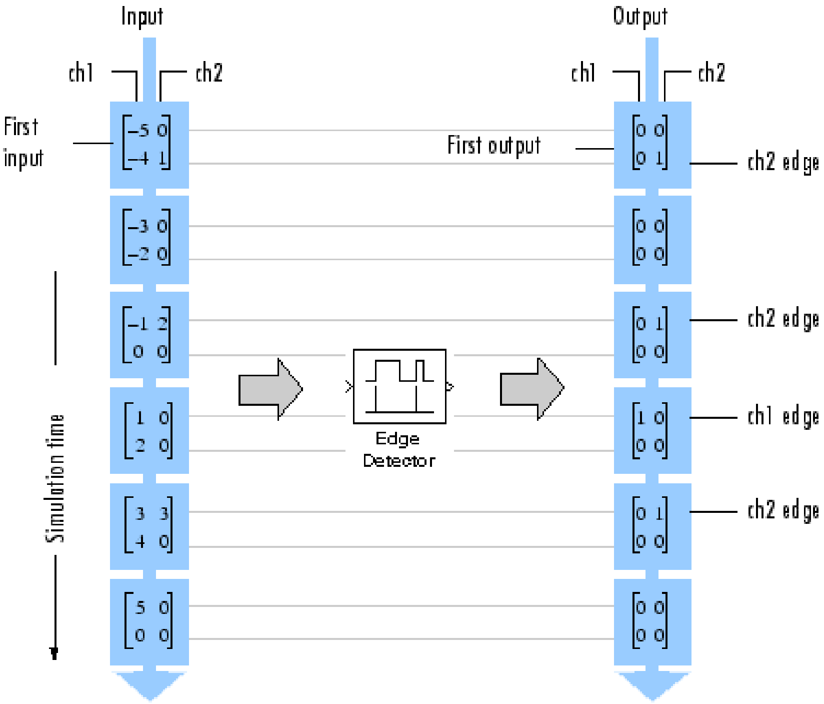
The output has the same dimension and sample rate as the input. When you set the **Input processing** parameter to `Columns as channels (frame based)`, the block counts an edge that is split across two consecutive frames in the frame that contains the nonzero value. For example, if there is a zero at the bottom of the first frame and a nonzero value at the top of the second frame, the block counts the edge in the second frame.

Examples

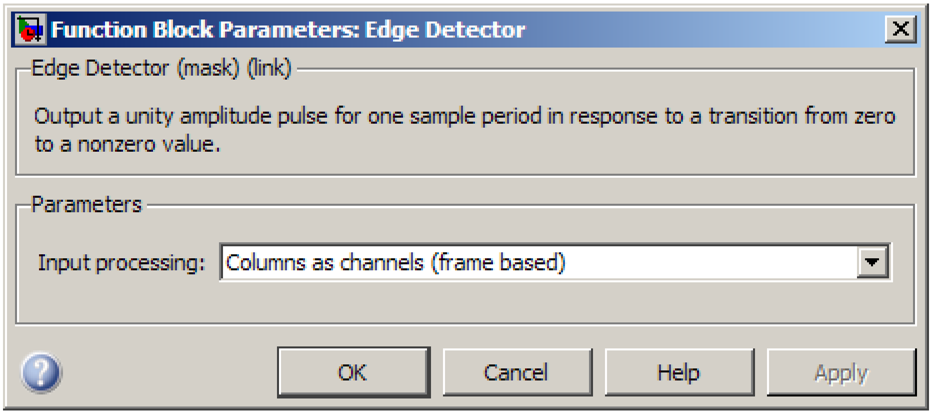
In the ex_edgedetector_ref model, the **Input processing** parameter of the Edge Detector block is set to `Columns as channels (frame based)`. Thus, the block interprets the 3-by-2 input as a multichannel signal with a frame size of 3. The Matrix Concatenate block concatenates the two input channels of the original signal with the two output channels of the Edge Detector block to create the four-channel workspace variable `sp_examples_yout`.



As shown in the following figure, the block finds edges at sample 7 in channel 1, and at samples 2, 5, and 9 in channel 2.



Dialog Box



Function Block Parameters: Edge Detector

Edge Detector (mask) (link)

Output a unity amplitude pulse for one sample period in response to a transition from zero to a nonzero value.

Parameters

Input processing: Columns as channels (frame based)

Input processing

Specify how the block should process the input. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` — When you select this option, the block treats each column of the input as a separate channel.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

Note: The `Inherited (this choice will be removed - see release notes)` option will be removed in a future release. See "Frame-Based Processing" in the *DSP System Toolbox Release Notes* for more information.

Supported Data Types

- Double-precision floating point
- Single-precision floating point
- Fixed point (signed and unsigned)
- Boolean — The block might output Boolean values depending on the input data type, and whether Boolean support is enabled or disabled.

- 8-, 16-, and 32-bit signed integers
- 8-, 16-, and 32-bit unsigned integers
- Enumerated

See Also

Counter	DSP System Toolbox
Event-Count Comparator	DSP System Toolbox

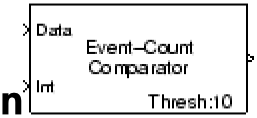
Event-Count Comparator

Detect threshold crossing of accumulated nonzero inputs

Library

Signal Management / Switches and Counters

`dspswit3`



Description

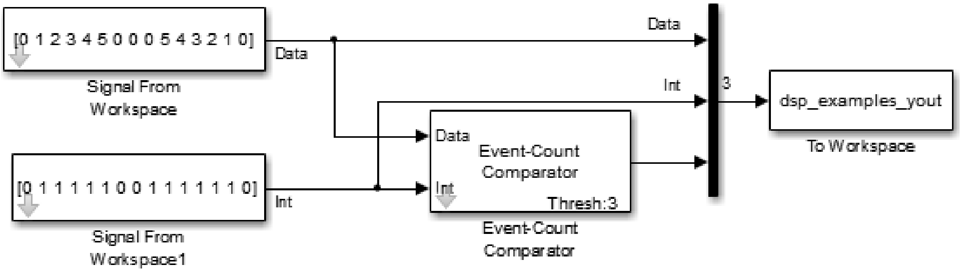
The Event-Count Comparator block records the number of nonzero inputs to the Data port during the period that the block is enabled by a high signal (the value 1) at the Int port. Both inputs must be scalars.

When the number of accumulated nonzero inputs first equals the **Event threshold** setting, the block waits one additional sample interval, and then sets the output high (1). The block holds the output high until recording is restarted by a low-to-high (0-to-1) transition at the Int port.

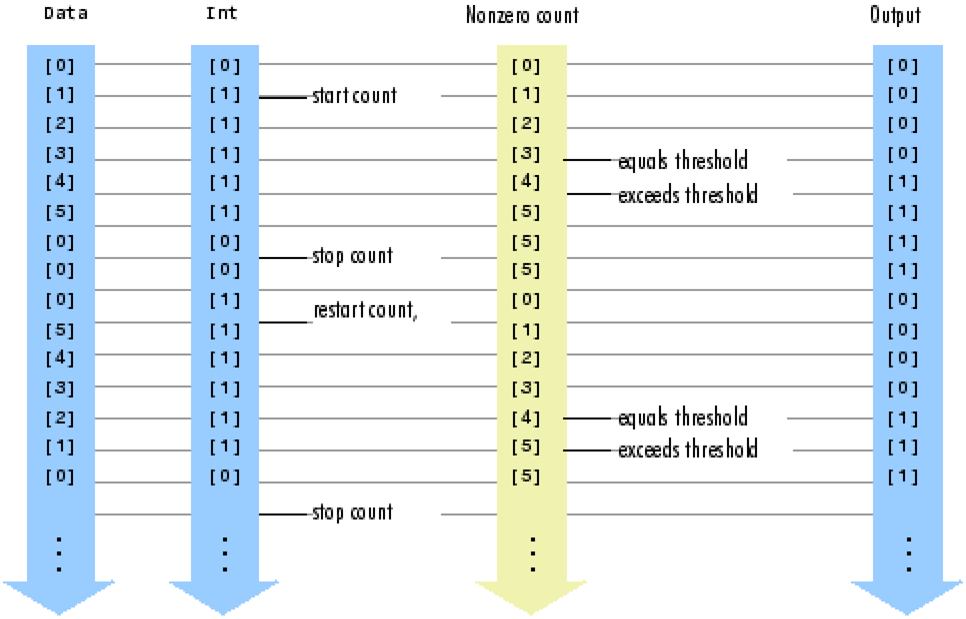
The Event-Count Comparator block accepts real and complex floating-point and fixed-point inputs. However, because the block has discrete state, it does not support constant or continuous sample times. Therefore, at least one input or output port of the Event-Count Comparator block must be connected to a block whose **Sample time** parameter is discrete. The Event-Count Comparator block inherits this non-infinite discrete sample time.

Examples

In the ex_eventcountcomp_ref model, the Event-Count Comparator block (**Event threshold** = 3) detects two threshold crossings in the input to the Data port, one at sample 4 and one at sample 12.

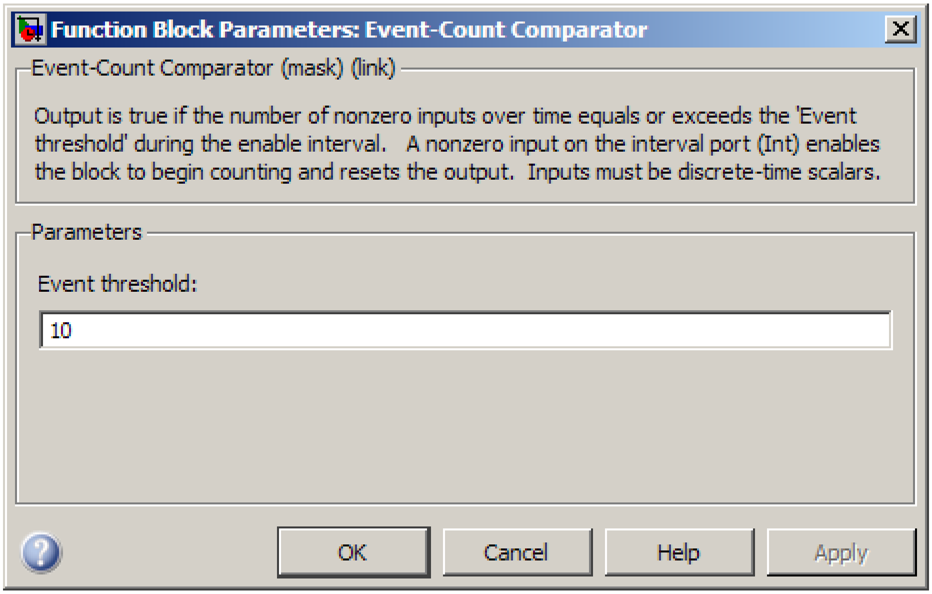


All inputs and outputs are multiplexed into the workspace variable `yout`, whose contents are shown in the figure below. The two left columns in the illustration show the inputs to the Data and Int ports, the center column shows the state of the block's internal counter, and the right column shows the block's output.



Data	Int		Nonzero count		Output
[0]	[0]		[0]		[0]
[1]	[1]	start count	[1]		[0]
[2]	[1]		[2]		[0]
[3]	[1]		[3]	equals threshold	[0]
[4]	[1]		[4]	exceeds threshold	[1]
[5]	[1]		[5]		[1]
[0]	[0]		[5]		[1]
[0]	[0]	stop count	[5]		[1]
[0]	[1]	restart count,	[0]		[0]
[5]	[1]		[1]		[0]
[4]	[1]		[2]		[0]
[3]	[1]		[3]		[0]
[2]	[1]		[4]	equals threshold	[1]
[1]	[1]		[5]	exceeds threshold	[1]
[0]	[0]		[5]		[1]
		stop count			
⋮	⋮		⋮		⋮

Dialog Box



Function Block Parameters: Event-Count Comparator

Event-Count Comparator (mask) (link)

Output is true if the number of nonzero inputs over time equals or exceeds the 'Event threshold' during the enable interval. A nonzero input on the interval port (Int) enables the block to begin counting and resets the output. Inputs must be discrete-time scalars.

Parameters

Event threshold:

10

Event threshold

Specify the value against which to compare the number of nonzero inputs. “Tunable”.

Supported Data Types

- Double-precision floating point
- Single-precision floating point
- Fixed point (signed and unsigned)
- Boolean
- 8-, 16-, and 32-bit signed integers
- 8-, 16-, and 32-bit unsigned integers
- Enumerated

Extract Diagonal

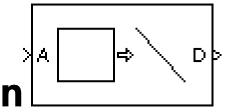
Extract main diagonal of input matrix

Library

Math Functions / Matrices and Linear Algebra / Matrix Operations

`dspmtrx3`

Description

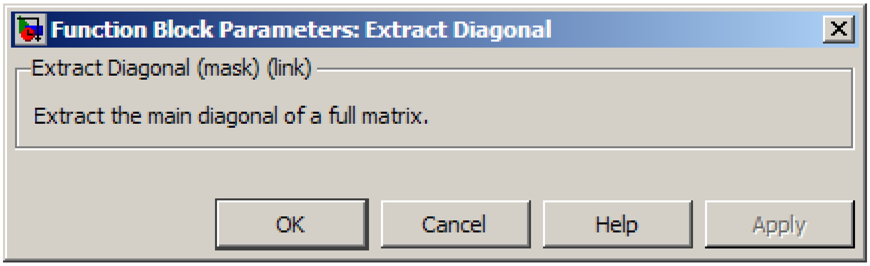


The Extract Diagonal block populates the unoriented output vector with the elements on the main diagonal of the M-by-N input matrix A.

```
D = diag(A)     Equivalent MATLAB code
```

The output vector has length `min(M,N)`.

Dialog Box



Function Block Parameters: Extract Diagonal

Extract Diagonal (mask) (link)

Extract the main diagonal of a full matrix.

Supported Data Types

- Double-precision floating point

- Single-precision floating point
- Fixed point (signed and unsigned)
- Boolean — Block outputs are always Boolean.
- 8-, 16-, and 32-bit signed integers
- 8-, 16-, and 32-bit unsigned integers

See Also

Constant Diagonal Matrix	DSP System Toolbox
Create Diagonal Matrix	DSP System Toolbox
Extract Triangular Matrix	DSP System Toolbox
`diag`	MATLAB

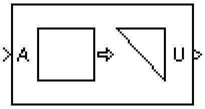
Extract Triangular Matrix

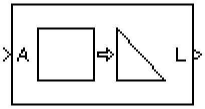
Extract lower or upper triangle from input matrices

Library

Math Functions / Matrices and Linear Algebra / Matrix Operations

`dspmtrx3`





Description

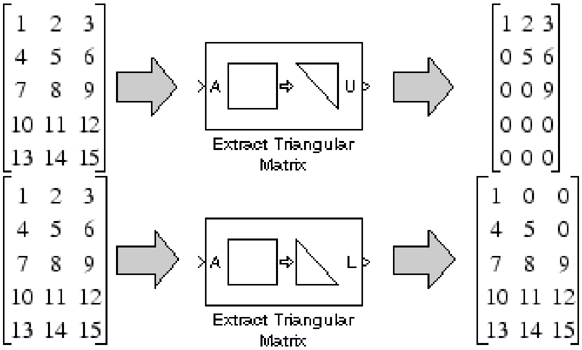
The Extract Triangular Matrix block creates a triangular matrix output from the upper or lower triangular elements of an M-by-N input matrix. The block treats length-M unoriented vector inputs as an M-by-1 matrix.

The **Extract** parameter selects between the two components of the input:

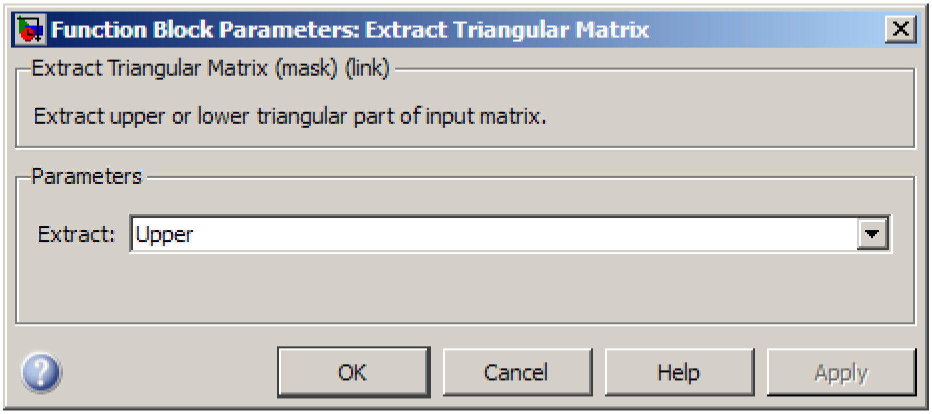
- `Upper` — Copies the elements on and above the main diagonal of the input matrix to an output matrix of the same size. The first *row* of the output matrix is therefore identical to the first *row* of the input matrix. The elements below the main diagonal of the output matrix are zero.
- `Lower` — Copies the elements on and below the main diagonal of the input matrix to an output matrix of the same size. The first *column* of the output matrix is therefore identical to the first *column* of the input matrix. The elements above the main diagonal of the output matrix are zero.

Examples

The ex_extracttriang_ref model below shows the extraction of upper and lower triangles from a 5-by-3 input matrix.



Dialog Box



Function Block Parameters: Extract Triangular Matrix

Extract Triangular Matrix (mask) (link)

Extract upper or lower triangular part of input matrix.

Parameters

Extract: Upper

Extract

The component of the matrix to copy to the output: upper triangle or lower triangle.

Supported Data Types

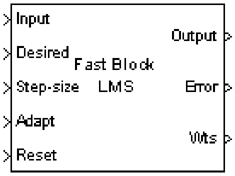
Fast Block LMS Filter

Compute output, error, and weights using LMS adaptive algorithm

Library

Filtering / Adaptive Filters

dspadpt3



Fast Block LMS Filter

Description

The Fast Block LMS Filter block implements an adaptive least mean-square (LMS) filter, where the adaptation of the filter weights occurs once for every block of data samples. The block estimates the filter weights, or coefficients, needed to convert the input signal into the desired signal. Connect the signal you want to filter to the Input port. The input signal can be a scalar or a column vector. Connect the signal you want to model to the Desired port. The desired signal must have the same data type, complexity, and dimensions as the input signal. The Output port outputs the filtered input signal. The Error port outputs the result of subtracting the output signal from the desired signal.

The block calculates the filter weights using the Block LMS Filter equations. For more information, see Block LMS Filter. The Fast Block LMS Filter block implements the convolution operation involved in the calculations of the filtered output, y, and the weight update function in the frequency domain using the FFT algorithm used in the Overlap-Save FFT Filter block. See Overlap-Save FFT Filter for more information.

Use the **Filter length** parameter to specify the length of the filter weights vector.

The **Block size** parameter determines how many samples of the input signal are acquired before the filter weights are updated. The input frame length must be a multiple of the **Block size** parameter.

The **Step-size (mu)** parameter corresponds to μ in the equations. You can either specify a step-size using the input port, Step-size, or enter a value in the Block Parameters: Block LMS Filter dialog box.

Use the **Leakage factor (0 to 1)** parameter to specify the leakage factor, $0 < 1 - \mu\alpha \leq 1$, in the leaky LMS algorithm shown below.

$$\mathbf{w}(k) = (1 - \mu\alpha)\mathbf{w}(k-1) - f(\mathbf{u}(n), e(n), \mu)$$

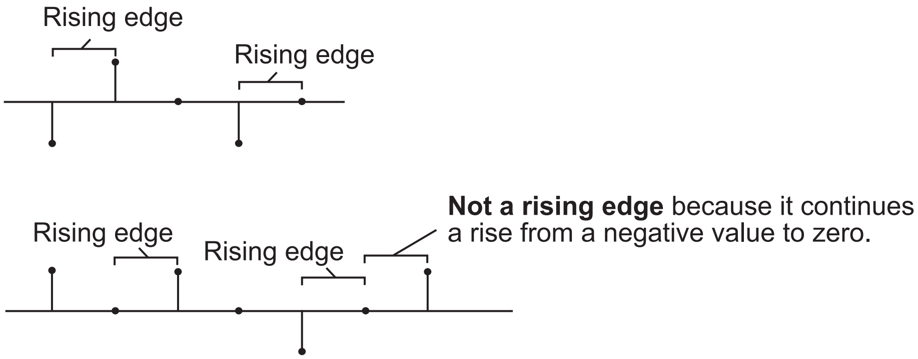
Enter the initial filter weights, $\mathbf{w}(0)$, as a vector or a scalar in the **Initial value of filter weights** text box. When you enter a scalar, the block uses the scalar value to create a vector of filter weights. This vector has length equal to the filter length and all of its values are equal to the scalar value.

When you select the **Adapt port** check box, an Adapt port appears on the block. When the input to this port is nonzero, the block continuously updates the filter weights. When the input to this port is zero, the filter weights remain at their current values.

When you want to reset the value of the filter weights to their initial values, use the **Reset input** parameter. The block resets the filter weights whenever a reset event is detected at the Reset port. The reset signal rate must be the same rate as the data signal input.

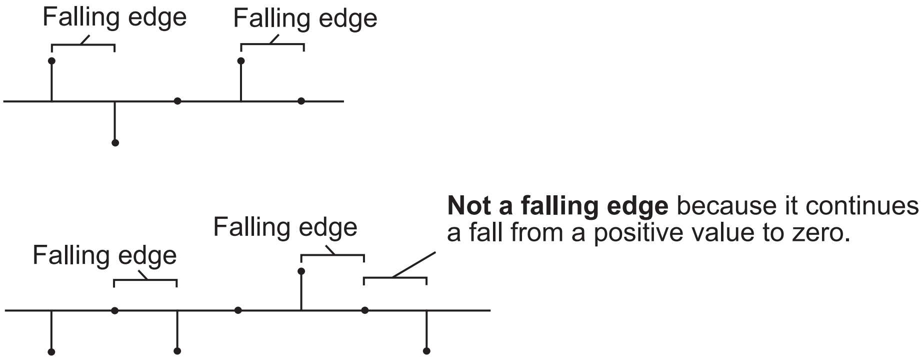
From the **Reset input** list, select `None` to disable the Reset port. To enable the Reset port, select one of the following from the **Reset input** list:

- `Rising edge` — Triggers a reset operation when the Reset input does one of the following:
  - Rises from a negative value to a positive value or zero
  - Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero (see the following figure)



Rising edge
Rising edge
Rising edge
Rising edge
Not a rising edge because it continues a rise from a negative value to zero.

- `Falling edge` — Triggers a reset operation when the Reset input does one of the following:
  - Falls from a positive value to a negative value or zero
  - Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero (see the following figure)

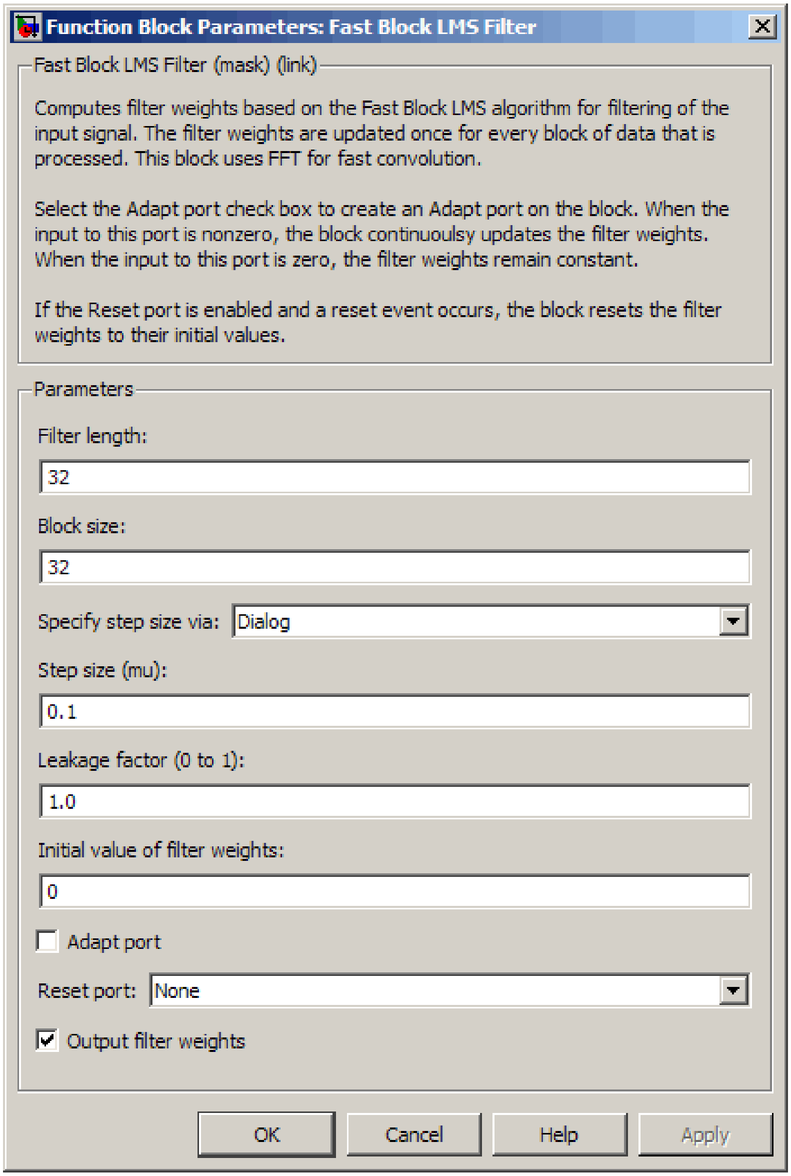


Falling edge
Falling edge
Falling edge
Falling edge
Not a falling edge because it continues a fall from a positive value to zero.

- `Either edge` — Triggers a reset operation when the Reset input is a `Rising edge` or `Falling edge` (as described above)
- `Non-zero sample` — Triggers a reset operation at each sample time that the Reset input is not zero

Select the **Output filter weights** check box to create a Wts port on the block. For each iteration, the block outputs the current updated filter weights from this port.

Dialog Box



Function Block Parameters: Fast Block LMS Filter

Fast Block LMS Filter (mask) (link)

Computes filter weights based on the Fast Block LMS algorithm for filtering of the input signal. The filter weights are updated once for every block of data that is processed. This block uses FFT for fast convolution.

Select the Adapt port check box to create an Adapt port on the block. When the input to this port is nonzero, the block continuoulsy updates the filter weights. When the input to this port is zero, the filter weights remain constant.

If the Reset port is enabled and a reset event occurs, the block resets the filter weights to their initial values.

Parameters

Filter length: 32

Block size: 32

Specify step size via: Dialog

Step size (mu): 0.1

Leakage factor (0 to 1): 1.0

Initial value of filter weights: 0

□ Adapt port

Reset port: None

☑ Output filter weights

Filter length

Enter the length of the FIR filter weights vector. The sum of the **Block size** and the **Filter length** must be a power of 2.

Block size

Enter the number of samples to acquire before the filter weights are updated. The number of rows in the input must be an integer multiple of the **Block size**. The sum of the **Block size** and the **Filter length** must be a power of 2.

Specify step-size via

Select `Dialog` to enter a value for mu, or select `Input port` to specify mu using the Step-size input port.

Step-size (mu)

Enter the step-size. "Tunable".

Leakage factor (0 to 1)

Enter the leakage factor, $0 < 1 - \mu\alpha \leq 1$. "Tunable".

Initial value of filter weights

Specify the initial values of the FIR filter weights.

Adapt port

Select this check box to enable the Adapt input port.

Reset input

Select this check box to enable the Reset input port.

Output filter weights

Select this check box to export the filter weights from the Wts port.

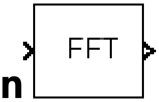
FFT

Fast Fourier transform (FFT) of input

Library

Transforms

`dspxfrm3`



Description

The FFT block computes the fast Fourier transform (FFT) of each row of a sample-based 1-by-P input vector, u, or across the first dimension (P) of an N-D input array, u. For user-specified FFT lengths, not equal to P, zero padding or truncating, or modulo-length data wrapping occurs before the FFT operation, as per Orfanidis [1]:

```
y = fft(u,M)  % P # M
```

Wrapping:

```
y(:,l) = fft(datawrap(u(:,l),M))  % P > M; l = 1,...,N
```

Truncating:

```
y (:,l) = fft(u,M)     % P > M; l = 1,...,N
```

When the input length, P, is greater than the FFT length, M, you may see magnitude increases in your FFT output. These magnitude increases occur because the FFT block uses modulo-M data wrapping to preserve all available input samples.

To avoid such magnitude increases, you can truncate the length of your input sample, P, to the FFT length, M. To do so, place a Pad block before the FFT block in your model.

The kth entry of the lth output channel, $y(k, l)$, equals the kth point of the M-point discrete Fourier transform (DFT) of the lth input channel:

$$y(k,l) = \sum_{p=1}^{P} u(p,l)e^{-j2\pi(p-1)(k-1)/M} \qquad k = 1,\ldots,M$$

The block uses one of two possible FFT implementations. You can select an implementation based on the FFTW library [3], [4], or an implementation based on a collection of Radix-2 algorithms. You can select `Auto` to allow the block to choose the implementation.

FFTW Implementation

The FFTW implementation provides an optimized FFT calculation including support for power-of-two and non-power-of-two transform lengths in both simulation and code generation. Generated code using the FFTW implementation will be restricted to those computers which are capable of running MATLAB. The input data type must be floating-point.

Radix-2 Implementation

The Radix-2 implementation supports bit-reversed processing, fixed or floating-point data, and allows the block to provide portable C-code generation using the Simulink Coder. The dimension M of the M-by-N input matrix, must be a power of two. To work with other input sizes, use the Pad block to pad or truncate these dimensions to powers of two, or if possible choose the FFTW implementation.

With Radix-2 selected, the block implements one or more of the following algorithms:

- Butterfly operation
- Double-signal algorithm
- Half-length algorithm
- Radix-2 decimation-in-time (DIT) algorithm
- Radix-2 decimation-in-frequency (DIF) algorithm

Radix-2 Algorithms for Real and Complex Signals

Complexity of Input	Output Ordering	Algorithms Used for FFT Computation
Complex	Linear	Bit-reversed operation and radix-2 DIT

Complexity of Input	Output Ordering	Algorithms Used for FFT Computation
Complex	Bit-reversed	Radix-2 DIF
Real	Linear	Bit-reversed operation and radix-2 DIT in conjunction with the half-length and double-signal algorithms
Real	Bit-reversed	Radix-2 DIF in conjunction with the half-length and double-signal algorithms

The efficiency of the FFT algorithm can be enhanced for real input signals by forming complex-valued sequences from the real-valued sequences prior to the computation of the DFT. When there are $2N$+1 real input channels, the FFT block forms these complex-valued sequences by applying the double-signal algorithm to the first $2N$ input channels, and the half-length algorithm to the last odd-numbered channel.

For real input signals with fixed-point data types, it is possible to see different numerical results in the output of the last odd numbered channel, even when all input channels are identical. This numerical difference results from differences in the double-signal algorithm and the half-length algorithm.

You can eliminate this numerical difference in two ways:

- Using full precision arithmetic for fixed-point input signals
- Changing the input data type to floating point

For more information on the double-signal and half-length algorithms, see Proakis [2]. “Efficient Computation of the DFT of Two Real Sequences” on page 475 describes the double signal algorithm. “Efficient Computation of the DFT of a 2N-Point Real Sequence” on page 476 describes the half-length algorithm.

Radix-2 Optimization for the Table of Trigonometric Values

In certain situations, the block’s Radix–2 algorithm computes all the possible trigonometric values of the twiddle factor

$$e^{j\frac{2\pi k}{K}}$$

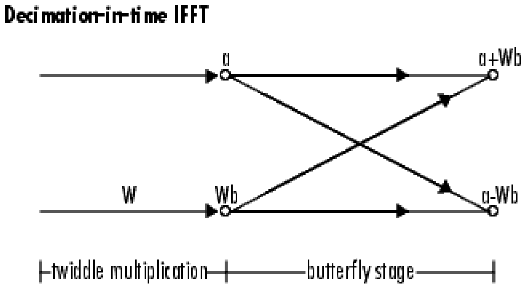
where K is the greater value of either M or N and $k = 0,\cdots,K-1$. The block stores these values in a table and retrieves them during simulation. The number of table entries for fixed-point and floating-point is summarized in the following table:

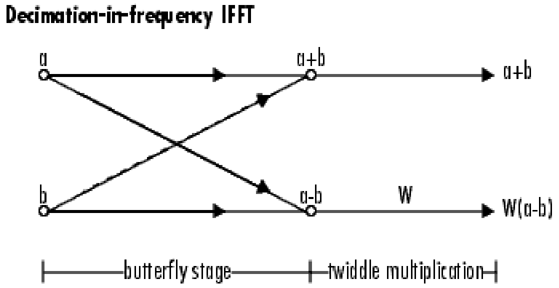
Number of Table Entries for N-Point FFT	
floating-point	3 *N*/4
fixed-point	*N*

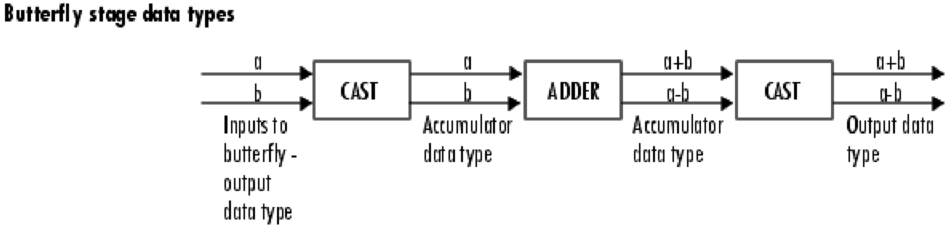
Fixed-Point Data Types

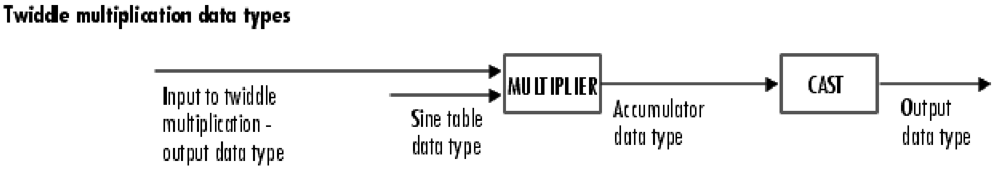
The following diagrams show the data types used in the FFT block for fixed-point signals. You can set the sine table, accumulator, product output, and output data types displayed in the diagrams in the FFT dialog box as discussed in “Dialog Box” on page 1-525.

Inputs to the FFT block are first cast to the output data type and stored in the output buffer. Each butterfly stage then processes signals in the accumulator data type, with the final output of the butterfly being cast back into the output data type. The block multiplies in a twiddle factor before each butterfly stage in a decimation-in-time FFT and after each butterfly stage in a decimation-in-frequency FFT.









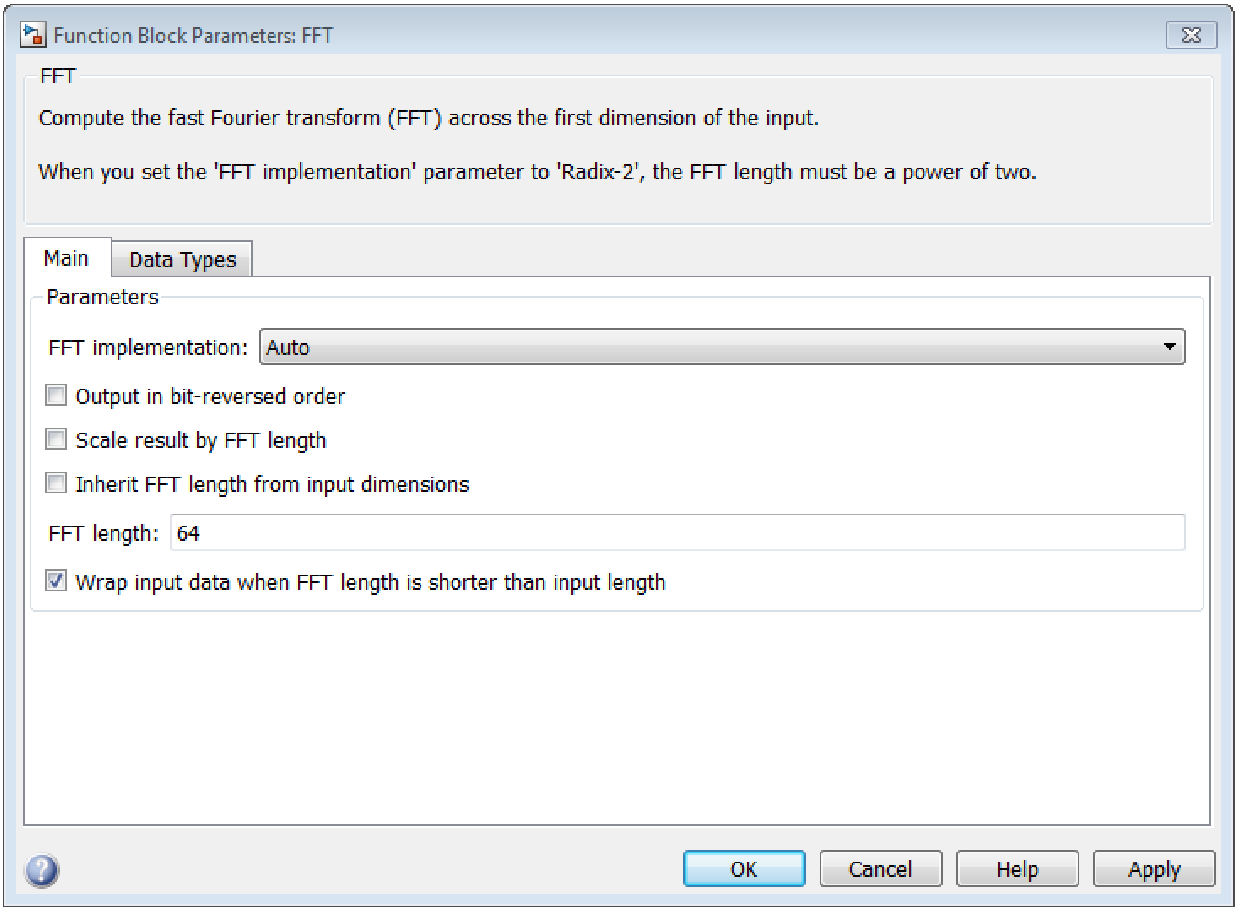
Twiddle multiplication data types
MULTIPLIER
CAST
Input to twiddle multiplication - output data type
Sine table data type
Accumulator data type
Output data type

The output of the multiplier appears in the accumulator data type because both of the inputs to the multiplier are complex. For details on the complex multiplication performed, see “Multiplication Data Types”.

Note: When the block input is fixed point, all internal data types are signed fixed point.

Dialog Box

The **Main** pane of the FFT block dialog appears as follows.



Function Block Parameters: FFT

FFT

Compute the fast Fourier transform (FFT) across the first dimension of the input.

When you set the 'FFT implementation' parameter to 'Radix-2', the FFT length must be a power of two.

Parameters

FFT implementation: Auto

□ Output in bit-reversed order

□ Scale result by FFT length

□ Inherit FFT length from input dimensions

FFT length: 64

☑ Wrap input data when FFT length is shorter than input length

FFT implementation

Set this parameter to `FFTW` [3], [4] to support an arbitrary length input signal. The block restricts generated code with FFTW implementation to host computers capable of running MATLAB.

Set this parameter to `Radix-2` for bit-reversed processing, fixed or floating-point data, or for portable C-code generation using the Simulink Coder. The dimension *M* of the *M*-by-*N* input matrix, must be a power of two. To work with other input sizes, use the Pad block to pad or truncate these dimensions to powers of two, or if possible choose the FFTW implementation. See “Radix-2 Implementation” on page 1-521.

Set this parameter to `Auto` to let the block choose the FFT implementation. For non-power-of-two transform lengths, the block restricts generated code to MATLAB host computers.

Output in bit-reversed order

Designate the order of the output channel elements relative to the ordering of the input elements. When you select this check box, the output channel elements appear in bit-reversed order relative to the input ordering. If you clear this check box, the output channel elements appear in linear order relative to the input ordering.

Linearly ordering the output requires extra data sorting manipulation, so in some situations it might be better to output in bit-reversed order.

Note: The FFT block calculates its output in bit-reversed order. Linearly ordering the FFT block output requires an extra bit-reversal operation. Thus, in many situations, you can increase the speed of the FFT block by selecting the **Output in bit-reversed order** check box.

For more information ordering of the output, see “Linear and Bit-Reversed Output Order”.

Scale result by FFT length

When you select this parameter, the block divides the output of the FFT by the FFT length. This option is useful when you want the output of the FFT to stay in the same amplitude range as its input. This is particularly useful when working with fixed-point data types.

Inherit FFT length from input dimensions

Select to inherit the FFT length from the input dimensions. When you select this check box, the input length must be a power of two. When you do not select this check box, the **FFT length** parameter becomes available to specify the length.

FFT length

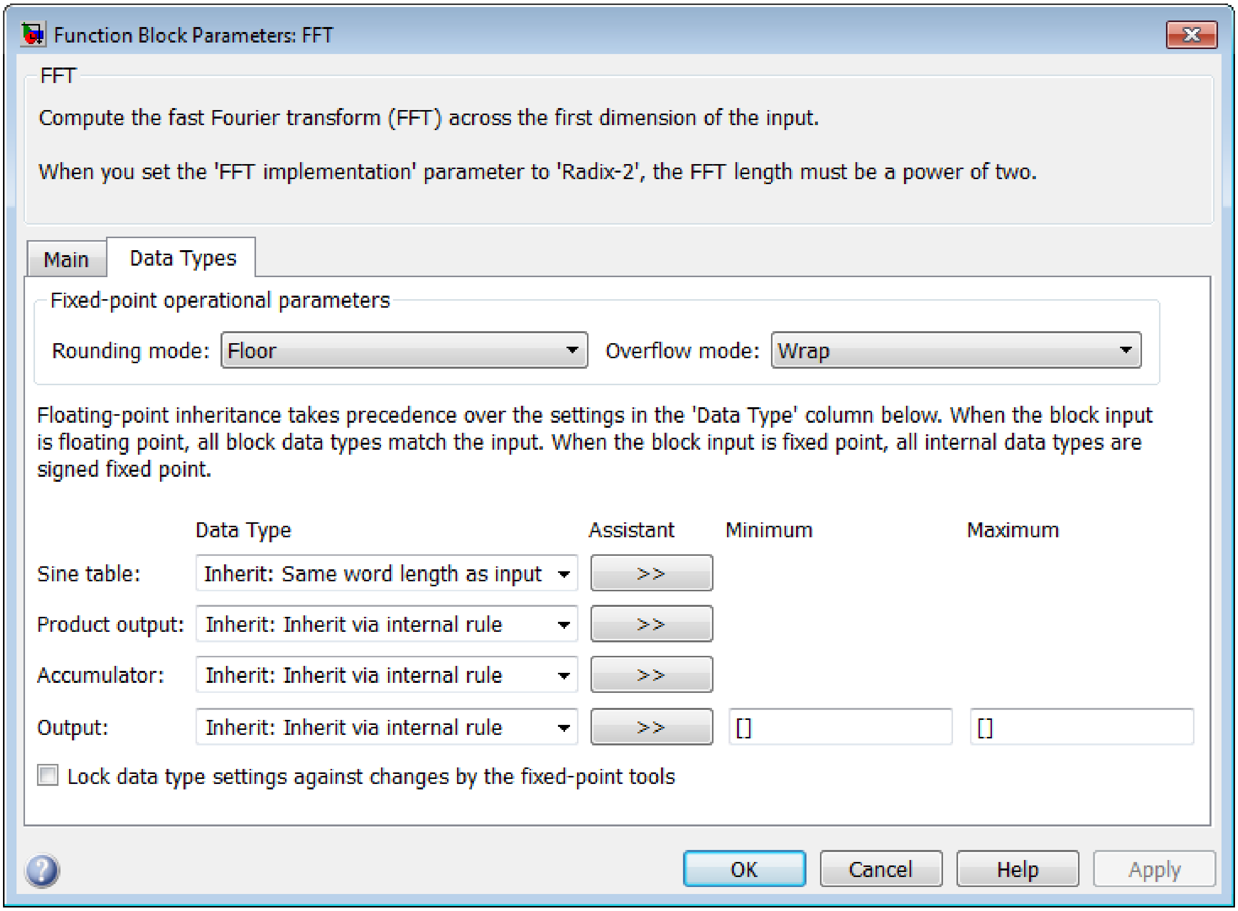
Specify FFT length. This parameter becomes available only when you do not select the **Inherit FFT length from input dimensions** parameter.

When you set the **FFT implementation** parameter to `Radix-2`, or when you check the **Output in bit-reversed order** check box, this value must be a power of two.

Wrap input data when FFT length is shorter than input length

Choose to wrap or truncate the input, depending on the FFT length. If this parameter is checked, modulo-length data wrapping occurs before the FFT operation, given FFT length is shorter than the input length. If this property is unchecked, truncation of the input data to the FFT length occurs before the FFT operation. The default is checked.

The **Data Types** pane of the FFT block dialog appears as follows.



Function Block Parameters: FFT

FFT

Compute the fast Fourier transform (FFT) across the first dimension of the input.

When you set the 'FFT implementation' parameter to 'Radix-2', the FFT length must be a power of two.

Fixed-point operational parameters

Rounding mode: Floor   Overflow mode: Wrap

Floating-point inheritance takes precedence over the settings in the 'Data Type' column below. When the block input is floating point, all block data types match the input. When the block input is fixed point, all internal data types are signed fixed point.

	Data Type	Assistant	Minimum	Maximum
Sine table:	Inherit: Same word length as input	>>		
Product output:	Inherit: Inherit via internal rule	>>		
Accumulator:	Inherit: Inherit via internal rule	>>		
Output:	Inherit: Inherit via internal rule	>>	[]	[]

□ Lock data type settings against changes by the fixed-point tools

Rounding mode

Select the “rounding mode” for fixed-point operations. The sine table values do not obey this parameter; instead, they always round to `Nearest`.

Overflow mode

Select the “overflow mode” for fixed-point operations. The sine table values do not obey this parameter; instead, they are always saturated.

Sine table data type

Choose how you specify the word length of the values of the sine table. The fraction length of the sine table values always equals the word length minus one. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Same word length as input`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16)`

The sine table values do not obey the **Rounding mode** and **Overflow mode** parameters; instead, they are always saturated and rounded to `Nearest`.

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Sine table data type** parameter.

See “Specify Data Types Using Data Type Assistant” in “Simulink User's Guide” for more information.

Product output data type

Specify the product output data type. See and “Multiplication Data Types” for illustrations depicting the use of the product output data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Product output data type** parameter.

See “Specify Data Types Using Data Type Assistant” in “Simulink User's Guide” for more information.

Accumulator data type

Specify the accumulator data type. See for illustrations depicting the use of the accumulator data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Accumulator data type** parameter.

See “Specify Data Types Using Data Type Assistant” in “Simulink User's Guide” for more information.

Output data type

Specify the output data type. See for illustrations depicting the use of the output data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`.

  When you select `Inherit: Inherit via internal rule`, the block calculates the output word length and fraction length automatically. The equations that the block uses to calculate the ideal output word length and fraction length depend on the setting of the **Divide butterfly outputs by two** check box.

  - When you select the **Divide butterfly outputs by two** check box, the ideal output word and fraction lengths are the same as the input word and fraction lengths.
  - When you clear the **Divide butterfly outputs by two** check box, the block computes the ideal output word and fraction lengths according to the following equations:

$$WL_{ideal\ output} = WL_{input} + floor(\log_2(FFT\ length - 1)) + 1$$

$$FL_{ideal\ output} = FL_{input}$$

  Using these ideal results, the internal rule then selects word lengths and fraction lengths that are appropriate for your hardware. For more information, see “Inherit via Internal Rule”.

- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Specify Block Output Data Types” in “Simulink User's Guide” for more information.

Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

Examples

See the section on “Transform Time-Domain Data into Frequency Domain” in the *DSP System Toolbox User's Guide*.

Filter Realization Wizard

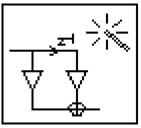
Construct filter realizations using digital filter blocks or Sum, Gain, and Delay blocks

Library

Filtering / Filter Implementations

`dsparch4`

Description



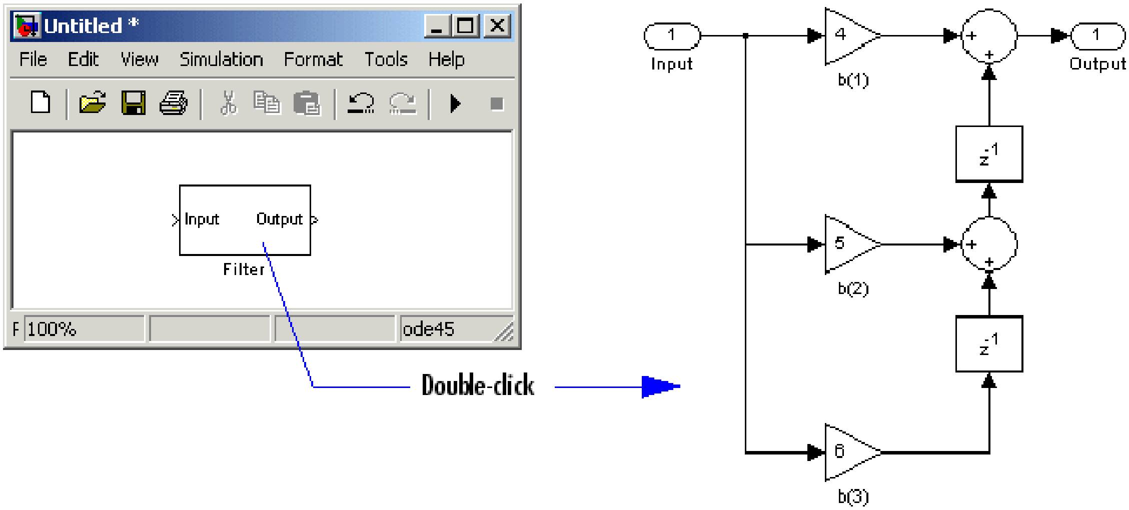
Note: Use this block to implement fixed-point or floating-point digital filters using Sum, Gain, and Delay blocks or digital filter blocks from the DSP System Toolbox library. You can either design a filter by using the block parameters, or import the coefficients of a filter you have designed elsewhere.

The following blocks also implement digital filters, but serve slightly different purposes:

- Discrete FIR Filter and Biquad Filter— Use to implement floating-point or fixed-point filters that you have already designed
- Digital Filter Design — Use to design, analyze, and then implement floating-point filters.

The Filter Realization Wizard is a tool for automatically implementing a digital filter. You must specify a filter, its structure, and the data types for the inputs, outputs, and computations. The filter can support double-precision, single-precision, or fixed-point data types.

The Filter Realization Wizard can implement a digital filter in one of two ways. It can use digital filter blocks from the DSP System Toolbox library, or it can create a subsystem block that implements the specified filter using Sum, Gain, and Delay blocks. If the Filter Realization Wizard creates a block, double-click the block to open the dialog box. If it creates a subsystem, double-click the subsystem block to see the filter implementation as shown in the figure below.



For more information about filter implementation, see “Specify the Filter Implementation” on page 1-535.

The parameters of the Filter Realization Wizard are a part of a larger GUI, the Filter Design and Analysis Tool (`fdatool`). You can use FDATool to design and analyze your filter, and then use the Filter Realization Wizard parameters to implement the filter in your models.

Specify the Filter and Data Types

To specify a purely double-precision filter, you can either design a filter using the **Design Filter** panel, or import a filter using the **Import Filter** panel. (You can import `dfilt` filter objects as well as vectors of filter coefficients designed using Signal Processing Toolbox and DSP System Toolbox functions.)

You can also specify a fixed-point filter or a single-precision filter by using the **Set Quantization Parameters** panel.

Note: *Running* a model containing implementations of fixed-point filters requires the Fixed-Point Designer product, but you can still edit models containing such filter implementations without it. See the Fixed-Point Designer documentation for more information.

See the following topics to learn how to use the panels to specify your filter:

- For more information on the **Design Filter** panel, see “FDATool” in the Signal Processing Toolbox documentation.
- For more information on the **Import Filter** panel, see “Importing a Filter Design” in the Signal Processing Toolbox documentation.
- For more information on the **Set Quantization Parameters** panel, see “Access the Quantization Features of FDATool”.

To open a panel, click the appropriate button in the lower-left corner of FDATool.

Supported Filter Structures

The Filter Realization Wizard supports the following structures:

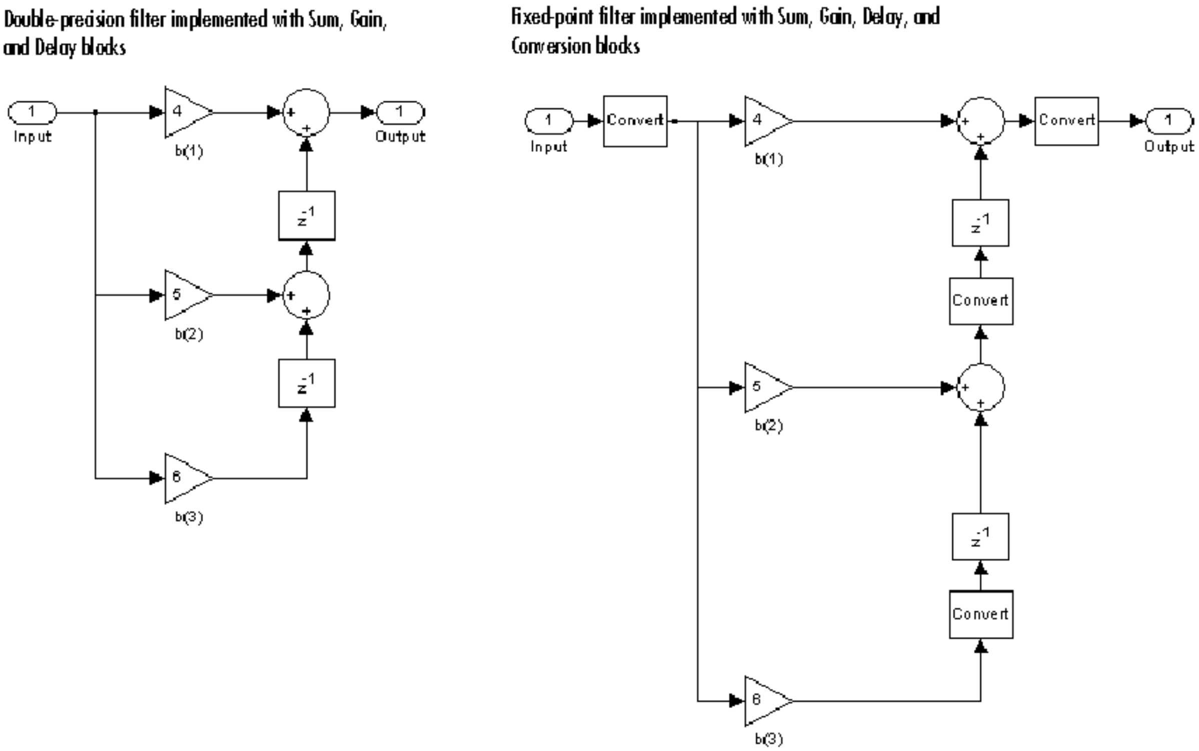
- Direct form I
- Direct form I, second-order sections
- Direct form I transposed
- Direct form I transposed, second-order sections
- Direct form II
- Direct form II, second-order sections
- Direct form II transposed
- Direct form II transposed, second-order sections
- Direct form FIR
- Direct form FIR transposed
- Direct form symmetric FIR
- Direct form antisymmetric FIR
- Lattice all-pass

- Lattice AR
- Lattice ARMA
- Lattice MA for maximum phase
- Lattice MA for minimum phase
- Cascade
- Parallel

Specify the Filter Implementation

You can determine how the Filter Realization Wizard models the specified filter using the **Build model using basic elements** check box. When you select this check box, the Filter Realization Wizard creates a subsystem block that implements your filter using Sum, Gain, and Delay blocks. When you clear this check box, the Filter Realization Wizard uses a digital filter block to implement your filter. The **Build model using basic elements** check box is available only when your filter can be implemented using a digital filter block available in the DSP System Toolbox library.

The Filter Realization Wizard can generate a subsystem that represents either a double-precision or fixed-point filter. You must install the Fixed-Point Designer product to simulate a fixed-point filter. You can still edit the blocks used to implement the filter without installing the Fixed-Point Designer product.



Double-precision filter implemented with Sum, Gain, and Delay blocks

Fixed-point filter implemented with Sum, Gain, Delay, and Conversion blocks

Implementations of Double-Precision and Fixed-Point Filters

Command Line Alternative

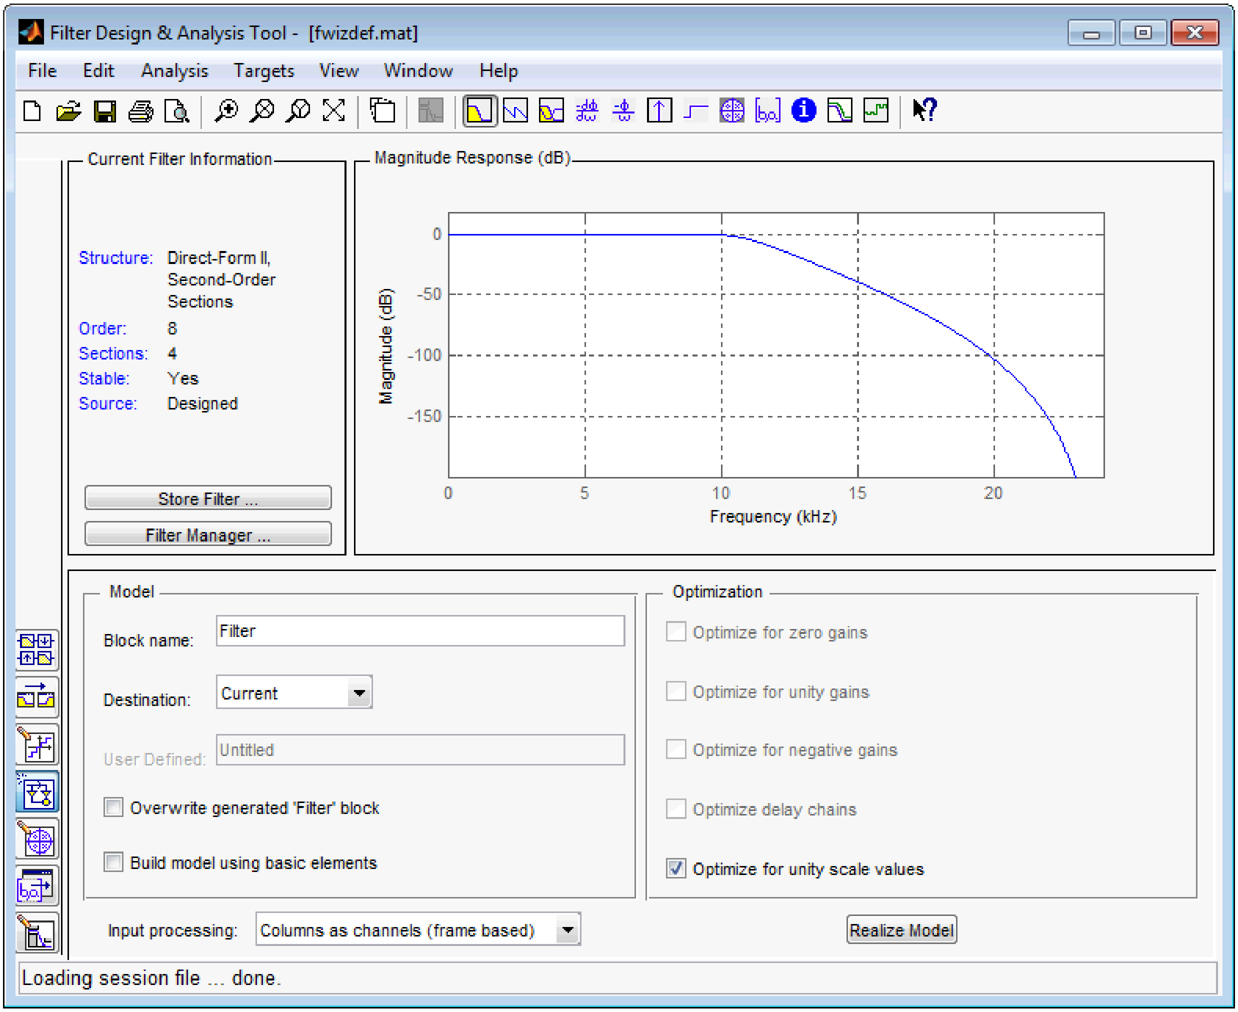
The `dfilt` (digital filter) object has a method, `realizemdl`, that allows you to access the capabilities of the Filter Realization Wizard from the command line.

For more information about the `realizemdl` method, see the following sections:

- The topic on “Methods” in the `dfilt` reference page.
- The `realizemdl` reference page.

Dialog Box

Note: The following parameters for the Filter Realization Wizard are in the **Realize Model** pane of the Filter Design and Analysis Tool (FDATool) GUI. To open different panels of FDATool, click the different buttons at the lower-left corner. For more information about relevant panels, see “Specify the Filter and Data Types” on page 1-533.



Structure: Direct-Form II, Second-Order Sections
Order: 8
Sections: 4
Stable: Yes
Source: Designed

Block name: Filter
Destination: Current
User Defined: Untitled
□ Overwrite generated 'Filter' block
□ Build model using basic elements

□ Optimize for zero gains
□ Optimize for unity gains
□ Optimize for negative gains
□ Optimize delay chains
☑ Optimize for unity scale values

Input processing: Columns as channels (frame based)

Loading session file ... done.

Block Name

Enter the name of the new filter block.

Destination

Specify where the new filter block should be created. This can be in a new model or in the current (most recently selected) model.

User Defined

Specify the name of the target subsystem in which the Filter Realization Wizard should create the new filter block.

Overwrite generated block “Filter” block

When selected, the block overwrites any filter block in the current model with the name specified in the **Block Name** parameter. This parameter is enabled when the **Destination** parameter is set to `Current`.

Build model using basic elements

Select this check box to implement your filter using Sum, Gain, and Delay blocks. Clear this check box to implement your filter using digital filter blocks from the DSP System Toolbox library. This parameter is available only when your filter can be modeled using an available digital filter block.

Optimize for zero gains

Select this check box to remove zero-gain paths from the filter structure. For an example, see “Optimize the Filter Structure”.

Optimize for unity gains

Select this check box to substitute gains equal to 1 with a wire (short circuit). For an example, see “Optimize the Filter Structure”.

Optimize for negative gains

Select this check box to substitute gains equal to -1 with a wire (short circuit), and change the corresponding sums to subtractions. For an example, see “Optimize the Filter Structure”.

Optimize delay chains

Select this check box to substitute any delay chains made up of *n* unit delays with a single delay by *n*. For an example, see “Optimize the Filter Structure”.

Optimize for unity scale values

Select this check box to remove all scale value multiplications by 1 from the filter structure.

Input processing

Specify how the generated filter block or subsystem block processes the input. Depending on the type of filter you are designing, one or both of the following options may be available:

- `Columns as channels (frame based)` — When you select this option, the block treats each column of the input as a separate channel.

- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

For more information about sample- and frame-based processing, see "Sample- and Frame-Based Concepts".

Rate options

For multirate filters, specify how the block should process the input. You can set this parameter to one of the following options:

- `Enforce single-rate processing` — When you select this option, the block maintains the input sample rate.
- `Allow multirate processing` — When you select this option, the block adjusts the rate at the output to accommodate an increased or reduced number of samples.

Realize Model

Click to create a filter block according to the settings you've specified. When the **Build model using basic elements** check box is selected, the filter is implemented as a subsystem block consisting of Sum, Gain, and Delay blocks. To see the filter implementation, double-click the subsystem block in your model.

Note: For more information about relevant parameters in other panels of FDATool, see "Specify the Filter and Data Types" on page 1-533.

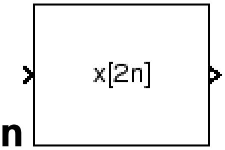
FIR Decimation

Filter and downsample input signals

Library

Filtering / Multirate Filters

`dspmlti4`



Description

The FIR Decimation block resamples the discrete-time input at a rate *K* times slower than the input sample rate, where *K* is the integer value you specify for the **Decimation factor** parameter. To do so, the block implements a polyphase filter structure and performs the following operations:

1. Filters the data in each channel of the input using a direct-form FIR filter.
2. Downsamples each channel of filtered data by discarding *K*–1 consecutive samples following each sample that is retained.

The block uses a polyphase filter implementation because it is more efficient than straightforward filter-then-decimate algorithms. See Fliege [1] for more information.

You can use the FIR Decimation block inside triggered subsystems when you set the **Rate options** parameter to `Enforce single-rate processing`.

This block supports variable-size input. This means that while the block is simulating, the frame size (number of rows) can change. The output dimensions always equal those of the input signal.

Specifying the Filter Coefficients

The FIR Decimation block can operate in two different modes. Select the mode in the **Coefficient source** group box. If you select:

- **Dialog parameters**, you enter information about the filter such as structure and coefficients in the block dialog box.
- **Multirate filter object (MFILT)**, you specify the filter using an `mfilt` object.

When you select **Dialog parameters**, you use the **FIR filter coefficients** parameter to specify the numerator coefficients of the FIR filter transfer function $H(z)$.

$$H(z) = B(z) = b_1 + b_2 z^{-1} + \ldots + b_m z^{-(m-1)}$$

You can generate the FIR filter coefficient vector, `[b(1) b(2) ... b(m)]`, using one of the Signal Processing Toolbox filter design functions (such as `intfilt`).

The filter you specify should be a lowpass filter with a normalized cutoff frequency no greater than $1/K$. The block internally initializes all filter states to zero.

Note: You can use the "block" method to create your own filter blocks directly from your `mfilt` objects.

Frame-Based Processing

When you set the **Input processing** parameter to `Columns as channels (frame based)`, the block resamples each column of the input over time. In this mode, the block can perform either single-rate or multirate processing. You can use the **Rate options** parameter to specify how the block resamples the input:

- When you set the **Rate options** parameter to `Enforce single-rate processing`, the input and output of the block have the same sample rate. To decimate the output while maintaining the input sample rate, the block resamples the data in each column of the input such that the frame size of the output (M_o) is $1/K$ times that of the input ($M_o = M_i/K$),

  In this mode, the input frame size, M_i, must be a multiple of the **Decimation factor**, K.

  For an example of single-rate FIR Decimation, see "Example 1 — Single-Rate Processing" on page 1-546.
- When you set the **Rate options** parameter to `Allow multirate processing`, the input and output of the FIR Decimation block are the same size, but the sample

rate of the output is K times slower than that of the input. In this mode, the block treats an M_i-by-N matrix input as N independent channels. The block decimates each column of the input over time by keeping the frame size constant (M_i=M_o), and making the output frame period (T_{fo}) K times longer than the input frame period (T_{fo} = K*T_{fi}).

See “Example 2— Multirate Frame-Based Processing” on page 1-546 for an example that uses the FIR Decimation block in this mode.

Sample-Based Processing

When you set the **Input processing** parameter to `Elements as channels (sample based)`, the block treats an M-by-N matrix input as M*N independent channels, and decimates each channel over time. The output sample period (T_{so}) is K times longer than the input sample period (T_{so} = K*T_{si}), and the input and output sizes are identical.

Latency

When you use the FIR Decimation block in sample-based processing mode, the block always has zero-tasking latency. *Zero-tasking latency* means that the block propagates the first filtered input sample (received at time t= 0) as the first output sample. That first output sample is then followed by filtered input samples K+1, 2K+1, and so on.

When you use the FIR Decimation block in frame-based processing mode with a frame size greater than one, the block may exhibit *one-frame latency*. Cases of one-frame latency can occur when the input frame size is greater than one, and you set the **Input processing** and **Rate options** parameters of the FIR Decimation block as follows:

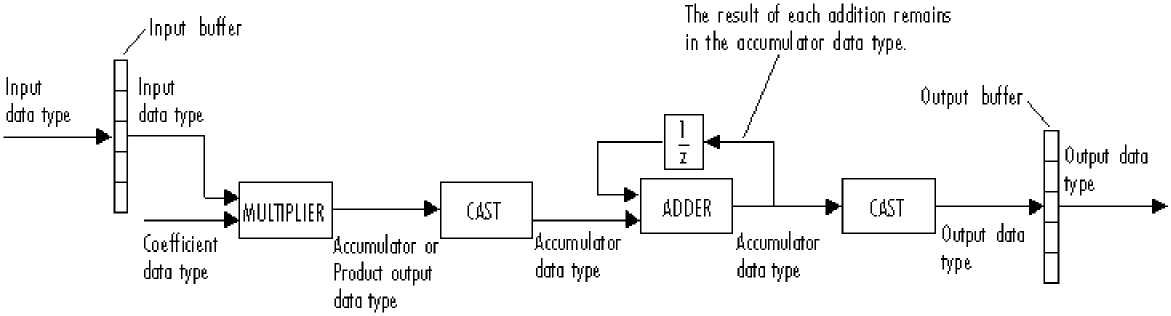
- **Input processing** = `Columns as channels (frame based)`
- **Rate options** = `Allow multirate processing`

In cases of one-frame latency, you can define the value of the first M_i output rows by setting the **Output buffer initial conditions** parameter. The default value of the **Output buffer initial conditions** parameter is `0`. However, you can enter a matrix containing one value for each channel of the input, or a scalar value to be applied to all channels. The first filtered input sample (first filtered row of the input matrix) appears in the output as sample M_i+ 1. That sample is then followed by filtered input samples K+ 1, 2K+ 1, and so on.

Note: For more information on latency and the Simulink tasking modes, see “Excess Algorithmic Delay (Tasking Latency)” in the *DSP System Toolbox User's Guide* and “Scheduling ” in the *Simulink Coder User's Guide*.

Fixed-Point Data Types

The following diagram shows the data types used within the FIR Decimation block for fixed-point signals.



You can set the coefficient, product output, accumulator, and output data types in the block dialog box as discussed in the “Dialog Box” on page 1-547 section. This diagram shows that data is stored in the input buffer with the same data type and scaling as the input. The block stores filtered data and any initial conditions in the output buffer using the output data type and scaling that you set in the block dialog box.

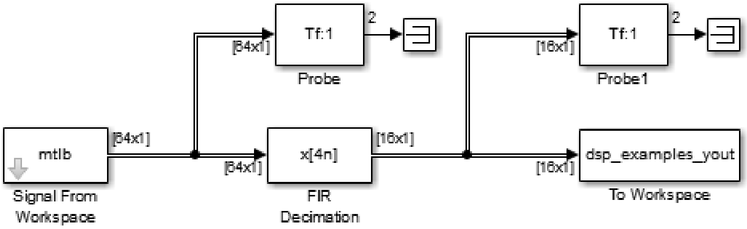
When at least one of the inputs to the multiplier is real, the output of the multiplier is in the product output data type. When both inputs to the multiplier are complex, the result of the multiplication is in the accumulator data type. For details on the complex multiplication performed by this block, see “Multiplication Data Types” in the *DSP System Toolbox User's Guide*.

Note: When the block input is fixed point, all internal data types are signed fixed-point values.

Examples

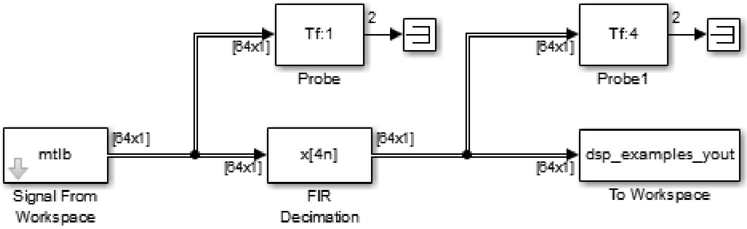
Example 1 — Single-Rate Processing

In the ex_firdecimation_ref2 model, the FIR Decimation block decimates a single-channel input with a frame size of 64. Because the block is doing single-rate processing and the **Decimation factor** parameter is set to 4, the output of the FIR Decimation block has a frame size of 16. As shown in the following figure, the input and output of the FIR Decimation block have the same sample rate.



Example 2— Multirate Frame-Based Processing

In the ex_firdecimation_ref1 model, the FIR Decimation block decimates a single-channel input with a frame period of one second. Because the block is doing multirate frame-based processing and the **Decimation factor** parameter is set to 4, the frame period of the output is four seconds. As shown in the following figure, the input and output of the FIR Decimation block have the same frame size, but the sample rate of the output is four times that of the input.



Example 3

The ex_polyphasedec model illustrates the underlying polyphase implementations of the FIR Decimation block. Run the model, and view the results on the scope. The output of the FIR Decimation block matches the output of the Polyphase Decimation Filter block.

Example 4

The ex_mrf_nlp model illustrates the use of the FIR Decimation block in a number of multistage multirate filters.

Dialog Box

Coefficient Source

The FIR Decimation block can operate in two different modes. Select the mode in the **Coefficient source** group box. If you select

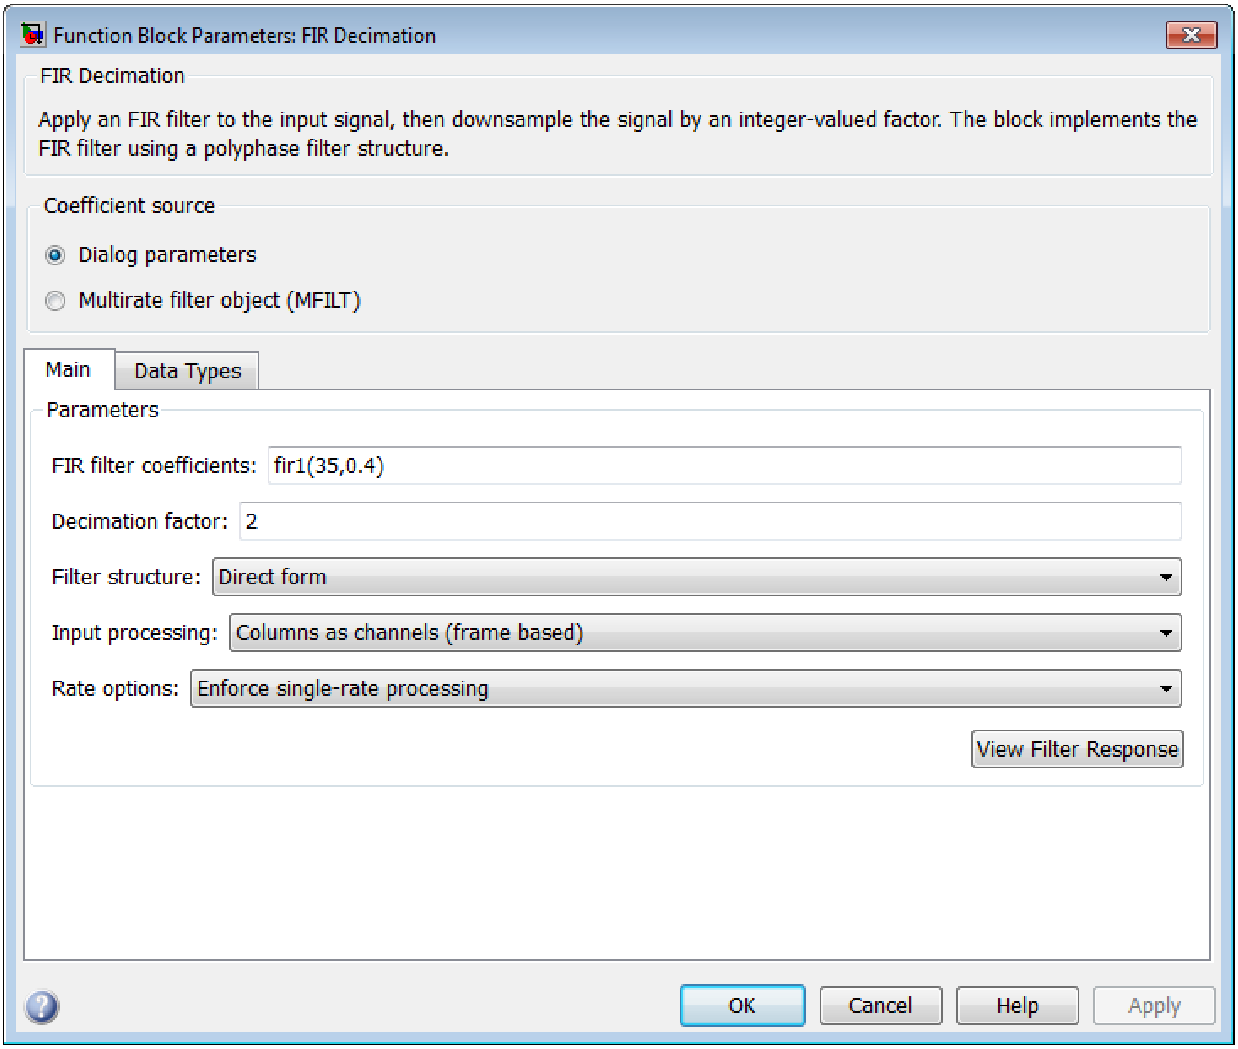
- **Dialog parameters**, you enter information about the filter such as structure and coefficients in the block mask.
- **Multirate filter object (MFILT)**, you specify the filter using an `mfilt` object.

Different items appear on the FIR Decimation block dialog depending on whether you select **Dialog parameters** or **Multirate filter object (MFILT)** in the **Coefficient source** group box. See the following sections for details:

- “Specify Filter Characteristics in Dialog” on page 1-547
- “Specify Multirate Filter Object” on page 1-554

Specify Filter Characteristics in Dialog

The **Main** pane of the FIR Decimation block dialog appears as follows when you select **Dialog parameters** in the **Coefficient source** group box.



Function Block Parameters: FIR Decimation

FIR Decimation

Apply an FIR filter to the input signal, then downsample the signal by an integer-valued factor. The block implements the FIR filter using a polyphase filter structure.

Coefficient source

● Dialog parameters

○ Multirate filter object (MFILT)

Parameters

FIR filter coefficients: fir1(35,0.4)

Decimation factor: 2

Filter structure: Direct form

Input processing: Columns as channels (frame based)

Rate options: Enforce single-rate processing

FIR filter coefficients

Specify the lowpass FIR filter coefficients, in descending powers of z.

Decimation factor

Specify the integer factor, K, by which to decrease the sample rate of the input sequence.

Filter Structure

Choose whether to implement a `Direct form` or `Direct form transposed` filter.

Input processing

Specify how the block should process the input. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` — When you select this option, the block treats each column of the input as a separate channel.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

Note: The `Inherited (this choice will be removed - see release notes)` option will be removed in a future release. See “Frame-Based Processing” in the *DSP System Toolbox Release Notes* for more information.

Rate options

Specify the method by which the block should decimate the input. You can select one of the following options:

- `Enforce single-rate processing` — When you select this option, the block maintains the input sample rate and decimates the signal by decreasing the output frame size by a factor of *K*. To select this option, you must set the **Input processing** parameter to `Columns as channels (frame based)`.
- `Allow multirate processing` — When you select this option, the block decimates the signal such that the output sample rate is *K* times slower than the input sample rate.

Output buffer initial conditions

In the case of *one-frame latency*, this parameter specifies the output of the block until the first filtered input sample is available. The default value of this parameter is `0`, but you can enter a matrix containing one value for each channel, or a scalar value to be applied to all signal channels. This parameter appears only when you configure the block to perform multirate processing.

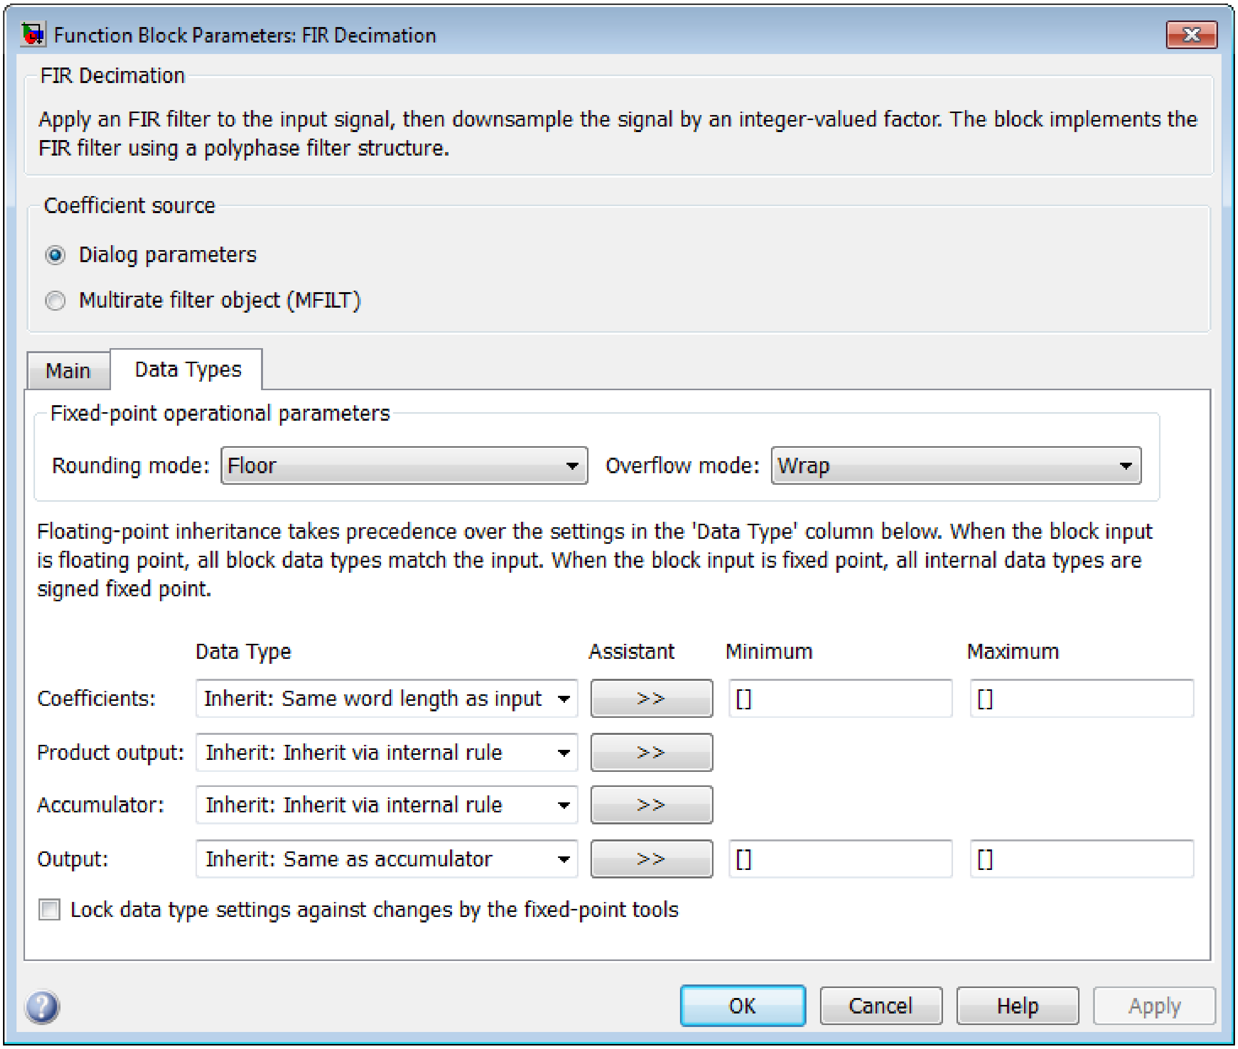
See “Latency” on page 1-544 for more information about latency in the FIR Decimation block.

View filter response

This button opens the Filter Visualization Tool (`fvtool`) from the Signal Processing Toolbox product and displays the filter response of the filter defined in the block. For more information on FVTool, see the Signal Processing Toolbox documentation.

Note: If you specify a filter in the **Multirate filter variable** parameter, you must apply the filter by clicking the **Apply** button before using the **View filter response** button.

The **Data Types** pane of the FIR Decimation block dialog appears as follows when you select **Dialog parameters** in the **Coefficient source** group box.



Function Block Parameters: FIR Decimation

FIR Decimation

Apply an FIR filter to the input signal, then downsample the signal by an integer-valued factor. The block implements the FIR filter using a polyphase filter structure.

Coefficient source

● Dialog parameters

○ Multirate filter object (MFILT)

Fixed-point operational parameters

Rounding mode: Floor   Overflow mode: Wrap

Floating-point inheritance takes precedence over the settings in the 'Data Type' column below. When the block input is floating point, all block data types match the input. When the block input is fixed point, all internal data types are signed fixed point.

	Data Type	Assistant	Minimum	Maximum
Coefficients:	Inherit: Same word length as input	>>	[]	[]
Product output:	Inherit: Inherit via internal rule	>>		
Accumulator:	Inherit: Inherit via internal rule	>>		
Output:	Inherit: Same as accumulator	>>	[]	[]

□ Lock data type settings against changes by the fixed-point tools

Rounding mode

Select the “rounding mode” for fixed-point operations. The filter coefficients do not obey this parameter; they always round to `Nearest`.

Note: The **Rounding mode** and **Overflow mode** settings have no effect on numerical results when all the following conditions exist:

- **Product output data type** is `Inherit: Inherit via internal rule`
- **Accumulator data type** is `Inherit: Inherit via internal rule`
- **Output data type** is `Inherit: Same as accumulator`

With these data type settings, the block is effectively operating in full precision mode.

Overflow mode

Select the “overflow mode” for fixed-point operations. The filter coefficients do not obey this parameter; they are always saturated.

Coefficients data type

Specify the coefficients data type. See “Fixed-Point Data Types” on page 1-545 and “Multiplication Data Types” for illustrations depicting the use of the coefficients data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same word length as input`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Coefficients data type** parameter.

See “Specify Data Types Using Data Type Assistant” in “Simulink User's Guide” for more information.

Product output data type

Specify the product output data type. See “Fixed-Point Data Types” on page 1-545 and “Multiplication Data Types” for illustrations depicting the use of the product output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Product output data type** parameter.

See “Specify Data Types Using Data Type Assistant” in “Simulink User's Guide” for more information.

Accumulator data type

Specify the accumulator data type. See “Fixed-Point Data Types” on page 1-545 for illustrations depicting the use of the accumulator data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Accumulator data type** parameter.

See “Specify Data Types Using Data Type Assistant” in “Simulink User's Guide” for more information.

Output data type

Specify the output data type. See “Fixed-Point Data Types” on page 1-545 for illustrations depicting the use of the output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as accumulator`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Specify Block Output Data Types” in “Simulink User's Guide” for more information.

Minimum

Specify the minimum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges”)

- Automatic scaling of fixed-point data types

Maximum

Specify the maximum value that the block should output. The default value is [ ] (unspecified). Simulink software uses this value to perform:

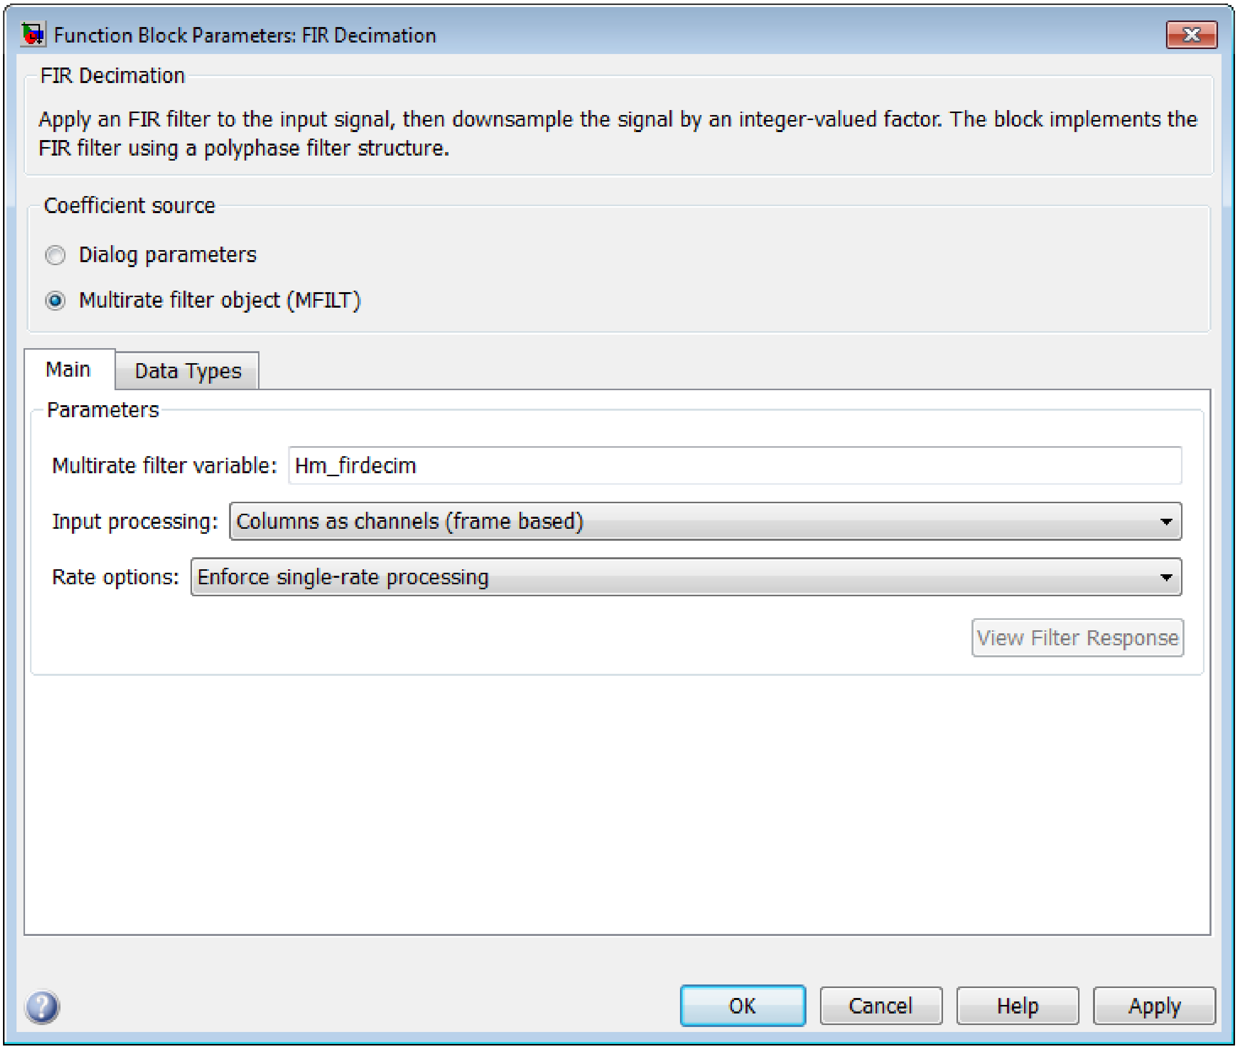
- Simulation range checking (see “Signal Ranges”)
- Automatic scaling of fixed-point data types

Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

Specify Multirate Filter Object

The **Main** pane of the FIR Decimation block dialog appears as follows when you select **Multirate filter object (MFILT)** in the **Coefficient source** group box.



Function Block Parameters: FIR Decimation

FIR Decimation

Apply an FIR filter to the input signal, then downsample the signal by an integer-valued factor. The block implements the FIR filter using a polyphase filter structure.

Coefficient source

○ Dialog parameters

● Multirate filter object (MFILT)

Parameters

Multirate filter variable: Hm_firdecim

Input processing: Columns as channels (frame based)

Rate options: Enforce single-rate processing

Multirate filter variable

Specify the multirate filter object (`mfilt`) that you would like the block to implement. You can do this in one of three ways:

- You can fully specify the `mfilt` object in the block mask.

- You can enter the variable name of a `mfilt` object that is defined in any workspace.
- You can enter a variable name for a `mfilt` object that is not yet defined, as shown in the default value.

For more information on creating `mfilt` objects, see the `mfilt` function reference page.

Input processing

Specify how the block should process the input. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` — When you select this option, the block treats each column of the input as a separate channel.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

Note: The `Inherited (this choice will be removed - see release notes)` option will be removed in a future release. See “Frame-Based Processing” in the *DSP System Toolbox Release Notes* for more information.

Rate options

Specify the method by which the block should decimate the input. You can select one of the following options:

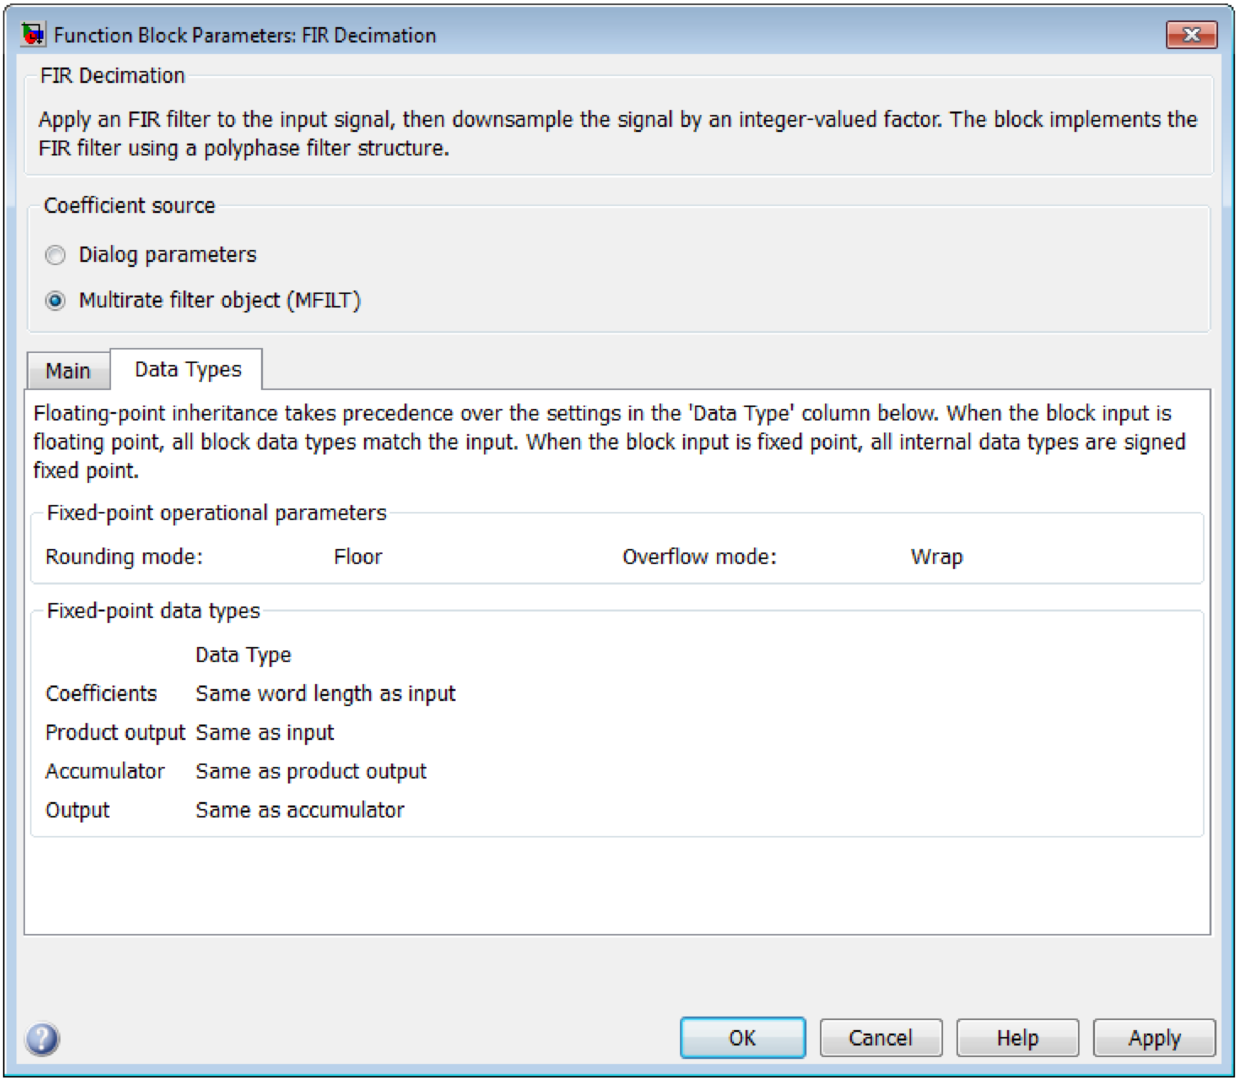
- `Enforce single-rate processing` — When you select this option, the block maintains the input sample rate, and decimates the signal by decreasing the input frame size by a factor of *K*. To select this option, you must set the **Input processing** parameter to `Columns as channels (frame based)`.
- `Allow multirate processing` — When you select this option, the block decimates the sample rate such that the output sample rate is *K* times slower than the input sample rate.

View filter response

This button opens the Filter Visualization Tool (`fvtool`) from the Signal Processing Toolbox product and displays the filter response of the `mfilt` object specified in the **Multirate filter variable** parameter. For more information on FVTool, see the Signal Processing Toolbox documentation.

Note: If you specify a filter in the **Multirate filter variable** parameter, you must apply the filter by clicking the **Apply** button before using the **View filter response** button.

The **Data Types** pane of the FIR Decimation block dialog appears as follows when you select **Multirate filter object (MFILT)** in the **Coefficient source** group box.



Function Block Parameters: FIR Decimation

FIR Decimation

Apply an FIR filter to the input signal, then downsample the signal by an integer-valued factor. The block implements the FIR filter using a polyphase filter structure.

Coefficient source

○ Dialog parameters

● Multirate filter object (MFILT)

Floating-point inheritance takes precedence over the settings in the 'Data Type' column below. When the block input is floating point, all block data types match the input. When the block input is fixed point, all internal data types are signed fixed point.

Fixed-point operational parameters

Rounding mode: Floor   Overflow mode: Wrap

Fixed-point data types

	Data Type
Coefficients	Same word length as input
Product output	Same as input
Accumulator	Same as product output
Output	Same as accumulator

The fixed-point settings of the filter object specified on the **Main** pane are displayed on the **Data Types** pane. You cannot change these settings directly on the block mask. To change the fixed-point settings you must edit the filter object directly.

For more information on multirate filter objects, see the `mfilt` function reference page.

HDL Code Generation

This block supports HDL code generation using HDL Coder. HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic. For more information on implementations, properties, and restrictions for HDL code generation, see FIR Decimation.

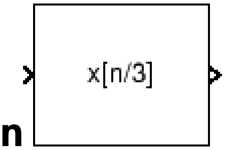
FIR Interpolation

Upsample and filter input signals

Library

Filtering / Multirate Filters

`dspmlti4`



Description

The FIR Interpolation block resamples the discrete-time input at a rate *L* times faster than the input sample rate, where *L* is the integer value you specify for the **Interpolation factor** parameter. To do so, the block implements a polyphase filter structure and performs the following operations:

- Upsamples each channel of the input to a higher rate by inserting *L*–1 zeros between samples.
- Filters each channel of the upsampled data using a direct-form FIR filter.

The block uses a polyphase filter implementation because it is more efficient than straightforward upsample-then-filter algorithms. See Fliege [1] for more information.

You can use the FIR Interpolation block inside triggered subsystems when you set the **Rate options** parameter to `Enforce single-rate processing`.

Specifying the Filter Coefficients

The FIR Interpolation block can operate in two different modes. Select the mode in the **Coefficient source** group box. If you select:

- **Dialog parameters**, you enter information about the filter such as structure and coefficients in the block dialog box.

- **Input port**, you specify the filter as an input to the block.
- **Multirate filter object (MFILT)**, you specify the filter using an `mfilt` object.

When you select **Dialog parameters**, you use the **FIR filter coefficients** parameter to specify the numerator coefficients of the FIR filter transfer function *H*(*z*).

$$H(z) = B(z) = b_1 + b_2 z^{-1} + \ldots + b_m z^{-(m-1)}$$

You can generate the FIR filter coefficient vector, `[b(1) b(2) ... b(m)]`, using one of the Signal Processing Toolbox filter design functions (such as `intfilt`).

The filter you specify should be a lowpass filter with a length greater than the interpolation factor (m>L) and a normalized cutoff frequency no greater than **1**/*L*. The block internally initializes all filter states to zero.

Note: You can use the “block” method to create your own filter blocks directly from your `mfilt` objects.

Frame-Based Processing

When you set the **Input processing** parameter to `Columns as channels (frame based)`, the block resamples each column of the input over time. In this mode, the block can perform either single-rate or multirate processing. You can use the **Rate options** parameter to specify how the block resamples the input:

- When you set the **Rate options** parameter to `Enforce single-rate processing`, the input and output of the block have the same sample rate. To interpolate the output while maintaining the input sample rate, the block resamples the data in each column of the input such that the frame size of the output (M_o) is L times larger than that of the input ($M_o = M_i*L$).

  For an example of single-rate FIR Interpolation, see “Example 1 — Single-Rate Processing” on page 1-566.
- When you set the **Rate options** parameter to `Allow multirate processing`, the input and output of the FIR Interpolation block are the same size. However, the sample rate of the output is L times faster than that of the input. In this mode, the block treats an M_i-by-N matrix input as N independent channels. The block interpolates each column of the input over time by keeping the frame size constant

(M_i=M_o), while making the output frame period (T_{fo}) L times shorter than the input frame period ($T_{fo} = T_{fi}/L$).

See "Example 2 — Multirate Frame-Based Processing" on page 1-566 for an example that uses the FIR Interpolation block in this mode.

Sample-Based Processing

When you set the **Input processing** parameter to `Elements as channels (sample based)`, the block treats an M-by-N matrix input as $M*N$ independent channels, and interpolates each channel over time. The output sample period (T_{so}) is L times shorter than the input sample period ($T_{so} = T_{si}/L$), while the input and output sizes remain identical.

Latency

When you run your models in Simulink `SingleTasking` mode or set the **Input processing** parameter to `Columns as channels (frame based)` and the **Rate options** parameter to `Enforce single-rate processing`, the FIR Interpolation block always has zero-tasking latency. *Zero-tasking latency* means that the block propagates the first filtered input sample (received at time t=0) as the first output sample. That first output sample is then followed by L–1 interpolated values, the second filtered input sample, and so on.

The only time the FIR Interpolation block exhibits latency is when you set the **Rate options** parameter set to `Allow multirate processing` and run your models in Simulink `MultiTasking` mode. The amount of latency for multirate, multitasking operation depends on the setting of the **Input processing** parameter, as shown in the following table.

Input processing	Latency
`Elements as channels (sample based)`	L samples
`Columns as channels (frame based)`	L frames (M_i samples per frame)

When the block exhibits latency, the default initial condition is zero. Alternatively, you can use the **Output buffer initial conditions** parameter to specify a matrix of initial conditions containing one value for each channel or a scalar initial condition to be applied to all channels. The block scales the **Output buffer initial conditions** by the **Interpolation factor** and outputs the scaled initial conditions until the first filtered input sample becomes available.

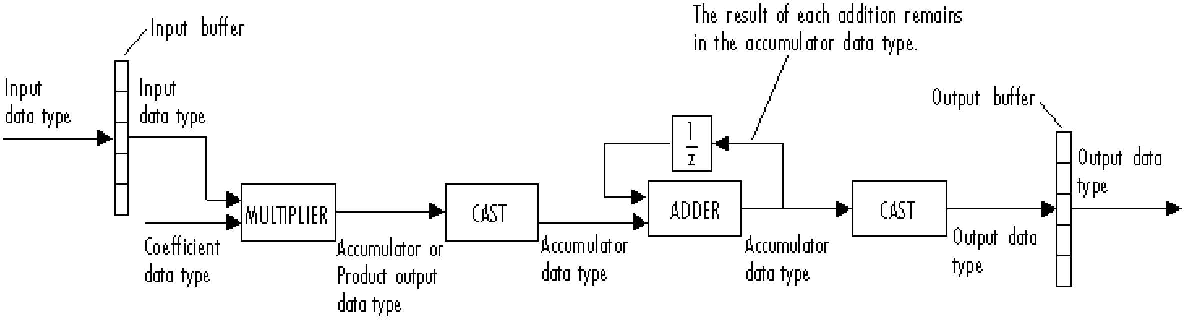
When the block is in sample-based processing mode, the block outputs the scaled initial conditions at the start of each channel, followed immediately by the first filtered input sample, then L–1 interpolated values, and so on.

When the block is in frame-based processing mode and using the default initial condition of zero, the first M_i*L output rows contain zeros, where M_i is the input frame size. The first filtered input sample (first filtered row of the input matrix) appears in the output as sample M_i*L+**1**. That value is then followed by L–1 interpolated values, the second filtered input sample, and so on.

Note For more information on latency and the Simulink tasking modes, see “Excess Algorithmic Delay (Tasking Latency)” in the *DSP System Toolbox User's Guide* and “Scheduling ” in the *Simulink Coder User's Guide*.

Fixed-Point Data Types

The following diagram shows the data types used within the FIR Interpolation block for fixed-point signals.



You can set the coefficient, product output, accumulator, and output data types in the block dialog as discussed in “Dialog Box” on page 1-567 section. This diagram shows that input data is stored in the input buffer with the same data type and scaling as the input. The block stores filtered data and any initial conditions in the output buffer using the output data type and scaling that you set in the block dialog box.

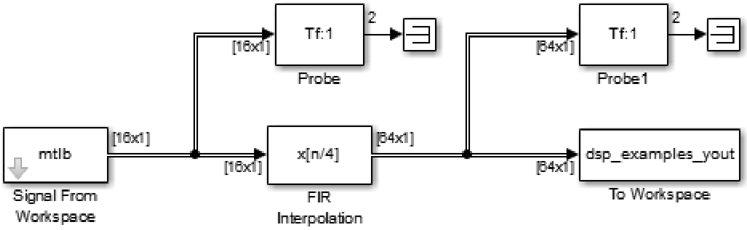
When at least one of the inputs to the multiplier is real, the output of the multiplier is in the product output data type. When both inputs to the multiplier are complex, the result of the multiplication is in the accumulator data type. For details on the complex multiplication performed by this block, see “Multiplication Data Types” in the *DSP System Toolbox User's Guide*.

Note: When the block input is fixed point, all internal data types are signed fixed point.

Examples

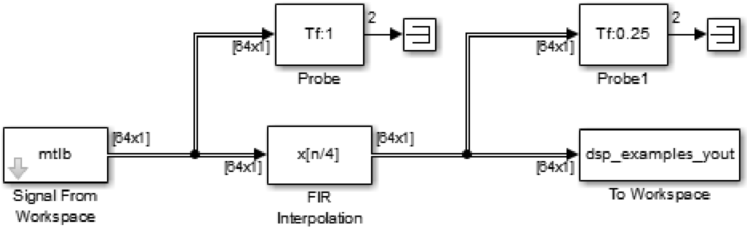
Example 1 — Single-Rate Processing

In the ex_firinterpolation_ref2, the FIR Interpolation block interpolates a single-channel input with a frame size of 16. Because the block is doing single-rate processing and the **Interpolation factor** parameter is set to 4, the output of the FIR Interpolation block has a frame size of 64. As shown in the following figure, the input and output of the FIR Interpolation block have the same sample rate.



Example 2 — Multirate Frame-Based Processing

In the ex_firinterpolation_ref1, the FIR Interpolation block interpolates a single-channel input with a frame period of 1 second (**Sample time** = 1/64 and **Samples per frame** = 64). Because the block is doing multirate frame-based processing and the **Interpolation factor** parameter is set to 4, the output of the FIR Interpolation block has a frame period of 0.25 seconds. As shown in the following figure, the input and output of the FIR Interpolation block have the same frame size, but the sample rate of the output is 1/4 times that of the input.



Example 3

The ex_polyphaseinterp model illustrates the underlying polyphase implementations of the FIR Interpolation block. Run the model, and view the results on the scope. The output of the FIR Interpolation block matches the output of the Polyphase Interpolation Filter block.

Example 4

The ex_mrf_nlp model illustrates the use of the FIR Interpolation block in a number of multistage multirate filters.

Dialog Box

Coefficient Source

The FIR Interpolation block can operate in three different modes. Select the mode in the **Coefficient source** group box. If you select

- **Dialog parameters**, you enter information about the filter such as structure and coefficients in the block mask.
- **Input port**, you specify the filter with a **Num** input port. The **Num** input port appears when you select the **Input port** option.
- **Multirate filter object (MFILT)**, you specify the filter using an `mfilt` object.

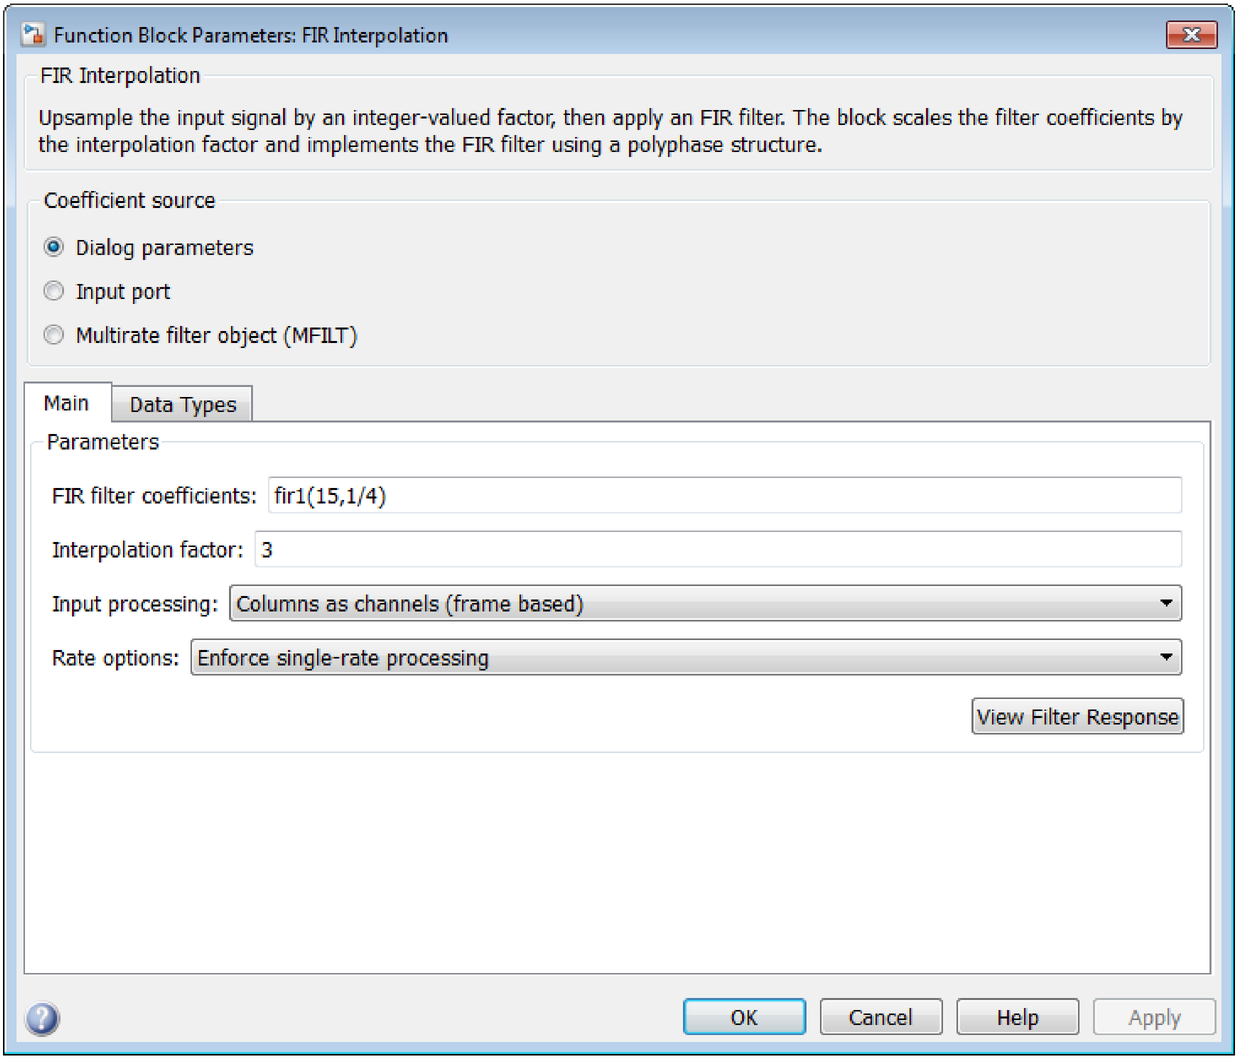
Different items appear on the FIR Interpolation block dialog depending on whether you select **Dialog parameters** or **Multirate filter object (MFILT)** in the **Coefficient source** group box. See the following sections for details:

- “Specify Filter Characteristics in Dialog” on page 1-568

- "Specify Multirate Filter Object" on page 1-574

Specify Filter Characteristics in Dialog

The **Main** pane of the FIR Interpolation block dialog appears as follows when you select **Dialog parameters** in the **Coefficient source** group box.



Function Block Parameters: FIR Interpolation

FIR Interpolation

Upsample the input signal by an integer-valued factor, then apply an FIR filter. The block scales the filter coefficients by the interpolation factor and implements the FIR filter using a polyphase structure.

Coefficient source

● Dialog parameters

○ Input port

○ Multirate filter object (MFILT)

Main | Data Types

Parameters

FIR filter coefficients: fir1(15,1/4)

Interpolation factor: 3

Input processing: Columns as channels (frame based)

Rate options: Enforce single-rate processing

FIR filter coefficients

Specify the FIR filter coefficients, in descending powers of z.

Interpolation factor

Specify the integer factor, L, by which to increase the sample rate of the input sequence.

Input processing

Specify how the block should process the input. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` — When you select this option, the block treats each column of the input as a separate channel.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

Note: The `Inherited (this choice will be removed - see release notes)` option will be removed in a future release. See "Frame-Based Processing" in the *DSP System Toolbox Release Notes* for more information.

Rate options

Specify the method by which the block should interpolate the input. You can select one of the following options:

- `Enforce single-rate processing` — When you select this option, the block maintains the input sample rate, and interpolates the signal by increasing the output frame size by a factor of L. To select this option, you must set the **Input processing** parameter to `Columns as channels (frame based)`.
- `Allow multirate processing` — When you select this option, the block interpolates the signal such that the output sample rate is L times faster than the input sample rate.

Output buffer initial conditions

In cases of nonzero latency, the block divides this parameter by the **Interpolation factor** and outputs the results at the output port until the first filtered input sample is available. The default initial condition value is `0`, but you can enter a matrix containing one value for each channel, or a scalar to be applied to all signal channels. This parameter appears only when you configure the block to perform multirate processing.

Output buffer initial conditions are stored in the output data type and scaling.

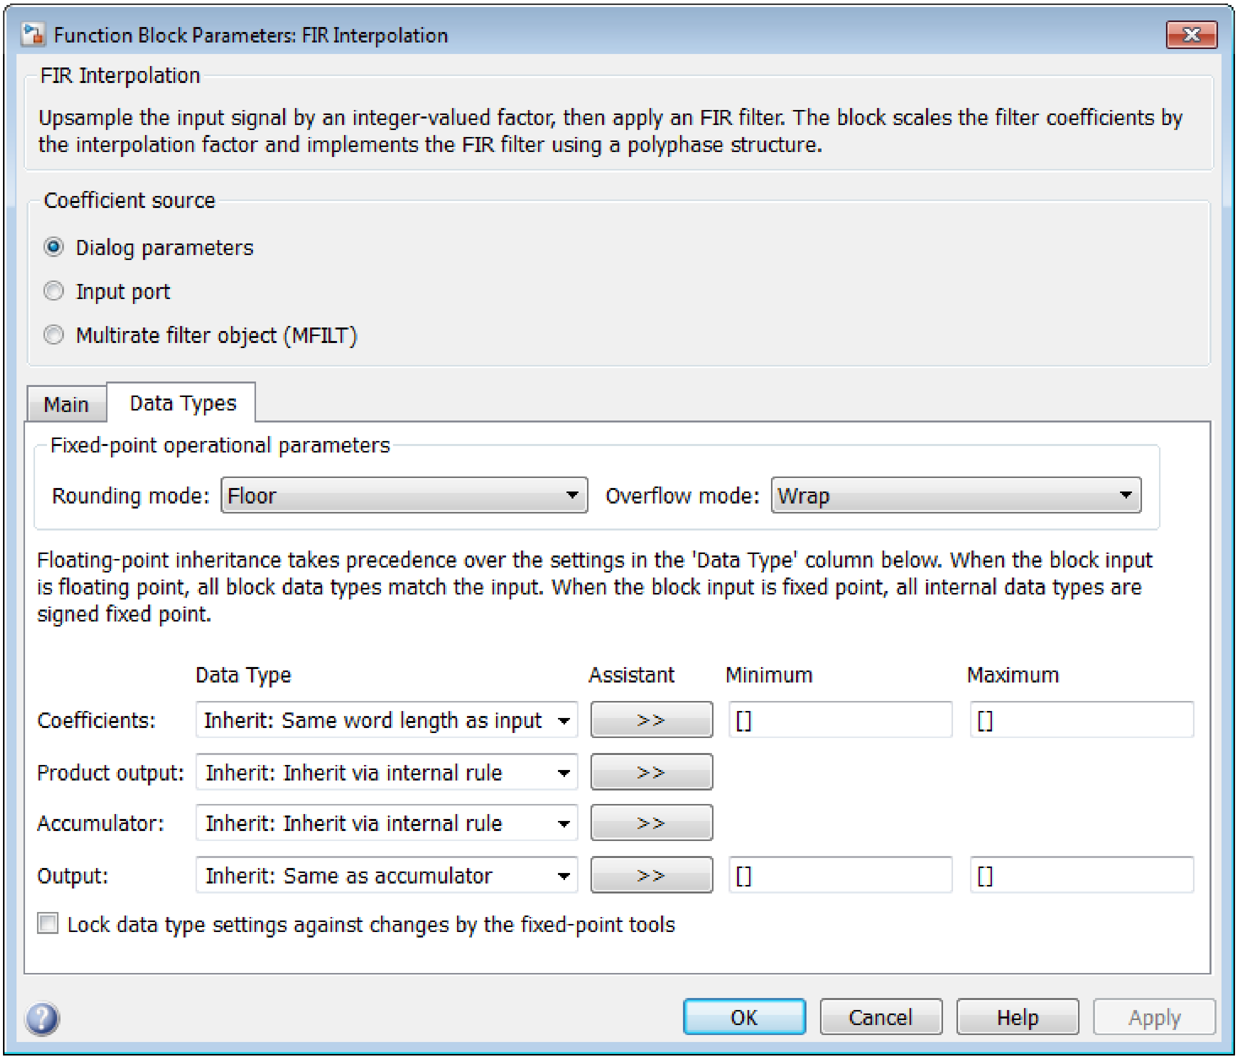
See "Latency" on page 1-564 for more information about latency in the FIR Interpolation block.

View filter response

This button opens the Filter Visualization Tool (`fvtool`) from the Signal Processing Toolbox product and displays the filter response of the filter defined in the block. For more information on FVTool, see the Signal Processing Toolbox documentation.

Note: If you specify a filter in the **Multirate filter variable** parameter, you must apply the filter by clicking the **Apply** button before using the **View filter response** button.

The **Data Types** pane of the FIR Interpolation block dialog appears as follows when you select **Dialog parameters** in the **Coefficient source** group box.



Function Block Parameters: FIR Interpolation

□ Lock data type settings against changes by the fixed-point tools

Rounding mode

Select the “rounding mode” for fixed-point operations. The filter coefficients do not obey this parameter; they always round to `Nearest`.

Note: The **Rounding mode** and **Overflow mode** settings have no effect on numerical results when all the following conditions exist:

- **Product output data type** is `Inherit: Inherit via internal rule`
- **Accumulator data type** is `Inherit: Inherit via internal rule`
- **Output data type** is `Inherit: Same as accumulator`

With these data type settings, the block is effectively operating in full precision mode.

Overflow mode

Select the "overflow mode" for fixed-point operations. The filter coefficients do not obey this parameter; they are always saturated.

Coefficients data type

Specify the coefficients data type. See "Fixed-Point Data Types" on page 1-565 and "Multiplication Data Types" for illustrations depicting the use of the coefficients data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same word length as input`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Coefficients data type** parameter.

See "Specify Data Types Using Data Type Assistant" in "Simulink User's Guide" for more information.

Product output data type

Specify the product output data type. See "Fixed-Point Data Types" on page 1-565 and "Multiplication Data Types" for illustrations depicting the use of the product output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Product output data type** parameter.

See “Specify Data Types Using Data Type Assistant” in “Simulink User's Guide” for more information.

Accumulator data type

Specify the accumulator data type. See “Fixed-Point Data Types” on page 1-565 for illustrations depicting the use of the accumulator data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Accumulator data type** parameter.

See “Specify Data Types Using Data Type Assistant” in “Simulink User's Guide” for more information.

Output data type

Specify the output data type. See “Fixed-Point Data Types” on page 1-565 for illustrations depicting the use of the output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as accumulator`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Specify Block Output Data Types” in “Simulink User's Guide” for more information.

Minimum

Specify the minimum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges”)

- Automatic scaling of fixed-point data types

Maximum

Specify the maximum value that the block should output. The default value is [ ] (unspecified). Simulink software uses this value to perform:

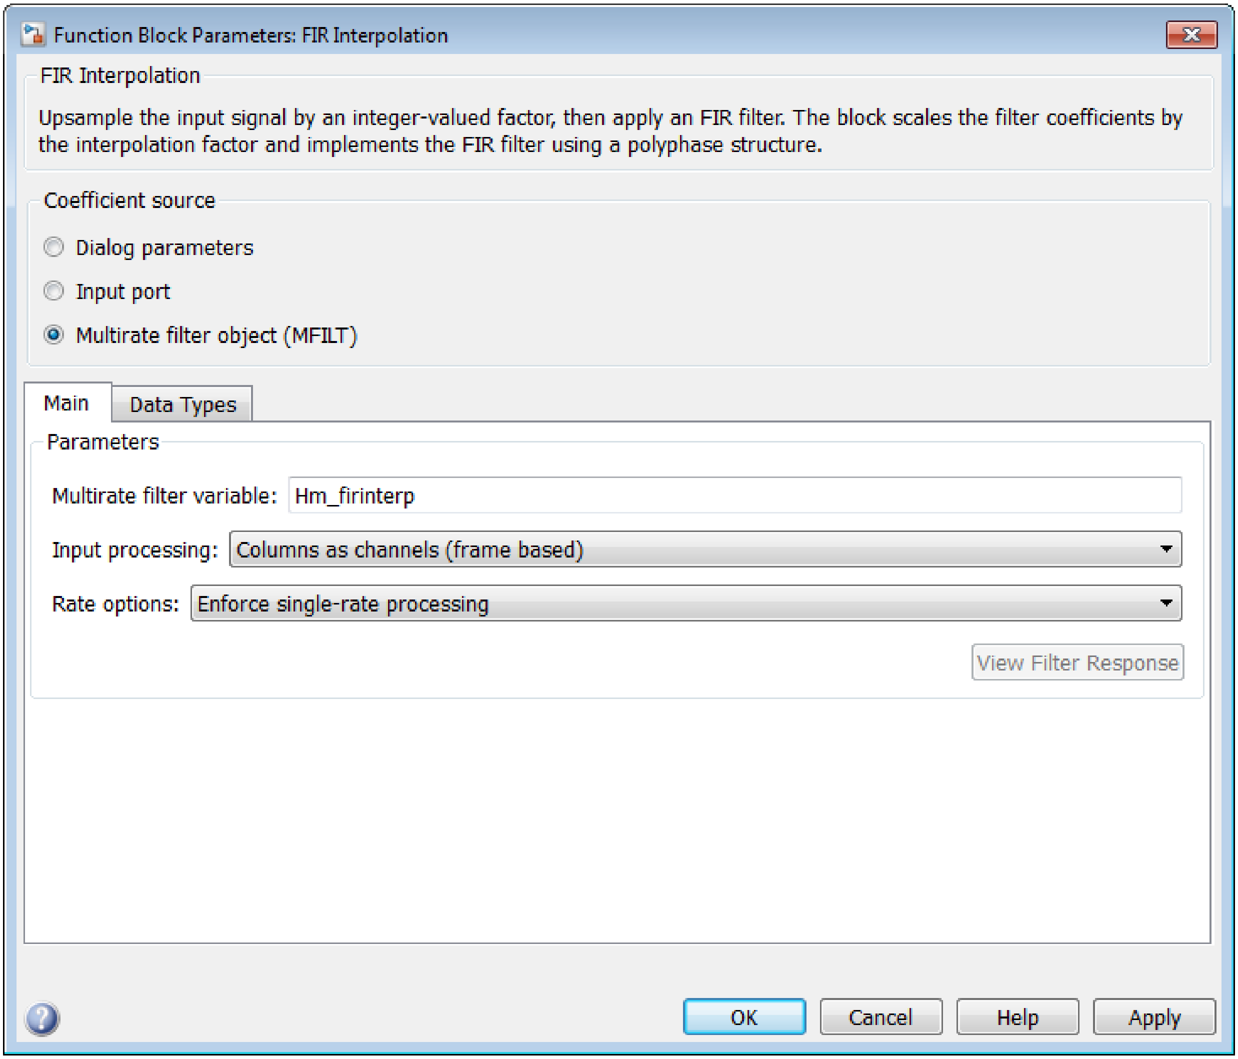
- Simulation range checking (see "Signal Ranges")
- Automatic scaling of fixed-point data types

Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

Specify Multirate Filter Object

The **Main** pane of the FIR Interpolation block dialog appears as follows when you select **Multirate filter object (MFILT)** in the **Coefficient source** group box.



Function Block Parameters: FIR Interpolation

FIR Interpolation

Upsample the input signal by an integer-valued factor, then apply an FIR filter. The block scales the filter coefficients by the interpolation factor and implements the FIR filter using a polyphase structure.

Coefficient source

○ Dialog parameters

○ Input port

● Multirate filter object (MFILT)

Parameters

Multirate filter variable: Hm_firinterp

Input processing: Columns as channels (frame based)

Rate options: Enforce single-rate processing

Multirate filter variable

Specify the multirate filter object (`mfilt`) that you would like the block to implement. You can do this in one of three ways:

- You can fully specify the `mfilt` object in the block mask.

- You can enter the variable name of a `mfilt` object that is defined in any workspace.
- You can enter a variable name for a `mfilt` object that is not yet defined, as shown in the default value.

For more information on creating `mfilt` objects, see the `mfilt` function reference page.

Input processing

Specify how the block should process the input. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` — When you select this option, the block treats each column of the input as a separate channel.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

Note: The `Inherited (this choice will be removed - see release notes)` option will be removed in a future release. See "Frame-Based Processing" in the *DSP System Toolbox Release Notes* for more information.

Rate options

Specify the method by which the block should interpolate the input. You can select one of the following options:

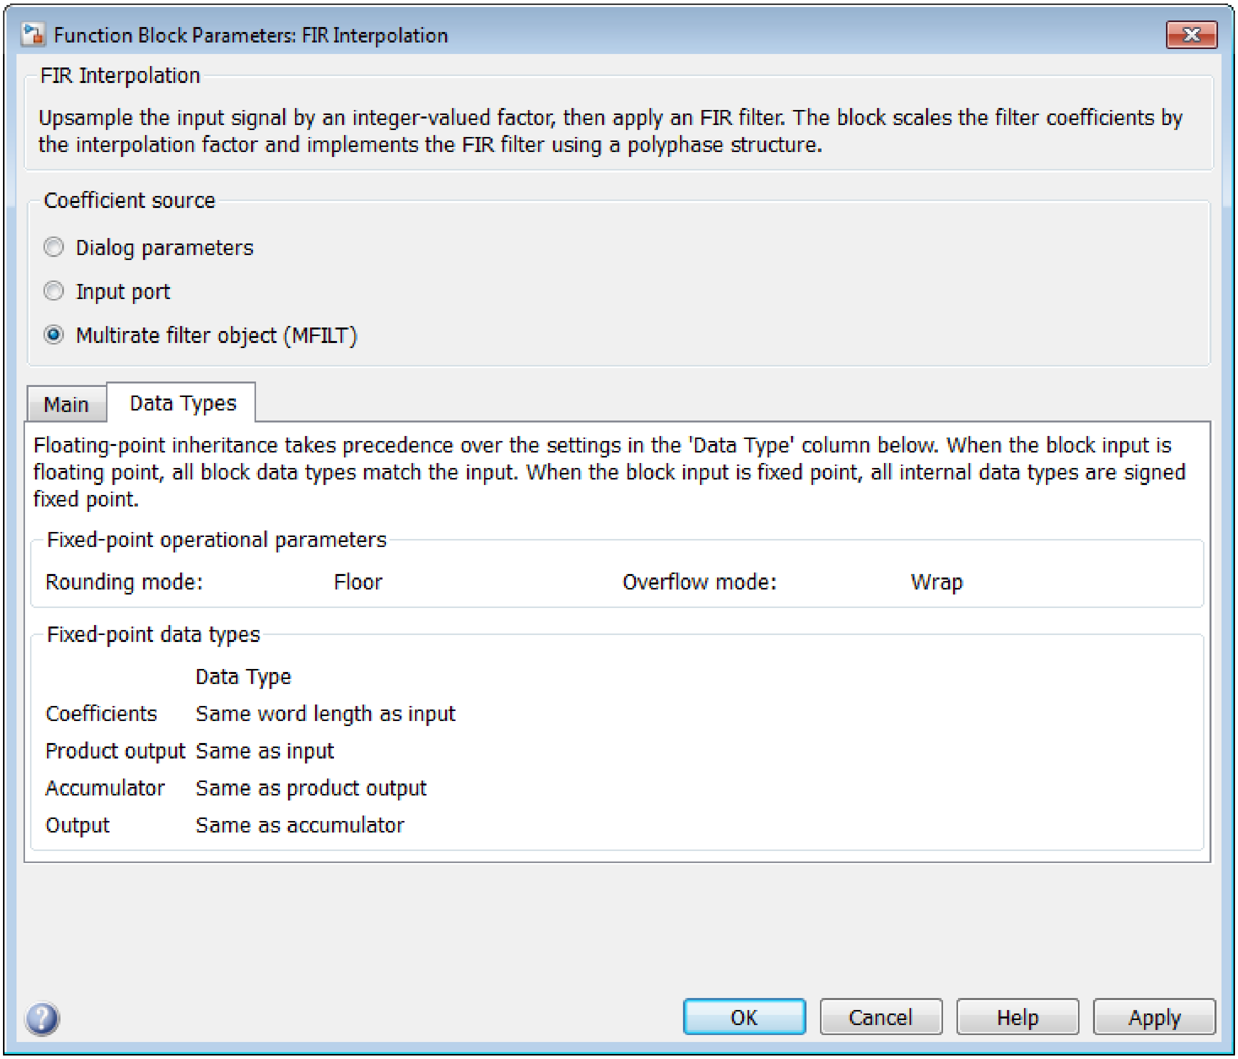
- `Enforce single-rate processing` — When you select this option, the block maintains the input sample rate, and interpolates the signal by increasing the output frame size by a factor of L. To select this option, you must set the **Input processing** parameter to `Columns as channels (frame based)`.
- `Allow multirate processing` — When you select this option, the block interpolates the signal such that the output sample rate is L times faster than the input sample rate.

View filter response

This button opens the Filter Visualization Tool (`fvtool`) from the Signal Processing Toolbox product and displays the filter response of the `mfilt` object specified in the **Multirate filter variable** parameter. For more information on FVTool, see the Signal Processing Toolbox documentation.

Note: If you specify a filter in the **Multirate filter variable** parameter, you must apply the filter by clicking the **Apply** button before using the **View filter response** button.

The **Data Types** pane of the FIR Interpolation block dialog appears as follows when you select **Multirate filter object (MFILT)** in the **Coefficient source** group box.



FIR Interpolation

Upsample the input signal by an integer-valued factor, then apply an FIR filter. The block scales the filter coefficients by the interpolation factor and implements the FIR filter using a polyphase structure.

Coefficient source

○ Dialog parameters

○ Input port

● Multirate filter object (MFILT)

Floating-point inheritance takes precedence over the settings in the 'Data Type' column below. When the block input is floating point, all block data types match the input. When the block input is fixed point, all internal data types are signed fixed point.

Fixed-point operational parameters

Rounding mode: Floor

Overflow mode: Wrap

Fixed-point data types

	Data Type
Coefficients	Same word length as input
Product output	Same as input
Accumulator	Same as product output
Output	Same as accumulator

The fixed-point settings of the filter object specified on the **Main** pane are displayed on the **Data Types** pane. You cannot change these settings directly on the block mask. To change the fixed-point settings you must edit the filter object directly.

For more information on multirate filter objects, see the `mfilt` function reference page.

HDL Code Generation

This block supports HDL code generation using HDL Coder. HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic. For more information on implementations, properties, and restrictions for HDL code generation, see FIR Interpolation.

FIR Rate Conversion

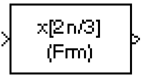
Upsample, filter, and downsample input signals

Library

Filtering / Multirate Filters

`dspmlti4`

Description



The FIR Rate Conversion block resamples the discrete-time input such that its sample period is *K*/*L* times the input sample period (T_{si}). *K* is the integer value you specify for the **Decimation factor** parameter, and *L* is the integer value you specify for the **Interpolation factor** parameter.

The block treats each column of the input as a separate channel, and resamples the data in each channel independently over time. To do so, the block implements a polyphase filter structure and performs the following operations:

1. Upsamples the input to a higher rate by inserting *L*-1 zeros between input samples.
2. Passes the upsampled data through a direct-form II transpose FIR filter.
3. Downsamples the filtered data to a lower rate by discarding *K*-1 consecutive samples following each sample that the block retains.

The polyphase filter implementation is more efficient than a straightforward upsample-filter-decimate algorithm. See Orfanidis [1] for more information.

Specifying the Resampling Rate

You specify the resampling rate of the FIR Rate Conversion block using the **Decimation factor** and **Interpolation factor** parameters. For an M_{i}-by-*N* matrix input, the **Decimation factor**, *K*, and the **Interpolation factor**, *L*, must satisfy the following requirements:

- K and L must be relatively prime integers; that is, the ratio K/L cannot be reduced to a ratio of smaller integers.
- $\frac{K}{L} = \frac{M_i}{M_o}$, where M_i and M_o are the integer frame sizes of the input and output, respectively.

You can satisfy the second requirement by setting the **Decimation factor**, K, equal to the input frame size, M_i. When you do so, the output frame size, M_o, equals the **Interpolation factor**, L.

By changing the frame size in this way, the block is able to hold the frame period constant ($T_\mathrm{fi} = T_\mathrm{fo}$) and achieve the desired conversion of the sample period, such that

$$T_{so} = \frac{K}{L} \times T_{si}$$

where T_so is the output sample period.

Specifying the FIR Filter Coefficients

You can specify the FIR filter coefficients in one of two ways:

- To specify the coefficients on the dialog, select the **Dialog parameters** option in the **Coefficient source** group box.
- To specify the coefficients using an `mfilt` object, select the **Multirate filter object (MFILT)** option in the **Coefficient source** group box.

When you select the **Dialog parameters** option, you use the **FIR filter coefficients** parameter to specify the numerator coefficients of the FIR filter transfer function $H(z)$.

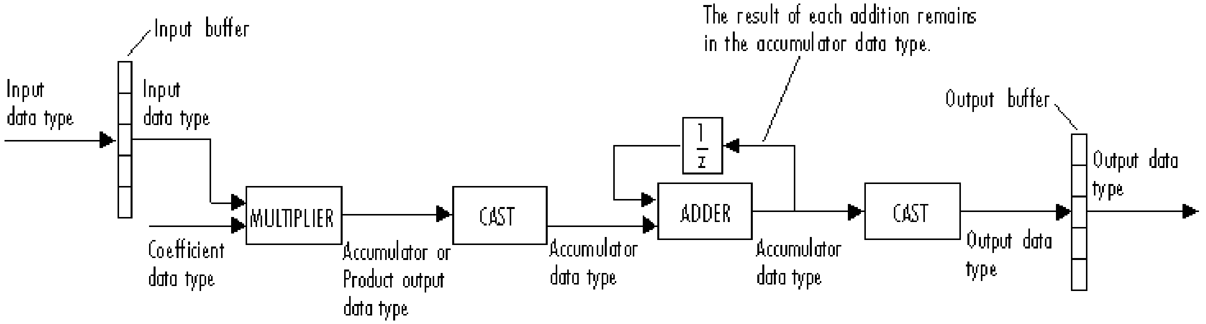
$$H(z) = B(z) = b_1 + b_2 z^{-1} + \ldots + b_m z^{-(m-1)}$$

You can generate the FIR filter coefficient vector, `[b(1) b(2) ... b(m)]`, using one of the Signal Processing Toolbox filter design functions (such as `intfilt`).

The coefficient vector you specify must have a length greater than the interpolation factor ($m>L$). The FIR filter must be a lowpass filter with a normalized cutoff frequency, no greater than `min(1/`L`,1/`K`)`. The block internally initializes all filter states to zero.

Fixed-Point Data Types

The following diagram shows the data types used within the FIR Rate Conversion block for fixed-point signals.



You can set the coefficient, product output, accumulator, and output data types in the block dialog box as discussed in “Dialog Box” on page 1-584. The diagram shows that input data is stored in the input buffer in the same data type and scaling as the input. Filtered data resides in the output buffer in the output data type and scaling that you set in the block dialog. The block stores any initial conditions in the output buffer using the output data type and scaling that you set in the block dialog box.

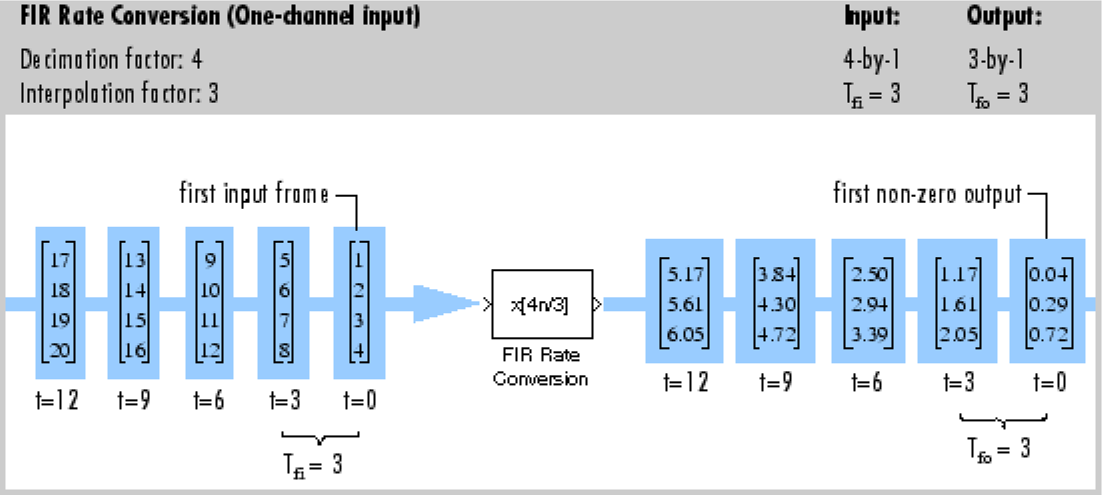
The output of the multiplier is in the product output data type when at least one of the inputs to the multiplier is real. When both of the inputs to the multiplier are complex, the result of the multiplication is in the accumulator data type. For details on the complex multiplication performed, see “Multiplication Data Types”.

Note: When the block input is fixed point, all internal data types are signed fixed point.

Examples

Example 1

The following figure shows how the FIR Rate Conversion block converts a 4-by-1 input with a sample period of 3/4, to a 3-by-1 output with a sample period of 1. The frame period (T_f) of 3 remains constant.



Example 2

The ex_audio_src model provides a simple illustration of one way to convert a speech signal from one sample rate to another. In this model, the data is first sampled at 22,050 Hz and then resampled at 8000 Hz. If you listen to the output, you can hear that the high frequency content has been removed from the signal, although the speech sounds basically the same.

Dialog Box

Coefficient Source

The FIR Rate Conversion block can operate in two different modes. Select the mode in the **Coefficient source** group box. If you select

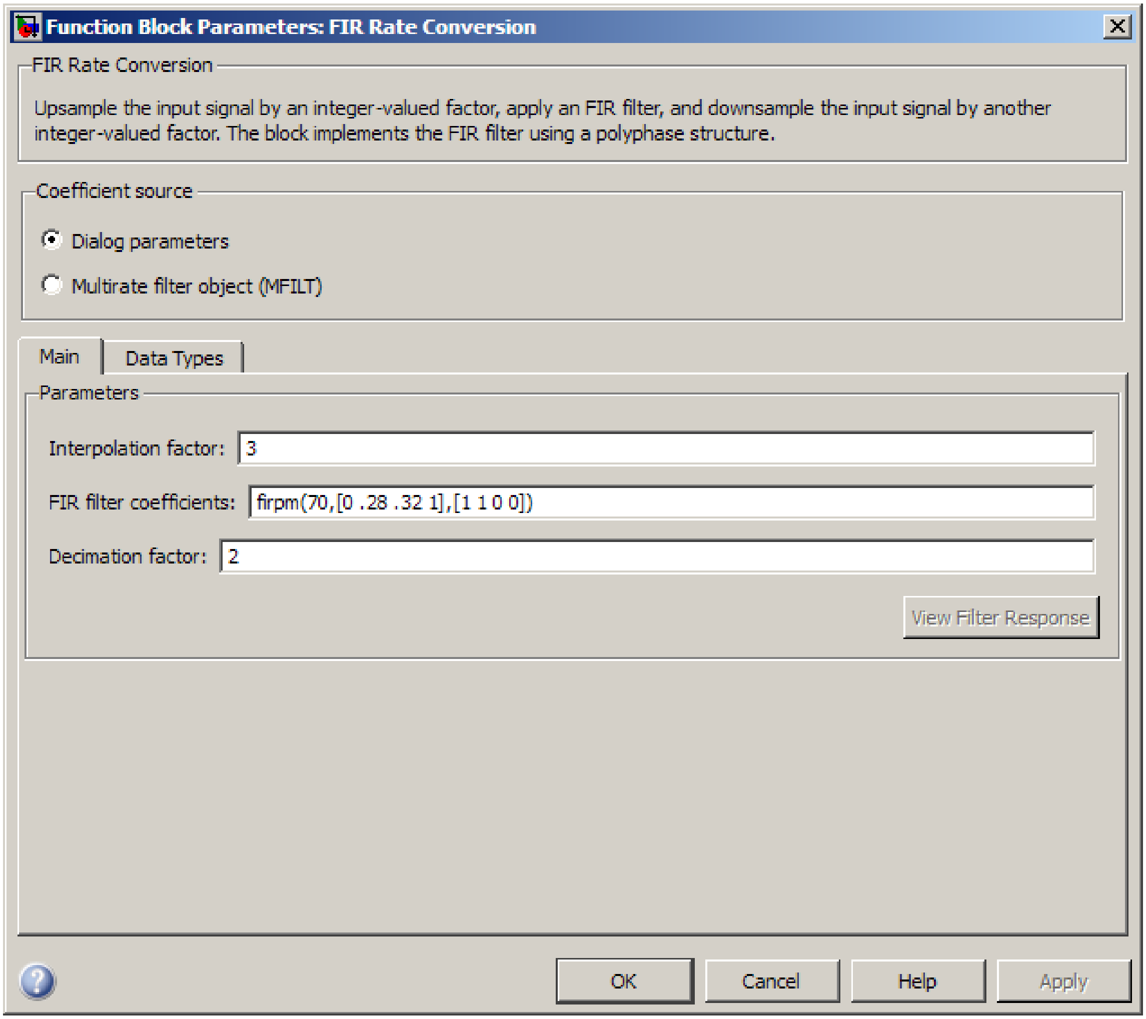
- **Dialog parameters**, you enter information about the filter such as structure and coefficients in the block mask.
- **Multirate filter object (MFILT)**, you specify the filter using an `mfilt` object.

Different items appear on the FIR Rate Conversion block dialog depending on whether you select **Dialog parameters** or **Multirate filter object (MFILT)** in the **Coefficient source** group box. See the following sections for details:

- "Specify Filter Characteristics in Dialog" on page 1-585
- "Specify Multirate Filter Object" on page 1-590

Specify Filter Characteristics in Dialog

The **Main** pane of the FIR Rate Conversion block dialog appears as follows when **Dialog parameters** is selected in the **Coefficient source** group box.



Function Block Parameters: FIR Rate Conversion

FIR Rate Conversion

Upsample the input signal by an integer-valued factor, apply an FIR filter, and downsample the input signal by another integer-valued factor. The block implements the FIR filter using a polyphase structure.

Coefficient source

● Dialog parameters

○ Multirate filter object (MFILT)

Parameters

Interpolation factor: 3

FIR filter coefficients: firpm(70,[0 .28 .32 1],[1 1 0 0])

Decimation factor: 2

Interpolation factor

Specify the integer factor, *L*, by which to upsample the signal before filtering.

FIR filter coefficients

Specify the FIR filter coefficients in descending powers of *z*.

Decimation factor

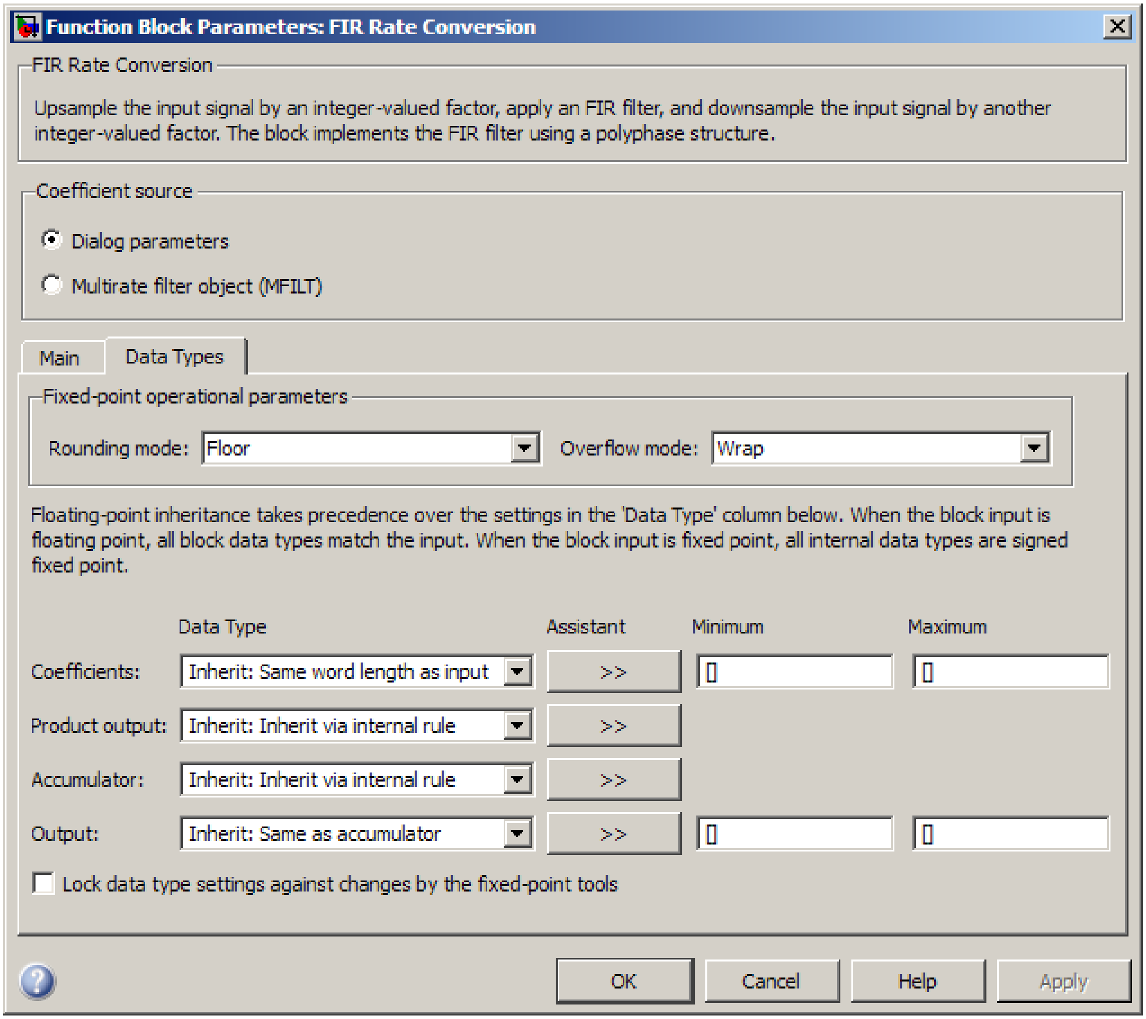
Specify the integer factor, *K*, by which to downsample the signal after filtering.

View filter response

This button opens the Filter Visualization Tool (`fvtool`) from the Signal Processing Toolbox product and displays the filter response of the filter defined in the block. For more information on FVTool, see the Signal Processing Toolbox documentation.

Note: If you specify a filter in the **Multirate filter variable** parameter, you must apply the filter by clicking the **Apply** button before using the **View filter response** button.

The **Data Types** pane of the FIR Rate Conversion block dialog appears as follows when **Dialog parameters** is specified in the **Coefficient source** group box.



Function Block Parameters: FIR Rate Conversion

FIR Rate Conversion

Upsample the input signal by an integer-valued factor, apply an FIR filter, and downsample the input signal by another integer-valued factor. The block implements the FIR filter using a polyphase structure.

Coefficient source

● Dialog parameters

○ Multirate filter object (MFILT)

Fixed-point operational parameters

Rounding mode: Floor

Overflow mode: Wrap

Floating-point inheritance takes precedence over the settings in the 'Data Type' column below. When the block input is floating point, all block data types match the input. When the block input is fixed point, all internal data types are signed fixed point.

	Data Type	Assistant	Minimum	Maximum
Coefficients:	Inherit: Same word length as input	>>	[]	[]
Product output:	Inherit: Inherit via internal rule	>>		
Accumulator:	Inherit: Inherit via internal rule	>>		
Output:	Inherit: Same as accumulator	>>	[]	[]

□ Lock data type settings against changes by the fixed-point tools

Rounding mode

Select the “rounding mode” for fixed-point operations. The filter coefficients do not obey this parameter; they always round to `Nearest`.

Note: The **Rounding mode** and **Overflow mode** settings have no effect on numerical results when all the following conditions exist:

- **Product output data type** is `Inherit: Inherit via internal rule`
- **Accumulator data type** is `Inherit: Inherit via internal rule`
- **Output data type** is `Inherit: Same as accumulator`

With these data type settings, the block is effectively operating in full precision mode.

Overflow mode

Select the “overflow mode” for fixed-point operations. The filter coefficients do not obey this parameter; they are always saturated.

Coefficients data type

Specify the coefficients data type. See “Fixed-Point Data Types” on page 1-583 and “Multiplication Data Types” for illustrations depicting the use of the coefficients data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same word length as input`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Coefficients data type** parameter.

See “Specify Data Types Using Data Type Assistant” in “Simulink User's Guide” for more information.

Product output data type

Specify the product output data type. See “Fixed-Point Data Types” on page 1-583 and “Multiplication Data Types” for illustrations depicting the use of the product output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Product output data type** parameter.

See “Specify Data Types Using Data Type Assistant” in “Simulink User's Guide” for more information.

Accumulator data type

Specify the accumulator data type. See “Fixed-Point Data Types” on page 1-583 for illustrations depicting the use of the accumulator data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Accumulator data type** parameter.

See “Specify Data Types Using Data Type Assistant” in “Simulink User's Guide” for more information.

Output data type

Specify the output data type. See “Fixed-Point Data Types” on page 1-583 for illustrations depicting the use of the output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as accumulator`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Specify Block Output Data Types” in “Simulink User's Guide” for more information.

Minimum

Specify the minimum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges”)
- Automatic scaling of fixed-point data types

Maximum

Specify the maximum value that the block should output. The default value is [ ] (unspecified). Simulink software uses this value to perform:

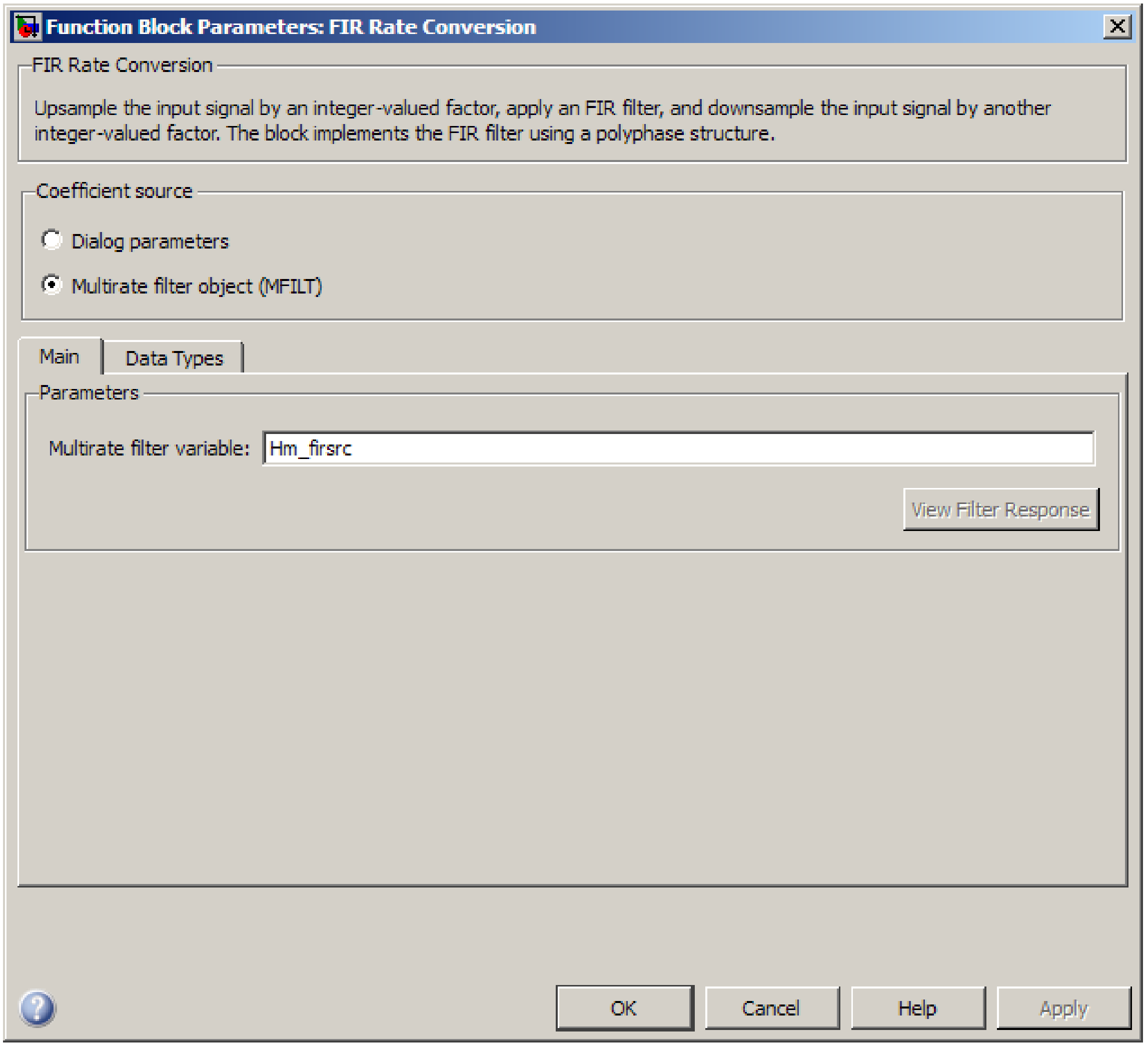
- Simulation range checking (see "Signal Ranges")
- Automatic scaling of fixed-point data types

Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

Specify Multirate Filter Object

The **Main** pane of the FIR Rate Conversion block dialog appears as follows when **Multirate filter object (MFILT)** is specified in the **Coefficient source** group box.



Function Block Parameters: FIR Rate Conversion

FIR Rate Conversion

Upsample the input signal by an integer-valued factor, apply an FIR filter, and downsample the input signal by another integer-valued factor. The block implements the FIR filter using a polyphase structure.

Coefficient source

○ Dialog parameters

● Multirate filter object (MFILT)

Parameters

Multirate filter variable: Hm_firsrc

Multirate filter variable

Specify the multirate filter object (`mfilt`) that you would like the block to implement. You can do this in one of three ways:

- You can fully specify the `mfilt` object in the block mask.

- You can enter the variable name of a `mfilt` object that is defined in any workspace.
- You can enter a variable name for a `mfilt` object that is not yet defined, as shown in the default value.

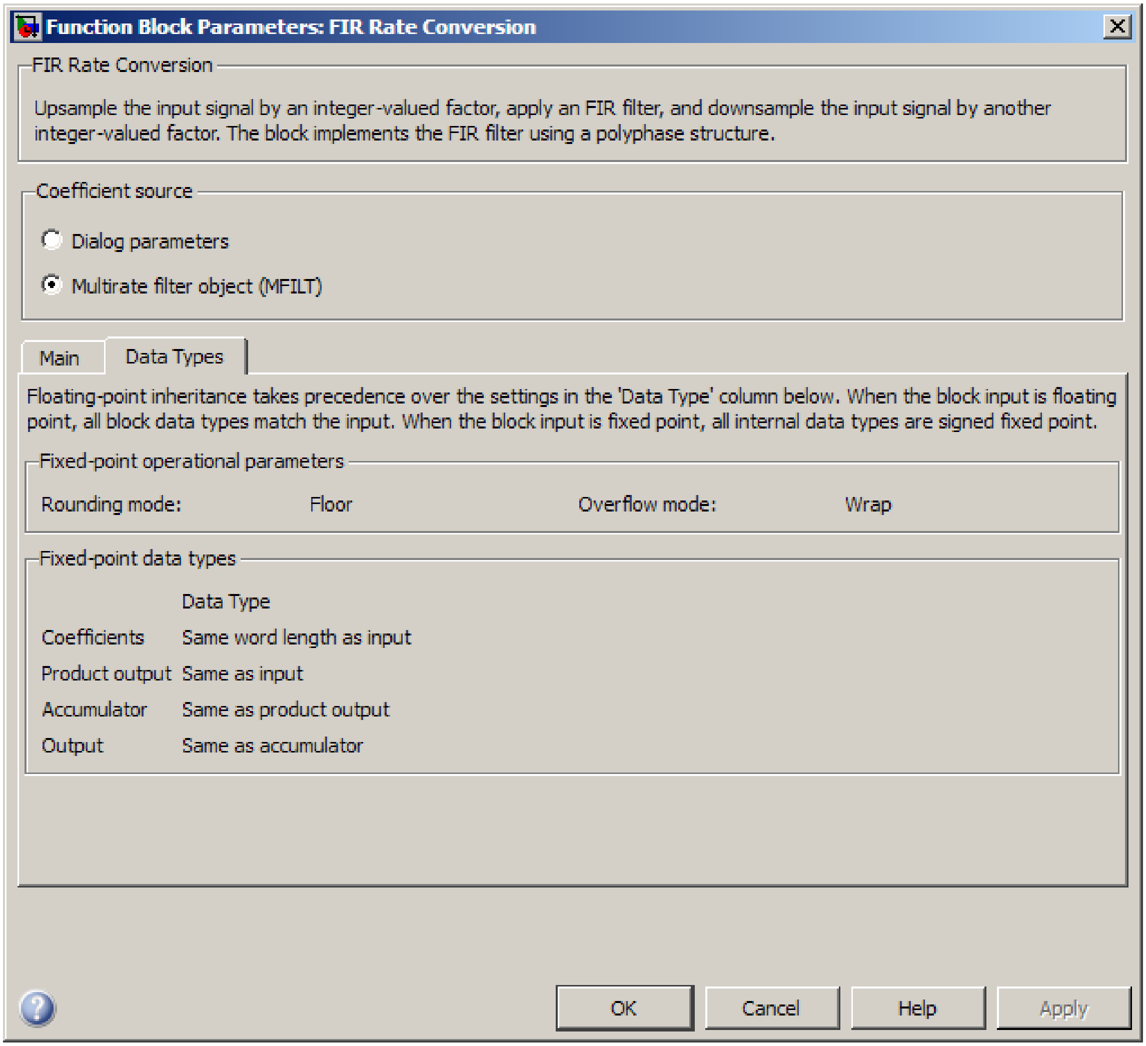
For more information on creating `mfilt` objects, see the `mfilt` function reference page.

View filter response

This button opens the Filter Visualization Tool (`fvtool`) from the Signal Processing Toolbox product and displays the filter response of the `mfilt` object specified in the **Multirate filter variable** parameter. For more information on FVTool, see the Signal Processing Toolbox documentation.

Note: If you specify a filter in the **Multirate filter variable** parameter, you must apply the filter by clicking the **Apply** button before using the **View filter response** button.

The **Data Types** pane of the FIR Rate Conversion block dialog appears similar to the following dialog when **Multirate filter object (MFILT)** is specified in the **Coefficient source** group box. The fixed-point data types you see depend on the `mfilt` object you use.



Function Block Parameters: FIR Rate Conversion

FIR Rate Conversion

Upsample the input signal by an integer-valued factor, apply an FIR filter, and downsample the input signal by another integer-valued factor. The block implements the FIR filter using a polyphase structure.

Flip

Flip input vertically or horizontally

Library

Signal Management / Indexing

`dspindex`

Description

The Flip block vertically or horizontally reverses the *M*-by-*N* input matrix, *u*. The output always has the same dimensionality as the input.

When you set the **Flip along** parameter to `Columns`, the block flips the input *vertically* so the first row of the input becomes the last row of the output.

```
y = flipud(u)      % Equivalent MATLAB code
```

When flipping the input vertically, the block treats length-*M* unoriented vector inputs as *M*-by-1 column vectors.

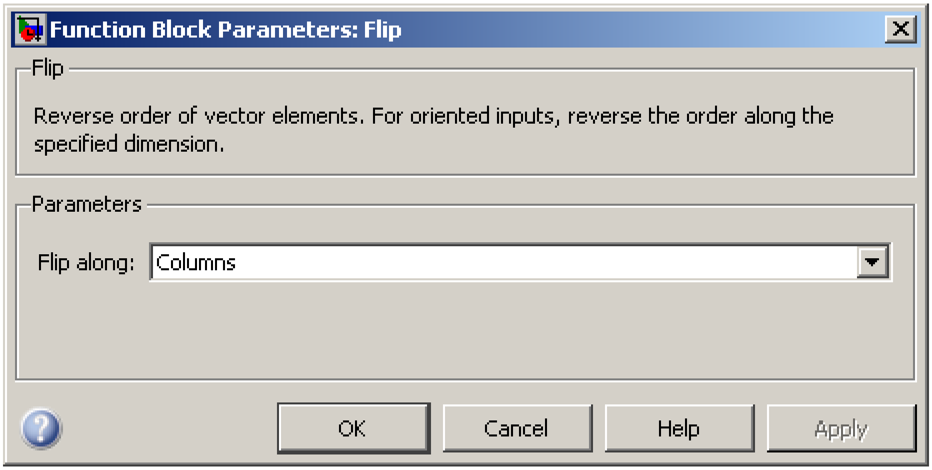
When you set the **Flip along** parameter to `Rows`, the block flips the input *horizontally* so the first column of the input becomes the last column of the output.

```
y = fliplr(u)      % Equivalent MATLAB code
```

When flipping the input horizontally, the block treats length-*N* unoriented vector inputs as 1-by-*N* row vectors.

This block supports Simulink virtual buses.

Dialog Box



Function Block Parameters: Flip

Flip

Reverse order of vector elements. For oriented inputs, reverse the order along the specified dimension.

Parameters

Flip along: Columns

Flip along

Specify the dimension along which to flip the input. When you set this parameter to `Columns`, the block flips the input vertically. When you set this parameter to `Rows`, the block flips the input horizontally.

Supported Data Types

Port	Supported Data Types

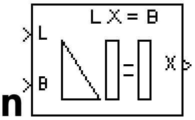
Forward Substitution

Solve *LX*=*B* for *X* when *L* is lower triangular matrix

Library

Math Functions / Matrices and Linear Algebra / Linear System Solvers

```
dspsolvers
```



Description

The Forward Substitution block solves the linear system *LX*=*B* by simple forward substitution of variables, where:

- *L* is the lower triangular *M*-by-*M* matrix input to the L port.
- *B* is the *M*-by-*N* matrix input to the B port.

The *M*-by-*N* matrix output *X* is the solution of the equations. The block does not check the rank of the inputs.

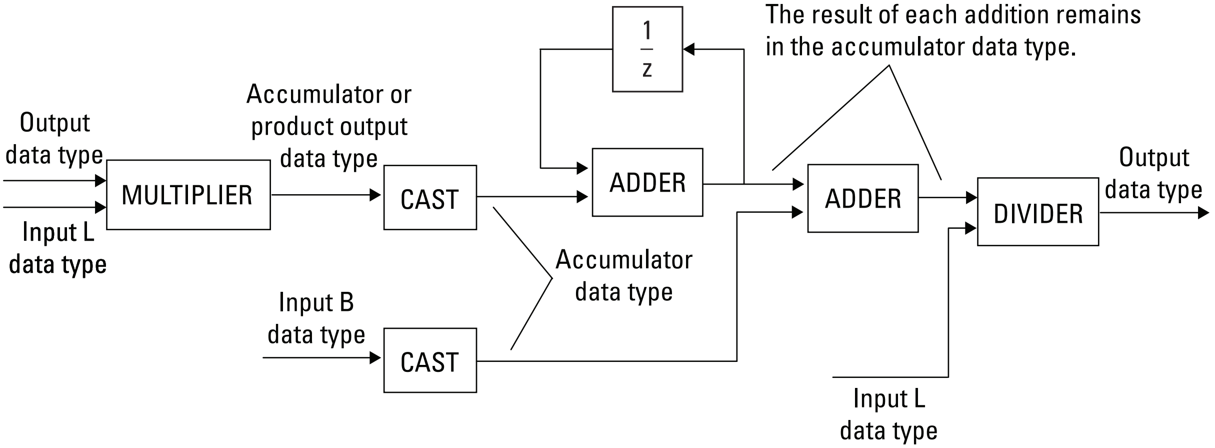
The block only uses the elements in the *lower triangle* of input *L* and ignores the upper elements. When you select **Input L is unit-lower triangular**, the block assumes the elements on the diagonal of *L* are 1s. This is useful when matrix *L* is the result of another operation, such as an LDL decomposition, that uses the diagonal elements to represent the *D* matrix.

The block treats a length-*M* vector input at port B as an *M*-by-1 matrix.

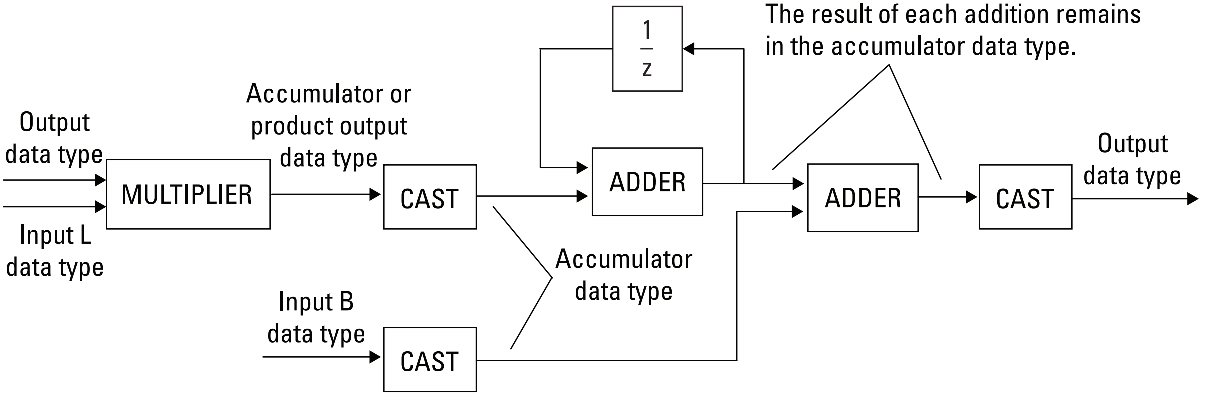
Fixed-Point Data Types

The following diagram shows the data types used within the Forward Substitution block for fixed-point signals.

When input L is not unit-lower triangular:



When input L is unit-lower triangular:

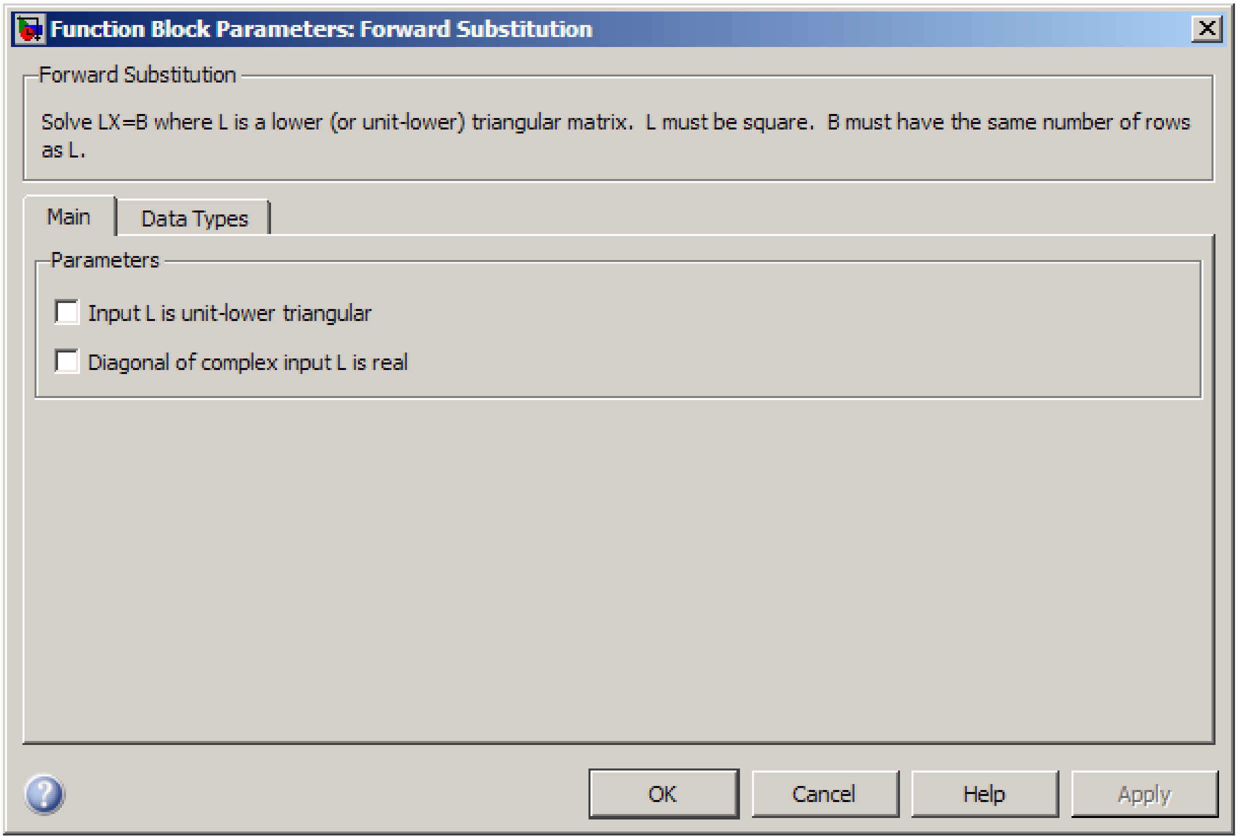


You can set the product output, accumulator, and output data types in the block dialog box, as discussed in the following section.

The output of the multiplier is in the product output data type when the input is real. When the input is complex, the result of the multiplication is in the accumulator data type. For details on the complex multiplication performed, see “Multiplication Data Types”.

Dialog Box

The **Main** pane of the Forward Substitution block dialog box appears as follows.



Function Block Parameters: Forward Substitution

Forward Substitution

Solve LX=B where L is a lower (or unit-lower) triangular matrix. L must be square. B must have the same number of rows as L.

Parameters

□ Input L is unit-lower triangular

□ Diagonal of complex input L is real

Input L is unit-lower triangular

Select this check box only when all elements on the diagonal of *L* have a value of 1. When you do so, the block optimizes its behavior by skipping an unnecessary divide operation.

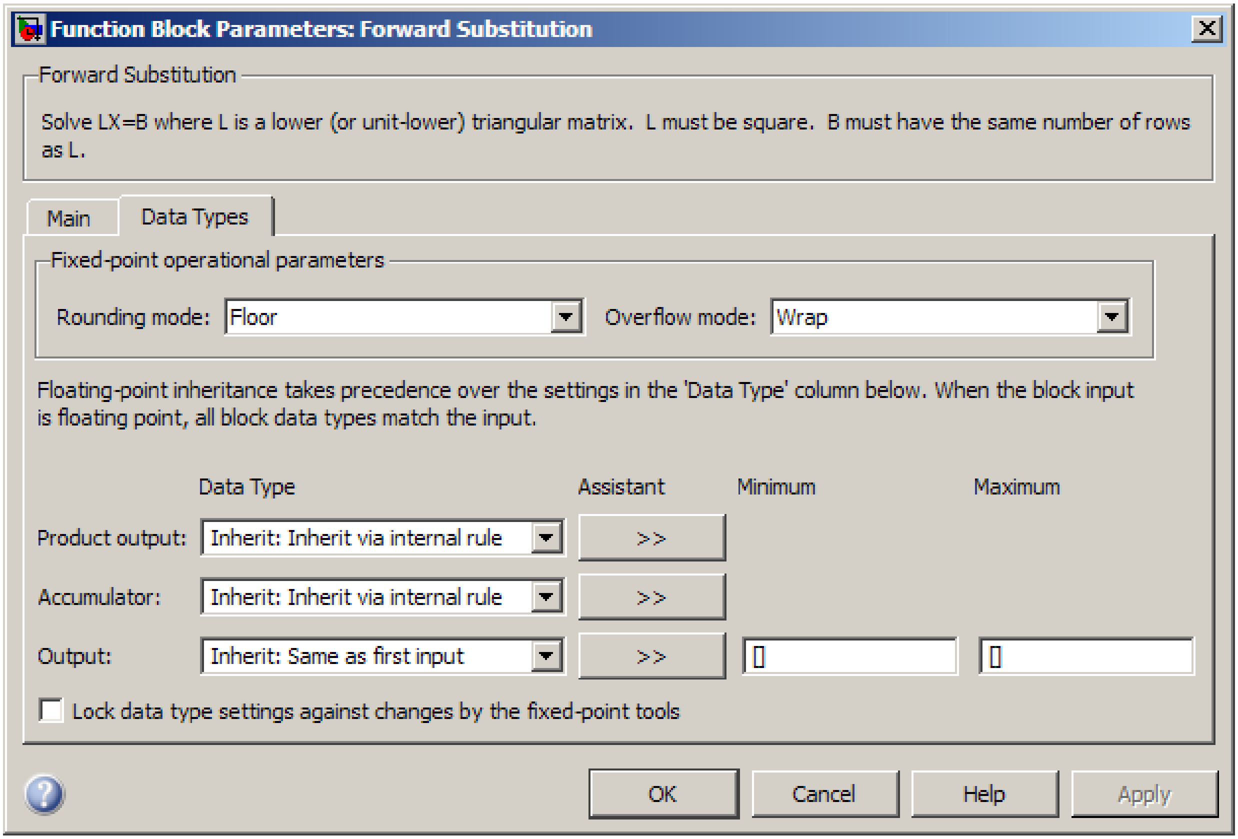
Do not select this check box if there are any elements on the diagonal of *L* that do not have a value of 1. When you clear the **Input L is unit-lower triangular** check box, the block always performs the necessary divide operation.

Diagonal of complex input L is real

Select to optimize simulation speed when the diagonal elements of complex input *L* are real. This parameter is only visible when **Input L is unit-upper triangular** is not selected.

Note: When L is a complex fixed-point signal, you must select either **Input L is unit-lower triangular** or **Diagonal of complex input L is real**. In such a case, the block ignores any imaginary part of the diagonal of L.

The **Data Types** pane of the Forward Substitution block dialog box appears as follows.



Function Block Parameters: Forward Substitution

Forward Substitution

Solve LX=B where L is a lower (or unit-lower) triangular matrix. L must be square. B must have the same number of rows as L.

Fixed-point operational parameters

Rounding mode: Floor

Overflow mode: Wrap

Floating-point inheritance takes precedence over the settings in the 'Data Type' column below. When the block input is floating point, all block data types match the input.

	Data Type	Assistant	Minimum	Maximum
Product output:	Inherit: Inherit via internal rule	>>		
Accumulator:	Inherit: Inherit via internal rule	>>		
Output:	Inherit: Same as first input	>>	[]	[]

□ Lock data type settings against changes by the fixed-point tools

Note: Floating-point inheritance takes precedence over the data type settings defined on this pane. When inputs are floating point, the block ignores these settings, and all internal data types are floating point.

Rounding mode

Select the "rounding mode" for fixed-point operations.

Overflow mode

Select the "overflow mode" for fixed-point operations.

Product output data type

Specify the product output data type. See “Fixed-Point Data Types” on page 1-599 and “Multiplication Data Types” for illustrations depicting the use of the product output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Product output data type** parameter.

See “Specify Data Types Using Data Type Assistant” in “Simulink User's Guide” for more information.

Accumulator data type

Specify the accumulator data type. See “Fixed-Point Data Types” on page 1-599 for illustrations depicting the use of the accumulator data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Accumulator data type** parameter.

See “Specify Data Types Using Data Type Assistant” in “Simulink User's Guide” for more information.

Output data type

Specify the output data type. See “Fixed-Point Data Types” on page 1-599 for illustrations depicting the use of the output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as first input`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Specify Block Output Data Types” in “Simulink User's Guide” for more information.

Minimum

Specify the minimum value that the block should output. The default value is [ ] (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges”)
- Automatic scaling of fixed-point data types

Maximum

Specify the maximum value that the block should output. The default value is [ ] (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges”)
- Automatic scaling of fixed-point data types

Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

Supported Data Types

Port	Supported Data Types
L	• Double-precision floating point • Single-precision floating point • Fixed point (signed only) • 8-, 16-, and 32-bit signed integers
B	• Double-precision floating point • Single-precision floating point • Fixed point (signed only) • 8-, 16-, and 32-bit signed integers
X	• Double-precision floating point • Single-precision floating point • Fixed point (signed only)

Port	Supported Data Types
	• 8-, 16-, and 32-bit signed integers

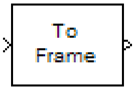
Frame Conversion

Specify sampling mode of output signal

Library

Signal Management / Signal Attributes

`dspsigattribs`

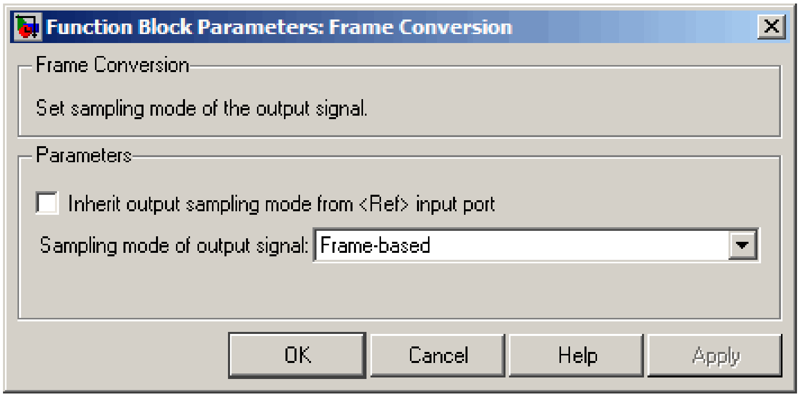


Description

The Frame Conversion block passes the input through to the output and sets the output sampling mode to the value of the **Sampling mode of output signal** parameter, which can be either `Frame-based` or `Sample-based`. The output sampling mode can also be inherited from the signal at the Ref (reference) input port, which you make visible by selecting the **Inherit output sampling mode from <Ref> input port** check box.

The Frame Conversion block does not make any changes to the input signal other than the sampling mode. In particular, the block does not rebuffer or resize 2-D inputs. Because 1-D vectors cannot be frame based, when the input is a length-M 1-D vector and the block is in `Frame-based` mode, the output is a frame-based M-by-1 matrix — that is, a single channel.

Dialog Box



Function Block Parameters: Frame Conversion

Frame Conversion

Set sampling mode of the output signal.

Parameters

□ Inherit output sampling mode from <Ref> input port

Sampling mode of output signal: Frame-based

Inherit output sampling mode from <Ref> input port

Select to enable the Ref port from which the block inherits the output sampling mode.

Sampling mode of output signal

Specify the sampling mode of the output signal, `Frame-based` or `Sample-based`.

HDL Code Generation

This block supports HDL code generation using HDL Coder. HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic. For more information on implementations, properties, and restrictions for HDL code generation, see Frame Conversion.

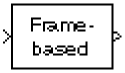
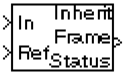
Frame Status Conversion (Obsolete)

Specify frame status of output as sample based or frame based

Library

dspobslib





Description

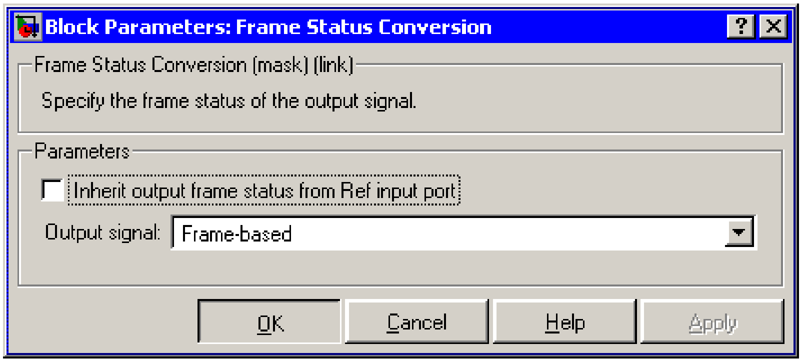
Note The Frame Status Conversion block is still supported but is likely to be obsoleted in a future release. We strongly recommend replacing this block with the Frame Conversion block.

The Frame Status Conversion block passes the input through to the output, and sets the output frame status to the **Output signal** parameter, which can be either `Frame-based` or `Sample-based`. The output frame status can also be inherited from the signal at the `Ref` (reference) input port, which is made visible by selecting the **Inherit output frame status from Ref input port** check box.

When the **Output signal** parameter setting or the inherited signal's frame status differs from the input frame status, the block changes the input frame status accordingly, but does not otherwise alter the signal. In particular, the block does not rebuffer or resize 2-D inputs. Because 1-D vectors cannot be frame based, when the input is a length-M 1-D vector, and the **Output signal** parameter is set to `Frame-based`, the output is a frame-based M-by-1 matrix (that is, a single channel).

When the **Output signal** parameter or the inherited signal's frame status matches the input frame status, the block passes the input through to the output unaltered.

Dialog Box



Block Parameters: Frame Status Conversion

Frame Status Conversion (mask) (link)

Specify the frame status of the output signal.

Parameters

□ Inherit output frame status from Ref input port

Output signal: Frame-based

Inherit output frame status from Ref input port

When selected, enables the `Ref` input port from which the block inherits the output frame status.

Output signal

The output frame status, `Frame-based` or `Sample-based`.

Supported Data Types

Port	Supported Data Types
In	• Double-precision floating point • Single-precision floating point • Fixed point (signed only) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Ref	• Double-precision floating point • Single-precision floating point • Fixed point (signed only) • Boolean

Port	Supported Data Types
	• 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Output	• Double-precision floating point • Single-precision floating point • Fixed point (signed only) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers

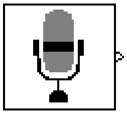
From Audio Device

Read audio data from computer's audio device

Library

Sources

`dspsrcs4`



Description

The From Audio Device block reads audio data from an audio device in real time. This block is not supported for use with the Simulink Model block.

Use the **Device** parameter to specify the device from which to acquire audio. This parameter is automatically populated based on the audio devices installed on your system. If you plug or unplug an audio device from your system, type `clear mex` at the MATLAB command prompt to update this list.

Use the **Number of channels** parameter to specify the number of audio channels in the signal. For example:

- Enter `2` if the audio source is two channels (stereo).
- Enter `1` if the audio source is single channel (mono).
- Enter `6` if you are working with a 5.1 speaker system.

The block's output is an *M*-by-*N* matrix, where *M* is the number of consecutive samples and *N* is the number of audio channels.

Use the **Sample rate (Hz)** parameter to specify the number of samples per second in the signal. If the audio data is processed in uncompressed pulse code modulation (PCM) format, it should typically be sampled at one of the standard audio device rates: 8000, 11025, 22050, 44100, or 48000 Hz.

The range of supported audio device sample rates and data type formats, depend on both the sound card and the API which is chosen for the sound card.

Use the **Device data type** parameter to specify the data type of the audio data that the device is placing in the buffer. You can choose:

- `8-bit integer`
- `16-bit integer`
- `24-bit integer`
- `32-bit float`
- `Determine from output data type`

If you choose `Determine from output data type`, the following table summarizes the block's behavior.

Output Data Type	Device Data Type
Double-precision floating point or single-precision floating point	32-bit floating point
32-bit integer	24-bit integer
16-bit integer	16-bit integer
8-bit integer	8-bit integer

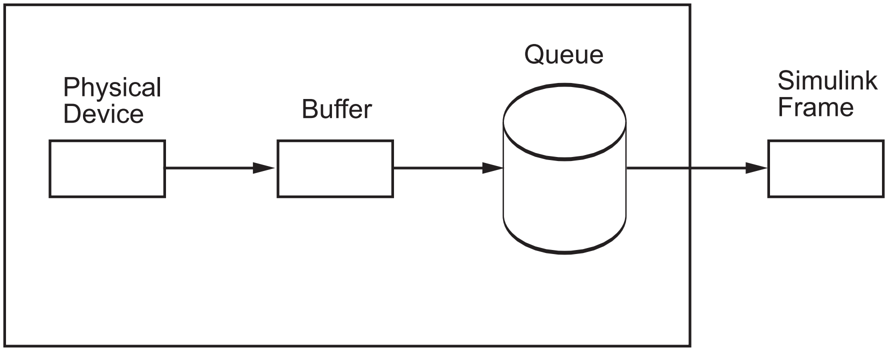
If you choose `Determine from output data type` and the device does not support a data type, the block uses the next lowest precision data type supported by the device.

Use the **Frame size (samples)** parameter to specify the number of samples in the block's output. Use the **Output data type** parameter to specify the data type of audio data output by the block.

The generated code for this block relies on prebuilt .dll files. You can run this code outside the MATLAB environment, or redeploy it, but be sure to account for these extra .dll files when doing so. The packNGo function creates a single zip file containing all of the pieces required to run or rebuild this code. See `packNGo` for more information.

Buffering

The From Audio Device block buffers the data from the audio device using the process illustrated by the following figure.



From Audio Device Block

1. At the start of the simulation, the audio device begins writing the input data to a buffer. This data has the data type specified by the **Device data type** parameter.
2. When the buffer is full, the From Audio Device block writes the contents of the buffer to the queue. Specify the size of this queue using the **Queue duration (seconds)** parameter.
3. As the audio device appends audio data to the bottom of the queue, the From Audio Device block pulls data from the top of the queue to fill the Simulink frame. This data has the data type specified by the **Output data type** parameter.

Select the **Automatically determine buffer size** check box to allow the block to calculate a conservative buffer size using the following equation:

$$size = 2^{\left\lfloor \log_2 \frac{sr}{10} \right\rfloor}$$

In this equation, *size* is the buffer size, and *sr* is the sample rate. If you clear this check box, the **Buffer size (samples)** parameter appears on the block. Use this parameter to specify the buffer size in samples.

When the simulation throughput rate is lower than the hardware throughput rate, the queue, which is initially empty, fills up. If the queue is full, the block drops the incoming data from the audio device. You can monitor dropped samples using the optional `Overrun` output port. When the simulation throughput rate is higher than the hardware throughput rate, the From Audio Device block waits for new samples to become available.

Channel Mapping

The term *Channel Mapping* refers to a 1-to-1 mapping that associates channels on the selected audio device to channels of the data. When you record audio, channel mapping allows you to specify which channel of the audio data directs input to a specific channel of audio. You can specify channel mapping as a vector of audio channel indices corresponding to each channel of data being read. The default value in the **Device Input Channels** parameter is 1:MAXINPUTCHANNELS. If you do not select the default mapping, you must specify the **Device Input Channels** parameter in the dialog box.

Example: The selected input audio device contains 8 channels. You want to read data from only channels 2, 4, 6, and redirect the data as follows:

- Audio Device channel 2 to first data channel
- Audio Device channel 4 to second data channel
- Audio Device channel 6 to third data channel

Thus you would specify the **Device Input Channels** as [2 4 6].

Troubleshooting

Not Keeping Up in Real Time

When Simulink cannot keep up with an audio device that is operating in real time, the queue fills up and the block begins to lose audio data. Select the **Output number of samples by which the queue was overrun** check box to add an output port indicating when the queue was full. Here are several ways to deal with this situation:

- *Increase the queue duration.*

  The **Queue duration (seconds)** parameter specifies the duration of the signal, in seconds, that can be buffered during the simulation. This is the maximum length of time that the block's data demand can lag behind the hardware's data supply.
- *Increase the buffer size.*

  The size of the buffer processed in each interrupt from the audio device affects the performance of your model. If the buffer is too small, a large portion of hardware resources are used to write data to the queue. If the buffer is too big, Simulink must wait for the device to fill the buffer before it moves the data to the queue, which introduces latency.

- *Increase the simulation throughput rate.*

  Two useful methods for improving simulation throughput rates are increasing the signal frame size and compiling the simulation into native code:

  - Increase frame sizes and convert sample-based signals to frame-based signals throughout the model to reduce the amount of block-to-block communication overhead. This can increase throughput rates in many cases. However, larger frame sizes generally result in greater model latency due to initial buffering operations.
  - Generate executable code with Simulink Coder code generation software. Native code runs much faster than Simulink and should provide rates adequate for real-time audio processing.

Other ways to improve throughput rates include simplifying the model and running the simulation on a faster PC processor. For other ideas on improving simulation performance, see “Delay and Latency” and “Performance” in the Simulink documentation.

Running an Executable Outside MATLAB

To run your generated standalone executable application in Shell, you need to set your environment to the following:

Platform	Command

Mac	`setenv DYLD_LIBRARY_PATH $LD_LIBRARY_PATH: $MATLABROOT/bin/maci64 (csh/tcsh)`
	`export DYLD_LIBRARY_PATH $LD_LIBRARY_PATH: $MATLABROOT/bin/maci64 (Bash)`

Linux	`setenv LD_LIBRARY_PATH $LD_LIBRARY_PATH: $MATLABROOT/bin/glnxa64 (csh/tcsh)`
	`export LD_LIBRARY_PATH $LD_LIBRARY_PATH: $MATLABROOT/bin/glnxa64 (Bash)`

Platform	Command

Windows	`set PATH = $MATLABROOT\bin\win32;`
	`%PATH%`
	
	`set PATH = $MATLABROOT\bin\win64;`
	`%PATH%`

Audio Hardware API

The To Audio Device and From Audio Device blocks use the open-source PortAudio library in order to communicate with the audio hardware on a given computer. The PortAudio library supports a range of API's designed to communicate with the audio hardware on a given platform. The following API choices were made when building the PortAudio library for the DSP System Toolbox product:

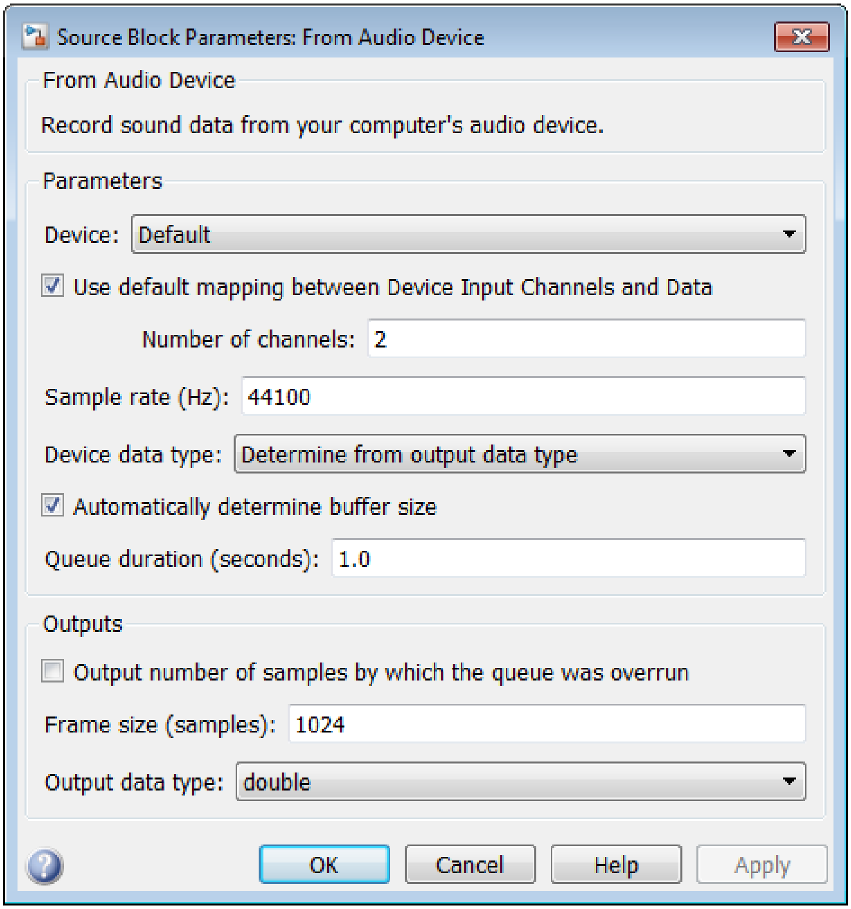
- Windows®: DirectSound, WDM—KS, ASIO™
- Linux®: OSS, ALSA
- Mac: CoreAudio

For Windows, the default is DirectSound, for Linux, the default is ALSA, and for Mac there is only one choice. To select or change the Audio Hardware API, select **Preferences** from the MATLAB Toolstrip. Then select DSP System Toolbox from the tree menu. In the **DSP System Toolbox Preferences** dialog box, the option is disabled if no device corresponds to that particular audio API.

Example

To learn how to measure and tune audio throughput using this block, see the "Measuring Audio Latency" example. To open this example enter `audiolatencymeasurement` at the MATLAB command prompt.

Dialog Box



Source Block Parameters: From Audio Device

From Audio Device

Record sound data from your computer's audio device.

Parameters

Device: Default

☑ Use default mapping between Device Input Channels and Data

Number of channels: 2

Sample rate (Hz): 44100

Device data type: Determine from output data type

☑ Automatically determine buffer size

Queue duration (seconds): 1.0

Outputs

□ Output number of samples by which the queue was overrun

Frame size (samples): 1024

Output data type: double

Device

Specify the device from which to acquire audio data.

Use default mapping between Device Input Channels and Data

Select this check box to have the default mapping, where the data from the first channel of audio device is sent to the first channel of the input data, data from second channel of audio device is sent to second channel of data and so on. The maximum number of channels in the input data is determined by the **Number of channels** property.

Number of channels

Specify the number of audio channels. This parameter is visible when the **Use default mapping between Device Input Channels and Data** check box is enabled.

Device Input Channels

Specify the channel mapping. This parameter is visible when the **Use default mapping between Device Input Channels and Data** check box is disabled.

Sample rate (Hz)

Specify the number of samples per second in the signal.

Device data type

Specify the data type used by the device to acquire audio data.

Automatically determine buffer size

Select this check box to enable the block to use a conservative buffer size.

Buffer size (samples)

Specify the size of the buffer that the block uses to communicate with the audio device. This parameter is visible when the **Automatically determine buffer size** check box is cleared.

Queue duration (seconds)

Specify the size of the queue in seconds.

Output number of samples by which the queue was overrun

Select this check box to output the number of samples lost to queue overrun since the last transfer of a frame from the audio device. You can use this value to debug throughput problems and adjust the queues and buffers in your model. To learn how to improve throughput, see "Troubleshooting" on page 1-1480.

Frame size (samples)

Specify the number of samples in the block's output signal.

Output data type

Select the data type of the block's output.

Supported Data Types

Port	Supported Data Types
Output	• Double-precision floating point

Port	Supported Data Types
	• Single-precision floating point • 32-bit signed integers • 16-bit signed integers • 8-bit unsigned integers
Overrun	32-bit signed integer

From Multimedia File

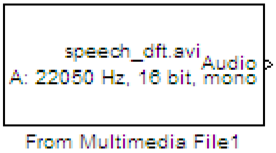
Read multimedia file

Library

Sources

`dspsrcs4`

Description



The From Multimedia File block reads audio samples, video frames, or both from a multimedia file. The block imports data from the file into a Simulink model.

Note: This block supports code generation for the host computer that has file I/O available. You cannot use this block with Real-Time Windows Target™ software because that product does not support file I/O.

The generated code for this block relies on prebuilt library files. You can run this code outside the MATLAB environment, or redeploy it, but be sure to account for these extra library files when doing so. The packNGo function creates a single zip file containing all of the pieces required to run or rebuild this code. See `packNGo` for more information.

To run an executable file that was generated from a model containing this block, you may need to add precompiled shared library files to your system path. See “Understanding C Code Generation” for details.

Supported Platforms and File Types

The supported file formats available to you depends on the codecs installed on your system.

Windows Platforms Supported File Formats

With the necessary Windows DirectShow codecs installed on your system, the From Multimedia File Block supports many video and audio file formats. This block performs best on platforms with Version 9.0 or later of DirectX® software.

The following table lists the most common file formats.

Multimedia Types	File Name Extensions
Image files	`.jpg`,`.bmp`,`.png`
Video files	`.qt`, `.mov`, `.avi`, `.asf`, `.asx`, `.wmv`, `.mpg`, `.mpeg`, `.mp2`, `.mp4`, `.m4v`
Audio files	`.wav`, `.wma`, `.aif`, `.aifc`, `.aiff`, `.mp3`, `.au`, `.snd, .mp4, .m4a, .flac, .ogg`

The default for image files is `.png`, , for video files is `.avi`, and for audio files is `.mp3`.

Windows XP x64 platform ships with a limited set of 64-bit video and audio codecs. If the From Multimedia File block cannot work on a compressed multimedia file, try one of the two alternatives:

- Run the 32-bit version of MATLAB on your Windows XP x64 platform. Windows XP x64 ships with many 32-bit codecs.
- Save the multimedia file to a file format supported by the From Multimedia File block.

If you use Windows, use Windows Media® Player Version 11 or later with this block for best results.

Non-Windows Platform Supported File Formats

The following table lists the most common file formats.

Multimedia Types	File Name Extensions
Video files	`.avi`, `.mj2`, `.mov`, `.mp4`,`.m4v`
Audio files	Uncompressed `.avi, .mp3, .mp4, .m4a, .wav, .flac, .ogg`

The default for video files is `.avi`, and for audio files is `.mp3`.

Ports

The output ports of the From Multimedia File block change according to the content of the multimedia file. If the file contains only video frames, the **Image**, intensity **I**, or **R**,**G**,**B** ports appear on the block. If the file contains only audio samples, the **Audio** port appears on the block. If the file contains both audio and video, you can select the data to emit. The following table describes available ports.

Port	Description
Image	M-by-N-by-P color video signal where P is the number of color planes.
I	M-by-N matrix of intensity values.
R, **G**, **B**	Matrix that represents one plane of the RGB video stream. Outputs from the R, G, or B ports must have same dimensions.
Audio	Vector of audio data.
Y, Cb, Cr	Matrix that represents one frame of the YCbCr video stream. The Y, Cb, Cr ports produce the following outputs: Y: $M\,x\,N$ Cb: $M\,x\,\frac{N}{2}$ Cr: $M\,x\,\frac{N}{2}$

Sample Rates

The sample rate that the block uses depends on the audio and video sample rate. While the FMMF block operates at a single rate in Simulink, the underlying audio and video streams can produce different rates. In some cases, when the block outputs both audio and video, makes a small adjustment to the video rate.

Sample Time Calculations Used for Video and Audio Files

Sample time = $\dfrac{ceil(AudioSampleRate/FPS)}{AudioSampleRate}$.

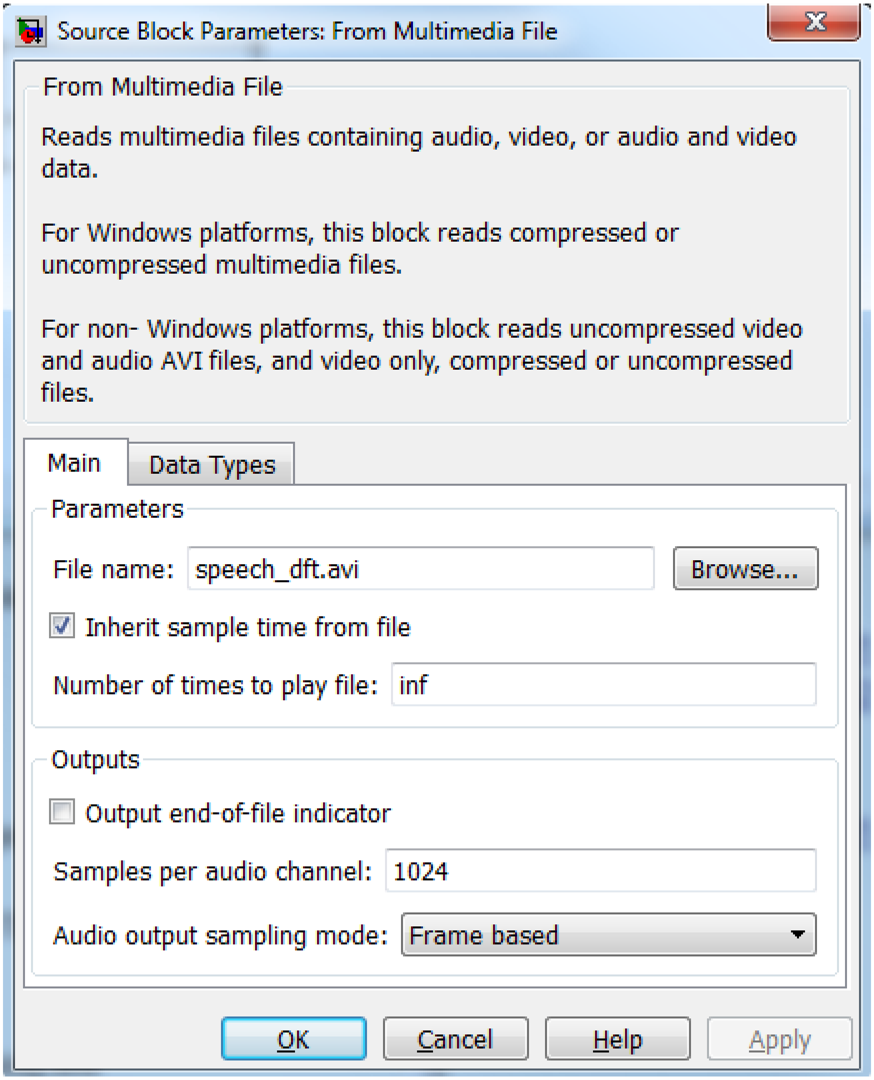
When audio sample time, $\dfrac{AudioSampleRate}{FPS}$ is noninteger, the equation cannot reduce to $\dfrac{1}{FPS}$.

In this case, to prevent synchronization problems, the block drops the corresponding video frame when the audio stream leads the video stream by more than $\dfrac{1}{FPS}$.

In summary, the block outputs one video frame at each Simulink time step. To calculate the number of audio samples to output at each time step, the block divides the audio sample rate by the video frame rate (fps). If the audio sample rate does not divide evenly by the number of video frames per second, the block rounds the number of audio samples up to the nearest whole number. If necessary, the block periodically drops a video frame to maintain synchronization for large files.

Dialog Box

The **Main** pane of the From Multimedia File block dialog appears as follows.



Source Block Parameters: From Multimedia File

From Multimedia File

Reads multimedia files containing audio, video, or audio and video data.

For Windows platforms, this block reads compressed or uncompressed multimedia files.

For non- Windows platforms, this block reads uncompressed video and audio AVI files, and video only, compressed or uncompressed files.

Parameters

File name: speech_dft.avi

☑ Inherit sample time from file

Number of times to play file: inf

Outputs

□ Output end-of-file indicator

Samples per audio channel: 1024

Audio output sampling mode: Frame based

File name

Specify the name of the multimedia file from which to read. The block determines the type of file (audio and video, audio only, or video only) and provides the associated parameters.

If the location of the file does not appear on your MATLAB path, use the **Browse** button to specify the full path. Otherwise, if the location of this file appears on your MATLAB path, enter only the file name. On Windows platforms, this parameter supports URLs that point to MMS (Microsoft Media Server) streams.

Inherit sample time from file

Select the **Inherit sample time from file** check box if you want the block sample time to be the same as the multimedia file. If you clear this check box, enter the block sample time in the **Desired sample time** parameter field. The file that the From Multimedia File block references, determines the block default sample time. You can also set the sample time for this block manually. If you do not know the intended sample rate of the video, let the block inherit the sample rate from the multimedia file.

Desired sample time

Specify the block sample time. This parameter becomes available if you clear the **Inherit sample time from file** check box.

Number of times to play file

Enter a positive integer or `inf` to represent the number of times to play the file.

Output end-of-file indicator

Use this check box to determine whether the output is the last video frame or audio sample in the multimedia file. When you select this check box, a Boolean output port labeled EOF appears on the block. The output from the EOF port defaults to 1 when the last video frame or audio sample is output from the block. Otherwise, the output from the EOF port defaults to 0.

Multimedia outputs

Specify `Video and audio`, `Video only`, or `Audio only` output file type. This parameter becomes available only when a video signal has both audio and video.

Samples per audio channel

Specify number of samples per audio channel. This parameter becomes available for files containing audio.

Output color format

Specify whether you want the block to output `RGB`, `Intensity`, or `YCbCr 4:2:2` video frames. This parameter becomes available only for a signal that contains video. If you select `RGB`, use the **Image signal** parameter to specify how to output a color signal.

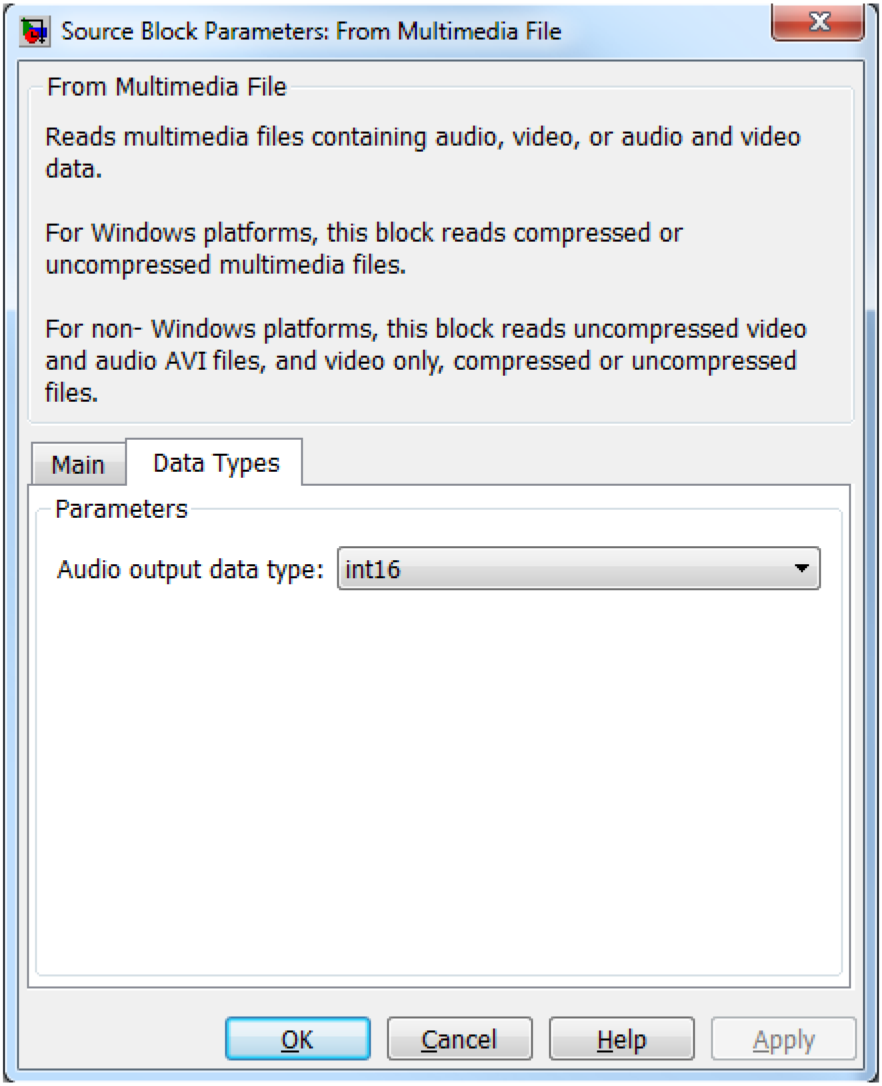
Image signal

Specify how to output a color video signal. If you select `One multidimensional signal`, the block outputs an *M*-by-*N*-by-*P* color video signal, where *P* is the number of color planes, at one port. If you select `Separate color signals`, additional ports appear on the block. Each port outputs one *M*-by-*N* plane of an RGB video stream. This parameter becomes available only if you set the **Image color space** parameter to `RGB` and the signal contains video.

Audio output sampling mode

Select Sample based or Frame based output. If the input to the block has 3 or more dimensions, you must select Sample based output. This parameter appears when you specify a file containing audio for the **File name** parameter.

The **Data Types** pane of the To Multimedia File block dialog box appears as follows.



Source Block Parameters: From Multimedia File

From Multimedia File

Reads multimedia files containing audio, video, or audio and video data.

For Windows platforms, this block reads compressed or uncompressed multimedia files.

For non- Windows platforms, this block reads uncompressed video and audio AVI files, and video only, compressed or uncompressed files.

Audio output data type: int16

Audio output data type

Set the data type of the audio samples output at the Audio port. This parameter becomes available only if the multimedia file contains audio. You can choose `double`, `single`, `int16`, or `uint8` types.

Video output data type

Set the data type of the video frames output at the **R**, **G**, **B**, or **Image** ports. This parameter becomes available only if the multimedia file contains video. You can choose `double`, `single`, `int8`, `uint8`, `int16`, `uint16`, `int32`, `uint32`, or `Inherit from file` types.

Troubleshooting

Running an Executable Outside MATLAB

To run your generated standalone executable application in Shell, you need to set your environment to the following:

Platform	Command

Mac	`setenv DYLD_LIBRARY_PATH $LD_LIBRARY_PATH: $MATLABROOT/bin/maci64 (csh/tcsh)`
	`export DYLD_LIBRARY_PATH $LD_LIBRARY_PATH: $MATLABROOT/bin/maci64 (Bash)`

Linux	`setenv LD_LIBRARY_PATH $LD_LIBRARY_PATH: $MATLABROOT/bin/glnxa64 (csh/tcsh)`
	`export LD_LIBRARY_PATH $LD_LIBRARY_PATH: $MATLABROOT/bin/glnxa64 (Bash)`

Windows	`set PATH = $MATLABROOT\bin\win32;%PATH%`
	`set PATH = $MATLABROOT\bin\win64;%PATH%`

Supported Data Types

For source blocks to display video data properly, double- and single-precision floating-point pixel values must be between 0 and 1. For other data types, the pixel values must be between the minimum and maximum values supported by their data type.

Port	Supported Data Types	Supports Complex Values?
Image	• Double-precision floating point • Single-precision floating point • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers	No
R, G, B	Same as the Image port	No
Audio	• Double-precision floating point • Single-precision floating point • 16-bit signed integers • 8-bit unsigned integers	No
Y, Cb,Cr	Same as the Image port	No

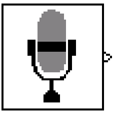
From Wave Device (Obsolete)

Read audio data from standard audio device in real-time (32-bit Windows operating systems only)

Library

dspwin32

Description



Note The From Wave Device block is still supported but is likely to be obsoleted in a future release. We strongly recommend replacing this block with the From Audio Device block.

The From Wave Device block reads audio data from a standard Windows audio device in real-time. It is compatible with most popular Windows hardware, including Sound Blaster cards. (Models that contain both this block and the To Wave Device block require a *duplex-capable* sound card.)

The **Use default audio device** parameter allows the block to detect and use the system's default audio hardware. This option should be selected on systems that have a single sound device installed, or when the default sound device on a multiple-device system is the desired source. In cases when the default sound device is not the desired input source, clear **Use default audio device**, and select the desired device in the **Audio device menu** parameter.

When the audio source contains two channels (stereo), the **Stereo** check box should be selected. When the audio source contains a single channel (mono), the **Stereo** check box should be cleared. For stereo input, the block's output is an *M*-by-2 matrix containing one frame (*M* consecutive samples) of audio data from each of the two channels. For mono input, the block's output is an *M*-by-1 matrix containing one frame (*M* consecutive samples) of audio data from the mono input. The frame size, *M*, is specified by the

Samples per frame parameter. For M=1, the output is sample based; otherwise, the output is frame based.

The audio data is processed in uncompressed pulse code modulation (PCM) format, and should typically be sampled at one of the standard Windows audio device rates: 8000, 11025, 22050, or 44100 Hz. You can select one of these rates from the **Sample rate** parameter. To specify a different rate, select the **User-defined** option and enter a value in the **User-defined sample rate** parameter.

The **Sample Width (bits)** parameter specifies the number of bits used to represent the signal samples read by the audio device. The following settings are available:

- 8 — allocates 8 bits to each sample, allowing a resolution of 256 levels
- 16 — allocates 16 bits to each sample, allowing a resolution of 65536 levels
- 24 — allocates 24 bits to each sample, allowing a resolution of 16777216 levels (only for use with 24-bit audio devices)

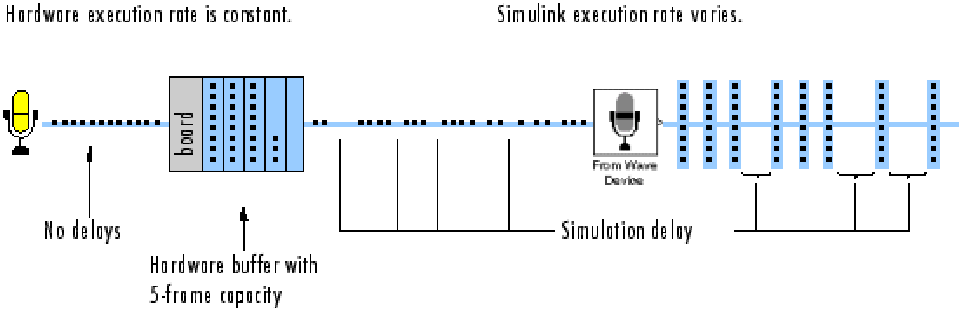
Higher sample width settings require more memory but yield better fidelity. The output from the block is independent of the **Sample width (bits)** setting. The output data type is determined by the **Data type** parameter setting.

Buffering

Since the audio device accepts real-time audio input, Simulink software must read a continuous stream of data from the device throughout the simulation. Delays in reading data from the audio hardware can result in hardware errors or distortion of the signal. This means that the From Wave Device block must read data from the audio hardware as quickly as the hardware itself acquires the signal. However, the block often *cannot* match the throughput rate of the audio hardware, especially when the simulation is running from within Simulink rather than as generated code. (Simulink operations are generally slower than comparable hardware operations, and execution speed routinely varies during the simulation as the host operating system services other processes.) The block must therefore rely on a buffering strategy to ensure that signal data can be read on schedule without losing samples.

At the start of the simulation, the audio device begins writing the input data to a (hardware) buffer with a capacity of T_b seconds. The From Wave Device block immediately begins pulling the earliest samples off the buffer (first in, first out) and collecting them in length-M frames for output. As the audio device continues to append inputs to the bottom of the buffer, the From Wave Device block continues to pull inputs off the top of the buffer at the best possible rate.

The following figure shows an audio signal being acquired and output with a frame size of 8 samples. The buffer of the sound board is approaching its five-frame capacity at the instant shown, which means that the hardware is adding samples to the buffer more rapidly than the block is pulling them off. (If the signal sample rate was 8 kHz, this small buffer could hold approximately 0.005 second of data.



Hardware execution rate is constant.
Simulink execution rate varies.
board
From Wave Device
No delays
Hardware buffer with 5-frame capacity
Simulation delay

When the simulation throughput rate is higher than the hardware throughput rate, the buffer remains empty throughout the simulation. If necessary, the From Wave Device block simply waits for new samples to become available on the buffer (the block does not interpolate between samples). More typically, the simulation throughput rate is lower than the hardware throughput rate, and the buffer tends to fill over the duration of the simulation.

Troubleshooting

When the buffer size is too small in relation to the simulation throughput rate, the buffer might fill before the entire length of signal is processed. This usually results in a device error or undesired device output. When this problem occurs, you can choose to either increase the buffer size or the simulation throughput rate:

- *Increase the buffer size*

  The **Queue duration** parameter specifies the duration of signal, T_b (in real-time seconds), that can be buffered in hardware during the simulation. Equivalently, this is the maximum length of time that the block's data acquisition can lag the hardware's data acquisition. The number of frames buffered is approximately

$$\frac{T_b F_s}{M}$$

where F_s is the sample rate of the signal and M is the number of samples per frame. The required buffer size for a given signal depends on the signal length, the frame size, and the speed of the simulation. Note that increasing the buffer size might increase model latency.

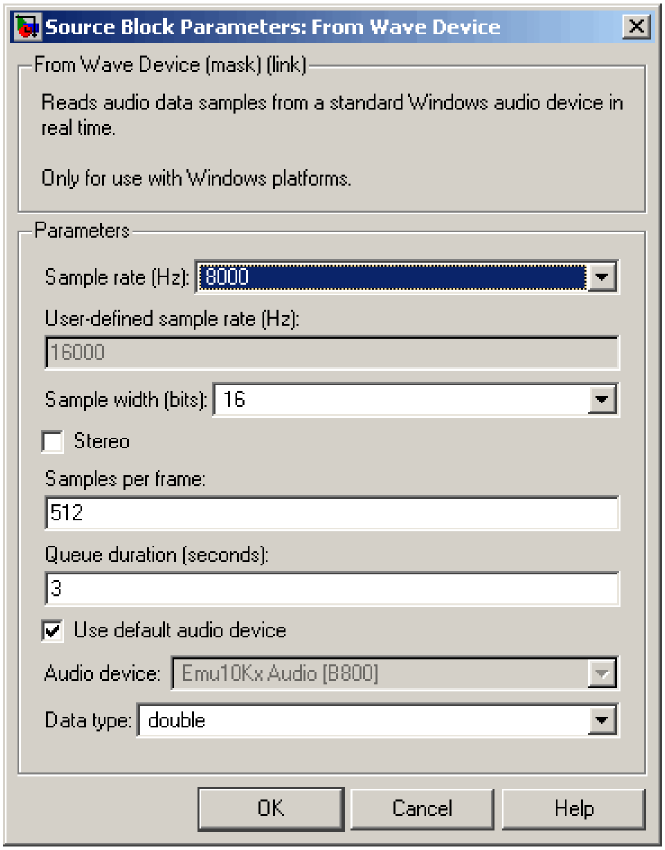
- *Increase the simulation throughput rate*

  Two useful methods for improving simulation throughput rates are increasing the signal frame size and compiling the simulation into native code:

  - Increase frame sizes (and convert sample-based signals to frame-based signals) throughout the model to reduce the amount of block-to-block communication overhead. This can drastically increase throughput rates in many cases. However, larger frame sizes generally result in greater model latency due to initial buffering operations.
  - Generate executable code with Simulink Coder. Native code runs much faster than Simulink, and should provide rates adequate for real-time audio processing.

More general ways to improve throughput rates include simplifying the model, and running the simulation on a faster PC processor. See “Delay and Latency” and “Performance” in the Simulink documentation for other ideas on improving simulation performance.

Dialog Box



Source Block Parameters: From Wave Device

From Wave Device (mask) (link)

Reads audio data samples from a standard Windows audio device in real time.

Parameters

Sample rate (Hz): 8000

User-defined sample rate (Hz):

16000

Sample width (bits): 16

□ Stereo

Samples per frame:

512

Queue duration (seconds):

3

☑ Use default audio device

Audio device: Emu10Kx Audio [B800]

Data type: double

Sample rate (Hz)

The sample rate of the audio data to be acquired. Select one of the standard Windows rates or the `User-defined` option.

User-defined sample rate (Hz)

The (nonstandard) sample rate of the audio data to be acquired.

Sample width (bits)

The number of bits used to represent each signal sample.

Stereo

Specifies stereo (two-channel) inputs when selected, mono (one-channel) inputs when cleared. Stereo output is M-by-2; mono output is M-by-1.

Samples per frame

The number of audio samples in each successive output frame, M. When the value of this parameter is 1, the block outputs a sample-based signal.

Queue duration (seconds)

The length of signal (in seconds) to buffer to the hardware at the start of the simulation.

Use default audio device

Reads audio input from the system's default audio device when selected. Clear to enable the **Audio device ID** parameter and select a device.

Audio device

The name of the audio device from which to read the audio output (lists the names of the installed audio device drivers). Select **Use default audio device** when the system has only a single audio card installed.

Data type

The data type of the output: double-precision, single-precision, signed 16-bit integer, or unsigned 8-bit integer.

Supported Data Types

- Double-precision floating point
- Single-precision floating point
- 16-bit signed integer
- 8-bit unsigned integer

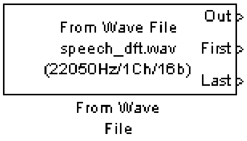
From Wave File (Obsolete)

Read audio data from Microsoft Wave (`.wav`) file

Library

`dspwin32`



Description

Note: The From Wave File block is still supported but is likely to be obsoleted in a future release. We strongly recommend replacing this block with the From Multimedia File block.

The From Wave File block streams audio data from a Microsoft® Wave (`.wav`) file and generates a signal with one of the data types and amplitude ranges in the following table.

Note: AVI files are the only supported file type for non-Windows platforms.

Output Data Type	Output Amplitude Range
`double`	±1
`single`	±1
`int16`	-32768 to 32767 (-2^{15} to 2^{15} - 1)
`uint8`	0 to 255

The audio data must be in uncompressed pulse code modulation (PCM) format.

```
y = wavread('filename')       % Equivalent MATLAB code
```

The block supports 8-, 16-, 24-, and 32-bit Microsoft Wave (`.wav`) files.

The **File name** parameter can specify an absolute or relative path to the file. When the file is on the MATLAB path or in the current folder (the folder returned by typing `pwd` at the MATLAB command line), you need only specify the file name. You do not need to specify the `.wav` extension.

Note: The From Wave File block does not support .wav file names that contain a + character. To read .wav files that have a + character in the file name, use the From Multimedia File block.

For an audio file containing *C* channels, the block's output is an *M*-by-*C* matrix containing one frame (*M* consecutive samples) of audio data from each channel. The frame size, *M*, is specified by the **Samples per output frame** parameter. For *M*=1, the output is sample based; otherwise, the output is frame based.

The output frame period, T_{fo}, is

$$T_{fo} = \frac{M}{F_s}$$

where F_s is the data sample rate in Hz.

To reduce the required number of file accesses, the block acquires *L* consecutive samples from the file during each access, where *L* is specified by the **Minimum number of samples for each read from file** parameter ($L \geq M$). For $L < M$, the block instead acquires *M* consecutive samples during each access. Larger values of *L* result in fewer file accesses, which reduces run-time overhead.

Use the **Data type** parameter to specify the data type of the block's output. Your choices are `double`, `single`, `uint8`, or `int16`.

Select the **Loop** check box if you want to play the file more than once. Then, enter the number of times to play the file. The number you enter must be a positive integer or `inf`.

Use the **Number of times to play file** parameter to enter the number of times to play the file. The number you enter must be a positive integer or `inf`, to play the file until you stop the simulation.

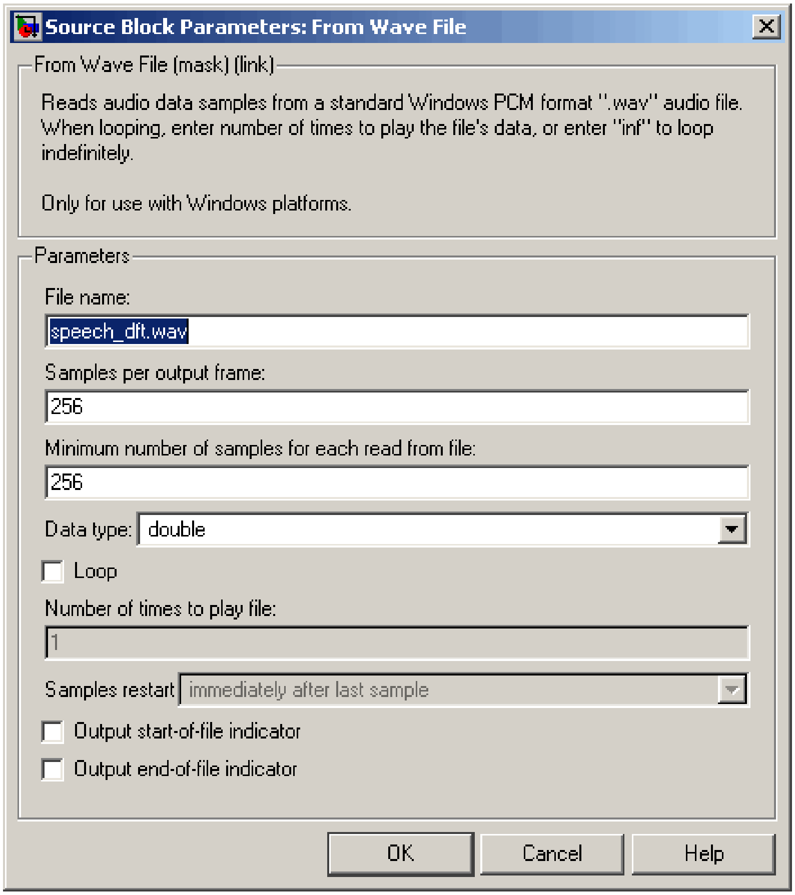
The **Samples restart** parameter determines whether the samples from the audio file repeat immediately or repeat at the beginning of the next frame output from the output port. When you select `immediately after last sample`, the samples repeat immediately. When you select `at beginning of next frame`, the frame containing the last sample value from the audio file is zero padded until the frame is filled. The block then places the first sample of the audio file in the first position of the next output frame.

Use the **Output start-of-file indicator** parameter to determine when the first audio sample in the file is output from the block. When you select this check box, a Boolean output port labeled SOF appears on the block. The output from the SOF port is 1 when the first audio sample in the file is output from the block. Otherwise, the output from the SOF port is 0.

Use the **Output end-of-file indicator** parameter to determine when the last audio sample in the file is output from the block. When you select this check box, a Boolean output port labeled EOF appears on the block. The output from the EOF port is 1 when the last audio sample in the file is output from the block. Otherwise, the output from the EOF port is 0.

The block icon shows the name, sample rate (in Hz), number of channels (1 or 2), and sample width (in bits) of the data in the specified audio file. All sample rates are supported; the sample width must be either 8, 16, 24, or 32 bits.

Dialog Box



Source Block Parameters: From Wave File

From Wave File (mask) (link)

Reads audio data samples from a standard Windows PCM format ".wav" audio file. When looping, enter number of times to play the file's data, or enter "inf" to loop indefinitely.

Only for use with Windows platforms.

Parameters

File name: speech_dft.wav

Samples per output frame: 256

Minimum number of samples for each read from file: 256

Data type: double

□ Loop

Number of times to play file: 1

Samples restart: immediately after last sample

□ Output start-of-file indicator

□ Output end-of-file indicator

File name

Enter the path and name of the file to read. Paths can be relative or absolute.

Note: The From Wave File block does not support .wav file names that contain a + character. To read .wav files that have a + character in the file name, use the From Multimedia File block.

Samples per output frame

Enter the number of samples in each output frame, *M*. When the value of this parameter is `1`, the block outputs a sample-based signal.

Minimum number of samples for each read from file

Enter the number of consecutive samples to acquire from the file with each file access, *L*.

Data type

Select the output data type: `double`, `single`, `uint8`, or `int16`. The data type setting determines the output's amplitude range.

Loop

Select this check box if you want to play the file more than once.

Number of times to play file

Enter the number of times you want to play the file.

Samples restart

Select `immediately after last sample` to repeat the audio file immediately. Select `at beginning of next frame` to place the first sample of the audio file in the first position of the next output frame.

Output start-of-file indicator

Use this check box to determine whether the output contains the first audio sample in the file.

Output end-of-file indicator

Use this check box to determine whether the output contains the last audio sample in the file.

Supported Data Types

- Double-precision floating point
- Single-precision floating point
- 16-bit signed integer
- 8-bit unsigned integer

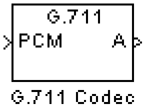
G711 Codec

Quantize narrowband speech input signals

Library

Quantizers

`dspquant2`



Description

The G711 Codec block is a logarithmic scalar quantizer designed for narrowband speech. Narrowband speech is defined as a voice signal with an analog bandwidth of 4 kHz and a Nyquist sampling frequency of 8 kHz. The block quantizes a narrowband speech input signal so that it can be transmitted using only 8-bits. The G711 Codec block has three modes of operation: encoding, decoding, and conversion. You can choose the block's mode of operation by setting the **Mode** parameter.

If, for the **Mode** parameter, you choose `Encode PCM to A-law`, the block assumes that the linear PCM input signal has a dynamic range of 13 bits. Because the block always operates in saturation mode, it assigns any input value above $2^{12}-1$ to $2^{12}-1$ and any input value below -2^{12} to -2^{12}. The block implements an A-law quantizer on the input signal and outputs A-law index values. When you choose `Encode PCM to mu-law`, the block assumes that the linear PCM input signal has a dynamic range of 14 bits. Because the block always operates in saturation mode, it assigns any input value above $2^{13}-1$ to $2^{13}-1$ and any input value below -2^{13} to -2^{13}. The block implements a mu-law quantizer on the input signal and outputs mu-law index values.

If, for the **Mode** parameter, you choose `Decode A-law to PCM`, the block decodes the input A-law index values into quantized output values using an A-law lookup table. When you choose `Decode mu-law to PCM`, the block decodes the input mu-law index values into quantized output values using a mu-law lookup table.

If, for the **Mode** parameter, you choose `Convert A-law to mu-law`, the block converts the input A-law index values to mu-law index values. When you choose `Convert mu-law to A-law`, the block converts the input mu-law index values to A-law index values.

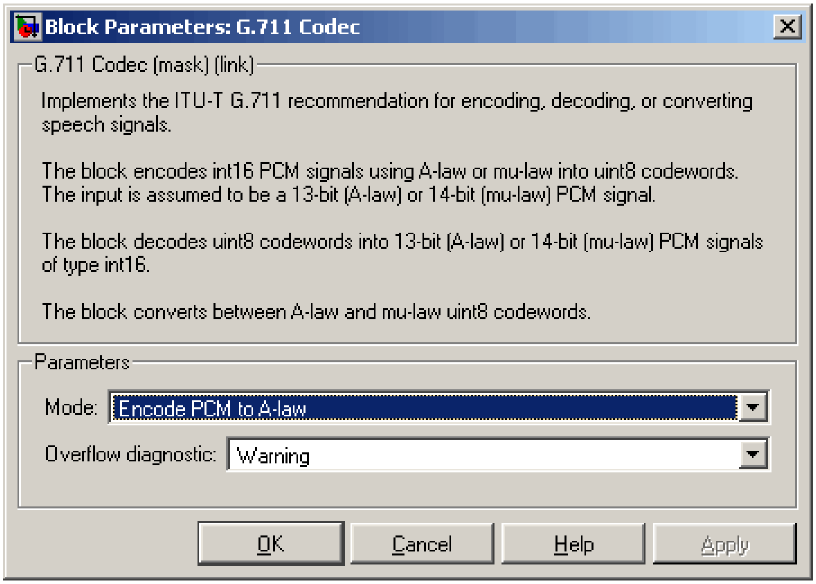
Note Set the **Mode** parameter to `Convert A-law to mu-law` or `Convert mu-law to A-law` only when the input to the block is A-law or mu-law index values.

If, for the **Mode** parameter, you choose `Encode PCM to A-law` or `Encode PCM to mu-law`, the **Overflow diagnostic** parameter appears on the block parameters dialog box. Use this parameter to determine the behavior of the block when overflow occurs. The following options are available:

- `Ignore` — Proceed with the computation and do not issue a warning message.
- `Warning` — Display a warning message in the MATLAB Command Window, and continue the simulation.
- `Error` — Display an error dialog box and terminate the simulation.

Note Like all diagnostic parameters on the Configuration Parameters dialog box, **Overflow diagnostic** parameter is set to `Ignore` in the code generated for this block by Simulink Coder code generation software.

Dialog Box



G.711 Codec (mask) (link)

Implements the ITU-T G.711 recommendation for encoding, decoding, or converting speech signals.

The block encodes int16 PCM signals using A-law or mu-law into uint8 codewords. The input is assumed to be a 13-bit (A-law) or 14-bit (mu-law) PCM signal.

The block decodes uint8 codewords into 13-bit (A-law) or 14-bit (mu-law) PCM signals of type int16.

The block converts between A-law and mu-law uint8 codewords.

Parameters

Mode: Encode PCM to A-law

Overflow diagnostic: Warning

Mode

- When you choose `Encode PCM to A-law`, the block implements an A-law encoder.
- When you choose `Encode PCM to mu-law`, the block implements a mu-law encoder.
- When you choose `Decode A-law to PCM`, the block decodes the input index values into quantized output values using an A-law lookup table.
- When you choose `Decode mu-law to PCM`, the block decodes the input index values into quantized output values using a mu-law lookup table.
- When you choose `Convert A-law to mu-law`, the block converts the input A-law index values to mu-law index values.
- When you choose `Convert mu-law to A-law`, the block converts the input mu-law index values to A-law index values.

Overflow diagnostic

Use this parameter to determine the behavior of the block when overflow occurs.

- Select `Ignore` to proceed with the computation without a warning message.
- Select `Warning` to display a warning message in the MATLAB Command Window and continue the simulation.
- Select `Error` to display an error dialog box and terminate the simulation.

This parameter is only visible if, for the **Mode** parameter, you select `Encode PCM to A-law` or `Encode PCM to mu-law`.

Halfband Filter

Design halfband filter

Library

Filtering / Filter Designs

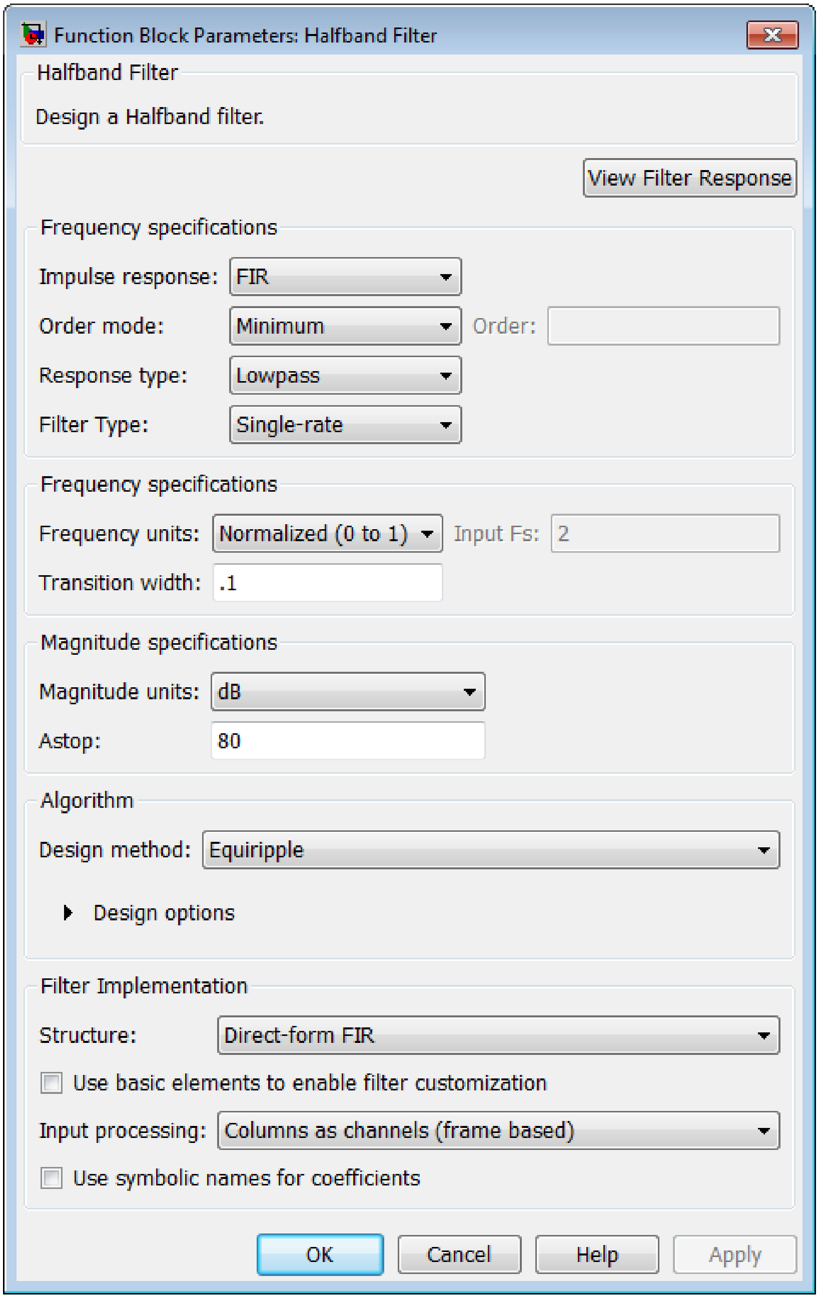
`dspfdesign`

Description

This block brings the filter design capabilities of the “`filterbuilder`” function to the Simulink environment.

Dialog Box

See “Halfband Filter Design Dialog Box — Main Pane” for more information about the parameters of this block. The **Data Types** and **Code Generation** panes are not available for blocks in the DSP System Toolbox Filter Designs library.



Function Block Parameters: Halfband Filter

Halfband Filter

Design a Halfband filter.

Filter Implementation

Structure: Direct-form FIR

□ Use basic elements to enable filter customization

Input processing: Columns as channels (frame based)

□ Use symbolic names for coefficients

View filter response

This button opens the Filter Visualization Tool (`fvtool`) from the Signal Processing Toolbox product. You can use the tool to display:

- Magnitude response, phase response, and group delay in the frequency domain.
- Impulse response and step response in the time domain.
- Pole-zero information.

The tool also helps you evaluate filter performance by providing information about filter order, stability, and phase linearity. For more information on FVTool, see the Signal Processing Toolbox documentation.

Filter Specifications

In this group, you specify your filter type and order.

Impulse response

Select either `FIR` or `IIR` from the drop-down list. `FIR` is the default. When you choose an impulse response, the design methods and structures you can use to implement your filter change accordingly.

Note: The design methods and structures for FIR filters are not the same as the methods and structures for IIR filters.

Order mode

Select either `Minimum` (the default) or `Specify` from the drop-down list. Selecting `Specify` enables the **Order** option (see the following sections) so you can enter the filter order.

Response type

Specify the filter response as `Lowpass` (the default) or `Highpass`.

Filter type

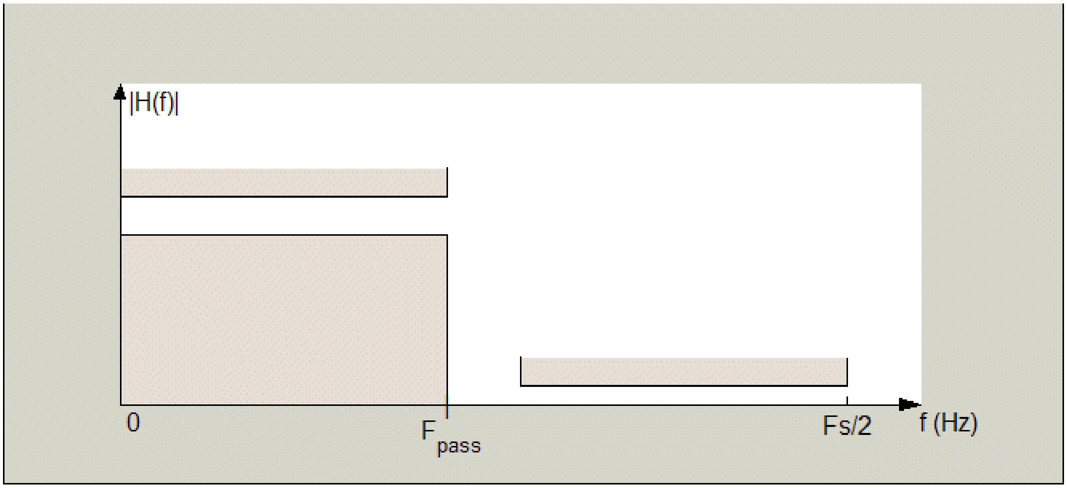
Select `Single-rate`, `Decimator`, or `Interpolator`. By default, the block specifies a single-rate filter.

Order

Enter the filter order. This option is enabled only when the **Filter order mode** is set to `Specify`.

Frequency Specifications

The parameters in this group allow you to specify your filter response curve. Graphically, the filter specifications for a halfband lowpass filter look similar to those shown in the following figure.



In the figure, the transition region lies between the end of the passband and the start of the stopband. The width is defined explicitly by the value of **Transition width**.

Frequency constraints

When **Order mode** is `Specify`, set this parameter to `Unconstrained` or `Transition width`.

Frequency units

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select `Normalized (0–1)` to enter frequencies in normalized form. This behavior is the default. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—`Hz`, `kHz`, `MHz`, or `GHz`. Selecting one of the unit options enables the **Input Fs** parameter.

Input Fs

Fs, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is

available when you select one of the frequency options from the **Frequency units** list.

Transition width

Specify the width of the transition between the end of the passband and the edge of the stopband. Specify the value in normalized frequency units or the absolute units you select in **Frequency units**.

Magnitude Specifications

Parameters in this group specify the filter response in the passbands and stopbands.

Magnitude constraints

Specify `Unconstrained` (the default), or select `Stopband attenuation` to constrain the response in the stopband explicitly.

Magnitude units

Specify the units for any parameter you provide in magnitude specifications. From the drop-down list, select one of the following options:

- `Linear` — Specify the magnitude in linear units.
- `dB` — Specify the magnitude in decibels (default).

Astop

When **Magnitude units** is `Stopband attenuation`, enter the filter attenuation in the stopband in the units you choose for **Magnitude units**, either linear or decibels.

Algorithm

The parameters in this group allow you to specify the design method and structure of your filter.

Design Method

Lists the design methods available for the frequency and magnitude specifications you entered. For FIR halfband filters, the available design options are `equiripple`, and `Kaiser window`. For IIR halfband filters, the available design options are `Butterworth`, `elliptic`, and `IIR quasi-linear phase`.

Design Options

The following design options are available for FIR halfband filters when the user specifies an equiripple design:

Minimum phase

Select the checkbox to specify a minimum-phase design.

Stopband Shape

Stopband shape lets you specify how the stopband changes with increasing frequency. Choose one of the following options:

- `Flat` — Specifies that the stopband is flat. The attenuation does not change as the frequency increases.
- `Linear` — Specifies that the stopband attenuation changes linearly as the frequency increases. Change the slope of the stopband by setting **Stopband decay**.
- `1/f` — Specifies that the stopband attenuation changes exponentially as the frequency increases, where `f` is the frequency. Set the power (exponent) for the decay in **Stopband decay**.

Stopband Decay

When you set Stopband shape, Stopband decay specifies the amount of decay applied to the stopband. the following conditions apply to Stopband decay based on the value of Stopband Shape:

- When you set **Stopband shape** to `Flat`, **Stopband decay** has no affect on the stopband.
- When you set **Stopband shape** to `Linear`, enter the slope of the stopband in units of dB/rad/s. The block applies that slope to the stopband.
- When you set **Stopband shape** to `1/f`, enter a value for the exponent n in the relation $(1/f)^n$ to define the stopband decay. The block applies the $(1/f)^n$ relation to the stopband to result in an exponentially decreasing stopband attenuation.

Filter Implementation

Structure

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter.

Use basic elements to enable filter customization

Select this check box to implement the filter as a subsystem of basic Simulink blocks. Clear the check box to implement the filter as a high-level subsystem. By default, this check box is cleared.

The high-level implementation provides better compatibility across various filter structures, especially filters that would contain algebraic loops when constructed using basic elements. On the other hand, using basic elements enables the following optimization parameters:

- **Optimize for zero gains** — Terminate chains that contain Gain blocks with a gain of zero.
- **Optimize for unit gains** — Remove Gain blocks that scale by a factor of one.
- **Optimize for delay chains** — Substitute delay chains made up of *n* unit delays with a single delay by *n*.
- **Optimize for negative gains** — Use subtraction in Sum blocks instead of negative gains in Gain blocks.

Optimize for unit-scale values

Select this check box to scale unit gains between sections in SOS filters. This parameter is available only for SOS filters.

Input processing

Specify how the block should process the input. The available options may vary depending on he settings of the **Filter Structure** and **Use basic elements for filter customization** parameters. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` — When you select this option, the block treats each column of the input as a separate channel.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

Note: The `Inherited (this choice will be removed — see release notes)` option will be removed in a future release. See “Frame-Based Processing” in the *DSP System Toolbox Release Notes* for more information.

Rate options

When the **Filter type** parameter specifies a multirate filter, select the rate processing rule for the block from following options:

- `Enforce single-rate processing` — When you select this option, the block maintains the sample rate of the input.
- `Allow multirate processing` — When you select this option, the block adjusts the rate at the output to accommodate an increased or reduced number of samples. To select this option, you must set the **Input processing** parameter to `Elements as channels (sample based)`.

Use symbolic names for coefficients

Select this check box to enable the specification of coefficients using MATLAB variables. The available coefficient names differ depending on the filter structure. Using symbolic names allows tuning of filter coefficients in generated code. By default, this check box is cleared.

Supported Data Types

Port	Supported Data Types

Complex to Magnitude-Angle HDL Optimized

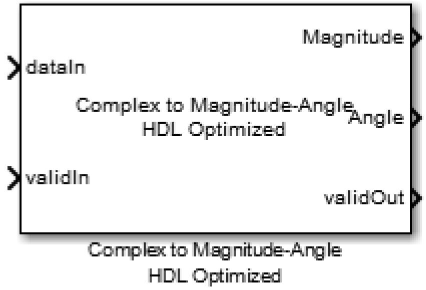
Compute magnitude and/or phase angle of complex signal—optimized for HDL code generation using the CORDIC algorithm

Library

Math Operations

`dspmathops`

Description



Magnitude
dataIn
Complex to Magnitude-Angle HDL Optimized
Angle
validIn
validOut
Complex to Magnitude-Angle HDL Optimized

The Complex to Magnitude-Angle HDL Optimized block computes the magnitude and/or phase angle of a complex signal. It provides hardware-friendly control signals. The block uses a pipelined Coordinate Rotation Digital Computer (CORDIC) algorithm to achieve an efficient HDL implementation.

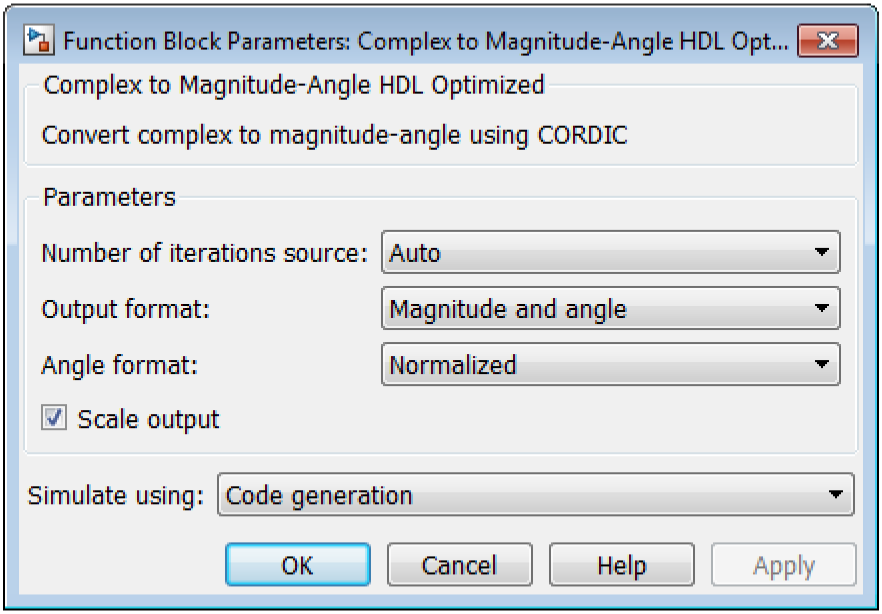
Signal Attributes

The following table provides descriptions of the port signals.

Port	Direction	Description	Data Type
`dataIn`	Input	Complex scalar input data.	• `fixdt()` • `int32/16/8`

Port	Direction	Description	Data Type
			• uint32/16/8 double/single are allowed for simulation but not for HDL code generation.
validIn	Input	Indicates that the input data is valid. When validIn is high, the block captures the dataIn value.	boolean
magnitude	Output	Scalar output data.	Same as dataIn
angle	Output	Scalar output data. Optional.	Same as dataIn
validOut	Output	Indicates that the output data is valid. When the magnitude or angle output is ready, the block sets validOut high .	boolean

Dialog Box and Parameters



Function Block Parameters: Complex to Magnitude-Angle HDL Opt...

Complex to Magnitude-Angle HDL Optimized

Convert complex to magnitude-angle using CORDIC

Parameters

Number of iterations source: Auto

Output format: Magnitude and angle

Angle format: Normalized

☑ Scale output

Simulate using: Code generation

Number of iterations source

Specifies the source of **Number of iterations** for the CORDIC algorithm. Select `Auto` to set the number of iterations to the input word length − 1. If the input is `double` or `single`, `Auto` sets the number of iterations to 16. Select `Property` to set the number of iterations from **Number of iterations**. The default is `Auto`.

Number of iterations

Specifies the number of CORDIC iterations the block executes. This parameter is visible only when **Number of iterations source** is set to `Property`. The number of iterations must be less than or equal to the input data word length − 1.

Output format

Specifies which output ports are active. You can select `Magnitude`, `Angle`, or `Magnitude and angle`. The default is `Magnitude and angle`.

Angle format

Specifies the format of the `angle` output. You can select `Normalized` or `Radians`. Select `Normalized` to return output in a fixed-point format that normalizes the angles in the range [–1,1]. For more information see “Normalized Angle Format”. Select `Radians` to return output as a fixed-point value between π and −π. The default format is `Normalized`.

Scale output

Scales output by the inverse of the CORDIC gain factor. The default value is selected.

Note: If you turn off output scaling, and apply the CORDIC gain elsewhere in your design, you must exclude the π/4 term. The quadrant mapping algorithm replaces the first CORDIC iteration by mapping inputs onto the angle range [0,π/4]. Therefore, the initial rotation does not contribute a gain term.

Simulate using

Type of simulation to run. This parameter does not affect generated HDL code.

- `Code generation` (default)

  Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than `Interpreted execution`.

- `Interpreted execution`

  Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than `Code generation`.

Troubleshooting

If the input is 0+0i, the output angle is undefined. The block does not implement correction logic to force the output to 0. You can ignore this output angle.

Algorithm

CORDIC Algorithm

The CORDIC algorithm is a hardware-friendly method for performing trigonometric functions. It is an iterative algorithm that approximates the solution by converging toward the ideal point. The block uses CORDIC vectoring mode to iteratively rotate the input onto the real axis.

The Givens method for rotating a complex number $x+iy$ by an angle θ is as follows. The direction of rotation, d, is +1 for counterclockwise and −1 for clockwise.

$$\begin{aligned} x_r &= x\cos\theta - dy\sin\theta \\ y_r &= y\cos\theta + dx\sin\theta \end{aligned}$$

For a hardware implementation, factor out the $\cos\theta$ to leave a $\tan\theta$ term.

$$\begin{aligned} x_r &= \cos\theta\left(x - dy\tan\theta\right) \\ y_r &= \cos\theta\left(y + dx\tan\theta\right) \end{aligned}$$

To rotate the vector onto the real axis, choose a series of rotations of θ_n so that $\tan\theta_n = 2^{-n}$. Remove the $\cos\theta$ term so each iterative rotation uses only shift and add operations.

$$Rx_n = x_{n-1} - d_n y_{n-1} 2^{-n}$$
$$Ry_n = y_{n-1} + d_n x_{n-1} 2^{-n}$$

Combine the missing cosθ terms from each iteration into a constant, and apply it with a single multiplier to the result of the final rotation. The output magnitude is the scaled final value of *x*. The output angle, *z*, is the sum of the rotation angles.

$$x_r = \left(\cos\theta_0 \cos\theta_1 \ldots \cos\theta_n\right) Rx_N$$
$$z = \sum_{0}^{N} d_n \theta_n$$

Modified CORDIC Algorithm

The convergence region for the standard CORDIC rotation is ≈±99.7°. To work around this limitation, before doing any rotation, the block maps the input into the [0,π/4] range using the following algorithm.

```
if abs(x) > abs(y)
  input_mapped = [abs(x), abs(y)];
else
  input_mapped = [abs(y), abs(x)];
end
```

At each iteration, the block rotates the vector towards the real axis. The rotation is counterclockwise when *y* is negative, and clockwise when *y* is positive.

Quadrant mapping saves hardware resources and reduces latency by reducing the number of CORDIC pipeline stages by one. The CORDIC gain factor, *Kn*, therefore does not include the n=0, or cos(π/4) term.

$$K_n = c\text{os}\,\theta_1 \ldots \cos\theta_n = \cos(26.565) \cdot \cos(14.036) \cdot \cos(7.125) \cdot \cos(3.576)$$

After the CORDIC iterations are complete, the block corrects the angle back to its original location. First it adjusts the angle to the correct side of π/4.

```
if abs(x) > abs(y)
  angle_unmapped = CORDIC_out;
```

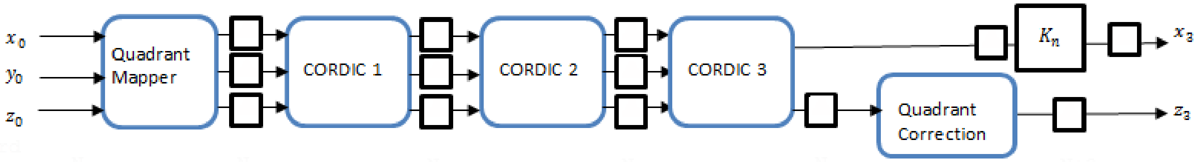
```
else
  angle_unmapped = (pi/2) - CORDIC_out;
end
```

Then it flips the angle to the original quadrant.

```
if (x < 0)
  if (y < 0)
    output_angle = - pi + angle_unmapped;
  else
    output_angle = pi - angle_unmapped;
else
  if (y<0)
    output_angle = -angle_unmapped;
```

Architecture

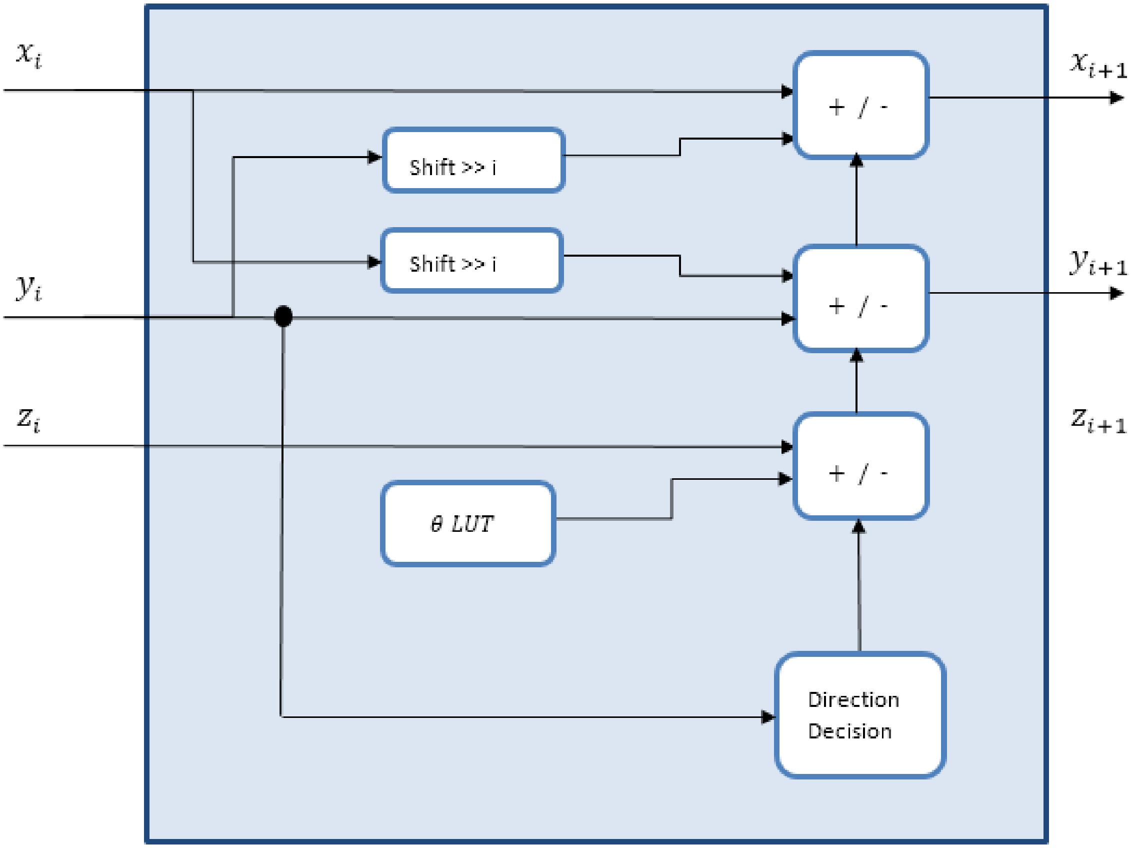
The block generates a pipelined HDL architecture to maximize throughput. Each CORDIC iteration is done in one pipeline stage. The gain multiplier, if enabled, is implemented with Canonical Signed Digit (CSD) logic.



Input Word Length	Output Magnitude Word Length
fixdt(0,WL,FL)	fixdt(0,WL+2,FL)
fixdt(1,WL,FL)	fixdt(1,WL+1,FL)

Input Word Length	Output Angle Word Length	
fixdt([ ],WL,FL)	Radians	fixdt(1,WL+3,WL)
	Normalized	fixdt(1,WL+3,WL+2)

The CORDIC logic at each pipeline stage implements one iteration. For each pipeline stage, the shift and angle rotation are constants.

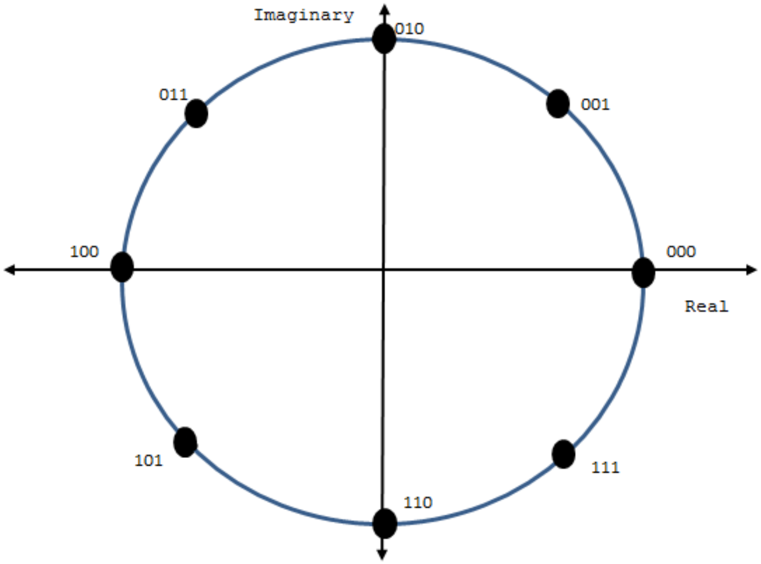


When you set **Output format** to `Magnitude`, the block does not generate HDL code for the angle accumulation and quadrant correction logic.

Normalized Angle Format

This format normalizes the fixed-point radian angle values around the unit circle. This is a more efficient use of bits than a range of [0,2π] radians. Normalized angle format also enables wraparound at 0/2π without additional detect and correct logic.

For example, representing the angle with 3 bits results in the following normalized values.



Using the mapping described in “Modified CORDIC Algorithm”, the block normalizes the angles across [0,π/4] and maps them to the correct octant at the end of the calculation.

Control Signals

The `validIn` signal qualifies the input data. When the output data calculated from a valid input reaches the end of the pipeline, the block asserts the `validOut` signal.

Latency

The output is valid **Number of iterations** + 2 cycles after valid input.

When you set **Number of iterations source** to `Auto`, the number of iterations is input word length – 1, and the latency is input word length + 1. If the input is `double` or `single` type, the number of iterations is 16, and the latency is 18.

HDL Code Generation

This block supports HDL code generation using HDL Coder. HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic. For more information on implementations, properties, and restrictions for HDL code generation, see Complex to Magnitude-Angle HDL Optimized in the HDL Coder documentation.

Performance

When generated HDL code for the default configuration, with output scaling disabled and `fixdt(1,16,12)` input, is synthesized into a Xilinx® Virtex®–6 (XC6VLX240T-1FFG1156) FPGA, the design achieves 260 MHz clock frequency. It uses the following resources.

Resource	Uses
LUT	882

HDL Minimum Resource FFT

FFT— optimized for HDL code generation using minimum hardware resources

Library

Obsolete

`dspobs`

Description

The HDL Minimum Resource FFT block implements an FFT architecture that uses minimal hardware resources. The HDL Minimum Resource FFT block supports the Radix-2 with decimation-in-time (DIT) algorithm for FFT computation. See the “FFT” block for more information about this algorithm.

The results returned by the HDL Minimum Resource FFT block are bit-for-bit compatible with results returned by the FFT block. The operation of the HDL Minimum Resource FFT block differs from the FFT block, due to the requirements of hardware realization. The HDL Minimum Resource FFT block:

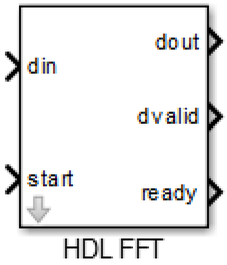
- Requires serial input
- Generates serial output
- Operates in burst I/O mode

The HDL Minimum Resource FFT block provides handshaking signals to support these features.

- “Block Inputs and Outputs” on page 1-665
- “Parameters and Dialog Box” on page 1-668
- “Signal Processing with the HDL FFT Block” on page 1-671

Block Inputs and Outputs

As shown in the following figure, the HDL Minimum Resource FFT block has two input ports and three output ports. Two of these ports are for data input and output signals. The other ports are for control signals.



The input ports are:

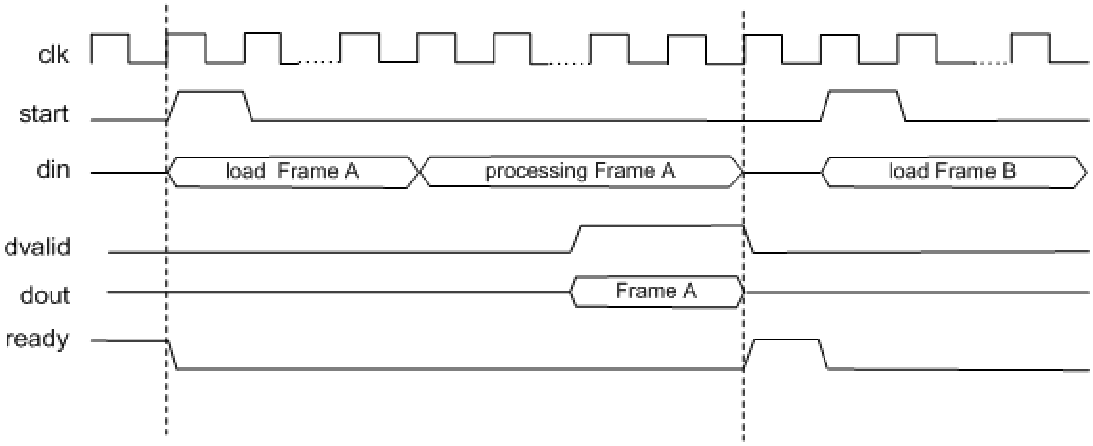
- `din`: The input data signal. A complex signal is required.
- `start`: Boolean control signal. When this signal is asserted true (1), the HDL Minimum Resource FFT block initiates processing of a data frame.

The output ports are:

- `dout`: Data output signal. The Radix-2 with DIT algorithm produces output with linear ordering.
- `dvalid`: Boolean control signal. The HDL Minimum Resource FFT block asserts this signal true (1) when a burst of valid output data is available at the `dout` port.
- `ready`: Boolean control signal. The HDL Minimum Resource FFT block asserts this signal true (1) to indicate that it is ready to process a new frame.

Configuring Control Signals

For efficient hardware deployment of the HDL Minimum Resource FFT block, the timing of the block's input and output data streams must be considered carefully. The following figure shows the timing relationships between the system clock and the `start`, `ready`, and `dvalid` signals.



When `ready` is asserted, the `start` signal (active high) triggers the block. The high cycle period of the `start` signal does not affect the behavior of the block.

One clock cycle after the `start` trigger, the block begins to load data and the `ready` signal is deasserted. During the interval when the block is loading, processing, and outputting data, `ready` is low and the `start` signal is ignored.

The `dvalid` signal is asserted high for N clock cycles (where N is the FFT length) after processing is complete. `ready` is asserted again after the N-point FFT outputs are sent out.

The expression `Tcycle` denotes the total number of clock cycles required by the HDL Minimum Resource FFT block to complete an FFT of length N. `Tcycle` is defined as follows:

- Where N >8

  ```
  Tcycle =  3N/2-2 + log2(N)*(N/2+3);
  ```
- Where N = 8

  ```
  Tcycle =  3N/2-1 +log2(N)*(N/2+3);
  ```

Given `Tcycle`, you can then define the period between assertions of the HDL Minimum Resource FFT `start` signal in a way that is suitable to your application. In the “Using the Minimum Resource HDL FFT” example, this period is computed and assigned to the variable `startLen`, as follows:

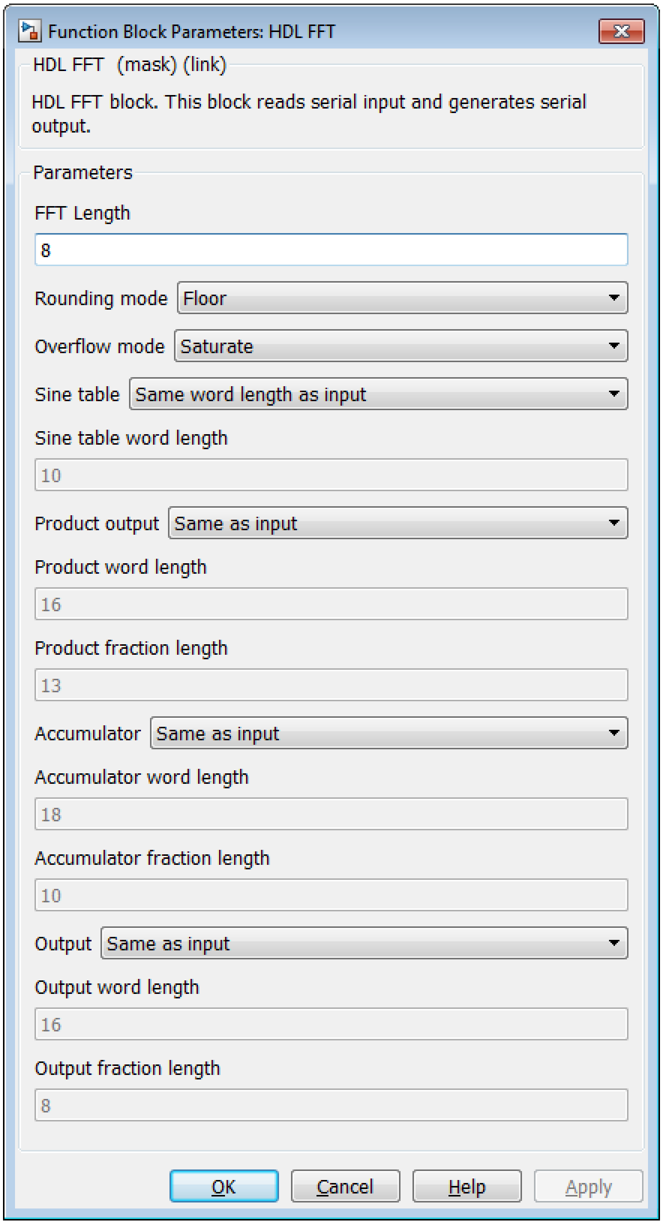
```
if (N<=8)
startLen = (ceil(Tcycle/N)+1)*N;
else
startLen = ceil(Tcycle/N)*N;
end
```

In the example model, `startLen` determines the period of a Pulse Generator that drives the HDL Minimum Resource FFT block's `start` input. These values are computed in the model's initialization function (`InitFcn`), which is defined in the **Callbacks** pane of the Simulink Model Explorer.

The HDL Minimum Resource FFT block asserts and deasserts the `ready` and `dvalid` signals automatically. These signals are routed to the model components that write to and read from the HDL Minimum Resource FFT block.

Parameters and Dialog Box

The following figure shows the HDL Minimum Resource FFT block dialog box, with parameters at their default settings.



Function Block Parameters: HDL FFT

HDL FFT (mask) (link)

HDL FFT block. This block reads serial input and generates serial output.

Parameters

FFT Length

8

Rounding mode Floor

Overflow mode Saturate

Sine table Same word length as input

Sine table word length

10

Product output Same as input

Product word length

16

Product fraction length

13

Accumulator Same as input

Accumulator word length

18

Accumulator fraction length

10

Output Same as input

Output word length

16

Output fraction length

8

FFT Length

Default: 8

The FFT length must be a power of 2, in the range 2^3 .. 2^{16}.

Rounding mode

Default: `Floor`

The HDL Minimum Resource FFT block supports all rounding modes of the FFT block. See also the “FFT” block reference section.

Overflow mode

Default: `Saturate`

The HDL Minimum Resource FFT block supports all overflow modes of the FFT block. See also the “FFT” block reference section.

Sine table

Default: `Same word length as input`

Choose how you specify the word length of the values of the sine table. The fraction length of the sine table values is equal to the word length minus one.

- When you select `Same word length as input`, the word length of the sine table values match that of the input to the block.
- When you select `Specify word length`, you can enter the word length of the sine table values, in bits, in the **Sine table word length** field. The sine table values do not obey the **Rounding mode** and **Overflow mode** parameters; they always saturate and round to `Nearest`.

Product output

Default: `Same as input`

Use this parameter to specify how you want to designate the product output word and fraction lengths:

- When you select `Same as input`, these characteristics match those of the input to the block.

- When you select `Binary point scaling`, you can enter the word length and the fraction length of the product output, in bits, in the **Product word length** and **Product fraction length** fields.

Accumulator

Default: `Same as input`

Use this parameter to specify how you want to designate the accumulator word and fraction lengths:

When you select `Same as product output`, these characteristics match those of the product output.

- When you select `Same as input`, these characteristics match those of the input to the block.
- When you select `Binary point scaling`, you can enter the word length and the fraction length of the accumulator, in bits, in the **Accumulator word length** and **Accumulator fraction length** fields.

Output

Default: `Same as input`

Choose how you specify the output word length and fraction length:

- When you select `Same as input`, these characteristics match those of the input to the block.
- When you select `Binary point scaling`, you can enter the word length and the fraction length of the output, in bits, in the **Output word length** and **Output fraction length** fields.

Note: The HDL FFT block skips the divide-by-two operation on butterfly outputs for fixed-point signals.

Signal Processing with the HDL FFT Block

To get started with the HDL Minimum Resource FFT block, run the “Using the Minimum Resource HDL FFT” example, which is located in the HDL Coder/Signal Processing example library.

The example illustrates the use of the HDL Minimum Resource FFT block in simulation. The model includes buffering and control logic that handles serial input and output. In the example, a complex source signal is stored as a series of samples in a FIFO. Samples from the FIFO are processed serially by the HDL Minimum Resource FFT block, which emits a stream of scalar FFT data.

For comparison, the same source signal is also processed by the frame-based FFT block. The output frames from the FFT block are buffered into a FIFO and compared to the output of the HDL Minimum Resource FFT block. Examination of the results shows the outputs to be identical.

HDL Streaming FFT

Radix-2 FFT with decimation-in-frequency (DIF) — optimized for HDL code generation

Library

Obsolete

`dspobs`

Description

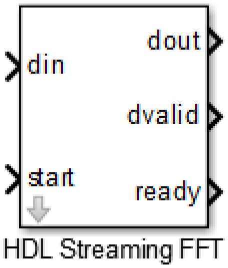
Note: The HDL Streaming FFT block will be deprecated in future releases. Use the “FFT HDL Optimized” block instead.

The HDL Streaming FFT block returns results identical to results returned by the Radix-2 DIF algorithm of the FFT block.

- “Block Inputs and Outputs” on page 1-673
- “Timing Description” on page 1-674
- “Parameters and Dialog Box” on page 1-677

Block Inputs and Outputs

As shown in the following figure, the HDL Streaming FFT block has two input ports and three output ports. Two of these ports are for data input and output signals. The other ports are for control signals.



The block has the following input ports:

- `din`: The input data signal. The coder requires a complex fixed-point signal.
- `start`: Boolean control signal. When `start` asserts true (1), the HDL Streaming FFT block initiates processing of a data frame.

The block has the following output ports:

- `dout`: Data output signal.
- `dvalid`: Boolean control signal. The HDL Streaming FFT block asserts this signal true (1) when a stream of valid output data is available at the `dout` port.
- `ready`: Boolean control signal. The HDL Streaming FFT block asserts this signal true (1) to indicate that it is ready to process a new frame.

Timing Description

The HDL Streaming FFT block operates in one of two modes:

- *Continuous data streaming* mode: In this mode, the HDL Streaming FFT block expects to receive a continuous stream of data at `din`. After an initial delay, the block produces a continuous stream of data at `dout`.
- *Non-continuous data streaming* mode: In this mode, the HDL Streaming FFT block receives non-continuous bursts of streaming data at `din`. After an initial delay, the block produces non-continuous bursts of streaming data at `dout`.

The behavior of the control signals determines the timing mode of the block.

Continuous Data Streaming Timing

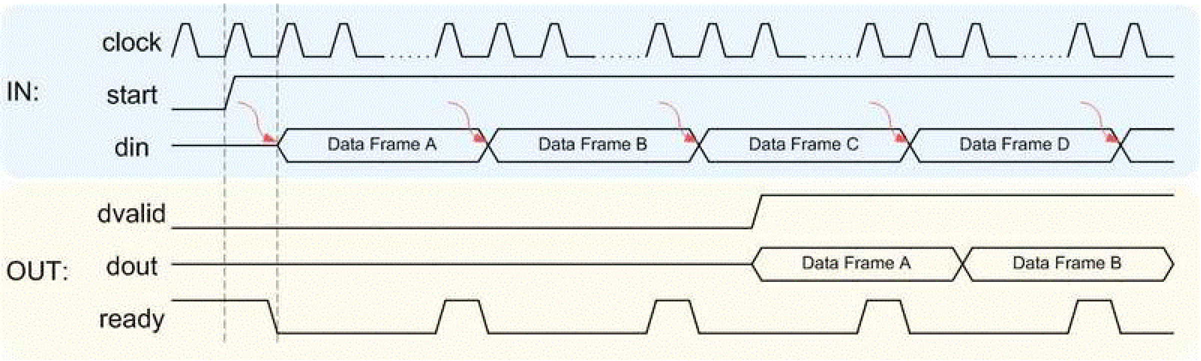
Assertion of the `start` signal (active high) triggers processing by the HDL Streaming FFT block. To initiate continuous data stream processing, assert the `start` signal in one of the following ways:

- Hold the start signal high (as shown in figure "Continuous Data Streaming With Start Signal Held High").
- Pulse the start signal every N clock cycles, where N is the FFT length (as shown in figure "Continuous Data Streaming With Pulsed Start Signal").

One clock cycle after the `start` trigger, the block begins to load data at `din`. After the first frame of streaming data, the block starts to receive the next frame of streaming data.

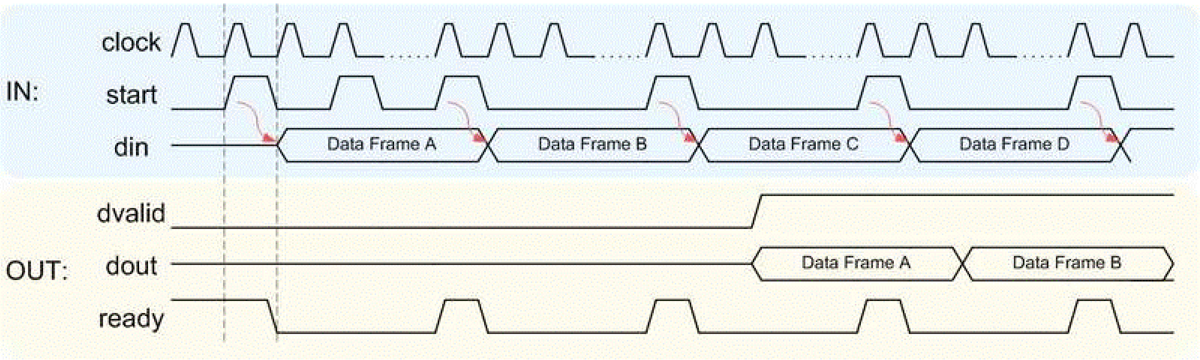
Meanwhile, the block performs the FFT calculation on the incoming data frames and outputs the results continuously at `dout`. The HDL Streaming FFT block asserts and deasserts the `ready` and `dvalid` signals automatically. The block asserts `dvalid` high whenever the output data stream is valid. The block asserts `ready` high to indicate that the block is ready to load a new data frame. When `ready` is low, the block ignores the `start` signal.

The following figures illustrate continuous data streaming. Each data frame corresponds to a stream of N input data values, where N is the FFT length.



Continuous Data Streaming With Start Signal Held High

Note: The `start` signal can be a single cycle pulse; it need not be held high for the entire data frame. When processing for a frame begins, further pulses on `start` do not affect processing of that frame. However, a start pulse must occur at the beginning of each data frame.



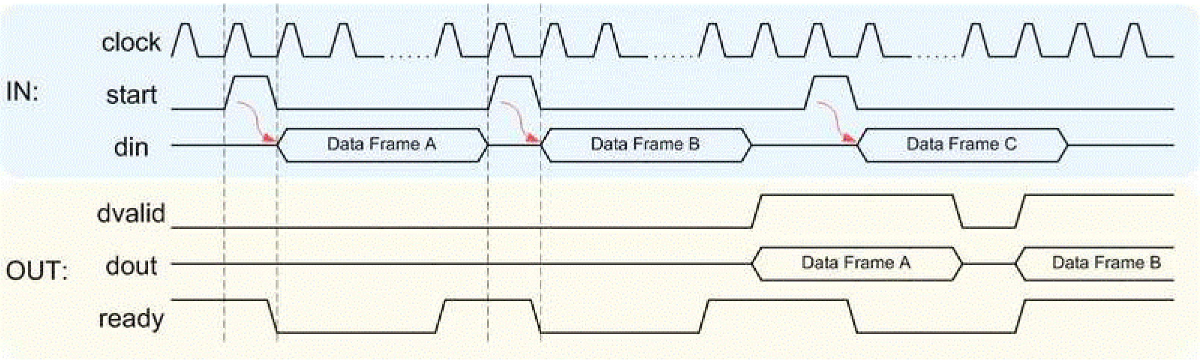
Continuous Data Streaming With Pulsed Start Signal

Non-Continuous Data Streaming Timing

In this mode, the HDL Streaming FFT block receives continuous bursts of streaming data at din. After an initial delay, the block produces non-continuous bursts of streaming data at dout. Breaks occur between data frames when the following condition exist:

- The start signal does not assert every N clock cycles (where N is the FFT length)
- The start signal is not continuously held high.

Non-continuous data streaming mode allows you more flexibility in determining the intervals between input data streams.

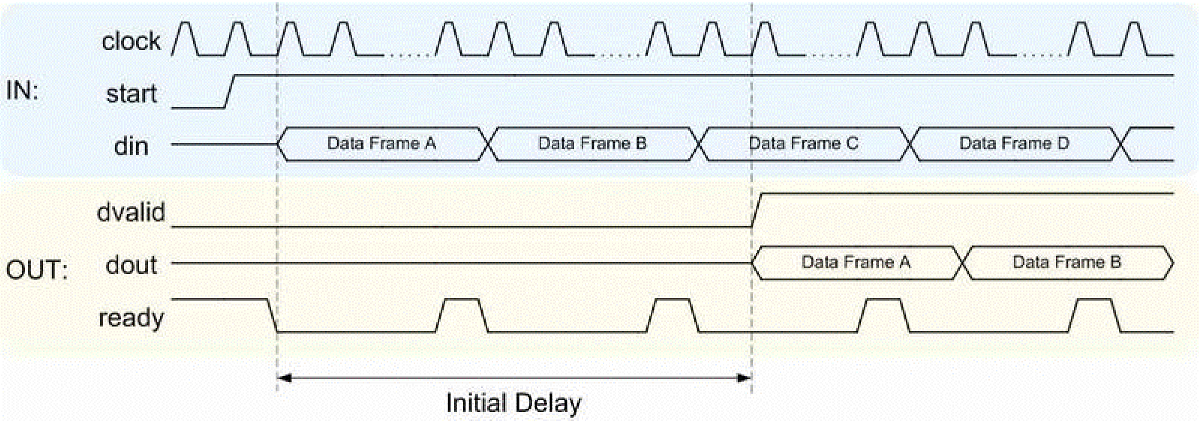


Initial Delay

The initial delay of the HDL Streaming FFT block is the interval between the following times:

- The time the block begins to receive the first frame of input data
- The time the block asserts `dvalid` and produces the first valid output data.

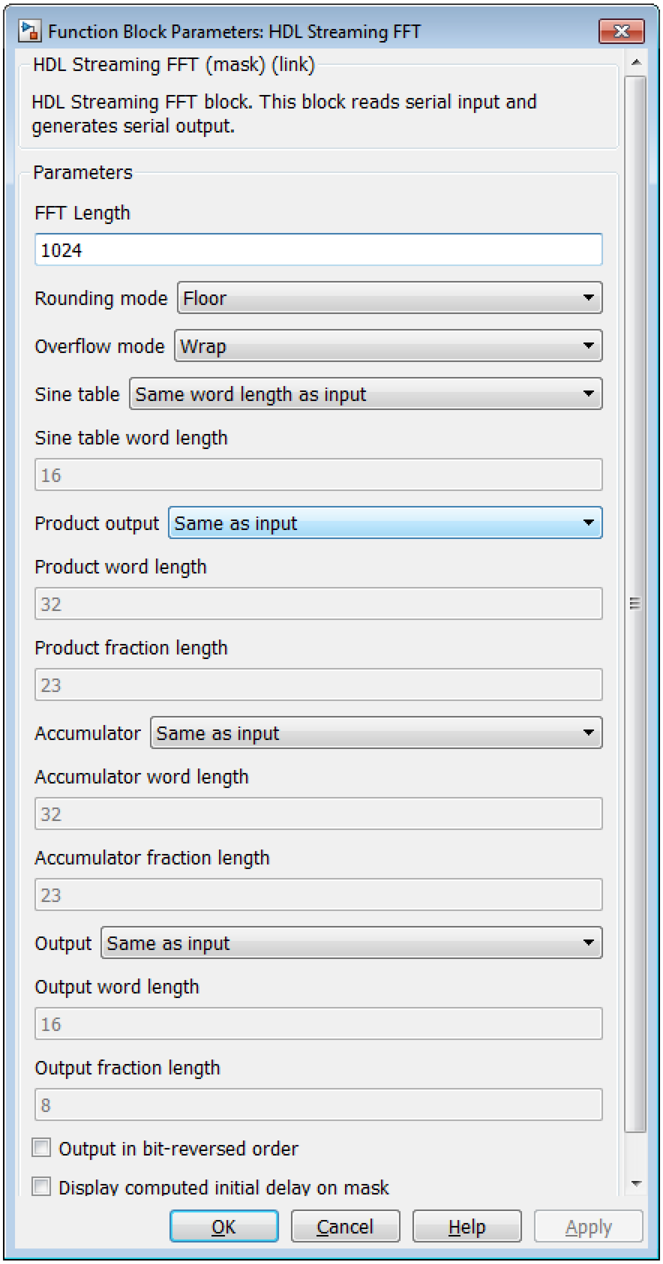
The initial delay represents the time the block uses to load a data frame, calculate the FFT, and output the beginning of the first output frame. The following figure illustrates the initial delay.



If you select the block option **Display computed initial delay on mask**, the block icon displays the initial delay. The display represents the delay time as Z^{-n}, where n is the delay time in samples.

Parameters and Dialog Box

The following figure shows the HDL Streaming FFT block dialog box, with parameters at their default settings.



Function Block Parameters: HDL Streaming FFT

HDL Streaming FFT (mask) (link)

HDL Streaming FFT block. This block reads serial input and generates serial output.

Parameters

FFT Length

1024

Rounding mode: Floor

Overflow mode: Wrap

Sine table: Same word length as input

Sine table word length

16

Product output: Same as input

Product word length

32

Product fraction length

23

Accumulator: Same as input

Accumulator word length

32

Accumulator fraction length

23

Output: Same as input

Output word length

16

Output fraction length

8

□ Output in bit-reversed order

□ Display computed initial delay on mask

FFT Length

Default: 1024

The FFT length must be a power of 2, in the range 2^3 to 2^{16}.

Rounding mode

Default: `Floor`

The HDL Streaming FFT block supports all rounding modes of the FFT block. See also the “FFT” block reference.

Overflow mode

Default: `Wrap`

The HDL Streaming FFT block supports all overflow modes of the FFT block. See also the “FFT” block reference.

Sine table

Default: `Same word length as input`

Choose how you specify the word length of the values of the sine table. The fraction length of the sine table values is equal to the word length minus one.

- When you select `Same word length as input`, the word lengths of the sine table values match the word lengths of the block inputs.
- When you select `Specify word length`, you can enter the word length of the sine table values, in bits, in the **Sine table word length** field. The sine table values do not obey the **Rounding mode** and **Overflow mode** parameters. They always saturate and round to `Nearest`.

Product output

Default: `Same as input`

Use this parameter to specify how you want to designate the product output word and fraction lengths:

- When you select `Same as input`, these characteristics match the characteristics of the input to the block.

- `Binary point scaling`: Enter the word length and the fraction length of the product output, in bits, in the **Product word length** and **Product fraction length** fields.

Accumulator

Default: `Same as input`

Use this parameter to specify how you want to designate the accumulator word and fraction lengths:

When you select `Same as product output`, these characteristics match the characteristics of the product output.

- When you select `Same as input`, these characteristics match the characteristics of the input to the block.
- `Binary point scaling`: Enter the word length and the fraction length of the accumulator, in bits, in the **Accumulator word length** and **Accumulator fraction length** fields.

Output

Default: `Same as input`

Choose how you specify the output word length and fraction length:

- `Same as input`: these characteristics match the characteristics of the input to the block.
- `Binary point scaling`: lets you enter the word length and fraction length of the output, in bits, in the **Output word length** and **Output fraction length** fields.

Output in bit-reversed order

Default: Off

- On: The output data stream is in bit-reversed order.
- Off: The output data stream is in natural order.

For more information about the effects of bit reversal, see “Linear and Bit-Reversed Output Order” in the documentation.

Display computed initial delay on mask

Default: Off

- On: The block icon displays the initial delay as Z^{-n}, where n is the delay time in samples.
- Off: The block icon does not display the initial delay.

Note: Sine table, **Product output**, **Accumulator**, and **Output** do not support:

- `Inherit via internal rule`
- `Slope and bias scaling`

FFT HDL Optimized

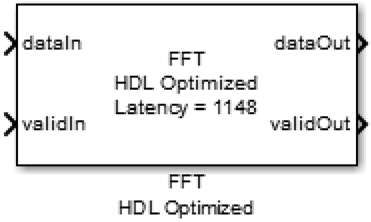
Fast Fourier transform—optimized for HDL code generation

Library

Transforms

`dspxfrm3`

Description



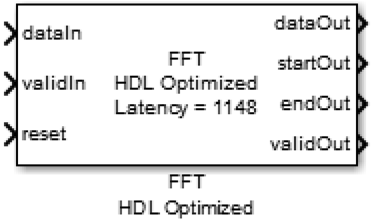
The FFT HDL Optimized block implements a pipelined Radix-2 FFT algorithm which provides hardware speed and area optimization for streaming data applications. The block accepts scalar real or complex input, provides hardware-friendly control signals, and has optional output frame control signals. Vector input is supported for simulation but not for HDL code generation.

This block provides an option to synthesize the lookup table to a ROM when using HDL Coder with an FPGA target. To enable this feature, right-click the block, select **HDL Code > HDL Block Properties** and set **LUTRegisterResetType** to `none`.

The FFT HDL Optimized block replaces the demo block HDL Streaming FFT.

Signal Attributes

The following image illustrates the port signals of the interface for the FFT HDL Optimized block.



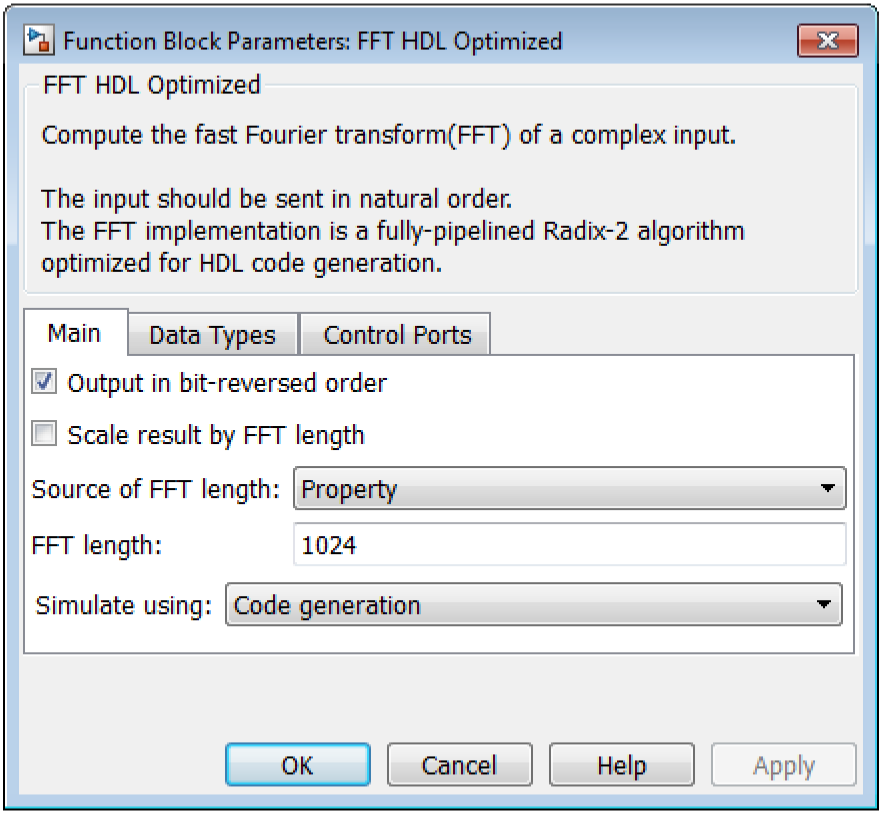
The following table provides the descriptions of the port signals.

Port	Direction	Description	Data Type
`dataIn`	Input	Scalar or column vector (FFT length x 1) real or complex input data. . If `dataIn` is a vector, all other ports must be vectors of matching size. Scalar input is required for HDL code generation.	• `fixdt()` • `int64/32/16/8` • `uint64/32/16/8` `double/single` are allowed for simulation but not for HDL code generation.
`validIn`	Input	Indicates that the input data is valid. When `validIn` is high, the block captures the value on `dataIn` . This port is optional for simulation, but required for HDL code generation.	`boolean`
`resetIn`	Input	Optional. Reset internal state. When `resetIn` is high, the block stops current calculation and clears all internal state. The block begins fresh calculations when `resetIn` is low and `validIn` starts a new frame.	`boolean`
`dataOut`	Output	Frequency channel output data. The data width and format is the same as the input data port. The output order is reversed by default.	Same as `dataIn`

Port	Direction	Description	Data Type
validOut	Output	Indicates that the output data is valid. The block sets validOut high when dataOut is ready.	boolean
startOut	Output	Optional. When enabled, the block sets startOut high during the first valid cycle of a frame of output data.	boolean
endOut	Output	Optional. When enabled, the block sets endOut high during the last valid cycle of a frame of output data.	boolean

Dialog Box and Parameters

Main



Function Block Parameters: FFT HDL Optimized

FFT HDL Optimized

Compute the fast Fourier transform(FFT) of a complex input.

The input should be sent in natural order.
The FFT implementation is a fully-pipelined Radix-2 algorithm optimized for HDL code generation.

☑ Output in bit-reversed order

□ Scale result by FFT length

Source of FFT length: Property

FFT length: 1024

Simulate using: Code generation

Output in bit-reversed order

When selected, the output elements are bit-reversed relative to the input order. When cleared, the output elements are in linear order. The default value is selected. The FFT algorithm calculates output in bit-reversed order and an extra reversal operation is done when providing linear output. For more information, see “Linear and Bit-Reversed Output Order”.

Scale result by FFT length

When selected, the FFT result is divided by the FFT length. The default value is not selected. This adjustment keeps the output of the FFT in the same amplitude range as its input. The block implements an overall 1/N scale factor by scaling the result of each pipeline stage by 2. Scaling at each stage avoids overflow.

Source of FFT length

Select the source of the FFT length. When you select `Property` , the FFT length is set by the `FFT length` field in the mask. If you use `Property` with vector input, the input vector width must be less than or equal to the FFT length. When you select `Auto`, the FFT length is inferred from the input vector data width. The `Auto` FFT length option is not supported for scalar input. The default is `Property`.

FFT length

Specify the number of data points used for one FFT calculation. This value is used when **Source of FFT length** is set to `Property`. The default value is 1024. The FFT length must be a power of 2 between 2^3 and 2^{16} for HDL code generation. If the input is a vector, the width must be less than or equal to the FFT Length.

Simulate using

Type of simulation to run. This parameter does not affect generated HDL code.

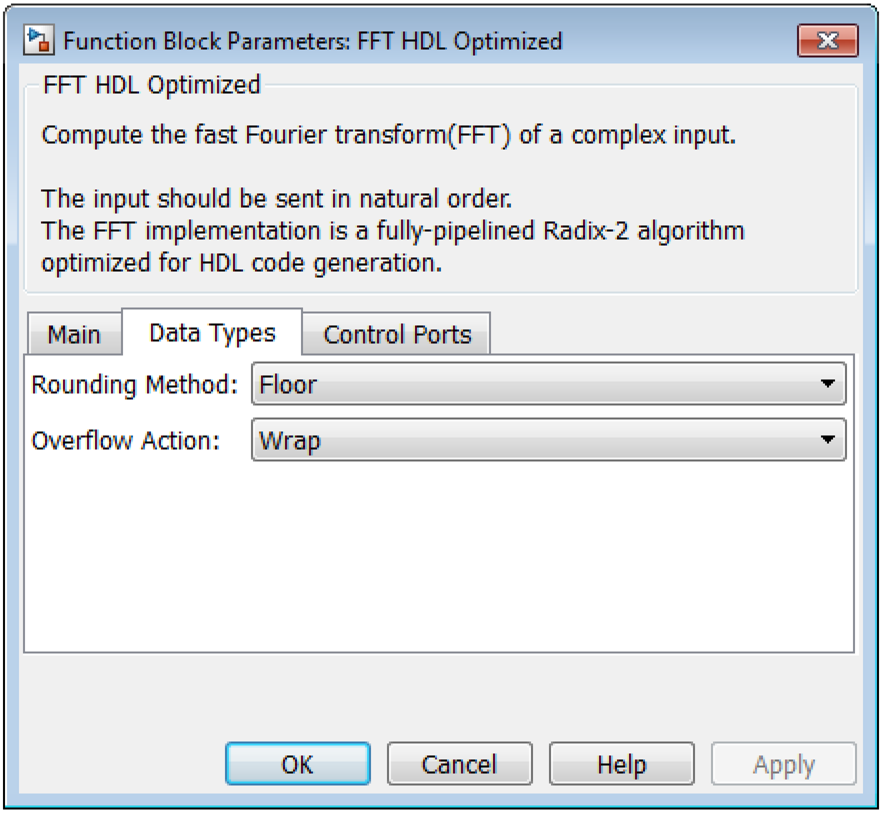
- `Code generation` (default)

  Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than `Interpreted execution`.

- `Interpreted execution`

  Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than `Code generation`.

Data Types



Function Block Parameters: FFT HDL Optimized

FFT HDL Optimized

Compute the fast Fourier transform(FFT) of a complex input.

The input should be sent in natural order.
The FFT implementation is a fully-pipelined Radix-2 algorithm
optimized for HDL code generation.

Rounding Method: Floor

Overflow Action: Wrap

These options specify how numerical type limitations are handled in fixed point calculations. The FFT block uses fixed point arithmetic for internal calculations when the input is any integer or fixed point data type. These options do not apply when the input is single or double type.

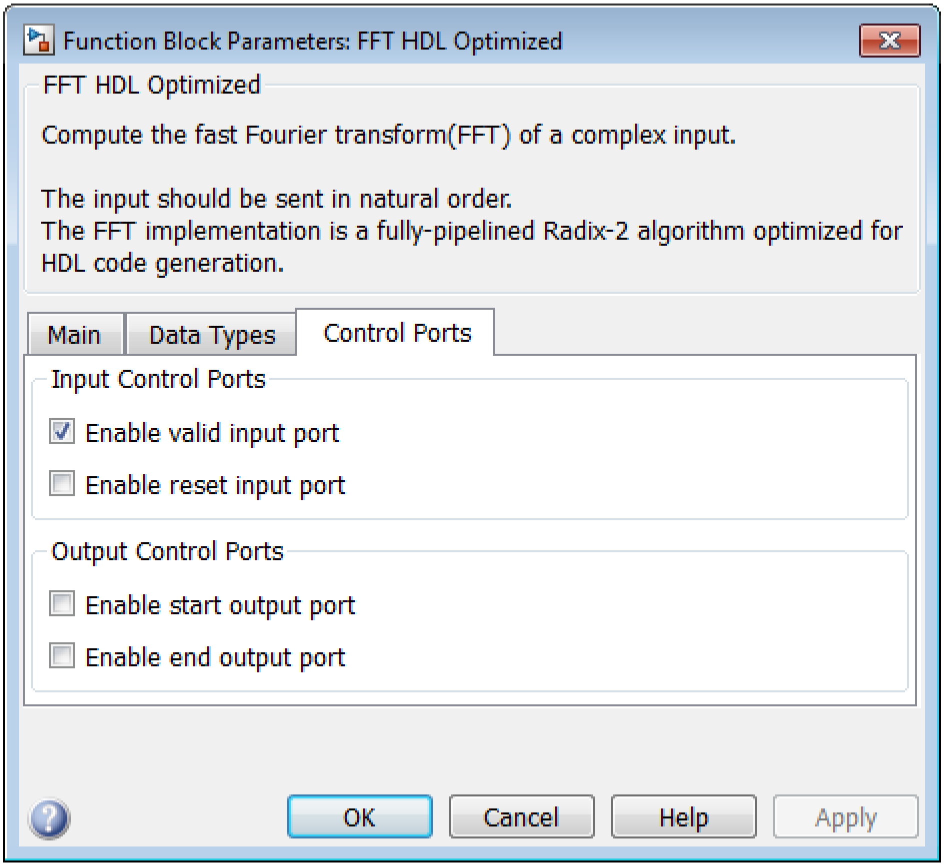
Rounding Method

The default “rounding method” for internal fixed point calculations is `Floor`.

Overflow Action

The default “overflow action” for internal fixed point calculations is `Wrap`.

Control Ports



Function Block Parameters: FFT HDL Optimized

FFT HDL Optimized

Compute the fast Fourier transform(FFT) of a complex input.

The input should be sent in natural order.
The FFT implementation is a fully-pipelined Radix-2 algorithm optimized for HDL code generation.

Input Control Ports

☑ Enable valid input port

□ Enable reset input port

Output Control Ports

□ Enable start output port

□ Enable end output port

Enable valid input port

When selected, the `validIn` port is present on the block icon and input data is qualified by the `validIn` signal. The default value is selected.

Enable reset input port

When selected, the `resetIn` port is present on the block icon. When `resetIn` is high, the block stops the current calculation and clears all internal state. The block begins fresh calculations when `resetIn` is low and `validIn` starts a new frame. The default value is not selected.

Enable start output port

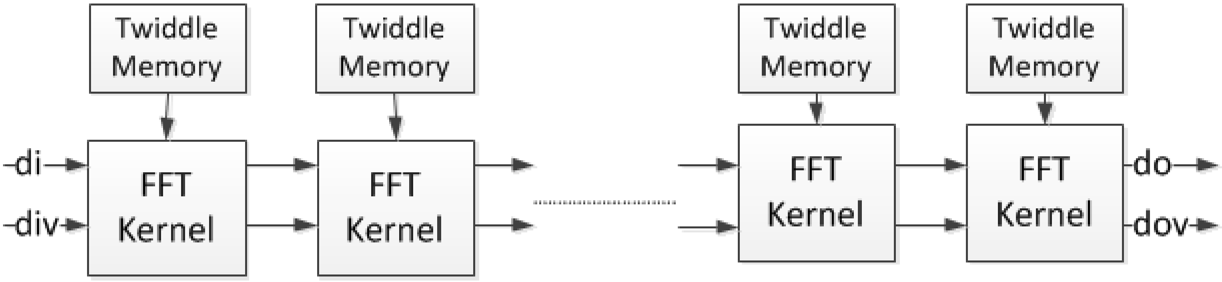
When selected, the `startOut` port is present on the block icon, and this output signal is asserted for the first cycle of an output frame. The default value is not selected.

Enable end output port

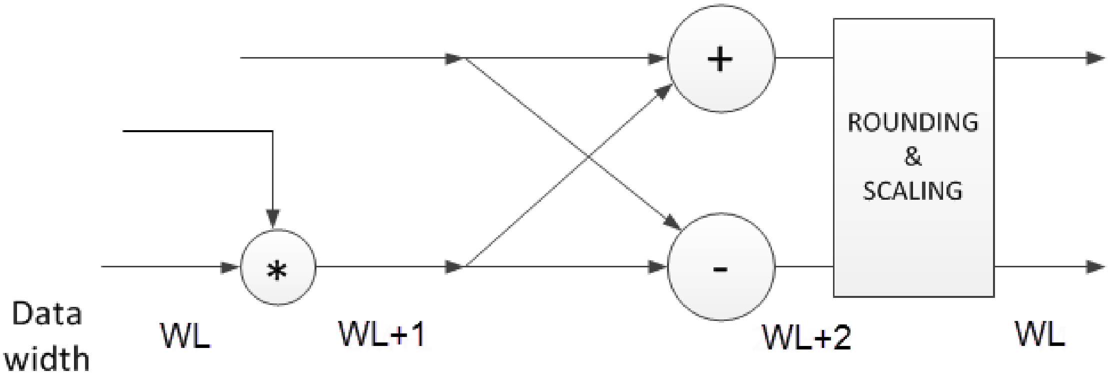
When selected, the `endOut` port is present on the block icon, and this output signal is asserted for the last cycle of an output frame. The default value is not selected.

Algorithm

The FFT HDL Optimized block implements a pipelined Radix–2 algorithm with decimation in time. This architecture is efficient for streaming input data. There are $\log_2(N)$ pipeline stages. Each pipeline stage, or kernel, contains memory, a controller, and a complex Radix-2 butterfly.



Using decimation in time, each kernel multiplies by the twiddle factor and then adds samples in a butterfly. The kernel architecture minimizes the number of multipliers and adders. Within each kernel, data is processed in full precision. The kernel rounds to the output data width after the butterfly sum. If you select **Scale result by FFT length**, the block scales the result of each pipeline stage by 2. Scaling at each stage avoids overflow, and results in a overall scale factor of 1/N. If scaling is disabled, the block can overflow and show a warning. You can avoid overflow by increasing the input word length by log2(N), where N is the FFT Length.



The twiddle factors have the same bit width as the input data. They use 2 integer bits and the remainder are fractional bits. Each butterfly multiplier is therefore WLxWL.

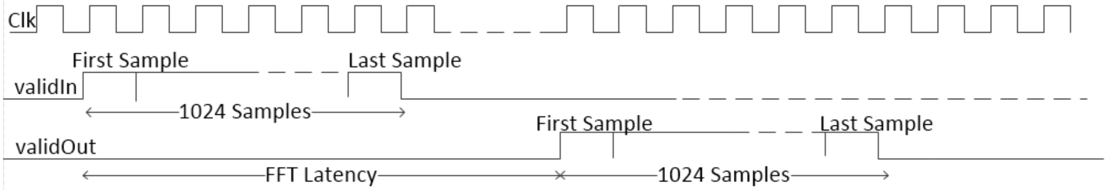
Control Signals

The `validIn` control signal is required for HDL code generation. It is optional for simulation. If you enable the `validIn` port, input data is processed only when `validIn` is high. Output data is valid when `validOut` is high.

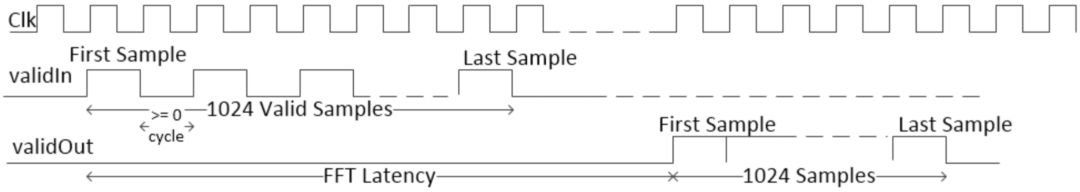
The block provides an optional reset port. When `resetIn` is high, the block stops the current calculation and clears all internal state. The block begins fresh calculations when `resetIn` is low and `validIn` starts a new frame.

Timing Diagram

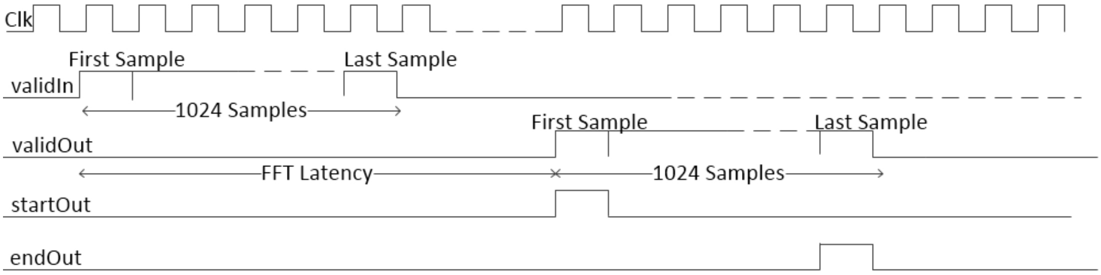
This diagram illustrates `validIn` and `validOut` signals for a FFT length of 1024.



The `validIn` signal can be noncontiguous. Data accompanied by a `validIn` is stored until a frame is filled, and output in a contiguous frame of N (FFT length) cycles. This diagram illustrates noncontiguous input and contiguous output for an FFT length of 1024.



There are optional `startOut` and `endOut` signals to indicate frame boundaries. If you enable `startOut`, it pulses for one cycle with the first `validOut` of the frame. If you enable `endOut`, it pulses for one cycle with the last `validOut` of the frame. This diagram illustrates the output framing signals for a FFT length of 1024.



Latency

The latency varies with the FFT length. If you set **Source of FFT length** to `Property`, the latency is displayed on the block icon. The displayed latency is the number of cycles between the first valid input and the first valid output, assuming the input is contiguous. The icon latency is updated when you change **FFT length**. If you set **Source of FFT length** to `Auto`, the latency is not displayed because the FFT length is not known until you compile the model.

HDL Code Generation

This block supports HDL code generation using HDL Coder. HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

For more information on implementations, properties, and restrictions for HDL code generation, see FFT HDL Optimized in the HDL Coder documentation.

Performance

When generated HDL code for the default configuration (FFT length 1024) with 16 bit input is synthesized into a Xilinx Virtex–6 (XC6VLX75T-1FF484) FPGA, the design achieves 295 MHz clock frequency. The latency is 1148 cycles. It uses the following resources.

Resource	Uses
LUT	4060
FFS	5160
Xilinx LogiCORE DSP48	16
Block RAM (16K)	6

Performance of the synthesized HDL code will vary with your target and synthesis options. For instance, natural order output uses more RAM than bit-reversed output, and real input uses less RAM than complex input.

□ Enable end output port

Enable valid input port

When selected, the `validIn` port is present on the block icon and input data is qualified by the `validIn` signal. The default value is selected.

Enable reset input port

When selected, the `resetIn` port is present on the block icon. When `resetIn` is high, the block stops the current calculation and clears all internal state. The block begins fresh calculations when `resetIn` is low and `validIn` starts a new frame. The default value is not selected.

Enable start output port

When selected, the startOut port is present on the block icon, and this output signal is asserted for the first cycle of an output frame. The default value is not selected.

Enable end output port

When selected, the endOut port is present on the block icon, and this output signal is asserted for the last cycle of an output frame. The default value is not selected.

Algorithm

The IFFT HDL Optimized block implements a pipelined Radix–2 algorithm with decimation in time. It implements the reverse function of the FFT HDL Optimized block. For more information, refer to the FFT HDL Optimized block page.

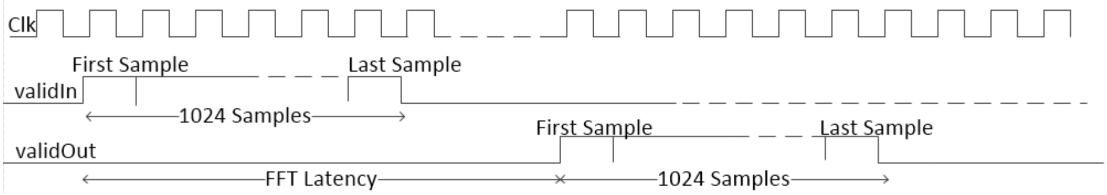
Control Signals

The validIn control signal is required for HDL code generation. It is optional for simulation. If enabled, input data is processed only when validIn is high. Output data is valid when validOut is high.

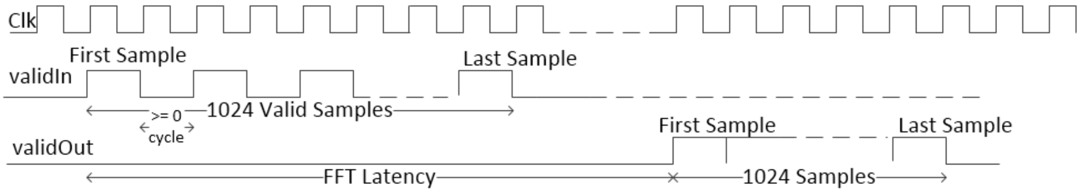
The block provides an optional reset port. When resetIn is high, the block stops the current calculation and clears all internal state. The block begins fresh calculations when resetIn is low and validIn starts a new frame.

Timing Diagram

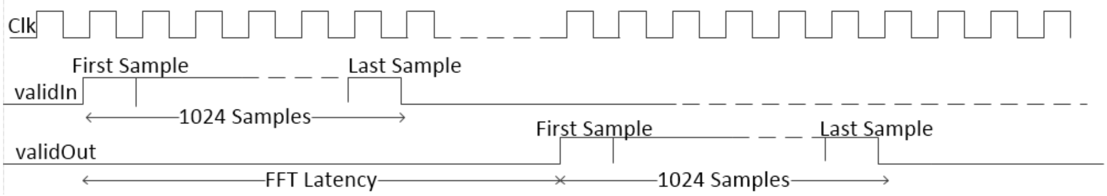
This diagram illustrates validIn and validOut signals for a FFT length of 1024.



The validIn signal can be noncontiguous. Data accompanied by a validIn is stored until a frame is filled, and output in a contiguous frame of N (FFT length) cycles. This diagram illustrates noncontiguous input and contiguous output for an FFT length of 1024.



There are optional `startOut` and `endOut` signals to indicate frame boundaries. If you enable `startOut`, it pulses for one cycle with the first `validOut` of the frame. If you enable `endOut`, it pulses for one cycle with the last `validOut` of the frame. This diagram illustrates the output framing signals for a FFT length of 1024.



Latency

The latency varies with the FFT length. If you set **Source of FFT length** to `Property`, the latency is displayed on the block icon. The displayed latency is the number of cycles between the first valid input and the first valid output, assuming the input is contiguous. The icon latency is updated when you change **FFT length**. If you set **Source of FFT length** to `Auto`, the latency is not displayed because the FFT length is not known until you compile the model.

HDL Code Generation

This block supports HDL code generation using HDL Coder. HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic. For more information on implementations, properties, and restrictions for HDL code generation, see IFFT HDL Optimized in the HDL Coder documentation.

Performance

When generated HDL code for the default configuration (FFT length 1024) with 16 bit input is synthesized into a Xilinx Virtex–6 (XC6VLX75T-1FF484) FPGA, the design achieves 295 MHz clock frequency. The latency is 1148 cycles. It uses the following resources.

Resource	Uses
LUT	4060
FFS	5160
Xilinx LogiCORE DSP48	16
Block RAM (16K)	6

Performance of the synthesized HDL code will vary with your target and synthesis options. For instance, natural order output uses more RAM than bit-reversed output, and real input uses less RAM than complex input.

Design method: Equiripple

▸ Design options

Filter Implementation

Structure: Direct-form FIR

□ Use basic elements to enable filter customization

Input processing: Columns as channels (frame based)

□ Use symbolic names for coefficients

View filter response

This button opens the Filter Visualization Tool (`fvtool`) from the Signal Processing Toolbox product. You can use the tool to display:

- Magnitude response, phase response, and group delay in the frequency domain.
- Impulse response and step response in the time domain.
- Pole-zero information.

The tool also helps you evaluate filter performance by providing information about filter order, stability, and phase linearity. For more information on FVTool, see the Signal Processing Toolbox documentation.

Filter Specifications

In this group, you specify your filter format, such as the impulse response and the filter order.

Impulse response

Select either `FIR` or `IIR` from the drop-down list. `FIR` is the default. When you choose an impulse response, the design methods and structures you can use to implement your filter change accordingly.

Note: The design methods and structures for FIR filters are not the same as the methods and structures for IIR filters.

Order mode

Select `Minimum` (the default) or `Specify`. Selecting `Specify` enables the **Order** option so you can enter the filter order. When you set the **Impulse response** to `IIR`, you can specify different numerator and denominator orders. To specify a different denominator order, you must select the **Denominator order** check box.

Order

Enter the filter order. This option is enabled only if you set the **Order mode** to `Specify`.

Denominator order

Select this check box to specify a different denominator order. This option is enabled only if you set the **Impulse response** to `IIR` and the **Order mode** to `Specify`.

Filter type

Select `Single-rate`, `Decimator`, `Interpolator`, or `Sample-rate converter`. Your choice determines the type of filter as well as the design methods and structures that are available to implement your filter. By default, the block specifies a single-rate filter.

- Selecting `Decimator` or `Interpolator` activates the **Decimation Factor** or the **Interpolation Factor** options respectively.
- Selecting `Sample-rate converter` activates both factors.

Decimation Factor

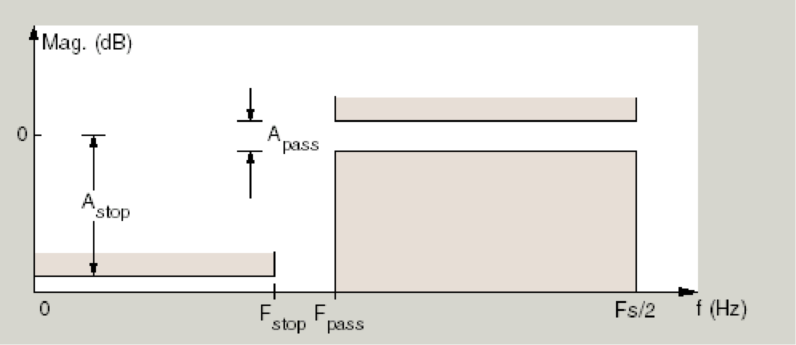
Enter the decimation factor. This option is enabled only if the **Filter type** is set to `Decimator` or `Sample-rate converter`. The default value is 2.

Interpolation Factor

Enter the interpolation factor. This option is enabled only if the **Filter type** is set to `Interpolator` or `Sample-rate converter`. The default value is 2.

Frequency Specifications

The parameters in this group allow you to specify your filter response curve. Graphically, the filter specifications look similar to those shown in the following figure.



In the figure, the region between specification values Fstop and Fpass represents the transition region where the filter response is not constrained.

Frequency constraints

When **Order mode** is `Specify`, select the filter features that the block uses to define the frequency response characteristics. The list contains the following options, when available for the filter specifications.

- `Stopband edge and passband edge` — Define the filter by specifying the frequencies for the edges for the stop- and passbands.
- `Passband edge` — Define the filter by specifying the edge of the passband.
- `Stopband edge` — Define the filter by specifying the edge of the stopband.
- `Stopband edge and 3 dB point` — For IIR filters, define the filter by specifying the frequency of the 3 dB point in the filter response and the edge of the stopband.
- `3 dB point` — Define the filter response by specifying the location of the 3 dB point. The 3 dB point is the frequency for the point three decibels below the passband value.
- `3 dB point and passband edge` — For IIR filters, define the filter by specifying the frequency of the 3 dB point in the filter response and the edge of the passband.
- `6 dB point` — For FIR filters, define the filter response by specifying the location of the 6 dB point. The 6 dB point is the frequency for the point six decibels below the passband value.

Frequency units

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select `Normalized (0–1)` to enter frequencies in normalized form. This behavior is the default. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—`Hz`, `kHz`, `MHz`, or `GHz`. Selecting one of the unit options enables the **Input Fs** parameter.

Input Fs

Fs, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available when you select one of the frequency options from the **Frequency units** list.

Fstop

Enter the frequency at the edge of the end of the stopband. Specify the value in either normalized frequency units or the absolute units you select in **Frequency units**.

Fpass

Enter the frequency at the edge of the start of the passband. Specify the value in either normalized frequency units or the absolute units you select in **Frequency units**.

F3dB

When **Frequency constraints** is `3 dB point`, `Stopband edge and 3 dB point`, or `3 dB point and passband edge`, specify the frequency of the 3 dB point. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

F6dB

When **Frequency constraints** is `6 dB point`, specify the frequency of the 6 dB point. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

Magnitude Specifications

Parameters in this group specify the filter response in the passbands and stopbands.

Magnitude constraints

This option is only available when you specify the order of your filter design. Depending on the setting of the **Frequency constraints** parameter, some combination of the following options will be available for the **Magnitude constraints** parameter: `Unconstrained`, `Passband ripple`, `Passband ripple and stopband attenuation` or `Stopband attenuation`.

Magnitude units

Specify the units for any parameter you provide in magnitude specifications. From the drop-down list, select one of the following options:

- `Linear` — Specify the magnitude in linear units.
- `dB` — Specify the magnitude in decibels (default).
- `Squared` — Specify the magnitude in squared units.

Astop

Enter the filter attenuation in the stopband in the units you choose for **Magnitude units**, either linear or decibels.

Apass

Enter the filter ripple allowed in the passband in the units you choose for **Magnitude units**, either linear or decibels.

Algorithm

The parameters in this group allow you to specify the design method and structure of your filter.

Design Method

Lists the design methods available for the frequency and magnitude specifications you entered. When you change the specifications for a filter, such as changing the impulse response, the methods available to design filters changes as well. The default IIR design method is usually Butterworth, and the default FIR method is `Equiripple`.

Scale SOS filter coefficients to reduce chance of overflow

Selecting this parameter directs the design to scale the filter coefficients to reduce the chances that the inputs or calculations in the filter overflow and exceed the representable range of the filter. Clearing this option removes the scaling. This parameter applies only to IIR filters.

Design Options

The options for each design are specific for each design method. This section does not present all of the available options for all designs and design methods. There are many more that you encounter as you select different design methods and filter specifications. The following options represent some of the most common ones available.

Density factor

Density factor controls the density of the frequency grid over which the design method optimization evaluates your filter response function. The number of equally spaced points in the grid is the value you enter for **Density factor** times (filter order + 1).

Increasing the value creates a filter that more closely approximates an ideal equiripple filter but increases the time required to design the filter. The default value of 20 represents a reasonable trade between the accurate approximation to the ideal filter and the time to design the filter.

Phase constraint

Specify the phase constraint of the filter as `Linear`, `Maximum`, or `Minimum`.

Minimum order

When you select this parameter, the design method determines and design the minimum order filter to meet your specifications. Some filters do not provide this parameter. Select Any, Even, or Odd from the drop-down list to direct the design to be any minimum order, or minimum even order, or minimum odd order.

Match Exactly

Specifies that the resulting filter design matches either the passband or stopband or both bands when you select passband or stopband or both from the drop-down list.

Stopband Shape

Stopband shape lets you specify how the stopband changes with increasing frequency. Choose one of the following options:

- Flat — Specifies that the stopband is flat. The attenuation does not change as the frequency increases.
- Linear — Specifies that the stopband attenuation changes linearly as the frequency increases. Change the slope of the stopband by setting **Stopband decay**.
- 1/f — Specifies that the stopband attenuation changes exponentially as the frequency increases, where f is the frequency. Set the power (exponent) for the decay in **Stopband decay**.

Stopband Decay

When you set Stopband shape, Stopband decay specifies the amount of decay applied to the stopband. the following conditions apply to Stopband decay based on the value of Stopband Shape:

- When you set **Stopband shape** to Flat, **Stopband decay** has no affect on the stopband.
- When you set **Stopband shape** to Linear, enter the slope of the stopband in units of dB/rad/s. filterbuilder applies that slope to the stopband.
- When you set **Stopband shape** to 1/f, enter a value for the exponent *n* in the relation $(1/f)^n$ to define the stopband decay. filterbuilder applies the $(1/f)^n$ relation to the stopband to result in an exponentially decreasing stopband attenuation.

Filter Implementation

Structure

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. By default, FIR filters use direct-form structure, and IIR filters use direct-form II filters with SOS.

Use basic elements to enable filter customization

Select this check box to implement the filter as a subsystem of basic Simulink blocks. Clear the check box to implement the filter as a high-level subsystem. By default, this check box is cleared.

The high-level implementation provides better compatibility across various filter structures, especially filters that would contain algebraic loops when constructed using basic elements. On the other hand, using basic elements enables the following optimization parameters:

- **Optimize for zero gains** — Terminate chains that contain Gain blocks with a gain of zero.
- **Optimize for unit gains** — Remove Gain blocks that scale by a factor of one.
- **Optimize for delay chains** — Substitute delay chains made up of *n* unit delays with a single delay by *n*.
- **Optimize for negative gains** — Use subtraction in Sum blocks instead of negative gains in Gain blocks.

Optimize for unit-scale values

Select this check box to scale unit gains between sections in SOS filters. This parameter is available only for SOS filters.

Input processing

Specify how the block should process the input. The available options may vary depending on he settings of the **Filter Structure** and **Use basic elements for filter customization** parameters. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` — When you select this option, the block treats each column of the input as a separate channel.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

Note: The `Inherited (this choice will be removed — see release notes)` option will be removed in a future release. See “Frame-Based Processing” in the *DSP System Toolbox Release Notes* for more information.

Rate options

When the **Filter type** parameter specifies a multirate filter, select the rate processing rule for the block from following options:

- `Enforce single-rate processing` — When you select this option, the block maintains the sample rate of the input.
- `Allow multirate processing` — When you select this option, the block adjusts the rate at the output to accommodate an increased or reduced number of samples. To select this option, you must set the **Input processing** parameter to `Elements as channels (sample based)`.

Use symbolic names for coefficients

Select this check box to enable the specification of coefficients using MATLAB variables. The available coefficient names differ depending on the filter structure. Using symbolic names allows tuning of filter coefficients in generated code. By default, this check box is cleared.

View filter response

This button opens the Filter Visualization Tool (`fvtool`) from the Signal Processing Toolbox product. You can use the tool to display:

- Magnitude response, phase response, and group delay in the frequency domain.
- Impulse response and step response in the time domain.
- Pole-zero information.

The tool also helps you evaluate filter performance by providing information about filter order, stability, and phase linearity. For more information on FVTool, see the Signal Processing Toolbox documentation.

Filter Specifications

In this group, you specify your filter format, such as the impulse response and the filter order.

Impulse response

Select either `FIR` or `IIR` from the drop-down list. `FIR` is the default. When you choose an impulse response, the design methods and structures you can use to implement your filter change accordingly.

Note: The design methods and structures for FIR filters are not the same as the methods and structures for IIR filters.

Filter order mode

Select either `Minimum` (the default) or `Specify` from the drop-down list. Selecting `Specify` enables the **Order** option (see the following sections) so you can enter the filter order.

Filter type

Select `Single-rate`, `Decimator`, `Interpolator`, or `Sample-rate converter`. Your choice determines the type of filter as well as the design methods and structures that are available to implement your filter. By default, the block specifies a single-rate filter.

- Selecting `Decimator` or `Interpolator` activates the **Decimation Factor** or the **Interpolation Factor** options respectively.

- Selecting `Sample-rate converter` activates both factors.

Order

Enter the filter order. This option is enabled only if `Specify` was selected for **Filter order mode**.

Decimation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to `Decimator` or `Sample-rate converter`. The default value is 2.

Interpolation Factor

Enter the interpolation factor. This option is enabled only if the **Filter type** is set to `Interpolator` or `Sample-rate converter`. The default value is 2.

Frequency Specifications

The parameters in this group allow you to specify your filter response curve.

Frequency units

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select `Normalized (0–1)` to enter frequencies in normalized form. This behavior is the default. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—`Hz`, `kHz`, `MHz`, or `GHz`. Selecting one of the unit options enables the **Input Fs** parameter.

Input Fs

Fs, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available when you select one of the frequency options from the **Frequency units** list.

Transition width

Specify the width of the transitions at the ends of the passband. Specify the value in normalized frequency units or the absolute units you select in **Frequency units**.

Magnitude Specifications

Parameters in this group specify the filter response in the passbands and stopbands.

Magnitude units

Specify the units for any parameter you provide in magnitude specifications. From the drop-down list, select one of the following options:

- `Linear` — Specify the magnitude in linear units.
- `dB` — Specify the magnitude in decibels (default)
- `Squared` — Specify the magnitude in squared units.

Apass

Enter the filter ripple allowed in the passband in the units you choose for **Magnitude units**, either linear or decibels.

Algorithm

The parameters in this group allow you to specify the design method and structure of your filter.

Design Method

Lists the design methods available for the frequency and magnitude specifications you entered. When you change the specifications for a filter, such as changing the impulse response, the methods available to design filters changes as well. The default FIR method is `Equiripple`.

Design Options

The options for each design are specific for each design method. This section does not present all of the available options for all designs and design methods. There are many more that you encounter as you select different design methods and filter specifications. The following options represent some of the most common ones available.

Density factor

Density factor controls the density of the frequency grid over which the design method optimization evaluates your filter response function. The number of equally spaced points in the grid is the value you enter for **Density factor** times (filter order + 1).

Increasing the value creates a filter that more closely approximates an ideal equiripple filter but increases the time required to design the filter. The default value of 20 represents a reasonable trade between the accurate approximation to the ideal filter and the time to design the filter.

FIR Type

Specify whether to design a type 3 or a type 4 FIR filter. The filter type is defined as follows:

- Type 3 — FIR filter with even order antisymmetric coefficients
- Type 4 — FIR filter with odd order antisymmetric coefficients

Select either `3` or `4` from the drop-down list.

Filter Implementation

Structure

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. By default, FIR filters use `Direct-form FIR`, and IIR filters use `Cascade minimum-multiplier allpass`.

Use basic elements to enable filter customization

Select this check box to implement the filter as a subsystem of basic Simulink blocks. Clear the check box to implement the filter as a high-level subsystem. By default, this check box is cleared.

The high-level implementation provides better compatibility across various filter structures, especially filters that would contain algebraic loops when constructed using basic elements. On the other hand, using basic elements enables the following optimization parameters:

- **Optimize for zero gains** — Terminate chains that contain Gain blocks with a gain of zero.
- **Optimize for unit gains** — Remove Gain blocks that scale by a factor of one.
- **Optimize for delay chains** — Substitute delay chains made up of *n* unit delays with a single delay by *n*.
- **Optimize for negative gains** — Use subtraction in Sum blocks instead of negative gains in Gain blocks.

Input processing

Specify how the block should process the input. The available options may vary depending on he settings of the **Filter Structure** and **Use basic elements for filter customization** parameters. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` — When you select this option, the block treats each column of the input as a separate channel.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

Note: The `Inherited (this choice will be removed — see release notes)` option will be removed in a future release. See “Frame-Based Processing” in the *DSP System Toolbox Release Notes* for more information.

Rate options

When the **Filter type** parameter specifies a multirate filter, select the rate processing rule for the block from following options:

- `Enforce single-rate processing` — When you select this option, the block maintains the sample rate of the input.
- `Allow multirate processing` — When you select this option, the block adjusts the rate at the output to accommodate an increased or reduced number of samples. To select this option, you must set the **Input processing** parameter to `Elements as channels (sample based)`.

Use symbolic names for coefficients

Select this check box to enable the specification of coefficients using MATLAB variables. The available coefficient names differ depending on the filter structure. Using symbolic names allows tuning of filter coefficients in generated code. By default, this check box is cleared.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point
Output	• Double-precision floating point • Single-precision floating point

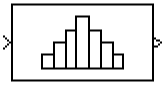
Histogram

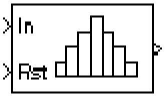
Generate histogram of input or sequence of inputs

Library

Statistics

`dspstat3`





Description

The Histogram block computes the frequency distribution of the elements in the input. You must use the **Find the histogram over** parameter to specify whether the block computes the histogram for `Each column` of the input or of the `Entire input`. The **Running histogram** check box allows you to select between basic operation and running operation, as described below.

The block distributes the elements of the input into the number of discrete bins specified by the **Number of bins** parameter, `n`.

```
y = hist(u,n)     % Equivalent MATLAB code
```

The Histogram block sorts all complex input values into bins according to their magnitude.

The histogram value for a given bin represents the frequency of occurrence of the input values bracketed by that bin. You specify the upper boundary of the highest-valued bin in the **Upper limit of histogram** parameter, B_M, and the lower boundary of the lowest-valued bin in the **Lower limit of histogram** parameter, B_m. The bins have equal width of

$$\Delta = \frac{B_M - B_m}{n}$$

and centers located at

$$B_m + \left(k + \frac{1}{2}\right)\Delta \qquad k = 0,1,2,\ldots,n-1$$

Input values that fall on the border between two bins are placed into the lower valued bin; that is, each bin includes its upper boundary. For example, a bin of width 4 centered on the value 5 contains the input value 7, but not the input value 3. Input values greater than the **Upper limit of histogram** parameter or less than **Lower limit of histogram** parameter are placed into the highest valued or lowest valued bin, respectively.

The values you enter for the **Upper limit of histogram** and **Lower limit of histogram** parameters must be real-valued scalars. `NaN` and `inf` are not valid values for the **Upper limit of histogram** and **Lower limit of histogram** parameters.

Basic Operation

When the **Running histogram** check box is not selected, the Histogram block computes the frequency distribution of the current input.

When you set the **Find the histogram over** parameter to `Each column`, the Histogram block computes a histogram for each column of the *M*-by-*N* matrix independently. The block outputs an *n*-by-*N* matrix, where *n* is the **Number of bins** you specify. The *j*th column of the output matrix contains the histogram for the data in the *j*th column of the *M*-by-*N* input matrix.

When you set the **Find the histogram over** parameter to `Entire input`, the Histogram block computes the frequency distribution for the entire input vector, matrix or N-D array. The block outputs an *n*-by-1 vector, where *n* is the **Number of bins** you specify.

Running Operation

When you select the **Running histogram** check box, the Histogram block computes the frequency distribution of both the past and present data for successive inputs. The block resets the histogram (by emptying all of the bins) when it detects a reset event at the optional Rst port. See "Resetting the Running Histogram" on page 1-722 for more information on how to trigger a reset.

When you set the **Find the histogram over** parameter to `Each column`, the Histogram block computes a running histogram for each column of the *M*-by-*N* matrix. The block outputs an *n*-by-*N* matrix, where *n* is the **Number of bins** you specify. The *j*th column of the output matrix contains the running histogram for the *j*th column of the *M*-by-*N* input matrix.

When you set the **Find the histogram over** parameter to `Entire input`, the Histogram block computes a running histogram for the data in the first dimension of the input. The block outputs an *n*-by-1 vector, where *n* is the **Number of bins** you specify.

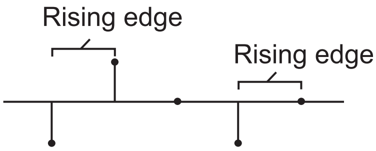
Note: When the Histogram block is used in running mode and the input data type is non-floating point, the output of the histogram is stored as a `uint32` data type. The largest number that can be represented by this data type is $2^{32}-1$. If the range of the `uint32` data type is exceeded, the output data will wrap back to 0.

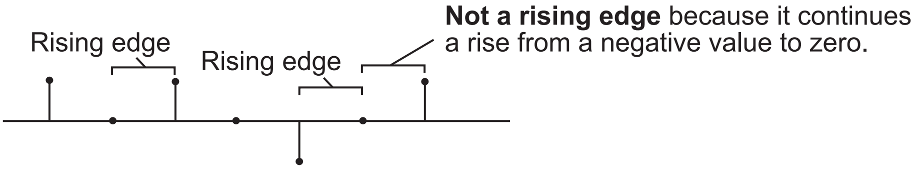
Resetting the Running Histogram

The block resets the running histogram whenever a reset event is detected at the optional Rst port. The reset signal and the input data signal must be the same rate.

You specify the reset event using the **Reset port** menu:

- `None` — Disables the Rst port
- `Rising edge` — Triggers a reset operation when the Rst input does one of the following:
  - Rises from a negative value to a positive value or zero
  - Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero (see the following figure)

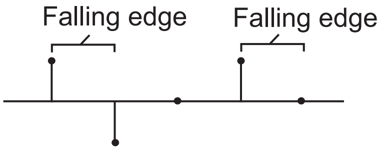


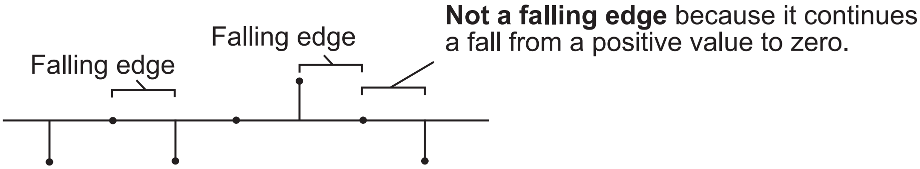


Not a rising edge because it continues a rise from a negative value to zero.
Rising edge
Rising edge

- `Falling edge` — Triggers a reset operation when the `Rst` input does one of the following:

  - Falls from a positive value to a negative value or zero
  - Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero (see the following figure)





Not a falling edge because it continues a fall from a positive value to zero.
Falling edge
Falling edge

- `Either edge` — Triggers a reset operation when the `Rst` input is a `Rising edge` or `Falling edge` (as described earlier)
- `Non-zero sample` — Triggers a reset operation at each sample time that the `Rst` input is not zero

Examples

Real Input Data

The bin boundaries created by the Histogram block are determined by the data type of the input:

- Bin boundaries for real, double-precision input are cast into the data type `double`.
- Bin boundaries for real, fixed-point input are cast into the `int8` data type.

The following example shows the differences in the output of the Histogram block based on the data type of the input.

To create this model you need the following blocks.

Block	Library	Quantity
Constant	Simulink /Sources library	2
Display	Sinks	2
Histogram	Statistics	2

The parameter settings for the Double Precision Input Constant block are:

- **Constant value** = `double([1 2 3 4 5]')`
- **Interpret vector parameters as 1-D** = Clear this check box.
- **Sampling mode** = `Sample based`
- **Sample time** = `inf`

The parameter settings for the Fixed-Point Input Constant block are:

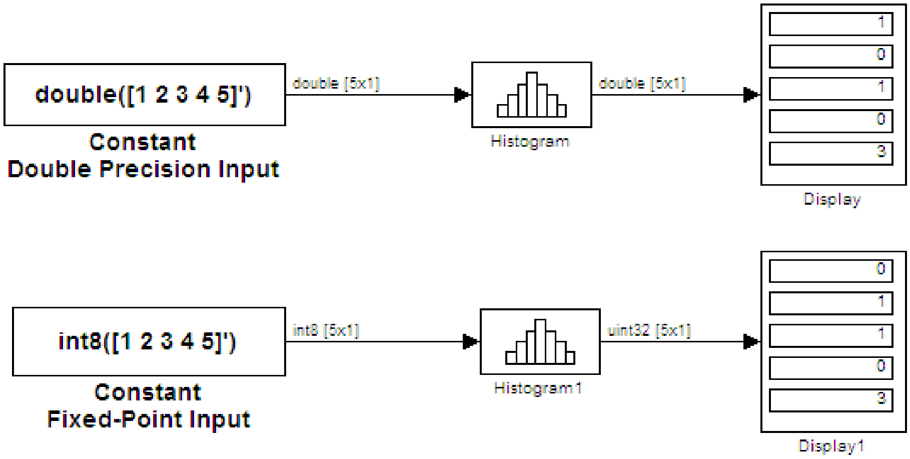
- **Constant value** = `int8([1 2 3 4 5]')`
- **Interpret vector parameters as 1-D** = Clear this check box.
- **Sampling mode** = `Sample based`
- **Sample time** = `inf`

The parameter settings for both Histogram blocks are:

- **Lower limit of histogram** = 1
- **Upper limit of histogram** = 3

- **Number of bins** = 5
- **Find the histogram over** = `Entire input`
- **Normalized** = Clear this check box.
- **Running histogram** = Clear this check box.

Connect the blocks as shown in the following figure, and run your model.



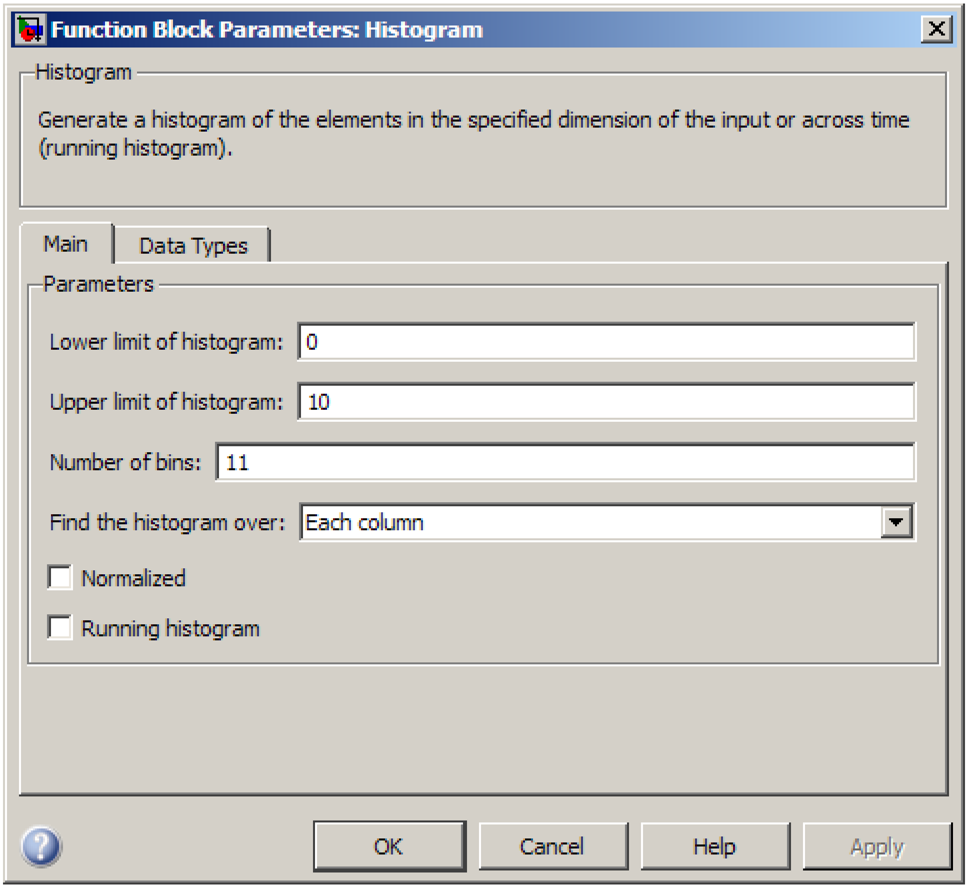
Running the fixed-point model generates the following warning:

```
Warning: The bin width resulting from the specified parameters is
less than the precision of the input data type. This might cause
unexpected results. Since bin width is calculated by ((upper limit
- lower limit)/number of bins), you could increase upper limit or
decrease lower limit or number of bins.
```

This warning alerts you that it is not a good use case to have a histogram where 2 or more bin boundaries are the same. As the warning suggests, increasing the range of the limits of the histogram, or decreasing the number of bins, can correct this problem.

Dialog Box

The **Main** pane of the Histogram block dialog appears as follows.



Function Block Parameters: Histogram

Histogram

Generate a histogram of the elements in the specified dimension of the input or across time (running histogram).

Parameters

Lower limit of histogram: 0

Upper limit of histogram: 10

□ Running histogram

Lower limit of histogram

Enter a real-valued scalar for the lower boundary, B_m, of the lowest-valued bin. `NaN` and `inf` are not valid values for B_m. “Tunable”.

Upper limit of histogram

Enter a real-valued scalar for the upper boundary, B_M, of the highest-valued bin. `NaN` and `inf` are not valid values for B_M. “Tunable”.

Number of bins

The number of bins, n, in the histogram.

Find the histogram over

Specify whether the block finds the histogram over the entire input or along each column of the input.

Note: The `Inherited (this choice will be removed - see release notes)` option will be removed in a future release.

Normalized

When selected, the output vector, *v*, is normalized such that `sum(v) = 1`.

Use of this parameter is not supported for fixed-point signals.

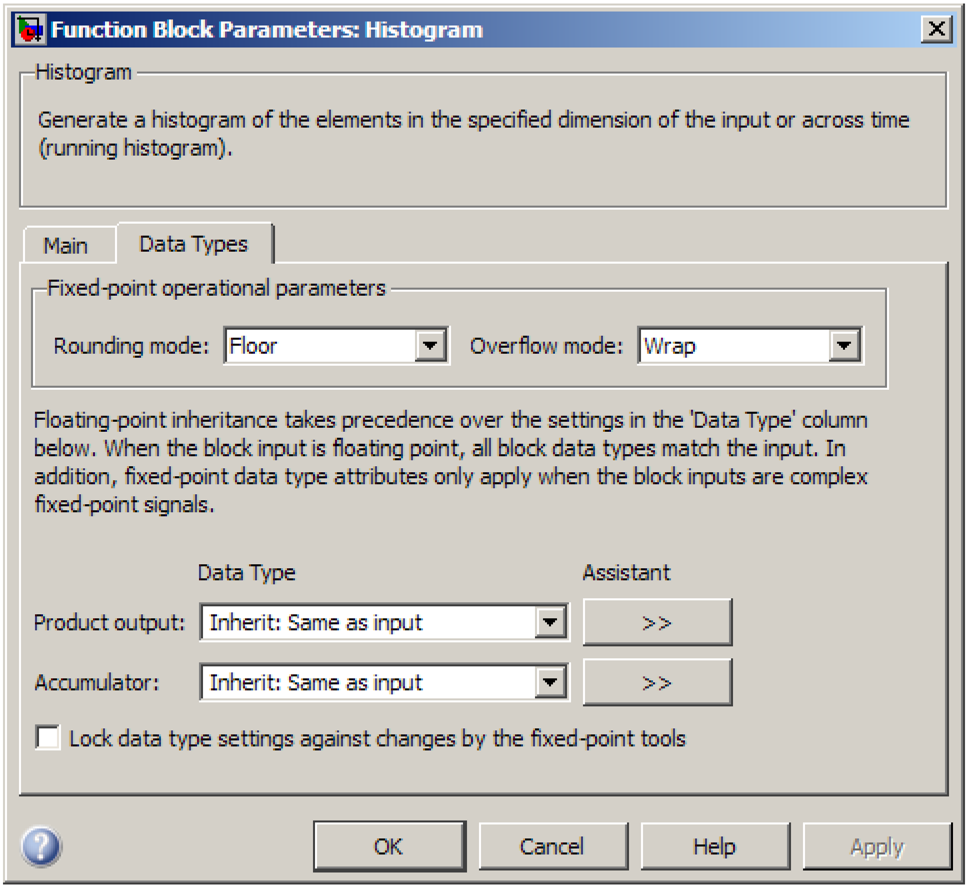
Running histogram

Set to enable the running histogram operation, and clear to enable basic histogram operation. For more information, see “Basic Operation” on page 1-721 and “Running Operation” on page 1-721.

Reset port

The type of event that resets the running histogram. For more information, see “Resetting the Running Histogram” on page 1-722. The reset signal and the input data signal must be the same rate. This parameter is enabled only when you select the **Running histogram** check box. For more information, see “Running Operation” on page 1-721.

The **Data Types** pane of the Histogram block dialog appears as follows.



Function Block Parameters: Histogram

Histogram

Generate a histogram of the elements in the specified dimension of the input or across time (running histogram).

Fixed-point operational parameters

Rounding mode: Floor

Overflow mode: Wrap

Floating-point inheritance takes precedence over the settings in the 'Data Type' column below. When the block input is floating point, all block data types match the input. In addition, fixed-point data type attributes only apply when the block inputs are complex fixed-point signals.

	Data Type	Assistant
Product output:	Inherit: Same as input	>>
Accumulator:	Inherit: Same as input	>>

□ Lock data type settings against changes by the fixed-point tools

Note: The fixed-point parameters listed are only used for fixed-point complex inputs, which are distributed by squared magnitude.

Rounding mode

Select the "rounding mode" for fixed-point operations.

Overflow mode

Select the "overflow mode" for fixed-point operations.

Product output data type

Specify the product output data type. See “Multiplication Data Types” for illustrations depicting the use of the product output data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`
- An expression that evaluates to a valid data type, for example, `fixdt([],16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Product output data type** parameter.

See “Specify Data Types Using Data Type Assistant” in “Simulink User's Guide” for more information.

Accumulator data type

Specify the accumulator data type. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`
- An expression that evaluates to a valid data type, for example, `fixdt([],16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Accumulator data type** parameter.

See “Specify Data Types Using Data Type Assistant” in “Simulink User's Guide” for more information.

Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

Supported Data Types

Port	Supported Data Types
In	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers

Port	Supported Data Types
Output	• Double-precision floating point • Single-precision floating point • 32-bit unsigned integers
Rst	• Double-precision floating point • Single-precision floating point • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers

IDCT

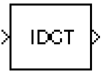
Inverse discrete cosine transform (IDCT) of input

Library

Transforms

`dspxfrm3`

Description



The IDCT block computes the inverse discrete cosine transform (IDCT) of each channel in the M-by-N input matrix, `u`.

```
y = idct(u)     % Equivalent MATLAB code
```

When the input is a sample-based row vector, the IDCT block computes the inverse discrete cosine transform across the vector dimension of the input. For all other N-D input arrays, the block computes the IDCT across the first dimension. The size of the first dimension (frame size), must be a power of two. To work with other frame sizes, use the Pad block to pad or truncate the frame size to a power-of-two length.

When the input is an M-by-N matrix, the block treats each input column as an independent channel containing M consecutive samples. The block outputs an M-by-N matrix whose lth column contains the length-M IDCT of the corresponding input column.

$$y(m,l) = \sum_{k=1}^{M} w(k)u(k,l)\cos\frac{\pi(2m-1)(k-1)}{2M}, \qquad m = 1,\ldots,M$$

where

$$w(k) = \begin{cases} \dfrac{1}{\sqrt{M}}, & k = 1 \\ \sqrt{\dfrac{2}{M}}, & 2 \le k \le M \end{cases}$$

The **Output sampling mode** parameter allows you to select the sampling mode of the output. If the input is an N-D array with 3 or more dimensions, the **Output sampling mode** must be `Sample based`. The output sample rate and data type (real/complex) are the same as those of the input.

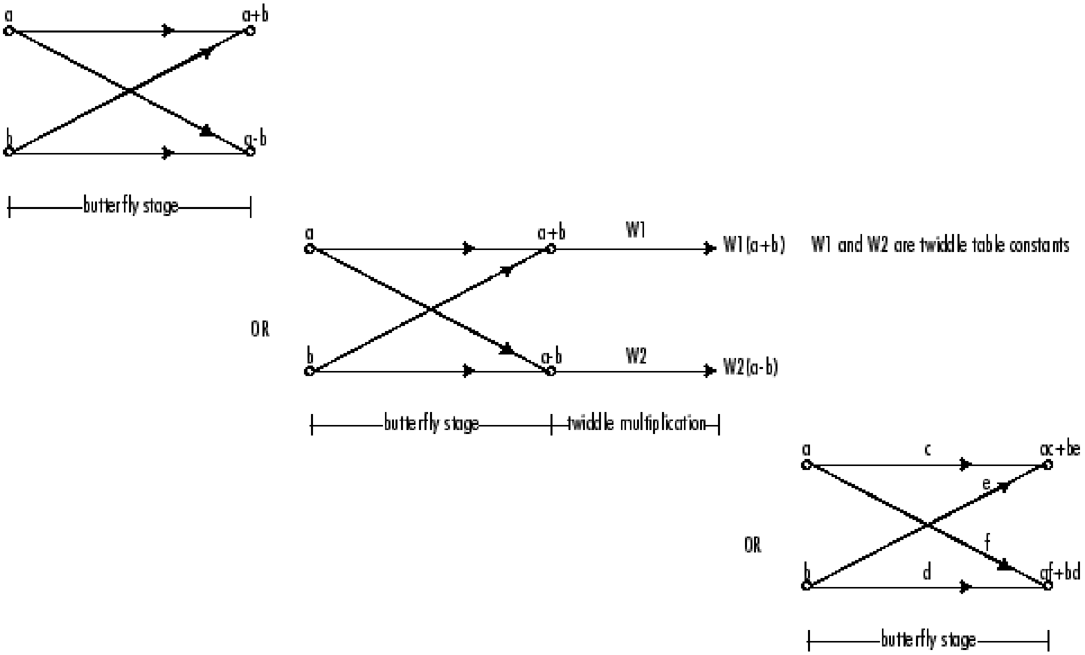
The **Sine and cosine computation** parameter determines how the block computes the necessary sine and cosine values. This parameter has two settings, each with its advantages and disadvantages, as described in the following table.

Sine and Cosine Computation Parameter Setting	Sine and Cosine Computation Method	Effect on Block Performance
`Table lookup`	The block computes and stores the trigonometric values before the simulation starts, and retrieves them during the simulation. When you generate code from the block, the processor running the generated code stores the trigonometric values computed by the block in a speed-optimized table, and retrieves the values during code execution.	The block usually runs much more quickly, but requires extra memory for storing the precomputed trigonometric values.
`Trigonometric fcn`	The block computes sine and cosine values during the simulation. When you generate code from the block, the processor running the generated code computes the sine and cosine values while the code runs.	The block usually runs more slowly, but does not need extra data memory. For code generation, the block requires a support library to emulate the trigonometric functions, increasing the size of the generated code.

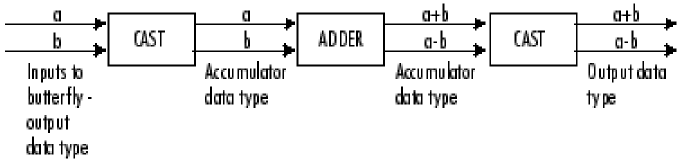
Fixed-Point Data Types

The following diagrams show the data types used within the IDCT block for fixed-point signals. You can set the sine table, accumulator, product output, and output data types displayed in the diagrams in the IDCT block dialog as discussed in “Dialog Box” on page 1-734.

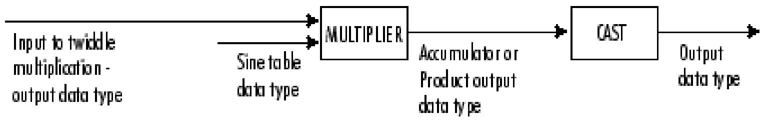
Inputs to the IDCT block are first cast to the output data type and stored in the output buffer. Each butterfly stage processes signals in the accumulator data type, with the final output of the butterfly being cast back into the output data type.



Butterfly Stage Data Types



Twiddle Multiplication Data Types



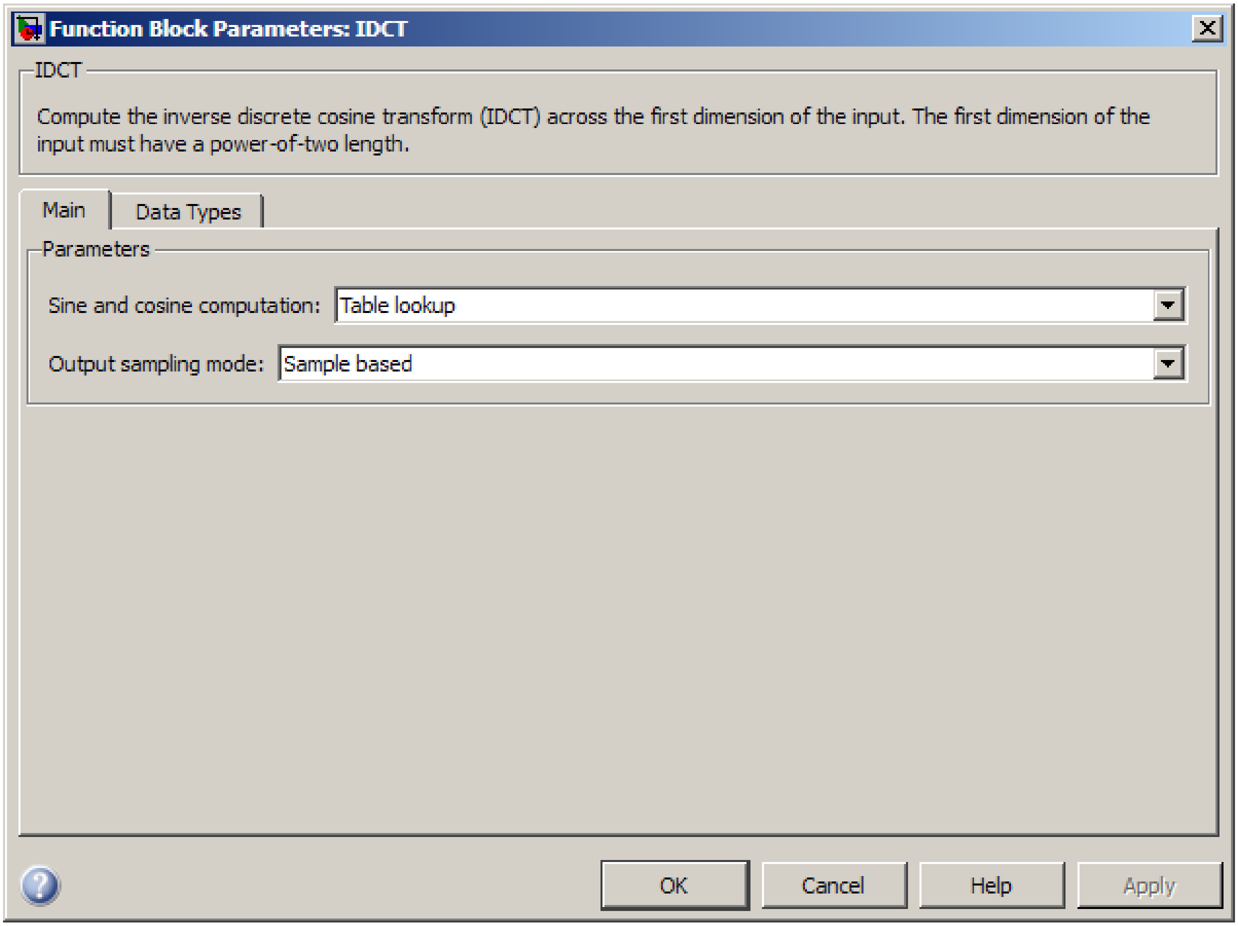
Input to twiddle multiplication - output data type
Sine table data type
MULTIPLIER
Accumulator or Product output data type
CAST
Output data type

The output of the multiplier is in the product output data type when at least one of the inputs to the multiplier is real. When both of the inputs to the multiplier are complex, the result of the multiplication is in the accumulator data type. For details on the complex multiplication performed, see “Multiplication Data Types”.

Note: When the block input is fixed point, all internal data types are signed fixed point.

Dialog Box

The **Main** pane of the IDCT block dialog appears as follows.



Function Block Parameters: IDCT

IDCT

Compute the inverse discrete cosine transform (IDCT) across the first dimension of the input. The first dimension of the input must have a power-of-two length.

Parameters

Sine and cosine computation: Table lookup

Output sampling mode: Sample based

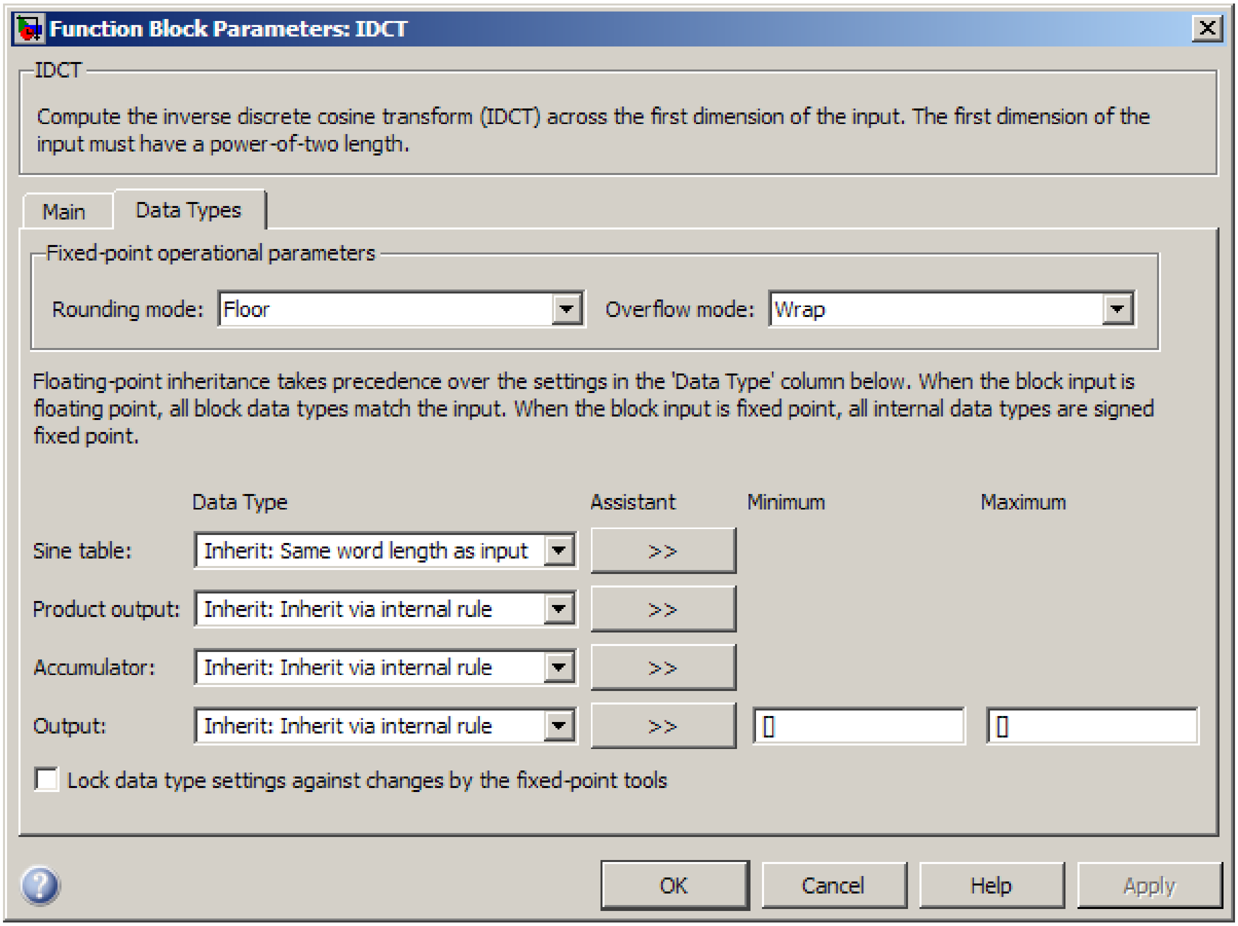
Sine and cosine computation

Sets the block to compute sines and cosines by either looking up sine and cosine values in a speed-optimized table (`Table lookup`), or by making sine and cosine function calls (`Trigonometric fcn`). See the table in the “Description ” section.

Output sampling mode

Select `Sample based` or `Frame based` output. If the input to the IDCT block has 3 or more dimensions, you must select `Sample based` output.

The **Data Types** pane of the IDCT block dialog appears as follows.



Function Block Parameters: IDCT

IDCT

Compute the inverse discrete cosine transform (IDCT) across the first dimension of the input. The first dimension of the input must have a power-of-two length.

Fixed-point operational parameters

Rounding mode: Floor

Overflow mode: Wrap

Floating-point inheritance takes precedence over the settings in the 'Data Type' column below. When the block input is floating point, all block data types match the input. When the block input is fixed point, all internal data types are signed fixed point.

	Data Type	Assistant	Minimum	Maximum
Sine table:	Inherit: Same word length as input	>>		
Product output:	Inherit: Inherit via internal rule	>>		
Accumulator:	Inherit: Inherit via internal rule	>>		
Output:	Inherit: Inherit via internal rule	>>	[]	[]

□ Lock data type settings against changes by the fixed-point tools

Rounding mode

Select the “rounding mode” for fixed-point operations. The sine table values do not obey this parameter; they always round to `Nearest`.

Overflow mode

Select the “overflow mode” for fixed-point operations. The sine table values do not obey this parameter; instead, they are always saturated.

Sine table data type

Choose how you specify the word length of the values of the sine table. The fraction length of the sine table values always equals the word length minus one. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Same word length as input`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16)`

The sine table values do not obey the **Rounding mode** and **Overflow mode** parameters; instead, they are always saturated and rounded to `Nearest`.

Product output data type

Specify the product output data type. See “Fixed-Point Data Types” on page 1-732 and “Multiplication Data Types” for illustrations depicting the use of the product output data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Product output data type** parameter.

See “Specify Data Types Using Data Type Assistant” in “Simulink User's Guide” for more information.

Accumulator data type

Specify the accumulator data type. See “Fixed-Point Data Types” on page 1-732 for illustrations depicting the use of the accumulator data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`

- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Accumulator data type** parameter.

See “Specify Data Types Using Data Type Assistant” in “Simulink User's Guide” for more information.

Output data type

Specify the output data type. See “Fixed-Point Data Types” on page 1-732 for illustrations depicting the use of the output data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`.

  When you select `Inherit: Inherit via internal rule`, the block calculates the output word length and fraction length automatically. The internal rule first calculates an ideal output word length and fraction length using the following equations:

$$WL_{ideal\ output} = WL_{input} + floor(\log_2(DCT\ length - 1)) + 1$$

$$FL_{ideal\ output} = FL_{input}$$

  Using these ideal results, the internal rule then selects word lengths and fraction lengths that are appropriate for your hardware. For more information, see “Inherit via Internal Rule”.
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Specify Block Output Data Types” in “Simulink User's Guide” for more information.

Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Output	• Double-precision floating point • Single-precision floating point • Fixed point (signed only) • 8-, 16-, and 32-bit signed integers

Identity Matrix

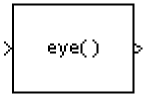
Generate matrix with ones on main diagonal and zeros elsewhere

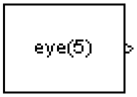
Library

- Sources

  `dspsrcs4`
- Math Functions / Matrices and Linear Algebra / Matrix Operations

  `dspmtrx3`





Description

The Identity Matrix block generates a rectangular matrix with ones on the main diagonal and zeros elsewhere.

When you select the **Inherit output port attributes from input port** check box, the input port is enabled, and an *M*-by-*N* matrix input generates an *M*-by-*N* matrix output with the same sample period as the input. The values in the input matrix are ignored.

```
y = eye([M N])      % Equivalent MATLAB code
```

When you do not select the **Inherit output port attributes from input port** check box, the input port is disabled, and the dimensions of the output matrix are determined by the **Matrix size** parameter. A scalar value, *M*, specifies an *M*-by-*M* identity matrix, while a two-element vector, [*M N*], specifies an *M*-by-*N* unit-diagonal matrix. You can specify the output sample period using the **Sample time** parameter.

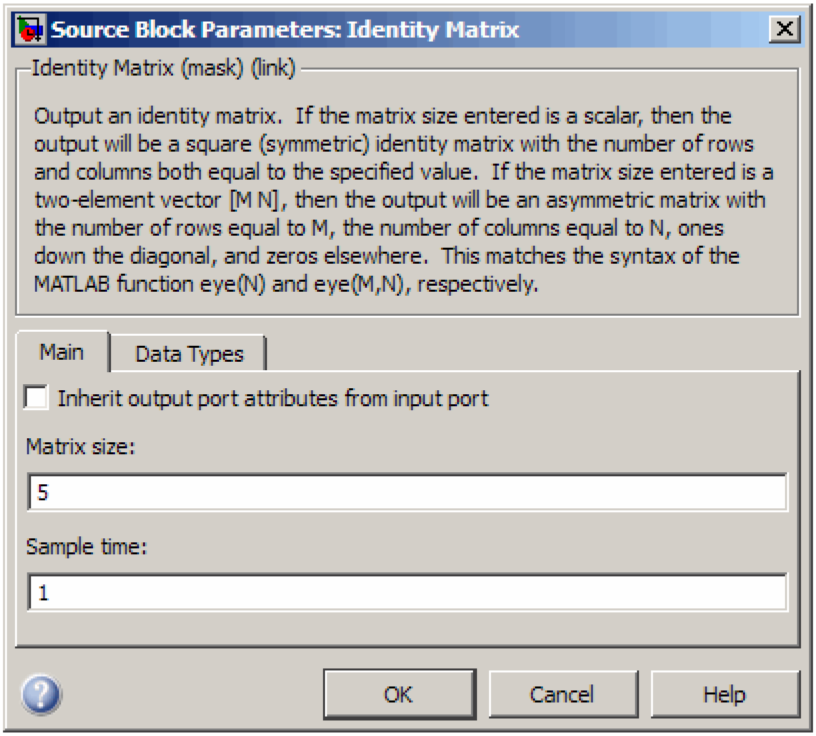
Examples

Set **Matrix size** to `[3 6]` to generate the 3-by-6 unit-diagonal matrix below.

$$\begin{bmatrix} 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 \end{bmatrix}$$

Dialog Box

The **Main** pane of the Identity Matrix block dialog appears as follows.



Source Block Parameters: Identity Matrix

Identity Matrix (mask) (link)

Output an identity matrix. If the matrix size entered is a scalar, then the output will be a square (symmetric) identity matrix with the number of rows and columns both equal to the specified value. If the matrix size entered is a two-element vector [M N], then the output will be an asymmetric matrix with the number of rows equal to M, the number of columns equal to N, ones down the diagonal, and zeros elsewhere. This matches the syntax of the MATLAB function eye(N) and eye(M,N), respectively.

□ Inherit output port attributes from input port

Matrix size: 5

Sample time: 1

Inherit output port attributes from input port

Enables the input port when selected. In this mode, the output inherits its dimensions, sample period, and data type from the input. The output is always real.

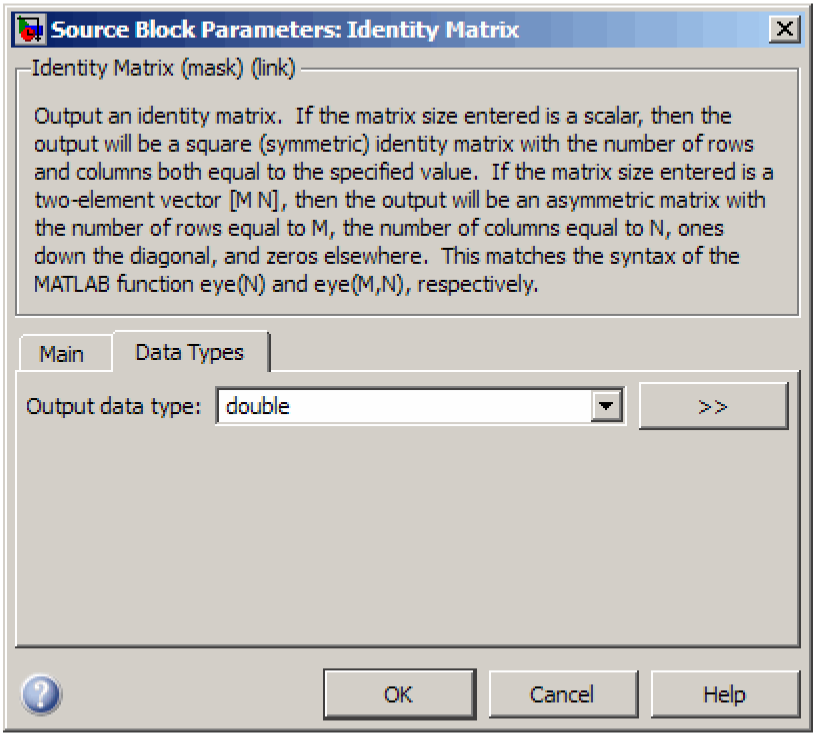
Matrix size

The number of rows and columns in the output matrix: a scalar *M* for a square *M*-by-*M* output, or a vector [*M N*] for an *M*-by-*N* output. This parameter is disabled when you select **Inherit input port attributes from input port**.

Sample time

The discrete sample period of the output. This parameter is disabled when you select **Inherit input port attributes from input port**.

The **Data Types** pane of the Identity Matrix block dialog appears as follows.



Source Block Parameters: Identity Matrix

Identity Matrix (mask) (link)

Output an identity matrix. If the matrix size entered is a scalar, then the output will be a square (symmetric) identity matrix with the number of rows and columns both equal to the specified value. If the matrix size entered is a two-element vector [M N], then the output will be an asymmetric matrix with the number of rows equal to M, the number of columns equal to N, ones down the diagonal, and zeros elsewhere. This matches the syntax of the MATLAB function eye(N) and eye(M,N), respectively.

Output data type: double

Output data type

Specify the output data type for this block. You can select one of the following:

- A rule that inherits a data type, for example, `Inherit: Inherit via back propagation`. When you select this option, the output data type and scaling matches that of the next downstream block.

- A built in data type, such as `double`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Specify Block Output Data Types” in “Simulink User's Guide” for more information.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point • Fixed point • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Output	• Double-precision floating point • Single-precision floating point • Fixed point • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers

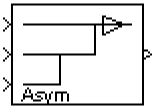
IDWT

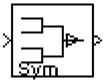
Inverse discrete wavelet transform (IDWT) of input or reconstruct signals from subbands with smaller bandwidths and slower sample rates

Library

Transforms

`dspxfrm3`





Description

The IDWT block is the same as the Dyadic Synthesis Filter Bank block in the Multirate Filters library, but with different default settings. See the Dyadic Synthesis Filter Bank block reference page for more information on how to use the block.

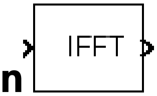
IFFT

Inverse fast Fourier transform (IFFT) of input

Library

Transforms

`dspxfrm3`



Description

The IFFT block computes the inverse fast Fourier transform (IFFT) of each row of a sample-based 1-by-*P* input vector, or across the first dimension (*P*) of an *N-D* input array.

When you specify an FFT length not equal to the length of the input vector, (or first dimension of the input array), the block implements zero-padding, truncating, or modulo-*M*, (FFT length) data wrapping. This occurs before the IFFT operation, as per Orfanidis [1].

```
y = ifft(u,M)  % P # M
```

Wrapping:

```
y(:,l) = ifft(datawrap(u(:,l),M))  % P > M; l = 1,...,N
```

Truncating:

```
y (:,l) = ifft(u,M)     % P > M; l = 1,...,N
```

When the input length, *P*, is greater than the FFT length, *M*, you may see magnitude increases in your IFFT output. These magnitude increases occur because the IFFT block uses modulo-*M* data wrapping to preserve all available input samples.

To avoid such magnitude increases, you can truncate the length of your input sample, *P*, to the FFT length, *M*. To do so, place a Pad block before the IFFT block in your model.

The *k*th entry of the *l*th output channel, *y*(*k*, *l*), is equal to the *k*th point of the *M*-point inverse discrete Fourier transform (IDFT) of the *l*th input channel:

$$y(k,l) = \frac{1}{M}\sum_{p=1}^{P} u(p,l)e^{j2\pi(p-1)(k-1)/M} \qquad k = 1,\ldots,M$$

The output of this block has the same dimensions as the input. If the input signal has a floating-point data type, the data type of the output signal uses the same floating-point data type. Otherwise, the output can be any fixed-point data type. The block computes scaled and unscaled versions of the IFFT.

The input to this block can be floating-point or fixed-point, real or complex, and conjugate symmetric. The block uses one of two possible FFT implementations. You can select an implementation based on the FFTW library [1], [2], or an implementation based on a collection of Radix-2 algorithms. You can select `Auto` to allow the block to choose the implementation.

FFTW Implementation

The FFTW implementation provides an optimized FFT calculation including support for power-of-two and non-power-of-two transform lengths in both simulation and code generation. Generated code using the FFTW implementation will be restricted to MATLAB host computers. The data type must be floating-point. Refer to Simulink Coder for more details on generating code.

Radix-2 Implementation

The Radix-2 implementation supports bit-reversed processing, fixed or floating-point data, and allows the block to provide portable C-code generation using the Simulink Coder. The dimension M of the M-by-N input matrix, must be a power of two. To work with other input sizes, use the Pad block to pad or truncate these dimensions to powers of two, or if possible choose the FFTW implementation.

With Radix-2 selected, the block implements one or more of the following algorithms:

- Butterfly operation
- Double-signal algorithm
- Half-length algorithm
- Radix-2 decimation-in-time (DIT) algorithm
- Radix-2 decimation-in-frequency (DIF) algorithm

Radix-2 Algorithms for Real or Complex Input Complexity

Parameter Settings	Algorithms Used for IFFT Computation
 ☐ Input is in bit-reversed order ☐ Input is conjugate symmetric	Bit-reversal operation and radix-2 DIT
 ☑ Input is in bit-reversed order ☐ Input is conjugate symmetric	Radix-2 DIT
 ☐ Input is in bit-reversed order ☑ Input is conjugate symmetric	Bit-reversal operation and radix-2 DIT in conjunction with the half-length and double-signal algorithms
 ☑ Input is in bit-reversed order ☑ Input is conjugate symmetric	Radix-2 DIT in conjunction with the half-length and double-signal algorithms

Radix-2 Optimization for the Table of Trigonometric Values

In certain situations, the block’s Radix–2 algorithm computes all the possible trigonometric values of the twiddle factor

$$e^{j\frac{2\pi k}{K}}$$

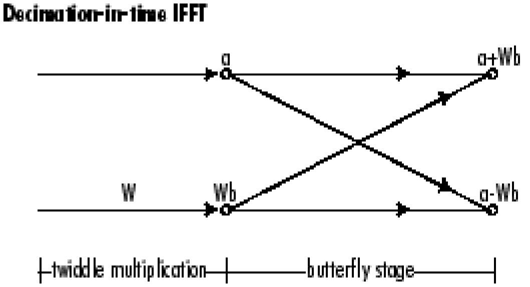
where K is the greater value of either M or N and $k = 0, \cdots, K-1$. The block stores these values in a table and retrieves them during simulation. The number of table entries for fixed-point and floating-point is summarized in the following table:

Number of Table Entries for N-Point FFT	
floating-point	3 N/4
fixed-point	N

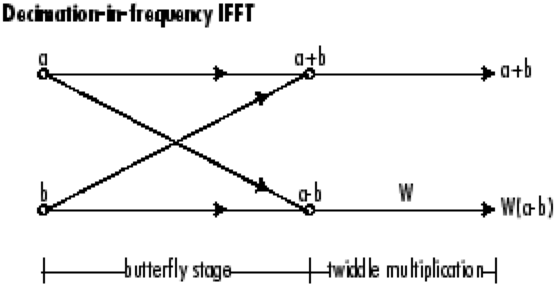
Fixed-Point Data Types

The following diagrams show the data types used in the IFFT block for fixed-point signals. You can set the sine table, accumulator, product output, and output data types displayed in the diagrams in the IFFT dialog box as discussed in “Dialog Box” on page 1-750.

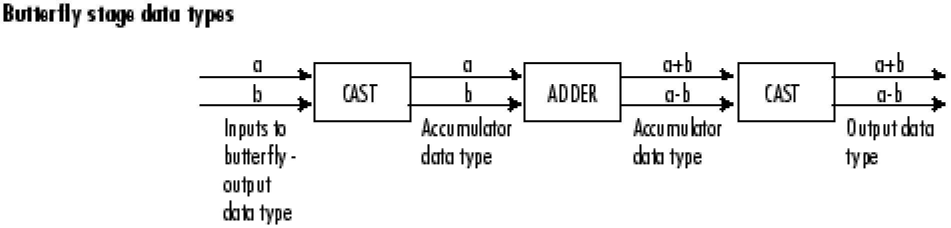
Inputs to the IFFT block are first cast to the output data type and stored in the output buffer. Each butterfly stage then processes signals in the accumulator data type, with the final output of the butterfly being cast back into the output data type. The block multiplies in a twiddle factor before each butterfly stage in a decimation-in-time IFFT and after each butterfly stage in a decimation-in-frequency IFFT.



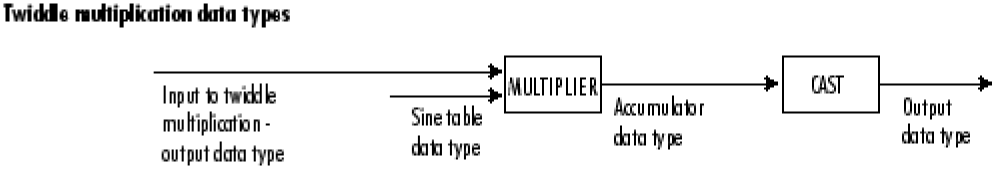
Decimation-in-time IFFT



Decimation-in-frequency IFFT



Butterfly stage data types



Twiddle multiplication data types

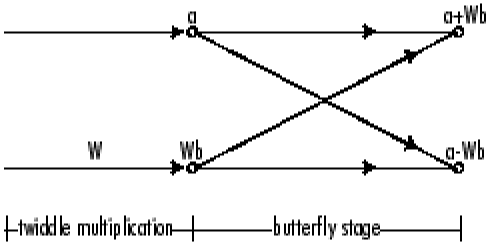
The multiplier output appears in the accumulator data type because both of the inputs to the multiplier are complex. For details on the complex multiplication performed, refer to “Multiplication Data Types” in the DSP System Toolbox documentation.

Fixed-Point Data Types

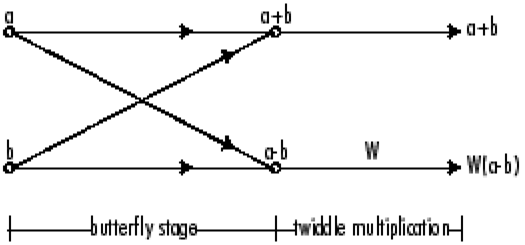
The following diagrams show the data types used within the IFFT block for fixed-point signals. You can set the sine table, accumulator, product output, and output data types displayed in the diagrams in the IFFT block dialog, as discussed in “Dialog Box” on page 1-750.

The IFFT block first casts input to the output data type and then stores it in the output buffer. Each butterfly stage then processes signals in the accumulator data type, with the final output of the butterfly being cast back into the output data type. The block multiplies in a twiddle factor before each butterfly stage in a decimation-in-time IFFT, and after each butterfly stage in a decimation-in-frequency IFFT.

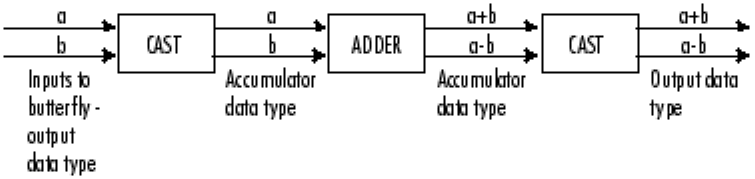
Decimation-in-time IFFT



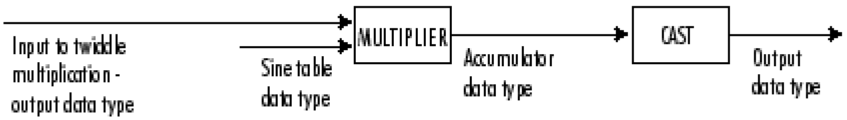
Decimation-in-frequency IFFT



Butterfly stage data types



Twiddle multiplication data types

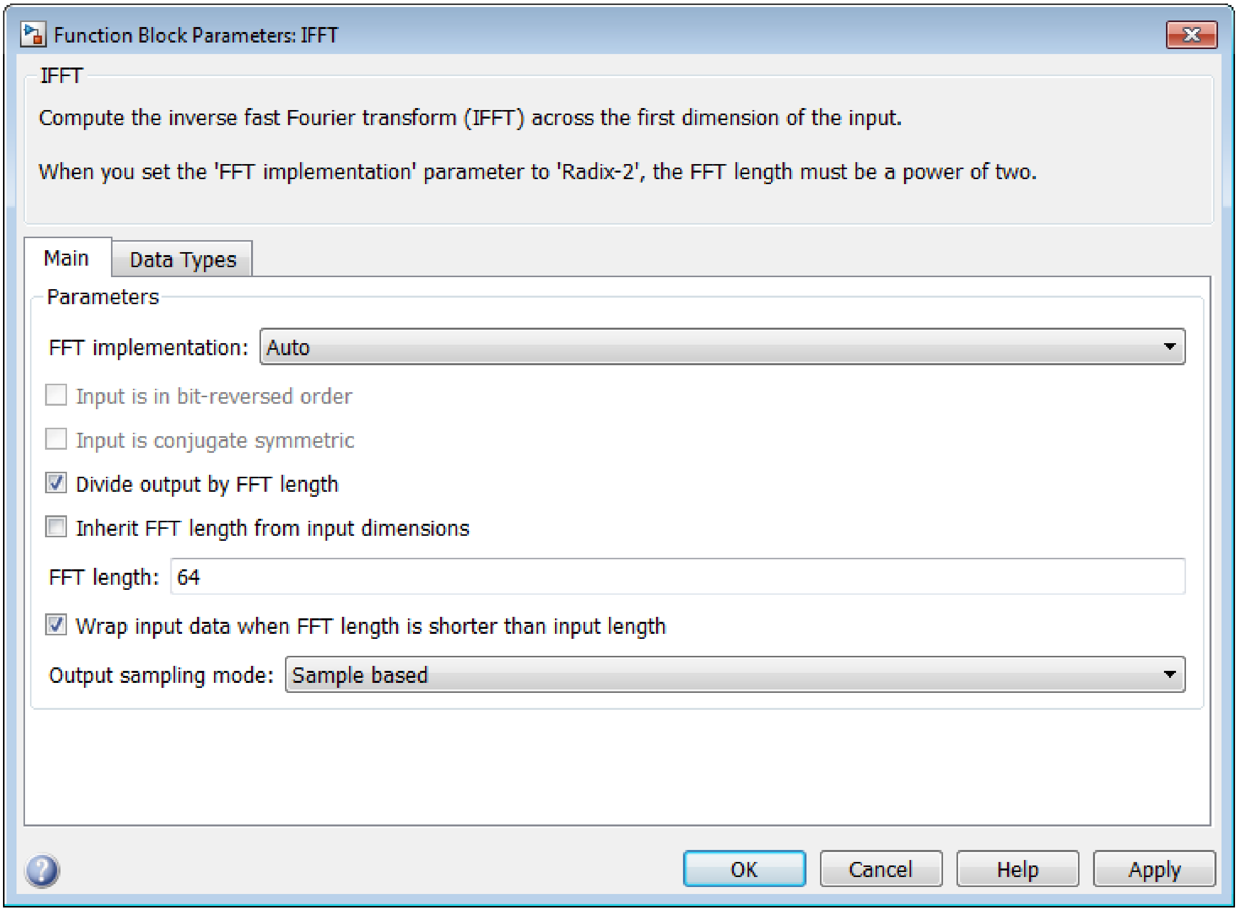


The output of the multiplier is in the accumulator data type because both of the inputs to the multiplier are complex. For details on the complex multiplication performed, see “Multiplication Data Types”.

Note: When the block input is fixed point, all internal data types are signed fixed point.

Dialog Box

The **Main** pane of the IFFT block dialog appears as follows.



Function Block Parameters: IFFT

IFFT

Compute the inverse fast Fourier transform (IFFT) across the first dimension of the input.

When you set the 'FFT implementation' parameter to 'Radix-2', the FFT length must be a power of two.

FFT implementation: Auto

□ Input is in bit-reversed order

□ Input is conjugate symmetric

☑ Divide output by FFT length

□ Inherit FFT length from input dimensions

FFT length: 64

☑ Wrap input data when FFT length is shorter than input length

Output sampling mode: Sample based

FFT implementation

Set this parameter to `FFTW` [1], [2] to support an arbitrary length input signal. The block restricts generated code with FFTW implementation to MATLAB host computers.

Set this parameter to `Radix-2` for bit-reversed processing, fixed or floating-point data, or for portable C-code generation using the Simulink Coder. The dimension *M* of the *M*-by-*N* input matrix, must be a power of two. To work with other input sizes, use the Pad block to pad or truncate these dimensions to powers of two, or if possible choose the FFTW implementation. See “Radix-2 Implementation” on page 1-745.

Set this parameter to `Auto` to let the block choose the FFT implementation. For non-power-of-two transform lengths, the block restricts generated code to MATLAB host computers.

Input is in bit-reversed order

Select or clear this check box to designate the order of the input channel elements. Select this check box when the input should appear in reversed order, and clear it when the input should appear in linear order. The block yields invalid outputs when you do not set this parameter correctly. This check box only appears when you set the **FFT implementation** parameter to `Radix-2` or `Auto`.

You cannot select this check box if you have cleared the **Inherit FFT length from input dimensions** check box, and you are specifying the FFT length using the **FFT length** parameter. Also, it cannot be selected when you set the **FFT implementation** parameter to `FFTW`.

For more information on ordering of the output, see “Linear and Bit-Reversed Output Order”.

Input is conjugate symmetric

Select this option when the block inputs conjugate symmetric data and you want real-valued outputs. Selecting this check box optimizes the block's computation method.

The FFT block yields conjugate symmetric output when you input real-valued data. Taking the IFFT of a conjugate symmetric input matrix produces real-valued output. Therefore, if the input to the block is both floating point and conjugate symmetric, and you select the this check box, the block produces real-valued outputs.

You cannot select this check box if you have cleared the **Inherit FFT length from input dimensions** check box, and you are specifying the FFT length using the **FFT length** parameter.

If you input conjugate symmetric data to the IFFT block and do not select this check box, the IFFT block outputs a complex-valued signal with small imaginary parts. The block outputs invalid data if you select this option with non conjugate symmetric input data.

Divide output by FFT length

When you select this check box, the block computes its output according to the IDFT equation, discussed in the Description section.

When you clear this check box, the block computes the output using a modified version of the IDFT: $M \cdot y(k,l)$, which is defined by the following equation:

$$M \cdot y(k,l) = \sum_{p=1}^{P} u(p,l) e^{j2\pi(p-1)(k-1)/M} \quad k = 1,\ldots,M$$

Notice, the modified IDFT equation does not include the multiplication factor of 1/*M*.

Inherit FFT length from input dimensions

Select to inherit the FFT length from the input dimensions. If you do not select this parameter, the **FFT length** parameter becomes available to specify the length. You cannot clear this parameter when you select either the **Input is in bit-reversed order** or the **Input is conjugate symmetric** parameter.

FFT length

Specify FFT length. This parameter only becomes available if you do not select the **Inherit FFT length from input dimensions** parameter.

When you set the **FFT implementation** parameter to `Radix-2`, or when you check the **Output in bit-reversed order** check box, this value must be a power of two.

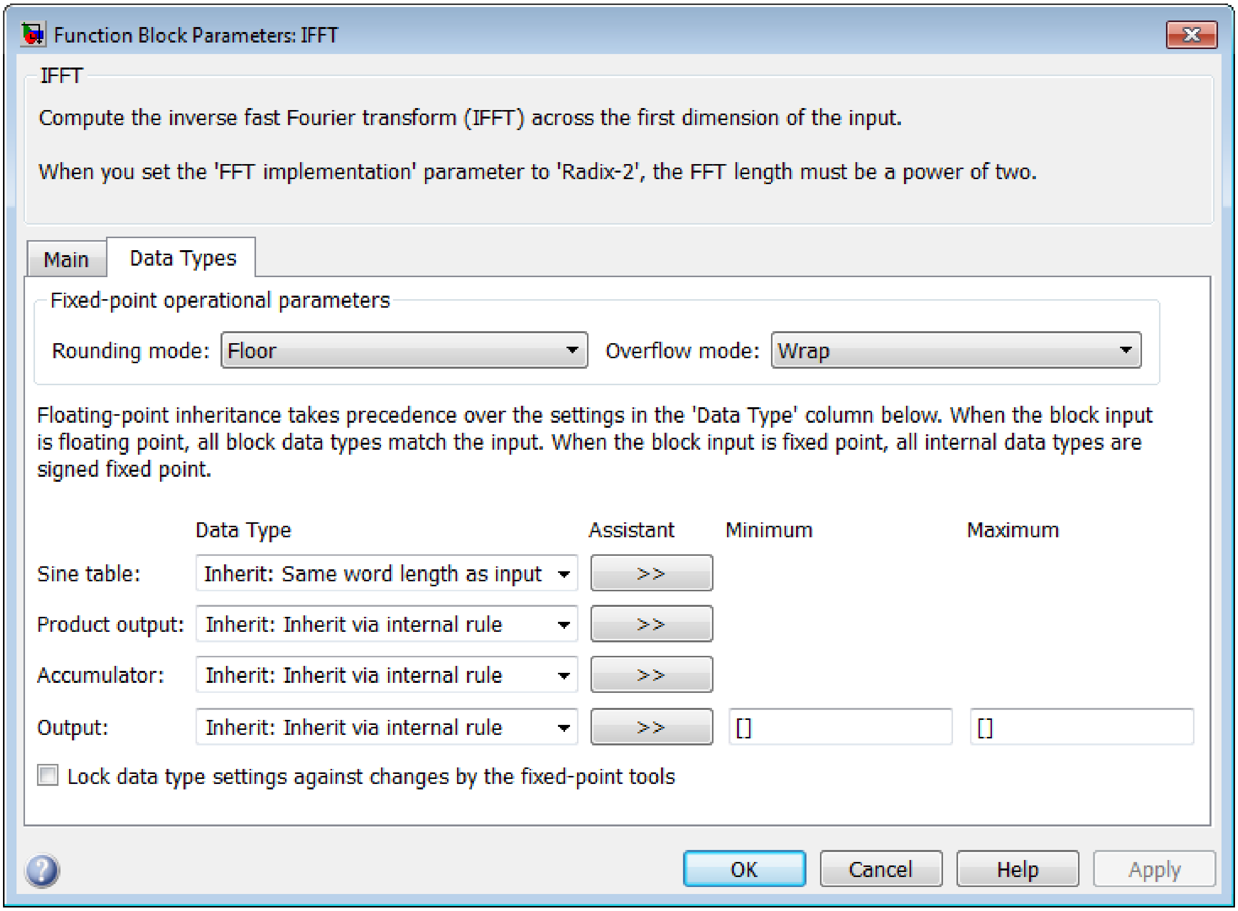
Wrap input data when FFT length is shorter than input length

Choose to wrap or truncate the input, depending on the FFT length. If this parameter is checked, modulo-length data wrapping occurs before the FFT operation, given FFT length is shorter than the input length. If this property is unchecked, truncation of the input data to the FFT length occurs before the FFT operation. The default is checked.

Output sampling mode

Select `Sample based` or `Frame based` output. If the input to the IFFT block has 3 or more dimensions, you must select `Sample based` output.

The **Data Types** pane of the IFFT block dialog appears as follows.



Function Block Parameters: IFFT

IFFT

Compute the inverse fast Fourier transform (IFFT) across the first dimension of the input.

When you set the 'FFT implementation' parameter to 'Radix-2', the FFT length must be a power of two.

Fixed-point operational parameters

Rounding mode: Floor

Overflow mode: Wrap

Floating-point inheritance takes precedence over the settings in the 'Data Type' column below. When the block input is floating point, all block data types match the input. When the block input is fixed point, all internal data types are signed fixed point.

	Data Type	Assistant	Minimum	Maximum
Sine table:	Inherit: Same word length as input	>>		
Product output:	Inherit: Inherit via internal rule	>>		
Accumulator:	Inherit: Inherit via internal rule	>>		
Output:	Inherit: Inherit via internal rule	>>	[]	[]

□ Lock data type settings against changes by the fixed-point tools

Rounding mode

Select the “rounding mode” for fixed-point operations. The sine table values do not obey this parameter; instead, they always round to `Nearest`.

Overflow mode

Select the “overflow mode” for fixed-point operations. The sine table values do not obey this parameter; instead, they are always saturated.

Sine table data type

Choose how you specify the word length of the values of the sine table. The fraction length of the sine table values always equals the word length minus one. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Same word length as input`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16)`

The sine table values do not obey the **Rounding mode** and **Overflow mode** parameters; instead, they are always saturated and rounded to `Nearest`.

Product output data type

Specify the product output data type. See “Fixed-Point Data Types” on page 1-748 and “Multiplication Data Types” for illustrations depicting the use of the product output data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Product output data type** parameter.

See “Specify Data Types Using Data Type Assistant” in “Simulink User's Guide” for more information.

Accumulator data type

Specify the accumulator data type. See “Fixed-Point Data Types” on page 1-748 for illustrations depicting the use of the accumulator data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Accumulator data type** parameter.

See “Specify Data Types Using Data Type Assistant” in “Simulink User's Guide” for more information.

Output data type

Specify the output data type. See “Fixed-Point Data Types” on page 1-748 for illustrations depicting the use of the output data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`.

  When you select `Inherit: Inherit via internal rule`, the block calculates the output word length and fraction length automatically. The equations that the block uses to calculate the ideal output word length and fraction length depend on the setting of the **Divide output by FFT length** check box.

  - When you select the **Divide output by FFT length** check box, the ideal output word and fraction lengths are the same as the input word and fraction lengths.
  - When you clear the **Divide output by FFT length** check box, the block computes the ideal output word and fraction lengths according to the following equations:

$$WL_{ideal\,output} = WL_{input} + floor(\log_2(FFT\ length - 1)) + 1$$

$$FL_{ideal\,output} = FL_{input}$$

  Using these ideal results, the internal rule then selects word lengths and fraction lengths that are appropriate for your hardware. For more information, see “Inherit via Internal Rule”.

- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Specify Block Output Data Types” in “Simulink User's Guide” for more information.

Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

Examples

See “Transform Frequency-Domain Data into Time Domain” in the *DSP System Toolbox User's Guide*.

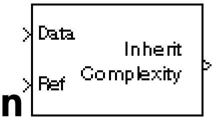
Inherit Complexity

Change complexity of input to match reference signal

Library

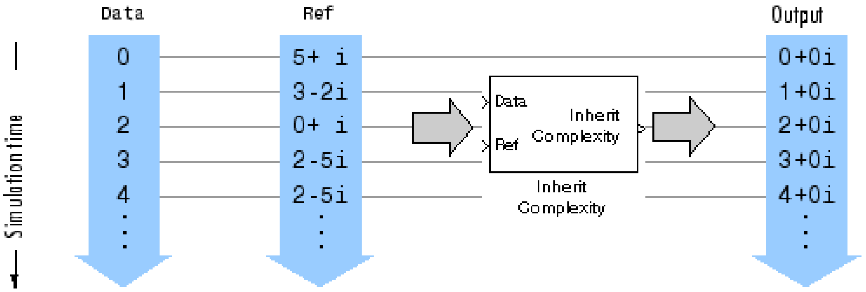
Signal Management / Signal Attributes

`dspsigattribs`

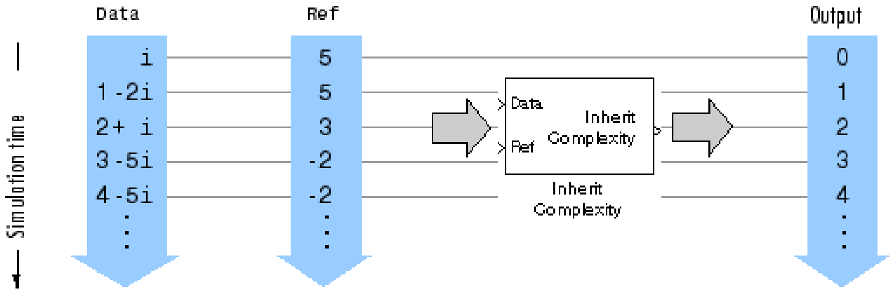


Description

The Inherit Complexity block alters the input data at the Data port to match the complexity of the reference input at the Ref port. When the Data input is real, and the Ref input is complex, the block appends a zero-valued imaginary component, `0i`, to each element of the Data input.

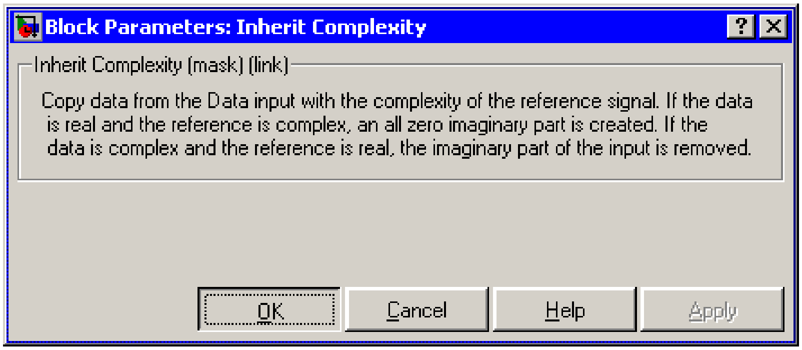


When the `Data` input is complex, and the `Ref` input is real, the block outputs the real component of the `Data` input.



When both the `Data` input and `Ref` input are real, or when both the `Data` input and `Ref` input are complex, the block propagates the `Data` input with no change.

Dialog Box



Block Parameters: Inherit Complexity

Inherit Complexity (mask) (link)

Copy data from the Data input with the complexity of the reference signal. If the data is real and the reference is complex, an all zero imaginary part is created. If the data is complex and the reference is real, the imaginary part of the input is removed.

Supported Data Types

Port	Supported Data Types
Data	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers

Port	Supported Data Types
Ref	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Output	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers

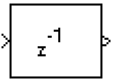
Integer Delay (Obsolete)

Delay input by integer number of sample periods

Library

`dspobslib`

Description



Note: The Integer Delay block will be removed from the product in a future release. We strongly recommend replacing this block with the Delay block.

The Integer Delay block delays a discrete-time input by the number of sample intervals specified in the **Delay** parameter. Noninteger delay values are rounded to the nearest integer, and negative delays are clipped at 0.

Sample-Based Operation

When the input is a sample-based M-by-N matrix, the block treats each of the $M*N$ matrix elements as an independent channel. The **Delay** parameter, v, can be an M-by-N matrix of positive integers that specifies the number of sample intervals to delay each channel of the input, or a scalar integer by which to equally delay all channels.

For example, when the input is M-by-1 and v is the matrix `[v(1) v(2) ... v(M)]'`, the first channel is delayed by `v(1)` sample intervals, the second channel is delayed by `v(2)` sample intervals, and so on. Note that when a channel is delayed for Δ sample-time units, the output sample at time t is the input sample at time $t - \Delta$. When $t - \Delta$ is negative, then the output is the corresponding value specified by the **Initial conditions** parameter.

A 1-D vector of length M is treated as an M-by-1 matrix, and the output is 1-D.

The **Initial conditions** parameter specifies the output of the block during the initial delay in each channel. The initial delay for a particular channel is the time elapsed from the start of the simulation until the first input in that channel is propagated to the output. Both fixed and time-varying initial conditions can be specified in a variety of ways to suit the dimensions of the input.

Fixed Initial Conditions

A fixed initial condition in sample-based mode can be specified as one of the following:

- Scalar value to be repeated at each sample time of the initial delay (for every channel). For a 2-by-2 input with the parameter settings below,

  
  Delay (samples):
  [1 2; 3 4]
  Initial conditions:
  -1

  the block generates the following sequence of matrices at the start of the simulation,

  $$\begin{bmatrix} -1 & -1 \\ -1 & -1 \end{bmatrix}, \begin{bmatrix} u_{11}^{1} & -1 \\ -1 & -1 \end{bmatrix}, \begin{bmatrix} u_{11}^{2} & u_{12}^{1} \\ -1 & -1 \end{bmatrix}, \begin{bmatrix} u_{11}^{3} & u_{12}^{2} \\ u_{21}^{1} & -1 \end{bmatrix}, \begin{bmatrix} u_{11}^{4} & u_{12}^{3} \\ u_{21}^{2} & u_{22}^{1} \end{bmatrix}, \ldots$$

  where u_{ij}^{k} is the *i,j*th element of the *k*th matrix in the input sequence.

- Array of size *M*-by-*N*-by-*d*. In this case, you can set different fixed initial conditions for each element of a sample-based input. This setting is explained further in the Array bullet in “Time-Varying Initial Conditions” on page 1-762.

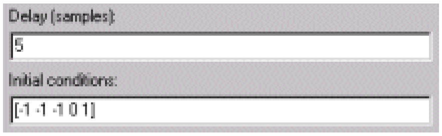
Initial conditions cannot be specified by full matrices.

Time-Varying Initial Conditions

A time-varying initial condition in sample-based mode can be specified in one of the following ways:

- Vector of length *d*, where *d* is the maximum value specified for any channel in the **Delay** parameter. The vector can be a *L*-by-*d*, 1-by-*d*, or 1-by-1-by-*d*. The d elements of the vector are output in sequence, one at each sample time of the initial delay.

  For a scalar input and the parameters shown below,



Delay (samples):

5

Initial conditions:

[-1 -1 -1 0 1]

the block outputs the sequence `-1, -1, -1, 0, 1,...` at the start of the simulation.

- Array of dimension *M*-by-*N*-by-*d*, where *d* is the value specified for the **Delay** parameter (the maximum value when the **Delay** is a vector) and *M* and *N* are the number of rows and columns, respectively, in the input matrix. The *d* pages of the array are output in sequence, one at each sample time of the initial delay. For a 2-by-3 input, and the parameters below,

  
  Delay (samples):

  3

  Initial conditions:

  cat(3, [1 2 3; 4 5 6], [2 4 6; 1 3 5], [3 6 9; 0 4 8])

  the block outputs the matrix sequence

  $$\begin{bmatrix}1 & 2 & 3\\4 & 5 & 6\end{bmatrix}, \begin{bmatrix}2 & 4 & 6\\1 & 3 & 5\end{bmatrix}, \begin{bmatrix}3 & 6 & 9\\0 & 4 & 8\end{bmatrix}$$

  at the start of the simulation. Note that setting **Initial conditions** to an array with the same matrix for each entry implements constant initial conditions; a different constant initial condition for each input matrix element (channel).

Initial conditions cannot be specified by full matrices.

Frame-Based Operation

When the input is a frame-based *M*-by-*N* matrix, the block treats each of the *N* columns as an independent channel, and delays each channel as specified by the **Delay** parameter.

For frame-based inputs, the **Delay** parameter can be a scalar integer by which to equally delay all channels. It can also be a 1-by-*N* row vector, each element of which serves as the delay for the corresponding channel of the *N*-channel input. Likewise, it can also be an *M*-by-1 column vector, each element of which serves as the delay for one of the corresponding *M* samples for each channel. The **Delay** parameter can be an *M*-by-*N* matrix of positive integers as well; in this case, each element of each channel is delayed by the corresponding element in the delay matrix. For instance, if the fifth element of the third column of the delay matrix was 3, then the fifth element of the third channel of the input matrix is always delayed by three sample-time units.

When a channel is delayed for Δ sample-time units, the output sample at time *t* is the input sample at time *t* – Δ. When *t* – Δ is negative, then the output is the corresponding value specified in the **Initial conditions** parameter.

The **Initial conditions** parameter specifies the output during the initial delay. Both fixed and time-varying initial conditions can be specified. The initial delay for a particular channel is the time elapsed from the start of the simulation until the first input in that channel is propagated to the output.

Fixed Initial Conditions

The settings shown below specify fixed initial conditions. The value entered in the **Initial conditions** parameter is repeated at the output for each sample time of the initial delay. A fixed initial condition in frame-based mode can be one of the following:

- Scalar value to be repeated for all channels of the output at each sample time of the initial delay. For a general *M*-by-*N* input with the parameter settings below,

  
  Delay (samples):
  5
  Initial conditions:
  0

  the first five samples in each of the *N* channels are zero. Notice that when the frame size is larger than the delay, all of these zeros are all included in the first output from the block.
- Array of size 1-by-*N*-by-*D*. In this case, you can also specify different fixed initial conditions for each channel. See “Time-Varying Initial Conditions” on page 1-765 for details.

Initial conditions cannot be specified by full matrices.

Time-Varying Initial Conditions

The following settings specify time-varying initial conditions. For time-varying initial conditions, the values specified in the **Initial conditions** parameter are output in sequence during the initial delay. A time-varying initial condition in frame-based mode can be specified in the following ways:

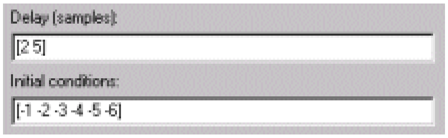
- Vector of length D, where each of the N channels have the same initial conditions sequence specified in the vector. D is defined as follows:
  - When an element of the delay entry is less than the frame size,

    $D = d + 1$

    where d is the maximum delay.
  - When the all elements of the delay entry are greater than the input frame size,

    $D = d + \texttt{input frame size} - 1$

  Only the first d entries of the initial condition vector are used; the rest of the values are ignored, but you must include them nonetheless. For a two-channel ramp input `[1:100; 1:100]'` with a frame size of 4 and the parameter settings below,



Delay (samples):
[2 5]

Initial conditions:
[-1 -2 -3 -4 -5 -6]

the block outputs the following sequence of frames at the start of the simulation.

$$\begin{bmatrix} -4 & -1 \\ -5 & -2 \\ 1 & -3 \\ 2 & -4 \end{bmatrix}, \begin{bmatrix} 3 & -5 \\ 4 & 1 \\ 5 & 2 \\ 6 & 3 \end{bmatrix}, \begin{bmatrix} 7 & 4 \\ 8 & 5 \\ 9 & 6 \\ 10 & 7 \end{bmatrix}, \ldots$$

Note that since one of the delays, 2, is less than the frame size of the input, 4, the length of the **Initial conditions** vector is the sum of the maximum delay and 1 (5+1), which is 6. The first five entries of the initial conditions vector are used by the channel with the maximum delay, and the rest of the entries are ignored. Since the first channel is delayed for less than the maximum delay (2 sample time units), it only makes use of two of the initial condition entries.

- Array of size 1-by-*N*-by-*D*, where *D* is defined in “Time-Varying Initial Conditions” on page 1-765. In this case, the *k*th entry of each 1-by-*N* entry in the array corresponds to an initial condition for the *k*th channel of the input matrix. Thus, a 1-by-*N*-by-*D* initial conditions input allows you to specify different initial conditions for each channel. For instance, for a two-channel ramp input `[1:100; 1:100]'` with a frame size of 4 and the parameter settings below,

  
  Delay (samples):
  5

  Initial conditions:
  cat(3, [-1 -2], [-3 -4], [-5 -6], [-7 -8], [-9 -10], [0 0], [0 0], [0 0])

  the block outputs the following sequence of frames at the start of the simulation.

  $$\begin{bmatrix} -1 & -2 \\ -3 & -4 \\ -5 & -6 \\ -7 & -8 \end{bmatrix}, \begin{bmatrix} -9 & -10 \\ 1 & 1 \\ 2 & 2 \\ 3 & 3 \end{bmatrix}, \begin{bmatrix} 4 & 4 \\ 5 & 5 \\ 6 & 6 \\ 7 & 7 \end{bmatrix}, \ldots$$

  Note that the channels have distinct time varying initial conditions; the initial conditions for channel 1 correspond to the first entry of each length-2 row vector in the initial conditions array, and the initial conditions for channel 2 correspond to the second entry of each row vector in the initial conditions array. Only the first five entries in the initial conditions array are used; the rest are ignored.

  The 1-by-*N*-by-*D* array entry can also specify different fixed initial conditions for every channel; in this case, every 1-by-*N* entry in the array would be identical, so that the initial conditions for each column are fixed over time.

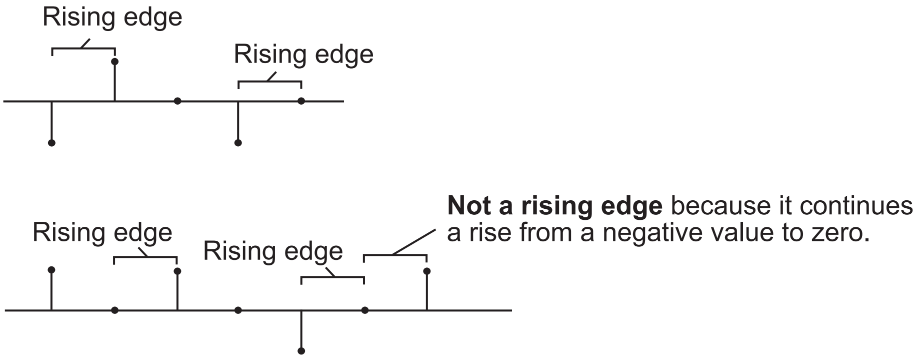
Initial conditions cannot be specified by full matrices.

Resetting the Delay

The block resets the delay whenever it detects a reset event at the optional Rst port. The reset sample time must be a positive integer multiple of the input sample time.

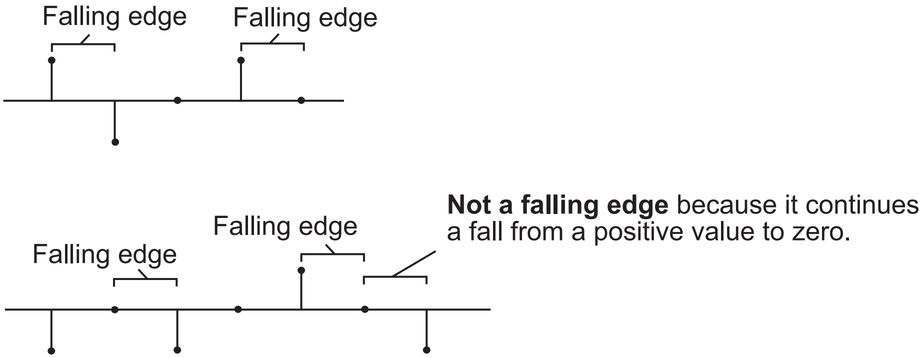
You specify the reset event in the **Reset port** parameter:

- `None` disables the Rst port.
- `Rising edge` — Triggers a reset operation when the Rst input does one of the following:
  - Rises from a negative value to a positive value or zero
  - Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero (see the following figure)



Rising edge
Rising edge
Rising edge
Rising edge
Not a rising edge because it continues
a rise from a negative value to zero.

- `Falling edge` — Triggers a reset operation when the `Rst` input does one of the following:
  - Falls from a positive value to a negative value or zero
  - Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero (see the following figure)



Falling edge
Falling edge
Falling edge
Falling edge
Not a falling edge because it continues
a fall from a positive value to zero.

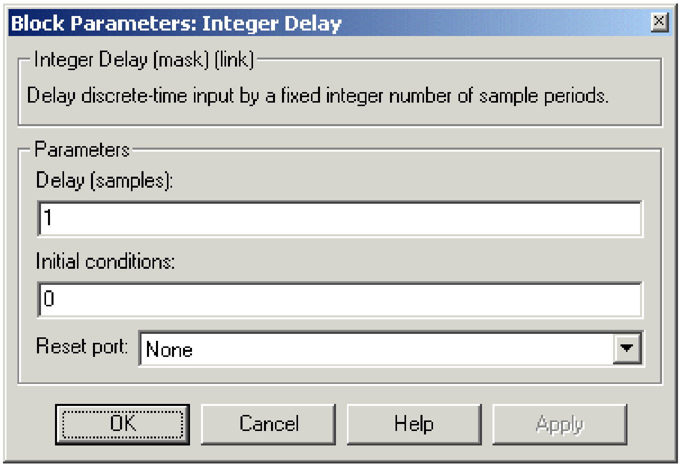
- `Either edge` — Triggers a reset operation when the `Rst` input is a `Rising edge` or `Falling edge` (as described above).
- `Non-zero sample` — Triggers a reset operation at each sample time that the `Rst` input is not zero.

> **Note** When running simulations in the Simulink `MultiTasking` mode, sample-based reset signals have a one-sample latency, and frame-based reset signals have one frame of latency. Thus, there is a one-sample or one-frame delay between the time the block detects a reset event, and when it applies the reset. For more information on latency and the Simulink tasking modes, see "Excess Algorithmic Delay (Tasking Latency)" and "Scheduling " in the *Simulink Coder User's Guide*.

Examples

The dspafxr example illustrates an audio reverberation system built around the Integer Delay block.

Dialog Box



Block Parameters: Integer Delay

Integer Delay (mask) (link)

Delay discrete-time input by a fixed integer number of sample periods.

Parameters

Delay (samples): 1

Initial conditions: 0

Reset port: None

Delay

The number of sample periods to delay the input signal.

Initial conditions

The value of the block's output during the initial delay.

Reset port

Determines the reset event that causes the block to reset the delay. For more information, see “Resetting the Delay” on page 1-766.

Supported Data Types

- Double-precision floating point
- Single-precision floating point
- Fixed point (signed only)
- Boolean — The block accepts Boolean inputs to the Rst port, which is enabled by the **Reset port** parameter.
- 8-, 16-, and 32-bit signed integers
- 8-, 16-, and 32-bit unsigned integers

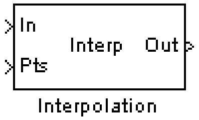
Interpolation

Interpolate values of real input samples

Library

Signal Operations

`dspsigops`



Description

The Interpolation block interpolates discrete, real, inputs using linear or FIR interpolation. The block accepts both sample- and frame-based input data in the form of a vector, matrix, or sample-based N-D array. The block outputs a scalar, vector, matrix, or N-D array of the interpolated values, which has the same frame status as the input data.

You must specify the interpolation points (times at which to interpolate values) in a one-based interpolation array, I_{Pts}. An entry of 1 in I_{Pts} refers to the first sample of the input data, an entry of 2.5 refers to the sample half-way between the second and third input sample, and so on. Depending on the dimensions of the input data, I_{Pts} can be a scalar, a length-P row or column vector, a P-by-N frame-based matrix, or a sample-based N-D array where P is the size of the first dimension of the N-D array. In most cases, P can be any positive integer. For more information about valid interpolation arrays, refer to the tables in “How the Block Applies Interpolation Arrays to Inputs” on page 1-771.

In most cases, the block applies I_{Pts} across the first dimension of an N-D input array, or to each input vector. You can set the block to apply the same interpolation array for all input data (static interpolation points entered on the block mask) or to use a different interpolation array for each N-D array, matrix, or vector input (time-varying interpolation points received via the Pts input port).

Specifying Static Interpolation Points

To supply the block with a static interpolation array (an interpolation array applied to every vector or N-D array of input data), perform the following steps:

- Set the **Source of interpolation points** parameter to `Specify via dialog`.
- Enter the interpolation array in the **Interpolation points** parameter. To learn about interpolation arrays, see “How the Block Applies Interpolation Arrays to Inputs” on page 1-771.

Specifying Time-Varying Interpolation Points

To supply the block with time-varying interpolation arrays (where the block uses a different interpolation array for each vector or N-D array input), perform the following steps:

1. Set the **Source of interpolation points** parameter to `Input port`, the **Pts** port appears on the block.
2. Generate a signal of interpolation arrays, and supply it to the Pts port. The block uses the input to this port as the interpolation points. To learn about interpolation arrays, see “How the Block Applies Interpolation Arrays to Inputs” on page 1-771.

How the Block Applies Interpolation Arrays to Inputs

The interpolation array I_{Pts} represents the points in time at which to interpolate values of the input signal. An entry of 1 in I_{Pts} refers to the first sample of the input, an entry of 2.5 refers to the sample half-way between the second and third input sample, and so on. In most cases, when I_{Pts} is a vector, it can be of any length.

Valid values in the interpolation array, I_{Pts}, range from 1 to the number of samples in each channel of the input. To learn how the block handles out of range interpolation values, see “Handling Out-of-Range Interpolation Points” on page 1-775.

Depending on the dimension and frame status of the input and the dimension of I_{Pts}, the block usually applies I_{Pts} to the input in one of the following ways:

- Applies the I_{Pts} array across the first dimension of a sample-based N-D array or frame-based matrix input, resulting in a sample-based N-D array or frame-based matrix output.
- Applies the vector I_{Pts} to each input vector (as if the input vector were a single channel), resulting in a vector output with the same orientation as the input (row or column).

The following tables summarize how the block applies the interpolation array I_{Pts} to all the possible types of sample- and frame-based inputs, and show the resulting output dimensions.

The first table describes the block's behavior when the **Source of interpolation points** is `Specify via dialog` and the input is sample based.

Input Dimensions (Sample Based)	Valid Dimensions of Interpolation Array I_{Pts}	How Block Applies I_{Pts} to Input	Output Dimensions (Sample Based)
N-D Array (ex. M-by-N-by-Q)	1-by-P row	Applies I_{Pts} to the first dimension of the input array	P-by-N-by-Q array
	P-by-1 column		
	P-by-N-by-Q array	Applies the columns of I_{Pts} to the corresponding columns of the input array	
M-by-1 column	1-by-P row (block treats I_n as a column)	Applies I_{Pts} to the input column	P-by-1 column
	P-by-1 column		
1-by-N row	1-by-P row	Applies I_n to the input row	1-by-P row
	P-by-1 column		

Input Dimensions (Sample Based)	Valid Dimensions of Interpolation Array I_{Pts}	How Block Applies I_{Pts} to Input	Output Dimensions (Sample Based)
	(block treats I_{Pts} as a row)		

The next table describes the block's behavior when the **Source of interpolation points** is `Specify via dialog` and the input is frame based.

Input Dimensions (Frame Based)	Valid Dimensions of Interpolation Array I_{Pts}	How Block Applies I_{Pts} to Input	Output Dimensions (Frame Based)
M-by-N matrix	1-by-N row	Applies each column of I_{Pts} (each element of I_{Pts}) to the corresponding column of the input matrix	1-by-N row
	P-by-1 column	Applies I_{Pts} to each input column	P-by-N matrix
	P-by-N matrix	Applies the columns of I_{Pts} to the corresponding columns of the input matrix	
M-by-1 column	1-by-P row (block treats I_{Pts} as a column)	Applies I_{Pts} to the input column	P-by-1 column
	P-by-1 column		
1-by-N row (not recommended)	1-by-N row	Not Applicable. Block copies input vector	1-by-N row, a copy of the input vector
	P-by-1 column		P-by-N matrix where each row is a copy of the input vector
	P-by-N matrix		

The next table describes the block's behavior when the **Source of interpolation points** is `Input port` and the input is sample based.

Input Dimensions (Sample Based)	Valid Dimensions of Interpolation Array I_{Pts}	How Block Applies I_{Pts} to Input	Output Dimensions (Sample Based)
N-D Array (ex. M-by-N-by-Q)	Sample-based 1-by-P row	Applies I_{Pts} to the first dimension of the input array	P-by-N-by-Q array
	Sample- or frame-based P-by-1 column		
	Sample-based P-by-N-by-Q array	Applies the columns of I_{Pts} to the corresponding columns of the input array	
M-by-1 column	Sample-based 1-by-P row	Applies I_{Pts} to the input column	P-by-1 column
	Sample- or frame-based P-by-1 column		
1-by-N row	Sample-based 1-by-P row	Applies I_{Pts} to the input row	1-by-P row
	Sample or frame-based P-by-1 column		

The next table describes the block's behavior when the **Source of interpolation points** is `Input port` and the input is frame based.

Input Dimensions (Frame Based)	Valid Dimensions of Interpolation Array I_{Pts}	How Block Applies I_{Pts} to Input	Output Dimensions (Frame Based)
M-by-N matrix	Frame-based 1-by-N row	Applies each column of I_{Pts} (each element of I_{Pts}) to the corresponding column of the input matrix	1-by-N row
	Sample-based 1-by-P row	Applies I_{Pts} to each input column	P-by-N matrix
	Frame- or sample-based P-by-1 column		

Input Dimensions (Frame Based)	Valid Dimensions of Interpolation Array I_{Pts}	How Block Applies I_{Pts} to Input	Output Dimensions (Frame Based)
	Frame- or sample-based P-by-N matrix	Applies the columns of I_{Pts} to the corresponding columns of the input matrix	
M-by-1 column	Sample-based 1-by-P row	Applies I_{Pts} to the input column	P-by-1 column
	Frame- or sample-based P-by-1 column		
1-by-N row (not recommended)	Frame-based 1-by-N row	Not Applicable. Block copies input vector	1-by-N row, a copy of the input vector
	Sample-based 1-by-P row		P-by-N matrix where each row is a copy of the input vector
	Frame- or sample-based P-by-1 column		
	Frame- or sample-based P-by-N matrix		

Handling Out-of-Range Interpolation Points

Valid values in the interpolation array I_{Pts} range from 1 to the number of samples in each channel of the input. For instance, given a length-5 input vector `D`, all entries of I_{Pts} must range from 1 to 5. I_{Pts} cannot contain entries such as 7 or -9, since there is no 7th or -9th entry in `D`.

The **Out of range interpolation points** parameter sets how the block handles interpolation points that are fall outside the valid range, and has the following settings:

- `Clip` — The block replaces any out-of-range values in I_{Pts} with the closest value in the valid range (from 1 to the number of input samples), and then proceeds with computations using the clipped version of I_{Pts}.
- `Clip and warn` — In addition to `Clip`, the block issues a warning at the MATLAB command line every time clipping occurs.

- `Error` — When the block encounters an out-of-range value in I_{Pts}, the simulation stops, and the block issues an error at the MATLAB command line.

Example of Clipping

Suppose the block is set to clip out-of-range interpolation points, and gets the following input vector and interpolation points:

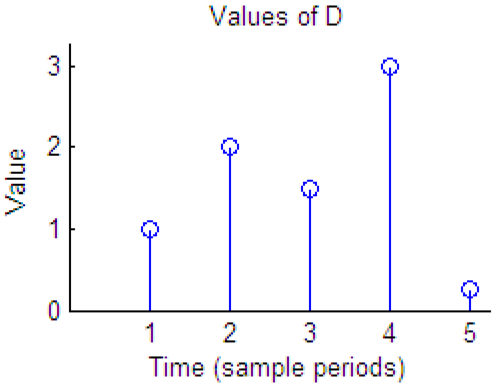
- `D = [11 22 33 44]'`
- $\mathtt{I}_{\mathtt{Pts}}$ `= [10 2.6 -3]'`

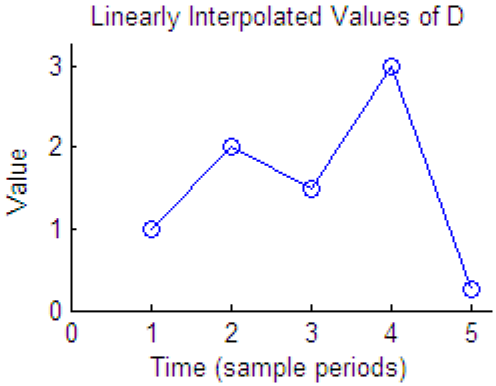
Because D has four samples, valid interpolation points range from 1 to 4. The block clips the interpolation point 10 to 4 and the point -3 to 1, resulting in the clipped interpolation vector $\mathtt{I}_{\mathtt{PtsClipped}}$ `= [4 2.6 1]'`.

Linear Interpolation Mode

When **Interpolation Mode** is set to `Linear`, the block interpolates data values by assuming that the data varies linearly between samples taken at adjacent sample times.

For instance, if the input signal D = [1 2 1.5 3 0.25]', the following plot on the left shows the samples in D, and the plot on the right shows the linearly interpolated values between the samples in D.



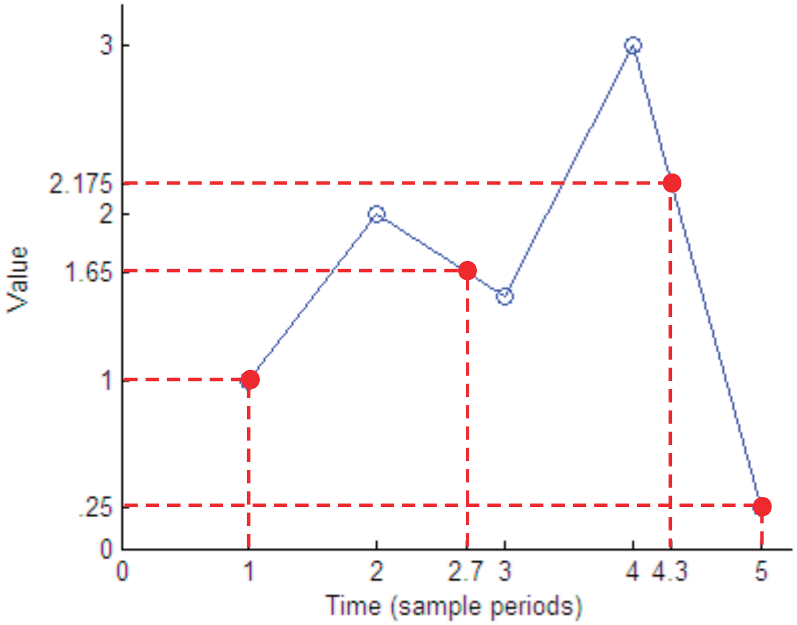


The following figure illustrates the case of a block in linear interpolation mode that is set to clip out-of-range interpolation points. The vector D supplies the input data and the vector I_{Pts} supplies the interpolation points:

- `D = [1 2 1.5 3 0.25]'`
- I_{Pts} `= [-4 2.7 4.3 10]'`

The block clips the invalid interpolation points, and outputs the linearly interpolated values in a vector, `[1 1.65 2.175 0.25]'`.

Interpolated Values of D at Clipped Interpolation Points



D = [1 2 1.5 3 0.25]′
I_{pts} = [-4 2.7 4.3 10]′

Valid interpolation points range from 1 to 5, so -4 is clipped to 1 and 10 is clipped to 5.

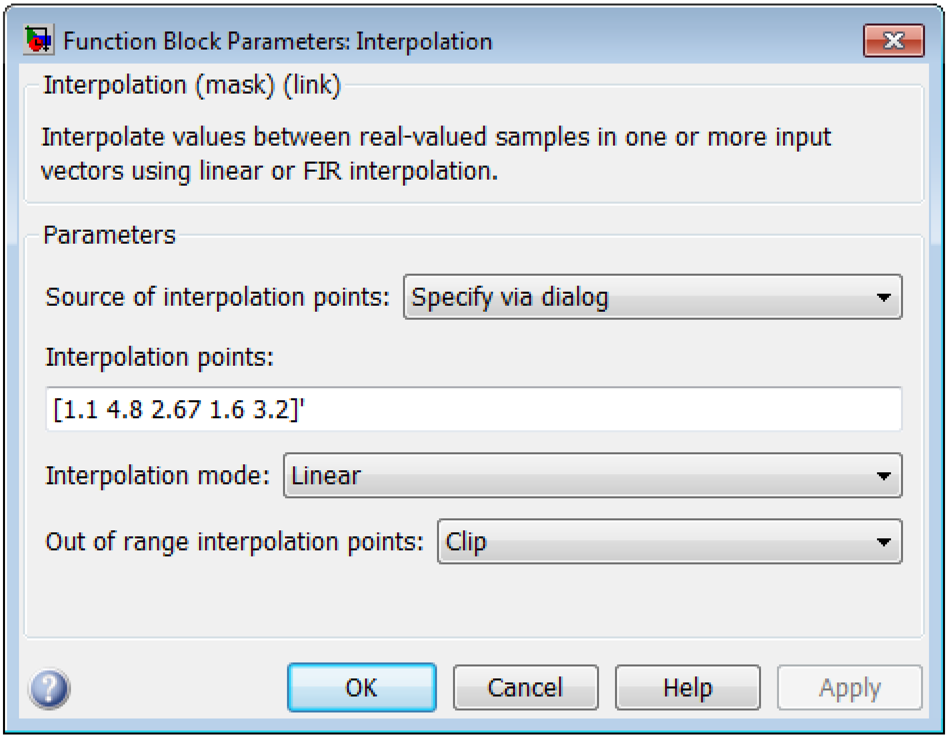
Clipped I_{pts} = [1 2.7 4.3 5]′

Output = [1 1.65 2.175 0.25]′

FIR Interpolation Mode

When **Interpolation Mode** is set to `FIR`, the block interpolates data values using an FIR interpolation filter, specified by various block parameters. See in the Variable Fractional Delay block reference for more information.

Dialog Box



Function Block Parameters: Interpolation

Interpolation (mask) (link)

Interpolate values between real-valued samples in one or more input vectors using linear or FIR interpolation.

Parameters

Source of interpolation points: Specify via dialog

Interpolation points:

[1.1 4.8 2.67 1.6 3.2]'

Interpolation mode: Linear

Out of range interpolation points: Clip

Source of interpolation points

Choose how you want to specify the interpolation points. If you select `Specify via dialog`, the **Interpolation points** parameter become available. Use this option for static interpolation points. If you select `Input port`, the Pts port appears on the block. The block uses the input to this port as the interpolation points. Use this option for time-varying interpolation points. For more information, see “Specifying Static Interpolation Points” on page 1-771 and “Specifying Time-Varying Interpolation Points” on page 1-771.

Interpolation points

The array of points in time at which to interpolate the input signal (I_{Pts}). An entry of 1 in I_{Pts} refers to the first sample of the input, an entry of 2.5 refers to the sample half-way between the second and third input sample, and so on. See “How the Block Applies Interpolation Arrays to Inputs” on page 1-771. “Tunable”.

Interpolation mode

Sets the block to interpolate by either linear or FIR interpolation. For more information, see “Linear Interpolation Mode” on page 1-776 and “FIR Interpolation Mode” on page 1-777.

Interpolation filter half-length

Specify the half-length of the FIR interpolation filter (P). To perform the interpolation in FIR mode, the block uses the nearest 2*P low-rate samples. In most cases, P low-rate samples must appear below and above each interpolation point. However, if you interpolate at a low-rate sample point, the block includes that low-rate sample in the required 2*P samples and requires only 2*P–1 neighboring low-rate samples. If an interpolation point does not have the required number of neighboring low-rate samples, the block interpolates that point using linear interpolation.

This parameter becomes available only when the **Interpolation mode** is set to FIR. For more information, see “FIR Interpolation Mode” on page 1-777.

Interpolation points per input sample

Also known as the *upsampling factor*, this parameter defines the number of points per input sample (L) at which the block computes a unique FIR interpolation filter. To perform the FIR Interpolation, the block uses a polyphase structure with L filter arms of length 2*P.

For example, if L=4, the block constructs a polyphase filter with four arms. The block then interpolates at points corresponding to 1 +*i*/**L**, 2 +*i*/**L**, 3 +*i*/**L**..., where the integers 1, 2, and 3 represent the low-rate samples, and *i*=0,1,2,3. To interpolate at a point that does not directly correspond to an arm of the polyphase filter requires an extra computation. The block first rounds that point down to the nearest value that does correspond to an arm of the polyphase filter. Thus, to interpolate at the point 2.2, the block rounds 2.2 down to 2, and computes the FIR interpolation using the first arm of the polyphase filter structure. Similarly, to interpolate the point 2.65, the block rounds the value down to 2.5 and uses the third arm of the polyphase filter structure.

This parameter becomes available only when the **Interpolation mode** is set to FIR. For more information, see “FIR Interpolation Mode” on page 1-777.

Normalized input bandwidth

The bandwidth of the input divided by Fs/2 (half the input sample frequency).

This parameter is only available when the **Interpolation mode** is set to FIR. For more information, see “FIR Interpolation Mode” on page 1-777.

Out of range interpolation points

When an interpolation point is out of range, this parameter sets the block to either clip the interpolation point, clip the value and issue a warning at the MATLAB command line, or stop the simulation and issue an error at the MATLAB command line. For more information, see "Handling Out-of-Range Interpolation Points" on page 1-775.

Supported Data Types

Port	Supported Data Types
In	• Double-precision floating point • Single-precision floating point
Pts	• Double-precision floating point • Single-precision floating point
Out	• Double-precision floating point • Single-precision floating point

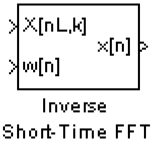
Inverse Short-Time FFT

Recover time-domain signals by performing inverse short-time, fast Fourier transform (FFT)

Library

Transforms

`dspxfrm3`



Description

The Inverse Short-Time FFT block reconstructs the time-domain signal from the frequency-domain output of the Short-Time FFT block using a two-step process. First, the block performs the overlap add algorithm shown below.

$$x[n] = \frac{L}{W(0)} \sum_{p=-\infty}^{\infty} \left[\frac{1}{N} \sum_{k=0}^{N-1} X[pL,k] e^{j2\pi kn/N} \right]$$

Then, the block rebuffers the signal in order to reconstruct the time-domain signal. Depending on the analysis window used by the Short-Time FFT block, the Inverse Short-Time FFT block might or might not achieve perfect reconstruction of the time domain signal.

Connect your complex-valued, single-channel or multichannel input signal to the X(n,k) port. The block accepts unoriented vector, column vector and matrix input. The block outputs the real or complex-valued, single-channel or multichannel inverse short-time FFT at port x(n).

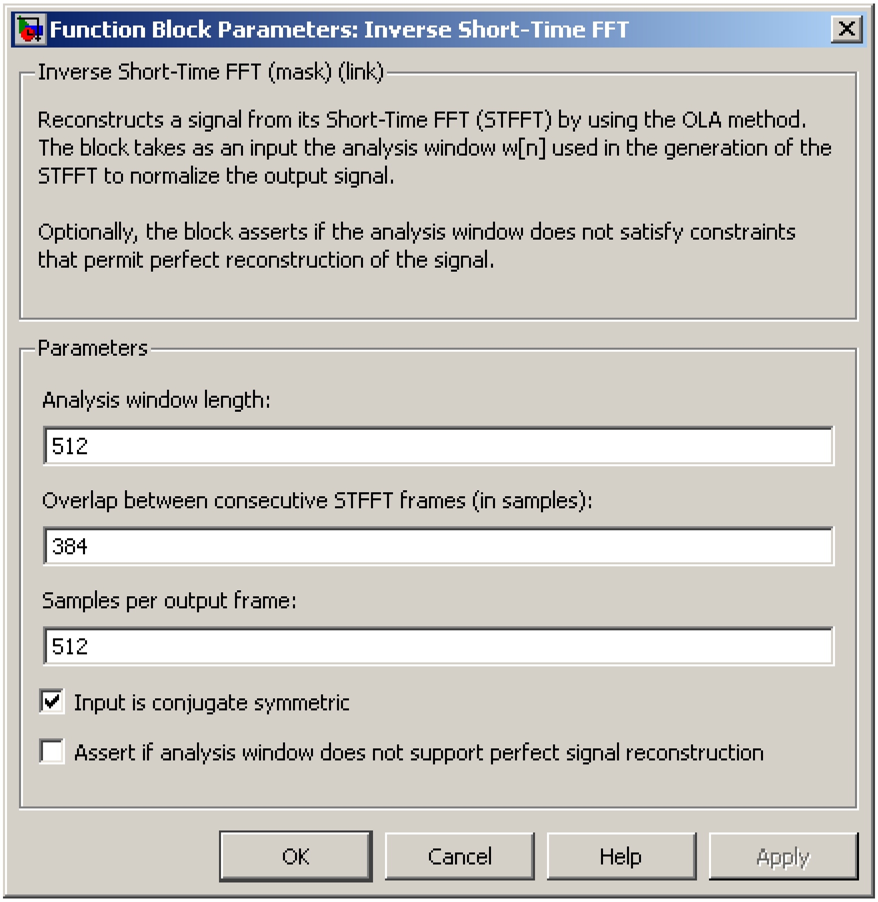
Connect your complex-valued, single-channel analysis window to the w(n) port. When you select the **Assert if analysis window does not support perfect signal**

reconstruction check box, the block displays an error when the input signal cannot be perfectly reconstructed. The block uses the values you enter for the **Analysis window length (W)** and **Reconstruction error tolerance**, or maximum amount of allowable error in the reconstruction process, to determine if the signal can be perfectly reconstructed.

Examples

The dspstsa example illustrates how to use the Short-Time FFT and Inverse Short-Time FFT blocks to remove the background noise from a speech signal.

Dialog Box



Function Block Parameters: Inverse Short-Time FFT

Inverse Short-Time FFT (mask) (link)

Reconstructs a signal from its Short-Time FFT (STFFT) by using the OLA method. The block takes as an input the analysis window w[n] used in the generation of the STFFT to normalize the output signal.

Optionally, the block asserts if the analysis window does not satisfy constraints that permit perfect reconstruction of the signal.

Parameters

Analysis window length: 512

Overlap between consecutive STFFT frames (in samples): 384

Samples per output frame: 512

☑ Input is conjugate symmetric

☐ Assert if analysis window does not support perfect signal reconstruction

Analysis window length

Enter the length of the analysis window. This parameter is visible when you select the **Assert if analysis window does not support perfect signal reconstruction** check box.

Overlap between consecutive STFFT frames (in samples)

Enter the number of samples of overlap for each frame of the Short-Time FFT block's input signal. This value should be the same as the **Overlap between consecutive windows (in samples)** parameter in the Short-Time FFT block parameters dialog.

Samples per output frame

Enter the desired frame size of the output signal.

Input is conjugate symmetric

Select this check box when the input to the block is both floating point and conjugate symmetric, and you want real-valued outputs. When you select this check box when the input is not conjugate symmetric, the output of the block is invalid. This parameter cannot be used for fixed-point signals.

Assert if analysis window does not support perfect signal reconstruction

Select this check box to display an error when the analysis window used by the Short-Time FFT block does not support perfect signal reconstruction.

Reconstruction error tolerance

Enter the amount of acceptable error in the reconstruction of the original signal. This parameter is visible when you select the **Assert if analysis window does not support perfect signal reconstruction** check box.

Design method: Equiripple

Design options

Filter Implementation

Structure: Direct-form FIR

□ Use basic elements to enable filter customization

Input processing: Columns as channels (frame based)

□ Use symbolic names for coefficients

View filter response

This button opens the Filter Visualization Tool (`fvtool`) from the Signal Processing Toolbox product. You can use the tool to display:

- Magnitude response, phase response, and group delay in the frequency domain.
- Impulse response and step response in the time domain.
- Pole-zero information.

The tool also helps you evaluate filter performance by providing information about filter order, stability, and phase linearity. For more information on FVTool, see the Signal Processing Toolbox documentation.

Filter Specifications

In this group, you specify your filter format, such as the impulse response and the filter order.

Order mode

Select either `Minimum` (the default) or `Specify` from the drop-down list. Selecting `Specify` enables the **Order** option (see the following sections) so you can enter the filter order.

Response type

Select `Lowpass` or `Highpass` to design an inverse sinc lowpass or highpass filter.

Filter type

Select `Single-rate`, `Decimator`, `Interpolator`, or `Sample-rate converter`. Your choice determines the type of filter as well as the design methods and structures that are available to implement your filter. By default, the block specifies a single-rate filter.

- Selecting `Decimator` or `Interpolator` activates the **Decimation Factor** or the **Interpolation Factor** options respectively.
- Selecting `Sample-rate converter` activates both factors.

Order

Enter the filter order. This option is enabled only if you set the **Order mode** to `Specify`.

Decimation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to `Decimator` or `Sample-rate converter`. The default value is 2.

Interpolation Factor

Enter the interpolation factor. This option is enabled only if the **Filter type** is set to `Interpolator` or `Sample-rate converter`. The default value is 2.

Frequency Specifications

The parameters in this group allow you to specify your filter response curve.

Regions between specification values such as **Fpass** and **Fstop** represent transition regions where the filter response is not constrained.

Frequency constraints

When **Order mode** is `Specify`, select the filter features that the block uses to define the frequency response characteristics. The list contains the following options, when available for the filter specifications.

- `Passband and stopband edges` — Define the filter by specifying the frequencies for the edges for the stop- and passbands.
- `Passband edges` — For IIR filters, define the filter by specifying frequencies for the edges of the passband.
- `Stopband edges` — For IIR filters, define the filter by specifying frequencies for the edges of the stopbands.
- `6 dB point` — For FIR filters, define the filter response by specifying the locations of the 6 dB point. The 6 dB point is the frequency for the point six decibels below the passband value.

Frequency units

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select `Normalized (0–1)` to enter frequencies in normalized form. This behavior is the default. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—`Hz`, `kHz`, `MHz`, or `GHz`. Selecting one of the unit options enables the **Input Fs** parameter.

Input Fs

Fs, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is

available when you select one of the frequency options from the **Frequency units** list.

Fpass

Enter the frequency at the end of the passband. Specify the value in either normalized frequency units or the absolute units you select in **Frequency units**.

Fstop

Enter the frequency at the start of the stopband. Specify the value in either normalized frequency units or the absolute units you select in **Frequency units**.

F6dB

When **Frequency constraints** is `6 dB point`, specify the frequency of the 6 dB point. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

Magnitude Specifications

Parameters in this group specify the filter response in the passbands and stopbands.

Magnitude units

Specify the units for any parameter you provide in magnitude specifications. From the drop-down list, select one of the following options:

- `Linear` — Specify the magnitude in linear units.
- `dB` — Specify the magnitude in decibels (default)
- `Squared` — Specify the magnitude in squared units.

Apass

Enter the filter ripple allowed in the passband in the units you choose for **Magnitude units**, either linear or decibels.

Astop

Enter the filter attenuation in the stopband in the units you choose for **Magnitude units**, either linear or decibels.

Algorithm

The parameters in this group allow you to specify the design method and structure of your filter.

Design Method

Lists the design methods available for the frequency and magnitude specifications you entered. When you change the specifications for a filter, such as changing the impulse response, the methods available to design filters changes as well. The default FIR method is `Equiripple`.

Design Options

The options for each design are specific for each design method. This section does not present all of the available options for all designs and design methods. There are many more that you encounter as you select different design methods and filter specifications. The following options represent some of the most common ones available.

Density factor

Density factor controls the density of the frequency grid over which the design method optimization evaluates your filter response function. The number of equally spaced points in the grid is the value you enter for **Density factor** times (filter order + 1).

Increasing the value creates a filter that more closely approximates an ideal equiripple filter but increases the time required to design the filter. The default value of 20 represents a reasonable trade between the accurate approximation to the ideal filter and the time to design the filter.

Phase constraint

Specify the phase constraint of the filter as `Linear`, `Maximum`, or `Minimum`.

Minimum order

When you select this parameter, the design method determines and design the minimum order filter to meet your specifications. Some filters do not provide this parameter. Select `Any`, `Even`, or `Odd` from the drop-down list to direct the design to be any minimum order, or minimum even order, or minimum odd order.

Stopband Shape

Stopband shape lets you specify how the stopband changes with increasing frequency. Choose one of the following options;

- `Flat` — Specifies that the stopband is flat. The attenuation does not change as the frequency increases.
- `Linear` — Specifies that the stopband attenuation changes linearly as the frequency increases. Change the slope of the stopband by setting **Stopband decay**.

- `1/f` — Specifies that the stopband attenuation changes exponentially as the frequency increases, where `f` is the frequency. Set the power (exponent) for the decay in **Stopband decay**.

Stopband Decay

When you set **Stopband shape**, **Stopband decay** specifies the amount of decay applied to the stopband. the following conditions apply to **Stopband decay** based on the value of **Stopband Shape**:

- When you set **Stopband shape** to `Flat`, **Stopband decay** has no affect on the stopband.
- When you set **Stopband shape** to `Linear`, enter the slope of the stopband in units of dB/rad/s. The block applies that slope to the stopband.
- When you set **Stopband shape** to `1/f`, enter a value for the exponent *n* in the relation $(1/f)^n$ to define the stopband decay. The block applies the $(1/f)^n$ relation to the stopband to result in an exponentially decreasing stopband attenuation.

Sinc frequency factor

A frequency dilation factor. The **Sinc frequency factor**, *C* , parameterizes the passband magnitude response for a lowpass design through H(ω) = sinc(Cω)^(-P) and through H(ω) = sinc(C(1-ω))^(-P) for a highpass design.

Sinc power

Negative power of passband magnitude response. The **Sinc power**, *P*, parameterizes the passband magnitude response for a lowpass design through H(ω) = sinc(Cω)^(-P) and through H(ω) = sinc(C(1-ω))^(-P) for a highpass design.

Filter Implementation

Structure

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. By default, FIR filters use direct-form structure, and IIR filters use direct-form II filters with SOS.

Use basic elements to enable filter customization

Select this check box to implement the filter as a subsystem of basic Simulink blocks. Clear the check box to implement the filter as a high-level subsystem. By default, this check box is cleared.

The high-level implementation provides better compatibility across various filter structures, especially filters that would contain algebraic loops when constructed using basic elements. On the other hand, using basic elements enables the following optimization parameters:

- **Optimize for zero gains** — Terminate chains that contain Gain blocks with a gain of zero.
- **Optimize for unit gains** — Remove Gain blocks that scale by a factor of one.
- **Optimize for delay chains** — Substitute delay chains made up of *n* unit delays with a single delay by *n*.
- **Optimize for negative gains** — Use subtraction in Sum blocks instead of negative gains in Gain blocks.

Input processing

Specify how the block should process the input. The available options may vary depending on he settings of the **Filter Structure** and **Use basic elements for filter customization** parameters. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` — When you select this option, the block treats each column of the input as a separate channel.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

Note: The `Inherited (this choice will be removed — see release notes)` option will be removed in a future release. See “Frame-Based Processing” in the *DSP System Toolbox Release Notes* for more information.

Rate options

When the **Filter type** parameter specifies a multirate filter, select the rate processing rule for the block from following options:

- `Enforce single-rate processing` — When you select this option, the block maintains the sample rate of the input.
- `Allow multirate processing` — When you select this option, the block adjusts the rate at the output to accommodate an increased or reduced number of samples. To select this option, you must set the **Input processing** parameter to `Elements as channels (sample based)`.

Use symbolic names for coefficients

Select this check box to enable the specification of coefficients using MATLAB variables. The available coefficient names differ depending on the filter structure. Using symbolic names allows tuning of filter coefficients in generated code. By default, this check box is cleared.

Supported Data Types

Port	Supported Data Types

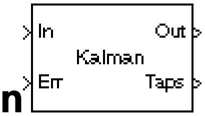
Output	• Double-precision floating point • Single-precision floating point

Kalman Adaptive Filter (Obsolete)

Compute filter estimates for inputs using Kalman adaptive filter algorithm

Library

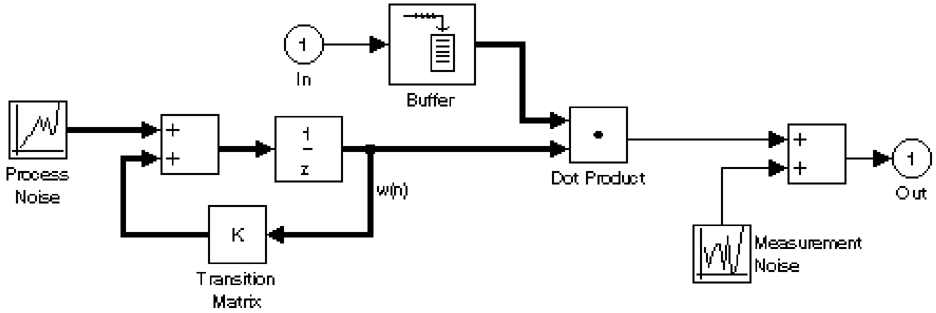
dspobslib



Description

Note The Kalman Adaptive Filter block is still supported but is likely to be obsoleted in a future release. We strongly recommend replacing this block with the Kalman Filter block.

The Kalman Adaptive Filter block computes the optimal linear minimum mean-square estimate (MMSE) of the FIR filter coefficients using a one-step predictor algorithm. This Kalman filter algorithm is based on the following physical realization of a dynamic system.



The Kalman filter assumes that there are no deterministic changes to the filter taps over time (that is, the transition matrix is identity), and that the only observable output from the system is the filter output with additive noise. The corresponding Kalman filter is expressed in matrix form as

$$
\begin{aligned}
&g(n) = \frac{K(n-1)u(n)}{u^H(n)K(n-1)u(n) + Q_M} \\
&y(n) = u^H(n)\widehat{w}(n) \\
&e(n) = d(n) - y(n) \\
&\widehat{w}(n+1) = \widehat{w}(n) + e(n)g(n) \\
&K(n) = K(n-1) - g(n)u^H(n)K(n-1) + Q_p
\end{aligned}
$$

The variables are as follows

Variable	Description
n	The current algorithm iteration
$u(n)$	The buffered input samples at step n
$K(n)$	The correlation matrix of the state estimation error
$g(n)$	The vector of Kalman gains at step n
$\widehat{w}(n)$	The vector of filter-tap estimates at step n
$y(n)$	The filtered output at step n
$e(n)$	The estimation error at step n
$d(n)$	The desired response at step n
Q_M	The correlation matrix of the measurement noise
Q_P	The correlation matrix of the process noise

The correlation matrices, Q_M and Q_P, are specified in the parameter dialog by scalar variance terms to be placed along the matrix diagonals, thus ensuring that these matrices are symmetric. The filter algorithm based on this constraint is also known as the random-walk Kalman filter.

The implementation of the algorithm in the block is optimized by exploiting the symmetry of the input covariance matrix $K(n)$. This decreases the total number of computations by a factor of two.

The block icon has port labels corresponding to the inputs and outputs of the Kalman algorithm. Note that inputs to the In and Err ports must be sample-based scalars with the same complexity. The signal at the Out port is a scalar, while the signal at the Taps port is a sample-based vector.

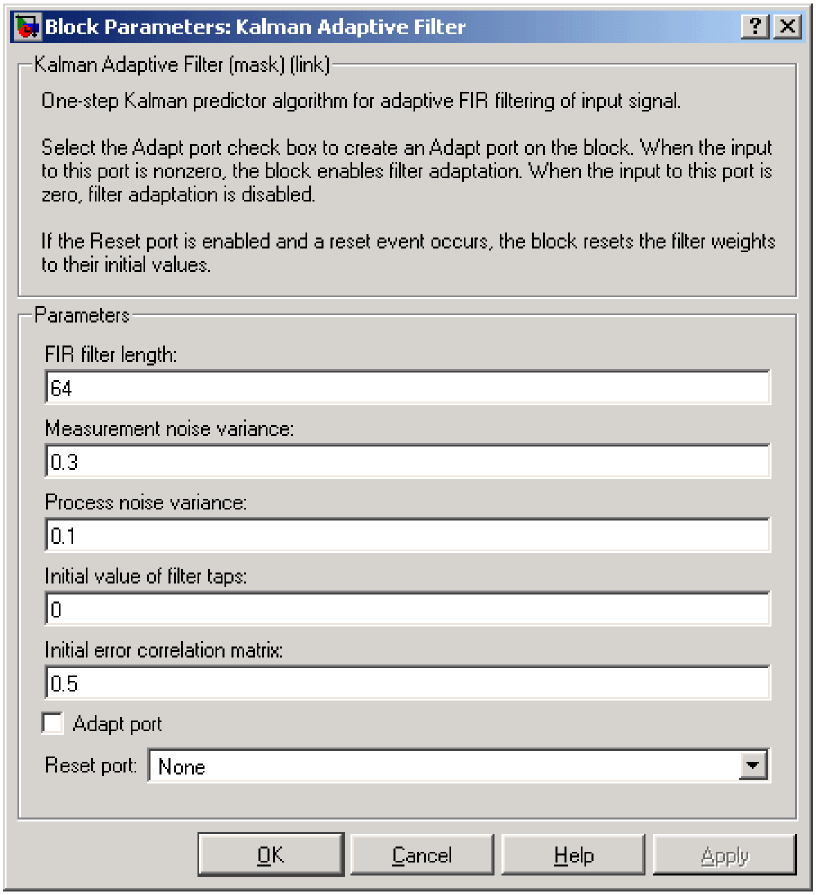
Block Ports	Corresponding Variables
In	u, the scalar input, which is internally buffered into the vector *u(n)*
Out	*y(n)*, the filtered scalar output
Err	*e(n)*, the scalar estimation error
Taps	$\hat{w}(n)$, the vector of filter-tap estimates

An optional Adapt input port is added when you select the **Adapt port** check box in the dialog. When this port is enabled, the block continuously adapts the filter coefficients while the Adapt input is nonzero. A zero-valued input to the `Adapt` port causes the block to stop adapting, and to hold the filter coefficients at their current values until the next nonzero Adapt input.

The **FIR filter length** parameter specifies the length of the filter that the Kalman algorithm estimates. The **Measurement noise variance** and the **Process noise variance** parameters specify the correlation matrices of the measurement and process noise, respectively. The **Measurement noise variance** must be a scalar, while the **Process noise variance** can be a vector of values to be placed along the diagonal, or a scalar to be repeated for the diagonal elements.

The **Initial value of filter taps** specifies the initial value $\hat{w}(0)$ as a vector, or as a scalar to be repeated for all vector elements. The **Initial error correlation matrix** specifies the initial value *K(0)*, and can be a diagonal matrix, a vector of values to be placed along the diagonal, or a scalar to be repeated for the diagonal elements.

Dialog Box



Block Parameters: Kalman Adaptive Filter

Kalman Adaptive Filter (mask) (link)

One-step Kalman predictor algorithm for adaptive FIR filtering of input signal.

Select the Adapt port check box to create an Adapt port on the block. When the input to this port is nonzero, the block enables filter adaptation. When the input to this port is zero, filter adaptation is disabled.

If the Reset port is enabled and a reset event occurs, the block resets the filter weights to their initial values.

Parameters

FIR filter length: 64

Measurement noise variance: 0.3

Process noise variance: 0.1

Initial value of filter taps: 0

Initial error correlation matrix: 0.5

□ Adapt port

Reset port: None

FIR filter length

The length of the FIR filter.

Measurement noise variance

The value to appear along the diagonal of the measurement noise correlation matrix. “Tunable”.

Process noise variance

The value to appear along the diagonal of the process noise correlation matrix. “Tunable”.

Initial value of filter taps

The initial FIR filter coefficients.

Initial error correlation matrix

The initial value of the error correlation matrix.

Adapt port

Enables the `Adapt` port.

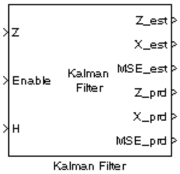
Kalman Filter

Predict or estimate states of dynamic systems

Library

Filtering/Adaptive Filters

`dspadpt3`



Description

Use the Kalman Filter block to predict or estimate the state of a dynamic system from a series of incomplete and/or noisy measurements. Suppose you have a noisy linear system that is defined by the following equations:

$$x_k = Ax_{k-1} + w_{k-1}$$
$$z_k = Hx_k + v_k$$

This block can use the previously estimated state, $\hat{x}_{k-1}$, to predict the current state at time k, x_k^-, as shown by the following equation:

$$x_k^- = A\hat{x}_{k-1}$$
$$P_k^- = A\hat{P}_{k-1}A^T + Q$$

The block can also use the current measurement, z_k, and the predicted state, x_k^-, to estimate the current state value at time k, $\hat{x}_k$, so that it is a more accurate approximation:

$$K_k = P_k^- H^T \left(H P_k^- H^T + R \right)^{-1}$$

$$\hat{x}_k = x_k^- + K_k \left(z_k - H x_k^- \right)$$

$$\hat{P}_k = \left(I - K_k H \right) P_k^-$$

The variables in the previous equations are defined in the following table.

Variable	Definition	Default Value or Initial Condition
x	State	N/A
$\hat{x}$	Estimated state	`zeros([6, 1])`
x^-	Predicted state	N/A
A	State transition matrix	$\begin{bmatrix} 1 & 0 & 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 \end{bmatrix}$
w	Process noise	N/A
z	Measurement	N/A
H	Measurement matrix	$\begin{bmatrix} 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 \end{bmatrix}$
v	Measurement noise	N/A
$\hat{P}$	Estimated error covariance	`10*eye(6)`
P^-	Predicted error covariance	N/A
Q	Process noise covariance	`0.05*eye(6)`
K	Kalman gain	N/A

Variable	Definition	Default Value or Initial Condition
R	Measurement noise covariance	`eye(4)`
I	Identity matrix	N/A

In the previous equations, z is a vector of measurement values. Most of the time, the block processes Z, an M-by-N matrix, where M is the number of measurement values and N is the number of filters.

Use the **Number of filters** parameter to specify the number of filters to use to predict or estimate the current value.

Use the **Enable filters** parameter to specify which filters are enabled or disabled at each time step. If you select `Always`, the filters are always enabled. If you choose `Specify via input port <Enable>`, the Enable port appears on the block. The input to this port must be a row vector of 1s and 0s whose length is equal to the number of filters. For example, if there are 3 filters and the input to the Enable port is [1 0 1], only the first and third filter are enabled at this time step. If you select the **Reset the estimated state and estimated error covariance when filters are disabled** check box, the estimated and predicted states as well as the estimated error covariance that correspond to the disabled filters are reset to their initial values.

Note: All filters have the same state transition matrix, measurement matrix, initial conditions, and noise covariance, but their state, measurement, enable, and MSE signals are unique. Within the state, measurement, enable, and MSE signals, each column corresponds to a filter.

Use the **Measurement matrix source** parameter to specify how to enter the measurement matrix values. If you select `Specify via dialog`, the **Measurement matrix** parameter appears in the dialog box. If you select `Input port <H>`, the H port appears on the block. Use this port to specify your measurement matrix.

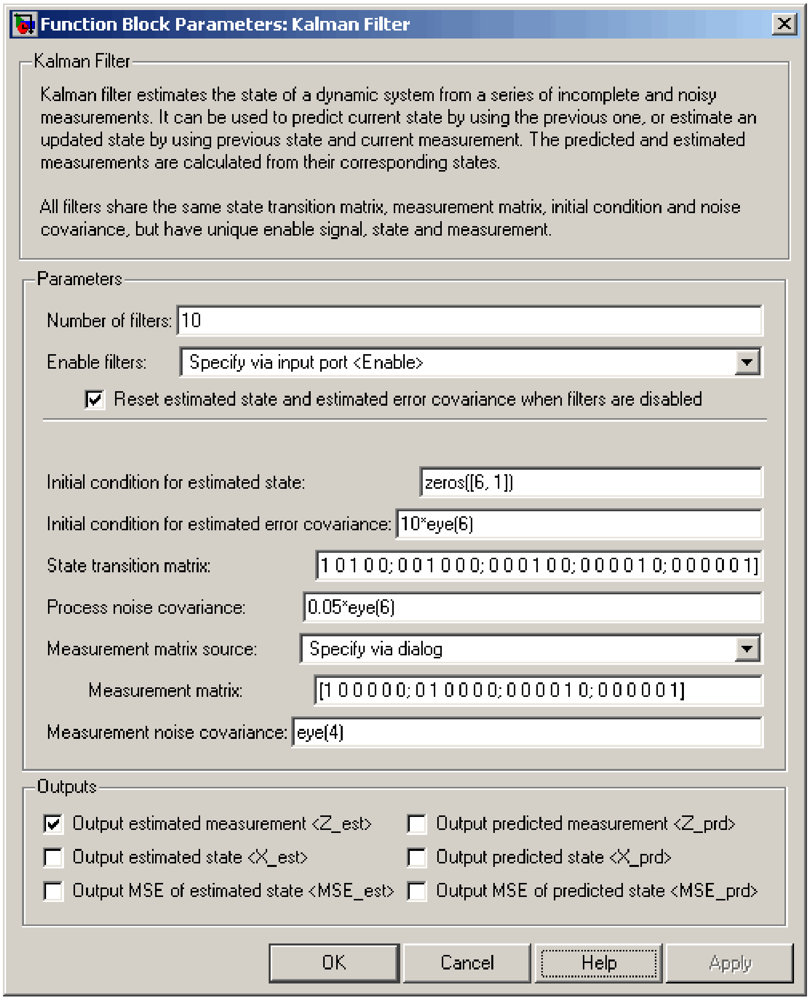
See the Radar Tracking example for a demonstration of how to use this block. You can open this example by typing

```
aero_radmod_dsp
```

at the MATLAB command prompt.

Dialog Box

The Kalman Filter dialog box appears as shown in the following figure.



Function Block Parameters: Kalman Filter

Kalman Filter

Kalman filter estimates the state of a dynamic system from a series of incomplete and noisy measurements. It can be used to predict current state by using the previous one, or estimate an updated state by using previous state and current measurement. The predicted and estimated measurements are calculated from their corresponding states.

All filters share the same state transition matrix, measurement matrix, initial condition and noise covariance, but have unique enable signal, state and measurement.

Parameters

Number of filters: 10

Enable filters: Specify via input port <Enable>

☑ Reset estimated state and estimated error covariance when filters are disabled

Initial condition for estimated state: zeros([6, 1])

Initial condition for estimated error covariance: 10*eye(6)

State transition matrix: 1 0 1 0 0; 0 0 1 0 0 0; 0 0 0 1 0 0; 0 0 0 0 1 0; 0 0 0 0 0 1]

Process noise covariance: 0.05*eye(6)

Measurement matrix source: Specify via dialog

Measurement matrix: [1 0 0 0 0 0; 0 1 0 0 0 0; 0 0 0 0 1 0; 0 0 0 0 0 1]

Measurement noise covariance: eye(4)

Outputs

☑ Output estimated measurement <Z_est>
□ Output predicted measurement <Z_prd>
□ Output estimated state <X_est>
□ Output predicted state <X_prd>
□ Output MSE of estimated state <MSE_est>
□ Output MSE of predicted state <MSE_prd>

Number of filters

Specify the number of filters to use to predict or estimate the current value.

Enable filters

Specify which filters are enabled or disabled at each time step. If you select `Always`, the filters are always enabled. If you choose `Specify via input port <Enable>`, the Enable port appears on the block.

Reset the estimated state and estimated error covariance when filters are disabled

If you select this check box, the estimated and predicted states as well as the estimated error covariance that correspond to the disabled filters are reset to their initial values. This parameter is visible if, for the **Enable filters** parameter, you select `Specify via input port <Enable>`.

Initial condition for estimated state

Enter the initial condition for the estimated state.

Initial condition for estimated error covariance

Enter the initial condition for the estimated error covariance.

State transition matrix

Enter the state transition matrix.

Process noise covariance

Enter the process noise covariance.

Measurement matrix source

Specify how to enter the measurement matrix values. If you select `Specify via dialog`, the **Measurement matrix** parameter appears in the dialog box. If you select `Input port <H>`, the H port appears on the block.

Measurement matrix

Enter the measurement matrix values. This parameter is visible if you select `Specify via dialog` for the **Measurement matrix source** parameter.

Measurement noise covariance

Enter the measurement noise covariance.

Output estimated measurement <Z_est>

Select this check box if you want the block to output the estimated measurement.

Output estimated state <X_est>

Select this check box if you want the block to output the estimated state.

Output MSE of estimated state <MSE_est>

Select this check box if you want the block to output the mean-squared error of the estimated state.

Output predicted measurement <Z_prd>

Select this check box if you want the block to output the predicted measurement.

Output predicted state <X_prd>

Select this check box if you want the block to output the predicted state.

Output MSE of predicted state <MSE_prb>

Select this check box if you want the block to output the mean-squared error of the predicted state.

LDL Solver	DSP System Toolbox

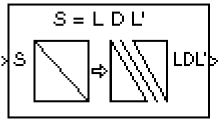
LDL Factorization

Factor square Hermitian positive definite matrices into lower, upper, and diagonal components

Library

Math Functions / Matrices and Linear Algebra / Matrix Factorizations

`dspfactors`



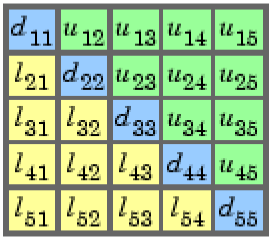
Description

The LDL Factorization block uniquely factors the square Hermitian positive definite input matrix S as

$$S = LDL^*$$

where L is a lower triangular square matrix with unity diagonal elements, D is a diagonal matrix, and L^* is the Hermitian (complex conjugate) transpose of L. Only the diagonal and lower triangle of the input matrix are used, and any imaginary component of the diagonal entries is disregarded.

The block's output is a composite matrix with lower triangle elements l_{ij} from L, diagonal elements d_{ij} from D, and upper triangle elements u_{ij} from L^*. The output format is shown below for a 5-by-5 matrix.



d_{11}	u_{12}	u_{13}	u_{14}	u_{15}
l_{21}	d_{22}	u_{23}	u_{24}	u_{25}
l_{31}	l_{32}	d_{33}	u_{34}	u_{35}
l_{41}	l_{42}	l_{43}	d_{44}	u_{45}
l_{51}	l_{52}	l_{53}	l_{54}	d_{55}

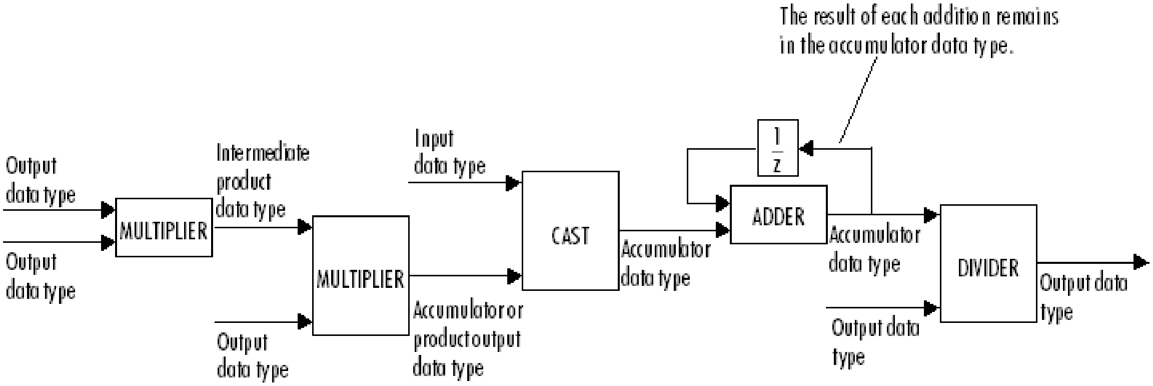
$$u_{ij} = l_{ji}^*$$

LDL factorization requires half the computation of Gaussian elimination (LU decomposition), and is always stable. It is more efficient than Cholesky factorization because it avoids computing the square roots of the diagonal elements.

The algorithm requires that the input be square and Hermitian positive definite. When the input is not positive definite, the block reacts with the behavior specified by the **Non-positive definite input** parameter.

Fixed-Point Data Types

The following diagram shows the data types used within the LDL Factorization block for fixed-point signals.

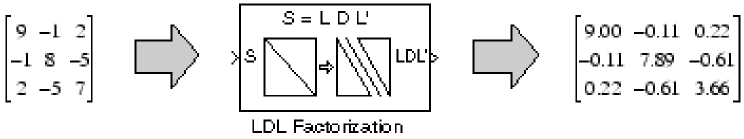


You can set the intermediate product, product output, accumulator, and output data types in the block dialog as discussed below.

The output of the second multiplier is in the product output data type when the input is real. When the input is complex, the result of the multiplication is in the accumulator data type. For details on the complex multiplication performed, see “Multiplication Data Types”.

Examples

LDL decomposition of a 3-by-3 Hermitian positive definite matrix:

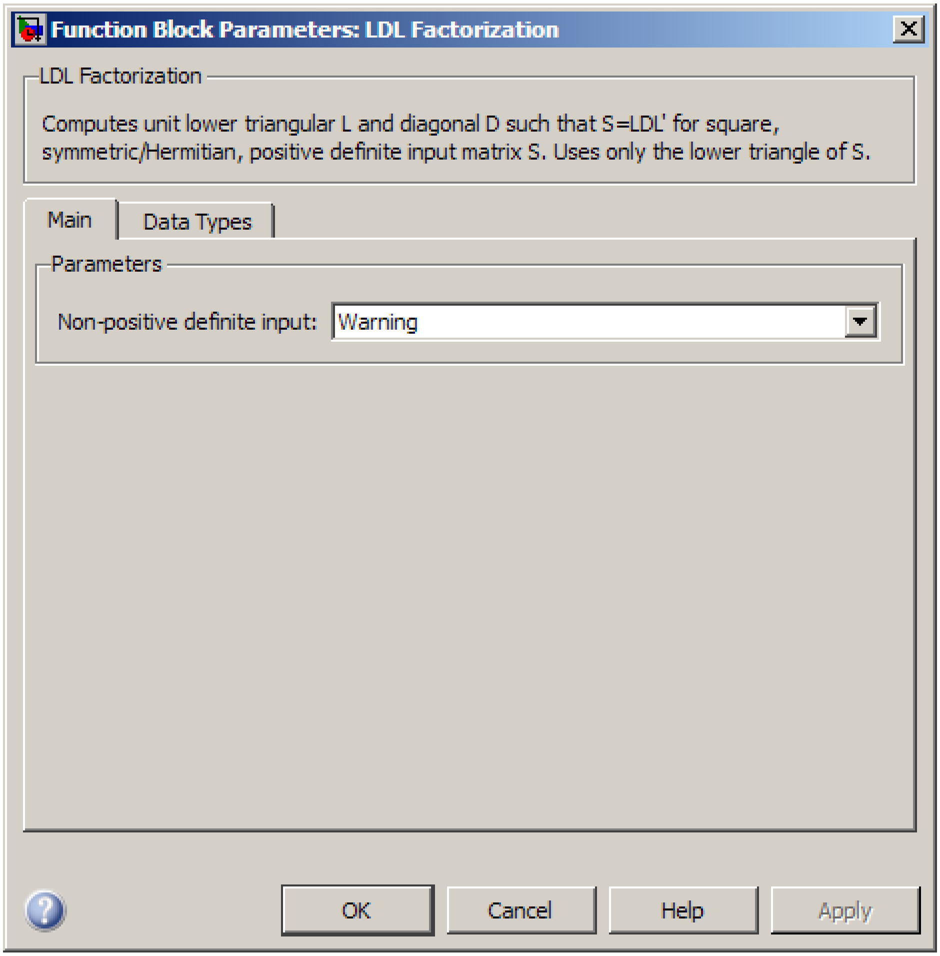


$$\begin{bmatrix} 9 & -1 & 2 \\ -1 & 8 & -5 \\ 2 & -5 & 7 \end{bmatrix} \Rightarrow \begin{bmatrix} 9.00 & -0.11 & 0.22 \\ -0.11 & 7.89 & -0.61 \\ 0.22 & -0.61 & 3.66 \end{bmatrix}$$

$$L = \begin{bmatrix} 1 & 0 & 0 \\ -0.11 & 1 & 0 \\ 0.22 & -0.61 & 1 \end{bmatrix} \quad D = \begin{bmatrix} 9.00 & 0 & 0 \\ 0 & 7.89 & 0 \\ 0 & 0 & 3.66 \end{bmatrix} \quad L' = \begin{bmatrix} 1 & -0.11 & 0.22 \\ 0 & 1 & -0.61 \\ 0 & 0 & 1 \end{bmatrix}$$

Dialog Box

The **Main** pane of the LDL Factorization block dialog appears as follows.



Function Block Parameters: LDL Factorization

LDL Factorization

Computes unit lower triangular L and diagonal D such that S=LDL' for square, symmetric/Hermitian, positive definite input matrix S. Uses only the lower triangle of S.

Non-positive definite input: Warning

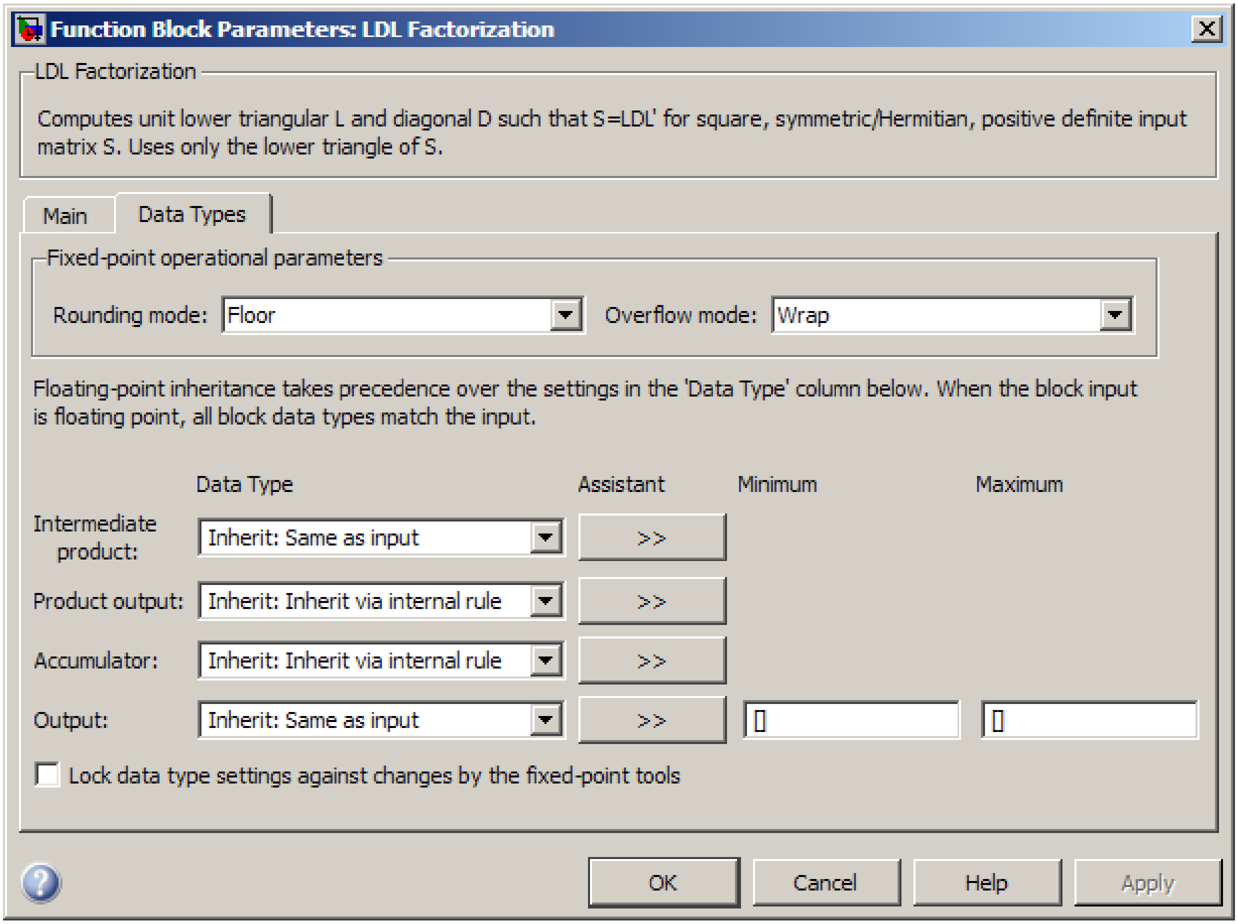
Non-positive definite input

Specify the action when nonpositive definite matrix inputs occur:

- `Ignore` — Proceed with the computation and do not issue an alert. The output is not a valid factorization. A partial factorization is present in the upper left corner of the output.
- `Warning` — Display a warning message in the MATLAB Command Window, and continue the simulation. The output is not a valid factorization. A partial factorization is present in the upper left corner of the output.

- `Error` — Display an error dialog and terminate the simulation.

The **Data Types** pane of the LDL Factorization block dialog appears as follows.



Function Block Parameters: LDL Factorization

LDL Factorization

Computes unit lower triangular L and diagonal D such that S=LDL' for square, symmetric/Hermitian, positive definite input matrix S. Uses only the lower triangle of S.

Fixed-point operational parameters

Rounding mode: Floor

Overflow mode: Wrap

Floating-point inheritance takes precedence over the settings in the 'Data Type' column below. When the block input is floating point, all block data types match the input.

	Data Type	Assistant	Minimum	Maximum
Intermediate product:	Inherit: Same as input	>>		
Product output:	Inherit: Inherit via internal rule	>>		
Accumulator:	Inherit: Inherit via internal rule	>>		
Output:	Inherit: Same as input	>>	[]	[]

□ Lock data type settings against changes by the fixed-point tools

Rounding mode

Select the "rounding mode" for fixed-point operations.

Overflow mode

Select the "overflow mode" for fixed-point operations.

Intermediate product

Specify the intermediate product data type. As shown in “Fixed-Point Data Types” on page 1-808, the output of the multiplier is cast to the intermediate product data type before the next element of the input is multiplied into it. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as input`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Product output data type** parameter.

See “Specify Data Types Using Data Type Assistant” in “Simulink User's Guide” for more information.

Product output data type

Specify the product output data type. See “Fixed-Point Data Types” on page 1-808 and “Multiplication Data Types” for illustrations depicting the use of the product output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Product output data type** parameter.

See “Specify Data Types Using Data Type Assistant” in “Simulink User's Guide” for more information.

Accumulator data type

Specify the accumulator data type. See “Fixed-Point Data Types” on page 1-808 for illustrations depicting the use of the accumulator data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Accumulator data type** parameter.

See “Specify Data Types Using Data Type Assistant” in “Simulink User's Guide” for more information.

Output data type

Specify the output data type. See “Fixed-Point Data Types” on page 1-808 for illustrations depicting the use of the output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as input`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Specify Block Output Data Types” in “Simulink User's Guide” for more information.

Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

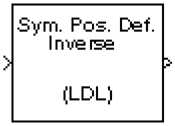
LDL Inverse

Compute inverse of Hermitian positive definite matrix using LDL factorization

Library

Math Functions / Matrices and Linear Algebra / Matrix Inverses

`dspinverses`



Description

The LDL Inverse block computes the inverse of the Hermitian positive definite input matrix S by performing an LDL factorization.

$$S^{-1} = \left(LDL^{*}\right)^{-1}$$

L is a lower triangular square matrix with unity diagonal elements, *D* is a diagonal matrix, and L^{*} is the Hermitian (complex conjugate) transpose of *L*. Only the diagonal and lower triangle of the input matrix are used, and any imaginary component of the diagonal entries is disregarded.

LDL factorization requires half the computation of Gaussian elimination (LU decomposition), and is always stable. It is more efficient than Cholesky factorization because it avoids computing the square roots of the diagonal elements.

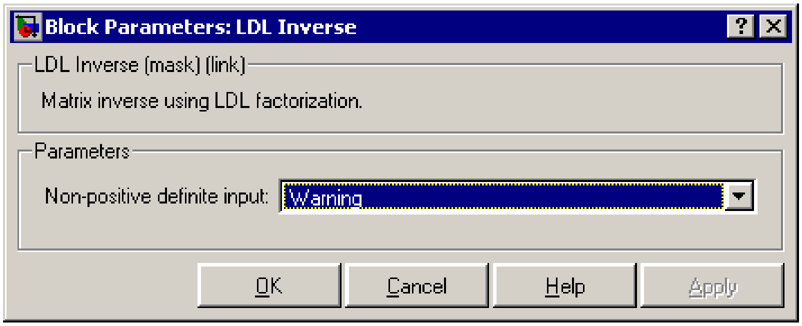
The algorithm requires that the input be Hermitian positive definite. When the input is not positive definite, the block reacts with the behavior specified by the **Non-positive definite input** parameter. The following options are available:

- `Ignore` — Proceed with the computation and do not issue an alert. The output is not a valid inverse.

- `Warning` — Display a warning message in the MATLAB command window, and continue the simulation. The output is not a valid inverse.
- `Error` — Display an error dialog and terminate the simulation.

Note The **Non-positive definite input** parameter is a diagnostic parameter. Like all diagnostic parameters on the Configuration Parameters dialog, it is set to `Ignore` in the code generated for this block by Simulink Coder code generation software.

Dialog Box



Block Parameters: LDL Inverse

LDL Inverse (mask) (link)

Matrix inverse using LDL factorization.

Parameters

Non-positive definite input: Warning

Non-positive definite input

Response to nonpositive definite matrix inputs.

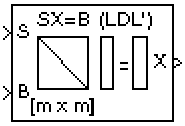
LDL Solver

Solve *SX*=*B* for *X* when *S* is square Hermitian positive definite matrix

Library

Math Functions / Matrices and Linear Algebra / Linear System Solvers

`dspsolvers`



Description

The LDL Solver block solves the linear system *S*X=*B* by applying LDL factorization to the matrix at the S port, which must be square (*M*-by-*M*) and Hermitian positive definite. Only the diagonal and lower triangle of the matrix are used, and any imaginary component of the diagonal entries is disregarded. The input to the B port is the right side *M*-by-*N* matrix, *B*. The *M*-by-*N* output matrix *X* is the unique solution of the equations.

A length-*M* unoriented vector input for right side *B* is treated as an *M*-by-1 matrix.

When the input is not positive definite, the block reacts with the behavior specified by the **Non-positive definite input** parameter. The following options are available:

- `Ignore` — Proceed with the computation and do not issue an alert. The output is not a valid solution.
- `Warning` — Proceed with the computation and display a warning message in the MATLAB Command Window. The output is not a valid solution.
- `Error` — Display an error dialog and terminate the simulation.

Note The **Non-positive definite input** parameter is a diagnostic parameter. Like all diagnostic parameters on the Configuration Parameters dialog, it is set to `Ignore` in the code generated for this block by Simulink Coder code generation software.

Algorithm

The LDL algorithm uniquely factors the Hermitian positive definite input matrix S as
$S = LDL^*$

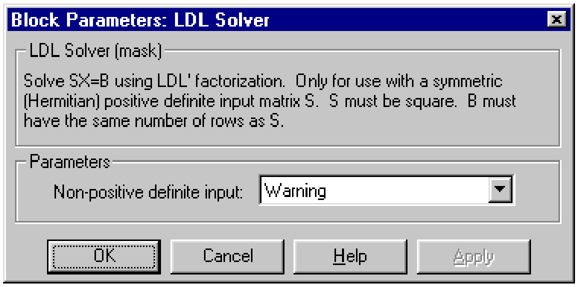
where L is a lower triangular square matrix with unity diagonal elements, D is a diagonal matrix, and L^* is the Hermitian (complex conjugate) transpose of L.

The equation
$LDL^*X = B$

is solved for X by the following steps:

1. Substitute
   $Y = DL^*X$
2. Substitute
   $Z = L^*X$
3. Solve one diagonal and two triangular systems.
   $LY = B$
   $DZ = Y$
   $L^*X = Z$

Dialog Box



Block Parameters: LDL Solver

LDL Solver (mask)

Solve SX=B using LDL' factorization. Only for use with a symmetric (Hermitian) positive definite input matrix S. S must be square. B must have the same number of rows as S.

Parameters

Non-positive definite input: Warning

Non-positive definite input

Response to nonpositive definite matrix inputs.

Supported Data Types

- Double-precision floating point
- Single-precision floating point

Least Squares Polynomial Fit

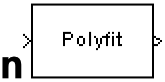
Compute polynomial coefficients that best fit input data in least-squares sense

Library

Math Functions / Polynomial Functions

```
dsppolyfun
```

Description



The Least Squares Polynomial Fit block computes the coefficients of the *n*th order polynomial that best fits the input data in the least-squares sense, where you specify *n* in the **Polynomial order** parameter. A distinct set of *n*+1 coefficients is computed for each column of the *M*-by-*N* input, *u*.

For a given input column, the block computes the set of coefficients, c_1, c_2, ..., c_{n+1}, that minimizes the quantity

$$\sum_{i=1}^{M}(u_i - \hat{u}_i)^2$$

where u_i is the *i*th element in the input column, and

$$\hat{u}_i = f(x_i) = c_1 x_i^n + c_2 x_i^{n-1} + \ldots + c_{n+1}$$

The values of the independent variable, x_1, x_2, ..., x_M, are specified as a length-*M* vector by the **Control points** parameter. The same *M* control points are used for all *N* polynomial fits, and can be equally or unequally spaced. The equivalent MATLAB code is shown below.

```
c = polyfit(x,u,n)      % Equivalent MATLAB code
```

For convenience, the block treats length-M unoriented vector input as an M-by-1 matrix.

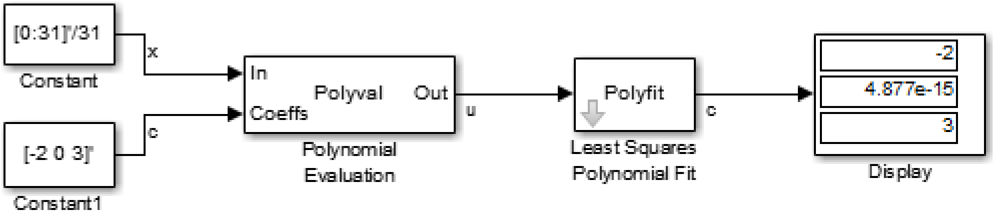
Each column of the (n+1)-by-N output matrix, c, represents a set of n+1 coefficients describing the best-fit polynomial for the corresponding column of the input. The coefficients in each column are arranged in order of descending exponents, c_1, c_2, ..., c_{n+1}.

Examples

In the ex_leastsquarespolyfit_ref model below, the Polynomial Evaluation block uses the second-order polynomial

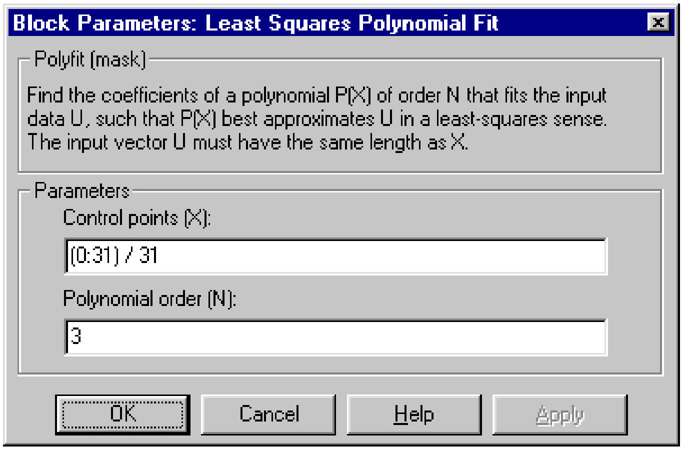
$$y = -2u^2 + 3$$

to generate four values of dependent variable y from four values of independent variable u, received at the top port. The polynomial coefficients are supplied in the vector `[-2 0 3]` at the bottom port. Note that the coefficient of the first-order term is zero.



The **Control points** parameter of the Least Squares Polynomial Fit block is configured with the same four values of independent variable u that are used as input to the Polynomial Evaluation block, `[1 2 3 4]`. The Least Squares Polynomial Fit block uses these values together with the input values of dependent variable y to reconstruct the original polynomial coefficients.

Dialog Box



Block Parameters: Least Squares Polynomial Fit

Polyfit (mask)

Find the coefficients of a polynomial P(X) of order N that fits the input data U, such that P(X) best approximates U in a least-squares sense. The input vector U must have the same length as X.

Parameters

Control points (X): (0:31) / 31

Polynomial order (N): 3

Control points

The values of the independent variable to which the data in each input column correspond. For an *M*-by-*N* input, this parameter must be a length-*M* vector. “Tunable”.

Polynomial order

The order, *n*, of the polynomial to be used in constructing the best fit. The number of coefficients is *n*+1.

Supported Data Types

- Double-precision floating point
- Single-precision floating point

Polynomial Stability Test	DSP System Toolbox

`polyfit`	MATLAB

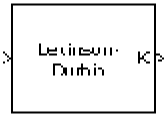
Levinson-Durbin

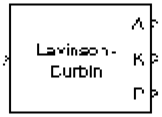
Solve linear system of equations using Levinson-Durbin recursion

Library

Math Functions / Matrices and Linear Algebra / Linear System Solvers

`dspsolvers`





Description

The Levinson-Durbin block solves the nth-order system of linear equations
$Ra = b$

in the cases where:

- R is a Hermitian, positive-definite, Toeplitz matrix.
- b is identical to the first column of R shifted by one element and with the opposite sign.

$$\begin{bmatrix} r(1) & r^*(2) & \cdots & r^*(n) \\ r(2) & r(1) & \cdots & r^*(n-1) \\ \vdots & \vdots & \ddots & \vdots \\ r(n) & r(n-1) & \cdots & r(1) \end{bmatrix} \begin{bmatrix} a(2) \\ a(3) \\ \vdots \\ a(n+1) \end{bmatrix} = \begin{bmatrix} -r(2) \\ -r(3) \\ \vdots \\ -r(n+1) \end{bmatrix}$$

The input to the block, r `= [`r`(1)` r`(2) ...` r`(`n`+1)]`, can be a vector or a matrix. If the input is a matrix, the block treats each column as an independent channel and solves it separately. Each channel of the input contains lags *0* through *n* of an autocorrelation sequence, which appear in the matrix *R*.

The block can output the polynomial coefficients, *A*, the reflection coefficients, *K*, and the prediction error power, *P*, in various combinations. The **Output(s)** parameter allows you to enable the *A* and *K* outputs by selecting one of the following settings:

- `A` — For each channel, port A outputs *A*=`[1` *a*`(2)` *a*`(3) ...` *a*`(`*n*`+1)]`, the solution to the Levinson-Durbin equation. *A* has the same dimension as the input. You can also view the elements of each output channel as the coefficients of an *n*th-order autoregressive (AR) process.
- `K` — For each channel, port K outputs *K*=`[`*k*`(1)` *k*`(2) ...` *k*`(`*n*`)]`, which contains *n* reflection coefficients and has the same dimension as the input, less one element. A scalar input channel causes an error when you select `K`. You can use reflection coefficients to realize a lattice representation of the AR process described later in this page.
- `A and K` — The block outputs both representations at their respective ports. A scalar input channel causes an error when you select `A and K`.

Select the **Output prediction error power (P)** check box to output the prediction error power for each channel, *P*. For each channel, *P* represents the power of the output of an FIR filter with taps *A* and input autocorrelation described by *r*, where *A* represents a prediction error filter and *r* is the input to the block. In this case, *A* is a whitening filter. *P* has one element per input channel.

When you select the **If the value of lag 0 is zero, A=[1 zeros], K=[zeros], P=0** check box (default), an input channel whose *r*`(1)` element is zero generates a zero-valued output. When you clear this check box, an input with *r*`(1) = 0` generates `NaN`s in the output. In general, an input with *r*`(1) = 0` is invalid because it does not construct a positive-definite matrix *R*. Often, however, blocks receive zero-valued inputs at the start of a simulation. The check box allows you to avoid propagating `NaN`s during this period.

Applications

One application of the Levinson-Durbin formulation implemented by this block is in the Yule-Walker AR problem, which concerns modeling an unknown system as an autoregressive process. You would model such a process as the output of an all-pole IIR filter with white Gaussian noise input. In the Yule-Walker problem, the use of the signal's autocorrelation sequence to obtain an optimal estimate leads to an $Ra = b$ equation of the type shown above, which is most efficiently solved by Levinson-Durbin recursion. In this case, the input to the block represents the autocorrelation sequence, with `r(1)` being the zero-lag value. The output at the block's A port then contains the coefficients of the autoregressive process that optimally models the system. The coefficients are ordered in descending powers of *z*, and the AR process is minimum phase. The prediction error, *G*, defines the gain for the unknown system, where $G = \sqrt{P}$:

$$H(z) = \frac{G}{A(z)} = \frac{G}{1 + a(2)z^{-1} + \ \dots \ + a(n+1)z^{-n}}$$

The output at the block's K port contains the corresponding reflection coefficients, `[`*k*`(1)` *k*`(2) ...` *k*`(n)]`, for the lattice realization of this IIR filter. The Yule-Walker AR Estimator block implements this autocorrelation-based method for AR model estimation, while the Yule-Walker Method block extends the method to spectral estimation.

Another common application of the Levinson-Durbin algorithm is in linear predictive coding, which is concerned with finding the coefficients of a moving average (MA) process (or FIR filter) that predicts the next value of a signal from the current signal sample and a finite number of past samples. In this case, the input to the block represents the signal's autocorrelation sequence, with *r*`(1)` being the zero-lag value, and the output at the block's A port contains the coefficients of the predictive MA process (in descending powers of *z*).

$$H(z) = A(z) = 1 + a(2)z^{-1} + \ \dots \ a(n+1)z^{-n}$$

These coefficients solve the following optimization problem:

$$\overset{\min}{\{a_i\}}$$

$$E\left[\left|x_n - \sum_{i=1}^{N} a_i x_{n-i}\right|^2\right]$$

Again, the output at the block's K port contains the corresponding reflection coefficients, `[k(1) k(2) ... k(n)]`, for the lattice realization of this FIR filter.

The Autocorrelation LPC block in the Linear Prediction library implements this autocorrelation-based prediction method.

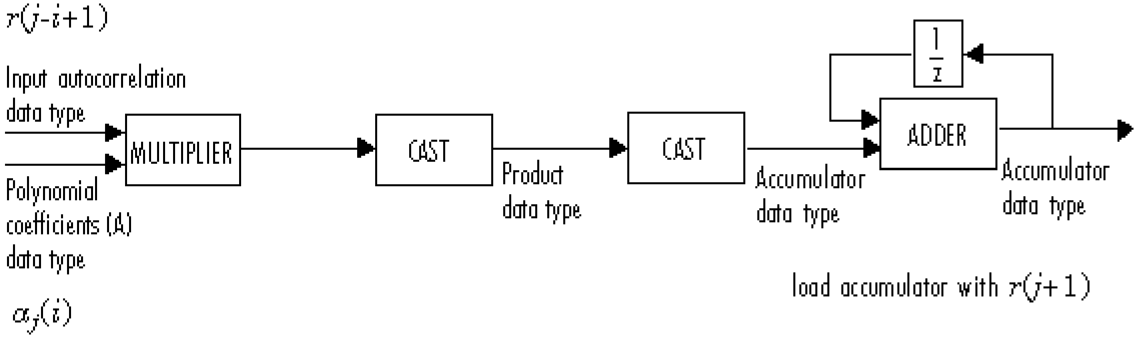
Fixed-Point Data Types

The diagrams in this section show the data types used within the Levinson-Durbin block for fixed-point signals.

After initialization the block performs *n* updates. At the (*j*+1) update,

$$\text{value in accumulator } = r(j+1) + \sum a_j(i) \times r\left(j-i+1\right)$$

The following diagram displays the fixed-point data types used in this calculation:



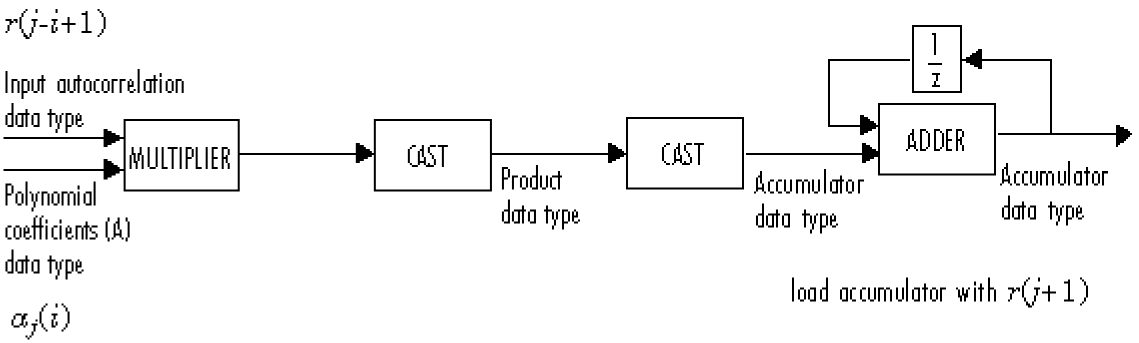
The block then updates the reflection coefficients *K* according to

$$K_{j+1} = \text{ value in accumulator } / P_j$$

The block then updates the prediction error power *P* according to

$$P_{j+1} = P_j - P_j \times K_{j+1} \times \text{conj}\left(K_{j+1}\right)$$

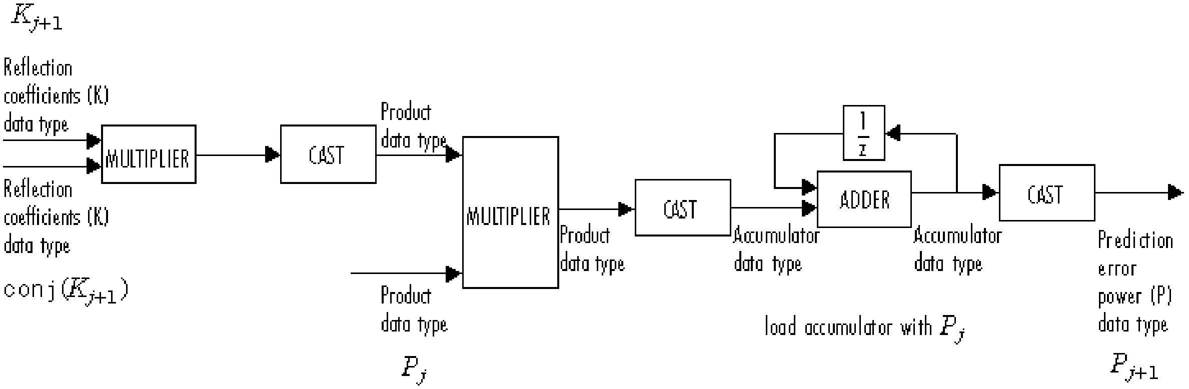
The next diagram displays the fixed-point data types used in this calculation:



The polynomial coefficients A are then updated according to

$$a_{j+1}(i) = a_j(i) + K_{j+1} \times \mathrm{conj}\left(\mathrm{a_j}(j-1+i)\right)$$

This diagram displays the fixed-point data types used in this calculation:

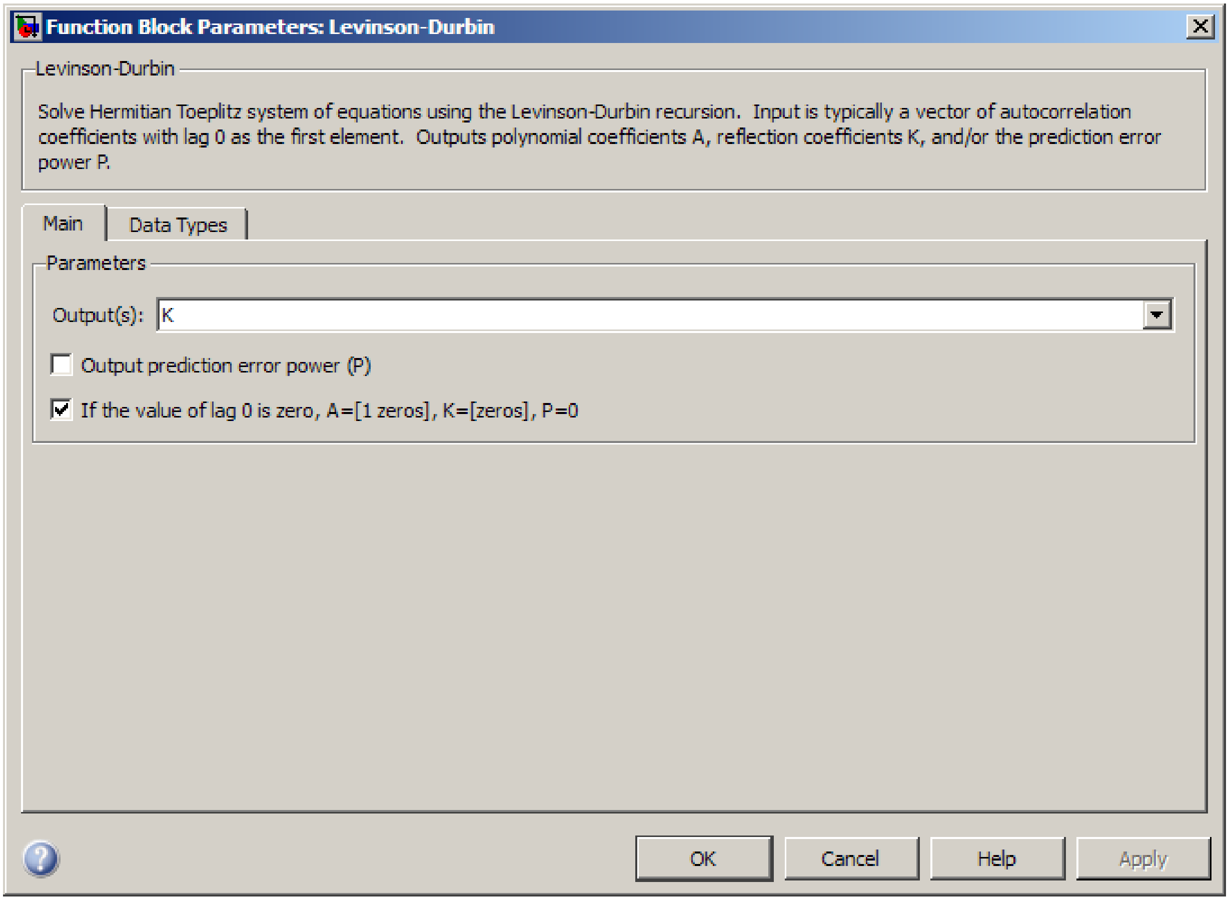


Algorithm

The algorithm requires $O(n^2)$ operations for each input channel. This implementation is therefore much more efficient for large n than standard Gaussian elimination, which requires $O(n^3)$ operations per channel.

Dialog Box

The **Main** pane of the Levinson-Durbin block dialog box appears as follows.



Function Block Parameters: Levinson-Durbin

Levinson-Durbin

Solve Hermitian Toeplitz system of equations using the Levinson-Durbin recursion. Input is typically a vector of autocorrelation coefficients with lag 0 as the first element. Outputs polynomial coefficients A, reflection coefficients K, and/or the prediction error power P.

Parameters

Output(s): K

□ Output prediction error power (P)

☑ If the value of lag 0 is zero, A=[1 zeros], K=[zeros], P=0

Output(s)

Specify the solution representation of $Ra = b$ to output: model coefficients (A), reflection coefficients (K), or both (A and K). When the input is a scalar or row vector, you must set this parameter to A.

Output prediction error power (P)

Select to output the prediction error at port P.

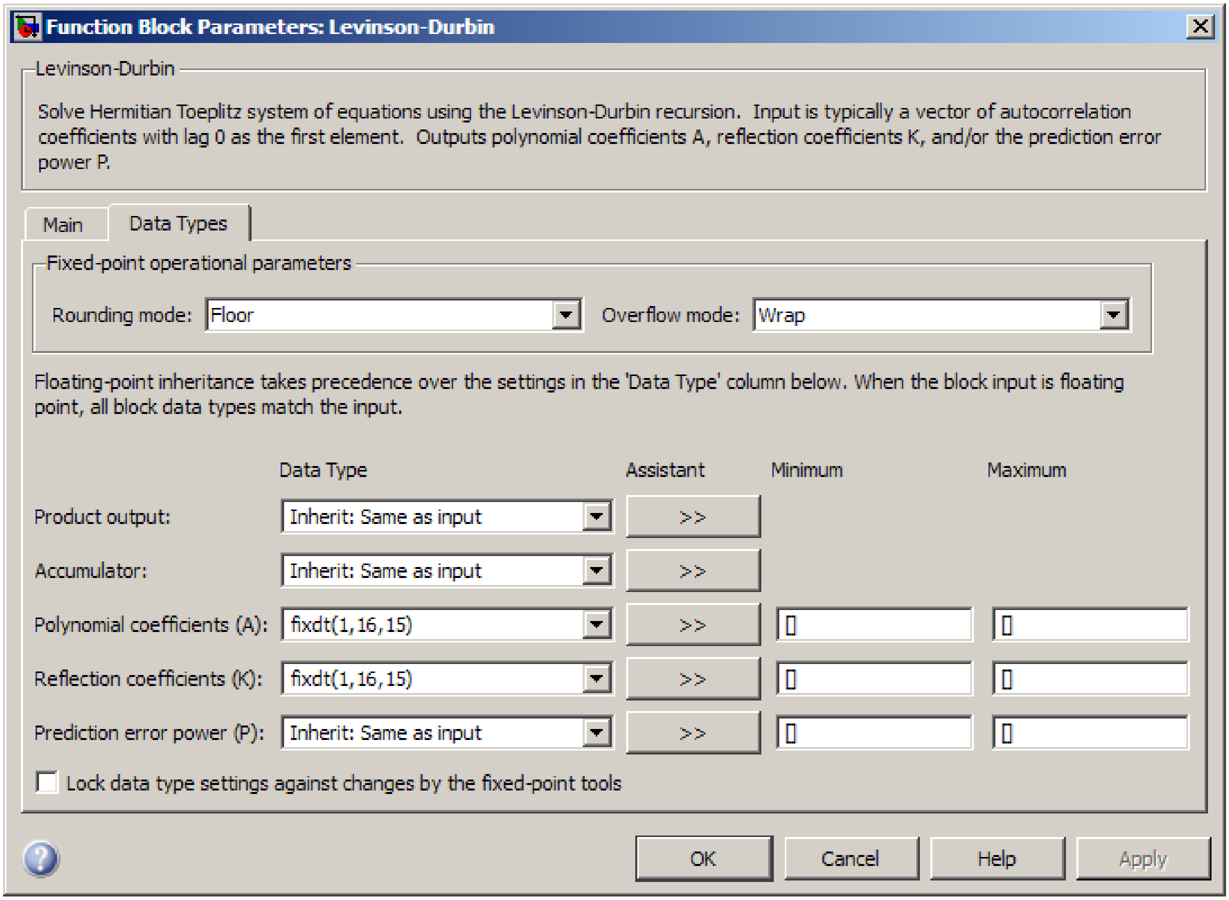
If the value of lag 0 is zero, A=[1 zeros], K=[zeros], P=0

When you select this check box and the first element of the input, `r(1)`, is zero, the block outputs the following vectors, as appropriate:

- `A = [1 zeros(1,n)]`
- `K = [zeros(1,n)]`
- `P = 0`

When you clear this check box, the block outputs a vector of `NaN`s for each channel whose `r(1)` element is zero.

The **Data Types** pane of the Levinson-Durbin block dialog box appears as follows.



Function Block Parameters: Levinson-Durbin

Levinson-Durbin

Solve Hermitian Toeplitz system of equations using the Levinson-Durbin recursion. Input is typically a vector of autocorrelation coefficients with lag 0 as the first element. Outputs polynomial coefficients A, reflection coefficients K, and/or the prediction error power P.

Fixed-point operational parameters

Rounding mode: Floor

Overflow mode: Wrap

Floating-point inheritance takes precedence over the settings in the 'Data Type' column below. When the block input is floating point, all block data types match the input.

	Data Type	Assistant	Minimum	Maximum
Product output:	Inherit: Same as input	>>		
Accumulator:	Inherit: Same as input	>>		
Polynomial coefficients (A):	fixdt(1,16,15)	>>	[]	[]
Reflection coefficients (K):	fixdt(1,16,15)	>>	[]	[]
Prediction error power (P):	Inherit: Same as input	>>	[]	[]

□ Lock data type settings against changes by the fixed-point tools

Note: Floating-point inheritance takes precedence over the data type settings defined on this pane. When inputs are floating point, the block ignores these settings, and all internal data types are floating point.

Rounding mode

Select the "rounding mode" for fixed-point operations.

Overflow mode

Select the "overflow mode" for fixed-point operations.

Product output data type

Specify the product output data type. See “Fixed-Point Data Types” on page 1-828 and “Multiplication Data Types” for illustrations depicting the use of the product output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as input`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Product output data type** parameter.

See “Specify Data Types Using Data Type Assistant” in “Simulink User's Guide” for more information.

Accumulator data type

Specify the accumulator data type. See “Fixed-Point Data Types” on page 1-828 for illustrations depicting the use of the accumulator data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as input`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Accumulator data type** parameter.

See “Specify Data Types Using Data Type Assistant” in “Simulink User's Guide” for more information.

Polynomial coefficients (A)

Specify the polynomial coefficients (*A*) data type. See “Fixed-Point Data Types” on page 1-828 for illustrations depicting the use of the A data type in this block. You can set it to an expression that evaluates to a valid data type, for example, `fixdt(1,16,15)`.

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **A** parameter.

See “Specify Data Types Using Data Type Assistant” in “Simulink User's Guide” for more information.

Reflection coefficients (K)

Specify the polynomial coefficients (*A*) data type. See “Fixed-Point Data Types” on page 1-828 for illustrations depicting the use of the K data type in this block. You can set it to an expression that evaluates to a valid data type, for example, `fixdt(1,16,15)`.

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **K** parameter.

See “Specify Data Types Using Data Type Assistant” in “Simulink User's Guide” for more information.

Prediction error power (P)

Specify the prediction error power (*P*) data type. See “Fixed-Point Data Types” on page 1-828 for illustrations depicting the use of the P data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as input`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **P** parameter.

See “Specify Data Types Using Data Type Assistant” in “Simulink User's Guide” for more information.

Minimum

Specify the minimum values that the polynomial coefficients, reflection coefficients, or prediction error power should have. The default value is `[]` (unspecified).Simulink software uses this value to perform:

- Parameter range checking (see “Check Parameter Values”)
- Automatic scaling of fixed-point data types

Maximum

Specify the maximum values that the polynomial coefficients, reflection coefficients, or prediction error power should have. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Check Parameter Values”)

- Automatic scaling of fixed-point data types

Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

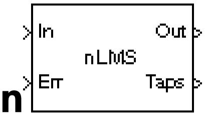
LMS Adaptive Filter (Obsolete)

Compute filter estimates for input using LMS adaptive filter algorithm

Library

dspobslib



Description

Note The LMS Adaptive Filter block is still supported but is likely to be obsoleted in a future release. We strongly recommend replacing this block with the LMS Filter block.

The LMS Adaptive Filter block implements an adaptive FIR filter using the stochastic gradient algorithm known as the normalized least mean-square (LMS) algorithm.

$$y(n) = \hat{w}^H(n-1)u(n)$$
$$e(n) = d(n) - y(n)$$
$$\hat{w}(n) = \hat{w}(n-1) + \frac{u(n)}{a + u^H(n)u(n)}\mu e^*(n)$$

The variables are as follows.

Variable	Description
n	The current algorithm iteration
$u(n)$	The buffered input samples at step n
$\hat{w}(n)$	The vector of filter-tap estimates at step n
$y(n)$	The filtered output at step n
$e(n)$	The estimation error at step n

Variable	Description
$d(n)$	The desired response at step n
μ	The adaptation step size

To overcome potential numerical instability in the tap-weight update, a small positive constant (a = 1e-10) has been added in the denominator.

To turn off normalization, clear the **Use normalization** check box in the parameter dialog. The block then computes the filter-tap estimate as

$$\hat{w}(n) = \hat{w}(n-1) + u(n)\mu e^{*}(n)$$

The block icon has port labels corresponding to the inputs and outputs of the LMS algorithm. Note that inputs to the In and Err ports must be sample-based scalars. The signal at the Out port is a scalar, while the signal at the Taps port is a sample-based vector.

Block Ports	Corresponding Variables
`In`	u, the scalar input, which is internally buffered into the vector $u(n)$
`Out`	$y(n)$, the filtered scalar output
`Err`	$e(n)$, the scalar estimation error
`Taps`	$\hat{w}(n)$, the vector of filter-tap estimates

An optional `Adapt` input port is added when you select the **Adapt input** check box in the dialog. When this port is enabled, the block continuously adapts the filter coefficients while the `Adapt` input is nonzero. A zero-valued input to the Adapt port causes the block to stop adapting, and to hold the filter coefficients at their current values until the next nonzero `Adapt` input.

The **FIR filter length** parameter specifies the length of the filter that the LMS algorithm estimates. The **Step size** parameter corresponds to μ in the equations. Typically, for convergence in the mean square, μ must be greater than 0 and less than

2. The **Initial value of filter taps** specifies the initial value $\hat{w}(0)$ as a vector, or as a scalar to be repeated for all vector elements. The **Leakage factor** specifies the value of

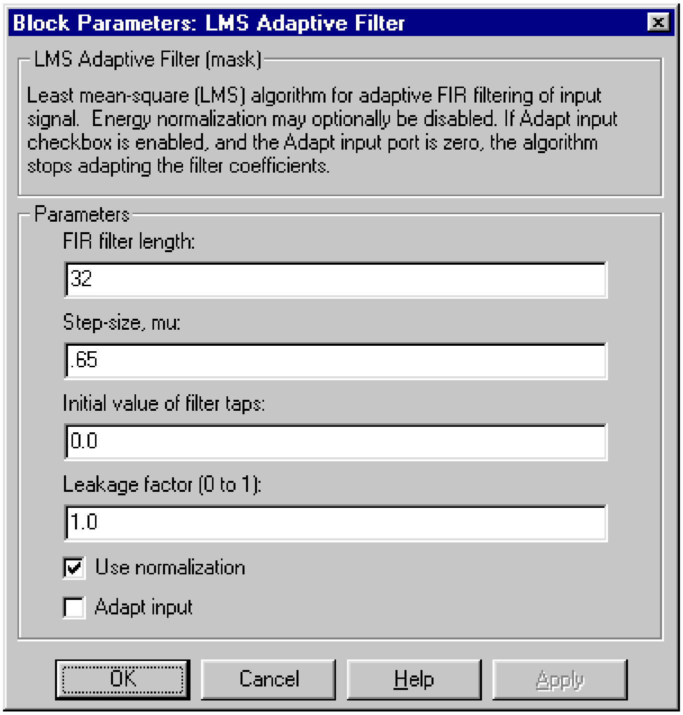
the leakage factor, 1 –μ α, in the leaky LMS algorithm below. This parameter must be between 0 and 1.

$$\hat{w}(n+1) = (1-\mu\alpha)\hat{w}(n) + \frac{u(n)}{u^H(n)u(n)}\mu e^*(n)$$

Examples

See the lmsadeq and lmsadtde demos.

Dialog Box



Block Parameters: LMS Adaptive Filter

LMS Adaptive Filter (mask)

Least mean-square (LMS) algorithm for adaptive FIR filtering of input signal. Energy normalization may optionally be disabled. If Adapt input checkbox is enabled, and the Adapt input port is zero, the algorithm stops adapting the filter coefficients.

Parameters

FIR filter length: 32

Step-size, mu: .65

Initial value of filter taps: 0.0

Leakage factor (0 to 1): 1.0

☑ Use normalization

☐ Adapt input

FIR filter length

The length of the FIR filter.

Step-size

The step-size, usually in the range (0, 2). “Tunable”.

Initial value of filter taps

The initial FIR filter coefficients.

Leakage factor

The leakage factor, in the range [0, 1]. “Tunable”.

Use normalization

Select this check box to compute the filter-tap estimate using the normalized equations.

Adapt input

Enables the Adapt port when selected.

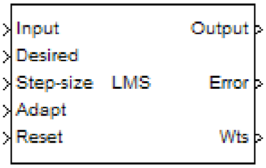
LMS Filter

Compute output, error, and weights using LMS adaptive algorithm

Library

Filtering / Adaptive Filters

`dspadpt3`



Description

The LMS Filter block can implement an adaptive FIR filter using five different algorithms. The block estimates the filter weights, or coefficients, needed to minimize the error, *e(n)*, between the output signal *y(n)* and the desired signal, *d(n)*. Connect the signal you want to filter to the Input port. The input signal can be a scalar or a column vector. Connect the desired signal to the Desired port. The desired signal must have the same data type, complexity, and dimensions as the input signal. The Output port outputs the filtered input signal, which is the estimate of the desired signal. The Error port outputs the result of subtracting the output signal from the desired signal.

When you select `LMS` for the **Algorithm** parameter, the block calculates the filter weights using the least mean-square (LMS) algorithm. This algorithm is defined by the following equations.

$$\begin{aligned} y(n) &= \mathbf{w}^{T}(n-1)\mathbf{u}(n) \\ e(n) &= d(n) - y(n) \\ \mathbf{w}(n) &= \alpha\mathbf{w}(n-1) + f(\mathbf{u}(n), e(n), \mu) \end{aligned}$$

The various LMS adaptive filter algorithms available in this block are defined as:

- LMS:

  $$f(\mathbf{u}(n),e(n),\mu) = \mu e(n)\mathbf{u}^*(n)$$

- Normalized LMS:

  $$f(\mathbf{u}(n),e(n),\mu) = \mu e(n)\frac{\mathbf{u}^*(n)}{\varepsilon + \mathbf{u}^H(n)\mathbf{u}(n)}$$

- Sign-Error LMS:

  $$f\,(\mathbf{u}(n),e(n),\mu) = \mu\, sign(e(n))\mathbf{u}*(n)$$

- Sign-Data LMS:

  $$f\,(\mathbf{u}(n),e(n),\mu) = \mu e(n) sign(\mathbf{u}(n))$$

  where **u**(n) is real.
- Sign-Sign LMS:

  $$f\,(\mathbf{u}(n),e(n),\mu) = \mu\, sign(e(n)) sign(\mathbf{u}(n))$$

  where **u**(n) is real.

The variables are as follows:

Variable	Description
n	The current time index
u(*n*)	The vector of buffered input samples at step *n*
u*(*n*)	The complex conjugate of the vector of buffered input samples at step *n*
w(*n*)	The vector of filter weight estimates at step *n*
y(n)	The filtered output at step *n*
e(n)	The estimation error at step *n*
d(n)	The desired response at step *n*

Variable	Description
μ	The adaptation step size
α	The leakage factor (0 < α ≤ 1)

In NMLS, to overcome potential numerical instability in the update of the weights, a small positive constant, epsilon, has been added in the denominator. For double-precision floating-point input, epsilon is 2.2204460492503131e-016. For single-precision floating-point input, epsilon is 1.192092896e-07. For fixed-point input, epsilon is 0.

Use the **Filter length** parameter to specify the length of the filter weights vector.

The **Step size (mu)** parameter corresponds to μ in the equations. For convergence of the normalized LMS equations, $0<\mu<2$. You can either specify a step size using the input port, Step-size, or by entering a value in the Block Parameters: LMS Filter dialog.

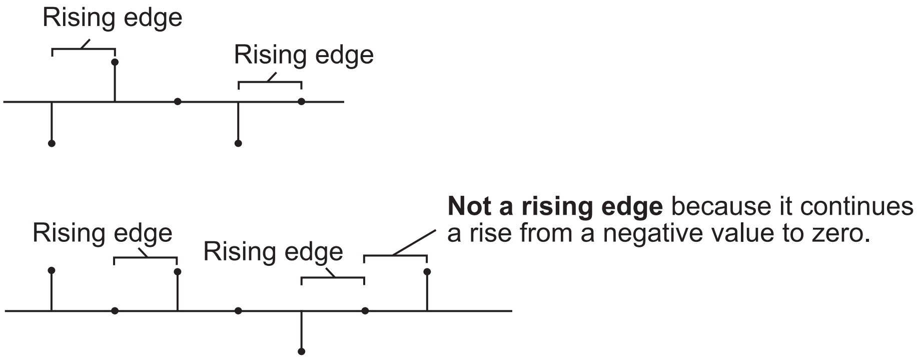
Enter the initial filter weights **w**(0) as a vector or a scalar in the **Initial value of filter weights** text box. When you enter a scalar, the block uses the scalar value to create a vector of filter weights. This vector has length equal to the filter length and all of its values are equal to the scalar value.

When you select the **Adapt port** check box, an Adapt port appears on the block. When the input to this port is greater than zero, the block continuously updates the filter weights. When the input to this port is less than or equal to zero, the filter weights remain at their current values.

When you want to reset the value of the filter weights to their initial values, use the **Reset port** parameter. The block resets the filter weights whenever a reset event is detected at the Reset port. The reset signal rate must be the same rate as the data signal input.

From the **Reset port** list, select `None` to disable the Reset port. To enable the Reset port, select one of the following from the **Reset port** list:

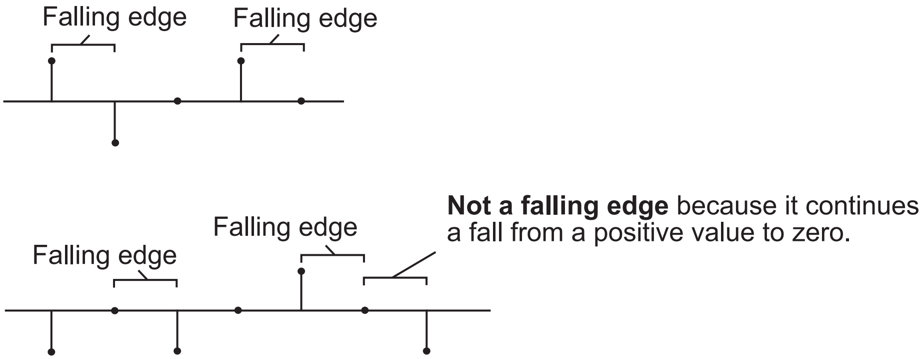
- `Rising edge` — Triggers a reset operation when the Reset input does one of the following:
  - Rises from a negative value to a positive value or zero
  - Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero (see the following figure)



Rising edge
Rising edge
Rising edge
Rising edge
Not a rising edge because it continues a rise from a negative value to zero.

- `Falling edge` — Triggers a reset operation when the Reset input does one of the following:

  - Falls from a positive value to a negative value or zero
  - Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero (see the following figure)



Falling edge
Falling edge
Falling edge
Falling edge
Not a falling edge because it continues a fall from a positive value to zero.

- `Either edge` — Triggers a reset operation when the Reset input is a `Rising edge` or `Falling edge` (as described above)
- `Non-zero sample` — Triggers a reset operation at each sample time that the Reset input is not zero

Select the **Output filter weights** check box to create a Wts port on the block. For each iteration, the block outputs the current updated filter weights from this port.

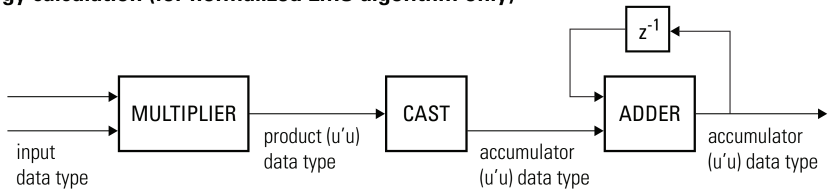
Fixed-Point Data Types

The following diagrams show the data types used within the LMS Filter block for fixed-point signals; the table summarizes the definitions of variables used in the diagrams:

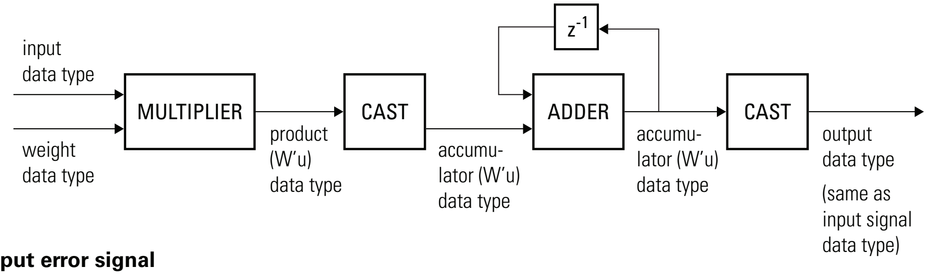
Variable	Definition
$\mathbf{u}$	Input vector
$\mathbf{W}$	Vector of filter weights
μ	Step size
e	Error
Q	Quotient, $Q = \frac{\mu \cdot e}{\mathbf{u'u}}$
Product $\mathbf{u'u}$	Product data type in Energy calculation diagram
Accumulator $\mathbf{u'u}$	Accumulator data type in Energy calculation diagram
Product $\mathbf{W'u}$	Product data type in Convolution diagram
Accumulator $\mathbf{W'u}$	Accumulator data type in Convolution diagram
Product $\mu \cdot e$	Product data type in Product of step size and error diagram
Product $Q \cdot \mathbf{u}$	Product and accumulator data type in Weight update diagram. [1]

[1] The accumulator data type for this quantity is automatically set to be the same as the product data type. The minimum, maximum, and overflow information for this accumulator is logged as part of the product information. Autoscaling treats this product and accumulator as one data type.

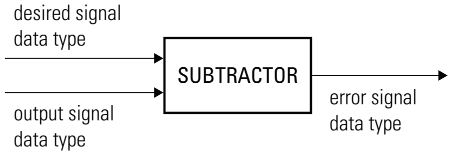
Energy calculation (for normalized LMS algorithm only)



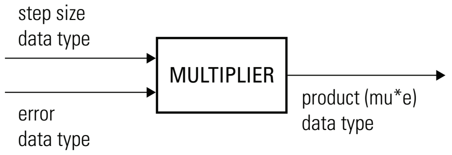
Convolution



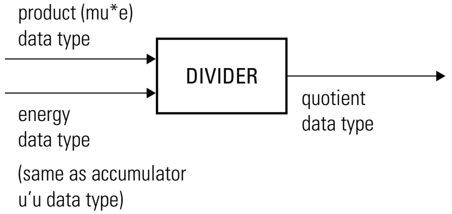
Output error signal



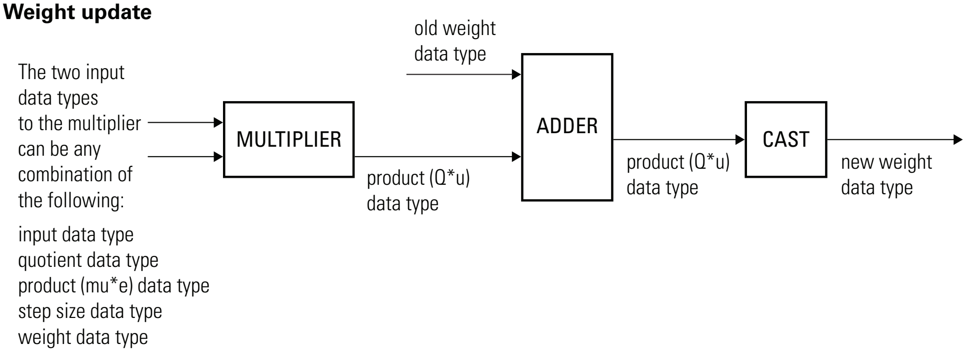
Product of step size and error (for LMS and Sign-Data LMS algorithms only)



Quotient (for normalized LMS only)



Weight update



You can set the data type of the parameters, weights, products, quotient, and accumulators in the block mask. Fixed-point inputs, outputs, and mask parameters of this block must have the following characteristics:

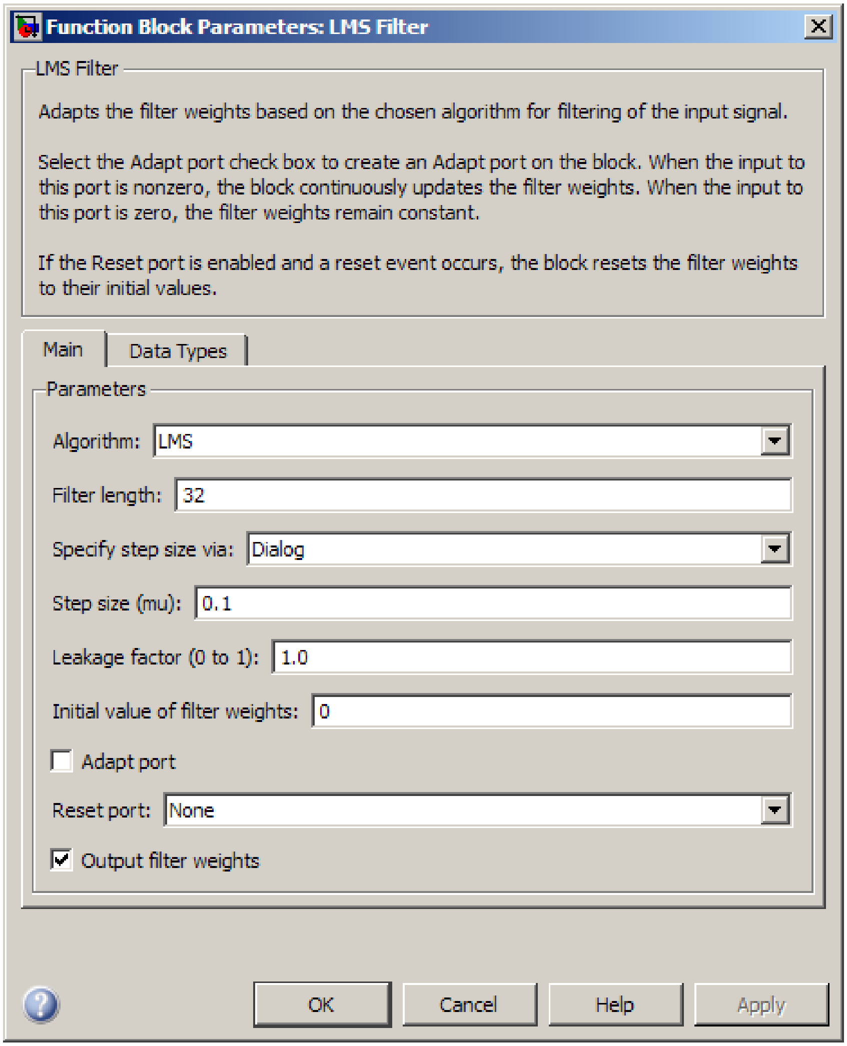
- The input signal and the desired signal must have the same word length, but their fraction lengths can differ.
- The step size and leakage factor must have the same word length, but their fraction lengths can differ.

- The output signal and the error signal have the same word length and the same fraction length as the desired signal.
- The quotient and the product output of the **u'u**, **W'u**, $\mu \cdot e$, and $Q \cdot \mathbf{u}$ operations must have the same word length, but their fraction lengths can differ.
- The accumulator data type of the **u'u** and **W'u** operations must have the same word length, but their fraction lengths can differ.

The output of the multiplier is in the product output data type if at least one of the inputs to the multiplier is real. If both of the inputs to the multiplier are complex, the result of the multiplication is in the accumulator data type. For details on the complex multiplication performed, see “Multiplication Data Types”.

Dialog Box

The **Main** pane of the LMS Filter block dialog appears as follows.



Function Block Parameters: LMS Filter

LMS Filter

Adapts the filter weights based on the chosen algorithm for filtering of the input signal.

Select the Adapt port check box to create an Adapt port on the block. When the input to this port is nonzero, the block continuously updates the filter weights. When the input to this port is zero, the filter weights remain constant.

If the Reset port is enabled and a reset event occurs, the block resets the filter weights to their initial values.

Main | Data Types

Parameters

Algorithm: LMS

Filter length: 32

Specify step size via: Dialog

Step size (mu): 0.1

Leakage factor (0 to 1): 1.0

Initial value of filter weights: 0

□ Adapt port

Reset port: None

☑ Output filter weights

Algorithm

Choose the algorithm used to calculate the filter weights.

Filter length

Enter the length of the FIR filter weights vector.

Specify step size via

Select `Dialog` to enter a value for step size in the Block parameters: LMS Filter dialog. Select `Input port` to specify step size using the Step-size input port.

Step size (mu)

Enter the step size μ. “Tunable”.

Leakage factor (0 to 1)

Enter the leakage factor, $0 < 1 - \mu\alpha \leq 1$. “Tunable”.

Initial value of filter weights

Specify the initial values of the FIR filter weights.

Adapt port

Select this check box to enable the Adapt input port.

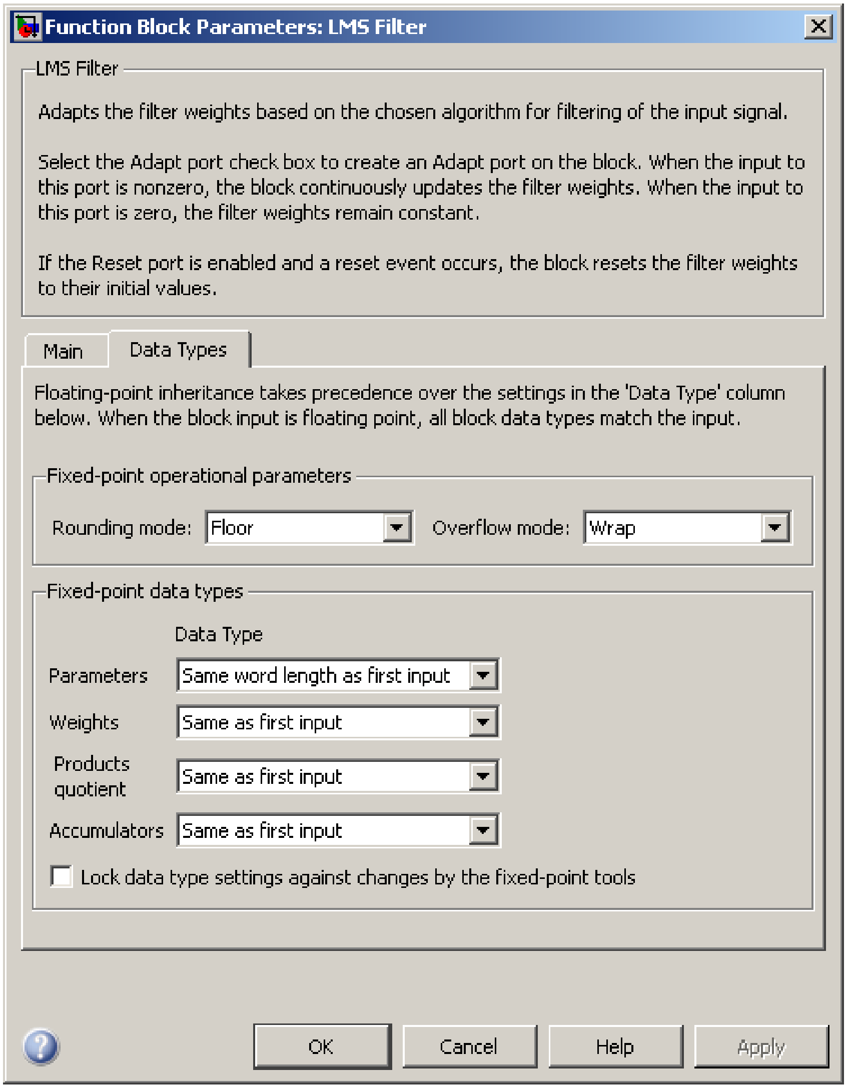
Reset port

Select this check box to enable the Reset input port.

Output filter weights

Select this check box to export the filter weights from the Wts port.

The **Data Types** pane of the LMS Filter block dialog appears as follows.



LMS Filter

Adapts the filter weights based on the chosen algorithm for filtering of the input signal.

Select the Adapt port check box to create an Adapt port on the block. When the input to this port is nonzero, the block continuously updates the filter weights. When the input to this port is zero, the filter weights remain constant.

If the Reset port is enabled and a reset event occurs, the block resets the filter weights to their initial values.

Floating-point inheritance takes precedence over the settings in the 'Data Type' column below. When the block input is floating point, all block data types match the input.

Fixed-point operational parameters

Rounding mode: Floor   Overflow mode: Wrap

Fixed-point data types

	Data Type
Parameters	Same word length as first input
Weights	Same as first input
Products quotient	Same as first input
Accumulators	Same as first input

□ Lock data type settings against changes by the fixed-point tools

Rounding mode

Select the “rounding mode” for fixed-point operations.

Overflow mode

Select the “overflow mode” for fixed-point operations.

Parameters

This parameter is visible if, for the **Specify step size via** parameter, you choose `Dialog`. Choose how you specify the word length and the fraction length of the leakage factor and step size:

- When you select `Same word length as first input`, the word length of the leakage factor and step size match that of the first input to the block. In this mode, the fraction length of the leakage factor and step size is automatically set to the binary-point only scaling that provides you with the best precision possible given the value and word length of the coefficients.
- When you select `Specify word length`, you can enter the word length of the leakage factor and step size, in bits. In this mode, the fraction length of the leakage factor and step size is automatically set to the binary-point only scaling that provides you with the best precision possible given the value and word length of the coefficients.
- When you select `Binary point scaling`, you can enter the word length and the fraction length of the leakage factor and step size, in bits. The leakage factor and the step size must have the same word length, but the fraction lengths can differ.
- When you select `Slope and bias scaling`, you can enter the word length, in bits, and the slope of the leakage factor and step size. The leakage factor and the step size must have the same word length, but the slopes can differ. This block requires a power-of-two slope and a bias of zero.

If, for the **Specify step size via** parameter, you choose `Input port`, the word length of the leakage factor is the same as the word length of the step size input at the Step size port. The fraction length of the leakage factor is automatically set to the best precision possible based on the word length of the leakage factor.

Weights

Choose how you specify the word length and fraction length of the filter weights of the block:

- When you select `Same as first input`, the word length and fraction length of the filter weights match those of the first input to the block.
- When you select `Binary point scaling`, you can enter the word length and the fraction length of the filter weights, in bits.
- When you select `Slope and bias scaling`, you can enter the word length, in bits, and the slope of the filter weights. This block requires a power-of-two slope and a bias of zero.

Products & quotient

Choose how you specify the word length and fraction length of **u'u**, **W'u**, $\mu \cdot e$, $Q \cdot \mathbf{u}$, and the quotient, Q. Here, **u** is the input vector, **W** is the vector of filter weights, μ is the step size, *e* is the error, and *Q* is the quotient, which is defined as $Q = \frac{\mu \cdot e}{\mathbf{u'u}}$

- When you select `Same as first input`, the word length and fraction length of these quantities match those of the first input to the block.
- When you select `Binary point scaling`, you can enter the word length and the fraction length of these quantities, in bits. The word length of the quantities must be the same, but the fraction lengths can differ.
- When you select `Slope and bias scaling`, you can enter the word length, in bits, and the slope of these quantities. The word length of the quantities must be the same, but the slopes can differ. This block requires a power-of-two slope and a bias of zero.

Accumulators

Use this parameter to specify how you would like to designate the word and fraction lengths of the accumulators for the **u'u** and **W'u** operations.

Note This parameter is *not* used to designate the word and fraction lengths of the accumulator for the $Q \cdot \mathbf{u}$ operation. The accumulator data type for this quantity is automatically set to be the same as the product data type. The minimum, maximum, and overflow information for this accumulator is logged as part of the product information. Autoscaling treats this product and accumulator as one data type.

See “Fixed-Point Data Types” on page 1-845 and “Multiplication Data Types” for illustrations depicting the use of the accumulator data type in this block:

- When you select `Same as first input`, these characteristics match those of the input to the block.
- When you select `Binary point scaling`, you can enter the word length and the fraction length of the accumulators, in bits. The word length of both the accumulators must be the same, but the fraction lengths can differ.
- When you select `Slope and bias scaling`, you can enter the word length, in bits, and the slope of the accumulators. The word length of both the accumulators

must be the same, but the slopes can differ. This block requires a power-of-two slope and a bias of zero.

Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

HDL Code Generation

This block supports HDL code generation using HDL Coder. HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic. For more information on implementations, properties, and restrictions for HDL code generation, see LMS Filter.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point • Signed fixed point
Desired	• Must be the same as Input for floating-point signals • Must be any signed fixed-point data type when Input is fixed point
Step-size	• Must be the same as Input for floating-point signals • Must be any signed fixed-point data type when Input is fixed point
Adapt	• Double-precision floating point • Single-precision floating point • Boolean • 8-, 16-, and 32-bit signed integers

Port	Supported Data Types
Reset	• Double-precision floating point • Single-precision floating point • Boolean • 8-, 16-, and 32-bit signed integers
Output	• Must be the same as Input for floating-point signals • Must be the same as Desired for fixed-point signals
Error	• Must be the same as Input for floating-point signals • Must be the same as Desired for fixed-point signals
Wts	• Must be the same as Input for floating-point signals • Obeys the **Weights** parameter for fixed-point signals

Lowpass Filter

Design lowpass filter

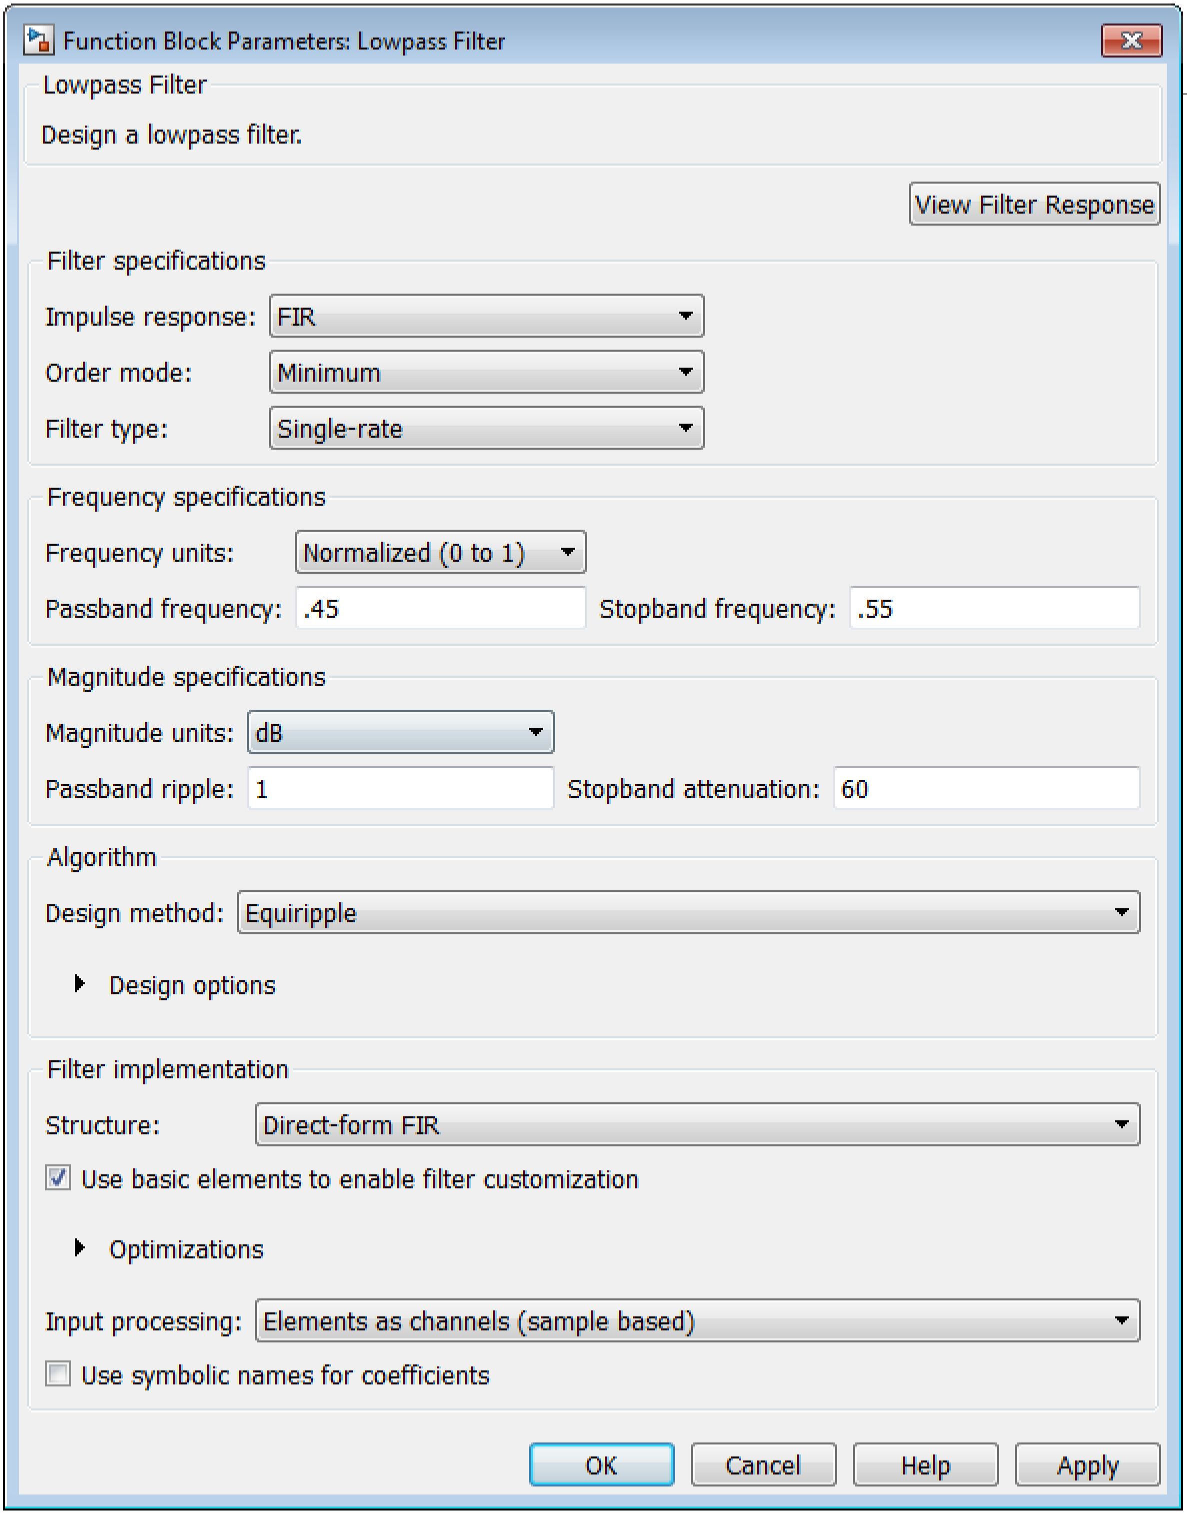
Library

Filtering / Filter Designs

dspfdesign

Description

This block brings the filter design capabilities of the “filterbuilder” function to the Simulink environment.



Function Block Parameters: Lowpass Filter

Lowpass Filter

Design a lowpass filter.

Filter specifications

Impulse response: FIR

Order mode: Minimum

Filter type: Single-rate

Frequency specifications

Frequency units: Normalized (0 to 1)

Passband frequency: .45 Stopband frequency: .55

Magnitude specifications

Magnitude units: dB

Passband ripple: 1 Stopband attenuation: 60

Algorithm

Design method: Equiripple

▸ Design options

Filter implementation

Structure: Direct-form FIR

☑ Use basic elements to enable filter customization

▸ Optimizations

Input processing: Elements as channels (sample based)

□ Use symbolic names for coefficients

View filter response

This button opens the Filter Visualization Tool (`fvtool`) from the Signal Processing Toolbox product. You can use the tool to display:

- Magnitude response, phase response, and group delay in the frequency domain.
- Impulse response and step response in the time domain.
- Pole-zero information.

The tool also helps you evaluate filter performance by providing information about filter order, stability, and phase linearity. For more information on FVTool, see the Signal Processing Toolbox documentation.

Filter Specifications

In this group, you specify your filter format, such as the impulse response and the filter order.

Impulse response

Select either `FIR` or `IIR` from the drop-down list. `FIR` is the default. When you choose an impulse response, the design methods and structures you can use to implement your filter change accordingly.

Note: The design methods and structures for FIR filters are not the same as the methods and structures for IIR filters.

Order mode

Select `Minimum` (the default) or `Specify`. Selecting `Specify` enables the **Order** option so you can enter the filter order. When you set the **Impulse response** to `IIR`, you can specify different numerator and denominator orders. To specify a different denominator order, you must select the **Denominator order** check box.

Order

Enter the filter order. This option is enabled only if you set the **Order mode** to `Specify`.

Denominator order

Select this check box to specify a different denominator order. This option is enabled only if you set the **Impulse response** to `IIR` and the **Order mode** to `Specify`.

Filter type

Select `Single-rate`, `Decimator`, `Interpolator`, or `Sample-rate converter`. Your choice determines the type of filter as well as the design methods and structures that are available to implement your filter. By default, the block specifies a single-rate filter.

- Selecting `Decimator` or `Interpolator` activates the **Decimation Factor** or the **Interpolation Factor** options respectively.
- Selecting `Sample-rate converter` activates both factors.

Decimation Factor

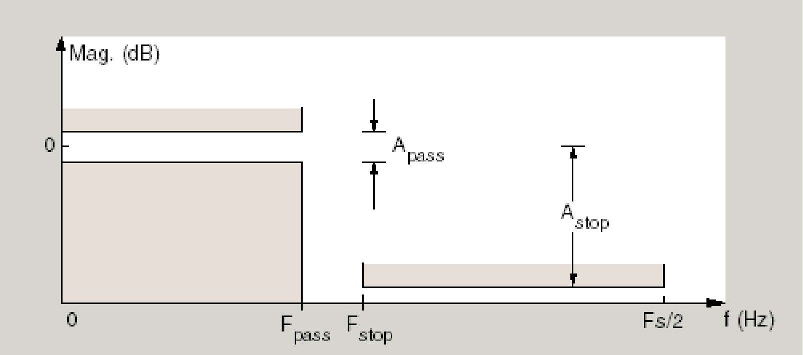
Enter the decimation factor. This option is enabled only if the **Filter type** is set to `Decimator` or `Sample-rate converter`. The default value is 2.

Interpolation Factor

Enter the interpolation factor. This option is enabled only if the **Filter type** is set to `Interpolator` or `Sample-rate converter`. The default value is 2.

Frequency Specifications

The parameters in this group allow you to specify your filter response curve. Graphically, the filter specifications look similar to the one shown in the following figure.



In the figure, regions between specification values such as F_{pass} and F_{stop} represent transition regions where the filter response is not constrained.

Frequency constraints

When **Order mode** is `Specify`, select the filter features that the block uses to define the frequency response characteristics. The list contains the following options, when available for the filter specifications.

- `Passband and Stopband frequencies` — Define the filter by specifying the frequencies for the edges for the stop- and passbands.
- `Passband frequency` — Define the filter by specifying the edge of the passband.
- `Stopband frequency` — Define the filter by specifying the edge of the stopband.
- `Hafband power (3dB) frequency` — Define the filter response by specifying the location of the 3 dB point. The 3 dB point is the frequency for the point three decibels below the passband value.
- `Cutoff (6dB) frequency` — For FIR filters, define the filter response by specifying the location of the 6 dB point. The 6 dB point is the frequency for the point six decibels below the passband value.

Frequency units

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select `Normalized (0–1)` to enter frequencies in normalized form. This behavior is the default. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—`Hz`, `kHz`, `MHz`, or `GHz`. Selecting one of the unit options enables the **Input sample rate** parameter.

Input sample rate

Input sample rate, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available when you select one of the frequency options from the **Frequency units** list.

Passband frequency

Enter the frequency at the end of the passband. Specify the value in either normalized frequency units or the absolute units you select in **Frequency units**.

Stopband frequency

Enter the frequency at the start of the stopband. Specify the value in either normalized frequency units or the absolute units you select in **Frequency units**.

Half power (3dB) frequency

When **Frequency constraints** is `Half power (3dB) frequency`, specify the frequency of the 3 dB point. Specify the value in either normalized frequency units or the absolute units you select in **Frequency units**.

Cutoff (6dB) frequency

When **Frequency constraints** is `Cutoff (6dB) frequency`, specify the frequency of the 6 dB point. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

Magnitude Specifications

Parameters in this group specify the filter response in the passbands and stopbands.

Magnitude constraints

This option is only available when you specify the order of your filter design. Depending on the setting of the **Frequency constraints** parameter, some combination of the following options will be available for the **Magnitude constraints** parameter: `Unconstrained`, and `Passband ripple and stopband attenuation`.

Magnitude units

Specify the units for any parameter you provide in magnitude specifications. From the drop-down list, select one of the following options:

- `Linear` — Specify the magnitude in linear units.
- `dB` — Specify the magnitude in decibels (default)

Passband ripple

Enter the filter ripple allowed in the passband in the units you choose for **Magnitude units**, either linear or decibels.

Stopband attenuation

Enter the filter attenuation in the stopband in the units you choose for **Magnitude units**, either linear or decibels.

Algorithm

The parameters in this group allow you to specify the design method and structure of your filter.

Design Method

Lists the design methods available for the frequency and magnitude specifications you entered. When you change the specifications for a filter, such as changing the impulse response, the methods available to design filters changes as well. The default IIR design method is usually `Elliptic`, and the default FIR method is `Equiripple`.

Scale SOS filter coefficients to reduce chance of overflow

Selecting this parameter directs the design to scale the filter coefficients to reduce the chances that the inputs or calculations in the filter overflow and exceed the representable range of the filter. Clearing this option removes the scaling. This parameter applies only to IIR filters.

Design Options

The options for each design are specific for each design method. This section does not present all of the available options for all designs and design methods. There are many more that you encounter as you select different design methods and filter specifications. The following options represent some of the most common ones available.

Density factor

Density factor controls the density of the frequency grid over which the design method optimization evaluates your filter response function. The number of equally spaced points in the grid is the value you enter for **Density factor** times (filter order + 1).

Increasing the value creates a filter that more closely approximates an ideal equiripple filter but increases the time required to design the filter. The default value of 16 represents a reasonable trade between the accurate approximation to the ideal filter and the time to design the filter.

Phase constraint

Specify the phase constraint of the filter as `Linear`, `Maximum`, or `Minimum`.

Minimum order

When you select this parameter, the design method determines and design the minimum order filter to meet your specifications. Some filters do not provide this parameter. Select `Any`, `Even`, or `Odd` from the drop-down list to direct the design to be any minimum order, or minimum even order, or minimum odd order.

Match Exactly

Specifies that the resulting filter design matches either the passband or stopband or both bands when you select `passband` or `stopband` or `both` from the drop-down list.

Stopband Shape

Stopband shape lets you specify how the stopband changes with increasing frequency. Choose one of the following options:

- `Flat` — Specifies that the stopband is flat. The attenuation does not change as the frequency increases.
- `Linear` — Specifies that the stopband attenuation changes linearly as the frequency increases. Change the slope of the stopband by setting **Stopband decay**.
- `1/f` — Specifies that the stopband attenuation changes exponentially as the frequency increases, where `f` is the frequency. Set the power (exponent) for the decay in **Stopband decay**.

Stopband Decay

When you set Stopband shape, Stopband decay specifies the amount of decay applied to the stopband. the following conditions apply to Stopband decay based on the value of Stopband Shape:

- When you set **Stopband shape** to `Flat`, **Stopband decay** has no affect on the stopband.
- When you set **Stopband shape** to `Linear`, enter the slope of the stopband in units of dB/rad/s. The block applies that slope to the stopband.
- When you set **Stopband shape** to `1/f`, enter a value for the exponent *n* in the relation $(1/f)^n$ to define the stopband decay. The block applies the $(1/f)^n$ relation to the stopband to result in an exponentially decreasing stopband attenuation.

Filter Implementation

Structure

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. By default, FIR filters use direct-form structure, and IIR filters use direct-form II filters with SOS.

Use basic elements to enable filter customization

Select this check box to implement the filter as a subsystem of basic Simulink blocks. Clear the check box to implement the filter as a high-level subsystem. By default, this check box is cleared.

The high-level implementation provides better compatibility across various filter structures, especially filters that would contain algebraic loops when constructed using basic elements. On the other hand, using basic elements enables the following optimization parameters:

- **Optimize for zero gains** — Terminate chains that contain Gain blocks with a gain of zero.
- **Optimize for unit gains** — Remove Gain blocks that scale by a factor of one.
- **Optimize for delay chains** — Substitute delay chains made up of *n* unit delays with a single delay by *n*.
- **Optimize for negative gains** — Use subtraction in Sum blocks instead of negative gains in Gain blocks.

Optimize for unit scale values

Select this check box to scale unit gains between sections in SOS filters. This parameter is available only for SOS filters (Impulse response: IIR).

Input processing

Specify how the block should process the input. The available options may vary depending on he settings of the **Filter Structure** and **Use basic elements for filter customization** parameters. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` — When you select this option, the block treats each column of the input as a separate channel.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

Note: The `Inherited (this choice will be removed – see release notes)` option will be removed in a future release. See “Frame-Based Processing” in the *DSP System Toolbox Release Notes* for more information.

Rate options

When the **Filter type** parameter specifies a multirate filter, select the rate processing rule for the block from following options:

- `Enforce single-rate processing` — When you select this option, the block maintains the sample rate of the input.
- `Allow multirate processing` — When you select this option, the block adjusts the rate at the output to accommodate an increased or reduced number of

samples. To select this option, you must set the **Input processing** parameter to `Elements as channels (sample based)`.

Use symbolic names for coefficients

Select this check box to enable the specification of coefficients using MATLAB variables. The available coefficient names differ depending on the filter structure. Using symbolic names allows tuning of filter coefficients in generated code. By default, this check box is cleared.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point
Output	• Double-precision floating point • Single-precision floating point

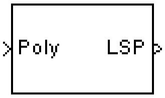
LPC to LSF/LSP Conversion

Convert linear prediction coefficients to line spectral pairs or line spectral frequencies

Library

Estimation / Linear Prediction

`dsplp`



Description

The LPC to LSF/LSP Conversion block takes a vector or matrix of linear prediction coefficients (LPCs) and converts it to a vector or matrix of line spectral pairs (LSPs) or line spectral frequencies (LSFs). When converting LPCs to LSFs, the block outputs match those of the `poly2lsf` function.

The block input must be a sample-based row vector, which is treated as a single channel, or a matrix, which is treated as a single channel per column.

The input LPCs for each channel, 1, a_1, a_2, ..., a_m, must be the denominator of the transfer function of a stable all-pole filter with the form given in the first equation of "Requirements for Valid Outputs" on page 1-866. A length-M+1 input channel yields a length-M output channel. Inputs can be sample based or frame based, but outputs are always sample based.

See other sections of this reference page to learn about how to ensure that you get valid outputs, how to detect invalid outputs, how the block computes the LSF/LSP values, and more.

Requirements for Valid Outputs

To get valid outputs, your inputs and the **Root finding coarse grid points** parameter value must meet these requirements:

- The input LPCs for each channel, 1, a_1, a_2, ..., a_m, must come from the denominator of the following transfer function, $H(z)$, of a stable all-pole filter (all roots of $H(z)$ must be inside the unit circle). Note that the first term in *H(z)*'s denominator must be 1. When the input LPCs do not come from a transfer function of the following form, the block outputs are invalid.

$$H(z) = \frac{1}{1 + a_1 z^{-1} + a_2 z^{-2} + \ \dots \ + a_m z^{-m}}$$

- The **Root finding coarse grid points** parameter value must be large enough so that the block can find all the LSP or LSF values. (The output LSFs and LSPs are roots of polynomials related to the input LPC polynomial; the block looks for these roots to produce the output. For details, see “LSF and LSP Computation Method: Chebyshev Polynomial Method for Root Finding” on page 1-873.) When you do not set **Root finding coarse grid points** to a high enough value relative to the number of LPCs, the block might not find all the LSPs or LSFs and yield invalid outputs as described in “Root Finding Method Limitations: Failure to Find Roots” on page 1-876.

To learn about recognizing invalid inputs and outputs and parameters for dealing with them, see “Handling and Recognizing Invalid Inputs and Outputs” on page 1-868.

Setting Outputs to LSFs or LSPs

Set the **Output** parameter to one of the following settings to determine whether the block outputs LSFs or LSPs:

- `LSF in radians (0 pi)` — Block outputs the LSF values between 0 and π radians in increasing order. The block does not output the guaranteed LSF values, 0 and π.
- `LSF normalized in range (0 0.5)` — Block outputs normalized LSF values in increasing order, computed by dividing the LSF values between 0 and π radians by 2π. The block does not output the guaranteed normalized LSF values, 0 and 0.5.
- `LSP in range (-1 1)` — Block outputs LSP values in decreasing order, equal to the cosine of the LSF values between 0 and π radians. The block does not output the guaranteed LSP values, -1 and 1.

Adjusting Output Computation Time and Accuracy with Root Finding Parameters

The values n and k determine the block's output computation time and accuracy, where

- n is the value of the **Root finding coarse grid points** parameter (choose this value with care; see the note below).

- k is the value of the **Root finding bisection refinement** parameter.
- Decreasing the values of n and k decreases the output computation time, but also decreases output accuracy:
  - The upper bound of block's computation time is proportional to $k \cdot (n-1)$.
  - Each LSP output is within $1/(n \cdot 2^k)$ of the actual LSP value.
  - Each LSF output is within ΔLSF of the actual LSF value, LSF_{act}, where

$$\Delta LSF = \left| a\cos(LSF_{act}) - a\cos\left(LSF_{act} + 1/\left(n \cdot 2^k\right)\right) \right|$$

Note When the value of the **Root finding coarse grid points** parameter is too small relative to the number of LPCs, the block might output invalid data as described in “Requirements for Valid Outputs” on page 1-866. Also see “Handling and Recognizing Invalid Inputs and Outputs” on page 1-868.

Notable Input and Output Properties

- To get valid outputs, your input LPCs and the value of the **Root finding coarse grid points** parameter must meet the requirements described in “Requirements for Valid Outputs” on page 1-866.
- Length-L+1 input channel yields length-L output channel
- Output is always sample based
- **Output** parameter determines the output type (see “Setting Outputs to LSFs or LSPs” on page 1-867):
  - LSFs — frequencies, w_k, where $0 < w_k < \pi$ and $w_k < w_{k+1}$
  - Normalized LSFs — $w_k / 2\pi$
  - LSPs — $\cos(w_k)$

Handling and Recognizing Invalid Inputs and Outputs

The block outputs invalid data when your input LPCs and the value of the **Root finding coarse grid points** parameter do not meet the requirements described in

"Requirements for Valid Outputs" on page 1-866. The following topics describe what invalid outputs look like, and how to set the block parameters provided for handling invalid inputs and outputs:

- "What Invalid Outputs Look Like" on page 1-869
- "Parameters for Handling Invalid Inputs and Outputs" on page 1-869

What Invalid Outputs Look Like

The channels of an invalid output have the same dimensions, sizes, and frame statues as the channels of a valid output. However, invalid output channels do not contain all the LSP or LSF values. Instead, they contain none or some of the LSP and LSF values and the rest of the output is filled with place holder values (-1, 0.5, or π) depending on the **Output** parameter setting).

In short, all invalid outputs in a channel end in one of the place holder values (-1, 0.5, or π) as illustrated in the following table. To learn how to use the block's parameters for handling invalid inputs and outputs, see the next section.

Output Parameter Setting	Place Holder	Sample Invalid Outputs
`LSF in radians (0 pi)`	π	$\begin{bmatrix} w_1 & w_2 & w_3 & \pi & \pi & \pi & \pi & \pi \end{bmatrix}$
`LSF normalized in range (0 0.5)`	`0.5`	$\begin{bmatrix} w_1 \\ w_2 \\ 0.5 \end{bmatrix}$
`LSP in range (-1 1)`	`-1`	$\begin{bmatrix} \cos(w_{13}) \\ \cos(w_{23}) \\ -1 \\ -1 \\ -1 \end{bmatrix}$

Parameters for Handling Invalid Inputs and Outputs

You must set how the block handles invalid inputs and outputs by setting these parameters:

- **Show output validity status (1=valid, 0=invalid)** — Set this parameter to activate a second output port that outputs a vector with one Boolean element per channel; `1` when the output of the corresponding channel is valid, and `0` when the output is invalid. The LSF and LSP outputs are invalid when the block fails to find all the LSF or LSP values or when the input LPCs are unstable (for details, see "Requirements for Valid Outputs" on page 1-866). See the previous section to learn how to recognize invalid outputs.
- **If current output is invalid, overwrite with previous output** — Select this check box to cause the block to overwrite invalid outputs with the previous output. When you set this parameter you also need to consider these parameters:

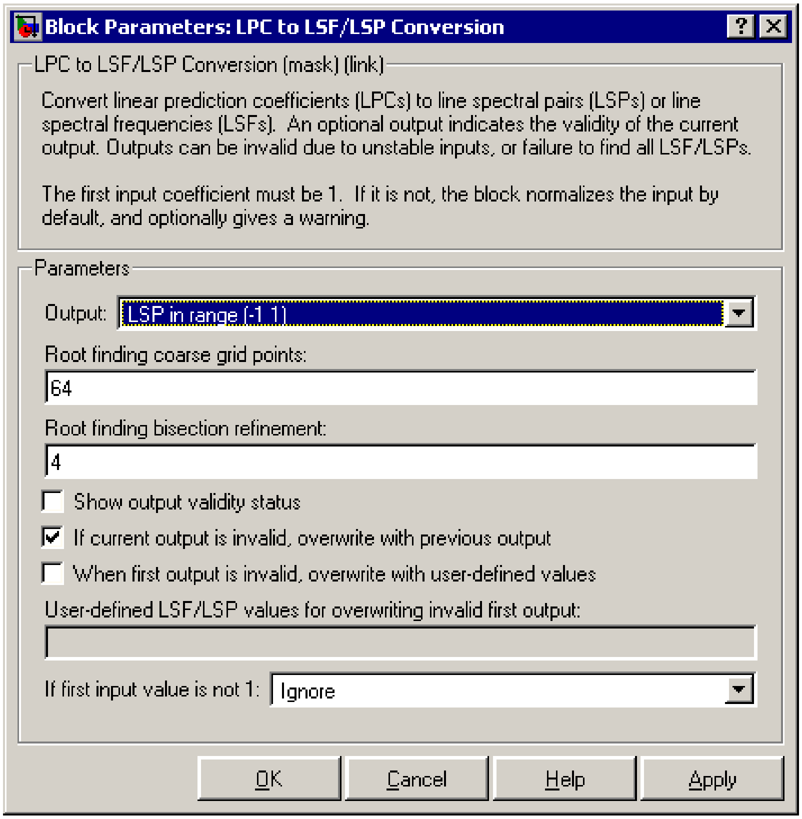
  - **When first output is invalid, overwrite with user-defined values** — When the first input is unstable, you can overwrite the invalid first output with either

    - The default values, by clearing this check box
    - Values you specify, by selecting this check box

    The default initial overwrite values are the LSF or LSP representations of an all-pass filter. The vector that is used to overwrite invalid output is stored as an internal state.
  - **User-defined LSP/LSF values for overwriting invalid first output** — Specify a vector of values for overwriting an invalid first output if you selected the **When first output is invalid, overwrite with user-defined values** parameter. For multichannel inputs, provide a matrix with the same number of channels as the input, or one vector that will be applied to every channel. The vector or matrix of LSP/LSF values you specify should have the same dimension, size, and frame status as the other outputs.
- **If first input value is not 1** — The block output in any channel is invalid when the first coefficient in an LPC vector is not 1; this parameter determines what the block does when given such inputs:

  - `Ignore` — Proceed with computations as if the first coefficient is 1.
  - `Normalize` — Divide the input LPCs by the value of the first coefficient before computing the output.
  - `Normalize and warn` — In addition to `Normalize`, display a warning message at the MATLAB command line.
  - `Error` — Stop the simulation and display an error message at the MATLAB command line.

Dialog Box



Block Parameters: LPC to LSF/LSP Conversion

LPC to LSF/LSP Conversion (mask) (link)

Convert linear prediction coefficients (LPCs) to line spectral pairs (LSPs) or line spectral frequencies (LSFs). An optional output indicates the validity of the current output. Outputs can be invalid due to unstable inputs, or failure to find all LSF/LSPs.

The first input coefficient must be 1. If it is not, the block normalizes the input by default, and optionally gives a warning.

Parameters

Output: LSP in range (-1 1)

Root finding coarse grid points: 64

Root finding bisection refinement: 4

□ Show output validity status

☑ If current output is invalid, overwrite with previous output

□ When first output is invalid, overwrite with user-defined values

User-defined LSF/LSP values for overwriting invalid first output:

If first input value is not 1: Ignore

Output

Specifies whether to convert the input linear prediction polynomial coefficients (LPCs) to `LSP in range (-1 1)`, `LSF in radians (0 pi)`, or `LSF normalized in range (0 0.5)`. See “Setting Outputs to LSFs or LSPs” on page 1-867 for descriptions of the three settings.

Root finding coarse grid points

The value *n*, where the block divides the interval (-1, 1) into *n* subintervals of equal length, and looks for roots (LSP values) in each subinterval. You must pick *n* large enough or the block output might be invalid as described in “Requirements for Valid Outputs” on page 1-866. To learn how the block uses this parameter to compute the output, see “LSF and LSP Computation Method: Chebyshev Polynomial Method for Root Finding" on page 1-873. Also see "Adjusting Output Computation Time and Accuracy with Root Finding Parameters" on page 1-867. "Tunable".

Root finding bisection refinement

The value k, where each LSP output is within $1/(n \cdot 2^k)$ of the actual LSP value, where n is the value of the **Root finding coarse grid points** parameter. To learn how the block uses this parameter to compute the output, see "LSF and LSP Computation Method: Chebyshev Polynomial Method for Root Finding" on page 1-873. Also see "Adjusting Output Computation Time and Accuracy with Root Finding Parameters" on page 1-867. "Tunable".

Show output validity status

Set this parameter to activate a second output port that outputs a vector with one Boolean element per channel; 1 when the output of the corresponding channel is valid, and 0 when the output is invalid. The LSF and LSP outputs are invalid when the block fails to find all the LSF or LSP values or when the input LPCs are unstable (for details, see "Requirements for Valid Outputs" on page 1-866).

If current output is invalid, overwrite with previous output

Selecting this check box causes the block to overwrite invalid outputs with the previous output. Setting this parameter activates other parameters for taking care of initial overwrite values (when the very first output of the block is invalid). For more information, see "Parameters for Handling Invalid Inputs and Outputs" on page 1-869.

When first output is invalid, overwrite with user-defined values

When the first input is unstable, you can overwrite the invalid first output with either

- The default values, by clearing this check box
- Values you specify, by selecting this check box

The default initial overwrite values are the LSF or LSP representations of an all-pass filter. The vector that is used to overwrite invalid output is stored as an internal state. For more information, see "Parameters for Handling Invalid Inputs and Outputs" on page 1-869.

User-defined LSP/LSF values for overwriting invalid first output

Specify a vector of values for overwriting an invalid first output if you selected the **When first output is invalid, overwrite with user-defined values** parameter. For multichannel inputs, provide a matrix with the same number of channels as the input, or one vector that will be applied to every channel. The vector or matrix of

LSP/LSF values you specify should have the same dimension, size, and frame status as the other outputs.

If first input value is not 1

Determines what the block does when the first coefficient of an input is not `1`. The block can either proceed with computations as when the first coefficient is 1 (`Ignore`); divide the input LPCs by the value of the first coefficient before computing the output (`Normalize`); in addition to `Normalize`, display a warning message at the MATLAB command line (`Normalize and warn`); stop the simulation and display an error message at the MATLAB command line (`Error`). For more information, see "Parameters for Handling Invalid Inputs and Outputs" on page 1-869.

Theory

LSF and LSP Computation Method: Chebyshev Polynomial Method for Root Finding

Note To learn the principles on which the block's LSP and LSF computation method is based, see the reference listed in "References" on page 1-878.

To compute LSP outputs for each channel, the block relies on the fact that LSP values are the roots of two particular polynomials related to the input LPC polynomial; the block finds these roots using the Chebyshev polynomial root finding method, described next. To compute LSF outputs, the block computes the arc cosine of the LSPs, outputting values ranging from 0 to π radians.

Root Finding Method

LSPs, which are the roots of two particular polynomials, always lie in the range (-1, 1). (The guaranteed roots at 1 and -1 are factored out.) The block finds the LSPs by looking for a sign change of the two polynomials' values between points in the range (-1, 1). The block searches a maximum of $k(n-1)$ points, where

- n is the value of the **Root finding coarse grid points** parameter.
- k is the value of the **Root finding bisection refinement** parameter.

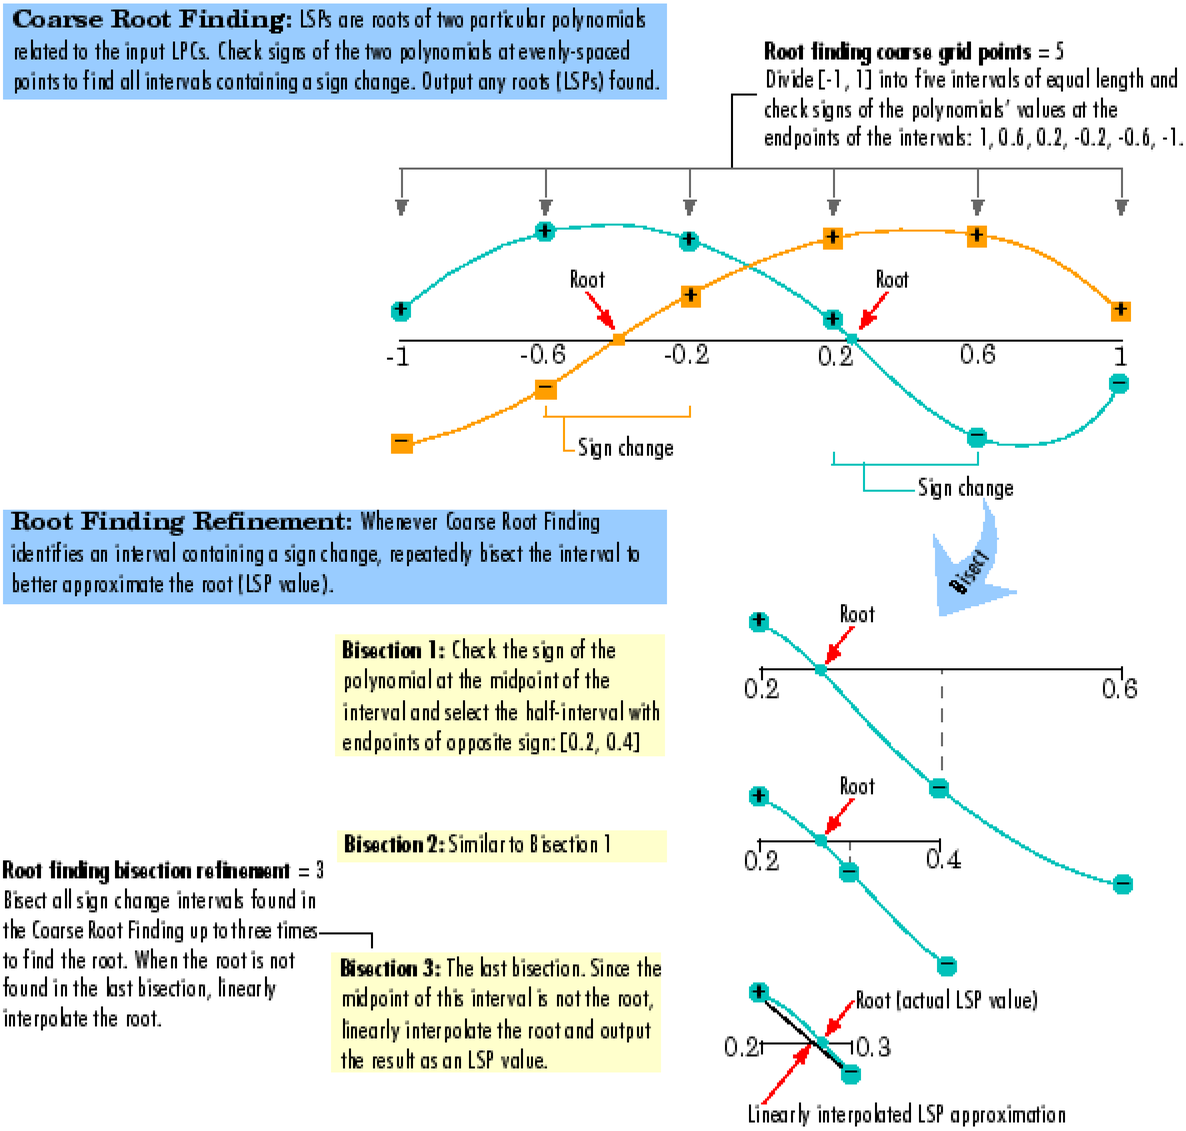
The block's method for choosing which points to check consists of the following two steps:

1. **Coarse Root Finding** —- The block divides the interval [-1, 1] into *n* intervals, each of length 2/*n*, and checks the signs of both polynomials' values at the endpoints of the intervals. The block starts checking signs at 1, and continues checking signs at 1 – 4/*n*, 1 – 6/*n*, and so on at steps of length 2/*n*, outputting any point if it is a root. The block stops searching in these situations:

   a. The block finds a sign change of a polynomial's values between two adjacent points. An interval containing a sign change is guaranteed to contain a root, so the block further searches the interval as described in Step 2, Root Finding Refinement.
   b. The block finds and outputs all *M* roots (given a length-*M*+1 LPC input).
   c. The block fails to find all *M* roots and yields invalid outputs as described in "Handling and Recognizing Invalid Inputs and Outputs" on page 1-868.

2. **Root Finding Refinement** — When the block finds a sign change in an interval, [*a*, *b*], it searches for the root guaranteed to lie in the interval by following these steps:

   a. **Check if Midpoint Is a Root** — The block checks the sign of the midpoint of the interval [*a*, *b*]. The block outputs the midpoint if it is a root, and continues Step 1, Coarse Root Finding, at the next point, *a* – 2/*n*. Otherwise, the block selects the half-interval with endpoints of opposite sign (either [*a*, (*a* + *b*)/2] or [(*a* + *b*)/2, *b*]) and executes Step 2b, Stop or Continue Root Finding Refinement.
   b. **Stop or Continue Root Finding Refinement** — When the block has repeated Step 2a *k* times (*k* is the value of the **Root finding bisection refinement** parameter), the block linearly interpolates the root by using the half-interval's endpoints, outputs the result as an LSP value, and returns to Step 1, Coarse Root Finding. Otherwise, the block repeats Step 2a using the half-interval.



Coarse Root Finding: LSPs are roots of two particular polynomials related to the input LPCs. Check signs of the two polynomials at evenly-spaced points to find all intervals containing a sign change. Output any roots (LSPs) found.

Root finding coarse grid points = 5
Divide [-1, 1] into five intervals of equal length and check signs of the polynomials' values at the endpoints of the intervals: 1, 0.6, 0.2, -0.2, -0.6, -1.

Root Finding Refinement: Whenever Coarse Root Finding identifies an interval containing a sign change, repeatedly bisect the interval to better approximate the root (LSP value).

Bisection 1: Check the sign of the polynomial at the midpoint of the interval and select the half-interval with endpoints of opposite sign: [0.2, 0.4]

Bisection 2: Similar to Bisection 1

Root finding bisection refinement = 3
Bisect all sign change intervals found in the Coarse Root Finding up to three times to find the root. When the root is not found in the last bisection, linearly interpolate the root.

Bisection 3: The last bisection. Since the midpoint of this interval is not the root, linearly interpolate the root and output the result as an LSP value.

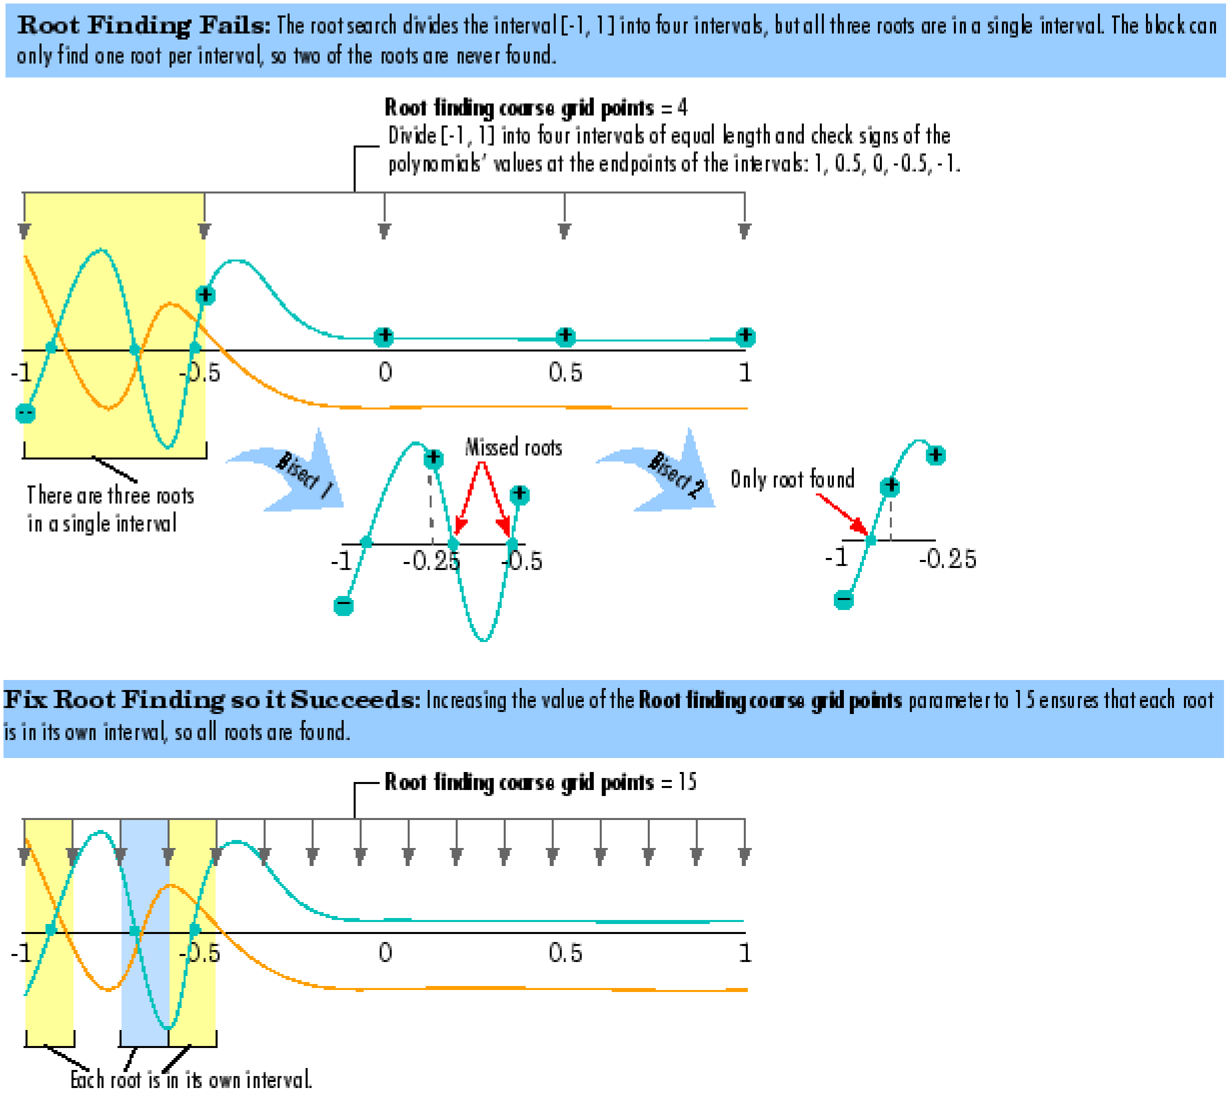
Coarse Root Finding and Root Finding Refinement

Root Finding Method Limitations: Failure to Find Roots

The block root finding method described above can fail, causing the block to produce invalid outputs (for details on invalid outputs, see "Handling and Recognizing Invalid Inputs and Outputs" on page 1-868).

In particular, the block can fail to find some roots if the value of the **Root finding coarse grid points** parameter, *n*, is too small. If the polynomials oscillate quickly and have roots that are very close together, the root finding might be too coarse to identify roots that are very close to each other, as illustrated in Fixing a Failed Root Finding.

For higher-order input LPC polynomials, you should increase the **Root finding coarse grid points** value to ensure the block finds all the roots and produces valid outputs.



Root Finding Fails: The root search divides the interval [-1, 1] into four intervals, but all three roots are in a single interval. The block can only find one root per interval, so two of the roots are never found.

Root finding course grid points = 4

Divide [-1, 1] into four intervals of equal length and check signs of the polynomials' values at the endpoints of the intervals: 1, 0.5, 0, -0.5, -1.

There are three roots in a single interval

Missed roots

Only root found

Fix Root Finding so it Succeeds: Increasing the value of the **Root finding course grid points** parameter to 15 ensures that each root is in its own interval, so all roots are found.

Root finding course grid points = 15

Each root is in its own interval.

Fixing a Failed Root Finding

Supported Data Types

- Double-precision floating point
- Single-precision floating point
- Boolean — Supported only by the optional output port that appears when you set the parameter, **Show output validity status (1=valid, 0=invalid)**

LSF/LSP to LPC Conversion

Convert line spectral frequencies or line spectral pairs to linear prediction coefficients

Library

Estimation / Linear Prediction

`dsplp`

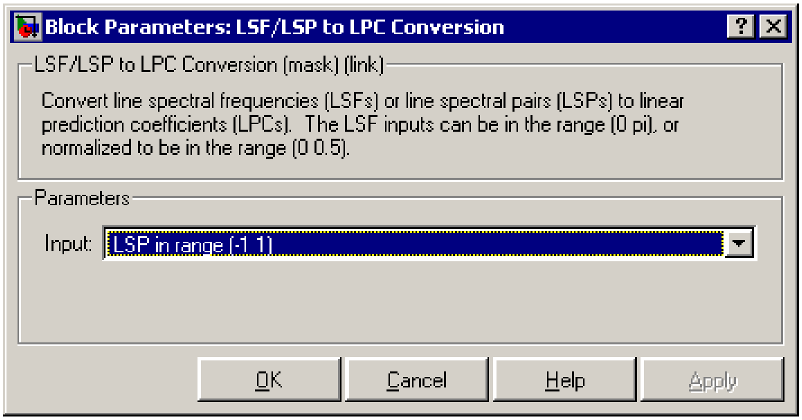
Description

The LSF/LSP to LPC Conversion block takes a vector or matrix of line spectral pairs (LSPs) or line spectral frequencies (LSFs) and converts it to a vector or matrix of linear prediction polynomial coefficients (LPCs). When converting LSFs to LPCs, the block outputs match those of the `lsf2poly` function.

The block input must be a sample-based row vector, which is treated as a single channel, or a matrix, which is treated as a single channel per column. Each input channel must be in the same format, which you specify in the **Input** parameter:

- `LSF in range (0 pi)` — Vector of LSF values between 0 and π radians in increasing order. Do not include the guaranteed LSF values, 0 and π.
- `LSF normalized in range (0 0.5)` — Vector of normalized LSF values in increasing order, (compute by dividing the LSF values between 0 and π radians by 2π). Do not include the guaranteed normalized LSF values, 0 and 0.5.
- `LSP in range (-1 1)` — Vector of LSP values in decreasing order, equal to the cosine of the LSF values between 0 and π radians. Do not include the guaranteed LSP values, -1 and 1.

Dialog Box



Block Parameters: LSF/LSP to LPC Conversion

LSF/LSP to LPC Conversion (mask) (link)

Convert line spectral frequencies (LSFs) or line spectral pairs (LSPs) to linear prediction coefficients (LPCs). The LSF inputs can be in the range (0 pi), or normalized to be in the range (0 0.5).

Parameters

Input: LSP in range (-1 1)

Input

Specifies whether to convert `LSP in range (-1 1)`, `LSF in range (0 pi)`, or `LSF normalized in range (0 0.5)` to linear prediction coefficients (LPCs).

Supported Data Types

- Double-precision floating point
- Single-precision floating point

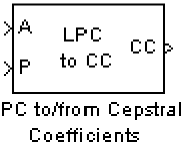
LPC to/from Cepstral Coefficients

Convert linear prediction coefficients to cepstral coefficients or cepstral coefficients to linear prediction coefficients

Library

Estimation / Linear Prediction

`dsplp`



Description

The LPC to/from Cepstral Coefficients block either converts linear prediction coefficients (LPCs) to cepstral coefficients (CCs) or cepstral coefficients to linear prediction coefficients. Set the **Type of conversion** parameter to `LPCs to cepstral coefficients` or `Cepstral coefficients to LPCs` to select the domain into which you want to convert your coefficients. The LPC port corresponds to LPCs, and the CC port corresponds to the CCs. For more information, see “Algorithm” on page 1-883.

The block input must be a sample-based row vector, which is treated as a single channel, or a matrix, which is treated as a single channel per column.

Consider a signal $x(n)$ as the input to an FIR analysis filter represented by LPCs. The output of this analysis filter, $e(n)$, is known as the prediction error signal. The power of this error signal is denoted by P, the prediction error power.

When you select `LPCs to cepstral coefficients` from the **Type of conversion** list, you can specify the prediction error power in two ways. From the **Specify P** list, choose `via input port` to input the prediction error power using input port P. The input to the port must be a vector with length equal to the number of input channels. Select `assume P equals 1` to set the prediction error power equal to 1 for all channels.

When you select `LPCs to cepstral coefficients` from the **Type of conversion** list, the **Output size same as input size** check box appears. When you select this check box, the length of the input vector of LPCs is equal to the output vector of CCs. When you do not select this check box, enter a positive scalar for the **Length of output cepstral coefficients** parameter.

When you select `LPCs to cepstral coefficients` from the **Type of conversion** list, you can use the **If first input value is not 1** parameter to specify the behavior of the block when the first coefficient of the LPC vector is not 1. The following options are available:

- `Replace it with 1` —- Changes the first value of the coefficient vector to 1. The other coefficient values are unchanged.
- `Normalize` — Divides the entire vector of coefficients by the first coefficient so that the first coefficient of the LPC vector is 1.
- `Normalize and Warn` — Divides the entire vector of coefficients by the first coefficient so that the first coefficient of the LPC vector is 1. The block displays a warning message telling you that your vector of coefficients has been normalized.
- `Error` — Displays an error telling you that the first coefficient of the LPC vector is not 1.

When you select `Cepstral coefficients to LPCs` from the **Type of conversion** list, the **Output P** check box appears on the block. Select this check box when you want to output the prediction error power from output port P.

Algorithm

The cepstral coefficients are the coefficients of the Fourier transform representation of the logarithm magnitude spectrum. Consider a sequence, $x(n)$, having a Fourier transform $X(\omega)$. The cepstrum, $c_x(n)$, is defined by the inverse Fourier transform of $C_x(\omega)$, where $C_x(\omega) = \log_e X\,(\omega)$. See the Real Cepstrum block reference page for information on computing cepstrum coefficients from time-domain signals.

LPC to CC

When in this mode, this block uses a recursion technique to convert LPCs to CCs.

The LPC vector is defined by $\begin{bmatrix} a_0 & a_1 & a_2 & \dots & a_p \end{bmatrix}$ and the CC vector is defined by $\begin{bmatrix} c_0 & c_1 & c_2 & \dots & c_p & \dots & c_{n-1} \end{bmatrix}$. The recursion is defined by the following equations:

$$c_0 = \log_e P$$

$$c_m = -a_m + \frac{1}{m} \sum_{k=1}^{m-1} \left[-(m-k) \cdot a_k \cdot c_{(m-k)} \right], 1 \le m \le p$$

$$c_m = \sum_{k=1}^{p} \left[\frac{-(m-k)}{m} \cdot a_k \cdot c_{(m-k)} \right], p < m < n$$

CC to LPC

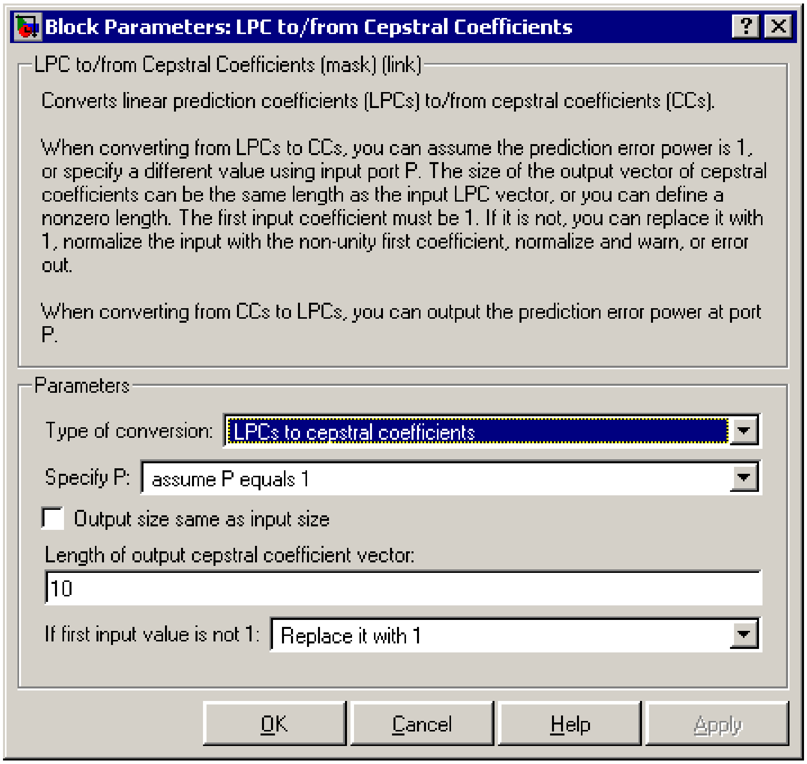
When in this mode, this block uses a recursion technique to convert CCs to LPCs. The CC vector is defined by $\begin{bmatrix} c_0 & c_1 & c_2 & \ldots & c_p & \ldots & c_n \end{bmatrix}$ and the LPC vector is defined by $\begin{bmatrix} a_0 & a_1 & a_2 & \ldots & a_p \end{bmatrix}$. The recursion is defined by the following equations

$$a_m = -c_m - \frac{1}{m} \sum_{k=1}^{m-1} \left[(m-k) \cdot c_{(m-k)} \cdot a_k \right]$$

$$P = \exp(C_0)$$

where $m = 1, 2, \ldots, p$.

Dialog Box



Block Parameters: LPC to/from Cepstral Coefficients

LPC to/from Cepstral Coefficients (mask) (link)

Converts linear prediction coefficients (LPCs) to/from cepstral coefficients (CCs).

When converting from LPCs to CCs, you can assume the prediction error power is 1, or specify a different value using input port P. The size of the output vector of cepstral coefficients can be the same length as the input LPC vector, or you can define a nonzero length. The first input coefficient must be 1. If it is not, you can replace it with 1, normalize the input with the non-unity first coefficient, normalize and warn, or error out.

When converting from CCs to LPCs, you can output the prediction error power at port P.

Parameters

Type of conversion: LPCs to cepstral coefficients

Specify P: assume P equals 1

□ Output size same as input size

Length of output cepstral coefficient vector:

10

If first input value is not 1: Replace it with 1

Type of conversion

Choose `LPCs to cepstral coefficients` or `Cepstral coefficients to LPCs` to specify the domain into which you want to convert your coefficients.

Specify P

Choose `via input port` to input the values of prediction error power using input port P. Select `assume P equals 1` to set the prediction error power equal to 1.

Output size same as input size

When you select this check box, the length of the input vector of LPCs is equal to the output vector of CCs.

Length of output cepstral coefficients

Enter a positive scalar that is the length of each output channel of CCs.

If first input value is not 1

Select what you would like the block to do when the first coefficient of the LPC vector is not 1. You can choose `Replace it with 1`, `Normalize`, `Normalize and Warn`, and `Error`.

Output P

Select this check box to output the prediction error power for each channel from output port P.

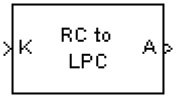
LPC to/from RC

Convert linear prediction coefficients to reflection coefficients or reflection coefficients to linear prediction coefficients

Library

Estimation / Linear Prediction

dsplp



LPC to/from RC

Description

The LPC to/from RC block either converts linear prediction coefficients (LPCs) to reflection coefficients (RCs) or reflection coefficients to linear prediction coefficients. Set the **Type of conversion** parameter to `LPC to RC` or `RC to LPC` to select the domain into which you want to convert your coefficients. The A port corresponds to LPC coefficients, and the K port corresponds to the RC coefficients. For more information, see “Algorithm” on page 1-888.

The block input must be a sample-based row vector, which is treated as a single channel, or a matrix, which is treated as a single channel per column.

Consider a signal $x\ (n)$ as the input to an FIR analysis filter represented by LPC coefficients. The output of the this analysis filter, $e\ (n)$, is known as the prediction error signal. The power of this error signal is denoted by P. When the zero lag autocorrelation coefficient of $x\ (n)$ is one, the autocorrelation sequence and prediction error power are said to be normalized.

Select the **Output normalized prediction error power** check box to enable port P. The normalized prediction error power output at `P` is a vector with one element per input channel. Each element varies between zero and one.

Select the **Output LPC filter stability** check box to output the stability of the filter represented by the LPCs or RCs. The synthesis filter represented by the LPCs is stable when the absolute value of each of the roots of the LPC polynomial is less than one. The lattice filter represented by the RCs is stable when the absolute value of each reflection coefficient is less than 1. When the filter is stable, the block outputs a Boolean value of `1` for each input channel at the S port. When the filter is unstable, the block outputs a Boolean value of `0` for each input channel at the S port.

If first input value is not 1 parameter specifies the behavior of the block when the first coefficient of the LPC coefficient vector in any channel is not 1. The following options are available:

- `Replace it with 1` — Changes the first value of the coefficient channel to 1. The other coefficient values are unchanged.
- `Normalize` — Divides the entire channel of coefficients by the first coefficient so that the first coefficient of the LPC coefficient vector is 1.
- `Normalize and Warn` — Divides the entire channel of coefficients by the first coefficient so that the first coefficient of the LPC coefficient vector is 1. The block displays a warning message telling you that your vector of coefficients has been normalized.
- `Error` — Displays an error telling you that the first coefficient of the LPC coefficient channel is not 1.

Algorithm

LPC to RC

When in this mode, this block uses backward Levinson recursion to convert linear prediction coefficients (LPCs) to reflection coefficients (RCs). For a given Nth order LPC vector $LPC_N = [\ 1 \quad a_{N1} \quad a_{N2} \quad \dots \quad a_{NN}\ ]$, the block calculates the Nth reflection coefficient value using the formula $\gamma_N = -a_{NN}$. The block then finds the lower order LPC vectors , $LPC_{N-1}, LPC_{N-2}, \ldots, LPC_1$, using the following recursion.

for $p = N, N-1, \ldots, 2,$

$$\gamma_p = a_{pp}$$

$$F = 1 - \gamma_p{}^2$$

$$a_{p-1,m} = \frac{a_{p,m}}{F} - \frac{\gamma_p a_{p,p-m}}{F}, \quad 1 \le m < p$$

end

Finally, $\gamma_1 = -a_{11}$. The reflection coefficient vector is $[\gamma_1, \quad \gamma_2, \quad \dots, \quad \gamma_N]$.

RC to LPC

When in this mode, this block uses Levinson recursion to convert reflection coefficients (RCs) to linear prediction coefficients (LPCs). In this case, the input to the block is $RC = [\gamma_1 \quad \gamma_2 \quad \dots \quad \gamma_N]$. The zeroth order LPC vector term is 1. Starting with this term, the block uses recursion to calculate the higher order LPC vectors, $LPC_2, LPC_3, \dots LPC_N$, until it has calculated the entire LPC matrix.

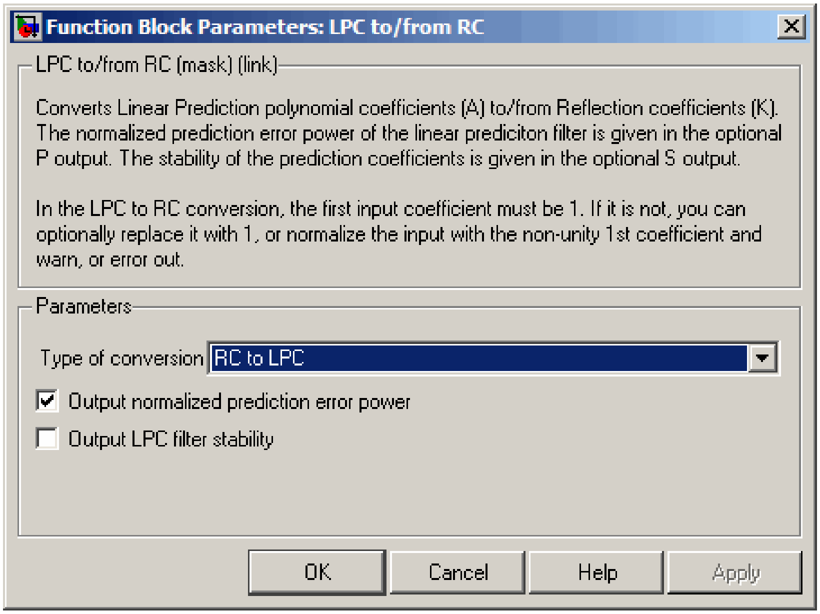
$$LPC_{matrix} = \begin{bmatrix} LPC_0 \\ LPC_1 \\ LPC_2 \\ \cdots \\ LPC_N \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 & 0 & \cdots & 0 \\ 1 & a_{11} & 0 & 0 & \cdots & 0 \\ 1 & a_{21} & a_{22} & 0 & \cdots & 0 \\ 1 & a_{31} & a_{32} & a_{33} & \cdots & 0 \\ \cdots & \cdots & \cdots & \cdots & \cdots & \cdots \\ 1 & a_{N1} & a_{N2} & a_{N3} & \cdots & a_{NN} \end{bmatrix}$$

This LPC matrix consists of LPC vectors of order 0 through *N* found by using the Levinson recursion. The following are the formulas for the recursion steps, for *p* = 0, 1, ...,*N* – 1.

$$a_{p+1,m} = a_{p,m} + \gamma_{p+1} a_{p,p+1-m}, \quad 1 \le m \le p$$

$$a_{p+1,p+1} = \gamma_{p+1}$$

Dialog Box



Function Block Parameters: LPC to/from RC

LPC to/from RC (mask) (link)

Converts Linear Prediction polynomial coefficients (A) to/from Reflection coefficients (K). The normalized prediction error power of the linear prediciton filter is given in the optional P output. The stability of the prediction coefficients is given in the optional S output.

In the LPC to RC conversion, the first input coefficient must be 1. If it is not, you can optionally replace it with 1, or normalize the input with the non-unity 1st coefficient and warn, or error out.

Parameters

Type of conversion: RC to LPC

☑ Output normalized prediction error power

□ Output LPC filter stability

Type of conversion

Select `LPC to RC` or `RC to LPC` to select the domain into which you want to convert your coefficients.

Output normalized prediction error power

Select this check box to output the normalized prediction error power at port P.

Output LPC filter stability

Select this check box to output the stability of the filter. When the filter represented by the LPCs or RCs is stable, the block outputs a Boolean value of `1` for each input channel at the S port. When the filter represented by the LPCs or RCs is unstable, the block outputs a Boolean value of `0` for each input channel at the S port.

If first input value is not 1

Select what you would like the block to do when the first coefficient of the LPC coefficient vector is not 1. You can choose `Replace it with 1`, `Normalize`, `Normalize and Warn`, and `Error`.

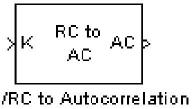
LPC/RC to Autocorrelation

Convert linear prediction coefficients or reflection coefficients to autocorrelation coefficients

Library

Estimation / Linear Prediction

dsplp



Description

The LPC/RC to Autocorrelation block either converts linear prediction coefficients (LPCs) to autocorrelation coefficients (ACs) or reflection coefficients (RCs) to autocorrelation coefficients (ACs). Set the **Type of conversion** parameter to `LPC to autocorrelation` or `RC to autocorrelation` to select the domain from which you want to convert your coefficients. The A port corresponds to LPC coefficients, and the K port corresponds to the RC coefficients.

The block input must be a sample-based row vector, which is treated as a single channel, or a matrix, which is treated as a single channel per column.

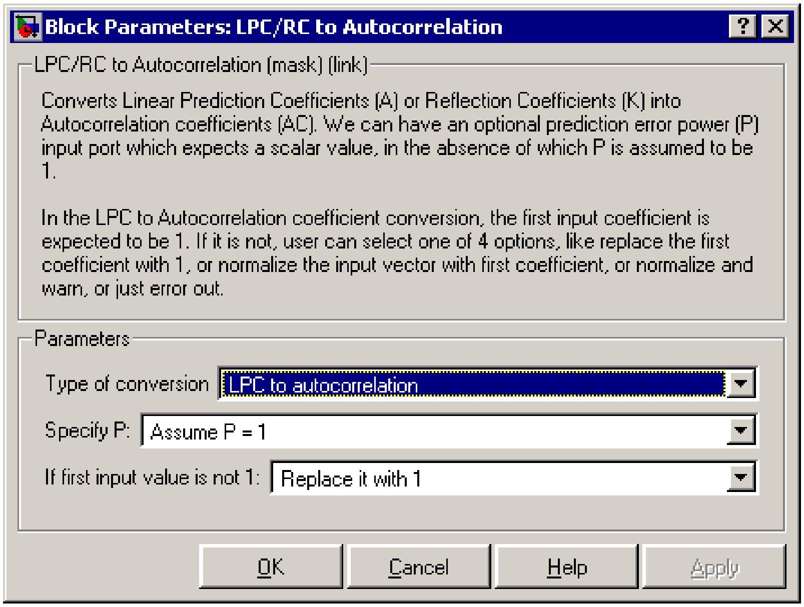
Use the **Specify P** parameter to set the value of the prediction error power. You can set this parameter to 1 by selecting `Assume P=1`. When you select `Via input port`, a P port appears on the block. You can use this port to input the value of the actual, non-unity prediction error power for each channel. The length of this vector must equal the number of channels in the input.

The **If first input value is not 1** parameter specifies the behavior of the block when the first coefficient of the LPC coefficient vector is not 1. The following options are available:

- `Replace it with 1` — The block changes the first value of the coefficient vector to 1. The rest of the coefficient values are unchanged.

- `Normalize` — The block divides the entire vector of coefficients by the first coefficient so that the first coefficient of the LPC coefficient vector is 1.
- `Normalize and Warn` — The block divides the entire vector of coefficients by the first coefficient so that the first coefficient of the LPC coefficient vector is 1. The block displays a warning message telling you that your vector of coefficients has been normalized.
- `Error` — The block displays an error telling you that the first coefficient of the LPC coefficient vector is not 1.

Dialog Box



Block Parameters: LPC/RC to Autocorrelation

LPC/RC to Autocorrelation (mask) (link)

Converts Linear Prediction Coefficients (A) or Reflection Coefficients (K) into Autocorrelation coefficients (AC). We can have an optional prediction error power (P) input port which expects a scalar value, in the absence of which P is assumed to be 1.

In the LPC to Autocorrelation coefficient conversion, the first input coefficient is expected to be 1. If it is not, user can select one of 4 options, like replace the first coefficient with 1, or normalize the input vector with first coefficient, or normalize and warn, or just error out.

Parameters

Type of conversion: LPC to autocorrelation

Specify P: Assume P = 1

If first input value is not 1: Replace it with 1

Type of conversion

From the list select `LPC to autocorrelation` or `RC to autocorrelation` to specify the domain from which you want to convert your coefficients.

Specify P

From the list select `Assume P=1` or `Via input port` to specify the value of prediction error power.

If first input value is not 1

Select what you would like the block to do when the first coefficient of the LPC coefficient vector is not 1. You can choose `Replace it with 1`, `Normalize`, `Normalize and Warn`, and `Error`.

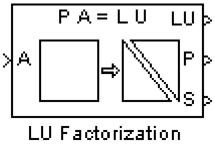
LU Factorization

Factor square matrix into lower and upper triangular components

Library

Math Functions / Matrices and Linear Algebra / Matrix Factorizations

`dspfactors`



Description

The LU Factorization block factors a row-permuted version of the square input matrix A as $A_p = L^*U$, where L is a unit-lower triangular matrix, U is an upper triangular matrix, and A_p contains the rows of A permuted as indicated by the permutation index vector P. The block uses the pivot matrix A_p instead of the exact input matrix A because it improves the numerical accuracy of the factorization. You can determine the singularity of the input matrix A by enabling the optional output port S. When A is singular, the block outputs a `1` at port S; when A is nonsingular, it outputs a `0`.

To improve efficiency, the output of the LU Factorization block at port LU is a composite matrix containing both the lower triangle elements of L and the upper triangle elements of U. Thus, the output is in a different format than the output of the MATLAB `lu` function, which returns L and U as separate matrices. To convert the output from the block's `LU` port to separate L and U matrices, use the following code:

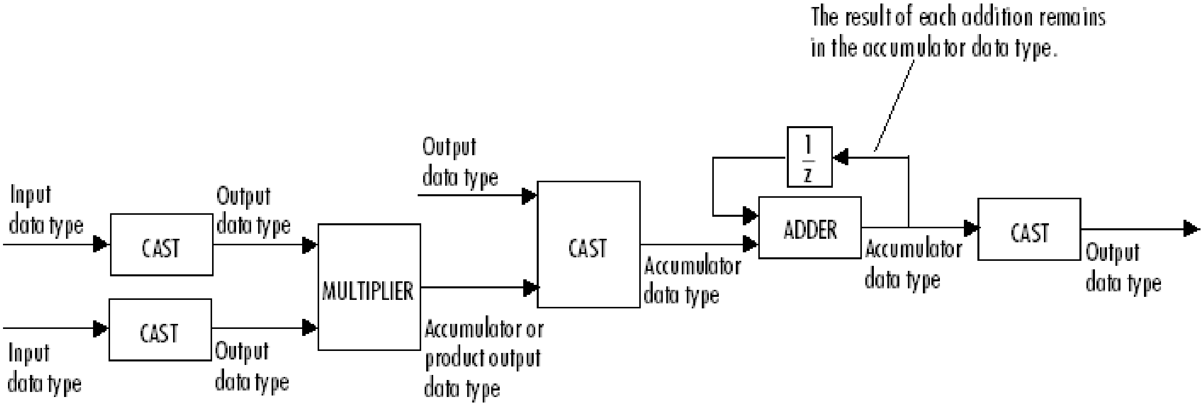
```
L = tril(LU,-1)+eye(size(LU));
U = triu(LU);
```

If you compare the results produced by these equations to the actual output of the MATLAB `lu` function, you may see slightly different values. These differences are due to rounding error, and are expected.

See the `lu` function reference page in the MATLAB documentation for more information about LU factorizations.

Fixed-Point Data Types

The following diagram shows the data types used within the LU Factorization block for fixed-point signals.



You can set the product output, accumulator, and output data types in the block dialog as discussed below.

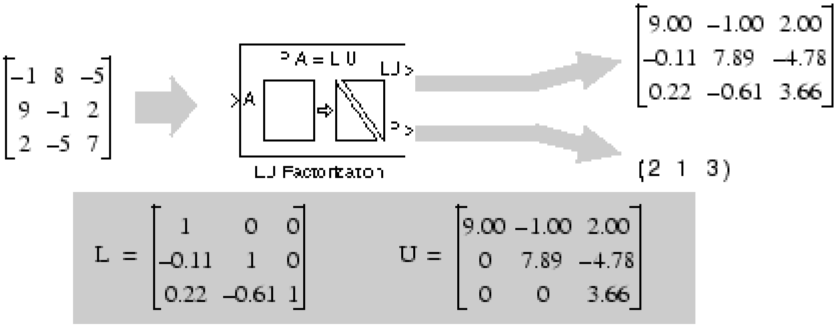
The output of the multiplier is in the product output data type when the input is real. When the input is complex, the result of the multiplication is in the accumulator data type. For details on the complex multiplication performed, see “Multiplication Data Types”.

Examples

The row-pivoted matrix A_p and permutation index vector P computed by the block are shown below for 3-by-3 input matrix A.

$$A = \begin{bmatrix} -1 & 8 & -5 \\ 9 & -1 & 2 \\ 2 & -5 & 7 \end{bmatrix} \qquad P = \begin{pmatrix} 2 & 1 & 3 \end{pmatrix} \qquad A_P = \begin{bmatrix} 9 & -1 & 2 \\ -1 & 8 & -5 \\ 2 & -5 & 7 \end{bmatrix}$$

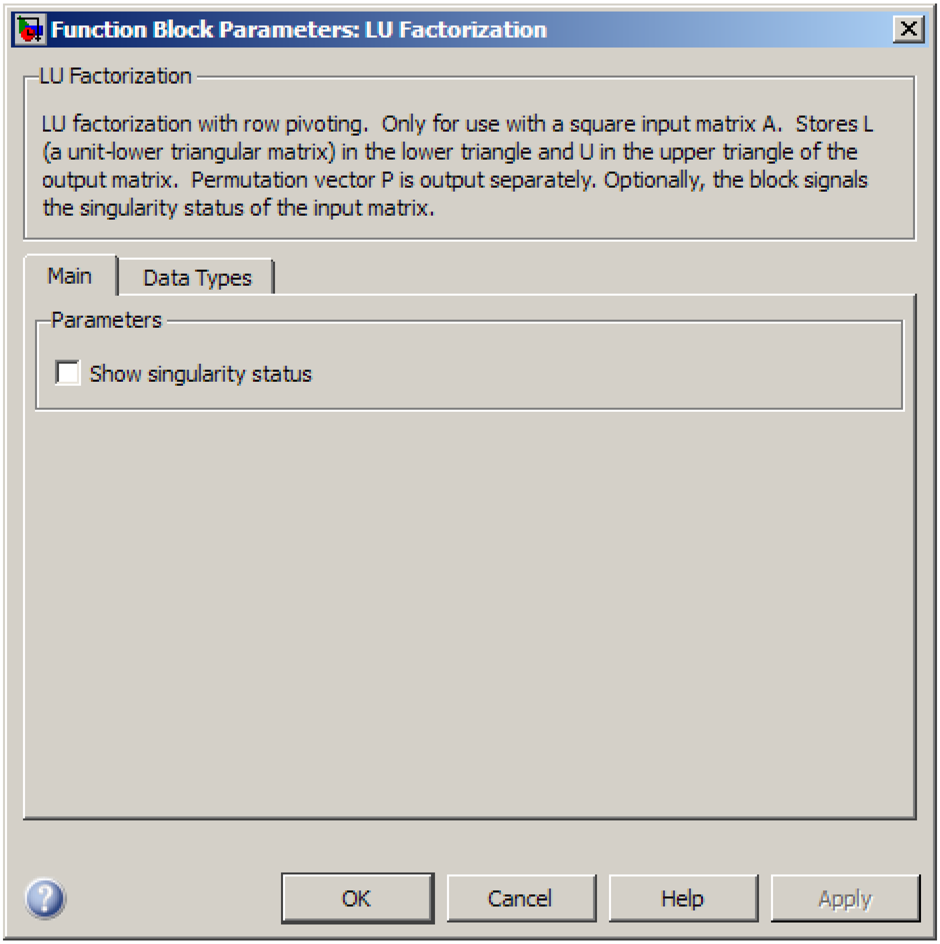
The LU output is a composite matrix whose lower subtriangle forms L and whose upper triangle forms U.



See “Factor a Matrix into Upper and Lower Submatrices Using the LU Factorization Block” in the *DSP System Toolbox User's Guide* for another example using the LU Factorization block.

Dialog Box

The **Main** pane of the LU Factorization block dialog appears as follows.



Function Block Parameters: LU Factorization

LU Factorization

LU factorization with row pivoting. Only for use with a square input matrix A. Stores L (a unit-lower triangular matrix) in the lower triangle and U in the upper triangle of the output matrix. Permutation vector P is output separately. Optionally, the block signals the singularity status of the input matrix.

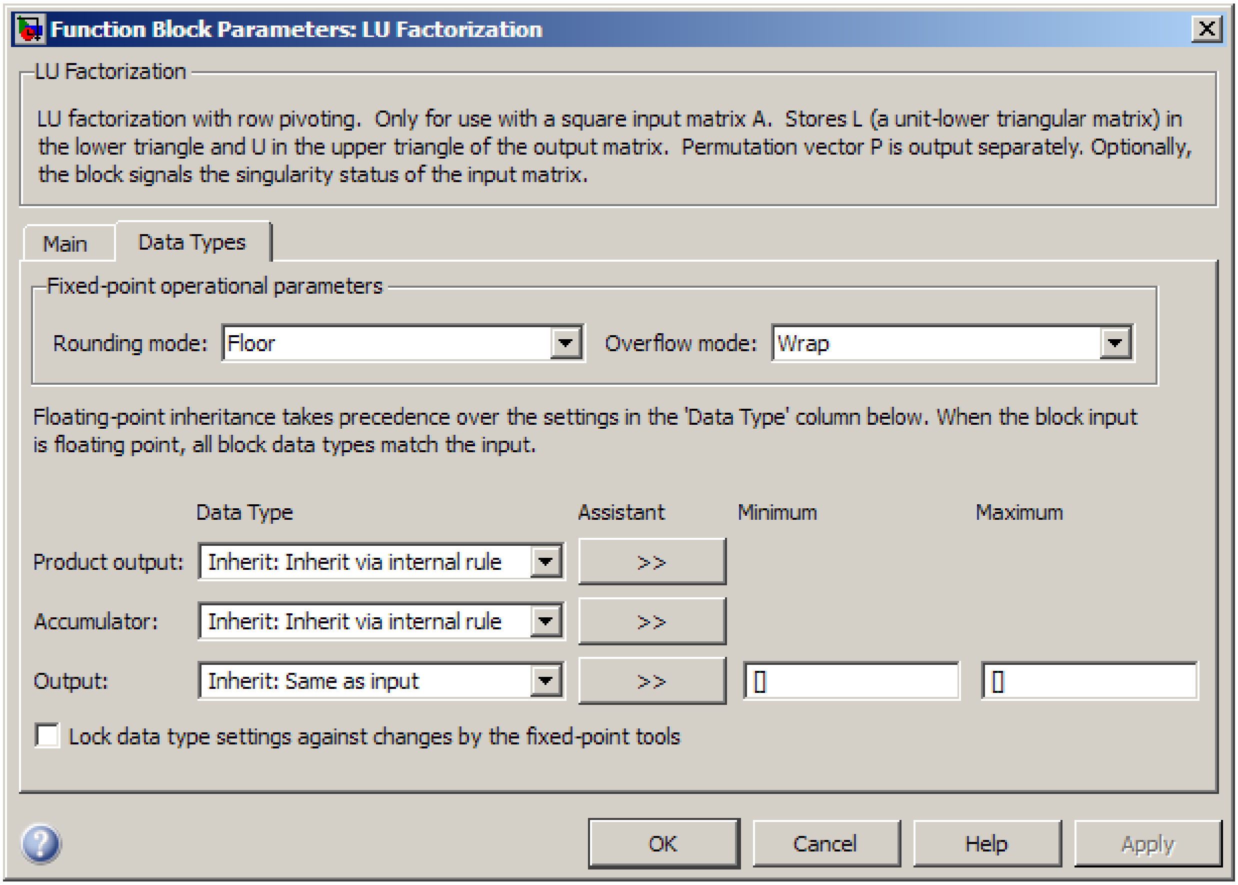
Parameters

□ Show singularity status

Show singularity status

Select to output the singularity of the input at port S, which outputs Boolean data type values of 1 or 0. An output of 1 indicates that the current input is singular, and an output of 0 indicates the current input is nonsingular.

The **Data Types** pane of the LU Factorization block dialog appears as follows.



Function Block Parameters: LU Factorization

LU Factorization

LU factorization with row pivoting. Only for use with a square input matrix A. Stores L (a unit-lower triangular matrix) in the lower triangle and U in the upper triangle of the output matrix. Permutation vector P is output separately. Optionally, the block signals the singularity status of the input matrix.

Fixed-point operational parameters

Rounding mode: Floor

Overflow mode: Wrap

Floating-point inheritance takes precedence over the settings in the 'Data Type' column below. When the block input is floating point, all block data types match the input.

	Data Type	Assistant	Minimum	Maximum
Product output:	Inherit: Inherit via internal rule	>>		
Accumulator:	Inherit: Inherit via internal rule	>>		
Output:	Inherit: Same as input	>>	[]	[]

□ Lock data type settings against changes by the fixed-point tools

Rounding mode

Select the "rounding mode" for fixed-point operations.

Overflow mode

Select the "overflow mode" for fixed-point operations.

Product output data type

Specify the product output data type. See "Fixed-Point Data Types" on page 1-896 and "Multiplication Data Types" for illustrations depicting the use of the product output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`

- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Product output data type** parameter.

See “Specify Data Types Using Data Type Assistant” in “Simulink User's Guide” for more information.

Accumulator data type

Specify the accumulator data type. See “Fixed-Point Data Types” on page 1-896 for illustrations depicting the use of the accumulator data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Accumulator data type** parameter.

See “Specify Data Types Using Data Type Assistant” in “Simulink User's Guide” for more information.

Output data type

Specify the output data type. See “Fixed-Point Data Types” on page 1-896 for illustrations depicting the use of the output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as input`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Specify Block Output Data Types” in “Simulink User's Guide” for more information.

Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

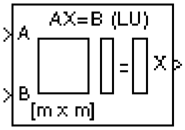
LU Solver

Solve *AX*=*B* for *X* when *A* is square matrix

Library

Math Functions / Matrices and Linear Algebra / Linear System Solvers

`dspsolvers`



Description

The LU Solver block solves the linear system *AX*=*B* by applying LU factorization to the *M*-by-*M* matrix at the A port. The input to the B port is the right side *M*-by-*N* matrix, *B*. The *M*-by-*N* matrix output *X* is the unique solution of the equations.

The block treats length-*M* unoriented vector input to the input port *B* as an *M*-by-1 matrix.

Algorithm

The LU algorithm factors a row-permuted variant (A_p) of the square input matrix *A* as

$$A_p = LU$$

where *L* is a lower triangular square matrix with unity diagonal elements, and *U* is an upper triangular square matrix.

The matrix factors are substituted for A_p in

$$A_p X = B_p$$

where B_p is the row-permuted variant of B, and the resulting equation

$$LUX = B_p$$

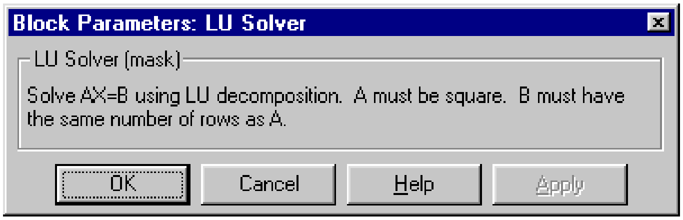
is solved for X by making the substitution $Y = UX$, and solving two triangular systems.

$$LY = B_p$$
$$UX = Y$$

Examples

See “Solve AX=B Using the LU Solver Block” in the *DSP System Toolbox User's Guide*.

Dialog Box



Block Parameters: LU Solver

LU Solver (mask)

Solve AX=B using LU decomposition. A must be square. B must have the same number of rows as A.

Magnitude FFT

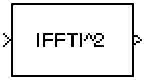
Compute nonparametric estimate of spectrum using periodogram method

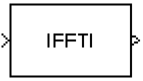
Library

- Estimation / Power Spectrum Estimation

  `dspspect3`
- Transforms

  `dspxfrm3`





Description

The Magnitude FFT block computes a nonparametric estimate of the spectrum using the periodogram method.

When the **Output** parameter is set to `Magnitude squared`, the block output for an M-by-N input u is equivalent to

```
y = abs(fft(u,nfft)).^2       % M # nfft
```

When the **Output** parameter is set to `Magnitude`, the block output for an input u is equivalent to

```
y = abs(fft(u,nfft))         % M # nfft
```

When $M > N_{fft}$, the block wraps the input to N_{fft} before computing the FFT using one of the above equations:

```
y(:,k)=datawrap(u(:,k),nfft)     % 1 # k # N
```

When $M > N_{fft}$, the block can also truncate the input:

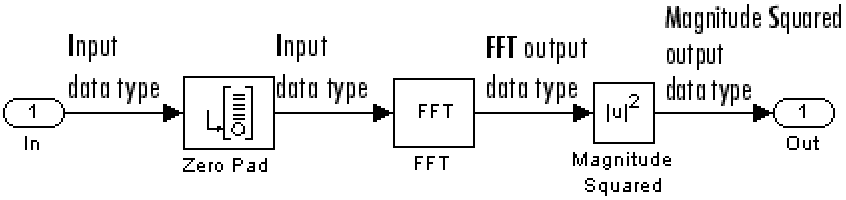
```
y(:,k)=abs(fft(u,nfft))        % 1 # k # N
```

The block treats an M-by-N matrix input as M sequential time samples from N independent channels. The block computes a separate estimate for each of the N independent channels and generates an N_{fft}-by-N matrix output. Each column of the output matrix contains the estimate of the corresponding input column's power spectral density at N_{fft} equally spaced frequency points in the range $[0,F_s)$, where F_s represents the signal's sample frequency. The block always outputs sample–based data.

The Magnitude FFT block supports real and complex floating-point inputs. The block also supports real fixed-point inputs in both `Magnitude` and `Magnitude squared` modes, and complex fixed-point inputs in the `Magnitude squared` mode.

Fixed-Point Data Types

The following diagram shows the data types used within the Magnitude FFT subsystem block for fixed-point signals.



The settings for the fixed-point parameters of the FFT block in the diagram above are as follows:

- Sine table — `Same word length as input`
- Integer rounding mode — `Floor`
- Saturate on integer overflow — unchecked
- Product output — `Inherit via internal rule`
- Accumulator — `Inherit via internal rule`
- Output — `Inherit via internal rule`

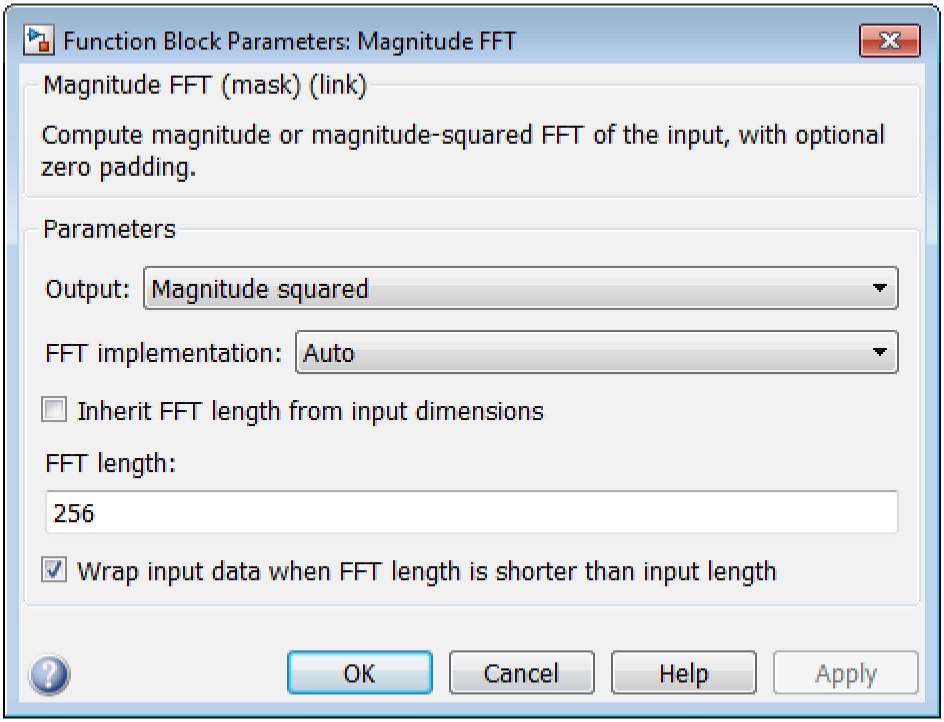
The settings for the fixed-point parameters of the Magnitude Squared block in the diagram above are as follows:

- Integer rounding mode — `Floor`
- Saturate on integer overflow — checked
- Output — `Inherit via internal rule`

Examples

The dspsacomp example compares the periodogram method with several other spectral estimation methods.

Dialog Box



Function Block Parameters: Magnitude FFT

Magnitude FFT (mask) (link)

Compute magnitude or magnitude-squared FFT of the input, with optional zero padding.

Parameters

Output: Magnitude squared

FFT implementation: Auto

□ Inherit FFT length from input dimensions

FFT length:

256

☑ Wrap input data when FFT length is shorter than input length

Output

Specify whether the block computes the magnitude FFT or magnitude-squared FFT of the input.

FFT implementation

Set this parameter to FFTW [1], [2] to support an arbitrary length input signal. The block restricts generated code with FFTW implementation to MATLAB host computers.

Set this parameter to `Radix-2` for bit-reversed processing, fixed or floating-point data, or for portable C-code generation using the Simulink Coder. The first dimension *M*, of the input matrix must be a power of two. To work with other input sizes, use the Pad block to pad or truncate these dimensions to powers of two, or if possible choose the FFTW algorithm.

Set this parameter to `Auto` to let the block choose the FFT implementation. For non-power-of-two transform lengths, the block restricts generated code to MATLAB host computers.

Inherit FFT length from input dimensions

Select to use the input frame size as the number of data points, on which to perform the FFT. When you select this check box, this number must be a power of two. When you do not select this check box, the **FFT length** parameter specifies the number of data points.

FFT length

Enter the number of data points on which to perform the FFT, N_{fft}. When N_{fft} is larger than the input frame size, each frame is zero-padded as needed. When N_{fft} is smaller than the input frame size, each frame is wrapped as needed. This parameter is enabled when you clear the **Inherit FFT length from input dimensions** check box.

When you set the **FFT implementation** parameter to `Radix-2`, this value must be a power of two.

Wrap input data when FFT length is shorter than input length

Choose to wrap or truncate the input, depending on the **FFT length**. If this parameter is checked, modulo-length data wrapping occurs before the FFT operation, given **FFT length** is shorter than the input length. If this property is unchecked, truncation of the input data to the FFT length occurs before the FFT operation. The default is checked.

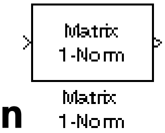
Matrix 1-Norm

Compute 1-norm of matrix

Library

Math Functions / Matrices and Linear Algebra / Matrix Operations

```
dspmtrx3
```



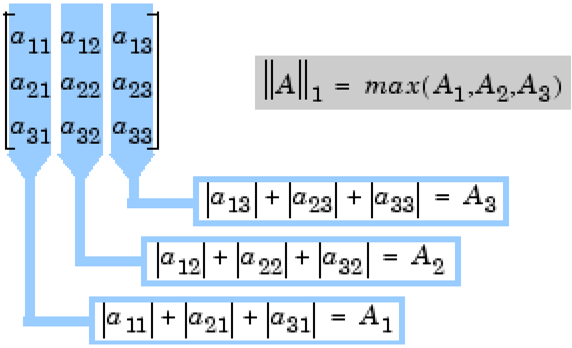
Description

The Matrix 1-Norm block computes the 1-norm, or maximum column-sum, of an *M*-by-*N* input matrix, *A*.

$$y = \|A\|_1 = \max_{1 \le j \le N} \sum_{i=1}^{M} |a_{ij}|$$

This is equivalent to

```
y = max(sum(abs(A)))      % Equivalent
MATLAB code
```



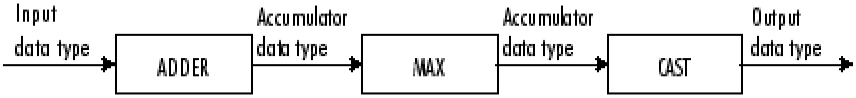
a_{11} a_{12} a_{13}
a_{21} a_{22} a_{23}
a_{31} a_{32} a_{33}
$\|A\|_1 = max(A_1, A_2, A_3)$
$|a_{13}| + |a_{23}| + |a_{33}| = A_3$
$|a_{12}| + |a_{22}| + |a_{32}| = A_2$
$|a_{11}| + |a_{21}| + |a_{31}| = A_1$

The block treats length-M unoriented vector input as an M-by-1 matrix. The output, y, is always a scalar.

The Matrix 1-Norm block supports real and complex floating-point inputs, and real fixed-point inputs.

Fixed-Point Data Types

The following diagram shows the data types used within the Matrix 1-Norm block for fixed-point signals.

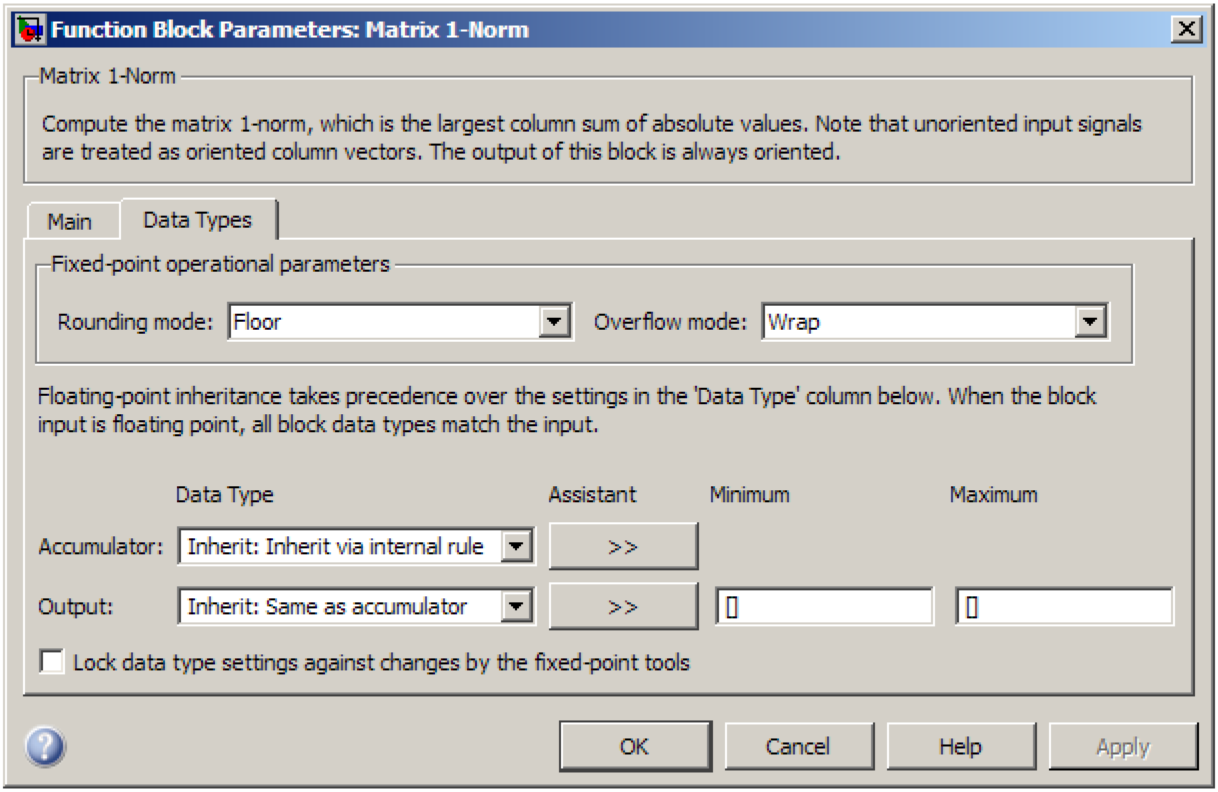


The block calculations are all done in the accumulator data type until the `max` is performed. The result is then cast to the output data type. You can set the accumulator and output data types in the block dialog as discussed in “Dialog Box” on page 1-914 below.

Dialog Box

There are no parameters on the **Main** pane of this dialog.

The **Data types** pane of the Matrix 1-Norm block dialog appears as follows.



Matrix 1-Norm

Compute the matrix 1-norm, which is the largest column sum of absolute values. Note that unoriented input signals are treated as oriented column vectors. The output of this block is always oriented.

Fixed-point operational parameters

Rounding mode: Floor

Overflow mode: Wrap

Floating-point inheritance takes precedence over the settings in the 'Data Type' column below. When the block input is floating point, all block data types match the input.

	Data Type	Assistant	Minimum	Maximum
Accumulator:	Inherit: Inherit via internal rule	>>		
Output:	Inherit: Same as accumulator	>>	[]	[]

□ Lock data type settings against changes by the fixed-point tools

Note: Floating-point inheritance takes precedence over the data type settings defined on this pane. When inputs are floating point, the block ignores these settings, and all internal data types are floating point.

Rounding mode

Select the “rounding mode” for fixed-point operations.

Overflow mode

Select the “overflow mode” for fixed-point operations.

Accumulator data type

Specify the accumulator data type. See “Fixed-Point Data Types” on page 1-914 for illustrations depicting the use of the accumulator data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`
- An expression that evaluates to a valid data type, for example, `fixdt([],16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Accumulator data type** parameter.

See “Specify Data Types Using Data Type Assistant” in “Simulink User's Guide” for more information.

Output data type

Specify the output data type. See “Fixed-Point Data Types” on page 1-914 for illustrations depicting the use of the output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as accumulator`
- An expression that evaluates to a valid data type, for example, `fixdt([],16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Specify Block Output Data Types” in “Simulink User's Guide” for more information.

Minimum

Specify the minimum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges”)
- Automatic scaling of fixed-point data types

Maximum

Specify the maximum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges”)

- Automatic scaling of fixed-point data types

Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

Math Functions / Matrices and Linear Algebra / Matrix Operations

`dspmtrx3`

Description

The Matrix Multiply block is an implementation of the Simulink Product block. See Product for more information.

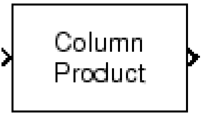
Matrix Product

Multiply matrix elements along rows, columns, or entire input

Library

Math Functions / Matrices and Linear Algebra / Matrix Operations

`dspmtrx3`



Description

The Matrix Product block multiplies the elements of an M-by-N input matrix u along its rows, its columns, or over all its elements.

When the **Multiply over** parameter is set to `Rows`, the block multiplies across the elements of each row and outputs the resulting M-by-1 matrix. The block treats length-N unoriented vector input as a 1-by-N matrix.

$$\begin{bmatrix} u_{11} & u_{12} & u_{13} \\ u_{21} & u_{22} & u_{23} \\ u_{31} & u_{32} & u_{33} \end{bmatrix} \Rightarrow \begin{bmatrix} y_1 \\ y_2 \\ y_3 \end{bmatrix} = \begin{bmatrix} \left(\prod_{j=1}^{3} u_{1j} \right) \\ \left(\prod_{j=1}^{3} u_{2j} \right) \\ \left(\prod_{j=1}^{3} u_{3j} \right) \end{bmatrix}$$

When the **Multiply over** parameter is set to `Columns`, the block multiplies down the elements of each column and outputs the resulting 1-by-N matrix. The block treats length-M unoriented vector input as an M-by-1 matrix.

$$\begin{bmatrix} u_{11} & u_{12} & u_{13} \\ u_{21} & u_{22} & u_{23} \\ u_{31} & u_{32} & u_{33} \end{bmatrix}$$

$$\Downarrow$$

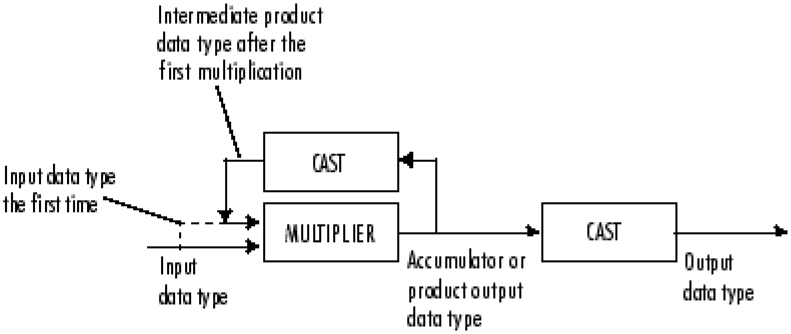
$$\begin{bmatrix} y_1 & y_2 & y_3 \end{bmatrix} = \left[\left(\prod_{i=1}^{3} u_{i1}\right) \left(\prod_{i=1}^{3} u_{i2}\right) \left(\prod_{i=1}^{3} u_{i3}\right)\right]$$

When the **Multiply over** parameter is set to `Entire input`, the block multiplies all the elements of the input together and outputs the resulting scalar.

$$\begin{bmatrix} u_{11} & u_{12} & u_{13} \\ u_{21} & u_{22} & u_{23} \\ u_{31} & u_{32} & u_{33} \end{bmatrix} \Rightarrow y = \left(\prod_{i=1}^{3} \prod_{j=1}^{3} u_{ij}\right)$$

Fixed-Point Data Types

The following diagram shows the data types used within the Matrix Product block for fixed-point signals.

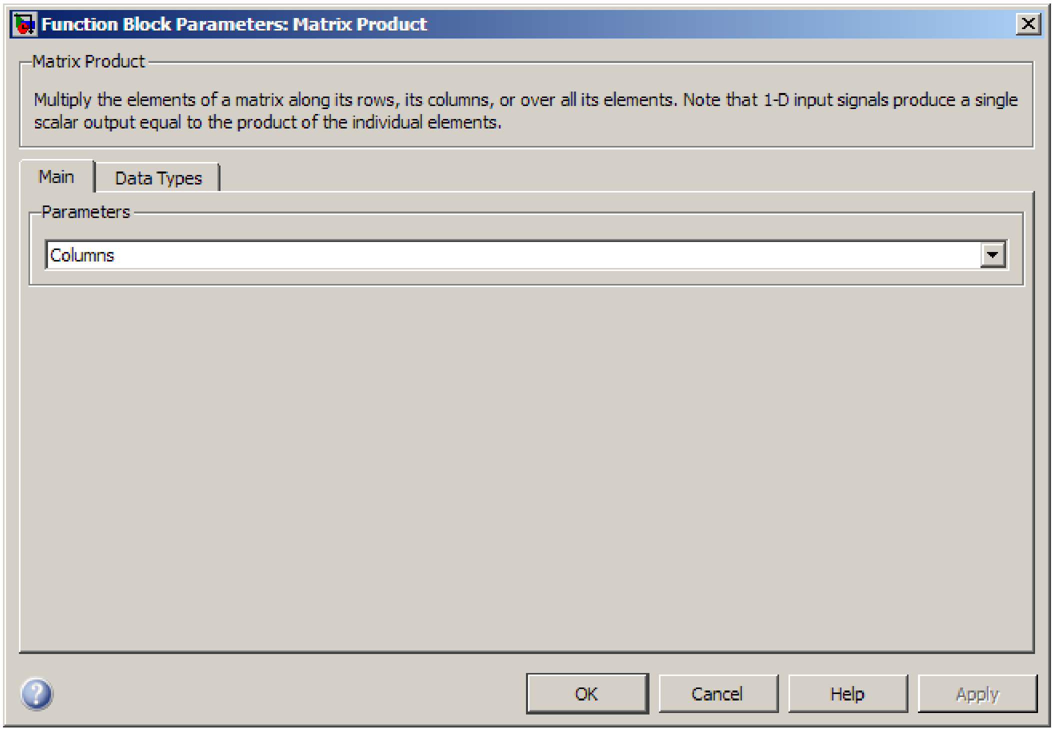


Intermediate product data type after the first multiplication
Input data type the first time
CAST
MULTIPLIER
CAST
Input data type
Accumulator or product output data type
Output data type

The output of the multiplier is in the product output data type when at least one of the inputs to the multiplier is real. When both of the inputs to the multiplier are complex, the result of the multiplication is in the accumulator data type. For details on the complex multiplication performed, see “Multiplication Data Types”. You can set the accumulator, product output, intermediate product, and output data types in the block dialog as discussed in "Dialog Box" on page 1-924 below.

Dialog Box

The **Main** pane of the Matrix Product block dialog appears as follows.



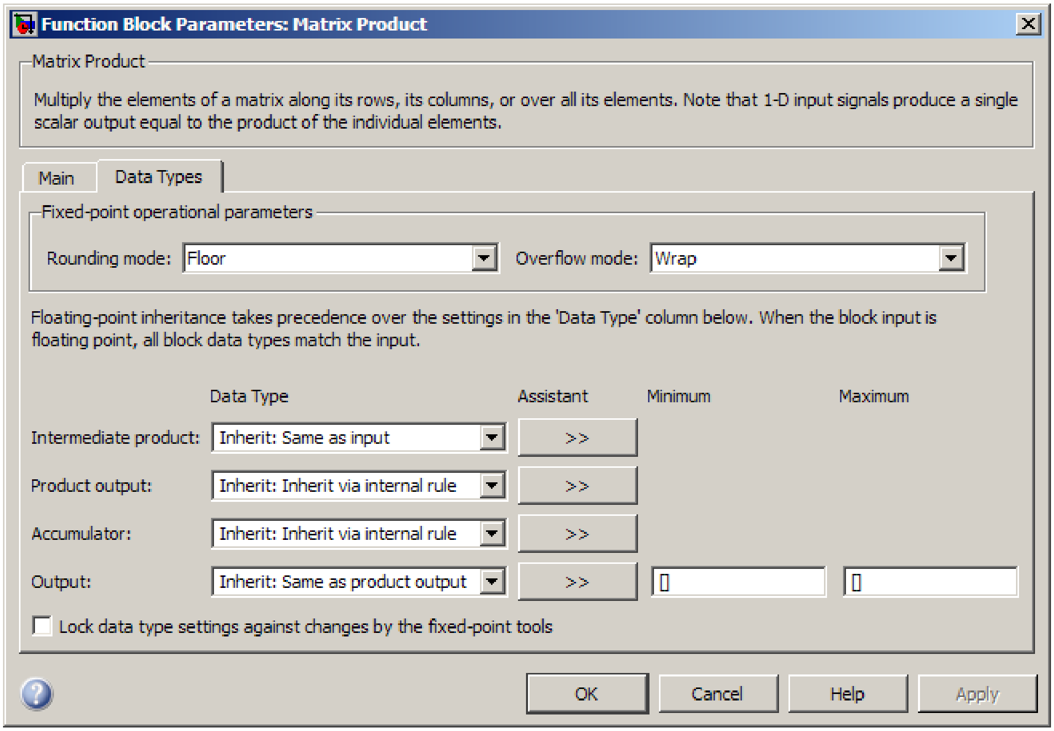
Multiply the elements of a matrix along its rows, its columns, or over all its elements. Note that 1-D input signals produce a single scalar output equal to the product of the individual elements.

Columns

Multiply over

Indicate whether to multiply together the elements of each row, each column, or the entire input.

The **Data Types** pane of the Matrix Product block dialog appears as follows.



Function Block Parameters: Matrix Product

Matrix Product

Multiply the elements of a matrix along its rows, its columns, or over all its elements. Note that 1-D input signals produce a single scalar output equal to the product of the individual elements.

Fixed-point operational parameters

Rounding mode: Floor

Overflow mode: Wrap

Floating-point inheritance takes precedence over the settings in the 'Data Type' column below. When the block input is floating point, all block data types match the input.

	Data Type	Assistant	Minimum	Maximum
Intermediate product:	Inherit: Same as input	>>		
Product output:	Inherit: Inherit via internal rule	>>		
Accumulator:	Inherit: Inherit via internal rule	>>		
Output:	Inherit: Same as product output	>>	[]	[]

□ Lock data type settings against changes by the fixed-point tools

Note: Floating-point inheritance takes precedence over the data type settings defined on this pane. When inputs are floating point, the block ignores these settings, and all internal data types are floating point.

Rounding mode

Select the “rounding mode” for fixed-point operations.

Overflow mode

Select the “overflow mode” for fixed-point operations.

Intermediate product

Specify the intermediate product data type. As shown in “Fixed-Point Data Types” on page 1-923, the output of the multiplier is cast to the intermediate product data type before the next element of the input is multiplied into it. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as input`
- An expression that evaluates to a valid data type, for example, `fixdt([],16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Product output data type** parameter.

See “Specify Data Types Using Data Type Assistant” in “Simulink User's Guide” for more information.

Product output data type

Specify the product output data type. See “Fixed-Point Data Types” on page 1-923 and “Multiplication Data Types” for illustrations depicting the use of the product output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`
- An expression that evaluates to a valid data type, for example, `fixdt([],16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Product output data type** parameter.

See “Specify Data Types Using Data Type Assistant” in “Simulink User's Guide” for more information.

Accumulator data type

Specify the accumulator data type. See “Fixed-Point Data Types” on page 1-923 for illustrations depicting the use of the accumulator data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`
- An expression that evaluates to a valid data type, for example, `fixdt([],16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Accumulator data type** parameter.

See “Specify Data Types Using Data Type Assistant” in “Simulink User's Guide” for more information.

Output data type

Specify the output data type. See “Fixed-Point Data Types” on page 1-923 for illustrations depicting the use of the output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as product output`
- An expression that evaluates to a valid data type, for example, `fixdt([],16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Specify Block Output Data Types” in “Simulink User's Guide” for more information.

Minimum

Specify the minimum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges”)
- Automatic scaling of fixed-point data types

Maximum

Specify the maximum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges”)
- Automatic scaling of fixed-point data types

Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point

Port	Supported Data Types
	• Fixed point • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Output	• Double-precision floating point • Single-precision floating point • Fixed point • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers

Matrix Square

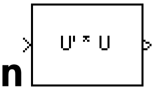
Compute square of input matrix

Library

Math Functions / Matrices and Linear Algebra / Matrix Operations

`dspmtrx3`

Description



The Matrix Square block computes the square of an M-by-N input matrix, u, by premultiplying with the Hermitian transpose.

```
y = u' * u     % Equivalent MATLAB code
```

The block treats length-M unoriented vector inputs as an M-by-1 matrix. When the input is an M-by-N matrix, the output of the block is an N-by-N matrix.

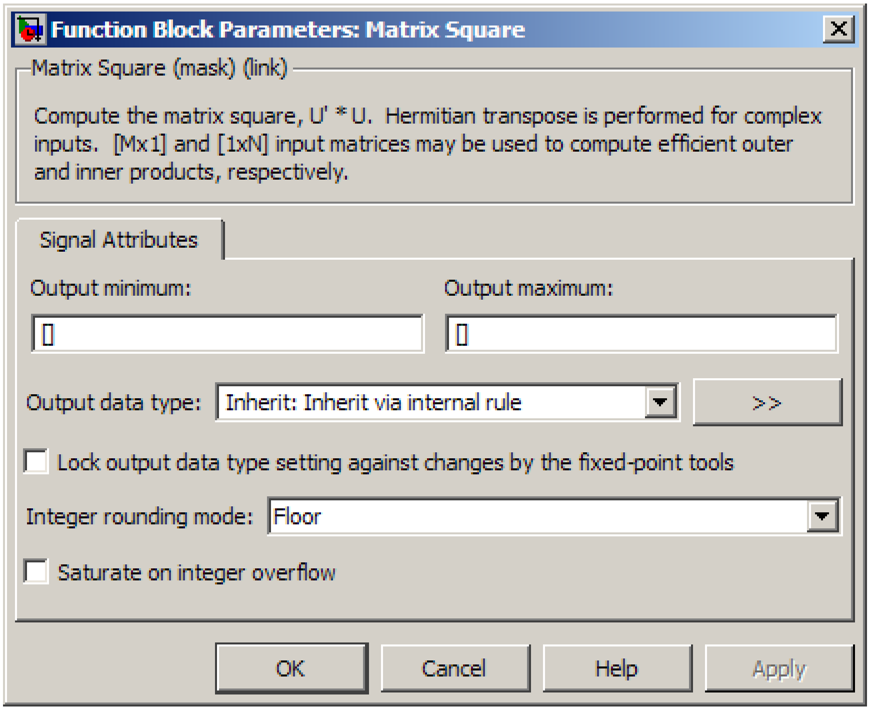
Applications

The Matrix Square block is useful in a variety of applications:

- General matrix squares — The Matrix Square block computes the output matrix, y, without explicitly forming u'. It is therefore more efficient than other methods for computing the matrix square.
- Sum of squares — When the input is a column vector (N=1), the block's operation is equivalent to a multiply-accumulate (MAC) process, or inner product. The output is the sum of the squares of the input, and is always a real scalar.
- Correlation matrix — When the input is a row vector (M=1), the output, y, is the symmetric autocorrelation matrix, or outer product.

Dialog Box

The **Signal Attributes** pane of the Matrix Square block dialog appears as follows.



Function Block Parameters: Matrix Square

Matrix Square (mask) (link)

Compute the matrix square, U' * U. Hermitian transpose is performed for complex inputs. [Mx1] and [1xN] input matrices may be used to compute efficient outer and inner products, respectively.

Signal Attributes

Output minimum: []

Output maximum: []

Output data type: Inherit: Inherit via internal rule

□ Lock output data type setting against changes by the fixed-point tools

Integer rounding mode: Floor

□ Saturate on integer overflow

Output minimum

Specify the minimum value the block should output. The default value is [ ] (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges”)
- Automatic scaling of fixed-point data types

Output maximum

Specify the maximum value the block should output. The default value is [ ] (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges”)
- Automatic scaling of fixed-point data types

Output data type

Specify the output data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`
- An expression that evaluates to a valid data type, for example, `fixdt([],16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Specify Block Output Data Types” in “Simulink User's Guide” for more information.

Lock output data type setting against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the **Output data type** you specify on the block mask.

Integer rounding mode

Select the “rounding mode” for fixed-point operations.

Overflow mode

Select this check box to have overflows saturate to the maximum or minimum value that the data type can represent. If you clear this check box, the block wraps all overflows. See “overflow mode” for more information.

When you select this check box, saturation applies to every internal operation on the block, not just the output or result. In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code

Supported Data Types

- Double-precision floating point
- Single-precision floating point

Matrix Sum

Sum matrix elements along rows, columns, or entire input

Library

Math Functions / Matrices and Linear Algebra / Matrix Operations

`dspmtrx3`

Description

The Matrix Sum block is an implementation of the Simulink Sum block. See Sum for more information.

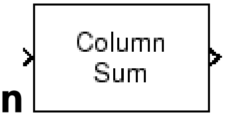
Matrix Sum (Obsolete)

Sum matrix elements along rows, columns, or entire input

Library

Math Functions / Matrices and Linear Algebra / Matrix Operations

`dspobslib`



Description

The Matrix Sum block sums the elements of an M-by-N input matrix u along its rows, its columns, or over all its elements.

When the **Sum over** parameter is set to `Rows`, the block sums across the elements of each row and outputs the resulting M-by-1 matrix. A length-N 1-D vector input is treated as a 1-by-N matrix.

$$\begin{bmatrix} u_{11} & u_{12} & u_{13} \\ u_{21} & u_{22} & u_{23} \\ u_{31} & u_{32} & u_{33} \end{bmatrix} \Rightarrow \begin{bmatrix} y_1 \\ y_2 \\ y_3 \end{bmatrix} = \begin{bmatrix} \left(\sum_{j=1}^{3} u_{1j} \right) \\ \left(\sum_{j=1}^{3} u_{2j} \right) \\ \left(\sum_{j=1}^{3} u_{3j} \right) \end{bmatrix}$$

When the **Sum over** parameter is set to `Columns`, the block sums down the elements of each column and outputs the resulting 1-by-N matrix. A length-M 1-D vector input is treated as a M-by-1 matrix.

$$\begin{bmatrix} u_{11} & u_{12} & u_{13} \\ u_{21} & u_{22} & u_{23} \\ u_{31} & u_{32} & u_{33} \end{bmatrix}$$

$$\Downarrow$$

$$\begin{bmatrix} y_1 & y_2 & y_3 \end{bmatrix} = \left[\left(\sum_{i=1}^{3} u_{i1} \right) \left(\sum_{i=1}^{3} u_{i2} \right) \left(\sum_{i=1}^{3} u_{i3} \right) \right]$$

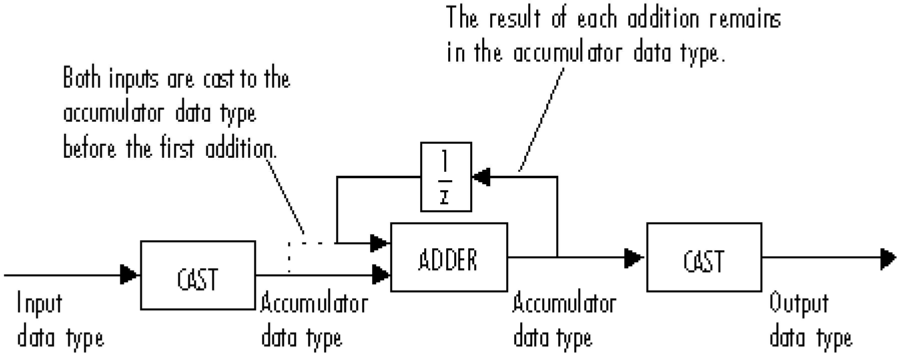
When the **Sum over** parameter is set to `Entire input`, the block sums all the elements of the input together and outputs the resulting scalar.

$$\begin{bmatrix} u_{11} & u_{12} & u_{13} \\ u_{21} & u_{22} & u_{23} \\ u_{31} & u_{32} & u_{33} \end{bmatrix} \Rightarrow y = \left(\sum_{i=1}^{3} \sum_{j=1}^{3} u_{ij} \right)$$

The output of the Matrix Sum block has the same frame status as the input. This block accepts real and complex fixed-point and floating-point inputs except for complex unsigned fixed-point inputs.

Fixed-Point Data Types

The following diagram shows the data types used within the Matrix Sum block for fixed-point signals.



The result of each addition remains
in the accumulator data type.
Both inputs are cast to the
accumulator data type
before the first addition.

data type

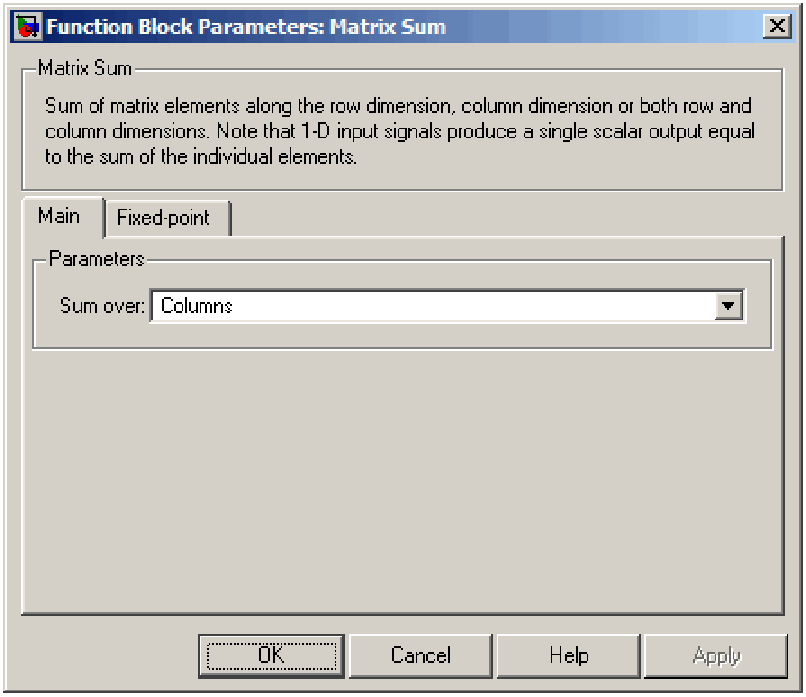
You can set the accumulator and output data types in the block dialog as discussed in "Dialog Box" on page 1-936 below.

Dialog Box

The **Main** pane of the Matrix Sum block dialog appears as follows.



Function Block Parameters: Matrix Sum

Matrix Sum

Sum of matrix elements along the row dimension, column dimension or both row and column dimensions. Note that 1-D input signals produce a single scalar output equal to the sum of the individual elements.

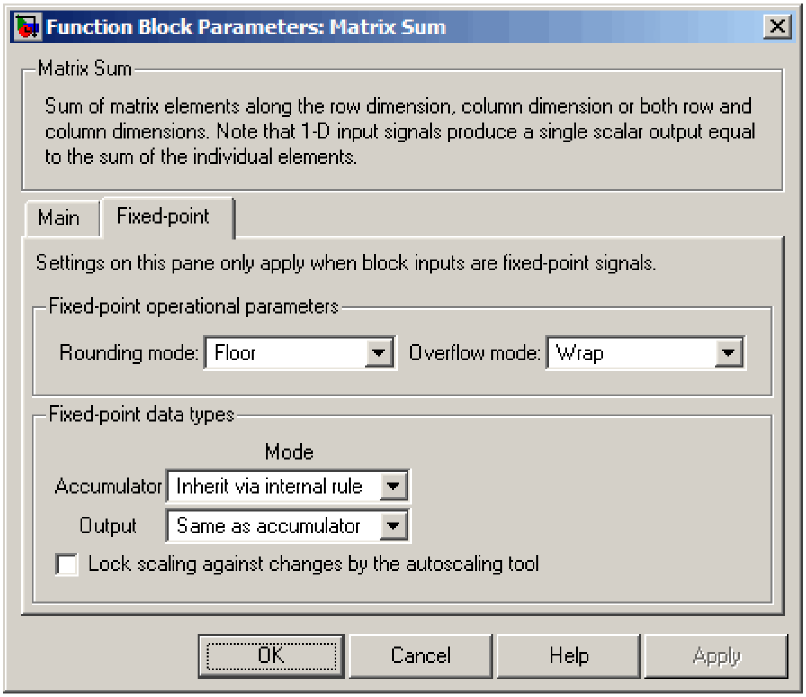
Parameters

Sum over: Columns

Sum over

Indicate whether to sum the elements of each row, each column, or of the entire input.

The **Fixed-point** pane of the Matrix Sum block dialog appears as follows.



Function Block Parameters: Matrix Sum

Matrix Sum

Sum of matrix elements along the row dimension, column dimension or both row and column dimensions. Note that 1-D input signals produce a single scalar output equal to the sum of the individual elements.

Settings on this pane only apply when block inputs are fixed-point signals.

Fixed-point operational parameters

Rounding mode: Floor Overflow mode: Wrap

Fixed-point data types

Mode

Accumulator: Inherit via internal rule

Output: Same as accumulator

□ Lock scaling against changes by the autoscaling tool

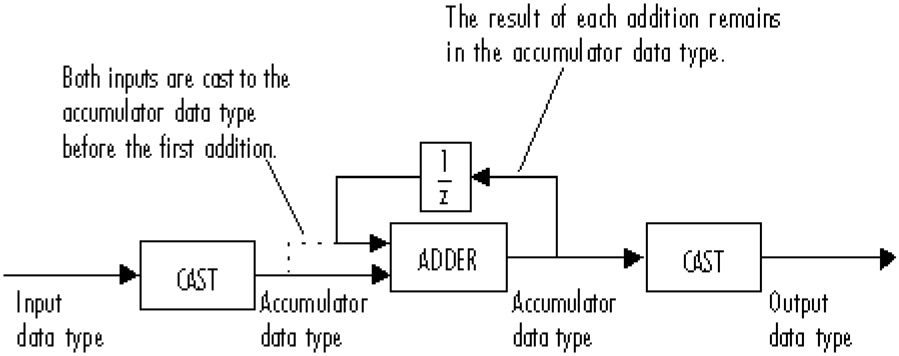
Rounding mode

Select the “rounding mode” for fixed-point operations.

Overflow mode

Select the “overflow mode” for fixed-point operations.

Accumulator



The result of each addition remains in the accumulator data type.
Both inputs are cast to the accumulator data type before the first addition.
1/z
CAST
ADDER
CAST
Input data type
Accumulator data type
Accumulator data type
Output data type

As depicted above, the elements of the block input are cast to the accumulator data type before they are added together. The output of the adder remains in the accumulator data type as each element of the input is added to it. Use this parameter to specify how you would like to designate this accumulator word and fraction lengths:

- When you select `Inherit via internal rule`, the accumulator word length and fraction length are calculated automatically. For information about how the accumulator word and fraction lengths are calculated when an internal rule is used, see “Inherit via Internal Rule”.
- When you select `Same as input`, these characteristics match those of the input to the block.
- When you select `Binary point scaling`, you can enter the word length and the fraction length of the accumulator, in bits.
- When you select `Slope and bias scaling`, you can enter the word length, in bits, and the slope of the accumulator. This block requires power-of-two slope and a bias of zero.

Output

Choose how you specify the output word length and fraction length:

- When you select `Same as accumulator`, these characteristics match those of the accumulator.
- When you select `Same as input`, these characteristics match those of the input to the block.
- When you select `Binary point scaling`, you can enter the word length and the fraction length of the output, in bits.

- When you select `Slope and bias scaling`, you can enter the word length, in bits, and the slope of the output. This block requires power-of-two slope and a bias of zero.

Lock scaling against changes by the autoscaling tool

Select this parameter to prevent any fixed-point scaling you specify in this block mask from being overridden by the autoscaling feature of the Fixed-Point Tool. See the `fxptdlg` reference page for more information.

Supported Data Types

Port	Supported Data Types

`sum`	MATLAB

Matrix Viewer

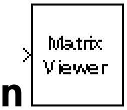
Display matrices as color images

Library

Sinks

`dspsnks4`

Description



The Matrix Viewer block displays an *M*-by-*N* matrix input by mapping the matrix element values to a specified range of colors. The display is updated as each new input is received. This block treats an unoriented length *M* vector input as an *M*-by-1 matrix.

You can use the Matrix Viewer block in models running in Normal or Accelerator simulation modes. The software does not support this block in models running in Rapid Accelerator or External mode. For more information about these modes, see “How Acceleration Modes Work” in the *Simulink User's Guide*.

Image Properties

Select the **Image Properties** tab to show the image property parameters, which control the colormap and display.

You specify the mapping of matrix element values to colors in the **Colormap matrix**, **Minimum input value**, and **Maximum input value** parameters. For a colormap with *L* colors, the colormap matrix has dimension *L*-by-3, with one row for each color and one column for each element of the RGB triple that defines the color. Examples of RGB triples are

```
[ 1   0   0 ]   (red)
[ 0   0   1 ]   (blue)
[0.8 0.8 0.8]   (light gray)
```

See the `ColorSpec` property in the MATLAB documentation for complete information about defining RGB triples.

MATLAB provides a number of functions for generating predefined colormaps, such as `hot`, `cool`, `bone`, and `autumn`. Each of these functions accepts the colormap size as an argument, and can be used in the **Colormap matrix** parameter. For example, when you specify `gray(128)` for the **Colormap matrix** parameter, the matrix is displayed in 128 shades of gray. The color in the first row of the colormap matrix represents the value specified by the **Minimum input value** parameter, and the color in the last row represents the value specified by the **Maximum input value** parameter. Values between the minimum and maximum are quantized and mapped to the intermediate rows of the colormap matrix.

The documentation for the MATLAB `colormap` function provides complete information about specifying colormap matrices, and includes a complete list of the available colormap functions.

Axis Properties

Select the **Axis Properties** tab to show the axis property parameters, which control labeling and positioning.

The **Axis origin** parameter determines where the first element of the input matrix, U(1,1), is displayed. When you specify `Upper left corner`, the matrix is displayed in matrix orientation, with U(1,1) in the upper-left corner.

$$\begin{bmatrix} U_{11} & U_{12} & U_{13} & U_{14} \\ U_{21} & U_{22} & U_{23} & U_{24} \\ U_{31} & U_{32} & U_{33} & U_{34} \\ U_{41} & U_{42} & U_{43} & U_{44} \end{bmatrix}$$

When you specify `Lower left corner`, the matrix is flipped vertically to image orientation, with U(1,1) in the lower-left corner.

$$\begin{bmatrix} U_{41} & U_{42} & U_{43} & U_{44} \\ U_{31} & U_{32} & U_{33} & U_{34} \\ U_{21} & U_{22} & U_{23} & U_{24} \\ U_{11} & U_{12} & U_{13} & U_{14} \end{bmatrix}$$

Axis zoom, when selected, causes the image display to completely fill the figure window. Axis titles are not displayed. This option can also be selected from the pop-up menu that is displayed when you right-click in the figure window. When **Axis zoom** is cleared, the axis labels and titles are displayed in a gray border surrounding the image axes.

Figure Window

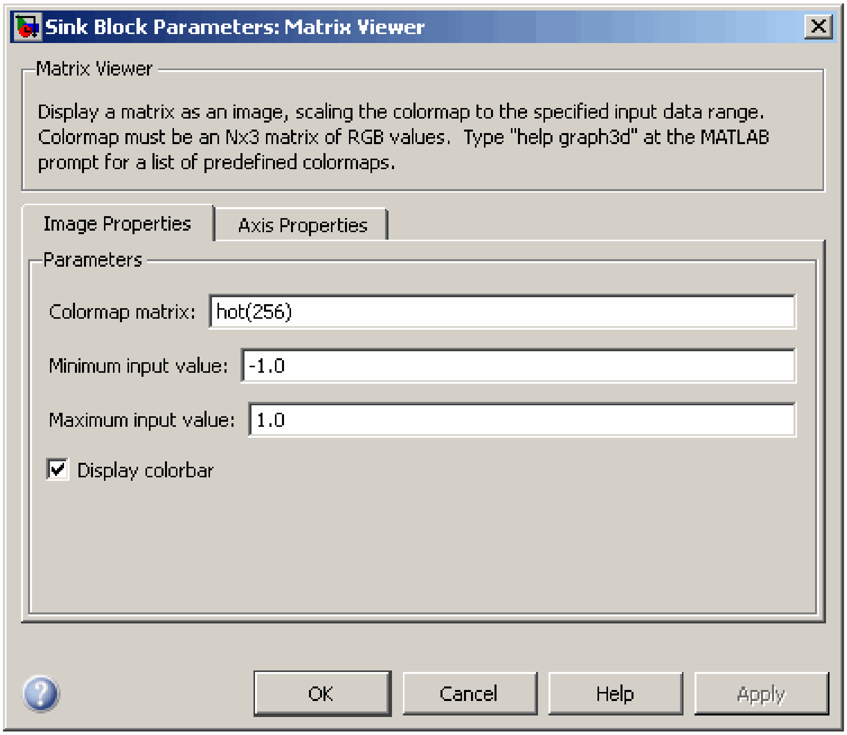
The image title in the figure title bar is the same as the block title. The axis tick marks reflect the size of the input matrix; the *x*-axis is numbered from 1 to *N* (number of columns), and the *y*-axis is numbered from 1 to *M* (number of rows).

Right-click the image in the figure window to access the following menu items:

- **Refresh** erases all data on the scope display except for the most recent image.
- **Autoscale** recomputes the minimum and maximum input values to fit the range of values observed in a series of 10 consecutive inputs. The numerical limits selected by the autoscale feature are shown in the **Minimum input value** and **Maximum input value** parameters, where you can make further adjustments to them manually.
- **Axis zoom**, when selected, causes the image to completely fill the figure window. Axis titles are not displayed. When **Axis zoom** is cleared, the axis labels and titles are displayed in a gray border surrounding the scope axes. This option can also be set in the Axis Properties pane of the parameter dialog.
- **Colorbar**, when selected, displays a bar with the specified colormap to the right of the image axes.
- **Save Position** automatically updates the **Figure position** parameter in the **Axis Properties** pane to reflect the figure window's current position and size on the screen. To make the scope window open at a particular location on the screen when the simulation runs, drag the window to the desired location, resize it, and select **Save Position**. The parameter dialog must be closed when you select **Save Position** for the **Figure position** parameter to be updated.

Dialog Box

The **Image Properties** pane of the Matrix Viewer block appears as follows.



Sink Block Parameters: Matrix Viewer

Matrix Viewer

Display a matrix as an image, scaling the colormap to the specified input data range. Colormap must be an Nx3 matrix of RGB values. Type "help graph3d" at the MATLAB prompt for a list of predefined colormaps.

Colormap matrix: hot(256)

Minimum input value: -1.0

Maximum input value: 1.0

☑ Display colorbar

Colormap matrix

A 3-column matrix defining the colormap as a set of RGB triples, or a call to a colormap-generating function such as `hot` or `spring`. See the `ColorSpec` property for complete information about defining RGB triples, and the MATLAB `colormap` function for a list of colormap-generating functions. "Tunable".

Minimum input value

The input value to be mapped to the color defined in the first row of the colormap matrix. Right-click in the figure window and select `Autoscale` from pop-up menu to set this parameter to the minimum value observed in a series of 10 consecutive matrix inputs. "Tunable".

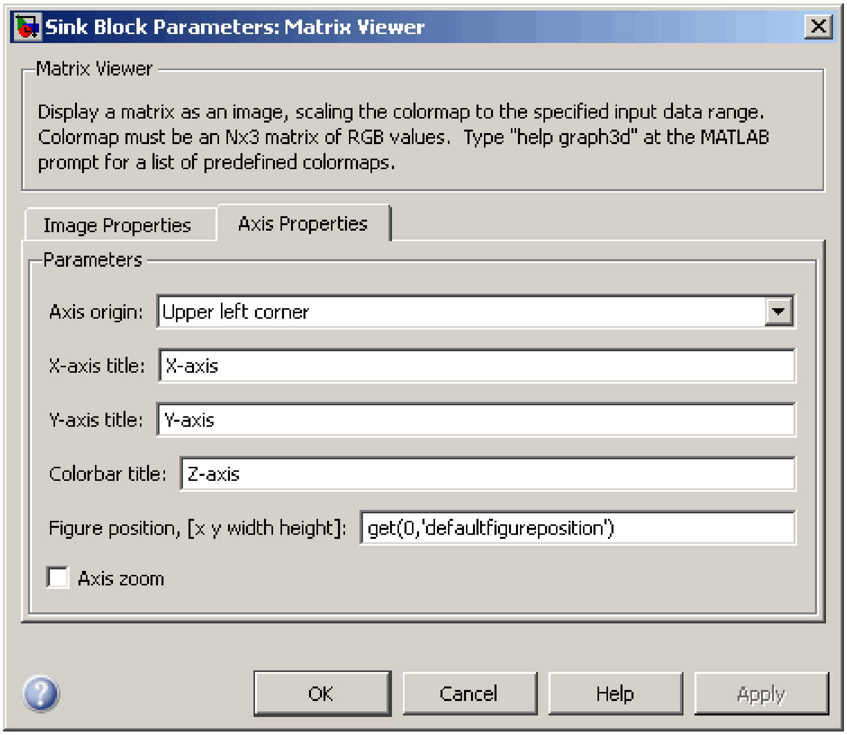
Maximum input value

The input value to be mapped to the color defined in the last row of the colormap matrix. Right-click in the figure window and select `Autoscale` from the pop-up menu to set this parameter to the maximum value observed in a series of 10 consecutive matrix inputs. "Tunable".

Display colorbar

Select to display a bar with the selected colormap to the right of the image axes. "Tunable".

The **Axis Properties** pane of the Matrix Viewer block appears as follows.



Sink Block Parameters: Matrix Viewer

Matrix Viewer

Display a matrix as an image, scaling the colormap to the specified input data range. Colormap must be an Nx3 matrix of RGB values. Type "help graph3d" at the MATLAB prompt for a list of predefined colormaps.

`image`	MATLAB

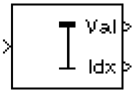
Maximum

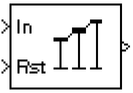
Find maximum values in input or sequence of inputs

Library

Statistics

`dspstat3`





Description

The Maximum block identifies the value and/or position of the largest element in each row or column of the input, along vectors of a specified dimension of the input, or of the entire input. The Maximum block can also track the maximum values in a sequence of inputs over a period of time. The **Mode** parameter specifies the block's mode of operation and can be set to `Value`, `Index`, `Value and Index`, or `Running`.

The Maximum block supports real and complex floating-point, fixed-point, and Boolean inputs. Real fixed-point inputs can be either signed or unsigned, while complex fixed-point inputs must be signed. The data type of the maximum values output by the block match the data type of the input. The index values output by the block are `double` when the input is `double`, and `uint32` otherwise.

For the `Value`, `Index`, and `Value and Index` modes, the Maximum block produces identical results as the MATLAB `max` function when it is called as `[y I] = max(u,[],D)`, where *u* and *y* are the input and output, respectively, *D* is the dimension, and *I* is the index.

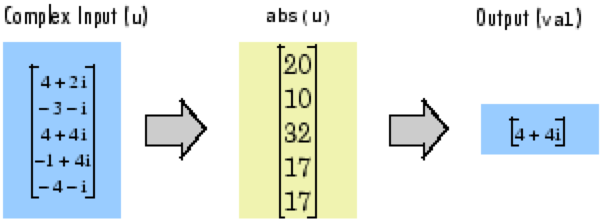
Value Mode

When the **Mode** parameter is set to `Value`, the block computes the maximum value in each row or column of the input, along vectors of a specified dimension of the input, or of the entire input at each sample time, and outputs the array y. Each element in y is the maximum value in the corresponding column, row, vector, or entire input. The output y depends on the setting of the **Find the maximum value over** parameter. For example, consider a 3-dimensional input signal of size M-by-N-by-P:

- `Each row` — The output at each sample time consists of an M-by-1-by-P array, where each element contains the maximum value of each vector over the second dimension of the input. For an input that is an M-by-N matrix, the output at each sample time is an M-by-1 column vector.
- `Each column` — The output at each sample time consists of a 1-by-N-by-P array, where each element contains the maximum value of each vector over the first dimension of the input. For an input that is an M-by-N matrix, the output at each sample time is a 1-by-N row vector.

  In this mode, the block treats length-M unoriented vector inputs as M-by-1 column vectors.
- `Entire input` — The output at each sample time is a scalar that contains the maximum value in the M-by-N-by-P input matrix.
- `Specified dimension` — The output at each sample time depends on **Dimension**. If **Dimension** is set to `1`, the output is the same as that when you select `Each column`. If **Dimension** is set to `2`, the output is the same as when you select `Each row`. If **Dimension** is set to `3`, the output at each sample time is an M-by-N matrix containing the maximum value of each vector over the third dimension of the input.

For complex inputs, the block selects the value in each row or column of the input, along vectors of a specified dimension of the input, or of the entire input that has the maximum magnitude squared as shown below. For complex value $u = a + bi$, the magnitude squared is $a^2 + b^2$.



Index Mode

When **Mode** is set to `Index`, the block computes the maximum value in each row or column of the input, along vectors of a specified dimension of the input, or of the entire input, and outputs the index array *I*. Each element in *I* is an integer indexing the maximum value in the corresponding column, row, vector, or entire input. The output *I* depends on the setting of the **Find the maximum value over** parameter. For example, consider a 3-dimensional input signal of size *M*-by-*N*-by-*P*:

- `Each row` — The output at each sample time consists of an *M*-by-1-by-*P* array, where each element contains the index of the maximum value of each vector over the second dimension of the input. For an input that is an *M*-by-*N* matrix, the output at each sample time is an *M*-by-1 column vector.
- `Each column` — The output at each sample time consists of a 1-by-*N*-by-*P* array, where each element contains the index of the maximum value of each vector over the first dimension of the input. For an input that is an *M*-by-*N* matrix, the output at each sample time is a 1-by-*N* row vector.

  In this mode, the block treats length-*M* unoriented vector inputs as *M*-by-1 column vectors.
- `Entire input` — The output at each sample time is a 1-by-3 vector that contains the location of the maximum value in the *M*-by-*N*-by-*P* input matrix. For an input that is an *M*-by-*N* matrix, the output will be a 1-by-2 vector.
- `Specified dimension` — The output at each sample time depends on **Dimension**. If **Dimension** is set to 1, the output is the same as when you select `Each column`. If **Dimension** is set to 2, the output is the same as when you select `Each row`. If **Dimension** is set to 3, the output at each sample time is an *M*-by-*N* matrix containing the indices of the maximum values of each vector over the third dimension of the input.

When a maximum value occurs more than once, the computed index corresponds to the first occurrence. For example, when the input is the column vector `[3 2 1 2 3]'`, the computed one-based index of the maximum value is `1` rather than `5` when `Each column` is selected.

When inputs to the block are double-precision values, the index values are double-precision values. Otherwise, the index values are 32-bit unsigned integer values.

Value and Index Mode

When **Mode** is set to `Value and Index`, the block outputs both the maxima and the indices.

Running Mode

When **Mode** is set to `Running`, the block tracks the maximum value of each channel in a time sequence of *M*-by-*N* inputs. In this mode, you must also specify a value for the **Input processing** parameter:

- When you select `Elements as channels (sample based)`, the block outputs an *M*-by-*N* array. Each element y_{ij} of the output contains the maximum value observed in element u_{ij} for all inputs since the last reset.
- When you select `Columns as channels (frame based)`, the block outputs an *M*-by-*N* matrix. Each element y_{ij} of the output contains the maximum value observed in the *j*th column of all inputs since the last reset, up to and including element u_{ij} of the current input.

Running Mode for Variable-Size Inputs

When your inputs are of variable size, and you set the **Mode** to `Running` , there are two options:

- If you set the **Input processing** parameter to `Elements as channels (sample based)`, the state is reset.
- If you set the **Input processing** parameter to `Columns as channels (frame based)`, then there are two cases:
  - When the input size difference is in the number of channels (i.e., number of columns), the state is reset.
  - When the input size difference is in the length of channels (i.e., number of rows), there is no reset and the running operation is carried out as usual.

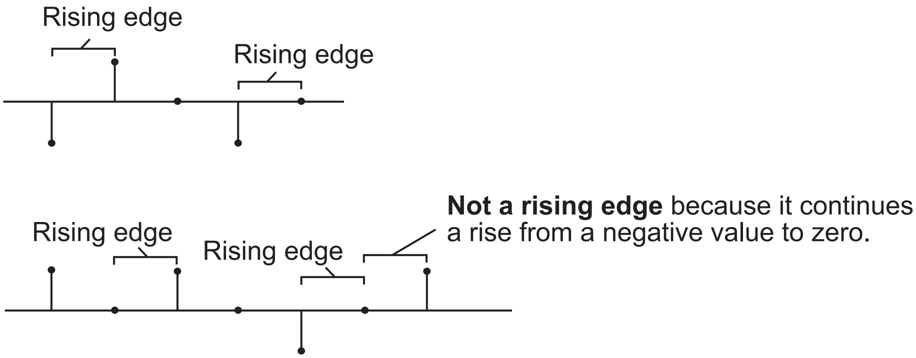
Resetting the Running Maximum

The block resets the running maximum whenever a reset event is detected at the optional Rst port. The reset sample time must be a positive integer multiple of the input sample time.

When a reset event occurs while the **Input processing** parameter is set to `Elements as channels (sample based)`, the running maximum for each channel is initialized to the value in the corresponding channel of the current input. Similarly, when the **Input processing** parameter is set to `Columns as channels (frame based)`, the running maximum for each channel is initialized to the earliest value in each channel of the current input.

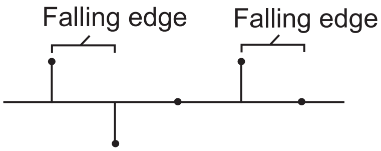
You specify the reset event in the **Reset port** menu:

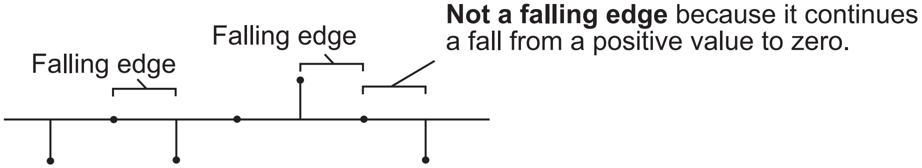
- `None` — Disables the Rst port.
- `Rising edge` — Triggers a reset operation when the Rst input does one of the following:
  - Rises from a negative value to a positive value or zero
  - Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero (see the following figure)



Rising edge
Rising edge
Rising edge
Rising edge
Not a rising edge because it continues a rise from a negative value to zero.

- `Falling edge` — Triggers a reset operation when the `Rst` input does one of the following:
  - Falls from a positive value to a negative value or zero
  - Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero (see the following figure)





Falling edge
Falling edge
Not a falling edge because it continues a fall from a positive value to zero.

- `Either edge` — Triggers a reset operation when the `Rst` input is a `Rising edge` or `Falling edge` (as described above)
- `Non-zero sample` — Triggers a reset operation at each sample time that the `Rst` input is not zero

Note: When running simulations in the Simulink `MultiTasking` mode, reset signals have a one-sample latency. Therefore, when the block detects a reset event, there is a one-sample delay at the reset port rate before the block applies the reset. For more information on latency and the Simulink tasking modes, see "Excess Algorithmic Delay (Tasking Latency)" and "Scheduling " in the *Simulink Coder User's Guide*.

ROI Processing

To calculate the statistical value within a particular region of interest (ROI) of the input, select the **Enable ROI processing** check box. This applies to any mode other than running mode and when you set the **Find the maximum value over** parameter to `Entire input` and you select the **Enable ROI processing** check box. ROI processing applies only for 2-D inputs.

Note: Full ROI processing is available only if you have a Computer Vision System Toolbox™ license. If you do not have a Computer Vision System Toolbox license, you can still use ROI processing, but are limited to the **ROI type** `Rectangles`.

Use the **ROI type** parameter to specify whether the ROI is a rectangle, line, label matrix, or binary mask. A binary mask is a binary image that enables you to specify which pixels to highlight, or select. In a label matrix, pixels equal to 0 represent the background, pixels equal to 1 represent the first object, pixels equal to 2 represent the second object, and so on. When the **ROI type** parameter is set to `Label matrix`, the Label and Label Numbers ports appear on the block. Use the Label Numbers port to specify the objects in the label matrix for which the block calculates statistics. The input to this port must be a vector of scalar values that correspond to the labeled regions in the label matrix. For more information about the format of the input to the ROI port when the ROI is a rectangle or a line, see the Draw Shapes block reference page.

For rectangular ROIs, use the **ROI portion to process** parameter to specify whether to calculate the statistical value for the entire ROI or just the ROI perimeter.

Use the **Output** parameter to specify the block output. The block can output separate statistical values for each ROI or the statistical value for all specified ROIs. This parameter is not available if, for the **ROI type** parameter, you select `Binary mask`.

If, for the **ROI type** parameter, you select `Rectangles` or `Lines`, the **Output flag indicating if ROI is within image bounds** check box appears in the dialog box. If you select this check box, the Flag port appears on the block. The following tables describe the Flag port output based on the block parameters.

Output = Individual statistics for each ROI

Flag Port Output	Description
0	ROI is completely outside the input image.
1	ROI is completely or partially inside the input image.

Output = Single statistic for all ROIs

Flag Port Output	Description
0	All ROIs are completely outside the input image.
1	At least one ROI is completely or partially inside the input image.

If the ROI is partially outside the image, the block only computes the statistical values for the portion of the ROI that is within the image.

If, for the **ROI type** parameter, you select `Label matrix`, the **Output flag indicating if input label numbers are valid** check box appears in the dialog box. If you select this check box, the Flag port appears on the block. The following tables describe the Flag port output based on the block parameters.

Output = Individual statistics for each ROI

Flag Port Output	Description
0	Label number is not in the label matrix.
1	Label number is in the label matrix.

Output = Single statistic for all ROIs

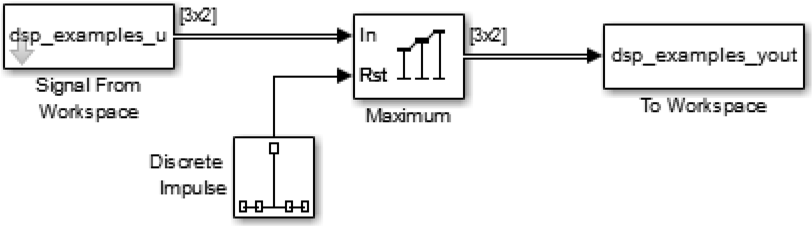
Flag Port Output	Description
0	None of the label numbers are in the label matrix.
1	At least one of the label numbers is in the label matrix.

Fixed-Point Data Types

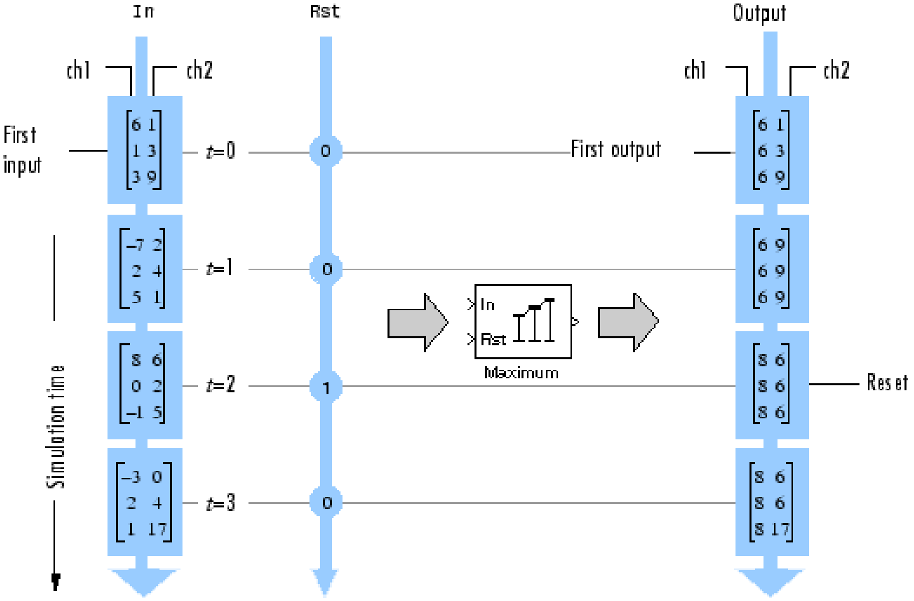
The parameters on the **Data Types** pane of the block dialog are only used for complex fixed-point inputs. The sum of the squares of the real and imaginary parts of such an input are formed before a comparison is made, as described in “Value Mode” on page 1-946. The results of the squares of the real and imaginary parts are placed into the product output data type. The result of the sum of the squares is placed into the accumulator data type. These parameters are ignored for other types of inputs.

Examples

In the following ex_maximum_ref model, the Maximum block calculates the running maximum of a 3-by-2 matrix input, `dsp_examples_u`. The **Input processing** parameter is set to `Columns as channels (frame based)`, so the block processes the input as a two channel signal with a frame size of three. The running maximum is reset at *t*=2 by an impulse to the block's Rst port.

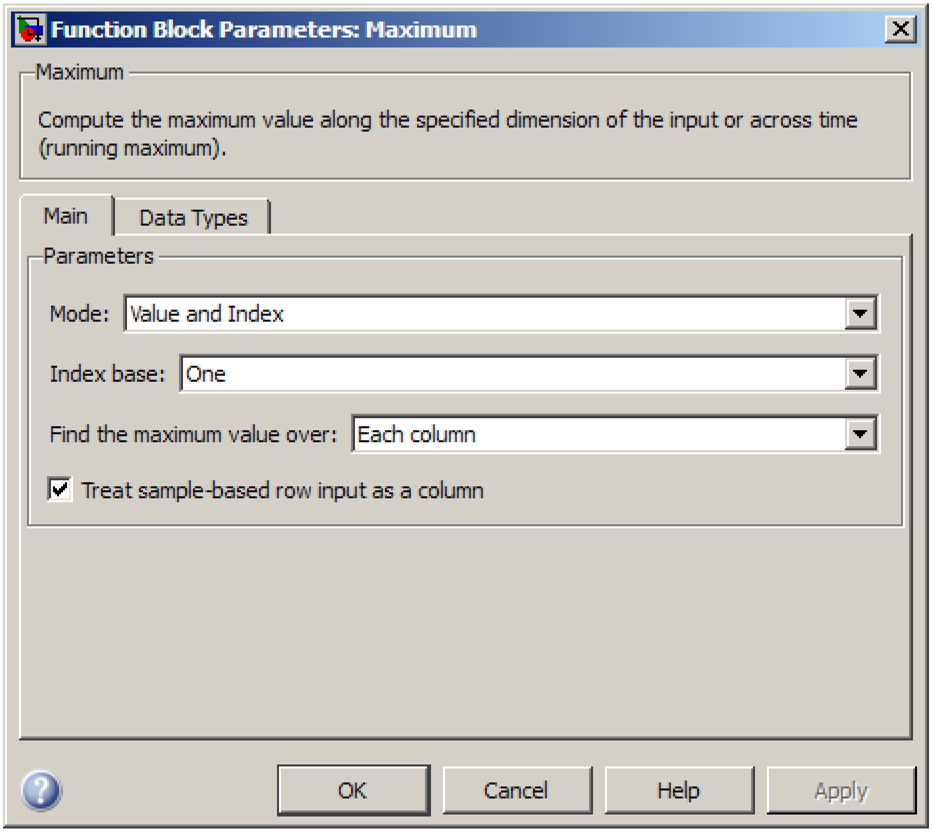


The operation of the block is shown in the following figure.



Dialog Box

The **Main** pane of the Maximum block dialog appears as follows.



Maximum

Compute the maximum value along the specified dimension of the input or across time (running maximum).

Parameters

Mode: Value and Index

Index base: One

Find the maximum value over: Each column

☑ Treat sample-based row input as a column

Mode

Specify the block's mode of operation:

- `Value` — Output the maximum value of each input
- `Index` — Output the index of the maximum value
- `Value and index` — Output both the value and the index
- `Running` — Track the maximum value of the input sequence over time

For more information, see Description.

Input processing

Specify how the block should process the input when computing the running maximum. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` — When you select this option, the block treats each column of the input as a separate channel.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

This parameter appears only when you set the **Mode** to `Running`.

Note: The option `Inherit from input (this choice will be removed - see release notes)` will be removed in a future release. See "Frame-Based Processing" in the *DSP System Toolbox Release Notes* for more information.

Index base

Specify whether the index of the maximum value is reported using one-based or zero-based numbering. This parameter is only visible when the **Mode** parameter is set to `Index` or `Value and index`.

Find the maximum value over

Specify whether to find the maximum value along rows, columns, entire input, or the dimension specified in the **Dimension** parameter. For more information, see Description.

Treat sample-based row input as a column

Select to treat sample-based length-*M* row vector inputs as *M*-by-1 column vectors. This parameter is only visible when the **Find the maximum value of** parameter is set to `Each column`.

Note: This check box will be removed in a future release. See "Sample-Based Row Vector Processing Changes" for more information.

Reset port

Specify the reset event that causes the block to reset the running maximum. The sample time of the input to the Rst port must be a positive integer multiple of the input sample time. This parameter appears only when you set the **Mode** parameter to `Running`. For information about the possible values of this parameter, see "Resetting the Running Maximum" on page 1-949.

Dimension

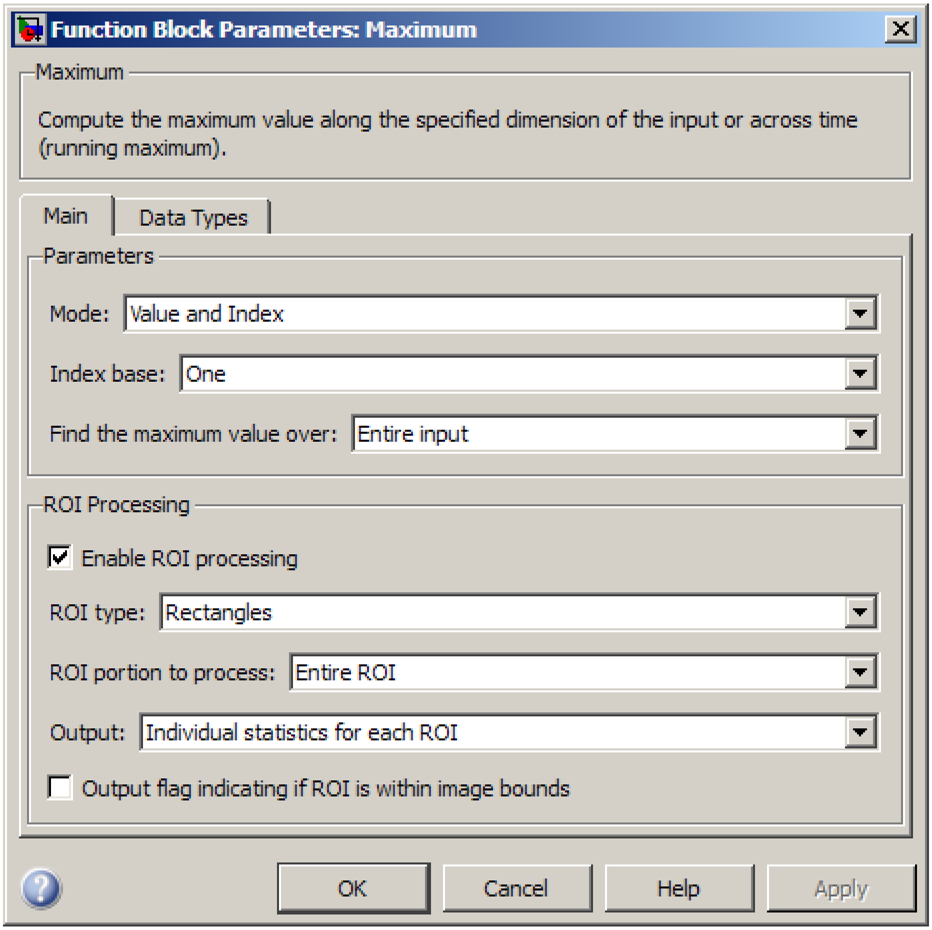
Specify the dimension (one-based value) of the input signal, over which the maximum is computed. The value of this parameter cannot exceed the number of dimensions in the input signal. This parameter is only visible when the **Find the maximum value over** parameter is set to `Specified dimension`.

Enable ROI processing

Select this check box to calculate the statistical value within a particular region of each image. This parameter appears only when you set the **Find the maximum value over** parameter to `Entire input`, and the block is not in running mode.

Note: Full ROI processing is available only if you have a Computer Vision System Toolbox license. If you do not have a Computer Vision System Toolbox license, you can still use ROI processing, but are limited to the **ROI type** `Rectangles`.

The ROI processing parameters appear on the dialog box as follows.



Function Block Parameters: Maximum

Maximum

Compute the maximum value along the specified dimension of the input or across time (running maximum).

Parameters

Mode: Value and Index

Index base: One

Find the maximum value over: Entire input

ROI Processing

☑ Enable ROI processing

ROI type: Rectangles

ROI portion to process: Entire ROI

Output: Individual statistics for each ROI

□ Output flag indicating if ROI is within image bounds

ROI type

Specify the type of ROI you want to use. Your choices are `Rectangles`, `Lines`, `Label matrix`, or `Binary mask`.

ROI portion to process

Specify whether you want to calculate the statistical value for the entire ROI or just the ROI perimeter. This parameter appears only if you specify an **ROI type** of `Rectangles`.

Output

Specify the block output. The block can output a vector of separate statistical values for each ROI or a scalar value that represents the statistical value for all the specified ROIs. This parameter is not available if, for the **ROI type** parameter, you select `Binary mask`.

Output flag

☑ **Output flag indicating if ROI is within image bounds**

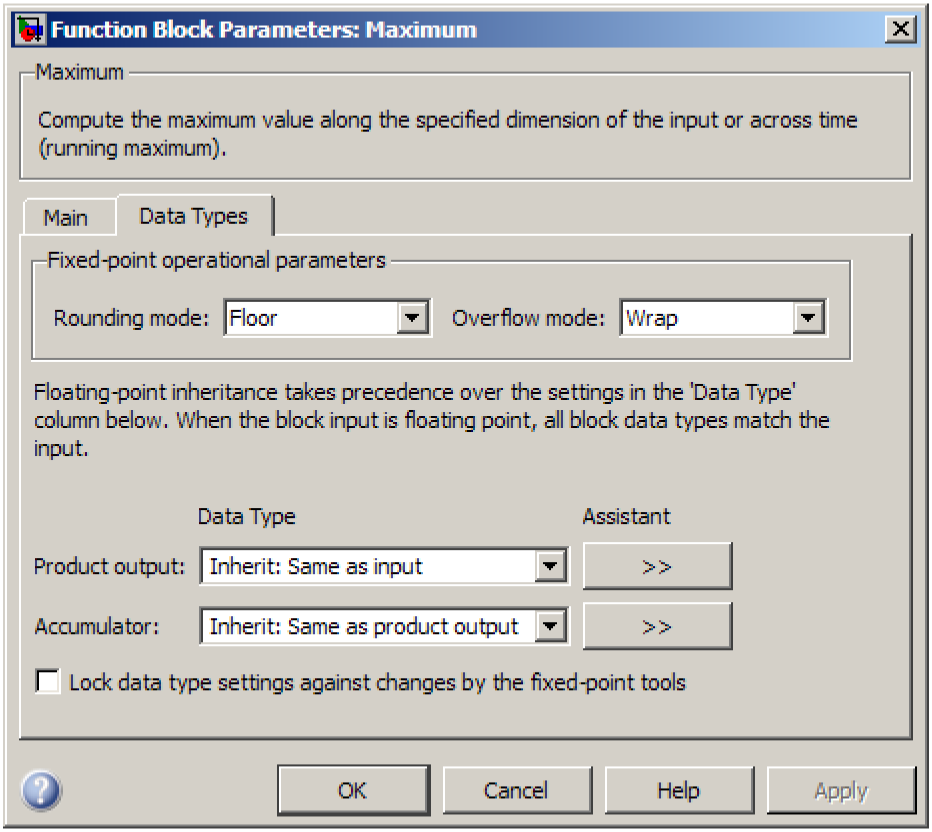
☑ **Output flag indicating if label numbers are valid**

When you select either of these check boxes, the Flag port appears on the block. For a description of the Flag port output, see the tables in "ROI Processing" on page 1-951.

The **Output flag indicating if ROI is within image bounds** check box is only visible when you select `Rectangles` or `Lines` as the **ROI type**.

The **Output flag indicating if label numbers are valid** check box is only visible when you select `Label matrix` for the **ROI type** parameter.

The **Data Types** pane of the Maximum block dialog appears as follows.



Function Block Parameters: Maximum

Maximum

Compute the maximum value along the specified dimension of the input or across time (running maximum).

Fixed-point operational parameters

Rounding mode: Floor

Overflow mode: Wrap

Floating-point inheritance takes precedence over the settings in the 'Data Type' column below. When the block input is floating point, all block data types match the input.

	Data Type	Assistant
Product output:	Inherit: Same as input	>>
Accumulator:	Inherit: Same as product output	>>

□ Lock data type settings against changes by the fixed-point tools

Note: The parameters on the **Data Types** pane are only used for complex fixed-point inputs. The sum of the squares of the real and imaginary parts of such an input are formed before a comparison is made, as described in "Value Mode" on page 1-946. The results of the squares of the real and imaginary parts are placed into the product output data type. The result of the sum of the squares is placed into the accumulator data type. These parameters are ignored for other types of inputs.

Rounding mode

Select the "rounding mode" for fixed-point operations.

Overflow mode

Select the “overflow mode” for fixed-point operations.

Product output data type

Specify the product output data type. See “Fixed-Point Data Types” on page 1-953 and “Multiplication Data Types” for illustrations depicting the use of the product output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as input`
- An expression that evaluates to a valid data type, for example, `fixdt([],16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Product output data type** parameter.

See “Specify Data Types Using Data Type Assistant” in “Simulink User's Guide” for more information.

Accumulator data type

Specify the accumulator data type. See “Fixed-Point Data Types” on page 1-953 for illustrations depicting the use of the accumulator data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Same as product output`
- An expression that evaluates to a valid data type, for example, `fixdt([],16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Accumulator data type** parameter.

See “Specify Data Types Using Data Type Assistant” in “Simulink User's Guide” for more information.

Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

HDL Code Generation

This block supports HDL code generation using HDL Coder. HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

For more information on implementations, properties, and restrictions for HDL code generation, see Maximum.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Reset	• Double-precision floating point • Single-precision floating point • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Idx	• Double-precision floating point • 32-bit unsigned integers
Val	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers

Mean	DSP System Toolbox
Minimum	DSP System Toolbox

MinMax	Simulink
`max`	MATLAB
`dsp.Maximum`	DSP System Toolbox

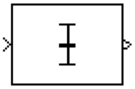
Mean

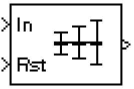
Find mean value of input or sequence of inputs

Library

Statistics

`dspstat3`





Description

The Mean block computes the mean of each row or column of the input, along vectors of a specified dimension of the input, or of the entire input. The Mean block can also track the mean value in a sequence of inputs over a period of time. To track the mean value in a sequence of inputs, select the **Running mean** check box.

Basic Operation

When you do not select the **Running mean** check box, the block computes the mean value in each row or column of the input, along vectors of a specified dimension of the input, or of the entire input at each individual sample time. Each element in the output array `y` is the mean value of the corresponding column, row, vector, or entire input. The output array `y` depends on the setting of the **Find the mean value over** parameter. For example, consider a 3-dimensional input signal of size *M*-by-*N*-by-*P*:

- `Entire input` — The output at each sample time is a scalar that contains the mean value of the *M*-by-*N*-by-*P* input matrix.

  ```
  y = mean(u(:))     % Equivalent MATLAB code
  ```

- `Each row` — The output at each sample time consists of an *M*-by-1-by-*P* array, where each element contains the mean value of each vector over the second dimension of the input. For an input that is an *M*-by-*N* matrix, the output at each sample time is an *M*-by-1 column vector.

```
y = mean(u,2)     % Equivalent MATLAB code
```

- `Each column` — The output at each sample time consists of a 1-by-N-by-P array, where each element contains the mean value of each vector over the first dimension of the input. For an input that is an M-by-N matrix, the output at each sample time is a 1-by-N row vector.

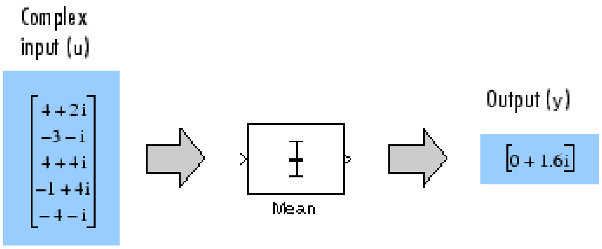
  ```
  y = mean(u)     % Equivalent MATLAB code
  ```

  In this mode, the block treats length-M unoriented vector inputs as M-by-1 column vectors.

- `Specified dimension` — The output at each sample time depends on the value of the **Dimension** parameter. If you set the **Dimension** to `1`, the output is the same as when you select `Each column`. If you set the **Dimension** to `2`, the output is the same as when you select `Each row`. If you set the **Dimension** to `3`, the output at each sample time is an M-by-N matrix containing the mean value of each vector over the third dimension of the input.

  ```
  y = mean(u,Dimension)     % Equivalent MATLAB code
  ```

The mean of a complex input is computed independently for the real and imaginary components, as shown in the following figure.



Running Operation

When you select the **Running mean** check box, the block tracks the mean value of each channel in a time sequence of inputs. In this mode, you must also specify a value for the **Input processing** parameter:

- When you select `Elements as channels (sample based)`, the block outputs an M-by-N array. Each element y_{ij} of the output contains the mean value of the elements u_{ij} for all inputs since the last reset.

- When you select `Columns as channels (frame based)`, the block outputs an *M*-by-*N* matrix. Each element y_{ij} of the output contains the mean of the values in the *j*th column of all inputs since the last reset, up to and including element u_{ij} of the current input.

Running Operation for Variable-Size Inputs

When your inputs are of variable size, and you select the **Running mean** check box, there are two options:

- If you set the **Input processing** parameter to `Elements as channels (sample based)`, the state is reset.
- If you set the **Input processing** parameter to `Columns as channels (frame based)`, then there are two cases:
  - When the input size difference is in the number of channels (i.e., number of columns), the state is reset.
  - When the input size difference is in the length of channels (i.e., number of rows), there is no reset and the running operation is carried out as usual.

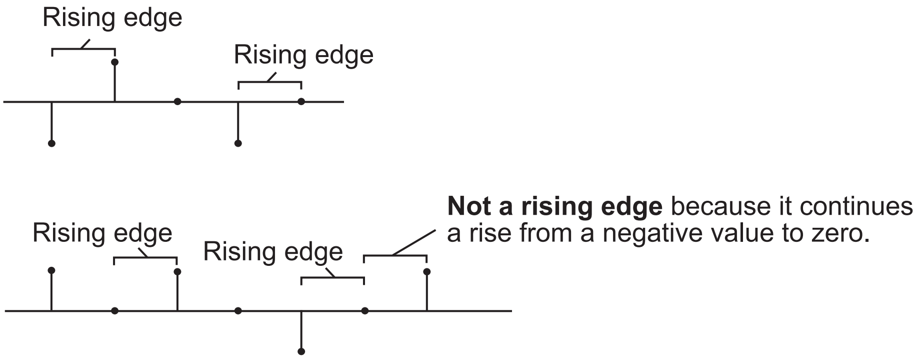
Resetting the Running Mean

The block resets the running mean whenever a reset event is detected at the optional Rst port. The reset sample time must be a positive integer multiple of the input sample time.

When a reset event occurs while the **Input processing** parameter is set to `Elements as channels (sample based)`, the running mean for each channel is initialized to the value in the corresponding channel of the current input. Similarly, when the **Input processing** parameter is set to `Columns as channels (frame based)`, the running mean for each channel is initialized to the earliest value in each channel of the current input.

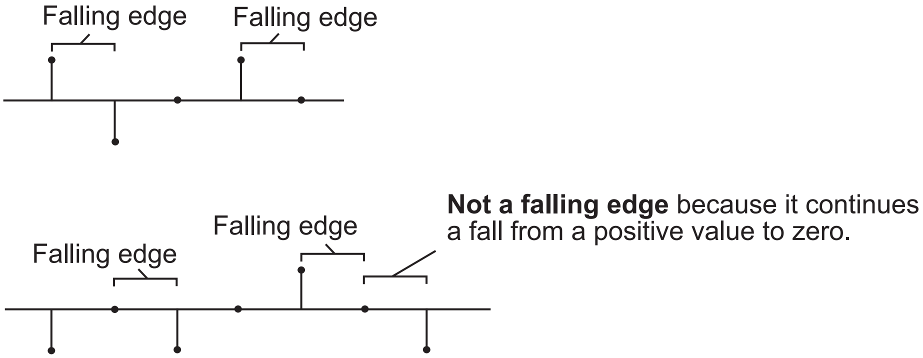
You specify the reset event by the **Reset port** parameter:

- `None` disables the Rst port.
- `Rising edge` — Triggers a reset operation when the Rst input does one of the following:
  - Rises from a negative value to a positive value or zero
  - Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero (see the following figure)



Rising edge
Rising edge
Rising edge
Rising edge
Not a rising edge because it continues a rise from a negative value to zero.

- `Falling edge` — Triggers a reset operation when the `Rst` input does one of the following:
  - Falls from a positive value to a negative value or zero
  - Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero (see the following figure)



Falling edge
Falling edge
Falling edge
Falling edge
Not a falling edge because it continues a fall from a positive value to zero.

- `Either edge` — Triggers a reset operation when the `Rst` input is a `Rising edge` or `Falling edge` (as described earlier)
- `Non-zero sample` — Triggers a reset operation at each sample time that the `Rst` input is not zero

Note: When running simulations in the Simulink MultiTasking mode, reset signals have a one-sample latency. Therefore, when the block detects a reset event, there is

a one-sample delay at the reset port rate before the block applies the reset. For more information on latency and the Simulink tasking modes, see "Excess Algorithmic Delay (Tasking Latency)" and "Scheduling " in the *Simulink Coder User's Guide*.

ROI Processing

To calculate the statistical value within a particular region of interest (ROI) of the input, select the **Enable ROI processing** check box. This option is only available when the **Find the mean value over** parameter is set to `Entire input` and the **Running mean** check box is not selected. ROI processing is only supported for 2-D inputs.

Note: Full ROI processing is only available to users who have a Computer Vision System Toolbox license. If you only have a DSP System Toolbox license, you can still use ROI processing, but are limited to the **ROI type** `Rectangles`.

Use the **ROI type** parameter to specify whether the ROI is a rectangle, line, label matrix, or binary mask. A binary mask is a binary image that enables you to specify which pixels to highlight, or select. In a label matrix, pixels equal to 0 represent the background, pixels equal to 1 represent the first object, pixels equal to 2 represent the second object, and so on. When the **ROI type** parameter is set to `Label matrix`, the Label and Label Numbers ports appear on the block. Use the Label Numbers port to specify the objects in the label matrix for which the block calculates statistics. The input to this port must be a vector of scalar values that correspond to the labeled regions in the label matrix. For more information about the format of the input to the ROI port when the ROI is a rectangle or a line, see the Draw Shapes block reference page.

For rectangular ROIs, use the **ROI portion to process** parameter to specify whether to calculate the statistical value for the entire ROI or just the ROI perimeter.

Use the **Output** parameter to specify the block output. The block can output separate statistical values for each ROI or the statistical value for all specified ROIs. This parameter is not available if, for the **ROI type** parameter, you select `Binary mask`.

If, for the **ROI type** parameter, you select `Rectangles` or `Lines`, the **Output flag indicating if ROI is within image bounds** check box appears in the dialog box. If you select this check box, the Flag port appears on the block. The following tables describe the Flag port output based on the block parameters.

Output = Individual statistics for each ROI

Flag Port Output	Description
0	ROI is completely outside the input image.
1	ROI is completely or partially inside the input image.

Output = Single statistic for all ROIs

Flag Port Output	Description
0	All ROIs are completely outside the input image.
1	At least one ROI is completely or partially inside the input image.

If the ROI is partially outside the image, the block only computes the statistical values for the portion of the ROI that is within the image.

If, for the **ROI type** parameter, you select `Label matrix`, the **Output flag indicating if input label numbers are valid** check box appears in the dialog box. If you select this check box, the Flag port appears on the block. The following tables describe the Flag port output based on the block parameters.

Output = Individual statistics for each ROI

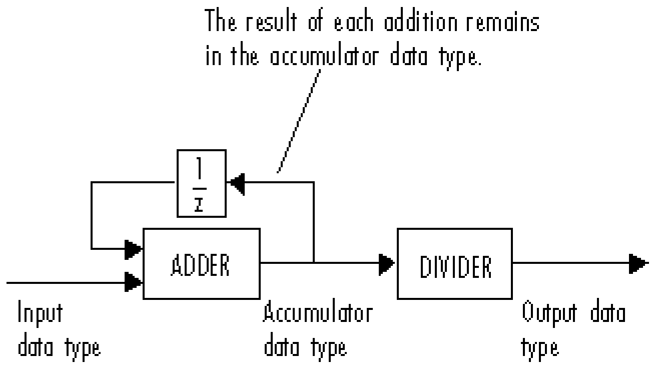
Flag Port Output	Description
0	Label number is not in the label matrix.
1	Label number is in the label matrix.

Output = Single statistic for all ROIs

Flag Port Output	Description
0	None of the label numbers are in the label matrix.
1	At least one of the label numbers is in the label matrix.

Fixed-Point Data Types

The following diagram shows the data types used within the Mean block for fixed-point signals.



The result of each addition remains
in the accumulator data type.

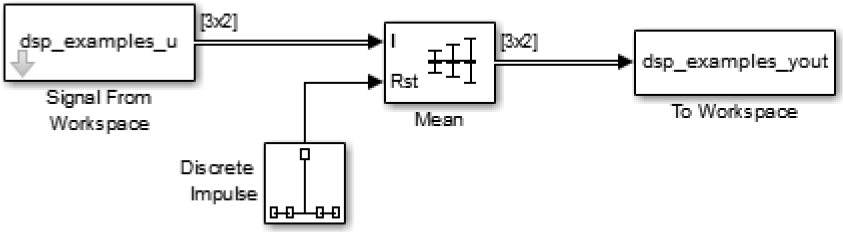
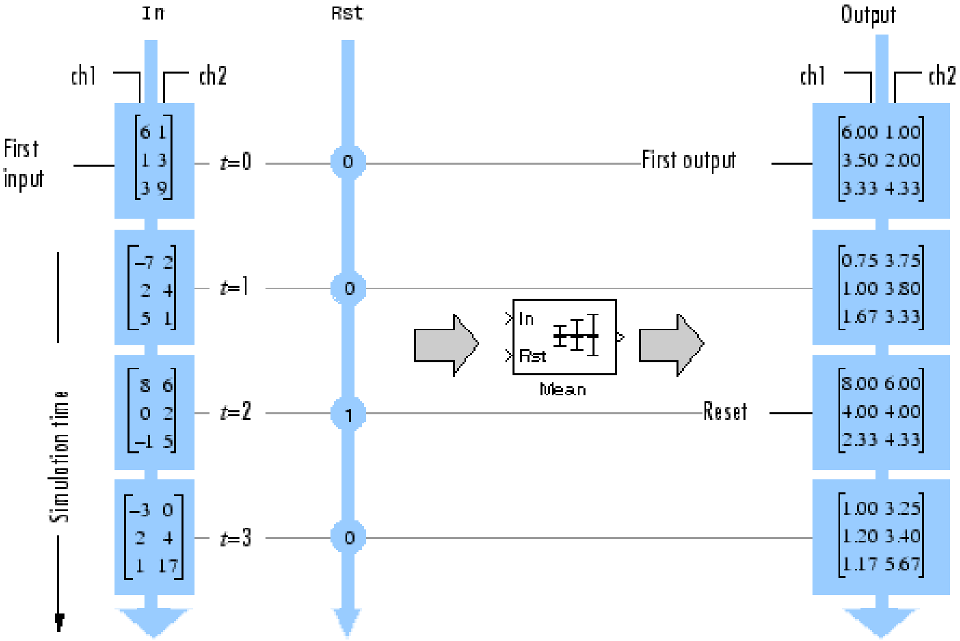
You can set the accumulator and output data types in the block dialog, as discussed in "Dialog Box" on page 1-971.

Examples

In the ex_mean_ref model, the Mean block calculates the running mean of a 3-by-2 matrix input, *u*. The **Input processing** parameter is set to `Columns as channels (frame based)`, so the block processes the input as a two channel signal with a frame size of three. The running mean is reset at *t*=2 by an impulse to the block's Rst port.

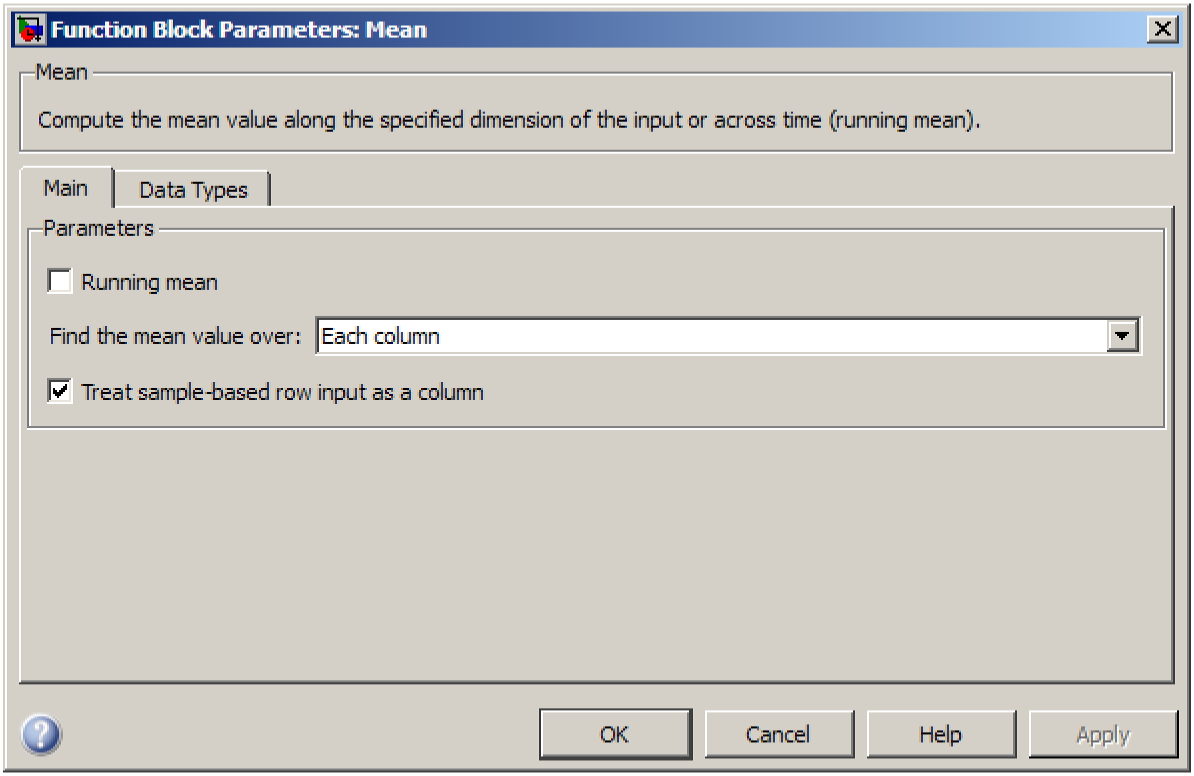


The operation of the block is shown in the following figure.



Dialog Box

The **Main** pane of the Mean block dialog appears as follows.



Function Block Parameters: Mean

Mean

Compute the mean value along the specified dimension of the input or across time (running mean).

Parameters

□ Running mean

Find the mean value over: Each column

☑ Treat sample-based row input as a column

Running mean

Enables running operation when selected.

Input processing

Specify how the block should process the input when computing the running mean. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` — When you select this option, the block treats each column of the input as a separate channel.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

This parameter appears only when you select the **Running mean** check box.

Note: The option `Inherit from input (this choice will be removed - see release notes)` will be removed in a future release. See "Frame-Based Processing" in the *DSP System Toolbox Release Notes* for more information.

Reset port

Specify the reset event that causes the block to reset the running mean. The sample time of the input to the Rst port must be a positive integer multiple of the input sample time. This parameter appears only when you select the **Running mean** check box. For more information, see "Resetting the Running Mean" on page 1-966.

Find the mean value over

Specify whether to find the mean value along rows, columns, entire input, or the dimension specified in the **Dimension** parameter. For more information, see "Basic Operation" on page 1-964.

Treat sample-based row input as a column

Select to treat sample-based length-M row vector inputs as M-by-1 column vectors. This parameter is only visible when the **Find the mean value over** parameter is set to `Each column`.

Note: This check box will be removed in a future release. See "Sample-Based Row Vector Processing Changes" for more information.

Dimension

Specify the dimension (one-based value) of the input signal, over which the mean is computed. The value of this parameter cannot exceed the number of dimensions in the input signal. This parameter is only visible when the **Find the mean value over** parameter is set to `Specified dimension`.

Enable ROI Processing

Select this check box to calculate the statistical value within a particular region of each image. This parameter is only available when the **Find the mean value over** parameter is set to `Entire input`, and the block is not in running mode.

Note: Full ROI processing is available only if you have a Computer Vision System Toolbox license. If you do not have a Computer Vision System Toolbox license, you can still use ROI processing, but are limited to the **ROI type** `Rectangles`.

ROI type

Specify the type of ROI you want to use. Your choices are `Rectangles`, `Lines`, `Label matrix`, or `Binary mask`.

ROI portion to process

Specify whether you want to calculate the statistical value for the entire ROI or just the ROI perimeter. This parameter is only visible if, for the **ROI type** parameter, you specify `Rectangles`.

Output

Specify the block output. The block can output a vector of separate statistical values for each ROI or a scalar value that represents the statistical value for all the specified ROIs. This parameter is not available if, for the **ROI type** parameter, you select `Binary mask`.

Output flag

☑ **Output flag indicating if ROI is within image bounds**

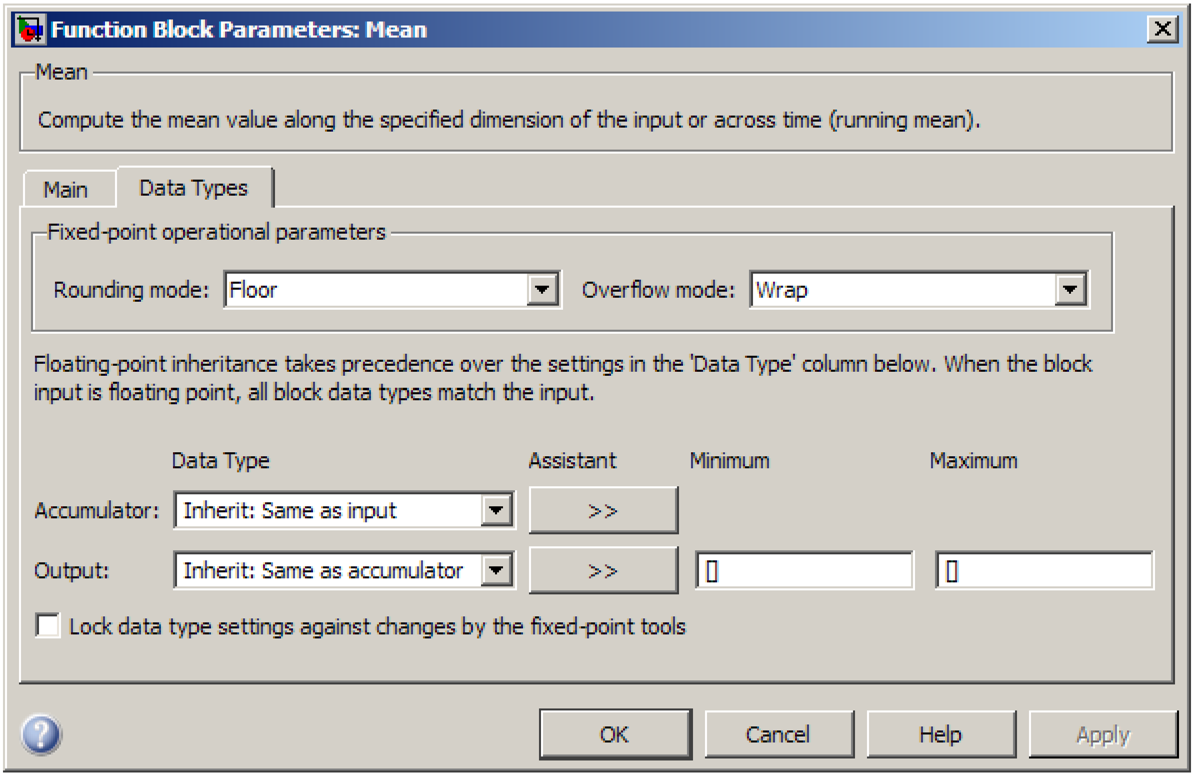
☑ **Output flag indicating if label numbers are valid**

When you select either of these check boxes, the Flag port appears on the block. For a description of the Flag port output, see the tables in "ROI Processing" on page 1-968.

The **Output flag indicating if ROI is within image bounds** check box is only visible when you select `Rectangles` or `Lines` as the **ROI type**.

The **Output flag indicating if label numbers are valid** check box is only visible when you select `Label matrix` for the **ROI type** parameter.

The **Data Types** pane of the Mean block dialog appears as follows.



Function Block Parameters: Mean

Mean

Compute the mean value along the specified dimension of the input or across time (running mean).

Fixed-point operational parameters

Rounding mode: Floor

Overflow mode: Wrap

Floating-point inheritance takes precedence over the settings in the 'Data Type' column below. When the block input is floating point, all block data types match the input.

	Data Type	Assistant	Minimum	Maximum
Accumulator:	Inherit: Same as input	>>		
Output:	Inherit: Same as accumulator	>>	[]	[]

□ Lock data type settings against changes by the fixed-point tools

Rounding mode

Select the "rounding mode" for fixed-point operations.

Overflow mode

Select the "overflow mode" for fixed-point operations.

Accumulator data type

Specify the accumulator data type. See "Fixed-Point Data Types" on page 1-969 for illustrations depicting the use of the accumulator data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Same as input`
- An expression that evaluates to a valid data type, for example, `fixdt([],16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Accumulator data type** parameter.

See “Specify Data Types Using Data Type Assistant” in “Simulink User's Guide” for more information.

Output data type

Specify the output data type. See “Fixed-Point Data Types” on page 1-969 for illustrations depicting the use of the output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as accumulator`
- An expression that evaluates to a valid data type, for example, `fixdt([],16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Specify Block Output Data Types” in “Simulink User's Guide” for more information.

Minimum

Specify the minimum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges”)
- Automatic scaling of fixed-point data types

Maximum

Specify the maximum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges”)
- Automatic scaling of fixed-point data types

Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point • Fixed point • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Reset	• Double-precision floating point • Single-precision floating point • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
ROI	Rectangles and lines: • Double-precision floating point • Single-precision floating point • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers Binary Mask: • Boolean
Label	• 8-, 16-, and 32-bit unsigned integers
Label Numbers	• 8-, 16-, and 32-bit unsigned integers
Output	• Double-precision floating point • Single-precision floating point • Fixed point • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers

Median

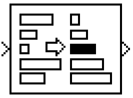
Find median value of input

Library

Statistics

`dspstat3`

Description



The Median block computes the median value of each row or column of the input, along vectors of a specified dimension of the input, or of the entire input. The median of a set of input values is calculated as follows:

1. The values are sorted.
2. If the number of values is odd, the median is the middle value.
3. If the number of values is even, the median is the average of the two middle values.

For a given input *u*, the size of the output array `y` depends on the setting of the **Find the median value over** parameter. For example, consider a 3-dimensional input signal of size *M*-by-*N*-by-*P*:

- `Entire input` — The output at each sample time is a scalar that contains the median value of the *M*-by-*N*-by-*P* input matrix.

  ```
  y = median(u(:))     % Equivalent MATLAB code
  ```

- `Each row` — The output at each sample time consists of an *M*-by-1-by-*P* array, where each element contains the median value of each vector over the second dimension of the input. For an input that is an *M*-by-*N* matrix, the output is an *M*-by-1 column vector.

  ```
  y = median(u,2)     % Equivalent MATLAB code
  ```

- `Each column` — The output at each sample time consists of a 1-by-*N*-by-*P* array, where each element contains the median value of each vector over the first dimension of the input. For an input that is an *M*-by-*N* matrix, the output at each sample time is a 1-by-*N* row vector.

  ```
  y = median(u)     % Equivalent MATLAB code
  ```

  For convenience, length-*M* 1-D vector inputs are treated as *M*-by-1 column vectors when the block is in this mode. Sample-based length-*M* row vector inputs are also treated as *M*-by-1 column vectors when the **Treat sample-based row input as a column** check box is selected.
- `Specified dimension` — The output at each sample time depends on **Dimension**. If **Dimension** is set to `1`, the output is the same as when you select `Each column`. If **Dimension** is set to `2`, the output is the same as when you select `Each row`. If **Dimension** is set to `3`, the output at each sample time is an *M*-by-*N* matrix containing the median value of each vector over the third dimension of the input.

  ```
  y = median(u,Dimension)     % Equivalent MATLAB code
  ```

The block sorts complex inputs according to their magnitude.

Fixed-Point Data Types

For fixed-point inputs, you can specify accumulator, product output, and output data types as discussed in “Dialog Box” on page 1-981. Not all these fixed-point parameters are applicable for all types of fixed-point inputs. The following table shows when each kind of data type and scaling is used.

	Output data type	Accumulator data type	Product output data type
Even *M*	X	X	
Odd *M*	X		
Odd *M* and complex	X	X	X
Even *M* and complex	X	X	X

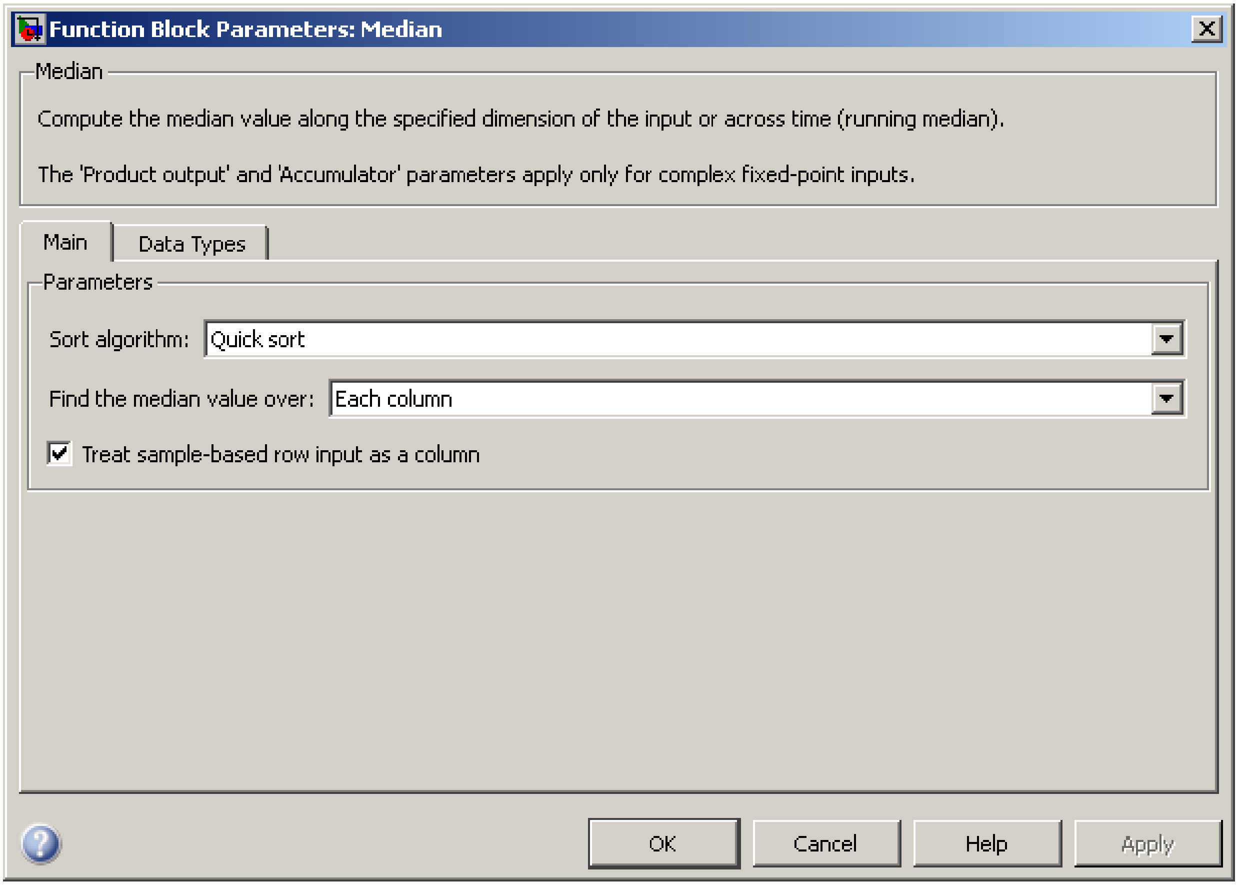
The accumulator and output data types and scalings are used for fixed-point signals when *M* is even. The result of the sum performed while calculating the average of the two central rows of the input matrix is stored in the accumulator data type and scaling. The total result of the average is then put into the output data type and scaling.

The accumulator and product output parameters are used for complex fixed-point inputs. The sum of the squares of the real and imaginary parts of such an input are formed before the input elements are sorted, as described in Description. The results of the squares of the real and imaginary parts are placed into the product output data type and scaling. The result of the sum of the squares is placed into the accumulator data type and scaling.

For fixed-point inputs that are both complex and have even *M*, the data types are used in all of the ways described. Therefore, in such cases, the accumulator type is used in two different ways.

Dialog Box

The **Main** pane of the Median block dialog appears as follows.



Function Block Parameters: Median

Median

Compute the median value along the specified dimension of the input or across time (running median).

The 'Product output' and 'Accumulator' parameters apply only for complex fixed-point inputs.

Parameters

Sort algorithm: Quick sort

Find the median value over: Each column

☑ Treat sample-based row input as a column

Sort algorithm

Specify whether to sort the elements of the input using a `Quick sort` or an `Insertion sort` algorithm.

Find the median value over

Specify whether to find the median value along rows, columns, entire input, or the dimension specified in the **Dimension** parameter. For more information, see Description.

Treat sample-based row input as a column

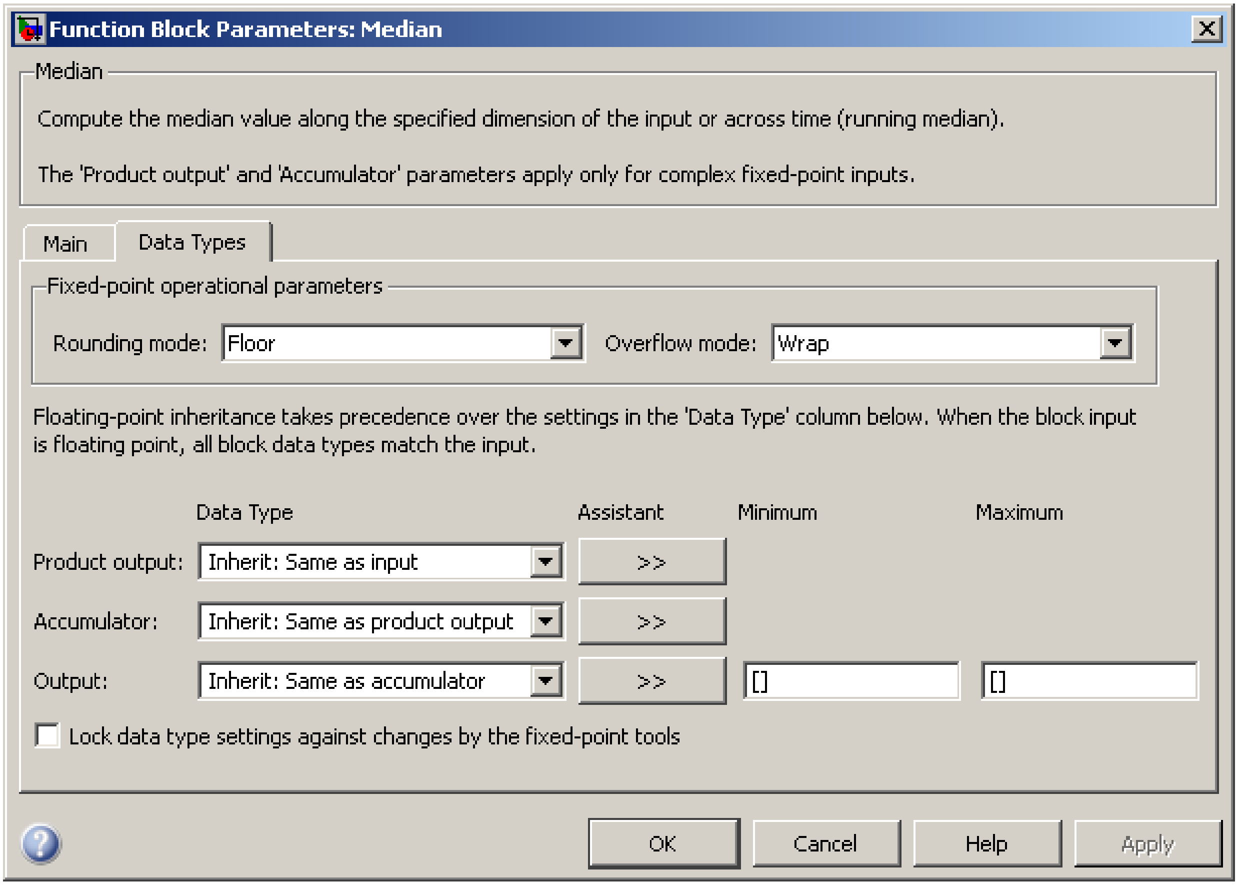
Select to treat sample-based length-*M* row vector inputs as *M*-by-1 column vectors. This parameter is only visible when the **Find the median value over** parameter is set to `Each column`.

Note: This check box will be removed in a future release. See "Sample-Based Row Vector Processing Changes" for more information.

Dimension

Specify the dimension (one-based value) of the input signal, over which the median is computed. The value of this parameter cannot exceed the number of dimensions in the input signal. This parameter is only visible when the **Find the median value over** parameter is set to `Specified dimension`.

The **Data Types** pane of the Median block dialog appears as follows.



Function Block Parameters: Median

Median

Compute the median value along the specified dimension of the input or across time (running median).

The 'Product output' and 'Accumulator' parameters apply only for complex fixed-point inputs.

Main | Data Types

Fixed-point operational parameters

Rounding mode: Floor   Overflow mode: Wrap

Floating-point inheritance takes precedence over the settings in the 'Data Type' column below. When the block input is floating point, all block data types match the input.

	Data Type	Assistant	Minimum	Maximum
Product output:	Inherit: Same as input	>>		
Accumulator:	Inherit: Same as product output	>>		
Output:	Inherit: Same as accumulator	>>	[]	[]

□ Lock data type settings against changes by the fixed-point tools

Note: Floating-point inheritance takes precedence over the data type settings defined on this pane. When inputs are floating point, the block ignores these settings, and all internal data types are floating point.

Rounding mode

Select the “rounding mode” for fixed-point operations.

Overflow mode

Select the “overflow mode” for fixed-point operations.

Product output data type

Specify the product output data type. See “Fixed-Point Data Types” on page 1-980 and “Multiplication Data Types” for illustrations depicting the use of the product output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as input`
- An expression that evaluates to a valid data type, for example, `fixdt([],16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Product output data type** parameter.

See “Specify Data Types Using Data Type Assistant” in “Simulink User's Guide” for more information.

Accumulator data type

Specify the accumulator data type. See “Fixed-Point Data Types” on page 1-980 for illustrations depicting the use of the accumulator data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Same as product output`
- An expression that evaluates to a valid data type, for example, `fixdt([],16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Accumulator data type** parameter.

See “Specify Data Types Using Data Type Assistant” in “Simulink User's Guide” for more information.

Output data type

Specify the output data type. See “Fixed-Point Data Types” on page 1-980 for illustrations depicting the use of the output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as accumulator`
- An expression that evaluates to a valid data type, for example, `fixdt([],16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Specify Block Output Data Types” in “Simulink User's Guide” for more information.

Minimum

Specify the minimum value that the block should output. The default value is [ ] (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges”)
- Automatic scaling of fixed-point data types

Maximum

Specify the maximum value that the block should output. The default value is [ ] (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges”)
- Automatic scaling of fixed-point data types

Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • 8-, 16-, 32-, and 128-bit signed integers • 8-, 16-, 32-, and 128-bit unsigned integers
Output	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • 8-, 16-, 32-, and 128-bit signed integers • 8-, 16-, 32-, and 128-bit unsigned integers

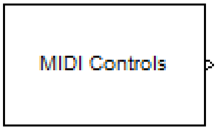
MIDI Controls

Output values from controls on MIDI control surface

Library

Sources

`dspsrcs4`



Description

The MIDI Controls block outputs values from controls on a MIDI control surface in real time.

Use the **MIDI device** parameter to specify the name of the MIDI control surface device from which to receive control values. You can choose:

- `Default`
- `Specify other`

If you choose `Default`, the block looks for a MATLAB preference with a group named `midi` and preference named `DefaultDevice`. You can set this preference using the MATLAB `setpref` function. For example, if the desired device is named `BCF2000`, you can type the following command at the MATLAB command line:

```
>> setpref('midi', 'DefaultDevice', 'BCF2000');
```

If the block does not find this preference, it then attempts to choose a device using an algorithm that is unspecified and platform dependent.

If you choose `Specify other`, then a **MIDI device name** edit box appears for you to enter a MATLAB expression for the device name. Enter any MATLAB expression that can evaluate to a string. Literal names must be enclosed in quotes, (for example, `'BCF2000'`).

You can determine the name of your MIDI device using the MATLAB function `midiid`, discussed in “Identifying MIDI Device Names and Control Numbers” on page 1-990.

Use the **MIDI controls** parameter to specify the controls on the MIDI device to which the block should respond. This parameter also determines the size of the block output port. You can choose:

- `Respond to any control`
- `Respond to specified controls`

If you choose `Respond to any control`, then the block output will be a scalar. This scalar outputs the value from any and all controls that are manipulated on the MIDI device. Use this option in simple cases when you need only a single control value and the control to which it responds is unimportant.

If you choose `Respond to specified controls`, then a **MIDI control numbers** edit box opens. In this box, enter a MATLAB expression for the device control numbers. Enter any MATLAB expression that can evaluate to a row vector of real double-precision values. The block outputs a 1-D vector with one element corresponding to the output of each specified control.

Use the **Initial values** parameter to specify the value of the block output when simulation starts. The MIDI protocol transmits control values only when a control changes. This protocol provides no means for the block to query the current value of a control. Thus, the block must have some initial value to output until it receives a control change from the device.

Use the **Send initial values to device at start** check box to synchronize the device controls with the block outputs when simulation starts. Some MIDI control surfaces are bidirectional, meaning that they not only send control values but can also receive them. For example, some devices have motorized controls that move to the appropriate position when they receive a control value. If you have such a bidirectional device, select this check box. The block attempts to send the initial values to the device when the simulation starts. No diagnostic message appears if the attempt fails.

The generated code for this block relies on prebuilt .dll files. You can run this code outside the MATLAB environment, or redeploy. However you must account for these extra .dll files when doing so. The packNGo function creates a single .zip file containing all of the pieces required to run or rebuild this code. See `packNGo` for more information.

Output Port

The MIDI Controls block output is a vector whose width is determined by the **MIDI controls** and **MIDI control numbers** parameters previously described. The output data type can be either real double-precision floating point, or uint8 integer if the output mode is `'Raw MIDI'`. The output values range from 0.0 to 1.0, inclusively, and in the raw mode, they range from 0 to 127, inclusively. The output port back inherits its sample time.

Identifying MIDI Device Names and Control Numbers

To specify a particular control on a particular MIDI device, you must know the name assigned to the device by the operating system. In addition, a number is always associated with the control. You can interactively discover this information using the MATLAB function, `midiid`. Follow these steps to identify device names and control numbers:

1. Verify that MIDI control surface device is correctly connected to the host computer running MATLAB.

   Note: For the most consistent behavior, MathWorks recommends that you connect your MIDI control surface device to your computer before starting MATLAB. In some circumstances MATLAB may not be able to find your device if you connect it after starting your MATLAB session. Also, it may not find your device if you disconnect it and reconnect it during your MATLAB session.

2. Type the following command at the MATLAB command line.

   ```
   >> [ctlnum devname] = midiid
   ```

   You are prompted to move the control in which you are interested.

   ```
   >> [ctlnum devname] = midiid
   Move the control you wish to identify; type ^C to abort.
   Waiting for control message ...
   ```

3. Move the control. `midiid` detects the movement and returns the device name and control number.

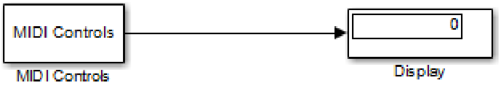
```
>> [ctlnum devname] = midiid
Move the control you wish to identify; type ^C to abort.
Waiting for control message ... done
ctlnum =
        1081
devname =
        BCF2000
>>
```

4. Use the device name in the block dialog, or set it as the default device using `setpref`. Then, enter the control number in the block dialog. Concatenate the number with other control numbers as needed.

Examples

How to Output Values from Controls

Use this example to familiarize yourself with how to set controls in the MIDI Controls block as it interacts with the MIDI control surface.



Open the ex_simplemidi model, and follow these steps:

Connect a MIDI device to the computer.

Use `midiid` to determine the name of the device, and set it on the MIDI Controls block.

Verify that any control changes the display value.

Use `midiid` to determine the number of a particular control, and set that on the MIDI Controls block.

Verify that a particular control changes the display value and that other controls do not.

Use `midiid` to determine the number of a few more controls, and set those on the MIDI Controls block.

Verify that the display block shows the correct number of values. Also verify that the controls you specified change the appropriate display values and that the other controls do not change the values.

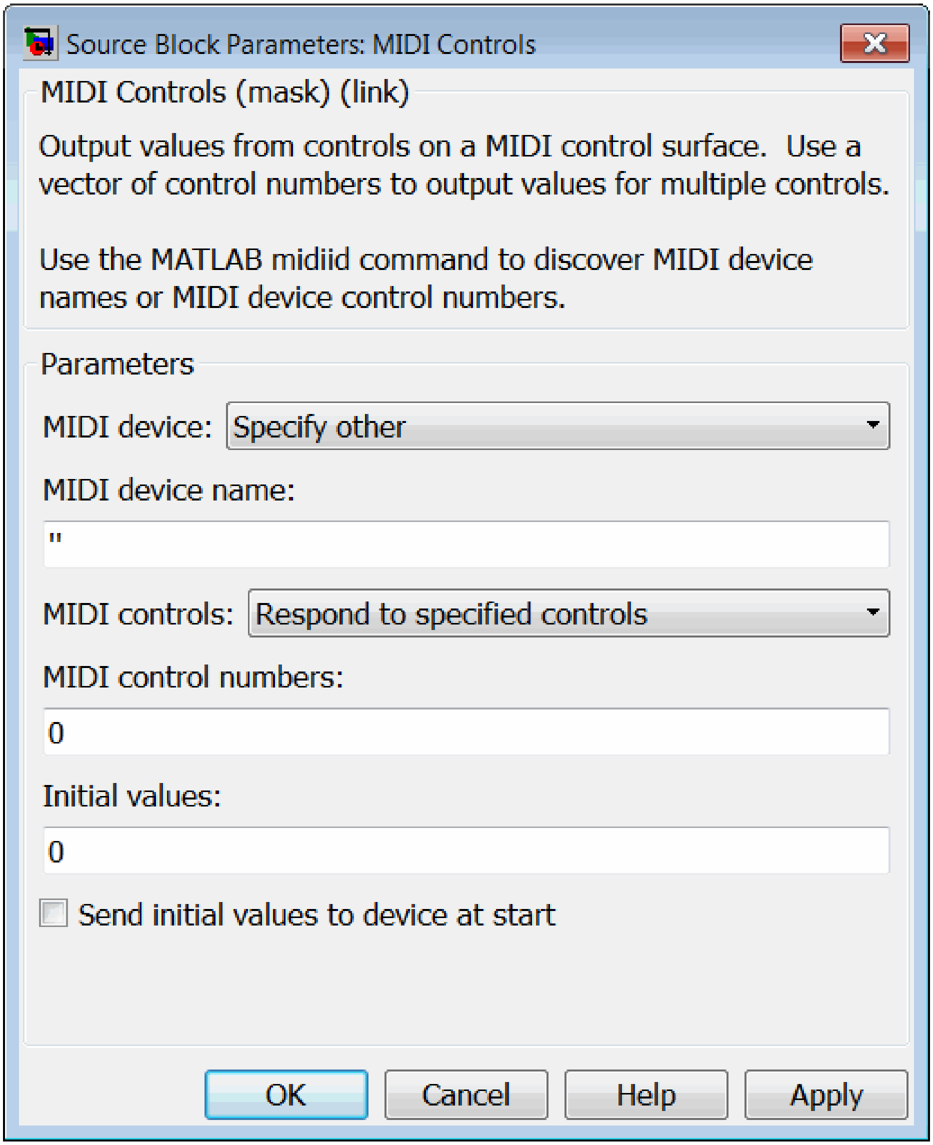
Set each control to have a unique initial value.

Verify that the correct initial values appear on the display when the model starts.

If your MIDI device is bidirectional, on the MIDI Controls block, select the **Send initial values to device at start** check box.

Verify that the controls are set to the correct initial values when the model starts.

Dialog Box



Source Block Parameters: MIDI Controls

MIDI Controls (mask) (link)

Output values from controls on a MIDI control surface. Use a vector of control numbers to output values for multiple controls.

Use the MATLAB midiid command to discover MIDI device names or MIDI device control numbers.

Parameters

MIDI device: Specify other

MIDI device name:

''

MIDI controls: Respond to specified controls

MIDI control numbers:

0

Initial values:

0

□ Send initial values to device at start

MIDI device

Specify whether to use a default MIDI device, or specify a particular device by name.

MIDI device name

Specify the name of a particular MIDI control surface device from which to receive control values.

MIDI controls

Specify whether to respond to any control on the MIDI device or respond to particular specified controls.

MIDI control numbers

Specify particular controls to which the block should respond.

Initial values

Specify initial values to output when simulation starts.

Send initial values to device at start

Select this check box to attempt to synchronize a bidirectional MIDI device with block initial values when simulation starts.

Supported Data Types

Port	Supported Data Types
Output	• Double-precision floating point, uint8 integer

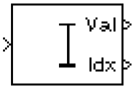
Minimum

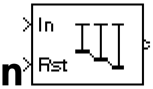
Find minimum values in input or sequence of inputs

Library

Statistics

`dspstat3`





Description

The Minimum block identifies the value and/or position of the smallest element in each row or column of the input, along vectors of a specified dimension of the input, or of the entire input. The Minimum block can also track the minimum values in a sequence of inputs over a period of time. The **Mode** parameter specifies the block's mode of operation, and can be set to `Value`, `Index`, `Value and Index`, or `Running`.

The Minimum block supports real and complex floating-point, fixed-point, and Boolean inputs. Real fixed-point inputs can be either signed or unsigned, while complex fixed-point inputs must be signed. The data type of the minimum values output by the block match the data type of the input. The index values output by the block are `double` when the input is `double`, and `uint32` otherwise.

For the `Value`, `Index`, and `Value and Index` modes, the Minimum block produces identical results as the MATLAB `min` function when it is called as `[y I] = min(u,[],D)`, where *u* and *y* are the input and output, respectively, *D* is the dimension, and *I* is the index.

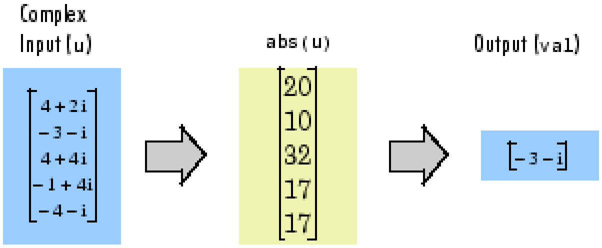
Value Mode

When the **Mode** parameter is set to `Value`, the block computes the minimum value in each row or column of the input, along vectors of a specified dimension of the input, or of the entire input at each sample time, and outputs the array *y*. Each element in *y* is the minimum value in the corresponding column, row, vector, or entire input. The output *y* depends on the setting of the **Find the minimum value over** parameter. For example, consider a 3-dimensional input signal of size *M*-by-*N*-by-*P*:

- `Each row` — The output at each sample time consists of an *M*-by-1-by-*P* array, where each element contains the minimum value of each vector over the second dimension of the input. For an input that is an *M*-by-*N* matrix, the output at each sample time is an *M*-by-1 column vector.
- `Each column` — The output at each sample time consists of a 1-by-*N*-by-*P* array, where each element contains the minimum value of each vector over the first dimension of the input. For an input that is an *M*-by-*N* matrix, the output at each sample time is a 1-by-*N* row vector.

  In this mode, the block treats length-*M* unoriented vector inputs as *M*-by-1 column vectors.
- `Entire input` — The output at each sample time is a scalar that contains the minimum value in the *M*-by-*N*-by-*P* input matrix.
- `Specified dimension` — The output at each sample time depends on **Dimension**. If **Dimension** is set to `1`, the output is the same as when you select `Each column`. If **Dimension** is set to `2`, the output is the same as when you select `Each row`. If **Dimension** is set to `3`, the output at each sample time is an *M*-by-*N* matrix containing the minimum value of each vector over the third dimension of the input.

For complex inputs, the block selects the value in each row or column of the input, along vectors of a specified dimension of the input, or of the entire input that has the minimum magnitude squared as shown below. For complex value $u = a + bi$, the magnitude squared is $a^2 + b^2$.



Index Mode

When **Mode** is set to `Index`, the block computes the minimum value in each row or column of the input, along vectors of a specified dimension of the input, or of the entire input, and outputs the index array *I*. Each element in *I* is an integer indexing the minimum value in the corresponding column, row, vector, or entire input. The output *I* depends on the setting of the **Find the minimum value over** parameter. For example, consider a 3-dimensional input signal of size *M*-by-*N*-by-*P*:

- `Each row` — The output at each sample time consists of an *M*-by-1-by-*P* array, where each element contains the index of the minimum value of each vector over the second dimension of the input. For an input that is an *M*-by-*N* matrix, the output at each sample time is an *M*-by-1 column vector.
- `Each column` — The output at each sample time consists of a 1-by-*N*-by-*P* array, where each element contains the index of the minimum value of each vector over the first dimension of the input. For an input that is an *M*-by-*N* matrix, the output at each sample time is a 1-by-*N* row vector.

  In this mode, the block treats length-*M* unoriented vector inputs as *M*-by-1 column vectors.
- `Entire input` — The output at each sample time is a 1-by-3 vector that contains the location of the minimum value in the *M*-by-*N*-by-*P* input matrix. For an input that is an *M*-by-*N* matrix, the output will be a 1-by-2 vector.
- `Specified dimension` — The output at each sample time depends on **Dimension**. If **Dimension** is set to 1, the output is the same as when you select `Each column`. If **Dimension** is set to 2, the output is the same as when you select `Each row`. If **Dimension** is set to 3, the output at each sample time is an *M*-by-*N* matrix containing the indices of the minimum values of each vector over the third dimension of the input.

When a minimum value occurs more than once, the computed index corresponds to the first occurrence. For example, when the input is the column vector `[-1 2 3 2 -1]'`, the computed one-based index of the minimum value is `1` rather than `5` when `Each column` is selected.

Value and Index Mode

When **Mode** is set to `Value and Index`, the block outputs both the minima and the indices.

Running Mode

When **Mode** is set to `Running`, the block tracks the minimum value of each channel in a time sequence of M-by-N inputs. In this mode, you must also specify a value for the **Input processing** parameter:

- When you select `Elements as channels (sample based)`, the block outputs an M-by-N array. Each element y_{ij} of the output contains the minimum value observed in element u_{ij} for all inputs since the last reset.
- When you select `Columns as channels (frame based)`, the block outputs an M-by-N matrix. Each element y_{ij} of the output contains the minimum value observed in the jth column of all inputs since the last reset, up to and including element u_{ij} of the current input.

Running Mode for Variable-Size Inputs

When your inputs are of variable size, and you set the **Mode** to `Running` , there are two options:

- If you set the **Input processing** parameter to `Elements as channels (sample based)`, the state is reset.
- If you set the **Input processing** parameter to `Columns as channels (frame based)`, then there are two cases:
  - When the input size difference is in the number of channels (i.e., number of columns), the state is reset.
  - When the input size difference is in the length of channels (i.e., number of rows), there is no reset and the running operation is carried out as usual.

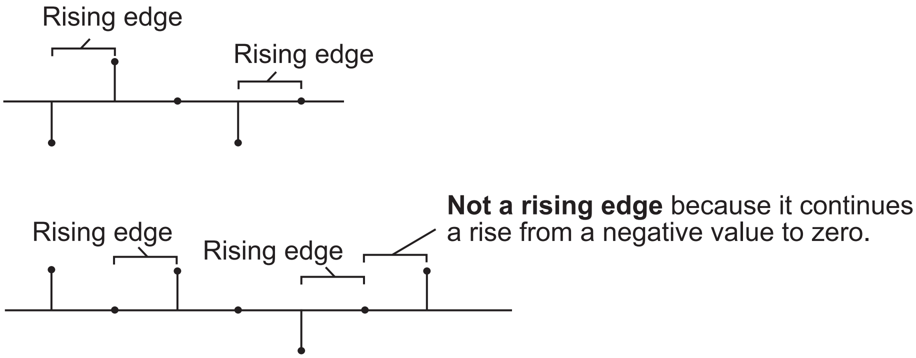
Resetting the Running Minimum

The block resets the running minimum whenever a reset event is detected at the optional Rst port. The reset sample time must be a positive integer multiple of the input sample time.

When a reset event occurs while the **Input processing** parameter is set to `Elements as channels (sample based)`, the running minimum for each channel is initialized to the value in the corresponding channel of the current input. Similarly, when the **Input processing** parameter is set to `Columns as channels (frame based)`, the running minimum for each channel is initialized to the earliest value in each channel of the current input.

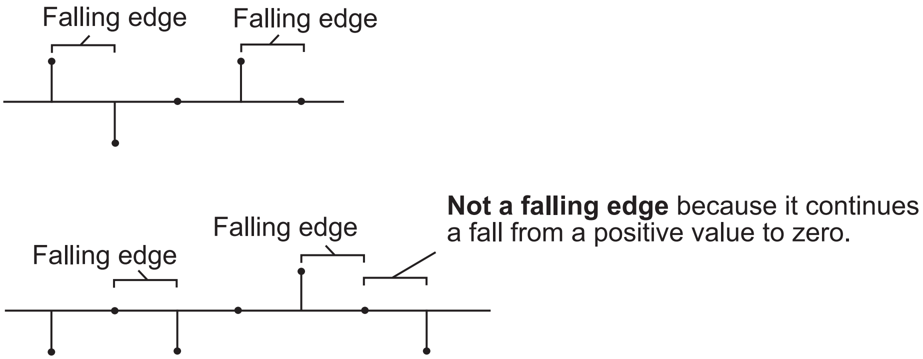
You specify the reset event by the **Reset port** parameter:

- `None` — Disables the Rst port
- `Rising edge` — Triggers a reset operation when the Rst input does one of the following:
  - Rises from a negative value to a positive value or zero
  - Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero (see the following figure)



Rising edge
Rising edge
Rising edge
Rising edge
Not a rising edge because it continues a rise from a negative value to zero.

- `Falling edge` — Triggers a reset operation when the `Rst` input does one of the following:
  - Falls from a positive value to a negative value or zero
  - Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero (see the following figure)



Falling edge
Falling edge
Falling edge
Falling edge
Not a falling edge because it continues a fall from a positive value to zero.

- `Either edge` — Triggers a reset operation when the `Rst` input is a `Rising edge` or `Falling edge` (as described above)
- `Non-zero sample` — Triggers a reset operation at each sample time that the `Rst` input is not zero

---

Note: When running simulations in the Simulink `MultiTasking` mode, reset signals have a one-sample latency. Therefore, when the block detects a reset event, there is a one-sample delay at the reset port rate before the block applies the reset. For more information on latency and the Simulink tasking modes, see “Excess Algorithmic Delay (Tasking Latency)” and “Scheduling ” in the *Simulink Coder User's Guide*.

ROI Processing

To calculate the statistical value within a particular region of interest (ROI) of the input, select the **Enable ROI processing** check box. This applies to any mode other than the running mode and when you set the **Find the minimum value over** parameter to `Entire input` and you select the **Enable ROI processing** check box. ROI processing applies only for 2-D inputs.

Note Full ROI processing is only available to users who have a Computer Vision System Toolbox license. If you only have a DSP System Toolbox license, you can still use ROI processing, but are limited to the **ROI type** `Rectangles`.

Use the **ROI type** parameter to specify whether the ROI is a rectangle, line, label matrix, or binary mask. A binary mask is a binary image that enables you to specify which pixels to highlight, or select. In a label matrix, pixels equal to 0 represent the background, pixels equal to 1 represent the first object, pixels equal to 2 represent the second object, and so on. When the **ROI type** parameter is set to `Label matrix`, the Label and Label Numbers ports appear on the block. Use the Label Numbers port to specify the objects in the label matrix for which the block calculates statistics. The input to this port must be a vector of scalar values that correspond to the labeled regions in the label matrix. For more information about the format of the input to the ROI port when the ROI is a rectangle or a line, see the Draw Shapes block reference page.

For rectangular ROIs, use the **ROI portion to process** parameter to specify whether to calculate the statistical value for the entire ROI or just the ROI perimeter.

Use the **Output** parameter to specify the block output. The block can output separate statistical values for each ROI or the statistical value for all specified ROIs. This parameter is not available if, for the **ROI type** parameter, you select `Binary mask`.

If, for the **ROI type** parameter, you select `Rectangles` or `Lines`, the **Output flag indicating if ROI is within image bounds** check box appears in the dialog box. If you select this check box, the Flag port appears on the block. The following tables describe the Flag port output based on the block parameters.

Output = Individual statistics for each ROI

Flag Port Output	Description
0	ROI is completely outside the input image.
1	ROI is completely or partially inside the input image.

Output = Single statistic for all ROIs

Flag Port Output	Description
0	All ROIs are completely outside the input image.
1	At least one ROI is completely or partially inside the input image.

If the ROI is partially outside the image, the block only computes the statistical values for the portion of the ROI that is within the image.

If, for the **ROI type** parameter, you select `Label matrix`, the **Output flag indicating if input label numbers are valid** check box appears in the dialog box. If you select this check box, the Flag port appears on the block. The following tables describe the Flag port output based on the block parameters.

Output = Individual statistics for each ROI

Flag Port Output	Description
0	Label number is not in the label matrix.
1	Label number is in the label matrix.

Output = Single statistic for all ROIs

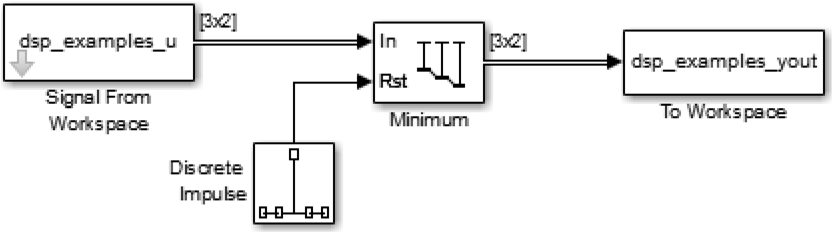
Flag Port Output	Description
0	None of the label numbers are in the label matrix.
1	At least one of the label numbers is in the label matrix.

Fixed-Point Data Types

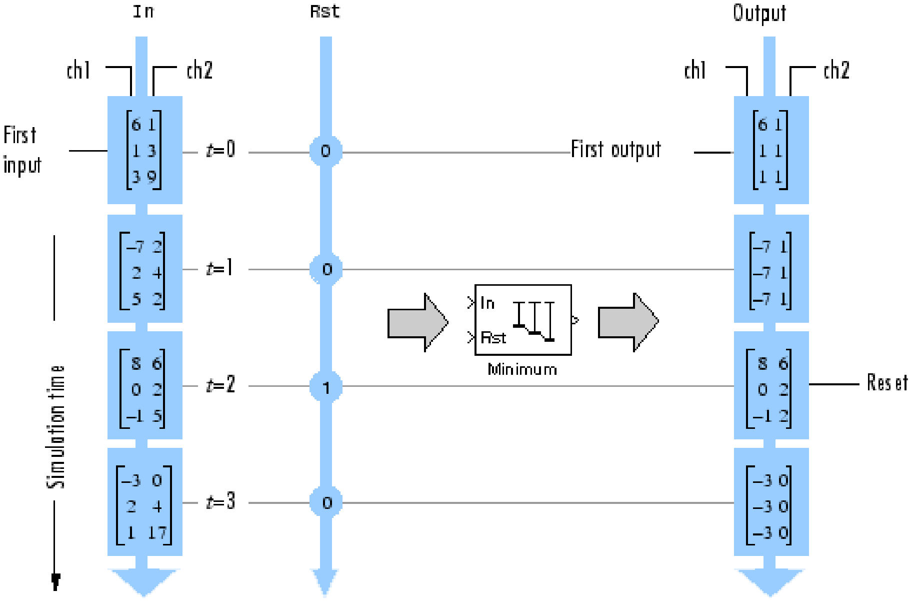
The parameters on the **Data Types** pane of the block dialog are only used for complex fixed-point inputs. The sum of the squares of the real and imaginary parts of such an input are formed before a comparison is made, as described in “Value Mode” on page 1-995. The results of the squares of the real and imaginary parts are placed into the product output data type. The result of the sum of the squares is placed into the accumulator data type. These parameters are ignored for other types of inputs.

Examples

In the following ex_minimum_ref model, the Minimum block calculates the running minimum of a 3-by-2 matrix input. The **Input processing** parameter is set to `Columns as channels (frame based)`, so the block processes the input as a two channel signal with a frame size of three. The running minimum is reset at *t*=2 by an impulse to the block's Rst port.

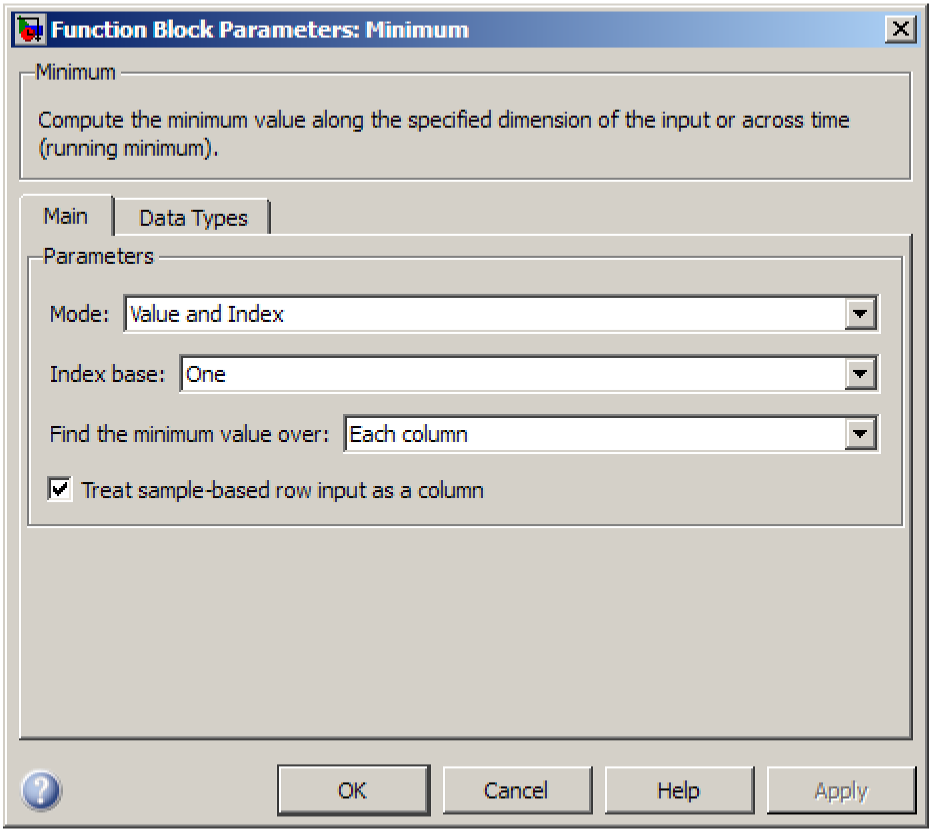


The operation of the block is shown in the following figure.



Dialog Box

The **Main** pane of the Minimum block dialog appears as follows.



Function Block Parameters: Minimum

Minimum

Compute the minimum value along the specified dimension of the input or across time (running minimum).

Parameters

Mode: Value and Index

Index base: One

Find the minimum value over: Each column

☑ Treat sample-based row input as a column

Mode

Specify the block's mode of operation:

- `Value` — Output the minimum value of each input
- `Index` — Output the index of the minimum value
- `Value and index` — Output both the value and the index
- `Running` — Track the minimum value of the input sequence over time

For more information, see Description.

Index base

Specify whether the index of the minimum value is reported using one-based or zero-based numbering. This parameter is only visible when the **Mode** parameter is set to `Index` or `Value and index`.

Find the minimum value over

Specify whether to find the minimum value along rows, columns, entire input, or the dimension specified in the **Dimension** parameter. For more information, see Description.

Input processing

Specify how the block should process the input when computing the running minimum. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` — When you select this option, the block treats each column of the input as a separate channel.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

This parameter appears only when you set the **Mode** to `Running`.

Note: The option `Inherit from input (this choice will be removed - see release notes)` will be removed in a future release. See "Frame-Based Processing" in the *DSP System Toolbox Release Notes* for more information.

Reset port

Specify the reset event that causes the block to reset the running minimum. The sample time of the input to the Rst port must be a positive integer multiple of the input sample time. This parameter appears only when you set the **Mode** parameter to `Running`. For information about the possible values of this parameter, see "Resetting the Running Minimum" on page 1-998.

Treat sample-based row input as a column

Select to treat sample-based length-M row vector inputs as M-by-1 column vectors. This parameter is only visible when the **Find the minimum value of** parameter is set to `Each column`.

Note: This check box will be removed in a future release. See "Sample-Based Row Vector Processing Changes" for more information.

Dimension

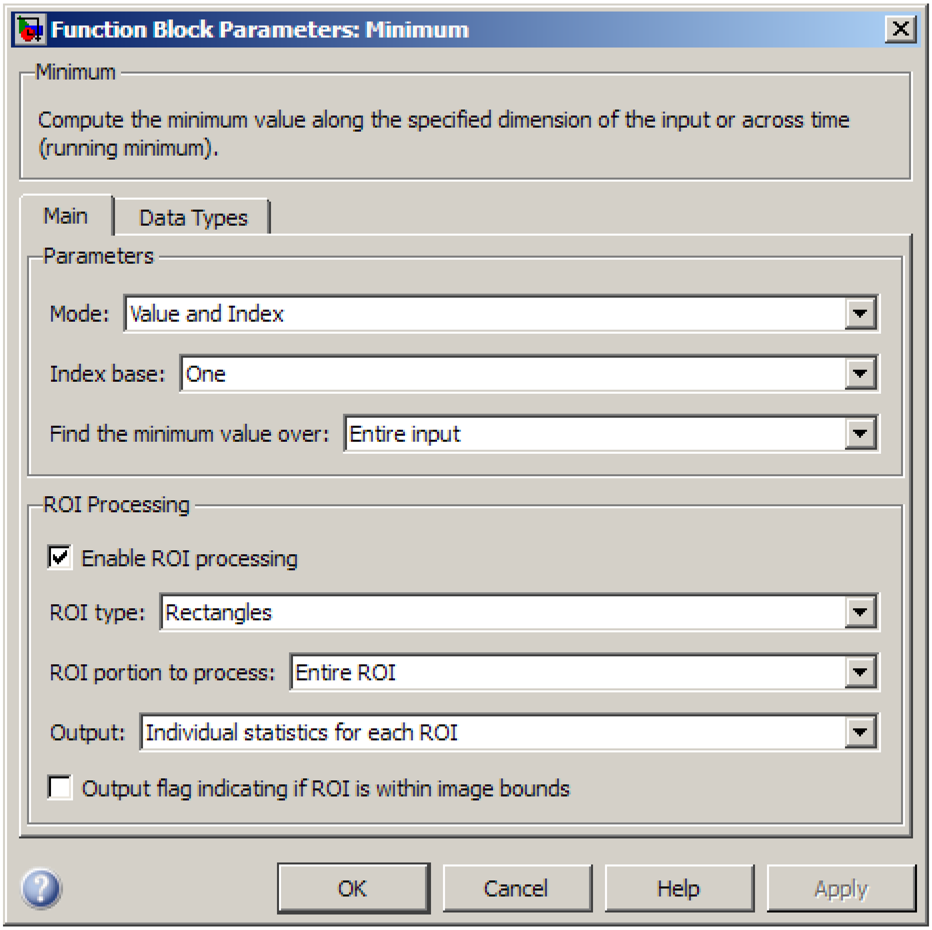
Specify the dimension (one-based value) of the input signal, over which the minimum is computed. The value of this parameter cannot exceed the number of dimensions in the input signal. This parameter is only visible when the **Find the minimum value over** parameter is set to `Specified dimension`.

Enable ROI processing

Select this check box to calculate the statistical value within a particular region of each image. This parameter is only available when the **Find the minimum value over** parameter is set to `Entire input`, and the block is not in running mode.

Note: Full ROI processing is only available to users who have a Computer Vision System Toolbox license. If you only have a DSP System Toolbox license, you can still use ROI processing, but are limited to the **ROI type** `Rectangles`.

The ROI processing parameters appear as follows.



Function Block Parameters: Minimum

Minimum

Compute the minimum value along the specified dimension of the input or across time (running minimum).

Parameters

Mode: Value and Index

Index base: One

Find the minimum value over: Entire input

ROI Processing

☑ Enable ROI processing

ROI type: Rectangles

ROI portion to process: Entire ROI

Output: Individual statistics for each ROI

□ Output flag indicating if ROI is within image bounds

ROI type

Specify the type of ROI you want to use. Your choices are `Rectangles`, `Lines`, `Label matrix`, or `Binary mask`.

ROI portion to process

Specify whether you want to calculate the statistical value for the entire ROI or just the ROI perimeter. This parameter is only visible if, for the **ROI type** parameter, you specify `Rectangles`.

Output

Specify the block output. The block can output a vector of separate statistical values for each ROI or a scalar value that represents the statistical value for all the specified ROIs. This parameter is not available if, for the **ROI type** parameter, you select `Binary mask`.

Output flag

☑ **Output flag indicating if ROI is within image bounds**

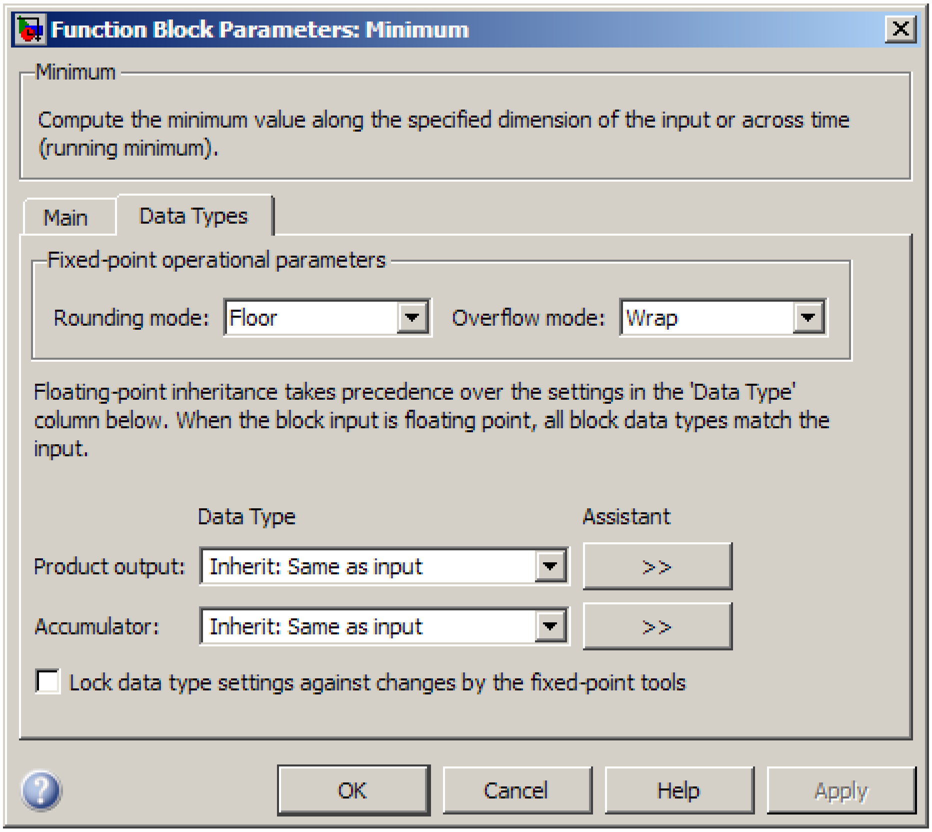
☑ **Output flag indicating if label numbers are valid**

When you select either of these check boxes, the Flag port appears on the block. For a description of the Flag port output, see the tables in "ROI Processing" on page 1-1000.

The **Output flag indicating if ROI is within image bounds** check box is only visible when you select `Rectangles` or `Lines` as the **ROI type**.

The **Output flag indicating if label numbers are valid** check box is only visible when you select `Label matrix` for the **ROI type** parameter.

The **Data Types** pane of the Minimum block dialog appears as follows.



Function Block Parameters: Minimum

Minimum

Compute the minimum value along the specified dimension of the input or across time (running minimum).

Fixed-point operational parameters

Rounding mode: Floor   Overflow mode: Wrap

Floating-point inheritance takes precedence over the settings in the 'Data Type' column below. When the block input is floating point, all block data types match the input.

	Data Type	Assistant
Product output:	Inherit: Same as input	>>
Accumulator:	Inherit: Same as input	>>

□ Lock data type settings against changes by the fixed-point tools

Note: The parameters on the **Data Types** pane are only used for complex fixed-point inputs. The sum of the squares of the real and imaginary parts of such an input are formed before a comparison is made, as described in “Value Mode” on page 1-995. The results of the squares of the real and imaginary parts are placed into the product output data type. The result of the sum of the squares is placed into the accumulator data type. These parameters are ignored for other types of inputs.

Rounding mode

Select the “rounding mode” for fixed-point operations.

Overflow mode

Select the “overflow mode” for fixed-point operations.

Product output data type

Specify the product output data type. See “Fixed-Point Data Types” on page 1-1002 and “Multiplication Data Types” for illustrations depicting the use of the product output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as input`
- An expression that evaluates to a valid data type, for example, `fixdt([],16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Product output data type** parameter.

See “Specify Data Types Using Data Type Assistant” in “Simulink User's Guide” for more information.

Accumulator data type

Specify the accumulator data type. See “Fixed-Point Data Types” on page 1-1002 for illustrations depicting the use of the accumulator data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Same as input`
- An expression that evaluates to a valid data type, for example, `fixdt([],16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Accumulator data type** parameter.

See “Specify Data Types Using Data Type Assistant” in “Simulink User's Guide” for more information.

Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

HDL Code Generation

This block supports HDL code generation using HDL Coder. HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

For more information on implementations, properties, and restrictions for HDL code generation, see Minimum.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Reset	• Double-precision floating point • Single-precision floating point • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Idx	• Double-precision floating point • 32-bit unsigned integers
Val	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers

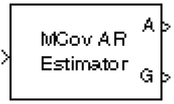
Modified Covariance AR Estimator

Compute estimate of autoregressive (AR) model parameters using modified covariance method

Library

Estimation / Parametric Estimation

`dspparest3`



Description

The Modified Covariance AR Estimator block uses the modified covariance method to fit an autoregressive (AR) model to the input data. This method minimizes the forward and backward prediction errors in the least squares sense. The input is a frame of consecutive time samples, which is assumed to be the output of an AR system driven by white noise. The block computes the normalized estimate of the AR system parameters, *A(z)*, independently for each successive input.

$$H(z) = \frac{G}{A(z)} = \frac{G}{1 + a(2)z^{-1} + \ldots + a(p+1)z^{-p}}$$

You specify the order, *p*, of the all-pole model in the **Estimation order** parameter. To guarantee a valid output, you must set the **Estimation order** parameter to be less than or equal to two thirds the input vector length.

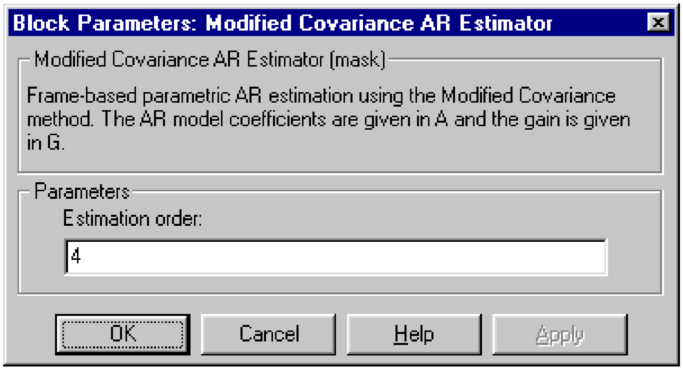
The output port labeled A outputs the normalized estimate of the AR model coefficients in descending powers of *z*.

```
[1 a(2) ... a(p+1)]
```

The scalar gain, *G*, is output from the output port labeled G.

See the Burg AR Estimator block reference page for a comparison of the Burg AR Estimator, Covariance AR Estimator, Modified Covariance AR Estimator, and Yule-Walker AR Estimator blocks.

Dialog Box



Block Parameters: Modified Covariance AR Estimator

Modified Covariance AR Estimator (mask)

Frame-based parametric AR estimation using the Modified Covariance method. The AR model coefficients are given in A and the gain is given in G.

Parameters

Estimation order: 4

Estimation order

Specify the order of the AR model, *p*.

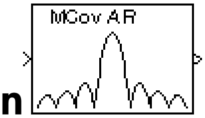
Modified Covariance Method

Power spectral density estimate using modified covariance method

Library

Estimation / Power Spectrum Estimation

`dspspect3`



Description

The Modified Covariance Method block estimates the power spectral density (PSD) of the input using the modified covariance method. This method fits an autoregressive (AR) model to the signal. It does so by minimizing the forward and backward prediction errors in the least squares sense. The **Estimation order** parameter value specifies the order of the all-pole model. To guarantee a valid output, the **Estimation order** parameter must be less than or equal to two thirds of the input vector length. The block computes the spectrum from the FFT of the estimated AR model parameters.

The input must be a sample-based vector (row, column, or 1-D) or frame-based vector (column only). This input represents a frame of consecutive time samples from a single-channel signal. The block outputs a column vector containing the estimate of the power spectral density of the signal at N_{fft} equally spaced frequency points. The frequency points are in the range $[0,F_s)$, where F_s is the sampling frequency of the signal.

Selecting **Inherit FFT length from estimation order**, specifies that N_{fft} is one greater than the estimation order. Clearing the **Inherit FFT length from estimation order** check box allows you to use the **FFT length** parameter to specify N_{fft} as a power of 2. The block zero-pads or wraps the input to N_{fft} before computing the FFT. The output is always sample based.

When you select the **Inherit sample time from input** check box, the block computes the frequency data from the sample period of the input signal. For the block to produce valid output, the following conditions must hold:

- The input to the block is the original signal, with no samples added or deleted (by insertion of zeros, for example).
- The sample period of the time-domain signal in the simulation equals the sample period of the original time series.

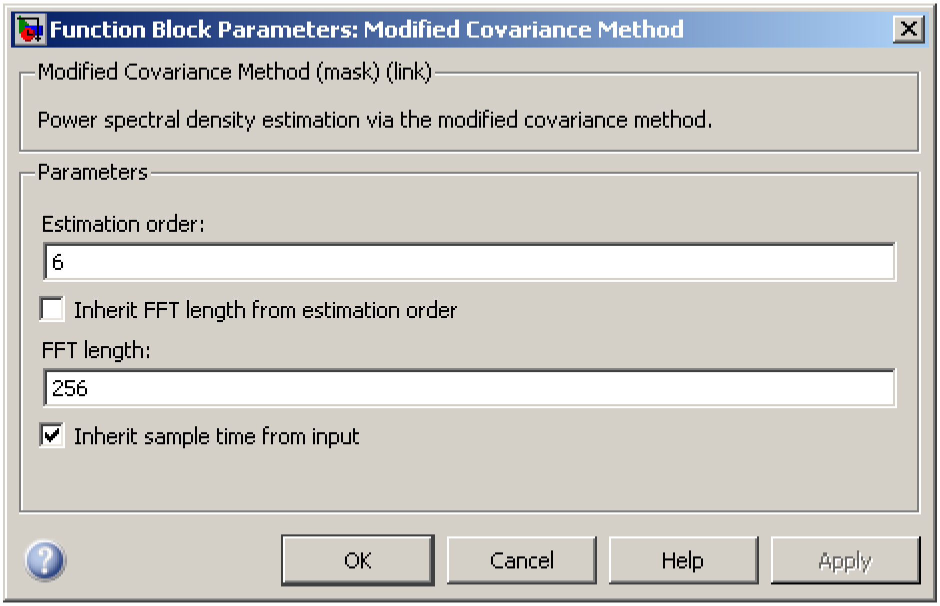
If these conditions do not hold, clear the **Inherit sample time from input** check box. You can then specify a sample time using the **Sample time of original time series** parameter.

See the Burg Method block reference for a comparison of the Burg Method, Covariance Method, Modified Covariance Method, and Yule-Walker Method blocks.

Examples

The dspsacomp example compares the modified covariance method with several other spectral estimation methods.

Dialog Box



Function Block Parameters: Modified Covariance Method

Modified Covariance Method (mask) (link)

Power spectral density estimation via the modified covariance method.

Parameters

Estimation order:

6

□ Inherit FFT length from estimation order

FFT length:

256

☑ Inherit sample time from input

Estimation order

Specify the order of the AR model. To guarantee a valid output, the **Estimation order** parameter must be less than or equal to two thirds of the input vector length.

Inherit FFT length from estimation order

When you select this check box, the option specifies that the FFT length is one greater than the estimation order. To specify the number of points on which to perform the FFT, clear this check box. You can then specify a power of two FFT length using the **FFT length** parameter.

FFT length

Enter the number of data points, N_{fft}, on which to perform the FFT. When N_{fft} is larger than the input frame size, the block zero-pads each frame as needed. When N_{fft} is smaller than the input frame size, the block wraps each frame as needed. This parameter becomes visible only when you clear the **Inherit FFT length from estimation order** check box.

Inherit sample time from input

If you select the **Inherit sample time from input** check box, the block computes the frequency data from the sample period of the input signal. For the block to produce valid output, the following conditions must hold:

- The input to the block is the original signal, with no samples added or deleted (by insertion of zeros, for example).
- The sample period of the time-domain signal in the simulation equals the sample period of the original time series.

If these conditions do not hold, clear the **Inherit sample time from input** check box. You can then specify a sample time using the **Sample time of original time series** parameter.

Sample time of original time series

Specify the sample time of the original time-domain signal. This parameter becomes visible only when you clear the **Inherit sample time from input** check box.

Multiphase Clock

Generate multiple binary clock signals

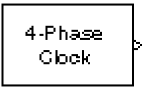
Library

- Sources

  `dspsrcs4`
- Signal Management / Switches and Counters

  `dspswit3`

Description



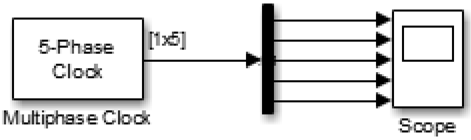
The Multiphase Clock block generates a 1-by-*N* vector of clock signals, where you specify the integer *N* in the **Number of phases** parameter. Each of the *N* phases has the same frequency, *f*, specified in hertz by the **Clock frequency** parameter.

The clock signal indexed by the **Starting phase** parameter is the first to become active, at *t*=0. The other signals in the output vector become active in turn, each one lagging the preceding signal's activation by 1/(*N**f*) seconds, the phase interval. The period of the output is therefore 1/(*N**f*) seconds.

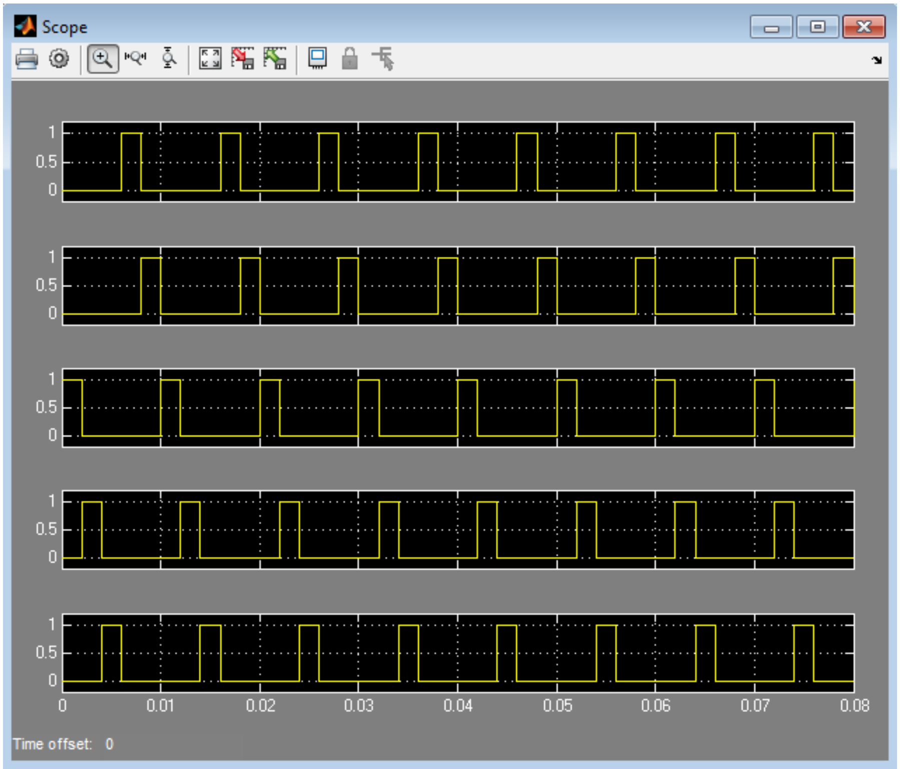
The active level can be either high (1) or low (0), as specified by the **Active level (polarity)** parameter. The duration of the active level, *D*, is set by the **Number of phase intervals over which the clock is active**. This value, which can be an integer value between 1 and *N*-1, specifies the number of phase intervals that each signal should remain in the active state after becoming active. The active duty cycle of the signal is *D*/*N*.

Examples

In the following ex_multiphaseclock_ref model, the Multiphase Clock block generates a 100 Hz five-phase output in which the third signal is first to become active. The block uses a high active level with a duration of one interval.

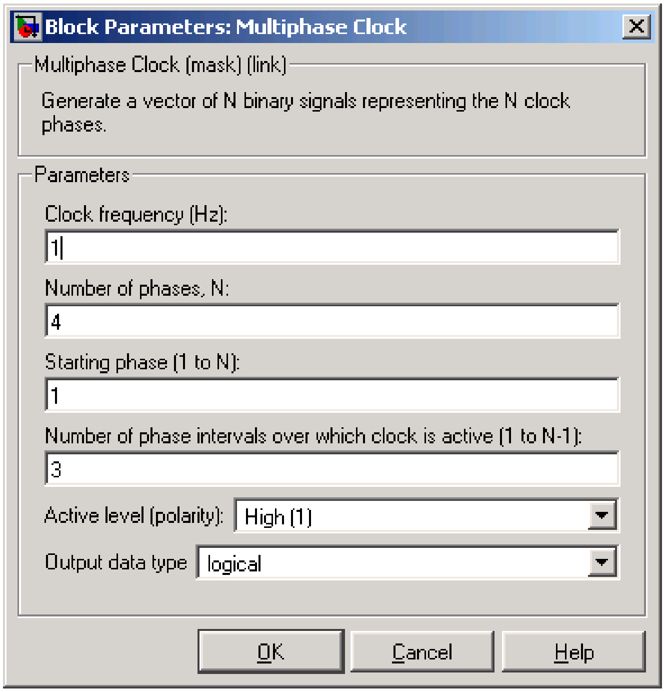


The Scope window below shows the Multiphase Clock block's output. Note that the first active level appears at *t*=0 on `y(3)`, the second active level appears at *t*=0.002 on `y(4)`, the third active level appears at *t*=0.004 on `y(5)`, the fourth active level appears at *t*=0.006 on `y(1)`, and the fifth active level appears at *t*=0.008 on `y(2)`. Each signal becomes active 1/(5*100) seconds after the previous signal.



To experiment further, try changing the **Number of phase intervals over which clock is active** setting to **3** so that the active-level duration is three phase intervals (60% duty cycle).

Dialog Box



Multiphase Clock (mask) (link)

Generate a vector of N binary signals representing the N clock phases.

Parameters

Clock frequency (Hz): 1

Number of phases, N: 4

Starting phase (1 to N): 1

Number of phase intervals over which clock is active (1 to N-1): 3

Active level (polarity): High (1)

Output data type logical

Clock frequency

The frequency of all output clock signals.

Number of phases

The number of different phases, *N*, in the output vector.

Starting phase

The vector index of the output signal to first become active.

Number of phase intervals over which clock is active

The duration of the active level for every output signal.

Active level

The active level, `High (1)` or `Low (0)`.

Output data type

The output data type.

Supported Data Types

- Double-precision floating point
- Single-precision floating point
- Boolean

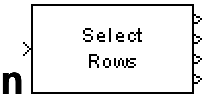
Multiport Selector

Distribute arbitrary subsets of input rows or columns to multiple output ports

Library

Signal Management / Indexing

`dspindex`



Description

The Multiport Selector block extracts multiple subsets of rows or columns from *M*-by-*N* input matrix *u*, and propagates each new submatrix to a distinct output port. The block treats an unoriented length-*M* vector input as an *M*-by-1 matrix.

The **Indices to output** parameter is a cell array whose *k*th cell contains a one-dimensional indexing expression specifying the subset of input rows or columns to be propagated to the *k*th output port. The total number of cells in the array determines the number of output ports on the block.

When you set the **Select** parameter to `Rows`, the block uses the one-dimensional indices you specify to select matrix rows, and all elements on the chosen rows are included. When you set the **Select** parameter to `Columns`, the block uses the one-dimensional indices you specify to select matrix columns, and all elements on the chosen columns are included. A given input row or column can appear any number of times in any of the outputs, or not at all.

When an index references a nonexistent row or column of the input, the block reacts with the action you specify using the **Invalid index** parameter.

Examples

Example 1

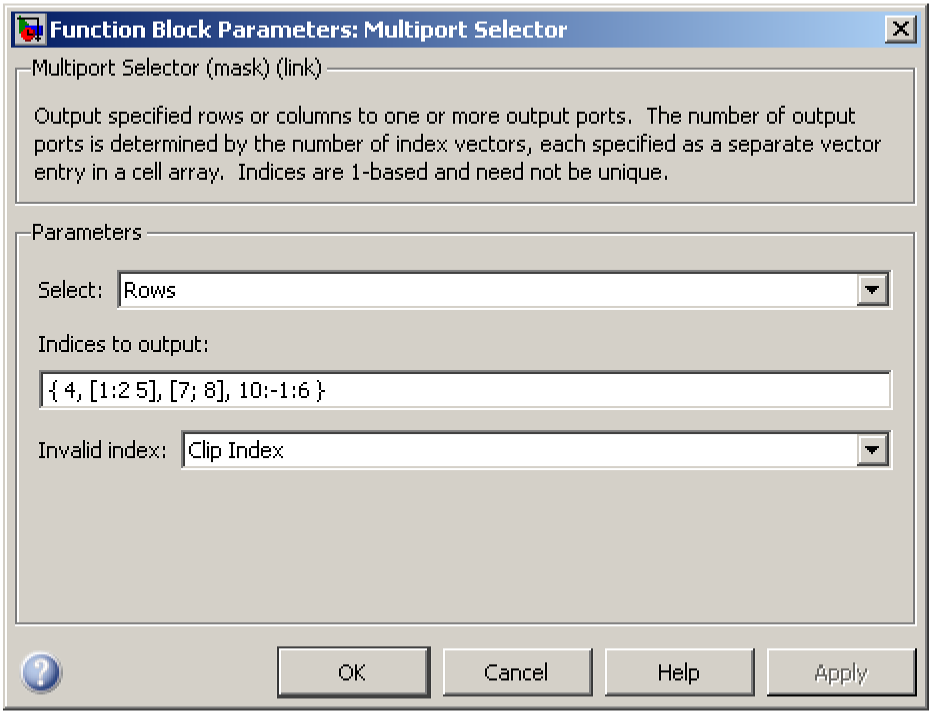
Consider the following **Indices to output** cell array:

```
{4,[1:2 5],[7;8],10:-1:6}
```

This is a four-cell array, which requires the block to generate four independent outputs (each at a distinct port). The table below shows the dimensions of these outputs when **Select** = `Rows` and the input dimension is *M*-by-*N*.

Cell	Expression	Description	Output Size
1	`4`	Row 4 of input	1-by-*N*
2	`[1:2 5]`	Rows 1, 2, and 5 of input	3-by-*N*
3	`[7;8]`	Rows 7 and 8 of input	2-by-*N*
4	`10:-1:6`	Rows 10, 9, 8, 7, and 6 of input	5-by-*N*

Dialog Box



Function Block Parameters: Multiport Selector
Multiport Selector (mask) (link)

Output specified rows or columns to one or more output ports. The number of output ports is determined by the number of index vectors, each specified as a separate vector entry in a cell array. Indices are 1-based and need not be unique.

Parameters

Select: Rows

Indices to output:

{ 4, [1:2 5], [7; 8], 10:-1:6 }

Invalid index: Clip Index

Select

Specify the dimension of the input to select, `Rows` or `Columns`.

Indices to output

A cell array specifying the row- or column-subsets to propagate to each of the output ports. The number of cells in the array determines the number of output ports on the block.

Invalid index

Specify how the block handles an invalid index value. You can select one of the following options:

- `Clip index` — Clip the index to the nearest valid value, and do not issue an alert.

  For example, if the block receives a `64`-by-`4` input and the **Select** parameter is set to `Rows`, the block clips an index of `72` to `64`. For the same input, if the **Select** parameter is set to `Columns`, the block clips an index of `72` to `4`. In both cases, the block clips an index of `-2` to `1`.
- `Clip and warn` — Clip the index to the nearest valid value and display a warning message at the MATLAB command line.
- `Generate error` — Display an error dialog box and terminate the simulation.

HDL Code Generation

This block supports HDL code generation using HDL Coder. HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic. For more information on implementations, properties, and restrictions for HDL code generation, see Multiport Selector.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned)

Port	Supported Data Types
	• Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers • Enumerated
Outputs	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers • Enumerated

N-Sample Enable

Output ones or zeros for specified number of sample times

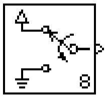
Library

- Sources

  `dspsrcs4`
- Signal Management / Switches and Counters

  `dspswit3`

Description



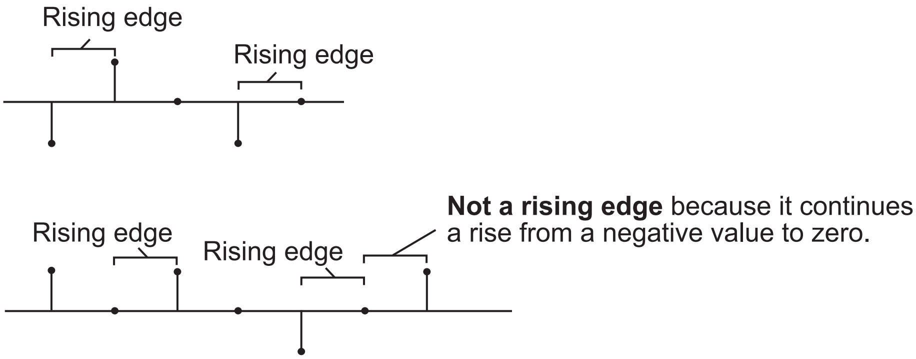
The N-Sample Enable block outputs the inactive value (`0` or `1`, whichever is not selected in the **Active level** parameter) during the first *N* sample times, where *N* is the **Trigger count** value. Beginning with output sample *N*+1, the block outputs the active value (`1` or `0`, whichever you select in the **Active level** parameter) until a reset event occurs or the simulation terminates.

The output of the block is always a scalar.

The **Reset input** check box enables the Rst input port. At any time during the count, a trigger event at the input port resets the counter to its initial state. This block supports triggered subsystems when you select the **Reset input** check box.

You specify the triggering event in the **Trigger type** pop-up menu:

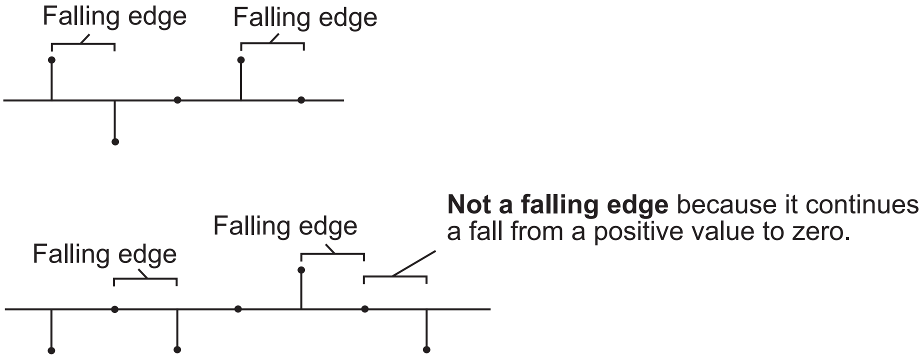
- `Rising edge` — Triggers a reset operation when the `Rst` input does one of the following:
  - Rises from a negative value to a positive value or zero
  - Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero (see the following figure)



Rising edge
Rising edge
Rising edge
Rising edge
Not a rising edge because it continues
a rise from a negative value to zero.

- `Falling edge` — Triggers a reset operation when the `Rst` input does one of the following:

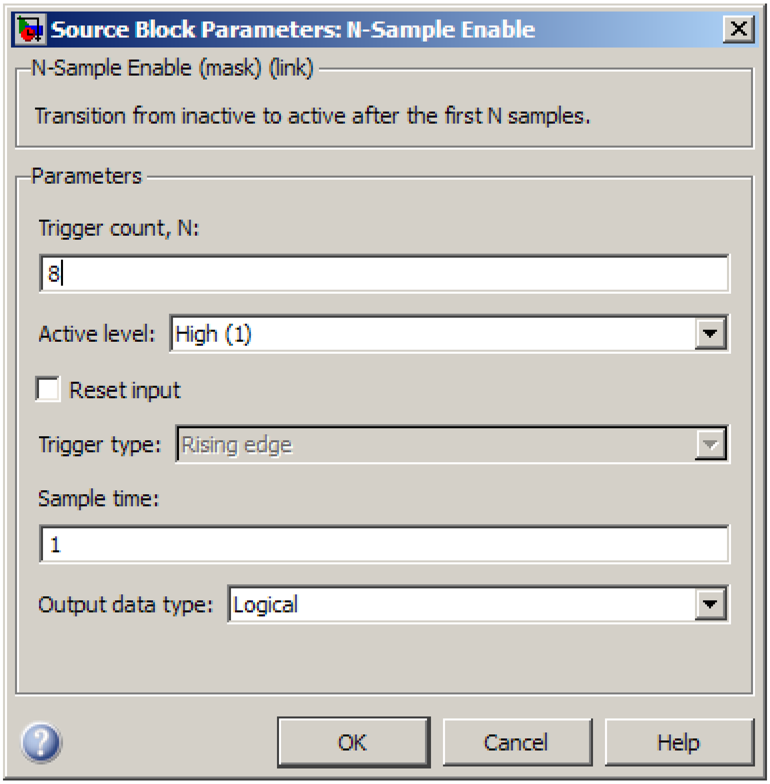
  - Falls from a positive value to a negative value or zero
  - Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero (see the following figure)



Falling edge
Falling edge
Falling edge
Falling edge
Not a falling edge because it continues
a fall from a positive value to zero.

- `Either edge` — Triggers a reset operation when the `Rst` input is a `Rising edge` or `Falling edge` (as described above).
- `Non-zero sample` — Triggers a reset operation at each sample time that the `Rst` input is not zero.

Dialog Box



Source Block Parameters: N-Sample Enable

N-Sample Enable (mask) (link)

Transition from inactive to active after the first N samples.

Parameters

Trigger count, N: 8

Active level: High (1)

□ Reset input

Trigger type: Rising edge

Sample time: 1

Output data type: Logical

Trigger count

Specify the number of samples for which the block outputs the active value. “Tunable”.

Active level

Specify the value to output after the first *N* sample times, 0 or 1. “Tunable”.

Reset input

Select to enable the Rst input port.

Trigger type

Select type of event that triggers a reset when the Rst port is enabled.

Sample time

Specify the sample period, T_s, for the block's counter. The block switches from the active value to the inactive value at $t = T_s*(N+1)$.

Output data type

Select the output data type.

Supported Data Types

- Double-precision floating point
- Boolean — The block accepts Boolean inputs to the Rst port, which is enabled when you select the **Reset input** parameter.

N-Sample Switch	DSP System Toolbox

N-Sample Switch

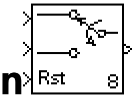
Switch between two inputs after specified number of sample periods

Library

Signal Management / Switches and Counters

`dspswit3`

Description



The N-Sample Switch block outputs the signal connected to the top input port during the first *N* sample times after the simulation begins or the block is reset, where you specify *N* in the **Switch count** parameter. Beginning with output sample *N*+1, the block outputs the signal connected to the bottom input until the next reset event or the end of the simulation.

You specify the sample period of the output in the **Sample time** parameter (that is, the output sample period is not inherited from the sample period of either input). The block applies a zero-order hold at the input ports, so the value the block reads from a given port between input sample times is the value of the most recent input to that port.

Both inputs must have the same dimension, except in the following two cases:

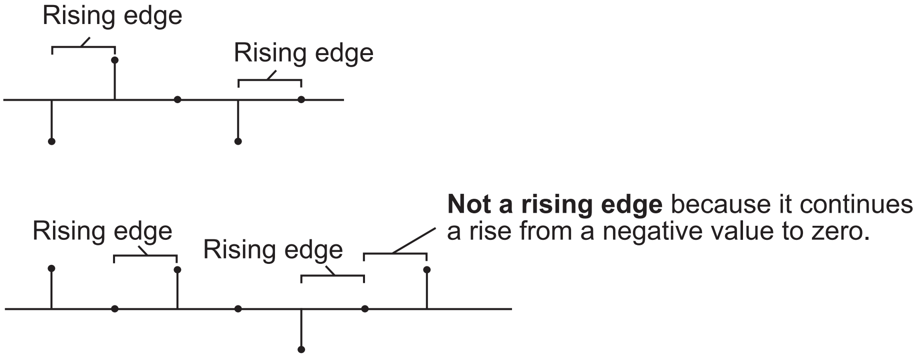
- When one input is a scalar, the block expands the scalar input to match the size of the other input.
- When one input is an unoriented vector and the other input is a row or column vector with the same number of elements, the block reshapes the unoriented vector to match the dimension of the other input.

The **Reset input** check box enables the Rst input port. At any time during the count, a trigger event at the Rst port resets the counter to zero. The reset sample time must be a positive integer multiple of the input sample time. This block supports triggered subsystems when you select the **Reset input** check box.

You specify the triggering event in the **Trigger type** pop-up menu, and can be one of the following:

- `Rising edge` — Triggers a reset operation when the `Rst` input does one of the following:

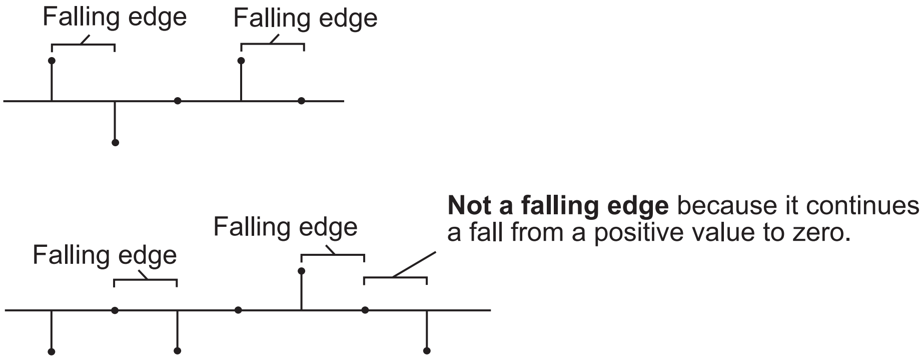
  - Rises from a negative value to a positive value or zero
  - Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero (see the following figure)



Rising edge
Rising edge
Rising edge
Rising edge
Not a rising edge because it continues a rise from a negative value to zero.

- `Falling edge` — Triggers a reset operation when the `Rst` input does one of the following:

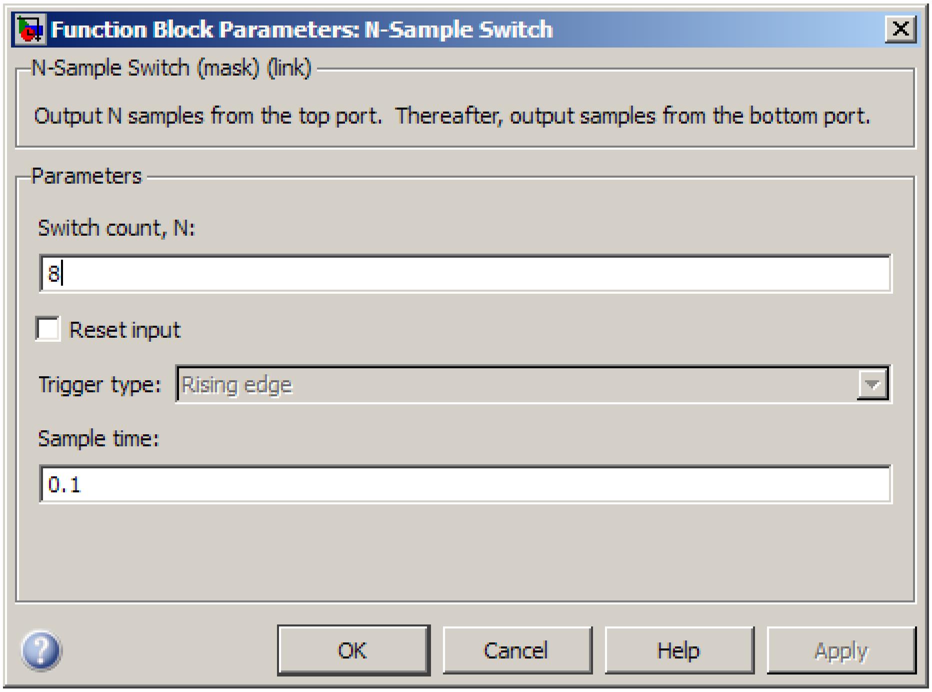
  - Falls from a positive value to a negative value or zero
  - Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero (see the following figure)



Falling edge
Falling edge
Falling edge
Falling edge
Not a falling edge because it continues a fall from a positive value to zero.

- `Either edge` — Triggers a reset operation when the `Rst` input is a `Rising edge` or `Falling edge` (as described above).
- `Non-zero sample` — Triggers a reset operation at each sample time that the `Rst` input is not zero.

Dialog Box



Function Block Parameters: N-Sample Switch

N-Sample Switch (mask) (link)

Output N samples from the top port. Thereafter, output samples from the bottom port.

Parameters

Switch count, N:

8

□ Reset input

Trigger type: Rising edge

Sample time:

0.1

Switch count

The number of sample periods, *N*, for which the output is connected to the top input before switching to the bottom input. “Tunable”.

Reset input

Enables the Rst input port when selected. The rate of the reset signal must be a positive integer multiple of the rate of the data signal input.

Trigger type

The type of event at the Rst port that resets the block's counter. This parameter is enabled when you select **Reset input**. “Tunable”.

Sample time

The sample period, T_s, for the block's counter. The block switches inputs at $t=T_s*(N+1)$.

Supported Data Types

- Double-precision floating point
- Single-precision floating point
- Fixed point (signed and unsigned)
- Boolean — The block accepts Boolean inputs to the Rst port, which is enabled when you set the **Reset input** parameter.
- 8-, 16-, and 32-bit signed integers
- 8-, 16-, and 32-bit unsigned integers

NCO

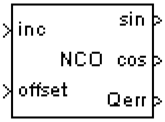
Generate real or complex sinusoidal signals

Library

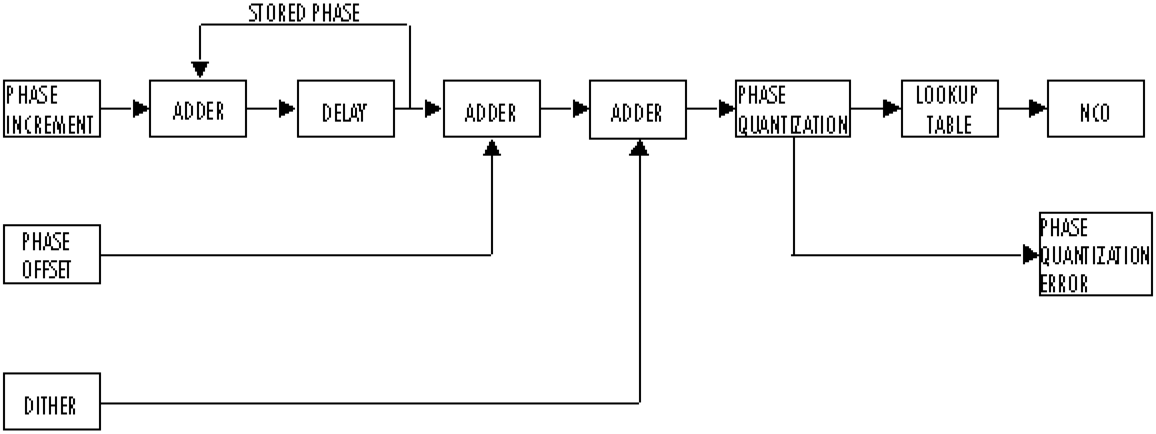
Signal Operations

`dspsigops`

Description



The NCO block generates a multichannel real or complex sinusoidal signal, with independent frequency and phase in each output channel. The amplitude of the created signal is always 1. The block implements the algorithm as shown in the following diagram:



The implementation of a numerically controlled oscillator (NCO) has two distinct parts. First, a phase accumulator accumulates the phase increment and adds in the phase offset. In this stage, an optional internal dither signal can also be added. The NCO output is then calculated by quantizing the results of the phase accumulator section and using them to select values from a lookup table. Since the lookup table contains a finite set of entries, in its normal mode of operation, the NCO block allows the adder's numeric values to overflow and wrap around. The Fixed-Point infrastructure then causes overflow warnings to appear on the command line. This overflow is of no consequence.

Given a desired output frequency F_0, calculate the value of the **Phase increment** block parameter with

$$phase\ increment = \left(\frac{F_0 \cdot 2^N}{F_s}\right)$$

where N is the accumulator word length and

$$F_s = \frac{1}{T_s} = \frac{1}{sample\ time}$$

The frequency resolution of an NCO is defined by

$$\Delta f = \frac{1}{T_s \cdot 2^N}\ \mathrm{Hz}$$

Given a desired phase offset (in radians), calculate the **Phase offset** block parameter with

$$phase\ offset = \frac{2^N \cdot desired\ phase\ offset}{2\pi}$$

The spurious free dynamic range (SFDR) is estimated as follows for a lookup table with 2^P entries, where P is the number of quantized accumulator bits:

$$SFDR = (6P)\ \mathrm{dB} \qquad \text{without dither}$$
$$SFDR = (6P + 12)\ \mathrm{dB} \qquad \text{with dither}$$

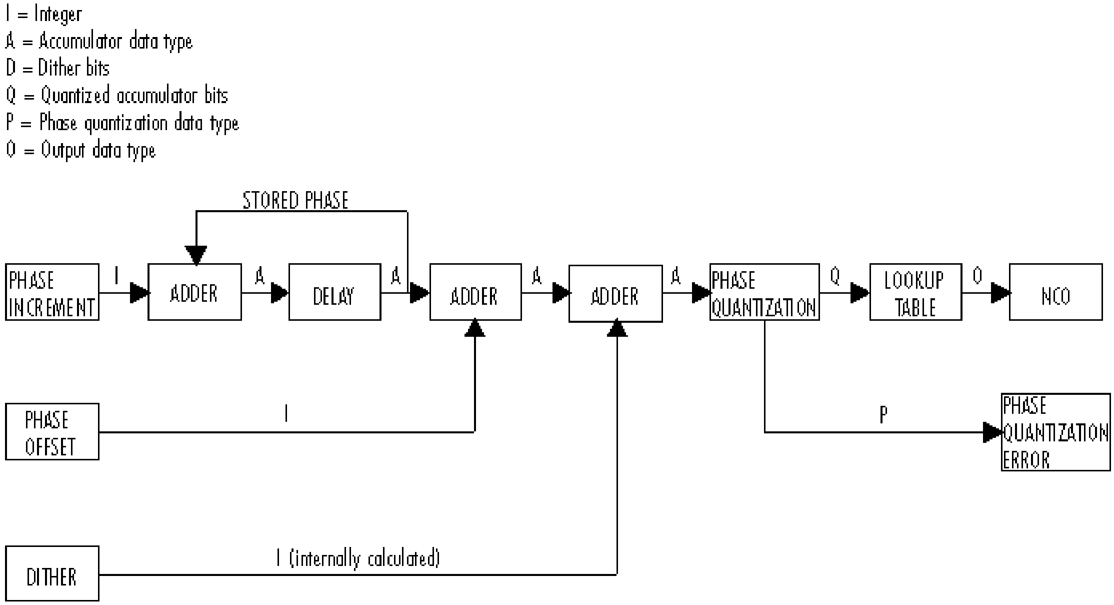
This block uses a quarter-wave lookup table technique that stores table values from 0 to π/2. The block calculates other values on demand using the accumulator data type, then casts them into the output data type. This can lead to quantization effects at the range limits of a given data type. For example, consider a case where you would expect the value of the sine wave to be –1 at π. Because the lookup table value at that point must be calculated, the block might not yield exactly –1, depending on the precision of the accumulator and output data types.

The NCO block supports real inputs only. All outputs are real except for the output signal in `Complex exponential` mode.

To produce a multichannel output, specify a vector quantity for the **Phase increment** and **Phase offset** parameters. Both parameters must have the same length, which defines the number of output channels. Each element of each vector is applied to a different output channel.

Fixed-Point Data Types

The following diagram shows the data types used within the NCO block.



- You can set the accumulator and output data types in the block dialog as discussed in "Dialog Box" on page 1-1042 below.

Note: The lookup table for this block is constructed from double-precision floating-point values. Thus, the maximum amount of precision you can achieve in your output is 53 bits. Setting the word length of the **Output** data type to values greater than 53 bits does not improve the precision of your output.

- The phase increment and phase offset inputs must be integers or fixed-point data types with zero fraction length.
- You specify the number of quantized accumulator bits in the **Number of quantized accumulator bits** parameter.
- The phase quantization error word length is equal to the accumulator word length minus the number of quantized accumulator bits, and the fraction length is zero.

Examples

The NCO block is used in the GSM Digital Down Converter product example. Open this example by typing `dspddc` at the MATLAB command line.

You can also try the following example. Design an NCO source with the following specifications:

- Desired output frequency $F_0 = 510$ Hz
- Frequency resolution $\Delta f = 0.05$ Hz
- Spurious free dynamic range $SFDR \geq 90$ dB
- Sample period $T_s = 1/8000$ s
- Desired phase offset $\pi / 2$

1 Calculate the number of required accumulator bits from the equation for frequency resolution:

$$\Delta f = \frac{1}{T_s \cdot 2^N}\,\mathrm{Hz}$$
$$0.05 = \frac{1}{\frac{1}{8000} \cdot 2^N}\,\mathrm{Hz}$$
$$N = 18$$

Note that N must be an integer value. The value of N is rounded up to the nearest integer; 18 accumulator bits are needed to accommodate the value of the frequency resolution.

2 Using this best value of N, calculate the frequency resolution that will be achieved by the NCO block:

$$\Delta f = \frac{1}{T_s \cdot 2^N}\,\mathrm{Hz}$$
$$\Delta f = \frac{1}{\frac{1}{8000} \cdot 2^{18}}\ \mathrm{Hz}$$
$$\Delta f = 0.0305$$

3 Calculate the number of quantized accumulator bits from the equation for spurious free dynamic range and the fact that for a lookup table with 2^P entries, P is the number of quantized accumulator bits:

$$SFDR = (6P + 12)\,\mathrm{dB}$$
$$96\ \mathrm{dB} = (6P + 12)\ \mathrm{dB}$$
$$P = 14$$

4 Select the number of dither bits. In general, a good choice for the number of dither bits is the accumulator word length minus the number of quantized accumulator bits; in this case 4.

5 Calculate the phase increment:

$$phase\ increment = \mathrm{round}(\frac{F_0 \cdot 2^N}{F_s})$$

$$phase\ increment = \mathrm{round}(\frac{510 \cdot 2^{18}}{8000})$$

$$phase\ increment = 16712$$

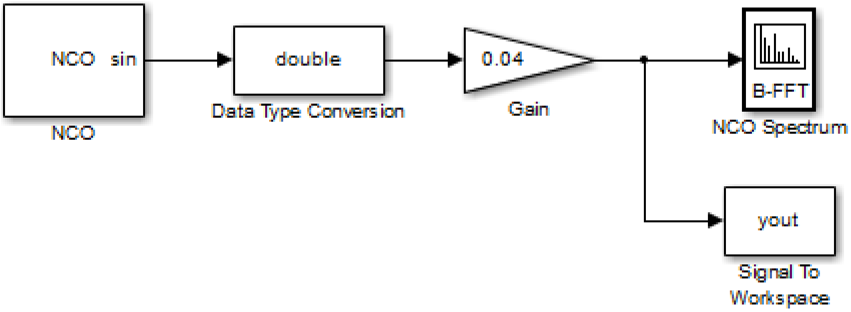
6 Calculate the phase offset:

$$phase\ offset = \frac{2^{accumulator\ word\ length} \cdot desired\ phase\ offset}{2\pi}$$

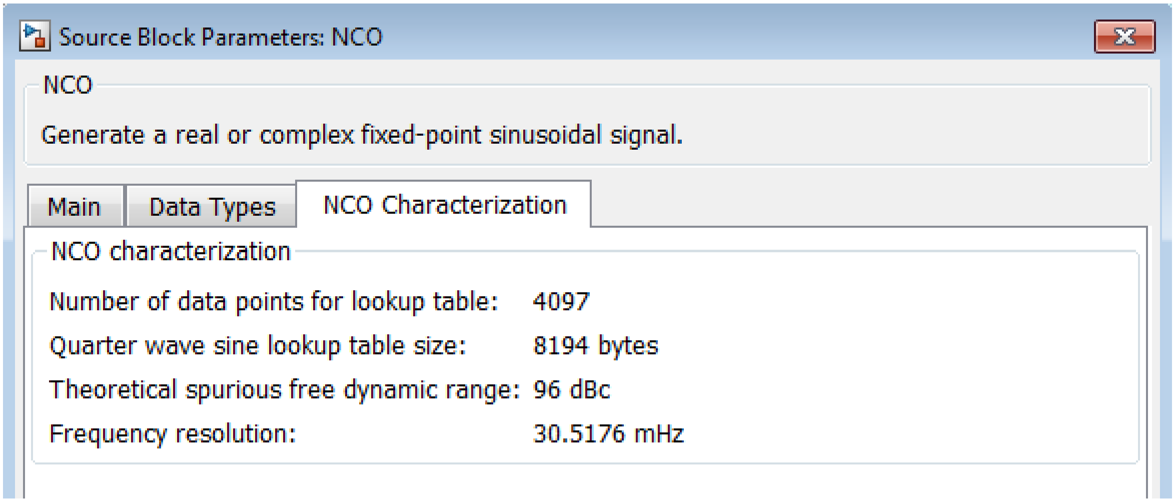
$$phase\ offset = \frac{2^{18} \cdot \frac{\pi}{2}}{2\pi}$$

$$phase\ offset = 65536$$

7 Type `ex_nco_example` at the MATLAB command line to open the following model:



The NCO block in the model is populated with the specifications and quantities you just calculated. The output word length and fraction length depend on the constraints of your hardware; this example uses a word length of 16 and a fraction length of 14. You can verify that the specifications of this problem have been met by looking at the **NCO Characterization** pane of the NCO block.



NCO

Generate a real or complex fixed-point sinusoidal signal.

NCO characterization

Number of data points for lookup table: 4097

Quarter wave sine lookup table size: 8194 bytes

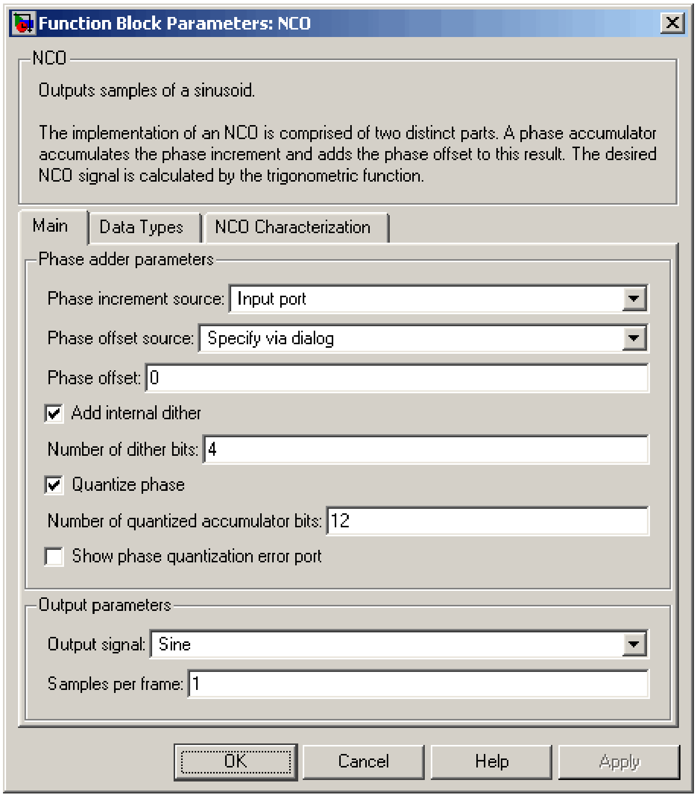
Theoretical spurious free dynamic range: 96 dBc

Frequency resolution: 30.5176 mHz

8 Experiment with the model to observe the effects on the output shown on the Spectrum Analyzer. For example, try turning dithering on and off, and try changing the number of dither bits.

Dialog Box

The **Main** pane of the NCO dialog appears as follows.



NCO

Outputs samples of a sinusoid.

The implementation of an NCO is comprised of two distinct parts. A phase accumulator accumulates the phase increment and adds the phase offset to this result. The desired NCO signal is calculated by the trigonometric function.

Phase adder parameters

Phase increment source: Input port

Phase offset source: Specify via dialog

Phase offset: 0

☑ Add internal dither

Number of dither bits: 4

☑ Quantize phase

Number of quantized accumulator bits: 12

☐ Show phase quantization error port

Output parameters

Output signal: Sine

Samples per frame: 1

Phase increment source

Choose how you specify the phase increment. The phase increment can come from an input port or from the dialog.

- If you select `Input port`, the inc port appears on the block icon.
- If you select `Specify via dialog`, the **Phase increment** parameter appears.

Phase increment

Specify the phase increment. Only integer data types, including fixed-point data types with zero fraction length, are allowed. The dimensions of the phase increment are dictated by those of the phase offset:

- When you specify the phase offset on the block dialog box, the phase increment must be a scalar or a vector with the same length as the phase offset. The block applies each element of the vector to a different channel, and therefore the vector length defines the number of output channels.

- When you specify the phase offset via an input port, the offset port treats each column of the input as an independent channel. The phase increment length must equal the number of columns in the input to the offset port.

This parameter is visible only if you set the **Phase increment source** parameter to `Specify via dialog`.

Phase offset source

Choose how you specify the phase offset. The phase offset can come from an input port or from the dialog.

- If you select `Input port`, the offset port appears on the block icon.
- If you select `Specify via dialog`, the **Phase offset** parameter appears.

When you specify the phase offset via an input port, it can be a scalar, vector, or a full matrix. The block treats each column of the input to the offset port as an independent channel. The number of channels in the phase offset must match the number of channels in the data input. For each frame of the input, the block can apply different phase offsets to each sample and channel. Only integer data types, including fixed-point data types with zero fraction length, are allowed.

Phase offset

Specify the phase offset. When you specify the phase offset using this parameter rather than via an input port, it must be a scalar or vector with the same length as the phase increment. Scalars are expanded to a vector with the same length as the phase increment. Each element of the phase offset vector is applied to a different channel of the input, and therefore the vector length defines the number of output channels. Only integer data types, including fixed-point data types with zero fraction length, are allowed.

This parameter is visible only if `Specify via dialog` is selected for the **Phase offset source** parameter.

Add internal dither

Select to add internal dithering to the NCO algorithm. Dithering is added using the PN Sequence Generator from the Communications System Toolbox™ product.

Number of dither bits

Specify the number of dither bits.

This parameter is visible only if **Add internal dither** is selected.

Quantize phase

Select to enable quantization of the accumulated phase.

Number of quantized accumulator bits

Specify the number of quantized accumulator bits. This determines the number of entries in the lookup table. The number of quantized accumulator bits must be less than the accumulator word length.

This parameter is visible only if **Quantize phase** is selected.

Show phase quantization error port

Select to output the phase quantization error. When you select this, the Qerr port appears on the block icon.

This parameter is visible only if **Quantize phase** is selected.

Output signal

Choose whether the block should output a `Sine`, `Cosine`, `Complex exponential`, or `Sine and cosine` signals. If you select `Sine and cosine`, the two signals output on different ports.

Sample time

Specify the sample time in seconds when the block is acting as a source. When either the phase increment or phase offset come in via block input ports, the sample time is inherited and this parameter is not visible.

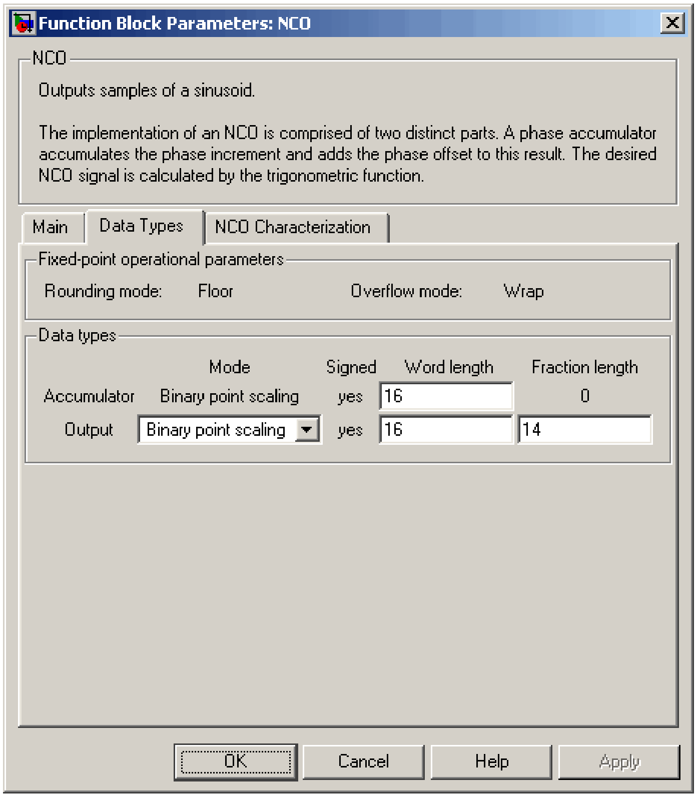
Samples per frame

Specify the number of samples per frame. When the value of this parameter is `1`, the block outputs a sample-based signal. When the value is greater than 1, the block outputs a frame-based signal of the specified size. In frame-based mode, the phase increment and phase offset can vary from channel to channel and from frame to frame, but they are constant along each channel in a given frame.

When the phase offset input port exists, it has the same frame status as any output port present. When the phase increment input port exists, it does not support frames.

This parameter is only visible if either **Phase increment source** or **Phase offset source** is set to `Specify via dialog`.

The **Data Types** pane of the NCO dialog appears as follows.



NCO

Outputs samples of a sinusoid.

The implementation of an NCO is comprised of two distinct parts. A phase accumulator accumulates the phase increment and adds the phase offset to this result. The desired NCO signal is calculated by the trigonometric function.

Fixed-point operational parameters

Rounding mode: Floor   Overflow mode: Wrap

Data types

	Mode	Signed	Word length	Fraction length
Accumulator	Binary point scaling	yes	16	0
Output	Binary point scaling	yes	16	14

Rounding mode

The “rounding mode” used for this block when inputs are fixed point is always `Floor`.

Overflow mode

The “overflow mode” used for this block when inputs are fixed point is always `Wrap`.

Accumulator

Specify the word length of the accumulator data type. The fraction length is always zero; this is an integer data type.

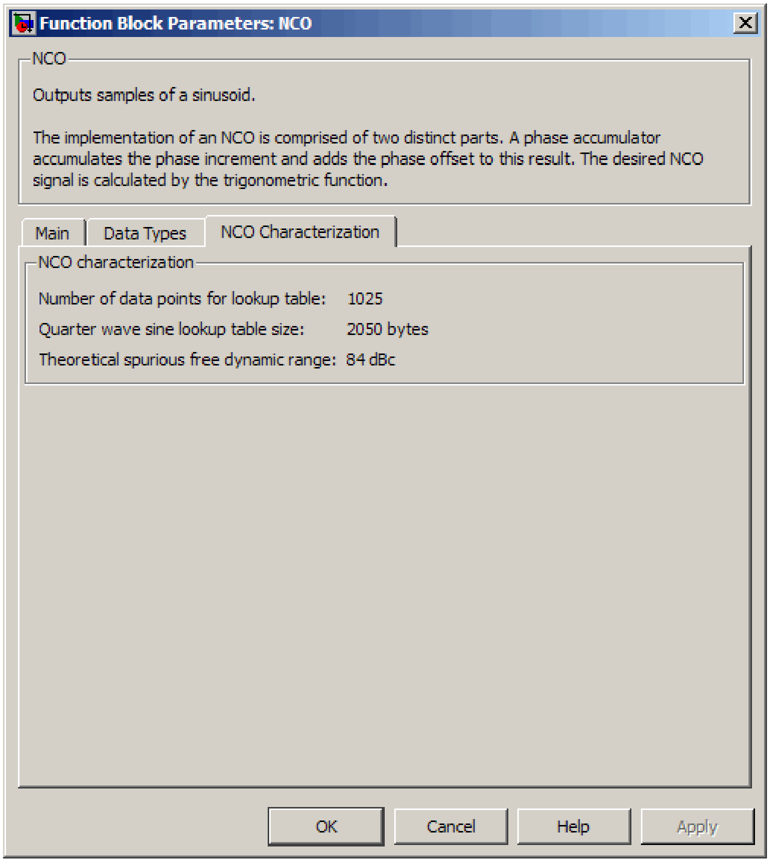
Output

Specify the output data type.

- Choose `double` or `single` for a floating-point implementation.
- When you select `Binary point scaling`, you can enter the word length and the fraction length of the output, in bits.

Note: The lookup table for this block is constructed from double-precision floating-point values. Thus, the maximum amount of precision you can achieve in your output is 53 bits. Setting the word length of the **Output** data type to values greater than 53 bits does not improve the precision of your output.

The **NCO Characterization** pane of the NCO dialog appears as follows.



Outputs samples of a sinusoid.

The implementation of an NCO is comprised of two distinct parts. A phase accumulator accumulates the phase increment and adds the phase offset to this result. The desired NCO signal is calculated by the trigonometric function.

Number of data points for lookup table: 1025

Quarter wave sine lookup table size: 2050 bytes

Theoretical spurious free dynamic range: 84 dBc

The **NCO Characterization** pane does not have any parameters. Instead, it provides you with details on the NCO signal currently being implemented by the block:

- `Number of data points for lookup table` — The lookup table is implemented as a quarter-wave sine table. The number of lookup table data points is defined by

$$2^{\text{number of quantized accumulator bits}-2}+1$$

- `Quarter wave sine lookup table size` — The quarter wave sine lookup table size is defined by

$$\frac{(\text{number of data points for lookup table})\cdot(\text{output word length})}{8}\text{ bytes}$$

- `Theoretical spurious free dynamic range` — The spurious free dynamic range (SFDR) is calculated as follows for a lookup table with 2^P entries:

$$\begin{array}{ll} SFDR=(6P)\text{ dB} & \text{without dither} \\ SFDR=(6P+12)\text{ dB} & \text{with dither} \end{array}$$

Supported Data Types

Port	Supported Data Types
inc	• Fixed point with zero fraction length • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
offset	• Fixed point with zero fraction length • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
sin	• Double-precision floating point • Single-precision floating point • Fixed point
Qerr	• 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers

NCO HDL Optimized

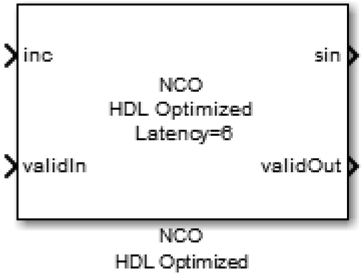
Generate real or complex sinusoidal signals—optimized for HDL code generation

Library

Signal Operations

`dspsigops`

Description

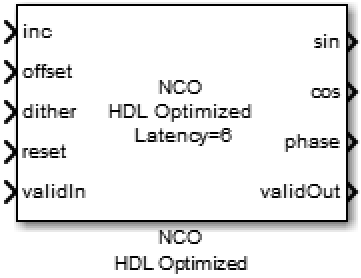


The NCO HDL Optimized block generates real or complex sinusoidal signals, while providing hardware-friendly control signals. It uses the same phase accumulation and lookup table technology as implemented in the NCO block. It provides the following features:

- A lookup table compression option to reduce the lookup table size with less than one LSB loss in precision. See “Lookup Table Algorithm” for more detail.
- An option to synthesize the lookup table to a ROM when using HDL Coder with an FPGA target. To enable this feature, right-click the block, select **HDL Code > HDL Block Properties** and set **LUTRegisterResetType** to `none`.
- An optional input port for external dither.
- An optional reset port that triggers a reset of the phase to its initial value during the sinusoid output generation.
- An optional output port for the current NCO phase.

Signal Attributes

The following image illustrates the port signals of the interface for the NCO HDL Optimized block.



The following table provides the descriptions of the port signals.

Port	Direction	Description	Data Type
`inc`	Input	Phase increment source when you select input port	Scalar integer of type int32/16/8, uint32/16/8, fixdt([],N,0)
`offset`	Input	Phase offset source when you select input port	Scalar integer of type int32/16/8, uint32/16/8, fixdt([],N,0)
`dither`	Input	Dither source when you select input port	Scalar integer of type int32/16/8, uint32/16/8, fixdt([],N,0)
`reset`	Input	Reset the accumulator to zero	Boolean
`validIn`	Input	Increment the phase when `validIn` input is high. When `validIn` is low, the phase is held.	Boolean
`Sin`	Output	Generated sine output	Double/single/signed binary point scaling
`Cos`	Output	Generated cosine output	Double/single/signed binary point scaling

Port	Direction	Description	Data Type
`phase`	Output	Current phase of NCO	fixdt(1,M,0). M is the quantized accumulator bits.
`validOut`	Output	`validOut` indicates whether the data output is valid or not. When `validOut` is high, the data output is valid. When `validOut` is low, the data output is not valid.	Boolean

Function Block Parameters: NCO HDL Optimized

NCO HDL Optimized

Generate real or complex sinusoidal signals

Algorithm parameters

Phase increment source: Input port

Phase offset source: Property

Phase offset: 0

Dither source: Property

Number of dither bits: 4

☑ Quantize phase

Number of quantizer accumulator bits: 12

☐ Enable look up table compression method

☐ Enable reset input port

Output parameters

Type of output signal: Sine

☐ Show phase port

Simulate using: Code generation

Phase increment source

Defines how you specify the phase increment. You can set the phase increment with an input port or you can enter a value in the dialog box. The default value is `Input` port. If you select Property, the **Phase increment** parameter appears in the dialog box.

Phase increment

Specify the phase increment. The default value is 100. This value is scalar.

This parameter is visible when you set **Phase increment source** to Property.

Phase offset source

Defines how you specify the phase offset. You can set the phase offset from an input port or from the dialog box. The default value is Property. If you select Input port, the offset port appears on the block icon.

Phase offset

Specify the phase offset. The default value is 0. This value is scalar. You can use integer data types, including fixed-point data types with zero fraction length.

This parameter is visible when you set **Phase offset source** to Property.

Dither source

Defines how you specify the dither. The default value is Property. You can set the dither from an input port or from the dialog box. If you select Property, the **Number of dither bits** parameter appears in the dialog box. If you select Input port, a port appears on the block. If you select None , the block does not add dither.

Number of dither bits

Specify the dither bits. The default value is 4. This value must be a positive integer.

This option is visible when you set **Dither source** to Property.

Quantize phase

Select to enable quantization of the accumulated phase. The default value is selected.

When you select **Quantize phase**, the **Number of quantizer accumulator bits** parameter appears.

Number of quantizer accumulator bits

Specify the number of quantized accumulator bits. The default value is 12. This parameter determines the number of entries needed in the lookup table of sine values. The number of quantized accumulator bits must be less than the accumulator word length.

This parameter is visible only if you select **Quantize phase**.

Enable lookup table compression method

Compress the lookup table when selected. The default value is not selected.

Enable reset input port

Reset the accumulator to 0 when selected. The default value is not selected.

Type of output signal

Choose whether the block output is `Sine`, `Cosine`, `Complex exponential`, or `Sine and cosine` signals. If you select complex exponential, the output is of the form `sine + j*cosine`. If you select `Sine and cosine`, the sine and cosine values are sent out on different ports. The default is `Sine`.

Show phase port

Output the current phase when selected. The default is not selected.

Simulate using

Type of simulation to run. This parameter does not affect generated HDL code.

- `Code generation` (default)

  Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than `Interpreted execution`.

- `Interpreted execution`

  Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than `Code generation`.

Word length: 16

Fraction length: 14

Rounding Mode

The "rounding mode" when inputs are fixed point is `Floor`.

Overflow Mode

The "overflow mode" when inputs are fixed point is `Wrap`.

(Accumulator) **Data Type**

The output data type is `Binary point scaling`.

(Accumulator) **Signed**

The accumulator data type is signed.

(Accumulator) **Word length**

Accumulator word length. Default value is 16.

(Accumulator) **Fraction length**

Accumulator fraction length. Value is 0.

(Output) **Data Type**

Select `double`, `single`, or `Binary point scaling`. The default is `Binary point scaling`.

If you select `Binary point scaling`, the parameters for output word length and fraction length appear. All output data types are signed.

(Output) **Signed**

All output data types are signed.

(Output) **Word length**

Output word length. Default value is 16.

(Output) **Fraction length**

Output fraction length. Default value is 14.

Algorithms

Lookup Table Algorithm

When you select lookup table (LUT) compression, the NCO HDL Optimized block applies the Sunderland compression method. Sunderland techniques use trigonometric identities to divide each phase of the quarter sine wave into three components and express it as:

$$\sin(A+B+C) = \sin(A+B)\cos C + \cos A \cos B \cos C - \sin A \sin B \sin C$$

If the phase has 12 bits, the components are defined as:

- A , the four most significant bits

$$(0 \le A \le \frac{\pi}{2})$$

- B, the following four bits

$$(0 \le B \le \frac{\pi}{2} \times 2^{-4})$$

- C, the four least significant bits

$$(0 \le C \le \frac{\pi}{2} \times 2^{-8})$$

Because C is small enough that sin(C)#1 and cos(C)#0 , the equation is approximated by:

$$\sin(A+B+C) \approx \sin(A+B) + \cos A \sin C$$

The NCO HDL Optimized block implements this equation with one LUT for sin(A+B) and one LUT for cos(A)sin(C). The second term is a fine correction factor that you can truncate to fewer bits without losing precision. With the default accumulator size of 16 bits, and the example phase width of 12 bits, the LUTs use only 2^8×16 plus 2^8×4 bits (5kb). A quarter sine lookup table would use 2^{12}×16 bits (65kb). This approximation is accurate within 1 LSB which gives an SNR of at least 60 dB on the output. See L. Cordesses, "Direct Digital Synthesis: A Tool for Periodic Wave Generation (Part 1)", IEEE Signal Processing Magazine, DSP Tips & Tricks column, pp. 50–54, Vol. 21, No. 4 July 2004.

Control Signals

There are two input control signals, `reset` and `validIn`, and one output control signal, `validOut`. When `reset` is high, the block sets the phase accumulator to zero. When `validIn` is high, the block increments the phase. When `validIn` is low, the block stops the phase accumulator and holds its state. When `validOut` is high, the output is valid.

Latency

The latency of the NCO HDL Optimized block is 6 cycles.

HDL Code Generation

This block supports HDL code generation using HDL Coder. HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic. For more information on implementations, properties, and restrictions for HDL code generation, see NCO HDL Optimized in the HDL Coder documentation.

Normalization

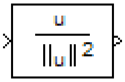
Perform vector normalization along rows, columns, or specified dimension

Library

Math Functions / Math Operations

`dspmathops`

Description



The Normalization block independently normalizes each row, column, or vector of the specified dimension of the input. The block accepts both fixed- and floating-point signals in the squared 2-norm mode, but only floating-point signals in the 2-norm mode. The output always has the same dimensions as the input.

This block treats an arbitrarily dimensioned input *U* as a collection of vectors oriented along the specified dimension. The block normalizes these vectors by either their norm or the square of their norm.

For example, consider a 3-dimensional input *U(i,j,k)* and assume that you want to normalize along the second dimension. First, define the 2-dimensional intermediate quantity *V(i,k)* such that each element of *V* is the norm of one of the vectors in *U*:

$$V(i,k) = \left(\sum_{j=1}^{J} U^2(i,j,k) \right)^{1/2}$$

Given *V*, the output of the block *Y(i, j,k)* in 2-norm mode is

$$Y(i,j,k) = \frac{U(i,j,k)}{V(i,k)+b}$$

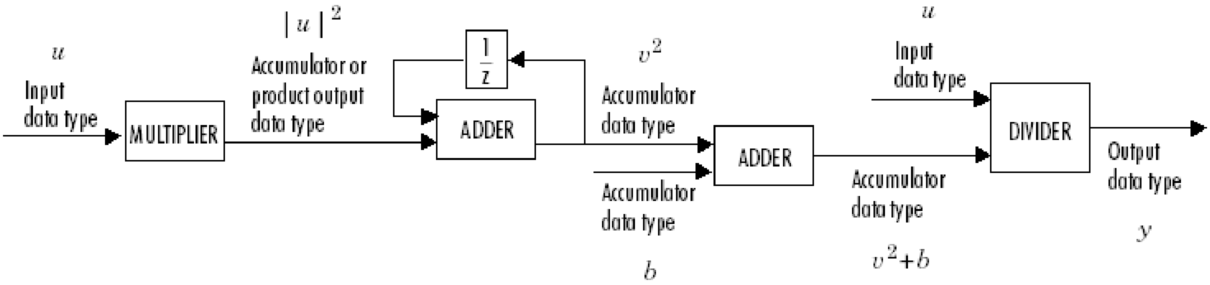
In squared 2-norm mode, the block output is

$$Y(i,j,k) = \frac{U(i,j,k)}{V(i,k)^2 + b}$$

The normalization bias, b, is typically chosen to be a small positive constant (for example, 1e-10) that prevents potential division by zero.

Fixed-Point Data Types

The following diagram shows the data types used within the Normalization block for fixed-point signals (squared 2-norm mode only).



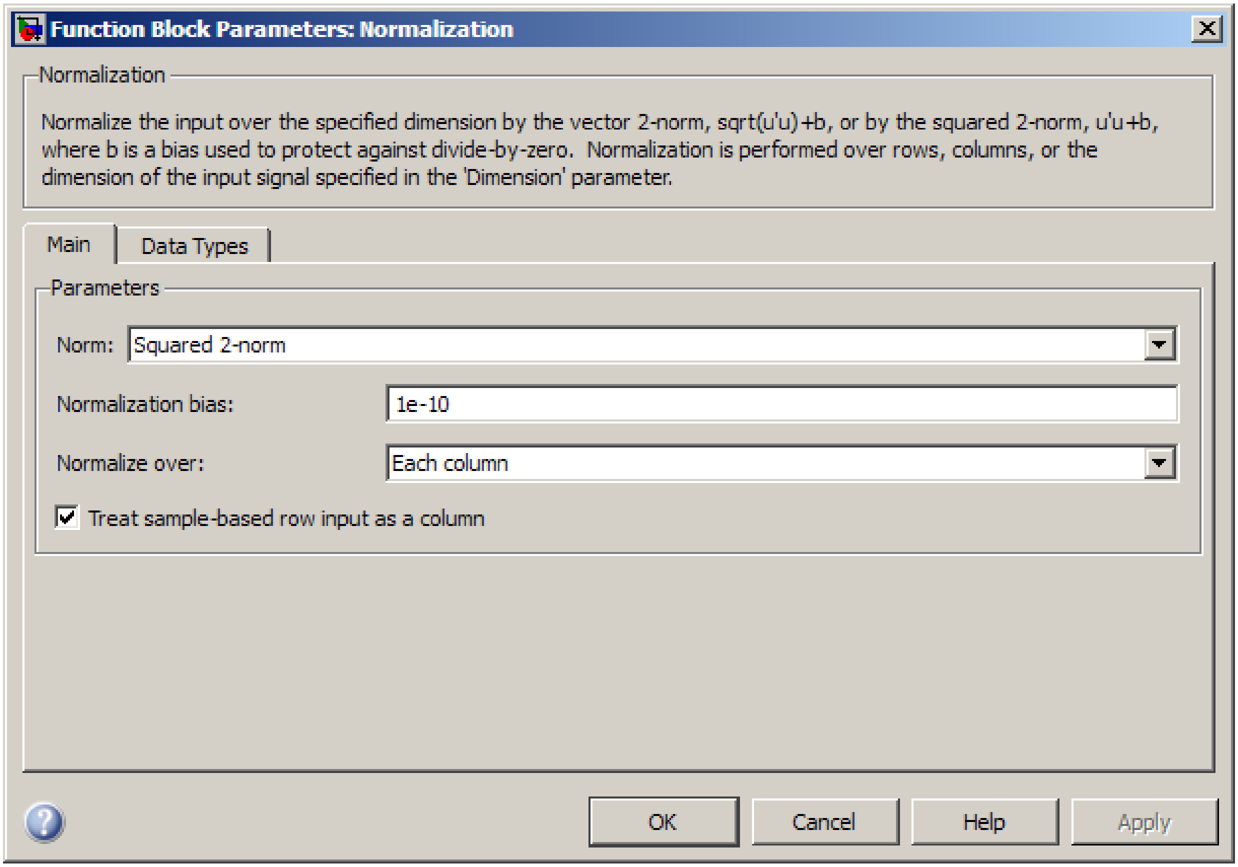
The output of the multiplier is in the product output data type when the input is real. When the input is complex, the result of the multiplication is in the accumulator data type. For details on the complex multiplication performed, see “Multiplication Data Types”. You can set the accumulator, product output, and output data types in the block dialog as discussed in “Dialog Box” on page 1-1061.

Examples

See “Zero Algorithmic Delay” in the *DSP System Toolbox User's Guide* for an example.

Dialog Box

The **Main** pane of the Normalization dialog appears as follows.



Function Block Parameters: Normalization

Normalization

Normalize the input over the specified dimension by the vector 2-norm, sqrt(u'u)+b, or by the squared 2-norm, u'u+b, where b is a bias used to protect against divide-by-zero. Normalization is performed over rows, columns, or the dimension of the input signal specified in the 'Dimension' parameter.

Parameters

Norm: Squared 2-norm

Normalization bias: 1e-10

Normalize over: Each column

☑ Treat sample-based row input as a column

Norm

Specify the type of normalization to perform, `2-norm` or `Squared 2-norm`. `2-norm` mode supports floating-point signals only. `Squared 2-norm` supports both fixed-point and floating-point signals.

Normalization bias

Specify the real value *b* to be added in the denominator to avoid division by zero. "Tunable".

Normalize over

Specify whether to normalize along rows, columns, or the dimension specified in the **Dimension** parameter.

Dimension

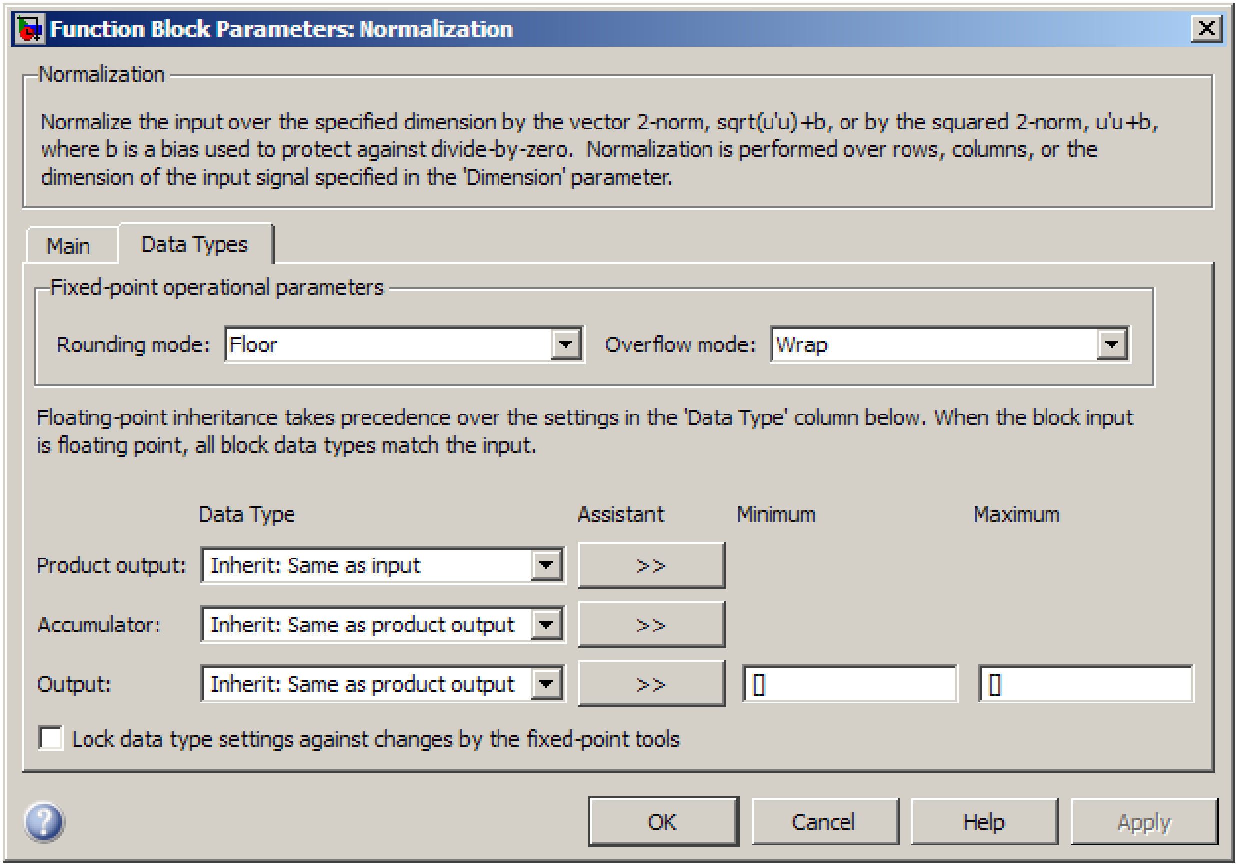
Specify the one-based value of the dimension over which to normalize. The value of this parameter cannot exceed the number of dimensions in the input signal. This parameter is only visible if `Specified dimension` is selected for the **Normalize over** parameter.

Treat sample-based row input as a column

Select to treat a sample-based row input as a column.

Note: This check box will be removed in a future release. See "Sample-Based Row Vector Processing Changes" for more information.

The **Data Types** pane of the Normalization dialog appears as follows.



Function Block Parameters: Normalization

Normalization

Normalize the input over the specified dimension by the vector 2-norm, sqrt(u'u)+b, or by the squared 2-norm, u'u+b, where b is a bias used to protect against divide-by-zero. Normalization is performed over rows, columns, or the dimension of the input signal specified in the 'Dimension' parameter.

Fixed-point operational parameters

Rounding mode: Floor

Overflow mode: Wrap

Floating-point inheritance takes precedence over the settings in the 'Data Type' column below. When the block input is floating point, all block data types match the input.

	Data Type	Assistant	Minimum	Maximum
Product output:	Inherit: Same as input	>>		
Accumulator:	Inherit: Same as product output	>>		
Output:	Inherit: Same as product output	>>	[]	[]

□ Lock data type settings against changes by the fixed-point tools

Note The parameters on this pane are only applicable to fixed-point signals when the block is in squared 2-norm mode. See “Fixed-Point Data Types” on page 1-1061 for a diagram of how the product output, accumulator, and output data types are used in this case.

Rounding mode

Select the “rounding mode” for fixed-point operations.

Overflow mode

Select the “overflow mode” for fixed-point operations.

Product output data type

Specify the product output data type. See “Fixed-Point Data Types” on page 1-1061 and “Multiplication Data Types” for illustrations depicting the use of the product output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as input`
- An expression that evaluates to a valid data type, for example, `fixdt([],16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Product output data type** parameter.

See “Specify Data Types Using Data Type Assistant” in “Simulink User's Guide” for more information.

Accumulator data type

Specify the accumulator data type. See “Fixed-Point Data Types” on page 1-1061 for illustrations depicting the use of the accumulator data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Same as product output`
- An expression that evaluates to a valid data type, for example, `fixdt([],16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Accumulator data type** parameter.

See “Specify Data Types Using Data Type Assistant” in “Simulink User's Guide” for more information.

Output data type

Specify the output data type. See “Fixed-Point Data Types” on page 1-1061 for illustrations depicting the use of the output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as product output`
- An expression that evaluates to a valid data type, for example, `fixdt([],16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Specify Block Output Data Types” in “Simulink User's Guide” for more information.

Minimum

Specify the minimum value that the block should output. The default value is `[ ]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges”)
- Automatic scaling of fixed-point data types

Maximum

Specify the maximum value that the block should output. The default value is `[ ]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges”)
- Automatic scaling of fixed-point data types

Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Output	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers

Nyquist Filter

Design Nyquist filter

Library

Filtering / Filter Designs

`dspfdesign`

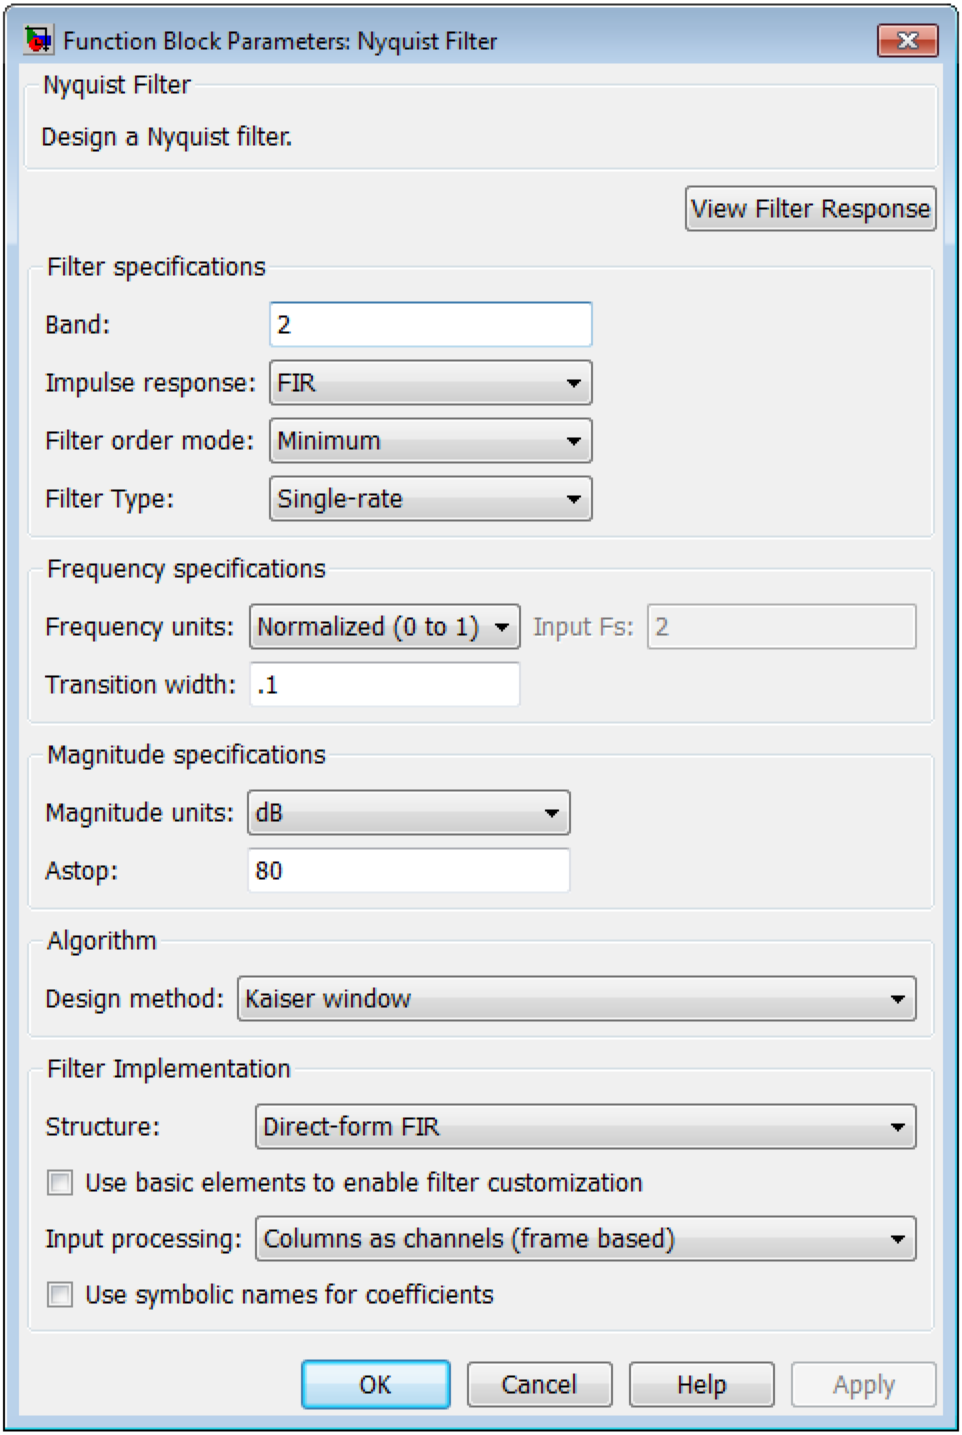
Description

This block brings the filter design capabilities of the “`filterbuilder`” function to the Simulink environment.

Dialog Box

See “Nyquist Filter Design Dialog Box — Main Pane” for more information about the parameters of this block. The **Data Types** and **Code Generation** panes are not available for blocks in the DSP System Toolbox Filter Designs library.

Parameters of this block that do not change filter order or structure are tunable.



Function Block Parameters: Nyquist Filter

Nyquist Filter

Design a Nyquist filter.

Filter specifications

Band: 2

Impulse response: FIR

Filter order mode: Minimum

Filter Type: Single-rate

Frequency specifications

Frequency units: Normalized (0 to 1)

Input Fs: 2

Transition width: .1

Magnitude specifications

Magnitude units: dB

Astop: 80

Algorithm

Design method: Kaiser window

Filter Implementation

Structure: Direct-form FIR

□ Use basic elements to enable filter customization

Input processing: Columns as channels (frame based)

□ Use symbolic names for coefficients

View filter response

This button opens the Filter Visualization Tool (`fvtool`) from the Signal Processing Toolbox product. You can use the tool to display:

- Magnitude response, phase response, and group delay in the frequency domain.
- Impulse response and step response in the time domain.
- Pole-zero information.

The tool also helps you evaluate filter performance by providing information about filter order, stability, and phase linearity. For more information on FVTool, see the Signal Processing Toolbox documentation.

Filter Specifications

In this group, you specify your filter format, such as the impulse response and the filter order.

Band

Specifies the location of the center of the transition region between the passband and the stopband. The center of the transition region, F_c, is calculated using the value for **Band**:

$F_c = F_s/(2 \cdot \textbf{Band})$.

The default value, `2`, corresponds to a halfband filter.

Impulse response

Select either `FIR` or `IIR` from the drop-down list. `FIR` is the default. When you choose an impulse response, the design methods and structures you can use to implement your filter change accordingly. These options are both available only when **Band** is `2`. For values of **Band** greater than `2`, only FIR designs are supported.

Note: The design methods and structures for FIR filters are not the same as the methods and structures for IIR filters.

Filter order mode

Select either `Minimum` (the default) or `Specify` from the drop-down list. Selecting `Specify` enables the **Order** option (see the following sections) so you can enter the filter order.

Filter type

Select `Single-rate`, `Decimator`, `Interpolator`, or `Sample-rate converter`. Your choice determines the type of filter as well as the design methods and structures that are available to implement your filter. By default, the block specifies a single-rate filter.

- Selecting `Decimator` or `Interpolator` activates the **Decimation Factor** or the **Interpolation Factor** options respectively.
- Selecting `Sample-rate converter` activates both factors.

Order

Enter the filter order. This option is enabled only if `Specify` was selected for **Filter order mode**.

Decimation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to `Decimator` or `Sample-rate converter`. The default value is 2.

Interpolation Factor

Enter the interpolation factor. This option is enabled only if the **Filter type** is set to `Interpolator` or `Sample-rate converter`. The default value is 2.

Frequency Specifications

The parameters in this group allow you to specify your filter response curve.

Frequency constraints

Select the filter features that the block uses to define the frequency response characteristics.

Frequency units

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select `Normalized (0–1)` to enter frequencies in normalized form. This behavior is the default. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—`Hz`, `kHz`, `MHz`, or `GHz`. Selecting one of the unit options enables the **Input Fs** parameter.

Input Fs

Fs, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available when you select one of the frequency options from the **Frequency units** list.

Transition width

Specify the width of the transition between the end of the passband and the edge of the stopband. Specify the value in normalized frequency units or the absolute units you select in **Frequency units**.

Magnitude Specifications

Parameters in this group specify the filter response in the passbands and stopbands.

Magnitude units

Specify the units for any parameter you provide in magnitude specifications. From the drop-down list, select one of the following options:

- `Linear` — Specify the magnitude in linear units.
- `dB` — Specify the magnitude in decibels (default)
- `Squared` — Specify the magnitude in squared units.

Astop

Enter the filter attenuation in the stopband in the units you choose for **Magnitude units**, either linear or decibels.

Algorithm

The parameters in this group allow you to specify the design method and structure of your filter.

Design Method

Lists the design methods available for the frequency and magnitude specifications you entered. When you change the specifications for a filter, such as changing the impulse response, the methods available to design filters changes as well. The default IIR design method is `Butterworth`, and the default FIR method is `Kaiser window`.

Scale SOS filter coefficients to reduce chance of overflow

Selecting this parameter directs the design to scale the filter coefficients to reduce the chances that the inputs or calculations in the filter overflow and exceed the representable range of the filter. Clearing this option removes the scaling. This parameter applies only to IIR filters.

Design Options

The options for each design are specific for each design method. This section does not present all of the available options for all designs and design methods. There are many more that you encounter as you select different design methods and filter specifications. The following options represent some of the most common ones available.

Density factor

Density factor controls the density of the frequency grid over which the design method optimization evaluates your filter response function. The number of equally spaced points in the grid is the value you enter for **Density factor** times (filter order + 1).

Increasing the value creates a filter that more closely approximates an ideal equiripple filter but increases the time required to design the filter. The default value of 20 represents a reasonable trade between the accurate approximation to the ideal filter and the time to design the filter.

Minimum order

When you select this parameter, the design method determines and design the minimum order filter to meet your specifications. Some filters do not provide this parameter. Select `Any`, `Even`, or `Odd` from the drop-down list to direct the design to be any minimum order, or minimum even order, or minimum odd order.

Stopband Shape

Stopband shape lets you specify how the stopband changes with increasing frequency. Choose one of the following options:

- `Flat` — Specifies that the stopband is flat. The attenuation does not change as the frequency increases.
- `Linear` — Specifies that the stopband attenuation changes linearly as the frequency increases. Change the slope of the stopband by setting **Stopband decay**.

Stopband Decay

When you set Stopband shape, Stopband decay specifies the amount of decay applied to the stopband. the following conditions apply to Stopband decay based on the value of Stopband Shape:

- When you set **Stopband shape** to `Flat`, **Stopband decay** has no affect on the stopband.
- When you set **Stopband shape** to `Linear`, enter the slope of the stopband in units of dB/rad/s. The block applies that slope to the stopband.
- When you set **Stopband shape** to `1/f`, enter a value for the exponent *n* in the relation $(1/f)^n$ to define the stopband decay. The block applies the $(1/f)^n$ relation to the stopband to result in an exponentially decreasing stopband attenuation.

Filter Implementation

Structure

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter.

Use basic elements to enable filter customization

Select this check box to implement the filter as a subsystem of basic Simulink blocks. Clear the check box to implement the filter as a high-level subsystem. By default, this check box is cleared.

The high-level implementation provides better compatibility across various filter structures, especially filters that would contain algebraic loops when constructed using basic elements. On the other hand, using basic elements enables the following optimization parameters:

- **Optimize for zero gains** — Terminate chains that contain Gain blocks with a gain of zero.
- **Optimize for unit gains** — Remove Gain blocks that scale by a factor of one.
- **Optimize for delay chains** — Substitute delay chains made up of *n* unit delays with a single delay by *n*.
- **Optimize for negative gains** — Use subtraction in Sum blocks instead of negative gains in Gain blocks.

Input processing

Specify how the block should process the input. The available options may vary depending on he settings of the **Filter Structure** and **Use basic elements for filter customization** parameters. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` — When you select this option, the block treats each column of the input as a separate channel.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

Note: The `Inherited (this choice will be removed — see release notes)` option will be removed in a future release. See “Frame-Based Processing” in the *DSP System Toolbox Release Notes* for more information.

Rate options

When the **Filter type** parameter specifies a multirate filter, select the rate processing rule for the block from following options:

- `Enforce single-rate processing` — When you select this option, the block maintains the sample rate of the input.
- `Allow multirate processing` — When you select this option, the block adjusts the rate at the output to accommodate an increased or reduced number of samples. To select this option, you must set the **Input processing** parameter to `Elements as channels (sample based)`.

Use symbolic names for coefficients

Select this check box to enable the specification of coefficients using MATLAB variables. The available coefficient names differ depending on the filter structure. Using symbolic names allows tuning of filter coefficients in generated code. By default, this check box is cleared.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point
Output	• Double-precision floating point • Single-precision floating point

Octave Filter

Design octave filter

Library

Filtering / Filter Designs

`dspfdesign`

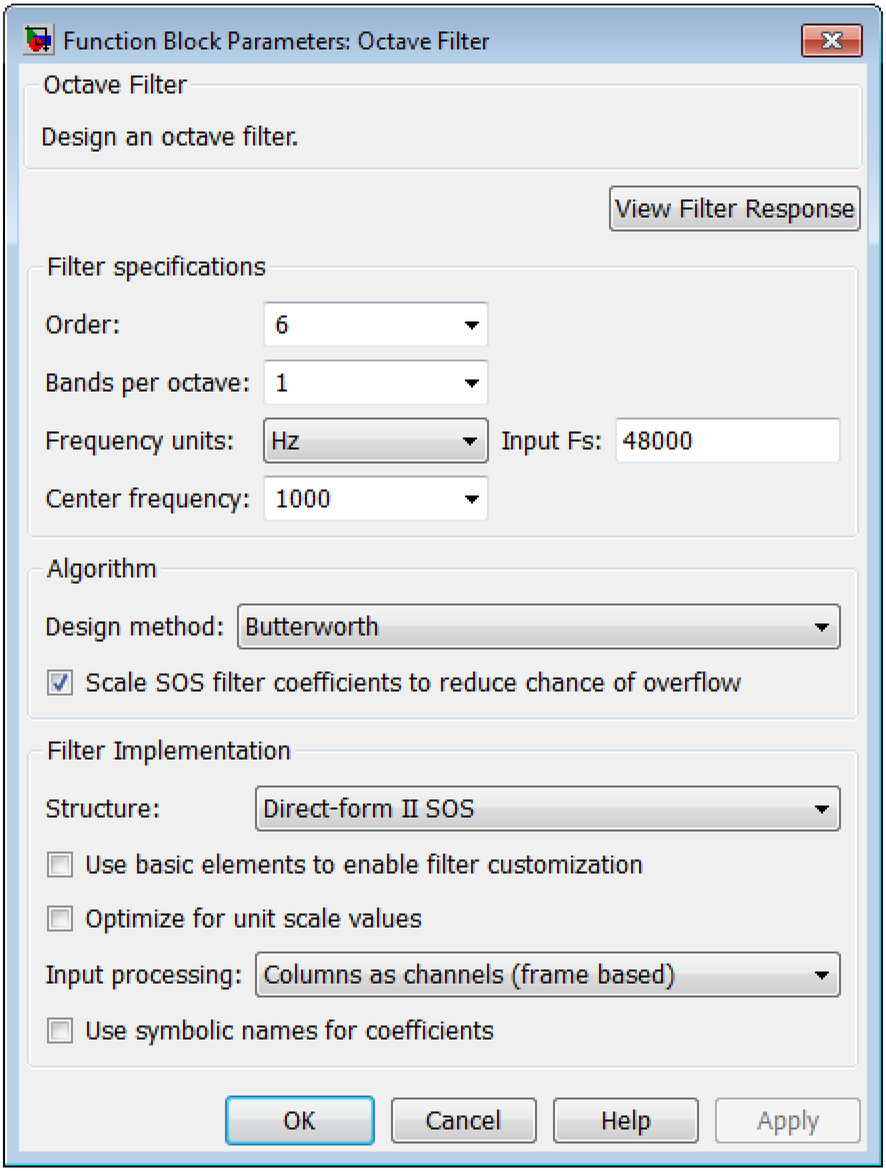
Description

This block brings the filter design capabilities of the “`filterbuilder`” function to the Simulink environment.

Dialog Box

See “Octave Filter Design Dialog Box — Main Pane” for more information about the parameters of this block. The **Data Types** and **Code Generation** panes are not available for blocks in the DSP System Toolbox Filter Designs library.

Parameters of this block that do not change filter order or structure are tunable.



Function Block Parameters: Octave Filter

Octave Filter

Design an octave filter.

Filter specifications

Order: 6

Bands per octave: 1

Frequency units: Hz   Input Fs: 48000

Center frequency: 1000

Algorithm

Design method: Butterworth

☑ Scale SOS filter coefficients to reduce chance of overflow

Filter Implementation

Structure: Direct-form II SOS

□ Use basic elements to enable filter customization

□ Optimize for unit scale values

Input processing: Columns as channels (frame based)

□ Use symbolic names for coefficients

View filter response

This button opens the Filter Visualization Tool (`fvtool`) from the Signal Processing Toolbox product. You can use the tool to display:

- Magnitude response, phase response, and group delay in the frequency domain.
- Impulse response and step response in the time domain.
- Pole-zero information.

The tool also helps you evaluate filter performance by providing information about filter order, stability, and phase linearity. For more information on FVTool, see the Signal Processing Toolbox documentation.

Filter Specifications

Order

Specify filter order. Possible values are: `4, 6, 8, 10`.

Bands per octave

Specify the number of bands per octave. Possible values are: `1, 3, 6, 12, 24`.

Frequency units

Specify frequency units as `Hz` or `kHz`.

Input Fs

Specify the input sampling frequency in the frequency units specified previously.

Center Frequency

Select from the drop-down list of available center frequency values.

Algorithm

Design Method

Butterworth is the design method used for this type of filter.

Scale SOS filter coefficients to reduce chance of overflow

Select the check box to scale the filter coefficients.

Filter Implementation

Structure

Specify filter structure. Choose from:

- Direct-form I SOS
- Direct-form II SOS
- Direct-form I transposed SOS
- Direct-form II transposed SOS

Use basic elements to enable filter customization

Select this check box to implement the filter as a subsystem of basic Simulink blocks. Clear the check box to implement the filter as a high-level subsystem. By default, this check box is cleared.

The high-level implementation provides better compatibility across various filter structures, especially filters that would contain algebraic loops when constructed using basic elements. On the other hand, using basic elements enables the following optimization parameters:

- **Optimize for zero gains** — Terminate chains that contain Gain blocks with a gain of zero.
- **Optimize for unit gains** — Remove Gain blocks that scale by a factor of one.
- **Optimize for delay chains** — Substitute delay chains made up of *n* unit delays with a single delay by *n*.
- **Optimize for negative gains** — Use subtraction in Sum blocks instead of negative gains in Gain blocks.

Optimize for unit-scale values

Select this check box to scale unit gains between sections in SOS filters. This parameter is available only for SOS filters.

Input processing

Specify how the block should process the input. The available options may vary depending on he settings of the **Filter Structure** and **Use basic elements for filter customization** parameters. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` — When you select this option, the block treats each column of the input as a separate channel.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

Note: The `Inherited (this choice will be removed — see release notes)` option will be removed in a future release. See "Frame-Based Processing" in the *DSP System Toolbox Release Notes* for more information.

Rate options

When the **Filter type** parameter specifies a multirate filter, select the rate processing rule for the block from following options:

- `Enforce single-rate processing` — When you select this option, the block maintains the sample rate of the input.
- `Allow multirate processing` — When you select this option, the block adjusts the rate at the output to accommodate an increased or reduced number of samples. To select this option, you must set the **Input processing** parameter to `Elements as channels (sample based)`.

Use symbolic names for coefficients

Select this check box to enable the specification of coefficients using MATLAB variables. The available coefficient names differ depending on the filter structure. Using symbolic names allows tuning of filter coefficients in generated code. By default, this check box is cleared.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point
Output	• Double-precision floating point • Single-precision floating point

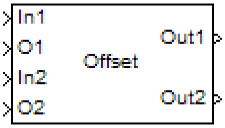
Offset

Truncate vectors by removing or keeping beginning or ending values

Library

Signal Operations

`dspsigops`



Description

The Offset block removes or keeps values from the beginning or end of the input vectors. You specify the length of the output vectors using the **Output port length** parameter. The inputs to the In ports (In1, In2, ...) can be scalars or vectors, but they must be the same size and data type. The offset values are the inputs to the O ports (O1, O2, ...); they must be scalar values with the same data type. These offset values should be integer values because they determine the number of values the block discards or retains from each input vector. The block rounds any offset value that is a noninteger value to the nearest integer value. There is one output port for each pair of In and O ports.

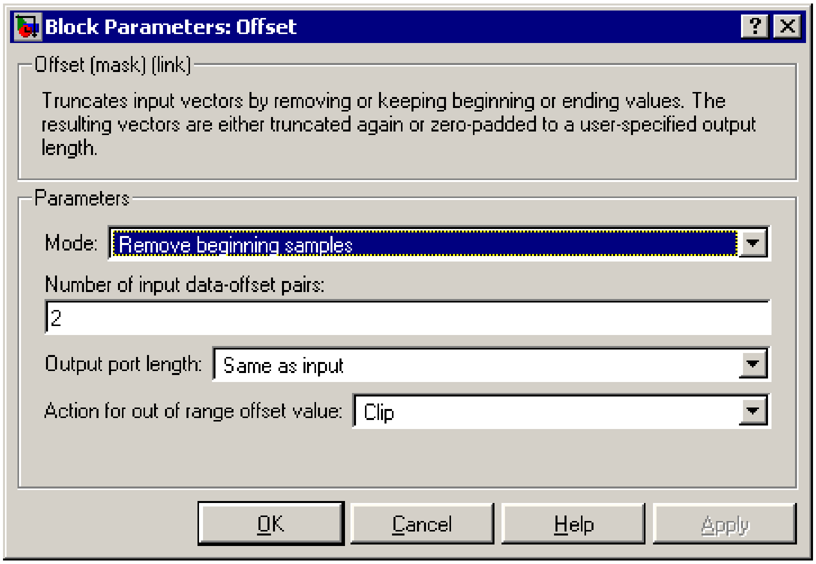
Use the **Mode** parameter to determine which values the block discards or retains from the input vector. To discard the initial values of the vector, select `Remove beginning samples`. To discard the final values of the vector, select `Remove ending samples`. To retain the initial values of the vector, select `Keep beginning samples`. To retain the final values of a vector, select `Keep ending` samples.

Use the **Number of input data-offset pairs** parameter to specify the number of inputs to the block. The number of input ports is twice the scalar value you enter. For example, if you enter `3`, ports In1, O1, In2, O2, In3, and O3 appear on the block.

The block uses the **Output port length** parameter to determine the length of the output vectors. If you select `Same as input`, the block outputs vectors that are the same length as the input to the In ports. If you select `User-defined`, the **Output length** parameter appears. Enter a scalar that represents the desired length of the output vectors. If your desired output length is greater than the number of values you extracted from your input vector, the block zero-pads the end of the vector to reach the length you specified.

Use the **Action for out of range offset value** parameter to determine how the block behaves when an offset value is not in the range 0 ≤ offset value ≤ *N*, where *N* is the input vector length. Select `Clip` if you want any offset values less than 0 to be set to 0 and any offset values greater than *N* to be set to *N*. Select `Clip and warn` if you want to be warned when any offset values less than 0 are set to 0 and any offset values greater than *N* are set to *N*. Select `Error` if you want the simulation to stop and display an error when the offset values are out of range.

Dialog Box



Block Parameters: Offset

Offset (mask) (link)

Truncates input vectors by removing or keeping beginning or ending values. The resulting vectors are either truncated again or zero-padded to a user-specified output length.

Parameters

Mode: Remove beginning samples

Number of input data-offset pairs: 2

Output port length: Same as input

Action for out of range offset value: Clip

Mode

Use this parameter to determine which values the block discards or retains from the input vector. Your choices are `Remove beginning samples`, `Remove ending samples`, `Keep beginning samples`, and `Keep ending samples`.

Number of input data-offset pairs

Specify the number of inputs to the block. The number of input ports is twice the scalar value you enter.

Output port length

Use this parameter to specify the length of the output vectors. If you select `Same as input`, the output vectors are the same length as the input vectors. If you select `User-defined`, you can enter the desired length of the output vectors.

Output length

Enter a scalar that represents the desired length of the output vectors. This parameter is visible if, for the **Output port length** parameter, you select `User-defined`.

Action for out of range offset value

Use this parameter to determine how the block behaves when an offset value is not in the range such that 0 ≤ offset value ≤ *N*, where *N* is the input vector length. When you want any offset values less than 0 to be set to 0 and any offset values greater than *N* to be set to *N*, select `Clip`. When you want to be warned when any offset values less than 0 are set to 0 and any offset values greater than *N* are set to *N*, select `Clip and warn`. When you want the simulation to stop and display an error when the offset values are out of range, select `Error`.

Supported Data Types

Port	Supported Data Types
In	• Double-precision floating point • Single-precision floating point • Fixed point (signed only) • 8-, 16-, and 32-bit signed integers
O	• Double-precision floating point • Single-precision floating point • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Out	• Double-precision floating point • Single-precision floating point • Fixed point (signed only) • 8-, 16-, and 32-bit signed integers

Overlap-Add FFT Filter

Implement overlap-add method of frequency-domain filtering

Library

Filtering / Filter Implementations

`dsparch4`

Description

The Overlap-Add FFT Filter block uses an FFT to implement the *overlap-add method*, a technique that combines successive frequency-domain filtered sections of an input sequence.

The block accepts vector or matrix inputs, and treats each column of the input as an individual channel. The block unbuffers the input data into row vectors such that the length of the output vector is equal to the number of channels in the input. The data output rate of the block is M times faster than its data input rate, where M is the length of the columns in the input (frame-size).

The block breaks the scalar input sequence `u`, of length `nu`, into length-`L` nonoverlapping data sections,

which it linearly convolves with the filter's FIR coefficients,

$$H(z) = B(z) = b_1 + b_2 z^{-1} + \ldots + b_{n+1} z^{-n}$$

The numerator coefficients for H(z) are specified as a vector by the **FIR coefficients** parameter. The coefficient vector, `b = [b(1) b(2) ... b(n+1)]`, can be generated by one of the filter design functions in the Signal Processing Toolbox product, such as fir1. All filter states are internally initialized to zero.

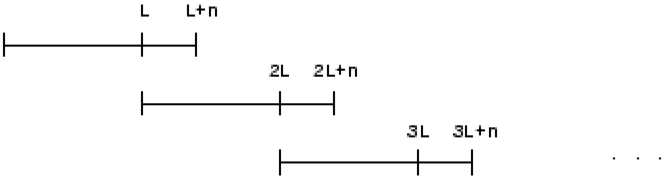
When either the filter coefficients or the inputs to the block are complex, the **Output** parameter should be set to Complex. Otherwise, the default **Output** setting, Real, instructs the block to take only the real part of the solution.

The block's overlap-add operation is equivalent to

```
y = ifft(fft(u(i:i+L-1),nfft) .* fft(b,nfft))
```

where you specify nfft in the **FFT size** parameter as a power-of-two value greater (typically *much* greater) than n+1. Values for **FFT size** that are not powers of two are rounded upwards to the nearest power-of-two value to obtain nfft.

The block overlaps successive output sections by n points and sums them.



The first L samples of each summation are output in sequence. The block chooses the parameter L based on the filter order and the FFT size.

```
L = nfft - n
```

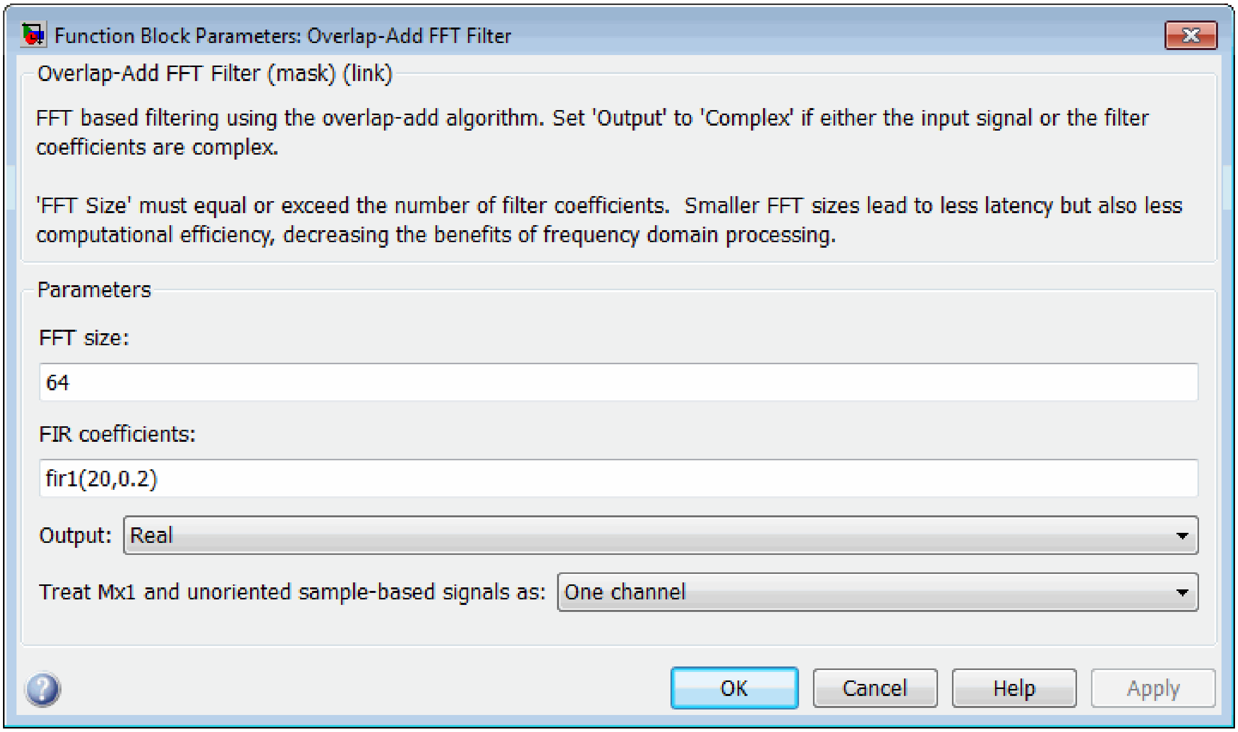
Latency

In *single-tasking* operation, the Overlap-Add FFT Filter block has a latency of nfft-n+1 samples. The first nfft-n+1 consecutive outputs from the block are zero; the first filtered input value appears at the output as sample nfft-n+2.

In *multitasking* operation, the Overlap-Add FFT Filter block has a latency of 2*(nfft-n)+1 samples. The first 2*(nfft-n)+1 consecutive outputs from the block are zero; the first filtered input value appears at the output as sample 2*(nfft-n)+3.

Note: For more information on latency and the Simulink software tasking modes, see “Excess Algorithmic Delay (Tasking Latency)” and “Scheduling ” in the Simulink Coder documentation.

Dialog Box



Function Block Parameters: Overlap-Add FFT Filter

Overlap-Add FFT Filter (mask) (link)

FFT based filtering using the overlap-add algorithm. Set 'Output' to 'Complex' if either the input signal or the filter coefficients are complex.

'FFT Size' must equal or exceed the number of filter coefficients. Smaller FFT sizes lead to less latency but also less computational efficiency, decreasing the benefits of frequency domain processing.

Parameters

FFT size: 64

FIR coefficients: fir1(20,0.2)

Output: Real

Treat Mx1 and unoriented sample-based signals as: One channel

FFT size

The size of the FFT, which should be a power-of-two value greater than the length of the specified FIR filter.

FIR coefficients

The filter numerator coefficients.

Output

The complexity of the output; `Real` or `Complex`. When the input signal or the filter coefficients are complex, this should be set to `Complex`.

Treat Mx1 and unoriented sample-based signals as

Specify how the block treats sample-based *M*-by-1 column vectors and unoriented sample-based vectors of length *M*. You can select one of the following options:

- `One channel` — When you select this option, the block treats *M*-by-1 and unoriented sample-based inputs as a column vector (one channel).
- `M channels (this choice will be removed – see release notes)` — When you select this option, the block treats *M*-by-1 and unoriented sample-based inputs as a 1-by-*M* row vector.

Note: This parameter will be removed in a future release. At that time, the block will always treat *M*-by-1 and unoriented vectors as a single channel.

Overlap-Save FFT Filter	DSP System Toolbox product

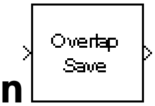
Overlap-Save FFT Filter

Implement overlap-save method of frequency-domain filtering

Library

Filtering / Filter Implementations

`dsparch4`



Description

The Overlap-Save FFT Filter block uses an FFT to implement the *overlap-save method*, a technique that combines successive frequency-domain filtered sections of an input sequence.

The block accepts vector or matrix inputs, and treats each column of the input as an individual channel. The block unbuffers the input data into row vectors such that the length of the output vector is equal to the number of channels in the input. The data output rate of the block is *M* times faster than its data input rate, where *M* is the length of the columns in the input (frame-size).

Overlapping sections of input `u` are circularly convolved with the FIR filter coefficients

$$H(z) = B(z) = b_1 + b_2 z^{-1} + \ldots + b_{n+1} z^{-n}$$

The numerator coefficients for *H*(*z*) are specified as a vector by the **FIR coefficients** parameter. The coefficient vector, `b = [b(1) b(2) ... b(n+1)]`, can be generated by one of the filter design functions in the Signal Processing Toolbox product, such as `fir1`. All filter states are internally initialized to zero.

When either the filter coefficients or the inputs to the block are complex, the **Output** parameter should be set to `Complex`. Otherwise, the default **Output** setting, `Real`, instructs the block to take only the real part of the solution.

The circular convolution of each section is computed by multiplying the FFTs of the input section and filter coefficients, and computing the inverse FFT of the product.

```
y = ifft(fft(u(i:i+(L-1)),nfft) .* fft(b,nfft))
```

where you specify `nfft` in the **FFT size** parameter as a power of two value greater (typically *much* greater) than `n+1`. Values for **FFT size** that are not powers of two are rounded upwards to the nearest power-of-two value to obtain `nfft`.

The first `n` points of the circular convolution are invalid and are discarded. The Overlap-Save FFT Filter block outputs the remaining `nfft-n` points, which are equivalent to the linear convolution.

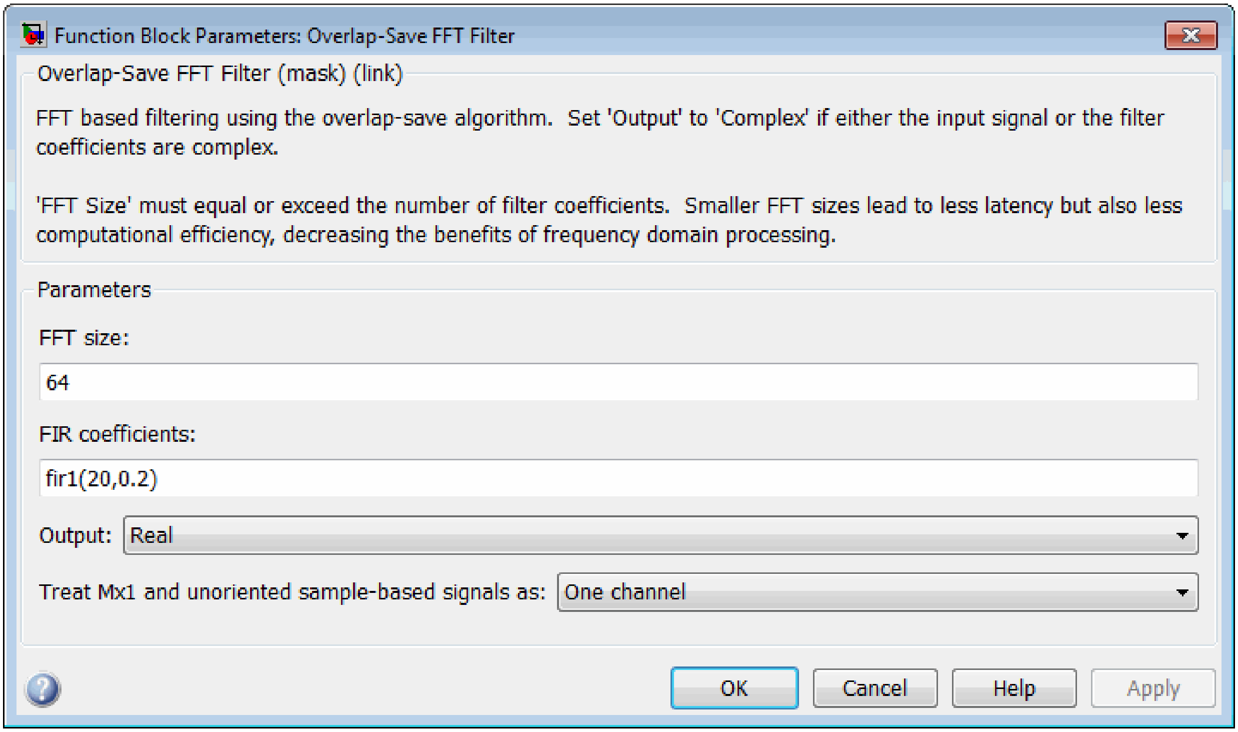
Latency

In *single-tasking* operation, the Overlap-Save FFT Filter block has a latency of `nfft-n+1` samples. The first `nfft-n+1` consecutive outputs from the block are zero; the first filtered input value appears at the output as sample `nfft-n+2`.

In *multitasking* operation, the Overlap-Save FFT Filter block has a latency of `2*(nfft-n+1)` samples. The first `2*(nfft-n+1)` consecutive outputs from the block are zero; the first filtered input value appears at the output as sample `2*(nfft-n)+3`.

Note: For more information on latency and the Simulink environment tasking modes, see “Excess Algorithmic Delay (Tasking Latency)” and “Scheduling ” in the Simulink Coder documentation.

Dialog Box



Function Block Parameters: Overlap-Save FFT Filter
Overlap-Save FFT Filter (mask) (link)

FFT based filtering using the overlap-save algorithm. Set 'Output' to 'Complex' if either the input signal or the filter coefficients are complex.

'FFT Size' must equal or exceed the number of filter coefficients. Smaller FFT sizes lead to less latency but also less computational efficiency, decreasing the benefits of frequency domain processing.

Parameters

FFT size: 64

FIR coefficients: fir1(20,0.2)

Output: Real

Treat Mx1 and unoriented sample-based signals as: One channel

FFT size

The size of the FFT, which should be a power of two value greater than the length of the specified FIR filter.

FIR coefficients

The filter numerator coefficients.

Output

The complexity of the output; `Real` or `Complex`. When the input signal or the filter coefficients are complex, this should be set to `Complex`.

Treat Mx1 and unoriented sample-based signals as

Specify how the block treats sample-based *M*-by-1 column vectors and unoriented sample-based vectors of length *M*. You can select one of the following options:

- `One channel` — When you select this option, the block treats *M*-by-1 and unoriented sample-based inputs as a column vector (one channel).
- `M channels (this choice will be removed – see release notes)` — When you select this option, the block treats *M*-by-1 and unoriented sample-based inputs as a 1-by-*M* row vector.

Note: This parameter will be removed in a future release. At that time, the block will always treat *M*-by-1 and unoriented vectors as a single channel.

Overwrite Values

Overwrite submatrix or subdiagonal of input

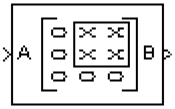
Library

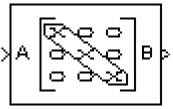
- Math Functions / Matrices and Linear Algebra / Matrix Operations

  `dspmtrx3`

- Signal Management / Indexing

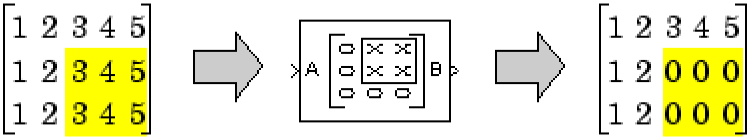
  `dspindex`





Description

The Overwrite Values block overwrites a contiguous submatrix or subdiagonal of an input matrix. You can provide the overwriting values by typing them in a block parameter, or through an additional input port, which is useful for providing overwriting values that change at each time step.



The block accepts scalars, vectors and matrices. The output always has the same size as the original input signal, not necessarily the same size as the signal containing the overwriting values. The input(s) and output of this block must have the same data type.

Specifying the Overwriting Values

The **Source of overwriting value(s)** parameter determines how you must provide the overwriting values, and has the following settings.

- `Specify via dialog` — You must provide the overwriting value(s) in the **Overwrite with** parameter. The block uses the same overwriting values to overwrite the specified portion of the input at each time step. To learn how to specify valid overwriting values, see "Valid Overwriting Values" on page 1-1093.
- `Second input port` — You must provide overwriting values through a second block input port, `V`. Use this setting to provide different overwriting values at each time step. The output inherits its size and rate from the input signal, *not* the overwriting values.

  The rate at which you provide the overwriting values through input port `V` must match the rate at which the block receives each input matrix at input port `A`. In other words, the input signals must have the same Simulink sample time.

Valid Overwriting Values

The overwriting values can be a single constant, vector, or matrix, depending on the portion of the input you are overwriting, regardless of whether you provide the overwriting values through an input port or by providing them in the **Overwrite with** parameter.

Valid Overwriting Values

Portion of Input to Overwrite	Valid Overwriting Values	Example
A single element in the input $\begin{bmatrix} x & x & x & x & x \\ x & x & x & x & x \\ x & x & x & x & x \\ x & x & x & x & x \end{bmatrix}$	Any constant value, v	v `= 9` $\begin{bmatrix} x & x & x & x & x \\ x & x & x & 9 & x \\ x & x & x & x & x \\ x & x & x & x & x \end{bmatrix}$

Portion of Input to Overwrite	Valid Overwriting Values	Example
A length-k portion of the diagonal 	Any length-k column or row vector, v	$k = 3 \qquad v = [2 \quad 4 \quad 6] \quad \text{or} \quad \begin{bmatrix} 2 \\ 4 \\ 6 \end{bmatrix}$ A length-k portion of a row 	Any length-k row vector, v	$k = 3 \qquad v = [2 \quad 4 \quad 6]$ A length-k portion of a column 	Any length-k column vector, v	$k = 2 \qquad v = \begin{bmatrix} 4 \\ 6 \end{bmatrix}$ An m-by-n submatrix 	Any m-by-n matrix, v	$m = 2$ $n = 3 \qquad v = \begin{bmatrix} 4 & 5 & 6 \\ 7 & 8 & 9 \end{bmatrix}$ 
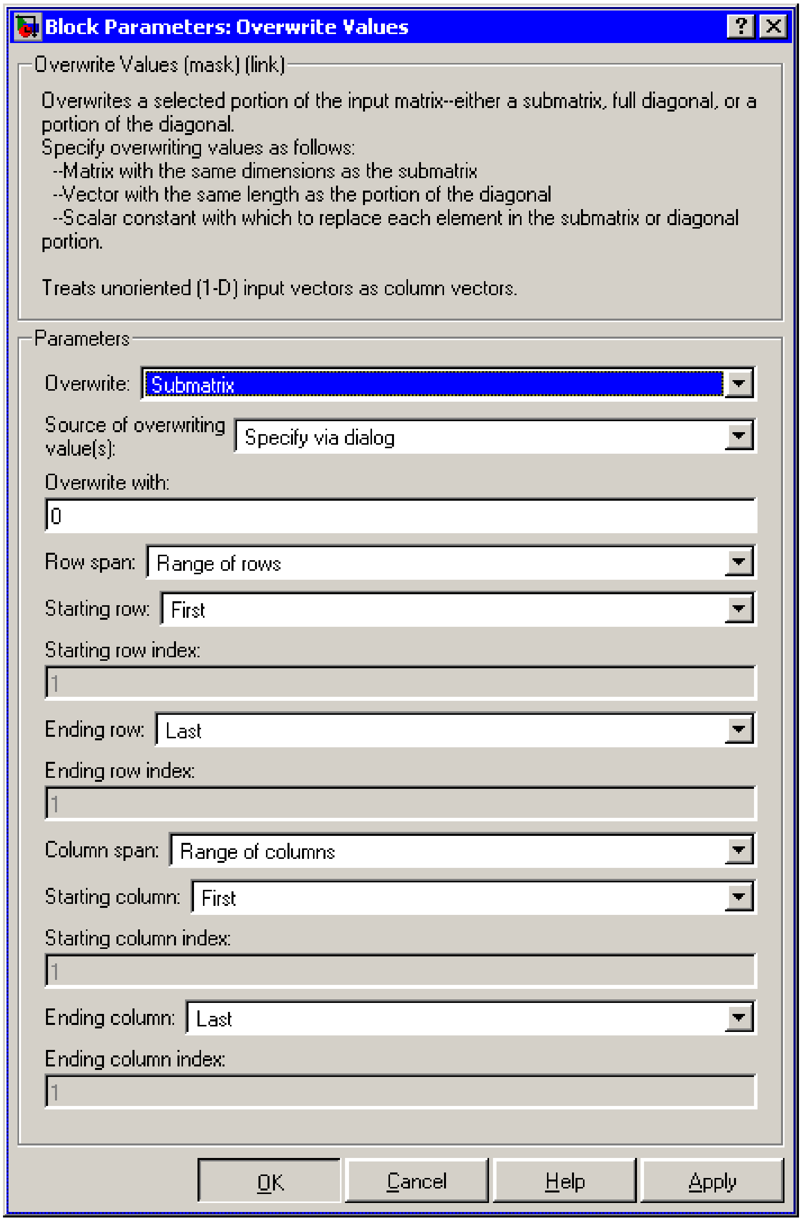
This block supports Simulink virtual buses.

Dialog Box



Block Parameters: Overwrite Values

Overwrite Values (mask) (link)

Overwrites a selected portion of the input matrix--either a submatrix, full diagonal, or a portion of the diagonal.
Specify overwriting values as follows:
 --Matrix with the same dimensions as the submatrix
 --Vector with the same length as the portion of the diagonal
 --Scalar constant with which to replace each element in the submatrix or diagonal portion.

Treats unoriented (1-D) input vectors as column vectors.

Parameters

Overwrite: Submatrix

Source of overwriting value(s): Specify via dialog

Overwrite with:
0

Row span: Range of rows

Starting row: First

Starting row index:
1

Ending row: Last

Ending row index:
1

Column span: Range of columns

Starting column: First

Starting column index:
1

Ending column: Last

Ending column index:
1

Note Only some of the following parameters are visible in the dialog box at any one time.

Overwrite

Determines whether to overwrite a specified submatrix or a specified portion of the diagonal.

Source of overwriting value(s)

Determines where you must provide the overwriting values: either through an input port, or by providing them in the **Overwrite with** parameter. For more information, see “Specifying the Overwriting Values” on page 1-1093.

Overwrite with

The value(s) with which to overwrite the specified portion of the input matrix. Enabled only when **Source of overwriting value(s)** is set to `Specify via dialog`. To learn how to specify valid overwriting values, see “Valid Overwriting Values” on page 1-1093.

Row span

The range of input rows to be overwritten. Options are `All rows`, `One row`, or `Range of rows`. For descriptions of these options, see “Dialog Box” on page 1-1096.

Row/Starting row

The input row that is the first row of the submatrix that the block overwrites. For a description of the options for the **Row** and **Starting row** parameters, see Settings for Row, Column, Starting Row, and Starting Column Parameters. **Row** is enabled when **Row span** is set to `One row`, and **Starting row** when **Row span** is set to `Range of rows`.

Row index/Starting row index

Index of the input row that is the first row of the submatrix that the block overwrites. See how to use these parameters in Settings for Row, Column, Starting Row, and Starting Column Parameters. **Row index** is enabled when **Row** is set to `Index`, and **Starting row index** when **Starting row** is set to `Index`.

Row offset/Starting row offset

The offset of the input row that is the first row of the submatrix that the block overwrites. See how to use these parameters in Settings for Row, Column, Starting Row, and Starting Column Parameters. **Row offset** is enabled when **Row** is set to `Offset from middle` or `Offset from last`, and **Starting row offset** is enabled when **Starting row** is set to `Offset from middle` or `Offset from last`.

Ending row

The input row that is the last row of the submatrix that the block overwrites. For a description of this parameter's options, see Settings for Ending Row and Ending Column Parameters. This parameter is enabled when **Row span** is set to `Range of rows`, and **Starting row** is set to any option but `Last`.

Ending row index

Index of the input row that is the last row of the submatrix that the block overwrites. See how to use this parameter in Settings for Ending Row and Ending Column Parameters. Enabled when **Ending row** is set to `Index`.

Ending row offset

The offset of the input row that is the last row of the submatrix that the block overwrites. See how to use this parameter in Settings for Ending Row and Ending Column Parameters. Enabled when **Ending row** is set to `Offset from middle` or `Offset from last`.

Column span

The range of input columns to be overwritten. Options are `All columns`, `One column`, or `Range of columns`. For descriptions of the analogous row options, see "Dialog Box" on page 1-1096.

Column/Starting column

The input column that is the first column of the submatrix that the block overwrites. For a description of the options for the **Column** and **Starting column** parameters, see Settings for Row, Column, Starting Row, and Starting Column Parameters. **Column** is enabled when **Column span** is set to `One column`, and **Starting column** when **Column span** is set to `Range of columns`.

Column index/Starting column index

Index of the input column that is the first column of the submatrix that the block overwrites. See how to use these parameters in Settings for Row, Column, Starting Row, and Starting Column Parameters. **Column index** is enabled when **Column** is set to `Index`, and **Starting column index** when **Starting column** is set to `Index`.

Column offset/Starting column offset

The offset of the input column that is the first column of the submatrix that the block overwrites. See how to use these parameters in Settings for Row, Column, Starting Row, and Starting Column Parameters. **Column offset** is enabled when **Column** is set to `Offset from middle` or `Offset from last`, and **Starting column offset** is enabled when **Starting column** is set to `Offset from middle` or `Offset from last`.

Ending column

The input column that is the last column of the submatrix that the block overwrites. For a description of this parameter's options, see Settings for Ending Row and Ending Column Parameters. This parameter is enabled when **Column span** is set to `Range of columns`, and **Starting column** is set to any option but `Last`.

Ending column index

Index of the input column that is the last column of the submatrix that the block overwrites. See how to use this parameter in Settings for Ending Row and Ending Column Parameters. This parameter is enabled when **Ending column** is set to `Index`.

Ending column offset

The offset of the input column that is the last column of the submatrix that the block overwrites. See how to use this parameter in Settings for Ending Row and Ending Column Parameters. This parameter is enabled when **Ending column** is set to `Offset from middle` or `Offset from last`.

Diagonal span

The range of diagonal elements to be overwritten. Options are `All elements`, `One element`, or `Range of elements`. For descriptions of these options, see "Overwriting a Subdiagonal" on page 1-1103.

Element/Starting element

The input diagonal element that is the first element in the subdiagonal that the block overwrites. For a description of the options for the **Element** and **Starting element** parameters, see Element and Starting Element Parameters. **Element** is enabled when **Element span** is set to `One element`, and **Starting element** when **Element span** is set to `Range of elements`.

Element index/Starting element index

Index of the input diagonal element that is the first element of the subdiagonal that the block overwrites. See how to use these parameters in Element and Starting Element Parameters. **Element index** is enabled when **Element** is set to `Index`, and **Starting element index** when **Starting element** is set to `Index`.

Element offset/Starting element offset

The offset of the input diagonal element that is the first element of the subdiagonal that the block overwrites. See how to use these parameters in Element and Starting Element Parameters. **Element offset** is enabled when **Element** is set to `Offset from middle` or `Offset from last`, and **Starting element offset** is enabled when **Starting element** is set to `Offset from middle` or `Offset from last`.

Ending element

The input diagonal element that is the last element of the subdiagonal that the block overwrites. For a description of this parameter's options, see Ending Element Parameters. This parameter is enabled when **Element span** is set to `Range of elements`, and **Starting element** is set to any option but `Last`.

Ending element index

Index of the input diagonal element that is the last element of the subdiagonal that the block overwrites. See how to use this parameter in Ending Element Parameters. This parameter is enabled when **Ending element** is set to `Index`.

Ending element offset

The offset of the input diagonal element that is the last element of the subdiagonal that the block overwrites. See how to use this parameter in Ending Element Parameters. This parameter is enabled when **Ending element** is set to `Offset from middle` or `Offset from last`.

Examples

Overwriting a Submatrix

To overwrite a submatrix, follow these steps:

1. Set the **Overwrite** parameter to `Submatrix`.
2. Specify the overwriting values as described in "Specifying the Overwriting Values" on page 1-1093.
3. Specify which rows and columns of the input matrix are contained in the submatrix that you want to overwrite by setting the **Row span** parameter to one of the following options and the **Column span** to the analogous column-related options:

   - `All rows` — The submatrix contains all rows of the input matrix.
   - `One row` — The submatrix contains only one row of the input matrix, which you must specify in the **Row** parameter, as described in the following table.
   - `Range of rows` — The submatrix contains one or more rows of the input, which you must specify in the **Starting Row** and **Ending row** parameters, as described in the following tables.
4. When you set **Row span** to `One row` or `Range of rows`, you need to further specify the row(s) contained in the submatrix by setting the **Row** or **Starting**

row and **Ending row** parameters. Likewise, when you set **Column span** to `One column` or `Range of columns`, you must further specify the column(s) contained in the submatrix by setting the **Column** or **Starting column** and **Ending column** parameters. For descriptions of the settings for these parameters, see the following tables.

Settings for Row, Column, Starting Row, and Starting Column Parameters

Settings for Specifying the Submatrix's First Row or Column	First Row of Submatrix (Only row for Row span = One row)	First Column of Submatrix (Only row for Row span = One row)
`First`	First row of the input	First column of the input
`Index`	Input row specified in the **Row index** parameter	Input column specified in the **Column index** parameter
`Offset from last`	Input row with the index `M - rowOffset` where `M` is the number of input rows, and `rowOffset` is the value of the **Row offset** or **Starting row offset** parameter	Input column with the index `N - colOffset` where `N` is the number of input columns, and `colOffset` is the value of the **Column offset** or **Starting column offset** parameter
`Last`	Last row of the input	Last column of the input
`Offset from middle`	Input row with the index `floor(M/2 + 1 - rowOffset)` where `M` is the number of input rows, and `rowOffset` is the value of the **Row offset** or **Starting row offset** parameter	Input column with the index `floor(N/2 + 1 - rowOffset)` where `N` is the number of input columns, and `colOffset` is the value of the or **Column offset** or **Starting column offset** parameter
`Middle`	Input row with the index `floor(M/2 + 1)` where `M` is the number of input rows	Input columns with the index `floor(N/2 + 1)` where `N` is the number of input columns

Settings for Ending Row and Ending Column Parameters

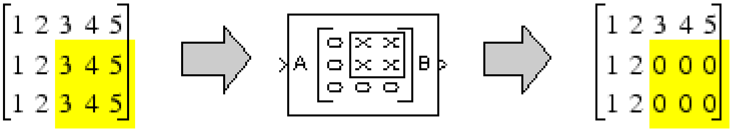
Settings for Specifying the Submatrix's Last Row or Column	Last Row of Submatrix	Last Column of Submatrix
`Index`	Input row specified in the **Ending row index** parameter	Input column specified in the **Ending column index** parameter
`Offset from last`	Input row with the index `M - rowOffset` where `M` is the number of input rows, and `rowOffset` is the value of the **Ending row offset** parameter	Input column with the index `N - colOffset` where `N` is the number of input columns, and `colOffset` is the value of the **Ending column offset** parameter
`Last`	Last row of the input	Last column of the input
`Offset from middle`	Input row with the index `floor(M/2 + 1 - rowOffset)` where `M` is the number of input rows, and `rowOffset` is the value of the **Ending row offset** parameter	Input column with the index `floor(N/2 + 1 - rowOffset)` where `N` is the number of input columns, and `colOffset` is the value of the **Ending column offset** parameter
`Middle`	Input row with the index `floor(M/2 + 1)` where `M` is the number of input rows	Input columns with the index `floor(N/2 + 1)` where `N` is the number of input columns

For example, to overwrite the lower-right 2-by-3 submatrix of a 3-by-5 input matrix with all zeros, enter the following set of parameters:

- **Overwrite** = `Submatrix`
- **Source of overwriting value(s)** = `Specify via dialog`
- **Overwrite with** = `0`
- **Row span** = `Range of rows`
- **Starting row** = `Index`
- **Starting row index** = `2`
- **Ending row** = `Last`
- **Column span** = `Range of columns`
- **Starting column** = `Offset from last`
- **Starting column offset** = `2`

- **Ending column** = `Last`

The following figure shows the block with the above settings overwriting a portion of a 3-by-5 input matrix.



There are often several possible parameter combinations that select the *same* submatrix from the input. For example, instead of specifying `Last` for **Ending column**, you could select the same submatrix by specifying

- **Ending column** = `Index`
- **Ending column index** = 5

Overwriting a Subdiagonal

To overwrite a subdiagonal, follow these steps:

1. Set the **Overwrite** parameter to `Diagonal`.
2. Specify the overwriting values as described in "Specifying the Overwriting Values" on page 1-1093.
3. Specify the subdiagonal that you want to overwrite by setting the **Diagonal span** parameter to one of the following options:

   - `All elements` — Overwrite the entire input diagonal.
   - `One element` — Overwrite one element in the diagonal, which you must specify in the **Element** parameter (described below).
   - `Range of elements` — Overwrite a portion of the input diagonal, which you must specify in the **Starting element** and **Ending element** parameters, as described in the following table.
4. When you set **Diagonal span** to `One element` or `Range of elements`, you need to further specify which diagonal element(s) to overwrite by setting the **Element** or **Starting element** and **Ending element** parameters. See the following tables.

Element and Starting Element Parameters

Settings for Element and Starting Element Parameters	First Element in Subdiagonal (Only element when Diagonal span = One element)
`First`	Diagonal element in first row of the input
`Index`	*k*th diagonal element, where *k* is the value of the **Element index** or **Starting element index** parameter
`Offset from last`	Diagonal element in the row with the index `M - offset` where `M` is the number of input rows, and `offset` is the value of the **Element offset** or **Starting element offset** parameter
`Last`	Diagonal element in the last row of the input
`Offset from middle`	Diagonal element in the input row with the index `floor(M/2 + 1 - offset)` where `M` is the number of input rows, and `offset` is the value of the **Element offset** or **Starting element offset** parameter
`Middle`	Diagonal element in the input row with the index `floor(M/2 + 1)` where `M` is the number of input rows

Ending Element Parameters

Settings for Ending Element Parameter	Last Element in Subdiagonal
`Index`	*k*th diagonal element, where *k* is the value of the **Ending element index** parameter
`Offset from last`	Diagonal element in the row with the index `M - offset` where `M` is the number of input rows, and `offset` is the value of the **Ending element offset** parameter
`Last`	Diagonal element in the last row of the input
`Offset from middle`	Diagonal element in the input row with the index `floor(M/2 + 1 - offset)` where `M` is the number of input rows, and `offset` is the value of the **Ending element offset** parameter
`Middle`	Diagonal element in the input row with the index `floor(M/2 + 1)`

Settings for Ending Element Parameter	Last Element in Subdiagonal
	where M is the number of input rows

Supported Data Types

The input(s) and output of this block must have the same data type.

Port	Supported Data Types
A	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
V	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
B	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers

Pad

Pad or truncate specified dimension(s)

Library

Signal Operations

`dspsigops`

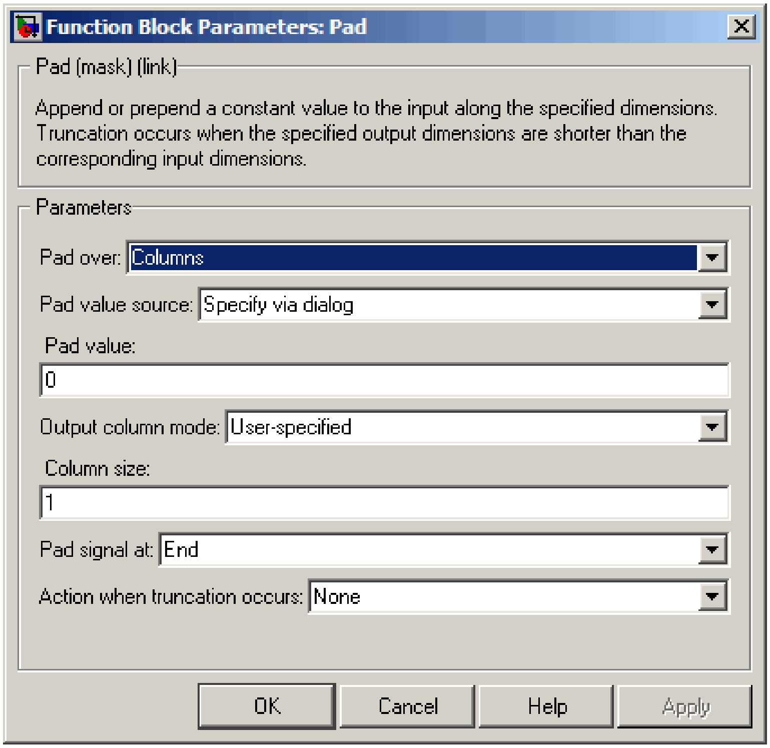
Description

The Pad block extends or crops the dimensions of the input by padding or truncating along its columns, rows, columns and rows, or any dimension(s) you specify. Truncation occurs when you specify output dimensions that are shorter than the corresponding input dimensions. If the input and output lengths are the same, the block is a pass-through.

You can enter the pad value in the block mask or via an input port. You can enter output sizes in the block mask, or have the block pad the specified dimensions until their length is the next highest power of two. The **Pad signal at** parameter controls whether the specified input dimensions are padded or truncated at their beginning, end, or both. For odd pad or truncation lengths, the extra pad value or truncation is applied to the end of the signal. When the block is in `Specified dimensions` mode, you can specify either the output size or the pad size.

You can have the block warn or error when an input signal is truncated using the **Action when truncation occurs** parameter.

Dialog Box



Function Block Parameters: Pad

Pad (mask) (link)

Append or prepend a constant value to the input along the specified dimensions. Truncation occurs when the specified output dimensions are shorter than the corresponding input dimensions.

Parameters

Pad over: Columns

Pad value source: Specify via dialog

Pad value: 0

Output column mode: User-specified

Column size: 1

Pad signal at: End

Action when truncation occurs: None

Pad over

Specify the dimensions over which to pad or truncate: `Columns`, `Rows`, `Columns and rows`, `None`, or `Specified dimensions`.

Dimensions to pad

Specify the one-based dimension(s) over which to pad or truncate. The value for this parameter can be a scalar or a vector. For example, specify `1` to pad columns. Specify `[1 2]` to pad columns and rows. Specify `[1 3 5]` to pad the first, third, and fifth dimensions.

This parameter is only visible when `Specified dimensions` is selected for the **Pad over** parameter.

Pad value source

Choose how you specify the pad value. The pad value can come from an input port or from the dialog:

- If you select `Input port`, the `PVal` port appears on the block icon.
- If you select `Specify via dialog`, the **Pad value** parameter appears.

Pad value

Specify the constant scalar value with which to pad the input. “Tunable”.

This parameter is only visible when `Specify via dialog` is selected for the **Pad value source** parameter.

Output column mode

Choose how you specify the column length of the output:

- If you select `User-specified`, the **Column size** parameter appears.
- If you select `Next power of two`, the block pads the output columns until their length is the next highest power of two. If the column length is already a power of two, the columns are not padded.

This parameter is only visible when `Columns` or `Columns and rows` is selected for the **Pad over** parameter.

Column size

Specify the column length of the output. If the specified column length is longer than the input column length, the columns are padded. If the specified column length is shorter than the input column length, the columns are truncated. This parameter is only visible when `User-specified` is selected for the **Output column mode** parameter.

Output row mode

Choose how you specify the output row length of the output:

- If you select `User-specified`, the **Row size** parameter appears.
- If you select `Next power of two`, the block pads the output rows until their length is the next highest power of two. If the row length is already a power of two, the rows are not padded.

This parameter is only visible when `Rows` or `Columns and rows` is selected for the **Pad over** parameter.

Row size

Specify the row length of the output. If the specified row length is longer than the input row length, the rows are padded. If the specified row length is shorter than the input row length, the rows are truncated. This parameter is only visible when `User-specified` is selected for the **Output row mode** parameter.

Specify

Choose whether you want to control the output length of the specified dimensions by specifying the pad size or the output size.

This parameter is only visible when `Specified dimensions` is selected for the **Pad over** parameter.

Pad size at beginning

Specify how many values to add to the beginning of the input signal along the specified dimension(s). This parameter must be a scalar or a vector with the same number of elements as the **Dimensions to pad** parameter. Each element in the **Pad size at beginning** parameter gives the pad length for the beginning of the corresponding dimension in the **Dimensions to pad** parameter. Values of this parameter must be zero or a positive integer.

This parameter is only visible if `Pad size` is selected for the **Specify** parameter.

Pad size at end

Specify how many values to add to the end of the input signal along the specified dimension(s). This parameter must be a scalar or a vector with the same number of elements as the **Dimensions to pad** parameter. Each element in the **Pad size at end** parameter gives the pad length for the end of the corresponding dimension in the **Dimensions to pad** parameter. Values of this parameter must be zero or a positive integer.

This parameter is only visible if `Pad size` is selected for the **Specify** parameter.

Output size mode

Choose how you specify the output length of the specified dimensions:

- If you select `User-specified`, the **Output size** parameter appears.
- If you select `Next power of two`, the block pads the specified dimensions until their length is the next highest power of two. If the dimension length is already a power of two, no padding occurs in that dimension.

This parameter is only visible if `Output size` is selected for the **Specify** parameter.

Output size

Specify the output length of the specified dimension(s). This parameter must be a scalar or a vector with the same number of elements as the **Dimensions to pad** parameter. Each element in the **Output size** vector gives the output length for the corresponding dimension in the **Dimensions to pad** vector. If the specified length is longer than the input length for a given dimensions, that dimension is padded. If the specified length is shorter than the input length for a given dimension, that dimension is truncated.

This parameter is only visible if `Output size` is selected for the **Specify** parameter.

Pad signal at

Specify whether to pad or truncate the signal at the `Beginning`, `End`, or `Beginning and end` of the specified dimension(s). When you select `Beginning and end`, half the pad length is added to the beginning of the signal, and half is added to the end of the signal. For an odd pad length, the extra value is added to the end of the signal. This also applies to truncation. In this mode, an equal number of values are truncated from the beginning and the end of the signal. In the case of an odd truncation length, the extra value is removed from the end of the signal.

Action when truncation occurs

Choose `None` when you do not want to be notified that the input is truncated. Select `Warning` to display a warning when the input is truncated. Choose `Error` when to display an error and terminate the simulation when the input is truncated.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating-point • Single-precision floating-point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Output	• Double-precision floating-point • Single-precision floating-point

Port	Supported Data Types
	• Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers

Bandwidth 0.3

Passband width: 0.2

Gain specifications

Gain constraints: Reference, center frequency, bandwidth, passband

Gain units: dB

Reference gain: -10

Center frequency gain: 0

Bandwidth gain: db(sqrt(.5))

Passband gain: -1

Algorithm

Design method: Chebyshev type I

☑ Scale SOS filter coefficients to reduce chance of overflow

Filter Implementation

Structure: Direct-form II SOS

☐ Use basic elements to enable filter customization

☐ Optimize for unit scale values

Input processing: Columns as channels (frame based)

☐ Use symbolic names for coefficients

View filter response

This button opens the Filter Visualization Tool (`fvtool`) from the Signal Processing Toolbox product. You can use the tool to display:

- Magnitude response, phase response, and group delay in the frequency domain.
- Impulse response and step response in the time domain.
- Pole-zero information.

The tool also helps you evaluate filter performance by providing information about filter order, stability, and phase linearity. For more information on FVTool, see the Signal Processing Toolbox documentation.

Filter Specifications

Order mode

Select `Minimum` to design a minimum order filter that meets the design specifications, or `Specify` to enter a specific filter order. The order mode also affects the possible frequency constraints, which in turn limit the gain specifications. For example, if you specify a `Minimum` order filter, the available frequency constraints are:

- `Center frequency, bandwidth, passband width`
- `Center frequency, bandwidth, stopband width`

If you select `Specify`, the available frequency constraints are:

- `Center frequency, bandwidth`
- `Center frequency, quality factor`
- `Shelf type, cutoff frequency, quality factor`
- `Shelf type, cutoff frequency, shelf slope parameter`
- `Low frequency, high frequency`

Order

Specify the filter order. This parameter is enabled only if the **Order mode** is set to `Specify`.

Frequency specifications

Depending on the filter order, the possible frequency constraints change. Once you choose the frequency constraints, the input boxes in this area change to reflect the selection.

Frequency constraints

Select the specification to represent the frequency constraints. The following options are available:

- `Center frequency, bandwidth, passband width` (available for minimum order only)
- `Center frequency, bandwidth, stopband width` (available for minimum order only)
- `Center frequency, bandwidth` (available for a specified order only)
- `Center frequency, quality factor` (available for a specified order only)
- `Shelf type, cutoff frequency, quality factor` (available for a specified order only)
- `Shelf type, cutoff frequency, shelf slope parameter` (available for a specified order only)
- `Low frequency, high frequency` (available for a specified order only)

Frequency units

Select the frequency units from the available drop down list (`Normalized, Hz, kHz, MHz, GHz`). If `Normalized` is selected, then the **Input Fs** box is disabled for input.

Input Fs

Enter the input sampling frequency. This input box is disabled for input if `Normalized` is selected in the **Frequency units** input box.

Center frequency

Enter the center frequency in the units specified by the value in **Frequency units**.

Bandwidth

The bandwidth determines the frequency points at which the filter magnitude is attenuated by the value specified as the **Bandwidth gain** in the **Gain specifications** section. By default, the **Bandwidth gain** defaults to `db(sqrt(.5))`, or –3 dB relative to the center frequency. The **Bandwidth** property only applies when the **Frequency constraints** are: `Center frequency,` bandwidth, passband width, Center frequency, bandwidth, stopband width, or Center frequency, bandwidth.

Passband width

The passband width determines the frequency points at which the filter magnitude is attenuated by the value specified as the **Passband gain** in the **Gain specifications** section. This option is enabled only if the filter is of minimum order, and the frequency constraint selected is Center frequency, bandwidth, passband width.

Stopband width

The stopband width determines the frequency points at which the filter magnitude is attenuated by the value specified as the **Stopband gain** in the **Gain specifications** section. This option is enabled only if the filter is of minimum order, and the frequency constraint selected is Center frequency, bandwidth, stopband width.

Low frequency

Enter the low frequency cutoff. This option is enabled only if the filter order is user specified and the frequency constraint selected is Low frequency, high frequency. The filter magnitude is attenuated by the amount specified in **Bandwidth gain**.

High frequency

Enter the high frequency cutoff. This option is enabled only if the filter order is user specified and the frequency constraint selected is Low frequency, high frequency. The filter magnitude is attenuated by the amount specified in **Bandwidth gain**.

Gain Specifications

Depending on the filter order and frequency constraints, the possible gain constraints change. Also, once you choose the gain constraints the input boxes in this area change to reflect the selection.

Gain constraints

Select the specification array to represent gain constraints, and remember that not all of these options are available for all configurations. The following is a list of all available options:

- Reference, center frequency, bandwidth, passband
- Reference, center frequency, bandwidth, stopband

- `Reference, center frequency, bandwidth, passband, stopband`
- `Reference, center frequency, bandwidth`

Gain units

Specify the gain units either `dB` or `squared`. These units are used for all gain specifications in the dialog box.

Reference gain

The reference gain determines the level to which the filter magnitude attenuates in **Gain units**. The reference gain is a *floor* gain for the filter magnitude response. For example, you may use the reference gain together with the **Center frequency gain** to leave certain frequencies unattenuated (reference gain of 0 dB) while boosting other frequencies.

Bandwidth gain

Specifies the gain in **Gain units** at which the bandwidth is defined. This property applies only when the **Frequency constraints** specification contains a `bandwidth` parameter, or is `Low frequency, high frequency`.

Center frequency gain

Specify the center frequency in **Gain units**

Passband gain

The passband gain determines the level in **Gain units** at which the passband is defined. The passband is determined either by the **Passband width** value, or the **Low frequency** and **High frequency** values in the **Frequency specifications** section.

Stopband gain

The stopband gain is the level in **Gain units** at which the stopband is defined. This property applies only when the **Order mode** is minimum and the **Frequency constaints** are `Center frequency, bandwidth, stopband width`.

Boost/cut gain

The boost/cut gain applies only when the designing a shelving filter. Shelving filters include the `Shelf type` parameter in the **Frequency constraints** specification. The gain in the passband of the shelving filter is increased by **Boost/cut gain** dB from a *floor* gain of 0 dB.

Algorithm

Design method

Select the design method from the drop-down list. Different methods are available depending on the chosen filter constraints.

Scale SOS filter coefficients to reduce chance of overflow

Select the check box to scale the filter coefficients.

Filter Implementation

Structure

Specify filter structure. Choose from:

- Direct-form I SOS
- Direct-form II SOS
- Direct-form I transposed SOS
- Direct-form II transposed SOS

Use basic elements to enable filter customization

Select this check box to implement the filter as a subsystem of basic Simulink blocks. Clear the check box to implement the filter as a high-level subsystem. By default, this check box is cleared.

The high-level implementation provides better compatibility across various filter structures, especially filters that would contain algebraic loops when constructed using basic elements. On the other hand, using basic elements enables the following optimization parameters:

- **Optimize for zero gains** — Terminate chains that contain Gain blocks with a gain of zero.
- **Optimize for unit gains** — Remove Gain blocks that scale by a factor of one.
- **Optimize for delay chains** — Substitute delay chains made up of *n* unit delays with a single delay by *n*.
- **Optimize for negative gains** — Use subtraction in Sum blocks instead of negative gains in Gain blocks.

Optimize for unit-scale values

Select this check box to scale unit gains between sections in SOS filters. This parameter is available only for SOS filters.

Input processing

Specify how the block should process the input. The available options may vary depending on he settings of the **Filter Structure** and **Use basic elements for filter customization** parameters. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` — When you select this option, the block treats each column of the input as a separate channel.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

Note: The `Inherited (this choice will be removed — see release notes)` option will be removed in a future release. See "Frame-Based Processing" in the *DSP System Toolbox Release Notes* for more information.

Rate options

When the **Filter type** parameter specifies a multirate filter, select the rate processing rule for the block from following options:

- `Enforce single-rate processing` — When you select this option, the block maintains the sample rate of the input.
- `Allow multirate processing` — When you select this option, the block adjusts the rate at the output to accommodate an increased or reduced number of samples. To select this option, you must set the **Input processing** parameter to `Elements as channels (sample based)`.

Use symbolic names for coefficients

Select this check box to enable the specification of coefficients using MATLAB variables. The available coefficient names differ depending on the filter structure. Using symbolic names allows tuning of filter coefficients in generated code. By default, this check box is cleared.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point

Port	Supported Data Types
Output	• Double-precision floating point • Single-precision floating point

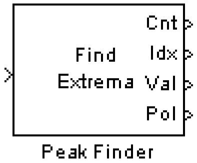
Peak Finder

Determine whether each value of input signal is local minimum or maximum

Library

Signal Operations

`dspsigops`



Description

The Peak Finder block counts the number of local extrema in each column of the real-valued input signal. The block outputs the number of local extrema at the Cnt port. You can also configure the block to output the extrema indices, the extrema values, and a binary indicator of whether or not the extrema are maxima or minima.

To qualify as an extrema, a point has to be larger (or smaller) than both of its neighboring points. Thus, end points are never considered extrema.

If you select the **Output peak indices** check box, the Idx port appears on the block. The block outputs the zero-based extrema indices at the Idx port. If you select the **Output peak values** check box, the Val port appears on the block. The block outputs the extrema values at the Val port. If you select either of these check boxes and set the **Peak type(s)** to `Maxima and Minima`, the Pol port also appears on the block. If the signal value is a maximum, the block outputs a 1 at the Pol ("Polarity") port. If the signal value is a minimum, the block outputs a 0 at the Pol port.

Use the **Maximum number of peaks to find** parameter to specify how many extrema to look for in each input signal. The block stops searching the input signal once this maximum number of extrema has been found.

If you select the **Ignore peaks within threshold of neighboring values** check box, the block no longer detects low-amplitude peaks. This feature allows the block to ignore noise within a threshold value that you define. Enter a threshold value for the **Threshold** parameter. Now, the current value is a maximum if (current – previous) > threshold and (current – next) > threshold. The current value is a minimum if (current – previous) < –threshold and (current – next) < –threshold.

Examples

Example 1

Consider the input vector

```
[9 6 10 3 4 5 0 12]
```

The table below shows the analysis made by the Peak Finder block. Note that the first and last input signal values are not considered:

Previous, current, and next values	9 6 10	6 10 3	10 3 4	3 4 5	4 5 0	5 0 12
Current value if it is an extremum	6	10	3	—	5	0
Index of current value if it is an extremum	1	2	3	—	5	6
Polarity of current value if it is an extremum	0	1	0	—	1	0

Therefore, for this example the outputs at the block ports are

Cnt: `5`

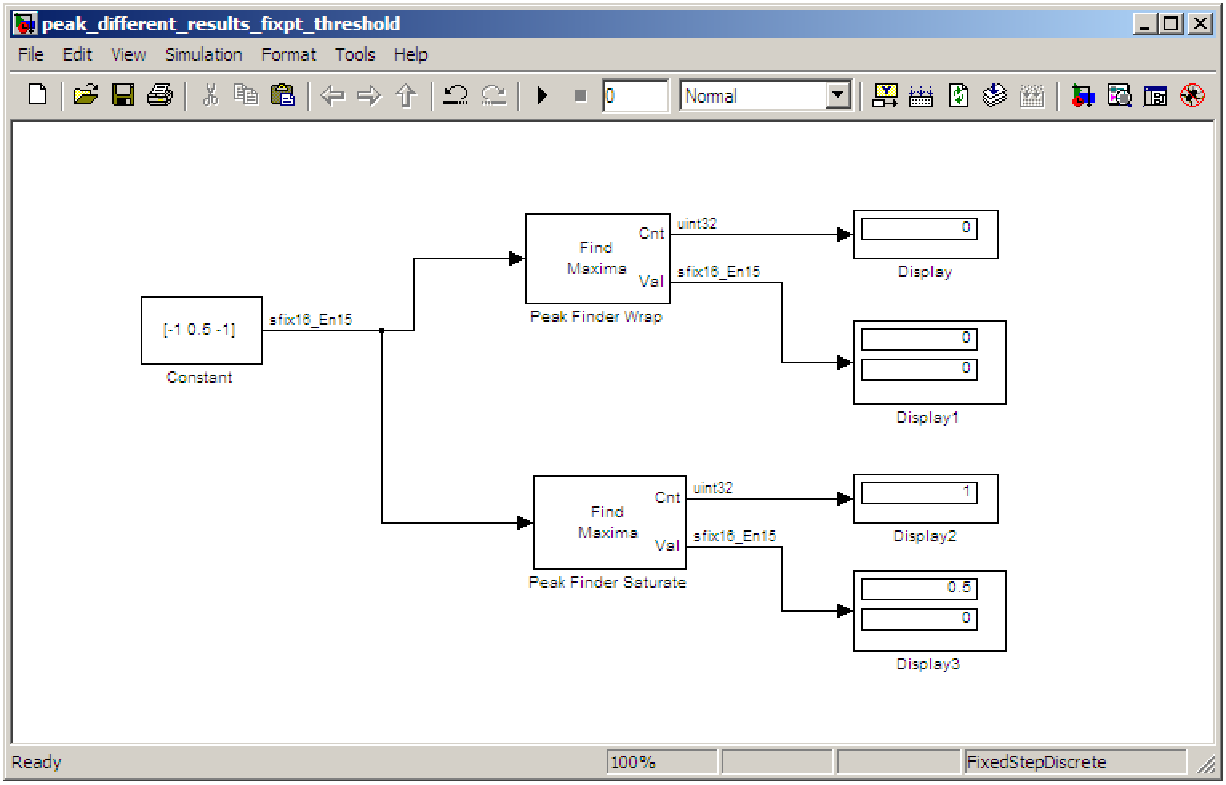
Idx: `[1 2 3 5 6]`

Val: `[6 10 3 5 0]`

Pol: `[0 1 0 1 0]`

Example 2

Note that the **Overflow mode** parameter can affect the output of the block when the input is fixed point. Consider the following model:



In this model, the settings in the Constant block are

- **Constant value** — `[-1 0.5 -1]`
- **Interpret vector parameters as 1-D** — not selected
- **Sampling mode** — `Sample based`
- **Sample time** — `1`
- **Output data type** — `<data type expression>`
- **Mode** — `Fixed point`
- **Sign** — `Signed`
- **Scaling** — `Binary point`
- **Word length** — `16`
- **Fraction length** — `15`

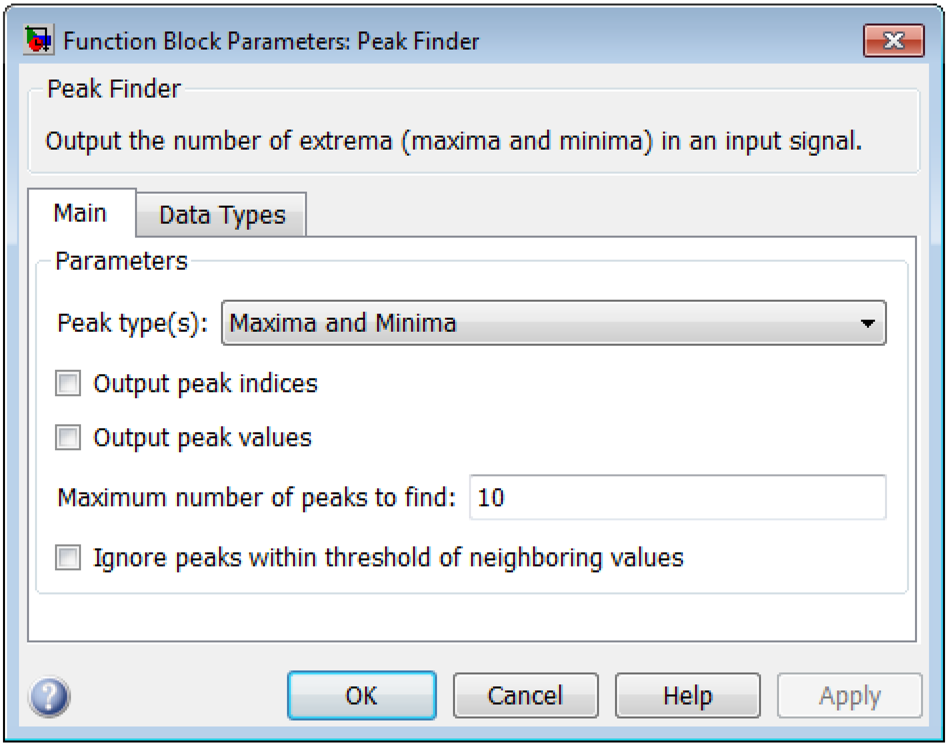
The settings in the Peak Finder blocks are

- **Peak type(s)** — `Maxima`
- **Output peak indices** — not selected
- **Output peak values** — selected
- **Maximum number of peaks to find** — `2`
- **Ignore peaks within threshold of neighboring values** — selected
- **Threshold** — `0.25`
- **Overflow mode** — `Wrap` for Peak Finder Wrap, `Saturate` for Peak Finder Saturate

Setting the **Overflow mode** parameter of the Peak Finder Wrap block to `Wrap` causes the calculations (current – previous) > threshold and (current – next) > threshold to wrap on overflow, thereby causing the maximum to be missed.

Dialog Box

The **Main** pane of the Peak Finder block dialog appears as follows.



Function Block Parameters: Peak Finder

Peak Finder

Output the number of extrema (maxima and minima) in an input signal.

Parameters

Peak type(s): Maxima and Minima

□ Output peak indices

□ Output peak values

Maximum number of peaks to find: 10

□ Ignore peaks within threshold of neighboring values

Peak type(s)

Specify whether you are looking for maxima, minima, or both.

Output peak indices

Select this check box if you want the block to output the extrema indices at the Idx port.

Output peak values

Select this check box if you want the block to output the extrema values at the Val port.

Maximum number of peaks to find

Enter the number of extrema to look for in each input signal. The block stops searching the input signal for extrema once the maximum number of extrema has been found. The value of this parameter must be an integer greater than or equal to one.

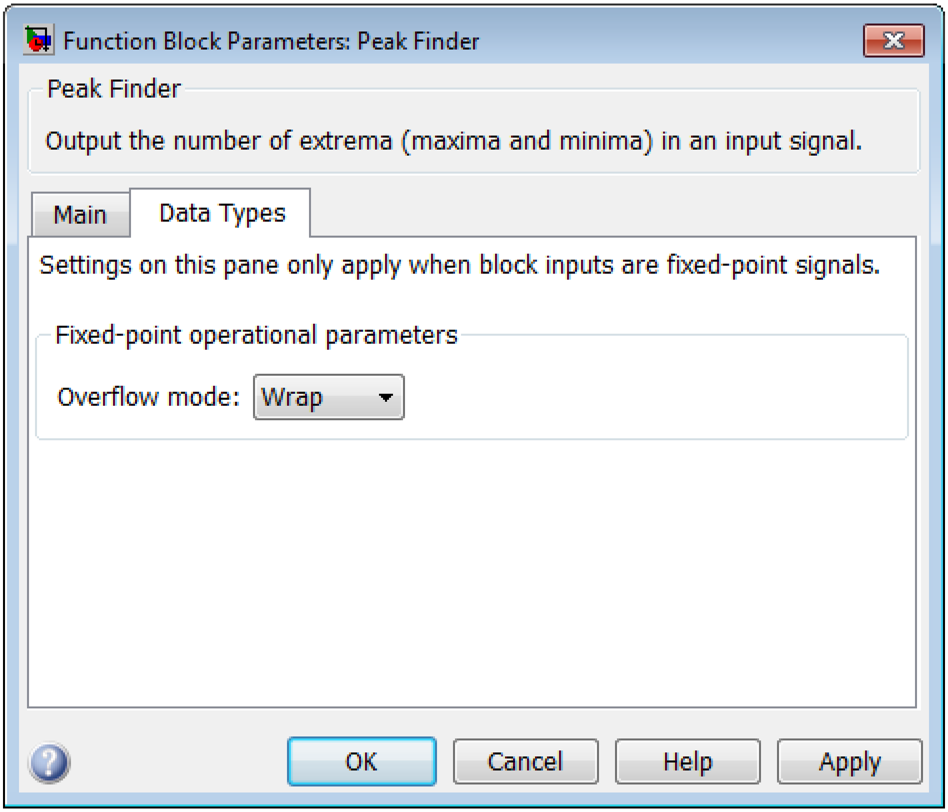
Ignore peaks within threshold of neighboring values

Select this check box if you want to eliminate the detection of peaks whose amplitudes are within a specified threshold of neighboring values.

Threshold

Enter your threshold value. This parameter appears if you select the **Ignore peaks within threshold of neighboring values** check box.

When you select the **Ignore peaks within threshold of neighboring values** check box, the **Data Types** pane of the Peak Finder block appears as follows.



Function Block Parameters: Peak Finder

Peak Finder

Output the number of extrema (maxima and minima) in an input signal.

Settings on this pane only apply when block inputs are fixed-point signals.

Fixed-point operational parameters

Overflow mode: Wrap

Overflow mode

Select the “overflow mode” to be used when block inputs are fixed point.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Cnt	• 32-bit unsigned integers
Idx	• 32-bit unsigned integers
Val	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Pol	• Boolean

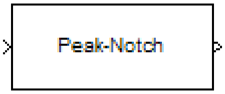
Peak-Notch Filter

Design peak or notch filter

Library

Filtering / Filter Designs

`dspfdesign`



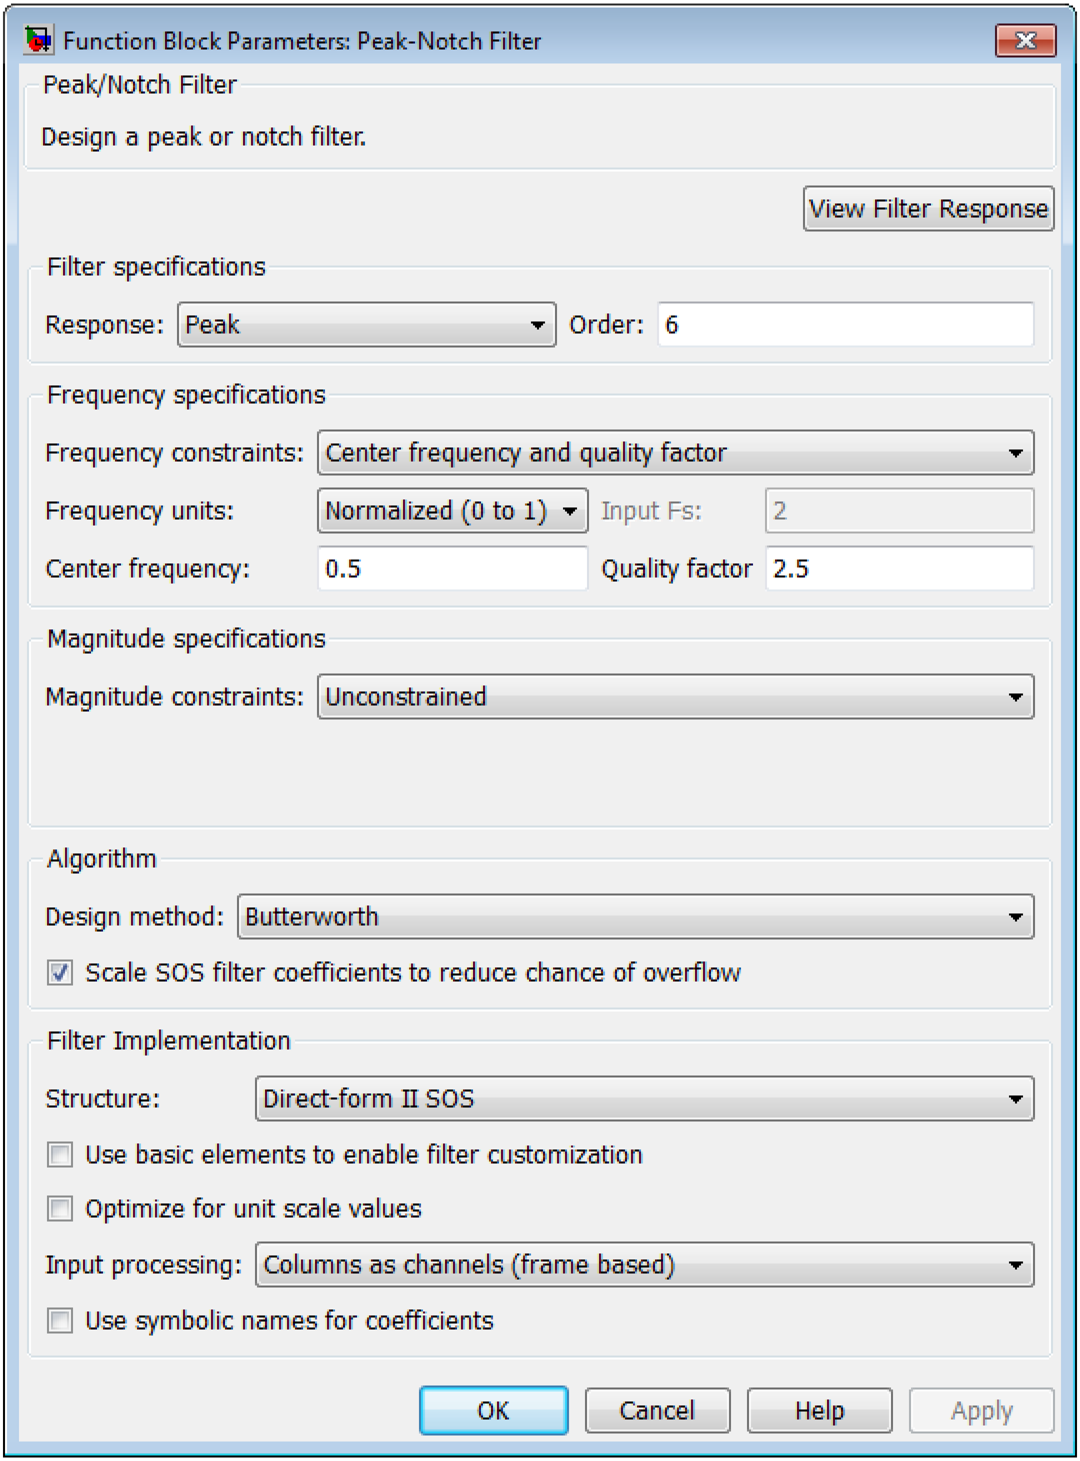
Description

This block brings the filter design capabilities of the “`filterbuilder`” function to the Simulink environment.

Dialog Box

See “Peak/Notch Filter Design Dialog Box — Main Pane” for more information about the parameters of this block. The **Data Types** and **Code Generation** panes are not available for blocks in the DSP System Toolbox Filter Designs library.

Parameters of this block that do not change filter order or structure are tunable.



Function Block Parameters: Peak-Notch Filter

Peak/Notch Filter

Design a peak or notch filter.

Filter specifications

Response: Peak

Order: 6

☑ Scale SOS filter coefficients to reduce chance of overflow

Filter Implementation

Structure: Direct-form II SOS

☐ Use basic elements to enable filter customization

☐ Optimize for unit scale values

Input processing: Columns as channels (frame based)

☐ Use symbolic names for coefficients

View filter response

This button opens the Filter Visualization Tool (`fvtool`) from the Signal Processing Toolbox product. You can use the tool to display:

- Magnitude response, phase response, and group delay in the frequency domain.
- Impulse response and step response in the time domain.
- Pole-zero information.

The tool also helps you evaluate filter performance by providing information about filter order, stability, and phase linearity. For more information on FVTool, see the Signal Processing Toolbox documentation.

Filter Specifications

In this area you can specify whether you want to design a peaking filter or a notching filter, as well as the order of the filter.

Response

Select `Peak` or `Notch` from the drop-down list. The rest of the parameters that specify are equivalent for either filter type.

Order

Enter the filter order. The order must be even.

Frequency Specifications

This group of parameters allows you to specify frequency constraints and units.

Frequency Constraints

Select the frequency constraints for filter specification. There are two choices as follows:

- `Center frequency and quality factor`
- `Center frequency and bandwidth`

Frequency units

The frequency units are normalized by default. If you specify units other than normalized, the block assumes that you wish to specify an input sampling frequency, and enables this input box. The choice of frequency units are: Normalized (0 to 1), Hz, kHz, MHz, GHz.

Input Fs

This input box is enabled if **Frequency units** other than Normalized (0 to 1) are specified. Enter the input sampling frequency.

Center frequency

Enter the center frequency in the units specified previously.

Quality Factor

This input box is enabled only when Center frequency and quality factor is chosen for the **Frequency Constraints**. Enter the quality factor.

Bandwidth

This input box is enabled only when Center frequency and bandwidth is chosen for the **Frequency Constraints**. Enter the bandwidth.

Magnitude Specifications

This group of parameters allows you to specify the magnitude constraints, as well as their values and units.

Magnitude Constraints

Depending on the choice of constraints, the other input boxes are enabled or disabled. Select from four magnitude constraints available:

- Unconstrained
- Passband ripple
- Stopband attenuation
- Passband ripple and stopband attenuation

Magnitude units

Select the magnitude units: either dB or squared.

Apass

This input box is enabled if the magnitude constraints selected are Passband ripple or Passband ripple and stopband attenuation. Enter the passband ripple.

Astop

This input box is enabled if the magnitude constraints selected are `Stopband attenuation` or `Passband ripple and stopband attenuation`. Enter the stopband attenuation.

Algorithm

The parameters in this group allow you to specify the design method and structure of your filter.

Design Method

Lists all design methods available for the frequency and magnitude specifications you entered. When you change the specifications for a filter the methods available to design filters changes as well.

Scale SOS filter coefficients to reduce chance of overflow

Selecting this parameter directs the design to scale the filter coefficients to reduce the chances that the inputs or calculations in the filter overflow and exceed the representable range of the filter. Clearing this option removes the scaling. This parameter applies only to IIR filters.

Filter Implementation

Structure

Specify filter structure. Choose from:

- Direct-form I SOS
- Direct-form II SOS
- Direct-form I transposed SOS
- Direct-form II transposed SOS

Use basic elements to enable filter customization

Select this check box to implement the filter as a subsystem of basic Simulink blocks. Clear the check box to implement the filter as a high-level subsystem. By default, this check box is cleared.

The high-level implementation provides better compatibility across various filter structures, especially filters that would contain algebraic loops when constructed using basic elements. On the other hand, using basic elements enables the following optimization parameters:

- **Optimize for zero gains** — Terminate chains that contain Gain blocks with a gain of zero.
- **Optimize for unit gains** — Remove Gain blocks that scale by a factor of one.
- **Optimize for delay chains** — Substitute delay chains made up of *n* unit delays with a single delay by *n*.
- **Optimize for negative gains** — Use subtraction in Sum blocks instead of negative gains in Gain blocks.

Optimize for unit-scale values

Select this check box to scale unit gains between sections in SOS filters. This parameter is available only for SOS filters.

Input processing

Specify how the block should process the input. The available options may vary depending on he settings of the **Filter Structure** and **Use basic elements for filter customization** parameters. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` — When you select this option, the block treats each column of the input as a separate channel.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

Note: The `Inherited (this choice will be removed — see release notes)` option will be removed in a future release. See “Frame-Based Processing” in the *DSP System Toolbox Release Notes* for more information.

Rate options

When the **Filter type** parameter specifies a multirate filter, select the rate processing rule for the block from following options:

- `Enforce single-rate processing` — When you select this option, the block maintains the sample rate of the input.
- `Allow multirate processing` — When you select this option, the block adjusts the rate at the output to accommodate an increased or reduced number of samples. To select this option, you must set the **Input processing** parameter to `Elements as channels (sample based)`.

Use symbolic names for coefficients

Select this check box to enable the specification of coefficients using MATLAB variables. The available coefficient names differ depending on the filter structure. Using symbolic names allows tuning of filter coefficients in generated code. By default, this check box is cleared.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point
Output	• Double-precision floating point • Single-precision floating point

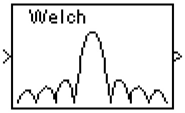
Periodogram

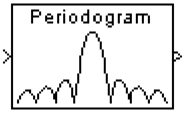
Power spectral density or mean-square spectrum estimate using periodogram method

Library

Estimation / Power Spectrum Estimation

`dspspect3`





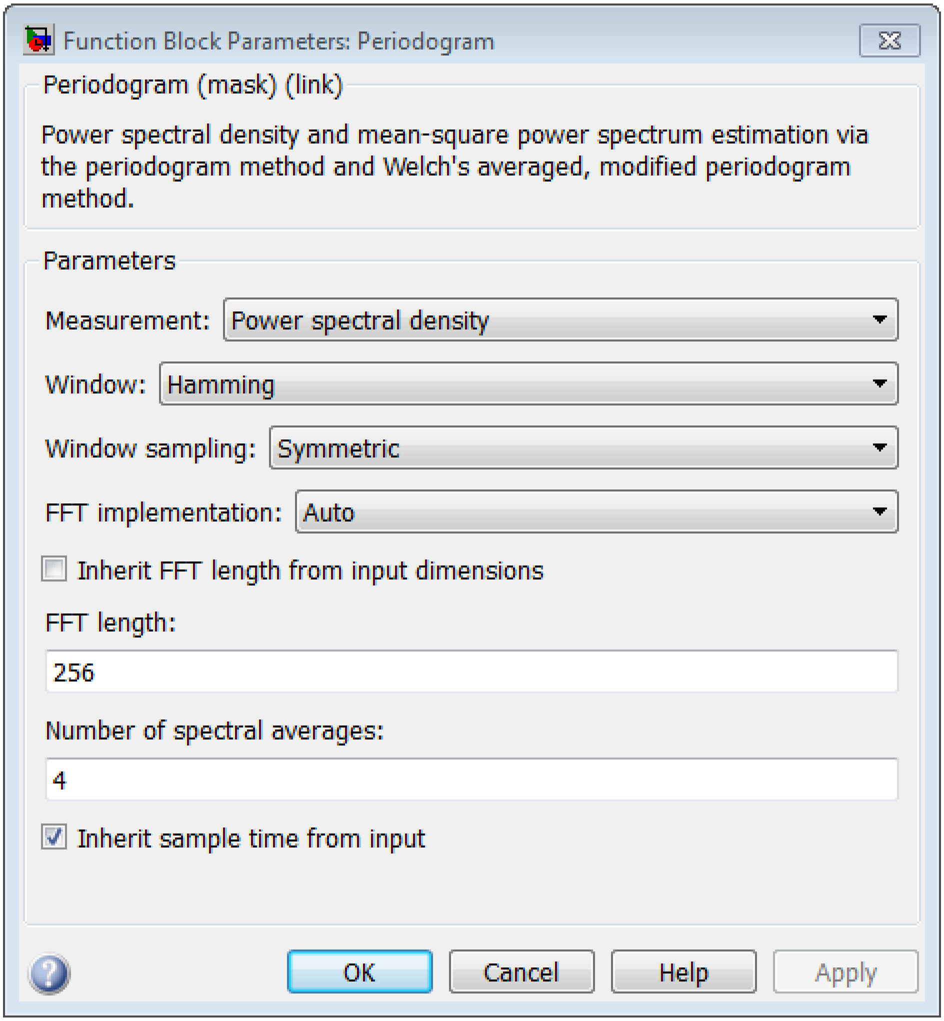
Description

The Periodogram block estimates the power spectral density (PSD) or mean-square spectrum (MSS) of the input. It does so by using the periodogram method and Welch's averaged, modified periodogram method. The block averages the squared magnitude of the FFT computed over windowed sections of the input. It then normalizes the spectral average by the square of the sum of the window samples. See “Periodogram” and “Welch's Method” in the Signal Processing Toolbox documentation for more information.

The block treats M-by-N frame-based matrix input and M-by-N sample-based matrix input as M sequential time samples from N independent channels. The block computes a separate estimate for each of the N independent channels and generates an N_{fft}-by-N matrix output.

Each column of the output matrix contains the estimate of the power spectral density of the corresponding input column at N_{fft} equally spaced frequency points. The frequency points are in the range $[0,\mathrm{F_s})$, where $\mathrm{F_s}$ is the sampling frequency of the signal. The block always outputs sample-based data.

Dialog Box



Function Block Parameters: Periodogram

Periodogram (mask) (link)

Power spectral density and mean-square power spectrum estimation via the periodogram method and Welch's averaged, modified periodogram method.

Parameters

Measurement: Power spectral density

Window: Hamming

Window sampling: Symmetric

FFT implementation: Auto

□ Inherit FFT length from input dimensions

FFT length:

256

Number of spectral averages:

4

☑ Inherit sample time from input

Measurement

Specify the type of measurement for the block to perform: `Power spectral density` or `Mean-square spectrum`. “Tunable”.

Window

Select the type of window to apply. See the Window Function block reference page for more details. “Tunable”.

Stopband attenuation in dB

Enter the level, in decibels (dB), of stopband attenuation, R_s, for the Chebyshev window. This parameter becomes visible if, for the **Window** parameter, you choose `Chebyshev`. “Tunable”.

Beta

Enter the ß parameter for the Kaiser window. This parameter becomes visible if, for the **Window** parameter, you chose `Kaiser`. Increasing **Beta** widens the mainlobe and decreases the amplitude of the sidelobes in the displayed frequency magnitude response. “Tunable”. See the Window Function block reference page for more details.

Window sampling

From the list, choose `Symmetric` or `Periodic`. See the Window Function block reference page for more details.“Tunable”.

FFT implementation

Set this parameter to `FFTW` [1], [2] to support an arbitrary length input signal. The block restricts generated code with FFTW implementation to MATLAB host computers.

Set this parameter to `Radix-2` for bit-reversed processing, fixed or floating-point data, or for portable C-code generation using the Simulink Coder. The first dimension *M*, of the input matrix must be a power of two. To work with other input sizes, use the Pad block to pad or truncate these dimensions to powers of two, or if possible choose the FFTW implementation.

Set this parameter to `Auto` to let the block choose the FFT implementation. For non-power-of-two transform lengths, the block restricts generated code to MATLAB host computers.

Inherit FFT length from input dimensions

When you select this check box, the block uses the input frame size as the number of data points, N_{fft}, on which to perform the FFT. To specify the number of points on which to perform the FFT, clear the **Inherit FFT length from estimation order** check box. You can then specify a power of two FFT length using the **FFT length** parameter.

FFT length

Enter the number of data points on which to perform the FFT, N_{fft}. When N_{fft} is larger than the input frame size, the block zero-pads each frame as needed. When

N_{fft} is smaller than the input frame size, the block wraps each frame as needed. This parameter becomes visible only when you clear the **Inherit FFT length from input dimensions** check box.

When you set the **FFT implementation** parameter to `Radix-2`, this value must be a power of two.

Number of spectral averages

Specify the number of spectra to average. When you set this value to `1`, the block computes the periodogram of the input. When you set this value greater `1`, the block implements “Welch's Method” to compute a modified periodogram of the input.

Inherit sample time from input

If you select the **Inherit sample time from input** check box, the block computes the frequency data from the sample period of the input signal. For the block to produce valid output, the following conditions must hold:

- The input to the block is the original signal, with no samples added or deleted (by insertion of zeros, for example).
- The sample period of the time-domain signal in the simulation equals the sample period of the original time series.

If these conditions do not hold, clear the **Inherit sample time from input** check box. You can then specify a sample time using the **Sample time of original time series** parameter.

Sample time of original time series

Specify the sample time of the original time-domain signal. This parameter becomes visible only when you clear the **Inherit sample time from input** check box.

Example

The dspstfft example provides an illustration of using the Periodogram and Matrix Viewer blocks to create a spectrogram. The dspsacomp example compares the Periodogram block with several other spectral estimation methods.

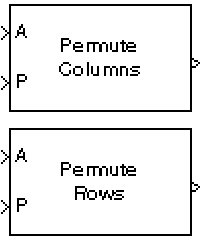
Permute Matrix

Reorder matrix rows or columns

Library

Math Functions / Matrices and Linear Algebra / Matrix Operations

`dspmtrx3`



Description

The Permute Matrix block reorders the rows or columns of M-by-N input matrix `A` as specified by indexing input `P`.

When the **Permute** parameter is set to `Rows`, the block uses the rows of `A` to create a new matrix with the same column dimension. Input `P` is a length-L vector whose elements determine where each row from `A` should be placed in the L-by-N output matrix.

```
% Equivalent MATLAB code
y = [A(P(1),:) ; A(P(2),:) ; A(P(3),:) ; ... ; A(P(end),:)]
```

For row permutation, the block treats length-M unoriented vector input at the `A` port as an M-by-1 matrix.

When the **Permute** parameter is set to `Columns`, the block uses the columns of `A` to create a new matrix with the same row dimension. Input `P` is a length-L vector whose elements determine where each column from `A` should be placed in the M-by-L output matrix.

```
% Equivalent MATLAB code
y = [A(:,P(1)) A(:,P(2)) A(:,P(3)) ... A(:,P(end))]
```

For column permutation, the block treats length-N unoriented vector input at the A port as a 1-by-N matrix.

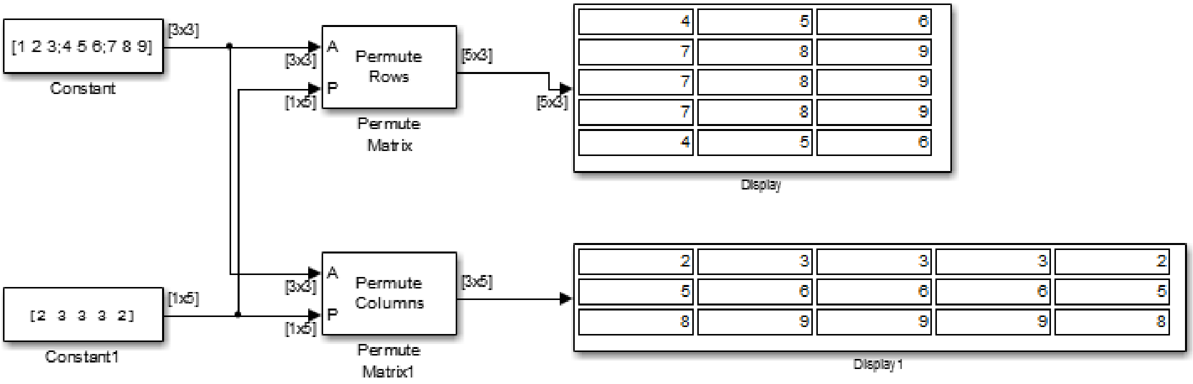
When an index value in input P references a nonexistent row or column of matrix A, the block reacts with the behavior specified by the **Invalid permutation index** parameter. The following options are available:

- `Clip index` — Clip the index to the nearest valid value (1 or M for row permutation, and 1 or N for column permutation), and *do not* issue an alert. Example: For a 3-by-7 input matrix, a column index of 9 is clipped to 7, and a row index of -2 is clipped to 1.
- `Clip and warn` — Display a warning message in the MATLAB command window, and clip the index as described above.
- `Generate error` — Display an error dialog box and terminate the simulation.

When length of the permutation vector P is not equal to the number of rows or columns of the input matrix A, you can choose to get an error dialog box and terminate the simulation by selecting **Error when length of P is not equal to Permute dimension size**.

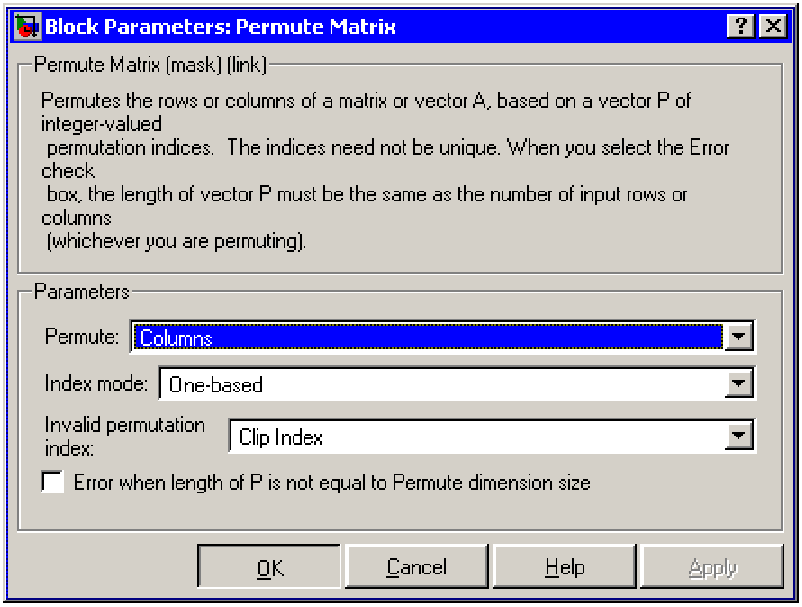
Examples

In the model below, the top Permute Matrix block places the second row of the input matrix in both the first and fifth rows of the output matrix, and places the third row of the input matrix in the three middle rows of the output matrix. The bottom Permute Matrix block places the second column of the input matrix in both the first and fifth columns of the output matrix, and places the third column of the input matrix in the three middle columns of the output matrix.



As shown in the example above, rows and columns of A can appear any number of times in the output, or not at all.

Dialog Box



Block Parameters: Permute Matrix

Permute Matrix (mask) (link)

Permutes the rows or columns of a matrix or vector A, based on a vector P of integer-valued
permutation indices. The indices need not be unique. When you select the Error check
box, the length of vector P must be the same as the number of input rows or columns
(whichever you are permuting).

Parameters

Permute: Columns

Index mode: One-based

Invalid permutation index: Clip Index

☐ Error when length of P is not equal to Permute dimension size

Permute

Method of constructing the output matrix; by permuting rows or columns of the input.

Index mode

When set to `One-based`, a value of `1` in the permutation vector `P` refers to the first row or column of the input matrix `A`. When set to `Zero-based`, a value of `0` in `P` refers to the first row or column of `A`.

Invalid permutation index

Response to an invalid index value. “Tunable”.

Error when length of P is not equal to Permute dimension size

Option to display an error dialog box and terminate the simulation when the length of the permutation vector `P` is not equal to the number of rows or columns of the input matrix `A`.

Supported Data Types

Port	Supported Data Types
A	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers • Enumerated
P	• Double-precision floating point • Single-precision floating point • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers • Enumerated
Output	• Double-precision floating point • Single-precision floating point

Port	Supported Data Types
	• Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers • Enumerated

See “Reorder Channels in Multichannel Frame-Based Signals” for related information.

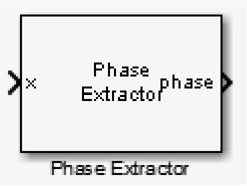
Phase Extractor

Extract the unwrapped phase of a complex input

Library

Signal Operations

`dspsigops`



Description

The Phase Extractor block extracts the unwrapped phase of a complex input. The input can be a vector or matrix. For 2D inputs, the block treats each column as an independent channel. The first dimension is the length of the channel. The second dimension is the number of channels. The block treats 1D inputs as one channel.

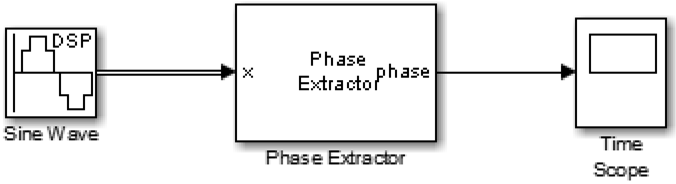
The block preserves the input size and dimension, and the output port rate equals the input port rate.

Examples

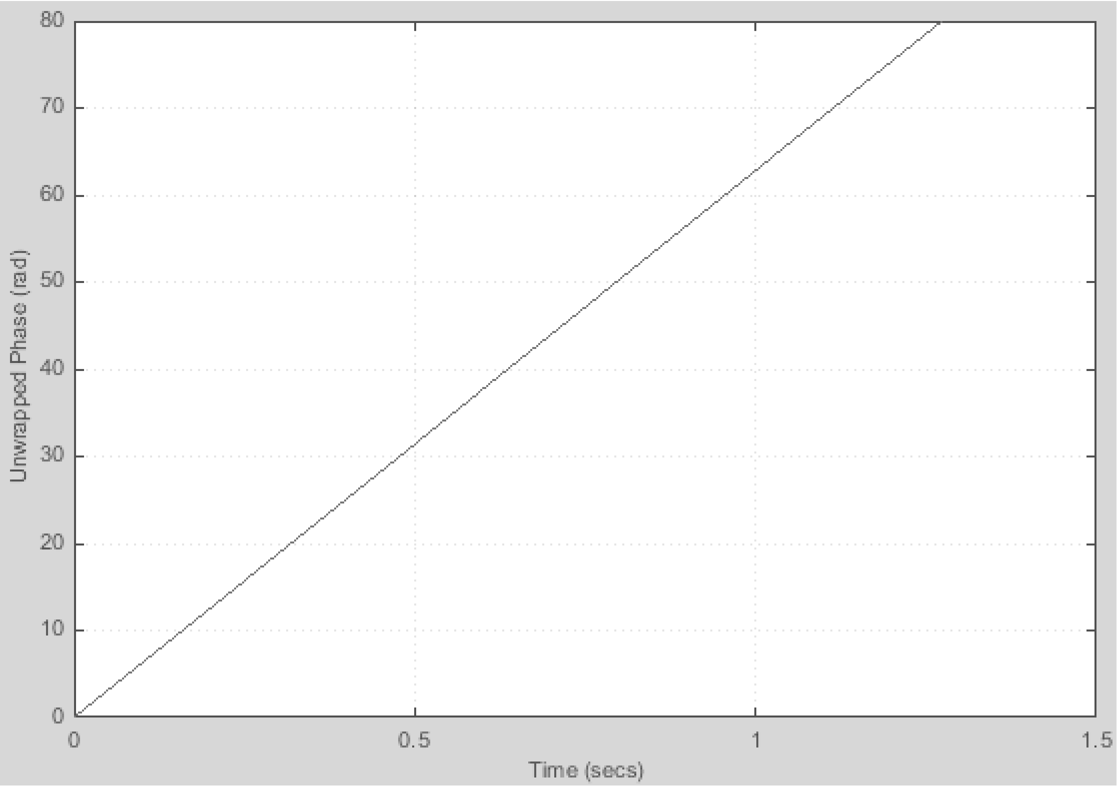
This example shows how to use the Phase Extractor block to extract the phase of a sign wave. The DSP Sine Wave block represents the system input signal. Set the DSP Sine Wave block parameters to the following:

- **Frequency** set to `10` Hz
- **Sample mode** set to `Discrete`
- **Output complexity** set to `Complex`
- **Sample time** set to `1/1000`
- **Sample per frame** set to `128`

Do not select the Phase Extractor block parameter **Unwrap phase only within the frame**.

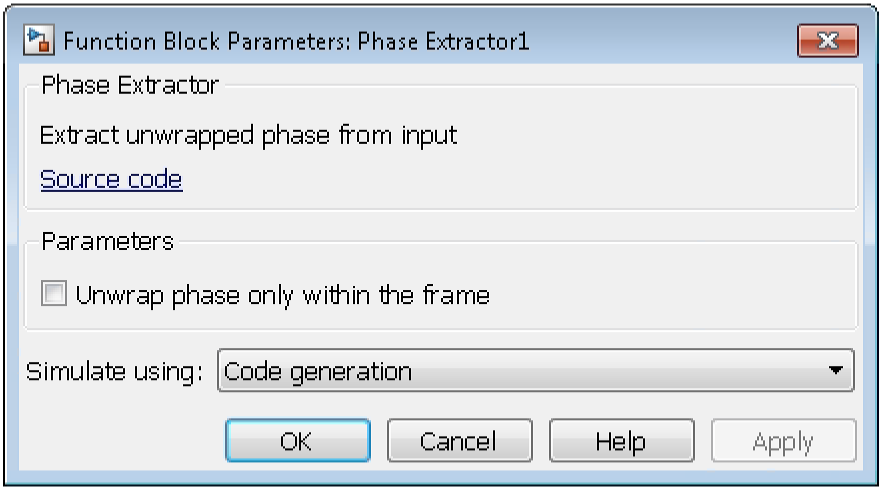


The Time Scope block displays the extracted phase.



Dialog Box

The Phase Extractor block dialog appears as follows.



Function Block Parameters: Phase Extractor1

Phase Extractor

Extract unwrapped phase from input

Source code

Parameters

□ Unwrap phase only within the frame

Simulate using: Code generation

Unwrap phase only within the frame

When you clear this check box, the block ignores boundaries between the input frames. When you select this check box, the block treats each frame of input data independently, and resets the initial phase value for each new input frame.

Simulate using

Select the simulation type from the following:

- `Code generation`
- `Interpreted execution`

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point

Port	Supported Data Types
Output	• Double-precision floating point • Single-precision floating point

Algorithm

Consider an input frame of length N:

$$\begin{pmatrix} x_1 \\ x_2 \\ \vdots \\ x_N \end{pmatrix}$$

The `step` method acts on this frame and produces this output:

$$\begin{pmatrix} \Phi_1 \\ \Phi_2 \\ \vdots \\ \Phi_N \end{pmatrix}$$

where:

$$\Phi_i = \Phi_{i-1} + \mathrm{angle}(x_{i-1}^{*} x_i)$$

Here, i runs from 1 to N. The `angle` function returns the phase angle in radians.

If the input signal consists of multiple frames:

- If you set `TreatFramesIndependently` to `true`, the `step` method treats each frame independently. Therefore, in each frame, the `step` method calculates the phase using the preceding formula where:
  - Φ_0 is 0.
  - x_0 is 1.

- If you set `TreatFramesIndependently` to `false`, the `step` method ignores boundaries between frames. Therefore, in each frame, the `step` method calculates the phase using the preceding formula where:
  - Φ_0 is the last unwrapped phase from the previous frame.
  - x_0 is the last sample from the previous frame.

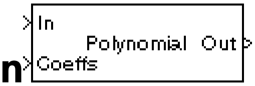
Polynomial Evaluation

Evaluate polynomial expression

Library

Math Functions / Polynomial Functions

`dsppolyfun`



Description

The Polynomial Evaluation block applies a polynomial function to the real or complex input at the `In` port.

```
y = polyval(u)      % Equivalent MATLAB code
```

The Polynomial Evaluation block performs these types of operation more efficiently than the equivalent construction using Simulink Sum and Math Function blocks.

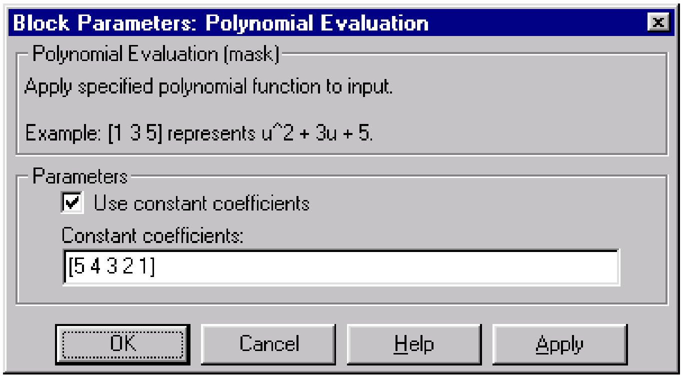
When you select the **Use constant coefficients** check box, you specify the polynomial expression in the **Constant coefficients** parameter. When you do not select **Use constant coefficients**, a variable polynomial expression is specified by the input to the `Coeffs` port. In both cases, the polynomial is specified as a vector of real or complex coefficients in order of descending exponents.

The table below shows some examples of the block's operation for various coefficient vectors.

Coefficient Vector	Equivalent Polynomial Expression
`[1 2 3 4 5]`	$y = u^4 + 2u^3 + 3u^2 + 4u + 5$
`[1 0 3 0 5]`	$y = u^4 + 3u^2 + 5$
`[1 2+i 3 4-3i 5i]`	$y = u^4 + (2+i)u^3 + 3u^2 + (4-3i)u + 5i$

Each element of a vector or matrix input to the `In` port is processed independently, and the output size is the same as the input.

Dialog Box



Block Parameters: Polynomial Evaluation

Polynomial Evaluation (mask)

Apply specified polynomial function to input.

Example: [1 3 5] represents u^2 + 3u + 5.

Parameters

☑ Use constant coefficients

Constant coefficients: [5 4 3 2 1]

Use constant coefficients

Select to enable the **Constant coefficients** parameter and disable the `Coeffs` input port.

Constant coefficients

Specify the vector of polynomial coefficients to apply to the input, in order of descending exponents. This parameter is enabled when you select the **Use constant coefficients** check box.

Supported Data Types

- Double-precision floating point
- Single-precision floating point

Sum	Simulink
`polyval`	MATLAB

Polynomial Stability Test

Use Schur-Cohn algorithm to determine whether all roots of input polynomial are inside unit circle

Library

Math Functions / Polynomial Functions

`dsppolyfun`

Description

The Polynomial Stability Test block uses the Schur-Cohn algorithm to determine whether all roots of a polynomial are within the unit circle.

```
y = all(abs(roots(u)) < 1)        % Equivalent MATLAB code
```

Each column of the M-by-N input matrix u contains M coefficients from a distinct polynomial,

$$f(x) = u_1 x^{M-1} + u_2 x^{M-2} + \ldots + u_M$$

arranged in order of descending exponents, u_1, u_2, ..., u_M. The polynomial has order M-1 and positive integer exponents.

Inputs to the block represent the polynomial coefficients as shown in the previous equation. The block always treats length-M unoriented vector input as an M-by-1 matrix.

The output is a 1-by-N matrix with each column containing the value `1` or `0`. The value `1` indicates that the polynomial in the corresponding column of the input is stable; that is, the magnitudes of all solutions to $f(x) = 0$ are less than 1. The value `0` indicates that the polynomial in the corresponding column of the input might be unstable; that is, the magnitude of at least one solution to $f(x) = 0$ is greater than or equal to 1.

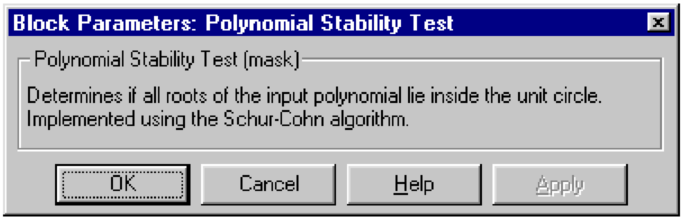
Applications

This block is most commonly used to check the pole locations of the denominator polynomial, $A(z)$, of a transfer function, $H(z)$.

$$H(z) = \frac{B(z)}{A(z)} = \frac{b_1 + b_2 z^{-1} + \ldots + b_m z^{-(m-1)}}{a_1 + a_2 z^{-1} + \ldots + a_n z^{-(n-1)}}$$

The poles are the n-1 roots of the denominator polynomial, $A(z)$. When any poles are located outside the unit circle, the transfer function $H(z)$ is unstable. As is typical in DSP applications, the transfer function above is specified in descending powers of z^{-1} rather than z.

Dialog Box



Block Parameters: Polynomial Stability Test
Polynomial Stability Test (mask)

Determines if all roots of the input polynomial lie inside the unit circle. Implemented using the Schur-Cohn algorithm.

Supported Data Types

- Double-precision floating point
- Single-precision floating point
- Boolean — Block outputs are always Boolean.

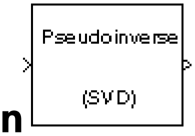
Pseudoinverse

Compute Moore-Penrose pseudoinverse of matrix

Library

Math Functions / Matrices and Linear Algebra / Matrix Inverses

dspinverses



Description

The Pseudoinverse block computes the Moore-Penrose pseudoinverse of input matrix *A*.

```
[U,S,V] = svd(A,0)       % Equivalent MATLAB code
```

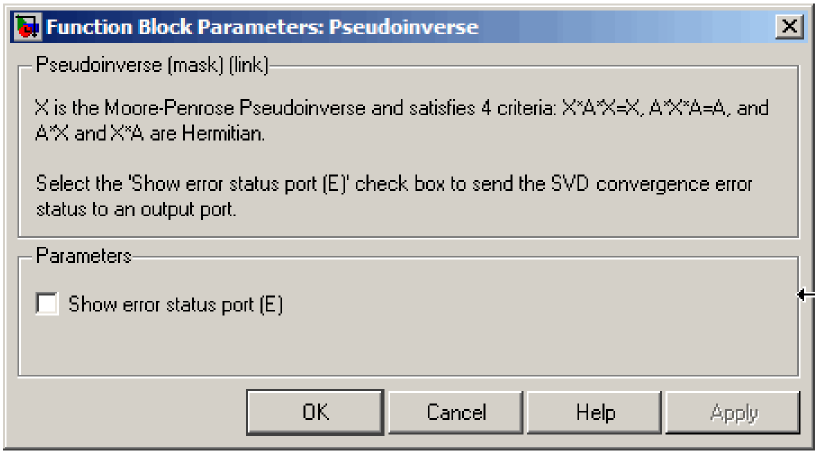
The pseudoinverse of *A* is the matrix $A^{\dagger}$ such that

$$A^{\dagger} = VS^{\dagger}U^{*}$$

where *U* and *V* are orthogonal matrices, and *S* is a diagonal matrix. The pseudoinverse has the following properties:

- $AA^{\dagger} = (AA^{\dagger})^{*}$
- $A^{\dagger}A = (A^{\dagger}A)^{*}$
- $AA^{\dagger}A = A$
- $A^{\dagger}AA^{\dagger} = A^{\dagger}$

Dialog Box



Function Block Parameters: Pseudoinverse

Pseudoinverse (mask) (link)

X is the Moore-Penrose Pseudoinverse and satisfies 4 criteria: X*A*X=X, A*X*A=A, and A*X and X*A are Hermitian.

Select the 'Show error status port (E)' check box to send the SVD convergence error status to an output port.

Parameters

□ Show error status port (E)

Show error status port

Select to enable the E output port, which reports a failure to converge. The possible values you can receive on the port are:

- 0 — The pseudoinverse calculation converges.
- 1 — The pseudoinverse calculation does not converge.

If the pseudoinverse calculation fails to converge, the output at port X is an undefined matrix of the correct size.

Pulse Shaping Filter

Design pulse shaping filter

Library

Filtering / Filter Designs

`dspfdesign`

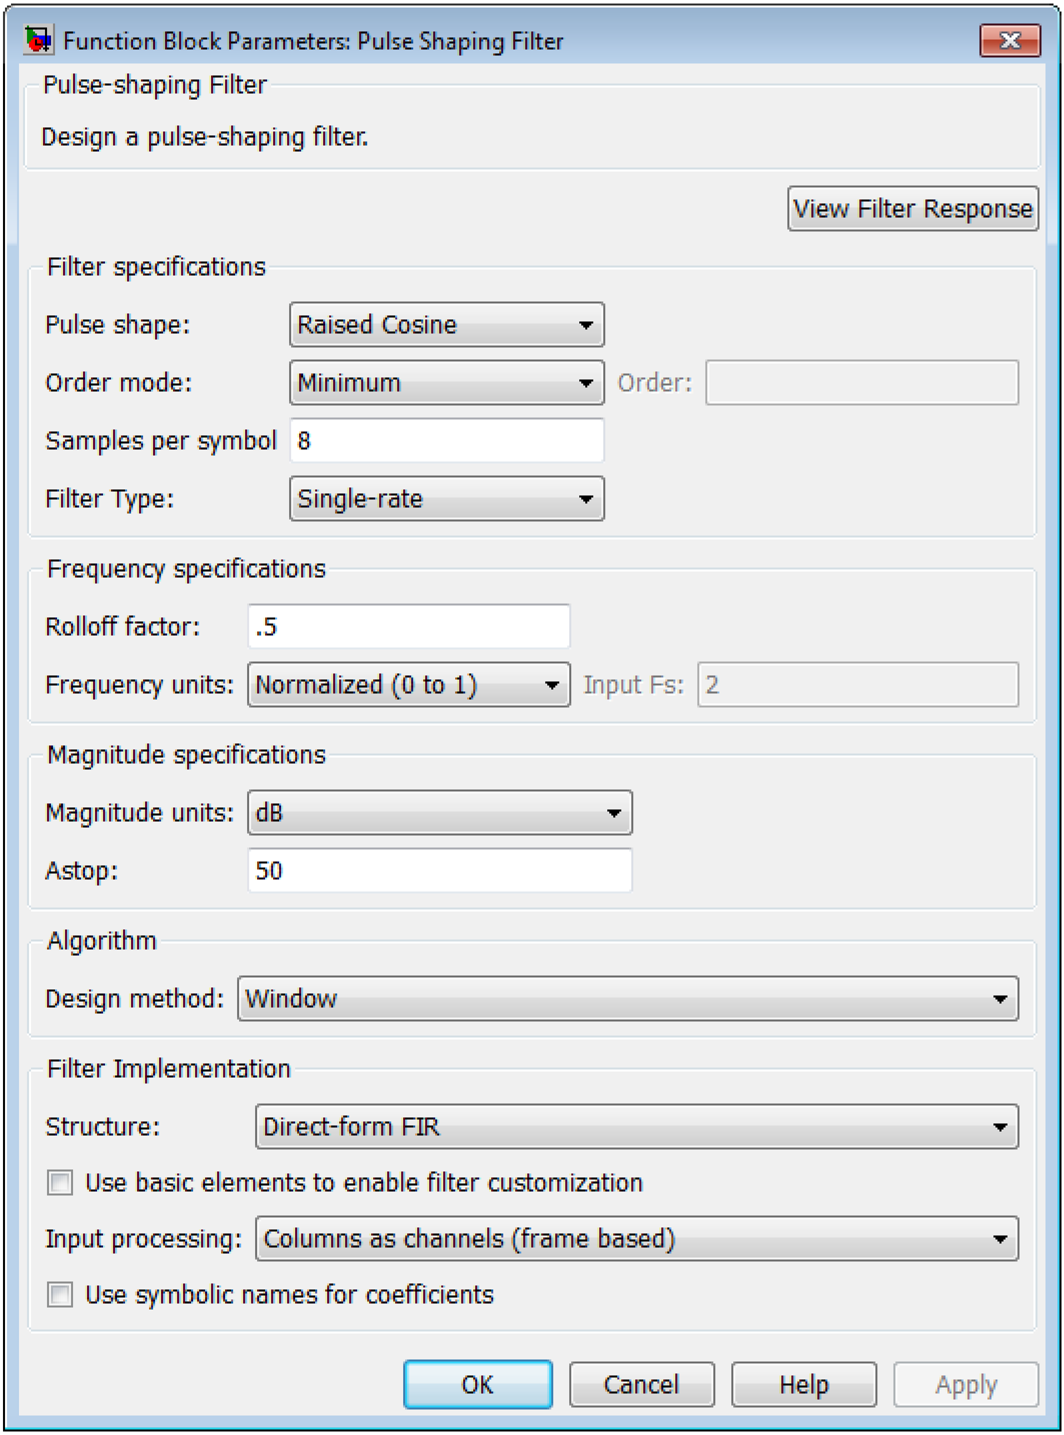
Description

This block brings the filter design capabilities of the “`filterbuilder`” function to the Simulink environment.

Dialog Box

See “Pulse-shaping Filter Design Dialog Box—Main Pane” for more information about the parameters of this block. The **Data Types** and **Code** panes are not available for blocks in the DSP System Toolbox Filter Designs library.

Parameters of this block that do not change filter order or structure are tunable.



Function Block Parameters: Pulse Shaping Filter

Pulse-shaping Filter

Design a pulse-shaping filter.

Filter specifications

Pulse shape: Raised Cosine

Order mode: Minimum

Order:

Samples per symbol 8

Filter Type: Single-rate

Frequency specifications

Rolloff factor: .5

Frequency units: Normalized (0 to 1)

Input Fs: 2

Magnitude specifications

Magnitude units: dB

Astop: 50

Algorithm

Design method: Window

Filter Implementation

Structure: Direct-form FIR

□ Use basic elements to enable filter customization

Input processing: Columns as channels (frame based)

□ Use symbolic names for coefficients

View filter response

This button opens the Filter Visualization Tool (`fvtool`) from the Signal Processing Toolbox product. You can use the tool to display:

- Magnitude response, phase response, and group delay in the frequency domain.
- Impulse response and step response in the time domain.
- Pole-zero information.

The tool also helps you evaluate filter performance by providing information about filter order, stability, and phase linearity. For more information on FVTool, see the Signal Processing Toolbox documentation.

Filter Specifications

In this group, you specify the shape and length of the filter.

Pulse shape

Select the shape of the impulse response from the following options:

- `Raised Cosine`
- `Square Root Raised Cosine`
- `Gaussian`

Order mode

This specification is only available for raised cosine and square root raised cosine filters. For these filters, select one of the following options:

- `Minimum`— This option will result in the minimum-length filter satisfying the user-specified **Frequency specifications**.
- `Specify order`—This option allows the user to construct a raised cosine or square root cosine filter of a specified order by entering an even number in the **Order** input box. The length of the impulse response will be `Order+1` .
- `Specify symbols`—This option enables the user to specify the length of the impulse response in an alternative manner. If `Specify symbols` is chosen, the **Order** input box changes to the **Number of symbols** input box.

Samples per symbol

Specify the oversampling factor. Increasing the oversampling factor guards against aliasing and improves the FIR filter approximation to the ideal frequency response.

If **Order** is specified in **Number of symbols**, the filter length will be **Number of symbols*Samples per symbol**+1. The product **Number of symbols*Samples per symbol** must be an even number.

If a Gaussian filter is specified, the filter length must be specified in **Number of symbols** and **Samples per symbol**. The product **Number of symbols*Samples per symbol** must be an even number. The filter length will be **Number of symbols*Samples per symbol**+1.

Frequency specifications

In this group, you specify the frequency response of the filter. For raised cosine and square root raised cosine filters, the frequency specifications include:

`Rolloff factor`

The rolloff factor takes values in the range [0,1]. The smaller the rolloff factor, the steeper the transition in the stopband.

`Frequency units`

The frequency units are normalized by default. If you specify units other than normalized, the block assumes that you wish to specify an input sampling frequency, and enables this input box. The choice of frequency units are: `Normalized (0 to 1), Hz, kHz, MHz, GHz`

For a Gaussian pulse shape, the available frequency specifications are:

`Bandwidth-time product`

This option allows the user to specify the width of the Gaussian filter. Note that this is independent of the length of the filter. The bandwidth-time product (`BT`) must be a positive real number. Smaller values of the bandwidth-time product result in larger pulse widths in time and steeper stopband transitions in the frequency response.

`Frequency units`

The frequency units are normalized by default. If you specify units other than normalized, the block assumes that you wish to specify an input sampling frequency, and enables this input box. The choice of frequency units are: `Normalized (0 to 1), Hz, kHz, MHz, GHz`

Magnitude specifications

If the **Order mode** is specified as `minimum`, the magnitude units may be selected from:

- `dB` — Specify the magnitude in decibels (default).
- `Linear` — Specify the magnitude in linear units.

Algorithm

The only design method available for FIR pulse-shaping filters is the window method.

Filter Implementation

Structure

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. FIR filters use direct-form structure.

Use basic elements to enable filter customization

Select this check box to implement the filter as a subsystem of basic Simulink blocks. Clear the check box to implement the filter as a high-level subsystem. By default, this check box is cleared.

The high-level implementation provides better compatibility across various filter structures, especially filters that would contain algebraic loops when constructed using basic elements. On the other hand, using basic elements enables the following optimization parameters:

- **Optimize for zero gains** — Terminate chains that contain Gain blocks with a gain of zero.
- **Optimize for unit gains** — Remove Gain blocks that scale by a factor of one.
- **Optimize for delay chains** — Substitute delay chains made up of *n* unit delays with a single delay by *n*.
- **Optimize for negative gains** — Use subtraction in Sum blocks instead of negative gains in Gain blocks.

Optimize for unit-scale values

Select this check box to scale unit gains between sections in SOS filters. This parameter is available only for SOS filters.

Input processing

Specify how the block should process the input. The available options may vary depending on he settings of the **Filter Structure** and **Use basic elements for**

filter customization parameters. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` — When you select this option, the block treats each column of the input as a separate channel.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

Note: The `Inherited (this choice will be removed — see release notes)` option will be removed in a future release. See "Frame-Based Processing" in the *DSP System Toolbox Release Notes* for more information.

Rate options

When the **Filter type** parameter specifies a multirate filter, select the rate processing rule for the block from following options:

- `Enforce single-rate processing` — When you select this option, the block maintains the sample rate of the input.
- `Allow multirate processing` — When you select this option, the block adjusts the rate at the output to accommodate an increased or reduced number of samples. To select this option, you must set the **Input processing** parameter to `Elements as channels (sample based)`.

Use symbolic names for coefficients

Select this check box to enable the specification of coefficients using MATLAB variables. The available coefficient names differ depending on the filter structure. Using symbolic names allows tuning of filter coefficients in generated code. By default, this check box is cleared.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point
Output	• Double-precision floating point • Single-precision floating point

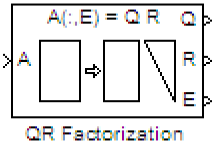
QR Factorization

Factor arbitrary matrix into unitary and upper triangular components

Library

Math Functions / Matrices and Linear Algebra / Matrix Factorizations

`dspfactors`



Description

The QR Factorization block uses a sequence of Householder transformations to triangularize the input matrix A. The block factors a column permutation of the M-by-N input matrix A as
$A_e = QR$

The column-pivoted matrix A_e contains the columns of A permuted as indicated by the contents of length-N permutation vector E.

```
Ae = A(:,E)     % Equivalent MATLAB code
```

The block selects a column permutation vector E, which ensures that the diagonal elements of matrix R are arranged in order of decreasing magnitude.

$$|r_{i+1,j+1}| < |r_{i,j}| \qquad i = j$$

The size of matrices Q and R depends on the setting of the **Output size** parameter:

- When you select `Economy` for the output size, Q is an M-by-min(M,N) unitary matrix, and R is a min(M,N)-by-N upper-triangular matrix.

```
[Q R E] = qr(A,0)   % Equivalent MATLAB code
```

- When you select `Full` for the output size, Q is an M-by-M unitary matrix, and R is a M-by-N upper-triangular matrix.

```
[Q R E] = qr(A)      % Equivalent MATLAB code
```

The block treats length-M unoriented vector input as an M-by-1 matrix.

QR factorization is an important tool for solving linear systems of equations because of good error propagation properties and the invertability of unitary matrices:
$Q^{-1} = Q'$

where Q' is the complex conjugate transpose of Q.

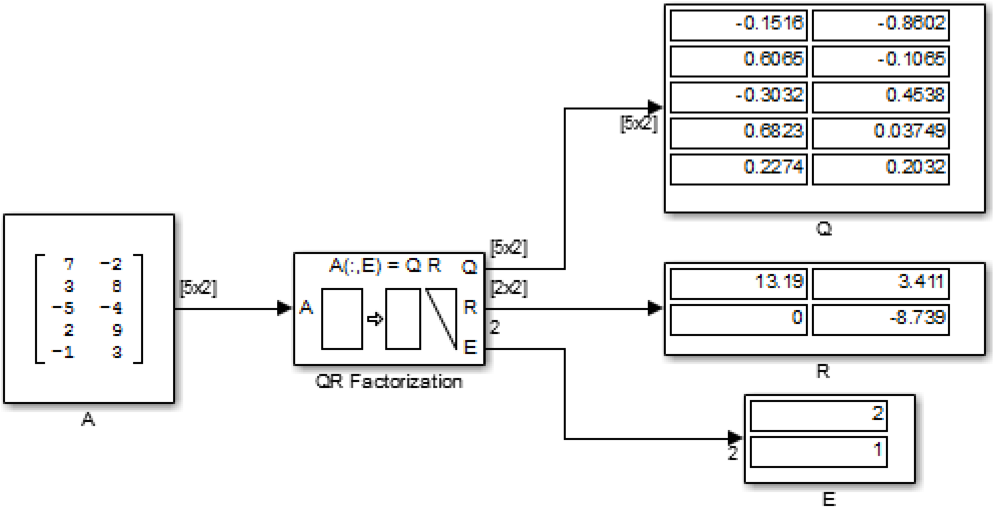
Unlike LU and Cholesky factorizations, the matrix A does not need to be square for QR factorization. However, QR factorization requires twice as many operations as LU Factorization (Gaussian elimination).

Examples

The **Output size** parameter of the QR factorization block has two settings: `Economy` and `Full`. When the M-by-N input matrix A has dimensions such that $M > N$, the dimensions of output matrices Q and R differ depending on the setting of the **Output size** parameter. If, however, the size of the input matrix A is such that $M \leq N$, output matrices Q and R have the same dimensions, regardless of whether the **Output size** is set to `Economy` or `Full`.

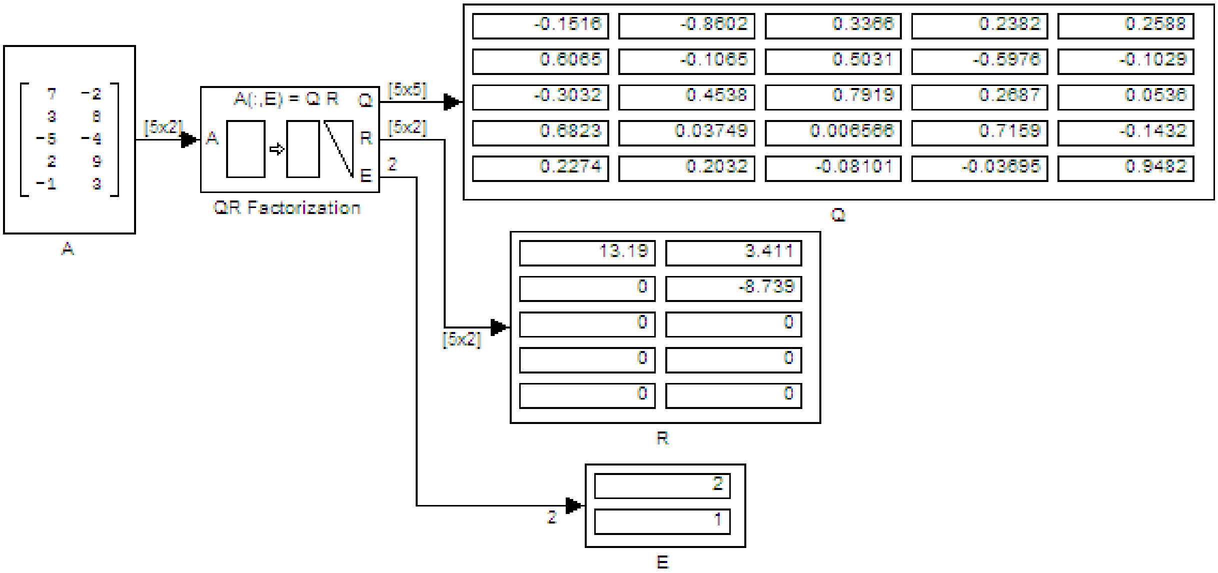
The input to the QR Factorization block in the following model is a `5`-by-`2` matrix A. When you change the setting of the **Output size** parameter from `Economy` to `Full`, the dimensions of the output given by the QR Factorization block also change.

1. Open the model by typing `ex_qrfactorization_ref` at the MATLAB command line.
2. Double-click the QR Factorization block, set the **Output size** parameter to `Economy`, and run the model.



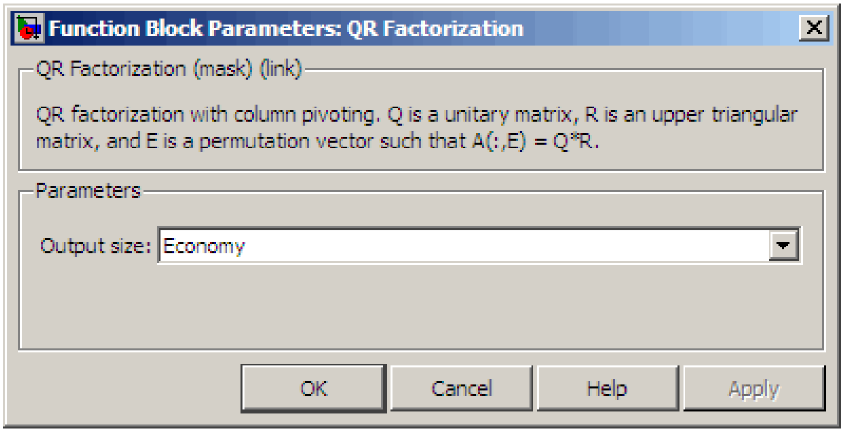
The QR Factorization block outputs a 5-by-2 matrix *Q* and a 2-by-2 matrix *R*.

3 Change the **Output size** parameter of the QR Factorization block to `Full` and rerun the model.



The QR Factorization block outputs a 5-by-5 matrix Q and a 5-by-2 matrix R.

Dialog Box



Function Block Parameters: QR Factorization

QR Factorization (mask) (link)

QR factorization with column pivoting. Q is a unitary matrix, R is an upper triangular matrix, and E is a permutation vector such that A(:,E) = Q*R.

Parameters

Output size: Economy

Output size

Specify the size of output matrices Q and R:

- `Economy` — When this output size is selected, the block outputs an M-by-min(M,N) unitary matrix Q and a min(M,N)-by-N upper-triangular matrix R.
- `Full` — When this output size is selected, the block outputs an M-by-M unitary matrix Q and a M-by-N upper-triangular matrix R.

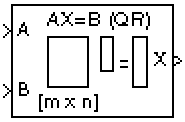
QR Solver

Find minimum-norm-residual solution to A*X*=B

Library

Math Functions / Matrices and Linear Algebra / Linear System Solvers

`dspsolvers`



Description

The QR Solver block solves the linear system A*X*=B, which can be overdetermined, underdetermined, or exactly determined. The system is solved by applying QR factorization to the M-by-N matrix, A, at the `A` port. The input to the `B` port is the right side M-by-L matrix, B. The block treats length-M unoriented vector input as an M-by-1 matrix.

The output at the `X` port is the N-by-L matrix, X. X is chosen to minimize the sum of the squares of the elements of B-AX. When B is a vector, this solution minimizes the vector 2-norm of the residual (B-AX is the residual). When B is a matrix, this solution minimizes the matrix Frobenius norm of the residual. In this case, the columns of X are the solutions to the L corresponding systems $AX_k=B_k$, where B_k is the kth column of B, and X_k is the kth column of *X*.

X is known as the minimum-norm-residual solution to AX=B. The minimum-norm-residual solution is unique for overdetermined and exactly determined linear systems, but it is not unique for underdetermined linear systems. Thus when the QR Solver is applied to an underdetermined system, the output *X* is chosen such that the number of nonzero entries in X is minimized.

Algorithm

QR factorization factors a column-permuted variant (A_e) of the M-by-N input matrix A as

$A_e = QR$

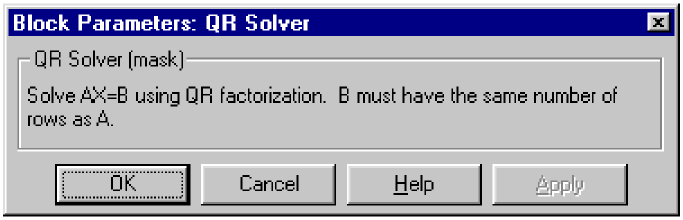
where Q is a M-by-min(M,N) unitary matrix, and R is a min(M,N)-by-N upper-triangular matrix.

The factored matrix is substituted for A_e in
$A_e X = B_e$

and
$QRX = B_e$

is solved for X by noting that $Q^{-1} = Q^*$ and substituting $Y = Q^* B_e$. This requires computing a matrix multiplication for Y and solving a triangular system for X.
$RX = Y$

Dialog Box



Block Parameters: QR Solver

Quantizer

Discretize input at specified interval

Library

Quantizers

`dspquant2`

Description

The Quantizer block is an implementation of the Simulink Quantizer block. See Quantizer for more information.

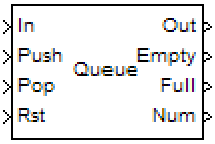
Queue

Store inputs in FIFO register

Library

Signal Management / Buffers

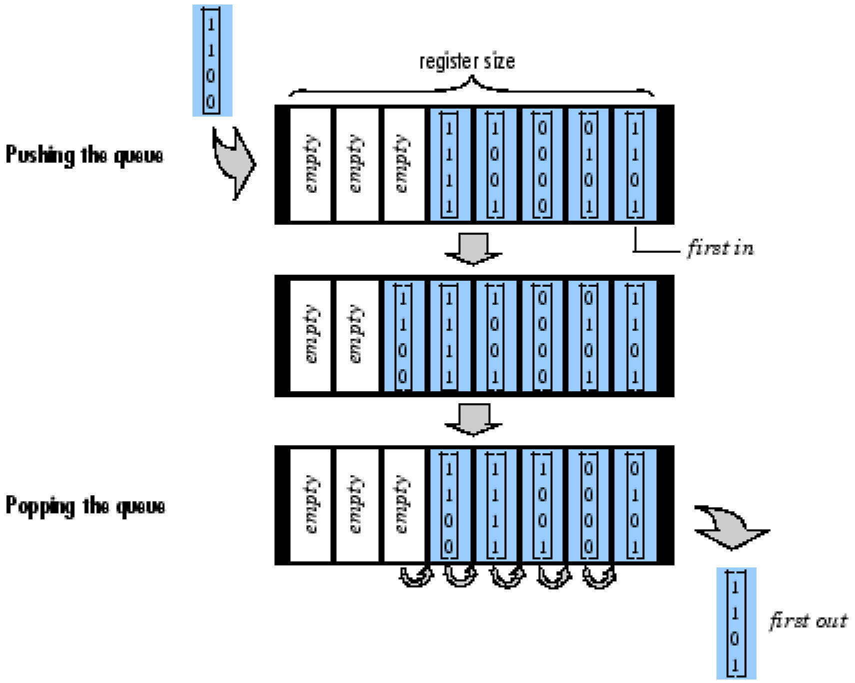
`dspbuff3`



Description

The Queue block stores a sequence of input samples in a first in, first out (FIFO) register. The register capacity is set by the **Register size** parameter, and inputs can be scalars, vectors, or matrices.

The block *pushes* the input at the `In` port onto the end of the queue when a trigger event is received at the `Push` port. When a trigger event is received at the `Pop` port, the block *pops* the first element off the queue and holds the `Out` port at that value. The first input to be pushed onto the queue is always the first to be popped off.



A trigger event at the optional `Rst` port empties the queue contents. When you select **Clear output port on reset**, then a trigger event at the `Rst` port empties the queue *and* sets the value at the `Out` port to zero. This setting also applies when a disabled subsystem containing the Queue block is reenabled; the `Out` port value is only reset to zero in this case when you select **Clear output port on reset**.

When you select the **Allow direct feedthrough** check box and two or more of the control input ports are triggered at the same time step, the operations are executed in the following order:

1. `Rst`
2. `Push`
3. `Pop`

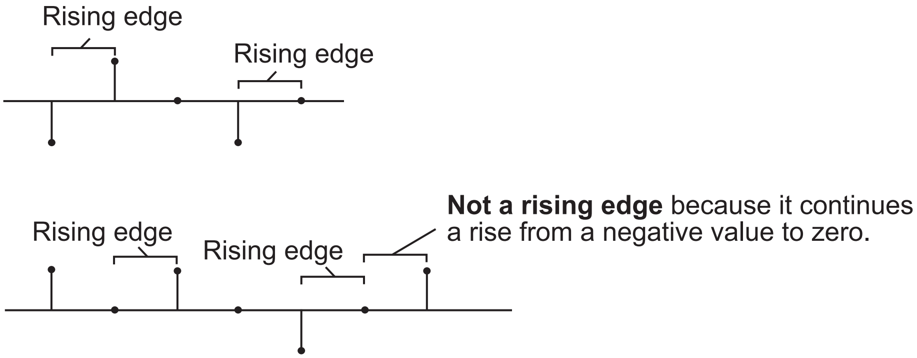
When you clear the **Allow direct feedthrough** check box and two or more of the control input ports are triggered at the same time step, the operations are executed in the following order:

1. `Rst`
2. `Pop`
3. `Push`

The rate of the trigger signal must be the same as the rate of the data signal input. You specify the triggering event for the `Push`, `Pop`, `and Rst` ports by the **Trigger type** pop-up menu:

- `Rising edge` — Triggers execution of the block when the trigger input does one of the following:

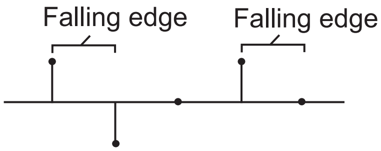
  - Rises from a negative value to a positive value or zero
  - Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero; see the following figure

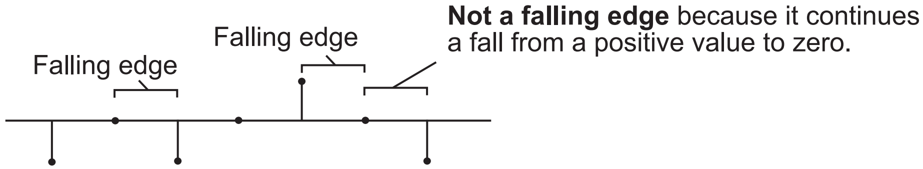


Rising edge
Rising edge
Rising edge
Rising edge
Not a rising edge because it continues a rise from a negative value to zero.

- `Falling edge` — Triggers execution of the block when the trigger input does one of the following:

  - Falls from a positive value to a negative value or zero
  - Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero; see the following figure





Falling edge
Falling edge
Not a falling edge because it continues a fall from a positive value to zero.

- `Either edge` — Triggers execution of the block when the trigger input is a `Rising edge` or `Falling edge` (as described above).
- `Non-zero sample` — Triggers execution of the block at each sample time that the trigger input is not zero.

Note: If your model contains any referenced models that use a Queue block with the **Push onto full register** parameter set to `Dynamic reallocation`, you cannot simulate your top-level model in Simulink Accelerator mode.

The **Push onto full register** parameter specifies the block's behavior when a trigger is received at the `Push` port but the register is full. The **Pop empty register** parameter specifies the block's behavior when a trigger is received at the `Pop` port but the register is empty. The following options are available for both cases:

- `Ignore` — Ignore the trigger event, and continue the simulation.
- `Warning` — Ignore the trigger event, but display a warning message in the MATLAB Command Window.
- `Error` — Display an error dialog box and terminate the simulation.

Note The **Push onto full register** and **Pop empty register** parameters are diagnostic parameters. Like all diagnostic parameters on the Configuration Parameters dialog box, they are set to `Ignore` in the code generated for this block by Simulink Coder code generation software.

The **Push onto full register** parameter additionally offers the **Dynamic reallocation** option, which dynamically resizes the register to accept as many additional inputs as memory permits. To find out how many elements are on the queue at a given time, enable the `Num` output port by selecting the **Show number of register entries port** parameter.

Note: When `Dynamic reallocation` is selected, the **System target file** parameter on the **Code Generation** pane of the Model Configuration Parameters dialog box must be set to `grt_malloc.tlc — Generic Real-Time Target with dynamic memory allocation`.

Examples

Example 1

The table below illustrates the Queue block's operation for a **Register size** of 4, **Trigger type** of `Either edge`, and **Clear output port on reset** enabled. Because the block triggers on both rising and falling edges in this example, each transition from `1` to `0` or `0` to `1` in the `Push`, `Pop`, and `Rst` columns below represents a distinct trigger event. A `1` in the `Empty` column indicates an empty queue, while a `1` in the `Full` column indicates a full queue.

In	Push	Pop	Rst	Queue	Out	Empty	Full	Num
1	0	0	0		0	1	0	0
2	1	0	0		0	0	0	1
3	0	0	0		0	0	0	2
4	1	0	0		0	0	0	3
5	0	0	0		0	0	1	4
6	0	1	0		2	0	0	3
7	0	0	0		3	0	0	2

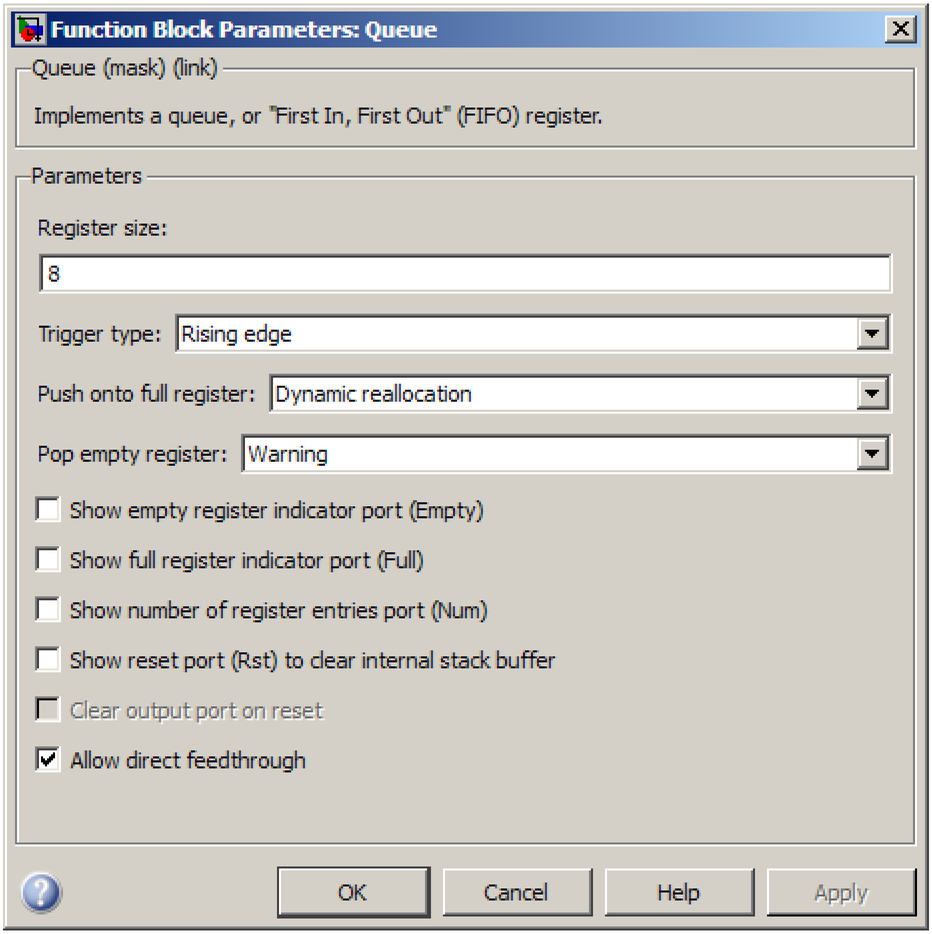
In	Push	Pop	Rst	Queue	Out	Empty	Full	Num
8	0	1	0		4	0	0	1
9	0	0	0		5	1	0	0
10	1	0	0		5	0	0	1
11	0	0	0		5	0	0	2
12	1	0	1		0	0	0	1

Note that at the last step shown, the `Push` and `Rst` ports are triggered simultaneously. The `Rst` trigger takes precedence, and the queue is first cleared and then pushed.

Example 2

The dspqdemo example provides another example of the operation of the Queue block.

Dialog Box



Function Block Parameters: Queue

Queue (mask) (link)

Implements a queue, or "First In, First Out" (FIFO) register.

Parameters

Register size:

8

Trigger type: Rising edge

Push onto full register: Dynamic reallocation

Pop empty register: Warning

□ Show empty register indicator port (Empty)

□ Show full register indicator port (Full)

□ Show number of register entries port (Num)

□ Show reset port (Rst) to clear internal stack buffer

□ Clear output port on reset

☑ Allow direct feedthrough

Register size

The number of entries that the FIFO register can hold.

Trigger type

The type of event that triggers the block's execution. The rate of the trigger signal must be the same as the rate of the data signal input.

Push onto full register

Response to a trigger received at the `Push` port when the register is full. Inputs to this port must have the same built-in data type as inputs to the `Pop` and `Rst` input ports.

When `Dynamic reallocation` is selected, the **System target file** parameter on the **Code Generation** pane of the Model Configuration Parameters dialog box must be set to `grt_malloc.tlc — Generic Real-Time Target with dynamic memory allocation`.

Pop empty register

Response to a trigger received at the `Pop` port when the register is empty. Inputs to this port must have the same built-in data type as inputs to the `Push` and `Rst` input ports.

Show empty register indicator port

Enable the `Empty` output port, which is high (`1`) when the queue is empty, and low (`0`) otherwise.

Show full register indicator port

Enable the `Full` output port, which is high (`1`) when the queue is full, and low (`0`) otherwise. The `Full` port remains low when you select `Dynamic reallocation` from the **Push onto full register** parameter.

Show number of register entries port

Enable the `Num` output port, which tracks the number of entries currently on the queue. When inputs to the `In` port are double-precision values, the outputs from the `Num` port are double-precision values. Otherwise, the outputs from the `Num` port are 32-bit unsigned integer values.

Show reset port to clear internal stack buffer

Enable the `Rst` input port, which empties the queue when the trigger specified by the **Trigger type** is received. Inputs to this port must have the same built-in data type as inputs to the `Push` and `Pop` input ports.

Clear output port on reset

Reset the `Out` port to zero, in addition to clearing the queue, when a trigger is received at the `Rst` input port.

Allow direct feedthrough

When you select this check box, the input data is available immediately at the output port of the block. You can turn off direct feedthrough and delay the input data by an extra frame by clearing the **Allow direct feedthrough** check box.

Supported Data Types

Port	Supported Data Types
In	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Push	• Double-precision floating point • Single-precision floating point • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers Inputs to this port must have the same built-in data type as inputs to the Pop and Rst input ports
Pop	• Double-precision floating point • Single-precision floating point • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers Inputs to this port must have the same built-in data type as inputs to the Push and Rst input ports.
Rst	• Double-precision floating point • Single-precision floating point • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers Inputs to this port must have the same built-in data type as inputs to the Push and Pop input ports.

Port	Supported Data Types
Out	• Double-precision floating point • Single-precision floating point • Fixed point (signed only) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Empty	• Double-precision floating point • Boolean
Full	• Double-precision floating point • Boolean
Num	• Double-precision floating point The block outputs a double-precision floating-point value at this port when the data type of the In port is double-precision floating-point. • 32-bit unsigned integers The block outputs a 32-bit unsigned integer value at this port when the data type of the In port is anything other than double-precision floating-point.

Random Source

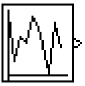
Generate randomly distributed values

Library

Sources

`dspsrcs4`

Description



The Random Source block generates a frame of M values drawn from a uniform or Gaussian pseudorandom distribution, where you specify M in the **Samples per frame** parameter.

This reference page contains a detailed discussion of the following Random Source block topics:

- “Distribution Type” on page 1-1185
- “Output Complexity” on page 1-1186
- “Output Repeatability” on page 1-1187
- “Specifying the Initial Seed” on page 1-1188
- “Sample Period” on page 1-1189
- “Dialog Box” on page 1-1189
- “Supported Data Types” on page 1-1192
- “See Also” on page 1-1192

Distribution Type

When the **Source type** parameter is set to `Uniform`, the output samples are drawn from a uniform distribution whose minimum and maximum values are specified by the **Minimum** and **Maximum** parameters, respectively. All values in this range are equally likely to be selected. A length-N vector specified for one or both of these parameters generates an N-channel output (M-by-N matrix) containing a unique random distribution in each channel.

For example, specify

- **Minimum** = `[ 0 0 -3 -3]`
- **Maximum** = `[10 10 20 20]`

to generate a four-channel output whose first and second columns contain random values in the range [0, 10], and whose third and fourth columns contain random values in the range [-3, 20]. When you specify only one of the **Minimum** and **Maximum** parameters as a vector, the block scalar expands the other parameter so it is the same length as the vector.

When the **Source type** parameter is set to `Gaussian`, you must also set the **Method** parameter, which determines the method by which the block computes the output, and has the following settings:

- `Ziggurat` — Produces Gaussian random values by using the Ziggurat method.
- `Sum of uniform values` — Produces Gaussian random values by adding and scaling uniformly distributed random signals based on the central limit theorem. This theorem states that the probability distribution of the sum of a sufficiently high number of random variables approaches the Gaussian distribution. You must set the **Number of uniform values to sum** parameter, which determines the number of uniformly distributed random numbers to sum to produce a single Gaussian random value.

For both settings of the **Method** parameter, the output samples are drawn from the normal distribution defined by the **Mean** and **Variance** parameters. A length-N vector specified for one or both of the **Mean** and **Variance** parameters generates an N-channel output (M-by-N frame matrix) containing a distinct random distribution in each column. When you specify only one of these parameters as a vector, the block scalar expands the other parameter so it is the same length as the vector.

Output Complexity

The block's output can be either real or complex, as determined by the `Real` and `Complex` options in the **Complexity** parameter. These settings control all channels of the output, so real and complex data cannot be combined in the same output. For complex output with a `Uniform` distribution, the real and imaginary components in each channel are both drawn from the same uniform random distribution, defined by the **Minimum** and **Maximum** parameters for that channel.

For complex output with a `Gaussian` distribution, the real and imaginary components in each channel are drawn from normal distributions with different means. In this case, the **Mean** parameter for each channel should specify a complex value; the real component of the **Mean** parameter specifies the mean of the real components in the channel, while the imaginary component specifies the mean of the imaginary components in the channel. When either the real or imaginary component is omitted from the **Mean** parameter, a default value of 0 is used for the mean of that component.

For example, a **Mean** parameter setting of `[5+2i 0.5 3i]` generates a three-channel output with the following means.

Channel 1 mean	*real* = 5	*imaginary* = 2
Channel 2 mean	*real* = 0.5	*imaginary* = 0
Channel 3 mean	*real* = 0	*imaginary* = 3

For complex output, the **Variance** parameter, σ^2, specifies the *total variance* for each output channel. This is the sum of the variances of the real and imaginary components in that channel.

$$\sigma^2 = \sigma^2_{\mathrm{Re}} + \sigma^2_{\mathrm{Im}}$$

The specified variance is equally divided between the real and imaginary components, so that

$$\sigma^2_{\mathrm{Re}} = \frac{\sigma^2}{2}$$

$$\sigma^2_{\mathrm{Im}} = \frac{\sigma^2}{2}$$

Output Repeatability

The **Repeatability** parameter determines whether or not the block outputs the same signal each time you run the simulation. You can set the parameter to one of the following options:

- `Repeatable` — Outputs the same signal each time you run the simulation. The first time you run the simulation, the block randomly selects an initial seed. The block reuses these same initial seeds every time you rerun the simulation.
- `Specify seed` — Outputs the same signal each time you run the simulation. Every time you run the simulation, the block uses the initial seed(s) specified in the **Initial seed** parameter. Also see "Specifying the Initial Seed" on page 1-1188.
- `Not repeatable` — Does not output the same signal each time you run the simulation. Every time you run the simulation, the block randomly selects an initial seed.

Specifying the Initial Seed

When you set the **Repeatability** parameter to `Specify seed`, you must set the **Initial seed** parameter. The **Initial seed** parameter specifies the initial seed for the pseudorandom number generator. The generator produces an identical sequence of pseudorandom numbers each time it is executed with a particular initial seed.

Specifying Initial Seeds for Real Outputs

To specify the N initial seeds for an N-channel real-valued output, **Complexity** parameter set to `Real`, provide one of the following in the **Initial seed** parameter:

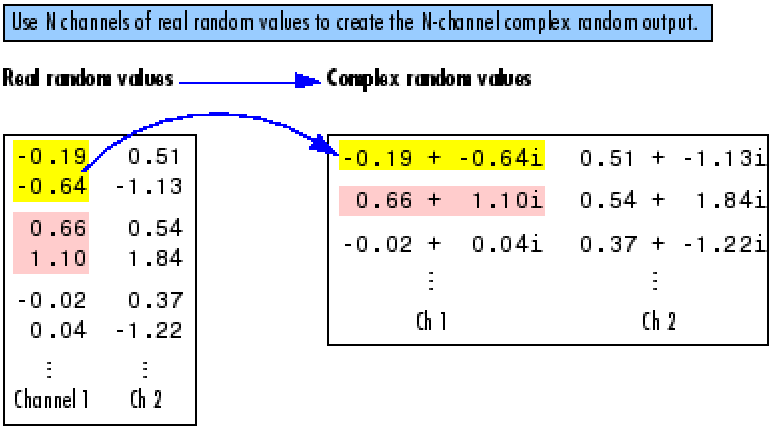
- Length-N vector of initial seeds — Uses each vector element as an initial seed for the corresponding channel in the N-channel output.
- Single scalar — Uses the scalar to generate N random values, which it uses as the seeds for the N-channel output.

Specifying Initial Seeds for Complex Outputs

To specify the initial seeds for an N-channel complex-valued output, **Complexity** parameter set to `Complex`, provide one of the following in the **Initial seed** parameter:

- Length-N vector of initial seeds — Uses each vector element as an initial seed for generating N channels of *real* random values. The block uses pairs of adjacent values in each of these channels as the real and imaginary components of the final output, as illustrated in the following figure.
- Single scalar — Uses the scalar to generate N random values, which it uses as the seeds for generating N channels of *real* random values. The block uses pairs of

adjacent values in each of these channels as the real and imaginary components of the final output, as illustrated in the following figure.



Use N channels of real random values to create the N-channel complex random output.
Real random values
Complex random values
-0.19 0.51

⋮ ⋮
Ch 1 Ch 2

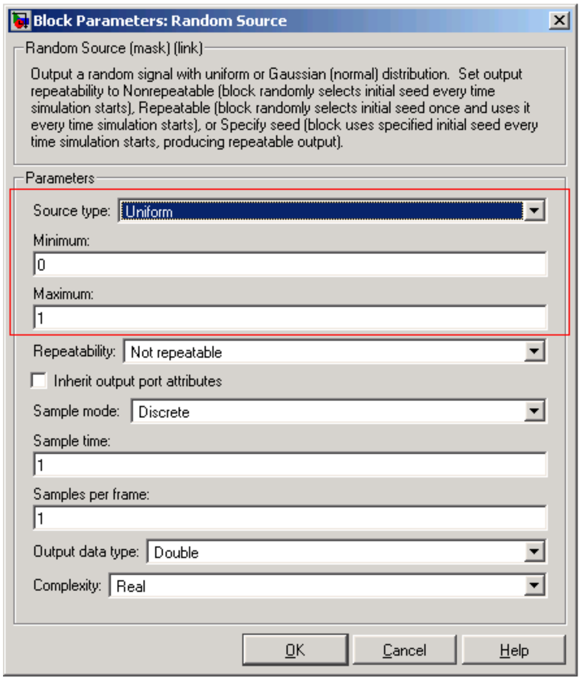
Sample Period

The **Sample time** parameter value, T_s, specifies the random sequence sample period when the **Sample mode** parameter is set to `Discrete`. In this mode, the block generates the number of samples specified by the **Samples per frame** parameter value, M, and outputs this frame with a period of $M*T_s$. For M=1, the output is sample based; otherwise, the output is frame based.

When **Sample mode** is set to `Continuous`, the block is configured for continuous-time operation, and the **Sample time** and **Samples per frame** parameters are disabled. Note that many DSP System Toolbox blocks do not accept continuous-time inputs.

Dialog Box

Only some of the parameters described below are visible in the dialog box at any one time.



Block Parameters: Random Source

Random Source (mask) (link)

Output a random signal with uniform or Gaussian (normal) distribution. Set output repeatability to Nonrepeatable (block randomly selects initial seed every time simulation starts), Repeatable (block randomly selects initial seed once and uses it every time simulation starts), or Specify seed (block uses specified initial seed every time simulation starts, producing repeatable output).

Parameters

Source type: Uniform

Minimum: 0

Maximum: 1

Repeatability: Not repeatable

□ Inherit output port attributes

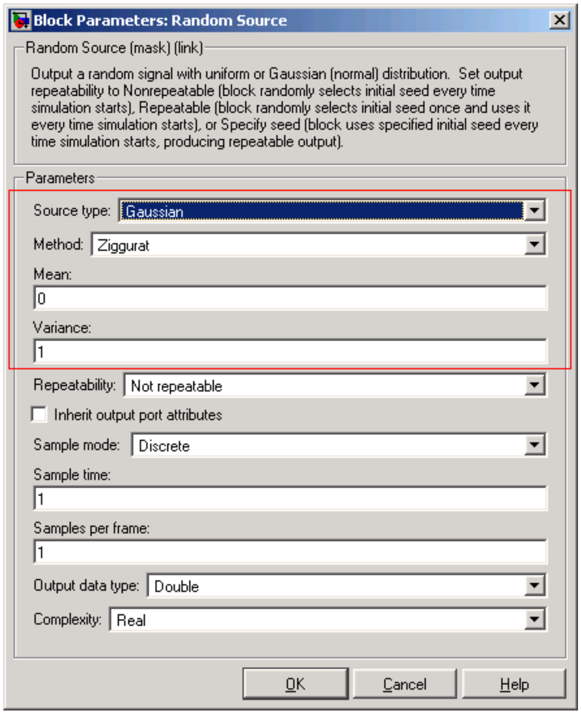
Sample mode: Discrete

Sample time: 1

Samples per frame: 1

Output data type: Double

Complexity: Real



Block Parameters: Random Source

Random Source (mask) (link)

Output a random signal with uniform or Gaussian (normal) distribution. Set output repeatability to Nonrepeatable (block randomly selects initial seed every time simulation starts), Repeatable (block randomly selects initial seed once and uses it every time simulation starts), or Specify seed (block uses specified initial seed every time simulation starts, producing repeatable output).

Parameters

Source type: Gaussian

Method: Ziggurat

Mean: 0

Variance: 1

Repeatability: Not repeatable

□ Inherit output port attributes

Sample mode: Discrete

Sample time: 1

Samples per frame: 1

Output data type: Double

Complexity: Real

Source type

The distribution from which to draw the random values, `Uniform` or `Gaussian`. For more information, see “Distribution Type” on page 1-1185.

Method

The method by which the block computes the Gaussian random values, `Ziggurat` or `Sum of uniform values`. This parameter is enabled when **Source type** is set to `Gaussian`. For more information, see “Distribution Type” on page 1-1185.

Minimum

The minimum value in the uniform distribution. This parameter is enabled when you select `Uniform` from the **Source type** parameter. “Tunable”.

Maximum

The maximum value in the uniform distribution. This parameter is enabled when you select you select `Uniform` from the **Source type** parameter. “Tunable”.

Number of uniform values to sum

The number of uniformly distributed random values to sum to compute a single number in a Gaussian random distribution. This parameter is enabled when the **Source type** parameter is set to `Gaussian`, and the **Method** parameter is set to `Sum of uniform values`. For more information, see "Distribution Type" on page 1-1185.

Mean

The mean of the Gaussian (normal) distribution. This parameter is enabled when you select `Gaussian` from the **Source type** parameter. "Tunable".

Variance

The variance of the Gaussian (normal) distribution. This parameter is enabled when you select `Gaussian` from the **Source type** parameter. "Tunable".

Repeatability

The repeatability of the block output: `Not repeatable`, `Repeatable`, or `Specify seed`. In the `Repeatable` and `Specify seed` settings, the block outputs the same signal every time you run the simulation. For details, see "Output Repeatability" on page 1-1187.

Initial seed

The initial seed(s) to use for the random number generator when you set the **Repeatability** parameter to `Specify seed`. For details, see "Specifying the Initial Seed" on page 1-1188. "Tunable".

Inherit output port attributes

When you select this check box, block inherits the sample mode, sample time, output data type, complexity, and signal dimensions of a sample-based signal from a downstream block. When you select this check box, the **Sample mode**, **Sample time**, **Samples per frame**, **Output data type**, and **Complexity** parameters are disabled.

Suppose you want to back propagate a 1-D vector. The output of the Random Source block is a length M sample-based 1-D vector, where length M is inherited from the downstream block. When the **Minimum**, **Maximum**, **Mean**, or **Variance** parameter specifies N channels, the 1-D vector output contains M/N samples from each channel. An error occurs in this case when M is not an integer multiple of N.

Suppose you want to back propagate a M-by-N signal. When N>1, your signal has N channels. When N = 1, your signal has M channels. The value of the **Minimum**, **Maximum**, **Mean**, or **Variance** parameter can be a scalar or a vector of length equal to the number of channels. You can specify these parameters as either row or column vectors, except when the signal is a row vector. In this case, the **Minimum**, **Maximum**, **Mean**, or **Variance** parameter must also be specified as a row vector.

Sample mode

The sample mode, `Continuous` or `Discrete`. This parameter is enabled when the **Inherit output port attributes** check box is cleared.

Sample time

The sample period, T_s, of the random output sequence. The output frame period is $M*T_s$. This parameter is enabled when the **Inherit output port attributes** check box is cleared.

Samples per frame

The number of samples, M, in each output frame. When the value of this parameter is `1`, the block outputs a sample-based signal.

This parameter is enabled when the **Inherit output port attributes** check box is cleared.

Output data type

The data type of the output, single-precision or double-precision. This parameter is enabled when the **Inherit output port attributes** check box is cleared.

Complexity

The complexity of the output, `Real` or `Complex`. This parameter is enabled when the **Inherit output port attributes** check box is cleared.

Supported Data Types

- Double-precision floating-point
- Single-precision floating-point

Real Cepstrum

Compute real cepstrum of input

Library

Transforms

`dspxfrm3`

Description

The Real Cepstrum block computes the real cepstrum of each column in the real-valued *M*-by-*N* input matrix, `u`. The block treats each column of the input as an independent channel containing *M* consecutive samples. The block does not accept complex-valued inputs.

The output is a real M_o-by-*N* matrix, where you specify M_o in the **FFT length** parameter. Each output column contains the length-M_o real cepstrum of the corresponding input column.

```
y = real(ifft(log(abs(fft(u,Mo)))))
```

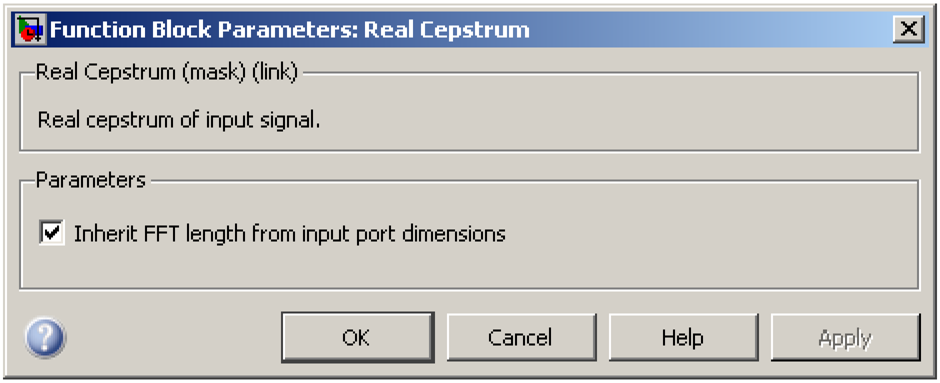
or, more compactly,

```
y = rceps(u,Mo)
```

When you select the **Inherit FFT length from input port dimensions** check box, the output frame size matches the input frame size (M_o=*M*). In this case, the block processes *sample-based* length-*M* row vector inputs as a single channel (that is, as an *M*-by-1 column vector), and returns the result as a length-*M* column vector. The block *always* processes unoriented vector inputs as a single channel, and returns the result as a length-*M* column vector.

The output port rate is the same as the input port rate.

Dialog Box



Function Block Parameters: Real Cepstrum

Real Cepstrum (mask) (link)

Real cepstrum of input signal.

Parameters

☑ Inherit FFT length from input port dimensions

Inherit FFT length from input port dimensions

When you select this check box, the output frame size matches the input frame size.

FFT length

The number of frequency points at which to compute the FFT, which is also the output frame size, M_o. This parameter is visible only when you clear the **Inherit FFT length from input port dimensions** check box.

Supported Data Types

- Double-precision floating point
- Single-precision floating point

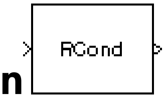
Reciprocal Condition

Compute reciprocal condition of square matrix in 1-norm

Library

Math Functions / Matrices and Linear Algebra / Matrix Operations

```
dspmtrx3
```



Description

The Reciprocal Condition block computes the reciprocal of the condition number for a square input matrix A.

```
y = rcond(A)     % Equivalent MATLAB code
```

or

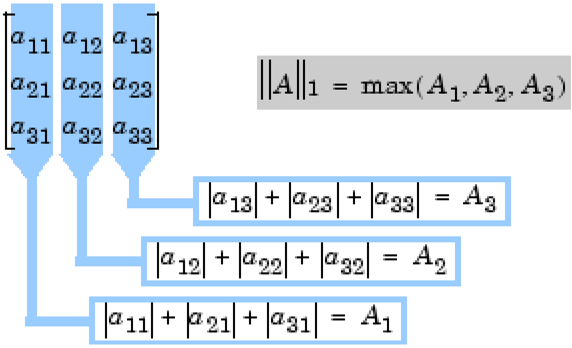
$$y = \frac{1}{\kappa} = \frac{1}{\left\|A^{-1}\right\|_1 \left\|A\ \right\|_1}$$

where κ is the condition number ($\kappa \ge 1$), and y is the scalar output ($0 \le y < 1$).

The matrix 1-norm, $\|A\|_1$, is the maximum column-sum in the M-by-M matrix A.

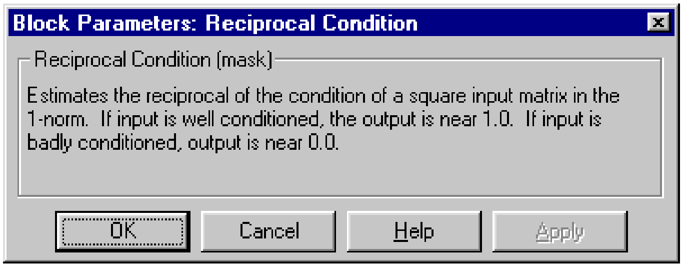
$$\|A\|_1 = \overset{\max}{1 \le j \le M} \sum_{i=1}^{M} \left|a_{ij}\right|$$

For a 3-by-3 matrix:



$\begin{bmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \\ a_{31} & a_{32} & a_{33} \end{bmatrix}$
$\|A\|_1 = \max(A_1, A_2, A_3)$
$|a_{13}| + |a_{23}| + |a_{33}| = A_3$
$|a_{12}| + |a_{22}| + |a_{32}| = A_2$
$|a_{11}| + |a_{21}| + |a_{31}| = A_1$

Dialog Box



Block Parameters: Reciprocal Condition

Reciprocal Condition (mask)

Estimates the reciprocal of the condition of a square input matrix in the 1-norm. If input is well conditioned, the output is near 1.0. If input is badly conditioned, output is near 0.0.

Repeat

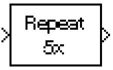
Resample input at higher rate by repeating values

Library

Signal Operations

`dspsigops`

Description



The Repeat block upsamples each channel of the M_i-by-N input to a rate L times higher than the input sample rate. To do so, the block repeats each consecutive input sample L times at the output. You specify the integer L in the **Repetition count** parameter.

You can use the Repeat block inside of triggered subsystems when you set the **Rate options** parameter to `Enforce single-rate processing`.

Frame-Based Processing

When you set the **Input processing** parameter to `Columns as channels (frame based)`, the block upsamples each column of the input over time. In this mode, the block can perform either single-rate or multirate processing. You can use the **Rate options** parameter to specify how the block upsamples the input:

- When you set the **Rate options** parameter to `Enforce single-rate processing`, the input and output of the block have the same sample rate. In this mode, the block outputs a signal with a proportionally larger frame *size* than the input. The block upsamples each channel independently by repeating each row of the input matrix L times at the output. For upsampling by a factor of L, the output frame size is L times larger than the input frame size ($M_o = M_i*L$), but the input and output frame rates are equal.

  For an example of single-rate upsampling, see Example: Single-Rate Processing.

- When you set the **Rate options** parameter to `Allow multirate processing`, the block treats an M_i-by-N matrix input as N independent channels. The block generates the output at the faster (upsampled) rate by using a proportionally shorter frame *period* at the output port than at the input port. For L repetitions of the input, the output frame period is L times shorter than the input frame period ($T_{fo} = T_{fi}/L$). In this mode, the output always has the same frame size as the input.

  See Example: Multirate, Frame-Based Processing for an example that uses the Repeat block in this mode.

Sample-Based Processing

When you set the **Input processing** parameter to `Elements as channels (sample based)`, the block treats an M-by-N matrix input as $M*N$ independent channels, and upsamples each channel over time. The block upsamples each channel over time such that the output sample rate is L times higher than the input sample rate ($T_{so} = T_{si}/L$). In this mode, the output is always the same size as the input.

Zero Latency

The Repeat block has *zero-tasking latency* for all single-rate operations. The block is in a single-rate mode if you set the **Repetition count** parameter to `1` or if you set the **Input processing** parameter to `Columns as channels (frame based)` and the **Rate options** parameter to `Enforce single-rate processing`.

The Repeat block also has zero-tasking latency for multirate operations if you run your model in Simulink single-tasking mode.

Zero-tasking latency means that the block repeats the first input (received at t=**0**) for the first L output samples, the second input for the next L output samples, and so on.

Nonzero Latency

The Repeat block has tasking latency for multirate, multitasking operation:

- In multirate, sample-based processing mode, the initial condition for each channel is repeated for the first L output samples. The channel's first input appears as output sample L+1. The **Initial conditions** parameter can be an M_i-by-N matrix containing one value for each channel, or a scalar to be applied to all signal channels.

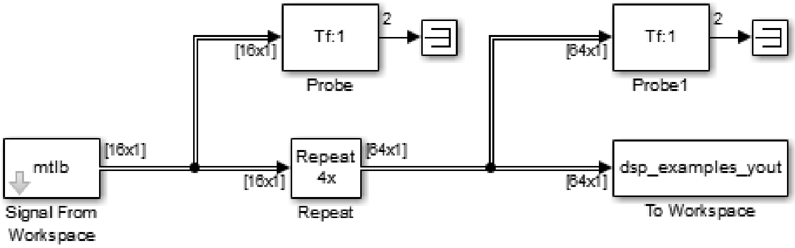
- In multirate, frame-based processing mode, the first row of the initial condition matrix is repeated for the first L output samples, the second row of the initial condition matrix is repeated for the next L output samples, and so on. The first row of the first input matrix appears in the output as sample M_iL+1. The **Initial conditions** parameter can be an M_i-by-N matrix, or a scalar to be repeated across all elements of the M_i-by-N matrix.

Note: For more information on latency and the Simulink tasking modes, see "Excess Algorithmic Delay (Tasking Latency)" and "Scheduling " in the *Simulink Coder User's Guide*.

Examples

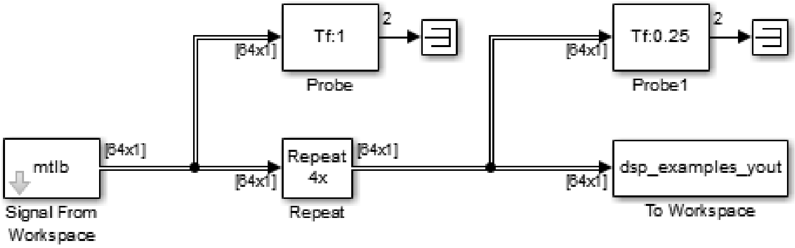
Example: Single-Rate Processing

In the ex_repeat_ref2 model, the Repeat block resamples a single-channel input with a frame size of 16. The block repeats input values to upsample the input by a factor of 4. Thus, the output of the block has a frame size of 64. The input and output frame rates are identical.

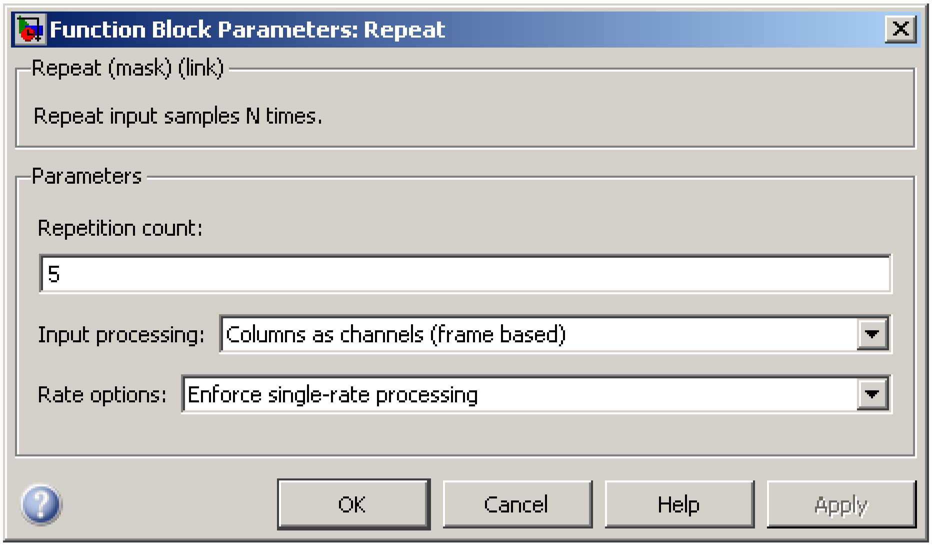


Example: Multirate, Frame-Based Processing

In the ex_repeat_ref1 model, the Repeat block resamples a single-channel input with a frame period of 1 second. The block repeats input values to upsample the input by a factor of 4. Thus, the output of the block has a frame period of 0.25 seconds. The input and output frame sizes are identical.



Dialog Box



Function Block Parameters: Repeat

Repeat (mask) (link)

Repeat input samples N times.

Parameters

Repetition count: 5

Input processing: Columns as channels (frame based)

Rate options: Enforce single-rate processing

Repetition count

The integer number of times, L, that the input value is repeated at the output. This is the factor by which the block increases the output frame size or sample rate.

Input processing

Specify how the block should process the input. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` — When you select this option, the block treats each column of the input as a separate channel. In this mode, the block can perform single-rate or multirate processing.

- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel. In this mode, the block always performs multirate processing.

Note: The option `Inherit from input (this choice will be removed - see release notes)` will be removed in a future release. See “Frame-Based Processing” in the *DSP System Toolbox Release Notes* for more information.

Rate options

Specify the method by which the block upsamples the input. You can select one of the following options:

- `Enforce single-rate processing` — When you select this option, the block maintains the input sample rate by increasing the output frame size by a factor of *L*. To select this option, you must set the **Input processing** parameter to `Columns as channels (frame based)`.
- `Allow multirate processing` — When you select this option, the block resamples the signal such that the output sample rate is *L* times faster than the input sample rate.

Initial conditions

The value with which the block is initialized for cases of nonzero latency; a scalar or matrix. This parameter appears only when you configure the block to perform multirate processing.

HDL Code Generation

This block supports HDL code generation using HDL Coder. HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic. For more information on implementations, properties, and restrictions for HDL code generation, see Repeat.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point

Port	Supported Data Types
	• Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers

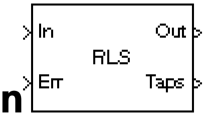
RLS Adaptive Filter (Obsolete)

Compute filter estimates for input using RLS adaptive filter algorithm

Library

dspobslib



Description

Note The RLS Adaptive Filter block is still supported but is likely to be obsoleted in a future release. We strongly recommend replacing this block with the RLS Filter block.

The RLS Adaptive Filter block recursively computes the recursive least squares (RLS) estimate of the FIR filter coefficients.

The corresponding RLS filter is expressed in matrix form as

$$
\begin{aligned}
k(n) &= \frac{\lambda^{-1}P(n-1)u(n)}{1+\lambda^{-1}u^H(n)P(n-1)u(n)}\\
y(n) &= \hat{w}^H(n-1)u(n)\\
e(n) &= d(n)-y(n)\\
\hat{w}(n) &= \hat{w}(n-1)+k(n)e^*(n)\\
P(n) &= \lambda^{-1}P(n-1)-\lambda^{-1}k(n)u^H(n)P(n-1)
\end{aligned}
$$

where λ^{-1} denotes the reciprocal of the exponential weighting factor. The variables are as follows

Variable	Description
n	The current algorithm iteration

Variable	Description
$u(n)$	The buffered input samples at step n
$P(n)$	The inverse correlation matrix at step n
$k(n)$	The gain vector at step n
$\hat{w}(n)$	The vector of filter-tap estimates at step n
$y(n)$	The filtered output at step n
$e(n)$	The estimation error at step n
$d(n)$	The desired response at step n
λ	The exponential memory weighting factor

The block icon has port labels corresponding to the inputs and outputs of the RLS algorithm. Note that inputs to the `In` and `Err` ports must be sample-based scalars. The signal at the `Out` port is a scalar, while the signal at the `Taps` port is a sample-based vector.

Block Ports	Corresponding Variables
`In`	u, the scalar input, which is internally buffered into the vector $u(n)$
`Out`	$y(n)$, the filtered scalar output
`Err`	$e(n)$, the scalar estimation error
`Taps`	$\hat{w}(0)$, the vector of filter-tap estimates

An optional `Adapt` input port is added when you select the **Adapt input** check box in the dialog box. When this port is enabled, the block continuously adapts the filter coefficients while the `Adapt` input is nonzero. A zero-valued input to the `Adapt` port causes the block to stop adapting, and to hold the filter coefficients at their current values until the next nonzero `Adapt` input.

The implementation of the algorithm in the block is optimized by exploiting the symmetry of the inverse correlation matrix $P(n)$. This decreases the total number of computations by a factor of two.

The **FIR filter length** parameter specifies the length of the filter that the RLS algorithm estimates. The **Memory weighting factor** corresponds to λ in the equations, and specifies how quickly the filter “forgets” past sample information. Setting λ=1 specifies an infinite memory; typically, 0.95≤λ≤1.

The **Initial value of filter taps** specifies the initial value $\hat{w}(0)$ as a vector, or as a scalar to be repeated for all vector elements. The initial value of $P(n)$ is

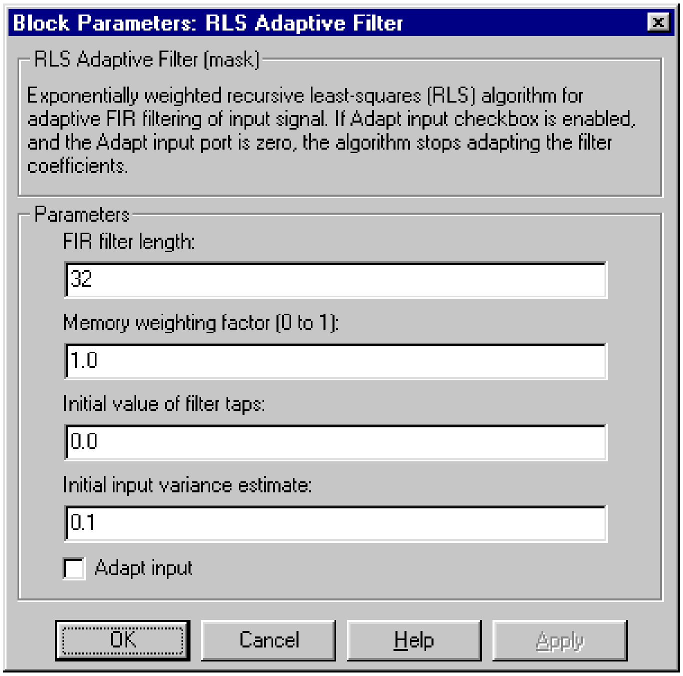
$$I\frac{1}{\hat{\sigma}^2}$$

where you specify $\hat{\sigma}^2$ in the **Initial input variance estimate** parameter.

Examples

The rlsdemo example illustrates a noise cancellation system built around the RLS Adaptive Filter block.

Dialog Box



Block Parameters: RLS Adaptive Filter

RLS Adaptive Filter (mask)

Exponentially weighted recursive least-squares (RLS) algorithm for adaptive FIR filtering of input signal. If Adapt input checkbox is enabled, and the Adapt input port is zero, the algorithm stops adapting the filter coefficients.

Parameters

FIR filter length: 32

Memory weighting factor (0 to 1): 1.0

Initial value of filter taps: 0.0

Initial input variance estimate: 0.1

□ Adapt input

FIR filter length

The length of the FIR filter.

Memory weighting factor

The exponential weighting factor, in the range `[0,1]`. A value of `1` specifies an infinite memory. “Tunable”.

Initial value of filter taps

The initial FIR filter coefficients.

Initial input variance estimate

The initial value of 1/P(*n*).

Adapt input

Enables the `Adapt` port.

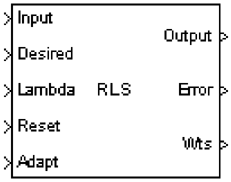
RLS Filter

Compute filtered output, filter error, and filter weights for given input and desired signal using RLS adaptive filter algorithm

Library

Filtering / Adaptive Filters

`dspadpt3`



RLS Filter

Description

The RLS Filter block recursively computes the least squares estimate (RLS) of the FIR filter weights. The block estimates the filter weights, or coefficients, needed to convert the input signal into the desired signal. Connect the signal you want to filter to the Input port. The input signal can be a scalar or a column vector. Connect the signal you want to model to the Desired port. The desired signal must have the same data type, complexity, and dimensions as the input signal. The Output port outputs the filtered input signal. The Error port outputs the result of subtracting the output signal from the desired signal.

The corresponding RLS filter is expressed in matrix form as

$$\mathbf{k}(n) = \frac{\lambda^{-1}\mathbf{P}(n-1)\mathbf{u}(n)}{1+\lambda^{-1}\mathbf{u}^{H}(n)\mathbf{P}(n-1)\mathbf{u}(n)}$$

$$y(n) = \mathbf{w}(n-1)\mathbf{u}(n)$$

$$e(n) = d(n) - y(n)$$

$$\mathbf{w}(n) = \mathbf{w}(n-1) + \mathbf{k}^{H}(n)e(n)$$

$$\mathbf{P}(n) = \lambda^{-1}\mathbf{P}(n-1) - \lambda^{-1}\mathbf{k}(n)\mathbf{u}^{H}(n)\mathbf{P}(n-1)$$

where λ^{-1} denotes the reciprocal of the exponential weighting factor. The variables are as follows

Variable	Description
n	The current time index
$\mathbf{u}(n)$	The vector of buffered input samples at step n
$\mathbf{P}(n)$	The inverse covariance matrix at step n
$\mathbf{k}(n)$	The gain vector at step n
$\mathbf{w}(n)$	The vector of filter-tap estimates at step n
$y(n)$	The filtered output at step n
$e(n)$	The estimation error at step n
$d(n)$	The desired response at step n
λ	The forgetting factor

The implementation of the algorithm in the block is optimized by exploiting the symmetry of the inverse covariance matrix $P(n)$. This decreases the total number of computations by a factor of two.

Use the **Filter length** parameter to specify the length of the filter weights vector.

The **Forgetting factor (0 to 1)** parameter corresponds to λ in the equations. It specifies how quickly the filter "forgets" past sample information. Setting λ=1 specifies an infinite memory. Typically, $1-\frac{1}{2L}<\lambda<1$, where L is the filter length. You can specify a forgetting factor using the input port, Lambda, or enter a value in the **Forgetting factor (0 to 1)** parameter in the Block Parameters: RLS Filter dialog box.

Enter the initial filter weights, $\widehat{w}(0)$, as a vector or a scalar for the **Initial value of filter weights** parameter. When you enter a scalar, the block uses the scalar value to create a vector of filter weights. This vector has length equal to the filter length and all of its values are equal to the scalar value.

The initial value of $P(n)$ is

$$\frac{1}{\sigma^2}I$$

where you specify σ^2 in the **Initial input variance estimate** parameter.

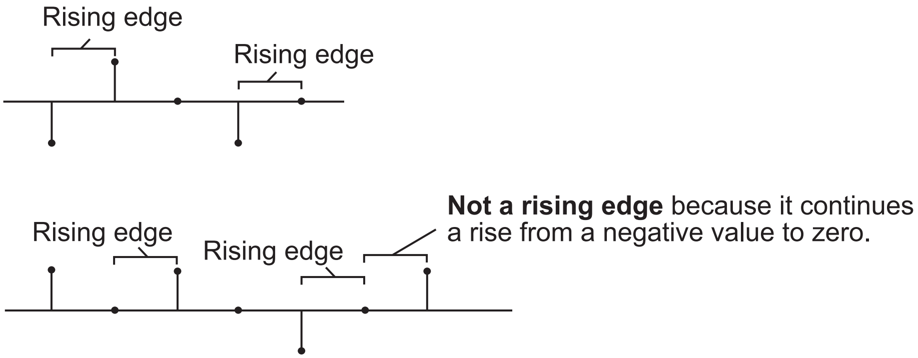
When you select the **Adapt port** check box, an Adapt port appears on the block. When the input to this port is nonzero, the block continuously updates the filter weights. When the input to this port is zero, the filter weights remain at their current values.

When you want to reset the value of the filter weights to their initial values, use the **Reset input** parameter. The block resets the filter weights whenever a reset event is detected at the Reset port. The reset signal rate must be the same rate as the data signal input.

From the **Reset input** list, select `None` to disable the Reset port. To enable the Reset port, select one of the following from the **Reset input** list:

- `Rising edge` — Triggers a reset operation when the Reset input does one of the following:

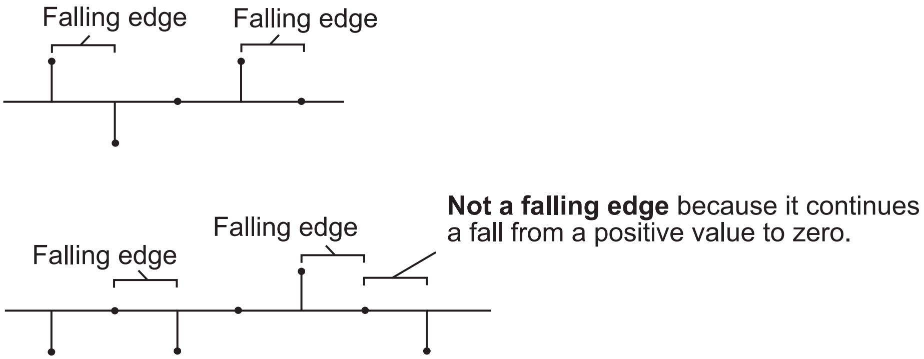
  - Rises from a negative value to a positive value or zero
  - Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero; see the following figure



Rising edge
Rising edge
Rising edge
Rising edge
Not a rising edge because it continues a rise from a negative value to zero.

- `Falling edge` — Triggers a reset operation when the Reset input does one of the following:

  - Falls from a positive value to a negative value or zero
  - Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero; see the following figure



Falling edge
Falling edge
Falling edge
Falling edge
Not a falling edge because it continues a fall from a positive value to zero.

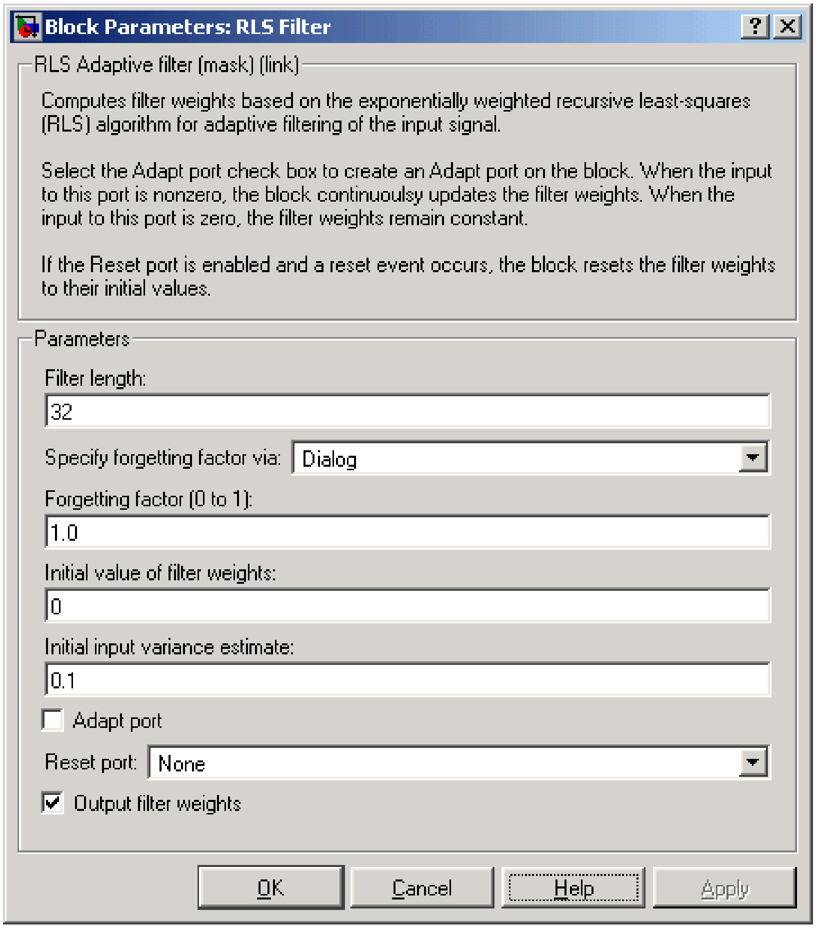
- `Either edge` — Triggers a reset operation when the Reset input is a `Rising edge` or `Falling edge`, as described above
- `Non-zero sample` — Triggers a reset operation at each sample time that the Reset input is not zero

Select the **Output filter weights** check box to create a Wts port on the block. For each iteration, the block outputs the current updated filter weights from this port.

Examples

The rlsdemo example illustrates a noise cancellation system built around the RLS Filter block.

Dialog Box



Block Parameters: RLS Filter

RLS Adaptive filter (mask) (link)

Computes filter weights based on the exponentially weighted recursive least-squares (RLS) algorithm for adaptive filtering of the input signal.

Select the Adapt port check box to create an Adapt port on the block. When the input to this port is nonzero, the block continuoulsy updates the filter weights. When the input to this port is zero, the filter weights remain constant.

If the Reset port is enabled and a reset event occurs, the block resets the filter weights to their initial values.

Parameters

Filter length: 32

Specify forgetting factor via: Dialog

Forgetting factor (0 to 1): 1.0

Initial value of filter weights: 0

Initial input variance estimate: 0.1

□ Adapt port

Reset port: None

☑ Output filter weights

Filter length

Enter the length of the FIR filter weights vector.

Specify forgetting factor via

Select `Dialog` to enter a value for the forgetting factor in the Block parameters: RLS Filter dialog box. Select `Input port` to specify the forgetting factor using the Lambda input port.

Forgetting factor (0 to 1)

Enter the exponential weighting factor in the range 0 $\leq\lambda\leq$1. A value of 1 specifies an infinite memory. "Tunable".

Initial value of filter weights

Specify the initial values of the FIR filter weights.

Initial input variance estimate

The initial value of 1/P(*n*).

Adapt port

Select this check box to enable the Adapt input port.

Reset input

Select this check box to enable the Reset input port.

Output filter weights

Select this check box to export the filter weights from the Wts port.

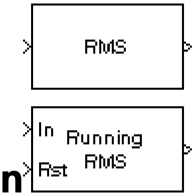
RMS

Compute root-mean-square value of input or sequence of inputs

Library

Statistics

`dspstat3`



Description

The RMS block computes the RMS value of each row or column of the input, along vectors of a specified dimension of the input, or of the entire input. The RMS block can also track the RMS value in a sequence of inputs over a period of time. The **Running RMS** parameter selects between basic operation and running operation.

Basic Operation

When you do not select the **Running RMS** check box, the block computes the RMS value of each row or column of the input, along vectors of a specified dimension of the input, or of the entire input at each individual sample time, and outputs the array *y*. Each element in *y* is the RMS value of the corresponding column, row, vector, or entire input. The output *y* depends on the setting of the **Find the RMS value over** parameter. For example, consider a 3-dimensional input signal of size *M*-by-*N*-by-*P*:

- `Entire input` — The output at each sample time is a scalar that contains the RMS value of the entire input.
- `Each row` — The output at each sample time consists of an *M*-by-1-by-*P* array, where each element contains the RMS value of each vector over the second dimension of the input. For an input that is an *M*-by-*N* matrix, the output at each sample time is an *M*-by-1 column vector.

- `Each column` — The output at each sample time consists of a 1-by-*N*-by-*P* array, where each element contains the RMS value of each vector over the first dimension of the input. For an input that is an *M*-by-*N* matrix, the output at each sample time is a 1-by-*N* row vector.

  In this mode, the block treats length-*M* unoriented vector inputs as *M*-by-1 column vectors.
- `Specified dimension` — The output at each sample time depends on **Dimension**. If **Dimension** is set to 1, the output is the same as that when you select `Each column`. If **Dimension** is set to 2, the output is the same as when you select `Each row`. If **Dimension** is set to 3, the output at each sample time is an *M*-by-*N* matrix containing the RMS value of each vector over the third dimension of the input.

The RMS value of the *j*th column of an *M*-by-*N* input matrix *u* is given by

$$y_j = \sqrt{\frac{\sum_{i=1}^{M} \left|u_{ij}\right|^2}{M}} \qquad 1 \le j \le N$$

```
y = sqrt(sum(u.*conj(u))/size(u,1))     % Equivalent MATLAB code
```

Running Operation

When you select the **Running RMS** check box, the block tracks the RMS value of successive inputs to the block. In this mode, you must also specify a value for the **Input processing** parameter:

- When you select `Elements as channels (sample based)`, the block outputs an *M*-by-*N* array. Each element y_{ij} of the output contains the RMS value of the element u_{ij} over all inputs since the last reset.
- When you select `Columns as channels (frame based)`, the block outputs an *M*-by-*N* matrix. Each element y_{ij} of the output contains the RMS value of the *j*th column over all inputs since the last reset, up to and including element u_{ij} of the current input.

Running Operation for Variable-Size Inputs

When your inputs are of variable size, and you select the **Running RMS** check box, there are two options:

- If you set the **Input processing** parameter to `Elements as channels (sample based)`, the state is reset.
- If you set the **Input processing** parameter to `Columns as channels (frame based)`, then there are two cases:
  - When the input size difference is in the number of channels (i.e., number of columns), the state is reset.
  - When the input size difference is in the length of channels (i.e., number of rows), there is no reset and the running operation is carried out as usual.

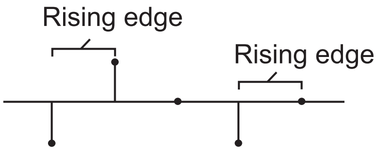
Resetting the Running RMS

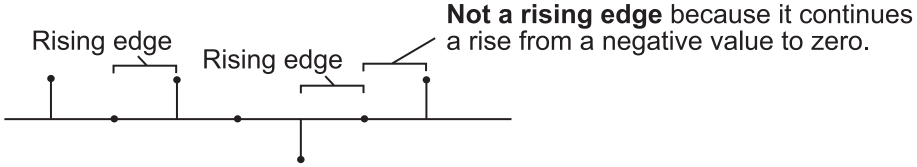
The block resets the running RMS whenever a reset event is detected at the optional `Rst` port. The reset sample time must be a positive integer multiple of the input sample time.

When a reset event occurs while the **Input processing** parameter is set to `Elements as channels (sample based)`, the running RMS for each channel is initialized to the value in the corresponding channel of the current input. Similarly, when the **Input processing** parameter is set to `Columns as channels (frame based)`, the running RMS for each channel is initialized to the earliest value in each channel of the current input.

You specify the reset event in the **Reset port** parameter:

- `None` disables the `Rst` port.
- `Rising edge` — Triggers a reset operation when the `Rst` input does one of the following:
  - Rises from a negative value to a positive value or zero
  - Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero (see the following figure)

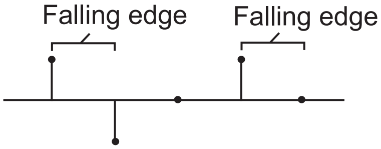


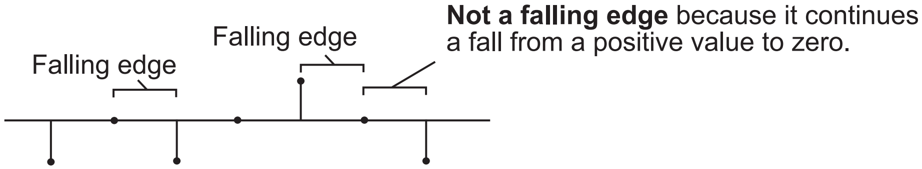


Rising edge
Rising edge
Not a rising edge because it continues a rise from a negative value to zero.

- `Falling edge` — Triggers a reset operation when the `Rst` input does one of the following:

  - Falls from a positive value to a negative value or zero
  - Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero (see the following figure)





Falling edge
Falling edge
Not a falling edge because it continues a fall from a positive value to zero.

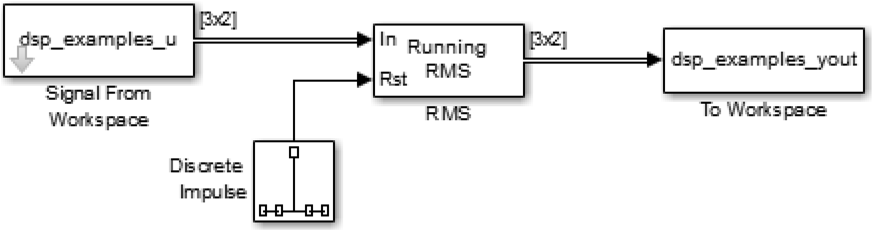
- `Either edge` — Triggers a reset operation when the `Rst` input is a `Rising edge` or `Falling edge`, as described earlier
- `Non-zero sample` — Triggers a reset operation at each sample time that the `Rst` input is not zero

Note: When running simulations in the Simulink MultiTasking mode, reset signals have a one-sample latency. Therefore, when the block detects a reset event, there is

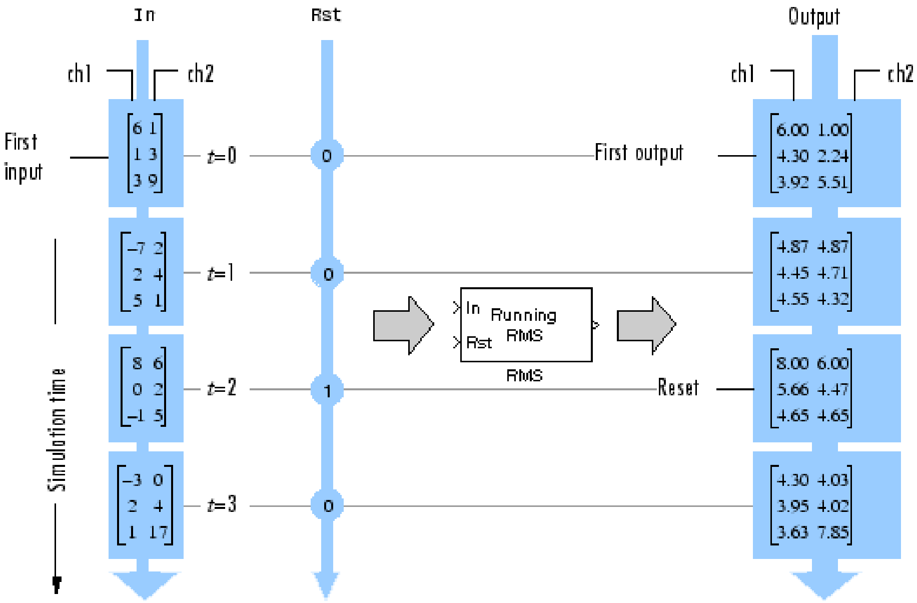
a one-sample delay at the reset port rate before the block applies the reset. For more information on latency and the Simulink tasking modes, see “Excess Algorithmic Delay (Tasking Latency)” and “Scheduling ” in the *Simulink Coder User's Guide*.

Examples

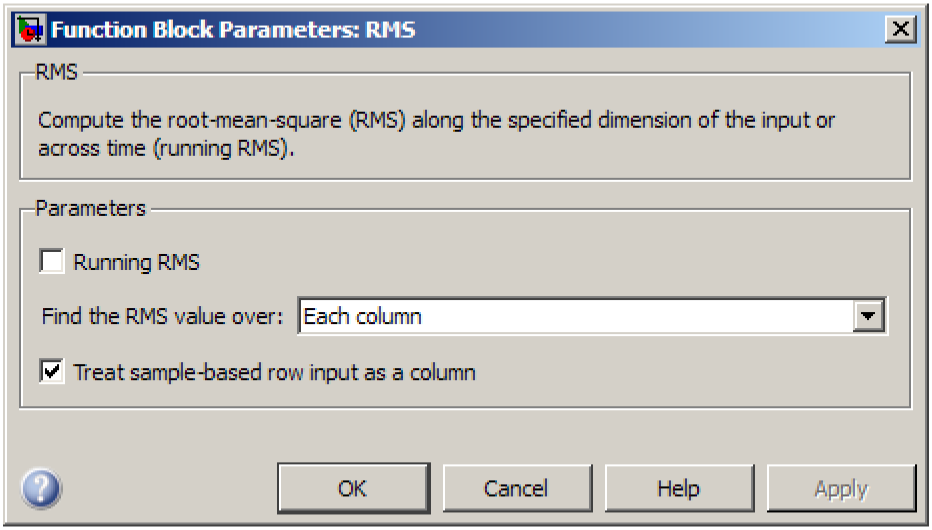
In the following ex_rms_ref model, the RMS block calculates the running RMS of a 3-by-2 matrix input, `u`. The **Input processing** parameter is set to `Columns as channels (frame based)`, so the block processes the input as a two channel signal with a frame size of three. The running RMS is reset at *t*=2 by an impulse to the block's `Rst` port.



The operation of the block is shown in the following figure.



Dialog Box



Function Block Parameters: RMS

RMS

Compute the root-mean-square (RMS) along the specified dimension of the input or across time (running RMS).

Parameters

□ Running RMS

Find the RMS value over: Each column

☑ Treat sample-based row input as a column

Running RMS

Enables running operation when selected.

Input processing

Specify how the block should process the input when computing the running RMS. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` — When you select this option, the block treats each column of the input as a separate channel.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

This parameter appears only when you select the **Running RMS** check box.

Note: The option `Inherit from input (this choice will be removed - see release notes)` will be removed in a future release. See "Frame-Based Processing" in the *DSP System Toolbox Release Notes* for more information.

Reset port

Specify the reset event that causes the block to reset the running RMS. The sample time of the input to the Rst port must be a positive integer multiple of the input sample time. This parameter appears only when you select the **Running RMS** check box. For more information, see "Resetting the Running RMS" on page 1-1218.

Find the RMS value over

Specify whether to find the RMS value along rows, columns, entire input, or the dimension specified in the **Dimension** parameter. For more information, see "Basic Operation" on page 1-1216.

Treat sample-based row input as a column

Select to treat sample-based length-M row vector inputs as M-by-1 column vectors. This parameter is only visible when the **Find the RMS value over** parameter is set to `Each column`.

Note: This check box will be removed in a future release. See "Sample-Based Row Vector Processing Changes" for more information.

Dimension

Specify the dimension (one-based value) of the input signal, over which the RMS value is computed. The value of this parameter cannot exceed the number of dimensions in the input signal. This parameter is only visible when the **Find the RMS value over** parameter is set to `Specified dimension`.

Supported Data Types

- Double-precision floating point
- Single-precision floating point
- Boolean — The block accepts Boolean inputs to the `Rst` port.

Variance	DSP System Toolbox

Sample and Hold

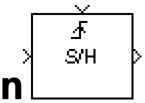
Sample and hold input signal

Library

Signal Operations

`dspsigops`

Description



The Sample and Hold block acquires the input at the signal port whenever it receives a trigger event at the trigger port (marked by ⨍). The block then holds the output at the acquired input value until the next triggering event occurs.

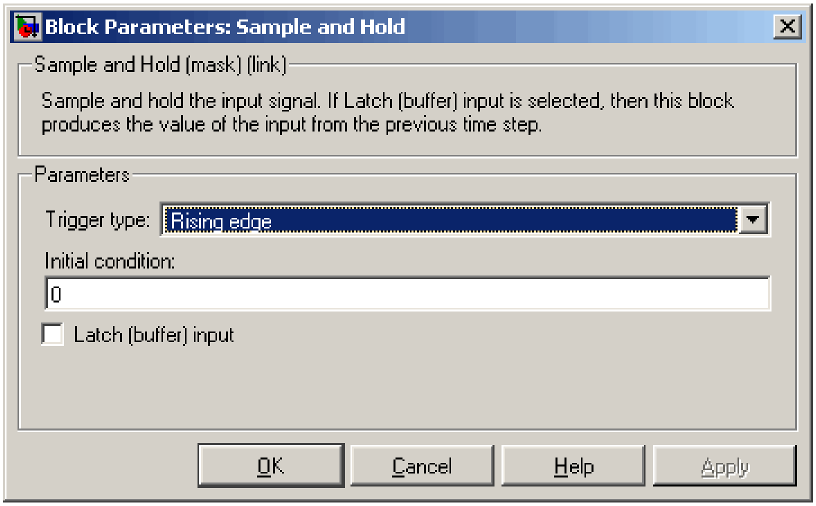
The trigger input must be a sample-based scalar with sample rate equal to the input frame rate at the signal port. You specify the trigger event using the **Trigger type** parameter:

- `Rising edge` triggers the block to acquire the signal input when the trigger input rises from a negative value or zero to a positive value.
- `Falling edge` triggers the block to acquire the signal input when the trigger input falls from a positive value or zero to a negative value.
- `Either edge` triggers the block to acquire the signal input when the trigger input either rises from a negative value or zero to a positive value or falls from a positive value or zero to a negative value.

You specify the block's output prior to the first trigger event using the **Initial condition** parameter. When the acquired input is an M-by-N matrix, the **Initial condition** can be an M-by-N matrix, or a scalar to be repeated across all elements of the matrix. When the input is a length-M unoriented vector, the **Initial condition** can be a length-M row or column vector, or a scalar to be repeated across all elements of the vector.

If you select the **Latch (buffer) input** check box, the block outputs the value of the input from the previous time step until the next triggering event occurs. To use this block in a loop, select this check box.

Dialog Box



Block Parameters: Sample and Hold

Sample and Hold (mask) (link)

Sample and hold the input signal. If Latch (buffer) input is selected, then this block produces the value of the input from the previous time step.

Parameters

Trigger type: Rising edge

Initial condition:

0

□ Latch (buffer) input

Trigger type

The type of event that triggers the block to acquire the input signal.

Initial condition

The block's output prior to the first trigger event.

Latch (buffer) input

If you select this check box, the block outputs the value of the input from the previous time step until the next triggering event occurs.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers

Port	Supported Data Types
Trigger	• Any data type supported by the Trigger block
Outputs	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers

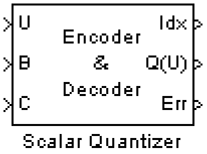
Scalar Quantizer (Obsolete)

Convert input signal into set of quantized output values or index values, or convert set of index values into quantized output signal

Library

dspobslib



Description

Note The Scalar Quantizer block is still supported but is likely to be obsoleted in a future release. We strongly recommend replacing this block with the Scalar Quantizer Encoder block or the Scalar Quantizer Decoder block.

The Scalar Quantizer block has three modes of operation. In `Encoder` mode, the block maps each input value to a quantization region by comparing the input value to the quantizer boundary points defined in the **Boundary points** parameter. The block outputs the index of the associated region. In `Decoder` mode, the block transforms the input index values into quantized output values, defined in the **Codebook** parameter. In the `Encoder and Decoder` mode, the block performs both the encoding and decoding operations. The block outputs the index values and the quantized output values.

You can select how you want to enter the **Boundary points** and/or **Codebook** values using the **Source of quantizer** parameters. When you select `Specify via dialog`, type the parameters into the block parameters dialog box. Select `Input ports`, and port B and/or C appears on the block. In `Encoder` and `Encoder and decoder` mode, the input to port B is used as the **Boundary points**. In `Decoder` and `Encoder and decoder` mode, the input to port C is used as the **Codebook**.

In `Encoder` and `Encoder and decoder` mode, the **Boundary points** are the values used to break up the input signal into regions. Each region is specified by an index number. When your first boundary point is `-inf` and your last boundary point is `inf`, your quantizer is unbounded. When your first and last boundary point is finite, your quantizer is bounded. When only your first or last boundary point is `-inf` or `inf`, your quantizer is semi-bounded.

For instance, when your input signal ranges from 0 to 11, you can create a bounded quantizer using the following boundary points:

```
[0 0.5 3.7 5.8 6.0 11]
```

The boundary points can have equal or varied spacing. Any input values between 0 and 0.5 would correspond to index 0. Input values between 0.5 and 3.7 would correspond to index 1, and so on.

Suppose you wanted to create an unbounded quantizer with the following boundary points:

```
[-inf 0 2 5.5 7.1 10 inf]
```

When your input signal has values less than 0, these values would be assigned to index 0. When your input signal has values greater than 10, these values would be assigned to index 6.

When an input value is the same as a boundary point, the **Tie-breaking rule** parameter defines the index to which the value is assigned. When you want the input value to be assigned to the lower index value, select `Choose the lower index`. To assign the input value with the higher index, select `Choose the higher index`.

In `Decoder` and `Encoder and decoder` mode, the **Codebook** is a vector of quantized output values that correspond to each index value.

In `Encoder` and `Encoder and decoder` mode, the **Searching method** determines how the appropriate quantizer index is found. Select `Linear` and the Scalar Quantizer block compares the input value to the first region defined by the first two boundary points. When the input value does not fall within this region, the block then compares the input value to the next region. This process continues until the input value is determined to be within a region and is associated with the appropriate index value. The computational cost of this process is of the order P, where P is the number of boundary points.

Select `Binary` for the **Searching method** and the block compares the input value to the middle value of the boundary points vector. When the input value is larger than this boundary point, the block discards the boundary points that are lower than this middle value. The block then compares the input value to the middle boundary point of the new range, defined by the remaining boundary points. This process continues until the input value is associated with the appropriate index value. The computational cost of this process is of the order $\log_2 P$, where P is the number of boundary points. In most cases, the `Binary` option is faster than the `Linear` option.

In `Decoder` mode, the input to this block is a vector of index values, where $0 \leq$ index $<N$ and N is the length of the codebook vector. Use the **Action for out of range input** parameter to determine what happens when an input index value is out of this range. When you want any index values less than 0 to be set to 0 and any index values greater than or equal to N to be set to N -1, select `Clip`. When you want to be warned when any index values less than 0 are set to 0 and any index values greater than or equal to N are set to N -1, select `Clip and warn`. When you want the simulation to stop and display an error when the index values are out of range, select `Error`.

In `Encoder and decoder` mode, you can select the **Output the quantization error** check box. The quantization error is the difference between the input value and the quantized output value. Select this check box to output the quantization error for each input value from the Err port on this block.

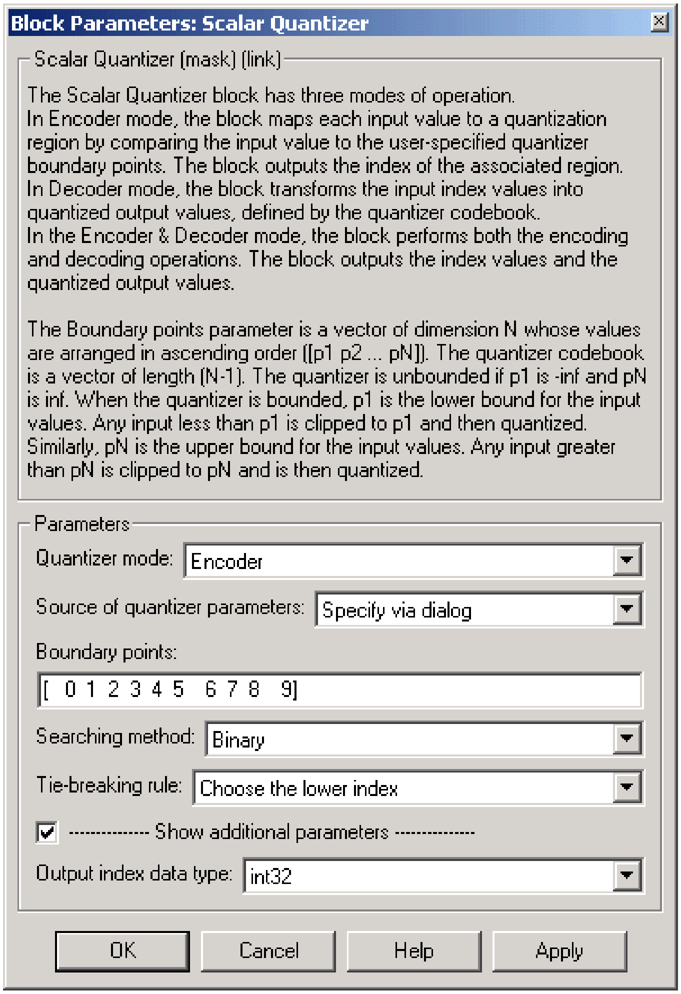
Data Type Support

In `Encoder` mode, the input data values and the boundary points can be the input to the block at ports U and B. Similarly, in `Encoder and decoder` mode, the codebook values can also be the input to the block at port C. The data type of the input data values, boundary points, and codebook values can be `double`, `single`, `uint8`, `uint16`, `uint32`, `int8`, `int16`, or `int32`. In `Decoder` mode, the input to the block can be the index values and the codebook values. The data type of the index input to the block at port Idx can be `uint8`, `uint16`, `uint32`, `int8`, `int16`, or `int32`. The data type of the codebook values can be `double`, `single`, `uint8`, `uint16`, `uint32`, `int8`, `int16`, or `int32`.

In `Encoder` mode, the output of the block is the index values. In `Encoder and decoder` mode, the output can also include the quantized output values and the quantization error. In `Encoder` and `Encoder and decoder` mode, use the **Output index data type** parameter to specify the data type of the index output from the block at port Idx. The data type of the index output can be `uint8`, `uint16`, `uint32`, `int8`, `int16`, or `int32`. The data type of the quantized output and the quantization error can be `double`, `single`, `uint8`, `uint16`, `uint32`, `int8`, `int16`, or `int32`. In `Decoder` mode, the output of the block is the quantized output values. Use the **Output data type** parameter to specify the data type of the quantized output values. The data type can be `double`, `single`, `uint8`, `uint16`, `uint32`, `int8`, `int16`, `int32`.

Note The input data, codebook values, boundary points, quantization error, and the quantized output values must have the same data type whenever they are present in any of the quantizer modes.

Dialog Box



Block Parameters: Scalar Quantizer

Scalar Quantizer (mask) (link)

The Scalar Quantizer block has three modes of operation.
In Encoder mode, the block maps each input value to a quantization region by comparing the input value to the user-specified quantizer boundary points. The block outputs the index of the associated region.
In Decoder mode, the block transforms the input index values into quantized output values, defined by the quantizer codebook.
In the Encoder & Decoder mode, the block performs both the encoding and decoding operations. The block outputs the index values and the quantized output values.

The Boundary points parameter is a vector of dimension N whose values are arranged in ascending order ([p1 p2 ... pN]). The quantizer codebook is a vector of length (N-1). The quantizer is unbounded if p1 is -inf and pN is inf. When the quantizer is bounded, p1 is the lower bound for the input values. Any input less than p1 is clipped to p1 and then quantized. Similarly, pN is the upper bound for the input values. Any input greater than pN is clipped to pN and is then quantized.

Parameters

Quantizer mode: Encoder

The Boundary points parameter is a vector of dimension N whose values are arranged in ascending order ([p1 p2 ... pN]). The quantizer codebook is a vector of length (N-1). The quantizer is unbounded if p1 is -inf and pN is inf. When the quantizer is bounded, p1 is the lower bound for the input values. Any input less than p1 is clipped to p1 and then quantized. Similarly, pN is the upper bound for the input values. Any input greater than pN is clipped to pN and is then quantized.

Parameters

Quantizer mode: Encoder and decoder

Source of quantizer parameters: Specify via dialog

Boundary points:

[0 1 2 3 4 5 6 7 8 9]

Codebook:

[0.0 1.5 2.5 3.5 4.5 5.5 6.5 7.5 8.5]

Searching method: Binary

Tie-breaking rule: Choose the lower index

☑ Output the quantization error

☑ -------------- Show additional parameters --------------

Output index data type: int32

Quantizer mode

Specify `Encoder`, `Decoder`, or `Encoder and decoder` as a mode of operation.

Source of quantizer parameters

Choose Specify via dialog to type the parameters into the block parameters dialog box. Select Input ports to specify the parameters using the block's input ports. In Encoder and Encoder and decoder mode, input the **Boundary points** using port B. In Decoder and Encoder and decoder mode, input the **Codebook** values using port C.

Boundary points

Enter a vector of values that represent the boundary points of the quantizer regions. “Tunable”.

Codebook

Enter a vector of quantized output values that correspond to each index value. “Tunable”.

Searching method

Select Linear and the block finds the region in which the input value is located using a linear search. Select Binary and the block finds the region in which the input value is located using a binary search.

Tie-breaking rule

Set this parameter to determine the behavior of the block when the input value is the same as the boundary point. When you select Choose the lower index, the input value is assigned to lower index value. When you select Choose the higher index, the value is assigned to the higher index.

Action for out of range input

Choose the block's behavior when an input index value is out of range, where $0 \leq$ index $<N$ and N is the length of the codebook vector. Select Clip, when you want any index values less than 0 to be set to 0 and any index values greater than or equal to N to be set to N -1. Select Clip and warn, when you want to be warned when any index values less than 0 are set to 0 and any index values greater than or equal to N are set to N -1. Select Error, when you want the simulation to stop and display an error when the index values are out of range.

Output the quantization error

In Encoder and decoder mode, select this check box to output the quantization error from the Err port on this block.

Output index data type

In Encoder and Encoder and decoder mode, specify the data type of the index output from the block at port Idx. The data type can be uint8, uint16, uint32, int8, int16, or int32. This parameter becomes visible when you select the **Show additional parameters** check box.

Output data type

In `Decoder` mode, specify the data type of the quantized output. The data type can be `uint8`, `uint16`, `uint32`, `int8`, `int16`, `int32`, `single`, or `double`. This parameter becomes visible when you select `Specify via dialog` for the **Source of quantizer parameters** and you select the **Show additional parameters** check box.

Supported Data Types

- Double-precision floating point
- Single-precision floating point
- Fixed point
- 8-, 16-, and 32-bit signed integers
- 8-, 16-, and 32-bit unsigned integers

For more information on what data types are supported for each quantizer mode, see “Data Type Support” on page 1-1229.

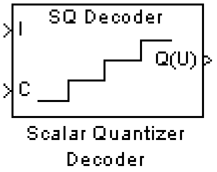
Scalar Quantizer Decoder

Convert each index value into quantized output value

Library

Quantizers

`dspquant2`



Description

The Scalar Quantizer Decoder block transforms the zero-based input index values into quantized output values. The set of all possible quantized output values is defined by the **Codebook values** parameter.

Use the **Codebook values** parameter to specify a matrix containing all possible quantized output values. You can select how you want to enter the codebook values using the **Source of codebook** parameter. When you select `Specify via dialog`, type the codebook values into the block parameters dialog box. When you select `Input port`, port C appears on the block. The block uses the input to port C as the **Codebook values** parameter.

The input to this block is a vector of integer index values, where $0 \leq$ index $<N$ and N is the number of distinct codeword vectors in the codebook matrix. Use the **Action for out of range index value** parameter to determine what happens when an input index value is outside this range. When you want any index value less than 0 to be set to 0 and any index value greater than or equal to N to be set to N -1, select `Clip`. When you want to be warned when clipping occurs, select `Clip and warn`. When you want the simulation to stop and the block to display an error when the index values are out of range, select `Error`.

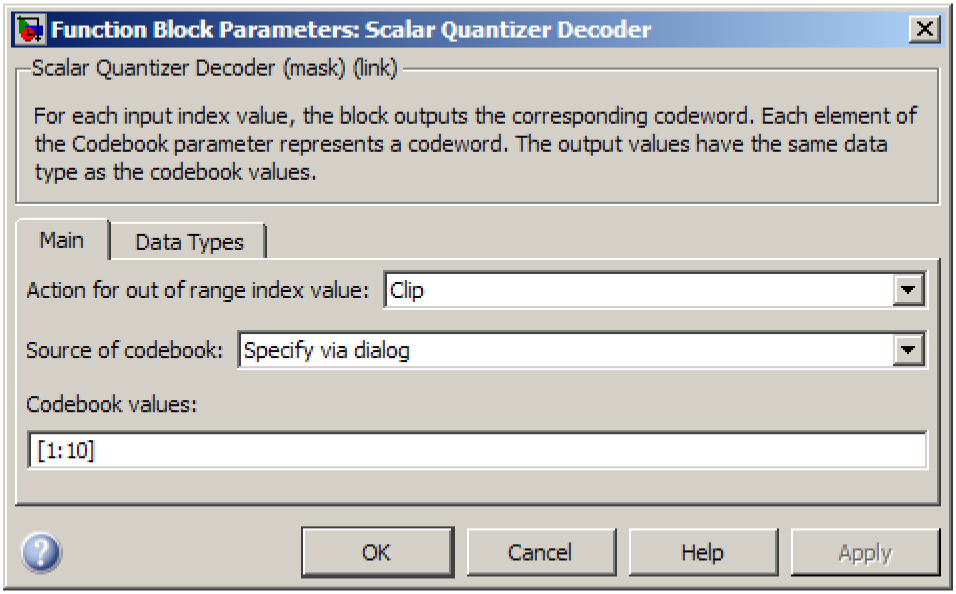
Data Type Support

The data type of the index values input at port I can be `uint8`, `uint16`, `uint32`, `int8`, `int16`, or `int32`. The data type of the codebook values input at port C can be `double`, `single`, or Fixed-point.

The output of the block is the quantized output values. If, for the **Source of codebook** parameter, you select `Specify via dialog`, the **Codebook and output data type** parameter appears. You can use this parameter to specify the data type of the codebook and quantized output values. In this case, the data type of the output values can be `Same as input`, `double`, `single`, `Fixed-point`, or `User-defined`. If, for the **Source of codebook** parameter you select `Input port`, the quantized output values have the same data type as the codebook values input at port C.

Dialog Box

The **Main** pane of the Scalar Quantizer Decoder block dialog appears as follows.



Scalar Quantizer Decoder (mask) (link)

For each input index value, the block outputs the corresponding codeword. Each element of the Codebook parameter represents a codeword. The output values have the same data type as the codebook values.

Action for out of range index value: Clip

Source of codebook: Specify via dialog

Codebook values: [1:10]

Action for out of range index value

Use this parameter to determine the block's behavior when an input index value is out of range, where 0 ≤ index <N and N is the length of the codebook vector. Select `Clip`, when you want any index values less than 0 to be set to 0 and any index values greater than or equal to N to be set to N -1. Select `Clip and warn`, when you want to be warned when clipping occurs. Select `Error`, when you want the simulation to stop and the block to display an error when the index values are outside the range.

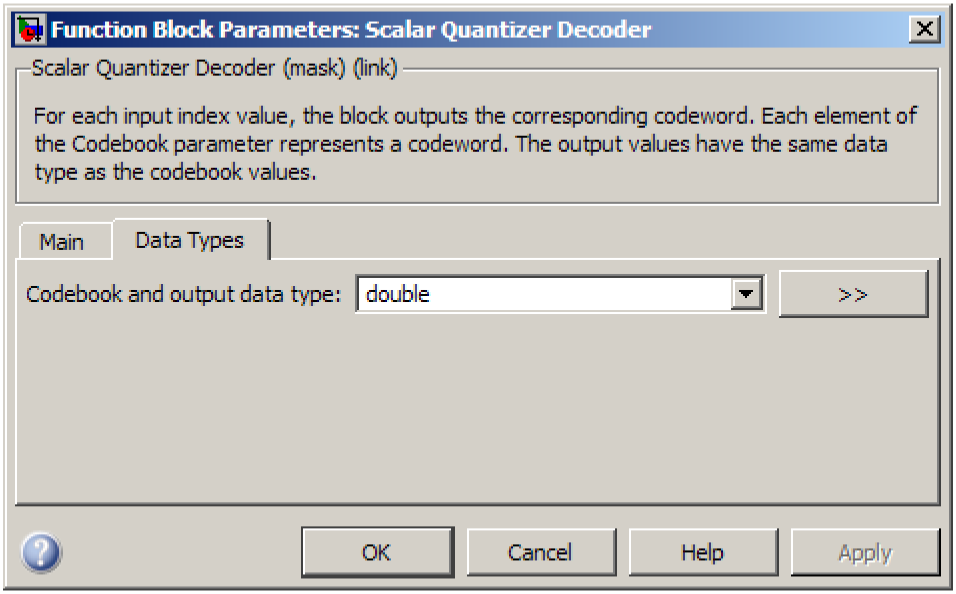
Source of codebook

Choose `Specify via dialog` to type the codebook values into the block parameters dialog box. Select `Input port` to specify the codebook using input port C.

Codebook values

Enter a vector of quantized output values that correspond to each index value. "Tunable".

The **Data Types** pane of the Scalar Quantizer Decoder block dialog appears as follows.



Function Block Parameters: Scalar Quantizer Decoder

Scalar Quantizer Decoder (mask) (link)

For each input index value, the block outputs the corresponding codeword. Each element of the Codebook parameter represents a codeword. The output values have the same data type as the codebook values.

Codebook and output data type: double

Codebook and output data type

Specify the data type of the codebook and quantized output values. You can select one of the following:

- A rule that inherits a data type, for example, `Inherit: Same as input`.

- A built in data type, such as `double`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Specify Block Output Data Types” in “Simulink User's Guide” for more information.

This parameter is available only when you set the **Source of codebook** parameter to `Specify via dialog`. If you set the **Source of codebook** parameter to `Input port`, the output values have the same data type as the input codebook values.

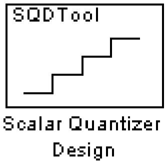
Scalar Quantizer Design

Start Scalar Quantizer Design Tool (SQDTool) to design scalar quantizer using Lloyd algorithm

Library

Quantizers

`dspquant2`



Description

Double-click on the Scalar Quantizer Design block to start SQDTool, a GUI that allows you to design and implement a scalar quantizer. Based on your input values, SQDTool iteratively calculates the codebook values that minimize the mean squared error until the stopping criteria for the design process is satisfied. The block uses the resulting quantizer codebook values and boundary points to implement your scalar quantizer encoder and/or decoder.

For the **Training Set** parameter, enter a set of observations, or samples, of the signal you want to quantize. This data can be any variable defined in the MATLAB workspace including a variable created using a MATLAB function, such as the default value `randn(10000,1)`.

You have two choices for the **Source of initial codebook** parameter. Select `Auto-generate` to have the block choose the values of the initial codebook vector. In this case, the minimum training set value becomes the first codeword, and the maximum training set value becomes the last codeword. Then, the remaining initial codewords are equally spaced between these two values to form a codebook vector of length N, where N is the **Number of levels** parameter. When you select `User defined`, enter the initial codebook values in the **Initial codebook** field. Then, set the **Source of initial boundary points** parameter. You can select `Mid-points` to locate the boundary points at the midpoint between the codewords. To calculate the mid-points, the block internally arranges the initial codebook values in ascending order. You can also choose `User defined` and enter your own boundary points in the **Initial boundary points (unbounded)** field. Only one boundary point can be located between two codewords. When you select `User defined` for the **Source of initial boundary points** parameter, the values you enter in the **Initial codebook** and **Initial boundary points (unbounded)** fields must be arranged in ascending order.

Note This block assumes that you are designing an unbounded quantizer. Therefore, the first and last boundary points are always `-inf` and `inf` regardless of any other boundary point values you might enter.

After you have specified the quantization parameters, the block performs an iterative process to design the optimal scalar quantizer. Each step of the design process involves using the Lloyd algorithm to calculate codebook values and quantizer boundary points. Then, the block calculates the squared quantization error and checks whether the stopping criteria has been satisfied.

The two possible options for the **Stopping criteria** parameter are `Relative threshold` and `Maximum iteration`. When you want the design process to stop when the fractional drop in the squared quantization error is below a certain value, select `Relative threshold`. Then, for **Relative threshold**, type the maximum acceptable fractional drop. When you want the design process to stop after a certain number of iterations, choose `Maximum iteration`. Then, enter the maximum number of iterations you want the block to perform in the **Maximum iteration** field. For **Stopping criteria**, you can also choose `Whichever comes first` and enter a **Relative threshold** and **Maximum iteration** value. The block stops iterating as soon as one of these conditions is satisfied.

With each iteration, the block quantizes the training set values based on the newly calculated codebook values and boundary points. When the training point lies on a boundary point, the algorithm uses the **Tie-breaking rules** parameter to determine which region the value is associated with. When you want the training point to be assigned to the lower indexed region, select `Lower indexed codeword`. To assign the training point with the higher indexed region, select `Higher indexed codeword`.

The **Searching methods** parameter determines how the block compares the training points to the boundary points. Select `Linear search` and SQDTool compares each training point to each quantization region sequentially. This process continues until all the training points are associated with the appropriate regions.

Select Binary search for the **Searching methods** parameter and the block compares the training point to the middle value of the boundary points vector. When the training point is larger than this boundary point, the block discards the lower boundary points. The block then compares the training point to the middle boundary point of the new range, defined by the remaining boundary points. This process continues until the training point is associated with the appropriate region.

Click **Design and Plot** to design the quantizer with the parameter values specified on the left side of the GUI. The performance curve and the staircase character of the quantizer are updated and displayed in the figures on the right side of the GUI.

Note You must click **Design and Plot** to apply any changes you make to the parameter values in the SQDTool dialog box.

SQDTool can export parameter values that correspond to the figures displayed in the GUI. Click the **Export Outputs** button, or press **Ctrl+E**, to export the **Final Codebook**, **Final Boundary Points**, and **Error** values to the workspace, a text file, or a MAT-file. The **Error** values represent the mean squared error for each iteration.

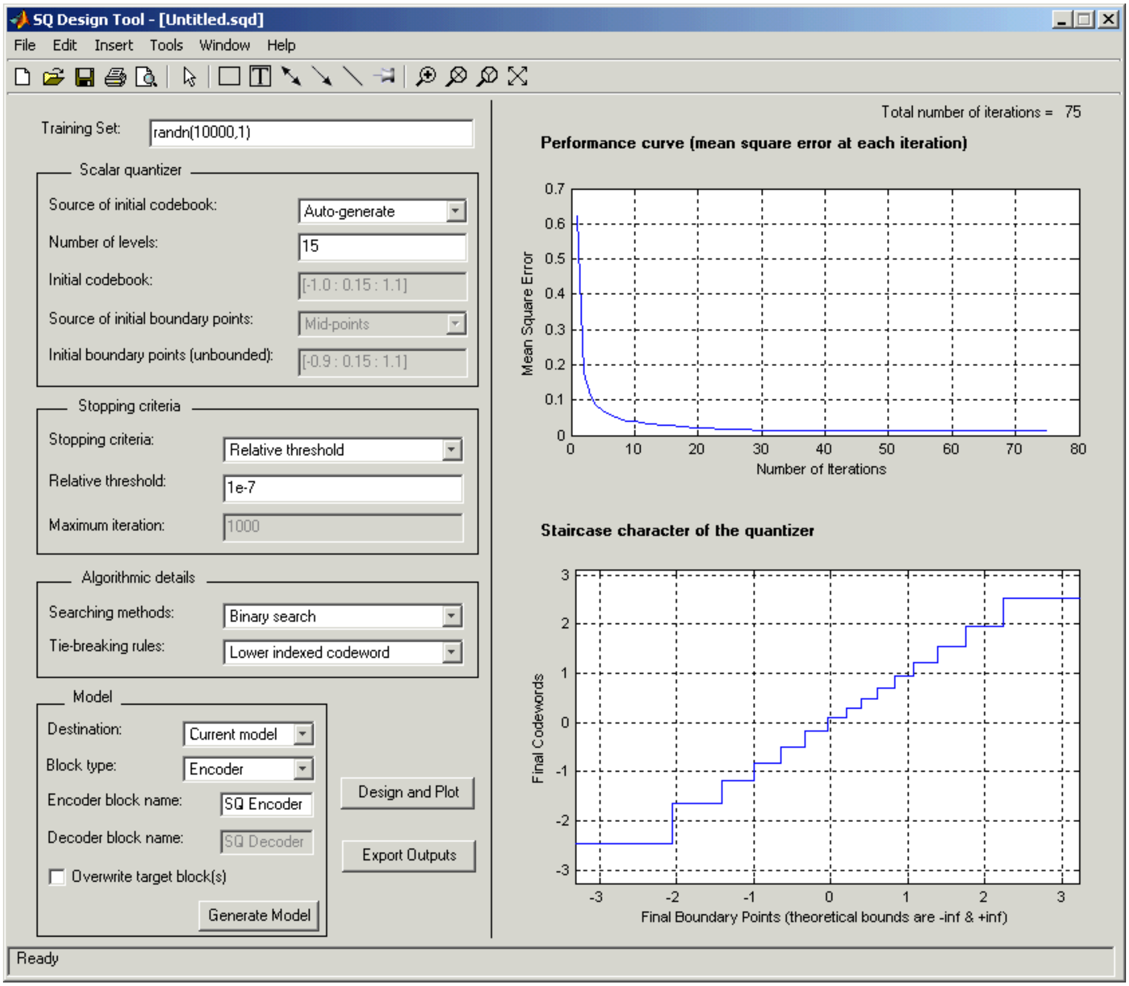
In the **Model** section of the GUI, specify the destination of the block that will contain the parameters of your quantizer. For **Destination**, select Current model to create a block with your parameters in the model you most recently selected. Type gcs in the MATLAB Command Window to display the name of your current model. Select New model to create a block in a new model file.

From the **Block type** list, select Encoder to design a Scalar Quantizer Encoder block. Select Decoder to design a Scalar Quantizer Decoder block. Select Both to design a Scalar Quantizer Encoder block and a Scalar Quantizer Decoder block.

In the **Encoder block name** field, enter a name for the Scalar Quantizer Encoder block. In the **Decoder block name** field, enter a name for the Scalar Quantizer Decoder block. When you have a Scalar Quantizer Encoder and/or Decoder block in your destination model with the same name, select the **Overwrite target block(s)** check box to replace the block's parameters with the current parameters. When you do not select this check box, a new Scalar Quantizer Encoder and/or Decoder block is created in your destination model.

Click **Generate Model**. SQDTool uses the parameters that correspond to the current plots to set the parameters of the Scalar Quantizer Encoder and/or Decoder blocks.

Dialog Box



SQ Design Tool - [Untitled.sqd]

Training Set: randn(10000,1)

Scalar quantizer

Source of initial codebook: Auto-generate

Number of levels: 15

Initial codebook: [-1.0 : 0.15 : 1.1]

Source of initial boundary points: Mid-points

Initial boundary points (unbounded): [-0.9 : 0.15 : 1.1]

Stopping criteria

Stopping criteria: Relative threshold

Relative threshold: 1e-7

Maximum iteration: 1000

Algorithmic details

Searching methods: Binary search

Tie-breaking rules: Lower indexed codeword

Model

Destination: Current model

Block type: Encoder

Encoder block name: SQ Encoder

Decoder block name: SQ Decoder

□ Overwrite target block(s)

Total number of iterations = 75

Ready

Training Set

Enter the samples of the signal you would like to quantize. This data set can be a MATLAB function or a variable defined in the MATLAB workspace. The typical length of this data vector is `1e6`.

Source of initial codebook

Select `Auto-generate` to have the block choose the initial codebook values. Select `User defined` to enter your own initial codebook values.

Number of levels

Enter the length of the codebook vector. For a b-bit quantizer, the length should be $N = 2^b$.

Initial codebook

Enter your initial codebook values. From the **Source of initial codebook** list, select `User defined` in order to activate this parameter.

Source of initial boundary points

Select `Mid-points` to locate the boundary points at the midpoint between the codebook values. Choose `User defined` to enter your own boundary points. From the **Source of initial codebook** list, select `User defined` in order to activate this parameter.

Initial boundary points (unbounded)

Enter your initial boundary points. This block assumes that you are designing an unbounded quantizer. Therefore, the first and last boundary point are `-inf` and `inf`, regardless of any other boundary point values you might enter. From the **Source of initial boundary points** list, select `User defined` in order to activate this parameter.

Stopping criteria

Choose `Relative threshold` to enter the maximum acceptable fractional drop in the squared quantization error. Choose `Maximum iteration` to specify the number of iterations at which to stop. Choose `Whichever comes first` and the block stops the iteration process as soon as the relative threshold or maximum iteration value is attained.

Relative threshold

Type the value that is the maximum acceptable fractional drop in the squared quantization error.

Maximum iteration

Enter the maximum number of iterations you want the block to perform. From the **Stopping criteria** list, select `Maximum iteration` in order to activate this parameter.

Searching methods

Choose `Linear search` to use a linear search method when comparing the training points to the boundary points. Choose `Binary search` to use a binary search method when comparing the training points to the boundary points.

Tie-breaking rules

When a training point lies on a boundary point, choose `Lower indexed codeword` to assign the training point to the lower indexed quantization region. Choose `Higher indexed codeword` to assign the training point to the higher indexed region.

Design and Plot

Click this button to display the performance curve and the staircase character of the quantizer in the figures on the right side of the GUI. These plots are based on the current parameter settings.

You must click **Design and Plot** to apply any changes you make to the parameter values in the SQDTool GUI.

Export Outputs

Click this button, or press **Ctrl+E**, to export the **Final Codebook**, **Final Boundary Points**, and **Error** values to the workspace, a text file, or a MAT-file.

Destination

Choose `Current model` to create a Scalar Quantizer block in the model you most recently selected. Type `gcs` in the MATLAB Command Window to display the name of your current model. Choose `New model` to create a block in a new model file.

Block type

Select `Encoder` to design a Scalar Quantizer Encoder block. Select `Decoder` to design a Scalar Quantizer Decoder block. Select `Both` to design a Scalar Quantizer Encoder block and a Scalar Quantizer Decoder block.

Encoder block name

Enter a name for the Scalar Quantizer Encoder block.

Decoder block name

Enter a name for the Scalar Quantizer Decoder block.

Overwrite target block(s)

When you do not select this check box and a Scalar Quantizer Encoder and/or Decoder block with the same block name exists in the destination model, a new Scalar Quantizer Encoder and/or Decoder block is created in the destination model. When you select this check box and a Scalar Quantizer Encoder and/or Decoder block with the same block name exists in the destination model, the parameters of these blocks are overwritten by new parameters.

Generate Model

Click this button and SQDTool uses the parameters that correspond to the current plots to set the parameters of the Scalar Quantizer Encoder and/or Decoder blocks.

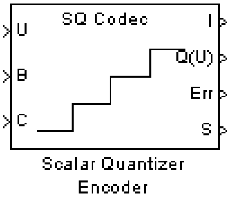
Scalar Quantizer Encoder

Encode each input value by associating it with index value of quantization region

Library

Quantizers

`dspquant2`



Description

The Scalar Quantizer Encoder block maps each input value to a quantization region by comparing the input value to the quantizer boundary points defined in the **Boundary points** parameter. The block outputs the zero-based index of the associated region.

You can select how you want to enter the **Boundary points** using the **Source of quantizer parameters**. When you select `Specify via dialog`, type the boundary points into the block parameters dialog box. When you select `Input port`, port B appears on the block. The block uses the input to port B as the **Boundary points** parameter.

Use the **Boundary points** parameter to specify the boundary points for your quantizer. These values are used to break up the set of input numbers into regions. Each region is specified by an index number.

Let `N` be the number of quantization regions. When the codebook is defined as `[c1 c2 c3 ... cN]`, and the **Boundary points** parameter is defined as `[p0 p1 p2 p3 ... pN]`, then `p0<c1<p1<c2 ... p(N-1)<cN<pN` for a regular quantizer. When your quantizer is bounded, from the **Partitioning** list, select `Bounded`. You need to specify N +1 boundary points, or `[p0 p1 p2 p3 ... pN]`. When your quantizer is unbounded, from the **Partitioning** list, select `Unbounded`. You need to specify N-1 boundary points, or`[p1 p2 p3 ... p(N-1)]`; the block sets `p0` equal to `-inf` and `pN` equal to `inf`.

The block uses the **Partitioning** parameter to interpret the boundary points you enter. For instance, to create a bounded quantizer, from the **Partitioning** list, select `Bounded` and enter the following boundary points:

```
[0 0.5 3.7 5.8 6.0 11]
```

The block assigns any input values between 0 and 0.5 to index 0, input values between 0.5 and 3.7 to index 1, and so on. The block assigns any values that are less than 0 to index 0, the lowest index value. The block assigns any values that are greater than 11 to index 4, the highest index value.

To create an unbounded quantizer, from the **Partitioning** list, select `Unbounded` and enter the following boundary points:

```
[0 0.5 3.7 5.8 6.0 11]
```

The block assigns any input values between 0 and 0.5 to index 1, input values between 0.5 and 3.7 to index 2, and so on. The block assigns any input values less than 0 to index 0 and any values greater than 11 to index 6.

The **Searching method** parameter determines how the appropriate quantizer index is found. When you select `Linear`, the Scalar Quantizer Encoder block compares the input value to the first region defined by the first two boundary points. When the input value does not fall within this region, the block then compares the input value to the next region. This process continues until the input value is determined to be within a region and is associated with the appropriate index value. The computational cost of this process is of the order P, where P is the number of boundary points.

When you select `Binary` for the **Searching method**, the block compares the input value to the middle value of the boundary points vector. When the input value is larger than this boundary point, the block discards the boundary points that are lower than this middle value. The block then compares the input value to the middle boundary point of the new range, defined by the remaining boundary points. This process continues until the input value is associated with the appropriate index value. The computational cost of this process is of the order $\log_2 P$, where P is the number of boundary points. In most cases, the `Binary` option is faster than the `Linear` option.

When an input value is the same as a boundary point, the **Tie-breaking rule** parameter determines the region to which the value is assigned. When you want the input value to be assigned to the lower indexed region, select `Choose the lower index`. To assign the input value with the higher indexed region, select `Choose the higher index`.

Select the **Output codeword** check box to output the codeword values that correspond to each index value at port Q(U).

Select the **Output the quantization error** check box to output the quantization error for each input value from the Err port on this block. The quantization error is the difference between the input value and the quantized output value.

When you select either the **Output codeword** check box or the **Output quantization error** check box, you must also enter your codebook values. If, from the **Source of quantizer parameters** list, you choose `Specify via dialog`, use the **Codebook** parameter to enter a vector of quantized output values that correspond to each region. If, from the **Source of quantizer parameters** list, you choose `Input port`, use input port C to specify your codebook values.

If, for the **Partitioning** parameter, you select `Bounded`, the **Output clipping status** check box and the **Action for out of range input** parameter appear. When you select the **Output clipping status** check box, port S appears on the block. Any time an input value is outside the range defined by the **Boundary points** parameter, the block outputs a 1 at the S port. When the value is inside the range, the blocks outputs a 0.

You can use the **Action for out of range input** parameter to determine the block's behavior when an input value is outside the range defined by the **Boundary points** parameter. Suppose the boundary points for a bounded quantizer are defined as `[p0 p1 p2 p3 ... pN]` and the possible index values are defined as `[i0 i1 i2 ... i(N-1)]`, where `i0=0` and `i0<i1<i2<...<i(N-1)`. When you want any input value less than `p0` to be assigned to index value `i0` and any input values greater than `pN` to be assigned to index value `i(N-1)`, select `Clip`. When you want to be warned when clipping occurs, select `Clip and warn`. When you want the simulation to stop and the block to display an error when the index values are out of range, select `Error`.

The Scalar Quantizer Encoder block accepts real floating-point and fixed-point inputs. For more information on the data types accepted by each port, see “Data Type Support” on page 1-1250 or “Supported Data Types” on page 1-1256.

Data Type Support

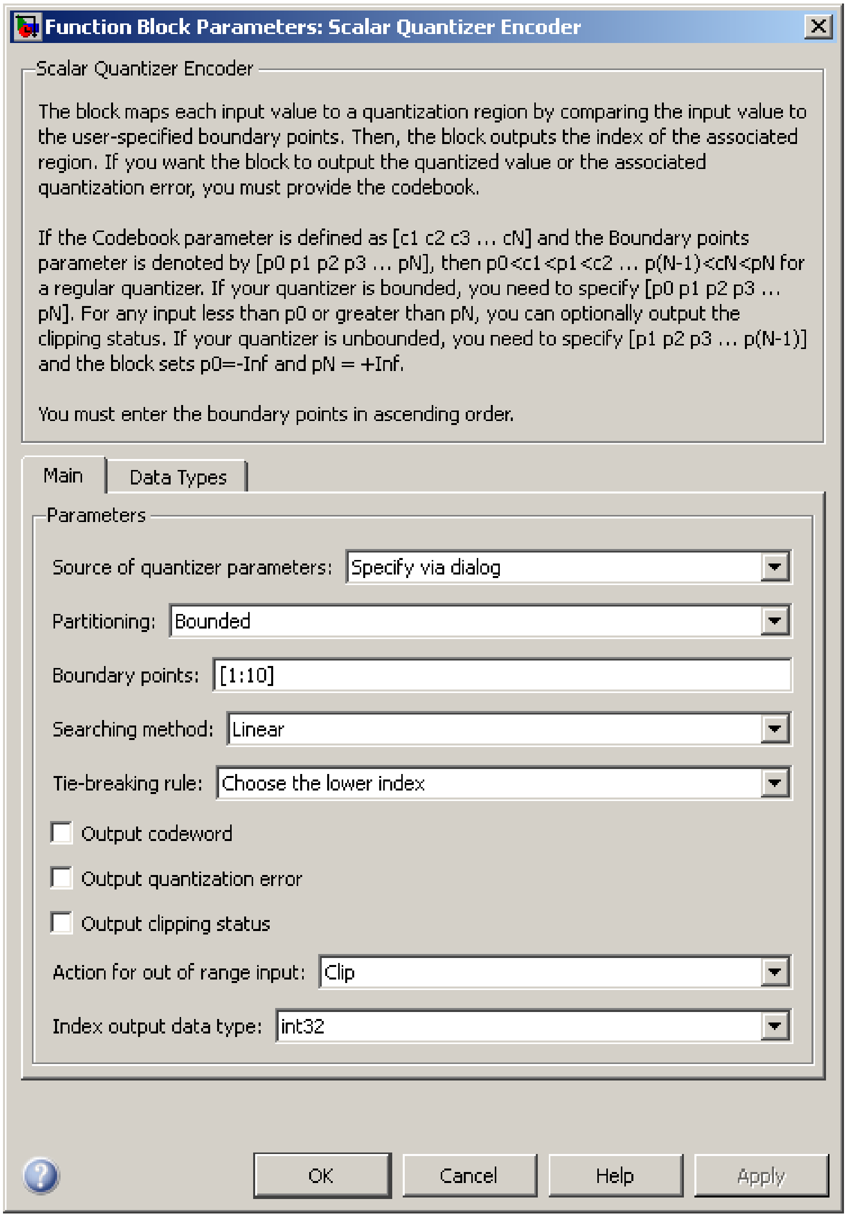
The input data values, boundary points, and codebook values can be input to the block at ports U, B, and C, respectively. The data type of the inputs can be `double`, `single`, or Fixed-point.

The outputs of the block can be the index values, the quantized output values, the quantization error, and the clipping status. Use the **Index output data type** parameter to specify the data type of the index output from the block at port I. You can choose `int8`, `uint8`, `int16`, `uint16`, `int32`, or `uint32`. The data type of the quantized output and the quantization error can be `double`, `single`, or Fixed-point. The clipping status values output at port S are Boolean values.

Note The input data, boundary points, codebook values, quantized output values, and the quantization error must have the same data type whenever they are present.

Dialog Box

The **Main** pane of the Scalar Quantizer Encoder block dialog appears as follows.



Function Block Parameters: Scalar Quantizer Encoder

Scalar Quantizer Encoder

The block maps each input value to a quantization region by comparing the input value to the user-specified boundary points. Then, the block outputs the index of the associated region. If you want the block to output the quantized value or the associated quantization error, you must provide the codebook.

If the Codebook parameter is defined as [c1 c2 c3 ... cN] and the Boundary points parameter is denoted by [p0 p1 p2 p3 ... pN], then p0<c1<p1<c2 ... p(N-1)<cN<pN for a regular quantizer. If your quantizer is bounded, you need to specify [p0 p1 p2 p3 ... pN]. For any input less than p0 or greater than pN, you can optionally output the clipping status. If your quantizer is unbounded, you need to specify [p1 p2 p3 ... p(N-1)] and the block sets p0=-Inf and pN = +Inf.

You must enter the boundary points in ascending order.

Source of quantizer parameters: Specify via dialog

Partitioning: Bounded

Boundary points: [1:10]

Searching method: Linear

Tie-breaking rule: Choose the lower index

☐ Output codeword

☐ Output quantization error

☐ Output clipping status

Action for out of range input: Clip

Index output data type: int32

Source of quantizer parameters

Choose Specify via dialog to enter the boundary points and codebook values using the block parameters dialog box. Select Input port to specify the parameters using the block's input ports. Input the boundary points and codebook values using ports B and C, respectively.

Partitioning

When your quantizer is bounded, select Bounded. When your quantizer is unbounded, select Unbounded.

Boundary points

Enter a vector of values that represent the boundary points of the quantizer regions. This parameter is visible when you select Specify via dialog from the **Source of quantizer parameters** list. “Tunable”.

Searching method

When you select Linear, the block finds the region in which the input value is located using a linear search. When you select Binary, the block finds the region in which the input value is located using a binary search.

Tie-breaking rule

Set this parameter to determine the behavior of the block when the input value is the same as the boundary point. When you select Choose the lower index, the input value is assigned to lower indexed region. When you select Choose the higher index, the value is assigned to the higher indexed region.

Output codeword

Select this check box to output the codeword values that correspond to each index value at port Q(U).

Output quantization error

Select this check box to output the quantization error for each input value at port Err.

Codebook

Enter a vector of quantized output values that correspond to each index value. If, for the **Partitioning** parameter, you select Bounded and your boundary points vector has length N, then you must specify a codebook of length N-1. If, for the **Partitioning** parameter, you select Unbounded and your boundary points vector has length N, then you must specify a codebook of length N+1.

This parameter is visible when you select Specify via dialog from the **Source of quantizer parameters** list and you select either the **Output codeword** or **Output quantization error** check box. “Tunable”.

Output clipping status

When you select this check box, port S appears on the block. Any time an input value is outside the range defined by the **Boundary points** parameter, the block outputs a 1 at this port. When the value is inside the range, the block outputs a 0. This parameter is visible when you select `Bounded` from the **Partitioning** list.

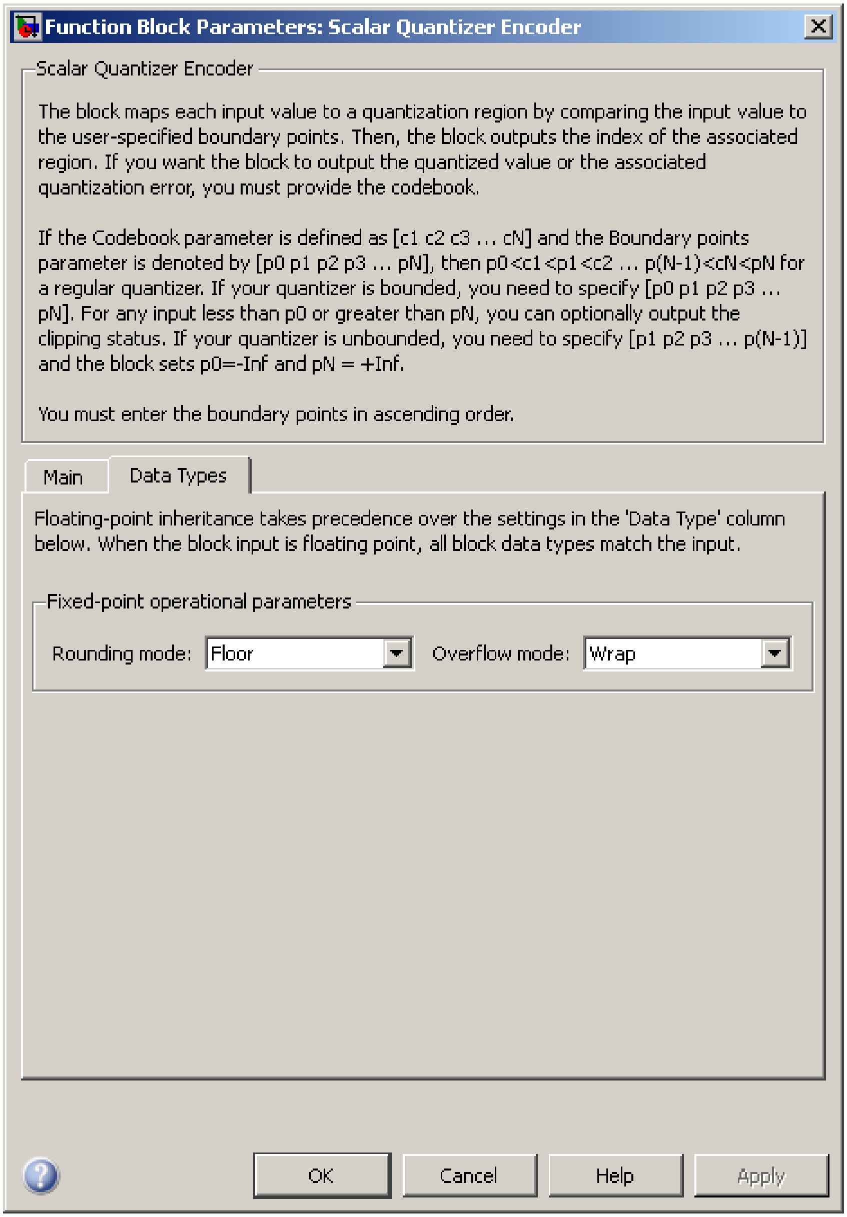
Action for out of range input

Use this parameter to determine the behavior of the block when an input value is outside the range defined by the **Boundary points** parameter. Suppose the boundary points are defined as `[p0 p1 p2 p3 ... pN]` and the index values are defined as `[i0 i1 i2 ... i(N-1)]`. When you want any input value less than `p0` to be assigned to index value `i0` and any input values greater than `pN` to be assigned to index value `i(N-1)`, select `Clip`. When you want to be warned when clipping occurs, select `Clip and warn`. When you want the simulation to stop and the block to display an error when the index values are out of range, select `Error`. This parameter is visible when you select `Bounded` from the **Partitioning** list.

Index output data type

Specify the data type of the index output from the block at port I. You can choose `int8`, `uint8`, `int16`, `uint16`, `int32`, or `uint32`.

The **Data Types** pane of the Scalar Quantizer Encoder block dialog appears as follows.



Function Block Parameters: Scalar Quantizer Encoder

Scalar Quantizer Encoder

The block maps each input value to a quantization region by comparing the input value to the user-specified boundary points. Then, the block outputs the index of the associated region. If you want the block to output the quantized value or the associated quantization error, you must provide the codebook.

If the Codebook parameter is defined as [c1 c2 c3 ... cN] and the Boundary points parameter is denoted by [p0 p1 p2 p3 ... pN], then p0<c1<p1<c2 ... p(N-1)<cN<pN for a regular quantizer. If your quantizer is bounded, you need to specify [p0 p1 p2 p3 ... pN]. For any input less than p0 or greater than pN, you can optionally output the clipping status. If your quantizer is unbounded, you need to specify [p1 p2 p3 ... p(N-1)] and the block sets p0=-Inf and pN = +Inf.

You must enter the boundary points in ascending order.

Floating-point inheritance takes precedence over the settings in the 'Data Type' column below. When the block input is floating point, all block data types match the input.

Fixed-point operational parameters

Rounding mode: Floor

Overflow mode: Wrap

Rounding mode

Select the "rounding mode" for fixed-point operations.

Overflow mode

Select the "overflow mode" to be used when block inputs are fixed point.

Supported Data Types

Port	Supported Data Types
U	• Double-precision floating point • Single-precision floating point • Fixed point (signed only) • 8-, 16-, and 32-bit signed integers
B	• Double-precision floating point • Single-precision floating point • Fixed point (signed only) • 8-, 16-, and 32-bit signed integers
C	• Double-precision floating point • Single-precision floating point • Fixed point (signed only) • 8-, 16-, and 32-bit signed integers
I	• 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Q(U)	• Double-precision floating point • Single-precision floating point • Fixed point (signed only) • 8-, 16-, and 32-bit signed integers

Port	Supported Data Types
Err	• Double-precision floating point • Single-precision floating point • Fixed point (signed only) • 8-, 16-, and 32-bit signed integers
S	• Boolean

For more information on what data types are supported for each quantizer mode, see "Data Type Support" on page 1-1250.

Selector

Select input elements from vector, matrix, or multidimensional signal

Library

Signal Management / Indexing

`dspindex`

Description

The Selector block is an implementation of the Simulink Selector block. See Selector for more information.

HDL Code Generation

This block supports HDL code generation using HDL Coder. HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic. For more information on implementations, properties, and restrictions for HDL code generation, see Selector.

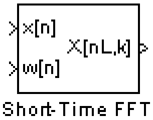
Short-Time FFT

Nonparametric estimate of spectrum using short-time, fast Fourier transform (FFT) method

Library

Transforms

`dspxfrm3`



Description

The Short-Time FFT block computes a nonparametric estimate of the spectrum. The block buffers, applies a window, and zero pads the input signal. The block then takes the FFT of the signal, transforming it into the frequency domain.

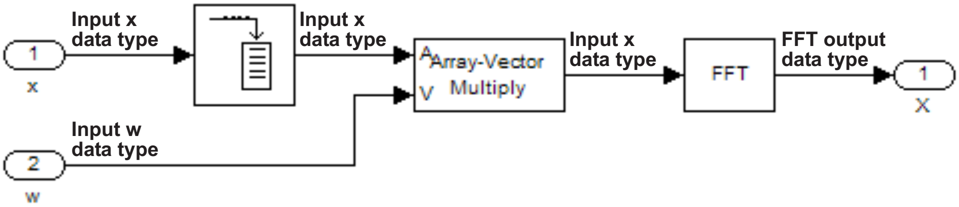
Connect your single-channel analysis window to the w(n) port. For the **Analysis window length** parameter, enter the length of the analysis window, *W*. The block buffers the input signal such that it has a frame length of *W*

Connect your single-channel or multichannel input signal to the x(n) port. After the block buffers and windows this signal, it zero-pads the signal before computing the FFT. For the **FFT length** parameter, enter the length to which the block pads the input signal. For the **Overlap between consecutive windows (in samples)** parameter, enter the number of samples to overlap each frame of the input signal.

The block outputs the complex-valued, single-channel or multichannel short-time FFT at port X(n,k).

Fixed-Point Data Types

The following diagram shows the data types used within the Short-Time FFT subsystem block for fixed-point signals.



The settings for the fixed-point parameters of the Array-Vector Multiply block in the diagram above are as follows:

- **Rounding Mode** — `Floor`
- **Overflow Mode** — `Wrap`
- **Product output** — `Inherit via internal rule`
- **Accumulator** — `Inherit via internal rule`
- **Output** — `Same as first input`

The settings for the fixed-point parameters of the FFT block in the diagram above are as follows:

- **Rounding Mode** — `Floor`
- **Overflow Mode** — `Wrap`
- **Sine table** — `Same word length as input`
- **Product output** — `Inherit via internal rule`
- **Accumulator** — `Inherit via internal rule`
- **Output** — `Inherit via internal rule`

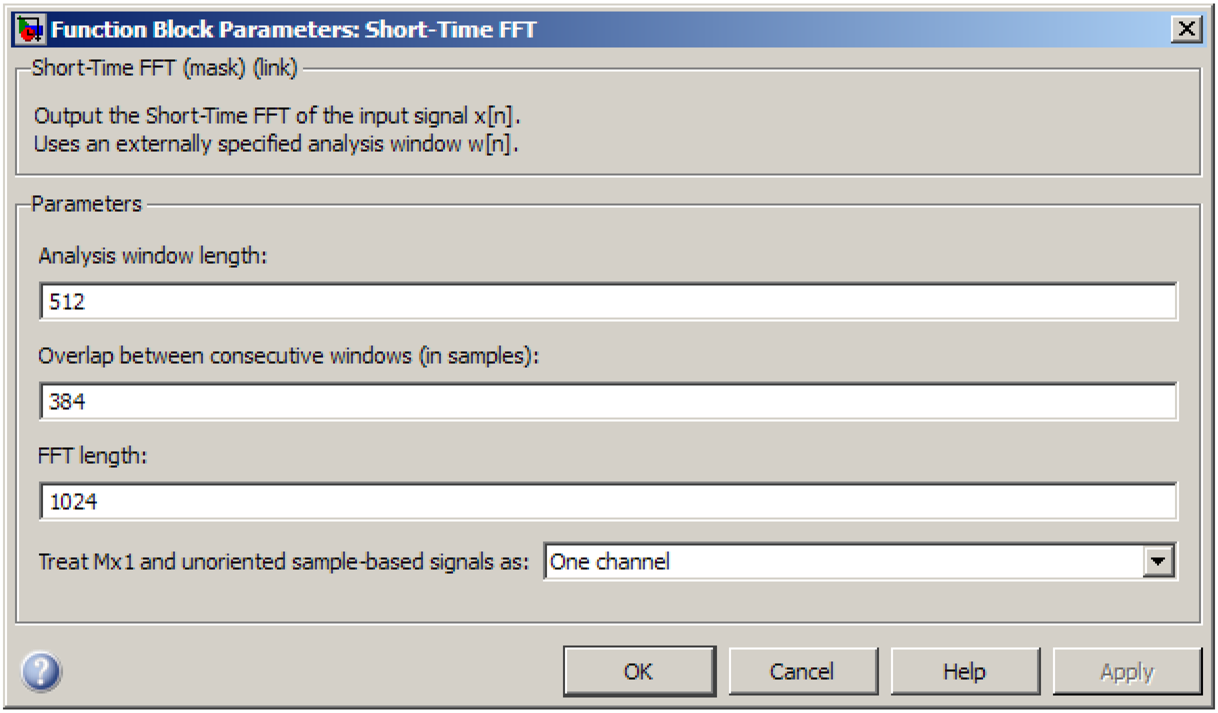
See the FFT and Array-Vector Multiply block reference pages for more information.

Examples

The `dspstsa` example illustrates how to use the Short-Time FFT and Inverse Short-Time FFT blocks to remove the background noise from a speech signal.

```
open_system('dspstsa')
```

Dialog Box



Function Block Parameters: Short-Time FFT

Short-Time FFT (mask) (link)

Output the Short-Time FFT of the input signal x[n].
Uses an externally specified analysis window w[n].

Parameters

Analysis window length: 512

Overlap between consecutive windows (in samples): 384

FFT length: 1024

Treat Mx1 and unoriented sample-based signals as: One channel

Analysis window length

Specify the frame length of the analysis window. The **Analysis window length** must be a positive integer value greater than one.

Overlap between consecutive windows (in samples)

Enter the number of samples of overlap for each frame of the input signal.

FFT length

Enter the length to which the block pads the input signal.

Treat Mx1 and unoriented sample-based signals as

Specify how the block treats sample-based *M*-by-1 column vectors and unoriented sample-based vectors of length *M*. You can select one of the following options:

- `One channel` — When you select this option, the block treats *M*-by-1 and unoriented sample-based inputs as a column vector (one channel).

- `M channels (this choice will be removed — see release notes)` — When you select this option, the block treats M-by-1 and unoriented sample-based inputs as a 1-by-M row vector.

Note: This parameter will be removed in a future release. See the *DSP System Toolbox Release Notes* for more information.

Signal From Workspace

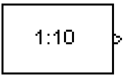
Import signal from MATLAB workspace

Library

Sources

`dspsrcs4`

Description



The Signal From Workspace block imports a signal from the MATLAB workspace into the Simulink model. The **Signal** parameter specifies the name of a MATLAB workspace variable containing the signal to import, or any valid MATLAB expression defining a matrix or 3-D array.

When the **Signal** parameter specifies an M-by-N matrix (M≠1), each of the N columns is treated as a distinct channel. You specify the frame size in the **Samples per frame** parameter, M_o, and the output is an M_o-by-N matrix containing M_o consecutive samples from each signal channel. You specify the output sample period in the **Sample time** parameter, T_s, and the output frame period is M_o*T_s. For M_o=1, the output is sample based; otherwise the output is frame based. For convenience, an imported row vector (M=1) is treated as a single channel, so the output dimension is M_o-by-1.

When the **Signal** parameter specifies an M-by-N-by-P array, each of the P pages (an M-by-N matrix) is output in sequence with period T_s. The **Samples per frame** parameter must be set to `1`, and the output is always sample based.

Initial and Final Conditions

Unlike the Simulink From Workspace block, the Signal From Workspace block holds the output value constant between successive output frames (that is, no linear interpolation takes place). Additionally, the initial signal values are always produced immediately at *t*=0.

When the block has output all of the available signal samples, it can start again at the beginning of the signal, or simply repeat the final value or generate zeros until the end of the simulation. (The block does not extrapolate the imported signal beyond the last sample.) The **Form output after final data value by** parameter controls this behavior:

- When you specify `Setting To Zero`, the block generates zero-valued outputs for the duration of the simulation after generating the last frame of the signal.
- When you specify `Holding Final Value`, the block repeats the final sample for the duration of the simulation after generating the last frame of the signal.
- When you specify `Cyclic Repetition`, the block repeats the signal from the beginning after it reaches the last sample in the signal. If the frame size you specify in the **Samples per frame** parameter does not evenly divide the input length, a buffer block is inserted into the Signal From Workspace subsystem, and the model becomes multirate. If you do not want your model to become multirate, make sure the frame size evenly divides the input signal length.

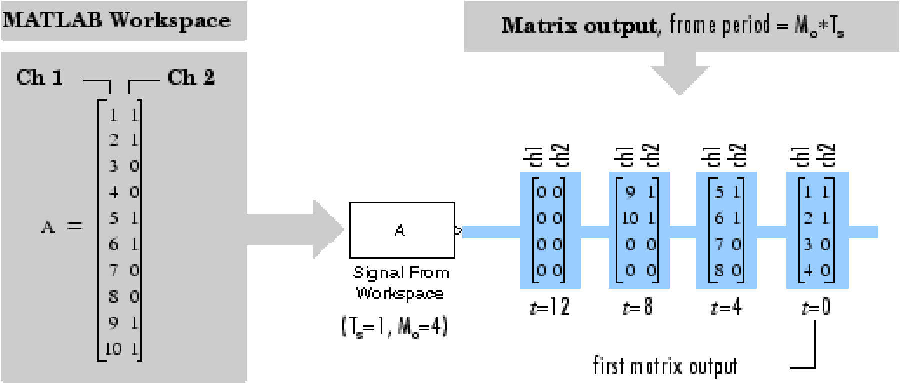
  Select the **Warn when frame size does not evenly divide input length** parameter to be alerted when the input length is not an integer multiple of the frame size and your model will become multirate. Use the Model Explorer to turn these warnings on or off model-wide:

  a. Select **Model Explorer** from the **View** menu in your model.
  b. In the **Search** bar of the Model Explorer, search `by Property Name` for the `ignoreOrWarnInputAndFrameLengths` property. Each block with the **Warn when frame size does not evenly divide input length** check box appears in the list in the **Contents** pane.
  c. Select each of the blocks for which you wish to toggle the warning parameter, and select or deselect the check box in the `ignoreOrWarnInputAndFrameLengths` column.

Examples

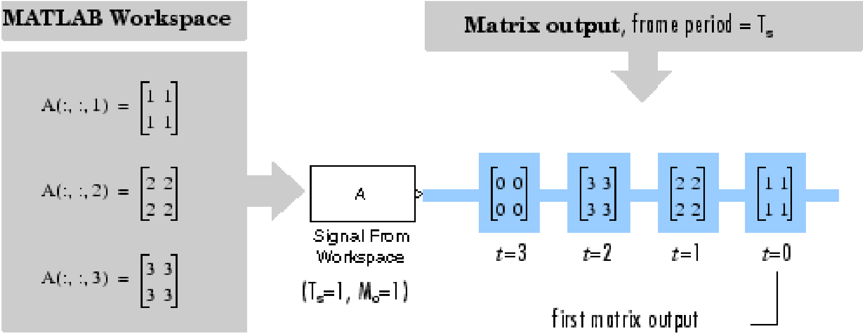
Example 1

In the first model, ex_signal_from_workspace_fb, the Signal From Workspace imports a two-channel signal from the workspace matrix,`A`. The **Sample time** is set to `1` and the **Samples per frame** is set to `4`, so the output is frame based with a frame size of 4 and a frame period of 4 seconds. The **Form output after final data value by** parameter specifies `Setting To Zero`, so all outputs after the third frame (at *t*=8) are zero.



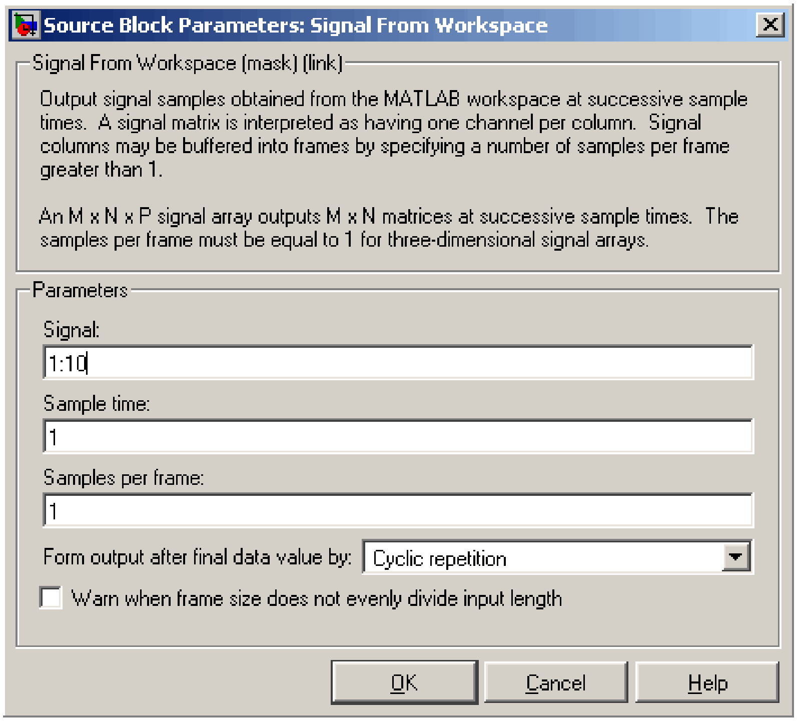
Example 2

In the second model, ex_signal_from_workspace_sb, the Signal From Workspace block imports a sample-based matrix signal from the 3-D workspace array, `A`. Again, the **Form output after final data value by** parameter specifies `Setting To Zero`, so all outputs after the third (at *t*=2) are zero.



The **Samples per frame** parameter is set to `1` for 3-D input.

Dialog Box



Source Block Parameters: Signal From Workspace

Signal From Workspace (mask) (link)

Output signal samples obtained from the MATLAB workspace at successive sample times. A signal matrix is interpreted as having one channel per column. Signal columns may be buffered into frames by specifying a number of samples per frame greater than 1.

An M x N x P signal array outputs M x N matrices at successive sample times. The samples per frame must be equal to 1 for three-dimensional signal arrays.

Parameters

Signal: 1:10

Sample time: 1

Samples per frame: 1

Form output after final data value by: Cyclic repetition

☐ Warn when frame size does not evenly divide input length

Signal

The name of the MATLAB workspace variable from which to import the signal, or a valid MATLAB expression specifying the signal.

Sample time

The sample period, T_s, of the output. The output frame period is M_o*T_s.

Samples per frame

The number of samples, M_o, to buffer into each output frame. This value must be 1 when you specify a 3-D array in the **Signal** parameter.

Form output after final data value by

Specifies the output after all of the specified signal samples have been generated. The block can output zeros for the duration of the simulation (`Setting to zero`), repeat the final data sample (`Holding Final Value`) or repeat the entire signal from the beginning (`Cyclic Repetition`).

Warn when frame size does not evenly divide input length

Select this parameter to be alerted when the input length is not an integer multiple of the frame size and your model will become multirate. For more information, see "Initial and Final Conditions" on page 1-1264.

This parameter is only visible when `Cyclic Repetition` is selected for the **Form output after final data value by** parameter.

Supported Data Types

- Double-precision floating point
- Single-precision floating point
- Fixed point (signed and unsigned)
- 8-, 16-, and 32-bit signed integers
- 8-, 16-, and 32-bit unsigned integers

Sine Wave

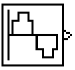
Generate continuous or discrete sine wave

Library

Sources

`dspsrcs4`

Description



The Sine Wave block generates a multichannel real or complex sinusoidal signal, with independent amplitude, frequency, and phase in each output channel. A real sinusoidal signal is generated when the **Output complexity** parameter is set to `Real`, and is defined by an expression of the type

$$y = A\sin(2\pi ft + \phi)$$

where you specify *A* in the **Amplitude** parameter, *f* in hertz in the **Frequency** parameter, and # in radians in the **Phase offset** parameter. A complex exponential signal is generated when the **Output complexity** parameter is set to `Complex`, and is defined by an expression of the type

$$y = Ae^{j(2\pi ft+\phi)} = A\{\cos(2\pi ft+\phi) + j\sin(2\pi ft+\phi)\}$$

Sections of This Reference Page

- "Supported Data Types" on page 1-1279
- "See Also" on page 1-1279

Generating Multichannel Outputs

For both real and complex sinusoids, the **Amplitude**, **Frequency**, and **Phase offset** parameter values (*A*, *f*, and #) can be scalars or length-*N* vectors, where *N* is the desired number of channels in the output. When you specify at least one of these parameters as a length-*N* vector, scalar values specified for the other parameters are applied to every channel.

For example, to generate the three-channel output containing the real sinusoids below, set **Output complexity** to `Real` and the other parameters as follows:

- **Amplitude** = `[1 2 3]`
- **Frequency** = `[1000 500 250]`
- **Phase offset** = `[0 0 pi/2]`

$$y = \begin{cases} \sin(2000\pi t) & \text{(channel 1)} \\ 2\sin(1000\pi t) & \text{(channel 2)} \\ 3\sin\left(500\pi t + \dfrac{\pi}{2}\right) & \text{(channel 3)} \end{cases}$$

Output Sample Time and Samples Per Frame

In all discrete modes, the block buffers the sampled sinusoids into frames of size M, where you specify M in the **Samples per frame** parameter. The output is a frame-based M-by-N matrix with frame period M*T_s, where you specify T_s in the **Sample time** parameter. For M=1, the output is sample based.

Sample Mode

The **Sample mode** parameter specifies the block's sampling property, which can be `Continuous` or `Discrete`:

- `Continuous`

In continuous mode, the sinusoid in the *i*th channel, y_i, is computed as a continuous function,

$$y_i = A_i \sin\left(2\pi f_i t + \phi_i\right) \quad \text{(real)}$$

or

$$y_i = A_i e^{j(2\pi f_i t + \phi_i)} \qquad \text{(complex)}$$

and the block's output is continuous. In this mode, the block's operation is the same as that of a Simulink Sine Wave block with **Sample time** set to `0`. This mode offers high accuracy, but requires trigonometric function evaluations at each simulation step, which is computationally expensive. Additionally, because this method tracks absolute simulation time, a discontinuity will eventually occur when the time value reaches its maximum limit.

Note also that many DSP System Toolbox blocks do not accept continuous-time inputs.

- `Discrete`

  In discrete mode, the block's discrete-time output can be generated by directly evaluating the trigonometric function, by table lookup, or by a differential method. The three options are explained below.

Discrete Computational Methods

When you select `Discrete` from the **Sample mode** parameter, the secondary **Computation method** parameter provides three options for generating the discrete sinusoid:

- `Trigonometric Fcn`
- `Table Lookup`

- `Differential`

Note: To generate fixed-point sinusoids, you must select `Table Lookup`.

Trigonometric Fcn

The trigonometric function method computes the sinusoid in the *i*th channel, y_{i}, by sampling the continuous function

$$y_i = A_i \sin(2\pi f_i t + \phi_i) \quad \text{(real)}$$

or

$$y_i = A_i e^{j(2\pi f_i t+\phi_i)} \qquad \text{(complex)}$$

with a period of T_s, where you specify T_s in the **Sample time** parameter. This mode of operation shares the same benefits and liabilities as the `Continuous` sample mode described above.

At each sample time, the block evaluates the sine function at the appropriate time value *within the first cycle* of the sinusoid. By constraining trigonometric evaluations to the first cycle of each sinusoid, the block avoids the imprecision of computing the sine of very large numbers, and eliminates the possibility of discontinuity during extended operations (when an absolute time variable might overflow). This method therefore avoids the memory demands of the table lookup method at the expense of many more floating-point operations.

Table Lookup

The table lookup method precomputes the *unique* samples of every output sinusoid at the start of the simulation, and recalls the samples from memory as needed. Because a table of finite length can only be constructed when all output sequences repeat, the method requires that the period of every sinusoid in the output be evenly divisible by the sample period. That is, $1/(f_i T_s) = k_i$ must be an integer value for every channel $i = 1, 2, ..., N$.

When the **Optimize table for** parameter is set to `Speed`, the table constructed for each channel contains k_i elements. When the **Optimize table for** parameter is set to `Memory`, the table constructed for each channel contains $k_i/4$ elements.

For long output sequences, the table lookup method requires far fewer floating-point operations than any of the other methods, but can demand considerably more memory, especially for high sample rates (long tables). This is the recommended method for models that are intended to emulate or generate code for DSP hardware, and that therefore need to be optimized for execution speed.

Note: The lookup table for this block is constructed from double-precision floating-point values. Thus, when you use the `Table lookup` computation mode, the maximum amount of precision you can achieve in your output is 53 bits. Setting the word length of the **Output** or **User-defined** data type to values greater than 53 bits does not improve the precision of your output.

Differential

The differential method uses an incremental algorithm. This algorithm computes the output samples based on the output values computed at the previous sample time (and precomputed update terms) by making use of the following identities.

$$\sin(t+T_s) = \sin(t)\cos(T_s) + \cos(t)\sin(T_s)$$
$$\cos(t+T_s) = \cos(t)\cos(T_s) - \sin(t)\sin(T_s)$$

The update equations for the sinusoid in the ith channel, y_i, can therefore be written in matrix form as

$$\begin{bmatrix} \sin\{2\pi f_i(t+T_s)+\phi_i\} \\ \cos\{2\pi f_i(t+T_s)+\phi_i\} \end{bmatrix} = \begin{bmatrix} \cos(2\pi f_i T_s) & \sin(2\pi f_i T_s) \\ -\sin(2\pi f_i T_s) & \cos(2\pi f_i T_s) \end{bmatrix} \begin{bmatrix} \sin(2\pi f_i t+\phi_i) \\ \cos(2\pi f_i t+\phi_i) \end{bmatrix}$$

where you specify T_s in the **Sample time** parameter. Since T_s is constant, the right-hand matrix is a constant and can be computed once at the start of the simulation. The value of $A_i\sin[2\pi f_i(t+T_s)+\#_i]$ is then computed from the values of $\sin(2\pi f_i t+\#_i)$ and $\cos(2\pi f_i t+\#_i)$ by a simple matrix multiplication at each time step.

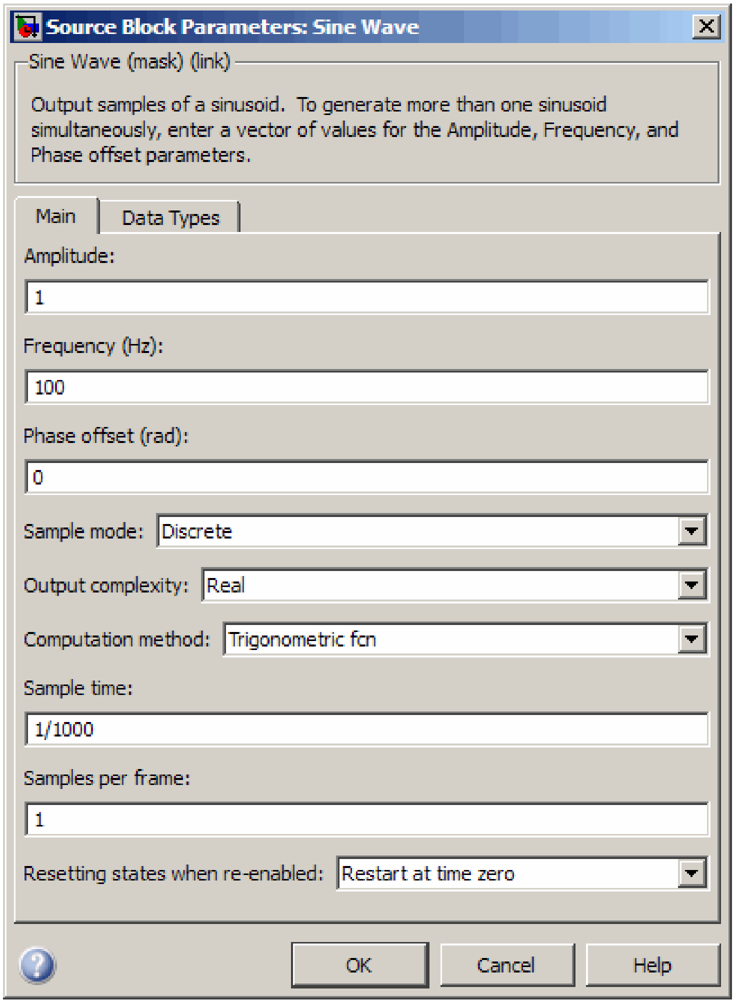
This mode offers reduced computational load, but is subject to drift over time due to cumulative quantization error. Because the method is not contingent on an absolute time value, there is no danger of discontinuity during extended operations (when an absolute time variable might overflow).

Examples

The dspsinecomp example provides a comparison of all the available sine generation methods.

Dialog Box

The **Main** pane of the Sine Wave block dialog appears as follows.



Source Block Parameters: Sine Wave

Sine Wave (mask) (link)

Output samples of a sinusoid. To generate more than one sinusoid simultaneously, enter a vector of values for the Amplitude, Frequency, and Phase offset parameters.

Amplitude: 1

Frequency (Hz): 100

Phase offset (rad): 0

Sample mode: Discrete

Output complexity: Real

Computation method: Trigonometric fcn

Sample time: 1/1000

Samples per frame: 1

Resetting states when re-enabled: Restart at time zero

Amplitude

A length-*N* vector containing the amplitudes of the sine waves in each of *N* output channels, or a scalar to be applied to all *N* channels. The vector length must be the same as that specified for the **Frequency** and **Phase offset** parameters. “Tunable” when **Computation method** is to `Trigonometric fcn` or `Differential`.

Frequency

A length-*N* vector containing frequencies, in Hertz, of the sine waves in each of *N* output channels, or a scalar to be applied to all *N* channels. The vector length must be the same as that specified for the **Amplitude** and **Phase offset** parameters. You can specify positive, zero, or negative frequencies. “Tunable” when **Sample mode** is `Continuous` or **Computation method** is `Trigonometric fcn`.

Phase offset

A length-*N* vector containing the phase offsets, in radians, of the sine waves in each of *N* output channels, or a scalar to be applied to all *N* channels. The vector length must be the same as that specified for the **Amplitude** and **Frequency** parameters. “Tunable” when **Sample mode** is `Continuous` or **Computation method** is `Trigonometric fcn`.

Sample mode

The block's sampling behavior, `Continuous` or `Discrete`. This parameter is not tunable.

Output complexity

The type of waveform to generate: `Real` specifies a real sine wave, `Complex` specifies a complex exponential. This parameter is not tunable.

Computation method

The method by which discrete-time sinusoids are generated: `Trigonometric fcn`, `Table lookup`, or `Differential`. This parameter is not tunable. For more information on each of the available options, see “Discrete Computational Methods” on page 1-1271 in the Description section.

This parameter is only visible when you set the **Sample mode** to `Discrete`.

Note: To generate fixed-point sinusoids, you must set the **Computation method** to `Table lookup`.

Optimize table for

Optimizes the table of sine values for `Speed` or `Memory` (this parameter is only visible when the **Computation method** parameter is set to `Table lookup`). When optimized for speed, the table contains *k* elements, and when optimized for memory, the table contains *k*/4 elements, where *k* is the number of input samples in one full period of the sine wave.

Sample time

The period with which the sine wave is sampled, T_s. The block's output frame period is $M*T_s$, where you specify M in the **Samples per frame** parameter. This parameter is disabled when you select `Continuous` from the **Sample mode** parameter. This parameter is not tunable.

Samples per frame

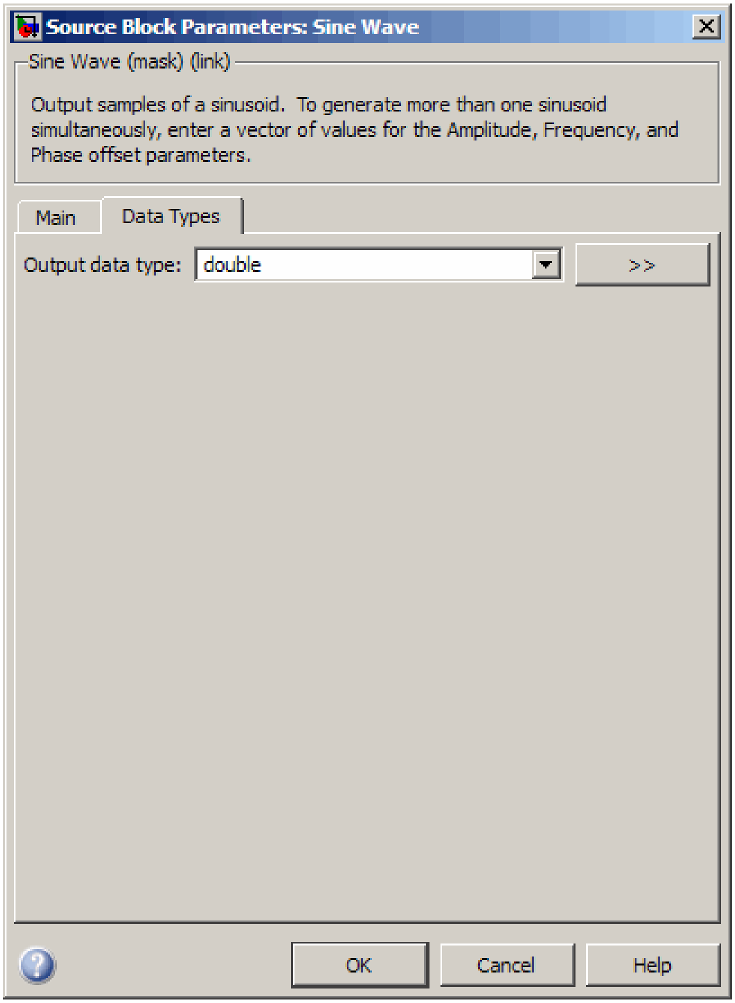
The number of consecutive samples from each sinusoid to buffer into the output frame, M. When the value of this parameter is `1`, the block outputs a sample-based signal.

This parameter is disabled when you select `Continuous` from the **Sample mode** parameter.

Resetting states when re-enabled

This parameter only applies when the Sine Wave block is located inside an enabled subsystem and the **States when enabling** parameter of the Enable block is set to `reset`. This parameter determines the behavior of the Sine Wave block when the subsystem is re-enabled. The block can either reset itself to its starting state (`Restart at time zero`), or resume generating the sinusoid based on the current simulation time (`Catch up to simulation time`). This parameter is disabled when you select `Continuous` from the **Sample mode** parameter.

The **Data Types** pane of the Sine Wave block dialog appears as follows.



Source Block Parameters: Sine Wave

Sine Wave (mask) (link)

Output samples of a sinusoid. To generate more than one sinusoid simultaneously, enter a vector of values for the Amplitude, Frequency, and Phase offset parameters.

Output data type: double

Output data type

Specify the output data type for this block. You can select one of the following:

- A rule that inherits a data type, for example, `Inherit: Inherit via back propagation`. When you select this option, the output data type and scaling matches that of the next downstream block.
- A built in data type, such as `double`

- An expression that evaluates to a valid data type, for example, `fixdt(1,16)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Specify Block Output Data Types” in “Simulink User's Guide” for more information.

Note: The lookup table for this block is constructed from double-precision floating-point values. Thus, when you use the `Table lookup` computation mode, the maximum amount of precision you can achieve in your output is 53 bits. Setting the word length of the **Output** or **User-defined** data type to values greater than 53 bits does not improve the precision of your output.

HDL Code Generation

This block supports HDL code generation using HDL Coder. HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic. For more information on implementations, properties, and restrictions for HDL code generation, see Sine Wave.

Supported Data Types

- Double-precision floating point
- Single-precision floating point
- Fixed point (signed only)
- 8-, 16-, and 32-bit signed integers

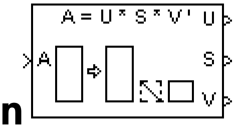
Singular Value Decomposition

Factor matrix using singular value decomposition

Library

Math Functions / Matrices and Linear Algebra / Matrix Factorizations

`dspfactors`



Description

The Singular Value Decomposition block factors the M-by-N input matrix A such that

$$A = U \cdot diag(S) \cdot V^*$$

where

- U is an M-by-P matrix
- V is an N-by-P matrix
- S is a length-P vector
- P is defined as min(M,N)

When

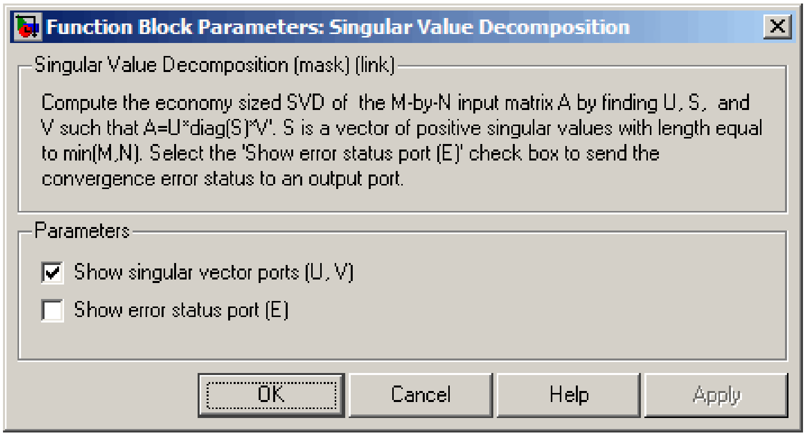
- $M = N$, U and V are both M-by-M unitary matrices
- $M > N$, V is an N-by-N unitary matrix, and U is an M-by-N matrix whose columns are the first N columns of a unitary matrix
- $N > M$, U is an M-by-M unitary matrix, and V is an N-by-M matrix whose columns are the first M columns of a unitary matrix

In all cases, S is an unoriented vector of positive singular values having length P.

Length-N row inputs are treated as length-N columns.

Note that the first (maximum) element of output S is equal to the 2-norm of the matrix A.

Dialog Box



Function Block Parameters: Singular Value Decomposition

Singular Value Decomposition (mask) (link)

Compute the economy sized SVD of the M-by-N input matrix A by finding U, S, and V such that A=U*diag(S)*V'. S is a vector of positive singular values with length equal to min(M,N). Select the 'Show error status port (E)' check box to send the convergence error status to an output port.

Parameters

☑ Show singular vector ports (U, V)

□ Show error status port (E)

Show singular vector ports

Select to enable the U and V output ports.

Show error status port

Select to enable the E output port, which reports a failure to converge. The possible values you can receive on the port are:

- 0 — The singular value decomposition calculation converges.
- 1 — The singular value decomposition calculation does not converge.

If the singular value decomposition calculation fails to converge, the output at ports U, S, and V are undefined matrices of the correct size.

Sort

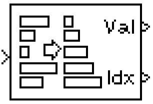
Sort input elements by value

Library

Statistics

`dspstat3`

Description



The Sort block ranks the values of the input elements using either a quick sort or an insertion sort algorithm. The quick sort algorithm uses a recursive sort method and is faster at sorting more than 32 elements. The insertion sort algorithm uses a non-recursive method and is faster at sorting less than 32 elements. You should also always use the insertion sort algorithm when you are generating code from the Sort block if you do not want recursive function calls in your code. To specify the sort method, use the **Sort algorithm** parameter.

The **Mode** parameter specifies the block's mode of operation, and can be set to `Value`, `Index`, or `Value and index`.

Value Mode

When **Mode** is set to `Value`, the block sorts the elements in each column of the *M*-by-*N* input matrix `u` in order of ascending or descending value, as specified by the **Sort order** parameter.

```
val = sort(u)
val = flipud(sort(u))
```

The output at each sample time, `val`, is an *M*-by-*N* matrix containing the sorted columns of `u`.

The block sorts complex inputs according to their magnitude.

Index Mode

When **Mode** is set to `Index`, the block sorts the elements in each column of the *M*-by-*N* input matrix `u`,

```
[val,idx] = sort(u)
[val,idx] = flipud(sort(u))
```

and outputs the *M*-by-*N* index matrix, `idx`. The `j`th column of `idx` is an index vector that permutes the `j`th column of `u` to the desired sorting order.

```
val(:,j) = u(idx(:,j),j)
```

The index value outputs are always 32-bit unsigned integer values.

Value and Index Mode

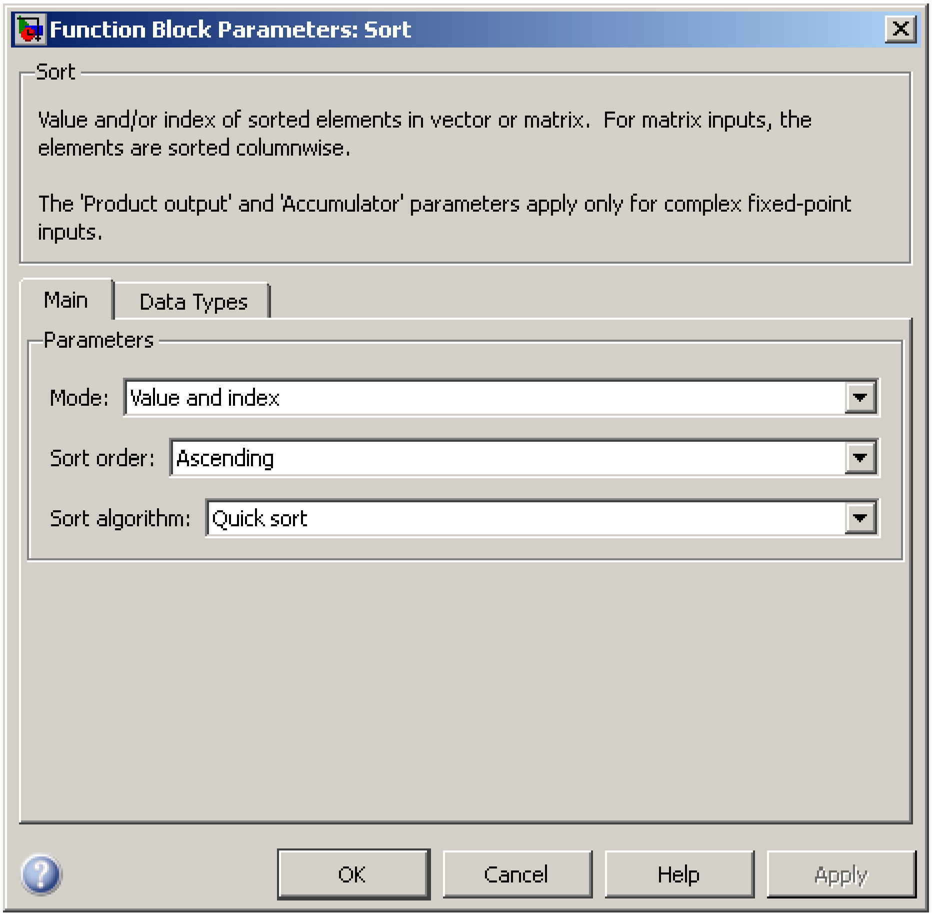
When **Mode** is set to `Value and index`, the block outputs both the sorted matrix, `val`, and the index matrix, `idx`.

Fixed-Point Data Types

The parameters on the **Data Types** pane are only used for complex fixed-point inputs. Complex fixed-point inputs are sorted by magnitude squared. The sum of the squares of the real and imaginary parts of such an input are formed before a comparison is made, as described in “Value Mode” on page 1-1284. The results of the squares of the real and imaginary parts are placed into the product output data type. The result of the sum of the squares is placed into the accumulator data type. These parameters are ignored for other types of inputs.

Dialog Box

The **Main** pane of the Sort block dialog appears as follows.



Function Block Parameters: Sort

Sort

Value and/or index of sorted elements in vector or matrix. For matrix inputs, the elements are sorted columnwise.

The 'Product output' and 'Accumulator' parameters apply only for complex fixed-point inputs.

Parameters

Mode: Value and index

Sort order: Ascending

Sort algorithm: Quick sort

Mode

Specify the block's mode of operation: Output the sorted matrix (`Value`), the index matrix (`Index`), or both (`Value and index`).

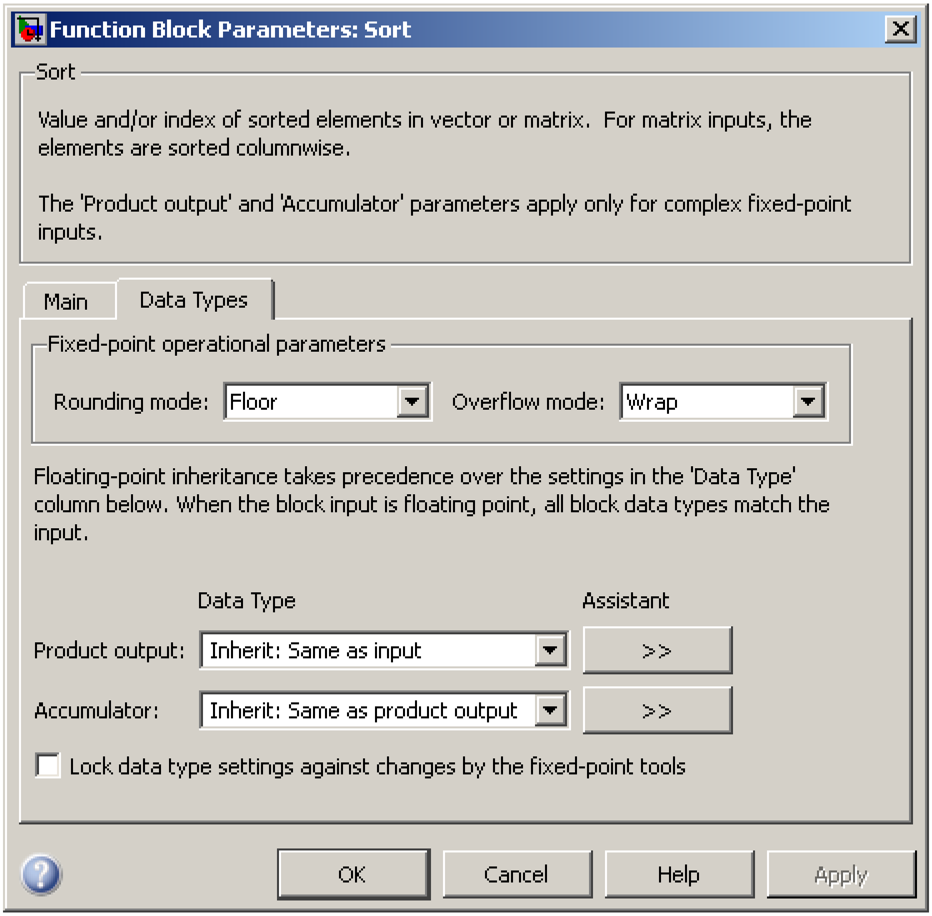
Sort order

Specify the order in which to sort the training points, `Descending` or `Ascending`.

Sort algorithm

Specify whether the elements of the input are sorted using a `Quick sort` or an `Insertion sort` algorithm.

The **Data Types** pane of the Sort block dialog appears as follows.



Function Block Parameters: Sort

Sort

Value and/or index of sorted elements in vector or matrix. For matrix inputs, the elements are sorted columnwise.

The 'Product output' and 'Accumulator' parameters apply only for complex fixed-point inputs.

Fixed-point operational parameters

Rounding mode: Floor

Overflow mode: Wrap

Floating-point inheritance takes precedence over the settings in the 'Data Type' column below. When the block input is floating point, all block data types match the input.

	Data Type	Assistant
Product output:	Inherit: Same as input	>>
Accumulator:	Inherit: Same as product output	>>

□ Lock data type settings against changes by the fixed-point tools

Note The parameters on the **Data Types** pane are only used for complex fixed-point inputs. The sum of the squares of the real and imaginary parts of such an input are formed before a comparison is made, as described in "Value Mode" on page 1-1284. The results of the squares of the real and imaginary parts are placed into the product output data type. The result of the sum of the squares is placed into the accumulator data type. These parameters are ignored for other types of inputs.

Rounding mode

Select the “rounding mode” for fixed-point operations.

Overflow mode

Select the “overflow mode” for fixed-point operations.

Product output data type

Specify the product output data type. See “Fixed-Point Data Types” on page 1-1285 and “Multiplication Data Types” for illustrations depicting the use of the product output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as input`
- An expression that evaluates to a valid data type, for example, `fixdt([],16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Product output data type** parameter.

See “Specify Data Types Using Data Type Assistant” in “Simulink User's Guide” for more information.

Accumulator data type

Specify the accumulator data type. See “Fixed-Point Data Types” on page 1-1285 for illustrations depicting the use of the accumulator data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Same as product output`
- An expression that evaluates to a valid data type, for example, `fixdt([],16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Accumulator data type** parameter.

See “Specify Data Types Using Data Type Assistant” in “Simulink User's Guide” for more information.

Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • 8-, 16-, 32-, and 128-bit unsigned integers • 8-, 16-, 32-, and 128-bit signed integers
Val	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • 8-, 16-, 32-, and 128-bit unsigned integers • 8-, 16-, 32-, and 128-bit signed integers
Idx	• 32-bit unsigned integers

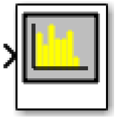
Spectrum Analyzer

Display frequency spectrum of time-domain signals

Library

Sinks

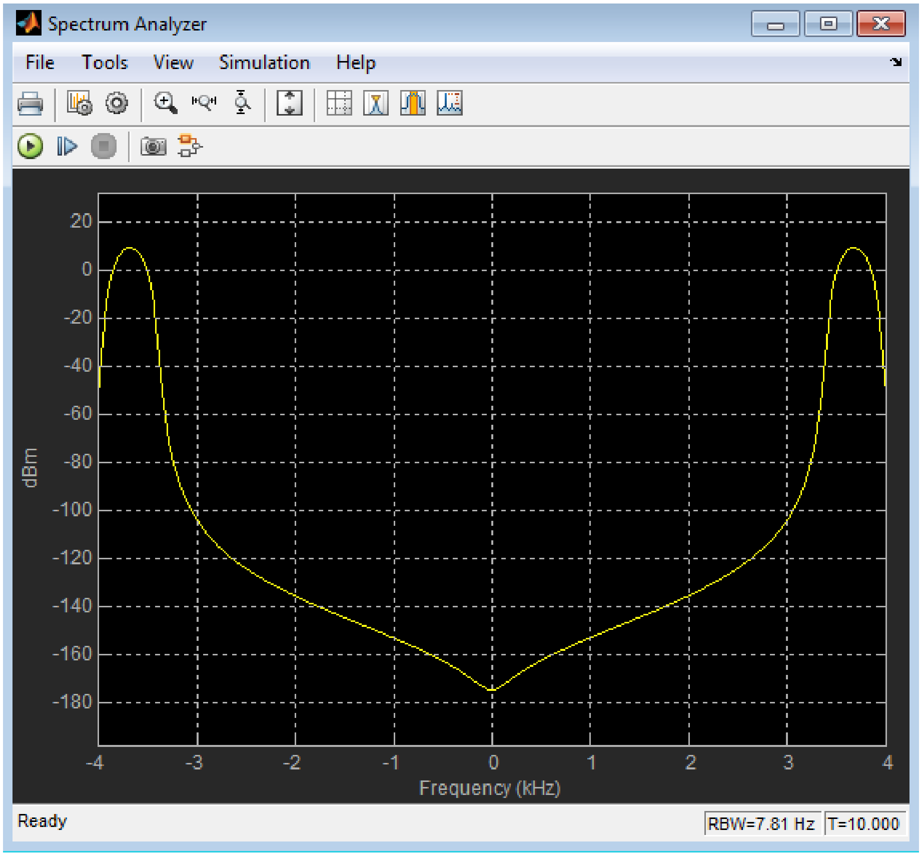
`dspsnks4`



Description

The Spectrum Analyzer block, hereafter referred to as the scope, displays frequency spectra of signals. The Spectrum Analyzer block accepts input signals with the following characteristics:

- Discrete sample time
- Real- or complex-valued
- Fixed number of channels of variable length
- Floating- or fixed-point data type



You can use the Spectrum Analyzer block in models running in Normal or Accelerator simulation modes. You can also use the Spectrum Analyzer block in models running in Rapid Accelerator or External simulation modes, with some limitations. See the “Supported Simulation Modes” on page 1-1346 section for more information.

You can use the Spectrum Analyzer block inside of all subsystems and conditional subsystems. *Conditional subsystems* include enabled subsystems, triggered subsystems, enabled and triggered subsystems, and function-call subsystems. See “Conditional Subsystems” in the Simulink documentation for more information.

For an example that uses the Spectrum Analyzer, see the “Display Frequency-Domain Data in Spectrum Analyzer” example in the DSP System Toolbox documentation.

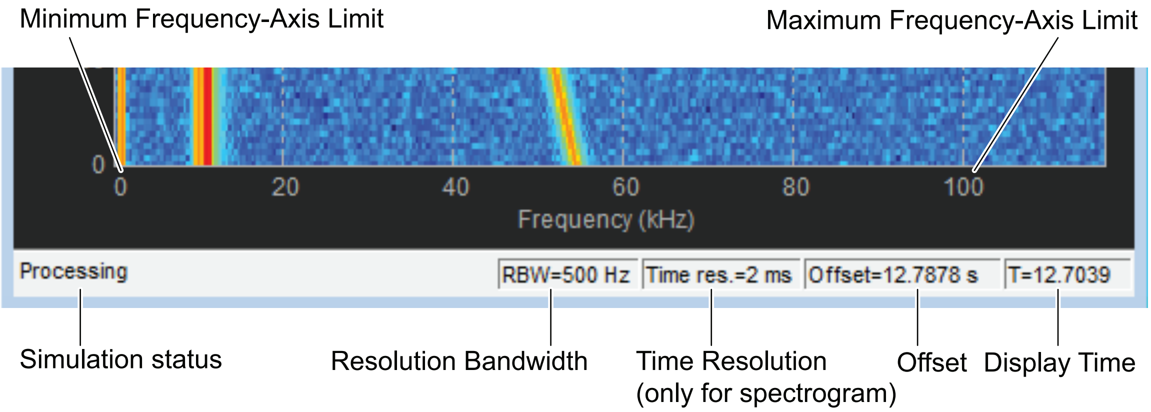
See the following sections for more information on the Spectrum Analyzer:

- “Signal Display” on page 1-1292
- “Toolbar” on page 1-1297
- “Simulation Toolbar” on page 1-1300
- “Spectrum Settings” on page 1-1301
- “Measurements Panels” on page 1-1309
- “Visuals — Spectrum Properties” on page 1-1325
- “Style Dialog Box” on page 1-1327
- “Tools — Axes Scaling Properties” on page 1-1329
- “Algorithms” on page 1-1333
- “Differences from Spectrum Scope Block” on page 1-1341
- “Supported Data Types” on page 1-1346
- “Supported Simulation Modes” on page 1-1346

Note: For information about the Spectrum Analyzer System object, see `dsp.SpectrumAnalyzer`.

Signal Display

The Spectrum Analyzer indicates the spectrum computation settings that are represented in the current display. Check the **Resolution Bandwidth**, **Time Resolution**, and **Offset** indicators on the status bar in the scope window for this information. These indicators relate to the **Minimum Frequency-Axis limit** and **Maximum Frequency-Axis limit** values on the *frequency*-axis of the scope window. The values specified by these indicators may be changed by modifying parameters in the **Spectrum Settings** panel. You can also view the object state and the amount of time data that correspond to the current display. Check the **Simulation Status** and **Simulation time** indicators on the status bar in the scope window for this information. The following figure highlights these aspects of the Spectrum Analyzer window.



Processing

RBW=500 Hz | Time res.=2 ms | Offset=12.7878 s | T=12.7039

Note: To prevent the scope from opening when you run your model, right-click on the scope icon and select `Comment Out`. If the scope is already open, you can still comment it out in the model. When you do so, the scope displays a message, “No data can be shown because this scope is commented out.” Select `Uncomment` to turn the scope back on.

- **Frequency Span** — The range of values shown on the *frequency*-axis on the Spectrum Analyzer window.

Details

Spectrum Analyzer sets the frequency span using the values of parameters on the **Main options** pane of the **Spectrum Settings** panel.

- `Span (Hz)` and `CF (Hz)` visible — The **Frequency Span** value equals the **Span** parameter in the **Main options** pane.
- `FStart (Hz)` and `FStop (Hz)` — The **Frequency Span** value equals the difference of the **FStop** and **FStart** parameters in the **Main options** pane, as given by the formula: $f_{span} = f_{stop} - f_{start}$.

By default, the **Full Span** check box in the **Main options** pane is enabled. In this case, the Spectrum Analyzer computes and plots the spectrum over the entire *Nyquist* frequency interval. When the **Two-sided spectrum** check box in the **Trace options** pane is enabled, the Nyquist interval is $\left[-\frac{SampleRate}{2},\frac{SampleRate}{2}\right]+FrequencyOffset$ hertz.

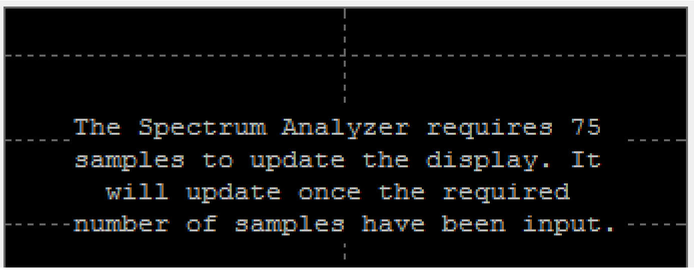
- **Resolution Bandwidth** — The smallest positive frequency or frequency interval that can be resolved.

Details

Spectrum Analyzer sets the resolution bandwidth using the value of the frequency resolution parameter on the **Main options** pane of the **Spectrum Settings** panel. By default, this parameter is set to `RBW (Hz)` and `'Auto'`. In this case, the Spectrum Analyzer determines the appropriate value to ensure that there are 1024 RBW intervals over the specified **Frequency Span**.

You can set the resolution bandwidth to whatever value you choose. For this reason, there is a minimum boundary on the number of input samples required to compute a spectral update. This number of input samples required to compute one spectral update is shown as **Samples/update** in the **Main options** pane. This value is directly related to *RBW* by the following equation:

$N_{samples}=\frac{\left(1-\frac{O_p}{100}\right)\times NENBW\times F_s}{RBW}$. Overlap percentage, O_p, is the value of the **Overlap %** parameter in the **Window Options** pane of the **Spectrum Settings** panel. *NENBW* is the normalized effective noise bandwidth, a factor of the windowing method used, which is shown in the **Window Options** pane. F_s is the sample rate. In some cases, the number of samples provided in the input are not sufficient to achieve the resolution bandwidth that you specify. When this situation occurs, Spectrum Analyzer produces a message on the display, as shown in the following figure.



```
The Spectrum Analyzer requires 75
samples to update the display. It
will update once the required
number of samples have been input.
```

Spectrum Analyzer removes this message and displays a spectral estimate as soon as enough data has been input.

If the frequency resolution setting on the **Main options** pane of the **Spectrum Settings** is `Window length`, you specify the window length and the resulting RBW is $\frac{NENBW * Fs}{N_{window}}$. The **Samples/update** in this case is directly related to *RBW* by the following equation: $N_{samples} = \left(1 - \frac{O_p}{100}\right) N_{window}$

- **Time Resolution** — The time resolution for a spectrogram line.

Details

Time resolution is the amount of data, in seconds, used to compute a spectrogram line. The minimum attainable resolution is the amount of data time it takes to compute a single spectral estimate. **Time Resolution** is displayed only when the spectrum **Type** is `Spectrogram`.

- **Offset** — The constant frequency offset to apply to the entire spectrum.

Details

Spectrum Analyzer adds this constant offset parameter to the values on the *frequency*-axis using the value of **Offset** on the **Trace options** pane of the **Spectrum Settings** panel. The offset is the current time value at the middle of the interval of the line displayed at 0 seconds. The actual time of a particular spectrogram line is the offset minus the *y*-axis time listing. You must take this parameter into consideration when you set the **Span (Hz)** and **CF (Hz)** parameters on the **Main options** pane of the **Spectrum Settings** panel to ensure that the frequency span is within Nyquist limits. The offset is displayed on the plot only when the spectrum **Type** is `Spectrogram`.

- **Simulation Status** — Provides the current status of the model simulation.

Details

The status can be one of the following conditions:

- `Processing` — Occurs after you construct the `SpectrumAnalyzer` object.
- `Stopped` — Occurs after you run the release method.

The **Simulation Status** is part of the **Status Bar** in the Spectrum Analyzer window. You can choose to hide or display the entire **Status Bar**. From the Spectrum Analyzer menu, select **View** > **Status Bar**.

- **Display time** — The amount of time that has progressed since the last update to the Spectrum Analyzer display.

Details

Every time data is processed by the block, the simulation time increases by the number of rows in the input signal divided by the sample rate, as given by the following formula: $t_{sim} = t_{sim} + \frac{\text{length(0:length(xsine))-1}}{\text{SampleRate}}$. When **Reduce Plot Rate to Improve Performance** is checked, the simulation time and display time might differ. At the beginning of a simulation, you can modify the **SampleRate** parameter on the **Main options** pane of the **Spectrum Settings** panel.

The **Display time** indicator is a component of the **Status Bar** in the Spectrum Analyzer window. You can choose to hide or display the entire **Status Bar**. From the Spectrum Analyzer menu, select **View** > **Status Bar** .

For more information, see “Spectrum Settings” on page 1-1301.

Reduce Plot Rate to Improve Performance

By default, Spectrum Analyzer updates the display at fixed intervals of time at a rate not exceeding 20 hertz. If you want Spectrum Analyzer to plot a spectrum on every simulation time step, you can disable the **Reduce Plot Rate to Improve Performance** option. In the Spectrum Analyzer menu, select **Simulation** > **Reduce Plot Rate to Improve Performance** to clear the check box. “Tunable”.

Note: When this check box is selected, Spectrum Analyzer may display a misleading spectrum in some situations. For example, if the input signal is wide-band with non-stationary behavior, such as a chirp signal, Spectrum Analyzer might display a stationary spectrum. The reason for this behavior is that Spectrum Analyzer buffers the input signal data and only updates the display periodically at approximately 20 times per second. Therefore, Spectrum Analyzer does not render changes to the spectrum that occur and elapse between updates, which gives the impression of an incorrect spectrum. To ensure that spectral estimates are as accurate as possible, clear the **Reduce Plot Rate to Improve Performance** check box. When you clear this box, Spectrum Analyzer calculates spectra whenever there is enough data, rendering results correctly.

Toolbar

The Spectrum Analyzer toolbar contains the following buttons.

Print, Settings, and Properties Buttons

Button	Menu Location	Shortcut Keys	Description
🖨	**File** > **Print**	**Ctrl+P**	Print the current Spectrum Analyzer window. To enable printing, run the `release` method. To print the current scope window to a figure rather than sending it to your printer, select **File** > **Print to figure**.
⚙	**View** > **Spectrum Settings**	N/A	Open or close the **Spectrum Settings** panel. You can modify the settings in this panel to control the manner in which the spectrum is calculated.

Button	Menu Location	Shortcut Keys	Description
			See the “Spectrum Settings” on page 1-1301 section for more information.
⚙	**View > Properties**	N/A	Open the **Visuals — Spectrum Options** dialog box. See the “Visuals — Spectrum Properties” on page 1-1325 section for more information.

Axes Control Buttons

🔍	**Tools > Zoom In**	N/A	When this tool is active, you can zoom in on the scope window. To do so, click in the center of your area of interest, or click and drag your cursor to draw a rectangular area of interest inside the scope window.
↔🔍	**Tools > Zoom X**	N/A	When this tool is active, you can zoom in on the *x*-axis. To do so, click inside the scope window, or click and drag your cursor along the *x*-axis over your area of interest.
↕🔍	**Tools > Zoom Y**	N/A	When this tool is active, you can zoom in on the *y*-axis. To do so, click inside the scope window, or click and drag your cursor along the *y*-axis over your area of interest.
↕	**Tools > Scaling Properties**	**Ctrl+A**	Click this button to scale the axes in the active scope window. Alternatively, you can enable automatic axes scaling by selecting one of the following options from the **Tools** menu: • **Automatically Scale Limits** — When you select this option, the scope scales the axes as needed during simulation. • **Scale Limits after 10 Updates** — When you select this option, the scope scales the axes

			after 10 updates. The scope does not scale the axes again during the simulation. • **Scale Limits at Stop** — When you select this option, the scope scales the axes each time the simulation is stopped.

Note: The axes control (zoom) buttons do not change the settings related to frequency span for Spectrum Analyzer. These buttons are purely graphical. Spectrum computations are not affected when you zoom.

Measurements Buttons

	Tools > Measurements > Cursor Measurements	N/A	Open or close the **Cursor Measurements** panel. This panel controls the display of vertical and horizontal cursors on the spectrum display. See the “Cursor Measurements Panel” on page 1-1311 section for more information.
	Tools > Measurements > Peak Finder	N/A	Open or close the **Peak Finder** panel. This panel displays maxima and the frequencies at which they occur, allowing the settings for peak threshold, maximum number of peaks, and peak excursion to be modified. See the “Peak Finder Panel” on page 1-1313 section for more information.
	Tools > Measurements > Channel Measurements	N/A	Open or close the **Channel Measurements** panel. This panel displays occupied bandwidth and ACPR channel measurements. See the “Channel Measurements Panel” on page 1-1317 section for more information.
	Tools > Measurements > Distortion Measurements	N/A	Open or close the **Distortion Measurements** panel. This panel displays harmonic and intermodulation distortion measurements.

			See the “Distortion Measurements Panel” on page 1-1320 section for more information.
◹	**Tools** > **Measurements** > **CCDF Measurements**	N/A	Open or close the **CCDF Measurements** panel. This panel displays complimentary cumulative distribution function measurements. See the “CCDF Measurements Panel” on page 1-1323 section for more information.

You can control whether this toolbar appears in the Spectrum Analyzer window. From the Spectrum Analyzer menu, select **View** > **Toolbar**.

Simulation Toolbar

The Simulation Toolbar contains the following buttons.

Button	Menu Location	Shortcut Keys	Description
⚙	**Simulation** > **Simulation Stepping Options**	N/A	Open the **Simulation Stepping Options** dialog box. This button appears only when you have previous stepping disabled.
◁	**Simulation** > **Step Back**	N/A	Advance the model simulation backward by one time step. This button appears only when you have previous stepping enabled and the model simulation is paused.
▶	**Simulation** > **Run**	**Ctrl+T**, **p**, **Space**	Start the model simulation. This button appears only when the model simulation is stopped.
▶	**Simulation** > **Continue**	**p**, **Space**	Continue the model simulation. This button appears only when the model simulation is paused.
⏸	**Simulation** > **Pause**	**p**, **Space**	Pause the model simulation. This button appears only when the model simulation is running.
▷	**Simulation** > **Step Forward**	**Right arrow**,	Advance the model simulation forward by one time step. This button starts the model

Button	Menu Location	Shortcut Keys	Description
		Page Down	simulation, allows it to run for one time step, and then pauses it again. The scope window then updates with the latest data.
⏹	**Simulation** > **Stop**	**Ctrl+T**, **s**	Stop the model simulation. This button appears only when the model simulation is running or paused.
📷	**Simulation** > **Simulink Snapshot**	N/A	Take a snapshot of the current scope display. This button temporarily freezes the scope display, while allowing simulation to continue running. To unfreeze the scope display and view the current simulation data, toggle this button to turn off snapshot mode.
	View > **Highlight Simulink Block**	**Ctrl+L**	Bring the model window forward, and highlight the scope block whose display you are currently viewing. The scope block that corresponds to the active scope window flashes three times in the model.

You can control whether this toolbar appears in the scope window. From the scope menu, select **View** > **Simulation Toolbar**.

To see a full listing of the shortcut keys for these simulation controls, from the scope menu, select **Help** > **Keyboard Command Help**.

Spectrum Settings

The **Spectrum Settings** panel appears at the right side of the Spectrum Analyzer figure. This panel enables you to modify settings to control the manner in which the spectrum is calculated. You can choose to hide or display the **Spectrum Settings** panel. In the Spectrum Analyzer menu, select **View** > **Spectrum Settings**. Alternatively, in the Spectrum Analyzer toolbar, select the Spectrum Settings button.

▶ Window options

▶ Trace options

The **Spectrum Settings** panel is separated into three panes, labeled **Main Options**, **Window Options**, and **Trace Options**. You can expand each pane to see the available options.

Main Options Pane

The **Main Options** pane enables you to modify the main options.

- **Type** — The type of spectrum to display. Available options are `Power`, `Power density`, and `Spectrogram`. When you set this parameter to `Power`, the Spectrum Analyzer shows the power spectrum. When you set this parameter to `Power` `density`, the Spectrum Analyzer shows the power spectral density. The power spectral density is the magnitude of the spectrum normalized to a bandwidth of 1 hertz. When you set this parameter to `Spectrogram`, the Spectrum Analyzer shows the spectrogram, which displays frequency content over time. The most recent spectrogram update is at the bottom of the display and time scrolls from the bottom to the top of the display.“Tunable”

- **Channel** — Select the signal channel for which the spectrogram settings apply. This option displays only when the **Type** is `Spectrogram` and only if there is more than one signal channel input.

  Sample rate (Hz) — The sample rate, in hertz, of the input signals.

  Note: The Spectrum Analyzer block always sets this parameter to `Inherited`. The sample rate is always the same as the input signal, and cannot be modified directly.

- **Full frequency span** — Enable this check box to have Spectrum Analyzer compute and plot the spectrum over the entire *Nyquist* frequency interval. By default, when the **Two-sided spectrum** check box is also enabled, the Nyquist interval is $\left[-\frac{SampleRate}{2},\frac{SampleRate}{2}\right]+FrequencyOffset$ hertz. If you clear the **Two-sided spectrum** check box, the Nyquist interval is $\left[0,\frac{SampleRate}{2}\right]+FrequencyOffset$ hertz. “Tunable”.
- **Span (Hz)** and **CF (Hz)**, or **FStart (Hz)** and **FStop (Hz)** — When **Span (Hz)** is showing in the **Main Options** pane, you define the range of values shown on the *frequency*-axis on the Spectrum Analyzer window using frequency span and center frequency. From the drop-down list, select **FStart (Hz)** to define the range of *frequency*-axis values using start frequency and stop frequency instead.

  - **Span (Hz)** — The frequency span, in hertz. This parameter defines the range of values shown on the *frequency*-axis on the Spectrum Analyzer window. “Tunable”.
  - **CF (Hz)** — The center frequency, in hertz. This parameter defines the value shown at the middle point of the *frequency*-axis on the Spectrum Analyzer window. “Tunable”.
  - **FStart (Hz)** — The start frequency, in hertz. This parameter defines the value shown at the leftmost side of the *frequency*-axis on the Spectrum Analyzer window. “Tunable”.

- **FStop (Hz)** — The stop frequency, in hertz. The parameter defines the value shown at the rightmost side of the *frequency*-axis on the Spectrum Analyzer window. “Tunable”.

- **RBW (Hz) / Window length** — The frequency resolution method.

  If set to **RBW (Hz)**, the resolution bandwidth, in hertz. This property defines the smallest positive frequency that can be resolved. By default, this property is set to `Auto`. In this case, the Spectrum Analyzer determines the appropriate value to ensure that there are 1024 *RBW* intervals over the specified **Frequency Span**.

  If you set this property to a numeric value, then you must specify a value that ensures there are at least two *RBW* intervals over the specified frequency span. In other words, the ratio of the overall frequency span to *RBW* must be at least two: $\frac{span}{RBW} > 2$.

  “Tunable”.

  If set to **Window length**, the length of the window, in samples, used to control the frequency resolution and compute the spectral estimates. The window length must be an integer scalar greater than 2.

  . “Tunable”.

  The time resolution value is determined based on frequency resolution method, the RBW setting, and the time resolution setting.

Frequency Resolution	RBW Setting	Time Resolution Setting	Time Resolution
`'RBW'`	`'Auto'`	`'Auto'`	1/RBW s
`'RBW'`	`'Auto'`	Manually entered	Time Resolution s
`'RBW'`	Manually entered	`'Auto'`	1/RBW s
`'RBW'`	Manually entered	Manually entered	Must be equal to or greater than the minimum attainable time resolution, 1/RBW s. Several spectral estimates are combined into one spectrogram line to obtain the desired time

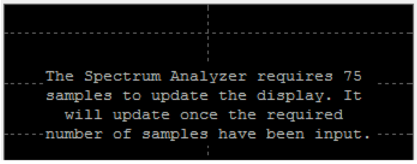
Frequency Resolution	RBW Setting	Time Resolution Setting	Time Resolution
			resolution. Interpolation is used to obtain time resolution values that are not integer multiples of 1/RBW s.
`'Window Length'`	—	`'Auto'`	1/RBW s RBW = *(NENBW**Fs)/Window Length, where *NENBW* is the normalized effective noise bandwidth of the specified window.
`'Window Length'`	—	Manually entered	Must be equal to or greater than the minimum attainable time resolution, *(NENBW**Fs)/ Window Length. Several spectral estimates are combined into one spectrogram line to obtain the desired time resolution. Interpolation is used to obtain time resolution values that are not integer multiples of 1/RBW s.

- **NFFT** — The number of Fast Fourier Transform (FFT) points. You can set the **NFFT** only when in Window length mode. This property defines the length of the FFT that Spectrum Analyzer uses to compute spectral estimates. Acceptable options are `Auto` or a positive, scalar integer. The **NFFT** value must be greater than or equal to the **Window length**. By default, when **NFFT** is set to `Auto`, Spectrum Analyzer sets the number of FFT points to the window length. When in RBW mode, an FFT length is used that equals the window length required to achieve the specified RBW value.

  When this property is set to a positive integer, this property is equivalent to the `n` parameter that you can set when you run the MATLAB `fft` function. “Tunable”.

- **Time res. (s)** — The time resolution, in seconds. Time resolution is the amount of data, in seconds, used to compute a spectrogram line. The minimum attainable resolution is the amount of data time it takes to compute a single spectral estimate. The tooltip displays the minimum attainable resolution given the current settings. This property applies only to spectrograms. “Tunable”

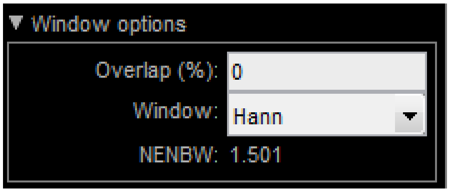
- **Time span (s)** — The time span over which the Spectrum Analyzer displays the spectrogram, in seconds. The time span is the product of the desired number of spectral lines and the time resolution. The tooltip displays the minimum allowable time span, given the current settings. If the time span is set to `Auto`, 100 spectral lines are used. This property applies only to spectrograms.“Tunable”
- **Samples/update** — The number of input samples required to compute one spectral update. You cannot modify this property; it is shown here for display purposes only. This property is directly related to *RBW* by the following equation: $N_{samples} = \frac{\left(1-\frac{O_p}{100}\right)\times NENBW \times F_s}{RBW}$ or to the window length by this equation: $N_{samples} = \left(1-\frac{O_p}{100}\right) x\ WindowLength$. *NENBW* is the normalized effective noise bandwidth, a factor of the windowing method used, which is shown in the **Window Options** pane. F_s is the sample rate. If the number of samples provided in the input are not sufficient to achieve the resolution bandwidth that you specify, Spectrum Analyzer produces a message on the display as shown in the following figure.



The Spectrum Analyzer requires 75 samples to update the display. It will update once the required number of samples have been input.

Window Options Pane

The **Window Options** pane enables you to modify the window options.



▼ Window options

Overlap (%): 0

Window: Hann

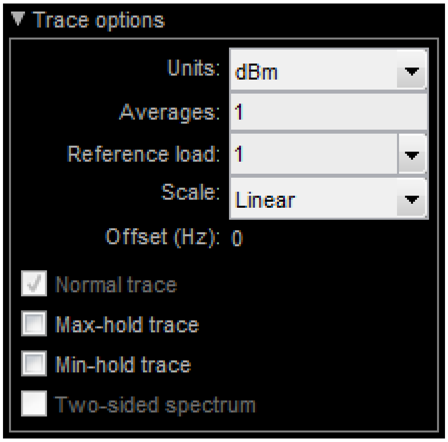
NENBW: 1.501

- **Overlap (%)** — The segment overlap percentage. This parameter defines the amount of overlap between the previous and current buffered data segments. The overlap creates a window segment that is used to compute a spectral estimate. The value must be greater than or equal to zero and less than 100. “Tunable”.

- **Window** — The windowing method to apply to the spectrum. Windowing is used to control the effect of sidelobes in spectral estimation. The window you specify affects the window length required to achieve a resolution bandwidth and the required number of samples per update. For more information about windowing, see “Windows” in the Signal Processing Toolbox documentation. “Tunable”.
- **Attenuation (dB)** — The sidelobe attenuation, in decibels (dB). This property applies only when you set the **Window** parameter to `Chebyshev` or `Kaiser`. You must specify a value greater than or equal to `45`. “Tunable”.
- **NENBW** — Normalized Effective Noise Bandwidth of the window. You cannot modify this parameter; it is a readout shown here for display purposes only. This parameter is a measure of the noise performance of the window. It is the width of a rectangular filter that accumulates the same noise power with the same peak power gain. NENBW can be calculated from the windowing function using the following equation: $NENBW = N_{window} \frac{\sum_{n=1}^{N_{window}} w^2(n)}{\left[\sum_{n=1}^{N_{window}} w(n)\right]^2}$. The rectangular window has the smallest NENBW, with a value of 1. All other windows have a larger NENBW value. For example, the Hann window has an NENBW value of approximately 1.5.

Trace Options Pane

The **Trace Options** pane enables you to modify the trace options.



▼ Trace options

Units: dBm

Averages: 1

Reference load: 1

Scale: Linear

Offset (Hz): 0

☑ Normal trace

□ Max-hold trace

□ Min-hold trace

□ Two-sided spectrum

- **Units** — The units of the spectrum. Available options are `dBm`, `dBW`, and `Watts`. "Tunable".
- **Averages** — Specify as a positive, scalar integer the number of spectral averages. This property applies only when the Spectrum **Type** is `Power` or `Power density`. Spectrum Analyzer computes the current power spectrum estimate by computing a running average of the last *N* power spectrum estimates. This property defines the number of spectral averages, *N*. "Tunable".
- **Reference load** — The reference load, in ohms, used to scale the spectrum. Specify as a real, positive scalar the load, in ohms, that the Spectrum Analyzer uses as a reference to compute power values. "Tunable".
- **Scale** — Linear or logarithmic scale. This property applies only when the Spectrum **Type** is `Power` or `Power density`. When the frequency span contains negative frequency values, Spectrum Analyzer disables the logarithmic option. "Tunable".
- **Offset** — The constant frequency offset to apply to the entire spectrum. This constant offset parameter is simply added to the values on the *frequency*-axis in the Spectrum Analyzer window. It is not used in any spectral computations. You must take this parameter into consideration when you set the **Span (Hz)** and **CF (Hz)** parameters to ensure that the frequency span is within Nyquist limits. The Nyquist interval is $\left[-\frac{SampleRate}{2},\frac{SampleRate}{2}\right]+FrequencyOffset$ hertz if **Two-sided spectrum** is selected, and $\left[0,\frac{SampleRate}{2}\right]+FrequencyOffset$ hertz otherwise.

- **Normal trace** — Normal trace view. This property applies only when the Spectrum **Type** is `Power` or `Power density`. By default, when this check box is enabled, Spectrum Analyzer calculates and plots the power spectrum or power spectrum density. Spectrum Analyzer performs a smoothing operation by averaging a number of spectral estimates. To clear this check box, you must first select either the **Max hold trace** or the **Min hold trace** check box. “Tunable”.
- **Max hold trace** — Maximum hold trace view. This property applies only when the Spectrum **Type** is `Power` or `Power density`. Select this check box to enable Spectrum Analyzer to plot the maximum spectral values of all the estimates obtained. “Tunable”.
- **Min hold trace** — Minimum hold trace view. This property applies only when the Spectrum **Type** is `Power` or `Power density`. Select this check box to enable Spectrum Analyzer to plot the minimum spectral values of all the estimates obtained. “Tunable”.
- **Two-sided spectrum** — Select this check box to enable two-sided spectrum view. In this view, both negative and positive frequencies are shown. If you clear this check box, Spectrum Analyzer shows a one-sided spectrum with only positive frequencies. Spectrum Analyzer requires that this parameter is selected when the input signal is complex-valued.

Measurements Panels

The Measurements panels are the other four panels that appear to the right side of the Spectrum Analyzer figure. These panels are labeled **Trace selection**, **Cursor Measurements**, **Peak Finder**, **Channel Measurements**, **Distortion Measurements**, and **CCDF Measurements**.

Measurements Panel Buttons

Each of the Measurements panels contains the following buttons that enable you to modify the appearance of the current panel.

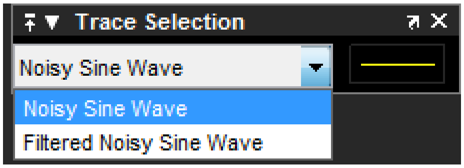
Button	Description
⤒	Move the current panel to the top. When you are displaying more than one panel, this action moves the current panel above all the other panels.

Button	Description
▼	Collapse the current panel. When you first enable a panel, by default, it displays one or more of its panes. Click this button to hide all of its panes to conserve space. After you click this button, it becomes the expand button ▶.
▶	Expand the current panel. This button appears after you click the collapse button to hide the panes in the current panel. Click this button to display the panes in the current panel and show measurements again. After you click this button, it becomes the collapse button ▼ again.
↗	Undock the current panel. This button lets you move the current panel into a separate window that can be relocated anywhere on your screen. After you click this button, it becomes the dock button ↘ in the new window.
↘	Dock the current panel. This button appears only after you click the undock button. Click this button to put the current panel back into the right side of the Scope window. After you click this button, it becomes the undock button ↗ again.
✕	Close the current panel. This button lets you remove the current panel from the right side of the Scope window.

Some panels have their measurements separated by category into a number of panes. Click the pane expand button ▶ to show each pane that is hidden in the current panel. Click the pane collapse button ▼ to hide each pane that is shown in the current panel.

Trace Selection Panel

When you use the scope to view multiple signals, the Trace Selection panel appears if you have more than one signal displayed and you click on any of the other Measurements panels. The Measurements panels display information about only the signal chosen in this panel. Choose the signal name for which you would like to display time domain measurements. See the following figure.



You can choose to hide or display the **Trace Selection** panel. In the Scope menu, select **Tools** > **Measurements** > **Trace Selection**.

Cursor Measurements Panel

The **Cursor Measurements** panel displays screen cursors. You can choose to hide or display the **Cursor Measurements** panel. In the Scope menu, select **Tools** > **Measurements** > **Cursor Measurements**. Alternatively, in the Scope toolbar, click the Cursor Measurements button.

The **Cursor Measurements** panel appears as follows for power and power density spectra.

	Freq. (kHz)	Power (dBm)
1	29.125	-31.098
2	87.375	-32.501
Δ	58.250	1.402 dB

Channel Power: 27.000 dBm

The **Cursor Measurements** panel appears as follows for spectrograms.

Note: You must pause the spectrogram display before you can use cursors.

	Freq. (kHz)	Time (s)	Pwr. (dBm)
1	29.125	0.074	-35.383
2	87.375	0.223	-32.001
Δ	58.250	148.712 m	3.383

The **Cursor Measurements** panel is separated into two panes, labeled **Settings** and **Measurements**. You can expand each pane to see the available options.

You can use the mouse or the left and right arrow keys to move vertical or waveform cursors and the up and down arrow keys for horizontal cursors.

Settings Pane

The **Settings** pane enables you to modify the type of screen cursors used for calculating measurements. When more than one signal is displayed, you can assign cursors to each trace individually.

- **Screen Cursors** — Shows screen cursors (for power and power density spectra only).
- **Horizontal** — Shows horizontal screen cursors (for power and power density spectra only).
- **Vertical** — Shows vertical screen cursors (for power and power density spectra only).
- **Waveform Cursors** — Shows cursors that attach to the input signals (for power and power density spectra only).
- **Lock Cursor Spacing** — Locks the frequency difference between the two cursors.
- **Snap to Data** — Positions the cursors on signal data points.

Measurements Pane

The **Measurements** pane displays the frequency (Hz), time (s), and power (dBm) value measurements. Time is displayed only in spectrogram mode. **Channel Power** shows the total power between the cursors.

- **1 |** — Shows or enables you to modify the frequency or time (for spectrograms only), or both, at cursor number one.
- **2 :** — Shows or enables you to modify the frequency or time (for spectrograms only), or both, at cursor number two.
- **Δ** — Shows the absolute value of the difference in the frequency, time (for spectrograms only), and power between cursor number one and cursor number two.
- **Channel Power** — Shows the total power in the channel defined by the cursors.

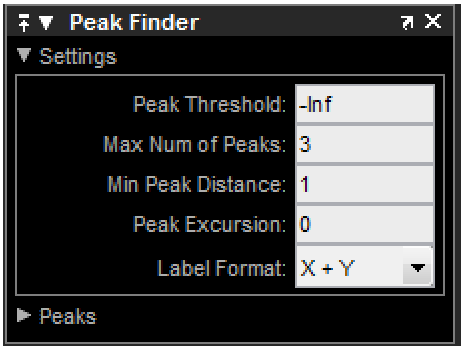
The letter after the value associated with a measurement indicates the abbreviation for the appropriate International System of Units (SI) prefix, such as *m* for *milli-*.

Abbreviation	Name	Multiplier
a	atto	10^–18
f	femto	10^–15
p	pico	10^–12
n	nano	10^–9
μ	micro	10^–6
m	milli	10^–3
		10^0
k	kilo	10^3
M	mega	10^6
G	giga	10^9
T	tera	10^12
P	peta	10^15
E	exa	10^18

Peak Finder Panel

The **Peak Finder** panel displays the maxima, showing the *x*-axis values at which they occur. This panel allows you to modify the settings for peak threshold, maximum number of peaks, and peak excursion. You can choose to hide or display the **Peak Finder** panel.

In the scope menu, select **Tools** > **Measurements** > **Peak Finder**. Alternatively, in the scope toolbar, select the Peak Finder button.



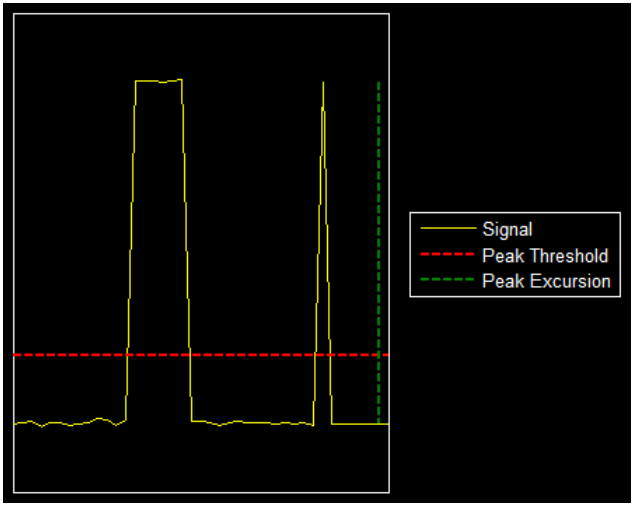
Peak Threshold: -Inf
Max Num of Peaks: 3
Min Peak Distance: 1
Peak Excursion: 0
Label Format: X + Y

The **Peak finder** panel is separated into two panes, labeled **Settings** and **Peaks**. You can expand each pane to see the available options.

Settings Pane

The **Settings** pane enables you to modify the parameters used to calculate the peak values within the displayed portion of the input signal. For more information on the algorithms this pane uses, see the Signal Processing Toolbox `findpeaks` function reference.

- **Peak Threshold** — The level above which peaks are detected. This setting is equivalent to the `MINPEAKHEIGHT` parameter, which you can set when you run the `findpeaks` function.
- **Max Num of Peaks** — The maximum number of peaks to show. The value you enter must be a scalar integer between 1 and 99. This setting is equivalent to the `NPEAKS` parameter, which you can set when you run the `findpeaks` function.
- **Min Peaks Distance** — The minimum number of samples between adjacent peaks. This setting is equivalent to the `MINPEAKDISTANCE` parameter, which you can set when you run the `findpeaks` function.
- **Peak Excursion** — The minimum height difference between a peak and its neighboring samples. Peak excursion is illustrated alongside peak threshold in the following figure.



The *peak threshold* is a minimum value necessary for a sample value to be a peak. The *peak excursion* is the minimum difference between a peak sample and the samples to its left and right in the time domain. In the figure, the green vertical line illustrates the lesser of the two height differences between the labeled peak and its neighboring samples. This height difference must be greater than the **Peak Excursion** value for the labeled peak to be classified as a peak. Compare this setting to peak threshold, which is illustrated by the red horizontal line. The amplitude must be above this horizontal line for the labeled peak to be classified as a peak.

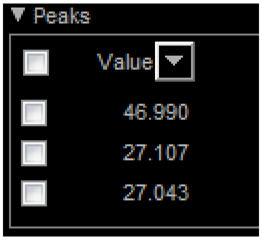
The peak excursion setting is equivalent to the `THRESHOLD` parameter, which you can set when you run the `findpeaks` function.

- **Label Format** — The coordinates to display next to the calculated peak values on the plot. To see peak values, you must first expand the **Peaks** pane and select the check boxes associated with individual peaks of interest. By default, both *x*-axis and *y*-axis values are displayed on the plot. Select which axes values you want to display next to each peak symbol on the display.

  - `X+Y` — Display both *x*-axis and *y*-axis values.
  - `X` — Display only *x*-axis values.
  - `Y` — Display only *y*-axis values.

Peaks Pane

The **Peaks** pane displays all of the largest calculated peak values. It also shows the coordinates at which the peaks occur, using the parameters you define in the **Settings** pane. You set the **Max Num of Peaks** parameter to specify the number of peaks shown in the list.



▼ Peaks

□	Value ▼
□	46.990
□	27.107
□	27.043

The numerical values displayed in the **Value** column are equivalent to the `pks` output argument returned when you run the `findpeaks` function. The numerical values displayed in the second column are similar to the `locs` output argument returned when you run the `findpeaks` function.

The Peak Finder displays the peak values in the **Peaks** pane. By default, the **Peak Finder** panel displays the largest calculated peak values in the **Peaks** pane in decreasing order of peak height. Use the sort descending button (▼) to rearrange the category and order by which Peak Finder displays peak values. Click this button again to sort the peaks in ascending order instead. When you do so, the arrow changes direction to become the sort ascending button (▲). A filled sort button indicates that the peak values are currently sorted in the direction of the button arrow. If the sort button is not filled (▽), then the peak values are sorted in the opposite direction of the button arrow. The **Max Num of Peaks** parameter still controls the number of peaks listed.

Use the check boxes to control which peak values are shown on the display. By default, all check boxes are cleared and the **Peak Finder** panel hides all the peak values. To show all the peak values on the display, select the check box in the top-left corner of the **Peaks** pane. To hide all the peak values on the display, clear this check box. To show an individual peak, select the check box directly to the left of its **Value** listing. To hide an individual peak, clear the check box directly to the left of its **Value** listing.

The Peaks are valid for any units of the input signal. The letter after the value associated with each measurement indicates the abbreviation for the appropriate International

System of Units (SI) prefix, such as *m* for *milli-*. For example, if the input signal is measured in volts, an *m* next to a measurement value indicates that this value is in units of millivolts.

Abbreviation	Name	Multiplier
a	atto	10^–18
f	femto	10^–15
p	pico	10^–12
n	nano	10^–9
u	micro	10^–6
m	milli	10^–3
		10^0
k	kilo	10^3
M	mega	10^6
G	giga	10^9
T	tera	10^12
P	peta	10^15
E	exa	10^18

Channel Measurements Panel

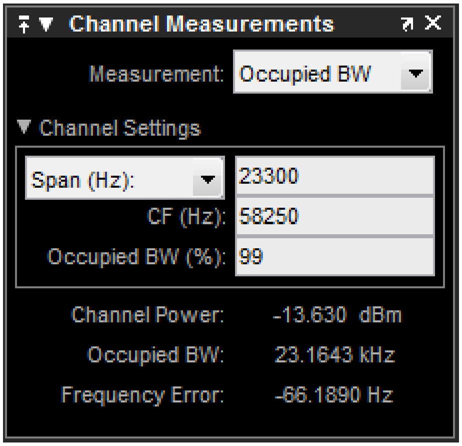
The **Channel Measurements** panel displays occupied bandwidth or adjacent channel power ratio (ACPR) measurements. You can choose to hide or display this pane in the Scope menu by selecting **Tools** > **Measurements** > **Channel Measurements**.

Alternatively, in the Scope toolbar, click the Cursor Measurements button.

In addition to the measurements, the **Channel Measurements** panel has an expandable **Channel Settings** pane.

- **Measurement** — The type of measurement data to display. Available options are `Occupied BW` or `ACPR`. See "Algorithms" on page 1-1333 for information on how Occupied BW is calculated. ACPR is the adjacent channel power ratio, which is the ratio of the main channel power to the adjacent channel power.

When you select `Occupied BW` as the **Measurement**, the following fields appear.



Channel Measurements

Measurement: Occupied BW

Channel Settings

Span (Hz): 23300

CF (Hz): 58250

Occupied BW (%): 99

Channel Power: -13.630 dBm

Occupied BW: 23.1643 kHz

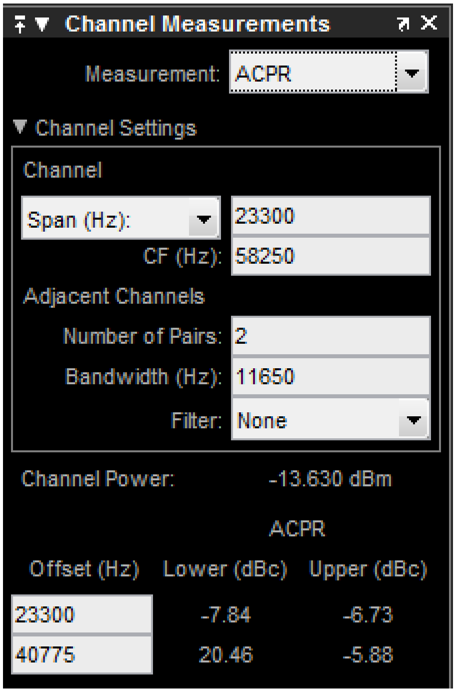
Frequency Error: -66.1890 Hz

- **Channel Settings** — Enables you to modify the parameters for calculating the channel measurements.

Channel Settings for Occupied BW

  - Select the frequency span of the channel, `Span(Hz)`, and specify the center frequency **CF (Hz)** of the channel. Alternatively, select the starting frequency, `FStart(Hz)`, and specify the starting frequency and ending frequency (**FStop (Hz)**) values of the channel.
  - **CF (Hz)** — The center frequency of the channel.
  - **Occupied BW (%)** — The percentage of the total integrated power of the spectrum centered on the selected channel frequency over which to compute the occupied bandwidth.
- **Channel Power** — The total power in the channel.
- **Occupied BW** — The bandwidth containing the specified **Occupied BW (%)** of the total power of the spectrum. This setting is available only if you select `Occupied BW` as the **Measurement** type.
- **Frequency Error** — The difference between the center of the occupied band and the center frequency (**CF**) of the channel. This setting is available only if you select `Occupied BW` as the **Measurement** type.

When you select ACPR as the **Measurement**, the following fields appear.



Channel Measurements

Measurement: ACPR

▼ Channel Settings

Channel

Span (Hz): 23300

CF (Hz): 58250

Adjacent Channels

Number of Pairs: 2

Bandwidth (Hz): 11650

Filter: None

Channel Power: -13.630 dBm

	ACPR	
Offset (Hz)	Lower (dBc)	Upper (dBc)
23300	-7.84	-6.73
40775	20.46	-5.88

- **Channel Settings** — Enables you to modify the parameters for calculating the channel measurements.

Channel Settings for ACPR

- Select the frequency span of the channel, `Span (Hz)`, and specify the center frequency **CF (Hz)** of the channel. Alternatively, select the starting frequency, `FStart(Hz)`, and specify the starting frequency and ending frequency (**FStop (Hz)**) values of the channel.
- **CF (Hz)** — The center frequency of the channel.
- **Number of Pairs** — The number of pairs of adjacent channels.
- **Bandwidth (Hz)** — The bandwidth of the adjacent channels.
- **Filter** — The filter to use for both main and adjacent channels. Available filters are `None`, `Gaussian`, and `RRC` (root-raised cosine).

- **Channel Power** — The total power in the channel.
- **Offset (Hz)** — The center frequency of the adjacent channel with respect to the center frequency of the main channel. This setting is available only if you select `ACPR` as the **Measurement** type.
- **Lower (dBc)** — The power ratio of the lower sideband to the main channel. This setting is available only if you select `ACPR` as the **Measurement** type.
- **Upper (dBc)** — The power ratio of the upper sideband to the main channel. This setting is available only if you select `ACPR` as the **Measurement** type.

Distortion Measurements Panel

The **Distortion Measurements** panel displays harmonic distortion and intermodulation distortion measurements. You can choose to hide or display this panel in the Scope menu by selecting **Tools** > **Measurements** > **Distortion Measurements**. Alternatively, in the Scope toolbar, click the Distortion Measurements button.

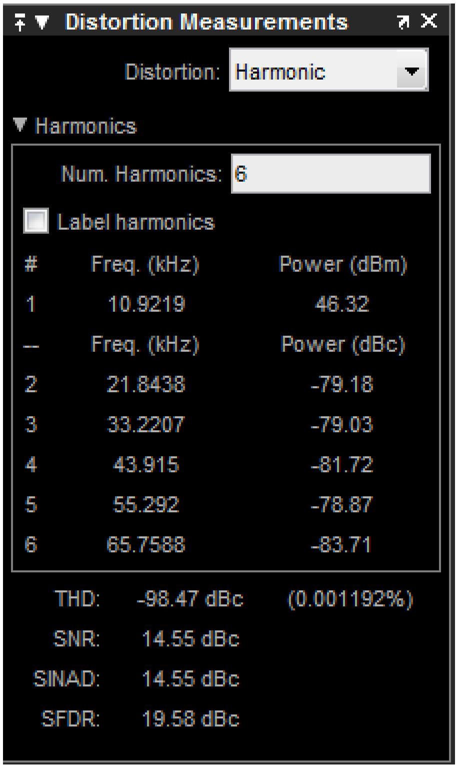
The **Distortion Measurements** panel has an expandable **Harmonics** pane, which shows measurement results for the specified number of harmonics.

Note: For an accurate measurement, ensure that the fundamental signal (for harmonics) or primary tones (for intermodulation) is larger than any spurious or harmonic content. To do so, you may need to adjust the resolution bandwidth (`RBW`) of the spectrum analyzer. Make sure that the bandwidth is low enough to isolate the signal and harmonics from spurious and noise content. In general, you should set the RBW so that there is at least a 10dB separation between the peaks of the sinusoids and the noise floor. You may also need to select a different spectral window to obtain a valid measurement.

- **Distortion** — The type of distortion measurements to display. Available options are `Harmonic` or `Intermodulation`. Select `Harmonic` if your system input is a single sinusoid. Select `Intermodulation` if your system input is two equal amplitude sinusoids. Intermodulation can help you determine distortion when only a small portion of the available bandwidth will be used.

  See “Algorithms” on page 1-1333 for information on how distortion measurements are calculated.

When you select `Harmonic` as the **Distortion**, the following fields appear.



Distortion Measurements

Distortion: Harmonic

▼ Harmonics

Num. Harmonics: 6

□ Label harmonics

#	Freq. (kHz)	Power (dBm)
1	10.9219	46.32
--	Freq. (kHz)	Power (dBc)
2	21.8438	-79.18
3	33.2207	-79.03
4	43.915	-81.72
5	55.292	-78.87
6	65.7588	-83.71

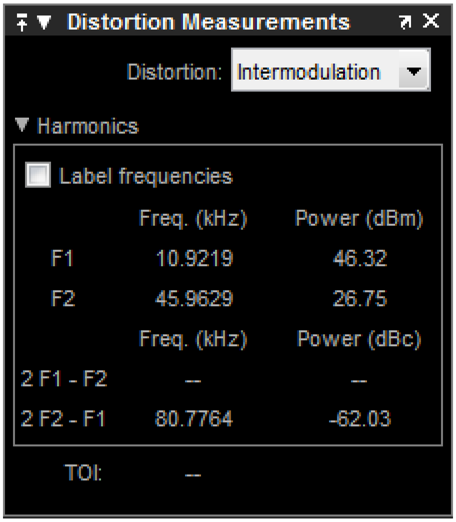
THD:	-98.47 dBc	(0.001192%)
SNR:	14.55 dBc	
SINAD:	14.55 dBc	
SFDR:	19.58 dBc	

The harmonic distortion measurement automatically locates the largest sinusoidal component (fundamental signal frequency). It then computes the harmonic frequencies and power in each harmonic in your signal. Any DC component is ignored. Any harmonics that are outside the spectrum analyzer's frequency span are not included in the measurements. Adjust your frequency span so that it includes all the desired harmonics.

Note: To best view the harmonics, make sure that your fundamental frequency is set high enough to resolve the harmonics. However, this frequency should not be so high that aliasing occurs. For the best display of harmonic distortion, your plot should not show skirts, which indicate frequency leakage. Additionally, the noise floor should be visible. Using a Kaiser window with a large sidelobe attenuation may help to reduce the skirts.

- **Num. Harmonics** — Number of harmonics to display, including the fundamental frequency. Valid values of **Num. Harmonics** are from `2` to `10`. The default value is `6`.
- **Label Harmonics** — Select **Label Harmonics** to add numerical labels to each harmonic in the spectrum display.
- **1** — The fundamental frequency, in hertz, and its power, in decibels of the measured power referenced to one milliwatt (dBm).
- **2, 3, ...** — The harmonics frequencies, in hertz, and their power in decibels relative to the carrier (dBc). If the harmonics are at the same level or exceed the fundamental frequency, reduce the input power.
- **THD** — The total harmonic distortion. This value represents the ratio of the power in the harmonics, D, to the power in the fundamental frequency, S. If the noise power is too high in relation to the harmonics, the THD value is not accurate. In this case, lower the resolution bandwidth or select a different spectral window. $THD = 10\log_{10}(D/S)$.
- **SNR** — Signal-to-noise ratio (SNR). This value represents the ratio of power in the fundamental frequency, S, to the power of all nonharmonic content, N, including spurious signals, in decibels relative to the carrier (dBc). $SNR = 10\log_{10}(S/N)$. If you see – – as the reported SNR, your signal's total non-harmonic content is less than 30% of the total signal.
- **SINAD** — Signal-to-noise-and-distortion. This value represents the ratio of the power in the fundamental frequency, S to all other content (including noise, N, and harmonic distortion, D), in decibels relative to the carrier (dBc). $SINAD = 10\log_{10}(S/(N+D)$.
- **SFDR** — Spurious free dynamic range (SFDR). This value represents the ratio of the power in the fundamental frequency, S, to power of the largest spurious signal, R, regardless of where it falls in the frequency spectrum. The worst spurious signal may or may not be a harmonic of the original signal. SFDR represents the smallest value of a signal that can be distinguished from a large interfering signal. SFDR includes harmonics. $SFDR = 10\log_{10}(S/R)$.

When you select `Intermodulation` as the **Distortion**, the following fields appear.



Distortion Measurements

Distortion: Intermodulation

Harmonics

□ Label frequencies

	Freq. (kHz)	Power (dBm)
F1	10.9219	46.32
F2	45.9629	26.75
	Freq. (kHz)	Power (dBc)
2 F1 - F2	--	--
2 F2 - F1	80.7764	-62.03

TOI: --

The intermodulation distortion measurement automatically locates the fundamental, first-order frequencies (F1 and F2). It then computes the frequencies of the third-order intermodulation products (2*F1-F2 and 2*F2-F1).

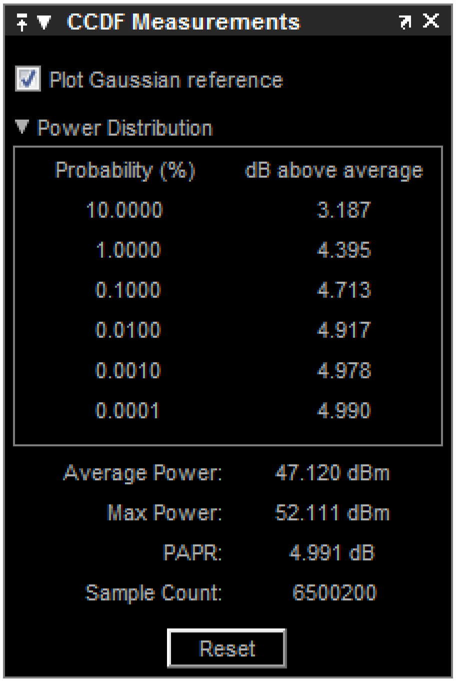
- **Label frequencies** — Select **Label frequencies** to add numerical labels to the first-order intermodulation product and third-order frequencies in the spectrum analyzer display.
- **F1** — Lower fundamental first-order frequency
- **F2** — Upper fundamental first-order frequency
- **2F1 - F2** — Lower intermodulation product from third-order harmonics
- **2F2 - F1** — Upper intermodulation product from third-order harmonics
- **TOI** — Third-order intercept point. If the noise power is too high in relation to the harmonics, the TOI value will not be accurate. In this case, you should lower the resolution bandwidth or select a different spectral window. If the TOI has the same amplitude as the input two-tone signal, reduce the power of that input signal.

CCDF Measurements Panel

The **CCDF Measurements** panel displays complimentary cumulative distribution function measurements. CCDF measurements in this scope show the probability of a signal’s instantaneous power being a specified level above the signal’s average power. These measurements are useful indicators of a signal’s dynamic range.

To compute the CCDF measurements, each input sample is quantized to 0.01 dB increments. Using a histogram 100 dB wide (10,000 points at 0.01 dB increments), the largest peak encountered is placed in the last bin of the histogram. If a new peak is encountered, the histogram shifts to make room for that new peak.

You can choose to hide or display this panel in the Scope menu by selecting **Tools** > **Measurements** > **CCDF Measurements**. Alternatively, in the Scope toolbar, click the Distortion Measurements button.



CCDF Measurements

☑ Plot Gaussian reference

▼ Power Distribution

Probability (%)	dB above average
10.0000	3.187
1.0000	4.395
0.1000	4.713
0.0100	4.917
0.0010	4.978
0.0001	4.990

Average Power:	47.120 dBm
Max Power:	52.111 dBm
PAPR:	4.991 dB
Sample Count:	6500200

- **Plot Gaussian reference** — Select **Plot Gaussian reference** to show the Gaussian white noise reference signal on the plot.
- **Probability (%)** — The percentage of the signal that contains the power level above the value listed in the **dB above average** column
- **dB above average** — The expected minimum power level at the associated **Probability (%)**.

- **Average Power** — The average power level of the signal since the start of simulation or from the last reset.

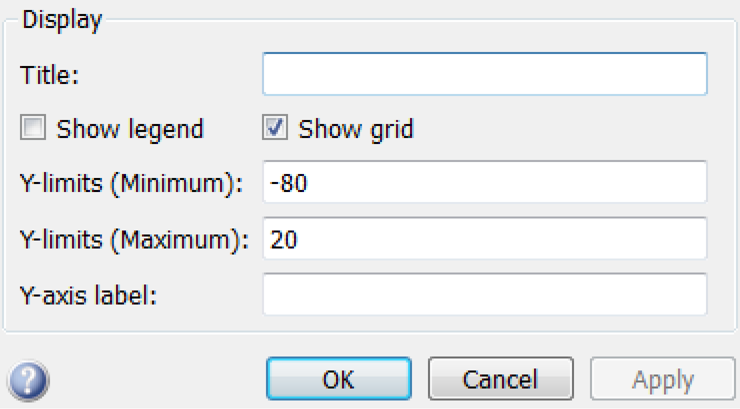
  Max Power — The maximum power level of the signal since the start of simulation or from the last reset.
- **PAPR** — The ratio of the peak power to the average power of the signal. PAPR should be less that 100 dB to obtain accurate CCDF measurements. If PAPR is above 100 dB, only the highest 100 dB power levels are plotted in the display and shown in the distribution table.
- **Sample Count** — The total number of samples used to compute the CCDF.
- **Reset** — Clear all current CCDF measurements and restart.

Visuals — Spectrum Properties

The Visuals—Spectrum Properties dialog box controls the visual configuration settings of the Spectrum Analyzer display. From the Spectrum Analyzer menu, select **View** > **Configuration Properties** to open this dialog box. Alternatively, in the Spectrum Analyzer toolbar, click the Configuration Properties ⚙ button.

Display Pane

When the Spectrum **Type** is `Power` or `Power density`, the **Display** pane of the Visuals—Spectrum Properties dialog box appears as follows:



Display

Title:

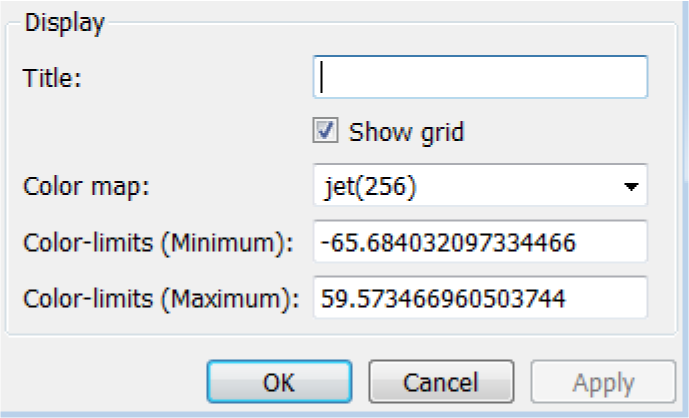
□ Show legend ☑ Show grid

Y-limits (Minimum): -80

Y-limits (Maximum): 20

Y-axis label:

When the Spectrum **Type** is `Spectrogram` the **Display** pane of the Visuals—Spectrum Properties dialog box appears as follows:



Display

Title:

☑ Show grid

Color map: jet(256)

Color-limits (Minimum): -65.684032097334466

Color-limits (Maximum): 59.573466960503744

Title

Specify the display title as a string. Enter `%<SignalLabel>` to use the signal labels in the Simulink Model as the axes titles. This property is “Tunable”.

By default, the display has no title.

Show legend

Select this check box to show the legend in the display. The channel legend displays a name for each channel of each input signal. When the legend appears, you can place it anywhere inside of the scope window. To turn the legend off, clear the **Show legend** check box. This parameter applies only when the Spectrum **Type** is `Power` or `Power density`. “Tunable”

You can edit the name of any channel in the legend. To do so, double-click the current name, and enter a new channel name. By default, if the signal has multiple channels, the scope uses an index number to identify each channel of that signal. To change the appearance of any channel of any input signal in the scope window, from the scope menu, select **View** > **Style**.

Show grid

When you select this check box, a grid appears in the display of the scope figure. To hide the grid, clear this check box. “Tunable”

Y-limits (Minimum)

Specify the minimum value of the *y*-axis. “Tunable”

Y-limits (Maximum)

Specify the maximum value of the *y*-axis. “Tunable”

Y-axis label

Specify the text for the scope to display to the left of the *y*-axis. Regardless of this property, Spectrum Analyzer always displays power units after this text as one of `'dBm'`, `'dBW'`, `'Watts'`, `'dBm/Hz'`, `'dBW/Hz'`, or `'Watts/Hz'`. “Tunable”.

Color map

Select the color map for the spectrogram, or enter a 3-column matrix expression for the color map. See `colormap` for information. “Tunable”.

Color-limits (Minimum)

Set the signal power for the minimum color value of the spectrogram. “Tunable”.

Color-limits (Maximum)

Set the signal power for the maximum color value of the spectrogram. “Tunable”.

Style Dialog Box

In the **Style** dialog box, you can customize the style of power and power density displays. This dialog box is not available in spectrogram view. You are able to change the color of the figure, the background and foreground colors of the axes, and properties of the lines. From the Spectrum Analyzer menu, select **View** > **Style** to open this dialog box.

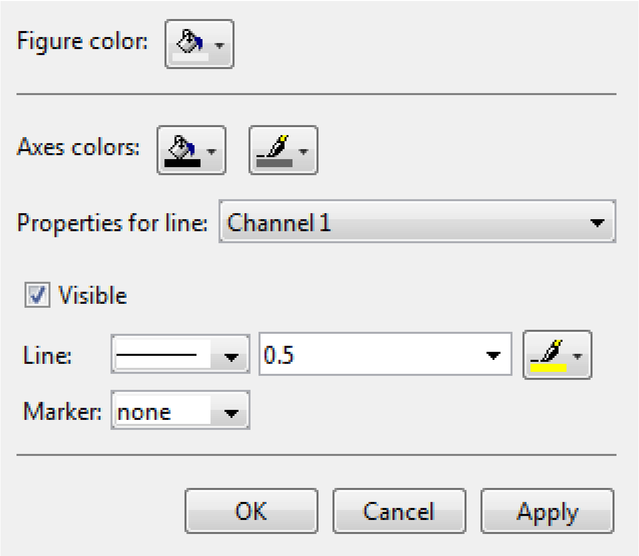


Figure color:

Axes colors:

Properties for line: Channel 1

☑ Visible

Line: 0.5

Marker: none

Properties

The **Style** dialog box allows you to modify the following properties of the Spectrum Analyzer figure:

Figure color

Specify the color that you want to apply to the background of the scope figure. By default, the figure color is gray.

Axes colors

Specify the color that you want to apply to the background of the axes.

Properties for line

Specify the channel for which you want to modify the visibility, line properties, and marker properties.

Visible

Specify whether the selected channel should be visible. If you clear this check box, the line disappears.

Line

Specify the line style, line width, and line color for the selected channel.

Marker

Specify marks for the selected channel to show at its data points. This parameter is similar to the `Marker` property for the MATLAB Handle Graphics® plot objects. You can choose any of the marker symbols from the following table.

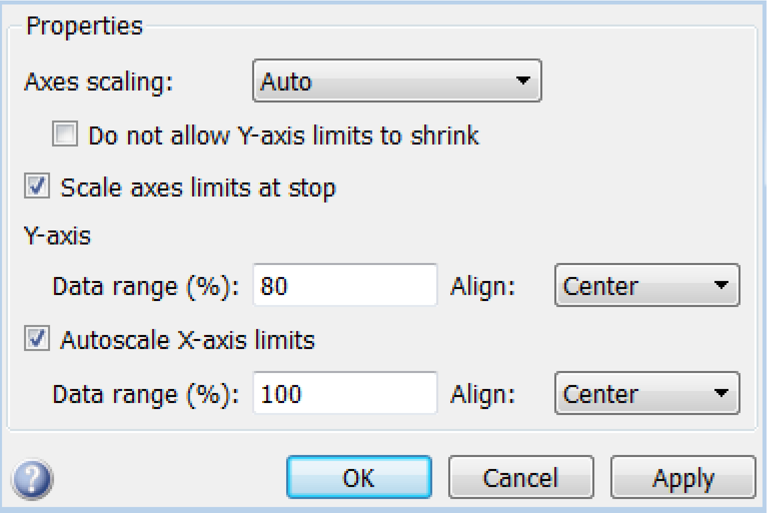
Specifier	Marker Type
none	No marker (default)
○	Circle
□	Square
×	Cross
•	Point
+	Plus sign
*	Asterisk
◇	Diamond
▽	Downward-pointing triangle
△	Upward-pointing triangle
◁	Left-pointing triangle
▷	Right-pointing triangle
☆	Five-pointed star (pentagram)
✡	Six-pointed star (hexagram)

Tools — Axes Scaling Properties

The Tools — Axes Scaling Properties dialog box allows you to automatically zoom in on and zoom out of your data. You can also scale the axes and color of the Spectrum Analyzer. In the Spectrum Analyzer menu, select **Tools** > **Scaling Properties** to open this dialog box.

Properties

The Tools—Axes Scaling Properties dialog box appears as follows for power and power density views.



Properties

Axes scaling: Auto

□ Do not allow Y-axis limits to shrink

☑ Scale axes limits at stop

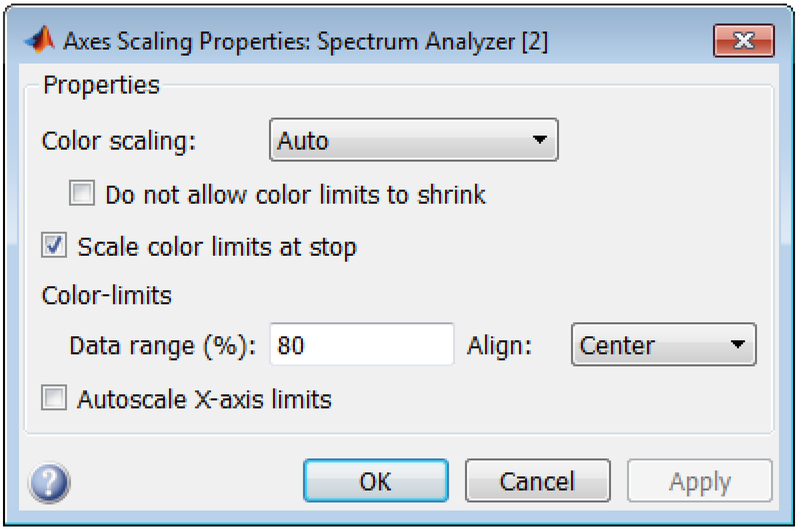
Y-axis

Data range (%): 80 Align: Center

☑ Autoscale X-axis limits

Data range (%): 100 Align: Center

For spectrogram view, the Tools—Axes Scaling Properties dialog box appears as follows.



Axes Scaling Properties: Spectrum Analyzer [2]

Properties

Color scaling: Auto

□ Do not allow color limits to shrink

☑ Scale color limits at stop

Color-limits

Data range (%): 80 Align: Center

□ Autoscale X-axis limits

Axes scaling/Color scaling

Specify when the scope should automatically scale the axes. If the spectrogram is displayed, specify when the scope should automatically scale the color. You can select one of the following options:

- `Manual` — When you select this option, the scope does not automatically scale the axes or color. You can manually scale the axes or color in any of the following ways:
  - Select **Tools** > **Scaling Properties**.
  - Press one of the **Scale Axis Limits** toolbar buttons.
  - When the scope figure is the active window, press **Ctrl** and **A** simultaneously.
- `Auto` — When you select this option, the scope scales the axes or color as needed, both during and after simulation. Selecting this option shows the **Do not allow Y-axis limits to shrink** or **Do not allow color limits to shrink** .
- `After N Updates` — Selecting this option causes the scope to scale the axes or color after a specified number of updates. Selecting this option shows the **Number of updates** edit box.

By default, this parameter is set to `Auto`, and the scope does not shrink the *y*-axis limits when scaling the axes or color. “Tunable”.

Do not allow Y-axis limits to shrink / Do not allow color limits to shrink

When you select this property, the *y*-axis are only allowed to grow during axes scaling operations. If the spectrogram is displayed, selecting this property allows the color limits to only grow during axis scaling. If you clear this check box, the *y*-axis or color limits may shrink during axes scaling operations.

This property appears only when you select `Auto` for the **Axis scaling** or **Color scaling** property. When you set the **Axes scaling** or **Color scaling** property to `Manual` or `After N Updates`, the *y*-axis or color limits are allowed to shrink. “Tunable”.

Number of updates

Specify as a positive integer the number of updates after which to scale the axes. If the spectrogram is displayed, this property specifies the number of updates after which to scale the color. This property appears only when you select `After N Updates` for the **Axes scaling** or **Color scaling** property. “Tunable”.

Scale axes limits at stop/Scale color limits at stop

Select this check box to scale the axes when the simulation stops. If the spectrogram is displayed, select this check box to scale the color when the simulation stops. The *y*-axis is always scaled. The *x*-axis limits are only scaled if you also select the **Scale X-axis limits** check box.

Y-axis Data range (%) / Color-limits Data range

Set the percentage of the *y*-axis that the scope should use to display the data when scaling the axes. If the spectrogram is displayed, set the percentage of the power values range within the color map. Valid values are between 1 and 100. For example, if you set this property to `100`, the Scope scales the *y*-axis limits such that your data uses the entire *y*-axis range. If you then set this property to `30`, the scope increases the *y*-axis range or color such that your data uses only 30% of the *y*-axis range or color. "Tunable".

Y-axis Align / Color-limits Align

Specify where the scope should align your data with respect to the *y*-axis when it scales the axes. If the spectrogram is displayed, specify where the scope should align your data with respect to the *y*-axis when it scales the color. You can select `Top`, `Center`, or `Bottom`. "Tunable".

Autoscale X-axis limits

Check this box to allow the scope to scale the *x*-axis limits when it scales the axes. If **Axes scaling** is set to `Auto`, checking **Scale X-axis limits** only scales the data currently within the axes, not the entire signal in the data buffer. "Tunable".

X-axis Data range (%)

Set the percentage of the *x*-axis that the Scope should use to display the data when scaling the axes. Valid values are between 1 and 100. For example, if you set this property to `100`, the Scope scales the *x*-axis limits such that your data uses the entire*x*-axis range. If you then set this property to `30`, the Scope increases the *x*-axis range such that your data uses only 30% of the *x*-axis range. Use the *x*-axis **Align** property to specify data placement with respect to the *x*-axis.

This property appears only when you select the **Scale X-axis limits** check box. "Tunable".

X-axis Align

Specify how the Scope should align your data with respect to the x-axis: `Left`, `Center`, or `Right`. This property appears only when you select the **Scale X-axis limits** check box. “Tunable”.

Algorithms

Spectrum Analyzer uses the `RBW` or the `Window Length` setting in the **Spectrum Settings** panel to determine the data window length. The value of the `FrequencyResolutionMethod` property determines whether RBW or window length is used. Then, it partitions the input signal into a number of windowed data segments. Finally, Spectrum Analyzer uses the modified periodogram method to compute spectral updates, averaging the windowed periodograms for each segment.

Spectral content is estimated by finding peaks in the spectrum. When the algorithm detects a peak, it ignores all adjacent content that decreases monotonically from the peak. After recording the width of the peak, it subsequently clears its content.

1. Spectrum Analyzer requires that a minimum number of samples have been provided before it computes a spectral estimate. This number of input samples required to compute one spectral update is shown as **Samples/update** in the **Main options** pane. This value is directly related to resolution bandwidth, *RBW*, by the following equation or to the window length, by the equation shown in step 1b.

$$N_{samples} = \frac{\left(1 - \frac{O_p}{100}\right) \times NENBW \times F_s}{RBW}$$

The normalized effective noise bandwidth, *NENBW*, is a factor that depends on the windowing method. Spectrum Analyzer shows NENBW in the **Window Options** pane of the **Spectrum Settings** panel. Overlap percentage, O_p, is the value of the **Overlap %** parameter in the **Window Options** pane of the **Spectrum Settings** panel. F_s is the sample rate of the input signal. Spectrum Analyzer shows sample rate in the **Main Options** pane of the **Spectrum Settings** panel.

   a. When in RBW mode, the window length required to compute one spectral update, N_{window}, is directly related to the resolution bandwidth and normalized effective noise bandwidth by the following equation.

$$N_{window} = \frac{NENBW \times F_s}{RBW}$$

When in WindowLength mode, the window length is used as specified.

b The number of input samples required to compute one spectral update, $N_{samples}$, is directly related to the window length and the amount of overlap by the following equation.

$$N_{samples} = \left(1 - \frac{O_p}{100}\right) N_{window}$$

When you increase the overlap percentage, fewer new input samples are needed to compute a new spectral update. For example, if the window length is 100, then the number of input samples required to compute one spectral update is given as shown in the following table.

O_p	$N_{samples}$
0%	100
50%	50
80%	20

c The normalized effective noise bandwidth, *NENBW*, is a window parameter determined by the window length, N_{window}, and the type of window used. If $w(n)$ denotes the vector of N_{window} window coefficients, then *NENBW* is given by the following equation.

$$NENBW = N_{window} \frac{\sum_{n=1}^{N_{window}} w^2(n)}{\left[\sum_{n=1}^{N_{window}} w(n)\right]^2}$$

d When in RBW mode, you can set the resolution bandwidth using the value of the **RBW** parameter on the **Main options** pane of the **Spectrum Settings** panel. You must specify a value to ensure that there are at least two RBW intervals over the specified frequency span. The ratio of the overall span to RBW must be greater than two, as given in the following equation.

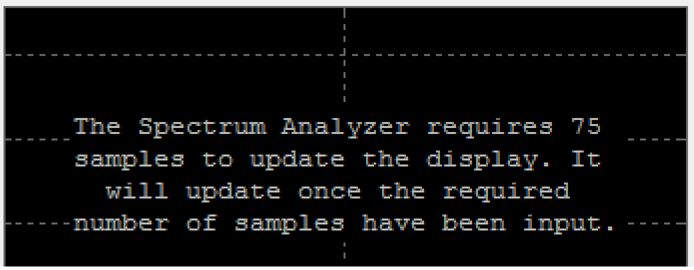
$$\frac{span}{RBW} > 2$$

By default, the **RBW** parameter on the **Main options** pane is set to `Auto`. In this case, the Spectrum Analyzer determines the appropriate value to ensure that there are 1024 RBW intervals over the specified frequency span. Thus, when you set **RBW** to `Auto`, it is calculated by the following equation. $RBW_{auto} = \frac{span}{1024}$

e When in window length mode, you specify N_{window} and the resulting RBW is

$$\frac{NENBW * Fs}{N_{window}}$$

In some cases, the number of samples provided in the input are not sufficient to achieve the resolution bandwidth that you specify. When this situation occurs, Spectrum Analyzer produces a message on the display, as shown in the following figure.



```
The Spectrum Analyzer requires 75
samples to update the display. It
will update once the required
number of samples have been input.
```

Spectrum Analyzer removes this message and displays a spectral estimate as soon as enough data has been input. Notice that this behavior differs from the Spectrum Scope block in versions R2012b and earlier. If the **Buffer input** check box was selected, the Spectrum Scope block computed a spectral update using the number of samples given by the **Buffer size** parameter. Otherwise, the Spectrum Scope block computed a spectral update using the number of samples in each frame.

2 Spectrum Analyzer calculates and plots the power spectrum, power spectrum density, or spectrogram computed by the modified *Periodogram* estimator. For more information about the Periodogram method, see `periodogram` in the Signal Processing Toolbox documentation.

Power Spectral Density — The power spectral density (PSD) is given by the following equation.

$$PSD(f) = \frac{1}{P}\sum_{p=1}^{P}\frac{\left|\sum_{n=1}^{N_{FFT}} x^{(p)}[n]e^{-j2\pi f(n-1)T}\right|^{2}}{F_s \times \sum_{n=1}^{N_{window}} w^{2}[n]}$$

In this equation, $x[n]$ is the discrete input signal. On every input signal frame, Spectrum Analyzer generates as many overlapping windows as possible, each window denoted as $x^{(p)}[n]$, and computes their periodograms. Spectrum Analyzer displays a running average of the P most current periodograms.

Power Spectrum — The power spectrum is the product of the power spectral density and the resolution bandwidth, as given by the following equation.

$$P_{spectrum}(f) = PSD(f) \times RBW = PSD(f) \times \frac{F_s \times NENBW}{N_{window}} = \frac{1}{P}\sum_{p=1}^{P}\frac{\left|\sum_{n=1}^{N_{FFT}} x^{(p)}[n]e^{-j2\pi f(n-1)T}\right|^{2}}{\left[\sum_{n=1}^{N_{window}} w[n]\right]^{2}}$$

Spectrogram — Each line of the spectrogram is one periodogram. The time resolution of each line is 1/RBW, which is the minimum attainable resolution. Achieving the resolution you want may require combining several periodograms may be combined. You then useinterpolation to calculate noninteger values of 1/RBW. In the spectrogram display, time scrolls from bottom to top, so the most recent data is shown at the bottom of the display. The offset shows the time value at which the center of the most current spectrogram line occurred.

Note: The number of FFT points (N_{fft}) is independent of the window length (N_{window}). You can set them to different values provided that N_{fft} is greater than or equal to N_{window}.

The **Occupied BW** is calculated as follows.

- Calculate the total power in the measured frequency range.
- Determine the lower frequency value. Starting at the lowest frequency in the range and moving upward, the power distributed in each frequency is summed until this sum is $\frac{100\text{ - }Occupied\ BW\ \%}{2}$ of the total power.
- Determine the upper frequency value. Starting at the highest frequency in the range and moving downward, the power distributed in each frequency is summed until it reaches $\frac{100\text{ - }Occupied\ BW\ \%}{2}$ of the total power.
- The bandwidth between the lower and upper power frequency values is the occupied bandwidth.
- The frequency halfway between the lower and upper frequency values is the center frequency.

The **Distortion Measurements** are computed as follows.

1. Spectral content is estimated by finding peaks in the spectrum. When the algorithm detects a peak, it ignores all adjacent content that decreases monotonically from the peak. After recording the width of the peak, it subsequently clears its content. Using this method, all spectral content centered at DC (0 Hz) is removed from the spectrum and the amount of bandwidth cleared (W_0) is recorded.
2. The fundamental power (P_1) is determined from the remaining maximum value of the displayed spectrum. A local estimate (Fe_1) of the fundamental frequency is made by computing the central moment of the power in the vicinity of the peak. The bandwidth of the fundamental power content (W_1) is recorded. Then, the power associated from the fundamental is removed as in step 1.
3. The power and width of the second, and higher order harmonics (P_2, W_2, P_3, W_3, etc.) are determined in succession by examining the frequencies closest to the appropriate multiple of the local estimate (Fe_1). Any spectral content that decreases in a monotonically about the harmonic frequency is removed from the spectrum first before proceeding to the next harmonic.

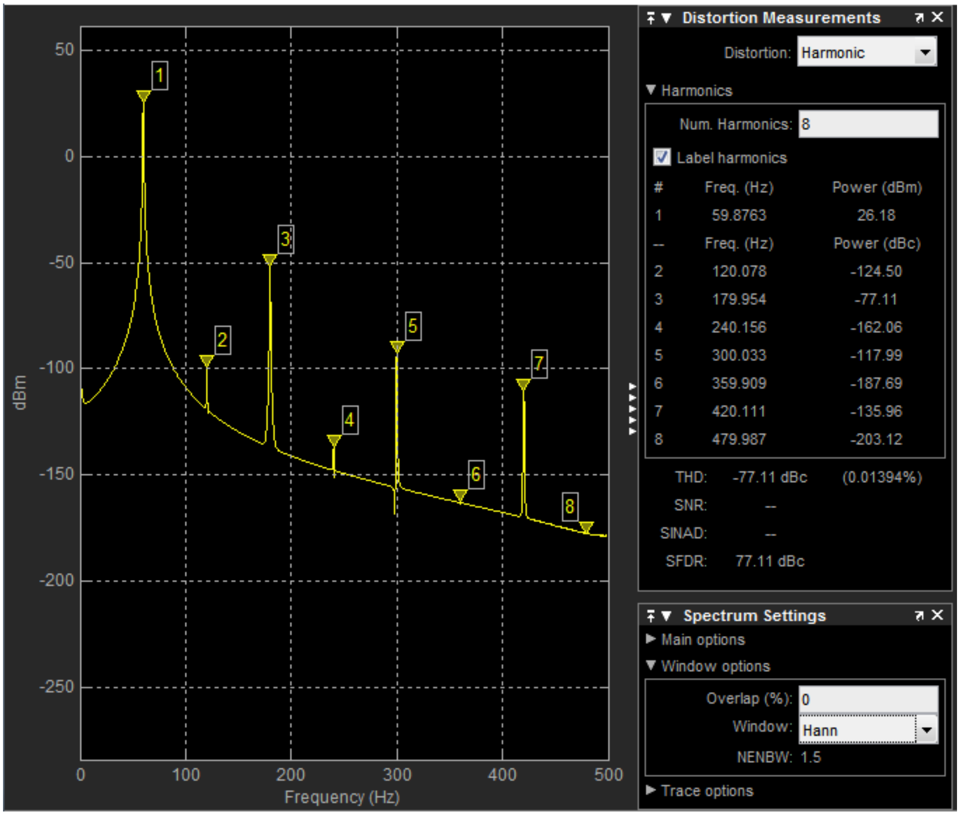
4. Once the DC, fundamental, and harmonic content is removed from the spectrum, the power of the remaining spectrum is examined for its sum ($P_{remaining}$) peak value ($P_{maxspur}$), and its median value ($P_{estnoise}$).
5. The sum of all the removed bandwidth is computed as $W_{sum} = W_0+W_1+W_2+...+W_n$.

   The sum of powers of the second and higher order harmonics are computed as $P_{harmonic} = P_2+P_3+P_4+...+P_n$.
6. The sum of the noise power is then estimated as $P_{noise} = (P_{remaining}\text{*dF} + P_{estnoise}*W_{sum})/RBW$, where dF is the absolute difference between frequency bins, and RBW is the resolution bandwidth of the window.
7. The metrics for SNR, THD, SINAD, and SFDR are then computed from the estimates.

   - THD = 10*log10($P_{harmonic}/P_1$)
   - SINAD = 10*$\log_{10}$($P_1/(P_{harmonic} + P_{noise})$
   - SNR = 10*$\log_{10}$(P_1/P_{noise})
   - SFDR = 10*$\log_{10}$(P_1/max($P_{maxspur}$, max(P_2,P_3,...,P_n))

The following considerations apply to **Distortion Measurements**.

- The harmonic distortion measurements use the spectrum trace shown in the display as the input to the measurements. The default Hann window setting of the Spectrum Analyzer may exhibit leakage that can completely mask the noise floor of the measured signal.



Distortion: Harmonic

Num. Harmonics: 8

☑ Label harmonics

#	Freq. (Hz)	Power (dBm)
1	59.8763	26.18
--	Freq. (Hz)	Power (dBc)
2	120.078	-124.50
3	179.954	-77.11
4	240.156	-162.06
5	300.033	-117.99
6	359.909	-187.69
7	420.111	-135.96
8	479.987	-203.12

THD: -77.11 dBc (0.01394%)

SNR: --

SINAD: --

SFDR: 77.11 dBc

Overlap (%): 0

Window: Hann

NENBW: 1.5

The harmonic measurements attempt to correct for leakage by ignoring all frequency content that decreases monotonically away from the maximum of harmonic peaks. If the window leakage covers more than 70% of the frequency bandwidth in your spectrum, you may see a blank reading (–) reported for **SNR** and **SINAD**. Consider using a Kaiser window with a high attenuation (up to 330dB) to minimize spectral leakage if your application can tolerate the increased equivalent noise bandwidth (ENBW) of the Kaiser window.

Attenuation (dB): 300

NENBW: 3.229

- The DC component is ignored.
- After windowing, the width of each harmonic component masks the noise power in the neighborhood of the fundamental frequency and harmonics. To estimate the noise power in each region, Spectrum Analyzer computes the median noise level in the nonharmonic areas of the spectrum. It then extrapolates that value into each region.
- *N*th order intermodulation products occur at

  *A*F1 + B*F2*

  where *F1* and *F2* are the sinusoid input frequencies and $|A| + |B| = N$. *A* and *B* are integer values.

- For intermodulation measurements, the third-order intercept (TOI) point is computed as follows, where P is power in decibels of the measured power referenced to one milliwatt (dBm).:
  - $TOI_{lower} = P_{F1} + (P_{F2} - P_{(2F1-F2)})/2$
  - $TOI_{upper} = P_{F2} + (P_{F1} - P_{(2F2-F1)})/2$
  - $TOI\ = + (TOI_{lower} + TOI_{upper})/2$

Differences from Spectrum Scope Block

All Simulink models containing Spectrum Scope blocks load with Spectrum Analyzer blocks in R2013a or later. Several options that were available on the Parameters dialog box of the Spectrum Scope block are no longer available or have changed. The parameters of Spectrum Scope map to Spectrum Analyzer parameters in the following manner.

R2012b Spectrum Scope Block Parameters dialog box Tab name	R2012b Spectrum Scope Parameter	R2013a Spectrum Analyzer Change	R2013a Spectrum Analyzer Equivalent Parameter
Scope Properties	**Buffer input** check box	R2013a Spectrum Analyzer does not require that input signals are buffered. Spectrum Analyzer determines the number of samples needed using the value of the **RBW** parameter. Regardless of whether the input is a frame-based or sample-based signal, Spectrum Analyzer calculates the spectrum once it has acquired the requisite number of samples.	For Spectrum Scope blocks in R2012b or earlier models, the equivalent R2013a Spectrum Analyzer **RBW** value is given by the equation: $$RBW = \frac{NENBW \times F_s}{N_{window}}$$ In the preceding equation, *NENBW* is the window constant calculated for a window length of 1000, F_s is the sample rate of the block,

R2012b Spectrum Scope Block Parameters dialog box Tab name	R2012b Spectrum Scope Parameter	R2013a Spectrum Analyzer Change	R2013a Spectrum Analyzer Equivalent Parameter
			and N_{window} is the buffer length. If the input signal to the R2012b Spectrum Scope block was frame-based and the **Buffer input** check box was cleared, then the R2013a Spectrum Analyzer computes the **RBW** value with N_{window} set to the frame size of the input signal.
Scope Properties	**Buffer size** parameter	R2013a Spectrum Analyzer uses the **RBW** parameter to determine the requisite number of samples to calculate the spectrum, instead of using the buffer size or frame length.	For Spectrum Scope blocks in R2012b or earlier models, if the input signal was frame-based and the **Buffer input** check box was selected, then the R2013a Spectrum Analyzer computes the **RBW** value with N_{window} set to the value of the **Buffer size** parameter.

R2012b Spectrum Scope Block Parameters dialog box Tab name	R2012b Spectrum Scope Parameter	R2013a Spectrum Analyzer Change	R2013a Spectrum Analyzer Equivalent Parameter
Scope Properties	**Buffer Overlap** parameter	R2013a Spectrum Analyzer has an **Overlap %** parameter that is directly related to buffer overlap.	R2013a Spectrum Analyzer will compute its **Overlap %** using the equation: $$O_p = {}^{O_l}\!/\!{}_{N_{window}} \times 100$$ In the preceding equation, O_p is **Overlap %** parameter value, O_l is the R2012b Spectrum Scope **Buffer overlap** parameter value, and N_{window} is the buffer length.
Scope Properties	**Treat Mx1 and unoriented sample-based signals as**	R2013a Spectrum Analyzer defaults to treating Mx1 and unoriented sample-based signals as one channel.	Spectrum Scope blocks in R2012b or earlier models with **Treat Mx1 and unoriented sample-based signals as** set to `M Channels` will have the Spectrum Analyzer property `TreatMby1SignalAsOneChannel` set to `false`. This property is available only via the Scope Configuration object.
Scope Properties	**Window** parameter	R2013a Spectrum Analyzer does not have the `Bartlett`, `Blackman`, `Triang`, or `Hanning` settings.	Spectrum Scope blocks in R2012b or earlier models with a window parameter set to any of these values will have their **Window** parameter set to `Hann` in the R2013a Spectrum Analyzer.

R2012b Spectrum Scope Block Parameters dialog box Tab name	R2012b Spectrum Scope Parameter	R2013a Spectrum Analyzer Change	R2013a Spectrum Analyzer Equivalent Parameter
Scope Properties	**Window Sampling** parameter	R2013a Spectrum Analyzer does not have a `Periodic` option. All window sampling is now symmetric in the R2013a Spectrum Analyzer.	n/a
Display Properties	**Persistence** check box — this setting would execute the equivalent of the MATLAB `hold on` command, adding another line for each spectrum computation on the display.	This option is not available in the R2013a Spectrum Analyzer, which has replaced this feature with the trace options, **Normal Trace**, **Max Hold Trace**, and **Min Hold Trace**.	Spectrum Scope blocks in R2012b or earlier models with persistence enabled will have their **Max Hold Trace** check box selected in the R2013a Spectrum Analyzer.
Display Properties	**Compact Display** check box	There is no equivalent capability in the R2013a Spectrum Analyzer.	n/a
Axis Properties	**Inherit Sample time from input** check box	R2013a Spectrum Analyzer always uses the sample time of the input signal.	n/a

R2012b Spectrum Scope Block Parameters dialog box Tab name	R2012b Spectrum Scope Parameter	R2013a Spectrum Analyzer Change	R2013a Spectrum Analyzer Equivalent Parameter
Axis Properties	**Frequency display limits** parameter	R2013a Spectrum Analyzer determines the range of frequencies calculated based on the **Full Span**, **FStart (Hz)**, and **FStop (Hz)** parameters.	If this parameter was set to: • `Auto` — R2013a Spectrum Analyzer selects the **Full Span** check box on the Spectrum Settings panel, Main options pane. • `User-defined` — R2013a Spectrum Analyzer clears the **Full Span** check box on the Spectrum Settings panel Main options pane.
Axis Properties	**Minimum frequency (Hz)** parameter	R2013a Spectrum Analyzer determines the range of frequencies calculated based on the **Full Span**, **FStart (Hz)**, and **FStop (Hz)** parameters.	If the `User-defined` parameter was chosen, then this parameter maps to the R2013a Spectrum Analyzer **FStart (Hz)** parameter.
Axis Properties	**Maximum frequency (Hz)** parameter	R2013a Spectrum Analyzer determines the range of frequencies calculated based on the **Full Span**, **FStart (Hz)**, and **FStop (Hz)** parameters.	If the `User-defined` parameter was chosen, then this parameter maps to the R2013a Spectrum Analyzer **FStop (Hz)** parameter.

R2012b Spectrum Scope Block Parameters dialog box Tab name	R2012b Spectrum Scope Parameter	R2013a Spectrum Analyzer Change	R2013a Spectrum Analyzer Equivalent Parameter
Line Properties	**Line visibilities**, **Line styles**, **Line markers**, and **Line colors** parameters	There are no equivalent capabilities in the R2013a Spectrum Analyzer.	Once the simulation has started, you can modify the line styles, markers, and colors using the Style dialog box.

The R2012b Spectrum Scope allowed you to retain the axes limits over multiple simulations by selecting **Axes** > **Save Axes Settings**. There is no equivalent capability in the R2013a Spectrum Analyzer. However, you can automatically scale the axes to a specified range using the Tools — Axes Scaling Properties dialog box.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned)

Supported Simulation Modes

You can use the scope block in models running the following supported simulation modes.

Mode	Supported	Notes and Limitations
Normal	Yes	

Mode	Supported	Notes and Limitations
Accelerator	Yes	
Rapid Accelerator	Yes	You can use Rapid Accelerator mode as a method to increase the execution speed of your Simulink model. Rapid Accelerator mode creates an executable that includes the solver and model methods. This executable resides outside MATLAB and Simulink. Rapid Accelerator mode uses External mode to communicate with Simulink. For more information about Rapid Accelerator mode, see "Acceleration" in the Simulink documentation.
PIL	No	
SIL	No	
External	Yes	You can use External mode to tune block parameters in real time and view block outputs in many types of blocks and subsystems. External mode establishes communication between a host system, where the Simulink environment resides, and a target system, where the executable runs after it is generated by the code generation and build process. For more information about External mode, see "Host/Target Communication" in the Simulink Coder documentation. The scope does not support data archiving. See "Set External Mode Data Archiving Parameters" in the Real-Time Windows Target documentation.

For more information about these modes, see "How Acceleration Modes Work" in the Simulink documentation.

Stack

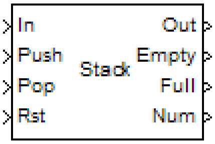
Store inputs into LIFO register

Library

Signal Management / Buffers

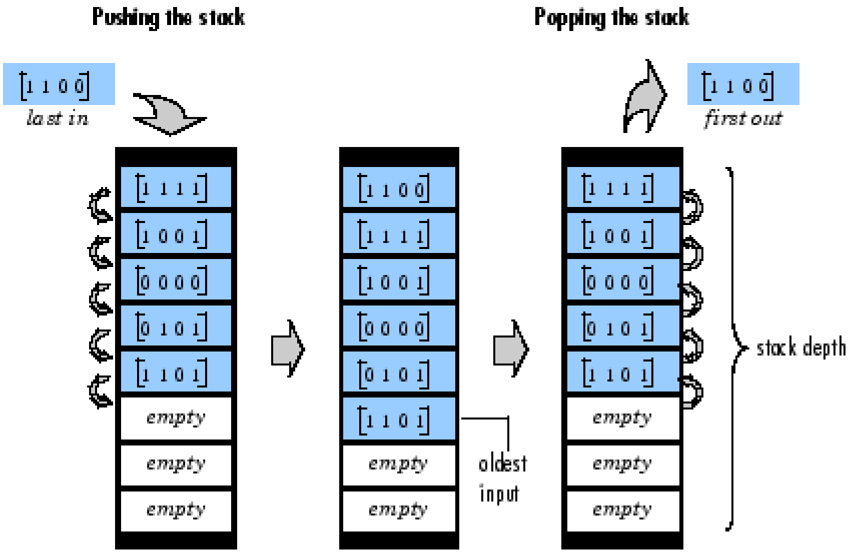
`dspbuff3`

Description



The Stack block stores a sequence of input samples in a last in, first out (LIFO) register. The register capacity is set by the **Stack depth** parameter, and inputs can be scalars, vectors, or matrices.

The block *pushes* the input at the `In` port onto the top of the stack when a trigger event is received at the `Push` port. When a trigger event is received at the `Pop` port, the block *pops* the top element off the stack and holds the `Out` port at that value. The last input to be pushed onto the stack is always the first to be popped off.



A trigger event at the optional `Rst` port empties the stack contents. When you select **Clear output port on reset**, then a trigger event at the `Rst` port empties the stack *and* sets the value at the `Out` port to zero. This setting also applies when a disabled subsystem containing the Stack block is reenabled; the `Out` port value is only reset to zero in this case when you select **Clear output port on reset**.

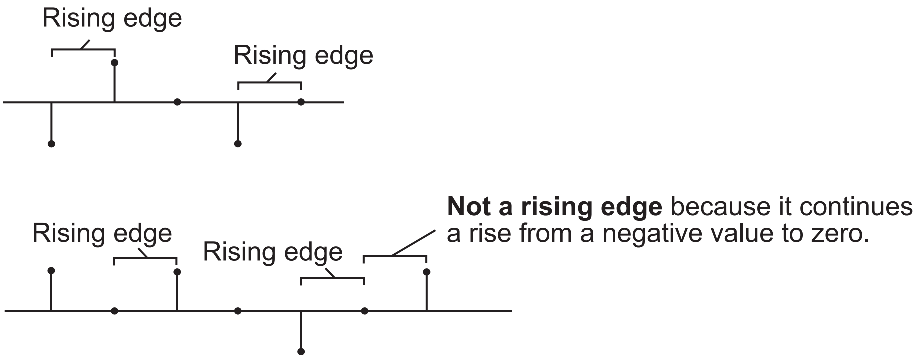
When two or more of the control input ports are triggered at the same time step, the operations are executed in the following order:

1. `Rst`
2. `Push`
3. `Pop`

The rate of the trigger signal must be the same as the rate of the data signal input. You specify the triggering event for the `Push`, `Pop`, and `Rst` ports in the **Trigger type** pop-up menu:

- `Rising edge` — Triggers execution of the block when the trigger input does one of the following:
  - Rises from a negative value to a positive value or zero

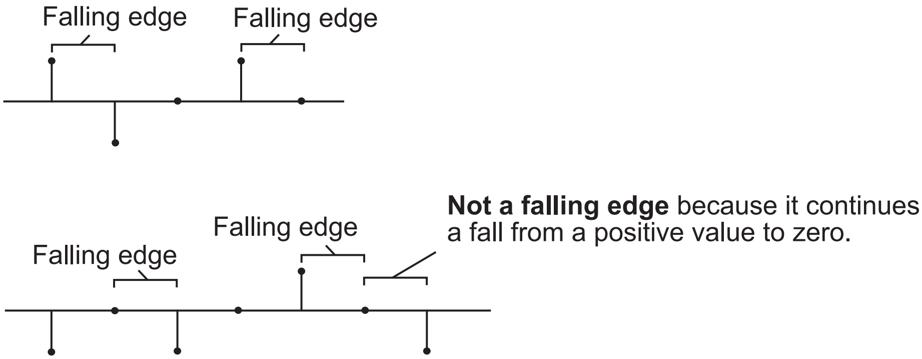
- Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero (see the following figure)



Rising edge
Rising edge
Rising edge
Rising edge
Not a rising edge because it continues a rise from a negative value to zero.

- `Falling edge` — Triggers execution of the block when the trigger input does one of the following:

  - Falls from a positive value to a negative value or zero
  - Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero (see the following figure)



Falling edge
Falling edge
Falling edge
Falling edge
Not a falling edge because it continues a fall from a positive value to zero.

- `Either edge` — Triggers execution of the block when the trigger input is a `Rising edge` or `Falling edge` (as described above).
- `Non-zero sample` — Triggers execution of the block at each sample time that the trigger input is not zero.

Note: If your model contains any referenced models that use a Stack block with the **Push full stack** parameter set to `Dynamic reallocation`, you cannot simulate your top-level model in Simulink Accelerator mode.

The **Push full stack** parameter specifies the block's behavior when a trigger is received at the `Push` port but the register is full. The **Pop empty stack** parameter specifies the block's behavior when a trigger is received at the `Pop` port but the register is empty. The following options are available for both cases:

- `Ignore` — Ignore the trigger event, and continue the simulation.
- `Warning` — Ignore the trigger event, but display a warning message in the MATLAB command window.
- `Error` — Display an error dialog box and terminate the simulation.

Note The **Push full stack** and **Pop empty stack** parameters are diagnostic parameters. Like all diagnostic parameters on the Configuration Parameters dialog box, they are set to `Ignore` in the code generated for this block by Simulink Coder code generation software.

The **Push full stack** parameter additionally offers the **Dynamic reallocation** option, which dynamically resizes the register to accept as many additional inputs as memory permits. To find out how many elements are on the stack at a given time, enable the `Num` output port by selecting the **Show number of stack entries port** parameter.

Note: When `Dynamic reallocation` is selected, the **System target file** parameter on the **Code Generation** pane of the Model Configuration Parameters dialog box must be set to `grt_malloc.tlc — Generic Real-Time Target with dynamic memory allocation`.

Examples

Example 1

The table below illustrates the Stack block's operation for a **Stack depth** of 4, **Trigger type** of `Either edge`, and **Clear output port on reset** enabled. Because the block triggers on both rising and falling edges in this example, each transition from 1 to 0 or 0 to 1 in the Push, Pop, and Rst columns below represents a distinct trigger event. A 1 in the Empty column indicates an empty buffer, while a 1 in the Full column indicates a full buffer.

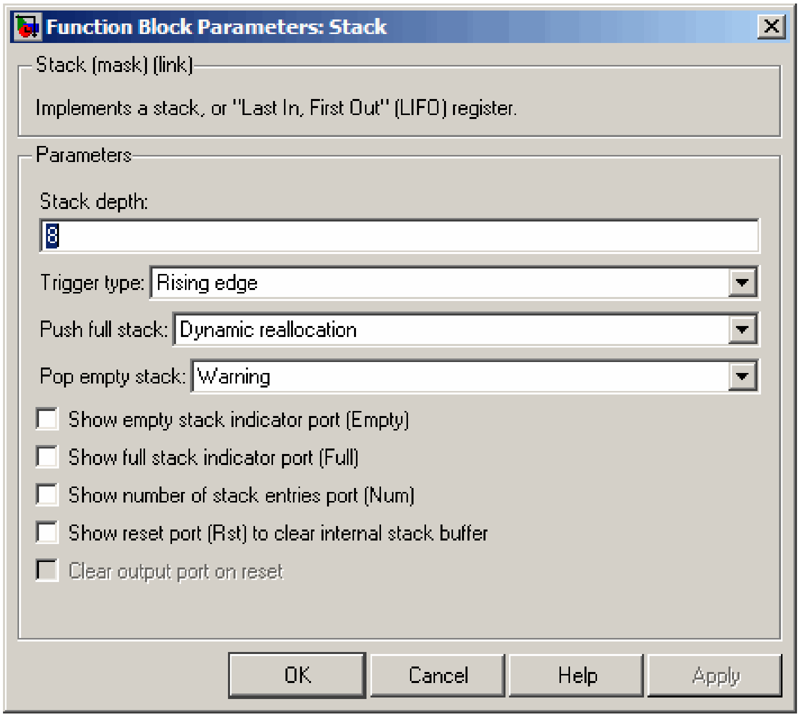
In	Push	Pop	Rst	Stack	Out	Empty	Full	Num
1	0	0	0		0	1	0	0
2	1	0	0		0	0	0	1
3	0	0	0		0	0	0	2
4	1	0	0		0	0	0	3
5	0	0	0		0	0	1	4
6	0	1	0		5	0	0	3
7	0	0	0		4	0	0	2
8	0	1	0		3	0	0	1
9	0	0	0		2	1	0	0
10	1	0	0		2	0	0	1
11	0	0	0		2	0	0	2
12	1	0	1		0	0	0	1

Note that at the last step shown, the Push and Rst ports are triggered simultaneously. The Rst trigger takes precedence, and the stack is first cleared and then pushed.

Example 2

The dspqdemo example provides an example of the related Queue block.

Dialog Box



Function Block Parameters: Stack

Stack (mask) (link)

Implements a stack, or "Last In, First Out" (LIFO) register.

Parameters

Stack depth: 8

Trigger type: Rising edge

Push full stack: Dynamic reallocation

Pop empty stack: Warning

□ Show empty stack indicator port (Empty)

□ Show full stack indicator port (Full)

□ Show number of stack entries port (Num)

□ Show reset port (Rst) to clear internal stack buffer

□ Clear output port on reset

Stack depth

The number of entries that the LIFO register can hold.

Trigger type

The type of event that triggers the block's execution. The rate of the trigger signal must be the same as the rate of the data signal input.

Push full stack

Response to a trigger received at the `Push` port when the register is full. Inputs to this port must have the same built-in data type as inputs to the `Pop` and `Rst` input ports.

When `Dynamic reallocation` is selected, the **System target file** parameter on the **Code Generation** pane of the Model Configuration Parameters dialog box must be set to `grt_malloc.tlc — Generic Real-Time Target with dynamic memory allocation`.

Pop empty stack

Response to a trigger received at the Pop port when the register is empty. Inputs to this port must have the same built-in data type as inputs to the Push and Rst input ports.

Show empty stack indicator port

Enable the Empty output port, which is high (1) when the stack is empty, and low (0) otherwise.

Show full stack indicator port

Enable the Full output port, which is high (1) when the stack is full, and low (0) otherwise. The Full port remains low when you select **Dynamic reallocation** from the **Push full stack** parameter.

Show number of stack entries port

Enable the Num output port, which tracks the number of entries currently on the stack. When inputs to the In port are double-precision values, the outputs from the Num port are double-precision values. Otherwise, the outputs from the Num port are 32-bit unsigned integer values.

Show reset port to clear internal stack buffer

Enable the Rst input port, which empties the stack when the trigger specified by the **Trigger type** is received. Inputs to this port must have the same built-in data type as inputs to the Push and Pop input ports.

Clear output port on reset

Reset the Out port to zero (in addition to clearing the stack) when a trigger is received at the Rst input port.

Supported Data Types

Port	Supported Data Types
In	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers

Port	Supported Data Types
Push	• Double-precision floating point • Single-precision floating point • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers Inputs to this port must have the same built-in data type as inputs to the Pop and Rst input ports
Pop	• Double-precision floating point • Single-precision floating point • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers Inputs to this port must have the same built-in data type as inputs to the Push and Rst input ports.
Rst	• Double-precision floating point • Single-precision floating point • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers Inputs to this port must have the same built-in data type as inputs to the Push and Pop input ports.
Out	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers

Port	Supported Data Types
Empty	• Double-precision floating point • Boolean
Full	• Double-precision floating point • Boolean
Num	• Double-precision floating point The block outputs a double-precision floating-point value at this port when the data type of the In port is double-precision floating-point. • 32-bit unsigned integers The block outputs a 32-bit unsigned integer value at this port when the data type of the In port is anything other than double-precision floating-point.

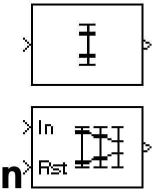
Standard Deviation

Find standard deviation of input or sequence of inputs

Library

Statistics

`dspstat3`



Description

The Standard Deviation block computes the standard deviation of each row or column of the input, along vectors of a specified dimension of the input, or of the entire input. The Standard Deviation block can also track the standard deviation of a sequence of inputs over a period of time. The **Running standard deviation** parameter selects between basic operation and running operation.

Basic Operation

When you do not select the **Running standard deviation** check box, the block computes the standard deviation of each row or column of the input, along vectors of a specified dimension of the input, or of the entire input at each individual sample time, and outputs the array *y*. Each element in *y* contains the standard deviation of the corresponding column, row, vector, or entire input. The output *y* depends on the setting of the **Find the standard deviation value over** parameter. For example, consider a 3-dimensional input signal of size *M*-by-*N*-by-*P*:

- `Entire input` — The output at each sample time is a scalar that contains the standard deviation of the entire input.

  ```
  y = std(u(:))     % Equivalent MATLAB code
  ```
- `Each Row` — The output at each sample time consists of an *M*-by-1-by-*P* array, where each element contains the standard deviation of each vector over the second

dimension of the input. For an input that is an M-by-N matrix, the output at each sample time is an M-by-1 column vector.

```
y = std(u,0,2)     % Equivalent MATLAB code
```

- `Each Column` — The output at each sample time consists of a 1-by-N-by-P array, where each element contains the standard deviation of each vector over the first dimension of the input. For an input that is an M-by-N matrix, the output at each sample time is a 1-by-N row vector.

  ```
  y = std(u,0,1)     % Equivalent MATLAB code
  ```

  In this mode, the block treats length-M unoriented vector inputs as M-by-1 column vectors.

- `Specified Dimension` — The output at each sample time depends on **Dimension**. If **Dimension** is set to `1`, the output is the same as when you select `Each column`. If **Dimension** is set to `2`, the output is the same as when you select `Each row`. If **Dimension** is set to `3`, the output at each sample time is an M-by-N matrix containing the standard deviation of each vector over the third dimension of the input.

  ```
  y = std(u,0,Dimension)     % Equivalent MATLAB code
  ```

For purely real or purely imaginary inputs, the standard deviation of the jth column of an M-by-N input matrix is the square root of its variance:

$$y_j = \sigma_j = \sqrt{\frac{\sum_{i=1}^{M} \left| u_{ij} - \mu_j \right|^2}{M-1}} \qquad 1 \le j \le N$$

For complex inputs, the output is the *total standard deviation*, which equals the square root of the *total variance*, or the square root of the sum of the variances of the real and imaginary parts. The standard deviation of each column in an M-by-N input matrix is given by:

$$\sigma_j = \sqrt{\sigma_{j,\mathrm{Re}}^2 + \sigma_{j,\mathrm{Im}}^2}$$

Note: The total standard deviation does *not* equal the sum of the real and imaginary standard deviations.

Running Operation

When you select the **Running standard deviation** check box, the block tracks the standard deviation of successive inputs to the block. In this mode, you must also specify a value for the **Input processing** parameter:

- When you select `Elements as channels (sample based)`, the block outputs an *M*-by-*N* array. Each element y_{ij} of the output contains the standard deviation of the element u_{ij} over all inputs since the last reset.
- When you select `Columns as channels (frame based)`, the block outputs an *M*-by-*N* matrix. Each element y_{ij} of the output contains the standard deviation of the *j*th column over all inputs since the last reset, up to and including element u_{ij} of the current input.

Running Operation for Variable-Size Inputs

When your inputs are of variable size, and you select the **Running standard deviation** check box, there are two options:

- If you set the **Input processing** parameter to `Elements as channels (sample based)`, the state is reset.
- If you set the **Input processing** parameter to `Columns as channels (frame based)`, then there are two cases:
  - When the input size difference is in the number of channels (i.e., number of columns), the state is reset.
  - When the input size difference is in the length of channels (i.e., number of rows), there is no reset and the running operation is carried out as usual.

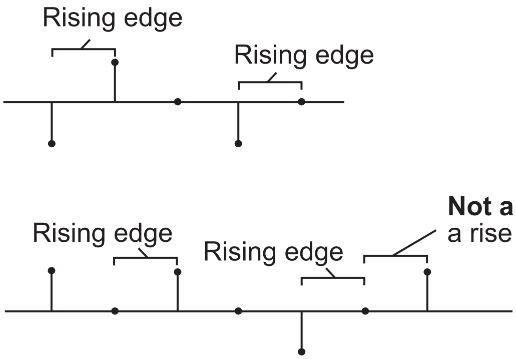
Resetting the Running Standard Deviation

The block resets the running standard deviation whenever a reset event is detected at the optional `Rst` port. The reset sample time must be a positive integer multiple of the input sample time.

You specify the reset event in the **Reset port** parameter:

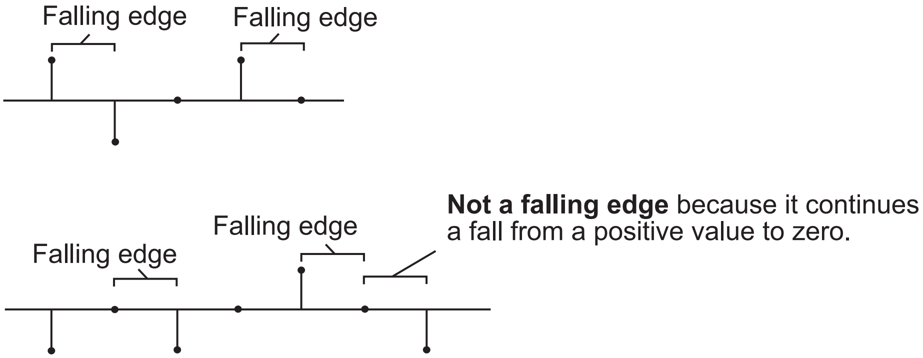
- `None` disables the `Rst` port.
- `Rising edge` — Triggers a reset operation when the `Rst` input does one of the following:

- Rises from a negative value to a positive value or zero
- Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero (see the following figure)



Rising edge
Rising edge
Rising edge
Rising edge
Not a rising edge because it continues a rise from a negative value to zero.

- `Falling edge` — Triggers a reset operation when the `Rst` input does one of the following:
  - Falls from a positive value to a negative value or zero
  - Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero (see the following figure)



Falling edge
Falling edge
Falling edge
Falling edge
Not a falling edge because it continues a fall from a positive value to zero.

- `Either edge` — Triggers a reset operation when the `Rst` input is a `Rising edge` or `Falling edge` (as described earlier)
- `Non-zero sample` — Triggers a reset operation at each sample time that the `Rst` input is not zero

Note: When running simulations in the Simulink MultiTasking mode, reset signals have a one-sample latency. Therefore, when the block detects a reset event, there is a one-sample delay at the reset port rate before the block applies the reset. For more information on latency and the Simulink tasking modes, see "Excess Algorithmic Delay (Tasking Latency)" and "Scheduling " in the *Simulink Coder User's Guide*.

ROI Processing

To calculate the statistical value within a particular region of interest (ROI) of the input, select the **Enable ROI processing** check box. This option is only available when the **Find the standard deviation value over** parameter is set to `Entire input` and the **Running standard deviation** check box is not selected. ROI processing is only supported for 2-D inputs.

Note: Full ROI processing is available only if you have a Computer Vision System Toolbox license. If you do not have a Computer Vision System Toolbox license, you can still use ROI processing, but are limited to the **ROI type** `Rectangles`.

Use the **ROI type** parameter to specify whether the ROI is a rectangle, line, label matrix, or binary mask. A binary mask is a binary image that enables you to specify which pixels to highlight, or select. In a label matrix, pixels equal to 0 represent the background, pixels equal to 1 represent the first object, pixels equal to 2 represent the second object, and so on. When the **ROI type** parameter is set to `Label matrix`, the Label and Label Numbers ports appear on the block. Use the Label Numbers port to specify the objects in the label matrix for which the block calculates statistics. The input to this port must be a vector of scalar values that correspond to the labeled regions in the label matrix. For more information about the format of the input to the ROI port when the ROI is a rectangle or a line, see the Draw Shapes block reference page.

For rectangular ROIs, use the **ROI portion to process** parameter to specify whether to calculate the statistical value for the entire ROI or just the ROI perimeter.

Use the **Output** parameter to specify the block output. The block can output separate statistical values for each ROI or the statistical value for all specified ROIs. This parameter is not available if, for the **ROI type** parameter, you select `Binary mask`.

If, for the **ROI type** parameter, you select `Rectangles` or `Lines`, the **Output flag indicating if ROI is within image bounds** check box appears in the dialog box. If you select this check box, the Flag port appears on the block. The following tables describe the Flag port output based on the block parameters.

Output = Individual statistics for each ROI

Flag Port Output	Description
0	ROI is completely outside the input image.
1	ROI is completely or partially inside the input image.

Output = Single statistic for all ROIs

Flag Port Output	Description
0	All ROIs are completely outside the input image.
1	At least one ROI is completely or partially inside the input image.

If the ROI is partially outside the image, the block only computes the statistical values for the portion of the ROI that is within the image.

If, for the **ROI type** parameter, you select `Label matrix`, the **Output flag indicating if input label numbers are valid** check box appears in the dialog box. If you select this check box, the Flag port appears on the block. The following tables describe the Flag port output based on the block parameters.

Output = Individual statistics for each ROI

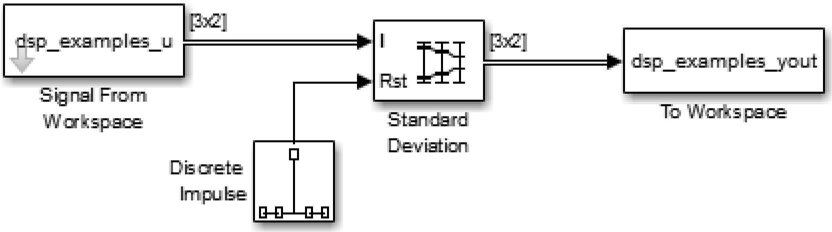
Flag Port Output	Description
0	Label number is not in the label matrix.
1	Label number is in the label matrix.

Output = Single statistic for all ROIs

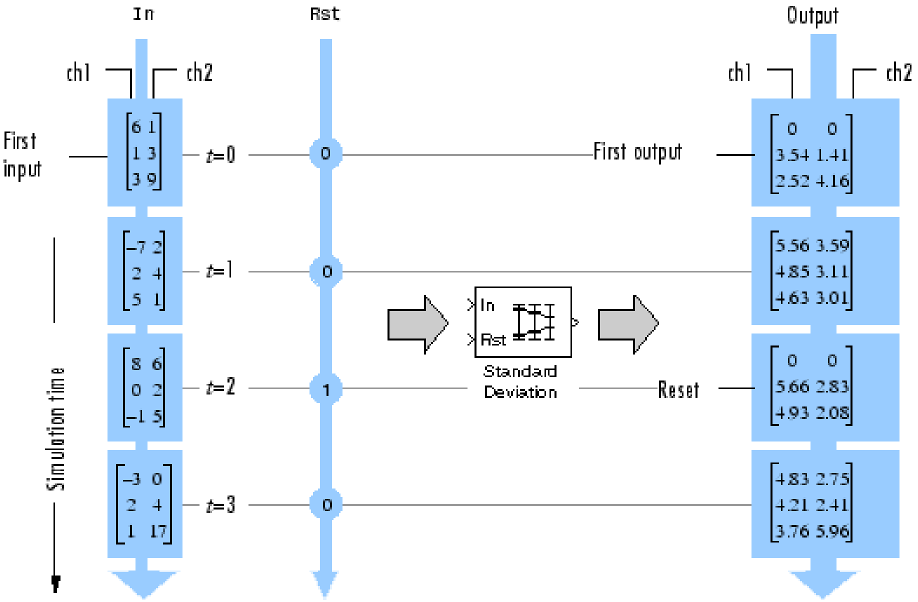
Flag Port Output	Description
0	None of the label numbers are in the label matrix.
1	At least one of the label numbers is in the label matrix.

Examples

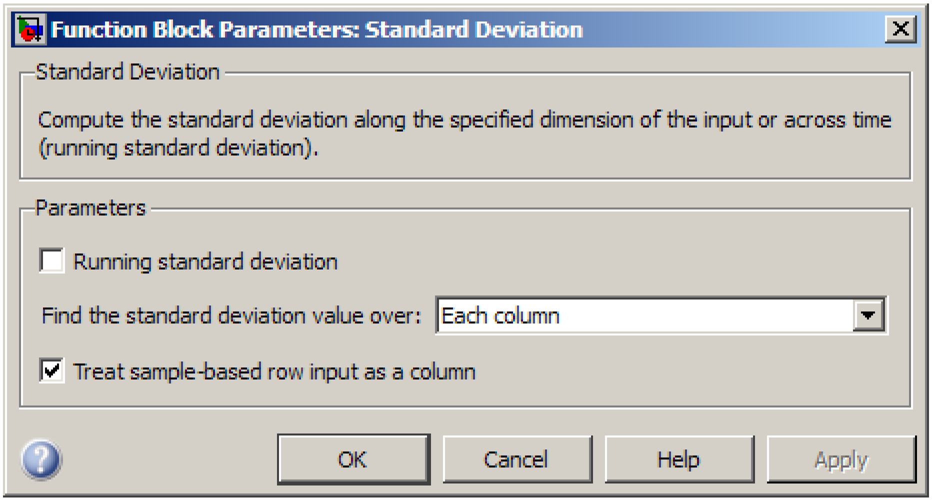
In the following ex_standarddeviation_ref model, the Standard Deviation block calculates the running standard deviation of a 3-by-2 matrix input, `u`. The **Input processing** parameter is set to `Columns as channels (frame based)`, so the block processes the input as a two channel signal with a frame size of three. The running standard deviation is reset at *t*=2 by an impulse to the block's `Rst` port.



The operation of the block is shown in the following figure.



Dialog Box



Function Block Parameters: Standard Deviation

Standard Deviation

Compute the standard deviation along the specified dimension of the input or across time (running standard deviation).

Parameters

□ Running standard deviation

Find the standard deviation value over: Each column

☑ Treat sample-based row input as a column

Running standard deviation

Enables running operation when selected.

Input processing

Specify how the block should process the input when computing the running standard deviation. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` — When you select this option, the block treats each column of the input as a separate channel.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

This parameter appears only when you select the **Running standard deviation** check box.

Note: The option `Inherit from input (this choice will be removed - see release notes)` will be removed in a future release. See "Frame-Based Processing" in the *DSP System Toolbox Release Notes* for more information.

Reset port

Specify the reset event that causes the block to reset the running standard deviation. The sample time of the input to the Rst port must be a positive integer multiple of the input sample time. This parameter appears only when you select the **Running standard deviation** check box. For more information, see “Resetting the Running Standard Deviation” on page 1-1359.

Find the standard deviation value over

Specify whether to find the standard deviation value along rows, columns, entire input, or the dimension specified in the **Dimension** parameter. For more information, see “Basic Operation” on page 1-1357.

Treat sample-based row input as a column

Select to treat sample-based length-*M* row vector inputs as *M*-by-1 column vectors. This parameter is only visible when the **Find the standard deviation value over** parameter is set to `Each column`.

Note: This check box will be removed in a future release. See “Sample-Based Row Vector Processing Changes” for more information.

Dimension

Specify the dimension (one-based value) of the input signal, over which the standard deviation is computed. The value of this parameter cannot exceed the number of dimensions in the input signal. This parameter is only visible when the **Find the standard deviation value over** parameter is set to `Specified dimension`.

Enable ROI Processing

Select this check box to calculate the statistical value within a particular region of each image. This parameter is only available when the **Find the standard deviation value over** parameter is set to `Entire input`, and the block is not in running mode.

Note Full ROI processing is available only when you have a Computer Vision System Toolbox license. If you do not have a Computer Vision System Toolbox license, you can still use ROI processing, but are limited to the **ROI type** `Rectangles`.

ROI type

Specify the type of ROI you want to use. Your choices are `Rectangles`, `Lines`, `Label matrix`, or `Binary mask`.

ROI portion to process

Specify whether you want to calculate the statistical value for the entire ROI or just the ROI perimeter. This parameter is only visible if, for the **ROI type** parameter, you specify `Rectangles`.

Output

Specify the block output. The block can output a vector of separate statistical values for each ROI or a scalar value that represents the statistical value for all the specified ROIs. This parameter is not available if, for the **ROI type** parameter, you select `Binary mask`.

Output flag

☑ **Output flag indicating if ROI is within image bounds**

☑ **Output flag indicating if label numbers are valid**

When you select either of these check boxes, the Flag port appears on the block. For a description of the Flag port output, see the tables in “ROI Processing” on page 1-1361.

The **Output flag indicating if ROI is within image bounds** check box is only visible when you select `Rectangles` or `Lines` as the **ROI type**.

The **Output flag indicating if label numbers are valid** check box is only visible when you select `Label matrix` for the **ROI type** parameter.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point
Reset	• Double-precision floating point • Single-precision floating point • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers

Port	Supported Data Types
ROI	Rectangles and lines: • Double-precision floating point • Single-precision floating point • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers Binary Mask: • Boolean
Label	• 8-, 16-, and 32-bit unsigned integers
Label Numbers	• 8-, 16-, and 32-bit unsigned integers
Output	• Double-precision floating point • Single-precision floating point
Flag	• Boolean

Submatrix

Select subset of elements (submatrix) from matrix input

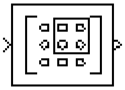
Library

- Math Functions / Matrices and Linear Algebra / Matrix Operations

  `dspmtrx3`
- Signal Management / Indexing

  `dspindex`

Description



The Submatrix block extracts a contiguous submatrix from the *M*-by-*N* input matrix `u`. The block treats length-*M* unoriented vector input as an *M*-by-`1` matrix. The **Row span** parameter provides three options for specifying the range of rows in `u` to be retained in submatrix output `y`:

- `All rows`

  Specifies that `y` contains all *M* rows of `u`.
- `One row`

  Specifies that `y` contains only one row from `u`. The **Row** parameter (described below) is enabled to allow selection of the desired row.
- `Range of rows`

  Specifies that `y` contains one or more rows from `u`. The **Starting row** and **Ending row** parameters (described below) are enabled to allow selection of the desired range of rows.

The **Column span** parameter contains a corresponding set of three options for specifying the range of columns in `u` to be retained in submatrix `y`: `All columns`, `One column`, or `Range of columns`. The `One column` option enables the **Column** parameter, and `Range of columns` options enable the **Starting column** and **Ending column** parameters.

Range Specification Options

When you select `One row` or `Range of rows` from the **Row span** parameter, you specify the desired row or range of rows in the **Row** parameter, or the **Starting row** and **Ending row** parameters. Similarly, when you select `One column` or `Range of columns` from the **Column span** parameter, you specify the desired column or range of columns in the **Column** parameter, or the **Starting column** and **Ending column** parameters.

The **Row**, **Column**, **Starting row** or **Starting column** can be specified in six ways:

- `First`

  For rows, this specifies that the first row of `u` should be used as the first row of `y`. When all columns are to be included, this is equivalent to `y(1,:) = u(1,:)`.

  For columns, this specifies that the first column of `u` should be used as the first column of `y`. When all rows are to be included, this is equivalent to `y(:,1) = u(:,1)`.
- `Index`

  For rows, this specifies that the row of `u`, `firstrow`, forward-indexed by the **Row index** parameter or the **Starting row index** parameter, should be used as the first row of `y`. When all columns are to be included, this is equivalent to `y(1,:) = u(firstrow,:)`.

  For columns, this specifies that the column of `u`, forward-indexed by the **Column index** parameter or the **Starting column index** parameter, `firstcol`, should be used as the first column of `y`. When all rows are to be included, this is equivalent to `y(:,1) = u(:,firstcol)`.
- `Offset from last`

  For rows, this specifies that the row of `u` offset from row *M* by the **Row offset** or **Starting row offset** parameter, `firstrow`, should be used as the first row of `y`. When all columns are to be included, this is equivalent to `y(1,:) = u(M-firstrow,:)`.

For columns, this specifies that the column of `u` offset from column *N* by the **Column offset** or **Starting column offset** parameter, `firstcol`, should be used as the first column of `y`. When all rows are to be included, this is equivalent to `y(:,1) = u(:,N-firstcol)`.

- `Last`

  For rows, this specifies that the last row of `u` should be used as the only row of `y`. When all columns are to be included, this is equivalent to `y = u(M,:)`.

  For columns, this specifies that the last column of `u` should be used as the only column of `y`. When all rows are to be included, this is equivalent to `y = u(:,N)`.

- `Offset from middle`

  When you select this option, the block selects the first row or column of the output `y` by adding the specified offset to the middle row or column of the input `u`. When the number, *X*, of input rows or columns is even, the block defines the middle one as *X*/2 +1. When the number of input rows or columns is odd, the block defines the middle one as **`ceil`**(*X*/2).

  When all columns are to be included, the following code defines the starting row: `y(1,:) = u(MiddleRow+Offset,:)`, where `Offset` is the value of the **Row offset** or **Starting row offset** parameter. When all rows are to be included, the following code defines the starting column: `y(1,:) = u(:,MiddleColumn+Offset)`, where `Offset` is the value of the **Column offset** or **Starting column offset** parameter.

- `Middle`

  When you select this option, the block uses the middle row or column of the input `u` as the first row or column of the output `y`. When the number, *X*, of input rows or columns is even, the block defines the middle one as *X*/2 +1. When the number of input rows or columns is odd, the block defines the middle one as **`ceil`**(*X*/2).

  When all columns are to be included, the following code defines the starting row: `y = u(MiddleRow,:)`. When all rows are to be included, the following code defines the starting column: `y = u(:,MiddleColumn)`.

The **Ending row** or **Ending column** can similarly be specified in five ways:

- `Index`

For rows, this specifies that the row of `u` forward-indexed by the **Ending row index** parameter, `lastrow`, should be used as the last row of `y`. When all columns are to be included, this is equivalent to `y(end,:) = u(lastrow,:)`.

For columns, this specifies that the column of `u` forward-indexed by the **Ending column index** parameter, `lastcol`, should be used as the last column of `y`. When all rows are to be included, this is equivalent to `y(:,end) = u(:,lastcol)`.

- `Offset from last`

  For rows, this specifies that the row of `u` offset from row *M* by the **Ending row offset** parameter, `lastrow`, should be used as the last row of `y`. When all columns are to be included, this is equivalent to `y(end,:) = u(M-lastrow,:)`.

  For columns, this specifies that the column of `u` offset from column *N* by the **Ending column offset** parameter, `lastcol`, should be used as the last column of `y`. When all rows are to be included, this is equivalent to `y(:,end) = u(:,N-lastcol)`.

- `Last`

  For rows, this specifies that the last row of `u` should be used as the last row of `y`. When all columns are to be included, this is equivalent to `y(end,:) = u(M,:)`.

  For columns, this specifies that the last column of `u` should be used as the last column of `y`. When all rows are to be included, this is equivalent to `y(:,end) = u(:,N)`.

- `Offset from middle`

  When you select this option, the block selects the last row or column of the output `y` by adding the specified offset to the middle row or column of the input `u`. When the number, *X*, of input rows or columns is even, the block defines the middle one as *X*/2 +1. When the number of input rows or columns is odd, the block defines the middle one as **`ceil`**(*X*/2).

  When all columns are to be included, the following code defines the ending row: `y(end,:) = u(MiddleRow+Offset,:)`, where `Offset` is the value of the **Ending row offset** parameter. When all rows are to be included, the following code defines the ending column: `y(:,end) = u(:,MiddleColumn+Offset)`, where `Offset` is the value of the **Ending column offset** parameter.

- `Middle`

When you select this option, the block uses the middle row or column of the input `u` as the last row or column of the output `y`. When the number, *X*, of input rows or columns is even, the block defines the middle one as *X*/2 +1. When the number of input rows or columns is odd, the block defines the middle one as **`ceil`**(*X*/2).

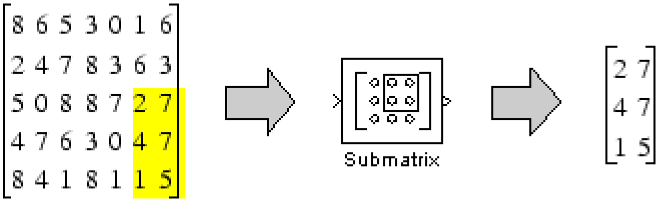
When all columns are to be included, the following code defines the ending row: `y(end,:) = u(MiddleRow,:)`. When all rows are to be included, the following code defines the ending column: `y(:,end) = u(:,MiddleColumn)`.

This block supports Simulink virtual buses.

Examples

The ex_submatrix_ref model uses a Submatrix block to extract a 3-by-2 submatrix from the lower-right corner of a 5-by-7 input matrix.

The following figure shows the operation of the Submatrix block with a 5-by-7 input matrix of random integer elements, `randi([0 9],5,7)`.

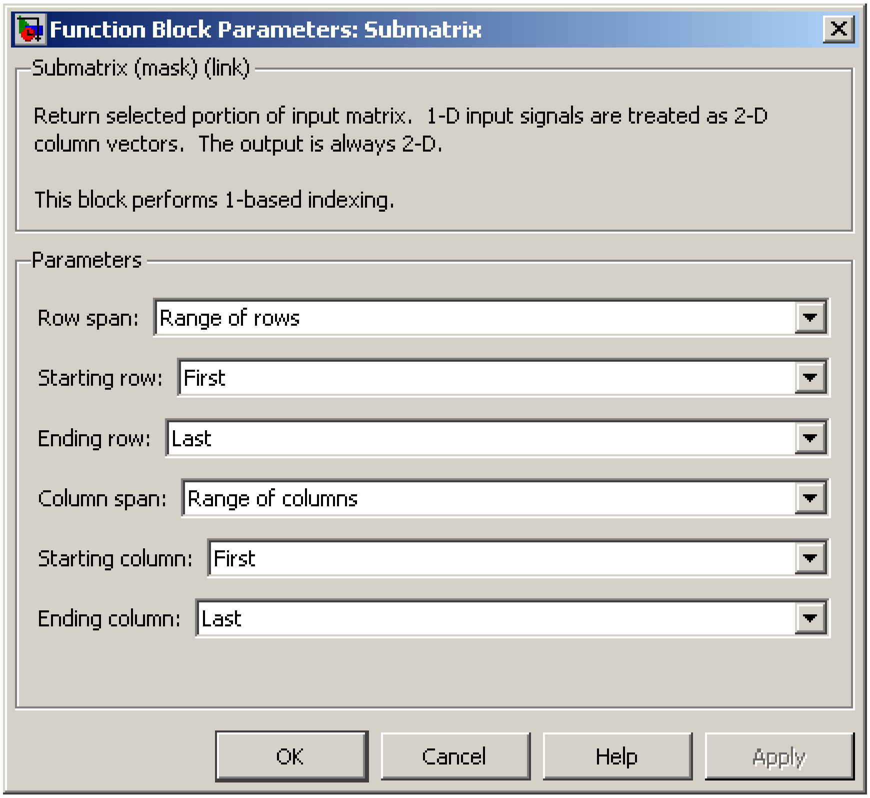


$$\begin{bmatrix} 8 & 6 & 5 & 3 & 0 & 1 & 6 \\ 2 & 4 & 7 & 8 & 3 & 6 & 3 \\ 5 & 0 & 8 & 8 & 7 & 2 & 7 \\ 4 & 7 & 6 & 3 & 0 & 4 & 7 \\ 8 & 4 & 1 & 8 & 1 & 1 & 5 \end{bmatrix} \quad \begin{bmatrix} 2 & 7 \\ 4 & 7 \\ 1 & 5 \end{bmatrix}$$

There are often several possible parameter combinations that you can use to select the *same* submatrix from the input. For example, in the case of a 5-by-7 input matrix, instead of specifying `Last` for **Ending column**, you could select the same submatrix by specifying

- **Ending column** = `Index`
- **Ending column index** = `7`

Dialog Box



Function Block Parameters: Submatrix

Submatrix (mask) (link)

Return selected portion of input matrix. 1-D input signals are treated as 2-D column vectors. The output is always 2-D.

This block performs 1-based indexing.

Parameters

Row span: Range of rows

Starting row: First

Ending row: Last

Column span: Range of columns

Starting column: First

Ending column: Last

The parameters displayed in the dialog box vary for different menu combinations. Only some of the parameters listed below are visible in the dialog box at any one time.

Row span

The range of input rows to be retained in the output. Options are `All rows`, `One row`, or `Range of rows`.

Row/Starting row

The input row to be used as the first row of the output. **Row** is enabled when you select `One row` from **Row span**, and **Starting row** when you select `Range of rows` from **Row span**.

Row index/Starting row index

The index of the input row to be used as the first row of the output. **Row index** is enabled when you select `Index` from Row, and **Starting row index** when you select `Index` from **Starting row**.

Row offset/Starting row offset

The offset of the input row to be used as the first row of the output. **Row offset** is enabled when you select `Offset from middle` or `Offset from last` from **Row**, and Starting row offset is enabled when you select `Offset from middle` or `Offset from last` from **Starting row**.

Ending row

The input row to be used as the last row of the output. This parameter is enabled when you select `Range of rows` from **Row span** and you select any option but `Last` from **Starting row**.

Ending row index

The index of the input row to be used as the last row of the output. This parameter is enabled when you select `Index` from **Ending row**.

Ending row offset

The offset of the input row to be used as the last row of the output. This parameter is enabled when you select `Offset from middle` or `Offset from last` from **Ending row**.

Column span

The range of input columns to be retained in the output. Options are `All columns`, `One column`, or `Range of columns`.

Column/Starting column

The input column to be used as the first column of the output. **Column** is enabled when you select `One column` from **Column span**, and **Starting column** is enabled when you select `Range of columns` from **Column span**.

Column index/Starting column index

The index of the input column to be used as the first column of the output. **Column index** is enabled when you select `Index` from Column, and **Starting column index** is enabled when you select `Index` from **Starting column**.

Column offset/Starting column offset

The offset of the input column to be used as the first column of the output. **Column offset** is enabled when you select `Offset from middle` or `Offset from last` from Column. **Starting column offset** is enabled when you select `Offset from middle` or `Offset from last` from **Starting column**.

Ending column

The input column to be used as the last column of the output. This parameter is enabled when you select `Range of columns` from **Column span** and you select any option but `Last` from **Starting column**.

Ending column index

The index of the input column to be used as the last column of the output. This parameter is enabled when you select `Index` from **Ending column**.

Ending column offset

The offset of the input column to be used as the last column of the output. This parameter is enabled when you select `Offset from middle` or `Offset from last` from **Ending column**.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers • Enumerated
Output	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers • Enumerated

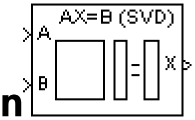
SVD Solver

Solve *AX*=*B* using singular value decomposition

Library

Math Functions / Matrices and Linear Algebra / Linear System Solvers

`dspsolvers`



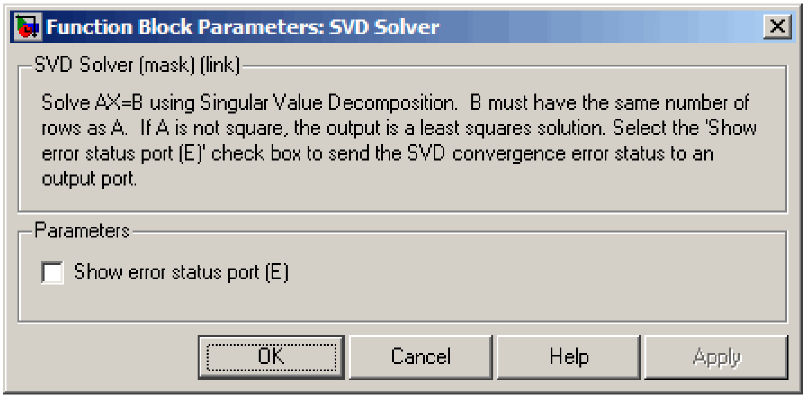
Description

The SVD Solver block solves the linear system *AX*=*B*, which can be overdetermined, underdetermined, or exactly determined. The system is solved by applying singular value decomposition (SVD) factorization to the *M*-by-*N* matrix *A*, at the A port. The input to the B port is the right side *M*-by-*L* matrix, *B*. The block treats length-*M* unoriented vector input as an *M*-by-1 matrix.

The output at the X port is the *N*-by-*L* matrix, *X*. *X* is chosen to minimize the sum of the squares of the elements of *B*-*AX* (the residual). When *B* is a vector, this solution minimizes the vector 2-norm of the residual. When *B* is a matrix, this solution minimizes the matrix Frobenius norm of the residual. In this case, the columns of *X* are the solutions to the *L* corresponding systems AX_k=B_k, where B_k is the *k*th column of *B*, and X_k is the *k*th column of *X*.

X is known as the minimum-norm-residual solution to *AX*=*B*. The minimum-norm-residual solution is unique for overdetermined and exactly determined linear systems, but it is not unique for underdetermined linear systems. Thus when the SVD Solver block is applied to an underdetermined system, the output *X* is chosen such that the number of nonzero entries in *X* is minimized.

Dialog Box



Function Block Parameters: SVD Solver

SVD Solver (mask) (link)

Solve AX=B using Singular Value Decomposition. B must have the same number of rows as A. If A is not square, the output is a least squares solution. Select the 'Show error status port (E)' check box to send the SVD convergence error status to an output port.

Parameters

□ Show error status port (E)

Show error status port

Select to enable the E output port, which reports a failure to converge. The possible values you can receive on the port are:

- 0 — The singular value decomposition calculation converges.
- 1 — The singular value decomposition calculation does not converge.

If the singular value decomposition calculation fails to converge, the output at port X is an undefined matrix of the correct size.

Supported Data Types

Port	Supported Data Types
A	• Double-precision floating point • Single-precision floating point
B	• Double-precision floating point • Single-precision floating point
X	• Double-precision floating point • Single-precision floating point
E	• Boolean

Time Scope

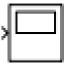
Display time-domain signals

Library

Sinks

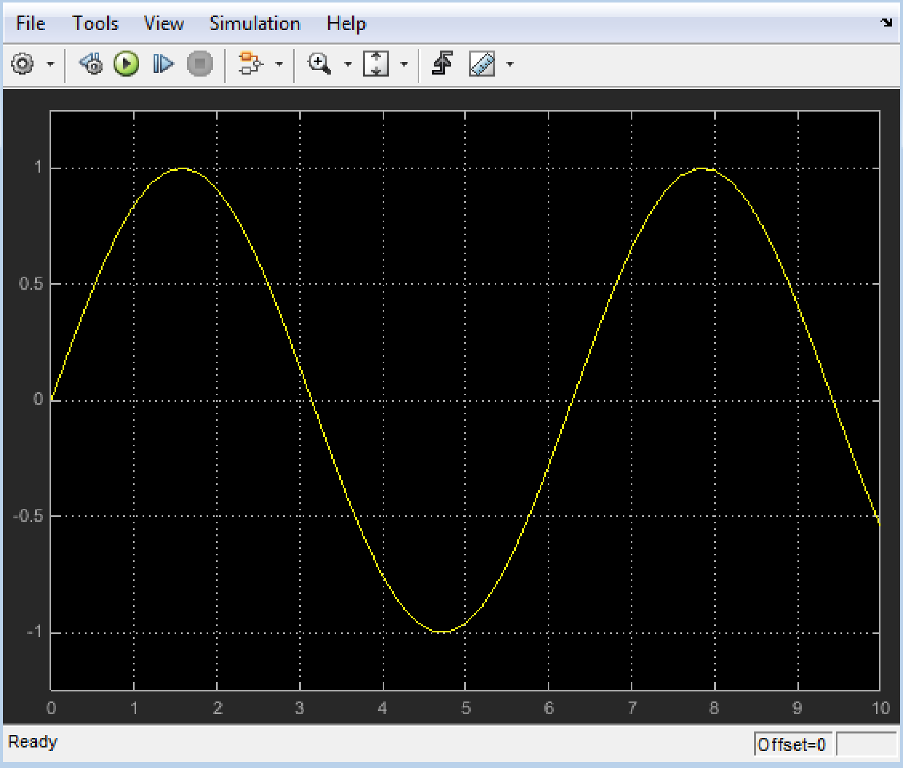
`dspsnks4`

Description



The Time Scope block displays signals in the time domain. The Time Scope block accepts input signals with the following characteristics:

- Continuous or discrete sample time
- Real- or complex-valued
- Fixed or variable size dimensions
- Floating- or fixed-point data type
- N-dimensional
- Simulink enumerations



You can use the Time Scope block in models running in Normal or Accelerator simulation modes. You can also use the Time Scope block in models running in Rapid Accelerator or External simulation modes, with some limitations. See the “Supported Simulation Modes” on page 1-1471 section for more information.

You can use the Time Scope block inside of all subsystems and conditional subsystems. *Conditional subsystems* include enabled subsystems, triggered subsystems, enabled and triggered subsystems, and function-call subsystems. See “Conditional Subsystems” in the Simulink documentation for more information.

For an example that uses the Time Scope block, see the “Display Time-Domain Data” section in the DSP System Toolbox documentation.

See the following sections for more information on the Time Scope:

- “Displaying Multiple Signals” on page 1-1382

Note: For information about the Time Scope System object, see `dsp.TimeScope`.

For information on controlling the Time Scope programmatically, see `Simulink.scopes.TimeScopeConfiguration` and “Control Time Scope Programmatically” in the Simulink documentation.

Displaying Multiple Signals

Multiple Signal Input

You can configure the Time Scope block to show multiple signals within the same display or on separate displays. By default, the signals appear as different-colored lines on the same display. The signals can have different dimensions, sample rates, and data types. Each signal can be either real or complex valued. You can set the number of input ports on the Time Scope block in the following ways:

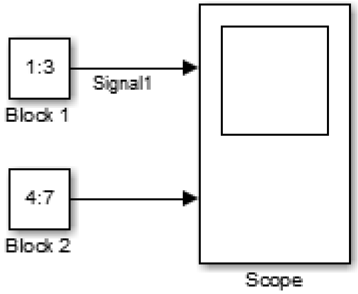
- Right-click the Time Scope block in your model to bring up the context menu. Point your cursor to the **Signals & Ports** > **Number of Input Ports** item on the context menu. You can then select the number of input ports for the Time Scope block. If the desired number of input signals is 1, 2, or 3, then click on the appropriate value. To configure a Time Scope block to have more than three input ports, select **More**, and enter a number for the **Number of input ports** parameter.

- Open the Time Scope window by double-clicking the Time Scope block in your model. In the scope menu, select **File** > **Number of Input Ports**.
- Open the Time Scope window by double-clicking the Time Scope block in your model. In the scope menu, select **View** > **Configuration Properties** and set the **Number of input ports** on the **Main** tab.

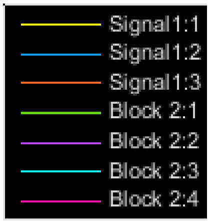
An input signal may contain multiple channels, depending on its dimensions. Multiple channels of data are always shown as different-colored lines on the same display.

Multiple Signal Names

By default, the scope names each channel according to either its signal name or the name of the block from which it comes. If the signal has multiple channels, the scope uses an index number to identify each channel of that signal. For example, a 2-channel signal named `Signal1` would have the following default names in the channel legend: `Signal1:1`, `Signal1:2`. In the following example, there is one 3-channel input signal and one 4-channel input signal to the scope block, one signal named `Signal1` and one unnamed signal coming from a block named `Block2`.



To see all the signal names, run the simulation and show the legend. To show the legend, select **View** > **Configuration Properties**, click the **Display** tab, and select the **Show Legend** check box. The following legend appears in the display.



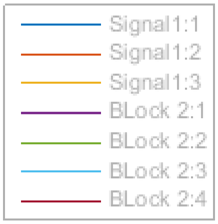
Note: Continuous signals appear as straight lines in the legend. Discrete signals appear as step-shaped lines.

The scope does not display signal names that were labeled within an unmasked subsystem. You must label all input signals to the scope block that originate from an unmasked subsystem.

Multiple Signal Colors

By default, the scope has a black axes background and chooses line colors for each channel in the same manner as the Simulink Scope block. When the scope axes background is black, it assigns each channel of each input signal a line color in the order shown above.

If there are more than 7 channels, then the scope repeats this order to assign line colors to the remaining channels. To choose line colors for each channel in the same manner as the MATLAB `plot` function, change the axes background color to any color except black. To change the axes background color to white, select **View** > **Style**, click the Axes background color button (), and select white from the color palette. Run the simulation again. The following legend appears in the display.



When the scope axes background is not black, it assigns each channel of each input signal a line color in order shown above.If there are more than 7 channels, then the scope repeats this order to assign line colors to the remaining channels. To manually modify any line color, select **View** > **Style** to open the Style dialog box. Next to **Properties for line**, select the signal name whose color you want to change. Then, next to **Line**, click the Line color button (✎) and select any color from the palette.

Multiple Time Offsets

You can offset all channels of an input signal by the same number of seconds or offset each channel independently. To offset all channels equally, select **View** > **Configuration Properties**, and specify a scalar value for the **Time display offset** parameter on the **Main** pane. To offset each channel independently, specify a vector of offset values. When you specify a **Time display offset** vector of length *N*, the scope offsets the input channels as follows:

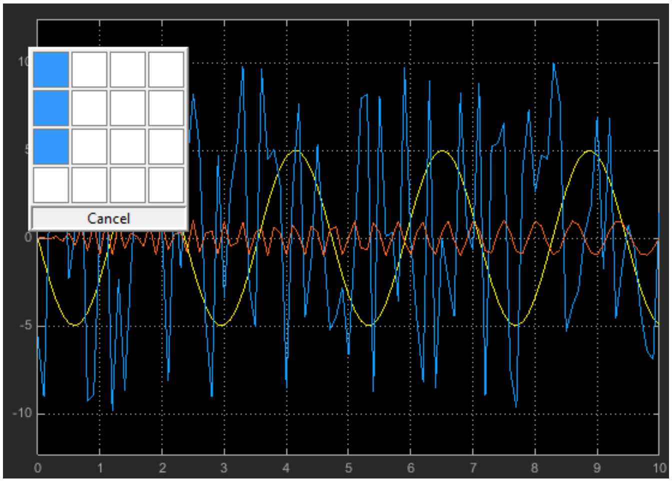
- When *N* is equal to the number of input channels, the scope offsets each channel according to its corresponding value in the offset vector.
- When *N* is less than the number of input channels, the scope applies the values you specify in the offset vector to the first *N* input channels. The scope does not offset the remaining channels.
- When *N* is greater than the number of input channels, the scope offsets each input channel according to the corresponding value in the offset vector. The scope ignores all values in the offset vector that do not correspond to a channel of the input.

Multiple Displays

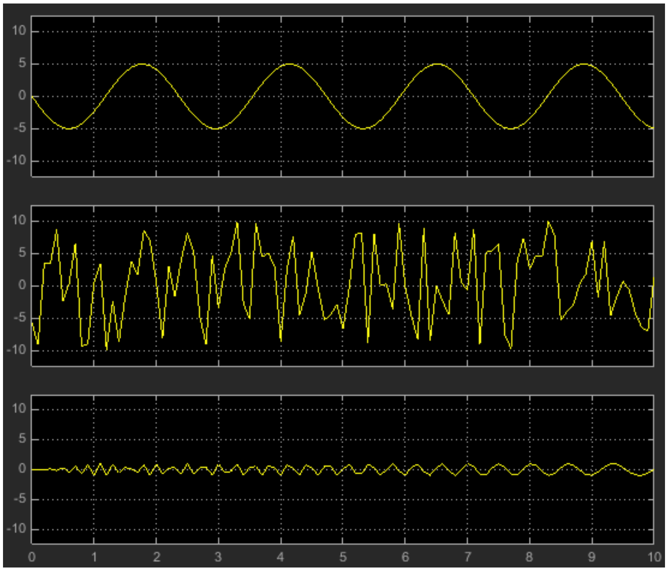
You can display multiple channels of data on different displays in the scope window. In the scope toolbar, select **View** > **Layout**, or select the Layout button (⊞) in the dropdown below the Configuration Properties button.

Note: The **Layout** menu item and button are not available when the scope is in snapshot mode.

This feature allows you to tile the window into a number of separate displays, up to a grid of 4 rows and 4 columns. For example, if there are three inputs to the scope, you can display the signals in separate displays by selecting row 3, column 1, as shown in the following figure.



After you select row 3, column 1, the scope window is partitioned into three separate displays, as shown in the following figure.

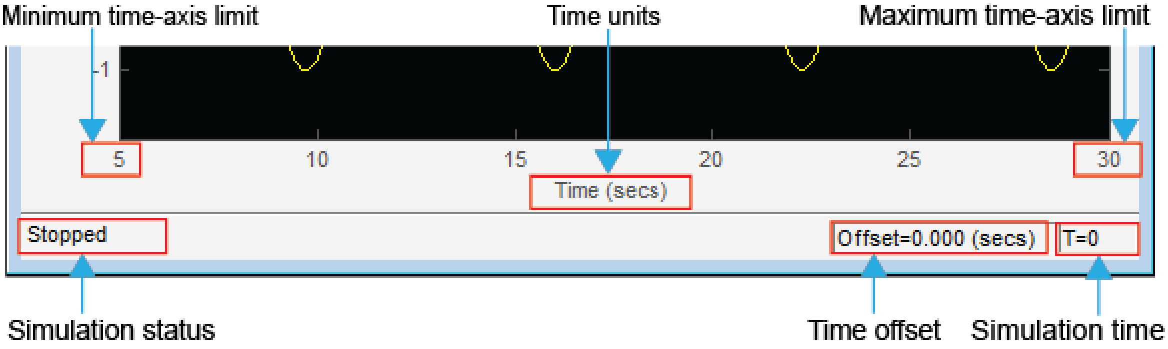


When you use the Layout option to tile the window into multiple displays, the display highlighted in yellow is referred to as the *active display*. The scope dialog boxes reference the active display.

Signal Display

Time Scope uses the simulation start time and stop time in order to determine the default time range. However, you can define the length of simulation time for which the Time Scope displays data. To change the signal display settings, select **View > Configuration Properties** to bring up the Configuration Properties dialog box. Then, modify the values for the **Time span** and **Time display offset** parameters on the **Time** tab. For example, if you set the **Time span** to `20` seconds and the **Time display offset** to `0`, the scope displays 20 seconds' worth of simulation data at a time. The values on the *time*-axis of the Time Scope display remain the same throughout simulation.

To communicate the simulation time that corresponds to the current display, the scope uses the **Time units**, **Time offset**, and **Simulation time** indicators on the scope window. The following figure highlights these and other important aspects of the Time Scope window.



Note: To prevent the scope from opening when you run your model, right-click on the scope icon and select `Comment Out`. If the scope is already open, you can still comment it out in the model. When you do so, the scope displays a message, "No data can be shown because this scope is commented out." Select `Uncomment` to turn the scope back on.

- **Minimum time-axis limit** — The Time Scope sets the minimum *time*-axis limit using the value of the **Time display offset** parameter on the **Main** tab of the Visuals —Time Domain Properties dialog box. If you specify a vector of values for the **Time display offset** parameter, the scope uses the smallest of those values to set the minimum *time*-axis limit.

- **Maximum time-axis limit** — The Time Scope sets the maximum *time*-axis limit by summing the value of **Time display offset** parameter with the value of the **Time span** parameter. If you specify a vector of values for the **Time display offset** parameter, the scope sets the maximum *time*-axis limit by summing the largest of those values with the value of the **Time span** parameter.
- **Simulation status** — Provides the current status of the model simulation. The status can be one of the following conditions:

  - `Initializing`
  - `Ready`
  - `Running`
  - `Paused`

  The **Simulation status** is part of the **Status Bar** in the Time Scope window. You can choose to hide or display the entire **Status Bar**. From the Time Scope menu, select **View** > **Status Bar**.
- **Time units** — The units used to describe the *time*-axis. The Time Scope sets the time units using the value of the **Time Units** parameter on the **Time** tab of the Configuration Properties dialog box. By default, this parameter is set to `Metric (based on Time Span)` and displays in metric units such as milliseconds, microseconds, minutes, days, etc. You can change it to `Seconds` to always display the *time*-axis values in units of seconds. You can change it to `None` to not display any units on the *time*-axis. When you set this parameter to `None`, then Time Scope shows only the word `Time` on the *time*-axis.

  To hide both the word `Time` and the values on the *time*-axis, set the **Show time-axis labels** parameter to `None`. To hide both the word `Time` and the values on the *time*-axis in all displays except the bottom ones in each column of displays, set this parameter to `Bottom Displays Only`. This behavior differs from the Simulink Scope block, which always shows the values but never shows a label on the *x*-axis.
- **Time offset** — The **Time offset** value helps you determine the simulation times for which the scope is displaying data. The value is always in the range `0`≤ `Time offset`≤ **Simulation time**. Therefore, add the Time offset to the fixed time span values on the *time*-axis to get the overall simulation time.

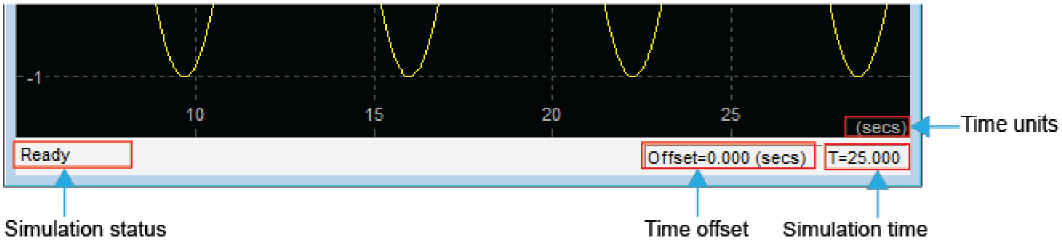
  For example, if you set the **Time span** to `20` seconds, and you see a **Time offset** of `0 (secs)` on the scope window. This value indicates that the scope is displaying data for the first `0` to `20` seconds of simulation time. If the **Time offset** changes to `20` `(secs)`, the scope displays data for simulation times from 20 seconds to 40 seconds. The scope continues to update the **Time offset** value until the simulation is complete.

- **Simulation time** — When the model is running or simulation has been paused, the scope displays the current simulation time. This time is the amount of time that the Time Scope has spent processing the input. If the model simulation completes or is stopped, the scope displays the time at which the simulation stopped. The **Simulation time** is part of the **Status Bar** in the Time Scope window. You can choose to hide or display the entire **Status Bar**. From the Time Scope menu, select **View** > **Status Bar** .

Note: In some situations, the Time Scope block simulation time can be different from the Simulink simulation time. For multirate input signals, which have different sample times, and input signals originating from conditionally-executed subsystems, such as Triggered and Enabled subsystems, separate Time Scope blocks may report different simulation times. The Time Scope block reports the simulation time as the time corresponding to the last point in the display.

Axes Maximization

When the scope is in maximized axes mode, the following figure highlights the important indicators on the scope window.



To toggle this mode, in the scope menu, select **View** > **Configuration Properties**. In the **Main** pane, locate the **Maximize axes** parameter.

Specify whether to display the scope in maximized axes mode. In this mode, each of the axes is expanded to fit into the entire display. To conserve space, labels do not appear in each display. Instead, tick-mark values appear on top of the plotted data. You can select one of the following options:

- `Auto` — In this mode, the axes appear maximized in all displays only if the `Title` and `YLabel` properties are empty for every display. If you enter any value in any display for either of these properties, the axes are not maximized.
- `On` — In this mode, the axes appear maximized in all displays. Any values entered into the `Title` and `YLabel` properties are hidden.
- `Off` — In this mode, none of the axes appear maximized.

This property is "Tunable".

The default setting is `Auto`.

Reduce Updates to Improve Performance

By default, the scope updates the displays periodically at a rate not exceeding 20 hertz. If you would like the scope to update on every simulation time step, you can disable the **Reduce Updates to Improve Performance** option. However, as a recommended practice, leave this option enabled because doing so can significantly improve the speed of the simulation.

In the Time Scope menu, select **Simulation** > **Reduce Updates to Improve Performance** to clear the check box. Alternatively, use the **Ctrl+R** shortcut to toggle this setting.

Toolbar

The Time Scope toolbar contains the following buttons. You can control whether this toolbar appears in the Time Scope window. From the Time Scope menu, select **View** > **Toolbar**.

Configuration Properties Buttons

Button	Menu Location	Shortcut Keys	Description
⚙	**View** > **Configuration Properties**	N/A	Open the **Configuration Properties** dialog box.

			See the “Configuration Properties Dialog Box” on page 1-1436 section for more information.
	View > Style	N/A	You access the Style button from the menu under the Configuration Properties icon. Configure the scope display. You can change the color of the figure containing the displays, the background and foreground colors of display axes, and properties of lines in a display. See the “Style Dialog Box” on page 1-1450 section for more information.
⊞	**View > Layout**	N/A	You access the Layout button from the menu under the Configuration Properties icon. Arrange the layout of displays in the Time Scope. This feature allows you to tile your screen into a number of separate displays, up to a grid of 4 rows and 4 columns. You may find multiple displays useful when the Time Scope takes multiple input signals. The default display is 1 row and 1 column. See the “Multiple Displays” on page 1-1385 section for more information.

Simulation Buttons

Button	Menu Location	Shortcut Keys	Description
	Simulation > Stepping Options	N/A	Open the **Simulation Stepping Options** dialog box. This button appears only when you have stepping backward disabled. See the “Stepping Options” on page 1-1453 section for more information.
◁	**Simulation > Step Back**	N/A	Advance the model simulation backward by one time step. This button appears only when you have stepping backward enabled and the model simulation is paused.
▶	**Simulation > Run**	**Ctrl+T**, **p**, **Space**	Start the model simulation. This button appears only when the model simulation is stopped.

Button	Menu Location	Shortcut Keys	Description
▶	**Simulation > Continue**	**p**, **Space**	Continue the model simulation. This button appears only when the model simulation is paused.
⏸	**Simulation > Pause**	**p**, **Space**	Pause the model simulation. This button appears only when the model simulation is running.
⏵	**Simulation > Step Forward**	**Right arrow**, **Page Down**	Advance the model simulation forward by one time step. This button starts the model simulation, allows it to run for one time step, and then pauses it again. The scope window then updates with the latest data.
■	**Simulation > Stop**	**Ctrl+T**, **s**	Stop the model simulation. This button appears only when the model simulation is running or paused.
	View > Highlight Simulink Block	**Ctrl+L**	Bring the model window forward, and highlight the Time Scope block whose display you are currently viewing. The Time Scope block that corresponds to the active Time Scope window flashes three times in the model.
📷	**Simulation > Simulink Snapshot**	N/A	You access the Simulation Snapshot button from the menu under the Highlight Simulink Block icon. Take a snapshot of the current scope display. This button temporarily freezes the scope display, while allowing simulation to continue running. To unfreeze the scope display and view the current simulation data, toggle this button to turn off snapshot mode. Snapshot mode is not available if the scope is commented out in the block diagram.

To see a full listing of the shortcut keys for these simulation controls, from the Time Scope menu, select **Help > Keyboard Command Help**.

Zoom and Axes Control Buttons

Button	Menu Location	Shortcut Keys	Description
🔍	**Tools > Zoom In**	N/A	When this tool is active, you can zoom in on the scope window. To do so, click in the center of your area of interest, or click and drag your cursor to draw a rectangular area of interest inside the scope window.
↔	**Tools > Zoom X**	N/A	You access the Zoom X button from the menu under the Zoom In icon. When this tool is active, you can zoom in on the *x*-axis. To do so, click inside the scope window, or click and drag your cursor along the *x*-axis over your area of interest.
↕	**Tools > Zoom Y**	N/A	You access the Zoom Y button from the menu under the Zoom In icon. When this tool is active, you can zoom in on the *y*-axis. To do so, click inside the scope window, or click and drag your cursor along the *y*-axis over your area of interest.
✋	**Tools > Pan**	N/A	You access the Pan button from the menu under the Zoom In icon. When this tool is active, you can pan on the scope window. To do so, click in the center of your area of interest and drag your cursor to the left, right, up, or down, to move the position of the display.
⇕	**Tools > Scale Y-Axis Limits**	**Ctrl+A**	Click this button to scale the axes in the active scope window. Alternatively, you can enable automatic axes scaling by selecting one of the following options from the **Tools** menu: • **Automatically Scale Axes Limits** — When you select this option, the scope scales the axes as needed during simulation. • **Scale Axes Limits after 10 Updates** — When you select this option, the scope scales

Button	Menu Location	Shortcut Keys	Description
			the axes after 10 updates. The scope does not scale the axes again during the simulation. • **Scale Axes Limits at Stop** — When you select this option, the scope scales the axes each time the simulation is stopped.
↔	**Tools > Scale X-Axis Limits**	N/A	You access the Scale X-Axis Limits button from the menu under the current Axis Limits icon. Click this button to scale the axes in the X direction in the active scope window. Alternatively, you can enable automatic axes scaling by selecting one of the following options from the **Tools** menu: • **Automatically Scale Axes Limits** — When you select this option, the scope scales the axes as needed during simulation. • **Scale Axes Limits after 10 Updates** — When you select this option, the scope scales the axes after 10 updates. The scope does not scale the axes again during the simulation. • **Scale Axes Limits at Stop** — When you select this option, the scope scales the axes each time the simulation is stopped.

Button	Menu Location	Shortcut Keys	Description
	Tools > Scale X & Y Axes Limits	N/A	You access the Scale X & Y Axes Limits button from the menu under the current Axis Limits icon. Click this button to scale the axes in both the X and Y directions in the active scope window. Alternatively, you can enable automatic axes scaling by selecting one of the following options from the **Tools** menu: • **Automatically Scale Axes Limits** — When you select this option, the scope scales the axes as needed during simulation. • **Scale Axes Limits after 10 Updates** — When you select this option, the scope scales the axes after 10 updates. The scope does not scale the axes again during the simulation. • **Scale Axes Limits at Stop** — When you select this option, the scope scales the axes each time the simulation is stopped.

Measurements Buttons

	Tools > Triggers	N/A	Open or close the **Triggers** panel. This panel allows you to pause the display only when certain events occur. You can use the Triggers panel when you want to align or search for interesting events. Triggers can be configured to both select and align specific regions of interest in the display area of the scope. See the “Triggers Panel” on page 1-1398 section for more information.
	Tools > Measurements >	N/A	Open or close the **Cursor Measurements** panel. This panel puts screen cursors on all the displays.

	Cursor Measurements		See the "Cursor Measurements Panel" on page 1-1415 section for more information.
	Tools > **Measurements** > **Signal Statistics**	N/A	You access the Signal Statistics button from the menu under the current Measurements icon. Open or close the **Signal Statistics** panel. This panel displays the maximum, minimum, peak-to-peak difference, mean, median, RMS values of a selected signal, and the times at which the maximum and minimum occur. See the "Signal Statistics Panel" on page 1-1417 section for more information.
	Tools > **Measurements** > **Bilevel Measurements**	N/A	You access the Bilevel Measurements button from the menu under the current Measurements icon. Open or close the **Bilevel Measurements** panel. This panel displays information about a selected signal's transitions, overshoots or undershoots, and cycles. See the "Bilevel Measurements Panel" on page 1-1419 section for more information.
	Tools > **Measurements** > **Peak Finder**	N/A	You access the Peak Finder button from the menu under the current Measurements icon. Open or close the **Peak Finder** panel. This panel displays maxima and the times at which they occur, allowing the settings for peak threshold, maximum number of peaks, and peak excursion to be modified. See the "Peak Finder Panel" on page 1-1313 section for more information.

Measurements Panels

The Measurements panels are the panels that appear to the right side of the Time Scope GUI. These panels are labeled **Trace selection**, **Cursor measurements**,**Signal statistics**, **Bilevel measurements**, and **Peak finder**.

The Time Domain Measurements panels only appear if the **Measurements** tool is enabled in the Tools—Axes Scaling Properties dialog box. To open this dialog box, in the Time Scope menu, select **File** > **Configuration** and click the **Tools** pane. If you disable the tool by clearing the **Enabled** check box, the Time Domain Measurements tools no longer display in the Time Scope figure. You can reenable the tool at any time by selecting the **Enabled** check box. See the "Tools—Axes Scaling Properties" on page 1-1455 section for more information.

Measurements Panel Buttons

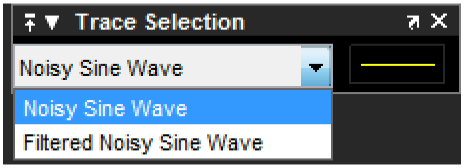
Each of the Measurements panels contains the following buttons that enable you to modify the appearance of the current panel.

Button	Description
⤒	Move the current panel to the top. When you are displaying more than one panel, this action moves the current panel above all the other panels.
▼	Collapse the current panel. When you first enable a panel, by default, it displays one or more of its panes. Click this button to hide all of its panes to conserve space. After you click this button, it becomes the expand button ▶.
▶	Expand the current panel. This button appears after you click the collapse button to hide the panes in the current panel. Click this button to display the panes in the current panel and show measurements again. After you click this button, it becomes the collapse button ▼ again.
↗	Undock the current panel. This button lets you move the current panel into a separate window that can be relocated anywhere on your screen. After you click this button, it becomes the dock button ↘ in the new window.
↘	Dock the current panel. This button appears only after you click the undock button. Click this button to put the current panel back into the right side of the Scope window. After you click this button, it becomes the undock button ↗ again.
✕	Close the current panel. This button lets you remove the current panel from the right side of the Scope window.

Some panels have their measurements separated by category into a number of panes. Click the pane expand button ▶ to show each pane that is hidden in the current panel. Click the pane collapse button ▼ to hide each pane that is shown in the current panel.

Trace Selection Panel

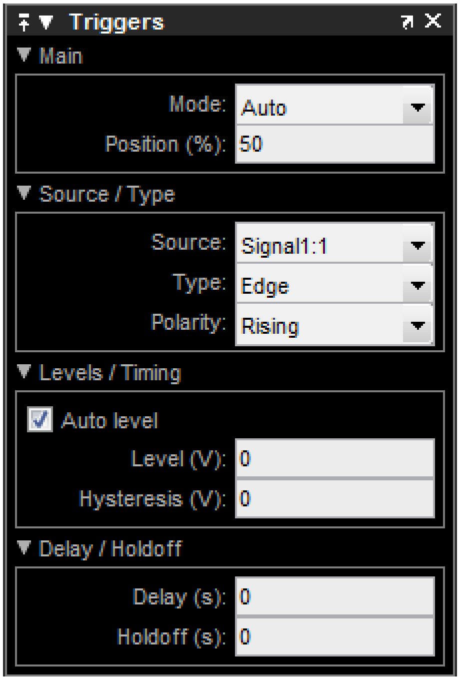
When you use the scope to view multiple signals, the Trace Selection panel appears if you have more than one signal displayed and you click on any of the other Measurements panels. The Measurements panels display information about only the signal chosen in this panel. Choose the signal name for which you would like to display time domain measurements. See the following figure.



You can choose to hide or display the **Trace Selection** panel. In the Scope menu, select **Tools** > **Measurements** > **Trace Selection**.

Triggers Panel

The **Triggers** panel allows you to pause the display only when certain events occur. You can use the Triggers panel when you want to align or search for interesting events. You can configure triggers to both select and align specific regions of interest in the display area of the scope. Triggers work across multiple displays. You can also choose to hide or display the **Triggers** panel. In the scope toolbar, click the Triggers button ( ). Alternatively, in the scope menu, select **Tools** > **Triggers**.



Triggers

Main

Mode: Auto

Position (%): 50

Source / Type

Source: Signal1:1

Type: Edge

Polarity: Rising

Levels / Timing

☑ Auto level

Level (V): 0

Hysteresis (V): 0

Delay / Holdoff

Delay (s): 0

Holdoff (s): 0

When the **Triggers** panel is displayed, triangle pointers appear at the top and right side of the axes on each display. These markers indicate the time position (▼) and level (◀) at the event. The color of the markers corresponds to the color of the source signal.

Note: The scope does not display an event until at least a full time span is completely viewable inside the display. To prevent data from being shown twice in the display, the scope suppresses the alignment of recurring events until a full time span has elapsed since the previous update.

Main Pane

The **Main** pane lets you choose how often the display updates and in what position the trigger indicator appears.

- **Mode** — Define how often the display should update.

  - **Auto** — The scope aligns and displays data from the latest trigger event. If no event is found after a full time span has elapsed, then the scope displays the last available data. Use this mode to see your data and have it align whenever a trigger event occurs.
  - **Normal** — The scope aligns and displays data only from the latest trigger event. Use this mode to search for infrequently occurring events in your data.
  - **Once** — The scope displays data on the next encountered trigger event and freezes the display. The scope ignores subsequent data until you press the **Rearm** button.
  - **Off** — The scope does not make acquisitions. Triggering is disabled. This setting is equivalent to hiding the **Triggers** panel. You can use panning only if **Mode** is set to **Off**.

  If mode is set to either **Normal** or **Once** and the Triggers panel does not encounter any event, the display remains blank. Set **Mode** to **Auto** if you want the scope to display signal data regularly, in addition to trigger events.

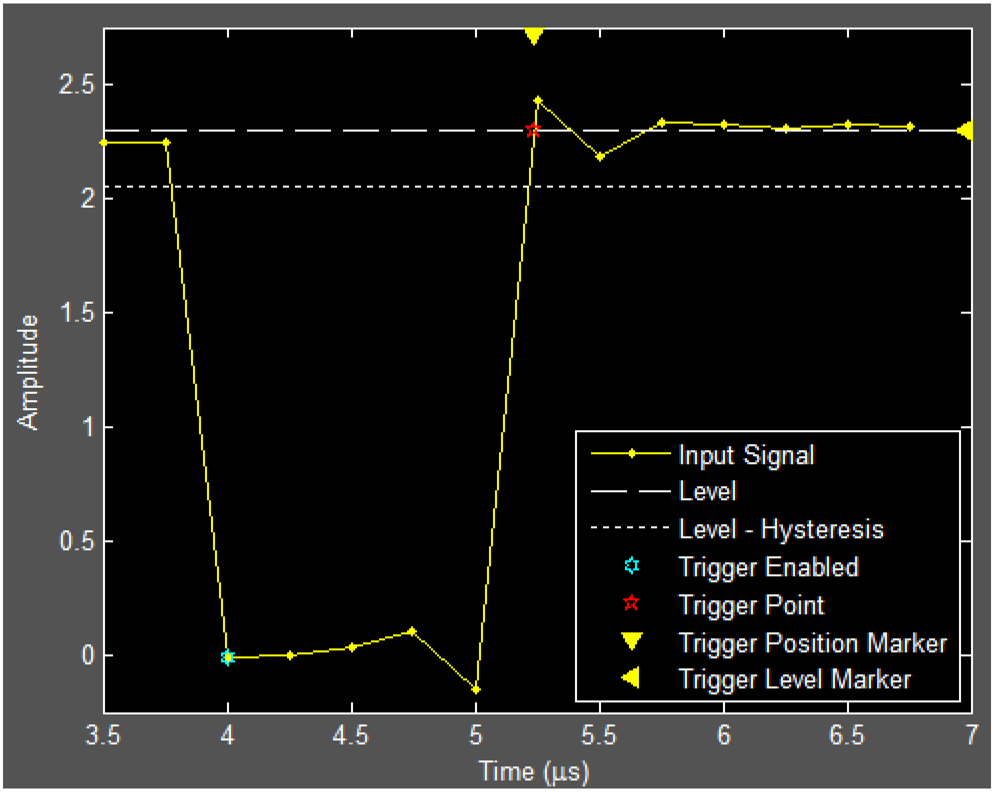
- **Position (%)** — Specify, as a percentage of the total time span within the active display, the horizontal position in which the trigger indicator appears. A position value of 0 corresponds to the minimum *time*-axis value at the far-left side of the display. A position value of 100 corresponds to the maximum *time*-axis value at the far-right side of the display. Drag the trigger position indicator to the left or right to adjust its position.

Source / Type Pane

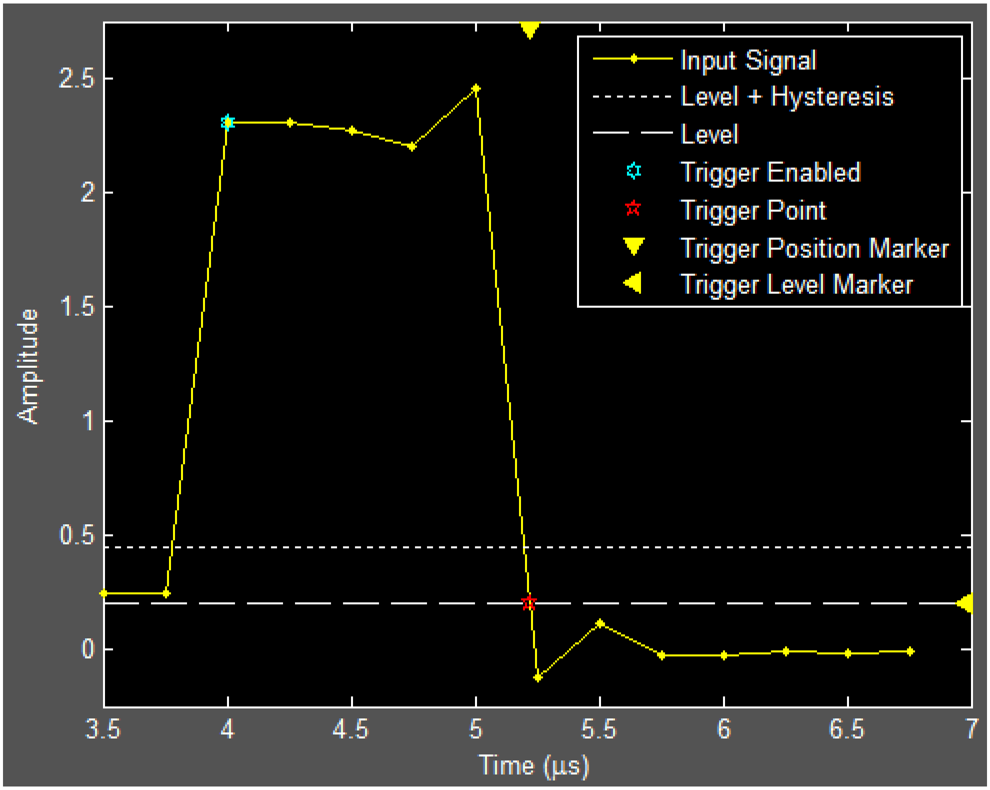
The **Source / Type** pane lets you choose the source of the trigger and the type of events on which to stop.

- **Source** — Assign the trigger source to a particular channel. If you are viewing a magnitude/phase plot, you can trigger off the magnitude or the phase. If you are not viewing the magnitude/phase plot, you can trigger off the real or imaginary data. If the input signal has multiple channels, the scope assigns an index number to identify each channel of that signal. For more information, see “Multiple Signal Input”.
- **Type** — Select the type of trigger to use.

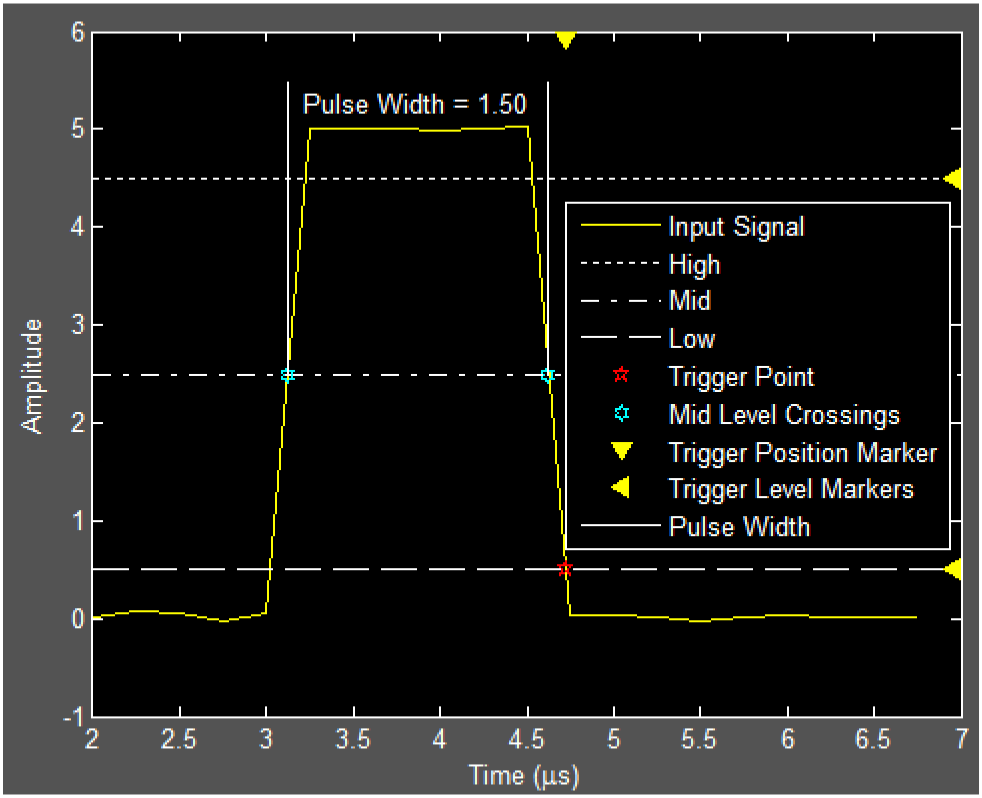
  - **Edge** — Trigger when the scope crosses a level threshold. In the case of a rising edge, the scope enables the trigger event when the signal value becomes less than the level threshold minus hysteresis. The scope disables the trigger event when the signal becomes greater than the level threshold for the first time. The scope uses linear interpolation to generate a trigger event at the time when the signal crosses the level threshold, as shown in the following figure.



In the case of a falling edge, the scope enables the trigger event when the signal value becomes greater than the level threshold plus hysteresis. The scope disables the trigger event when the signal becomes less than the level threshold for the first time. The scope uses linear interpolation to generate a trigger event at the time when the signal crosses the level threshold, as shown in the following figure.

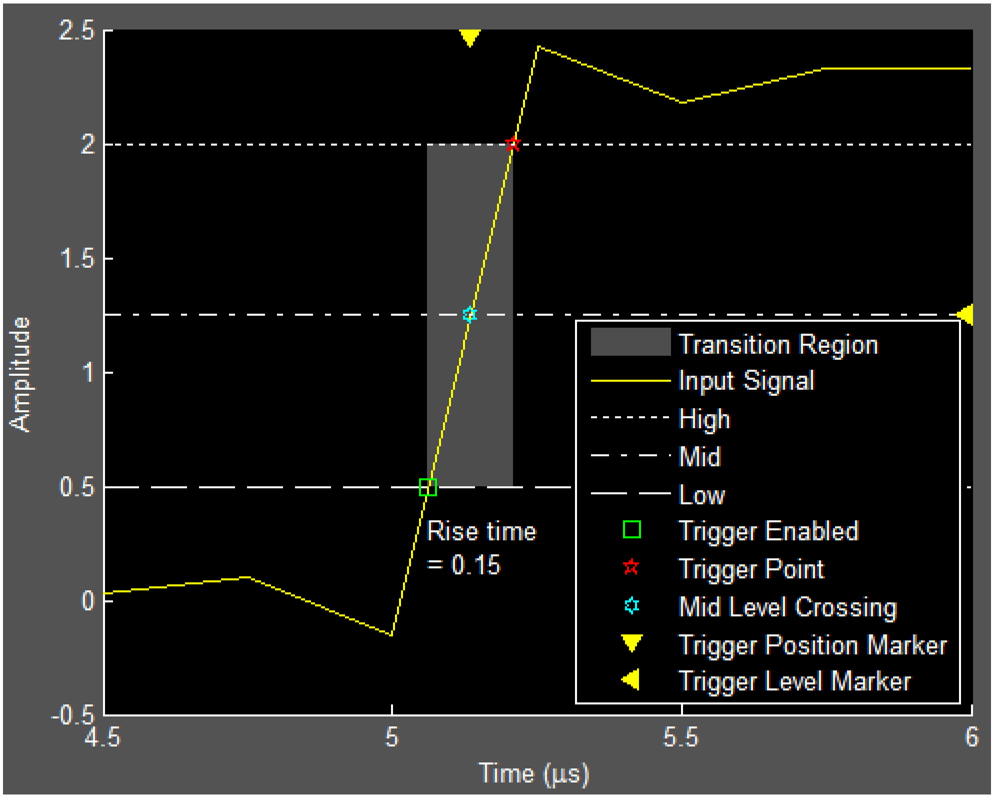


- **Pulse Width** — Trigger when the scope encounters a pulse whose width falls inside or outside specified time limits. You specify the range of valid time limits in the **Levels / Timing** pane. In the case of a positive-polarity pulse, the scope encounters a trigger event when the signal crosses the low threshold for the second time. The scope measures the pulse width as the time between the first and second crossings of the middle threshold, located halfway between the high and low thresholds, as shown in the following figure.

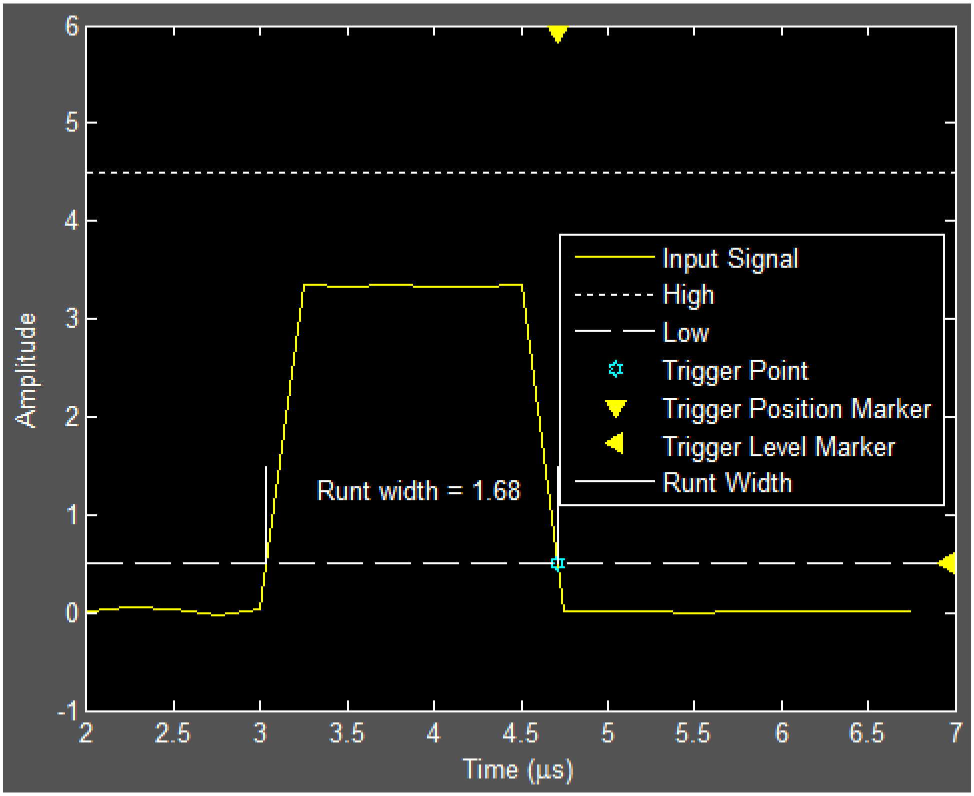


Note: A *Glitch*-type trigger looks for a pulse or spike whose duration is less than a specified amount. You can implement a *Glitch* type trigger by using a **Pulse Width** type trigger and manually setting the **Max Width** parameter.

- **Transition** — Trigger on a rising or falling edge that crosses two levels, high and low, inside or outside a specified time interval. You specify the range of valid transition times in the **Levels / Timing** pane. In the case of a rising transition, the scope encounters the trigger event when the signal crosses the high threshold. The transition time is when the signal crosses the middle threshold, located halfway between the high and low thresholds, as shown in the following figure.

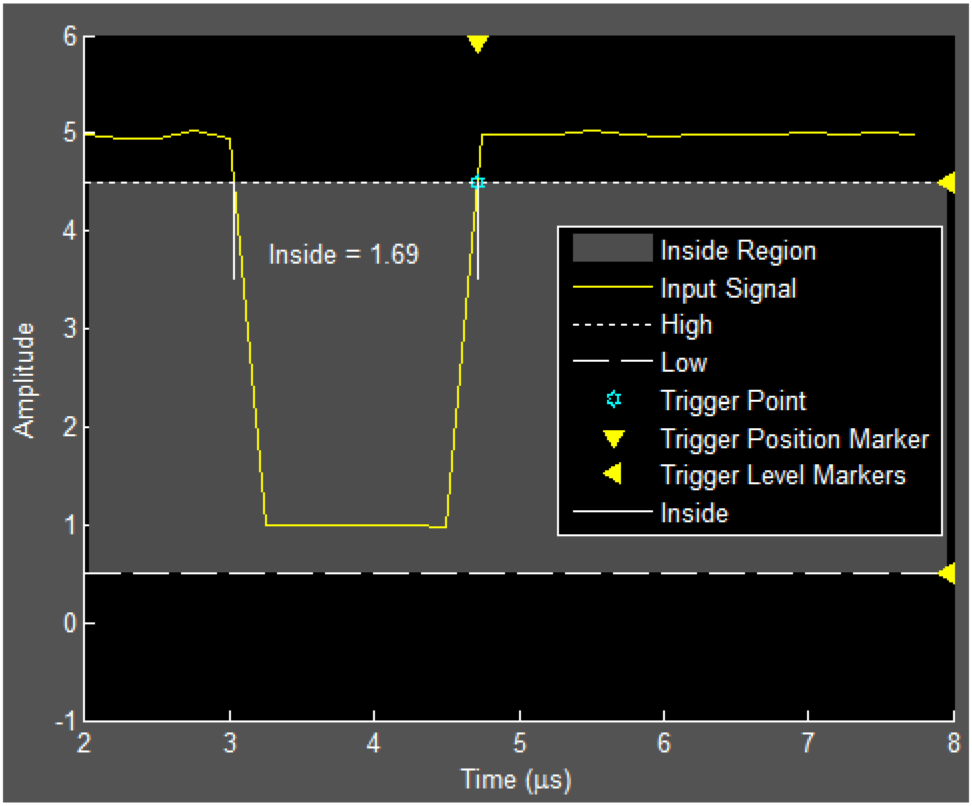


- **Runt** — Trigger on a runt pulse, which crosses one threshold, high or low, but not both. In the case of a positive-polarity runt pulse, the scope encounters a trigger event when the signal crosses the low threshold the second time, without ever crossing the high threshold. The scope measures the runt width as the time between the first and second crossings of the low threshold, as shown in the following figure. The runt width is the **Max Width** – **Min Width**. Any runt pulse width that is less than the minimum width or greater than the maximum width will not generate a trigger event.

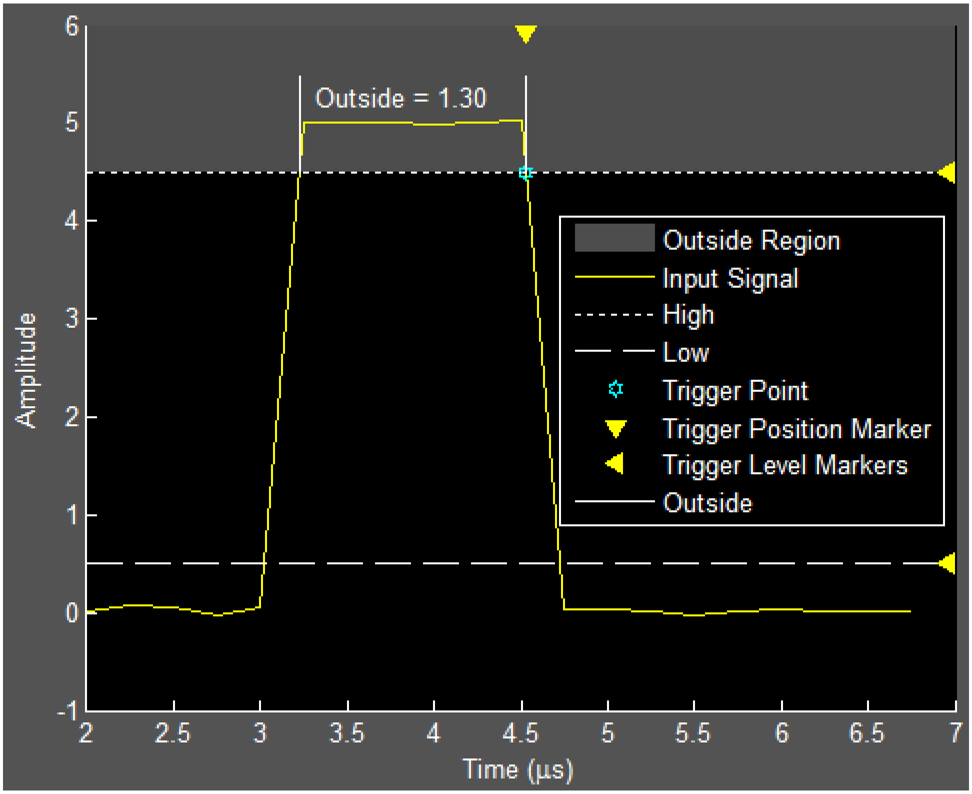


Note: You can also replicate a **Runt**-type trigger by using a **Window**-type trigger and setting **Polarity** to **Inside**.

- **Window** — Trigger when the input signal stays within or outside the region defined by the high and low thresholds for a period of time. In the case of an inside window, the scope encounters a trigger event when the signal enters and exits the inside region, as shown in the following figure.

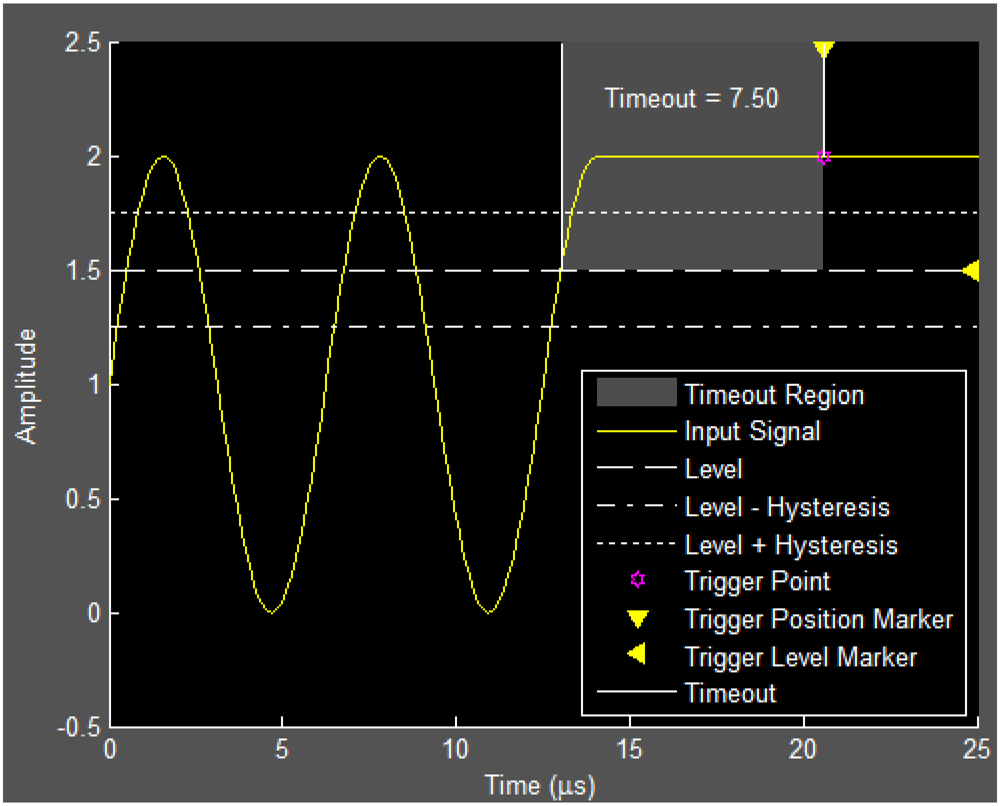


In the case of an outside window, the scope encounters a trigger event when the signal enters and exits the outside region, as shown in the following figure.

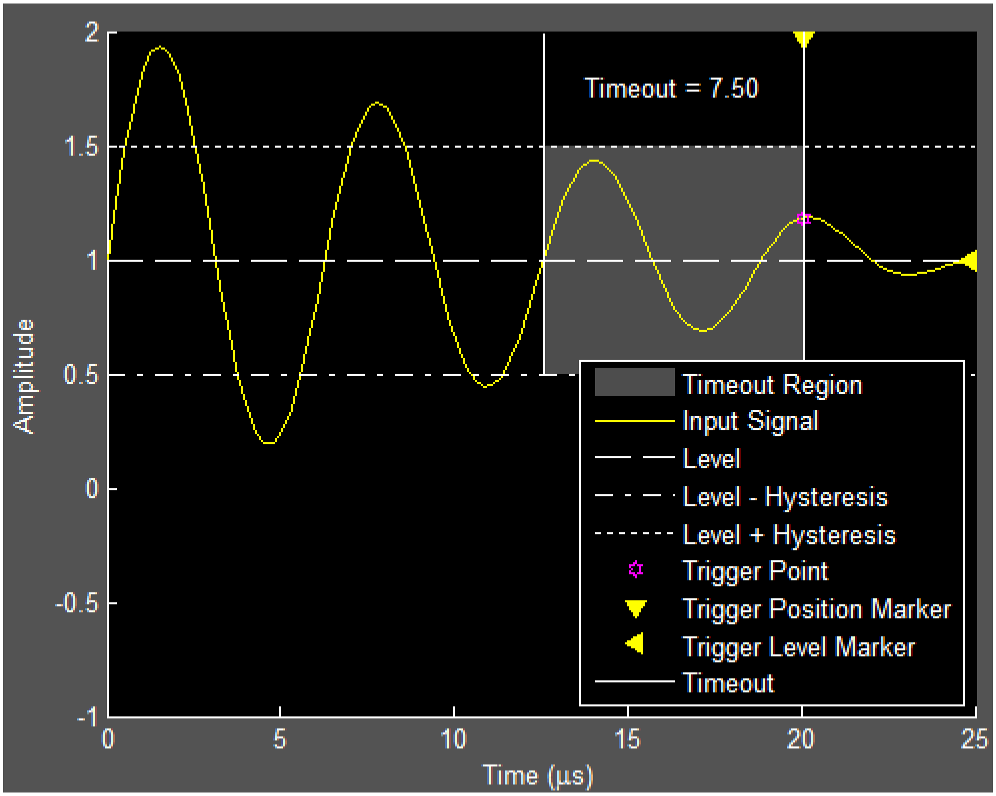


The scope encounters a trigger event when the signal crosses either the high or low threshold the second time.

- **Timeout** — Trigger when the input signal stays above or below a voltage threshold longer than a specified time. In the case of a timeout trigger with polarity set to `Either` and a timeout duration of 7.50 seconds, the scope can encounter the trigger event 7.50 seconds after the signal crosses the level threshold the last time, as shown in the following figure.



Alternatively, the scope can encounter the trigger event when the signal stays within the boundaries defined by the hysteresis for 7.50 seconds after the signal crosses the level threshold, as shown in the following figure.



- **Polarity** — Select the polarity of the trigger type. The option you choose for **Type** directly affects the options available for **Polarity**, as shown in the following table.

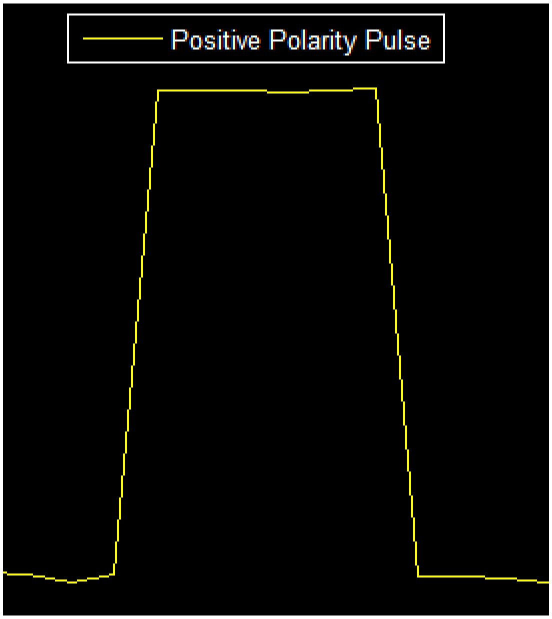
Trigger Type	Polarity Options
Edge	Rising, Falling, Either
Pulse Width	Positive, Negative, Either
Transition	Rise Time, Fall Time, Either
Runt	Positive, Negative, Either
Window	Inside, Outside, Either
Timeout	Rising, Falling, Either

When you set **Type** to `Edge`, the polarity options are:

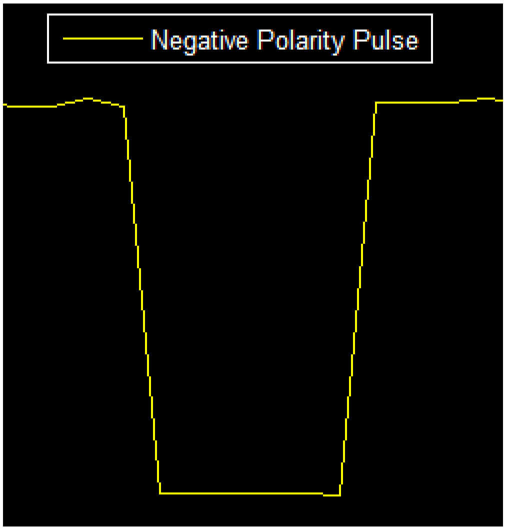
- **Rising** — Trigger on a *rising edge*, a transition from a low-state level to a high-state level.
- **Falling** — Trigger on a *falling edge*, transition from a high-state level to a low-state level.
- **Either** — Trigger on both rising edges and falling edges.

When you set **Type** to `Pulse Width` or `Runt`, the polarity options are:

- **Positive** — Trigger on a positive-polarity pulse, as shown in the following figure.



- **Negative** — Trigger on a negative-polarity pulse, as shown in the following figure.



- **Either** — Trigger on both positive-polarity and negative-polarity pulses.

When you set **Type** to `Transition`, the polarity options are:

- **Rise Time** — Trigger based on how long the signal takes to transition from the low threshold to the high threshold.
- **Fall Time** — Trigger based on how long the signal takes to transition from the high threshold to the low threshold.
- **Either** — Trigger based on how long it takes to make either a rising or falling transition.

When you set **Type** to `Window`, the polarity options are:

- **Inside** — Trigger when the signal stays within the low and high levels for a specified time duration.
- **Outside** — Trigger when the signal stays outside of the low and high levels for a specified time duration.
- **Either** — Trigger on both inside and outside windows.

When you set **Type** to `Timeout`, the polarity options are:

- **Rising** — Trigger when the signal does not cross the reference level from below.

- **Falling** — Trigger when the signal does not cross the reference level from above.
- **Either** — Trigger when the signal does not cross the reference level from either direction.

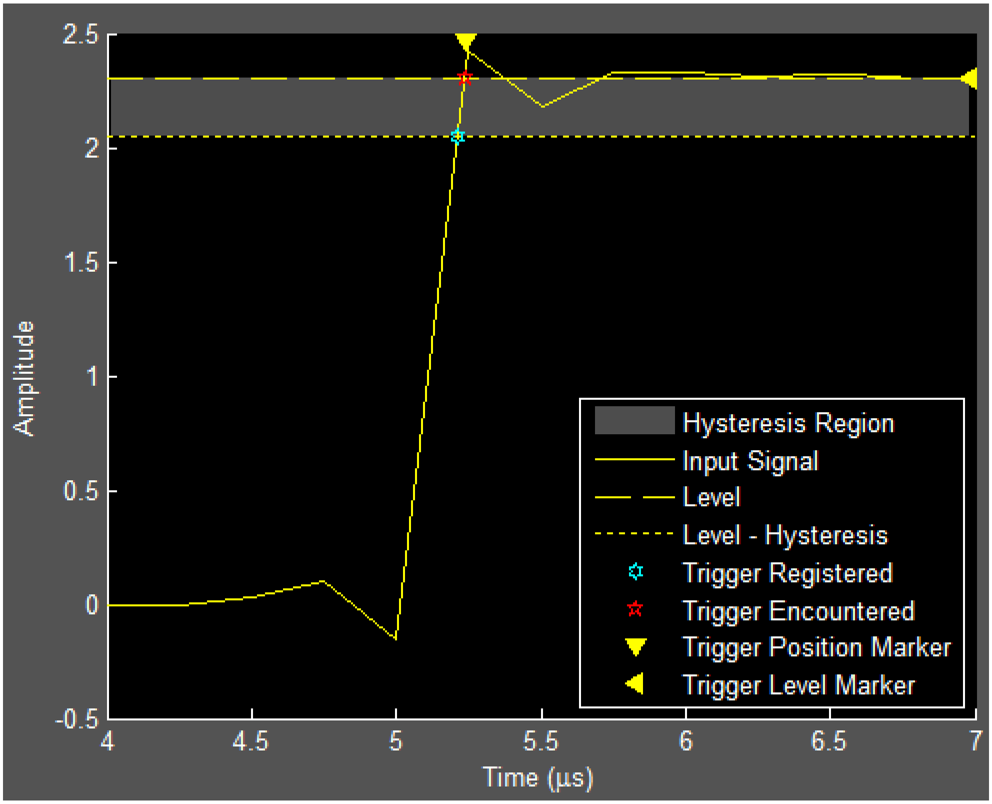
Levels / Timing Pane

The **Levels / Timing** pane enables you to set the trigger level and hysteresis value. The option you choose for **Type** directly affects which level and timing parameters are available, as shown in the following table.

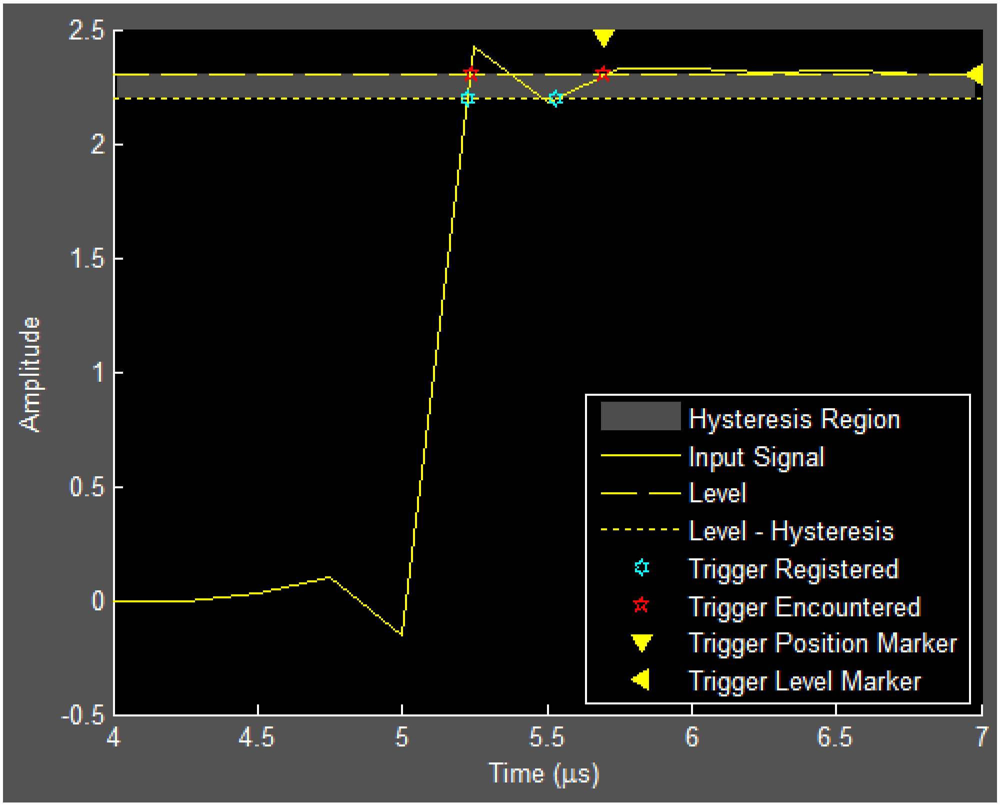
Trigger Type	Level Parameters	Auto-Level Setting	Timing Parameters
Edge	Level, Hysteresis	Level = 50%	n/a
Pulse Width	High, Low	High = 90%, Low = 10%	Min Width, Max Width
Transition	High, Low	High = 90%, Low = 10%	Min Time, Max Time
Runt	High, Low	High = 90%, Low = 10%	Min Width, Max Width
Window	High, Low	High = 90%, Low = 10%	Min Time, Max Time
Timeout	Level, Hysteresis	n/a	Timeout

- **Auto level** — Enable the Triggers panel to automatically choose the level parameters. If you set the trigger type to **Edge**, this option sets the **Level** parameter to 50% of the range of the source signal. If you set the trigger type to **Timeout**, the Triggers panel does not show this option. Setting the trigger type to other menu choices results in **High** and **Low** parameter adjustment. **Auto level** sets the **High** parameter to 90% of the range of the source signal and the **Low** parameter to 10% of the range of the source signal.
- **Level (V)** — Specify, in volts, the trigger level. This parameter is visible when you set **Type** to `Edge` or `Timeout`.
- **Hysteresis (V)** — Specify, in volts, the hysteresis or noise reject value. This parameter is visible when you set **Type** to `Edge` or `Timeout`. If the signal jitters inside this range and briefly crosses the trigger level, the scope does not register an event. In the case of an edge trigger with rising polarity, the scope ignores any times

that the signal crosses the trigger level within the hysteresis region, as shown in the following figure.



You can reduce the hysteresis region size by decreasing the hysteresis value. If you set the hysteresis value to 0.07 in this example, then the scope also considers the second rising edge to be a trigger event, as shown in the following figure.



- **High (V)** — Specify, in volts, the value that denotes a positive polarity, or high-state level. This parameter is visible when you set **Type** to `Pulse Width`, `Transition`, `Runt`, or `Window`.
- **Low (V)** — Specify, in volts, the value that denotes a negative polarity, or low-state level. This parameter is visible when you set **Type** to `Pulse Width`, `Transition`, `Runt`, or `Window`.
- **Min Width (s)** — Specify, in seconds, the minimum pulse width. This parameter is visible when you set **Type** to `Pulse Width` or `Runt`.
- **Max Width (s)** — Specify, in seconds, the maximum pulse width. This parameter is visible when you set **Type** to `Pulse Width` or `Runt`.
- **Min Time (s)** — Specify, in seconds, the minimum duration. This parameter is visible when you set **Type** to `Transition` or `Window`.

- **Max Time (s)** — Specify, in seconds, the maximum duration. This parameter is visible when you set **Type** to `Transition` or `Window`.
- **Timeout (s)** — Specify, in seconds, the timeout duration. This parameter is visible when you set **Type** to `Timeout`.

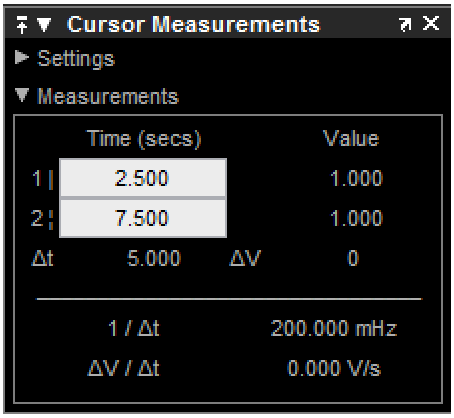
Delay / Holdoff Pane

The **Delay / Holdoff** pane enables you to offset the trigger position by a fixed delay or set the minimum possible time between trigger events.

- **Delay (s)** — Specify, in seconds, the fixed delay time by which to offset the trigger position. This parameter controls the amount of time the scope waits after a trigger event occurs before displaying a signal.
- **Holdoff (s)** — Specify, in seconds, the minimum possible time between trigger events. This amount of time is used to suppress data acquisition after a valid trigger event is encountered. A trigger holdoff prevents repeated occurrences of a trigger from occurring during the portion of a burst that is of interest.

Cursor Measurements Panel

The **Cursor Measurements** panel displays screen cursors. You can choose to hide or display the **Cursor Measurements** panel. In the Scope menu, select **Tools** > **Measurements** > **Cursor Measurements**. Alternatively, in the Scope toolbar, click the Cursor Measurements ✎ button.



Cursor Measurements

▶ Settings

▼ Measurements

	Time (secs)		Value
1	2.500		1.000
2	7.500		1.000
Δt	5.000	ΔV	0

1 / Δt	200.000 mHz
ΔV / Δt	0.000 V/s

The **Cursor Measurements** panel is separated into two panes, labeled **Settings** and **Measurements**. You can expand each pane to see the available options.

You can use the mouse or the left and right arrow keys to move vertical or waveform cursors and the up and down arrow keys for horizontal cursors.

Settings Pane

The **Settings** pane enables you to modify the type of screen cursors used for calculating measurements. When more than one signal is displayed, you can assign cursors to each trace individually.

- **Screen Cursors** — Shows screen cursors (for power and power density spectra only).
- **Horizontal** — Shows horizontal screen cursors (for power and power density spectra only).
- **Vertical** — Shows vertical screen cursors (for power and power density spectra only).
- **Waveform Cursors** — Shows cursors that attach to the input signals (for power and power density spectra only).
- **Lock Cursor Spacing** — Locks the frequency difference between the two cursors.
- **Snap to Data** — Positions the cursors on signal data points.

Measurements Pane

The **Measurements** pane shows the time and value measurements.

- **1 |**— Shows or enables you to modify the time or value at cursor number one, or both.
- **2 :**— Shows or enables you to modify the time or value at cursor number two, or both.
- **Δt**— Shows the absolute value of the difference in the times between cursor number one and cursor number two.
- **ΔV**— Shows the absolute value of the difference in signal amplitudes between cursor number one and cursor number two.
- **1/Δt**— Shows the rate, the reciprocal of the absolute value of the difference in the times between cursor number one and cursor number two.
- **ΔV/Δt**— Shows the scope, the ratio of the absolute value of the difference in signal amplitudes between cursors to the absolute value of the difference in the times between cursors.

Signal Statistics Panel

The **Signal Statistics** panel displays the maximum, minimum, peak-to-peak difference, mean, median, and RMS values of a selected signal. It also shows the *x*-axis indices at which the maximum and minimum values occur. You can choose to hide or display the **Signal Statistics** panel. In the Scope menu, select **Tools** > **Measurements** > **Signal Statistics**. Alternatively, in the scope toolbar, click the Signal Statistics button.

	Value	Time (secs)
Max	1.000	0.000
Min	1.000	0.000
Peak to Peak	0	
Mean	1.000	
Median	1.000	
RMS	1.000	

Signal Statistics Measurements

The **Signal Statistics** panel shows statistics about the portion of the input signal within the *x*-axis and *y*-axis limits of the active display. The statistics shown are:

- **Max** — Shows the maximum or largest value within the displayed portion of the input signal. For more information on the algorithm this measurement uses, see the MATLAB `max` function reference.
- **Min** — Shows the minimum or smallest value within the displayed portion of the input signal. For more information on the algorithm this measurement uses, see the MATLAB `min` function reference.
- **Peak to Peak** — Shows the difference between the maximum and minimum values within the displayed portion of the input signal. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `peak2peak` function reference.
- **Mean** — Shows the average or mean of all the values within the displayed portion of the input signal. For more information on the algorithm this measurement uses, see the MATLAB `mean` function reference.
- **Median** — Shows the median value within the displayed portion of the input signal. For more information on the algorithm this measurement uses, see the MATLAB `median` function reference.
- **RMS** — Shows the difference between the maximum and minimum values within the displayed portion of the input signal. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `rms` function reference.

When you use the zoom options in the Scope, the Signal Statistics measurements automatically adjust to the time range shown in the display. In the Scope toolbar, click the **Zoom In** or **Zoom X** button to constrict the *x*-axis range of the display, and the statistics shown reflect this time range. For example, you can zoom in on one pulse to make the **Signal Statistics** panel display information about only that particular pulse.

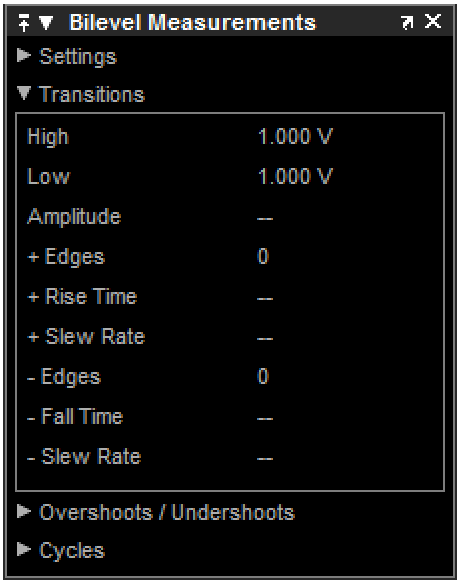
The Signal Statistics measurements are valid for any units of the input signal. The letter after the value associated with each measurement represents the appropriate International System of Units (SI) prefix, such as *m* for *milli-*. For example, if the input signal is measured in volts, an *m* next to a measurement value indicates that this value is in units of millivolts. The SI prefixes are shown in the following table:

Abbreviation	Name	Multiplier
a	atto	10^-18
f	femto	10^-15
p	pico	10^–12
n	nano	10^-9

Abbreviation	Name	Multiplier
u	micro	10^-6
m	milli	10^-3
		10^0
k	kilo	10^3
M	mega	10^6
G	giga	10^9
T	tera	10^12
P	peta	10^15
E	exa	10^18

Bilevel Measurements Panel

The **Bilevel Measurements** panel shows information about a selected signal's transitions, overshoots or undershoots, and cycles. You can choose to hide or display the **Bilevel Measurements** panel. In the Scope menu, select **Tools** > **Measurements** > **Bilevel Measurements**. Alternatively, in the Scope toolbar, you can select the Bilevel Measurements button.

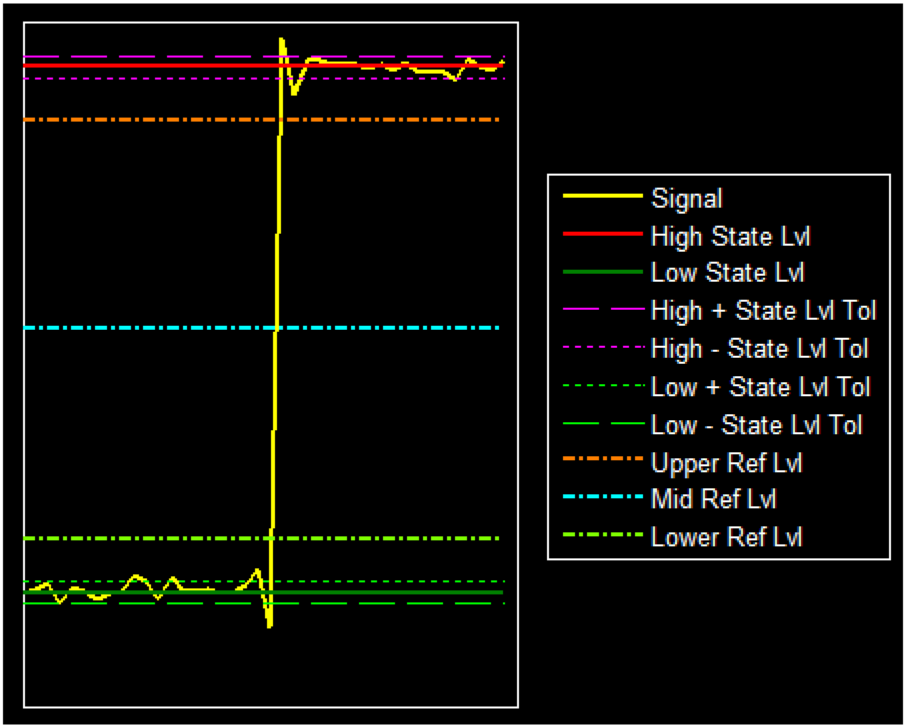


High	1.000 V
Low	1.000 V
Amplitude	--
+ Edges	0
+ Rise Time	--
+ Slew Rate	--
- Edges	0
- Fall Time	--
- Slew Rate	--

The **Bilevel Measurements** panel is separated into four panes, labeled **Settings**, **Transitions**, **Overshoots / Undershoots**, and **Cycles**. You can expand each pane to see the available options.

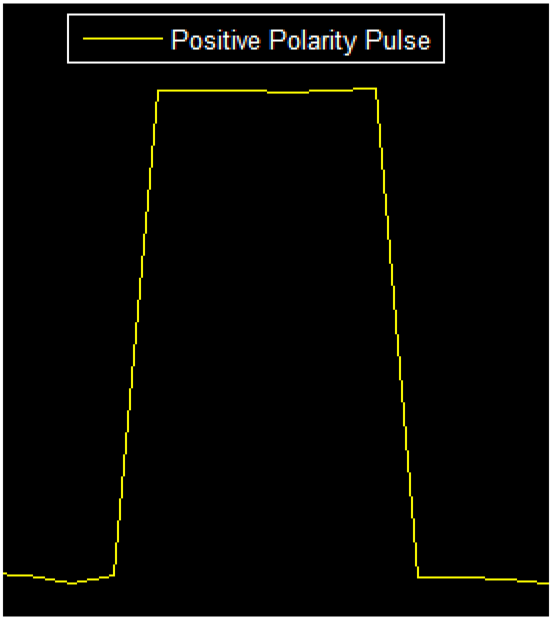
Settings Pane

The **Settings** pane enables you to modify the properties used to calculate various measurements involving transitions, overshoots, undershoots, and cycles. You can modify the high-state level, low-state level, state-level tolerance, upper-reference level, mid-reference level, and lower-reference level, as shown in the following figure.

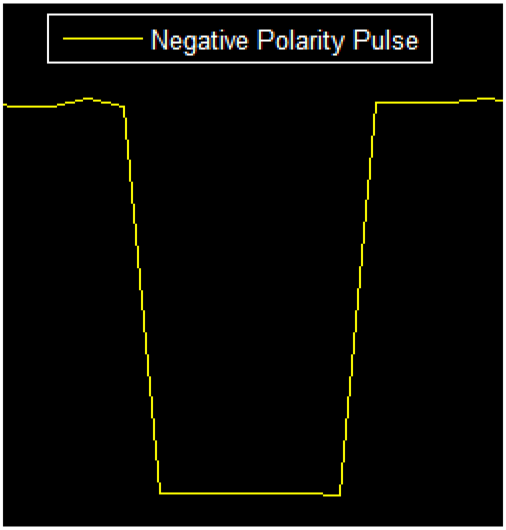


- **Auto State Level** — When this check box is selected, the Bilevel measurements panel autodetects the high- and low- state levels of a bilevel waveform. For more information on the algorithm this option uses, see the Signal Processing Toolbox `statelevels` function reference. When this check box is cleared, you may enter in values for the high- and low- state levels manually.

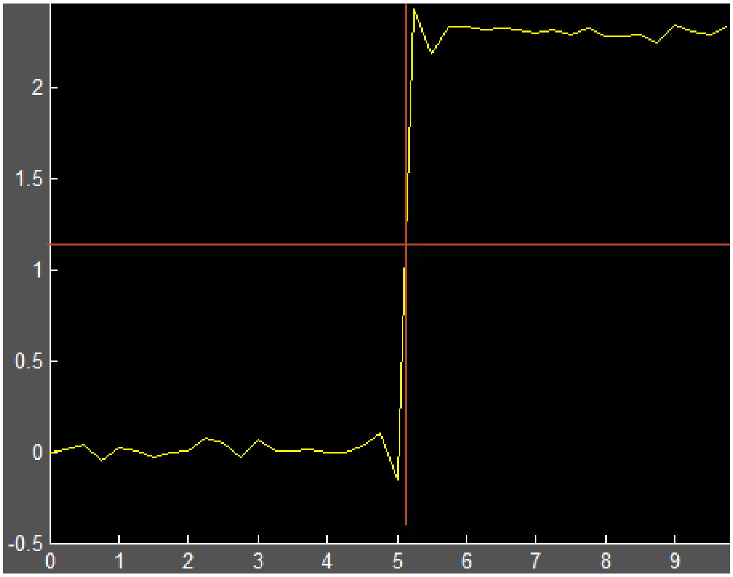
  - **High** — Used to manually specify the value that denotes a positive polarity, or high-state level, as shown in the following figure.



- **Low** — Used to manually specify the value that denotes a negative polarity, or low-state level, as shown in the following figure.



- **State Level Tolerance** — Tolerance within which the initial and final levels of each transition must be within their respective state levels. This value is expressed as a percentage of the difference between the high- and low-state levels.
- **Upper Ref Level** — Used to compute the end of the rise-time measurement or the start of the fall time measurement. This value is expressed as a percentage of the difference between the high- and low-state levels.
- **Mid Ref Level** — Used to determine when a transition occurs. This value is expressed as a percentage of the difference between the high- and low- state levels. In the following figure, the mid-reference level is shown as the horizontal line, and its corresponding mid-reference level instant is shown as the vertical line.

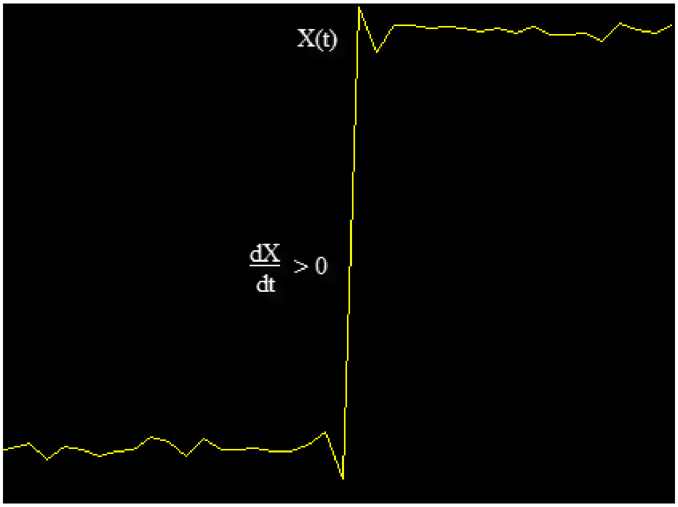


- **Lower Ref Level** — Used to compute the end of the fall-time measurement or the start of the rise-time measurement. This value is expressed as a percentage of the difference between the high- and low-state levels.
- **Settle Seek** — The duration after the mid-reference level instant when each transition occurs used for computing a valid settling time. This value is equivalent to the input parameter, `D`, which you can set when you run the `settlingtime` function. The settling time is displayed in the **Overshoots/Undershoots** pane.

Transitions Pane

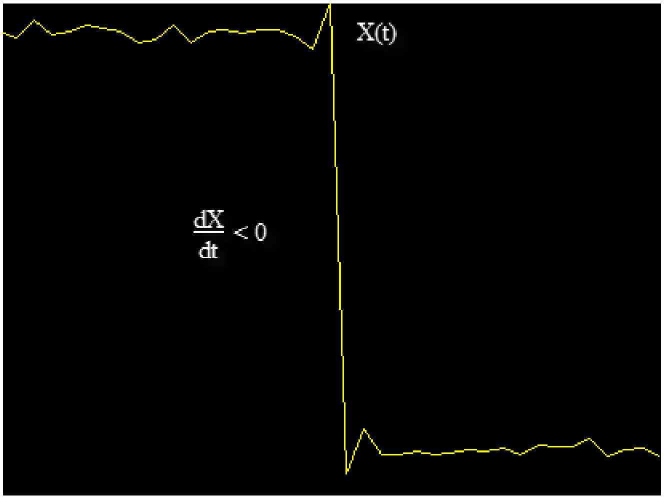
The **Transitions** pane displays calculated measurements associated with the input signal changing between its two possible state level values, high and low.

A positive-going transition, or *rising edge*, in a bilevel waveform is a transition from the low-state level to the high-state level. A positive-going transition has a slope value greater than zero. The following figure shows a positive-going transition.



Whenever there is a plus sign (+) next to a text label, this symbol refers to measurement associated with a rising edge, a transition from a low-state level to a high-state level.

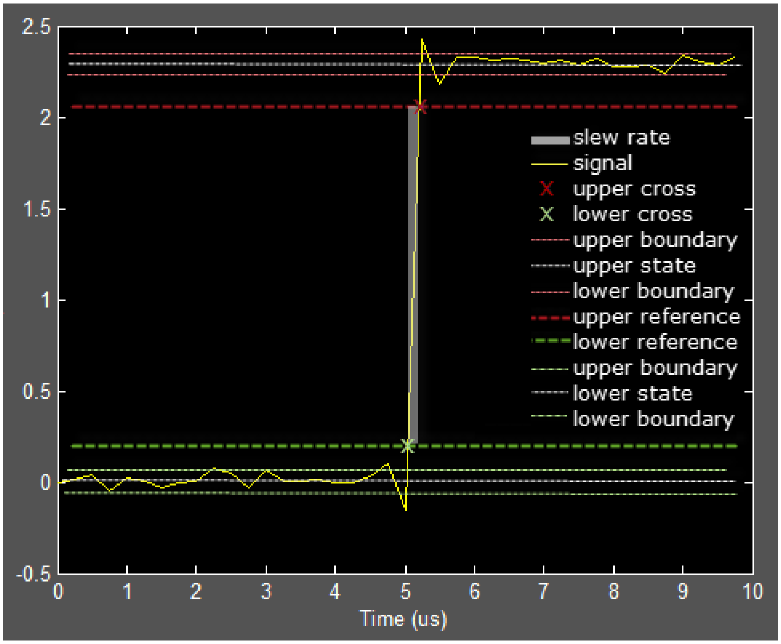
A negative-going transition, or falling edge, in a bilevel waveform is a transition from the high-state level to the low-state level. A negative-going transition has a slope value less than zero. The following figure shows a negative-going transition.



Whenever there is a minus sign (–) next to a text label, this symbol refers to measurement associated with a falling edge, a transition from a high-state level to a low-state level.

The Transition measurements assume that the amplitude of the input signal is in units of volts. You must convert all input signals to volts for the Transition measurements to be valid.

- **High** — The high-amplitude state level of the input signal over the duration of the **Time Span** parameter. You can set **Time Span** in the **Main** pane of the Visuals —Time Domain Properties dialog box. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `statelevels` function reference.
- **Low** — The low-amplitude state level of the input signal over the duration of the **Time Span** parameter. You can set **Time Span** in the **Main** pane of the Visuals —Time Domain Properties dialog box. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `statelevels` function reference.
- **Amplitude** — Difference in amplitude between the high-state level and the low-state level.
- **+ Edges** — Total number of positive-polarity, or rising, edges counted within the displayed portion of the input signal.
- **+ Rise Time** — Average amount of time required for each rising edge to cross from the lower-reference level to the upper-reference level. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `risetime` function reference.
- **+ Slew Rate** — Average slope of each rising-edge transition line within the upper- and lower-percent reference levels in the displayed portion of the input signal. The region in which the slew rate is calculated appears in gray in the following figure.

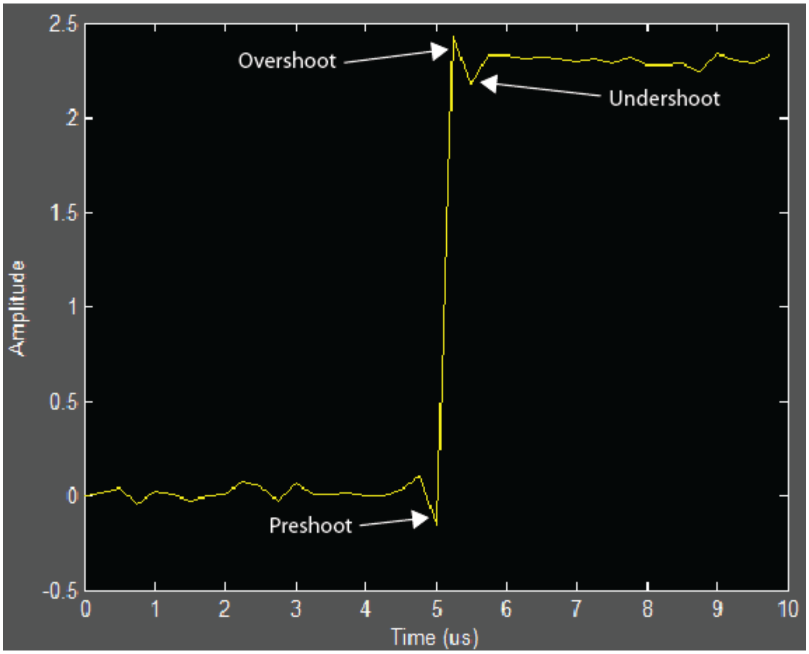


For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `slewrate` function reference.

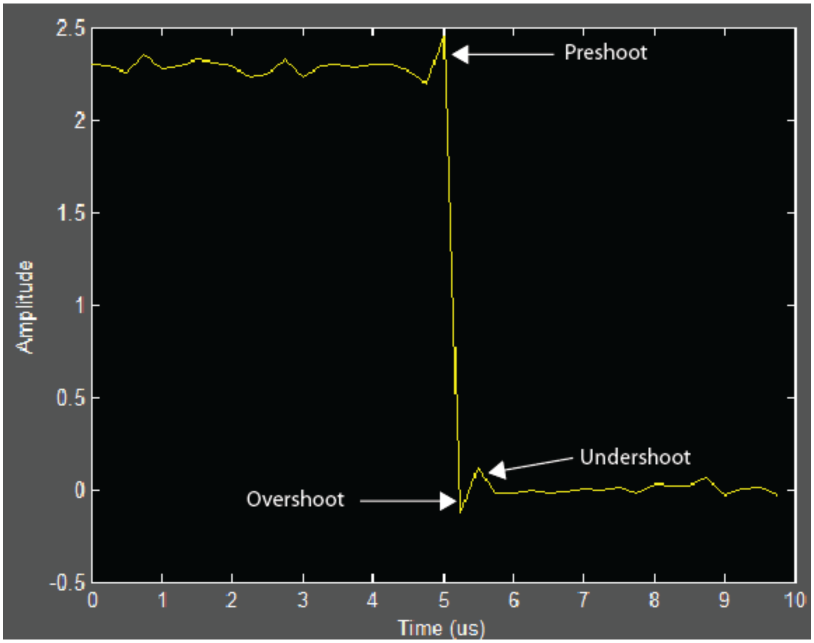
- – **Edges** — Total number of negative-polarity or falling edges counted within the displayed portion of the input signal.
- – **Fall Time** — Average amount of time required for each falling edge to cross from the upper-reference level to the lower-reference level. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `falltime` function reference.
- – **Slew Rate** — Average slope of each falling edge transition line within the upper- and lower-percent reference levels in the displayed portion of the input signal. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `slewrate` function reference.

Overshoots/Undershoots

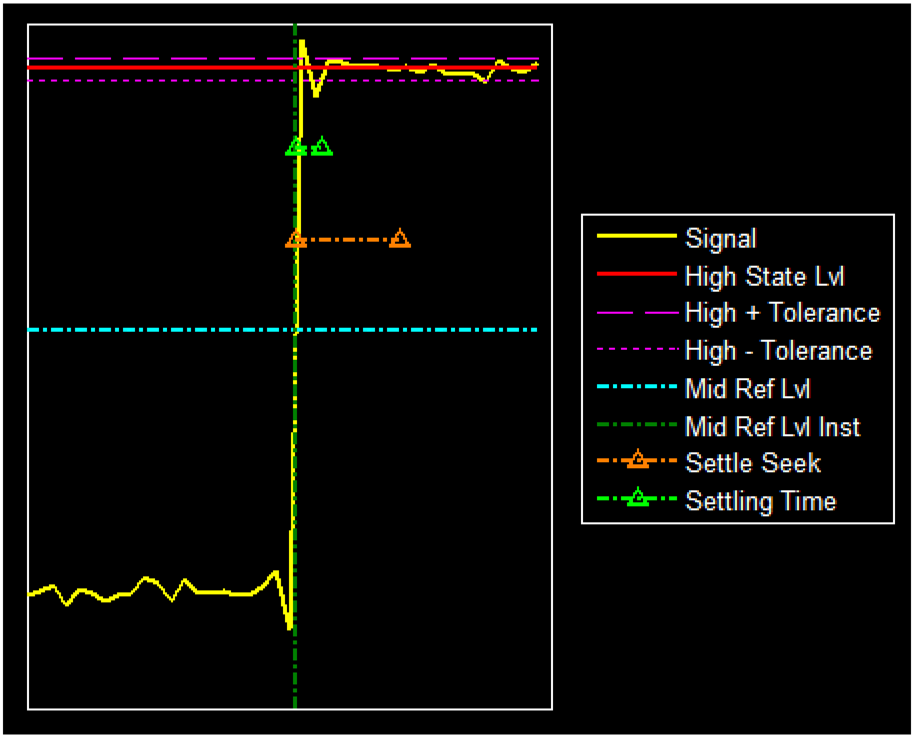
The **Overshoots/Undershoots** pane displays calculated measurements involving the distortion and damping of the input signal. *Overshoot* and *undershoot* refer to the amount that a signal respectively exceeds and falls below its final steady-state value. *Preshoot* refers to the amount prior to a transition that a signal varies from its initial steady-state value. This figure shows preshoot, overshoot, and undershoot for a rising-edge transition.



The next figure shows preshoot, overshoot, and undershoot for a falling-edge transition.



- **+ Preshoot** — Average lowest aberration in the region immediately preceding each rising transition.
- **+ Overshoot** — Average highest aberration in the region immediately following each rising transition. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `overshoot` function reference.
- **+ Undershoot** — Average lowest aberration in the region immediately following each rising transition. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `undershoot` function reference.
- **+ Settling Time** — Average time required for each rising edge to enter and remain within the tolerance of the high-state level for the remainder of the settle seek duration. The settling time is the time after the mid-reference level instant when the signal crosses into and remains in the tolerance region around the high-state level. This crossing is illustrated in the following figure.



You can modify the settle seek duration parameter in the **Settings** pane. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `settlingtime` function reference.

- – **Preshoot** — Average highest aberration in the region immediately preceding each falling transition.
- – **Overshoot** — Average highest aberration in the region immediately following each falling transition. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `overshoot` function reference.
- – **Undershoot** — Average lowest aberration in the region immediately following each falling transition. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `undershoot` function reference.
- – **Settling Time** — Average time required for each falling edge to enter and remain within the tolerance of the low-state level for the remainder of the settle seek duration. The settling time is the time after the mid-reference level instant when

the signal crosses into and remains in the tolerance region around the low-state level. You can modify the settle seek duration parameter in the **Settings** pane. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `settlingtime` function reference.

Cycles

The **Cycles** pane displays calculated measurements pertaining to repetitions or trends in the displayed portion of the input signal.

- **Period** — Average duration between adjacent edges of identical polarity within the displayed portion of the input signal. The Bilevel measurements panel calculates period as follows. It takes the difference between the mid-reference level instants of the initial transition of each positive-polarity pulse and the next positive-going transition. These mid-reference level instants appear as red dots in the following figure.

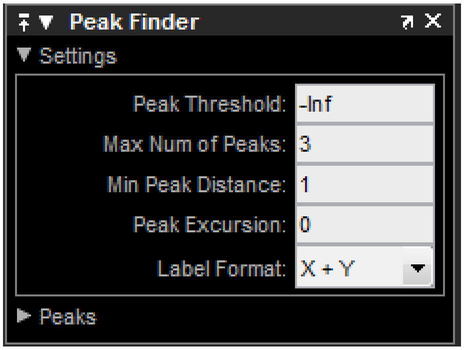
  
  For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `pulseperiod` function reference.

- **Frequency** — Reciprocal of the average period. Whereas period is typically measured in some metric form of seconds, or seconds per cycle, frequency is typically measured in hertz or cycles per second.
- **+ Pulses** — Number of positive-polarity pulses counted.
- **+ Width** — Average duration between rising and falling edges of each positive-polarity pulse within the displayed portion of the input signal. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `pulsewidth` function reference.
- **+ Duty Cycle** — Average ratio of pulse width to pulse period for each positive-polarity pulse within the displayed portion of the input signal. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `dutycycle` function reference.
- **– Pulses** — Number of negative-polarity pulses counted.
- **– Width** — Average duration between rising and falling edges of each negative-polarity pulse within the displayed portion of the input signal. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `pulsewidth` function reference.
- **– Duty Cycle** — Average ratio of pulse width to pulse period for each negative-polarity pulse within the displayed portion of the input signal. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `dutycycle` function reference.

When you use the zoom options in the Scope, the bilevel measurements automatically adjust to the time range shown in the display. In the Scope toolbar, click the **Zoom In** or **Zoom X** button to constrict the *x*-axis range of the display, and the statistics shown reflect this time range. For example, you can zoom in on one rising edge to make the **Bilevel Measurements** panel display information about only that particular rising edge. However, this feature does not apply to the **High** and **Low** measurements.

Peak Finder Panel

The **Peak Finder** panel displays the maxima, showing the *x*-axis values at which they occur. This panel allows you to modify the settings for peak threshold, maximum number of peaks, and peak excursion. You can choose to hide or display the **Peak Finder** panel. In the scope menu, select **Tools** > **Measurements** > **Peak Finder**. Alternatively, in the scope toolbar, select the Peak Finder button.



Peak Threshold: -Inf

Max Num of Peaks: 3

Min Peak Distance: 1

Peak Excursion: 0

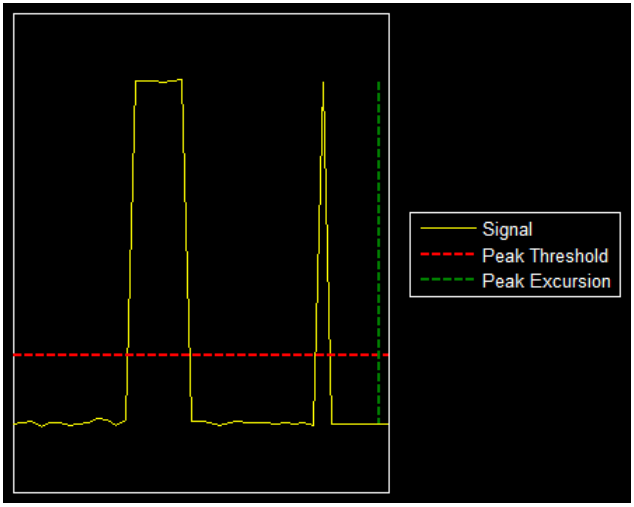
Label Format: X + Y

The **Peak finder** panel is separated into two panes, labeled **Settings** and **Peaks**. You can expand each pane to see the available options.

Settings Pane

The **Settings** pane enables you to modify the parameters used to calculate the peak values within the displayed portion of the input signal. For more information on the algorithms this pane uses, see the Signal Processing Toolbox `findpeaks` function reference.

- **Peak Threshold** — The level above which peaks are detected. This setting is equivalent to the `MINPEAKHEIGHT` parameter, which you can set when you run the `findpeaks` function.
- **Max Num of Peaks** — The maximum number of peaks to show. The value you enter must be a scalar integer between 1 and 99. This setting is equivalent to the `NPEAKS` parameter, which you can set when you run the `findpeaks` function.
- **Min Peaks Distance** — The minimum number of samples between adjacent peaks. This setting is equivalent to the `MINPEAKDISTANCE` parameter, which you can set when you run the `findpeaks` function.
- **Peak Excursion** — The minimum height difference between a peak and its neighboring samples. Peak excursion is illustrated alongside peak threshold in the following figure.



The *peak threshold* is a minimum value necessary for a sample value to be a peak. The *peak excursion* is the minimum difference between a peak sample and the samples to its left and right in the time domain. In the figure, the green vertical line illustrates the lesser of the two height differences between the labeled peak and its neighboring samples. This height difference must be greater than the **Peak Excursion** value for the labeled peak to be classified as a peak. Compare this setting to peak threshold, which is illustrated by the red horizontal line. The amplitude must be above this horizontal line for the labeled peak to be classified as a peak.

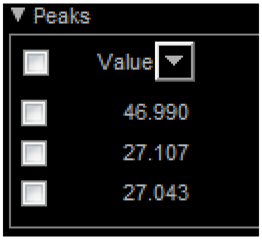
The peak excursion setting is equivalent to the `THRESHOLD` parameter, which you can set when you run the `findpeaks` function.

- **Label Format** — The coordinates to display next to the calculated peak values on the plot. To see peak values, you must first expand the **Peaks** pane and select the check boxes associated with individual peaks of interest. By default, both *x*-axis and *y*-axis values are displayed on the plot. Select which axes values you want to display next to each peak symbol on the display.

  - `X+Y` — Display both *x*-axis and *y*-axis values.
  - `X` — Display only *x*-axis values.
  - `Y` — Display only *y*-axis values.

Peaks Pane

The **Peaks** pane displays all of the largest calculated peak values. It also shows the coordinates at which the peaks occur, using the parameters you define in the **Settings** pane. You set the **Max Num of Peaks** parameter to specify the number of peaks shown in the list.



□	Value ▼
□	46.990
□	27.107
□	27.043

The numerical values displayed in the **Value** column are equivalent to the `pks` output argument returned when you run the `findpeaks` function. The numerical values displayed in the second column are similar to the `locs` output argument returned when you run the `findpeaks` function.

The Peak Finder displays the peak values in the **Peaks** pane. By default, the **Peak Finder** panel displays the largest calculated peak values in the **Peaks** pane in decreasing order of peak height. Use the sort descending button (▼) to rearrange the category and order by which Peak Finder displays peak values. Click this button again to sort the peaks in ascending order instead. When you do so, the arrow changes direction to become the sort ascending button (▲). A filled sort button indicates that the peak values are currently sorted in the direction of the button arrow. If the sort button is not filled (▽), then the peak values are sorted in the opposite direction of the button arrow. The **Max Num of Peaks** parameter still controls the number of peaks listed.

Use the check boxes to control which peak values are shown on the display. By default, all check boxes are cleared and the **Peak Finder** panel hides all the peak values. To show all the peak values on the display, select the check box in the top-left corner of the **Peaks** pane. To hide all the peak values on the display, clear this check box. To show an individual peak, select the check box directly to the left of its **Value** listing. To hide an individual peak, clear the check box directly to the left of its **Value** listing.

The Peaks are valid for any units of the input signal. The letter after the value associated with each measurement indicates the abbreviation for the appropriate International

System of Units (SI) prefix, such as *m* for *milli-*. For example, if the input signal is measured in volts, an *m* next to a measurement value indicates that this value is in units of millivolts.

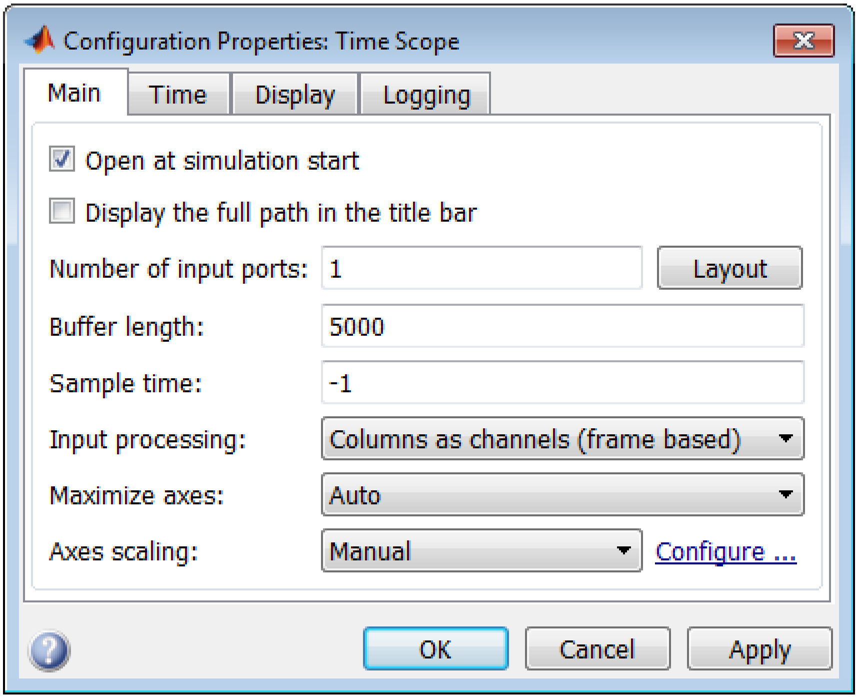
Abbreviation	Name	Multiplier
a	atto	10^–18
f	femto	10^–15
p	pico	10^–12
n	nano	10^–9
u	micro	10^–6
m	milli	10^–3
		10^0
k	kilo	10^3
M	mega	10^6
G	giga	10^9
T	tera	10^12
P	peta	10^15
E	exa	10^18

Configuration Properties Dialog Box

The Configuration Properties dialog box controls various properties about the Time Scope displays. From the Time Scope menu, select **View > Configuration Properties** to open this dialog box. Alternatively, in the Time Scope toolbar, click the Configuration Properties ⚙ button.

Main Pane

The **Main** pane of the Configuration Properties dialog box appears as follows.



Configuration Properties: Time Scope

☑ Open at simulation start

□ Display the full path in the title bar

Number of input ports: 1

Buffer length: 5000

Sample time: -1

Input processing: Columns as channels (frame based)

Maximize axes: Auto

Axes scaling: Manual

Open at simulation start

Select this check box to ensure that the scope opens when the simulation starts. The following table summarizes the interaction between the **Open at simulation start** check box and the Scope figure.

Open at simulation start	Scope figure status when model saved	Scope figure opens
Checked	Closed	At simulation start
Checked	Open	At model loading
Not checked	Closed	Only if you double-click the Scope block icon in the model
Not checked	Open	At model loading

Display the full path in the title bar

Select this check box to display in the title bar the path of this scope in this model.

Number of input ports

Specify the number of input ports that should appear on the left side of the scope block.

Layout

Specify the arrangement of scope displays in the scope window. The display highlighted in blue is referred to as the *active display*. The scope dialog boxes reference the active display.

Buffer length

Specify the size of the buffer that the scope holds in its memory cache. If your signal has *M* rows of data and *N* data points in each row, *M* x *N* is the number of data points per time step. Multiply this result by the number of time steps for your model to obtain the required buffer length. For example, if you have 10 rows of data with each row having 100 data points and your run will be 10 time steps, you should enter 10,000 (which is 10 x 100 x 10) as the buffer length.

The default setting is `5000`.

Sample time

Specify the sampling time in seconds. If you enter -1, the sample time of the input signal is used.

Input processing

Specify whether the Time Scope should treat the input signal as `Columns as channels (frame based)` or `Elements as channels (sample based)`.

Frame-based processing is only available for discrete input signals. For more information about frame-based input channels, see the “What Is Frame-Based Processing?” section in the DSP System Toolbox documentation. For an example that uses the Time Scope block and frame-based input signals, see the “Display Time-Domain Data” section in the DSP System Toolbox documentation.

Maximize axes

Specify whether to display the scope in maximized axes mode. In this mode, each of the axes is expanded to fit into the entire display. To conserve space, labels do not appear in each display. Instead, tick-mark values appear on top of the plotted data. You can select one of the following options:

- Auto — In this mode, the axes appear maximized in all displays only if the Title and YLabel properties are empty for every display. If you enter any value in any display for either of these properties, the axes are not maximized.
- On — In this mode, the axes appear maximized in all displays. Any values entered into the Title and YLabel properties are hidden.
- Off — In this mode, none of the axes appear maximized.

This property is "Tunable".

The default setting is Auto.

Axes scaling

Specify when the scope should automatically scale the axes. You can select one of the following options:

- Manual — When you select this option, the scope does not automatically scale the axes. You can manually scale the axes in any of the following ways:
  - Select **Tools** > **Axes Scaling Properties**.
  - Press one of the **Scale Axis Limits** toolbar buttons.
  - When the scope figure is the active window, press **Ctrl** and **A** simultaneously.
- Auto — When you select this option, the scope scales the axes as needed, both during and after simulation. Selecting this option shows the **Do not allow Y-axis limits to shrink** check box.
- After N Updates — Selecting this option causes the scope to scale the axes after a specified number of updates. Selecting this option shows the **Number of updates** edit box.

By default, this property is set to Auto. This property is "Tunable".

Note: Click the link labeled **Configure** to the right of the **Axes scaling** property to see additional axes scaling properties. After you click this button, its label changes to **Hide**. To hide these additional properties, click the **Hide** link.

Number of updates

Enter the number of updates that occur before the scope scales the axes. This field shows only if you set **Axes scaling** to After N Updates.

Scale axes limits at stop

Select this check box to scale the axes when the simulation stops. The *y*-axis is always scaled. The *x*-axis limits are only scaled if you also select the **Scale X-axis limits** check box.

Do not allow Y-axis limits to shrink

When you select this property, the *y*-axis is allowed only to grow during axes scaling operations. If you clear this check box, the *y*-axis or color limits may shrink during axes scaling operations.

This property appears only when you select `Auto` for the **Axis scaling** property. When you set the **Axes scaling** property to `Manual` or `After N Updates`, the *y*-axis or color limits are allowed to shrink. "Tunable".

Y-axis Data range (%)

Set the percentage of the *y*-axis that the scope should use to display the data when scaling the axes. Valid values are between 1 and 100. For example, if you set this property to `100`, the Scope scales the *y*-axis limits such that your data uses the entire *y*-axis range. If you then set this property to `30`, the scope increases the *y*-axis range such that your data uses only 30% of the *y*-axis range. "Tunable".

Y-axis Align

Specify where the scope should align your data with respect to the *y*-axis when it scales the axes. You can select `Top`, `Center`, or `Bottom`. "Tunable".

Autoscale X-axis limits

Check this box to allow the scope to scale the *x*-axis limits when it scales the axes. If **Axes scaling** is set to `Auto`, checking **Scale X-axis limits** only scales the data currently within the axes, not the entire signal in the data buffer. "Tunable".

X-axis Data range (%)

Set the percentage of the *x*-axis that the Scope should use to display the data when scaling the axes. Valid values are between 1 and 100. For example, if you set this property to `100`, the Scope scales the *x*-axis limits such that your data uses the entire*x*-axis range. If you then set this property to `30`, the Scope increases the *x*-axis range such that your data uses only 30% of the *x*-axis range. Use the *x*-axis **Align** property to specify data placement with respect to the *x*-axis.

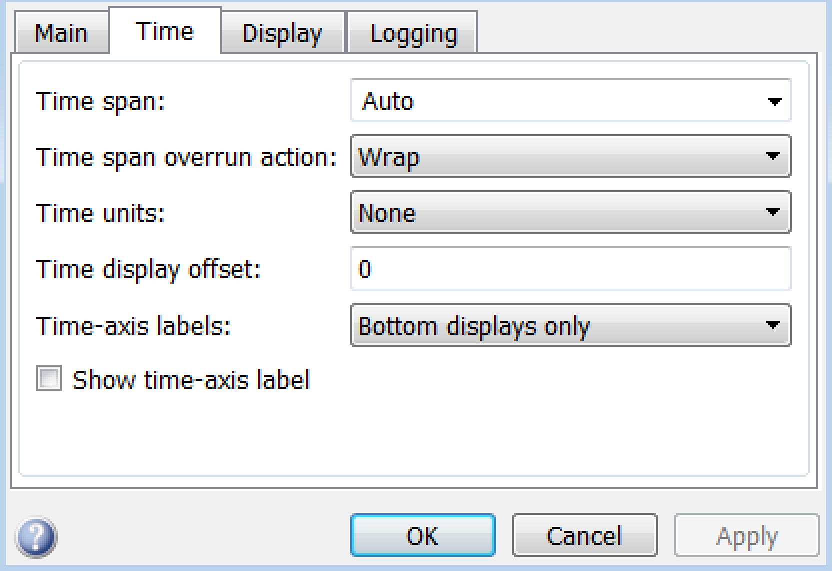
This property appears only when you select the **Scale X-axis limits** check box. “Tunable”.

X-axis Align

Specify how the Scope should align your data with respect to the *x*-axis: `Left`, `Center`, or `Right`. This property appears only when you select the **Scale X-axis limits** check box. “Tunable”.

Time Pane

The **Time** pane of the Configuration Properties dialog box appears as follows.



Time span: Auto

Time span overrun action: Wrap

Time units: None

Time display offset: 0

Time-axis labels: Bottom displays only

□ Show time-axis label

Time span

Specify the time span, either by selecting a predefined option or by entering a numeric value in seconds. You can select one of the following options:

- `Auto` — In this mode, Time Scope automatically calculates the appropriate value for time span.

  The Time Scope block calculates the minimum and maximum *time*-axis limits as follows:

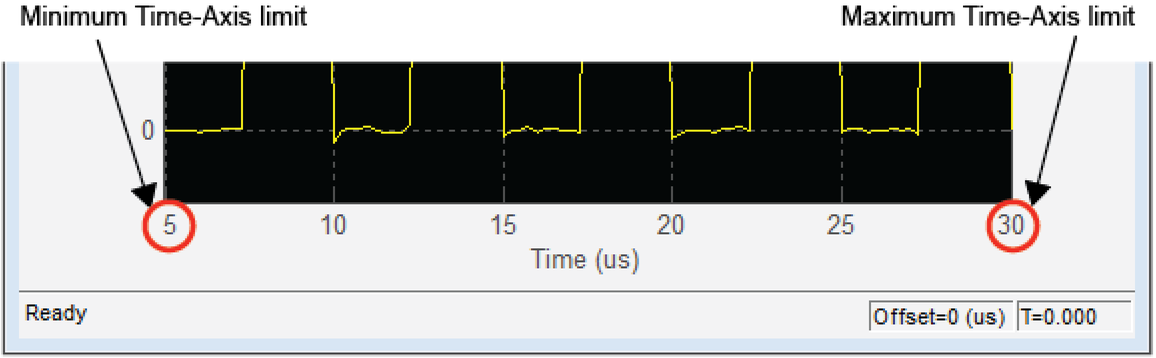
  - Minimum *time*-axis limit = Simulation “Start time”
  - Maximum *time*-axis limit = Simulation “Stop time” + max(*FrameRate* * (*FrameSize*–1) / *FrameSize*)

  FrameSize is a vector equal to the number of rows in each input signal. *FrameRate* is the reciprocal of the sample time for each frame. The Time Scope System object calculates the minimum and maximum *time*-axis limits as follows:

  - Minimum *time*-axis limit = min(`TimeDisplayOffset`)
  - Maximum *time*-axis limit = max(`TimeDisplayOffset`) + max(1/`SampleRate`.**FrameSize*)

  where “`TimeDisplayOffset`” and “`SampleRate`” are the values of their respective properties. This property is “Tunable”.
- `One frame period` — In this mode, the Time Scope uses the frame period of the input signal to the Time Scope block. This option is only available when the **Input processing** parameter is set to `Columns as channels (frame based)`. This option is not available when you set the **Input processing** parameter to `Elements as channels (sample based)`.
- `<user defined>` — In this mode, you specify the time span by replacing the text `<user defined>` with a numeric value in seconds.

The scope sets the *time*-axis limits using the value of this property and the value of the **Time display offset** property. For example, if you set the **Time display offset** to `5e-6` and the **Time span** to `25e-6`, the scope sets the *time*-axis limits as shown in the following figure.



This property is “Tunable”.

Time span overrun action

Specify how the scope displays new data beyond the visible time span. You can select one of the following options:

- `Wrap` — In this mode, the scope displays new data until the data reaches the maximum *time*-axis limit. When the data reaches the maximum *time*-axis limit of the scope window, the scope clears the display. The scope then updates the time offset value and begins displaying subsequent data points starting from the minimum *time*-axis limit.
- `Scroll` — In this mode, the scope scrolls old data to the left to make room for new data on the right side of the scope display. This mode is graphically intensive and can affect run-time performance. However, it is beneficial for debugging and monitoring time-varying signals.

This property is “Tunable”.

The default setting is `Wrap`.

Time units

Specify the units used to describe the *time*-axis. You can select one of the following options:

- `Metric` — In this mode, the scope converts the times on the *time*-axis to the most appropriate measurement units. These can include milliseconds, microseconds, nanoseconds, minutes, days, etc. The scope chooses the appropriate measurement units based on the minimum *time*-axis limit and the maximum *time*-axis limit of the scope window.
- `Seconds` — In this mode, the scope always displays the units on the *time*-axis as seconds.
- `None` — In this mode, the scope does not display any units on the *time*-axis. The scope only shows the word `Time` on the *time*-axis.

This property is “Tunable”.

The default setting is `Metric`.

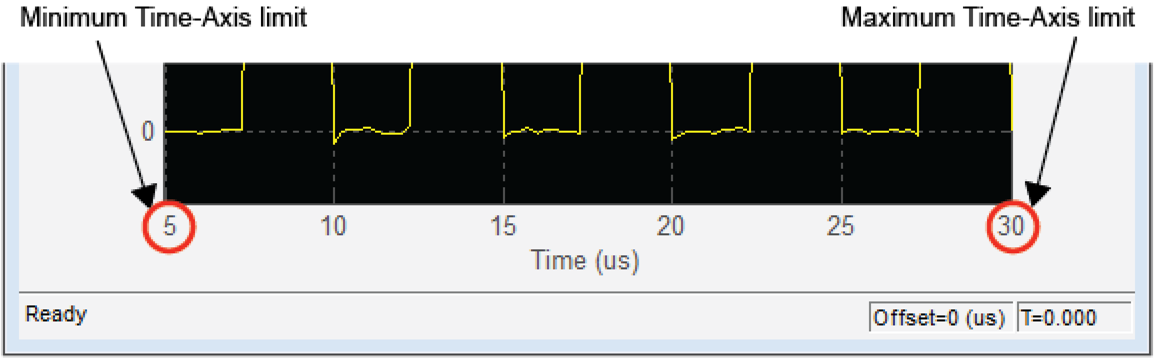
Time display offset

This property allows you to offset the values displayed on the *time*-axis by a specified number of seconds. When you specify a scalar value, the scope offsets all channels equally. When you specify a vector of offset values, the scope offsets each channel independently. “Tunable”.

When you specify a **Time display offset** vector of length *N*, the scope offsets the input channels as follows:

- When *N* is equal to the number of input channels, the scope offsets each channel according to its corresponding value in the offset vector.
- When *N* is less than the number of input channels, the scope applies the values you specify in the offset vector to the first *N* input channels. The scope does not offset the remaining channels.
- When *N* is greater than the number of input channels, the scope offsets each input channel according to the corresponding value in the offset vector. The scope ignores all values in the offset vector that do not correspond to a channel of the input.

The scope computes the *time*-axis range using the values of the **Time display offset** and **Time span** properties. For example, if you set the **Time display offset** to `5e-6` and the **Time span** to `25e-6`, the scope sets the *time*-axis limits as shown in the following figure.



Similarly, when you specify a vector of values, the scope sets the minimum *time*-axis limit using the smallest value in the vector. To set the maximum *time*-axis limit, the scope sums the largest value in the vector with the value of the **Time span** property. For more information, see “Signal Display” on page 1-1387.

Time-axis labels

Specify how to display the time units used to describe the *time*-axis. The default setting is `All`. You can select one of the following options:

- `All` — The *time*-axis labels appear in all displays.
- `None` — The *time*-axis labels do not appear in the displays.
- `Bottom Displays Only` — The *time*-axis labels appear in only the bottom row of the displays.

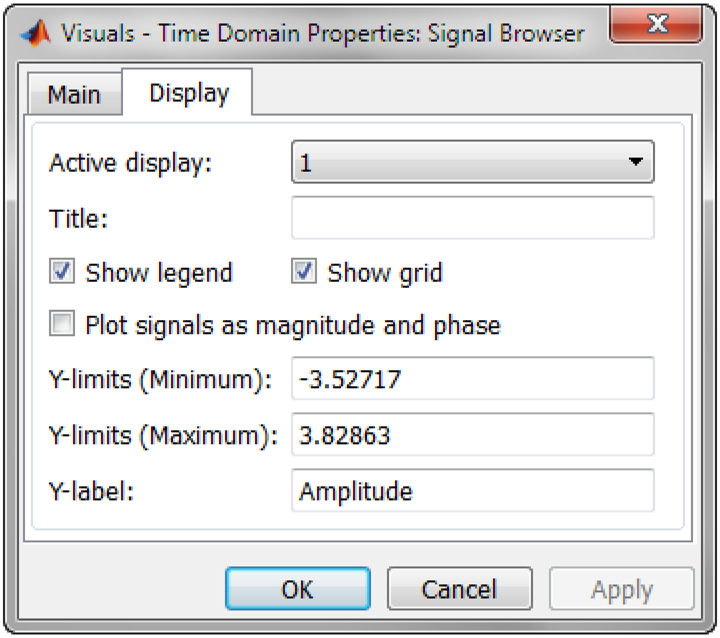
“Tunable”.

Show time-axis label

Select this check box to show the time-axis label on the scope display. This check box is not available if **Time-axis labels** is `None`.

Display Pane

The **Display** pane of the Configuration Properties dialog box appears as follows.



Visuals - Time Domain Properties: Signal Browser

Active display: 1

Title:

☑ Show legend ☑ Show grid

□ Plot signals as magnitude and phase

Y-limits (Minimum): -3.52717

Y-limits (Maximum): 3.82863

Y-label: Amplitude

Active display

Specify the active display as an integer to get and set relevant properties. The number of a display corresponds to its column-wise placement index. Set this property to control which display should have its axes colors, line properties, marker properties, and visibility changed. “Tunable”

When you use the Layout option to tile the window into multiple displays, the display highlighted in blue is referred to as the *active display*. The default setting is `1`.

Title

Specify the active display title as a string. Enter `%<SignalLabel>` to use the signal labels in the Simulink Model as the axes titles. By default, the active display has no title. “Tunable”.

Show legend

Select this check box to show the legend in the display. The channel legend displays a name for each channel of each input signal. When the legend appears, you can place it anywhere inside of the scope window. To turn the legend off, clear the **Show legend** check box. This parameter applies only when the Spectrum **Type** is `Power` or `Power density`. “Tunable”

You can edit the name of any channel in the legend. To do so, double-click the current name, and enter a new channel name. By default, the scope names each channel according to either its signal name or the name of the block from which it comes. If the signal has multiple channels, the scope uses an index number to identify each channel of that signal.

Time Scope does not display signal names that were labeled within an unmasked subsystem. You must label all input signals to the scope block that originate from an unmasked subsystem.

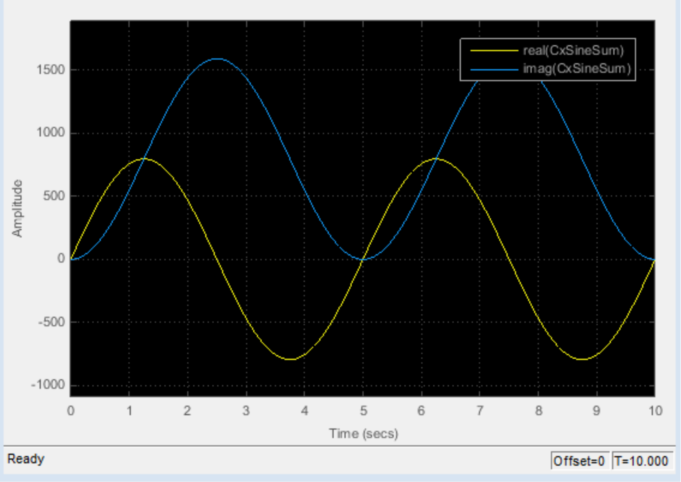
To change the appearance of any channel of any input signal in the scope window, from the menu, select **View > Style**.

Show grid

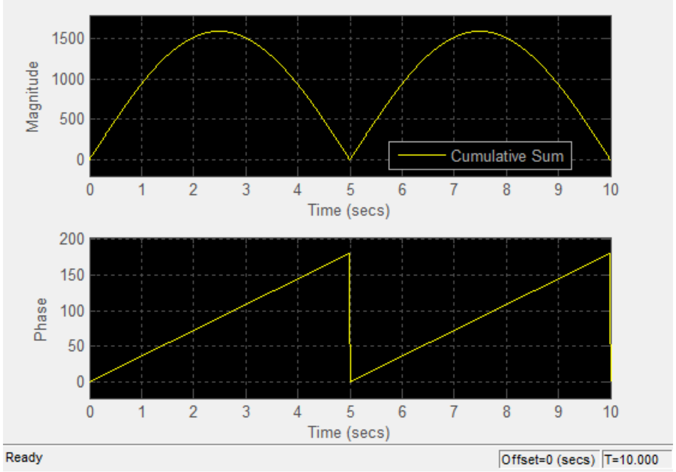
When you select this check box, a grid appears in the display of the scope figure. To hide the grid, clear this check box. “Tunable”

Plot signals as magnitude and phase

When you select this check box, the scope splits the display into a magnitude plot and a phase plot. By default, this check box is cleared. If the input signal is complex valued, the scope plots the real and imaginary portions on the same axes. These real and imaginary portions appear as different-colored lines on the same axes, as shown in the following figure.



Selecting this check box and clicking the **Apply** or **OK** button changes the display. The magnitude of the input signal appears on the top axes and its phase, in degrees, appears on the bottom axes. See the following figure.



This feature is particularly useful for complex-valued input signals. If the input is a real-valued signal, selecting this check box returns the absolute value of the signal for the magnitude. The phase is 0 degrees for nonnegative input and 180 degrees for negative input. "Tunable"

Y-limits (Minimum)

Specify the minimum value of the *y*-axis. "Tunable"

When you select the **Plot signal(s) as magnitude and phase** check box, the value of this property always applies to the magnitude plot on the top axes. The phase plot on the bottom axes is always limited to a minimum value of -180 degrees.

Y-limits (Maximum)

Specify the maximum value of the *y*-axis. "Tunable"

When you select the **Plot signal(s) as magnitude and phase** check box, the value of this property always applies to the magnitude plot on the top axes. The phase plot on the bottom axes is always limited to a maximum value of 180 degrees.

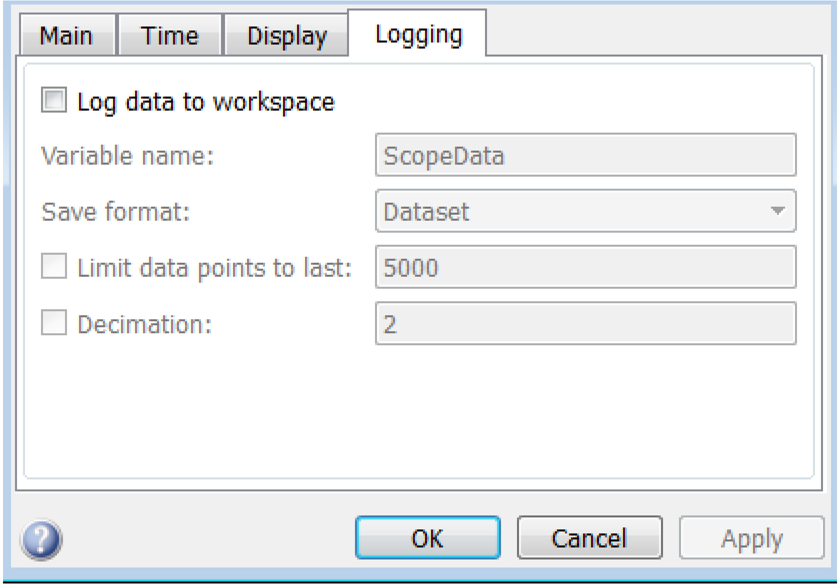
Y-label

Specify as a string the text for the scope to display to the left of the *y*-axis. "Tunable"

This property becomes invisible when you select the **Plot signal(s) as magnitude and phase** check box. When you enable that property, the *y*-axis label always appears as `Magnitude` on the top axes and `Phase` on the bottom axes.

Logging Pane

The **Logging** pane of the Configuration Properties dialog box appears as follows.



□ Log data to workspace

Variable name: ScopeData

Save format: Dataset

□ Limit data points to last: 5000

□ Decimation: 2

Log data to workspace

When you select this check box, the scope logs data in the format you select in **Save format**.

The default setting is unchecked and no data is logged.

Variable name

Specify as a string the name of the variable in the MATLAB workspace to which the scope logs data. Any existing variable is overwritten.

Save format

Select the format in which to save logged data. Unless otherwise noted, you can save logged data for single- and multi-port data, sample-based and frame-based data, variable-size data, MAT-file logging, and external mode archiving. Valid values for **Save format** are:

- `Structure With Time` — Save logged data as a structure with associated time information to the MATLAB workspace. Structure With Time format does not support single- or multi-port frame-based data.

- Structure — Save logged data as a structure to the MATLAB workspace. Structure format does not support multi-port, frame-based data.
- Array — Save logged data as an array with associated time information to the MATLAB workspace. Array format does not support multi-port sample-based data, single- or multi-port frame-based data, or variable-size data.
- Dataset — Save logged data as a dataset object to the MATLAB workspace. Dataset format does not support variable-size data, MAT-file logging, or external mode archiving. See Simulink.SimulationData.Dataset for information.

Limit data points to last

When you select this check box, the scope limits the number of data points that it stores in a variable. Specify as a positive integer the number of data points at the end of the simulation data that the scope logs.

The default setting is unchecked, so that all data is logged. When checked, the default is the last 5000 data points.

Decimation

When you select this check box, the scope logs every Nth data point, where N is the decimation factor you specify.

The default setting is unchecked, so that logged data is not decimated. When checked, the default decimation rate is 2.

Style Dialog Box

In the **Style** dialog box, you can customize the style of displays. You can change the color of the figure containing the displays, the background and foreground colors of display axes, and properties of lines in a display. From the scope menu, select **View > Style** or select the Style button () in the dropdown below the Configuration Properties button to open this dialog box.

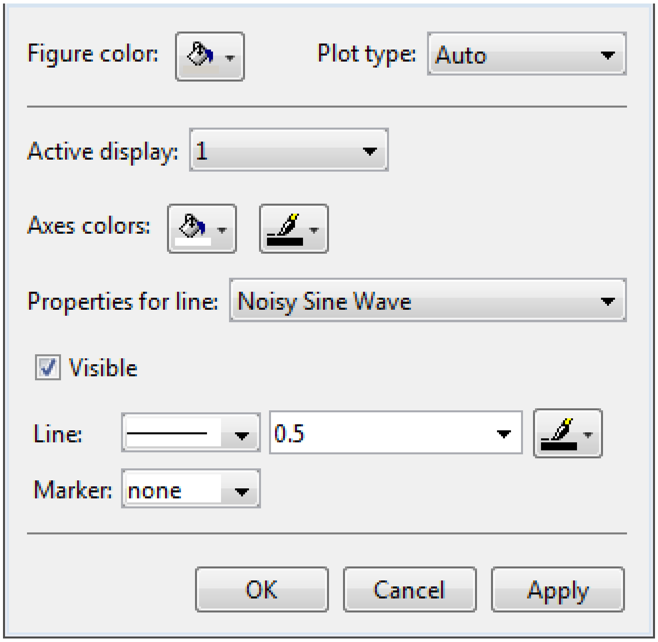


Figure color:

Plot type: Auto

Active display: 1

Axes colors:

Properties for line: Noisy Sine Wave

☑ Visible

Line: 0.5

Marker: none

Properties

The **Style** dialog box allows you to modify the following properties of the scope figure:

Figure color

Specify the color that you want to apply to the background of the scope figure. By default, the figure color is gray.

Plot type

Specify the type of plot to use. The default setting is `Line`. Valid values for **Plot type** are:

- `Line` — Displays input signal as lines connecting each of the sampled values. This approach is similar to the functionality of the MATLAB `line` or `plot` function.
- `Stairs` — Displays input signal as a *stairstep* graph. A stairstep graph is made up of only horizontal lines and vertical lines. Each horizontal line represents the signal value for a discrete sample period and is connected to two vertical lines. Each

vertical line represents a change in values occurring at a sample. This approach is equivalent to the MATLAB `stairs` function. Stairstep graphs are useful for drawing time history graphs of digitally sampled data.

- `Auto` — Displays input signal as a line graph if it is a continuous signal and displays input signal as a stairstep graph if it is a discrete signal.

This property is "Tunable".

Active display

Specify the active display as an integer to get and set relevant properties. The number of a display corresponds to its column-wise placement index. Set this property to control which display should have its axes colors, line properties, marker properties, and visibility changed. "Tunable"

When you use the Layout option to tile the window into multiple displays, the display highlighted in blue is referred to as the *active display*. The default setting is `1`.

Axes colors

Specify the color that you want to apply to the background of the axes for the active display.

Properties for line

Specify the signal for which you want to modify the visibility, line properties, and marker properties.

Visible

Specify whether the selected signal on the active display should be visible. If you clear this check box, the line disappears.

Line

Specify the line style, line width, and line color for the selected signal on the active display.

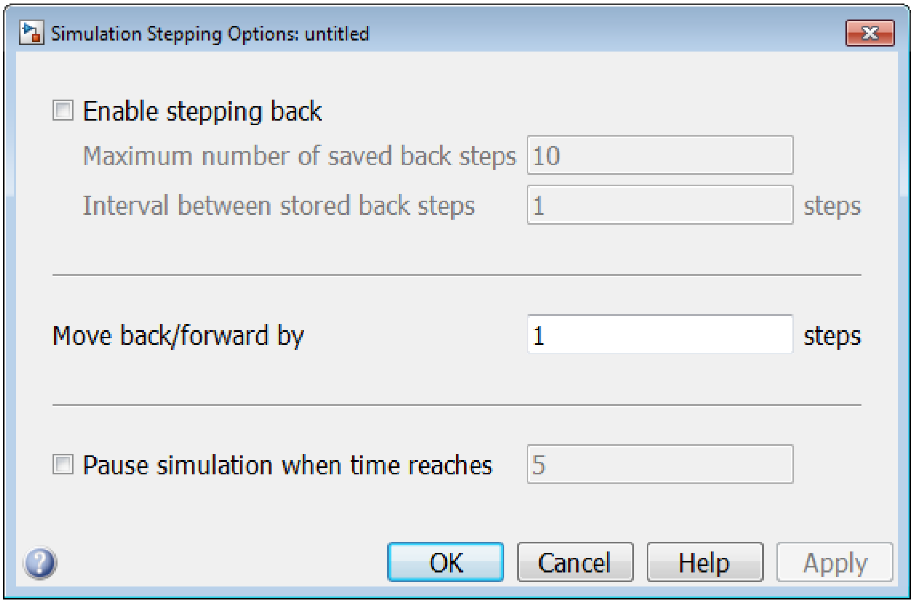
Marker

Specify marks for the selected signal on the active display to show at data points. This property is similar to the `Marker` property for the MATLAB Handle Graphics plot objects. You can choose any of the marker symbols from the following table.

Specifier	Marker Type
none	No marker (default)
○	Circle
□	Square
×	Cross
•	Point
+	Plus sign
✳	Asterisk
◇	Diamond
▽	Downward-pointing triangle
△	Upward-pointing triangle
◁	Left-pointing triangle
▷	Right-pointing triangle
☆	Five-pointed star (pentagram)
✡	Six-pointed star (hexagram)

Stepping Options

The Simulation Stepping Options dialog box lets you control the simulation behavior. You can pause the simulation at a specified time, enable stepping back, or specify options for stepping back. You can also modify the number of steps by which to step forward or backward. To open this dialog box, in the Time Scope menu, select **Simulation** > **Stepping Options** to open this dialog box. Alternatively, if stepping back is disabled, in the Time Scope toolbar, click the step back button.



Simulation Stepping Options: untitled

□ Enable stepping back

Maximum number of saved back steps 10

Interval between stored back steps 1 steps

Move back/forward by 1 steps

□ Pause simulation when time reaches 5

The Simulation Stepping Options dialog box is not unique to Time Scope; it can also be launched from any Simulink model. To open this dialog box from any Simulink model, select **Simulation** > **Stepping Options**. For more information, see “How Simulation Stepper Helps With Model Analysis” and “Simulation Stepping Options” in the Simulink documentation.

Enable stepping back

Select this check box to enable the Time Scope to take steps back in time. When selected, Time Scope enables the step back button (◀‖) on the simulation toolbar.

Maximum number of saved back steps

Specify the maximum number of back steps that the Time Scope saves in memory. To maximize simulation speed, the value for this property should be kept small. The default setting is 10.

Interval between stored back steps

Specify the number of steps between back steps that the Time Scope saves in memory for stepping backward. Set this property to a larger number to increase the time span of a back step without increasing the amount of memory used. The default setting is 1.

Move back/forward by

Specify the number of steps forward or backward that the Scope progresses when you click the step forward (|▷) and step back (◁|) buttons. The default setting is 1.

Pause simulation when time reaches

Select this check box to enable the Scope to pause the simulation when it reaches a specified time.

Pause simulation when time reaches

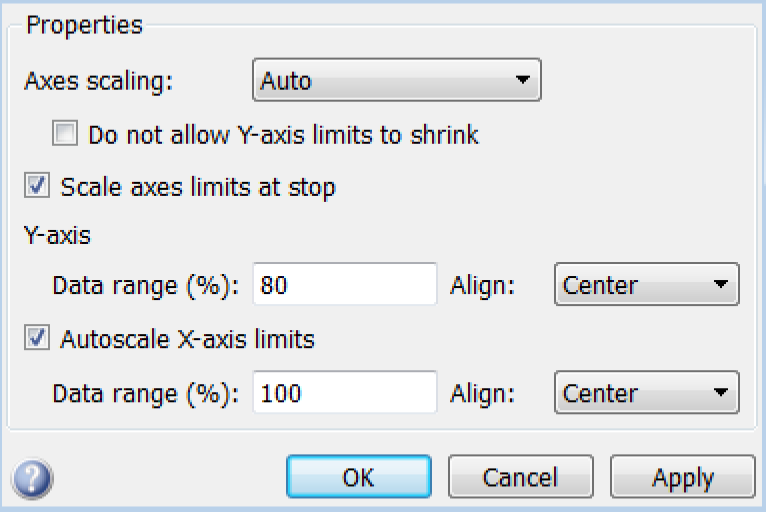
Specify the time at which you want Scope to pause when the check box is selected.

Tools—Axes Scaling Properties

Select **Tools** > **Axes Scaling Properties** to open the Axes Scaling Properties dialog box. This dialog box provides you with the ability to automatically zoom in on and zoom out of your data, and to scale the axes of the Scope.

Properties

The Tools—Axes Scaling Properties dialog box appears as follows.



Properties

Axes scaling: Auto

□ Do not allow Y-axis limits to shrink

☑ Scale axes limits at stop

Y-axis

Data range (%): 80 Align: Center

☑ Autoscale X-axis limits

Data range (%): 100 Align: Center

Axes scaling

Specify when the scope should automatically scale the axes. You can select one of the following options:

- `Manual` — When you select this option, the scope does not automatically scale the axes. You can manually scale the axes in any of the following ways:
  - Select **Tools** > **Axes Scaling Properties**.
  - Press one of the **Scale Axis Limits** toolbar buttons.
  - When the scope figure is the active window, press **Ctrl** and **A** simultaneously.
- `Auto` — When you select this option, the scope scales the axes as needed, both during and after simulation. Selecting this option shows the **Do not allow Y-axis limits to shrink** check box.
- `After N Updates` — Selecting this option causes the scope to scale the axes after a specified number of updates. Selecting this option shows the **Number of updates** edit box.

By default, this property is set to `Auto`. This property is “Tunable”.

Do not allow Y-axis limits to shrink

When you select this property, the *y*-axis is allowed only to grow during axes scaling operations. If you clear this check box, the *y*-axis or color limits may shrink during axes scaling operations.

This property appears only when you select `Auto` for the **Axis scaling** property. When you set the **Axes scaling** property to `Manual` or `After N Updates`, the *y*-axis or color limits are allowed to shrink. “Tunable”.

Number of updates

Specify as a positive integer the number of updates after which to scale the axes. This property appears only when you select `After N Updates` for the **Axes scaling** property. “Tunable”.

Scale axes limits at stop

Select this check box to scale the axes when the simulation stops. The *y*-axis is always scaled. The *x*-axis limits are only scaled if you also select the **Scale X-axis limits** check box.

Y-axis Data range (%)

Set the percentage of the *y*-axis that the scope should use to display the data when scaling the axes. Valid values are between 1 and 100. For example, if you set this property to `100`, the Scope scales the *y*-axis limits such that your data uses the entire *y*-axis range. If you then set this property to `30`, the scope increases the *y*-axis range such that your data uses only 30% of the *y*-axis range. “Tunable”.

Y-axis Align

Specify where the scope should align your data with respect to the *y*-axis when it scales the axes. You can select `Top`, `Center`, or `Bottom`. “Tunable”.

Autoscale X-axis limits

Check this box to allow the scope to scale the *x*-axis limits when it scales the axes. If **Axes scaling** is set to `Auto`, checking **Scale X-axis limits** only scales the data currently within the axes, not the entire signal in the data buffer. “Tunable”.

X-axis Data range (%)

Set the percentage of the *x*-axis that the Scope should use to display the data when scaling the axes. Valid values are between 1 and 100. For example, if you set this property to `100`, the Scope scales the *x*-axis limits such that your data uses the entire*x*-axis range. If you then set this property to `30`, the Scope increases the *x*-axis range such that your data uses only 30% of the *x*-axis range. Use the *x*-axis **Align** property to specify data placement with respect to the *x*-axis.

This property appears only when you select the **Scale X-axis limits** check box. "Tunable".

X-axis Align

Specify how the Scope should align your data with respect to the *x*-axis: `Left`, `Center`, or `Right`. This property appears only when you select the **Scale X-axis limits** check box. "Tunable".

Examples

The first few examples illustrate how to use the Time Scope block to view a variety of input signals in the time domain.

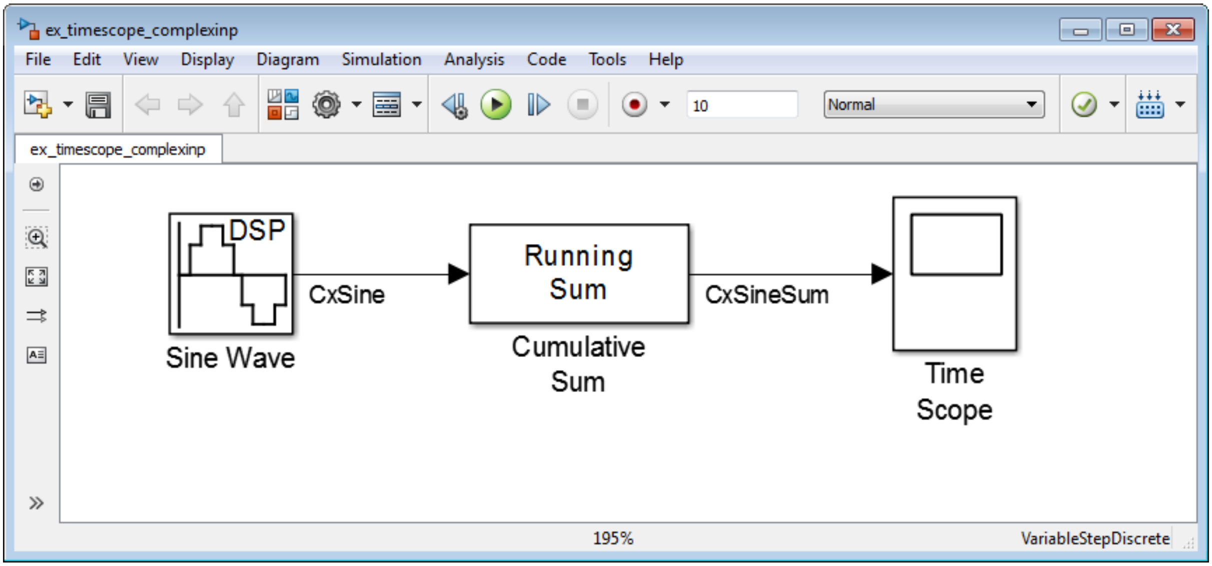
- "Example: Display Complex-valued Input Signal" on page 1-1458
- "Example: Display Input Signal of Changing Size" on page 1-1461
- "Example: Display Simulink Enumeration Input Signal" on page 1-1463

The remaining examples demonstrate how to use the Measurements Panels in the Time Scope figure to glean information about the input signals.

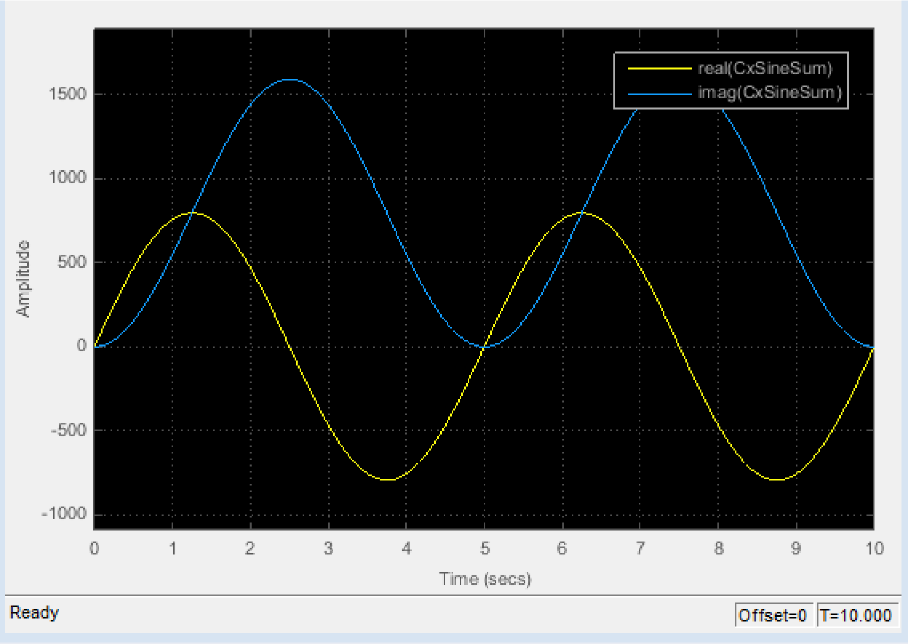
- "Example: Use Bilevel Measurements Panel with Clock Input Signal" on page 1-1465
- "Example: Find Heart Rate Using Peak Finder Panel with ECG Input Signal" on page 1-1468

Example: Display Complex-valued Input Signal

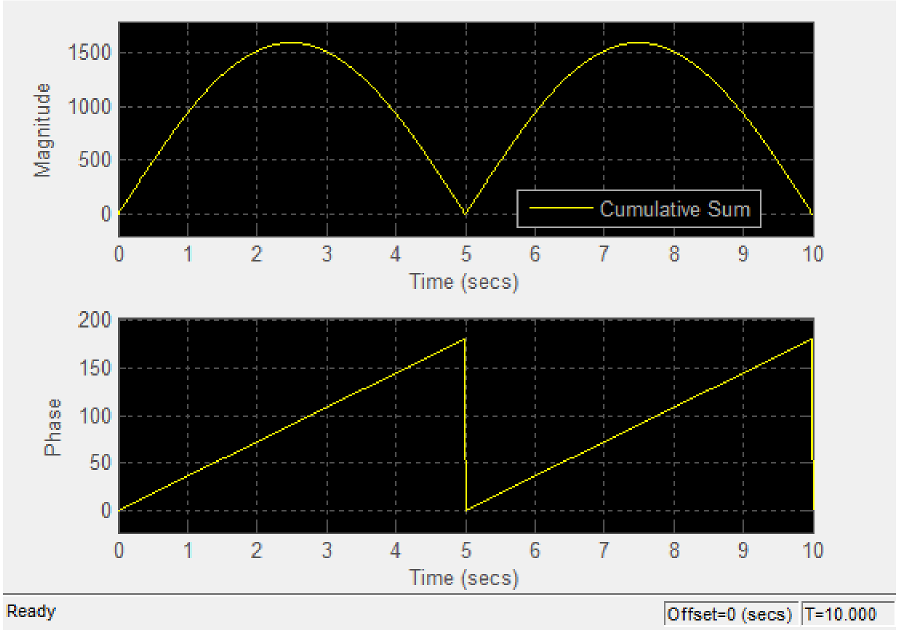
At the MATLAB command prompt, type `ex_timescope_complexinp` to open the example model. The following Simulink model appears.



By default, when the input is a complex-valued signal, Time Scope plots the real and imaginary portions on the same axes. These real and imaginary portions appear as different-colored lines on the same axes within the same active display. Run your model to see the time domain output, as shown in the following figure.

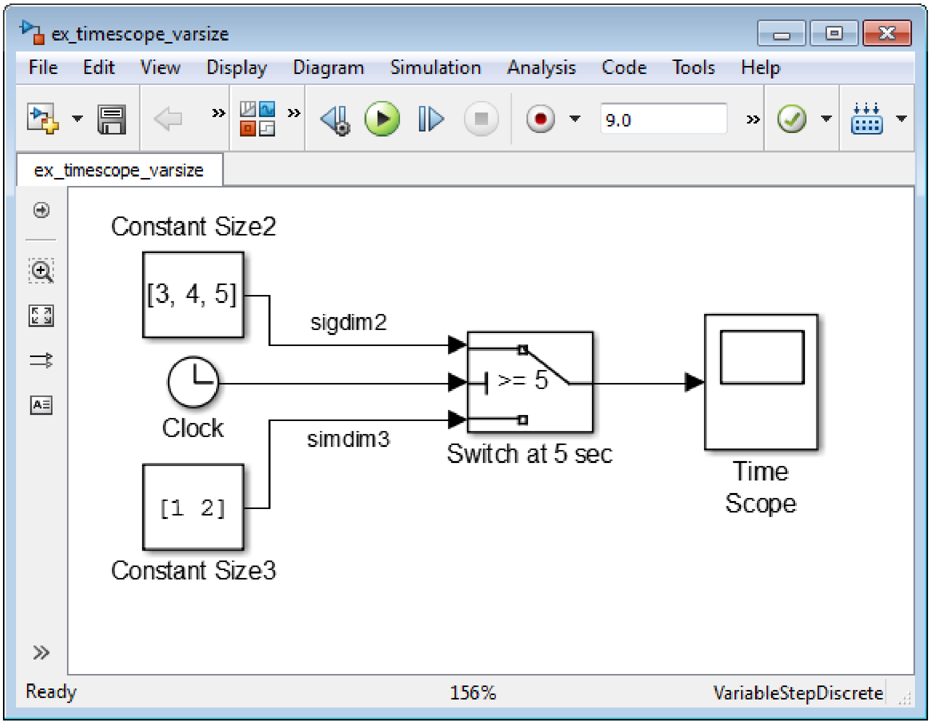


The Configuration Properties dialog box controls the visual configuration settings of the Scope displays. From the Scope menu, select **View** > **Configuration Properties** to open this dialog box. Go to the Display tab. Selecting the **Plot signal(s) as magnitude and phase** check box specifies the Scope to plot the magnitude and phase of the input signal. The magnitude and phase appear on two separate axes within the same active display. After you select this check box, click **OK**. The active display shows the magnitude of the input signal on the top axes. The signal phase, in degrees, appears on the bottom axes. See the following figure.

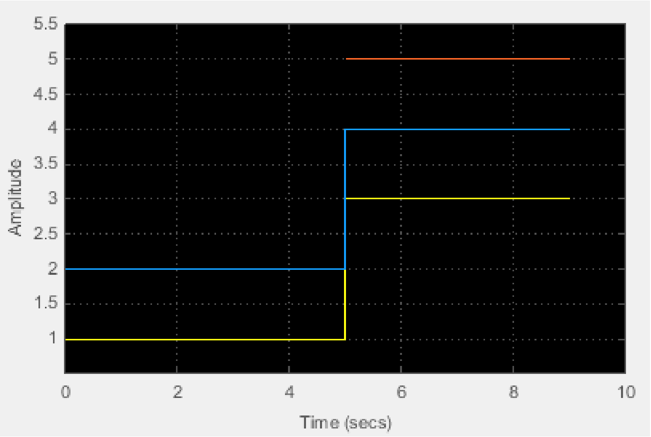


Example: Display Input Signal of Changing Size

At the MATLAB command prompt, type `ex_timescope_varsize` to open the example model. The following Simulink model appears.



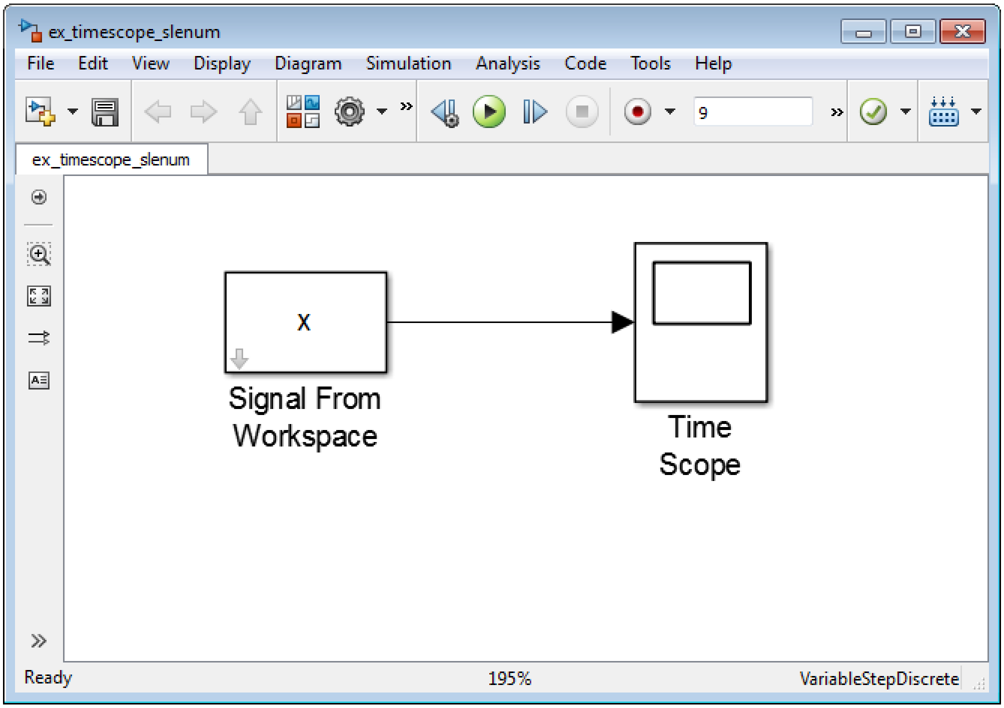
In this example, the size of the input signal to the Time Scope block changes as the simulation progresses. When the simulation time is less than 5 seconds, Time Scope plots the signal connected to the third input port of the Switch block, which has signal dimensions 1 by 2. After 5 seconds, Time Scope plots the signal connected to the first input port of the Switch block, which has signal dimensions 1 by 3. Run your model to see the time domain output, as shown in the following figure.



As you can see in the figure, the third line on the display, colored red, appears only after 5 seconds.

Example: Display Simulink Enumeration Input Signal

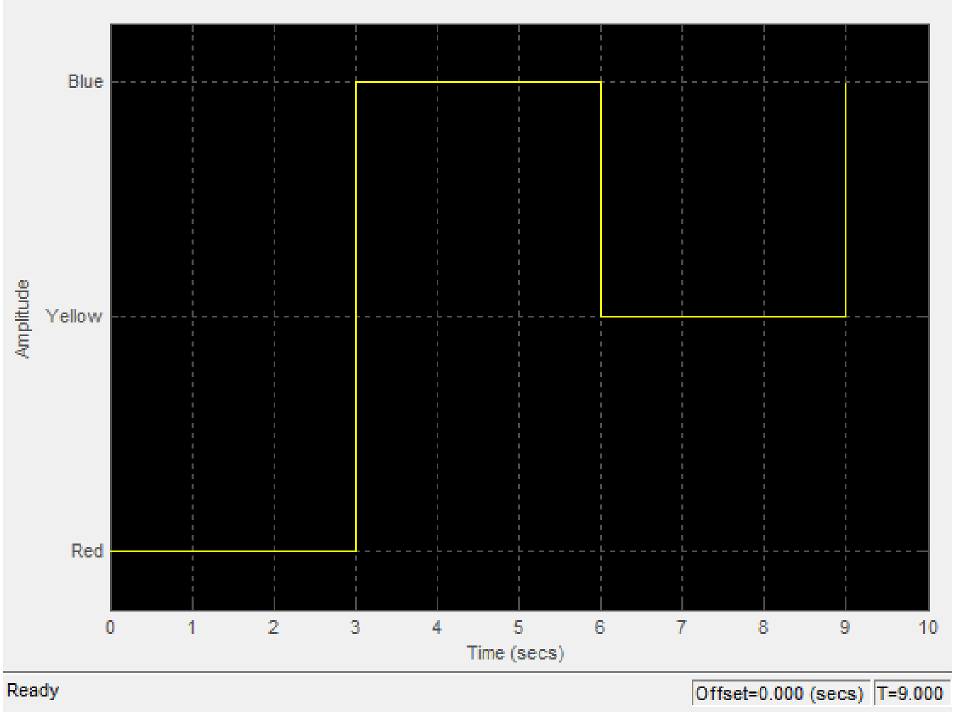
At the MATLAB command prompt, type `ex_timescope_slenum` to open the example model. The following Simulink model appears.



In this example, Simulink imports the variable *x*, which is a Simulink enumeration data type, from the MATLAB workspace. This variable is created when the model loads because the commands that construct it reside in the model pre-load function. To view these commands, in the Simulink menu, select **File** > **Model Properties** > **Model Properties**. The following lines of MATLAB code appear when you click the **Callbacks** tab.

```
if ~exist('BasicColors','class')
    Simulink.defineIntEnumType('BasicColors', ...
        {'Red', 'Yellow', 'Blue'}, ...
        [0;1;2], ...
        'Description', 'Basic colors', ...
        'DefaultValue', 'Blue', ...
        'AddClassNameToEnumNames', true);
end
x = [BasicColors(0), BasicColors(2), BasicColors(1)];
```

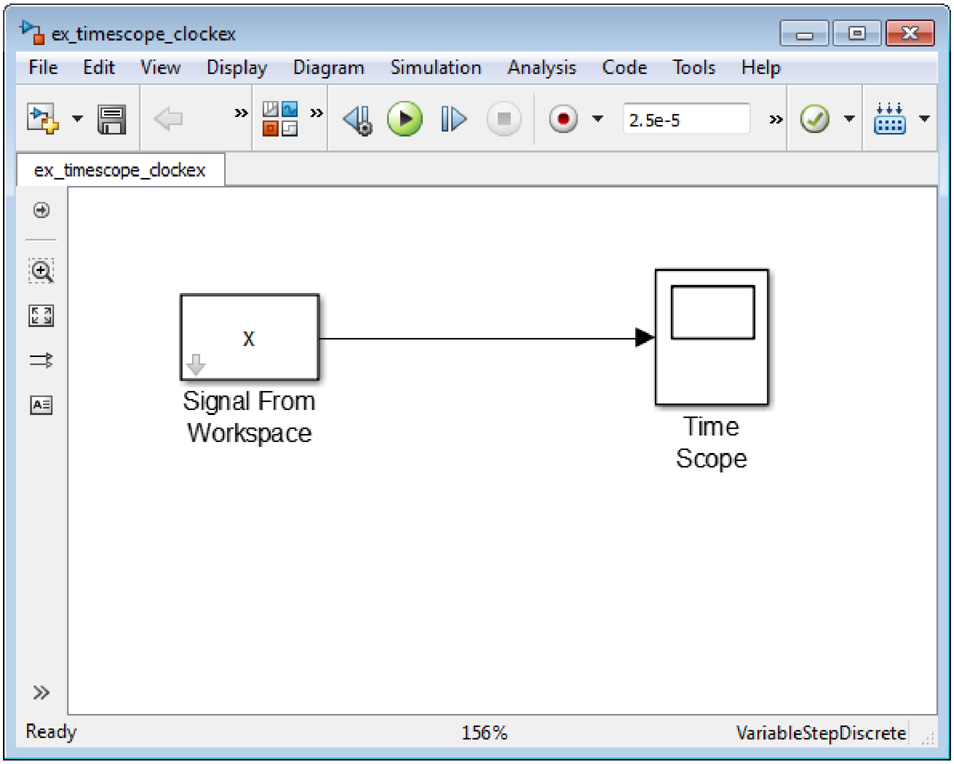
The Signal from Workspace block has a Sample time of 3 seconds. Thus, the input signal changes to the next value in the vector *x* every 3 seconds. Run your model to see the time domain output, as shown in the following figure.



As you can see in the figure, the *y*-axis shows the units of amplitude as one of Red, Yellow, or Blue. The input signal value changes from Red to Blue at 3 seconds and from Blue to Yellow at 6 seconds.

Example: Use Bilevel Measurements Panel with Clock Input Signal

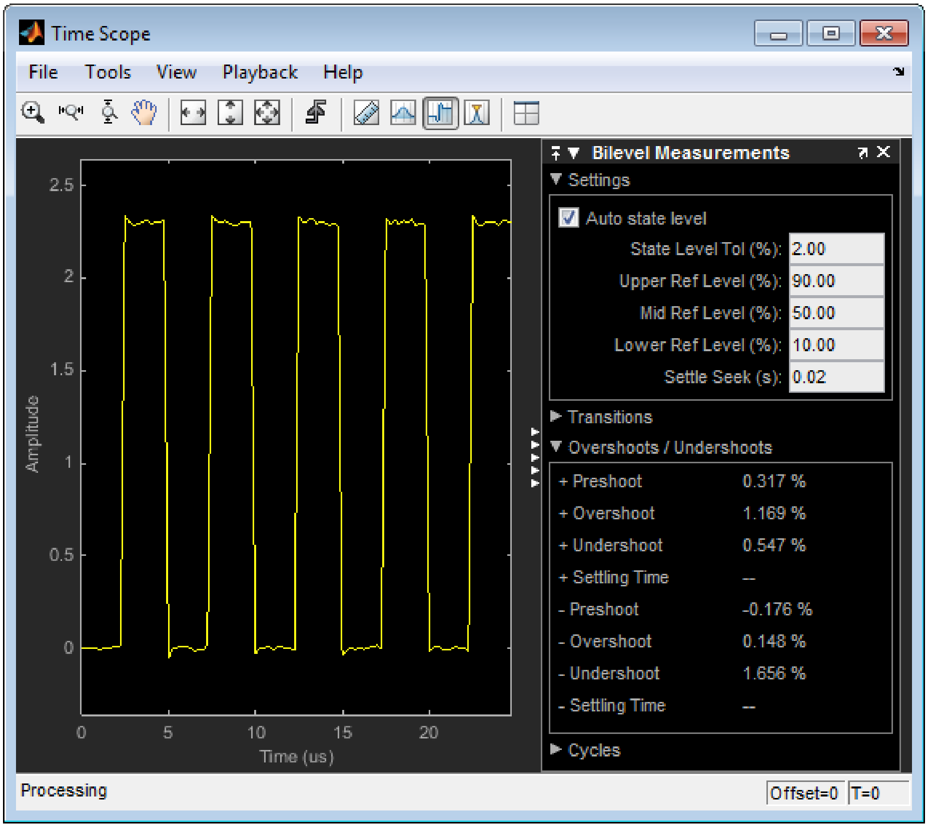
At the MATLAB command prompt, type `ex_timescope_clockex` to open the example model. The following Simulink model appears.



In this example, Simulink imports the variable *x* from the MATLAB workspace. This variable is created when the model loads because the commands that construct it reside in the Preload function. To view these commands, in the Simulink menu, select **File** > **Model Properties** > **Model Properties**. The Model Properties dialog box appears. Click the **Callbacks** tab. The following lines of MATLAB code appear.

```
load clockex;
ts = t(2)-t(1);
```

Run your model to see the time domain output. To show the **Bilevel Measurements** panel, in the Time Scope menu, select **Tools** > **Measurements** > **Bilevel Measurements**. To collapse the **Transitions** pane, click the pane collapse button (▼) next to that label. To expand the **Settings** pane and the **Overshoots / Undershoots** pane, click the pane expand button (▶) next to each label. The Time Scope figure appears as shown in the following figure.



Bilevel Measurements

▼ Settings

☑ Auto state level

State Level Tol (%): 2.00

Upper Ref Level (%): 90.00

Mid Ref Level (%): 50.00

Lower Ref Level (%): 10.00

Settle Seek (s): 0.02

▶ Transitions

▼ Overshoots / Undershoots

+ Preshoot	0.317 %
+ Overshoot	1.169 %
+ Undershoot	0.547 %
+ Settling Time	--
- Preshoot	-0.176 %
- Overshoot	0.148 %
- Undershoot	1.656 %
- Settling Time	--

▶ Cycles

As you can see in the figure, the value for the rising edge **Settling Time** parameter is initially not displayed. The reason for this is that the default value for the **Settle Seek** parameter is too large for this example. In this case, the settle seek time is longer than the entire simulation duration. Enter a value for settle seek of `2e-6`, and press the **Enter** key. Time Scope now displays a rising edge settling time value of `118.392 ns`.

The settling time value displayed is actually the statistical average of the settling times for all five rising edges. To show the settling time for only one rising edge, you can zoom in on that transition. In the Time Scope toolbar, click the Zoom X button ( ). Click on the display near a value of 2 microseconds on the *time*-axis. Drag to the right and release near a value of 4 microseconds on the *time*-axis. Time Scope updates the rising edge **Settling Time** value to reflect the new time window, as shown in the following figure.

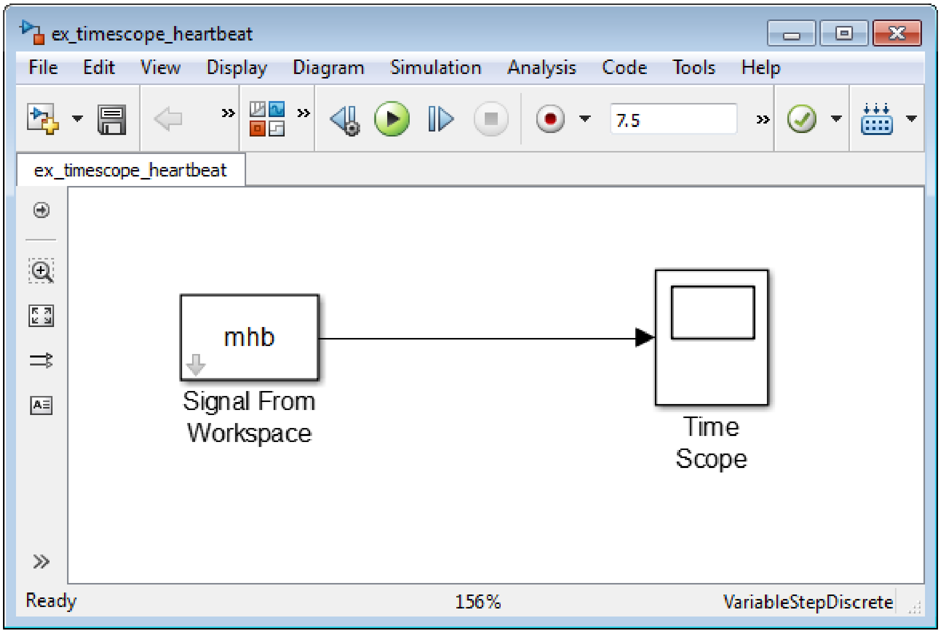
Example: Find Heart Rate Using Peak Finder Panel with ECG Input Signal

At the MATLAB command prompt, type `ex_timescope_heartbeat` to open the example model. The following Simulink model appears.



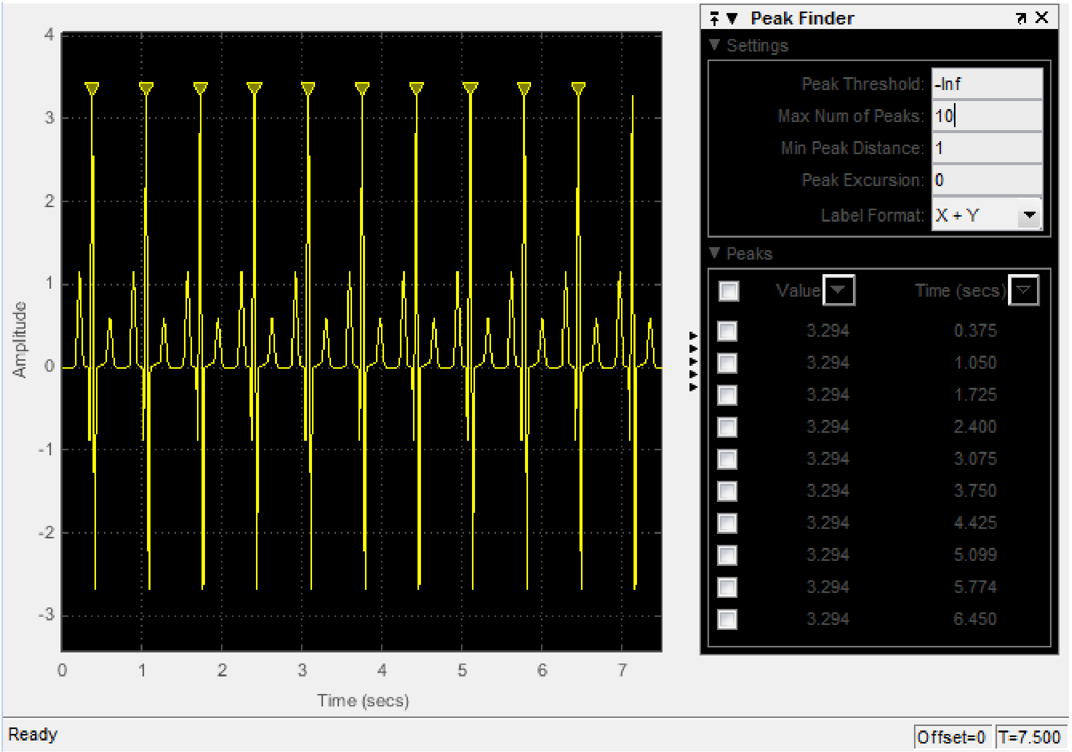
In this example, Simulink imports the variable *mhb* from the MATLAB workspace. The variable *mhb* is created when the model loads because the commands that construct *mhb* are in the Preload function. To view these commands, in the Simulink menu, select **File** > **Model Properties** > **Model Properties**. The Model Properties dialog box appears. Click the **Callbacks** tab. The following lines of MATLAB code appear.

```
x1 = 3.5*ecg(2700).';
y1 = sgolayfilt(kron(ones(1,13),x1),0,21);
n = (1:30000)';
del = round(2700*rand(1));
mhb = y1(n + del);
ts = 0.00025;
```

This example uses the Savitzky-Golay filter in Signal Processing Toolbox. For more information, see the “sgolayfilt” function reference page or run the `sgolaydemo` example.

Run your model to see the time domain output. To show the **Peak Finder** panel, in the Time Scope menu, select **Tools** > **Measurements** > **Peak Finder**. To expand the **Settings** pane, click the pane expand button (▶) next to that label. Enter a value for **Max Num of Peaks** of 10 and press the **Enter** key. Time Scope now displays in the

Peaks pane a list of 10 peak amplitude values, and the times at which they occur, as shown in the following figure.



Peak Finder

▼ Settings

Peak Threshold: -Inf

Max Num of Peaks: 10

Min Peak Distance: 1

Peak Excursion: 0

Label Format: X + Y

▼ Peaks

□	Value	Time (secs)
□	3.294	0.375
□	3.294	1.050
□	3.294	1.725
□	3.294	2.400
□	3.294	3.075
□	3.294	3.750
□	3.294	4.425
□	3.294	5.099
□	3.294	5.774
□	3.294	6.450

Ready Offset=0 T=7.500

As you can see from the list of peak values, there is a constant time difference of 0.675 seconds between each heartbeat. Therefore, the heart rate of the ECG signal is given by the following equation.

$$\frac{60\,\frac{\text{sec}}{\text{min}}}{0.675\,\frac{\text{sec}}{\text{beat}}} = 88.89\,\frac{\text{beats}}{\text{min}}(\text{bpm})$$

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers • Simulink enumerations

Supported Simulation Modes

You can use the scope block in models running the following supported simulation modes.

Mode	Supported	Notes and Limitations
Normal	Yes	
Accelerator	Yes	
Rapid Accelerator	Yes	You can use Rapid Accelerator mode as a method to increase the execution speed of your Simulink model. Rapid Accelerator mode creates an executable that includes the solver and model methods. This executable resides outside MATLAB and Simulink. Rapid Accelerator mode uses External mode to communicate with Simulink. For more information about Rapid Accelerator mode, see “Acceleration” in the Simulink documentation.
PIL	No	

Mode	Supported	Notes and Limitations
SIL	No	
External	Yes	You can use External mode to tune block parameters in real time and view block outputs in many types of blocks and subsystems. External mode establishes communication between a host system, where the Simulink environment resides, and a target system, where the executable runs after it is generated by the code generation and build process. For more information about External mode, see “Host/Target Communication” in the Simulink Coder documentation. The scope does not support data archiving. See “Set External Mode Data Archiving Parameters” in the Real-Time Windows Target documentation.

For more information about these modes, see “How Acceleration Modes Work” in the Simulink documentation.

How To

- “Display Time-Domain Data”

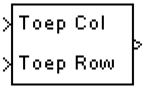
Toeplitz

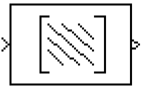
Generate matrix with Toeplitz symmetry

Library

Math Functions / Matrices and Linear Algebra / Matrix Operations

dspmtrx3





Description

The Toeplitz block generates a Toeplitz matrix from inputs defining the first column and first row. The top input (`Col`) is a vector containing the values to be placed in the first *column* of the matrix, and the bottom input (`Row`) is a vector containing the values to be placed in the first *row* of the matrix.

```
y = toeplitz(Col,Row)       % Equivalent MATLAB code
```

The other elements of the matrix obey the relationship

```
y(i,j) = y(i-1,j-1)
```

and the output has dimension `[length(Col) length(Row)]`. The y(1,1) element is inherited from the `Col` input. For example, the following inputs

```
Col = [1 2 3 4 5]
Row = [7 7 3 3 2 1 3]
```

produce the Toeplitz matrix

$$\begin{bmatrix} 1 & 7 & 3 & 3 & 2 & 1 & 3 \\ 2 & 1 & 7 & 3 & 3 & 2 & 1 \\ 3 & 2 & 1 & 7 & 3 & 3 & 2 \\ 4 & 3 & 2 & 1 & 7 & 3 & 3 \\ 5 & 4 & 3 & 2 & 1 & 7 & 3 \end{bmatrix}$$

When you select the **Symmetric** check box, the block generates a symmetric (Hermitian) Toeplitz matrix from a single input, `u`, defining both the first row and first column of the matrix.

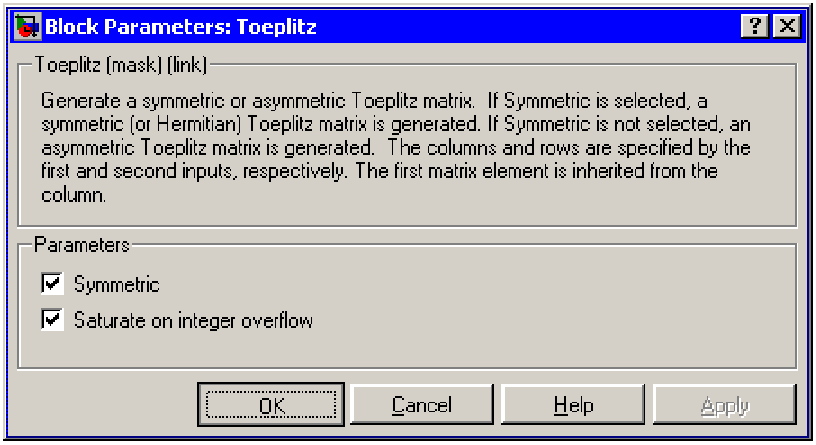
```
y = toeplitz(u)       % Equivalent MATLAB code
```

The output has dimension `[length(u) length(u)]`. For example, the Toeplitz matrix generated from the input vector `[1 2 3 4]` is

$$\begin{bmatrix} 1 & 2 & 3 & 4 \\ 2 & 1 & 2 & 3 \\ 3 & 2 & 1 & 2 \\ 4 & 3 & 2 & 1 \end{bmatrix}$$

The Toeplitz block supports real and complex floating-point and fixed-point inputs.

Dialog Box



Toeplitz (mask) (link)

Generate a symmetric or asymmetric Toeplitz matrix. If Symmetric is selected, a symmetric (or Hermitian) Toeplitz matrix is generated. If Symmetric is not selected, an asymmetric Toeplitz matrix is generated. The columns and rows are specified by the first and second inputs, respectively. The first matrix element is inherited from the column.

Parameters

☑ Symmetric

☑ Saturate on integer overflow

Symmetric

When selected, enables the single-input configuration for symmetric Toeplitz matrix output.

Saturate on integer overflow

When you generate a symmetric Toeplitz matrix with this block, if the input vector is complex, the output is a symmetric Hermitian matrix whose elements satisfy the relationship

$$y(i, j) = \mathrm{conj}(y(j, i))$$

For fixed-point signals the conjugate operation could result in an overflow. When you select this parameter, overflows saturate. This parameter is only visible with the **Symmetric** parameter is selected. This parameter is ignored for floating-point signals.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers (real signals only)
Toep Col	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Toep Row	• Double-precision floating point • Single-precision floating point

Port	Supported Data Types
	• Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Output	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers

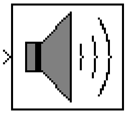
To Audio Device

Write audio data to computer's audio device

Library

Sinks

`dspsnks4`



Description

The To Audio Device block sends audio data to your computer's audio device. This block is not supported for use with the Simulink Model block.

Use the **Device** parameter to specify the device to which you want to send the audio data. This parameter is automatically populated based on the audio devices installed on your system. If you plug or unplug an audio device from your system, type `clear mex` at the MATLAB command prompt to update the list.

Select the **Inherit sample rate from input** check box if you want the block to inherit the sample rate of the audio signal from the input to the block. If you clear this check box, the **Sample rate (Hz)** parameter appears on the block. Use this parameter to specify the number of samples per second in the signal.

The range of supported audio device sample rates and data type formats, depend on both the sound card and the API which is chosen for the sound card.

Use the **Device data type** to specify the data type of the audio data that is sent to the device. You can choose:

- `8-bit integer`
- `16-bit integer`
- `24-bit integer`
- `32-bit float`

- `Determine from input data type`

If you choose `Determine from input data type`, the following table summarizes the block's behavior.

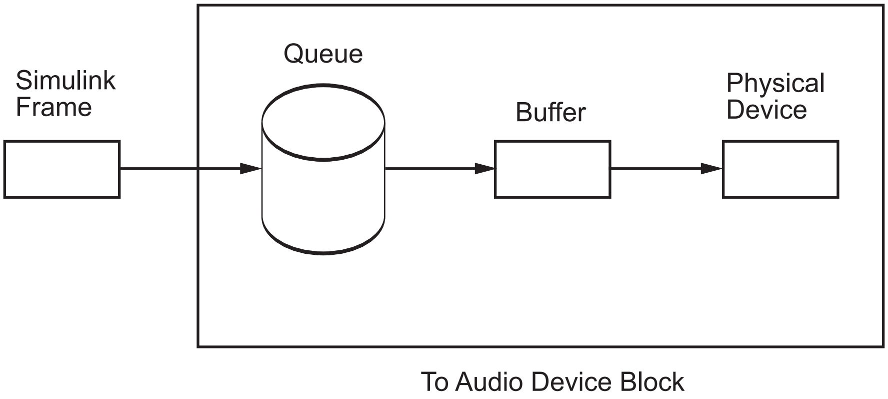
Input Data Type	Device Data Type
Double-precision floating point or single-precision floating point	32-bit floating point
32-bit integer	24-bit integer
16-bit integer	16-bit integer
8-bit integer	8-bit integer

If you choose `Determine from input data type` and the device does not support the input data type, the block uses the next lowest-precision data type supported by the device.

The generated code for this block relies on prebuilt .dll files. You can run this code outside the MATLAB environment, or redeploy it, but be sure to account for these extra .dll files when doing so. The packNGo function creates a single zip file containing all of the pieces required to run or rebuild this code. See `packNGo` for more information.

Buffering

The To Audio Device block buffers the data from a Simulink signal using the process illustrated by the following figure.



1. At the start of the simulation, the queue is filled with silence. Specify the size of this queue using the **Queue duration (seconds)** parameter. As Simulink runs, the block appends Simulink frames to the bottom of the queue.
2. At each time step, the blocks sends a buffer of samples from the top of the queue to the audio device. Select the **Automatically determine buffer size** check box to allow the block to use a conservative buffer size. See the From Audio Device block reference page for the equation the block uses to calculate this buffer size. If you clear this check box, the **Buffer size (samples)** parameter appears on the block. Use this parameter to specify the size of the buffer in samples.
3. The block writes the buffer of audio data to the device. If the queue did not contain enough data to completely fill the buffer, the block fills the remaining portion of the buffer with zeros. This data has a the data type specified by the **Device data type** parameter.

When the simulation throughput rate is lower than the hardware throughput rate, the queue, which is initially full, becomes empty. If the queue is empty, the block sends zeros (silence) to the audio device. You can monitor inserted zeroes using the optional `Underrun` output port. When the simulation throughput rate is higher than the hardware throughput rate, the To Audio Device block waits to write data to the queue.

To minimize the chance of dropouts, the block checks to make sure the queue duration is at least as large as the maximum of the buffer size and the frame size. If it is not, the queue duration is automatically set to this maximum value.

Channel Mapping

The term *Channel Mapping* refers to a 1-to-1 mapping that associates channels on the selected audio device to channels of the data. When you play audio, channel mapping allows you to specify which channel of the audio device directs input to a specific channel of audio data. You can specify channel mapping as a vector of output channel indices corresponding to each output channel of data being written. The default value in the **Device Output Channels** parameter is 1:MAXOUTPUTCHANNELS. If you do not select the default mapping, you must specify the **Device Output Channels** parameter in the dialog box.

Example: The selected output audio device contains 8 channels. The data being output has dimensions N×3 (3–channel data). You want the output to be redirected as follows:

- Fist data channel to Audio Device channel 3
- Second data channel to Audio Device channel 1

- Third data channel to Audio Device channel 8

Thus, you would specify the **Device Output Channels** as [3 1 8].

Troubleshooting

Not Keeping Up in Real Time

When Simulink cannot keep up with an audio device that is operating in real time, the queue becomes empty and gaps occur in the audio data that the block sends to the device. Select the **Output number of samples by which the queue was underrun** check box to add an output port indicating when the queue was empty. Here are several ways to deal with this situation:

- *Increase the queue duration.*

  The **Queue duration (seconds)** parameter specifies the duration of the signal, in seconds, that can be buffered during the simulation. This is the maximum length of time that the block's data supply can lag the hardware's data demand.
- *Increase the buffer size.*

  The size of the buffer processed in each interrupt from the audio device affects the performance of your model. If the buffer is too small, a large portion of hardware resources are used to write data to the device. If the buffer is too big, Simulink must wait for the device to empty the buffer before it can write the data to the queue, which introduces latency.
- *Increase the simulation throughput rate.*

  Two useful methods for improving simulation throughput rates are increasing the signal frame size and compiling the simulation into native code:

  - Increase frame sizes and use frame-based processing throughout the model to reduce the amount of block-to-block communication overhead. This can increase throughput rates in many cases. However, larger frame sizes generally result in greater model latency due to initial buffering operations.
  - Generate executable code with Simulink Coder code generation software. Native code runs much faster than Simulink and should provide rates adequate for real-time audio processing.

Other ways to improve throughput rates include simplifying the model and running the simulation on a faster PC processor. For other ideas on improving simulation performance, see “Delay and Latency” and “Performance” in the Simulink documentation.

Running an Executable Outside MATLAB

To run your generated standalone executable application in Shell, you need to set your environment to the following:

Platform	Command

Mac	`setenv DYLD_LIBRARY_PATH $LD_LIBRARY_PATH: $MATLABROOT/ bin/maci64 (csh/tcsh)`
	`export DYLD_LIBRARY_PATH $LD_LIBRARY_PATH: $MATLABROOT/ bin/maci64 (Bash)`

Linux	`setenv LD_LIBRARY_PATH $LD_LIBRARY_PATH: $MATLABROOT/ bin/glnxa64 (csh/tcsh)`
	`export LD_LIBRARY_PATH $LD_LIBRARY_PATH: $MATLABROOT/ bin/glnxa64 (Bash)`

Windows	`set PATH = $MATLABROOT\bin\win32; %PATH%`
	`set PATH = $MATLABROOT\bin\win64; %PATH%`

Channel-to-Speaker Mapping on Windows Operating Systems

The To Audio Device and From Audio Device blocks can support multiple channels. On Windows operating systems, the channel-to-speaker mapping is defined as listed below. This mapping only applies when your sound card is properly configured and capable of receiving the audio data you send. If the number of channels on the card does not match the number of channels on the block, or if you specify a data type for the **Device data type** parameter that is not supported by your device, the Windows mixer intervenes to translate from one format to another. If the Windows mixer does intervene, the channel-to-speaker mapping might differ from what is specified here.

- Single channel input — Front center speaker

  On systems with two speakers, the front center channel is split between the right and left speakers.
- Multichannel input — Channels are assigned to speakers as follows:
  - One channel — Front center
  - Two channels — Front left, front right
  - Four channels — Front left, front right, rear left, rear right
  - Six channels — Front left, front right, front center, low frequency, rear left, rear right
  - Eight channels — Front left, front right, front center, low frequency, rear left, rear right, front left center, front right center
  - For all other channel combinations, the channel assignment is dictated by the audio card.

Audio Hardware API

The To Audio Device and From Audio Device blocks use the open-source PortAudio library in order to communicate with the audio hardware on a given computer. The PortAudio library supports a range of API's designed to communicate with the audio hardware on a given platform. The following API choices were made when building the PortAudio library for the DSP System Toolbox product:

- Windows: DirectSound, WDM-KS, ASIO
- Linux: ALSA, OSS
- Mac: CoreAudio

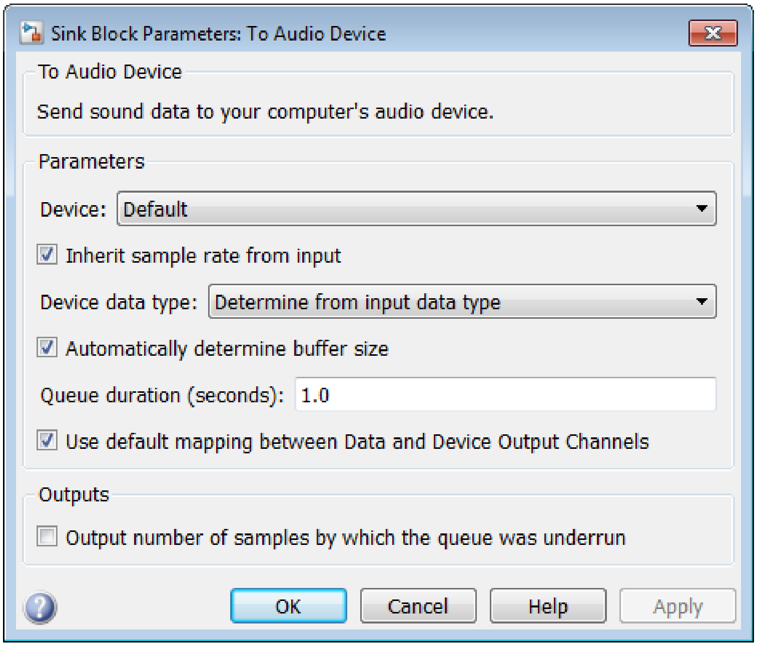
For Windows, the default is DirectSound, for Linux, the default is ALSA, and for Mac there is only one choice. To select or change the Audio Hardware API, select **Preferences** from the MATLAB Toolstrip. Then select DSP System Toolbox from the tree menu. In the **DSP System Toolbox Preferences** dialog box, the option is disabled if no device corresponds to that particular audio API.

Example

For a demonstration of how to use this block, see the “Positional Audio” example. To open this example, enter `dspAudioPos` at the MATLAB command prompt.

To learn how to measure and tune audio throughput using this block, see the "Measuring Audio Latency" example. To open this example, enter `audiolatencymeasurement` at the MATLAB command prompt.

Dialog Box



Sink Block Parameters: To Audio Device

To Audio Device

Send sound data to your computer's audio device.

Parameters

Device: Default

☑ Inherit sample rate from input

Device data type: Determine from input data type

☑ Automatically determine buffer size

Queue duration (seconds): 1.0

☑ Use default mapping between Data and Device Output Channels

Outputs

□ Output number of samples by which the queue was underrun

Device

Specify which device to send the audio data to.

Inherit sample rate from input

Select this check box if you want the block to inherit the sample rate of the audio signal from the input to the block.

Sample rate (Hz)

Specify the number of samples per second in the signal. This parameter is visible when the **Inherit sample rate from input** check box is cleared.

Device data type

Specify the data type of the audio data sent to the device.

Automatically determine buffer size

Select this check box to allow the block to calculate a conservative buffer size.

Buffer size (samples)

Specify the size of the buffer. This parameter is visible when the **Automatically determine buffer size** check box is cleared.

Queue duration (seconds)

Specify the size of the queue in seconds.

Use default mapping between Data and Device Output Channels

Select this check box to have the default mapping, where the data from the first channel of audio device is sent to the first channel of the input data, data from second channel of audio device is sent to second channel of data and so on. The maximum number of channels in the input data is determined by the **Number of channels** property.

Device Output Channels

Specify the channel mapping. This parameter is visible when the **Use default mapping between Device Input Channels and Data** check box is disabled.

Output number of samples by which the queue was underrun

Select this check box to output the number of zero samples inserted into the audio stream due to queue underrun since the last transfer of a frame to the audio device. You can use this value to debug throughput problems and adjust the queues and buffers in your model. To learn how to improve throughput, see “Troubleshooting” on page 1-1480.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point • 32-bit signed integers • 16-bit signed integers • 8-bit unsigned integers
Underrun	32-bit signed integer

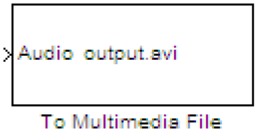
To Multimedia File

Write video frames and audio samples to multimedia file

Library

Sinks

`dspsnks4`



Description

The To Multimedia File block writes video frames, audio samples, or both to a multimedia (`.avi, .wav, .wma, .mp4, .ogg, .flac, or .wmv`) file.

You can compress the video frames or audio samples by selecting a compression algorithm. You can connect as many of the input ports as you want. Therefore, you can control the type of video and/or audio the multimedia file receives.

Note This block supports code generation for platforms that have file I/O available. You cannot use this block with Real-Time Windows Target software, because that product does not support file I/O.

This block performs best on platforms with Version 11 or later of Windows Media Player software. This block supports only uncompressed RGB24 AVI files on Linux and Mac platforms.

Windows 7 UAC (User Account Control), may require administrative privileges to encode `WMV` and `WMA` files.

The generated code for this block relies on prebuilt library files. You can run this code outside the MATLAB environment, or redeploy it, but be sure to account for these extra library files when doing so. The packNGo function creates a single zip file containing all of the pieces required to run or rebuild this code. See `packNGo` for more information.

To run an executable file that was generated from a model containing this block, you may need to add precompiled shared library files to your system path. See "Understanding C Code Generation" for details.

Cross-Platform Supported File Formats for Audio Files

Audio files can be of the following formats on all platforms:

- WAV
- FLAC
- OGG
- MPEG4 (only on Windows 7 and Mac OS X)

The default format is WAV. This block supports MPEG-4 AAC audio files on Windows 7, and Mac OS X. You can use both M4A and MP4 extensions. The following platform specific restrictions apply when writing these files:

Windows 7	Mac OS X
• Only sample rates of 44100 and 48000 Hz are supported.	• Only mono or stereo outputs are allowed.
• Only mono or stereo outputs are allowed.	
• The output data is padded on both the front and back of the signal, with extra samples of silence. Windows AAC encoder places sharp fade-in and fade-out on audio signal, causing signal to be slightly longer in samples when written to disk.	• Not all sampling rates are supported, although the Mac Audio Toolbox API do not explicitly specify a restriction.
• A minimum of 1025 samples must be written to the MPEG-4 AAC file.	

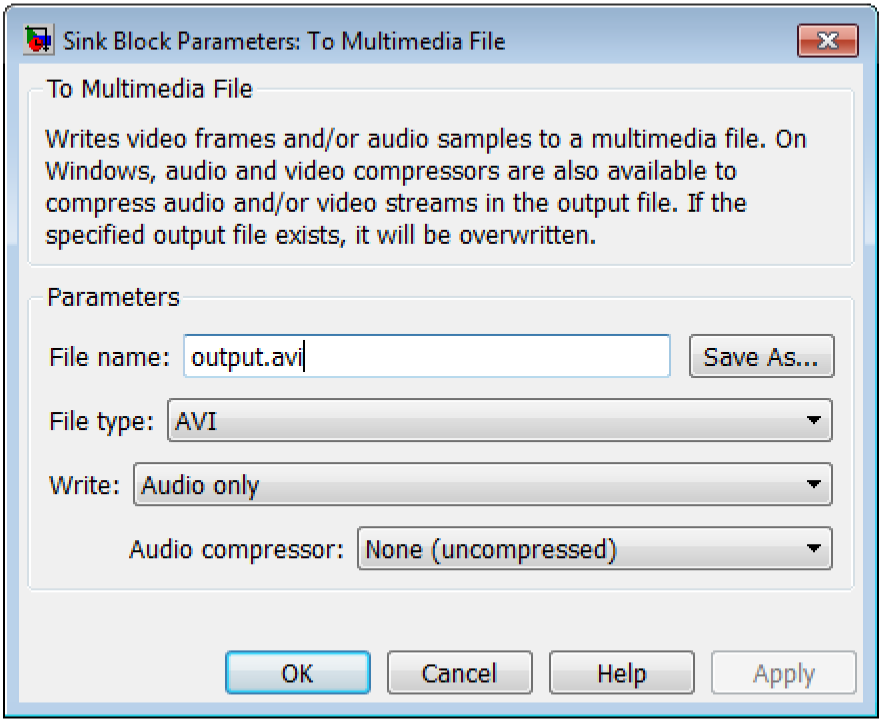
Ports

Port	Description
Image	*M*-by-*N*-by-3 matrix RGB, Intensity, or YCbCr 4:2:2 signal.

Port	Description
R, G, B	Matrix that represents one plane of the RGB video stream. Inputs to the R, G, or B port must have the same dimensions and data type.
Audio	Vector of audio data
Y, Cb, Cr	Matrix that represents one frame of the YCbCr video stream. The Y, Cb, and Cr ports use the following dimensions: Y: M x N Cb: M x $\frac{N}{2}$ Cr: M x $\frac{N}{2}$

Dialog Box

The **Main** pane of the To Multimedia File block dialog appears as follows.



Sink Block Parameters: To Multimedia File

To Multimedia File

Writes video frames and/or audio samples to a multimedia file. On Windows, audio and video compressors are also available to compress audio and/or video streams in the output file. If the specified output file exists, it will be overwritten.

Parameters

File name: output.avi

File type: AVI

Write: Audio only

Audio compressor: None (uncompressed)

File name

Specify the name of the multimedia file. The block saves the file in your current folder. To specify a different file or location, click the **Save As...** button.

File type

Specify the file type of the multimedia file. You can select `avi`, `wav`, `wma`, or `wmv`.

Write

Specify whether the block writes video frames, audio samples, or both to the multimedia file. You can select `Video and audio`, `Video only`, or `Audio only`.

Audio compressor

Select the type of compression algorithm to use to compress the audio data. This compression reduces the size of the multimedia file. Choose `None (uncompressed)` to save uncompressed audio data to the multimedia file.

Note: The other items available in this parameter list are the audio compression algorithms installed on your system. For information about a specific audio compressor, see the documentation for that compressor.

Audio data type

Select the audio data type. You can use the **Audio data type** parameter only for uncompressed wave files.

Video compressor

Select the type of compression algorithm to use to compress the video data. This compression reduces the size of the multimedia file. Choose `None (uncompressed)` to save uncompressed video data to the multimedia file.

Note: The other items available in this parameter list are the video compression algorithms installed on your system. For information about a specific video compressor, see the documentation for that compressor.

File color format

Select the color format of the data stored in the file. You can select either `RGB` or `YCbCr 4:2:2`.

Image signal

Specify how the block accepts a color video signal. If you select `One multidimensional signal`, the block accepts an *M*-by-*N*-by-*P* color video signal, where *P* is the number of color planes, at one port. If you select `Separate color signals`, additional ports appear on the block. Each port accepts one *M*-by-*N* plane of an RGB video stream.

Troubleshooting

Running an Executable Outside MATLAB

To run your generated standalone executable application in Shell, you need to set your environment to the following:

Platform	Command

Mac	`setenv DYLD_LIBRARY_PATH $LD_LIBRARY_PATH: $MATLABROOT/bin/maci64 (csh/tcsh)`
	`export DYLD_LIBRARY_PATH $LD_LIBRARY_PATH: $MATLABROOT/bin/maci64 (Bash)`

Linux	`setenv LD_LIBRARY_PATH $LD_LIBRARY_PATH: $MATLABROOT/bin/glnxa64 (csh/tcsh)`
	`export LD_LIBRARY_PATH $LD_LIBRARY_PATH: $MATLABROOT/bin/glnxa64 (Bash)`

Windows	`set PATH = $MATLABROOT\bin\win32;%PATH%`
	`set PATH = $MATLABROOT\bin\win64;%PATH%`

Supported Data Types

For the block to display video data properly, double- and single-precision floating-point pixel values must be between 0 and 1. Any other data type requires the pixel values between the minimum and maximum values supported by their data type.

Check the specific codecs you are using for supported audio rates.

Port	Supported Data Types	Supports Complex Values?
Image	• Double-precision floating point • Single-precision floating point • Boolean • 8-, 16- 32-bit signed integers • 8-, 16- 32-bit unsigned integers	No
R, G, B	Same as Image port	No

Port	Supported Data Types	Supports Complex Values?
Audio	• Double-precision floating point • Single-precision floating point • 16-bit signed integers • 32-bit signed integers • 8-bit unsigned integers	No
Y, Cb, Cr	Same as Image port	No

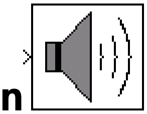
To Wave Device (Obsolete)

Send audio data to standard Windows audio device in real time

Library

dspwin32

Description



Note The To Wave Device block is still supported but is likely to be obsoleted in a future release. We strongly recommend replacing this block with the To Audio Device block.

The To Wave Device block sends audio data to a standard Windows audio device in real time. It is compatible with most popular Windows hardware, including Sound Blaster cards. The data is sent to the hardware in uncompressed pulse code modulation (PCM) format, and should typically be sampled at one of the standard Windows audio device rates: 8000, 11025, 22050, or 44100 Hz. Some hardware might support other rates in addition to these.

Note: Models that contain both the To Wave Device block and the From Wave Device block require a duplex-capable sound card.

The **Use default audio device** check box allows the To Wave Device block to detect and use the system's default audio hardware. You should select this option for systems that have a single sound device installed, or when the default sound device on a multiple-device system is your desired target. When the default sound device is *not* your desired output device, clear **Use default audio device**, and set the desired hardware in the **Audio device** parameter. This parameter lists the names of the installed audio devices.

The block input can contain audio data from a mono or stereo signal. A mono signal is represented as either a sample-based scalar or a frame-based length-*M* vector, where *M* is frame size. A stereo signal is represented as a sample-based length-2 vector or a frame-based M-by-2 matrix.

When the input data type is `uint8`, the block conveys the signal samples to the audio device using 8 bits. When the input data type is `double`, `single`, `int16`, or fixed point with a word length of 16 and a fraction length of 15, the block conveys the signal samples to the audio device using 16 bits by default. For inputs of data type `double` and `single`, you can also set the block to convey the signal samples using 24 bits by selecting the **Enable 24-bit output for double- and single-precision input signals** check box. The 24-bit sample width requires more memory but in general yields better fidelity.

The amplitude of the input must be in a valid range that depends on the input data type, as shown in the following table. Amplitudes outside the valid range are clipped to the nearest allowable value.

Input Data Type	Valid Input Amplitude Range
`double`	$-1 \le amplitude < 1$
`single`	$-1 \le amplitude < 1$
`int16`	$-32768 \le amplitude \le 32767$
`uint8`	$0 \le amplitude \le 255$
Fixed point with a word length of 16 and a fraction length of 15	$-1 \le amplitude \le 1 - 2^{-15}$

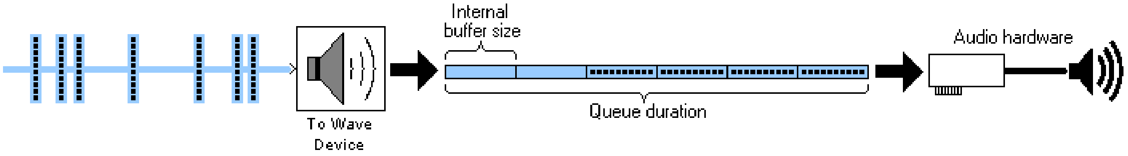
Buffering

Because audio devices generate real-time audio output, the Simulink environment must maintain a continuous flow of data to a device throughout simulation. Delays in passing data to the audio hardware can result in hardware errors or distortion of the output. This means that the To Wave Device block must in principle supply data to the audio hardware as quickly as the hardware reads the data. However, the To Wave Device block often *cannot* match the throughput rate of the audio hardware, especially when the simulation is running within Simulink rather than as generated code. Simulink execution speed can vary during the simulation as the host operating system services other processes. The block must therefore rely on a buffering strategy to ensure that signal data is available to the hardware on demand.

Note: This block requires real-time execution of the parent model for best performance.

The following block parameters control the memory management for this block:

- **Queue duration**
- **Automatically determine internal buffer size** or **User-defined internal buffer size**
- **Initial output delay**



The **Queue duration** parameter defines the overall size of the block's buffer. The block reads in chunks of data in the size of the input dimensions and stores them in the buffer. The internal buffer size defines the dimensions of the block output to the hardware. You can define the internal buffer size yourself in the **User-defined internal buffer size parameter**. If you select **Automatically determine internal buffer size** instead, the internal buffer size is calculated for you according to the following rules:

- If the input to the block has a frame size of 32 samples or larger, the internal buffer size be the same as the input frame size.
- If the input to the block has a frame size smaller than 32 samples, the internal buffer size is based on the input sample rate according to the following table, where

$$F_s = sampling\ frequency = \frac{1}{sample\ time}$$

F_s (Hz)	Internal Buffer Size (samples)
$F_s < 8000$	$\min(64, 2 * F_s)$
$8000 \le F_s < 22{,}050$	128
$22{,}050 \le F_s < 44{,}100$	256
$44{,}100 \le F_s < 96{,}000$	512

F_s (Hz)	Internal Buffer Size (samples)
$F_s \geq 96{,}000$	1024

To minimize the chance of dropouts, the block checks to make sure that the queue duration is at least as big as twice the internal buffer size. If it is not, the queue duration is automatically set to twice the internal buffer size.

The **Initial output delay** parameter enables you to preload the buffer before the block starts to output data to the audio device, which can be helpful for models that do not run in real time. However, for real-time applications, it is best to set the initial output delay to zero (one frame of delay), or as close to zero as possible.

Troubleshooting

If you are getting undesirable audio output using the To Wave Device block, first determine whether your model can run in real time. Replace the To Wave Device block with a To Wave File block, run the model, and compare the model's simulation stop time to the elapsed time on your watch. If the model simulation stop time is less than the elapsed time on your watch, your model can probably run in real time. Then,

- If your model can run in real time,

  1. Select **Automatically determine internal buffer size**. This alone might solve the problem. If not,
  2. Try increasing the **Queue duration** parameter to a relatively large value, such as 0.5 s.

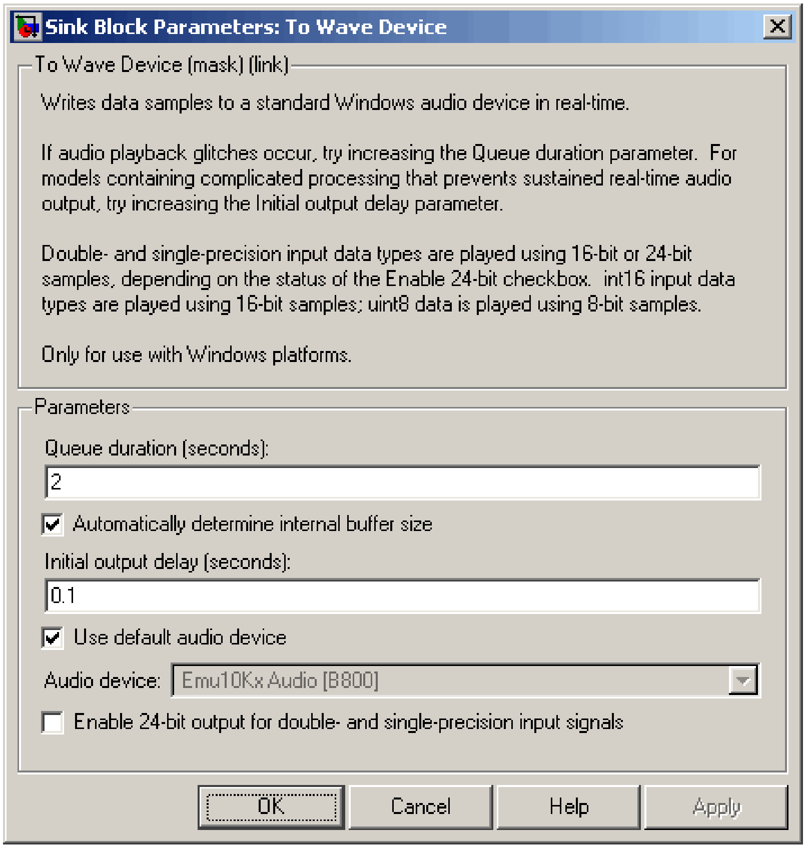
  If one or both of these options restores desirable audio output, you can try reducing the internal buffer size and/or queue duration until the quality of the audio output again degrades.

- If your model is not running in real time, try to make it run in real time by

  1. Optimizing the model (using a more efficient implementation), or
  2. Using a Simulink “Acceleration” mode, or
  3. Generating stand-alone code

  If none of these are possible, but the model only runs for a short period of time, set the **Queue duration** parameter to a size equal to a significant fraction of the model stop time and use a similarly large initial delay. This is not an optimal solution, but might work in some cases.

Dialog Box



Sink Block Parameters: To Wave Device

To Wave Device (mask) (link)

Writes data samples to a standard Windows audio device in real-time.

If audio playback glitches occur, try increasing the Queue duration parameter. For models containing complicated processing that prevents sustained real-time audio output, try increasing the Initial output delay parameter.

Double- and single-precision input data types are played using 16-bit or 24-bit samples, depending on the status of the Enable 24-bit checkbox. int16 input data types are played using 16-bit samples; uint8 data is played using 8-bit samples.

Only for use with Windows platforms.

Parameters

Queue duration (seconds): 2

☑ Automatically determine internal buffer size

Initial output delay (seconds): 0.1

☑ Use default audio device

Audio device: Emu10Kx Audio [B800]

☐ Enable 24-bit output for double- and single-precision input signals

Queue duration (seconds)

Specify the overall buffer size. To minimize the chance of dropouts, the block checks to make sure that the queue duration is as least as large as twice the internal buffer size. If it is not, the queue duration is automatically set to twice the internal buffer size.

Automatically determine internal buffer size

Select to have the block automatically select the internal buffer size for you. For details, see “Buffering” on page 1-1494.

User-defined internal buffer size (samples)

Define the internal buffer size, or the size of the chunks of data sent by the block to the audio hardware device.

This parameter is only visible when **Automatically determine internal buffer size** is not selected.

Initial output delay (seconds)

Specify the amount of time by which to delay the initial output to the audio device. During this time data accumulates in the block's buffer. Any value less than or equal to the queue duration specifies the smallest possible initial delay, which is a single frame.

Use default audio device

Select to direct audio output to the system's default audio device.

Audio device

This parameter lists the names of the installed audio devices. Specify the name of the audio device to receive the audio output. Select **Use default audio device** when the system has only a single audio card installed.

This parameter is only enabled when the **Use default audio device** check box is not selected.

Enable 24-bit output for double and single precision input signals

Select to output 24-bit data when inputs are double- or single-precision. Otherwise, the block outputs 16-bit data for double- and single-precision inputs.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point • Signed fixed point with a word length of 16 and a fraction length of 15 • 16-bit signed integers • 8-bit unsigned integers

To Wave File (Obsolete)	DSP System Toolbox
`audioplayer`	MATLAB
`sound`	MATLAB

To Wave File (Obsolete)

Write audio data to file in Microsoft Wave (`.wav`) format

Library

`dspwin32`

Description

Note The To Wave File block is still supported but is likely to be obsoleted in a future release. We strongly recommend replacing this block with the To Multimedia File block.

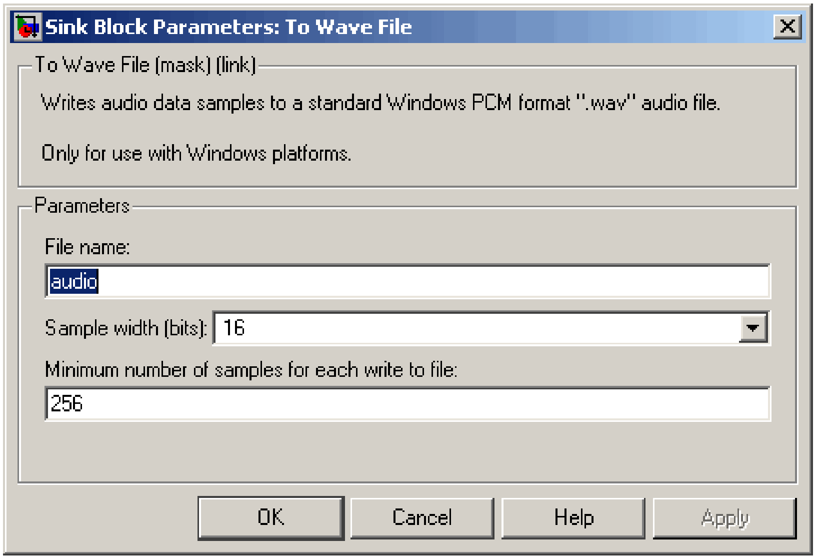
The To Wave File block streams audio data to a Microsoft Wave (`.wav`) file in the uncompressed pulse code modulation (PCM) format. For compatibility reasons, the sample rate of the discrete-time input signal should typically be one of the standard Windows audio device rates (8000, 11025, 22050, or 44100 Hz), although the block supports arbitrary rates.

The input to the block, u, can contain audio data with one or more channels. A signal with C channels is represented as a sample-based length-C vector or a frame-based M-by-C matrix. The amplitude of the input should be in the range ±1. Values outside this range are clipped to the nearest allowable value.

```
wavwrite(u,Fs,bits,'filename')    % Equivalent MATLAB code
```

Note: AVI files are the only supported file type for non-Windows platforms.

Dialog Box



Sink Block Parameters: To Wave File

To Wave File (mask) (link)

Writes audio data samples to a standard Windows PCM format ".wav" audio file.

Only for use with Windows platforms.

Parameters

File name: audio

Sample width (bits): 16

Minimum number of samples for each write to file: 256

File name

Specify the path and name of the file to write. Paths can be relative or absolute. You do not need to specify the `.wav` extension.

Sample width (bits)

Specify the number of bits used to represent the signal samples in the file. The higher sample width settings require more memory but yield better fidelity for double- and single-precision inputs:

- `8` — Allocates 8 bits to each sample, allowing a resolution of 256 levels
- `16` — Allocates 16 bits to each sample, allowing a resolution of 65536 levels
- `24` — Allocates 24 bits to each sample, allowing a resolution of 16777216 levels
- `32` — Allocates 32 bits to each sample, allowing a resolution of 2^{32} levels ranging from -1 to 1

The 8-, 16-, and 24-bit modes output integer data, while the 32-bit mode outputs single-precision floating-point data.

Minimum number of samples for each write to file

Specify the number of consecutive samples, L, to write with each file access. To reduce the required number of file accesses, the block writes L consecutive samples to the file during each access for $L \geq M$. For $L < M$, the block instead writes M consecutive samples during each access. Larger values of L result in fewer file accesses, which reduces run-time overhead.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point • Signed fixed point with a word length of 16 and a fraction length of 15 • 16-bit signed integers • 8-bit unsigned integers

To Workspace

Write data to MATLAB workspace

Library

Sinks

`dspsnks4`

Description

The To Workspace block is an implementation of the Simulink To Workspace block. See To Workspace for more information.

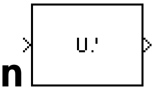
Transpose

Transpose matrix

Library

Math Functions / Matrices and Linear Algebra / Matrix Operations

`dspmtrx3`



Description

The Transpose block transposes the M-by-N input matrix to size N-by-M. When you select the **Hermitian** check box, the block performs the Hermitian (complex conjugate) transpose.

```
y = u'    % Equivalent MATLAB code
```

$$\begin{bmatrix} u_{11} & u_{12} & u_{13} \\ u_{21} & u_{22} & u_{23} \end{bmatrix} \xrightarrow{u'} \begin{bmatrix} u_{11}^{*} & u_{21}^{*} \\ u_{12}^{*} & u_{22}^{*} \\ u_{13}^{*} & u_{23}^{*} \end{bmatrix}$$

When you do not select the **Hermitian** check box, the block performs the nonconjugate transpose.

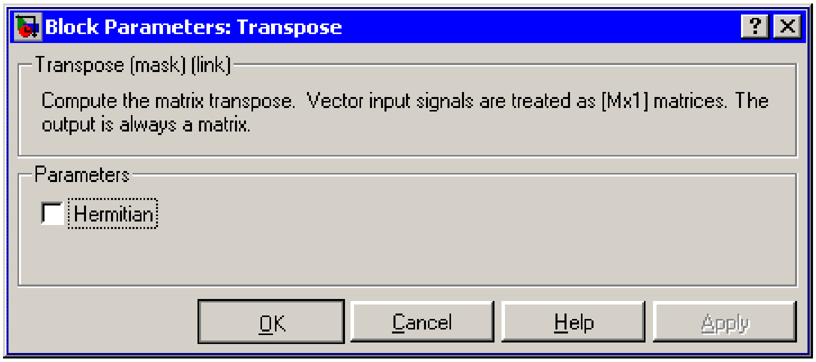
```
y = u.'    % Equivalent MATLAB code
```

$$\begin{bmatrix} u_{11} & u_{12} & u_{13} \\ u_{21} & u_{22} & u_{23} \end{bmatrix} \xrightarrow{u.'} \begin{bmatrix} u_{11} & u_{21} \\ u_{12} & u_{22} \\ u_{13} & u_{23} \end{bmatrix}$$

The block treats length-M vector input as an M-by-1 matrix.

The Transpose block supports real and complex floating-point and fixed-point data types. When **Hermitian** is selected, the block input must be a signed data type.

Dialog Box



Block Parameters: Transpose

Transpose (mask) (link)

Compute the matrix transpose. Vector input signals are treated as [Mx1] matrices. The output is always a matrix.

Parameters

□ Hermitian

Hermitian

When selected, specifies the complex conjugate transpose.

Saturate on integer overflow

This parameter is only visible when the **Hermitian** parameter is selected because overflows can occur when computing the complex conjugate of complex fixed-point signals. When you select this parameter, such overflows saturate. This parameter is ignored for floating-point signals and for real-valued fixed-point signals.

Supported Data Types

When **Hermitian** is selected, the block input must be a signed data type.

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers

Port	Supported Data Types
Output	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers

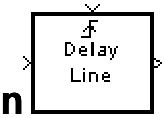
Triggered Delay Line (Obsolete)

Buffer sequence of inputs into frame-based output

Library

`dspobslib`



Description

Note The Triggered Delay Line block is still supported but is likely to be obsoleted in a future release. We strongly recommend replacing this block with the Delay Line block.

The Triggered Delay Line block acquires a collection of M_o input samples into a frame, where you specify M_o in the **Delay line size** parameter. The block buffers a single sample from input 1 whenever it is triggered by the control signal at input 2 (↑). When the next triggering event occurs, the newly acquired input sample is appended to the output frame so that the new output overlaps the previous output by M_o-1 samples. Between triggering events the block ignores input 1 and holds the output at its last value.

You specify the triggering event at input 2 in the **Trigger type** pop-up menu:

- `Rising edge` triggers execution of the block when the trigger input rises from a negative value to zero or a positive value, or from zero to a positive value.
- `Falling edge` triggers execution of the block when the trigger input falls from a positive value to zero or a negative value, or from zero to a negative value.
- `Either edge` triggers execution of the block when either a rising or falling edge (as described above) occurs.

The Triggered Delay Line block has zero latency, so the new input appears at the output in the same simulation time step. The output frame period is the same as the input sample period, T_{fo}=T_{si}.

Sample-Based Operation

In sample-based operation, the Triggered Delay Line block buffers a sequence of sample-based length-N vector inputs (1-D, row, or column) into a sequence of overlapping sample-based M_o-by-N matrix outputs, where you specify M_o in the **Delay line size** parameter (M_o>1). That is, each input vector becomes a *row* in the sample-based output matrix. When M_o=1, the input is simply passed through to the output, and retains the same dimension. Sample-based full-dimension matrix inputs are not accepted.

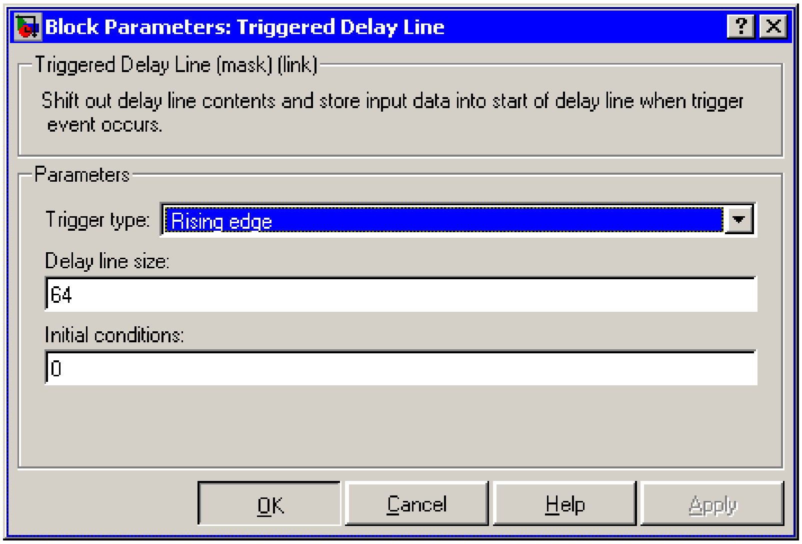
Frame-Based Operation

In frame-based operation, the Triggered Delay Line block rebuffers a sequence of frame-based M_i-by-N matrix inputs into an sequence of overlapping frame-based M_o-by-N matrix outputs, where M_o is the output frame size specified by the **Delay line size** parameter (that is, the number of consecutive samples from the input frame to rebuffer into the output frame). M_o can be greater or less than the input frame size, M_i. Each of the N input channels is rebuffered independently.

Initial Conditions

The Triggered Delay Line block's buffer is initialized to the value specified by the **Initial condition** parameter. The block always outputs this buffer at the first simulation step (*t*=0). When the block's output is a vector, the **Initial condition** can be a vector of the same size or a scalar value to be repeated across all elements of the initial output. When the block's output is a matrix, the **Initial condition** can be a matrix of the same size or a scalar to be repeated across all elements of the initial output.

Dialog Box



Triggered Delay Line (mask) (link)

Shift out delay line contents and store input data into start of delay line when trigger event occurs.

Parameters

Trigger type: Rising edge

Delay line size:

64

Initial conditions:

0

Trigger type

The type of event that triggers the block's execution.

Delay line size

The length of the output frame (number of rows in output matrix), M_o.

Initial condition

The value of the block's initial output, a scalar, vector, or matrix.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers

Port	Supported Data Types
Trigger	• Any data type supported by the Trigger block
Output	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers

Triggered Signal From Workspace

Import signal samples from MATLAB workspace when triggered

Library

Signal Operations

`dspsigops`

Description

The Triggered Signal From Workspace block imports signal samples from the MATLAB workspace into the Simulink model when triggered by the control signal at the input port (↑). The **Signal** parameter specifies the name of a MATLAB workspace variable containing the signal to import, or any valid MATLAB expression defining a matrix or 3-D array.

When the **Signal** parameter specifies an M-by-N matrix ($M \neq 1$), each of the N columns is treated as a distinct channel. You specify the frame size in the **Samples per frame** parameter, M_o, and the output when triggered is an M_o-by-N matrix containing M_o consecutive samples from each signal channel. For $M_o=1$, the output is sample based; otherwise the output is frame based. For convenience, an imported row vector (M=1) is treated as a single channel, so the output dimension is M_o-by-1.

When the **Signal** parameter specifies an M-by-N-by-P array, the block generates a single page of the array (an M-by-N matrix) at each trigger time. The **Samples per frame** parameter must be set to `1`, and the output is always sample based.

Trigger Event

You specify the triggering event at the input port in the **Trigger type** pop-up menu:

- `Rising edge` triggers execution of the block when the trigger input rises from a negative value to zero or a positive value, or from zero to a positive value.

- `Falling edge` triggers execution of the block when the trigger input falls from a positive value to zero or a negative value, or from zero to a negative value.
- `Either edge` triggers execution of the block when either a rising or falling edge (as described above) occurs.

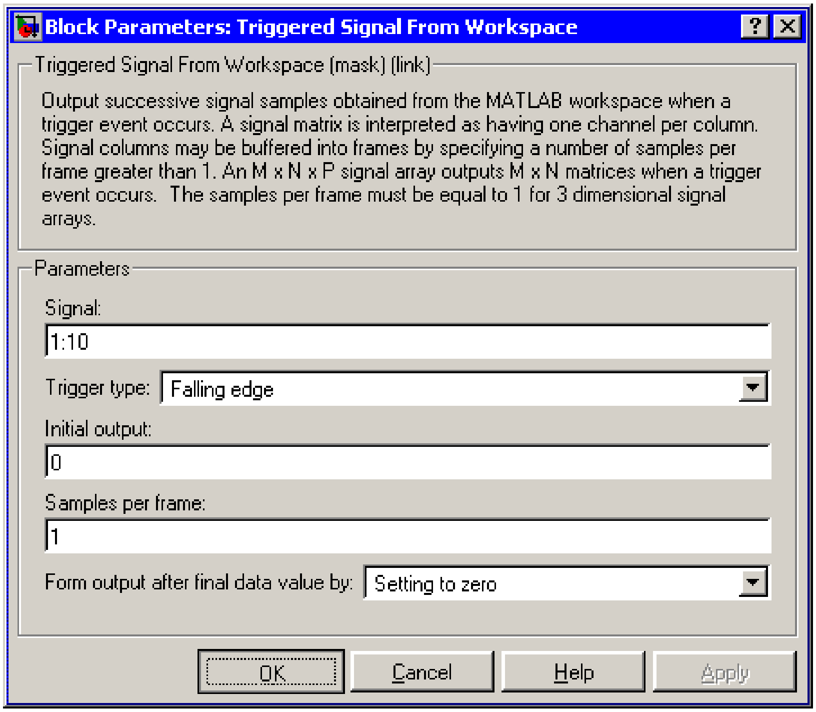
Initial and Final Conditions

The **Initial output** parameter specifies the output of the block from the start of the simulation until the first trigger event arrives. Between trigger events, the block holds the output value constant at its most recent value (that is, no linear interpolation takes place). For single-channel signals, the **Initial output** parameter value can be a vector of length M_o or a scalar to repeat across the M_o elements of the initial output frames. For matrix outputs (M_o-by-N or M-by-N), the **Initial output** parameter value can be a matrix of the same size or a scalar to be repeated across all elements of the initial output.

When the block has output all of the available signal samples, it can start again at the beginning of the signal, or simply repeat the final value or generate zeros until the end of the simulation. (The block does not extrapolate the imported signal beyond the last sample.) The **Form output after final data value by** parameter controls this behavior:

- When you specify `Setting To Zero`, the block generates zero-valued outputs for the duration of the simulation after generating the last frame of the signal.
- When you specify `Holding Final Value`, the block repeats the final sample for the duration of the simulation after generating the last frame of the signal.
- When you specify `Cyclic Repetition`, the block repeats the signal from the beginning after generating the last frame. When there are not enough samples at the end of the signal to fill the final frame, the block zero-pads the final frame as necessary to ensure that the output for each cycle is identical (for example, the *i*th frame of one cycle contains the same samples as the *i*th frame of any other cycle).

Dialog Box



Triggered Signal From Workspace (mask) (link)

Output successive signal samples obtained from the MATLAB workspace when a trigger event occurs. A signal matrix is interpreted as having one channel per column. Signal columns may be buffered into frames by specifying a number of samples per frame greater than 1. An M x N x P signal array outputs M x N matrices when a trigger event occurs. The samples per frame must be equal to 1 for 3 dimensional signal arrays.

Parameters

Signal: 1:10

Trigger type: Falling edge

Initial output: 0

Samples per frame: 1

Form output after final data value by: Setting to zero

Signal

The name of the MATLAB workspace variable from which to import the signal, or a valid MATLAB expression specifying the signal.

Trigger type

The type of event that triggers the block's execution.

Initial output

The value to output until the first trigger event is received.

Samples per frame

The number of samples, M_o, to buffer into each output frame. This value must be 1 when you specify a 3-D array in the **Signal** parameter.

Form output after final data value by

Specifies the output after all of the specified signal samples have been generated. The block can output zeros for the duration of the simulation (`Setting to zero`), repeat the final data sample (`Holding Final Value`) or repeat the entire signal from the beginning (`Cyclic Repetition`).

Supported Data Types

- Double-precision floating point
- Single-precision floating point
- Fixed point (signed and unsigned)
- 8-, 16-, and 32-bit signed integers
- 8-, 16-, and 32-bit unsigned integers

Triggered To Workspace	DSP System Toolbox

Triggered To Workspace

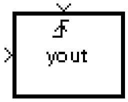
Write input sample to MATLAB workspace when triggered

Library

Sinks

`dspsnks4`

Description



The Triggered To Workspace block creates a matrix or array variable in the MATLAB workspace, where it stores the acquired inputs at the end of a simulation. The block overwrites an existing variable with the same name.

When you set the **Save 2-D signals as** parameter to `2-D array (concatenate along first dimension`, the block saves an *M*-by-*N* input as a *P*-by-*N* matrix, where *P* is the **Maximum number of rows** parameter. When the simulation progresses long enough for the block to acquire more than *P* samples, the block stores only the most recent *P* samples. The **Decimation factor**, *D*, allows you to store only every *D*th input matrix.

When you set the **Save 2-D signals as** parameter to `3-D array (concatenate along third dimension`, the block saves an *M*-by-*N* input as a three-dimensional array in which each *M*-by-*N* page represents a single sample from each of the *M*N* channels (the most recent input matrix occupies the last page). The maximum size of this variable is limited to *M*-by-*N*-by-*P*, where *P* is the **Maximum number of rows** parameter. When the simulation progresses long enough for the block to acquire more than *P* inputs, it stores only the last *P* inputs. The **Decimation factor**, *D*, allows you to store only every *D*th input matrix.

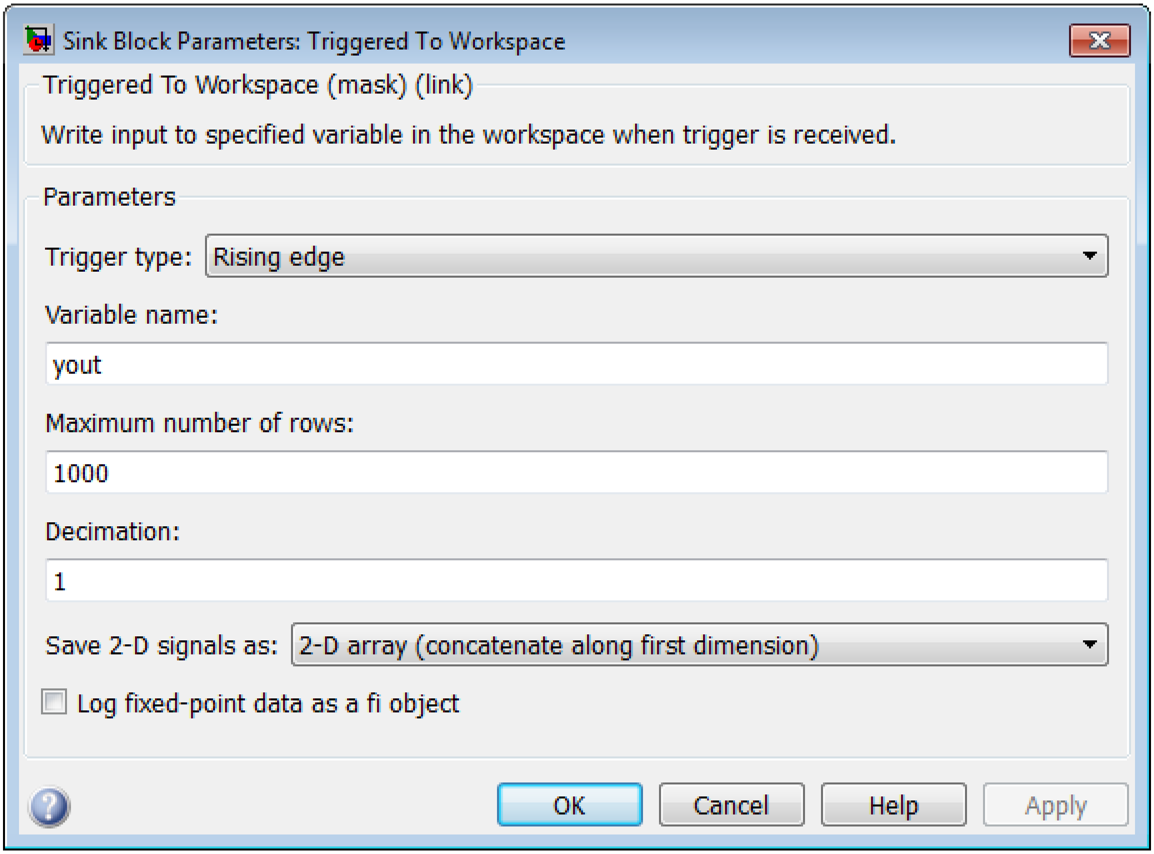
The block acquires and buffers a single frame from input 1 whenever it is triggered by the control signal at input 2 (⮥). At all other times, the block ignores input 1. You specify the triggering event at input 2 in the **Trigger type** pop-up menu:

- `Rising edge` triggers execution of the block when the trigger input rises from a negative value to zero or a positive value, or from zero to a positive value.
- `Falling edge` triggers execution of the block when the trigger input falls from a positive value to zero or a negative value, or from zero to a negative value.
- `Either edge` triggers execution of the block when either a rising or falling edge (as described above) occurs.

To save a record of the sample time corresponding to each sample value, open the Configuration Parameters dialog box. In the **Select** pane, click **Data Import/Export**. In the **Save to workspace** section, select the **Time** check box.

The nontriggered version of this block is the To Workspace block.

Dialog Box



Sink Block Parameters: Triggered To Workspace

Triggered To Workspace (mask) (link)

Write input to specified variable in the workspace when trigger is received.

Parameters

Trigger type: Rising edge

Variable name: yout

Maximum number of rows: 1000

Decimation: 1

Save 2-D signals as: 2-D array (concatenate along first dimension)

□ Log fixed-point data as a fi object

Trigger type

The type of event that triggers the block's execution.

Variable name

The name of the workspace variable in which to store the data.

Maximum number of rows

The maximum number of rows (one row per time step) to be saved, *P*.

Decimation

The decimation factor, *D*.

Save 2-D signals as

Specify whether the block saves 2-D signals as a 2-D or 3-D array in the MATLAB workspace:

- `2-D array (concatenate along first dimension)` — When you select this option, the block vertically concatenates each *M*-by-*N* matrix input with the previous input to produce a 2-D output array.
- `3-D array (concatenate along third dimension)` — When you select this option, the block saves an *M*-by-*N* input signal as a 3-D array. The maximum size of this 3-D array is limited to *M*-by-*N*-by-*P*, where *P* is the **Maximum number of rows** parameter. When the simulation progresses long enough for the block to acquire more than *P* inputs, the block stores only the last *P* inputs. The **Decimation factor**, *D*, allows you to store only every *D*th input matrix.

Note: The `Inherit from input (this choice will be removed - see release notes)` option will be removed in a future release. See the *DSP System Toolbox Release Notes* for more information.

Log fixed-point data as a fi object

Select to log fixed-point data to the MATLAB workspace as a Fixed-Point Designer `fi` object. Otherwise, fixed-point data is logged to the workspace as `double`.

Supported Data Types

Port	Supported Data Types
Input	• Any data type supported by the To Workspace block

Two-Channel Analysis Subband Filter

Decompose signal into high-frequency and low-frequency subbands

Library

Filtering / Multirate Filters

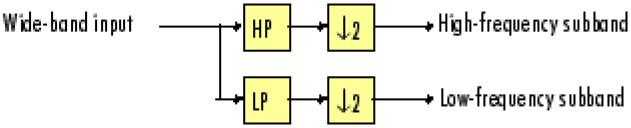
`dspmlti4`

Hi band
Lo band

Description

The Two-Channel Analysis Subband Filter block decomposes the input into high-frequency and low-frequency subbands, each with half the bandwidth and half the sample rate of the input.

The block filters the input with a pair of highpass and lowpass FIR filters, and then downsamples the results by 2, as illustrated in the following figure.



The block implements the FIR filtering and downsampling steps together using a polyphase filter structure, which is more efficient than the straightforward filter-then-decimate algorithm shown in the preceding figure. Each subband is the first phase of the respective polyphase filter. You can implement a multilevel dyadic analysis filter bank by connecting multiple copies of this block or by using the Dyadic Analysis Filter Bank block. See “Creating Multilevel Dyadic Analysis Filter Banks” on page 1-1522 for more information.

You must provide a vector of filter coefficients for the lowpass and highpass FIR filters. Each filter should be a half-band filter that passes the frequency band that the other filter stops.

See the following topics for more information about this block:

- "Specifying the FIR Filters" on page 1-1520
- "Frame-Based Processing" on page 1-1520
- "Sample-Based Processing" on page 1-1521
- "Latency" on page 1-1521
- "Creating Multilevel Dyadic Analysis Filter Banks" on page 1-1522

Specifying the FIR Filters

You must provide the vector of numerator coefficients for the lowpass and highpass filters in the **Lowpass FIR filter coefficients** and **Highpass FIR filter coefficients** parameters.

For example, to specify a filter with the following transfer function, enter the vector `[b(1) b(2) ... b(m)]`.

$$H(z) = B(z) = b_1 + b_2 z^{-1} + \ldots + b_m z^{-(m-1)}$$

Each filter should be a half-band filter that passes the frequency band that the other filter stops. You can use the Two-Channel Synthesis Subband Filter block to reconstruct the input to this block. To do so, you must design perfect reconstruction filters to use in the synthesis subband filter.

The best way to design perfect reconstruction filters is to use the Wavelet Toolbox `wfilters` function in to design both the filters both in this block and in the Two-Channel Synthesis Subband Filter block. You can also use other DSP System Toolbox and Signal Processing Toolbox functions. To learn how to design your own perfect reconstruction filters, see "References" on page 1-1530.

The Two-Channel Analysis Subband Filter block initializes all filter states to zero.

Frame-Based Processing

When you set the **Input processing** parameter to `Columns as channels (frame based)`, the block accepts an *M*-by-*N* matrix. The block treats each column of the input as the high- or low-frequency subbands of the corresponding output channel. You can use the **Rate options** parameter to specify how the block resamples the input:

- When you set the **Rate options** parameter to `Enforce single-rate processing`, the input to the block can be an *M*-by-*N* matrix, where *M* is a multiple of two. The block treats each column of the input as an independent channel and decomposes each channel over time. The block outputs two matrices, where each column of the output is the high- or low-frequency subband of the corresponding input column. To maintain the input sample rate, the block decreases the output frame size by a factor of two.
- When you set the **Rate options** parameter to `Allow multirate processing`, the block treats an M_i-by-*N* matrix input as *N* independent channels and decomposes each channel over time. The block outputs two *M*-by-*N* matrices, where each column of the output is the high- or low-frequency subband of the corresponding input column. The input and output frame *sizes* are the same, but the frame *rate* of the output is half that of the input. Thus, the overall sample rate of the output is half that of the input.

  In this mode, the block has one frame of latency, as described in the "Latency" on page 1-1521 section.

Sample-Based Processing

When you set the **Input processing** parameter to `Elements as channels (sample based)`, the block treats an *M*-by-*N* matrix input as $M \cdot N$ independent channels. The block decomposes each channel over time and outputs two *M*-by-*N* matrices whose sample rates are half the input sample rate. Each element in the output matrix is the high- or low-frequency subband output of the corresponding element of the input matrix.

Depending on the setting of your Simulink configuration parameters, the output may have one sample of latency, as described in the "Latency" on page 1-1521 section.

Latency

When you set the **Input processing** parameter to `Columns as channels (frame based)` and the **Rate options** parameter to `Enforce single-rate processing`, the Two-Channel Analysis Subband Filter block always has zero-tasking latency. *Zero-tasking latency* means that the block propagates the first input sample (received at time *t*=0) as the first output sample.

When you set the **Rate options** parameter to `Allow multirate processing`, the Two-Channel Analysis Subband Filter block may exhibit latency. The amount of latency depends on the setting of the **Input processing** parameter of this block, and the setting of the Simulink **Tasking mode for periodic sample times** configuration parameter. The following table summarizes the conditions that produce latency when the block is performing multirate processing.

Input processing	Tasking mode for periodic sample times	Latency
`Elements as channels (sample based)`	`SingleTasking`	None.
	`MultiTasking` or `Auto`	One sample. The first output sample in each channel always has a value of `0`.
`Columns as channels (frame based)`	`SingleTasking`, `MultiTasking` or `Auto`	One frame. All samples in the first output frame have a value of `0`.

Note: For more information on latency and the Simulink tasking modes, see “Excess Algorithmic Delay (Tasking Latency)” in the *DSP System Toolbox User's Guide* and “Scheduling ” in the *Simulink Coder User's Guide*.

Creating Multilevel Dyadic Analysis Filter Banks

The Two-Channel Analysis Subband Filter block is the basic unit of a dyadic analysis filter bank. You can connect several of these blocks to implement an *n*-level filter bank, as illustrated in the following figure. For a review of dyadic analysis filter banks, see the Dyadic Analysis Filter Bank block reference page.

When you create a filter bank by connecting multiple copies of this block, the output values of the filter bank differ depending on whether there is latency. Though the output values differ, both sets of values are valid; the difference arises from changes in latency. See the “Latency” on page 1-1521 section for more information about when latency can occur in the Two-Channel Analysis Subband Filter block.

In some cases, rather than connecting several Two-Channel Analysis Subband Filter blocks, you can use the Dyadic Analysis Filter Bank block, which is faster and requires less memory. In particular, the Dyadic Analysis Filter Bank block is more efficient under the following conditions:

- The frame size of the signal you are decomposing is a multiple of 2^n.
- You are decomposing the signal into n+1 or 2^n subbands.

In all other cases, use Two-Channel Analysis Subband Filter blocks to implement your filter banks.

3: Asym
Dyadic Analysis Filter Bank

Both implementations of the dyadic analysis filter bank decompose a frame-based signal with frame size a multiple of 2^n into n+1 subbands, where n = 3.

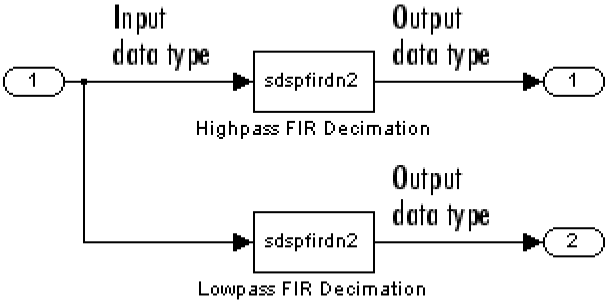
In this case, the Dyadic Analysis Filter Bank block's implementation is more efficient.

Use the Two-Channel Analysis Subband Filter block implementation for other cases, such as to handle sample-based inputs, or to handle frame-based inputs whose frame size is not a multiple of 2^n.

The Dyadic Analysis Filter Bank block allows you to specify the filter bank filters by providing vectors of filter coefficients, just as this block does. The Dyadic Analysis Filter Bank block provides an additional option of using wavelet-based filters that the block designs by using a wavelet you specify.

Fixed-Point Data Types

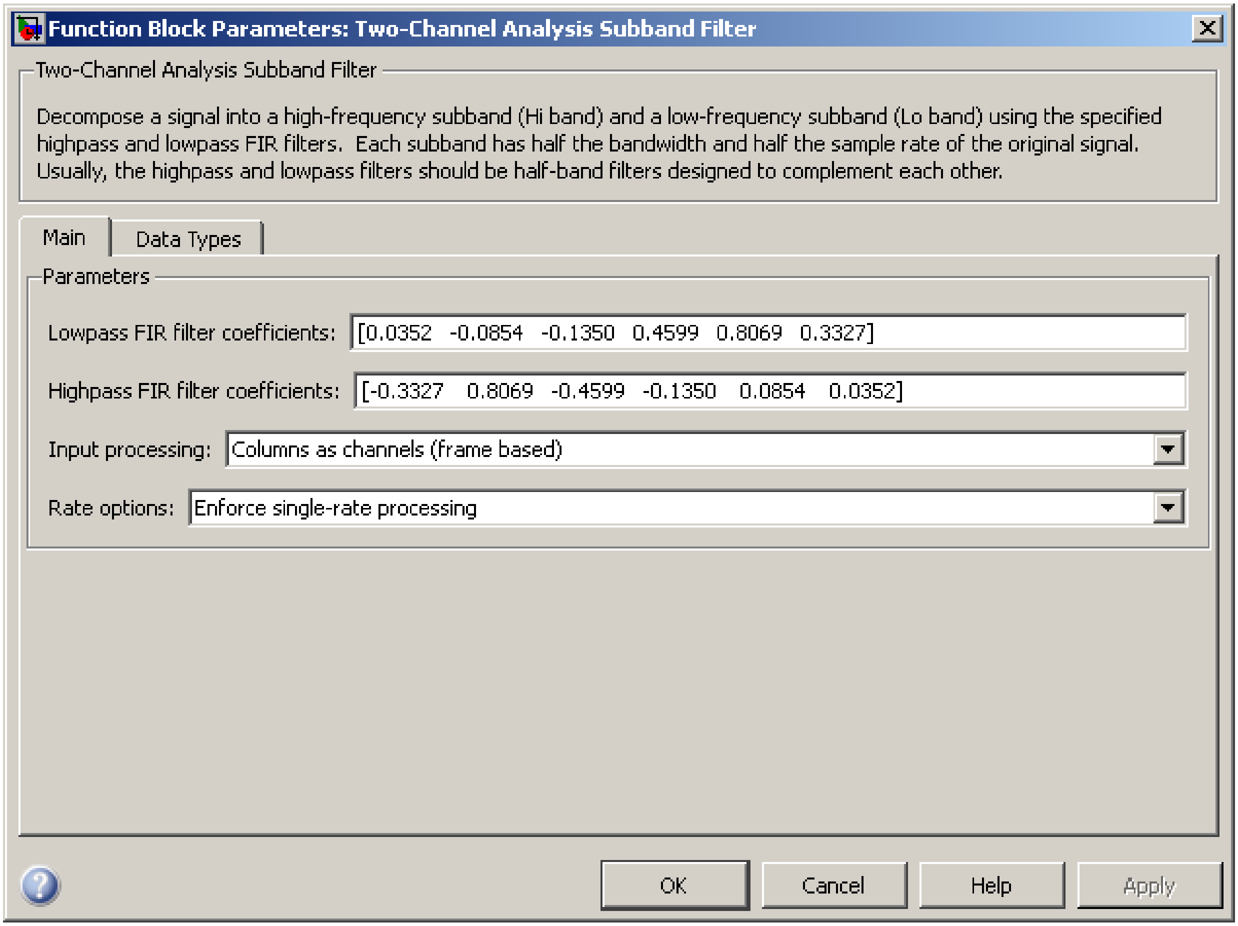
The Two-Channel Analysis Subband Filter Bank block is composed of two FIR Decimation blocks as shown in the following diagram.



For fixed-point signals, you can set the coefficient, product output, accumulator, and output data types of the FIR Decimation blocks as discussed in “Dialog Box” on page 1-1524. For a diagram showing the usage of these data types, see the FIR Decimation block reference page.

Dialog Box

The **Main** pane of the Two-Channel Analysis Subband Filter block dialog appears as follows.



Function Block Parameters: Two-Channel Analysis Subband Filter

Two-Channel Analysis Subband Filter

Decompose a signal into a high-frequency subband (Hi band) and a low-frequency subband (Lo band) using the specified highpass and lowpass FIR filters. Each subband has half the bandwidth and half the sample rate of the original signal. Usually, the highpass and lowpass filters should be half-band filters designed to complement each other.

Parameters

Lowpass FIR filter coefficients: [0.0352 -0.0854 -0.1350 0.4599 0.8069 0.3327]

Highpass FIR filter coefficients: [-0.3327 0.8069 -0.4599 -0.1350 0.0854 0.0352]

Input processing: Columns as channels (frame based)

Rate options: Enforce single-rate processing

Lowpass FIR filter coefficients

Specify a vector of lowpass FIR filter coefficients, in descending powers of z. The lowpass filter should be a half-band filter that passes the frequency band stopped by the filter specified in the **Highpass FIR filter coefficients** parameter. The default values of this parameter specify a filter based on a third-order Daubechies wavelet. When you use the Two-Channel Synthesis Subband Filter block to reconstruct the input to this block, you need to design perfect reconstruction filters to use in the synthesis subband filter. For more information, see “Specifying the FIR Filters” on page 1-1520.

Highpass FIR filter coefficients

Specify a vector of highpass FIR filter coefficients, in descending powers of z. The highpass filter should be a half-band filter that passes the frequency band stopped by the filter specified in the **Lowpass FIR filter coefficients** parameter. The default values of this parameter specify a filter based on a third-order Daubechies wavelet. When you use the Two-Channel Synthesis Subband Filter block to reconstruct the input to this block, you need to design perfect reconstruction filters to use in the synthesis subband filter. For more information, see “Specifying the FIR Filters” on page 1-1520.

Input processing

Specify how the block should process the input. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` — When you select this option, the block treats each column of the input as a separate channel.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

Note: The `Inherited (this choice will be removed - see release notes)` option will be removed in a future release. See “Frame-Based Processing” in the *DSP System Toolbox Release Notes* for more information.

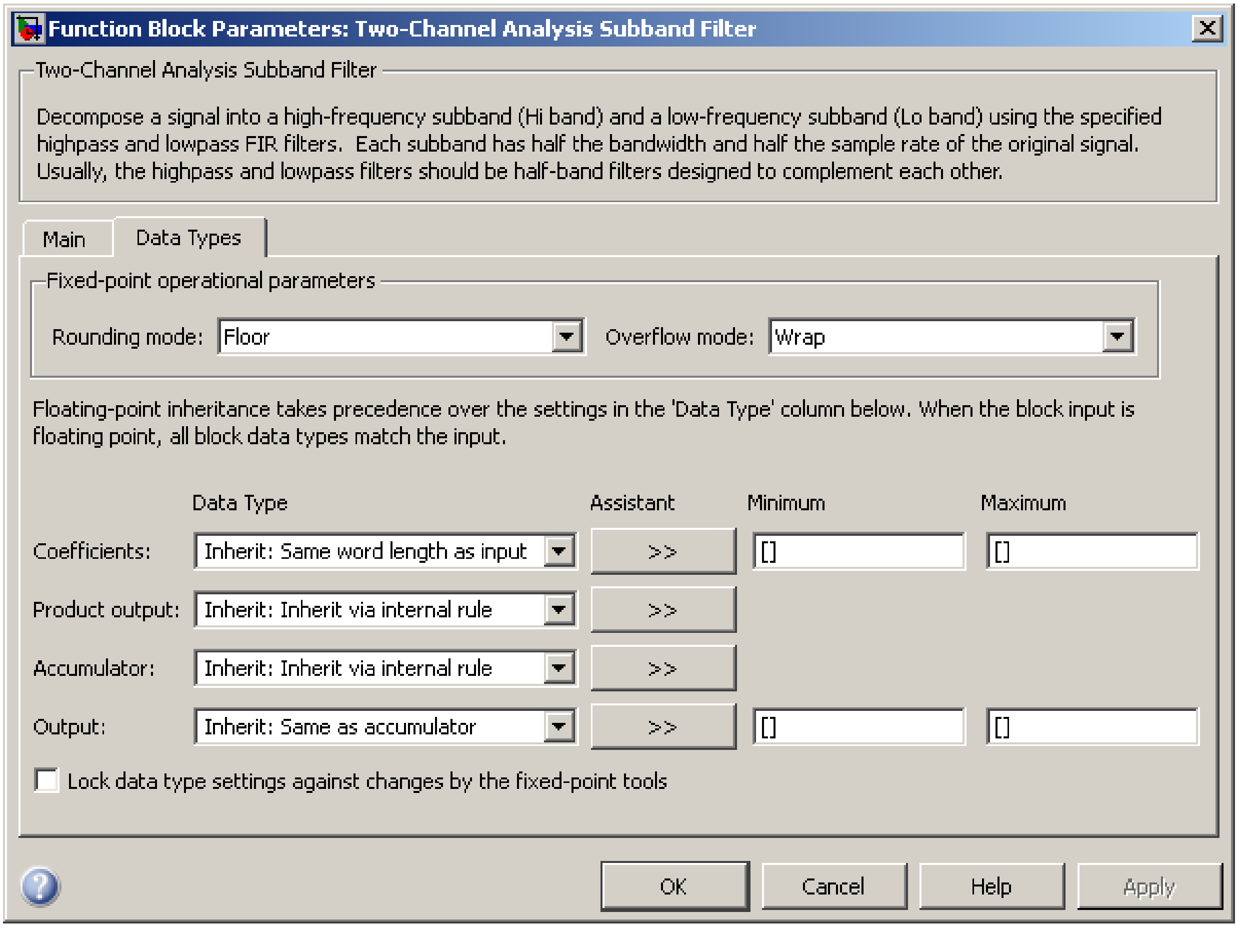
Rate options

Specify the rate processing rule for the block. You can set this parameter to one of the following options:

- `Enforce single-rate processing` — When you select this option, the block treats each column of the input as an independent channel and decomposes each channel over time. The output has the same sample rate as the input, but the output frame size is half that of the input frame size. To select this option, you must set the **Input processing** parameter to `Columns as channels (frame based)`.
- `Allow multirate processing` — When you select this option, the input and output of the block are the same size, but the sample rate of the output is half that of the input.

Some settings of this parameter cause the block to have nonzero latency. See “Latency” on page 1-1521 for more information.

The **Data Types** pane of the Two-Channel Analysis Subband Filter block dialog appears as follows.



Function Block Parameters: Two-Channel Analysis Subband Filter

Two-Channel Analysis Subband Filter

Decompose a signal into a high-frequency subband (Hi band) and a low-frequency subband (Lo band) using the specified highpass and lowpass FIR filters. Each subband has half the bandwidth and half the sample rate of the original signal. Usually, the highpass and lowpass filters should be half-band filters designed to complement each other.

Fixed-point operational parameters

Rounding mode: Floor

Overflow mode: Wrap

Floating-point inheritance takes precedence over the settings in the 'Data Type' column below. When the block input is floating point, all block data types match the input.

	Data Type	Assistant	Minimum	Maximum
Coefficients:	Inherit: Same word length as input	>>	[]	[]
Product output:	Inherit: Inherit via internal rule	>>		
Accumulator:	Inherit: Inherit via internal rule	>>		
Output:	Inherit: Same as accumulator	>>	[]	[]

□ Lock data type settings against changes by the fixed-point tools

Rounding mode

Select the “rounding mode” for fixed-point operations. The filter coefficients do not obey this parameter; they are always rounded to `Nearest`.

Note: The **Rounding mode** and **Overflow mode** settings have no effect on numerical results when all the following conditions exist:

- **Product output data type** is `Inherit: Inherit via internal rule`
- **Accumulator data type** is `Inherit: Inherit via internal rule`
- **Output data type** is `Inherit: Same as accumulator`

With these data type settings, the block is effectively operating in full precision mode.

Overflow mode

Select the “overflow mode” for fixed-point operations. The filter coefficients do not obey this parameter; they are always saturated.

Coefficients data type

Specify the coefficients data type. See “Fixed-Point Data Types” on page 1-1523 and “Multiplication Data Types” for illustrations depicting the use of the coefficients data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same word length as input`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Coefficients data type** parameter.

See “Specify Data Types Using Data Type Assistant” in “Simulink User's Guide” for more information.

Product output data type

Specify the product output data type. See “Fixed-Point Data Types” on page 1-1523 and “Multiplication Data Types” for illustrations depicting the use of the product output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`

  Note The actual product output word length may be equal to or greater than the calculated ideal product output word length, depending on the settings on the **Hardware Implementation** pane of the Configuration Parameters dialog box.

- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Product output data type** parameter.

See “Specify Data Types Using Data Type Assistant” in “Simulink User's Guide” for more information.

Accumulator data type

Specify the accumulator data type. See “Fixed-Point Data Types” on page 1-1523 for illustrations depicting the use of the accumulator data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Accumulator data type** parameter.

See “Specify Data Types Using Data Type Assistant” in “Simulink User's Guide” for more information.

Output data type

Specify the output data type. See “Fixed-Point Data Types” on page 1-1523 for illustrations depicting the use of the output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as accumulator`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Specify Block Output Data Types” in “Simulink User's Guide” for more information.

Minimum

Specify the minimum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges”)

- Automatic scaling of fixed-point data types

Maximum

Specify the maximum value that the block should output. The default value is [ ] (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges”)
- Automatic scaling of fixed-point data types

Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

Two-Channel Synthesis Subband Filter

Reconstruct signal from high-frequency and low-frequency subbands

Library

Filtering / Multirate Filters

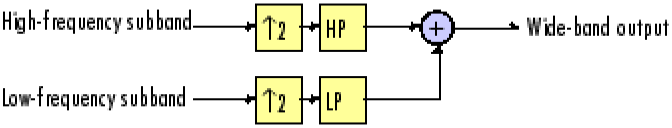
`dspmlti4`

Hi band
Lo band

Description

The Two-Channel Synthesis Subband Filter block reconstructs a signal from its high-frequency and low-frequency subbands, each with half the bandwidth and half the sample rate of the original signal. Use this block to reconstruct signals decomposed by the Two-Channel Analysis Subband Filter block.

The block upsamples the high- and low-frequency subbands by 2, and then filters the results with a pair of highpass and lowpass FIR filters, as illustrated in the following figure.



The block implements the FIR filtering and downsampling steps together using a polyphase filter structure, which is more efficient than the straightforward interpolate-then-filter algorithm shown in the preceding figure. You can implement a multilevel dyadic synthesis filter bank by connecting multiple copies of this block or by using the Dyadic Synthesis Filter Bank block. For more information, see “Creating Multilevel Dyadic Synthesis Filter Banks” on page 1-1535.

You must provide a vector of filter coefficients for the lowpass and highpass FIR filters. Each filter should be a half-band filter that passes the frequency band that the other filter stops. You can use this block to reconstruct the output of a Two-Channel Analysis

Subband Filter block. To do so, you must design the filters in this block such that they perfectly reconstruct the outputs of the analysis filters.

See the following topics for more information about this block:

- "Specifying the FIR Filters" on page 1-1533
- "Frame-Based Processing" on page 1-1533
- "Sample-Based Processing" on page 1-1534
- "Latency" on page 1-1535
- "Creating Multilevel Dyadic Synthesis Filter Banks" on page 1-1535

Specifying the FIR Filters

You must provide the vector of numerator coefficients for the lowpass and highpass filters in the **Lowpass FIR filter coefficients** and **Highpass FIR filter coefficients** parameters.

For example, to specify a filter with the following transfer function, enter the vector `[b(1) b(2) ... b(m)]`.

$$H(z) = B(z) = b_1 + b_2 z^{-1} + \ldots + b_m z^{-(m-1)}$$

Each filter should be a half-band filter that passes the frequency band that the other filter stops. You can use this block to reconstruct the output of a Two-Channel Analysis Subband Filter block. To do so, you must design the filters in this block such that they perfectly reconstruct the outputs of the analysis filters.

The best way to design perfect reconstruction filters is to use the Wavelet Toolbox `wfilters` function for the filters in both this block *and* in the corresponding Two-Channel Analysis Subband Filter block. You can also use DSP System Toolbox and Signal Processing Toolbox functions. To learn how to design your own perfect reconstruction filters, see "References" on page 1-1543.

The Two-Channel Synthesis Subband Filter block initializes all filter states to zero.

Frame-Based Processing

When you set the **Input processing** parameter to `Columns as channels (frame based)`, the block accepts any two *M*-by-*N* matrices with the same frame rates. The block treats each column of the input as the high- or low-frequency subbands of the corresponding output channel. You can use the **Rate options** parameter to specify how the block resamples the input:

- When you set the **Rate options** parameter to `Enforce single-rate processing`, the input to the block can be any two *M*-by-*N* matrices with the same frame rate. The block treats each input column as the high- or low-frequency subbands of the corresponding output channel. The input to the topmost input port should contain the high-frequency subbands. The block outputs one matrix, where each column is reconstructed from the corresponding columns of each input matrix. The input and output frame *rates* are the same, but the frame *size* of the output is twice that of the input.
- When you set the **Rate options** parameter to `Allow multirate processing`, the block treats each column of the input as the high- or low-frequency subbands of the corresponding output channel. The input to the topmost input port should contain the high-frequency subbands. The block outputs one matrix, where each column is reconstructed from the corresponding columns of the input matrices. The input and output frame *sizes* are the same, but the frame *rate* of the output is twice that of the input. Thus, the overall sample rate of the output is twice that of the input sample rate.

  In this mode, the block has one frame of latency, as described in the “Latency” on page 1-1535 section.

Sample-Based Processing

When you set the **Input processing** parameter to `Elements as channels (sample based)`, the block accepts any two *M*-by-*N* matrices with the same sample rates. The block treats each *M*-by-*N* matrix as $M \cdot N$ independent subbands. Each element of the input matrices is the high- or low-frequency subband of the corresponding channel in the output matrix. The input to the topmost input port should contain the high-frequency subbands. The block outputs one matrix with the same dimensions as the input matrices, but a sample rate that is twice that of the input. The block reconstructs each element of the output from the corresponding elements in the input matrices.

Depending on the setting of your Simulink configuration parameters, the output may have one sample of latency, as described in the “Latency” on page 1-1535 section.

Latency

When you set the **Input processing** parameter to `Columns as channels (frame based)` and the **Rate options** parameter to `Enforce single-rate processing`, the Two-Channel Synthesis Subband Filter block always has zero-tasking latency. *Zero-tasking latency* means that the block propagates the first input sample (received at time *t*= 0) as the first output sample.

When you set the **Rate options** parameter to `Allow multirate processing`, the Two-Channel Synthesis Subband Filter block may exhibit latency. The amount of latency depends on the setting of the **Input processing** parameter of this block and the setting of the Simulink **Tasking mode for periodic sample times** configuration parameter. The following table summarizes the conditions that produce latency when the block is performing multirate processing.

Input processing	Tasking mode for periodic sample times	Latency
`Elements as channels (sample based)`	`SingleTasking`	None.
	`MultiTasking` or `Auto`	One sample. The first output sample in each channel always has a value of `0`.
`Columns as channels (frame based)`	`SingleTasking`, `MultiTasking` or `Auto`	One frame. All samples in the first output frame have a value of `0`.

Note: For more information on latency and the Simulink tasking modes, see “Excess Algorithmic Delay (Tasking Latency)” in the *DSP System Toolbox User's Guide* and “Scheduling ” in the *Simulink Coder User's Guide*.

Creating Multilevel Dyadic Synthesis Filter Banks

The Two-Channel Synthesis Subband Filter block is the basic unit of a dyadic synthesis filter bank. You can connect several of these blocks to implement an *n*-level filter bank, as illustrated in the following figure. For a review of dyadic synthesis filter banks, see the Dyadic Synthesis Filter Bank block reference page.

When you create a filter bank by connecting multiple copies of this block, the output values of the filter bank differ depending on whether there is latency. Though the output values differ, both sets of values are valid; the difference arises from changes in latency. See the “Latency” on page 1-1535 section for more information about when latency can occur in the Two-Channel Analysis Subband Filter block.

In some cases, rather than connecting several Two-Channel Analysis Subband Filter blocks, you can use the Dyadic Analysis Filter Bank block, which is faster and requires less memory. In particular, the Dyadic Analysis Filter Bank block is more efficient under the following conditions:

- You are reconstructing a signal from 2^n or n+ 1 subbands.
- The frame size of the signal you are reconstructing is a multiple of 2^n.
- The properties of the subbands you are working with match those of the outputs of the Dyadic Analysis Filter Bank block. These properties are described in the Dyadic Analysis Filter Bank reference page.

Hi band
Lo band
[4x1]
[8x1]
[2x1]
Two-Channel Synthesis Subband Filter
Dyadic Synthesis Filter Bank block implementation
3: Asym
Dyadic Synthesis Filter Bank

Both implementations of the dyadic analysis filter bank reconstruct a frame-based signal from n+1 subbands, where n = 3.

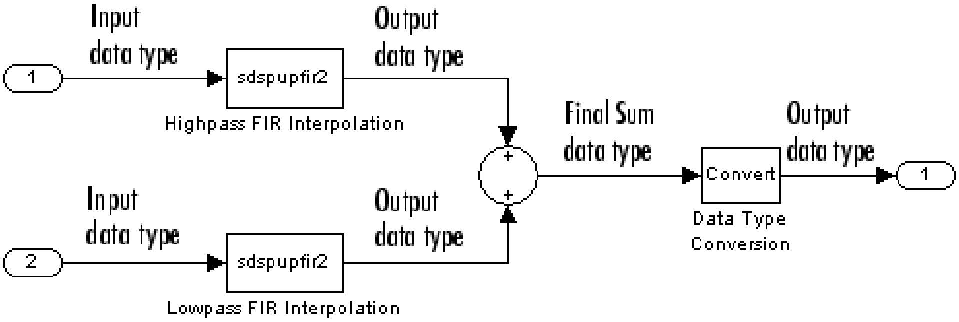
In this case, the Dyadic Synthesis Filter Bank block's implementation is more efficient, since the input subbands have the properties of the outputs of a Dyadic Analysis Filter Bank block.

Use the Two-Channel Synthesis Subband Filter block implementation for other cases, such as to handle separate sample-based vectors or matrices of subbands (rather than a single sample-based vector or matrix of concatenated subbands), or to output sample-based signals.

The Dyadic Synthesis Filter Bank block allows you to specify the filter bank filters by providing vectors of filter coefficients, just as this block does. The Dyadic Synthesis Filter Bank block provides an additional option of using wavelet-based filters that the block designs by using a wavelet you specify.

Fixed-Point Data Types

The Two-Channel Synthesis Subband Filter block is composed of two FIR Interpolation blocks as shown in the following diagram.

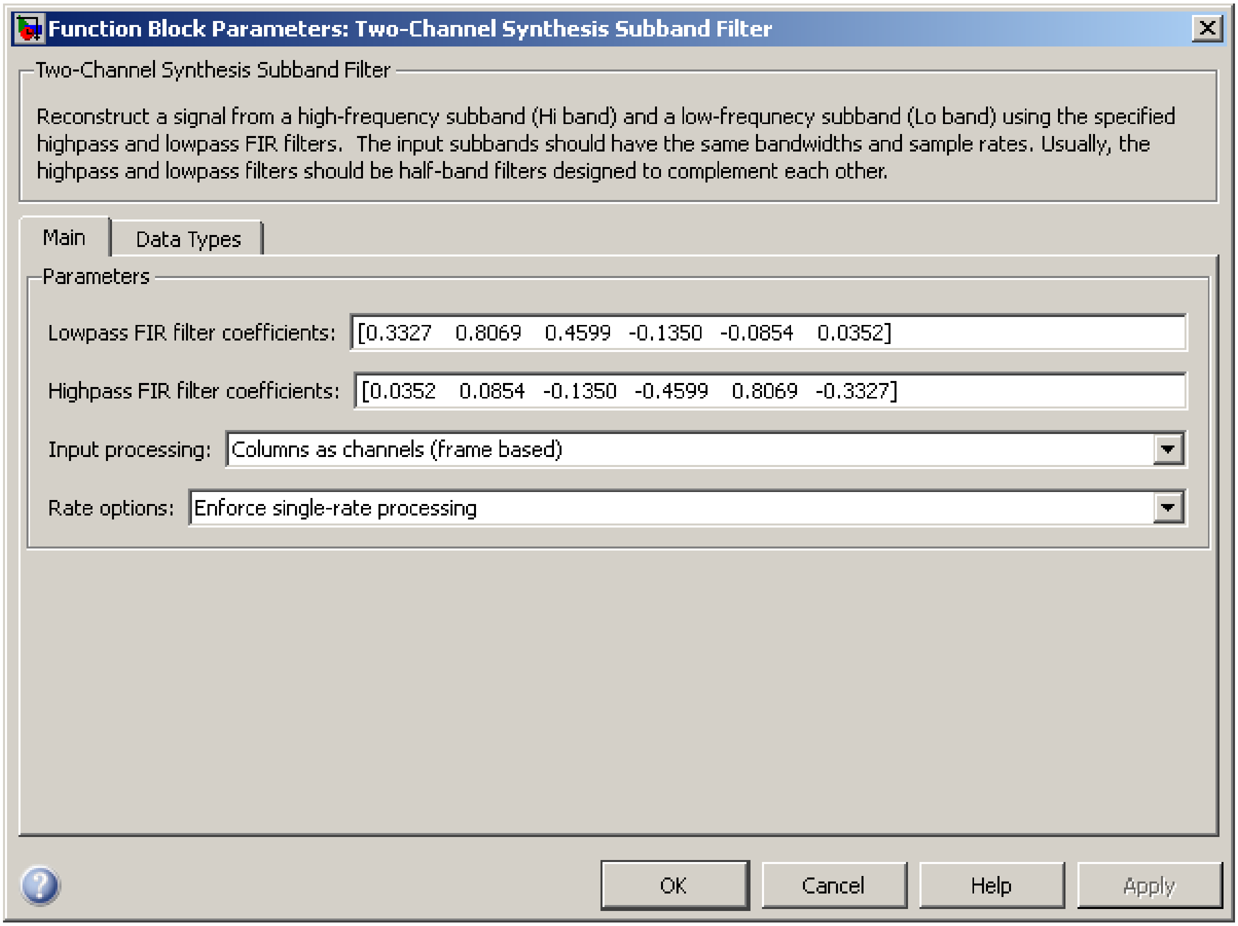


For fixed-point signals, you can set the coefficient, product output, accumulator, and output data types used in the FIR Interpolation blocks as discussed in “Dialog Box” on page 1-1537. For a diagram showing the usage of these data types within the FIR blocks, see the FIR Interpolation block reference page.

In addition, the inputs to the Sum block shown in the previous diagram are accumulated using the accumulator data type. The output of the Sum block is then cast from the accumulator data type to the output data type. Therefore the output of the Two-Channel Synthesis Subband Filter block is in the output data type. You also set these data types in the block dialog box as discussed in the “Dialog Box” on page 1-1537 section.

Dialog Box

The **Main** pane of the Two-Channel Synthesis Subband Filter block dialog appears as follows.



Function Block Parameters: Two-Channel Synthesis Subband Filter

Two-Channel Synthesis Subband Filter

Reconstruct a signal from a high-frequency subband (Hi band) and a low-frequnecy subband (Lo band) using the specified highpass and lowpass FIR filters. The input subbands should have the same bandwidths and sample rates. Usually, the highpass and lowpass filters should be half-band filters designed to complement each other.

Parameters

Lowpass FIR filter coefficients: [0.3327 0.8069 0.4599 -0.1350 -0.0854 0.0352]

Highpass FIR filter coefficients: [0.0352 0.0854 -0.1350 -0.4599 0.8069 -0.3327]

Input processing: Columns as channels (frame based)

Rate options: Enforce single-rate processing

Lowpass FIR filter coefficients

A vector of lowpass FIR filter coefficients, in descending powers of *z*. The lowpass filter should be a half-band filter that passes the frequency band stopped by the filter specified in the **Highpass FIR filter coefficients** parameter. To use this block to reconstruct the output of a Two-Channel Analysis Subband Filter block, you must design the filters in this block to perfectly reconstruct the outputs of the analysis filters. For more information, see "Specifying the FIR Filters" on page 1-1533.

Highpass FIR filter coefficients

A vector of highpass FIR filter coefficients, in descending powers of *z*. The highpass filter should be a half-band filter that passes the frequency band stopped by the filter specified in the **Lowpass FIR filter coefficients** parameter. To use this block to reconstruct the output of a Two-Channel Analysis Subband Filter block, you must design the filters in this block to perfectly reconstruct the outputs of the analysis filters. For more information, see "Specifying the FIR Filters" on page 1-1533.

Input processing

Specify how the block should process the input. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` — When you select this option, the block treats each column of the input as a separate channel.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

Note: The `Inherited (this choice will be removed - see release notes)` option will be removed in a future release. See "Frame-Based Processing" in the *DSP System Toolbox Release Notes* for more information.

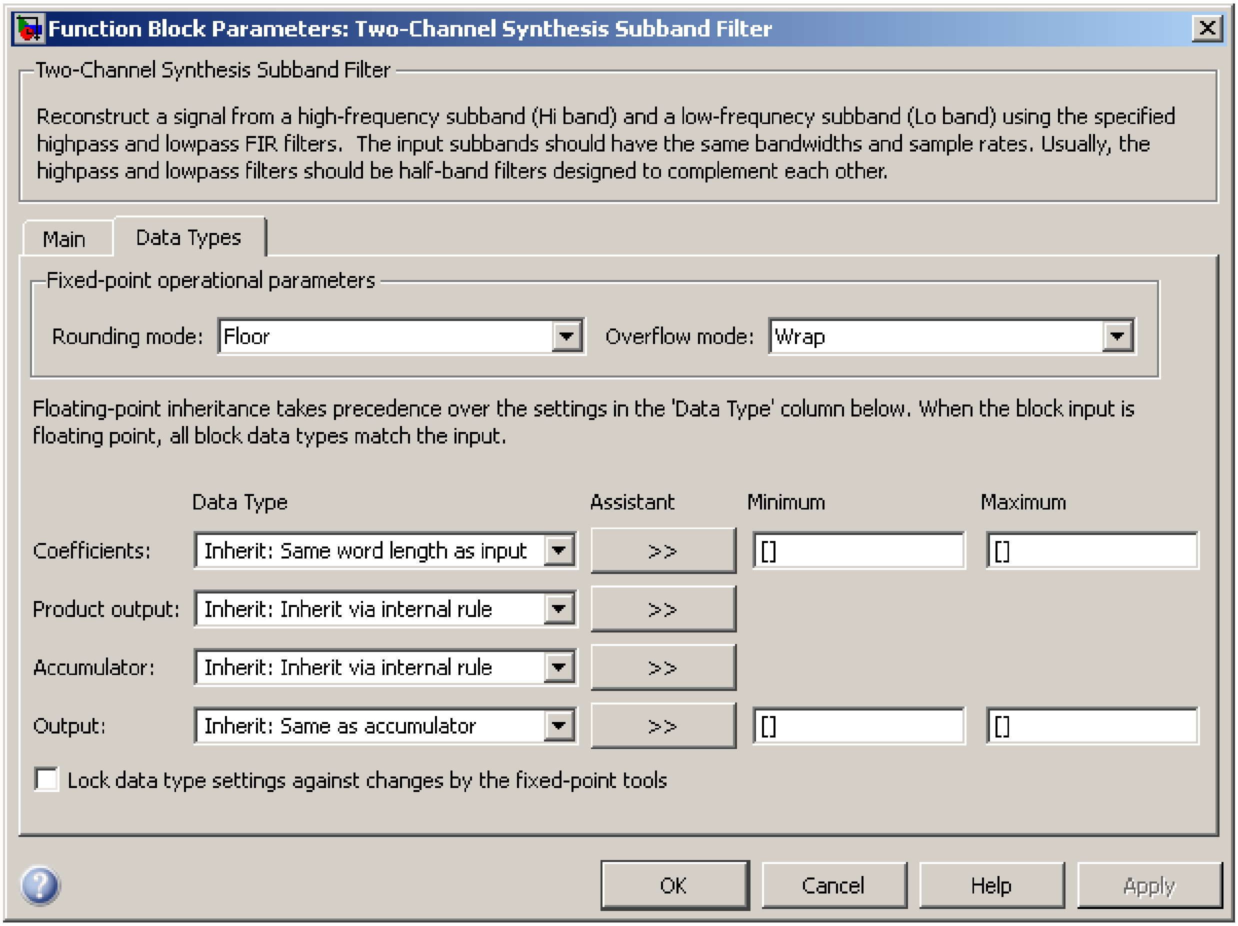
Rate options

Specify the rate processing rule for the block. You can set this parameter to one of the following options:

- `Enforce single-rate processing` — When you select this option, the block treats each column of the input as an independent channel and reconstructs each channel over time. The output has the same sample rate as the input, but the output frame size is twice that of the input frame size. To select this option, you must set the **Input processing** parameter to `Columns as channels (frame based)`.
- `Allow multirate processing` — When you select this option, the input and output of the block are the same size, but the sample rate of the output is twice that of the input.

Some settings of this parameter cause the block to have nonzero latency. See "Latency" on page 1-1535 for more information.

The **Data Types** pane of the Two-Channel Synthesis Subband Filter block dialog appears as follows.



Function Block Parameters: Two-Channel Synthesis Subband Filter

Two-Channel Synthesis Subband Filter

Reconstruct a signal from a high-frequency subband (Hi band) and a low-frequnecy subband (Lo band) using the specified highpass and lowpass FIR filters. The input subbands should have the same bandwidths and sample rates. Usually, the highpass and lowpass filters should be half-band filters designed to complement each other.

Fixed-point operational parameters

Rounding mode: Floor

Overflow mode: Wrap

Floating-point inheritance takes precedence over the settings in the 'Data Type' column below. When the block input is floating point, all block data types match the input.

	Data Type	Assistant	Minimum	Maximum
Coefficients:	Inherit: Same word length as input	>>	[]	[]
Product output:	Inherit: Inherit via internal rule	>>		
Accumulator:	Inherit: Inherit via internal rule	>>		
Output:	Inherit: Same as accumulator	>>	[]	[]

□ Lock data type settings against changes by the fixed-point tools

Round mode

Select the “rounding mode” for fixed-point operations. The filter coefficients do not obey this parameter; they always round to `Nearest`.

Note: The **Rounding mode** and **Overflow mode** settings have no effect on numerical results when all the following conditions exist:

- **Product output data type** is `Inherit: Inherit via internal rule`
- **Accumulator data type** is `Inherit: Inherit via internal rule`

- **Output data type** is `Inherit: Same as accumulator`

With these data type settings, the block is effectively operating in full precision mode.

Overflow mode

Select the “overflow mode” for fixed-point operations. The filter coefficients do not obey this parameter; they are always saturated.

Coefficients data type

Specify the coefficients data type. See “Fixed-Point Data Types” on page 1-1537 and “Multiplication Data Types” for illustrations depicting the use of the coefficients data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same word length as input`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Coefficients data type** parameter.

See “Specify Data Types Using Data Type Assistant” in “Simulink User's Guide” for more information.

Product output data type

Specify the product output data type. See “Fixed-Point Data Types” on page 1-1537 and “Multiplication Data Types” for illustrations depicting the use of the product output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`

  Note The actual product output word length may be equal to or greater than the calculated ideal product output word length, depending on the settings on the **Hardware Implementation** pane of the Configuration Parameters dialog box.

- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Product output data type** parameter.

See “Specify Data Types Using Data Type Assistant” in “Simulink User's Guide” for more information.

Accumulator data type

Specify the accumulator data type. See “Fixed-Point Data Types” on page 1-1537 for illustrations depicting the use of the accumulator data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Accumulator data type** parameter.

See “Specify Data Types Using Data Type Assistant” in “Simulink User's Guide” for more information.

Output data type

Specify the output data type. See “Fixed-Point Data Types” on page 1-1537 for illustrations depicting the use of the output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as accumulator`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Specify Block Output Data Types” in “Simulink User's Guide” for more information.

Minimum

Specify the minimum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges”)

- Automatic scaling of fixed-point data types

Maximum

Specify the maximum value that the block should output. The default value is [ ] (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see "Signal Ranges")
- Automatic scaling of fixed-point data types

Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

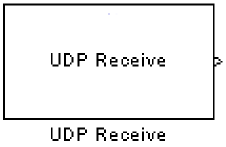
UDP Receive

Receive `uint8` vector as UDP message

Library

Sources

`dspsrcs4`

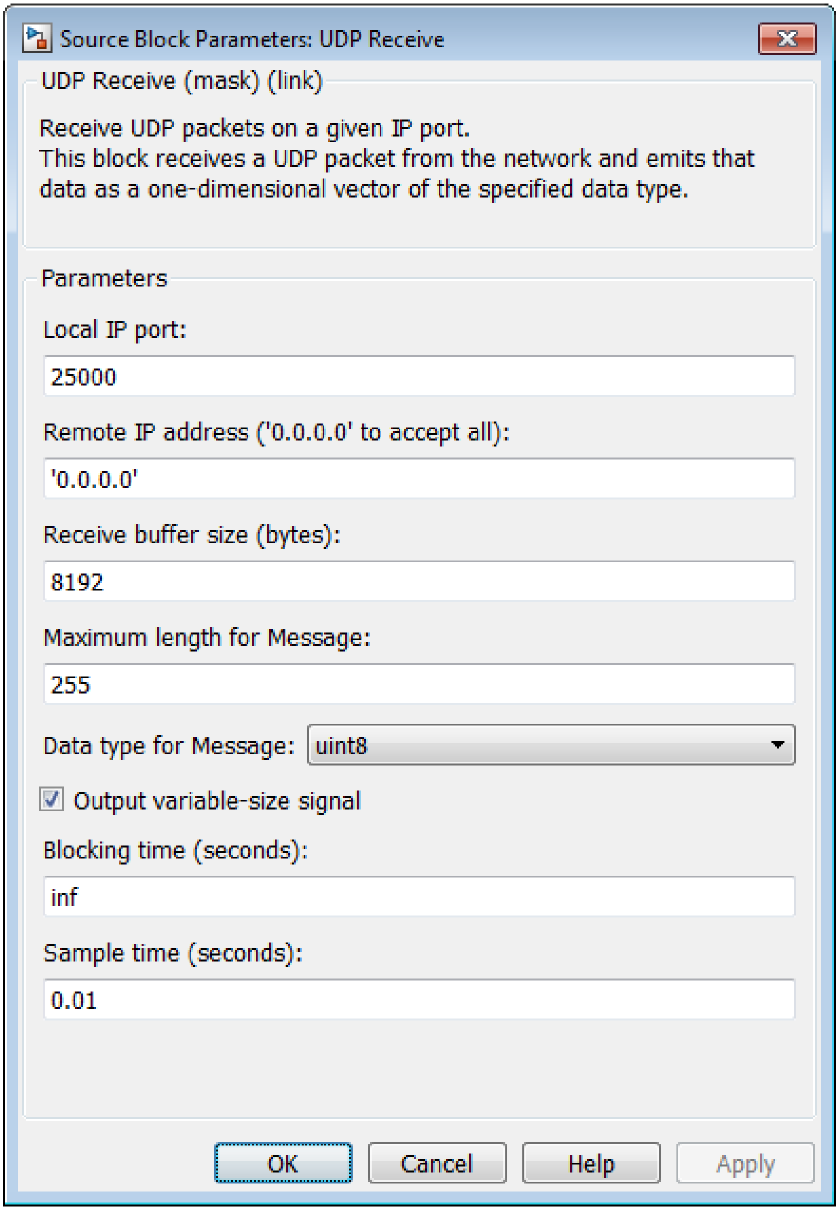


Description

The UDP Receive block receives UDP packets from an IP network port and saves them to its buffer. With each sample, the block output, emits the contents of a single UDP packet as a data vector.

The generated code for this block relies on prebuilt .dll files. You can run this code outside the MATLAB environment, or redeploy it, but be sure to account for these extra .dll files when doing so. The packNGo function creates a single zip file containing all of the pieces required to run or rebuild this code. See `packNGo` for more information.

Dialog



Source Block Parameters: UDP Receive

UDP Receive (mask) (link)

Receive UDP packets on a given IP port.
This block receives a UDP packet from the network and emits that data as a one-dimensional vector of the specified data type.

Parameters

Local IP port:

25000

Remote IP address ('0.0.0.0' to accept all):

'0.0.0.0'

Receive buffer size (bytes):

8192

Maximum length for Message:

255

Data type for Message: uint8

☑ Output variable-size signal

Blocking time (seconds):

inf

Sample time (seconds):

0.01

Local IP port

Specify the IP port number upon which to receive UDP packets. This value defaults to 25000. The value can range 1–65535.

Note: On Linux, to set the IP port number below 1024, run MATLAB with root privileges. For example, at the Linux command line, enter:

```
sudo matlab
```

Remote IP address ('0.0.0.0' to accept all)

Specify the IP address from which to accept packets. Entering a specific IP address blocks UDP packets from other addresses. To accept packets from any IP address, enter '0.0.0.0'. This value defaults to '0.0.0.0'.

Receive buffer size (bytes)

Make the receive buffer large enough to avoid data loss caused by buffer overflows. This value defaults to 8192.

Maximum length for Message

Specify the maximum length, in vector elements, of the data output vector. Set this parameter to a value equal or greater than the data size of a UDP packet. The system truncates data that exceeds this length. This value defaults to 255.

If you disable **Output variable-size signal**, the block outputs a fixed-length output the same length as the **Maximum length for Message**.

Data type for Message

Set the data type of the vector elements in the Message output. Match the data type with the data input used to create the UDP packets. This option defaults to uint8.

Output variable-size signal

If your model supports signals of varying length, enable the **Output variable-size signal** parameter. This checkbox defaults to selected (enabled). In that case:

- The output vector varies in length, depending on the amount of data in the UDP packet.
- The block emits the data vector from a single unlabeled output.

If your model does not support signals of varying length, disable the **Output variable-size signal** parameter. In that case:

- The block emits a fixed-length output the same length as the **Maximum length for Message**.
- If the UDP packet contains less data than the fixed-length output, the difference contains invalid data.
- The block emits the data vector from the **Message** output.
- The block emits the length of the valid data from the **Length** output.
- The block dialog box displays the **Data type for Length** parameter.

In both cases, the block truncates data that exceeds the **Maximum length for Message**.

Data type for Length

Set the data type of the Length output. This option defaults to `double`.

Blocking time (seconds)

For each sample, wait this length of time for a UDP packet before returning control to the scheduler. This value defaults to `inf`, which indicates to wait indefinitely.

Note: This parameter appears only in the Embedded Coder® UDP Receive block.

Sample time (seconds)

Specify how often the scheduler runs this block. Enter a value greater than zero. In real-time operation, setting this option to a large value reduces the likelihood of dropped UDP messages. This value defaults to a sample time of 0.01 s.

UDP Send

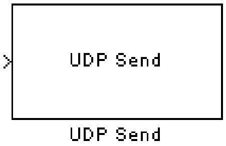
Send UDP message

Library

Sinks

`dspsnks4`

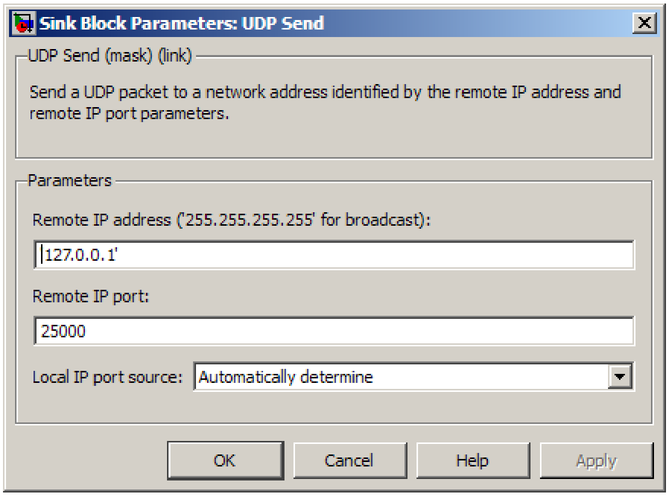
Description



The UDP Send block transmits an input vector as a UDP message over an IP network port.

Note: Some Simulink blocks and `.exe` files built from models that contain those blocks require shared libraries, such as `.dll` files on Windows. The UDP Send block requires `networkdevice.dll`. To meet this requirement, open the `packNGo` topic, and follow the example to package the code files for your model. The resulting compressed folder contains the `.dll` files that the model requires, including `networkdevice.dll`. To run this type of `.exe` file outside a MATLAB environment, place the required `.dll` files in the same folder as the `.exe` file, or place them in a folder on the Windows system path.

Dialog Box



Sink Block Parameters: UDP Send

UDP Send (mask) (link)

Send a UDP packet to a network address identified by the remote IP address and remote IP port parameters.

Parameters

Remote IP address ('255.255.255.255' for broadcast): '127.0.0.1'

Remote IP port: 25000

Local IP port source: Automatically determine

IP address ('255.255.255.255' for broadcast)

Specify the IP address or hostname to which the block sends the message. To broadcast the UDP message, retain the default value, `'127.0.0.1'`.

Remote IP port

Specify the port to which the block sends the message. The value defaults to 25000, but the values range from 1–65535.

Note: On Linux, to set the IP port number below 1024, run MATLAB with root privileges. For example, at the Linux command line, enter:

```
    sudo matlab
```

Local IP port source

To let the system automatically assign the port number, select `Assign automatically`. To specify the IP port number using the **Local IP port** parameter, select `Specify`.

Local IP port

Specify the IP port number from which the block sends the message.

If the receiving address expects messages from a particular port number, enter that number here.

Unbuffer

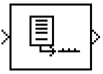
Unbuffer input frame into sequence of scalar outputs

Library

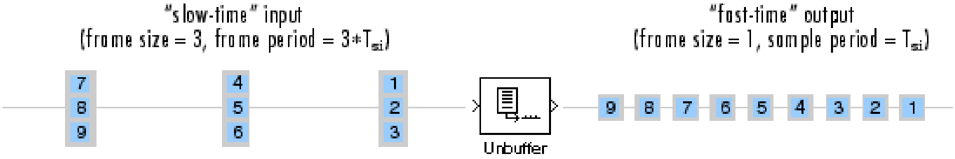
Signal Management / Buffers

`dspbuff3`

Description



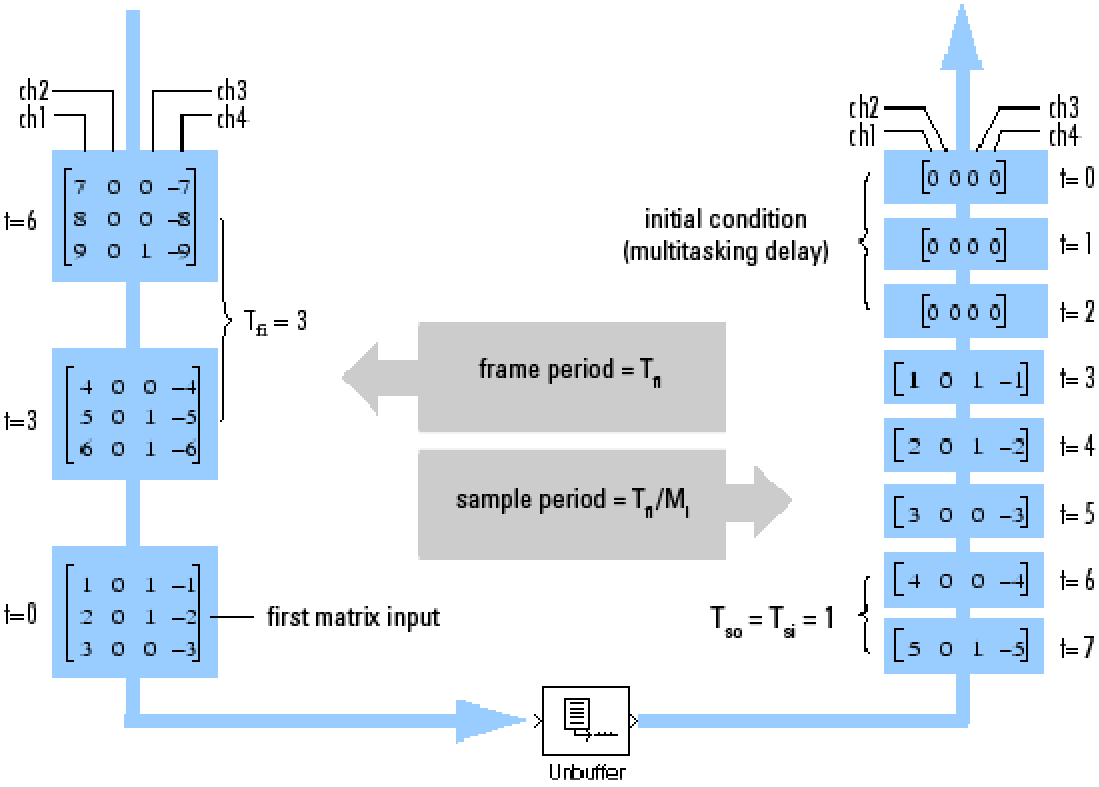
The Unbuffer block unbuffers an M_{i}-by-N input into a 1-by-N output. That is, inputs are unbuffered *row-wise* so that each matrix row becomes an independent time-sample in the output. The rate at which the block receives inputs is generally less than the rate at which the block produces outputs.



"slow-time" input
(frame size = 3, frame period = 3*T_si)
"fast-time" output
(frame size = 1, sample period = T_si)
7
8
9
4
5
6
1
2
3
Unbuffer
9 8 7 6 5 4 3 2 1

The block adjusts the output rate so that the *sample period* is the same at both the input and output, $T_{so}=T_{si}$. Therefore, the output sample period for an input of frame size M_{i} and frame period T_{fi} is T_{fi}/M_{i}, which represents a *rate* M_{i} times higher than the input frame rate. In the example above, the block receives inputs only once every three sample periods, but produces an output once every sample period. To rebuffer inputs to a larger or smaller frame size, use the Buffer block.

In the model below, the block unbuffers a four-channel input with a frame size of three. The **Initial conditions** parameter is set to zero and the tasking mode is set to multitasking, so the first three outputs are zero vectors.



Zero Latency

The Unbuffer block has *zero-tasking latency* in Simulink single-tasking mode. Zero-tasking latency means that the first input sample (received at t=0) appears as the first output sample.

Nonzero Latency

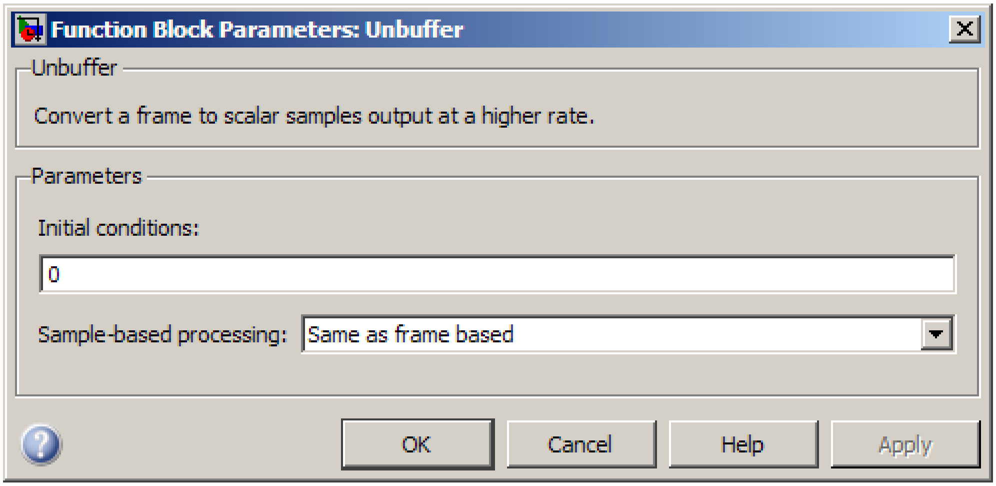
For *multitasking* operation, the Unbuffer block's buffer is initialized with the value specified by the **Initial conditions** parameter, and the block begins unbuffering this frame at the start of the simulation. Inputs to the block are therefore delayed by one buffer length, or M_i samples.

The **Initial conditions** parameter can be one of the following:

- A scalar to be repeated for the first M_i output samples of every channel
- A length-M_i vector containing the values of the first M_i output samples for every channel
- An M_i-by-N matrix containing the values of the first M_i output samples in each of N channels

Note For more information on latency and the Simulink tasking modes, see "Excess Algorithmic Delay (Tasking Latency)" and "Scheduling " in the *Simulink Coder User's Guide*.

Dialog Box



Function Block Parameters: Unbuffer

Unbuffer

Convert a frame to scalar samples output at a higher rate.

Parameters

Initial conditions: 0

Sample-based processing: Same as frame based

Initial conditions

The value of the block's initial output for cases of nonzero latency. You can specify a scalar, vector, or matrix.

Sample-based processing

Specify how the block processes sample-based inputs. You can select one of the following options:

- `Same as frame based` — When you select this option, the block performs frame-based processing on sample-based inputs. The block unbuffers M_i-by-N

matrix inputs into a 1-by-N output. Each row of the input matrix becomes an independent time-sample in the output.

- `Pass through (this choice will be removed — see release notes)` — When you select this option and the input to the block is sample based, the block does not unbuffer the input. The output of the block is the same as the input.

Note: This parameter will be removed in a future release.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Output	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers

Uniform Decoder

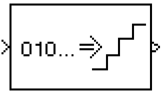
Decode integer input into floating-point output

Library

Quantizers

`dspquant2`

Description



The Uniform Decoder block performs the inverse operation of the Uniform Encoder block, and reconstructs quantized floating-point values from encoded integer input. The block adheres to the definition for uniform decoding specified in ITU-T Recommendation G.701.

Inputs can be real or complex values of the following six integer data types: `uint8`, `uint16`, `uint32`, `int8`, `int16`, or `int32`.

The block first casts the integer input values to floating-point values, and then uniquely maps (decodes) them to one of 2^B uniformly spaced floating-point values in the range [-V, (1-2^{1-B})V], where you specify B in the **Bits** parameter (as an integer between 2 and 32) and V is a floating-point value specified by the **Peak** parameter. The smallest input value representable by B bits (0 for an unsigned input data type; -2^{B-1} for a signed input data type) is mapped to the value -V. The largest input value representable by B bits (2^B-1 for an unsigned input data type; 2^{B-1}-1 for a signed input data type) is mapped to the value (1-2^{1-B})V. Intermediate input values are linearly mapped to the intermediate values in the range [-V, (1-2^{1-B})V].

To correctly decode values encoded by the Uniform Encoder block, the **Bits** and **Peak** parameters of the Uniform Decoder block should be set to the same values as the **Bits** and **Peak** parameters of the Uniform Encoder block. The **Overflow mode** parameter specifies the Uniform Decoder block's behavior when the integer input is outside the range representable by B bits. When you select **Saturate**, *unsigned* input values greater than 2^B-1 saturate at 2^B-1; *signed* input values greater than 2^{B-1}-1 or less than -2^{B-1} saturate at those limits. The real and imaginary components of complex inputs saturate independently.

When you select **Wrap**, *unsigned* input values, u, greater than 2^B-1 are wrapped back into the range [0, 2^B-1] using mod-2^B arithmetic.

```
u = mod(u,2^B)
```

Signed input values, u, greater than 2^{B-1}-1 or less than -2^{B-1} are wrapped back into that range using mod-2^B arithmetic.

```
u = (mod(u+2^B/2,2^B)-(2^B/2))
```

The real and imaginary components of complex inputs wrap independently.

The **Output type** parameter specifies whether the decoded floating-point output is single or double precision. Either level of output precision can be used with any of the six integer input data types.

Examples

See example model ex_uniform_decoder.

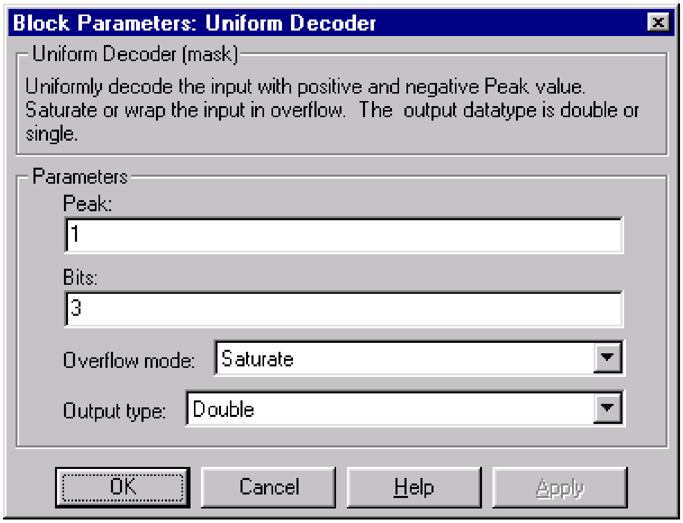
In this example, the input to the block is the uint8 output of a Uniform Encoder block. This block has comparable settings: **Peak** = 2, **Bits** = 3, and **Output type** = Unsigned. (Comparable settings ensure that inputs to the Uniform Decoder block do not saturate or wrap. See the example on the Uniform Encoder block reference page for more about these settings.)

The real and complex components of each input are independently mapped to one of 2^3 distinct levels in the range [-2.0,1.5].

```
0  is mapped to  -2.0
1  is mapped to  -1.5
2  is mapped to  -1.0
3  is mapped to  -0.5
4  is mapped to   0.0
5  is mapped to   0.5
6  is mapped to   1.0
```

```
7  is mapped to   1.5
```

Dialog Box



Block Parameters: Uniform Decoder

Uniform Decoder (mask)

Uniformly decode the input with positive and negative Peak value. Saturate or wrap the input in overflow. The output datatype is double or single.

Parameters

Peak: 1

Bits: 3

Overflow mode: Saturate

Output type: Double

Peak

Specify the largest amplitude represented in the encoded input. To correctly decode values encoded with the Uniform Encoder block, set the **Peak** parameters in both blocks to the same value.

Bits

Specify the number of input bits, B, used to encode the data. (This can be less than the total number of bits supplied by the input data type.) To correctly decode values encoded with the Uniform Encoder block, set the **Bits** parameters in both blocks to the same value.

Overflow mode

Specify the block's behavior when the integer input is outside the range representable by B bits. Out-of-range inputs can either saturate at the extreme value, or wrap back into range.

Output type

Specify the precision of the floating-point output, `single` or `double`.

Uniform Encoder

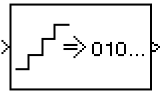
Quantize and encode floating-point input into integer output

Library

Quantizers

`dspquant2`

Description



The Uniform Encoder block performs the following two operations on each floating-point sample in the input vector or matrix:

1. Quantizes the value using the same precision
2. Encodes the quantized floating-point value to an integer value

In the first step, the block quantizes an input value to one of 2^B uniformly spaced levels in the range $[-V, (1\text{-}2^{1\text{-}B})V]$, where you specify B in the **Bits** parameter and you specify V in the **Peak** parameter. The quantization process rounds both positive and negative inputs *downward* to the nearest quantization level, with the exception of those that fall exactly on a quantization boundary. The real and imaginary components of complex inputs are quantized independently.

The number of bits, B, can be any integer value between 2 and 32, inclusive. Inputs greater than $(1\text{-}2^{1\text{-}B})V$ or less than $-V$ saturate at those respective values. The real and imaginary components of complex inputs saturate independently.

In the second step, the quantized floating-point value is uniquely mapped (encoded) to one of 2^B integer values. When the **Output type** is set to `Unsigned integer`, the smallest quantized floating-point value, $-V$, is mapped to the integer 0, and the largest quantized floating-point value, $(1\text{-}2^{1\text{-}B})V$, is mapped to the integer $2^B\text{-}1$. Intermediate quantized floating-point values are linearly (uniformly) mapped to the intermediate integers in the range [0, 2^B-1]. For efficiency, the block automatically selects an *unsigned* output data type (`uint8`, `uint16`, or `uint32`) with the minimum number of bits equal to or greater than B.

When the **Output type** is set to `Signed integer`, the smallest quantized floating-point value, $-V$, is mapped to the integer -2^{B-1}, and the largest quantized floating-point value, $(1-2^{1-B})V$, is mapped to the integer $2^{B-1}-1$. Intermediate quantized floating-point values are linearly mapped to the intermediate integers in the range $[-2^{B-1}, 2^{B-1}-1]$. The block automatically selects a *signed* output data type (`int8`, `int16`, or `int32`) with the minimum number of bits equal to or greater than B.

Inputs can be real or complex, double or single precision. The output data types that the block uses are shown in the table below. Note that most of the DSP System Toolbox blocks accept only double-precision inputs. Use the Simulink Data Type Conversion block to convert integer data types to double precision. See “Data Types” in the Simulink documentation for a complete discussion of data types, as well as a list of Simulink blocks capable of reduced-precision operations.

Bits	Unsigned Integer	Signed Integer
2 to 8	`uint8`	`int8`
9 to 16	`uint16`	`int16`
17 to 32	`uint32`	`int32`

The Uniform Encoder block operations adhere to the definition for uniform encoding specified in ITU-T Recommendation G.701.

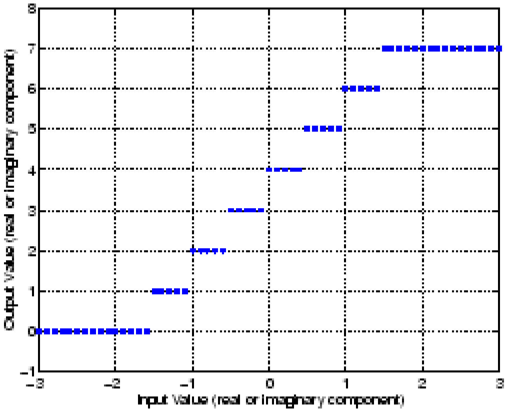
Examples

See example model ex_uniform_encoder.

In this example, the following parameters are set:

- **Peak** = 2
- **Bits** = 3
- **Output type** = `Unsigned`

The following figure illustrates uniform encoding.



The real and complex components of each input (horizontal axis) are independently quantized to one of 2^3 distinct levels in the range `[-2,1.5]`. These components are then mapped to one of 2^3 integer values in the range `[0,7]`.

```
-2.0  is mapped to  0
-1.5  is mapped to  1
-1.0  is mapped to  2
-0.5  is mapped to  3
 0.0  is mapped to  4
 0.5  is mapped to  5
 1.0  is mapped to  6
 1.5  is mapped to  7
```

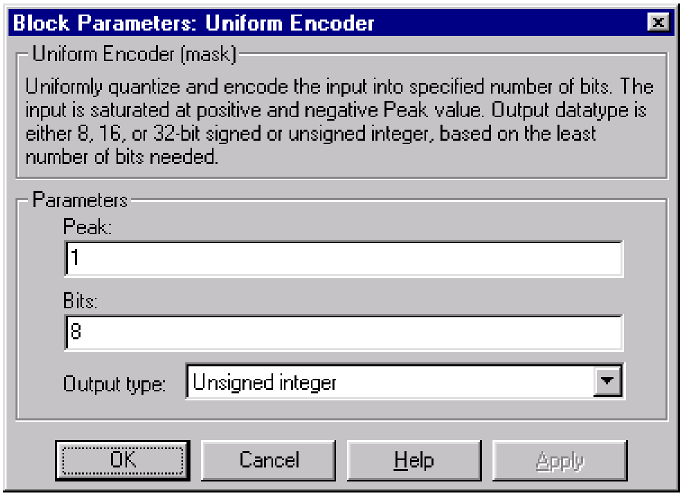
This table shows the results for a few particular inputs.

Input	Quantized Input	Output	Notes
`1.6`	`1.5+0.0i`	`7+4i`	
`-0.4`	`-0.5+0.0i`	`3+4i`	
`-3.2`	`-2.0+0.0i`	`4i`	Saturation (real)
`0.4-1.2i`	`0.0-1.5i`	`4+i`	
`0.4-6.0i`	`0.0-2.0i`	`4`	Saturation (imaginary)

Input	Quantized Input	Output	Notes
`-4.2+3.5i`	`-2.0+2.0i`	`7i`	Saturation (real and imaginary)

The output data type is automatically set to `uint8`, the most efficient format for this input range.

Dialog Box



Block Parameters: Uniform Encoder

Uniform Encoder (mask)

Uniformly quantize and encode the input into specified number of bits. The input is saturated at positive and negative Peak value. Output datatype is either 8, 16, or 32-bit signed or unsigned integer, based on the least number of bits needed.

Parameters

Peak: 1

Bits: 8

Output type: Unsigned integer

Peak

The largest input amplitude to be encoded, *V*. Real or imaginary input values greater than $(1\text{-}2^{1\text{-}B})V$ or less than $-V$ saturate (independently for complex inputs) at those limits.

Bits

Specify the number of bits, *B*, needed to represent the integer output. The number of levels at which the block quantizes the floating-point input is 2^B.

Output type

The data type of the block's output, `Unsigned integer` or `Signed integer`. Unsigned outputs are `uint8`, `uint16`, or `uint32`, while signed outputs are `int8`, `int16`, or `int32`.

Unwrap

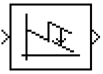
Unwrap signal phase

Library

Signal Operations

dspsigops

Description



The Unwrap block unwraps each channel of the input by adding or subtracting appropriate multiples of 2π to each channel element. The input can be a vector or matrix, and must have radian phase entries. The block recognizes phase discontinuities larger than the **Tolerance** parameter setting. For more information about phase unwrapping, see the "Definition of Phase Unwrap" on page 1-1569.

The block preserves the input size and dimension, and the output port rate equals the input port rate.

Unwrap Method

The Unwrap block unwraps each channel of its input matrix or input vector by adding 2π*k* to each successive channel element, and updating *k* at each *phase jump*. A phase jump occurs when the difference between two adjacent phase value entries exceeds the value of the **Tolerance** parameter.

The following code illustrates how the block unwraps the data in a given input channel u.

```
k=0;    % initialize k to 0
i=1;    % initialize the counter to 1
alpha=pi;   % set alpha to the desired Tolerance. In this case, pi

for i = 1:(size(u)-1)
```

```
    yout(i,:)=u(i)+(2*pi*k); % add 2*pi*k to ui
    if((abs(u(i+1)-u(i)))>(abs(alpha)))  %if diff is greater than alpha, increment or d

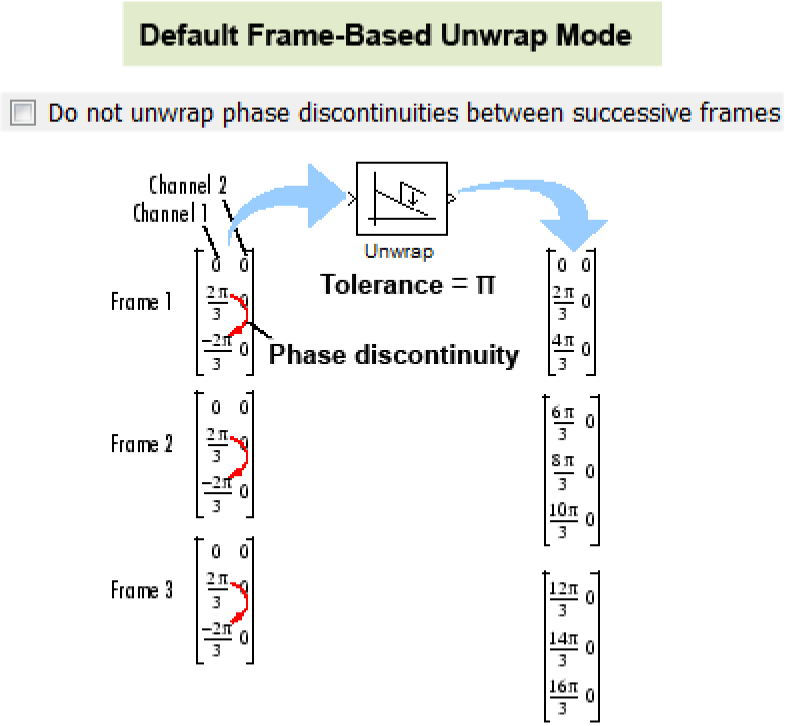
        if u(i+1)<u(i)   % if the phase jump is negative, increment k
            k=k+1;
        else             % if the phase jump is positive, decrement k
            k=k-1;
        end
    end
end
yout((i+1),:)=u(i+1)+(2*pi*k); % add 2*pi*k to the last element of the input
```

Frame-Based Processing

When you configure the block to perform frame-based processing, the block supports two different unwrap modes. In both modes, the block adds 2π*k* to each input channel's elements, and updates *k* at each phase discontinuity. The difference between the two modes is how often the block resets the initial phase value (*k*) to zero. You can choose to unwrap data across frame boundaries (default), or to unwrap only within input frames, by resetting the initial phase value each time a new input frame is received.

Unwrapping Across Frame Boundaries

In the default mode, the block ignores boundaries between input frames, and continues to unwrap the data in each channel without resetting the initial phase value to zero. To specify this mode, clear the **Do not unwrap phase discontinuities between successive frames** check box. The following figure illustrates how the block unwraps data in this mode.

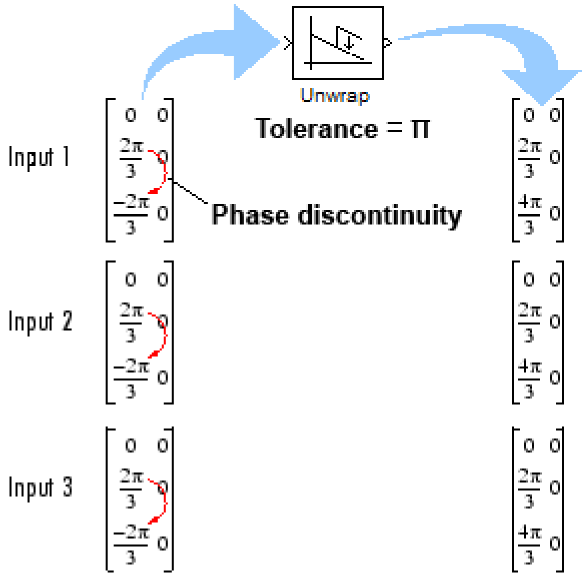


Unwrapping Within Frames

When you select the **Do not unwrap phase discontinuities between successive frames** check box, the block treats each frame of input data independently. In this mode, the block resets the initial phase value to zero each time a new input frame is received. The following figure illustrates how the block unwraps data in this mode.

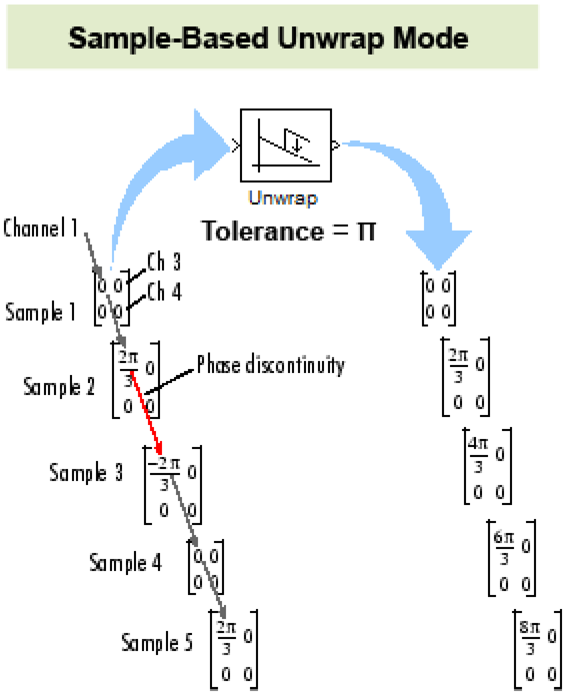
Nondefault Frame-Based Unwrap Mode

☑ Do not unwrap phase discontinuities between successive frames



Sample-Based Processing

When you configure the block to perform sample-based processing, the block treats each element of the input as an individual channel. The block unwraps the data in each channel of the input, and does not reset the initial phase to zero each time a new input is received. The following figure illustrates how the block unwraps data when performing sample-based processing.

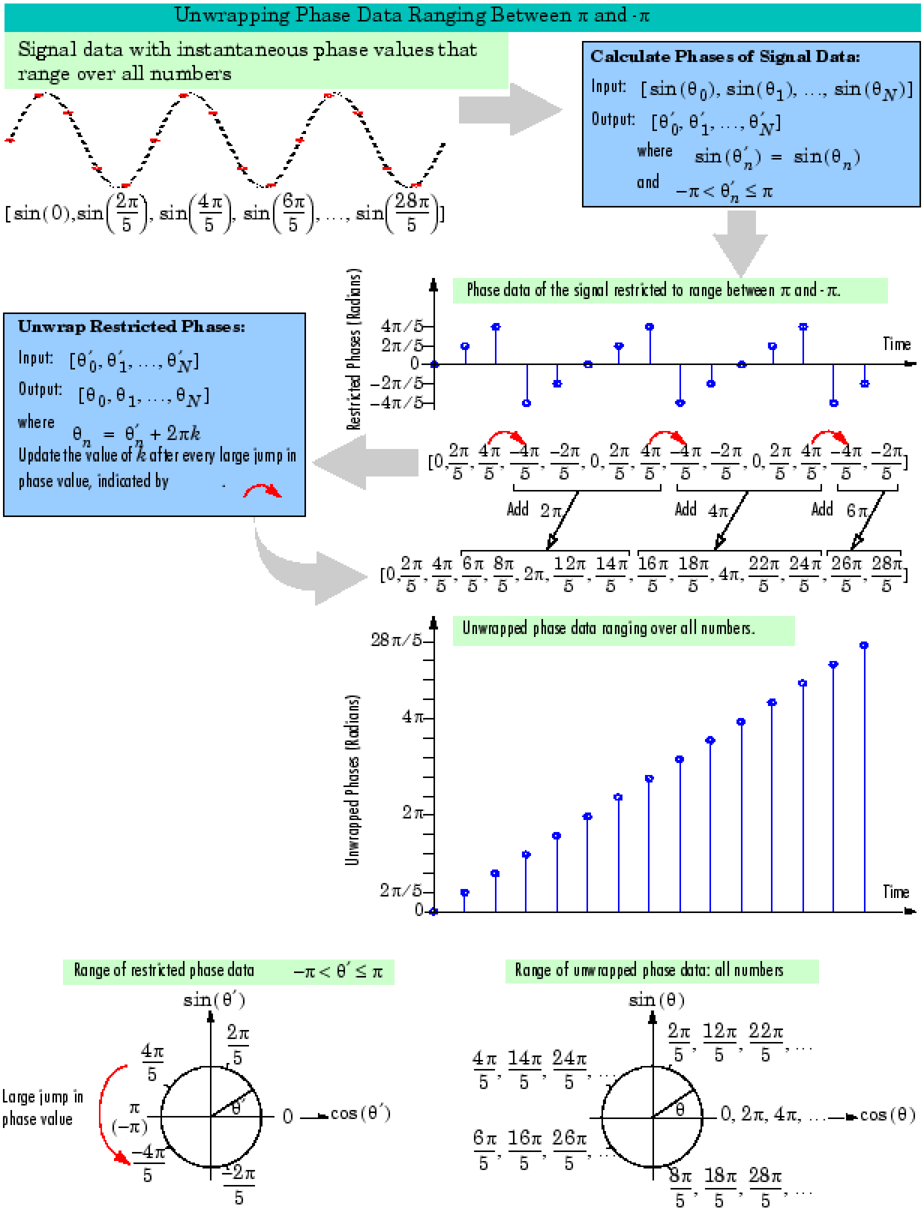


Definition of Phase Unwrap

Algorithms that compute the phase of a signal often only output phases between –π and π. For instance, such algorithms compute the phase of sin(2π + 3) to be 3, since sin(3) = sin(2π + 3), and since the actual phase, 2π + 3, is not between –π and π. Such algorithms compute the phases of sin(–4π + 3) and sin(16π + 3) to be 3 as well.

Phase unwrap or unwrap is a process often used to reconstruct a signal's original phase. Unwrap algorithms add appropriate multiples of 2π to each phase input to restore original phase values, as illustrated in the following diagram. See “Unwrap Method” on page 1-1565 for more information on the unwrap algorithm used by this block.

The following figure illustrates the concept of phase unwrapping.



Unwrapping Phase Data Ranging Between π and -π
Signal data with instantaneous phase values that range over all numbers

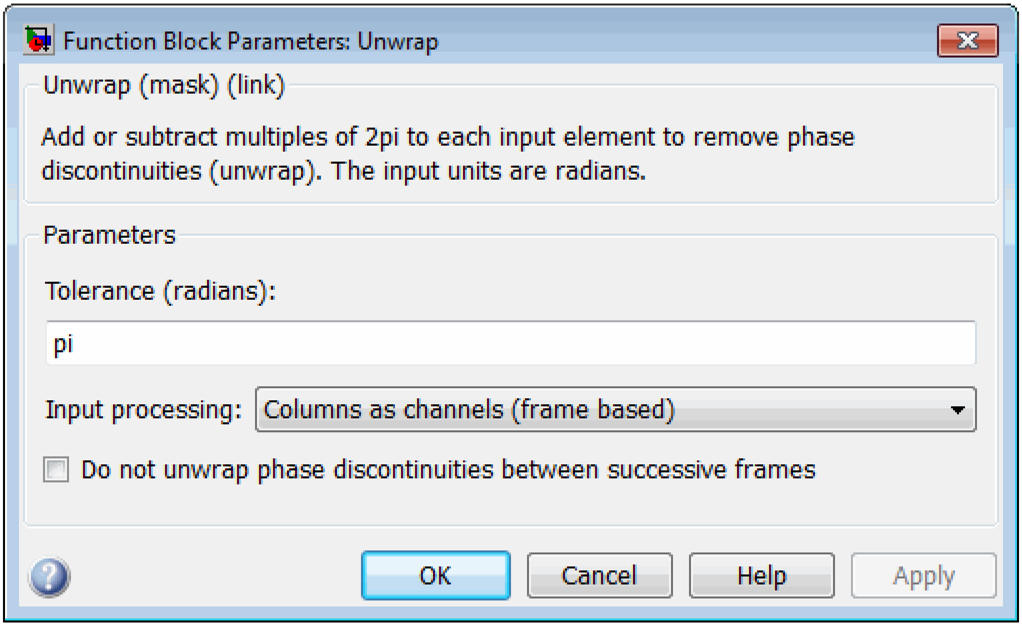
Dialog Box



Function Block Parameters: Unwrap

Unwrap (mask) (link)

Add or subtract multiples of 2pi to each input element to remove phase discontinuities (unwrap). The input units are radians.

Parameters

Tolerance (radians): pi

Input processing: Columns as channels (frame based)

□ Do not unwrap phase discontinuities between successive frames

Tolerance

The jump size that the block recognizes as a true phase discontinuity. The default is set to π (rather than a smaller value) to avoid altering legitimate signal features. To increase the block's sensitivity, set the **Tolerance** to a value slightly less than π.

Input processing

Specify how the block should process the input. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` — When you select this option, the block treats each column of the input as a separate channel.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

Note: The `Inherited (this choice will be removed - see release notes)` option will be removed in a future release. See "Frame-Based Processing" in the *DSP System Toolbox Release Notes* for more information.

Do not unwrap phase discontinuities between successive frames

When you clear this check box, the block ignores boundaries between input frames and does not reset the initial phase value to zero each time a new input is received. In this mode, the block continuously unwraps the data in each column of the input. When you select this check box, the block treats each frame of input data independently, and resets the initial phase value for each new input frame. See the "Frame-Based Processing" on page 1-1566 section for more information.

This parameter is available only when you configure the block to perform frame-based processing. In sample-based processing mode, the block does not reset the initial phase value to zero for each new input. See "Sample-Based Processing" on page 1-1568 for more information.

Supported Data Types

- Double-precision floating point
- Single-precision floating point

Upsample

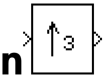
Resample input at higher rate by inserting zeros

Library

Signal Operations

`dspsigops`

Description



The Upsample block resamples each channel of the M_i-by-N input at a rate L times higher than the input sample rate by inserting L-1 zeros between consecutive samples. You specify the integer L in the **Upsample factor** parameter. The **Sample offset** parameter, D, allows you to delay the output samples by an integer number of sample periods. Doing so enables you to select any of the L possible output phases. The value you specify for the **Sample offset** parameter must be in the range $0 \le D < (L-1)$.

You can use this block inside of triggered subsystems when you set the **Rate options** parameter to `Enforce single-rate processing`.

Frame-Based Processing

When you set the **Input processing** parameter to `Columns as channels (frame based)`, the block upsamples each column of the input over time. In this mode, the block can perform either single-rate or multirate processing. You can use the **Rate options** parameter to specify how the block upsamples the input:

- When you set the **Rate options** parameter to `Enforce single-rate processing`, the input and output of the block have the same sample rate. In this mode, the block outputs a signal with a proportionally larger frame *size* than the input. For upsampling by a factor of L, the output frame size is L times larger than the input frame size ($M_o = M_i*L$), but the input and output frame rates are equal.

  For an example of single-rate upsampling, see Example: Single-Rate Processing.

- When you set the **Rate options** parameter to `Allow multirate processing`, the block treats an M_i-by-N matrix input as N independent channels. The block upsamples each column of the input over time by keeping the frame size constant (M_i=M_o), and making the output frame period (T_{fo}) L times shorter than the input frame period ($T_{fo} = T_{fi}/L$).

  See Example: Multirate, Frame-Based Processing for an example that uses the Upsample block in this mode.

Sample-Based Processing

When you set the **Input processing** parameter to `Elements as channels (sample based)`, the block treats an M-by-N matrix input as M*N independent channels, and upsamples each channel over time. In this mode, the block always performs multirate processing. The output sample rate is L times higher than the input sample rate (T_{so} = T_{si}/L), and the input and output sizes are identical.

Zero Latency

The Upsample block has *zero-tasking latency* for all single-rate operations. The block is in a single-rate mode if you set the **Upsample factor** parameter to `1` or if you set the **Input processing** parameter to `Columns as channels (frame based)` and the **Rate options** parameter to `Enforce single-rate processing`.

The Upsample block also has zero-tasking latency for multirate operations if you run your model in Simulink single-tasking mode.

Zero-tasking latency means that the block propagates the first input (received at t=0) immediately following the D consecutive zeros specified by the **Sample offset** parameter. This output (D+1) is followed in turn by the L-1 inserted zeros and the next input sample.

Nonzero Latency

The Upsample block has tasking latency for multirate, multitasking operation:

- In multirate, sample-based processing mode, the initial condition for each channel appears as output sample D+1, and is followed by L-1 inserted zeros. The channel's first input appears as output sample D+L+1. The **Initial conditions** parameter can be an M_i-by-N matrix containing one value for each channel, or a scalar to be applied to all signal channels.

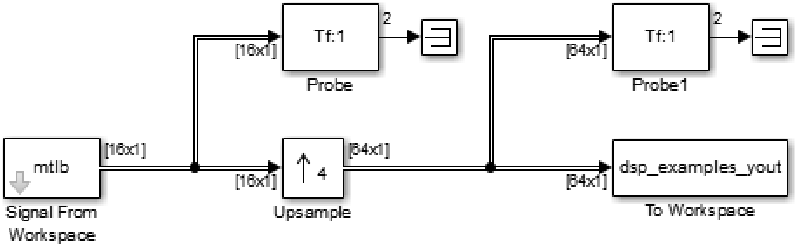
- In multirate, frame-based processing mode, the first row of the initial condition matrix appears as output sample D+1, and is followed by L-1 inserted rows of zeros, the second row of the initial condition matrix, and so on. The first row of the first input matrix appears in the output as sample M_iL+D+1. The **Initial conditions** parameter can be an M_i-by-N matrix, or a scalar to be repeated across all elements of the input matrix.

Note: For more information on latency and the Simulink tasking modes, see "Excess Algorithmic Delay (Tasking Latency)" and "Scheduling " in the *Simulink Coder User's Guide*.

Examples

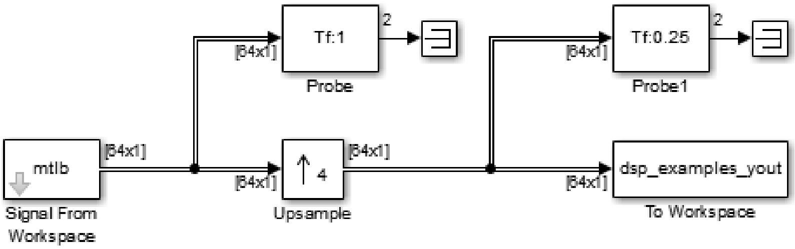
Example: Single-Rate Processing

In the ex_upsample_ref2 model, the Upsample block resamples a single-channel input with a frame size of 16. The block upsamples the input by a factor of 4. Thus, the output of the block has a frame size of 64. Because the block is in single-rate processing mode, the input and output frame rates are identical.

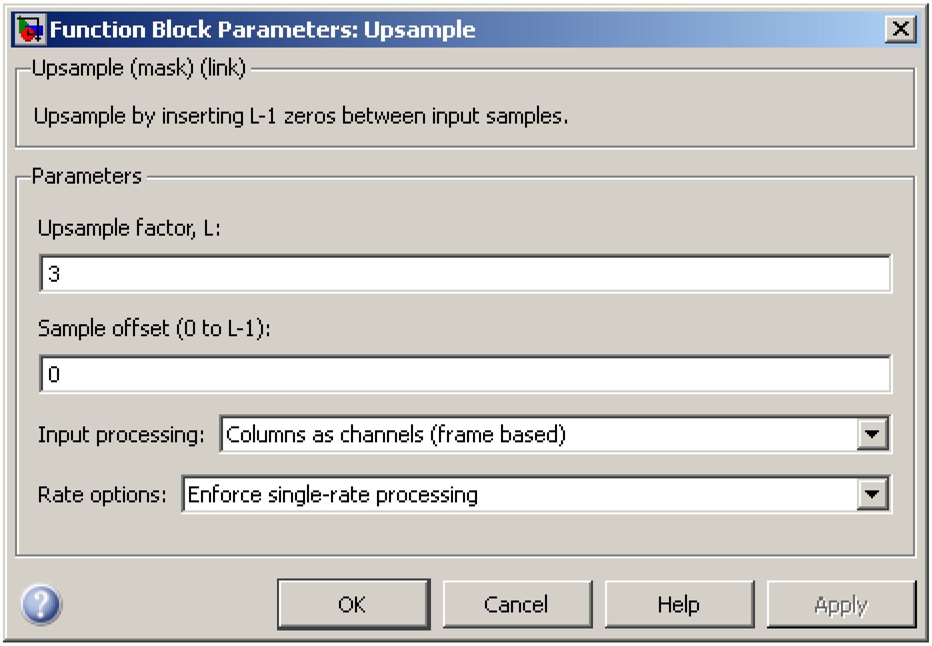


Example: Multirate, Frame-Based Processing

In the ex_upsample_ref1 model, the Upsample block resamples a single-channel input with a frame period of 1 second. The block upsamples the input by a factor of 4. Thus, the output of the block has a frame period of 0.25 seconds. Because the block is in multirate processing mode, the input and output frame sizes are identical.



Dialog Box



Function Block Parameters: Upsample

Upsample (mask) (link)

Upsample by inserting L-1 zeros between input samples.

Parameters

Upsample factor, L: 3

Sample offset (0 to L-1): 0

Input processing: Columns as channels (frame based)

Rate options: Enforce single-rate processing

Upsample factor

The integer factor, L, by which to increase the input sample rate.

Sample offset

The sample offset, D, which must be an integer in the range [0,L-1].

Input processing

Specify how the block should process the input. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` — When you select this option, the block treats each column of the input as a separate channel. In this mode, the block can perform single-rate or multirate processing.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel. In this mode, the block always performs multirate processing.

Note: The option `Inherit from input (this choice will be removed - see release notes)` will be removed in a future release. See "Frame-Based Processing" in the *DSP System Toolbox Release Notes* for more information.

Rate options

Specify the method by which the block upsamples the input. You can select one of the following options:

- `Enforce single-rate processing` — When you select this option, the block maintains the input sample rate by increasing the output frame size by a factor of *L*. To select this option, you must set the **Input processing** parameter to `Columns as channels (frame based)`.
- `Allow multirate processing` — When you select this option, the block resamples the signal such that the output sample rate is *L* times faster than the input sample rate.

Initial conditions

The value with which the block is initialized for cases of nonzero latency, a scalar or matrix. This value appears in the output as sample D+1. This parameter appears only when you configure the block to perform multirate processing.

HDL Code Generation

This block supports HDL code generation using HDL Coder. HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic. For more information on implementations, properties, and restrictions for HDL code generation, see Upsample.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Output	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers

Variable Fractional Delay

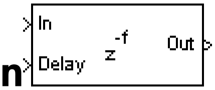
Delay input by time-varying fractional number of sample periods

Library

Signal Operations

`dspsigops`

Description



The Variable Fractional Delay block delays each element of the discrete-time N-D input array, *u*, by a variable number of sample intervals. The input delay values can be integer or noninteger values. The block provides three different interpolation modes: `Linear`, `FIR`, and `Farrow`.

The block computes the value for each channel of the output based on the stored samples in memory most closely indexed by the `Delay` input, *v*, and the interpolation method specified by the **Interpolation mode** parameter.

- In `Linear` interpolation mode, the block stores the D_{max}+1 most recent samples received at the In port for each channel, where D_{max} is the value you specify for the **Maximum delay (Dmax) in samples** parameter.
- In `FIR` interpolation mode, the block stores the $D_{max}+P+1$ most recent samples received at the In port for each channel, where *P* is the value you specify for the **Interpolation filter half-length (P)** parameter.
- In `Farrow` interpolation mode, the block stores the $D_{max}+\frac{N}{2}+1$ most recent samples received at the In port for each channel, where *N* is the value you specify for the **Farrow filter length (N)** parameter.

The Variable Fractional Delay block assumes that the input values at the `Delay` port are between D_{min} and D_{max}, where D_{min} appears in the `Valid delay range` section on the **Main** pane of the block mask, and D_{max} is the value of the **Maximum delay (Dmax) in**

samples parameter. The block clips delay values less than D_{min} to D_{min} and delay values greater than D_{max} to D_{max}.

You must consider additional factors when selecting valid `Delay` values for the `FIR` and `Farrow` interpolation modes. For more information about these considerations, refer to or , respectively.

The Variable Fractional Delay block is similar to the Variable Integer Delay block, in that they both store a minimum of D_{max}+1 past samples in memory. The Variable Fractional Delay block differs only in the way that these stored samples are accessed; a fractional delay requires the computation of a value by interpolation from the nearby samples in memory.

Sample-Based Processing

When you set the **Input processing** parameter to `Elements as channels (sample based)`, the block treats each element of the N-D input array, u, as an independent channel. The input to the Delay port, v, must either be an N-D array of the same size and dimension as the input u, or be a scalar value, such that $D_{min} \le v \le D_{max}$.
