Create a simple System object, `AddOne`, which subclasses from `matlab.System`. You place this code into a MATLAB file, `AddOne.m`.

```
classdef AddOne < matlab.System
% ADDONE Compute an output value that increments the input by one

    methods (Access = protected)
       % stepImpl method is called by the step method.
       function y = stepImpl(~,x)
          y = x + 1;
```

```
            end
        end
end
```

Use this object by creating an instance of `AddOne`, providing an input, and using the `step` method.

```
hAdder = AddOne;
x = 1;
y = step(hAdder,x)
```

Assign the `Nontunable` attribute to the `InitialValue` property, which you define in your class definition file.

```
properties (Nontunable)
    InitialValue
end
```

- “Define Property Attributes”

cloneImpl

Class: matlab.System
Package: matlab

Copy System object

Syntax

```
cloneImpl(obj)
```

Description

`cloneImpl(obj)` copies a System object by using the `saveObjectImpl` and `loadObjectImpl` methods. The default `cloneImpl` copies an object and its current state but does not copy any private or protected properties. If the object you clone is locked and you use the default `cloneImpl`, the new object will also be locked. If you define your own `cloneImpl` and the associated `saveObjectImpl` and `loadObjectImpl`, you can specify whether to clone the object's state and whether to clone the object's private and protected properties.

`cloneImpl` is called by the `clone` method.

Note: You must set `Access = protected` for this method.

You cannot modify any properties in this method.

Input Arguments

`obj`

System object handle of object to clone.

Examples

Clone a System Object

Use the `cloneImpl` method in your class definition file to copy a System object

```
methods (Access = protected)
   function obj2 = cloneImpl(obj1)
      s = saveObject (obj1);
      obj2 = loadObject(s);
   end
end
```

See Also

`saveObjectImpl` | `loadObjectImpl`

How To

- "Clone System Object"

getDiscreteStateImpl

Class: matlab.System
Package: matlab

Discrete state property values

Syntax

```
s = getDiscreteStateImpl(obj)
```

Description

`s = getDiscreteStateImpl(obj)` returns a struct `s` of state values. The field names of the struct are the object's `DiscreteState` property names. To restrict or change the values returned by `getDiscreteState` method, you can override this `getDiscreteStateImpl` method.

`getDiscreteStatesImpl` is called by the `getDiscreteState` method, which is called by the `setup` method.

Note: You must set `Access = protected` for this method.

You cannot modify any properties in this method.

Input Arguments

`obj`

System object handle

Output Arguments

`s`

Struct of state values.

Examples

Get Discrete State Values

Use the `getDiscreteStateImpl` method in your class definition file to get the discrete states of the object.

```
methods (Access = protected)
   function s = getDiscreteStateImpl(obj)
   end
end
```

See Also

`setupImpl`

How To

- “Define Property Attributes”

getInputNamesImpl

Class: matlab.System
Package: matlab

Names of the input ports of the System block

Syntax

```
[name1,name2,...] = getInputNamesImpl(obj)
```

Description

`[name1,name2,...] = getInputNamesImpl(obj)` returns the names of the input ports to System object, `obj` implemented in a MATLAB System block. The number of returned input names matches the number of inputs returned by the `getNumInputs` method. If you change a property value that changes the number of inputs, the names of those inputs also change.

`getInputNamesImpl` is called by the `getInputNames` method by the MATLAB System block.

Note: You must set `Access = protected` for this method.

Input Arguments

`obj`

System object handle

Output Arguments

`name1,name2,...`

Names of the inputs for the specified object.

Default: empty string

Examples

Specify Input Port Name

Specify in your class definition file the names of two input ports as `'upper'` and `'lower'`.

```
methods (Access = protected)
   function varargout = getInputNamesImpl(obj)
      numInputs = getNumInputs(obj);
      varargout = cell(1,numInputs);
      varargout{1} = 'upper';
      if numInputs > 1
         varargout{2} = 'lower';
      end
   end
end
```

See Also

`getNumInputsImpl` | `getOutputNamesImpl`

How To

- "Validate Property and Input Values"

getNumInputsImpl

Class: matlab.System
Package: matlab

Number of input arguments passed to step and setup methods

Syntax

```
num = getNumInputsImpl(obj)
```

Description

`num = getNumInputsImpl(obj)` returns the number of inputs `num` (excluding the System object handle) expected by the `step` method.

If your `step` method has a variable number of inputs (uses `varargin`), you should implement the `getNumInputsImpl` method in your class definition file. If the number of inputs expected by the `step` method is fixed (does not use `varargin`), the default `getNumInputsImpl` determines the required number of inputs directly from the `step` method. In this case, you do not need to include `getNumInputsImpl` in your class definition file.

`getNumInputsImpl` is called by the `getNumInputs` method and by the `setup` method if the number of inputs has not been determined already.

Note: You must set `Access = protected` for this method.

You cannot modify any properties in this method.

Input Arguments

`obj`

System object handle

Output Arguments

`num`

Number of inputs expected by the `step` method for the specified object.

Default: 1

Examples

Set Number of Inputs

Specify the number of inputs (2, in this case) expected by the `step` method.

```
methods (Access = protected)
   function num = getNumInputsImpl(~)
      num = 2;
   end
end
```

Set Number of Inputs to Zero

Specify that the `step` method will not accept any inputs.

```
methods (Access = protected)
   function num = getNumInputsImpl(~)
      num = 0;
   end
end
```

See Also

`setupImpl` | `stepImpl` | `getNumOutputsImpl` | `getNumOutputsImpl`

How To

- "Change Number of Step Inputs or Outputs"

getNumOutputsImpl

Class: matlab.System
Package: matlab

Number of outputs returned by `step` method

Syntax

```
num = getNumOutputsImpl (obj)
```

Description

`num = getNumOutputsImpl (obj)` returns the number of outputs from the `step` method.

If the number of outputs expected by the `step` method is fixed (does not use `varargout`), the object determines the required number of outputs from the `step` method. In this case, you do not need to implement the `getNumOutputsImpl` method.

If your `step` method has a variable number of outputs (uses `varargout`), implement the `getNumOutputsImpl` method in your class definition file to determine the number of outputs. Use `nargout` in the `stepImpl` method to assign the expected number of outputs.

`getNumOutputsImpl` is called by the `getNumOutputs` method, if the number of outputs has not been determined already.

Note: You must set `Access = protected` for this method.

You cannot modify any properties in this method.

Input Arguments

`obj`

System object handle

Output Arguments

num

Number of outputs to be returned by the step method for the specified object.

Examples

Set Number of Outputs

Specify the number of outputs (2, in this case) returned from the step method.

```
methods (Access = protected)
   function num = getNumOutputsImpl(~)
      num = 2;
   end
end
```

Set Number of Outputs to Zero

Specify that the step method does not return any outputs.

```
methods (Access = protected)
   function num = getNumOutputsImpl(~)
      num = 0;
   end
end
```

Using nargout in stepImpl

Use nargout in the stepImpl method when you have a variable number of outputs and will generate code.

```
methods (Access = protected)
   function varargout = stepImpl(~,varargin)
      for i = 1:nargout
         varargout{i} = varargin{i}+1;
      end
   end
end
```

stepImpl | getNumInputsImpl | setupImpl

How To

- “Change Number of Step Inputs or Outputs”

getOutputNamesImpl

Class: matlab.System
Package: matlab

Names of System block output ports

Syntax

```
[name1,name2,...] = getOutputNamesImpl(obj)
```

Description

`[name1,name2,...] = getOutputNamesImpl(obj)` returns the names of the output ports from System object, `obj` implemented in a MATLAB System block. The number of returned output names matches the number of outputs returned by the `getNumOutputs` method. If you change a property value that affects the number of outputs, the names of those outputs also change.

`getOutputNamesImpl` is called by the `getOutputNames` method and by the MATLAB System block.

Note: You must set `Access = protected` for this method.

Input Arguments

`obj`

System object handle

Output Arguments

`name1,name2,...`

Names of the outputs for the specified object.

Default: empty string

Examples

Specify Output Port Name

Specify the name of an output port as `'count'`.

```
methods (Access = protected)
   function outputName = getOutputNamesImpl(~)
      outputName = 'count';
   end
end
```

See Also

`getNumOutputsImpl` | `getInputNamesImpl`

How To

- “Validate Property and Input Values”

infoImpl

Class: matlab.System
Package: matlab

Information about System object

Syntax

```
s = infoImpl(obj,varargin)
```

Description

`s = infoImpl(obj,varargin)` lets you set up information to return about the current configuration of a System object `obj`. This information is returned in a struct from the `info` method. The varargin argument is optional. The default `infoImpl` method, which is used if you do not include `infoImpl` in your class definition file, returns an empty struct.

`infoImpl` is called by the `info` method.

Note: You must set `Access = protected` for this method.

Input Arguments

`obj`

System object handle

`varargin`

Allow variable number of inputs

Examples

Define infoImpl to return System object information

Define the `infoImpl` method to return current count information for `info(obj)`.

```
methods (Access = protected)
   function s = infoImpl(obj)
      s = struct('Count',obj.pCount);
   end
end
```

How To

- "Define System Object Information"

isInactivePropertyImpl

Class: matlab.System
Package: matlab

Active or inactive flag for properties

Syntax

```
flag = isInactivePropertyImpl(obj,prop)
```

Description

`flag = isInactivePropertyImpl(obj,prop)` specifies whether a public, non-state property is inactive for the current object configuration. An *inactive property* is a property that is not relevant to the object, given the values of other properties. Inactive properties are not shown if you use the `disp` method to display object properties. If you attempt to use public access to directly access or use `get` or `set` on an inactive property, a warning occurs.

`isInactiveProperty` is called by the `disp` method and by the `get` and `set` methods.

Note: You must set `Access = protected` for this method.

Input Arguments

`obj`

System object handle

`prop`

Public, non-state property name

Output Arguments

`flag`

Logical scalar value indicating whether the input property `prop` is inactive for the current object configuration.

Examples

Set Inactive Property

Display the `InitialValue` property only when the `UseRandomInitialValue` property value is `false`.

```
methods (Access = protected)
  function flag = isInactivePropertyImpl(obj,propertyName)
    if strcmp(propertyName,'InitialValue')
      flag = obj.UseRandomInitialValue;
    else
      flag = false;
    end
  end
end
```

See Also

`setProperties`

How To

- “Hide Inactive Properties”

loadObjectImpl

Class: matlab.System
Package: matlab

Load saved System object from MAT file

Syntax

```
loadObjectImpl(obj)
```

Description

`loadObjectImpl(obj)` loads a saved System object, obj, from a MAT file. Your `loadObjectImpl` method should correspond to your `saveObjectImpl` method to ensure that all saved properties and data are loaded.

Note: You must set `Access = protected` for this method.

Input Arguments

`obj`

System object handle

Examples

Load System Object

Load a saved System object. In this case, the object contains a child object, protected and private properties, and a discrete state.

```
methods (Access = protected)
   function loadObjectImpl(obj, s, wasLocked)
```

```
      % Load child System objects
      obj.child = matlab.System.loadObject(s.child);

      % Save protected & private properties
      obj.protected = s.protected;
      obj.pdependentprop = s.pdependentprop;

      % Save state only if locked when saved
      if wasLocked
        obj.state = s.state;
      end

      % Call base class method
      loadObjectImpl@matlab.System(obj,s,wasLocked);
    end
  end
```

See Also

`saveObjectImpl`

How To

- “Load System Object”
- “Save System Object”

processTunedPropertiesImpl

Class: matlab.System
Package: matlab

Action when tunable properties change

Syntax

```
processTunedPropertiesImpl(obj)
```

Description

`processTunedPropertiesImpl(obj)` specifies the actions to perform when one or more tunable property values change. This method is called as part of the next call to the `step` method after a tunable property value changes. A property is tunable only if its `Nontunable` attribute is `false`, which is the default.

`processTunedPropertiesImpl` is called by the `step` method.

Note: You must set `Access = protected` for this method.

You cannot modify any tunable properties in this method if its System object will be used in the Simulink MATLAB System block.

Tips

Use this method when a tunable property affects a different property value. For example, two property values determine when to calculate a lookup table. You want to perform that calculation when either property changes. You also want the calculation to be done only once if both properties change before the next call to the `step` method.

Input Arguments

obj

System object handle

Examples

Specify Action When Tunable Property Changes

Use `processTunedPropertiesIempl` to recalculate the lookup table if the value of either the `NumNotes` or `MiddleC` property changes.

```
methods (Access = protected)
   function processTunedPropertiesImpl(obj)
      % Generate a lookup table of note frequencies
      obj.pLookupTable = obj.MiddleC * (1+log(1:obj.NumNotes)/log(12));
    end
end
```

See Also

`validatePropertiesImpl` | `setProperties`

How To

- "Validate Property and Input Values"
- "Define Property Attributes"

releaseImpl

Class: matlab.System
Package: matlab

Release resources

Syntax

`releaseImpl(obj)`

Description

`releaseImpl(obj)` releases any resources used by the System object, such as file handles. This method also performs any necessary cleanup tasks. To release resources for a System object, you must use `releaseImpl` instead of a destructor.

`releaseImpl` is called by the `release` method. `releaseImpl` is also called when the object is deleted or cleared from memory, or when all references to the object have gone out of scope.

Note: You must set `Access = protected` for this method.

Input Arguments

`obj`

System object handle

Examples

Close a File and Release Its Resources

Use the `releaseImpl` method to close a file.

```
methods (Access = protected)
   function releaseImpl(obj)
     fclose(obj.pFileID);
   end
end
```

See Also

resetImpl

How To

- “Release System Object Resources”

resetImpl

Class: matlab.System
Package: matlab

Reset System object states

Syntax

```
resetImpl(obj)
```

Description

`resetImpl(obj)` defines the state reset equations for the System object. Typically you reset the states to a set of initial values. This is useful for initialization at the start of simulation.

`resetImpl` is called by the `reset` method. It is also called by the `setup` method, after the `setupImpl` method.

Note: You must set `Access = protected` for this method.

You cannot modify any tunable properties in this method if its System object will be used in the Simulink MATLAB System block.

Input Arguments

`obj`

System object handle

Examples

Reset Property Value

Use the `reset` method to reset the state of the counter stored in the `pCount` property to zero.

```
methods (Access = protected)
   function resetImpl(obj)
      obj.pCount = 0;
   end
end
```

See Also

`releaseImpl`

How To

- "Reset Algorithm State"

saveObjectImpl

Class: matlab.System
Package: matlab

Save System object in MAT file

Syntax

```
saveObjectImpl(obj)
```

Description

`saveObjectImpl(obj)` defines what System object obj property and state values are saved in a MAT file when a user calls `save` on that object. `save` calls `saveObject`, which then calls `saveObjectImpl`. If you do not define a `saveObjectImpl` method for your System object class, only public properties and properties with the `DiscreteState` attribute are saved. To save any private or protected properties or state information, you must define a `saveObjectImpl` in your class definition file.

You should save the state of an object only if the object is locked. When the user loads that saved object, it loads in that locked state.

To save child object information, you use the associated `saveObject` method within the `saveObjectImpl` method.

End users can use `load`, which calls `loadObjectImpl` to load a System object into their workspace.

Note: You must set `Access = protected` for this method.

Input Arguments

`obj`

System object handle

Examples

Define Property and State Values to Save

Define what is saved for the System object. Call the base class version of `saveObjectImpl` to save public properties. Then, save any child System objects and any protected and private properties. Finally, save the state, if the object is locked.

```
methods (Access = protected)
   function s = saveObjectImpl(obj)
      s = saveObjectImpl@matlab.System(obj);
      s.child = matlab.System.saveObject(obj.child);
      s.protected = obj.protected;
      s.pdependentprop = obj.pdependentprop;
      if isLocked(obj)
         s.state = obj.state;
      end
   end
end
```

See Also

`loadObjectImpl`

How To

- “Save System Object”
- “Load System Object”

setProperties

Class: matlab.System
Package: matlab

Set property values from name-value pair inputs

Syntax

```
setProperties(obj,numargs,name1,value1,name2,value2,...)
setProperties(obj,numargs,arg1,...,argm,name1,value1,name2,value2,...,'ValueOn
```

Description

`setProperties(obj,numargs,name1,value1,name2,value2,...)` provides the name-value pair inputs to the System object constructor. Use this syntax if every input must specify both name and value.

Note: To allow standard name-value pair handling at construction, define `setProperties` for your System object.

`setProperties(obj,numargs,arg1,...,argm,name1,value1,name2,value2,...,'ValueOn` provides the value-only inputs, followed by the name-value pair inputs to the System object during object construction. Use this syntax if you want to allow users to specify one or more inputs by their values only.

Input Arguments

`obj`

System object handle

`numargs`

Number of inputs passed in by the object constructor

name1,name2,...

Name of property

value1,value2,...

Value of the property

arg1,arg2,...

Value of property (for value-only input to the object constructor)

ValueOnlyPropName1,ValueOnlyPropName2,...

Name of the value-only property

Examples

Setup Value-Only Inputs

Set up an object so users can specify value-only inputs for VProp1, VProp2, and other property values via name-value pairs when constructing the object. In this example, VProp1 and VProp2 are the names of value-only properties.

```
methods
   function obj = MyFile(varargin)
      setProperties(obj,nargin,varargin{:},'VProp1','VProp2');
   end
end
```

How To

- “Set Property Values at Construction Time”

setupImpl

Class: matlab.System
Package: matlab

Initialize System object

Syntax

```
setupImpl(obj)
setupImpl(obj,input1,input2,...)
```

Description

`setupImpl(obj)` sets up a System object and implements one-time tasks that do not depend on any inputs to the `stepImpl` method for this object. To acquire resources for a System object, you must use `setupImpl` instead of a constructor. `setupImpl` executes the first time the `step` method is called on an object after that object has been created. It also executes the next time `step` is called after an object has been released. You typically use `setupImpl` to set private properties so they do not need to be calculated each time `stepImpl` method is called.

`setupImpl(obj,input1,input2,...)` sets up a System object using one or more of the `stepImpl` input specifications. The number and order of inputs must match the number and order of inputs defined in the `stepImpl` method. You pass the inputs into `setupImpl` to use the specifications, such as size and datatypes in the one-time calculations. You do not use the `setupImpl` method to set up input values.

`setupImpl` is called by the `setup` method, which is done automatically as the first subtask of the `step` method on an unlocked System object.

Note: You can omit this method from your class definition file if your System object does not require any setup tasks.

You must set `Access = protected` for this method.

Do not use `setupImpl` to initialize or reset states. For states, use the `resetImpl` method.

You cannot modify any tunable properties in this method if its System object will be used in the Simulink MATLAB System block.

Tips

To validate properties or inputs use the `validatePropertiesImpl`, `validateInputsImpl`, or `setProperties` methods. Do not include validation in `setupImpl`.

Input Arguments

`obj`

System object handle

`input1,input2,...`

Inputs to the `stepImpl` method

Examples

Setup a File for Writing

This example shows how to open a file for writing using the `setupImpl` method in your class definition file.

```
methods (Access = protected)
   function setupImpl(obj)
      obj.pFileID = fopen(obj.Filename,'wb');
      if obj.pFileID < 0
         error('Opening the file failed');
       end
    end
end
```

Check input size

This examples shows how to use `setupImpl` to check that the size of a `stepImpl` method input matches the size of a state property.

```
properties (Access = private)
     myState = [1 2];
  end

  methods (Access = protected)
     function setupImpl(obj,u)
        if any(size(obj.myState) ~= size(u))
           error('Size of "myState" does not match size of input "u"');
        end
     end

     function y = stepImpl(obj,u)
        y = obj.myState;
        obj.myState = u;
     end
  end
end
```

How To

- "Initialize Properties and Setup One-Time Calculations"
- "Set Property Values at Construction Time"

stepImpl

Class: matlab.System
Package: matlab

System output and state update equations

Syntax

```
[output1,output2,...] = stepImpl(obj,input1,input2,...)
```

Description

`[output1,output2,...] = stepImpl(obj,input1,input2,...)` defines the algorithm to execute when you call the `step` method on the specified object `obj`. The `step` method calculates the outputs and updates the object's state values using the inputs, properties, and state update equations.

`stepImpl` is called by the `step` method.

Note: You must set `Access = protected` for this method.

Tips

The number of input arguments and output arguments must match the values returned by the `getNumInputsImpl` and `getNumOutputsImpl` methods, respectively

Input Arguments

`obj`

System object handle

`input1,input2,...`

Inputs to the `step` method

Output Arguments

`output`

Output returned from the `step` method.

Examples

Specify System Object Algorithm

Use the `stepImpl` method to increment two numbers.

```
methods (Access = protected)
   function [y1,y2] = stepImpl(obj,x1,x2)
      y1 = x1 + 1;
      y2 = x2 + 1;
    end
end
```

How To

- "Define Basic System Objects"
- "Change Number of Step Inputs or Outputs"

supportsMultipleInstanceImpl

Class: matlab.System
Package: matlab

Support System object in Simulink For Each subsystem

Syntax

```
flag = supportsMultipleInstanceImpl(obj)
```

Description

`flag = supportsMultipleInstanceImpl(obj)` indicates whether you can use the System object in a Simulink For Each subsystem via the MATLAB System block. To enable For Each support, you must include the `supportsMultipleInstanceImpl` in your class definition file and have it return `true`. Do not enable For Each support if your System object allocates exclusive resources that may conflict with other System objects, such as allocating file handles, memory by address, or hardware resources.

During Simulink model compilation and propagation, the MATLAB System block calls the `supportMultipleInstance` method, which then calls the `supportsMultipleInstanceImpl` method to determine For Each support.

Note: You must set `Access = protected` for this method.

You cannot modify any properties in this method.

Input Arguments

`obj`

System object handle

Output Arguments

`flag`

Boolean value indicating whether the System object can be used in a For Each subsystem. The default value, if you do not include the `supportMultipleInstance` method, is `false`.

Examples

Enable For-Each Support for System Object

Specify in your class definition file that the System object can be used in a Simulink For Each subsystem.

```
methods (Access = protected)
   function flag = supportsMultipleInstanceImpl(obj)
       flag = true;
   end
end
```

See Also

`matlab.System`

How To

- "Enable For Each Subsystem Support"

validateInputsImpl

Class: matlab.System
Package: matlab

Validate inputs to step method

Syntax

```
validateInputsImpl(obj,input1,input2,...)
```

Description

`validateInputsImpl(obj,input1,input2,...)` validates inputs to the `step` method at the beginning of initialization. Validation includes checking data types, complexity, cross-input validation, and validity of inputs controlled by a property value.

`validateInputsImpl` is called by the `setup` method before `setupImpl`. `validateInputsImpl` executes only once.

Note: You must set `Access = protected` for this method.

You cannot modify any properties in this method. Use the `processTunedPropertiesImpl` method or `setupImpl` method to modify properties.

Input Arguments

`obj`

System object handle

`input1,input2,...`

Inputs to the `setup` method

Examples

Validate Input Type

Validate that the input is numeric.

```
methods (Access = protected)
   function validateInputsImpl(~,x)
      if ~isnumeric(x)
         error('Input must be numeric');
      end
   end
end
```

`validatePropertiesImpl` | `setupImpl`

How To

- "Validate Property and Input Values"

validatePropertiesImpl

Class: matlab.System
Package: matlab

Validate property values

Syntax

```
validatePropertiesImpl(obj)
```

Description

`validatePropertiesImpl(obj)` validates interdependent or interrelated property values at the beginning of object initialization, such as checking that the dependent or related inputs are the same size.

`validatePropertiesImpl` is the first method called by the `setup` method. `validatePropertiesImpl` also is called before the `processTunedPropertiesImpl` method.

Note: You must set `Access = protected` for this method.

You cannot modify any properties in this method. Use the `processTunedPropertiesImpl` method or `setupImpl` method to modify properties.

Input Arguments

`obj`

System object handle

Examples

Validate a Property

Validate that the useIncrement property is true and that the value of the increment property is greater than zero.

```
methods (Access = protected)
   function validatePropertiesImpl(obj)
      if obj.useIncrement && obj.increment < 0
         error('The increment value must be positive');
      end
    end
end
```

How To

- “Validate Property and Input Values”

matlab.system.display.Header class

Package: matlab.system.display

Header for System objects properties

Syntax

```
matlab.system.display.Header(N1,V1,...Nn,Vn)
matlab.system.display.Header(Obj,...)
```

Description

`matlab.system.display.Header(N1,V1,...Nn,Vn)` defines a header for the System object, with the header properties defined in Name-Value (`N`,`V`) pairs. You use `matlab.system.display.Header` within the `getHeaderImpl` method. The available header properties are

- `Title` — Header title string. The default value is an empty string.
- `Text` — Header description text string. The default value is an empty string.
- `ShowSourceLink` — Show link to source code for the object.

`matlab.system.display.Header(Obj,...)` creates a header for the specified System object (`Obj`) and sets the following property values:

- `Title` — Set to the `Obj` class name.
- `Text` — Set to help summary for `Obj`.
- `ShowSourceLink` — Set to `true` if `Obj` is MATLAB code. In this case, the **Source Code** link is displayed. If `Obj` is P-coded and the source code is not available, set this property to `false`.

You can use `mfilename('class')` from within this method to get the name of the System object. If you set any Name-Value pairs, those property values override the default settings.

Methods

getHeaderImpl	Header for System object display

Examples

Define System Block Header

Define a header in your class definition file.

```
methods (Static, Access = protected)
   function header = getHeaderImpl
      header = matlab.system.display.Header(mfilename('class'), ...
          'Title','AlternativeTitle',...
          'Text','An alternative class description');
   end
end
```

The resulting output appears as follows. In this case, **Source code** appears because the `ShowSourceLink` property was set to `true`.

getHeaderImpl

Class: matlab.system.display.Header
Package: matlab.system.display

Header for System object display

Syntax

```
header = getHeaderImpl
```

Description

`header = getHeaderImpl` returns the header to display for the System object. If you do not specify the `getHeaderImpl` method, no title or text appears for the header in the block dialog box.

`getHeaderImpl` is called by the MATLAB System block

Note: You must set `Access = protected` and `Static` for this method.

Output Arguments

`header`

Header text

Examples

Define Header for System Block Dialog Box

Define a header in your class definition file for the `EnhancedCounter` System object.

```
 methods (Static, Access = protected)
```

```
    function header = getHeaderImpl
       header = matlab.system.display.Header('EnhancedCounter',...
           'Title','Enhanced Counter');
    end
 end
```

`getPropertyGroupsImpl`

How To

- "Add Header to System Block Dialog"

matlab.system.display.Section class

Package: matlab.system.display

Property group section for System objects

Syntax

```
matlab.system.display.Section(N1,V1,...Nn,Vn)
matlab.system.display.Section(Obj,...)
```

Description

`matlab.system.display.Section(N1,V1,...Nn,Vn)` creates a property group section for displaying System object properties, which you define using property Name-Value pairs (N,V). You use `matlab.system.display.Section` to define property groups using the `getPropertyGroupsImpl` method. The available Section properties are

- `Title` — Section title string. The default value is an empty string.
- `TitleSource` — Source of section title string. Valid values are `'Property'` and `'Auto'`. The default value is `'Property'`, which uses the string from the `Title` property. If the `Obj` name is given, the default value is `Auto`, which uses the `Obj` name.
- `Description` — Section description string. The default value is an empty string.
- `PropertyList` — Section property list as a cell array of property names. The default value is an empty array. If the `Obj` name is given, the default value is all eligible display properties.

Note: Certain properties are not eligible for display either in a dialog box or in the System object summary on the command-line. Property types that cannot be displayed are: hidden, abstract, private or protected access, discrete state, and continuous state. Dependent properties do not display in a dialog box, but do display in the command-line summary.

`matlab.system.display.Section(Obj,...)` creates a property group section for the specified System object (`Obj`) and sets the following property values:

- `TitleSource` — Set to `'Auto'`, which uses the `Obj` name.
- `PropertyList` — Set to all publically-available properties in the `Obj`.

You can use `mfilename('class')` from within this method to get the name of the System object. If you set any Name-Value pairs, those property values override the default settings.

Methods

Examples

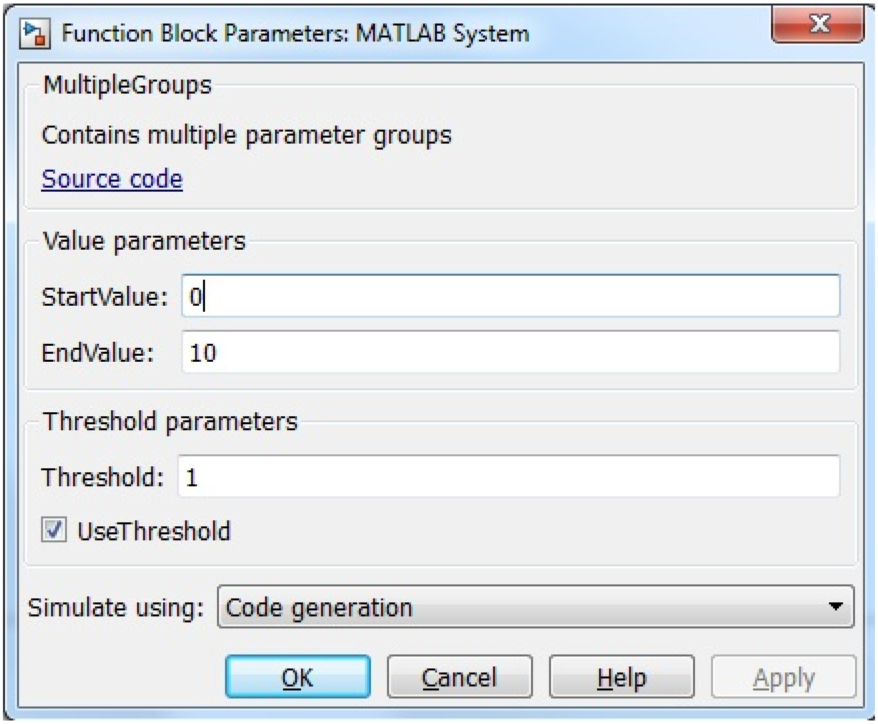
Define Property Groups

Define two property groups in your class definition file by specifying their titles and property lists.

```
methods (Static, Access = protected)
   function groups = getPropertyGroupsImpl
      valueGroup = matlab.system.display.Section(...
           'Title','Value parameters',...
           'PropertyList',{'StartValue','EndValue'});

      thresholdGroup = matlab.system.display.Section(...
           'Title','Threshold parameters',...
           'PropertyList',{'Threshold','UseThreshold'});
      groups = [valueGroup,thresholdGroup];
   end
end
```

When you specify the System object in the MATLAB System block, the resulting dialog box appears as follows.



Function Block Parameters: MATLAB System

How To

- “Object-Oriented Programming”
- “Class Attributes”
- “Property Attributes”
- “Add Property Groups to System Object and Block Dialog”

getPropertyGroupsImpl

Class: matlab.system.display.Section
Package: matlab.system.display

Property groups for System object display

Syntax

```
group = getPropertyGroupsImpl
```

Description

`group = getPropertyGroupsImpl` returns the groups of properties to display. You define property sections (`matlab.system.display.Section`) and section groups (`matlab.system.display.SectionGroup`) within this method. Sections arrange properties into groups. Section groups arrange sections and properties into groups. If a System object, included through the MATLAB System block, has a section, but that section is not in a section group, its properties appear above the block dialog tab panels.

If you do not include a `getPropertyGroupsImpl` method in your code, all public properties are included in the dialog box by default. If you include a `getPropertyGroupsImpl` method but do not list a property, that property does not appear in the dialog box.

`getPropertyGroupsImpl` is called by the MATLAB System block and when displaying the object at the command line.

Note: You must set `Access = protected` and `Static` for this method.

Output Arguments

`group`

Property group or groups

Examples

Define Block Dialog Tabs

Define two block dialog tabs, each containing specific properties. For this example, you use the `getPropertyGroupsImpl`, `matlab.system.display.SectionGroup`, and `matlab.system.display.Section` methods in your class definition file.

```
methods (Static, Access = protected)
   function groups = getPropertyGroupsImpl
      valueGroup = matlab.system.display.Section(...
           'Title','Value parameters',...
           'PropertyList',{'StartValue','EndValue'});

      thresholdGroup = matlab.system.display.Section(...
           'Title','Threshold parameters',...
           'PropertyList',{'Threshold','UseThreshold'});

      mainGroup = matlab.system.display.SectionGroup(...
           'Title','Main', ...
           'Sections',[valueGroup,thresholdGroup]);

      initGroup = matlab.system.display.SectionGroup(...
           'Title','Initial conditions', ...
           'PropertyList',{'IC1','IC2','IC3'});

      groups = [mainGroup,initGroup];
   end
end
```

The resulting dialog box appears as follows.

How To

- “Add Property Groups to System Object and Block Dialog”

matlab.system.display.SectionGroup class

Package: matlab.system.display

Section group for System objects

Syntax

```
matlab.system.display.SectionGroup(N1,V1,...Nn,Vn)
matlab.system.display.SectionGroup(Obj,...)
```

Description

`matlab.system.display.SectionGroup(N1,V1,...Nn,Vn)` creates a group for displaying System object properties and display sections created with `matlab.system.display.Section`. You define such sections or properties using property Name-Value pairs (`N`,`V`). A section group can contain both properties and sections. You use `matlab.system.display.SectionGroup` to define section groups using the `getPropertyGroupsImpl` method. Section groups display as separate tabs in the MATLAB System block. The available Section properties are

- `Title` — Group title string. The default value is an empty string.
- `TitleSource` — Source of group title string. Valid values are `'Property'` and `'Auto'`. The default value is `'Property'`, which uses the string from the `Title` property. If the `Obj` name is given, the default value is `Auto`, which uses the `Obj` name.
- `Description` — Group or tab description that appears above any properties or panels. The default value is an empty string.
- `PropertyList` — Group or tab property list as a cell array of property names. The default value is an empty array. If the `Obj` name is given, the default value is all eligible display properties.
- `Sections` — Group sections as an array of section objects. If the `Obj` name is given, the default value is the default section for the `Obj`.

`matlab.system.display.SectionGroup(Obj,...)` creates a section group for the specified System object (`Obj`) and sets the following property values:

- `TitleSource` — Set to `'Auto'`.
- `Sections` — Set to `matlab.system.display.Section` object for `Obj`.

You can use `mfilename('class')` from within this method to get the name of the System object. If you set any Name-Value pairs, those property values override the default settings.

Methods

Examples

Define Block Dialog Tabs

Define in your class definition file two tabs, each containing specific properties. For this example, you use the `matlab.system.display.SectionGroup`, `matlab.system.display.Section`, and `getPropertyGroupsImpl` methods.

```
methods (Static, Access = protected)
   function groups = getPropertyGroupsImpl
      valueGroup = matlab.system.display.Section(...
           'Title','Value parameters',...
           'PropertyList',{'StartValue','EndValue'});

      thresholdGroup = matlab.system.display.Section(...
           'Title','Threshold parameters',...
           'PropertyList',{'Threshold','UseThreshold'});

      mainGroup = matlab.system.display.SectionGroup(...
           'Title','Main', ...
           'Sections',[valueGroup,thresholdGroup]);

      initGroup = matlab.system.display.SectionGroup(...
           'Title','Initial conditions', ...
           'PropertyList',{'IC1','IC2','IC3'});

      groups = [mainGroup,initGroup];
   end
end
```

The resulting dialog appears as follows when you add the object to Simulink with the MATLAB System block.

matlab.system.mixin.CustomIcon class

Package: matlab.system.mixin

Custom icon mixin class

Description

`matlab.system.mixin.CustomIcon` is a class that defines the `getIcon` method. This method customizes the name of the icon used for the System object implemented through a MATLAB System block.

To use this method, you must subclass from this class in addition to the `matlab.System` base class. Type the following syntax as the first line of your class definition file, where `ObjectName` is the name of your object:

```
classdef ObjectName < matlab.system &...
    matlab.system.mixin.CustomIcon
```

Methods

getIconImpl	Name to display as block icon

See Also

`matlab.System`

Tutorials

How To

- "Object-Oriented Programming"
- "Class Attributes"
- "Property Attributes"

getIconImpl

Class: matlab.system.mixin.CustomIcon
Package: matlab.system.mixin

Name to display as block icon

Syntax

```
icon = getIconImpl(obj)
```

Description

`icon = getIconImpl(obj)` returns the string or cell array of strings to display on the block icon of the System object implemented through the MATLAB System block. If you do not specify the `getIconImpl` method, the block displays the class name of the System object as the block icon. For example, if you specify `pkg.MyObject` in the MATLAB System block, the default icon is labeled `My Object`

`getIconImpl` is called by the `getIcon` method, which is used by the MATLAB System block during Simulink model compilation.

Note: You must set `Access = protected` for this method.

Input Arguments

`obj`

System object handle

Output Arguments

`icon`

String or cell array of strings to display as the block icon. Each cell is displayed as a separate line.

Examples

Add System Block Icon Name

Specify in your class definition file the name of the block icon as `'Enhanced Counter'` using two lines.

```
methods (Access = protected)
   function icon = getIconImpl(~)
      icon = {'Enhanced','Counter'};
   end
end
```

matlab.system.mixin.FiniteSource class

Package: matlab.system.mixin

Finite source mixin class

Description

`matlab.system.mixin.FiniteSource` is a class that defines the `isDone` method, which reports the state of a finite data source, such as an audio file.

To use this method, you must subclass from this class in addition to the `matlab.System` base class. Type the following syntax as the first line of your class definition file, where `ObjectName` is the name of your object:

```
classdef ObjectName < matlab.System &...
    matlab.system.mixin.FiniteSource
```

Methods

isDoneImpl	End-of-data flag

`matlab.System`

Tutorials

- "Define Finite Source Objects"

How To

- "Object-Oriented Programming"
- "Class Attributes"
- "Property Attributes"

isDoneImpl

Class: matlab.system.mixin.FiniteSource
Package: matlab.system.mixin

End-of-data flag

Syntax

```
status = isDoneImpl(obj)
```

Description

`status = isDoneImpl(obj)` indicates if an end-of-data condition has occurred. The `isDone` method should return `false` when data from a finite source has been exhausted, typically by having read and output all data from the source. You should also define the result of future reads from an exhausted source in the `isDoneImpl` method.

`isDoneImpl` is called by the `isDone` method.

Note: You must set `Access = protected` for this method.

Input Arguments

`obj`

System object handle

Output Arguments

`status`

Logical value, `true` or `false`, that indicates if an end-of-data condition has occurred or not, respectively.

Examples

Check for End-of-Data

Set up the `isDoneImpl` method in your class definition file so the `isDone` method checks whether the object has completed eight iterations.

```
methods (Access = protected)
   function bdone = isDoneImpl(obj)
      bdone = obj.NumIters==8;
   end
end
```

`matlab.system.mixin.FiniteSource`

How To

- “Define Finite Source Objects”

matlab.system.mixin.Nondirect class

Package: matlab.system.mixin

Nondirect feedthrough mixin class

Description

`matlab.system.mixin.Nondirect` is a class that uses the `output` and `update` methods to process nondirect feedthrough data through a System object.

For System objects that use direct feedthrough, the object's input is needed to generate the output at that time. For these direct feedthrough objects, the `step` method calculates the output and updates the state values. For nondirect feedthrough, however, the object's output depends only on the internal states at that time. The inputs are used to update the object states. For these objects, calculating the output with `outputImpl` is separated from updating the state values with `updateImpl`. If you use the `matlab.system.mixin.Nondirect` mixin and include the `stepImpl` method in your class definition file, an error occurs. In this case, you must include the `updateImpl` and `outputImpl` methods instead.

The following cases describe when System objects in Simulink use direct or nondirect feedthrough.

- System object supports code generation and does not inherit from the `Propagates` mixin — Simulink automatically infers the direct feedthrough settings from the System object code.
- System object supports code generation and inherits from the `Propagates` mixin — Simulink does not automatically infer the direct feedthrough settings. Instead, it uses the value returned by the `isInputDirectFeedthroughImpl` method.
- System object does not support code generation — Default `isInputDirectFeedthrough` method returns false, indicating that direct feedthrough is not enabled. To override the default behavior, implement the `isInputDirectFeedthroughImpl` method in your class definition file.

Use the `Nondirect` mixin to allow a System object to be used in a Simulink feedback loop. A delay object is an example of a nondirect feedthrough object.

To use this mixin, you must subclass from this class in addition to subclassing from the `matlab.System` base class. Type the following syntax as the first line of your class definition file, where `ObjectName` is the name of your object:

```
classdef ObjectName < matlab.system &...
    matlab.system.mixin.Nondirect
```

Methods

isInputDirectFeedthroughImpl	Direct feedthrough status of input
outputImpl	Output calculation from input or internal state of System object
updateImpl	Update object states based on inputs

See Also

`matlab.system`

Tutorials

- “Use Update and Output for Nondirect Feedthrough”

How To

- “Object-Oriented Programming”
- “Class Attributes”
- “Property Attributes”

isInputDirectFeedthroughImpl

Class: matlab.system.mixin.Nondirect
Package: matlab.system.mixin

Direct feedthrough status of input

Syntax

```
[flag1,...,flagN] = isInputDirectFeedthroughImpl(obj,u1,u2,...,uN)
```

Description

`[flag1,...,flagN] = isInputDirectFeedthroughImpl(obj,u1,u2,...,uN)` indicates whether each input is a direct feedthrough input. If direct feedthrough is `true`, the output depends on the input at each time instant.

Note: You must set `Access = protected` for this method.

You cannot modify any properties or implement or access tunable properties in this method.

If you do not include the `isInputDirectFeedthroughImpl` method in your System object class definition file, all inputs are assumed to be direct feedthrough.

The following cases describe when System objects in Simulink code generation use direct or nondirect feedthrough.

- System object supports code generation and does not inherit from the `Propagates` mixin — Simulink automatically infers the direct feedthrough settings from the System object code.
- System object supports code generation and inherits from the `Propagates` mixin — Simulink does not automatically infer the direct feedthrough settings. Instead, it uses the value returned by the `isInputDirectFeedthroughImpl` method.
- System object does not support code generation — Default `isInputDirectFeedthrough` method returns false, indicating that direct

feedthrough is not enabled. To override the default behavior, implement the `isInputDirectFeedthroughImpl` method in your class definition file.

`isInputDirectFeedthroughImpl` is called by the `isInputDirectFeedthrough` method.

Input Arguments

`obj`

System object handle

`u1,u2,...,uN`

Specifications of the inputs to the algorithm or `step` method.

Output Arguments

`flag1,...,flagN`

Logical value or either `true` or `false`. This value indicates whether the corresponding input is direct feedthrough or not, respectively. The number of outputs must match the number of outputs returned by the `getNumOutputs` method.

Examples

Specify Input as Nondirect Feedthrough

Use `isInputDirectFeedthroughImpl` in your class definition file to mark the inputs as nondirect feedthrough.

```
methods (Access = protected)
   function flag = isInputDirectFeedthroughImpl(~,~)
      flag = false;
   end
end
```

See Also

`matlab.system.mixin.Nondirect`

How To

- “Use Update and Output for Nondirect Feedthrough”

outputImpl

Class: matlab.system.mixin.Nondirect
Package: matlab.system.mixin

Output calculation from input or internal state of System object

Syntax

```
[y1,y2,...,yN] = outputImpl(obj,u1,u2,...,uN)
```

Description

`[y1,y2,...,yN] = outputImpl(obj,u1,u2,...,uN)` implements the output equations for the System object. The output values are calculated from the states and property values. Any inputs that you set to nondirect feedthrough are ignored during output calculation.

`outputImpl` is called by the `output` method. It is also called before the `updateImpl` method in the `step` method. For sink objects, calling `updateImpl` before `outputImpl` locks the object. For all other types of objects, calling `updateImpl` before `outputImpl` causes an error.

Note: You must set `Access = protected` for this method.

You cannot modify any tunable properties in this method if its System object will be used in the Simulink MATLAB System block.

Input Arguments

`obj`

System object handle

`u1,u2,...uN`

Inputs from the algorithm or `step` method. The number of inputs must match the number of inputs returned by the `getNumInputs` method. Nondirect feedthrough inputs are ignored during normal execution of the System object. However, for code generation, you must provide these inputs even if they are empty.

Output Arguments

`y1,y2,...yN`

Outputs calculated from the specified algorithm. The number of outputs must match the number of outputs returned by the `getNumOutputs` method.

Examples

Set Up Output that Does Not Depend on Input

Specify in your class definition file that the output does not directly depend on the current input with the `outputImpl` method. `PreviousInput` is a property of the `obj`.

```
methods (Access = protected)
   function [y] = outputImpl(obj, ~)
      y = obj.PreviousInput(end);
   end
end
```

See Also

`matlab.system.mixin.Nondirect`

How To

- "Use Update and Output for Nondirect Feedthrough"

updateImpl

Class: matlab.system.mixin.Nondirect
Package: matlab.system.mixin

Update object states based on inputs

Syntax

```
updateImpl(obj,u1,u2,...,uN)
```

Description

`updateImpl(obj,u1,u2,...,uN)` implements the state update equations for the system. You use this method when your algorithm outputs depend only on the object's internal state and internal properties. Do not use this method to update the outputs from the inputs.

`updateImpl` is called by the `update` method and after the `outputImpl` method in the `step` method. For sink objects, calling `updateImpl` before `outputImpl` locks the object. For all other types of objects, calling `updateImpl` before `outputImpl` causes an error.

Note: You must set `Access = protected` for this method.

You cannot modify any tunable properties in this method if its System object will be used in the Simulink MATLAB System block.

Input Arguments

`obj`

System object handle

`u1,u2,...uN`

Inputs to the algorithm or `step` method. The number of inputs must match the number of inputs returned by the `getNumInputs` method.

Examples

Set Up Output that Does Not Depend on Current Input

Update the object with previous inputs. Use `updateImpl` in your class definition file. This example saves the `u` input and shifts the previous inputs.

```
methods (Access = protected)
   function updateImpl(obj,u)
      obj.PreviousInput = [u obj.PreviousInput(1:end-1)];
   end
end
```

`matlab.system.mixin.Nondirect`

How To

- “Use Update and Output for Nondirect Feedthrough”

matlab.system.mixin.Propagates class

Package: matlab.system.mixin

Signal characteristics propagation mixin class

Description

`matlab.system.mixin.Propagates` defines the output size, data type, and complexity of a System object. It is called by the MATLAB System block during Simulink model compilation. Implement the methods of this class when Simulink cannot infer the output specifications directly from the inputs. If you do not include this mixin in your class definition file and Simulink cannot infer the output specifications, an error occurs. Use this mixin class and its methods when you include your System object in Simulink via the MATLAB System block.

To use this mixin, subclass from this `matlab.system.mixin.Propagates` in addition to subclassing from the `matlab.System` base class. Type the following syntax as the first line of your class definition file. `ObjectName` is the name of your System object.

```
classdef ObjectName < matlab.System &...
    matlab.system.mixin.Propagates
```

Methods

getDiscreteStateSpecificationImpl	Discrete state size, data type, and complexity
getOutputDataTypeImpl	Data types of output ports
getOutputSizeImpl	Sizes of output ports
isOutputComplexImpl	Complexity of output ports
isOutputFixedSizeImpl	Fixed- or variable-size output ports

propagatedInputComplexity	Complexity of input during Simulink propagation
propagatedInputDataType	Data type of input during Simulink propagation
propagatedInputFixedSize	Fixed-size status of input during Simulink propagation
propagatedInputSize	Size of input during Simulink propagation

Note: If your System object has exactly one input and one output and no discrete property states, you do not have to implement any of these methods. The `matlab.system.mixin.Propagates` provides default values in this case.

getDiscreteStateSpecificationImpl

Class: matlab.system.mixin.Propagates
Package: matlab.system.mixin

Discrete state size, data type, and complexity

Syntax

```
[sz,dt,cp] = getDiscreteStateSpecificationImpl(obj,name)
```

Description

`[sz,dt,cp] = getDiscreteStateSpecificationImpl(obj,name)` returns the size, data type, and complexity of the property, `name`. This property must be a discrete state property. You must define this method if your System object has discrete state properties and is used in the MATLAB System block. If you define this method for a property that is not discrete state, an error occurs during model compilation.

You always set the `getDiscreteStateSpecificationImpl` method access to `protected` because it is an internal method that users do not directly call or run.

`getDiscreteStateSpecificationImpl` is called by the MATLAB System block during Simulink model compilation.

Note: You must set `Access = protected` for this method.

You cannot modify any properties in this method.

Input Arguments

obj

System object handle

name

Name of discrete state property of the System object

Output Arguments

sz

Vector containing the length of each dimension of the property.

Default: `[1 1]`

dt

Data type of the property. For built-in data types, dt is a string. For fixed-point data types, dt is a numerictype object.

Default: `double`

cp

Complexity of the property as a scalar, logical value, where `true` = complex and `false` = real.

Default: `false`

Examples

Specify Discrete State Property Size, Data Type, and Complexity

Specify in your class definition file the size, data type, and complexity of a discrete state property.

```
methods (Access = protected)
   function [sz,dt,cp] = getDiscreteStateSpecificationImpl(~,name)
      sz = [1 1];
      dt = 'double';
      cp = false;
   end
```

```
end
```

`matlab.system.mixin.Propagates`

How To

- “Specify Discrete State Output Specification”

getOutputDataTypeImpl

Class: matlab.system.mixin.Propagates
Package: matlab.system.mixin

Data types of output ports

Syntax

```
[dt_1,dt_2,...,dt_n] = getOutputDataTypeImpl(obj)
```

Description

`[dt_1,dt_2,...,dt_n] = getOutputDataTypeImpl(obj)` returns the data types of each output port. The number of outputs must match the value returned from the `getNumOutputs` method or the number of output arguments listed in the `step` method.

For System objects with one input and one output and where you want the input and output data types to be the same, you do not need to implement this method. In this case `getOutputDataTypeImpl` assumes the input and output data types are the same and returns the data type of the input.

If your System object has more than one input or output or you need the output and input data types to be different, you must implement the `getOutputDataTypeImpl` method to define the output data type. You also must implement the `propagatedInputDataType` method.

During Simulink model compilation and propagation, the MATLAB System block calls the `getOutputDataType` method, which then calls the `getOutputDataTypeImpl` method to determine the output data type.

Note: You must set `Access = protected` for this method.

You cannot modify any properties in this method.

Input Arguments

obj

System object handle

Output Arguments

dt_1,dt_2,...

Data type of the property. For built-in data types, dt is a string. For fixed-point data types, dt is a numerictype object.

Examples

Specify Output Data Type

Specify in your class definition file the data type of a System object with one output.

```
methods (Access = protected)
   function dt_1 = getOutputDataTypeImpl(~)
      dt_1 = 'double';
   end
end
```

getOutputSizeImpl

Class: matlab.system.mixin.Propagates
Package: matlab.system.mixin

Sizes of output ports

Syntax

```
[sz_1,sz_2,...,sz_n] = getOutputSizeImpl(obj)
```

Description

`[sz_1,sz_2,...,sz_n] = getOutputSizeImpl(obj)` returns the sizes of each output port. The number of outputs must match the value returned from the `getNumOutputs` method or the number of output arguments listed in the `step` method.

For System objects with one input and one output and where you want the input and output sizes to be the same, you do not need to implement this method. In this case `getOutputSizeImpl` assumes the input and output sizes are the same and returns the size of the input. For variable-size inputs, the output size is the maximum input size.

If your System object has more than one input or output or you need the output and input sizes to be different, you must implement the `getOutputSizeImpl` method to define the output size. You also must use the `propagatedInputSize` method if the output size differs from the input size.

During Simulink model compilation and propagation, the MATLAB System block calls the `getOutputSize` method, which then calls the `getOutputSizeImpl` method to determine the output size.

Note: You must set `Access = protected` for this method.

You cannot modify any properties in this method.

Input Arguments

obj

System object handle

Output Arguments

sz_1,sz_2,...

Vector containing the size of each output port.

Examples

Specify Output Size

Specify in your class definition file the size of a System object output.

```
methods (Access = protected)
   function sz_1 = getOutputSizeImpl(obj)
      sz_1 = [1 1];
   end
end
```

isOutputComplexImpl

Class: matlab.system.mixin.Propagates
Package: matlab.system.mixin

Complexity of output ports

Syntax

```
[cp_1,cp_2,...,cp_n] = isOutputComplexImpl(obj)
```

Description

`[cp_1,cp_2,...,cp_n] = isOutputComplexImpl(obj)` returns whether each output port has complex data. The number of outputs must match the value returned from the `getNumOutputs` method or the number of output arguments listed in the `step` method.

For System objects with one input and one output and where you want the input and output complexities to be the same, you do not need to implement this method. In this case `isOutputComplexImpl` assumes the input and output complexities are the same and returns the complexity of the input.

If your System object has more than one input or output or you need the output and input complexities to be different, you must implement the `isOutputComplexImpl` method to define the output complexity. You also must use the `propagatedInputComplexity` method if the output complexity differs from the input complexity.

During Simulink model compilation and propagation, the MATLAB System block calls the `isOutputComplex` method, which then calls the `isOutputComplexImpl` method to determine the output complexity.

Note: You must set `Access = protected` for this method.

You cannot modify any properties in this method.

Input Arguments

obj

System object handle

Output Arguments

cp_1,cp_2,...

Logical, scalar value indicating whether the specific output port is complex (`true`) or real (`false`).

Examples

Specify Output as Real-Valued

Specify in your class definition file that the output from a System object is a real value.

```
methods (Access = protected)
   function c1 = isOutputComplexImpl(obj)
       c1 = false;
   end
end
```

isOutputFixedSizeImpl

Class: matlab.system.mixin.Propagates
Package: matlab.system.mixin

Fixed- or variable-size output ports

Syntax

```
[flag_1,flag_2,...flag_n] = isOutputFixedSizeImpl(obj)
```

Description

`[flag_1,flag_2,...flag_n] = isOutputFixedSizeImpl(obj)` indicates whether each output port is fixed size. The number of outputs must match the value returned from the `getNumOutputs` method or the number of output arguments listed in the `step` method.

For System objects with one input and one output and where you want the input and output fixed sizes to be the same, you do not need to implement this method. In this case `isOutputFixedSizeImpl` assumes the input and output fixed sizes are the same and returns the fixed size of the input.

If your System object has more than one input or output or you need the output and input fixed sizes to be different, you must implement the `isOutputFixedSizeImpl` method to define the output fixed size. You also must use the `propagatedInputFixedSize` method if the output fixed size status differs from the input fixed size status.

During Simulink model compilation and propagation, the MATLAB System block calls the `isOutputFixedSize` method, which then calls the `isOutputFixedSizeImpl` method to determine the output fixed size.

Note: You must set `Access = protected` for this method.

You cannot modify any properties in this method.

Input Arguments

obj

System object handle

Output Arguments

flag_1,flag2,...

Logical, scalar value indicating whether the specific output port is fixed size (`true`) or variable size (`false`).

Examples

Specify Output as Fixed-Point

Specify in your class definition file that the output from a System object is a fixed-point value.

```
methods (Access = protected)
   function c1 = isOutputFixedSizeImpl(obj)
      c1 = true;
   end
end
```

propagatedInputComplexity

Class: matlab.system.mixin.Propagates
Package: matlab.system.mixin

Complexity of input during Simulink propagation

Syntax

```
flag = propagatedInputComplexity(obj,index)
```

Description

`flag = propagatedInputComplexity(obj,index)` returns `true` or `false` to indicate whether the input argument for the indicated System object is complex. `index` specifies the `step` method input for which to return the complexity flag.

You can use `propagatedInputComplexity` only from within the `isOutputComplexImpl` method in your class definition file. Use `isOutputComplexImpl` when:

- Your System object has more than one input or output.
- The input complexity determines the output complexity.
- The output complexity must differ from the input complexity.

Input Arguments

`obj`

System object

`index`

Index of the specified `step` method input. Do not count the `obj` in the `index`. The first step input is always `obj`.

Output Arguments

flag

Complexity of the specified input, returned as true or false

Examples

Match Input and Output Complexity

Get the complexity of the second input to the step method and set the output to match it. Assume that the first input of the step method has no impact on the output complexity.

```
methods (Access = protected)
   function outcomplx = isOutputComplexImpl(obj)
      outcomplx = propagatedInputComplexity(obj,2);
   end
end
```

propagatedInputDataType

Class: matlab.system.mixin.Propagates
Package: matlab.system.mixin

Data type of input during Simulink propagation

Syntax

```
dt = propagatedInputDataType(obj,index)
```

Description

`dt = propagatedInputDataType(obj,index)` returns the data type of an input argument for a System object. `index` specifies the `step` method input for which to return the data type. You can only call this method from within the method in your class definition file.

You can use `propagatedInputDataType` only from within `getOutputDataTypeImpl`. Use `getOutputDataTypeImpl` when:

- Your System object has more than one input or output.
- The input data type status determines the output data type.
- The output data type must differ from the input data type.

Input Arguments

`obj`

System object

`index`

Index of the specified `step` method input. Do not count the `obj` in the `index`. The first step input is always `obj`.

Output Arguments

`dt`

Data type of the specified `step` method input, returned as a string for floating-point input or as a numerictype for fixed-point input.

Examples

Match Input and Output Data Type

Get the data type of the second input to the `step` method. If the second input data type is `double`, then the output data type is `int32`. For all other cases, the output data type matches the second input data type. Assume that the first input to the `step` method has no impact on the output.

```
methods (Access = protected)
   function dt = getOutputDataTypeImpl(obj)
       if strcmpi(propagatedInputDataType(obj,2),'double')
           dt = 'int32';
       else
           dt = propagatedInputDataType(obj,2);
       end
   end
end
```

propagatedInputFixedSize

Class: matlab.system.mixin.Propagates
Package: matlab.system.mixin

Fixed-size status of input during Simulink propagation

Syntax

```
flag = propagatedInputFixedSize(obj,index)
```

Description

`flag = propagatedInputFixedSize(obj,index)` returns `true` or `false` to indicate whether an input argument of a System object is fixed size. `index` specifies the `step` method input for which to return the fixed-size flag.

You can use `propagatedInputFixedSize` only from within `isOutputFixedSizeImpl`. Use `isOutputFixedSizeImpl` when:

- Your System object has more than one input or output.
- The input fixed-size status determines the output fixed-size status.
- The output fixed-size status must differ from the input fixed-size status.

Input Arguments

`obj`

System object

`index`

Index of the specified `step` method input. Do not count the `obj` in the `index`. The first step input is always `obj`.

Output Arguments

`flag`

Fixed-size status of the specified `step` method input, returned as `true` or `false`.

Examples

Match Fixed-Size Status of Input and Output

Get the fixed-size status of the third input to the `step` method and set the output to match it. Assume that the first and second inputs to the `step` method have no impact on the output.

```
methods (Access = protected)
   function outtype = isOutputFixedSizeImpl(obj)
      outtype = propagatedInputFixedSize(obj,3)
   end
end
```

propagatedInputSize

Class: matlab.system.mixin.Propagates
Package: matlab.system.mixin

Size of input during Simulink propagation

Syntax

```
sz = propagatedInputSize(obj,index)
```

Description

`sz = propagatedInputSize(obj,index)` returns, as a vector, the input size of the specified System object. `index` specifies the input to the `step` method for which to return the size information. (Do not count the `obj` in the `index`. The first input is always `obj`.)

You can use `propagatedInputSize` only from within the `getOutputSizeImpl` method in your class definition file. Use `getOutputSizeImpl` when:

- Your System object has more than one input or output.
- The input size determines the output size.
- The output size must differ from the input size.

Input Arguments

`obj`

System object

`index`

Index of the specified `step` method input

Output Arguments

sz

Size of the specified input, returned as a vector

Examples

Match Size of Input and Output

Get the size of the second input to the step method. If the first dimension of the second input to the step method has a size greater than 1, then set the output size to a 1 x 2 vector. For all other cases, the output is a 2 x 1 matrix. Assume that the first input to the step method has no impact on the output size.

```
methods (Access = protected)
   function outsz = getOutputSizeImpl(obj)
       sz = propagatedInputSize(obj,2);
       if sz(1) == 1
           outsz = [1,2];
       else
           outsz = [2,1];
       end
   end
end
```

matlab.system.mixin.Propagates | getOutputSizeImpl

How To

- “Set Output Size”

matlab.system.StringSet class

Package: matlab.system

Set of valid string values

Description

`matlab.system.StringSet` defines a list of valid string values for a property. This class validates the string in the property and enables tab completion for the property value. A *StringSet* allows only predefined or customized strings as values for the property.

A `StringSet` uses two linked properties, which you must define in the same class. One is a public property that contains the current string value. This public property is displayed to the user. The other property is a hidden property that contains the list of all possible string values. This hidden property should also have the transient attribute so its value is not saved to disk when you save the System object.

The following considerations apply when using StringSets:

- The string property that holds the current string can have any name.
- The property that holds the `StringSet` must use the same name as the string property with the suffix “Set” appended to it. The string set property is an instance of the `matlab.system.StringSet` class.
- Valid strings, defined in the `StringSet`, must be declared using a cell array. The cell array cannot be empty nor can it have any empty strings. Valid strings must be unique and are case-insensitive.
- The string property must be set to a valid `StringSet` value.

Examples

Set String Property Values

Set the string property, `Flavor`, and the `StringSet` property, `FlavorSet` in your class definition file.

```
properties
  Flavor = 'Chocolate';
end

properties (Hidden,Transient)
  FlavorSet = ...
    matlab.system.StringSet({'Vanilla','Chocolate'});
end
```

spbscopes.SpectrumAnalyzerConfiguration class

Package: spbscopes

Configure Spectrum Analyzer for programmatic access

Description

The `spbscopes.SpectrumAnalyzerConfiguration` object contains the scope configuration information for the Spectrum Analyzer block.

Construction

Call the `get_param` function, specifying a Spectrum Analyzer block.

`htsc = get_param(gcbh,'ScopeConfiguration')` constructs a new Spectrum Analyzer Configuration object.

Properties

`CenterFrequency`

Frequency over which frequency span is centered

Specify as a real scalar the center frequency, in hertz, of the frequency span over which the Spectrum Analyzer computes and plots the spectrum. This property applies when you set the `FrequencySpan` property to `'Span and center frequency'`. The overall frequency span, defined by the `Span` and `CenterFrequency` properties, must fall within the Nyquist frequency interval. When the `PlotAsTwoSidedSpectrum` property is set to `true`, the interval is $\left[-\frac{SampleRate}{2},\frac{SampleRate}{2}\right]+FrequencyOffset$ hertz. When the `PlotAsTwoSidedSpectrum` property is set to `false`, the interval is $\left[0,\frac{SampleRate}{2}\right]+FrequencyOffset$ hertz.

This property is “Tunable”.

Default: `0`

`FFTLength`

FFT length

Specify as a positive, scalar integer the length of the FFT that the Spectrum Analyzer uses to compute spectral estimates. This property applies only when you set the `FrequencyResolutionMethod` property to `'WindowLength'` and the `FFTLengthSource` property to `'Property'`. The `FFTLength` must be greater than or equal to the `WindowLength`. You cannot control the FFT length when the `FrequencyResolutionMethod` property is `'RBW'`. In that case, the FFT length is set as the window length required to achieve the specified resolution bandwidth value or 1024, whichever is larger.

This property is “Tunable”.

Default: `128`

`FFTLengthSource`

Source of the FFT length value

Specify the source of the FFT length value as one of `'Auto'` or `'Property'`.

- When you set this property to `'Auto'`, the Spectrum Analyzer sets the FFT length to the window length specified in the `WindowLength` property or to 1024, whichever is larger.
- When you set this property to `'Property'`, specify the number of FFT points using the `FFTLength` property. The `FFTLength` must be greater than the `WindowLength`.

This property applies only when you set the `FrequencyResolutionMethod` property to `'WindowLength'` and the `FFTLengthSource` property to `'Property'`.

This property is “Tunable”.

Default: `'Auto'`

`FrequencyOffset`

Frequency offset

Specify as a real, scalar value a frequency offset, in hertz. The *frequency*-axis values are offset by the value specified in this property. The overall span must fall within the *Nyquist* frequency interval. When the `PlotAsTwoSidedSpectrum` property is `true`, the Nyquist interval is $\left[-\frac{SampleRate}{2},\frac{SampleRate}{2}\right]+FrequencyOffset$ hertz. When you set the `PlotAsTwoSidedSpectrum` property to `false`, the Nyquist interval is $\left[0,\frac{SampleRate}{2}\right]+FrequencyOffset$ hertz. You can control the overall span in different ways based on how you set the `FrequencySpan` property.

Default: `0`

`FrequencyResolutionMethod`

Frequency resolution method

Specify how to control the frequency resolution of the spectrum analyzer as either `'RBW'` or `'WindowLength'`. When you set this property to `'RBW'`, the `RBWSource` and `RBW` properties control the frequency resolution (in Hz) of the analyzer. When you set this property to `'WindowLength'`, the `WindowLength` property controls the frequency resolution.

In this case, the frequency resolution of the analyzer is defined as $\frac{NENBW * Fs}{N_{window}}$ where *NENBW* is the normalized effective noise bandwidth of the window currently specified in the `Window` property. You can control the number of FFT points only when the `FrequencyResolutionMethod` property is `'WindowLength'`. When the `FrequencyResolutionMethod` property is `'RBW'`, the FFT length is the window length that results from achieving the specified RBW value or 1024, whichever is larger.

This property is “Tunable”.

Default: `'RBW'`

`FrequencyScale`

Frequency scale

Specify the frequency scale as either `'Linear'` or `'Log'`. This property applies only when you set the `SpectrumType` property to `'Power'` or `'Power density'`. When you set the `FrequencyScale` property to `'Log'`, the Spectrum Analyzer displays the frequencies on the *x*-axis on a logarithmic scale. To use the `'Log'` setting, you must also set the `PlotAsTwoSidedSpectrum` property to `false`. When the `PlotAsTwoSidedSpectrum` property is `true`, you must set this property to `'Linear'`.

This property is “Tunable”.

Default: `'Linear'`

FrequencySpan

Frequency span mode

Specify the frequency span mode as one of `'Full'`, `'Span and center frequency'`, or `'Start and stop frequencies'`.

- When you set this property to `'Full'`, the Spectrum Analyzer computes and plots the spectrum over the entire *Nyquist* frequency interval. When the `PlotAsTwoSidedSpectrum` property is `true`, the Nyquist interval is $\left[-\frac{SampleRate}{2},\frac{SampleRate}{2}\right]+FrequencyOffset$ hertz. If you set the `PlotAsTwoSidedSpectrum` property to `false`, the Nyquist interval is $\left[0,\frac{SampleRate}{2}\right]+FrequencyOffset$ hertz.
- When you set this property to `'Span and center frequency'`, the Spectrum Analyzer computes and plots the spectrum over the interval specified by the `Span` and `CenterFrequency` properties.
- When you set this property to `'Start and stop frequencies'`, the Spectrum Analyzer computes and plots the spectrum over the interval specified by the `StartFrequency` and `StopFrequency` properties.

This property is “Tunable”.

Default: `'Full'`

Name

Caption to display on Spectrum Analyzer window

Specify as a string the caption to display on the scope window. This property is “Tunable”.

Default: `'Spectrum Analyzer'`

`OpenAtSimulationStart`

Open scope when starting simulation

Set this property to `true` to open the scope when the simulation starts. Set this property to `false` to prevent the scope from opening at the start of simulation.

Default: `true`

`OverlapPercent`

Overlap percentage

Specify as a real, scalar value, the percentage overlap between the previous and current buffered data segments. The overlap creates a window segment that is used to compute a spectral estimate. The value must be greater than or equal to zero and less than 100. This property is “Tunable”.

Default: `0`

`PlotAsTwoSidedSpectrum`

Two sided spectrum flag

Set this property to `true` to compute and plot two-sided spectral estimates. Set this property to `false` to compute and plot one-sided spectral estimates. If you set this property to `false`, then the input signal must be real valued. When the input signal is complex valued, you must set this property to `true`.

When this property is `false`, Spectrum Analyzer uses *power folding*. The *y*-axis values are twice the amplitude that they would be if this property were set to `true`, except at 0 and the Nyquist frequency. A one-sided PSD contains the total power of the signal in the frequency interval from DC to half of the Nyquist rate. For more information, see the `pwelch` function reference page.

Default: `true`

`PlotMaxHoldTrace`

Max-hold trace flag

Set this property to `true` to compute and plot the maximum-hold spectrum of each input channel. The maximum-hold spectrum at each frequency bin is computed by keeping the maximum value of all the power spectrum estimates. When you toggle this property, the Spectrum Analyzer resets its maximum-hold computations. This property applies only when you set the `SpectrumType` property to `'Power'` or `'Power density'`.

This property is “Tunable”.

See also: `PlotMinHoldTrace` and `PlotNormalTrace`.

Default: `false`

`PlotMinHoldTrace`

Min-hold trace flag

Set this property to `true` to compute and plot the minimum-hold spectrum of each input channel. The minimum-hold spectrum at each frequency bin is computed by keeping the minimum value of all the power spectrum estimates. When you toggle this property, the Spectrum Analyzer resets its minimum-hold computations. This property applies only when you set the `SpectrumType` property to `'Power'` or `'Power density'`.

This property is “Tunable”.

See also: `PlotMaxHoldTrace` and`PlotNormalTrace`.

Default: `false`

`PlotNormalTrace`

Normal trace flag

Set this property to `false` to remove the display of the normal traces. These traces display the free-running spectral estimates. Note that even when the traces are removed from the display, the Spectrum Analyzer continues its spectral computations. This property applies only when you set the `SpectrumType` property to `'Power'` or `'Power density'`.

This property is “Tunable”.

See also: `PlotMaxHoldTrace` and `PlotMinHoldTrace`.

Default: `true`

`Position`

Spectrum Analyzer window position in pixels

Specify, in pixels, the size and location of the scope window as a 4-element double vector of the form, `[left bottom width height]`. You can place the scope window in a specific position on your screen by modifying the values to this property. This property is "Tunable".

Default: The default depends on your screen resolution. By default, the Spectrum Analyzer window appears in the center of your screen with a width of `800` pixels and height of `450` pixels.

`PowerUnits`

Power units

Specify the units in which the Spectrum Analyzer displays power values as either `'dBm'`, `'dBW'`, or `'Watts'`.

This property is "Tunable".

Default: `'dBm'`

`RBW`

Resolution bandwidth

Specify as a real, positive scalar the resolution bandwidth (RBW), in hertz. RBW controls the spectral resolution of Spectrum Analyzer. This property applies only when you set the `FrequencyResolutionMethod` property to `'RBW'` and the `RBWSource` property to `'Property'`. You must specify a value to ensure that there are at least two RBW intervals over the specified frequency span. Thus, the ratio of the overall span to RBW must be greater than two: $\frac{span}{RBW} > 2$. You can specify the overall span in different ways based on how you set the "`FrequencySpan`" property.

This property is "Tunable".

See also: `RBWSource`.

Default: `9.76`

`RBWSource`

Source of resolution bandwidth value

Specify the source of the resolution bandwidth (RBW) as either `'Auto'` or `'Property'`. This property is relevant only when you set the `FrequencyResolutionMethod` property to `'RBW'`.

- When you set this property to `'Auto'`, the Spectrum Analyzer adjusts the spectral estimation resolution to ensures that there are 1024 RBW intervals over the defined frequency span.
- When you set this property to `'Property'`, specify the resolution bandwidth directly using the `RBW` property.

This property is “Tunable”.

See also: `RBW`.

Default: `'Auto'`

`ReducePlotRate`

Reduce plot rate to improve performance

When you set this property to `true`, the scope logs data for later use and updates the display at fixed intervals of time. Data occurring between these fixed intervals might not be plotted. When you set this property to `false`, the scope updates every time it computes the power spectrum. Use the `false` setting when you do not want to miss any spectral updates at the expense of slower simulation speed. The simulation speed is faster when this property is set to `true`. This property is “Tunable”.

Default: `true`

`ReferenceLoad`

Reference load

Specify as a real, positive scalar the load, in ohms, that the Spectrum Analyzer uses as a reference to compute power values.

This property is “Tunable”.

Default: `1`

`SampleRate`

Sample rate of input

Specify the sample rate, in hertz, of the input signals.

The sample rate must be a finite numeric scalar.

Default: `10e3`

`ShowGrid`

Option to enable or disable grid display

When you set this property to `true`, the grid appears. When you set this property to `false`, the grid is hidden. This property is “Tunable”.

Default: `false`

`ShowLegend`

Show or hide legend

When you set this property to `true`, the scope displays a legend with automatic string labels for each input channel. When you set this property to `false`, the scope does not display a legend. This property applies only when you set the “`SpectrumType`” property to `'Power'` or `'Power density'`. This property is “Tunable”.

Default: `false`

`SidelobeAttenuation`

Sidelobe attenuation of window

Specify as a real, positive scalar the window sidelobe attenuation, in decibels (dB). This property applies only when you set the `Window` property to `'Chebyshev'` or `'Kaiser'`. The value must be greater than or equal to `45`.

This property is “Tunable”.

Default: `60`

Span

Frequency span over which spectrum is computed and plotted

Specify as a real, positive scalar the frequency span, in hertz, over which the Spectrum Analyzer computes and plots the spectrum. This property applies only when you set the `FrequencySpan` property to `'Span and center frequency'`. The overall span, defined by this property and the `CenterFrequency` property, must fall within the *Nyquist* frequency interval. When the `PlotAsTwoSidedSpectrum` property is `true`, the Nyquist interval is $\left[-\frac{SampleRate}{2}, \frac{SampleRate}{2}\right] + FrequencyOffset$ hertz. When you set the PlotAsTwoSidedSpectrum property to `false`, the Nyquist interval is $\left[0, \frac{SampleRate}{2}\right] + FrequencyOffset$ hertz.

This property is “Tunable”.

Default: `10e3`

SpectralAverages

Number of spectral averages

Specify as a positive, scalar integer the number of spectral averages. This property applies only when you set the `SpectrumType` property to `'Power'` or `'Power density'`. The Spectrum Analyzer computes the current power spectrum estimate by computing a running average of the last *N* power spectrum estimates. This property defines the number of spectral averages, *N*.

This property is “Tunable”.

Default: `1`

SpectrumType

Spectrum type

Specify the spectrum type as one of `'Power'`, `'Power density'`, or `'Spectrogram'`.

- When you set this property to `'Power'`, the Spectrum Analyzer shows the power spectrum.

- When you set this property to `'Power density'`, the Spectrum Analyzer shows the power spectral density. The power spectral density is the magnitude squared of the spectrum normalized to a bandwidth of 1 hertz.
- When you set this property to `'Spectrogram'`, the Spectrum Analyzer open a spectrogram view, which shows frequency content over time. Each line of the spectrogram is one periodogram. Time scrolls from the bottom to the top of the display. The most recent spectrogram update is at the bottom of the display.

This property is “Tunable”.

Default: `'Power'`

`StartFrequency`

Start frequency over which spectrum is computed

Specify as a real scalar the start frequency, in hertz, over which the Spectrum Analyzer computes and plots the spectrum. This property applies only when you set the `FrequencySpan` property to `'Start and stop frequencies'`. The overall span, which is defined by `StopFrequency` and this property, must fall within the *Nyquist* frequency interval. When the `PlotAsTwoSidedSpectrum` property is `true`, the Nyquist interval is $\left[-\frac{SampleRate}{2},\frac{SampleRate}{2}\right]+FrequencyOffset$ hertz. If you set the PlotAsTwoSidedSpectrum property to `false`, the Nyquist interval is $\left[0,\frac{SampleRate}{2}\right]+FrequencyOffset$ hertz.

This property is “Tunable”.

Default: `-5e3`

`StopFrequency`

Stop frequency over which spectrum is computed

Specify as a real scalar the stop frequency, in hertz, over which the Spectrum Analyzer computes and plots the spectrum. This property applies only when you set the `FrequencySpan` property to `'Start and stop frequencies'`. The overall span, defined by this property and the `StartFrequency` property, must fall within the *Nyquist* frequency interval. When the `PlotAsTwoSidedSpectrum` property is set to `true`, the interval is $\left[-\frac{SampleRate}{2},\frac{SampleRate}{2}\right]+FrequencyOffset$ hertz. When the PlotAsTwoSidedSpectrum property is set to `false`, the interval is $\left[0,\frac{SampleRate}{2}\right]+FrequencyOffset$ hertz.

This property is “Tunable”.

Default: `5e3`

`Title`

Display title

Specify the display title as a string. Enter `%<SignalLabel>` to use the signal labels in the Simulink Model as the axes titles. This property is “Tunable”.

Default: `''`

`TreatMby1SignalsAsOneChannel`

Treat unoriented sample-based input signal as a column vector

Set this property to `true` to treat *M*-by-1 and unoriented sample-based inputs as a column vector, or one channel. Set this property to `false` to treat *M*-by-1 and unoriented sample-based inputs as a 1-by-*M* row vector.

Default: `true`

`Window`

Window function

Specify a window function for the spectral estimator as one of the options in the following table. For information on any window function, follow the link to the corresponding function reference in the Signal Processing Toolbox documentation.

Window Option	Corresponding Function in Signal Processing Toolbox
`'Rectangular'`	`rectwin`
`'Chebyshev'`	`chebwin`

Window Option	Corresponding Function in Signal Processing Toolbox
`'Flat Top'`	`flattopwin`
`'Hamming'`	`hamming`
`'Hann'`	`hann`
`'Kaiser'`	`kaiser`

This property is “Tunable”.

Default: `'Hann'`

`WindowLength`

The window length

Control the frequency resolution by specifying the window length, in samples used to compute the spectral estimates. The window length must be an integer scalar greater than 2. This property applies only when you set the `FrequencyResolutionMethod` property to `'WindowLength'`, which controls the frequency resolution based on your window length setting. The resulting resolution bandwidth (RBW) is $\frac{NENBW * Fs}{N_{window}}$ where N_{window} is the `WindowLength` value.

This property is “Tunable”.

See also: `Window`,

Default: `1024`

`YLabel`

The label for the *y*-axis

Specify as a string the text for the scope to display to the left of the *y*-axis. “Tunable”

This property applies only when you set the `SpectrumType` property to `'Power'` or `'Power density'`. Regardless of this property, Spectrum Analyzer always displays power units as one of `'dBm'`, `'dBW'`, `'Watts'`, `'dBm/Hz'`, `'dBW/Hz'`, `'Watts/Hz'`.

See also: `PowerUnits`“”.

Default: `''`

`YLimits`

The limits for the *y*-axis

Specify the *y*-axis limits as a 2-element numeric vector, `[ymin ymax]`. This property is “Tunable”.

This property applies only when you set the `SpectrumType` property to `'Power'` or `'Power density'`. The units directly depend upon the `PowerUnits` property.

Default: `[-80, 20]`

Examples

Example: Construct a Spectrum Analyzer Configuration Object

Create a new Simulink model with a randomly-generated name.

```
sysname=char(randi(26,1,7)+96);
new_system(sysname);
```

Add a new Spectrum Analyzer block to the model.

```
add_block('built-in/SpectrumAnalyzer',[sysname,'/SpectrumAnalyzer'])
```

Call the `get_param` function to retrieve the default Spectrum Analyzer block configuration properties.

```
hsac = get_param([sysname,'/SpectrumAnalyzer'],'ScopeConfiguration')
```

```
hsac =

  SpectrumAnalyzerConfiguration with properties:

                            Name: 'SpectrumAnalyzer'
           OpenAtSimulationStart: 1
                         Visible: 0
                        Position: [680 390 560 420]
                      SampleRate: '10e3'
                    SpectrumType: 'Power'
                   FrequencySpan: 'Full'
```

```
                       Span: '10e3'
            CenterFrequency: '0'
             StartFrequency: '-5e3'
              StopFrequency: '5e3'
  FrequencyResolutionMethod: 'RBW'
                  RBWSource: 'Auto'
                        RBW: '9.76'

Functions — Alphabetical List

adaptfilt

Adaptive filter

Syntax

```
ha = adaptfilt.algorithm('input1',input2,...)
```

Description

`ha = adaptfilt.`*`algorithm`*`('input1',input2,...)` returns the adaptive filter object `ha` that uses the adaptive filtering technique specified by *`algorithm`*. When you construct an adaptive filter object, include an *`algorithm`* specifier to implement a specific adaptive filter. Note that you do not enclose the algorithm option in single quotation marks as you do for most strings. To construct an adaptive filter object you must supply an *`algorithm`* string — there is no default algorithm, although every constructor creates a default adaptive filter when you do not provide input arguments such as `input1` or `input2` in the calling syntax.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

Algorithms

For adaptive filter (`adaptfilt`) objects, the *`algorithm`* string determines which adaptive filter algorithm your `adaptfilt` object implements. Each available algorithm entry appears in one of the tables along with a brief description of the algorithm. Click on the algorithm in the first column to get more information about the associated adaptive filter technique.

Least Mean Squares (LMS) Based FIR Adaptive Filters

adaptfilt.algorithm String	Algorithm Used to Generate Filter Coefficients
`adaptfilt.adjlms`	Use the Adjoint LMS FIR adaptive filter algorithm
`adaptfilt.blms`	Use the Block LMS FIR adaptive filter algorithm
`adaptfilt.blmsfft`	Use the FFT-based Block LMS FIR adaptive filter algorithm
`adaptfilt.dlms`	Use the delayed LMS FIR adaptive filter algorithm
`adaptfilt.filtxlms`	Use the filtered-x LMS FIR adaptive filter algorithm
`adaptfilt.lms`	Use the LMS FIR adaptive filter algorithm
`adaptfilt.nlms`	Use the normalized LMS FIR adaptive filter algorithm
`adaptfilt.sd`	Use the sign-data LMS FIR adaptive filter algorithm
`adaptfilt.se`	Use the sign-error LMS FIR adaptive filter algorithm
`adaptfilt.ss`	Use the sign-sign LMS FIR adaptive filter algorithm

For further information about an adapting algorithm, refer to the reference page for the algorithm.

Recursive Least Squares (RLS) Based FIR Adaptive Filters

adaptfilt.algorithm String	Algorithm Used to Generate Filter Coefficients
`adaptfilt.ftf`	Use the fast transversal least squares adaptation algorithm
`adaptfilt.qrdrls`	Use the QR-decomposition RLS adaptation algorithm
`adaptfilt.hrls`	Use the householder RLS adaptation algorithm
`adaptfilt.hswrls`	Use the householder SWRLS adaptation algorithm
`adaptfilt.rls`	Use the recursive-least squares (RLS) adaptation algorithm

adaptfilt.algorithm String	Algorithm Used to Generate Filter Coefficients
`adaptfilt.swrls`	Use the sliding window (SW) RLS adaptation algorithm
`adaptfilt.swftf`	Use the sliding window FTF adaptation algorithm

For more complete information about an adapting algorithm, refer to the reference page for the algorithm.

Affine Projection (AP) FIR Adaptive Filters

adaptfilt.algorithm String	Algorithm Used to Generate Filter Coefficients
`adaptfilt.ap`	Use the affine projection algorithm that uses direct matrix inversion
`adaptfilt.apru`	Use the affine projection algorithm that uses recursive matrix updating
`adaptfilt.bap`	Use the block affine projection adaptation algorithm

To find more information about an adapting algorithm, refer to the reference page for the algorithm.

FIR Adaptive Filters in the Frequency Domain (FD)

adaptfilt.algorithm String	Algorithm Used to Generate Filter Coefficients
`adaptfilt.fdaf`	Use the frequency domain adaptation algorithm
`adaptfilt.pbfdaf`	Use the partition block version of the FDAF algorithm
`adaptfilt.pbufdaf`	Use the partition block unconstrained version of the FDAF algorithm
`adaptfilt.tdafdct`	Use the transform domain adaptation algorithm using DCT
`adaptfilt.tdafdft`	Use the transform domain adaptation algorithm using DFT
`adaptfilt.ufdaf`	Use the unconstrained FDAF algorithm for adaptation

For more information about an adapting algorithm, refer to the reference page for the algorithm.

Lattice Based (L) FIR Adaptive Filters

adaptfilt.algorithm String	Algorithm Used to Generate Filter Coefficients
`adaptfilt.gal`	Use the gradient adaptive lattice filter adaptation algorithm
`adaptfilt.lsl`	Use the least squares lattice adaptation algorithm
`adaptfilt.qrdlsl`	Use the QR decomposition least squares lattice adaptation algorithm

For more information about an adapting algorithm, refer to the reference page for the algorithm.

Properties for All Adaptive Filter Objects

Each reference page for an algorithm and `adaptfilt.algorithm` object specifies which properties apply to the adapting algorithm and how to use them.

Methods for Adaptive Filter Objects

As is true with all objects, methods enable you to perform various operations on `adaptfilt` objects. To use the methods, you apply them to the object handle that you assigned when you constructed the `adaptfilt` object.

Most of the analysis methods that apply to `dfilt` objects also work with `adaptfilt` objects. Methods like `freqz` rely on the filter coefficients in the `adaptfilt` object. Since the coefficients change each time the filter adapts to data, you should view the results of using a method as an analysis of the filter at a moment in time for the object. Use caution when you apply an analysis method to your adaptive filter objects — always check that your result approached your expectation.

In particular, the Filter Visualization Tool (FVTool) supports all of the `adaptfilt` objects. Analyzing and viewing your `adaptfilt` objects is straightforward — use the `fvtool` method with the name of your object

```
fvtool(objectname)
```

to launch FVTool and work with your object.

Some methods share their names with functions in Signal Processing Toolbox software, or even functions in this toolbox. Functions that share names with methods behave in a similar way. Using the same name for more than one function or method is called *overloading* and is common in many toolboxes.

Method	Description
`adaptfilt/coefficients`	Return the instantaneous adaptive filter coefficients
`adaptfilt/filter`	Apply an `adaptfilt` object to your signal
`adaptfilt/freqz`	Plot the instantaneous adaptive filter frequency response
`adaptfilt/grpdelay`	Plot the instantaneous adaptive filter group delay
`adaptfilt/impz`	Plot the instantaneous adaptive filter impulse response.
`adaptfilt/info`	Return the adaptive filter information.
`adaptfilt/isfir`	Test whether an adaptive filter is an finite impulse response (FIR) filters.
`adaptfilt/islinphase`	Test whether an adaptive filter is linear phase
`adaptfilt/ismaxphase`	Test whether an adaptive filter is maximum phase
`adaptfilt/isminphase`	Test whether an adaptive filter is minimum phase
`adaptfilt/isreal`	True whether an adaptive filter has real coefficients
`adaptfilt/isstable`	Test whether an adaptive filter is stable
`adaptfilt/maxstep`	Return the maximum step size for an adaptive filter
`adaptfilt/msepred`	Return the predicted mean square error
`adaptfilt/msesim`	Return the measured mean square error via simulation.
`adaptfilt/phasez`	Plot the instantaneous adaptive filter phase response
`adaptfilt/reset`	Reset an adaptive filter to initial conditions
`adaptfilt/stepz`	Plot the instantaneous adaptive filter step response
`adaptfilt/tf`	Return the instantaneous adaptive filter transfer function

Method	Description
adaptfilt/zerophase	Plot the instantaneous adaptive filter zerophase response
adaptfilt/zpk	Return a matrix containing the instantaneous adaptive filter zero, pole, and gain values
adaptfilt/zplane	Plot the instantaneous adaptive filter in the Z-plane

Working with Adaptive Filter Objects

The next sections cover viewing and changing the properties of `adaptfilt` objects. Generally, modifying the properties is the same for `adaptfilt`, `dfilt`, and `mfilt` objects and most of the same methods apply to all.

Viewing Object Properties

As with any object, you can use `get` to view a `adaptfilt` object's properties. To see a specific property, use

```
 get(ha,'property')
```

To see all properties for an object, use

```
get(ha)
```

Changing Object Properties

To set specific properties, use

```
set(ha,'property1',value1,'property2',value2,...)
```

You must use single quotation marks around the property name so MATLAB treats them as strings.

Copying an Object

To create a copy of an object, use `copy`.

```
ha2 = copy(ha)
```

Note Using the syntax `ha2 = ha` copies only the object handle and does not create a new object — `ha` and `ha2` are not independent. When you change the characteristics of `ha2`, those of `ha` change as well.

Using Filter States

Two properties control your adaptive filter states.

- `States` — stores the current states of the filter. Before the filter is applied, the states correspond to the initial conditions and after the filter is applied, the states correspond to the final conditions.
- `PersistentMemory` — resets the filter before filtering. The default value is `false` which causes the properties that are modified by the filter, such as `coefficients` and `states`, to be reset to the value you specified when you constructed the object, before you use the object to filter data. Setting `PersistentMemory` to `true` allows the object to retain its current properties between filtering operations, rather than resetting the filter to its property values at construction.

Examples

Construct an LMS adaptive filter object and use it to identify an unknown system. For this example, use 500 iteration of the adapting process to determine the unknown filter coefficients. Using the LMS algorithm represents one of the most straightforward technique for adaptive filters.

```
x  = randn(1,500);     % Input to the filter
b  = fir1(31,0.5);     % FIR system to be identified
n  = 0.1*randn(1,500); % Observation noise signal
d  = filter(b,1,x)+n;  % Desired signal
mu = 0.008;            % LMS step size.
ha = adaptfilt.lms(32,mu);
[y,e] = filter(ha,x,d);
subplot(2,1,1); plot(1:500,[d;y;e]);
title('System Identification of an FIR Filter');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,1,2); stem([b.',ha.coefficients.']);
legend('Actual','Estimated');
xlabel('Coefficient #'); ylabel('Coefficient Value');  grid on;
```

adaptfilt.adjlms

FIR adaptive filter that uses adjoint LMS algorithm

Syntax

```
ha = adaptfilt.adjlms(l,step,leakage,pathcoeffs,pathest,...
errstates,pstates,coeffs,states)
```

Description

`ha = adaptfilt.adjlms(l,step,leakage,pathcoeffs,pathest,... errstates,pstates,coeffs,states)` constructs object `ha,` an FIR adjoint LMS adaptive filter. `l` is the adaptive filter length (the number of coefficients or taps) and must be a positive integer. `l` defaults to 10 when you omit the argument. `step` is the adjoint LMS step size. It must be a nonnegative scalar. When you omit the `step` argument, `step` defaults to 0.1.

`leakage` is the adjoint LMS leakage factor. It must be a scalar between 0 and 1. When `leakage` is less than one, you implement a leaky version of the `adjlms` algorithm to determine the filter coefficients. `leakage` defaults to 1 specifying no leakage in the algorithm.

`pathcoeffs` is the secondary path filter model. This vector should contain the coefficient values of the secondary path from the output actuator to the error sensor.

`pathest` is the estimate of the secondary path filter model. `pathest` defaults to the values in `pathcoeffs`.

`errstates` is a vector of error states of the adaptive filter. It must have a length equal to the filter order of the secondary path model estimate. `errstates` defaults to a vector of zeros of appropriate length. `pstates` contains the secondary path FIR filter states. It must be a vector of length equal to the filter order of the secondary path model. `pstates` defaults to a vector of zeros of appropriate length. The initial filter coefficients for the secondary path filter compose vector `coeffs`. It must be a length `l` vector. `coeffs` defaults to a length `l` vector of zeros. `states` is a vector containing the initial filter states. It must be a vector of length `l+ne`-1, where `ne` is the length of `errstates`. When you omit `states`, it defaults to an appropriate length vector of zeros.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

Properties

In the syntax for creating the `adaptfilt` object, the input options are properties of the object created. This table lists the properties for the adjoint LMS object, their default values, and a brief description of the property.

Property	Default Value	Description
`Algorithm`	None	Specifies the adaptive filter algorithm the object uses during adaptation
`Coefficients`	Length l vector with zeros for all elements	Adjoint LMS FIR filter coefficients. Should be initialized with the initial coefficients for the FIR filter prior to adapting. You need `l` entries in `coefficients`. Updated filter coefficients are returned in `coefficients` when you use `s` as an output argument.
`ErrorStates`	[0,...,0]	A vector of the error states for your adaptive filter, with length equal to the order of your secondary path filter.
`FilterLength`	10	The number of coefficients in your adaptive filter.
`Leakage`	1	Specifies the leakage parameter. Allows you to implement a leaky algorithm. Including a leakage factor can improve the results of the algorithm by forcing the algorithm to continue to adapt even after it reaches a minimum value. Ranges between 0 and 1.
`SecondaryPathCoeffs`	No default	A vector that contains the coefficient values of your secondary path from the output actuator to the error sensor.
`SecondaryPathEstimate`	`pathcoeffs` values	An estimate of the secondary path filter model.

Property	Default Value	Description
`SecondaryPathStates`	Length of the secondary path filter. All elements are zeros.	The states of the secondary path filter, the unknown system
`States`	l+ne+1, where ne is `length(errstates)`	Contains the initial conditions for your adaptive filter and returns the states of the FIR filter after adaptation. If omitted, it defaults to a zero vector of length equal to l +ne+1. When you use `adaptfilt.adjlms` in a loop structure, use this element to specify the initial filter states for the adapting FIR filter.
`Stepsize`	0.1	Sets the adjoint LMS algorithm step size used for each iteration of the adapting algorithm. Determines both how quickly and how closely the adaptive filter converges to the filter solution.
`PersistentMemory`	`false` or `true`	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter. `PersistentMemory` returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. Defaults to `false`.

Examples

Demonstrate active noise control of a random noise signal that runs for 1000 samples.

```
x  = randn(1,1000);      % Noise source
g  = fir1(47,0.4);       % FIR primary path system model
n  = 0.1*randn(1,1000);  % Observation noise signal
d  = filter(g,1,x)+n;    % Signal to be canceled (desired)
b  = fir1(31,0.5);       % FIR secondary path system model
mu = 0.008;              % Adjoint LMS step size
ha = adaptfilt.adjlms(32,mu,1,b);
[y,e] = filter(ha,x,d);
plot(1:1000,d,'b',1:1000,e,'r');
title('Active Noise Control of a Random Noise Signal');
```

```
legend('Original','Attenuated');
xlabel('Time Index'); ylabel('Signal Value');  grid on;
```

Reviewing the figure shows that the adaptive filter attenuates the original noise signal as you expect.

adaptfilt.ap

FIR adaptive filter that uses direct matrix inversion

Syntax

```
ha = adaptfilt.ap(l,step,projectord,offset,coeffs,states,...
errstates,epsstates)
```

Description

`ha = adaptfilt.ap(l,step,projectord,offset,coeffs,states,... errstates,epsstates)` constructs an affine projection FIR adaptive filter `ha` using direct matrix inversion.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.ap`.

Input Argument	Description
`l`	Adaptive filter length (the number of coefficients or taps) and it must be a positive integer. `l` defaults to 10.
`step`	Affine projection step size. This is a scalar that should be a value between zero and one. Setting `step` equal to one provides the fastest convergence during adaptation. `step` defaults to 1.
`projectord`	Projection order of the affine projection algorithm. `projectord` defines the size of the input signal covariance matrix and defaults to two.
`offset`	Offset for the input signal covariance matrix. You should initialize the covariance matrix to a diagonal matrix whose diagonal entries

Input Argument	Description
	are equal to the offset you specify. `offset` should be positive. `offset` defaults to one.
`coeffs`	Vector containing the initial filter coefficients. It must be a length `l` vector, the number of filter coefficients. `coeffs` defaults to length `l` vector of zeros when you do not provide the argument for input.
`states`	Vector of the adaptive filter states. states defaults to a vector of zeros which has length equal to (`l` + `projectord` - 2).
`errstates`	Vector of the adaptive filter error states. `errstates` defaults to a zero vector with length equal to (`projectord` - 1).
`epsstates`	Vector of the epsilon values of the adaptive filter. `epsstates` defaults to a vector of zeros with (`projectord` - 1) elements.

Properties

Since your `adaptfilt.ap` filter is an object, it has properties that define its behavior in operation. Note that many of the properties are also input arguments for creating `adaptfilt.ap` objects. To show you the properties that apply, this table lists and describes each property for the affine projection filter object.

Name	Range	Description
`Algorithm`	None	Defines the adaptive filter algorithm the object uses during adaptation
`FilterLength`	Any positive integer	Reports the length of the filter, the number of coefficients or taps
`ProjectionOrder`	1 to as large as needed.	Projection order of the affine projection algorithm. `ProjectionOrder` defines the size of the input signal covariance matrix and defaults to two.
`OffsetCov`	Matrix of values	Contains the offset covariance matrix
`Coefficients`	Vector of elements	Vector containing the initial filter coefficients. It must be a length `l` vector, the number of filter coefficients. `coeffs` defaults to length `l` vector of zeros when you do not provide the argument for input.

Name	Range	Description
`States`	Vector of elements, data type double	Vector of the adaptive filter states. states defaults to a vector of zeros which has length equal to (`l` + `projectord` - 2).
`ErrorStates`	Vector of elements	Vector of the adaptive filter error states. `errstates` defaults to a zero vector with length equal to (`projectord` - 1).
`EpsilonStates`	Vector of elements	Vector of the epsilon values of the adaptive filter. `epsstates` defaults to a vector of zeros with (`projectord` - 1) elements.
`StepSize`	Any scalar from zero to one, inclusive	Specifies the step size taken between filter coefficient updates
`PersistentMemory`	`false` or `true`	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter. `PersistentMemory` returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. Defaults to `true`.

Examples

Quadrature phase shift keying (QPSK) adaptive equalization using a 32-coefficient FIR filter. Run the adaptation for 1000 iterations.

```
D  = 16;                     % Number of samples of delay
b  = exp(j*pi/4)*[-0.7 1];   % Numerator coefficients of channel
a  = [1 -0.7];               % Denominator coefficients of channel
ntr= 1000;                   % Number of iterations
s  = sign(randn(1,ntr+D)) + j*sign(randn(1,ntr+D));% Baseband Signal
n  = 0.1*(randn(1,ntr+D) + j*randn(1,ntr+D));      % Noise signal
r  = filter(b,a,s)+n;        % Received signal
x  = r(1+D:ntr+D);    % Input signal (received signal)
d  = s(1:ntr);        % Desired signal (delayed QPSK signal)
mu = 0.1;             % Step size
po = 4;               % Projection order
offset = 0.05;        % Offset for covariance matrix
ha = adaptfilt.ap(32,mu,po,offset);
[y,e] = filter(ha,x,d);
```

```
subplot(2,2,1); plot(1:ntr,real([d;y;e])); title('In-Phase Components');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,2,2); plot(1:ntr,imag([d;y;e]));
title('Quadrature Components');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,2,3); plot(x(ntr-100:ntr),'.');
axis([-3 3 -3 3]); title('Received Signal Scatter Plot');
axis('square');  xlabel('Real[x]'); ylabel('Imag[x]'); grid on;
subplot(2,2,4); plot(y(ntr-100:ntr),'.'); axis([-3 3 -3 3]);
title('Equalized Signal Scatter Plot');
axis('square'); xlabel('Real[y]'); ylabel('Imag[y]'); grid on;
```

The four plots shown reveal the QPSK process at work.

`msesim`

adaptfilt.apru

FIR adaptive filter that uses recursive matrix updating

Syntax

```
ha = adaptfilt.apru(l,step,projectord,offset,coeffs,states,
...errstates,epsstates)
```

Description

`ha = adaptfilt.apru(l,step,projectord,offset,coeffs,states,`
`...errstates,epsstates)` constructs an affine projection FIR adaptive filter `ha` using recursive matrix updating.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.apru`.

Input Argument	Description
`l`	Adaptive filter length (the number of coefficients or taps). It must be a positive integer. `l` defaults to 10.
`step`	Affine projection step size. This is a scalar that should be a value between zero and one. Setting `step` equal to one provides the fastest convergence during adaptation. `step` defaults to 1.
`projectord`	Projection order of the affine projection algorithm. `projectord` defines the size of the input signal covariance matrix and defaults to two.
`offset`	Offset for the input signal covariance matrix. You should initialize the covariance matrix to a diagonal matrix whose diagonal entries are equal to the offset you specify. `offset` should be positive. `offset` defaults to one.

Input Argument	Description
coeffs	Vector containing the initial filter coefficients. It must be a length l vector, the number of filter coefficients. coeffs defaults to length l vector of zeros when you do not provide the argument for input.
states	Vector of the adaptive filter states. states defaults to a vector of zeros which has length equal to (l + projectord - 2).
errstates	Vector of the adaptive filter error states. errstates defaults to a zero vector with length equal to (projectord - 1).
epsstates	Vector of the epsilon values of the adaptive filter. epsstates defaults to a vector of zeros with (projectord - 1) elements.

Properties

Since your adaptfilt.apru filter is an object, it has properties that define its behavior in operation. Note that many of the properties are also input arguments for creating adaptfilt.apru objects. To show you the properties that apply, this table lists and describes each property for the affine projection filter object.

Name	Range	Description
Algorithm	None	Defines the adaptive filter algorithm the object uses during adaptation
FilterLength	Any positive integer	Reports the length of the filter, the number of coefficients or taps
ProjectionOrder	1 to as large as needed.	Projection order of the affine projection algorithm. ProjectionOrder defines the size of the input signal covariance matrix and defaults to two.
OffsetCov	Matrix of values	Contains the offset covariance matrix
Coefficients	Vector of elements	Vector containing the initial filter coefficients. It must be a length l vector, the number of filter coefficients. coeffs defaults to length l vector of zeros when you do not provide the argument for input.

Name	Range	Description
States	Vector of elements, data type double	Vector of the adaptive filter states. states defaults to a vector of zeros which has length equal to (l + projectord - 2).
ErrorStates	Vector of elements	Vector of the adaptive filter error states. errstates defaults to a zero vector with length equal to (projectord - 1).
EpsilonStates	Vector of elements	Vector of the epsilon values of the adaptive filter. epsstates defaults to a vector of zeros with (projectord - 1) elements.
StepSize	Any scalar from zero to one, inclusive	Specifies the step size taken between filter coefficient updates
PersistentMemory	false or true	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter. PersistentMemory returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. Defaults to true.

Examples

Demonstrate quadrature phase shift keying (QPSK) adaptive equalization using a 32-coefficient FIR filter. This example runs the adaptation process for 1000 iterations.

```
D  = 16;                        % Number of samples of delay
b  = exp(1j*pi/4)*[-0.7 1];      % Numerator coefficients of channel
a  = [1 -0.7];                  % Denominator coefficients of channel
ntr= 1000;                      % Number of iterations
s  = sign(randn(1,ntr+D)) + 1j*sign(randn(1,ntr+D)); % Baseband
n  = 0.1*(randn(1,ntr+D) + 1j*randn(1,ntr+D));  % Noise signal
r  = filter(b,a,s)+n;     % Received signal
x  = r(1+D:ntr+D); % Input signal (received signal)
d  = s(1:ntr);     % Desired signal (delayed QPSK signal)
mu = 0.1;                      % Step size
```

```
po = 4;                               % Projection order
offset = 0.05;                           % Offset
ha = adaptfilt.apru(32,mu,po,offset); [y,e] = filter(ha,x,d);
subplot(2,2,1); plot(1:ntr,real([d;y;e])); title('In-Phase Components');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,2,2); plot(1:ntr,imag([d;y;e])); title('Quadrature Components');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,2,3); plot(x(ntr-100:ntr),'.'); axis([-3 3 -3 3]);
title('Received Signal Scatter Plot');
axis('square');  xlabel('Real[x]'); ylabel('Imag[x]'); grid on;
subplot(2,2,4); plot(y(ntr-100:ntr),'.'); axis([-3 3 -3 3]);
title('Equalized Signal Scatter Plot');
axis('square'); xlabel('Real[y]'); ylabel('Imag[y]'); grid on;
```

In the following component and scatter plots, you see the results of QPSK equalization.

adaptfilt.bap

FIR adaptive filter that uses block affine projection

Syntax

```
ha = adaptfilt.bap(l,step,projectord,offset,coeffs,states)
```

Description

`ha = adaptfilt.bap(l,step,projectord,offset,coeffs,states)` constructs a block affine projection FIR adaptive filter `ha`.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.bap`.

Input Argument	Description
`l`	Adaptive filter length (the number of coefficients or taps) and it must be a positive integer. `l` defaults to 10.
`step`	Affine projection step size. This is a scalar that should be a value between zero and one. Setting `step` equal to one provides the fastest convergence during adaptation. `step` defaults to 1.
`projectord`	Projection order of the affine projection algorithm. `projectord` defines the size of the input signal covariance matrix and defaults to two.
`offset`	Offset for the input signal covariance matrix. You should initialize the covariance matrix to a diagonal matrix whose diagonal entries are equal to the offset you specify. `offset` should be positive. `offset` defaults to one.

Input Argument	Description
`coeffs`	Vector containing the initial filter coefficients. It must be a length `l` vector, the number of filter coefficients. `coeffs` defaults to length `l` vector of zeros when you do not provide the argument for input.
`states`	Vector of the adaptive filter states. states defaults to a vector of zeros which has length equal to (`l` + `projectord` - 2).

Properties

Since your `adaptfilt.bap` filter is an object, it has properties that define its behavior in operation. Note that many of the properties are also input arguments for creating `adaptfilt.bap` objects. To show you the properties that apply, this table lists and describes each property for the affine projection filter object.

Name	Range	Description
`Algorithm`	None	Defines the adaptive filter algorithm the object uses during adaptation
`FilterLength`	Any positive integer	Reports the length of the filter, the number of coefficients or taps
`ProjectionOrder`	1 to as large as needed.	Projection order of the affine projection algorithm. `ProjectionOrder` defines the size of the input signal covariance matrix and defaults to two.
`OffsetCov`	Matrix of values	Contains the offset covariance matrix
`Coefficients`	Vector of elements	Vector containing the initial filter coefficients. It must be a length `l` vector, the number of filter coefficients. `coeffs` defaults to length `l` vector of zeros when you do not provide the argument for input.
`States`	Vector of elements, data type double	Vector of the adaptive filter states. states defaults to a vector of zeros which has length equal to (`l` + `projectord` - 2).

Name	Range	Description
`StepSize`	Any scalar from zero to one, inclusive	Specifies the step size taken between filter coefficient updates
`PersistentMemory`	`false` or `true`	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter. `PersistentMemory` returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. Defaults to `true`.

Examples

Show an example of quadrature phase shift keying (QPSK) adaptive equalization using a 32-coefficient FIR filter.

```
D  = 16;                                 % delay
b  = exp(1j*pi/4)*[-0.7 1];              % Numerator coefficients
a  = [1 -0.7];                          % Denominator coefficients
ntr= 1000;                              % Number of iterations
s  = sign(randn(1,ntr+D))+1j*sign(randn(1,ntr+D));% Baseband signal
n  = 0.1*(randn(1,ntr+D) + 1j*randn(1,ntr+D));   % Noise signal
r  = filter(b,a,s)+n;                         % Received signal
x  = r(1+D:ntr+D);                       % Input signal (received signal)
d  = s(1:ntr);                     % Desired signal (delayed QPSK signal)
mu = 0.5;                          % Step size
po = 4;                            % Projection order
offset = 1.0;                      % Offset for covariance matrix
ha = adaptfilt.bap(32,mu,po,offset);
[y,e] = filter(ha,x,d); subplot(2,2,1);
plot(1:ntr,real([d;y;e]));
title('In-Phase Components'); legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,2,2); plot(1:ntr,imag([d;y;e]));
title('Quadrature Components');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,2,3); plot(x(ntr-100:ntr),'.'); axis([-3 3 -3 3]);
title('Received Signal Scatter Plot'); axis('square');
xlabel('Real[x]'); ylabel('Imag[x]'); grid on;
subplot(2,2,4); plot(y(ntr-100:ntr),'.'); axis([-3 3 -3 3]);
title('Equalized Signal Scatter Plot'); axis('square');
xlabel('Real[y]'); ylabel('Imag[y]'); grid on;
```

Using the block affine projection object in QPSK results in the plots shown here.

adaptfilt.blms

FIR adaptive filter that uses BLMS

Syntax

```
ha = adaptfilt.blms(l,step,leakage,blocklen,coeffs,states)
```

Description

`ha = adaptfilt.blms(l,step,leakage,blocklen,coeffs,states)` constructs an FIR block LMS adaptive filter `ha`, where `l` is the adaptive filter length (the number of coefficients or taps) and must be a positive integer. `l` defaults to 10.

`step` is the block LMS step size. You must set step to a nonnegative scalar. You can use function `maxstep` to determine a reasonable range of step size values for the signals being processed. When unspecified, `step` defaults to 0.

`leakage` is the block LMS leakage factor. It must be a scalar between 0 and 1. If you set leakage to be less than one, you implement the leaky block LMS algorithm. `leakage` defaults to 1 specifying no leakage in the adapting algorithm.

`blocklen` is the block length used. It must be a positive integer and the signal vectors `d` and `x` should be divisible by `blocklen`. Larger block lengths result in faster per-sample execution times but with poor adaptation characteristics. When you choose `blocklen` such that `blocklen` + `length(coeffs)` is a power of 2, use `adaptfilt.blmsfft`. `blocklen` defaults to `l`.

`coeffs` is a vector of initial filter coefficients. it must be a length `l` vector. `coeffs` defaults to length `l` vector of zeros.

`states` contains a vector of your initial filter states. It must be a length `l` vector and defaults to a length `l` vector of zeros when you do not include it in your calling function.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

Properties

In the syntax for creating the `adaptfilt` object, the input options are properties of the object created. This table lists the properties for the adjoint LMS object, their default values, and a brief description of the property.

Property	Default Value	Description
`Algorithm`	None	Defines the adaptive filter algorithm the object uses during adaptation
`FilterLength`	Any positive integer	Reports the length of the filter, the number of coefficients or taps
`Coefficients`	Vector of elements	Vector containing the initial filter coefficients. It must be a length `l` vector where `l` is the number of filter coefficients. `coeffs` defaults to length `l` vector of zeros when you do not provide the argument for input.
`States`	Vector of elements	Vector of the adaptive filter states. `states` defaults to a vector of zeros which has length equal to `l`
`Leakage`		Specifies the leakage parameter. Allows you to implement a leaky algorithm. Including a leakage factor can improve the results of the algorithm by forcing the algorithm to continue to adapt even after it reaches a minimum value. Ranges between 0 and 1.
`BlockLength`	Vector of length `l`	Size of the blocks of data processed in each iteration
`StepSize`	0.1	Sets the block LMS algorithm step size used for each iteration of the adapting algorithm. Determines both how quickly and how closely the adaptive filter converges to the filter solution. Use `maxstep` to determine the maximum usable step size.
`PersistentMemory`	`false` or `true`	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are

Property	Default Value	Description
		the values in place when you create the filter. `PersistentMemory` returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. Defaults to `false`.

Examples

Use an adaptive filter to identify an unknown 32nd-order FIR filter. In this example 500 input samples result in 500 iterations of the adaptation process. You see in the plot that follows the example code that the adaptive filter has determined the coefficients of the unknown system under test.

```
x  = randn(1,500);        % Input to the filter
b  = fir1(31,0.5);        % FIR system to be identified
no  = 0.1*randn(1,500);   % Observation noise signal
d  = filter(b,1,x)+no;    % Desired signal
mu = 0.008;               % Block LMS step size
n  = 5;                   % Block length
ha = adaptfilt.blms(32,mu,1,n);
[y,e] = filter(ha,x,d);
subplot(2,1,1); plot(1:500,[d;y;e]);
title('System Identification of an FIR Filter');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,1,2); stem([b.',ha.coefficients.']);
legend('Actual','Estimated');
xlabel('Coefficient #'); ylabel('Coefficient Value');
grid on;
```

Based on looking at the figures here, the adaptive filter correctly identified the unknown system after 500 iterations, or fewer. In the lower plot, you see the comparison between the actual filter coefficients and those determined by the adaptation process.

See Also

`adaptfilt.blmsfft` | `adaptfilt.fdaf` | `adaptfilt.lms`

adaptfilt.blmsfft

FIR adaptive filter that uses FFT-based BLMS

Syntax

```
ha = adaptfilt.blmsfft(l,step,leakage,blocklen,coeffs,
states)
```

Description

`ha = adaptfilt.blmsfft(l,step,leakage,blocklen,coeffs, states)` constructs an FIR block LMS adaptive filter object `ha` where `l` is the adaptive filter length (the number of coefficients or taps) and must be a positive integer. `l` defaults to 10. `step` is the block LMS step size. It must be a nonnegative scalar. The function `maxstep` may be helpful to determine a reasonable range of step size values for the signals you are processing. `step` defaults to 0.

`leakage` is the block LMS leakage factor. It must also be a scalar between 0 and 1. When `leakage` is less than one, the `adaptfilt.blmsfft` implements a leaky block LMS algorithm. `leakage` defaults to 1 (no leakage). `blocklen` is the block length used. It must be a positive integer such that

```
blocklen + length(coeffs)
```

is a power of two; otherwise, an `adaptfilt.blms` algorithm is used for adapting. Larger block lengths result in faster execution times, with poor adaptation characteristics as the cost of the speed gained. `blocklen` defaults to `l`. Enter your initial filter coefficients in `coeffs`, a vector of length `l`. When omitted, `coeffs` defaults to a length `l` vector of all zeros. `states` contains a vector of initial filter states; it must be a length `l` vector. `states` defaults to a length `l` vector of all zeros when you omit the `states` argument in the calling syntax.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

Properties

In the syntax for creating the adaptfilt object, the input options are properties of the object you create. This table lists the properties for the block LMS object, their default values, and a brief description of the property.

Property	Default Value	Description
Algorithm	None	Defines the adaptive filter algorithm the object uses during adaptation
FilterLength	Any positive integer	Reports the length of the filter, the number of coefficients or taps
Coefficients	Vector of elements	Vector containing the initial filter coefficients. It must be a length l vector where l is the number of filter coefficients. coefficients defaults to length l vector of zeros when you do not provide the argument for input.
States	Vector of elements of length l	Vector of the adaptive filter states. states defaults to a vector of zeros which has length equal to l
Leakage	1	Specifies the leakage parameter. Allows you to implement a leaky algorithm. Including a leakage factor can improve the results of the algorithm by forcing the algorithm to continue to adapt even after it reaches a minimum value. Ranges between 0 and 1.
BlockLength	Vector of length l	Size of the blocks of data processed in each iteration
StepSize	0.1	Sets the block LMS algorithm step size used for each iteration of the adapting algorithm. Determines both how quickly and how closely the adaptive filter converges to the filter solution. Use maxstep to determine the maximum usable step size.
PersistentMemory	false or true	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are

Property	Default Value	Description
		the values in place when you create the filter. `PersistentMemory` returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. Defaults to `false`.

Examples

Identify an unknown FIR filter with 32 coefficients using 512 iterations of the adapting algorithm.

```
x  = randn(1,512);       % Input to the filter
b  = fir1(31,0.5);       % FIR system to be identified
no  = 0.1*randn(1,512);  % Observation noise signal
d  = filter(b,1,x)+no;   % Desired signal
mu = 0.008;              % Step size
n  = 16;                 % Block length
ha = adaptfilt.blmsfft(32,mu,1,n);
[y,e] = filter(ha,x,d);
subplot(2,1,1); plot(1:500,[d(1:500);y(1:500);e(1:500)]);
title('System Identification of an FIR Filter');
legend('Desired','Output','Error'); xlabel('Time Index');
ylabel('Signal Value');
subplot(2,1,2); stem([b.',ha.coefficients.']);
legend('actual','estimated'); grid on;
xlabel('Coefficient #'); ylabel('Coefficient Value');
```

As a result of running the adaptation process, filter object `ha` now matches the unknown system FIR filter `b`, based on comparing the filter coefficients derived during adaptation.

`adaptfilt.blms` | `adaptfilt.fdaf` | `adaptfilt.lms` | `filter`

adaptfilt.dlms

FIR adaptive filter that uses delayed LMS

Syntax

```
ha = adaptfilt.dlms(l,step,leakage,delay,errstates,coeffs,
...states)
```

Description

`ha = adaptfilt.dlms(l,step,leakage,delay,errstates,coeffs, ...states)` constructs an FIR delayed LMS adaptive filter `ha.`

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.dlms`.

Input Argument	Description
`l`	Adaptive filter length (the number of coefficients or taps) and it must be a positive integer. `l` defaults to 10.
`step`	LMS step size. It must be a nonnegative scalar. You can use `maxstep` to determine a reasonable range of step size values for the signals being processed. `step` defaults to 0.
`leakage`	Your LMS leakage factor. It must be a scalar between 0 and 1. When `leakage` is less than one, `adaptfilt.lms` implements a leaky LMS algorithm. When you omit the `leakage` property in the calling syntax, it defaults to 1 providing no leakage in the adapting algorithm.
`delay`	Update delay given in time samples. This scalar should be a positive integer — negative delays do not work. `delay` defaults to 1.

Input Argument	Description
errstates	Vector of the error states of your adaptive filter. It must have a length equal to the update delay (delay) in samples. errstates defaults to an appropriate length vector of zeros.
coeffs	Vector of initial filter coefficients. it must be a length l vector. coeffs defaults to length l vector with elements equal to zero.
states	Vector of initial filter states for the adaptive filter. It must be a length l-1 vector. states defaults to a length l-1 vector of zeros.

Properties

In the syntax for creating the adaptfilt object, the input options are properties of the object you create. This table lists the properties for the block LMS object, their default values, and a brief description of the property.

Property	Default Value	Description
Algorithm	None	Defines the adaptive filter algorithm the object uses during adaptation
Coefficients	Vector of elements	Vector containing the initial filter coefficients. It must be a length l vector where l is the number of filter coefficients. coeffs defaults to length l vector of zeros when you do not provide the argument for input. LMS FIR filter coefficients. Should be initialized with the initial coefficients for the FIR filter prior to adapting. You need l entries in coeffs.
Delay	1	Specifies the update delay for the adaptive algorithm.
ErrorStates	Vector of zeros with the number of elements equal to delay	A vector comprising the error states for the adaptive filter.
FilterLength	Any positive integer	Reports the length of the filter, the number of coefficients or taps.

Property	Default Value	Description
Leakage	1	Specifies the leakage parameter. Allows you to implement a leaky algorithm. Including a leakage factor can improve the results of the algorithm by forcing the algorithm to continue to adapt even after it reaches a minimum value. Ranges between 0 and 1.
PersistentMemory	false or true	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. PersistentMemory returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. Defaults to false.
StepSize	0.1	Sets the LMS algorithm step size used for each iteration of the adapting algorithm. Determines both how quickly and how closely the adaptive filter converges to the filter solution.
States	Vector of elements, data type double	Vector of the adaptive filter states. states defaults to a vector of zeros which has length equal to (l + projectord - 2).

Examples

System identification of a 32-coefficient FIR filter. Refer to the figure that follows to see the results of the adapting filter process.

```
x  = randn(1,500);      % Input to the filter
b  = fir1(31,0.5);      % FIR system to be identified
n  = 0.1*randn(1,500); % Observation noise signal
d  = filter(b,1,x)+n;   % Desired signal
mu = 0.008;             % LMS step size.
delay = 1;              % Update delay
```

```
ha = adaptfilt.dlms(32,mu,1,delay);
[y,e] = filter(ha,x,d);
subplot(2,1,1); plot(1:500,[d;y;e]);
title('System Identification of an FIR Filter');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,1,2); stem([b.',ha.coefficients.']);
legend('Actual','Estimated'); grid on;
xlabel('Coefficient #'); ylabel('Coefficient Value');
```

Using a delayed LMS adaptive filter in the process to identify an unknown filter appears to work as planned, as shown in this figure.

adaptfilt.fdaf

FIR adaptive filter that uses frequency-domain with bin step size normalization

Syntax

```
ha = adaptfilt.fdaf(l,step,leakage,delta,lambda,blocklen,
offset,...coeffs,states)
```

Description

`ha = adaptfilt.fdaf(l,step,leakage,delta,lambda,blocklen, offset,...coeffs,states)` constructs a frequency-domain FIR adaptive filter `ha` with bin step size normalization. If you omit all the input arguments you create a default object with l = 10 and `step` = 1.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.fdaf`.

Input Argument	Description
`l`	Adaptive filter length (the number of coefficients or taps). l must be a positive integer; it defaults to 10 when you omit the argument.
`step`	Step size of the adaptive filter. This is a scalar and should lie in the range (0,1]. `step` defaults to 1.
`leakage`	Leakage parameter of the adaptive filter. If this parameter is set to a value between zero and one, you implement a leaky FDAF algorithm. `leakage` defaults to 1 — no leakage provided in the algorithm.
`delta`	Initial common value of all of the FFT input signal powers. Its initial value should be positive. `delta` defaults to 1.

Input Argument	Description
lambda	Specifies the averaging factor used to compute the exponentially-windowed FFT input signal powers for the coefficient updates. lambda should lie in the range (0,1]. lambda defaults to 0.9.
blocklen	Block length for the coefficient updates. This must be a positive integer. For faster execution, (blocklen + l) should be a power of two. blocklen defaults to l.
offset	Offset for the normalization terms in the coefficient updates. Use this to avoid divide by zeros or by very small numbers when any of the FFT input signal powers become very small. offset defaults to zero.
coeffs	Initial time-domain coefficients of the adaptive filter. coeff should be a length l vector. The adaptive filter object uses these coefficients to compute the initial frequency-domain filter coefficients via an FFT computed after zero-padding the time-domain vector by the blocklen.
states	The adaptive filter states. states defaults to a zero vector that has length equal to l.

Properties

Since your adaptfilt.fdaf filter is an object, it has properties that define its behavior in operation. Note that many of the properties are also input arguments for creating adaptfilt.fdaf objects. To show you the properties that apply, this table lists and describes each property for the adaptfilt.fdaf filter object.

Name	Range	Description
Algorithm	None	Defines the adaptive filter algorithm the object uses during adaptation.
AvgFactor	(0, 1]	Specifies the averaging factor used to compute the exponentially-windowed FFT input signal powers for the coefficient updates. Same as the input argument lambda.
BlockLength	Any integer	Block length for the coefficient updates. This must be a positive integer. For faster

Name	Range	Description
		execution, (`blocklen` + l) should be a power of two. `blocklen` defaults to l.
`FFTCoefficients`		Stores the discrete Fourier transform of the filter coefficients in `coeffs`.
`FFTStates`		States for the FFT operation.
`FilterLength`	Any positive integer	Reports the length of the filter, the number of coefficients or taps.
`Leakage`		Leakage parameter of the adaptive filter. if this parameter is set to a value between zero and one, you implement a leaky FDAF algorithm. `leakage` defaults to 1 — no leakage provided in the algorithm.
`Offset`	Any positive real value	Offset for the normalization terms in the coefficient updates. Use this to avoid dividing by zero or by very small numbers when any of the FFT input signal powers become very small. `offset` defaults to zero.
`PersistentMemory`	`false` or `true`	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter. `PersistentMemory` returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. Defaults to `false`.
`Power`		A vector of 2*`l` elements, each initialized with the value `delta` from the input arguments. As you filter data, `Power` gets updated by the filter process.
`StepSize`	Any scalar from zero to one, inclusive	Specifies the step size taken between filter coefficient updates

Examples

Quadrature Phase Shift Keying (QPSK) adaptive equalization using 1024 iterations of a 32-coefficient FIR filter. After this example code, a figure demonstrates the equalization results.

```
D = 16;                         % Number of samples of delay
b  = exp(1j*pi/4)*[-0.7 1];      % Numerator coefficients of channel
a  = [1 -0.7];                  % Denominator coefficients of channel
ntr= 1024;                      % Number of iterations
s  = sign(randn(1,ntr+D))+1j*sign(randn(1,ntr+D));  %QPSK signal
n  = 0.1*(randn(1,ntr+D) + 1j*randn(1,ntr+D));       % Noise signal
r  = filter(b,a,s)+n;            % Received signal
x  = r(1+D:ntr+D);               % Input signal (received signal)
d  = s(1:ntr);                   % Desired signal (delayed QPSK signal)
del = 1;                         % Initial FFT input powers
mu  = 0.1;                       % Step size
lam = 0.9;                       % Averaging factor
ha = adaptfilt.fdaf(32,mu,1,del,lam);
[y,e] = filter(ha,x,d);
subplot(2,2,1); plot(1:ntr,real([d;y;e])); title('In-Phase Components');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('signal value');
subplot(2,2,2); plot(1:ntr,imag([d;y;e])); title('Quadrature Components');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('signal value');
subplot(2,2,3); plot(x(ntr-100:ntr),'.'); axis([-3 3 -3 3]);
title('Received Signal Scatter Plot'); axis('square');
xlabel('Real[x]'); ylabel('Imag[x]'); grid on;
subplot(2,2,4); plot(y(ntr-100:ntr),'.'); axis([-3 3 -3 3]);
title('Equalized Signal Scatter Plot'); axis('square');
xlabel('Real[y]'); ylabel('Imag[y]'); grid on;
```

adaptfilt.filtxlms

FIR adaptive filter that uses filtered-x LMS

Syntax

```
ha = adaptfilt.filtxlms(l,step,leakage,pathcoeffs,
pathest,...errstates,pstates,coeffs,states)
```

Description

`ha = adaptfilt.filtxlms(l,step,leakage,pathcoeffs, pathest,...errstates,pstates,coeffs,states)` constructs an filtered-x LMS adaptive filter `ha.`

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.filtxlms`.

Input Argument	Description
`l`	Adaptive filter length (the number of coefficients or taps) and it must be a positive integer. `l` defaults to 10.
`step`	Filtered LMS step size. it must be a nonnegative scalar. `step` defaults to 0.1.
`leakage`	is the filtered-x LMS leakage factor. it must be a scalar between 0 and 1. If it is less than one, a leaky version of `adaptfilt.filtxlms` is implemented. `leakage` defaults to 1 (no leakage).
`pathcoeffs`	is the secondary path filter model. this vector should contain the coefficient values of the secondary path from the output actuator to the error sensor.

Input Argument	Description
pathest	is the estimate of the secondary path filter model. pathest defaults to the values in pathcoeffs.
fstates	is a vector of filtered input states of the adaptive filter. fstates defaults to a zero vector of length equal to (l - 1).
pstates	are the secondary path FIR filter states. it must be a vector of length equal to the (length(pathcoeffs) - 1). pstates defaults to a vector of zeros of appropriate length.
coeffs	is a vector of initial filter coefficients. it must be a length l vector. coeffs defaults to length l vector of zeros.
states	Vector of initial filter states. states defaults to a zero vector of length equal to the larger of (length(pathcoeffs) - 1) and (length(pathest) - 1).

Properties

In the syntax for creating the adaptfilt object, the input options are properties of the object created. This table lists the properties for the adjoint LMS object, their default values, and a brief description of the property.

Property	Default Value	Description
Algorithm	None	Defines the adaptive filter algorithm the object uses during adaptation
Coefficients	Vector of elements	Vector containing the initial filter coefficients. It must be a length l vector where l is the number of filter coefficients. coeffs defaults to length l vector of zeros when you do not provide the argument for input.
FilteredInputStates	l-1	Vector of filtered input states with length equal to l - 1.
FilterLength	Any positive integer	Reports the length of the filter, the number of coefficients or taps

Property	Default Value	Description
States	Vector of elements	Vector of the adaptive filter states. states defaults to a vector of zeros which has length equal to (l + projectord - 2)
SecondaryPathCoeffs	No default	A vector that contains the coefficient values of your secondary path from the output actuator to the error sensor
SecondaryPathEstimate	pathcoeffs values	An estimate of the secondary path filter model
SecondaryPathStates	Vector of size (length (pathcoeffs) -1) with all elements equal to zero.	The states of the secondary path FIR filter — the unknown system
StepSize	0.1	Sets the filtered-x algorithm step size used for each iteration of the adapting algorithm. Determines both how quickly and how closely the adaptive filter converges to the filter solution.

Examples

Demonstrate active noise control of a random noise signal over 1000 iterations.

As the figure that follows this code demonstrates, the filtered-x LMS filter successfully controls random noise in this context.

```
x  = randn(1,1000);      % Noise source
g  = fir1(47,0.4);       % FIR primary path system model
n  = 0.1*randn(1,1000);  % Observation noise signal
d  = filter(g,1,x)+n;    % Signal to be cancelled
b  = fir1(31,0.5);       % FIR secondary path system model
mu = 0.008;              % Filtered-X LMS step size
ha = adaptfilt.filtxlms(32,mu,1,b);
[y,e] = filter(ha,x,d); plot(1:1000,d,'b',1:1000,e,'r');
title('Active Noise Control of a Random Noise Signal');
legend('Original','Attenuated');
```

```
xlabel('Time Index'); ylabel('Signal Value');  grid on;
```

adaptfilt.ftf

Fast transversal LMS adaptive filter

Syntax

```
ha = adaptfilt.ftf(l,lambda,delta,gamma,gstates,coeffs,
states)
```

Description

`ha = adaptfilt.ftf(l,lambda,delta,gamma,gstates,coeffs, states)` constructs a fast transversal least squares adaptive filter object `ha`.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.ftf.`

Input Argument	Description
`l`	Adaptive filter length (the number of coefficients or taps) and it must be a positive integer. `l` defaults to 10.
`lambda`	RLS forgetting factor. This is a scalar that should lie in the range (1-0.5/`l`, 1]. `lambda` defaults to 1.
`delta`	Soft-constrained initialization factor. This scalar should be positive and sufficiently large to prevent an excessive number of Kalman gain rescues. `delta` defaults to one.
`gamma`	Conversion factor. `gamma` defaults to one specifying soft-constrained initialization.
`gstates`	States of the Kalman gain updates. `gstates` defaults to a zero vector of length `l`.

Input Argument	Description
coeffs	Length l vector of initial filter coefficients. coeffs defaults to a length l vector of zeros.
states	Vector of initial filter States. states defaults to a zero vector of length (l-1).

Properties

Since your adaptfilt.ftf filter is an object, it has properties that define its operating behavior. Note that many of the properties are also input arguments for creating adaptfilt.ftf objects. To show you the properties that apply, this table lists and describes each property for the fast transversal least squares filter object.

Name	Range	Description
Algorithm	None	Defines the adaptive filter algorithm the object uses during adaptation
BkwdPrediction		Returns the predicted samples generated during adaptation. Refer to “[2]” in the bibliography for details about linear prediction.
Coefficients	Vector of elements	Vector containing the initial filter coefficients. It must be a length l vector where l is the number of filter coefficients. coeffs defaults to length l vector of zeros when you do not provide the argument for input.
ConversionFactor		Conversion factor. Called gamma when it is an input argument, it defaults to the matrix [1 -1] that specifies soft-constrained initialization.
FilterLength	Any positive integer	Reports the length of the filter, the number of coefficients or taps
ForgettingFactor		RLS forgetting factor. This is a scalar that should lie in the range (1-0.5/l, 1]. lambda defaults to 1.

Name	Range	Description
FwdPrediction		Contains the predicted values for samples during adaptation. Compare these to the actual samples to get the error and power.
InitFactor		Soft-constrained initialization factor. This scalar should be positive and sufficiently large to prevent an excessive number of Kalman gain rescues. delta defaults to one.
KalmanGain		Empty when you construct the object, this gets populated after you run the filter.
PersistentMemory	false or true	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. PersistentMemory returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. Defaults to false.
States	Vector of elements, data type double	Vector of the adaptive filter states. states defaults to a vector of zeros which has length equal to (l + projectord - 2).

Examples

System Identification of a 32-coefficient FIR filter by running the identification process for 500 iterations.

```
x  = randn(1,500);    % Input to the filter
b  = fir1(31,0.5);    % FIR system to be identified
n  = 0.1*randn(1,500);% Observation noise signal
d  = filter(b,1,x)+n; % Desired signal
N  = 31;              % Adaptive filter order
lam = 0.99;           % RLS forgetting factor
del = 0.1;            % Soft-constrained initialization factor
ha = adaptfilt.ftf(32,lam,del);
```

```
[y,e] = filter(ha,x,d);
subplot(2,1,1); plot(1:500,[d;y;e]);
title('System Identification of an FIR Filter');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('signal value');
subplot(2,1,2); stem([b.',ha.Coefficients.']);
legend('Actual','Estimated'); grid on;
xlabel('coefficient #'); ylabel('Coefficient Value');
```

For this example of identifying an unknown system, the figure shows that the adaptation process identifies the filter coefficients for the unknown FIR filter within the first 150 iterations.

adaptfilt.gal

FIR adaptive filter that uses gradient lattice

Syntax

```
ha = adaptfilt.gal(l,step,leakage,offset,rstep,delta,
lambda,...rcoeffs,coeffs,states)
```

Description

`ha = adaptfilt.gal(l,step,leakage,offset,rstep,delta, lambda,...rcoeffs,coeffs,states)` constructs a gradient adaptive lattice FIR filter `ha`.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.gal`.

Input Argument	Description
`l`	Length of the joint process filter coefficients. It must be a positive integer and must be equal to the length of the reflection coefficients plus one. `l` defaults to 10.
`step`	Joint process step size of the adaptive filter. This scalar should be a value between zero and one. `step` defaults to 0.
`leakage`	Leakage factor of the adaptive filter. It must be a scalar between 0 and 1. Setting leakage less than one implements a leaky algorithm to estimate both the reflection and the joint process coefficients. `leakage` defaults to 1 (no leakage).
`offset`	Specifies an optional offset for the denominator of the step size normalization term. It must be a scalar greater or equal to zero. A non-zero `offset` is useful to avoid divide-by-near-zero conditions

Input Argument	Description
	when the input signal amplitude becomes very small. `offset` defaults to 1.
`rstep`	Reflection process step size of the adaptive filter. This scalar should be a value between zero and one. `rstep` defaults to `step`.
`delta`	Initial common value of the forward and backward prediction error powers. It should be a positive value. 0.1 is the default value for `delta`.
`lambda`	Specifies the averaging factor used to compute the exponentially windowed forward and backward prediction error powers for the coefficient updates. `lambda` should lie in the range (0, 1]. `lambda` defaults to the value (1 - `step`).
`rcoeffs`	Vector of initial reflection coefficients. It should be a length (l-1) vector. `rcoeffs` defaults to a zero vector of length (`l`-1).
`coeffs`	Vector of initial joint process filter coefficients. It must be a length `l` vector. `coeffs` defaults to a length l vector of zeros.
`states`	Vector of the backward prediction error states of the adaptive filter. `states` defaults to a zero vector of length (`l`-1).

Properties

Since your `adaptfilt.gal` filter is an object, it has properties that define its behavior in operation. Note that many of the properties are also input arguments for creating `adaptfilt.gal` objects. To show you the properties that apply, this table lists and describes each property for the affine projection filter object.

Name	Range	Description
`Algorithm`	None	Defines the adaptive filter algorithm the object uses during adaptation
`AvgFactor`		Specifies the averaging factor used to compute the exponentially-windowed forward and backward prediction error powers for the coefficient updates. Same as the input argument `lambda`.

Name	Range	Description
BkwdPredErrorPower		Returns the minimum mean-squared prediction error. Refer to “[2]” in the bibliography for details about linear prediction
Coefficients	Vector of elements	Vector containing the initial filter coefficients. It must be a length l vector where l is the number of filter coefficients. coeffs defaults to length l vector of zeros when you do not provide the argument for input.
FilterLength	Any positive integer	Reports the length of the filter, the number of coefficients or taps
FwdPredErrorPower		Returns the minimum mean-squared prediction error in the forward direction. Refer to “[2]” in the bibliography for details about linear prediction.
Leakage	0 to 1	Leakage parameter of the adaptive filter. If this parameter is set to a value between zero and one, you implement a leaky GAL algorithm. leakage defaults to 1 — no leakage provided in the algorithm.
Offset		Offset for the normalization terms in the coefficient updates. Use this to avoid dividing by zero or by very small numbers when input signal amplitude becomes very small. offset defaults to one.
PersistentMemory	false or true	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. PersistentMemory returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. Defaults to false.

Name	Range	Description
`ReflectionCoeffs`		Coefficients determined for the reflection portion of the filter during adaptation.
`ReflectionCoeffsStep`		Size of the steps used to determine the reflection coefficients.
`States`	Vector of elements	Vector of the adaptive filter states. `states` defaults to a vector of zeros which has length equal to (`l` + `projectord` - 2).
`StepSize`	0 to 1	Specifies the step size taken between filter coefficient updates

Examples

Perform a Quadrature Phase Shift Keying (QPSK) adaptive equalization using a 32-coefficient adaptive filter over 1000 iterations.

```
D  = 16;                     % Number of delay samples
b  = exp(1j*pi/4)*[-0.7 1];   % Numerator coefficients
a  = [1 -0.7];               % Denominator coefficients
ntr= 1000;                   % Number of iterations
s  = sign(randn(1,ntr+D)) + 1j*sign(randn(1,ntr+D)); % QPSK signal
n  = 0.1*(randn(1,ntr+D) + 1j*randn(1,ntr+D));   % Noise signal
r  = filter(b,a,s)+n;        % Received signal
x  = r(1+D:ntr+D);           % Input signal (received signal)
d  = s(1:ntr);               % Desired signal (delayed QPSK signal)
L = 32;                      % filter length
mu = 0.007;                  % Step size
ha = adaptfilt.gal(L,mu);
[y,e] = filter(ha,x,d);
subplot(2,2,1); plot(1:ntr,real([d;y;e]));
title('In-Phase Components');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('signal value');
subplot(2,2,2); plot(1:ntr,imag([d;y;e]));
title('Quadrature Components');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,2,3); plot(x(ntr-100:ntr),'.');  axis([-3 3 -3 3]);
title('Received Signal Scatter Plot');  axis('square');
xlabel('Real[x]'); ylabel('Imag[x]');  grid on;
subplot(2,2,4); plot(y(ntr-100:ntr),'.');
axis([-3 3 -3 3]); title('Equalized Signal Scatter Plot');
axis('square'); xlabel('Real[y]'); ylabel('Imag[y]');  grid on;
```

To see the results, look at this figure.

adaptfilt.hrls

FIR adaptive filter that uses householder (RLS)

Syntax

```
ha = adaptfilt.hrls(l,lambda,sqrtinvcov,coeffs,states)
```

Description

`ha = adaptfilt.hrls(l,lambda,sqrtinvcov,coeffs,states)` constructs an FIR householder RLS adaptive filter `ha`.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.hrls`.

Input Argument	Description
`l`	Adaptive filter length (the number of coefficients or taps) and it must be a positive integer. `l` defaults to 10.
`lambda`	RLS forgetting factor. This is a scalar and should lie in the range (0, 1]. `lambda` defaults to 1 meaning the adaptation process retains infinite memory.
`sqrtinvcov`	Square-root of the inverse of the sliding window input signal covariance matrix. This square matrix should be full-ranked.
`coeffs`	Vector of initial filter coefficients. It must be a length `l` vector. `coeffs` defaults to being a length `l` vector of zeros.
`states`	Vector of initial filter states. It must be a length `l`-1 vector. `states` defaults to a length `l`-1 vector of zeros.

Properties

Since your `adaptfilt.hrls` filter is an object, it has properties that define its behavior in operation. Note that many of the properties are also input arguments for creating `adaptfilt.hrls` objects. To show you the properties that apply, this table lists and describes each property for the affine projection filter object.

Name	Range	Description
`Algorithm`	None	Defines the adaptive filter algorithm the object uses during adaptation
`Coefficients`	Vector of elements	Vector containing the initial filter coefficients. It must be a length `l` vector where `l` is the number of filter coefficients. `coeffs` defaults to length `l` vector of zeros when you do not provide the argument for input.
`FilterLength`	Any positive integer	Reports the length of the filter, the number of coefficients or taps
`ForgettingFactor`	Scalar	RLS forgetting factor. This is a scalar and should lie in the range (0, 1]. Same as input argument `lambda`. It defaults to 1 meaning the adaptation process retains infinite memory.
`KalmanGain`	Vector of size (`l`,1)	Empty when you construct the object, this gets populated after you run the filter.
`PersistentMemory`	`false` or `true`	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. `PersistentMemory` returns to zero any state that the filter changes during processing. Defaults to `false`.
`SqrtInvCov`	Matrix of doubles	Square root of the inverse of the sliding window input signal covariance matrix. This square matrix should be full-ranked.

Name	Range	Description
`States`	Vector of elements, data type double	Vector of the adaptive filter states. `states` defaults to a vector of zeros which has length equal to (`l` - 1).

Examples

Use 500 iterations of an adaptive filter object to identify a 32-coefficient FIR filter system. Both the example code and the resulting figure show the successful filter identification through adaptive filter processing.

```
x  = randn(1,500);     % Input to the filter
b  = fir1(31,0.5);     % FIR system to be identified
n  = 0.1*randn(1,500); % Observation noise signal
d  = filter(b,1,x)+n;  % Desired signal
G0 = sqrt(10)*eye(32); % Initial sqrt correlation matrix inverse
lam = 0.99;            % RLS forgetting factor
ha = adaptfilt.hrls(32,lam,G0);
[y,e] = filter(ha,x,d);
subplot(2,1,1); plot(1:500,[d;y;e]);
title('System Identification of an FIR Filter');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,1,2); stem([b.',ha.Coefficients.']);
legend('Actual','Estimated'); grid on;
 xlabel('Coefficient #'); ylabel('Coefficient Value');
```

adaptfilt.hswrls | adaptfilt.qrdrls | adaptfilt.rls

adaptfilt.hswrls

FIR adaptive filter that uses householder sliding window RLS

Syntax

```
ha = adaptfilt.hswrls(l,lambda,sqrtinvcov,swblocklen,
dstates,coeffs,states)
```

Description

`ha = adaptfilt.hswrls(l,lambda,sqrtinvcov,swblocklen, dstates,coeffs,states)` constructs an FIR householder sliding window recursive-least-square adaptive filter `ha`.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.hswrls`.

Input Argument	Description
`l`	Adaptive filter length (the number of coefficients or taps) and it must be a positive integer. `l` defaults to 10.
`lambda`	Recursive least square (RLS) forgetting factor. This is a scalar and should lie in the range (0, 1]. `lambda` defaults to 1 meaning the adaptation process retains infinite memory.
`sqrtinvcov`	Square-root of the inverse of the sliding window input signal covariance matrix. This square matrix should be full-ranked.
`swblocklen`	Block length of the sliding window. This integer must be at least as large as the filter length. `swblocklen` defaults to 16.
`dstates`	Desired signal states of the adaptive filter. `dstates` defaults to a zero vector with length equal to (`swblocklen` - 1).
`coeffs`	Vector of initial filter coefficients. It must be a length `l` vector. `coeffs` defaults to being a length `l` vector of zeros.

Input Argument	Description
states	Vector of initial filter states. It must be a length (l + swblocklen - 2) vector. states defaults to a length (l + swblocklen -2) vector of zeros.

Properties

Since your adaptfilt.hswrls filter is an object, it has properties that define its behavior in operation. Note that many of the properties are also input arguments for creating adaptfilt.hswrls objects. To show you the properties that apply, this table lists and describes each property for the affine projection filter object.

Name	Range	Description
Algorithm	None	Defines the adaptive filter algorithm the object uses during adaptation
Coefficients	Vector of elements	Vector containing the initial filter coefficients. It must be a length l vector where l is the number of filter coefficients. coeffs defaults to length l vector of zeros when you do not provide the argument for input.
DesiredSignalStates	Vector	Desired signal states of the adaptive filter. dstates defaults to a zero vector with length equal to (swblocklen - 1).
FilterLength	Any positive integer	Reports the length of the filter, the number of coefficients or taps
ForgettingFactor	Scalar	Root-least-square (RLS) forgetting factor. This is a scalar and should lie in the range (0, 1]. Same as input argument lambda. It defaults to 1 meaning the adaptation process retains infinite memory.
KalmanGain	(l,1) vector	Empty when you construct the object, this gets populated after you run the filter.

Name	Range	Description
`PersistentMemory`	`false` or `true`	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. `PersistentMemory` returns to zero any state that the filter changes during processing. Defaults to `false`.
`SqrtInvCov`	`l`-by-`l` Matrix	Square-root of the inverse of the sliding window input signal covariance matrix. This square matrix should be full-ranked.
`States`	Vector of elements, data type double	Vector of the adaptive filter states. `states` defaults to a vector of zeros which has length equal to (`l` + `projectord` - 2).
`SwBlockLength`	Integer	Block length of the sliding window. This integer must be at least as large as the filter length. `swblocklen` defaults to 16.

Examples

System Identification of a 32-coefficient FIR filter.

```
x  = randn(1,500);     % Input to the filter
b  = fir1(31,0.5);     % FIR system to be identified
n  = 0.1*randn(1,500); % Observation noise signal
d  = filter(b,1,x)+n;  % Desired signal
G0 = sqrt(10)*eye(32); % Initial sqrt correlation matrix inverse
lam = 0.99;            % RLS forgetting factor
N  = 64;               % block length
ha = adaptfilt.hswrls(32,lam,G0,N);
[y,e] = filter(ha,x,d);
subplot(2,1,1); plot(1:500,[d;y;e]);
title('System Identification of an FIR Filter');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,1,2); stem([b.',ha.Coefficients.']);
```

```
legend('Actual','Estimated'); grid on;
xlabel('Coefficient #'); ylabel('Coefficient Value');
```

In the pair of plots shown in the figure you see the comparison of the desired and actual output for the adapting filter and the coefficients of both filters, the unknown and the adapted.

adaptfilt.lms

FIR adaptive filter that uses LMS

Syntax

```
ha = adaptfilt.lms(l,step,leakage,coeffs,states)
```

Description

`ha = adaptfilt.lms(l,step,leakage,coeffs,states)` constructs an FIR LMS adaptive filter object `ha.`

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.lms`.

Input Argument	Description
`l`	Adaptive filter length (the number of coefficients or taps) and it must be a positive integer. `l` defaults to 10.
`step`	LMS step size. It must be a nonnegative scalar. You can use `maxstep` to determine a reasonable range of step size values for the signals being processed. `step` defaults to 0.1.
`leakage`	Your LMS leakage factor. It must be a scalar between 0 and 1. When `leakage` is less than one, `adaptfilt.lms` implements a leaky LMS algorithm. When you omit the `leakage` property in the calling syntax, it defaults to 1 providing no leakage in the adapting algorithm.
`coeffs`	Vector of initial filter coefficients. it must be a length `l` vector. `coeffs` defaults to length `l` vector with elements equal to zero.
`states`	Vector of initial filter states for the adaptive filter. It must be a length `l`-1 vector. `states` defaults to a length l-1 vector of zeros.

Properties

In the syntax for creating the `adaptfilt` object, the input options are properties of the object created. This table lists the properties for the `adaptfilt.lms` object, their default values, and a brief description of the property.

Property	Range	Property Description
`Algorithm`	None	Reports the adaptive filter algorithm the object uses during adaptation
`Coefficients`	Vector of elements	Vector containing the initial filter coefficients. It must be a length `l` vector where `l` is the number of filter coefficients. `coeffs` defaults to a length `l` vector of zeros when you do not provide the vector as an input argument.
`FilterLength`	Any positive integer	Reports the length of the filter, the number of coefficients or taps
`Leakage`	0 to 1	LMS leakage factor. It must be a scalar between zero and one. When it is less than one, a leaky NLMS algorithm results. `leakage` defaults to 1 (no leakage).
`PersistentMemory`	`false` or `true`	Determine whether the filter states and coefficients get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter. `PersistentMemory` returns to zero any property value that the filter changes during processing. Property values that the filter does not change are not affected. Defaults to `false`.
`States`	Vector of elements, data type double	Vector of the adaptive filter states. `states` defaults to a vector of zeros which has length equal to (`l` - 1).
`StepSize`	0 to 1	LMS step size. It must be a scalar between zero and one. Setting this step

Property	Range	Property Description
		size value to one provides the fastest convergence. `step` defaults to 0.1.

Examples

Use 500 iterations of an adapting filter system to identify and unknown 32nd-order FIR filter.

```
x  = randn(1,500);     % Input to the filter
b  = fir1(31,0.5);     % FIR system to be identified
n  = 0.1*randn(1,500); % Observation noise signal
d  = filter(b,1,x)+n;  % Desired signal
mu = 0.008;            % LMS step size.
ha = adaptfilt.lms(32,mu);
[y,e] = filter(ha,x,d);
subplot(2,1,1); plot(1:500,[d;y;e]);
title('System Identification of an FIR Filter');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,1,2); stem([b.',ha.coefficients.']);
legend('Actual','Estimated');
xlabel('Coefficient #'); ylabel('Coefficient Value');  grid on;
```

Using LMS filters in an adaptive filter architecture is a time honored means for identifying an unknown filter. By running the example code provided you can demonstrate one process to identify an unknown FIR filter.

adaptfilt.lsl

Least squares lattice adaptive filter

Syntax

```
ha = adaptfilt.lsl(l,lambda,delta,coeffs,states)
```

Description

`ha = adaptfilt.lsl(l,lambda,delta,coeffs,states)` constructs a least squares lattice adaptive filter ha.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.lsl`.

Input Argument	Description
`l`	Length of the joint process filter coefficients. It must be a positive integer and must be equal to the length of the prediction coefficients plus one. L defaults to 10.
`lambda`	Forgetting factor of the adaptive filter. This is a scalar and should lie in the range (0, 1]. `lambda` defaults to 1. `lambda` = 1 denotes infinite memory while adapting to find the new filter.
`delta`	Soft-constrained initialization factor in the least squares lattice algorithm. It should be positive. `delta` defaults to 1.
`coeffs`	Vector of initial joint process filter coefficients. It must be a length `l` vector. `coeffs` defaults to a length `l` vector of all zeros.
`states`	Vector of the backward prediction error states of the adaptive filter. `states` defaults to a length `l` vector of all zeros, specifying soft-constrained initialization for the algorithm.

Properties

Since your `adaptfilt.lsl` filter is an object, it has properties that define its behavior in operation. Note that many of the properties are also input arguments for creating `adaptfilt.lsl` objects. To show you the properties that apply, this table lists and describes each property for the filter object.

Name	Range	Description
`Algorithm`	None	Defines the adaptive filter algorithm the object uses during adaptation.
`BkwdPrediction`		Returns the predicted samples generated during adaptation. Refer to “[2]” in the bibliography for details about linear prediction.
`Coefficients`	Vector of elements	Vector containing the initial filter coefficients. It must be a length `l` vector where `l` is the number of filter coefficients. `coeffs` defaults to length `l` vector of zeros when you do not provide the argument for input.
`FilterLength`	Any positive integer	Reports the length of the filter, the number of coefficients or taps.
`ForgettingFactor`		Forgetting factor of the adaptive filter. This is a scalar and should lie in the range (0, 1]. It defaults to 1. Setting `forgetting factor =` 1 denotes infinite memory while adapting to find the new filter. Note that this is the `lambda` input argument.
`FwdPrediction`		Contains the predicted values for samples during adaptation. Compare these to the actual samples to get the error and power.
`InitFactor`		Soft-constrained initialization factor. This scalar should be positive and sufficiently large to prevent an

Name	Range	Description
		excessive number of Kalman gain rescues. `delta` defaults to one.
`PersistentMemory`	`false` or `true`	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. `PersistentMemory` returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. Defaults to `false`.
`States`	Vector of elements, data type double	Vector of the adaptive filter states. `states` defaults to a vector of zeros which has length equal to `l`.

Examples

Demonstrate Quadrature Phase Shift Keying (QPSK) adaptive equalization using a 32-coefficient adaptive filter running for 1000 iterations. After you review the example code, the figure shows the results of running the example to use QPSK adaptive equalization with a 32nd-order FIR filter. The error between the in-phase and quadrature components, as shown by the errors plotted in the upper plots, falls to near zero. Also, the equalized signal shows the clear quadrature nature.

```
D  = 16;                      % Number of samples of delay
b  = exp(1j*pi/4)*[-0.7 1];    % Numerator coefficients of channel
a  = [1 -0.7];                % Denominator coefficients of channel
ntr= 1000;                    % Number of iterations
s  = sign(randn(1,ntr+D))+1j*sign(randn(1,ntr+D));  % QPSK signal
n  = 0.1*(randn(1,ntr+D) + 1j*randn(1,ntr+D));      % Noise signal
r  = filter(b,a,s)+n;         % Received signal
x  = r(1+D:ntr+D);            % Input signal (received signal)
d  = s(1:ntr);                % Desired signal (delayed QPSK signal)
lam = 0.995;                  % Forgetting factor
del = 1;                      % initialization factor
ha = adaptfilt.lsl(32,lam,del);
[y,e] = filter(ha,x,d);
subplot(2,2,1); plot(1:ntr,real([d;y;e]));
title('In-Phase Components');
```

```
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,2,2); plot(1:ntr,imag([d;y;e]));
title('Quadrature Components');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,2,3); plot(x(ntr-100:ntr),'.');  axis([-3 3 -3 3]);
title('Received Signal Scatter Plot');  axis('square');
xlabel('Real[x]'); ylabel('Imag[x]');  grid on;
subplot(2,2,4); plot(y(ntr-100:ntr),'.');  axis([-3 3 -3 3]);
title('Equalized Signal Scatter Plot');  grid on;
axis('square'); xlabel('Real[y]'); ylabel('Imag[y]');
```

adaptfilt.nlms

Normalized least mean squares adaptive filter

Syntax

```
ha = adaptfilt.nlms(l,step,leakage,offset,coeffs,states)
```

Description

`ha = adaptfilt.nlms(l,step,leakage,offset,coeffs,states)` constructs a normalized least-mean squares (NLMS) FIR adaptive filter object named `ha.`

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.nlms`.

Input Argument	Description
`l`	Adaptive filter length (the number of coefficients or taps) and it must be a positive integer. `l` defaults to 10.
`step`	NLMS step size. It must be a scalar between 0 and 2. Setting this step size value to one provides the fastest convergence. `step` defaults to 1.
`leakage`	NLMS leakage factor. It must be a scalar between zero and one. When it is less than one, a leaky NLMS algorithm results. `leakage` defaults to 1 (no leakage).
`offset`	Specifies an optional offset for the denominator of the step size normalization term. You must specify offset to be a scalar greater than or equal to zero. Nonzero offsets can help avoid a divide-by-near-zero condition that causes errors. Use this to avoid dividing by zero (or by very small numbers) when the square of the input data norm becomes very small (when the

Input Argument	Description
	input signal amplitude becomes very small). When you omit it, `offset` defaults to zero.
`coeffs`	Vector composed of your initial filter coefficients. Enter a length `l` vector. `coeffs` defaults to a vector of zeros with length equal to the filter order.
`states`	Your initial adaptive filter states appear in the `states` vector. It must be a vector of length `l`-1. `states` defaults to a length `l`-1 vector with zeros for all of the elements.

Properties

In the syntax for creating the `adaptfilt` object, the input options are properties of the object you create. This table lists the properties for normalized LMS objects, their default values, and a brief description of the property.

Property	Range	Property Description
`Algorithm`	None	Reports the adaptive filter algorithm the object uses during adaptation
`Coefficients`	Vector of elements	Vector containing the initial filter coefficients. It must be a length `l` vector where `l` is the number of filter coefficients. `coeffs` defaults to length `l` vector of zeros when you do not provide the argument for input.
`FilterLength`	Any positive integer	Reports the length of the filter, the number of coefficients or taps
`Leakage`	0 to 1	NLMS leakage factor. It must be a scalar between zero and one. When it is less than one, a leaky NLMS algorithm results. `leakage` defaults to 1 (no leakage).
`Offset`	0 or greater	Specifies an optional offset for the denominator of the step size normalization term. You must specify offset to be a scalar greater than or equal to zero. Nonzero

Property	Range	Property Description
		offsets can help avoid a divide-by-near-zero condition that causes errors. Use this to avoid dividing by zero (or by very small numbers) when the square of the input data norm becomes very small (when the input signal amplitude becomes very small). When you omit it, `offset` defaults to zero.
`PersistentMemory`	`false` or `true`	Determine whether the filter states and coefficients get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter. `PersistentMemory` returns to zero any property value that the filter changes during processing. Property values that the filter does not change are not affected. Defaults to `false`.
`States`	Vector of elements, data type double	Vector of the adaptive filter states. `states` defaults to a vector of zeros which has length equal to (`l` - 1).
`StepSize`	0 to 1	NLMS step size. It must be a scalar between zero and one. Setting this step size value to one provides the fastest convergence. `step` defaults to one.

Examples

To help you compare this algorithm's performance to other LMS-based algorithms, such as BLMS or LMS, this example demonstrates the NLMS adaptive filter in use to identify the coefficients of an unknown FIR filter of order equal to 32 — an example used in other adaptive filter examples.

```
x  = randn(1,500);     % Input to the filter
b  = fir1(31,0.5);     % FIR system to be identified
n  = 0.1*randn(1,500); % Observation noise signal
d  = filter(b,1,x)+n;  % Desired signal
mu = 1;                % NLMS step size
```

```
offset = 50;           % NLMS offset
ha = adaptfilt.nlms(32,mu,1,offset);
[y,e] = filter(ha,x,d);
subplot(2,1,1);
plot(1:500,[d;y;e]);
legend('Desired','Output','Error');
title('System Identification of FIR Filter');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,1,2);
stem([b', ha.coefficients']);
legend('Actual','Estimated'); grid on;
xlabel('Coefficient #'); ylabel('Coefficient Value');
```

As you see from the figure, the `nlms` variant again closely matches the actual filter coefficients in the unknown FIR filter.

adaptfilt.pbfdaf

Partitioned block frequency-domain FIR adaptive filter

Syntax

```
ha = adaptfilt.pbfdaf(l,step,leakage,delta,lambda,blocklen,
offset,coeffs,states)
```

Description

`ha = adaptfilt.pbfdaf(l,step,leakage,delta,lambda,blocklen, offset,coeffs,states)` constructs a partitioned block frequency-domain FIR adaptive filter `ha` that uses bin step size normalization during adaptation.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.pbfdaf`.

Input Argument	Description
`l`	Adaptive filter length (the number of coefficients or taps) and it must be a positive integer. L defaults to 10.
`step`	Step size of the adaptive filter. This is a scalar and should lie in the range (0,1]. `step` defaults to 1.
`leakage`	Leakage parameter of the adaptive filter. When you set this argument to a value between zero and one, a leaky version of the PBFDAF algorithm is implemented. `leakage` defaults to 1— no leakage.
`delta`	Initial common value of all of the FFT input signal powers. Its initial value should be positive. delta defaults to 1.
`lambda`	Averaging factor used to compute the exponentially windowed FFT input signal powers for the coefficient updates. `lambda` should lie in the range (0,1]. `lambda` defaults to 0.9.

Input Argument	Description
blocklen	Block length for the coefficient updates. This must be a positive integer such that (l/blocklen) is also an integer. For faster execution, blocklen should be a power of two. blocklen defaults to two.
offset	Offset for the normalization terms in the coefficient updates. This can be useful to avoid divide by zeros conditions, or dividing by very small numbers, if any of the FFT input signal powers become very small. offset defaults to zero.
coeffs	Initial time-domain coefficients of the adaptive filter. It should be a vector of length l. The PBFDAF algorithm uses these coefficients to compute the initial frequency-domain filter coefficient matrix via FFTs.
states	Specifies the filter initial conditions. states defaults to a zero vector of length l.

Properties

Since your adaptfilt.pbfdaf filter is an object, it has properties that define its behavior in operation. Note that many of the properties are also input arguments for creating adaptfilt.pbfdaf objects. To show you the properties that apply, this table lists and describes each property for the filter object.

Name	Range	Description
Algorithm	None	Defines the adaptive filter algorithm the object uses during adaptation.
AvgFactor		Averaging factor used to compute the exponentially windowed FFT input signal powers for the coefficient updates. AvgFactor should lie in the range (0,1]. AvgFactor defaults to 0.9. Called lambda as an input argument.
BlockLength		Block length for the coefficient updates. This must be a positive integer such that (l/blocklen) is also an integer. For

Name	Range	Description
		faster execution, blocklen should be a power of two. blocklen defaults to two.
FilterLength	Any positive integer	Reports the length of the filter, the number of coefficients or taps.
FFTCoefficients		Stores the discrete Fourier transform of the filter coefficients in coeffs.
FFTStates		States for the FFT operation.
Leakage	0 to 1	Leakage parameter of the adaptive filter. When you set this argument to a value between zero and one, a leaky version of the PBFDAF algorithm is implemented. leakage defaults to 1 — no leakage.
Offset		Offset for the normalization terms in the coefficient updates. This can be useful to avoid divide by zeros conditions, or dividing by very small numbers, if any of the FFT input signal powers become very small. offset defaults to zero.
PersistentMemory	false or true	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter. PersistentMemory returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. Defaults to false.
Power		A vector of 2*l elements, each initialized with the value delta from the input arguments. As you filter data, Power gets updated by the filter process.
StepSize	0 to 1	Step size of the adaptive filter. This is a scalar and should lie in the range (0,1]. step defaults to 1.

Examples

An example of Quadrature Phase Shift Keying (QPSK) adaptive equalization using a 32-coefficient FIR filter.

```
D  = 16;                       % Number of samples of delay
b  = exp(1j*pi/4)*[-0.7 1];     % Numerator coefficients of channel
a  = [1 -0.7];                 % Denominator coefficients of channel
ntr = 1000;                    % Number of iterations
s  = sign(randn(1,ntr+D))+1j*sign(randn(1,ntr+D)); % Baseband QPSK signal
n  = 0.1*(randn(1,ntr+D) + 1j*randn(1,ntr+D));     % Noise signal
r  = filter(b,a,s)+n;    % Received signal
x  = r(1+D:ntr+D);             % Input signal (received signal)
d  = s(1:ntr);                  % Desired signal (delayed QPSK signal)
del = 1;                        % Initial FFT input powers
mu  = 0.1;                      % Step size
lam = 0.9;                      % Averaging factor
N   = 8;                        % Block size
ha = adaptfilt.pbfdaf(32,mu,1,del,lam,N);
[y,e] = filter(ha,x,d);
subplot(2,2,1); plot(1:ntr,real([d;y;e])); title('In-Phase Components');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,2,2); plot(1:ntr,imag([d;y;e]));
title('Quadrature Components');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,2,3); plot(x(ntr-100:ntr),'.');  axis([-3 3 -3 3]);
 title('Received Signal Scatter Plot');
axis('square');  xlabel('Real[x]'); ylabel('Imag[x]');  grid on;
subplot(2,2,4); plot(y(ntr-100:ntr),'.');  axis([-3 3 -3 3]);
title('Equalized Signal Scatter Plot');
axis('square'); xlabel('Real[y]'); ylabel('Imag[y]');  grid on;subplot(2,2,4); plot(y(ntr-100:ntr),'.');  ax
title('Equalized Signal Scatter Plot');
axis('square'); xlabel('Real[y]'); ylabel('Imag[y]');  grid on;
```

In the figure shown, the four subplots provide the details of the results of the QPSK process used in the equalization for this example.

adaptfilt.pbufdaf

Partitioned block unconstrained frequency-domain adaptive filter

Syntax

```
ha = adaptfilt.pbufdaf(l,step,leakage,delta,lambda,
blocklen,...offset,coeffs,states)
```

Description

`ha = adaptfilt.pbufdaf(l,step,leakage,delta,lambda, blocklen,...offset,coeffs,states)` constructs a partitioned block unconstrained frequency-domain FIR adaptive filter `ha` with bin step size normalization.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.pbufdaf`.

Input Argument	Description
`l`	Adaptive filter length (the number of coefficients or taps) and it must be a positive integer. L defaults to 10.
`step`	Step size of the adaptive filter. This is a scalar and should lie in the range (0,1]. `step` defaults to 1.
`leakage`	Leakage parameter of the adaptive filter. When you set this argument to a value between zero and one, a leaky version of the PBFDAF algorithm is implemented. `leakage` defaults to 1 — no leakage.
`delta`	Initial common value of all of the FFT input signal powers. Its initial value should be positive. delta defaults to 1.
`lambda`	Averaging factor used to compute the exponentially windowed FFT input signal powers for the coefficient updates. `lambda` should lie in the range (0,1]. `lambda` defaults to 0.9.

Input Argument	Description
`blocklen`	Block length for the coefficient updates. This must be a positive integer such that (`l/blocklen`) is also an integer. For faster execution, `blocklen` should be a power of two. `blocklen` defaults to two.
`offset`	Offset for the normalization terms in the coefficient updates. This can be useful to avoid divide by zeros conditions, or dividing by very small numbers, if any of the FFT input signal powers become very small. `offset` defaults to zero.
`coeffs`	Initial time-domain coefficients of the adaptive filter. It should be a vector of length `l`. The PBFDAF algorithm uses these coefficients to compute the initial frequency-domain filter coefficient matrix via FFTs.
`states`	Specifies the filter initial conditions. `states` defaults to a zero vector of length `l`.

Properties

Since your `adaptfilt.pbufdaf` filter is an object, it has properties that define its behavior in operation. Note that many of the properties are also input arguments for creating `adaptfilt.pbufdaf` objects. To show you the properties that apply, this table lists and describes each property for the filter object.

Name	Range	Description
`Algorithm`	None	Defines the adaptive filter algorithm the object uses during adaptation
`AvgFactor`		Averaging factor used to compute the exponentially windowed FFT input signal powers for the coefficient updates. `AvgFactor` should lie in the range (0,1]. `AvgFactor` defaults to 0.9. Called `lambda` as an input argument.
`BlockLength`		Block length for the coefficient updates. This must be a positive integer such that (`l/blocklen`) is also an integer. For

Name	Range	Description
		faster execution, blocklen should be a power of two. blocklen defaults to two.
FilterLength	Any positive integer	Reports the length of the filter, the number of coefficients or taps
FFTCoefficients		Stores the discrete Fourier transform of the filter coefficients in coeffs.
FFTStates		States for the FFT operation.
Leakage	0 to 1	Leakage parameter of the adaptive filter. When you set this argument to a value between zero and one, a leaky version of the PBFDAF algorithm is implemented. leakage defaults to 1 — no leakage.
Offset		Offset for the normalization terms in the coefficient updates. This can be useful to avoid divide by zeros conditions, or dividing by very small numbers, if any of the FFT input signal powers become very small.voffset defaults to zero.
PersistentMemory	false or true	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter. PersistentMemory returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. Defaults to false.
Power	2*l element vector	A vector of 2*l elements, each initialized with the value delta from the input arguments. As you filter data, Power gets updated by the filter process.
StepSize	0 to 1	Step size of the adaptive filter. This is a scalar and should lie in the range (0,1]. step defaults to 1.

Examples

Demonstrating Quadrature Phase Shift Keying (QPSK) adaptive equalization using a 32-coefficient FIR filter. To perform the equalization, this example runs for 1000 iterations.

```
D  = 16;      % Number of samples of delay
b  = exp(1j*pi/4)*[-0.7 1]; % Numerator coefficients of channel
a  = [1 -0.7];             % Denominator coefficients of channel
ntr= 1000;                 % Number of iterations
s  = sign(randn(1,ntr+D))+1j*sign(randn(1,ntr+D)); % Baseband QPSK signal
n  = 0.1*(randn(1,ntr+D) + 1j*randn(1,ntr+D)); % Noise signal
r  = filter(b,a,s)+n;          % Received signal
x  = r(1+D:ntr+D);             % Input signal (received signal)
d  = s(1:ntr);                 % Desired signal (delayed QPSK signal)
del = 1;                       % Initial FFT input powers
mu  = 0.1;                     % Step size
lam = 0.9;                     % Averaging factor
N   = 8;                       % Block size
ha = adaptfilt.pbufdaf(32,mu,1,del,lam,N);
[y,e] = filter(ha,x,d);

title('In-Phase Components'); legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,2,2); plot(1:ntr,imag([d;y;e]));
title('Quadrature Components');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,2,3); plot(x(ntr-100:ntr),'.'); axis([-3 3 -3 3]);
title('Received Signal Scatter Plot'); axis('square');
xlabel('Real[x]'); ylabel('Imag[x]'); grid on;
subplot(2,2,4); plot(y(ntr-100:ntr),'.'); axis([-3 3 -3 3]);
title('Equalized Signal Scatter Plot'); axis('square');
xlabel('Real[y]'); ylabel('Imag[y]'); grid on;
```

You can compare this algorithm to another, such as the `pbfdaf` version. Use the same example of QPSK adaptation. The following figure shows the results.

adaptfilt.qrdlsl

QR-decomposition-based least-squares lattice adaptive filter

Syntax

```
ha = adaptfilt.qrdlsl(l,lambda,delta,coeffs,states)
```

Description

`ha = adaptfilt.qrdlsl(l,lambda,delta,coeffs,states)` returns a QR-decomposition-based least squares lattice adaptive filter `ha`.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.qrdlsl`.

Input Argument	Description
`l`	Length of the joint process filter coefficients. It must be a positive integer and must be equal to the length of the prediction coefficients plus one. L defaults to 10.
`lambda`	Forgetting factor of the adaptive filter. This is a scalar and should lie in the range (0, 1]. `lambda` defaults to 1. `lambda` = 1 denotes infinite memory while adapting to find the new filter.
`delta`	Soft-constrained initialization factor in the least squares lattice algorithm. It should be positive. `delta` defaults to 1.
`coeffs`	Vector of initial joint process filter coefficients. It must be a length `l` vector. `coeffs` defaults to a length `l` vector of all zeros.
`states`	Vector of the angle normalized backward prediction error states of the adaptive filter

Properties

Since your `adaptfilt.qrdlsl` filter is an object, it has properties that define its behavior in operation. Note that many of the properties are also input arguments for creating `adaptfilt.qrdlsl` objects. To show you the properties that apply, this table lists and describes each property for the filter object.

Name	Range	Description
`Algorithm`	None	Defines the adaptive filter algorithm the object uses during adaptation
`BkwdPrediction`		Returns the predicted samples generated during adaptation. Refer to “[2]” in the bibliography for details about linear prediction.
`Coefficients`	Vector of elements	Vector containing the initial filter coefficients. It must be a length `l` vector where `l` is the number of filter coefficients. `coeffs` defaults to length `l` vector of zeros when you do not provide the argument for input.
`FilterLength`	Any positive integer	Reports the length of the filter, the number of coefficients or taps
`ForgettingFactor`		Forgetting factor of the adaptive filter. This is a scalar and should lie in the range (0, 1]. It defaults to 1. Setting `forgetting factor` = 1 denotes infinite memory while adapting to find the new filter. Note that this is the `lambda` input argument.
`FwdPrediction`		Returns the predicted samples generated during adaptation in the forward direction. Refer to “[2]” in the bibliography for details about linear prediction.
`InitFactor`		Soft-constrained initialization factor. This scalar should be positive and sufficiently large to prevent an excessive number of

Name	Range	Description
		Kalman gain rescues. `delta` defaults to one.
`PersistentMemory`	`false` or `true`	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. `PersistentMemory` returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. Defaults to `false`.
`States`	Vector of elements, data type double	Vector of the adaptive filter states. `states` defaults to a vector of zeros which has length equal to `l -1`

Examples

Implement Quadrature Phase Shift Keying (QPSK) adaptive equalization using a 32-coefficient adaptive filter. To see the results of the equalization process in this example, look at the figure that follows the example code.

```
D  = 16;                       % Number of samples of delay
b  = exp(1j*pi/4)*[-0.7 1];     % Numerator coefficients of channel
a  = [1 -0.7];                 % Denominator coefficients of channel
ntr= 1000;                     % Number of iterations
s  = sign(randn(1,ntr+D))+1j*sign(randn(1,ntr+D)); % Baseband  QPSK signal
n  = 0.1*(randn(1,ntr+D) + 1j*randn(1,ntr+D));   % Noise signal
r  = filter(b,a,s)+n;      % Received signal
x  = r(1+D:ntr+D);         % Input signal (received signal)
d  = s(1:ntr);             % Desired signal (delayed QPSK signal)
lam = 0.995;               % Forgetting factor
del = 1;                   % Soft-constrained initialization factor
ha = adaptfilt.qrdlsl(32,lam,del);
[y,e] = filter(ha,x,d);
subplot(2,2,1); plot(1:ntr,real([d;y;e]));
title('In-Phase Components'); legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,2,2); plot(1:ntr,imag([d;y;e]));
title('Quadrature Components'); legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
```

```
subplot(2,2,3); plot(x(ntr-100:ntr),'.'); axis([-3 3 -3 3]);
title('Received Signal Scatter Plot'); axis('square');
xlabel('Real[x]'); ylabel('Imag[x]'); grid on;
subplot(2,2,4); plot(y(ntr-100:ntr),'.'); axis([-3 3 -3 3]);
title('Equalized Signal Scatter Plot'); axis('square');
xlabel('Real[y]'); ylabel('Imag[y]'); grid on;
```

`adaptfilt.qrdrls` | `adaptfilt.gal` | `adaptfilt.ftf` | `adaptfilt.lsl`

adaptfilt.qrdrls

FIR adaptive filter that uses QR-decomposition-based RLS

Syntax

```
ha = adaptfilt.qrdrls(l,lambda,sqrtcov,coeffs,states)
```

Description

`ha = adaptfilt.qrdrls(l,lambda,sqrtcov,coeffs,states)` constructs an FIR QR-decomposition-based recursive-least squares (RLS) adaptive filter object `ha`.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.qrdrls`.

Input Argument	Description
`l`	Adaptive filter length (the number of coefficients or taps) and it must be a positive integer.`l` defaults to 10.
`lambda`	RLS forgetting factor. This is a scalar and should lie within the range (0, 1]. `lambda` defaults to 1.
`sqrtcov`	Upper-triangular Cholesky (square root) factor of the input covariance matrix. Initialize this matrix with a positive definite upper triangular matrix.
`coeffs`	Vector of initial filter coefficients. It must be a length `l` vector. `coeffs` defaults to length `l` vector whose elements are zeros.
`states`	Vector of initial filter states. It must be a length `l`-1 vector. `states` defaults to a length `l`-1 vector of zeros.

Properties

Since your `adaptfilt.qrdrls` filter is an object, it has properties that define its behavior in operation. Note that many of the properties are also input arguments for creating `adaptfilt.qrdrls` objects. To show you the properties that apply, this table lists and describes each property for the filter object.

Name	Range	Description
`Algorithm`	None	Defines the adaptive filter algorithm the object uses during adaptation
`Coefficients`	Vector of length `l`	Vector containing the initial filter coefficients. It must be a length `l` vector where `l` is the number of filter coefficients. `coeffs` defaults to length `l` vector of zeros when you do not provide the argument for input.
`FilterLength`	Any positive integer	Reports the length of the filter, the number of coefficients or taps
`ForgettingFactor`	Scalar	Forgetting factor of the adaptive filter. This is a scalar and should lie in the range (0, 1]. It defaults to 1. Setting `forgetting factor` = 1 denotes infinite memory while adapting to find the new filter. Note that this is the `lambda` input argument.
`PersistentMemory`	`false` or `true`	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. `PersistentMemory` returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. Defaults to `false`.

Name	Range	Description
SqrtCov	Square matrix with each dimension equal to the filter length l	Upper-triangular Cholesky (square root) factor of the input covariance matrix. Initialize this matrix with a positive definite upper triangular matrix.
States	Vector of elements	Vector of the adaptive filter states. states defaults to a vector of zeros which has length equal to (l + projectord - 2).

Examples

System Identification of a 32-coefficient FIR filter (500 iterations).

```
x  = randn(1,500);       % Input to the filter
b  = fir1(31,0.5);       % FIR system to be identified
n  = 0.1*randn(1,500);   % Observation noise signal
d  = filter(b,1,x)+n;    % Desired signal
G0 = sqrt(.1)*eye(32);   % Initial sqrt correlation matrix
lam = 0.99;              % RLS forgetting factor
ha = adaptfilt.qrdrls(32,lam,G0);
[y,e] = filter(ha,x,d);
subplot(2,1,1); plot(1:500,[d;y;e]);
title('System Identification of an FIR Filter');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,1,2); stem([b.',ha.Coefficients.']);
legend('Actual','Estimated'); grid on;
xlabel('Coefficient #'); ylabel('Coefficient Value');
```

Using this variant of the RLS algorithm successfully identifies the unknown FIR filter, as shown here.

adaptfilt.rls

Recursive least-squares FIR adaptive filter

Syntax

```
ha = adaptfilt.rls(l,lambda,invcov,coeffs,states)
```

Description

`ha = adaptfilt.rls(l,lambda,invcov,coeffs,states)` constructs an FIR direct form RLS adaptive filter `ha.`

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.rls`.

Input Argument	Description
`l`	Adaptive filter length (the number of coefficients or taps) and it must be a positive integer. `l` defaults to 10.
`lambda`	RLS forgetting factor. This is a scalar and should lie in the range (0, 1]. `lambda` defaults to 1.
`invcov`	Inverse of the input signal covariance matrix. For best performance, you should initialize this matrix to be a positive definite matrix.
`coeffs`	Vector of initial filter coefficients. it must be a length `l` vector. `coeffs` defaults to length `l` vector with elements equal to zero.
`states`	Vector of initial filter states for the adaptive filter. It must be a length `l`-1 vector. `states` defaults to a length l-1 vector of zeros.

Properties

Since your `adaptfilt.rls` filter is an object, it has properties that define its behavior in operation. Note that many of the properties are also input arguments for creating `adaptfilt.rls` objects. To show you the properties that apply, this table lists and describes each property for the filter object.

Name	Range	Description
`Algorithm`	None	Defines the adaptive filter algorithm the object uses during adaptation.
`Coefficients`	Vector containing `l` elements	Vector containing the initial filter coefficients. It must be a length `l` vector where `l` is the number of filter coefficients. `coeffs` defaults to length `l` vector of zeros when you do not provide the argument for input.
`FilterLength`	Any positive integer	Reports the length of the filter, the number of coefficients or taps. Remember that filter length is filter order + 1.
`ForgettingFactor`	Scalar	Forgetting factor of the adaptive filter. This is a scalar and should lie in the range (0, 1]. It defaults to 1. Setting `forgetting factor` = 1 denotes infinite memory while adapting to find the new filter. Note that this is the `lambda` input argument.
`InvCov`	Matrix of size `l`-by-`l`	Upper-triangular Cholesky (square root) factor of the input covariance matrix. Initialize this matrix with a positive definite upper triangular matrix.
`KalmanGain`	Vector of size (`l`,1)	Empty when you construct the object, this gets populated after you run the filter.
`PersistentMemory`	`false` or `true`	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. `PersistentMemory` returns

Name	Range	Description
		to zero any state that the filter changes during processing. Defaults to `false`.
`States`	Double array	Vector of the adaptive filter states. `states` defaults to a vector of zeros which has length equal to (`l` + `projectord` - 2).

Examples

System Identification of a 32-coefficient FIR filter over 500 adaptation iterations.

```
x  = randn(1,500);     % Input to the filter
b  = fir1(31,0.5);     % FIR system to be identified
n  = 0.1*randn(1,500); % Observation noise signal
d  = filter(b,1,x)+n;  % Desired signal
P0 = 10*eye(32); % Initial sqrt correlation matrix inverse
lam = 0.99;            % RLS forgetting factor
ha = adaptfilt.rls(32,lam,P0);
[y,e] = filter(ha,x,d);
subplot(2,1,1); plot(1:500,[d;y;e]);
title('System Identification of an FIR Filter');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,1,2); stem([b.',ha.Coefficients.']);
legend('Actual','Estimated');
xlabel('Coefficient #'); ylabel('Coefficient valUe');  grid on;
```

In this example of adaptive filtering using the RLS algorithm to update the filter coefficients for each iteration, the figure shown reveals the fidelity of the derived filter after adaptation.

adaptfilt.sd

Sign-data FIR adaptive filter

Syntax

```
ha = adaptfilt.sd(l,step,leakage,coeffs,states)
```

Description

`ha = adaptfilt.sd(l,step,leakage,coeffs,states)` constructs an FIR sign-data adaptive filter object `ha.`

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.sd`.

Input Argument	Description
`l`	Adaptive filter length (the number of coefficients or taps) and it must be a positive integer. `l` defaults to 10.
`step`	SD step size. It must be a nonnegative scalar. `step` defaults to 0.1
`leakage`	Your SD leakage factor. It must be a scalar between 0 and 1. When `leakage` is less than one, `adaptfilt.sd` implements a leaky SD algorithm. When you omit the `leakage` property in the calling syntax, it defaults to 1 providing no leakage in the adapting algorithm.
`coeffs`	Vector of initial filter coefficients. it must be a length `l` vector. `coeffs` defaults to length `l` vector with elements equal to zero.
`states`	Vector of initial filter states for the adaptive filter. It must be a length `l`-1 vector. `states` defaults to a length l-1 vector of zeros.

Properties

In the syntax for creating the `adaptfilt` object, the input options are properties of the object you create. This table lists the properties for sign-data objects, their default values, and a brief description of the property.

Property	Default Value	Description
`Al gorithm`	Sign-data	Defines the adaptive filter algorithm the object uses during adaptation.
`Coefficients`	`zeros`(1,l)	Vector containing the initial filter coefficients. It must be a length `l` vector where `l` is the number of filter coefficients. `coeffs` defaults to length `l` vector of zeros when you do not provide the argument for input. Should be initialized with the initial coefficients for the FIR filter prior to adapting. You need `l` entries in `coefficients`.
`FilterLength`	10	Reports the length of the filter, the number of coefficients or taps.
`Leakage`	0	Specifies the leakage parameter. Allows you to implement a leaky algorithm. Including a leakage factor can improve the results of the algorithm by forcing the algorithm to continue to adapt even after it reaches a minimum value. Ranges between 0 and 1. Defaults to 0.
`PersistentMemory`	`false` or `true`	Determine whether the filter states and coefficients get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter. `PersistentMemory` returns to zero any property value that the filter changes during processing. Property values that the filter does not change are not affected. Defaults to `false`.

Property	Default Value	Description
`States`	`zeros(l-1,1)`	Vector of the adaptive filter states. `states` defaults to a vector of zeros which has length equal to (`l` - 1).
`StepSize`	0.1	Sets the SD algorithm step size used for each iteration of the adapting algorithm. Determines both how quickly and how closely the adaptive filter converges to the filter solution.

Examples

Adaptive line enhancement using a 32-coefficient FIR filter to perform the enhancement. This example runs for 5000 iterations, as you see in property `iter`.

```
d  = 1;                         % Number of samples of delay
ntr= 5000;                      % Number of iterations
v  = sin(2*pi*0.05*[1:ntr+d]);  % Sinusoidal signal
n  = randn(1,ntr+d);            % Noise signal
x  = v(1:ntr)+n(1:ntr);         % Input signal
d  = v(1+d:ntr+d)+n(1+d:ntr+d); % Desired signal
mu = 0.0001;                    % Sign-data step size.
ha = adaptfilt.sd(32,mu);
[y,e] = filter(ha,x,d);
subplot(2,1,1); plot(1:ntr,[d;y;v(1:end-1)]);
axis([ntr-100 ntr -3 3]);
title('Adaptive Line Enhancement of a Noisy Sinusoidal Signal');
legend('Observed','Enhanced','Original');
 xlabel('Time Index'); ylabel('Signal Value');
[pxx,om] = pwelch(x(ntr-1000:ntr));
 pyy = pwelch(y(ntr-1000:ntr));
subplot(2,1,2);
plot(om/pi,10*log10([pxx/max(pxx),pyy/max(pyy)]));
axis([0 1 -60 20]); legend('Observed','Enhanced');
xlabel('Normalized Frequency (\times \pi rad/sample)');
ylabel('Power Spectral Density'); grid on;
```

Each of the variants — sign-data, sign-error, and sign-sign — uses the same example. You can compare the results by viewing the figure shown for each adaptive filter method — `adaptfilt.sd`, `adaptfilt.se`, and `adaptfilt.ss`.

`adaptfilt.lms` | `adaptfilt.se` | `adaptfilt.ss`

adaptfilt.se

FIR adaptive filter that uses sign-error algorithm

Syntax

```
ha = adaptfilt.se(l,step,leakage,coeffs,states)
```

Description

`ha = adaptfilt.se(l,step,leakage,coeffs,states)` constructs an FIR sign-error adaptive filter `ha`.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.se`.

Input Argument	Description
`l`	Adaptive filter length (the number of coefficients or taps) and it must be a positive integer. `l` defaults to 10.
`step`	SE step size. It must be a nonnegative scalar. You can use `maxstep` to determine a reasonable range of step size values for the signals being processed. `step` defaults to 0.1
`leakage`	Your SE leakage factor. It must be a scalar between 0 and 1. When `leakage` is less than one, `adaptfilt.se` implements a leaky SE algorithm. When you omit the `leakage` property in the calling syntax, it defaults to 1 providing no leakage in the adapting algorithm.
`coeffs`	Vector of initial filter coefficients. it must be a length `l` vector. `coeffs` defaults to length `l` vector with elements equal to zero.

Input Argument	Description
states	Vector of initial filter states for the adaptive filter. It must be a length l-1 vector. states defaults to a length l-1 vector of zeros.

Properties

In the syntax for creating the adaptfilt object, the input options are properties of the object you create. This table lists the properties for the sign-error SD object, their default values, and a brief description of the property.

Property	Default Value	Description
Algorithm	Sign-error	Defines the adaptive filter algorithm the object uses during adaptation
Coefficients	zeros(1,l)	Vector containing the initial filter coefficients. It must be a length l vector where l is the number of filter coefficients. coeffs defaults to length l vector of zeros when you do not provide the argument for input. Should be initialized with the initial coefficients for the FIR filter prior to adapting.
FilterLength	10	Reports the length of the filter, the number of coefficients or taps
Leakage	1	Specifies the leakage parameter. Allows you to implement a leaky algorithm. Including a leakage factor can improve the results of the algorithm by forcing the algorithm to continue to adapt even after it reaches a minimum value. Ranges between 0 and 1. Defaults to one if omitted.
PersistentMemory	false or true	Determine whether the filter states and coefficients get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter.

Property	Default Value	Description
		`PersistentMemory` returns to zero any property value that the filter changes during processing. Property values that the filter does not change are not affected. Defaults to `false`.
`States`	`zeros(l`-1,1)	Vector of the adaptive filter states. `states` defaults to a vector of zeros which has length equal to (`l` -1).
`StepSize`	0.1	Sets the SE algorithm step size used for each iteration of the adapting algorithm. Determines both how quickly and how closely the adaptive filter converges to the filter solution.

Use `inspect(ha)` to view or change the object properties graphically using the MATLAB Property Inspector.

Examples

Adaptive line enhancement using a 32-coefficient FIR filter running over 5000 iterations.

```
d = 1;                        % Number of samples of delay
ntr= 5000;                    % Number of iterations
v = sin(2*pi*0.05*(1:ntr+d));    % Sinusoidal signal
n = randn(1,ntr+d);           % Noise signal
x = v(1:ntr)+n(1:ntr);        % Input signal --(delayed desired signal)
d = v(1+d:ntr+d)+n(1+d:ntr+d);  % Desired signal
mu = 0.0001;                    % Sign-error step size
ha = adaptfilt.se(32,mu);
[y,e] = filter(ha,x,d);
subplot(2,1,1);
plot(1:ntr,[d;y;v(1:end-1)]);
axis([ntr-100 ntr -3 3]);
title('Adaptive Line Enhancement of Noisy Sinusoid');
legend('Observed','Enhanced','Original');
xlabel('Time Index'); ylabel('Signal Value');
HWelch = spectrum.welch;
InputPsd = psd(HWelch,x(ntr-1000:ntr));
OutputPsd = psd(HWelch,y(ntr-1000:ntr));
CompPsdEst = [InputPsd.Data/max(InputPsd.Data), OutputPsd.Data/max(OutputPsd.Data)];
subplot(2,1,2); plot(InputPsd.Frequencies/pi,10*log10(CompPsdEst));
axis([0 1 -60 20]); legend('Observed','Enhanced');
xlabel('Normalized Frequency (\times \pi rad/sample)');
```

```
ylabel('Power Spectral Density'); grid on;
```

Compare the figure shown here to the ones for `adaptfilt.sd` and `adaptfilt.ss` to see how the variants perform on the same example.

`adaptfilt.sd` | `adaptfilt.ss` | `adaptfilt.lms`

adaptfilt.ss

FIR adaptive filter that uses sign-sign algorithm

Syntax

```
ha = adaptfilt.ss(l,step,leakage,coeffs,states)
```

Description

`ha = adaptfilt.ss(l,step,leakage,coeffs,states)` constructs an FIR sign-error adaptive filter `ha`.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.ss`.

Input Argument	Description
`l`	Adaptive filter length (the number of coefficients or taps) and it must be a positive integer. `l` defaults to 10.
`step`	SS step size. It must be a nonnegative scalar. `step` defaults to 0.1.
`leakage`	Your SS leakage factor. It must be a scalar between 0 and 1. When `leakage` is less than one, `adaptfilt.lms` implements a leaky SS algorithm. When you omit the `leakage` property in the calling syntax, it defaults to 1 providing no leakage in the adapting algorithm.
`coeffs`	Vector of initial filter coefficients. it must be a length `l` vector. `coeffs` defaults to length `l` vector with elements equal to zero.
`states`	Vector of initial filter states for the adaptive filter. It must be a length `l` -1 vector. `states` defaults to a length l-1 vector of zeros.

adaptfilt.ss can be called for a block of data, when x and d are vectors, or in “sample by sample mode” using a For-loop with the method filter:

```
for n = 1:length(x)
ha = adaptfilt.ss(25,0.9);
[y(n),e(n)] = filter(ha,(x(n),d(n),s));
end
```

Properties

In the syntax for creating the adaptfilt object, most of the input options are properties of the object you create. This table lists the properties for sign-sign objects, their default values, and a brief description of the property.

Property	Default Value	Description
Algorithm	Sign-sign	Defines the adaptive filter algorithm the object uses during adaptation
Coefficients	zeros(1,l)	Vector containing the initial filter coefficients. It must be a length l vector where l is the number of filter coefficients. coeffs defaults to length l vector of zeros when you do not provide the argument for input. Should be initialized with the initial coefficients for the FIR filter prior to adapting.
FilterLength	10	Reports the length of the filter, the number of coefficients or taps
Leakage	1	Specifies the leakage parameter. Allows you to implement a leaky algorithm. Including a leakage factor can improve the results of the algorithm by forcing the algorithm to continue to adapt even after it reaches a minimum value. Ranges between 0 and 1. 1 is the default value.
PersistentMemory	false or true	Determine whether the filter states and coefficients get restored to their starting values for each filtering operation. The starting values are the values

Property	Default Value	Description
		in place when you create the filter. PersistentMemory returns to zero any property value that the filter changes during processing. Property values that the filter does not change are not affected. Defaults to false.
States	zeros(l-1,1)	Vector of the adaptive filter states. states defaults to a vector of zeros which has length equal to (l-1).
StepSize	0.1	Sets the SE algorithm step size used for each iteration of the adapting algorithm. Determines both how quickly and how closely the adaptive filter converges to the filter solution.

Examples

Demonstrating adaptive line enhancement using a 32-coefficient FIR filter provides a good introduction to the sign-sign algorithm.

```
d = 1;                       % Number of samples of delay
ntr= 5000;                   % Number of iterations
v = sin(2*pi*0.05*(1:ntr+d));    % Sinusoidal signal
n = randn(1,ntr+d);          % Noise signal
x = v(1:ntr)+n(1:ntr);       % Input signal --(delayed desired signal)
d = v(1+d:ntr+d)+n(1+d:ntr+d);  % Desired signal
mu = 0.0001;                    % Sign-error step size
ha = adaptfilt.ss(32,mu);
[y,e] = filter(ha,x,d);
subplot(2,1,1);
plot(1:ntr,[d;y;v(1:end-1)]);
axis([ntr-100 ntr -3 3]);
title('Adaptive Line Enhancement of Noisy Sinusoid');
legend('Observed','Enhanced','Original');
xlabel('Time Index'); ylabel('Signal Value');
[InputPsd,wi] = pwelch(x(ntr-1000:ntr));
[OutputPsd,wo] = pwelch(y(ntr-1000:ntr));
CompPsdEst = [InputPsd/max(InputPsd), OutputPsd/max(OutputPsd)];
subplot(2,1,2); plot(wi/pi,10*log10(CompPsdEst));
axis([0 1 -60 20]); legend('Observed','Enhanced');
xlabel('Normalized Frequency (\times \pi rad/sample)');
ylabel('Power Spectral Density'); grid on;
```

This example is the same as the ones used for the sign-data and sign-error examples. Comparing the figures shown for each of the others lets you assess the performance of each for the same task.

adaptfilt.swftf

FIR adaptive filter that uses sliding window fast transversal least squares

Syntax

```
ha = adaptfilt.swftf(l,delta,blocklen,gamma,gstates,
dstates,...coeffs,states)
```

Description

`ha = adaptfilt.swftf(l,delta,blocklen,gamma,gstates, dstates,...coeffs,states)` constructs a sliding window fast transversal least squares adaptive filter `ha`.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.swftf.`

Input Argument	Description
`l`	Adaptive filter length (the number of coefficients or taps) and it must be a positive integer. `l` defaults to 10.
`delta`	Soft-constrained initialization factor. This scalar should be positive and sufficiently large to maintain stability. `delta` defaults to 1.
`blocklen`	Block length of the sliding window. This must be an integer at least as large as the filter length `l`, which is the default value.
`gamma`	Conversion factor. `gamma` defaults to the matrix [1 -1] that specifies soft-constrained initialization.
`gstates`	States of the Kalman gain updates. `gstates` defaults to a zero vector of length (`l` + `blocklen` - 1).
`dstates`	Desired signal states of the adaptive filter. `dstates` defaults to a zero vector of length equal to (`blocklen` - 1). For a default object, `dstates` is (`l`-1).

Input Argument	Description
coeffs	Vector of initial filter coefficients. It must be a length l vector. coeffs defaults to length l vector of all zeros.
states	Vector of initial filter states. states defaults to a zero vector of length equal to (l + blocklen - 2).

Properties

Since your adaptfilt.swftf filter is an object, it has properties that define its behavior in operation. Note that many of the properties are also input arguments for creating adaptfilt.swftf objects. To show you the properties that apply, this table lists and describes each property for the filter object.

Name	Range	Description
Algorithm	None	Defines the adaptive filter algorithm the object uses during adaptation
BkwdPredictions		Returns the predicted samples generated during adaptation. Refer to "[2]" in the bibliography for details about linear prediction.
BlockLength		Block length of the sliding window. This must be an integer at least as large as the filter length l, which is the default value.
Coefficients	Vector of elements	Vector containing the initial filter coefficients. It must be a length l vector where l is the number of filter coefficients. coeffs defaults to length l vector of zeros when you do not provide the argument for input.
ConversionFactor		Conversion factor. Called gamma when it is an input argument, it defaults to the matrix [1 -1] that specifies soft-constrained initialization.
DesiredSignal States		Desired signal states of the adaptive filter. dstates defaults to a zero vector with length equal to (blocklen - 1).

Name	Range	Description
FilterLength	Any positive integer	Reports the length of the filter, the number of coefficients or taps
FwdPrediction		Contains the predicted values for samples during adaptation. Compare these to the actual samples to get the error and power.
InitFactor		Soft-constrained initialization factor. This scalar should be positive and sufficiently large to prevent an excessive number of Kalman gain rescues. delta defaults to one.
KalmanGain		Empty when you construct the object, this gets populated after you run the filter.
KalmanGainStates		Contains the states of the Kalman gains for the adaptive algorithm. Initialized to a vector of double data type entries.
PersistentMemory	false or true	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. PersistentMemory returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. Defaults to false.
States	Vector of elements, data type double	Vector of the adaptive filter states. states defaults to a vector of zeros which has length equal to (l + projectord - 2).

Examples

Over 500 iterations, perform a system identification of a 32-coefficient FIR filter.

```
x  = randn(1,500);     % Input to the filter
b  = fir1(31,0.5);     % FIR system to be identified
n  = 0.1*randn(1,500); % Observation noise signal
d  = filter(b,1,x)+n;  % Desired signal
L  = 32;               % Adaptive filter length
```

```
del = 0.1;              % Soft-constrained initialization factor
N  = 64;                % block length
ha = adaptfilt.swftf(L,del,N);
[y,e] = filter(ha,x,d);
subplot(2,1,1); plot(1:500,[d;y;e]);
title('System Identification of an FIR Filter');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,1,2); stem([b.',ha.Coefficients.']);
legend('Actual','Estimated');
xlabel('Coefficient #'); ylabel('Coefficient Value');  grid on;
```

Review the figure for the results of the example. When you evaluate the example you should get the same results, within the differences in the random noise signal you use.

adaptfilt.swrls

FIR adaptive filter that uses window recursive least squares (RLS)

Syntax

```
ha = adaptfilt.swrls(l,lambda,invcov,swblocklen,
dstates,...coeffs,states)
```

Description

`ha = adaptfilt.swrls(l,lambda,invcov,swblocklen, dstates,...coeffs,states)` constructs an FIR sliding window RLS adaptive filter `ha`.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.swrls`.

Input Argument	Description
`l`	Adaptive filter length (the number of coefficients or taps). It must be a positive integer. `l` defaults to 10.
`lambda`	RLS forgetting factor. This is a scalar and should lie within the range (0, 1]. `lambda` defaults to 1.
`invcov`	Inverse of the input signal covariance matrix. You should initialize `invcov` to a positive definite matrix.
`swblocklen`	Block length of the sliding window. This integer must be at least as large as the filter length. `swblocklen` defaults to 16.
`dstates`	Desired signal states of the adaptive filter. `dstates` defaults to a zero vector with length equal to (`swblocklen` - 1).
`coeffs`	Vector of initial filter coefficients. It must be a length `l` vector. `coeffs` defaults to length `l` vector of all zeros.

Input Argument	Description
`states`	Vector of initial filter states. `states` defaults to a zero vector of length equal to (l + `swblocklen` - 2).

Properties

Since your `adaptfilt.swrls` filter is an object, it has properties that define its behavior in operation. Note that many of the properties are also input arguments for creating `adaptfilt.swrls` objects. To show you the properties that apply, this table lists and describes each property for the filter object.

Name	Range	Description
`Algorithm`	None	Defines the adaptive filter algorithm the object uses during adaptation
`Coefficients`	Any vector of `l` elements	Vector containing the initial filter coefficients. It must be a length `l` vector where `l` is the number of filter coefficients. `coeffs` defaults to length `l` vector of zeros when you do not provide the argument for input.
`DesiredSignalStates`	Vector	Desired signal states of the adaptive filter. `dstates` defaults to a zero vector with length equal to (`swblocklen` - 1).
`FilterLength`	Any positive integer	Reports the length of the filter, the number of coefficients or taps
`ForgettingFactor`	Scalar	Forgetting factor of the adaptive filter. This is a scalar and should lie in the range (0, 1]. It defaults to 1. Setting `forgetting factor` = 1 denotes infinite memory while adapting to find the new filter. Note that this is the `lambda` input argument.
`InvCov`	Matrix	Square matrix with each dimension equal to the filter length `l`.

Name	Range	Description
KalmanGain	Vector with dimensions (l,1)	Empty when you construct the object, this gets populated after you run the filter.
PersistentMemory	false or true	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. PersistentMemory returns to zero any state that the filter changes during processing. Defaults to false.
States	Vector of elements, data type double	Vector of the adaptive filter states. states defaults to a vector of zeros which has length equal to (l + swblocklen - 2)
SwBlockLength	Integer	Block length of the sliding window. This integer must be at least as large as the filter length. swblocklen defaults to 16.

Examples

System Identification of a 32-coefficient FIR filter. Use 500 iterations to adapt to the unknown filter. After the example code, you see a figure that plots the results of the running the code.

```
x  = randn(1,500);     % Input to the filter
b  = fir1(31,0.5);     % FIR system to be identified
n  = 0.1*randn(1,500); % Observation noise signal
d  = filter(b,1,x)+n;  % Desired signal
P0 = 10*eye(32);       % Initial correlation matrix inverse
lam = 0.99;            % RLS forgetting factor
N  = 64;               % Block length
ha = adaptfilt.swrls(32,lam,P0,N);
[y,e] = filter(ha,x,d);
subplot(2,1,1); plot(1:500,[d;y;e]);
 title('System Identification of an FIR Filter');
legend('Desired','Output','Error');
```

```
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,1,2); stem([b.',ha.Coefficients.']);
legend('Actual','Estimated');
xlabel('Coefficient #'); ylabel('Coefficient Value');  grid on;
```

In the figure you see clearly that the adaptive filter process successfully identified the coefficients of the unknown FIR filter. You knew it had to or many things that you take for granted, such as modems on computers, would not work.

adaptfilt.tdafdct

Adaptive filter that uses discrete cosine transform

Syntax

```
ha = adaptfilt.tdafdct(l,step,leakage,offset,delta,lambda,
coeffs,states)
```

Description

`ha = adaptfilt.tdafdct(l,step,leakage,offset,delta,lambda,` `coeffs,states)` constructs a transform-domain adaptive filter ha object that uses the discrete cosine transform to perform filter adaptation.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.tdafdct`.

Input Argument	Description
`l`	Adaptive filter length (the number of coefficients or taps) and it must be a positive integer. `l` defaults to 10.
`step`	Adaptive filter step size. It must be a nonnegative scalar. You can use `maxstep` to determine a reasonable range of step size values for the signals being processed. `step` defaults to 0.
`leakage`	Leakage parameter of the adaptive filter. When you set this argument to a value between zero and one, you are implementing a leaky version of the TDAFDCT algorithm. `leakage` defaults to 1 — no leakage.
`offset`	Offset for the normalization terms in the coefficient updates. You can use this argument to avoid dividing by zero or by very small numbers when any of the FFT input signal powers become very small. `offset` defaults to zero.

Input Argument	Description
delta	Initial common value of all of the transform domain powers. Its initial value should be positive. delta defaults to 5.
lambda	Averaging factor used to compute the exponentially-windowed estimates of the powers in the transformed signal bins for the coefficient updates. lambda should lie between zero and one. For default filter objects, lambda equals (1 - step).
coeffs	Initial time domain coefficients of the adaptive filter. Set it to be a length l vector. coeffs defaults to a zero vector of length l.
states	Initial conditions of the adaptive filter. states defaults to a zero vector with length equal to (l - 1).

Properties

Since your adaptfilt.tdafdct filter is an object, it has properties that define its behavior in operation. Note that many of the properties are also input arguments for creating adaptfilt.tdafdct objects. To show you the properties that apply, this table lists and describes each property for the transform domain filter object.

Name	Range	Description
Algorithm	None	Defines the adaptive filter algorithm the object uses during adaptation.
AvgFactor		Averaging factor used to compute the exponentially-windowed estimates of the powers in the transformed signal bins for the coefficient updates. AvgFactor should lie between zero and one. For default filter objects, AvgFactor equals (1 - step). lambda is the input argument that represent AvgFactor.
Coefficients	Vector of elements	Vector containing the initial filter coefficients. It must be a length l vector where l is the number of filter coefficients. coeffs defaults to length l vector of zeros when you do not provide the argument for input.

Name	Range	Description
FilterLength	Any positive integer	Reports the length of the filter, the number of coefficients or taps.
Leakage	0 to 1	Leakage parameter of the adaptive filter. When you set this argument to a value between zero and one, you are implementing a leaky version of the TDAFDFT algorithm. leakage defaults to 1 — no leakage.
Offset		Offset for the normalization terms in the coefficient updates. You can use this argument to avoid dividing by zeros or by very small numbers when any of the FFT input signal powers become very small. offset defaults to zero.
PersistentMemory	false or true	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter. PersistentMemory returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. Defaults to false.
Power	2*l element vector	A vector of 2*l elements, each initialized with the value delta from the input arguments. As you filter data, Power gets updated by the filter process.
States	Vector of elements, data type double	Vector of the adaptive filter states. states defaults to a vector of zeros which has length equal to (l + projectord - 2).

Name	Range	Description
StepSize	0 to 1	Step size. It must be a nonnegative scalar, greater than zero and less than or equal to 1. You can use maxstep to determine a reasonable range of step size values for the signals being processed. step defaults to 0.

For checking the values of properties for an adaptive filter object, use get(ha) or enter the object name, without a trailing semicolon, at the MATLAB prompt.

Examples

Using 1000 iterations, perform a Quadrature Phase Shift Keying (QPSK) adaptive equalization using a 32-coefficient FIR filter.

```
D  = 16;                        % Number of samples of delay
b  = exp(1j*pi/4)*[-0.7 1];      % Numerator coefficients of channel
a  = [1 -0.7];                  % Denominator coefficients of channel
ntr= 1000;                      % Number of iterations
s  = sign(randn(1,ntr+D)) + 1j*sign(randn(1,ntr+D)); %QPSK signal
n  = 0.1*(randn(1,ntr+D) + 1j*randn(1,ntr+D)); % Noise signal
r  = filter(b,a,s)+n;           % Received signal
x  = r(1+D:ntr+D);              % Input signal (received signal)
d  = s(1:ntr);                  % Desired signal (delayed QPSK signal)
L  = 32;                        % filter length
mu = 0.01;                      % Step size
ha = adaptfilt.tdafdct(L,mu);
[y,e] = filter(ha,x,d);
subplot(2,2,1);
plot(1:ntr,real([d;y;e])); title('In-Phase Components');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,2,2); plot(1:ntr,imag([d;y;e]));
title('Quadrature Components');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,2,3); plot(x(ntr-100:ntr),'.');
axis([-3 3 -3 3]); title('Received Signal Scatter Plot');
axis('square');  xlabel('Real[x]'); ylabel('Imag[x]'); grid on;
subplot(2,2,4); plot(y(ntr-100:ntr),'.'); axis([-3 3 -3 3]);
title('Equalized Signal Scatter Plot'); grid on;
axis('square'); xlabel('Real[y]'); ylabel('Imag[y]');
```

Compare the plots shown in this figure to those in the other time domain filter variations. The comparison should help you select and understand how the variants differ.

adaptfilt.tdafdft

Adaptive filter that uses discrete Fourier transform

Syntax

```
ha = adaptfilt.tdafdft(l,step,leakage,offset,
delta,lambda,...coeffs,states)
```

Description

`ha = adaptfilt.tdafdft(l,step,leakage,offset, delta,lambda,...coeffs,states)` constructs a transform-domain adaptive filter object `ha` using a discrete Fourier transform.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.tdafdft`.

Input Argument	Description
`l`	Adaptive filter length (the number of coefficients or taps) and it must be a positive integer. `l` defaults to 10.
`step`	Adaptive filter step size. It must be a nonnegative scalar. You can use `maxstep` to determine a reasonable range of step size values for the signals being processed. `step` defaults to 0.
`leakage`	Leakage parameter of the adaptive filter. When you set this argument to a value between zero and one, you are implementing a leaky version of the TDAFDFT algorithm. `leakage` defaults to 1 — no leakage.
`offset`	Offset for the normalization terms in the coefficient updates. You can use this argument to avoid dividing by zeros or by very small numbers when any of the FFT input signal powers become very small. `offset` defaults to zero.

Input Argument	Description
delta	Initial common value of all of the transform domain powers. Its initial value should be positive. delta defaults to 5.
lambda	Averaging factor used to compute the exponentially-windowed estimates of the powers in the transformed signal bins for the coefficient updates. lambda should lie between zero and one. For default filter objects, LAMBDA equals (1 - step).
coeffs	Initial time domain coefficients of the adaptive filter. Set it to be a length l vector. coeffs defaults to a zero vector of length l.
states	Initial conditions of the adaptive filter. states defaults to a zero vector with length equal to (l - 1).

Properties

Since your adaptfilt.tdafdft filter is an object, it has properties that define its behavior in operation. Note that many of the properties are also input arguments for creating adaptfilt.tdafdft objects. To show you the properties that apply, this table lists and describes each property for the transform domain filter object.

Name	Range	Description
Algorithm	None	Defines the adaptive filter algorithm the object uses during adaptation
AvgFactor		Averaging factor used to compute the exponentially-windowed estimates of the powers in the transformed signal bins for the coefficient updates. AvgFactor should lie between zero and one. For default filter objects, AvgFactor equals (1 - step). lambda is the input argument that represent AvgFactor.
Coefficients	Vector of elements	Vector containing the initial filter coefficients. It must be a length l vector where l is the number of filter coefficients. coeffs defaults to length l vector of zeros when you do not provide the argument for input.

Name	Range	Description
FilterLength	Any positive integer	Reports the length of the filter, the number of coefficients or taps
Leakage	0 to 1	Leakage parameter of the adaptive filter. When you set this argument to a value between zero and one, you are implementing a leaky version of the TDAFDFT algorithm. leakage defaults to 1 — no leakage.
Offset		Offset for the normalization terms in the coefficient updates. You can use this argument to avoid dividing by zeros or by very small numbers when any of the FFT input signal powers become very small. offset defaults to zero.
PersistentMemory	false or true	Determines whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter. PersistentMemory returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. Defaults to false.
Power	2*l element vector	A vector of 2*l elements, each initialized with the value delta from the input arguments. As you filter data, Power gets updated by the filter process.
States	Vector of elements, data type double	Vector of the adaptive filter states. states defaults to a vector of zeros which has length equal to (l + projectord - 2).
StepSize	0 to 1	Step size. It must be a nonnegative scalar, greater than zero and less than or equal to 1. step defaults to 0.

Examples

Quadrature Phase Shift Keying (QPSK) adaptive equalization using a 32-coefficient FIR filter (1000 iterations).

```
D  = 16;                       % Number of samples of delay
b  = exp(1j*pi/4)*[-0.7 1];     % Numerator coefficients of channel
a  = [1 -0.7];                 % Denominator coefficients of channel
ntr= 1000;                     % Number of iterations
s  = sign(randn(1,ntr+D)) + 1j*sign(randn(1,ntr+D));% Baseband QPSK signal
n  = 0.1*(randn(1,ntr+D) + 1j*randn(1,ntr+D));      % Noise signal
r  = filter(b,a,s)+n;           % Received signal
x  = r(1+D:ntr+D);              % Input signal (received signal)
d  = s(1:ntr);                  % Desired signal (delayed QPSK signal)
L  = 32;                       % filter length
mu = 0.01;                     % Step size
ha = adaptfilt.tdafdft(L,mu);
[y,e] = filter(ha,x,d);
subplot(2,2,1); plot(1:ntr,real([d;y;e]));
title('In-Phase Components');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,2,2); plot(1:ntr,imag([d;y;e]));
title('Quadrature Components');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,2,3); plot(x(ntr-100:ntr),'.');
 axis([-3 3 -3 3]); title('Received Signal Scatter Plot');
axis('square');  xlabel('Real[x]'); ylabel('Imag[x]'); grid on;
subplot(2,2,4); plot(y(ntr-100:ntr),'.');
axis([-3 3 -3 3]); title('Equalized Signal Scatter Plot');
axis('square'); xlabel('Real[y]'); ylabel('Imag[y]'); grid on;
```

All of the time domain adaptive filter reference pages use this QPSK example. By comparing the results for each variation you get an idea of the differences in the way each one performs.

This figure demonstrates the results of running the example code shown.

`adaptfilt.tdafdct` | `adaptfilt.fdaf` | `adaptfilt.blms`

adaptfilt.ufdaf

FIR adaptive filter that uses unconstrained frequency-domain with quantized step size normalization

Syntax

```
ha = adaptfilt.ufdaf(l,step,leakage,delta,lambda,blocklen,
offset,coeffs,states)
```

Description

`ha = adaptfilt.ufdaf(l,step,leakage,delta,lambda,blocklen, offset,coeffs,states)` constructs an unconstrained frequency-domain FIR adaptive filter `ha` with quantized step size normalization.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.ufdaf`.

Input Argument	Description
`l`	Adaptive filter length (the number of coefficients or taps) and it must be a positive integer. `l` defaults to 10.
`step`	Adaptive filter step size. It must be a nonnegative scalar. `step` defaults to 0.
`leakage`	Leakage parameter of the adaptive filter. When you set this argument to a value between zero and one, you are implementing a leaky version of the UFDAF algorithm. `leakage` defaults to 1 — no leakage.
`delta`	Initial common value of all of the FFT input signal powers. the initial value of delta should be positive, and it defaults to 1.

Input Argument	Description
lambda	Specifies the averaging factor used to compute the exponentially-windowed FFT input signal powers for the coefficient updates. lambda should lie in the range (0,1]. For default UFDAF filter objects, lambda defaults to 0.9.
blocklen	Block length for the coefficient updates. This must be a positive integer. For faster execution, (blocklen l) should be a power of two. blocklen defaults to l.
offset	Offset for the normalization terms in the coefficient updates. This can help you avoid divide by zero conditions, or divide by very small numbers conditions, when any of the FFT input signal powers become very small. Default value is zero.
coeffs	Initial time-domain coefficients of the adaptive filter. It should be a length l vector. The filter object uses these coefficients to compute the initial frequency-domain filter coefficients via an FFT computed after zero-padding the time-domain vector by blocklen.
states	Adaptive filter states. states defaults to a zero vector with length equal to l.

Properties

Since your adaptfilt.ufdaf filter is an object, it has properties that define its behavior in operation. Note that many of the properties are also input arguments for creating adaptfilt.ufdaf objects. To show you the properties that apply, this table lists and describes each property for the filter object.

Name	Range	Description
Algorithm	None	Defines the adaptive filter algorithm the object uses during adaptation
AvgFactor		Specifies the averaging factor used to compute the exponentially-windowed FFT input signal powers for the coefficient updates. AvgFactor should lie in the range (0,1]. For default UFDAF filter objects, AvgFactor

Name	Range	Description
		defaults to 0.9. Note that AvgFactor and lambda are the same thing — lambda is an input argument and AvgFactor a property of the object.
`BlockLength`		Block length for the coefficient updates. This must be a positive integer. For faster execution, (`blocklen` + `1`) should be a power of two. `blocklen` defaults to `1`.
`FFTCoefficients`		Stores the discrete Fourier transform of the filter coefficients in `coeffs`.
`FFTStates`		States for the FFT operation.
`FilterLength`	Any positive integer	Reports the length of the filter, the number of coefficients or taps
`Leakage`	0 to 1	Leakage parameter of the adaptive filter. When you set this argument to a value between zero and one, you are implementing a leaky version of the UFDAF algorithm. `leakage` defaults to 1 — no leakage.
`Offset`		Offset for the normalization terms in the coefficient updates. This can help you avoid divide by zero conditions, or divide by very small numbers conditions, when any of the FFT input signal powers become very small. Default value is zero.

Name	Range	Description
PersistentMemory	false or true	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter. PersistentMemory returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. Defaults to false.
Power	2*l element vector	A vector of 2*l elements, each initialized with the value delta from the input arguments. As you filter data, Power gets updated by the filter process.
StepSize	0 to 1	Adaptive filter step size. It must be a nonnegative scalar. You can use maxstep to determine a reasonable range of step size values for the signals being processed. step defaults to 0.

Examples

Show an example of Quadrature Phase Shift Keying (QPSK) adaptive equalization using a 32-coefficient adaptive filter. For fidelity, use 1024 iterations. The figure that follows the code provides the information you need to assess the performance of the equalization process.

```
D  = 16;                       % Number of samples of delay
b  = exp(1j*pi/4)*[-0.7 1];     % Numerator coefficients of channel
a  = [1 -0.7];                 % Denominator coefficients of channel
ntr= 1024;                     % Number of iterations
s = sign(randn(1,ntr+D))+1j*sign(randn(1,ntr+D));% Baseband QPSK signal
n  = 0.1*(randn(1,ntr+D) + 1j*randn(1,ntr+D));
r  = filter(b,a,s)+n;% Received signal
x  = r(1+D:ntr+D);   % Input signal (received signal)
d  = s(1:ntr);       % Desired signal (delayed QPSK signal)
del = 1;            %Initial FFT input powers
mu  = 0.1;           % Step size
lam = 0.9;          % Averaging factor
ha = adaptfilt.ufdaf(32,mu,1,del,lam);
```

```
[y,e] = filter(ha,x,d);
subplot(2,2,1);  plot(1:1000,real([d(1:1000);y(1:1000);e(1:1000)]));
title('In-Phase Components'); legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,2,2); plot(1:ntr,imag([d;y;e]));
title('Quadrature Components'); legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,2,3); plot(x(ntr-100:ntr),'.'); axis([-3 3 -3 3]);
title('Received Signal Scatter Plot'); axis('square');
xlabel('Real[x]'); ylabel('Imag[x]'); grid on;
subplot(2,2,4); plot(y(ntr-100:ntr),'.'); axis([-3 3 -3 3]);
title('Equalized Signal Scatter Plot'); axis('square');
xlabel('Real[y]'); ylabel('Imag[y]'); grid on;
```

allpass2wdf

Allpass to Wave Digital Filter coefficient transformation

Syntax

```
w = allpass2wdf(a)
W = allpass2wdf(A)
```

Description

`w = allpass2wdf(a)` accepts a vector of real allpass polynomial filter coefficients a, and returns the transformed coefficient w. w can be used with allpass filter objects such as `dsp.AllpassFilter`, and `dsp.CoupledAllpassFilter`, with Structure set to `'Wave Digital Filter'`.

`W = allpass2wdf(A)` accepts the cell array of allpass polynomial coefficient vectors A. Each cell of A holds the coefficients of a section of a cascade allpass filter. W is also a cell array, and each cell of W contains the transformed version of the coefficients in the corresponding cell of A. W can be used with allpass filter objects such as `dsp.AllpassFilter` and `dsp.CoupledAllpassFilter`, with structure set to `'Wave Digital Filter'`.

Examples

Allpass coefficients

This example illustrates the use of allpass2wdf to enable Wave Digital Filter as Structure of dsp.AllpassFilter.

```
a = [0 0.5];    % Original 2nd order allpass coefficients
smm = dsp.AllpassFilter('AllpassCoefficients', a);
w = allpass2wdf(a); % Convert coefficients to Wave Digital Filter form
swdf = dsp.AllpassFilter('Structure', 'Wave Digital Filter',...
    'WDFCoefficients', w);
in = randn(512, 1);
out_mm = step(smm, in);
```

```
out_wdf = step(swdf, in);
max(out_mm-out_wdf);  % Compare numerical difference of filter outputs
```

Input Arguments

a — allpass filter coefficients

(default) | vector of real numbers

Numeric vector of allpass filter coefficients, specified as real numbers. a can have length only equal to 1,2, and 4. When the length is 4, the first and third components must both be zero. a can be a row or a column vector.

Example: `0.7`

Data Types: `double` | `single`

A — allpass filter coefficients

(default) | vector of cells

Cascade of allpass filter coefficients, specified as a cell vector. Every cell of A must contain a real vector of length 1,2, or 4. When the length is 4, the first and third components must both be zero. A can be a row or column vector of cells.

Example: `{0.7, [0.1, 0.2]}`

Data Types: `double` | `single`

Output Arguments

w — transformed version of the coefficients a

(default) | vector of real numbers

Numeric vector of transformed coefficients, determined as a real number, to use with single-section allpass filter objects having `Structure` set to `'Wave Digital Filter'`. w is always returned as a numeric row vector.

Example: `0.7`

Data Types: `double` | `single`

W — transformed version of the coefficients cell array A

(default) | vector of cell

Cascade of transformed allpass filter coefficients, determined as a cell array, to use with multi-section allpass filter objects having `Structure` set to `'Wave Digital Filter'`. W is always returned as a column of cells.

Example: `{0.7;[0.2,-0.0833]}`

Data Types: `double` | `single`

More About

Algorithms

In the more general case, the input coefficients A define a cascade or multisection allpass filter. `allpass2wdf` applies separately to each section of the same transformation used in the single-section case. In the single-section case, the numeric coefficients vector a contains a standard polynomial representation of an allpass filter of order 1, 2, or 4. For example, in the first order case,

$$a = [a_1]$$

represents the first order transfer function:

$$H_1(z) = \frac{z^{-1} + a_1}{1 + a_1 z^{-1}}$$

and in the second order case,

$$a = [a_1, a_2]$$

represents the second order transfer function:

$$H_2(z) = \frac{z^{-2} + a_1 z^{-1} + a_2}{1 + a_1 z^{-1} + a_2 z^{-2}}$$

.

The allpass transfer functions H_1 and H_2 can also have the following alternative representations, using decoupled coefficients in vector w_1 or w_2 respectively.

$$\tilde{H}1(z) = \frac{z^{-1} + w_1}{1 + w_1 z^{-1}}$$

$$\tilde{H}2(z) = \frac{z^{-2} + w_2(1 + w_1)z^{-1} + w_1}{1 + w_2(1 + w_1)z^{-1} + w_1 z^{-2}}$$

For allpass coefficients, w is often used to derive adaptor multipliers for Wave Digital Filter structures, and it is required by a number of allpass based filters in DSP System Toolbox when `Structure` is set to `'Wave Digital Filter'` (e.g. `dsp.AllpassFilter`, and `dsp.CoupledAllpassFilter`).

For a given vector of section coefficients a, `allpass2wdf` computes the corresponding vector w such that

$$when\ i\ =\ 1,\ 2\ or\ 4$$

$$\tilde{H}_i(z) = H_i(z)$$

This results in using the following formulas:

$$for\ order\ 1:$$
$$w_1 = a_1$$
$$for\ order\ 2:$$
$$w_1 = a_2$$
$$w_2 = \frac{a_1}{1 + a_2}$$
$$for\ order\ 4:$$
$$w_1 = a_4$$
$$w_3 = \frac{a_2}{1 + a_4}$$
$$w_2 = w_4 = 0$$

allpassbpc2bpc

Allpass filter for complex bandpass transformation

Syntax

```
[AllpassNum,AllpassDen] = allpassbpc2bpc(Wo,Wt)
```

Description

`[AllpassNum,AllpassDen] = allpassbpc2bpc(Wo,Wt)` returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the first-order allpass mapping filter for performing a complex bandpass to complex bandpass frequency transformation. This transformation effectively places two features of an original filter, located at frequencies W_{o1} and W_{o2}, at the required target frequency locations W_{t1} and W_{t2}. It is assumed that W_{t2} is greater than W_{t1}. In most of the cases the features selected for the transformation are the band edges of the filter passbands. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter, F_1 and F_2, with F_1 preceding F_2. Feature F_1 will still precede F_2 after the transformation. However, the distance between F_1 and F_2 will not be the same before and after the transformation.

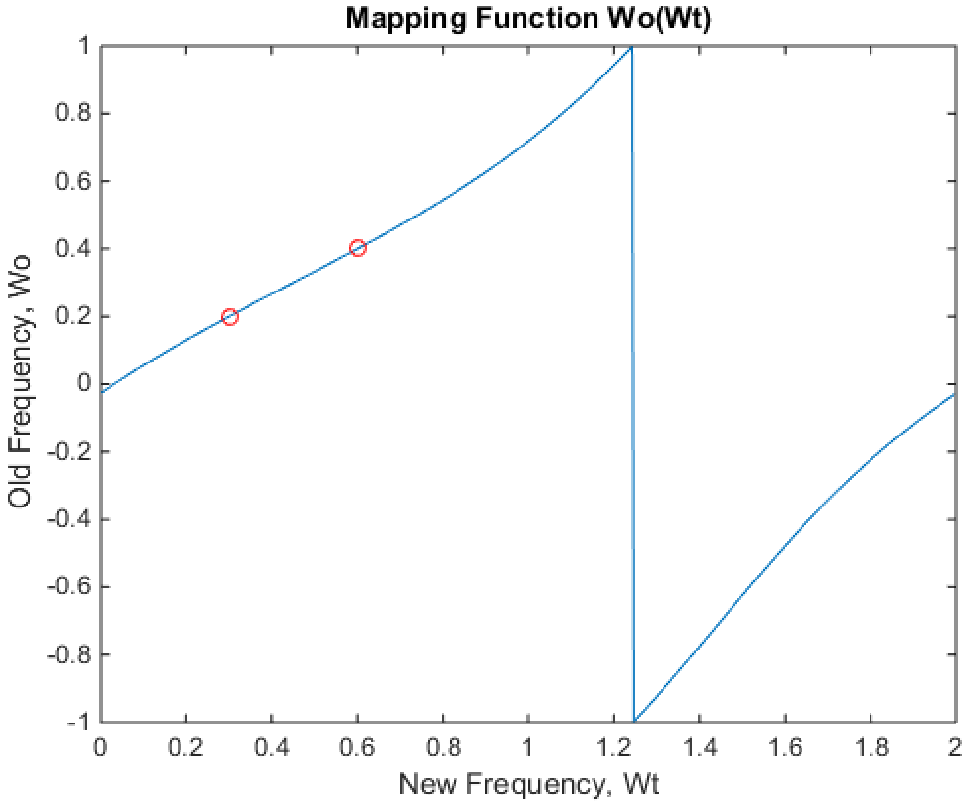
This transformation can also be used for transforming other types of filters; e.g., complex notch filters or resonators can be repositioned at two distinct desired frequencies at any place around the unit circle. This is very attractive for adaptive systems.

Examples

Design of the allpass mapping filter

This example shows how to design allpass mapping filter, changing the complex bandpass filter with the band edges at $W_{o1} = 0.2$ and $W_{o2} = 0.4$ to the new band edges of $W_{t1} = 0.3$ and $W_{t2} = 0.6$. Find the frequency response of the allpass mapping filter:

```
Wo = [0.2, 0.4]; Wt = [0.3, 0.6];
[AllpassNum, AllpassDen] = allpassbpc2bpc(Wo, Wt);
[ha, f] = freqz(AllpassNum, AllpassDen, 'whole');
plot(f/pi,-angle(ha)/pi, Wt, Wo, 'ro'); title('Mapping Function Wo(Wt)');
xlabel('New Frequency, Wt'); ylabel('Old Frequency, Wo');
```



Arguments

Variable	Description
`Wo`	Frequency values to be transformed from the prototype filter
`Wt`	Desired frequency locations in the transformed target filter

Variable	Description
AllpassNum	Numerator of the mapping filter
AllpassDen	Denominator of the mapping filter

Frequencies must be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.

allpasslp2bp

Allpass filter for lowpass to bandpass transformation

Syntax

```
[AllpassNum,AllpassDen] = allpasslp2bp(Wo,Wt)
```

Description

`[AllpassNum,AllpassDen] = allpasslp2bp(Wo,Wt)` returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the second-order allpass mapping filter for performing a real lowpass to real bandpass frequency transformation. This transformation effectively places one feature of an original filter, located at frequency $-W_o$, at the required target frequency location, W_{t1}, and the second feature, originally at $+W_o$, at the new location, W_{t2}. It is assumed that W_{t2} is greater than W_{t1}. This transformation implements the "DC mobility," which means that the Nyquist feature stays at Nyquist, but the DC feature moves to a location dependent on the selection of W_t.

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter, F_1 and F_2, with F_1 preceding F_2. Feature F_1 will still precede F_2 after the transformation. However, the distance between F_1 and F_2 will not be the same before and after the transformation.

Choice of the feature subject to the lowpass to bandpass transformation is not restricted only to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

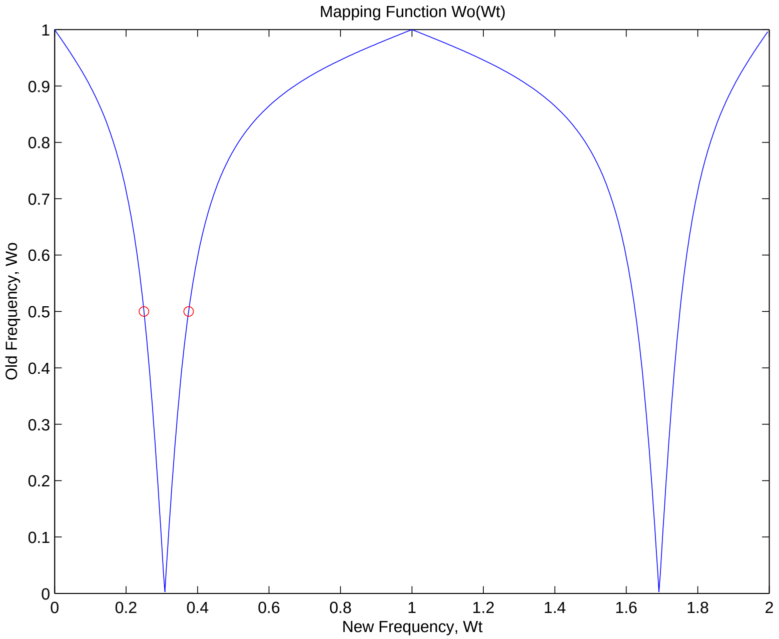
Lowpass to bandpass transformation can also be used for transforming other types of filters; e.g., real notch filters or resonators can be doubled and repositioned at two distinct desired frequencies.

Examples

Design the allpass mapping filter changing the lowpass filter with cutoff frequency at W_o=0.5 to the real–valued bandpass filter with cutoff frequencies at W_{t1}0.25 and W_{t2}=0.375.

Compute the frequency response and plot the phase response normalized to π, which is in effect the mapping function $W_o(W_t)$. Please note that the transformation works in the same way for both positive and negative frequencies:

```
Wo = 0.5; Wt = [0.25, 0.375];
[AllpassNum, AllpassDen] = allpasslp2bp(Wo, Wt);
[h, f] = freqz(AllpassNum, AllpassDen, 'whole');
plot(f/pi, abs(angle(h))/pi, Wt, Wo, 'ro');
title('Mapping Function Wo(Wt)');
xlabel('New Frequency, Wt'); ylabel('Old Frequency, Wo');
```



Arguments

Variable	Description
`Wo`	Frequency value to be transformed from the prototype filter
`Wt`	Desired frequency locations in the transformed target filter
`AllpassNum`	Numerator of the mapping filter
`AllpassDen`	Denominator of the mapping filter

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

allpasslp2bpc

Allpass filter for lowpass to complex bandpass transformation

Syntax

```
[AllpassNum,AllpassDen] = allpasslp2bpc(Wo,Wt)
```

Description

`[AllpassNum,AllpassDen] = allpasslp2bpc(Wo,Wt)` returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the first-order allpass mapping filter for performing a real lowpass to complex bandpass frequency transformation. This transformation effectively places one feature of an original filter, located at frequency -W_o, at the required target frequency location, W_{t1}, and the second feature, originally at +W_o, at the new location, W_{t2}. It is assumed that W_{t2} is greater than W_{t1}.

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter, F_1 and F_2, with F_1 preceding F_2. Feature F_1 will still precede F_2 after the transformation. However, the distance between F_1 and F_2 will not be the same before and after the transformation.

Choice of the feature subject to the lowpass to bandpass transformation is not restricted only to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

Lowpass to bandpass transformation can also be used for transforming other types of filters; e.g., real notch filters or resonators can be doubled and positioned at two distinct desired frequencies at any place around the unit circle forming a pair of complex notches/ resonators. This transformation can be used for designing bandpass filters for radio receivers from the high-quality prototype lowpass filter.

Examples

Design the allpass mapping filter changing the real lowpass filter with the cutoff frequency of W_o=`0.5` into a complex bandpass filter with band edges of W_{t1}=`0.2` and

W_{t2}=0.4 precisely defined. Calculate the frequency response of the mapping filter in the full range:

```
Wo = 0.5; Wt = [0.2,0.4];
[AllpassNum, AllpassDen] = allpasslp2bpc(Wo, Wt);
[h, f] = freqz(AllpassNum, AllpassDen, 'whole');
```

Arguments

Variable	Description
Wo	Frequency value to be transformed from the prototype filter. It should be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.
Wt	Desired frequency locations in the transformed target filter. They should be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.
AllpassNum	Numerator of the mapping filter
AllpassDen	Denominator of the mapping filter

allpasslp2bs

Allpass filter for lowpass to bandstop transformation

Syntax

```
[AllpassNum,AllpassDen] = allpasslp2bs(Wo,Wt)
```

Description

`[AllpassNum,AllpassDen] = allpasslp2bs(Wo,Wt)` returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the second-order allpass mapping filter for performing a real lowpass to real bandstop frequency transformation. This transformation effectively places one feature of an original filter, located at frequency $-W_o$, at the required target frequency location, W_{t1}, and the second feature, originally at $+W_o$, at the new location, W_{t2}. It is assumed that W_{t2} is greater than W_{t1}. This transformation implements the "Nyquist Mobility," which means that the DC feature stays at DC, but the Nyquist feature moves to a location dependent on the selection of W_o and W_t.

Relative positions of other features of an original filter change in the target filter. This means that it is possible to select two features of an original filter, F_1 and F_2, with F_1 preceding F_2. After the transformation feature F_2 will precede F_1 in the target filter. However, the distance between F_1 and F_2 will not be the same before and after the transformation.

Choice of the feature subject to the lowpass to bandstop transformation is not restricted only to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

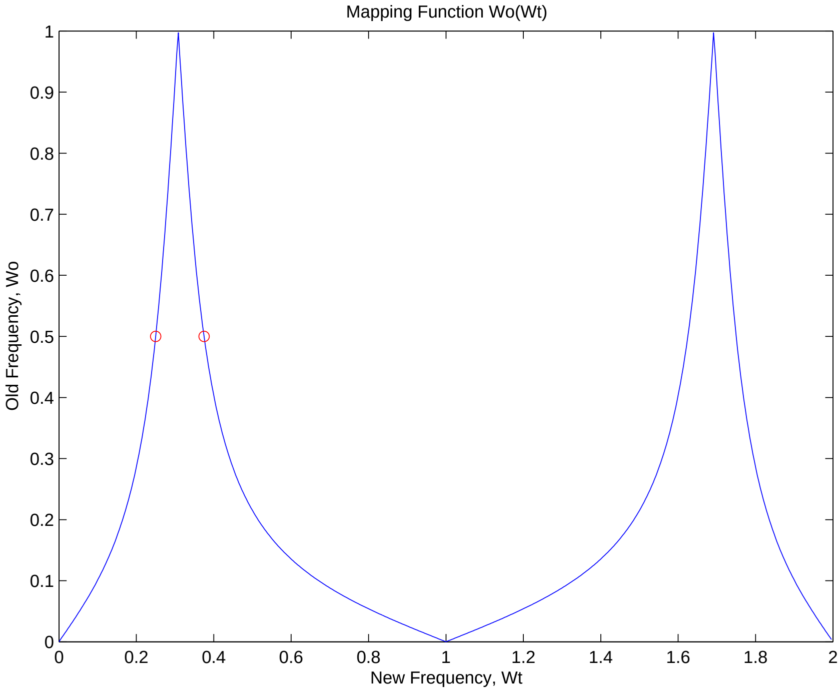
Examples

Design the allpass filter changing the lowpass filter with cutoff frequency at W_o=`0.5` to the real bandstop filter with cutoff frequencies at W_{t1}=`0.25` and W_{t2}=`0.375`:

```
Wo = 0.5; Wt = [0.25, 0.375];
```

```
[AllpassNum, AllpassDen] = allpasslp2bs(Wo, Wt);
[h, f] = freqz(AllpassNum, AllpassDen, 'whole');
plot(f/pi, abs(angle(h))/pi, Wt, Wo, 'ro');
title('Mapping Function Wo(Wt)');
xlabel('New Frequency, Wt'); ylabel('Old Frequency, Wo');
```

In the figure, you find the mapping filter function as determined by the example. Note the response is normalized to π:



Arguments

Variable	Description
Wo	Frequency value to be transformed from the prototype filter
Wt	Desired frequency locations in the transformed target filter
AllpassNum	Numerator of the mapping filter

Variable	Description
AllpassDen	Denominator of the mapping filter

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

allpasslp2bsc

Allpass filter for lowpass to complex bandstop transformation

Syntax

```
[AllpassNum,AllpassDen] = allpasslp2bsc(Wo,Wt)
```

Description

`[AllpassNum,AllpassDen] = allpasslp2bsc(Wo,Wt)` returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the first-order allpass mapping filter for performing a real lowpass to complex bandstop frequency transformation. This transformation effectively places one feature of an original filter, located at frequency -W_o, at the required target frequency location, W_{t1}, and the second feature, originally at +W_o, at the new location, W_{t2}. It is assumed that W_{t2} is greater than W_{t1}. Additionally the transformation swaps passbands with stopbands in the target filter.

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter, F_1 and F_2, with F_1 preceding F_2. Feature F_1 will still precede F_2 after the transformation. However, the distance between F_1 and F_2 will not be the same before and after the transformation.

Choice of the feature subject to the lowpass to bandstop transformation is not restricted only to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

Lowpass to bandpass transformation can also be used for transforming other types of filters; e.g., real notch filters or resonators can be doubled and positioned at two distinct desired frequencies at any place around the unit circle forming a pair of complex notches/ resonators. This transformation can be used for designing bandstop filters for band attenuation or frequency equalizers, from the high-quality prototype lowpass filter.

Examples

Design the allpass filter changing the real lowpass filter with the cutoff frequency of W_o=0.5 into a complex bandstop filter with band edges of W_{t1}=0.2 and W_{t2}=0.4 precisely defined:

```
Wo = 0.5; Wt = [0.2,0.4];
[AllpassNum, AllpassDen] = allpasslp2bsc(Wo, Wt);
[h, f] = freqz(AllpassNum, AllpassDen, 'whole');
```

Arguments

Variable	Description
Wo	Frequency value to be transformed from the prototype filter. It should be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.
Wt	Desired frequency locations in the transformed target filter. They should be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.
AllpassNum	Numerator of the mapping filter
AllpassDen	Denominator of the mapping filter

allpasslp2hp

Allpass filter for lowpass to highpass transformation

Syntax

```
[AllpassNum,AllpassDen] = allpasslp2hp(Wo,Wt)
```

Description

`[AllpassNum,AllpassDen] = allpasslp2hp(Wo,Wt)` returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the first-order allpass mapping filter for performing a real lowpass to real highpass frequency transformation. This transformation effectively places one feature of an original filter, located originally at frequency, W_o, at the required target frequency location, W_t, at the same time rotating the whole frequency response by half of the sampling frequency. Result is that the DC and Nyquist features swap places.

Relative positions of other features of an original filter change in the target filter. This means that it is possible to select two features of an original filter, F_1 and F_2, with F_1 preceding F_2. After the transformation feature F_2 will precede F_1 in the target filter. However, the distance between F_1 and F_2 will not be the same before and after the transformation.

Choice of the feature subject to the lowpass to highpass transformation is not restricted to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband.

Lowpass to highpass transformation can also be used for transforming other types of filters; e.g., notch filters or resonators can change their position in a simple way by using the lowpass to highpass transformation.

Examples

Design the allpass filter changing the lowpass filter to the highpass filter with its cutoff frequency moved from W_o=`0.5` to W_t=`0.25`.

Plot the phase response normalized to π, which is in effect the mapping function $W_o(W_t)$. Please note that the transformation works in the same way for both positive and negative frequencies:

```
Wo = 0.5; Wt = 0.25;
[AllpassNum, AllpassDen] = allpasslp2hp(Wo, Wt);
[h, f] = freqz(AllpassNum, AllpassDen, 'whole');
plot(f/pi, abs(angle(h))/pi, Wt, Wo, 'ro');
title('Mapping Function Wo(Wt)');
xlabel('New Frequency, Wt');
ylabel('Old Frequency, Wo');
```

Arguments

Variable	Description
Wo	Frequency value to be transformed from the prototype filter
Wt	Desired frequency location in the transformed target filter
AllpassNum	Numerator of the mapping filter
AllpassDen	Denominator of the mapping filter

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

allpasslp2lp

Allpass filter for lowpass to lowpass transformation

Syntax

```
[AllpassNum,AllpassDen] = allpasslp2lp(Wo,Wt)
```

Description

`[AllpassNum,AllpassDen] = allpasslp2lp(Wo,Wt)` returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the first-order allpass mapping filter for performing a real lowpass to real lowpass frequency transformation. This transformation effectively places one feature of an original filter, located originally at frequency W_o, at the required target frequency location, W_t.

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter, F_1 and F_2, with F_1 preceding F_2. Feature F_1 will still precede F_2 after the transformation. However, the distance between F_1 and F_2 will not be the same before and after the transformation.

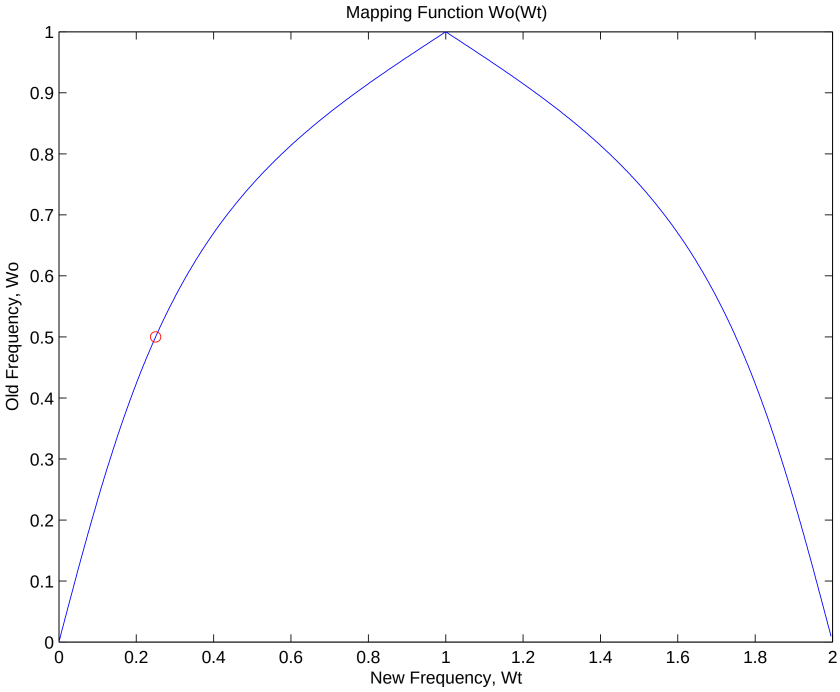
Choice of the feature subject to the lowpass to lowpass transformation is not restricted to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband and so on.

Lowpass to lowpass transformation can also be used for transforming other types of filters; e.g., notch filters or resonators can change their position in a simple way by applying the lowpass to lowpass transformation.

Examples

Design the allpass filter changing the lowpass filter cutoff frequency originally at W_o=`0.5` to W_t=`0.25`. Plot the phase response normalized to π, which is in effect the mapping function $W_o(W_t)$. Please note that the transformation works in the same way for both positive and negative frequencies:

```
Wo = 0.5; Wt = 0.25;
[AllpassNum, AllpassDen] = allpasslp2lp(Wo, Wt);
[h, f] = freqz(AllpassNum, AllpassDen, 'whole');
plot(f/pi, abs(angle(h))/pi, Wt, Wo, 'ro');
title('Mapping Function Wo(Wt)');
xlabel('New Frequency, Wt'); ylabel('Old Frequency, Wo');
```



As shown in the figure, `allpasslp2lp` generates a mapping function that converts your prototype lowpass filter to a target lowpass filter with different passband specifications.

Arguments

Variable	Description
`Wo`	Frequency value to be transformed from the prototype filter
`Wt`	Desired frequency location in the transformed target filter

Variable	Description
`AllpassNum`	Numerator of the mapping filter
`AllpassDen`	Denominator of the mapping filter

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

allpasslp2mb

Allpass filter for lowpass to M-band transformation

Syntax

```
[AllpassNum,AllpassDen] = allpasslp2mb(Wo,Wt)
[AllpassNum,AllpassDen] = allpasslp2mb(Wo,Wt,Pass)
```

Description

`[AllpassNum,AllpassDen] = allpasslp2mb(Wo,Wt)` returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the `M`th-order allpass mapping filter for performing a real lowpass to real multipassband frequency transformation. Parameter `M` is the number of times an original feature is replicated in the target filter. This transformation effectively places one feature of an original filter, located at frequency W_o, at the required target frequency locations, W_{t1},...,W_{tM}. By default the DC feature is kept at its original location.

`[AllpassNum,AllpassDen] = allpasslp2mb(Wo,Wt,Pass)` allows you to specify an additional parameter, `Pass`, which chooses between using the "DC Mobility" and the “Nyquist Mobility.” In the first case the Nyquist feature stays at its original location and the DC feature is free to move. In the second case the DC feature is kept at an original frequency and the Nyquist feature is movable.

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter, F_1 and F_2, with F_1 preceding F_2. Feature F_1 will still precede F_2 after the transformation. However, the distance between F_1 and F_2 will not be the same before and after the transformation.

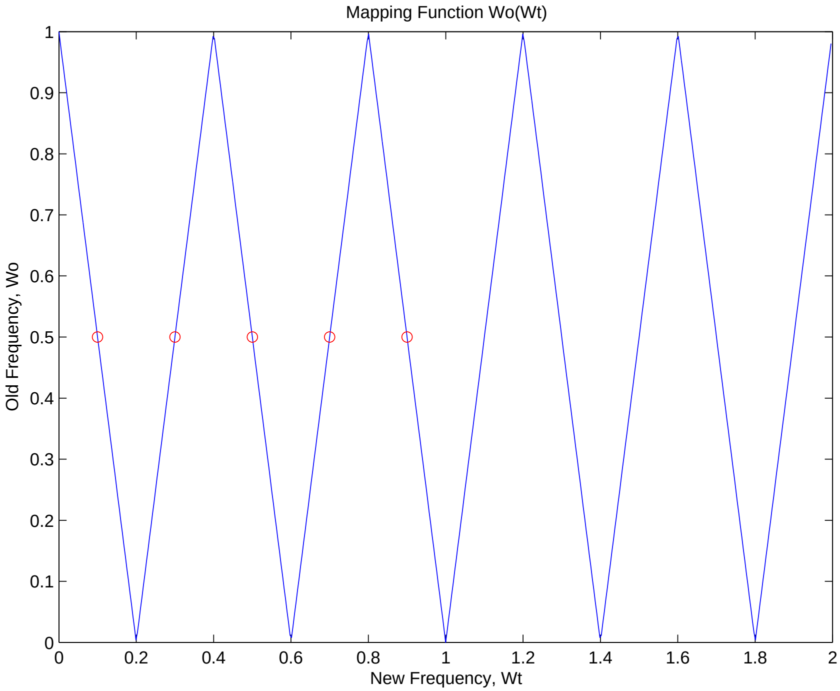
Choice of the feature subject to this transformation is not restricted to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

This transformation can also be used for transforming other types of filters; e.g., notch filters or resonators can be easily replicated at a number of required frequency locations without redesigning them. A good application would be an adaptive tone cancellation circuit reacting to the changing number and location of tones.

Examples

Design the allpass filter changing the real lowpass filter with the cutoff frequency of W_o=0.5 into a real multiband filter with band edges of W_t=[1:2:9]/10 precisely defined. Plot the phase response normalized to π, which is in effect the mapping function $W_o(W_t)$. Please note that the transformation works in the same way for both positive and negative frequencies:

```
Wo = 0.5; Wt = [1:2:9]/10;
[AllpassNum, AllpassDen] = allpasslp2mb(Wo, Wt);
[h, f] = freqz(AllpassNum, AllpassDen, 'whole');
plot(f/pi, abs(angle(h))/pi, Wt, Wo, 'ro');
title('Mapping Function Wo(Wt)');
xlabel('New Frequency, Wt'); ylabel('Old Frequency, Wo');
```



Arguments

Variable	Description
Wo	Frequency value to be transformed from the prototype filter
Wt	Desired frequency locations in the transformed target filter
Pass	Choice (`'pass'`/`'stop'`) of passband/stopband at DC, `'pass'` being the default
AllpassNum	Numerator of the mapping filter
AllpassDen	Denominator of the mapping filter

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

allpasslp2mbc

Allpass filter for lowpass to complex M-band transformation

Syntax

```
[AllpassNum,AllpassDen] = allpasslp2mbc(Wo,Wt)
```

Description

`[AllpassNum,AllpassDen] = allpasslp2mbc(Wo,Wt)` returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the `M`th-order allpass mapping filter for performing a real lowpass to complex multipassband frequency transformation. Parameter `M` is the number of times an original feature is replicated in the target filter. This transformation effectively places one feature of an original filter, located at frequency W_o, at the required target frequency locations, W_{t1},...,W_{tM}.

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter, F_1 and F_2, with F_1 preceding F_2. Feature F_1 will still precede F_2 after the transformation. However, the distance between F_1 and F_2 will not be the same before and after the transformation.

Choice of the feature subject to this transformation is not restricted to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

This transformation can also be used for transforming other types of filters; e.g., notch filters or resonators can be easily replicated at a number of required frequency locations without the need to design them again. A good application would be an adaptive tone cancellation circuit reacting to the changing number and location of tones.

Examples

Design the allpass filter changing the real lowpass filter with the cutoff frequency of W_o=`0.5` into a complex multiband filter with band edges of W_t=`[-3+1:2:9]/10` precisely defined:

```
Wo = 0.5; Wt = [-3+1:2:9]/10;
[AllpassNum, AllpassDen] = allpasslp2mbc(Wo, Wt);
```

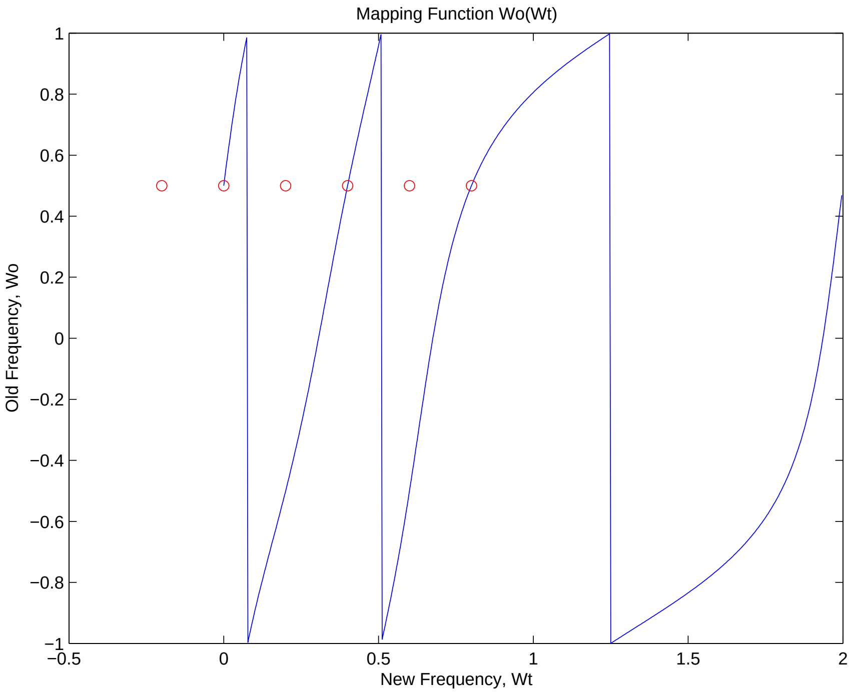
Calculate the frequency response of the mapping filter in the full range:

```
[h, f] = freqz(AllpassNum, AllpassDen, 'whole');
```

Plot the phase response normalized to π, which is in effect the mapping function $W_o(W_t)$. Please note that the transformation works in the same way for both positive and negative frequencies:

```
plot(f/pi, angle(h)/pi, Wt, Wo, 'ro');
 title('Mapping Function Wo(Wt)');
xlabel('New Frequency, Wt'); ylabel('Old Frequency, Wo');
```

In this example, the resulting mapping function converts real filters to multiband complex filters.



Arguments

Variable	Description
Wo	Frequency value to be transformed from the prototype filter. It should be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.
Wt	Desired frequency locations in the transformed target filter. They should be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.
AllpassNum	Numerator of the mapping filter
AllpassDen	Denominator of the mapping filter

`iirlp2mbc` | `zpklp2mbc`

allpasslp2xc

Allpass filter for lowpass to complex N-point transformation

Syntax

```
[AllpassNum,AllpassDen] = allpasslp2xc(Wo,Wt)
```

Description

`[AllpassNum,AllpassDen] = allpasslp2xc(Wo,Wt)` returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the `N`th-order allpass mapping filter, where `N` is the allpass filter order, for performing a real lowpass to complex multipoint frequency transformation. Parameter `N` also specifies the number of replicas of the prototype filter created around the unit circle after the transformation. This transformation effectively places `N` features of the, original filter located at frequencies W_{o1},...,W_{oN}, at the required target frequency locations, W_{t1},...,W_{tM}.

Relative positions of other features of an original filter are the same in the target filter for the Nyquist mobility and are reversed for the DC mobility. For the Nyquist mobility this means that it is possible to select two features of an original filter, F_1 and F_2, with F_1 preceding F_2. Feature F_1 will still precede F_2 after the transformation. However, the distance between F_1 and F_2 will not be the same before and after the transformation. For DC mobility feature F_2 will precede F_1 after the transformation.

Choice of the feature subject to this transformation is not restricted to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones. The only condition is that the features must be selected in such a way that when creating `N` bands around the unit circle, there will be no band overlap.

This transformation can also be used for transforming other types of filters; e.g., notch filters or resonators can be easily replicated at a number of required frequency locations. A good application would be an adaptive tone cancellation circuit reacting to the changing number and location of tones.

Examples

Design the allpass filter moving four features of an original complex filter given in W_o to the new independent frequency locations W_t. Please note that the transformation creates N replicas of an original filter around the unit circle, where N is the order of the allpass mapping filter:

```
Wo = [-0.2, 0.3, -0.7, 0.4]; Wt = [0.3, 0.5, 0.7, 0.9];
[AllpassNum, AllpassDen] = allpasslp2xc(Wo, Wt);
[h, f] = freqz(AllpassNum, AllpassDen, 'whole');
```

Arguments

Variable	Description
Wo	Frequency values to be transformed from the prototype filter
Wt	Desired frequency locations in the transformed target filter
AllpassNum	Numerator of the mapping filter
AllpassDen	Denominator of the mapping filter

Frequencies must be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.

allpasslp2xn

Allpass filter for lowpass to N-point transformation

Syntax

```
[AllpassNum,AllpassDen] = allpasslp2xn(Wo,Wt)
[AllpassNum,AllpassDen] = allpasslp2xn(Wo,Wt,Pass)
```

Description

`[AllpassNum,AllpassDen] = allpasslp2xn(Wo,Wt)` returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the `N`th-order allpass mapping filter, where `N` is the allpass filter order, for performing a real lowpass to real multipoint frequency transformation. Parameter `N` also specifies the number of replicas of the prototype filter created around the unit circle after the transformation. This transformation effectively places `N` features of an original filter, located at frequencies W_{o1},...,W_{oN}, at the required target frequency locations, W_{t1},...,W_{tM}. By default the DC feature is kept at its original location.

`[AllpassNum,AllpassDen] = allpasslp2xn(Wo,Wt,Pass)` allows you to specify an additional parameter, `Pass`, which chooses between using the "DC Mobility" and the "Nyquist Mobility." In the first case the Nyquist feature stays at its original location and the DC feature is free to move. In the second case the DC feature is kept at an original frequency and the Nyquist feature is movable.

Relative positions of other features of an original filter are the same in the target filter for the Nyquist mobility and are reversed for the DC mobility. For the Nyquist mobility this means that it is possible to select two features of an original filter, F_1 and F_2, with F_1 preceding F_2. Feature F_1 will still precede F_2 after the transformation. However, the distance between F_1 and F_2 will not be the same before and after the transformation. For DC mobility feature F_2 will precede F_1 after the transformation.

Choice of the feature subject to this transformation is not restricted to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones. The only condition is that the features must be selected in such a way that when creating N bands around the unit circle, there will be no band overlap.

This transformation can also be used for transforming other types of filters; e.g., notch filters or resonators can be easily replicated at a number of required frequency locations without the need of designing them again. A good application would be an adaptive tone cancellation circuit reacting to the changing number and location of tones.

Arguments

Variable	Description
Wo	Frequency values to be transformed from the prototype filter
Wt	Desired frequency locations in the transformed target filter
Pass	Choice (`'pass'`/`'stop'`) of passband/stopband at DC, `'pass'` being the default
AllpassNum	Numerator of the mapping filter
AllpassDen	Denominator of the mapping filter

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

`iirlp2xn` | `zpklp2xn`

allpassrateup

Allpass filter for integer upsample transformation

Syntax

```
[AllpassNum,AllpassDen] = allpassrateup(N)
```

Description

`[AllpassNum,AllpassDen] = allpassrateup(N)` returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the `N`th-order allpass mapping filter for performing the rateup frequency transformation, which creates `N` equal replicas of the prototype filter frequency response.

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter, F_1 and F_2, with F_1 preceding F_2. Feature F_1 will still precede F_2 after the transformation. However, the distance between F_1 and F_2 will not be the same before and after the transformation.

Examples

Design the allpass filter creating the effect of upsampling the digital filter four times:

Choose any feature from an original filter, say at W_o=`0.2`:

```
N = 4;
Wo = 0.2; Wt = Wo/N + 2*[0:N-1]/N;
[AllpassNum, AllpassDen] = allpassrateup(N);
```

Calculate the frequency response of the mapping filter in the full range:

```
[h, f] = freqz(AllpassNum, AllpassDen, 'whole');
```

Arguments

Variable	Description
N	Frequency replication ratio (upsampling ratio)

Variable	Description
AllpassNum	Numerator of the mapping filter
AllpassDen	Denominator of the mapping filter

See Also

`iirrateup` | `zpkrateup`

allpassshift

Allpass filter for real shift transformation

Syntax

```
[AllpassNum,AllpassDen] = allpassshift(Wo,Wt)
```

Description

`[AllpassNum,AllpassDen] = allpassshift(Wo,Wt)` returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the second-order allpass mapping filter for performing a real frequency shift transformation. This transformation places one selected feature of an original filter, located at frequency W_o, at the required target frequency location, W_t. This transformation implements the “DC mobility,” which means that the Nyquist feature stays at Nyquist, but the DC feature moves to a location dependent on the selection of W_o and W_t.

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter, F_1 and F_2, with F_1 preceding F_2. Feature F_1 will still precede F_2 after the transformation. However, the distance between F_1 and F_2 will not be the same before and after the transformation.

Choice of the feature subject to the real shift transformation is not restricted to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

This transformation can also be used for transforming other types of filters; e.g., notch filters or resonators can be moved to a different frequency by applying a shift transformation. In such a way you can avoid designing the filter from the beginning.

Examples

Design the allpass filter precisely shifting one feature of the lowpass filter originally at W_o=`0.5` to the new frequencies of W_t=`0.25`:

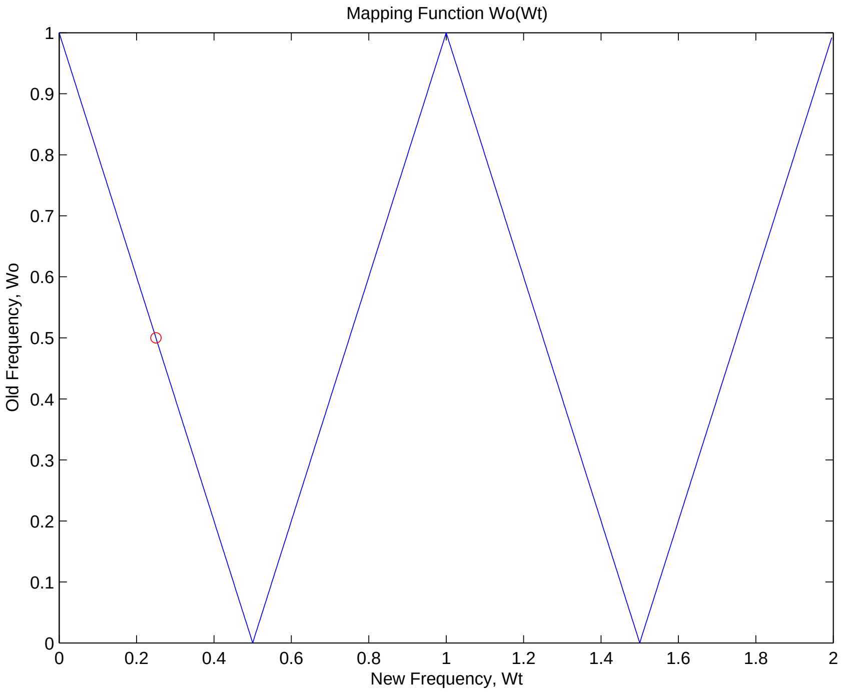
```
Wo = 0.5; Wt = 0.25;
[AllpassNum, AllpassDen] = allpassshift(Wo, Wt);
```

Calculate the frequency response of the mapping filter in the full range:

```
[h, f] = freqz(AllpassNum, AllpassDen, 'whole');
```

Plot the phase response normalized to π, which is in effect the mapping function `W`$_o$`(W`$_t$`)`. Please note that the transformation works in the same way for both positive and negative frequencies:

```
plot(f/pi, abs(angle(h))/pi, Wt, Wo, 'ro');
title('Mapping Function Wo(Wt)');
xlabel('New Frequency, Wt'); ylabel('Old Frequency, Wo');
```



Arguments

Variable	Description
Wo	Frequency value to be transformed from the prototype filter

Variable	Description
`Wt`	Desired frequency location in the transformed target filter
`AllpassNum`	Numerator of the mapping filter
`AllpassDen`	Denominator of the mapping filter

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

See Also

`iirshift` | `zpkshift`

allpassshiftc

Allpass filter for complex shift transformation

Syntax

```
[AllpassNum,AllpassDen] = allpassshiftc(Wo,Wt)
[AllpassNum,AllpassDen] = allpassshiftc(0,0.5)
[AllpassNum,AllpassDen] = allpassshiftc(0,-0.5)
```

Description

`[AllpassNum,AllpassDen] = allpassshiftc(Wo,Wt)` returns the numerator, `AllpassNum`, and denominator, `AllpassDen`, vectors of the allpass mapping filter for performing a complex frequency shift of the frequency response of the digital filter by an arbitrary amount.

`[AllpassNum,AllpassDen] = allpassshiftc(0,0.5)` calculates the allpass filter for doing the Hilbert transformation, a 90 degree counterclockwise rotation of an original filter in the frequency domain.

`[AllpassNum,AllpassDen] = allpassshiftc(0,-0.5)` calculates the allpass filter for doing an inverse Hilbert transformation, i.e. a 90 degree clockwise rotation of an original filter in the frequency domain.

Examples

Design the allpass filter precisely rotating the whole filter by the amount defined by the location of the selected feature from an original filter, W_o=`0.5`, and its required position in the target filter, W_t=`0.25`:

```
Wo = 0.5; Wt = 0.25;
[AllpassNum, AllpassDen] = allpassshiftc(Wo, Wt);
```

Calculate the frequency response of the mapping filter in the full range:

```
[h, f] = freqz(AllpassNum, AllpassDen, 'whole');
```

Arguments

Variable	Description
Wo	Frequency value to be transformed from the prototype filter
Wt	Desired frequency location in the transformed target filter
AllpassNum	Numerator of the mapping filter
AllpassDen	Denominator of the mapping filter

Frequencies must be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.

`iirshiftc` | `zpkshiftc`

autoscale

Automatic dynamic range scaling

Syntax

```
autoscale(hd,x)
hnew = autoscale(hd,x)
```

Description

`autoscale(hd,x)` provides dynamic range scaling for each node of the filter `hd`. This method runs signal `x` through `hd` in floating-point to simulate filtering. `autoscale` uses the maximum and minimum data obtained from that simulation at each filter node to set fraction lengths to cover the simulation full range and maximize the precision. Word lengths are not changed during autoscaling.

`hnew = autoscale(hd,x)` If you request an output, `autoscale` returns a new filter with the scaled fraction lengths. The original filter is not changed.

For introductory demonstrations of the automatic scale process, refer to the following demos in the toolbox:

- Fixed-Point Scaling of an Elliptic IIR Filter
- Floating-Point to Fixed-Point Conversion of IIR Filters
- Floating-Point to Fixed-Point Conversion of FIR Filters

Examples

Demonstrate dynamic range scaling in a lattice ARMA filter:

```
hd = design(fdesign.bandpass,'ellip');
hd = convert(hd,'latticearma');
hd.arithmetic = 'fixed';
rng(4); x = rand(100,10); % Training input data.
hd(2) = autoscale(hd,x);
```

```
hfvt = fvtool(hd,'Analysis','magestimate','Showreference','off');
legend(hfvt, 'Before Autoscaling', 'After Autoscaling')
```

block

Generate block from multirate or multistage filter

Syntax

```
block(hm)
block(hm,'propertyname1',propertyvalue1,'propertyname2',propertyvalue2,...)
```

Description

`block(hm)` generates a DSP System Toolbox block equivalent to `hm`.

`block(hm,'propertyname1',propertyvalue1,'propertyname2',propertyvalue2,...)` generates a DSP System Toolbox block using the options specified in the property name/ property value pairs. The valid properties and their values are

Property Name	Property Values	Description and Values
`Destinatior`	`'current'` (default), `'new'`, or *`Subsystemname`*.	Determine which Simulink model gets the block. Enter `'current'`, `'new'`, or specify the name of an existing subsystem with *`subsystemname`*. `'current'` adds the block to your current Simulink model. Specifying `'new'` opens a new model and adds the block. Specifying `'new'` opens a new model and adds the block. If you provide the name of a subsystem in *`subsystemname`*, `block` adds the new block to your specified subsystem.
`Blockname`	`'filter'` (default)	Specify the name of the generated block. The name appears below the block in the model. When you do not specify a block name, the default is `filter`.
`OverwriteBl`	`'off'` (default), or `'on'`.	Tell `block` whether to overwrite an existing block of the same name, or create a new

Property Name	Property Values	Description and Values
		block. `'off'` is the default setting—`block` does not overwrite existing blocks with matching names. Switching from `'off'` to `'on'` directs `block` to overwrite existing blocks.
`MapStates`	`'off'` (default), or `'on'`.	Specify whether to apply the current filter states to the new block. This lets you save states from a filter object you may have used or configured in a specific way. The default setting of `'off'` means the states are not transferred to the block. Choosing `'on'` preserves the current filter states in the block.
`Link2Obj`	`'off'` (default), or `'on'`.	Specify how to set the **Coefficient source** in the block mask. The default setting is `'off'` and the **Coefficient source** is set to **Dialog parameters**. Setting `Link2Obj` to `'on'` sets the **Coefficient source** to **Discrete-time filter object (DFILT)**. The `Link2Obj` and `MapCoeffstoPorts` cannot be simultaneously `'on'`.
`MapCoeffstc`	`'off'` (default) or `'on'`	Specify whether to map the coefficients of the filter to the ports of the block. The `Link2Obj` and `MapCoeffstoPorts` cannot be simultaneously `'on'`. See `mfilt` for a list of supported filter objects.
`CoeffNames`	`{'Num'}` (default FIR) `{'Num','Den'}` (default direct form IIR) `{'Num','Den','g'}` (default IIR SOS), `{'K'}` (default form lattice)	Specify the coefficient variable names as string variables in a cell array. `MapCoeffsToPorts` must be set to `'on'` for this property to apply.

Property Name	Property Values	Description and Values
InputProces	'columns as channels' (default), 'elements as channels' , or 'inherited'	Specify sample-based (elements as channels) or frame-based (columns as channels) processing. The Inherited (this choice will be removed - see release notes) option will be removed in a future release.
RateOption	'enforce single rate' (default) or 'allow multirate'	Specify how the block adjusts the rate at the output to accommodate the reduced number of samples. This parameter applies only when InputProcessing is 'columns as channels'.

Using block to Realize Fixed-Point Multirate Filters

When the source filter hm is fixed-point, the input word and fraction lengths for the block are derived from the block input signal. The realization process issues a warning and ignores the input word and input fraction lengths that are part of the source filter object, choosing to inherit the settings from the input data. Other fixed-point properties map directly to settings for word and fraction length in the realized block.

Examples

Two examples of using block demonstrate the syntax capabilities. Both examples start from an mfilt object with interpolation factor of three. In the first example, use block with the default syntax, letting the function determine the block name and configuration.

```
hm = mfilt.firdecim(3);
```

Now use the default syntax to create a block.

```
block(hm);
```

In this second example, define the block name to meet your needs by using the property name/property value pair input arguments.

```
block(hm, 'blockname', 'firdecim');
```

The figure below shows the blocks in a Simulink model. When you try these examples, you see that the second block writes over the first block location. You can avoid this by moving the first block before you generate the second, always naming your block with the `blockname` property, or setting the `Destination` property to `new` which puts the filter block in a new Simulink model.

butter

Butterworth IIR filter design using specification object

Syntax

```
hd = design(d,'butter')
hd = design(d,'butter',designoption,value...)
```

Description

`hd = design(d,'butter')` designs a Butterworth IIR digital filter using the specifications supplied in the object `d`.

`hd = design(d,'butter',designoption,value...)` returns a Butterworth IIR filter where you specify a design option and value.

To determine the available design options, use `designopts` with the specification object and the design method as input arguments as shown.

```
designopts(d,'method')
```

For complete help about using `butter`, refer to the command line help system. For example, to get specific information about using `butter` with `d`, the specification object, enter the following at the MATLAB prompt.

```
help(d,'butter')
```

Examples

Construct a default lowpass filter specification object and design a Butterworth filter:

```
d = fdesign.lowpass;
hd = design(d,'butter','matchexactly','stopband');
```

Construct a highpass filter specification object and design a Butterworth filter:

```
%Order 8 and 3 dB frequency 0.6*pi radians/sample
```

```
d = fdesign.highpass('N,F3dB',8,.6);
hd = design(d,'butter');
fvtool(hd)

ca2tf

Convert coupled allpass filter to transfer function form

Syntax

```
[b,a]=ca2tf(d1,d2)
[b,a]=ca2tf(d1,d2,beta)
[b,a,bp]=ca2tf(d1,d2)
[b,a,bp]=ca2tf(d1,d2,beta)
```

Description

`[b,a]=ca2tf(d1,d2)` returns the vector of coefficients `b` and the vector of coefficients `a` corresponding to the numerator and the denominator of the transfer function

$$H(z) = B(z) / A(z) = \frac{1}{2}[H1(z) + H2(z)]$$

`d1` and `d2` are real vectors corresponding to the denominators of the allpass filters `H1(z)` and `H2(z)`.

`[b,a]=ca2tf(d1,d2,beta)` where `d1`, `d2` and `beta` are complex, returns the vector of coefficients `b` and the vector of coefficients `a` corresponding to the numerator and the denominator of the transfer function

$$H(z) = B(z) / A(z) = \frac{1}{2}\left[-(\bar{\beta}) \cdot H1(z) + \beta \cdot H2(z)\right]$$

`[b,a,bp]=ca2tf(d1,d2)`, where `d1` and `d2` are real, returns the vector `bp` of real coefficients corresponding to the numerator of the power complementary filter G(z)

$$G(z) = Bp(z) / A(z) = \frac{1}{2}[H1(z) - H2(z)]$$

`[b,a,bp]=ca2tf(d1,d2,beta)`, where `d1`, `d2` and `beta` are complex, returns the vector of coefficients `bp` of real or complex coefficients that correspond to the numerator of the power complementary filter G(z)

$$G(z) = Bp(z) / A(z) = \frac{1}{2_j}\left[-(\bar{\beta}) \cdot H1(z) + \beta \cdot H2(z)\right]$$

Examples

Create a filter, convert the filter to coupled allpass form, and convert the result back to the original structure (create the power complementary filter as well).

```
[b,a]=cheby1(10,.5,.4);
[d1,d2,beta]=tf2ca(b,a);            % tf2ca returns the %
                                    denominators of the % allpasses.
[num,den,numpc]=ca2tf(d1,           % Reconstruct the original
d2,beta);                           % filter plus the power %
                                    complementary one.
[h,w,s]=freqz(num,den);
hpc = freqz(numpc,den);
s.plot = 'mag';
s.yunits = 'sq';
freqzplot([h hpc],w,s);             % Plot the mag response of the %
                                    original filter and the % power
                                    complementary one.
```

cheby1

Chebyshev Type I filter using specification object

Syntax

```
hd = design(d,'cheby1')
hd = design(d,'cheby1',designoption,value,designoption,
value,...)
```

Description

`hd = design(d,'cheby1')` designs a type I Chebyshev IIR digital filter using the specifications supplied in the object `d`. Depending on the filter specification object, `cheby1` may or may not be a valid design. Use `designmethods` with the filter specification object to determine if a Chebyshev type I filter design is possible.

`hd = design(d,'cheby1',designoption,value,designoption, value,...)` returns a type I Chebyshev IIR filter where you specify design options as input arguments.

To determine the available design options, use `designopts` with the specification object and the design method as input arguments as shown.

```
designopts(d,'method')
```

For complete help about using `cheby1`, refer to the command line help system. For example, to get specific information about using `cheby1` with `d`, the specification object, enter the following at the MATLAB prompt.

```
help(d,'cheby1')
```

Examples

These examples use filter specification objects to construct Chebyshev type I filters. In the first example, you use the `matchexactly` option to ensure the performance of the filter in the passband.

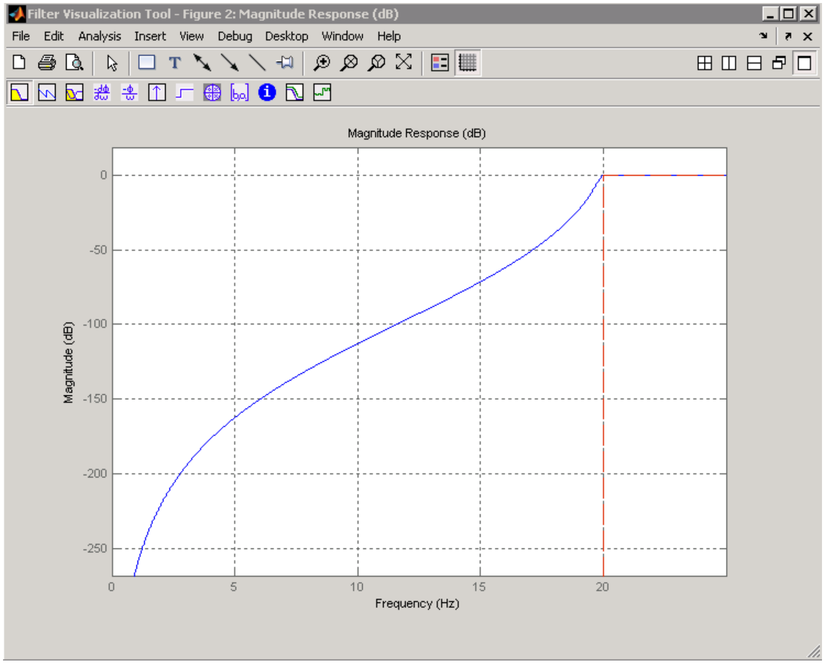
```
d = fdesign.lowpass; designopts(d,'cheby1');
hd = design(d,'cheby1','matchexactly','passband');
```

Specify the filter order, passband edge frequency, and the passband ripple to get the filter exactly as required.

```
d = fdesign.highpass('n,fp,ap',7,20,.4,50);
hd = design(d,'cheby1');
```

Use `fvtool` to view the resulting filter.

```
fvtool(hd)
```



By design, `cheby1` returns filters that use second-order sections (SOS). For many applications, and for most fixed-point applications, SOS filters are particularly well-suited.

`design` | `designmethods` | `fdesign`

cheby2

Chebyshev Type II filter using specification object

Syntax

```
hd = design(d,'cheby2')
hd = design(d,'cheby2',designoption,value,designoption,
value,...)
```

Description

`hd = design(d,'cheby2')` designs a Chebyshev II IIR digital filter using the specifications supplied in the object `d`.

`hd = design(d,'cheby2',designoption,value,designoption, value,...)` returns a Chebyshev II IIR filter where you specify design options as input arguments.

To determine the available design options, use `designopts` with the specification object and the design method as input arguments as shown.

```
designopts(d,'method')
```

For complete help about using `cheby1`, refer to the command line help system. For example, to get specific information about using `cheby2` with `d`, the specification object, enter the following at the MATLAB prompt.

```
help(d,'cheby2')
```

Examples

These examples use filter specification objects to construct Chebyshev type I filters. In the first example, you use the `matchexactly` option to ensure the performance of the filter in the passband.

```
d = fdesign.lowpass;
```

```
hd = design(d,'cheby2','matchexactly','passband');
```

`cheby2` also designs highpass, bandpass, and bandstop filters. Here is a highpass filter where you specify the filter order, the stopband edge frequency. and the stopband attenuation to get the filter exactly as required.

```
d = fdesign.highpass('n,fst,ast',5,20,55,50);
hd=design(d,'cheby2');
```

The Filter Visualization Tool shows the highpass filter meets the specifications.

```
fvtool(hd)
```

cl2tf

Convert coupled allpass lattice to transfer function form

Syntax

```
[b,a] = cl2tf(k1,k2)
[b,a] = cl2tf(k1,k2,beta)
[b,a,bp] = cl2tf(k1,k2)
[b,a,bp] = cl2tf(k1,k2,beta)
```

Description

`[b,a] = cl2tf(k1,k2)` returns the numerator and denominator vectors of coefficients `b` and `a` corresponding to the transfer function

$$H(z) = B(z) / A(z) = \frac{1}{2}[H1(z) + H2(z)]$$

where *H1(z)* and *H2(z)* are the transfer functions of the allpass filters determined by `k1` and `k2`, and `k1` and `k2` are real vectors of reflection coefficients corresponding to allpass lattice structures.

`[b,a] = cl2tf(k1,k2,beta)` where `k1`, `k2` and `beta` are complex, returns the numerator and denominator vectors of coefficients b and a corresponding to the transfer function

$$H(z) = B(z) / A(z) = \frac{1}{2}\left[-(\bar{\beta}) \cdot H1(z) + \beta \cdot H2(z)\right]$$

`[b,a,bp] = cl2tf(k1,k2)` where `k1` and `k2` are real, returns the vector `bp` of real coefficients corresponding to the numerator of the power complementary filter *G(z)*

$$G(z) = Bp(z) / A(z) = \frac{1}{2}[H1(z) - H2(z)]$$

`[b,a,bp] = cl2tf(k1,k2,beta)` where `k1`, `k2` and `beta` are complex, returns the vector of coefficients `bp` of possibly complex coefficients corresponding to the numerator of the power complementary filter *G(z)*

$$G(z) = Bp(z)\,/\,A(z) = \frac{1}{2_j}\left[-(\bar{\beta})\cdot H1(z) + \beta \cdot H2(z)\right]$$

Examples

```
[b,a]=cheby1(10,.5,.4);  %TF2CL returns the reflection coeffs
[k1,k2,beta]=tf2cl(b,a); % Reconstruct the original filter
% plus the power complementary one.
[num,den,numpc]=cl2tf(k1,k2,beta);
[h,w]=freqz(num,den); hpc = freqz(numpc,den);
% and the power complementary one.

coeffs

Coefficients for filters

Syntax

```
s = coeffs(ha)
s = coeffs(hd)
s = coeffs(hm)
s = coeffs(hs)
s = coeffs(hs,Name,Value)
```

Description

`s = coeffs(ha)` returns a structure containing the coefficients of the adaptive filter `ha`.

`s = coeffs(hd)` returns a structure containing the coefficients of the discrete-time filter `hd`.

`s = coeffs(hm)` returns a structure containing the coefficients of the multirate filter `hm`.

`s = coeffs(hs)` returns filter coefficients for the filter System object `hs`.

`s = coeffs(hs,Name,Value)` returns filter coefficients for the filter System object `hs` with additional options specified by one or more Name,Value pair arguments.

Input Arguments

ha

Adaptive `adaptfilt` filter object.

hd

Discrete-time `dfilt` filter object.

hm

Multirate mfilt filter object. CIC-based filters do not have coefficients, so the function does not support CIC filter structures such as mfilt.cicdecim.

hs

Filter System object.

The following Filter System objects are supported by this analysis function:

Filter System objects
dsp.FIRFilter
dsp.FIRInterpolator
dsp.CICInterpolator
dsp.FIRDecimator
dsp.CICDecimator
dsp.FIRRateConverter
dsp.BiquadFilter
dsp.IIRFilter
dsp.AllpoleFilter
dsp.AllpassFilter
dsp.CoupledAllpassFilter

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

'Arithmetic' — The types of values:
‘double’ | 'single' | 'fixed'

For filter System object inputs only, specify the arithmetic used during analysis. When you specify 'double' or 'single', the function performs double- or single-precision analysis. When you specify `'fixed'` , the arithmetic changes depending on the setting of the `CoefficientDataType` property and whether the System object is locked or unlocked.

Details for Fixed-Point Arithmetic

System Object State	Coefficient Data Type	Rule
Unlocked	`'Same as input'`	The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Unlocked	`'Custom'`	The function performs fixed-point analysis based on the setting of the `CustomCoefficientsDataType` property.
Locked	`'Same as input'`	When the input data type is `'double'` or `'fixed'`, the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Locked	`'Custom'`	The function performs fixed-point analysis based on the setting of the `CustomCoefficientsDataType` property.

When you do not specify the arithmetic, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type.

Output Arguments

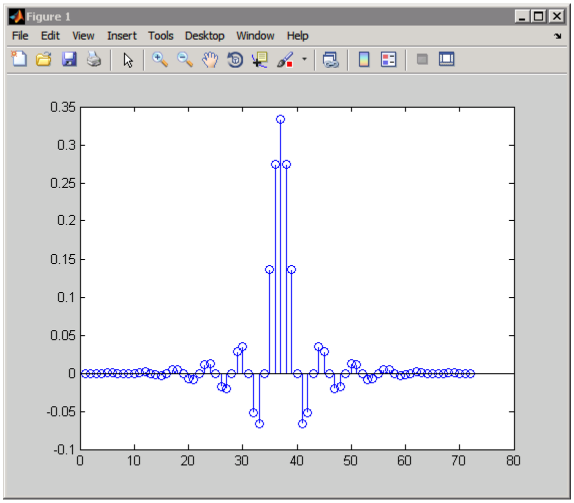
s

Structure with a single field, `Numerator`, containing filter coefficients. For adaptive filters, `s` contains the instantaneous frequency response available at the time you use the function.

Examples

`coeffs` works the same way for all filters. This example uses a multirate filter `hm` to demonstrate the function.

```
hm=mfilt.firdecim(3);
s=coeffs(hm);
stem(s.Numerator)
```



The filter coefficients may be extracted by typing `s.Numerator` at the command prompt.

coeread

Read Xilinx COE file

Syntax

```
hd = coeread(filename)
```

Description

`hd = coeread(filename)` extracts the Distributed Arithmetic FIR filter coefficients defined in the XILINX CORE Generator .COE file specified by `filename`. It returns a `dfilt` object, the fixed-point filter `hd`. If you do not provide the file type extension `.coe` with the `filename`, the function assumes the `.coe` extension.

See Also

`coewrite` | `dfilt` | `dfilt.dffir`

coewrite

Write Xilinx COE file

Syntax

```
coewrite(hd)
coewrite(hd,radix)
coewrite(...,filename)
```

Description

`coewrite(hd)` writes a XILINX Distributed Arithmetic FIR filter coefficient .COE file which can be loaded into the XILINX CORE Generator. The coefficients are extracted from the fixed-point `dfilt` object `hd`. Your fixed-point filter must be a direct form FIR structure `dfilt` object with one section and whose `Arithmetic` property is set to `fixed`. You cannot export single-precision, double-precision, or floating-point filters as `.coe` files, nor multiple-section filters. To enable you to provide a name for the file, `coewrite` displays a dialog box where you fill in the file name. If you do not specify the name of the output file, the default file name is `untitled.coe`.

`coewrite(hd,radix)` indicates the radix (number base) used to specify the FIR filter coefficients. Valid `radix` values are `2` for binary, `10` for decimal, and `16` for hexadecimal (default).

`coewrite(...,filename)` writes a XILINX.COE file to `filename`. If you omit the file extension, `coewrite` adds the `.coe` extension to the name of the file.

The `coewrite` function always generates the XILINX.COE file in your current folder. To use this function, you must have write permission in your current folder.

Examples

`coewrite` generates an ASCII text file that contains the filter coefficients in a format the XILINX CORE Generator can read and load. In this example, you create a 30th-order fixed-point filter and generate the .coe file that includes the filter coefficients as well as associated information about the filter.

```
b = firceqrip(30,0.4,[0.05 0.03]); hq = dfilt.dffir(b);
set(hq,'arithmetic','fixed'); coewrite(hq,10,'mycoefile');
```

The coewrite function generates the output file, mycoefile.coe, in your current folder. The .coe file contains the radix, coefficient width, and filter coefficients. The file reports the filter coefficients in column-major order. The radix, coefficient width, and filter coefficients are the minimum set of data needed in a .coe file.

coeread | dfilt | dfilt.dffir

constraincoeffwl

Constrain coefficient wordlength

Syntax

```
Hq = constraincoeffwl(Hd,wordlength)
Hq = constraincoeffwl(Hd,wordlength,'Ntrials',N)
Hq = constraincoeffwl(Hd,wordlength,...,'NoiseShaping',NSFlag)
Hq = constraincoeffwl(Hd,wordlength,...,'Apasstol',Apasstol)
Hq = constraincoeffwl(Hd,wordlength,...,'Astoptol',Astoptol)
```

Description

`Hq = constraincoeffwl(Hd,wordlength)` returns a fixed-point filter `Hq` meeting the design specifications of the single-stage or multistage FIR filter object `Hd` with a wordlength of at most `wordlength` bits. For multistage filters, `wordlength` can either be a scalar or vector. If `wordlength` is a scalar, the same wordlength is used for all stages. If `wordlength` is a vector, each stage uses the corresponding element in the vector. The vector length must equal the number of stages. `Hd` must be generated using `fdesign` and `design`. `constraincoeffwl` uses a stochastic noise-shaping procedure by default to minimize the wordlength. To obtain repeatable results on successive function calls, initialize the uniform random number generator `rand`

`Hq = constraincoeffwl(Hd,wordlength,'Ntrials',N)` specifies the number of Monte Carlo trials to use. `Hq` is first filter among the trials to meet the specifications in `Hd` with a wordlength of at most `wordlength`.

`Hq = constraincoeffwl(Hd,wordlength,...,'NoiseShaping',NSFlag)` enables or disables the stochastic noise-shaping procedure in the constraint of the wordlength. By default `NSFlag` is `true`. Setting `NSFlag` to `false` constrains the wordlength without using noise-shaping.

`Hq = constraincoeffwl(Hd,wordlength,...,'Apasstol',Apasstol)` specifies the passband ripple tolerance in dB. `'Apasstol'` defaults to `1e-4`.

`Hq = constraincoeffwl(Hd,wordlength,...,'Astoptol',Astoptol)` specifies the stopband tolerance in dB. `'Astoptol'` defaults to `1e-2`

You must have the Fixed-Point Designer software installed to use this function.

Examples

Design fixed-point filter with a wordlength of at most 11 bits:

```
Hf = fdesign.lowpass('Fp,Fst,Ap,Ast',.4,.5,1,60);
Hd = design(Hf,'equiripple'); % 43 coefficients
Hq = constraincoeffwl(Hd,11); % 45 11-bit coefficients
hfvt = fvtool(Hd,Hq,'showreference','off');
legend(hfvt,'Floating-point Filter','Fixed-point Filter');
```

design | fdesign | maximizestopband | measure | rand | minimizecoeffwl

Tutorials

- “Fixed-Point Data Types”

convert

Convert filter structure of discrete-time or multirate filter

Syntax

```
hq = convert(hq,newstruct)
hm = convert(hm,newstruct)
```

Description

Discrete-Time Filters

`hq = convert(hq,newstruct)` returns a quantized filter whose structure has been transformed to the filter structure specified by string `newstruct`. You can enter any one of the following quantized filter structures:

- `'antisymmetricfir'`: Antisymmetric finite impulse response (FIR)
- `'df1'`: Direct form I
- `'df1t'`: Direct form I transposed
- `'df1sos'`: Direct-Form I, Second-Order Sections
- `'df1tsos'`: Direct-Form I Transposed, Second-Order Sections
- `'df2'`: Direct form II
- `'df2t'`: Direct form II transposed. Default filter structure
- `'df2sos'`: Direct-Form II, Second-Order Sections
- `'df2tsos'`: Direct-Form II Transposed, Second-Order Sections
- `'dffir'`: FIR
- `'dffirt'`: Direct form FIR transposed
- `'latcallpass'`: Lattice allpass
- `'latticeca'`: Lattice coupled-allpass
- `'latticecapc'`: Lattice coupled-allpass power-complementary
- `'latticear'`: Lattice autoregressive (AR)

- `'latticemamax'`: Lattice moving average (MA) maximum phase
- `'latticemamin'`: Lattice moving average (MA) minimum phase
- `'latticearma'`: Lattice ARMA
- `'statespace'`: Single-input/single-output state-space
- `'symmetricfir'`: Symmetric FIR. Even and odd forms

All filters can be converted to the following structures:

- `'df1'`: Direct form I
- `'df1t'`: Direct form I transposed
- `'df1sos'`: Direct-Form I, Second-Order Sections
- `'df1tsos'`: Direct-Form I Transposed, Second-Order Sections
- `'df2'`: Direct form II
- `'df2t'`: Direct form II transposed. Default filter structure
- `'df2sos'`: Direct-Form II, Second-Order Sections
- `'df2tsos'`: Direct-Form II Transposed, Second-Order Sections
- `'statespace'`: Single-input/single-output state-space
- `'symmetricfir'`: Symmetric FIR. Even and odd forms

For the following filter classes, you can specify other conversions as well:

- Minimum phase FIR filters can be converted to `latticemamin`
- Maximum phase FIR filters can be converted to `latticemamax`
- Allpass filters can be converted to `latcallpass`

`convert` generates an error when you specify a conversion that is not possible.

Multirate Filters

`hm = convert(hm,newstruct)` returns a multirate filter whose structure has been transformed to the filter structure specified by string `newstruct`. You can enter any one of the following multirate filter structures, defined by the strings shown, for `newstruct`:

Cascaded Integrator-Comb Structure

- `cicdecim` — CIC-based decimator

- cicinterp — CIC-based interpolator

FIR Structures

- firdecim — FIR decimator
- firtdecim — transposed FIR decimator
- firfracdecim — FIR fractional decimator
- firinterp — FIR interpolator
- firfracinterp — FIR fractional interpolator
- firsrc — FIR sample rate change filter
- firholdinterp — FIR interpolator that uses hold interpolation between input samples
- firlinearinterp — FIR interpolator that uses linear interpolation between input samples
- fftfirinterp — FFT-based FIR interpolator

You cannot convert between the FIR and CIC structures.

Examples

```
[b,a]=ellip(5,3,40,.7); hq = dfilt.df2t(b,a);
hq2 = convert(hq,'df1');
```

For an example of changing the structure of a multirate filter, try the following conversion from a CIC interpolator to a CIC interpolator with zero latency.

```
hm = mfilt.cicinterp(2,2,3,8,8);
```

Note: The above example will generate a warning:

```
Warning: Using reference filter for structure conversion.
Fixed-point attributes will not be converted.
```

Since CIC interpolators only use fixed-point arithmetic, the user may disregard this warning. The fixed-point structure will not be lost on conversion.

See Also

mfilt | dfilt

cost

Estimate cost of discrete-time or multirate filter

Syntax

```
c = cost(hd)
c = cost(hm)
c = cost(hs)
c = cost(hs,Name,Value)
```

Description

`c = cost(hd)` returns a cost estimate `c` for the discrete-time filter `hd`.

`c = cost(hm)` return a cost estimate `c` for the multirate filter `hm`.

`c = cost(hs)` returns a cost estimate `c` for the filter System object `hs`.

`c = cost(hs,Name,Value)` returns a cost estimate `c` for the filter System object `hs` with additional options specified by one or more Name,Value pair arguments.

Input Arguments

hd

Discrete-time `dfilt` filter object.

hm

Multirate `mfilt` filter object.

hs

Filter System object.

The following Filter System objects are supported by this analysis function:

Filter System objects
dsp.FIRFilter
dsp.FIRInterpolator
dsp.CICInterpolator
dsp.FIRDecimator
dsp.CICDecimator
dsp.FIRRateConverter
dsp.BiquadFilter
dsp.IIRFilter
dsp.AllpoleFilter
dsp.AllpassFilter
dsp.CoupledAllpassFilter

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

'Arithmetic' — Value types:
‘double’ | 'single' | 'fixed'

For filter System object inputs only, specify the arithmetic used during analysis. When you specify 'double' or 'single', the function performs double- or single-precision analysis. When you specify 'fixed' , the arithmetic changes depending on the setting of the CoefficientDataType property and whether the System object is locked or unlocked.

Details for Fixed-Point Arithmetic

System Object State	Coefficient Data Type	Rule
Unlocked	'Same as input'	The function assumes that the coefficient data

System Object State	Coefficient Data Type	Rule
		type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Unlocked	`'Custom'`	The function performs fixed-point analysis based on the setting of the `CustomCoefficientsDataType` property.
Locked	`'Same as input'`	When the input data type is `'double'` or `'fixed'`, the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Locked	`'Custom'`	The function performs fixed-point analysis based on the setting of the `CustomCoefficientsDataType` property.

When you do not specify the arithmetic for non-CIC structures, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type. CIC structures only support fixed-point arithmetic.

Output Arguments

c

Cost estimate. `c` has the following fields.

Estimated Value	Field Name	Description
`Number of Multiplications`	`nmult`	Number of multiplications during the filter run. `nmult`

Estimated Value	Field Name	Description
		ignores multiplications by -1, 0, and 1 in the total multiple.
`Number of Additions`	`nadd`	Number of additions during the filter run.
`Number of States`	`nstates`	Number of states the filter uses.
`Multiplications per Input Sample`	`multperinputsample`	Number of multiplication operations performed for each input sample
`Additions per Input Sample`	`addperinputsample`	Number of addition operations performed for each input sample

Examples

These examples show you the `cost` method applied to `dfilt` and `mfilt` objects.

```
hd = design(fdesign.lowpass);
c = cost(hd);
```

When you are using a multirate filter object, `cost` works the same way.

```
d = fdesign.decimator(4,'cic');
hm = design(d,'multisection');
```

See Also

`qreport`

cumsec

Vector of SOS filters for cumulative sections

Syntax

```
h = cumsec(hd)
h = cumsec(hd,indices)
h = cumsec(hd,indices,secondary)
cumsec(hd,...)
h = cumsec(hs)
h = cumsec(hs,Name,Value)
```

Description

`h = cumsec(hd)` returns a vector `h` of SOS filter objects with the cumulative sections. Each element in `h` is a filter with the structure of the original filter. The first element is the first filter section of `hd`. The second element of `h` is a filter that represents the combination of the first and second sections of `hd`. The third element of `h` is a filter which combines sections 1, 2, and 3 of `hd`. This pattern continues until the final element of `h` contains all the sections of `hd` and should be identical to `hd`.

`h = cumsec(hd,indices)` returns a vector `h` of SOS filter objects whose indices into the original filter are in the vector `indices`.

`h = cumsec(hd,indices,secondary)` uses the secondary scaling points `secondary` in the sections to determine where the sections should be split.

`cumsec(hd,...)` uses FVTool to plot the magnitude response of the cumulative sections.

`h = cumsec(hs)` returns the cumulative sections of the `dsp.BiquadFilter` filter System object `hs`. You can also use the optional input arguments `indices` and `secondary` with this syntax. You can also omit the output argument `h` to use FVTool to plot the magnitude response of the cumulative sections.

`h = cumsec(hs,Name,Value)` returns the cumulative sections of the filter System object `hs` with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

hd

Discrete-time dfilt.df1sos, dfilt.df2tsos, dfilt.df2sos, or dfilt.df1tsosfilter object.

hs

dsp.BiquadFilter filter System object.

indices

Filter indices. Use indices to specify the filter sections cumsec uses to compute the cumulative responses.

secondary

This option applies only when hd is a df2sos and df1tsos filter. For these second-order section structures, the secondary scaling points refer to the scaling locations between the recursive and the nonrecursive parts of the section (the "middle" of the section). Argument secondary accepts either true or false. By default, secondary is false.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

'Arithmetic' — Value types:

‘double’ | 'single' | 'fixed'

For filter System object inputs only, specify the arithmetic used during analysis. When you specify 'double' or 'single', the function performs double- or single-precision analysis. When you specify 'fixed' , the arithmetic changes depending on the setting of the CoefficientDataType property and whether the System object is locked or unlocked.

Details for Fixed-Point Arithmetic

System Object State	Coefficient Data Type	Rule
Unlocked	`'Same as input'`	The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Unlocked	`'Custom'`	The function performs fixed-point analysis based on the setting of the `CustomCoefficientsDataType` property.
Locked	`'Same as input'`	When the input data type is `'double'` or `'fixed'`, the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Locked	`'Custom'`	The function performs fixed-point analysis based on the setting of the `CustomCoefficientsDataType` property.

When you do not specify the arithmetic, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type.

Examples

To demonstrate how `cumsec` works, this example plots the relative responses of the sections of a sixth-order filter SOS filter with three sections. Each curve adds one more section to form the filter response.

```
hs = fdesign.lowpass('n,fc',6,.4); hd = butter(hs);
h = cumsec(hd); hfvt = fvtool(h);
legend(hfvt,'First Section','First Two Sections','Overall  Filter');
```

scale | scalecheck

denormalize

Undo filter coefficient and gain changes caused by normalize

Syntax

```
denormalize(hq)
```

Description

`denormalize(hq)` reverses the coefficient changes you make when you use `normalize` with `hq`. The filter coefficients do not change if you call `denormalize(hq)` before you use `normalize(hq)`. Calling `denormalize` more than once on a filter does not change the coefficients after the first `denormalize` call.

Examples

Make a quantized filter `hq` and normalize the filter coefficients. After normalizing the coefficients, restore them to their original values by reversing the effects of the `normalize` function.

```
d=fdesign.highpass('n,F3dB',14,0.45);
hd =design(d,'butter');
hd.arithmetic='fixed';
normalize(hd)
NormSOSMatrix = hd.sosMatrix;
denormalize(hd)
eqSOSMatrices = isequal(NormSOSMatrix,hd.sosMatrix);
% returns a 0
```

See Also

`normalize`

design

Apply design method to filter specification object

Syntax

```
H = design(D)
H = design(D,METHOD)
H = design(D,METHOD,PARAM1,VALUE1,PARAM2,VALUE2,...)
H = design(D,METHOD,OPTS)
Hs = design(D,...,'SystemObject',sysobjflag)
```

Description

`H = design(D)` uses the filter specifications object `D` to generate a filter `H`. When you do not provide a design method as an input argument, `design` uses a default design method. Use `designmethods(D,'default')` to see the default design method for your filter specifications object.

`H = design(D,METHOD)` forces the design method specified by the string `METHOD`. `METHOD` must be one of the strings returned by `designmethods`. Use `designmethods(D,'default')` to determine which algorithm is used by default.

The design method you provide as the `designmethod` input argument must be one of the methods returned by

```
designmethods(d)
```

To help you design filters more quickly, the input argument `METHOD` accepts a variety of special keywords that force `design` to behave in different ways. The following table presents the keywords you can use for `METHOD` and how `design` responds to the keyword.

Designmethod Keyword	Description of the design Response
`'FIR'`	Forces `design` to produce an FIR filter. When no FIR design method exists for object `D`, `design` returns an error.
`'IIR'`	Forces `design` to produce an IIR filter. When no IIR design method exists for object `D`, `design` returns an error.

Designmethod Keyword	Description of the design Response
'ALLFIR'	Produces filters from every applicable FIR design method for the specifications in D, one filter for each design method. As a result, design returns multiple filters in the output object.
'ALLIIR'	Produces filters from every applicable IIR design method for the specifications in D, one filter for each design method. As a result, design returns multiple filters in the output object.
'ALL'	Designs filters using all applicable design methods for the specifications object D. As a result, design returns multiple filters, one for each design method. design uses the design methods in the order that designmethods(D) returns them.

Keywords are not case sensitive

When design returns multiple filters in the output object, use indexing to see the individual filters. For example, to see the third filter in H, enter

```
H(3)
```

H = design(D,METHOD,PARAM1,VALUE1,PARAM2,VALUE2,...) specifies design-method options. Use help(D,METHOD) for complete information on which design-method-specific options are available. You can also use designopts(D,METHOD) for a less-detailed listing of the design-method-specific options.

H = design(D,METHOD,OPTS) specifies design-method options using the structure OPTS. OPTS is usually obtained from designopts and then specified as an input to design. Use help(D,METHOD) for more information on optional inputs.

Hs = design(D,...,'SystemObject',*sysobjflag*) uses the filter specifications object D to generate a filter System object Hs when *sysobjflag* is true. To generate System objects, you must have the DSP System Toolbox product installed. When *sysobjflag* is false, the function generates a dfilt or mfilt object H, as described previously. Design methods and design options for filter System objects are not necessarily the same as those for dfilt and mfilt objects. To check design methods for System objects, use designmethods with the 'SystemObject',*sysobjflag* syntax.

If you are specifying design-method-specific options using OPTS, you can also set OPTS.SystemObject to true instead of calling design with the 'SystemObject',*sysobjflag* syntax.

Examples

Design an FIR equiripple lowpass filter. The passband edge frequency is 0.2π radians/sample, and the stopband edge frequency is 0.25π radians/sample. The passband ripple is 0.5 dB, and the stopband attenuation is 40 dB.

```
D = fdesign.lowpass('Fp,Fst,Ap,Ast',0.2,0.25,0.5,40);
H = design(D); % Uses the default equiripple method.
```

If you have the DSP System Toolbox software installed, you can design a minimum-phase FIR equiripple filter. Design a minimum–phase filter and compare the pole-zero plots of the original and minimum-phase designs.

```
Hmin = design(D,'equiripple','MinPhase',true);
hfvt = fvtool([H Hmin],'analysis','polezero');
legend(hfvt,'Original Design','Minimum Phase Design');
```

Design a Butterworth lowpass filter. The passband edge frequency is 0.2π radians/sample, and the stopband edge frequency is 0.25π radians/sample. The passband ripple is 0.5 dB, and the stopband attenuation is 40 dB. Obtain help on the design options specific to the Butterworth design method. Design the filter with the "MatchExactly' option set to 'Passband'.

```
D = fdesign.lowpass('Fp,Fst,Ap,Ast',0.2,0.25,0.5,40);
% Query design-method-specific options
help(D,'butter')
% Match passband exactly
H = design(D,'butter','MatchExactly','passband');
```

If you have the DSP System Toolbox software, you can specify the *P*-th norm scaling on the second-order sections. Use L-infinity norm scaling in the time domain.

```
H = design(D,'butter','MatchExactly','passband','SOSScaleNorm','linf');
```

If you have the DSP System Toolbox software, you can create a filter System object.

```
Hs = design(D,'SystemObject',true);
```

designmethods | designopts

designmethods

Methods available for designing filter from specification object

Syntax

```
M = designmethods(D)
M = designmethods(D,'default')
M = designmethods(D,TYPE)
M = designmethods(D,'full')
Ms = designmethods(D,...,'SystemObject',sysobjflag)
```

Description

`M = designmethods(D)` returns the available design methods for the filter specification object, `D`, and the current value of the `Specification` property.

`M = designmethods(D,'default')` returns the default design method for the filter specification object `D` and the current value of the `Specification` property.

`M = designmethods(D,TYPE)` returns either the `TYPE` design methods that apply to D. `TYPE` can be either `'FIR'` or `'IIR'`.

`M = designmethods(D,'full')` returns the full name for each of the available design methods. For example, `designmethods` with the `'full'` argument returns `Butterworth` for the `butter` method.

`Ms = designmethods(D,...,'SystemObject',`*`sysobjflag`*`)` returns the available design methods for designing filter System objects when *`sysobjflag`* is `true`. To use System objects, you must have the DSP System Toolbox product installed. When *`sysobjflag`* is `false`, the function checks methods for creating `dfilt` and `mfilt` objects, as described previously. Design methods and design options for filter System objects are not necessarily the same as those for `dfilt` and `mfilt` objects.

Examples

Construct a lowpass filter specification object and determine the valid design methods. Obtain detailed command line help on the Chebyshev type I design method.

```
D =fdesign.lowpass('Fp,Fst,Ap,Ast',500,600,0.5,60,1e4);
M = designmethods(D)
help(D,M{2})
```

The last line of the example is equivalent to `help(D,'cheby1')`.

If you have DSP System Toolbox software installed, use the `'SystemObject',`*`sysobjflag`* syntax to return design methods for a filter System object:

```
Ms = designmethods(D,'SystemObject',true);
```

See Also

`design` | `designopts` | `fdesign`

designopts

Valid input arguments and values for specification object and method

Syntax

```
OPTS = designopts(D,METHOD)
```

Description

`OPTS = designopts(D,METHOD)` returns a structure array with the default design parameters used by the design method `METHOD`. `METHOD` must be one of the strings returned by `designmethods`.

Use `help(D,METHOD)` to get a description of the design parameters.

If you have DSP System Toolbox software installed, `OPTS` has the `SystemObject` property if at least one of the structures available for that design method is supported by System objects. However, not all structures for that design method are supported by System objects.

Examples

Create a lowpass filter with a numerator and denominator order of 10 and a 3-dB frequency of 0.2π radians/sample. Obtain the default design parameters for a Butterworth design, and test whether the filter structure is a direct-form II biquad.

```
D = fdesign.lowpass('Nb,Na,F3dB',10,10,0.2);
OPTS = designopts(D,'butter');
if (OPTS.FilterStructure == 'df2sos')
    fprintf('The default filter structure is Direct-Form II\n');
    fprintf('with second-order sections.\n');
end
```

If you have DSP System Toolbox software installed, `OPTS` has the `SystemObject` property.

dfilt

Discrete-time filter

Syntax

```
hd = dfilt.structure(input1,...)
hd = [dfilt.structure(input1,...), dfilt.structure(input1,...),...]
hd = design(d,'designmethod')
```

Description

`hd = dfilt.`*`structure`*`(input1,...)` returns a discrete-time filter, `hd`, of type *`structure`*. Each structure takes one or more inputs. When you specify a `dfilt.`*`structure`* with no inputs, a default filter is created.

Note You must use a *`structure`* with `dfilt`.

`hd = [dfilt.`*`structure`*`(input1,...), dfilt.`*`structure`*`(input1,...),...]` returns a vector containing `dfilt` filters.

Structures

Structures for `dfilt.structure` specify the type of filter structure. Available types of structures for `dfilt` are shown below.

dfilt.structure	Description	Coefficient Mapping Support in realizemdl
`dfilt.allpass`	Allpass filter	Supported
`dfilt.cascadeallpas`	Cascade of allpass filter sections	Supported
`dfilt.cascadewdfall`	Cascade of allpass wave digital filters	Supported
`dfilt.delay`	Delay	Not supported
`dfilt.df1`	Direct-form I	Supported

dfilt.structure	Description	Coefficient Mapping Support in realizemdl
`dfilt.df1sos`	Direct-form I, second-order sections	Supported
`dfilt.df1t`	Direct-form I transposed	Supported
`dfilt.df1tsos`	Direct-form I transposed, second-order sections	Supported
`dfilt.df2`	Direct-form II	Supported
`dfilt.df2sos`	Direct-form II, second-order sections	Supported
`dfilt.df2t`	Direct-form II transposed	Supported
`dfilt.df2tsos`	Direct-form II transposed, second-order sections	Supported
`dfilt.dffir`	Direct-form FIR	Supported
`dfilt.dffirt`	Direct-form FIR transposed	Supported
`dfilt.dfsymfir`	Direct-form symmetric FIR	Supported
`dfilt.dfasymfir`	Direct-form antisymmetric FIR	Supported
`dfilt.farrowfd`	Generic fractional delay Farrow filter	Supported
`dfilt.farrowlinearf`	Linear fractional delay Farrow filter	Not supported
`dfilt.fftfir`	Overlap-add FIR	Not supported
`dfilt.latticeallpas`	Lattice allpass	Supported
`dfilt.latticear`	Lattice autoregressive (AR)	Supported
`dfilt.latticearma`	Lattice autoregressive moving-average (ARMA)	Supported
`dfilt.latticemamax`	Lattice moving-average (MA) for maximum phase	Supported
`dfilt.latticemamin`	Lattice moving-average (MA) for minimum phase	Supported
`dfilt.calattice`	Coupled, allpass lattice	Supported

dfilt.structure	Description	Coefficient Mapping Support in realizemdl
`dfilt.calatticepc`	Coupled, allpass lattice with power complementary output	Supported
`dfilt.statespace`	State-space	Supported
`dfilt.scalar`	Scalar gain object	Supported
`dfilt.wdfallpass`	Allpass wave digital filter object	Supported
`dfilt.cascade`	Filters arranged in series	Supported
`dfilt.parallel`	Filters arranged in parallel	Supported

For more information on each structure, refer to its reference page.

`hd = design(d,'designmethod')` returns the `dfilt` object `hd` resulting from the filter specification object `d` and the design method you specify in *`designmethod`*. When you omit the `designmethod` argument, `design` uses the default design method to construct a filter from the object `d`.

With this syntax, you design filters by:

1. Specifying the filter specifications, such as the response shape (perhaps highpass) and details (passband edges and attenuation).
2. Selecting a method (such as `equiripple`) to design the filter.
3. Applying the method to the specifications object with `design(d,'designmethod')`.

Using the specification-based technique can be more effective than the coefficient-based filter design techniques.

Design Methods for Design Syntax

When you use the `hd = design(d,'`*`designmethod`*`')` syntax, you have a range of design methods available depending on `d`, the filter specification object. The next table lists all of the design methods in the toolbox.

Design Method String	Filter Design Result
`butter`	Butterworth IIR

Design Method String	Filter Design Result
cheby1	Chebyshev Type I IIR
cheby2	Chebyshev Type II IIR
ellip	Elliptic IIR
equiripple	Equiripple with the same ripple in the pass and stopbands
firls	Least-squares FIR
freqsamp	Frequency-Sampled FIR
ifir	Interpolated FIR
iirlpnorm	Least Pth norm IIR
iirls	Least-Squares IIR
kaiserwin	Kaiser-windowed FIR
lagrange	Fractional delay filter
multistage	Multistage FIR
window	Windowed FIR

As the specifications object d changes, the available methods for designing filters from d also change. For instance, if d is a lowpass filter with the default specification 'Fp,Fst,Ap,Ast', the applicable methods are:

```
% Create an object to design a lowpass filter.
d=fdesign.lowpass;
designmethods(d) % What design methods apply to object d?
```

If you change the specification string to 'N,F3dB', the available design methods change:

```
d=fdesign.lowpass('N,F3dB');
designmethods(d)
```

Analysis Methods

Methods provide ways of performing functions directly on your dfilt object without having to specify the filter parameters again. You can apply these methods directly on the variable you assigned to your dfilt object.

For example, if you create a dfilt object, hd, you can check whether it has linear phase with islinphase(hd), view its frequency response plot with fvtool(hd), or obtain its frequency response values with `h = freqz(hd)`. You can use all of the methods described here in this way.

Note If your variable `hd` is a 1-D array of `dfilt` filters, the method is applied to each object in the array. Only `freqz`, `grpdelay`, `impz`, `is*`, `order`, and `stepz` methods can be applied to arrays. The `zplane` method can be applied to an array only if `zplane` is used without outputs.

Some of the methods listed here have the same name as functions in Signal Processing Toolbox software. They behave similarly.

Method	Description
`addstage`	Adds a stage to a `cascade` or `parallel` object, where a stage is a separate, modular filter. Refer to `dfilt.cascade` and `dfilt.parallel`.
`block`	`block(hd)` creates a block of the `dfilt` object. The `block` method can specify these properties and values: `'Destination'` indicates where to place the block. `'Current'` places the block in the current Simulink model. `'New'` creates a new model. Default value is `'Current'`. `'Blockname'` assigns the entered string to the block name. Default name is `'Filter'`. `'OverwriteBlock'`indicates whether to overwrite the block generated by the block method (`'on'`) and defined by `Blockame`. Default is `'off'`. `'MapStates'` specifies initial conditions in the block (`'on'`). Default is `'off'`. Refer to "Using Filter States" in Signal Processing Toolbox documentation.
`cascade`	Returns the series combination of two `dfilt` objects. Refer to `dfilt.cascade`.
`coeffs`	Returns the filter coefficients in a structure containing fields that use the same property names as those in the original `dfilt`.

Method	Description
`convert`	Converts a `dfilt` object from one filter structure, to another filter structure.
`fcfwrite`	Writes a filter coefficient ASCII file. The file can contain a single filter or a vector of objects. The file can contain multirate filters (mfilt) or adaptive filters (adaptfilt). The default file name is `untitled.fcf`. `fcfwrite(hd,filename)` writes to a disk file named `filename` in the current working folder. The `.fcf` extension is added automatically. `fcfwrite(...,fmt)` writes the coefficients in the format `fmt`, where valid `fmt` strings are: `'hex'` for hexadecimal `'dec'` for decimal `'bin'` for binary representation
`fftcoeffs`	Returns the frequency-domain coefficients used when filtering with a `dfilt.fftfir`
`filter`	Performs filtering using the `dfilt` object.
`firtype`	Returns the type (1-4) of a linear phase FIR filter.
`freqz`	Plots the frequency response in `fvtool`. Unlike the `freqz` function, this `dfilt` `freqz` method has a default length of 8192.
`grpdelay`	Plots the group delay in `fvtool`.
`impz`	Plots the impulse response in `fvtool`.
`impzlength`	Returns the length of the impulse response.
`info`	Displays `dfilt` information, such as filter structure, length, stability, linear phase, and, when appropriate, lattice and ladder length.
`isallpass`	Returns a logical `1` (i.e., true) if the `dfilt` object in an allpass filter or a logical `0` (i.e., false) if it is not.

Method	Description
`iscascade`	Returns a logical `1` if the `dfilt` object is cascaded or a logical `0` if it is not.
`isfir`	Returns a logical `1` if the `dfilt` object has finite impulse response (FIR) or a logical `0` if it does not.
`islinphase`	Returns a logical `1` if the `dfilt` object is linear phase or a logical `0` if it is not.
`ismaxphase`	Returns a logical `1` if the `dfilt` object is maximum-phase or a logical `0` if it is not.
`isminphase`	Returns a logical `1` if the `dfilt` object is minimum-phase or a logical `0` if it is not.
`isparallel`	Returns a logical `1` if the `dfilt` object has parallel stages or a logical `0` if it does not.
`isreal`	Returns a logical `1` if the `dfilt` object has real-valued coefficients or a logical 0 if it does not.
`isscalar`	Returns a logical `1` if the `dfilt` object is a scalar or a logical `0` if it is not scalar.
`issos`	Returns a logical `1` if the `dfilt` object has second-order sections or a logical `0` if it does not.
`isstable`	Returns a logical `1` if the `dfilt` object is stable or a logical `0` if it are not.
`nsections`	Returns the number of sections in a second-order sections filter. If a multistage filter contains stages with multiple sections, using `nsections` returns the total number of sections in all the stages (a stage with a single section returns 1).
`nstages`	Returns the number of stages of the filter, where a stage is a separate, modular filter.
`nstates`	Returns the number of states for an object.
`order`	Returns the filter order. If `hd` is a single-stage filter, the order is given by the number of delays needed for a minimum realization of the filter. If `hd` has multiple stages, the order is given by the number of delays needed for a minimum realization of the overall filter.

Method	Description
`parallel`	Returns the parallel combination of two `dfilt` filters. Refer to `dfilt.parallel`.
`phasez`	Plots the phase response in `fvtool`.

Method	Description
`realizemdl`	(Available only with Simulink.) `realizemdl(hd)` creates a Simulink model containing a subsystem block realization of your `dfilt`. `realizemdl(hd,p1,v1,p2,v2,...)` creates the block using the properties `p1`, `p2`,... and values `v1`, `v2`,... specified. The following properties are available: `'Blockname'` specifies the name of the block. The default value is `'Filter'`. `'Destination'` specifies whether to add the block to a current Simulink model or create a new model. Valid values are `'Current'` and `'New'`. `'OverwriteBlock'` specifies whether to overwrite an existing block that was created by `realizemdl` or create a new block. Valid values are `'on'` and `'off'`. Only blocks created by `realizemdl` are overwritten. The following properties optimize the block structure. Specifying `'on'` turns the optimization on and `'off'` creates the block without optimization. The default for each block is `'off'.` `'OptimizeZeros'` removes zero-gain blocks. `'OptimizeOnes'` replaces unity-gain blocks with a direct connection. `'OptimizeNegOnes'` replaces negative unity-gain blocks with a sign change at the nearest summation block. `'OptimizeDelayChains'` replaces delay chains made up of *n* unit delays with a single delay by *n*.

Method	Description
removestage	Removes a stage from a cascade or parallel dfilt. Refer to dfilt.cascade and dfilt.parallel.
setstage	Overwrites a stage of a cascade or parallel dfilt. Refer to dfilt.cascade and dfilt.parallel.
sos	Converts the dfilt to a second-order sections dfilt. If hd has a single section, the returned filter has the same class. sos(hd,flag) specifies the ordering of the second-order sections. If flag='UP', the first row contains the poles closest to the origin, and the last row contains the poles closest to the unit circle. If flag='down', the sections are ordered in the opposite direction. The zeros are always paired with the poles closest to them. sos(hd,flag,scale) specifies the scaling of the gain and the numerator coefficients of all second-order sections. scale can be 'none', 'inf' (infinity-norm), or 'two' (2-norm). Using infinity-norm scaling with up ordering minimizes the probability of overflow in the realization. Using 2-norm scaling with down ordering minimizes the peak roundoff noise.
ss	Converts the dfilt to state-space. To see the separate A,B,C,D matrices for the state-space model, use [A,B,C,D]=ss(hd).
stepz	Plots the step response in fvtool stepz(hd,n) computes the first n samples of the step response. stepz(hd,n,Fs) separates the time samples by T = 1/ Fs, where Fs is assumed to be in hertz.
sysobj	Converts the dfilt to a filter System object. See the reference page for a list of supported objects.
tf	Converts the dfilt to a transfer function.
zerophase	Plots the zero-phase response in fvtool.

Method	Description
`zpk`	Converts the `dfilt` to zeros-pole-gain form.
`zplane`	Plots a pole-zero plot in `fvtool`.

Viewing Properties

As with any object, use `get` to view a `dfilt` properties. To see a specific property, use

```
 get(hd,'property')
```

To see all properties for an object, use

```
get(hd)
```

Note `dfilt` objects include an `arithmetic` property. You can change the internal arithmetic of the filter from double- precision to single-precision using: `hd.arithmetic = 'single'`.

If you have Fixed-Point Designer software, you can change the `arithmetic` property to fixed-point using: `hd.arithmetic = 'fixed'`

Changing Properties

To set specific properties, use

```
set(hd,'property1',value,'property2',value,...)
```

You must use single quotation marks around the property name. Use single quotation marks around the `value` argument when the value is a string, such as `specifyall` or `fixed`.

Copying an Object

To create a copy of an object, use the `copy` method.

```
h2 = copy(hd)
```

Note Using the syntax `H2 = hd` copies only the object handle and does not create a new, independent object.

Converting Between Filter Structures

To change the filter structure of a `dfilt` object `hd`, use

```
hd2 = convert(hd,'structure_string');
```

where `structure_string` is any valid structure name in single quotation marks. If `hd` is a `cascade` or `parallel` structure, each stage is converted to the new structure.

Using Filter States

Two properties control the filter states:

- `states` — Stores the current states of the filter. Before the filter is applied, the states correspond to the initial conditions and after the filter is applied, the states correspond to the final conditions. For `df1`, `df1t`, `df1sos` and `df1tsos` structures, `states` returns a `filtstates` object.
- `PersistentMemory` — Controls whether filter `states` are saved. The default value is `'false'`, which causes the initial conditions to be reset to zero before filtering and turns off the display of `states` information. Setting `PersistentMemory` to `'true'` allows the filter to use your initial conditions or to reuse the final conditions from a previous filtering operation as the initial conditions of the next filtering operation. The `true` setting also displays information about the filter `states`.

Note If you set the `states` and want to use them for filtering, you must set `PersistentMemory` to `'true'` before you use the filter.

Examples

Create a direct-form I filter, and use a method to see if it is stable.

```
[b,a] = butter(8,0.25);
hd = dfilt.df1(b,a);
isstable(hd)
```

If a `dfilt`'s numerator values do not fit on a single line, a description of the vector is displayed. To see the specific numerator values for this example, use

```
B = get(hd,'numerator');
```

```
% or
B1 = hd.numerator;
```

Create an array containing two `dfilt` objects, apply a method and verify that the method acts on both objects. Use a method to test whether the objects are FIR objects.

```
b = fir1(5,.5);
hd = dfilt.dffir(b);          % Create an FIR filter object
[b,a] = butter(5,.5);         % Create IIR filter
hd(2) = dfilt.df2t(b,a);       % Create DF2T object and place
                               % in the second column of hd.
[h,w] = freqz(hd);
test_fir = isfir(hd)
% hd(1) is FIR and hd(2) is not.
```

Refer to the reference pages for each structure for more examples.

dfilt.allpass

Allpass filter

Syntax

```
hd = dfilt.allpass(c)
```

Description

`hd = dfilt.allpass(c)` constructs an allpass filter with the minimum number of multipliers from the elements in vector `c`. To be valid, `c` must contain one, two, three, or four real elements. The number of elements in `c` determines the order of the filter. For example, `c` with two elements creates a second-order filter and `c` with four elements creates a fourth-order filter.

The transfer function for the allpass filter is defined by

$$H(z) = \frac{c(n) + c(n-1)z^{-1} + \ldots + z^{-n}}{1 + c(1)z^{-1} + \ldots + c(n)z^{-n}}$$

given the coefficients in `c`.

To construct a cascade of allpass filter objects, use `dfilt.cascadeallpass`. For more information about creating cascades of allpass filters, refer to `dfilt.cascadeallpass`.

Properties

The following table provides a list of all the properties associated with an allpass `dfilt` object.

Property Name	Brief Description
`AllpassCoefficients`	Contains the coefficients for the allpass filter object

Property Name	Brief Description
FilterStructure	Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering — gains, delays, sums, products, and input/output.
PersistentMemory	Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. False is the default setting.
States	This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. They also provide linkage between the sections of a multisection filter, such as a cascade filter. For details, refer to filtstates in Signal Processing Toolbox documentation or in the Help system.

Examples

This example constructs and displays the information about a second-order allpass filter that uses the minimum number of multipliers.

```
c = [1.5, 0.7];
% Create a second-order dfilt object.
hd = dfilt.allpass(c);
```

dfilt.calattice

Coupled-allpass, lattice filter

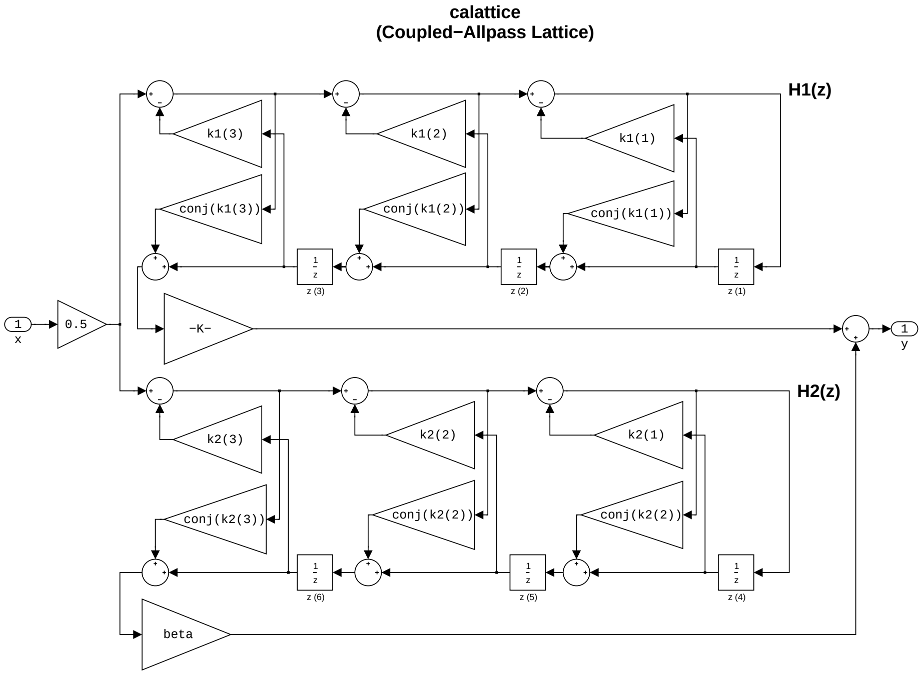
Syntax

```
hd = dfilt.calattice(k1,k2,beta)
hd = dfilt.calattice
```

Description

`hd = dfilt.calattice(k1,k2,beta)` returns a discrete-time, coupled-allpass, lattice filter object `hd`, which is two allpass, lattice filter structures coupled together. The lattice coefficients for each structure are vectors `k1` and `k2`. Input argument `beta` is shown in the diagram below.

`hd = dfilt.calattice` returns a default, discrete-time coupled-allpass, lattice filter object, `hd`. The default values are `k1` = `k2` = [], which is the default value for `dfilt.latticeallpass`, and `beta` = 1. This filter passes the input through to the output unchanged.



Examples

Specify a third-order lattice coupled-allpass filter structure for a `dfilt` filter, `hd` with the following code.

```
k1 = [0.9511 + 1j*0.3088; 0.7511 + 1j*0.1158];
k2 = 0.7502 - 1j*0.1218;
beta = 0.1385 + 1j*0.9904;
hd = dfilt.calattice(k1,k2,beta);
```

The `Allpass1` and `Allpass2` properties store vectors of coefficients.

See Also

`dfilt.calatticepc` | `dfilt` | `dfilt.latticeallpass` | `dfilt.latticear` | `dfilt.latticearma` | `dfilt.latticemamax` | `dfilt.latticemamin`

dfilt.calatticepc

Coupled-allpass, power-complementary lattice filter

Syntax

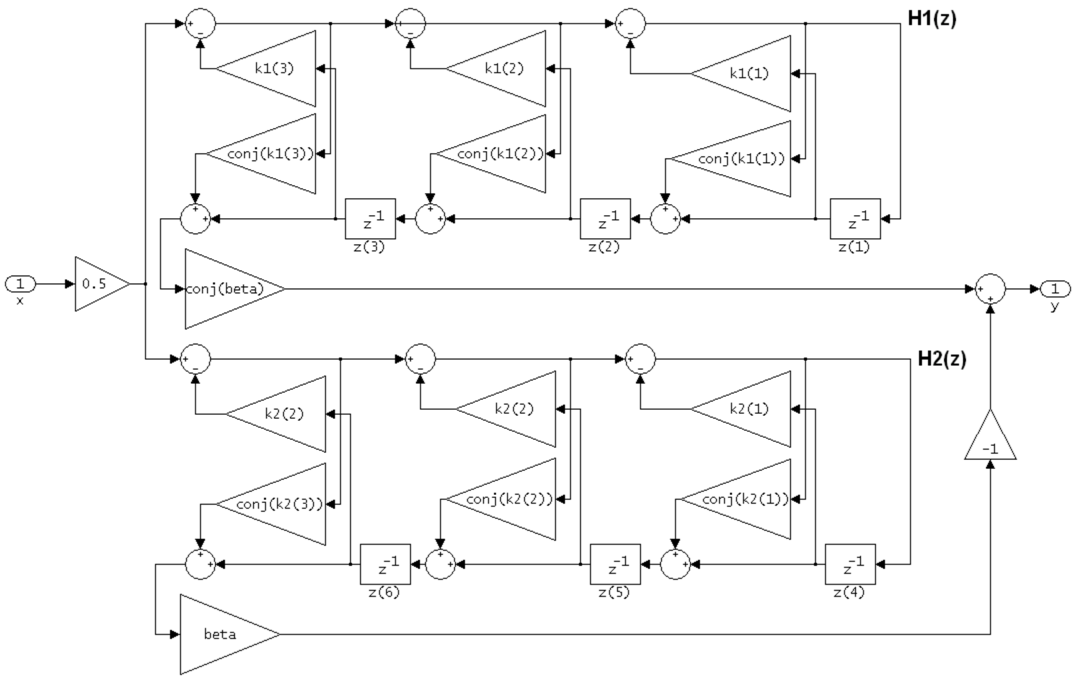
```
hd = dfilt.calatticepc(k1,k2)
hd = dfilt.calatticepc
```

Description

`hd = dfilt.calatticepc(k1,k2)` returns a discrete-time, coupled-allpass, lattice filter object `hd`, with power-complementary output. This object is two allpass lattice filter structures coupled together to produce complementary output. The lattice coefficients for each structure are vectors, `k1` and `k2`, respectively. `beta` is shown in the following diagram.

`hd = dfilt.calatticepc` returns a default, discrete-time, coupled-allpass, lattice filter object `hd`, with power-complementary output. The default values are `k1` = `k2` = [], which is the default value for the `dfilt.latticeallpass`. The default for `beta` = 1. This filter passes the input through to the output unchanged.

calatticepc
(Coupled Allpass Lattice, Power Complementary output)



Examples

Specify a third-order lattice coupled-allpass power complementary filter structure for a filter `hd` with the following code. You see from the returned properties that `Allpass1` and `Allpass2` contain vectors of coefficients for the constituent filters.

```
k1 = [0.9511 + 0.3088i; 0.7511 + 0.1158i];
k2 = 0.7502 - 0.1218i;
beta = 0.1385 + 0.9904i;
hd = dfilt.calatticepc(k1,k2,beta);
```

To see the coefficients for `Allpass1`, check the property values.

```
get(hd,'Allpass1')
```

dfilt.cascade

Cascade of discrete-time filters

Syntax

Refer to `dfilt.cascade` in Signal Processing Toolbox documentation for more information.

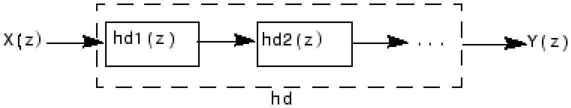
Description

`hd = dfilt.cascade(filterobject1,filterobject2,...)` returns a discrete-time filter object `hd` of type `cascade`, which is a serial interconnection of two or more filter objects `filterobject1`, `filterobject2`, and so on. `dfilt.cascade` accepts any combination of `dfilt` objects (discrete time filters) to cascade, as well as Farrow filter objects.

You can use the standard notation to cascade one or more filters:

```
cascade(hd1,hd2,...)
```

where `hd1`, `hd2`, and so on can be mixed types, such as `dfilt` objects and `mfilt` objects.



`hd1`, `hd2`, and so on can be fixed-point filters. All filters in the cascade must be the same arithmetic format — `double`, `single`, or `fixed`. `hd`, the filter object returned, inherits the format of the cascaded filters.

Examples

Cascade a lowpass filter and a highpass filter to produce a bandpass filter.

```
[b1,a1]=butter(8,0.6);    % Lowpass
[b2,a2]=butter(8,0.4,'high');  % Highpass
```

```
h1=dfilt.df2t(b1,a1);
h2=dfilt.df2t(b2,a2);
hcas=dfilt.cascade(h1,h2);   % Bandpass with passband 0.4-0.6
% View stage 1 with hcas.Stage(1)
```

See Also

`dfilt` | `dfilt.parallel` | `dfilt.scalar`

dfilt.cascadeallpass

Cascade of allpass discrete-time filters

Syntax

```
hd = dfilt.cascadeallpass(c1,c2,...)
```

Description

`hd = dfilt.cascadeallpass(c1,c2,...)` constructs a cascade of allpass filters, each of which uses the minimum number of multipliers, given the filter coefficients provided in `c1`, `c2`, and so on.

Each vector `c` represents one section in the cascade filter. `c` vectors must contain one, two, three, or four elements as the filter coefficients for each section. As a result of the design algorithm, each section is a `dfilt.allpass` structure whose coefficients are given in the matching `c` vector, such as the `c1` vector contains the coefficients for the first stage.

States for each section are shared between sections.

Vectors `c` do not have to be the same length. You can combine various length vectors in the input arguments. For example, you can cascade fourth-order sections with second-order sections, or first-order sections.

For more information about the vectors `ci` and about the transfer function of each section, refer to `dfilt.allpass`.

Generally, you do not construct these allpass cascade filters directly. Instead, they result from the design process for an IIR filter. Refer to the first example in Examples for more about using `dfilt.cascadeallpass` to design an IIR filter.

Properties

In the next table, the row entries are the filter properties and a brief description of each property.

Property Name	Brief Description
AllpassCoefficients	Contains the coefficients for the allpass filter object
FilterStructure	Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering — gains, delays, sums, products, and input/output.
PersistentMemory	Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. False is the default setting.
States	This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. They also provide linkage between the sections of a multisection filter, such as a cascade filter. For details, refer to filtstates in Signal Processing Toolbox documentation or in the Help system.

Examples

Two examples show how dfilt.cascadeallpass works in very different applications — designing a halfband IIR filter and constructing an allpass cascade of dfilt objects.

First, design the IIR halfband filter using cascaded allpass filters. Each branch of the parallel cascade construction is a cascadeallpass filter object.

```
tw = 100;  % Transition width of filter to be designed, 100 Hz.
ast = 80;  % Stopband attenuation of filter to be designed, 80dB.
fs = 2000; % Sampling frequency of signal to be filtered.
% Store halfband design specs in the specifications object d.
d = fdesign.halfband('tw,ast',tw,ast,fs);
```

Now perform the actual filter design. hd contains two dfilt.cascadeallpass objects.

```
hd = design(d,'ellip','filterstructure','cascadeallpass');
% Get summary information about one dfilt.cascadeallpass stage.
StageInfo = hd.Stage(1).Stage(1);
```

This second example constructs a `dfilt.cascadeallpass` filter object directly given allpass coefficients for the input vectors.

```
section1 = 0.8;
section2 = [1.2,0.7];
section3 = [1.3,0.9];
hd = dfilt.cascadeallpass(section1,section2,section3);
% Get information about the filter
% return informatio in character array
S = info(hd);
```

dfilt.cascadewdfallpass

Cascade allpass WDF filters to construct allpass WDF

Syntax

```
hd = dfilt.cascadewdfallpass(c1,c2,...)
```

Description

`hd = dfilt.cascadewdfallpass(c1,c2,...)` constructs a cascade of allpass wave digital filters given the allpass coefficients in the vectors `c1`, `c2`, and so on.

Each `c` vector contains the coefficients for one section of the cascaded filter. `C` vectors must have one, two, or four elements (coefficients). Three element vectors are not supported.

When the `c` vector has four elements, the first and third elements of the vector must be 0. Each section of the cascade is an allpass wave digital filter, from `dfilt.wdfallpass`, with the coefficients given by the corresponding c vector. That is, the first section has coefficients from vector `c1`, the second section coefficients come from `c2`, and on until all of the `c` vectors are used.

You can mix the lengths of the `c` vectors. They do not need to be the same length. For example, you can cascade several fourth-order sections (`length`(`c`) = 4) with first or second-order sections.

Wave digital filters are usually used to create other filters. This toolbox uses them to implement halfband filters, which the first example in Examples demonstrates. They are most often building blocks for filters.

Generally, you do not construct these WDF allpass cascade filters directly. Instead, they result from the design process for an IIR filter. Refer to the first example in Examples for more about using `dfilt.cascadewdfallpass` to design an IIR filter.

For more information about the `c` vectors and the transfer function for the allpass filters, refer to `dfilt.wdfallpass`.

Properties

In the next table, the row entries are the filter properties and a brief description of each property.

Property Name	Brief Description
`AllpassCoefficients`	Contains the coefficients for the allpass wave digital filter object
`FilterStructure`	Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering — gains, delays, sums, products, and input/output.
`PersistentMemory`	Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. `False` is the default setting.
`States`	This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. They also provide linkage between the sections of a multisection filter, such as a cascade filter. For details, refer to `filtstates` in Signal Processing Toolbox documentation or in the Help system.

Examples

To demonstrate two approaches to using `dfilt.cascadewdfallpass` to design a filter, these examples show both direct construction and construction as part of another filter.

The first design shown creates an IIR halfband filter that uses lattice wave digital filters. Each branch of the parallel connection in the lattice is an allpass cascade wave digital filter.

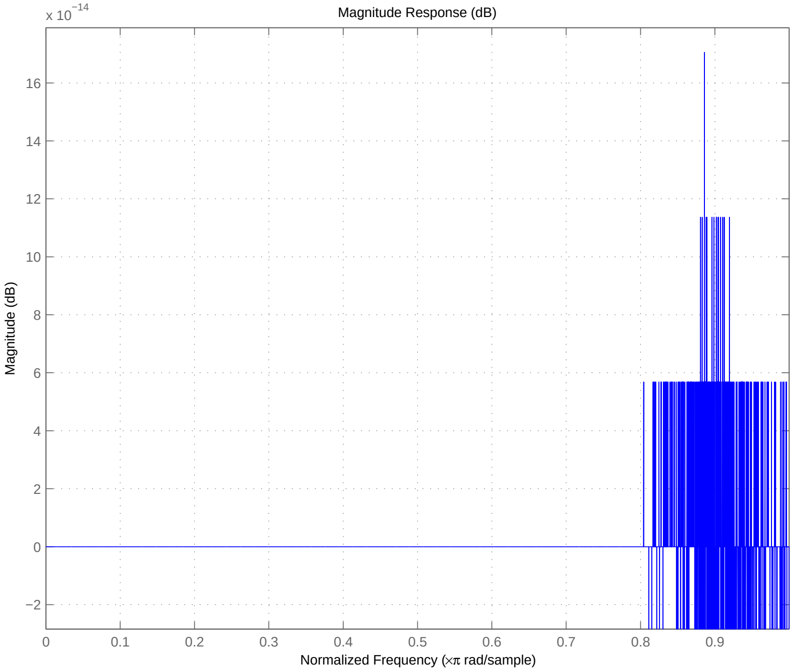
```
tw = 100;  % Transition width of filter, 100 Hz.
ast = 80;  % Stopband attenuation of filter, 80 dB.
fs = 2000; % Sampling frequency of signal to filter.
% Store halfband specs.
d = fdesign.halfband('tw,ast',tw,ast,fs);
```

Now perform the actual halfband design process. hd contains two dfilt.cascadewdfallpass filters.

```
hd = design(d,'ellip','filterstructure','cascadewdfallpass');
% Summary info on dfilt.cascadewdfallpass.
StageSummary = hd.stage(1).stage(2);
```

This example demonstrates direct construction of a dfilt.cascadewdfallpass filter with allpass coefficients.

```
section1 = 0.8;
section2 = [1.5,0.7];
section3 = [1.8,0.9];
hd = dfilt.cascadewdfallpass(section1,section2,section3);
```



See Also

dfilt | dfilt.wdfallpass

dfilt.delay

Delay filter

Syntax

```
Hd = dfilt.delay
Hd = dfilt.delay(latency)
```

Description

`Hd = dfilt.delay` returns a discrete-time filter, `Hd`, of type `delay`, which adds a single delay to any signal filtered with `Hd`. The filtered signal has its values shifted by one sample.

`Hd = dfilt.delay(latency)` returns a discrete-time filter, `Hd`, of type `delay`, which adds the number of delay units specified in `latency` to any signal filtered with `Hd`. The filtered signal has its values shifted by the `latency` number of samples. The values that appear before the shifted signal are the filter states.

Examples

Create a `delay` filter with a `latency` of 4 and filter a simple signal to view the impact of applying a delay.

```
h = dfilt.delay(4);
Fs = 1000;
t = 0:1/Fs:1;
sig = cos(2*pi*100*t);
y = filter(h,sig);
subplot(211);
stem(sig,'markerfacecolor',[0 0 1]);
axis([0 20 -2 2]);
title('Input Signal');
subplot(212);
stem(y,'markerfacecolor',[0 0 1]);
axis([0 20 -2 2]);
```

```
title('Delayed Signal');
```

`dfilt`

dfilt.df1

Discrete-time, direct-form I filter

Syntax

Refer to `dfilt.df1` in Signal Processing Toolbox documentation.

Description

`hd = dfilt.df1` returns a default discrete-time, direct-form I filter object that uses double-precision arithmetic. By default, the numerator and denominator coefficients b and a are set to 1. With these coefficients the filter passes the input to the output without changes.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hd` as follows:

- To change to single-precision filtering, enter

  ```
  set(hd,'arithmetic','single');
  ```
- To change to fixed-point filtering, enter

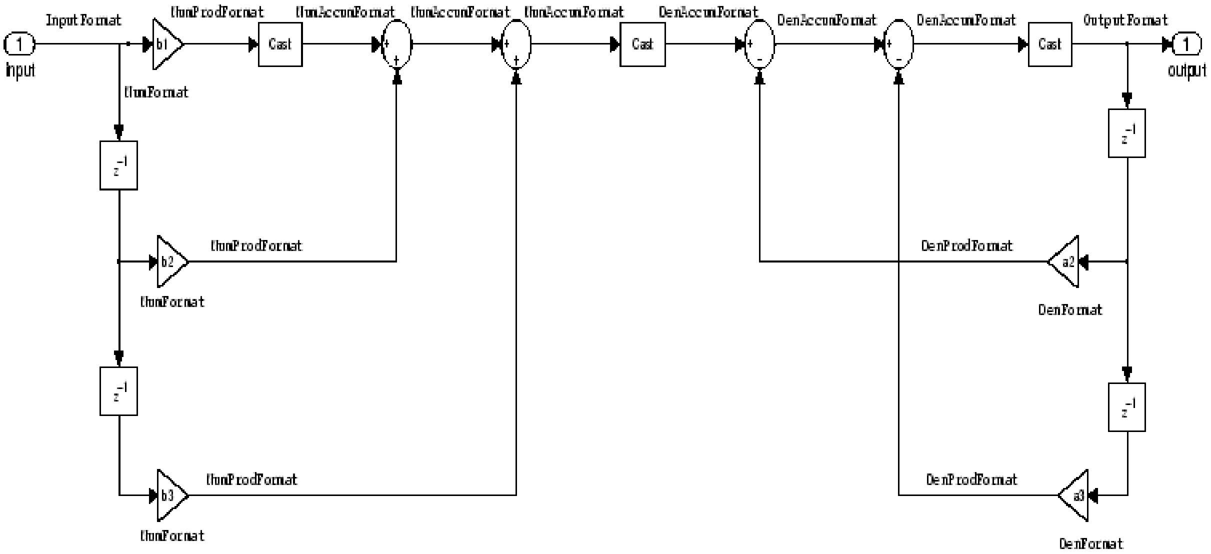
  ```
  set(hd,'arithmetic','fixed');
  ```

For more information about the property `Arithmetic`, refer to “Arithmetic”.

Note `a(1)`, the leading denominator coefficient, cannot be 0. To allow you to change the arithmetic setting to `fixed` or `single`, `a(1)` must be equal to 1.

Fixed-Point Filter Structure

The following figure shows the signal flow for the direct-form I filter implemented by `dfilt.df1`. To help you see how the filter processes the coefficients, input, output, and states of the filter, as well as numerical operations, the figure includes the locations of the arithmetic and data type format elements within the signal flow.



Notes About the Signal Flow Diagram

To help you understand where and how the filter performs fixed-point arithmetic during filtering, the figure shows various labels associated with data and functional elements in the filter. The following table describes each label in the signal flow and relates the label to the filter properties that are associated with it.

The labels use a common format — a prefix followed by the word "format." In this use, "format" means the word length and fraction length associated with the filter part referred to by the prefix.

For example, the InputFormat label refers to the word length and fraction length used to interpret the data input to the filter. The format properties `InputWordLength` and `InputFracLength` (as shown in the table) store the word length and the fraction length in bits. Or consider NumFormat, which refers to the word and fraction lengths (`CoeffWordLength`, `NumFracLength`) associated with representing filter numerator coefficients.

Signal Flow Label	Corresponding Word Length Property	Corresponding Fraction Length Property	Related Properties
DenAccumFormat	`AccumWordLength`	`DenAccumFracLength`	`AccumMode`, `CastBeforeSum`

Signal Flow Label	Corresponding Word Length Property	Corresponding Fraction Length Property	Related Properties
DenFormat	`CoeffWordLength`	`DenFracLength`	`CoeffAutoScale` , `SignedDenominator`
DenProdFormat	`CoeffWordLength`	`DenProdFracLength`	`ProductMode`, `ProductWordLength`
InputFormat	`InputWordLength`	`InputFracLength`	None
NumAccumFormat	`AccumWordLength`	`NumAccumFracLength`	`AccumMode`, `CastBeforeSum`
NumFormat	`CoeffWordLength`	`NumFracLength`	`CoeffAutoScale`, `Signed`, `Numerator`
NumProdFormat	`CoeffWordLength`	`NumProdFracLength`	`ProductWordLength`, `ProductMode`
OutputFormat	`OutputWordLength`	`OutputFracLength`	`OutputMode`

Most important is the label position in the diagram, which identifies where the format applies.

As one example, look at the label DenProdFormat, which always follows a denominator coefficient multiplication element in the signal flow. The label indicates that denominator coefficients leave the multiplication element with the word length and fraction length associated with product operations that include denominator coefficients. From reviewing the table, you see that the DenProdFormat refers to the properties `ProdWordLength`, `ProductMode` and `DenProdFracLength` that fully define the denominator format after multiply (or product) operations.

Properties

In this table you see the properties associated with df1 implementations of `dfilt` objects.

Note The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You might not see all of the listed properties all the time. To view all the properties for a filter at any time, use `get(hd)` where `hd` is a filter.

For further information about the properties of this filter or any `dfilt` object, refer to "Fixed-Point Filter Properties".

Property Name	Brief Description
`AccumMode`	Determines how the accumulator outputs stored values. Choose from full precision (`FullPrecision`), or whether to keep the most significant bits (`KeepMSB`) or least significant bits (`KeepLSB`) when output results need shorter word length than the accumulator supports. To let you set the word length and the precision (the fraction length) used by the output from the accumulator, set `AccumMode` to `SpecifyPrecision`.
`AccumWordLength`	Sets the word length used to store data in the accumulator/buffer.
`Arithmetic`	Defines the arithmetic the filter uses. Gives you the options `double`, `single`, and `fixed`. In short, this property defines the operating mode for your filter.
`CastBeforeSum`	Specifies whether to cast numeric data to the appropriate accumulator format (as shown in the signal flow diagrams) before performing sum operations.
`CoeffAutoScale`	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to `false` enables you to change the `NumFracLength` and `DenFracLength` properties to specify the precision used.
`CoeffWordLength`	Specifies the word length to apply to filter coefficients.
`DenAccumFracLength`	Specifies the fraction length the filter algorithm uses to interpret the results of product operations involving denominator coefficients. You can change the value for this property when you set `AccumMode` to `SpecifyPrecision`.
`DenFracLength`	Set the fraction length the filter uses to interpret denominator coefficients. `DenFracLength` is always available, but it is read-only until you set `CoeffAutoScale` to `false`.
`Denominator`	Stores the denominator coefficients for the IIR filter.

Property Name	Brief Description
DenProdFracLength	Specifies how the filter algorithm interprets the results of product operations involving denominator coefficients. You can change this property value when you set ProductMode to SpecifyPrecision.
FilterStructure	Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering — gains, delays, sums, products, and input/ output.
InputFracLength	Specifies the fraction length the filter uses to interpret input data.
InputWordLength	Specifies the word length applied to interpret input data.
NumAccumFracLength	Specifies how the filter algorithm interprets the results of addition operations involving numerator coefficients. You can change the value of this property after you set AccumMode to SpecifyPrecision.
Numerator	Holds the numerator coefficient values for the filter.
NumFracLength	Sets the fraction length used to interpret the value of numerator coefficients.
NumProdFracLength	Specifies how the filter algorithm interprets the results of product operations involving numerator coefficients. Available to be changed when you set ProductMode to SpecifyPrecision.
OutputFracLength	Determines how the filter interprets the filter output data. You can change the value of OutputFracLength when you set OutputMode to SpecifyPrecision.
OutputWordLength	Determines the word length used for the output data.

Property Name	Brief Description
`OverflowMode`	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either `saturate` (limit the output to the largest positive or negative representable value) or `wrap` (set overflowing values to the nearest representable value using modular arithmetic). The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow — they maintain full precision.
`ProductMode`	Determines how the filter handles the output of product operations. Choose from full precision (`FullPrecision`), or whether to keep the most significant bit (`KeepMSB`) or least significant bit (`KeepLSB`) in the result when you need to shorten the data words. For you to be able to set the precision (the fraction length) used by the output from the multiplies, you set `ProductMode` to `SpecifyPrecision`.
`ProductWordLength`	Specifies the word length to use for multiplication operation results. This property becomes writable (you can change the value) when you set `ProductMode` to `SpecifyPrecision`.
`PersistentMemory`	Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. `False` is the default setting.

Property Name	Brief Description
`RoundMode`	Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths). • `ceil` - Round toward positive infinity. • `convergent` - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software. • `fix` - Round toward zero. • `floor` - Round toward negative infinity. • `nearest` - Round toward nearest. Ties round toward positive infinity. • `round` - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers. The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.
`Signed`	Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.
`States`	This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. The states use `fi` objects, with the associated properties from those objects. For details, refer to `filtstates` in Signal Processing Toolbox documentation or in the Help system.

Examples

Specify a second-order direct-form I structure for a `dfilt` object, `hd`, with the following code:

```
b = [0.3 0.6 0.3];
a = [1 0 0.2];
hd = dfilt.df1(b,a);
% Convert hd to fixed-point filter
set(hd,'arithmetic','fixed')
```

See Also

`dfilt` | `dfilt.df1t` | `dfilt.df2` | `dfilt.df2t`

dfilt.df1sos

Discrete-time, SOS direct-form I filter

Syntax

Refer to `dfilt.df1sos` in Signal Processing Toolbox documentation.

Description

`hd = dfilt.df1sos(s)` returns a discrete-time, second-order section, direct-form I filter object `hd`, with coefficients given in the `s` matrix.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hd` as follows:

- To change to single-precision filtering, enter

  ```
  set(hd,'arithmetic','single');
  ```
- To change to fixed-point filtering, enter

  ```
  set(hd,'arithmetic','fixed');
  ```

For more information about the property `Arithmetic`, refer to “Arithmetic”.

`hd = dfilt.df1sos(b1,a1,b2,a2,...)` returns a discrete-time, second-order section, direct-form I filter object `hd`, with coefficients for the first section given in the `b1` and `a1` vectors, for the second section given in the `b2` and `a2` vectors, and so on.

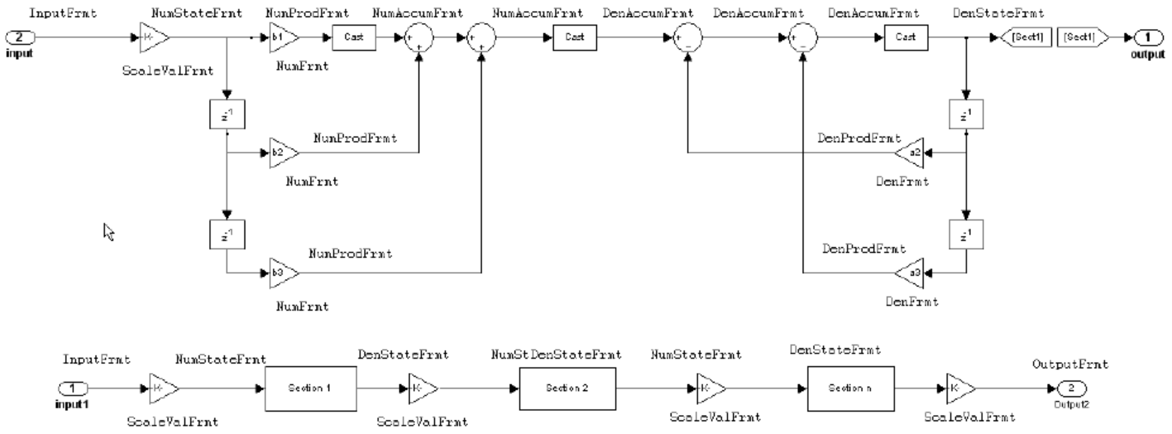
`hd = dfilt.df1sos(...,g)` includes a gain vector `g`. The elements of `g` are the gains for each section. The maximum length of `g` is the number of sections plus one. When you do not specify `g`, all gains default to one.

`hd = dfilt.df1sos` returns a default, discrete-time, second-order section, direct-form I filter object, `hd`. This filter passes the input through to the output unchanged.

Note The leading coefficient of the denominator `a(1)` cannot be 0. To allow you to change the arithmetic setting to `fixed` or `single`, `a(1)` must be equal to 1.

Fixed-Point Filter Structure

The following figure shows the signal flow for the direct-form I filter implemented in second-order sections by `dfilt.df1sos`. To help you see how the filter processes the coefficients, input, and states of the filter, as well as numerical operations, the figure includes the locations of the formatting objects within the signal flow.



Notes About the Signal Flow Diagram

To help you understand where and how the filter performs fixed-point arithmetic during filtering, the figure shows various labels associated with data and functional elements in the filter. The following table describes each label in the signal flow and relates the label to the filter properties that are associated with it.

The labels use a common format — a prefix followed by the letters “frmt” (format). In this use, “frmt“ means the word length and fraction length associated with the filter part referred to by the prefix.

For example, the InputFrmt label refers to the word length and fraction length used to interpret the data input to the filter. The format properties `InputWordLength` and `InputFracLength` (as shown in the table) store the word length and the fraction length in bits. Similarly consider NumFrmt, which refers to the word and fraction lengths (`CoeffWordLength`, `NumFracLength`) associated with representing filter numerator coefficients.

Signal Flow Label	Corresponding Word Length Property	Corresponding Fraction Length Property	Related Properties
DenAccumFrmt	AccumWordLength	DenAccumFracLength	AccumMode, CastBeforeSum
DenFrmt	CoeffWordLength	DenFracLength	CoeffAutoScale, Signed, Denominator
DenProdFrmt	CoeffWordLength	DenProdFracLength	ProductMode, ProductWordLength
DenStateFrmt	DenStateWordLength	DenStateFracLength	CastBeforeSum, States
InputFrmt	InputWordLength	InputFracLength	None
NumAccumFrmt	AccumWordLength	NumAccumFracLength	AccumMode, CastBeforeSum
NumFrmt	CoeffWordLength	NumFracLength	CoeffAutoScale, Signed, Numerator
NumProdFrmt	CoeffWordLength	NumProdFracLength	ProductWordLength, ProductMode
NumStateFrmt	NumStateWordLength	NumStateFracLength	States
OutputFrmt	OutputWordLength	OutputFracLength	OutputMode
ScaleValueFrmt	CoeffWordLength	ScaleValueFracLength	CoeffAutoScale, ScaleValues

Most important is the label position in the diagram, which identifies where the format applies.

As one example, look at the label DenProdFrmt, which always follows a denominator coefficient multiplication element in the signal flow. The label indicates that denominator coefficients leave the multiplication element with the word length and fraction length associated with product operations that include denominator coefficients. From reviewing the table, you see that the DenProdFrmt refers to the properties ProdWordLength, ProductMode and DenProdFracLength that fully define the denominator format after multiply (or product) operations.

Properties

In this table you see the properties associated with SOS implementation of direct-form I `dfilt` objects.

Note The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You might not see all of the listed properties all the time. To view all the properties for a filter at any time, use

```
get(hd)
```

where `hd` is a filter.

For further information about the properties of this filter or any `dfilt` object, refer to "Fixed-Point Filter Properties".

Property Name	Brief Description
`AccumMode`	Determines how the accumulator outputs stored values. Choose from full precision (`FullPrecision`), or whether to keep the most significant bits (`KeepMSB`) or least significant bits (`KeepLSB`) when output results need shorter word length than the accumulator supports. To let you set the word length and the precision (the fraction length) used by the output from the accumulator, set `AccumMode` to `SpecifyPrecision`.
`AccumWordLength`	Sets the word length used to store data in the accumulator/buffer.
`Arithmetic`	Defines the arithmetic the filter uses. Gives you the options `double`, `single`, and `fixed`. In short, this property defines the operating mode for your filter.
`CastBeforeSum`	Specifies whether to cast numeric data to the appropriate accumulator format (as shown in the signal flow diagrams) before performing sum operations.
`CoeffAutoScale`	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value

Property Name	Brief Description
	to false enables you to change the NumFracLength and DenFracLength properties to specify the precision used.
CoeffWordLength	Specifies the word length to apply to filter coefficients.
DenAccumFracLength	Specifies the fraction length used to interpret data in the accumulator used to hold the results of sum operations. You can change the value for this property when you set AccumMode to SpecifyPrecision.
DenFracLength	Set the fraction length the filter uses to interpret denominator coefficients. DenFracLength is always available, but it is read-only until you set CoeffAutoScale to false.
DenProdFracLength	Specifies how the filter algorithm interprets the results of product operations involving denominator coefficients. You can change this property value when you set ProductMode to SpecifyPrecision.
DenStateFracLength	Specifies the fraction length used to interpret the states associated with denominator coefficients in the filter.
DenStateWordLength	Specifies the word length used to represent the states associated with denominator coefficients in the filter.
FilterStructure	Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering—gains, delays, sums, products, and input/output.
InputFracLength	Specifies the fraction length the filter uses to interpret input data.
InputWordLength	Specifies the word length applied to interpret input data.
NumAccumFracLength	Specifies how the filter algorithm interprets the results of addition operations involving numerator coefficients. You can change the value of this property after you set AccumMode to SpecifyPrecision.
NumFracLength	Sets the fraction length used to interpret the value of numerator coefficients.

Property Name	Brief Description
`NumStateFracLength`	Specifies the fraction length used to interpret the states associated with numerator coefficient operations in the filter.
`NumWordFracLength`	Specifies the word length used to interpret the states associated with numerator coefficient operations in the filter.
`OptimizeScaleValues`	When true, the filter skips multiplication-by-one scaling. When false, the filter performs multiplication-by-one scaling.
`OutputFracLength`	Determines how the filter interprets the filter output data. You can change the value of `OutputFracLength` when you set `OutputMode` to `SpecifyPrecision`.
`OutputMode`	Sets the mode the filter uses to scale the filtered data for output. You have the following choices: • `AvoidOverflow` — directs the filter to set the output data word length and fraction length to avoid causing the data to overflow. • `BestPrecision` — directs the filter to set the output data word length and fraction length to maximize the precision in the output data. • `SpecifyPrecision` — lets you set the word and fraction lengths used by the output data from filtering.
`OutputWordLength`	Determines the word length applied for the output data.
`OverflowMode`	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either `saturate` (limit the output to the largest positive or negative representable value) or `wrap` (set overflowing values to the nearest representable value using modular arithmetic). The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow—they maintain full precision.

Property Name	Brief Description
ProductMode	Determines how the filter handles the output of product operations. Choose from full precision (FullPrecision), or whether to keep the most significant bit (KeepMSB) or least significant bit (KeepLSB) in the result when you need to shorten the data words. For you to be able to set the precision (the fraction length) used by the output from the multiplies, you set ProductMode to SpecifyPrecision.
ProductWordLength	Specifies the word length to use for multiplication operation results. This property becomes writable (you can change the value) when you set ProductMode to SpecifyPrecision.
PersistentMemory	Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. False is the default setting.

Property Name	Brief Description
`RoundMode`	Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths). • `ceil` - Round toward positive infinity. • `convergent` - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software. • `fix` - Round toward zero. • `floor` - Round toward negative infinity. • `nearest` - Round toward nearest. Ties round toward positive infinity. • `round` - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers. The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.
`ScaleValueFracLength`	Scale values work with SOS filters. Setting this property controls how your filter interprets the scale values by setting the fraction length. Only available when you disable `AutoScaleMode` by setting it to `false`.
`ScaleValues`	Scaling for the filter objects in SOS filters.
`Signed`	Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.
`SosMatrix`	Holds the filter coefficients as property values. Displays the matrix in the format [sections x coefficients/section datatype]. A `[15x6 double]` SOS matrix represents a filter with 6 coefficients per section and 15 sections, using data type `double` to represent the coefficients.

Property Name	Brief Description
`States`	This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. The states use `fi` objects, with the associated properties from those objects. For details, refer to `filtstates` in Signal Processing Toolbox documentation or in the Help system.
`StateWordLength`	Sets the word length used to represent the filter states.

Examples

Specify a fixed-point, second-order section, direct-form I `dfilt` object with the following code:

```
b = [0.3 0.6 0.3];
a = [1 0 0.2];
hd = dfilt.df1sos(b,a);
% Convert to fixed-point filter
hd.arithmetic = 'fixed';
```

See Also

`dfilt` | `dfilt.df2tsos`

dfilt.df1t

Discrete-time, direct-form I transposed filter

Syntax

Refer to `dfilt.df1t` in Signal Processing Toolbox documentation.

Description

`hd = dfilt.df1t(b,a)` returns a discrete-time, direct-form I transposed filter object `hd`, with numerator coefficients `b` and denominator coefficients `a`.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hd` as follows:

- To change to single-precision filtering, enter

  ```
  set(hd,'arithmetic','single');
  ```
- To change to fixed-point filtering, enter

  ```
  set(hd,'arithmetic','fixed');
  ```

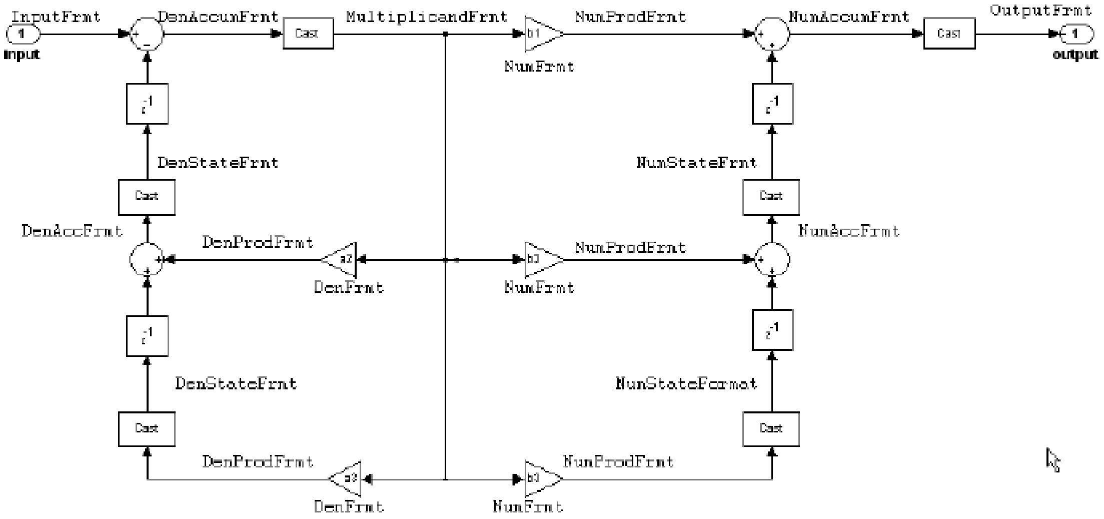
For more information about the property `Arithmetic`, refer to “Arithmetic”.

`hd = dfilt.df1t` returns a default, discrete-time, direct-form I transposed filter object `hd`, with `b`=1 and `a`=1. This filter passes the input through to the output unchanged.

Note The leading coefficient of the denominator `a(1)` cannot be 0. To allow you to change the arithmetic setting to `fixed` or `single`, `a(1)` must be equal to 1.

Fixed-Point Filter Structure

The following figure shows the signal flow for the transposed direct-form I filter implemented by `dfilt.df1t`. To help you see how the filter processes the coefficients, input, and states of the filter, as well as numerical operations, the figure includes the locations of the formatting objects within the signal flow.



Notes About the Signal Flow Diagram

To help you understand where and how the filter performs fixed-point arithmetic during filtering, the figure shows various labels associated with data and functional elements in the filter. The following table describes each label in the signal flow and relates the label to the filter properties that are associated with it.

The labels use a common format — a prefix followed by the letters “frmt” (format). In this use, “frmt” means the word length and fraction length associated with the filter part referred to by the prefix.

For example, the InputFrmt label refers to the word length and fraction length used to interpret the data input to the filter. The format properties `InputWordLength` and `InputFracLength` (as shown in the table) store the word length and the fraction length in bits. Or consider NumFrmt, which refers to the word and fraction lengths (`CoeffWordLength`, `NumFracLength`) associated with representing filter numerator coefficients.

Signal Flow Label	Corresponding Word Length Property	Corresponding Fraction Length Property	Related Properties
DenAccumFrmt	AccumWordLength	DenAccumFracLength	AccumMode, CastBeforeSum
DenFrmt	CoeffWordLength	DenFracLength	CoeffAutoScale, , Signed, Denominator
DenProdFrmt	CoeffWordLength	DenProdFracLength	ProductMode, ProductWordLength
DenStateFrmt	DenStateWordLength	DenStateFracLength	CastBeforeSum, States
InputFrmt	InputWordLength	InputFracLength	None
Multiplicandfrmt	Multiplicand-WordLength	Multiplicand-FracLength	CastBeforeSum
NumAccumFrmt	AccumWordLength	NumAccumFracLength	AccumMode, CastBeforeSum
NumFrmt	CoeffWordLength	NumFracLength	CoeffAutoScale, Signed, Numerator
NumProdFrmt	CoeffWordLength	NumProdFracLength	ProductWordLength, ProductMode
NumStateFrmt	NumStateWordLength	NumStateFracLength	States
OutputFrmt	OutputWordLength	OutputFracLength	OutputMode

Most important is the label position in the diagram, which identifies where the format applies.

As one example, look at the label DenProdFrmt, which always follows a denominator coefficient multiplication element in the signal flow. The label indicates that denominator coefficients leave the multiplication element with the word length and fraction length associated with product operations that include denominator coefficients. From reviewing the table, you see that the DenProdFrmt refers to the properties ProdWordLength, ProductMode and DenProdFracLength that fully define the denominator format after multiply (or product) operations.

Properties

In this table you see the properties associated with df1t implementation of `dfilt` objects.

Note The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You might not see all of the listed properties all the time. To view all the properties for a filter at any time, use

```
get(hd)
```

where `hd` is a filter.

For further information about the properties of this filter or any `dfilt` object, refer to "Fixed-Point Filter Properties".

Property Name	Brief Description
`AccumMode`	Determines how the accumulator outputs stored values. Choose from full precision (`FullPrecision`), or whether to keep the most significant bits (`KeepMSB`) or least significant bits (`KeepLSB`) when output results need shorter word length than the accumulator supports. To let you set the word length and the precision (the fraction length) used by the output from the accumulator, set `AccumMode` to `SpecifyPrecision`.
`AccumWordLength`	Sets the word length used to store data in the accumulator/buffer.
`Arithmetic`	Defines the arithmetic the filter uses. Gives you the options `double`, `single`, and `fixed`. In short, this property defines the operating mode for your filter.
`CastBeforeSum`	Specifies whether to cast numeric data to the appropriate accumulator format (as shown in the signal flow diagrams) before performing sum operations.
`CoeffAutoScale`	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this

Property Name	Brief Description
	off by setting the value to `false` enables you to change the `NumFracLength` and `DenFracLength` properties to specify the precision used.
`CoeffWordLength`	Specifies the word length to apply to filter coefficients.
`DenAccumFracLength`	Specifies the fraction length used to interpret data in the accumulator used to hold the results of sum operations. You can change the value for this property when you set `AccumMode` to `SpecifyPrecision`.
`DenFracLength`	Set the fraction length the filter uses to interpret denominator coefficients. `DenFracLength` is always available, but it is read-only until you set `CoeffAutoScale` to `false`.
`Denominator`	Holds the denominator coefficients for the filter.
`DenProdFracLength`	Specifies how the filter algorithm interprets the results of product operations involving denominator coefficients. You can change this property value when you set `ProductMode` to `SpecifyPrecision`.
`DenStateFracLength`	Specifies the fraction length used to interpret the states associated with denominator coefficients in the filter.
`FilterStructure`	Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering — gains, delays, sums, products, and input/output.
`InputFracLength`	Specifies the fraction length the filter uses to interpret input data.
`InputWordLength`	Specifies the word length applied to interpret input data.
`MultiplicandFracLength`	Sets the fraction length for values (multiplicands) used in multiply operations in the filter.
`MultiplicandWordLength`	Sets the word length applied to the values input to a multiply operation (the multiplicands).

Property Name	Brief Description
NumAccumFracLength	Specifies how the filter algorithm interprets the results of addition operations involving numerator coefficients. You can change the value of this property after you set AccumMode to SpecifyPrecision.
Numerator	Holds the numerator coefficient values for the filter.
NumFracLength	Sets the fraction length used to interpret the value of numerator coefficients.
NumProdFracLength	Specifies how the filter algorithm interprets the results of product operations involving numerator coefficients. Available to be changed when you set ProductMode to SpecifyPrecision.
NumStateFracLength	For IIR filters, this defines the binary point location applied to the numerator states of the filter. Specifies the fraction length used to interpret the states associated with numerator coefficient operations in the filter.
OutputFracLength	Determines how the filter interprets the filter output data. You can change the value of OutputFracLength when you set OutputMode to SpecifyPrecision.
OutputMode	Sets the mode the filter uses to scale the filtered data for output. You have the following choices: • AvoidOverflow — directs the filter to set the output data word length and fraction length to avoid causing the data to overflow. • BestPrecision — directs the filter to set the output data word length and fraction length to maximize the precision in the output data. • SpecifyPrecision — lets you set the word and fraction lengths used by the output data from filtering.
OutputWordLength	Determines the word length used for the output data.

Property Name	Brief Description
OverflowMode	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either saturate (limit the output to the largest positive or negative representable value) or wrap (set overflowing values to the nearest representable value using modular arithmetic). The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow—they maintain full precision.
ProductMode	Determines how the filter handles the output of product operations. Choose from full precision (FullPrecision), or whether to keep the most significant bit (KeepMSB) or least significant bit (KeepLSB) in the result when you need to shorten the data words. For you to be able to set the precision (the fraction length) used by the output from the multiplies, you set ProductMode to SpecifyPrecision.
ProductWordLength	Specifies the word length to use for multiplication operation results. This property becomes writable (you can change the value) when you set ProductMode to SpecifyPrecision.
PersistentMemory	Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. False is the default setting.

Property Name	Brief Description
RoundMode	Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths). • ceil - Round toward positive infinity. • convergent - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software. • fix - Round toward zero. • floor - Round toward negative infinity. • nearest - Round toward nearest. Ties round toward positive infinity. • round - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers. The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.
Signed	Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.
StateAutoScale	Setting autoscaling for filter states to true reduces the possibility of overflows occurring during fixed-point operations. Set to false, StateAutoScale lets the filter select the fraction length to limit the overflow potential.
States	This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions.
StateWordLength	Sets the word length used to represent the filter states.

Examples

Specify a second-order direct-form I transposed filter structure for a `dfilt` object, `hd`, with the following code:

```
b = [0.3 0.6 0.3];
a = [1 0 0.2];
hd = dfilt.df1t(b,a);
% Convert filter to single-precision arithmetic
set(hd,'arithmetic','single')
```

See Also

`dfilt` | `dfilt.df1` | `dfilt.df2` | `dfilt.df2t`

dfilt.df1tsos

Discrete-time, SOS direct-form I transposed filter

Syntax

Refer to `dfilt.df1tsos` in Signal Processing Toolbox documentation.

Description

`hd = dfilt.df1tsos(s)` returns a discrete-time, second-order section, direct-form I, transposed filter object `hd`, with coefficients given in the `s` matrix.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hd` as follows:

- To change to single-precision filtering, enter

  ```
  set(hd,'arithmetic','single');
  ```
- To change to fixed-point filtering, enter

  ```
  set(hd,'arithmetic','fixed');
  ```

For more information about the property `Arithmetic`, refer to .

`hd = dfilt.df1tsos(b1,a1,b2,a2,...)` returns a discrete-time, second-order section, direct-form I, transposed filter object `hd`, with coefficients for the first section given in the `b1` and `a1` vectors, for the second section given in the `b2` and `a2` vectors, etc.

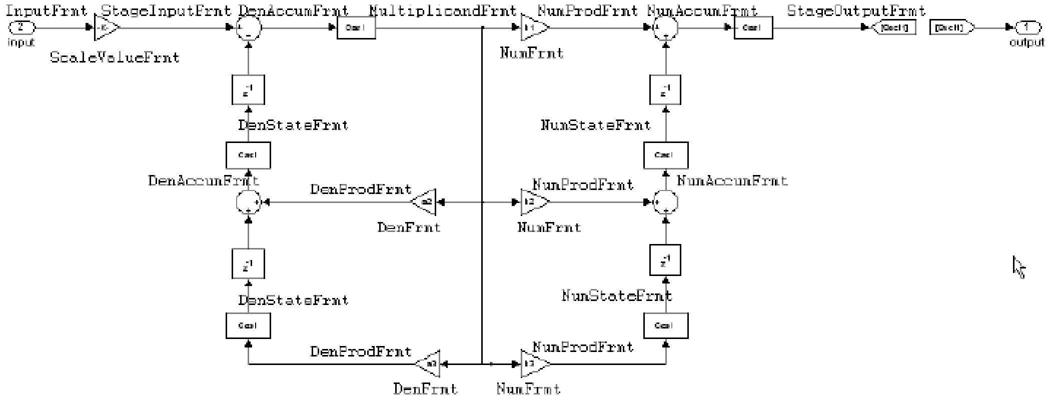
`hd = dfilt.df1tsos(...,g)` includes a gain vector `g`. The elements of `g` are the gains for each section. The maximum length of `g` is the number of sections plus one. If `g` is not specified, all gains default to one.

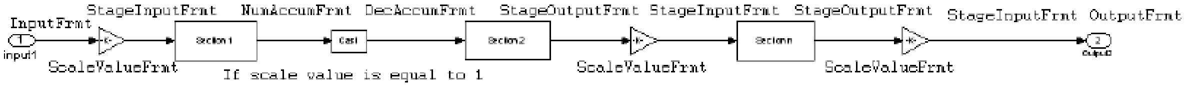
`hd = dfilt.df1tsos` returns a default, discrete-time, second-order section, direct-form I, transposed filter object, `hd`. This filter passes the input through to the output unchanged.

Note The leading coefficient of the denominator `a(1)` cannot be 0. To allow you to change the arithmetic setting to `fixed` or `single`, `a(1)` must be equal to 1.

Fixed-Point Filter Structure

The following figure shows the signal flow for the direct-form I transposed filter implemented using second-order sections by `dfilt.df1tsos`. To help you see how the filter processes the coefficients, input, and states of the filter, as well as numerical operations, the figure includes the locations of the formatting objects within the signal flow.





Notes About the Signal Flow Diagram

To help you understand where and how the filter performs fixed-point arithmetic during filtering, the figure shows various labels associated with data and functional elements in the filter. The following table describes each label in the signal flow and relates the label to the filter properties that are associated with it.

The labels use a common format — a prefix followed by the letters “frmt” (format). In this use, “frmt” means the word length and fraction length associated with the filter part referred to by the prefix.

For example, the InputFrmt label refers to the word length and fraction length used to interpret the data input to the filter. The format properties `InputWordLength` and InputFracLength (as shown in the table) store the word length and the fraction length in bits. Or consider NumFrmt, which refers to the word and fraction lengths (CoeffWordLength, NumFracLength) associated with representing filter numerator coefficients.

Signal Flow Label	Corresponding Word Length Property	Corresponding Fraction Length Property	Related Properties
DenAccumFrmt	AccumWordLength	DenAccumFracLength	AccumMode, CastBeforeSum
DenFrmt	CoeffWordLength	DenFracLength	CoeffAutoScale, Signed, Denominator
DenProdFrmt	CoeffWordLength	DenProdFracLength	ProductMode, ProductWordLength
DenStateFrmt	DenStateWordLength	DenStateFracLength	CastBeforeSum, States
InputFrmt	InputWordLength	InputFracLength	None
MultiplicandFrmt	Multiplicand-WordLength	Multiplicand-FracLength	CastBeforeSum
NumAccumFrmt	AccumWordLength	NumAccumFracLength	AccumMode, CastBeforeSum
NumFrmt	CoeffWordLength	NumFracLength	CoeffAutoScale, Signed, Numerator
NumProdFrmt	CoeffWordLength	NumProdFracLength	ProductWordLength, ProductMode
NumStateFrmt	NumStateWordLength	NumStateFracLength	States
OutputFrmt	OutputWordLength	OutputFracLength	OutputMode
ScaleValueFrmt	CoeffWordLength	ScaleValue-FracLength	CoeffAutoScale, ScaleValues

Most important is the label position in the diagram, which identifies where the format applies.

As one example, look at the label DenProdFrmt, which always follows a denominator coefficient multiplication element in the signal flow. The label indicates that denominator coefficients leave the multiplication element with the word length and fraction length associated with product operations that include denominator coefficients. From reviewing the table, you see that the DenProdFrmt refers to the properties ProdWordLength, ProductMode and DenProdFracLength that fully define the denominator format after multiply (or product) operations.

Properties

In this table you see the properties associated with SOS implementation of transposed direct-form I dfilt objects.

Note The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You might not see all of the listed properties all the time. To view all the properties for a filter at any time, use

```
get(hd)
```

where hd is a filter.

For further information about the properties of this filter or any dfilt object, refer to "Fixed-Point Filter Properties".

Property Name	Brief Description
AccumMode	Determines how the accumulator outputs stored values. Choose from full precision (FullPrecision), or whether to keep the most significant bits (KeepMSB) or least significant bits (KeepLSB) when output results need shorter word length than the accumulator supports. To let you set the word length and the precision (the fraction length) used by the output from the accumulator, set AccumMode to SpecifyPrecision.
AccumWordLength	Sets the word length used to store data in the accumulator/buffer.
Arithmetic	Defines the arithmetic the filter uses. Gives you the options double, single, and fixed. In short, this property defines the operating mode for your filter.

Property Name	Brief Description
CastBeforeSum	Specifies whether to cast numeric data to the appropriate accumulator format (as shown in the signal flow diagrams) before performing sum operations.
CoeffAutoScale	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to false enables you to change the NumFracLength and DenFracLength properties to specify the precision used.
CoeffWordLength	Specifies the word length to apply to filter coefficients.
DenAccumFracLength	Specifies the fraction length used to interpret data in the accumulator used to hold the results of sum operations. You can change the value for this property when you set AccumMode to SpecifyPrecision.
DenFracLength	Set the fraction length the filter uses to interpret denominator coefficients. DenFracLength is always available, but it is read-only until you set CoeffAutoScale to false.
DenProdFracLength	Specifies how the filter algorithm interprets the results of product operations involving denominator coefficients. You can change this property value when you set ProductMode to SpecifyPrecision.
DenStateFracLength	Specifies the fraction length used to interpret the states associated with denominator coefficients in the filter.
FilterStructure	Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering—gains, delays, sums, products, and input/output.

Property Name	Brief Description
`InputFracLength`	Specifies the fraction length the filter uses to interpret input data.
`InputWordLength`	Specifies the word length applied to interpret input data.
`MultiplicandFracLength`	Sets the fraction length for values (multiplicands) used in multiply operations in the filter.
`MultiplicandWordLength`	Sets the word length applied to the values input to a multiply operation (the multiplicands)
`NumAccumFracLength`	Specifies how the filter algorithm interprets the results of addition operations involving numerator coefficients. You can change the value of this property after you set `AccumMode` to `SpecifyPrecision`.
`Numerator`	Holds the numerator coefficient values for the filter.
`NumProdFracLength`	Specifies how the filter algorithm interprets the results of product operations involving numerator coefficients. Available to be changed when you set `ProductMode` to `SpecifyPrecision`.
`NumStateFracLength`	For IIR filters, this defines the binary point location applied to the numerator states of the filter. Specifies the fraction length used to interpret the states associated with numerator coefficient operations in the filter.
`NumStateWordLength`	For IIR filters, this defines the word length applied to the numerator states of the filter. Specifies the word length used to interpret the states associated with numerator coefficient operations in the filter.
`OptimizeScaleValues`	When true, the filter skips multiplication-by-one scaling. When false, the filter performs multiplication-by-one scaling.

Property Name	Brief Description
`OutputFracLength`	Determines how the filter interprets the filter output data. You can change the value of `OutputFracLength` when you set `OutputMode` to `SpecifyPrecision`.
`OutputMode`	Sets the mode the filter uses to scale the filtered data for output. You have the following choices: • `AvoidOverflow` — directs the filter to set the output data word length and fraction length to avoid causing the data to overflow. • `BestPrecision` — directs the filter to set the output data word length and fraction length to maximize the precision in the output data. • `SpecifyPrecision` — lets you set the word and fraction lengths used by the output data from filtering.
`OutputWordLength`	Determines the word length used for the output data.
`OverflowMode`	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either `saturate` (limit the output to the largest positive or negative representable value) or `wrap` (set overflowing values to the nearest representable value using modular arithmetic). The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow—they maintain full precision.

Property Name	Brief Description
ProductMode	Determines how the filter handles the output of product operations. Choose from full precision (FullPrecision), or whether to keep the most significant bit (KeepMSB) or least significant bit (KeepLSB) in the result when you need to shorten the data words. For you to be able to set the precision (the fraction length) used by the output from the multiplies, you set ProductMode to SpecifyPrecision.
ProductWordLength	Specifies the word length to use for multiplication operation results. This property becomes writable (you can change the value) when you set ProductMode to SpecifyPrecision.
PersistentMemory	Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. False is the default setting.

Property Name	Brief Description
RoundMode	Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths). • ceil - Round toward positive infinity. • convergent - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software. • fix - Round toward zero. • floor - Round toward negative infinity. • nearest - Round toward nearest. Ties round toward positive infinity. • round - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers. The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.
ScaleValueFracLength	Scale values work with SOS filters. Setting this property controls how your filter interprets the scale values by setting the fraction length. Only available when you disable AutoScaleMode by setting it to false.
ScaleValues	Scaling for the filter objects in SOS filters.
Signed	Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.

Property Name	Brief Description
SosMatrix	Holds the filter coefficients as property values. Displays the matrix in the format [sections x coefficients/sectiondatatype]. A [15x6 double] SOS matrix represents a filter with 6 coefficients per section and 15 sections, using data type double to represent the coefficients.
StateAutoScale	Setting autoscaling for filter states to true reduces the possibility of overflows occurring during fixed-point operations. Set to false, StateAutoScale lets the filter select the fraction length to limit the overflow potential.
States	This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions.
StateWordLength	Sets the word length used to represent the filter states.

Examples

With the following code, this example specifies a second-order section, direct-form I transposed dfilt object for a filter. Then convert the filter to fixed-point operation.

```
b = [0.3 0.6 0.3];
a = [1 0 0.2];
hd = dfilt.df1tsos(b,a);
set(hd,'arithmetic','fixed')
```

See Also

dfilt | dfilt.df1sos | dfilt.df2sos | dfilt.df2tsos

dfilt.df2

Discrete-time, direct-form II filter

Syntax

Refer to `dfilt.df2` in Signal Processing Toolbox documentation.

Description

`hd = dfilt.df2(b,a)` returns a discrete-time, direct-form II filter object `hd`, with numerator coefficients `b` and denominator coefficients `a`.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hd` as follows:

- To change to single-precision filtering, enter

  ```
  set(hd,'arithmetic','single');
  ```

- To change to fixed-point filtering, enter

  ```
  set(hd,'arithmetic','fixed');
  ```

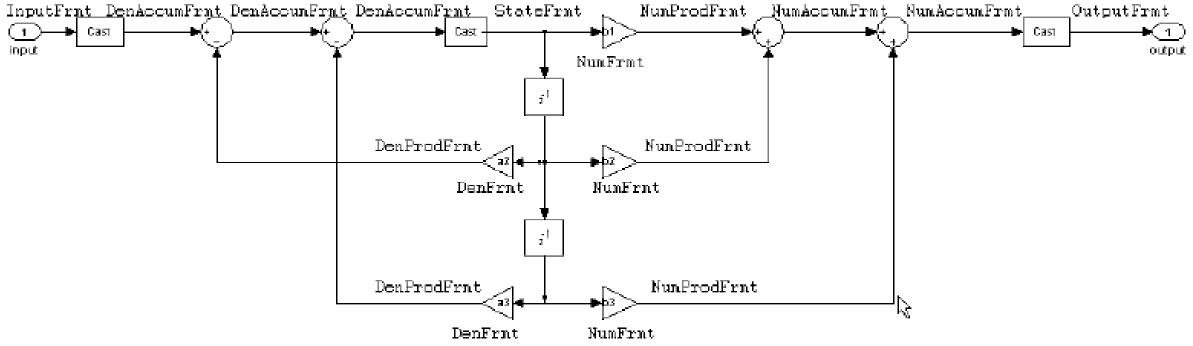
For more information about the property `Arithmetic`, refer to “Arithmetic”.

`hd = dfilt.df2` returns a default, discrete-time, direct-form II filter object `hd`, with `b` = 1 and `a` = 1. This filter passes the input through to the output unchanged.

Note The leading coefficient of the denominator `a(1)` cannot be 0. To allow you to change the arithmetic setting to `fixed` or `single`, `a(1)` must be equal to 1.

Fixed-Point Filter Structure

The following figure shows the signal flow for the direct-form II filter implemented by `dfilt.df2`. To help you see how the filter processes the coefficients, input, and states of the filter, as well as numerical operations, the figure includes the locations of the formatting objects within the signal flow.



Notes About the Signal Flow Diagram

To help you understand where and how the filter performs fixed-point arithmetic during filtering, the figure shows various labels associated with data and functional elements in the filter. The following table describes each label in the signal flow and relates the label to the filter properties that are associated with it.

The labels use a common format — a prefix followed by the letters“frmt” (format). In this use, “frmt” means the word length and fraction length associated with the filter part referred to by the prefix.

For example, the InputFrmt label refers to the word length and fraction length used to interpret the data input to the filter. The format properties `InputWordLength` and `InputFracLength` (as shown in the table) store the word length and the fraction length in bits. Or consider NumFrmt, which refers to the word and fraction lengths (`CoeffWordLength`, `NumFracLength`) associated with representing filter numerator coefficients.

Signal Flow Label	Corresponding Word Length Property	Corresponding Fraction Length Property	Related Properties
DenAccumFrmt	`AccumWordLength`	`DenAccumFracLength`	`AccumMode`, `CastBeforeSum`

NumFrmt	`CoeffWordLength`	`NumFracLength`	`CoeffAutoScale`, `Signed`, `Numerator`
NumProdFrmt	`CoeffWordLength`	`NumProdFracLength`	`ProductWordLength`, `ProductMode`
OutputFrmt	`OutputWordLength`	`OutputFracLength`	`OutputMode`
StateFrmt	`StateWordLength`	`StateFracLength`	`States`

Most important is the label position in the diagram, which identifies where the format applies.

As one example, look at the label DenProdFrmt, which always follows a denominator coefficient multiplication element in the signal flow. The label indicates that denominator coefficients leave the multiplication element with the word length and fraction length associated with product operations that include denominator coefficients. From reviewing the table, you see that the DenProdFrmt refers to the properties `ProdWordLength`, `ProductMode` and `DenProdFracLength` that fully define the denominator format after multiply (or product) operations.

Properties

In this table you see the properties associated with the df2 implementation of `dfilt` objects.

Note The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You might not see all of the listed properties all the time. To view all the properties for a filter at any time, use

```
get(hd)
```

where hd is a filter.

For further information about the properties of this filter or any dfilt object, refer to “Fixed-Point Filter Properties”.

Property Name	Brief Description
AccumMode	Determines how the accumulator outputs stored values. Choose from full precision (FullPrecision), or whether to keep the most significant bits (KeepMSB) or least significant bits (KeepLSB) when output results need shorter word length than the accumulator supports. To let you set the word length and the precision (the fraction length) used by the output from the accumulator, set AccumMode to SpecifyPrecision.
AccumWordLength	Sets the word length used to store data in the accumulator/buffer.
Arithmetic	Defines the arithmetic the filter uses. Gives you the options double, single, and fixed. In short, this property defines the operating mode for your filter.
CastBeforeSum	Specifies whether to cast numeric data to the appropriate accumulator format (as shown in the signal flow diagrams) before performing sum operations.
CoeffAutoScale	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to false enables you to change the NumFracLength and DenFracLength properties to specify the precision used.
CoeffWordLength	Specifies the word length to apply to filter coefficients.
DenAccumFracLength	Specifies the fraction length used to interpret data in the accumulator used to hold the results of sum operations. You can change the value for this property when you set AccumMode to SpecifyPrecision.
DenFracLength	Set the fraction length the filter uses to interpret denominator coefficients. DenFracLength is always available, but it is read-only until you set CoeffAutoScale to false.

Property Name	Brief Description
Denominator	Holds the denominator coefficients for IIR filters.
DenProdFracLength	Specifies how the filter algorithm interprets the results of product operations involving denominator coefficients. You can change this property value when you set ProductMode to SpecifyPrecision.
FilterStructure	Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering — gains, delays, sums, products, and input/output.
InputFracLength	Specifies the fraction length the filter uses to interpret input data.
InputWordLength	Specifies the word length applied to interpret input data.
NumAccumFracLength	Specifies how the filter algorithm interprets the results of addition operations involving numerator coefficients. You can change the value of this property after you set AccumMode to SpecifyPrecision.
Numerator	Holds the numerator coefficient values for the filter.
NumFracLength	Sets the fraction length used to interpret the value of numerator coefficients.
NumProdFracLength	Specifies how the filter algorithm interprets the results of product operations involving numerator coefficients. Available to be changed when you set ProductMode to SpecifyPrecision.
OutputFracLength	Determines how the filter interprets the filter output data. You can change the value of OutputFracLength when you set OutputMode to SpecifyPrecision.

Property Name	Brief Description
OutputMode	Sets the mode the filter uses to scale the filtered data for output. You have the following choices: • AvoidOverflow — directs the filter to set the output data word length and fraction length to avoid causing the data to overflow. • BestPrecision — directs the filter to set the output data word length and fraction length to maximize the precision in the output data. • SpecifyPrecision — lets you set the word and fraction lengths used by the output data from filtering.
OutputWordLength	Determines the word length used for the output data.
OverflowMode	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either saturate (limit the output to the largest positive or negative representable value) or wrap (set overflowing values to the nearest representable value using modular arithmetic). The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow—they maintain full precision.
ProductMode	Determines how the filter handles the output of product operations. Choose from full precision (FullPrecision), or whether to keep the most significant bit (KeepMSB) or least significant bit (KeepLSB) in the result when you need to shorten the data words. For you to be able to set the precision (the fraction length) used by the output from the multiplies, you set ProductMode to SpecifyPrecision.
PersistentMemory	Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. False is the default setting.

Property Name	Brief Description
RoundMode	Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths). • ceil - Round toward positive infinity. • convergent - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software. • fix - Round toward zero. • floor - Round toward negative infinity. • nearest - Round toward nearest. Ties round toward positive infinity. • round - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers. The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.
Signed	Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.
StateFracLength	When you set StateAutoScale to false, you enable the StateFracLength property that lets you set the fraction length applied to interpret the filter states.
States	This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions.
StateWordLength	Sets the word length used to represent the filter states.

Examples

Specify a second-order direct-form II filter structure for a `dfilt` object, `hd`, with the following code:

```
b = [0.3 0.6 0.3];
a = [1 0 0.2];
hd = dfilt.df2(b,a);
% Change filter to fixed-point
set(hd,'arithmetic','fixed')
```

See Also

`dfilt` | `dfilt.df1` | `dfilt.df1t` | `dfilt.df2t`

dfilt.df2sos

Discrete-time, SOS, direct-form II filter

Syntax

Refer to `dfilt.df2sos` in Signal Processing Toolbox documentation.

Description

`hd = dfilt.df2sos(s)` returns a discrete-time, second-order section, direct-form II filter object `hd`, with coefficients given in the `s` matrix.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hd` as follows:

- To change to single-precision filtering, enter

  ```
  set(hd,'arithmetic','single');
  ```
- To change to fixed-point filtering, enter

  ```
  set(hd,'arithmetic','fixed');
  ```

For more information about the property `Arithmetic`, refer to “Arithmetic”.

`hd = dfilt.df2sos(b1,a1,b2,a2,...)` returns a discrete-time, second-order section, direct-form II object, `hd`, with coefficients for the first section given in the `b1` and `a1` vectors, for the second section given in the `b2` and `a2` vectors, etc.

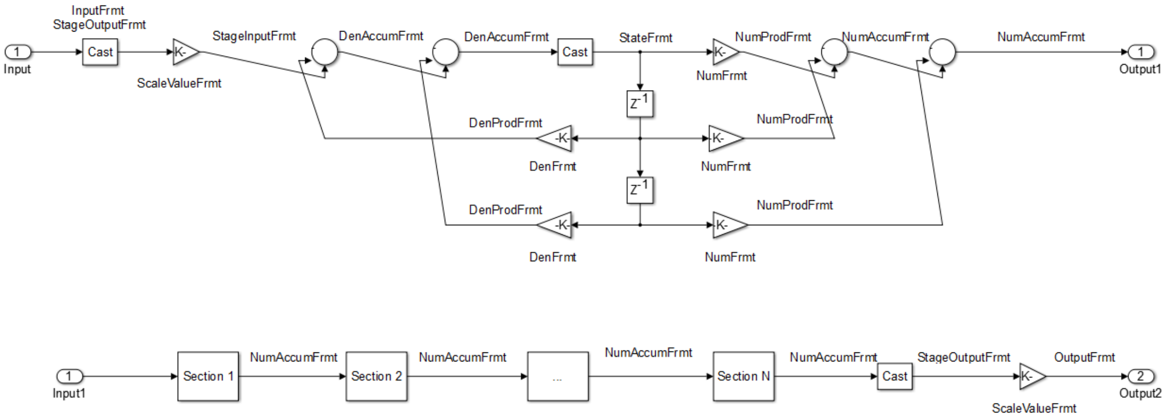
`hd = dfilt.df2sos(...,g)` includes a gain vector `g`. The elements of `g` are the gains for each section. The maximum length of `g` is the number of sections plus one. If `g` is not specified, all gains default to one.

`hd = dfilt.df2sos` returns a default, discrete-time, second-order section, direct-form II filter object, `hd`. This filter passes the input through to the output unchanged.

Note The leading coefficient of the denominator `a(1)` cannot be 0. To allow you to change the arithmetic setting to `fixed` or `single`, `a(1)` must be equal to 1.

Fixed-Point Filter Structure

The figure below shows the signal flow for the direct-form II filter implemented with second-order sections by `dfilt.df2sos`. To help you see how the filter processes the coefficients, input, and states of the filter, as well as numerical operations, the figure includes the locations of the formatting objects within the signal flow.



Notes About the Signal Flow Diagram

To help you understand where and how the filter performs fixed-point arithmetic during filtering, the figure shows various labels associated with data and functional elements in the filter. The following table describes each label in the signal flow and relates the label to the filter properties that are associated with it.

The labels use a common format — a prefix followed by the letters “frmt” (format). In this use, “frmt” means the word length and fraction length associated with the filter part referred to by the prefix.

For example, the InputFrmt label refers to the word length and fraction length used to interpret the data input to the filter. The frmt properties `InputWordLength` and `InputFracLength` (as shown in the table) store the word length and the fraction length in bits. Or consider NumFrmt, which refers to the word and fraction lengths (CoeffWordLength, NumFracLength) associated with representing filter numerator coefficients.

Signal Flow Label	Corresponding Word Length Property	Corresponding Fraction Length Property	Related Properties
DenAccumFrmt	AccumWordLength	DenAccumFracLength	AccumMode, CastBeforeSum
DenFrmt	CoeffWordLength	DenFracLength	CoeffAutoScale, Signed, sosMatrix
DenProdFrmt	CoeffWordLength	DenProdFracLength	ProductMode, ProductWordLength, sosMatrix
InputFrmt	InputWordLength	InputFracLength	None
NumAccumFrmt	AccumWordLength	NumAccumFracLength	AccumMode, CastBeforeSum
NumFrmt	CoeffWordLength	NumFracLength	CoeffAutoScale, Signed, sosMatrix
NumProdFrmt	CoeffWordLength	NumProdFracLength	ProductWordLength, ProductMode
OutputFrmt	OutputWordLength	OutputFracLength	OutputMode
ScaleValueFrmat	CoeffWordLength	ScaleValue-FracLength	CoeffAutoScale, ScaleValues
SectionInputFormt	SectionInput-WordLength	SectionInput-FracLength	SectionInput-AutoScale
SectionOutputFrmt	SectionOutput-WordLength	SectionOutput-FracLength	SectionOutput-AutoScale
StateFrmt	StateWordLength	StateFracLength	CastBeforeSum, States

Most important is the label position in the diagram, which identifies where the format applies.

As one example, look at the label DenProdFrmt, which always follows a denominator coefficient multiplication element in the signal flow. The label indicates that denominator coefficients leave the multiplication element with the word length and fraction length associated with product operations that include denominator coefficients. From reviewing the table, you see that the DenProdFrmt refers to the properties `ProdWordLength`, `ProductMode` and `DenProdFracLength` that fully define the denominator format after multiply (or product) operations.

Properties

In this table you see the properties associated with second-order section implementation of direct-form II `dfilt` objects.

Note The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You might not see all of the listed properties all the time. To view all the properties for a filter at any time, use

```
get(hd)
```

where `hd` is a filter.

For further information about the properties of this filter or any `dfilt` object, refer to “Fixed-Point Filter Properties”.

Property Name	Brief Description
`AccumMode`	Determines how the accumulator outputs stored values. Choose from full precision (`FullPrecision`), or whether to keep the most significant bits (`KeepMSB`) or least significant bits (`KeepLSB`) when output results need shorter word length than the accumulator supports. To let you set the word length and the precision (the fraction length) used by the output from the accumulator, set `AccumMode` to `SpecifyPrecision`.
`AccumWordLength`	Sets the word length used to store data in the accumulator/buffer.
`Arithmetic`	Defines the arithmetic the filter uses. Gives you the options `double`, `single`, and `fixed`. In short, this property defines the operating mode for your filter.

Property Name	Brief Description
CastBeforeSum	Specifies whether to cast numeric data to the appropriate accumulator format (as shown in the signal flow diagrams) before performing sum operations.
CoeffAutoScale	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to false enables you to change the NumFracLength and DenFracLength properties to specify the precision used.
CoeffWordLength	Specifies the word length to apply to filter coefficients.
DenAccumFracLength	Specifies the fraction length used to interpret data in the accumulator used to hold the results of sum operations. You can change the value for this property when you set AccumMode to SpecifyPrecision.
DenFracLength	Set the fraction length the filter uses to interpret denominator coefficients. DenFracLength is always available, but it is read-only until you set CoeffAutoScale to false.
DenProdFracLength	Specifies how the filter algorithm interprets the results of product operations involving denominator coefficients. You can change this property value when you set ProductMode to SpecifyPrecision.
FilterStructure	Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering—gains, delays, sums, products, and input/output.
InputFracLength	Specifies the fraction length the filter uses to interpret input data.
InputWordLength	Specifies the word length applied to interpret input data.
NumAccumFracLength	Specifies how the filter algorithm interprets the results of addition operations involving numerator coefficients. You can change the value of this property after you set AccumMode to SpecifyPrecision.

Property Name	Brief Description
NumFracLength	Sets the fraction length used to interpret the value of numerator coefficients.
NumProdFracLength	Specifies how the filter algorithm interprets the results of product operations involving numerator coefficients. Available to be changed when you set ProductMode to SpecifyPrecision.
OptimizeScaleValues	When true, the filter skips multiplication-by-one scaling. When false, the filter performs multiplication-by-one scaling.
OutputFracLength	Determines how the filter interprets the filter output data. You can change the value of OutputFracLength when you set OutputMode to SpecifyPrecision.
OutputMode	Sets the mode the filter uses to scale the filtered data for output. You have the following choices: • AvoidOverflow — directs the filter to set the output data word length and fraction length to avoid causing the data to overflow. • BestPrecision — directs the filter to set the output data word length and fraction length to maximize the precision in the output data. • SpecifyPrecision — lets you set the word and fraction lengths used by the output data from filtering.
OutputWordLength	Determines the word length used for the output data.
OverflowMode	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either saturate (limit the output to the largest positive or negative representable value) or wrap (set overflowing values to the nearest representable value using modular arithmetic). The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow — they maintain full precision.

Property Name	Brief Description
ProductMode	Determines how the filter handles the output of product operations. Choose from full precision (FullPrecision), or whether to keep the most significant bit (KeepMSB) or least significant bit (KeepLSB) in the result when you need to shorten the data words. For you to be able to set the precision (the fraction length) used by the output from the multiplies, you set ProductMode to SpecifyPrecision.
ProductWordLength	Specifies the word length to use for multiplication operation results. This property becomes writable (you can change the value) when you set ProductMode to SpecifyPrecision.
PersistentMemory	Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. False is the default setting.

Property Name	Brief Description
RoundMode	Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths). • ceil - Round toward positive infinity. • convergent - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software. • fix - Round toward zero. • floor - Round toward negative infinity. • nearest - Round toward nearest. Ties round toward positive infinity. • round - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers. The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.
ScaleValueFracLength	Scale values work with SOS filters. Setting this property controls how your filter interprets the scale values by setting the fraction length. Only available when you disable AutoScaleMode by setting it to false.
ScaleValues	Scaling for the filter objects in SOS filters.
SectionInputAutoScale	Tells the filter whether to set the stage input data format to minimize the occurrence of overflow conditions.
SectionInputFracLength	Lets you set the fraction length for section inputs in SOS filters, if you set SectionInputAutoScale to false.
SectionInputWordLength	Lets you set the word length for section inputs in SOS filters, if you set SectionInputAutoScale to false.

Property Name	Brief Description
SectionOutputAutoScale	Tells the filter whether to set the section output data format to minimize the occurrence of overflow conditions.
SectionOutputFracLength	Lets you set the fraction length for section outputs in SOS filters, if you set SectionOutputAutoScale to off.
SectionOutputWordLength	Lets you set the word length for section outputs in SOS filters, if you set SectionOutputAutoScale to false.
Signed	Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.
SosMatrix	Holds the filter coefficients as property values. Displays the matrix in the format [sections x coefficients/section datatype]. A [15x6 double] SOS matrix represents a filter with 6 coefficients per section and 15 sections, using data type double to represent the coefficients.
StateFracLength	When you set StateAutoScale to false, you enable the StateFracLength property that lets you set the fraction length applied to interpret the filter states.
States	This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions.
StateWordLength	Sets the word length used to represent the filter states.

Examples

Specify a second-order section, direct-form II dfilt object for a Butterworth filter converted to second-order sections, with the following code:

```
[z,p,k] = butter(30,0.5);
[s,g] = zp2sos(z,p,k);
hd = dfilt.df2sos(s,g);
% Convert filter to fixed-point
hd.arithmetic='fixed';
```

See Also

`dfilt` | `dfilt.df1sos` | `dfilt.df1tsos` | `dfilt.df2tsos`

dfilt.df2t

Discrete-time, direct-form II transposed filter

Syntax

Refer to `dfilt.df2t` in Signal Processing Toolbox documentation.

Description

`hd = dfilt.df2t(b,a)` returns a discrete-time, direct-form II transposed filter object `hd`, with numerator coefficients `b` and denominator coefficients `a`.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hd` as follows:

- To change to single-precision filtering, enter

```
set(hd,'arithmetic','single');
```

- To change to fixed-point filtering, enter

```
set(hd,'arithmetic','fixed');
```

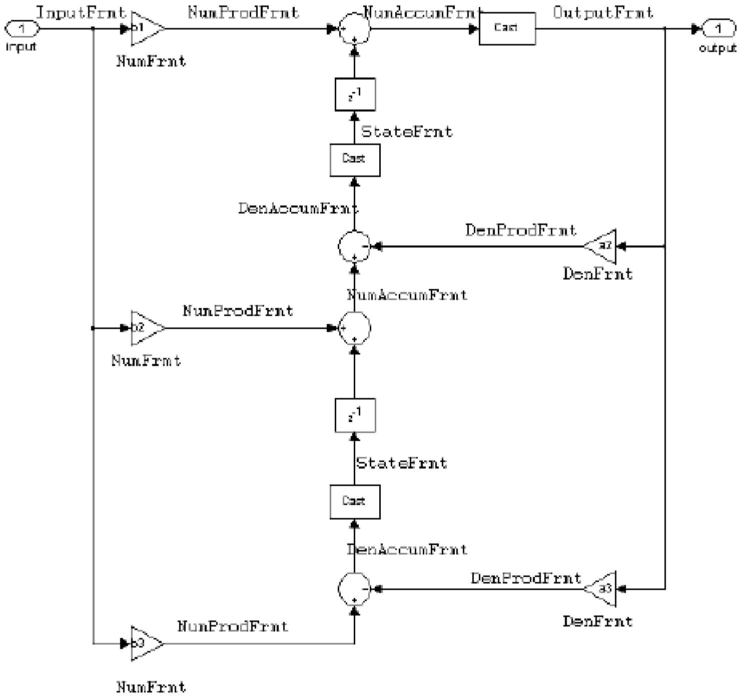
For more information about the property `Arithmetic`, refer to “Arithmetic”.

`hd = dfilt.df2t` returns a default, discrete-time, direct-form II transposed filter object `hd`, with `b` = 1 and `a` = 1. This filter passes the input through to the output unchanged.

Note The leading coefficient of the denominator `a(1)` cannot be 0. To allow you to change the arithmetic setting to `fixed` or `single`, `a(1)` must be equal to 1.

Fixed-Point Filter Structure

The following figure shows the signal flow for the direct-form II transposed filter implemented by `dfilt.df2t`. To help you see how the filter processes the coefficients, input, and states of the filter, as well as numerical operations, the figure includes the locations of the formatting objects within the signal flow.



Notes About the Signal Flow Diagram

To help you understand where and how the filter performs fixed-point arithmetic during filtering, the figure shows various labels associated with data and functional elements in the filter. The following table describes each label in the signal flow and relates the label to the filter properties that are associated with it.

The labels use a common format — a prefix followed by the letters “frmt.” In this use, “frmt” means the word length and fraction length associated with the filter part referred to by the prefix.

For example, the InputFrmt label refers to the word length and fraction length used to interpret the data input to the filter. The format properties `InputWordLength` and InputFracLength (as shown in the table) store the word length and the fraction length in bits. Or consider NumFrmt, which refers to the word and fraction lengths (CoeffWordLength, NumFracLength) associated with representing filter numerator coefficients.

Signal Flow Label	Corresponding Word Length Property	Corresponding Fraction Length Property	Related Properties
DenAccumFrmt	AccumWordLength	DenAccumFracLength	AccumMode, CastBeforeSum
DenFrmt	CoeffWordLength	DenFracLength	CoeffAutoScale,Signed, Denominator
DenProdFrmt	CoeffWordLength	DenProdFracLength	ProductMode, ProductWordLength
InputFrmt	InputWordLength	InputFracLength	None
NumAccumFrmt	AccumWordLength	NumAccumFracLength	AccumMode, CastBeforeSum
NumFrmt	CoeffWordLength	NumFracLength	CoeffAutoScale, Signed, Numerator
NumProdFrmt	CoeffWordLength	NumProdFracLength	ProductWordLength, ProductMode
OutputFrmt	OutputWordLength	OutputFracLength	None
StateFrmt	StateWordLength	StateFracLength	States

Most important is the label position in the diagram, which identifies where the format applies.

As one example, look at the label DenProdFrmt, which always follows a denominator coefficient multiplication element in the signal flow. The label indicates that denominator coefficients leave the multiplication element with the word length and fraction length associated with product operations that include denominator coefficients. From reviewing the table, you see that the DenProdFrmt refers to the properties ProdWordLength, ProductMode and DenProdFracLength that fully define the denominator format after multiply (or product) operations.

Properties

In this table you see the properties associated with df2t implementation of dfilt objects.

Note The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You might not see all of the listed properties all the time. To view all the properties for a filter at any time, use

```
get(hd)
```

where hd is a filter.

For further information about the properties of this filter or any dfilt object, refer to "Fixed-Point Filter Properties".

Property Name	Brief Description
AccumMode	Determines how the accumulator outputs stored values. Choose from full precision (FullPrecision), or whether to keep the most significant bits (KeepMSB) or least significant bits (KeepLSB) when output results need shorter word length than the accumulator supports. To let you set the word length and the precision (the fraction length) used by the output from the accumulator, set AccumMode to SpecifyPrecision.
AccumWordLength	Sets the word length used to store data in the accumulator/buffer.
Arithmetic	Defines the arithmetic the filter uses. Gives you the options double, single, and fixed. In short, this property defines the operating mode for your filter.
CastBeforeSum	Specifies whether to cast numeric data to the appropriate accumulator format (as shown in the signal flow diagrams) before performing sum operations.
CoeffAutoScale	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value

Property Name	Brief Description
	to false enables you to change the NumFracLength and DenFracLength properties to specify the precision used.
CoeffWordLength	Specifies the word length to apply to filter coefficients.
DenAccumFracLength	Specifies the fraction length used to interpret data in the accumulator used to hold the results of sum operations. You can change the value for this property when you set AccumMode to SpecifyPrecision.
DenFracLength	Set the fraction length the filter uses to interpret denominator coefficients. DenFracLength is always available, but it is read-only until you set CoeffAutoScale to false.
Denominator	Holds the denominator coefficients for IIR filters.
DenProdFracLength	Specifies how the filter algorithm interprets the results of product operations involving denominator coefficients. You can change this property value when you set ProductMode to SpecifyPrecision.
FilterStructure	Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering—gains, delays, sums, products, and input/output.
InputFracLength	Specifies the fraction length the filter uses to interpret input data.
InputWordLength	Specifies the word length applied to interpret input data.
NumAccumFracLength	Specifies how the filter algorithm interprets the results of addition operations involving numerator coefficients. You can change the value of this property after you set AccumMode to SpecifyPrecision.
Numerator	Holds the numerator coefficient values for the filter.
NumFracLength	Sets the fraction length used to interpret the value of numerator coefficients.
NumProdFracLength	Specifies how the filter algorithm interprets the results of product operations involving numerator coefficients. Available to be changed when you set ProductMode to SpecifyPrecision.

Property Name	Brief Description
`OutputFracLength`	Determines how the filter interprets the filter output data.
`OutputWordLength`	Determines the word length used for the output data.
`OverflowMode`	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either `saturate` (limit the output to the largest positive or negative representable value) or `wrap` (set overflowing values to the nearest representable value using modular arithmetic). The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow — they maintain full precision.
`ProductMode`	Determines how the filter handles the output of product operations. Choose from full precision (`FullPrecision`), or whether to keep the most significant bit (`KeepMSB`) or least significant bit (`KeepLSB`) in the result when you need to shorten the data words. For you to be able to set the precision (the fraction length) used by the output from the multiplies, you set `ProductMode` to `SpecifyPrecision`.
`ProductWordLength`	Specifies the word length to use for multiplication operation results. This property becomes writable (you can change the value) when you set `ProductMode` to `SpecifyPrecision`.
`PersistentMemory`	Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. `False` is the default setting.

Property Name	Brief Description
RoundMode	Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths). • ceil - Round toward positive infinity. • convergent - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software. • fix - Round toward zero. • floor - Round toward negative infinity. • nearest - Round toward nearest. Ties round toward positive infinity. • round - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers. The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.
Signed	Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.
StateAutoScale	Setting autoscaling for filter states to true reduces the possibility of overflows occurring during fixed-point operations. Set to false, StateAutoScale lets the filter select the fraction length to limit the overflow potential.
StateFracLength	When you set StateAutoScale to false, you enable the StateFracLength property that lets you set the fraction length applied to interpret the filter states.
States	This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions.
StateWordLength	Sets the word length used to represent the filter states.

Examples

Create a fixed-point filter by specifying a second-order direct-form II transposed filter structure for a `dfilt` object, and then converting the double-precision arithmetic setting to fixed-point.

```
b = [0.3 0.6 0.3];
a = [1 0 0.2];
hd = dfilt.df2t(b,a);
% Convert filter to fixed-point
set(hd,'arithmetic','fixed')
```

See Also

`dfilt` | `dfilt.df1` | `dfilt.df1t` | `dfilt.df2`

dfilt.df2tsos

Discrete-time, SOS direct-form II transposed filter

Syntax

Refer to `dfilt.df2tsos` in Signal Processing Toolbox documentation.

Description

`hd = dfilt.df2tsos(s)` returns a discrete-time, second-order section, direct-form II, transposed filter object `hd`, with coefficients given in the matrix `s`.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hd` as follows:

- To change to single-precision filtering, enter

  ```
  set(hd,'arithmetic','single');
  ```
- To change to fixed-point filtering, enter

  ```
  set(hd,'arithmetic','fixed');
  ```

For more information about the property `Arithmetic`, refer to “Arithmetic”.

`hd = dfilt.df2tsos(b1,a1,b2,a2,...)` returns a discrete-time, second-order section, direct-form II, transposed filter object `hd`, with coefficients for the first section given in the `b1` and `a1` vectors, for the second section given in the `b2` and `a2` vectors, etc.

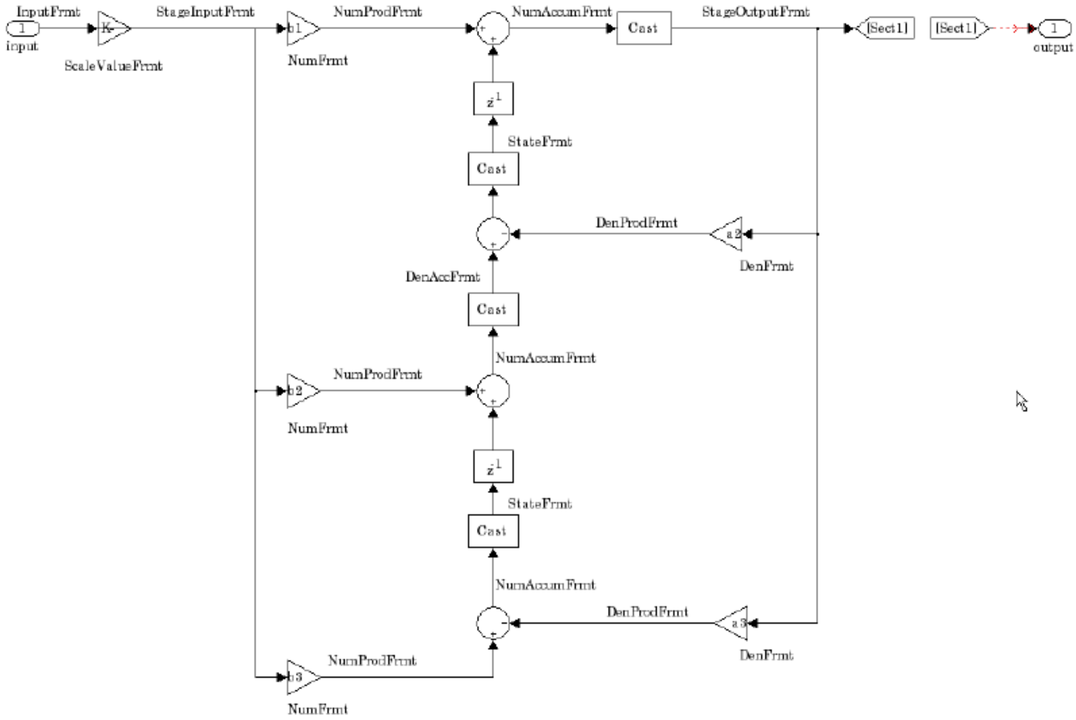
`hd = dfilt.df2tsos(...,g)` includes a gain vector `g`. The elements of `g` are the gains for each section. The maximum length of `g` is the number of sections plus one. If `g` is not specified, all gains default to one.

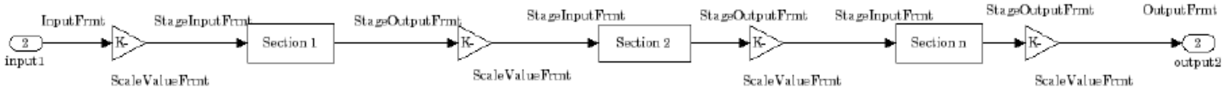
`hd = dfilt.df2tsos` returns a default, discrete-time, second-order section, direct-form II, transposed filter object, `hd`. This filter passes the input through to the output unchanged.

Note The leading coefficient of the denominator `a(1)` cannot be 0. To allow you to change the arithmetic setting to `fixed` or `single`, `a(1)` must be equal to 1.

Fixed-Point Filter Structure

The figure below shows the signal flow for the second-order section transposed direct-form II filter implemented by `dfilt.dftsos`. To help you see how the filter processes the coefficients, input, and states of the filter, as well as numerical operations, the figure includes the locations of the formatting objects within the signal flow.





Notes About the Signal Flow Diagram

To help you understand where and how the filter performs fixed-point arithmetic during filtering, the figure shows various labels associated with data and functional elements in the filter. The following table describes each label in the signal flow and relates the label to the filter properties that are associated with it.

The labels use a common format — a prefix followed by the letters “frmt” (format). In this use, “frmt” indicates the word length and fraction length associated with the filter part referred to by the prefix.

For example, the InputFrmt label refers to the word length and fraction length used to interpret the data input to the filter. The format properties `InputWordLength` and `InputFracLength` (as shown in the table) store the word length and the fraction length in bits. Or consider NumFrmt, which refers to the word and fraction lengths (`CoeffWordLength`, `NumFracLength`) associated with representing filter numerator coefficients.

SectionInputFormt	`SectionInputWordLength`	`SectionInputFracLength`	
SectionOutputFrmt	`SectionOutputWordLength`	`SectionOutputFracLength`	
StateFrmt	`StateWordLength`	`StateFracLength`	`States`

Most important is the label position in the diagram, which identifies where the format applies.

As one example, look at the label DenProdFrmt, which always follows a denominator coefficient multiplication element in the signal flow. The label indicates that denominator coefficients leave the multiplication element with the word length and fraction length associated with product operations that include denominator coefficients. From reviewing the table, you see that the DenProdFrmt refers to the properties `ProdWordLength`, `ProductMode` and `DenProdFracLength` that fully define the denominator format after multiply (or product) operations.

Properties

In this table you see the properties associated with second-order section implementation of transposed direct-form II `dfilt` objects.

Note The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You might not see all of the listed properties all the time. To view all the properties for a filter at any time, use

```
get(hd)
```

where `hd` is a filter.

For further information about the properties of this filter or any `dfilt` object, refer to “Fixed-Point Filter Properties”.

Property Name	Brief Description
AccumMode	Determines how the accumulator outputs stored values. Choose from full precision (FullPrecision), or whether to keep the most significant bits (KeepMSB) or least significant bits (KeepLSB) when output results need shorter word length than the accumulator supports. To let you set the word length and the precision (the fraction length) used by the output from the accumulator, set AccumMode to SpecifyPrecision.
AccumWordLength	Sets the word length used to store data in the accumulator/buffer.
Arithmetic	Defines the arithmetic the filter uses. Gives you the options double, single, and fixed. In short, this property defines the operating mode for your filter.
CastBeforeSum	Specifies whether to cast numeric data to the appropriate accumulator format (as shown in the signal flow diagrams) before performing sum operations.
CoeffAutoScale	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to false enables you to change the NumFracLength and DenFracLength properties to specify the precision used.
CoeffWordLength	Specifies the word length to apply to filter coefficients.
DenAccumFracLength	Specifies the fraction length used to interpret data in the accumulator used to hold the results of sum operations. You can change the value for this property when you set AccumMode to SpecifyPrecision.
DenFracLength	Set the fraction length the filter uses to interpret denominator coefficients. DenFracLength is always available, but it is read-only until you set CoeffAutoScale to false.
DenProdFracLength	Specifies how the filter algorithm interprets the results of product operations involving denominator coefficients. You can change this property value when you set ProductMode to SpecifyPrecision.

Property Name	Brief Description
`FilterStructure`	Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering — gains, delays, sums, products, and input/output.
`InputFracLength`	Specifies the fraction length the filter uses to interpret input data.
`InputWordLength`	Specifies the word length applied to interpret input data.
`NumAccumFracLength`	Specifies how the filter algorithm interprets the results of addition operations involving numerator coefficients. You can change the value of this property after you set `AccumMode` to `SpecifyPrecision`.
`NumFracLength`	Sets the fraction length used to interpret the value of numerator coefficients.
`NumProdFracLength`	Specifies how the filter algorithm interprets the results of product operations involving numerator coefficients. Available to be changed when you set `ProductMode` to `SpecifyPrecision`.
`OptimizeScaleValues`	When true, the filter skips multiplication-by-one scaling. When false, the filter performs multiplication-by-one scaling.
`OutputFracLength`	Determines how the filter interprets the filter output data. You can change the value of `OutputFracLength` when you set `OutputMode` to `SpecifyPrecision`.
`OutputMode`	Sets the mode the filter uses to scale the filtered data for output. You have the following choices: • `AvoidOverflow` — directs the filter to set the output data word length and fraction length to avoid causing the data to overflow. • `BestPrecision` — directs the filter to set the output data word length and fraction length to maximize the precision in the output data. • `SpecifyPrecision` — lets you set the word and fraction lengths used by the output data from filtering.
`OutputWordLength`	Determines the word length used for the output data.

Property Name	Brief Description
`OverflowMode`	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either `saturate` (limit the output to the largest positive or negative representable value) or `wrap` (set overflowing values to the nearest representable value using modular arithmetic). The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow — they maintain full precision.
`ProductMode`	Determines how the filter handles the output of product operations. Choose from full precision (`FullPrecision`), or whether to keep the most significant bit (`KeepMSB`) or least significant bit (`KeepLSB`) in the result when you need to shorten the data words. For you to be able to set the precision (the fraction length) used by the output from the multiplies, you set `ProductMode` to `SpecifyPrecision`.
`ProductWordLength`	Specifies the word length to use for multiplication operation results. This property becomes writable (you can change the value) when you set `ProductMode` to `SpecifyPrecision`.
`PersistentMemory`	Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. `False` is the default setting.

Property Name	Brief Description
`RoundMode`	Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths). • `ceil` - Round toward positive infinity. • `convergent` - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software. • `fix` - Round toward zero. • `floor` - Round toward negative infinity. • `nearest` - Round toward nearest. Ties round toward positive infinity. • `round` - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers. The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.
`ScaleValueFracLength`	Scale values work with SOS filters. Setting this property controls how your filter interprets the scale values by setting the fraction length. Only available when you disable `AutoScaleMode` by setting it to `false`.
`ScaleValues`	Scaling for the filter objects in SOS filters.
`Signed`	Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.
`SosMatrix`	Holds the filter coefficients as property values — you use `set` and `get` to modify them. Displays the matrix in the format [sections x coefficients/section data type]. A `[15x6 double]` SOS matrix represents a filter with 6 coefficients per section and 15 sections, using data type `double` to represent the coefficients.

Property Name	Brief Description
`SectionInputFracLength`	Lets you set the fraction length for section inputs in SOS filters, if you set `SectionInputAutoScale` to `false`.
`SectionInputWordLength`	Lets you set the word length for section inputs in SOS filters, if you set `SectionInputAutoScale` to `false`.
`SectionOutputFracLength`	Lets you set the fraction length for section outputs in SOS filters, if you set `SectionOutputAutoScale` to `off`.
`SectionOutputWordLength`	Lets you set the word length for section outputs in SOS filters, if you set `SectionOutputAutoScale` to `false`.
`StateAutoScale`	Setting autoscaling for filter states to `true` reduces the possibility of overflows occurring during fixed-point operations. Set to `false`, `StateAutoScale` lets the filter select the fraction length to limit the overflow potential.
`StateFracLength`	When you set `StateAutoScale` to `false`, you enable the `StateFracLength` property that lets you set the fraction length applied to interpret the filter states.
`States`	This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions.
`StateWordLength`	Sets the word length used to represent the filter states.

Examples

Construct a second-order section Butterworth filter for fixed-point filtering. Start by specifying a Butterworth filter, and then convert the filter to second-order sections, with the following code:

```
[z,p,k] = butter(30,0.5);
[s,g] = zp2sos(z,p,k);
hd = dfilt.df2tsos(s,g);
% convert filter to fixed-point
hd.arithmetic='fixed';
```

dfilt.dfasymfir

Discrete-time, direct-form antisymmetric FIR filter

Syntax

Refer to `dfilt.dfasymfir` in Signal Processing Toolbox documentation.

Description

`hd = dfilt.dfasymfir(b)` returns a discrete-time, direct-form, antisymmetric FIR filter object `hd`, with numerator coefficients `b`.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hd` as follows:

- To change to single-precision filtering, enter

  ```
  set(hd,'arithmetic','single');
  ```
- To change to fixed-point filtering, enter

  ```
  set(hd,'arithmetic','fixed');
  ```

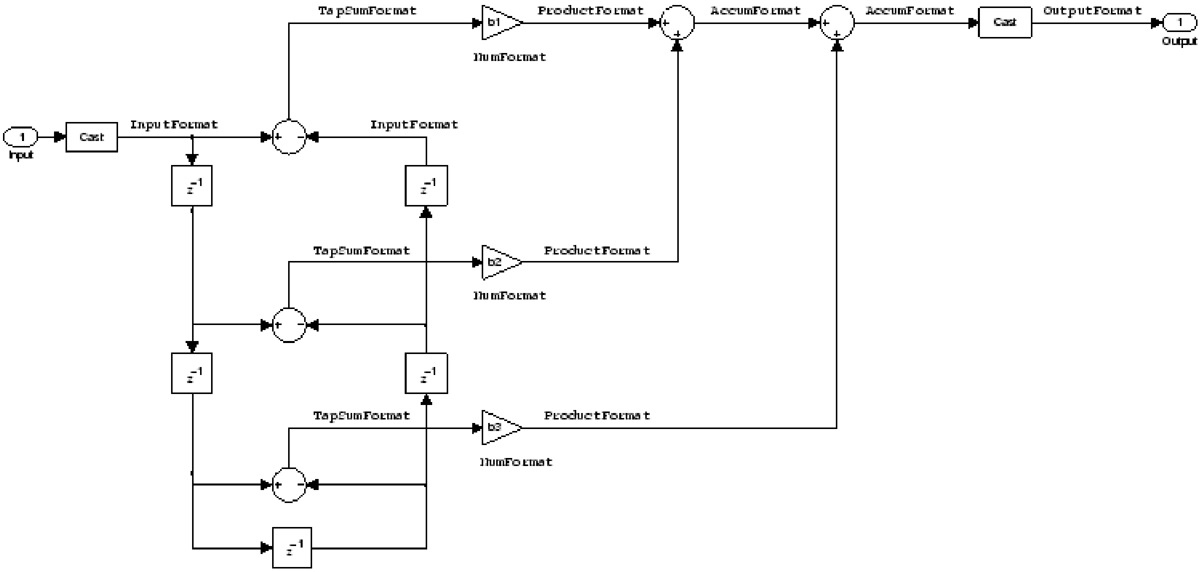
For more information about the property `Arithmetic`, refer to “Arithmetic”.

`hd = dfilt.dfasymfir` returns a default, discrete-time, direct-form, antisymmetric FIR filter object `hd`, with `b`=1. This filter passes the input through to the output unchanged.

Note Only the coefficients in the first half of vector `b` are used because `dfilt.dfasymfir` assumes the coefficients in the second half are antisymmetric to those in the first half. For example, in the figure coefficients, b(4) = -b(3), b(5) = -b(2), and b(6) = -b(1).

Fixed-Point Filter Structure

The following figure shows the signal flow for the odd-order antisymmetric FIR filter implemented by `dfilt.dfasymfir`. The even-order filter uses similar flow. To help you see how the filter processes the coefficients, input, and states of the filter, as well as numerical operations, the figure includes the locations of the formatting objects within the signal flow.



Notes About the Signal Flow Diagram

To help you understand where and how the filter performs fixed-point arithmetic during filtering, the figure shows various labels associated with data and functional elements in the filter. The following table describes each label in the signal flow and relates the label to the filter properties that are associated with it.

The labels use a common format — a prefix followed by the word “format.” In this use, "format" means the word length and fraction length associated with the filter part referred to by the prefix.

For example, the InputFormat label refers to the word length and fraction length used to interpret the data input to the filter. The format properties `InputWordLength` and InputFracLength (as shown in the table) store the word length and the fraction length in bits. Or consider NumFormat, which refers to the word and fraction lengths (CoeffWordLength, NumFracLength) associated with representing filter numerator coefficients.

Signal Flow Label	Corresponding Word Length Property	Corresponding Fraction Length Property	Related Properties
AccumFormat	AccumWordLength	AccumFracLength	None
InputFormat	InputWordLength	InputFracLength	None
NumFormat	CoeffWordLength	NumFracLength	CoeffAutoScale, , Signed, Numerator
OutputFormat	OutputWordLength	OutputFracLength	None
ProductFormat	ProductWordLength	ProductFracLength	None
TapSumFormat	InputWordLength	InputFracLength	InputFormat

Most important is the label position in the diagram, which identifies where the format applies.

As one example, look at the label ProductFormat, which always follows a coefficient multiplication element in the signal flow. The label indicates that coefficients leave the multiplication element with the word length and fraction length associated with product operations that include coefficients. From reviewing the table, you see that the ProductFormat refers to the properties ProductFracLength and ProductWordLength that fully define the coefficient format after multiply (or product) operations.

Properties

In this table you see the properties associated with an antisymmetric FIR implementation of dfilt objects.

Note The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You might not see all of the listed properties all the time. To view all the properties for a filter at any time, use

```
get(hd)
```

where hd is a filter.

For further information about the properties of this filter or any dfilt object, refer to "Fixed-Point Filter Properties".

Name	Values	Description
AccumFracLength	Any positive or negative integer number of bits [27]	Specifies the fraction length used to interpret data output by the accumulator.
AccumWordLength	Any integer number of bits[33]	Sets the word length used to store data in the accumulator.
Arithmetic	fixed for fixed-point filters	Setting this to fixed allows you to modify other filter properties to customize your fixed-point filter.
CoeffAutoScale	[true], false	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to false enables you to change the NumFracLength property value to specify the precision used.
CoeffWordLength	Any integer number of bits [16]	Specifies the word length to apply to filter coefficients.
FilterInternals	[FullPrecision], SpecifyPrecision	Controls whether the filter automatically sets the output word and fraction lengths, product word and fraction lengths, and the accumulator word and fraction lengths to maintain the best precision results during filtering. The default value, FullPrecision, sets automatic word and fraction length determination by the filter. SpecifyPrecision makes the output and accumulator-related properties available so you can set your own word and fraction lengths for them.
InputFracLength	Any positive or negative integer number of bits [15]	Specifies the fraction length the filter uses to interpret input data. Also controls TapSumFracLength.

Name	Values	Description
InputWordLength	Any integer number of bits [16]	Specifies the word length applied to interpret input data. Also determines TapSumWordLength.
NumFracLength	Any positive or negative integer number of bits [14]	Sets the fraction length used to interpret the numerator coefficients.
OutputFracLength	Any positive or negative integer number of bits [29]	Determines how the filter interprets the filter output data. You can change the value of OutputFracLength when you set FilerInternals to SpecifyPrecision.
OutputWordLength	Any integer number of bits [33]	Determines the word length used for the output data. You make this property editable by setting FilterInternals to SpecifyPrecision.
OverflowMode	saturate, [wrap]	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either saturate (limit the output to the largest positive or negative representable value) or wrap (set overflowing values to the nearest representable value using modular arithmetic). The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow — they maintain full precision.
ProductFracLength	Any positive or negative integer number of bits [27]	Specifies the fraction length to use for multiplication operation results. This property becomes writable (you can change the value) when you set ProductMode to SpecifyPrecision.
ProductWordLength	Any integer number of bits [33]	Specifies the word length to use for multiplication operation results. This property becomes writable (you can change the value) when you set ProductMode to SpecifyPrecision.

Name	Values	Description
`RoundMode`	`[convergent]`, `ceil`, `fix`, `floor`, `nearest`, `round`	Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths). • `ceil` - Round toward positive infinity. • `convergent` - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software. • `fix` - Round toward zero. • `floor` - Round toward negative infinity. • `nearest` - Round toward nearest. Ties round toward positive infinity. • `round` - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers. The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.
`Signed`	[true], false	Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.
`States`	`fi` object to match the filter arithmetic setting	Contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. The states use `fi` objects, with the associated properties from those objects. For details, refer to fixed-point objects in Fixed-Point Designer documentation.

Examples

Odd Order

Specify a fifth-order direct-form antisymmetric FIR filter structure for a `dfilt` object, `hd`, with the following code:

```
b = [-0.008 0.06 -0.44 0.44 -0.06 0.008];
hd = dfilt.dfasymfir(b);
```

Even Order

Specify a fourth-order direct-form antisymmetric FIR filter structure for `dfilt` object `hd`, with the following code:

```
b = [-0.01 0.1 0.0 -0.1 0.01];
hd = dfilt.dfasymfir(b);
hd.arithmetic='fixed';
FilterCoefs = get(hd,'numerator');
% or equivalently
FilterCoefs = hd.numerator;
```

`dfilt` | `dfilt.dffir` | `dfilt.dffirt` | `dfilt.dfsymfir`

dfilt.dffir

Discrete-time, direct-form FIR filter

Syntax

Refer to `dfilt.dffir` in Signal Processing Toolbox documentation.

Description

`hd = dfilt.dffir(b)` returns a discrete-time, direct-form finite impulse response (FIR) filter object `hd`, with numerator coefficients `b`.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hd` as follows:

- To change to single-precision filtering, enter

  ```
  set(hd,'arithmetic','single');
  ```

- To change to fixed-point filtering, enter

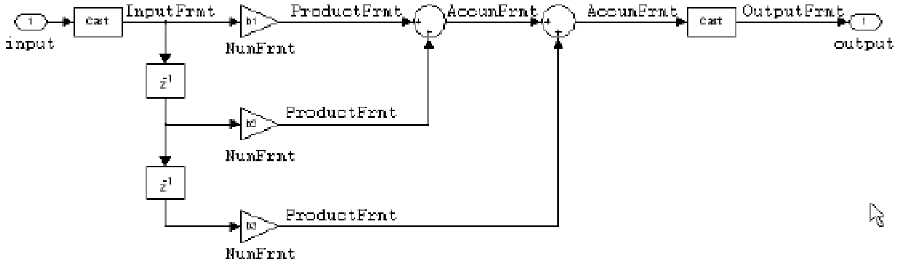
  ```
  set(hd,'arithmetic','fixed');
  ```

For more information about the property `Arithmetic`, refer to “Arithmetic”.

`hd = dfilt.dffir` returns a default, discrete-time, direct-form FIR filter object `hd`, with `b=1`. This filter passes the input through to the output unchanged.

Fixed-Point Filter Structure

The following figure shows the signal flow for the direct-form FIR filter implemented by `dfilt.dffir`. To help you see how the filter processes the coefficients, input, and states of the filter, as well as numerical operations, the figure includes the locations of the formatting objects within the signal flow.



Notes About the Signal Flow Diagram

To help you understand where and how the filter performs fixed-point arithmetic during filtering, the figure shows various labels associated with data and functional elements in the filter. The following table describes each label in the signal flow and relates the label to the filter properties that are associated with it.

The labels use a common format — a prefix followed by the letters“frmt” (format). In this use, “frmt” indicates the word length and fraction length associated with the filter part referred to by the prefix.

For example, the InputFrmt label refers to the word length and fraction length used to interpret the data input to the filter. The format properties `InputWordLength` and `InputFracLength` (as shown in the table) store the word length and the fraction length in bits. Or consider NumFrmt, which refers to the word and fraction lengths (`CoeffWordLength`, `NumFracLength`) associated with representing filter numerator coefficients.

Signal Flow Label	Corresponding Word Length Property	Corresponding Fraction Length Property	Related Properties
AccumFrmt	`AccumWordLength`	`AccumFracLength`	None
InputFrmt	`InputWordLength`	`InputFracLength`	None
NumFrmt	`CoeffWordLength`	`NumFracLength`	`CoeffAutoScale, Signed, Numerator`
OutputFrmt	`OutputWordLength`	`OutputFracLength`	None

Signal Flow Label	Corresponding Word Length Property	Corresponding Fraction Length Property	Related Properties
ProductFrmt	`ProductWordLength`	`ProductFracLength`	None

Most important is the label position in the diagram, which identifies where the format applies.

As one example, look at the label ProductFrmt, which always follows a coefficient multiplication element in the signal flow. The label indicates that coefficients leave the multiplication element with the word length and fraction length associated with product operations that include coefficients. From reviewing the table, you see that the ProductFrmt refers to the properties `ProductFracLength` and `ProductWordLength` that fully define the coefficient format after multiply (or product) operations.

Properties

In this table you see the properties associated with direct-form FIR implementation of `dfilt` objects.

Note The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You might not see all of the listed properties all the time. To view all the properties for a filter at any time, use

```
get(hd)
```

where `hd` is a filter.

For further information about the properties of this filter or any `dfilt` object, refer to "Fixed-Point Filter Properties".

Name	Values	Description
`AccumFracLength`	Any positive or negative integer number of bits [30]	Specifies the fraction length used to interpret data output by the accumulator.
`AccumWordLength`	Any integer number of bits[34]	Sets the word length used to store data in the accumulator.

Name	Values	Description
`Arithmetic`	fixed for fixed-point filters	Setting this to `fixed` allows you to modify other filter properties to customize your fixed-point filter.
`CoeffAutoScale`	[true], false	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to `false` enables you to change the `NumFracLength` property value to specify the precision used.
`CoeffWordLength`	Any integer number of bits [16]	Specifies the word length to apply to filter coefficients.
`FilterInternals`	[FullPrecision], SpecifyPrecision	Controls whether the filter automatically sets the output word and fraction lengths, product word and fraction lengths, and the accumulator word and fraction lengths to maintain the best precision results during filtering. The default value, `FullPrecision`, sets automatic word and fraction length determination by the filter. `SpecifyPrecision` makes the output and accumulator-related properties available so you can set your own word and fraction lengths for them.
`InputFracLength`	Any positive or negative integer number of bits [15]	Specifies the fraction length the filter uses to interpret input data.
`InputWordLength`	Any integer number of bits [16]	Specifies the word length applied to interpret input data.
`NumFracLength`	Any positive or negative integer number of bits [14]	Sets the fraction length used to interpret the numerator coefficients.
`OutputFracLength`	Any positive or negative integer number of bits [32]	Determines how the filter interprets the filter output data. You can change the value of `OutputFracLength` when you set `FilerInternals` to `SpecifyPrecision`.
`OutputWordLength`	Any integer number of bits [39]	Determines the word length used for the output data. You make this property editable by setting `FilterInternals` to `SpecifyPrecision`.

Name	Values	Description
OverflowMode	saturate, [wrap]	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either saturate (limit the output to the largest positive or negative representable value) or wrap (set overflowing values to the nearest representable value using modular arithmetic). The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow — they maintain full precision.
ProductFracLength	Any positive or negative integer number of bits [30]	Specifies the fraction length to use for multiplication operation results. This property becomes writable (you can change the value) when you set ProductMode to SpecifyPrecision.
ProductWordLength	Any integer number of bits [32]	Specifies the word length to use for multiplication operation results. This property becomes writable (you can change the value) when you set ProductMode to SpecifyPrecision.

Name	Values	Description
`RoundMode`	`[convergent]`, `ceil`, `fix`, `floor`, `nearest`, `round`	Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths). • `ceil` - Round toward positive infinity. • `convergent` - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software. • `fix` - Round toward zero. • `floor` - Round toward negative infinity. • `nearest` - Round toward nearest. Ties round toward positive infinity. • `round` - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers. The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.
`Signed`	[true], false	Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.
`States`	`fi` object to match the filter arithmetic setting	Contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. The states use `fi` objects, with the associated properties from those objects. For details, refer to fixed-point objects in Fixed-Point Designer documentation.

Examples

Specify a second-order direct-form FIR filter structure for a `dfilt` object `hd`, with the following code that constructs the filter in double-precision format and then converts the filter to fixed-point operation:

```
b = [0.05 0.9 0.05];
hd = dfilt.dffir(b);
% Create fixed-point filter
hd.arithmetic='fixed';
% Change FilterInternals property to
% SpecifyPrecision enabling other properites
hd.FilterInternals='SpecifyPrecision';
```

dfilt.dffirt

Discrete-time, direct-form FIR transposed filter

Syntax

Refer to `dfilt.dffirt` in Signal Processing Toolbox documentation.

Description

`hd = dfilt.dffirt(b)` returns a discrete-time, direct-form FIR transposed filter object `hd`, with numerator coefficients `b`.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hd` as follows:

- To change to single-precision filtering, enter

  ```
  set(hd,'arithmetic','single');
  ```

- To change to fixed-point filtering, enter

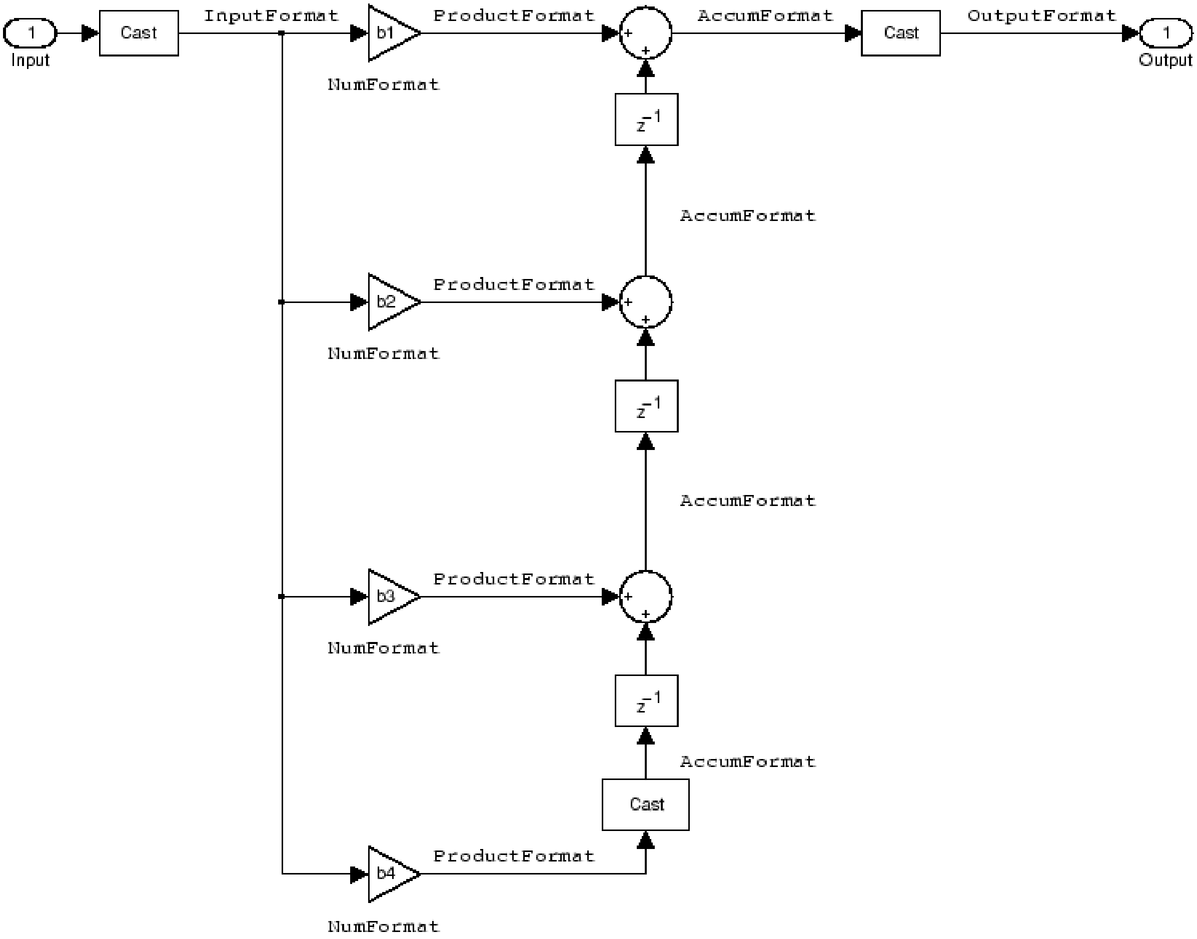
  ```
  set(hd,'arithmetic','fixed');
  ```

For more information about the property `Arithmetic`, refer to “Arithmetic”.

`hd = dfilt.dffirt` returns a default, discrete-time, direct-form FIR transposed filter object `hd`, with `b` = 1. This filter passes the input through to the output unchanged.

Fixed-Point Filter Structure

The following figure shows the signal flow for the transposed direct-form FIR filter implemented by `dfilt.dffirt`. To help you see how the filter processes the coefficients, input, and states of the filter, as well as numerical operations, the figure includes the locations of the formatting objects within the signal flow.



Notes About the Signal Flow Diagram

To help you understand where and how the filter performs fixed-point arithmetic during filtering, the figure shows various labels associated with data and functional elements in the filter. The following table describes each label in the signal flow and relates the label to the filter properties that are associated with it.

The labels use a common format — a prefix followed by the word “format.” In this use, “format” means the word length and fraction length associated with the filter part referred to by the prefix.

For example, the InputFormat label refers to the word length and fraction length used to interpret the data input to the filter. The format properties `InputWordLength` and `InputFracLength` (as shown in the table) store the word length and the fraction length in bits. Or consider NumFormat, which refers to the word and fraction lengths (`CoeffWordLength`, `NumFracLength`) associated with representing filter numerator coefficients.

Signal Flow Label	Corresponding Word Length Property	Corresponding Fraction Length Property	Related Properties
AccumFormat	`AccumWordLength`	`AccumFracLength`	None
InputFormat	`InputWordLength`	`InputFracLength`	None
NumFormat	`CoeffWordLength`	`NumFracLength`	`CoeffAutoScale`, `Signed`, `Numerator`
OutputFormat	`OutputWordLength`	`OutputFracLength`	None
ProductFormat	`ProductWordLength`	`ProductFracLength`	None

Most important is the label position in the diagram, which identifies where the format applies.

As one example, look at the label ProductFormat, which always follows a coefficient multiplication element in the signal flow. The label indicates that coefficients leave the multiplication element with the word length and fraction length associated with product operations that include coefficients. From reviewing the table, you see that the ProductFormat refers to the properties `ProductFracLength` and `ProductWordLength` that fully define the coefficient format after multiply (or product) operations.

Properties

In this table you see the properties associated with the transposed direct-form FIR implementation of `dfilt` objects.

Note The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You might not see all of the listed properties all the time. To view all the properties for a filter at any time, use

```
get(hd)
```

where hd is a filter.

For further information about the properties of this filter or any dfilt object, refer to “Fixed-Point Filter Properties”.

Name	Values	Description
AccumFracLength	Any positive or negative integer number of bits [30]	Specifies the fraction length used to interpret data output by the accumulator.

Ties round toward positive infinity. • `round` - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers. The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.
`Signed`	[true], false	Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.
`States`	`fi` object to match the filter arithmetic setting	Contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. The states use `fi` objects, with the associated properties from those objects. For details, refer to fixed-point objects in Fixed-Point Designer documentation.

Examples

Specify a second-order direct-form FIR transposed filter structure for a `dfilt` object, `hd`, with the following code:

```
b = [0.05 0.9 0.05];
hd = dfilt.dffirt(b);
set(hd,'arithmetic','fixed')
```

See Also

`dfilt` | `dfilt.dffir` | `dfilt.dfasymfir` | `dfilt.dfsymfir`

dfilt.dfsymfir

Discrete-time, direct-form symmetric FIR filter

Syntax

Refer to `dfilt.dfsymfir` in Signal Processing Toolbox documentation.

Description

`hd = dfilt.dfsymfir(b)` returns a discrete-time, direct-form symmetric FIR filter object `hd`, with numerator coefficients `b`.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hd` as follows:

- To change to single-precision filtering, enter

  ```
  set(hd,'arithmetic','single');
  ```
- To change to fixed-point filtering, enter

  ```
  set(hd,'arithmetic','fixed');
  ```

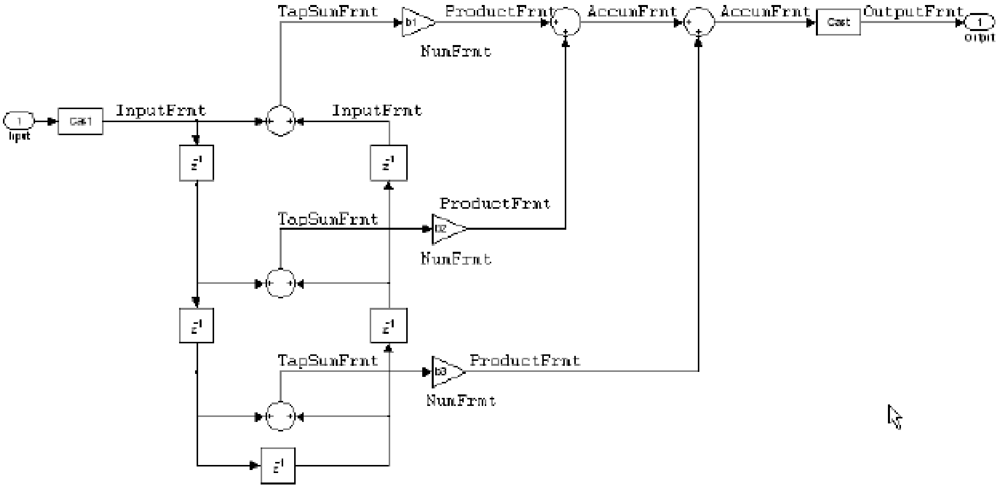
For more information about the property `Arithmetic`, refer to “Arithmetic”.

`hd = dfilt.dfsymfir` returns a default, discrete-time, direct-form symmetric FIR filter object `hd`, with `b=1`. This filter passes the input through to the output unchanged.

Note Only the coefficients in the first half of vector `b` are used because `dfilt.dfsymfir` assumes the coefficients in the second half are symmetric to those in the first half. In the following figure, for example, b(3) = 0, b(4) = b(2) and b(5) = b(1).

Fixed-Point Filter Structure

In the following figure you see the signal flow diagram for the symmetric FIR filter that `dfilt.dfsymfir` implements.



Notes About the Signal Flow Diagram

To help you understand where and how the filter performs fixed-point arithmetic during filtering, the figure shows various labels associated with data and functional elements in the filter. The following table describes each label in the signal flow and relates the label to the filter properties that are associated with it.

The labels use a common format — a prefix followed by the letters“frmt” (format). In this use, “frmt” indicates the word length and fraction length associated with the filter part referred to by the prefix.

For example, the InputFrmt label refers to the word length and fraction length used to interpret the data input to the filter. The format properties `InputWordLength` and `InputFracLength` (as shown in the table) store the word length and the fraction length in bits. Or consider NumFrmt, which refers to the word and fraction lengths (`CoeffWordLength`, `NumFracLength`) associated with representing filter numerator coefficients.

Signal Flow Label	Corresponding Word Length Property	Corresponding Fraction Length Property	Related Properties
AccumFrmt	`AccumWordLength`	`AccumFracLength`	None

Signal Flow Label	Corresponding Word Length Property	Corresponding Fraction Length Property	Related Properties
InputFrmt	`InputWordLength`	`InputFracLength`	None
NumFrmt	`CoeffWordLength`	`NumFracLength`	`CoeffAutoScale`, `Signed`, `Numerator`
OutputFrmt	`OutputWordLength`	`OutputFracLength`	None
ProductFrmt	`ProductWordLength`	`ProductFracLength`	None
TapSumFrmt	`InputWordLength`	`InputFracLength`	None

Most important is the label position in the diagram, which identifies where the format applies.

As one example, look at the label ProductFrmt, which always follows a coefficient multiplication element in the signal flow. The label indicates that coefficients leave the multiplication element with the word length and fraction length associated with product operations that include coefficients. From reviewing the table, you see that the ProductFrmt refers to the properties `ProductFracLength` and `ProductWordLength` that fully define the coefficient format after multiply (or product) operations.

Properties

In this table you see the properties associated with the symmetric FIR implementation of `dfilt` objects.

Note The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You might not see all of the listed properties all the time. To view all the properties for a filter at any time, use

```
get(hd)
```

where `hd` is a filter.

For further information about the properties of this filter or any `dfilt` object, refer to "Fixed-Point Filter Properties".

Name	Values	Description
`AccumFracLength`	Any positive or negative integer number of bits [27]	Specifies the fraction length used to interpret data output by the accumulator.
`AccumWordLength`	Any integer number of bits[33]	Sets the word length used to store data in the accumulator.
`Arithmetic`	fixed for fixed-point filters	Setting this to `fixed` allows you to modify other filter properties to customize your fixed-point filter.
`CoeffAutoScale`	[true], false	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to `false` enables you to change the `NumFracLength` property value to specify the precision used.
`CoeffWordLength`	Any integer number of bits [16]	Specifies the word length to apply to filter coefficients.
`FilterInternals`	[FullPrecision], SpecifyPrecision	Controls whether the filter automatically sets the output word and fraction lengths, product word and fraction lengths, and the accumulator word and fraction lengths to maintain the best precision results during filtering. The default value, `FullPrecision`, sets automatic word and fraction length determination by the filter. `SpecifyPrecision` makes the output and accumulator-related properties available so you can set your own word and fraction lengths for them.
`InputFracLength`	Any positive or negative integer number of bits [15]	Specifies the fraction length the filter uses to interpret input data.
`InputWordLength`	Any integer number of bits [16]	Specifies the word length applied to interpret input data.
`NumFracLength`	Any positive or negative integer number of bits [14]	Sets the fraction length used to interpret the numerator coefficients.

Name	Values	Description
`OutputFracLength`	Any positive or negative integer number of bits [29]	Determines how the filter interprets the filter output data. You can change the value of `OutputFracLength` when you set `FilerInternals` to `SpecifyPrecision`.
`OutputWordLength`	Any integer number of bits [33]	Determines the word length used for the output data. You make this property editable by setting `FilterInternals` to `SpecifyPrecision`.
`OverflowMode`	saturate, [wrap]	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either `saturate` (limit the output to the largest positive or negative representable value) or `wrap` (set overflowing values to the nearest representable value using modular arithmetic). The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow—they maintain full precision.
`ProductFracLength`	Any positive or negative integer number of bits [29]	Specifies the fraction length to use for multiplication operation results. This property becomes writable (you can change the value) when you set `ProductMode` to `SpecifyPrecision`.
`ProductWordLength`	Any integer number of bits [33]	Specifies the word length to use for multiplication operation results. This property becomes writable (you can change the value) when you set `ProductMode` to `SpecifyPrecision`.

Name	Values	Description
RoundMode	[convergent], ceil, fix, floor, nearest, round	Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths). • ceil - Round toward positive infinity. • convergent - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software. • fix - Round toward zero. • floor - Round toward negative infinity. • nearest - Round toward nearest. Ties round toward positive infinity. • round - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers. The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.
Signed	[true], false	Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.
States	fi object to match the filter arithmetic setting	Contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. The states use fi objects, with the associated properties from those objects. For details, refer to fixed-point objects in Fixed-Point Designer documentation.

Examples

Odd Order

Specify a fifth-order direct-form symmetric FIR filter structure for a `dfilt` object `hd`, with the following code:

```
b = [-0.008 0.06 0.44 0.44 0.06 -0.008];
hd = dfilt.dfsymfir(b);
% Create fixed-point filter
set(hd,'arithmetic','fixed')
% Change FilterInternals property to
% SpecifyPrecision
hd.Filterinternals='SpecifyPrecision';
```

Even Order

Specify a fourth-order, fixed-point, direct-form symmetric FIR filter structure for a `dfilt` object `hd`, with the following code:

```
b = [-0.01 0.1 0.8 0.1 -0.01];
hd = dfilt.dfsymfir(b);
set(hd,'arithmetic','fixed');
```

dfilt.farrowfd

Fractional Delay Farrow filter

Syntax

```
Hd = dfilt.farrowfd(D, COEFFS)
```

Description

`Hd = dfilt.farrowfd(D, COEFFS)` Constructs a discrete-time fractional delay Farrow filter with COEFFS coefficients and D delay.

Examples

Farrow filters can be designed with the dfilt.farrowfd filter designer.

```
coeffs = [-1/6 1/2 -1/3 0;1/2 -1 -1/2 1;
-1/2 1/2 1 0;1/6 0 -1/6 0];
Hd = dfilt.farrowfd(0.5, coeffs);
```

Design a cubic fractional delay filter with the Lagrange method.

```
fdelay = .2; % Fractional delay
d = fdesign.fracdelay(fdelay,'N',3);
Hd = design(d, 'lagrange', 'FilterStructure', 'farrowfd');
fvtool(Hd, 'Analysis', 'grpdelay');

More About

- `dfilt`

dfilt.farrowlinearfd

Farrow Linear Fractional Delay filter

Syntax

```
Hd = dfilt.farrowlinearfd(D)
```

Description

`Hd = dfilt.farrowlinearfd(D)` Constructs a discrete-time linear fractional delay Farrow filter with the delay D.

Examples

Farrow linear fractional delay filter with 1/2 sample delay:

```
 Hd = dfilt.farrowlinearfd(0.5);
n = cos(pi/10*(0:159));
y = filter(Hd,x);
stem(x(1:40));
axis([0 40 -2 2]);
hold on;
stem(y(1:40),'color',[1 0 0],'markerfacecolor',[1 0 0 ]);
legend('Orignal Signal','Filtered Signal','Location','best');
```

For more information about fractional delay filter implementations, see the “Fractional Delay Filters Using Farrow Structures” example, farrowdemo.

More About

- `dfilt`

dfilt.fftfir

Discrete-time, overlap-add, FIR filter

Syntax

```
Hd = dfilt.fftfir(b,len)
Hd = dfilt.fftfir(b)
Hd = dfilt.fftfir
```

Description

This object uses the overlap-add method of block FIR filtering, which is very efficient for streaming data.

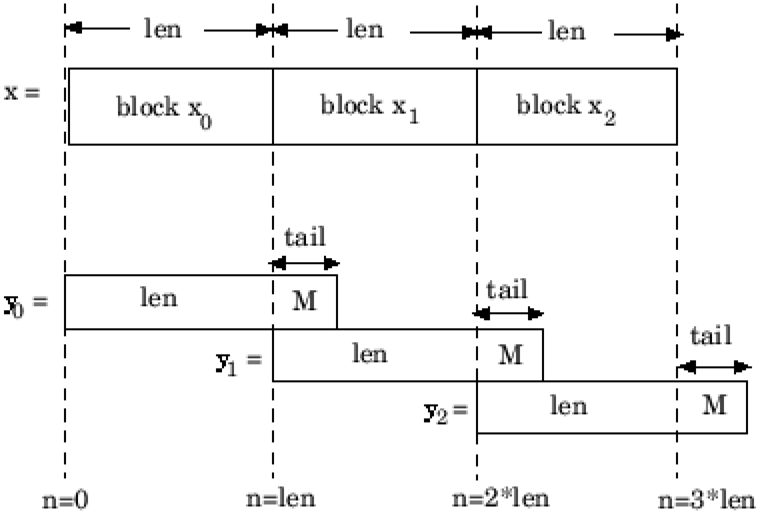
`Hd = dfilt.fftfir(b,len)` returns a discrete-time, FFT, FIR filter, `Hd`, with numerator coefficients, `b` and block length, `len`. The block length is the number of input points to use for each overlap-add computation.

`Hd = dfilt.fftfir(b)` returns a discrete-time, FFT, FIR filter, `Hd`, with numerator coefficients, `b` and block length, `len`=100.

`Hd = dfilt.fftfir` returns a default, discrete-time, FFT, FIR filter, `Hd`, with the numerator `b=1` and block length, `len`=100. This filter passes the input through to the output unchanged.

Note When you use a `dfilt.fftfir` object to filter, the input signal length must be an integer multiple of the object's block length, `len`. The resulting number of FFT points = (filter length + the block length - 1). The filter is most efficient if the number of FFT points is a power of 2.

The `fftfir` uses an overlap-add block processing algorithm, which is represented as follows,



where `len` is the block length and `M` is the length of the numerator-1, (`length(b)-1`), which is also the number of states. The output of each convolution is a block that is longer than the input block by a tail of (`length(b)-1`) samples. These tails overlap the next block and are added to it. The states reported by `dfilt.fftfir` are the tails of the final convolution.

Examples

Create an FFT FIR discrete-time filter with coefficients from a 30th order lowpass equiripple design:

```
b = firpm(30,[0 .1 .2 .5]*2,[1 1 0 0]);
Hd = dfilt.fftfir(b);
% To obtain frequency domain coefficients
% used in filtering
Coeffs = fftcoeffs(Hd);
```

`dfilt` | `dfilt.dffir` | `dfilt.dfasymfir` | `dfilt.dffirt` | `dfilt.dfsymfir`

dfilt.latticeallpass

Discrete-time, lattice allpass filter

Syntax

Refer to `dfilt.latticeallpass` in Signal Processing Toolbox documentation.

Description

`hd = dfilt.latticeallpass(k)` returns a discrete-time, lattice allpass filter object `hd`, with lattice coefficients, `k`.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hd` as follows:

- To change to single-precision filtering, enter

  ```
  set(hd,'arithmetic','single');
  ```

- To change to fixed-point filtering, enter

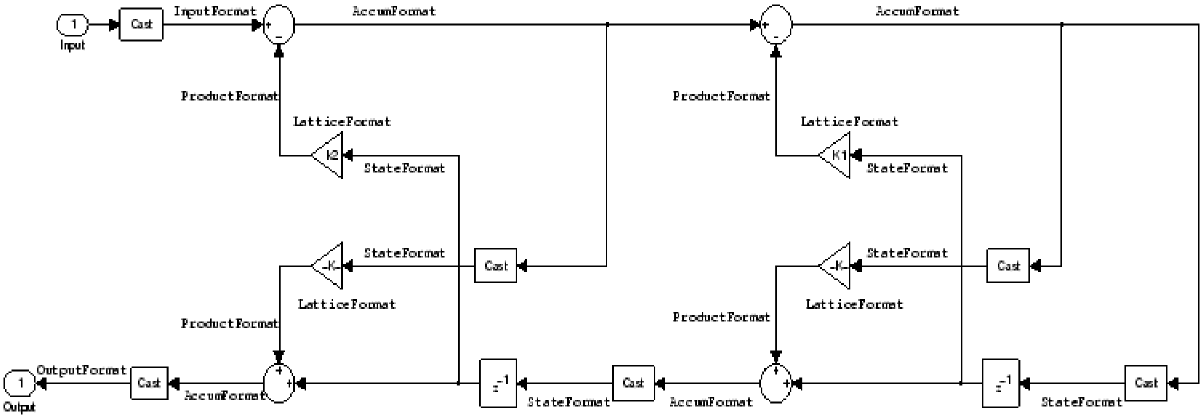
  ```
  set(hd,'arithmetic','fixed');
  ```

For more information about the property `Arithmetic`, refer to “Arithmetic”.

`hd = dfilt.latticeallpass` returns a default, discrete-time, lattice allpass filter object `hd`, with `k=[ ]`. This filter passes the input through to the output unchanged.

Fixed-Point Filter Structure

The following figure shows the signal flow for the allpass lattice filter implemented by `dfilt.latticeallpass`. To help you see how the filter processes the coefficients, input, and states of the filter, as well as numerical operations, the figure includes the locations of the formatting objects within the signal flow.



Notes About the Signal Flow Diagram

To help you understand where and how the filter performs fixed-point arithmetic during filtering, the figure shows various labels associated with data and functional elements in the filter. The following table describes each label in the signal flow and relates the label to the filter properties that are associated with it.

The labels use a common format — a prefix followed by the word “format.” In this use, “format” means the word length and fraction length associated with the filter part referred to by the prefix.

For example, the InputFormat label refers to the word length and fraction length used to interpret the data input to the filter. The format properties `InputWordLength` and `InputFracLength` (as shown in the table) store the word length and the fraction length in bits. Or consider NumFormat, which refers to the word and fraction lengths (`CoeffWordLength`, `NumFracLength`) associated with representing filter numerator coefficients.

Signal Flow Label	Corresponding Word Length Property	Corresponding Fraction Length Property	Related Properties
AccumFormat	`AccumWordLength`	`AccumFracLength`	`AccumMode`
InputFormat	`InputWordLength`	`InputFracLength`	None
LatticeFormat	`CoeffWordLength`	`LatticeFracLength`	`CoeffAutoScale`
OutputFormat	`OutputWordLength`	`OutputFracLength`	`OutputMode`

Signal Flow Label	Corresponding Word Length Property	Corresponding Fraction Length Property	Related Properties
ProductFormat	`ProductWordLength`	`ProductFracLength`	`ProductMode`
StateFormat	`StateWordLength`	`StateFracLength`	`States`

Most important is the label position in the diagram, which identifies where the format applies.

As one example, look at the label ProductFormat, which always follows a coefficient multiplication element in the signal flow. The label indicates that coefficients leave the multiplication element with the word length and fraction length associated with product operations that include coefficients. From reviewing the table, you see that the ProductFormat refers to the properties `ProductFracLength`, `ProductWordLength`, and `ProductMode` that fully define the coefficient format after multiply (or product) operations.

Properties

In this table you see the properties associated with the allpass lattice implementation of `dfilt` objects.

Note The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You might not see all of the listed properties all the time. To view all the properties for a filter at any time, use

```
get(hd)
```

where `hd` is a filter.

For further information about the properties of this filter or any `dfilt` object, refer to “Fixed-Point Filter Properties”.

Property Name	Brief Description
`AccumFracLength`	Specifies the fraction length used to interpret data output by the accumulator. This is a property of FIR filters and lattice filters. IIR filters have two similar properties

Property Name	Brief Description
	—DenAccumFracLength and NumAccumFracLength — that let you set the precision for numerator and denominator operations separately.
AccumMode	Determines how the accumulator outputs stored values. Choose from full precision (FullPrecision), or whether to keep the most significant bits (KeepMSB) or least significant bits (KeepLSB) when output results need shorter word length than the accumulator supports. To let you set the word length and the precision (the fraction length) used by the output from the accumulator, set AccumMode to SpecifyPrecision.
AccumWordLength	Sets the word length used to store data in the accumulator/ buffer.
Arithmetic	Defines the arithmetic the filter uses. Gives you the options double, single, and fixed. In short, this property defines the operating mode for your filter.
CastBeforeSum	Specifies whether to cast numeric data to the appropriate accumulator format (as shown in the signal flow diagrams) before performing sum operations.
CoeffAutoScale	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to false enables you to change the LatticeFracLength property value to specify the precision used.
CoeffWordLength	Specifies the word length to apply to filter coefficients.
FilterStructure	Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering — gains, delays, sums, products, and input/output.
InputFracLength	Specifies the fraction length the filter uses to interpret input data.
InputWordLength	Specifies the word length applied to interpret input data.
Lattice	Any lattice structure coefficients. No default value.
LatticeFracLength	Sets the fraction length applied to the lattice coefficients.

Property Name	Brief Description
OutputFracLength	Determines how the filter interprets the filter output data. You can change the value of OutputFracLength when you set OutputMode to SpecifyPrecision.
OutputMode	Sets the mode the filter uses to scale the filtered data for output. You have the following choices: • AvoidOverflow — directs the filter to set the output data word length and fraction length to avoid causing the data to overflow. • BestPrecision — directs the filter to set the output data word length and fraction length to maximize the precision in the output data. • SpecifyPrecision — lets you set the word and fraction lengths used by the output data from filtering.
OutputWordLength	Determines the word length used for the output data.
OverflowMode	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either saturate (limit the output to the largest positive or negative representable value) or wrap (set overflowing values to the nearest representable value using modular arithmetic). The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow—they maintain full precision.
ProductFracLength	For the output from a product operation, this sets the fraction length used to interpret the data. This property becomes writable (you can change the value) when you set ProductMode to SpecifyPrecision.
ProductMode	Determines how the filter handles the output of product operations. Choose from full precision (FullPrecision), or whether to keep the most significant bit (KeepMSB) or least significant bit (KeepLSB) in the result when you need to shorten the data words. For you to be able to set the precision (the fraction length) used by the output from the multiplies, you set ProductMode to SpecifyPrecision.

Property Name	Brief Description
`ProductWordLength`	Specifies the word length to use for multiplication operation results. This property becomes writable (you can change the value) when you set `ProductMode` to `SpecifyPrecision`.
`PersistentMemory`	Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. `False` is the default setting.
`RoundMode`	Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths). • `ceil` - Round toward positive infinity. • `convergent` - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software. • `fix` - Round toward zero. • `floor` - Round toward negative infinity. • `nearest` - Round toward nearest. Ties round toward positive infinity. • `round` - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers. The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.
`Signed`	Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.
`StateFracLength`	When you set `StateAutoScale` to `false`, you enable the `StateFracLength` property that lets you set the fraction length applied to interpret the filter states.

Property Name	Brief Description
States	This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. The states use fi objects, with the associated properties from those objects. For details, refer to filtstates in Signal Processing Toolbox documentation or in the Help system.
StateWordLength	Sets the word length used to represent the filter states.

Examples

Specify a third-order lattice allpass filter structure for a dfilt object hd, with the following code:

```
k = [.66 .7 .44];
hd=dfilt.latticeallpass(k);
% convert to fixed-point arithmetic
hd.arithmetic = 'fixed';
```

dfilt.latticear

Discrete-time, lattice, autoregressive filter

Syntax

Refer to `dfilt.latticear` in Signal Processing Toolbox documentation.

Description

`hd = dfilt.latticear(k)` returns a discrete-time, lattice autoregressive filter object `hd`, with lattice coefficients, `k`.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hd` as follows:

- To change to single-precision filtering, enter

  ```
  set(hd,'arithmetic','single');
  ```
- To change to fixed-point filtering, enter

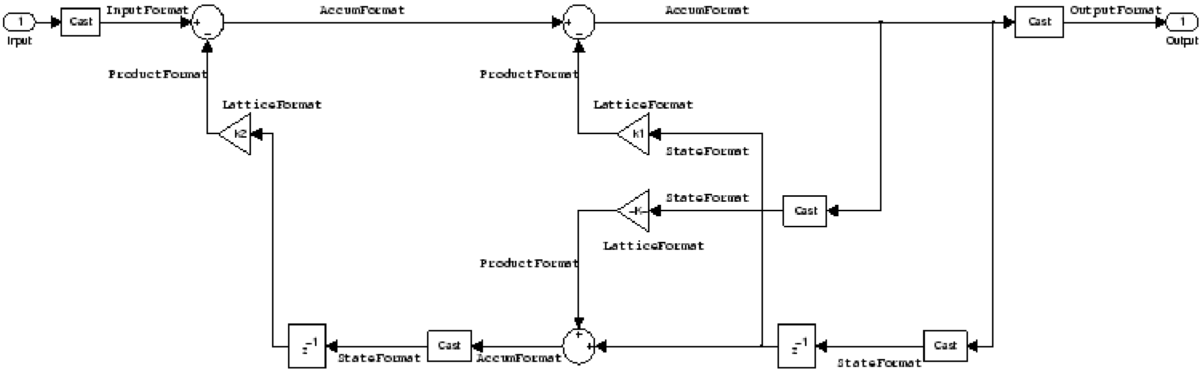
  ```
  set(hd,'arithmetic','fixed');
  ```

For more information about the property `Arithmetic`, refer to “Arithmetic”.

`hd = dfilt.latticear` returns a default, discrete-time, lattice autoregressive filter object `hd`, with `k=[ ]`. This filter passes the input through to the output unchanged.

Fixed-Point Filter Structure

The following figure shows the signal flow for the autoregressive lattice filter implemented by `dfilt.latticear`. To help you see how the filter processes the coefficients, input, and states of the filter, as well as numerical operations, the figure includes the locations of the formatting objects within the signal flow.



Notes About the Signal Flow Diagram

To help you understand where and how the filter performs fixed-point arithmetic during filtering, the figure shows various labels associated with data and functional elements in the filter. The following table describes each label in the signal flow and relates the label to the filter properties that are associated with it.

The labels use a common format — a prefix followed by the word “format.” In this use, “format” means the word length and fraction length associated with the filter part referred to by the prefix.

For example, the InputFormat label refers to the word length and fraction length used to interpret the data input to the filter. The format properties `InputWordLength` and `InputFracLength` (as shown in the table) store the word length and the fraction length in bits. Or consider NumFormat, which refers to the word and fraction lengths (`CoeffWordLength`, `NumFracLength`) associated with representing filter numerator coefficients.

Signal Flow Label	Corresponding Word Length Property	Corresponding Fraction Length Property	Related Properties
AccumFormat	`AccumWordLength`	`AccumFracLength`	`AccumMode`
InputFormat	`InputWordLength`	`InputFracLength`	None
LatticeFormat	`CoeffWordLength`	`LatticeFracLength`	`CoeffAutoScale`
OutputFormat	`OutputWordLength`	`OutputFracLength`	`OutputMode`
ProductFormat	`ProductWordLength`	`ProductFracLength`	`ProductMode`

Signal Flow Label	Corresponding Word Length Property	Corresponding Fraction Length Property	Related Properties
StateFormat	`StateWordLength`	`StateFracLength`	`States`

Most important is the label position in the diagram, which identifies where the format applies.

As one example, look at the label ProductFormat, which always follows a coefficient multiplication element in the signal flow. The label indicates that coefficients leave the multiplication element with the word length and fraction length associated with product operations that include coefficients. From reviewing the table, you see that the ProductFormat refers to the properties `ProductFracLength`, `ProductWordLength`, and `ProductMode` that fully define the coefficient format after multiply (or product) operations.

Properties

In this table you see the properties associated with the autoregressive lattice implementation of `dfilt` objects.

Note The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You might not see all of the listed properties all the time. To view all the properties for a filter at any time, use

```
get(hd)
```

where `hd` is a filter.

For further information about the properties of this filter or any `dfilt` object, refer to "Fixed-Point Filter Properties".

Property Name	Brief Description
`AccumFracLength`	Specifies the fraction length used to interpret data output by the accumulator. This is a property of FIR filters and lattice filters. IIR filters have two similar properties — `DenAccumFracLength` and `NumAccumFracLength` — that

Property Name	Brief Description
	let you set the precision for numerator and denominator operations separately.
AccumMode	Determines how the accumulator outputs stored values. Choose from full precision (FullPrecision), or whether to keep the most significant bits (KeepMSB) or least significant bits (KeepLSB) when output results need shorter word length than the accumulator supports. To let you set the word length and the precision (the fraction length) used by the output from the accumulator, set AccumMode to SpecifyPrecision.
AccumWordLength	Sets the word length used to store data in the accumulator/buffer.
Arithmetic	Defines the arithmetic the filter uses. Gives you the options double, single, and fixed. In short, this property defines the operating mode for your filter.

CoeffAutoScale	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to false enables you to change the LatticeFracLength to specify the precision used.
CoeffWordLength	Specifies the word length to apply to filter coefficients.
FilterStructure	Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering —gains, delays, sums, products, and input/output.
InputFracLength	Specifies the fraction length the filter uses to interpret input data.
InputWordLength	Specifies the word length applied to interpret input data.
Lattice	Any lattice structure coefficients.
LatticeFracLength	Sets the fraction length applied to the lattice coefficients.

Property Name	Brief Description
OutputFracLength	Determines how the filter interprets the filter output data. You can change the value of OutputFracLength when you set OutputMode to SpecifyPrecision.
OutputMode	Sets the mode the filter uses to scale the filtered data for output. You have the following choices: • AvoidOverflow — directs the filter to set the output data word length and fraction length to avoid causing the data to overflow. • BestPrecision — directs the filter to set the output data word length and fraction length to maximize the precision in the output data. • SpecifyPrecision — lets you set the word and fraction lengths used by the output data from filtering.
OutputWordLength	Determines the word length used for the output data.
OverflowMode	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either saturate (limit the output to the largest positive or negative representable value) or wrap (set overflowing values to the nearest representable value using modular arithmetic). The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow — they maintain full precision.
ProductFracLength	For the output from a product operation, this sets the fraction length used to interpret the data. This property becomes writable (you can change the value) when you set ProductMode to SpecifyPrecision.
ProductMode	Determines how the filter handles the output of product operations. Choose from full precision (FullPrecision), or whether to keep the most significant bit (KeepMSB) or least significant bit (KeepLSB) in the result when you need to shorten the data words. For you to be able to set the precision (the fraction length) used by the output from the multiplies, you set ProductMode to SpecifyPrecision.

Property Name	Brief Description
ProductWordLength	Specifies the word length to use for multiplication operation results. This property becomes writable (you can change the value) when you set ProductMode to SpecifyPrecision.
PersistentMemory	Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. False is the default setting.
RoundMode	Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths). • ceil - Round toward positive infinity. • convergent - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software. • fix - Round toward zero. • floor - Round toward negative infinity. • nearest - Round toward nearest. Ties round toward positive infinity. • round - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers. The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.
Signed	Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.
StateFracLength	When you set StateAutoScale to false, you enable the StateFracLength property that lets you set the fraction length applied to interpret the filter states.

Property Name	Brief Description
`States`	This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. The states use `fi` objects, with the associated properties from those objects. For details, refer to `filtstates` in Signal Processing Toolbox documentation or in the Help system.
`StateWordLength`	Sets the word length used to represent the filter states.

Examples

Specify a third-order lattice autoregressive filter structure for a `dfilt` object, `hd`, with the following code that creates a fixed-point filter.

```
k = [.66 .7 .44];
hd1=dfilt.latticear(k);
hd1.arithmetic='fixed';
specifyall(hd1);
```

dfilt.latticearma

Discrete-time, lattice, autoregressive, moving-average filter

Syntax

Refer to `dfilt.latticearma` in Signal Processing Toolbox documentation.

Description

`hd = dfilt.latticearma(k)` returns a discrete-time, lattice moving-average autoregressive filter object `hd`, with lattice coefficients, `k`.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hd` as follows:

- To change to single-precision filtering, enter

  ```
  set(hd,'arithmetic','single');
  ```
- To change to fixed-point filtering, enter

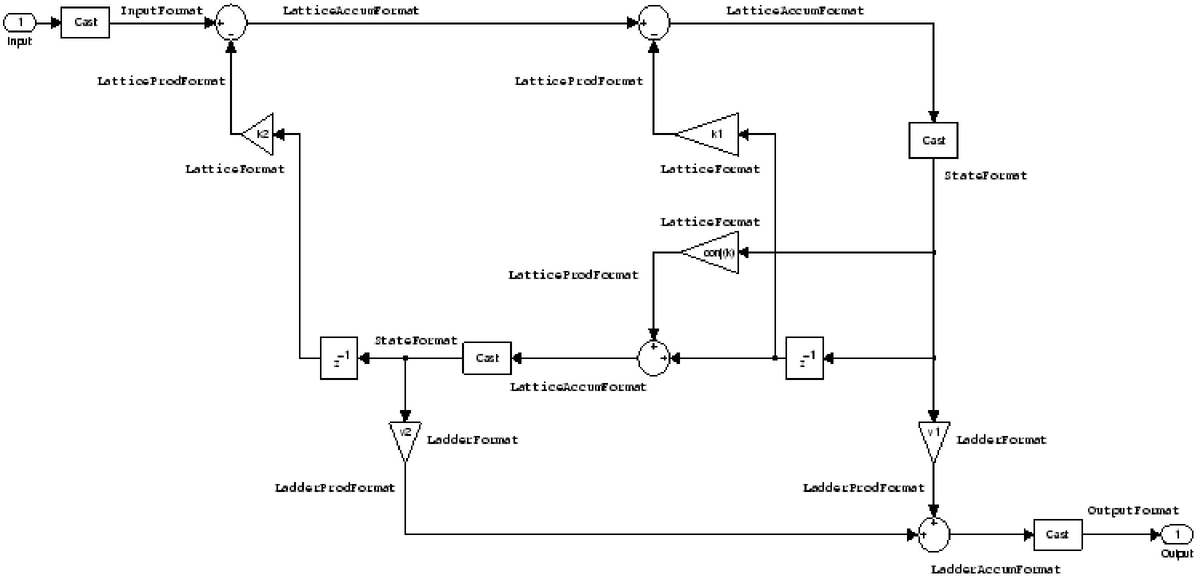
  ```
  set(hd,'arithmetic','fixed');
  ```

For more information about the property `Arithmetic`, refer to “Arithmetic”.

`hd dfilt.latticearma` returns a default, discrete-time, lattice moving-average, autoregressive filter object `hd`, with `k` = [ ]. This filter passes the input through to the output unchanged.

Fixed-Point Filter Structure

The following figure shows the signal flow for the autoregressive lattice filter implemented by `dfilt.latticearma`. To help you see how the filter processes the coefficients, input, and states of the filter, as well as numerical operations, the figure includes the locations of the formatting objects within the signal flow.



Notes About the Signal Flow Diagram

To help you understand where and how the filter performs fixed-point arithmetic during filtering, the figure shows various labels associated with data and functional elements in the filter. The following table describes each label in the signal flow and relates the label to the filter properties that are associated with it.

The labels use a common format — a prefix followed by the word "format." In this use, "format" means the word length and fraction length associated with the filter part referred to by the prefix.

For example, the InputFormat label refers to the word length and fraction length used to interpret the data input to the filter. The format properties `InputWordLength` and `InputFracLength` (as shown in the table) store the word length and the fraction length in bits. Or consider NumFormat, which refers to the word and fraction lengths (`CoeffWordLength`, `NumFracLength`) associated with representing filter numerator coefficients.

Signal Flow Label	Corresponding Word Length Property	Corresponding Fraction Length Property	Related Properties
InputFormat	`InputWordLength`	`InputFracLength`	None

Signal Flow Label	Corresponding Word Length Property	Corresponding Fraction Length Property	Related Properties
LadderAccumFormat	AccumWordLength	LadderAccumFracLength	AccumMode
LadderFormat	CoeffWordLength	LadderFracLength	CoeffAutoScale
LadderProdFormat	ProductWordLength	LadderProdFracLength	ProductMode
LatticeAccumFormat	AccumWordLength	LatticeAccum-FracLength	AccumMode
LatticeFormat	CoeffWordLength	LatticeFracLength	CoeffAutoScale
LatticeProdFormat	ProductWordLength	LatticeProdFracLength	ProductMode
OutputFormat	OutputWordLength	OutputFracLength	OutputMode
StateFormat	StateWordLength	StateFracLength	States

Most important is the label position in the diagram, which identifies where the format applies.

As one example, look at the label LatticeProdFormat, which always follows a coefficient multiplication element in the signal flow. The label indicates that lattice coefficients leave the multiplication element with the word length and fraction length associated with product operations that include coefficients. From reviewing the table, you see that the LatticeProdFormat refers to the properties ProductWordLength, LatticeProdFracLength, and ProductMode that fully define the coefficient format after multiply (or product) operations.

Properties

In this table you see the properties associated with the autoregressive moving-average lattice implementation of dfilt objects.

Note The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You might not see all of the listed properties all the time. To view all the properties for a filter at any time, use

```
get(hd)
```

where hd is a filter.

For further information about the properties of this filter or any `dfilt` object, refer to "Fixed-Point Filter Properties".

Property Name	Brief Description
`AccumFracLength`	Specifies the fraction length used to interpret data output by the accumulator. This is a property of FIR filters and lattice filters. IIR filters have two similar properties — `DenAccumFracLength` and `NumAccumFracLength` — that let you set the precision for numerator and denominator operations separately.
`AccumMode`	Determines how the accumulator outputs stored values. Choose from full precision (`FullPrecision`), or whether to keep the most significant bits (`KeepMSB`) or least significant bits (`KeepLSB`) when output results need shorter word length than the accumulator supports. To let you set the word length and the precision (the fraction length) used by the output from the accumulator, set `AccumMode` to `SpecifyPrecision`.
`AccumWordLength`	Sets the word length used to store data in the accumulator/buffer.
`Arithmetic`	Defines the arithmetic the filter uses. Gives you the options `double`, `single`, and `fixed`. In short, this property defines the operating mode for your filter.
`CastBeforeSum`	Specifies whether to cast numeric data to the appropriate accumulator format (as shown in the signal flow diagrams) before performing sum operations.
`CoeffAutoScale`	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to `false` enables you to change the `LatticeFracLength` property to specify the precision used.
`CoeffWordLength`	Specifies the word length to apply to filter coefficients.
`FilterStructure`	Describes the signal flow for the filter object, including all of the active elements that perform operations

Property Name	Brief Description
	during filtering—gains, delays, sums, products, and input/output.
`InputFracLength`	Specifies the fraction length the filter uses to interpret input data.
`InputWordLength`	Specifies the word length applied to interpret input data.
`Ladder`	Stores the ladder coefficients for lattice ARMA (`dfilt.latticearma`) filters.
`LadderAccumFracLength`	Sets the fraction length used to interpret the output from sum operations that include the ladder coefficients. You can change this property value after you set `AccumMode` to `SpecifyPrecision`.
`LadderFracLength`	Determines the precision used to represent the ladder coefficients in ARMA lattice filters.
`Lattice`	Stores the lattice structure coefficients.
`LatticeFracLength`	Sets the fraction length applied to the lattice coefficients.
`OutputFracLength`	Determines how the filter interprets the filter output data. You can change the value of `OutputFracLength` when you set `OutputMode` to `SpecifyPrecision`.
`OutputMode`	Sets the mode the filter uses to scale the filtered data for output. You have the following choices: • `AvoidOverflow` — directs the filter to set the output data word length and fraction length to avoid causing the data to overflow. • `BestPrecision` — directs the filter to set the output data word length and fraction length to maximize the precision in the output data. • `SpecifyPrecision` — lets you set the word and fraction lengths used by the output data from filtering.
`OutputWordLength`	Determines the word length used for the output data.

Property Name	Brief Description
OverflowMode	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either saturate (limit the output to the largest positive or negative representable value) or wrap (set overflowing values to the nearest representable value using modular arithmetic). The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow—they maintain full precision.
ProductFracLength	For the output from a product operation, this sets the fraction length used to interpret the data. This property becomes writable (you can change the value) when you set ProductMode to SpecifyPrecision.
ProductMode	Determines how the filter handles the output of product operations. Choose from full precision (FullPrecision), or whether to keep the most significant bit (KeepMSB) or least significant bit (KeepLSB) in the result when you need to shorten the data words. For you to be able to set the precision (the fraction length) used by the output from the multiplies, you set ProductMode to SpecifyPrecision.
ProductWordLength	Specifies the word length to use for multiplication operation results. This property becomes writable (you can change the value) when you set ProductMode to SpecifyPrecision.
PersistentMemory	Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. False is the default setting.

Property Name	Brief Description
RoundMode	Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths). • ceil - Round toward positive infinity. • convergent - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software. • fix - Round toward zero. • floor - Round toward negative infinity. • nearest - Round toward nearest. Ties round toward positive infinity. • round - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers. The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.
Signed	Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.
StateFracLength	When you set StateAutoScale to false, you enable the StateFracLength property that lets you set the fraction length applied to interpret the filter states.
States	This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. The states use fi objects, with the associated properties from those objects. For details, refer to filtstates in Signal Processing Toolbox documentation or in the Help system.
StateWordLength	Sets the word length used to represent the filter states.

dfilt.latticemamax

Discrete-time, lattice, moving-average filter with maximum phase

Syntax

Refer to `dfilt.latticemamax` in Signal Processing Toolbox documentation.

Description

`hd = dfilt.latticemamax(k)` returns a discrete-time, lattice, moving-average filter object `hd`, with lattice coefficients `k`.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hd` as follows:

- To change to single-precision filtering, enter

  ```
  set(hd,'arithmetic','single');
  ```
- To change to fixed-point filtering, enter

  ```
  set(hd,'arithmetic','fixed');
  ```

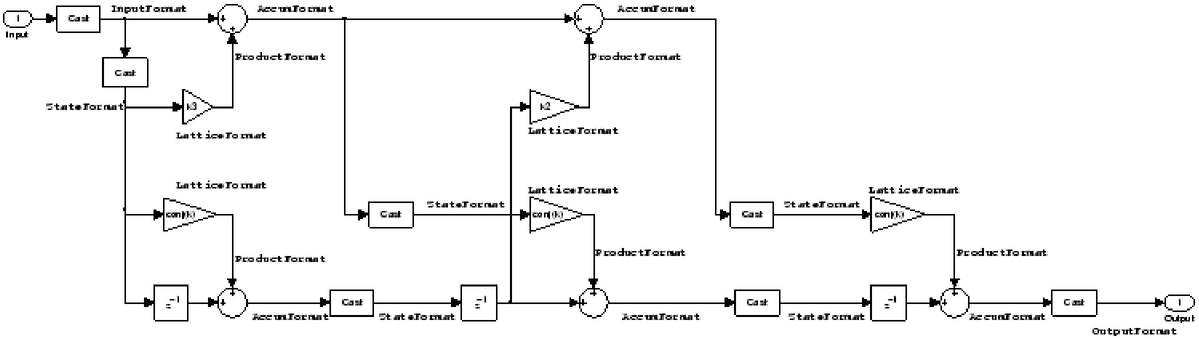
For more information about the property `Arithmetic`, refer to “Arithmetic”.

Note When the `k` coefficients define a maximum phase filter, the resulting filter in this structure is maximum phase. When your coefficients do not define a maximum phase filter, placing them in this structure does not produce a maximum phase filter.

`hd = dfilt.latticemamax` returns a default discrete-time, lattice, moving-average filter object `hd`, with `k` = [ ]. This filter passes the input through to the output unchanged.

Fixed-Point Filter Structure

The following figure shows the signal flow for the maximum phase implementation of a moving-average lattice filter implemented by `dfilt.latticemamax`. To help you see how the filter processes the coefficients, input, and states of the filter, as well as numerical operations, the figure includes the locations of the formatting objects within the signal flow.



Notes About the Signal Flow Diagram

To help you understand where and how the filter performs fixed-point arithmetic during filtering, the figure shows various labels associated with data and functional elements in the filter. The following table describes each label in the signal flow and relates the label to the filter properties that are associated with it.

The labels use a common format — a prefix followed by the word “format.” In this use, “format” means the word length and fraction length associated with the filter part referred to by the prefix.

For example, the InputFormat label refers to the word length and fraction length used to interpret the data input to the filter. The format properties `InputWordLength` and `InputFracLength` (as shown in the table) store the word length and the fraction length in bits. Or consider NumFormat, which refers to the word and fraction lengths (`CoeffWordLength`, `NumFracLength`) associated with representing filter numerator coefficients.

Signal Flow Label	Corresponding Word Length Property	Corresponding Fraction Length Property	Related Properties
AccumFormat	`AccumWordLength`	`AccumFracLength`	`AccumMode`
InputFormat	`InputWordLength`	`InputFracLength`	None
LatticeFormat	`CoeffWordLength`	`LatticeFracLength`	`CoeffAutoScale`
OutputFormat	`OutputWordLength`	`OutputFracLength`	`OutputMode`

Signal Flow Label	Corresponding Word Length Property	Corresponding Fraction Length Property	Related Properties
ProductFormat	`ProductWordLength`	`ProductFracLength`	`ProductMode`
StateFormat	`StateWordLength`	`StateFracLength`	`States`

Most important is the label position in the diagram, which identifies where the format applies.

As one example, look at the label ProductFormat, which always follows a coefficient multiplication element in the signal flow. The label indicates that coefficients leave the multiplication element with the word length and fraction length associated with product operations that include coefficients. From reviewing the table, you see that the ProductFormat refers to the properties `ProductFracLength`, `ProductWordLength`, and `ProductMode` that fully define the coefficient format after multiply (or product) operations.

Properties

In this table you see the properties associated with the maximum phase, moving average lattice implementation of `dfilt` objects.

Note The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You might not see all of the listed properties all the time. To view all the properties for a filter at any time, use

```
get(hd)
```

where `hd` is a filter.

For further information about the properties of this filter or any `dfilt` object, refer to "Fixed-Point Filter Properties".

Property Name	Brief Description
`AccumFracLength`	Specifies the fraction length used to interpret data output by the accumulator. This is a property of FIR filters and lattice filters. IIR filters have two similar properties —

Property Name	Brief Description
	DenAccumFracLength and NumAccumFracLength — that let you set the precision for numerator and denominator operations separately.
AccumMode	Determines how the accumulator outputs stored values. Choose from full precision (FullPrecision), or whether to keep the most significant bits (KeepMSB) or least significant bits (KeepLSB) when output results need shorter word length than the accumulator supports. To let you set the word length and the precision (the fraction length) used by the output from the accumulator, set AccumMode to SpecifyPrecision.
AccumWordLength	Sets the word length used to store data in the accumulator/ buffer.
Arithmetic	Defines the arithmetic the filter uses. Gives you the options double, single, and fixed. In short, this property defines the operating mode for your filter.
CastBeforeSum	Specifies whether to cast numeric data to the appropriate accumulator format (as shown in the signal flow diagrams) before performing sum operations.
CoeffAutoScale	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to false enables you to change the LatticeFracLength property to specify the precision used.
CoeffWordLength	Specifies the word length to apply to filter coefficients.
FilterStructure	Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering —gains, delays, sums, products, and input/output.
InputFracLength	Specifies the fraction length the filter uses to interpret input data.
InputWordLength	Specifies the word length applied to interpret input data.
Lattice	Any lattice structure coefficients.
LatticeFracLength	Sets the fraction length applied to the lattice coefficients.

Property Name	Brief Description
OutputFracLength	Determines how the filter interprets the filter output data. You can change the value of OutputFracLength when you set OutputMode to SpecifyPrecision.
OutputMode	Sets the mode the filter uses to scale the filtered data for output. You have the following choices: • AvoidOverflow — directs the filter to set the output data word length and fraction length to avoid causing the data to overflow. • BestPrecision — directs the filter to set the output data word length and fraction length to maximize the precision in the output data. • SpecifyPrecision — lets you set the word and fraction lengths used by the output data from filtering.
OutputWordLength	Determines the word length used for the output data.
OverflowMode	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either saturate (limit the output to the largest positive or negative representable value) or wrap (set overflowing values to the nearest representable value using modular arithmetic). The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow—they maintain full precision.
ProductFracLength	For the output from a product operation, this sets the fraction length used to interpret the data. This property becomes writable (you can change the value) when you set ProductMode to SpecifyPrecision.
ProductMode	Determines how the filter handles the output of product operations. Choose from full precision (FullPrecision), or whether to keep the most significant bit (KeepMSB) or least significant bit (KeepLSB) in the result when you need to shorten the data words. For you to be able to set the precision (the fraction length) used by the output from the multiplies, you set ProductMode to SpecifyPrecision.

Property Name	Brief Description
ProductWordLength	Specifies the word length to use for multiplication operation results. This property becomes writable (you can change the value) when you set ProductMode to SpecifyPrecision.
PersistentMemory	Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. False is the default setting.
RoundMode	Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths). • ceil - Round toward positive infinity. • convergent - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software. • fix - Round toward zero. • floor - Round toward negative infinity. • nearest - Round toward nearest. Ties round toward positive infinity. • round - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers. The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.
Signed	Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.
StateFracLength	When you set StateAutoScale to false, you enable the StateFracLength property that lets you set the fraction length applied to interpret the filter states.

Property Name	Brief Description
`States`	This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. The states use `fi` objects, with the associated properties from those objects. For details, refer to `filtstates` in Signal Processing Toolbox documentation or in the Help system.
`StateWordLength`	Sets the word length used to represent the filter states.

Examples

Specify a fourth-order lattice, moving-average, maximum phase filter structure for a `dfilt` object, `hd`, with the following code:

```
k = [.66 .7 .44 .33];
hd = dfilt.latticemamax(k);
```

See Also

`dfilt` | `dfilt.latticeallpass` | `dfilt.latticear` | `dfilt.latticearma` | `dfilt.latticemamin`

dfilt.latticemamin

Discrete-time, lattice, moving-average filter with minimum phase

Syntax

Refer to `dfilt.latticemamin` in Signal Processing Toolbox documentation.

Description

`hd = dfilt.latticemamin(k)` returns a discrete-time, lattice, moving-average, minimum phase, filter object `hd`, with lattice coefficients `k`.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hd` as follows:

- To change to single-precision filtering, enter

  ```
  set(hd,'arithmetic','single');
  ```

- To change to fixed-point filtering, enter

  ```
  set(hd,'arithmetic','fixed');
  ```

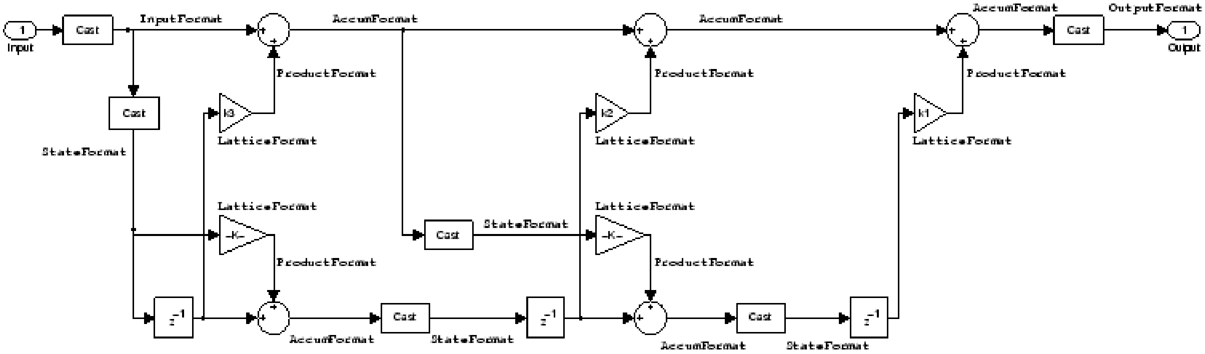
For more information about the property `Arithmetic`, refer to “Arithmetic”.

Note When the `k` coefficients define a minimum phase filter, the resulting filter in this structure is minimum phase. When your coefficients do not define a minimum phase filter, placing them in this structure does not produce a minimum phase filter.

`hd = dfilt.latticemamin` returns a default discrete-time, lattice, moving-average, minimum phase, filter object `hd`, with `k=[ ]`. This filter passes the input through to the output unchanged.

Fixed-Point Filter Structure

The following figure shows the signal flow for the minimum phase implementation of a moving-average lattice filter implemented by `dfilt.latticemamin`. To help you see how the filter processes the coefficients, input, and states of the filter, as well as numerical operations, the figure includes the locations of the formatting objects within the signal flow.



Notes About the Signal Flow Diagram

To help you understand where and how the filter performs fixed-point arithmetic during filtering, the figure shows various labels associated with data and functional elements in the filter. The following table describes each label in the signal flow and relates the label to the filter properties that are associated with it.

The labels use a common format — a prefix followed by the word "format." In this use, "format" means the word length and fraction length associated with the filter part referred to by the prefix.

For example, the InputFormat label refers to the word length and fraction length used to interpret the data input to the filter. The format properties `InputWordLength` and `InputFracLength` (as shown in the table) store the word length and the fraction length in bits. Or consider NumFormat, which refers to the word and fraction lengths (`CoeffWordLength`, `NumFracLength`) associated with representing filter numerator coefficients.

Signal Flow Label	Corresponding Word Length Property	Corresponding Fraction Length Property	Related Properties
AccumFormat	`AccumWordLength`	`AccumFracLength`	`AccumMode`
InputFormat	`InputWordLength`	`InputFracLength`	None
LatticeFormat	`CoeffWordLength`	`LatticeFracLength`	`CoeffAutoScale`
OutputFormat	`OutputWordLength`	`OutputFracLength`	`OutputMode`
ProductFormat	`ProductWordLength`	`ProductFracLength`	`ProductMode`
StateFormat	`StateWordLength`	`StateFracLength`	`States`

Most important is the label position in the diagram, which identifies where the format applies.

As one example, look at the label ProductFormat, which always follows a coefficient multiplication element in the signal flow. The label indicates that coefficients leave the multiplication element with the word length and fraction length associated with product operations that include coefficients. From reviewing the table, you see that the ProductFormat refers to the properties `ProductFracLength`, `ProductWordLength`, and `ProductMode` that fully define the coefficient format after multiply (or product) operations.

Properties

In this table you see the properties associated with the minimum phase, moving average lattice implementation of `dfilt` objects.

Note The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You might not see all of the listed properties all the time. To view all the properties for a filter at any time, use

```
get(hd)
```

where `hd` is a filter.

For further information about the properties of this filter or any `dfilt` object, refer to "Fixed-Point Filter Properties".

Property Name	Brief Description
AccumFracLength	Specifies the fraction length used to interpret data output by the accumulator. This is a property of FIR filters and lattice filters. IIR filters have two similar properties — DenAccumFracLength and NumAccumFracLength — that let you set the precision for numerator and denominator operations separately.
AccumMode	Determines how the accumulator outputs stored values. Choose from full precision (FullPrecision), or whether to keep the most significant bits (KeepMSB) or least significant bits (KeepLSB) when output results need shorter word length than the accumulator supports. To let you set the word length and the precision (the fraction length) used by the output from the accumulator, set AccumMode to SpecifyPrecision.
AccumWordLength	Sets the word length used to store data in the accumulator/ buffer.
Arithmetic	Defines the arithmetic the filter uses. Gives you the options double, single, and fixed. In short, this property defines the operating mode for your filter.
CastBeforeSum	Specifies whether to cast numeric data to the appropriate accumulator format (as shown in the signal flow diagrams) before performing sum operations.
CoeffAutoScale	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to false enables you to change the LatticeFracLength property to specify the precision used.
CoeffWordLength	Specifies the word length to apply to filter coefficients.
FilterStructure	Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering — gains, delays, sums, products, and input/output.
InputFracLength	Specifies the fraction length the filter uses to interpret input data.
InputWordLength	Specifies the word length applied to interpret input data.

Property Name	Brief Description
`Lattice`	Any lattice structure coefficients.
`LatticeFracLength`	Sets the fraction length applied to the lattice coefficients.
`OutputFracLength`	Determines how the filter interprets the filter output data. You can change the value of `OutputFracLength` when you set `OutputMode` to `SpecifyPrecision`.
`OutputMode`	Sets the mode the filter uses to scale the filtered data for output. You have the following choices: • `AvoidOverflow` — directs the filter to set the output data word length and fraction length to avoid causing the data to overflow. • `BestPrecision` — directs the filter to set the output data word length and fraction length to maximize the precision in the output data. • `SpecifyPrecision` — lets you set the word and fraction lengths used by the output data from filtering.
`OutputWordLength`	Determines the word length used for the output data.
`OverflowMode`	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either `saturate` (limit the output to the largest positive or negative representable value) or `wrap` (set overflowing values to the nearest representable value using modular arithmetic). The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow — they maintain full precision.
`ProductFracLength`	For the output from a product operation, this sets the fraction length used to interpret the data. This property becomes writable (you can change the value) when you set `ProductMode` to `SpecifyPrecision`.

Property Name	Brief Description
ProductMode	Determines how the filter handles the output of product operations. Choose from full precision (FullPrecision), or whether to keep the most significant bit (KeepMSB) or least significant bit (KeepLSB) in the result when you need to shorten the data words. For you to be able to set the precision (the fraction length) used by the output from the multiplies, you set ProductMode to SpecifyPrecision.
ProductWordLength	Specifies the word length to use for multiplication operation results. This property becomes writable (you can change the value) when you set ProductMode to SpecifyPrecision.
PersistentMemory	Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. False is the default setting.
RoundMode	Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths). • ceil - Round toward positive infinity. • convergent - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software. • fix - Round toward zero. • floor - Round toward negative infinity. • nearest - Round toward nearest. Ties round toward positive infinity. • round - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers. The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.

Property Name	Brief Description
`Signed`	Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.
`StateFracLength`	When you set `StateAutoScale` to `false`, you enable the `StateFracLength` property that lets you set the fraction length applied to interpret the filter states.
`States`	This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. The states use `fi` objects, with the associated properties from those objects. For details, refer to `filtstates` in Signal Processing Toolbox documentation or in the Help system.
`StateWordLength`	Sets the word length used to represent the filter states.

Examples

Specify a third-order lattice, moving-average, minimum phase, filter structure for a `dfilt` object, `hd`, with the following code:

```
k = [.66 .7 .44];
hd = dfilt.latticemamin(k);
```

See Also

`dfilt` | `dfilt.latticeallpass` | `dfilt.latticear` | `dfilt.latticearma` | `dfilt.latticemamax`

dfilt.parallel

Discrete-time, parallel structure filter

Syntax

Refer to `dfilt.parallel` in Signal Processing Toolbox documentation.

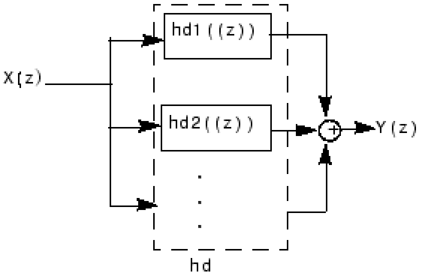
Description

`hd = dfilt.parallel(hd1,hd2,...)` returns a discrete-time filter object `hd`, which is a structure of two or more `dfilt` filter objects, `hd1`, `hd2`, and so on arranged in parallel.

You can also use the standard notation to combine filters into a parallel structure.

```
parallel(hd1,hd2,...)
```

In this syntax, `hd1`, `hd2`, and so on can be a mix of `dfilt` objects, `mfilt` objects, and `adaptfilt` objects.



`hd1`, `hd2`, and so on can be fixed-point filters. All filters in the parallel structure must be the same arithmetic format — double, single, or fixed. `hd`, the filter returned, inherits the format of the individual filters.

See Also

`dfilt` | `dfilt.cascade` | `parallel` | `dfilt.cascade` | `dfilt.parallel`

dfilt.scalar

Discrete-time, scalar filter

Syntax

Refer to `dfilt.scalar` in Signal Processing Toolbox documentation.

Description

`dfilt.scalar(g)` returns a discrete-time, scalar filter object with gain `g`, where `g` is a scalar.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hd` as follows:

- To change to single-precision filtering, enter

  ```
  set(hd,'arithmetic','single');
  ```
- To change to fixed-point filtering, enter

  ```
  set(hd,'arithmetic','fixed');
  ```

For more information about the property `Arithmetic`, refer to “Arithmetic”.

`dfilt.scalar` returns a default, discrete-time scalar gain filter object `hd`, with gain `1`.

Properties

In this table you see the properties associated with the scalar implementation of `dfilt` objects.

Note The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You might not see all of the listed properties all the time. To view all the properties for a filter at any time, use

```
get(hd)
```

where hd is a filter.

For further information about the properties of this filter or any dfilt object, refer to "Fixed-Point Filter Properties".

Property Name	Brief Description
Arithmetic	Defines the arithmetic the filter uses. Gives you the options double, single, and fixed. In short, this property defines the operating mode for your filter.
CastBeforeSum	Specifies whether to cast numeric data to the appropriate accumulator format (as shown in the signal flow diagrams) before performing sum operations.
CoeffAutoScale	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to false enables you to change the CoeffFracLength property to specify the precision used.
CoeffFracLength	Set the fraction length the filter uses to interpret coefficients. CoeffFracLength is always available, but it is read-only until you set CoeffAutoScale to false.
CoeffWordLength	Specifies the word length to apply to filter coefficients.
FilterStructure	Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering — gains, delays, sums, products, and input/output.
Gain	Returns the gain for the scalar filter. Scalar filters do not alter the input data except by adding gain.
InputFracLength	Specifies the fraction length the filter uses to interpret input data.
InputWordLength	Specifies the word length applied to interpret input data.
OutputFracLength	Determines how the filter interprets the filter output data. You can change the value of OutputFracLength when you set OutputMode to SpecifyPrecision.
OutputMode	Sets the mode the filter uses to scale the filtered data for output. You have the following choices:

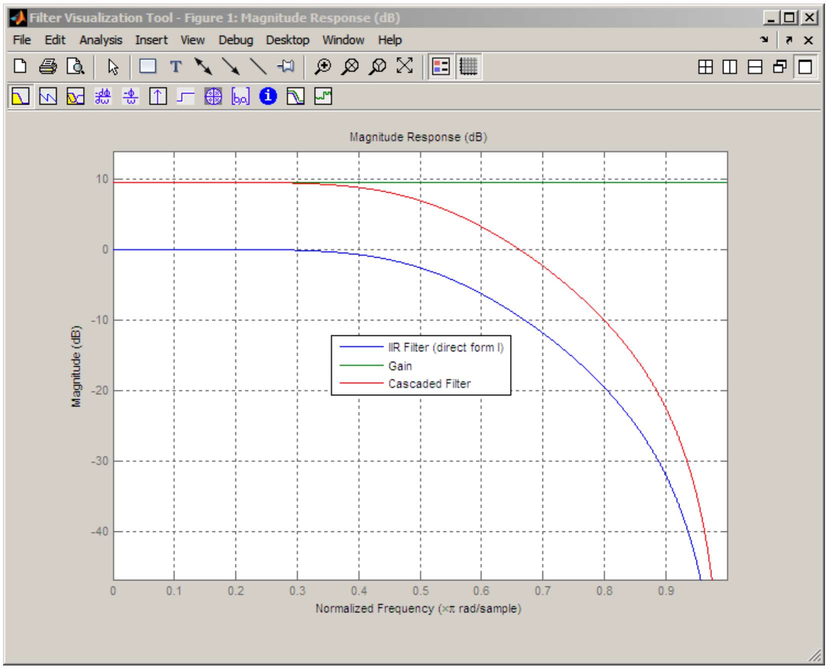
Property Name	Brief Description
	• `AvoidOverflow` — directs the filter to set the output data word length and fraction length to avoid causing the data to overflow. • `BestPrecision` — directs the filter to set the output data word length and fraction length to maximize the precision in the output data. • `SpecifyPrecision` — lets you set the word and fraction lengths used by the output data from filtering.
`OutputWordLength`	Determines the word length used for the output data.
`OverflowMode`	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either `saturate` (limit the output to the largest positive or negative representable value) or `wrap` (set overflowing values to the nearest representable value using modular arithmetic). The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow — they maintain full precision.
`PersistentMemory`	Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. `False` is the default setting.

Property Name	Brief Description
RoundMode	Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths). • ceil - Round toward positive infinity. • convergent - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software. • fix - Round toward zero. • floor - Round toward negative infinity. • nearest - Round toward nearest. Ties round toward positive infinity. • round - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers. The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.
Signed	Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.
States	This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. The states use fi objects, with the associated properties from those objects. For details, refer to filtstates in Signal Processing Toolbox documentation or in the Help system.

Examples

Create a direct-form I filter object hd_filt and a scalar object with a gain of 3 hd_gain and cascade them together.

```
b = [0.3 0.6 0.3];
a = [1 0 0.2];
hd_filt = dfilt.df1(b,a);
hd_gain = dfilt.scalar(3);
hd_cascade=cascade(hd_gain,hd_filt);
fvtool_handle = fvtool(hd_filt,hd_gain,hd_cascade);
legend(fvtool_handle,'IIR Filter (direct form I)',...
'Gain','Cascaded Filter');
```



To view the stages of the cascaded filter, use

```
hd.Stage(1)
```

and

```
hd.Stage(2)
```

See Also

`dfilt` | `dfilt.cascade`

dfilt.wdfallpass

Wave digital allpass filter

Syntax

```
hd = dfilt.wdfallpass(c)
```

Description

`hd = dfilt.wdfallpass(c)` constructs an allpass wave digital filter structure given the allpass coefficients in vector `c`.

Vector `c` must have, one, two, or four elements (filter coefficients). Filters with three coefficients are not supported. When you use `c` with four coefficients, the first and third coefficients must be 0.

Given the coefficients in `c`, the transfer function for the wave digital allpass filter is defined by

$$H(z) = \frac{c(n) + c(n-1)z^{-1} + \ldots + z^{-n}}{1 + c(1)z^{-1} + \ldots + c(n)z^{-n}}$$

Internally, the allpass coefficients are converted to wave digital filters for filtering. Note that `dfilt.wdfallpass` allows only stable filters. Also note that the leading coefficient in the denominator, a 1, does not need to be included in vector `c`.

Use the constructor `dfilt.cascadewdfallpass` to cascade `wdfallpass` filters.

To compare these filters to other similar filters, `dfilt.wdfallpass` and `dfilt.cascadewdfallpass` filters have the same number of multipliers as the non-wave digital filters `dfilt.allpass` and `dfilt.cascadeallpass`. However, the wave digital filters use fewer states and they may require more adders in the filter structure.

Wave digital filters are usually used to create other filters. This toolbox uses them to implement halfband filters, which the first example in Examples demonstrates. They are most often building blocks for filters.

Properties

In the next table, the row entries are the filter properties and a brief description of each property.

Property Name	Brief Description
`AllpassCoefficients`	Contains the coefficients for the allpass wave digital filter object
`FilterStructure`	Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering — gains, delays, sums, products, and input/output.
`PersistentMemory`	Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. `False` is the default setting.
`States`	This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. They also provide linkage between the sections of a multisection filter, such as a cascade filter. For details, refer to `filtstates` in Signal Processing Toolbox documentation or in the Help system.

Filter Structure

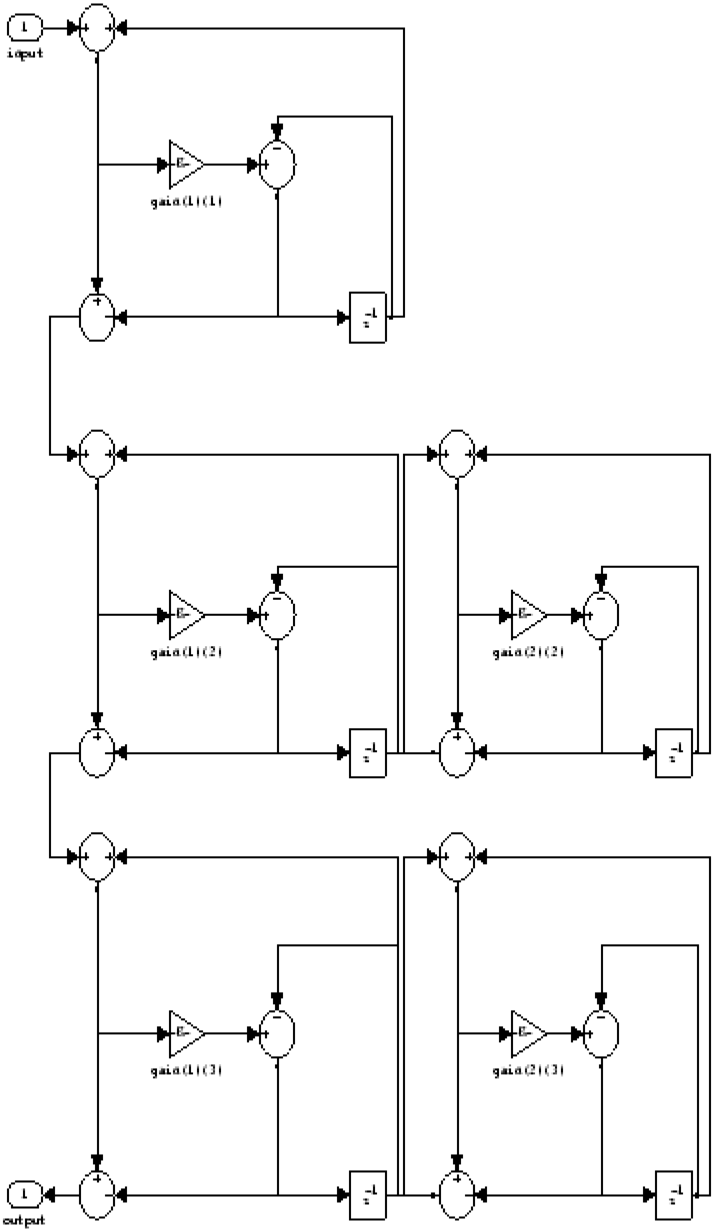
When you change the order of the wave digital filters in the cascade, the filter structure changes as well.

As shown in this example, `realizemdl` lets you see the filter structure used for your filter, if you have Simulink installed.

```
section11=0.8;
section12=[1.5,0.7];
section13=[1.8,0.9];
hd1=dfilt.cascadewdfallpass(section11,section12,section13);
```

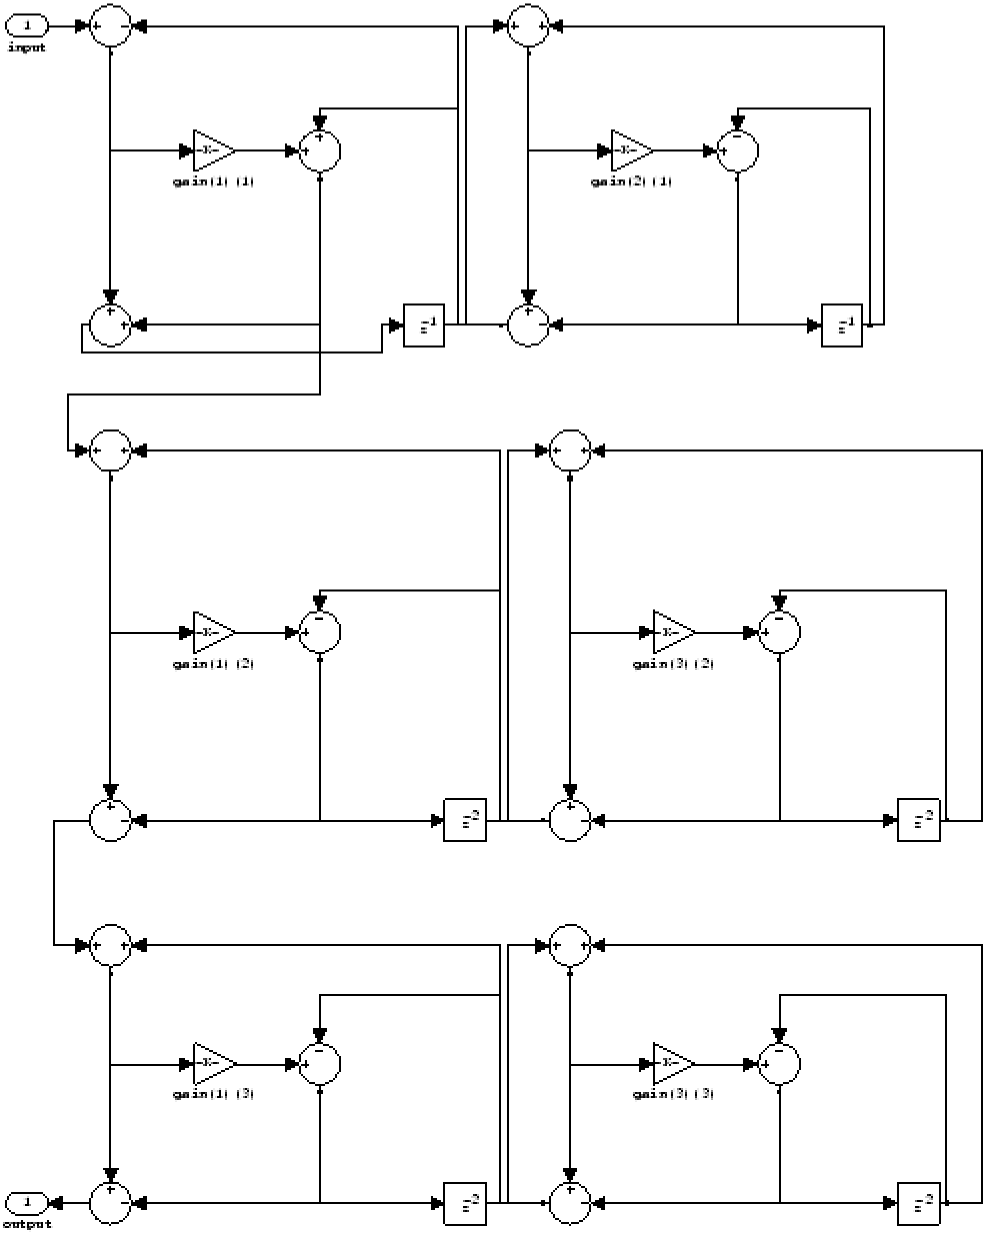
```
section21=[0.8,0.4];
section22=[0,1.5,0,0.7];
section23=[0,1.8,0,0.9];
hd2=dfilt.cascadewdfallpass(section21,section22,section23);
% If you have Simulink
realizemdl(hd2)
```

hd1 has this filter structure with three sections.



1
input
gain(1)(1)
gain(1)(2)
gain(2)(2)
gain(1)(3)
gain(2)(3)
1
output

The filter structure for hd2 is somewhat different, with the different orders and interconnections between the three sections.



1
input
-K-
gain(1)(1)
-K-
gain(2)(1)
z^{-1}
z^{-1}
-K-
gain(1)(2)
-K-
gain(3)(2)
z^{-2}
z^{-2}
-K-
gain(1)(3)
-K-
gain(3)(3)
z^{-2}
z^{-2}
1
output

Examples

Construct a second-order wave digital allpass filter with two coefficients. Note that to use `realizemdl`, you must have Simulink.

```
c = [1.5,0.7];
hd = dfilt.wdfallpass(c);
```

With Simulink installed, `realizemdl` returns this structure for `hd`.

disp

Filter properties and values

Syntax

```
disp(h)
```

Description

disp(h) lists the property names and property values for any filter object, such as a dfilt object or adaptfilt object. Similar to omitting the closing semicolon from an expression on the command line, except that disp does not display the variable name.

The following examples illustrate the default display for an adaptive filter ha and a multirate filter hm.

```
ha=adaptfilt.rls;
fprintf('Displaying properties for default RLS adaptive filter:\n');
fprintf('\n');
disp(ha)
pause(2);
hm=mfilt.cicdecim(6);
fprintf('Displaying properties for cascaded integrator-comb decimator\n');
fprintf('with a decimation factor of 6:\n');
fprintf('\n');
disp(hm)
```

See Also

set

double

Cast fixed-point filter to use double-precision arithmetic

Syntax

```
hd = double(h)
```

Description

`hd = double(h)` returns a new filter `hd` that has the same structure and coefficients as `h`, but whose arithmetic property is set to `double` to use double-precision arithmetic for filtering. `double(h)` is not the same as the `reffilter(h)` function:

- `hd`, the filter returned by `double` has the quantized coefficients of `h` represented in double-precision floating-point format
- The reference filter returned by `reffilter` has double-precision, floating-point coefficients that have not been quantized.

You might find `double(h)` useful to isolate the effects of quantizing the coefficients of a filter by using `double` to create a filter `hd` that operates in double-precision but uses the quantized filter coefficients.

Examples

Use the same filter, once with fixed-point arithmetic and once with floating-point, to compare fixed-point filtering with double-precision floating-point filtering.

```
h = dfilt.dffir(firgr(27,[0 .4 .6 1],...
[1 1 0 0]));                  % Lowpass filter.
% Set h to use fixed-point arithmetic to filter.
% Quantize the coeffs.
h.arithmetic = 'fixed';
% Cast h to double-precision
hd = double(h);
% Set up an input signal.
n = 0:99; x = sin(0.7*pi*n(:));
```

```
y = filter(h,x);                    % Fixed-point output.
yd = filter(hd,x);                  % Floating-point output.
FixedFloatNormDiff=norm(yd-double(y),inf);
```

`reffilter`

dsp.util.getLogsArray

Package: dsp.util

Return logged signal as MATLAB array

Syntax

```
Array = dsp.util.getLogsArray(LogObject,Format2D,'SignalPath',PATH)
Array = dsp.util.getLogsArray(LogObject,Format2D,'SignalName',NAME)
```

Description

`Array = dsp.util.getLogsArray(LogObject,Format2D,'SignalPath',PATH)` returns a MATLAB array that contains a signal in LogObject. You must specify the PATH to the signal in LogObject using the Name,Value pair argument.

`Array = dsp.util.getLogsArray(LogObject,Format2D,'SignalName',NAME)` returns a MATLAB array that contains a signal in LogObject. You must specify the NAME of the signal in LogObject using the Name,Value pair argument.

Input Arguments

`LogObject`

Specify the name of the object that contains your logged signals. Valid classes for LogObject depend on the syntax you use:

- When you specify PATH as a `dsp.util.SignalPath` object, LogObject can be either a `Simulink.SimulationData.Dataset` or `Simulink.SimulationData.Signal` object.
- When you specify PATH as the full path to a block in a Simulink model, LogObject must be a `Simulink.SimulationData.Dataset` object.
- When you specify the NAME of a signal in LogObject, LogObject can be an object of class `timeseries`, `Simulink.SimulationData.Dataset`, or `Simulink.SimulationData.Signal`.

Format2D

Specify a logical value to determine whether the function formats 3-D logged signals as a 2-D or 3-D MATLAB array. When you set this property to `true`, the function uses the following formula to format the 3-D logged signal into a 2-D MATLAB array:

```
dim = size(signal);
ntimes = dim(1)*dim(3);
Array = reshape(permute(signal,[1 3 2]),[ntimes dim(2)]);
```

When you set this property to `false`, the function returns the logged signal without any reformatting.

PATH

Specify the path to the logged signal in LogObject. You can specify the path using a `dsp.util.SignalPath` object, or you can provide the full path to a block in your Simulink model. To get the full path to a block in your Simulink model, use the `gcb` command.

NAME

Specify the name of the signal in LogObject.

Output Arguments

Array

The output Array is a MATLAB array that contains the specified logged signal. When the input is a 3-D logged signal, the dimensions of Array depend on the value you specify for Format2D:

- When Format2D is `true`, Array is a 2-D MATLAB array.
- When Format2D is `false`, Array is a 3-D MATLAB array.

When the input is not a 3-D signal, the dimensions of the output Array match those of the input.

Examples

Note: To run the following examples, you must first load ex_logsout.mat which contains a `Simulink.SimulationData.Dataset` object. Alternatively, you can open and simulate the ex_log_utils Simulink model. Doing so will log signals and generate the necessary `ex_logsout` object.

Extract a unique signal named Signal3x4 from ex_logsout.

```
dsp.util.getLogsArray(ex_logsout, true, 'SignalName','Signal3x4')
```

Extract a unique signal named Signal3x4 from ex_logsout as a 3-D array.

```
dsp.util.getLogsArray(ex_logsout, false, 'SignalName','Signal3x4')
```

Find and extract a specific signal from multiple signals that have the same name.

Because `ex_logsout` contains multiple signals named `Signal2x4`, you must use the `dsp.util.getSignalPath` function to find the paths to each of those signals.

```
paths = dsp.util.getSignalPath(ex_logsout, 'Signal2x4')
% paths is a 2x1 array of dsp.util.SignalPath objects. Next, examine
% the BlockPath property of each paths object.
paths.BlockPath
% Find the signal path that corresponds to the logged signal you are
% interested in. For example paths(2). You can then use the
% dsp.util.getLogsArray function and provide the 'SignalPath' name-value
% pair argument.
dsp.util.getLogsArray(ex_logsout, true, 'SignalPath', paths(2))
```

Find and extract a signal from a bus.

Use the `dsp.util.getSignalPath` function to get paths to all the signals in the bus named `Bus1`.

```
buspaths = dsp.util.getSignalPath(ex_logsout, 'Bus1')
% buspaths is a 2x1 array of dsp.util.SignalPath objects. Examine the
% BusElement property of each buspaths object.
buspaths.BusElement
% Select a signal path. For example buspaths(1). This is the path to the
% signal named 'Signal3x4' in bus 'Bus' that is contained in bus 'Bus1'.
% Now that you have the path to the signal, call dsp.util.getLogsArray
% using the 'SignalPath' name-value pair argument.
dsp.util.getLogsArray(ex_logsout, true, 'SignalPath', buspaths(1))
```

dsp.util.getSignalPath

Package: dsp.util

Paths to logged signals

Syntax

```
Path = dsp.util.getSignalPath(LogObject, SignalName)
```

Description

`Path = dsp.util.getSignalPath(LogObject, SignalName)` returns all paths to signals in LogObject with name SignalName. The output Path is a `dsp.util.SignalPath` object or an array of `dsp.util.SignalPath` objects.

Input Arguments

`LogObject`

Specify the name of the object that contains your logged signals. LogObject must be a `Simulink.SimulationData.Dataset` or `Simulink.SimulationData.Signal` object.

`SignalName`

Specify the name of a logged signal in LogObject.

Output Arguments

`Path`

The output Path contains the path to all signals named SignalName in LogObject.

- If LogObject contains a unique signal with name SignalName, the function returns a single dsp.util.SignalPath object.
- If LogObject contains more than one signal with the specified name, the function returns an array of dsp.util.SignalPath objects.

Examples

Note: To run the following examples, you must first load ex_logsout.mat which contains a Simulink.SimulationData.Dataset object. Alternatively, you can open and simulate the ex_log_utils Simulink model. Doing so will log signals and generate the necessary ex_logsout object.

Find and extract a specific signal from multiple signals that have the same name.

Because ex_logsout contains multiple signals named Signal2x4, you must use the dsp.util.getSignalPath function to find the paths to each of those signals.

```
paths = dsp.util.getSignalPath(ex_logsout, 'Signal2x4')
% paths is a 2x1 array of dsp.util.SignalPath objects. Next, examine
% the BlockPath property of each paths object.
paths.BlockPath
% Find the signal path that corresponds to the logged signal you are
% interested in. For example paths(2). You can then use the
% dsp.util.getLogsArray function and provide the 'SignalPath' name-value
% pair argument.
dsp.util.getLogsArray(ex_logsout, true, 'SignalPath', paths(2))
```

Find and extract a signal from a bus.

Use the dsp.util.getSignalPath function to get paths to all the signals in the bus named Bus1.

```
buspaths = dsp.util.getSignalPath(ex_logsout, 'Bus1')
% buspaths is a 2x1 array of dsp.util.SignalPath objects. Examine the
% BusElement property of each buspaths object.
buspaths.BusElement
% Select a signal path. For example buspaths(1). This is the path to the
% signal named 'Signal3x4' in bus 'Bus' that is contained in bus 'Bus1'.
% Now that you have the path to the signal, call dsp.util.getLogsArray
% using the 'SignalPath' name-value pair argument.
dsp.util.getLogsArray(ex_logsout, true, 'SignalPath', buspaths(1))
```

More About

Tips

- To return the path to an unnamed signal in LogObject, set SignalName to the empty string ('').

- "Export Signal Data Using Signal Logging"
- "Configure a Signal for Logging"
- "Specify the Signal Logging Data Format"

dsp.util.SignalPath class

Package: dsp.util

Properties of paths to signals

Description

`dsp.util.SignalPath` objects contain path information for signals in `Simulink.SimulationData.Dataset` objects. You get `Simulink.SimulationData.Dataset` objects when you use `Dataset` logging to log signals from a Simulink model.

Construction

`dsp.util.SignalPath` objects are returned by the `dsp.util.getSignalPath` function and can be used as input to the `dsp.util.getLogsArray` function.

Properties

`SignalName`

Contains the name of the signal output by the block at the specified BlockPath.

`BlockPath`

Provides the `Simulink.SimulationData.BlockPath` to the block in the Simulink model from which the signal originates.

`PortIndex`

Provides the output port index of the block from which the logged signal SignalName originates.

`BusElement`

Provides a string description of a signal in a logged bus. When SignalPath is not a logged bus, this property will be an empty string.

If the SignalPath object is a logged bus signal, the BusElement string will be formatted as follows:

- When the bus contains a nonbus signal, BusElement is the name of that signal.
- When the bus contains a nested bus that contains a nonbus signal, BusElement will be a dot-separated string consisting of the name of the nested bus followed by the name of the non-bus signal. For example: `nestbus.signal1`
- When the bus contains nested busses within nested busses to any depth, BusElement will be a dot-separated string. This string contains each of the nested bus names, and ends with the nonbus signal name. For example: `outernestedbus.innernestedbus.signal1`

dsp_links

Identify whether blocks in model are current, deprecated, or obsolete

Syntax

```
dsp_links
dsp_links('modelname')
```

Description

`dsp_links` returns a structure with three elements that identify whether the DSP System Toolbox blocks in the current model are current, deprecated, or obsolete. Each element is one of the three block categories and contains a cell array of strings. Each string is the name of a library block in the current model.

`dsp_links('modelname')` returns the three-element structure for the specified model.

Examples

Display block support information for the specified model, and then find the name of the first current block:

```
sys = 'dspcochlear';
load_system(sys)     % Load the dspcochlear model
links = dsp_links(sys) % Run dsp_links on the model
links.current{1}     % Find the name of the first current block
```

More About

Obsolete Blocks

Obsolete blocks are blocks that the toolbox no longer supports. In some cases, these blocks no longer function properly.

Deprecated Blocks

Deprecated blocks are blocks that the toolbox still supports but are likely to become obsolete in a future release. Refer to the block reference page for suggested replacements.

Current Blocks

Current blocks are blocks that the toolbox supports and that represent the latest block functionality.

See Also

`liblinks`

dsplib

Open top-level DSP System Toolbox library

Syntax

```
dsplib
```

Description

`dsplib` opens the top-level DSP System Toolbox block library model.

Examples

View and gain access to the DSP System Toolbox blocks:

```
dsplib
```

Alternatives

To view and gain access to the DSP System Toolbox blocks using the Simulink library browser:

- Type `simulink` at the MATLAB command line, and then expand the DSP System Toolbox node in the library browser.
- Click the Simulink icon from the MATLAB Toolstrip.

dspstartup

Configure Simulink environment for signal processing systems

Syntax

```
dspstartup
```

Description

`dspstartup` configures Simulink environment parameters with settings appropriate for a typical signal processing project. You can use the `dspstartup` function in the following ways:

- At the MATLAB command line. Doing so configures the Simulink environment in your current session for signal processing projects.
- By adding a call to the `dspstartup` function from your `startup.m` file. When you do so, MATLAB configures your Simulink environment for typical signal processing projects each time you launch MATLAB.

When the function successfully configures your Simulink environment, MATLAB displays the following message in the command window.

```
Changed default Simulink settings for signal processing
systems (dspstartup.m).
```

The `dspstartup.m` file executes the following commands.

```
set_param(0, ...
          'SingleTaskRateTransMsg','error', ...
          'multiTaskRateTransMsg', 'error', ...
          'Solver',                'fixedstepdiscrete', ...
          'SolverMode',            'SingleTasking', ...
          'StartTime',             '0.0', ...
          'StopTime',              'inf', ...
          'FixedStep',             'auto', ...
          'SaveTime',              'off', ...
          'SaveOutput',            'off', ...
          'AlgebraicLoopMsg',      'error', ...
```

```
         'SignalLogging',         'off');
```

Examples

Add a call to the `dspstartup` function from your `startup.m` file:

1. To find out if there is a `startup.m` file on your MATLAB path, run the following code at the MATLAB command line:

   ```
   which startup.m
   ```

2. If MATLAB returns `'startup.m' not found`, see "Startup Options" in the MATLAB documentation to learn more about the `startup.m` file.

   If MATLAB returns a path to your `startup.m` file, open that file for editing.

   ```
   edit startup.m
   ```

3. Add a call to the `dspstartup` function. Your `startup.m` file now resembles the following code sample:

   ```
   %STARTUP   Startup file
   %   This file is executed when MATLAB starts up, if it exists
   %   anywhere on the path.  In this case, the startup.m file
   %   runs the dspstartup.m file to configure the Simulink
   %   environment with settings appropriate for typical
   %   signal processing projects.

   dspstartup;
   ```

ellip

Elliptic filter using specification object

Syntax

```
hd = design(d,'ellip')
hd = design(d,'ellip',designoption,value,designoption,...
value,...)
```

Description

`hd = design(d,'ellip')` designs an elliptical IIR digital filter using the specifications supplied in the object `h`.

`hd = design(d,'ellip',designoption,value,designoption,... value,...)` returns an elliptical or Cauer FIR filter where you specify design options as input arguments.

To determine the available design options, use `designopts` with the specification object and the design method as input arguments as shown.

```
designopts(d,'method')
```

For complete help about using `ellip`, refer to the command line help system. For example, to get specific information about using `ellip` with `d`, the specification object, enter the following at the MATLAB prompt.

```
help(d,'ellip')
```

Examples

These examples demonstrate how to use `ellip` to design filters based on filter specification objects.

Example 1

Construct the default bandpass filter specification object and design an elliptic filter.

```
d = fdesign.bandpass;
hd = design(d,'ellip','matchexactly','both');
```

Example 2

Construct a lowpass object with order, passband-edge frequency, stopband-edge frequency, and passband ripple specifications, and then design an elliptic filter.

```
d = fdesign.lowpass('n,fp,fst,ap',6,20,25,.8,80);
design(d,'ellip'); % Starts FVtool to display the filter.

`butter` | `cheby1` | `cheby2`

euclidfactors

Euclid factors for multirate filter

Syntax

```
[lo,mo] = euclidfactors(hm)
```

Description

`[lo,mo] = euclidfactors(hm)` returns integer factors `lo` and `mo` such that (`lo`*L)-(`mo`*M) = -1. L and M are relatively prime and represent the interpolation and decimation factors of the multirate filter `hm`.

`euclidfactors` works with the multirate filters `mfilt.firfracdecim` and `mfilt.firfracinterp`. You cannot return `lo` and `mo` for decimators or interpolators.

Examples

Use an FIR fractional decimator, with L = 5 and M = 7, to show what `euclidfactors` does.

Indeed, (`lo`*L)-(`mo`*M) = (4*5)-(3*7) = -1.

See Also

`polyphase` | `nstates`

equiripple

Equiripple single-rate or multirate FIR filter from specification object

Syntax

```
hd = design(d,'equiripple')
hd = design(d,'equiripple',designoption,value,designoption,
...value,...)
```

Description

`hd = design(d,'equiripple')` designs an equiripple FIR digital filter or multirate filter using the specifications supplied in the object `d`. Equiripple filter designs minimize the maximum ripple in the passbands and stopbands.

`hd` is either a `dfilt` object (a single-rate digital filter) or an `mfilt` object (a multirate digital filter) depending on the `Specification` property of the filter specification object `d` and the specifications object type — halfband or interpolator.

When you use `equiripple` with Nyquist filter specification objects, you might encounter design cases where the filter design does not converge. Convergence errors occur mostly at large filter orders, or small transition widths, or large stopband attenuations. These specifications, alone or combined, can cause design failures. For more information, refer to `fdesign.nyquist` in the online Help system.

`hd = design(d,'equiripple',designoption,value,designoption,
...value,...)` returns an equiripple FIR filter where you specify design options as input arguments.

To determine the available design options, use `designopts` with the specification object and the design method as input arguments as shown.

```
designopts(d,'method')
```

For complete help about using `equiripple`, refer to the command line help system. For example, to get specific information about using `equiripple` with `d`, the specification object, enter the following at the MATLAB prompt.

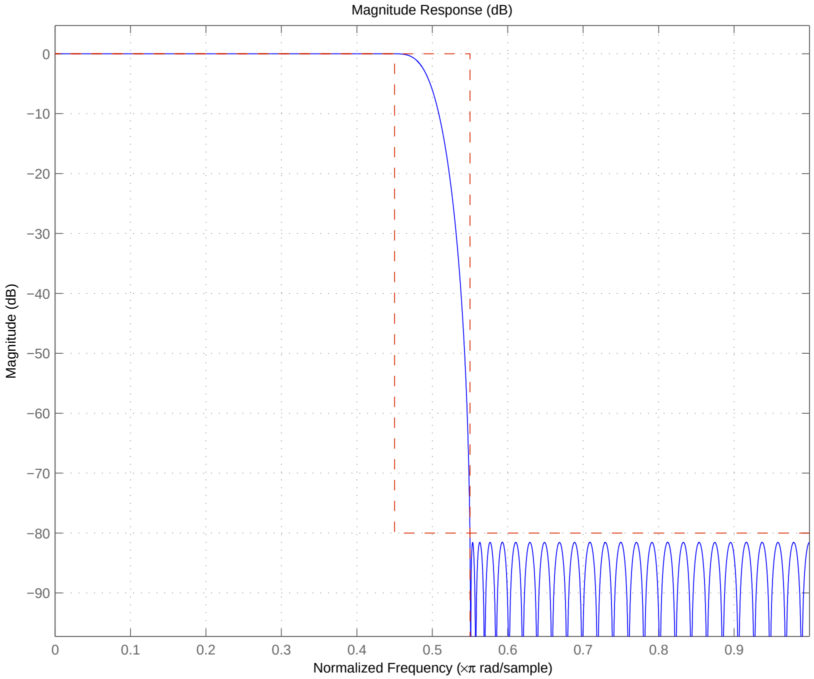
```
help(d,'equiripple')
```

Examples

Here is an example of designing a single-rate equiripple filter from a halfband filter specification object. Notice the `help` command used to learn about the options for the specification object and method.

```
d = fdesign.halfband('tw,ast',0.1,80);
designmethods(d)
help(d,'equiripple')
designopts(d,'equiripple')
hd = design(d,'equiripple','stopbandshape','flat');
fvtool(hd);
```

Displaying the filter in FVTool shows the equiripple nature of the filter.



`equiripple` also designs multirate filters. This example generates a halfband interpolator filter.

```
d = fdesign.interpolator(2); % Interpolation factor = 2.
hd = design(d,'equiripple');
```

This final example designs an equiripple filter with a direct-form structure by specifying the **`filterstructure`** argument. To set the design options for the filter, use the `designopts` method and options object `opts`.

```
d = fdesign.lowpass('fp,fst,ap,ast');
opts=designopts(d,'equiripple')
opts.FilterStructure='dffirt'
opts.MinPhase=1;
opts.DensityFactor=20;
opts
hd=design(d,'equiripple',opts)
```

Note: The `MaxPhase` design option for equripple FIR filters is currently only available for lowpass, highpass, bandpass, and bandstop filters.

fcfwrite

Write file containing filter coefficients

Syntax

```
fcfwrite(h)
fcfwrite(h,filename)
fcfwrite(...,'fmt')
```

Description

`fcfwrite(h)` writes a filter coefficient ASCII file in a folder you choose, or your current MATLAB working folder. `h` can be a single filter object or a vector of filter objects. On execution, `fcfwrite` opens the **Export Filter Coefficients to .FCF File** dialog box to let you assign a file name for the output file. You can choose the destination folder within this dialog as well.

The default file name is `untitled.fcf`. When you have DSP System Toolbox software, you can use `fcfwrite(h)` to write filter coefficient files for multirate filters, adaptive filters, and discrete-time filters.

`fcfwrite(h,filename)` writes the filter coefficients and general information to a text file called `filename` in your present MATLAB working folder and opens the file in the MATLAB editor for you to review or modify.

If you do not include a file extension in `filename`, `fcfwrite` adds the extension `fcf` to `filename`.

`fcfwrite(...,'fmt')` writes the filter coefficients in the format specified by the input argument `fmt`. Valid `fmt` values are `hex` for hexadecimal, `dec` for decimal, or `bin` for binary representation of the filter coefficients.

Examples

To demonstrate `fcfwrite`, create a fixed-point IIR filter at the command line, and then write the filter coefficients to a file named `iirfilter.fcf`.

```
d=fdesign.lowpass;
hd=design(d,'butter');
set(hd,'arithmetic','fixed');
fcfwrite(hd,'iirfilter.fcf');
```

Here is the output from `fcfwrite` as it appears in the MATLAB editor. Not shown here is the filename — `iirfilter.fcf` as specified and some comments at the top of the file.

```

fdatool

Open Filter Design and Analysis Tool

Syntax

```
fdatool
```

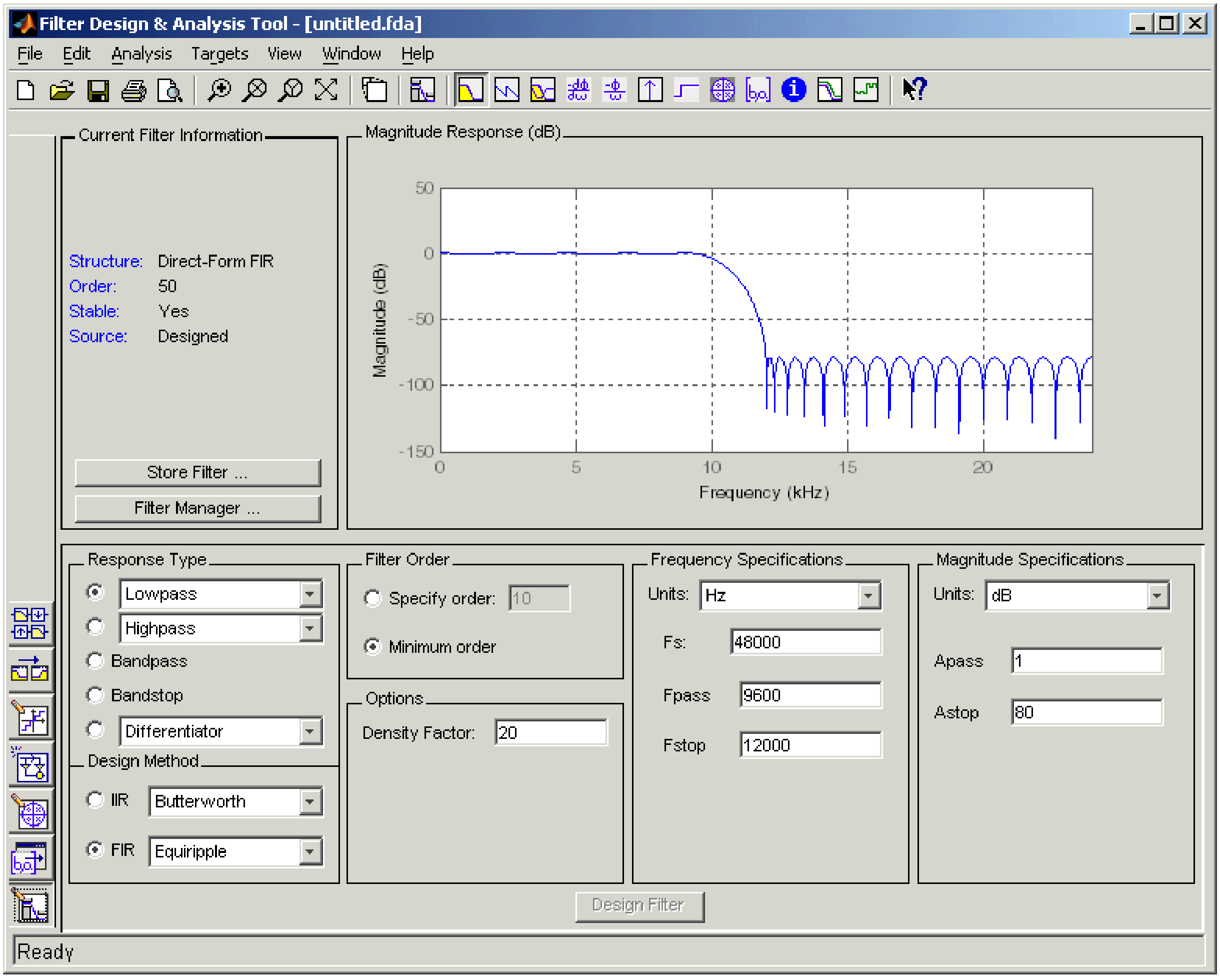
Description

`fdatool` opens the Filter Design and Analysis Tool (FDATool). Use this tool to:

- Design filters
- Quantize filters (with DSP System Toolbox software installed)
- Analyze filters
- Modify existing filter designs
- Create multirate filters (with DSP System Toolbox software installed)
- Realize Simulink models of quantized, direct-form, FIR filters (with DSP System Toolbox software installed)
- Perform digital frequency transformations of filters (with DSP System Toolbox software installed)

Refer to “Use FDATool with DSP System Toolbox Software” for more information about using the analysis, design, and quantization features of FDATool. For general information about using FDATool, refer to “Using FDATool”.

When you open FDATool and you have DSP System Toolbox software installed, FDATool incorporates features that are added by DSP System Toolbox software. With DSP System Toolbox software installed, FDATool lets you design and analyze quantized filters, as well as convert quantized filters to various filter structures, transform filters, design multirate filters, and realize models of filters.



Current Filter Information

Astop 80

Ready

Use the buttons on the sidebar to configure the design area to use various tools in FDATool.

Set Quantization Parameters — provides access to the properties of the quantizers that compose a quantized filter. When you click **Set Quantization Parameters**, you see FDATool displaying the quantization options at the bottom of the dialog box (the design area), as shown in the figure.

Transform Filter — clicking this button opens the *Frequency Transformations* pane so you can use digital frequency transformations to change the magnitude response of your filter.

Create a multirate filter — clicking this button switches FDATool to multirate filter design mode so you can design interpolators, decimators, and fractional rate change filters.

Realize Model — starting from your quantized, direct-form, FIR filter, clicking this button creates a Simulink model of your filter structure in new model window.

fdesign

Filter specification object

Syntax

```
d = fdesign.response
d = fdesign.response(spec)
d = fdesign.response(...,Fs)
d = fdesign.response(...,magunits)
```

Description

Filter Specification Objects

`d = fdesign.`*`response`* returns a filter specification object `d`, of filter response *`response`*. To create filters from `d`, use one of the design methods listed in “Using Filter Design Methods with Specification Objects” on page 4-440

Note: Several of the filter response types described below are only available if your installation includes the DSP System Toolbox. The DSP System Toolbox significantly expands the functionality available for the specification, design, and analysis of filters.

Here is how you design filters using `fdesign`.

1. Use `fdesign.`*`response`* to construct a filter specification object.
2. Use `designmethods` to determine which filter design methods work for your new filter specification object.
3. Use `design` to apply your filter design method from step 2 to your filter specification object to construct a filter object.
4. Use FVTool to inspect and analyze your filter object.

Note `fdesign` does not create filters. `fdesign` returns a filter specification object that contains the specifications for a filter, such as the passband cutoff or attenuation in the stopband. To design a filter hd from a filter specification object d, use d with a filter design method such as butter —hd = design(d,'butter').

response can be one of the entries in the following table that specify the filter response desired, such as a bandstop filter or an interpolator.

fdesign Response String	Description
arbgrpdelay	fdesign.arbgrpdelay creates an object to specify allpass arbitrary group delay filters. Requires the DSP System Toolbox
arbmag	fdesign.arbmag creates an object to specify IIR filters that have arbitrary magnitude responses defined by the input arguments.
arbmagnphase	fdesign.arbmagnphase creates an object to specify IIR filters that have arbitrary magnitude and phase responses defined by the input arguments. Requires the DSP System Toolbox.
audioweighting	fdesign.audioweighting creates a filter specification object for audio weighting filters. The supported audio weighting types are: A, C, C-message, ITU-T 0.41, and ITU-R 468-4 weighting. Requires the DSP System Toolbox
bandpass	fdesign.bandpass creates an object to specify bandpass filters.
bandstop	fdesign.bandstop creates an object to specify bandstop filters.
ciccomp	fdesign.ciccomp creates an object to specify filters that compensate for the CIC decimator or interpolator response curves. Requires the DSP System Toolbox.
comb	fdesign.comb creates an object to specify a notching or peaking comb filter. Requires the DSP System Toolbox.
decimator	fdesign.decimator creates an object to specify decimators. Requires the DSP System Toolbox
differentiator	fdesign.differentiator creates an object to specify an FIR differentiator filter.

fdesign Response String	Description
`fracdelay`	`fdesign.fracdelay` creates an object to specify fractional delay filters. Requires the DSP System Toolbox.
`halfband`	`fdesign.halfband` creates an object to specify halfband filters. Requires the DSP System Toolbox.
`highpass`	`fdesign.highpass` creates an object to specify highpass filters.
`hilbert`	`fdesign.hilbert` creates an object to specify an FIR Hilbert transformer.
`interpolator`	`fdesign.interpolator` creates an object to specify interpolators. Requires the DSP System Toolbox.
`isinchp`	`fdesign.isinchp` creates an object to specify an inverse sinc highpass filter. Requires the DSP System Toolbox.
`isinclp`	`fdesign.isinclp` creates an object to specify an inverse sinc lowpass filters. Requires the DSP System Toolbox.
`lowpass`	`fdesign.lowpass` creates an object to specify lowpass filters.
`notch`	`fdesign.notch` creates an object to specify notch filters. Requires the DSP System Toolbox.
`nyquist`	`fdesign.nyquist` creates an object to specify nyquist filters. Requires the DSP System Toolbox.
`octave`	`fdesign.octave` creates an object to specify octave and fractional octave filters. Requires the DSP System Toolbox.
`parameq`	`fdesign.parameq` creates an object to specify parametric equalizer filters. Requires the DSP System Toolbox.
`peak`	`fdesign.peak` creates an object to specify peak filters. Requires the DSP System Toolbox.
`polysrc`	`fdesign.polysrc` creates an object to specify polynomial sample-rate converter filters. Requires the DSP System Toolbox.
`rsrc`	`fdesign.rsrc` creates an object to specify rational-factor sample-rate convertors. Requires the DSP System Toolbox.

Use the `doc fdesign.`*`response`* syntax at the MATLAB prompt to get help on a specific structure. Using `doc` in a syntax like

```
doc fdesign.lowpass
doc fdesign.bandstop
```

gets more information about the lowpass or bandstop structure objects.

Each `response` has a property `Specification` that defines the specifications to use to design your filter. You can use defaults or specify the `Specification` property when you construct the specifications object.

With the strings for the `Specification` property, you provide filter constraints such as the filter order or the passband attenuation to use when you construct your filter from the specification object.

Properties

`fdesign` returns a filter specification object. Every filter specification object has the following properties.

Property Name	Default Value	Description
`Response`	Depends on the chosen type	Defines the type of filter to design, such as an interpolator or bandpass filter. This is a read-only value.
`Specification`	Depends on the chosen type	Defines the filter characteristics used to define the desired filter performance, such as the cutoff frequency `Fc` or the filter order `N`.
`Description`	Depends on the filter type you choose	Contains descriptions of the filter specifications used to define the object, and the filter specifications you use when you create a filter from the object. This is a read-only value.
`NormalizedFrequency`	Logical `true`	Determines whether the filter calculation uses normalized frequency from 0 to 1, or the

Property Name	Default Value	Description
		frequency band from 0 to Fs/2, the sampling frequency. Accepts either `true` or `false` without single quotation marks. Audio weighting filters do not support normalized frequency.

In addition to these properties, filter specification objects may have other properties as well, depending on whether they design `dfilt` objects or `mfilt` objects.

Added Properties for mfilt Objects	Description
`DecimationFactor`	Specifies the amount to decrease the sampling rate. Always a positive integer.
`InterpolationFactor`	Specifies the amount to increase the sampling rate. Always a positive integer.
`PolyphaseLength`	Polyphase length is the length of each polyphase subfilter that composes the decimator or interpolator or rate-change factor filters. Total filter length is the product of `pl` and the rate change factors. `pl` must be an even integer.

`d = fdesign.`*`response`*`(spec)`. In `spec`, you specify the variables to use that define your filter design, such as the passband frequency or the stopband attenuation. The specifications are applied to the filter design method you choose to design your filter.

For example, when you create a default lowpass filter specification object, `fdesign.lowpass` sets the passband frequency `Fp`, the stopband frequency `Fst`, the stopband attenuation `Ast`, and the passband ripple `Ap` :

```
H = fdesign.lowpass
% Use without a terminating semicolon
% to display the filter specifications
```

The default specification `'Fp,Fst,Ap,Ast'` is only one of the possible specifications for `fdesign.lowpass`. To see all available specifications:

```
H = fdesign.lowpass;
set(H,'specification')
```

The DSP System Toolbox software supports all available specification strings. The Signal Processing Toolbox supports a subset of the specification strings. See the reference pages for the filter specification object to determine which specification strings your installation supports.

One important note is that the specification string you choose determines which design methods apply to the filter specifications object.

Specifications that do not contain the filter order result in minimum order designs when you invoke the `design` method:

```
d = fdesign.lowpass;
% Specification is Fp,Fst,Ap,Ast
Hd = design(d,'equiripple');
length(Hd.Numerator) % Returns 43
% Filter order is 42
fvtool(Hd) % View magnitude
```

`d = fdesign.`*`response`*`(...,Fs)` specifies the sampling frequency in Hz to use in the filter specifications. The sampling frequency is a scalar trailing all other input arguments. If you specify a sampling frequency, all frequency specifications are in Hz.

`d = fdesign.`*`response`*`(...,magunits)` specifies the units for any magnitude specification you provide in the input arguments. `magunits` can be one of the following strings:

- `'linear'` — specify the magnitude in linear units
- `'dB'` — specify the magnitude in decibels
- `'squared'` — specify the magnitude in power units

When you omit the `magunits` argument, `fdesign` assumes that all magnitudes are in decibels. Note that `fdesign` stores all magnitude specifications in decibels (converting to decibels when necessary) regardless of how you specify the magnitudes.

Using Filter Design Methods with Specification Objects

After you create a filter specification object, you use a filter design method to implement your filter with a selected algorithm. Use `designmethods` to determine valid design methods for your filter specification object.

```
d = fdesign.lowpass('N,Fc,Ap,Ast',10,0.2,0.5,40);
```

```
designmethods(d)
% Design FIR equiripple filter
hd = design(d,'equiripple');
```

When you use any of the design methods without providing an output argument, the resulting filter design appears in FVTool by default.

Along with filter design methods, `fdesign` works with supporting methods that help you create filter specification objects or determine which design methods work for a given specifications object.

Supporting Function	Description
`setspecs`	Set all of the specifications simultaneously.
`designmethods`	Return the design methods.
`designopts`	Return the input arguments and default values that apply to a specifications object and method

You can set filter specification values by passing them after the `Specification` argument, or by passing the values without the `Specification` string.

Filter object constructors take the input arguments in the same order as `setspecs` and the order in the strings for `Specification`. Enter `doc setspecs` at the prompt for more information about using `setspecs`.

When the first input to `fdesign` is not a valid `Specification` string like '`n,fc`', `fdesign` assumes that the input argument is a filter specification and applies it using the default `Specification` string —`fp,fst,ap,ast` for a lowpass object, for example.

Examples

The following examples require only the Signal Processing Toolbox.

Example 1–Bandstop Filter

A bandstop filter specification object for data sampled at 8 kHz. The stopband between 2 and 2.4 kHz is attenuated at least 80 dB:

```
H = fdesign.bandstop('Fp1,Fst1,Fst2,Fp2,Ap1,Ast,Ap2',...
           1600,2000,2400,2800,1,80,1,8000);
```

Example 2–Lowpass Filter

A lowpass filter specification object for data sampled at 10 kHz. The passband frequency is 500 Hz and the stopband frequency is 750 Hz. The passband ripple is set to 1 dB and the required attenuation in the stopband is 80 dB.

```
H = fdesign.lowpass('Fp,Fst,Ap,Ast',500,750,1,80,10000);
```

Example 3–Highpass Filter

A default highpass filter specification object.

```
H = fdesign.highpass % Creates specifications object.
H.Description
```

Notice the correspondence between the property values in `Specification` and `Description` — in `Description` you see in words the definitions of the variables shown in `Specification`.

Example 4--Lowpass Butterworth Filter Specification and Design

Use a filter specification object to construct a lowpass Butterworth filter with the default `Specification`, `'Fp,Fst,Ap,Ast'`. Set the passband edge frequency to 0.4π rad/sample, the stopband frequency to 0.5π rad/sample, the passband ripple to 1 dB, and the stopband attenuation to 80 dB.

```
d = fdesign.lowpass(0.4,0.5,1,80);
```

Determine which design methods apply to `d`.

```
designmethods(d)
```

```

Design Methods for class fdesign.lowpass (Fp,Fst,Ap,Ast):

butter
cheby1
cheby2
ellip
equiripple
```

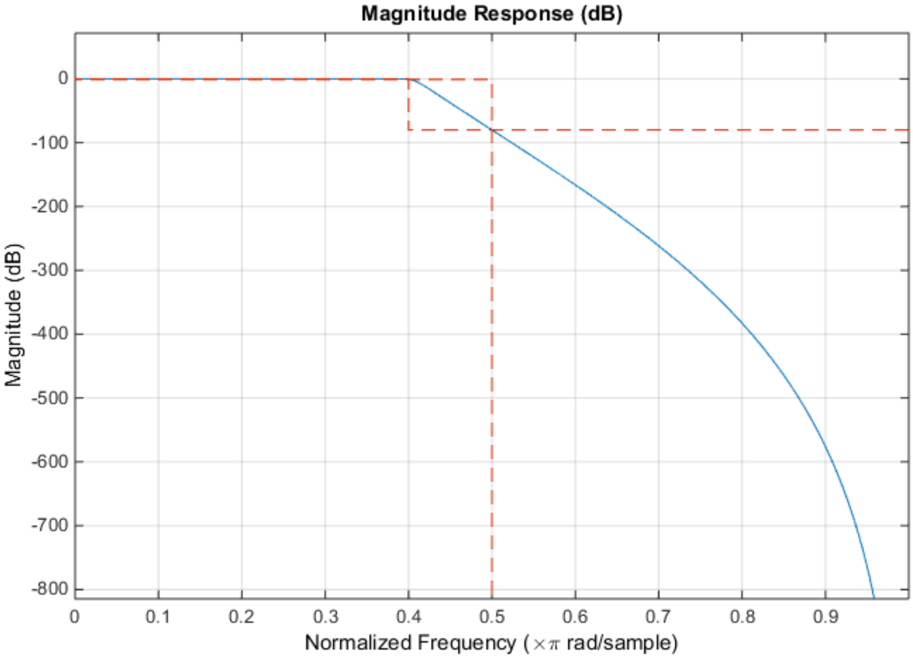
```
ifir
kaiserwin
multistage
```

You can use `d` and the `butter` design method to design a Butterworth filter.

```
hd = design(d,'butter','matchexactly','passband');
```

The resulting filter magnitude response shown by FVTool appears in the following figure.

```
fvtool(hd);
```



If you have the DSP System Toolbox™ software installed, the preceding figure appears with the filter specification mask.

fdesign.arbgrpdelay

Arbitrary group delay filter specification object

Syntax

```
D = fdesign.arbgrpdelay(SPEC)
D = fdesign.arbgrpdelay(SPEC,SPEC1,SPEC2,...)
D = fdesign.arbgrpdelay(N,F,Gd)
D = fdesign.arbgrpdelay(...,Fs)
```

Description

Arbitrary group delay filters are allpass filters you can use for correcting phase distortion introduced by other filters. `fdesign.arbgrpdelay` uses an iterative least *p*-th norm optimization procedure to minimize the phase response error [1].

`D = fdesign.arbgrpdelay(SPEC)` specifies an allpass arbitrary group delay filter with the `Specification` property set to SPEC. See "Input Arguments" on page 4-445 for a description of supported specifications.

`D = fdesign.arbgrpdelay(SPEC,SPEC1,SPEC2,...)` initializes the allpass arbitrary group delay filter specification object with specifications `SPEC1,SPEC2,...`. See SPEC for a description of supported specifications.

`D = fdesign.arbgrpdelay(N,F,Gd)` specifies an allpass arbitrary group delay filter. The filter order is equal to `N`, frequency vector equal to `F`, and group delay vector equal to `Gd`. See SPEC for a description of the filter order, frequency vector, and group delay vector inputs. See the example Allpass Filter with Arbitrary Group Delay for an example using this syntax.

`D = fdesign.arbgrpdelay(...,Fs)` specifies the sampling frequency in hertz as a trailing scalar. If you do not specify a sampling frequency, all frequencies are normalized frequencies and group delay values are in samples. If you specify a sampling frequency, group delay values are in seconds.

Tips

If your arbitrary group delay design produces the error `Poorly conditioned Hessian matrix`, attempt one or more of the following:

- Set the `MaxPoleRadius` IIR lp norm design option to some number less than 1. Set this option when you `design` your filter with the syntax:

  ```
  design(d,'iirlpnorm','MaxPoleRadius',0.95)
  ```
  See the Frequency Dispersion and Multiband Delay Equalization examples for the use of the `MaxPoleRadius` design option.
- Reduce the order of your filter design.

Input Arguments

SPEC

Specification string. SPEC is one of the following two strings. The entries are not case sensitive.

- `'N,F,Gd'`
- `'N,B,F,Gd'`

The string entries are defined as follows:

- `N` — Filter order. This value must be an even positive integer. The numerator and denominator orders are both equal to `N`. “Allpass Systems” on page 4-452 explains why the numerator and denominator filter orders are equal and the order must be even in `fdesign.arbgrpdelay`.
- `F` — Frequency vector for the group delay specifications. The elements of the frequency vector must increase monotonically. If you do not specify a sampling frequency, Fs, in hertz, the frequencies are normalized frequencies. For a single-band design, the first element of the normalized frequency vector must be zero and the last element must be 1. These correspond to 0 and π radians/sample respectively. For multiband designs, the union of the frequency vectors must range from [0,1].

  If you specify a sampling frequency, Fs, the first element of the frequency vector in a single-band design must be 0. The last element must be the Nyquist frequency, Fs/2. For multiband designs, the union of the frequency vectors must range from [0,Fs/2].

- Gd — Group delay vector. A vector with nonnegative elements equal in length to the frequency vector, F. The elements of Gd specify the nonnegative group delay at the corresponding element of the frequency vector, F.

  If you do not specify a sampling frequency, Fs, in Hertz, the group delays are in samples. If you specify a sampling frequency, the group delays are in seconds.
- B — Number of frequency bands. If you use this specification, you must specify a frequency and group delay vector for each band. The union of the frequency vectors must range from [0,1] in normalized frequency, or [0,Fs/2] when a sampling frequency is specified. The elements in the union of the frequency bands must be monotonically increasing.

  For example:

  ```
  filtorder = 14;
  freqband1 = [0 0.1 0.4]; grpdelay1 = [1 2 3];
  freqband2 = [0.5 0.8 1]; grpdelay2 = [3 2 1];
  D = fdesign.arbgrpdelay('N,B,F,Gd',filtorder,2,freqband1,grpdelay1,freqband2,grpdela
  ```

Default: 'N,F,Gd'

Fs

Sampling frequency. Specify the sampling frequency as a trailing positive scalar after all other input arguments. Specifying a sampling frequency forces the group delay units to be in seconds. If you specify a sampling frequency, the first element of the frequency vector must be 0. The last element must be the Nyquist frequency, Fs/2.

Output Arguments

D

Filter specification object. An allpass arbitrary group delay filter specification object containing the following modifiable properties: Specification, NormalizedFrequency, FilterOrder, Frequencies, and GroupDelay.

Use the normalizefreq method to change the NormalizedFrequency property after construction.

Examples

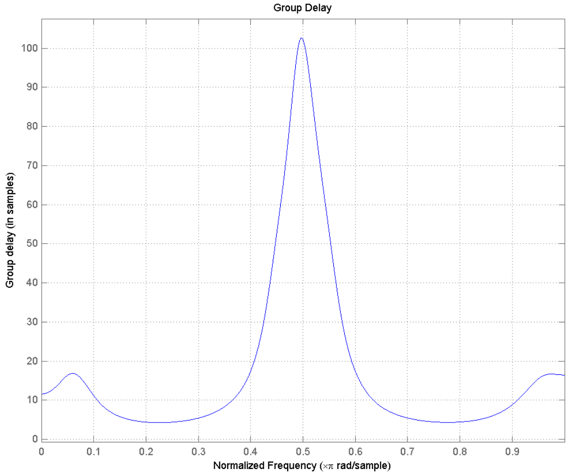
Construct a signal consisting of two discrete-time windowed sinusoids (wave packets) with disjoint time support to illustrate frequency dispersion. One discrete-time sinusoid has a frequency of π/2 radians/sample and the other has a frequency of π/4 radians/sample. There are 9 periods of the higher–frequency sinusoid that precede 5 periods of the lower–frequency signal.

Create the signal.

```
x = zeros(300,1);
x(1:36) = cos(pi/2*(0:35)).*hamming(36)';
x(40:40+39) = cos(pi/4*(0:39)).*hamming(40)';
```

Create an arbitrary group delay filter that delays the higher–frequency wave packet by approximately 100 samples.

```
N = 18;
f = 0:.1:1;
gd = ones(size(f));
% Delay pi/2 radians/sample by 100 samples
gd(6) = 100;
d = fdesign.arbgrpdelay(N,f,gd);
Hd = design(d,'iirlpnorm','MaxPoleRadius',0.9);
% Visualize the group delay
fvtool(Hd,'analysis','grpdelay');
```



Filter the input signal with the arbitrary group delay filter and illustrate the frequency dispersion. The high–frequency wave packet, which initially preceded the low–frequency wave packet, now occurs later because of the nonconstant group delay.

```
y = filter(Hd,x);
subplot(211)
plot(x); title('Input Signal');

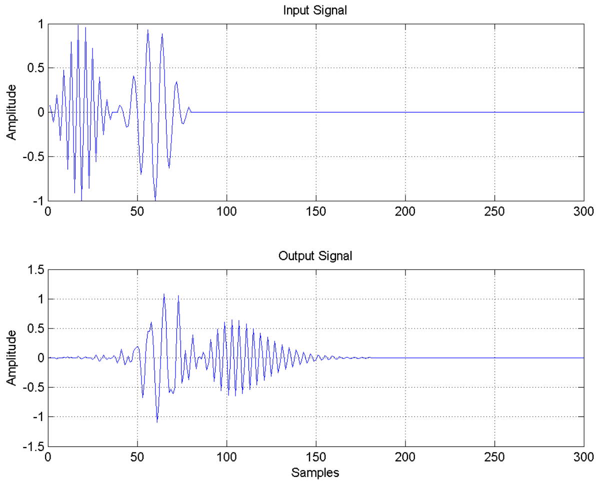
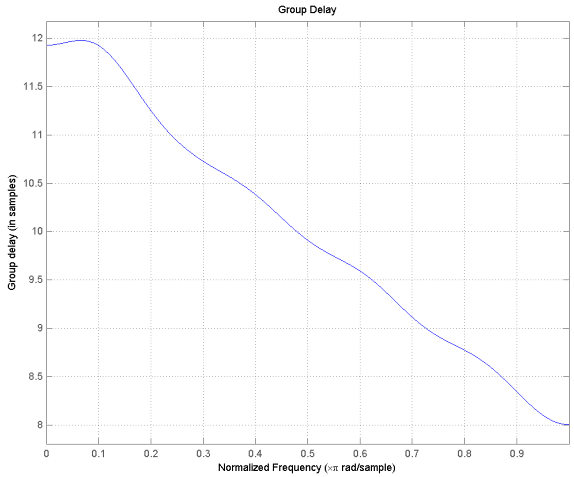
```



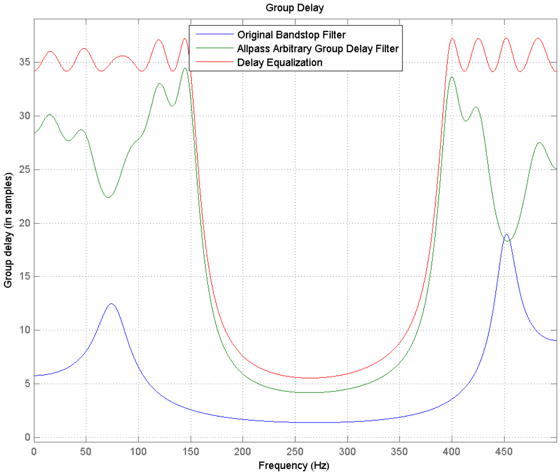
Design an allpass filter with an arbitrary group delay.

```
N = 10;
f = [0 0.02 0.04 0.06 0.08 0.1 0.25 0.5 0.75 1];
g = [5 5 5 5 5 5 4 3 2 1];
w = [2 2 2 2 2 2 1 1 1 1];
hgd = fdesign.arbgrpdelay(N,f,g);
Hgd = design(hgd,'iirlpnorm','Weights',w,'MaxPoleRadius',0.95);
fvtool(Hgd,'Analysis','grpdelay') ;
```



Perform multiband delay equalization outside the stopband.

```
Fs = 1e3;
Hcheby2 = design(fdesign.bandstop('N,Fst1,Fst2,Ast',10,150,400,60,Fs),'cheby2');
f1 = 0.0:0.5:150; % Hz
g1 = grpdelay(Hcheby2,f1,Fs).'/Fs; % seconds
f2 = 400:0.5:500; % Hz
g2 = grpdelay(Hcheby2,f2,Fs).'/Fs; % seconds
maxg = max([g1 g2]);
% Design an arbitrary group delay allpass filter to equalize the group
% delay of the bandstop filter. Use an order 18 multiband design and specify
% two bands.
hgd = fdesign.arbgrpdelay('N,B,F,Gd',18,2,f1,maxg-g1,f2,maxg-g2,Fs);
Hgd = design(hgd,'iirlpnorm','MaxPoleRadius',0.95);
Hcascade = cascade(Hcheby2,Hgd);
hft = fvtool(Hcheby2,Hgd,Hcascade,'Analysis','grpdelay','Fs',Fs);
    legend(hft,'Original Bandstop Filter','Allpass Arbitrary Group Delay Filter',...
    'Delay Equalization', 'Location','North');
```



Alternatives

`iirgrpdelay` — Returns an allpass arbitrary group delay filter. The `iirgrpdelay` function returns the numerator and denominator coefficients. This behavior differs from that of `fdesign.arbgrpdelay`, which returns the filter in second-order sections. `iirgrpdelay` accepts only normalized frequencies.

More About

Group Delay in Discrete-Time Filter Design

The frequency response of a rational discrete-time filter is:

$$H(e^{j\omega}) = \frac{B(e^{j\omega})}{A(e^{j\omega})}$$

The argument of the frequency response as a function of the angle, ω, is referred to as the *phase response*.

The negative of the first derivative of the argument with respect to ω is the group delay.

$$\tau(\omega) = -\frac{d}{d\omega} Arg(H(e^{j\omega}))$$

Systems with nonlinear phase responses have nonconstant group delay, which causes dispersion of the frequency components of the signal. You may not want this phase distortion even if the magnitude distortion introduced by the filter produces the desired effect. See Frequency Dispersion for an illustration of frequency dispersion resulting from nonconstant group delay.

In these cases, you can cascade the frequency-selective filter with an allpass filter that compensates for the group delay. This process is often referred to as *delay equalization*.

Allpass Systems

The general form of an allpass system function with a real-valued impulse response is:

$$H_{ap}(z) = \prod_{k=1}^{M} \frac{z^{-1} - d_k}{1 - d_k z^{-1}} \prod_{k=1}^{N} \frac{(z^{-1} - c_k)(z^{-1} - c_k^*)}{(1 - c_k z^{-1})(1 - c_k^* z^{-1})}$$

where the d_k denote the real-valued poles and the c_k denote the complex-valued poles, which occur in conjugate pairs.

The preceding equation demonstrates that allpass systems with real-valued impulse responses have *2N+M* zeros and poles. The poles and zeros occur in pairs with reciprocal magnitudes. The filter order is always the same for the numerator and denominator.

Because `fdesign.arbgrpdelay` uses robust second-order section (biquad) filter structures to implement the allpass arbitrary group delay filter, the filter order must be even.

Algorithms

`fdesign.arbgrpdelay` uses a least *p*-th norm iterative optimization described in [1].

fdesign.arbmag

Arbitrary response magnitude filter specification object

Syntax

```
D= fdesign.arbmag
D= fdesign.arbmag(SPEC)
D = fdesign.arbmag(SPEC,specvalue1,specvalue2,...)
D = fdesign.arbmag(specvalue1,specvalue2,specvalue3)
D = fdesign.arbmag(...,Fs)
```

Description

`D= fdesign.arbmag` constructs an arbitrary magnitude filter specification object `D`.

`D= fdesign.arbmag(SPEC)` initializes the `Specification` property to SPEC. The input argument SPEC must be one of the strings shown in the following table. Specification strings are not case sensitive.

Note: Specifications strings marked with an asterisk require the DSP System Toolbox software.

- `'N,F,A'` — Single band design (default)
- `'F,A,R'` — Single band minimum order design *
- `'N,B,F,A'` — Multiband design
- `'N,B,F,A,C'` — Constrained multiband design *
- `'B,F,A,R'` — Multiband minimum order design *
- `'Nb,Na,F,A'` — Single band design *
- `'Nb,Na,B,F,A'` — Multiband design *

The string entries are defined as follows:

- A — Amplitude vector. Values in A define the filter amplitude at frequency points you specify in f, the frequency vector. If you use A, you must use F as well. Amplitude values must be real. For complex values designs, use `fdesign.arbmagnphase`.
- B — Number of bands in the multiband filter
- C — Constrained band flag. This enables you to constrain the passband ripple in your multiband design. You cannot constrain the passband ripple in all bands simultaneously.
- F — Frequency vector. Frequency values in specified in F indicate locations where you provide specific filter response amplitudes. When you provide F, you must also provide A.
- N — Filter order for FIR filters and the numerator and denominator orders for IIR filters.
- Nb — Numerator order for IIR filters
- Na — Denominator order for IIR filter designs
- R — Ripple

By default, this method assumes that all frequency specifications are supplied in normalized frequency.

Specifying Frequency and Amplitude Vectors

F and A are the input arguments you use to define the filter response desired. Each frequency value you specify in F must have a corresponding response value in A. The following table shows how F and A are related.

Define the frequency vector F as `[0 0.25 0.3 0.4 0.5 0.6 0.7 0.75 1.0]`

Define the response vector A as `[1 1 0 0 0 0 0 1 1]`

These specifications connect F and A as shown here:

F (Normalized Frequency)	A (Response Desired at F)
0	1
0.25	1
0.3	0

F (Normalized Frequency)	A (Response Desired at F)
0.4	0
0.5	0
0.6	0
0.7	0
0.75	1
1.0	1

Different specifications can have different design methods available. Use `designmethods` to get a list of design methods available for a given specification string and filter specification object.

Use `designopts` to get a list of design options available for a filter specification object and a given design method. Enter `help(D,METHOD)` to get detailed help on the available design options for a given design method.

`D = fdesign.arbmag(SPEC,specvalue1,specvalue2,...)` initializes the specifications with `specvalue1`, `specvalue2`. Use `get(D,'Description')` for descriptions of the various specifications `specvalue1`, `specvalue2`, ... `specvalueN`.

`D = fdesign.arbmag(specvalue1,specvalue2,specvalue3)` uses the default specification string `'N,F,A'`, setting the filter order, filter frequency vector, and the amplitude vector to the values `specvalue1`, `specvalue2`, and `specvalue3`.

`D = fdesign.arbmag(...,Fs)` specifies the sampling frequency in Hz. All other frequency specifications are also assumed to be in Hz when you specify `Fs`.

Examples

Design of a multiband arbitrary-magnitude filter

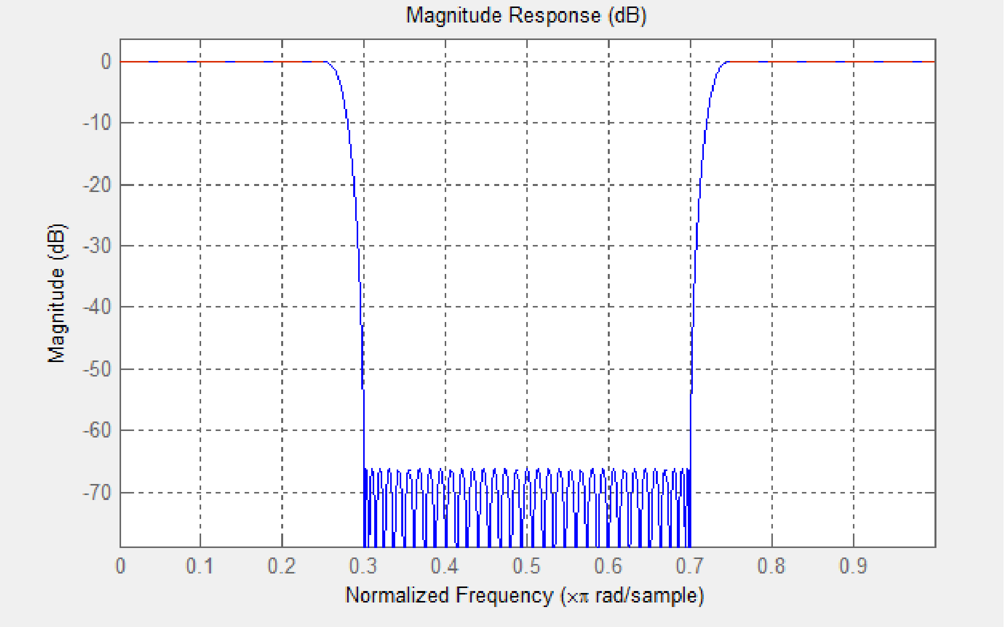
Use fdesign.arbmag to design a 3–band filter.

Use the given frequency and amplitude vectors in “Specifying Frequency and Amplitude Vectors” on page 4-455.

```
N = 150;
```

```
B = 3;
F = [0 .25 .3 .4 .5 .6 .7 .75 1];
A = [1 1 0 0 0 0 0 1 1];
A1 = A(1:2);
A2 = A(3:7);
A3 = A(8:end);
F1 = F(1:2);
F2 = F(3:7);
F3 = F(8:end);
d = fdesign.arbmag('N,B,F,A',N,B,F1,A1,F2,A2,F3,A3);
Hd = design(d);
fvtool(Hd)
```

A response with two passbands — one roughly between 0 and 0.25 and the second between 0.75 and 1 — results from the mapping between F and A.



Design of a single band arbitrary-magnitude filter

Use fdesign.arbmag to design a single band equiripple filter.

```
n = 120;
```

```
f = linspace(0,1,100);  % 100 frequency points.
as = ones(1,100)-f*0.2;
absorb = [ones(1,30),(1-0.6*bohmanwin(10))',...
ones(1,5), (1-0.5*bohmanwin(8))',ones(1,47)];
a = as.*absorb;
d = fdesign.arbmag('N,F,A',n,f,a);
hd1 = design(d,'equiripple');
```

If you have the DSP System Toolbox, you can design a minimum-phase equiripple filter.

```
hd2 = design(d,'equiripple','MinPhase',true);
hfvt = fvtool([hd1 hd2],'analysis','polezero');
legend(hfvt,'Equiripple Filter','Minimum-phase Equiripple Filter');
```

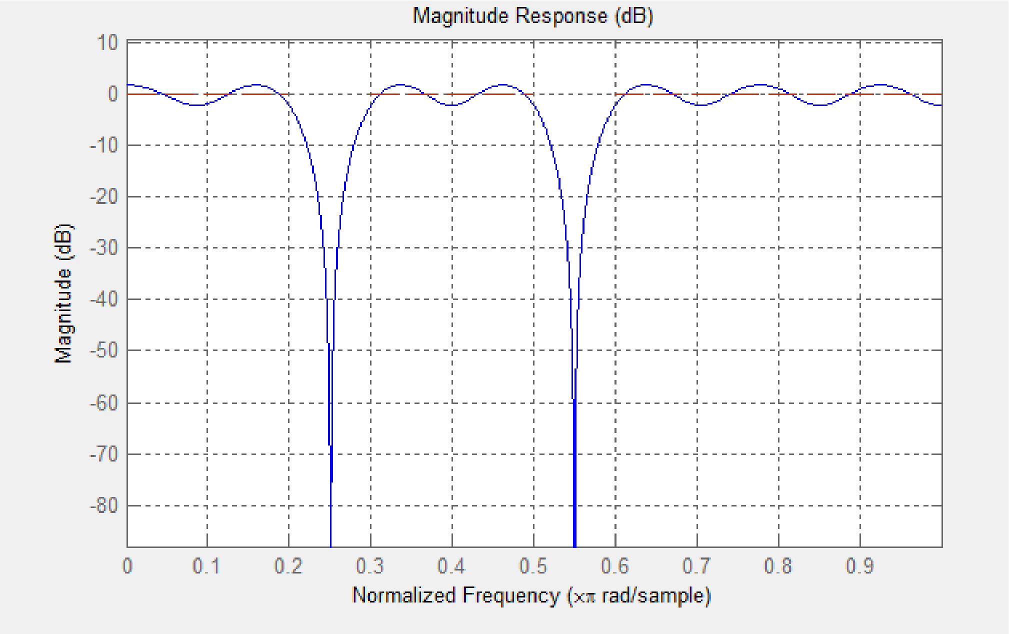
Design of a multiband minimum order arbitrary-magnitude filter

Use fdesign.arbmag to design a multiband minimum order filter.

This example requires the DSP System Toolbox.

Place the notches at 0.25π and 0.55π radians/sample

```
d = fdesign.arbmag('B,F,A,R');
d.NBands = 5;
d.B1Frequencies = [0 0.2];
d.B1Amplitudes = [1 1];
d.B1Ripple = 0.25;
d.B2Frequencies = 0.25;
d.B2Amplitudes = 0;
d.B3Frequencies = [0.3 0.5];
d.B3Amplitudes = [1 1];
d.B3Ripple = 0.25;
d.B4Frequencies = 0.55;
d.B4Amplitudes = 0;
d.B5Frequencies = [0.6 1];
d.B5Amplitudes = [1 1];
d.B5Ripple = 0.25;
Hd = design(d,'equiripple');
fvtool(Hd)
```



Design of a multiband constrained arbitrary-magnitude filter

Use fdesign.arbmag to design a multiband constrained FIR filter.

This example requires the DSP System Toolbox.

Force the frequency response at 0.15π radians/sample to 0 dB.

```
d = fdesign.arbmag('N,B,F,A,C',82,2);
d.B1Frequencies = [0 0.06 .1];
d.B1Amplitudes = [0 0 0];
d.B2Frequencies = [.15 1];
d.B2Amplitudes = [1 1];
% Design a filter with no constraints
Hd1 = design(d,'equiripple','B2ForcedFrequencyPoints',0.15);
% Add a constraint to the first band to increase attenuation
d.B1Constrained = true;
d.B1Ripple = .001;
Hd2 =  design(d,'equiripple','B2ForcedFrequencyPoints',0.15);
hfvt = fvtool(Hd1,Hd2);
legend(hfvt,'Original Design','Design with Constrained Stopband Ripple');
```

fdesign.arbmagnphase

Arbitrary response magnitude and phase filter specification object

Syntax

```
d = fdesign.arbmagnphase
d = fdesign.arbmagnphase(specification)
d = fdesign.arbmagnphase(specification,specvalue1,specvalue2,...)
d = fdesign.arbmagnphase(specvalue1,specvalue2,specvalue3)
d = fdesign.arbmagnphase(...,fs)
```

Description

`d = fdesign.arbmagnphase` constructs an arbitrary magnitude filter specification object `d`.

`d = fdesign.arbmagnphase(specification)` initializes the `Specification` property for specifications object `d` to the string in `specification`. The input argument `specification` must be one of the strings shown in the following table. Specification strings are not case sensitive.

Specification String	Description of Resulting Filter
`n,f,h`	Single band design (default). FIR and IIR (`n` is the order for both numerator and denominator).
`n,b,f,h`	FIR multiband design where `b` defines the number of bands.
`nb,na,f,h`	IIR single band design.

The following table describes the arguments in the strings.

Argument	Description
`b`	Number of bands in the multiband filter.
`f`	Frequency vector. Frequency values specified in `f` indicate locations where you provide specific filter response amplitudes. When you provide `f` you must also provide `h` which contains the response values.

Argument	Description
h	Complex frequency response values.
n	Filter order for FIR filters and the numerator and denominator orders for IIR filters (when not specified by nb and na).
nb	Numerator order for IIR filters.
na	Denominator order for IIR filter designs.

By default, this method assumes that all frequency specifications are supplied in normalized frequency.

Specifying f and h

f and h are the input arguments you use to define the filter response desired. Each frequency value you specify in f must have a corresponding response value in h. This example creates a filter with two passbands (b = 4) and shows how f and h are related. This example is for illustration only. It is not an actual filter.

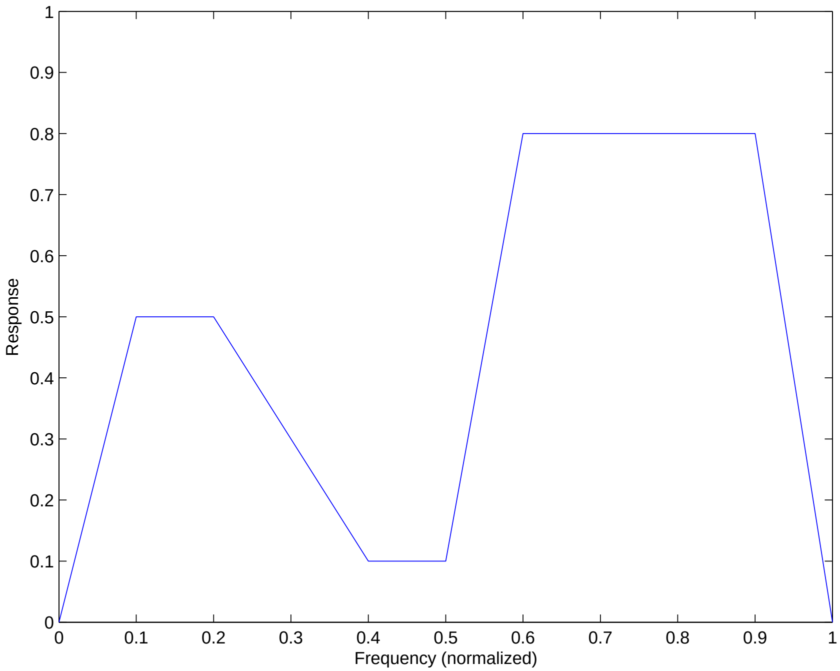
Define the frequency vector f as [0 0.1 0.2 0.4 0.5 0.6 0.9 1.0]

Define the response vector h as [0 0.5 0.5 0.1 0.1 0.8 0.8 0]

These specifications connectf and h as shown in the following table.

f (Normalized Frequency)	h (Response Desired at f)
0	0
0.1	0.5
0.2	0.5
0.4	0.1
0.5	0.1
0.6	0.8
0.9	0.8
1.0	0.0

A response with two passbands—one roughly between 0.1 and 0.2 and the second between 0.6 and 0.9—results from the mapping between f and h. Plotting f and h yields the following figure that resembles a filter with two passbands.



The second example in Examples shows this plot in more detail with a complex filter response for `h`. In the example, `h` uses complex values for the response.

Different specification types often have different design methods available. Use `designmethods(d)` to get a list of design methods available for a given specification string and specifications object.

`d = fdesign.arbmagnphase(specification,specvalue1,specvalue2,...)` initializes the filter specification object with `specvalue1`, `specvalue2`, and so on. Use `get(d,'description')` for descriptions of the various specifications `specvalue1`, `specvalue2`, ...`spec`*n*.

`d = fdesign.arbmagnphase(specvalue1,specvalue2,specvalue3)` uses the default specification string `n,f,h`, setting the filter order, filter frequency vector, and the complex frequency response vector to the values `specvalue1`, `specvalue2`, and `specvalue3`.

`d = fdesign.arbmagnphase(...,fs)` specifies the sampling frequency in Hz. All other frequency specifications are also assumed to be in Hz when you specify `fs`.

Examples

Use `fdesign.arbmagnphase` to model a complex analog filter:

```
d=fdesign.arbmagnphase('n,f,h',100); % N=100, f and h set to defaults.
design(d,'freqsamp');
```

For a more complex example, design a bandpass filter with low group delay by specifying the desired delay and using `f` and `h` to define the filter bands.

```
n = 50;     % Group delay of a linear phase filter would be 25.
gd = 12;    % Set the desired group delay for the filter.
f1=linspace(0,.25,30); % Define the first stopband frequencies.
f2=linspace(.3,.56,40);% Define the passband frequencies.
f3=linspace(.62,1,30); % Define the second stopband frequencies.
h1 = zeros(size(f1));  % Specify the filter response at the freqs in f1.
h2 = exp(-1j*pi*gd*f2); % Specify the filter response at the freqs in f2.
h3 = zeros(size(f3));  % Specify the response at the freqs in f3.
d=fdesign.arbmagnphase('n,b,f,h',50,3,f1,h1,f2,h2,f3,h3);
D = design(d,'equiripple');
fvtool(D,'Analysis','freq');
```

fdesign.audioweighting

Audio weighting filter specification object

Syntax

```
HAwf = fdesign.audioweighting
HAwf = fdesign.audioweighting(spec)
HAwf = fdesign.audioweighting(spec,specvalue1,specvalue2)
HAwf = fdesign.audioweighting(specvalue1,specvalue2)
HAwf = fdesign.audioweighting(...,Fs)
```

Description

Supported audio weighting filter types are: A weighting, C weighting, C-message, ITU-T 0.41, and ITU-R 468–4 weighting.

`HAwf = fdesign.audioweighting` constructs an audio weighting filter specification object *`HAwf`* with a weighting type of A and a filter class of 1. Use the `design` method to instantiate a `dfilt` object based on the specifications in *`HAwf`*. Use `designmethods` to find valid filter design methods. Because the standards for audio weighting filters are in Hz, normalized frequency specifications are not supported for `fdesign.audioweighting` objects. The default sampling frequency for A weighting, C weighting, C-message, and ITU-T 0.41 filters is 48 kHz. The default sampling frequency for the ITU-R 468–4 filter is 80 kHz. If you invoke the `normalizefreq` method, a warning is issued when you instantiate the `dfilt` object and the default sampling frequencies in Hz are used.

`HAwf = fdesign.audioweighting(spec)` returns an audio weighting filter specification object using default values for the specification string in *`spec`*. The following are valid entries for *`spec`*. The entries are not case sensitive.

- `'WT,Class'` (default *`spec`*)

  The `'WT,Class'` specification is valid for A weighting and C weighting filters of class 1 or 2.

  The weighting type is specified by the string: `'A'` or `'C'`. The class is the scalar 1 or 2.

The default values for `'WT,Class'` are `'A',1`.

- `'WT'`

  The `'WT'` specification is valid for C-message (default), ITU-T 0.41, and ITU-R 468–4 weighting filters.

  The weighting type is specified by the string: `'Cmessage'`, `'ITUT041'`, or `'ITUR4684'`.

`HAwf = fdesign.audioweighting(spec,specvalue1,specvalue2)` constructs an audio weighting filter specification object *HAwf* and sets its specifications at construction time.

`HAwf = fdesign.audioweighting(specvalue1,specvalue2)` constructs an audio weighting filter specification object *HAwf* with the specification `'WT,Class'` using the values you provide. The valid weighting types are `'A'` or `'C'`.

`HAwf = fdesign.audioweighting(...,Fs)` specifies the sampling frequency in Hz. The sampling frequency is a scalar trailing all other input arguments.

Input Arguments

Parameter Name/Value Pairs

'WT'

Weighting type

The weighting type defines the frequency response of the filter. The valid weighting types are: A weighting, C weighting, C-message, ITU-T 0.41, and ITU-R 468–4 weighting. The weighting types are described in “Definitions” on page 4- .

'Class'

Filter Class

Filter class is only applicable for A weighting and C weighting filters. The filter class describes the frequency-dependent tolerances specified in the relevant standards [1],

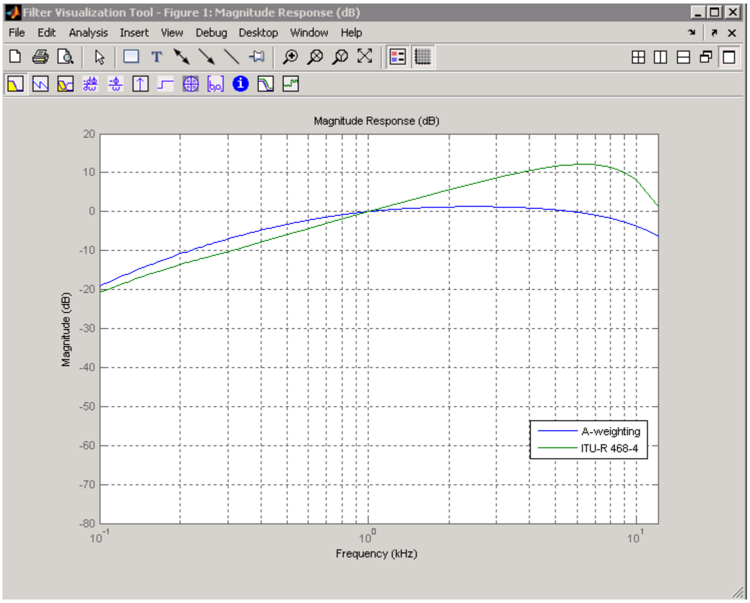
[2]. There are two possible class values: 1 and 2. Class 1 weighting filters have stricter tolerances than class 2 filters. The filter class value does not affect the design. The class value is only used to provide a specification mask in `fvtool` for the analysis of the filter design.

Default: 1

Examples

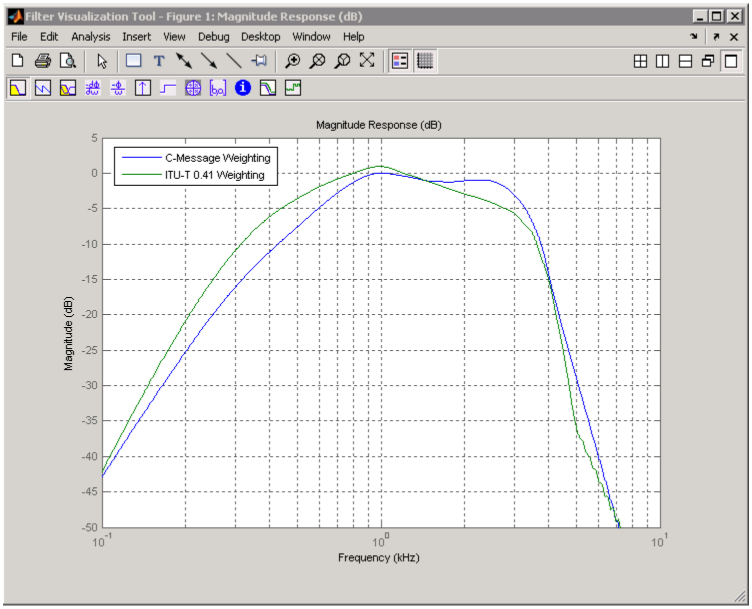
Compare class 1 A weighting and ITU-R 468–4 filters between 0.1 and 12 kHz:

```
HawfA = fdesign.audioweighting('WT,Class','A',1,44.1e3);
% Sampling frequency is 44.1 kHz
HawfITUR = fdesign.audioweighting('WT','ITUR4684',44.1e3);
Afilter = design(HawfA);
ITURfilter = design(HawfITUR);
hfvt = fvtool([Afilter ITURfilter]);
axis([0.1 12 -80 20]);
legend(hfvt,'A-weighting','ITU-R 468-4');
```



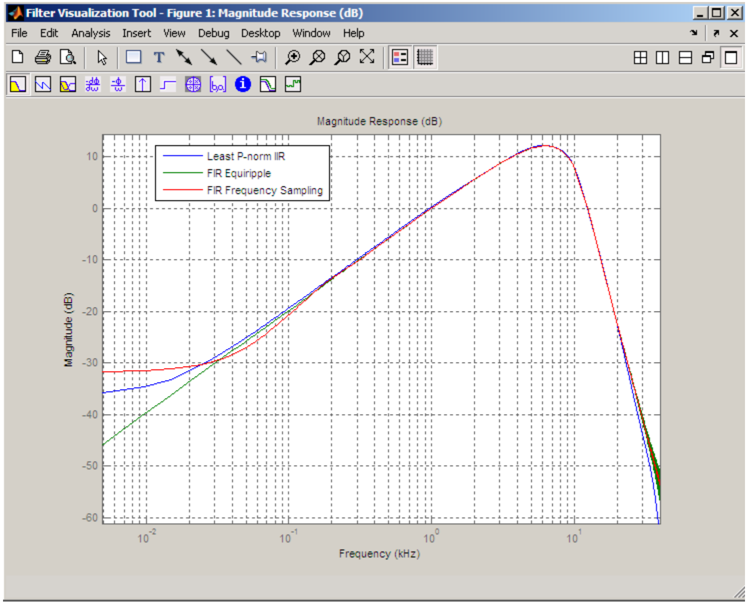
Compare C-message and ITU-T 0.41 filters:

```
hCmessage = fdesign.audioweighting('WT','Cmessage',24e3);
hITUT = fdesign.audioweighting('WT','ITUT041',24e3);
dCmessage = design(hCmessage);
dITUT = design(hITUT);
hfvt = fvtool([dCmessage dITUT]);
legend(hfvt,'C-Message Weighting','ITU-T 0.41 Weighting');
axis([0.1 10 -50 5]);
```



Construct an ITU-R 468–4 filter using all available design methods:

```
HAwf = fdesign.audioweighting('WT','ITUR4684');
ValidDesigns = designmethods(HAwf);
% returns iirlpnorm,equiripple,freqsamp in cell array
D = design(HAwf,'all'); % returns all designs
hfvt = fvtool(D);
legend(hfvt,'Least P-norm IIR','FIR Equiripple',...,
'FIR Frequency Sampling')
```



More About

A weighting

The specifications for the A weighting filter are found in ANSI standard S1.42-2001. The A weighting filter is based on the 40–phon Fletcher-Munson equal loudness contour [3]. One phon is equal to one dB sound pressure level (SPL) at one kHz. The Fletcher-Munson equal loudness contours are designed to account for frequency and level dependent differences in the perceived loudness of tonal stimuli. The 40–phon contour reflects the fact that the human auditory system is more sensitive to frequencies around 1–2 kHz than lower and higher frequencies. The filter roll off is more pronounced at lower frequencies and more modest at higher frequencies. While A weighting is based on the equal loudness contour for low-level (40–phon) tonal stimuli, it is commonly used in the United States for assessing potential health risks associated with noise exposure to narrowband and broadband stimuli at high levels.

C weighting

The specifications for the C weighting filter are found in ANSI standard S1.42-2001. The C weighting filter approximates the 100–phon Fletcher-Munson equal loudness contour for tonal stimuli. The C weighting magnitude response is essentially flat with 3–dB frequencies at 31.5 Hz and 8000 Hz. While C weighting is not as common as A weighting, sound level meters frequently have a C weighting filter option.

C-message

The specifications for the C–message weighting filter are found in Bell System Technical Reference, PUB 41009. C-message weighting filters are designed for measuring the impact of noise on telecommunications circuits used in speech transmission [6]. C-message weighting filters are commonly used in North America, while the ITU-T 0.41 filter is more commonly used outside of North America.

ITU-R 468–4

The specifications for the ITU-R 486–4 weighting filter are found in the International Telecommunication Union Recommendation ITU-R BS.468-4. ITU-R 486–4 is an equal loudness contour weighting filter. Unlike the A weighting filter, the ITU-R 468–4 filter describes subjective loudness judgements for broadband stimuli [4]. A common criticism of the A weighting filter is that it underestimates the loudness judgement of real-world stimuli particularly in the frequency band from about 1–9 kHz. A comparison of A weighting and ITU-R 468–4 weighting curves shows that the ITU-R 468–4 curve applies more gain between 1 and 10 kHz with a peak difference of approximately 12 dB around 6–7 kHz.

ITU-T 0.41

The specifications for the ITU-T 0.41 filter are found in the ITU-T Recommendation 0.41. ITU-T 0.41 weighting filters are designed for measuring the impact of noise on telecommunications circuits used in speech transmission [5]. ITU-T 0.41 weighting filters are commonly used outside of North America, while the C-message weighting filter is more common in North America.

fdesign.bandpass

Bandpass filter specification object

Syntax

```
D = fdesign.bandpass
D = fdesign.bandpass(SPEC)
D = fdesign.bandpass(spec,specvalue1,specvalue2,...)
D = fdesign.bandpass(specvalue1,specvalue2,specvalue3,
specvalue4,...specvalue4,specvalue5,specvalue6)
D = fdesign.bandpass(...,Fs)
D = fdesign.bandpass(...,MAGUNITS)
```

Description

`D = fdesign.bandpass` constructs a bandpass filter specification object `D`, applying default values for the properties `Fstop1`, `Fpass1`, `Fpass2`, `Fstop2`, `Astop1`, `Apass`, and `Astop2` — one possible set of values you use to specify a bandpass filter.

`D = fdesign.bandpass(SPEC)` constructs object `D` and sets its `Specification` property to `SPEC`. Entries in the `SPEC` string represent various filter response features, such as the filter order, that govern the filter design. Valid entries for `SPEC` are shown below and used to define the bandpass filter. The strings are not case sensitive.

Note: Specifications strings marked with an asterisk require the DSP System Toolbox software.

- `'Fst1,Fp1,Fp2,Fst2,Ast1,Ap,Ast2'` (default `spec`)
- `'N,F3dB1,F3dB2'`
- `"N,F3dB1,F3dB2,Ap'` *
- `'N,F3dB1,F3dB2,Ast'` *
- `'N,F3dB1,F3dB2,Ast1,Ap,Ast2'` *
- `'N,F3dB1,F3dB2,BWp` *

- `'N,F3dB1,F3dB2,BWst'` *
- `'N,Fc1,Fc2'`
- `'N,Fc1,Fc2,Ast1,Ap,Ast2'`
- `'N,Fp1,Fp2,Ap'`
- `'N,Fp1,Fp2,Ast1,Ap,Ast2'`
- `'N,Fst1,Fp1,Fp2,Fst2'`
- `'N,Fst1,Fp1,Fp2,Fst2,C'` *
- `'N,Fst1,Fp1,Fp2,Fst2,Ap'` *
- `'N,Fst1,Fst2,Ast'`
- `'Nb,Na,Fst1,Fp1,Fp2,Fst2'` *

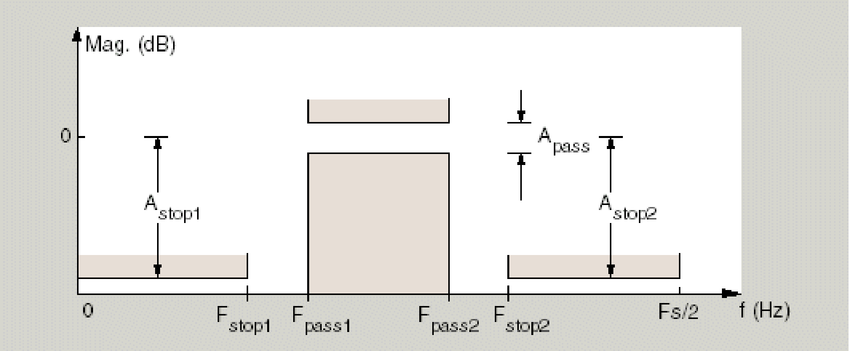
The string entries are defined as follows:

- `Ap` — amount of ripple allowed in the pass band. Also called Apass.
- `Ast1` — attenuation in the first stop band in decibels (the default units). Also called Astop1.
- `Ast2` — attenuation in the second stop band in decibels (the default units). Also called Astop2.
- `BWp` — bandwidth of the filter passband. Specified in normalized frequency units.
- `BWst` — bandwidth of the filter stopband. Specified in normalized frequency units.
- `C` — Constrained band flag. This enables you to specify passband ripple or stopband attenuation for fixed-order designs in one or two of the three bands.

  In the specification string `'N,Fst1,Fp1,Fp2,Fst2,C'`, you cannot specify constraints in both stopbands and the passband simultaneously. You can specify constraints in any one or two bands.
- `F3dB1` — cutoff frequency for the point 3 dB point below the passband value for the first cutoff. Specified in normalized frequency units. (IIR filters)
- `F3dB2` — cutoff frequency for the point 3 dB point below the passband value for the second cutoff. Specified in normalized frequency units. (IIR filters)
- `Fc1` — cutoff frequency for the point 6 dB point below the passband value for the first cutoff. Specified in normalized frequency units. (FIR filters)
- `Fc2` — cutoff frequency for the point 6 dB point below the passband value for the second cutoff. Specified in normalized frequency units. (FIR filters)

- `Fp1` — frequency at the edge of the start of the pass band. Specified in normalized frequency units. Also called Fpass1.
- `Fp2` — frequency at the edge of the end of the pass band. Specified in normalized frequency units. Also called Fpass2.
- `Fst1` — frequency at the edge of the start of the first stop band. Specified in normalized frequency units. Also called Fstop1.
- `Fst2` — frequency at the edge of the start of the second stop band. Specified in normalized frequency units. Also called Fstop2.
- `N` — filter order for FIR filters. Or both the numerator and denominator orders for IIR filters when na and nb are not provided.
- `Na` — denominator order for IIR filters
- `Nb` — numerator order for IIR filters

Graphically, the filter specifications look similar to those shown in the following figure.



Regions between specification values like `Fst1` and `Fp1` are transition regions where the filter response is not explicitly defined.

The filter design methods that apply to a bandpass filter specification object change depending on the `Specification` string. Use `designmethods` to determine which design methods apply to an object and the `Specification` property value.

Use `designopts` to determine the design options for a given design method. Enter `help(D,METHOD)` at the MATLAB command line to obtain detailed help on the design options for a given design method, `METHOD`.

`D = fdesign.bandpass(spec,specvalue1,specvalue2,...)` constructs an object `D` and sets its specifications at construction time.

`D = fdesign.bandpass(specvalue1,specvalue2,specvalue3, specvalue4,...specvalue4,specvalue5,specvalue6)` constructs `D`with the default `Specification` property string, using the values you provide as input arguments for `specvalue1,specvalue2,specvalue3,specvalue4,specvalue4,specvalue5, specvalue6` and `specvalue7`.

`D = fdesign.bandpass(...,Fs)` adds the argument `Fs`, specified in Hz to define the sampling frequency to use. In this case, all frequencies in the specifications are in Hz as well.

`D = fdesign.bandpass(...,MAGUNITS)` specifies the units for any magnitude specification you provide in the input arguments. `MAGUNITS` can be one of

- `'linear'` — specify the magnitude in linear units
- `'dB'` — specify the magnitude in dB (decibels)
- `'squared'` — specify the magnitude in power units

When you omit the `MAGUNITS` argument, `fdesign` assumes that all magnitudes are in decibels. Note that `fdesign` stores all magnitude specifications in decibels (converting to decibels when necessary) regardless of how you specify the magnitudes.

Examples

Filter a discrete-time signal with a bandpass filter. The signal is a sum of three discrete-time sinusoids, π/8, π/2, and 3π/4 radians/sample.

```
n = 0:159;
x = cos(pi/8*n)+cos(pi/2*n)+sin(3*pi/4*n);
```

Design an FIR equiripple bandpass filter to remove the lowest and highest discrete-time sinusoids.

```
d = fdesign.bandpass('Fst1,Fp1,Fp2,Fst2,Ast1,Ap,Ast2',1/4,3/8,5/8,6/8,60,1,60);
Hd = design(d,'equiripple');
```

Apply the filter to the discrete-time signal.

```
y = filter(Hd,x);
freq = 0:(2*pi)/length(x):pi;
xdft = fft(x);
```

```
ydft = fft(y);
plot(freq,abs(xdft(1:length(x)/2+1)));
hold on;
plot(freq,abs(ydft(1:length(x)/2+1)),'r','linewidth',2);
legend('Original Signal','Bandpass Signal');
```

Design an IIR Butterworth filter of order 10 with 3–dB frequencies of 1 and 1.2 kHz. The sampling frequency is 10 kHz

```
d = fdesign.bandpass('N,F3dB1,F3dB2',10,1e3,1.2e3,1e4);
Hd = design(d,'butter');
fvtool(Hd)
```

This example requires the DSP System Toolbox software.

Design a constrained-band FIR equiripple filter of order 100 with a passband of [1, 1.4] kHz. Both stopband attenuation values are constrained to 60 dB. The sampling frequency is 10 kHz.

```
d = fdesign.bandpass('N,Fst1,Fp1,Fp2,Fst2,C',100,800,1e3,1.4e3,1.6e3,1e4);
d.Stopband1Constrained = true; d.Astop1 = 60;
d.Stopband2Constrained = true; d.Astop2 = 60;
Hd = design(d,'equiripple');
fvtool(Hd);
measure(Hd)
```

The passband ripple is slightly over 2 dB. Because the design constrains both stopbands, you cannot constrain the passband ripple.

`fdesign`, `fdesign.bandstop`, `fdesign.highpass`, `fdesign.lowpass`

fdesign.bandstop

Bandstop filter specification object

Syntax

```
D = fdesign.bandstop
D = fdesign.bandstop(SPEC)
D = fdesign.bandstop(SPEC,specvalue1,specvalue2,...)
D = fdesign.bandstop(specvalue1,specvalue2,specvalue3,specvalue4,...
specvalue5,specvalue6,specvalue7)
D = fdesign.bandstop(...,Fs)
D = fdesign.bandstop(...,MAGUNITS)
```

Description

`D = fdesign.bandstop` constructs a bandstop filter specification object `D`, applying default values for the properties `Fpass1`, `Fstop1`, `Fstop2`, `Fpass2`, `Apass1`, `Astop1` and `Apass2`.

`D = fdesign.bandstop(SPEC)` constructs object `D` and sets the `Specification` property to `SPEC`. Entries in the `SPEC` string represent various filter response features, such as the filter order, that govern the filter design. Valid entries for `SPEC` are shown below. The strings are not case sensitive.

Note: Specifications strings marked with an asterisk require the DSP System Toolbox software.

- `'Fp1,Fst1,Fst2,Fp2,Ap1,Ast,Ap2'` (default spec)
- `'N,F3dB1,F3dB2'`
- `'N,F3dB1,F3dB2,Ap'` *
- `'N,F3dB1,F3dB2,Ap,Ast'` *
- `'N,F3dB1,F3dB2,Ast'` *
- `'N,F3dB1,F3dB2,BWp'` *

- `'N,F3dB1,F3dB2,BWst'` *
- `'N,Fc1,Fc2'`
- `'N,Fc1,Fc2,Ap1,Ast,Ap2'`
- `'N,Fp1,Fp2,Ap'`
- `'N,Fp1,Fp2,Ap,Ast'`
- `'N,Fp1,Fst1,Fst2,Fp2'`
- `'N,Fp1,Fst1,Fst2,Fp2,C'` *
- `'N,Fp1,Fst1,Fst2,Fp2,Ap'` *
- `'N,Fst1,Fst2,Ast'`
- `'Nb,Na,Fp1,Fst1,Fst2,Fp2'` *

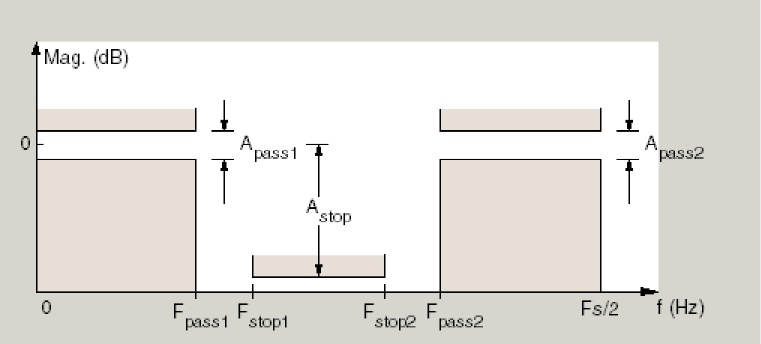
The string entries are defined as follows:

- `Ap` — amount of ripple allowed in the passband in decibels (the default units). Also called Apass.
- `Ap1` — amount of ripple allowed in the pass band in decibels (the default units). Also called Apass1.
- `Ap2` — amount of ripple allowed in the pass band in decibels (the default units). Also called Apass2.
- `Ast` — attenuation in the first stopband in decibels (the default units). Also called Astop1.
- `BWp` — bandwidth of the filter passband. Specified in normalized frequency units.
- `BWst` — bandwidth of the filter stopband. Specified in normalized frequency units.
- `C` — Constrained band flag. This enables you to specify passband ripple or stopband attenuation for fixed-order designs in one or two of the three bands.

  In the specification string `'N,Fp1,Fst1,Fst2,Fp2,C'`, you cannot specify constraints simultaneously in both passbands and the stopband. You can specify constraints in any one or two bands.
- `F3dB1` — cutoff frequency for the point 3 dB point below the passband value for the first cutoff.
- `F3dB2` — cutoff frequency for the point 3 dB point below the passband value for the second cutoff.
- `Fc1` — cutoff frequency for the point 6 dB point below the passband value for the first cutoff. (FIR filters)

- `Fc2` — cutoff frequency for the point 6 dB point below the passband value for the second cutoff. (FIR filters)
- `Fp1` — frequency at the start of the pass band. Also called Fpass1.
- `Fp2` — frequency at the end of the pass band. Also called Fpass2.
- `Fst1` — frequency at the end of the first stop band. Also called Fstop1.
- `Fst2` — frequency at the start of the second stop band. Also called Fstop2.
- `N` — filter order.
- `Na` — denominator order for IIR filters.
- `Nb` — numerator order for IIR filters.

Graphically, the filter specifications look similar to those shown in the following figure.



Regions between specification values like `Fp1` and `Fst1` are transition regions where the filter response is not explicitly defined.

The filter design methods that apply to a bandstop filter specification object change depending on the `Specification` string. Use `designmethods` to determine which design methods apply to an object and the `Specification` property value.

Use `designopts` to determine the design options for a given design method. Enter `help(D,METHOD)` at the MATLAB command line to obtain detailed help on the design options for a given design method, `METHOD`.

`D = fdesign.bandstop(SPEC,specvalue1,specvalue2,...)` constructs an object `D` and sets its specifications at construction time.

```
D = fdesign.bandstop(specvalue1,specvalue2,specvalue3,specvalue4,...
```

specvalue5,specvalue6,specvalue7) constructs an object D with the default Specification property string , using the values you provide in specvalue1,specvalue2,specvalue3,specvalue4,specvalue5, specvalue6 and specvalue7.

D = fdesign.bandstop(...,Fs) adds the argument Fs, specified in Hz to define the sampling frequency. If you specify the sampling frequency as a trailing scalar, all frequencies in the specifications are in Hz as well.

D = fdesign.bandstop(...,MAGUNITS) specifies the units for any magnitude specification you provide in the input arguments. MAGUNITS can be one of

- 'linear' — specify the magnitude in linear units
- 'dB' — specify the magnitude in dB (decibels)
- 'squared' — specify the magnitude in power units

When you omit the MAGUNITS argument, fdesign assumes that all magnitudes are in decibels. Note that fdesign stores all magnitude specifications in decibels (converting to decibels when necessary) regardless of how you specify the magnitudes.

Examples

Construct a bandstop filter to reject the discrete frequency band between 3π/8 and 5π/8 radians/sample. Apply the filter to a discrete-time signal consisting of the superposition of three discrete-time sinusoids.

Design an FIR equiripple filter and view the magnitude response.

```
d = fdesign.bandstop('Fp1,Fst1,Fst2,Fp2,Ap1,Ast,Ap2',2/8,3/8,5/8,6/8,1,60,1);
Hd = design(d,'equiripple');
fvtool(Hd)
```

Construct the discrete-time signal to filter.

```
n = 0:99;
x = cos(pi/5*n)+sin(pi/2*n)+cos(4*pi/5*n);
y = filter(Hd,x);
xdft = fft(x);
ydft = fft(y);
freq = 0:(2*pi)/length(x):pi;
plot(freq,abs(xdft(1:length(x)/2+1)));
```

```
hold on;
plot(freq,abs(ydft(1:length(y)/2+1)),'r','linewidth',2);
xlabel('Radians/Sample'); ylabel('Magnitude');
legend('Original Signal','Bandstop Signal');
```

Create a Butterworth bandstop filter for data sampled at 10 kHz. The stopband is [1,1.5] kHz. The order of the filter is 20.

```
d = fdesign.bandstop('N,F3dB1,F3dB2',20,1e3,1.5e3,1e4);
Hd = design(d,'butter');
fvtool(Hd);
```

Zoom in on the magnitude response plot to verify that the 3-dB down points are located at 1 and 1.5 kHz.

The following example requires the DSP System Toolbox license.

Design a constrained-band FIR equiripple filter of order 100 for data sampled at 10 kHz. You can specify constraints on at most two of the three bands: two passbands and one stopband. In this example, you choose to constrain the passband ripple to be 0.5 dB in each passband. Design the filter, visualize the magnitude response and measure the filter’s design.

```
d = fdesign.bandstop('N,Fp1,Fst1,Fst2,Fp2,C',100,800,1e3,1.5e3,1.7e3,1e4);
d.Passband1Constrained = true; d.Apass1 = 0.5;
d.Passband2Constrained = true; d.Apass2 = 0.5;
Hd = design(d,'equiripple');
fvtool(Hd);
measure(Hd)
```

With this order filter and passband ripple constraints, you achieve approximately 50 dB of stopband attentuation.

fdesign.ciccomp

CIC compensator filter specification object

Syntax

```
d= fdesign.ciccomp
d= fdesign.ciccomp(d,nsections,rcic)
d= fdesign.ciccomp(...,spec)
h = fdesign.ciccomp(...,spec,specvalue1,specvalue2,...)
```

Description

`d= fdesign.ciccomp` constructs a CIC compensator specifications object `d`, applying default values for the properties Fpass, Fstop, Apass, and Astop. In this syntax, the filter has two sections and the differential delay is 1.

Using `fdesign.ciccomp` with a design method creates a `dfilt` object, a single-rate discrete-time filter.

`d= fdesign.ciccomp(d,nsections,rcic)` constructs a CIC compensator specifications object with the filter differential delay set to `d`, the number of sections in the filter set to `nsections`, and the CIC rate change factor set to `rcic`. The default values of these parameters are: the differential delay equal to 1, the number of sections equal to 2, and the CIC rate change factor equal to 1.

If the CIC rate change factor is equal to 1, the filter passband response is an inverse sinc that is an approximation to the true inverse passband response of the CIC filter.

If you specify a CIC rate change factor not equal to 1, the filter passband response is an inverse Dirichlet sinc that matches exactly the true inverse passband response of the CIC filter.

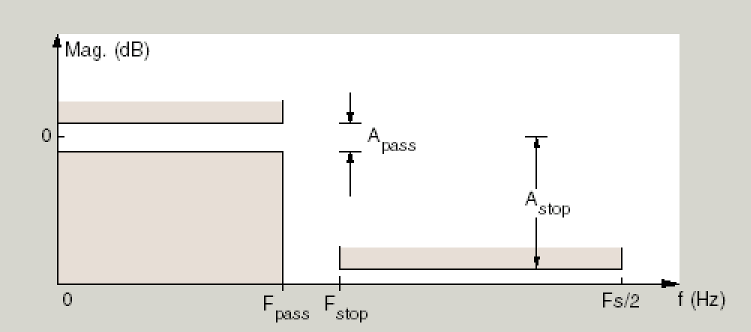
`d= fdesign.ciccomp(...,`*`spec`*`)` constructs a CIC Compensator specifications object and sets its `Specification` property to *`spec`*. Entries in the spec string represent various filter response features, such as the filter order, that govern the filter design. Valid entries for *`spec`* are shown in the list below. The strings are not case sensitive.

- `'fp,fst,ap,ast'` (default `spec`)
- `'n,fc,ap,ast'`
- `'n,fp,ap,ast'`
- `'n,fp,fst'`
- `'n,fst,ap,ast'`

The string entries are defined as follows:

- `ap` — amount of ripple allowed in the pass band in decibels (the default units). Also called Apass.
- `ast` — attenuation in the stop band in decibels (the default units). Also called Astop.
- `fc` — cutoff frequency for the point 6 dB point below the passband value. Specified in normalized frequency units.
- `fp` — frequency at the end of the pass band. Specified in normalized frequency units. Also called Fpass.
- `fst` — frequency at the start of the stop band. Specified in normalized frequency units. Also called Fstop.
- `n` — filter order.

In graphic form, the filter specifications look like this:



Regions between specification values like `fp` and `fst` are transition regions where the filter response is not explicitly defined.

The filter design methods that apply to a CIC compensator specifications object change depending on the `Specification` string. Use `designmethods` to determine which design method applies to an object and its specification string.

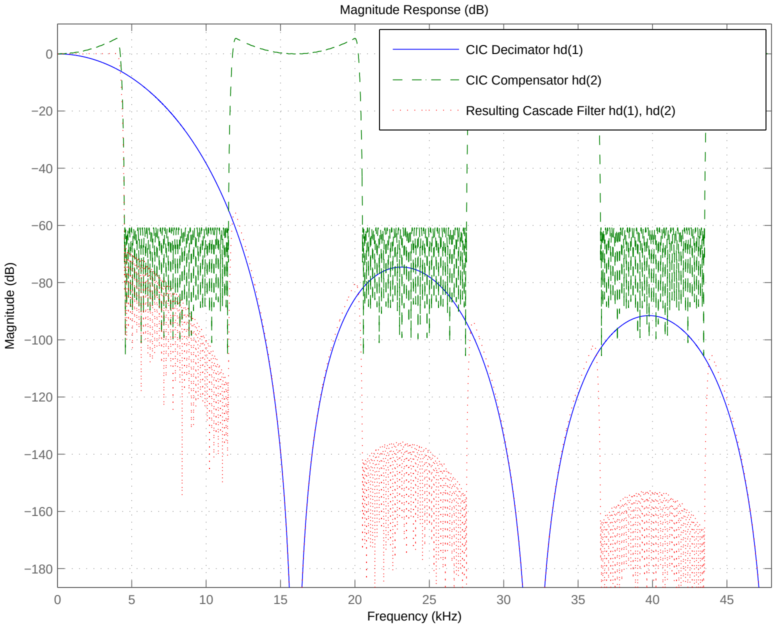
`h = fdesign.ciccomp(...,spec,specvalue1,specvalue2,...)` constructs an object and sets the specifications in the order they are specified in the `spec` input when you construct the object.

Designing CIC Compensators

Typically, when they develop filters, designers want flat passbands and transition regions that are as narrow as possible. CIC filters present a (sin*x*/*x*) profile in the passband and relatively wide transitions.

To compensate for this fall off in the passband, and to try to reduce the width of the transition region, you can use a CIC compensator filter that demonstrates an (*x*/sin*x*) profile in the passband. `fdesign.ciccomp` is specifically tailored to designing CIC compensators.

Here is a plot of a CIC filter and a compensator for that filter. The example that produces these filters follows the plot.



Given a CIC filter, how do you design a compensator for that filter? CIC compensators share three defining properties with the CIC filter — differential delay, d; number of sections, numberofsections; and the usable passband frequency, Fpass.

By taking the number of sections, passband, and differential delay from your CIC filter and using them in the definition of the CIC compensator, the resulting compensator filter effectively corrects for the passband droop of the CIC filter, and narrows the transition region.

As a demonstration of this concept, this example creates a CIC decimator and its compensator.

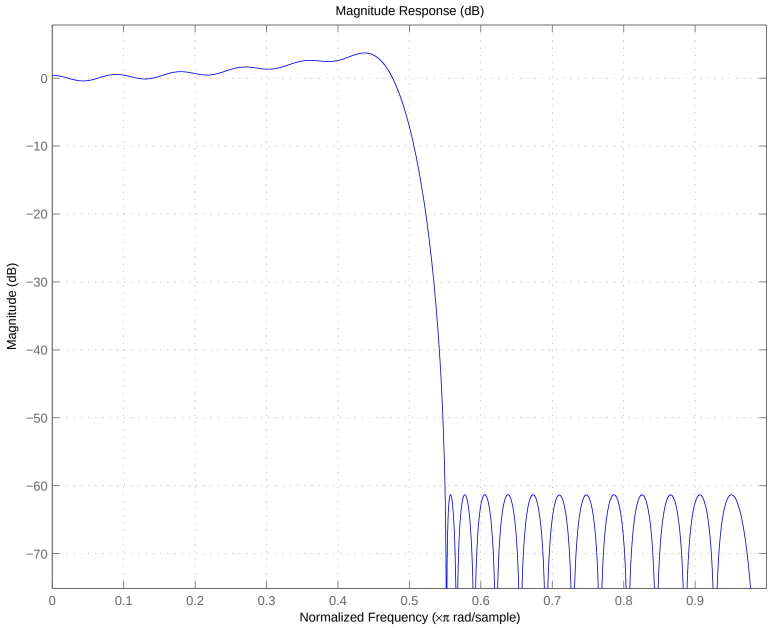
```
fs = 96e3;   % Input sampling frequency.
fpass = 4e3; % Frequency band of interest.
m = 6;  % Decimation factor.
hcic = design(fdesign.decimator(m,'cic',1,fpass,60,fs));
hd = cascade(dfilt.scalar(1/gain(hcic)),hcic);
hd(2) = design(fdesign.ciccomp(hcic.differentialdelay, ...
            hcic.numberofsections,fpass,4.5e3,.1,60,fs/m));
fvtool(hd(1),hd(2),...
cascade(hd(1),hd(2)),'Fs',[96e3 96e3/m 96e3])
```

You see the results in the preceding plot.

Examples

Designed to compensate for the rolloff inherent in CIC filters, CIC compensators can improve the performance of your CIC design. This example designs a compensator d with five sections and a differential delay equal to one. The plot displayed after the code shows the increasing gain in the passband that is characteristic of CIC compensators, to overcome the droop in the CIC filter passband. Ideally, cascading the CIC compensator with the CIC filter results in a lowpass filter with flat passband response and narrow transition region.

```
h = fdesign.ciccomp;
set(h, 'NumberOfSections', 5, 'DifferentialDelay', 1);
hd = equiripple(h);
fvtool(hd);
```



This compensator would work for a decimator or interpolator that had differential delay of 1 and 5 sections.

`fdesign.decimator` | `fdesign.interpolator`

fdesign.comb

IIR comb filter specification object

Syntax

```
d=fdesign.comb
d=fdesign.comb(combtype)
d=fdesign(combtype,specstring)
d=fdesign(combtype,specstring,specvalue1,specvalue2,...)
d=fdesign.comb(...,Fs)
```

Description

`fdesign.comb` specifies a peaking or notching comb filter. Comb filters amplify or attenuate a set of harmonically related frequencies.

`d=fdesign.comb` creates a notching comb filter specification object and applies default values for the filter order (`N=10`) and quality factor (`Q=16`).

`d=fdesign.comb(combtype)` creates a comb filter specification object of the specified type and applies default values for the filter order and quality factor. The valid entries for `combtype` are shown in the following table. The entries are not case-sensitive.

Argument	Description
`notch`	creates a comb filter that attenuates a set of harmonically related frequencies.
`peak`	creates a comb filter that amplifies a set of harmonically related frequencies.

`d=fdesign(combtype,`*`specstring`*`)` creates a comb filter specification object of type `combtype` and sets its `Specification` property to *`specstring`* with default values. The entries in *`specstring`* determine the number of peaks or notches in the comb filter as well as their bandwidth and slope. Valid entries for *`specstring`* are shown below. The entries are not case-sensitive.

- `'N,Q'` (default)

- `''N,BW'`
- `'L,BW,GWB,Nsh'`

The following table describes the arguments in *`specstring`*.

Argument	Description
`BW`	Bandwidth of the notch or peak. By default the bandwidth is calculated at the point –3 dB down from the center frequency of the peak or notch. For example, setting `BW=0.01` specifies that the –3 dB point will be +/- 0.005 (in normalized frequency) from the center of the notch or peak.
`GWB`	Gain at which the bandwidth is measured. This allows the user to specify the bandwidth of the notch or peak at a gain different from the –3 dB default.
`L`	Upsampling factor for a shelving filter of order `Nsh`. `L` determines the number of peaks or notches, which are equally spaced over the normalized frequency interval [-1,1].
`N`	Filter order. Specifies a filter with `N+1` numerator and denominator coefficients. The filter will have `N` peaks or notches equally spaced over the interval [–1,1] .
`Nsh`	Shelving filter order. `Nsh` represents a positive integer that determines the sharpness of the peaks or notches. The greater the value of the shelving filter order, the steeper the slope of the peak or notch. This results in a filter of order `L*Nsh`.
`Q`	Peak or notch quality factor. `Q` represents the ratio of the lowest center frequency peak or notch (not including DC) to the bandwidth calculated at the –3 dB point.

`d=fdesign(combtype,`*`specstring`*`,specvalue1,specvalue2,...)` creates an IIR comb filter specification object of type `combtype` and sets its `Specification` property to the values in `specvalue1,specvalue2,...`

`d=fdesign.comb(...,Fs)` creates an IIR comb filter specification object using the sampling frequency, `Fs`, of the signal to be filtered. The function assumes that `Fs` is in Hertz and must be specified as a scalar trailing all other provided values.

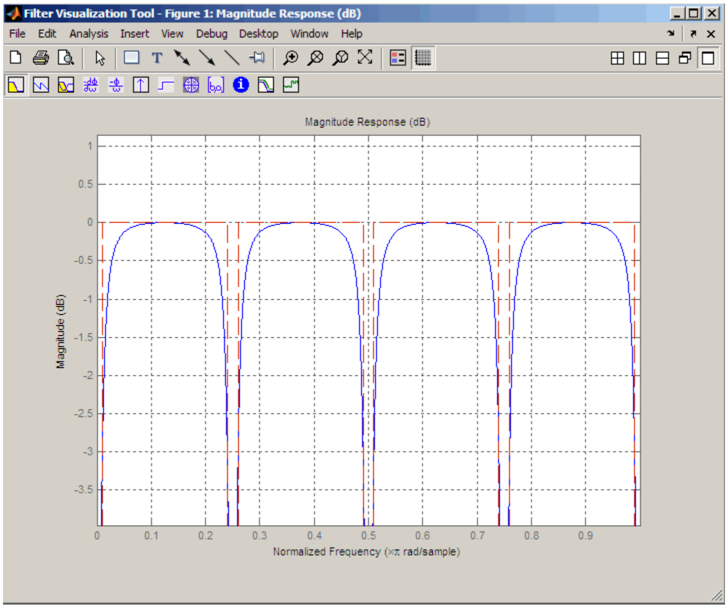
Examples

These examples demonstrate how to create IIR comb filter specification objects. First, create a default specification object.

```
d=fdesign.comb;
```

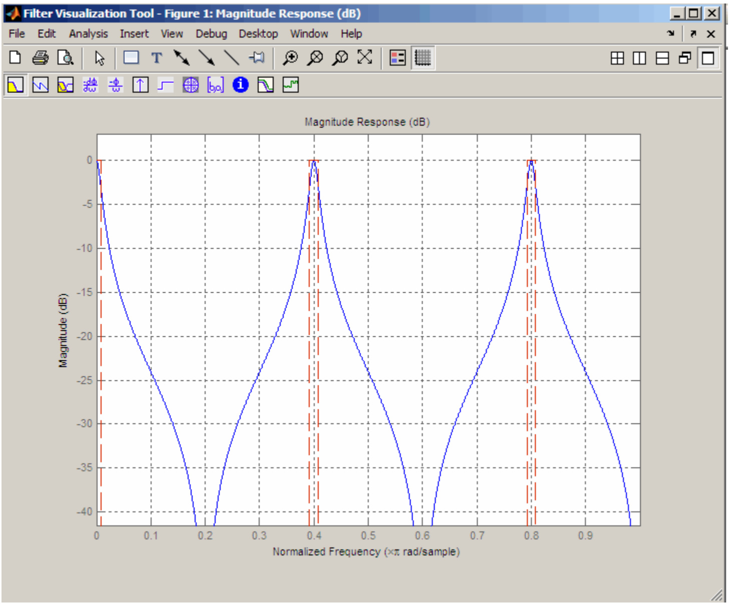
In the next example, create a notching filter of order 8 with a bandwidth of 0.02 (normalized frequency) referenced to the –3 dB point.

```
d  = fdesign.comb('notch','N,BW',8,0.02);
Hd = design(d);
fvtool(Hd)
```



Next, create a peaking comb filter with 5 peaks and a quality factor of 25.

```
d = fdesign.comb('peak','N,Q',5,25);
Hd = design(d);
fvtool(Hd)
```



In the next example, create a notching filter to remove interference at 60 Hz and its harmonics. The following code creates a filter with 10 notches and a notch bandwidth of 5 Hz referenced to the -4dB level. The filter has a shelving filter order of 4 and a sampling frequency of 600 Hz. Because the notches are equidistantly spaced in the interval [-300, 300] Hz, they occur at multiples of 60 Hz.

```
d = fdesign.comb('notch','L,BW,GBW,Nsh',10,5,-4,4,600);
Hd=design(d);
fvtool(Hd)
```

fdesign.decimator

Decimator filter specification object

Syntax

```
D = fdesign.decimator(M)
D = fdesign.decimator(M, RESPONSE)
D = fdesign.decimator(M, CICRESPONSE, D)
D = fdesign.decimator(M, RESPONSE, SPEC)
D = fdesign.decimator(...,SPEC,specvalue1,specvalue2,...)
D = fdesign.decimator(...,Fs)
D = fdesign.decimator(...,MAGUNITS)
```

Description

`D = fdesign.decimator(M)` constructs a decimator filter specification object `D` with the `DecimationFactor` property equal to the positive integer `M` and the `Response` property set to `'Nyquist'`. The default values for the transition width and stopband attenuation in the Nyquist design are 0.1π radians/sample and 80 dB. If `M` is unspecified, `M` defaults to 2.

`D = fdesign.decimator(M, RESPONSE)` constructs a decimator specification object with the decimation factor `M` and the `'Response'` property.

`D = fdesign.decimator(M, CICRESPONSE, D)` constructs a CIC or CIC compensator decimator specification object with the decimation factor, `M`, `'Response'` property equal to `'CIC'` or `'CICCOMP'`, and `D` equal to the differential delay. The differential delay, `D`, must precede any specification string.

Because you are designing multirate filters, the specification strings available are not the same as the specifications for designing single-rate filters. The decimation factor `M` is not included in the specification strings. Different filter responses support different specifications. The following table lists the supported response types and specification strings. The strings are not case sensitive.

Design String	Valid Specification Strings
'Arbitrary Magnitude'	See fdesign.arbmag for a description of the specification string entries. • 'N,F,A' (default string) • 'N,B,F,A'
'Arbitrary Magnitude and Phase'	See fdesign.arbmagnphase for a description of the specification string entries. • 'N,F,H' (default string) • 'N,B,F,H'
'Bandpass'	See fdesign.bandpass for a description of the specification string entries. • 'Fst1,Fp1,Fp2,Fst2,Ast1,Ap,Ast2' (default string) • 'N,Fc1,Fc2' • 'N,Fst1,Fp1,Fp2,Fst2'
'Bandstop'	See fdesign.bandstop for a description of the specification string entries. • 'N,Fc1,Fc2' • 'N,Fp1,Fst1,Fst2,Fp2' • 'Fp1,Fst1,Fst2,Fp2,Ap1,Ast,Ap2' (default string)
'CIC'	'Fp,Ast' — Only valid specification. Fp is the passband frequency and Ast is the stopband attenuation in decibels. To specify a CIC decimator, include the differential delay after 'CIC' and before the filter specification string: 'Fp,Ast'. For example: d = fdesign.decimator(2,'cic',4,'Fp,Ast',0.4,40);

Design String	Valid Specification Strings
`'CIC Compensator'`	See `fdesign.ciccomp` for a description of the specification string entries. • `'Fp,Fst,Ap,Ast'` (default string) • `'N,Fc,Ap,Ast'` • `'N,Fp,Ap,Ast'` • `'N,Fp,Fst'` • `'N,Fst,Ap,Ast'` To specify a CIC compensator decimator, include the differential delay after `'CICCOMP'` and before the filter specification string. For example: `d = fdesign.decimator(2,'ciccomp',4);`
`'Differentiator'`	`'N'` — filter order
`'Gaussian'`	`'Nsym,BT` — `Nsym` is the filter order in symbols and `BT` is the bandwidth-symbol time product. The specification string must be preceded by an integer-valued `SamplesPerSymbol`.
`'Halfband`	See `fdesign.halfband` for a description of the specification string entries. • `'TW,Ast'` (default string) • `'N,TW'` • `‘N’` • `'N,Ast'` If you use the quasi-linear IIR design method, `iirlinphase`, with a halfband specification, the interpolation factor must be 2.

Design String	Valid Specification Strings
'Highpass'	See fdesign.highpass for a description of the specification string entries. • 'Fst,Fp,Ast,Ap' (default string) • 'N,F3db' • 'N,Fc' • 'N,Fc,Ast,Ap' • 'N,Fp,Ast,Ap' • 'N,Fst,Ast,Ap' • 'N,Fst,Fp' • 'N,Fst,Ast,Ap' • 'N,Fst,Fp,Ast'
'Hilbert'	See fdesign.hilbert for a description of the specification string entries. • 'N,TW' (default string) • 'TW,Ap'
'Inverse-sinc Lowpass'	See fdesign.isinclp for a description of the specification string entries. • 'Fp,Fst,Ap,Ast' (default string) • 'N,Fc,Ap,Ast' • 'N,Fp,Fst' • 'N,Fst,Ap,Ast'
'Inverse-sinc Highpass'	See fdesign.isinchp for a description of the specification string entries. • 'Fst,Fp,Ast,Ap' (default string) • 'N,Fc,Ast,Ap' • 'N,Fst,Fp' • 'N,Fst,Ast,Ap'

Design String	Valid Specification Strings
'Lowpass'	See fdesign.lowpass for a description of the specification string entries. • 'Fp,Fst,Ap,Ast' (default string) • 'N,F3dB' • 'N,Fc' • 'N,Fc,Ap,Ast' • 'N,Fp,Ap,Ast' • 'N,Fp,Fst' • 'N,Fp,Fst,Ap' • 'N,Fp,Fst,Ast' • 'N,Fst,Ap,Ast'
'Nyquist'	See fdesign.nyquist for a description of the specification string entries. For all Nyquist specifications, you must specify the *L*th band. This typically corresponds to the DecimationFactor. • 'TW,Ast' (default string) • 'N' • 'N,Ast' • 'N,Ast'

D = fdesign.decimator(M, RESPONSE, SPEC) constructs object D and sets the Specification property to SPEC for the response type, RESPONSE. Entries in the SPEC string represent various filter response features, such as the filter order, that govern the filter design. Valid entries for SPEC depend on the RESPONSE type.

Because you are designing multirate filters, the specification strings available are not the same as the specifications for designing single-rate filters with such response types as fdesign.lowpass. The strings are not case sensitive.

The decimation factor M is not in the specification strings.

D = fdesign.decimator(...,SPEC,specvalue1,specvalue2,...) constructs an object D and sets its specifications at construction time.

D = fdesign.decimator(...,Fs) provides the sampling frequency of the signal to be filtered. Fs must be specified as a scalar trailing the other numerical values provided. Fs is assumed to be in Hz as are all other frequency values provided.

D = fdesign.decimator(...,MAGUNITS) specifies the units for any magnitude specification you provide in the input arguments. MAGUNITS can be one of

- 'linear' — specify the magnitude in linear units.
- 'dB' — specify the magnitude in dB (decibels).
- 'squared' — specify the magnitude in power units.

When you omit the MAGUNITS argument, fdesign assumes that all magnitudes are in decibels. Note that fdesign stores all magnitude specifications in decibels (converting to decibels when necessary) regardless of how you specify the magnitudes.

Examples

These examples show how to construct decimating filter specification objects. First, create a default specifications object without using input arguments except for the decimation factor m.

```
d = fdesign.decimator(2,'Nyquist',2,0.1,80) % Set tw=0.1, and ast=80.
```

Now create an object by passing a specification type string 'fst1,fp1,fp2,fst2,ast1,ap,ast2' and a design — the resulting object uses default values for the filter specifications. You must provide the design input argument, bandpass in this example, when you include a specification.

```
d=fdesign.decimator(8,'bandpass',...
'fst1,fp1,fp2,fst2,ast1,ap,ast2');
```

Create another decimating filter specification object, passing the specification values to the object rather than accepting the default values for fp,fst,ap,ast.

```
d=fdesign.decimator(3,'lowpass',.45,0.55,.1,60);
```

Now pass the filter specifications that correspond to the specifications — n,fc,ap,ast.

```
d=fdesign.decimator(3,'ciccomp',1,2,'n,fc,ap,ast',...
20,0.45,.05,50);
```

Now design a decimator using the equiripple design method.

```
hm = equiripple(d);
```

Pass a new specification type for the filter, specifying the filter order. Note that the inputs must include the differential delay dd with the CIC input argument to design a CIC specification object.

```
m = 5;
dd = 2;
d = fdesign.decimator(m,'cic',dd,'fp,ast',0.55,55);
```

In this example, you specify a sampling frequency as the last input argument. Here is it 1000 Hz. Design an equiripple filter and plot the magnitude response:

```
d=fdesign.decimator(8,'bandpass','fst1,fp1,fp2,fst2,ast1,ap,ast2',...
100,150,250,300,50,.05,50,1000);
fvtool(design(d,'equiripple'))
```

fdesign.differentiator

Differentiator filter specification object

Syntax

```
D = fdesign.differentiator
D = fdesign.differentiator(SPEC)
D = fdesign.differentiator(SPEC,specvalue1,specvalue2, ...)
D = fdesign.differentiator(specvalue1)
D = fdesign.differentiator(...,Fs)
D = fdesign.differentiator(...,MAGUNITS)
```

Description

`D = fdesign.differentiator` constructs a default differentiator filter designer `D` with the filter order set to 31.

`D = fdesign.differentiator(SPEC)` initializes the filter designer `Specification` property to `SPEC`. You provide one of the following strings as input to replace `SPEC`. The string you provide is not case sensitive.

Note: Specifications strings marked with an asterisk require the DSP System Toolbox software.

- `'N'` — Full band differentiator (default)
- `'N,Fp,Fst'` — Partial band differentiator
- `'N,Fp,Fst,Ap'` — Partial band differentiator *
- `'N,Fp,Fst,Ast'` — Partial band differentiator *
- `'Ap'` — Minimum order full band differentiator *
- `'Fp,Fst,Ap,Ast'` — Minimum order partial band differentiator *

The string entries are defined as follows:

- Ap — amount of ripple allowed in the pass band in decibels (the default units). Also called Apass.
- Ast — attenuation in the stop band in decibels (the default units). Also called Astop.
- Fp — frequency at the start of the pass band. Specified in normalized frequency units. Also called Fpass.
- Fst — frequency at the end of the stop band. Specified in normalized frequency units. Also called Fstop.
- N — filter order.

By default, fdesign.differentiator assumes that all frequency specifications are provided in normalized frequency units. Also, decibels is the default for all magnitude specifications.

Use designopts to determine the design options for a given design method. Enter help(D,METHOD) at the MATLAB command line to obtain detailed help on the design options for a given design method, METHOD.

D = fdesign.differentiator(SPEC,specvalue1,specvalue2, ...) initializes the filter designer specifications in SPEC with specvalue1, specvalue2, and so on. To get a description of the specifications specvalue1, specvalue2, and more, enter

```
get(d,'description')
```

at the Command prompt.

D = fdesign.differentiator(specvalue1) assumes the default specification string N, setting the filter order to the value you provide.

D = fdesign.differentiator(...,Fs) adds the argument Fs, specified in Hz to define the sampling frequency to use. In this case, all frequencies in the specifications are in Hz as well.

D = fdesign.differentiator(...,MAGUNITS) specifies the units for any magnitude specification you provide in the input arguments. MAGUNITS can be one of

- 'linear' — specify the magnitude in linear units
- 'dB' — specify the magnitude in dB (decibels)
- 'squared' — specify the magnitude in power units

When you omit the MAGUNITS argument, fdesign assumes that all magnitudes are in decibels. Note that fdesign stores all magnitude specifications in decibels (converting to decibels when necessary) regardless of how you specify the magnitudes.

Examples

Use an FIR equiripple differentiator to transform frequency modulation into amplitude modulation, which can be detected using an envelope detector.

Modulate a message signal consisting of a 20-Hz sine wave with a 1 kHz carrier frequency. The sampling frequency is 10 kHz .

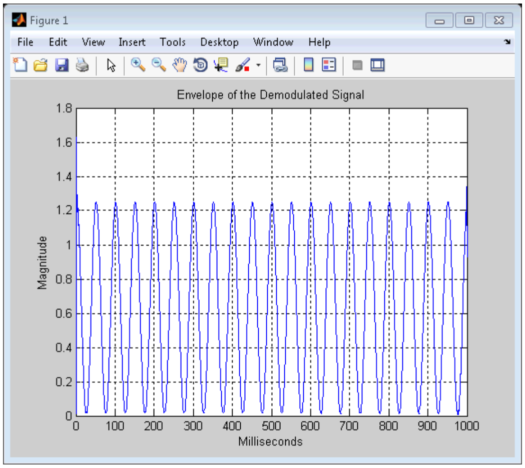
```
t = linspace(0,1,1e4);
x = cos(2*pi*20*t);
Fc = 1e3;
Fs = 1e4;
y = modulate(x,Fc,Fs,'fm');
```

Design the equiripple FIR differentiator of order 31.

```
d = fdesign.differentiator(31,1e4);
Hd = design(d,'equiripple');
```

Filter the modulated signal and take the Hilbert transform to obtain the envelope.

```
y1 = filter(Hd,y);
y1 = hilbert(y1);
% Plot the envelope
plot(t.*1000,abs(y1));
xlabel('Milliseconds'); ylabel('Magnitude');
grid on;
title('Envelope of the Demodulated Signal');
```



From the preceding figure, you see that the envelope completes two cycles every 100 milliseconds. The envelope is oscillating at 20 Hz, which corresponds to the frequency of the message signal.

Design an FIR differentiator using least squares and plot the zero phase response.

```
d = fdesign.differentiator(33); % Filter order is 33.
hd = design(d,'firls');
fvtool(hd,'magnitudedisplay','zero-phase',...
'frequencyrange','[-pi, pi)')
```

`design` | `fdesign`

fdesign.fracdelay

Fractional delay filter specification object

Syntax

```
d = fdesign.fracdelay(delta)
d = fdesign.fracdelay(delta,'N')
d = fdesign.fracdelay(delta,'N',n)
d = fdesign.fracdelay(delta,n)
d = fdesign.fracdelay(...,fs)
```

Description

`d = fdesign.fracdelay(delta)` constructs a default fractional delay filter designer `d` with the filter order set to 3 and the delay value set to `delta`. The fractional delay `delta` must be between 0 and 1 samples.

`d = fdesign.fracdelay(`*`delta,`*`'N')` initializes the filter designer specification string to `N`, where `N` specifies the fractional delay filter order and defaults to filter order of 3.

Use `designmethods(d)` to get a list of the design methods available for a specification string.

`d = fdesign.fracdelay(delta,'N',n)` initializes the filter designer to specification string `N` and sets the filter order to `n`.

`d = fdesign.fracdelay(delta,n)` assumes the default specification `N`, filter order, and sets the filter order to the value you provide in input `n`.

`d = fdesign.fracdelay(...,fs)` adds the argument `fs`, specified in units of Hertz (Hz) to define the sampling frequency. In this case, specify the fractional delay `delta` to be between 0 and 1/`fs`.

Examples

Design a second-order fractional delay filter of 0.2 samples using the Lagrange method. Implement the filter using a Farrow fractional delay (`fd`) structure.

```
d = fdesign.fracdelay(0.2,'N',2);
hd = design(d,'lagrange','filterstructure','farrowfd');
fvtool(hd,'analysis','grpdelay')
```

Design a cubic fractional delay filter with a sampling frequency of 8 kHz and fractional delay of 50 microseconds using the Lagrange method.

```
d = fdesign.fracdelay(50e-6,'N',3,8000);
Hd = design(d, 'lagrange', 'FilterStructure', 'farrowfd');
```

`design` | `designopts` | `fdesign` | `setspecs`

fdesign.halfband

Halfband filter specification object

Syntax

```
d = fdesign.halfband
d = fdesign.halfband('type',type)
d = fdesign.halfband(spec)
d = fdesign.halfband(spec,specvalue1,specvalue2,...)
d = fdesign.halfband(specvalue1,specvalue2)
d = fdesign.halfband(...,fs)
d = fdesign.halfband(...,magunits)
```

Description

`d = fdesign.halfband` constructs a halfband filter specification object `d`, applying default values for the properties `tw` and `ast`.

Using `fdesign.halfband` with a design method generates a `dfilt` object.

`d = fdesign.halfband('type',type)` initializes the filter designer 'Type' property with `type`. “`type`” must be either `lowpass` or `highpass` and is not case sensitive.

`d = fdesign.halfband(`*`spec`*`)` constructs object `d` and sets its '`Specification`' to *`spec`*. Entries in the `spec` string represent various filter response features, such as the filter order, that govern the filter design. Valid entries for *`spec`* are shown below. The strings are not case sensitive.

- `tw,ast` (default `spec`)
- `n,tw`
- `n`
- `n,ast`

The string entries are defined as follows:

- `ast` — attenuation in the stop band in decibels (the default units).
- `n` — filter order.

- tw — width of the transition region between the pass and stop bands. Specified in normalized frequency units.

By default, all frequency specifications are assumed to be in normalized frequency units. Moreover, all magnitude specifications are assumed to be in dB. Different specification types may have different design methods available.

The filter design methods that apply to a halfband filter specification object change depending on the Specification string. Use designmethods to determine which design method applies to an object and its specification string. Different filter design methods also have options that you can specify. Use designopts with the design method string to see the available options. For example:

```
f=fdesign.halfband('N,TW');
designmethods(f)
```

d = fdesign.halfband(spec,specvalue1,specvalue2,...) constructs an object d and sets its specifications at construction time.

d = fdesign.halfband(specvalue1,specvalue2) constructs an object d assuming the default Specification property string tw,ast, using the values you provide for the input arguments specvalue1 and specvalue2 for tw and ast.

d = fdesign.halfband(...,fs) adds the argument fs, specified in Hz to define the sampling frequency to use. In this case, all frequencies in the specifications are in Hz as well.

d = fdesign.halfband(...,magunits) specifies the units for any magnitude specification you provide in the input arguments. magunits can be one of

- linear — specify the magnitude in linear units
- dB — specify the magnitude in dB (decibels)
- squared — specify the magnitude in power units

When you omit the magunits argument, fdesign assumes that all magnitudes are in decibels. Note that fdesign stores all magnitude specifications in decibels (converting to decibels when necessary) regardless of how you specify the magnitudes.

Examples

Create a default halfband filter specifications object:

```
d=fdesign.halfband;
```

Create another halfband filter object, passing the specification values to the object rather than accepting the default values for `n` and `ast`.

```
 d = fdesign.halfband('n,ast', 42, 80);
```

For another example, pass the filter values that correspond to the default `Specification` — `n,ast`.

```
d = fdesign.halfband(.01, 80);
```

This example designs an equiripple FIR filter, starting by passing a new specification type and specification values to `fdesign.halfband`.

```
 hs = fdesign.halfband('n,ast',80,70);
hd =design(hs,'equiripple'); % Opens FVTool automatically.
```

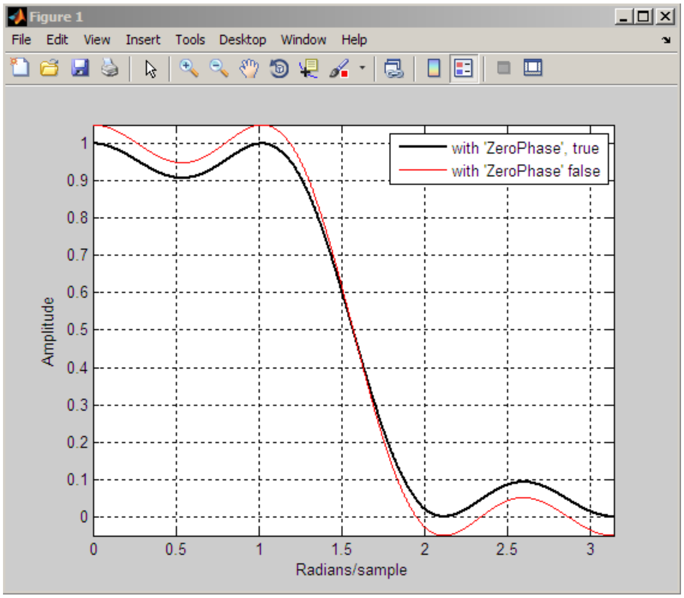
In this example, pass the specifications for the filter, and then design a least-squares FIR filter from the object, using `firls` as the design method.

```
 hs = fdesign.halfband('n,tw', 42, .04);
% designmethods(hs)
hd=design(hs,'firls');
```

Create two equiripple halfband filters with and without a nonnegative zero phase response:

```
f=fdesign.halfband('N,TW',12,0.2);
% Equiripple halfband filter with nonnegative zero phase response
Hd1=design(f,'equiripple','ZeroPhase',true);
% Equiripple halfband filter with zero phase false
% 'zerophase',false is the default
Hd2=design(f,'equiripple','ZeroPhase',false);
%Obtain real-valued amplitudes (not magnitudes)
[Hr_zerophase,W]=zerophase(Hd1);
[Hr,W]=zerophase(Hd2);
% Plot and compare response
plot(W,Hr_zerophase,'k','linewidth',2);
xlabel('Radians/sample'); ylabel('Amplitude');
hold on;
plot(W,Hr,'r');
axis tight; grid on;
legend('with ''ZeroPhase'', true','with ''ZeroPhase'' false');
```

Note that the amplitude of the zero phase response (black line) is nonnegative for all frequencies.



The `'ZeroPhase'` option is valid only for equiripple halfband designs with the `'N,TW'` specification. You cannot specify `'MinPhase'` and `'ZeroPhase'` to be simultaneously `'true'`.

`fdesign` | `fdesign.decimator` | `design` | `fdesign.interpolator` | `fdesign.nyquist` | `setspecs` | `zerophase`

fdesign.highpass

Highpass filter specification object

Syntax

```
D = fdesign.highpass
D = fdesign.highpass(SPEC)
D = fdesign.highpass(SPEC,specvalue1,specvalue2,...)
D = fdesign.highpass(specvalue1,specvalue2,specvalue3,
specvalue4)
D = fdesign.highpass(...,Fs)
D = fdesign.highpass(...,MAGUNITS)
```

Description

`D = fdesign.highpass` constructs a highpass filter specification object `D`, applying default values for the specification string, `'Fst,Fp,Ast,Ap'`.

`D = fdesign.highpass(SPEC)` constructs object `D` and sets the `Specification` property to `SPEC`. Entries in the `SPEC` string represent various filter response features, such as the filter order, that govern the filter design. Valid entries for `SPEC` are shown below. The strings are not case sensitive.

Note: Specifications strings marked with an asterisk require the DSP System Toolbox software.

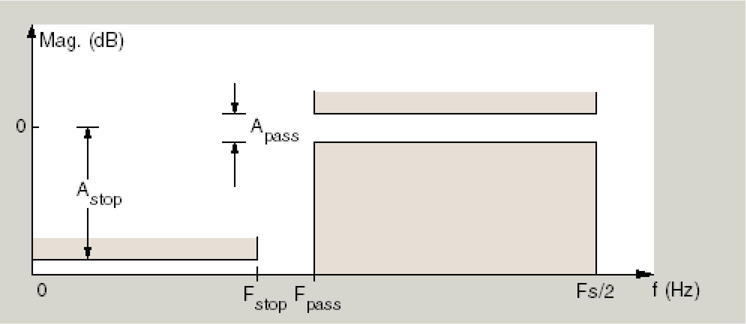
- `'Fst,Fp,Ast,Ap'` (default `spec`)
- `'N,F3db'`
- `'N,F3db,Ap'` *
- `'N,F3db,Ast'` *
- `'N,F3db,Ast,Ap'` *
- `'N,F3db,Fp` *

- `'N,Fc'`
- `'N,Fc,Ast,Ap'`
- `'N,Fp,Ap'`
- `'N,Fp,Ast,Ap'`
- `'N,Fst,Ast'`
- `'N,Fst,Ast,Ap'`
- `'N,Fst,F3db'` *
- `'N,Fst,Fp'`
- `'N,Fst,Fp,Ap'` *
- `'N,Fst,Fp,Ast'` *
- `'Nb,Na,Fst,Fp'` *

The string entries are defined as follows:

- `Ap` — amount of ripple allowed in the pass band in decibels (the default units). Also called Apass.
- `Ast` — attenuation in the stop band in decibels (the default units). Also called Astop.
- `F3db` — cutoff frequency for the point 3 dB point below the passband value. Specified in normalized frequency units.
- `Fc` — cutoff frequency for the point 6 dB point below the passband value. Specified in normalized frequency units.
- `Fp` — frequency at the start of the pass band. Specified in normalized frequency units. Also called Fpass.
- `Fst` — frequency at the end of the stop band. Specified in normalized frequency units. Also called Fstop.
- `N` — filter order.
- `Na` and `Nb` are the order of the denominator and numerator.

Graphically, the filter specifications look similar to those shown in the following figure.



Regions between specification values like `Fst` and `Fp` are transition regions where the filter response is not explicitly defined.

The filter design methods that apply to a highpass filter specification object change depending on the `Specification` string. Use `designmethods` to determine which design method applies to an object and its specification string.

Use `designopts` to determine which design options are valid for a given design method. For detailed information on design options for a given design method, `METHOD`, enter `help(D,METHOD)` at the MATLAB command line.

`D = fdesign.highpass(SPEC,specvalue1,specvalue2,...)` constructs an object `d` and sets its specification values at construction time.

`D = fdesign.highpass(specvalue1,specvalue2,specvalue3, specvalue4)` constructs an object `D` with the default `Specification` property and the values you enter for `specvalue1,specvalue2,...`.

`D = fdesign.highpass(...,Fs)` provides the sampling frequency for the filter specification object. `Fs` is in Hz and must be specified as a scalar trailing the other numerical values provided. If you specify a sampling frequency, all other frequency specifications are in Hz.

`D = fdesign.highpass(...,MAGUNITS)` specifies the units for any magnitude specification you provide in the input arguments. `MAGUNITS` can be one of

- `'linear'` — specify the magnitude in linear units
- `'dB'` — specify the magnitude in dB (decibels)
- `'squared'` — specify the magnitude in power units

When you omit the MAGUNITS argument, fdesign assumes that all magnitudes are in decibels. Note that fdesign stores all magnitude specifications in decibels (converting to decibels when necessary) regardless of how you specify the magnitudes.

Examples

Highpass filter a discrete-time signal consisting of two sine waves.

Create a highpass filter specification object. Specify the passband frequency to be 0.25π radians/sample and the stopband frequency to be 0.15π radians/sample. Specify 1 dB of allowable passband ripple and a stopband attenuation of 60 dB.

```
d = fdesign.highpass('Fst,Fp,Ast,Ap',0.15,0.25,60,1);
```

Query the valid design methods for your filter specification object, d.

```
designmethods(d)
```

Create an FIR equiripple filter and view the filter magnitude response with fvtool.

```
Hd = design(d,'equiripple');
fvtool(Hd);
```

Create a signal consisting of the sum of two discrete-time sinusoids with frequencies of π/8 and π/4 radians/sample and amplitudes of 1 and 0.25 respectively. Filter the discrete-time signal with the FIR equiripple filter object, Hd

```
n = 0:159;
x = cos((pi/8)*n)+0.25*sin((pi/4)*n);
y = filter(Hd,x);
Domega = (2*pi)/160;
freq = 0:(2*pi)/160:pi;
xdft = fft(x);
ydft = fft(y);
plot(freq,abs(xdft(1:length(x)/2+1)));
hold on;
plot(freq,abs(ydft(1:length(y)/2+1)),'r','linewidth',2);
legend('Original Signal','Lowpass Signal', ...
'Location','NorthEast');
ylabel('Magnitude'); xlabel('Radians/Sample');
```

Create a filter of order 10 with a 6-dB frequency of 9.6 kHz and a sampling frequency of 48 kHz.

```
d=fdesign.highpass('N,Fc',10,9600,48000);
designmethods(d)
% only valid design method is FIR window method
Hd = design(d);
% Display filter magnitude response
fvtool(Hd);
```

If you have the DSP System Toolbox software, you can specify the shape of the stopband and the rate at which the stopband decays.

Create two FIR equiripple filters with different linear stopband slopes. Specify the passband frequency to be 0.3π radians/sample and the stopband frequency to be 0.35π radians/sample. Specify 1 dB of allowable passband ripple and a stopband attenuation of 60 dB. Design one filter with a 20 dB/rad/sample stopband slope and another filter with 40 dB/rad/sample.

```
D = fdesign.highpass('Fst,Fp,Ast,Ap',0.3,0.35,60,1);
Hd1 = design(D,'equiripple','StopBandShape','linear','StopBandDecay',20);
Hd2 = design(D,'equiripple','StopBandShape','linear','StopBandDecay',40);
hfvt = fvtool([Hd1 Hd2]);
legend(hfvt,'20 dB/rad/sample','40 dB/rad/sample');
```

design | designmethods | fdesign

fdesign.hilbert

Hilbert filter specification object

Syntax

```
d = fdesign.hilbert
d = fdesign.hilbert(specvalue1,specvalue2)
d = fdesign.hilbert(spec)
d = fdesign.hilbert(spec,specvalue1,specvalue2)
d = fdesign.hilbert(...,Fs)
d = fdesign.hilbert(...,MAGUNITS)
```

Description

`d = fdesign.hilbert` constructs a default Hilbert filter designer `d` with `N`, the filter order, set to 30 and `TW`, the transition width set to 0.1π radians/sample.

`d = fdesign.hilbert(specvalue1,specvalue2)` constructs a Hilbert filter designer `d` assuming the default specification string `'N,TW'`. You input `specvalue1` and `specvalue2` for `N` and `TW`.

`d = fdesign.hilbert(`*`spec`*`)` initializes the filter designer `Specification` property to `spec`. You provide one of the following strings as input to replace `spec`. The specification strings are not case sensitive.

Note: Specifications strings marked with an asterisk require the DSP System Toolbox software.

- `'N,TW'` default spec string.
- `'TW,Ap'` *

The string entries are defined as follows:

- `Ap` — amount of ripple allowed in the pass band in decibels (the default units). Also called Apass.

- N — filter order.
- TW — width of the transition region between the pass and stop bands.

By default, fdesign.hilbert assumes that all frequency specifications are provided in normalized frequency units. Also, decibels is the default for all magnitude specifications.

Different specification strings may have different design methods available. Use designmethods(d) to get a list of the design methods available for a given specification string.

d = fdesign.hilbert(*spec*,specvalue1,specvalue2) initializes the filter designer specifications in spec with specvalue1, specvalue2, and so on. To get a description of the specifications specvalue1 and specvalue2, enter

```
get(d,'description')
```

at the Command prompt.

d = fdesign.hilbert(...,Fs) adds the argument Fs, specified in Hz to define the sampling frequency. In this case, all frequencies in the specifications are in Hz as well.

d = fdesign.hilbert(...,MAGUNITS) specifies the units for any magnitude specification you provide in the input arguments. MAGUNITS can be one of

- 'linear' — specify the magnitude in linear units
- 'dB' — specify the magnitude in dB (decibels)
- 'squared' — specify the magnitude in power units

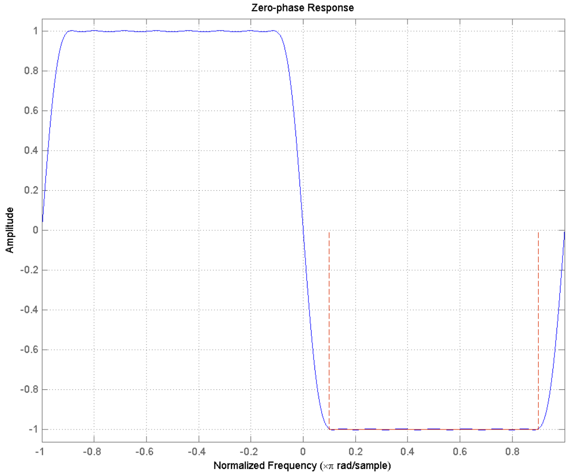
When you omit the MAGUNITS argument, fdesign assumes that all magnitudes are in decibels. Note that fdesign stores all magnitude specifications in decibels (converting to decibels when necessary) regardless of how you specify the magnitudes.

Examples

Design a Hilbert transformer of order 30 with a transition width of 0.2π radians/sample. Plot the zero phase response from [-π,π) radians/sample and the impulse response.

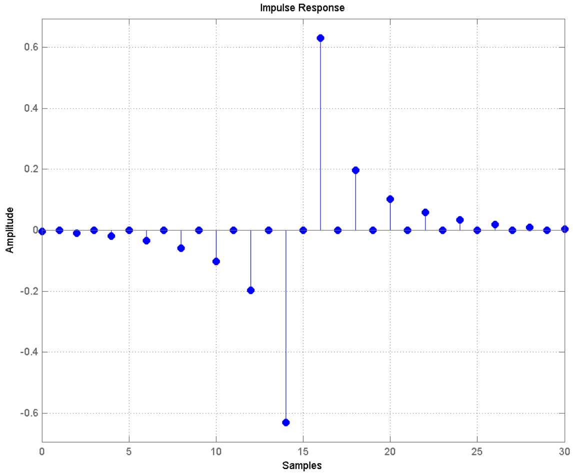
```
d = fdesign.hilbert('N,TW',30,0.2);
% Show available design methods
designmethods(d)
% Use least square minimization to obtain linear-phase FIR filter
Hd = design(d,'equiripple');
```

```
% Display zero phase response from [-pi,pi)
fvtool(Hd,'magnitudedisplay','zero-phase',...
'frequencyrange','[-pi, pi)')
```



The impulse response of this even order filter is antisymmetric (type III).

```
fvtool(Hd,'analysis','impulse')
```

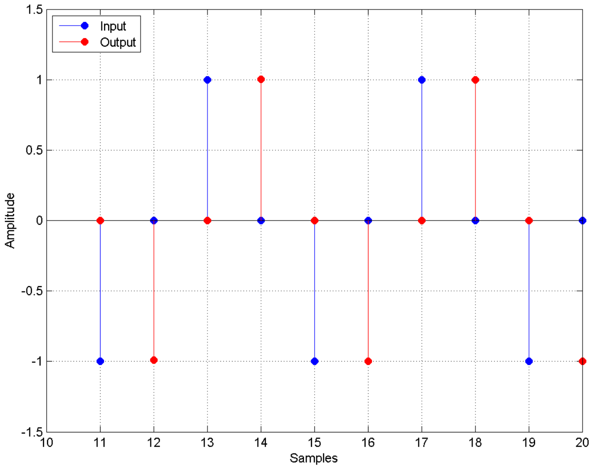


Apply the filter to a discrete-time sinusoid with a frequency of π/2 radians/sample.

```
n = 0:99;
x = cos(pi/2*n);
y = filter(Hd,x);
% Correct for the filter delay
Delay = floor(length(Hd.Numerator)/2);
y = y(Delay+1:end);
```

Plot a the filter input and output and validate the approximate π/2 phase shift obtained with the Hilbert transformer.

```
stem(x(1:end-Delay),'markerfacecolor',[0 0 1]);
hold on;
stem(y,'Color',[1 0 0],'markerfacecolor',[1 0 0]);
axis([10 20 -1.5 1.5]); grid on;
xlabel('Samples'); ylabel('Amplitude');
legend('Input','Output','Location','NorthWest')
```



Because the frequency of the discrete-time sinusoid is π/2 radians/sample, a one sample shift corresponds to a phase shift of π/2.

Form the analytic signal and demonstrate that the frequency content of the analytic signal is zero for negative frequencies and approximately twice the spectrum of the input for positive frequencies.

```
x1 = x(1:end-Delay);
% Form the analytic signal
xa = x1+1j*y;

fdesign.interpolator

Interpolator filter specification

Syntax

```
D = fdesign.interpolator(L)
D = fdesign.interpolator(L,RESPONSE)
D = fdesign.interpolator(L,CICRESPONSE,D)
D = fdesign.interpolator(L,RESPONSE,spec)
D = fdesign.interpolator(...,spec,specvalue1,specvalue2,...)
D = fdesign.interpolator(...,Fs)
d = fdesign.interpolator(...,MAGUNITS)
```

Description

`D = fdesign.interpolator(L)` constructs an interpolator filter specification object `D` with the `InterpolationFactor` property equal to the positive integer `L` and the `Response` property set to `'Nyquist'`. The default values for the transition width and stopband attenuation in the Nyquist design are 0.1π radians/sample and 80 dB. If `L` is unspecified, `L` defaults to 2.

`D = fdesign.interpolator(L,RESPONSE)` constructs a interpolator specification object with the interpolation factor `L` and the `'Response'` property set to one of the supported types.

`D = fdesign.interpolator(L,CICRESPONSE,D)` constructs a CIC or CIC compensator interpolator specification object with the interpolation factor, `L`, and `'Response'` property equal to `'CIC'` or `'CICCOMP'`. `D` is the differential delay. The differential delay, `D`, must precede any specification string.

`D = fdesign.interpolator(L,RESPONSE,spec)` constructs object `D` and sets its `Specification` property to `spec`. Entries in the `spec` string represent various filter response features, such as the filter order, that govern the filter design. Valid entries for `spec` depend on the design type of the specifications object.

When you add the `spec` input argument, you must also add the `RESPONSE` input argument.

Because you are designing multirate filters, the specification strings available are not the same as the specifications for designing single-rate filters with design methods such as `fdesign.lowpass`. The strings are not case sensitive.

The interpolation factor `L` is not in the specification strings. The different filter responses support different specifications. The following table lists the supported response types and specification strings.

Design String	Valid Specification Strings
`'Arbitrary Magnitude'`	See `fdesign.arbmag` for a description of the specification string entries. • `'N,F,A'` (default string) • `'N,B,F,A'`
`'Arbitrary Magnitude and Phase'`	See `fdesign.arbmagnphase` for a description of the specification string entries. • `'N,F,H'` (default string) • `'N,B,F,H'`
`'Bandpass'`	See `fdesign.bandpass` for a description of the specification string entries. • `'Fst1,Fp1,Fp2,Fst2,Ast1,Ap,Ast2'` (default string) • `'N,Fc1,Fc2'` • `'N,Fst1,Fp1,Fp2,Fst2'`
`'Bandstop'`	See `fdesign.bandstop` for a description of the specification string entries. • `'N,Fc1,Fc2'` • `'N,Fp1,Fst1,Fst2,Fp2'` • `'Fp1,Fst1,Fst2,Fp2,Ap1,Ast,Ap2'` (default string)
`'CIC'`	`'Fp,Ast'` — Only valid specification. `Fp` is the passband frequency and `Ast` is the stopband attenuation in decibels. To specify a CIC interpolator, include the differential delay after `'CIC'` and before the filter specification string: `'Fp,Ast'`. For example:

Design String	Valid Specification Strings

	`d =`
	`fdesign.interpolator(2,'cic',4,'Fp,Ast',0.4,40);`

`'CIC Compensator'`	See `fdesign.ciccomp` for a description of the specification string entries. • `'Fp,Fst,Ap,Ast'` (default string) • `'N,Fc,Ap,Ast'` • `'N,Fp,Ap,Ast'` • `'N,Fp,Fst'` • `'N,Fst,Ap,Ast'` To specify a CIC compensator interpolator, include the differential delay after `'CICCOMP'` and before the filter specification string. For example: `d = fdesign.interpolator(2,'ciccomp',4);`
`'Differentiator'`	`'N'` — filter order
`'Gaussian'`	`'Nsym,BT` — `Nsym` is the filter order in symbols and `BT` is the bandwidth-symbol time product. The specification string must be preceded by an integer-valued `SamplesPerSymbol`.
`'Halfband`	See `fdesign.halfband` for a description of the specification string entries. • `'TW,Ast'` (default string) • `'N,TW'` • `‘N’` • `'N,Ast'` If you use the quasi-linear IIR design method, `iirlinphase`, with a halfband specification, the interpolation factor must be 2.

Design String	Valid Specification Strings
`'Highpass'`	See `fdesign.highpass` for a description of the specification string entries. • `'Fst,Fp,Ast,Ap'` (default string) • `'N,F3db'` • `'N,Fc'` • `'N,Fc,Ast,Ap'` • `'N,Fp,Ast,Ap'` • `'N,Fst,Ast,Ap'` • `'N,Fst,Fp'` • `'N,Fst,Ast,Ap'` • `'N,Fst,Fp,Ast'`
`'Hilbert'`	See `fdesign.hilbert` for a description of the specification string entries. • `'N,TW'` (default string) • `'TW,Ap'`
`'Inverse-sinc Lowpass'`	See `fdesign.isinclp` for a description of the specification string entries. • `'Fp,Fst,Ap,Ast'` (default string) • `'N,Fc,Ap,Ast'` • `'N,Fp,Fst'` • `'N,Fst,Ap,Ast'`
`'Inverse-sinc Highpass'`	See `fdesign.isinchp` for a description of the specification string entries. • `'Fst,Fp,Ast,Ap'` (default string) • `'N,Fc,Ast,Ap'` • `'N,Fst,Fp'` • `'N,Fst,Ast,Ap'`

Design String	Valid Specification Strings
'Lowpass'	See `fdesign.lowpass` for a description of the specification string entries. • 'Fp,Fst,Ap,Ast' (default string) • 'N,F3dB' • 'N,Fc' • 'N,Fc,Ap,Ast' • 'N,Fp,Ap,Ast' • 'N,Fp,Fst' • 'N,Fp,Fst,Ap' • 'N,Fp,Fst,Ast' • 'N,Fst,Ap,Ast'
'Nyquist'	See `fdesign.nyquist` for a description of the specification string entries. For all Nyquist specifications, you must specify the Lth band. This typically corresponds to the interpolation factor so that the nonzero samples of the upsampler output are preserved. • 'TW,Ast' (default string) • 'N' • 'N,Ast' • 'N,Ast'

`D = fdesign.interpolator(...,spec,specvalue1,specvalue2,...)` constructs an object `D` and sets its specifications at construction time.

`D = fdesign.interpolator(...,Fs)` adds the argument `Fs`, specified in Hz, to define the sampling frequency to use. In this case, all frequencies in the specifications are in Hz as well.

`d = fdesign.interpolator(...,MAGUNITS)` specifies the units for any magnitude specification you provide in the input arguments. `MAGUNITS` can be one of

- `'linear'` — specify the magnitude in linear units.
- `'dB'` — specify the magnitude in dB (decibels).

- 'squared' — specify the magnitude in power units.

When you omit the MAGUNITS argument, fdesign assumes that all magnitudes are in decibels. Note that fdesign stores all magnitude specifications in decibels (converting to decibels when necessary) regardless of how you specify the magnitudes.

Examples

These examples show how to construct interpolating filter specification objects. First, create a default specifications object without using input arguments except for the interpolation factor l.

```
l = 2;
d = fdesign.interpolator(2);
```

Now create an object by passing a specification string 'fst1,fp1,fp2,fst2,ast1,ap,ast2' and a design — the resulting object uses default values for all of the filter specifications. You must provide the design input argument when you include a specification.

```
d=fdesign.interpolator(8,'bandpass','fst1,fp1,fp2,fst2,ast1,ap,ast2');
```

Create another interpolating filter object, passing the specification values to the object rather than accepting the default values for, in this case, fp,fst,ap,ast.

```
d=fdesign.interpolator(3,'lowpass',.45,0.55,.1,60);
```

Now pass the filter specifications that correspond to the specifications — n,fc,ap,ast.

```
d=fdesign.interpolator(3,'ciccomp',1,2,'n,fc,ap,ast',...
20,0.45,.05,50);
```

With the specifications object in your workspace, design an interpolator using the equiripple design method.

```
hm = design(d,'equiripple');
```

Pass a new specification type for the filter, specifying the filter order.

```
d = fdesign.interpolator(5,'CIC',1,'fp,ast',0.55,55);
```

With the specifications object in your workspace, design an interpolator using the `multisection` design method.

```
hm = design(d,'multisection');
```

In this example, you specify a sampling frequency as the right most input argument. Here, it is set to 1000 Hz.

```
d=fdesign.interpolator(8,'bandpass','fst1,fp1,fp2,fst2,ast1,ap,ast2',...
    0.25,0.35,.55,.65,50,.05,1e3);
```

In this, the last example, use the `linear` option for the filter specification object and specify the stopband ripple attenuation in linear form.

```
d = fdesign.interpolator(4,'lowpass','n,fst,ap,ast',15,0.55,.05,...
     1e3,'linear'); % 1e3 = 60dB.
```

Now design a CIC interpolator for a signal sampled at 19200 Hz. Specify the differential delay of 2 and set the attenuation of information beyond 50 Hz to be at least 80 dB.

The filter object sampling frequency is (`l` x `fs`) where `fs` is the sampling frequency of the input signal.

```
dd  = 2;     % Differential delay.
fp  = 50;    % Passband of interest.
ast = 80;    % Minimum attenuation of alias components in passband.
fs  = 600;   % Sampling frequency for input signal.
l   = 32;    % Interpolation factor.
d   = fdesign.interpolator(l,'cic',dd,'fp,ast',fp,ast,l*fs);
hm = design(d);  %Use the default design method.
```

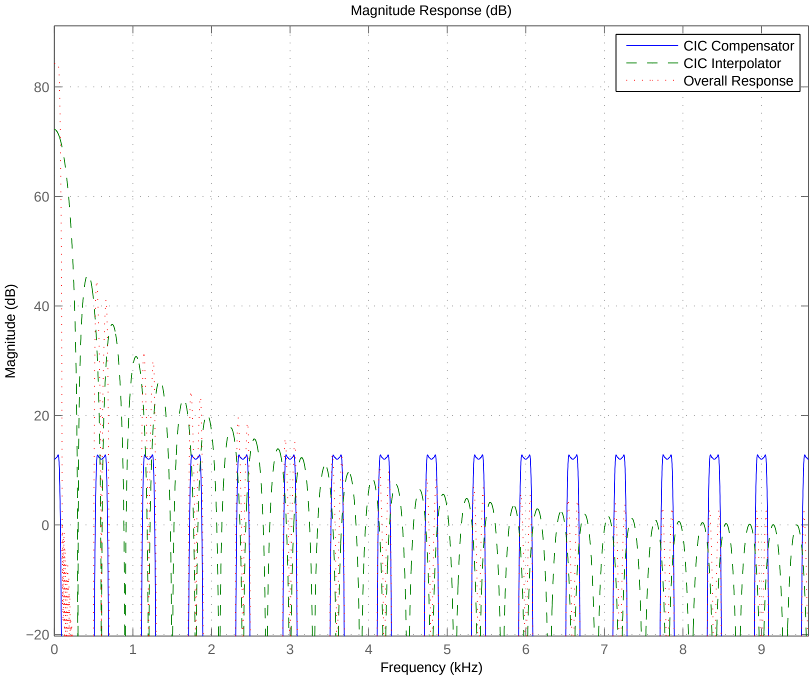
This next example results in a minimum-order CIC compensator that interpolates by 4 and compensates for the droop in the passband for the CIC filter `hm` from the previous example.

```
nsecs = hm.numberofsections;
d = fdesign.interpolator(4,'ciccomp',dd,nsecs,...
50,100,0.1,80,fs);
hmc = design(d,'equiripple');
hmc.arithmetic = 'fixed';
```

`hmc` is designed to compensate for `hm`. To see the effect of the compensating CIC filter, use FVTool to analyze both filters individually and include the compound filter response by cascading `hm` and `hmc`.

```
hfvt = fvtool(hmc,hm,cascade(hmc,hm),'fs',[fs,l*fs,l*fs],...
'showreference','off');
legend(hfvt,'CIC Compensator','CIC Interpolator',...
'Overall Response');
```

FVTool returns with this plot.

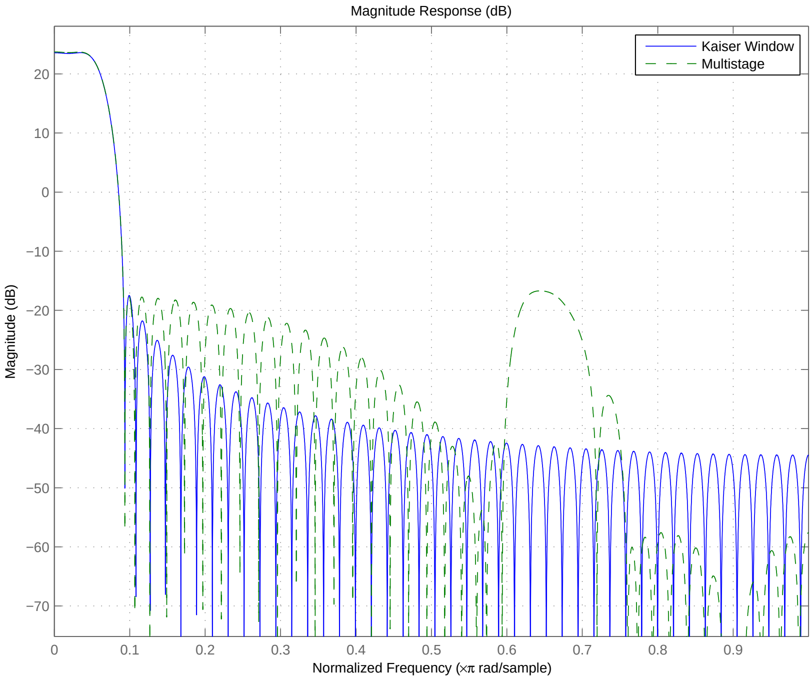


For the third example, use `fdesign.interpolator` to design a minimum-order Nyquist interpolator that uses a Kaiser window. For comparison, design a multistage interpolator as well and compare the responses.

```
l   = 15;   % Set the interpolation factor and the Nyquist band.
tw  = 0.05; % Specify the normalized transition width.
ast = 40;   % Set the minimum stopband attenuation in dB.
d   = fdesign.interpolator(l,'nyquist',l,tw,ast);
hm  = design(d,'kaiserwin');
```

```
hm2 = design(d,'multistage'); % Design the multistage interpolator.
hfvt = fvtool(hm,hm2);
legend(hfvt,'Kaiser Window','Multistage')
```

FVTool shows both responses.



Design a lowpass interpolator for an interpolation factor of 8. Compare the single-stage equiripple design to a multistage design with the same interpolation factor.

```
l = 8; % Interpolation factor.
d = fdesign.interpolator(l,'lowpass');
hm(1) = design(d,'equiripple');
% Use halfband filters whenever possible.
hm(2) = design(d,'multistage','usehalfbands',true);
hfvt = fvtool(hm);
legend(hfvt,'Single-Stage Equiripple','Multistage')
```

fdesign.isinchp

Inverse sinc highpass filter specification

Syntax

```
D = fdesign.isinchp
D = fdesign.isinchp(SPEC)
D = fdesign.isinchp(SPEC,specvalue1,specvalue2,...)
D = fdesign.isinchp(specvalue1,specvalue2,specvalue3,specvalue4)
D = fdesign.isinchp(...,Fs)
D = fdesign.isinchp(...,MAGUNITS)
```

Description

`D = fdesign.isinchp` constructs an inverse sinc highpass filter specification object `D`, applying default values for the default specification string `'Fst,Fp,Ast,Ap'`.

`D = fdesign.isinchp(SPEC)` constructs object `D` and sets the `Specification` property to `SPEC`. Entries in the `SPEC` string represent various filter response features, such as the filter order, that govern the filter design. Valid entries for `SPEC` are shown below. The strings are not case sensitive.

- `'Fst,Fp,Ast,Ap'` (default `spec`)
- `'N,Fc,Ast,Ap'`
- `'N,Fst,Fp'`
- `'N,Fp,Ast,Ap'`
- `'N,Fst,Ast,Ap'`

The string entries are defined as follows:

- `Ast` — attenuation in the stopband in decibels (the default units). Also called Astop.
- `Ap` — amount of ripple allowed in the passband in decibels (the default units). Also called Apass.
- `Fp` — frequency at the start of the passband. Specified in normalized frequency units. Also called Fpass.

- Fst — frequency at the end of the stopband. Specified in normalized frequency units. Also called Fstop.
- N — filter order.

The filter design methods that apply to an inverse sinc highpass filter specification object change depending on the value of the Specification property. Use designmethods to determine which design method applies to a specific Specification.

Use designopts to see the available design options for a specific design method. Enter help(D,METHOD) at the MATLAB command line to obtain detailed information on the design options for a given design method, METHOD.

D = fdesign.isinchp(SPEC,specvalue1,specvalue2,...) constructs an object D and sets the specifications at construction time.

D = fdesign.isinchp(specvalue1,specvalue2,specvalue3,specvalue4) constructs an object D assuming the default Specification property string 'Fst,Fp,Ast,Ap', using the values you provide in specvalue1,specvalue2, specvalue3, and specvalue4.

D = fdesign.isinchp(...,Fs) adds the argument Fs, specified in Hz to define the sampling frequency to use. In this case, all frequencies in the specifications are in Hz as well.

D = fdesign.isinchp(...,MAGUNITS) specifies the units for any magnitude specification you provide in the input arguments. MAGUNITS can be one of

- 'linear' — specify the magnitude in linear units
- 'dB' — specify the magnitude in dB (decibels)
- 'squared' — specify the magnitude in power units

When you omit the MAGUNITS argument, fdesign assumes that all magnitudes are in decibels. Note that fdesign stores all magnitude specifications in decibels (converting to decibels when necessary) regardless of how you specify the magnitudes.

The design method of fdesign.isinchp implements a filter with a passband magnitude response equal to:

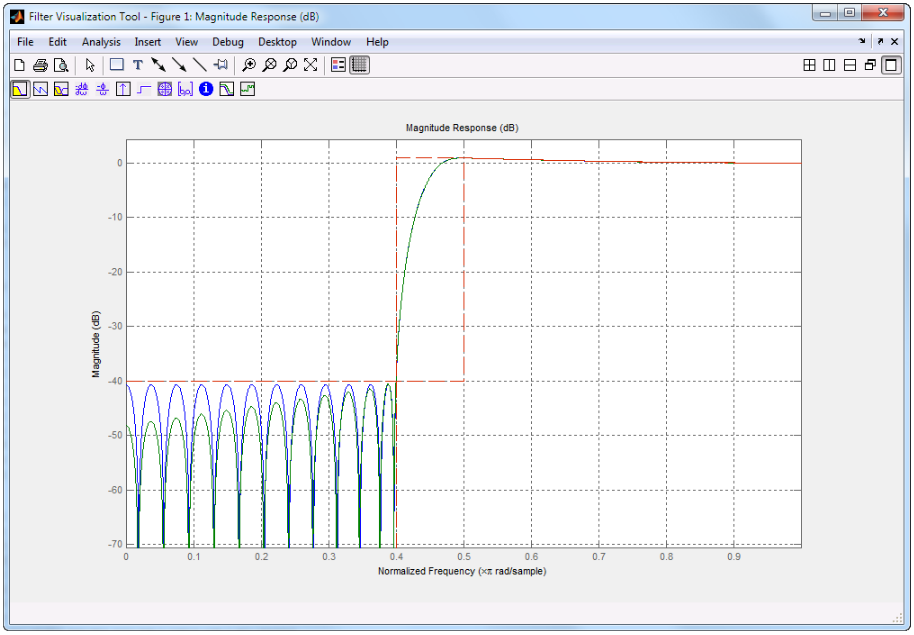
$$H(\omega) = sinc(C(1-\omega))^{-P}$$

You can control the values of the sinc frequency factor, C, and the sinc power, P, using the `'SincFrequencyFactor'` and `'SincPower'` options in the `design` method. `'SincFrequencyFactor'` and `'SincPower'` default to 0.5 and 1 respectively.

Examples

Design a minimum order inverse sinc highpass filter and shape the stopband to have a slope of 20 dB/radian/sample.

```
d = fdesign.isinchp('Fst,Fp,Ast,Ap',.4,.5,40,0.01);
Hd = design(d);
% Shape the stopband to have a linear slope of 20 dB/rad/sample
Hd1 = design(d,'StopbandShape','linear','StopbandDecay',20);
fvtool(Hd,Hd1);
```



Design a 50th order inverse sinc highpass filter. Set the sinc frequency factor to 0.25, and the sinc power to 16 to achieve a magnitude response in the passband of the form H(ω) = sinc(0.25*(1-ω))^(-16) .

```
d = fdesign.isinchp('N,Fst,Fp',50,.4,.5);
```

```
Hd = design(d,'SincFrequencyFactor',0.25,'SincPower',16);
fvtool(Hd);
```

fdesign.isinclp

Inverse sinc lowpass filter specification

Syntax

```
d = fdesign.isinclp
d = fdesign.isinclp(spec)
d = fdesign.isinclp(spec,specvalue1,specvalue2,...)
d = fdesign.isinclp(specvalue1,specvalue2,specvalue3,specvalue4)
d = fdesign.isinclp(...,Fs)
d = fdesign.isinclp(...,MAGUNITS)
```

Description

`d = fdesign.isinclp` constructs an inverse sinc lowpass filter specification object `d`, applying default values for the default specification string, `'Fp,Fst,Ap,Ast'`.

`d = fdesign.isinclp(`*`spec`*`)` constructs object `d` and sets its `'Specification'` to *`spec`*. Entries in the `spec` string represent various filter response features, such as the filter order, that govern the filter design. Valid entries for *`spec`* are shown below. The strings are not case sensitive.

- `'Fp,Fst,Ap,Ast'` (default `spec`)
- `'N,Fc,Ap,Ast'`
- `'N,Fp,Ap,Ast'`
- `'N,Fp,Fst'`
- `'N,Fst,Ap,Ast'`

The string entries are defined as follows:

- `Ast` — attenuation in the stopband in decibels (the default units). Also called Astop.
- `Ap` — amount of ripple allowed in the passband in decibels (the default units). Also called Apass.
- `Fp` — frequency at the start of the passband. Specified in normalized frequency units. Also called Fpass.

- `Fst` — frequency at the end of the stopband. Specified in normalized frequency units. Also called Fstop.
- `N` — filter order.

The filter design methods that apply to an inverse sinc lowpass filter specification object change depending on the `Specification` string. Use `designmethods` to determine which design method applies to an object and its specification string.

`d = fdesign.isinclp(spec,specvalue1,specvalue2,...)` constructs an object `d` and sets its specifications at construction time.

`d = fdesign.isinclp(specvalue1,specvalue2,specvalue3,specvalue4)` constructs an object `d` assuming the default `Specification` property string `'Fp,Fst,Ap,Ast'`, using the values you provide in `specvalue1,specvalue2, specvalue3, and specvalue4`.

`d = fdesign.isinclp(...,Fs)` adds the argument `Fs`, specified in Hz to define the sampling frequency to use. In this case, all frequencies in the specifications are in Hz as well.

`d = fdesign.isinclp(...,MAGUNITS)` specifies the units for any magnitude specification you provide in the input arguments. `MAGUNITS` can be one of

- `'linear'` — specify the magnitude in linear units
- `'dB'` — specify the magnitude in dB (decibels)
- `'squared'` — specify the magnitude in power units

When you omit the `MAGUNITS` argument, `fdesign` assumes that all magnitudes are in decibels. Note that `fdesign` stores all magnitude specifications in decibels (converting to decibels when necessary) regardless of how you specify the magnitudes.

The design method of `fdesign.isinclp` implements a filter with a passband magnitude response equal to:

$$H(\omega) = sinc(C\omega)^{-P}$$

You can control the values of the sinc frequency factor, *C*, and the sinc power, *P*, using the `'SincFrequencyFactor'` and `'SincPower'` options in the `design` method. `'SincFrequencyFactor'` and `'SincPower'` default to 0.5 and 1 respectively.

Examples

Pass the specifications for the default specification — `'Fp,Fst,Ap,Ast'` — as input arguments to the specifications object.

```
d = fdesign.isinclp(.4,.5,.01,40);
hd = design(d,'equiripple');
fvtool(hd);
```

Design a 50th order inverse sinc lowpass filter. Set the sinc frequency factor to 0.25 and the sinc power to 16 to achieve a magnitude response in the passband of the form `H(w) = sinc(0.25*w)^(-16)`.

```
 d = fdesign.isinclp('N,Fp,Fst',50,.4,.5);
 Hd = design(d,'SincFrequencyFactor',0.25,'SincPower',16);
 fvtool(Hd, 'MagnitudeDisplay', 'Magnitude');
```

fdesign.lowpass

Lowpass filter specification

Syntax

```
D = fdesign.lowpass
D = fdesign.lowpass(SPEC)
D = fdesign.lowpass(SPEC,specvalue1,specvalue2,...)
D = fdesign.lowpass(specvalue1,specvalue2,specvalue3,specvalue4)
D = fdesign.lowpass(...,Fs)
D = fdesign.lowpass(...,MAGUNITS)
```

Description

`D = fdesign.lowpass` constructs a lowpass filter specification object `D`, applying default values for the default specification string `'Fp,Fst,Ap,Ast'`.

`D = fdesign.lowpass(SPEC)` constructs object `D` and sets the `Specification` property to the string in `SPEC`. Entries in the `SPEC` string represent various filter response features, such as the filter order, that govern the filter design. Valid entries for `SPEC` are shown below. The strings are not case sensitive.

Note: Specifications strings marked with an asterisk require the DSP System Toolbox software.

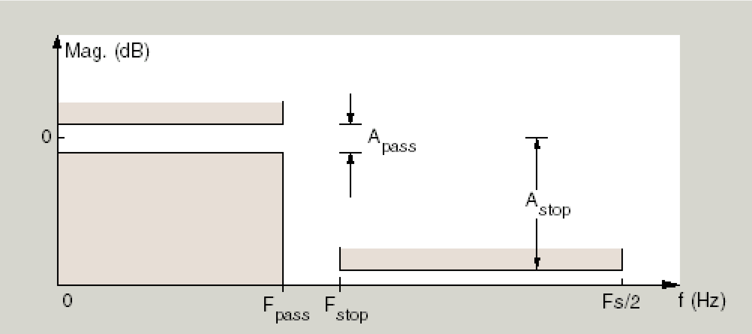
- `'Fp,Fst,Ap,Ast'` (default `spec`)
- `'N,F3db'`
- `'N,F3db,Ap'` *
- `'N,F3db,Ap,Ast'` *
- `'N,F3db,Ast'` *
- `'N,F3db,Fst'` *
- `'N,Fc'`

- 'N,Fc,Ap,Ast'
- 'N,Fp,Ap'
- 'N,Fp,Ap,Ast'
- 'N,Fp,Fst,Ap' *
- 'N,Fp,F3db' *
- 'N,Fp,Fst'
- 'N,Fp,Fst,Ast' *
- 'N,Fst,Ap,Ast' *
- 'N,Fst,Ast'
- 'Nb,Na,Fp,Fst' *

The string entries are defined as follows:

- Ap — amount of ripple allowed in the pass band in decibels (the default units). Also called Apass.
- Ast — attenuation in the stop band in decibels (the default units). Also called Astop.
- F3db — cutoff frequency for the point 3 dB point below the passband value. Specified in normalized frequency units.
- Fc — cutoff frequency for the point 6 dB point below the passband value. Specified in normalized frequency units.
- Fp — frequency at the start of the pass band. Specified in normalized frequency units. Also called Fpass.
- Fst — frequency at the end of the stop band. Specified in normalized frequency units. Also called Fstop.
- N — filter order.
- Na and Nb are the order of the denominator and numerator.

Graphically, the filter specifications look similar to those shown in the following figure.



Regions between specification values like `Fp` and `Fst` are transition regions where the filter response is not explicitly defined.

`D = fdesign.lowpass(SPEC,specvalue1,specvalue2,...)` constructs an object `D` and sets the specification values at construction time using `specvalue1`, `specvalue2`, and so on for all of the specification variables in `SPEC`.

`D = fdesign.lowpass(specvalue1,specvalue2,specvalue3,specvalue4)` constructs an object `D` with values for the default `Specification` property string `'Fp,Fst,Ap,Ast'` using the specifications you provide as input arguments `specvalue1,specvalue2,specvalue3,specvalue4`.

`D = fdesign.lowpass(...,Fs)` adds the argument `Fs`, specified in Hz to define the sampling frequency to use. In this case, all frequencies in the specifications are in Hz as well.

`D = fdesign.lowpass(...,MAGUNITS)` specifies the units for any magnitude specification you provide in the input arguments. `MAGUNITS` can be one of

- `'linear'` — specify the magnitude in linear units
- `'dB'` — specify the magnitude in dB (decibels)
- `'squared'` — specify the magnitude in power units

When you omit the `MAGNUNITS` argument, `fdesign` assumes that all magnitudes are in decibels. Note that `fdesign` stores all magnitude specifications in decibels (converting to decibels when necessary) regardless of how you specify the magnitudes.

Examples

Lowpass Filtering and Filter Visualization

Lowpass filter a discrete-time signal consisting of two sine waves.

Create a lowpass filter specification object. Specify the passband frequency to be 0.15π rad/sample and the stopband frequency to be 0.25π rad/sample. Specify 1 dB of allowable passband ripple and a stopband attenuation of 60 dB.

```
d = fdesign.lowpass('Fp,Fst,Ap,Ast',0.15,0.25,1,60);
```

Query the valid design methods for your filter specification object, `d`.

```
designmethods(d)
```

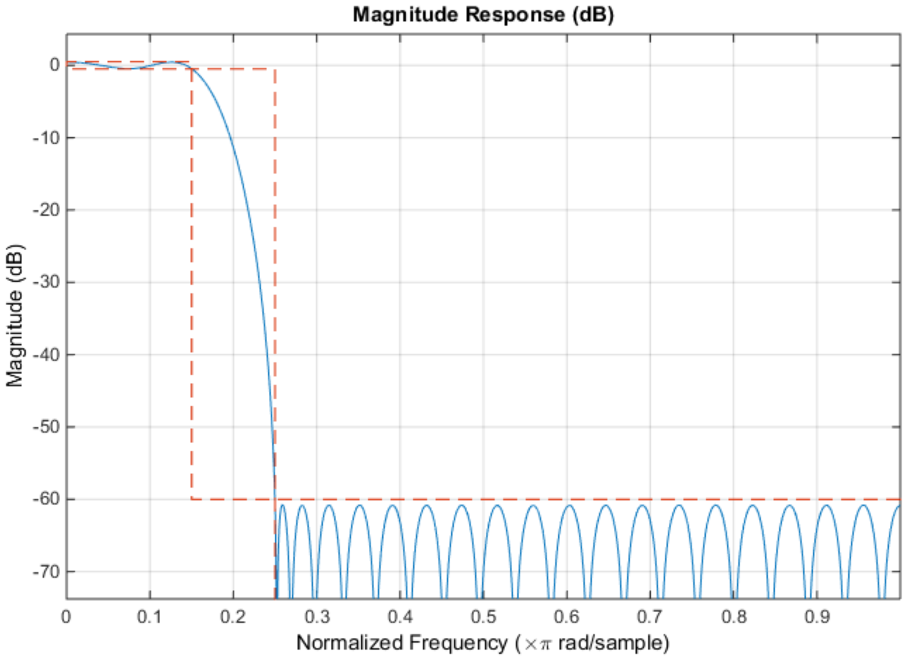
```

Design Methods for class fdesign.lowpass (Fp,Fst,Ap,Ast):

butter
cheby1
cheby2
ellip
equiripple
ifir
kaiserwin
multistage
```

Create an FIR equiripple filter and view the filter magnitude response with `fvtool`.

```
Hd = design(d,'equiripple');
fvtool(Hd)
```



Create a signal consisting of the sum of two discrete-time sinusoids with frequencies of $\pi/8$ and $\pi/4$ rad/sample and amplitudes of 1 and 0.25, respectively. Filter the discrete-time signal with the FIR equiripple filter object, Hd.

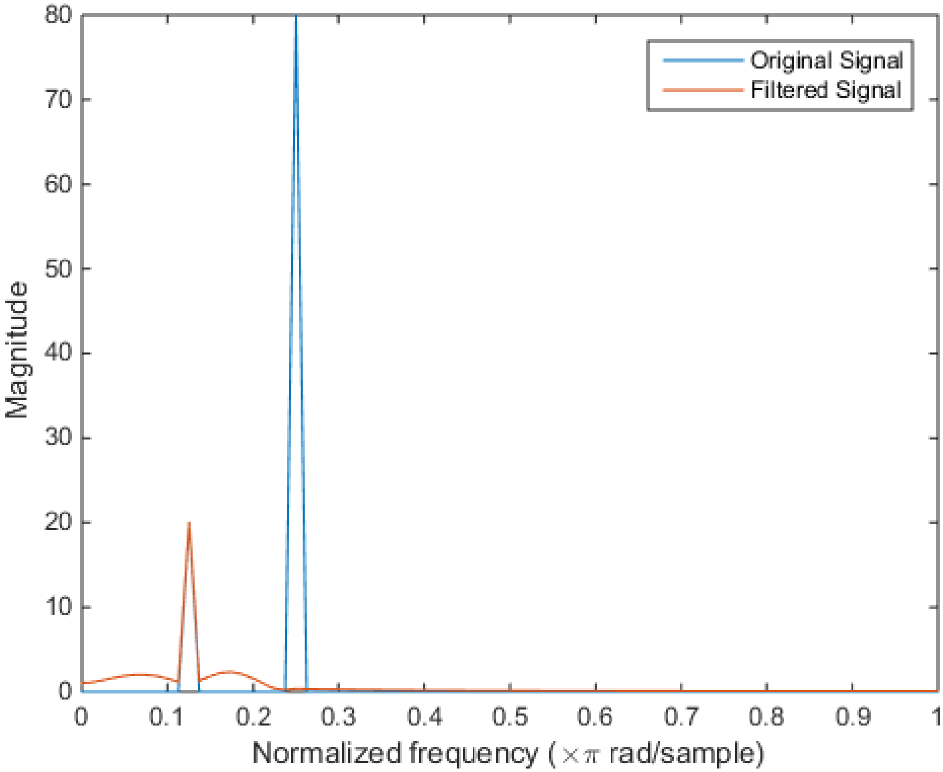
```
n = 0:159;
x = 0.25*cos((pi/8)*n)+sin((pi/4)*n);
y = filter(Hd,x);
```

Compute the Fourier transform of the original signal and the filtered signal. Verify that the high-frequency component has been filtered out.

```
freq = 0:(2*pi)/160:pi;
xdft = fft(x);
ydft = fft(y);

figure
plot(freq/pi,abs(xdft(1:length(x)/2+1)))
hold on
plot(freq/pi,abs(ydft(1:length(y)/2+1)))
```

```
legend('Original Signal','Filtered Signal')
ylabel('Magnitude')
xlabel('Normalized frequency (\times\pi rad/sample)')
```



Create a filter of order 10 with a 6-dB frequency of 9.6 kHz and a sampling frequency of 48 kHz. The only valid design method is the FIR window method.

```
d = fdesign.lowpass('N,Fc',10,9600,48000);
designmethods(d)

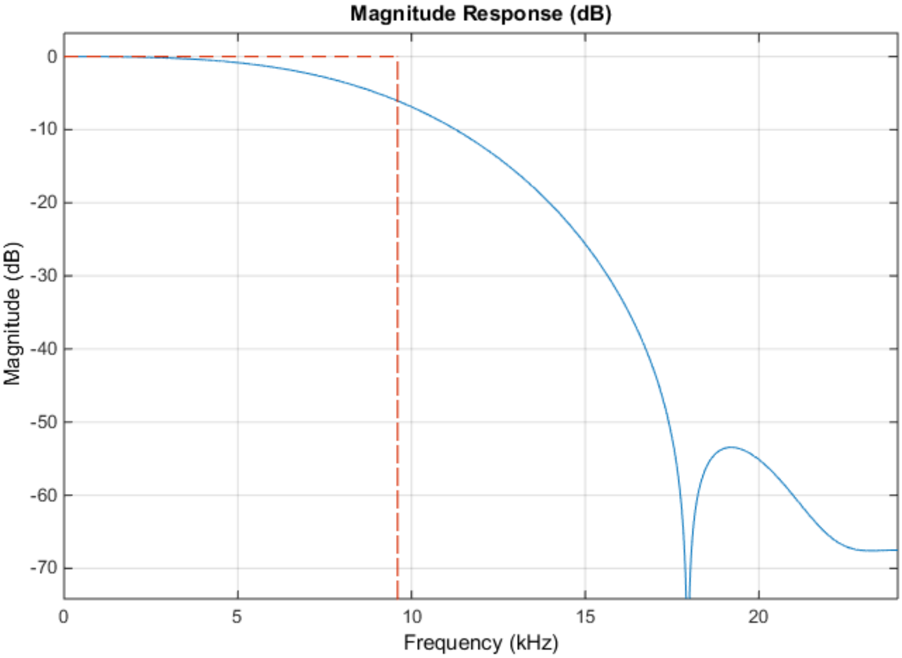
Hd = design(d);
```

```
Design Methods for class fdesign.lowpass (N,Fc):

window
```

Display the filter magnitude response. The -6 dB point is at 9.6 kHz, as expected.

```
fvtool(Hd)
```



If you have the DSP System Toolbox software, you can specify the shape of the stopband and the rate at which the stopband decays. The following example requires the DSP System Toolbox.

Create an FIR equiripple filter with a passband frequency of 0.2π rad/sample, a stopband frequency of 0.25π rad/sample, a passband ripple of 1 dB, and a stopband attenuation of 60 dB. Design the filter with a 20 dB/rad/sample linear stopband.

```
D = fdesign.lowpass('Fp,Fst,Ap,Ast',0.2,0.25,1,60);
```

```
Hd = design(D,'equiripple','StopbandShape','linear','StopbandDecay',20);
fvtool(Hd)
```

Notch filter specification

Syntax

```
d = fdesign.notch(specstring, value1, value2, ...)
d = fdesign.notch(n,f0,q)
d = fdesign.notch(...,Fs)
d = fdesign.notch(...,MAGUNITS)
```

Description

`d = fdesign.notch(specstring, value1, value2, ...)` constructs a notch filter specification object `d`, with a specification string set to `specstring` and values provided for all members of the `specstring`. The possible specification strings, which are not case sensitive, are listed as follows:

- 'N,F0,Q' (default)
- 'N,F0,Q,Ap'
- 'N,F0,Q,Ast'
- 'N,F0,Q,Ap,Ast'
- 'N,F0,BW'
- 'N,F0,BW,Ap'
- 'N,F0,BW,Ast'
- 'N,F0,BW,Ap,Ast'

where the variables are defined as follows:

- N - Filter Order (must be even)
- F0 - Center Frequency
- Q - Quality Factor
- BW - 3-dB Bandwidth

- Ap - Passband Ripple (decibels)
- Ast - Stopband Attenuation (decibels)

Different specification strings, resulting in different specification objects, may have different design methods available. Use the function `designmethods` to get a list of design methods available for a given specification. For example:

```
d  = fdesign.notch('N,F0,Q,Ap',6,0.5,10,1);
% designmethods(d) returns
% Design Methods for class fdesign.notch (N,F0,Q,Ap):
% cheby1
```

`d = fdesign.notch(n,f0,q)` constructs a notch filter specification object using the default `specstring ('N,F0,Q')` and setting the corresponding values to `n`, `f0`, and `q`.

By default, all frequency specifications are assumed to be in normalized frequency units. All magnitude specifications are assumed to be in decibels.

`d = fdesign.notch(...,Fs)` constructs a notch filter specification object while providing the sampling frequency of the signal to be filtered. `Fs` must be specified as a scalar trailing the other values provided. If you specify an `Fs`, it is assumed to be in Hz, as are all the other frequency values provided.

`d = fdesign.notch(...,MAGUNITS)` constructs a notch filter specification while providing the units for any magnitude specification given. `MAGUNITS` can be one of the following: `'linear'`, `'dB'`, or `'squared'`. If this argument is omitted, `'dB'` is assumed. The magnitude specifications are always converted and stored in decibels regardless of how they were specified. If `Fs` is provided, `MAGUNITS` must follow `Fs` in the input argument list.

Examples

Design a notching filter with a passband ripple of 1 dB.

```
    d  = fdesign.notch('N,F0,Q,Ap',6,0.5,10,1);
    Hd = design(d);
    fvtool(Hd)
```

fdesign.nyquist

Nyquist filter specification

Syntax

```
d = fdesign.nyquist
d = fdesign.nyquist(l, spec)
d = fdesign.nyquist(l,spec,specvalue1,specvalue2,...)
d = fdesign.nyquist(l,specvalue1,specvalue2)
d = fdesign.nyquist(...,fs)
d = fdesign.nyquist(...,magunits)
```

Description

`d = fdesign.nyquist` constructs a Nyquist or L-band filter specification object `d`, applying default values for the properties `tw` and `ast`. By default, the filter object designs a minimum-order half-band (L=2) Nyquist filter.

Using `fdesign.nyquist` with a design method generates a `dfilt` object.

`d = fdesign.nyquist(l, spec)` constructs object `d` and sets its `Specification` property to *`spec`*. Use `l` to specify the desired value for L. L = 2 designs a half-band FIR filter, L = 3 a third-band FIR filter, and so on. When you use a Nyquist filter as an interpolator, l or L is the interpolation factor. The first input argument must be l when you are not using the default syntax `d = fdesign.nyquist`.

Entries in the `spec` string represent various filter response features, such as the filter order, that govern the filter design. Valid entries for *`spec`* are shown below. The strings are not case sensitive.

- `tw`,`ast` (default `spec`)
- `n`,`tw`
- `n`
- `n`,`ast`

The string entries are defined as follows:

- ast — attenuation in the stop band in decibels (the default units).
- n — filter order.
- tw — width of the transition region between the pass and stop bands. Specified in normalized frequency units.

The filter design methods that apply to a Nyquist filter specification object change depending on the Specification string. Use designmethods to determine which design method applies to an object and its specification string. Different filter design methods also have options that you can specify. Use designopts with the design method string to see the available options. For example:

```
f=fdesign.nyquist(4,'N,TW');
designmethods(f)
```

d = fdesign.nyquist(l,spec,specvalue1,specvalue2,...) constructs an object d and sets its specification to *spec*, and the specification values to specvalue1, specvalue2, and so on at construction time.

d = fdesign.nyquist(l,specvalue1,specvalue2) constructs an object d with the values you provide in l, specvalue1,specvalue2 as the values for l, tw and ast.

d = fdesign.nyquist(...,fs) adds the argument fs, specified in Hz to define the sampling frequency to use. In this case, all frequencies in the specifications are in Hz as well.

d = fdesign.nyquist(...,magunits) specifies the units for any magnitude specification you provide in the input arguments. magunits can be one of

- linear — specify the magnitude in linear units
- dB — specify the magnitude in dB (decibels)
- squared — specify the magnitude in power units

When you omit the magunits argument, fdesign assumes that all magnitudes are in decibels. Note that fdesign stores all magnitude specifications in decibels (converting to decibels when necessary) regardless of how you specify the magnitudes.

Limitations of the Nyquist fdesign Object

Using Nyquist filter specification objects with the equiripple design method imposes a few limitations on the resulting filter, caused by the equiripple design algorithm.

- When you request a minimum-order design from `equiripple` with your Nyquist object, the design algorithm might not converge and can fail with a filter convergence error.
- When you specify the order of your desired filter, and use the `equiripple` design method, the design might not converge.
- Generally, the following specifications, alone or in combination with one another, can cause filter convergence problems with Nyquist objects and the `equiripple` design method.
  - very high order
  - small transition width
  - very large stopband attenuation

Note that halfband filters (filters where band = 2) do not exhibit convergence problems.

When convergence issues arise, either in the cases mentioned or in others, you might be able to design your filter with the `kaiserwin` method.

In addition, if you use Nyquist objects to design decimators or interpolators (where the interpolation or decimation factor is not a prime number), using multistage filter designs might be your best approach.

Examples

These examples show how to construct a Nyquist filter specification object. First, create a default specifications object without using input arguments.

```
d=fdesign.nyquist
```

Now create an object by passing a specification type string '`n,ast`' — the resulting object uses default values for `n` and `ast`.

```
d=fdesign.nyquist(2,'n,ast')
```

Create another Nyquist filter object, passing the specification values to the object rather than accepting the default values for `n` and `ast`.

```
d=fdesign.nyquist(3,'n,ast',42,80)
```

Finally, pass the filter specifications that correspond to the default `Specification` — `tw,ast`. When you pass only the values, `fdesign.nyquist` assumes the default `Specification` string.

```
d = fdesign.nyquist(4,.01,80)
```

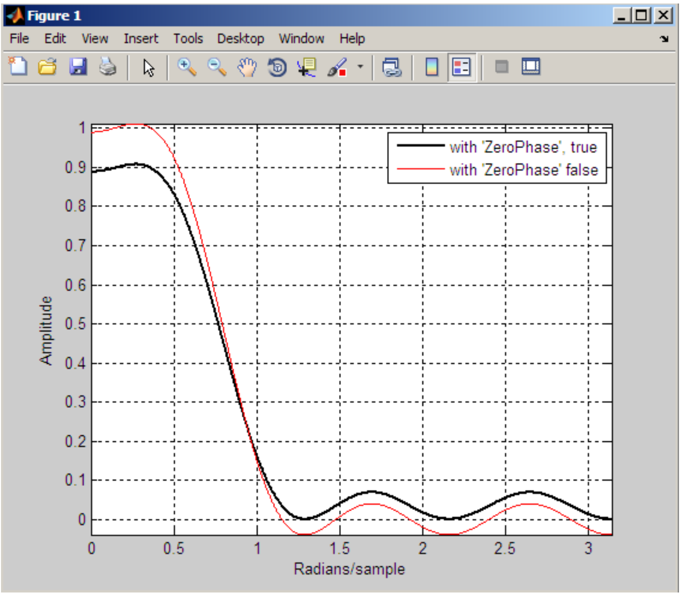
Now design a Nyquist filter using the `kaiserwin` design method.

```
hd = design(d,'kaiserwin')
```

Create two equiripple Nyquist 4th–band filters with and without a nonnegative zero phase response:

```
f=fdesign.nyquist(4,'N,TW',12,0.2);
% Equiripple Nyquist 4th-band filter with
% nonnegative zero phase response
Hd1=design(f,'equiripple','zerophase',true);
% Equiripple Nyquist 4th-band filter with 'ZeroPhase' set to false
% 'zerophase',false is the default
Hd2=design(f,'equiripple','zerophase',false);
%Obtain real-valued amplitudes (not magnitudes)
[Hr_zerophase,W]=zerophase(Hd1);
[Hr,W]=zerophase(Hd2);
% Plot and compare response
plot(W,Hr_zerophase,'k','linewidth',2);
xlabel('Radians/sample'); ylabel('Amplitude');
hold on;
plot(W,Hr,'r');
axis tight; grid on;
legend('with ''ZeroPhase'', true','with ''ZeroPhase'' false');
```

Note that the amplitude of the zero phase response (black line) is nonnegative for all frequencies.



The `'ZeroPhase'` option is valid only for equiripple Nyquist designs with the `'N,TW'` specification. You cannot specify `'MinPhase'` and `'ZeroPhase'` to be simultaneously `'true'`.

fdesign.octave

Octave filter specification

Syntax

```
d = fdesign.octave(l)
d = fdesign.octave(l, MASK)
d = fdesign.octave(l, MASK, spec)
d = fdesign.octave(..., Fs)
```

Description

`d = fdesign.octave(l)` constructs an octave filter specification object `d`, with `l` bands per octave. The default value for `l` is `1`.

`d = fdesign.octave(l, MASK)` constructs an octave filter specification object `d` with `l` bands per octave and `MASK` specification for the FVTool. The available values for mask are:

- `'class 0'`
- `'class 1'`
- `'class 2'`

`d = fdesign.octave(l, MASK, spec)` constructs an octave filter specification object `d` with `l` bands per octave, `MASK` specification for the FVTool, and the `spec` specification string. The specification strings available are:

- `'N, F0'`

(not case sensitive), where:

- `N` is the filter order
- `F0` is the center frequency. The center frequency is specified in normalized frequency units assuming a sampling frequency of 48 kHz, unless a sampling frequency in Hz is included in the specification: `d = fdesign.octave(..., Fs)`. If you specify an invalid center frequency, a warning is issued and the center frequency is rounded to the nearest valid value. You can determine the valid center frequencies for your

design by using `validfrequencies` with your octave filter specification object. For example:

```
d = fdesign.octave(1,'Class 1','N,F0',6,1000,44.1e3);
validcenterfreq = validfrequencies(d);
```

Valid center frequencies:

- Must be greater than 20 Hz and less than 20 kHz if you specify a sampling frequency. The range 20 Hz to 20 kHz is the standard range of human hearing.
- Are calculated according to the following algorithm if the number of bands per octave, `L`, is even

  ```
  G = 10^(3/10);
  x = -1000:1350;
  validcenterfreq = 1000*(G.^((2*x-59)/(2*L)));
  validcenterfreq = validcenterfreq(validcenterfreq>20 & validcenterfreq<2e4);
  ```

  Only center frequencies greater than 20 and less than 20000 are retained. Choosing a center frequency greater than your Nyquist frequency (1/2 the sampling rate) results in an error when you design the filter. If you do not specify a sampling frequency, the remaining center frequencies are divided by 24000 to obtain valid normalized center frequencies. For `fdesign.octave`, normalized frequency assumes a sampling frequency of 48 kHz.

  ```
  validcenterfreq = validcenterfreq/24000;
  ```

  - Are calculated according to the following algorithm if the number of bands per octave, `L`, is odd

    ```
    G = 10^(3/10);
    x = -1000:1350;
    validcenterfreq = 1000*(G.^((x-30)/L));
    validcenterfreq = validcenterfreq(validcenterfreq>20 & validcenterfreq<2e4);
    ```

    Only center frequencies greater than 20 and less than 20000 are retained. Choosing a center frequency greater than your Nyquist frequency (1/2 the sampling rate) results in an error when you design the filter. If you do not specify a sampling frequency, the remaining center frequencies are divided by 24000 to obtain valid normalized center frequencies. For `fdesign.octave`, normalized frequency assumes a sampling frequency of 48 kHz.

    ```
    validcenterfreq = validcenterfreq/24000;
    ```

Examples

Design an sixth order, octave-band class 0 filter with a center frequency of 1000 Hz and, a sampling frequency of 44.1 kHz.

```
d = fdesign.octave(1,'Class 0','N,F0',6,1000,44100);
Hd = design(d);
fvtool(Hd)
```

The following figure shows the magnitude response plot of the filter. The logarithmic scale for frequency is automatically set by FVTool for the octave filters.

`fdesign` | “Octave-Band and Fractional Octave-Band Filters”

fdesign.parameq

Parametric equalizer filter specification

Syntax

```
d = fdesign.parameq(spec, specvalue1, specvalue2, ...)
d = fdesign.parameq(... fs)
```

Description

`d = fdesign.parameq(spec, specvalue1, specvalue2, ...)` constructs a parametric equalizer filter design object, where `spec` is a non-case sensitive specification string. The choices for `spec` are as follows:

- `'F0, BW, BWp, Gref, G0, GBW, Gp'` (minimum order default)
- `'F0, BW, BWst, Gref, G0, GBW, Gst'`
- `'F0, BW, BWp, Gref, G0, GBW, Gp, Gst'`
- `'N, F0, BW, Gref, G0, GBW'`
- `'N, F0, BW, Gref, G0, GBW, Gp'`
- `'N, F0, Fc, Qa, G0'`
- `'N, F0, Fc, S, G0'`
- `'N, F0 ,BW, Gref, G0, GBW, Gst'`
- `'N, F0, BW, Gref, G0, GBW, Gp, Gst'`
- `'N, Flow, Fhigh, Gref, G0, GBW'`
- `'N, Flow, Fhigh, Gref, G0, GBW, Gp'`
- `'N, Flow, Fhigh, Gref, G0, GBW, Gst'`
- `'N, Flow, Fhigh, Gref, G0, GBW, Gp, Gst'`

where the parameters are defined as follows:

- BW — Bandwidth
- BWp — Passband Bandwidth

- BWst — Stopband Bandwidth
- Gref — Reference Gain (decibels)
- G0 — Center Frequency Gain (decibels)
- GBW — Gain at which Bandwidth (BW) is measured (decibels)
- Gp — Passband Gain (decibels)
- Gst — Stopband Gain (decibels)
- N — Filter Order
- F0 — Center Frequency
- Fc— Cutoff frequency
- Fhigh - Higher Frequency at Gain GBW
- Flow - Lower Frequency at Gain GBW
- Qa-Quality Factor
- S-Slope Parameter for Shelving Filters

Regardless of the specification string chosen, there are some conditions that apply to the specification parameters. These are as follows:

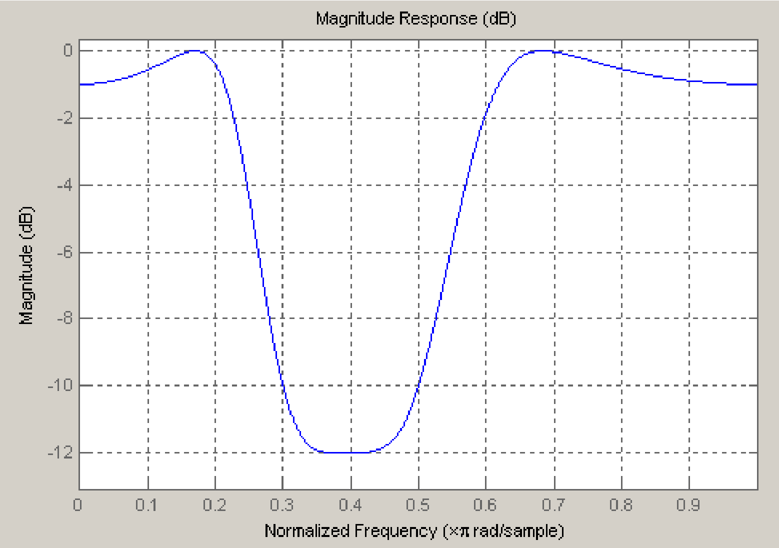
- Specifications for parametric equalizers must be given in decibels
- To boost the input signal, set `GO > Gref`; to cut, set `Gref > GO`
- For boost: `GO > Gp > GBW > Gst > Gref`; For cut: `GO < Gp < GBW < Gst < Gref`
- Bandwidth must satisfy: `BWst > BW > BWp`

`d = fdesign.parameq(... fs)` adds the input sampling frequency. Fs must be specified as a scalar trailing the other numerical values provided, and is assumed to be in Hz.

Examples

Design a Chebyshev Type II parametric equalizer filter that cuts by 12 dB:

```
d = fdesign.parameq('N,Flow,Fhigh,Gref,GO,GBW,Gst',...
      4,.3,.5,0,-12,-10,-1);
Hd = design(d,'cheby2');
fvtool(Hd)
```



Design a 4th order audio lowpass (F0 = 0) shelving filter with cutoff frequency of Fc = 0.25, quality factor Qa =10, and boost gain of G0 = 8 dB:

```
d = fdesign.parameq('N,F0,Fc,Qa,G0',4,0,0.25,10,8);
Hd = design(d);
fvtool(Hd)
```

`fdesign`

fdesign.peak

Peak filter specification

Syntax

```
d = fdesign.peak(specstring, value1, value2, ...)
d = fdesign.peak(n,f0,q)
d = fdesign.peak(...,Fs)
d = fdesign.peak(...,MAGUNITS)
```

Description

`d = fdesign.peak(specstring, value1, value2, ...)` constructs a peaking filter specification object `d`, with a specification string set to `specstring` and values provided for all members of the `specstring`. The possible specification strings, which are not case sensitive, are listed as follows:

- 'N,F0,Q' (default)
- 'N,F0,Q,Ap'
- 'N,F0,Q,Ast'
- 'N,F0,Q,Ap,Ast'
- 'N,F0,BW'
- 'N,F0,BW,Ap'
- 'N,F0,BW,Ast'
- 'N,F0,BW,Ap,Ast'

where the variables are defined as follows:

- N - Filter Order (must be even)
- F0 - Center Frequency
- Q - Quality Factor
- BW - 3-dB Bandwidth
- Ap - Passband Ripple (decibels)

- Ast - Stopband Attenuation (decibels)

Different specification strings, resulting in different specification objects, may have different design methods available. Use the function `designmethods` to get a list of design methods available for a given specification. For example:

```
>> d  = fdesign.peak('N,F0,Q,Ap',6,0.5,10,1);
>> designmethods(d)

Design Methods for class fdesign.peak (N,F0,Q,Ap):

cheby1
```

`d = fdesign.peak(n,f0,q)` constructs a peaking filter specification object using the default `specstring ('N,F0,Q')` and setting the corresponding values to `n`, `f0`, and `q`.

By default, all frequency specifications are assumed to be in normalized frequency units. All magnitude specifications are assumed to be in decibels.

`d = fdesign.peak(...,Fs)` constructs a peak filter specification object while providing the sampling frequency of the signal to be filtered. `Fs` must be specified as a scalar trailing the other values provided. If you specify an `Fs`, it is assumed to be in Hz, as all the other frequency values provided.

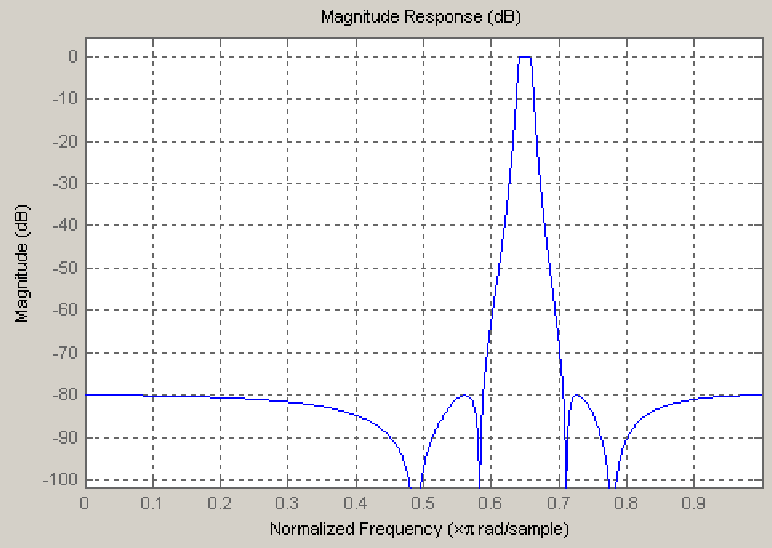
`d = fdesign.peak(...,MAGUNITS)` constructs a notch filter specification while providing the units for any magnitude specification given. `MAGUNITS` can be one of the following: `'linear'`, `'dB'`, or `'squared'`. If this argument is omitted, `'dB'` is assumed. The magnitude specifications are always converted and stored in decibels regardless of how they were specified. If `Fs` is provided, `MAGUNITS` must follow `Fs` in the input argument list.

Examples

Design a Chebyshev Type II peaking filter with a stopband attenuation of 80 dB:

```
d = fdesign.peak('N,F0,BW,Ast',8,.65,.02,80);
Hd = design(d,'cheby2');
fvtool(Hd)
```

This design produces a filter with the magnitude response shown in the following figure.



See Also

`fdesign` | `fdesign.notch` | `fdesign.parameq`

fdesign.polysrc

Construct polynomial sample-rate converter (POLYSRC) filter designer

Syntax

```
d = fdesign.polysrc(l,m)
d = fdesign.polysrc(l,m,'Fractional Delay','Np',Np)
d = fdesign.polysrc(...,Fs)
```

Description

`d = fdesign.polysrc(l,m)` constructs a polynomial sample-rate converter filter designer D with an interpolation factor L and a decimation factor M. L defaults to 3. M defaults to 2. L and M can be arbitrary positive numbers.

`d = fdesign.polysrc(l,m,'Fractional Delay','Np',Np)` initializes the filter designer specification with Np and sets the polynomial order to the value Np. If omitted Np defaults to 3.

`d = fdesign.polysrc(...,Fs)` specifies the sampling frequency (in Hz).

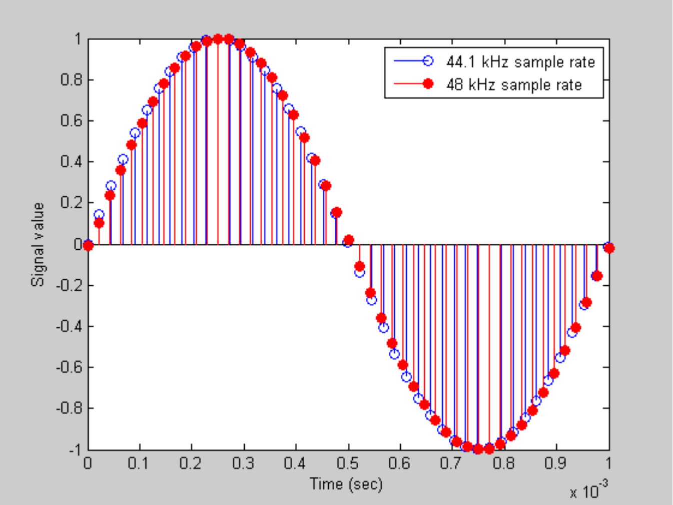
Examples

This example shows how to design sample-rate converter that uses a 3rd order Lagrange interpolation filter to convert from 44.1kHz to 48kHz:

```
[L,M] = rat(48/44.1);
f = fdesign.polysrc(L,M,'Fractional Delay','Np',3);
Hm = design(f,'lagrange');
% Original sampling frequency
Fs = 44.1e3;
% 9408 samples, 0.213 seconds long
n = 0:9407;
% Original signal, sinusoid at 1kHz
x  = sin(2*pi*1e3/Fs*n);
% 10241 samples, still 0.213 seconds
```

```
y = filter(Hm,x);
% Plot original sampled at 44.1kHz
stem(n(1:45)/Fs,x(1:45))
hold on
% Plot fractionally interpolated signal (48kHz) in red
stem((n(3:51)-2)/(Fs*L/M),y(3:51),'r','filled')
xlabel('Time (sec)');ylabel('Signal value')
legend('44.1 kHz sample rate','48 kHz sample rate')
```

This code generates the following figure.



For more information about Farrow SRCs, see the “Efficient Sample Rate Conversion between Arbitrary Factors” example, efficientsrcdemo.

fdesign

fdesign.pulseshaping

Pulse-shaping filter specification object

Syntax

```
D = fdesign.pulseshaping
D = fdesign.pulseshaping(sps)
D = fdesign.pulseshaping(sps,shape)
d = fdesign.pulseshaping(sps,shape,spec,value1,value2,...)
d = fdesign.pulseshaping(...,fs)
d = fdesign.pulseshaping(...,magunits)
```

Description

Note: The use of `fdesign.pulseshaping` is not recommended. Use `rcosdesign` or `gaussdesign` instead.

`D = fdesign.pulseshaping` constructs a specification object `D`, which can be used to design a minimum-order raised cosine filter object with a default stop band attenuation of 60dB and a rolloff factor of 0.25.

`D = fdesign.pulseshaping(sps)` constructs a minimum-order raised cosine filter specification object `d` with a positive integer-valued oversampling factor, `SamplesPerSymbol` .

`D = fdesign.pulseshaping(sps,shape)` constructs `d` where `shape` specifies the `PulseShape` property. Valid entries for `shape` are:

- `'Raised Cosine'`
- `'Square Root Raised Cosine'`
- `'Gaussian'`

`d = fdesign.pulseshaping(sps,shape,spec,value1,value2,...)` constructs `d` where `spec` defines the `Specification` properties. The string entries for `spec` specify various properties of the filter, including the order and frequency response. Valid entries for spec depend upon the shape property. For 'Raised Cosine' and 'Square Root Raised Cosine' filters, the valid entries for spec are:

- 'Ast,Beta' (minimum order; default)
- 'Nsym,Beta'
- 'N,Beta'

The string entries are defined as follows:

- Ast —stopband attenuation (in dB). The default stopband attenuation for a raised cosine filter is 60 dB. The default stopband attenuation for a square root raised cosine filter is 30 dB. If Ast is specified, the minimum-order filter is returned.
- Beta —rolloff factor expressed as a real-valued scalar ranging from 0 to 1. Smaller rolloff factors result in steeper transitions between the passband and stopband of the filter.
- Nsym —filter order in symbols. The length of the impulse response is given by Nsym*SamplesPerSymbol+1. The product Nsym*SamplesPerSymbol must be even.
- N —filter order (must be even). The length of the impulse response is N+1.

If the shape property is specified as 'Gaussian', the valid entries for spec are:

- 'Nsym,BT' (default)

The string entries are defined as follows:

- Nsym—filter order in symbols. Nsym defaults to 6. The length of the filter impulse response is Nsym*SamplesPerSymbol+1. The product Nsym*SamplesPerSymbol must be even.
- BT —the 3–dB bandwidth-symbol time product. BT is a positive real-valued scalar, which defaults to 0.3. Larger values of BT produce a narrower pulse width in time with poorer concentration of energy in the frequency domain.

d = fdesign.pulseshaping(...,fs) specifies the sampling frequency of the signal to be filtered. fs must be specified as a scalar trailing the other numerical values provided. For this case, fs is assumed to be in Hz and is used for analysis and visualization.

d = fdesign.pulseshaping(...,magunits) specifies the units for any magnitude specification you provide in the input arguments. Valid entries for magunits are:

- linear — specify the magnitude in linear units
- dB — specify the magnitude in dB (decibels)
- squared — specify the magnitude in power units

When you omit the magunits argument, fdesign assumes that all magnitudes are in decibels. Note that fdesign stores all magnitude specifications in decibels (converting to decibels when necessary) regardless of how you specify the magnitudes.

After creating the specification object d, you can use the design function to create a filter object such as h in the following example:

```
d = fdesign.pulseshaping(8,'Raised Cosine','Nsym,Beta',6,0.25);
h = design(d);
```

Normally, the Specification property of the specification object also determines which design methods you can use when you create the filter object. Currently, regardless of the Specification property, the design function uses the window design method with all fdesign.pulseshaping specification objects. The window method creates an FIR filter with a windowed impulse response.

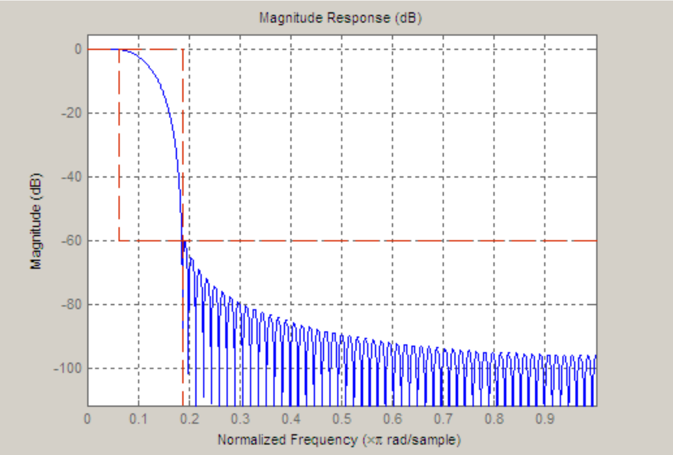
Examples

Pulse-shaping can be used to change the waveform of transmitted pulses so the signal bandwidth matches that of the communication channel. This helps to reduce distortion and intersymbol interference (ISI).

This example shows how to design a minimum-order raised cosine filter that provides a stop band attenuation of 60 dB, rolloff factor of 0.50, and 8 samples per symbol.

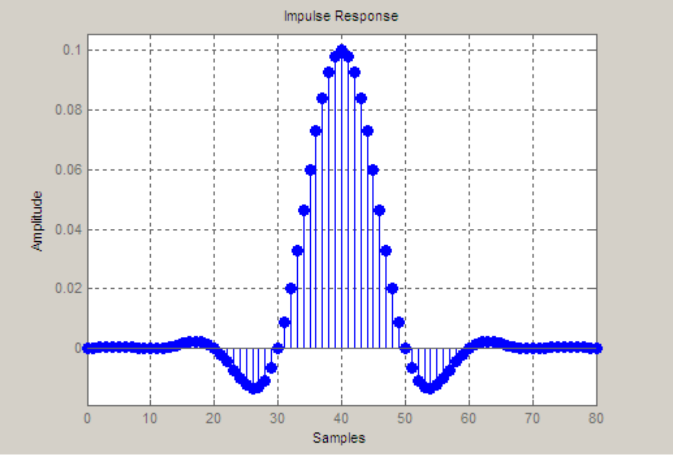
```
h  = fdesign.pulseshaping(8,'Raised Cosine','Ast,Beta',60,0.50);
    Hd = design(h);
    fvtool(Hd)
```

This code generates the following figure.



This example shows how to design a raised cosine filter that spans 8 symbol durations (i.e., of order 8 symbols), has a rolloff factor of 0.50, and oversampling factor of 10.

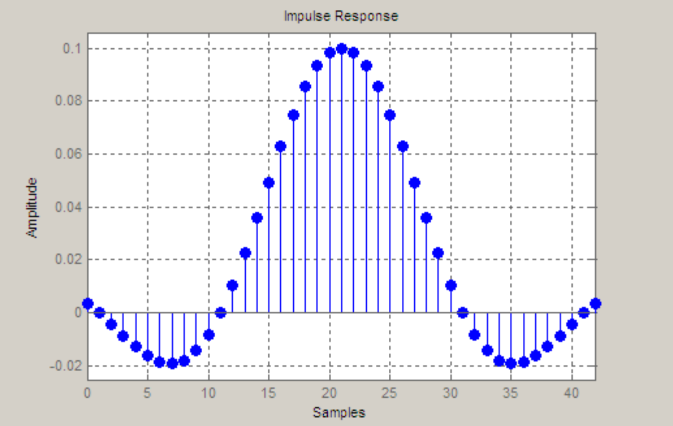
```
h  = fdesign.pulseshaping(10,'Raised Cosine','Nsym,Beta',8,0.50);
    Hd = design(h);
    fvtool(Hd, 'impulse')
```



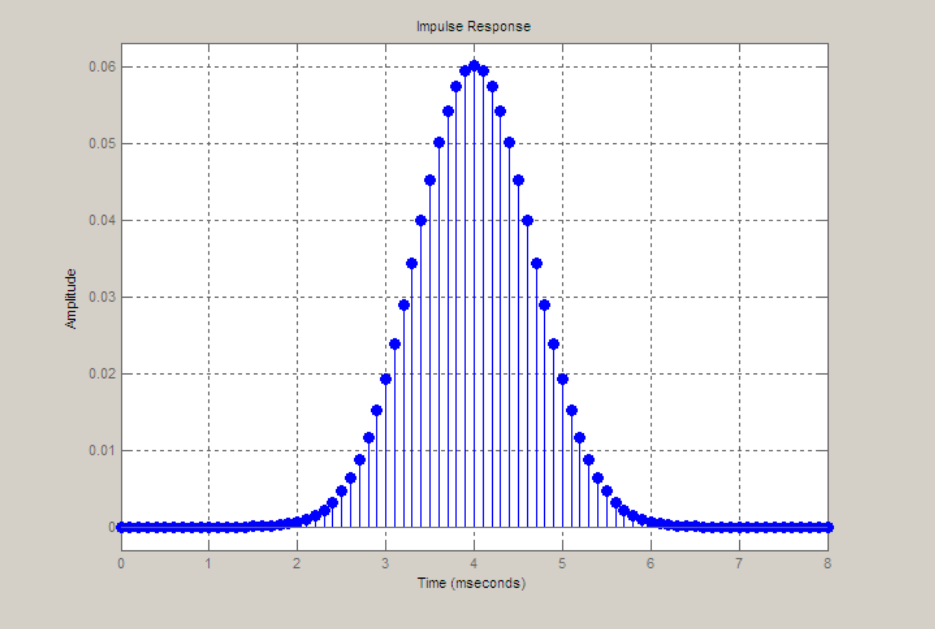
This example shows how to design a square root raised cosine filter of order 42, rolloff factor of 0.25, and 10 samples per symbol.

```
h  = fdesign.pulseshaping(10,'Square Root Raised Cosine','N,Beta',42);
```

```
Hd = design(h);
fvtool(Hd, 'impulse')
```



The following example demonstrates how to create a Gaussian pulse-shaping filter with an oversampling factor (sps) of 10, a bandwidth-time symbol product of 0.2, and 8 symbol periods. The sampling frequency is specified as 10 kHz.



fdesign.rsrc

Rational-factor sample-rate converter specification

Syntax

```
D = fdesign.rsrc(L,M)
D = fdesign.rsrc(L,M,RESPONSE)
D = fdesign.rsrc(L,M,CICRESPONSE,D)
D = fdesign.rsrc(L,M,RESPONSE,SPEC)
D = fdesign.rsrc(L,M,SPEC,specvalue1,specvalue2,...)
D = fdesign.rsrc(...,Fs)
D = fdesign.rsrc(...,MAGUNITS)
```

Description

`D = fdesign.rsrc(L,M)` constructs a rational-factor sample-rate filter specification object `D` with the `InterpolationFactor` property equal to the positive integer `L`, the `DecimationFactor` property equal to the positive integer `M` and the `Response` property set to `'Nyquist'`. The default values for the transition width and stopband attenuation in the Nyquist design are 0.1π radians/sample and 80 dB. If `L` is unspecified, `L` defaults to 3. If `M` is unspecified, `M` defaults to 2.

`D = fdesign.rsrc(L,M,RESPONSE)` constructs an rational-factor sample-rate converter with the interpolation factor `L`, decimation factor `M`, and the response you specify in `RESPONSE`.

`D = fdesign.rsrc(L,M,CICRESPONSE,D)` constructs a CIC or CIC compensator rational-factor sample-rate convertor filter specification object with the `'RESPONSE'` property equal to `'CIC'` or `'CICCOMP'`. `D` is the differential delay. The differential delay, `D`, must precede any specification string.

Because you are designing multirate filters, the specification strings available are not the same as the specifications for designing single-rate filters. The interpolation and decimation factors are not included in the specification strings. Different filter responses support different specifications. The following table lists the supported response types and specification strings. The strings are not case sensitive.

Design String	Valid Specification Strings
`'Arbitrary Magnitude'`	See `fdesign.arbmag` for a description of the specification string entries. • `'N,F,A'` (default string) • `'N,B,F,A'`
`'Arbitrary Magnitude and Phase'`	See `fdesign.arbmagnphase` for a description of the specification string entries. • `'N,F,H'` (default string) • `'N,B,F,H'`
`'Bandpass'`	See `fdesign.bandpass` for a description of the specification string entries. • `'Fst1,Fp1,Fp2,Fst2,Ast1,Ap,Ast2'` (default string) • `'N,Fc1,Fc2'` • `'N,Fst1,Fp1,Fp2,Fst2'`
`'Bandstop'`	See `fdesign.bandstop` for a description of the specification string entries. • `'N,Fc1,Fc2'` • `'N,Fp1,Fst1,Fst2,Fp2'` • `'Fp1,Fst1,Fst2,Fp2,Ap1,Ast,Ap2'` (default string)
`'CIC'`	`'Fp,Fst,Ap,Ast'` — Only valid specification. `Fp` is the passband frequency, `Fst` is the stopband frequency, `Ap` is the passband ripple, and `Ast` is the stopband attenuation in decibels. To specify a CIC rational-factor sample-rate convertor, include the differential delay after `'CIC'` and before the filter specification string: `'Fp,Ast'`. For example: `d = fdesign.rsrc(2,2,'cic',4);`

Design String	Valid Specification Strings
'CIC Compensator'	See `fdesign.ciccomp` for a description of the specification string entries. • `'Fp,Fst,Ap,Ast'` (default string) • `'N,Fc,Ap,Ast'` • `'N,Fp,Ap,Ast'` • `'N,Fp,Fst'` • `'N,Fst,Ap,Ast'` To specify a CIC compensator rational-factor sample-rate convertor, include the differential delay after `'CICCOMP'` and before the filter specification string. For example: `d = fdesign.rsrc(2,2,'ciccomp',4);`
'Differentiator'	`'N'` — filter order
'Gaussian'	`'Nsym,BT` — `Nsym` is the filter order in symbols and `BT` is the bandwidth-symbol time product. The specification string must be preceded by an integer-valued `SamplesPerSymbol`.
'Halfband	See `fdesign.halfband` for a description of the specification string entries. • `'TW,Ast'` (default string) • `'N,TW'` • `‘N’` • `'N,Ast'` If you use the quasi-linear IIR design method, `iirlinphase`, with a halfband specification, the interpolation factor must be 2.

Design String	Valid Specification Strings
'Highpass'	See fdesign.highpass for a description of the specification string entries. • 'Fst,Fp,Ast,Ap' (default string) • 'N,F3db' • 'N,Fc' • 'N,Fc,Ast,Ap' • 'N,Fp,Ast,Ap' • 'N,Fst,Ast,Ap' • 'N,Fst,Fp' • 'N,Fst,Ast,Ap' • 'N,Fst,Fp,Ast'
'Hilbert'	See fdesign.hilbert for a description of the specification string entries. • 'N,TW' (default string) • 'TW,Ap'
'Inverse-sinc Lowpass'	See fdesign.isinclp for a description of the specification string entries. • 'Fp,Fst,Ap,Ast' (default string)) • 'N,Fc,Ap,Ast' • 'N,Fp,Fst' • 'N,Fst,Ap,Ast'
'Inverse-sinc Highpass'	See fdesign.isinchp for a description of the specification string entries. • 'Fst,Fp,Ast,Ap' (default string)) • 'N,Fc,Ast,Ap' • 'N,Fst,Fp' • 'N,Fst,Ast,Ap'

Design String	Valid Specification Strings
'Lowpass'	See fdesign.lowpass for a description of the specification string entries. • 'Fp,Fst,Ap,Ast' (default string) • 'N,F3dB' • 'N,Fc' • 'N,Fc,Ap,Ast' • 'N,Fp,Ap,Ast' • 'N,Fp,Fst' • 'N,Fp,Fst,Ap' • 'N,Fp,Fst,Ast' • 'N,Fst,Ap,Ast'
'Nyquist'	See fdesign.nyquist for a description of the specification string entries. For all Nyquist specifications, you must specify the *L*th band. This typically corresponds to the interpolation factor so that the nonzero samples of the upsampler output are preserved. • 'TW,Ast' (default string) • 'N' • 'N,Ast' • 'N,Ast'

D = fdesign.rsrc(L,M,RESPONSE,SPEC) constructs object D and sets its Specification property to SPEC. Entries in the SPEC string represent various filter response features, such as the filter order, that govern the filter design. Valid entries for SPEC depend on the design type of the specifications object.

When you add the SPEC input argument, you must also add the RESPONSE input argument.

D = fdesign.rsrc(L,M,SPEC,specvalue1,specvalue2,...) constructs an object D and sets its specifications at construction time.

D = fdesign.rsrc(...,Fs) provides the sampling frequency of the signal to be filtered. Fs must be specified as a scalar trailing the other numerical values provided. Fs is assumed to be in Hz as are all other frequency values provided.

D = fdesign.rsrc(...,MAGUNITS) specifies the units for any magnitude specification you provide in the input arguments. MAGUNITS can be one of

- 'linear' — specify the magnitude in linear units.
- 'dB' — specify the magnitude in dB (decibels).
- 'squared' — specify the magnitude in power units.

When you omit the MAGUNITS argument, fdesign assumes that all magnitudes are in decibels. Note that fdesign stores all magnitude specifications in decibels (converting to decibels when necessary) regardless of how you specify the magnitudes.

Examples

Design a rational-factor sample-rate converter. Set the rational sample-rate change to 5/3. Use the default Nyquist design with a transition width of 0.05π radians/sample and stopband attenuation of 40 dB. The *L*th band factor in the Nyquist design is equal to the interpolation factor.

```
d = fdesign.rsrc(5,3,'nyquist',5,.05,40);
hm = design(d,'kaiserwin'); %design with Kaiser window
```

Design a rational-factor sample-rate converter. Set the rational sample-rate change to 5/3. Use a Nyquist design with the 'N,TW' specification string. Set the order equal to 12 and the transition width to 0.1π radians/sample. The *L*th band factor in the Nyquist design is equal to the interpolation factor.

```
d = fdesign.rsrc(5,3,'nyquist',5,'N,TW',12,0.1);
```

Design a rational-factor sample-rate converter. Assume the data are sampled at 10 kHz. Set the rational sample-rate change to 3/2. Use a Nyquist design with the 'N,TW' specification string. Set the order equal to 12 and the transition width to 100 Hz. The *L*th band factor in the Nyquist design is equal to the interpolation factor.

```
d = fdesign.rsrc(3,2,'nyquist',3,'N,TW',12,100,1e4);
hd = design(d,'equiripple');
```

fftcoeffs

Frequency-domain coefficients

Syntax

```
c = fftcoeffs(hd)
c = fftcoeffs(ha)
```

Description

`c = fftcoeffs(hd)` return the frequency-domain coefficients used when filtering with the `dfilt.fftfir` object. c contains the coefficients

`c = fftcoeffs(ha)` return the frequency-domain coefficients used when filtering with `adaptfilt` objects.

`fftcoeffs` applies to the following adaptive filter algorithms:

- `adaptfilt.fdaf`
- `adaptfilt.pbfdaf`
- `adaptfilt.pbufdaf`
- `adaptfilt.ufdaf`

Examples

This example demonstrates returning the FFT coefficients from the discrete-time filter `hd`.

```
b = [0.05 0.9 0.05];
len = 50;
hd = dfilt.fftfir(b,len);
c=fftcoeffs(hd);
```

Similarly, you can use `fftcoeffs` with the adaptive filters algorithms listed above. Start by constructing an adaptive filter `ha`.

```
d  = 16;                    % Number of samples of delay.
b  = exp(1j*pi/4)*[-0.7 1];  % Numerator coefficients of channel.
a  = [1 -0.7];              % Denominator coefficients of channel.
ntr= 1000;                  % Number of iterations.
s  = sign(randn(1,ntr+d)) +...
1j*sign(randn(1,ntr+d));     % Baseband QPSK signal.
n  = 0.1*(randn(1,ntr+d) + 1j*randn(1,ntr+d));  % Noise signal.
r  = filter(b,a,s)+n;       % Received signal.
x  = r(1+d:ntr+d);          % Input signal (received signal).
s  = s(1:ntr);              % Desired signal (delayed QPSK signal).
del = 1;                    % Initial FFT input powers.
mu  = 0.1;                  % Step size.
lam = 0.9;                  % Averaging factor.
blocksize   = 8;                    % Block size.
ha = adaptfilt.pbufdaf(32,mu,1,del,lam,blocksize);
```

Here are the coefficients before you filter a signal.

```
c=fftcoeffs(ha);
% all coefficients are zero
NumNonzero =nnz(c);
```

Filtering a signal `y` produces complex nonzero coefficients that you use `fftcoeffs` to see.

```
[y,e] = filter(ha,x,s);
c=fftcoeffs(ha);
```

filter

Filter data with filter object

Syntax

Fixed-Point Filter Syntaxes

```
y = filter(hd,x)
y = filter(hd,x,dim)
```

Adaptive Filter Syntax

```
y = filter(ha,x,d)
[y,e] = filter(ha,x,d)
```

Multirate Filter Syntax

```
y = filter(hm,x)
y = filter(hm,x,dim)
```

Description

This reference page contains three sections that describe the syntaxes for the filter objects:

- "Fixed-Point Filter Syntaxes" on page 4-583
- "Adaptive Filter Syntaxes" on page 4-584
- "Multirate Filter Syntaxes" on page 4-585

Fixed-Point Filter Syntaxes

`y = filter(hd,x)` filters a vector of real or complex input data `x` through a fixed-point filter `hd`, producing filtered output data `y`. The vectors `x` and `y` have the same length. filter stores the final conditions for the filter in the `States` property of `hd` — `hd.states`.

When you set the property `PersistentMemory` to `false` (the default setting), the initial conditions for the filter are set to zero before filtering starts. To use nonzero initial conditions for hd, set PersistentMemory to true. Then set hd.states to a vector of nstates(hd) elements, one element for each state to set. If you specify a scalar for hd.states, filter expands the scalar to a vector of the proper length for the states. All elements of the expanded vector have the value of the scalar.

If x is a matrix, y = filter(hd,x) filters along each column of x to produce a matrix y of independent channels. If x is a multidimensional array, y = filter(hd,x) filters x along the first nonsingleton dimension of x.

To use nonzero initial conditions when you are filtering a matrix x, set the filter states to a matrix of initial condition values. Set the initial conditions by setting the States property for the filter (hd.states) to a matrix of nstates(hd) rows and size(x,2) columns.

y = filter(hd,x,dim) applies the filter hd to the input data located along the specific dimension of x specified by dim.

When you are filtering multichannel data, dim lets you specify which dimension of the input matrix to filter along — whether a row represents a channel or a column represents a channel. When you provide the dim input argument, the filter operates along the dimension specified by dim. When your input data x is a vector or matrix and dim is 1, each column of x is treated as a one input channel. When dim is 2, the filter treats each row of the input x as a channel.

To filter multichannel data in a loop environment, you must use the dim input argument to set the proper processing dimension.

You specify the initial conditions for each channel individually, when needed, by setting hm.states to a matrix of nstates(hd) rows (one row containing the states for one channel of input data) and size(x,2) columns (one column containing the filter states for each channel).

Adaptive Filter Syntaxes

y = filter(ha,x,d) filters a vector of real or complex input data x through an adaptive filter object ha, producing the estimated desired response data y from the process of adapting the filter. The vectors x and y have the same length. Use d for the desired signal. Note that d and x must be the same length signal chains.

[y,e] = filter(ha,x,d) produces the estimated desired response data y and the prediction error e (refer to previous syntax for more information).

Multirate Filter Syntaxes

`y = filter(hm,x)` filters a vector of real or complex input data `x` through a multirate filter `hm`, producing filtered output data `y`. The length of vectors `x` and `y` differ by approximately the resampling factor. `filter` stores the final conditions for the filter in the `States` property of `hm` – `hm.states`.

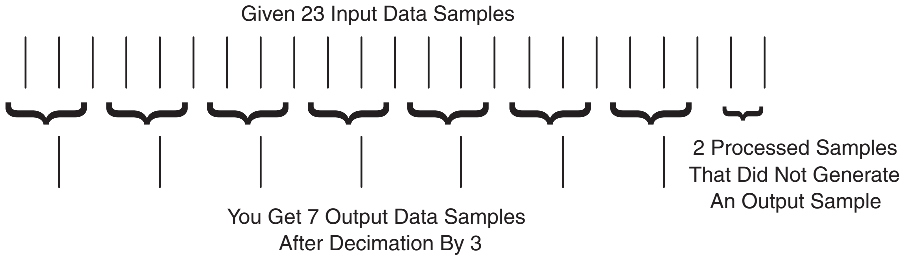
`y = filter(hm,x,dim)` applies the filter `hm` to the input data located along the specific dimension of `x` specified by `dim`.

When you are filtering multichannel data, `dim` lets you specify which dimension of the input matrix to filter along — whether a row represents a channel or a column represents a channel. When you provide the `dim` input argument, the filter operates along the dimension specified by `dim`. When your input data `x` is a vector or matrix and `dim` is 1, each column of `x` is treated as a one input channel. When `dim` is 2, the filter treats each row of the input `x` as a channel.

To filter multichannel data in a loop environment, you must use the `dim` input argument to set the processing dimension.

You specify the initial conditions for each channel individually, when needed, by setting `hm.states` to a matrix of `nstates(hm)` rows (one row containing the states for one channel of input data) and `size(x,2)` columns (one column containing the filter states for each channel).

The number of data samples in your input data set `x` does not need to be a multiple of the rate change factor `r` for the object. When the rate change factor is not an even divisor of the number of input samples `x`, `filter` processes the samples as shown in the following figure, where the rate change factor is 3 and the number of input samples is 23. Decimators always take the first input sample to generate the first output sample. After that, the next output sample comes after each `r` number of input samples.



Examples

Filter a signal using a filter with various initial conditions (IC) or no initial conditions.

```
x = randn(100,1);    % Original signal.
b = fir1(50,.4);     % 50th-order linear-phase FIR filter.
hd = dfilt.dffir(b);    % Direct-form FIR implementation.

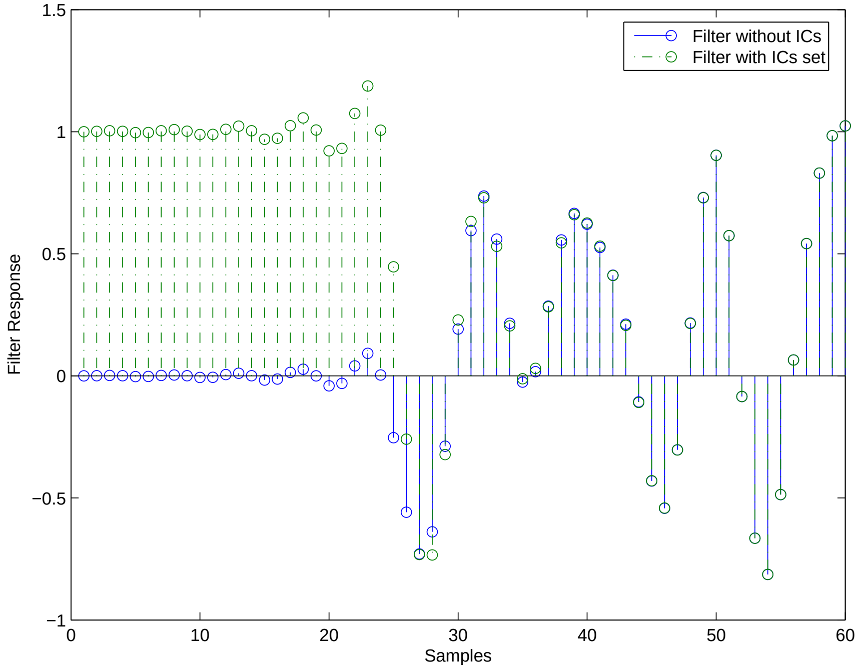
% Do not set specific initial conditions.

y1 = filter(hd,x);   % 'PersistentMemory'='false'(default).
zf = hd.states;      % Final conditions.
```

Now use nonzero initial conditions by setting ICs after before you filter.

```
hd.persistentmemory = true;
hd.states = 1;      % Uses scalar expansion.
y2 = filter(hd,x);
stem([y1 y2])       % Different sequences at beginning.
```

Looking at the stem plot shows that the sequences are different at the beginning of the filter process.



Here is one way to use `filter` with streaming data.

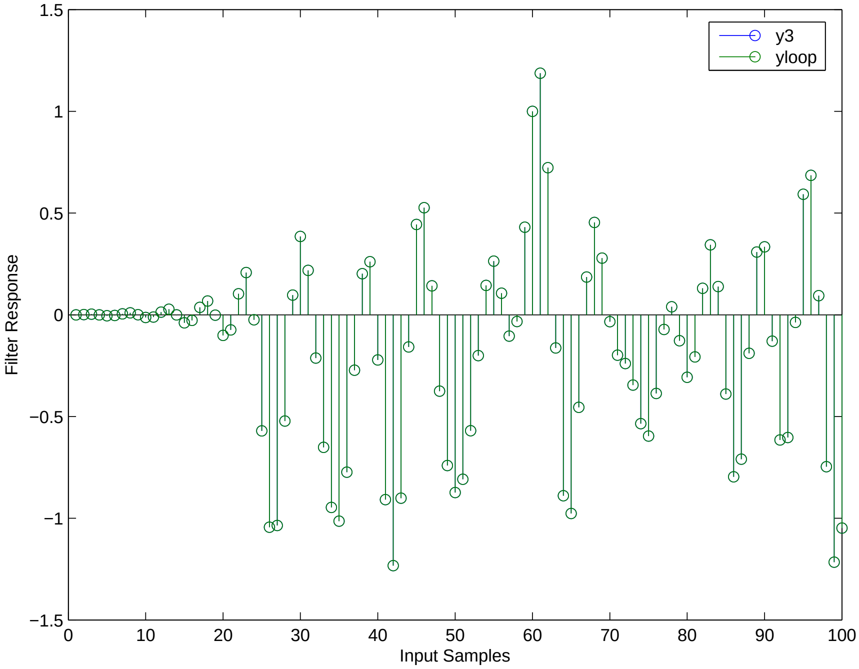
```
reset(hd);              % Clear filter history.
y3 = filter(hd,x);      % Filter entire signal in one block.
```

As an experiment, repeat the process, filtering the data as sections, rather than in streaming form.

```
reset(hd);                 % Clear filter history.
yloop = zeros(20,5);       % Preallocate output array.
xblock = reshape(x,[20 5]);
for i=1:5,
   yloop(:,i) = filter(hd,xblock(:,i));
end
```

Use a stem plot to see the comparison between streaming and block-by-block filtering.

```
stem([y3 yloop(:)]);
```



Filtering the signal section-by-section is equivalent to filtering the entire signal at once.

To show the similarity between filtering with discrete-time and with multirate filters, this example demonstrates multirate filtering.

```
Fs = 44.1e3;              % Original sampling frequency: 44.1kHz.
n = [0:10239].';          % 10240 samples, 0.232 second long signal.
x  = sin(2*pi*1e3/Fs*n); % Original signal, sinusoid at 1kHz.
m = 2;                    % Decimation factor.
hm = mfilt.firdecim(m);  % Use the default filter.
```

First, filter without setting initial conditions.

```
y1 = filter(hm,x);        % PersistentMemory is false (default).
zf = hm.states;           % Final conditions.
```

This time, set nonzero initial conditions before filtering the data.

```
hm.persistentmemory = true;
hm.states = 1;       % Uses scalar expansion to set ICs.
y2 = filter(hm,x);
stem([y1(1:60) y2(1:60)]) % Show the filtering results.
```

Note the different sequences at the start of filtering.

Finally, try filtering streaming data.

```
reset(hm);           % Clear the filter history.
y3 = filter(hm,x);   % Filter entire signal in one block.
```

As with the discrete-time filter, filtering the signal section by section is equivalent to filtering the entire signal at once.

```
reset(hm);            % Clear filter history again.
yloop = zeros(1024,5);  % Preallocate output array.
xblock = reshape(x,[2048 5]);
for i=1:5,
   yloop(:,i) = filter(hm,xblock(:,i));
end
stem([y3 yloop(:)]);
```

More About

Algorithms

Quantized Filters

The `filter` command implements fixed- or floating-point arithmetic on the quantized filter structure you specify.

The algorithm applied by `filter` when you use a discrete-time filter object on an input signal depends on the response you chose for the filter, such as lowpass or Nyquist or bandstop. To learn more about each filter algorithm, refer to the literature reference provided on the appropriate discrete-time filter reference page.

Note `dfilt/filter` does not normalize the filter coefficients automatically. Function `filter` supplied by MATLAB does normalize the coefficients.

Adaptive Filters

The algorithm used by `filter` when you apply an adaptive filter object to a signal depends on the algorithm you chose for your adaptive filter. To learn more about each adaptive filter algorithm, refer to the literature reference provided on the appropriate `adaptfilt.`*`algorithm`* reference page.

Multirate Filters

The algorithm applied by `filter` when you apply a multirate filter objects to signals depends on the algorithm you chose for the filter — the form of the multirate filter, such as decimator or interpolator. To learn more about each filter algorithm, refer to the literature reference provided on the appropriate multirate filter reference page.

filterbuilder

GUI-based filter design

Syntax

```
filterbuilder(h)
filterbuilder('response')
```

Description

`filterbuilder` starts a GUI-based tool for building filters. It relies on the `fdesign` object-object oriented filter design paradigm, and is intended to reduce development time during the filter design process. `filterbuilder` uses a specification-centered approach to find the best algorithm for the desired response.

Note: You must have the Signal Processing Toolbox installed to use `fdesign` and `filterbuilder`. Some of the features described below may be unavailable if your installation does not additionally include the DSP System Toolbox. You can verify the presence of both toolboxes by typing `ver` at the command prompt.

The `filterbuilder` GUI contains many features not available in FDATool. For more information on how to use `filterbuilder`, see “Filterbuilder Design Process”.

To use `filterbuilder`, enter `filterbuilder` at the MATLAB command line using one of three approaches:

- Simply enter `filterbuilder`. MATLAB opens a dialog for you to select a filter response type. After you select a filter response type, `filterbuilder` launches the appropriate filter design dialog box.
- Enter `filterbuilder(h)`, where h is an existing filter object. For example, if `h` is a bandpass filter, `filterbuilder(h)` opens the bandpass filter design dialog box. (The `h` object must have been created using `filterbuilder` or must be a `dfilt` ,`mfilt`, or filter System object created using fdesign.)

Note: You must have the DSP System Toolbox software to create and import filter System objects.

- Enter `filterbuilder('response')`, replacing *`response`* with a response string from the following table. MATLAB opens a filter design dialog that corresponds to the response string.

Note: You must have the DSP System Toolbox software to implement a number of the filter designs listed in the following table. If you only have the Signal Processing Toolbox software, you can design a limited set of the following filter-response types.

Response String	Description of Resulting Filter Design	Filter Object
arbgrpdelay	Arbitrary group delay filter design	`fdesign.arbgrpdelay`
arbmag	Arbitrary magnitude filter design	`fdesign.arbmag`
arbmagnphase	Arbitrary response filter (magnitude and phase)	`fdesign.arbmagnphase`
audioweighting	Audio weighting filter	`fdesign.audioweighting`
bandpass or `bp`	Bandpass filter	`fdesign.bandpass`
bandstop or `bs`	Bandstop filter	`fdesign.bandstop`

cic	CIC filter	`fdesign.decimator(M,'cic',...)`
		or
		`fdesign.interpolator(L,'cic',...`
		See `fdesign.decimator`
		and
		`fdesign.interpolator`

ciccomp	CIC compensator	`fdesign.ciccomp`
comb	Comb filter	`fdesign.comb`
diff	Differentiator filter	`fdesign.differentiator`
fracdelay	Fractional delay filter	`fdesign.fracdelay`

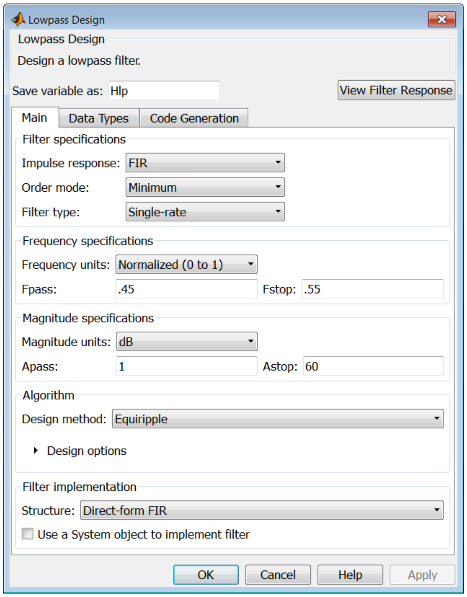
Response String	Description of Resulting Filter Design	Filter Object
halfband or `hb`	Halfband filter	`fdesign.halfband`
highpass or `hp`	Highpass filter	`fdesign.highpass`
hilb	Hilbert filter	`fdesign.hilbert`
isinc, isinclp, or isinchp	Inverse sinc lowpass or highpass filter	`fdesign.isinclp` and `fdesign.isinchp`
lowpass or `lp`	Lowpass filter (default)	`fdesign.lowpass`
notch	Notch filter	`fdesign.notch`
nyquist	Nyquist filter	`fdesign.nyquist`
octave	Octave filter	`fdesign.octave`
parameq	Parametric equalizer filter	`fdesign.parameq`
peak	Peak filter	`fdesign.peak`

Note: Because they do not change the filter structure, the magnitude specifications and design method are tunable when using `filterbuilder`.

Filterbuilder Design Panes

Main Design Pane

The main pane of filterbuilder varies depending on the filter response type, but the basic structure is the same. The following figure shows the basic layout of the dialog box.



Lowpass Design

Lowpass Design

Design a lowpass filter.

Save variable as: Hlp

Filter specifications

Impulse response: FIR

Order mode: Minimum

Filter type: Single-rate

Frequency specifications

Frequency units: Normalized (0 to 1)

Fpass: .45 Fstop: .55

Magnitude specifications

Magnitude units: dB

Apass: 1 Astop: 60

Algorithm

Design method: Equiripple

▸ Design options

Filter implementation

Structure: Direct-form FIR

□ Use a System object to implement filter

As you choose the response for the filter, the available options and design parameters displayed in the dialog box change. This display allows you to focus only on parameters that make sense in the context of your filter design.

Every filter design dialog box includes the options displayed at the top of the dialog box, shown in the following figure.

Save variable as: Hbp

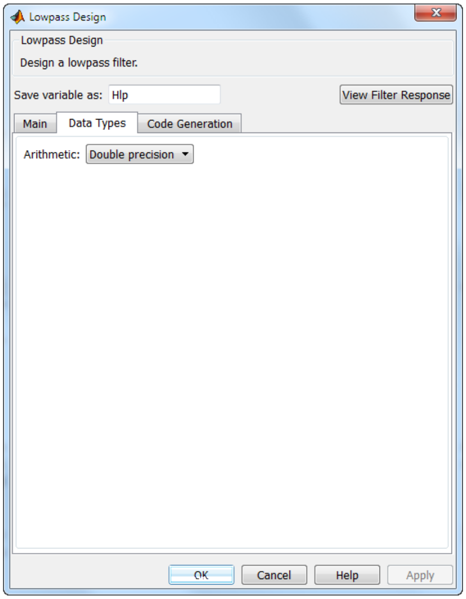
- **Save variable as** — When you click **Apply** to apply your changes or **OK** to close this dialog box, `filterbuilder` saves the current filter to your MATLAB workspace as a filter object with the name you enter.
- **View Filter Response** — Displays the magnitude response for the current filter specifications and design method by opening the Filter Visualization Tool (`fvtool`).

Note: The `filterbuilder` dialog box includes an **Apply** option. Each time you click **Apply**, `filterbuilder` writes the modified filter to your MATLAB workspace. This modified filter has the variable name you assign in **Save variable as**. To apply changes without overwriting the variable in you workspace, change the variable name in **Save variable as** before you click **Apply**.

There are three tabs in the Filterbuilder dialog box, containing three panes: **Main**, **Data Types**, and **Code Generation**. The first pane changes according to the filter being designed. The last two panes are the same for all filters. These panes are discussed in the following sections.

Data Types Pane

The second tab in the Filterbuilder dialog box is shown in the following figure.



Save variable as: Hlp

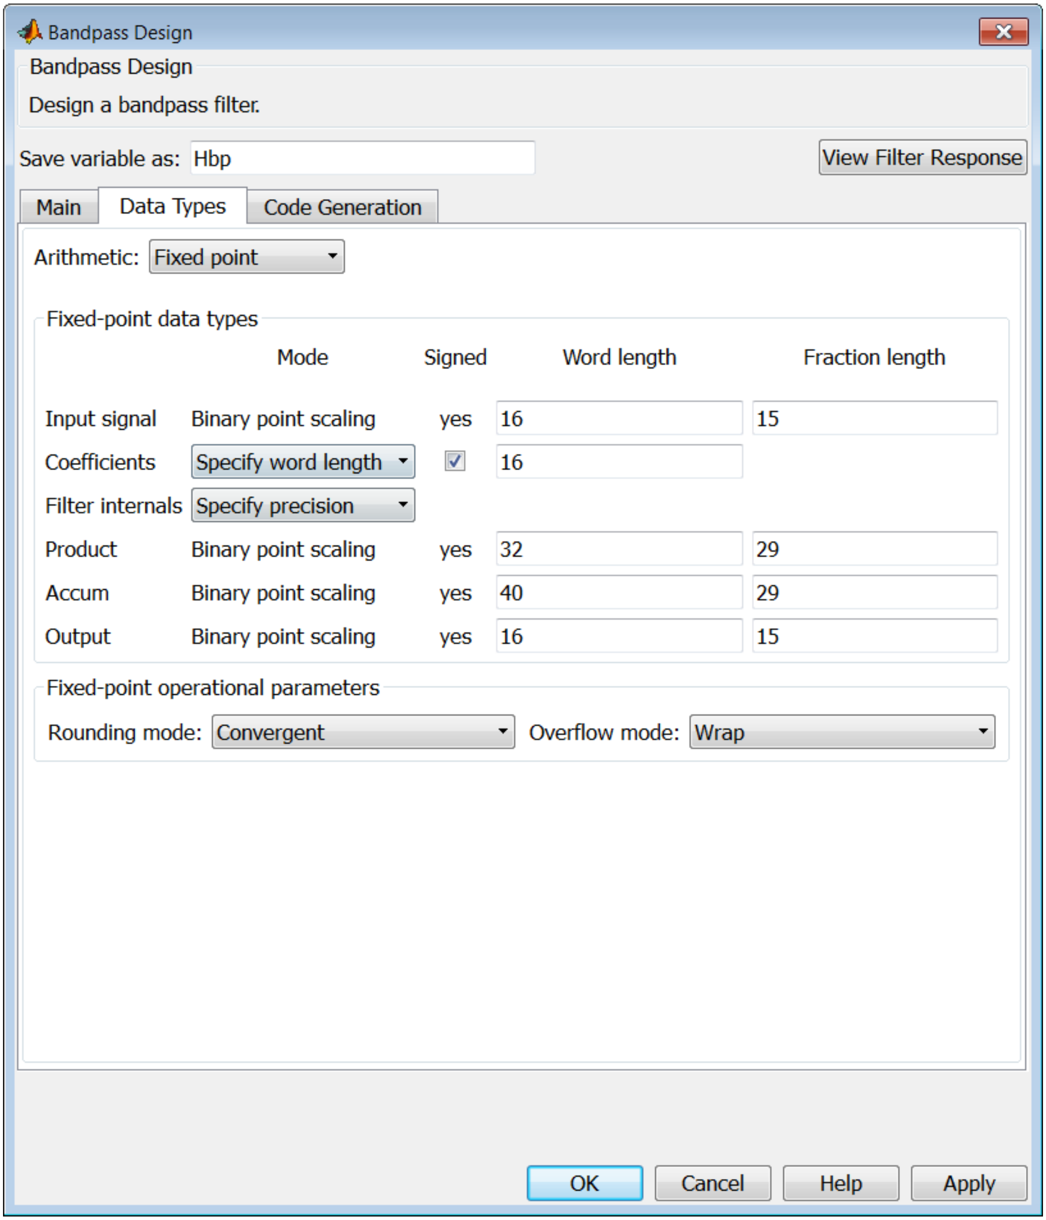
Arithmetic: Double precision

The **Arithmetic** drop down box allows the choice of `Double precision`, `Single precision`, or `Fixed point`. Some of these options may be unavailable depending on the filter parameters. The following table describes these options.

Arithmetic List Entry	Effect on the Filter
`Double precision`	All filtering operations and coefficients use double-precision, floating-point representations and math. When you use

Arithmetic List Entry	Effect on the Filter
	`filterbuilder` to create a filter, `double precision` is the default value for the Arithmetic property.
`Single precision`	All filtering operations and coefficients use single-precision floating-point representations and math.
`Fixed point`	This string applies selected default values, typically used on many digital processors, for the properties in the fixed-point filter. These properties include coefficient word lengths, fraction lengths, and various operating modes. This setting allows signed fixed data types only. Fixed-point filter design with `filterbuilder` is available only when you install Fixed-Point Designer software along with DSP System Toolbox software.

The following figure shows the **Data Types** pane after you select `Fixed point` for **Arithmetic** and set **Filter internals** to `Specify precision`. This figure shows the **Data Types** pane for the case where the **Use a System object to implement filter** check box is not selected in the **Main** pane.



Bandpass Design

Design a bandpass filter.

Save variable as: Hbp

Arithmetic: Fixed point

Fixed-point data types

	Mode	Signed	Word length	Fraction length
Input signal	Binary point scaling	yes	16	15
Coefficients	Specify word length	☑	16	
Filter internals	Specify precision			
Product	Binary point scaling	yes	32	29
Accum	Binary point scaling	yes	40	29
Output	Binary point scaling	yes	16	15

Fixed-point operational parameters

Rounding mode: Convergent Overflow mode: Wrap

Not all parameters described in the following section apply to all filters. For example, FIR filters do not have the **Section input** and **Section output** parameters.

Input signal

Specify the format the filter applies to data to be filtered. For all cases, `filterbuilder` implements filters that use binary point scaling and signed input. You set the word length and fraction length as needed.

Coefficients

Choose how you specify the word length and the fraction length of the filter numerator and denominator coefficients:

- `Specify word length` enables you to enter the word length of the coefficients in bits. In this mode, `filterbuilder` automatically sets the fraction length of the coefficients to the binary-point only scaling that provides the best possible precision for the value and word length of the coefficients.
- `Binary point scaling` enables you to enter the word length and the fraction length of the coefficients in bits. If applicable, enter separate fraction lengths for the numerator and denominator coefficients.
- The filter coefficients do not obey the **Rounding mode** and **Overflow mode** parameters that are available when you select `Specify precision` from the Filter internals list. Coefficients are always saturated and rounded to `Nearest`.

Section Input

Choose how you specify the word length and the fraction length of the fixed-point data type going into each section of an SOS filter. This parameter is visible only when the selected filter structure is IIR and SOS.

- `Binary point scaling` enables you to enter the word and fraction lengths of the section input in bits.
- `Specify word length` enables you to enter the word lengths in bits.

Section Output

Choose how you specify the word length and the fraction length of the fixed-point data type coming out of each section of an SOS filter. This parameter is visible only when the selected filter structure is IIR and SOS.

- `Binary point scaling` enables you to enter the word and fraction lengths of the section output in bits.
- `Specify word length` enables you to enter the output word lengths in bits.

State

Contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. Use this parameter to specify how to designate the state word and fraction lengths. This parameter is not visible for direct form and direct form I filter structures because `filterbuilder` deduces the state directly from the input format. States always use signed representation:

- `Binary point scaling` enables you to enter the word length and the fraction length of the accumulator in bits.
- `Specify precision` enables you to enter the word length and fraction length in bits (if available).

Product

Determines how the filter handles the output of product operations. Choose from the following options:

- `Full precision` — Maintain full precision in the result.
- `Keep LSB` — Keep the least significant bit in the result when you need to shorten the data words.
- `Specify Precision` — Enables you to set the precision (the fraction length) used by the output from the multiplies.

Filter internals

Specify how the fixed-point filter performs arithmetic operations within the filter. The affected filter portions are filter products, sums, states, and output. Select one of these options:

- `Full precision` — Specifies that the filter maintains full precision in all calculations for products, output, and in the accumulator.
- `Specify precision` — Set the word and fraction lengths applied to the results of product operations, the filter output, and the accumulator. Selecting this option enables the word and fraction length controls.

Signed

Selecting this option directs the filter to use signed representations for the filter coefficients.

Word length

Sets the word length for the associated filter parameter in bits.

Fraction length

Sets the fraction length for the associate filter parameter in bits.

Accum

Use this parameter to specify how you would like to designate the accumulator word and fraction lengths.

Determines how the accumulator outputs stored values. Choose from the following options:

- `Full precision` — Maintain full precision in the accumulator.
- `Keep MSB` — Keep the most significant bit in the accumulator.
- `Keep LSB` — Keep the least significant bit in the accumulator when you need to shorten the data words.
- `Specify Precision` — Enables you to set the precision (the fraction length) used by the accumulator.

Output

Sets the mode the filter uses to scale the output data after filtering. You have the following choices:

- `Avoid Overflow` — Set the output data fraction length to avoid causing the data to overflow. `Avoid overflow` is considered the conservative setting because it is independent of the input data values and range.
- `Best Precision` — Set the output data fraction length to maximize the precision in the output data.
- `Specify Precision` — Set the fraction length used by the filtered data.

Fixed-point operational parameters

Parameters in this group control how the filter rounds fixed-point values and how it treats values that overflow.

Rounding mode

Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths).

- `ceil` - Round toward positive infinity.
- `convergent` - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software.

- `zero/fix` - Round toward zero.
- `floor` - Round toward negative infinity.
- `nearest` - Round toward nearest. Ties round toward positive infinity.
- `round` - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers.

The choice you make affects everything except coefficient values and input data which always round. In most cases, products do not overflow—they maintain full precision.

Overflow mode

Sets the mode the filter uses to respond to overflow conditions in fixed-point arithmetic. Choose from the following options:

- `Saturate` — Limit the output to the largest positive or negative representable value.
- `Wrap` — Set overflowing values to the nearest representable value using modular arithmetic.

The choice you make affects everything except coefficient values and input data which always round. In most cases, products do not overflow—they maintain full precision.

Cast before sum

Specifies whether to cast numeric data to the appropriate accumulator format before performing sum operations. Selecting **Cast before sum** ensures that the results of the affected sum operations match most closely the results found on most digital signal processors. Performing the cast operation before the summation adds one or two additional quantization operations that can add error sources to your filter results.

If you clear **Cast before sum**, the filter prevents the addends from being cast to the sum format before the addition operation. Choose this setting to get the most accurate results from summations without considering the hardware your filter might use. The input format referenced by **Cast before sum** depends on the filter structure you are using.

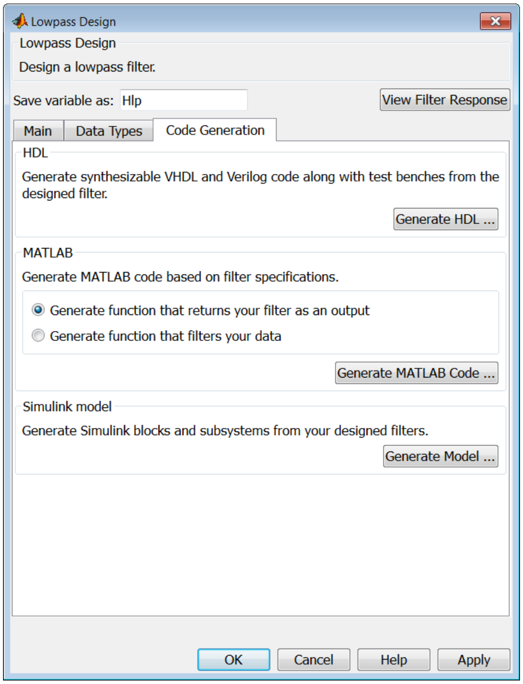
The effect of clearing or selecting **Cast before sum** is as follows:

- Cleared — Configures filter summation operations to retain the addends in the format carried from the previous operation.

- Selected — Configures filter summation operations to convert the input format of the addends to match the summation output format before performing the summation operation. Usually, selecting **Cast before sum** generates results from the summation that more closely match those found from digital signal processors.

Code Generation Pane

The code generation pane contains options for various implementations of the completed filter design. Depending on your installation, you can generate MATLAB, VHDL, and Verilog code from the designed filter. You can also choose to create or update a Simulink model from the designed filter. The following section explains these options.



Lowpass Design

Lowpass Design

Design a lowpass filter.

Save variable as: Hlp

HDL

Generate synthesizable VHDL and Verilog code along with test benches from the designed filter.

MATLAB

Generate MATLAB code based on filter specifications.

● Generate function that returns your filter as an output

○ Generate function that filters your data

Simulink model

Generate Simulink blocks and subsystems from your designed filters.

HDL

For more information on this option, see “Opening the Filter Design HDL Coder GUI From the filterbuilder GUI”.

MATLAB

Generate MATLAB code based on filter specifications

- **Generate function that returns your filter as an output**

  Selecting this option generates a function that designs either a DFILT/MFILT object or a system object (depending on whether you have selected the **Use a System object to implement the filter** check box) using fdesign. The function call returns a filter object.

- **Generate function that filters your data**

  Selecting this option generates a function that takes data as input, and outputs data filtered with the designed filter.

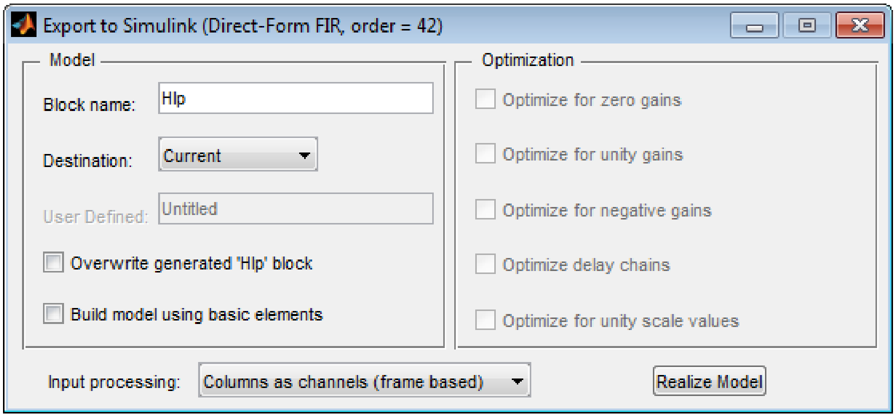
Clicking on the **Generate MATLAB code** button, brings up a Save File dialog. Specify the file name and location, and save. The filter is now contained in an editable file.

Simulink Model

Generate Simulink blocks and subsystems from your designed filters

When the **Use a System object to implement filter** check box is selected in the **Main** pane, you are able to generate Simulink models as long as the **Arithmetic** is not set to `Fixed point` in the **Data Types** pane. If the **Arithmetic** is set to `Fixed point`, the **Generate Model** button in the **Simulink model** panel will be disabled.

Clicking on the **Generate Model** button brings up the **Export to Simulink** dialog box, as shown in the following figure.



Export to Simulink (Direct-Form FIR, order = 42)

Model

Block name: Hlp

Destination: Current

User Defined: Untitled

☐ Overwrite generated 'Hlp' block

☐ Build model using basic elements

Optimization

☐ Optimize for zero gains

☐ Optimize for unity gains

☐ Optimize for negative gains

☐ Optimize delay chains

☐ Optimize for unity scale values

Input processing: Columns as channels (frame based)

You can set the following parameters in this dialog box:

- **Block Name** — The name for the new subsystem block, set to **Filter** by default.
- **Destination** — **Current** saves the generated model to the current Simulink model; **New** creates a new model to contain the generated block; **User Defined** creates a new model or subsystem to the user-specified location enumerated in the **User Defined** text box.
- **Overwrite generated 'Filter' block** — When this check box is selected, DSP System Toolbox software overwrites an existing block with the name specified in **Block Name**; when cleared, creates a new block with the same name.
- **Build model using basic elements** — When this check box is selected, DSP System Toolbox software builds the model using only basic blocks.
- **Optimize for zero gains** — When this check box is selected, DSP System Toolbox software removes all zero gain blocks from the model.
- **Optimize for unity gains** — When this check box is selected, DSP System Toolbox software replaces all unity gains with direct connections.
- **Optimize for negative gains** — When this check box is selected, DSP System Toolbox software removes all negative unity gain blocks, and changes sign at the nearest summation block.
- **Optimize delay chains** — When this check box is selected, DSP System Toolbox software replaces delay chains made up of *n* unit delays with a single delay by *n*.
- **Optimize for unity scale values** — When this check box is selected, DSP System Toolbox software removes all scale value multiplications by 1 from the filter structure.
- **Input processing** — Specify how the generated filter block or subsystem block processes the input. Depending on the type of filter you are designing, one or both of the following options may be available:

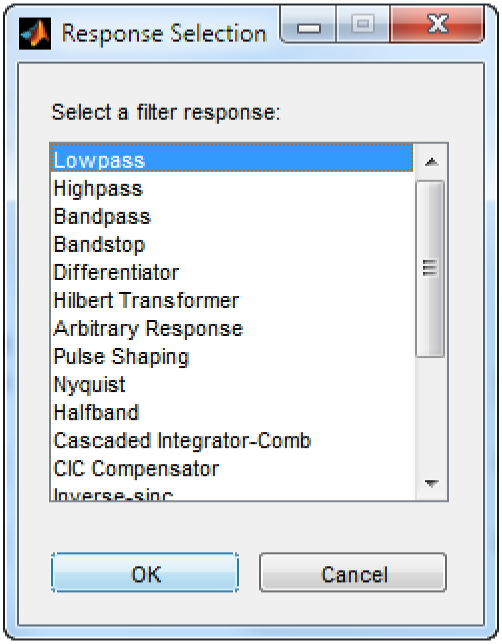
  - `Columns as channels (frame based)` — When you select this option, the block treats each column of the input as a separate channel.
  - `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

  For more information about sample- and frame-based processing, see “Sample- and Frame-Based Concepts”.
- **Realize Model** — DSP System Toolbox software builds the model with the set parameters.

Filter Responses

Select your filter response from the `filterbuilder` **Response Selection** main menu.

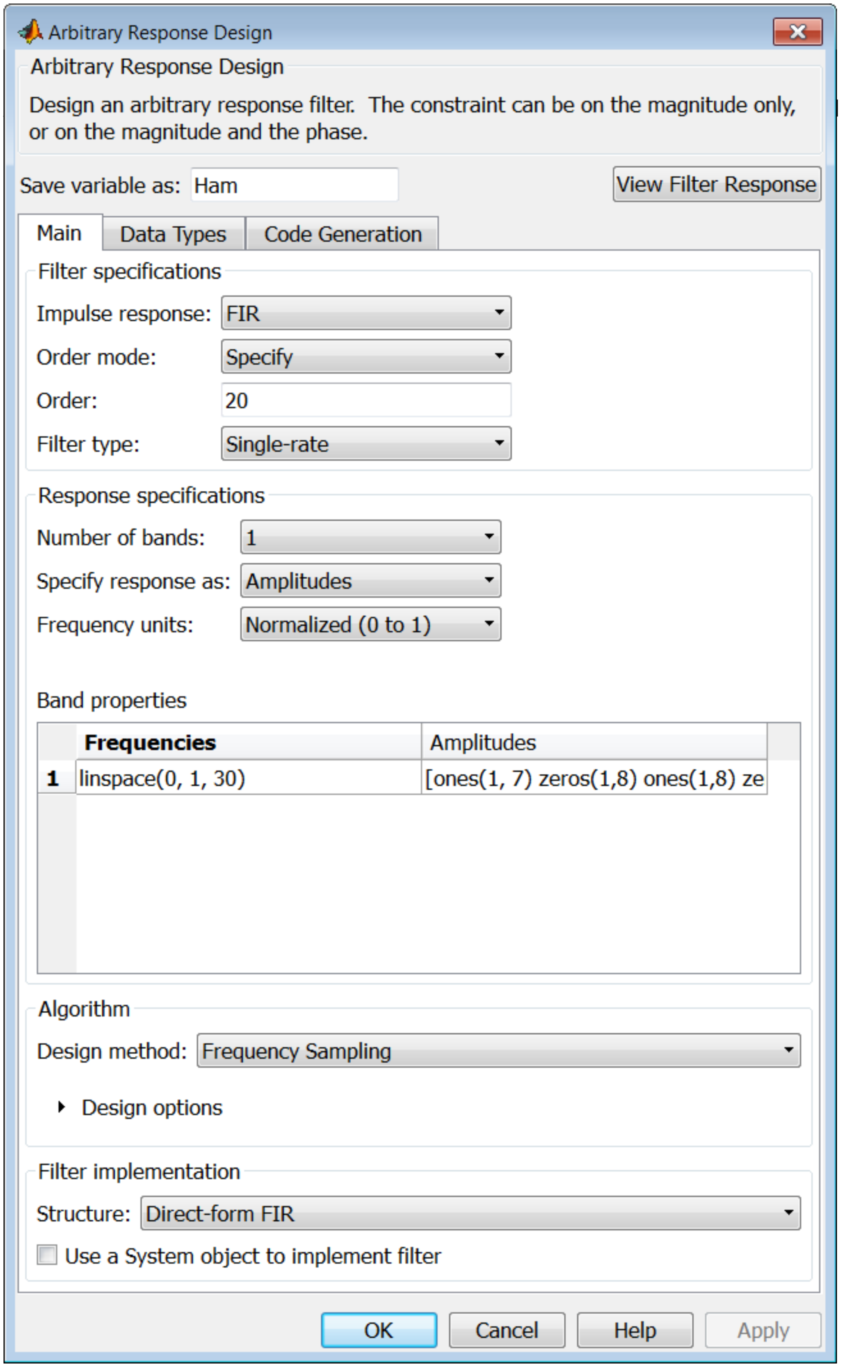
If you have the DSP System Toolbox software, the following **Response Selection** menu appears.



Select your desired filter response from the menu and design your filter.

The following sections describe the options available for each response type.

ne



Arbitrary Response Design

Arbitrary Response Design

Design an arbitrary response filter. The constraint can be on the magnitude only, or on the magnitude and the phase.

Save variable as: Ham

Filter specifications

Impulse response: FIR

Order mode: Specify

Order: 20

Filter type: Single-rate

Response specifications

Number of bands: 1

Specify response as: Amplitudes

Frequency units: Normalized (0 to 1)

Band properties

	Frequencies	Amplitudes
1	linspace(0, 1, 30)	[ones(1, 7) zeros(1,8) ones(1,8) ze

Algorithm

Design method: Frequency Sampling

Filter implementation

Structure: Direct-form FIR

□ Use a System object to implement filter

Filter specifications

Parameters in this group enable you to specify your filter format, such as the impulse response and the filter order.

Impulse response

This dialog only applies if you have the DSP System Toolbox software. Select either `FIR` or `IIR` from the drop down list, where `FIR` is the default impulse response. When you choose an impulse response, the design methods and structures you can use to implement your filter change accordingly. Arbitrary group delay designs are only available if **Impulse response** is `IIR`. Without the DSP System Toolbox, the only available arbitrary response filter design is FIR.

Order mode

This dialog only applies if you have the DSP System Toolbox software. Choose `Minimum` or `Specify`. Choosing `Specify` enables the **Order** dialog.

Order

This dialog only applies when **Order mode** is `Specify`. For an FIR design, specify the filter order. For an IIR design, you can specify an equal order for the numerator and denominator, or you can specify different numerator and denominator orders. The default is equal orders. To specify a different denominator order, check the **Denominator order** box. Because the Signal Processing Toolbox only supports FIR arbitrary-magnitude filters, you do not have the option to specify a denominator order.

Denominator order

Select the check box and enter the denominator order. This option is enabled only if `IIR` is selected for **Impulse response**.

Filter type

This dialog only applies if you have the DSP System Toolbox software and is only available for FIR filters. Select `Single-rate`, `Decimator`, `Interpolator`, or `Sample-rate converter`. Your choice determines the type of filter as well as the design methods and structures that are available to implement your filter. By default, `filterbuilder` specifies single-rate filters.

- Selecting `Decimator` or `Interpolator` activates the **Decimation Factor** or the **Interpolation Factor** options respectively.
- Selecting `Sample-rate converter` activates both factors.

When you design either a decimator or interpolator, the resulting filter is a bandpass filter that either decimates or interpolates your input signal.

Decimation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to `Decimator` or `Sample-rate converter`. The default factor value is 2 for `Decimator` and 3 for `Sample-rate converter`.

Interpolation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to `Interpolator` or `Sample-rate converter`. The default factor value is 2.

Response Specification

Number of Bands

Select the number of bands in the filter. Multiband design is available for both FIR and IIR filters.

Specify response as:

Specify the response as `Amplitudes`, `Magnitudes and phase`, `Frequency response`, or `Group delay`. `Amplitudes` is the only option if you do not have the DSP System Toolbox software. `Group delay` is only available for IIR designs.

Frequency units

Specify frequency units as either `Normalized`, `Hz`, `kHz`, `MHz`, or `GHz`.

Input Fs

Enter the input sampling frequency in the units specified in the **Frequency units** drop-down box. This option is enabled when **Frequency units** is set to an option in hertz.

Band Properties

These properties are modified automatically depending on the response chosen in the **Specify response as** drop-down box. Two or three columns are presented for input. The first column is always Frequencies. The other columns are either Amplitudes, Magnitudes, Phases, or Frequency Response. Enter the corresponding vectors of values for each column.

- **Frequencies** and **Amplitudes** — These columns are presented for input if you select `Amplitudes` in the **Specify response as** drop-down box.
- **Frequencies**, **Magnitudes**, and **Phases** — These columns are presented for input if the response chosen in the **Specify response as** drop-down box is `Magnitudes and phases`.
- **Frequencies** and **Frequency response** — These columns are presented for input if the response chosen in the **Specify response as** drop-down box is `Frequency response`.

Algorithm

The options for each design are specific for each design method. In the arbitrary response design, the available options also depend on the **Response specifications**. This section does not present all of the available options for all designs and design methods.

Design Method

Select the design method for the filter. Different methods are enabled depending on the defining parameters entered in the previous sections.

Design Options

- **Window** — Valid when the **Design method** is `Frequency Sampling`. Replace the square brackets with the name of a `window` function or function handle. For example, `'hamming'` or `@hamming`. If the window function takes parameters other than the length, use a cell array. For example, `{‘kaiser’,3.5}` or `{@chebwin,60}`.
- **Density factor** — Valid when the **Design method** is `equiripple`. Density factor controls the density of the frequency grid over which the design method optimization evaluates your filter response function. The number of equally spaced points in the grid is the value you enter for **Density factor** times (filter order + 1).

  Increasing the value creates a filter that more closely approximates an ideal equiripple filter but increases the time required to design the filter. The default value of 16 represents a reasonable trade between the accurate approximation to the ideal filter and the time to design the filter.

  The default changes to 20 for an IIR arbitrary group delay design.

- **Phase constraint** — Valid when the **Design method** is `equiripple`, you have the DSP System Toolbox installed, and **Specify response as** is set to `Amplitudes`. Choose one of `Linear`, `Minimum`, or `Maximum`.
- **Weights** — Uses the weights in **Weights** to weight the error for a single-band design. If you have multiple frequency bands, the **Weights** design option changes to **B1 Weights**, **B2 Weights** to designate the separate bands. Use **Bi Weights** to specify weights for the i-th band. The **Bi Weights** design option is only available when you specify the i-th band as an unconstrained.
- **Bi forced frequency point** — This option is only available in a multi-band constrained equiripple design when **Specify response as** is `Amplitudes`. **Bi forced frequency point** is the frequency point in the i-th band at which the response is forced to be zero. The index **i** corresponds to the frequency bands in **Band properties**. For example, if you specify two bands in **Band properties**, you have **B1 forced frequency point** and **B2 forced frequency point**.
- **Norm** — Valid only for IIR arbitrary group delay designs. **Norm** is the norm used in the optimization. The default value is 128, which essentially equals the L-infinity norm. The norm must be even.
- **Max pole radius** — Valid only for IIR arbitrary group delay designs. Constrains the maximum pole radius. The default is 0.999999. Reducing the **Max pole radius** can produce a transfer function more resistant to quantization.
- **Init norm** — Valid only for IIR arbitrary group delay designs. The initial norm used in the optimization. The default initial norm is 2.
- **Init numerator** — Specifies an initial estimate of the filter numerator coefficients.
- **Init denominator** — Specifies an initial estimate of the filter denominator coefficients. This may be useful in difficult optimization problems. In allpass filters, you only have to specify either the denominator or numerator coefficients. If you specify the denominator coefficients, you can obtain the numerator coefficients.

Filter implementation

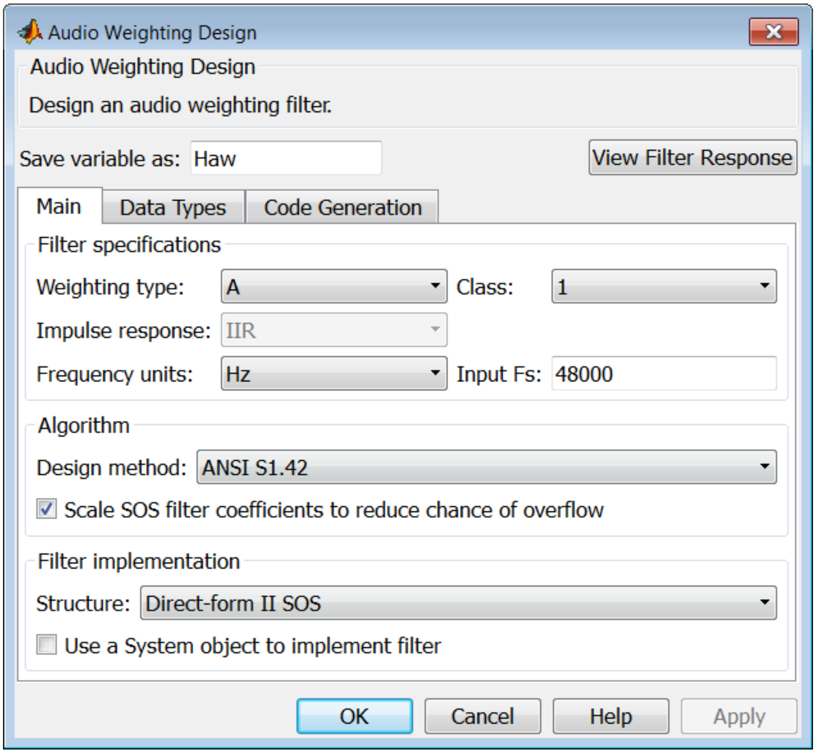
Structure

Select the structure for the filter. The available filter structures depend on the parameters you select for your filter.

Use a System object to implement filter

Selecting this check box gives you the choice of using a system object to implement the filter. By default the check box is turned off. When the current design method or structure is not supported by a system object filter, then this check box is disabled.

Audio Weighting Filter Design Dialog Box — Main Pane



Audio Weighting Design

Audio Weighting Design

Design an audio weighting filter.

Save variable as: Haw

Filter specifications

Weighting type: A

Class: 1

Impulse response: IIR

Frequency units: Hz

Input Fs: 48000

Algorithm

Design method: ANSI S1.42

☑ Scale SOS filter coefficients to reduce chance of overflow

Filter implementation

Structure: Direct-form II SOS

□ Use a System object to implement filter

Filter specifications

- **Weighting type** — The weighting type defines the frequency response of the filter. The valid weighting types are: A, C , C-message, ITU-T 0.41, and ITU-R 468–4 weighting. See `fdesign.audioweighting` for definitions of the weighting types.
- **Class** — Filter class is only applicable for A weighting and C weighting filters. The filter class describes the frequency-dependent tolerances specified in the relevant

standards. There are two possible class values: 1 and 2. Class 1 weighting filters have stricter tolerances than class 2 filters. The filter class value does not affect the design. The class value is only used to provide a specification mask in `fvtool` for the analysis of the filter design.

- **Impulse response** — Impulse response type as one of `IIR` or `FIR`. For A, C , C-message, and ITU-R 468–4 filter, IIR is the only option. For a ITU-T 0.41 weighting filter, FIR is the only option.
- **Frequency units** — Choose `Hz`, `kHz`, `MHz`, or `GHz`. Normalized frequency designs are not supported for audio weighting filters.
- **Input Fs** — The sampling frequency in **Frequency units**. For example, if **Frequency units** is set to `kHz`, setting **Input Fs** to 40 is equivalent to a 40 kHz sampling frequency.

Algorithm

- **Design method** — Valid design methods depend on the weighting type. For type A and C weighting filters, the only valid design type is `ANSI S1.42`. This is an IIR design method that follows ANSI standard S1.42–2001. For a C message filter, the only valid design method is `Bell 41009`, which is an IIR design method following the Bell System Technical Reference PUB 41009. For a ITU-R 468–4 weighting filter, you can design an IIR or FIR filter. If you choose an IIR design, the design method is `IIR least p-norm`. If you choose an FIR design, the design method choices are: `Equirriple` or `Frequency Sampling`. For an ITU-T 0.41 weighting filter, the available FIR design methods are `equirriple` or `Frequency Sampling`
- **Scale SOS filter coefficients to reduce chance of overflow** — Selecting this parameter directs the design to scale the filter coefficients to reduce the chances that the inputs or calculations in the filter overflow and exceed the representable range of the filter. Clearing this option removes the scaling. This parameter applies only to IIR filters.

Filter implementation

- **Structure** — For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. For audio weighting IIR filter designs, you can choose direct form I or II biquad (SOS). You can also choose to implement these structures in transposed form.

For FIR designs, you can choose direct form, direct-form transposed, direct-form symmetric, direct-form asymmetric structures, or an overlap and add structure.

- **Use a System object to implement filter** — Selecting this check box gives you the choice of using a system object to implement the filter. By default the check box is turned off. When the current design method or structure is not supported by a system object filter, then this check box is disabled.

☑ Uniform grid

Filter implementation

Structure: Direct-form FIR

☐ Use a System object to implement filter

Filter specifications

Parameters in this group enable you to specify your filter format, such as the impulse response and the filter order.

Impulse response

Select `FIR` or `IIR` from the drop-down list, where `FIR` is the default impulse response. When you choose an impulse response, the design methods and structures you can use to implement your filter change accordingly.

Note: The design methods and structures for FIR filters are not the same as the methods and structures for IIR filters.

Order mode

Select `Minimum` (the default) or `Specify` from the drop-down box. Selecting `Specify` enables the **Order** option so you can enter the filter order.

If you have the DSP System Toolbox software installed, you can specify IIR filters with different numerator and denominator orders. The default is equal orders. To specify a different denominator order, check the **Denominator order** box.

Filter type — This dialog only applies if you have the DSP System Toolbox software.

Select `Single-rate`, `Decimator`, `Interpolator`, or `Sample-rate converter`. Your choice determines the type of filter as well as the design methods and structures that are available to implement your filter. By default, `filterbuilder` specifies single-rate filters.

- Selecting `Decimator` or `Interpolator` activates the **Decimation Factor** or the **Interpolation Factor** options respectively.
- Selecting `Sample-rate converter` activates both factors.

Order

Enter the filter order. This option is enabled only if you select `Specify` for **Order mode**.

Decimation Factor

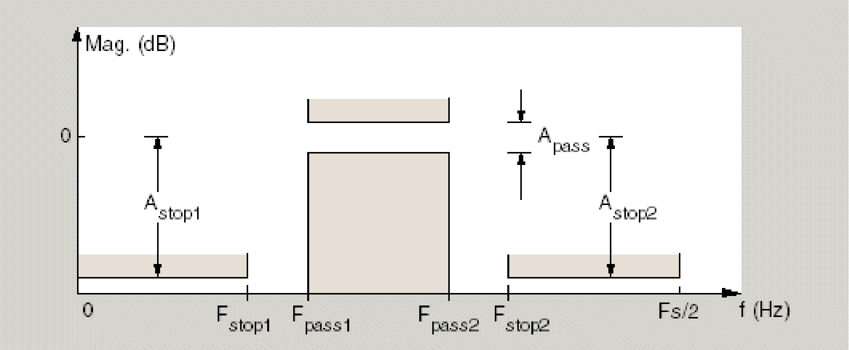
Enter the decimation factor. This option is enabled only if the **Filter type** is set to `Decimator` or `Sample-rate converter`. The default factor value is 2.

Interpolation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to `Interpolator` or `Sample-rate converter`. The default factor value is 2.

Frequency specifications

The parameters in this group allow you to specify your filter response curve. Graphically, the filter specifications look similar to those shown in the following figure.



In the figure, regions between specification values such as Fstop1 and Fpass1 represent transition regions where the filter response is not explicitly defined.

Frequency constraints

Select the filter features to use to define the frequency response characteristics. This dialog applies only when **Order mode** is **Specify**.

- `Passband and stopband edges` — Define the filter by specifying the frequencies for the edges for the stop- and passbands.
- `Passband edges` — Define the filter by specifying frequencies for the edges of the passband.
- `Stopband edges` — Define the filter by specifying frequencies for the edges of the stopbands.
- `3dB points` — Define the filter response by specifying the locations of the 3 dB points (IIR filters). The 3-dB point is the frequency for the point 3 dB below the passband value.

- `3dB points and passband width` — Define the filter by specifying frequencies for the 3-dB points in the filter response and the width of the passband. (IIR filters)
- `3dB points and stopband widths` — Define the filter by specifying frequencies for the 3-dB points in the filter response and the width of the stopband. (IIR filters)
- `6dB points` — Define the filter response by specifying the locations of the 6-dB points. The 6-dB point is the frequency for the point 6dB below the passband value. (FIR filters)

Frequency units

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select `Normalized (0—1)` to enter frequencies in normalized form. This behavior is the default. To enter frequencies in hertz, select one of the frequency units from the drop-down list—`Hz`, `kHz`, `MHz`, or `GHz`. Selecting one of the unit options enables the **Input Fs** parameter.

Input Fs

Fs, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available when you select one of the frequency options from the **Frequency units** list.

Fstop1

Enter the frequency at the edge of the end of the first stopband. Specify the value in either normalized frequency units or the absolute units you select in **Frequency units**.

Fpass1

Enter the frequency at the edge of the start of the passband. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

Fpass2

Enter the frequency at the edge of the end of the passband. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

Fstop2

Enter the frequency at the edge of the start of the second stopband. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

Magnitude specifications

The parameters in this group let you specify the filter response in the passbands and stopbands.

Magnitude constraints

Specify as `Unconstrained` or `Constrained bands`. You must have the DSP System Toolbox software to select `Constrained bands`. Selecting `Constrained bands` enables dialogs for both stopbands and the passband: **Astop1**, **Astop2**, and **Apass**. You cannot specify constraints for all three bands simultaneously.

Setting **Magnitude constraints** to `Constrained bands` enables the **Wstop** and **Wpass** options under **Design options**.

Magnitude units

Specify the units for any parameter you provide in magnitude specifications. Select one of the following options from the drop-down list.

- `Linear` — Specify the magnitude in linear units.
- `dB` — Specify the magnitude in dB (decibels). This is the default setting.
- `Squared` — Specify the magnitude in squared units.

Astop1

Enter the filter attenuation in the first stopband in the units you choose for **Magnitude units**, either linear or decibels.

Apass

Enter the filter ripple allowed in the passband in the units you choose for **Magnitude units**, either linear or decibels.

Astop2

Enter the filter attenuation in the second stopband in the units you choose for **Magnitude units**, either linear or decibels.

Algorithm

The parameters in this group allow you to specify the design method and structure that `filterbuilder` uses to implement your filter.

Design Method

Lists the design methods available for the frequency and magnitude specifications you entered. When you change the specifications for a filter, such as changing the impulse response, the methods available to design filters changes as well. The default IIR design method is usually Butterworth, and the default FIR method is equiripple.

Scale SOS filter coefficients to reduce chance of overflow

Selecting this parameter directs the design to scale the filter coefficients to reduce the chances that the inputs or calculations in the filter overflow and exceed the representable range of the filter. Clearing this option removes the scaling. This parameter applies only to IIR filters.

Design Options

The options for each design are specific for each design method. This section does not present all of the available options for all designs and design methods. There are many more that you encounter as you select different design methods and filter specifications. The following options represent some of the most common ones available.

Density factor

Density factor controls the density of the frequency grid over which the design method optimization evaluates your filter response function. The number of equally spaced points in the grid is the value you enter for **Density factor** times (filter order + 1).

Increasing the value creates a filter that more closely approximates an ideal equiripple filter but increases the time required to design the filter. The default value of 16 represents a reasonable trade between the accurate approximation to the ideal filter and the time to design the filter.

Phase constraint

Valid when the **Design method** is `equiripple` and you have the DSP System Toolbox installed. Choose one of `Linear`, `Minimum`, or `Maximum`.

Minimum order

This option only applies when you have the DSP System Toolbox software and **Order mode** is `Minimum`.

Select `Any` (default), `Even`, or `Odd`. Selecting `Even` or `Odd` forces the minimum-order design to be an even or odd order.

Wstop1

Weight for the first stopband.

Wpass

Passband weight.

Wstop2

Weight for the second stopband.

Max pole radius

Valid only for IIR designs. Constrains the maximum pole radius. The default is 1. Reducing the max pole radius can produce a transfer function more resistant to quantization.

Init norm

Valid only for IIR designs. The initial norm used in the optimization. The default initial norm is 2.

Init numerator

Specifies an initial estimate of the filter numerator coefficients. This may be useful in difficult optimization problems.

Init denominator

Specifies an initial estimate of the filter denominator coefficients. This may be useful in difficult optimization problems.

Filter implementation

Structure

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. By default, FIR filters use direct-form structure, and IIR filters use direct-form II filters with SOS.

Use a System object to implement filter

Selecting this check box gives you the choice of using a system object to implement the filter. By default the check box is turned off. When the current design method or structure is not supported by a system object filter, then this check box is disabled.

Parameters in this group enable you to specify your filter format, such as the impulse response and the filter order.

Impulse response

Select `FIR` or `IIR` from the drop-down list, where `FIR` is the default impulse response. When you choose an impulse response, the design methods and structures you can use to implement your filter change accordingly.

Note: The design methods and structures for FIR filters are not the same as the methods and structures for IIR filters.

Order mode

Select `Minimum` (the default) or `Specify` from the drop-down list. Selecting `Specify` enables the **Order** option so you can enter the filter order.

If you have the DSP System Toolbox software installed, you can specify IIR filters with different numerator and denominator orders. The default is equal orders. To specify a different denominator order, check the **Denominator order** box.

Filter type

Select `Single-rate`, `Decimator`, `Interpolator`, or `Sample-rate converter`. Your choice determines the type of filter as well as the design methods and structures that are available to implement your filter. By default, `filterbuilder` specifies single-rate filters.

- Selecting `Decimator` or `Interpolator` activates the **Decimation Factor** or the **Interpolation Factor** options respectively.
- Selecting `Sample-rate converter` activates both factors.

When you design either a decimator or an interpolator, the resulting filter is a bandpass filter that either decimates or interpolates your input signal.

Order

Enter the filter order. This option is enabled only if `Specify` was selected for **Order mode**.

Decimation Factor

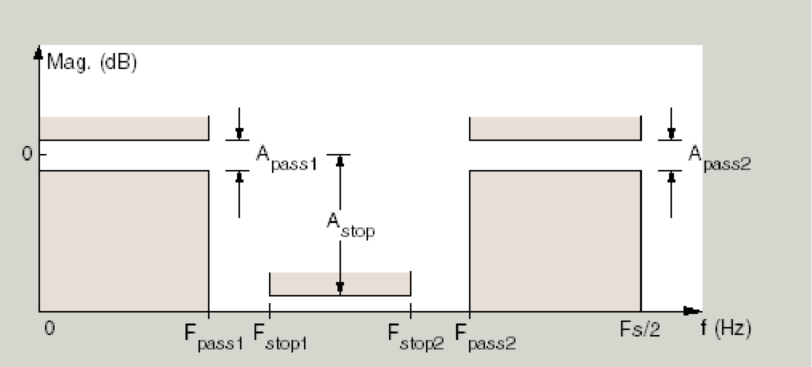
Enter the decimation factor. This option is enabled only if the **Filter type** is set to `Decimator` or `Sample-rate converter`. The default factor value is 2.

Interpolation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to `Interpolator` or `Sample-rate converter`. The default factor value is 2.

Frequency specifications

The parameters in this group allow you to specify your filter response curve. Graphically, the filter specifications look similar to those shown in the following figure.



Frequency constraints

Select the filter features to use to define the frequency response characteristics. This dialog applies only when **Order mode** is **Specify**.

- `Passband and stopband edges` — Define the filter by specifying the frequencies for the edges for the stop- and passbands.
- `Passband edges` — Define the filter by specifying frequencies for the edges of the passband.
- `Stopband edges` — Define the filter by specifying frequencies for the edges of the stopbands.
- `3dB points` — Define the filter response by specifying the locations of the 3 dB points (IIR filters). The 3 dB point is the frequency for the point 3 dB point below the passband value.

- `3dB points and passband width` — Define the filter by specifying frequencies for the 3 dB points in the filter response and the width of the passband (IIR filters).
- `3dB points and stopband widths` — Define the filter by specifying frequencies for the 3 dB points in the filter response and the width of the stopband (IIR filters).
- `6dB points` — Define the filter response by specifying the locations of the 6-dB points (FIR filters). The 6-dB point is the frequency for the point 6 dB point below the passband value.

Frequency units

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select `Normalized (0—1)` to enter frequencies in normalized form. This behavior is the default. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—`Hz`, `kHz`, `MHz`, or `GHz`. Selecting one of the unit options enables the **Input Fs** parameter.

Input Fs

Fs, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available when you select one of the frequency options from the **Frequency units** list.

Output Fs

When you design an interpolator, Fs represents the sampling frequency at the filter output rather than the filter input. This option is available only when you set **Filter type** is `interpolator`.

Fpass1

Enter the frequency at the edge of the end of the first passband. Specify the value in either normalized frequency units or the absolute units you select in **Frequency units**.

Fstop1

Enter the frequency at the edge of the start of the stopband. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

Fstop2

Enter the frequency at the edge of the end of the stopband. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

Fpass2

Enter the frequency at the edge of the start of the second passband. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

Magnitude specifications

The parameters in this group let you specify the filter response in the passbands and stopbands.

Magnitude constraints

Specify as `Unconstrained` or `Constrained bands`. You must have the DSP System Toolbox software to select `Constrained bands`. Selecting `Constrained bands` enables dialogs for both passbands and the stopband: **Apass1**, **Apass2**, and **Astop**. You cannot specify constraints for all three bands simultaneously.

Setting **Magnitude constraints** to `Constrained bands` enables the **Wstop** and **Wpass** options under **Design options**.

Magnitude units

Specify the units for any parameter you provide in magnitude specifications. Select one of the following options from the drop-down list.

- `Linear` — Specify the magnitude in linear units.
- `dB` — Specify the magnitude in decibels (default).
- `Squared` — Specify the magnitude in squared units.

Apass1

Enter the filter ripple allowed in the first passband in the units you choose for **Magnitude units**, either linear or decibels.

Astop

Enter the filter attenuation in the stopband in the units you choose for **Magnitude units**, either linear or decibels

Apass2

Enter the filter ripple allowed in the second passband in the units you choose for **Magnitude units**, either linear or decibels

Algorithm

The parameters in this group allow you to specify the design method and structure that `filterbuilder` uses to implement your filter.

Design Method

Lists the design methods available for the frequency and magnitude specifications you entered. When you change the specifications for a filter, such as changing the impulse response, the methods available to design filters changes as well. The default IIR design method is usually Butterworth, and the default FIR method is equiripple.

Scale SOS filter coefficients to reduce chance of overflow

Selecting this parameter directs the design to scale the filter coefficients to reduce the chances that the inputs or calculations in the filter overflow and exceed the representable range of the filter. Clearing this option removes the scaling. This parameter applies only to IIR filters.

Design Options

The options for each design are specific for each design method. This section does not present all of the available options for all designs and design methods. There are many more that you encounter as you select different design methods and filter specifications. The following options represent some of the most common ones available.

Density factor

Density factor controls the density of the frequency grid over which the design method optimization evaluates your filter response function. The number of equally spaced points in the grid is the value you enter for **Density factor** times (filter order + 1).

Increasing the value creates a filter that more closely approximates an ideal equiripple filter but increases the time required to design the filter. The default value of 16 represents a reasonable trade between the accurate approximation to the ideal filter and the time to design the filter.

Phase constraint

Valid when the **Design method** is `equiripple` and you have the DSP System Toolbox installed. Choose one of `Linear`, `Minimum`, or `Maximum`.

Minimum order

This option only applies when you have the DSP System Toolbox software and **Order mode** is `Minimum`.

Select `Any` (default), `Even`, or `Odd`. Selecting `Even` or `Odd` forces the minimum-order design to be an even or odd order.

Wpass1

Weight for the first passband.

Wstop

Stopband weight.

Wpass2

Weight for the second passband.

Match exactly

Specifies that the resulting filter design matches either the passband or stopband or both bands when you select `passband` or `stopband` .

Max pole radius

Valid only for IIR designs. Constrains the maximum pole radius. The default is 1. Reducing the max pole radius can produce a transfer function more resistant to quantization.

Init norm

Valid only for IIR designs. The initial norm used in the optimization. The default initial norm is 2.

Init numerator

Specifies an initial estimate of the filter numerator coefficients. This may be useful in difficult optimization problems.

Init denominator

Specifies an initial estimate of the filter denominator coefficients. This may be useful in difficult optimization problems.

Filter implementation

Structure

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. By default, FIR filters use direct-form structure, and IIR filters use direct-form II filters with SOS.

Use a System object to implement filter

Selecting this check box gives you the choice of using a system object to implement the filter. By default the check box is turned off. When the current design method or structure is not supported by a system object filter, then this check box is disabled.

Filter implementation

□ Use a System object to implement filter

Filter specifications

Parameters in this group enable you to specify your CIC filter format, such as the filter type and the differential delay.

Filter type

Select whether your filter will be a `decimator` or an `interpolator`. Your choice determines the type of filter and the design methods and structures that are available to implement your filter. Selecting `decimator` or `interpolator` activates the **Factor** option. When you design an interpolator, you enable the **Output Fs** parameter.

When you design either a decimator or interpolator, the resulting filter is a CIC filter that decimates or interpolates your input signal.

Differential Delay

Specify the differential delay of your CIC filter as an integer value greater than or equal to 1. The default value is 1. The differential delay changes the shape, number, and location of nulls in the filter response. Increasing the differential delay increases the sharpness of the nulls and the response between the nulls. In practice, differential delay values of 1 or 2 are the most common.

Factor

Specify the decimation or interpolation factor for your filter as an integer value greater than or equal to 1. The default value is 2.

Frequency specifications

Frequency units

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select `Normalized (0—1)` to enter frequencies in normalized form. This behavior is the default. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—`Hz`, `kHz`, `MHz`, or `GHz`. Selecting one of the unit options enables the **Input Fs** parameter.

Input Fs

Fs, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available when you select one of the frequency options from the **Frequency units** list.

Output Fs

Fs, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter output. When you provide an output sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available only when you design interpolators.

Fpass

Enter the frequency at the end of the passband. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

Magnitude specifications

Magnitude units

Specify the units for any parameter you provide in magnitude specifications. Select one of the following options from the drop-down list.

- `Linear` — Specify the magnitude in linear units.
- `dB` — Specify the magnitude in decibels (default).
- `Squared` — Specify the magnitude in squared units.

Astop

Enter the filter attenuation in the stopband in the units you choose for **Magnitude units**, either linear or decibels.

Filter implementation

Use a System object to implement filter

Selecting this check box gives you the choice of using a system object to implement the filter. By default the check box is turned off. When the current design method or structure is not supported by a system object filter, then this check box is disabled.

□ Use a System object to implement filter

Filter specifications

Parameters in this group enable you to specify your filter format, such as the filter order mode and the filter type.

Order mode

Select `Minimum` (the default) or `Specify` from the drop-down list. Selecting `Specify` enables the **Order** option (see the following sections) so you can enter the filter order.

Filter type

Select `Single-rate`, `Decimator`, `Interpolator`, or `Sample-rate converter`. Your choice determines the type of filter as well as the design methods and structures that are available to implement your filter. By default, `filterbuilder` specifies single-rate filters.

- Selecting `Decimator` or `Interpolator` activates the **Decimation Factor** or the **Interpolation Factor** options respectively.
- Selecting `Sample-rate converter` activates both factors.

When you design either a decimator or an interpolator, the resulting filter is a bandpass filter that either decimates or interpolates your input signal.

Order

Enter the filter order. This option is enabled only if `Specify` was selected for **Order mode**.

Decimation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to `Decimator` or `Sample-rate converter`. The default factor value is 2.

Interpolation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to `Interpolator` or `Sample-rate converter`. The default factor value is 2.

Number of CIC sections

Specify the number of sections in the CIC filter for which you are designing this compensator. Select the number of sections from the drop-down list or enter the number.

Differential Delay

Specify the differential delay of your target CIC filter. The default value is `1`. Most CIC filters use 1 or 2.

Frequency specifications

The parameters in this group allow you to specify your filter response curve.

Frequency specifications

Frequency units

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select `Normalized (0—1)` to enter frequencies in normalized form. This behavior is the default. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—`Hz`, `kHz`, `MHz`, or `GHz`. Selecting one of the unit options enables the **Input Fs** parameter.

Input Fs

Fs, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available when you select one of the frequency options from the **Frequency units** list.

Output Fs

Fs, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter output. When you provide an output sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available only when you design interpolators.

Fpass

Enter the frequency at the end of the passband. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

Fstop

Enter the frequency at the start of the stopband. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

Magnitude specifications

The parameters in this group let you specify the filter response in the passbands and stopbands.

Magnitude units

Specify the units for any parameter you provide in magnitude specifications. Select one of the following options from the drop-down list.

- `Linear` — Specify the magnitude in linear units.
- `dB` — Specify the magnitude in decibels (default).
- `Squared` — Specify the magnitude in squared units.

Apass

Enter the filter ripple allowed in the passband in the units you choose for **Magnitude units**, either linear or decibels

Algorithm

The parameters in this group allow you to specify the design method and structure that `filterbuilder` uses to implement your filter.

Design Method

Lists the design methods available for the frequency and magnitude specifications you entered. When you change the specifications for a filter, such as changing the impulse response, the methods available to design filters changes as well. The default IIR design method is usually Butterworth, and the default FIR method is equiripple.

Design Options

The options for each design are specific for each design method. This section does not present all of the available options for all designs and design methods. There are many more that you encounter as you select different design methods and filter specifications. The following options represent some of the most common ones available.

Density factor

Density factor controls the density of the frequency grid over which the design method optimization evaluates your filter response function. The number of equally spaced points in the grid is the value you enter for **Density factor** times (filter order + 1).

Increasing the value creates a filter that more closely approximates an ideal equiripple filter but increases the time required to design the filter. The default value of 16 represents a reasonable trade between the accurate approximation to the ideal filter and the time to design the filter.

Minimum phase

To design a filter that is minimum phase, select **Minimum phase**. Clearing the **Minimum phase** option removes the phase constraint—the resulting design is not minimum phase.

Minimum order

When you select this parameter, the design method determines and design the minimum order filter to meet your specifications. Some filters do not provide this parameter. Select `Any`, `Even`, or `Odd` from the drop-down list to direct the design to be any minimum order, or minimum even order, or minimum odd order.

Note: Generally, **Minimum order** designs are not available for IIR filters.

Match exactly

Specifies that the resulting filter design matches either the passband or stopband or both bands when you select `passband` or `stopband` or `both` from the drop-down list.

Stopband Shape

Stopband shape lets you specify how the stopband changes with increasing frequency. Choose one of the following options:

- `Flat` — Specifies that the stopband is flat. The attenuation does not change as the frequency increases.
- `Linear` — Specifies that the stopband attenuation changes linearly as the frequency increases. Change the slope of the stopband by setting **Stopband decay**.
- `1/f` — Specifies that the stopband attenuation changes exponentially as the frequency increases, where `f` is the frequency. Set the power (exponent) for the decay in **Stopband decay**.

Stopband Decay

When you set Stopband shape, Stopband decay specifies the amount of decay applied to the stopband. the following conditions apply to Stopband decay based on the value of Stopband Shape:

- When you set **Stopband shape** to `Flat`, **Stopband decay** has no affect on the stopband.
- When you set **Stopband shape** to `Linear`, enter the slope of the stopband in units of dB/rad/s. `filterbuilder` applies that slope to the stopband.

- When you set **Stopband shape** to `1/f`, enter a value for the exponent *n* in the relation $(1/f)^n$ to define the stopband decay. `filterbuilder` applies the $(1/f)^n$ relation to the stopband to result in an exponentially decreasing stopband attenuation.

Filter implementation

Structure

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. By default, FIR filters use direct-form structure, and IIR filters use direct-form II filters with SOS.

Use a System object to implement filter

Selecting this check box gives you the choice of using a system object to implement the filter. By default the check box is turned off. When the current design method or structure is not supported by a system object filter, then this check box is disabled.

Magnitude specifications

No magnitude constraints can be specified when specifying a filter order.

Algorithm

Design method: Butterworth

Filter implementation

Structure: Direct-form II

□ Use a System object to implement filter

Filter specifications

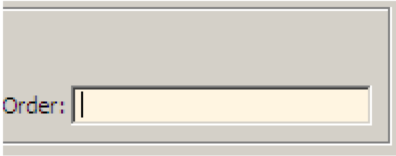
Parameters in this group enable you to specify the type of comb filter and the number of peaks or notches.

Comb Type

Select `Notch` or `Peak` from the drop-down list. `Notch` creates a comb filter that attenuates a set of harmonically related frequencies. `Peak` creates a comb filter that amplifies a set of harmonically related frequencies.

Order mode

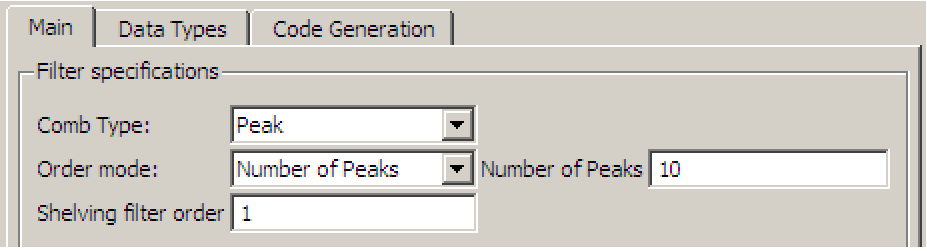
Select `Order` or `Number of Peaks/Notches` from the drop-down menu.



Order:

Select `Order` to enter the desired filter order in the dialog box. The comb filter has notches or peaks at increments of 2/`Order` in normalized frequency units.

Select `Number of Peaks` or `Number of Notches` to specify the number of peaks or notches and the `Shelving filter order`.



Filter specifications

Comb Type: Peak

Order mode: Number of Peaks

Number of Peaks 10

Shelving filter order 1

Shelving filter order

The `Shelving filter order` is a positive integer that determines the sharpness of the peaks or notches. Larger values result in sharper peaks or notches.

Frequency specifications

Parameters in this group enable you to specify the frequency constraints and frequency units.

Frequency specifications

Select `Quality factor` or `Bandwidth`.

`Quality factor` is the ratio of the center frequency of the peak or notch to the bandwidth calculated at the –3 dB point.

`Bandwidth` specifies the bandwidth of the peak or notch. By default the bandwidth is measured at the –3 dB point. For example, setting the bandwidth equal to 0.1 results in 3 dB frequencies at normalized frequencies 0.05 above and below the center frequency of the peak or notch.

Frequency Units

Specify the frequency units. The default is normalized frequency. Choosing an option in Hz enables the **Input Fs** dialog box.

Magnitude specifications

Specify the units for the magnitude specification and the gain at which the bandwidth is measured. This menu is disabled if you specify a filter order. Select one of the following magnitude units from the drop down list:

- `dB` — Specify the magnitude in decibels (default).
- `Squared` — Specify the magnitude in squared units.

Bandwidth gain — Specify the gain at which the bandwidth is measured. The default is –3 dB.

Algorithm

The parameters in this group allow you to specify the design method and structure that `filterbuilder` uses to implement your filter.

Design Method

The IIR Butterworth design is the only option for peaking or notching comb filters.

Filter implementation

Structure

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter.

Use a System object to implement filter

Selecting this check box gives you the choice of using a system object to implement the filter. By default the check box is turned off.

In the figure, regions between specification values such as **Fpass** (f_1) and **Fstop** (f_3) represent transition regions where the filter response is not explicitly defined.

Order mode

Select `Minimum` (the default) or `Specify` from the drop-down list. Selecting `Specify` enables the **Order** option (see the following sections) so you can enter the filter order.

Filter type

Select `Single-rate`, `Decimator`, `Interpolator`, or `Sample-rate converter`. Your choice determines the type of filter as well as the design methods and structures that are available to implement your filter. By default, `filterbuilder` specifies single-rate filters.

- Selecting `Decimator` or `Interpolator` activates the **Decimation Factor** or the **Interpolation Factor** options respectively.
- Selecting `Sample-rate converter` activates both factors.

When you design either a decimator or an interpolator, the resulting filter is a bandpass filter that either decimates or interpolates your input signal.

Order

Enter the filter order. This option is enabled only if `Specify` was selected for **Order mode**.

Decimation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to `Decimator` or `Sample-rate converter`. The default factor value is 2.

Interpolation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to `Interpolator` or `Sample-rate converter`. The default factor value is 2.

Frequency specifications

The parameters in this group allow you to specify your filter response curve.

Frequency constraints

This option is only available when you specify the order of the filter design. Supported options are `Unconstrained` and `Passband edge and stopband edge`.

Frequency units

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select `Normalized (0—1)` to enter frequencies in normalized form. This behavior is the default. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—`Hz`, `kHz`, `MHz`, or `GHz`. Selecting one of the unit options enables the **Input Fs** parameter.

Input Fs

Fs, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available when you select one of the frequency options from the **Frequency units** list.

Fpass

Enter the frequency at the end of the passband. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

Fstop

Enter the frequency at the start of the stopband. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

Magnitude specifications

The parameters in this group let you specify the filter response in the passbands and stopbands.

Magnitude constraints

This option is only available when you specify the order of your filter design. The options for **Magnitude constraints** depend on the value of the **Frequency constraints**. If the value of **Frequency constraints** is `Unconstrained`, **Magnitude constraints** must be `Unconstrained`. If the value of **Frequency constraints** is `Passband edge and stopband edge`, **Magnitude constraints** can be `Unconstrained`, `Passband ripple`, or `Stopband attenuation`.

Magnitude units

Specify the units for any parameter you provide in magnitude specifications. Select one of the following options from the drop-down list.

- `Linear` — Specify the magnitude in linear units.
- `dB` — Specify the magnitude in decibels (default).
- `Squared` — Specify the magnitude in squared units.

Apass

Enter the filter ripple allowed in the passband in the units you choose for **Magnitude units**, either linear or decibels.

Astop2

Enter the filter attenuation in the second stopband in the units you choose for **Magnitude units**, either linear or decibels.

Algorithm

The parameters in this group allow you to specify the design method and structure that `filterbuilder` uses to implement your filter.

Design Method

Lists the design methods available for the frequency and magnitude specifications you entered. When you change the specifications for a filter, such as changing the impulse response, the methods available to design filters changes as well. The default IIR design method is usually Butterworth, and the default FIR method is equiripple.

Scale SOS filter coefficients to reduce chance of overflow

Selecting this parameter directs the design to scale the filter coefficients to reduce the chances that the inputs or calculations in the filter overflow and exceed the representable range of the filter. Clearing this option removes the scaling. This parameter applies only to IIR filters.

Design Options

The options for each design are specific for each design method. This section does not present all of the available options for all designs and design methods. There are many more that you encounter as you select different design methods and filter specifications.

Density factor

Density factor controls the density of the frequency grid over which the design method optimization evaluates your filter response function. The number of equally spaced points in the grid is the value you enter for **Density factor** times (filter order + 1).

Increasing the value creates a filter that more closely approximates an ideal equiripple filter but increases the time required to design the filter. The default value of 16 represents a reasonable trade between the accurate approximation to the ideal filter and the time to design the filter.

Wpass

Passband weight. This option is only available for a specified-order design when **Frequency constraints** is equal to `Passband edge and stopband edge` and the **Design method** is `Equiripple`.

Wstop

Stopband weight. This option is only available for a specified-order design when **Frequency constraints** is equal to `Passband edge and stopband edge` and the **Design method** is `Equiripple`.

Filter implementation

Structure

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. By default, FIR filters use direct-form structure, and IIR filters use direct-form II filters with SOS.

Use a System object to implement filter

Selecting this check box gives you the choice of using a system object to implement the filter. By default the check box is turned off. When the current design method or structure is not supported by a system object filter, then this check box is disabled.

Filter specifications

Parameters in this group enable you to specify your filter type and order.

Impulse response

Select `FIR` or `IIR` from the drop-down list, where `FIR` is the default impulse response. When you choose an impulse response, the design methods and structures you can use to implement your filter change accordingly.

Note: The design methods and structures for FIR filters are not the same as the methods and structures for IIR filters.

Order mode

Select `Minimum` (the default) or `Specify` from the drop-down list. Selecting `Specify` enables the **Order** option (see the following sections) so you can enter the filter order.

Filter type

Select `Single-rate`, `Decimator`, or `Interpolator`. By default, `filterbuilder` specifies single-rate filters.

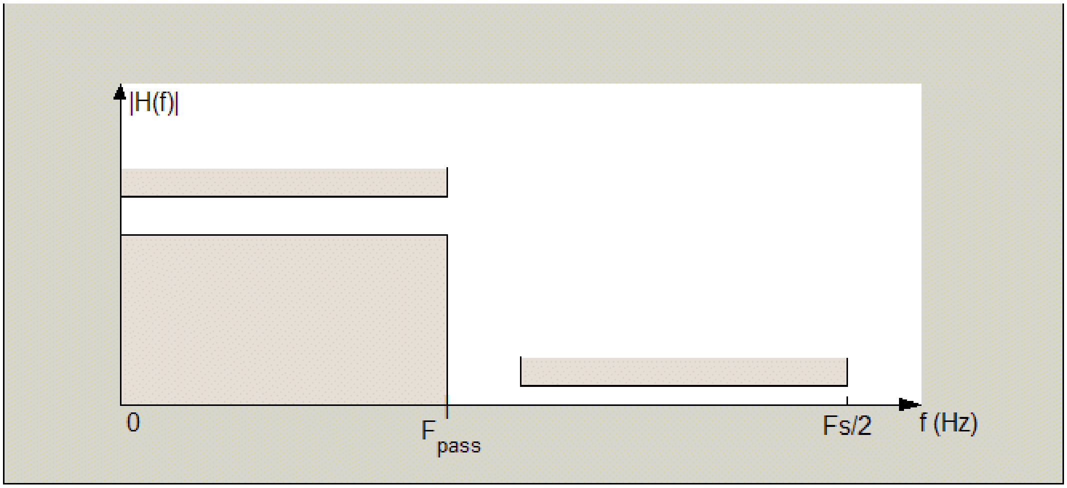
When you design either a decimator or an interpolator, the resulting filter is a bandpass filter that decimates or interpolates your input by a factor of two.

Order

Enter the filter order. This option is enabled only if `Specify` was selected for **Order mode**.

Frequency specifications

The parameters in this group allow you to specify your filter response curve. Graphically, the filter specifications for a halfband lowpass filter look similar to those shown in the following figure.



In the figure, the transition region lies between the end of the passband and the start of the stopband. The width is defined explicitly by the value of **Transition width**.

Frequency units

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select `Normalized (0–1)` to enter frequencies in normalized form. This behavior is the default. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—`Hz`, `kHz`, `MHz`, or `GHz`. Selecting one of the unit options enables the **Input Fs** parameter.

Input Fs

Fs, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available when you select one of the frequency options from the **Frequency units** list.

Transition width

Specify the width of the transition between the end of the passband and the edge of the stopband. Specify the value in normalized frequency units or the absolute units you select in **Frequency units**.

Magnitude specifications

The parameters in this group let you specify the filter response in the passbands and stopbands.

Magnitude units

Specify the units for any parameter you provide in magnitude specifications. Select one of the following options from the drop-down list.

- `Linear` — Specify the magnitude in linear units.
- `dB` — Specify the magnitude in decibels (default).

Astop

Enter the filter attenuation in the stopband in the units you choose for **Magnitude units**, either linear or decibels.

Algorithm

The parameters in this group allow you to specify the design method and structure that `filterbuilder` uses to implement your filter.

Design Method

Lists the design methods available for the frequency and magnitude specifications you entered. For FIR halfband filters, the available design options are `Equiripple` and `Kaiser window`. For IIR halfband filters, the available design options are `Butterworth`, `Elliptic`, and `IIR quasi-linear phase`.

Design Options

The following design options are available for FIR halfband filters when the user specifies an equiripple design:

Minimum phase

To design a filter that is minimum phase, select **Minimum phase**. Clearing the **Minimum phase** option removes the phase constraint—the resulting design is not minimum phase.

Stopband Shape

Stopband shape lets you specify how the stopband changes with increasing frequency. Choose one of the following options:

- `Flat` — Specifies that the stopband is flat. The attenuation does not change as the frequency increases.
- `Linear` — Specifies that the stopband attenuation changes linearly as the frequency increases. Change the slope of the stopband by setting **Stopband decay**.
- `1/f` — Specifies that the stopband attenuation changes exponentially as the frequency increases, where `f` is the frequency. Set the power (exponent) for the decay in **Stopband decay**.

Stopband Decay

When you set Stopband shape, Stopband decay specifies the amount of decay applied to the stopband. the following conditions apply to Stopband decay based on the value of Stopband Shape:

- When you set **Stopband shape** to `Flat`, **Stopband decay** has no affect on the stopband.
- When you set **Stopband shape** to `Linear`, enter the slope of the stopband in units of dB/rad/s. `filterbuilder` applies that slope to the stopband.
- When you set **Stopband shape** to `1/f`, enter a value for the exponent *n* in the relation $(1/f)^n$ to define the stopband decay. `filterbuilder` applies the $(1/f)^n$ relation to the stopband to result in an exponentially decreasing stopband attenuation.

Filter implementation

Structure

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter.

Use a System object to implement filter

Selecting this check box gives you the choice of using a system object to implement the filter. By default the check box is turned off. When the current design method or structure is not supported by a system object filter, then this check box is disabled.

□ Use a System object to implement filter

Filter specifications

Parameters in this group enable you to specify your filter format, such as the impulse response and the filter order.

Impulse response

Select `FIR` or `IIR` from the drop-down list, where `FIR` is the default impulse response. When you choose an impulse response, the design methods and structures you can use to implement your filter change accordingly.

Note: The design methods and structures for FIR filters are not the same as the methods and structures for IIR filters.

Order mode

Select `Minimum` (the default) or `Specify` from the drop-down list. Selecting `Specify` enables the **Order** option so you can enter the filter order.

If your **Impulse response** is `IIR`, you can specify an equal order for the numerator and denominator, or different numerator and denominator orders. The default is equal orders. To specify a different denominator order, check the **Denominator order** box.

Filter type

This option is only available if you have the DSP System Toolbox software. Select `Single-rate`, `Decimator`, `Interpolator`, or `Sample-rate converter`. Your choice determines the type of filter as well as the design methods and structures that are available to implement your filter. By default, `filterbuilder` specifies single-rate filters.

- Selecting `Decimator` or `Interpolator` activates the **Decimation Factor** or the **Interpolation Factor** options respectively.
- Selecting `Sample-rate converter` activates both factors.

When you design either a decimator or an interpolator, the resulting filter is a highpass filter that either decimates or interpolates your input signal.

Order

Enter the filter order. This option is enabled only if `Specify` was selected for **Order mode**.

Decimation Factor

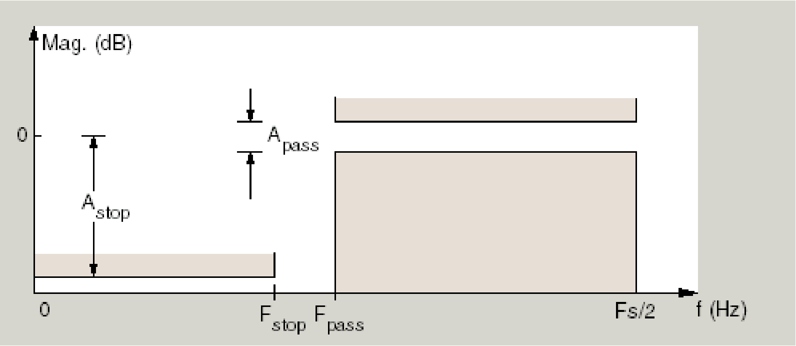
Enter the decimation factor. This option is enabled only if the **Filter type** is set to `Decimator` or `Sample-rate converter`. The default factor value is 2.

Interpolation Factor

Enter the interpolation factor. This option is enabled only if the **Filter type** is set to `Interpolator` or `Sample-rate converter`. The default factor value is 2.

Frequency specifications

The parameters in this group allow you to specify your filter response curve. Graphically, the filter specifications look similar to those shown in the following figure.



In the figure, the region between specification values Fstop and Fpass represents the transition region where the filter response is not explicitly defined.

Frequency constraints

Select the filter features to use to define the frequency response characteristics. The list contains the following options, when available for the filter specifications.

- `Stopband edge and passband edge` — Define the filter by specifying the frequencies for the edges for the stopband and passband.
- `Passband edge` — Define the filter by specifying the frequency for the edge of the passband.
- `Stopband edge` — Define the filter by specifying the frequency for the edges of the stopband.

- `Stopband edge and 3dB point` — Define the filter by specifying the stopband edge frequency and the 3-dB down point (IIR designs).
- `3dB point and passband edge` — Define the filter by specifying the 3-dB down point and passband edge frequency (IIR designs).
- `3dB point` — Define the filter by specifying the frequency for the 3-dB point (IIR designs or maxflat FIR).
- `6dB point` — Define the filter by specifying the frequency for the 6-dB point in the filter response (FIR designs).

Frequency units

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select `Normalized (0–1)` to enter frequencies in normalized form. This behavior is the default. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—`Hz`, `kHz`, `MHz`, or `GHz`. Selecting one of the unit options enables the **Input Fs** parameter.

Input Fs

Fs, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available when you select one of the frequency options from the **Frequency units** list.

Fpass

Enter the frequency at the of the passband. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

Fstop

Enter the frequency at the start of the stopband. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

Magnitude specifications

The parameters in this group let you specify the filter response in the passbands and stopbands.

Magnitude units

Specify the units for any parameter you provide in magnitude specifications. Select one of the following options from the drop-down list.

- `Linear` — Specify the magnitude in linear units.
- `dB` — Specify the magnitude in decibels (default).
- `Squared` — Specify the magnitude in squared units.

Astop

Enter the filter attenuation in the stopband in the units you choose for **Magnitude units**, either linear or decibels.

Apass

Enter the filter ripple allowed in the passband in the units you choose for **Magnitude units**, either linear or decibels.

Algorithm

The parameters in this group allow you to specify the design method and structure that `filterbuilder` uses to implement your filter.

Design Method

Lists the design methods available for the frequency and magnitude specifications you entered. When you change the specifications for a filter, such as changing the impulse response, the methods available to design filters changes as well. The default IIR design method is usually Butterworth, and the default FIR method is equiripple.

Scale SOS filter coefficients to reduce chance of overflow

Selecting this parameter directs the design to scale the filter coefficients to reduce the chances that the inputs or calculations in the filter overflow and exceed the representable range of the filter. Clearing this option removes the scaling. This parameter applies only to IIR filters.

Design Options

The options for each design are specific for each design method. This section does not present all of the available options for all designs and design methods. There are many more that you encounter as you select different design methods and filter specifications. The following options represent some of the most common ones available.

Density factor

Density factor controls the density of the frequency grid over which the design method optimization evaluates your filter response function. The number of equally spaced points in the grid is the value you enter for **Density factor** times (filter order + 1).

Increasing the value creates a filter that more closely approximates an ideal equiripple filter but increases the time required to design the filter. The default value of 16 represents a reasonable trade between the accurate approximation to the ideal filter and the time to design the filter.

Phase constraint

This option only applies when you have the DSP System Toolbox software and when the **Design method** is `equiripple`. Select one of `Linear`, `Minimum`, or `Maximum`.

Minimum order — This option only applies when you have the DSP System Toolbox software and the **Order mode** is `Minimum`.

Select `Any` (default), `Even`, or `Odd`. Selecting `Even` or `Odd` forces the minimum-order design to be an even or odd order.

Match Exactly

Specifies that the resulting filter design matches either the passband or stopband when you select `Passband` or `Stopband`.

Stopband Shape

Stopband shape lets you specify how the stopband changes with increasing frequency. Choose one of the following options:

- `Flat` — Specifies that the stopband is flat. The attenuation does not change as the frequency increases.
- `Linear` — Specifies that the stopband attenuation changes linearly as the frequency increases. Change the slope of the stopband by setting **Stopband decay**.
- `1/f` — Specifies that the stopband attenuation changes exponentially as the frequency increases, where `f` is the frequency. Set the power (exponent) for the decay in **Stopband decay**.

Stopband Decay

When you set Stopband shape, Stopband decay specifies the amount of decay applied to the stopband. the following conditions apply to Stopband decay based on the value of Stopband Shape:

- When you set **Stopband shape** to `Flat`, **Stopband decay** has no affect on the stopband.

- When you set **Stopband shape** to `Linear`, enter the slope of the stopband in units of dB/rad/s. `filterbuilder` applies that slope to the stopband.
- When you set **Stopband shape** to `1/f`, enter a value for the exponent *n* in the relation $(1/f)^n$ to define the stopband decay. `filterbuilder` applies the $(1/f)^n$ relation to the stopband to result in an exponentially decreasing stopband attenuation.

Wpass

Passband weight. This option only applies when **Impulse response** is `FIR` and **Order mode** is `Specify`.

Wstop

Stopband weight. This option only applies when **Impulse response** is `FIR` and **Order mode** is `Specify`.

Filter implementation

Structure

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. By default, FIR filters use direct-form structure, and IIR filters use direct-form II filters with SOS.

Use a System object to implement filter

Selecting this check box gives you the choice of using a system object to implement the filter. By default the check box is turned off. When the current design method or structure is not supported by a system object filter, then this check box is disabled.

Filter specifications

Parameters in this group enable you to specify your filter format, such as the impulse response and the filter order.

Impulse response

Select `FIR` or `IIR` from the drop-down list, where `FIR` is the default impulse response. When you choose an impulse response, the design methods and structures you can use to implement your filter change accordingly.

Note: The design methods and structures for FIR filters are not the same as the methods and structures for IIR filters.

Order mode

This option is only available if you have the DSP System Toolbox software. Select either `Minimum` (the default) or `Specify` from the drop-down list. Selecting `Specify` enables the **Order** option (see the following sections) so you can enter the filter order.

Filter type

This option is only available if you have the DSP System Toolbox software. Select `Single-rate`, `Decimator`, `Interpolator`, or `Sample-rate converter`. Your choice determines the type of filter as well as the design methods and structures that are available to implement your filter. By default, `filterbuilder` specifies single-rate filters.

- Selecting `Decimator` or `Interpolator` activates the **Decimation Factor** or the **Interpolation Factor** options respectively.
- Selecting `Sample-rate converter` activates both factors.

When you design either a decimator or an interpolator, the resulting filter is a bandpass filter that either decimates or interpolates your input signal.

Order

Enter the filter order. This option is enabled only if `Specify` was selected for **Order mode**.

Decimation Factor

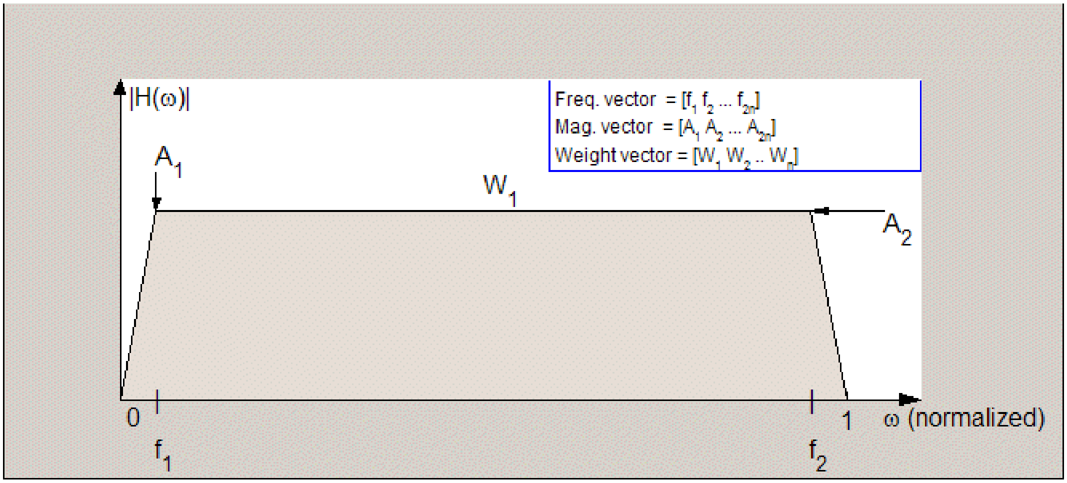
Enter the decimation factor. This option is enabled only if the **Filter type** is set to `Decimator` or `Sample-rate converter`. The default factor value is 2.

Interpolation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to `Interpolator` or `Sample-rate converter`. The default factor value is 2.

Frequency specifications

The parameters in this group allow you to specify your filter response curve. Graphically, the filter specifications look similar to those shown in the following figure.



|H(ω)|
Freq. vector = [f1 f2 ... f2n]
Mag. vector = [A1 A2 ... A2n]
Weight vector = [W1 W2 .. Wn]
A1
W1
A2
0
f1
f2
1
ω (normalized)

In the figure, the regions between 0 and f_1 and between f_2 and 1 represent the transition regions where the filter response is explicitly defined by the transition width.

Frequency units

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select `Normalized (0–1)` to enter frequencies in normalized form. This behavior is the default. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—`Hz`, `kHz`, `MHz`, or `GHz`. Selecting one of the unit options enables the **Input Fs** parameter.

Input Fs

Fs, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is

available when you select one of the frequency options from the **Frequency units** list.

Transition width

Specify the width of the transitions at the ends of the passband. Specify the value in normalized frequency units or the absolute units you select in **Frequency units**.

Magnitude specifications

The parameters in this group let you specify the filter response in the passbands and stopbands.

Magnitude units

Specify the units for any parameter you provide in magnitude specifications. Select one of the following options from the drop-down list.

- `Linear` — Specify the magnitude in linear units.
- `dB` — Specify the magnitude in decibels (default)
- `Squared` — Specify the magnitude in squared units.

Apass

Enter the filter ripple allowed in the passband in the units you choose for **Magnitude units**, either linear or decibels.

Algorithm

The parameters in this group allow you to specify the design method and structure that `filterbuilder` uses to implement your filter.

Design Method

Lists the design methods available for the frequency and magnitude specifications you entered. When you change the specifications for a filter, such as changing the impulse response, the methods available to design filters changes as well. The default IIR design method is usually Butterworth, and the default FIR method is equiripple.

Scale SOS filter coefficients to reduce chance of overflow

Selecting this parameter directs the design to scale the filter coefficients to reduce the chances that the inputs or calculations in the filter overflow and exceed the representable range of the filter. Clearing this option removes the scaling. This parameter applies only to IIR filters.

Design Options

The options for each design are specific for each design method. This section does not present all of the available options for all designs and design methods. There are many more that you encounter as you select different design methods and filter specifications. The following options represent some of the most common ones available.

Density factor

Density factor controls the density of the frequency grid over which the design method optimization evaluates your filter response function. The number of equally spaced points in the grid is the value you enter for **Density factor** times (filter order + 1).

Increasing the value creates a filter that more closely approximates an ideal equiripple filter but increases the time required to design the filter. The default value of 16 represents a reasonable trade between the accurate approximation to the ideal filter and the time to design the filter.

FIR Type

This option is only available in a minimum-order design. Specify whether to design a type 3 or a type 4 FIR filter. The filter type is defined as follows:

- Type 3 — FIR filter with even order antisymmetric coefficients
- Type 4 — FIR filter with odd order antisymmetric coefficients

Select 3 or 4 from the drop-down list.

Filter implementation

Structure

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. By default, FIR filters use direct-form structure, and IIR filters use direct-form II filters with SOS.

Use a System object to implement filter

Selecting this check box gives you the choice of using a system object to implement the filter. By default the check box is turned off. When the current design method or structure is not supported by a system object filter, then this check box is disabled.

Filter specifications

Parameters in this group enable you to specify your filter format, such as the impulse response and the filter order.

Order mode

Select `Minimum` (the default) or `Specify` from the drop-down list. Selecting `Specify` enables the **Order** option (see the following sections) so you can enter the filter order.

Response type

Select `Lowpass` or `Highpass` to design an inverse sinc lowpass or highpass filter.

Filter type

Select `Single-rate`, `Decimator`, `Interpolator`, or `Sample-rate converter`. Your choice determines the type of filter as well as the design methods and structures that are available to implement your filter. By default, `filterbuilder` specifies single-rate filters.

- Selecting `Decimator` or `Interpolator` activates the **Decimation Factor** or the **Interpolation Factor** options respectively.
- Selecting `Sample-rate converter` activates both factors.

When you design either a decimator or an interpolator, the resulting filter is a bandpass filter that either decimates or interpolates your input signal.

Order

Enter the filter order. This option is enabled only if `Specify` was selected for **Order mode**.

Decimation Factor

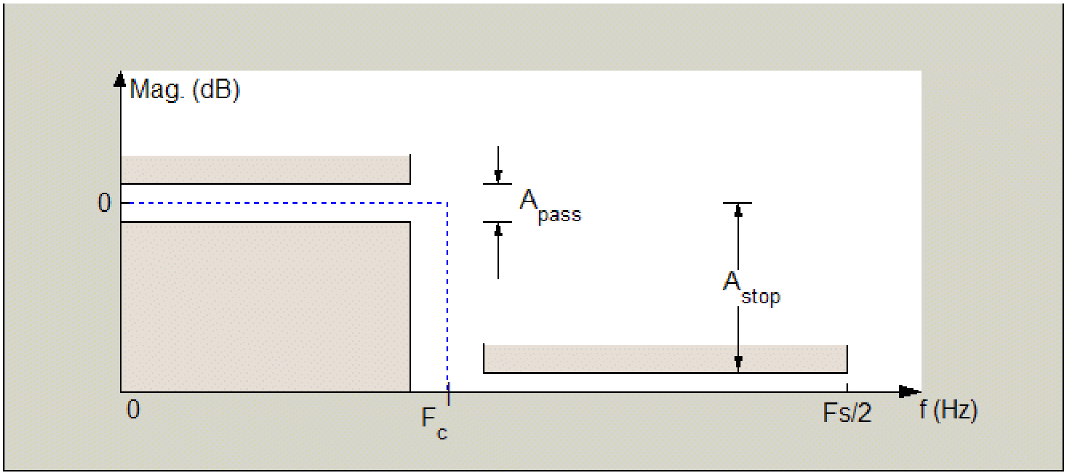
Enter the decimation factor. This option is enabled only if the **Filter type** is set to `Decimator` or `Sample-rate converter`. The default factor value is 2.

Interpolation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to `Interpolator` or `Sample-rate converter`. The default factor value is 2.

Frequency specifications

The parameters in this group allow you to specify your filter response curve. Graphically, the filter specifications look similar to those shown in the following figure.



Regions between specification values such as Fpass and Fstop represent transition regions where the filter response is not explicitly defined.

Frequency constraints

This option is only available when you specify the filter order. The following options are available:

- `Passband and stopband edges` — Define the filter by specifying the frequencies for the edges for the stop- and passbands.
- `Passband edge` — Define the filter by specifying frequencies for the edges of the passband.
- `Stopband edge` — Define the filter by specifying frequencies for the edges of the stopbands.
- `6dB point` — The 6-dB point is the frequency for the point 6 dB point below the passband value.

Frequency units

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select `Normalized (0–1)` to enter frequencies in normalized form. This behavior is the default. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—`Hz`, `kHz`, `MHz`, or `GHz`. Selecting one of the unit options enables the **Input Fs** parameter.

Input Fs

Fs, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available when you select one of the frequency options from the **Frequency units** list.

Fpass

Enter the frequency at the end of the passband. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

Fstop

Enter the frequency at the start of the stopband. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

Magnitude specifications

The parameters in this group let you specify the filter response in the passbands and stopbands.

Magnitude units

Specify the units for any parameter you provide in magnitude specifications. Select one of the following options from the drop-down list.

- `Linear` — Specify the magnitude in linear units.
- `dB` — Specify the magnitude in decibels (default)
- `Squared` — Specify the magnitude in squared units.

Apass

Enter the filter ripple allowed in the passband in the units you choose for **Magnitude units**, either linear or decibels.

Astop

Enter the filter attenuation in the stopband in the units you choose for **Magnitude units**, either linear or decibels.

Algorithm

The parameters in this group allow you to specify the design method and structure that `filterbuilder` uses to implement your filter.

Design Method

Lists the design methods available for the frequency and magnitude specifications you entered. When you change the specifications for a filter, such as changing the impulse response, the methods available to design filters changes as well. The default IIR design method is usually Butterworth, and the default FIR method is equiripple.

Design Options

The options for each design are specific for each design method. This section does not present all of the available options for all designs and design methods. There are many more that you encounter as you select different design methods and filter specifications. The following options represent some of the most common ones available.

Density factor

Density factor controls the density of the frequency grid over which the design method optimization evaluates your filter response function. The number of equally spaced points in the grid is the value you enter for **Density factor** times (filter order + 1).

Increasing the value creates a filter that more closely approximates an ideal equiripple filter but increases the time required to design the filter. The default value of 16 represents a reasonable trade between the accurate approximation to the ideal filter and the time to design the filter.

Phase constraint

Available options are `Linear`, `Minimum`, and `Maximum`.

Stopband Shape

Stopband shape lets you specify how the stopband changes with increasing frequency. Choose one of the following options;

- `Flat` — Specifies that the stopband is flat. The attenuation does not change as the frequency increases.
- `Linear` — Specifies that the stopband attenuation changes linearly as the frequency increases. Change the slope of the stopband by setting **Stopband decay**.
- `1/f` — Specifies that the stopband attenuation changes exponentially as the frequency increases, where `f` is the frequency. Set the power (exponent) for the decay in **Stopband decay**.

Stopband Decay

When you set Stopband shape, Stopband decay specifies the amount of decay applied to the stopband. the following conditions apply to Stopband decay based on the value of Stopband Shape:

- When you set **Stopband shape** to `Flat`, **Stopband decay** has no affect on the stopband.
- When you set **Stopband shape** to `Linear`, enter the slope of the stopband in units of dB/rad/s. `filterbuilder` applies that slope to the stopband.
- When you set **Stopband shape** to `1/f`, enter a value for the exponent *n* in the relation $(1/f)^n$ to define the stopband decay. `filterbuilder` applies the $(1/f)^n$ relation to the stopband to result in an exponentially decreasing stopband attenuation.

Sinc frequency factor

A frequency dilation factor. The sinc frequency factor, *C* , parameterizes the passband magnitude response for a lowpass design through H(ω) = sinc(Cω)^(-P) and for a highpass design through H(ω) = sinc(C(1-ω))^(-P).

Sinc power

Negative power of passband magnitude response. The sinc power, *P*, parameterizes the passband magnitude response for a lowpass design through H(ω) = sinc(Cω)^(-P) and for a highpass design through H(ω) = sinc(C(1-ω))^(-P).

Filter implementation

Structure

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. By default, FIR filters use direct-form structure.

□ Use a System object to implement filter

Filter specifications

Parameters in this group enable you to specify your filter format, such as the impulse response and the filter order.

Impulse response

Select FIR or IIR from the drop-down list, where FIR is the default impulse response. When you choose an impulse response, the design methods and structures you can use to implement your filter change accordingly.

Note: The design methods and structures for FIR filters are not the same as the methods and structures for IIR filters.

Order mode

Select Minimum (the default) or Specify from the drop-down list. Selecting Specify enables the **Order** option (see the following sections) so you can enter the filter order.

If your **Impulse response** is IIR, you can specify an equal order for the numerator and denominator, or different numerator and denominator orders. The default is equal orders. To specify a different denominator order, check the **Denominator order** box.

Filter type

This option is only available if you have the DSP System Toolbox. Select Single-rate, Decimator, Interpolator, or Sample-rate converter. Your choice determines the type of filter as well as the design methods and structures that are available to implement your filter. By default, filterbuilder specifies single-rate filters.

- Selecting Decimator or Interpolator activates the **Decimation Factor** or the **Interpolation Factor** options respectively.
- Selecting Sample-rate converter activates both factors.

When you design either a decimator or an interpolator, the resulting filter is a bandpass filter that either decimates or interpolates your input signal.

Order

Enter the filter order. This option is enabled only if Specify was selected for **Order mode**.

Decimation Factor

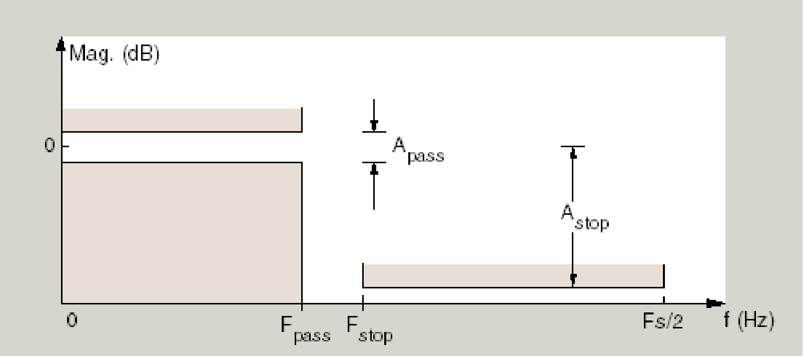
Enter the decimation factor. This option is enabled only if the **Filter type** is set to `Decimator` or `Sample-rate converter`. The default factor value is 2.

Interpolation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to `Interpolator` or `Sample-rate converter`. The default factor value is 2.

Frequency specifications

The parameters in this group allow you to specify your filter response curve. Graphically, the filter specifications look similar to the one shown in the following figure.



In the figure, regions between specification values such as F_{pass} and F_{stop} represent transition regions where the filter response is not explicitly defined.

Frequency constraints

Select the filter features to use to define the frequency response characteristics. The list contains the following options, when available for the filter specifications.

- `Passband and stopband edge` — Define the filter by specifying the frequencies for the edge of the stopband and passband.
- `Passband edge` — Define the filter by specifying the frequency for the edge of the passband.
- `Stopband edge` — Define the filter by specifying the frequency for the edges of the stopband.

- `Passband edge and 3dB point` — Define the filter by specifying the passband edge frequency and the 3-dB down point (IIR designs).
- `3dB point and stopband edge` — Define the filter by specifying the 3-dB down point and stopband edge frequency (IIR designs).
- `3dB point` — Define the filter by specifying the frequency for the 3-dB point (IIR designs or maxflat FIR).
- `6dB point` — Define the filter by specifying the frequency for the 6-dB point in the filter response (FIR designs).

Frequency units

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select `Normalized (0–1)` to enter frequencies in normalized form. This behavior is the default. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—`Hz`, `kHz`, `MHz`, or `GHz`. Selecting one of the unit options enables the **Input Fs** parameter.

Input Fs

Fs, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available when you select one of the frequency options from the **Frequency units** list.

Fpass

Enter the frequency at the of the passband. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

Fstop

Enter the frequency at the start of the stopband. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

Magnitude specifications

The parameters in this group let you specify the filter response in the passbands and stopbands.

Magnitude units

Specify the units for any parameter you provide in magnitude specifications. Select one of the following options from the drop-down list.

- `Linear` — Specify the magnitude in linear units.
- `dB` — Specify the magnitude in decibels (default)
- `Squared` — Specify the magnitude in squared units.

Apass

Enter the filter ripple allowed in the passband in the units you choose for **Magnitude units**, either linear or decibels.

Astop

Enter the filter attenuation in the stopband in the units you choose for **Magnitude units**, either linear or decibels.

Algorithm

The parameters in this group allow you to specify the design method and structure that `filterbuilder` uses to implement your filter.

Design Method

Lists the design methods available for the frequency and magnitude specifications you entered. When you change the specifications for a filter, such as changing the impulse response, the methods available to design filters changes as well. The default IIR design method is usually Butterworth, and the default FIR method is equiripple.

Scale SOS filter coefficients to reduce chance of overflow

Selecting this parameter directs the design to scale the filter coefficients to reduce the chances that the inputs or calculations in the filter overflow and exceed the representable range of the filter. Clearing this option removes the scaling. This parameter applies only to IIR filters.

Design Options

The options for each design are specific for each design method. This section does not present all of the available options for all designs and design methods. There are many more that you encounter as you select different design methods and filter specifications. The following options represent some of the most common ones available.

Density factor

Density factor controls the density of the frequency grid over which the design method optimization evaluates your filter response function. The number of equally spaced points in the grid is the value you enter for **Density factor** times (filter order + 1).

Increasing the value creates a filter that more closely approximates an ideal equiripple filter but increases the time required to design the filter. The default value of 16 represents a reasonable trade between the accurate approximation to the ideal filter and the time to design the filter.

Phase constraint

This option only applies when you have the DSP System Toolbox software and when the **Design method** is `equiripple`. Select one of `Linear`, `Minimum`, or `Maximum`.

Minimum order — This option only applies when you have the DSP System Toolbox software and the **Order mode** is `Minimum`.

Select `Any` (default), `Even`, or `Odd`. Selecting `Even` or `Odd` forces the minimum-order design to be an even or odd order.

Match Exactly

Specifies that the resulting filter design matches either the passband or stopband when you select `Passband` or `Stopband`.

Stopband Shape

Stopband shape lets you specify how the stopband changes with increasing frequency. Choose one of the following options:

- `Flat` — Specifies that the stopband is flat. The attenuation does not change as the frequency increases.
- `Linear` — Specifies that the stopband attenuation changes linearly as the frequency increases. Change the slope of the stopband by setting **Stopband decay**.
- `1/f` — Specifies that the stopband attenuation changes exponentially as the frequency increases, where `f` is the frequency. Set the power (exponent) for the decay in **Stopband decay**.

Stopband Decay

When you set Stopband shape, Stopband decay specifies the amount of decay applied to the stopband. the following conditions apply to Stopband decay based on the value of Stopband Shape:

- When you set **Stopband shape** to `Flat`, **Stopband decay** has no affect on the stopband.

- When you set **Stopband shape** to `Linear`, enter the slope of the stopband in units of dB/rad/s. `filterbuilder` applies that slope to the stopband.
- When you set **Stopband shape** to `1/f`, enter a value for the exponent *n* in the relation $(1/f)^n$ to define the stopband decay. `filterbuilder` applies the $(1/f)^n$ relation to the stopband to result in an exponentially decreasing stopband attenuation.

Wpass

Passband weight. This option only applies when **Impulse response** is `FIR` and **Order mode** is `Specify`.

Wstop

Stopband weight. This option only applies when **Impulse response** is `FIR` and **Order mode** is `Specify`.

Filter implementation

Structure

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. By default, FIR filters use direct-form structure, and IIR filters use direct-form II filters with SOS.

Use a System object to implement filter

Selecting this check box gives you the choice of using a system object to implement the filter. By default the check box is turned off. When the current design method or structure is not supported by a system object filter, then this check box is disabled.

Design method: Kaiser window

Filter implementation

Structure: Direct-form FIR

□ Use a System object to implement filter

Filter specifications

Parameters in this group enable you to specify your filter format, such as the impulse response and the filter order.

Band

Specifies the location of the center of the transition region between the passband and the stopband. The center of the transition region, bw, is calculated using the value for Band:

bw = Fs/(2*Band).

Impulse response

Select `FIR` or `IIR` from the drop-down list, where `FIR` is the default impulse response. When you choose an impulse response, the design methods and structures you can use to implement your filter change accordingly.

Note: The design methods and structures for FIR filters are not the same as the methods and structures for IIR filters.

Order mode

Select `Minimum` (the default) or `Specify` from the drop-down list. Selecting `Specify` enables the **Order** option (see the following sections) so you can enter the filter order.

Filter type

Select `Single-rate`, `Decimator`, `Interpolator`, or `Sample-rate converter`. Your choice determines the type of filter as well as the design methods and structures that are available to implement your filter. By default, `filterbuilder` specifies single-rate filters.

- Selecting `Decimator` or `Interpolator` activates the **Decimation Factor** or the **Interpolation Factor** options respectively.
- Selecting `Sample-rate converter` activates both factors.

When you design either a decimator or an interpolator, the resulting filter is a bandpass filter that either decimates or interpolates your input signal.

Order

Enter the filter order. This option is enabled only if `Specify` was selected for **Order mode**.

Decimation Factor

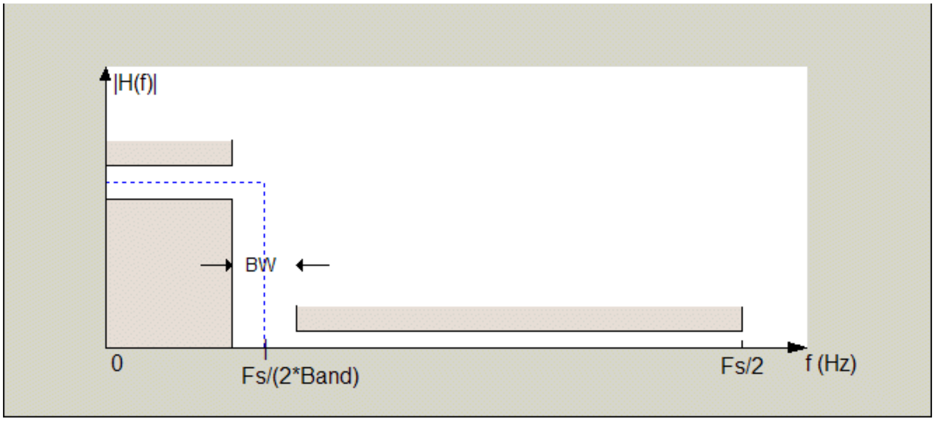
Enter the decimation factor. This option is enabled only if the **Filter type** is set to `Decimator` or `Sample-rate converter`. The default factor value is 2.

Interpolation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to `Interpolator` or `Sample-rate converter`. The default factor value is 2.

Frequency specifications

The parameters in this group allow you to specify your filter response curve. Graphically, the filter specifications look similar to those shown in the following figure.



In the figure, BW is the width of the transition region and **Band** determines the location of the center of the region.

Frequency constraints

Select the filter features to use to define the frequency response characteristics. The list contains the following options, when available for the filter specifications.

- `Passband and stopband edges` — Define the filter by specifying the frequencies for the edges for the stopbands and passbands.
- `Passband edges` — Define the filter by specifying frequencies for the edges of the passband.
- `Stopband edges` — Define the filter by specifying frequencies for the edges of the stopbands.
- `3 dB points` — Define the filter response by specifying the locations of the 3 dB points. The 3 dB point is the frequency for the point 3 dB point below the passband value.

- `3 dB points and passband width` — Define the filter by specifying frequencies for the 3 dB points in the filter response and the width of the passband.
- `3 dB points and stopband widths` — Define the filter by specifying frequencies for the 3 dB points in the filter response and the width of the stopband.

Frequency units

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select `Normalized (0—1)` to enter frequencies in normalized form. This behavior is the default. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—`Hz`, `kHz`, `MHz`, or `GHz`. Selecting one of the unit options enables the **Input Fs** parameter.

Input Fs

Fs, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available when you select one of the frequency options from the **Frequency units** list.

Transition width

Specify the width of the transition between the end of the passband and the edge of the stopband. Specify the value in normalized frequency units or the absolute units you select in **Frequency units**.

Magnitude specifications

The parameters in this group let you specify the filter response in the passbands and stopbands.

Magnitude units

Specify the units for any parameter you provide in magnitude specifications. Select one of the following options from the drop-down list.

- `Linear` — Specify the magnitude in linear units.
- `dB` — Specify the magnitude in decibels (default)
- `Squared` — Specify the magnitude in squared units.

Astop

Enter the filter attenuation in the stopband in the units you choose for **Magnitude units**, either linear or decibels.

Algorithm

The parameters in this group allow you to specify the design method and structure that `filterbuilder` uses to implement your filter.

Design Method

Lists the design methods available for the frequency and magnitude specifications you entered. When you change the specifications for a filter, such as changing the impulse response, the methods available to design filters changes as well. The default IIR design method is usually Butterworth, and the default FIR method is equiripple.

Scale SOS filter coefficients to reduce chance of overflow

Selecting this parameter directs the design to scale the filter coefficients to reduce the chances that the inputs or calculations in the filter overflow and exceed the representable range of the filter. Clearing this option removes the scaling. This parameter applies only to IIR filters.

Design Options

The options for each design are specific for each design method. This section does not present all of the available options for all designs and design methods. There are many more that you encounter as you select different design methods and filter specifications. The following options represent some of the most common ones available.

Density factor

Density factor controls the density of the frequency grid over which the design method optimization evaluates your filter response function. The number of equally spaced points in the grid is the value you enter for **Density factor** times (filter order + 1).

Increasing the value creates a filter that more closely approximates an ideal equiripple filter but increases the time required to design the filter. The default value of 16 represents a reasonable trade between the accurate approximation to the ideal filter and the time to design the filter.

Minimum phase

To design a filter that is minimum phase, select **Minimum phase**. Clearing the **Minimum phase** option removes the phase constraint—the resulting design is not minimum phase.

Minimum order

When you select this parameter, the design method determines and designs the minimum order filter to meet your specifications. Some filters do not provide this parameter. Select `Any`, `Even`, or `Odd` from the drop-down list to direct the design to be any minimum order, or minimum even order, or minimum odd order.

Note: Generally, **Minimum order** designs are not available for IIR filters.

Match Exactly

Specifies that the resulting filter design matches either the passband or stopband or both bands when you select `passband` or `stopband` or `both` from the drop-down list.

Stopband Shape

Stopband shape lets you specify how the stopband changes with increasing frequency. Choose one of the following options:

- `Flat` — Specifies that the stopband is flat. The attenuation does not change as the frequency increases.
- `Linear` — Specifies that the stopband attenuation changes linearly as the frequency increases. Change the slope of the stopband by setting **Stopband decay**.
- `1/f` — Specifies that the stopband attenuation changes exponentially as the frequency increases, where `f` is the frequency. Set the power (exponent) for the decay in **Stopband decay**.

Stopband Decay

When you set Stopband shape, Stopband decay specifies the amount of decay applied to the stopband. the following conditions apply to Stopband decay based on the value of Stopband Shape:

- When you set **Stopband shape** to `Flat`, **Stopband decay** has no affect on the stopband.
- When you set **Stopband shape** to `Linear`, enter the slope of the stopband in units of dB/rad/s. `filterbuilder` applies that slope to the stopband.

- When you set **Stopband shape** to `1/f`, enter a value for the exponent *n* in the relation $(1/f)^n$ to define the stopband decay. `filterbuilder` applies the $(1/f)^n$ relation to the stopband to result in an exponentially decreasing stopband attenuation.

Filter implementation

Structure

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. By default, FIR filters use direct-form structure, and IIR filters use direct-form II filters with SOS.

Use a System object to implement filter

Selecting this check box gives you the choice of using a system object to implement the filter. By default the check box is turned off. When the current design method or structure is not supported by a system object filter, then this check box is disabled.

Filter specifications

Order mode

Select `Minimum` to design a minimum order filter that meets the design specifications, or `Specify` to enter a specific filter order. The order mode also affects the possible frequency constraints, which in turn limit the gain specifications. For example, if you specify a `Minimum` order filter, the available frequency constraints are:

- `Center frequency, bandwidth, passband width`

- `Center frequency, bandwidth, stopband width`

If you select `Specify`, the available frequency constraints are:

- `Center frequency, bandwidth`
- `Center frequency, quality factor`
- `Shelf type, cutoff frequency, quality factor`
- `Shelf type, cutoff frequency, shelf slope parameter`
- `Low frequency, high frequency`

Order

This parameter is enabled only if the **Order mode** is set to `Specify`. Enter the filter order in this text box.

Frequency specifications

Depending on the filter order, the possible frequency constraints change. Once you choose the frequency constraints, the input boxes in this area change to reflect the selection.

Frequency constraints

Select the specification to represent the frequency constraints. The following options are available:

- `Center frequency, bandwidth, passband width` (available for minimum order only)
- `Center frequency, bandwidth, stopband width` (available for minimum order only)
- `Center frequency, bandwidth` (available for a specified order only)
- `Center frequency, quality factor` (available for a specified order only)
- `Shelf type, cutoff frequency, quality factor` (available for a specified order only)
- `Shelf type, cutoff frequency, shelf slope parameter` (available for a specified order only)
- `Low frequency, high frequency` (available for a specified order only)

Frequency units

Select the frequency units from the available drop down list (`Normalized, Hz, kHz, MHz, GHz`). If `Normalized` is selected, then the **Input Fs** box is disabled for input.

Input Fs

Enter the input sampling frequency. This input box is disabled for input if `Normalized` is selected in the **Frequency units** input box.

Center frequency

Enter the center frequency in the units specified by the value in **Frequency units**.

Bandwidth

The bandwidth determines the frequency points at which the filter magnitude is attenuated by the value specified as the **Bandwidth gain** in the **Gain specifications** section. By default, the **Bandwidth gain** defaults to `db(sqrt(.5))`, or –3 dB relative to the center frequency. The **Bandwidth** property only applies when the **Frequency constraints** are: `Center frequency, bandwidth, passband width`, `Center frequency, bandwidth, stopband width`, or `Center frequency, bandwidth`.

Passband width

The passband width determines the frequency points at which the filter magnitude is attenuated by the value specified as the **Passband gain** in the **Gain specifications** section. This option is enabled only if the filter is of minimum order, and the frequency constraint selected is `Center frequency, bandwidth, passband width`.

Stopband width

The stopband width determines the frequency points at which the filter magnitude is attenuated by the value specified as the **Stopband gain** in the **Gain specifications** section. This option is enabled only if the filter is of minimum order, and the frequency constraint selected is `Center frequency, bandwidth, stopband width`.

Low frequency

Enter the low frequency cutoff. This option is enabled only if the filter order is user specified and the frequency constraint selected is `Low frequency, high frequency`. The filter magnitude is attenuated by the amount specified in **Bandwidth gain**.

High frequency

Enter the high frequency cutoff. This option is enabled only if the filter order is user specified and the frequency constraint selected is `Low frequency,` `high frequency`. The filter magnitude is attenuated by the amount specified in **Bandwidth gain**.

Gain specifications

Depending on the filter order and frequency constraints, the possible gain constraints change. Also, once you choose the gain constraints the input boxes in this area change to reflect the selection.

Gain constraints

Select the specification array to represent gain constraints, and remember that not all of these options are available for all configurations. The following is a list of all available options:

- `Reference, center frequency, bandwidth, passband`
- `Reference, center frequency, bandwidth, stopband`
- `Reference, center frequency, bandwidth, passband, stopband`
- `Reference, center frequency, bandwidth`

Gain units

Specify the gain units either `dB` or `squared`. These units are used for all gain specifications in the dialog box.

Reference gain

The reference gain determines the level to which the filter magnitude attenuates in **Gain units**. The reference gain is a *floor* gain for the filter magnitude response. For example, you may use the reference gain together with the **Center frequency gain** to leave certain frequencies unattenuated (reference gain of 0 dB) while boosting other frequencies.

Bandwidth gain

Specifies the gain in **Gain units** at which the bandwidth is defined. This property applies only when the **Frequency constraints** specification contains a `bandwidth` parameter, or is `Low frequency, high frequency`.

Center frequency gain

Specify the center frequency in **Gain units**

Passband gain

The passband gain determines the level in **Gain units** at which the passband is defined. The passband is determined either by the **Passband width** value, or the **Low frequency** and **High frequency** values in the **Frequency specifications** section.

Stopband gain

The stopband gain is the level in **Gain units** at which the stopband is defined. This property applies only when the **Order mode** is minimum and the **Frequency constraints** are `Center frequency, bandwidth, stopband width`.

Boost/cut gain

The boost/cut gain applies only when the designing a shelving filter. Shelving filters include the `Shelf type` parameter in the **Frequency constraints** specification. The gain in the passband of the shelving filter is increased by **Boost/cut gain** dB from a *floor* gain of 0 dB.

Algorithm

Design method

Select the design method from the drop-down list. Different IIR design methods are available depending on the filter constraints you specify.

Scale SOS filter coefficients to reduce chance of overflow

Select the check box to scale the filter coefficients.

Filter implementation

Structure

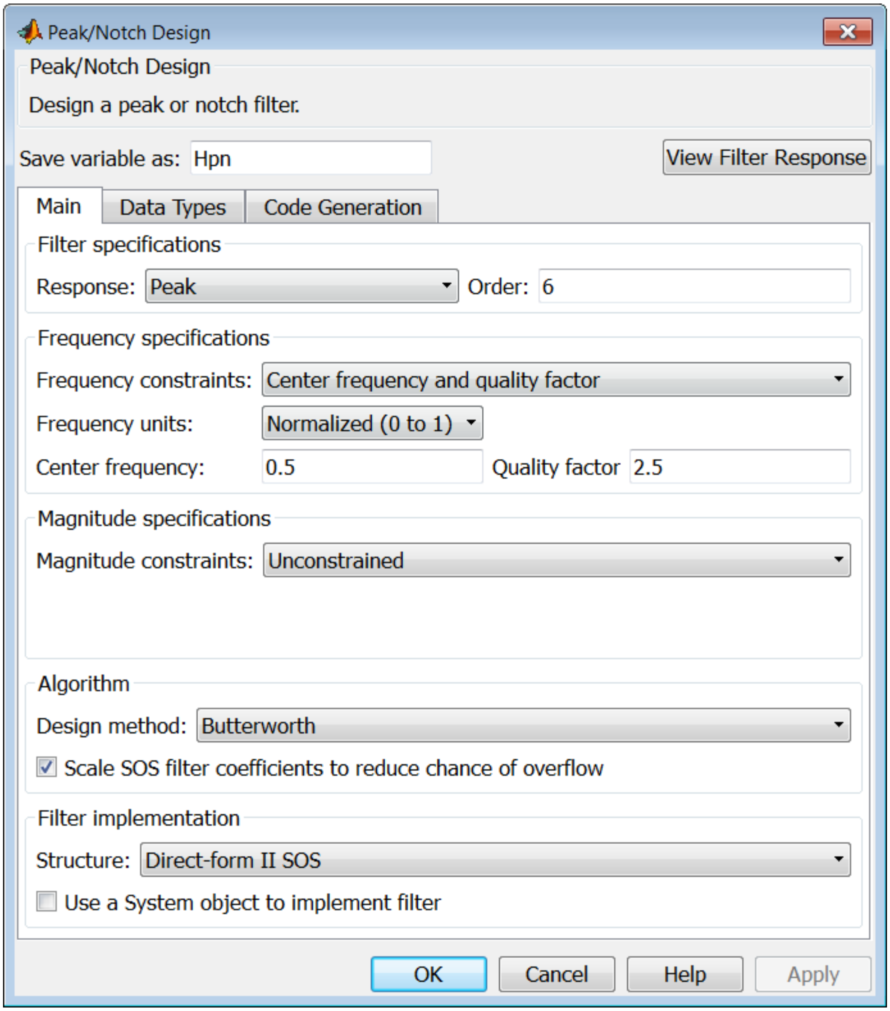
Select filter structure. The possible choices are:

- Direct-form I SOS
- Direct-form II SOS
- Direct-form I transposed SOS
- Direct-form II transposed SOS

Use a System object to implement filter

Selecting this check box gives you the choice of using a system object to implement the filter. By default the check box is turned off. When the current design method or structure is not supported by a system object filter, then this check box is disabled.

Peak/Notch Filter Design Dialog Box — Main Pane



Peak/Notch Design

Peak/Notch Design

Design a peak or notch filter.

Design method: Butterworth

☑ Scale SOS filter coefficients to reduce chance of overflow

Filter implementation

Structure: Direct-form II SOS

□ Use a System object to implement filter

Filter specifications

In this area you can specify whether you want to design a peaking filter or a notching filter, as well as the order of the filter.

Response

Select `Peak` or `Notch` from the drop-down box.

Order

Enter the filter order. The order must be even.

Frequency specifications

This group of parameters allows you to specify frequency constraints and units.

Frequency Constraints

Select the frequency constraints for filter specification. There are two choices as follows:

- `Center frequency and quality factor`
- `Center frequency and bandwidth`

Frequency units

The frequency units are normalized by default. If you specify units other than normalized, `filterbuilder` assumes that you wish to specify an input sampling frequency, and enables this input box. The choice of frequency units are: `Normalized (0 to 1)`, `Hz`, `kHz`, `MHz`, `GHz`.

Input Fs

This input box is enabled if **Frequency units** other than `Normalized (0 to 1)` are specified. Enter the input sampling frequency.

Center frequency

Enter the center frequency in the units you specified in **Frequency units**.

Quality Factor

This input box is enabled only when `Center frequency and quality factor` is chosen for the **Frequency Constraints**. Enter the quality factor.

Bandwidth

This input box is enabled only when `Center frequency and bandwidth` is chosen for the **Frequency Constraints**. Enter the bandwidth.

Magnitude specifications

This group of parameters allows you to specify the magnitude constraints, as well as their values and units.

Magnitude Constraints

Depending on the choice of constraints, the other input boxes are enabled or disabled. Select from four magnitude constraints available:

- `Unconstrained`
- `Passband ripple`
- `Stopband attenuation`
- `Passband ripple and stopband attenuation`

Magnitude units

Select the magnitude units: either `dB` or `squared`.

Apass

This input box is enabled if the magnitude constraints selected are `Passband ripple` or `Passband ripple and stopband attenuation`. Enter the passband ripple.

Astop

This input box is enabled if the magnitude constraints selected are `Stopband attenuation` or `Passband ripple and stopband attenuation`. Enter the stopband attenuation.

Algorithm

The parameters in this group allow you to specify the design method and structure that `filterbuilder` uses to implement your filter.

Design Method

Lists all design methods available for the frequency and magnitude specifications you entered. When you change the specifications for a filter the methods available to design filters changes as well.

Scale SOS filter coefficients to reduce chance of overflow

Selecting this parameter directs the design to scale the filter coefficients to reduce the chances that the inputs or calculations in the filter overflow and exceed the representable range of the filter. Clearing this option removes the scaling. This parameter applies only to IIR filters.

Filter implementation

Structure

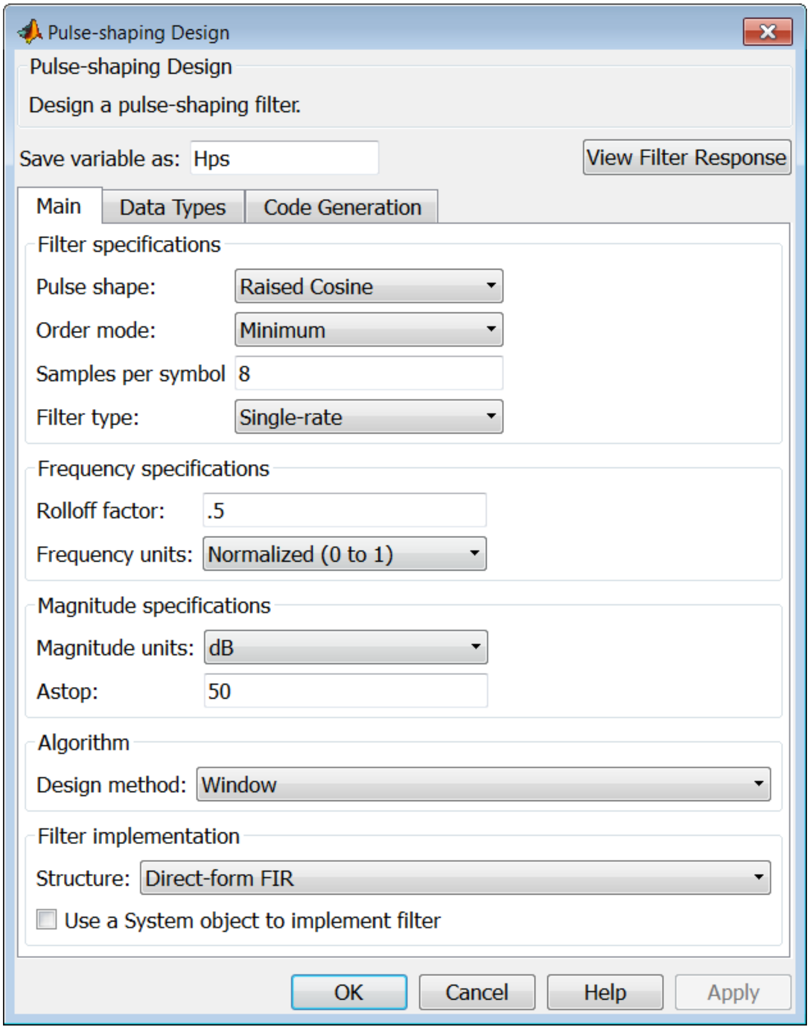
Lists all available filter structures for the filter specifications and design method you select. The typical options are:

- Direct-form I SOS
- Direct-form II SOS
- Direct-form I transposed SOS
- Direct-form II transposed SOS

Use a System object to implement filter

Selecting this check box gives you the choice of using a system object to implement the filter. By default the check box is turned off. When the current design method or structure is not supported by a system object filter, then this check box is disabled.

Pulse-shaping Filter Design Dialog Box—Main Pane



Pulse-shaping Design

Pulse-shaping Design

Design a pulse-shaping filter.

Save variable as: Hps

Filter specifications

Pulse shape: Raised Cosine

Order mode: Minimum

Samples per symbol 8

Filter type: Single-rate

Frequency specifications

Rolloff factor: .5

Frequency units: Normalized (0 to 1)

Magnitude specifications

Magnitude units: dB

Astop: 50

Algorithm

Design method: Window

Filter implementation

Structure: Direct-form FIR

□ Use a System object to implement filter

Filter specifications

Parameters in this group enable you to specify the shape and length of the filter.

Pulse shape

Select the shape of the impulse response from the following options:

- `Raised Cosine`
- `Square Root Raised Cosine`
- `Gaussian`

Order mode

This specification is only available for raised cosine and square root raised cosine filters. For these filters, select one of the following options:

- `Minimum`— This option will result in the minimum-length filter satisfying the user-specified **Frequency specifications**.
- `Specify order`—This option allows the user to construct a raised cosine or square root cosine filter of a specified order by entering an even number in the **Order** input box. The length of the impulse response will be `Order+1` .
- `Specify symbols`—This option enables the user to specify the length of the impulse response in an alternative manner. If `Specify symbols` is chosen, the **Order** input box changes to the **Number of symbols** input box.

Samples per symbol

Specify the oversampling factor. Increasing the oversampling factor guards against aliasing and improves the FIR filter approximation to the ideal frequency response. If **Order** is specified in **Number of symbols**, the filter length will be **Number of symbols*Samples per symbol**+1. The product **Number of symbols*Samples per symbol** must be an even number.

If a Gaussian filter is specified, the filter length must be specified in **Number of symbols** and **Samples per symbol**. The product **Number of symbols*Samples per symbol** must be an even number. The filter length will be **Number of symbols*Samples per symbol**+1.

Filter Type

This option is only available if you have the DSP System Toolbox software. Choose `Single rate`, `Decimator`, `Interpolator`, or `Sample-rate converter`. If you select `Decimator` or `Interpolator`, the decimation and interpolation factors default to the value of the **Samples per symbol**. If you select `Sample-rate converter`, the interpolation factor defaults to **Samples per symbol** and the decimation factor defaults to 3.

Frequency specifications

Parameters in this group enable you to specify the frequency response of the filter. For raised cosine and square root raised cosine filters, the frequency specifications include:

Rolloff factor

The rolloff factor takes values in the range [0,1]. The smaller the rolloff factor, the steeper the transition in the stopband.

Frequency units

The frequency units are normalized by default. If you specify units other than normalized, `filterbuilder` assumes that you wish to specify an input sampling frequency, and enables this input box. The choice of frequency units are: `Normalized (0 to 1), Hz, kHz, MHz, GHz`

For a Gaussian pulse shape, the available frequency specifications are:

Bandwidth-time product

This option allows the user to specify the width of the Gaussian filter. Note that this is independent of the length of the filter. The bandwidth-time product (BT) must be a positive real number. Smaller values of the bandwidth-time product result in larger pulse widths in time and steeper stopband transitions in the frequency response.

Frequency units

The frequency units are normalized by default. If you specify units other than normalized, `filterbuilder` assumes that you wish to specify an input sampling frequency, and enables this input box. The choice of frequency units are: `Normalized (0 to 1), Hz, kHz, MHz, GHz`

Magnitude specifications

If the **Order mode** is specified as `Minimum`, the **Magnitude units** may be selected from:

- `dB`—Specify the magnitude in decibels (default).
- `Linear`—Specify the magnitude in linear units.

Algorithm

The only **Design method** available for FIR pulse-shaping filters is the `Window` method.

Filter implementation

Structure

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. By default, FIR filters use direct-form structure.

Use a System object to implement filter

Selecting this check box gives you the choice of using a system object to implement the filter. By default the check box is turned off. When the current design method or structure is not supported by a system object filter, then this check box is disabled.

filtstates.cic

Store CIC filter states

Description

filtstates.cic objects hold the states information for CIC filters. Once you create a CIC filter, the states for the filter are stored in filtstates.cic objects, and you can access them and change them as you would any property of the filter. This arrangement parallels that of the filtstates object that IIR direct-form I filters use (refer to filtstates for more information).

Each States property in the CIC filter comprises two properties — Numerator and Comb — that hold filtstates.cic objects. Within the filtstates.cic objects are the numerator-related and comb-related filter states. The states are column vectors, where each column represents the states for one section of the filter. For example, a CIC filter with four decimator sections and four interpolator sections has filtstates.cic objects that contain four columns of states each.

Examples

To show you thefiltstates.cic object, create a CIC decimator and filter a signal:

```
fs = 44.1e3;             % Original sampling frequency: 44.1kHz.
n = 0:10239;             % 10240 samples, 0.232 second long signal.
x  = sin(2*pi*1e3/fs*n); % Original signal, sinusoid at 1kHz.
hm=mfilt.cicdecim(5,2,4);
y=filter(hm,x);
```

hm has nonzero states now.

You can use int to see the states as 32-bit integers.

```
s=hm.states;
int(s.Integrator)
```

See Also

mfilt | mfilt.cicdecim | mfilt.cicinterp | filtstates

fircband

Constrained-band equiripple FIR filter

Syntax

```
b = fircband(n,f,a,w,c)
b = fircband(n,f,a,s)
b = fircband(...,'1')
b = fircband(...,'minphase')
b = fircband(..., 'check')
b = fircband(...,{lgrid})
[b,err] = fircband(...)
[b,err,res] = fircband(...)
```

Description

`fircband` is a minimax filter design algorithm that you use to design the following types of real FIR filters:

- Types 1-4 linear phase
  - Type 1 is even order, symmetric
  - Type 2 is odd order, symmetric
  - Type 3 is even order, antisymmetric
  - Type 4 is odd order, antisymmetric
- Minimum phase
- Maximum phase
- Minimum order (even or odd), extra ripple
- Maximal ripple
- Constrained ripple
- Single-point band (notching and peaking)
- Forced gain

- Arbitrary shape frequency response curve filters

`b = fircband(n,f,a,w,c)` designs filters having constrained error magnitudes (ripples). `c` is a cell array of strings of the same length as `w`. The entries of `c` must be either `'c'` to indicate that the corresponding element in `w` is a constraint (the ripple for that band cannot exceed that value) or `'w'` indicating that the corresponding entry in `w` is a weight. There must be at least one unconstrained band — `c` must contain at least one **`w`** entry. For instance, Example 1 below uses a weight of one in the passband, and constrains the stopband ripple not to exceed 0.2 (about 14 dB).

A hint about using constrained values: if your constrained filter does not touch the constraints, increase the error weighting you apply to the unconstrained bands.

Notice that, when you work with constrained stopbands, you enter the stopband constraint according to the standard conversion formula for power — the resulting filter attenuation or constraint equals 20*log(*constraint*) where *constraint* is the value you enter in the function. For example, to set 20 dB of attenuation, use a value for the constraint equal to 0.1. This applies to constrained stopbands only.

`b = fircband(n,f,a,s)` is used to design filters with special properties at certain frequency points. `s` is a cell array of strings and must be the same length as `f` and `a`. Entries of `s` must be one of:

- `'`**`n`**`'` — normal frequency point.
- `'`**`s`**`'` — single-point band. The frequency band is given by a single point. You must specify the corresponding gain at this frequency point in `a`.
- `'`**`f`**`'` — forced frequency point. Forces the gain at the specified frequency band to be the value specified.
- `'`**`i`**`'` — indeterminate frequency point. Use this argument when bands abut one another (no transition region).

`b = fircband(...,'1')` designs a type 1 filter (even-order symmetric). You could also specify type 2 (odd-order symmetric), type 3 (even-order antisymmetric), or type 4 (odd-order antisymmetric) filters. Note there are restrictions on `a` at `f` = 0 or `f` = 1 for types 2, 3, and 4.

`b = fircband(...,'`**`minphase`**`')` designs a minimum-phase FIR filter. There is also '**`maxphase`**'.

`b = fircband(..., '`**`check`**`')` produces a warning when there are potential transition-region anomalies in the filter response.

`b = fircband(...,{lgrid})`, where {`lgrid`} is a scalar cell array containing an integer, controls the density of the frequency grid.

`[b,err] = fircband(...)` returns the unweighted approximation error magnitudes. `err` has one element for each independent approximation error.

`[b,err,res] = fircband(...)` returns a structure `res` of optional results computed by `fircband`, and contains the following fields:

Structure Field	Contents
`res.fgrid`	Vector containing the frequency grid used in the filter design optimization
`res.des`	Desired response on `fgrid`
`res.wt`	Weights on `fgrid`
`res.h`	Actual frequency response on the frequency grid
`res.error`	Error at each point (desired response - actual response) on the frequency grid
`res.iextr`	Vector of indices into `fgrid` of external frequencies
`res.fextr`	Vector of extremely frequencies
`res.order`	Filter order
`res.edgecheck`	Transition-region anomaly check. One element per band edge. Element values have the following meanings: 1 = OK , 0 = probable transition-region anomaly , -1 = edge not checked. Computed when you specify the `'check'` input option in the function syntax.
`res.iterations`	Number of Remez iterations for the optimization
`res.evals`	Number of function evaluations for the optimization

Examples

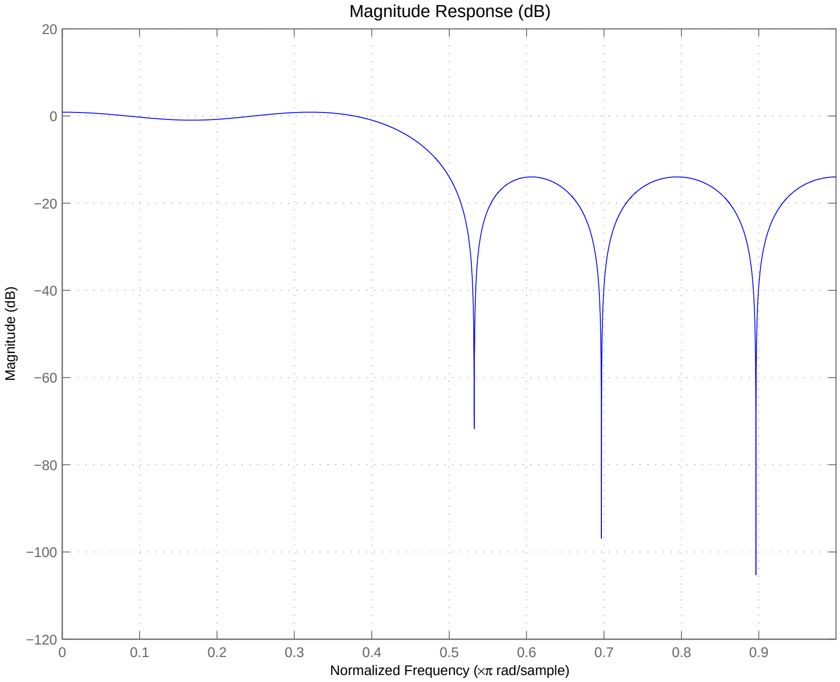
Two examples of designing filters with constrained bands.

Example 1

design a 12th-order lowpass filter with a constraint on the filter response.

```
b = fircband(12,[0 0.4 0.5 1], [1 1 0 0], ...
[1 0.2], {'w' 'c'});
```

Using `fvtool` to display the result `b` shows you the response of the filter you designed.



Example 2

design two filters of different order with the stopband constrained to 60 dB. Use excess order (80) in the second filter to improve the passband ripple.

```
b1=fircband(60,[0 .2 .25 1],[1 1 0 0],...
[1 .001],{'w','c'});
b2=fircband(80,[0 .2 .25 1],[1 1 0 0],...
[1 .001],{'w','c'});
hfvt = fvtool(b1,1,b2,1);
legend(hfvt,'Filter Order 60','Filter Order 80');
```

To set the stopband constraint to 60 dB, enter `0.001`, since 20*log(0.001) = -60, or 60 dB of signal attenuation.

fireqint

Equiripple FIR interpolators

Syntax

```
b = fireqint(n,l,alpha)
b = fireqint(n,l,alpha,w)
b = fireqint('minorder',l,alpha,r)
b = fireqint({'minorder',initord},l,alpha,r)
```

Description

`b = fireqint(n,l,alpha)` designs an FIR equiripple filter useful for interpolating input signals. `n` is the filter order and it must be an integer. `l`, also an integer, is the interpolation factor. `alpha` is the bandlimitedness factor, identical to the same feature in `intfilt`.

`alpha` is inversely proportional to the transition bandwidth of the filter. It also affects the bandwidth of the don't-care regions in the stopband. Specifying `alpha` allows you to control how much of the Nyquist interval your input signal occupies. This can be beneficial for signals to be interpolated because it allows you to increase the transition bandwidth without affecting the interpolation, resulting in better stopband attenuation for a given `l`. If you set `alpha` to 1, `fireqint` assumes that your signal occupies the entire Nyquist interval. Setting `alpha` to a value less than one allows for don't-care regions in the stopband. For example, if your input occupies half the Nyquist interval, you could set `alpha` to 0.5.

The signal to be interpolated is assumed to have zero (or negligible) power in the frequency band between (`alpha*π`) and π. `alpha` must therefore be a positive scalar between 0 and 1. `fireqint` treat such bands as don't-care regions for assessing filter design.

`b = fireqint(n,l,alpha,w)` allows you to specify a vector of weights in `w`. The number of weights required in `w` is given by 1 + `floor`(l/2). The weights in `w` are applied to the passband ripple and stopband attenuations. Using weights (values between 0 and 1) enables you to specify different attenuations in different parts of the stopband, as well as providing the ability to adjust the compromise between passband ripple and stopband attenuation.

`b = fireqint('`**`minorder`**`',l,alpha,r)` allows you to design a minimum-order filter that meets the design specifications. `r` is a vector of maximum deviations or ripples from the ideal filter magnitude response. When you use the input argument **`minorder`**, you must provide the vector `r`. The number of elements required in `r` is given by 1 + `floor`(`l`/2).

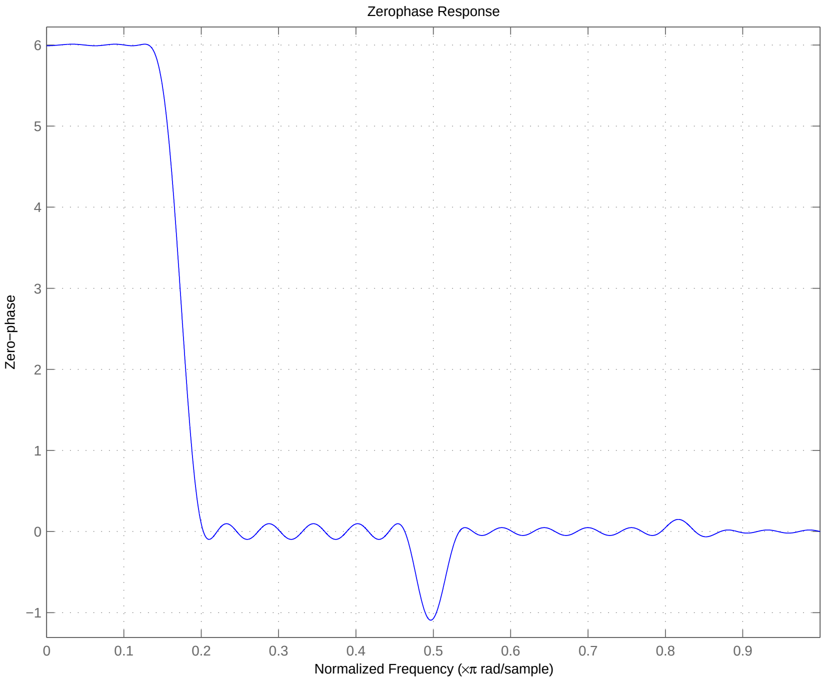
`b = fireqint({'`**`minorder`**`',initord},l,alpha,r)` adds the argument `initord` so you can provide an initial estimate of the filter order. Any positive integer is valid here. Again, you must provide `r`, the vector of maximum deviations or ripples, from the ideal filter magnitude response.

Examples

Design a minimum order interpolation filter for `l` = 6 and `alpha` = 0.8. A vector of ripples must be supplied with the input argument **`minorder`**.

```
b = fireqint('minorder',6,.8,[0.01 .1 .05 .02]);
hm = mfilt.firinterp(6,b); % Create a polyphase interpolator filter
zerophase(hm);
```

Here is the resulting plot of the zerophase response for `hm`.



For hm, the minimum order filter with the requested design specifications, here is the filter information.

```
hm =

FilterStructure: 'Direct-Form FIR Polyphase Interpolator'
         Arithmetic: 'double'
          Numerator: [1x70 double]
InterpolationFactor: 6
  PersistentMemory: false
```

firceqrip

Constrained equiripple FIR filter

Syntax

```
B = firceqrip(n,Fo,DEV)
B = firceqrip(...,'slope',r)
B = firceqrip(...,'passedge')
B = firceqrip(...,'stopedge')
B = firceqrip(...,'high')
B = firceqrip(...,'min')
B = firceqrip(...,'invsinc',C)
B = firceqrip(...,'invdiric',C)
```

Description

`B = firceqrip(n,Fo,DEV)` designs an order `n` filter (filter length equal `n` + 1) lowpass FIR filter with linear phase.

`firceqrip` produces the same equiripple lowpass filters that `firpm` produces using the Parks-McClellan algorithm. The difference is how you specify the filter characteristics for the function.

The input argument `Fo` specifies the frequency at the upper edge of the passband in normalized frequency (0<`Fo`<1). The two-element vector `dev` specifies the peak or maximum error allowed in the passband and stopbands. Enter `[d1 d2]` for `dev` where `d1` sets the passband error and `d2` sets the stopband error.

`B = firceqrip(...,'slope',r)` uses the input keyword '`slope`' and input argument `r` to design a filter with a nonequiripple stopband. `r` is specified as a positive constant and determines the slope of the stopband attenuation in dB/normalized frequency. Greater values of `r` result in increased stopband attenuation in dB/normalized frequency.

`B = firceqrip(...,'passedge')` designs a filter where `Fo` specifies the frequency at which the passband starts to rolloff.

`B = firceqrip(...,'stopedge')` designs a filter where `Fo` specifies the frequency at which the stopband begins.

`B = firceqrip(...,'high')` designs a high pass FIR filter instead of a lowpass filter.

`B = firceqrip(...,'min')` designs a minimum-phase filter.

`B = firceqrip(...,'invsinc',C)` designs a lowpass filter whose magnitude response has the shape of an inverse sinc function. This may be used to compensate for sinc-like responses in the frequency domain such as the effect of the zero-order hold in a D/A converter. The amount of compensation in the passband is controlled by `C`, which is specified as a scalar or two-element vector. The elements of `C` are specified as follows:

- If `C` is supplied as a real-valued scalar or the first element of a two-element vector, `firceqrip` constructs a filter with a magnitude response of 1/sinc(`C*`**`pi`**`*F`) where `F` is the normalized frequency.
- If `C` is supplied as a two-element vector, the inverse-sinc shaped magnitude response is raised to the positive power `C(2)`. If we set `P=C(2)`, `firceqrip` constructs a filter with a magnitude response 1/sinc(`C*`**`pi`**`*F`)^{P}.

If this FIR filter is used with a cascaded integrator-comb (CIC) filter, setting `C(2)` equal to the number of stages compensates for the multiplicative effect of the successive sinc-like responses of the CIC filters.

Note: Since the value of the inverse sinc function becomes unbounded at `C=1/F`, the value of `C` should be greater the reciprocal of the passband edge frequency. This can be expressed as `Fo<1/C`. For users familiar with CIC decimators, `C` is equal to 1/2 the product of the differential delay and decimation factor.

`B = firceqrip(...,'invdiric',C)` designs a lowpass filter with a passband that has the shape of an inverse Dirichlet sinc function. The frequency response of the inverse Dirichlet sinc function is given by

$$\{rC(\frac{\sin(f/2r)}{\sin(Cf/2)}\}^{p}$$

where *C*, *r*, and *p* are scalars. The input `C` can be a scalar or vector containing 2 or 3 elements. If `C` is a scalar, `p` and `r` equal 1. If `C` is a two-element vector, the first element is `C` and the second element is `p`, `[C p]`. If `C` is a three-element vector, the third element is `r`, `[C p r]`.

Examples

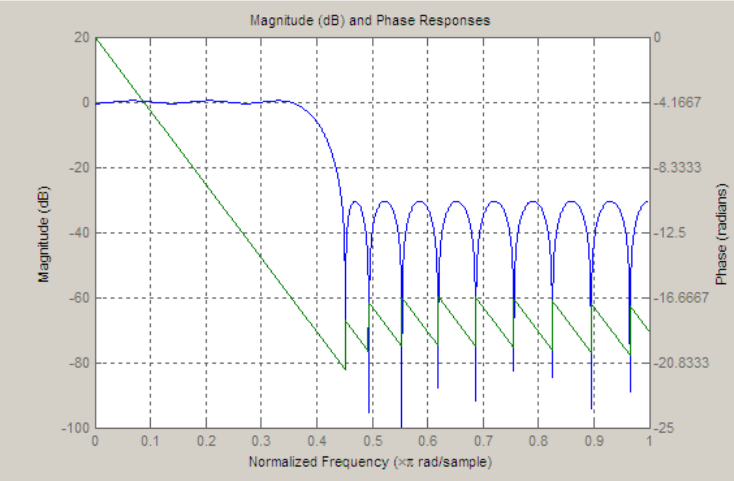
To introduce a few of the variations on FIR filters that you design with `firceqrip`, these five examples cover both the default syntax `b = firceqrip(n,wo,del)` and some of the optional input arguments. For each example, the input arguments `n`, `wo`, and `del` remain the same.

Example 1

Design an order = 30 FIR filter.

```
b = firceqrip(30,0.4,[0.05 0.03]); fvtool(b)
```

When the plot appears in the Filter Visualization Tool window, select **Analysis > Overlay Analysis > Phase Response**. Then select **View > Full View**. This displays the following plot.



Example 2

Design an order = 30 FIR filter with the `stopedge` keyword to define the response at the edge of the filter stopband.

```
b = firceqrip(30,0.4,[0.05 0.03],'stopedge'); fvtool(b)
```

Example 3

Design an order = 30 FIR filter with the `slope` keyword and r = 20.

```
b = firceqrip(30,0.4,[0.05 0.03],'slope',20,'stopedge'); fvtool(b)
```

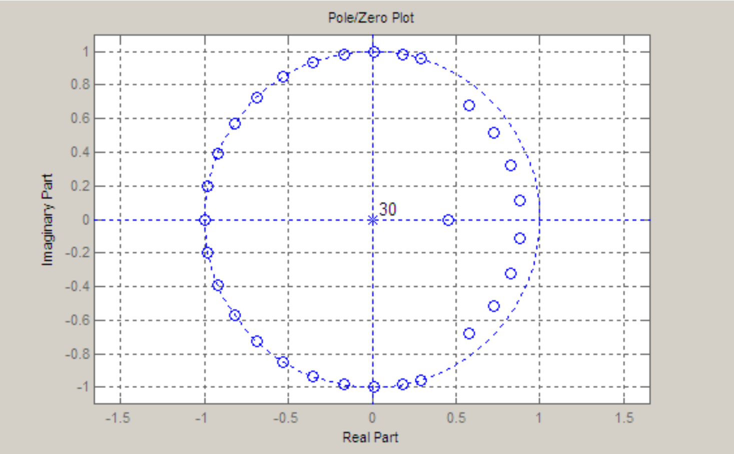
Example 4

Design an order = 30 FIR filter defining the stopband and specifying that the resulting filter is minimum phase with the **`min`** keyword.

```
b = firceqrip(30,0.4,[0.05 0.03],'stopedge','min'); fvtool(b)
```

Comparing this filter to the filter in Example 1, the cutoff frequency `wo` = `0.4` now applies to the edge of the stopband rather than the point at which the frequency response magnitude is 0.5.

Viewing the zero-pole plot shown here reveals this is a minimum phase FIR filter — the zeros lie on or inside the unit circle, z = 1.

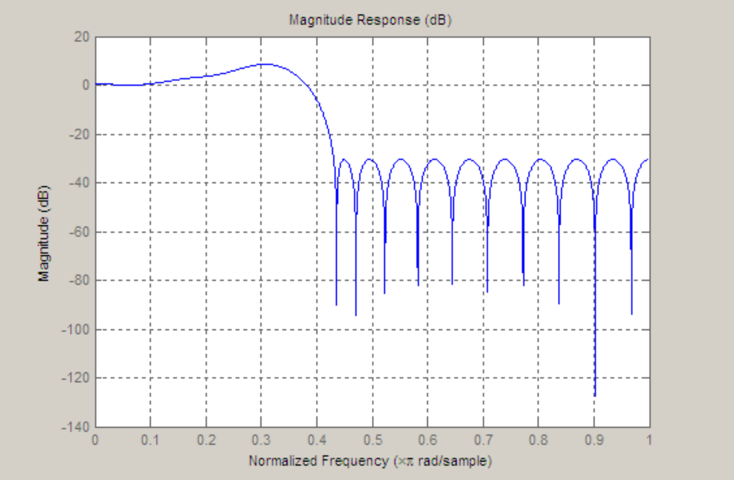


Example 5

Design an order = 30 FIR filter with the `invsinc` keyword to shape the filter passband with an inverse sinc function.

```
b = firceqrip(30,0.4,[0.05 0.03],'invsinc',[2 1.5]); fvtool(b)
```

With the inverse sinc function being applied defined as 1/sinc(2*w)$^{1.5}$, the figure shows the reshaping of the passband that results from using the **invsinc** keyword option, and entering c as the two-element vector [2 1.5].



Inverse-Dirichlet-Sinc–Shaped Passband

Design two order 30 constrained equiripple FIR filters with inverse-Dirichlet-sinc-shaped passbands. The cutoff frequency in both designs is π/4 radians/sample. Set C=1 in one design C=2 in the second design. The maximum passband and stopband ripple is 0.05. Set p=1 in one design and p=2 in the second design.

Design the filters.

```
b1 = firceqrip(30,0.25,[0.05 0.05],'invdiric',[1 1]);
b2 = firceqrip(30,0.25,[0.05 0.05],'invdiric',[2 2]);
```

Obtain the filter frequency responses using freqz. Plot the magnitude responses.

```
[h1,~] = freqz(b1,1);
[h2,w] = freqz(b2,1);
plot(w,abs(h1)); hold on;
plot(w,abs(h2),'r');
axis([0 pi 0 1.5]);
xlabel('Radians/sample');
ylabel('Magnitude');
```

```
legend('C=1 p=1','C=2 p=2');
```

Inspect the stopband ripple in the design with `C=1` and `p=1`. The constrained design sets the maximum ripple to be 0.05. Zoom in on the stopband from the cutoff frequency of π/4 radians/sample to 3π/4 radians/sample.

```
figure;
plot(w,abs(h1));
set(gca,'xlim',[pi/4 3*pi/4]);
grid on;
```

fircls

FIR Constrained Least Squares filter

Syntax

```
hd = design(d,'fircls')
hd = design(d,'fircls','FilterStructure',value)
hd = design(d,'fircls','PassbandOffset',value)
hd = design(d,'fircls','zerophase',value)
```

Description

`hd = design(d,'fircls')` designs a FIR Constrained Least Squares (CLS) filter, `hd`, from a filter specifications object, `d`.

`hd = design(d,'fircls','FilterStructure',value)` where `value` is one of the following filter structures:

- `'dffir'`, a discrete-time, direct-form FIR filter (the default value)
- `'dffirt'`, a discrete-time, direct-form FIR transposed filter
- `'dfsymfir'`, a discrete-time, direct-form symmetric FIR filter
- `'fftfir'`, a discrete-time, overlap-add, FIR filter

`hd = design(d,'fircls','PassbandOffset',value)` where `value` sets the passband band gain in dB. The `PassbandOffset` and `Ap` values affect the upper and lower approximation bound in the passband as follows:

- Lower bound = (`PassbandOffset`-Ap/2)
- Upper bound = (`PassbandOffset`+A/2)

For bandstop filters, the `PassbandOffset` is a vector of length two that specifies the first and second passband gains. The `PassbandOffset` value defaults to 0 for lowpass, highpass and bandpass filters. The `PassbandOffset` value defaults to [0 0] for bandstop filters.

`hd = design(d,'fircls','zerophase',value)` where `value` is either `'true'` ('1') or `'false'` ('0') . If `zerophase` is true, the lower approximation bound in the stopband is forced to zero (i.e., the filter has a zero phase response). Zerophase is false (0) by default.

To determine the available design options, use `designopts` with the specification object and the design method as input arguments as shown.

```
designopts(d,'fircls')
```

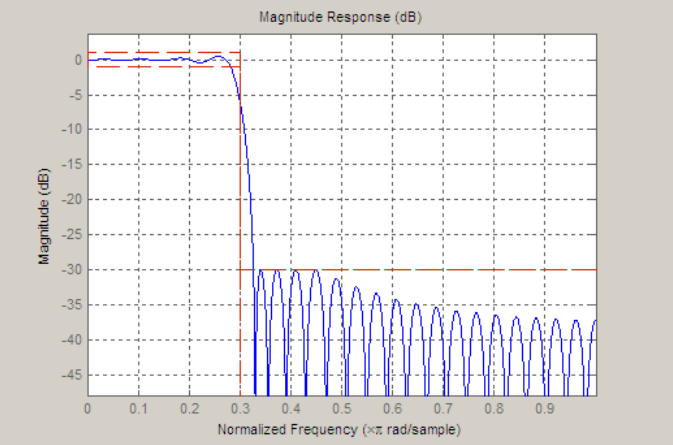
For complete help about using `fircls`, refer to the command line help system. For example, to get specific information about using `fircls` with `d`, the specification object, enter the following at the MATLAB prompt.

```
help(d,'fircls')
```

Examples

The following example designs a constrained least-squares FIR lowpass filter.

```
h  = fdesign.lowpass('n,fc,ap,ast', 50, 0.3, 2, 30);
Hd = design(h, 'fircls');
fvtool(Hd)
```



The following example constructs a constrained least-squares FIR bandpass filter.

```
d = fdesign.bandpass('N,Fc1,Fc2,Ast1,Ap,Ast2',...
30,0.4,0.6,60,1,60);
```

```
Hd = design(d, 'fircls');
fvtool(Hd)
```

firgr

Parks-McClellan FIR filter

Syntax

```
b = firgr(n,f,a,w)
b = firgr(n,f,a,'hilbert')
b = firgr(m,f,a,r),
b = firgr({m,ni},f,a,r)
b = firgr(n,f,a,w,e)
b = firgr(n,f,a,s)
b = firgr(n,f,a,s,w,e)
b = firgr(...,'1')
b = firgr(...,'minphase')
b = firgr(..., 'check')
b = firgr(...,{lgrid}),
[b,err] = firgr(...)
[b,err,res] = firgr(...)
b = firgr(n,f,fresp,w)
b = firgr(n,f,{fresp,p1,p2,...},w)
b = firgr(n,f,a,w)
```

Description

`firgr` is a minimax filter design algorithm you use to design the following types of real FIR filters:

- Types 1-4 linear phase:
  - Type 1 is even order, symmetric
  - Type 2 is odd order, symmetric
  - Type 3 is even order, antisymmetric
  - Type 4 is odd order, antisymmetric
- Minimum phase
- Maximum phase

- Minimum order (even or odd)
- Extra ripple
- Maximal ripple
- Constrained ripple
- Single-point band (notching and peaking)
- Forced gain
- Arbitrary shape frequency response curve filters

`b = firgr(n,f,a,w)` returns a length `n+1` linear phase FIR filter which has the best approximation to the desired frequency response described by `f` and `a` in the minimax sense. `w` is a vector of weights, one per band. When you omit `w`, all bands are weighted equally. For more information on the input arguments, refer to `firpm` in *Signal Processing Toolbox User's Guide*.

`b = firgr(n,f,a,'hilbert')` and `b = firgr(n,f,a,'differentiator')` design FIR Hilbert transformers and differentiators. For more information on designing these filters, refer to `firpm` in *Signal Processing Toolbox User's Guide*.

`b = firgr(m,f,a,r),` where `m` is one of '`minorder`', '`mineven`' or '`minodd`', designs filters repeatedly until the minimum order filter, as specified in `m`, that meets the specifications is found. `r` is a vector containing the peak ripple per frequency band. You must specify `r`. When you specify '`mineven`' or '`minodd`', the minimum even or odd order filter is found.

`b = firgr({m,ni},f,a,r)` where `m` is one of '`minorder`', '`mineven`' or '`minodd`', uses `ni` as the initial estimate of the filter order. `ni` is optional for common filter designs, but it must be specified for designs in which `firpmord` cannot be used, such as while designing differentiators or Hilbert transformers.

`b = firgr(n,f,a,w,e)` specifies independent approximation errors for different bands. Use this syntax to design extra ripple or maximal ripple filters. These filters have interesting properties such as having the minimum transition width. `e` is a cell array of strings specifying the approximation errors to use. Its length must equal the number of bands. Entries of `e` must be in the form '`e#`' where `#` indicates which approximation error to use for the corresponding band. For example, when `e = {'e1','e2','e1'}`, the first and third bands use the same approximation error `'e1'` and the second band uses a different one `'e2'`. Note that when all bands use the same approximation error, such as `{'e1','e1','e1',...}`, it is equivalent to omitting `e`, as in `b = firgr(n,f,a,w)`.

`b = firgr(n,f,a,s)` is used to design filters with special properties at certain frequency points. `s` is a cell array of strings and must be the same length as `f` and `a`. Entries of `s` must be one of:

- `'n'` — normal frequency point.
- `'s'` — single-point band. The frequency "band" is given by a single point. The corresponding gain at this frequency point must be specified in `a`.
- `'f'` — forced frequency point. Forces the gain at the specified frequency band to be the value specified.
- `'i'` — indeterminate frequency point. Use this argument when adjacent bands abut one another (no transition region).

For example, the following command designs a bandstop filter with zero-valued single-point stop bands (notches) at 0.25 and 0.55.

```
b = firgr(42,[0 0.2 0.25 0.3 0.5 0.55 0.6 1],...
[1 1 0 1 1 0 1 1],{'n' 'n' 's' 'n' 'n' 's' 'n' 'n'})
```

`b = firgr(82,[0 0.055 0.06 0.1 0.15 1],[0 0 0 0 1 1],...{'n' 'i' 'f' 'n' 'n' 'n'})` designs a highpass filter with the gain at 0.06 forced to be zero. The band edge at 0.055 is indeterminate since the first two bands actually touch. The other band edges are normal.

`b = firgr(n,f,a,s,w,e)` specifies weights and independent approximation errors for filters with special properties. The weights and properties are included in vectors `w` and `e`. Sometimes, you may need to use independent approximation errors to get designs with forced values to converge. For example,

```
b = firgr(82,[0 0.055 0.06 0.1 0.15 1], [0 0 0 0 1 1],...
{'n' 'i' 'f' 'n' 'n' 'n'}, [10 1 1] ,{'e1' 'e2' 'e3'});
```

`b = firgr(...,'1')` designs a type 1 filter (even-order symmetric). You can specify type 2 (odd-order symmetric), type 3 (even-order antisymmetric), and type 4 (odd-order antisymmetric) filters as well. Note that restrictions apply to `a` at f = 0 or f = 1 for FIR filter types 2, 3, and 4.

`b = firgr(...,'minphase')` designs a minimum-phase FIR filter. You can use the argument `'maxphase'` to design a maximum phase FIR filter.

`b = firgr(..., 'check')` returns a warning when there are potential transition-region anomalies.

`b = firgr(...,{lgrid})`, where `{lgrid}` is a scalar cell array. The value of the scalar controls the density of the frequency grid by setting the number of samples used along the frequency axis.

`[b,err] = firgr(...)` returns the unweighted approximation error magnitudes. `err` contains one element for each independent approximation error returned by the function.

`[b,err,res] = firgr(...)` returns the structure `res` comprising optional results computed by `firgr`. `res` contains the following fields.

Structure Field	Contents
`res.fgrid`	Vector containing the frequency grid used in the filter design optimization
`res.des`	Desired response on `fgrid`
`res.wt`	Weights on `fgrid`
`res.h`	Actual frequency response on the frequency grid
`res.error`	Error at each point (desired response - actual response) on the frequency grid
`res.iextr`	Vector of indices into `fgrid` of external frequencies
`res.fextr`	Vector of external frequencies
`res.order`	Filter order
`res.edgecheck`	Transition-region anomaly check. One element per band edge. Element values have the following meanings: 1 = OK, 0 = probable transition-region anomaly, -1 = edge not checked. Computed when you specify the `'check'` input option in the function syntax.
`res.iterations`	Number of `s` iterations for the optimization
`res.evals`	Number of function evaluations for the optimization

`firgr` is also a “function function,” allowing you to write a function that defines the desired frequency response.

`b = firgr(n,f,fresp,w)` returns a length N + 1 FIR filter which has the best approximation to the desired frequency response as returned by the user-defined function `fresp`. Use the following `firgr` syntax to call `fresp`:

```
[dh,dw] = fresp(n,f,gf,w)
```

where:

- `fresp` is the string variable that identifies the function that you use to define your desired filter frequency response.
- `n` is the filter order.
- `f` is the vector of frequency band edges which must appear monotonically between 0 and 1, where 1 is one-half of the sampling frequency. The frequency bands span `f(k)` to `f(k+1)` for `k` odd. The intervals `f(k+1)` to `f(k+2)` for `k` odd are "transition bands" or "don't care" regions during optimization.
- `gf` is a vector of grid points that have been chosen over each specified frequency band by `firgr`, and determines the frequencies at which `firgr` evaluates the response function.
- `w` is a vector of real, positive weights, one per band, for use during optimization. `w` is optional in the call to `firgr`. If you do not specify `w`, it is set to unity weighting before being passed to `fresp`.
- `dh` and `dw` are the desired frequency response and optimization weight vectors, evaluated at each frequency in grid `gf`.

`firgr` includes a predefined frequency response function named `'firpmfrf2'`. You can write your own based on the simpler `'firpmfrf'`. See the help for `private/firpmfrf` for more information.

`b = firgr(n,f,{`*`fresp`*`,p1,p2,...},w)` specifies optional arguments `p1`, `p2`,..., `pn` to be passed to the response function `fresp`.

`b = firgr(n,f,a,w)` is a synonym for `b = firgr(n,f,{'firpmfrf2',a},w)`, where `a` is a vector containing your specified response amplitudes at each band edge in `f`. By default, `firgr` designs symmetric (even) FIR filters. `'firpmfrf2'` is the predefined frequency response function. If you do not specify your own frequency response function (the `fresp` string variable), `firgr` uses '`firpmfrf2'`.

`b = firgr(...,'h')` and `b = firgr(...,'d')` design antisymmetric (odd) filters. When you omit the `'h'` or `'d'` arguments from the `firgr` command syntax, each frequency response function `fresp` can tell `firgr` to design either an even or odd filter. Use the command syntax `sym = `*`fresp`*`('defaults',{n,f,[],w,p1,p2,...})`.

`firgr` expects `fresp` to return `sym = 'even'` or `sym = 'odd'`. If `fresp` does not support this call, `firgr` assumes even symmetry.

For more information about the input arguments to `firgr`, refer to `firpm`.

Examples

These examples demonstrate some filters you might design using `firgr`.

Example 1

design an FIR filter with two single-band notches at 0.25 and 0.55

```
b1 = firgr(42,[0 0.2 0.25 0.3 0.5 0.55 0.6 1],[1 1 0 1 1 0 1 1],...
{'n' 'n' 's' 'n' 'n' 's' 'n' 'n'});
```

Example 2

design a highpass filter whose gain at 0.06 is forced to be zero. The gain at 0.055 is indeterminate since it should abut the band.

```
b2 = firgr(82,[0 0.055 0.06 0.1 0.15 1],[0 0 0 0 1 1],...
{'n' 'i' 'f' 'n' 'n' 'n'});
```

Example 3

design a second highpass filter with forced values and independent approximation errors.

```
b3 = firgr(82,[0 0.055 0.06 0.1 0.15 1], [0 0 0 0 1 1], ...
{'n' 'i' 'f' 'n' 'n' 'n'}, [10 1 1] ,{'e1' 'e2' 'e3'});
```

Use the filter visualization tool to view the results of the filters created in these examples.

```
fvtool(b1,1,b2,1,b3,1)
```

Here is the figure from FVTool.

firhalfband

Halfband FIR filter

Syntax

```
b = firhalfband(n,fp)
b = firhalfband(n,win)
b = firhalfband(n,dev,'dev')
b = firhalfband('minorder',fp,dev)
b = firhalfband('minorder',fp,dev,'kaiser')
b = firhalfband(...,'high')
b = firhalfband(...,'minphase')
```

Description

`b = firhalfband(n,fp)` designs a lowpass halfband FIR filter of order `n` with an equiripple characteristic. `n` must be an even integer. `fp` determines the passband edge frequency, and it must satisfy 0 < `fp` < 1/2, where 1/2 corresponds to $\pi/2$ rad/sample.

`b = firhalfband(n,win)` designs a lowpass Nth-order filter using the truncated, windowed-impulse response method instead of the equiripple method. `win` is an `n +1` length vector. The ideal impulse response is truncated to length `n + 1`, and then multiplied point-by-point with the window specified in `win`.

`b = firhalfband(n,dev,'dev')` designs an Nth-order lowpass halfband filter with an equiripple characteristic. Input argument `dev` sets the value for the maximum passband and stopband ripple allowed.

`b = firhalfband('minorder',fp,dev)` designs a lowpass minimum-order filter, with passband edge `fp`. The peak ripple is constrained by the scalar `dev`. This design uses the equiripple method.

`b = firhalfband('minorder',fp,dev,'kaiser')` designs a lowpass minimum-order filter, with passband edge `fp`. The peak ripple is constrained by the scalar `dev`. This design uses the Kaiser window method.

`b = firhalfband(...,'high')` returns a highpass halfband FIR filter.

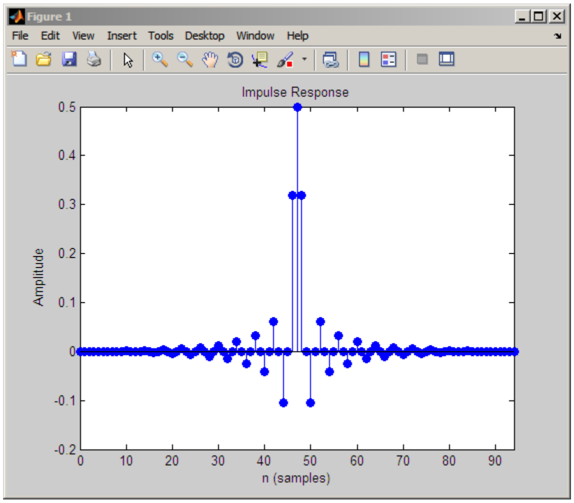
b = firhalfband(...,'**minphase**') designs a minimum-phase FIR filter such that the filter is a spectral factor of a halfband filter (recall that h = conv(b,fliplr(b)) is a halfband filter). This can be useful for designing perfect reconstruction, two-channel FIR filter banks. The **minphase** option for firhalfband is not available for the window-based halfband filter designs — b = firhalfband(n,win) and b = firhalfband('**minorder** ',fp,dev,'**kaiser**').

In the minimum phase cases, the filter order must be odd.

Examples

This example designs a minimum order halfband filter with specified maximum ripple:

```
b = firhalfband('minorder',.45,0.0001);
h = dfilt.dfsymfir(b);
impz(b) % Impulse response is zero for every other sample
```



The next example designs a halfband filter with specified maximum ripple of 0.0001 dB in the pass and stop bands.

```
b = firhalfband(98,0.0001,'dev');
h = mfilt.firdecim(2,b); % Create a polyphase decimator
freqz(h); % 80 dB attenuation in the stopband
```

firlp2lp

Convert FIR Type I lowpass to FIR Type 1 lowpass with inverse bandwidth

Syntax

```
g = firlp2lp(b)
```

Description

`g = firlp2lp(b)` transforms the Type I lowpass FIR filter `b` with zero-phase response Hr(w) to a Type I lowpass FIR filter `g` with zero-phase response [1 - Hr(π-w)].

When `b` is a narrowband filter, `g` will be a wideband filter and vice versa. The passband and stopband ripples of `g` will be equal to the stopband and passband ripples of `b`.

Examples

Overlay the original narrowband lowpass and the resulting wideband lowpass

```
b = firgr(36,[0 .2 .25 1],[1 1 0 0],[1 5]);
zerophase(b);
hold on
h = firlp2lp(b);
zerophase(h);
```

`firlp2hp` | `zerophase`

firlp2hp

Convert FIR lowpass filter to Type I FIR highpass filter

Syntax

```
g = firlp2hp(b)
g = firlp2hp(b,'narrow')
g = firlp2hp(b,'wide')
```

Description

`g = firlp2hp(b)` transforms the lowpass FIR filter `b` into a Type I highpass FIR filter `g` with zero-phase response Hr(π-w). Filter `b` can be any FIR filter, including a nonlinear-phase filter.

The passband and stopband ripples of `g` will be equal to the passband and stopband ripples of `b`.

`g = firlp2hp(b,'narrow')` transforms the lowpass FIR filter `b` into a Type I narrow band highpass FIR filter `g` with zero-phase response Hr(π-w). `b` can be any FIR filter, including a nonlinear-phase filter.

`g = firlp2hp(b,'wide')` transforms the Type I lowpass FIR filter `b` with zero-phase response Hr(w) into a Type I wide band highpass FIR filter `g` with zero-phase response 1 - Hr(w). Note the restriction that b must be a Type I linear-phase filter.

For this case, the passband and stopband ripples of `g` will be equal to the stopband and passband ripples of `b`.

Examples

Overlay the original narrowband lowpass (the prototype filter) and the post-conversion narrowband highpass and wideband highpass filters to compare and assess the conversion. The following plot shows the results.

```
b = firgr(36,[0 .2 .25 1],[1 1 0 0],[1 3]);
```

```
h = firlp2hp(b);
hfvt = fvtool(b,1,h,1);
legend(hfvt,'Prototype Lowpass','Narrowband Highpass');

firlpnorm

Least P-norm optimal FIR filter

Syntax

```
b = firlpnorm(n,f,edges,a)
b = firlpnorm(n,f,edges,a,w)
b = firlpnorm(n,f,edges,a,w,p)
b = firlpnorm(n,f,edges,a,w,p,dens)
b = firlpnorm(n,f,edges,a,w,p,dens,initnum)
b = firlpnorm(...,'minphase')
[b,err] = firlpnorm(...)
```

Description

`b = firlpnorm(n,f,edges,a)` returns a filter of numerator order `n` which represents the best approximation to the frequency response described by `f` and `a` in the least-Pth norm sense. P is set to 128 by default, which essentially equivalent to the infinity norm. Vector `edges` specifies the band-edge frequencies for multiband designs. `firlpnorm` uses an unconstrained quasi-Newton algorithm to design the specified filter.

`f` and `a` must have the same number of elements, which can exceed the number of elements in `edges`. This lets you specify filters with any gain contour within each band. However, the frequencies in `edges` must also be in vector `f`. Always use `freqz` to check the resulting filter.

Note `firlpnorm` uses a nonlinear optimization routine that may not converge in some filter design cases. Furthermore the algorithm is not well-suited for certain large-order (order > 100) filter designs.

`b = firlpnorm(n,f,edges,a,w)` uses the weights in `w` to weight the error. `w` has one entry per frequency point (the same length as `f` and `a`) which tells `firlpnorm` how much emphasis to put on minimizing the error in the vicinity of each frequency point relative to the other points. For example,

```
b = firlpnorm(20,[0 .15 .4 .5 1],[0 .4 .5 1],...
[1 1.6 1 0 0],[1 1 1 10 10])
```

designs a lowpass filter with a peak of 1.6 within the passband, and with emphasis placed on minimizing the error in the stopband.

`b = firlpnorm(n,f,edges,a,w,p)` where `p` is a two-element vector [`pmin pmax`] lets you specify the minimum and maximum values of `p` used in the least-pth algorithm. Default is `[2 128]` which essentially yields the L-infinity, or Chebyshev, norm. `pmin` and `pmax` should be even numbers. The design algorithm starts optimizing the filter with `pmin` and moves toward an optimal filter in the `pmax` sense. When `p` is the string '**`inspect`**', `firlpnorm` does not optimize the resulting filter. You might use this feature to inspect the initial zero placement.

`b = firlpnorm(n,f,edges,a,w,p,dens)` specifies the grid density `dens` used in the optimization. The number of grid points is [`dens*(n+1)`]. The default is 20. You can specify `dens` as a single-element cell array. The grid is equally spaced.

`b = firlpnorm(n,f,edges,a,w,p,dens,initnum)` lets you determine the initial estimate of the filter numerator coefficients in vector `initnum`. This can prove helpful for difficult optimization problems. The pole-zero editor in Signal Processing Toolbox software can be used for generating `initnum`.

`b = firlpnorm(...,'minphase')` where string '`minphase`' is the last argument in the argument list generates a minimum-phase FIR filter. By default, `firlpnorm` design mixed-phase filters. Specifying input option '`minphase`' causes `firlpnorm` to use a different optimization method to design the minimum-phase filter. As a result of the different optimization used, the minimum-phase filter can yield slightly different results.

`[b,err] = firlpnorm(...)` returns the least-pth approximation error `err`.

Examples

To demonstrate `firlpnorm`, here are two examples — the first designs a lowpass filter and the second a highpass, minimum-phase filter.

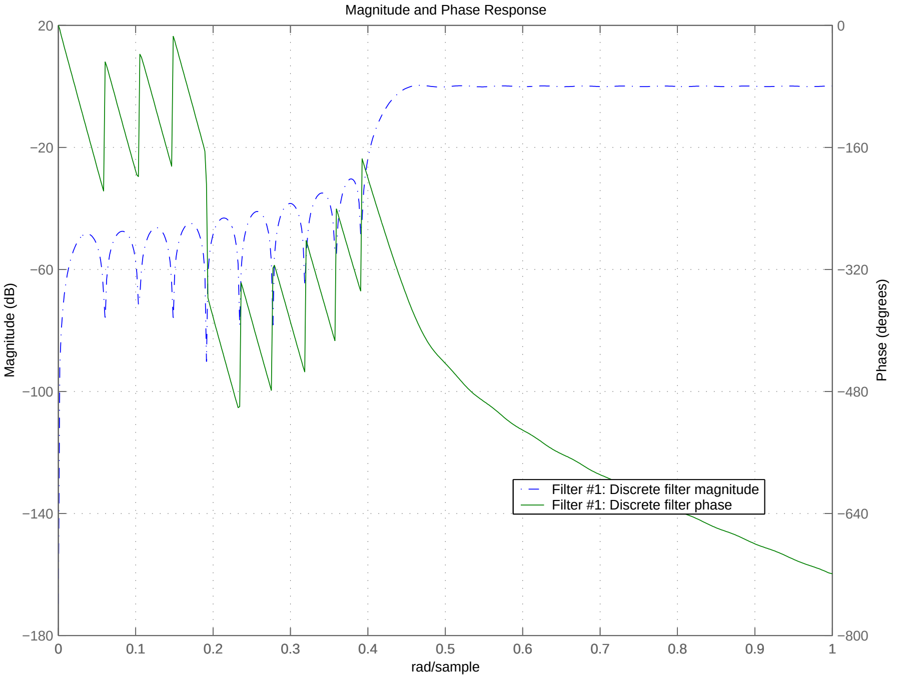
```
% Lowpass filter with a peak of 1.4 in the passband.
b = firlpnorm(22,[0 .15 .4 .5 1],[0 .4 .5 1],[1 1.4 1 0 0],...
[1 1 1 2 2]);
fvtool(b)
```

From the figure you see the resulting filter is lowpass, with the desired 1.4 peak in the passband (notice the 1.4 specified in vector a).

Now for the minimum-phase filter.

```
% Highpass minimum-phase filter optimized for the 4-norm.
b = firlpnorm(44,[0 .4 .45 1],[0 .4 .45 1],[0 0 1 1],[5 1 1 1],...
[2 4],'minphase');
fvtool(b)
```

As shown in the next figure, this is a minimum-phase, highpass filter.



The next zero-pole plot shows the minimum phase nature more clearly.

firls

Least-square linear-phase FIR filter design

Syntax

```
b = firls(n,f,a)
b = firls(n,f,a,w)
b = firls(n,f,a,ftype)
b = firls(n,f,a,w,ftype)
```

Description

`b = firls(n,f,a)` returns row vector `b` containing the `n+1` coefficients of the order `n` FIR filter. This filter has frequency-amplitude characteristics approximately matching those given by vectors, `f` and `a`.

`b = firls(n,f,a,w)` uses the weights in vector `w`, to weigh the error.

`b = firls(n,f,a,ftype)` specifies a filter type where `ftype` is:

- `'hilbert'`
- `'differentiator'`

`b = firls(n,f,a,w,ftype)` uses the weights in vector `w` to weigh the error. It also specifies a filter type where `ftype` is:

- `'hilbert'`
- `'differentiator'`

Examples

Design a Lowpass Filter with Transition Band

The following illustrates how to design a lowpass filter of order 225 with transition band.

Create the frequency and amplitude vectors, `f` and `a`.

```
f = [0 0.25 0.3 1]
a = [1 1 0 0]
```

Use `firls` to obtain the `n+1` coefficients of the order `n` lowpass FIR filter.

```
b = firls(255,f,a);
```

Design an Antisymmetric Filter with Piecewise Linear Passbands

The following shows how to design a 24th-order anti-symmetric filter with piecewise linear passbands, and plot the desired and actual amplitude responses.

Create the frequency and amplitude vectors, `f` and `a`.

```
f = [0 0.3 0.4 0.6 0.7 0.9];
a = [0 1 0 0 0.5 0.5];
```

Use `firls` to obtain the 25 coefficients of the filter.

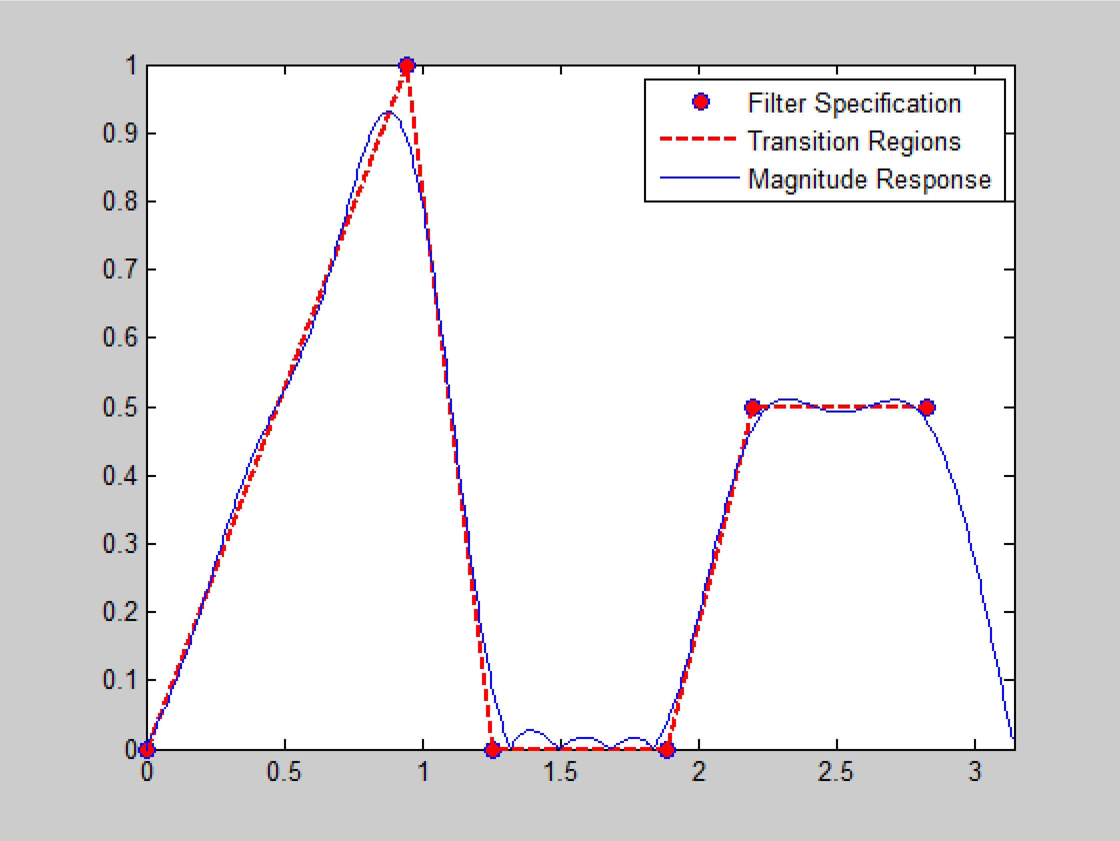
```
b = firls(24,f,a,'hilbert');
```

Plot the ideal amplitude response along with the transition regions.

```
plot(f.*pi,a,'o','markerfacecolor',[1 0 0]);
hold on;
plot(f.*pi,a,'r--','linewidth',2);
```

Use `freqz` to obtain the frequency response of the designed filter and plot the magnitude response of the filter.

```
[H,F] = freqz(b,1);
plot(F,abs(H));
set(gca,'xlim',[0 pi])
legend('Filter Specification','Transition Regions','Magnitude Response')
```



Input Arguments

n — Filter order

(default) | integer scalar

Order of the filter, specified as an integer scalar. For odd orders, the frequency response at the Nyquist frequency is necessarily 0. For this reason, `firls` always uses an even filter order for configurations with a passband at the Nyquist frequency. If you specify an odd-valued `n`, `firls` increments it by 1.

Example: 8

Data Types: `int8` | `int16` | `int32` | `int64`

`f` — Pairs of frequency points

vector of numeric values

Pairs of frequency points, specified as a vector of values ranging between 0 and 1, where 1 corresponds to the Nyquist frequency. The frequencies must be in increasing order, and duplicate frequency points are allowed. You can use duplicate frequency points to design filters exactly like those returned by the `fir1` and `fir2` functions with a rectangular (`rectwin`) window.

`f` and `a` are the same length. This length must be an even number.

Example: `[0 0.3 0.4 1]`

Data Types: `double` | `single`

`a` — Amplitude values

vector of numeric values

Amplitude values of the function at each frequency point, specified as a vector of the same length as `f`. This length must be an even number.

The desired amplitude at frequencies between pairs of points ($f(k)$, $f(k+1)$) for k odd, is the line segment connecting the points ($f(k)$, $a(k)$) and ($f(k+1)$, $a(k+1)$).

The desired amplitude at frequencies between pairs of points ($f(k)$, $f(k+1)$) for k even is unspecified. These are transition or “don't care” regions.

Example: `[1 1 0 0]`

Data Types: `double` | `single`

`w` — Weights

vector of numeric values

Weights to weigh the fit for each frequency band, specified as a vector of length half the length of `f` and `a`, so there is exactly one weight per band. `w` indicates how much emphasis to put on minimizing the integral squared error in each band, relative to the other bands.

Example: `[0.5 1]`

Data Types: `double` | `single`

`ftype` — Filter type

`'hilbert'` and `'differentiator'`

Filter type, specified as either `‘hilbert’` or `‘differentiator’`.

Example: ‘hilbert’

Data Types: `char`

Output Arguments

`b` — Filter coefficients

vector of numeric values

Filter coefficients, returned as a numeric vector of `n+1` values, where `n` is the filter order.

`b = firls(n,f,a)` designs a linear-phase filter of type I (`n` odd) and type II (`n`) . The output coefficients, or “taps,” in `b` obey the relation:
b(k) = b(n+2-k), k = 1, ... , n + 1

`b = firls(n,f,a,'hilbert')` designs a linear-phase filter with odd symmetry (type III and type IV). The output coefficients, or “taps,” in `b` obey the relation:
b(k) = –b(n+2-k), k = 1, ... , n + 1

`b = firls(n,f,a,'differentiator')` designs type III and type IV filters, using a special weighting technique. For nonzero amplitude bands, the integrated squared error has a weight of $(1/f)^2$. This weighting causes the error at low frequencies to be much smaller than at high frequencies. For FIR differentiators, which have an amplitude characteristic proportional to frequency, the filters minimize the relative integrated squared error. This value is the integral of the square of the ratio of the error to the desired amplitude.

More About

Diagnostics

Error and warning messages

One of the following diagnostic messages is displayed when an incorrect argument is used:

```
F must be even length.
F and A must be equal lengths.
Requires symmetry to be 'hilbert' or 'differentiator'.
Requires one weight per band.
Frequencies in F must be nondecreasing.
Frequencies in F must be in range [0,1].
```

A more serious warning message is

```
Warning: Matrix is close to singular or badly scaled.
```

This tends to happen when the product of the filter length and transition width grows large. In this case, the filter coefficients b might not represent the desired filter. You can check the filter by looking at its frequency response.

Algorithms

`firls` designs a linear-phase FIR filter. This filter minimizes the weighted, integrated squared error between an ideal piecewise linear function and the magnitude response of the filter over a set of desired frequency bands.

Reference [1] describes the theoretical approach behind `firls`. The function solves a system of linear equations involving an inner product matrix of size roughly `n/2` using the MATLAB \ operator.

This function designs type I, II, III, and IV linear-phase filters. Type I and II are the defaults for n even and odd respectively. The `'hilbert'` and `'differentiator'` flags produce type III (n even) and IV (n odd) filters. The various filter types have different symmetries and constraints on their frequency responses (see [2] for details).

Linear Phase Filter Type	Filter Order	Symmetry of Coefficients	Response H(f), f = 0	Response H(f), f = 1 (Nyquist)
Type I	Even	b(k) = b(n+2-k), k=1,..., n+1	No restriction	No restriction
Type II	Even	b(k) = b(n+2-k), k=1,..., n+1	No restriction	$H(1) = 0$
Type III	Odd	b(k) = –b(n+2-k), k=1,..., n+1	$H(0) = 0$	$H(1) = 0$
Type IV	Odd	b(k) = –b(n+2-k), k=1,..., n+1	$H(0) = 0$	No restriction

firminphase

Minimum-phase FIR spectral factor

Syntax

```
h = firminphase(b)
h = firminphase(b,nz)
```

Description

`h = firminphase(b)` computes the minimum-phase FIR spectral factor `h` of a linear-phase FIR filter `b`. Filter `b` must be real, have even order, and have nonnegative zero-phase response.

`h = firminphase(b,nz)` specifies the number of zeros, `nz`, of `b` that lie on the unit circle. You must specify `nz` as an even number to compute the minimum-phase spectral factor because every root on the unit circle must have even multiplicity. Including `nz` can help `firminphase` calculate the required FIR spectral factor. Zeros with multiplicity greater than two on the unit circle cause problems in the spectral factor determination.

Note You can find the maximum-phase spectral factor, `g`, by reversing `h`, such that *g = fliplr(h)*, and *b = conv(h, g)*.

Examples

This example designs a constrained least squares filter with a nonnegative zero-phase response, and then uses `firminphase` to compute the minimum-phase spectral factor.

```
f   = [0 0.4 0.8 1];
a   = [0 1 0];
up  = [0.02 1.02  0.01];
lo  = [0 0.98 0]; % The zeros insure nonnegative zero-phase resp.
n   = 32;
b   = fircls(n,f,a,up,lo);
h   = firminphase(b);
```

`firgr` | `fircls` | `zerophase`

firnyquist

Lowpass Nyquist (Lth-band) FIR filter

Syntax

```
b = firnyquist(n,l,r)
b = firnyquist('minorder',l,r,dev)
b = firnyquist(n,l,r,decay)
b = firnyquist(n,l,r,'nonnegative')
b = firnyquist(n,l,r,'minphase')
```

Description

`b = firnyquist(n,l,r)` designs an Nth order, Lth band, Nyquist FIR filter with a rolloff factor `r` and an equiripple characteristic.

The rolloff factor `r` is related to the normalized transition width `tw` by $tw = 2\pi(r/l)$ (rad/sample). The order, `n`, must be even. `l` must be an integer greater than one. If `l` is not specified, it defaults to `4`. `r` must satisfy `0< r < 1`. If `r` is not specified, it defaults to `0.5`.

`b = firnyquist('minorder',l,r,dev)` designs a minimum-order, Lth band Nyquist FIR filter with a rolloff factor `r` using the Kaiser window. The peak ripple is constrained by the scalar `dev`.

`b = firnyquist(n,l,r,decay)` designs an Nth order (`n`), Lth band (`l`), Nyquist FIR filter where the scalar `decay`, specifies the rate of decay in the stopband. `decay` must be nonnegative. If you omit or leave it empty, `decay` defaults to `0` which yields an equiripple stopband. A nonequiripple stopband (`decay` $\neq$0) may be desirable for decimation purposes.

`b = firnyquist(n,l,r,'nonnegative')` returns an FIR filter with nonnegative zero-phase response. This filter can be spectrally factored into minimum-phase and maximum-phase “square-root” filters. This allows you to use the spectral factors in applications such as matched-filtering.

`b = firnyquist(n,l,r,'minphase')` returns the minimum-phase spectral factor `bmin` of order `n`. `bmin` meets the condition `b=conv(bmin,bmax)` so that `b` is an

Lth band FIR Nyquist filter of order 2n with filter rolloff factor r. Obtain bmax, the maximum phase spectral factor by reversing the coefficients of bmin. For example, bmax = bmin(end:-1:1).

Examples

Example 1

This example designs a minimum phase factor of a Nyquist filter.

```
bmin = firnyquist(47,10,.45,'minphase');
b = firnyquist(2*47,10,.45,'nonnegative');
[h,w,s] = freqz(b); hmin = freqz(bmin);
fvtool(b,1,bmin,1);
```

Example 2

This example compares filters with different decay rates.

```
b1 = firnyquist(72,8,.3,0); % Equiripple
b2 = firnyquist(72,8,.3,15);
b3 = firnyquist(72,8,.3,25);
fvtool(b1,1,b2,1,b3,1);
```

[h0,h1,g0,g1] = firpr2chfb(n,dev,'dev')
[h0,h1,g0,g1] = firpr2chfb('minorder',fp,dev)
```

Description

`[h0,h1,g0,g1] = firpr2chfb(n,fp)` designs four FIR filters for the analysis sections (`h0` and `h1`) and synthesis section is (`g0` and `g1`) of a two-channel perfect reconstruction filter bank. The design corresponds to the orthogonal filter banks also known as power-symmetric filter banks.

`n` is the order of all four filters. It must be an odd integer. `fp` is the passband-edge for the lowpass filters `h0` and `g0`. The passband-edge argument `fp` must be less than 0.5. `h1` and `g1` are highpass filters with the passband-edge given by (1-`fp`).

`[h0,h1,g0,g1] = firpr2chfb(n,dev,'dev')` designs the four filters such that the maximum stopband ripple of `h0` is given by the scalar `dev`. Specify `dev` in linear units, not decibels. The stopband-ripple of `h1` is also be given by `dev`, while the maximum stopband-ripple for both `g0` and `g1` is (2*`dev`).

`[h0,h1,g0,g1] = firpr2chfb('minorder',fp,dev)` designs the four filters such that `h0` meets the passband-edge specification `fp` and the stopband-ripple `dev` using minimum order filters to meet the specification.

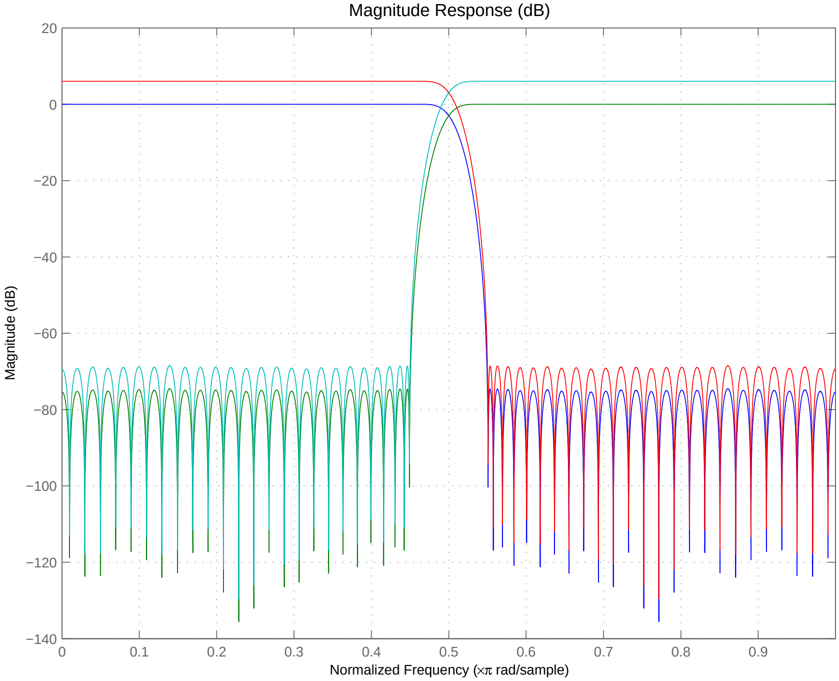
Examples

Design a filter bank with filters of order `n` equal to 99 and passband edges of 0.45 and 0.55.

```
n = 99;
```

```
[h0,h1,g0,g1] = firpr2chfb(n,.45);
fvtool(h0,1,h1,1,g0,1,g1,1);
```

Here are the filters, showing clearly the passband edges.



Use the following stem plots to verify perfect reconstruction using the filter bank created by `firpr2chfb`.

```
stem(1/2*conv(g0,h0)+1/2*conv(g1,h1))
n=0:n;
stem(1/2*conv((-1).^n.*h0,g0)+1/2*conv((-1).^n.*h1,g1))
stem(1/2*conv((-1).^n.*g0,h0)+1/2*conv((-1).^n.*g1,h1))
stem(1/2*conv((-1).^n.*g0,(-1).^n.*h0)+...
1/2*conv((-1).^n.*g1,(-1).^n.*h1))
stem(conv((-1).^n.*h1,h0)-conv((-1).^n.*h0,h1))
```

firtype

Type of linear phase FIR filter

Syntax

```
t = firtype(b)
t = firtype(d)
```

Description

`t = firtype(b)` determines the type, t, of an FIR filter with coefficients b. t can be 1, 2, 3, or 4. The filter must be real and have linear phase.

`t = firtype(d)` determines the type, t, of an FIR filter, `d`. t can be 1, 2, 3, or 4. The filter must be real and have linear phase.

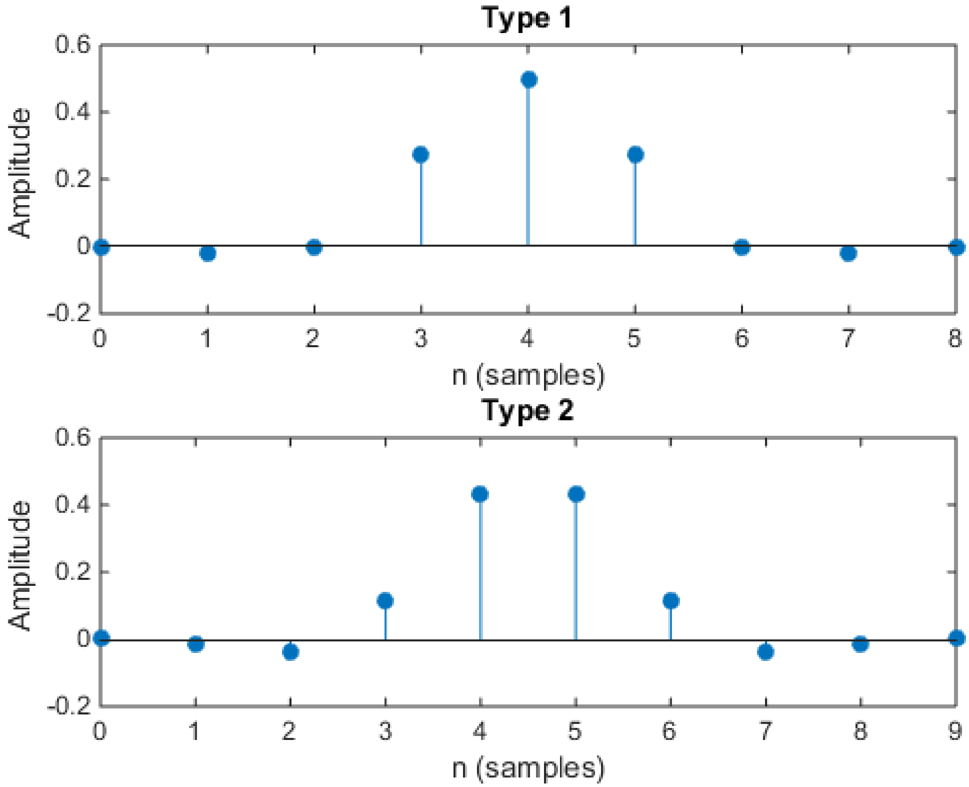
Examples

Types of Linear Phase Filters

Design two FIR filters using the window method, one of even order and the other of odd order. Determine their types and plot their impulse responses.

```
subplot(2,1,1)
b = fir1(8,0.5);
impz(b), title(['Type ' int2str(firtype(b))])

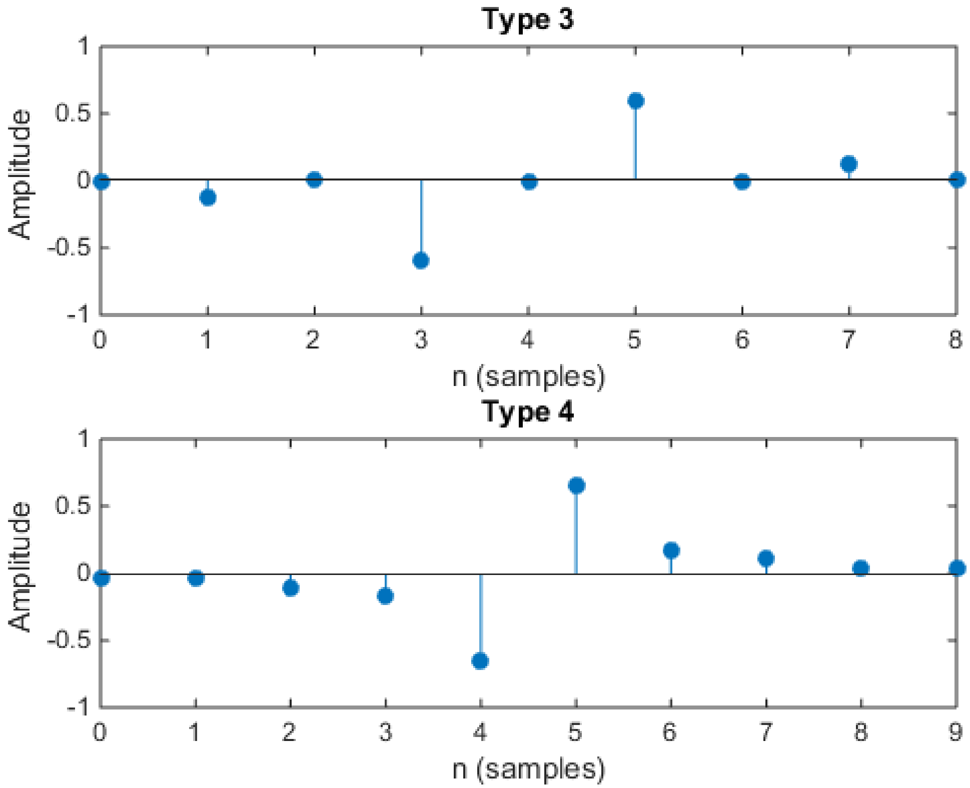
subplot(2,1,2)
b = fir1(9,0.5);
impz(b), title(['Type ' int2str(firtype(b))])
```



Design two equiripple Hilbert transformers, one of even order and the other of odd order. Determine their types and plot their impulse responses.

```
subplot(2,1,1)
b = firpm(8,[0.2 0.8],[1 1],'hilbert');
impz(b), title(['Type ' int2str(firtype(b))])

subplot(2,1,2)
b = firpm(9,[0.2 0.8],[1 1],'hilbert');
impz(b), title(['Type ' int2str(firtype(b))])
```



Types of FIR digitalFilter Objects

Use `designfilt` to design the filters from the previous example. Display their types.

```
d1 = designfilt('lowpassfir','DesignMethod','window', ...
                'FilterOrder',8,'CutoffFrequency',0.5);
disp(['d1 is of type ' int2str(firtype(d1))])
d2 = designfilt('lowpassfir','DesignMethod','window', ...
                'FilterOrder',9,'CutoffFrequency',0.5);
disp(['d2 is of type ' int2str(firtype(d2))])
d3 = designfilt('hilbertfir','DesignMethod','equiripple', ...
                'FilterOrder',8,'TransitionWidth',0.4);
disp(['d3 is of type ' int2str(firtype(d3))])
d4 = designfilt('hilbertfir','DesignMethod','equiripple', ...
                'FilterOrder',9,'TransitionWidth',0.4);
```

```
disp(['d4 is of type ' int2str(firtype(d4))])
```

```
d1 is of type 1
d2 is of type 2
d3 is of type 3
d4 is of type 4
```

Input Arguments

b — Filter coefficients

vector

Filter coefficients of the FIR filter, specified as a double- or single-precision real-valued row or column vector.

Data Types: `double` | `single`

d — FIR filter

`digitalFilter` object | filter System object | `dfilt` object | `mfilt` object

FIR filter, specified as any of the following:

- A `digitalFilter` object. Use `designfilt` to generate a digital filter based on frequency-response specifications.
- A Filter System object. You can use this input if you have a license for DSP System Toolbox software. `firtype` supports the following Filter System objects.

`dsp.AllpassFilter`
`dsp.AllpoleFilter`
`dsp.BiquadFilter`
`dsp.CICDecimator`
`dsp.CICInterpolator`
`dsp.CoupledAllpassFilter`
`dsp.FIRDecimator`
`dsp.FIRFilter`
`dsp.FIRInterpolator`
`dsp.FIRRateConverter`

```
dsp.IIRFilter
```

- A `dfilt` filter object. You can use this input if you have a license for DSP System Toolbox software.
- A multirate `mfilt` filter object. You can use this input if you have a license for DSP System Toolbox software.

Output Arguments

`t` — Filter type

1 | 2 | 3 | 4

Filter type, returned as either 1, 2, 3, or 4. Filter types are defined as follows:

- Type 1 — Even-order symmetric coefficients
- Type 2 — Odd-order symmetric coefficients
- Type 3 — Even-order antisymmetric coefficients
- Type 4 — Odd-order antisymmetric coefficients

freqrespest

Frequency response estimate via filtering

Syntax

```
[h,w] = freqrespest(H,L)
[h,w] = freqrespest(H,L,param1,value1,param2,value2,...)
[h,w] = freqrespest(H,L,opts)
freqrespest(H,...)
```

Description

`[h,w] = freqrespest(H,L)` estimates the frequency response of a `dfilt` object or a filter System object. A set of input data is filtered and then forming the ratio between output data and input data. The test input data comprises sinusoids with uniformly distributed random frequencies.

Use this technique for comparing the performance of fixed-point filters to that of another filter type. You can, for example, compare fixed—point frequency response estimate to that of a similar filter that uses quantized coefficients, but applies floating-point arithmetic internally. Such comparison determines whether the fixed-point filter performance closely matches the floating-point, quantized coefficients version of the filter.

`L` is the number of trials to use to compute the estimate. If you do not specify this value, `L` defaults to 10. More trials generates a more accurate estimate of the response, but require more time to compute the estimate.

`h` is the estimate of the complex frequency response. `w` contains the vector of frequencies at which `h` is estimated.

`[h,w] = freqrespest(H,L,param1,value1,param2,value2,...)` accepts `H` as either a `dfilt` object or a filter System object. This approach uses parameter value (PV) pairs as input arguments to specify optional parameters for the test. These parameters are the valid PV pairs. Enter the parameter names as string input arguments in single quotation marks. The following table provides valid parameters for `[h, w]`.

Parameter Name	Default Value	Description
`NFFT`	`512`	Number of FFT points to use.
`NormalizedFrequency`	`true`	Indicate whether to use normalized frequency or linear frequency. Values are `true` (use normalized frequency), or `false` (use linear frequency). When you specify `false`, you must supply the sampling frequency `Fs`.
`Fs`	`normalized`	Specify the sampling frequency when `NormalizedFrequency` is `false`. No default value. You must set `NormalizedFrequency` to `false` before setting a value for `Fs`.
`SpectrumRange`	`half`	Specify the spectrum range to be used as `whole` or `half` (default).
`CenterDC`	`false`	Specify whether to set the center of the spectrum to the DC value in the output plot. If you select `true`, both the negative and positive values appear in the plot. If you select `false`, DC appears at the origin of the axes.
`Arithmetic (only for filter System objects)`	`ARITH`	Analyze the filter System object, based on the arithmetic specified in the `ARITH` input. `ARITH` can be set to `double`, `single`, or `fixed`. The analysis tool assumes a double-precision filter when the arithmetic input is not specified and the filter System object is in an unlocked state.

If `H` is a filter System object, `freqrespest` requires knowledge of the input data type. Analysis cannot be performed if the input data type is not available. If you do not specify the `Arithmetic` parameter, i.e., use the syntax `[h,w] = freqrespest(H)` , then the following rules apply for this method:

- The System object state is `Unlocked` — `freqrespest` performs double precision analysis.

- The System object state is Locked — freqrespest performs analysis based on the locked input data type.

When you do specify the Arithmetic parameter, i.e., use the syntax [h,w] = freqrespest(H,'Arithmetic', ARITH)), review the following rules for this method. Which rule applies depends on the value you set for the Arithmetic parameter.

Value	System Object State	Rule
ARITH = ’double’	Unlocked	freqrespest performs double-precision analysis.
	Locked	freqrespest performs double-precision analysis.
ARITH = ‘single’	Unlocked	freqrespest performs single-precision analysis.
	Locked	freqrespest performs single-precision analysis.
ARITH = ‘fixed’	Unlocked	freqrespest produces an error because the fixed-point input data type is unknown.
	Locked	If the input data type is double or single, then freqrespest produces an error because the fixed-point input data type is unknown.
		When the input data is of fixed-point type, freqrespest performs analysis based on the locked input data type.

The following Filter System objects are supported by this analysis function:

Filter System objects
dsp.FIRFilter
dsp.BiquadFilter
dsp.IIRFilter

Filter System objects
dsp.AllpoleFilter
dsp.AllpassFilter
dsp.CoupledAllpassFilter

Regardless of whether H is a dfilt object or a filter System object, [h,w] = freqrespest(H,L,opts) uses an object, opts, to specify the optional input parameters. This specification is not done directly by specifying PV pairs as input arguments. Create opts with

```
opts = freqrespopts(H);
```

Because opts is an object, you use set to change the parameter values in opts before you use it with freqrespest. For example, you could specify a new sample rate with

```
set(opts,'fs',48e3); % Same as opts.fs=48e3
```

Regardless of whether H is a dfilt object or a filter System object, freqrespest(H,...) with no output argument launches FVTool.

freqrespest can also compute the frequency response of double-precision floating filters. Such filters cannot be converted to transfer-function form without introducing significant round off errors which affect the freqz frequency response computation. Examples of these kinds of filters include state-space or lattice filters, especially if they are high-order filters.

Examples

These examples demonstrate some uses for freqrespest.

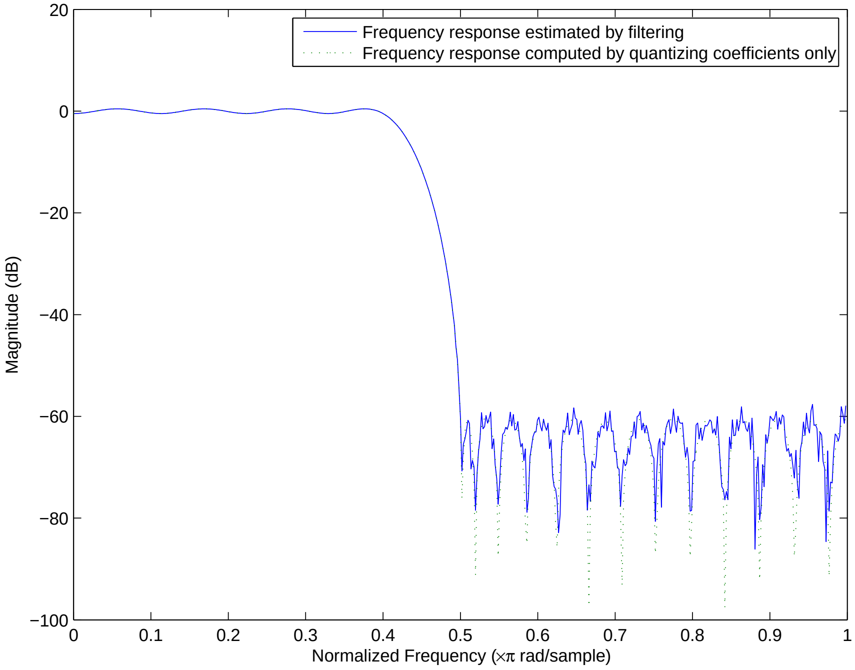
Example 1

Start by estimating the frequency response of a fixed-point FIR filter that has filter internals set to full precision.

```
hd = design(fdesign.lowpass(.4,.5,1,60),'equiripple');
hd.arithmetic = 'fixed';
[h,w] = freqrespest(hd); % This should be about the same as freqz.
```

Continuing with filter hd, change the value of the filterinternals property to specifyprecision and then specify the word lengths and precision (the fraction lengths) applied to the output from internal addition and multiplication operations. After you set the word and fraction lengths, use `freqrespest` to compute the frequency response estimate for the fixed-point filter.

```
hd.filterinternals = 'specifyprecision';
hd.outputwordlength=16;
hd.outputfraclength=15;
hd.productwordlength=16;
hd.productfraclength=15;
hd.accumwordlength=16;
hd.accumfraclength=15;
[h,w] = freqrespest(hd,2);
[h2,w2] = freqz(hd,512);
plot(w/pi,20*log10(abs([h,h2])))
legend('Frequency response estimated by filtering',...
'Freq. response computed by quantizing coefficients only');
xlabel('Normalized Frequency (\times\pi rad/sample)')
ylabel('Magnitude (dB)')
```



Example 2

freqrespest works with state-space filters as well. This example estimates the frequency response of a state-space filter.

```
fs = 315000;
wp = [320 3800]/(fs/2);
ws = [50 19000]/(fs/2);
rp=0.15; rs=60;
[n,wn]=cheb1ord(wp,ws,rp,rs);
[a,b,c,d] = cheby1(n,rp,wn);
hd = dfilt.statespace(a,b,c,d);
% Compare the following to freqz(hd,8192)
freqrespest(hd,1,'nfft',8192);
```

freqrespopts

Options for filter frequency response analysis

Syntax

```
opts = freqrespopts(H)
```

Description

`opts = freqrespopts(H)` uses the settings in the `dfilt` object or the filter System object, `H`, to create an object, `opts`. This object contains parameters and values for estimating the filter frequency response. You pass `opts` as an input argument to `freqrespest` to specify values for the input parameters.

`freqrespopts` allows you to use the same settings for `freqrespest` with multiple filters without specifying all of the parameters as input arguments to `freqrespest`.

The following Filter System objects are supported by this analysis function:

Filter System objects
`dsp.FIRFilter`
`dsp.BiquadFilter`
`dsp.IIRFilter`
`dsp.AllpoleFilter`
`dsp.AllpassFilter`
`dsp.CoupledAllpassFilter`

Examples

This example shows `freqrespopts` in use for setting options for `freqrespest`. `hd` and `hd2` are bandpass filters that use different design methods. The `opts` object makes it easier to set the same conditions for the frequency response estimate in `freqrespest`.

```
d=fdesign.bandpass('fst1,fp1,fp2,fst2,ast1,ap,ast2',...
0.25,0.3,0.45,0.5,60,0.1,60);

hd=design(d,'butter');
hd.arithmetic='fixed';
hd2=design(d,'cheby2')
hd2.arithmetic='fixed';
opts=freqrespopts(hd)

opts =

                   NFFT: 512
    NormalizedFrequency: true
                     Fs: 'Normalized'
          SpectrumRange: 'Half'
               CenterDC: false

opts.NFFT=256; % Same as set(opts,'nfft',256).
opts.NormalizedFrequency=false;
opts.fs=1.5e3;
opts.CenterDC=true

opts =

                   NFFT: 256
    NormalizedFrequency: false
                     Fs: 1500
          SpectrumRange: 'Whole'
               CenterDC: true
```

With `opts` configured as needed, use it as an input argument for `freqrespest`.

```
[h2,w2]=freqrespest(hd2,20,opts);
[h1,w1]=freqrespest(hd,20,opts);
```

See Also

`freqrespest` | `norm` | `scale` | `noisepsd` | `noisepsdopts`

freqsamp

Real or complex frequency-sampled FIR filter from specification object

Syntax

```
hd = design(d,'freqsamp')
hd = design(...,'filterstructure',structure)
hd = design(...,'window',window)
```

Description

`hd = design(d,'freqsamp')` designs a frequency-sampled filter specified by the filter specifications object `d`.

`hd = design(...,'filterstructure',structure)` returns a filter with the filter structure you specify by the `structure` input argument. `structure` is `dffir` by default and can be any one of the following filter structures.

Structure String	Description of Resulting Filter Structure
`dffir`	Direct-form FIR filter
`dffirt`	Transposed direct-form FIR filter
`dfsymfir`	Symmetrical direct-form FIR filter
`dfasymfir`	Asymmetrical direct-form FIR filter
`fftfir`	Fast Fourier transform FIR filter

`hd = design(...,'window',window)` designs filters using the window specified by the string in `window`. Provide the input argument `window` as

- A string for the window type. For example, use `'bartlett'`, or `'hamming'`. See `window` for the full list of windows available or refer to `window` in the *Signal Processing Toolbox User's Guide*.
- A function handle that references the `window` function. When the `window` function requires more than one input, use a cell array to hold the required arguments. The first example shows a cell array input argument.
- The window vector itself.

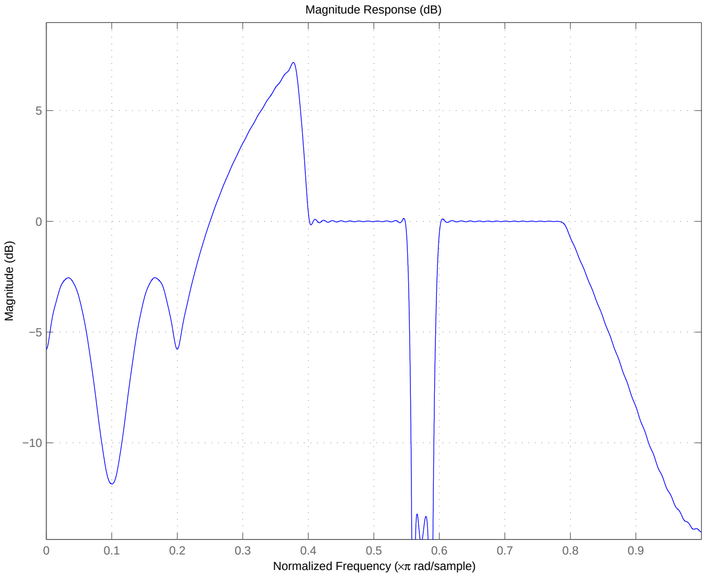
Examples

These examples design FIR filters that have arbitrary magnitude responses. In the first filter, the response has three distinct sections and the resulting filter is real.

The second example creates a complex filter.

```
b1 = 0:0.01:0.18;
b2 = [.2 .38 .4 .55 .562 .585 .6 .78];
b3 = [0.79:0.01:1];
a1 = .5+sin(2*pi*7.5*b1)/4;    % Sinusoidal response section.
a2 = [.5 2.3 1 1 -.2 -.2 1 1]; % Piecewise linear response section.
a3 = .2+18*(1-b3).^2;          % Quadratic response section.
f = [b1 b2 b3];
a = [a1 a2 a3];
n = 300;
d = fdesign.arbmag('n,f,a',n,f,a); % First specifications object.
hd = design(d,'freqsamp','window',{@kaiser,.5}); % Filter.
fvtool(hd)
```

The plot from FVTool shows the response for hd.



Now design the arbitrary-magnitude complex FIR filter. Recall that vector f contains frequency locations and vector a contains the desired filter response values at the locations specified in f.

```
f = [-1 -.93443 -.86885 -.80328 -.7377 -.67213 -.60656 -.54098 ...
-.47541,-.40984 -.34426 -.27869 -.21311 -.14754 -.081967 ...
-.016393 .04918 .11475,.18033 .2459 .31148 .37705 .44262 ...
 .5082 .57377 .63934 .70492 .77049,.83607 .90164 1];
a = [.0095848 .021972 .047249 .099869 .23119 .57569 .94032 ...
.98084 .99707,.99565 .9958 .99899 .99402 .99978 .99995 .99733 ...
.99731 .96979 .94936,.8196 .28502 .065469 .0044517 .018164 ...
.023305 .02397 .023141 .021341,.019364 .017379 .016061];
n = 48;
d = fdesign.arbmag('n,f,a',n,f,a); % Second spec. object.
hdc = design(d,'freqsamp','window','rectwin'); % Filter.
fvtool(hdc)
```

FVTool shows you the response for hdc from -1 to 1 in normalized frequency. design(d,...) returns a complex filter for hdc because the frequency vector includes negative frequency values.

freqz

Frequency response of filter

Syntax

```
[h,w] = freqz(hfilt)
[h,w] = freqz(hfilt,n)
freqz(hfilt)
[h,w] = freqz(hs)
[h,w] = freqz(hs,n)
[h,w] = freqz(hs,Name,Value)
freqz(hs)
```

Description

`freqz` returns the frequency response based on the current filter coefficients. This section describes common `freqz` operation with adaptive filters, discrete-time filters, multirate filters, and filter System objects. For more input options, refer to `freqz` in Signal Processing Toolbox documentation.

`[h,w] = freqz(hfilt)` returns the frequency response `h` and the corresponding frequencies `w` at which the filter response of `hfilt` is computed. The frequency response is evaluated at 8192 points equally spaced around the upper half of the unit circle.

`[h,w] = freqz(hfilt,n)` returns the frequency response `h` and corresponding frequencies `w` for the filter or vector of filters `hfilt`. The frequency response is evaluated at `n` points equally spaced around the upper half of the unit circle. `freqz` uses the transfer function associated with the filter to calculate the frequency response of the filter with the current coefficient values.

`freqz(hfilt)` uses FVTool to plot the magnitude and unwrapped phase of the frequency response of the filter `hfilt`. If `hfilt` is a vector of filters, `freqz` plots the magnitude response and phase for each filter in the vector.

`[h,w] = freqz(hs)` returns a frequency response for the filter System object hs using 8192 samples.

`[h,w] = freqz(hs,n)` returns a frequency response for the filter System object hs using `n` samples.

`[h,w] = freqz(hs,Name,Value)` returns a frequency response with additional options specified by one or more Name,Value pair arguments.

`freqz(hs)` uses FVTool to plot the magnitude and unwrapped phase of the frequency response of the filter System object `hs`.

Input Arguments

hfilt

`hfilt` is either:

- An adaptive `adaptfilt`, discrete-time `dfilt`, or multirate `mfilt` filter object
- A vector of adaptive, discrete-time, or multirate filter objects

hs

Filter System object.

The following Filter System objects are supported by this analysis function:

Filter System objects
`dsp.FIRFilter`
`dsp.FIRInterpolator`
`dsp.CICInterpolator`
`dsp.FIRDecimator`
`dsp.CICDecimator`
`dsp.FIRRateConverter`
`dsp.BiquadFilter`
`dsp.IIRFilter`
`dsp.AllpoleFilter`
`dsp.AllpassFilter`

Filter System objects
`dsp.CoupledAllpassFilter`

n

Number of samples. For an FIR filter where `n` is a power of two, the computation is done faster using FFTs.

Default: 8192

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'Arithmetic'` — Value types:
`‘double’ | 'single' | 'fixed'`

For filter System object inputs only, specify the arithmetic used during analysis. When you specify `'double'` or `'single'`, the function performs double- or single-precision analysis. When you specify `'fixed'` , the arithmetic changes depending on the setting of the `CoefficientDataType` property and whether the System object is locked or unlocked.

Details for Fixed-Point Arithmetic

System Object State	Coefficient Data Type	Rule
Unlocked	`'Same as input'`	The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Unlocked	`'Custom'`	The function performs fixed-point analysis based

System Object State	Coefficient Data Type	Rule
		on the setting of the `CustomCoefficientsDataType` property.
Locked	`'Same as input'`	When the input data type is `'double'` or `'fixed'`, the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Locked	`'Custom'`	The function performs fixed-point analysis based on the setting of the `CustomCoefficientsDataType` property.

When you do not specify the arithmetic for non-CIC structures, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type. CIC structures only support fixed-point arithmetic.

Output Arguments

h

Complex, `n`-element frequency response vector. If hfilt is a vector of filters, h is a complex, `length(hfilt)`-by-`n` matrix of frequency response vectors corresponding to each filter in hfilt. If `n` is not specified, the function uses a default value of 8192.

For adaptive filters, `h` is the instantaneous frequency response.

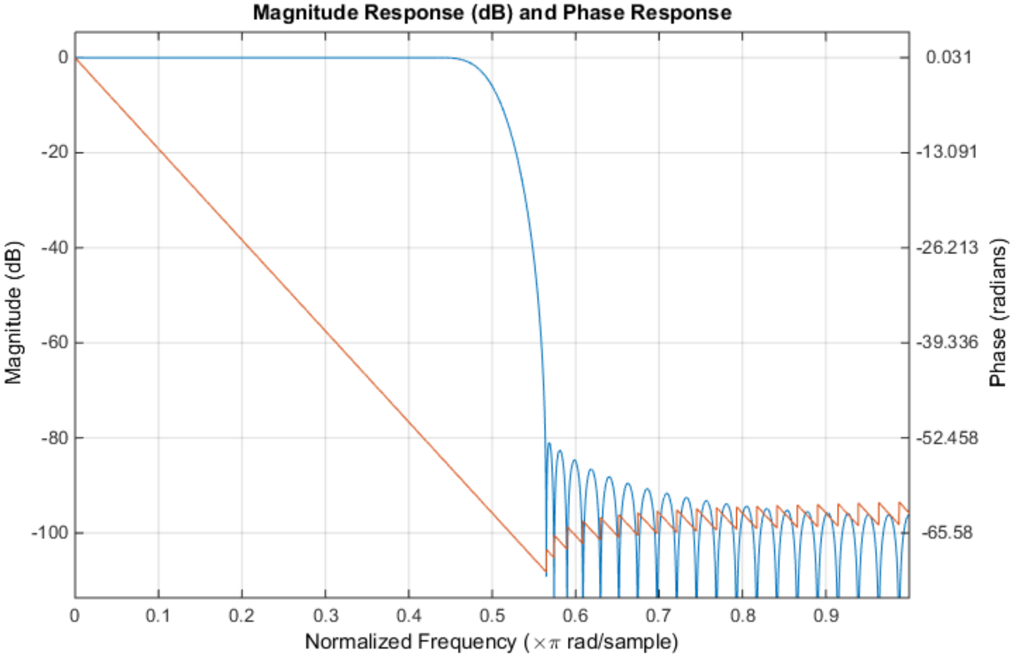
w

Frequency vector of length `n`, in radians/sample. `w` consists of `n` points equally spaced around the upper half of the unit circle (from 0 to π radians/sample). If `n` is not specified, the function uses a default value of 8192.

Examples

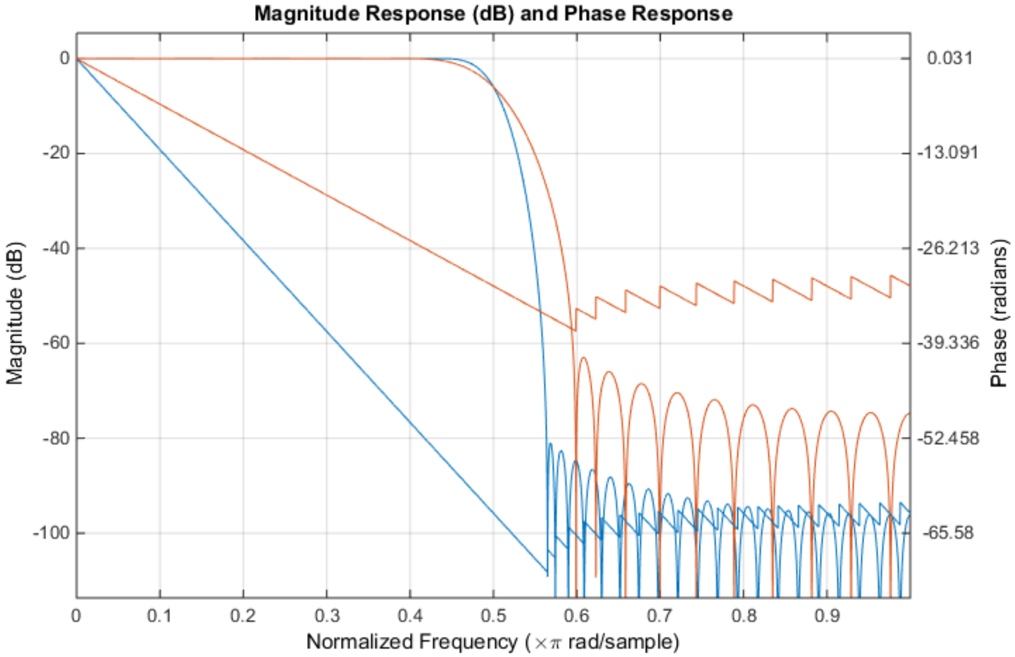
Plot the estimated frequency response of a filter. This example uses discrete-time filters, but `hd` can be any `adaptfilt` object, `dfilt` object, `mfilt` object, or filter System object. First plot the results for one filter.

```
b = fir1(80,0.5,kaiser(81,8));
hd = dfilt.dffir(b);
freqz(hd);
```



If you have more than one filter, you can plot them on the same figure using a vector of filters.

```
b = fir1(40,0.5,kaiser(41,6));
hd2 = dfilt.dffir(b);
h = [hd hd2];
freqz(h);
```



More About

Tips

There are several ways of analyzing the frequency response of filters. `freqz` accounts for quantization effects in the filter coefficients, but does not account for quantization effects in filtering arithmetic. To account for the quantization effects in filtering arithmetic, refer to function `noisepsd`.

Algorithms

`freqz` calculates the frequency response for a filter from the filter transfer function $Hq(z)$. The complex-valued frequency response is calculated by evaluating $Hq(e^{j\omega})$ at discrete values of w specified by the syntax you use. The integer input argument `n` determines the number of equally-spaced points around the upper half of the unit circle at which `freqz` evaluates the frequency response. The frequency ranges from 0 to π radians per sample when you do not supply a sampling frequency as an input argument. When you supply the scalar sampling frequency `fs` as an input argument to `freqz`, the frequency ranges from 0 to `fs`/2 Hz.

See Also

`adaptfilt` | `dfilt` | `mfilt` | `fvtool`

gain

CIC filter gain

Syntax

```
gain(hm)
gain(hm,j)
gain(hs)
```

Description

`gain(hm)` returns the gain of `hm`, the CIC decimation or interpolation filter.

When `hm` is a decimator, `gain` returns the gain for the overall CIC decimator.

When `hm` is an interpolator, the CIC interpolator inserts zeros into the input data stream, reducing the filter overall gain by $1/R$, where R is the interpolation factor, to account for the added zero valued samples. Therefore, the gain of a CIC interpolator is $(RM)^N/R$, where N is the number of filter sections and M is the filter differential delay. `gain(hm)` returns this value. The next example presents this case.

`gain(hm,j)` returns the gain of the `j`th section of a CIC interpolation filter. When you omit `j`, `gain` assumes that `j` is 2*N, where N is the number of sections, and returns the gain of the last section of the filter. This syntax does not apply when `hm` is a decimator.

`gain(hs)` returns the gain of the filter System object `hs`. The function supports the `dsp.CICDecimator` and `dsp.CICInterpolator` filter structures.

Examples

To compare the performance of two interpolators, one a CIC filter and the other an FIR filter, use gain to adjust the CIC filter output amplitude to match the FIR filter output amplitude. Start by creating an input data set—a sinusoidal signal `x`.

```
fs = 1000;          % Input sampling frequency.
```

```
t = 0:1/fs:1.5;     % Signal length = 1501 samples.
x = sin(2*pi*10*t); % Amplitude = 1 sinusoid.

l = 4; % Interpolation factor for FIR filter.
d = fdesign.interpolator(l);
hm = design(d,'multistage');
ym = filter(hm,x);

r = 4; % Interpolation factor for the CIC filter.
d = fdesign.interpolator(r,'cic');
hcic = design(d,'multisection');
ycic = filter(hcic,x);
gaincic = gain(hcic);
subplot(211);
plot(1:length(ym),[ym; double(ycic)]);
subplot(212)
plot(1:length(ym),[ym; double(ycic)/gain(hcic)]);
```

After correcting for the gain induced by the CIC interpolator, the figure shows the filters provide nearly identical interpolation.

`scale`

grpdelay

Filter group delay

Syntax

```
[gd,w]=grpdelay(hfilt)
[gd,w]=grpdelay(hfilt,n)
grpdelay(hfilt)
[gd,w] = grpdelay(hs)
[gd,w] = grpdelay(hs,n)
[gd,w] = grpdelay(hs,Name,Value)
grpdelay(hs)
```

Description

`grpdelay` returns the group delay based on the current filter coefficients. This section describes common `grpdelay` operation with adaptive filters, discrete-time filters, multirate filters, and filter System objects. For more input options, refer to `grpdelay` in Signal Processing Toolbox documentation.

`[gd,w]=grpdelay(hfilt)` returns the group delay, which is the derivative of the phase response `phi` of the filter `hfilt`, and the corresponding frequencies `w` at which the function evaluates the group delay. Group delay is

$$-\frac{d}{dw}(angle(w))$$

The group delay is evaluated at 8192 points equally spaced around the upper half of the unit circle.

`[gd,w]=grpdelay(hfilt,n)` returns the group delay `gd` of the filter `hfilt` and the corresponding frequencies `w` at which the function evaluates the group delay. The group delay is evaluated at n points equally spaced around the upper half of the unit circle.

`grpdelay(hfilt)` displays the group delay of `hfilt` in the Filter Visualization Tool (FVTool).

`[gd,w] = grpdelay(hs)` returns the group delay for the filter System object hs using 8192 samples.

`[gd,w] = grpdelay(hs,n)` returns the group delay for the filter System object hs using `n` samples.

`[gd,w] = grpdelay(hs,Name,Value)` returns the group delay with additional options specified by one or more Name,Value pair arguments.

`grpdelay(hs)` uses FVTool to plot the group delay of the filter System object `hs`.

Input Arguments

`hfilt`

`hfilt` is either:

- An adaptive `adaptfilt`, discrete-time `dfilt`, or multirate `mfilt` filter object
- A vector of adaptive, discrete-time, or multirate filter objects

`hs`

Filter System object.

The following Filter System objects are supported by this analysis function:

Filter System objects
`dsp.FIRFilter`
`dsp.FIRInterpolator`
`dsp.CICInterpolator`
`dsp.FIRDecimator`
`dsp.CICDecimator`
`dsp.FIRRateConverter`
`dsp.BiquadFilter`
`dsp.IIRFilter`
`dsp.AllpoleFilter`

Filter System objects
dsp.AllpassFilter
dsp.CoupledAllpassFilter

n

Number of samples. For an FIR filter where n is a power of two, the computation is done faster using FFTs.

Default: 8192

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

'Arithmetic' — Value types:
‘double’ | 'single' | 'fixed'

For filter System object inputs only, specify the arithmetic used during analysis. When you specify 'double' or 'single', the function performs double- or single-precision analysis. When you specify 'fixed' , the arithmetic changes depending on the setting of the CoefficientDataType property and whether the System object is locked or unlocked.

Details for Fixed-Point Arithmetic

System Object State	Coefficient Data Type	Rule
Unlocked	'Same as input'	The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.

System Object State	Coefficient Data Type	Rule
Unlocked	'Custom'	The function performs fixed-point analysis based on the setting of the CustomCoefficientsDataType property.
Locked	'Same as input'	When the input data type is 'double' or 'fixed', the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Locked	'Custom'	The function performs fixed-point analysis based on the setting of the CustomCoefficientsDataType property.

When you do not specify the arithmetic for non-CIC structures, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type. CIC structures only support fixed-point arithmetic.

Output Arguments

gd

Complex, n-element group-delay vector. If hfilt is a vector of filters, gd is a complex, length(hfilt)-by-n matrix of group-delay vectors whose columns correspond to each filter in hfilt. If n is not specified, the function uses a default value of 8192.

For adaptive filters, gd is the instantaneous group delay.

w

Frequency vector of length n, in radians/sample. w consists of n points equally spaced around the upper half of the unit circle (from 0 to π radians/sample). If hfilt is a vector of filters, w is a complex, `length(hfilt)`-by-`n` matrix of group-delay vectors whose columns correspond to each filter in hfilt. If `n` is not specified, the function uses a default value of 8192.

`phasez` | `zerophase`

help

Help for design method with filter specification

Syntax

`help(d,'designmethod')`

Description

`help(d,'designmethod')` displays help in the Command Window for the design algorithm `designmethod` for the current specifications of the filter specification object `d`. The string you enter for `designmethod` must be one of the strings returned by `designmethods` for `d`, the design object.

Examples

Get specific help for designing lowpass Butterworth filters. The first lowpass filter uses the default specification string `'Fp,Fst,Ap,Ast'` and returns help text specific to the specification string.

```
d = fdesign.lowpass;
designmethods(d)

Design Methods for class fdesign.lowpass (Fp,Fst,Ap,Ast):

butter
cheby1
cheby2
ellip
equiripple
ifir
kaiserwin
multistage

help(d,'butter')

DESIGN Design a Butterworth IIR filter.
HD = DESIGN(D, 'butter') designs a Butterworth filter specified
by the FDESIGN object D.

HD = DESIGN(..., 'FilterStructure', STRUCTURE) returns a filter
```

```
with the structure STRUCTURE.  STRUCTURE is 'df2sos' by default
and can be any of the following.

'df1sos'
'df2sos'
'df1tsos'
'df2tsos'

HD = DESIGN(..., 'MatchExactly', MATCH) designs a Butterworth
filter and matches the frequency and magnitude specification for
the band MATCH exactly. The other band will exceed the
specification.  MATCH can be 'stopband' or 'passband' and is
'stopband' by default.

% Example #1 - Compare passband and stopband MatchExactly.
h     = fdesign.lowpass('Fp,Fst,Ap,Ast', .1, .3, 1, 60);
Hd    = design(h, 'butter', 'MatchExactly', 'passband');
Hd(2) = design(h, 'butter', 'MatchExactly', 'stopband');

% Compare the passband edges in FVTool.
fvtool(Hd);
axis([.09 .11 -2 0]);
```

Note the discussion of the `MatchExactly` input option. When you use a design object that uses a different specification string, such as '`N,F3dB`', the help content for the `butter` design method changes.

In this case, the `MatchExactly` option does not appear in the help because it is not an available input argument for the specification string '`N,F3dB'`.

```
d=fdesign.lowpass('N,F3dB')

d =
               Response: 'Lowpass'
          Specification: 'N,F3dB'
            Description: {'Filter Order';'3dB Frequency'}
    NormalizedFrequency: true
            FilterOrder: 10
                   F3dB: 0.5

designmethods(d)

Design Methods for class fdesign.lowpass (N,F3dB):

butter

help(d,'butter

DESIGN Design a Butterworth IIR filter.
```

```
HD = DESIGN(D, 'butter') designs a Butterworth filter specified by

fdesign | design | designmethods | designopts

ifir

Interpolated FIR filter from filter specification

Syntax

```
[h,g] = ifir(l,type,f,dev)
[h,g,d] = ifir(l,type,f,dev)
[...] = ifir(...,str)
hd = ifir(d)
hd = design(d,'ifir',designoption1,value1,designoption2,value2,...)
```

Description

`[h,g] = ifir(l,type,f,dev)` designs a periodic filter `h(z`^{1}`)`, where `l` is the interpolation factor. It also finds an image-suppressor filter `g(z)`, such that the cascade of the two filters forms an efficient implementation that meets the desired response. This response is specified by `type`, with band edge frequencies contained in vector `f`. This is done while not exceeding the maximum deviations or ripples (linear) specified in vector `dev`.

`type` is a string with `'low'` for lowpass designs or `'high'` for highpass designs. `f` is a two-element vector with passband and stopband edge frequency values. For narrowband lowpass filters and wideband highpass filters, `l×f(2)` is less than `1`. For wideband lowpass filters and narrowband highpass filters, specify `f` so that `l×(1—f(1))` is less than `1`.

`dev` is a two-element vector that contains the peak ripple or deviation (linear) allowed for both the passband and the stopband.

The `ifir` design algorithm achieves an efficient design in the sense that it reduces the total number of multipliers required. To do this, the design problem is broken into two stages. In the first stage, the filter is upsampled to achieve the stringent specifications without using many multipliers. In the second stage, the filter removes the images created when upsampling the previous filter.

[h,g,d] = ifir(l,type,f,dev) returns a delay d that is connected in parallel with the cascade of h(z^{l}) and g(z) for both wideband lowpass and highpass filters. This is necessary to obtain the desired response.

[...] = ifir(...,str) uses the string specified in str to choose the algorithm level of optimization used. Possible values for str are 'simple', 'intermediate' (default) or 'advanced'. str provides for a tradeoff between design speed and filter order optimization. The 'advanced' option can result in substantial filter order reduction, especially for g(z).

hd = ifir(d) designs an FIR filter from design object d, using the interpolated FIR method. ifir returns hd as a cascade of two filters that act together to meet the specifications in d. The resulting filter is particularly efficient, having a low number of multipliers. However, if ifir determines that a single-stage filter is more efficient than the default two-stage design, it returns hd as a single-stage filter. ifir creates only linear phase filters. Generally, ifir uses an advanced optimization algorithm to create highly efficient FIR filters.

ifir returns hd as a single-rate dfilt object or a multirate mfilt object, based on the filter specifications you provide.

hd = design(d,'ifir',designoption1,value1,designoption2,value2,...) returns an interpolated FIR filter using the design options you specify.

To determine the available design options, use designopts with the specification object and the design method as input arguments:

```
designopts(d,'method')
```

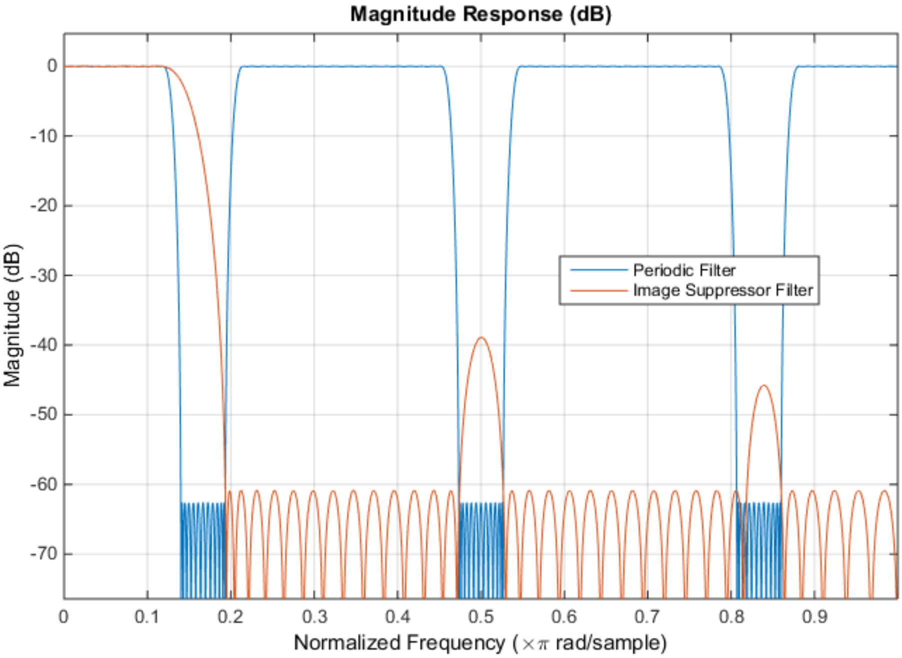
Examples

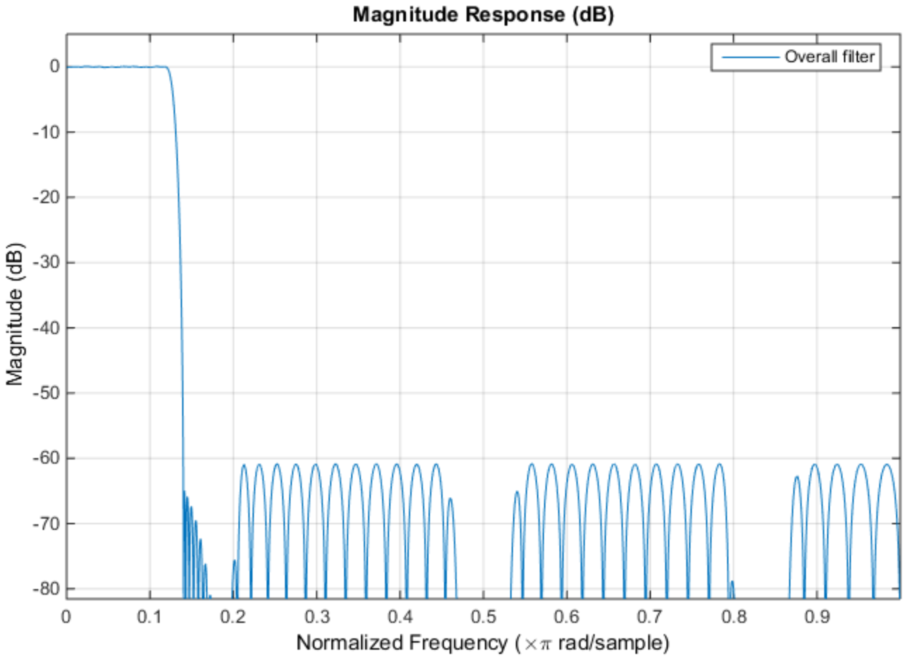
Narrowband lowpass design using an interpolation factor of 6

This example shows how to use the function ifir to design a narrowband lowpass filter.

```
[h,g]=ifir(6,'low',[.12 .14],[.01 .001]);
H = dfilt.dffir(h); G = dfilt.dffir(g);
hfv = fvtool(H,G);
legend(hfv,'Periodic Filter','Image Suppressor Filter');
```

```
Hcas = cascade(H,G);
hfv2 = fvtool(Hcas);
legend(hfv2,'Overall Filter');
```

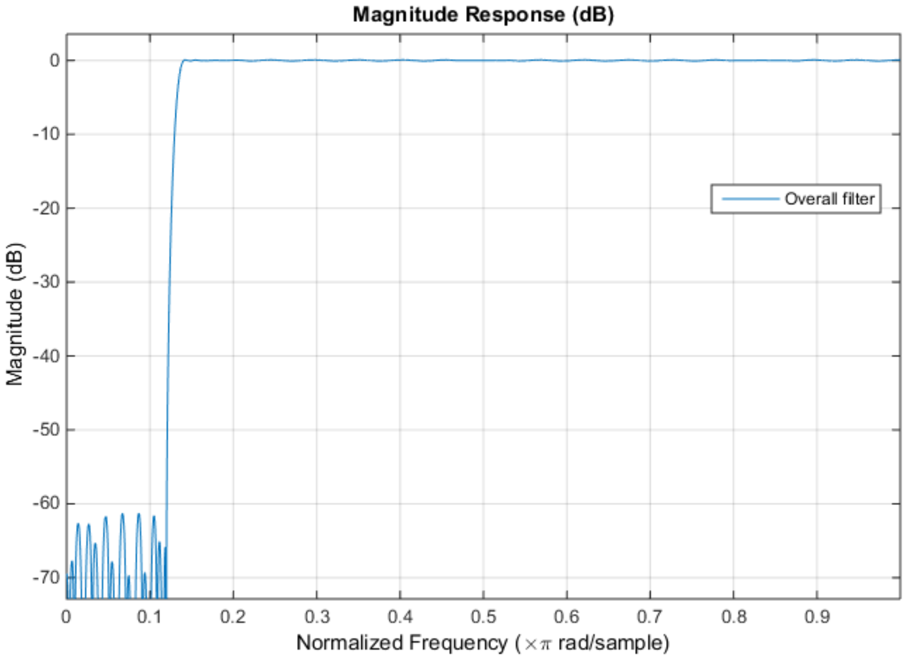




Wideband highpass design using an interpolation factor of 6

This example shows how to use `ifir` to design a wideband highpass filter.

```
[h,g,d]=ifir(6,'high',[.12 .14],[.001 .01]);
H = dfilt.dffir(h); G = dfilt.dffir(g);
Hb1 = cascade(H,G); % Branch 1
Hb2 = dfilt.dffir(d); % Branch 2
Hoverall = parallel(Hb1,Hb2); % Overall wideband highpass
hfv =  fvtool(Hoverall);
legend(hfv,'Overall Filter');
```



Design a lowpass and a wideband highpass filter

This example shows how to use `fdesign.lowpass` and `fdesign.highpass` to design a lowpass and a wideband highpass filter. After designing the filters, use `FVTool` to plot the response curves for both.

```
fpass = 0.2;
fstop = 0.24;
d1 = fdesign.lowpass(fpass, fstop);
hd1 = design(d1,'ifir');
fstop = 0.2;
fpass = 0.25;
astop = 40;
apass = 1;
d2 = fdesign.highpass(fstop,fpass,astop,apass);
hd2 = design(d2,'ifir');
fvtool(hd1,hd2)
```

iirbpc2bpc

Transform IIR complex bandpass filter to IIR complex bandpass filter with different characteristics

Syntax

```
[Num,Den,AllpassNum,AllpassDen] = iirbpc2bpc(B,A,Wo,Wt)
```

Description

`[Num,Den,AllpassNum,AllpassDen] = iirbpc2bpc(B,A,Wo,Wt)` returns the numerator and denominator vectors, `Num` and `Den` respectively, of the target filter transformed from the complex bandpass prototype by applying a first-order complex bandpass to complex bandpass frequency transformation.

It also returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the allpass mapping filter. The prototype lowpass filter is given with the numerator specified by `B` and the denominator specified by `A`.

This transformation effectively places two features of an original filter, located at frequencies W_{o1} and W_{o2}, at the required target frequency locations, W_{t1}, and W_{t2} respectively. It is assumed that W_{t2} is greater than W_{t1}. In most of the cases the features selected for the transformation are the band edges of the filter passbands. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter, F_1 and F_2, with F_1 preceding F_2. Feature F_1 will still precede F_2 after the transformation. However, the distance between F_1 and F_2 will not be the same before and after the transformation.

This transformation can also be used for transforming other types of filters; e.g., complex notch filters or resonators can be repositioned at two distinct desired frequencies at any place around the unit circle; e.g., in the adaptive system.

Examples

Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3, 0.1, 30, 0.409);
```

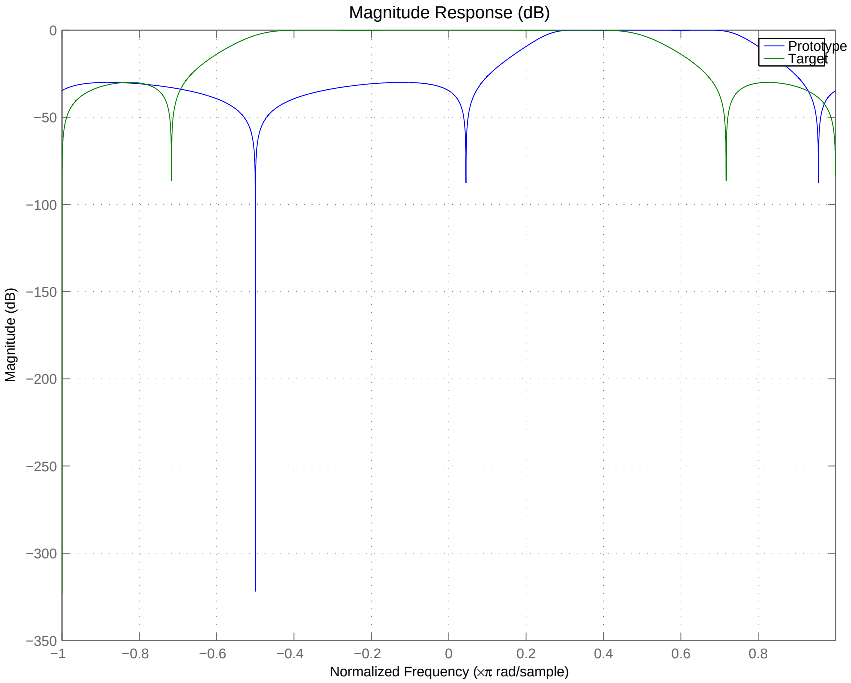
Create a complex passband from 0.25 to 0.75:

```
[b, a] = iirlp2bpc (b, a, 0.5, [0.25,0.75]);
[num, den] = iirbpc2bpc(b, a, [0.25, 0.75], [-0.5, 0.5]);
```

Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b, a, num, den);
```

Using FVTool to plot the filters shows you the comparison, presented in this figure.



Arguments

Variable	Description
B	Numerator of the prototype lowpass filter
A	Denominator of the prototype lowpass filter
Wo	Frequency values to be transformed from the prototype filter
Wt	Desired frequency locations in the transformed target filter
Num	Numerator of the target filter
Den	Denominator of the target filter
AllpassNum	Numerator of the mapping filter
AllpassDen	Denominator of the mapping filter

Frequencies must be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.

iircomb

IIR comb notch or peak filter

Syntax

```
[num,den] = iircomb(n,bw)
[num,den] = iircomb(n,bw,ab)
[num,den] = iircomb(...,'type')
```

Description

`[num,den] = iircomb(n,bw)` returns a digital notching filter with order `n` and with the width of the filter notch at -3 dB set to `bw`, the filter bandwidth. The filter order must be a positive integer. `n` also defines the number of notches in the filter across the frequency range from 0 to 2π — the number of notches equals `n`+1.

For the notching filter, the transfer function takes the form

$$H(z) = b\frac{1 - z^{-n}}{1 - \alpha z^{-n}}$$

where a and b are the positive scalars and n is the filter order or the number of notches in the filter minus 1.

The quality factor (Q factor) q for the filter is related to the filter bandwidth by $q = \omega_0/bw$ where ω_0 is the frequency to remove from the signal.

`[num,den] = iircomb(n,bw,ab)` returns a digital notching filter whose bandwidth, `bw`, is specified at a level of `-ab` decibels. Including the optional input argument `ab` lets you specify the magnitude response bandwidth at a level that is not the default -3 dB point, such as -6 dB or 0 dB.

`[num,den] = iircomb(...,'type')` returns a digital filter of the specified type. The input argument `type` can be either

- `'notch'` to design an IIR notch filter. Notch filters attenuate the response at the specified frequencies. This is the default type. When you omit the `type` input argument, `iircomb` returns a notch filter.

- `'peak'` to design an IIR peaking filter. Peaking filters boost the signal at the specified frequencies.

The transfer function for peaking filters is

$$H(z) = b\frac{1-z^{-n}}{1+az^{-n}}$$

Examples

Design and plot an IIR notch filter with 11 notches (equal to filter order plus 1) that removes a 60 Hz tone (`f0`) from a signal at 600 Hz (`fs`). For this example, set the Q factor for the filter to 35 and use it to specify the filter bandwidth.

```
fs = 600; fo = 60;  q = 35; bw = (fo/(fs/2))/q;
[b,a] = iircomb(fs/fo,bw,'notch'); % Note type flag 'notch'
fvtool(b,a);
```

Using the Filter Visualization Tool (FVTool) generates the following plot showing the filter notches. Note the notches are evenly spaced and one falls at exactly 60 Hz.

iirftransf

IIR frequency transformation of filter

Syntax

```
[OutNum,OutDen] = iirftransf(OrigNum,OrigDen,FTFNum,FTFDen)
```

Description

`[OutNum,OutDen] = iirftransf(OrigNum,OrigDen,FTFNum,FTFDen)` returns the numerator and denominator vectors, `OutNum` and `OutDen`, of the target filter, which is the result of transforming the prototype filter specified by the numerator, `OrigNum`, and denominator, `OrigDen`, with the mapping filter given by the numerator, `FTFNum`, and the denominator, `FTFDen`. If the allpass mapping filter is not specified, then the function returns an original filter.

Examples

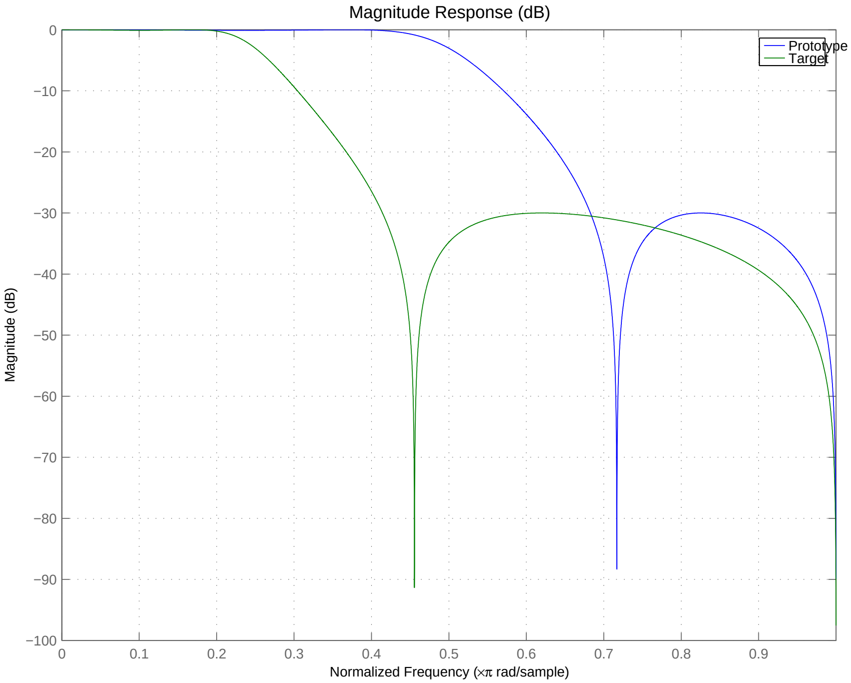
Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3, 0.1, 30, 0.409);
[AlpNum, AlpDen] = allpasslp2lp(0.5, 0.25);
[num, den] = iirftransf(b, a, AlpNum, AlpDen);
```

Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b, a, num, den);
```

Here's the comparison between the filters.



Arguments

Variable	Description
OrigNum	Numerator of the prototype lowpass filter
OrigDen	Denominator of the prototype lowpass filter
FTFNum	Numerator of the mapping filter
FTFDen	Denominator of the mapping filter
OutNum	Numerator of the target filter
OutDen	Denominator of the target filter

See Also

`zpkftransf`

iirgrpdelay

Optimal IIR filter with prescribed group-delay

Syntax

```
[num,den] = iirgrpdelay(n,f,edges,a)
[num,den] = iirgrpdelay(n,f,edges,a,w)
[num,den] = iirgrpdelay(n,f,edges,a,w,radius)
[num,den] = iirgrpdelay(n,f,edges,a,w,radius,p)
[num,den] = iirgrpdelay(n,f,edges,a,w,radius,p,dens)
[num,den] = iirgrpdelay(n,f,edges,a,w,radius,p,dens,initden)
[num,den] = iirgrpdelay(n,f,edges,a,w,radius,p,dens,initden,tau)
[num,den,tau] = iirgrpdelay(n,f,edges,a,w)
```

Description

`[num,den] = iirgrpdelay(n,f,edges,a)` returns an allpass IIR filter of order `n` (`n` must be even) which is the best approximation to the relative group-delay response described by `f` and `a` in the least-pth sense. `f` is a vector of frequencies between 0 and 1 and `a` is specified in samples. The vector `edges` specifies the band-edge frequencies for multi-band designs. `iirgrpdelay` uses a constrained Newton-type algorithm. Always check your resulting filter using `grpdelay` or `freqz`.

`[num,den] = iirgrpdelay(n,f,edges,a,w)` uses the weights in `w` to weight the error. `w` has one entry per frequency point and must be the same length as `f` and `a`). Entries in `w` tell `iirgrpdelay` how much emphasis to put on minimizing the error in the vicinity of each specified frequency point relative to the other points.

`f` and `a` must have the same number of elements. `f` and `a` can contains more elements than the vector `edges` contains. This lets you use `f` and `a` to specify a filter that has any group-delay contour within each band.

`[num,den] = iirgrpdelay(n,f,edges,a,w,radius)` returns a filter having a maximum pole radius equal to `radius`, where 0<`radius`<1. `radius` defaults to 0.999999. Filters whose pole radius you constrain to be less than 1.0 can better retain transfer function accuracy after quantization.

[num,den] = iirgrpdelay(n,f,edges,a,w,radius,p), where p is a two-element vector [pmin pmax], lets you determine the minimum and maximum values of p used in the least-pth algorithm. p defaults to [2 128] which yields filters very similar to the L-infinity, or Chebyshev, norm. pmin and pmax should be even. If p is the string 'inspect', no optimization occurs. You might use this feature to inspect the initial pole/zero placement.

[num,den] = iirgrpdelay(n,f,edges,a,w,radius,p,dens) specifies the grid density dens used in the optimization process. The number of grid points is (dens*(n+1)). The default is 20. dens can be specified as a single-element cell array. The grid is not equally spaced.

[num,den] = iirgrpdelay(n,f,edges,a,w,radius,p,dens,initden) allows you to specify the initial estimate of the denominator coefficients in vector initden. This can be useful for difficult optimization problems. The pole-zero editor in Signal Processing Toolbox software can be used for generating initden.

[num,den] = iirgrpdelay(n,f,edges,a,w,radius,p,dens,initden,tau) allows the initial estimate of the group delay offset to be specified by the value of tau, in samples.

[num,den,tau] = iirgrpdelay(n,f,edges,a,w) returns the resulting group delay offset. In all cases, the resulting filter has a group delay that approximates [a + tau]. Allpass filters can have only positive group delay and a non-zero value of tau accounts for any additional group delay that is needed to meet the shape of the contour specified by (f,a). The default for tau is max(a).

Hint: If the zeros or poles cluster together, your filter order may be too low or the pole radius may be too small (overly constrained). Try increasing n or radius.

For group-delay equalization of an IIR filter, compute a by subtracting the filter's group delay from its maximum group delay. For example,

```
[be,ae] = ellip(4,1,40,0.2);
f = 0:0.001:0.2;
g = grpdelay(be,ae,f,2);   % Equalize only the passband.
a = max(g)-g;
[num,den]=iirgrpdelay(8, f, [0 0.2], a);
```

iirlinphase

Quasi-linear phase IIR filter from halfband filter specification

Syntax

```
hd = design(d,'iirlinphase')
hd = design(...,'filterstructure',structure)
```

Description

`hd = design(d,'iirlinphase')` designs a quasi-linear phase filter `hd` specified by the filter specification object `d`.

`hd = design(...,'filterstructure',structure)` returns a filter with the structure specified by `structure`. By default, the filter structure is `df2sos` (direct-form II with second-order sections). You can substitute one of the following strings for `structure` to specify the structure of `hd`.

Structure String	Filter Structure
`df1sos`	Direct-form I IIR filter with second-order sections
`df2sos`	Direct-form II IIR filter with second-order sections
`df1tsos`	Transposed direct-form I IIR filter with second-order sections
`df2tsos`	Transposed direct-form II IIR filter with second-order sections

Examples

Design a quasi-linear phase, minimum-order halfband IIR filter with transition width of 0.36 and stopband attenuation of at least 80 dB.

```
tw = 0.36;
ast = 80;
d = fdesign.halfband('tw,ast',tw,ast); % Transition width,
                                       % stopband attenuation.
hd = design(d,'iirlinphase');
```

```
fvtool(hd)
```

Notice the characteristic halfband nature of the ripple in the stopband. If you measure the resulting filter, you see it meets the specifications.

```
measure(hd)
```

iirlp2bp

Transform IIR lowpass filter to IIR bandpass filter

Syntax

```
[Num,Den,AllpassNum,AllpassDen] = iirlp2bp(B,A,Wo,Wt)
[G,AllpassNum,AllpassDen] = iirlp2bp(Hd,Wo,Wt)
```

where `Hd` is a `dfilt` object

Description

`[Num,Den,AllpassNum,AllpassDen] = iirlp2bp(B,A,Wo,Wt)` returns the numerator and denominator vectors, `Num` and `Den` respectively, of the target filter transformed from the real lowpass prototype by applying a second-order real lowpass to real bandpass frequency mapping.

It also returns the numerator, `AllpassNum`, and the denominator `AllpassDen`, of the allpass mapping filter. The prototype lowpass filter is given with a numerator specified by `B` and a denominator specified by `A`.

This transformation effectively places one feature of an original filter, located at frequency -W_o, at the required target frequency location, W_{t1}, and the second feature, originally at +W_o, at the new location, W_{t2}. It is assumed that W_{t2} is greater than W_{t1}. This transformation implements the “DC Mobility,” meaning that the Nyquist feature stays at Nyquist, but the DC feature moves to a location dependent on the selection of W_ts.

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter, F_1 and F_2, with F_1 preceding F_2. Feature F_1 will still precede F_2 after the transformation. However, the distance between F_1 and F_2 will not be the same before and after the transformation.

Choice of the feature subject to the lowpass to bandpass transformation is not restricted only to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature: the stopband edge, the DC, the deep minimum in the stopband, or other ones.

Real lowpass to bandpass transformation can also be used for transforming other types of filters; e.g., real notch filters or resonators can be doubled and positioned at two distinct desired frequencies.

`[G,AllpassNum,AllpassDen] = iirlp2bp(Hd,Wo,Wt)` returns transformed `dfilt` object `G` with a real bandpass magnitude response. The coefficients `AllpassNum` and `AllpassDen` represent the allpass mapping filter for mapping the prototype filter frequency `Wo` and target frequencies vector `Wt`. Note that in this syntax `Hd` is a `dfilt` object with a lowpass magnitude response.

Examples

Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b,a] = ellip(3, 0.1, 30, 0.409);
```

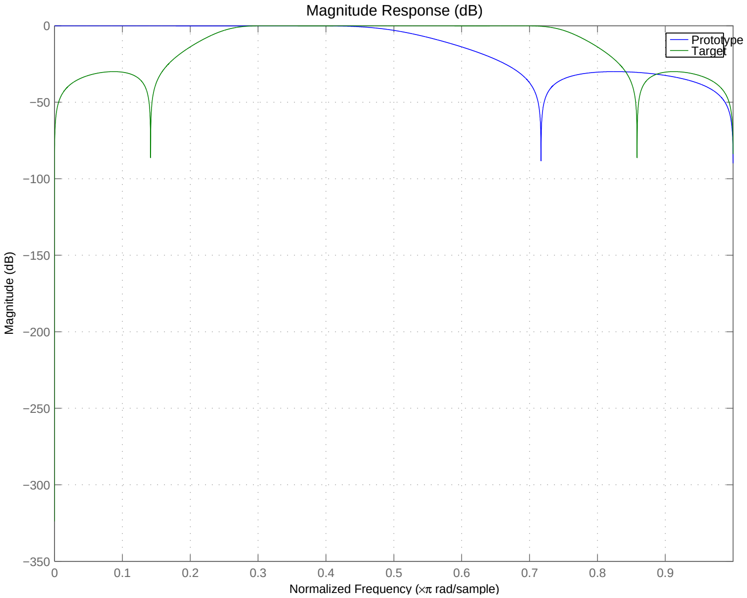
Create the real bandpass filter by placing the cutoff frequencies of the prototype filter at the band edge frequencies W_{t1}=`0.25` and W_{t2}=`0.75`:

```
[num,den] = iirlp2bp(b,a,0.5,[0.25,0.75]);
```

Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b,a,num,den);
```

You can compare the results in this figure to verify the transformation.



Arguments

Variable	Description
`B`	Numerator of the prototype lowpass filter
`A`	Denominator of the prototype lowpass filter
`Wo`	Frequency value to be transformed from the prototype filter
`Wt`	Desired frequency locations in the transformed target filter
`Num`	Numerator of the target filter
`Den`	Denominator of the target filter
`AllpassNum`	Numerator of the mapping filter
`AllpassDen`	Denominator of the mapping filter

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

iirlp2bpc

IIR lowpass to complex bandpass transformation

Syntax

```
[Num,Den,AllpassNum,AllpassDen] = iirlp2bpc(B,A,Wo,Wt)
[G,AllpassNum,AllpassDen] = iirlp2bpc(Hd,Wo,Wt)
```

where `Hd` is a `dfilt` object

Description

`[Num,Den,AllpassNum,AllpassDen] = iirlp2bpc(B,A,Wo,Wt)` returns the numerator and denominator vectors, `Num` and `Den` respectively, of the target filter transformed from the real lowpass prototype by applying a first-order real lowpass to complex bandpass frequency transformation.

It also returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the allpass mapping filter. The prototype lowpass filter is given with a numerator specified by `B` and a denominator specified by `A`.

This transformation effectively places one feature of an original filter, located at frequency -W_o, at the required target frequency location, W_{t1}, and the second feature, originally at +W_o, at the new location, W_{t2}. It is assumed that W_{t2} is greater than W_{t1}.

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter, F_1 and F_2, with F_1 preceding F_2. Feature F_1 will still precede F_2 after the transformation. However, the distance between F_1 and F_2 will not be the same before and after the transformation.

Choice of the feature subject to the lowpass to bandpass transformation is not restricted only to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

Lowpass to bandpass transformation can also be used for transforming other types of filters; for example real notch filters or resonators can be doubled and positioned at two distinct desired frequencies at any place around the unit circle forming a pair of complex notches/resonators. This transformation can be used for designing bandpass filters for radio receivers from the high-quality prototype lowpass filter.

`[G,AllpassNum,AllpassDen] = iirlp2bpc(Hd,Wo,Wt)` returns transformed `dfilt` object `G` with a bandpass magnitude response. The coefficients `AllpassNum` and `AllpassDen` represent the allpass mapping filter for mapping the prototype filter frequency `Wo` and the target frequencies vector `Wt`. Note that in this syntax `Hd` is a `dfilt` object with a lowpass magnitude response.

Examples

Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3, 0.1, 30, 0.409);
```

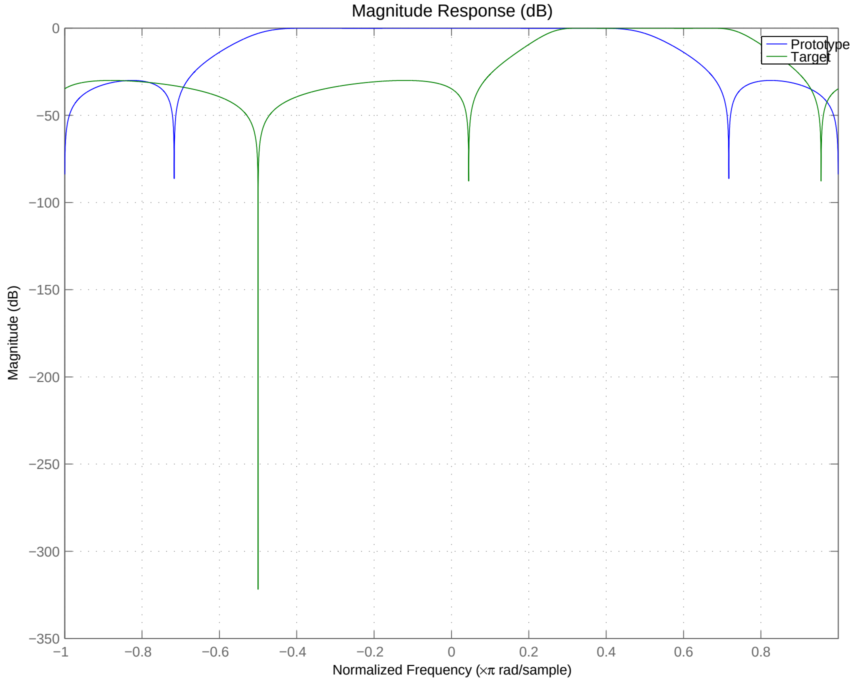
Move the cutoffs of the prototype filter to the new locations W_{t1}=0.25 and W_{t2}=0.75 creating a complex bandpass filter:

```
[num, den] = iirlp2bpc(b, a, 0.5, [0.25, 0.75]);
```

Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b, a, num, den);
```

Plotting the prototype and target filters together in FVTool lets you compare the filters.



Arguments

Variable	Description
B	Numerator of the prototype lowpass filter
A	Denominator of the prototype lowpass filter
Wo	Frequency value to be transformed from the prototype filter. It should be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.
Wt	Desired frequency locations in the transformed target filter. They should be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.
Num	Numerator of the target filter
Den	Denominator of the target filter

Variable	Description
AllpassNum	Numerator of the mapping filter
AllpassDen	Denominator of the mapping filter

iirlp2bs

Transform IIR lowpass filter to IIR bandstop filter

Syntax

```
[Num,Den,AllpassNum,AllpassDen] = iirlp2bs(B,A,Wo,Wt)
[G,AllpassNum,AllpassDen] = iirlp2bs(Hd,Wo,Wt)
```

where `Hd` is a `dfilt` object

Description

`[Num,Den,AllpassNum,AllpassDen] = iirlp2bs(B,A,Wo,Wt)` returns the numerator and denominator vectors, `Num` and `Den` respectively, of the target filter transformed from the real lowpass prototype by applying a second-order real lowpass to real bandstop frequency mapping.

It also returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the allpass mapping filter. The prototype lowpass filter is given with a numerator specified by `B` and a denominator specified by `A`.

This transformation effectively places one feature of an original filter, located at frequency -W_o, at the required target frequency location, W_{t1}, and the second feature, originally at +W_o, at the new location, W_{t2}. It is assumed that W_{t2} is greater than W_{t1}. This transformation implements the "Nyquist Mobility," which means that the DC feature stays at DC, but the Nyquist feature moves to a location dependent on the selection of W_o and W_ts.

Relative positions of other features of an original filter change in the target filter. This means that it is possible to select two features of an original filter, F_1 and F_2, with F_1 preceding F_2. After the transformation feature F_2 will precede F_1 in the target filter. However, the distance between F_1 and F_2 will not be the same before and after the transformation.

Choice of the feature subject to the lowpass to bandstop transformation is not restricted only to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

`[G,AllpassNum,AllpassDen] = iirlp2bs(Hd,Wo,Wt)` returns transformed `dfilt` object `G` with a bandstop magnitude response. The coefficients `AllpassNum` and `AllpassDen` represent the allpass mapping filter for mapping the prototype filter frequency `Wo` and the target frequencies vector `Wt`. Note that in this syntax `Hd` is a `dfilt` object with a lowpass magnitude response.

Examples

Design a prototype real IIR halfband filter using a standard elliptic approach:

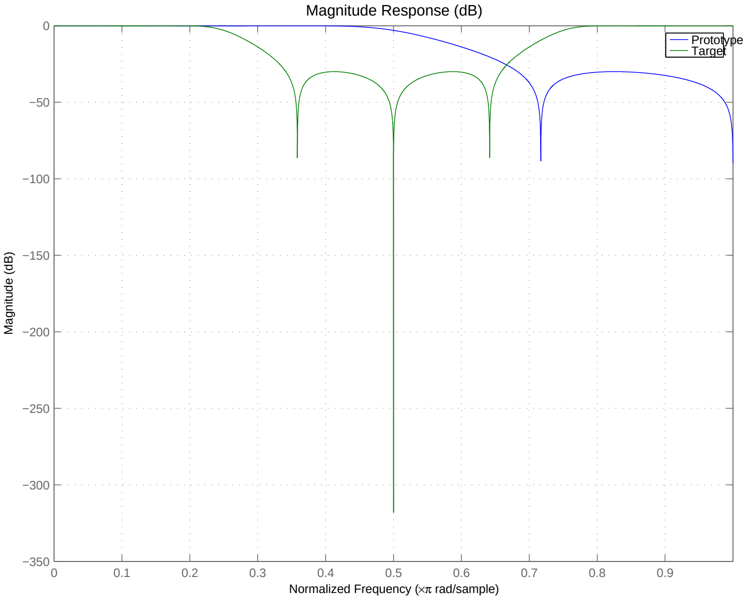
```
[b, a] = ellip(3, 0.1, 30, 0.409);
```

Create the real bandstop filter by placing the cutoff frequencies of the prototype filter at the band edge frequencies W_{t1}=`0.25` and W_{t2}=`0.75`:

```
[num, den] = iirlp2bs(b, a, 0.5, [0.25, 0.75]);
```

Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b, a, num, den);
```



With both filters plotted in the figure, you see clearly the results of the transformation.

Arguments

Variable	Description
`B`	Numerator of the prototype lowpass filter
`A`	Denominator of the prototype lowpass filter
`Wo`	Frequency value to be transformed from the prototype filter
`Wt`	Desired frequency locations in the transformed target filter
`Num`	Numerator of the target filter
`Den`	Denominator of the target filter
`AllpassNum`	Numerator of the mapping filter
`AllpassDen`	Denominator of the mapping filter

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

iirlp2bsc

Transform IIR lowpass filter to IIR complex bandstop filter

Syntax

```
[Num,Den,AllpassNum,AllpassDen] = iirlp2bsc(B,A,Wo,Wt)
[G,AllpassNum,AllpassDen] = iirlp2bsc(Hd,Wo,Wt)
```

where Hd is a dfilt object

Description

[Num,Den,AllpassNum,AllpassDen] = iirlp2bsc(B,A,Wo,Wt) returns the numerator and denominator vectors, Num and Den respectively, of the target filter transformed from the real lowpass prototype by applying a first-order real lowpass to complex bandstop frequency transformation.

It also returns the numerator, AllpassNum, and the denominator, AllpassDen, of the allpass mapping filter. The prototype lowpass filter is given with a numerator specified by B and the denominator specified by A.

This transformation effectively places one feature of an original filter, located at frequency -W_o, at the required target frequency location, W_{t1}, and the second feature, originally at +W_o, at the new location, W_{t2}. It is assumed that W_{t2} is greater than W_{t1}. Additionally the transformation swaps passbands with stopbands in the target filter.

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter, F_1 and F_2, with F_1 preceding F_2. Feature F_1 will still precede F_2 after the transformation. However, the distance between F_1 and F_2 will not be the same before and after the transformation.

Choice of the feature subject to the lowpass to bandstop transformation is not restricted only to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

Lowpass to bandpass transformation can also be used for transforming other types of filters; e.g., real notch filters or resonators can be doubled and positioned at two distinct desired frequencies at any place around the unit circle forming a pair of complex notches/ resonators. This transformation can be used for designing bandstop filters for band attenuation or frequency equalizers, from the high-quality prototype lowpass filter.

`[G,AllpassNum,AllpassDen] = iirlp2bsc(Hd,Wo,Wt)` returns transformed `dfilt` object `G` with a bandstop magnitude response. The coefficients `AllpassNum` and `AllpassDen` represent the allpass mapping filter for mapping the prototype filter frequency `Wo` and the target frequencies vector `Wt`. Note that in this syntax `Hd` is a `dfilt` object with a lowpass magnitude response.

Examples

Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3, 0.1, 30, 0.409);
```

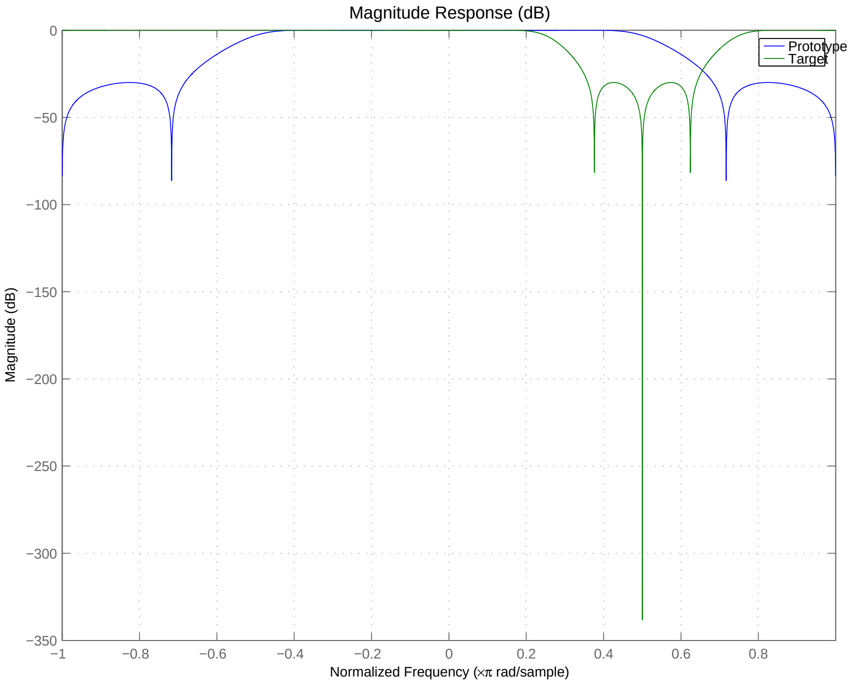
Move the cutoffs of the prototype filter to the new locations W_{t1}=`0.25` and W_{t2}=`0.75` creating a complex bandstop filter:

```
[num, den] = iirlp2bsc(b, a, 0.5, [0.25, 0.75]);
```

Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b, a, num, den);
```

The last command in the example plots both filters in the same window so you can compare the results.



Arguments

Variable	Description
B	Numerator of the prototype lowpass filter
A	Denominator of the prototype lowpass filter
Wo	Frequency value to be transformed from the prototype filter. It should be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.
Wt	Desired frequency locations in the transformed target filter. They should be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.
Num	Numerator of the target filter
Den	Denominator of the target filter

Variable	Description
AllpassNum	Numerator of the mapping filter
AllpassDen	Denominator of the mapping filter

iirlp2hp

Transform lowpass IIR filter to highpass filter

Syntax

```
[num,den] = iirlp2hp(b,a,wc,wd)
[G,AllpassNum,AllpassDen] = iirlp2hp(Hd,Wo,Wt)
```

where Hd is a dfilt object

Description

[num,den] = iirlp2hp(b,a,wc,wd) with input arguments b and a, the numerator and denominator coefficients (zeros and poles) for a lowpass IIR filter, iirlp2bp transforms the magnitude response from lowpass to highpass. num and den return the coefficients for the transformed highpass filter. For wc, enter a selected frequency from your lowpass filter. You use the chosen frequency to define the magnitude response value you want in the highpass filter. Enter one frequency for the highpass filter — the value that defines the location of the transformed point — in wd. Note that all frequencies are normalized between zero and one. Notice also that the filter order does not change when you transform to a highpass filter.

When you select wc and designate wd, the transformation algorithm sets the magnitude response at the wd values of your bandstop filter to be the same as the magnitude response of your lowpass filter at wc. Filter performance between the values in wd is not specified, except that the stopband retains the ripple nature of your original lowpass filter and the magnitude response in the stopband is equal to the peak response of your lowpass filter. To accurately specify the filter magnitude response across the stopband of your bandpass filter, use a frequency value from within the stopband of your lowpass filter as wc. Then your bandstop filter response is the same magnitude and ripple as your lowpass filter stopband magnitude and ripple.

The fact that the transformation retains the shape of the original filter is what makes this function useful. If you have a lowpass filter whose characteristics, such as rolloff or passband ripple, particularly meet your needs, the transformation function lets you create a new filter with the same characteristic performance features, but in a highpass version. Without designing the highpass filter from the beginning.

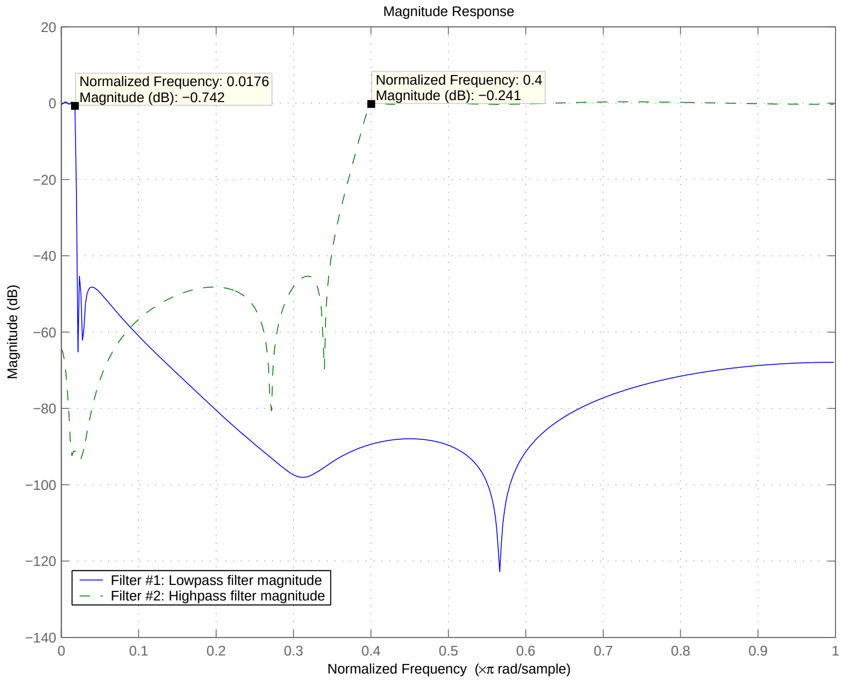
In some cases transforming your filter may cause numerical problems, resulting in incorrect conversion to the highpass filter. Use `fvtool` to verify the response of your converted filter.

`[G,AllpassNum,AllpassDen] = iirlp2hp(Hd,Wo,Wt)` returns transformed `dfilt` object `G` with a highpass magnitude response. The coefficients `AllpassNum` and `AllpassDen` represent the allpass mapping filter for mapping the prototype filter frequency `Wo` and the target frequencies vector `Wt`. Note that in this syntax `Hd` is a `dfilt` object with a lowpass magnitude response.

Examples

This example transforms an IIR filter from lowpass to high pass by moving the magnitude response at one frequency in the source filter to a new location in the transformed filter. To generate a highpass filter whose passband flattens out at 0.4, select the frequency in the lowpass filter where the passband starts to rolloff (`wc` = 0.0175) and move it to the new location at `wd` = 0.4.

```
[b,a] = iirlpnorm(10,6,[0 0.0175 0.02 0.0215 0.025 1],...
[0 0.0175 0.02 0.0215 0.025 1],[1 1 0 0 0 0],...
[1 1 1 1 10 10]);
wc = 0.0175;
wd = 0.4;
[num,den] = iirlp2hp(b,a,wc,wd);
fvtool(b,a,num,den);
```



In the figure showing the magnitude responses for the two filters, the transition band for the highpass filter is essentially the mirror image of the transition for the lowpass filter from 0.0175 to 0.025, stretched out over a wider frequency range. In the passbands, the filter share common ripple characteristics and magnitude.

iirlp2lp

Transform lowpass IIR filter to different lowpass filter

Syntax

```
[num,den] = iirlp2lp(b,a,wc,wd)
[G,AllpassNum,AllpassDen] = iirlp2lp(Hd,Wo,Wt)
```

where `Hd` is a `dfilt` object

Description

`[num,den] = iirlp2lp(b,a,wc,wd)` with input arguments `b` and `a`, the numerator and denominator coefficients (zeros and poles) for a lowpass IIR filter, `iirlp2lp` transforms the magnitude response from lowpass to highpass. `num` and `den` return the coefficients for the transformed highpass filter. For `wc`, enter a selected frequency from your lowpass filter. You use the chosen frequency to define the magnitude response value you want in the highpass filter. Enter one frequency for the highpass filter — the value that defines the location of the transformed point — in `wd`. Note that all frequencies are normalized between zero and one. Notice also that the filter order does not change when you transform to a highpass filter.

When you select `wc` and designate `wd`, the transformation algorithm sets the magnitude response at the `wd` values of your bandstop filter to be the same as the magnitude response of your lowpass filter at `wc`. Filter performance between the values in `wd` is not specified, except that the stopband retains the ripple nature of your original lowpass filter and the magnitude response in the stopband is equal to the peak response of your lowpass filter. To accurately specify the filter magnitude response across the stopband of your bandpass filter, use a frequency value from within the stopband of your lowpass filter as `wc`. Then your bandstop filter response is the same magnitude and ripple as your lowpass filter stopband magnitude and ripple.

The fact that the transformation retains the shape of the original filter is what makes this function useful. If you have a lowpass filter whose characteristics, such as rolloff or passband ripple, particularly meet your needs, the transformation function lets you create a new filter with the same characteristic performance features, but in a highpass version. Without designing the highpass filter from the beginning.

In some cases transforming your filter may cause numerical problems, resulting in incorrect conversion to the highpass filter. Use `fvtool` to verify the response of your converted filter.

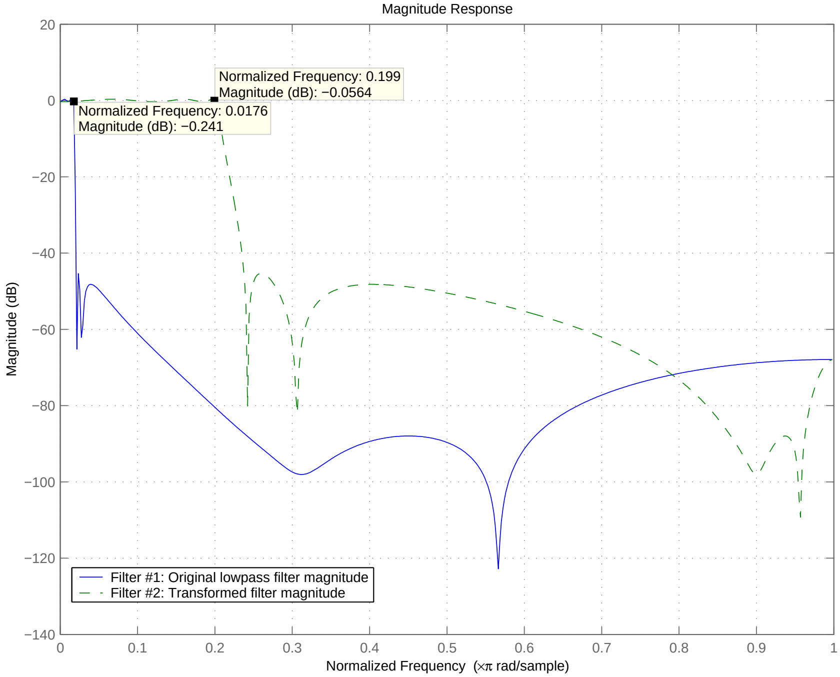
`[G,AllpassNum,AllpassDen] = iirlp2lp(Hd,Wo,Wt)` returns transformed `dfilt` object `G` with a lowpass magnitude response. The coefficients `AllpassNum` and `AllpassDen` represent the allpass mapping filter for mapping the prototype filter frequency `Wo` and the target frequencies vector `Wt`. Note that in this syntax `Hd` is a `dfilt` object with a lowpass magnitude response.

Examples

This example transforms an IIR filter from lowpass to high pass by moving the magnitude response at one frequency in the source filter to a new location in the transformed filter. To generate a lowpass filter whose passband extends out to 0.2, select the frequency in the lowpass filter where the passband starts to rolloff (`wc` = 0.0175) and move it to the new location at `wd` = 0.2.

```
[b,a] = iirlpnorm(10,6,[0 0.0175 0.02 0.0215 0.025 1],...
[0 0.0175 0.02 0.0215 0.025 1],[1 1 0 0 0 0],...
[1 1 1 1 10 10]);
wc = 0.0175;
wd = 0.2;
[num,den] = iirlp2lp(b,a,wc,wd);
fvtool(b,a,num,den);
```

Moving the edge of the passband from 0.0175 to 0.2 results in a new lowpass filter whose peak response in-band is the same as the original filter: same ripple, same absolute magnitude.



The rolloff is slightly less steep and the stopband profiles are the same for both filters; the new filter stopband is a “stretched” version of the original, as is the passband of the new filter.

iirlp2mb

Transform IIR lowpass filter to IIR M-band filter

Syntax

```
[Num,Den,AllpassNum,AllpassDen] = iirlp2mb(B,A,Wo,Wt)
[Num,Den,AllpassNum,AllpassDen]=iirlp2mb(B,A,Wo,Wt,Pass)
[G,AllpassNum,AllpassDen] = iirlp2mb(Hd,Wo,Wt)
[G,AllpassNum,AllpassDen] = iirlp2mb(...,Pass)
```

Description

`[Num,Den,AllpassNum,AllpassDen] = iirlp2mb(B,A,Wo,Wt)` returns the numerator and denominator vectors, `Num` and `Den` respectively, of the target filter transformed from the real lowpass prototype by applying an `M`th-order real lowpass to real multiple bandpass frequency mapping. By default the DC feature is kept at its original location.

`[Num,Den,AllpassNum,AllpassDen]=iirlp2mb(B,A,Wo,Wt,Pass)` allows you to specify an additional parameter, `Pass`, which chooses between using the “DC Mobility” and the “Nyquist Mobility.” In the first case the Nyquist feature stays at its original location and the DC feature is free to move. In the second case the DC feature is kept at an original frequency and the Nyquist feature is movable.

It also returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the allpass mapping filter. The prototype lowpass filter is given with a numerator specified by `B` and a denominator specified by `A`.

This transformation effectively places one feature of an original filter, located at frequency W_o, at the required target frequency locations, W_{t1},...,W_{tM}.

Relative positions of other features of an original filter do not change in the target filter. It is possible to select two features of an original filter, F_1 and F_2, with F_1 preceding F_2. Feature F_1 will still precede F_2 after the transformation. However, the distance between F_1 and F_2 will not be the same before and after the transformation.

Choice of the feature subject to this transformation is not restricted to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

This transformation can also be used for transforming other types of filters; e.g., notch filters or resonators can be easily replicated at a number of required frequency locations. A good application would be an adaptive tone cancellation circuit reacting to the changing number and location of tones.

`[G,AllpassNum,AllpassDen] = iirlp2mb(Hd,Wo,Wt)` returns transformed `dfilt` object `G` with an IIR real M-band filter frequency response. The coefficients `AllpassNum` and `AllpassDen` represent the allpass mapping filter for mapping the prototype filter frequency `Wo` and the target frequencies vector `Wt`. Note that in this syntax `Hd` is a `dfilt` object with a lowpass magnitude response.

`[G,AllpassNum,AllpassDen] = iirlp2mb(...,Pass)` returns transformed `dfilt` object `G` with an IIR real M-band filter frequency response. This syntax allows you to specify an additional parameter, `Pass`, which chooses between using the “DC Mobility” and the “Nyquist Mobility.” In the first case the Nyquist feature stays at its original location and the DC feature is free to move. In the second case the DC feature is kept at an original frequency and the Nyquist feature is allowed to move.

The coefficients `AllpassNum` and `AllpassDen` represent the allpass mapping filter for mapping the prototype filter frequency `Wo` and the target frequencies vector `Wt`. Note that in this syntax `Hd` is a `dfilt` object with a lowpass magnitude response.

Examples

Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3, 0.1, 30, 0.409);
```

Example 1

Create the real multiband filter with two passbands:

```
[num1, den1] = iirlp2mb(b, a, 0.5, [2 4 6 8]/10);
[num2, den2] = iirlp2mb(b, a, 0.5, [2 4 6 8]/10, 'pass');
```

The second code snippet uses the `pass` option to select the Nyquist mobility option. In this case the resulting filter is the same.

Example 2

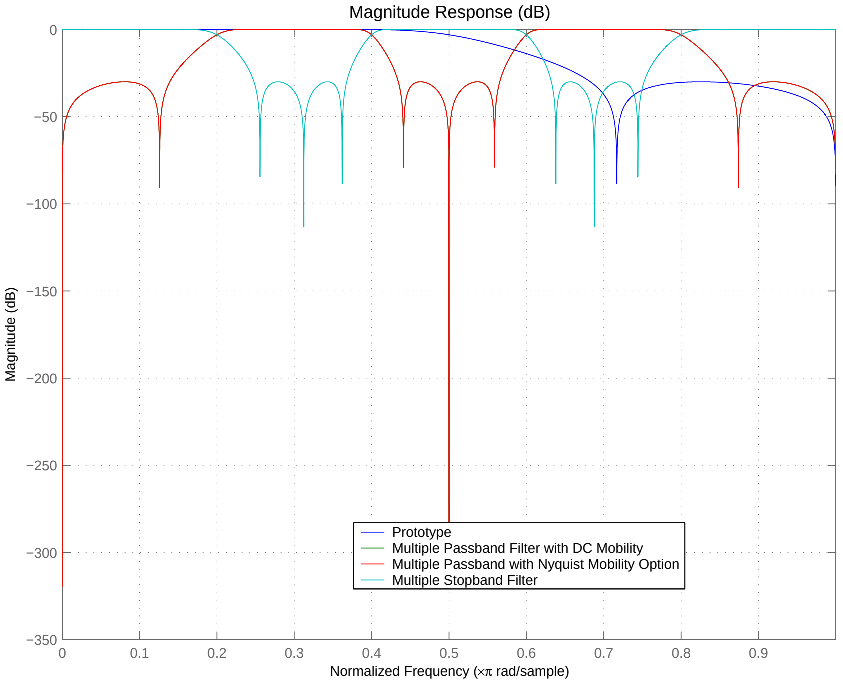
Create the real multiband filter with two stopbands:

```
[num3, den3] = iirlp2mb(b, a, 0.5, [2 4 6 8]/10, 'stop');
```

Verify the result by comparing the prototype filter with target filters:

```
fvtool(b, a, num1, den1, num2, den2, num3, den3);
```

Combining all of the filters, prototypes and targets, on one figure makes comparing them straightforward. Passbands for the filters in example 1 appear separately in the figure, although they overlap to a degree that makes them hard to identify — they have identical coefficients.



Arguments

Variable	Description
B	Numerator of the prototype lowpass filter
A	Denominator of the prototype lowpass filter
Wo	Frequency value to be transformed from the prototype filter
Wt	Desired frequency locations in the transformed target filter
Pass	Choice (`'pass'`/`'stop'`) of passband/stopband at DC, `'pass'` being the default
Num	Numerator of the target filter
Den	Denominator of the target filter
AllpassNum	Numerator of the mapping filter
AllpassDen	Denominator of the mapping filter

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

iirlp2mbc

Transform IIR lowpass filter to IIR complex M-band filter

Syntax

```
[Num,Den,AllpassNum,AllpassDen] = iirlp2mbc(B,A,Wo,Wc)
[G,AllpassNum,AllpassDen] = iirlp2mbc(Hd,Wo,Wt)
```

where Hd is a dfilt object

Description

[Num,Den,AllpassNum,AllpassDen] = iirlp2mbc(B,A,Wo,Wc) returns the numerator and denominator vectors, Num and Den respectively, of the target filter transformed from the real lowpass prototype by applying an Mth-order real lowpass to complex multibandpass frequency transformation.

It also returns the numerator, AllpassNum, and the denominator, AllpassDen, of the allpass mapping filter. The prototype lowpass filter is given with a numerator specified by B and a denominator specified by A.

This transformation effectively places one feature of an original filter, located at frequency W_o, at the required target frequency locations, W_{t1},...,W_{tM}.

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter, F_1 and F_2, with F_1 preceding F_2. Feature F_1 will still precede F_2 after the transformation. However, the distance between F_1 and F_2 will not be the same before and after the transformation.

Choice of the feature subject to this transformation is not restricted to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

This transformation can also be used for transforming other types of filters; e.g., notch filters or resonators can be easily replicated at a number of required frequency locations. A good application would be an adaptive tone cancellation circuit reacting to the changing number and location of tones.

`[G,AllpassNum,AllpassDen] = iirlp2mbc(Hd,Wo,Wt)` returns transformed `dfilt` object `G` with an IIR complex M-band filter frequency response. The coefficients `AllpassNum` and `AllpassDen` represent the allpass mapping filter for mapping the prototype filter frequency `Wo` and the target frequencies vector `Wt`. Note that in this syntax `Hd` is a `dfilt` object with a lowpass magnitude response.

Examples

Design a prototype real IIR halfband filter using a standard elliptic approach:

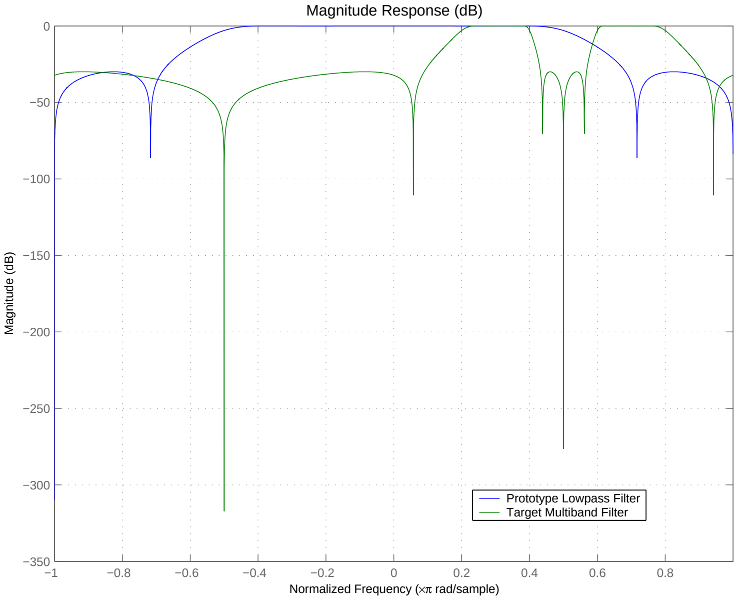
```
[b, a] = ellip(3, 0.1, 30, 0.409);
```

Now create a complex multiband filter with two passbands:

```
[num1, den1] = iirlp2mbc(b, a, 0.5, [2 4 6 8]/10);
```

Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b, a, num1, den1);
```



You see in the figure that `iirlp2mbc` replicates the desired feature at 0.5 in the lowpass filter at four locations in the multiband filter.

Arguments

Variable	Description
B	Numerator of the prototype lowpass filter.
A	Denominator of the prototype lowpass filter.
Wo	Frequency value to be transformed from the prototype filter. It should be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.
Wc	Desired frequency locations in the transformed target filter. They should be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.
Num	Numerator of the target filter.
Den	Denominator of the target filter.
AllpassNum	Numerator of the mapping filter.
AllpassDen	Denominator of the mapping filter.

`iirftransf` | `zpklp2mbc` | `allpasslp2mbc`

iirlp2xc

Transform IIR lowpass filter to IIR complex N-point filter

Syntax

```
[Num,Den,AllpassNum,AllpassDen] = iirlp2xc(B,A,Wo,Wt)
[G,AllpassNum,AllpassDen] = iirlp2xc(Hd,Wo,Wt)
```

where `Hd` is a `dfilt` object

Description

`[Num,Den,AllpassNum,AllpassDen] = iirlp2xc(B,A,Wo,Wt)` returns the numerator and denominator vectors, `Num` and `Den` respectively, of the target filter transformed from the real lowpass prototype by applying an `N`th-order real lowpass to complex multipoint frequency transformation.

It also returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the allpass mapping filter. The prototype lowpass filter is given with a numerator specified by `B` and a denominator specified by `A`.

Parameter `N` also specifies the number of replicas of the prototype filter created around the unit circle after the transformation. This transformation effectively places `N` features of an original filter, located at frequencies $W_{o1},...,W_{oN}$, at the required target frequency locations, $W_{t1},...,W_{tM}$.

Relative positions of other features of an original filter are the same in the target filter for the Nyquist mobility and are reversed for the DC mobility. For the Nyquist mobility this means that it is possible to select two features of an original filter, F_1 and F_2, with F_1 preceding F_2. Feature F_1 will still precede F_2 after the transformation. However, the distance between F_1 and F_2 will not be the same before and after the transformation. For DC mobility feature F_2 will precede F_1 after the transformation.

Choice of the feature subject to this transformation is not restricted to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature;

e.g., a stopband edge, DC, the deep minimum in the stopband, or other ones. The only condition is that the features must be selected in such a way that when creating N bands around the unit circle, there will be no band overlap.

This transformation can also be used for transforming other types of filters; e.g., notch filters or resonators can be easily replicated at a number of required frequency locations. A good application would be an adaptive tone cancellation circuit reacting to the changing number and location of tones.

[G,AllpassNum,AllpassDen] = iirlp2xc(Hd,Wo,Wt) returns transformed dfilt object G with an IIR complex N-point filter frequency response. The coefficients AllpassNum and AllpassDen represent the allpass mapping filter for mapping the prototype filter frequency Wo and the target frequencies vector Wt. Note that in this syntax Hd is a dfilt object with a lowpass magnitude response.

Examples

Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3, 0.1, 30, 0.409);
```

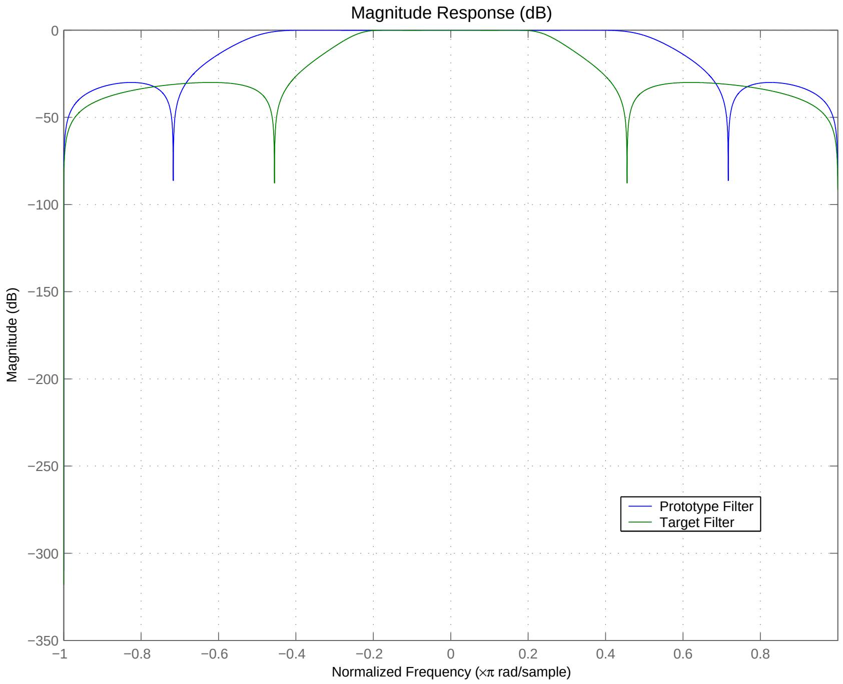
Create the complex bandpass filter from the real lowpass filter:

```
[num, den] = iirlp2xc(b, a, [-0.5 0.5], [-0.25 0.25]);
```

Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b, a, num, den);
```

Reviewing the coefficients and the figure produced by the example shows that the target filter has complex coefficients and is indeed a bandpass filter as expected.



Arguments

Variable	Description
B	Numerator of the prototype lowpass filter.
A	Denominator of the prototype lowpass filter.
Wo	Frequency values to be transformed from the prototype filter. They should be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.
Wt	Desired frequency locations in the transformed target filter. They should be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.
Num	Numerator of the target filter.
Den	Denominator of the target filter.

Variable	Description
AllpassNum	Numerator of the mapping filter.
AllpassDen	Denominator of the mapping filter.

`iirftransf` | `zpklp2xc` | `allpasslp2xc`

iirlp2xn

Transform IIR lowpass filter to IIR real N-point filter

Syntax

```
[Num,Den,AllpassNum,AllpassDen] = iirlp2xn(B,A,Wo,Wt)
[Num,Den,AllpassNum,AllpassDen]= iirlp2xn(B,A,Wo,Wt,Pass)
[G,AllpassNum,AllpassDen] = iirlp2xn(Hd,Wo,Wt)
[G,AllpassNum,AllpassDen] = iirlp2xn(...,Pass)
```

Description

`[Num,Den,AllpassNum,AllpassDen] = iirlp2xn(B,A,Wo,Wt)` returns the numerator and denominator vectors, `Num` and `Den` respectively, of the target filter transformed from the real lowpass prototype by applying an `N`th-order real lowpass to real multipoint frequency transformation, where `N` is the number of features being mapped. By default the DC feature is kept at its original location.

`[Num,Den,AllpassNum,AllpassDen]= iirlp2xn(B,A,Wo,Wt,Pass)` allows you to specify an additional parameter, `Pass`, which chooses between using the "DC Mobility" and the "Nyquist Mobility." In the first case the Nyquist feature stays at its original location and the DC feature is free to move. In the second case the DC feature is kept at an original frequency and the Nyquist feature is allowed to move.

It also returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the allpass mapping filter. The prototype lowpass filter is given with the numerator specified by `B` and the denominator specified by `A`.

Parameter `N` also specifies the number of replicas of the prototype filter created around the unit circle after the transformation. This transformation effectively places `N` features of an original filter, located at frequencies $W_{o1},...,W_{oN}$, at the required target frequency locations, $W_{t1},...,W_{tM}$.

Relative positions of other features of an original filter are the same in the target filter for the Nyquist mobility and are reversed for the DC mobility. For the Nyquist mobility this means that it is possible to select two features of an original filter, F_1 and F_2, with

F_1 preceding F_2. Feature F_1 will still precede F_2 after the transformation. However, the distance between F_1 and F_2 will not be the same before and after the transformation. For DC mobility feature F_2 will precede F_1 after the transformation.

Choice of the feature subject to this transformation is not restricted to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones. The only condition is that the features must be selected in such a way that when creating N bands around the unit circle, there will be no band overlap.

This transformation can also be used for transforming other types of filters; e.g., notch filters or resonators can be easily replicated at a number of required frequency locations. A good application would be an adaptive tone cancellation circuit reacting to the changing number and location of tones.

`[G,AllpassNum,AllpassDen] = iirlp2xn(Hd,Wo,Wt)` returns transformed `dfilt` object `G` with an IIR real N-point filter frequency response. The coefficients `AllpassNum` and `AllpassDen` represent the allpass mapping filter for mapping the prototype filter frequency `Wo` and the target frequencies vector `Wt`. Note that in this syntax `Hd` is a `dfilt` object with a lowpass magnitude response.

`[G,AllpassNum,AllpassDen] = iirlp2xn(...,Pass)` returns transformed `dfilt` object `G` with an IIR real N-point filter frequency response. This syntax allows you to specify an additional parameter, `Pass`, which chooses between using the "DC Mobility" and the "Nyquist Mobility." In the first case the Nyquist feature stays at its original location and the DC feature is free to move. In the second case the DC feature is kept at an original frequency and the Nyquist feature is allowed to move.

The coefficients `AllpassNum` and `AllpassDen` represent the allpass mapping filter for mapping the prototype filter frequency `Wo` and the target frequencies vector `Wt`. Note that in this syntax `Hd` is a `dfilt` object with a lowpass magnitude response.

Examples

Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3, 0.1, 30, 0.409);
```

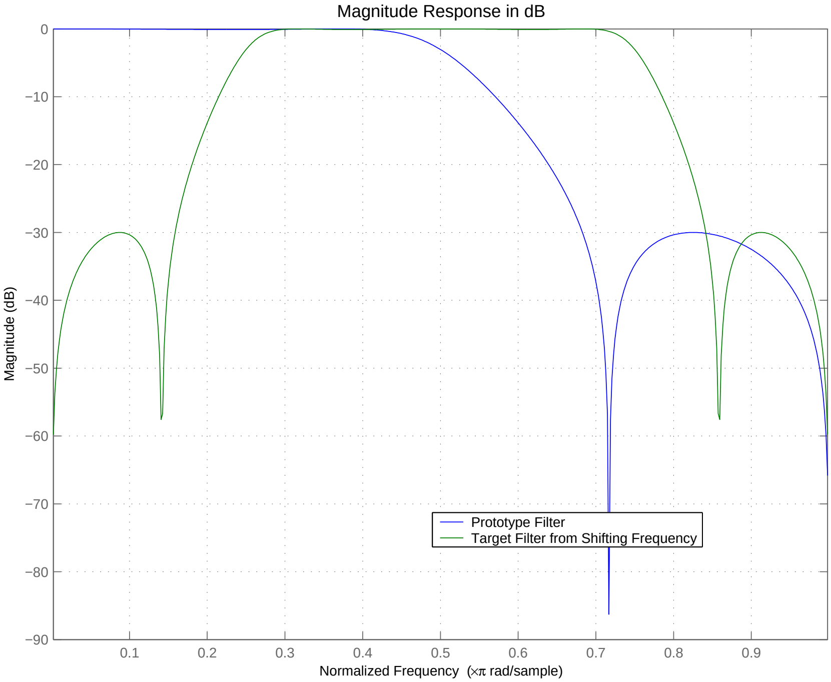
Move the cutoffs of the prototype filter to the new locations W_{t1}=`0.25` and W_{t2}=`0.75` creating a real bandpass filter:

```
[num, den] = iirlp2xn(b, a, [-0.5 0.5], [0.25 0.75], ...
pass');
```

Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b, a, num, den);
```

`iirlp2xn` has created the desired bandpass filter with the cutoff locations specified in the command.



Arguments

Variable	Description
B	Numerator of the prototype lowpass filter
A	Denominator of the prototype lowpass filter
Wo	Frequency values to be transformed from the prototype filter

Variable	Description
`Wt`	Desired frequency locations in the transformed target filter
`Pass`	Choice (`'pass'`/`'stop'`) of passband/stopband at DC, `'pass'` being the default
`Num`	Numerator of the target filter
`Den`	Denominator of the target filter
`AllpassNum`	Numerator of the mapping filter
`AllpassDen`	Denominator of the mapping filter

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

`iirftransf` | `zpklp2xn` | `allpasslp2xn`

iirlpnorm

Least P-norm optimal IIR filter

Syntax

```
[num,den] = iirlpnorm(n,d,f,edges,a)
[num,den] = iirlpnorm(n,d,f,edges,a,w)
[num,den] = iirlpnorm(n,d,f,edges,a,w,p)
[num,den] = iirlpnorm(n,d,f,edges,a,w,p,dens)
[num,den] = iirlpnorm(n,d,f,edges,a,w,p,dens,initnum,initden)
[num,den,err] = iirlpnorm(...)
[num,den,err,sos,g] = iirlpnorm(...)
```

Description

`[num,den] = iirlpnorm(n,d,f,edges,a)` returns a filter having a numerator order `n` and denominator order `d` which is the best approximation to the desired frequency response described by `f` and `a` in the least-pth sense. The vector `edges` specifies the band-edge frequencies for multi-band designs. An unconstrained quasi-Newton algorithm is employed and any poles or zeros that lie outside of the unit circle are reflected back inside. `n` and `d` should be chosen so that the zeros and poles are used effectively. See the "Hints" on page 4-839 section. Always use `freqz` to check the resulting filter.

`[num,den] = iirlpnorm(n,d,f,edges,a,w)` uses the weights in `w` to weight the error. `w` has one entry per frequency point (the same length as `f` and `a`) which tells `iirlpnorm` how much emphasis to put on minimizing the error in the vicinity of each frequency point relative to the other points. `f` and `a` must have the same number of elements, which may exceed the number of elements in `edges`. This allows for the specification of filters having any gain contour within each band. The frequencies specified in `edges` must also appear in the vector `f`. For example,

```
[num,den] = iirlpnorm(5,12,[0 .15 .4 .5 1],[0 .4 .5 1],...
[1 1.6 1 0 0],[1 1 1 10 10])
```

is a lowpass filter with a peak of 1.6 within the passband.

`[num,den] = iirlpnorm(n,d,f,edges,a,w,p)` where `p` is a two-element vector `[pmin pmax]` allows for the specification of the minimum and maximum values of `p` used in the least-pth algorithm. Default is [2 128] which essentially yields the L-infinity, or Chebyshev, norm. Pmin and pmax should be even. If p is the string 'inspect', no optimization will occur. This can be used to inspect the initial pole/zero placement.

[num,den] = iirlpnorm(n,d,f,edges,a,w,p,dens) specifies the grid density dens used in the optimization. The number of grid points is (dens*(n+d+1)). The default is 20. dens can be specified as a single-element cell array. The grid is not equally spaced.

[num,den] = iirlpnorm(n,d,f,edges,a,w,p,dens,initnum,initden) allows for the specification of the initial estimate of the filter numerator and denominator coefficients in vectors initnum and initden. initnum should be of length n+1, and initden should be of length d+1. This may be useful for difficult optimization problems. The pole-zero editor in Signal Processing Toolbox software can be used for generating initnum and initden.

[num,den,err] = iirlpnorm(...) returns the least-p^{th} approximation error, err.

[num,den,err,sos,g] = iirlpnorm(...) returns the second-order section representation in the matrix sos and gain g. For numerical reasons it may be beneficial to use sos and g in some cases.

Hints

- This is a weighted least-p^{th} optimization.
- Check the radii and locations of the poles and zeros for your filter. If the zeros are on the unit circle and the poles are well inside the unit circle, try increasing the order of the numerator or reducing the error weighting in the stopband.
- Similarly, if several poles have a large radii and the zeros are well inside of the unit circle, try increasing the order of the denominator or reducing the error weighting in the passband.

iirlpnormc

Constrained least Pth-norm optimal IIR filter

Syntax

```
[num,den] = iirlpnormc(n,d,f,edges,a)
[num,den] = iirlpnormc(n,d,f,edges,a,w)
[num,den] = iirlpnormc(n,d,f,edges,a,w,radius)
[num,den] = iirlpnormc(n,d,f,edges,a,w,radius,p)
[num,den] = iirlpnormc(n,d,f,edges,a,w,radius,p,dens)
[num,den] =
iirlpnormc(n,d,f,edges,a,w,radius,p,dens,initnum,initden)
[num,den,err] = iirlpnormc(...)
[num,den,err,sos,g] = iirlpnormc(...)
```

Description

`[num,den] = iirlpnormc(n,d,f,edges,a)` returns a filter having numerator order `n` and denominator order `d` which is the best approximation to the desired frequency response described by `f` and `a` in the least-pth sense. The vector `edges` specifies the band-edge frequencies for multi-band designs. A constrained Newton-type algorithm is employed. `n` and `d` should be chosen so that the zeros and poles are used effectively. See the Hints section. Always check the resulting filter using `fvtool`.

`[num,den] = iirlpnormc(n,d,f,edges,a,w)` uses the weights in `w` to weight the error. `w` has one entry per frequency point (the same length as `f` and `a`) which tells `iirlpnormc` how much emphasis to put on minimizing the error in the vicinity of each frequency point relative to the other points. `f` and `a` must have the same number of elements, which can exceed the number of elements in `edges`. This allows for the specification of filters having any gain contour within each band. The frequencies specified in `edges` must also appear in the vector `f`. For example,

```
[num,den] = iirlpnormc(5,5,[0 .15 .4 .5 1],[0 .4 .5 1],...
[1 1.6 1 0 0],[1 1 1 10 10])
```

designs a lowpass filter with a peak of 1.6 within the passband.

`[num,den] = iirlpnormc(n,d,f,edges,a,w,radius)` returns a filter having a maximum pole radius of `radius` where 0<`radius`<1. `radius` defaults to 0.999999. Filters that have a reduced pole radius may retain better transfer function accuracy after you quantize them.

`[num,den] = iirlpnormc(n,d,f,edges,a,w,radius,p)` where `p` is a two-element vector [`pmin pmax`] allows for the specification of the minimum and maximum values of `p` used in the least-pth algorithm. Default is [2 128] which essentially yields the L-infinity, or Chebyshev, norm. `pmin` and `pmax` should be even. If `p` is the string `'inspect'`, no optimization will occur. This can be used to inspect the initial pole/zero placement.

`[num,den] = iirlpnormc(n,d,f,edges,a,w,radius,p,dens)` specifies the grid density `dens` used in the optimization. The number of grid points is `(dens*(n+d+1))`. The default is 20. `dens` can be specified as a single-element cell array. The grid is not equally spaced.

`[num,den] = iirlpnormc(n,d,f,edges,a,w,radius,p,dens,initnum,initden)` allows for the specification of the initial estimate of the filter numerator and denominator coefficients in vectors `initnum` and `initden`. This may be useful for difficult optimization problems. The pole-zero editor in Signal Processing Toolbox software can be used for generating `initnum` and `initden`.

`[num,den,err] = iirlpnormc(...)` returns the least-Pth approximation error `err`.

`[num,den,err,sos,g] = iirlpnormc(...)` returns the second-order section representation in the matrix SOS and gain G. For numerical reasons you may find SOS and G beneficial in some cases.

Hints

- This is a weighted least-pth optimization.
- Check the radii and location of the resulting poles and zeros.
- If the zeros are all on the unit circle and the poles are well inside of the unit circle, try increasing the order of the numerator or reducing the error weighting in the stopband.

- Similarly, if several poles have a large radius and the zeros are well inside of the unit circle, try increasing the order of the denominator or reducing the error weight in the passband.
- If you reduce the pole radius, you might need to increase the order of the denominator.

The message

```
Poorly conditioned matrix. See the "help" file.
```

indicates that `iirlpnormc` cannot accurately compute the optimization because either:

a The approximation error is extremely small (try reducing the number of poles or zeros — refer to the hints above).

b The filter specifications have huge variation, such as `a=[1 1e9 0 0]`.

Examples

This example returns a lowpass filter whose pole radius is constrained to 0.8

```
[b,a,err,s,g] = iirlpnormc(6,6,[0 .4 .5 1],[0 .4 .5 1],...
[1 1 0 0],[1 1 1 1],.8);
hd = dfilt.df1sos(s,g); % Construct second-order sections filter.
fvtool(hd); % View filter's magnitude response
```

From the magnitude response shown here you see the lowpass nature of the filter. The pole/zero plot following shows that the poles are constrained to 0.8 as specified in the command.

iirls

Least-squares IIR filter from specification object

Syntax

```
hd = design(d,'iirls')
hd = design(d,'iirls',designoption,value,designoption,value,...)
```

Description

`hd = design(d,'iirls')` designs a least-squares filter specified by the filter specification object `d`.

Note The `iirls` algorithm might not be well behaved in all cases. Experience is your best guide to determining if the resulting filter meets your needs. When you use `iirls` to design a filter, review the filter carefully to ensure that it is appropriate for your use.

`hd = design(d,'iirls',designoption,value,designoption,value,...)` returns a least-squares IIR filter where you specify design options as input arguments.

To determine the available design options, use `designopts` with the specification object and the design method as input arguments as shown.

```
designopts(d,'method')
```

For complete help about using `iirls`, refer to the command line help system. For example, to get specific information about using `iirls` with `d`, the specification object, enter the following at the MATLAB prompt.

```
help(d,'iirls')
```

Examples

Starting from an arbitrary magnitude and phase design object `d`, generate a complex bandpass filter of order = 5. To make the example a little easier to do, use the default values for F, and H, the frequency vector and the complex desired frequency response.

```
d = fdesign.arbmagnphase('N,F,H',5);
d =

           Response: 'Arbitrary Magnitude and Phase'
      Specification: 'N,F,H'
        Description: {'Filter Order';'Frequency Vector';'
                        Complex Desired Frequency Response'
 NormalizedFrequency: true
         FilterOrder: 5
         Frequencies: [1x655 double]
        FreqResponse: [1x655 double]

design(d,'iirls'); % Opens FVTool to show the filter.
```

Displaying both the phase and magnitude response in FVTool shows you the filter.

iirnotch

Second-order IIR notch filter

Syntax

```
[num,den] = iirnotch(w0,bw)
[num,den] = iirnotch(w0,bw,ab)
```

Description

`[num,den] = iirnotch(w0,bw)` turns a digital notching filter with the notch located at `w0`, and with the bandwidth at the -3 dB point set to `bw`. To design the filter, `w0` must meet the condition 0.0 `w0` 1.0, where 1.0 corresponds to π radians per sample in the frequency range.

The quality factor (Q factor) `q` for the filter is related to the filter bandwidth by `q` `w0/bw` where ω_0 is `w0`, the frequency to remove from the signal.

`[num,den] = iirnotch(w0,bw,ab)` returns a digital notching filter whose bandwidth, `bw`, is specified at a level of `-ab` decibels. Including the optional input argument `ab` lets you specify the magnitude response bandwidth at a level that is not the default -3 dB point, such as -6 dB or 0 dB.

Examples

Design and plot an IIR notch filter that removes a 60 Hz tone (`f0`) from a signal at 300 Hz (`fs`). For this example, set the Q factor for the filter to 35 and use it to specify the filter bandwidth:

```
wo = 60/(300/2);  bw = wo/35;
[b,a] = iirnotch(wo,bw);
fvtool(b,a);
```

Shown in the next plot, the notch filter has the desired bandwidth with the notch located at 60 Hz, or 0.4π radians per sample. Compare this plot to the comb filter plot shown on the reference page for `iircomb`.

iirpeak

Second-order IIR peak or resonator filter

Syntax

```
[num,den] = iirpeak(w0,bw)
[num,den] = iirpeak(w0,bw,ab)
```

Description

`[num,den] = iirpeak(w0,bw)` turns a second-order digital peaking filter with the peak located at `w0`, and with the bandwidth at the +3 dB point set to `bw`. To design the filter, `w0` must meet the condition 0.0 < `w0` < 1.0, where 1.0 corresponds to π radians per sample in the frequency range.

The quality factor (Q factor) q for the filter is related to the filter bandwidth by `q` = `w0/bw` where ω_0 is `w0` the signal frequency to boost.

`[num,den] = iirpeak(w0,bw,ab)` returns a digital peaking filter whose bandwidth, `bw`, is specified at a level of `+ab` decibels. Including the optional input argument `ab` lets you specify the magnitude response bandwidth at a level that is not the default +3 dB point, such as +6 dB or 0 dB.

Examples

Design and plot an IIR peaking filter that boosts the frequency at 1.75 Khz in a signal and has bandwidth of 500 Hz at the -3 dB point:

```
fs = 10000; wo = 1750/(fs/2);  bw = 500/(fs/2);
[b,a] = iirpeak(wo,bw);
fvtool(b,a);
```

Shown in the next plot, the peak filter has the desired gain and bandwidth at 1.75 KHz.

iirpowcomp

Power complementary IIR filter

Syntax

```
[bp,ap] = iirpowcomp(b,a)
[bp,ap,c] = iirpowcomp(b,a)
```

Description

`[bp,ap] = iirpowcomp(b,a)` returns the coefficients of the power complementary IIR filter g(z) = bp(z)/ap(z) in vectors bp and ap, given the coefficients of the IIR filter h(z) = b(z)/a(z) in vectors b and a. b must be symmetric (Hermitian) or antisymmetric (antihermitian) and of the same length as a. The two power complementary filters satisfy the relation

$|H(w)|^2 + |G(w)|^2 = 1$.

`[bp,ap,c] = iirpowcomp(b,a)` where c is a complex scalar of magnitude = 1, forces bp to satisfy the generalized hermitian property

`conj(bp(end:-1:1)) = c*bp`.

When c is omitted, it is chosen as follows:

- When b is real, chooses C as 1 or -1, whichever yields bp real
- When b is complex, C defaults to 1

ap is always equal to a.

Examples

```
[b,a]=cheby1(10,.5,.4);
[bp,ap]=iirpowcomp(b,a);
Hd1 = dfilt.df2(b,a);
Hd2 = dfilt.df2(bp,ap);
```

```
hfvt = fvtool([Hd1,Hd2],'MagnitudeDisplay','Magnitude');
legend(hfvt,'Original Filter','Power Complementary Version');
```

The next figure presents the results of applying `iirpowcomp` to the Chebyshev filter — the power complementary version of the original filter.

iirrateup

Upsample IIR filter by integer factor

Syntax

```
[Num,Den,AllpassNum,AllpassDen] = iirrateup(B,A,N)
```

Description

`[Num,Den,AllpassNum,AllpassDen] = iirrateup(B,A,N)` returns the numerator and denominator vectors, `Num` and `Den` respectively, of the target filter being transformed from any prototype by applying an `N`th-order rateup frequency transformation, where `N` is the upsample ratio. Transformation creates `N` equal replicas of the prototype filter frequency response.

It also returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the allpass mapping filter. The prototype lowpass filter is given with a numerator specified by `B` and a denominator specified by `A`.

The relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter, F_1 and F_2, with F_1 preceding F_2. Feature F_1 will still precede F_2 after the transformation. However, the distance between F_1 and F_2 will not be the same before and after the transformation.

Examples

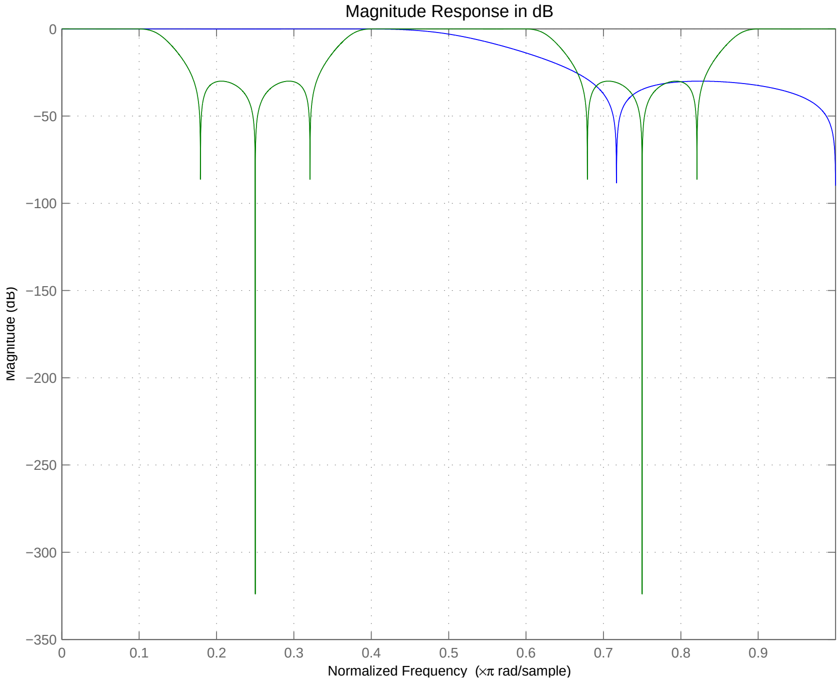
Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3, 0.1, 30, 0.409);
[num, den] = iirrateup(b, a, 4);
```

Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b, a, num, den);
```

As shown in the figure produced by FVTool, the transformed filter appears as expected.



Arguments

Variable	Description
B	Numerator of the prototype lowpass filter
A	Denominator of the prototype lowpass filter
N	Frequency multiplication ratio
Num	Numerator of the target filter
Den	Denominator of the target filter
AllpassNum	Numerator of the mapping filter
AllpassDen	Denominator of the mapping filter

`iirftransf` | `zpkrateup` | `allpassrateup`

iirshift

Shift frequency response of IIR filter

Syntax

```
[Num,Den,AllpassNum,AllpassDen] = iirshift(B,A,Wo,Wt)
```

Description

`[Num,Den,AllpassNum,AllpassDen] = iirshift(B,A,Wo,Wt)` returns the numerator and denominator vectors, `Num` and `Den` respectively, of the target filter transformed from the real lowpass prototype by applying a second-order real shift frequency mapping.

It also returns the numerator, `AllpassNum`, and the denominator of the allpass mapping filter, `AllpassDen`. The prototype lowpass filter is given with the numerator specified by `B` and the denominator specified by `A`.

This transformation places one selected feature of an original filter located at frequency W_o to the required target frequency location, W_t. This transformation implements the "DC Mobility," which means that the Nyquist feature stays at Nyquist, but the DC feature moves to a location dependent on the selection of W_o and W_t.

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter, F_1 and F_2, with F_1 preceding F_2. Feature F_1 will still precede F_2 after the transformation. However, the distance between F_1 and F_2 will not be the same before and after the transformation.

Choice of the feature subject to the real shift transformation is not restricted to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

This transformation can also be used for transforming other types of filters; e.g., notch filters or resonators can change their position in a simple way without designing them from the beginning.

Examples

Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3, 0.1, 30, 0.409);
```

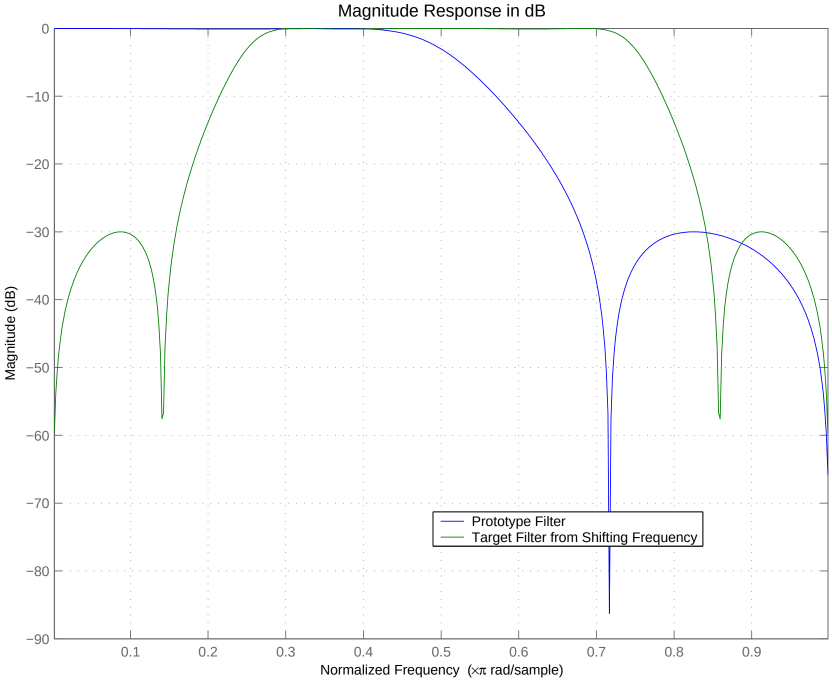
Perform the real frequency shift by defining where the selected feature of the prototype filter, originally at W_o=`0.5`, should be placed in the target filter, W_t=`0.75`:

```
Wo = 0.5; Wt = 0.75;
[num, den] = iirshift(b, a, Wo, Wt);
```

Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b, a, num, den);
```

Shifting the specified feature from the prototype to the target generates the response shown in the figure.



Arguments

Variable	Description
B	Numerator of the prototype lowpass filter
A	Denominator of the prototype lowpass filter
Wo	Frequency value to be transformed from the prototype filter
Wt	Desired frequency location in the transformed target filter
Num	Numerator of the target filter
Den	Denominator of the target filter
AllpassNum	Numerator of the mapping filter
AllpassDen	Denominator of the mapping filter

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

`iirftransf` | `zpkshift` | `allpassshift`

iirshiftc

Shift frequency response of IIR complex filter

Syntax

```
[Num,Den,AllpassNum,AllpassDen] = iirshiftc(B,A,Wo,Wc)
[Num,Den,AllpassNum,AllpassDen] = iirshiftc(B,A,0,0.5)
[Num,Den,AllpassNum,AllpassDen] = iirshiftc(B,A,0,-0.5)
```

Description

`[Num,Den,AllpassNum,AllpassDen] = iirshiftc(B,A,Wo,Wc)` returns the numerator and denominator vectors, `Num` and `Den` respectively, of the target filter transformed from the real lowpass prototype by applying a first-order complex frequency shift transformation. This transformation rotates all the features of an original filter by the same amount specified by the location of the selected feature of the prototype filter, originally at W_o, placed at W_t in the target filter.

It also returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the allpass mapping filter. The prototype lowpass filter is given with the numerator specified by `B` and the denominator specified by `A`.

`[Num,Den,AllpassNum,AllpassDen] = iirshiftc(B,A,0,0.5)` calculates the allpass filter for doing the Hilbert transformation, i.e. a 90 degree counterclockwise rotation of an original filter in the frequency domain.

`[Num,Den,AllpassNum,AllpassDen] = iirshiftc(B,A,0,-0.5)` calculates the allpass filter for doing an inverse Hilbert transformation, i.e. a 90 degree clockwise rotation of an original filter in the frequency domain.

Examples

Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3, 0.1, 30, 0.409);
```

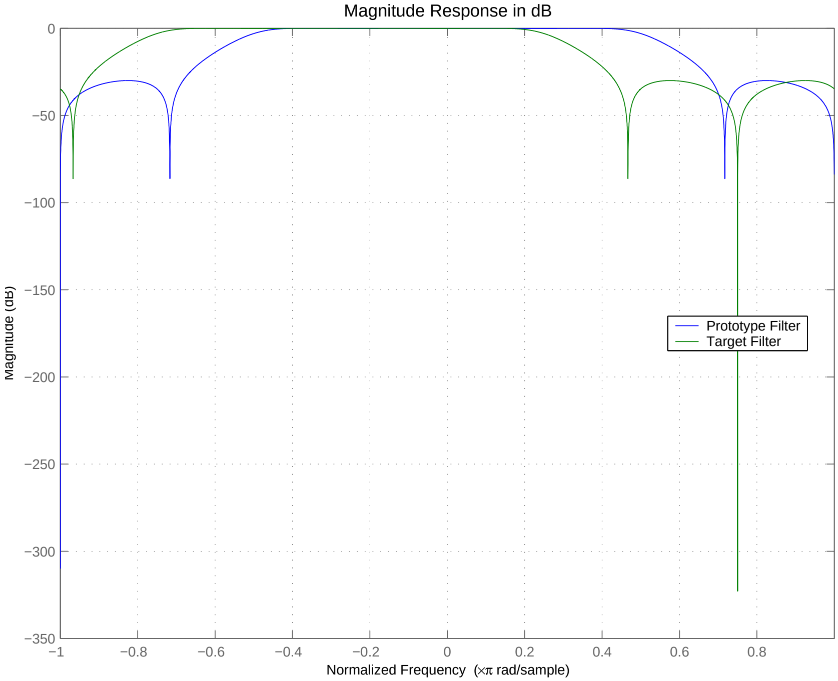
Rotate all features of the prototype filter in the frequency domain by the same amount by specifying where the selected feature of an original filter, W_o= `0.5`, should appear in the target filter, W_t= `0.25`:

```
[num, den] = iirshiftc(b, a, 0.5, 0.25);
```

Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b, a, num, den);
```

After applying the shift, the selected feature from the original filter is just where it should be, at W_t = `0.25`.



Arguments

Variable	Description
B	Numerator of the prototype lowpass filter

Variable	Description
A	Denominator of the prototype lowpass filter
Wo	Frequency value to be transformed from the prototype filter
Wt	Desired frequency location in the transformed target filter
Num	Numerator of the target filter
Den	Denominator of the target filter
AllpassNum	Numerator of the mapping filter
AllpassDen	Denominator of the mapping filter

Frequencies must be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.

impz

Filter impulse response

Syntax

```
[h,t] = impz(hfilt)
[h,t] = impz(hfilt,n)
[h,t] = impz(hfilt,n,fs)
[h,t] = impz(hfilt,[],fs)
impz(hfilt)
[h,t] = impz(hs)
[h,t] = impz(hs,Name,Value)
impz(hs)
```

Description

`impz` returns the impulse response based on the current filter coefficients. This section describes common `impz` operation with adaptive filters, discrete-time filters, multirate filters, and filter System objects. For more input options, refer to `impz` in Signal Processing Toolbox documentation.

`[h,t] = impz(hfilt)` returns the impulse response `h` and the corresponding time points `w` at which the impulse response of `hfilt` is computed. The impulse response is evaluated at 10 1-second intervals—`(0:9)'`.

`[h,t] = impz(hfilt,n)` returns the impulse response evaluated at `floor(n)` 1-second intervals—`(0:floor(n)-1)'`.

`[h,t] = impz(hfilt,n,fs)` returns the impulse response evaluated at `floor(n)` `1`/fs-second intervals—`(0:floor(n)-1)'/fs`.

`[h,t] = impz(hfilt,[],fs)` returns the impulse response evaluated at 10 `1`/fs-second intervals—`(0:9)'/fs`.

`impz(hfilt)` uses FVTool to plot the impulse response of the filter. You can also provide the optional input arguments n and fs with this syntax.

[h,t] = impz(hs) returns the impulse response for the filter System object hs. The impulse response is evaluated at 10 1-second intervals—(0:9)'. You can also provide the optional input arguments n and fs with this syntax.

[h,t] = impz(hs,Name,Value) returns an impulse response with additional options specified by one or more Name,Value pair arguments.

impz(hs) uses FVTool to plot the impulse response of the filter System object hs.

Note You can use impz for both real and complex filters. When you omit the output arguments, impz plots only the real part of the impulse response.

Input Arguments

hfilt

hfilt is either:

- An adaptive adaptfilt, discrete-time dfilt, or multirate mfilt filter object
- A vector of adaptive, discrete-time, or multirate filter objects

The multirate filter impulse response is computed relative to the rate at which the filter is running. When you specify fs (the sampling rate) as an input argument, impz assumes the filter is running at that rate.

For multistage cascades, impz forms a single-stage multirate filter that is equivalent to the cascade. It then computes the response relative to the rate at which the equivalent filter is running. impz does not support all multistage cascades. The function analyzes only those cascades for which there exists an equivalent single-stage filter.

As an example, consider a 2-stage interpolator where the first stage has an interpolation factor of 2 and the second stage has an interpolation factor of 4. In this case, an equivalent single-stage filter exists with an overall interpolation factor of 8. impz uses this equivalent filter for the analysis. If a sampling frequency fs is specified as an input argument to impz, the function interprets fs as the rate at which the equivalent filter is running.

hs

Filter System object.

The following Filter System objects are supported by this analysis function:

Filter System objects
dsp.FIRFilter
dsp.FIRInterpolator
dsp.CICInterpolator
dsp.FIRDecimator
dsp.CICDecimator
dsp.FIRRateConverter
dsp.BiquadFilter
dsp.IIRFilter
dsp.AllpoleFilter
dsp.AllpassFilter
dsp.CoupledAllpassFilter

n

Number of samples.

Default: 10

fs

Sampling frequency.

Default: 1

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

'Arithmetic' — Value types:
‘double’ | 'single' | 'fixed'

For filter System object inputs only, specify the arithmetic used during analysis. When you specify `'double'` or `'single'`, the function performs double- or single-precision analysis. When you specify `'fixed'` , the arithmetic changes depending on the setting of the `CoefficientDataType` property and whether the System object is locked or unlocked.

Details for Fixed-Point Arithmetic

System Object State	Coefficient Data Type	Rule
Unlocked	`'Same as input'`	The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Unlocked	`'Custom'`	The function performs fixed-point analysis based on the setting of the `CustomCoefficientsDataType` property.
Locked	`'Same as input'`	When the input data type is `'double'` or `'fixed'`, the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Locked	`'Custom'`	The function performs fixed-point analysis based on the setting of the `CustomCoefficientsDataType` property.

When you do not specify the arithmetic for non-CIC structures, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System

object is locked, the function performs analysis based on the locked input data type. CIC structures only support fixed-point arithmetic.

Output Arguments

h

Complex, n-element impulse response vector. If hfilt is a vector of filters, h is a complex, length(hfilt)-by-n matrix of impulse response vectors corresponding to each filter in hfilt. If n is not specified, the function uses a default value of 8192.

For adaptive filters, h is the instantaneous impulse response.

t

Time vector of length n, in seconds. t consists of n points equally spaced from 0 to floor(n)/fs. If n is not specified, the function uses a default value of 10. If fs is not specified, the function uses a default value of 1.

Examples

Create a discrete-time filter for a fourth-order, lowpass elliptic filter with a cutoff frequency of 0.4 times the Nyquist frequency. Use a second-order sections structure to resist quantization errors. Plot the first 50 samples of the impulse response, along with the reference impulse response.

```
d = fdesign.lowpass(.4,.5,1,80);
% Create a design object for the prototype filter.
```

Use ellip to design a minimum order discrete-time filter in second-order section form.

```
hd=design(d,'ellip');
```

Convert hd to fixed-point, and plot the impulse response:

```
impz(hd);
axis([1 75 -0.2 0.35])
```

`filter` | `stepz`

impzlength

Impulse response length

Syntax

```
len = impzlength(b,a)
len = impzlength(sos)
len = impzlength(d)
len = impzlength(hs)
len = impzlength(hd)
len = impzlength(___,tol)
```

Description

`len = impzlength(b,a)` returns the impulse response length for the causal discrete-time filter with the rational system function specified by the numerator, b, and denominator, a, polynomials in z^{-1}. For stable IIR filters, len is the effective impulse response sequence length. Terms in the IIR filter's impulse response after the len-th term are essentially zero.

`len = impzlength(sos)` returns the effective impulse response length for the IIR filter specified by the second order sections matrix, sos. `sos` is a K-by-6 matrix, where the number of sections, K, must be greater than or equal to 2. If the number of sections is less than 2, `impzlength` considers the input to be the numerator vector, `b`. Each row of `sos` corresponds to the coefficients of a second order (biquad) filter. The ith row of the `sos` matrix corresponds to `[bi(1) bi(2) bi(3) ai(1) ai(2) ai(3)]`.

`len = impzlength(d)` returns the impulse response length for the digital filter, d. Use `designfilt` to generate d based on frequency-response specifications.

`len = impzlength(hs)` returns the impulse response length for the filter System object, hs. You must have the DSP System Toolbox software to use `impzlength` with a filter System object.

`len = impzlength(hd)` returns the impulse response length for the `dfilt` or `mfilt` filter object, hd. You must have the DSP System Toolbox software to use `impzlength` with an `mfilt` object. You can also input an array of filter objects. If `hd` is an array of filter objects, each column of len is the impulse response length of the corresponding filter object.

`len = impzlength( ___ ,tol)` specifies a tolerance for estimating the effective length of an IIR filter's impulse response. By default, tol is `5e-5`. Increasing the value of tol estimates a shorter effective length for an IIR filter's impulse response. Decreasing the value of tol produces a longer effective length for an IIR filter's impulse response.

Examples

IIR Filter Effective Impulse Response Length — — Coefficients

Create a lowpass allpole IIR filter with a pole at 0.9. Calculate the effective impulse response length, obtain the impulse response, and plot the result.

```
b = 1;
a = [1 -0.9];
len = impzlength(b,a)
[h,t] = impz(b,a);
stem(t,h)
h(len)
```

The value of the impulse response at the estimate length has decayed to approximately 10^{-6}.

IIR Filter Effective Impulse Response Length — — Second Order Sections

Design a 4th-order lowpass elliptic filter with a cutoff frequency of 0.4π rad/sample. Specify 1 dB of passband ripple and 60 dB of stopband attenuation. Design the filter in pole-zero-gain form and obtain the second order section matrix using `zp2sos`. Determine the effective impulse response sequence length from the second order sections matrix.

```
[z,p,k] = ellip(4,1,60,.4);
[sos,g] = zp2sos(z,p,k);
len = impzlength(sos)
```

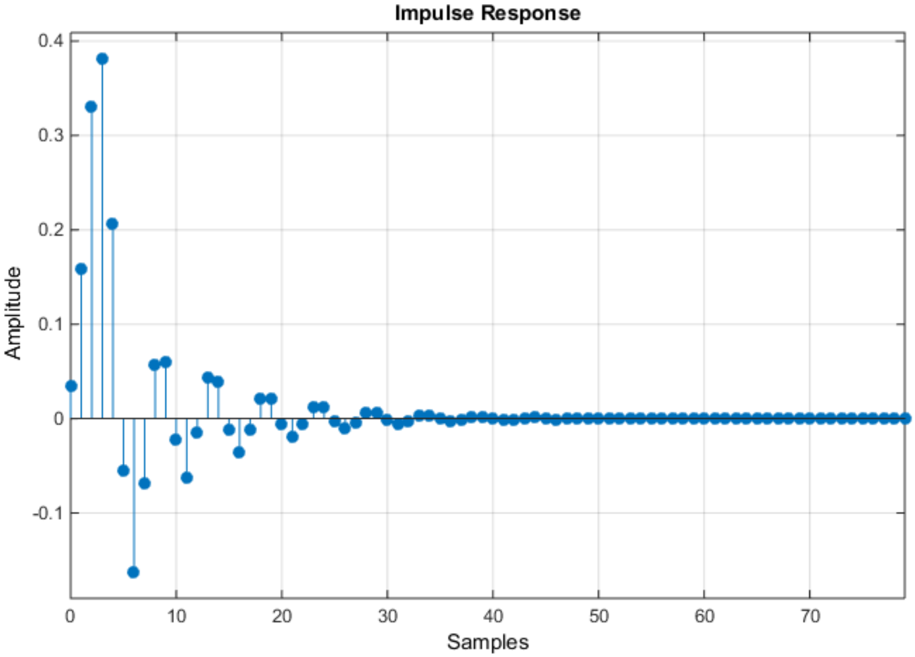
IIR Filter Effective Impulse Response Length --- --- Digital Filter

Use `designfilt` to design a 4th-order lowpass elliptic filter with normalized passband frequency 0.4π rad/sample. Specify 1 dB of passband ripple and 60 dB of stopband attenuation. Determine the effective impulse response sequence length and visualize it.

```
d = designfilt('lowpassiir','FilterOrder',4,'PassbandFrequency',0.4, ...
               'PassbandRipple',1,'StopbandAttenuation',60, ...
               'DesignMethod','ellip');
len = impzlength(d)
impz(d)
```

```
len =

    80
```



Impulse Response Length of Filter System object

This example requires DSP System Toolbox software.

Design a 4th-order lowpass elliptic filter with a cutoff frequency of 0.4π rad/sample. Specify 1 dB of passband ripple and 60 dB of stopband attenuation. Design the filter in pole-zero-gain form and obtain the second order section matrix using `zp2sos`. Create a biquad filter System object and input the System object to `impzlength`.

```
[z,p,k] = ellip(4,1,60,.4);
[sos,g] = zp2sos(z,p,k);
hBqdFilt = dsp.BiquadFilter('Structure','Direct form I',...
                                       'SOSMatrix', sos,...
                                       'ScaleValues',g);
len = impzlength(hBqdFilt)
```

Impulse Response Length — — Filter Objects

Design IIR Butterworth and FIR equiripple filters for data sampled at 1 kHz. The passband frequency is 100 Hz and the stopband frequency is 150 Hz. The passband ripple is 0.5 dB and there is 60 dB of stopband attenuation. Obtain `dfilt` objects for the filters and compare the filter impulse response sequence lengths.

```
d = fdesign.lowpass('Fp,Fst,Ap,Ast',100,150,0.5,60,1000);
Hd1 = design(d,'butter');
Hd2 = design(d,'equiripple');
len = impzlength([Hd1 Hd2])
```

Input Arguments

b — Numerator coefficients

vector | scalar

Numerator coefficients, specified as a scalar (allpole filter) or a vector.

Example: `b = fir1(20,0.25)`

Data Types: `single` | `double`
Complex Number Support: Yes

a — Denominator coefficients

vector | scalar

Denominator coefficients, specified as a scalar (FIR filter) or vector.

Data Types: `single` | `double`
Complex Number Support: Yes

`sos` — Matrix of second order sections

matrix

Matrix of second order sections, specified as a K-by-6 matrix. The system function of the K-th biquad filter has the rational Z-transform

$$H_k(z) = \frac{B_k(1) + B_k(2)z^{-1} + B_k(3)z^{-2}}{A_k(1) + A_k(2)z^{-1} + A_k(3)z^{-2}}.$$

The coefficients in the Kth row of the matrix, sos, are ordered as follows.

$$\begin{bmatrix} B_k(1) & B_k(2) & B_k(3) & A_k(1) & A_k(2) & A_k(3) \end{bmatrix}$$

The frequency response of the filter is the system function evaluated on the unit circle with

$$z = e^{j2\pi f}.$$

`d` — Digital filter

`digitalFilter` object

Digital filter, specified as a `digitalFilter` object. Use `designfilt` to generate a digital filter based on frequency-response specifications.

Example: `d = designfilt('lowpassiir','FilterOrder',3,'HalfPowerFrequency',0.5)` specifies a third-order Butterworth filter with normalized 3-dB frequency 0.5π rad/sample.

`hs` — Filter System object

filter System object

Filter System object, specified as one of the following:

- dsp.FIRFilter
- dsp.BiquadFilter
- dsp.FIRInterpolator
- dsp.CICInterpolator
- dsp.FIRDecimator
- dsp.CICDecimator
- dsp.FIRRateConverter

Using `impzlength` with a filter System object requires the DSP System Toolbox software.

`hd` — Filter object

`dfilt` object | `mfilt` object

Filter object, specified as a `dfilt` or `mfilt` object. You must have the DSP System Toolbox software to input an `mfilt` object.

`tol` — Tolerance for IIR filter effective impulse response length

`5e-5` (default) | positive scalar

Tolerance for IIR filter effective impulse response length, specified as a positive number. The tolerance determines the term in the absolutely summable sequence after which subsequent terms are considered to be 0. The default tolerance is `5e-5`. Increasing the tolerance returns a shorter effective impulse response sequence length. Decreasing the tolerance returns a longer effective impulse response sequence length.

Output Arguments

`len` — Length of impulse response

positive integer

Length of the impulse response, specified as a positive integer. For stable IIR filters with absolutely summable impulse responses, `impzlength` returns an effective length for the impulse response beyond which the coefficients are essentially zero. You can control this cutoff point by specifying the optional tol input argument.

`digitalFilter` | `designfilt` | `impz` | `zp2sos`

info

Information about filter

Syntax

```
info(h)
info(h,'short')
info(h,'long')
s = info(h)
```

Description

`info(h)` returns very basic information about the filter. The particulars depend on the filter type and structure.

`info(h,'short')` returns the same information as `info(h)`.

`info(h,'long')` returns the following information about the filter:

- Specifications such as the filter structure and filter order
- Information about the design method and options
- Performance measurements for the filter response, such as the passband cutoff or stopband attenuation, included in the `measure` method
- Cost of implementing the filter in terms of operations required to apply the filter to data, included in the `cost` method

When the filter uses fixed-point arithmetic, the function returns additional information about the filter, including the arithmetic setting and details about the filter internals.

`s = info(h)` returns filter information in the variable `s`. You can also provide the optional arguments `'short'` and `'long'` with this syntax.

Input Arguments

h

One of the following types of filter object or filter System object:

- Discrete-time filter (`dfilt`) object
- Multirate filter (`mfilt`) object
- Adaptive filter (`adaptfilt`) object
- Filter System object.

  The following Filter System objects are supported by this analysis function:

Filter System objects
`dsp.FIRFilter`
`dsp.FIRInterpolator`
`dsp.CICInterpolator`
`dsp.FIRDecimator`
`dsp.CICDecimator`
`dsp.FIRRateConverter`
`dsp.BiquadFilter`
`dsp.IIRFilter`
`dsp.AllpoleFilter`
`dsp.AllpassFilter`
`dsp.CoupledAllpassFilter`

`‘short’`

Input string that instructs the function to return basic information about the filter.

`‘long’`

Input string that instructs the function to return in-depth information about the filter.

Output Arguments

`s`

Variable for storing filter information.

Examples

Obtain short-format and long-format information about a filter.

int

States from CIC filter

Syntax

```
integerstates = int(hm.states)
```

Description

`integerstates = int(hm.states)` returns the states of a CIC filter in matrix form, rather than as the native `filtstates` object. An important point about `int` is that it quantizes the state values to the smallest number of bits possible while maintaining the values accurately.

Examples

For many users, the states of multirate filters are most useful as a matrix, but the CIC filters store the states as objects. Here is how you get the states from you CIC filter as a matrix.

```
hm = mfilt.cicdecim;
hs = hm.states; % Returns a FILTSTATES.CIC object hs.
states = int(hs); % Convert object hs to a signed integer matrix.
```

After using int to convert the states object to a matrix, here is what you get.

Before converting:

```
hm.states

ans =

    Integrator: [2x1 States]
          Comb: [2x1 States]
```

After the conversion and assigning the states to `states`:

```
states

states =
                0                 0
                0                 0
```

See Also

`filtstates.cic` | `mfilt.cicdecim` | `mfilt.cicinterp`

isallpass

Determine whether filter is allpass

Syntax

```
flag = isallpass(b,a)
flag = isallpass(sos)
flag = isallpass(d)
flag = isallpass(...,tol)
flag = isallpass(hs,...)
flag = isallpass(hs,'Arithmetic',arithtype)
flag = isallpass(hd)
```

Description

`flag = isallpass(b,a)` returns a logical output, flag, equal to `true` if the filter specified by numerator coefficients, `b`, and denominator coefficients, a, is an allpass filter. If the filter is not an allpass filter, flag is equal to `false`.

`flag = isallpass(sos)` returns `true` if the filter specified by second order sections matrix, sos, is an allpass filter. sos is a *K*-by-6 matrix, where the number of sections, *K*, must be greater than or equal to 2. Each row of sos corresponds to the coefficients of a second order (biquad) filter. The *i*th row of the sos matrix corresponds to `[bi(1) bi(2) bi(3) ai(1) ai(2) ai(3)]`.

`flag = isallpass(d)` returns `true` if the digital filter, d, is an allpass filter. Use `designfilt` to generate d based on frequency-response specifications.

`flag = isallpass(...,tol)` uses the tolerance, tol, to determine when two numbers are close enough to be considered equal. If not specified, tol, defaults to `eps^(2/3)`. Specifying a tolerance may be most helpful in fixed-point allpass filters.

`flag = isallpass(hs,...)` returns `true` if the filter System object, `hs`, is an allpass filter. You must have the DSP System Toolbox software to use this syntax.

`flag = isallpass(hs,'Arithmetic',`*`arithtype`*`)` analyzes the filter System object `hs` based on the specified *`arithtype`*. *`arithtype`* can be `'double'`, `'single'`, or 'fixed'. When you specify 'double' or 'single', the function performs double- or single-precision analysis. When you specify 'fixed' , the arithmetic changes depending on the setting of the CoefficientDataType property and whether the System object is locked or unlocked. You must have the DSP System Toolbox software to use this syntax.

Details for Fixed-Point Arithmetic

System Object State	Coefficient Data Type	Rule
Unlocked	'Same as input'	The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Unlocked	'Custom'	The function performs fixed-point analysis based on the setting of the CustomCoefficientsDataType property.
Locked	'Same as input'	When the input data type is 'double' or 'fixed', the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Locked	'Custom'	The function performs fixed-point analysis based on the setting of the CustomCoefficientsDataType property.

When you do not specify the arithmetic for non-CIC structures, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type. CIC structures only support fixed-point arithmetic.

`flag = isallpass(hd)` returns `true` if the filter object, `hd`, is an allpass filter.

Examples

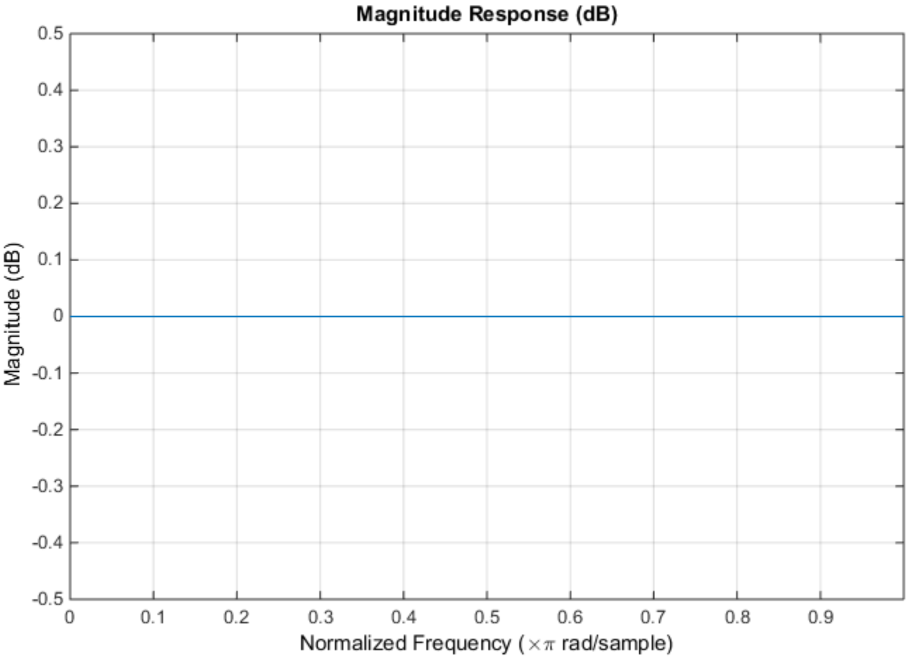
Allpass Filters

Create an allpass filter and verify that the frequency response is allpass.

```
b = [1/3 1/4 1/5 1];
a = fliplr(b);
flag = isallpass(b,a)
fvtool(b,a)
```

```
flag =

     1
```

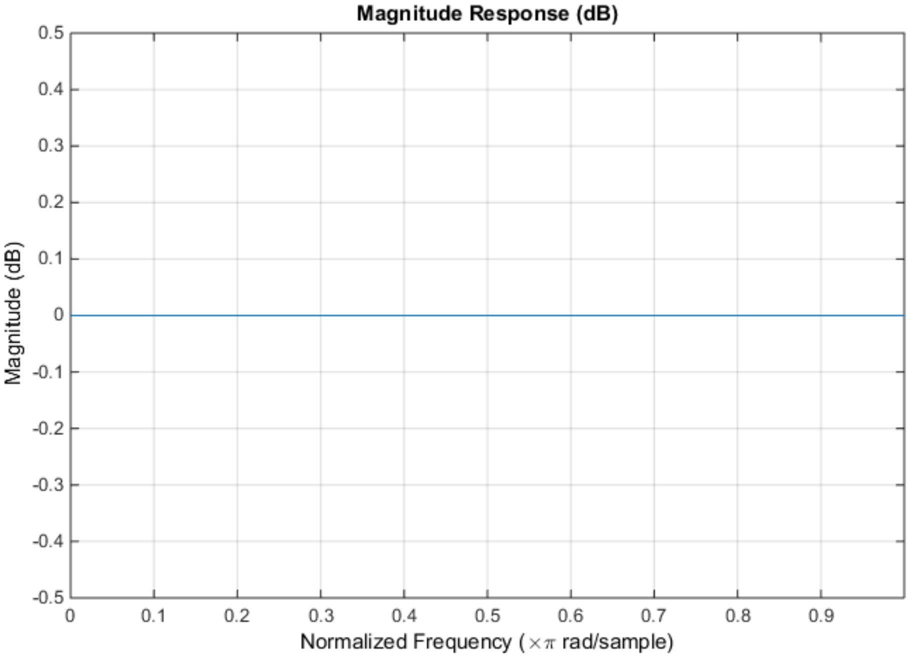


Create a lattice allpass filter and verify that the filter is allpass.

```
k = [1/2 1/3 1/4 1/5];
[b,a] = latc2tf(k,'allpass');
flag_isallpass = isallpass(b,a)
fvtool(b,a)
```

```
flag_isallpass =

     1
```



See Also

designfilt | digitalFilter | islinphase | ismaxphase | isminphase | isstable

isfir

Determine whether filter is FIR

Syntax

```
isfir(h)
isfir(hs)
```

Description

`isfir(h)` determines whether filter `h` is an FIR filter, returning `1` when the filter is an FIR filter, and `0` when it is IIR. `isfir` applies to `dfilt`, `mfilt`, and `adaptfilt` objects.

To determine whether `h` is an FIR filter, `isfir(h)` inspects filter `h` and determines whether the filter, in transfer function form, has a scalar denominator. If it does, it is an FIR filter.

`isfir(hs)` determines whether the filter System object `hs` is an FIR filter, returning `1` if true and `0` if false.

Examples

```
d = fdesign.lowpass;
h = design(d);
isfir(h)
ans =

     1
```

returns `1` for the status of filter `h`. The filter is an FIR structure with denominator reference coefficient equal to 1.

For multirate filters, `isfir` works the same way.

```
d = fdesign.interpolator(5); % Interpolate by 5.
h = design(d); % Use the default design method.
```

```
isfir(h)

ans =

     1
```

Use `isfir` with adaptive filters as well.

`isallpass` | `islinphase` | `ismaxphase` | `isminphase` | `isreal` | `issos` | `isstable`

islinphase

Determine whether filter has linear phase

Syntax

```
flag = islinphase(b,a)
flag = islinphase(sos)
flag = islinphase(d)
flag = islinphase(...,tol)
flag = islinphase(hs,...)
flag = islinphase(hs,'Arithmetic',arithtype)
flag = islinphase(h)
```

Description

`flag = islinphase(b,a)` returns a logical output, flag, equal to `true` if the filter coefficients in b and a define a linear phase filter. flag is equal to `false` if the filter does not have linear phase.

`flag = islinphase(sos)` returns `true` if the filter specified by second order sections matrix, sos, has linear phase. sos is a *K*-by-6 matrix, where the number of sections, *K*, must be greater than or equal to 2. Each row of sos corresponds to the coefficients of a second order (biquad) filter. The *i*th row of the sos matrix corresponds to `[bi(1) bi(2) bi(3) ai(1) ai(2) ai(3)]`.

`flag = islinphase(d)` returns `true` if the digital filter, d, has linear phase. Use `designfilt` to generate d based on frequency-response specifications.

`flag = islinphase(...,tol)` uses the tolerance, tol, to determine when two numbers are close enough to be considered equal. If not specified, tol, defaults to `eps^(2/3)`.

`flag = islinphase(hs,...)` determines whether the filter System object, `hs`, has linear phase. You must have the DSP System Toolbox to use `islinphase` with a System object.

`flag = islinphase(hs,'Arithmetic',`*`arithtype`*`)` analyzes the filter System object `hs` based on the specified *`arithtype`*. *`arithtype`* can be one of `'double'`, 'single', or 'fixed'. When you specify 'double' or 'single', the function performs double- or single-precision analysis. When you specify 'fixed' , the arithmetic changes depending on the setting of the CoefficientDataType property and whether the System object is locked or unlocked. You must have the DSP System Toolbox to use islinphase with a System object.

Details for Fixed-Point Arithmetic

System Object State	Coefficient Data Type	Rule
Unlocked	'Same as input'	The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Unlocked	'Custom'	The function performs fixed-point analysis based on the setting of the CustomCoefficientsDataType property.
Locked	'Same as input'	When the input data type is 'double' or 'fixed', the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Locked	'Custom'	The function performs fixed-point analysis based on the setting of the CustomCoefficientsDataType property.

When you do not specify the arithmetic for non-CIC structures, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System

object is locked, the function performs analysis based on the locked input data type. CIC structures only support fixed-point arithmetic.

`flag = islinphase(h)` determines if the filter object `h` has linear phase. `islinphase` accepts an `adapfilt`, `dfilt`, or `mfilt` object. To create an `adapfilt` or `mfilt` object, you must have the DSP System Toolbox software.

Examples

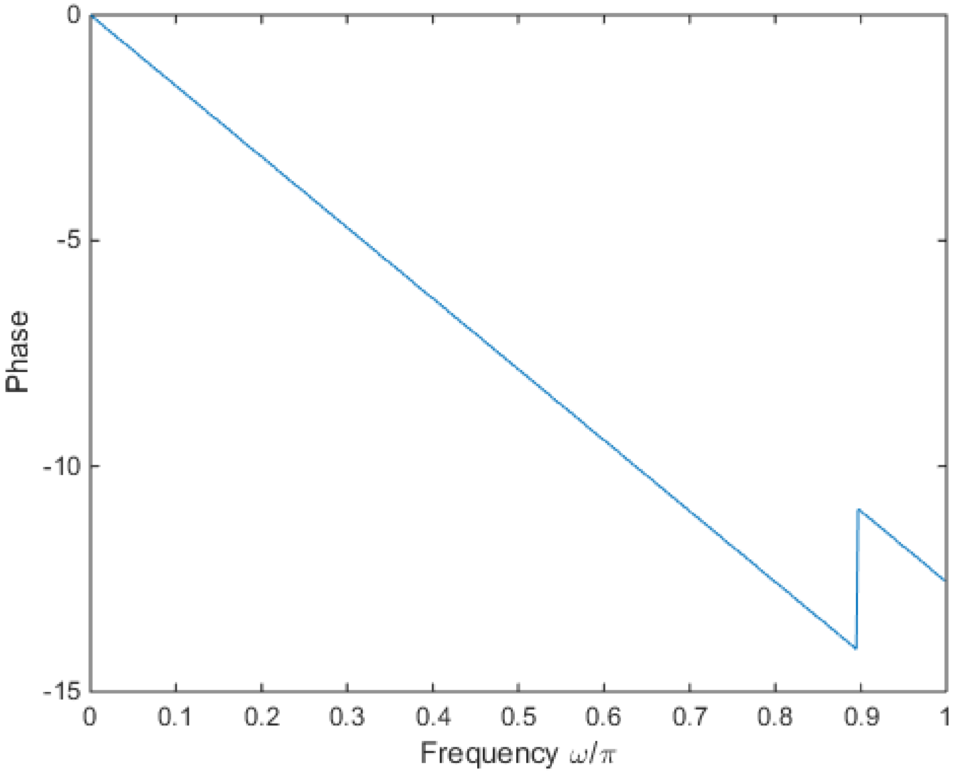
Linear and Nonlinear Phase

Use the window method to design a tenth-order lowpass FIR filter with normalized cutoff frequency 0.55. Verify that the filter has linear phase.

```
d = designfilt('lowpassfir','DesignMethod','window', ...
               'FilterOrder',10,'CutoffFrequency',0.55);
flag = islinphase(d)
[phs,w] = phasez(d);
plot(w/pi,phs)
xlabel('Frequency \omega/\pi')
ylabel('Phase')
```

```
flag =

     1
```



IIR filters in general do not have linear phase. Verify the statement by constructing eighth-order Butterworth, Chebyshev, and elliptic filters with similar specifications.

```
ord = 8;
Wcut = 0.35;
atten = 20;
rippl = 1;

[zb,pb,kb] = butter(ord,Wcut);
sosb = zp2sos(zb,pb,kb);

[zc,pc,kc] = cheby1(ord,rippl,Wcut);
sosc = zp2sos(zc,pc,kc);
```

```
[zd,pd,kd] = cheby2(ord,atten,Wcut);
sosd = zp2sos(zd,pd,kd);

[ze,pe,ke] = ellip(ord,rippl,atten,Wcut);
sose = zp2sos(ze,pe,ke);

fv = fvtool(sosb,sosc,sosd,sose,'Analysis','phase');
legend(fv,'Butterworth','Chebyshev I','Chebyshev II','Elliptic', ...
          'Location','East')
phs = [islinphase(sosb) islinphase(sosc) ...
       islinphase(sosd) islinphase(sose)]

phs =

     0     0     0     0
```

ismaxphase

Determine whether filter is maximum phase

Syntax

```
flag = ismaxphase(b,a)
flag = ismaxphase(sos)
flag = ismaxphase(d)
flag = ismaxphase(...,tol)
flag = ismaxphase(hs,...)
flag = ismaxphase(hs,'Arithmetic',arithtype)
flag = ismaxphase(h)
```

Description

`flag = ismaxphase(b,a)` returns a logical output, flag, equal to `true` if the filter specified by numerator coefficients, b, and denominator coefficients, a, is a maximum phase filter.

`flag = ismaxphase(sos)` returns `true` if the filter specified by second order sections matrix, sos, is a maximum phase filter. sos is a *K*-by-6 matrix, where the number of sections, *K*, must be greater than or equal to 2. Each row of sos corresponds to the coefficients of a second order (biquad) filter. The *i*th row of the sos matrix corresponds to `[bi(1) bi(2) bi(3) ai(1) ai(2) ai(3)]`.

`flag = ismaxphase(d)` returns `true` if the digital filter, `d`, has maximum phase. Use `designfilt` to generate d based on frequency-response specifications.

`flag = ismaxphase(...,tol)` uses the tolerance, tol, to determine when two numbers are close enough to be considered equal. If not specified, tol, defaults to `eps^(2/3)`.

`flag = ismaxphase(hs,...)` returns `true`if the filter System object `hs` is a maximum phase filter. You must have the DSP System Toolbox software to use this syntax.

`flag = ismaxphase(hs,'Arithmetic',`*`arithtype`*`)` analyzes the filter System object `hs` based on the specified *`arithtype`*. *`arithtype`* can be `'double'`, `'single'`, or `'fixed'`. When you specify `'double'` or `'single'`, the function performs double- or single-precision analysis. When you specify `'fixed'` , the arithmetic changes depending on the setting of the `CoefficientDataType` property and whether the System object is locked or unlocked. You must have the DSP System Toolbox software to use this syntax.

Details for Fixed-Point Arithmetic

System Object State	Coefficient Data Type	Rule
Unlocked	`'Same as input'`	The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Unlocked	`'Custom'`	The function performs fixed-point analysis based on the setting of the `CustomCoefficientsDataType` property.
Locked	`'Same as input'`	When the input data type is `'double'` or `'fixed'`, the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Locked	`'Custom'`	The function performs fixed-point analysis based on the setting of the `CustomCoefficientsDataType` property.

When you do not specify the arithmetic for non-CIC structures, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type. CIC structures only support fixed-point arithmetic.

`flag = ismaxphase(h)` returns `true` if the `dfilt` filter object `h` is a maximum phase filter. If you have the DSP System Toolbox software, `ismaxphase` works with `adapfilt` and `mfilt` objects.

Examples

Maximum- and Minimum-Phase Filters

Design maximum-phase and minimum-phase lattice filters and verify their phase type.

```
k = [1/6 1/1.4];
bmax = latc2tf(k,'max');
bmin = latc2tf(k,'min');
max_flag = ismaxphase(bmax)
min_flag = isminphase(bmin)
```

```
max_flag =

     1

min_flag =

     1
```

Given a filter defined with a set of single precision numerator and denominator coefficients, check if it is maximum phase for different values of the tolerance.

```
b = single([1 -0.9999]);
a = single([1 0.45]);
max_flag1 = ismaxphase(b,a)
max_flag2 = ismaxphase(b,a,1e-3)
```

```
max_flag1 =

     0

max_flag2 =
     1
```

See Also

designfilt | digitalFilter | isallpass | islinphase | isminphase | isstable

isminphase

Determine whether filter is minimum phase

Syntax

```
flag = isminphase(b,a)
flag = isminphase(sos)
flag = isminphase(d)
flag = isminphase(...,tol)
flag = isminphase(hs,...)
isminphase(hs,'Arithmetic',arithtype)
flag = isminphase(h)
```

Description

A filter is *minimum phase* when all the zeros of its transfer function are on or inside the unit circle, or the numerator is a scalar. An equivalent definition for a minimum phase filter is a causal and stable system with a causal and stable inverse.

`flag = isminphase(b,a)` returns a logical output, flag, equal to `true` if the filter specified by numerator coefficients, b, and denominator coefficients, a, is a minimum phase filter.

`flag = isminphase(sos)` returns `true` if the filter specified by second order sections matrix, sos, is minimum phase. sos is a K-by-6 matrix, where the number of sections, K, must be greater than or equal to 2. Each row of sos corresponds to the coefficients of a second order (biquad) filter. The ith row of the sos matrix corresponds to `[bi(1) bi(2) bi(3) ai(1) ai(2) ai(3)]`.

`flag = isminphase(d)` returns `true` if the digital filter, `d`, has minimum phase. Use `designfilt` to generate d based on frequency-response specifications.

`flag = isminphase(...,tol)` uses the tolerance, tol, to determine when two numbers are close enough to be considered equal. If not specified, tol, defaults to `eps^(2/3)`.

`flag = isminphase(hs,...)` determines whether the filter System object `hs` is minimum phase, returning `1` if true and `0` if false. You must have the DSP System Toolbox software to use this syntax.

`isminphase(hs,'Arithmetic',`*`arithtype`*`)` analyzes the filter System object `hs` based on the specified *`arithtype`*. *`arithtype`* can be `'double'`, `'single'`, or `'fixed'`. When you specify `'double'` or `'single'`, the function performs double- or single-precision analysis. When you specify `'fixed'` , the arithmetic changes depending on the setting of the `CoefficientDataType` property and whether the System object is locked or unlocked. You must have the DSP System Toolbox software to use this syntax.

Details for Fixed-Point Arithmetic

System Object State	Coefficient Data Type	Rule
Unlocked	`'Same as input'`	The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Unlocked	`'Custom'`	The function performs fixed-point analysis based on the setting of the `CustomCoefficientsDataType` property.
Locked	`'Same as input'`	When the input data type is `'double'` or `'fixed'`, the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Locked	`'Custom'`	The function performs fixed-point analysis based on the setting of the

System Object State	Coefficient Data Type	Rule
		CustomCoefficientsDataType property.

When you do not specify the arithmetic for non-CIC structures, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type. CIC structures only support fixed-point arithmetic.

`flag = isminphase(h)` determines if the `dfilt` filter object `h` is minimum phase. If you have the DSP System Toolbox software, `isminphase` works with `adapfilt` and `mfilt` objects.

Examples

Minimum Phase Filters

Design a sixth-order lowpass Butterworth IIR filter using second order sections. Specify a normalized 3-dB frequency of 0.15. Check if the filter has minimum phase.

```
[z,p,k] = butter(6,0.15);
SOS = zp2sos(z,p,k);
min_flag = isminphase(SOS)
```

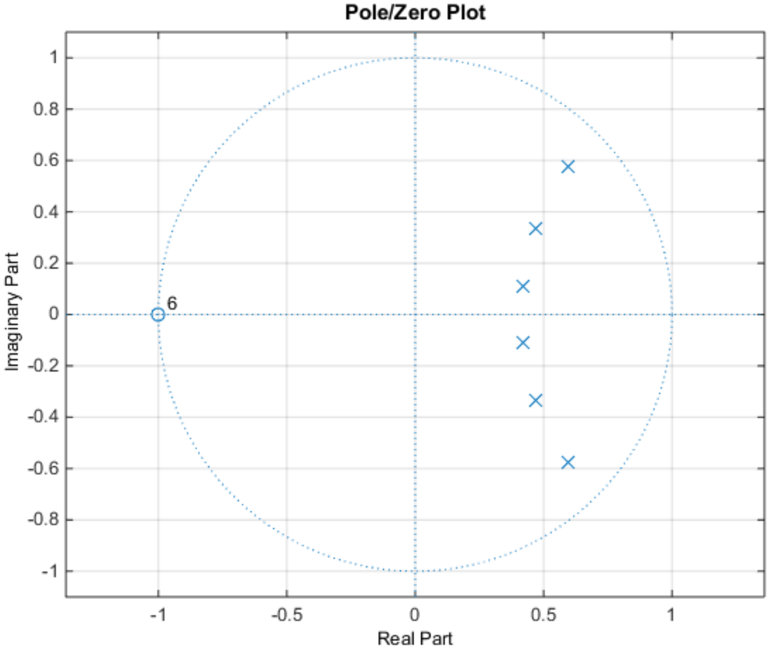
```
min_flag =

     1
```

Redesign the filter using `designfilt`. Check that the zeros and poles of the transfer function are on or within the unit circle.

```
d = designfilt('lowpassiir','DesignMethod','butter','FilterOrder',6, ...
               'HalfPowerFrequency',0.25);
d_flag = isminphase(d)
zplane(d)
```

```
d_flag =
     1
```



Given a filter defined with a set of single-precision numerator and denominator coefficients, check if it has minimum phase for different tolerance values.

```
b = single([1 1.00001]);
a = single([1 0.45]);
min_flag1 = isminphase(b,a)
min_flag2 = isminphase(b,a,1e-3)
```

```
min_flag1 =

     0

min_flag2 =
     1
```

See Also

`designfilt` | `digitalFilter` | `isallpass` | `islinphase` | `ismaxphase` | `isstable`

isreal

Determine whether filter uses real coefficients

Syntax

```
isreal(hd)
isreal(hs)
```

Description

`isreal(hd)` returns `1` (or true) if all filter coefficients for the filter `hd` are real, and returns `0` (or false) otherwise. Complex filters have one or more coefficients with nonzero imaginary parts.

`isreal(hs)` determines whether the filter coefficients of the filter System object `hs` are real, returning `1` if true and `0` if false.

Note Quantizing a filter cannot make a real filter into a complex filter.

Examples

Create a double-precision filter and a fixed-point filter. Then, test the coefficients of the fixed-point filter to see if they are strictly real.

```
d=fdesign.lowpass('n,fp,ap,ast',5,0.4,0.5,20);
hd=design(d,'ellip');
hd.arithmetic='fixed';
IsReal =isreal(hd);
% Returns a 1
```

See Also

`isfir` | `islinphase` | `ismaxphase` | `isminphase` | `issos` | `isstable` | `isallpass`

issos

Determine whether filter is SOS form

Syntax

```
issos(hd)
issoss(hs)
```

Description

`issos(hd)` determines whether quantized filter `hq` consists of second-order sections. Returns `1` if all sections of quantized filter `hq` have order less than or equal to two, and `0` otherwise.

`issoss(hs)` determines whether the filter System object `hs` consists of second-order sections, returning `1` if true and `0` if false.

Examples

By default, fdesign and design return SOS filters when possible. This example designs a lowpass SOS filter that uses fixed-point arithmetic.

```
d=fdesign.lowpass('n,fp,ap,ast',40,0.55,0.1,60);
hd=design(d,'ellip');
hd.arithmetic='fixed';
IsSOS=issos(hd);
```

The fixed-point filter `hd` is in second-order section form, as is the double-precision version.

See Also

`isallpass` | `isfir` | `islinphase` | `ismaxphase` | `isminphase` | `isreal` | `isstable`

isstable

Determine whether filter is stable

Syntax

```
flag = isstable(b,a)
flag = isstable(sos)
flag = isstable(d)
flag = isstable(hs)
flag = isstable(hs,'Arithmetic',arithtype)
flag = isstable(h)
```

Description

`flag = isstable(b,a)` returns a logical output, flag, equal to `true` if the filter specified by numerator coefficients, b, and denominator coefficients, a, is a stable filter. If the poles lie on or outside the circle, `isstable` returns `false`. If the poles are inside the circle, `isstable` returns `true`.

`flag = isstable(sos)` returns `true` if the filter specified by second order sections matrix, sos, is stable. sos is a K-by-6 matrix, where the number of sections, K, must be greater than or equal to 2. Each row of sos corresponds to the coefficients of a second order (biquad) filter. The ith row of the sos matrix corresponds to `[bi(1) bi(2) bi(3) ai(1) ai(2) ai(3)]`.

`flag = isstable(d)` returns `true` if the digital filter, `d`, is stable. Use `designfilt` to generate d based on frequency-response specifications.

`flag = isstable(hs)` returns `true` if the filter System object `hs` is stable. You must have the DSP System Toolbox software to use this syntax.

`flag = isstable(hs,'Arithmetic',`*`arithtype`*`)` analyzes the filter System object `hs` based on the specified *`arithtype`*. *`arithtype`* can be `'double'`, `'single'`, or `'fixed'`. When you specify `'double'` or `'single'`, the function performs double- or single-precision analysis. When you specify `'fixed'` , the arithmetic changes depending on the setting of the `CoefficientDataType` property and whether the System object is locked or unlocked. You must have the DSP System Toolbox software to use this syntax.

Details for Fixed-Point Arithmetic

System Object State	Coefficient Data Type	Rule
Unlocked	`'Same as input'`	The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Unlocked	`'Custom'`	The function performs fixed-point analysis based on the setting of the `CustomCoefficientsDataType` property.
Locked	`'Same as input'`	When the input data type is `'double'` or `'fixed'`, the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Locked	`'Custom'`	The function performs fixed-point analysis based on the setting of the `CustomCoefficientsDataType` property.

When you do not specify the arithmetic for non-CIC structures, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type. CIC structures only support fixed-point arithmetic.

`flag = isstable(h)` returns `true` if the filter object, `h`, is stable. If you have the DSP System Toolbox, you can use `isstable` with `adaptfilt` and `mfilt` objects.

Examples

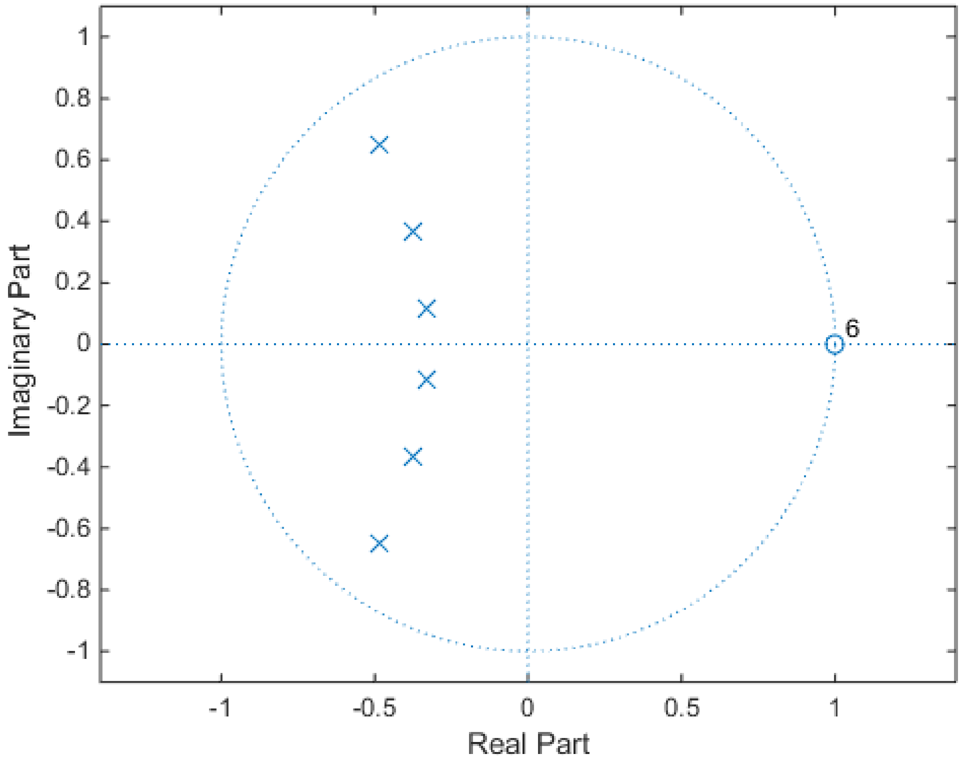
Filter Stability

Design a sixth-order Butterworth highpass IIR filter using second order sections. Specify a normalized 3-dB frequency of 0.7. Determine if the filter is stable.

```
[z,p,k] = butter(6,0.7,'high');
SOS = zp2sos(z,p,k);
flag = isstable(SOS)
zplane(z,p)
```

```
flag =

     1
```

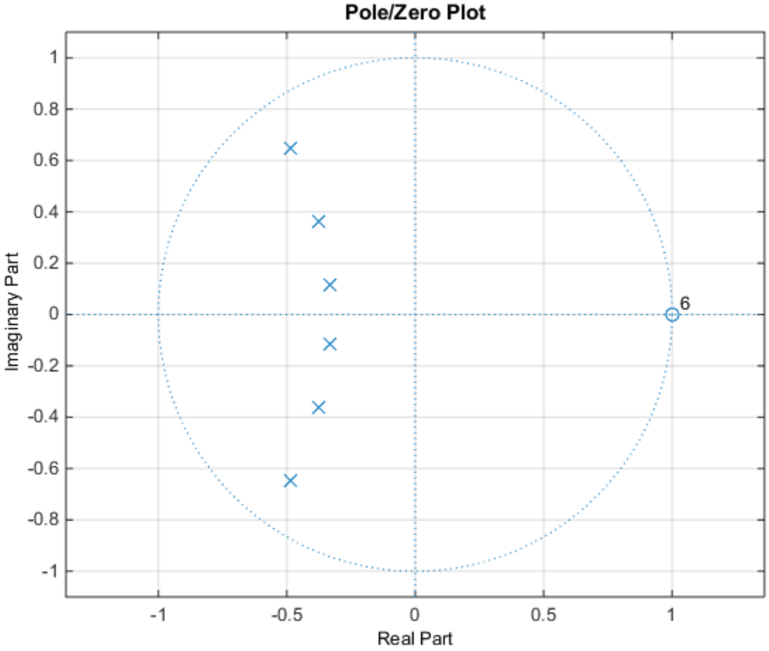


Redesign the filter using `designfilt` and check it for stability.

```
d = designfilt('highpassiir','DesignMethod','butter','FilterOrder',6, ...
                   'HalfPowerFrequency',0.7);
dflg = isstable(d)
zplane(d)
```

```
dflg =

      1
```



Create a filter and determine its stability at double and single precision.

```
b = [1 -0.5];
a = [1 -0.999999999];
act_flag1 = isstable(b,a)
act_flag2 = isstable(single(b),single(a))
```

```
act_flag1 =

     1

act_flag2 =

     0
```

designfilt | digitalFilter | isallpass | islinphase | ismaxphase | isminphase | zplane

kaiserwin

Kaiser window filter from specification object

Syntax

```
h = design(d,'kaiserwin')
h = design(d,'kaiserwin',designoption,value,designoption,...
value,...)
```

Description

`h = design(d,'kaiserwin')` designs a digital filter `hd`, or a multirate filter `hm` that uses a Kaiser window. For `kaiserwin` to work properly, the filter order in the specifications object must be even. In addition, higher order filters (filter order greater than 120) tend to be more accurate for smaller transition widths. `kaiserwin` returns a warning when your filter order may be too low to design your filter accurately.

`h = design(d,'kaiserwin',designoption,value,designoption,... value,...)` returns a filter where you specify design options as input arguments and the design process uses the Kaiser window technique.

To determine the available design options, use `designopts` with the specification object and the design method as input arguments as shown.

```
designopts(d,'method')
```

For complete help about using `kaiserwin`, refer to the command line help system. For example, to get specific information about using `kaiserwin` with `d`, the specification object, enter the following at the MATLAB prompt.

```
help(d,'kaiserwin')
```

Examples

This example designs a direct form FIR filter from a halfband filter specification object.

```
d=fdesign.halfband('n,tw',200,0.01)
```

```
hd= design(d,'kaiserwin','filterstructure','dffir')
```

In this example, `kaiserwin` uses an interpolating filter specification object:

```
d=fdesign.interpolator(4,'lowpass');
h = design(d,'kaiserwin');
```

`equiripple` | `firls`

lagrange

Fractional delay filter from `fdesign.fracdelay` specification object

Syntax

```
Hd = design(d,'lagrange')
hd = design(d,'lagrange',FilterStructure,structure)
```

Description

`Hd = design(d,'lagrange')` designs a fractional delay filter using the Lagrange method based on the specifications in `d`.

`hd = design(d,'lagrange',FilterStructure,`*`structure`*`)` specifies the Lagrange design method and the *`structure`* filter structure for `hd`. The sole valid filter structure string for `structure` is `fd`, describing the fractional delay structure.

Examples

This example uses a fractional delay of 0.30 samples. The `help` and `designopts` commands provide the details about designing fractional delay filters.

```
d=fdesign.fracdelay(.30)

d =

               Response: 'Fractional Delay'
          Specification: 'N'
            Description: {'Filter Order'}
              FracDelay: 0.3
    NormalizedFrequency: true
            FilterOrder: 3

designmethods(d)
```

```
Design Methods for class fdesign.fracdelay (N):

lagrange

help(d,'lagrange')

 DESIGN Design a Lagrange fractional delay filter.
 HD = DESIGN(D, 'lagrange') designs a Lagrange filter
specified by the FDESIGN object D.

HD = DESIGN(..., 'FilterStructure', STRUCTURE) returns
a filter with the structure STRUCTURE.  STRUCTURE is 'fd'
by default and can be any of the following:

    'fd'

% Example #1 - Design a linear Lagrange fractional
% delay filter of 0.2 samples.
h = fdesign.fracdelay(0.2,'N',2);
Hd = design(h, 'lagrange', 'FilterStructure', 'fd')

% Example #2 - Design a cubic Lagrange fractional
% delay filter.
Fs = 8000;      % Sampling frequency of 8kHz
fdelay = 50e-6; % Fractional delay of 50 microseconds.
h  = fdesign.fracdelay(fdelay,'N',3,Fs);
Hd = design(h, 'lagrange', 'FilterStructure', 'fd');
```

This example designs a linear Lagrange fractional delay filter where you set the delay to 0.2 seconds and the filter order `N` to 2.

```
h = fdesign.fracdelay(0.2,'N',2); .
hd = design(h,'lagrange','FilterStructure','fd')
```

Design a cubic Lagrange fractional delay filter with filter order equal to 3..

```
Fs = 8000;      % Sampling frequency of 8 kHz.
fdelay = 50e-6; % Fractional delay of 50 microseconds.
h  = fdesign.fracdelay(fdelay,'N',3,Fs);
hd = design(h,'lagrange','FilterStructure','fd');
```

liblinks

Check model for blocks from specific DSP System Toolbox libraries

Syntax

```
liblinks(lib)
liblinks(lib,sys)
liblinks(lib,sys,c)
```

Description

`liblinks(lib)` returns a cell array of strings that lists the blocks in the current model that are linked to the specified libraries. The input `lib` provides a cell array of strings with the library names. Use the library name visible in the title bar when you open a library model.

`liblinks(lib,sys)` acts on the named model `sys`.

`liblinks(lib,sys,c)` changes the foreground color of the returned blocks to the color `c`. Possible values of `c` are `'blue'`, `'green'`, `'red'`, `'cyan`', `'magenta'`, `'yellow'`, or `'black'`.

Examples

Check for blocks from the Sources library in the specified model:

```
rlsdemo
liblinks('dspsrcs4',gcs)
```

`dsp_links`

limitcycle

Response of single-rate, fixed-point IIR filter

Syntax

```
report = limitcycle(hd)
report = limitcycle(hd,ntrials,inputlengthfactor,stopcriterion)
```

Description

`report = limitcycle(hd)` returns the structure `report` that contains information about how filter `hd` responds to a zero-valued input vector. By default, the input vector has length equal to twice the impulse response length of the filter.

`limitcycle` returns a structure whose elements contain the details about the limit cycle testing. As shown in this table, the report includes the following details.

Output Object Property	Description
`LimitCycleType`	Contains one of the following results: • `Granular` — indicates that a granular overflow occurred. • `Overflow` — indicates that an overflow limit cycle occurred. • `None` — indicates that the test did not find any limit cycles.
`Zi`	Contains the initial condition value(s) that caused the detected limit cycle to occur.
`Output`	Contains the output of the filter in the steady state.
`Trial`	Returns the number of the Monte Carlo trial on which the limit cycle testing stopped. For example, `Trial = 10` indicates that testing stopped on the tenth Monte Carlo trial.

Using an input vector longer than the filter impulse response ensures that the filter is in steady-state operation during the limit cycle testing. `limitcycle` ignores output that occurs before the filter reaches the steady state. For example, if the filter impulse length is 500 samples, `limitcycle` ignores the filter output from the first 500 input samples.

To perform limit cycle testing on your IIR filter, you must set the filter `Arithmetic` property to `fixed` and `hd` must be a fixed-point IIR filter of one of the following forms:

- `df1` — direct-form I
- `df1t` — direct-form I transposed
- `df1sos` — direct-form I with second-order sections
- `df1tsos` — direct-form I transposed with second-order sections
- `df2` — direct-form II
- `df2t` — direct-form II transposed
- `df2sos` — direct-form II with second-order sections
- `df2tsos` — direct-form II transposed with second-order sections

When you use `limitcycle` without optional input arguments, the default settings are

- Run 20 Monte Carlo trials
- Use an input vector twice the length of the filter impulse response
- Stop testing if the simulation process encounters either a granular or overflow limit cycle

To determine the length of the filter impulse response, use `impzlength`:

```
impzlength(hd)
```

During limit cycle testing, if the simulation runs reveal both overflow and granular limit cycles, the overflow limit cycle takes precedence and is the limit cycle that appears in the report.

Each time you run `limitcycle`, it uses a different sequence of random initial conditions, so the results can differ from run to run.

Each Monte Carlo trial uses a new set of randomly determined initial states for the filter. Test processing stops when `limitcycle` detects a zero-input limit cycle in filter `hd`.

`report = limitcycle(hd,ntrials,inputlengthfactor,stopcriterion)` returns a report of how filter `hd` responds to a zero-valued input vector, using the following optional input arguments:

- `ntrials` — Number of Monte Carlo trials (default is 20).
- `inputlengthfactor` — integer factor used to calculate the length of the input vector. The length of the input vector comes from `(impzlength(hd) * inputlengthfactor)`, where `inputlengthfactor` = 2 is the default value.
- `stopcriterion` — the criterion for stopping the Monte Carlo trial processing. `stopcriterion` can be set to **`either`** (the default), **`granular`**, **`overflow`**. This table describes the results of each stop criterion.

stopcriterion Setting	Description
`either`	Stop the Monte Carlo trials when `limitcycle` detects either a granular or overflow limit cycle.
`granular`	Stop the Monte Carlo trials when `limitcycle` detects a granular limit cycle.
`overflow`	Stop the Monte Carlo trials when `limitcycle` detects an overflow limit cycle.

Note An important feature is that if you specify a specific limit cycle stop criterion, such as `overflow`, the Monte Carlo trials do not stop when testing encounters a granular limit cycle. You receive a warning that no `overflow` limit cycle occurred, but consider that a `granular` limit cycle might have occurred.

Examples

In this example, there is a region of initial conditions in which no limit cycles occur and a region where they do. If no limit cycles are detected before the Monte Carlo trials are over, the state sequence converges to zero. When a limit cycle is found, the states do not end at zero. Each time you run this example, it uses a different sequence of random initial conditions, so the plot you get can differ from the one displayed in the following figure.

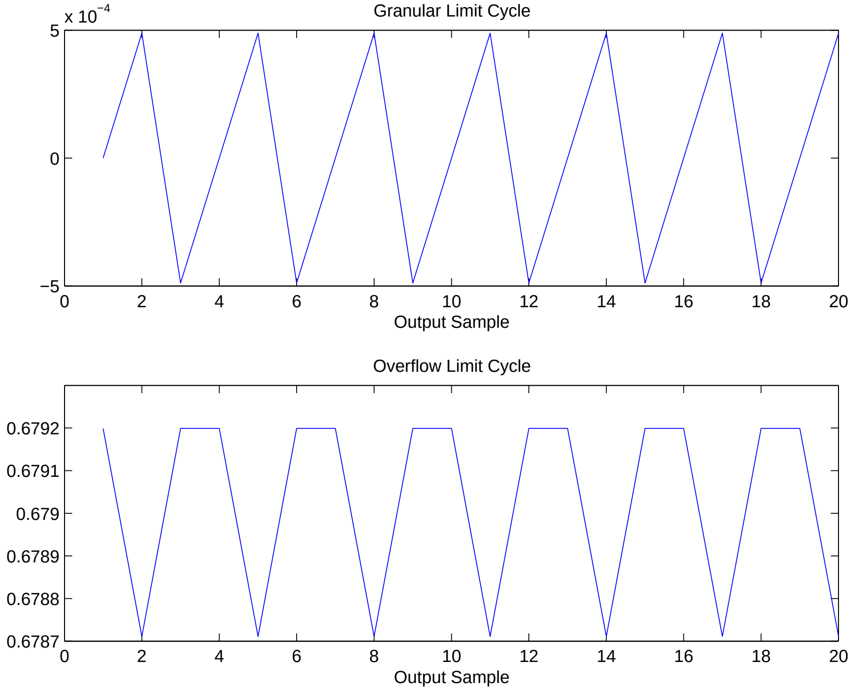
```
s = [1 0 0 1 0.9606 0.9849];
hd = dfilt.df2sos(s);
hd.arithmetic = 'fixed';
greport = limitcycle(hd,20,2,'granular')
oreport = limitcycle(hd,20,2,'overflow')
figure,
subplot(211),plot(greport.Output(1:20)), title('Granular Limit Cycle');
subplot(212),plot(oreport.Output(1:20)), title('Overflow Limit Cycle');

greport =
    LimitCycle: 'granular'
            Zi: [2x1 double]
        Output: [1303x1 embedded.fi]
         Trial: 1

oreport =

    LimitCycle: 'overflow'
            Zi: [2x1 double]
        Output: [1303x1 embedded.fi]
         Trial: 2
```

The plots shown in this figure present both limit cycle types — the first displays the small amplitude granular limit cycle, the second the larger amplitude overflow limit cycle.



As you see from the plots, and as is generally true, overflow limit cycles are much greater magnitude than granular limit cycles. This is why `limitcycle` favors overflow limit cycle detection and reporting.

maxflat

Maxflat FIR filter

Syntax

```
hd = design(d,'maxflat')
hd = design(d,'maxflat','FilterStructure',structure)
```

Description

`hd = design(d,'maxflat')` designs a maximally flat filter, `hd`, from a filter specification object, `d`.

`hd = design(d,'maxflat','FilterStructure',structure)` designs a maximally flat filter where `structure` is one of the following:

- `'dffir'`, a discrete-time, direct-form FIR filter (the default value)
- `'dffirt'`, a discrete-time, direct-form FIR transposed filter
- `'dfsymfir'`, a discrete-time, direct-form symmetric FIR filter
- `'fftfir'`, a discrete-time, overlap-add, FIR filter

Examples

Example 1: Design a lowpass filter with a maximally flat FIR structure.

```
d  = fdesign.lowpass('N,F3dB', 50, 0.3);
Hd = design(d, 'maxflat');
```

Example 2: Design a highpass filter with a maximally flat overlap-add FIR structure.

```
d  = fdesign.highpass('N,F3dB', 50, 0.7);
Hd=design(d,'maxflat','FilterStructure','fftfir');
```

maximizestopband

Maximize stopband attenuation of fixed-point filter

Syntax

```
Hq = maximizestopband(Hd,Wordlength)
Hq = maximizestopband(Hd,Wordlength,'Ntrials',N)
```

Description

Hq = maximizestopband(Hd,Wordlength) quantizes the single-stage or multistage FIR filter Hd and returns the fixed-point filter Hq with wordlength wordlength that maximizes the stopband attenuation. Hd must be generated using fdesign and design. For multistage filters, wordlength can either be a scalar or vector. If wordlength is a scalar, the same wordlength is used for all stages. If wordlength is a vector, each stage uses the corresponding element in the vector. The vector length must equal the number of stages. maximizestopband uses a stochastic noise-shaping procedure by default to minimize the wordlength. To obtain repeatable results on successive function calls, initialize the uniform random number generator rand

Hq = maximizestopband(Hd,Wordlength,'Ntrials',N) specifies the number of Monte Carlo trials to use in the maximization. Hq is the fixed-point filter with the largest stopband attenuation among the trials. The number of Monte Carlo trials N defaults to 1.

You must have the Fixed-Point Designer software installed to use this function.

Examples

Maximize stopband attenuation for 16–bit fixed-point filter.

```
Hf = fdesign.lowpass('Fp,Fst,Ap,Ast',0.4,0.45,0.5,60);
Hd = design(Hf,'equiripple');
WL = 16; % use 16 bits to represent coefficients
Hq = maximizestopband(Hd,WL);
% Compare stopband attenuation
md = measure(Hd);
```

```
mq = measure(Hq);
hfvt=fvtool(Hd,Hq,'showreference','off');
legend(hfvt,'Floating-point Filter','Fixed-point Filter');
```

maxstep

Maximum step size for adaptive filter convergence

Syntax

```
mumax = maxstep(ha,x)
[mumax,mumaxmse] = maxstep(ha,x)
```

Description

`mumax = maxstep(ha,x)` predicts a bound on the step size to provide convergence of the mean values of the adaptive filter coefficients. The columns of the matrix `x` contain individual input signal sequences. The signal set is assumed to have zero mean or nearly so.

`[mumax,mumaxmse] = maxstep(ha,x)` predicts a bound on the adaptive filter step size to provide convergence of the LMS adaptive filter coefficients in the mean-square sense. `maxstep` issues a warning when `ha.stepsize` is outside of the range 0 < `ha.stepsize` < `mumaxmse`/2.

`maxstep` is available for the following adaptive filter objects:

- `adaptfilt.blms`
- `adaptfilt.blmsfft`
- `adaptfilt.lms`
- `adaptfilt.nlms` (uses a different syntax. Refer to the text below.)
- `adaptfilt.se`

Note With `adaptfilt.nlms` filter objects, `maxstep` uses the following slightly different syntax:

```
mumax = maxstep(ha)
[mumax,mumaxmse] = maxstep(ha)
```

The maximum step size for convergence is fully defined by the filter object `ha`. Matrix `x` is not necessary. If you include an `x` input matrix, MATLAB returns an error.

Examples

Analyze and simulate a 32-coefficient (31st-order) LMS adaptive filter object. To demonstrate the adaptation process, run 2000 iterations and 50 trials.

```
% Specify [numiterations,numexamples] = size(x);
x = zeros(2000,50);
d = x;
obj = fdesign.lowpass('n,fc',31,0.5);
hd = design(obj,'window'); % FIR filter to identified.
coef = cell2mat(hd.coefficients); % Convert cell array to matrix.

for k=1:size(x,2);   % Create input and desired response signal
                     % matrices.
% Set the (k)th input to the filter.
  x(:,k) = filter(sqrt(0.75),[1 -0.5],sign(randn(size(x,1),1)));
  n = 0.1*randn(size(x,1),1);  % (k)th observation noise signal.
  d(:,k) = filter(coef,1,x(:,k))+n; % (k)th desired signal end.
end
mu = 0.1;                       % LMS step size.
ha = adaptfilt.lms(32,mu);
[mumax,mumaxmse] = maxstep(ha,x);

Warning: Step size is not in the range 0 < mu < mumaxmse/2:
Erratic behavior might result.

mumax

mumax =

    0.0623

measure

Measure filter magnitude response

Syntax

```
measure(hd)
measure(hm)
measure(hs)
measure(hs)
```

Description

`measure(hd)` returns measured values for specific points in the magnitude response curve for filter object `hd`. When you use a design object `d` to create a filter (by using `fdesign.`*`type`* to create `d`), you specify one or more values that define your desired filter response. `measure(hd)` tests the filter to determine the actual values in the magnitude response of the filter, such as the stopband attenuation or the passband ripple. Comparing the results returned by `measure` to the specifications you provided in the design object helps you assess whether the filter meets your design criteria.

Note To use `measure`, `hd`, `hm`, or `hs` must result from using a filter design method with a filter specifications object. `measure` works with multirate filters and discrete-time filters. The function does not support adaptive filters because you cannot use `fdesign.`*`type`* to construct adaptive filter specifications objects.

`measure(hd)` returns measurements for the discrete-time filter `hd`. The function determines the relevant specifications based on the response type of the design object you use to create the filter. For example, for single-rate lowpass filters made from design objects, `measure(hd)` returns the following filter specifications.

Lowpass Filter Specification	Description
`Sampling Frequency`	Filter sampling frequency.
`Passband Edge`	Location of the edge of the passband as it enters transition.

Lowpass Filter Specification	Description
`3-dB Point`	Location of the –3 dB point on the response curve.
`6-dB Point`	Location of the –6 dB point on the response curve.
`Stopband Edge`	Location of the edge of the transition band as it enters the stopband.
`Passband Ripple`	Ripple in the passband.
`Stopband Atten`	Attenuation in the stopband.
`Transition Width`	Width of the transition between the passband and stopband, in normalized frequency or absolute frequency. Measured between `Fpass` and `Fstop`.

In contrast, when you use a bandstop design object, `measure(hd)` returns these specifications for the resulting bandstop filter.

Bandstop Filter Specification	Description
`Sampling Frequency`	Filter sampling frequency.
`First Passband Edge`	Location of the edge of the first passband.
`First 3-dB Point`	Location of the edge of the –3 dB point in the first transition band.
`First 6-dB Point`	Location of the edge of the –6 dB point in the first transition band.
`First Stopband Edge`	Location of the start of the stopband.
`Second Stopband Edge`	Location of the end of the stopband.
`Second 6-dB Point`	Location of the edge of the –6 dB point in the second transition band.
`Second 3-dB Point`	Location of the edge of the –3 dB point in the second transition band.
`Second Passband Edge`	Location of the start of the second passband.
`First Passband Ripple`	Ripple in the first passband.
`Stopband Atten`	Attenuation in the stopband.
`Second Passband Edge`	Ripple in the second passband.
`First Transition Width`	Width of the first transition region. Measured between the –3 and –6 dB points.

Bandstop Filter Specification	Description
`Second Transition Width`	Width of the second transition region. Measured between the –6 and –3 dB points.

`measure(hm)` returns measurements for the multirate filter `hm`. The set of filter specifications that `measure` returns for multirate filters might be different from those for discrete-time filters.

The set of response measurements that `measure` returns depends on the response you use to design the filter. For example, when `hm` is an FIR lowpass interpolator (whose response is lowpass), `measure(hm)` returns the following set of measurements.

Interpolator Filter Specification	Description
`First Passband Edge`	Location of the edge of the passband as it enters transition.
`3-dB Point`	Location of the –3 dB point on the response curve.
`6-dB Point`	Location of the –6 dB point on the response curve.
`Stopband Edge`	Location of the edge of the transition band as it enters the stopband.
`Passband Ripple`	Ripple in the passband.
`Stopband Atten`	Attenuation in the stopband.
`Transition Width`	Width of the transition between the passband and stopband, in normalized frequency or absolute frequency. Measured between `Fpass` and `Fstop`.

For reference, the specification object `d` created the interpolator specifications shown in the preceding table:

```
d=fdesign.interpolator(6,'lowpass')

d =

          MultirateType: 'Interpolator'
    InterpolationFactor: 6
               Response: 'Lowpass'
          Specification: 'Fp,Fst,Ap,Ast'
            Description: {4x1 cell}
    NormalizedFrequency: true
                  Fpass: 0.133333333333333
```

```
                Fstop: 0.166666666666667
                Apass: 1
                Astop: 60
```

`measure(hs)` returns measurements for the filter System object `hs`. You must construct `hs` using `design` with the optional name-value pair argument `'SystemObject',true`.

`measure(hs)` returns measurements for the filter System object `hs` with additional options specified by one or more Name,Value pair arguments.

Input Arguments

`hd`

Discrete-time `dfilt` filter object.

`hm`

Multirate `mfilt` filter object.

`hs`

Filter System object.

The following Filter System objects are supported by this analysis function:

Filter System objects
`dsp.FIRFilter`
`dsp.FIRInterpolator`
`dsp.CICInterpolator`
`dsp.FIRDecimator`
`dsp.CICDecimator`
`dsp.FIRRateConverter`
`dsp.BiquadFilter`
`dsp.IIRFilter`
`dsp.AllpoleFilter`
`dsp.AllpassFilter`
`dsp.CoupledAllpassFilter`

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'Arithmetic'` — Value types:
`‘double’ | 'single' | 'fixed'`

For filter System object inputs only, specify the arithmetic used during analysis. When you specify `'double'` or `'single'`, the function performs double- or single-precision analysis. When you specify `'fixed'` , the arithmetic changes depending on the setting of the `CoefficientDataType` property and whether the System object is locked or unlocked.

Details for Fixed-Point Arithmetic

System Object State	Coefficient Data Type	Rule
Unlocked	`'Same as input'`	The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Unlocked	`'Custom'`	The function performs fixed-point analysis based on the setting of the `CustomCoefficientsDataType` property.
Locked	`'Same as input'`	When the input data type is `'double'` or `'fixed'`, the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.

System Object State	Coefficient Data Type	Rule
Locked	`'Custom'`	The function performs fixed-point analysis based on the setting of the `CustomCoefficientsDataType` property.

When you do not specify the arithmetic for non-CIC structures, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type. CIC structures only support fixed-point arithmetic.

Examples

For the first example, create a lowpass filter and check whether the actual filter meets the specifications. For this case, use normalized frequency for Fs, the default setting.

```
d2=fdesign.lowpass('Fp,Fst,Ap,Ast',0.45,0.55,0.1,80)

d2 =

               Response: 'Lowpass'
          Specification: 'Fp,Fst,Ap,Ast'
            Description: {4x1 cell}
    NormalizedFrequency: true
                  Fpass: 0.45
                  Fstop: 0.55
                  Apass: 0.1
                  Astop: 80

designmethods(d2)

Design Methods for class fdesign.lowpass (Fp,Fst,Ap,Ast):

butter
cheby1
cheby2
ellip
equiripple
```

```
ifir
kaiserwin
multistage

hd2=design(d2) % Use the default equiripple design method.

hd2 =

     FilterStructure: 'Direct-Form FIR'
          Arithmetic: 'double'
           Numerator: [1x68 double]
    PersistentMemory: false

measure(hd2)

ans =

Sampling Frequency : N/A (normalized frequency)
Passband Edge      : 0.45
3-dB Point         : 0.47794
6-dB Point         : 0.48909
Stopband Edge      : 0.55
Passband Ripple    : 0.09615 dB
Stopband Atten.    : 80.2907 dB
Transition Width   : 0.1
```

`Stopband Edge`, `Passband Edge`, `Passband Ripple`, and `Stopband Atten` all meet the specifications.

Now, using `Fs` in linear frequency, create a bandpass filter, and measure the magnitude response characteristics.

```
d=fdesign.bandpass

d =

               Response: 'Bandpass'
          Specification: 'Fst1,Fp1,Fp2,Fst2,Ast1,Ap,Ast2'
            Description: {7x1 cell}
    NormalizedFrequency: true
                 Fstop1: 0.35
                 Fpass1: 0.45
                 Fpass2: 0.55
                 Fstop2: 0.65
                 Astop1: 60
```

```
                   Apass: 1
                  Astop2: 60

normalizefreq(d,false,1.5e3) % Convert to linear freq.

hd=design(d,'cheby2');

measure(hd)

ans =

Second Stopband Atten.   : 60 dB
First Transition Width   : 0.075 kHz
Second Transition Width  : 0.075 kHz
```

`measure(hd)` returns the actual response values, in the units you chose. In this example, all frequencies appear in kilohertz because the sampling frequency is in kilohertz.

More About

Tips

For designs that do not specify some of the frequency constraints, the function may not be able to determine corresponding magnitude measurements. In these cases, a constraint can be passed in to `measure` to determine such measurements. For example:

```
f = fdesign.lowpass('N,F3dB,Ast',8,0.5,80);
H = design(f,'cheby2','SystemObject',true);
measure(H)
```

returns values of `Unknown` for the passband edge, passband ripple, and transition width measurements, but

```
f = fdesign.lowpass('N,F3dB,Ast',8,0.5,80);
H = design(f,'cheby2','SystemObject',true);
measure(H,'Fpass',0.4)
```

provides measurements for all returned values.

`design` | `fdesign` | `normalizefreq`

mfilt

Multirate filter

Syntax

```
hm = mfilt.structure(input1,input2,...)
```

Description

`hm = mfilt.structure(input1,input2,...)` returns the object `hm` of type *`structure`*. As with `dfilt` and `adaptfilt` objects, you must include the *`structure`* string to construct a multirate filter object. You can, however, construct a default multirate filter object of a given structure by not including input arguments in your calling syntax.

Multirate filters include decimators and interpolators, and fractional decimators and fractional interpolators where the resulting interpolation or decimation factor is not an integer.

Structures

Each of the following multirate filter structures has a reference page of its own.

Filter Structure String	Description of Resulting Multirate Filter	Coefficient Mapping Support in `realizemdl` and `block`
`mfilt.cascade`	Cascade multirate filters to form another filter	Supported
`mfilt.cicdecim`	Cascaded integrator-comb decimator	Not supported
`mfilt.cicinterp`	Cascaded integrator-comb interpolator	Not supported
`mfilt.farrowsrc`	Multirate Farrow filter	Supported.
`mfilt.fftfirinterp`	Overlap-add FIR polyphase interpolator	Not supported

Filter Structure String	Description of Resulting Multirate Filter	Coefficient Mapping Support in `realizemdl` and `block`
`mfilt.firdecim`	Direct-form FIR polyphase decimator	Supported
`mfilt.firinterp`	Direct-form FIR polyphase interpolator	Supported
`mfilt.firsrc`	Direct-form FIR polyphase sample rate converter	Supported
`mfilt.firtdecim`	Direct-form transposed FIR polyphase decimator	Supported
`mfilt.holdinterp`	FIR hold interpolator	Not supported
`mfilt.iirdecim`	IIR decimator	Supported
`mfilt.iirinterp`	IIR interpolator	Supported
`mfilt.linearinterp`	FIR Linear interpolator	Supported
`mfilt.iirwdfdecim`	IIR wave digital filter decimator	Supported
`mfilt.iirwdfinterp`	IIR wave digital filter interpolator	Supported

Copying mfilt Objects

To create a copy of an `mfilt` object, use the `copy` method.

```
h2 = copy(hd)
```

Note The syntax `hd2 = hd` copies only the object handle. It does not create a new object. `hd2` and `hd` are not independent. If you change the property value for one of the two, such as `hd2`, you are changing the property for both.

Examples

Decimation by a factor of two. Convert input sampled at 48 kHz to 24 kHz:

```
Fs = 4.8e4;
```

```
t =0:1/Fs:1-(1/Fs);
x = cos(2*pi*4000*t);
Hm=mfilt.firdecim(2);
% Note cutoff frequency of 1/2 normalized frequency
fvtool(Hm);
% Note the group delay of 34 samples
fvtool(Hm,'analysis','grpdelay');
y = filter(Hm,x);
% Note delay in output is consistent with 36/2
stem(y(1:48),'markerfacecolor',[0 0 1]);
```

Using existing coefficients to decimate a signal by a factor of two:

```
M = 2; % Decimation factor
  b = firhalfband('minorder',.45,0.0001);
  Hm = mfilt.firdecim(M,b);
  % Decimate a signal which consists of the sum of 2 sinusoids.
  N = 160;
  x = sin(2*pi*.05*[0:N-1]+pi/3)+cos(2*pi*.03*[0:N-1]+pi/3);
  y = filter(Hm,x);
```

Note Multirate filters can also have complex coefficients. For example, you can specify complex coefficients in the argument `num` passed to the filter structure. This works for all multirate filter structures.

```
m = 2;
num = [0.5 0.5+1j*0.2];
Hm = mfilt.firdecim(m, num);
y = filter(Hm, [1:10]);
```

mfilt.cascade

Cascade filter objects

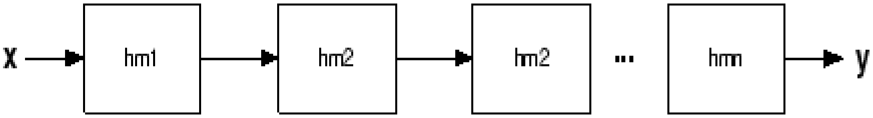
Syntax

```
hm = cascade(hm1,hm2,...,hmn)
```

Description

`hm = cascade(hm1,hm2,...,hmn)` creates filter object `hm` by cascading (connecting in series) the individual filter objects `hm1`, `hm2`, and so on to `hmn`.

In block diagram form, the cascade looks like this, with x as the input to the filter `hm` and y the output from the cascade filter `hm`:



`mfilt.cascade` accepts any combination of `mfilt` and `dfilt` objects (discrete time filters) to cascade, as well as Farrow filter objects.

Examples

Create a variety of `mfilt` objects and cascade them together.

```
hm(1) = mfilt.firdecim(12);
hm(2) = mfilt.firdecim(4);
h1 = mfilt.cascade(hm(1),hm(2));
hm(3) = mfilt.firinterp(4);
hm(4) = mfilt.firinterp(12);
h2 = mfilt.cascade(hm(3),hm(4));
% Cascade h1 and h2 together
h3 = mfilt.cascade(h1,h2,9600);
```

See Also

`dfilt.cascade`

mfilt.cicdecim

Fixed-point CIC decimator

Syntax

```
hm = mfilt.cicdecim(r,m,n,iwl,owl,wlps)
```

Description

`hm = mfilt.cicdecim(r,m,n,iwl,owl,wlps)` returns a cascaded integrator-comb (CIC) decimation filter object.

All of the input arguments are optional. To enter any optional value, you must include all optional values to the left of your desired value.

When you omit one or more input options, the omitted option applies the default values shown in the table below.

The following table describes the input arguments for creating `hm`.

Input Arguments	Description
`r`	Decimation factor applied to the input signal. Sharpens the response curve to let you change the shape of the response. `r` must be an integer value greater than or equal to 1. The default value is 2.
`m`	Differential delay. Changes the shape, number, and location of nulls in the filter response. Increasing `m` increases the sharpness of the nulls and the response between nulls. In practice, differential delay values of 1 or 2 are the most common. `m` must be an integer value greater than or equal to 1. The default value is 1.
`n`	Number of sections. Deepens the nulls in the response curve. Note that this is the number of either comb or integrator sections, not the total section count. 2 is the default value.
`iwl`	Word length of the input signal. Use any integer number of bits. The default value is 16 bits.

Input Arguments	Description
`owl`	Word length of the output signal. It can be any positive integer number of bits. By default, `owl` is 16 bits.
`wlps`	Defines the number of bits per word in each filter section while accumulating the data in the integrator sections or while subtracting the data during the comb sections (using 'wrap' arithmetic). Enter `wlps` as a scalar or vector of length `2*n`, where `n` is the number of sections. When `wlps` is a scalar, the scalar value is applied to each filter section. The default is 16 for each section in the decimator. When you elect to specify `wlps` as an input argument, the `FilterInternals` property automatically switches from the default value of `'FullPrecision'` to `'SpecifyWordLengths'`.

Constraints and Word Length Considerations

CIC decimators have the following constraint — the word lengths of the filter section must be monotonically decreasing. The word length of each filter section must be the same size as, or smaller than, the word length of the previous filter section.

The formula for B_{max}, the most significant bit at the filter output, is given in the Hogenauer paper in the References below.

$$B_{\max} = (N \log_2 RM + B_{in} - 1)$$

where B_{in} is the number of bits of the input.

The cast operations shown in the diagram in “Algorithms” on page 4-952 perform the changes between the word lengths of each section. When you specify word lengths that do not follow the constraints above, the constructor returns an error.

When you specify the word lengths correctly, the most significant bit B_{max} stays the same throughout the filter, while the word length of each section either decreases or stays the same. This can cause the fraction length to change throughout the filter as least significant bits are truncated to decrease the word length, as shown in “Algorithms” on page 4-952.

Properties of the Object

Objects have properties that control the way the object behaves. This table lists all the properties for the filter, with a description of each.

Name	Values	Default	Description
`Arithmetic`	`fixed`	`fixed`	Reports the kind of arithmetic the filter uses. CIC decimators are always fixed-point filters.
`DecimationFactor`	Any positive integer	2	Amount to reduce the input sampling rate.
`DifferentialDelay`	Any positive integer	1	Sets the differential delay for the filter. Usually a value of one or two is appropriate.
`FilterStructure`	`mfilt` structure string	None	Reports the type of filter object. You cannot set this property — it is always read only and results from your choice of `mfilt` objects.

`FilterInternals`	`FullPrecision,`
	`MinWordLengths,`
	`SpecifyPrecision,`
	`SpecifyWordLengths`
		`FullPrecision`	Set the usage mode for the filter. Refer to “Usage Modes” on page 4-944 below for details.

`InputFracLength`	Any positive integer	15	The number of bits applied to the fraction length to interpret the input data to the filter.
`InputOffset`	Integers in the range 0 ≤ **`InputOffset`** ≤ **`r-1`**	0	Contains a value derived from the number of input samples and the decimation factor — `InputOffset = mod(length(nx),m)` where `nx` is the number of

Name	Values	Default	Description
			input samples that have been processed so far and `m` is the decimation factor. The `InputOffset` property applies only when you set the `PersistentMemory` property to `true`. See "InputOffset" for more information.
`InputWordLength`	Any positive integer	16	The number of bits applied to the word length to interpret the input data to the filter.
`NumberOfSections`	Any positive integer	2	Number of sections used in the decimator. Generally called `n`. Reflects either the number of decimator or comb sections, not the total number of sections in the filter.
`OutputFracLength`	Any positive integer	15	The number of bits applied to the fraction length to interpret the output data from the filter. Read-only.
`OutputWordLength`	Any positive integer	16	The number of bits applied to the word length to interpret the output data from the filter.

Name	Values	Default	Description
PersistentMemory	false or true	false	Determines whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. PersistentMemory returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. When PersistentMemory is false, you cannot access the filter states. Setting PersistentMemory to true reveals the States property so you can modify the filter states.

Name	Values	Default	Description
SectionWord Lengths	Any integer or a vector of length 2*n.	16	Defines the bits per section used while accumulating the data in the integrator sections or while subtracting the data during the comb sections (using 'wrap' arithmetic). Enter SectionWordLengths as a scalar or vector of length 2*n, where n is the number of sections. When SectionWordLengths

Name	Values	Default	Description
			is a scalar, the scalar value is applied to each filter section. When SectionWordLengths is a vector of values, the values apply to the sections in order. The default is 16 for each section in the decimator. Available when FilterInternals is 'SpecifyWordLengths'.
States	filtstates.cic object	m+1-by-n matrix of zeros, after you call function int.	Stored conditions for the filter, including values for the integrator and comb sections before and after filtering. m is the differential delay of the comb section and n is the number of sections in the filter. The integrator states are stored in the first matrix row. States for the comb section fill the remaining rows in the matrix. Available for modification when PersistentMemory is true. Refer to the filtstates object in Signal Processing Toolbox documentation for more general information about the filtstates object.

Usage Modes

There are four modes of usage for this which are set using the FilterInternals property

- `FullPrecision` — All word and fraction lengths set to B_{max} + 1, called B_{accum} by Fred Harris in [3]. Full Precision is the default setting.
- `MinWordLengths` — Automatically set the sections for minimum word lengths.
- `SpecifyWordLengths` — Specify the word lengths for each section.
- `SpecifyPrecision` — Specify precision by providing values for the word and fraction lengths for each section.

Full Precision

In full precision mode, the word lengths of all sections and the output are set to B_{accum} as defined by

$$B_{accum} = ceil(N_{\sec s}(Log_2(D \times M)) + InputWordLength)$$

where N_{secs} is the number of filter sections.

Section fraction lengths and the fraction length of the output are set to the input fraction length.

Here is the display for this mode:

```
FilterStructure: 'Cascaded Integrator-Comb Decimator'
Arithmetic: 'fixed'
DifferentialDelay: 1
NumberOfSections: 2
DecimationFactor: 4
PersistentMemory: false

InputWordLength: 16
InputFracLength: 15

FilterInternals: 'FullPrecision'
```

Minimum Wordlengths

In minimum word length mode, you control the output word length explicitly. When the output word length is less than B_{accum}, roundoff noise is introduced at the output of the filter. Hogenauer's bit pruning theory (refer to [1]) states that one valid design criterion is to make the word lengths of the different sections of the filter smaller than B_{accum} as well, so that the roundoff noise introduced by all sections does not exceed the roundoff noise introduced at the output.

In this mode, the design calculates the word lengths of each section to meet the Hogenauer criterion. The algorithm subtracts the number of bits computed using eq. 21 in Hogenauer's paper from B_{accum} to determine the word length each section.

To compute the fraction lengths of the different sections, the algorithm notes that the bits thrown out for this word length criterion are least significant bits (LSB), therefore each bit thrown out at a particular section decrements the fraction length of that section by one bit compared to the input fraction length. Setting the output wordlength for the filter automatically sets the output fraction length as well.

Here is the display for this mode:

```
FilterStructure: 'Cascaded Integrator-Comb Decimator'
Arithmetic: 'fixed'
DifferentialDelay: 1
NumberOfSections: 2
DecimationFactor: 4
PersistentMemory: false

InputWordLength: 16
InputFracLength: 15

FilterInternals: 'MinWordLengths'

OutputWordLength: 16
```

Specify word lengths

In this mode, the design algorithm discards the LSBs, adjusting the fraction length so that unrecoverable overflow does not occur, always producing a reasonable output.

You can specify the word lengths for all sections and the output, but you cannot control the fraction lengths for those quantities.

To specify the word lengths, you enter a vector of length 2*(`NumberOfSections`), where each vector element represents the word length for a section. If you specify a scalar, such as B_{accum}, the full-precision output word length, the algorithm expands that scalar to a vector of the appropriate size, applying the scalar value to each section.

The CIC design does not check that the specified word lengths are monotonically decreasing. There are some cases where the word lengths are not necessarily monotonically decreasing, for example

```
hcic=mfilt.cicdecim;
hcic.FilterInternals='minwordlengths';
hcic.Outputwordlength=14;
```

which are valid CIC filters but the word lengths do not decrease monotonically across the sections.

Here is the display for the `SpecifyWordLengths` mode.

```
FilterStructure: 'Cascaded Integrator-Comb Decimator'
Arithmetic: 'fixed'
DifferentialDelay: 1
NumberOfSections: 2
DecimationFactor: 4
PersistentMemory: false

InputWordLength: 16
InputFracLength: 15

FilterInternals: 'SpecifyWordLengths'

SectionWordLengths: [19 18 18 17]

OutputWordLength: 16
```

Specify precision

In this mode, you have full control over the word length and fraction lengths of all sections and the filter output.

When you elect the `SpecifyPrecision` mode, you must enter a vector of length 2*(`NumberOfSections`) with elements that represent the word length for each section. When you enter a scalar such as B_{accum}, `mfilt.cicdecim` expands that scalar to a vector of the appropriate size and applies the scalar value to each section and the output. The design does not check that this vector is monotonically decreasing.

Also, you must enter a vector of length 2*(`NumberOfSections`) with elements that represent the fraction length for each section as well. When you enter a scalar such as B_{accum}, `mfilt.cicdecim` applies scalar expansion as done for the word lengths.

Here is the SpecifyPrecision display.

```
FilterStructure: 'Cascaded Integrator-Comb Decimator'
Arithmetic: 'fixed'
DifferentialDelay: 1
NumberOfSections: 2
DecimationFactor: 4
PersistentMemory: false

InputWordLength: 16
InputFracLength: 15

FilterInternals: 'SpecifyPrecision'

SectionWordLengths: [19 18 18 17]
SectionFracLengths: [14 13 13 12]

OutputWordLength: 16
OutputFracLength: 11
```

About the States of the Filter

In the states property you find the states for both the integrator and comb portions of the filter. states is a matrix of dimensions m + 1-by-n, with the states apportioned as follows:

- States for the integrator portion of the filter are stored in the first row of the state matrix.
- States for the comb portion fill the remaining rows in the state matrix.

To review the states of a CIC filter, use int to assign the states to a variable in MATLAB. As an example, here are the states for a CIC decimator hm before and after filtering a data set.

```
x = fi(ones(1,10),true,16,0); % Fixed-point input data.
hm = mfilt.cicdecim(2,1,2,16,16,16);
sts=int(hm.states)
set(hm,'InputFracLength',0); % Integer input specified.
y=filter(hm,x);
sts=int(hm.states)
```

STS is an integer matrix that int returns from the contents of the filtstates.cic object in hm.

Design Considerations

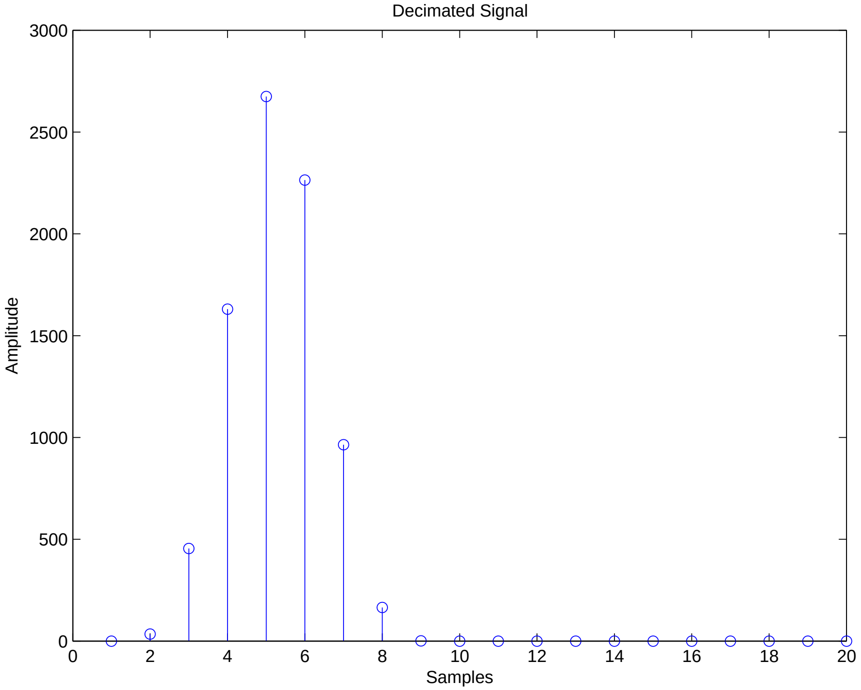
When you design your CIC decimation filter, remember the following general points:

- The filter output spectrum has nulls at $\omega = k * 2\pi/rm$ radians, $k = 1,2,3\ldots$.
- Aliasing and imaging occur in the vicinity of the nulls.
- n, the number of sections in the filter, determines the passband attenuation. Increasing n improves the filter ability to reject aliasing and imaging, but it also increases the droop (or rolloff) in the filter passband. Using an appropriate FIR filter in series after the CIC decimation filter can help you compensate for the induced droop.
- The DC gain for the filter is a function of the decimation factor. Raising the decimation factor increases the DC gain.

Examples

This example applies a decimation factor r equal to 8 to a 160-point impulse signal. The signal output from the filter has 160/r, or 20, points or samples. Choosing 10 bits for the word length represents a fairly common setting for analog to digital converters. The plot shown after the code presents the stem plot of the decimated signal, with 20 samples remaining after decimation:

```
m = 2;  % Differential delays in the filter.
n = 4;  % Filter sections
r = 8;   % Decimation factor
x = int16(zeros(160,1)); x(1) = 1;    % Create a 160-point
                                      % impulse signal.
hm = mfilt.cicdecim(r,m,n); % Expects 16-bit input
                            % by default.
y = filter(hm,x);
stem(double(y));    % Plot output as a stem plot.
xlabel('Samples'); ylabel('Amplitude');
title('Decimated Signal');
```



The next example demonstrates one way to compute the filter frequency response, using a 4-section decimation filter with the decimation factor set to 7:

```
hm = mfilt.cicdecim(7,1,4);
fvtool(hm)
```

FVTool provides ways for you to change the title and x labels to match the figure shown. Here's the frequency response plot for the filter. For details about the transfer function used to produce the frequency response, refer to [1] in the References section.

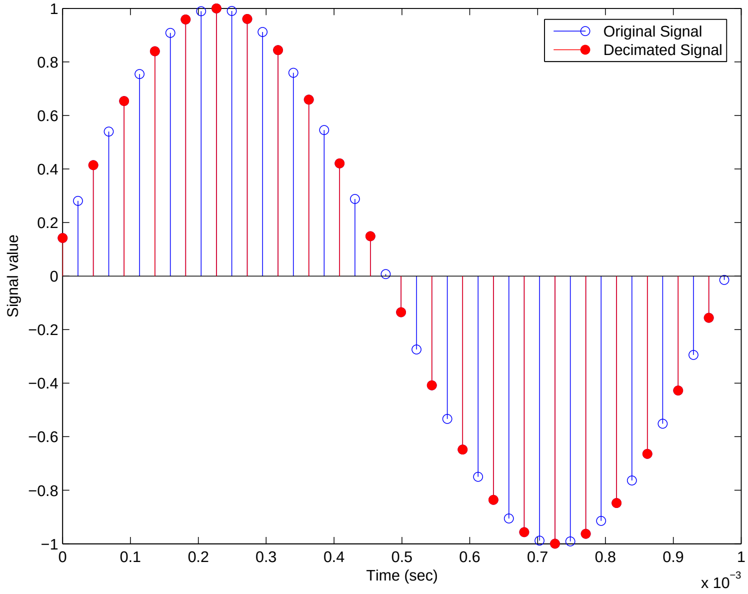
This final example demonstrates the decimator for converting from 44.1 kHz audio to 22.05 kHz — decimation by two. To overlay the before and after signals, scale the output and plot the signals on a stem plot.

```
r = 2;                  % Decimation factor.
hm = mfilt.cicdecim(r); % Use default NumberOfSections &
                        % DifferentialDelay property values.
fs = 44.1e3;            % Original sampling frequency: 44.1kHz.
n = 0:10239;            % 10240 samples, 0.232 second long signal.
x  = sin(2*pi*1e3/fs*n);% Original signal, sinusoid at 1kHz.

y_fi = filter(hm,x); % 5120 samples, still 0.232 seconds.

% Scale the output to overlay the stem plots.
x = double(x);
y = double(y_fi);
y = y/max(abs(y));
stem(n(1:44)/fs,x(2:45)); hold on;  % Plot original signal
                                     % sampled at 44.1kHz.
stem(n(1:22)/(fs/r),y(3:24),'r','filled'); % Plot decimated
                                          % signal (22.05kHz)
                                          % in red.
xlabel('Time (seconds)');ylabel('Signal Value');
```

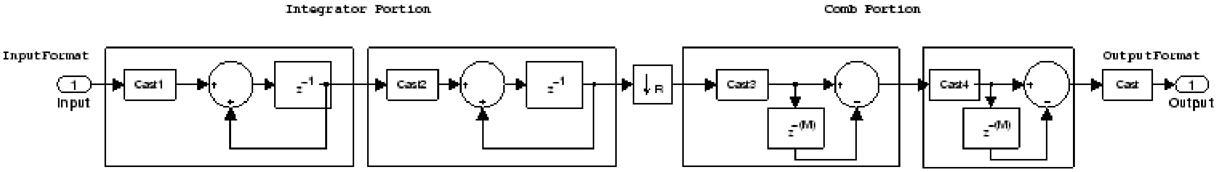


More About

Algorithms

To show how the CIC decimation filter is constructed, the following figure presents a block diagram of the filter structure for a two-section CIC decimation filter (n = 2). *fs* is the high sampling rate, the input to the decimation process.

For details about the bits that are removed in the Comb section, refer to [1] in References.



mfilt.cicdecim calculates the fraction length at each section of the decimator to avoid overflows at the output of the filter.

`mfilt` | `mfilt.cicinterp`

mfilt.cicinterp

Fixed-point CIC interpolator

Syntax

```
hm = mfilt.cicinterp(R,M,N,ILW,OWL,WLPS)
hm = mfilt.cicinterp
hm = mfilt.cicinterp(R,...)
```

Description

`hm = mfilt.cicinterp(R,M,N,ILW,OWL,WLPS)` constructs a cascaded integrator-comb (CIC) interpolation filter object that uses fixed-point arithmetic.

All of the input arguments are optional. To enter any optional value, you must include all optional values to the left of your desired value.

When you omit one or more input options, the omitted option applies the default values shown in the table below.

The following table describes the input arguments for creating `hm`.

Input Arguments	Description
`R`	Interpolation factor applied to the input signal. Sharpens the response curve to let you change the shape of the response. `R` must be an integer value greater than or equal to 1. The default value is 2.
`M`	Differential delay. Changes the shape, number, and location of nulls in the filter response. Increasing `M` increases the sharpness of the nulls and the response between nulls. In practice, differential delay values of 1 or 2 are the most common. `M` must be an integer value greater than or equal to 1. The default value is 1.
`N`	Number of sections. Deepens the nulls in the response curve. Note that this is the number of either comb or integrator sections, not the total section count. By default, the filter has two sections.
`IWL`	Word length of the input signal. Use any integer number of bits. The default value is 16 bits.

Input Arguments	Description
OWL	Word length of the output signal. It can be any positive integer number of bits. By default, OWL is 16 bits.
WLPS	Defines the number of bits per word in each filter section while accumulating the data in the integrator sections or while subtracting the data during the comb sections (using 'wrap' arithmetic). Enter WLPS as a scalar or vector of length 2*N, where N is the number of sections. When WLPS is a scalar, the scalar value is applied to each filter section. The default is 16 for each section in the integrator. When you elect to specify wlps as an input argument, the FilterInternals property automatically switches from the default value of 'FullPrecision' to 'SpecifyWordLengths'.

`hm = mfilt.cicinterp` constructs the CIC interpolator using the default values for the optional input arguments.

`hm = mfilt.cicinterp(R,...)` constructs the CIC interpolator applying the values you provide for `R` and any other values you specify as input arguments.

Constraints and Conversions

In Hogenauer [1], the author describes the constraints on CIC interpolator filters. `mfilt.cicinterp` enforces a constraint—the word lengths of the filter sections must be non-decreasing. That is, the word length of each filter section must be the same size as, or greater than, the word length of the previous filter section.

The formula for W_j, the minimum register width, is derived in [1]. The formula for W_j is given by

$$W_j = ceil(B_{in} + \log_2 G_j)$$

where G_j, the maximum register growth up to the jth section, is given by

$$G_j = \begin{cases} 2^j, & j = 1, 2, \ldots, N \\ \dfrac{2^{2N-j}(RM)^{j-N}}{R}, & j = N+1, \ldots, 2N \end{cases}$$

When the differential delay, M, is 1, there is also a special condition for the register width of the last comb, W_N, that is given by

$$W_N = B_{in} + N - 1 \;\; if \;\;\; M = 1$$

The conversions denoted by the cast blocks in the integrator diagrams in "Algorithms" on page 4-963 perform the changes between the word lengths of each section. When you specify word lengths that do not follow the constraints described in this section, `mfilt.cicinterp` returns an error.

The fraction lengths and scalings of the filter sections do not change. At each section the word length is either staying the same or increasing. The signal scaling can change at the output after the final filter section if you choose the output word length to be less than the word length of the final filter section.

Properties of the Object

The following table lists the properties for the filter with a description of each.

Name	Values	Default	Description
`Arithmetic`	`fixed`	`fixed`	Reports the kind of arithmetic the filter uses. CIC interpolators are always fixed-point filters.
`InterpolationFactor`	Any positive integer	2	Amount to increase the input sampling rate.
`DifferentialDelay`	Any positive integer	1	Sets the differential delay for the filter. Usually a value of one or two is appropriate.
`FilterStructure`	`mfilt` structure string	None	Reports the type of filter object, such as a interpolator or fractional integrator. You cannot set this property — it is always read only and results from your choice of `mfilt` objects.
`FilterInternals`	`FullPrecision`,	`FullPrecision`	Set the usage mode for the filter. Refer to "Usage Modes"

Name	Values	Default	Description
	MinWordLengths, SpecifyWordLengths, SpecifyPrecision		on page 4-960 below for details.
InputFracLength	Any positive integer	16	The number of bits applied as the fraction length to interpret the input data to the filter.
InputWordLength	Any positive integer	16	The number of bits applied to the word length to interpret the input data to the filter.
NumberOfSections	Any positive integer	2	Number of sections used in the interpolator. Generally called n. Reflects either the number of interpolator or comb sections, not the total number of sections in the filter.
OutputFracLength	Any positive integer	15	The number of bits applied to the fraction length to interpret the output data from the filter. Read-only.
OutputWordLength	Any positive integer	16	The number of bits applied to the word length to interpret the output data from the filter.

Name	Values	Default	Description
`PersistentMemory`	`false` or `true`	`false`	Determines whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. `PersistentMemory` returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. When `PersistentMemory` is `false`, you cannot access the filter states. Setting `PersistentMemory` to `true` reveals the `States` property so you can modify the filter states.

Name	Values	Default	Description
SectionWordLengths	Any integer or a vector of length 2^N, where N is a positive integer. This property only applies when the FilterInternals is SpecifyWordLengths.	16	Defines the bits per section used while accumulating the data in the integrator sections or while subtracting the data during the comb sections (using 'wrap' arithmetic). Enter SectionWordLengths as a scalar or vector of length 2*n, where n is the number of sections. When SectionWordLengths is a scalar, the scalar value is applied to each filter section. When SectionWordLengths is a vector of values, the values apply to the sections in order. The default is 16 for each section in the interpolator. Available when FilterInternals is 'SpecifyWordLengths'.

Name	Values	Default	Description
`States`	`filtstates.cic` object	`m`+1-by-`n` matrix of zeros, after you call function `int`.	Stored conditions for the filter, including values for the integrator and comb sections before and after filtering. `m` is the differential delay of the comb section and `n` is the number of sections in the filter. The integrator states are stored in the first matrix row. States for the comb section fill the remaining rows in the matrix. Available for modification when `PersistentMemory` is `true`. Refer to the `filtstates` object in Signal Processing Toolbox documentation for more general information about the `filtstates` object.

Usage Modes

There are usage modes which are set using the `FilterInternals` property:

- `FullPrecision` — In this mode, the word and fraction lengths of the filter sections and outputs are automatically selected for you. The output and last section word lengths are set to:

  $$\text{wordlength} = \text{ceil}(\log_2((RM)^N \;/\; R)) + I,$$

  where R is the interpolation factor, M is the differential delay, N is the number of filter sections, and I denotes the input word length.
- `MinWordLengths` — In this mode, you specify the word length of the filter output in the `OutputWordLength` property. The word lengths of the filter sections are automatically set in the same way as in the `FullPrecision` mode. The section fraction lengths are set to the input fraction length. The output fraction length is set

to the input fraction length minus the difference between the last section and output word lengths.

- SpecifyWordLengths — In this mode, you specify the word lengths of the filter sections and output in the SectionWordLengths and OutputWordLength properties. The fraction lengths of the filter sections are set such that the spread between word length and fraction length is the same as in full-precision mode. The output fraction length is set to the input fraction length minus the difference between the last section and output word lengths.
- SpecifyPrecision — In this mode, you specify the word and fraction lengths of the filter sections and output in the SectionWordLengths, SectionFracLengths, OutputWordLength, and OutputFracLength properties.

About the States of the Filter

In the states property you find the states for both the integrator and comb portions of the filter. states is a matrix of dimensions m+1-by-n, with the states apportioned as follows:

- States for the integrator portion of the filter are stored in the first row of the state matrix.
- States for the comb portion fill the remaining rows in the state matrix.

To review the states of a CIC filter, use the int method to assign the states. As an example, here are the states for a CIC interpolator hm before and after filtering data:

```
x = fi(cos(pi/4*[0:99]),true,16,0); % Fixed-point input data
hm = mfilt.cicinterp(2,1,2,16,16,16);
% get initial states-all zero
sts=int(hm.states)
set(hm,'InputFracLength',0); % Integer input specified
y=filter(hm,x);
sts=int(hm.states)
%sts =
%
%     -1     -1
%     -1     -1
```

Design Considerations

When you design your CIC interpolation filter, remember the following general points:

- The filter output spectrum has nulls at $\omega = k * 2\pi/rm$ radians, $k = 1,2,3....$
- Aliasing and imaging occur in the vicinity of the nulls.
- n, the number of sections in the filter, determines the passband attenuation. Increasing n improves the filter ability to reject aliasing and imaging, but it also increases the droop or rolloff in the filter passband. Using an appropriate FIR filter in series after the CIC interpolation filter can help you compensate for the induced droop.
- The DC gain for the filter is a function of the interpolation factor. Raising the interpolation factor increases the DC gain.

Examples

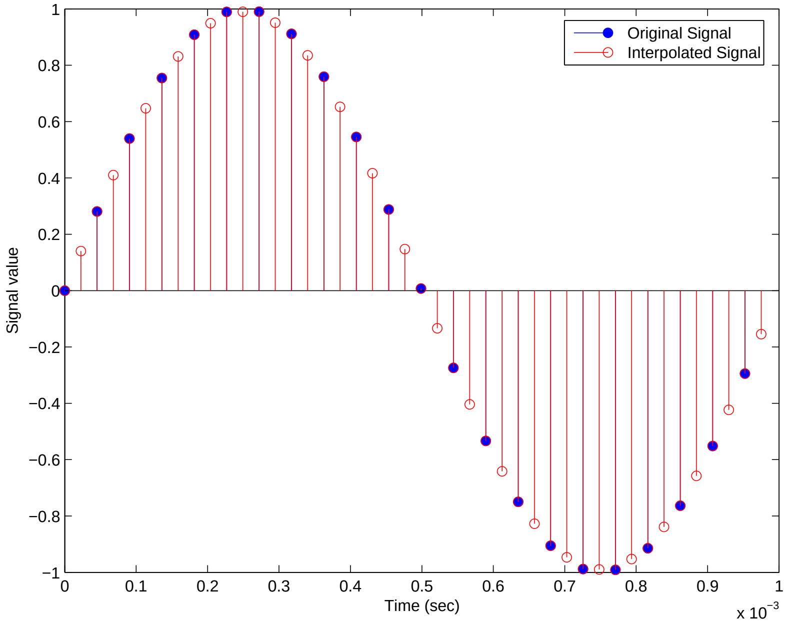
Demonstrate interpolation by a factor of two, in this case from 22.05 kHz to 44.1 kHz. Note the scaling required to see the results in the stem plot and to use the full range of the int16 data type.

```
R = 2;                       % Interpolation factor.
hm = mfilt.cicinterp(R);     % Use default NumberOfSections and
                             % DifferentialDelay property values.
fs = 22.05e3;                % Original sample frequency:22.05 kHz.
n = 0:5119;                 % 5120 samples, .232 second long signal.
x = sin(2*pi*1e3/fs*n);     % Original signal, sinusoid at 1 kHz.

y_fi = filter(hm,x); % 5120 samples, still 0.232 seconds.

% Scale the output to overlay stem plots correctly.
x = double(x);
y = double(y_fi);
y = y/max(abs(y));
stem(n(1:22)/fs,x(1:22),'filled'); % Plot original signal sampled
                                   % at 22.05 kHz.
hold on;
stem(n(1:44)/(fs*R),y(4:47),'r');  % Plot interpolated signal
                                   % (44.1 kHz) in red.
xlabel('Time (sec)');ylabel('Signal Value');
```

As you expect, the plot shows that the interpolated signal matches the input sine shape, with additional samples between each original sample.



Use the filter visualization tool (FVTool) to plot the response of the interpolator object. For example, to plot the response of an interpolator with an interpolation factor of 7, 4 sections, and 1 differential delay, do something like the following:

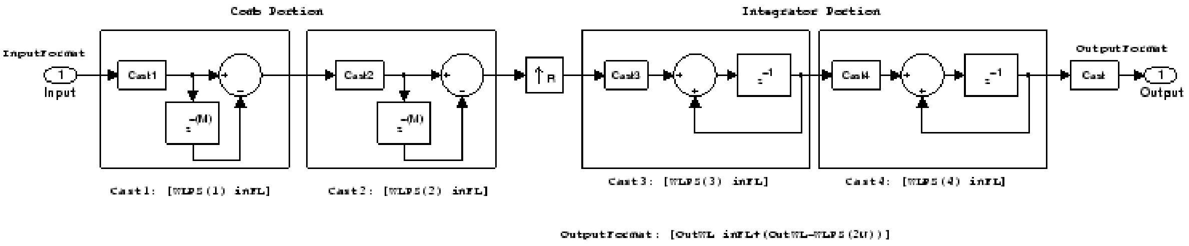
```
hm = mfilt.cicinterp(7,1,4)
fvtool(hm)
```

More About

Algorithms

To show how the CIC interpolation filter is constructed, the following figure presents a block diagram of the filter structure for a two-section CIC interpolation filter (n = 2). *fs* is the high sampling rate, the output from the interpolation process.

For details about the bits that are removed in the integrator section, refer to [1] in References.



When you select MinWordLengths, the filter section word lengths are automatically set to the minimum number of bits possible in a valid CIC interpolator. mfilt.cicinterp computes the wordlength for each section so the roundoff noise introduced by all sections is less than the roundoff noise introduced by the quantization at the output.

mfilt.farrowsrc

Sample rate converter with arbitrary conversion factor

Syntax

```
hm = mfilt.farrowsrc(L,M,C)
hm = mfilt.farrowsrc
hm = mfilt.farrowsrc(l,...)
```

Description

`hm = mfilt.farrowsrc(L,M,C)` returns a filter object that is a natural extension of `dfilt.farrowfd` with a time-varying fractional delay. It provides a economical implementation of a sample rate converter with an arbitrary conversion factor. This filter works well in the interpolation case, but may exhibit poor anti-aliasing properties in the decimation case.

Note: You can use the `realizemdl` method to create a Simulink block of a filter created using `mfilt.farrowsrc`.

Input Arguments

The following table describes the input arguments for creating `hm`.

Input Argument	Description
`l`	Interpolation factor for the filter. `l` specifies the amount to increase the input sampling rate. The default value of `l` is 3.
`m`	Decimation factor for the filter. `m` specifies the amount to decrease the input sampling rate. The default value for `m` is 2.
`c`	Coefficients for the filter. When no input arguments are specified, the default coefficients are `[-1 1; 1, 0]`

`hm = mfilt.farrowsrc` constructs the filter using the default values for `l`, `m`, and `c`.

`hm = mfilt.farrowsrc(l,...)` constructs the filter using the input arguments you provide and defaults for the argument you omit.

mfilt.farrowsrc Object Properties

Every multirate filter object has properties that govern the way it behaves when you use it. Note that many of the properties are also input arguments for creating `mfilt.farrowsrc` objects. The next table describes each property for an `mfilt.farrowsrc` filter object.

Name	Values	Description
`FilterStructure`	String	Reports the type of filter object. You cannot set this property — it is always read only and results from your choice of `mfilt` object.
`Arithmetic`	String	Reports the arithmetic precision used by the filter.
`Coefficients`	Vector	Vector containing the coefficients of the FIR lowpass filter
`InterpolationFactor`	Integer	Interpolation factor for the filter. It specifies the amount to increase the input sampling rate.
`DecimationFactor`	Integer	Decimation factor for the filter. It specifies the amount to increase the input sampling rate.
`PersistentMemory`	`false` or `true`	Determines whether the filter states are restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. `PersistentMemory` returns to zero any state that the filter changes during processing. States that the filter does not change are not affected.

Examples

Interpolation by a factor of 8. This object removes the spectral replicas in the signal after interpolation.

```
[L,M] = rat(48/44.1);
Hm = mfilt.farrowsrc(L,M);          % We use the default filter
Fs = 44.1e3;                        % Original sampling frequency
n = 0:9407;                         % 9408 samples, 0.213 seconds long
x  = sin(2*pi*1e3/Fs*n);            % Original signal, sinusoid at 1kHz
y = filter(Hm,x);                   % 10241 samples, still 0.213 seconds
stem(n(1:45)/Fs,x(1:45))            % Plot original sampled at 44.1kHz
hold on
% Plot fractionally interpolated signal (48kHz) in red
stem((n(2:50)-1)/(Fs*L/M),y(2:50),'r','filled')
xlabel('Time (sec)');ylabel('Signal value')
legend('44.1 kHz sample rate','48kHz sample rate')
```

The results of the example are shown in the following figure:

dsp.FarrowRateConverter

mfilt.fftfirinterp

Overlap-add FIR polyphase interpolator

Syntax

```
hm = mfilt.fftfirinterp(l,num,bl)
hm = mfilt.fftfirinterp
hm = mfilt.fftfirinterp(l,...)
```

Description

`hm = mfilt.fftfirinterp(l,num,bl)` returns a discrete-time FIR filter object that uses the overlap-add method for filtering input data.

The input arguments are optional. To enter any optional value, you must include all optional values to the left of your desired value.

When you omit one or more input options, the omitted option applies the default values shown in the table below.

The number of FFT points is given by `[bl+ceil(length(num)/l)-1]`. It is to your advantage to choose `bl` such that the number of FFT points is a power of two—using powers of two can improve the efficiency of the FFT and the associated interpolation process.

Input Arguments

The following table describes the input arguments for creating `hm`.

Input Argument	Description
`l`	Interpolation factor for the filter. `l` specifies the amount to increase the input sampling rate. It must be an integer. When you do not specify a value for `l` it defaults to 2.
`num`	Vector containing the coefficients of the FIR lowpass filter used for interpolation. When `num` is not provided as an input, `fftfirinterp` uses a lowpass Nyquist filter with gain equal to `l` and cutoff frequency equal to `π/l` by default.

Input Argument	Description
bl	Length of each block of input data used in the filtering. bl must be an integer. When you omit input bl, it defaults to 100

hm = mfilt.fftfirinterp constructs the filter using the default values for l, num, and bl.

hm = mfilt.fftfirinterp(l,...) constructs the filter using the input arguments you provide and defaults for the argument you omit.

mfilt.fftfirinterp Object Properties

Every multirate filter object has properties that govern the way it behaves when you use it. Note that many of the properties are also input arguments for creating mfilt.fftfirinterp objects. The next table describes each property for an mfilt.fftfirinterp filter object.

Name	Values	Description
FilterStructure		Reports the type of filter object. You cannot set this property — it is always read only and results from your choice of mfilt object.
Numerator		Vector containing the coefficients of the FIR lowpass filter used for interpolation.
InterpolationFactor		Interpolation factor for the filter. It specifies the amount to increase the input sampling rate. It must be an integer.
BlockLength		Length of each block of input data used in the filtering.
PersistentMemory	false or true	Determines whether the filter states are restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. PersistentMemory returns to zero any state that the filter changes during

Name	Values	Description
		processing. States that the filter does not change are not affected.
`States`		Stored conditions for the filter, including values for the interpolator states.

Examples

Interpolation by a factor of 8. This object removes the spectral replicas in the signal after interpolation.

```
l = 8;                         % Interpolation factor
hm = mfilt.fftfirinterp(l);    % We use the default filter
n = 8192;                      % Number of points
hm.blocklength = n;            % Set block length to number of points
fs = 44.1e3;                   % Original sample freq: 44.1 kHz.
n = 0:n-1;                     % 0.1858 secs of data
x = sin(2*pi*n*22e3/fs);       % Original signal, sinusoid at 22 kHz
y = filter(hm,x);              % Interpolated sinusoid
xu = l*upsample(x,8);          % Upsample to compare--the spectrum
                               % does not change
[px,f]=periodogram(xu,[],65536,l*fs);% Power spectrum of original
                                     % signal
[py,f]=periodogram(y,[],65536,l*fs); % Power spectrum of
                                     % interpolated signal
plot(f,10*log10(([fs*px,l*fs*py])))
legend('22  kHz sinusoid sampled at 44.1  kHz',...
'22  kHz sinusoid sampled at 352.8  kHz')
xlabel('Frequency (Hz)'); ylabel('Power Spectrum');
```

mfilt.firdecim

Direct-form FIR polyphase decimator

Syntax

```
hm = mfilt.firdecim(m)
hm = mfilt.firdecim(m,num)
```

Description

`hm = mfilt.firdecim(m)` returns a direct-form FIR polyphase decimator object `hm` with a decimation factor of `m`. A lowpass Nyquist filter of gain 1 and cutoff frequency of `π/m` is designed by default. This filter allows some aliasing in the transition band but it very efficient because the first polyphase component is a pure delay.

`hm = mfilt.firdecim(m,num)` uses the coefficients specified by `num` for the decimation filter. This lets you specify more completely the FIR filter to use for the decimator.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hm` as follows:

- To change to single-precision filtering, enter

  ```
  set(hm,'arithmetic','single');
  ```
- To change to fixed-point filtering, enter

  ```
  set(hm,'arithmetic','fixed');
  ```

Input Arguments

The following table describes the input arguments for creating `hm`.

Input Argument	Description
`m`	Decimation factor for the filter. m specifies the amount to reduce the sampling rate of the input signal. It must be an integer. When you do not specify a value for `m` it defaults to 2.

Input Argument	Description
num	Vector containing the coefficients of the FIR lowpass filter used for decimation. When num is not provided as an input, mfilt.firdecim constructs a lowpass Nyquist filter with gain of 1 and cutoff frequency equal to π/m by default. The default length for the Nyquist filter is 24*m. Therefore, each polyphase filter component has length 24.

Object Properties

This section describes the properties for both floating-point filters (double-precision and single-precision) and fixed-point filters.

Floating-Point Filter Properties

Every multirate filter object has properties that govern the way it behaves when you use it. Note that many of the properties are also input arguments for creating mfilt.firdecim objects. The next table describes each property for an mfilt.firdecim filter object.

Name	Values	Description
Arithmetic	Double, single, fixed	Defines the arithmetic the filter uses. Gives you the options double, single, and fixed. In short, this property defines the operation mode for your filter.
DecimationFactor	Integer	Decimation factor for the filter. m specifies the amount to reduce the sampling rate of the input signal. It must be an integer.
FilterStructure	String	Reports the type of filter object. You cannot set this property — it is always read only and results from your choice of mfilt object. Describes the signal flow for the filter object.

Name	Values	Description
InputOffset	Integers	Contains a value derived from the number of input samples and the decimation factor — InputOffset = mod(length(nx),m) where nx is the number of input samples that have been processed so far and m is the decimation factor.
Numerator	Vector	Vector containing the coefficients of the FIR lowpass filter used for decimation.
PersistentMemory	false, true	Determines whether the filter states get restored to zeros for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. PersistentMemory set to false returns filter states to the default values after filtering. States that the filter does not change are not affected. Setting this to true allows you to modify the States, InputOffset, and PolyphaseAccum properties.
PolyphaseAccum	0 in double, single, or fixed for the different filter arithmetic settings.	Differentiates between the adders in the filter that work in full precision at all times (PolyphaseAccum) and the adders in the filter that the user controls and that may introduce quantization effects when FilterInternals is set to SpecifyPrecision.

Name	Values	Description
`States`	`Double`, `single`, or `fi` matching the filter arithmetic setting.	This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. Double is the default setting for floating-point filters in double arithmetic.

Fixed-Point Filter Properties

This table shows the properties associated with the fixed-point implementation of the filter. You see one or more of these properties when you set Arithmetic to fixed. Some of the properties have different default values when they refer fixed point filters. One example is the property `PolyphaseAccum` which stores data as doubles when you use your filter in double-precision mode, but stores a `fi` object in fixed-point mode.

Note The table lists all of the properties that a fixed-point filter can have. Many of the properties listed are dynamic, meaning they exist only in response to the settings of other properties. To view all of the characteristics for a filter at any time, use `info(hm)` where `hm` is a filter.

For further information about the properties of this filter or any `mfilt` object, refer to "Multirate Filter Properties".

Name	Values	Description
`AccumFracLength`	Any positive or negative integer number of bits [32]	Specifies the fraction length used to interpret data output by the accumulator. This is a property of FIR filters.
`AccumWordLength`	Any integer number of bits [39]	Sets the word length used to store data in the accumulator.
`Arithmetic`	fixed for fixed-point filters	Setting this to `fixed` allows you to modify other filter properties to customize your fixed-point filter.
`CoeffAutoScale`	[true], false	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by

Name	Values	Description
		setting the value to `false` enables you to change the `NumFracLength` property value to specify the precision used.
`CoeffWordLength`	Any integer number of bits [16]	Specifies the word length to apply to filter coefficients.
`FilterInternals`	[FullPrecision], SpecifyPrecision	Controls whether the filter automatically sets the output word and fraction lengths, product word and fraction lengths, and the accumulator word and fraction lengths to maintain the best precision results during filtering. The default value, `FullPrecision`, sets automatic word and fraction length determination by the filter. `SpecifyPrecision` makes the output and accumulator-related properties available so you can set your own word and fraction lengths for them.
`InputFracLength`	Any positive or negative integer number of bits [15]	Specifies the fraction length the filter uses to interpret input data.
`InputWordLength`	Any integer number of bits[16]	Specifies the word length applied to interpret input data.
`OutputFracLength`	Any positive or negative integer number of bits [32]	Determines how the filter interprets the filter output data. You can change the value of `OutputFracLength` when you set `FilterInternals` to `SpecifyPrecision`.
`OutputWordLength`	Any integer number of bits [39]	Determines the word length used for the output data. You make this property editable by setting `FilterInternals` to `SpecifyPrecision`.

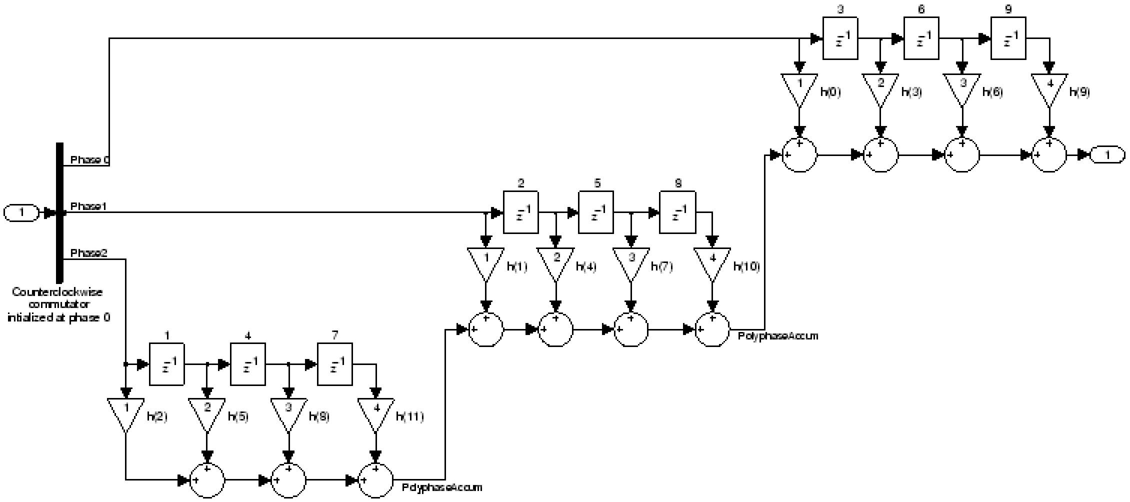
Name	Values	Description
`OverflowMode`	saturate, [wrap]	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either `saturate` (limit the output to the largest positive or negative representable value) or `wrap` (set overflowing values to the nearest representable value using modular arithmetic.) The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow — they maintain full precision.
`RoundMode`	[`convergent`], `ceil`, `fix`, `floor`, `nearest`, `round`	Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths). • `ceil` - Round toward positive infinity. • `convergent` - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software. • `fix` - Round toward zero. • `floor` - Round toward negative infinity. • `nearest` - Round toward nearest. Ties round toward positive infinity. • `round` - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers. The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.
`Signed`	[true], false	Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.

Name	Values	Description
`States`	`fi` object	This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. The states use `fi` objects, with the associated properties from those objects. For details, refer to fixed-point objects in Fixed-Point Designer documentation. For information about the ordering of the states, refer to the filter structure section.

Filter Structure

To provide decimation, `mfilt.firdecim` uses the following structure. At the input you see a commutator that operates counterclockwise, moving from position 0 to position 2, position 1, and back to position 0 as input samples enter the filter.

The following figure details the signal flow for the direct form FIR filter implemented by `mfilt.firdecim`.



Notice the order of the states in the filter flow diagram. States 1 through 9 appear in the diagram above each delay element. State 1 applies to the first delay element in phase

2. State 2 applies to the first delay element in phase 1. State 3 applies to the first delay element in phase 0. State 4 applies to the second delay in phase 2, and so on. When you provide the states for the filter as a vector to the `States` property, the above description explains how the filter assigns the states you specify.

In property value form, the states for a filter `hm` are

```
hm.states=[1:9];
```

Examples

Convert an input signal from 44.1 kHz to 22.05 kHz using decimation by a factor of 2. In the figure that appears after the example code, you see the results of the decimation.

```
m = 2;                          % Decimation factor.
hm = mfilt.firdecim(m);         % Use the default filter.
fs = 44.1e3;                    % Original sample freq: 44.1kHz.
n = 0:10239;                    % 10240 samples, 0.232 second long
                                % signal.
x  = sin(2*pi*1e3/fs*n);        % Original signal--sinusoid at 1kHz.
y = filter(hm,x);               % 5120 samples, 0.232 seconds.
stem(n(1:44)/fs,x(1:44))        % Plot original sampled at 44.1 kHz.
hold on                         % Plot decimated signal (22.05 kHz)
                                % in red.
stem(n(1:22)/(fs/m),y(13:34),'r','filled')
xlabel('Time (sec)');ylabel('Signal Value')
```

`mfilt.firtdecim` | `mfilt.firsrc` | `mfilt.cicdecim`

mfilt.firfracdecim (Obsolete)

Direct-form FIR polyphase fractional decimator

Syntax

```
hm = mfilt.firfracdecim(l,m,num)
```

Description

`mfilt.firfracdecim` will be removed in a future release. Use `mfilt.firsrc` instead.

`hm = mfilt.firfracdecim(l,m,num)` returns a direct-form FIR polyphase fractional decimator. Input argument `l` is the interpolation factor. `l` must be an integer. When you omit `l` in the calling syntax, it defaults to 2. `m` is the decimation factor. It must be an integer. If not specified, it defaults to l+1.

`num` is a vector containing the coefficients of the FIR lowpass filter used for decimation. If you omit `num`, a lowpass Nyquist filter of gain l and cutoff frequency of π/`max(l,m)` is used by default.

By specifying both a decimation factor and an interpolation factor, you can decimate your input signal by noninteger amounts. The fractional decimator first interpolates the input, then decimates to result in an output signal whose sample rate is `l/m` of the input rate. By default, the resulting decimation factor is 2/3 when you do not provide `l` and `m` in the calling syntax. Specify `l` smaller than `m` for proper decimation.

Input Arguments

The following table describes the input arguments for creating `hm`.

Input Argument	Description
`l`	Interpolation factor for the filter. It must be an integer. When you do not specify a value for `l` it defaults to 2.
`num`	Vector containing the coefficients of the FIR lowpass filter used for decimation. When `num` is not provided as an input, `firfracdecim` uses a lowpass Nyquist filter with gain equal to `l` and cutoff frequency equal to π/`max(l,m)` by default.

Input Argument	Description
m	Decimation factor for the filter. m specifies the amount to reduce the sampling rate of the input signal. It must be an integer. When you do not specify a value for m it defaults to l + 1.

mfilt.firfracdecim Object Properties

Every multirate filter object has properties that govern the way it behaves when you use it. Note that many of the properties are also input arguments for creating mfilt.firfracdecim objects. The next table describes each property for an mfilt.firfracdecim filter object.

Name	Values	Description
FilterStructure	String	Reports the type of filter object, such as a decimator or fractional decimator. You cannot set this property — it is always read only and results from your choice of mfilt object.
InputOffset	Integers	Contains the number of input data samples processed without generating an output sample. The default value is 0.
Numerator	Vector	Vector containing the coefficients of the FIR lowpass filter used for interpolation.
RateChangeFactors	[l,m]	Reports the decimation (m) and interpolation (l) factors for the filter object. Combining these factors results in the final rate change for the signal.
PersistentMemory	false or true	Determines whether the filter states are restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. PersistentMemory returns to zero any state that the filter changes during processing. States that the filter does not change are not affected.

Name	Values	Description
`States`	Matrix	Stored conditions for the delays between each interpolator phase, the filter states, and the states at the output of each phase in the filter. The number of states is (`lh`-1)*`m`+(l-1)*(`lo`+`mo`) where `lh` is the length of each subfilter, and `l` and `m` are the interpolation and decimation factors. `lo` and `mo`, the input and output delays between each interpolation phase, are integers from Euclid's theorem such that `lo`*l-`mo`*`m` = -1 (refer to the reference for more details). Use `euclidfactors` to get `lo` and `mo` for an `mfilt.firfracdecim` object

Examples

To demonstrate `firfracdecim`, perform a fractional decimation by a factor of 2/3. This is one way to downsample a 48 kHz signal to 32 kHz, commonly done in audio processing.

```
l  = 2; m = 3;               % Interpolation/decimation factors.
hm = mfilt.firfracdecim(l,m); % We use the default
fs = 48e3;                    % Original sample freq: 48 kHz.
n  = 0:10239;                 % 10240 samples, 0.213 second long
                              % signal
x  = sin(2*pi*1e3/fs*n);      % Original signal, sinusoid at 1 kHz
y  = filter(hm,x);            % 9408 samples, still 0.213 seconds
stem(n(1:49)/fs,x(1:49)); hold on; % Plot original signal sampled
                                   % at 48 kHz
stem(n(1:32)/(fs*l/m),y(13:44),'r','filled') % Plot decimated
                                             % signal at 32 kHz
xlabel('Time (sec)');
```

As shown, the plot clearly demonstrates the reduced sampling frequency of 32 kHz.

`mfilt.firsrc` | `mfilt.firinterp` | `mfilt.firdecim`

mfilt.firfracinterp (Obsolete)

Direct-form FIR polyphase fractional interpolator

Syntax

```
hm = mfilt.firfracinterp(l,m,num)
```

Description

`mfilt.firfracinterp` will be removed in a future release. Use `mfilt.firsrc` instead.

`hm = mfilt.firfracinterp(l,m,num)` returns a direct-form FIR polyphase fractional interpolator mfilt object. `l` is the interpolation factor. It must be an integer. If not specified, `l` defaults to 3.

`m` is the decimation factor. Like `l`, it must be an integer. If you do not specify `m` in the calling syntax, it defaults to 1. If you also do not specify a value for `l`, `m` defaults to 2.

`num` is a vector containing the coefficients of the FIR lowpass filter used for interpolation. If omitted, a lowpass Nyquist filter of gain `l` and cutoff frequency of π/`max(l,m)` is used by default.

By specifying both a decimation factor and an interpolation factor, you can interpolate your input signal by noninteger amounts. The fractional interpolator first interpolates the input, then decimates to result in an output signal whose sample rate is `l/m` of the input rate. For proper interpolation, you specify `l` to be greater than `m`. By default, the resulting interpolation factor is 3/2 when you do not provide `l` and `m` in the calling syntax.

Input Arguments

The following table describes the input arguments for creating `hm`.

Input Argument	Description
l	Interpolation factor for the filter. l specifies the amount to increase the input sampling rate. It must be an integer. When you do not specify a value for l it defaults to 3.
num	Vector containing the coefficients of the FIR lowpass filter used for interpolation. When num is not provided as an input, firfracinterp uses a lowpass Nyquist filter with gain equal to l and cutoff frequency equal to π/max(l,m) by default.
m	Decimation factor for the filter. m specifies the amount to reduce the sampling rate of the input signal. It must be an integer. When you do not specify a value for m it defaults to 1. When you do not specify l as well, m defaults to 2.

mfilt.firfracinterp Object Properties

Every multirate filter object has properties that govern the way it behaves when you use it. Note that many of the properties are also input arguments for creating mfilt.firfracinterp objects. The next table describes each property for an mfilt.firfracinterp filter object.

Name	Values	Description
FilterStructure		Reports the type of filter object. You cannot set this property — it is always read only and results from your choice of mfilt object.
Numerator		Vector containing the coefficients of the FIR lowpass filter used for interpolation.
RateChangeFactors	[l,m]	Reports the decimation (m) and interpolation (l) factors for the filter object. Combining these factors results in the final rate change for the signal.
PersistentMemory	false or true	Determines whether the filter states are restored to their starting values for each filtering operation. The starting values are the values in place when

Name	Values	Description
		you create the filter if you have not changed the filter since you constructed it. `PersistentMemory` returns to the default values any state that the filter changes during processing. States that the filter does not change are not affected.
`States`	Matrix	Stored conditions for the filter, including values for the interpolator and comb states.

Examples

To convert a signal from 32 kHz to 48 kHz requires fractional interpolation. This example uses the `mfilt.firfracinterp` object to upsample an input signal. Setting `l` = 3 and `m` = 2 returns the same `mfilt` object as the default `mfilt.firfracinterp` object.

```
l  = 3; m = 2;               % Interpolation/decimation factors.
hm = mfilt.firfracinterp(l,m);    % We use the default filter
fs = 32e3;                   % Original sample freq: 32 kHz.
n = 0:6799;                  % 6800 samples, 0.212 second long signal
x  = sin(2*pi*1e3/fs*n);     % Original signal, sinusoid at 1 kHz
y = filter(hm,x);            % 10200 samples, still 0.212 seconds
stem(n(1:32)/fs,x(1:32),'filled') % Plot original sampled at
                                  % 32 kHz
hold on;
% Plot fractionally interpolated signal (48 kHz) in red
stem(n(1:48)/(fs*l/m),y(20:67),'r')
xlabel('Time (sec)');ylabel('Signal Value')
```

The ability to interpolate by fractional amounts lets you raise the sampling rate from 32 to 48 kHz, something you cannot do with integral interpolators. Both signals appear in the following figure.

`mfilt.firsrc` | `mfilt.firinterp` | `mfilt.firdecim`

mfilt.firinterp

FIR filter-based interpolator

Syntax

```
Hm = mfilt.firinterp(L)
Hm = mfilt.firinterp(L,num)
```

Description

`Hm = mfilt.firinterp(L)` returns a FIR polyphase interpolator object `Hm` with an interpolation factor of `L` and gain equal to `L`. `L` defaults to 2 if unspecified.

`Hm = mfilt.firinterp(L,num)` uses the values in the vector `num` as the coefficients of the interpolation filter.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `Hm` as follows:

- To change to single-precision filtering, enter

  ```
  set(hm,'arithmetic','single');
  ```

- To change to fixed-point filtering, enter

  ```
  set(hm,'arithmetic','fixed');
  ```

Input Arguments

The following table describes the input arguments for creating `hm`.

Input Argument	Description
`l`	Interpolation factor for the filter. `l` specifies the amount to increase the input sampling rate. It must be an integer. When you do not specify a value for `l` it defaults to 2.

Input Argument	Description
num	Vector containing the coefficients of the FIR lowpass filter used for interpolation. When num is not provided as an input, firinterp uses a lowpass Nyquist filter with gain equal to l and cutoff frequency equal to π/l by default. The default length for the Nyquist filter is 24*l. Therefore, each polyphase filter component has length 24.

Object Properties

This section describes the properties for both floating-point filters (double-precision and single-precision) and fixed-point filters.

Floating-Point Filter Properties

Every multirate filter object has properties that govern the way it behaves when you use it. Note that many of the properties are also input arguments for creating mfilt.firinterp objects. The next table describes each property for an mfilt.firinterp filter object.

Name	Values	Description
Arithmetic	Double, single, fixed	Defines the arithmetic the filter uses. Gives you the options double, single, and fixed. In short, this property defines the operation mode for your filter.
FilterStructure	String	Reports the type of filter object. You cannot set this property — it is always read only and results from your choice of mfilt object. Describes the signal flow for the filter object.
InterpolationFactor	Integer	Interpolation factor for the filter. l specifies the amount to increase the sampling rate of the input signal. It must be an integer.
Numerator	Vector	Vector containing the coefficients of the FIR lowpass filter used for decimation.
PersistentMemory	[false], true	Determines whether the filter states get restored to zeros for each filtering operation.

Name	Values	Description
		The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. `PersistentMemory` set to `false` returns filter states to the default values after filtering. States that the filter does not change are not affected. Setting this to `true` allows you to modify the `States` property.
`States`	`Double`, `single`, matching the filter arithmetic setting.	Contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions.

Fixed-Point Filter Properties

This table shows the properties associated with the fixed-point implementation of the `mfilt.firinterp` filter.

Note The table lists all of the properties that a fixed-point filter can have. Many of the properties listed are dynamic, meaning they exist only in response to the settings of other properties. To view all of the characteristics for a filter at any time, use

```
info(hm)
```

where `hm` is a filter.

For further information about the properties of this filter or any `mfilt` object, refer to “Multirate Filter Properties”.

Name	Values	Description
`AccumFracLength`	Any positive or negative integer number of bits. [32]	Specifies the fraction length used to interpret data output by the accumulator. This is a property of FIR filters and lattice filters. IIR filters have two similar properties — `DenAccumFracLength` and `NumAccumFracLength` — that let you set the precision for numerator and denominator operations separately.

Name	Values	Description
`AccumWordLength`	Any integer number of bits[39]	Sets the word length used to store data in the accumulator.
`Arithmetic`	fixed for fixed-point filters	Setting this to `fixed` allows you to modify other filter properties to customize your fixed-point filter.
`CoeffAutoScale`	[true], false	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to `false` enables you to change the `NumFracLength` property value to specify the precision used.
`CoeffWordLength`	Any integer number of bits [16]	Specifies the word length to apply to filter coefficients.
`FilterInternals`	[FullPrecision], SpecifyPrecision	Controls whether the filter automatically sets the output word and fraction lengths, product word and fraction lengths, and the accumulator word and fraction lengths to maintain the best precision results during filtering. The default value, `FullPrecision`, sets automatic word and fraction length determination by the filter. `SpecifyPrecision` makes the output and accumulator-related properties available so you can set your own word and fraction lengths for them.
`InputFracLength`	Any positive or negative integer number of bits [15]	Specifies the fraction length the filter uses to interpret input data.
`InputWordLength`	Any integer number of bits [16]	Specifies the word length applied to interpret input data.
`NumFracLength`	Any positive or negative integer number of bits [14]	Sets the fraction length used to interpret the numerator coefficients.

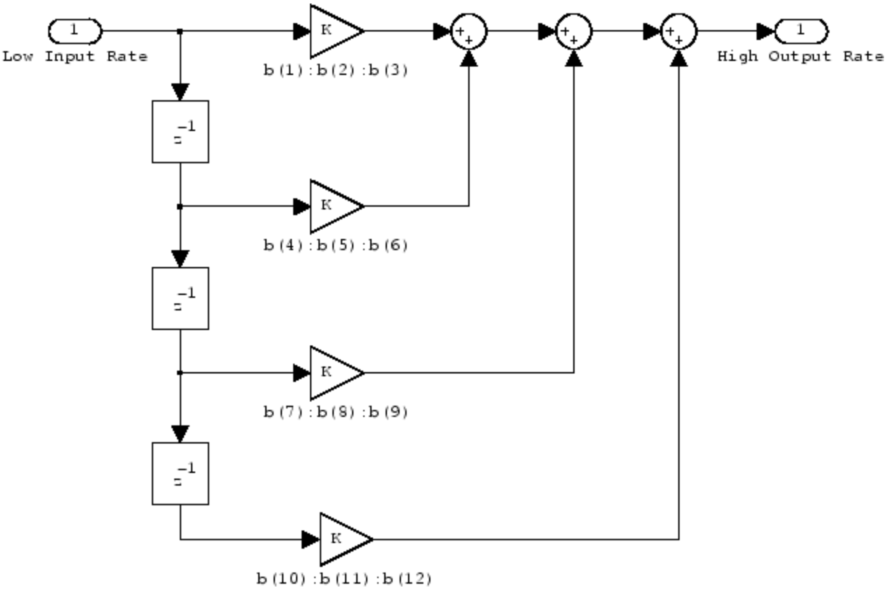
Name	Values	Description
OutputFracLength	Any positive or negative integer number of bits [32]	Determines how the filter interprets the filter output data. You can change the value of OutputFracLength when you set FilterInternals to SpecifyPrecision.
OutputWordLength	Any integer number of bits [39]	Determines the word length used for the output data. You make this property editable by setting FilterInternals to SpecifyPrecision.
OverflowMode	saturate, [wrap]	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either saturate (limit the output to the largest positive or negative representable value) or wrap (set overflowing values to the nearest representable value using modular arithmetic.) The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow — they maintain full precision.

Name	Values	Description
`RoundMode`	[`convergent`], `ceil`, `fix`, `floor`, `nearest`, `round`	Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths). • `ceil` - Round toward positive infinity. • `convergent` - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software. • `fix` - Round toward zero. • `floor` - Round toward negative infinity. • `nearest` - Round toward nearest. Ties round toward positive infinity. • `round` - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers. The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.
`Signed`	[true], false	Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.
`States`	`fi` object to match the filter arithmetic setting.	Contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. The states use `fi` objects, with the associated properties from those objects. For details, refer to fixed-point objects in Fixed-Point Designer documentation.

Filter Structure

To provide interpolation, mfilt.firinterp uses the following structure.

The following figure details the signal flow for the direct form FIR filter implemented by mfilt.firinterp. In the figure, the delay line updates happen at the lower input rate. The remainder of the filter — the sums and coefficients — operate at the higher output rate.



Examples

This example uses mfilt.firinterp to double the sample rate of a 22.05 kHz input signal. The output signal ends up at 44.1 kHz. Although l is set explicitly to 2, this represents the default interpolation value for mfilt.firinterp objects.

```
L = 2;                      % Interpolation factor.
Hm = mfilt.firinterp(L);    % Use the default filter.
fs = 22.05e3;                % Original sample freq: 22.05 kHz.
n = 0:5119;                   % 5120 samples, 0.232s long signal.
x  = sin(2*pi*1e3/fs*n);    % Original signal, sinusoid at 1 kHz.
y = filter(Hm,x);           % 10240 samples, still 0.232s.
```

```
stem(n(1:22)/fs,x(1:22),'filled') % Plot original sampled at
                                  % 22.05 kHz.
hold on;

% Plot interpolated signal (44.1 kHz) in red
stem(n(1:44)/(fs*L),y(25:68),'r')
xlabel('Time (sec)');ylabel('Signal Value')
legend('Original Signal','Interpolated Signal');
```

With interpolation by 2, the resulting signal perfectly matches the original, but with twice as many samples — one between each original sample, as shown in the following figure.

mfilt.firsrc

Direct-form FIR polyphase sample rate converter

Syntax

```
hm = mfilt.firsrc(l,m,num)
```

Description

`hm = mfilt.firsrc(l,m,num)` returns a direct-form FIR polyphase sample rate converter. `l` specifies the interpolation factor. It must be an integer and when omitted in the calling syntax, it defaults to 2.

`m` is the decimation factor. It must be an integer. If not specified, `m` defaults to 1. If `l` is also not specified, `m` defaults to 3 and the overall rate change factor is 2/3.

You specify the coefficients of the FIR lowpass filter used for sample rate conversion in `num`. If omitted, a lowpass Nyquist filter with gain `l` and cutoff frequency of π/`max`(`l`,`m`) is the default.

Combining an interpolation factor and a decimation factor lets you use `mfilt.firsrc` to perform fractional interpolation or decimation on an input signal. Using an `mfilt.firsrc` object applies a rate change factor defined by `l/m` to the input signal. For proper rate changing to occur, `l` and `m` must be relatively prime — meaning the ratio `l/m` cannot be reduced to a ratio of smaller integers.

When you are doing sample-rate conversion with large values of `l` or `m`, such as `l` or `m` greater than 20, using the `mfilt.firsrc` structure is the most effective approach.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hm` as follows:

- To change to single-precision filtering, enter

  ```
  set(hm,'arithmetic','single');
  ```

- To change to fixed-point filtering, enter

```
set(hm,'arithmetic','fixed');
```

Note: You can use the `realizemdl` method to create a Simulink block of a filter created using `mfilt.firsrc`.

Input Arguments

The following table describes the input arguments for creating `hm`.

Input Argument	Description
`l`	Interpolation factor for the filter. `l` specifies the amount to increase the input sampling rate. It must be an integer. When you do not specify a value for `l`, it defaults to 2.
`num`	Vector containing the coefficients of the FIR lowpass filter used for interpolation. When `num` is not provided as an input, `mfilt.firsrc` uses a lowpass Nyquist filter with gain equal to `l` and cutoff frequency equal to `π/max(l,m)` by default. The default length for the Nyquist filter is 24*`max(1,m)`. Therefore, each polyphase filter component has length 24.
`m`	Decimation factor for the filter. `m` specifies the amount to reduce the sampling rate of the input signal. It must be an integer. When you do not specify a value for `m`, it defaults to 1. When `l` is unspecified as well, `m` defaults to 3.

Object Properties

This section describes the properties for both floating-point filters (double-precision and single-precision) and fixed-point filters.

Floating-Point Filter Properties

Every multirate filter object has properties that govern the way it behaves when you use it. Note that many of the properties are also input arguments for creating `mfilt.firsrc` objects. The next table describes each property for an `mfilt.firsrc` filter object.

Name	Values	Description
`Arithmetic`	`[Double]`, `single`, `fixed`	Defines the arithmetic the filter uses. Gives you the options `double`, `single`, and `fixed`. In short, this property defines the operation mode for your filter.
`FilterStructure`	String	Reports the type of filter object. You cannot set this property — it is always read only and results from your choice of `mfilt` object. Describes the signal flow for the filter object.
`InputOffset`	Integers	Contains a value derived from the number of input samples and the decimation factor — `InputOffset = mod(length(nx),m)` where `nx` is the number of input samples and `m` is the decimation factor.
`Numerator`	Vector	Vector containing the coefficients of the FIR lowpass filter used for decimation.
`PersistentMemory`	`false`, `true`	Determines whether the filter states get restored to zeros for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. `PersistentMemory` set to `false` returns filter states to the default values after filtering. States that the filter does not change are not affected. Setting this to `true` allows you to modify the `States`, `InputOffset`, and `PolyphaseAccum` properties.
`RateChangeFactors`	Positive integers. [2 3]	Specifies the interpolation and decimation factors `[l m]` (the rate change factors) for changing the input sample rate by nonintegral amounts.
`States`	`Double`, `single`, matching the filter arithmetic setting.	Contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions.

Fixed-Point Filter Properties

This table shows the properties associated with the fixed-point implementation of the `mfilt.firsrc` filter.

Note The table lists all of the properties that a fixed-point filter can have. Many of the properties listed are dynamic, meaning they exist only in response to the settings of other properties. To view all of the characteristics for a filter at any time, use

```
info(hm)
```

where `hm` is a filter.

For further information about the properties of this filter or any `mfilt` object, refer to "Multirate Filter Properties".

Name	Values	Description
`AccumFracLength`	Any positive or negative integer number of bits. [32]	Specifies the fraction length used to interpret data output by the accumulator. This is a property of FIR filters.
`AccumWordLength`	Any integer number of bits [39]	Sets the word length used to store data in the accumulator.
`Arithmetic`	fixed for fixed-point filters	Setting this to `fixed` allows you to modify other filter properties to customize your fixed-point filter.
`CoeffAutoScale`	[true], false	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to `false` enables you to change the `NumFracLength` property value to specify the precision used.
`CoeffWordLength`	Any integer number of bits [16]	Specifies the word length to apply to filter coefficients.
`FilterInternals`	[FullPrecision], SpecifyPrecision	Controls whether the filter automatically sets the output word and fraction lengths, product word and fraction lengths, and the accumulator word and fraction lengths to maintain the best precision results during filtering. The default value, `FullPrecision`, sets automatic word and fraction length determination by the filter. `SpecifyPrecision` makes the output and accumulator-related properties available so you

Name	Values	Description
		can set your own word and fraction lengths for them.
InputFracLength	Any positive or negative integer number of bits [15]	Specifies the fraction length the filter uses to interpret input data.
InputWordLength	Any integer number of bits [16]	Specifies the word length applied to interpret input data.
NumFracLength	Any positive or negative integer number of bits [14]	Sets the fraction length used to interpret the numerator coefficients.
OutputFracLength	Any positive or negative integer number of bits [32]	Determines how the filter interprets the filter output data. You can change the value of OutputFracLength when you set FilterInternals to SpecifyPrecision.
OutputWordLength	Any integer number of bits [39]	Determines the word length used for the output data. You make this property editable by setting FilterInternals to SpecifyPrecision.
OverflowMode	saturate, [wrap]	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either saturate (limit the output to the largest positive or negative representable value) or wrap (set overflowing values to the nearest representable value using modular arithmetic.) The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow — they maintain full precision.
RateChangeFactors	Positive integers [2 3]	Specifies the interpolation and decimation factors [l m] (the rate change factors) for changing the input sample rate by nonintegral amounts.

Name	Values	Description
`RoundMode`	`[convergent]`, `ceil`, `fix`, `floor`, `nearest`, `round`	Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths). • `ceil` - Round toward positive infinity. • `convergent` - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software. • `fix` - Round toward zero. • `floor` - Round toward negative infinity. • `nearest` - Round toward nearest. Ties round toward positive infinity. • `round` - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers. The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.
`Signed`	[true], false	Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.
`States`	`fi` object	Contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. The states use `fi` objects, with the associated properties from those objects. For details, refer to fixed-point objects in Fixed-Point Designer documentation. For information about the ordering of the states, refer to the filter structure section.

Examples

This is an example of a common audio rate change process — changing the sample rate of a high end audio (48 kHz) signal to the compact disc sample rate (44.1 kHz). This conversion requires a rate change factor of 0.91875, or `l` = 147 and `m` = 160.

```
l  = 147; m = 160;           % Interpolation/decimation factors.
hm = mfilt.firsrc(l,m);      % Use the default FIR filter.
fs = 48e3;                   % Original sample freq: 48 kHz.
n = 0:10239;                 % 10240 samples, 0.213 seconds long.
x  = sin(2*pi*1e3/fs*n);     % Original signal, sinusoid at 1 kHz.
y = filter(hm,x);            % 9408 samples, still 0.213 seconds.
stem(n(1:49)/fs,x(1:49))     % Plot original sampled at 48 kHz.
hold on

% Plot fractionally decimated signal (44.1 kHz) in red
stem(n(1:45)/(fs*l/m),y(13:57),'r','filled')
xlabel('Time (sec)');ylabel('Signal Value')
```

Fractional decimation provides you the flexibility to pick and choose the sample rates you want by carefully selecting `l` and `m`, the interpolation and decimation factors, that result in the final fractional decimation. The following figure shows the signal after applying the rate change filter `hm` to the original signal.

`mfilt.firsrc` | `mfilt.firinterp` | `mfilt.firdecim`

mfilt.firtdecim

Direct-form transposed FIR filter

Syntax

```
hm = mfilt.firtdecim(m)
hm = mfilt.firtdecim(m,num)
```

Description

`hm = mfilt.firtdecim(m)` returns a polyphase decimator `mfilt` object `hm` based on a direct-form transposed FIR structure with a decimation factor of `m`. A lowpass Nyquist filter of gain 1 and cutoff frequency of π/`m` is the default.

`hm = mfilt.firtdecim(m,num)` uses the coefficients specified by `num` for the decimation filter. `num` is a vector containing the coefficients of the transposed FIR lowpass filter used for decimation. If omitted, a lowpass Nyquist filter with gain of 1 and cutoff frequency of π/`m` is the default.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hm` as follows:

- To change to single-precision filtering, enter

  ```
  set(hm,'arithmetic','single');
  ```

- To change to fixed-point filtering, enter

  ```
  set(hm,'arithmetic','fixed');
  ```

Input Arguments

The following table describes the input arguments for creating `hm`.

Input Argument	Description
`num`	Vector containing the coefficients of the FIR lowpass filter used for interpolation. When `num` is not provided as an input, `firtdecim` uses a lowpass Nyquist filter with gain equal to `l`

Input Argument	Description
	and cutoff frequency equal to π/m by default. The default length for the Nyquist filter is 24*m. Therefore, each polyphase filter component has length 24.
m	Decimation factor for the filter. m specifies the amount to reduce the sampling rate of the input signal. It must be an integer. When you do not specify a value for m it defaults to 2.

Object Properties

This section describes the properties for both floating-point filters (double-precision and single-precision) and fixed-point filters.

Floating-Point Filter Properties

Every multirate filter object has properties that govern the way it behaves when you use it. Note that many of the properties are also input arguments for creating mfilt.firtdecim objects. The next table describes each property for an mfilt.firtdecim filter object.

Name	Values	Description
Arithmetic	Double, single, fixed	Specifies the arithmetic the filter uses to process data while filtering.
DecimationFactor	Integer	Decimation factor for the filter. m specifies the amount to reduce the sampling rate of the input signal. It must be an integer.
FilterStructure	String	Reports the type of filter object. You cannot set this property — it is always read only and results from your choice of mfilt object. Also describes the signal flow for the filter object.
InputOffset	Integers	Contains a value derived from the number of input samples and the decimation factor — InputOffset = mod(length(nx),m) where nx is the number of input samples that have been processed so far and m is the decimation factor.

Name	Values	Description
Numerator	Vector	Vector containing the coefficients of the FIR lowpass filter used for decimation.
PersistentMemory	[false], true	Determines whether the filter states get restored to zeros for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. PersistentMemory set to false returns filter states to the default values after filtering. States that the filter does not change are not affected. Setting this to true allows you to modify the States, InputOffset, and PolyphaseAccum properties.
PolyphaseAccum	Double, single [0]	The idea behind having both PolyphaseAccum and Accum is to differentiate between the adders in the filter that work in full precision at all times (PolyphaseAccum) from the adders in the filter that the user controls and that may introduce quantization effects when FilterInternals is set to SpecifyPrecision.
States	Double, single matching the filter arithmetic setting.	Contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions.

Fixed-Point Filter Properties

This table shows the properties associated with the fixed-point implementation of the mfilt.firtdecim filter.

Note The table lists all of the properties that a fixed-point filter can have. Many of the properties listed are dynamic, meaning they exist only in response to the settings of other properties. To view all of the characteristics for a filter at any time, use

```
info(hm)
```

where hm is a filter.

For further information about the properties of this filter or any `mfilt` object, refer to "Multirate Filter Properties".

Name	Values	Description
`AccumFracLength`	Any positive or negative integer number of bits. [32]	Specifies the fraction length used to interpret data output by the accumulator. This is a property of FIR filters and lattice filters. IIR filters have two similar properties — `DenAccumFracLength` and `NumAccumFracLength` — that let you set the precision for numerator and denominator operations separately.
`AccumWordLength`	Any integer number of bits [39]	Sets the word length used to store data in the accumulator.
`Arithmetic`	fixed for fixed-point filters	Setting this to `fixed` allows you to modify other filter properties to customize your fixed-point filter.
`CoeffAutoScale`	[true], false	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to `false` enables you to change the `NumFracLength` property value to specify the precision used.
`CoeffWordLength`	Any integer number of bits [16]	Specifies the word length to apply to filter coefficients.
`FilterInternals`	[FullPrecision], SpecifyPrecision	Controls whether the filter automatically sets the output word and fraction lengths, product word and fraction lengths, and the accumulator word and fraction lengths to maintain the best precision results during filtering. The default value, `FullPrecision`, sets automatic word and fraction length determination by the filter. `SpecifyPrecision` makes the output and accumulator-related properties available so you can set your own word and fraction lengths for them.
`InputFracLength`	Any positive or negative integer number of bits [15]	Specifies the fraction length the filter uses to interpret input data.

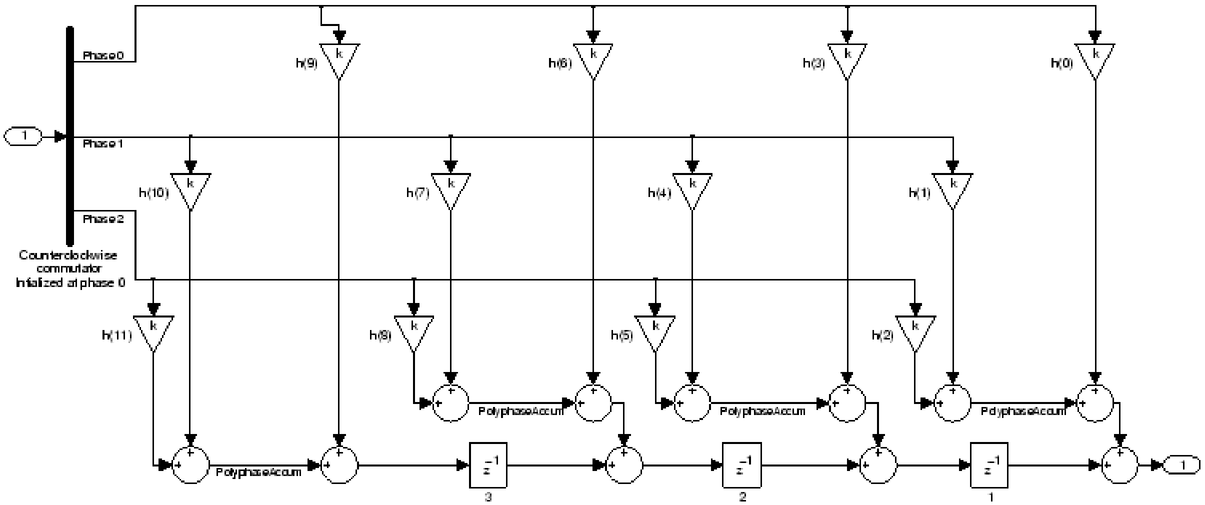
Name	Values	Description
InputWordLength	Any integer number of bits [16]	Specifies the word length applied to interpret input data.
NumFracLength	Any positive or negative integer number of bits [14]	Sets the fraction length used to interpret the numerator coefficients.
OutputFracLength	Any positive or negative integer number of bits [32]	Determines how the filter interprets the filter output data. You can change the value of OutputFracLength when you set FilterInternals to SpecifyPrecision.
OutputWordLength	Any integer number of bits [39]	Determines the word length used for the output data. You make this property editable by setting FilterInternals to SpecifyPrecision.
OverflowMode	saturate, [wrap]	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either saturate (limit the output to the largest positive or negative representable value) or wrap (set overflowing values to the nearest representable value using modular arithmetic.) The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow — they maintain full precision.
PolyphaseAccum	fi object with zeros to start	Differentiates between the adders in the filter that work in full precision at all times (PolyphaseAccum) and the adders in the filter that the user controls and that may introduce quantization effects when FilterInternals is set to SpecifyPrecision.

Name	Values	Description
`RoundMode`	`[convergent]`, `ceil`, `fix`, `floor`, `nearest`, `round`	Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths). • `ceil` - Round toward positive infinity. • `convergent` - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software. • `fix` - Round toward zero. • `floor` - Round toward negative infinity. • `nearest` - Round toward nearest. Ties round toward positive infinity. • `round` - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers. The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.
`Signed`	[true], false	Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.
`States`	`fi` object	Contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. The states use `fi` objects, with the associated properties from those objects. For details, refer to fixed-point objects in Fixed-Point Designer documentation. For information about the ordering of the states, refer to the filter structure section.

Filter Structure

To provide sample rate changes, `mfilt.firtdecim` uses the following structure. At the input you see a commutator that operates counterclockwise, moving from position 0 to position 2, position 1, and back to position 0 as input samples enter the filter. To keep track of the position of the commutator, the `mfilt` object uses the property `InputOffset` which reports the current position of the commutator in the filter.

The following figure details the signal flow for the direct form FIR filter implemented by `mfilt.firtdecim`.



Notice the order of the states in the filter flow diagram. States 1 through 3 appear in the following diagram at each delay element. State 1 applies to the third delay element in phase 2. State 2 applies to the second delay element in phase 2. State 3 applies to the first delay element in phase 2. When you provide the states for the filter as a vector to the `States` property, the above description explains how the filter assigns the states you specify.

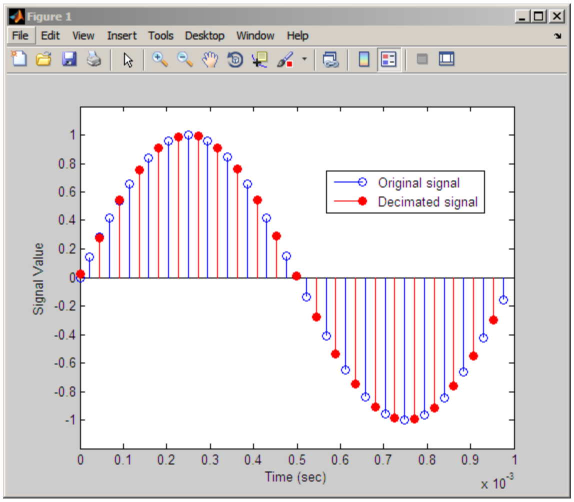
In property value form, the states for a filter `hm` are

```
hm.states=[1:3];
```

Examples

Demonstrate decimating an input signal by a factor of 2, in this case converting from 44.1 kHz down to 22.05 kHz. In the figure shown following the code, you see the results of decimating the signal.

```
m = 2;                    % Decimation factor.
hm = mfilt.firtdecim(m); % Use the default filter coeffs.
fs = 44.1e3;              % Original sample freq: 44.1 kHz.
n = 0:10239;              % 10240 samples, 0.232 second long signal
x  = sin(2*pi*1e3/fs*n); % Original signal--sinusoid at 1 kHz.
y = filter(hm,x);         % 5120 samples, 0.232 seconds.
stem(n(1:44)/fs,x(1:44)) % Plot original sampled at 44.1 kHz.
axis([0 0.001 -1.2 1.2]);
hold on                   % Plot decimated signal (22.05 kHz) in red
stem(n(1:22)/(fs/m),y(13:34),'r','filled')
xlabel('Time (sec)');ylabel('Signal Value');
legend('Original signal','Decimated signal','location','best');
```



See Also

mfilt.firdecim | mfilt.firsrc | mfilt.cicdecim

mfilt.holdinterp

FIR hold interpolator

Syntax

```
hm = mfilt.holdinterp(l)
```

Description

`hm = mfilt.holdinterp(l)` returns the object `hm` that represents a hold interpolator with the interpolation factor `l`. To work, `l` must be an integer. When you do not include `l` in the calling syntax, it defaults to 2. To perform interpolation by noninteger amounts, use one of the fractional interpolator objects, such as `mfilt.firsrc`.

When you use this hold interpolator, each sample added to the input signal between existing samples has the value of the most recent sample from the original signal. Thus you see something like a staircase profile where the interpolated samples form a plateau between the previous and next original samples. The example demonstrates this profile clearly. Compare this to the interpolation process for other interpolators in the toolbox, such as `mfilt.linearinterp`.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hm` as follows:

- To change to single-precision filtering, enter

  ```
  set(hm,'arithmetic','single');
  ```

- To change to fixed-point filtering, enter

  ```
  set(hm,'arithmetic','fixed');
  ```

Input Arguments

The following table describes the input arguments for creating `hm`.

Input Argument	Description
l	Interpolation factor for the filter. l specifies the amount to increase the input sampling rate. It must be an integer. When you do not specify a value for l it defaults to 2.

Object Properties

This section describes the properties for both floating-point filters (double-precision and single-precision) and fixed-point filters.

Floating-Point Filter Properties

Every multirate filter object has properties that govern the way it behaves when you use it. Note that many of the properties are also input arguments for creating `mfilt.holdinterp` objects. The next table describes each property for an `mfilt.interp` filter object.

Name	Values	Description
Arithmetic	Double, single, fixed	Specifies the arithmetic the filter uses to process data while filtering.
FilterStructure	String	Reports the type of filter object. You cannot set this property — it is always read only and results from your choice of mfilt object.
InterpolationFactor	Integer	Interpolation factor for the filter. l specifies the amount to increase the input sampling rate. It must be an integer.
PersistentMemory	'false' or 'true'	Determines whether the filter states are restored to zero for each filtering operation.
States	Double or single array	Filter states. states defaults to a vector of zeros that has length equal to nstates (hm). Always available, but visible in the display

Name	Values	Description
		only when PersistentMemory is true.

Fixed-Point Filter Properties

This table shows the properties associated with the fixed-point implementation of the mfilt.holdinterp filter.

Note The table lists all of the properties that a fixed-point filter can have. Many of the properties listed are dynamic, meaning they exist only in response to the settings of other properties. To view all of the characteristics for a filter at any time, use

```
info(hm)
```

where hm is a filter.

For further information about the properties of this filter or any mfilt object, refer to “Multirate Filter Properties”.

Name	Values	Description
Arithmetic	Double, single, fixed	Specifies the arithmetic the filter uses to process data while filtering.
FilterStructure	String	Reports the type of filter object. You cannot set this property — it is always read only and results from your choice of mfilt object.
InputFracLength	Any positive or negative integer number of bits [15]	Specifies the fraction length the filter uses to interpret input data.
InputWordLength	Any integer number of bits [16]	Specifies the word length applied to interpret input data.
InterpolationFactor	Integer	Interpolation factor for the filter. l specifies the amount to increase the input sampling rate. It must be an integer.

Name	Values	Description
`PersistentMemory`	`'false'` or `'true'`	Determine whether the filter states get restored to zero for each filtering operation
`States`	`fi` object	Contains the filter states before, during, and after filter operations. For hold interpolators, the states are always empty — hold interpolators do not have states. The states use `fi` objects, with the associated properties from those objects. For details, refer to fixed-point objects in Fixed-Point Designer documentation.

Filter Structure

Hold interpolators do not have filter coefficients and their filter structure is trivial.

Examples

To see the effects of hold-based interpolation, interpolate an input sine wave from 22.05 to 44.1 kHz. Note that each added sample retains the value of the most recent original sample.

```
l = 2;                              % Interpolation factor
hm = mfilt.holdinterp(l);
fs = 22.05e3;                       % Original sample freq: 22.05 kHz.
n = 0:5119;                         % 5120 samples, 0.232 second long signal
x  = sin(2*pi*1e3/fs*n);            % Original signal, sinusoid at 1 kHz
y = filter(hm,x);                   % 10240 samples, still 0.232 seconds
stem(n(1:22)/fs,x(1:22),'filled')   % Plot original sampled at
                                    % 22.05 kHz
hold on                             % Plot interpolated signal (44.1 kHz)
stem(n(1:44)/(fs*l),y(1:44),'r')
legend('Original Signal','Interpolated Signal','Location','best');
xlabel('Time (sec)');ylabel('Signal Value')
```

The following figure shows clearly the step nature of the signal that comes from interpolating the signal using the hold algorithm approach. Compare the output to the linear interpolation used in `mfilt.linearinterp`.

`mfilt.linearinterp` | `mfilt.firinterp` | `mfilt.firsrc` | `mfilt.cicinterp`

mfilt.iirdecim

IIR decimator

Syntax

```
hm = mfilt.iirdecim(c1,c2,...)
```

Description

`hm = mfilt.iirdecim(c1,c2,...)` constructs an IIR decimator filter given the coefficients specified in the cell arrays `c1`, `c2`, and so on. The resulting IIR decimator is a polyphase IIR filter where each phase is a cascade allpass IIR filter.

Each cell array `ci` contains a set of vectors representing a cascade of allpass sections. Each element in one cell array is one section. For more information about the contents of each cell array, refer to `dfilt.cascadeallpass`. The contents of the cell arrays are the same for both filter constructors and `mfilt.iirdecim` interprets them same way as `mfilt.cascadeallpass`.

The following exception applies to interpreting the contents of a cell array — if one of the cell arrays `ci` contains only one vector, and that vector comprises a series of 0s and one element equal to 1, that cell array represents a `dfilt.delay` section with latency equal to the number of zeros, rather than a `dfilt.cascadeallpass` section. This exception case occurs with quasi-linear phase IIR decimators.

Although the first example shows how to construct an IIR decimators explicitly, one usually constructs an IIR decimators filter as a result of designing an decimators, as shown in the subsequent examples.

Examples

When the coefficients are known, you can construct the IIR decimator directly using `mfilt.iirdecim`. For example, if the filter's coefficients are [0.6 0.5] for the first phase in the first stage, 0.7 for the second phase in the first stage and 0.8 for the third phase in the first stage; as well as 0.5 for the first phase in the second stage and 0.4 for the second phase in the second stage, construct the filter as shown here.

```
Hm = mfilt.iirdecim({[0.6 0.5] 0.7 0.8},{0.5 0.4})
```

Also refer to the “Quasi-Linear Phase Halfband and Dyadic Halfband Designs” section of the “IIR Polyphase Filter Design” example, iirallpassdemo example.

When the coefficients are not known, use the approach given by the following set of examples. Start by designing an elliptic halfband decimator with a decimation factor of 2. The example specifies the optional sampling frequency argument.

```
tw = 100;   % Transition width of filter.
ast = 80;   % Stopband attenuation of filter.
fs = 2000;  % Sampling frequency of signal to filter.
m = 2;      % Decimation factor.
hm = fdesign.decimator(m,'halfband','tw,ast',tw,ast,fs);
```

`hm` contains the specifications for a decimator defined by `tw`, `ast`, `m`, and `fs`.

Use the specification object `hm` to design a `mfilt.iirdecim` filter object.

```
d = design(hm,'ellip','filterstructure','iirdecim');
% Note that realizemdl requires Simulink
realizemdl(d)     % Build model of the filter.
```

Designing a linear phase decimator is similar to the previous example. In this case, design a halfband linear phase decimator with decimation factor of 2.

```
tw  = 100;  % Transition width of filter.
ast = 60;   % Stopband attenuation of filter.
fs  = 2000; % Sampling frequency of signal to filter.
m = 2;      % Decimation factor.
```

Create a specification object for the decimator.

```
hm = fdesign.decimator(m,'halfband','tw,ast',tw,ast,fs);
```

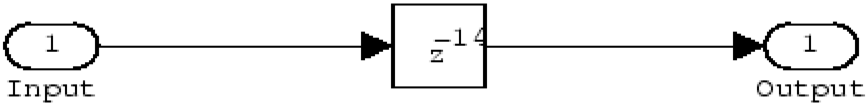
Finally, design the filter `d`.

```
d = design(hm,'iirlinphase','filterstructure','iirdecim');
% Note that realizemdl requires Simulink
realizemdl(d)  % Build model of the filter.
```

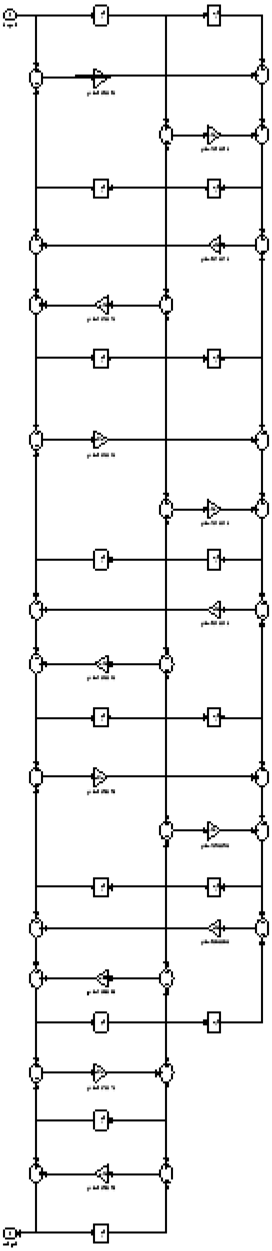
The filter implementation appears in this model, generated by `realizemdl` and Simulink.

Given the design specifications shown here

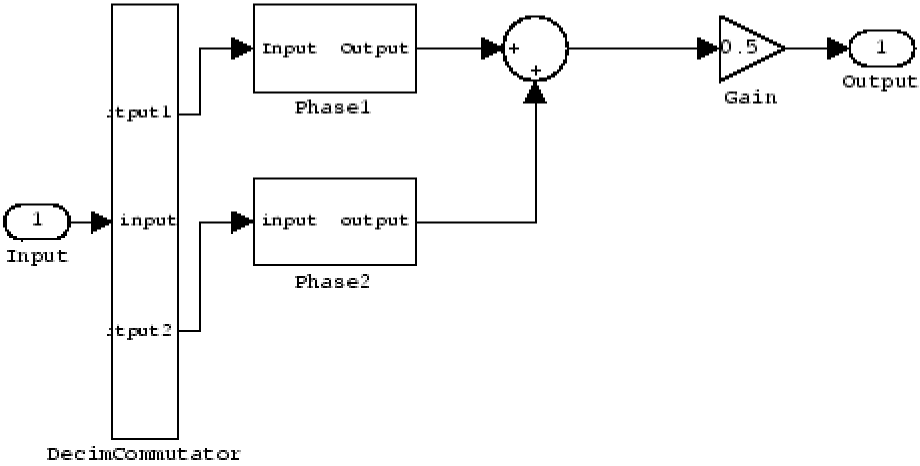
the first phase is a delay section with 0s and a 1 for coefficients and the second phase is a linear phase decimator, shown in the next models.



Phase 1 model



Phase 2 model



Overall model

`dfilt.cascadeallpass` | `mfilt` | `mfilt.iirinterp` | `mfilt.iirwdfdecim`

mfilt.iirinterp

IIR interpolator

Syntax

```
hm = mfilt.iirinterp(c1,c2,...)
```

Description

`hm = mfilt.iirinterp(c1,c2,...)` constructs an IIR interpolator filter given the coefficients specified in the cell arrays C1, C2, etc.

The IIR interpolator is a polyphase IIR filter where each phase is a cascade allpass IIR filter.

Each cell array `ci` contains a set of vectors representing a cascade of allpass sections. Each element in one cell array is one section. For more information about the contents of each cell array, refer to `dfilt.cascadeallpass`. The contents of the cell arrays are the same for both filter constructors and `mfilt.iirdecim` interprets them same way as `mfilt.cascadeallpass`.

The following exception applies to interpreting the contents of a cell array—if one of the cell arrays `ci` contains only one vector, and that vector comprises a series of 0s and a unique element equal to 1, that cell array represents a `dfilt.delay` section with latency equal to the number of zeros, rather than a `dfilt.cascadeallpass` section. This exception case occurs with quasi-linear phase IIR interpolators.

Although the first example shows how to construct an IIR interpolator explicitly, one usually constructs an IIR interpolator filter as a result of designing an interpolator, as shown in the subsequent examples.

Examples

When the coefficients are known, you can construct the IIR interpolator directly using `mfilt.iirinterp`. In the following example, a cascaded polyphase IIR interpolator filter is constructed using 2 phases for each of three stages. The coefficients are given below:

```
Phase1Sect1=0.0603;Phase1Sect2=0.4126; Phase1Sect3=0.7727;
Phase2Sect1=0.2160; Phase2Sect2=0.6044; Phase2Sect3=0.9239;
```

Next the filter is implemented by passing the above coefficients to `mfilt.iirinterp` as cell arrays, where each cell array represents a different phase.

```
Hm = mfilt.iirinterp({Phase1Sect1,Phase1Sect2,Phase1Sect3},...
{Phase2Sect1,Phase2Sect2,Phase2Sect3})

Hm =

        FilterStructure: 'IIR Polyphase Interpolator'
              Polyphase: Phase1: Section1: 0.0603
                                 Section2: 0.4126
                                 Section3: 0.7727
                           Phase2: Section1: 0.216
                                 Section2: 0.6044
                                 Section3: 0.9239
    InterpolationFactor: 2
       PersistentMemory: false
```

Also refer to the “Quasi-Linear Phase Halfband and Dyadic Halfband Designs” section of the “IIR Polyphase Filter Design” example, iirallpassdemo example.

When the coefficients are not known, use the approach given by the following set of examples. Start by designing an elliptic halfband interpolator with a interpolation factor of 2.

```
tw = 100;  % Transition width of filter.
ast = 80;   % Stopband attenuation of filter.
fs = 2000; % Sampling frequency of filter.
l  = 2;    % Interpolation factor.
d = fdesign.interpolator(l,'halfband','tw,ast',tw,ast,fs);
```

Specification object `d` stores the interpolator design specifics. With the details in `d`, design the filter, returning `hm`, an `mfilt.iirinterp` object. Use `hm` to realize the filter if you have Simulink installed.

```
hm = design(d,'ellip','filterstructure','iirinterp');
% Note that realizemdl requires Simulink
realizemdl(hm)     % Build model of the filter.
```

Designing a linear phase halfband interpolator follows the same pattern.

```
tw = 100;  % Transition width of filter.
```

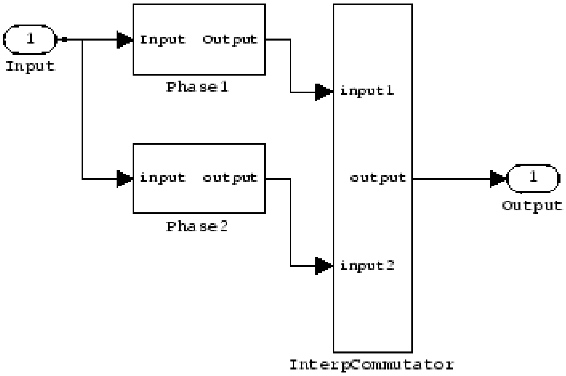
```
ast= 60;   % Stopband attenuation of filter.
fs = 2000; % Sampling frequency of filter.
l = 2;     % Interpolation factor.
d = fdesign.interpolator(l,'halfband','tw,ast',tw,ast,fs);
```

`fdesign.interpolator` returns a specification object that stores the design features for an interpolator.

Now perform the actual design that results in an `mfilt.iirinterp` filter, `hm`.

```
hm = design(d,'iirlinphase','filterstructure','iirinterp');
% Note that realizemdl requires Simulink
realizemdl(hm)     % Build model of the filter.
```

The toolbox creates a Simulink model for `hm`, shown here. Phase1, Phase2, and InterpCommutator are all subsystem blocks.



For more information about Multirate Filter Constructors see the “Getting Started with Multirate Filter (MFILT) Objects” example, mfiltgettingstarteddemo.

See Also

`dfilt.cascadeallpass` | `mfilt` | `mfilt.iirdecim` | `mfilt.iirwdfinterp`

mfilt.iirwdfdecim

IIR wave digital filter decimator

Syntax

```
hm = mfilt.iirwdfdecim(c1,c2,...)
```

Description

`hm = mfilt.iirwdfdecim(c1,c2,...)` constructs an IIR wave digital decimator given the coefficients specified in the cell arrays c1, c2, and so on. The IIR decimator `hm` is a polyphase IIR filter where each phase is a cascade wave digital allpass IIR filter.

Each cell array `ci` contains a set of vectors representing a cascade of allpass sections. Each element in one cell array is one section. For more information about the contents of each cell array, refer to `dfilt.cascadewdfallpass`. The contents of the cell arrays are the same for both filter constructors and `mfilt.iirwdfdecim` interprets them same way as `mfilt.cascadewdfallpass`.

The following exception applies to interpreting the contents of a cell array — if one of the cell arrays `ci` contains only one vector, and that vector comprises a series of 0s and one element equal to 1, that cell array represents a `dfilt.delay` section with latency equal to the number of zeros, rather than a `dfilt.cascadewdfallpass` section. This exception occurs with quasi-linear phase IIR decimators.

Usually you do not construct IIR wave digital filter decimators explicitly. Instead, you obtain an IIR wave digital filter decimator as a result of designing a halfband decimator. The first example in the following section illustrates this case.

Examples

Design an elliptic halfband decimator with a decimation factor equal to 2. Both examples use the `iirwdfdecim` filter structure (an input argument to the `design` method) to design the final decimator.

The first portion of this example generates a filter specification object `d` that stores the specifications for the decimator.

```
tw  = 100;  % Transition width of filter to design, 100 Hz.
ast = 80;   % Stopband attenuation of filter 80 dB.
fs  = 2000; % Sampling frequency of the input signal.
m   = 2;    % Decimation factor.
d = fdesign.decimator(m,'halfband','tw,ast',tw,ast,fs);
```

Now perform the actual design using `d`. Filter object `hm` is an `mfilt.iirwdfdecim` filter.

```
Hm = design(d,'ellip','FilterStructure','iirwdfdecim');
% Note that realizemdl requires Simulink
realizemdl(hm)     % Build model of the filter.
```

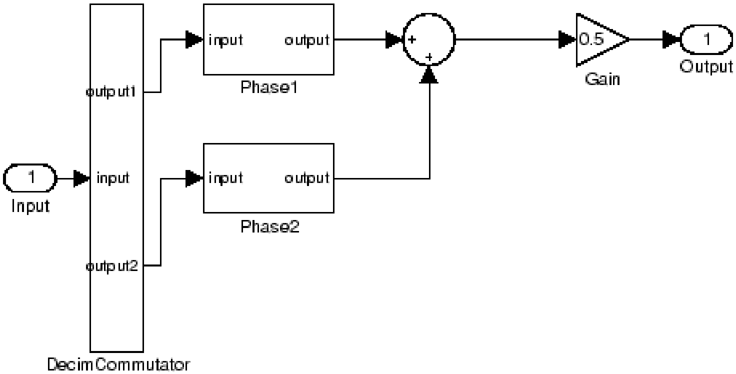
Design a linear phase halfband decimator for decimating a signal by a factor of 2.

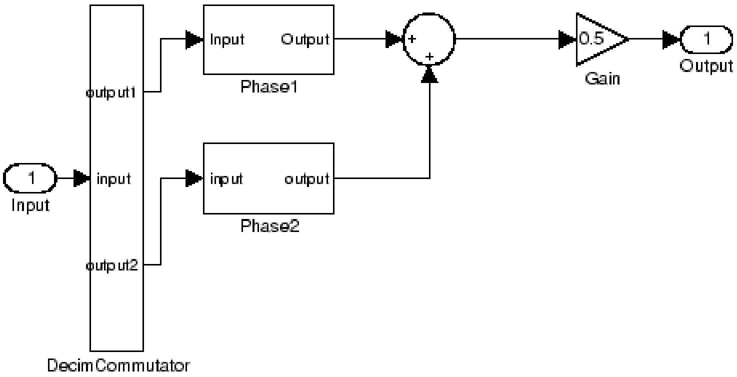
```
tw  = 100;  % Transition width of filter, 100 Hz.
ast = 60;   % Filter stopband attenuation = 80 dB
fs  = 2000; % Input signal sampling frequency.
m   = 2;    % Decimation factor.
d = fdesign.decimator(m,'halfband','tw,ast',tw,ast,fs);
```

Use `d` to design the final filter `hm`, an `mfilt.iirwdfdecim` object.

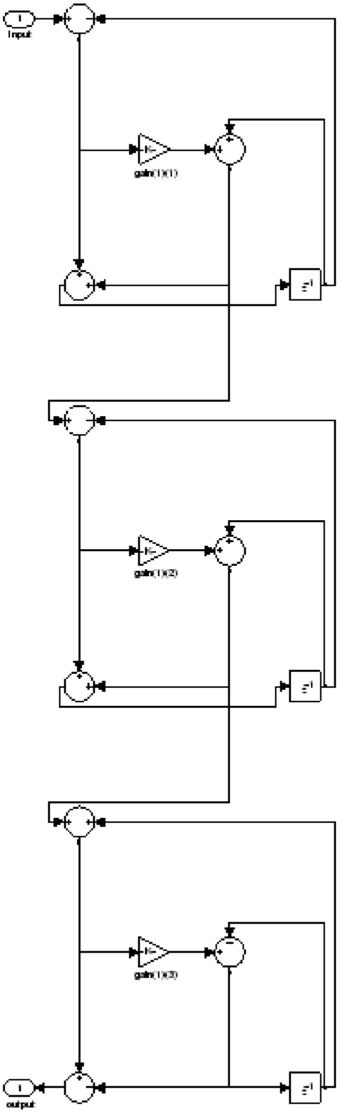
```
hm = design(d,'iirlinphase','filterstructure',...
'iirwdfdecim');
% Note that realizemdl requires Simulink
realizemdl(hm)     % Build model of the filter.
```

The models that `realizemdl` returns for each example appear below. At this level, the realizations of the filters are identical. The differences appear in the subsystem blocks Phase1 and Phase2.

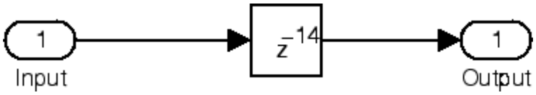




This is the Phase1 subsystem from the halfband model.



Phase1 subsystem from the linear phase model is less revealing—an allpass filter.



See Also

`dfilt.cascadewdfallpass` | `mfilt` | `mfilt.iirdecim` | `mfilt.iirwdfinterp`

mfilt.iirwdfinterp

IIR wave digital filter interpolator

Syntax

```
hm = mfilt.iirwdfinterp(c1,c2,...)
```

Description

`hm = mfilt.iirwdfinterp(c1,c2,...)` constructs an IIR wave digital interpolator given the coefficients specified in the cell arrays `c1`, `c2`, and so on. The IIR interpolator `hm` is a polyphase IIR filter where each phase is a cascade wave digital allpass IIR filter.

Each cell array `ci` contains a set of vectors representing a cascade of allpass sections. Each element in one cell array is one section. For more information about the contents of each cell array, refer to `dfilt.cascadewdfallpass`. The contents of the cell arrays are the same for both filter constructors and `mfilt.iirwdfinterp` interprets them same way as `mfilt.cascadewdfallpass`.

The following exception applies to interpreting the contents of a cell array — if one of the cell arrays `ci` contains only one vector, and that vector comprises a series of 0s and one element equal to 1, that cell array represents a `dfilt.delay` section with latency equal to the number of zeros, rather than a `dfilt.cascadewdfallpass` section. This exception occurs with quasi-linear phase IIR interpolators.

Usually you do not construct IIR wave digital filter interpolators explicitly. Rather, you obtain an IIR wave digital interpolator as a result of designing a halfband interpolator. The first example in the following section illustrates this case.

Examples

Design an elliptic halfband interpolator with interpolation factor equal to 2. At the end of the design process, hm is an IIR wave digital filter interpolator.

```
tw  = 100;  % Transition width of filter, 100 Hz.
```

```
ast = 80;   % Stopband attenuation of filter, 80 dB.
fs  = 2000; % Sampling frequency after interpolation.
l   = 2;    % Interpolation factor.
d = fdesign.interpolator(l,'halfband','tw,ast',tw,ast,fs);
```

The specification object `d` stores the interpolator design requirements. Now use `d` to design the actual filter `hm`.

```
hm = design(d,'ellip','filterstructure','iirwdfinterp');
```

If you have Simulink installed, you can realize your filter as a model built from DSP System Toolbox blocks.

```
% Note that realizemdl requires Simulink
realizemdl(hm)     % Build model of the filter.
```

For variety, design a linear phase halfband interpolator with an interpolation factor of 2.

```
tw  = 100;  % Transition width of filter, 100 Hz.
ast = 80;   % Stopband attenuation of filter, 80 dB.
fs  = 2000; % Sampling frequency after interpolation.
l   = 2;    % Interpolation factor.
d = fdesign.interpolator(l,'halfband','tw,ast',tw,ast,fs);
```

Now perform the actual design process with `d`. Filter `hm` is an IIR wave digital filter interpolator. As in the previous example, `realizemdl` returns a Simulink model of the filter if you have Simulink installed.

```
hm = design(d,'iirlinphase','filterstructure',...
'iirwdfinterp');
% Note that realizemdl requires Simulink
realizemdl(hm)     % Build model of the filter.
```

mfilt.linearinterp

Linear interpolator

Syntax

```
hm = mfilt.linearinterp(l)
```

Description

`hm = mfilt.linearinterp(l)` returns an FIR linear interpolator `hm` with an integer interpolation factor `l`. Provide `l` as a positive integer. The default value for the interpolation factor is 2 when you do not include the input argument `l`.

When you use this linear interpolator, the samples added to the input signal have values between the values of adjacent samples in the original signal. Thus you see something like a smooth profile where the interpolated samples continue a line between the previous and next original samples. The example demonstrates this smooth profile clearly. Compare this to the interpolation process for `mfilt.holdinterp`, which creates a stairstep profile.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hm` as follows:

- To change to single-precision filtering, enter

  ```
  set(hm,'arithmetic','single');
  ```
- To change to fixed-point filtering, enter

  ```
  set(hm,'arithmetic','fixed');
  ```

Input Arguments

The following table describes the input argument for `mfilt.linearinterp`.

Input Argument	Description
`l`	Interpolation factor for the filter. `l` specifies the amount to increase the input sampling rate. It must be an integer. When you do not specify a value for `l` it defaults to 2.

Object Properties

This section describes the properties for both floating-point filters (double-precision and single-precision) and fixed-point filters.

Floating-Point Filter Properties

Every multirate filter object has properties that govern the way it behaves when you use it. Note that many of the properties are also input arguments for creating `mfilt.linearinterp` objects. The next table describes each property for an `mfilt.linearinterp` filter object.

Name	Values	Description
`Arithmetic`	`Double`, `single`, `fixed`	Specifies the arithmetic the filter uses to process data while filtering.
`FilterStructure`	String	Reports the type of filter object. You cannot set this property — it is always read only and results from your choice of `mfilt` object.
`InterpolationFactor`	Integer	Interpolation factor for the filter. `l` specifies the amount to increase the input sampling rate. It must be an integer.
`PersistentMemory`	'`false`' or '`true`'	Determine whether the filter states get restored to zero for each filtering operation
`States`	Double or single array	Filter states. `states` defaults to a vector of zeros that has length equal to `nstates(hm)`. Always available, but visible in the display only when `PersistentMemory` is `true`.

Fixed-Point Filter Properties

This table shows the properties associated with the fixed-point implementation of the `mfilt.holdinterp` filter.

Note The table lists all of the properties that a fixed-point filter can have. Many of the properties listed are dynamic, meaning they exist only in response to the settings of other properties. To view all of the characteristics for a filter at any time, use

```
info(hm)
```

where `hm` is a filter.

For further information about the properties of this filter or any `mfilt` object, refer to "Multirate Filter Properties".

Name	Values	Description
`AccumFracLength`	Any positive or negative integer number of bits. Depends on L. [29 when L=2]	Specifies the fraction length used to interpret data output by the accumulator.
`AccumWordLength`	Any integer number of bits [33]	Sets the word length used to store data in the accumulator.
`Arithmetic`	fixed for fixed-point filters	Setting this to `fixed` allows you to modify other filter properties to customize your fixed-point filter.
`CoeffAutoScale`	[true], false	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to `false` enables you to change the `NumFracLength` property value to specify the precision used.
`CoeffWordLength`	Any integer number of bits [16]	Specifies the word length to apply to filter coefficients.
`FilterInternals`	[FullPrecision], SpecifyPrecision	Controls whether the filter automatically sets the output word and fraction lengths, product word and fraction lengths, and the accumulator word and fraction lengths to maintain the best precision results during filtering. The default value, `FullPrecision`, sets automatic word and fraction length determination

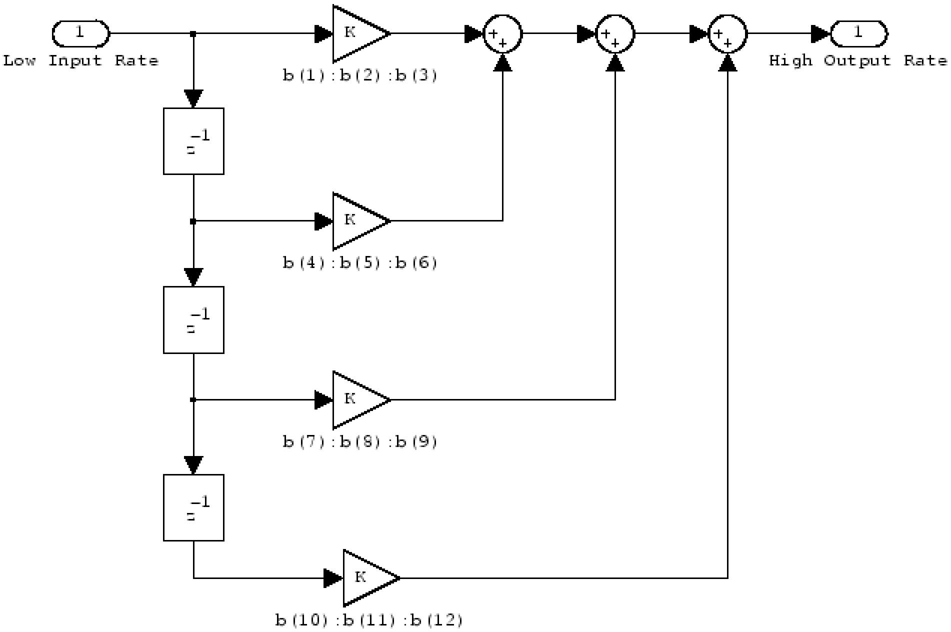
Name	Values	Description
		by the filter. SpecifyPrecision makes the output and accumulator-related properties available so you can set your own word and fraction lengths for them.
InputFracLength	Any positive or negative integer number of bits [15]	Specifies the fraction length the filter uses to interpret input data.
InputWordLength	Any integer number of bits [16]	Specifies the word length applied to interpret input data.
NumFracLength	Any positive or negative integer number of bits [14]	Sets the fraction length used to interpret the numerator coefficients.
OutputFracLength	Any positive or negative integer number of bits [29]	Determines how the filter interprets the filter output data. You can change the value of OutputFracLength when you set FilterInternals to SpecifyPrecision.
OutputWordLength	Any integer number of bits [33]	Determines the word length used for the output data. You make this property editable by setting FilterInternals to SpecifyPrecision.
OverflowMode	saturate, [wrap]	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either saturate (limit the output to the largest positive or negative representable value) or wrap (set overflowing values to the nearest representable value using modular arithmetic.) The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow — they maintain full precision.

Name	Values	Description
`RoundMode`	`[convergent]`, `ceil`, `fix`, `floor`, `nearest`, `round`	Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths). • `ceil` - Round toward positive infinity. • `convergent` - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software. • `fix` - Round toward zero. • `floor` - Round toward negative infinity. • `nearest` - Round toward nearest. Ties round toward positive infinity. • `round` - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers. The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.
`Signed`	[true], false	Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.

Name	Values	Description
`States`	`fi` object	Contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. The states use `fi` objects, with the associated properties from those objects. For details, refer to fixed-point objects in Fixed-Point Designer documentation. For information about the ordering of the states, refer to the filter structure in the following section.

Filter Structure

Linear interpolator structures depend on the FIR filter you use to implement the filter. By default, the structure is direct-form FIR.



Examples

Interpolation by a factor of 2 (used to convert the input signal sampling rate from 22.05 kHz to 44.1 kHz).

```
l = 2;                         % Interpolation factor
hm = mfilt.linearinterp(l);
fs = 22.05e3;                  % Original sample freq: 22.05 kHz.
n = 0:5119;                    % 5120 samples, 0.232 second long signal
x  = sin(2*pi*1e3/fs*n);       % Original signal, sinusoid at 1 kHz
y = filter(hm,x);              % 10240 samples, still 0.232 seconds
stem(n(1:22)/fs,x(1:22),'filled') % Plot original sampled at
                                  % 22.05 kHz
hold on                        % Plot interpolated signal (44.1
                               % kHz) in red
stem(n(1:44)/(fs*l),y(2:45),'r')
xlabel('Time (s)');ylabel('Signal Value')
```

Using linear interpolation, as compared to the hold approach of `mfilt.holdinterp`, provides greater fidelity to the original signal.

midicallback

Call function handle when MIDI controls change value

Syntax

```
oldfh = midicallback(h,newfh)
oldfh = midicallback(h,[])
fh= midicallback(h)
```

Description

`oldfh = midicallback(h,newfh)` sets newfh as the function handle to be called when h changes value, and returns the previous function handle, oldfh.

`oldfh = midicallback(h,[])` clears the function handle.

`fh= midicallback(h)` returns the current function handle.

Examples

Interactively Read MIDI Controls

Use the `midicallback` command with an anonymous function to interactively read MIDI controls.

```
h = midicontrols;
midicallback(h,@(h)disp(midiread(h)));
% Now move any control on the default MIDI device.
   0.6587
   0.6429
   0.6349
   0.6270
   0.6190
   0.6111
   0.6032
   0.5952
```

```
clear h
```

Input Arguments

h — Object that listens to the controls on a MIDI device

object

h is an object that listens to the controls on a MIDI device.

newfh — new function handle

function handle

The new function handle, which is set as the function handle to be called when h changes value. For information on what function handles are, see “Function Handles”.

Example: @myFunction

Output Arguments

oldfh — Old function handle

function handle

The function handle set by the previous call to midicallback.

Example: @myFunction

fh — Current function handle

function handle

The function handle set by the current call to midicallback.

Example: @myFunction

See Also

midicontrols | midiid | midiread | midisync | setpref

midicontrols

Open a group of MIDI controls for reading

Syntax

```
h = midicontrols
h = midicontrols(ControlNumbers)
h = midicontrols(ControlNumbers,InitialValues)
h = midicontrols( ___ ,'MIDIDevice',devicename)
h = midicontrols( ___ ,'OutputMode',mode)
```

Description

`h = midicontrols` returns an object that responds to any control on the default MIDI device. Calling `midiread` with the object, returns the double scalar value of the MIDI control that recently moved after the object was created. The value is normally in the range [0 1]. See `OutputMode` for an alternative. This object can only determine a control's value if the control is moved after the `midicontrols` object is created. If `midiread` is called before the control is moved, `midiread` returns a default initial value of `0`.

`h = midicontrols(ControlNumbers)` returns an object that responds to the MIDI controls specified by `ControlNumbers`. Calling `midiread` with the object, returns a double array of the same shape as `ControlNumbers`. Use `midiid` to interactively identify the control number of individual MIDI controls.

`h = midicontrols(ControlNumbers,InitialValues)` returns an object that uses the specified `InitialValues` when controls are not moved after the object is created. Because initial values are quantized for the underlying MIDI protocol, sometimes `midiread` returns an initial value that is slightly different from `InitialValues`.

`h = midicontrols( ___ ,'MIDIDevice',devicename)` specifies the MIDI device to which the object responds. Use `midiid` to interactively identify the name of a specific MIDI device. If you do not specify the `'MIDIDevice'` name-value pair, the default MIDI device is used. The MATLAB preference 'midi' `'DefaultDevice'` determines the default device.

`h = midicontrols(___,'OutputMode',mode)` specifies the range of values returned by `midiread` and accepted as `InitialValues`. This name-value pair is optional, and you can insert it only at the end of the argument list.

Examples

Respond to any Control on the Default Device

Create the object, and read from it:

```
h =midicontrols
midiread(h)
```

Move one of the controls, and read the data:

```
midiread(h)
```

Respond to a Specific Control

Make the object respond to a specific control:

```
h = midicontrols(1081);
```

Use Control Numbers and an Initial Value

Return a square array, with initial value of 0.5:

```
h = midicontrols([1081 1083; 1082 1084], 0.5);
```

Set Mode to raw, and Set an Initial Value

Return a square array, with the raw initial value of 63:

```
h = midicontrols([1081 1083; 1082 1084], 63, 'OutputMode', 'rawmidi');
```

Set the Default MIDI Device

Assume your MIDI device is a Behringer BCF2000. Set the default device this way:

```
setpref midi DefaultDevice BCF2000
```

This preference persists across MATLAB sessions, so you do not need to set it again unless you want to change devices.

Use Both ControlNumbers and DeviceName

Respond to control 1001 on a Behringer BCF2000:

```
h = midicontrols(1001, 'MIDIDevice', 'BCF2000');
```

Input Arguments

`ControlNumbers` — Identifying MIDI controls

integer values

`ControlNumbers` are integer-valued double-precision numbers. Each control on the MIDI device has a specific integer assigned to it by the device manufacturer. If `ControlNumbers` is [ ], then the `midicontrols` object responds to any control on the MIDI device. As a result, `midiread` returns a double scalar.

Example: `1081`

Data Types: `double` | `single` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`InitialValues` — Initial value of MIDI control

any numeric value within range

`InitialValues` must either be an array of the same size as `ControlNumbers` or a scalar. If you do not specify `InitialValues`, the default initial value is `0`. Typically, initial values must be in the range [0 1]. However, if you specify `‘rawmidi’` as `OutputMode`, the `InitialValues` range is between 0 and 127. Because the initial values are quantized for the underlying MIDI protocol, sometimes `midiread` returns an initial value that is slightly different from `InitialValues`.

Example: `0.3 or [0 0.3 0.6]`

Data Types: `double` | `single` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`devicename` — Name of device

character string

`devicename` is a character string assigned by the device manufacturer or the host operating system. The specified `devicename` can be a substring of the device’s exact name. If you do not specify the ‘`MIDIDevice`’ name-value pair, the default MIDI device is used. The MATLAB preference ‘`midi`’, ‘`DefaultDevice`’ determines the default device.

If you do not set the MATLAB preference, the host operating system chooses the default device in an unspecified way. Some systems have virtual (ie, software) MIDI devices installed. Even if you have only one hardware MIDI device attached to your system, the system may not choose it, which can cause confusion. As a best practice, use `midiid` to identify the name of the device you want. Then use `setpref` to set it as the default device.

Example: `'BCF2000 MIDI 1'`

Data Types: `char`

`mode` — Mode of output

character string

`mode` is a string and must be one of `‘normalized’` or `‘rawmidi’`. In normalized mode, values are in the range [0 1]. Also, initial values are quantized for the underlying MIDI protocol. In the raw MIDI mode, values are integers in the range [0 127], and the quantization of the initial values is not performed. The default of this name-value pair is ‘`normalized`’.

Example: `'rawmidi'`

Data Types: `char`

Output Arguments

`h` — Object that listens to the controls on a MIDI device

object

`h` is an object that listens to the controls on a MIDI device.

See Also

`midicallback` | `midiid` | `midiread` | `midisync` | `setpref`

midiid

Interactively identify MIDI control

Syntax

```
[ctl device] = midiid
```

Description

`[ctl device] = midiid` returns the control number and device name of the MIDI control moved by the user. Call the function at the MATLAB command prompt and then move the control you want to identify on the MIDI control surface. The function detects which control you move and returns the corresponding control number and device name that specify that control.

Examples

Retrieve Control Number and Device Name

Call `midiid`.

```
[ctl,dev] = midiid;
Move the control you wish to identify; type ^C to abort.
Waiting for control message...

ctl =
1002
dev =
nanoKONTROL
```

Output Arguments

`ctl` — Number associated with control being moved

integer values

`ctl` is an integer-valued double-precision number. Each control on the MIDI device has a specific integer assigned to it by the device manufacturer.

Example: `1003`

Data Types: `double`

`device` — Name of device
character string

`device` is a character string assigned by the device manufacturer or the host operating system.

Example: `'nanoKontrol'`

Data Types: `char`

See Also

`midicallback` | `midicontrols` | `midiread` | `midisync` | `setpref`

midiread

Return most recent value of MIDI controls

Syntax

```
v = midiread(h)
```

Description

`v = midiread(h)` returns the most recent value of the MIDI controls associated with `midicontrols` object, `h`. You must create `h` first before it can determine the values of its MIDI controls if they are moved. Calling `midiread` before the controls are moved, returns the initial values specified to `midicontrols`. In this case, when `h` is created. (or `0` if no initial values are specified).

Examples

Read Control Values

```
h = midicontrols;
v = midiread(h);
```

Input Arguments

h — Object that listens to the controls on a MIDI device

object

`h` is an object that listens to the controls on a MIDI device.

Output Arguments

v — Most recent value of MIDI controls

any numeric value

The output value depends on the OutputMode specified by midicontrols when h is created. If you specify that the OutputMode is normalized, then the midiread returns output values in the range [0 1]. Also, initial values are quantized and may be slightly different from those specified by midicontrols.

If you specify the mode as rawmidi, then midiread returns integer values in the range [0 127], and no quantization is required. If you do not specify the OutputMode, the default is normalized.

Example: 0.3 or [0 0.3 0.6]

Data Types: double | uint8

See Also

midicallback | midicontrols | midiid | midisync | setpref

midisync

Send values to MIDI controls to synchronize

Syntax

```
midisync(h)
midisync(h,Values)
```

Description

`midisync(h)` sends the initial values specified by `midicontrols`. `h` is created by the MIDI controls associated with the `midicontrols` object, `h`. You can use `midisync` with bidirectional MIDI devices that can both send and receive messages, and move a control in response to a received message. For example, when a `midicontrols` object is first created, it is often helpful to move the MIDI control to match the initial value of the object. Many MIDI devices are not bidirectional, and calling `midisync` with a unidirectional device has no effect. `midisync` cannot tell whether a value is successfully sent to a device or even whether the device is bidirectional. Therefore, no errors or warnings are generated if sending a value fails.

`midisync(h,Values)` sends `Values` to the MIDI controls associated with the `midicontrols` object, `h`. `Values` must follow the same rules as `InitialValue` arguments of `midicontrols`.

Examples

Send a Slider Change to MIDI Control

```
midisync(h, get(slider, 'Value'))
```

Create a GUI with a Single Slider, and Synchronize it with a MIDI Control

When you move either control, the other control tracks it. The resulting value appears on the command prompt.

```
function trivialmidigui(controlnum,DEVICENAME)
```

```
    slider = uicontrol('Style','slider');
    mc = midicontrols(controlnum,'MIDIDevice',DEVICENAME);
    midisync(mc);
    set(slider,'Callback',@slidercb);
    midicallback(mc, @mccb);

    function slidercb(slider,~)
        val = get(slider,'Value');
        midisync(mc, val);
        disp(val);
    end

    function mccb(mc)
        val = midiread(mc);
        set(slider,'Value',val);
        disp(val);
    end
end
```

Input Arguments

h — Object that listens to the controls on a MIDI device

object

h is an object that listens to the controls on a MIDI device.

Values — Values sent to select MIDI control

any numeric value in range

Values must either be an array the same size as ControlNumbers from midicontrols or a scalar. If you do not specify Values, the default value is whatever the InitialValues is from midicontrols. Typically, values must normally be in the range [0 1]. However, if you specify ‘rawmidi’ as OutputMode of midicontrols, the Values range is between 0 and 127.

Example: 0.3 or [0 0.3 0.6]

Data Types: double | single | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

See Also

midicallback | midicontrols | midiid | midiread | setpref

minimizecoeffwl

Minimum wordlength fixed-point filter

Syntax

```
Hq = minimizecoeffwl(Hd)
Hq = minimizecoeffwl(Hd,...,'NoiseShaping',NSFlag)
Hq = inimizecoeffwl(Hd,...,'NTrials',N)
Hq = minimizecoeffwl(Hd,...'Apasstol',Apasstol)
Hq = minimizecoeffwl(Hd,...,'Astoptol',Astoptol)
Hq = minimizecoeffwl(Hd,...,'MatchrefFilter',RefFiltFlag)
```

Description

`Hq = minimizecoeffwl(Hd)` returns the minimum wordlength fixed-point filter object `Hq` that meets the design specifications of the single-stage or multistage FIR filter object `Hd`. `Hd` must be generated using `fdesign` and `design`. If `Hd` is a multistage filter object, the procedure minimizes the wordlength for each stage separately. `minimizecoeffwl` uses a stochastic noise-shaping procedure by default to minimize the wordlength. To obtain repeatable results on successive function calls, initialize the uniform random number generator `rand`.

`Hq = minimizecoeffwl(Hd,...,'NoiseShaping',NSFlag)` enables or disables the stochastic noise-shaping procedure in the minimization of the wordlength. By default `NSFlag` is `true`. Setting `NSFlag` to `false` minimizes the wordlength without using noise-shaping.

`Hq = inimizecoeffwl(Hd,...,'NTrials',N)` specifies the number of Monte Carlo trials to use in the minimization. `Hq` is the filter with the minimum wordlength among the `N` trials that meets the specifications in `Hd`. `'NTrials'` defaults to one.

`Hq = minimizecoeffwl(Hd,...'Apasstol',Apasstol)` specifies the passband ripple tolerance in dB. `'Apasstol'` defaults to `1e-4`.

`Hq = minimizecoeffwl(Hd,...,'Astoptol',Astoptol)` specifies the stopband tolerance in dB. `'Astoptol'` defaults to `1e-2`.

`Hq = minimizecoeffwl(Hd,...,'MatchrefFilter',RefFiltFlag)` determines whether the fixed-point filter matches the filter order and transition width of the floating-point design. Setting `'MatchRefFilter'` to `true` returns a fixed-point filter with the same order and transition width as `Hd`. The `'MatchRefFilter'` property defaults to `false` and the resulting fixed-point filter may have a different order and transition width than the floating-point design `Hd`.

You must have the Fixed-Point Designer software installed to use this function.

Examples

Minimize wordlength for lowpass FIR equiripple filter:

```
f=fdesign.lowpass('Fp,Fst,Ap,Ast',0.2,0.3,1,60);
% Design filter with double-precision floating point
Hd=design(f,'equiripple');
% Find minimum wordlength fixed-point filter
% with 0.15 dB stopband tolerance
Hq=minimizecoeffwl(Hd,'MatchRefFilter',true,'Astoptol',0.15);
Hq1=minimizecoeffwl(Hd,'Astoptol',0.15);
% Hq.coeffwordlength is 14 bits.
% Hq1.coeffwordlength is 11 bits
hfvt=fvtool(Hd,Hq,Hq1,'showreference','off');
legend(hfvt,'44 coefficients floating-point',...
'44 coefficients 14 bits','48 coefficients 11 bits');
```

msepred

Predicted mean-squared error for adaptive filter

Syntax

```
[mmse,emse] = msepred(ha,x,d)
[mmse,emse,meanw,mse,tracek] = msepred(ha,x,d)
[mmse,emse,meanw,mse,tracek] = msepred(ha,x,d,m)
```

Description

`[mmse,emse] = msepred(ha,x,d)` predicts the steady-state values at convergence of the minimum mean-squared error (`mmse`) and the excess mean-squared error (`emse`) given the input and desired response signal sequences in `x` and `d` and the property values in the adaptfilt object `ha`.

`[mmse,emse,meanw,mse,tracek] = msepred(ha,x,d)` calculates three sequences corresponding to the analytical behavior of the LMS adaptive filter defined by `ha`:

- `meanw` — contains the sequence of coefficient vector means. The columns of matrix `meanw` contain predictions of the mean values of the LMS adaptive filter coefficients at each time instant. The dimensions of `meanw` are (`size`(`x`,1))-by-(`ha.length`).
- `mse` — contains the sequence of mean-square errors. This column vector contains predictions of the mean-square error of the LMS adaptive filter at each time instant. The length of `mse` is equal to `size`(`x`,1).
- `tracek` — contains the sequence of total coefficient error powers. This column vector contains predictions of the total coefficient error power of the LMS adaptive filter at each time instant. The length of `tracek` is equal to `size`(`x`,1).

`[mmse,emse,meanw,mse,tracek] = msepred(ha,x,d,m)` specifies an optional input argument `m` that is the decimation factor for computing `meanw`, `mse`, and `tracek`. When `m` > 1, `msepred` saves every `m`th predicted value of each of these sequences. When you omit the optional argument `m`, it defaults to one.

Note `msepred` is available for the following adaptive filters only: — `adaptfilt.blms` — `adaptfilt.blmsfft` — `adaptfilt.lms` — `adaptfilt.nlms` — `adaptfilt.se` Using `msepred` is the same for any `adaptfilt` object constructed by the supported filters.

Examples

Analyze and simulate a 32-coefficient adaptive filter using 25 trials of 2000 iterations each.

```
x = zeros(2000,25); d = x;     % Initialize variables
ha = fir1(31,0.5);             % FIR system to be identified
x = filter(sqrt(0.75),[1 -0.5],sign(randn(size(x))));
n = 0.1*randn(size(x));        % observation noise signal
d = filter(ha,1,x)+n;          % desired signal
l = 32;                        % Filter length
mu = 0.008;                    % LMS step size.
m  = 5;                        % Decimation factor for analysis
                               % and simulation results
ha = adaptfilt.lms(l,mu);
[mmse,emse,meanW,mse,traceK] = msepred(ha,x,d,m);
[simmse,meanWsim,Wsim,traceKsim] = msesim(ha,x,d,m);
nn = m:m:size(x,1);
subplot(2,1,1);
plot(nn,meanWsim(:,12),'b',nn,meanW(:,12),'r',nn,...
meanWsim(:,13:15),'b',nn,meanW(:,13:15),'r');
PlotTitle ={'Average Coefficient Trajectories for';...
            'W(12), W(13), W(14), and W(15)'};
title(PlotTitle);
legend('Simulation','Theory');
xlabel('Time Index'); ylabel('Coefficient Value');
subplot(2,2,3);
semilogy(nn,simmse,[0 size(x,1)],[(emse+mmse)...
(emse+mmse)],nn,mse,[0 size(x,1)],[mmse mmse]);
title('Mean-Square Error Performance');
axis([0 size(x,1) 0.001 10]);
legend('MSE (Sim.)','Final MSE','MSE','Min. MSE');
xlabel('Time Index'); ylabel('Squared Error Value');
subplot(2,2,4);
semilogy(nn,traceKsim,nn,traceK,'r');
title('Sum-of-Squared Coefficient Errors'); axis([0 size(x,1)...
0.0001 1]);
legend('Simulation','Theory');
xlabel('Time Index'); ylabel('Squared Error Value');
```

Viewing the plots in this figure you see the various error values plotted in both simulation and theory. Each subplot reveals more information about the results as the simulation converges with the theoretical performance.

`filter` | `maxstep` | `msesim`

msesim

Measured mean-squared error for adaptive filter

Syntax

```
mse = msesim(ha,x,d)
[mse,meanw,w,tracek] = msesim(ha,x,d)
[mse,meanw,w,tracek] = msesim(ha,x,d,m)
```

Description

`mse = msesim(ha,x,d)` returns the sequence of mean-square errors in column vector `mse`. The vector contains estimates of the mean-square error of the adaptive filter at each time instant during adaptation. The length of `mse` is equal to `size`(`x`,1). The columns of matrix `x` contain individual input signal sequences, and the columns of the matrix `d` contain corresponding desired response signal sequences.

`[mse,meanw,w,tracek] = msesim(ha,x,d)` calculates three parameters that correspond to the simulated behavior of the adaptive filter defined by `ha`:

- `meanw` — sequence of coefficient vector means. The columns of this matrix contain estimates of the mean values of the LMS adaptive filter coefficients at each time instant. The dimensions of `meanw` are (`size`(`x`,1))-by-(`ha.length`).
- `w` — estimate of the final values of the adaptive filter coefficients for the algorithm corresponding to `ha`.
- `tracek` — sequence of total coefficient error powers. This column vector contains estimates of the total coefficient error power of the LMS adaptive filter at each time instant. The length of `tracek` is equal to `size`(`X`,1).

`[mse,meanw,w,tracek] = msesim(ha,x,d,m)` specifies an optional input argument `m` that is the decimation factor for computing `meanw`, `mse`, and `tracek`. When `m` > 1, `msepsim` saves every `m`th predicted value of each of these sequences. When you omit the optional argument `m`, it defaults to one.

Examples

Simulation of a 32-coefficient FIR filter using 25 trials, each trial having 2000 iterations of the adaptation process.

```
x = zeros(2000,25); d = x;          % Initialize variables
ha = fir1(31,0.5);                  % FIR system to be identified
x = filter(sqrt(0.75),[1 -0.5],sign(randn(size(x))));
n = 0.1*randn(size(x));             % Observation noise signal
d = filter(ha,1,x)+n;               % Desired signal
l = 32;                             % Filter length
mu = 0.008;                         % LMS Step size.
m  = 5;                             % Decimation factor for analysis
                                    % and simulation results
ha = adaptfilt.lms(l,mu);
[simmse,meanWsim,Wsim,traceKsim] = msesim(ha,x,d,m);
nn = m:m:size(x,1);
subplot(2,1,1);
plot(nn,meanWsim(:,12),'b',nn,meanWsim(:,13:15),'b');
PlotTitle ={'Average Coefficient Trajectories for';...
            'W(12), W(13), W(14), and W(15)'};
title(PlotTitle);
xlabel('Time Index'); ylabel('Coefficient Value');
subplot(2,2,3);
semilogy(nn,simmse);
title('Mean-Square Error Performance'); axis([0 size(x,1) 0.001...
10]);
legend('Measured MSE');
xlabel('Time Index'); ylabel('Squared Error Value');
subplot(2,2,4);
semilogy(nn,traceKsim);
title('Sum-of-Squared Coefficient Errors'); axis([0 size(x,1)...
0.0001 1]);
xlabel('Time Index'); ylabel('Squared Error Value');
```

Calculating the mean squared error for an adaptive filter is one measure of the performance of the adapting algorithm. In this figure, you see a variety of measures of the filter, including the error values.

`filter` | `msepred`

multistage

Multistage filter from specification object

Syntax

```
hd = design(d,'multistage')
hd = design(...,'filterstructure',structure)
hd = design(...,'nstages',nstages)
hd = design(...,'usehalfbands',hb)
```

Description

`hd = design(d,'multistage')` designs a multistage filter whose response you specified by the filter specification object `d`.

`hd = design(...,'filterstructure',structure)` returns a filter with the structure specified by `structure`. Input argument `structure` is `dffir` by default and can also be one of the following strings.

structure String	Valid with These Responses
`firdecim`	Lowpass or Nyquist response
`firtdecim`	Lowpass or Nyquist response
`firinterp`	Lowpass or Nyquist response
`lowpass`	Default lowpass only

Multistage design applies to the default lowpass filter specification object and to decimators and interpolators that use either lowpass or Nyquist responses.

`hd = design(...,'nstages',nstages)` specifies `nstages`, the number of stages to be used in the design. `nstages` must be an integer or the string `auto`. To allow the design algorithm to use the optimal number of stages while minimizing the cost of using the resulting filter, `nstages` is `auto` by default. When you specify an integer for `nstages`, the design algorithm minimizes the cost for the number of stages you specify.

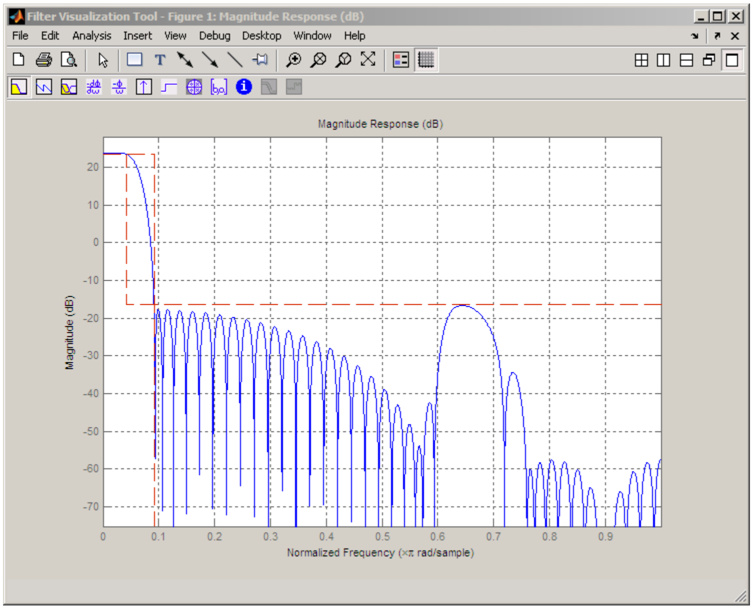
`hd = design(...,'usehalfbands',hb)` uses halfband filters when you set `hb` to `true`. The default value for `hb` is `false`.

Note: To see a list of the design methods available for your filter, use `designmethods(hd)`.

Examples

Design a minimum-order, multistage Nyquist interpolator.

```
l = 15;   % Interpolation factor. Also the Nyquist band.
tw = 0.05; % Normalized transition width
ast = 40;   % Minimum stopband attenuation in dB
d = fdesign.interpolator(l,'nyquist',l,'tw,ast',tw,ast);
hm = design(d,'multistage');
fvtool(hm);
```



Design a multistage lowpass interpolator with an interpolation factor of 8.

```
m = 8; % Interpolation factor;
d = fdesign.interpolator(m,'lowpass');
% Use halfband filters if possible.
hm = design(d,'multistage','Usehalfbands',true);
fvtool(hm);
```

This figure shows the response for `hm`.

`design` | `designopts`

noisepsd

Power spectral density of filter output due to roundoff noise

Syntax

```
hpsd = noisepsd(H,L)
hpsd = noisepsd(H,L,param1,value1,param2,value2,...)
hpsd = noisepsd(H,L,opts)
noisepsd(H,...)
```

Description

`hpsd = noisepsd(H,L)` computes the power spectral density (PSD) at the output of `dfilt` object or filter System object, `H`, occurring because of roundoff noise. This noise is produced by quantization errors within the filter. `L` is the number of trials used to compute the average. The PSD is computed from the average over the `L` trials. The more trials you specify, the better the estimate, but at the expense of longer computation time. When you do not explicitly specify `L`, the default is 10 trials.

`hpsd` is a `psd` data object. To extract the PSD vector (the data from the PSD) from `hpsd`, enter

```
get(hpsd,'data')
```

at the prompt. Plot the PSD data with `plot(hpsd)`. The average power of the output noise (the integral of the PSD) can be computed with `avgpower`, a method of `dspdata` objects:

```
avgpwr = avgpower(hpsd).
```

`hpsd = noisepsd(H,L,param1,value1,param2,value2,...)` where `H` can be either a `dfilt` object or a filter System object, specifies optional parameters via propertyname/propertyvalue pairs. Valid `psd` object property values are:

Property Name	Default Value	Description and Valid Entries
`Nfft`	512	Specify the number of FFT points to use to calculate the PSD.

Property Name	Default Value	Description and Valid Entries
NormalizedFrequency	true	Determine whether to use normalized frequency. Enter a logical value of true or false. Because this property is a logical value, and not a string, do not enclose the single quotation marks.
Fs	normalized	Specify the sampling frequency to use when you set NormalizedFrequency to false. Use any integer value greater than 1. Enter the value in Hz.
SpectrumType	onesided	Specify how noisepsd should generate the PSD. Options are onesided or twosided. If you choose a two-sided computation, you can also choose CenterDC = true. Otherwise, CenterDC must be false. • onesided converts the type to a spectrum that is calculated over half the Nyquist interval. All properties affected by the new frequency range are adjusted automatically. • twosided converts the type to a spectrum that is calculated over the whole Nyquist interval. All properties affected by the new frequency range are adjusted automatically.
CenterDC	false	Shift the zero-frequency component to the center of a two-sided spectrum. • When you set SpectrumType to onesided, it is changed to twosided and the data is converted to a two-sided spectrum. • Setting CenterDC to false shifts the data and the frequency values in the object so that DC is in the left edge of the spectrum. This operation does not affect the SpectrumType property setting.

Property Name	Default Value	Description and Valid Entries
`Arithmetic (only for filter System objects)`	`ARITH`	Analyze the filter System object, based on the arithmetic specified in the `ARITH` input. `ARITH` can be set to `double`, `single`, or `fixed`. The analysis tool assumes a double-precision filter when the arithmetic input is not specified and the filter System object is in an unlocked state.

Note If the spectrum data you specify is calculated over half the Nyquist interval and you do not specify a corresponding frequency vector, the default frequency vector assumes that the number of points in the whole FFT was even. Also, the plot option to convert to a whole or two-sided spectrum assumes the original whole FFT length is even.

System object

If `H` is a filter System object, `noisepsd` requires knowledge of the input data type. Analysis cannot be performed if the input data type is not available. If you do not specify the `Arithmetic` parameter, i.e., use the syntax `[h,w] = noisepsd(H)` , then the following rules apply to this method:

- The System object state is `Unlocked` — `noisepsd` performs double-precision analysis.
- The System object state is `Locked` — `noisepsd` performs analysis based on the locked input data type.

If you do specify the `Arithmetic` parameter, i.e., use the syntax `[h,w] = noisepsd(H,'Arithmetic', ARITH))`, review the following rules for this method. Which rule applies depends on the value you set for the `Arithmetic` parameter.

`Value`	System Object State	Rule
`ARITH = ’double’`	`Unlocked`	`noisepsd` performs double-precision analysis.
	`Locked`	`noisepsd` performs double-precision analysis.
`ARITH = ‘single’`	`Unlocked`	`noisepsd` performs single-precision analysis.

Value	System Object State	Rule
	Locked	noisepsd performs single-precision analysis.
ARITH = ‘fixed’	Unlocked	noisepsd produces an error because the fixed-point input data type is unknown.
	Locked	When the input data type is double or single, then noisepsd produces an error because since the fixed-point input data type is unknown.
		When the input data is of fixed-point type, noisepsd performs analysis based on the locked input data type.

The following Filter System objects are supported by this analysis function:

Filter System objects
dsp.FIRFilter
dsp.BiquadFilter
dsp.IIRFilter
dsp.AllpoleFilter
dsp.AllpassFilter
dsp.CoupledAllpassFilter

Regardless of whether H is a dfilt object or a filter System object, hpsd = noisepsd(H,L,opts) uses an options object, opts, to specify the optional input arguments. This specification is not made using property-value pairs in the command. Use opts = noisepsdopts(H) to create the object. opts then has the noisepsd settings from H. After creating opts, you change the property values before calling noisepsd:

```
set(opts,'fs',48e3); % Set Fs to 48 kHz.
```

Regardless of whether H is a dfilt object or a filter System object, noisepsd(H,...) with no output argument launches FVTool.

Examples

Compute the PSD of the output noise caused by the quantization processes in a fixed-point, direct form FIR filter.

```
b = firgr(27,[0 .4 .6 1],[1 1 0 0]);
h = dfilt.dffir(b); % Create the filter object.
% Quantize the filter to fixed-point.
h.arithmetic = 'fixed';
hpsd = noisepsd(h);
plot(hpsd)
```

`hpsd` looks similar to the following figure—the data resulting from the noise PSD calculation. You can review the data in `hpsd.data`.

`filter` | `noisepsdopts` | `norm` | `reorder` | `scale`

noisepsdopts

Options for running filter output noise PSD

Syntax

```
opts = noisepsdopts(H)
```

Description

`opts = noisepsdopts(H)` uses the current settings in the `dfilt` object or the filter System object, `H`, to create an options object, `opts`, that contains specified options for computing the output noise PSD. You can pass `opts` to the `scale` method as an input argument to apply scaling settings to a second-order filter.

`noisepsdopts` returns the options object, `opts`, with which you can set the following properties for `noisepsd`:

Property Name	Default Value	Description and Valid Entries
`Nfft`	`512`	Specify the number of FFT points to use to calculate the PSD.
`NormalizedFrequency`	`true`	Determine whether to use normalized frequency. Enter a logical value of the logical `true` or `false`. Because this property is a logical value, and not a string, do not enclose with single quotation marks.
`Fs`	`normalized`	Specify the sampling frequency to use when you set `NormalizedFrequency` to `false`. Use any integer value greater than 1. Enter the value in Hz.
`SpectrumType`	`onesided`	Specify how `noisepsd` should generate the PSD. Options are onesided or twosided. If you choose a two-sided computation, you can also choose

Property Name	Default Value	Description and Valid Entries
		`centerdc` = `true`. Otherwise, `centerdc` must be `false`. • `onesided` converts the type to a spectrum that is calculated over half the Nyquist interval. All properties affected by the new frequency range are adjusted automatically. • `twosided` converts the type to a spectrum that is calculated over the whole Nyquist interval. All properties affected by the new frequency range are adjusted automatically.
`CenterDC`	`false`	Shift the zero-frequency component to the center of a two-sided spectrum. • When you set `SpectrumType` to `onesided`, it is changed to `twosided` and the data is converted to a two-sided spectrum. • Setting `CenterDC` to `false` shifts the data and the frequency values in the object so that DC is in the left edge of the spectrum. This operation does not effect the `SpectrumType` property setting.
`Arithmetic (only for filter System objects)`	`ARITH`	Analyze the filter System object, based on the arithmetic specified in the `ARITH` input. `ARITH` can be set to `double`, `single`, or `fixed`. The analysis tool assumes a double-precision filter when the arithmetic input is not specified and the filter System object is in an unlocked state.

`noisepsd`

norm

P-norm of filter

Syntax

```
l = norm(ha)
l = norm(ha,pnorm)
l = norm(hd)
l = norm(hd,pnorm)
l = norm(hm)
l = norm(hm,pnorm)
```

Description

All of the variants of `norm` return the filter p-norm for the object in the syntax, either an adaptive filter, a digital filter, or a multirate filter. When you omit the `pnorm` argument, `norm` returns the L2-norm for the object.

Note that by Parseval's theorem, the L2-norm of a filter is equal to the l2 norm. This equality is not true for the other norm variants.

For adaptfilt Objects

`l = norm(ha)` returns the L2-norm of an adaptive filter.`l = norm(ha,pnorm)` adds the input argument `pnorm` to let you specify the norm returned. `pnorm` can be either

- Frequency-domain norms specified by one of `L1`, `L2`, or `Linf`
- Discrete-time domain norms specified by one of `l1`, `l2`, or `linf`

For dfilt Objects

`l = norm(hd)` returns the L2-norm of a discrete-time filter.

`l = norm(hd,pnorm)` includes input argument `pnorm` that lets you specify the norm returned. `pnorm` can be either

- Frequency-domain norms specified by one of `L1`, `L2`, or `Linf`
- Discrete-time domain norms specified by one of `l1`, `l2`, or `linf`

By Parseval's theorem, the L2-norm of a filter is equal to the l2 norm. This equality is not true for the other norm variants.

IIR filters respond slightly differently to `norm`. When you compute the l2, linf, L1, and L2 norms for an IIR filter, `norm(...,L2,tol)` lets you specify the tolerance for the accuracy in the computation. For l1, l2, L2, and linf, `norm` uses the tolerance to truncate the infinite impulse response that it uses to calculate the norm. For L1, `norm` passes the tolerance to the numerical integration algorithm. Refer to Examples to see this in use. You cannot specify `Linf` for the norm and include the `tol` option.

For mfilt Objects

`l = norm(hm)` returns the L2-norm of a multirate filter.

`l = norm(hm,pnorm)` includes argument `pnorm` to let you specify the norm returned. `pnorm` can be either

- Frequency-domain norms specified by one of `L1`, `L2`, or `Linf`
- Discrete-time domain norms specified by one of `l1`, `l2`, or `linf`

Note that, by Parseval's theorem, the L2-norm of a filter is equal to the l2 norm. This equality is not true for the other norm variants.

Examples

Adaptfilt Objects

For the adaptive filter example, compute the 2-norm of an `adaptfilt` object, here an LMS-based adaptive filter.

```
Ha = adaptfilt.lms; % norm(ha) is zero because all coeffs are zero
% Create some data to filter to generate filter coeffs
x = randn(100,1);
d = x + randn(100,1);
[y,e] = filter(Ha,x,d);
L2 = norm(Ha); % Now norm(ha) is nonzero
```

Dfilt Objects

To demonstrate the tolerance option used with an IIR filter (`dfilt` object), compute the 2-norm of filter `hd` with a tolerance of 1e-10.

```
H =fdesign.lowpass('n,fc',5,0.4);
Hd = butter(H);
L2=norm(Hd,'l2',1e-10);
```

Mfilt Objects

In this example, compute the infinity norm of an FIR polyphase interpolator, which is an `mfilt` object.

```
Hm = mfilt.firinterp;
Linf = norm(Hm,'linf');
```

See Also

`reorder` | `scale` | `scalecheck`

normalize

Normalize filter numerator or feed-forward coefficients

Syntax

```
normalize(hq)
g = normalize(hd)
```

Description

`normalize(hq)` normalizes the filter numerator coefficients for a quantized filter to have values between -1 and 1. The coefficients of `hq` change — `normalize` does not copy `hq` and return the copy. To restore the coefficients of `hq` to the original values, use `denormalize`.

Note that for lattice filters, the feed-forward coefficients stored in the property `lattice` are normalized.

`g = normalize(hd)` normalizes the numerator coefficients for the filter `hq` to between -1 and 1 and returns the gain `g` due to the normalization operation. Calling `normalize` again does not change the coefficients. `g` always returns the gain returned by the first call to normalize the filter.

Examples

Create a direct form II quantized filter that uses second-order sections. Then use `normalize` to maximize the use of the range of representable coefficients.

```
d=fdesign.lowpass('n,fp,ap,ast',8,.5,2,40);
hd=design(d,'ellip');
hd.arithmetic ='fixed';
```

Check the filter coefficients. Note that `InitialSOSMatrix(3,2)>1`

```
InitialSOSMatrix = hd.sosMatrix;
```

Use `normalize` to modify the coefficients into the range between -1 and 1. The output `g` contains the gains applied to each section of the SOS filter.

```
g = normalize(hd);
```

None of the numerator coefficients exceed -1 or 1.

See Also

`denormalize`

normalizefreq

Switch filter specification between normalized frequency and absolute frequency

Syntax

```
normalizefreq(d)
normalizefreq(d,flag)
normalizefreq(d,false,fs)
```

Description

`normalizefreq(d)` normalizes the frequency specifications in filter specifications object `d`. By default, the `NormalizedFrequency` property is set to `true` when you create a design object. You provide the design specifications in normalized frequency units. `normalizefreq` does not affect filters that already use normalized frequency.

If you use this syntax when `d` does not use normalized frequency specifications, all of the frequency specifications are normalized by `fs`/2 so they lie between 0 and 1, where `fs` is specified in the object. Included in the normalization are the filter properties that define the filter pass and stopband edge locations by frequency:

- `F3 dB` — Used by IIR filter specifications objects to describe the passband cutoff frequency
- `Fcutoff` — Used by FIR filter specifications objects to describe the passband cutoff frequency
- `Fpass` — Describes the passband edges
- `Fstop` — Describes the stopband edges

In this syntax, `normalizefreq(d)` assumes you specified `fs` when you created `d` or changed `d` to use absolute frequency specifications.

`normalizefreq(d,flag)` where `flag` is either **`true`** or **`false`**, specifies whether the `NormalizedFrequency` property value is `true` or `false` and therefore whether the filter normalizes the sampling frequency `fs` and other related frequency specifications. `fs` defaults to 1 for this syntax.

When you do not provide the input argument `flag`, it defaults to `true`. If you set `flag` to `false`, affected frequency specifications are multiplied by `fs`/2 to remove the normalization. Use this syntax to switch your filter between using normalized frequency specifications and not using normalized frequency specifications.

`normalizefreq(d,`**`false`**`,fs)` lets you specify a new sampling frequency `fs` when you set the `NormalizedFrequency` property to `false`.

Examples

These examples demonstrate using `normalizefreq` in both of the major syntax applications—setting the design object frequency specifications to use absolute frequency (normalizefreq(hd,**`false`**,fs)) and resetting a design object to using normalized frequencies (`normalizefreq(d)`).

Construct a highpass filter specifications object by specifying the passband and stopband edges and the desired attenuations in the bands. By default, provide the frequency specifications in normalized values between 0 and 1.

```
d=fdesign.highpass(0.35, 0.45, 60, 40);
```

`Fstop` and `Fpass` are in normalized form, and the property `NormalizedFrequency` is `true`.

Now use `normalizedfreq` to convert to absolute frequency specifications, with a sampling frequency of 1000 Hz.

```
normalizefreq(d,false,1e3);
```

Both of the attenuation specifications remain the same. The passband and stopband edge definitions now appear in Hz, where the new value represents the normalized values multiplied by `Fs`/2, or 500 Hz.

Converting to using normalized frequencies consists of using `normalizefreq` with the design object `d`.

```
normalizefreq(d)
```

For bandstop, bandpass, and multiple band filter specifications objects, `normalizefreq` works the same way for all band edge definitions. When you do not provide the sampling frequency Fs as an input argument and you are converting to absolute frequency specifications, normalizefreq sets Fs to 1, as shown in this example.

```
d=fdesign.bandstop(0.25,0.35,0.55,0.65,50,60);
normalizefreq(d,false)
```

See Also

fdesign.lowpass | fdesign.halfband | fdesign.highpass | fdesign.interpolator

nstates

Number of filter states

Syntax

```
n = nstates(hd)
n = nstates(hm)
```

Description

Discrete-Time Filters

`n = nstates(hd)` returns the number of states `n` in the discrete-time filter `hd`. The number of states depends on the filter structure and the coefficients.

Multirate Filters

`n = nstates(hm)` returns the number of states `n` in the multirate filter `hm`. The number of states depends on the filter structure and the coefficients.

Examples

Check the number of states for two different filters, one a direct form FIR filter, the other a multirate filter.

```
h = firls(30,[0 .1 .2 .5]*2,[1 1 0 0]);
hd = dfilt.dffir(h);
NstateDF = nstates(hd);
hm = mfilt.firsrc(2,3);
NstateMR = nstates(hm);
```

`mfilt`

order

Order of fixed-point filter

Syntax

```
n = order(hq)
n = order(hs)
```

Description

`n = order(hq)` returns the order `n` of the quantized filter `hq`. When `hq` is a single-section filter, `n` is the number of delays required for a minimum realization of the filter.

When `hq` has more than one section, `n` is the number of delays required for a minimum realization of the overall filter.

`n = order(hs)` returns the order `n` of the filter System object `hs`. The order depends on the filter structure and the reference double-precision floating-point coefficients. `hs` can be one of the following filter structures.

The following Filter System objects are supported by this analysis function:

Filter System objects
`dsp.FIRFilter`
`dsp.FIRInterpolator`
`dsp.CICInterpolator`
`dsp.FIRDecimator`
`dsp.CICDecimator`
`dsp.FIRRateConverter`
`dsp.BiquadFilter`
`dsp.IIRFilter`
`dsp.AllpoleFilter`

Filter System objects
dsp.AllpassFilter
dsp.CoupledAllpassFilter

Examples

Create a discrete-time filter, quantize it, and convert it to second-order section form. Then, use order to check the order of the filter.

```
[b,a] = ellip(4,3,20,.6); % Create the reference filter.
hq = dfilt.df2(b,a);
% Quantize the filter and convert to second-order sections.
set(hq,'arithmetic','fixed');

n=order(hq); % Check the order of the overall filter.
```

parallel

Multirate parallel filter structure

Syntax

```
hmp = parallel(hm1,hm2,...,hmn)
```

Description

`hmp = parallel(hm1,hm2,...,hmn)` returns a multirate filter `hmp` that is two or more `mfilt` objects `hm1`, `hm2`, and so on connected in a parallel structure. Each filter in the structure is one stage and all stages must have the same rate change factor.

Access the individual filters in the parallel structure by

`dfilt.parallel` | `mfilt`

phasedelay

Phase delay of filter

Syntax

```
[phi,w]=phasedelay(hfilt)
[phi,w]=phasedelay(hfilt,n)
phasedelay(hfilt)
[phi,w] = phasedelay(hs)
[phi,w] = phasedelay(hs,n)
[phi,w] = phasedelay(hs,Name,Value)
phasedelay(hs)
```

Description

`phasedelay` returns the phase delay based on the current filter coefficients. This section describes `phasedelay` operation for discrete-time filters and multirate filters. For more information about optional input arguments for `phasedelay`, refer to `phasedelay` in Signal Processing Toolbox documentation.

`[phi,w]=phasedelay(hfilt)` returns the phase response `phi` of the filter `hfilt` and the corresponding frequencies `w` at which the function evaluates the phase delay.

The phase delay is evaluated at 8192 points equally spaced around the upper half of the unit circle.

`[phi,w]=phasedelay(hfilt,n)` returns the phase delay `phi` of the filter `hfilt` and the corresponding frequencies `w` at which the function evaluates the phase delay. The phase delay is evaluated at n points equally spaced around the upper half of the unit circle.

`phasedelay(hfilt)` displays the phase delay of `hfilt` in the Filter Visualization Tool (FVTool).

`[phi,w] = phasedelay(hs)` returns the phase delay for the filter System object hs using 8192 samples.

`[phi,w] = phasedelay(hs,n)` returns the phase delay for the filter System object hs using `n` samples.

`[phi,w] = phasedelay(hs,Name,Value)` returns the phase delay with additional options specified by one or more Name,Value pair arguments.

`phasedelay(hs)` uses FVTool to plot the phase delay of the filter System object `hs`.

Input Arguments

`hfilt`

`hfilt` is either:

- A discrete-time `dfilt`, or multirate `mfilt` filter object
- A vector of discrete-time, or multirate filter objects

The multirate filter delay response is computed relative to the rate at which the filter is running. When you specify `fs` (the sampling rate) as an input argument, `phasedelay` assumes the filter is running at that rate.

For multistage cascades, `phasedelay` forms a single-stage multirate filter that is equivalent to the cascade. It then computes the response relative to the rate at which the equivalent filter is running. `phasedelay` does not support all multistage cascades. The function analyzes only those cascades for which there exists an equivalent single-stage filter.

As an example, consider a 2-stage interpolator where the first stage has an interpolation factor of 2 and the second stage has an interpolation factor of 4. In this case, an equivalent single-stage filter exists with an overall interpolation factor of 8. `phasedelay` uses this equivalent filter for the analysis. If a sampling frequency `fs` is specified as an input argument to `phasedelay`, the function interprets `fs` as the rate at which the equivalent filter is running.

`hs`

Filter System object.

The following Filter System objects are supported by this analysis function:

Filter System objects
`dsp.FIRFilter`
`dsp.FIRInterpolator`
`dsp.CICInterpolator`
`dsp.FIRDecimator`
`dsp.CICDecimator`
`dsp.FIRRateConverter`
`dsp.BiquadFilter`
`dsp.IIRFilter`
`dsp.AllpoleFilter`
`dsp.AllpassFilter`
`dsp.CoupledAllpassFilter`

n

Number of samples. For an FIR filter where `n` is a power of two, the computation is done faster using FFTs.

Default: 8192

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'Arithmetic'` — Value types:
‘double’ | 'single' | 'fixed'

For filter System object inputs only, specify the arithmetic used during analysis. When you specify `'double'` or `'single'`, the function performs double- or single-precision analysis. When you specify `'fixed'` , the arithmetic changes depending on the setting of the `CoefficientDataType` property and whether the System object is locked or unlocked.

Details for Fixed-Point Arithmetic

System Object State	Coefficient Data Type	Rule
Unlocked	`'Same as input'`	The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Unlocked	`'Custom'`	The function performs fixed-point analysis based on the setting of the `CustomCoefficientsDataType` property.
Locked	`'Same as input'`	When the input data type is `'double'` or `'fixed'`, the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Locked	`'Custom'`	The function performs fixed-point analysis based on the setting of the `CustomCoefficientsDataType` property.

When you do not specify the arithmetic for non-CIC structures, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type. CIC structures only support fixed-point arithmetic.

Output Arguments

`phi`

Complex, `n`-element phase-delay vector. If hfilt is a vector of filters, phi is a complex, `length(hfilt)`-by-`n` matrix of phase-delay vectors whose columns correspond to each filter in hfilt. If `n` is not specified, the function uses a default value of 8192.

For adaptive filters, `phi` is the instantaneous phase delay.

`w`

Frequency vector of length `n`, in radians/sample. `w` consists of `n` points equally spaced around the upper half of the unit circle (from 0 to π radians/sample). If hfilt is a vector of filters, w is a complex, `length(hfilt)`-by-`n` matrix of phase-delay vectors whose columns correspond to each filter in hfilt. If `n` is not specified, the function uses a default value of 8192.

Algorithms

You can provide `fs`, the sampling frequency, as an input as well. `phasedelay` uses `fs` to calculate the delay response and plots the response to `fs`/2.

`freqz` | `grpdelay` | `phasez` | `zerophase` | `zplane` | `freqz` | `fvtool` | `phasez` | `zerophase`

phasez

Unwrapped phase response for filter

Syntax

```
[phi,w]=phasez(hfilt)
[phi,w]=phasez(hfilt,n)
phasez(hfilt)
[phi,w] = phasez(hs)
[phi,w] = phasez(hs,n)
[phi,w] = phasez(hs,Name,Value)
phasez(hs)
```

Description

`phasez` returns the unwrapped phase response based on the current filter coefficients. This section describes `phasez` operation for adaptive filters, discrete-time filters, multirate filters, and filter System objects. For more information about optional input arguments for `phasez`, refer to `phasez` in Signal Processing Toolbox documentation.

`[phi,w]=phasez(hfilt)` returns the phase response `phi` of the filter `hfilt` and the corresponding frequencies `w` at which the function evaluates the phase response. The phase response is evaluated at 8192 points equally spaced around the upper half of the unit circle.

`[phi,w]=phasez(hfilt,n)` returns the phase response `phi` of the filter `hfilt` and the corresponding frequencies `w` at which the function evaluates the phase response. The phase response is evaluated at n points equally spaced around the upper half of the unit circle.

`phasez(hfilt)` displays the phase response of `hfilt` in the Filter Visualization Tool (FVTool).

`[phi,w] = phasez(hs)` returns a phase response for the filter System object hs using 8192 samples.

`[phi,w] = phasez(hs,n)` returns a phase response for the filter System object hs using `n` samples.

`[phi,w] = phasez(hs,Name,Value)` returns a phase response with additional options specified by one or more Name,Value pair arguments.

`phasez(hs)` uses FVTool to plot the phase response of the filter System object `hs`.

Input Arguments

`hfilt`

`hfilt` is either:

- An adaptive `adaptfilt`, discrete-time `dfilt`, or multirate `mfilt` filter object
- A vector of adaptive, discrete-time, or multirate filter objects

The multirate filter response is computed relative to the rate at which the filter is running. When you specify `fs` (the sampling rate) as an input argument, `phasez` assumes the filter is running at that rate.

For multistage cascades, `phasez` forms a single-stage multirate filter that is equivalent to the cascade. It then computes the response relative to the rate at which the equivalent filter is running. `phasez` does not support all multistage cascades. The function analyzes only those cascades for which there exists an equivalent single-stage filter.

As an example, consider a 2-stage interpolator where the first stage has an interpolation factor of 2 and the second stage has an interpolation factor of 4. In this case, an equivalent single-stage filter exists with an overall interpolation factor of 8. `phasez` uses this equivalent filter for the analysis. If a sampling frequency `fs` is specified as an input argument to `phasez`, the function interprets `fs` as the rate at which the equivalent filter is running.

`hs`

Filter System object.

The following Filter System objects are supported by this analysis function:

Filter System objects
`dsp.FIRFilter`

Filter System objects
`dsp.FIRInterpolator`
`dsp.CICInterpolator`
`dsp.FIRDecimator`
`dsp.CICDecimator`
`dsp.FIRRateConverter`
`dsp.BiquadFilter`
`dsp.IIRFilter`
`dsp.AllpoleFilter`
`dsp.AllpassFilter`
`dsp.CoupledAllpassFilter`

`n`

Number of samples. For an FIR filter where `n` is a power of two, the computation is done faster using FFTs.

Default: 8192

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'Arithmetic'` — Value types:
`‘double’ | 'single' | 'fixed'`

For filter System object inputs only, specify the arithmetic used during analysis. When you specify `'double'` or `'single'`, the function performs double- or single-precision analysis. When you specify `'fixed'` , the arithmetic changes depending on the setting of the `CoefficientDataType` property and whether the System object is locked or unlocked.

Details for Fixed-Point Arithmetic

System Object State	Coefficient Data Type	Rule
Unlocked	'Same as input'	The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Unlocked	'Custom'	The function performs fixed-point analysis based on the setting of the CustomCoefficientsDataType property.
Locked	'Same as input'	When the input data type is 'double' or 'fixed', the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Locked	'Custom'	The function performs fixed-point analysis based on the setting of the CustomCoefficientsDataType property.

When you do not specify the arithmetic for non-CIC structures, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type. CIC structures only support fixed-point arithmetic.

Output Arguments

phi

Complex, n-element phase response vector. If hfilt is a vector of filters, phi is a complex, length(hfilt)-by-n matrix of phase response vectors whose columns correspond to each filter in hfilt. If n is not specified, the function uses a default value of 8192.

For adaptive filters, phi is the instantaneous phase response.

w

Frequency vector of length n, in radians/sample. w consists of n points equally spaced around the upper half of the unit circle (from 0 to π radians/sample). If hfilt is a vector of filters, w is a complex, length(hfilt)-by-n matrix of phase response vectors whose columns correspond to each filter in hfilt. If n is not specified, the function uses a default value of 8192.

polyphase

Polyphase decomposition of multirate filter

Syntax

```
p = polyphase(hm)
polyphase(hm)
p = polyphase(hs)
p = polyphase(hs,Name,Value)
polyphase(hs)
```

Description

`p = polyphase(hm)` returns the polyphase matrix `p` of the multirate filter `hm`.

`polyphase(hm)` launches the Filter Visualization Tool (FVTool) with all the polyphase subfilters to allow you to analyze each component subfilter individually.

`p = polyphase(hs)` returns the polyphase matrix `p` of the multirate filter System object `hs`.

`p = polyphase(hs,Name,Value)` returns the polyphase matrix `p` of the multirate filter System object `hs`.

`polyphase(hs)` launches the Filter Visualization Tool (FVTool) with all the polyphase subfilters to allow you to analyze each component subfilter individually.

Input Arguments

hm

Multirate `mfilt` filter object. CIC-based filters do not have coefficients, so the function does not support CIC filter structures such as `mfilt.cicdecim`.

hs

Filter System object.

The following Filter System objects are supported by this analysis function:

Filter System objects
dsp.FIRInterpolator
dsp.FIRDecimator
dsp.FIRRateConverter

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

'Arithmetic' — Value types:
'double' | 'single' | 'fixed'

For filter System object inputs only, specify the arithmetic used during analysis. When you specify 'double' or 'single', the function performs double- or single-precision analysis. When you specify 'fixed' , the arithmetic changes depending on the setting of the CoefficientDataType property and whether the System object is locked or unlocked.

Details for Fixed-Point Arithmetic

System Object State	Coefficient Data Type	Rule
Unlocked	'Same as input'	The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Unlocked	'Custom'	The function performs fixed-point analysis based

System Object State	Coefficient Data Type	Rule
		on the setting of the `CustomCoefficientsDataType` property.
Locked	`'Same as input'`	When the input data type is `'double'` or `'fixed'`, the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Locked	`'Custom'`	The function performs fixed-point analysis based on the setting of the `CustomCoefficientsDataType` property.

When you do not specify the arithmetic for non-CIC structures, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type. CIC structures only support fixed-point arithmetic.

Output Arguments

p

Polyphase matrix `p` of the multirate filter. Each row in the matrix represents one subfilter of the multirate filter. The first row of matrix `p` represents the first subfilter, the second row the second subfilter, and so on to the last subfilter.

Examples

When you create a multirate filter that uses polyphase decomposition, polyphase lets you analyze the component filters individually by returning the components as rows in a matrix.

First, create an interpolate-by-eight filter.

```
hm=mfilt.firinterp(8)

hm =

         FilterStructure: 'Direct-Form FIR Polyphase Interpolator'
               Numerator: [1x192 double]
     InterpolationFactor: 8
        PersistentMemory: false
                  States: [23x1 double]
```

In this syntax, the matrix p contains all of the subfilters for hm, one filter per matrix row.

```
p=polyphase(hm)

p =

`mfilt`

qreport

Most recent fixed-point filtering operation report

Syntax

```
rlog = qreport(h)
```

Description

`rlog = qreport(h)` returns the logging report stored in the filter object `h` in the object `rlog`. The ability to log features of the filtering operation is integrated in the fixed-point filter object and the `filter` method.

Each time you filter a signal with `h`, new log data overwrites the results in the filter from the previous filtering operation. To save the log from a filtering simulation, change the name of the output argument for the operation before subsequent filtering runs.

Note `qreport` requires Fixed-Point Designer software and that filter `h` is a fixed-point filter. Data logging for `fi` operations is a preference you set for each MATLAB session. To learn more about logging, `LoggingMode`, and `fi` object preferences, refer to `fipref` in the Fixed-Point Designer documentation.

Also, you cannot use `qreport` to log the filtering operations from a fixed-point Farrow filter.

Enable logging during filtering by setting `LoggingMode` to `on` for `fi` objects for your MATLAB session. Trigger logging by setting the `Arithmetic` property for `h` to `fixed`, making `h` a fixed-point filter and filtering an input signal.

Using Fixed-Point Filtering Logging

Filter operation logging with `qreport` requires some preparation in MATLAB. Complete these steps before you use `qreport`.

1. Set the fixed-point object preference for LoggingMode to on for your MATLAB session. This setting enables data logging.

   ```
   fipref('LoggingMode','on')
   ```
2. Create your fixed-point filter.
3. Filter a signal with the filter.
4. Use qreport to return the filtering information stored in the filter object.

qreport provides a way to instrument your fixed-point filters and the resulting data log offers insight into how the filter responds to a particular input data signal.

Report object rlog contains a filter-structure-specific list of internal signals for the filter. Each signal contains

- Minimum and maximum values that were recorded during the last simulation. Minimum and maximum values correspond to values before quantization.
- Representable numerical range of the word length and fraction length format
- Number of overflows during filtering for that signal.

Examples

qreport depends on the LoggingMode preference for fixed-point objects. This example demonstrates the process for enabling and using qreport to log the results of filtering with a fixed-point filter. hd is a fixed-point direct-form FIR filter.

```
f = fipref('loggingmode','on');
hd = design(fdesign.lowpass,'equiripple');
hd.arithmetic = 'fixed';
fs = 1000;          % Input sampling frequency.
t = 0:1/fs:1.5;     % Signal length = 1501 samples.
x = sin(2*pi*10*t); % Amplitude = 1 sinusoid.
y = filter(hd,x);
rlog = qreport(hd)
```

View the logging report of a direct-form II, second-order sections IIR filter the same way. While this example sets loggingmode to on, you do that only once for a MATLAB session, unless you reset the mode to off during the session.

```
fipref('loggingmode','on');
hd = design(fdesign.lowpass,'ellip');
```

```
hd.arithmetic = 'fixed';
y = filter(hd,rand(100,1));
rlog = qreport(hd)
```

dfilt | mfilt

realizemdl

Simulink subsystem block for filter

Syntax

```
realizemdl(hq)
realizemdl(hq,Name,Value)
```

Description

`realizemdl(hq)` generates a model of filter `hq` in a Simulink subsystem block using sum, gain, and delay blocks from Simulink. The properties and values of `hq` define the resulting subsystem block parameters.

`realizemdl` requires Simulink. To accurately realize models of quantized filters, use Fixed-Point Designer.

`realizemdl(hq,Name,Value)` generates the model for `hq` with additional options specified by one or more Name,Value pair arguments. Using name-value pair arguments lets you control more fully the way the block subsystem model gets built. You can specify such details as where the block goes, what the name is, or how to optimize the block structure.

Note Subsystem filter blocks that you use `realizemdl` to create support sample-based input and output only. You cannot input or output frame-based signals with the block.

Input Arguments

hq

One of the following types of filter object or filter System object:

- Discrete-time filter (`dfilt`) object

- Multirate filter (`mfilt`) object.
- Filter System object.

  The following Filter System objects are supported by this analysis function:

Filter System objects
`dsp.FIRFilter`
`dsp.FIRInterpolator`
`dsp.FIRDecimator`
`dsp.FIRRateConverter`
`dsp.BiquadFilter`
`dsp.IIRFilter`
`dsp.AllpoleFilter`
`dsp.AllpassFilter`
`dsp.CoupledAllpassFilter`

Name-Value Pair Arguments

`'Destination'` — Destination choices:

`'current'` (default) | `'new'` | `subsystemname`

Specify whether to add the block to your current Simulink model or create a new model to contain the block. If you provide the name of a current subsystem in *`subsystemname`*, `realizemdl` adds the new block to the specified subsystem.

`'Blockname'` — The name of the block (not the default) :

`'filter'` (default)

Provide the name for the new subsystem block. By default the block is named Filter.

`'MapCoeffstoPorts'` — Value options:

`'off'` (default) | `'on'`

Specify whether to map the coefficients of the filter to the ports of the block.

`'MapStates'` — Value options:

`'off'` (default) | `'on'`

Specify whether to apply the current filter states to the realized model. Such specification allows you to save states from a filter object you may have used or configured in a specific way. The default setting of `'off'` means the states are not transferred to the model. Setting the property to `'on'` preserves the current filter states in the realized model.

`'OverwriteBlock'` — Value options:
`'off'` (default) | `'on'`

Specify whether to overwrite an existing block with the same name or create a new block.

`'OptimizeZeros'` — Value options:
`'off'` (default) | `'on'`

Specify whether to remove zero-gain blocks.

`'OptimizeOnes'` — Value options:
`'off'` (default) | `'on'`

Specify whether to replace unity-gain blocks with direct connections.

`'OptimizeNegOnes'` — Value options:
`'off'` (default) | `'on'`

Specify whether to replace negative unity-gain blocks with a sign change at the nearest sum block.

`'OptimizeDelayChains'` — Value options:
`'off'` (default) | `'on'`

Specify whether to replace delay chains made up of *n* unit delays with a single delay by *n*.

`'CoeffNames'` — Names of coefficients:
`{'Num'}` (default FIR) | `{'Num','Den'}` (default direct form IIR) | `{'Num','Den','g'}` (default IIR SOS) | `{'Num_1,'Num_2,'Num_3'...}` (default multistage) | `{'K'}` (default form lattice)

Specify the coefficient variable names as string variables in a cell array. `MapCoeffsToPorts` must be set to `'on'` for this property to apply.

`'InputProcessing'` — Possible input processing options:
`'columns as channels'` (default) | `'elements as channels'` | `'inherited'`

Specify sample-based ('elements as channels') or frame-based ('columns as channels') processing.

Note: The 'inherited' option will be removed in a future release.

'RateOption' — Rate options:
'enforce single rate' (default) | 'allow multirate'

Specify how the block adjusts the rate at the output to accommodate the reduced number of samples. This parameter applies only when InputProcessing is 'columns as channels'.

'Arithmetic' — Value types:
'double' | 'single' | 'fixed'

For filter System object inputs only, specify the arithmetic used during analysis. When you specify 'double' or 'single', the function performs double- or single-precision analysis. When you specify 'fixed' , the arithmetic changes depending on the setting of the CoefficientDataType property and whether the System object is locked or unlocked.

Details for Fixed-Point Arithmetic

System Object State	Coefficient Data Type	Rule
Unlocked	'Same as input'	The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Unlocked	'Custom'	The function performs fixed-point analysis based on the setting of the CustomCoefficientsDataType property.

System Object State	Coefficient Data Type	Rule
Locked	`'Same as input'`	When the input data type is `'double'` or `'fixed'`, the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Locked	`'Custom'`	The function performs fixed-point analysis based on the setting of the `CustomCoefficientsDataType` property.

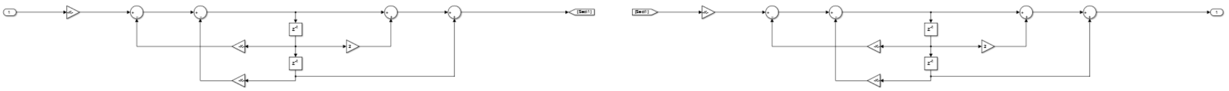
When you do not specify the arithmetic for non-CIC structures, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type. CIC structures only support fixed-point arithmetic.

Examples

Realize Simulink model of lowpass Butterworth filter:

```
d = fdesign.lowpass('N,F3dB',4,0.25);
Hd = design(d,'butter');
realizemdl(Hd);
```

The realized model is shown in the figure:



Realize Simulink model with coefficients mapped to ports:

```
d = fdesign.lowpass('N,F3dB',4,0.25);
Hd = design(d,'butter');
%Realize Simulink model and export coefficients
```

```
realizemdl(Hd,'MapCoeffsToPorts','on');
```

In this case, the filter is an IIR filter with a direct form II second-order sections structure. Setting MapCoeffstoPorts to 'on' exports the numerator coefficients, the denominator coefficients, and the gains to the MATLAB workspace using the default variable names Num, Den, and g. Each column of Num and Den represents one second-order section. You can modify the filter coefficients directly in the MATLAB workspace providing tunability to the realized Simulink model.

design | fdesign

rebuffer_delay

Number of samples of delay introduced by buffering and unbuffering operations

Syntax

```
d = rebuffer_delay(f,n,v)
d = rebuffer_delay(f,n,v,'mode')
```

Description

`d = rebuffer_delay(f,n,v)` returns the delay, in samples, introduced by the Buffer or Unbuffer block in multitasking operations.

`d = rebuffer_delay(f,n,v,'mode')` returns the delay, in samples, introduced by the Buffer or Unbuffer block in the specified tasking mode.

Input Arguments

`f`

Frame size of the input to the Buffer or Unbuffer block.

`n`

Size of the output buffer. Specify one of the following:

- The value of the **Output buffer size** parameter, if you are computing the delay introduced by a Buffer block.
- `1`, if you are computing the delay introduced by an Unbuffer block.

`v`

Amount of buffer overlap. Specify one of the following:

- The value of the **Buffer overlap** parameter, if you are computing the delay introduced by a Buffer block.

- `0`, if you are computing the delay introduced by an Unbuffer block.

`'mode'`

The tasking mode of the model. Specify one of the following options:

- `'singletasking'`
- `'multitasking'`

Default: `'multitasking'`

Examples

Compute the delay introduced by a Buffer block in a multitasking model:

1. Open a model containing a Buffer block. For this example, open the `ex_buffer_tut4` model by typing ex_buffer_tut4 at the MATLAB command line.
2. Double-click the Buffer block to open the block mask. Verify that you have the following settings:

   - **Output buffer size** = 3
   - **Buffer overlap** = 1
   - **Initial conditions** = 0

   Based on these settings, two of the required inputs to the `rebuffer_delay` function are as follows:

   - `n = 3`
   - `v = 1`
3. To determine the frame size of the input signal to the Buffer block, open the Signal From Workspace block mask. Verify that you have the following settings:

   - **Signal** = `sp_examples_src`
   - **Sample time** = `1`
   - **Samples per frame** = `4`

   Because **Samples per frame** = `4`, you know the `f` input to the `rebuffer_delay` function is `4`.

4 After you verify the values of all the inputs to the `rebuffer_delay` function, determine the delay that the Buffer block introduces in this multitasking model. To do so, type the following at the MATLAB command line:

```
d = rebuffer_delay(4,3,1)

d =
     8
```

Compute the delay introduced by an Unbuffer block in a multitasking model:

1 Open a model containing an Unbuffer block. For this example, open the `ex_unbuffer_ref1` model by typing ex_unbuffer_ref1 at the MATLAB command line.
2 To determine the frame size of the input to the Buffer block, open the Signal From Workspace block mask by double-clicking the block in your model. Verify that you have the following settings:

   - **Signal** = `sp_examples_src`
   - **Sample time** = `1`
   - **Samples per frame** = `3`

   Because **Samples per frame** = `3`, you know the `f` input to the `rebuffer_delay` function is `3`.
3 Use the `rebuffer_delay` function to determine the amount of delay that the Unbuffer block introduces in this multitasking model. To compute the delay introduced by the Unbuffer block, use `f = 3`, `n = 1` and `v = 0`.

```
d = rebuffer_delay(3,1,0)

d =
     3
```

More About

Multitasking

When you run a model in `MultiTasking` mode, Simulink processes groups of blocks with the same execution priority through each stage of simulation based on task priority. Multitasking mode helps to create valid models of real-world multitasking systems, where sections of your model represent concurrent tasks. The **Tasking mode for periodic sample times** parameter on the “Solver” pane of the Configuration Parameters dialog box controls this setting.

Singletasking

When you run a model in `SingleTasking` mode, Simulink processes all blocks through each stage of simulation together. The **Tasking mode for periodic sample times** parameter on the “Solver” pane of the Configuration Parameters dialog box controls this setting.

Buffer | Unbuffer

reffilter

Reference filter for fixed-point or single-precision filter

Syntax

```
href = reffilter(hd)
```

Description

`href = reffilter(hd)` returns a new filter `href` that has the same structure as `hd`, but uses the reference coefficients and has its arithmetic property set to `double`. Note that `hd` can be either a fixed-point filter (arithmetic property set to '`fixed`', or a single-precision floating-point filter whose arithmetic property is '`single`').

`reffilter(hd)` differs from `double(hd)` in that

- the filter `href` returned by `reffilter` has the reference coefficients of `hd`.
- `double(hd)` returns the quantized coefficients of `hd` represented in double-precision.

To check the performance of your fixed-point filter, use `href = reffilter(hd)` to quickly have the floating-point, double-precision version of `hd` available for comparison.

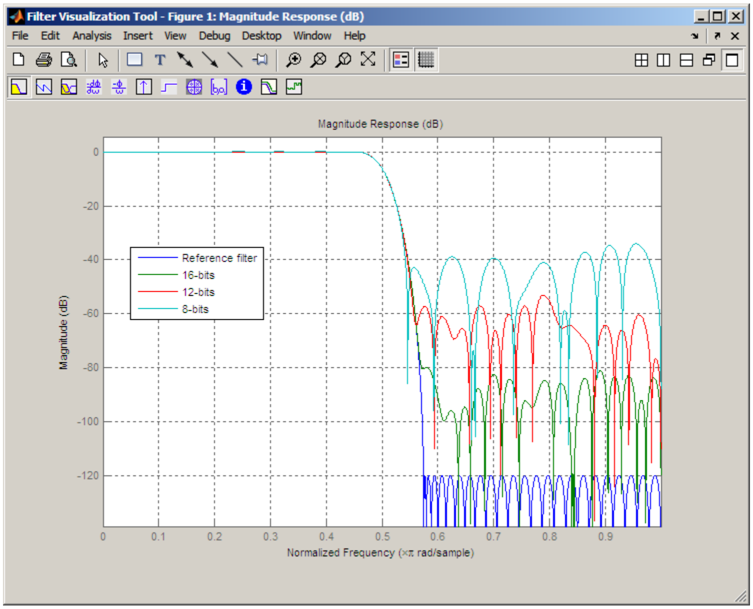
Examples

Compare several fixed-point quantizations of a filter with the same double-precision floating-point version of the filter.

```
h = dfilt.dffir(firceqrip(87,.5,[1e-3,1e-6])); % Lowpass filter.
h1 = copy(h); h2 = copy(h); % Create copies of h.
h.arithmetic = 'fixed';   % Set h to filter using fixed-point...
                          % arithmetic.
h1.arithmetic = 'fixed';  % Same for h1.
h2.arithmetic = 'fixed';  % Same for h2.
h.CoeffWordLength  = 16;  % Use 16 bits to represent the...
                          % coefficients.
h1.CoeffWordLength = 12;  % Use 12 bits to represent the...
                          % coefficients.
h2.CoeffWordLength =  8;  % Use 8 bits to represent the...
```

```
                                 % coefficients.
href = reffilter(h);
hfvt = fvtool(href,h,h1,h2);
set(hfvt,'ShowReference','off'); % Reference displayed once
                                 % already.
legend(hfvt,'Reference filter','16-bits','12-bits','8-bits');
```

The following plot, taken from FVTool, shows `href`, the reference filter, and the effects of using three different word lengths to represent the coefficients.



Filter Visualization Tool - Figure 1: Magnitude Response (dB)
File Edit Analysis Insert View Debug Desktop Window Help
Magnitude Response (dB)

Normalized Frequency (×π rad/sample)
Reference filter
16-bits
12-bits
8-bits

As expected, the fidelity of the fixed-point filters suffers as you change the representation of the coefficients. With `href` available, it is easy to see just how the fixed-point filter compares to the ideal.

`double`

reorder

Rearrange sections in SOS filter

Syntax

```
reorder(hd,order)
reorder(hd,numorder,denorder)
reorder(hd,numorder,denorder,svorder)
reorder(hd,filter_type)
reorder(hd,dir_flag)
reorder(hd,dir_flag,sv)
reorder(hs,...)
reorder(hs,...,Name,Value)
```

Description

`reorder(hd,order)` rearranges the sections of filter `hd` using the vector of indices provided in `order`.

`reorder(hd,numorder,denorder)` reorders the numerator and denominator separately using the vectors of indices in `numorder` and `denorder`.

`reorder(hd,numorder,denorder,svorder)` specifies that the scale values can be independently reordered.

`reorder(hd,filter_type)` reorders `hd` in a way suitable for the specified filter type. This reordering mode can be especially helpful for fixed-point implementations where the order of the filter sections can significantly affect your filter performance.

`reorder(hd,dir_flag)` specifies rearranges the sections according to proximity to the origin of the poles of the sections.

`reorder(hd,dir_flag,sv)` reorders scale values in addition to rearranging sections according to pole-origin proximity.

`reorder(hs,...)` rearranges the sections of the filter System object `hs` according to any of the preceding input arguments.

`reorder(hs,...,Name,Value)` rearranges the sections of the filter System object `hs` with additional options specified by one or more Name,Value pair arguments.

Input Arguments

`hd`

Discrete-time `dfilt.df1sos`, `dfilt.df2tsos`, `dfilt.df2sos`, or `dfilt.df1tsos`filter object.

`hs`

`dsp.BiquadFilter` filter System object.

`order`

Vector of indices used to reorder the filter sections. `order` does not need to contain all of the indices of the filter. Omitting one or more filter section indices removes the omitted sections from the filter. You can use a logical array to remove sections from the filter, but not to reorder it.

`numorder`

Vector of indices used to reorder the numerator. `numorder` and `denorder` must be the same length.

`denorder`

Vector of indices used to reorder the numerator. `numorder` and `denorder` must be the same length.

`svorder`

Independent reordering of scale values. When `svorder` is not specified, the scale values are reordered with the numerator. The output scale value always remains on the end when you use the argument `numorder` to reorder the scale values.

`filter_type` — Different types of filters:

`'auto'` | `'bandpass'` | `'bandstop'` | `'highpass'` | `'lowpass'`

Filter type. The `'auto'` option and automatic ordering only apply to filters that you used `fdesign` to create. With the `'auto'` option as an input argument, `reorder` automatically rearranges the filter sections depending on the specification response type of the design.

`dir_flag` — Direction options:
`'down'` | `'up'`

Pole direction flag. When `dir_flag` is `'up'`, the first filter section contains the poles closest to the origin, and the last section contains the poles closest to the unit circle. When `ir_flag` is `'down'`, the sections are ordered in the opposite direction. `reorder` always pairs zeros with the poles closest to them.

`sv` — Scale value options:
`'poles'` | `'zeros'`

Reorder scale values according to poles or zeros. By default the scale values are not reordered when you use the dir_flag input argument.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'Arithmetic'` — Value types:
`‘double’` | `'single'` | `'fixed'`

For filter System object inputs only, specify the arithmetic used during analysis. When you specify `'double'` or `'single'`, the function performs double- or single-precision analysis. When you specify `'fixed'` , the arithmetic changes depending on the setting of the `CoefficientDataType` property and whether the System object is locked or unlocked.

Details for Fixed-Point Arithmetic

System Object State	Coefficient Data Type	Rule
Unlocked	`'Same as input'`	The function assumes that the coefficient data type is signed, 16 bit, and

System Object State	Coefficient Data Type	Rule
		autoscaled. The function performs fixed-point analysis based on this assumption.
Unlocked	`'Custom'`	The function performs fixed-point analysis based on the setting of the `CustomCoefficientsDataType` property.
Locked	`'Same as input'`	When the input data type is `'double'` or `'fixed'`, the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Locked	`'Custom'`	The function performs fixed-point analysis based on the setting of the `CustomCoefficientsDataType` property.

When you do not specify the arithmetic, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type.

Examples

Being able to rearrange the order of the sections in a filter can be a powerful tool for controlling the filter process. This example uses `reorder` to change the sections of a `df2sos` filter. Let `reorder` do the reordering automatically in the first example. In the second, use `reorder` to specify the new order for the sections.

First use the automatic reordering option on a lowpass filter.

```
d = fdesign.lowpass('n,f3db',15,0.75);
hd = design(d,'butter');
```

```
hdreorder=reorder(hd,'auto');
```

For another example of using reorder, create an SOS filter in the direct form II implementation.

```
[z,p,k] = butter(15,.5);
[sos, g] = zp2sos(z,p,k);
hd = dfilt.df2sos(sos,g);
reorder(hd, [1 3:7 2 8]);
hfvt = fvtool(hd, 'analysis', 'coefficients');
```

Reorder the sections by moving the second section to be between the seventh and eighth sections.

```
    reorder(hd, [1 3:7 2 8]);
    hfvt = fvtool(hd, 'analysis', 'coefficients');
```

Remove the third, fourth, and seventh sections.

```
    hd1 = copy(hd);
    reorder(hd1, logical([1 1 0 0 1 1 0 1]));
    setfilter(hfvt, hd1);
```

Move the first filter to the end, and remove the eighth section

```
        hd2 = copy(hd);
    reorder(hd2, [2:7 1]);
    setfilter(hfvt, hd2);
```

Move the numerator and denominator independently.

```
    hd3 = copy(hd);
    reorder(hd3, [1 3:8 2], [1:8]);
    setfilter(hfvt, hd3);
```

`cumsec` | `scale` | `scaleopts`

reset

Reset filter properties to initial conditions

Syntax

```
reset(ha)
reset(hd)
reset(hm)
```

Description

`reset(ha)` resets all the properties of the adaptive filter `ha` that are updated when filtering to the value specified at construction. If you do not specify a value for any particular property when you construct an adaptive filter, the property value for that property is reset to the default value for the property.

`reset(hd)` resets all the properties of the discrete-time filter `hd` to their factory values that are modified when you run the filter. In particular, the `States` property is reset to zero.

`reset(hm)` resets all the properties of the multirate filter `hm` to their factory value that are modified when the filter is run. In particular, the `States` property is reset to zero when `hm` is a decimator. Additionally, the filter internal properties are also reset to their factory values.

Examples

Denoise a sinusoid and reset the filter after filtering with it.

```
h = adaptfilt.lms(5,.05,1,[0.5,0.5,0.5,0.5,0.5]);
n = filter(1,[1 1/2 1/3],.2*randn(1,2000));
d = sin((0:1999)*2*pi*0.005) + n; % Noisy sinusoid
x = n;
[y,e]= filter(h,x,d);             % e has denoised signal
disp(h)
reset(h); % Reset the coefficients and states.
```

```
disp(h)
```

See Also

`set`

scale

Scale sections of SOS filter

Syntax

```
scale(hd)
scale(hd,pnorm)
scale(hd,pnorm,Name,Value)
scale(hd,pnorm,opts)
scale(hs)
```

Description

`scale(hd)` scales the second-order section filter `hd` using peak magnitude response scaling (L-infinity, `'Linf'`). This scaling reduces the possibility of overflows when your filter `hd` operates in fixed-point arithmetic mode.

`scale(hd,pnorm)` specifies the norm used to scale the filter.

`scale(hd,pnorm,Name,Value)` scales the SOS filter with additional options specified by one or more Name,Value pair arguments.

`scale(hd,pnorm,opts)` uses an input scale options object `opts` to specify the optional scaling parameters instead of specifying parameter-value pairs.

`scale(hs)` scales the filter System object `hs`. You can also use pnorm, name-value pair arguments, or scale option objects with this syntax.

Input Arguments

hd

Discrete-time `dfilt` filter object.

With the `Arithmetic` property of `hd` set to `double` or `single`, the filter uses the default values for all options that you do not specify explicitly. When you set `Arithmetic` to fixed, the values used for the scaling options are set according to the settings in filter hd. However, if you specify a scaling option different from the settings in hd, the filter uses your explicit option selection for scaling purposes, but does not change the property setting in hd.

hs

dsp.BiquadFilter filter System object.

pnorm

Discrete-time-domain norm or a frequency-domain norm.

Valid time-domain norm values for pnorm are 'l1', 'l2', and 'linf'. Valid frequency-domain norm values are 'L1', 'L2', and 'Linf' . The 'L2' norm is equal to the 'l2' norm (by Parseval's theorem), but this equivalency does not hold for other norms — 'l1' is not the same as 'L1' and 'Linf' is not the same as 'linf'.

Filter norms can be ordered in terms of how stringent they are, as follows from most stringent to least: 'l1', 'Linf', 'l2' ('L2'), 'linf'. Using 'l1', the most stringent scaling, produces a filter that is least likely to overflow, but has the worst signal-to-noise ratio performance. The default scaling 'Linf' (default) is the most commonly used scaling norm.

opts

Scale options object. You can create the opts object using the scaleopts function.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

'Arithmetic'

For filter System object inputs only, specify the arithmetic used during analysis. When you specify 'double' or 'single', the function performs double- or single-precision analysis. When you specify 'fixed' , the arithmetic changes depending on the setting of the CoefficientDataType property and whether the System object is locked or unlocked.

Details for Fixed-Point Arithmetic

System Object State	Coefficient Data Type	Rule
Unlocked	'Same as input'	The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Unlocked	'Custom'	The function performs fixed-point analysis based on the setting of the CustomCoefficientsDataType property.
Locked	'Same as input'	When the input data type is 'double' or 'fixed', the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Locked	'Custom'	The function performs fixed-point analysis based on the setting of the CustomCoefficientsDataType property.

When you do not specify the arithmetic, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type.

'MaxNumerator'

Maximum allowed value for numerator coefficients.

Default: 2

'MaxScaleValue'

Maximum allowed scale values. The filter applies the `MaxScaleValue` limit only when you set `ScaleValueConstraint` to a value other than `unit` (the default setting). Setting `MaxScaleValue` to any numerical value automatically changes the `ScaleValueConstraint` setting to `none`.

Default: `'Not Used'`

'NumeratorConstraint'

Specifies whether and how to constrain numerator coefficient values. Possible options:

- `‘none’` (default)
- `‘normalized’`
- `‘po2’`
- `‘unit’`

'OverflowMode'

Sets the way the filter handles arithmetic overflow situations during scaling. If your device does not have guard bits available, and you are using saturation arithmetic for filtering, use `'satall'` instead of `'saturate'`. The default is `‘wrap’`.

'ScaleValueConstraint'

Specify whether to constrain the filter scale values, and how to constrain them. Choosing `'unit'` for the constraint disables the `MaxScaleValue` property setting. `'po2'` constrains the scale values to be powers of 2, while `'none'` removes any constraint on the scale values. `‘unit’` is the default value.

'sosReorder'

Reorder filter sections prior to applying scaling. Possible options:

- `‘auto’` (default)
- `‘none’`
- `‘up’`

- ‘down’
- ‘lowpass’
- ‘highpass’
- ‘bandpass’
- ‘bandstop’

Examples

Demonstrate the Linf-norm scaling of a lowpass elliptic filter with second-order sections. Start by creating a lowpass elliptical filter in zero, pole, gain (z,p,k) form.

```
[z,p,k] = ellip(5,1,50,.3);
[sos,g] = zp2sos(z,p,k);
hd = dfilt.df2sos(sos,g);
scale(hd,'linf','scalevalueconstraint','none','maxscalevalue',2)
```

cumsec | norm | reorder | scalecheck | scaleopts

scalecheck

Check scaling of SOS filter

Syntax

```
s = scalecheck(hd,pnorm)
s = scalecheck(hs,pnorm)
s = scalecheck(hs,pnorm,Name,Value)
```

Description

`s = scalecheck(hd,pnorm)` checks the scaling second-order section (SOS) `dfilt` filter object `hd`.

`s = scalecheck(hs,pnorm)` checks the scaling of the filter System object `hs`.

`s = scalecheck(hs,pnorm,Name,Value)` checks the scaling of the filter System object `hs` with additional options specified by one or more Name,Value pair arguments.

Input Arguments

hd

Discrete-time `dfilt.df1sos`, `dfilt.df2tsos`, `dfilt.df2sos`, or `dfilt.df1tsos`filter object.

hs

`dsp.BiquadFilter` filter System object.

pnorm — Different types of norm:

`'l1' | 'l2' | 'linf' | 'L1' | 'L2' | 'Linf'`

Discrete-time-domain norm or a frequency-domain norm.

Valid time-domain norm values for `pnorm` are `'l1'`, `'l2'`, and `'linf'`. Valid frequency-domain norm values are `'L1'`, `'L2'`, and `'Linf'`. The `'L2'` norm is equal to the `'l2'` norm (by Parseval's theorem), but this equivalency does not hold for other norms — `'l1'` is not the same as `'L1'` and `'Linf'` is not the same as `'linf'`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'Arithmetic'` — Value type:
`‘double’ | 'single' | 'fixed'`

For filter System object inputs only, specify the arithmetic used during analysis. When you specify `'double'` or `'single'`, the function performs double- or single-precision analysis. When you specify `'fixed'` , the arithmetic changes depending on the setting of the `CoefficientDataType` property and whether the System object is locked or unlocked.

Details for Fixed-Point Arithmetic

System Object State	Coefficient Data Type	Rule
Unlocked	`'Same as input'`	The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Unlocked	`'Custom'`	The function performs fixed-point analysis based on the setting of the `CustomCoefficientsDataType` property.
Locked	`'Same as input'`	When the input data type is `'double'` or `'fixed'`, the function assumes that the coefficient data

System Object State	Coefficient Data Type	Rule
		type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Locked	`'Custom'`	The function performs fixed-point analysis based on the setting of the `CustomCoefficientsDataType` property.

When you do not specify the arithmetic, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type.

Output Arguments

`s`

Filter scaling for a given p-norm. An optimally scaled filter has partial norms equal to one. In such cases, `s` contains all ones.

For direct-form I (`dfilt.df1sos`) and direct-form II transposed (`dfilt.df2tsos`) filters, the function returns the p-norm of the filter computed from the filter input to the output of each second-order section. Therefore, the number of elements in `s` is one less than the number of sections in the filter. This p-norm computation does not include the trailing scale value of the filter, which you can find by entering `hd.scalevalue(end)` at the MATLAB prompt.

For direct-form II (`dfilt.df2sos`) and direct-form I transposed (`dfilt.df1tsos`) filters, the function returns a row vector whose elements contain the p-norm from the filter input to the input of the recursive part of each second-order section. This computation of the p-norm corresponds to the input to the multipliers in these filter structures. These inputs correspond to the locations in the signal flow where overflow should be avoided.

When `hd` has nontrivial scale values, that is, if any scale values are not equal to one, `s` is a two-row matrix, rather than a vector. The first row elements of `s` report the p-norm of the filter computed from the filter input to the output of each second-order section. The elements of the second row of `s` contain the p-norm computed from the input of the filter to the input of each scale value between the sections. For `df2sos` and `df1tsos` filter structures, the last numerator and the trailing scale value for the filter are not included when `scalecheck` checks the scaling.

Examples

Check the Linf-norm scaling of a filter.

```
% Create filter design specifications
hs = fdesign.lowpass;
object.
hd = ellip(hs);       % Design an elliptic sos filter
scale(hd,'Linf');
s = scalecheck(hd,'Linf')
```

In another form:

```
[b,a]=ellip(10,.5,20,0.5);
[s,g]=tf2sos(b,a);
hd=dfilt.df1sos(s,g)

hd =

         FilterStructure: 'Direct-Form I, Second-Order Sections'
              Arithmetic: 'double'
               sosMatrix: [5x6 double]
             ScaleValues: [6x1 double]
        PersistentMemory: false
                  States: [1x1 filtstates.dfiir]

1x1 struct array with no fields.

scalecheck(hd,'Linf')

ans =

    0.7631    0.9627    0.9952    0.9994    1.0000
```

See Also

`norm` | `reorder` | `scale` | `scaleopts`

scaleopts

Options for scaling SOS filter

Syntax

```
opts = scaleopts(hd)
opts = scaleopts(hs)
opts = scaleopts(hs,Name,Value)
```

Description

`opts = scaleopts(hd)` uses the current settings in the `dfilt` filter `hd` to create an options object `opts` that contains specified scaling options for second-order section scaling. You can pass `opts` as an input to `scale` to apply scaling settings to a second-order filter.

`opts = scaleopts(hs)` creates an options object based on the current settings of the filter System object `hs`.

`opts = scaleopts(hs,Name,Value)` creates an options object with additional options specified by one or more Name,Value pair arguments.

Input Arguments

hd

Discrete-time `dfilt.df1sos`, `dfilt.df2tsos`, `dfilt.df2sos`, or `dfilt.df1tsos`filter object.

hs

`dsp.BiquadFilter` filter System object.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'Arithmetic'` — Value types:
`‘double’ | 'single' | 'fixed'`

For filter System object inputs only, specify the arithmetic used during analysis. When you specify `'double'` or `'single'`, the function performs double- or single-precision analysis. When you specify `'fixed'` , the arithmetic changes depending on the setting of the `CoefficientDataType` property and whether the System object is locked or unlocked.

Details for Fixed-Point Arithmetic

System Object State	Coefficient Data Type	Rule
Unlocked	`'Same as input'`	The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Unlocked	`'Custom'`	The function performs fixed-point analysis based on the setting of the `CustomCoefficientsDataType` property.
Locked	`'Same as input'`	When the input data type is `'double'` or `'fixed'`, the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Locked	`'Custom'`	The function performs fixed-point analysis based on the setting of the

System Object State	Coefficient Data Type	Rule
		`CustomCoefficientsDataType` property.

When you do not specify the arithmetic, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type.

Output Arguments

`opts`

Scaling object. The following table lists the properties of `opts`.

Parameter	Default	Description and Valid Value
`MaxNumerator`	`2`	Maximum allowed value for numerator coefficients.
`MaxScaleValue`	No default value	Maximum allowed scale values. The filter applies the `MaxScaleValue` limit only when you set `ScaleValueConstraint` to a value other than `unit`. Setting `MaxScaleValue` to a numerical value automatically changes the `ScaleValueConstraint` setting to `none`.
`NumeratorConstraint`	`none`	Specifies whether and how to constrain numerator coefficient values. Options are `none`, `normalize`, `po2`, and `unit`.
`OverflowMode`	`wrap`	Sets the way the filter handles arithmetic overflow situations during scaling. Choose one of`wrap` or `saturate` or `satall`.
`ScaleValueConstraint`	`unit`	Specify whether to constrain the filter scale values, and how to

Parameter	Default	Description and Valid Value
		constrain them. Valid options are `none`, `po2`, and `unit`.

Examples

From a filter `hd`, you can create an options scaling object that contains the scaling options settings you require.

```
[b,a]=ellip(10,.5,20,0.5);
[s,g]=tf2sos(b,a);
hd=dfilt.df1sos(s,g)
opts=scaleopts(hd)

opts =

            MaxNumerator: 2
     NumeratorConstraint: 'none'
            OverflowMode: 'wrap'
    ScaleValueConstraint: 'unit'
           MaxScaleValue: 'Not used'
```

set2int

Configure filter for integer filtering

Syntax

```
set2int(h)
set2int(h,coeffwl)
set2int(...,inwl)
g = set2int(...)
```

Description

These sections apply to both discrete-time (`dfilt`) and multirate (`mfilt`) filters.

`set2int(h)` scales the filter coefficients to integer values and sets the filter coefficient and input fraction lengths to zero.

`set2int(h,coeffwl)` uses the number of bits specified by `coeffwl` as the word length it uses to represent the filter coefficients.

`set2int(...,inwl)` uses the number of bits specified by `coeffwl` as the word length it uses to represent the filter coefficients and the number of bits specified by `inwl` as the word length to represent the input data.

`g = set2int(...)` returns the gain `g` introduced into the filter by scaling the filter coefficients to integers. `g` is always calculated to be a power of 2.

Note `set2int` does not work with CIC decimators or interpolators because they do not have coefficients.

Examples

These examples demonstrate some uses and ideas behind `set2int`.

The second parts of both examples depend on the following — after you filter a set of data, the input data and output data cover the same range of values, unless the filter process introduces gain in the output. Converting your filter object to integer form, and then filtering a set of data, does introduce gain into the system. When the examples refer to resetting the output to the same range as the input, the examples are accounting for this added gain feature.

Discrete-Time Filter Example

Two parts comprise this example. Part 1 compares the step response of an FIR filter in both the fractional and integer filter modes. Fractional mode filtering is essentially the opposite of integer mode. Integer mode uses a filter which has coefficients represented by integers. Fractional mode filters have coefficients represented in fractional form (nonzero fraction length).

```
b = rcosdesign(.25,4,25,'sqrt');
hd = dfilt.dffir(b);
hd.Arithmetic = 'fixed';
hd.InputFracLength = 0; % Integer inputs.
x = ones(100,1);
yfrac = filter(hd,x); % Fractional mode output.
g = set2int(hd);      % Convert to integer coefficients.
yint = filter(hd,x);  % Integer mode output.
```

Note that `yint` and `yfrac` are `fi` objects. Later in this example, you use the `fi` object properties `WordLength` and `FractionLength` to work with the output data.

Now use the gain `g` to rescale the output from the integer mode filter operation. Verify that the scaled integer output is equal to the fractional output.

```
yints = double(yint)/g;
MaxDiff=max(abs(yints-double(yfrac)));
```

Verify that the scaled integer output is equal to the fractional output.

```
 max(abs(yints-double(yfrac)))
```

In part two, the example reinterprets the output binary data, putting the input and the output on the same scale by weighting the most significant bits in the input and output data equally.

```
WL = yint.WordLength;
FL = yint.Fractionlength + log2(g);
```

```
yints2 = fi(zeros(size(yint)),true,WL,FL);
yints2.bin = yint.bin;
MaxDiff=max(abs(double(yints2)-double(yfrac)));
```

Multirate Filter Example

This two-part example starts by comparing the step response of a multirate filter in both fractional and integer modes. Fractional mode filtering is essentially the opposite of integer mode. Integer mode uses a filter which has coefficients represented by integers. Fractional mode filters have coefficients in fractional form with nonzero fraction lengths.

```
hm = mfilt.firinterp;
hm.Arithmetic = 'fixed';
hm.InputFracLength = 0; % Integer inputs.
x = ones(100,1);
yfrac = filter(hm,x);  % Fractional mode output.
g = set2int(hm);       %Convert to integer coefficients.
yint = filter(hm,x);   % Integer mode output.
```

Note that `yint` and `yfrac` are `fi` objects. In part 2 of this example, you use the `fi` object properties `WordLength` and `FractionLength` to work with the output data.

Now use the gain `g` to rescale the output from the integer mode filter operation.

```
yints = double(yint)/g;
```

Verify that the scaled integer output is equal to the fractional output.

```
max(abs(yints-double(yfrac)))
```

Part 2 demonstrates reinterpreting the output binary data by using the properties of `yint` to create a scaled version of `yint` named `yints2`. This process puts `yint` and `yints2` on the same scale by weighing the most significant bits of each object equally.

```
wl = yint.wordlength;
fl = yint.fractionlength + log2(g);
yints2 = fi(zeros(size(yint)),true,wl,fl);
yints2.bin = yint.bin;
max(abs(double(yints2)-double(yfrac)))
```

`mfilt`

setspecs

Specifications for filter specification object

Syntax

```
setspecs(D,specvalue1,specvalue2,...)
setspecs(D,Specification,specvalue1,specvalue2,...)
setspecs(...Fs)
setspecs(...,MAGUNITS)
```

Description

`setspecs(D,specvalue1,specvalue2,...)` sets the specifications in filter specification object, D, in the same order they appear in the `Specification` property.

`setspecs(D,Specification,specvalue1,specvalue2,...)` changes the specifications for an existing filter specification object and sets values for the new `Specification` property.

`setspecs(...Fs)` specifies the sampling frequency, `Fs`, in Hz. The sampling frequency must be a scalar trailing all other specifications. Entering a sampling frequency causes all other frequency specifications to be in Hz.

`setspecs(...,MAGUNITS)` specifies the units for any magnitude specifications. MAGUNITS can be one of the following: `'linear'`, `'dB'`, or `'squared'`. The default is `'dB'`. The magnitude specifications are always converted and stored in dB regardless of how the units are specified.

Use `SET(D,'SPECIFICATION')` to get the list of all available specification types for the filter specification object, D.

Examples

Construct a lowpass filter with specifications for the filter order and cutoff frequency (-6 dB). Use `setspecs` after construction to set the values of the filter order and cutoff frequency. Display the values in the MATLAB command window.

```
D = fdesign.lowpass('N,Fc');
setspecs(D,10,0.2);
D.FilterOrder
D.Fcutoff
```

Construct a highpass filter with specifications for the numerator order, denominator order, and 3-dB frequency. Assume the sampling frequency is 1 kHz. Use `setspecs` to set the numerator and denominator orders to 6. Set the 3-dB frequency to 250 Hz. In order to use frequency specifications in Hz, specify the sampling frequency as a trailing scalar.

```
D = fdesign.highpass('Nb,Na,F3dB');
setspecs(D,6,6,250,1000);
```

sos

Convert quantized filter to second–order sections (SOS) form

Syntax

```
Hq2 = sos(Hq)
Hq2 = sos(Hq, order)
Hq2 = sos(Hq, order, scale)
```

Description

`Hq2 = sos(Hq)` returns a quantized filter `Hq2` that has second-order sections and the `dft2` structure. Use the same optional arguments used in `tf2sos`.

`Hq2 = sos(Hq, order)` specifies the order of the sections in `Hq2`, where `order` is either of the following strings:

- `'down'` — to order the sections so the first section of `Hq2` contains the poles closest to the unit circle (L_∞ norm scaling)
- `'up'` — to order the sections so the first section of `Hq2` contains the poles farthest from the unit circle (L_2 norm scaling and the default)

`Hq2 = sos(Hq, order, scale)` also specifies the desired scaling of the gain and numerator coefficients of all second-order sections, where `scale` is one of the following strings:

- `'none'` — to apply no scaling (default)
- `'inf'` — to apply infinity-norm scaling
- `'two'` — to apply 2-norm scaling

`Hq2` is a `dsp.BiquadFilter` filter System object.

Use infinity-norm scaling in conjunction with up-ordering to minimize the probability of overflow in the filter realization. Consider using 2-norm scaling in conjunction with down-ordering to minimize the peak round-off noise.

When Hq is a fixed-point filter, the filter coefficients are normalized so that the magnitude of the maximum coefficient in each section is 1. The gain of the filter is applied to the first scale value of Hq2.

sos uses the direct form II transposed (dft2) structure to implement second- order section filters.

Examples

```
[b,a]=butter(8,.5);
Hq = dfilt.df2t(b,a);
Hq.arithmetic = 'fixed';
Hq1 = sos(Hq)

Hq1 =

         FilterStructure: 'Direct-Form II Transposed, Second-Order Sections'
              Arithmetic: 'double'
               sosMatrix: [4x6 double]
             ScaleValues: [0.00927734375;1;1;1;1]
     OptimizeScaleValues: true
        PersistentMemory: false
```

See Also

convert | dfilt | tf2sos

specifyall

Fixed-point scaling modes in direct-form FIR filter

Syntax

```
specifyall(hd)
specifyall(hd,false)
specifyall(hd,true)
specifyall(hs)
specifyall(hs,false)
```

Description

`specifyall` sets all of the `autoscale` property values of direct-form FIR filters to `false` and all `*modes` of the filters to `SpecifyPrecision`. In this table, you see the results of using `specifyall` with direct-form FIR filters.

Property Name	Default	Setting After Applying specifyall
`CoeffAutoScale`	`true`	`false`
`OutputMode`	`AvoidOverflow`	`SpecifyPrecision`
`ProductMode`	`FullPrecision`	`SpecifyPrecision`
`AccumMode`	`KeepMSB`	`SpecifyPrecision`
`RoundMode`	`convergent`	`convergent`
`OverflowMode`	`wrap`	`wrap`

`specifyall(hd)` gives you maximum control over all settings in a filter `hd` by setting all of the autoscale options that are `true` to `false`, turning off all autoscaling and resetting all modes — `OutputMode`, `ProductMode`, and `AccumMode` — to `SpecifyPrecision`. After you use `specifyall`, you must supply the property values for the mode- and scaling related properties.

`specifyall` provides an alternative to changing all these properties individually. Using `specifyall` changes all of the settings. To set some but not all of the modes, set each property as you require.

specifyall(hd,false) performs the opposite operation of specifyall(hd) by setting all of the autoscale options to true; all of the modes to their default values; and hiding the fraction length properties in the display, meaning you cannot access them to set them or view them.

specifyall(hd,true) is equivalent to specifyall(hd).

specifyall(hs) sets all the data type fixed-point properties of the filter System object hs to 'Custom' so that you can easily specify all the fixed-point settings. If the object has a FullPrecisionOverride property, its value is set to false. specifyall is intended as a shortcut to changing all the fixed-point properties one by one.

specifyall(hs,false) sets all fixed-point properties of the filter System object hs to their default values and sets the filter to full-precision mode, if possible.

Examples

This example demonstrates using specifyall to provide access to all of the fixed-point settings of an FIR filter implemented with the direct-form structure. Using specifyall disables all of the automatic filter scaling and reset the mode values.

```
b = fircband(12,[0 0.4 0.5 1],[1 1 0 0],[1 0.2],{'w' 'c'});
hd = dfilt.dffir(b);
hd.arithmetic = 'fixed'
specifyall(hd)
```

The mode properties InputMode, ProductMode, and AccumMode have the value SpecifyPrecision and the fraction length properties appear in the display. Now you use the properties (InputFracLength, ProdFracLength, AccumFracLength) to set the precision the filter applies to the input, product, and accumulator operations. CoeffAutoScale switches to false, which means that the filter coefficients will not be scaled automatically to prevent overflows. None of the other filter properties change when you apply specifyall.

double | reffilter

stepz

Step response for filter

Syntax

```
[h,t] = stepz(hfilt)
[h,t] = stepz(hfilt,n)
[h,t] = stepz(hfilt,n,fs)
[h,t] = stepz(hfilt,[],fs)
stepz(hfilt)
[h,t] = stepz(hs)
[h,t] = stepz(hs,Name,Value)
stepz(hs)
```

Description

`stepz` returns the step response based on the current filter coefficients. This section describes common `stepz` operation with adaptive filters, discrete-time filters, multirate filters, and filter System objects. For more input options, refer to `stepz` in Signal Processing Toolbox documentation.

`[h,t] = stepz(hfilt)` returns the impulse response `h` and the corresponding time points `w` at which the step response of `hfilt` is computed. The step response is evaluated at 10 1-second intervals—`(0:9)'`.

`[h,t] = stepz(hfilt,n)` returns the step response evaluated at `floor(n)` 1-second intervals—`(0:floor(n)-1)'`.

`[h,t] = stepz(hfilt,n,fs)` returns the step response evaluated at `floor(n)` `1`/fs-second intervals—`(0:floor(n)-1)'/fs`.

`[h,t] = stepz(hfilt,[],fs)` returns the step response evaluated at 10 `1`/fs-second intervals—`(0:9)'/fs`.

`stepz(hfilt)` uses FVTool to plot the step response of the filter. You can also provide the optional input arguments n and fs with this syntax.

`[h,t] = stepz(hs)` returns the step response for the filter System object hs. The impulse response is evaluated at 10 1-second intervals—`(0:9)'`. You can also provide the optional input arguments n and fs with this syntax.

`[h,t] = stepz(hs,Name,Value)` returns an step response with additional options specified by one or more Name,Value pair arguments.

`stepz(hs)` uses FVTool to plot the step response of the filter System object `hs`.

Note `stepz` works for both real and complex filters. When you omit the output arguments, `stepz` plots only the real part of the step response.

Input Arguments

`hfilt`

`hfilt` is either:

- An adaptive `adaptfilt`, discrete-time `dfilt`, or multirate `mfilt` filter object
- A vector of adaptive, discrete-time, or multirate filter objects

The multirate filter step response is computed relative to the rate at which the filter is running. When you specify `fs` (the sampling rate) as an input argument, `stepz` assumes the filter is running at that rate.

For multistage cascades, `stepz` forms a single-stage multirate filter that is equivalent to the cascade. It then computes the response relative to the rate at which the equivalent filter is running. `stepz` does not support all multistage cascades. The function analyzes only those cascades for which there exists an equivalent single-stage filter.

As an example, consider a 2-stage interpolator where the first stage has an interpolation factor of 2 and the second stage has an interpolation factor of 4. In this case, an equivalent single-stage filter exists with an overall interpolation factor of 8. `stepz` uses this equivalent filter for the analysis. If a sampling frequency `fs` is specified as an input argument to `stepz`, the function interprets `fs` as the rate at which the equivalent filter is running.

`hs`

Filter System object.

The following Filter System objects are supported by this analysis function:

Filter System objects
dsp.FIRFilter
dsp.FIRInterpolator
dsp.CICInterpolator
dsp.FIRDecimator
dsp.CICDecimator
dsp.FIRRateConverter
dsp.BiquadFilter
dsp.IIRFilter
dsp.AllpoleFilter
dsp.AllpassFilter
dsp.CoupledAllpassFilter

n

Number of samples.

Default: 10

fs

Sampling frequency.

Default: 1

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

'Arithmetic' — Value types:
‘double’ | 'single' | 'fixed'

For filter System object inputs only, specify the arithmetic used during analysis. When you specify 'double' or 'single', the function performs double- or single-precision analysis. When you specify 'fixed' , the arithmetic changes depending on the setting of the CoefficientDataType property and whether the System object is locked or unlocked.

Details for Fixed-Point Arithmetic

System Object State	Coefficient Data Type	Rule
Unlocked	'Same as input'	The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Unlocked	'Custom'	The function performs fixed-point analysis based on the setting of the CustomCoefficientsDataType property.
Locked	'Same as input'	When the input data type is 'double' or 'fixed', the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Locked	'Custom'	The function performs fixed-point analysis based on the setting of the CustomCoefficientsDataType property.

When you do not specify the arithmetic for non-CIC structures, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System

object is locked, the function performs analysis based on the locked input data type. CIC structures only support fixed-point arithmetic.

Output Arguments

h

Complex, `n`-element step response vector. If hfilt is a vector of filters, h is a complex, `length(hfilt)`-by-`n` matrix of step response vectors corresponding to each filter in hfilt. If `n` is not specified, the function uses a default value of 8192.

For adaptive filters, `h` is the instantaneous step response.

t

Time vector of length `n`, in seconds. `t` consists of `n` points equally spaced from 0 to `floor(n)/fs`. If `n` is not specified, the function uses a default value of 10. If `fs` is not specified, the function uses a default value of 1.

`freqz` | `impz`

sysobj

Create filter System object from discrete-time filter or multirate filter

Syntax

```
hs = sysobj(hfilt)
```

Description

`hs = sysobj(hfilt)` creates a new filter System object hs from the `dfilt` or `mfilt` object, hfilt.

The function supports a subset of `dfilt` and `mfilt` objects. The following table lists supported filter structures for hfilt and the filter System object that the function creates.

Single-rate or multirate filter	Filter System object
Lattice AR(`dfilt.latticear`)	`dsp.AllpoleFilter`
Coupled-allpass, power-complementary lattice filter (`dfilt.calatticepc`)	`dsp.CoupledAllpassFilter`
Coupled-allpass, lattice filter (`dfilt.calattice`)	`dsp.CoupledAllpassFilter`
Cascade of discrete time filters (`dfilt.cascade`)	`dsp.CoupledAllpassFilter`
Direct Form I (`dfilt.df1`)	`dsp.IIRFilter`
Direct Form I transposed (`dfilt.df1t`)	`dsp.IIRFilter`
Direct Form II (`dfilt.df2`)	`dsp.IIRFilter`
Direct Form II transposed (`dfilt.df2t`)	`dsp.IIRFilter`
Direct-form FIR (`dfilt.dffir`)	`dsp.FIRFilter`
Direct-form FIR transposed (`dfilt.dffirt`)	`dsp.FIRFilter`
Direct-form symmetric FIR (`dfilt.dfsymfir`)	`dsp.FIRFilter`

Single-rate or multirate filter	Filter System object
Direct-form antisymmetric FIR (`dfilt.dfasymfir`)	`dsp.FIRFilter`
Discrete-time, lattice, moving-average (`dfilt.latticemamin`)	`dsp.FIRFilter`
Discrete-time, second-order section, direct-form I (`dfilt.df1sos`)	`dsp.BiquadFilter`
Discrete-time, second-order section, direct-form I transposed (`dfilt.df1tsos`)	`dsp.BiquadFilter`
Discrete-time, second-order section, direct-form II (`dfilt.df2sos`)	`dsp.BiquadFilter`
Discrete-time, second-order section, direct-form II transposed (`dfilt.df2tsos`)	`dsp.BiquadFilter`
Direct-form FIR polyphase decimator (`mfilt.firdecim`)	`dsp.FIRDecimator`
Direct-form transposed FIR polyphase decimator (`mfilt.firtdecim`)	`dsp.FIRDecimator`
Fixed-point CIC decimator (`mfilt.cicdecim`)	`dsp.CICDecimator`
FIR polyphase interpolator (`mfilt.firinterp`)	`dsp.FIRInterpolator`
FIR linear interpolator (`mfilt.linearinterp`)	`dsp.FIRInterpolator`
Fixed-point CIC interpolator (`mfilt.cicinterp`)	`dsp.CICInterpolator`
Direct-form FIR polyphase sample rate converter (`mfilt.firsrc`)	`dsp.FIRRateConverter`

Input Arguments

`hfilt`

Discrete-time filter (`dfilt`) or multirate filter (`mfilt`) object. The preceding table lists supported filter structures.

The function interprets the PersistentMemory property differently for discrete-time and multirate filters:

- If hfilt is a discrete-time filter with the PersistentMemory property set to true, then the filter states are copied into the initial conditions properties of hs. Otherwise, initial conditions are ignored.
- Multirate-filter System objects do not have initial conditions. If hfilt is a multirate filter with the PersistentMemory property set to true, the initial conditions are not copied into hs, and the function issues a warning.

The function does not support some properties for SOS filter structures:

- If the CastBeforeSum property is set to false, the function issues a warning. dsp.BiquadFilter System objects always have a cast before a sum.
- If the Signed property is false, the function issues an error. dsp.BiquadFilter System objects do not support unsigned arithmetic.

Output Arguments

hs

Filter System object. The function maps almost all properties of hfilt into the filter System object. However, some properties are not mapped exactly:

- Filter System objects do not have a CoeffAutoScale property. The function specifies a word length and a fraction length regardless of whether the CoeffAutoScale property of hfilt is true or false.
- dsp.BiquadFilter System objects do not have a FullPrecisionOverride property. Full-precision values in hfilt are mapped to word and fraction lengths in hs. These settings correspond to the full-precision setting of the input data type.

Examples

Convert a discrete-time filter object to a System object:

```
hfilt = dfilt.df1sos; %Direct-form I SOS
hs = sysobj(hfilt);   %Biquadratic IIR filter
```

See Also

`block`

tf2ca

Transfer function to coupled allpass

Syntax

```
[d1,d2] = tf2ca(b,a)
[d1,d2] = tf2ca(b,a)
[d1,d2,beta] = tf2ca(b,a)
```

Description

`[d1,d2] = tf2ca(b,a)` where `b` is a real, symmetric vector of numerator coefficients and `a` is a real vector of denominator coefficients, corresponding to a stable digital filter, returns real vectors `d1` and `d2` containing the denominator coefficients of the allpass filters *H1(z)* and *H2(z)* such that

$$H(z) = \frac{B(z)}{A(z)} = \left(\frac{1}{2}\right)[H1(z) + H2(z)]$$

representing a coupled allpass decomposition.

`[d1,d2] = tf2ca(b,a)` where `b` is a real, antisymmetric vector of numerator coefficients and `a` is a real vector of denominator coefficients, corresponding to a stable digital filter, returns real vectors `d1` and `d2` containing the denominator coefficients of the allpass filters *H1(z)* and *H2(z)* such that

$$H(z) = \frac{B(z)}{A(z)} = \left(\frac{1}{2}\right)[H1(z) - H2(z)]$$

In some cases, the decomposition is not possible with real *H1(z)* and *H2(z)*. In those cases a generalized coupled allpass decomposition may be possible, as described in the following syntax.

`[d1,d2,beta] = tf2ca(b,a)` returns complex vectors `d1` and `d2` containing the denominator coefficients of the allpass filters *H1(z)* and *H2(z)*, and a complex scalar `beta`, satisfying `|beta|` = 1, such that

$$H(z)=\frac{B(z)}{A(z)}=\left(\frac{1}{2}\right)\left[\bar{\beta}\cdot H1(z)+\beta\cdot H2(z)\right]$$

representing the generalized allpass decomposition.

In the above equations, *H1(z)* and *H2(z)* are real or complex allpass IIR filters given by

$$H1(z)=\frac{fliplr(\overline{(D1(z))})}{D1(z)},H2(1)(z)=\frac{fliplr(\overline{(D2(1)(z))})}{D2(1)(z)}$$

where *D1(z)* and *D2(z)* are polynomials whose coefficients are given by `d1` and `d2`.

Note A coupled allpass decomposition is not always possible. Nevertheless, Butterworth, Chebyshev, and Elliptic IIR filters, among others, can be factored in this manner. For details, refer to Signal Processing Toolbox User's Guide.

Examples

```
[b,a]=cheby1(9,.5,.4);
[d1,d2]=tf2ca(b,a);  % TF2CA returns denominators of the allpass.
num = 0.5*conv(fliplr(d1),d2)+0.5*conv(fliplr(d2),d1);
den = conv(d1,d2);  % Reconstruct numerator and denonimator.
MaxDiff=max([max(b-num),max(a-den)]); % Compare original and reconstructed
       % numerator and denominators.
```

tf2cl

Transfer function to coupled allpass lattice

Syntax

```
[k1,k2] = tf2cl(b,a)
[k1,k2] = tf2cl(b,a)
[k1,k2,beta] = tf2cl(b,a)
```

Description

`[k1,k2] = tf2cl(b,a)` where `b` is a real, symmetric vector of numerator coefficients and `a` is a real vector of denominator coefficients, corresponding to a stable digital filter, will perform the coupled allpass decomposition

$$H(z) = \frac{B(z)}{A(z)} = \left(\frac{1}{2}\right)[H1(z) + H2(z)]$$

of a stable IIR filter *H(z)* and convert the allpass transfer functions *H1(z)* and *H2(z)* to a coupled lattice allpass structure with coefficients given in vectors `k1` and `k2`.

`[k1,k2] = tf2cl(b,a)` where `b` is a real, antisymmetric vector of numerator coefficients and `a` is a real vector of denominator coefficients, corresponding to a stable digital filter, performs the coupled allpass decomposition

$$H(z) = \frac{B(z)}{A(z)} = \left(\frac{1}{2}\right)[H1(z) - H2(z)]$$

of a stable IIR filter *H(z)* and converts the allpass transfer functions *H1(z)* and *H2(z)* to a coupled lattice allpass structure with coefficients given in vectors `k1` and `k2`.

In some cases, the decomposition is not possible with real *H1(z)* and *H2(z)*. In those cases, a generalized coupled allpass decomposition may be possible, using the syntax described below.

`[k1,k2,beta] = tf2cl(b,a)` performs the generalized allpass decomposition of a stable IIR filter *H(z)* and converts the complex allpass transfer functions *H1(z)* and *H2(z)* to corresponding lattice allpass filters

$$H(z) = \frac{B(z)}{A(z)} = \left(\frac{1}{2}\right)\left[\bar{\beta} \cdot H1(z) + \beta \cdot H2(z)\right]$$

where `beta` is a complex scalar of magnitude equal to 1.

Note Coupled allpass decomposition is not always possible. Nevertheless, Butterworth, Chebyshev, and Elliptic IIR filters, among others, can be factored in this manner. For details, refer to Signal Processing Toolbox User's Guide.

Examples

```
[b,a]=cheby1(9,.5,.4);
[k1,k2]=tf2cl(b,a); % Get the reflection coeffs. for the lattices.
[num1,den1]=latc2tf(k1,'allpass'); % Convert each allpass lattice
[num2,den2]=latc2tf(k2,'allpass'); % back to transfer function.
num = 0.5*conv(num1,den2)+0.5*conv(num2,den1);
den = conv(den1,den2); % Reconstruct numerator and denonimator.
MaxDiff=max([max(b-num),max(a-den)]); % Compare original and reconstructed
       % numerator and denominators.
```

validstructures

Structures for specification object with design method

Syntax

```
filtstruct = validstructures(D)
C = validstructures(D,METHOD)
Cs = validstructures(D,...,'SystemObject',sysobjflag)
```

Description

`filtstruct = validstructures(D)` returns a structure array containing all valid filter structures for the filter specification object, D, organized by design method. Each design method is a field in the structure array, filtstruct. The fields contain a cell array of strings.

`C = validstructures(D,METHOD)` returns the valid structures for the filter specification object, D, and the design method, METHOD, in a cell array of strings.

`Cs = validstructures(D,...,'SystemObject',`*`sysobjflag`*`)` returns the valid structures for designing a filter System object when *`sysobjflag`* is `true`. To use System objects, you must have the DSP System Toolbox product installed. When *`sysobjflag`* is `false`, the function returns valid structures for designing `dfilt` and `mfilt` objects, as described previously. Design methods and design options for filter System objects are not necessarily the same as those for `dfilt` and `mfilt` objects.

Examples

Design a default lowpass filter specification object. Return all valid design methods and structures in a structure array. Display the fieldnames to see all valid design methods. Display the valid filter structures for the `equiripple` field.

```
D = fdesign.lowpass;
filtstruct = validstructures(D);
fieldnames(filtstruct)
```

```
filtstruct.equiripple
```

Create a highpass filter of order 50 with a 3-dB frequency of 0.2. Obtain the available structures for a Butterworth design.

```
D = fdesign.highpass('N,F3dB',50,0.2);
C = validstructures(D,'butter');
```

If you have DSP System Toolbox software installed, use the `'SystemObject',`*`sysobjflag`* syntax to return valid structures for a filter System object:

```
Cs = validstructures(D,'butter','SystemObject',true);
```

wdf2allpass

Wave Digital Filter to allpass coefficient transformation

Syntax

```
a = wdf2allpass(w)
A = wdf2allpass(W)
```

Description

a = wdf2allpass(w) accepts a vector of transformed real allpass coefficients, w, and returns the conventional allpass polynomial version a. w is used by allpass filter objects such as dsp.AllpassFilter, and dsp.CoupledAllpassFilter, with Structure set to 'Wave Digital Filter'.

A = wdf2allpass(W) accepts the cell array of transformed allpass coefficient vectors W. Each cell of W contains the transformed real coefficients of a section of a cascade allpass filter. The output A is also a cell array, and each cell of A contains the conventional polynomial version of the corresponding cell of W. W is used by allpass filter objects such as dsp.AllpassFilter and dsp.CoupledAllpassFilter, with Structure set to 'Wave Digital Filter'. Every cell of W must contain a real vector of length 1,2, or 4. When the length is 4, the second and fourth components must both be zero. W can be a row or column vector of cells while A is always returned as column.

Examples

Wave Digital Filter Coefficients

This example illustrates the use of wdf2allpass to enable converting the Structure of dsp.AllpassFilter from 'Wave Digital Filter' back to 'Minimum Multiplier'.

```
w = [0.5 0];    % 2nd order allpass Wave Digital Filter coefficients
swdf = dsp.AllpassFilter('Structure', 'Wave Digital Filter',...
    'WDFCoefficients', w);
a = wdf2allpass(w); % Convert coefficients to allpass polynomial form
smm = dsp.AllpassFilter('AllpassCoefficients', a);
in = randn(512, 1);
```

```
out_wdf = step(swdf, in);
out_mm = step(smm, in);
max(out_wdf-out_mm);  % Compare numerical difference of filter outputs
```

Input Arguments

w — Transformed Wave Digital Filter allpass coefficients

(default) | vector of real numbers

Numeric vector of transformed Wave Digital Filter allpass coefficients, specified as a real number. w can have only length equal to 1,2, and 4. When the length is 4, the second and fourth components must both be zero. w can be a row or a column vector.

Example: `[0.3,-0.2]`

Data Types: `double` | `single`

W — Transformed Wave Digital Filter allpass coefficients

(default) | vector of cells

Cascade of allpass filter coefficients in transformed Wave Digital Filter form, specified as a cell vector. Every cell of W must contain a real vector of length 1, 2, or 4. When the length is 4, the second and fourth components must both be zero. W can be a row or a column vector of cells.

Example: `{[0.3,-0.2];0.5}`

Data Types: `double` | `single`

Output Arguments

a — allpass filter coefficients

(default) | vector of real numbers

Numeric vector of polynomial allpass coefficients, determined as a numeric row vector.

Example: `3.1`

Data Types: `double` | `single`

A — allpass filter coefficients

(default) | vector cell array

Cascade of allpass filter coefficient, determined as a column of cells, each containing a vector of length 1, 2, or 4.

Example: `{0.3 5.0 0.2}`

Data Types: `double` | `single`

More About

Algorithms

`wdf2allpass` provides the inverse operation of `allpass2wdf`, by transforming the transformed cascade of allpass coefficients W into their conventional polynomial representation A. Please refer to the reference page for `allpass2wdf` for more details about the two representations.

W defines a multisection allpass filter, and `wdf2allpass` applies separately to each section, with the same transformation used in the single-section case. In this case, the numeric coefficients vector w can have order 1, 2, or 4.

The relations between the vector of section coefficients a and w respectively depend on the order, as follows:

$$\begin{aligned}
&\textit{for order } 1:\\
&a_1 = w_1\\
&\textit{for order } 2:\\
&a_1 = w_2(1+w_1)\\
&a_2 = w_1\\
&\textit{for order } 4:\\
&a_2 = w_3(1+w_1)\\
&a_4 = w_1\\
&a_1 = a_3 = 0
\end{aligned}$$

window

FIR filter using windowed impulse response

Syntax

```
h = window(d,fcnhndl,fcnarg)
h = window(d,win)
```

description

`h = window(d,fcnhndl,fcnarg)` designs an FIR filter using the specifications in filter specification object `d`. Depending on the specification type of `d`, the returned filter is either a single-rate digital filter — a `dfilt`, or a multirate digital filter — an `mfilt`.

`fcnhndl` is a handle to a filter design function that returns a window vector, such as the `hamming` or `blackman` functions. `fcnarg` is an optional argument that returns a window. You pass the function to `window`. Refer to example 1 in the following section to see the function argument used to design the filter.

`h = window(d,win)` designs a filter using the vector you supply in `win`. The length of vector `win` must be the same as the impulse response of the filter, which is equal to the filter order plus one. Example 2 shows this being done.

Examples

These examples design filters using the two design techniques of specifying a function handle or passing a window vector as an input argument.

Example 1

Use a function handle and optional input arguments to design a multirate filter. We use a function handle to `hamming` to provide the window. Since this example creates a decimator filter specifications object, `window` returns a multirate filter.

```
d = fdesign.decimator(4,'lowpass','N,Fc',30,1000,10000);
% Lowpass decimator with a 6-dB down frequency of 1 kHz
% Order equal to 30 and sampling frequency 10 kHz
Hd =window(d,'window',@hamming);
fvtool(Hd)
```

zerophase

Zero-phase response for filter

Syntax

```
[hr,w] = zerophase(hfilt)
[hr,w] = zerophase(hfilt,n)
zerophase(hfilt)
[hr,w] = zerophase(hs)
[hr,w] = zerophase(hs,n)
[hr,w] = zerophase(hs,Name,Value)
zerophase(hs)
```

Description

`zerophase` returns the zero-phase response based on the current filter coefficients. This section describes common `zerophase` operation with adaptive, discrete-time, and multirate filters. For more input options, refer to `zerophase` in Signal Processing Toolbox documentation.

`[hr,w] = zerophase(hfilt)` returns the instantaneous zero-phase response hr and the frequencies w in radians at which `zerophase` evaluated the response. The zero-phase response is evaluated at 8192 points equally spaced around the upper half of the unit circle.

`[hr,w] = zerophase(hfilt,n)` returns the instantaneous zero-phase response hr and the frequencies w in radians at which `zerophase` evaluated the response. The zero-phase response is evaluated at `n` points equally spaced around the upper half of the unit circle.

`zerophase(hfilt)` displays the zero-phase response of `ha` in the Filter Visualization Tool (FVTool).

`[hr,w] = zerophase(hs)` returns a zero-phase response for the filter System object hs using 8192 samples.

`[hr,w] = zerophase(hs,n)` returns a zero-phase response for the filter System object hs using `n` samples.

`[hr,w] = zerophase(hs,Name,Value)` returns a zero-phase response with additional options specified by one or more Name,Value pair arguments.

`zerophase(hs)` uses FVTool to plot the zero-phase response of the filter System object `hs`.

Input Arguments

hfilt

`hfilt` is either:

- An adaptive `adaptfilt`, discrete-time `dfilt`, or multirate `mfilt` filter object
- A vector of adaptive, discrete-time, or multirate filter objects

The multirate filter zero-phase response is computed relative to the rate at which the filter is running. When you specify `fs` (the sampling rate) as an input argument, `zerophase` assumes the filter is running at that rate.

For multistage cascades, `zerophase` forms a single-stage multirate filter that is equivalent to the cascade. It then computes the response relative to the rate at which the equivalent filter is running. `zerophase` does not support all multistage cascades. The function analyzes only those cascades for which there exists an equivalent single-stage filter.

As an example, consider a 2-stage interpolator where the first stage has an interpolation factor of 2 and the second stage has an interpolation factor of 4. In this case, an equivalent single-stage filter exists with an overall interpolation factor of 8. `zerophase` uses this equivalent filter for the analysis. If a sampling frequency `fs` is specified as an input argument to `zerophase`, the function interprets `fs` as the rate at which the equivalent filter is running.

hs

Filter System object.

The following Filter System objects are supported by this analysis function:

Filter System objects
dsp.FIRFilter
dsp.FIRInterpolator
dsp.CICInterpolator
dsp.FIRDecimator
dsp.CICDecimator
dsp.FIRRateConverter
dsp.BiquadFilter
dsp.IIRFilter
dsp.AllpoleFilter
dsp.AllpassFilter
dsp.CoupledAllpassFilter

n

Number of samples. For an FIR filter where `n` is a power of two, the computation is done faster using FFTs.

Default: 8192

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'Arithmetic'` — Value type:
`‘double’ | 'single' | 'fixed'`

For filter System object inputs only, specify the arithmetic used during analysis. When you specify `'double'` or `'single'`, the function performs double- or single-precision analysis. When you specify `'fixed'` , the arithmetic changes depending on the setting of the `CoefficientDataType` property and whether the System object is locked or unlocked.

Details for Fixed-Point Arithmetic

System Object State	Coefficient Data Type	Rule
Unlocked	`'Same as input'`	The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Unlocked	`'Custom'`	The function performs fixed-point analysis based on the setting of the `CustomCoefficientsDataType` property.
Locked	`'Same as input'`	When the input data type is `'double'` or `'fixed'`, the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Locked	`'Custom'`	The function performs fixed-point analysis based on the setting of the `CustomCoefficientsDataType` property.

When you do not specify the arithmetic for non-CIC structures, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type. CIC structures only support fixed-point arithmetic.

Output Arguments

`hr`

Complex, `n`-element zero-phase response vector. If hfilt is a vector of filters, hr is a complex, `length(hfilt)`-by-`n` matrix of phase response vectors whose columns correspond to each filter in hfilt. If `n` is not specified, the function uses a default value of 8192.

For adaptive filters, `hr` is the instantaneous zero-phase response.

`w`

Frequency vector of length `n`, in radians/sample. `w` consists of `n` points equally spaced around the upper half of the unit circle (from 0 to π radians/sample). If hfilt is a vector of filters, w is a complex, `length(hfilt)`-by-`n` matrix of phase response vectors whose columns correspond to each filter in hfilt. If `n` is not specified, the function uses a default value of 8192.

zpkbpc2bpc

Zero-pole-gain complex bandpass frequency transformation

Syntax

```
[Z2,P2,K2,AllpassNum,AllpassDen] = zpkbpc2bpc(Z,P,K,Wo,Wt)
```

Description

`[Z2,P2,K2,AllpassNum,AllpassDen] = zpkbpc2bpc(Z,P,K,Wo,Wt)` returns zeros, Z_2, poles, P_2, and gain factor, K_2, of the target filter transformed from the complex bandpass prototype by applying a first-order complex bandpass to complex bandpass frequency transformation.

It also returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the allpass mapping filter. The original lowpass filter is given with zeros, `Z`, poles, `P`, and gain factor, `K`.

This transformation effectively places two features of an original filter, located at frequencies W_{o1} and W_{o2}, at the required target frequency locations, W_{t1}, and W_{t2} respectively. It is assumed that W_{t2} is greater than W_{t1}. In most of the cases the features selected for the transformation are the band edges of the filter passbands. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter, F_1 and F_2, with F_1 preceding F_2. Feature F_1 will still precede F_2 after the transformation. However, the distance between F_1 and F_2 will not be the same before and after the transformation.

This transformation can also be used for transforming other types of filters; e.g., complex notch filters or resonators can be repositioned at two distinct desired frequencies at any place around the unit circle; e.g., in the adaptive system.

Examples

Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3,0.1,30,0.409);
```

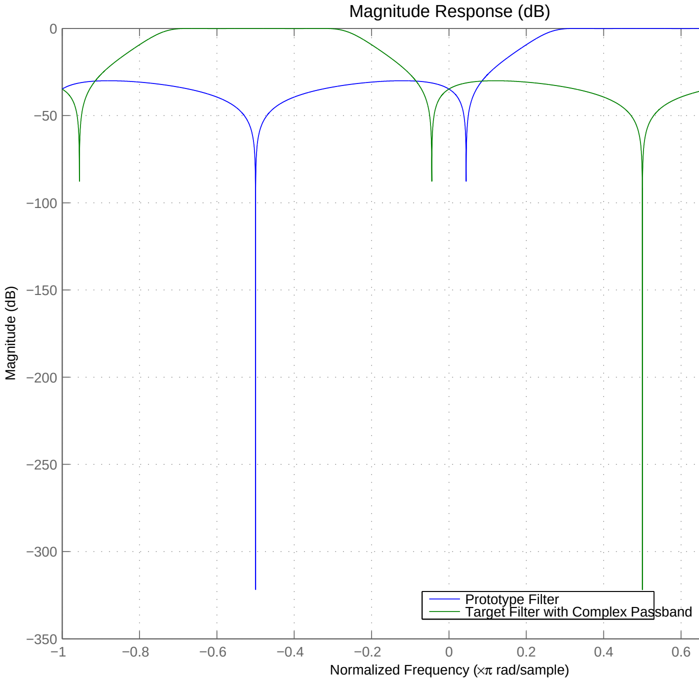
Create a complex passband from 0.25 to 0.75:

```
[b, a] = iirlp2bpc(b,a,0.5,[0.25,0.75]);
z = roots(b);
p = roots(a);
k = b(1);
[z2,p2,k2] = zpkbpc2bpc(z,p,k,[0.25, 0.75],[-0.75, -0.25]);
```

Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b, a, k2*poly(z2), poly(p2));
```

Comparing the filters in FVTool shows the example results. Use the features in FVTool to check the filter coefficients, or other filter analyses.



Arguments

Variable	Description
Z	Zeros of the prototype lowpass filter
P	Poles of the prototype lowpass filter
K	Gain factor of the prototype lowpass filter
Wo	Frequency value to be transformed from the prototype filter
Wt	Desired frequency location in the transformed target filter
Z2	Zeros of the target filter
P2	Poles of the target filter
K2	Gain factor of the target filter
AllpassNum	Numerator of the mapping filter
AllpassDen	Denominator of the mapping filter

Frequencies must be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.

See Also

zpkftransf | allpassbpc2bpc | iirbpc2bpc

zpkftransf

Zero-pole-gain frequency transformation

Syntax

```
[Z2,P2,K2] = zpkftransf(Z,P,K,AllpassNum,AllpassDen)
```

Description

`[Z2,P2,K2] = zpkftransf(Z,P,K,AllpassNum,AllpassDen)` returns zeros, Z_2, poles, P_2, and gain factor, K_2, of the transformed lowpass digital filter. The prototype lowpass filter is given with zeros, `Z`, poles, `P`, and gain factor, `K`. If `AllpassDen` is not specified it will default to 1. If neither `AllpassNum` nor `AllpassDen` is specified, then the function returns the input filter.

Examples

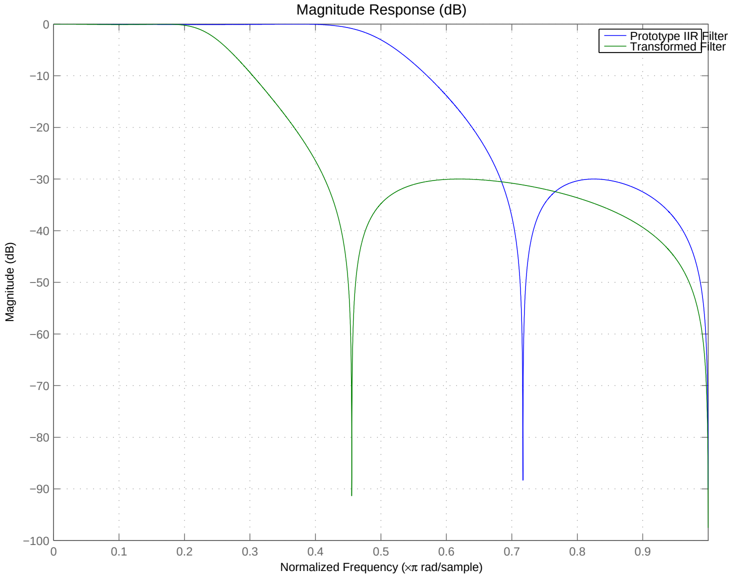
Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3,0.1,30,0.409);
[AlpNum, AlpDen] = allpasslp2lp(0.5, 0.25);
[z2, p2, k2] = zpkftransf(roots(b),roots(a),b(1),AlpNum,AlpDen);
```

Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b, a, k2*poly(z2), poly(p2));
```

After transforming the filter, you get the response shown in the figure, where the passband has been shifted towards zero.



Arguments

Variable	Description
`Z`	Zeros of the prototype lowpass filter
`P`	Poles of the prototype lowpass filter
`K`	Gain factor of the prototype lowpass filter
`FTFNum`	Numerator of the mapping filter
`FTFDen`	Denominator of the mapping filter
`Z2`	Zeros of the target filter
`P2`	Poles of the target filter
`K2`	Gain factor of the target filter

See Also

`iirftransf`

zpklp2bp

Zero-pole-gain lowpass to bandpass frequency transformation

Syntax

```
[Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2bp(Z,P,K,Wo,Wt)
```

Description

`[Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2bp(Z,P,K,Wo,Wt)` returns zeros, Z_2, poles, P_2, and gain factor, K_2, of the target filter transformed from the real lowpass prototype by applying a second-order real lowpass to real bandpass frequency mapping.

It also returns the numerator, `AllpassNum`, and the denominator `AllpassDen`, of the allpass mapping filter. The prototype lowpass filter is given with zeros, `Z`, poles, `P`, and gain factor, `K`.

This transformation effectively places one feature of an original filter, located at frequency $-W_o$, at the required target frequency location, W_{t1}, and the second feature, originally at $+W_o$, at the new location, W_{t2}. It is assumed that W_{t2} is greater than W_{t1}. This transformation implements the "DC Mobility," which means that the Nyquist feature stays at Nyquist, but the DC feature moves to a location dependent on the selection of W_t.

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter, F_1 and F_2, with F_1 preceding F_2. Feature F_1 will still precede F_2 after the transformation. However, the distance between F_1 and F_2 will not be the same before and after the transformation.

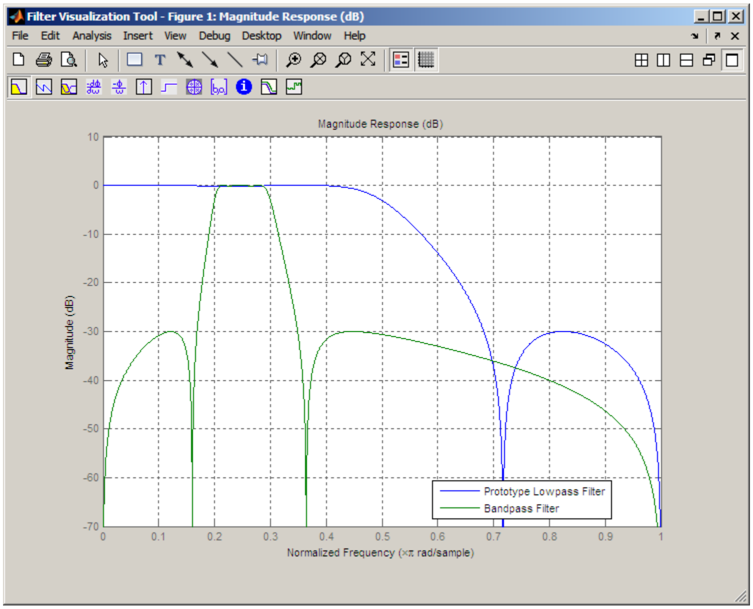
Choice of the feature subject to the lowpass to bandpass transformation is not restricted only to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

Real lowpass to bandpass transformation can also be used for transforming other types of filters; e.g., real notch filters or resonators can be easily doubled and positioned at two distinct, desired frequencies.

Examples

Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[B,A] = ellip(3,0.1,30,0.409);
Z = roots(B);
P = roots(A);
K = B(1);
[Z2,P2,K2] = zpklp2bp(Z,P,K, 0.5, [0.2 0.3]);
hfvt = fvtool(B,A,K2*poly(Z2),poly(P2));
legend(hfvt,'Prototype Lowpass Filter', 'Bandpass Filter');
axis([0 1 -70 10]);
```



Arguments

Variable	Description
Z	Zeros of the prototype lowpass filter
P	Poles of the prototype lowpass filter

Variable	Description
`K`	Gain factor of the prototype lowpass filter
`Wo`	Frequency value to be transformed from the prototype filter
`Wt`	Desired frequency location in the transformed target filter
`Z2`	Zeros of the target filter
`P2`	Poles of the target filter
`K2`	Gain factor of the target filter
`AllpassNum`	Numerator of the mapping filter
`AllpassDen`	Denominator of the mapping filter

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

zpklp2bpc

Zero-pole-gain lowpass to complex bandpass frequency transformation

Syntax

```
[Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2bpc(Z,P,K,Wo,Wt)
```

Description

`[Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2bpc(Z,P,K,Wo,Wt)` returns zeros, Z_2, poles, P_2, and gain factor, K_2, of the target filter transformed from the real lowpass prototype by applying a first-order real lowpass to complex bandpass frequency transformation.

It also returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the allpass mapping filter. The prototype lowpass filter is given with zeros, `Z`, poles, `P`, and gain factor, `K`.

This transformation effectively places one feature of an original filter, located at frequency $-W_o$, at the required target frequency location, W_{t1}, and the second feature, originally at $+W_o$, at the new location, W_{t2}. It is assumed that W_{t2} is greater than W_{t1}.

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter, F_1 and F_2, with F_1 preceding F_2. Feature F_1 will still precede F_2 after the transformation. However, the distance between F_1 and F_2 will not be the same before and after the transformation.

Choice of the feature subject to the lowpass to bandpass transformation is not restricted only to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

Lowpass to bandpass transformation can also be used for transforming other types of filters; e.g., real notch filters or resonators can be doubled and positioned at two distinct desired frequencies at any place around the unit circle forming a pair of complex notches/resonators. This transformation can be used for designing bandpass filters for radio receivers from the high-quality prototype lowpass filter.

Examples

Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3,0.1,30,0.409);
z = roots(b);
p = roots(a);
k = b(1);
[z2,p2,k2] = zpklp2bpc(z, p, k, 0.5, [0.2 0.3]);
```

Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b, a, k2*poly(z2), poly(p2));
```

Arguments

Variable	Description
Z	Zeros of the prototype lowpass filter
P	Poles of the prototype lowpass filter
K	Gain factor of the prototype lowpass filter
Wo	Frequency value to be transformed from the prototype filter. It should be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.
Wt	Desired frequency locations in the transformed target filter. They should be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.
Z2	Zeros of the target filter
P2	Poles of the target filter
K2	Gain factor of the target filter
AllpassNum	Numerator of the mapping filter
AllpassDen	Denominator of the mapping filter

zpklp2bs

Zero-pole-gain lowpass to bandstop frequency transformation

Syntax

```
[Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2bs(Z,P,K,Wo,Wt)
```

Description

`[Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2bs(Z,P,K,Wo,Wt)` returns zeros, Z_2, poles, P_2, and gain factor, K_2, of the target filter transformed from the real lowpass prototype by applying a second-order real lowpass to real bandstop frequency mapping.

It also returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the allpass mapping filter. The prototype lowpass filter is given with zeros, `Z`, poles, `P`, and gain factor, `K`.

This transformation effectively places one feature of an original filter, located at frequency $-W_o$, at the required target frequency location, W_{t1}, and the second feature, originally at $+W_o$, at the new location, W_{t2}. It is assumed that W_{t2} is greater than W_{t1}. This transformation implements the "Nyquist Mobility," which means that the DC feature stays at DC, but the Nyquist feature moves to a location dependent on the selection of W_o and W_ts.

Relative positions of other features of an original filter change in the target filter. This means that it is possible to select two features of an original filter, F_1 and F_2, with F_1 preceding F_2. After the transformation feature F_2 will precede F_1 in the target filter. However, the distance between F_1 and F_2 will not be the same before and after the transformation.

Choice of the feature subject to the lowpass to bandstop transformation is not restricted only to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

Examples

Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3,0.1,30,0.409);
z = roots(b);
p = roots(a);
k = b(1);
[z2,p2,k2] = zpklp2bs(z, p, k, 0.5, [0.2 0.3]);
```

Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b, a, k2*poly(z2), poly(p2));
```

Arguments

Variable	Description
Z	Zeros of the prototype lowpass filter
P	Poles of the prototype lowpass filter
K	Gain factor of the prototype lowpass filter
Wo	Frequency value to be transformed from the prototype filter
Wt	Desired frequency location in the transformed target filter
Z2	Zeros of the target filter
P2	Poles of the target filter
K2	Gain factor of the target filter
AllpassNum	Numerator of the mapping filter
AllpassDen	Denominator of the mapping filter

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

zpklp2bsc

Zero-pole-gain lowpass to complex bandstop frequency transformation

Syntax

```
[Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2bsc(Z,P,K,Wo,Wt)
```

Description

`[Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2bsc(Z,P,K,Wo,Wt)` returns zeros, Z_2, poles, P_2, and gain factor, K_2, of the target filter transformed from the real lowpass prototype by applying a first-order real lowpass to complex bandstop frequency transformation.

It also returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the allpass mapping filter. The prototype lowpass filter is given with zeros, `Z`, poles, `P`, and gain factor, `K`.

This transformation effectively places one feature of an original filter, located at frequency $-W_o$, at the required target frequency location, W_{t1}, and the second feature, originally at $+W_o$, at the new location, W_{t2}. It is assumed that W_{t2} is greater than W_{t1}. Additionally the transformation swaps passbands with stopbands in the target filter.

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter, F_1 and F_2, with F_1 preceding F_2. Feature F_1 will still precede F_2 after the transformation. However, the distance between F_1 and F_2 will not be the same before and after the transformation.

Choice of the feature subject to the lowpass to bandstop transformation is not restricted only to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

Lowpass to bandpass transformation can also be used for transforming other types of filters; e.g., real notch filters or resonators can be doubled and positioned at two distinct desired frequencies at any place around the unit circle forming a pair of complex notches/ resonators.

Examples

Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3,0.1,30,0.409);
z = roots(b);
p = roots(a);
k = b(1);
[z2,p2,k2] = zpklp2bsc(z, p, k, 0.5, [0.2, 0.3]);
```

Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b, a, k2*poly(z2), poly(p2));
```

Arguments

Variable	Description
Z	Zeros of the prototype lowpass filter

zpklp2hp

Zero-pole-gain lowpass to highpass frequency transformation

Syntax

```
[Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2hp(Z,P,K,Wo,Wt)
```

Description

`[Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2hp(Z,P,K,Wo,Wt)` returns zeros, Z_2, poles, P_2, and gain factor, K_2, of the target filter transformed from the real lowpass prototype by applying a first-order real lowpass to real highpass frequency mapping. This transformation effectively places one feature of an original filter, located at frequency W_o, at the required target frequency location, W_t, at the same time rotating the whole frequency response by half of the sampling frequency. Result is that the DC and Nyquist features swap places.

It also returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the allpass mapping filter. The prototype lowpass filter is given with zeros, `Z`, poles, `P`, and the gain factor, `K`.

Relative positions of other features of an original filter change in the target filter. This means that it is possible to select two features of an original filter, F_1 and F_2, with F_1 preceding F_2. After the transformation feature F_2 will precede F_1 in the target filter. However, the distance between F_1 and F_2 will not be the same before and after the transformation.

Choice of the feature subject to the lowpass to highpass transformation is not restricted to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, or the deep minimum in the stopband, or other ones.

Lowpass to highpass transformation can also be used for transforming other types of filters; e.g., notch filters or resonators can change their position in a simple way without designing them again.

Examples

Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3,0.1,30,0.409);
z = roots(b);
p = roots(a);
k = b(1);
[z2,p2,k2] = zpklp2hp(z, p, k, 0.5, 0.25);
```

Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b, a, k2*poly(z2), poly(p2));
```

Arguments

Variable	Description
Z	Zeros of the prototype lowpass filter
P	Poles of the prototype lowpass filter
K	Gain factor of the prototype lowpass filter
Wo	Frequency value to be transformed from the prototype filter
Wt	Desired frequency location in the transformed target filter
Z2	Zeros of the target filter
P2	Poles of the target filter
K2	Gain factor of the target filter
AllpassNum	Numerator of the mapping filter
AllpassDen	Denominator of the mapping filter

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

zpklp2lp

Zero-pole-gain lowpass to lowpass frequency transformation

Syntax

```
[Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2lp(Z,P,K,Wo,Wt)
```

Description

`[Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2lp(Z,P,K,Wo,Wt)` returns zeros, Z_2, poles, P_2, and gain factor, K_2, of the target filter transformed from the real lowpass prototype by applying a first-order real lowpass to real lowpass frequency mapping. This transformation effectively places one feature of an original filter, located at frequency W_o, at the required target frequency location, W_t.

It also returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the allpass mapping filter. The prototype lowpass filter is given with zeros, `Z`, poles, `P`, and gain factor, `K`.

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter, F_1 and F_2, with F_1 preceding F_2. Feature F_1 will still precede F_2 after the transformation. However, the distance between F_1 and F_2 will not be the same before and after the transformation.

Choice of the feature subject to the lowpass to lowpass transformation is not restricted to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

Lowpass to lowpass transformation can also be used for transforming other types of filters; e.g., notch filters or resonators can change their position in a simple way without designing them again.

Examples

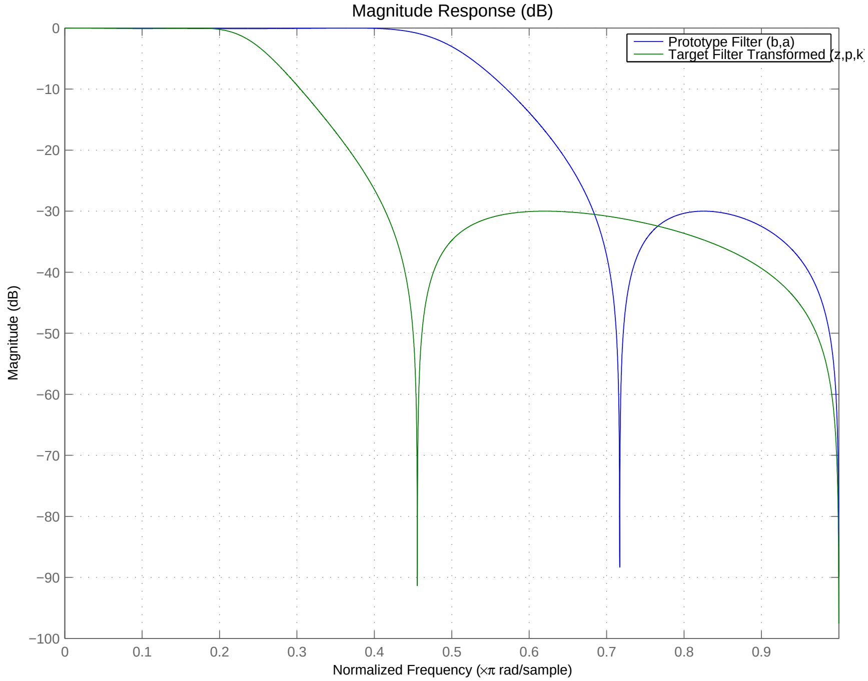
Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3, 0.1, 30, 0.409);
z = roots(b);
p = roots(a);
k = b(1);
[z2,p2,k2] = zpklp2lp(z, p, k, 0.5, 0.25);
```

Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b, a, k2*poly(z2), poly(p2));
```

Using `zpklp2lp` creates the desired half band IIR filter with the transformed features that you specify in the transformation function. This figure shows the results.



Arguments

Variable	Description
Z	Zeros of the prototype lowpass filter

Variable	Description
`P`	Poles of the prototype lowpass filter
`K`	Gain factor of the prototype lowpass filter
`Wo`	Frequency value to be transformed from the prototype filter
`Wt`	Desired frequency location in the transformed target filter
`Z2`	Zeros of the target filter
`P2`	Poles of the target filter
`K2`	Gain factor of the target filter
`AllpassNum`	Numerator of the mapping filter
`AllpassDen`	Denominator of the mapping filter

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

zpklp2mb

Zero-pole-gain lowpass to M-band frequency transformation

Syntax

```
[Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2mb(Z,P,K,Wo,Wt)
[Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2mb(Z,P,K,Wo,Wt,Pass)
```

Description

`[Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2mb(Z,P,K,Wo,Wt)` returns zeros, Z_2, poles, P_2, and gain factor, K_2, of the target filter transformed from the real lowpass prototype by applying an `M`th-order real lowpass to real multibandpass frequency mapping. By default the DC feature is kept at its original location.

`[Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2mb(Z,P,K,Wo,Wt,Pass)` allows you to specify an additional parameter, `Pass`, which chooses between using the “DC Mobility” and the "Nyquist Mobility". In the first case the Nyquist feature stays at its original location and the DC feature is free to move. In the second case the DC feature is kept at an original frequency and the Nyquist feature is allowed to move.

It also returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the allpass mapping filter. The prototype lowpass filter is given with zeros, `Z`, poles, `P`, and gain factor, `K`.

This transformation effectively places one feature of an original filter, located at frequency W_o, at the required target frequency locations, W_{t1},...,W_{tM}.

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter, F_1 and F_2, with F_1 preceding F_2. Feature F_1 will still precede F_2 after the transformation. However, the distance between F_1 and F_2 will not be the same before and after the transformation.

Choice of the feature subject to this transformation is not restricted to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

This transformation can also be used for transforming other types of filters; e.g., notch filters or resonators can be easily replicated at a number of required frequency locations. A good application would be an adaptive tone cancellation circuit reacting to the changing number and location of tones.

Examples

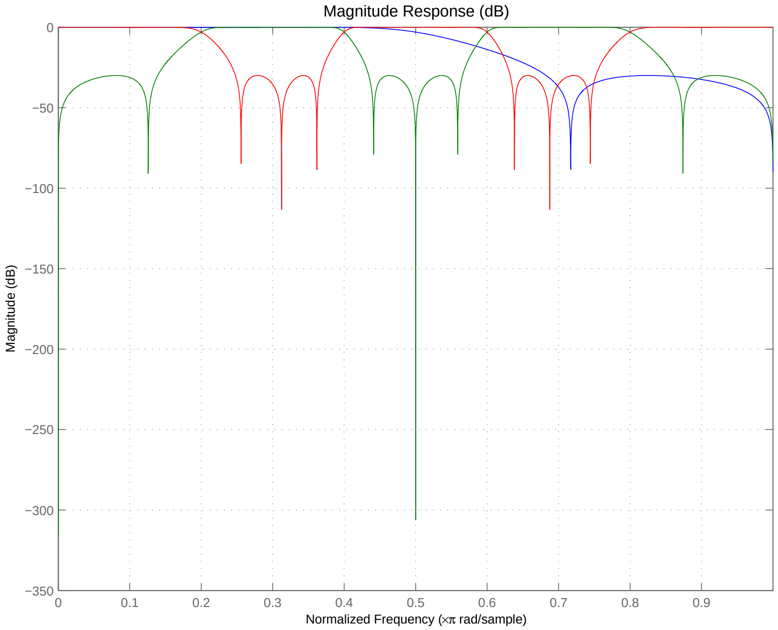
Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3,0.1,30,0.409);
z = roots(b);
p = roots(a);
k = b(1);
[z1,p1,k1] = zpklp2mb(z, p, k, 0.5, [2 4 6 8]/10, 'pass');
[z2,p2,k2] = zpklp2mb(z, p, k, 0.5, [2 4 6 8]/10, 'stop');
```

Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b, a, k1*poly(z1), poly(p1), k2*poly(z2), poly(p2));
```

The resulting multiband filter that replicates features from the prototype appears in the figure shown. Note the accuracy of the replication process.



Arguments

Variable	Description
`Z`	Zeros of the prototype lowpass filter
`P`	Poles of the prototype lowpass filter
`K`	Gain factor of the prototype lowpass filter
`Wo`	Frequency value to be transformed from the prototype filter
`Wt`	Desired frequency location in the transformed target filter
`Pass`	Choice (`'pass'`/`'stop'`) of passband/stopband at DC, `'pass'` being the default
`Z2`	Zeros of the target filter
`P2`	Poles of the target filter
`K2`	Gain factor of the target filter

Variable	Description
AllpassNum	Numerator of the mapping filter
AllpassDen	Denominator of the mapping filter

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

zpklp2mbc

Zero-pole-gain lowpass to complex M-band frequency transformation

Syntax

```
[Z2,P2,K2,AllpassNum,AllpassDen] = zpklpmbc(Z,P,K,Wo,Wt)
```

Description

`[Z2,P2,K2,AllpassNum,AllpassDen] = zpklpmbc(Z,P,K,Wo,Wt)` returns zeros, Z_2, poles, P_2, and gain factor, K_2, of the target filter transformed from the real lowpass prototype by applying an `M`th-order real lowpass to complex multibandpass frequency transformation.

It also returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the allpass mapping filter. The prototype lowpass filter is given with zeros, `Z`, poles, `P`, and gain factor, `K`.

This transformation effectively places one feature of an original filter, located at frequency W_o, at the required target frequency locations, W_{t1},...,W_{tM}.

Choice of the feature subject to this transformation is not restricted to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature, for example, the stopband edge, the DC, the deep minimum in the stopband, or other ones.

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter, F_1 and F_2, with F_1 preceding F_2. Feature F_1 will still precede F_2 after the transformation. However, the distance between F_1 and F_2 will not be the same before and after the transformation.

This transformation can also be used for transforming other types of filters; e.g., to replicate notch filters and resonators at any required location.

Examples

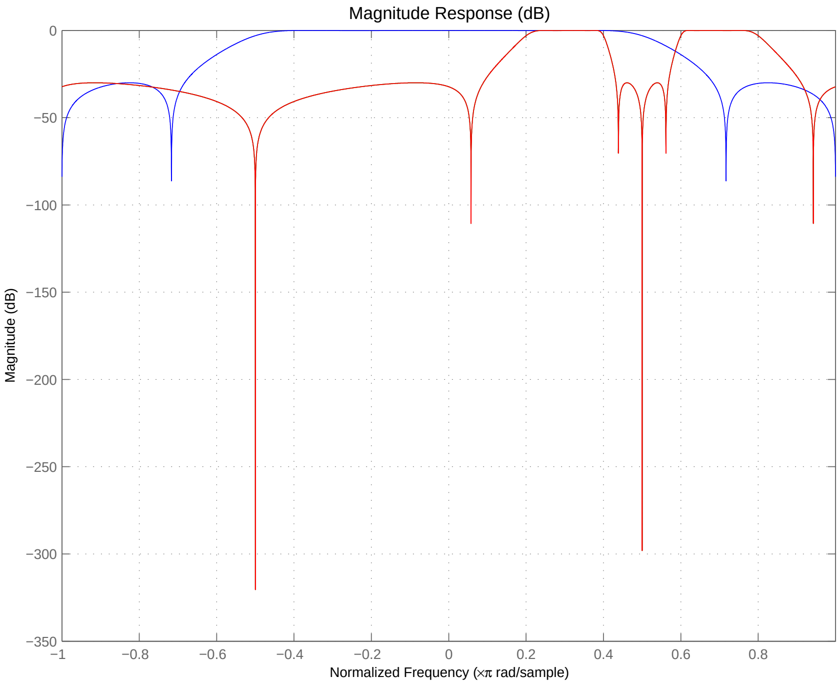
Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3,0.1,30,0.409);
z = roots(b);
p = roots(a);
k = b(1);
[z1,p1,k1] = zpklp2mbc(z, p, k, 0.5, [2 4 6 8]/10);
[z2,p2,k2] = zpklp2mbc(z, p, k, 0.5, [2 4 6 8]/10);
```

Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b, a, k1*poly(z1), poly(p1), k2*poly(z2), poly(p2));
```

You could review the coefficients to compare the filters, but the graphical comparison shown here is quicker and easier.



However, looking at the coefficients in FVTool shows the complex nature desired.

Arguments

Variable	Description
`Z`	Zeros of the prototype lowpass filter
`P`	Poles of the prototype lowpass filter
`K`	Gain factor of the prototype lowpass filter
`Wo`	Frequency value to be transformed from the prototype filter. It should be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.
`Wt`	Desired frequency locations in the transformed target filter. They should be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.
`Z2`	Zeros of the target filter
`P2`	Poles of the target filter
`K2`	Gain factor of the target filter
`AllpassNum`	Numerator of the mapping filter
`AllpassDen`	Denominator of the mapping filter

See Also

`zpkftransf` | `iirlp2mbc` | `allpasslp2mbc`

zpklp2xc

Zero-pole-gain lowpass to complex N-point frequency transformation

Syntax

```
[Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2xc(Z,P,K,Wo,Wt)
```

Description

`[Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2xc(Z,P,K,Wo,Wt)` returns zeros, Z_2, poles, P_2, and gain factor, K_2, of the target filter transformed from the real lowpass prototype by applying an Nth-order real lowpass to complex multipoint frequency transformation.

It also returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the allpass mapping filter. The prototype lowpass filter is given with zeros, `Z`, poles, `P`, and gain factor, `K`.

Parameter `N` also specifies the number of replicas of the prototype filter created around the unit circle after the transformation. This transformation effectively places `N` features of an original filter, located at frequencies W_{o1},...,W_{oN}, at the required target frequency locations, W_{t1},...,W_{tM}.

Relative positions of other features of an original filter are the same in the target filter for the Nyquist mobility and are reversed for the DC mobility. For the Nyquist mobility this means that it is possible to select two features of an original filter, F_1 and F_2, with F_1 preceding F_2. Feature F_1 will still precede F_2 after the transformation. However, the distance between F_1 and F_2 will not be the same before and after the transformation. For DC mobility feature F_2 will precede F_1 after the transformation.

Choice of the feature subject to this transformation is not restricted to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones. The only condition is that the features must be selected in such a way that when creating `N` bands around the unit circle, there will be no band overlap.

This transformation can also be used for transforming other types of filters; e.g., notch filters or resonators can be easily replicated at a number of required frequency locations. A good application would be an adaptive tone cancellation circuit reacting to the changing number and location of tones.

Examples

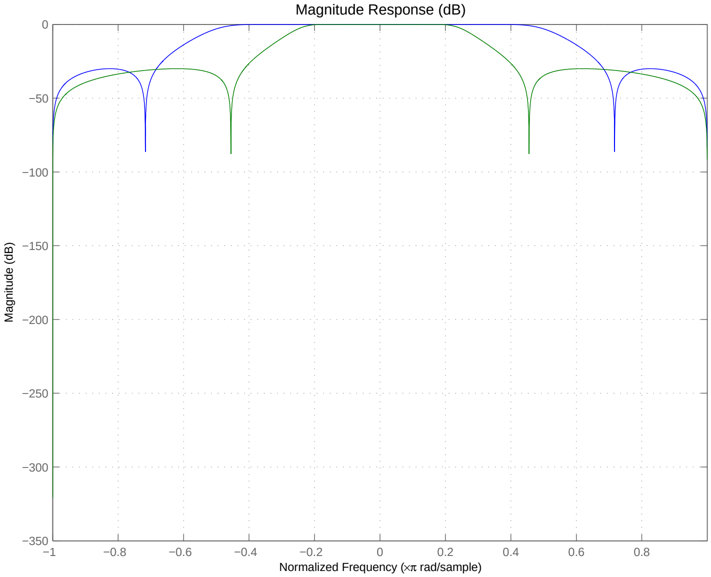
Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3,0.1,30,0.409);
z = roots(b);
p = roots(a);
k = b(1);
[z2,p2,k2] = zpklp2xc(z, p, k, [-0.5 0.5], [-0.25 0.25]);
```

Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b, a, k2*poly(z2), poly(p2));
```

Plotting the filters on the same axes lets you compare the results graphically, shown here.



Arguments

Variable	Description
`Z`	Zeros of the prototype lowpass filter
`P`	Poles of the prototype lowpass filter
`K`	Gain factor of the prototype lowpass filter
`Wo`	Frequency values to be transformed from the prototype filter. They should be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.
`Wt`	Desired frequency locations in the transformed target filter. They should be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.
`Z2`	Zeros of the target filter
`P2`	Poles of the target filter
`K2`	Gain factor of the target filter
`AllpassNum`	Numerator of the mapping filter
`AllpassDen`	Denominator of the mapping filter

zpklp2xn

Zero-pole-gain lowpass to N-point frequency transformation

Syntax

```
[Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2xn(Z,P,K,Wo,Wt)
[Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2xn(Z,P,K,Wo,Wt,Pass)
```

Description

`[Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2xn(Z,P,K,Wo,Wt)` returns zeros, Z_2, poles, P_2, and gain factor, K_2, of the target filter transformed from the real lowpass prototype by applying an `N`th-order real lowpass to real multipoint frequency transformation, where `N` is the number of features being mapped. By default the DC feature is kept at its original location.

`[Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2xn(Z,P,K,Wo,Wt,Pass)` allows you to specify an additional parameter, `Pass`, which chooses between using the "DC Mobility" and the "Nyquist Mobility". In the first case the Nyquist feature stays at its original location and the DC feature is free to move. In the second case the DC feature is kept at an original frequency and the Nyquist feature is allowed to move.

It also returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the allpass mapping filter. The prototype lowpass filter is given with zeros, `Z`, poles, `P`, and gain factor, `K`.

Parameter `N` also specifies the number of replicas of the prototype filter created around the unit circle after the transformation. This transformation effectively places `N` features of an original filter, located at frequencies $W_{o1},...,W_{oN}$, at the required target frequency locations, $W_{t1},...,W_{tM}$.

Relative positions of other features of an original filter are the same in the target filter for the Nyquist mobility and are reversed for the DC mobility. For the Nyquist mobility this means that it is possible to select two features of an original filter, F_1 and F_2, with F_1 preceding F_2. Feature F_1 will still precede F_2 after the transformation. However, the distance between F_1 and F_2 will not be the same before and after the transformation. For DC mobility feature F_2 will precede F_1 after the transformation.

Choice of the feature subject to this transformation is not restricted to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones. The only condition is that the features must be selected in such a way that when creating N bands around the unit circle, there will be no band overlap.

This transformation can also be used for transforming other types of filters; e.g., notch filters or resonators can be easily replicated at a number of required frequency locations. A good application would be an adaptive tone cancellation circuit reacting to the changing number and location of tones.

Examples

Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3,0.1,30,0.409);
z = roots(b);
p = roots(a);
k = b(1);
[z2,p2,k2] = zpklp2xn(z, p, k, [-0.5 0.5], [0 0.25], 'pass');
hfvt = fvtool(b, a, k2*poly(z2), poly(p2));
legend(hfvt,'Original Filter','Half-band Filter');
```

As demonstrated by the figure, the target filter has the desired response shape and values replicated from the prototype.

Arguments

Variable	Description
Z	Zeros of the prototype lowpass filter
P	Poles of the prototype lowpass filter
K	Gain factor of the prototype lowpass filter
Wo	Frequency value to be transformed from the prototype filter
Wt	Desired frequency location in the transformed target filter
Pass	Choice ('pass'/'stop') of passband/stopband at DC, 'pass' being the default
Z2	Zeros of the target filter

Variable	Description
P2	Poles of the target filter
K2	Gain factor of the target filter
AllpassDen	Numerator of the mapping filter
AllpassDen	Denominator of the mapping filter

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

zpkrateup

Zero-pole-gain complex bandpass frequency transformation

Syntax

```
[Z2,P2,K2,AllpassNum,AllpassDen] = zpkrateup(Z,P,K,N)
```

Description

`[Z2,P2,K2,AllpassNum,AllpassDen] = zpkrateup(Z,P,K,N)` returns zeros, Z_2, poles, P_2, and gain factor, K_2, of the target filter being transformed from any prototype by applying an Nth-order rateup frequency transformation, where N is the upsample ratio. Transformation creates N equal replicas of the prototype filter frequency response.

It also returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the allpass mapping filter. The original lowpass filter is given with zeros, Z, poles, P, and gain factor, K.

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter, F_1 and F_2, with F_1 preceding F_2. Feature F_1 will still precede F_2 after the transformation. However, the distance between F_1 and F_2 will not be the same before and after the transformation.

Examples

Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3,0.1,30,0.409);
z = roots(b);
p = roots(a);
k = b(1);
% Upsample the prototype filter 4 times
[z2,p2,k2] = zpkrateup(z, p, k, 4);
% Compare prototype filter with target filter
fvtool(b, a, k2*poly(z2), poly(p2));
```

Arguments

Variable	Description
Z	Zeros of the prototype lowpass filter
P	Poles of the prototype lowpass filter
K	Gain factor of the prototype lowpass filter
N	Integer upsampling ratio
Z2	Zeros of the target filter
P2	Poles of the target filter
K2	Gain factor of the target filter
AllpassNum	Numerator of the mapping filter
AllpassDen	Denominator of the mapping filter

Frequencies must be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.

zpkshift

Zero-pole-gain real shift frequency transformation

Syntax

```
[Z2,P2,K2,AllpassNum,AllpassDen] = zpkshift(Z,P,K,Wo,Wt)
```

Description

`[Z2,P2,K2,AllpassNum,AllpassDen] = zpkshift(Z,P,K,Wo,Wt)` returns the zeros,`Z2` , poles, `P2`, and gain factor, `K2`, of the target filter transformed from the zeros, poles, and gain factor of real lowpass prototype by applying a second-order real shift frequency mapping. It also returns the numerator, `AllpassNum`, and the denominator, `AllpassDen` of the allpass mapping filter.

This transformation places one selected feature of an original filter, located at frequency W_o, at the required target frequency location, W_t. This transformation implements the "DC Mobility," which means that the Nyquist feature stays at Nyquist, but the DC feature moves to a location dependent on the selection of W_o and W_t.

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter, F_1 and F_2, with F_1 preceding F_2. Feature F_1 will still precede F_2 after the transformation. However, the distance between F_1 and F_2 will not be the same before and after the transformation.

Choice of the feature subject to the real shift transformation is not restricted to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

This transformation can also be used for transforming other types of filters; e.g., notch filters or resonators can change their position in a simple way without the need to design them again.

Examples

Rotate frequency response by π/2 radians/sample:

```
[B,A] = ellip(10,0.1,40,0.25);
% Elliptic lowpass filter with passband frequency 0.25*pi rad/sample
Z = roots(B); % get roots of numerator polynomial- filter zeros
P = roots(A); % get roots of denominator polynomial- filter poles
K = B(1);
[Z2,P2,K2] = zpkshift(Z,P,K,0.25,0.75); % shift by 0.25*pi rad/sample
Num = poly(Z2);
Den = poly(P2);
hfvt = fvtool(B,A,K2*Num,Den);
legend(hfvt,'Original Filter','Rotate by \pi/2 radians/sample');
axis([0 1 -90 10]);
```

zpkshiftc

Zero-pole-gain complex shift frequency transformation

Syntax

```
[Z2,P2,K2,AllpassNum,AllpassDen] = zpkshiftc(Z,P,K,Wo,Wt)
[Num,Den,AllpassNum,AllpassDen] = zpkshiftc(Z,P,K,0,0.5)
[Num,Den,AllpassNum,AllpassDen] = zpkshiftc(Z,P,K,0,-0.5)
```

Description

`[Z2,P2,K2,AllpassNum,AllpassDen] = zpkshiftc(Z,P,K,Wo,Wt)` returns zeros, Z_2, poles, P_2, and gain factor, K_2, of the target filter transformed from the real lowpass prototype by applying a first-order complex frequency shift transformation. This transformation rotates all the features of an original filter by the same amount specified by the location of the selected feature of the prototype filter, originally at W_o, placed at W_t in the target filter.

It also returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the allpass mapping filter. The prototype lowpass filter is given with zeros, `Z`, poles, `P`, and the gain factor, `K`.

`[Num,Den,AllpassNum,AllpassDen] = zpkshiftc(Z,P,K,0,0.5)` performs the Hilbert transformation, i.e. a 90 degree counterclockwise rotation of an original filter in the frequency domain.

`[Num,Den,AllpassNum,AllpassDen] = zpkshiftc(Z,P,K,0,-0.5)` performs the inverse Hilbert transformation, i.e. a 90 degree clockwise rotation of an original filter in the frequency domain.

Examples

Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3,0.1,30,0.409);
z = roots(b);
p = roots(a);
k = b(1);
```

Rotation by #/4 Radians/Sample

Rotation by -0.25:

```
[z2,p2,k2] = zpkshiftc(z, p, k, 0.5, 0.25);
hfvt = fvtool(b,a,k2*poly(z2),poly(p2));
```

Rotation by #/2 Radians/Sample

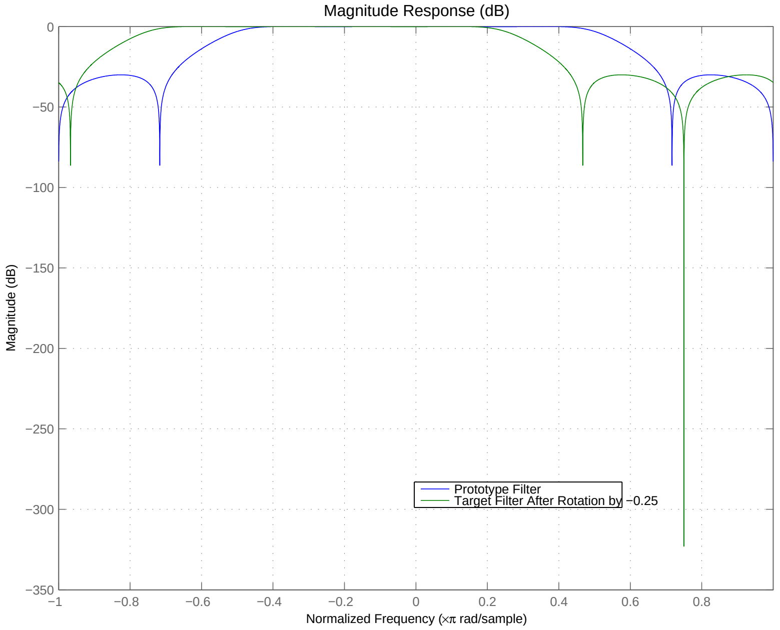
```
[z3,p3,k3] = zpkshiftc(z, p, k, 0, 0.5);
addfilter(hfvt,k3*poly(z3),poly(p3));
legend(hfvt,'Original Filter','Rotation by -\pi/4 radians/sample',...
    'Rotation by \pi/2 radians/sample');
```

Rotation by –#/2 Radians/Sample

```
[z2,p2,k2] = zpkshiftc(z, p, k, 0.5, -0.5);
fvtool(b, a, k2*poly(z2), poly(p2));
```

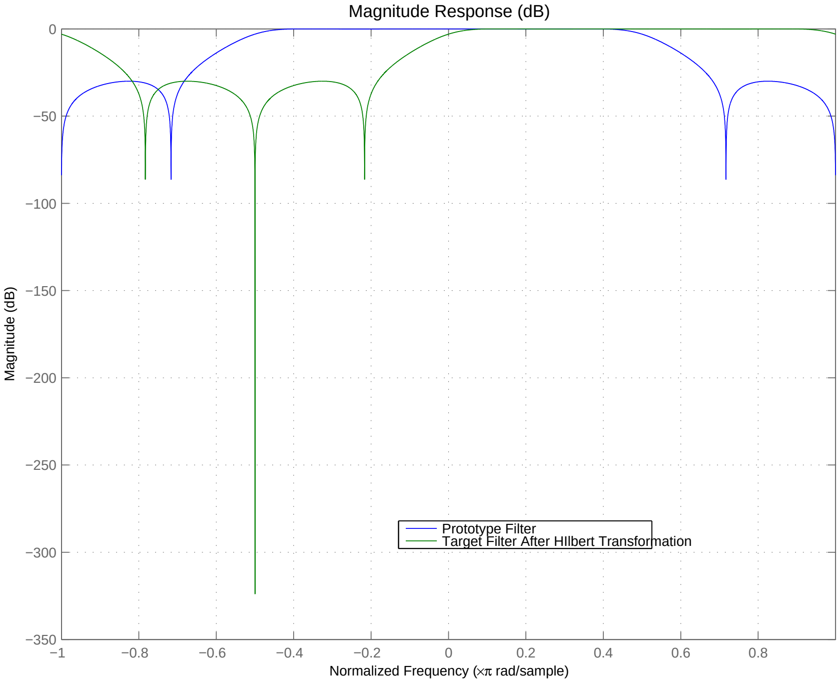
Result of Example 1

After performing the rotation, the resulting filter shows the features desired.



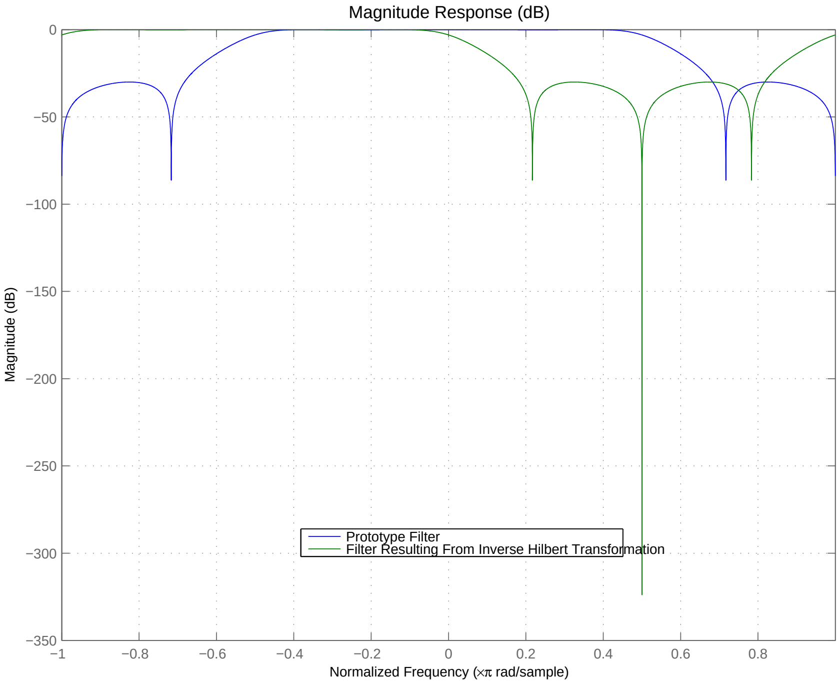
Result of Example 2

Similar to the first example, performing the Hilbert transformation generates the desired target filter, shown here.



Result of Example 3

Finally, using the inverse Hilbert transformation creates yet a third filter, as the figure shows.



Arguments

Variable	Description
`Z`	Zeros of the prototype lowpass filter
`P`	Poles of the prototype lowpass filter
`K`	Gain factor of the prototype lowpass filter
`Wo`	Frequency value to be transformed from the prototype filter
`Wt`	Desired frequency location in the transformed target filter
`Z2`	Zeros of the target filter
`P2`	Poles of the target filter
`K2`	Gain factor of the target filter
`AllpassDen`	Numerator of the mapping filter

Variable	Description
`AllpassDen`	Denominator of the mapping filter

Frequencies must be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.

zplane

Zero-poles plots for filters

Syntax

```
zplane(Hq)
zplane(Hq,plotoption)
zplane(Hq,plotoption,plotoption2)
zplane(Hq,Name,Value)
[zq,pq,kq] = zplane(Hq)
[zq,pq,kq,zr,pr,kr] = zplane(Hq)
```

Description

`zplane(Hq)` plots the zeros and poles of a quantized filter `Hq` in the current figure window. The poles and zeros of the quantized and unquantized filters are plotted by default. The symbol `o` represents a zero of the unquantized reference filter, and the symbol `x` represents a pole of that filter. The symbols □ and `+` are used to plot the zeros and poles of the quantized filter `Hq`. The plot includes the unit circle for reference.

`zplane(Hq,`*`plotoption`*`)` plots the poles and zeros associated with the quantized filter `Hq` according to one specified plot option. The string *`plotoption`* can be either of the following reference filter display options:

- **`'on'`** to display the poles and zeros of both the quantized filter and the associated reference filter (default)
- **`'off'`** to display the poles and zeros of only the quantized filter

`zplane(Hq,`*`plotoption`*`,`*`plotoption2`*`)` plots the poles and zeros associated with the quantized filter `Hq` according to two specified plot options. The string *`plotoption`* can be selected from the reference filter display options listed in the previous syntax. The string *`plotoption2`* can be selected from the section-by-section plotting style options described in the following list:

- **`'individual'`** to display the poles and zeros of each section of the filter in a separate figure window

- **'overlay'** to display the poles and zeros of all sections of the filter on the same plot
- **'tile'** to display the poles and zeros of each section of the filter in a separate plot in the same figure window

zplane(Hq,Name,Value) returns a phase response with additional options specified by one or more Name,Value pair arguments. Name-value pair arguments are only available if Hq is a filter System object.

[zq,pq,kq] = zplane(Hq) returns the vectors of zeros zq, poles pq, and gains kq. If Hq has *n* sections, zq, pq, and kq are returned as 1-by-*n* cell arrays. If there are no zeros (or no poles), zq (or pq) is set to the empty matrix [].

[zq,pq,kq,zr,pr,kr] = zplane(Hq) returns the vectors of zeros zr, poles pr, and gains kr of the reference filter associated with the quantized filter Hq. It also returns the vectors of zeros zq, poles pq, and gains kq for the quantized filter Hq.

Input Arguments

Hq

hfilt is either:

- An adaptive adaptfilt, discrete-time dfilt, or multirate mfilt filter object
- A filter System object.

  The following Filter System objects are supported by this analysis function:

Filter System objects
dsp.FIRFilter
dsp.FIRInterpolator
dsp.CICInterpolator
dsp.FIRDecimator
dsp.CICDecimator
dsp.FIRRateConverter
dsp.BiquadFilter
dsp.IIRFilter

Filter System objects
`dsp.AllpoleFilter`
`dsp.AllpassFilter`
`dsp.CoupledAllpassFilter`

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'Arithmetic'` — Value types:
`‘double’ | 'single' | 'fixed'`

For filter System object inputs only, specify the arithmetic used during analysis. When you specify `'double'` or `'single'`, the function performs double- or single-precision analysis. When you specify `'fixed'` , the arithmetic changes depending on the setting of the `CoefficientDataType` property and whether the System object is locked or unlocked.

Details for Fixed-Point Arithmetic

System Object State	Coefficient Data Type	Rule
Unlocked	`'Same as input'`	The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Unlocked	`'Custom'`	The function performs fixed-point analysis based on the setting of the `CustomCoefficientsDataType` property.

System Object State	Coefficient Data Type	Rule
Locked	'Same as input'	When the input data type is 'double' or 'fixed', the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Locked	'Custom'	The function performs fixed-point analysis based on the setting of the CustomCoefficientsDataType property.

When you do not specify the arithmetic for non-CIC structures, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type. CIC structures only support fixed-point arithmetic.

Output Arguments

zq

Zeros of quantized filter.

pq

Poles of quantized filter.

kq

Gains of quantized filter.

zr

Zeros of reference filter.

pr

Poles of reference filter.

kr

Gains of reference filter.

Examples

Create a quantized filter Hq from a fourth-order digital filter with cutoff frequency of 0.6. Plot the quantized and unquantized poles and zeros associated with this quantized filter.

```
[b,a] = ellip(4,.5,20,.6);
Hq = dfilt.df2(b, a);
Hq.arithmetic = 'fixed';
zplane(Hq);
```

Fixed-Point Filter Properties

Overview of Fixed-Point Filters

There is a distinction between fixed-point filters and quantized filters — quantized filters represent a superset that includes fixed-point filters.

When `dfilt` objects have their `Arithmetic` property set to `single` or `fixed`, they are quantized filters. However, after you set the `Arithmetic` property to `fixed`, the resulting filter is both quantized and fixed-point. Fixed-point filters perform arithmetic operations without allowing the binary point to move in response to the calculation — hence the name fixed-point. You can find out more about fixed-point arithmetic in your Fixed-Point Designer documentation or from the Help system.

With the `Arithmetic` property set to `single`, meaning the filter uses single-precision floating-point arithmetic, the filter allows the binary point to move during mathematical operations, such as sums or products. Therefore these filters cannot be considered fixed-point filters. But they are quantized filters.

The following sections present the properties for fixed-point filters, which includes all the properties for double-precision and single-precision floating-point filters as well.

Fixed-Point Objects and Filters

Fixed-point filters depend in part on fixed-point objects from Fixed-Point Designer software. You can see this when you display a fixed-point filter at the command prompt.

```
hd=dfilt.df2t

hd =

         FilterStructure: 'Direct-Form II Transposed'
              Arithmetic: 'double'
```

```
               Numerator: 1
             Denominator: 1
        PersistentMemory: false
                  States: [0x1 double]

set(hd,'arithmetic','fixed')
hd

hd =

         FilterStructure: 'Direct-Form II Transposed'
              Arithmetic: 'fixed'
               Numerator: 1
             Denominator: 1
        PersistentMemory: false
                  States: [1x1 embedded.fi]

         CoeffWordLength: 16
          CoeffAutoScale: true
                  Signed: true

         InputWordLength: 16
         InputFracLength: 15

        OutputWordLength: 16
        OutputFracLength: 15

         StateWordLength: 16
          StateAutoScale: true

             ProductMode: 'FullPrecision'

         AccumWordLength: 40
           CastBeforeSum: true

               RoundMode: 'convergent'
            OverflowMode: 'wrap'
```

Look at the States property, shown here

```
States: [1x1 embedded.fi]
```

The notation `embedded.fi` indicates that the states are being represented by fixed-point objects, usually called `fi` objects. If you take a closer look at the property `States`, you see how the properties of the `fi` object represent the values for the filter states.

```
hd.states

ans =

[]

              DataType: Fixed
               Scaling: BinaryPoint
                Signed: true
            WordLength: 16
        FractionLength: 15

             RoundMode: round
          OverflowMode: saturate
           ProductMode: FullPrecision
  MaxProductWordLength: 128
               SumMode: FullPrecision
      MaxSumWordLength: 128
         CastBeforeSum: true
```

To learn more about `fi` objects (fixed-point objects) in general, refer to your Fixed-Point Designer documentation.

As inputs (data to be filtered), fixed-point filters accept both regular double-precision values and `fi` objects. Which you use depends on your needs. How your filter responds to the input data is determined by the settings of the filter properties, discussed in the next few sections.

Summary — Fixed-Point Filter Properties

Discrete-time filters in this toolbox use objects that perform the filtering and configuration of the filter. As objects, they include properties and methods that are often referred to as functions — not strictly the same as MATLAB functions but mostly so) to provide filtering capability. In discrete-time filters, or `dfilt` objects, many of the properties are dynamic, meaning they become available depending on the settings of other properties in the `dfilt` object or filter.

Dynamic Properties

When you use a `dfilt.`*`structure`* function to create a filter, MATLAB displays the filter properties in the command window in return (unless you end the command with a semicolon which suppresses the output display). Generally you see six or seven properties, ranging from the property `FilterStructure` to `PersistentMemory`. These first properties are always present in the filter. One of the most important properties is `Arithmetic`. The `Arithmetic` property controls all of the dynamic properties for a filter.

Dynamic properties become available when you change another property in the filter. For example, when you change the `Arithmetic` property value to `fixed`, the display now shows many more properties for the filter, all of them considered dynamic. Here is an example that uses a direct form II filter. First create the default filter:

```
hd=dfilt.df2

hd =

         FilterStructure: 'Direct-Form II'
              Arithmetic: 'double'
               Numerator: 1
             Denominator: 1
        PersistentMemory: false
                  States: [0x1 double]
```

With the filter `hd` in the workspace, convert the arithmetic to fixed-point. Do this by setting the property `Arithmetic` to `fixed`. Notice the display. Instead of a few properties, the filter now has many more, each one related to a particular part of the filter and its operation. Each of the now-visible properties is dynamic.

```
hd.arithmetic='fixed'

hd =

         FilterStructure: 'Direct-Form II'
              Arithmetic: 'fixed'
               Numerator: 1
             Denominator: 1
        PersistentMemory: false
                  States: [1x1 embedded.fi]

         CoeffWordLength: 16
          CoeffAutoScale: true
                  Signed: true

         InputWordLength: 16
         InputFracLength: 15

        OutputWordLength: 16
```

```
          OutputMode: 'AvoidOverflow'

     StateWordLength: 16
     StateFracLength: 15

         ProductMode: 'FullPrecision'

     AccumWordLength: 40
       CastBeforeSum: true

           RoundMode: 'convergent'
        OverflowMode: 'wrap'
```

Even this list of properties is not yet complete. Changing the value of other properties such as the ProductMode or CoeffAutoScale properties may reveal even more properties that control how the filter works. Remember this feature about dfilt objects and dynamic properties as you review the rest of this section about properties of fixed-point filters.

An important distinction is you cannot change the value of a property unless you see the property listed in the default display for the filter. Entering the filter name at the MATLAB prompt generates the default property display for the named filter. Using get(filtername) does not generate the default display — it lists all of the filter properties, both those that you can change and those that are not available yet.

The following table summarizes the properties, static and dynamic, of fixed-point filters and provides a brief description of each. Full descriptions of each property, in alphabetical order, follow the table.

Property Name	Valid Values [Default Value]	Brief Description
AccumFracLength	Any positive or negative integer number of bits [29]	Specifies the fraction length used to interpret data output by the accumulator. This is a property of FIR filters and lattice filters. IIR filters have two similar properties — DenAccumFracLength and NumAccumFracLength — that let you set the precision for numerator and denominator operations separately.
AccumWordLength	Any positive integer number of bits [40]	Sets the word length used to store data in the accumulator/buffer.

Property Name	Valid Values [Default Value]	Brief Description
`Arithmetic`	[Double], single, fixed	Defines the arithmetic the filter uses. Gives you the options `double`, `single`, and `fixed`. In short, this property defines the operating mode for your filter.
`CastBeforeSum`	[True] or false	Specifies whether to cast numeric data to the appropriate accumulator format (as shown in the signal flow diagrams) before performing sum operations.
`CoeffAutoScale`	[True] or false	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to `false` enables you to change the `NumFracLength` and `DenFracLength` properties to specify the precision used.
`CoeffFracLength`	Any positive or negative integer number of bits [14]	Set the fraction length the filter uses to interpret coefficients. `CoeffFracLength` is not available until you set `CoeffAutoScale` to `false`. Scalar filters include this property.
`CoeffWordLength`	Any positive integer number of bits [16]	Specifies the word length to apply to filter coefficients.
`DenAccumFracLength`	Any positive or negative integer number of bits [29]	Specifies how the filter algorithm interprets the results of addition operations involving denominator coefficients.
`DenFracLength`	Any positive or negative integer number of bits [14]	Sets the fraction length the filter uses to interpret denominator coefficients. `DenFracLength` is always available, but it is read-only until you set `CoeffAutoScale` to `false`.
`Denominator`	Any filter coefficient value [1]	Holds the denominator coefficients for IIR filters.

Property Name	Valid Values [Default Value]	Brief Description
DenProdFracLength	Any positive or negative integer number of bits [29]	Specifies how the filter algorithm interprets the results of product operations involving denominator coefficients. You can change this property value after you set ProductMode to SpecifyPrecision.
DenStateFracLength	Any positive or negative integer number of bits [15]	Specifies the fraction length used to interpret the states associated with denominator coefficients in the filter.
FracDelay	Any decimal value between 0 and 1 samples	Specifies the fractional delay provided by the filter, in decimal fractions of a sample.
FDAutoScale	[True] or false	Specifies whether the filter automatically chooses the proper scaling to represent the fractional delay value without overflowing. Turning this off by setting the value to false enables you to change the FDWordLength and FDFracLength properties to specify the data format applied.
FDFracLength	Any positive or negative integer number of bits [5]	Specifies the fraction length to represent the fractional delay.
FDProdFracLength	Any positive or negative integer number of bits [34]	Specifies the fraction length to represent the result of multiplying the coefficients with the fractional delay.
FDProdWordLength	Any positive or negative integer number of bits [39]	Specifies the word length to represent result of multiplying the coefficients with the fractional delay.
FDWordLength	Any positive or negative integer number of bits [6]	Specifies the word length to represent the fractional delay.
DenStateWordLength	Any positive integer number of bits [16]	Specifies the word length used to represent the states associated with denominator coefficients in the filter.

Property Name	Valid Values [Default Value]	Brief Description
`FilterInternals`	`[FullPrecision]`, `SpecifyPrecision`	Controls whether the filter sets the output word and fraction lengths, and the accumulator word and fraction lengths automatically to maintain the best precision results during filtering. The default value, `FullPrecision`, sets automatic word and fraction length determination by the filter. `SpecifyPrecision` exposes the output and accumulator related properties so you can set your own word and fraction lengths for them.
`FilterStructure`	Not applicable.	Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering — gains, delays, sums, products, and input/output.
`InputFracLength`	Any positive or negative integer number of bits [15]	Specifies the fraction length the filter uses to interpret data to be processed by the filter.
`InputWordLength`	Any positive integer number of bits [16]	Specifies the word length applied to represent input data.
`Ladder`	Any ladder coefficients in double-precision data type [1]	`latticearma` filters include this property to store the ladder coefficients.
`LadderAccumFrac Length`	Any positive or negative integer number of bits [29]	`latticearma` filters use this to define the fraction length applied to values output by the accumulator that stores the results of ladder computations.
`LadderFracLength`	Any positive or negative integer number of bits [14]	`latticearma` filters use ladder coefficients in the signal flow. This property determines the fraction length used to interpret the coefficients.
`Lattice`	Any lattice structure coefficients. No default value.	Stores the lattice coefficients for lattice-based filters.

Property Name	Valid Values [Default Value]	Brief Description
`LatticeAccumFracLength`	Any positive or negative integer number of bits [29]	Specifies how the accumulator outputs the results of operations on the lattice coefficients.
`LatticeFracLength`	Any positive or negative integer number of bits [15]	Specifies the fraction length applied to the lattice coefficients.
`MultiplicandFracLength`	Any positive or negative integer number of bits [15]	Sets the fraction length for values used in product operations in the filter. Direct-form I transposed (df1t) filter structures include this property.
`MultiplicandWordLength`	Any positive integer number of bits [16]	Sets the word length applied to the values input to a multiply operation (the multiplicands). The filter structure df1t includes this property.
`NumAccumFracLength`	Any positive or negative integer number of bits [29]	Specifies how the filter algorithm interprets the results of addition operations involving numerator coefficients.
`Numerator`	Any double-precision filter coefficients [1]	Holds the numerator coefficient values for the filter.
`NumFracLength`	Any positive or negative integer number of bits [14]	Sets the fraction length used to interpret the numerator coefficients.
`NumProdFracLength`	Any positive or negative integer number of bits [29]	Specifies how the filter algorithm interprets the results of product operations involving numerator coefficients. You can change the property value after you set `ProductMode` to `SpecifyPrecision`.
`NumStateFracLength`	Any positive or negative integer number of bits [15]	For IIR filters, this defines the fraction length applied to the numerator states of the filter. Specifies the fraction length used to interpret the states associated with numerator coefficients in the filter.

Property Name	Valid Values [Default Value]	Brief Description
`NumStateWordLength`	Any positive integer number of bits [16]	For IIR filters, this defines the word length applied to the numerator states of the filter. Specifies the word length used to interpret the states associated with numerator coefficients in the filter.
`OutputFracLength`	Any positive or negative integer number of bits — [15] or [12] bits depending on the filter structure	Determines how the filter interprets the filtered data. You can change the value of `OutputFracLength` after you set `OutputMode` to `SpecifyPrecision`.
`OutputMode`	[AvoidOverflow], BestPrecision, SpecifyPrecision	Sets the mode the filter uses to scale the filtered input data. You have the following choices: • `AvoidOverflow` — directs the filter to set the output data fraction length to avoid causing the data to overflow. • `BestPrecision` — directs the filter to set the output data fraction length to maximize the precision in the output data. • `SpecifyPrecision` — lets you set the fraction length used by the filtered data.
`OutputWordLength`	Any positive integer number of bits [16]	Determines the word length used for the filtered data.

Property Name	Valid Values [Default Value]	Brief Description
OverflowMode	Saturate or [wrap]	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either saturate (limit the output to the largest positive or negative representable value) or wrap (set overflowing values to the nearest representable value using modular arithmetic. The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow — hey maintain full precision.
ProductFracLength	Any positive or negative integer number of bits [29]	For the output from a product operation, this sets the fraction length used to interpret the numeric data. This property becomes writable (you can change the value) after you set ProductMode to SpecifyPrecision.
ProductMode	[FullPrecision], KeepLSB, KeepMSB, SpecifyPrecision	Determines how the filter handles the output of product operations. Choose from full precision (FullPrecision), or whether to keep the most significant bit (KeepMSB) or least significant bit (KeepLSB) in the result when you need to shorten the data words. For you to be able to set the precision (the fraction length) used by the output from the multiplies, you set ProductMode to SpecifyPrecision.
ProductWordLength	Any positive number of bits. Default is 16 or 32 depending on the filter structure	Specifies the word length to use for the results of multiplication operations. This property becomes writable (you can change the value) after you set ProductMode to SpecifyPrecision.

Property Name	Valid Values [Default Value]	Brief Description
`PersistentMemory`	`True` or `[false]`	Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. `True` is the default setting.
`RoundMode`	[Convergent], ceil, fix, floor, nearest, round	Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths). • `ceil` - Round toward positive infinity. • `convergent` - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software. • `fix` - Round toward zero. • `floor` - Round toward negative infinity. • `nearest` - Round toward nearest. Ties round toward positive infinity. • `round` - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers. The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.

Property Name	Valid Values [Default Value]	Brief Description
ScaleValueFracLength	Any positive or negative integer number of bits [29]	Scale values work with SOS filters. Setting this property controls how your filter interprets the scale values by setting the fraction length. Available only when you disable CoeffAutoScale by setting it to false.
ScaleValues	[2 x 1 double] array with values of 1	Stores the scaling values for sections in SOS filters.
Signed	[True] or false	Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.
sosMatrix	[1 0 0 1 0 0]	Holds the filter coefficients as property values. Displays the matrix in the format [sections x coefficients/section datatype]. A [15x6 double] SOS matrix represents a filter with 6 coefficients per section and 15 sections, using data type double to represent the coefficients.
SectionInputAuto Scale	[True] or false	Specifies whether the filter automatically chooses the proper fraction length to prevent overflow by data entering a section of an SOS filter. Setting this property to false enables you to change the SectionInputFracLength property to specify the precision used. Available only for SOS filters.

Property Name	Valid Values [Default Value]	Brief Description
`SectionInputFrac Length`	Any positive or negative integer number of bits [29]	Section values work with SOS filters. Setting this property controls how your filter interprets the section values between sections of the filter by setting the fraction length. This applies to data entering a section. Compare to Section`OutputFracLength`. Available only when you disable Section`InputAutoScale` by setting it to `false`.
`SectionInputWord Length`	Any positive or negative integer number of bits [29]	Sets the word length used to represent the data moving into a section of an SOS filter.
`SectionOutputAuto Scale`	[True] or false	Specifies whether the filter automatically chooses the proper fraction length to prevent overflow by data leaving a section of an SOS filter. Setting this property to `false` enables you to change the SectionOutputFracLength property to specify the precision used.
`SectionOutputFrac Length`	Any positive or negative integer number of bits [29]	Section values work with SOS filters. Setting this property controls how your filter interprets the section values between sections of the filter by setting the fraction length. This applies to data leaving a section. Compare to Section`InputFracLength`. Available after you disable Section`OutputAutoScale` by setting it to `false`.
`SectionOutputWord Length`	Any positive or negative integer number of bits [32]	Sets the word length used to represent the data moving out of one section of an SOS filter.
`StateFracLength`	Any positive or negative integer number of bits [15]	Lets you set the fraction length applied to interpret the filter states.

Property Name	Valid Values [Default Value]	Brief Description
`States`	[1x1 embedded `fi`]	Contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. Notice that the states use `fi` objects, with the associated properties from those objects. For details, refer to `filtstates` in your Signal Processing Toolbox documentation or in the Help system.
`StateWordLength`	Any positive integer number of bits [16]	Sets the word length used to represent the filter states.
`TapSumFracLength`	Any positive or negative integer number of bits [15]	Sets the fraction length used to represent the filter tap values in addition operations. This is available after you set `TapSumMode` to `false`. Symmetric and antisymmetric FIR filters include this property.
`TapSumMode`	FullPrecision, KeepLSB, [KeepMSB], SpecifyPrecision	Determines how the accumulator outputs stored that involve filter tap weights. Choose from full precision (`FullPrecision`) to prevent overflows, or whether to keep the most significant bits (`KeepMSB`) or least significant bits (`KeepLSB`) when outputting results from the accumulator. To let you set the precision (the fraction length) used by the output from the accumulator, set `FilterInternals` to `SpecifyPrecision`. Symmetric and antisymmetric FIR filters include this property.
`TapSumWordLength`	Any positive number of bits [17]	Sets the word length used to represent the filter tap weights during addition. Symmetric and antisymmetric FIR filters include this property.

Property Details for Fixed-Point Filters

When you create a fixed-point filter, you are creating a filter object (a `dfilt` object). In this manual, the terms filter, `dfilt` object, and filter object are used interchangeably. To filter data, you apply the filter object to your data set. The output of the operation is the data filtered by the filter and the filter property values.

Filter objects have properties to which you assign property values. You use these property values to assign various characteristics to the filters you create, including

- The type of arithmetic to use in filtering operations
- The structure of the filter used to implement the filter (not a property you can set or change — you select it by the `dfilt.`*`structure`* function you choose)
- The locations of quantizations and cast operations in the filter
- The data formats used in quantizing, casting, and filtering operations

Details of the properties associated with fixed-point filters are described in alphabetical order on the following pages.

AccumFracLength

Except for state-space filters, all `dfilt` objects that use fixed arithmetic have this property that defines the fraction length applied to data in the accumulator. Combined with `AccumWordLength`, `AccumFracLength` helps fully specify how the accumulator outputs data after processing addition operations. As with all fraction length properties, `AccumFracLength` can be any integer, including integers larger than `AccumWordLength`, and positive or negative integers.

AccumWordLength

You use `AccumWordLength` to define the data word length used in the accumulator. Set this property to a value that matches your intended hardware. For example, many digital signal processors use 40-bit accumulators, so set `AccumWordLength` to 40 in your fixed-point filter:

```
set(hq,'arithmetic','fixed');
set(hq,'AccumWordLength',40);
```

Note that `AccumWordLength` only applies to filters whose `Arithmetic` property value is `fixed`.

Arithmetic

Perhaps the most important property when you are working with `dfilt` objects, `Arithmetic` determines the type of arithmetic the filter uses, and the properties or quantizers that compose the fixed-point or quantized filter. You use strings to set the `Arithmetic` property value.

The next table shows the valid strings for the Arithmetic property. Following the table, each property string appears with more detailed information about what happens when you select the string as the value for `Arithmetic` in your `dfilt`.

Arithmetic Property String	Brief Description of Effect on the Filter
`double`	All filtering operations and coefficients use double-precision floating-point representations and math. When you use `dfilt.`*`structure`* to create a filter object, `double` is the default value for the `Arithmetic` property.
`single`	All filtering operations and coefficients use single-precision floating-point representations and math.
`fixed`	This string applies selected default values for the properties in the fixed-point filter object, including such properties as coefficient word lengths, fraction lengths, and various operating modes. Generally, the default values match those you use on many digital signal processors. Allows signed fixed data types only. Fixed-point arithmetic filters are available only when you install Fixed-Point Designer software with this toolbox.

double

When you use one of the `dfilt.`*`structure`* methods to create a filter, the `Arithmetic` property value is `double` by default. Your filter is identical to the same filter without the `Arithmetic` property, as you would create if you used Signal Processing Toolbox software.

`Double` means that the filter uses double-precision floating-point arithmetic in all operations while filtering:

- All input to the filter must be double data type. Any other data type returns an error.
- The states and output are doubles as well.

- All internal calculations are done in double math.

When you use `double` data type filter coefficients, the reference and quantized (fixed-point) filter coefficients are identical. The filter stores the reference coefficients as double data type.

single

When your filter should use single-precision floating-point arithmetic, set the `Arithmetic` property to `single` so all arithmetic in the filter processing gets restricted to single-precision data type.

- Input data must be single data type. Other data types return errors.
- The filter states and filter output use single data type.

When you choose `single`, you can provide the filter coefficients in either of two ways:

- Double data type coefficients. With `Arithmetic` set to `single`, the filter casts the double data type coefficients to single data type representation.
- Single data type. These remain unchanged by the filter.

Depending on whether you specified single or double data type coefficients, the reference coefficients for the filter are stored in the data type you provided. If you provide coefficients in double data type, the reference coefficients are double as well. Providing single data type coefficients generates single data type reference coefficients. Note that the arithmetic used by the reference filter is always double.

When you use `reffilter` to create a reference filter from the reference coefficients, the resulting filter uses double-precision versions of the reference filter coefficients.

To set the `Arithmetic` property value, create your filter, then use `set` to change the `Arithmetic` setting, as shown in this example using a direct form FIR filter.

```
b=fir1(7,0.45);

hd=dfilt.dffir(b)

hd =

         FilterStructure: 'Direct-Form FIR'
              Arithmetic: 'double'
               Numerator: [1x8 double]
        PersistentMemory: false
```

```
                 States: [7x1 double]

set(hd,'arithmetic','single')
hd

hd =

         FilterStructure: 'Direct-Form FIR'
              Arithmetic: 'single'
               Numerator: [1x8 double]
        PersistentMemory: false
                  States: [7x1 single]
```

fixed

Converting your dfilt object to use fixed arithmetic results in a filter structure that uses properties and property values to match how the filter would behave on digital signal processing hardware.

Note The fixed option for the property Arithmetic is available only when you install Fixed-Point Designer software as well as DSP System Toolbox software.

After you set Arithmetic to fixed, you are free to change any property value from the default value to a value that more closely matches your needs. You cannot, however, mix floating-point and fixed-point arithmetic in your filter when you select fixed as the Arithmetic property value. Choosing fixed restricts you to using either fixed-point or floating point throughout the filter (the data type must be homogenous). Also, all data types must be signed. fixed does not support unsigned data types except for unsigned coefficients when you set the property Signed to false. Mixing word and fraction lengths within the fixed object is acceptable. In short, using fixed arithmetic assumes

- fixed word length.
- fixed size and dedicated accumulator and product registers.
- the ability to do either saturation or wrap arithmetic.
- that multiple rounding modes are available.

Making these assumptions simplifies your job of creating fixed-point filters by reducing repetition in the filter construction process, such as only requiring you to enter the accumulator word size once, rather than for each step that uses the accumulator.

Default property values are a starting point in tailoring your filter to common hardware, such as choosing 40-bit word length for the accumulator, or 16-bit words for data and coefficients.

In this `dfilt` object example, `get` returns the default values for `dfilt.df1t` structures.

```
[b,a]=butter(6,0.45);
hd=dfilt.df1(b,a)

hd =

         FilterStructure: 'Direct-Form I'
              Arithmetic: 'double'
               Numerator: [1x7 double]
             Denominator: [1x7 double]
        PersistentMemory: false
                  States: Numerator:  [6x1 double]
                          Denominator:[6x1 double]

set(hd,'arithmetic','fixed')
get(hd)
        PersistentMemory: false
         FilterStructure: 'Direct-Form I'
                  States: [1x1 filtstates.dfiir]
               Numerator: [1x7 double]
             Denominator: [1x7 double]
              Arithmetic: 'fixed'
         CoeffWordLength: 16
          CoeffAutoScale: 1
                  Signed: 1

            OverflowMode: 'wrap'
         InputWordLength: 16
         InputFracLength: 15
             ProductMode: 'FullPrecision'
        OutputWordLength: 16
        OutputFracLength: 15
           NumFracLength: 16
           DenFracLength: 14
       ProductWordLength: 32
       NumProdFracLength: 31
       DenProdFracLength: 29
         AccumWordLength: 40
```

```
      NumAccumFracLength: 31
      DenAccumFracLength: 29
           CastBeforeSum: 1
```

Here is the default display for hd.

```
hd

hd =

         FilterStructure: 'Direct-Form I'
              Arithmetic: 'fixed'
               Numerator: [1x7 double]
             Denominator: [1x7 double]
        PersistentMemory: false
                  States: Numerator:  [6x1 fi]
                          Denominator:[6x1 fi]

         CoeffWordLength: 16
          CoeffAutoScale: true
                  Signed: true

         InputWordLength: 16
         InputFracLength: 15

        OutputWordLength: 16
        OutputFracLength: 15

             ProductMode: 'FullPrecision'

         AccumWordLength: 40
           CastBeforeSum: true

               RoundMode: 'convergent'
            OverflowMode: 'wrap'
```

This second example shows the default property values for dfilt.latticemamax filter objects, using the coefficients from an fir1 filter.

```
b=fir1(7,0.45)

hdlat=dfilt.latticemamax(b)
```

```
hdlat =

         FilterStructure: [1x45 char]
              Arithmetic: 'double'
                 Lattice: [1x8 double]
        PersistentMemory: false
                  States: [8x1 double]

hdlat.arithmetic='fixed'

hdlat =

         FilterStructure: [1x45 char]
              Arithmetic: 'fixed'
                 Lattice: [1x8 double]
        PersistentMemory: false
                  States: [1x1 embedded.fi]

         CoeffWordLength: 16
          CoeffAutoScale: true
                  Signed: true

         InputWordLength: 16
         InputFracLength: 15

        OutputWordLength: 16
              OutputMode: 'AvoidOverflow'

         StateWordLength: 16
         StateFracLength: 15

             ProductMode: 'FullPrecision'

         AccumWordLength: 40
           CastBeforeSum: true

               RoundMode: 'convergent'
            OverflowMode: 'wrap'
```

Unlike the `single` or `double` options for `Arithmetic`, `fixed` uses properties to define the word and fraction lengths for each portion of your filter. By changing the property value of any of the properties, you control your filter performance. Every word length and fraction length property is independent — set the one you need and the others remain unchanged, such as setting the input word length with InputWordLength, while leaving the fraction length the same.

```
d=fdesign.lowpass('n,fc',6,0.45)

d =

               Response: 'Lowpass with cutoff'
          Specification: 'N,Fc'

```

Notice that the properties for the lattice filter `hdlat` and direct-form II filter `hd` are different, as befits their differing filter structures. Also, some properties are common to both objects, such as `RoundMode` and `PersistentMemory` and behave the same way in both objects.

Notes About Fraction Length, Word Length, and Precision

Word length and fraction length combine to make the format for a fixed-point number, where word length is the number of bits used to represent the value and fraction length specifies, in bits, the location of the binary point in the fixed-point representation. Therein lies a problem — fraction length, which you specify in bits, can be larger than the word length, or a negative number of bits. This section explains how that idea works and how you might use it.

Unfortunately fraction length is somewhat misnamed (although it continues to be used in this User's Guide and elsewhere for historical reasons).

Fraction length defined as the number of fractional bits (bits to the right of the binary point) is true only when the fraction length is positive and less than or equal to the word length. In MATLAB format notation you can use [word length fraction length]. For example, for the format [16 16], the second 16 (the fraction length) is the number of fractional bits or bits to the right of the binary point. In this example, all 16 bits are to the right of the binary point.

But it is also possible to have fixed-point formats of [16 18] or [16 -45]. In these cases the fraction length can no longer be the number of bits to the right of the binary point since the format says the word length is 16 — there cannot be 18 fraction length bits on the right. And how can there be a negative number of bits for the fraction length, such as [16 -45]?

A better way to think about fixed-point format [word length fraction length] and what it means is that the representation of a fixed-point number is a weighted sum of powers of two driven by the fraction length, or the two's complement representation of the fixed-point number.

Consider the format [B L], where the fraction length L can be positive, negative, 0, greater than B (the word length) or less than B. (B and L are always integers and B is always positive.)

Given a binary string b(1) b(2) b(3) ... b(B), to determine the two's-complement value of the string in the format described by [B L], use the value of the individual bits in the binary string in the following formula, where b(1) is the first binary bit (and most significant bit, MSB), b(2) is the second, and on up to b(B).

The decimal numeric value that those bits represent is given by

```
value =-b(1)*2^(B-L-1)+b(2)*2^(B-L-2)+b(3)*2^(B-L-3)+...+ b(B)*2^(-L)
```

L, the fraction length, represents the negative of the weight of the last, or least significant bit (LSB). L is also the step size or the precision provided by a given fraction length.

Precision

Here is how precision works.

When all of the bits of a binary string are zero except for the LSB (which is therefore equal to one), the value represented by the bit string is given by $2^{(-L)}$. If L is negative, for example L=-16, the value is 2^{16}. The smallest step between numbers that can be represented in a format where L=-16 is given by 1 x 2^{16} (the rightmost term in the formula above), which is 65536. Note the precision does not depend on the word length.

Take a look at another example. When the word length set to 8 bits, the decimal value 12 is represented in binary by 00001100. That 12 is the decimal equivalent of 00001100 tells you that you are using [8 0] data format representation — the word length is 8 bits and fraction length 0 bits, and the step size or precision (the smallest difference between two adjacent values in the format [8,0], is 2^0=1.

Suppose you plan to keep only the upper 5 bits and discard the other three. The resulting precision after removing the right-most three bits comes from the weight of the lowest remaining bit, the fifth bit from the left, which is 2^3=8, so the format would be [5,-3].

Note that in this format the step size is 8, I cannot represent numbers that are between multiples of 8.

In MATLAB, with Fixed-Point Designer software installed:

```
x=8;
q=quantizer([8,0]); % Word length = 8, fraction length = 0
xq=quantize(q,x);
binxq=num2bin(q,xq);
q1=quantizer([5 -3]); % Word length = 5, fraction length = -3
xq1 = quantize(q1,xq);
binxq1=num2bin(q1,xq1);
binxq

binxq =

00001000

binxq1

binxq1 =

00001
```

But notice that in [5,-3] format, 00001 is the two's complement representation for 8, not for 1; `q = quantizer([8 0])` and `q1 = quantizer([5 -3])` are not the same. They cover the about the same range — `range(q)>range(q1)` — but their quantization step is different — `eps(q)`= 8, and `eps(q1)=1`.

Look at one more example. When you construct a quantizer `q`

```
q = quantizer([a,b])
```

the first element in `[a,b]` is `a`, the word length used for quantization. The second element in the expression, `b`, is related to the quantization step — the numerical difference between the two closest values that the quantizer can represent. This is also related to the weight given to the LSB. Note that `2^(-b)` = `eps(q)`.

Now construct two quantizers, q1 and q2. Let q1 use the format [32,0] and let q2 use the format [16, -16].

```
q1 = quantizer([32,0])
q2 = quantizer([16,-16])
```

Quantizers q1 and q2 cover the same range, but q2 has less precision. It covers the range in steps of 2^{16}, while q covers the range in steps of 1.

This lost precision is due to (or can be used to model) throwing out 16 least-significant bits.

An important point to understand is that in dfilt objects and filtering you control which bits are carried from the sum and product operations in the filter to the filter output by setting the format for the output from the sum or product operation.

For instance, if you use [16 0] as the output format for a 32-bit result from a sum operation when the original format is [32 0], you take the lower 16 bits from the result. If you use [16 -16], you take the higher 16 bits of the original 32 bits. You could even take 16 bits somewhere in between the 32 bits by choosing something like [16 -8], but you probably do not want to do that.

Filter scaling is directly implicated in the format and precision for a filter. When you know the filter input and output formats, as well as the filter internal formats, you can scale the inputs or outputs to stay within the format ranges. For more information about scaling filters, refer to “Floating-Point to Fixed-Point Filter Conversion”.

Notice that overflows or saturation might occur at the filter input, filter output, or within the filter itself, such as during add or multiply or accumulate operations. Improper scaling at any point in the filter can result in numerical errors that dramatically change the performance of your fixed-point filter implementation.

CastBeforeSum

Setting the CastBeforeSum property determines how the filter handles the input values to sum operations in the filter. After you set your filter Arithmetic property value to fixed, you have the option of using CastBeforeSum to control the data type of some inputs (addends) to summations in your filter. To determine which addends reflect the CastBeforeSum property setting, refer to the reference page for the signal flow diagram for the filter structure.

CastBeforeSum specifies whether to cast selected addends to summations in the filter to the output format from the addition operation before performing the addition. When you specify `true` for the property value, the results of the affected sum operations match most closely the results found on most digital signal processors. Performing the cast operation before the summation adds one or two additional quantization operations that can add error sources to your filter results.

Specifying `CastBeforeSum` to be `false` prevents the addends from being cast to the output format before the addition operation. Choose this setting to get the most accurate results from summations without considering the hardware your filter might use.

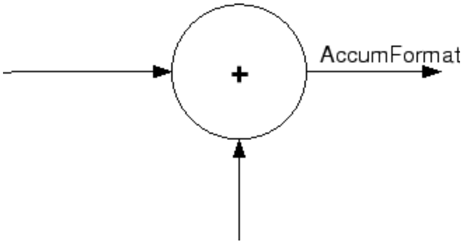
Notice that the output format for every sum operation reflects the value of the output property specified in the filter structure diagram. Which input property is referenced by `CastBeforeSum` depends on the structure.

Property Value	Description
`false`	Configures filter summation operations to retain the addends in the format carried from the previous operation.
`true`	Configures filter summation operations to convert the input format of the addends to match the summation output format before performing the summation operation. Usually this generates results from the summation that more closely match those found from digital signal processors

Another point — with `CastBeforeSum` set to `false`, the filter realization process inserts an intermediate data type format to hold temporarily the full precision sum of the inputs. A separate Convert block performs the process of casting the addition result to the accumulator format. This intermediate data format occurs because the Sum block in Simulink always casts input (addends) to the output data type.

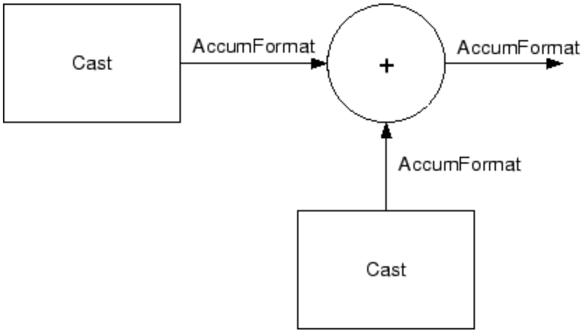
Diagrams of CastBeforeSum Settings

When `CastBeforeSum` is `false`, sum elements in filter signal flow diagrams look like this:



showing that the input data to the sum operations (the addends) retain their format word length and fraction length from previous operations. The addition process uses the existing input formats and then casts the output to the format defined by `AccumFormat`. Thus the output data has the word length and fraction length defined by `AccumWordLength` and `AccumFracLength`.

When `CastBeforeSum` is `true`, sum elements in filter signal flow diagrams look like this:



showing that the input data gets recast to the accumulator format word length and fraction length (AccumFormat) before the sum operation occurs. The data output by the addition operation has the word length and fraction length defined by `AccumWordLength` and `AccumFracLength`.

CoeffAutoScale

How the filter represents the filter coefficients depends on the property value of `CoeffAutoScale`. When you create a `dfilt` object, you use coefficients in double-precision format. Converting the `dfilt` object to fixed-point arithmetic forces the coefficients into a fixed-point representation. The representation the filter uses depends on whether the value of `CoeffAutoScale` is `true` or `false`.

- `CoeffAutoScale` = `true` means the filter chooses the fraction length to maintain the value of the coefficients as close to the double-precision values as possible. When you change the word length applied to the coefficients, the filter object changes the fraction length to try to accommodate the change. `true` is the default setting.
- `CoeffAutoScale` = `false` removes the automatic scaling of the fraction length for the coefficients and exposes the property that controls the coefficient fraction length

so you can change it. For example, if the filter is a direct form FIR filter, setting CoeffAutoScale = false exposes the NumFracLength property that specifies the fraction length applied to numerator coefficients. If the filter is an IIR filter, setting CoeffAutoScale = false exposes both the NumFracLength and DenFracLength properties.

Here is an example of using CoeffAutoScale with a direct form filter.

```
hd2=dfilt.dffir([0.3 0.6 0.3])

hd2 =

         FilterStructure: 'Direct-Form FIR'
              Arithmetic: 'double'
               Numerator: [0.3000 0.6000 0.3000]
        PersistentMemory: false
                  States: [2x1 double]

hd2.arithmetic='fixed'

hd2 =

         FilterStructure: 'Direct-Form FIR'
              Arithmetic: 'fixed'
               Numerator: [0.3000 0.6000 0.3000]
        PersistentMemory: false
                  States: [1x1 embedded.fi]

         CoeffWordLength: 16
          CoeffAutoScale: true
                  Signed: true

         InputWordLength: 16
         InputFracLength: 15

        OutputWordLength: 16
              OutputMode: 'AvoidOverflow'

             ProductMode: 'FullPrecision'

         AccumWordLength: 40
           CastBeforeSum: true

               RoundMode: 'convergent'
```

```
            OverflowMode: 'wrap'
```

To this point, the filter coefficients retain the original values from when you created the filter as shown in the `Numerator` property. Now change the `CoeffAutoScale` property value from `true` to `false`.

```
hd2.coeffautoScale=false

hd2 =

         FilterStructure: 'Direct-Form FIR'
              Arithmetic: 'fixed'
               Numerator: [0.3000 0.6000 0.3000]
        PersistentMemory: false
                  States: [1x1 embedded.fi]

         CoeffWordLength: 16
          CoeffAutoScale: false
           NumFracLength: 15
                  Signed: true

         InputWordLength: 16
         InputFracLength: 15

        OutputWordLength: 16
              OutputMode: 'AvoidOverflow'

             ProductMode: 'FullPrecision'

         AccumWordLength: 40
           CastBeforeSum: true

               RoundMode: 'convergent'
            OverflowMode: 'wrap'
```

With the `NumFracLength` property now available, change the word length to 5 bits.

Notice the coefficient values. Setting `CoeffAutoScale` to `false` removes the automatic fraction length adjustment and the filter coefficients cannot be represented by the current format of [5 15] — a word length of 5 bits, fraction length of 15 bits.

```
hd2.coeffwordlength=5

hd2 =
         FilterStructure: 'Direct-Form FIR'
              Arithmetic: 'fixed'
               Numerator: [4.5776e-004 4.5776e-004 4.5776e-004]
        PersistentMemory: false
                  States: [1x1 embedded.fi]

         CoeffWordLength: 5
          CoeffAutoScale: false
           NumFracLength: 15
                  Signed: true

         InputWordLength: 16
         InputFracLength: 15

        OutputWordLength: 16
              OutputMode: 'AvoidOverflow'

             ProductMode: 'FullPrecision'

         AccumWordLength: 40
           CastBeforeSum: true

               RoundMode: 'convergent'
            OverflowMode: 'wrap'
```

Restoring `CoeffAutoScale` to `true` goes some way to fixing the coefficient values. Automatically scaling the coefficient fraction length results in setting the fraction length to 4 bits. You can check this with `get(hd2)` as shown below.

```
hd2.coeffautoScale=true

hd2 =

         FilterStructure: 'Direct-Form FIR'
              Arithmetic: 'fixed'
               Numerator: [0.3125 0.6250 0.3125]
        PersistentMemory: false
                  States: [1x1 embedded.fi]

         CoeffWordLength: 5
          CoeffAutoScale: true
                  Signed: true
         InputWordLength: 16
         InputFracLength: 15

        OutputWordLength: 16
              OutputMode: 'AvoidOverflow'

             ProductMode: 'FullPrecision'

         AccumWordLength: 40
           CastBeforeSum: true

               RoundMode: 'convergent'
            OverflowMode: 'wrap'

get(hd2)
        PersistentMemory: false
FilterStructure: 'Direct-Form FIR'
                  States: [1x1 embedded.fi]
               Numerator: [0.3125 0.6250 0.3125]
              Arithmetic: 'fixed'
         CoeffWordLength: 5
          CoeffAutoScale: 1
                  Signed: 1
               RoundMode: 'convergent'
            OverflowMode: 'wrap'
         InputWordLength: 16
         InputFracLength: 15
        OutputWordLength: 16
              OutputMode: 'AvoidOverflow'
             ProductMode: 'FullPrecision'
           NumFracLength: 4
        OutputFracLength: 12
       ProductWordLength: 21
       ProductFracLength: 19
         AccumWordLength: 40
         AccumFracLength: 19
           CastBeforeSum: 1
```

Clearly five bits is not enough to represent the coefficients accurately.

CoeffFracLength

Fixed-point scalar filters that you create using `dfilt.scalar` use this property to define the fraction length applied to the scalar filter coefficients. Like the coefficient-fraction-length-related properties for the FIR, lattice, and IIR filters, CoeffFracLength is not displayed for scalar filters until you set CoeffAutoScale to false. Once you change the automatic scaling you can set the fraction length for the coefficients to any value you require.

As with all fraction length properties, the value you enter here can be any negative or positive integer, or zero. Fraction length can be larger than the associated word length, as well. By default, the value is 14 bits, with the CoeffWordlength of 16 bits.

CoeffWordLength

One primary consideration in developing filters for hardware is the length of a data word. CoeffWordLength defines the word length for these data storage and arithmetic locations:

- Numerator and denominator filter coefficients
- Tap sum in dfilt.dfsymfir and dfilt.dfasymfir filter objects
- Section input, multiplicand, and state values in direct-form SOS filter objects such as dfilt.df1t and dfilt.df2
- Scale values in second-order filters
- Lattice and ladder coefficients in lattice filter objects, such as dfilt.latticearma and dfilt.latticemamax
- Gain in dfilt.scalar

Setting this property value controls the word length for the data listed. In most cases, the data words in this list have separate fraction length properties to define the associated fraction lengths.

Any positive, integer word length works here, limited by the machine you use to develop your filter and the hardware you use to deploy your filter.

DenAccumFracLength

Filter structures df1, df1t, df2, and df2t that use fixed arithmetic have this property that defines the fraction length applied to denominator coefficients in the accumulator. In combination with AccumWordLength, the properties fully specify how the accumulator outputs data stored there.

As with all fraction length properties, DenAccumFracLength can be any integer, including integers larger than AccumWordLength, and positive or negative integers.

To be able to change the property value for this property, you set FilterInternals to SpecifyPrecision.

DenFracLength

Property DenFracLength contains the value that specifies the fraction length for the denominator coefficients for your filter. DenFracLength specifies the fraction length used to interpret the data stored in C. Used in combination with CoeffWordLength, these two properties define the interpretation of the coefficients stored in the vector that contains the denominator coefficients.

As with all fraction length properties, the value you enter here can be any negative or positive integer, or zero. Fraction length can be larger than the associated word length, as well. By default, the value is 15 bits, with the CoeffWordLength of 16 bits.

Denominator

The denominator coefficients for your IIR filter, taken from the prototype you start with, are stored in this property. Generally this is a 1-by-N array of data in double format, where N is the length of the filter.

All IIR filter objects include Denominator, except the lattice-based filters which store their coefficients in the Lattice property, and second-order section filters, such as dfilt.df1tsos, which use the SosMatrix property to hold the coefficients for the sections.

DenProdFracLength

A property of all of the direct form IIR dfilt objects, except the ones that implement second-order sections, DenProdFracLength specifies the fraction length applied to data output from product operations that the filter performs on denominator coefficients.

Looking at the signal flow diagram for the dfilt.df1t filter, for example, you see that denominators and numerators are handled separately. When you set ProductMode to SpecifyPrecision, you can change the DenProdFracLength setting manually. Otherwise, for multiplication operations that use the denominator coefficients, the filter sets the fraction length as defined by the ProductMode setting.

DenStateFracLength

When you look at the flow diagram for the dfilt.df1sos filter object, the states associated with denominator coefficient operations take the fraction length from this property. In combination with the `DenStateWordLength` property, these properties fully specify how the filter interprets the states.

As with all fraction length properties, the value you enter here can be any negative or positive integer, or zero. Fraction length can be larger than the associated word length, as well. By default, the value is 15 bits, with the `DenStateWordLength` of 16 bits.

DenStateWordLength

When you look at the flow diagram for the `dfilt.df1sos` filter object, the states associated with the denominator coefficient operations take the data format from this property and the `DenStateFracLength` property. In combination, these properties fully specify how the filter interprets the state it uses.

By default, the value is 16 bits, with the `DenStateFracLength` of 15 bits.

FilterInternals

Similar to the FilterInternals pane in FDATool, this property controls whether the filter sets the output word and fraction lengths automatically, and the accumulator word and fraction lengths automatically as well, to maintain the best precision results during filtering. The default value, `FullPrecision`, sets automatic word and fraction length determination by the filter. Setting `FilterInternals` to `SpecifyPrecision` exposes the output and accumulator related properties so you can set your own word and fraction lengths for them. Note that

FilterStructure

Every `dfilt` object has a `FilterStructure` property. This is a read-only property containing a string that declares the structure of the filter object you created.

When you construct filter objects, the `FilterStructure` property value is returned containing one of the strings shown in the following table. Property `FilterStructure` indicates the filter architecture and comes from the constructor you use to create the filter.

After you create a filter object, you cannot change the `FilterStructure` property value. To make filters that use different structures, you construct new filters using the appropriate methods, or use `convert` to switch to a new structure.

Default value

Since this depends on the constructor you use and the constructor includes the filter structure definition, there is no default value. When you try to create a filter without specifying a structure, MATLAB returns an error.

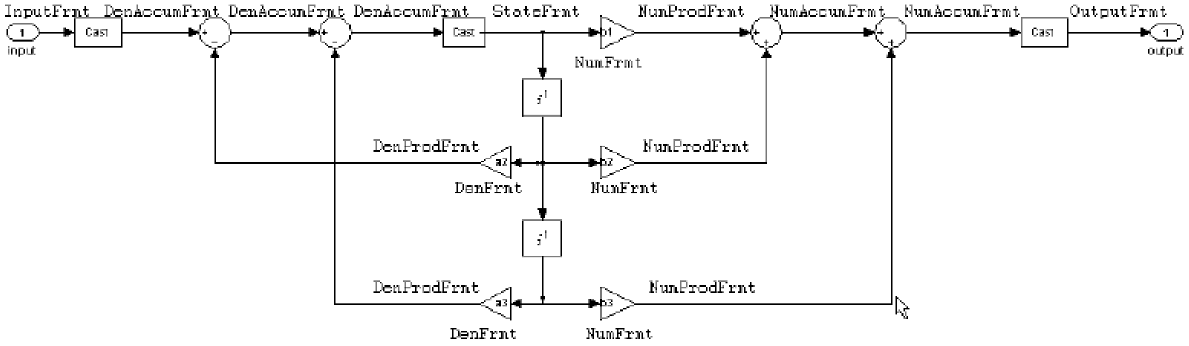
Filter Constructor Name	FilterStructure Property String and Filter Type
`'dfilt.df1'`	Direct form I
`'dfilt.df1sos'`	Direct form I filter implemented using second-order sections
`'dfilt.df1t'`	Direct form I transposed
`'dfilt.df2'`	Direct form II
`'dfilt.df2sos'`	Direct form II filter implemented using second order sections
`'dfilt.df2t'`	Direct form II transposed
`'dfilt.dfasymfir'`	Antisymmetric finite impulse response (FIR). Even and odd forms.
`'dfilt.dffir'`	Direct form FIR
`'dfilt.dffirt'`	Direct form FIR transposed
`'dfilt.latticeallpass'`	Lattice allpass
`'dfilt.latticear'`	Lattice autoregressive (AR)
`'dfilt.latticemamin'`	Lattice moving average (MA) minimum phase
`'dfilt.latticemamax'`	Lattice moving average (MA) maximum phase
`'dfilt.latticearma'`	Lattice ARMA
`'dfilt.dfsymfir'`	Symmetric FIR. Even and odd forms
`'dfilt.scalar'`	Scalar

Filter Structures with Quantizations Shown in Place

To help you understand how and where the quantizations occur in filter structures in this toolbox, the figure below shows the structure for a Direct Form II filter, including the quantizations (fixed-point formats) that compose part of the fixed-point filter. You see that one or more quantization processes, specified by the *format label, accompany each filter element, such as a delay, product, or summation element. The input to or output from each element reflects the result of applying the associated quantization as defined by the word length and fraction length format. Wherever a particular filter element appears in a filter structure, recall the quantization process that accompanies the element as it appears in this figure. Each filter reference page, such as the `dfilt.df2` reference page, includes the signal flow diagram showing the formatting elements that define the quantizations that occur throughout the filter flow.

For example, a product quantization, either numerator or denominator, follows every product (gain) element and a sum quantization, also either numerator or denominator, follows each sum element. The figure shows the `Arithmetic` property value set to `fixed`.

df2 IIR Filter Structure Including the Formatting Objects, with Arithmetic Property Value fixed



When your `df2` filter uses the `Arithmetic` property set to `fixed`, the filter structure contains the formatting features shown in the diagram. The formats included in the structure are fixed-point objects that include properties to set various word and fraction length formats. For example, the `NumFormat` or `DenFormat` in the fixed-point arithmetic filter set the properties for quantizing numerator or denominator coefficients according to word and fraction length settings.

When the leading denominator coefficient a(1) in your filter is not 1, choose it to be a power of two so that a shift replaces the multiply that would otherwise be used.

Fixed-Point Arithmetic Filter Structures

You choose among several filter structures when you create fixed-point filters. You can also specify filters with single or multiple cascaded sections of the same type. Because quantization is a nonlinear process, different fixed-point filter structures produce different results.

To specify the filter structure, you select the appropriate `dfilt.`*`structure`* method to construct your filter. Refer to the function reference information for `dfilt` and `set` for details on setting property values for quantized filters.

The figures in the following subsections of this section serve as aids to help you determine how to enter your filter coefficients for each filter structure. Each subsection contains an example for constructing a filter of the given structure.

Scale factors for the input and output for the filters do not appear in the block diagrams. The default filter structures do not include, nor assume, the scale factors. For filter scaling information, refer to `scale` in the Help system.

About the Filter Structure Diagrams

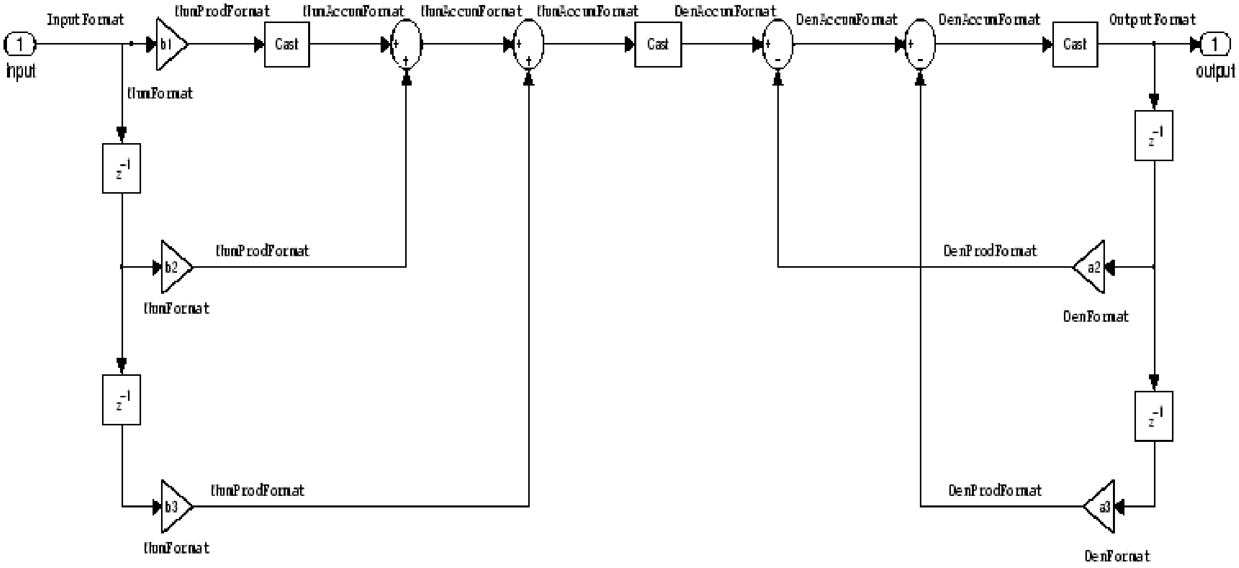
In the diagrams that accompany the following filter structure descriptions, you see the active operators that define the filter, such as sums and gains, and the formatting features that control the processing in the filter. Notice also that the coefficients are labeled in the figure. This tells you the order in which the filter processes the coefficients.

While the meaning of the block elements is straightforward, the labels for the formats that form part of the filter are less clear. Each figure includes text in the form *`labelFormat`* that represents the existence of a formatting feature at that point in the structure. The *`Format`* stands for formatting object and the *`label`* specifies the data that the formatting object affects.

For example, in the `dfilt.df2` filter shown above, the entries `InputFormat` and `OutputFormat` are the formats applied, that is the word length and fraction length, to the filter input and output data. For example, filter properties like `OutputWordLength` and `InputWordLength` specify values that control filter operations at the input and output points in the structure and are represented by the formatting objects `InputFormat` and `OutputFormat` shown in the filter structure diagrams.

Direct Form I Filter Structure

The following figure depicts the *direct form I* filter structure that directly realizes a transfer function with a second-order numerator and denominator. The numerator coefficients are numbered *b*(*i*), *i* =1, 2, 3; the denominator coefficients are numbered *a*(*i*), *i* = 1, 2, 3; and the states (used for initial and final state values in filtering) are labeled *z*(*i*). In the figure, the `Arithmetic` property is set to `fixed`.



Example — Specifying a Direct Form I Filter

You can specify a second-order direct form I structure for a quantized filter `hq` with the following code.

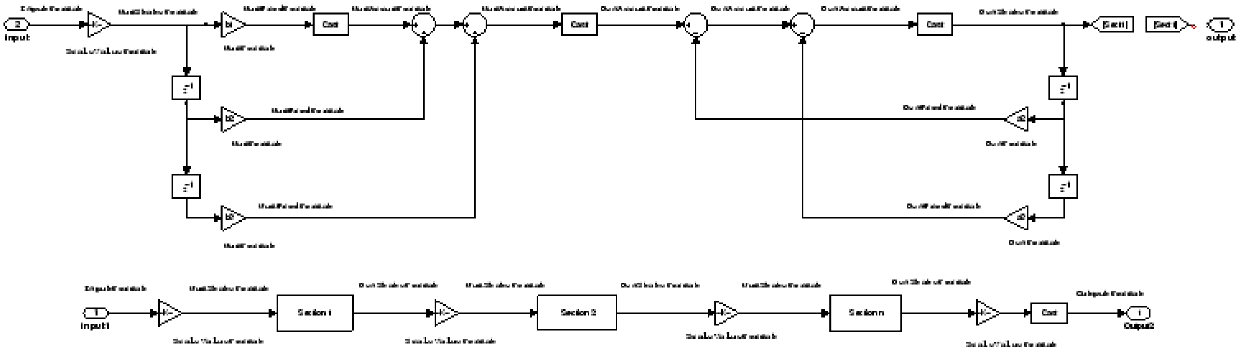
```
b = [0.3 0.6 0.3];
a = [1 0 0.2];
hq = dfilt.df1(b,a);
```

To create the fixed-point filter, set the `Arithmetic` property to `fixed` as shown here.

```
set(hq,'arithmetic','fixed');
```

Direct Form I Filter Structure With Second-Order Sections

The following figure depicts a *direct form I* filter structure that directly realizes a transfer function with a second-order numerator and denominator and second-order sections. The numerator coefficients are numbered *b*(*i*), *i* =1, 2, 3; the denominator coefficients are numbered $a(i)$, $i = 1, 2, 3$; and the states (used for initial and final state values in filtering) are labeled $z(i)$. In the figure, the `Arithmetic` property is set to `fixed` to place the filter in fixed-point mode.



Example — Specifying a Direct Form I Filter with Second-Order Sections

You can specify an eighth-order direct form I structure for a quantized filter `hq` with the following code.

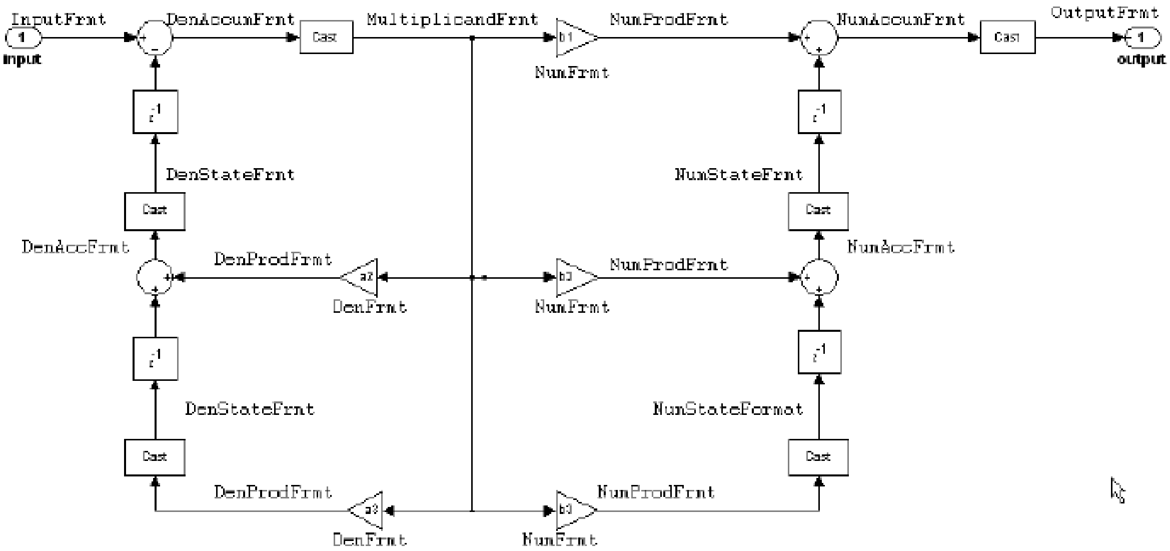
```
b = [0.3 0.6 0.3];
a = [1 0 0.2];
hq = dfilt.df1sos(b,a);
```

To create the fixed-point filter, set the `Arithmetic` property to `fixed`, as shown here.

```
set(hq,'arithmetic','fixed');
```

Direct Form I Transposed Filter Structure

The next signal flow diagram depicts a *direct form I transposed* filter structure that directly realizes a transfer function with a second-order numerator and denominator. The numerator coefficients are $b(i)$, $i = 1, 2, 3$; the denominator coefficients are $a(i)$, $i = 1, 2, 3$; and the states (used for initial and final state values in filtering) are labeled $z(i)$. With the `Arithmetic` property value set to `fixed`, the figure shows the filter with the properties indicated.



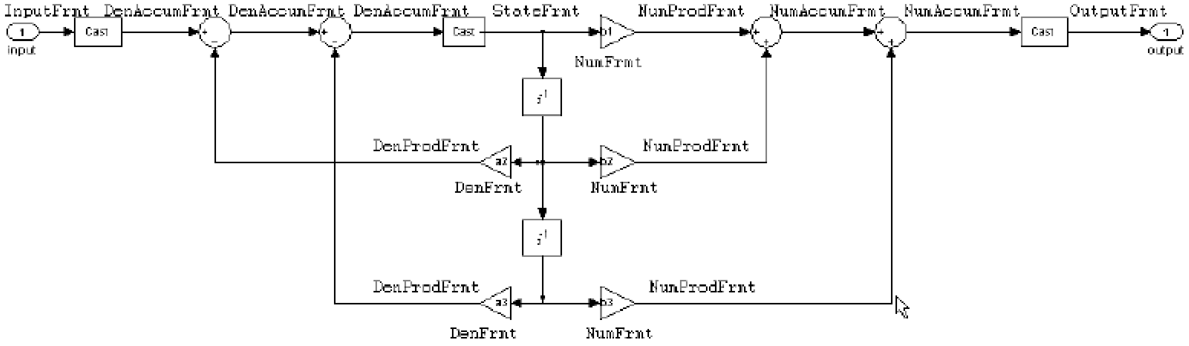
Example — Specifying a Direct Form I Transposed Filter

You can specify a second-order direct form I transposed filter structure for a quantized filter `hq` with the following code.

```
b = [0.3 0.6 0.3];
a = [1 0 0.2];
hq = dfilt.df1t(b,a);
set(hq,'arithmetic','fixed');
```

Direct Form II Filter Structure

The following graphic depicts a *direct form II* filter structure that directly realizes a transfer function with a second-order numerator and denominator. In the figure, the `Arithmetic` property value is `fixed`. Numerator coefficients are named $b(i)$; denominator coefficients are named $a(i)$, $i = 1, 2, 3$; and the states (used for initial and final state values in filtering) are named $z(i)$.



Use the method `dfilt.df2` to construct a quantized filter whose `FilterStructure` property is `Direct-Form II`.

Example — Specifying a Direct Form II Filter

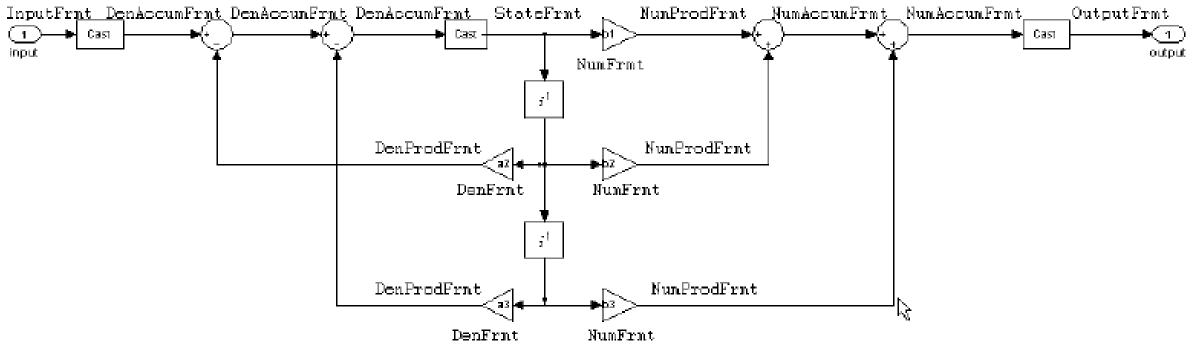
You can specify a second-order direct form II filter structure for a quantized filter `hq` with the following code.

```
b = [0.3 0.6 0.3];
a = [1 0 0.2];
hq = dfilt.df2(b,a);
hq.arithmetic = 'fixed'
```

To convert your initial double-precision filter `hq` to a quantized or fixed-point filter, set the `Arithmetic` property to `fixed`, as shown.

Direct Form II Filter Structure With Second-Order Sections

The following figure depicts *direct form II* filter structure using second-order sections that directly realizes a transfer function with a second-order numerator and denominator sections. In the figure, the `Arithmetic` property value is `fixed`. Numerator coefficients are labeled *b*(*i*); denominator coefficients are labeled *a*(*i*), *i* = 1, 2, 3; and the states (used for initial and final state values in filtering) are labeled *z*(*i*).



Use the method `dfilt.df2sos` to construct a quantized filter whose `FilterStructure` property is `Direct-Form II`.

Example — Specifying a Direct Form II Filter with Second-Order Sections

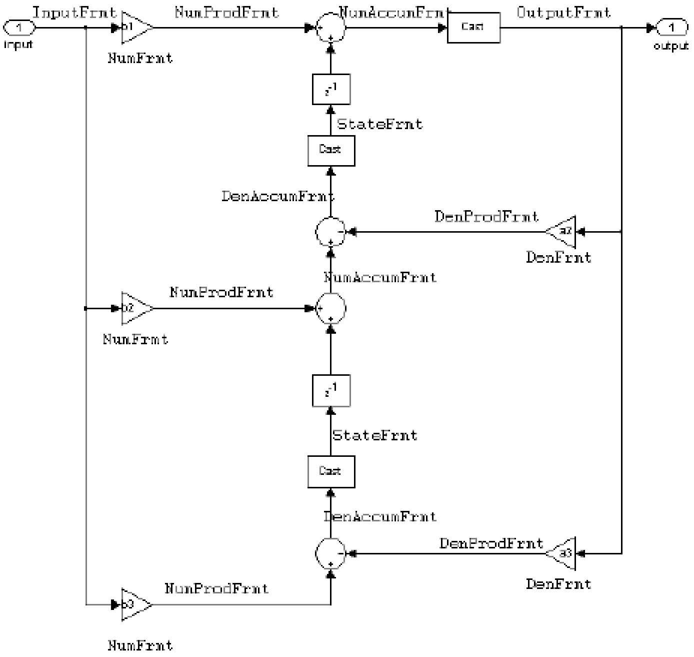
You can specify a tenth-order direct form II filter structure that uses second-order sections for a quantized filter `hq` with the following code.

```
b = [0.3 0.6 0.3];
a = [1 0 0.2];
hq = dfilt.df2sos(b,a);
hq.arithmetic = 'fixed'
```

To convert your prototype double-precision filter `hq` to a fixed-point filter, set the `Arithmetic` property to `fixed`, as shown.

Direct Form II Transposed Filter Structure

The following figure depicts the *direct form II transposed* filter structure that directly realizes transfer functions with a second-order numerator and denominator. The numerator coefficients are labeled $b(i)$, the denominator coefficients are labeled $a(i)$, $i = 1$, 2, 3, and the states (used for initial and final state values in filtering) are labeled $z(i)$. In the first figure, the `Arithmetic` property value is `fixed`.



Use the constructor `dfilt.df2t` to specify the value of the `FilterStructure` property for a filter with this structure that you can convert to fixed-point filtering.

Example — Specifying a Direct Form II Transposed Filter

Specifying or constructing a second-order direct form II transposed filter for a fixed-point filter `hq` starts with the following code to define the coefficients and construct the filter.

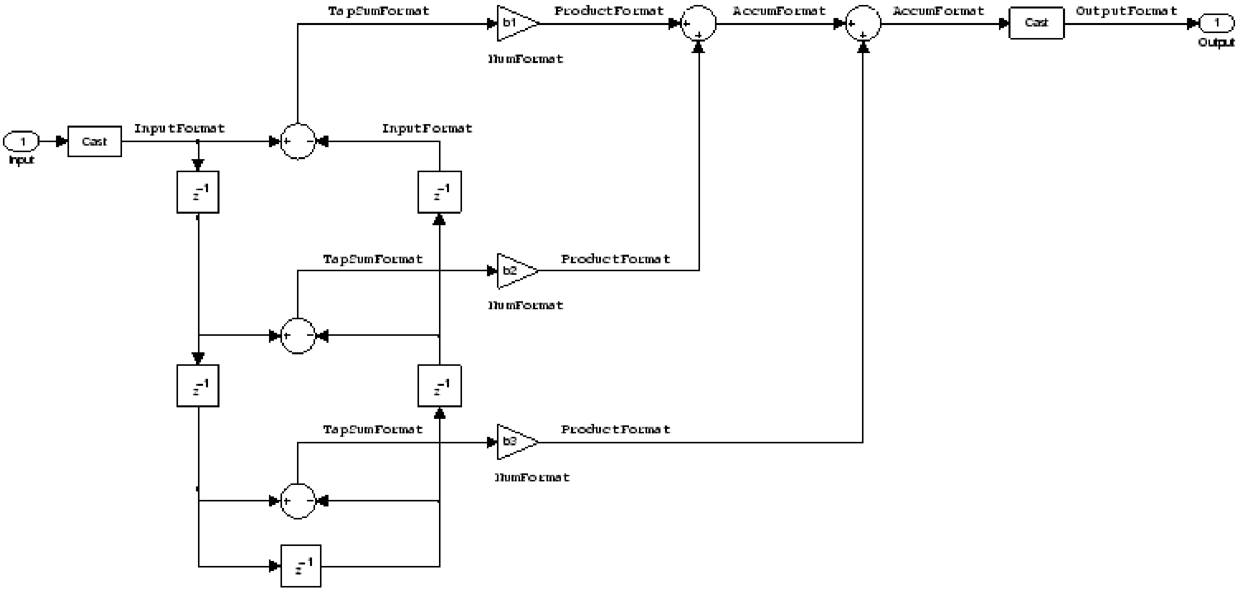
```
b = [0.3 0.6 0.3];
a = [1 0 0.2];
hd = dfilt.df2t(b,a);
```

Now create the fixed-point filtering version of the filter from `hd`, which is floating point.

```
hq = set(hd,'arithmetic','fixed');
```

Direct Form Antisymmetric FIR Filter Structure (Any Order)

The following figure depicts a *direct form antisymmetric FIR* filter structure that directly realizes a second-order antisymmetric FIR filter. The filter coefficients are labeled *b(i)*, and the initial and final state values in filtering are labeled *z*(*i*). This structure reflects the `Arithmetic` property set to `fixed`.



Use the method `dfilt.dfasymfir` to construct the filter, and then set the `Arithmetic` property to `fixed` to convert to a fixed-point filter with this structure.

Example — Specifying an Odd-Order Direct Form Antisymmetric FIR Filter

Specify a fifth-order direct form antisymmetric FIR filter structure for a fixed-point filter `hq` with the following code.

```
b = [-0.008 0.06 -0.44 0.44 -0.06 0.008];
hq = dfilt.dfasymfir(b);
set(hq,'arithmetic','fixed')

hq

hq =

         FilterStructure: 'Direct-Form Antisymmetric FIR'
              Arithmetic: 'fixed'
               Numerator: [-0.0080 0.0600 -0.4400 0.4400 -0.0600 0.0080]
        PersistentMemory: false
                  States: [1x1 fi object]

          CoeffWordLength: 16
           CoeffAutoScale: true
```

```
                  Signed: true

         InputWordLength: 16
         InputFracLength: 15

        OutputWordLength: 16
              OutputMode: 'AvoidOverflow'

              TapSumMode: 'KeepMSB'
        TapSumWordLength: 17

             ProductMode: 'FullPrecision'

         AccumWordLength: 40

           CastBeforeSum: true
               RoundMode: 'convergent'
            OverflowMode: 'wrap'

         InheritSettings: false
```

Example — Specifying an Even-Order Direct Form Antisymmetric FIR Filter

You can specify a fourth-order direct form antisymmetric FIR filter structure for a fixed-point filter hq with the following code.

```
b = [-0.01 0.1 0.0 -0.1 0.01];
hq = dfilt.dfasymfir(b);
hq.arithmetic='fixed'

hq =

         FilterStructure: 'Direct-Form Antisymmetric FIR'
              Arithmetic: 'fixed'
               Numerator: [-0.0100 0.1000 0 -0.1000 0.0100]
        PersistentMemory: false
                  States: [1x1 fi object]

         CoeffWordLength: 16
          CoeffAutoScale: true
                  Signed: true

         InputWordLength: 16
         InputFracLength: 15

        OutputWordLength: 16
              OutputMode: 'AvoidOverflow'

              TapSumMode: 'KeepMSB'
        TapSumWordLength: 17
        ProductMode: 'FullPrecision'

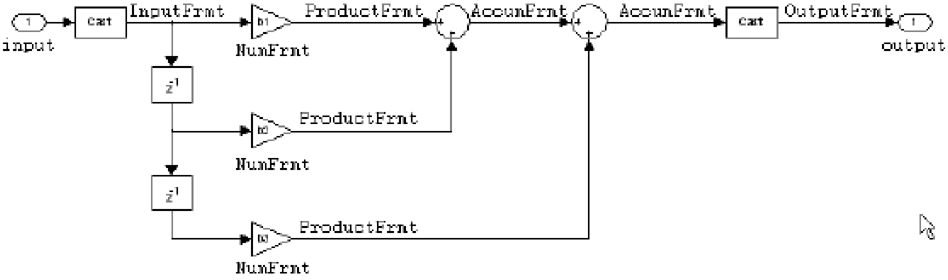
    AccumWordLength: 40

      CastBeforeSum: true
          RoundMode: 'convergent'
       OverflowMode: 'wrap'

    InheritSettings: false
```

Direct Form Finite Impulse Response (FIR) Filter Structure

In the next figure, you see the signal flow graph for a *direct form finite impulse response (FIR)* filter structure that directly realizes a second-order FIR filter. The filter coefficients are $b(i)$, $i = 1, 2, 3$, and the states (used for initial and final state values in filtering) are $z(i)$. To generate the figure, set the `Arithmetic` property to `fixed` after you create your prototype filter in double-precision arithmetic.



Use the `dfilt.dffir` method to generate a filter that uses this structure.

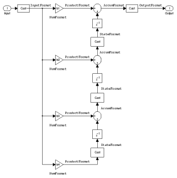
Example — Specifying a Direct Form FIR Filter

You can specify a second-order direct form FIR filter structure for a fixed-point filter `hq` with the following code.

```
b = [0.05 0.9 0.05];
hd = dfilt.dffir(b);
hq = set(hd,'arithmetic','fixed');
```

Direct Form FIR Transposed Filter Structure

This figure uses the filter coefficients labeled *b*(*i*), *i* = 1, 2, 3, and states (used for initial and final state values in filtering) are labeled *z*(*i*). These depict a *direct form finite impulse response (FIR) transposed* filter structure that directly realizes a second-order FIR filter.



With the `Arithmetic` property set to `fixed`, your filter matches the figure. Using the method `dfilt.dffirt` returns a double-precision filter that you convert to a fixed-point filter.

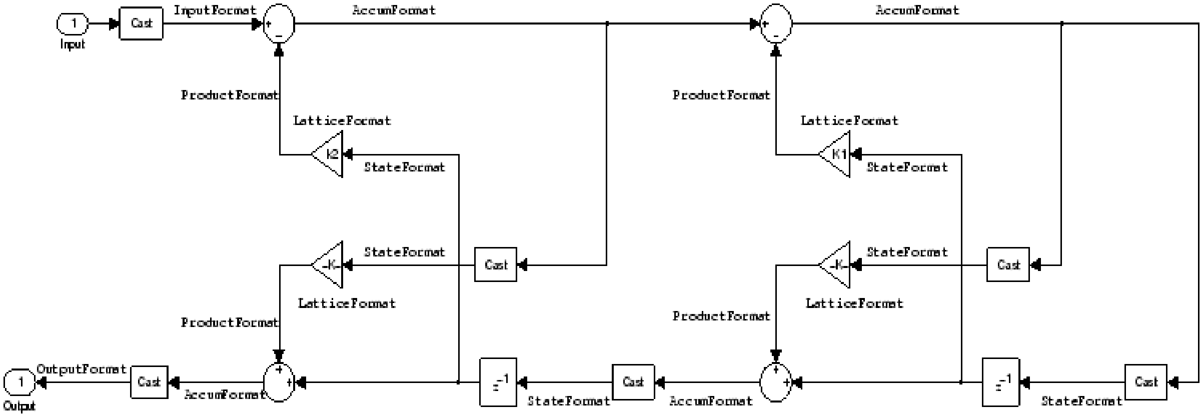
Example — Specifying a Direct Form FIR Transposed Filter

You can specify a second-order direct form FIR transposed filter structure for a fixed-point filter `hq` with the following code.

```
b = [0.05 0.9 0.05];
hd=dfilt.dffirt(b);
hq = copy(hd);
hq.arithmetic = 'fixed';
```

Lattice Allpass Filter Structure

The following figure depicts the *lattice allpass* filter structure. The pictured structure directly realizes third-order lattice allpass filters using fixed-point arithmetic. The filter reflection coefficients are labeled *k1*(*i*), *i* = 1, 2, 3. The states (used for initial and final state values in filtering) are labeled *z*(*i*).



To create a quantized filter that uses the lattice allpass structure shown in the figure, use the `dfilt.latticeallpass` method and set the `Arithmetic` property to `fixed`.

Example — Specifying a Lattice Allpass Filter

You can create a third-order lattice allpass filter structure for a quantized filter `hq` with the following code.

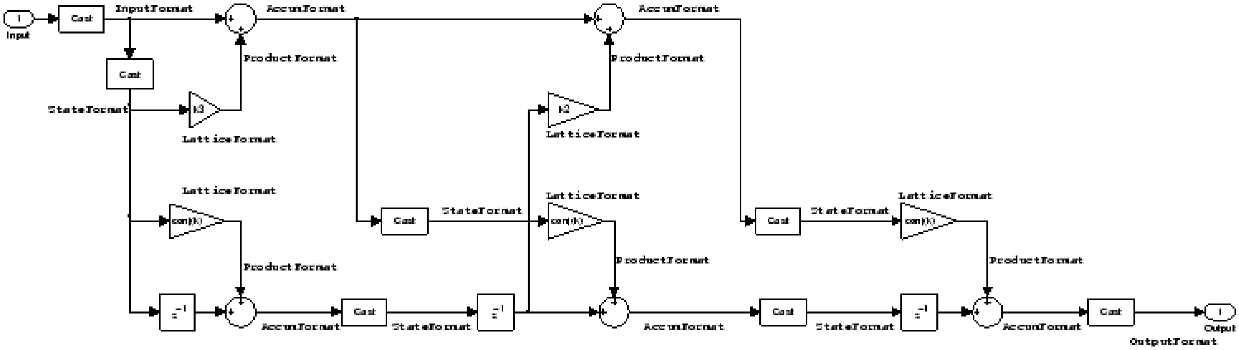
```
k = [.66 .7 .44];
hd=dfilt.latticeallpass(k);
set(hq,'arithmetic','fixed');
```

Lattice Moving Average Maximum Phase Filter Structure

In the next figure you see a *lattice moving average maximum phase* filter structure. This signal flow diagram directly realizes a third-order lattice moving average (MA) filter with the following phase form depending on the initial transfer function:

- When you start with a minimum phase transfer function, the upper branch of the resulting lattice structure returns a minimum phase filter. The lower branch returns a maximum phase filter.
- When your transfer function is neither minimum phase nor maximum phase, the lattice moving average maximum phase structure will not be maximum phase.
- When you start with a maximum phase filter, the resulting lattice filter is maximum phase also.

The filter reflection coefficients are labeled $k(i)$, $i = 1, 2, 3$. The states (used for initial and final state values in filtering) are labeled $z(i)$. In the figure, we set the `Arithmetic` property to fixed to reveal the fixed-point arithmetic format features that control such options as word length and fraction length.



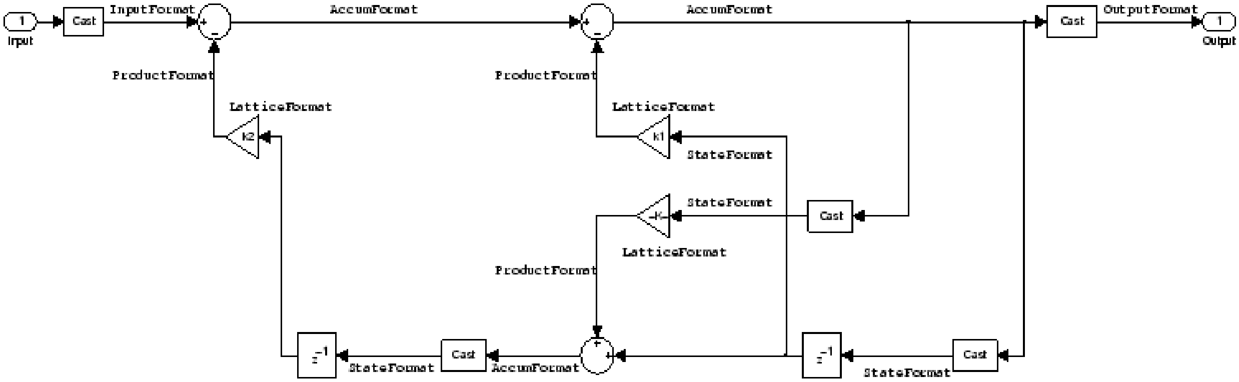
Example — Constructing a Lattice Moving Average Maximum Phase Filter

Constructing a fourth-order lattice MA maximum phase filter structure for a quantized filter hq begins with the following code.

```
k = [.66 .7 .44 .33];
hd=dfilt.latticemamax(k);
```

Lattice Autoregressive (AR) Filter Structure

The method dfilt.latticear directly realizes lattice autoregressive filters in the toolbox. The following figure depicts the third-order *lattice autoregressive (AR)* filter structure — with the Arithmetic property equal to fixed. The filter reflection coefficients are labeled $k(i)$, $i = 1, 2, 3$, and the states (used for initial and final state values in filtering) are labeled $z(i)$.



Example — Specifying a Lattice AR Filter

You can specify a third-order lattice AR filter structure for a quantized filter `hq` with the following code.

```
k = [.66 .7 .44];
hd=dfilt.latticear(k);
hq.arithmetic = 'custom';
```

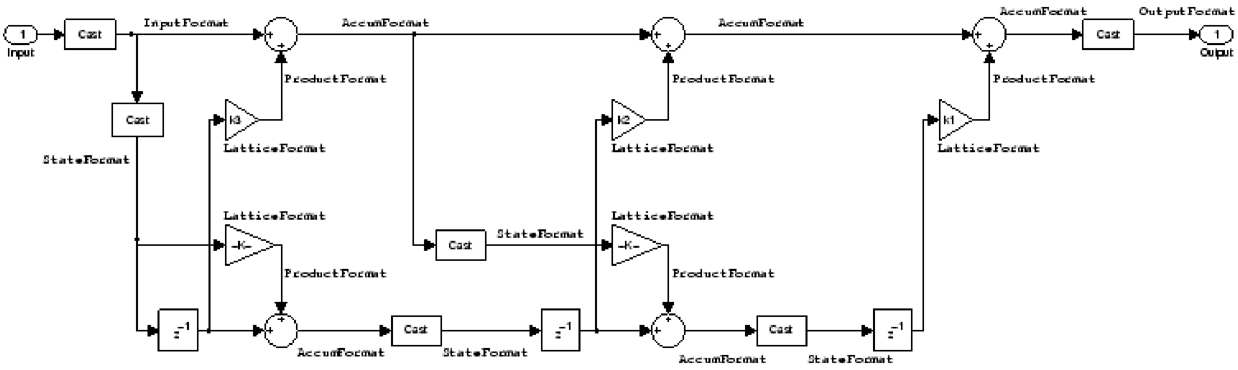
Lattice Moving Average (MA) Filter Structure for Minimum Phase

The following figures depict *lattice moving average (MA)* filter structures that directly realize third-order lattice MA filters for minimum phase. The filter reflection coefficients are labeled *k*(*i*), (*i*). = 1, 2, 3, and the states (used for initial and final state values in filtering) are labeled *z*(*i*). Setting the `Arithmetic` property of the filter to `fixed` results in a fixed-point filter that matches the figure.

This signal flow diagram directly realizes a third-order lattice moving average (MA) filter with the following phase form depending on the initial transfer function:

- When you start with a minimum phase transfer function, the upper branch of the resulting lattice structure returns a minimum phase filter. The lower branch returns a minimum phase filter.
- When your transfer function is neither minimum phase nor maximum phase, the lattice moving average minimum phase structure will not be minimum phase.
- When you start with a minimum phase filter, the resulting lattice filter is minimum phase also.

The filter reflection coefficients are labeled *k*((*i*).), *i* = 1, 2, 3. The states (used for initial and final state values in filtering) are labeled *z*((*i*).). This figure shows the filter structure when the`Arithmetic` property is set to `fixed` to reveal the fixed-point arithmetic format features that control such options as word length and fraction length.



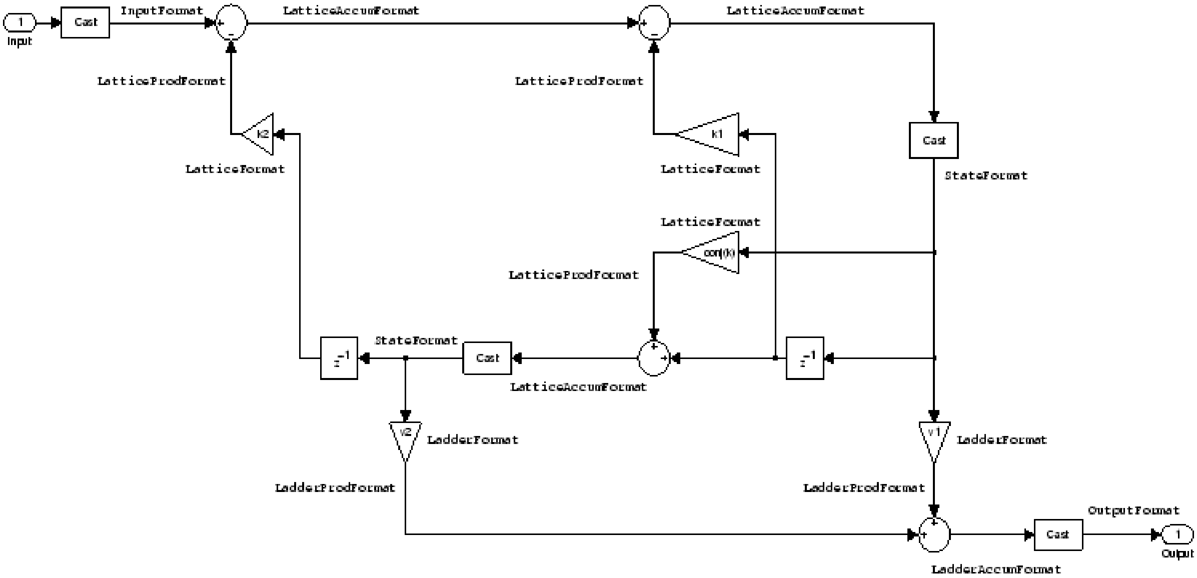
Example — Specifying a Minimum Phase Lattice MA Filter

You can specify a third-order lattice MA filter structure for minimum phase applications using variations of the following code.

```
k = [.66 .7 .44];
hd=dfilt.latticemamin(k);
set(hq,'arithmetic','fixed');
```

Lattice Autoregressive Moving Average (ARMA) Filter Structure

The figure below depicts a *lattice autoregressive moving average (ARMA)* filter structure that directly realizes a fourth-order lattice ARMA filter. The filter reflection coefficients are labeled *k*(*i*), (*i*). = 1, ..., 4; the ladder coefficients are labeled *v*(*i*), (*i*). = 1, 2, 3; and the states (used for initial and final state values in filtering) are labeled *z*(*i*).



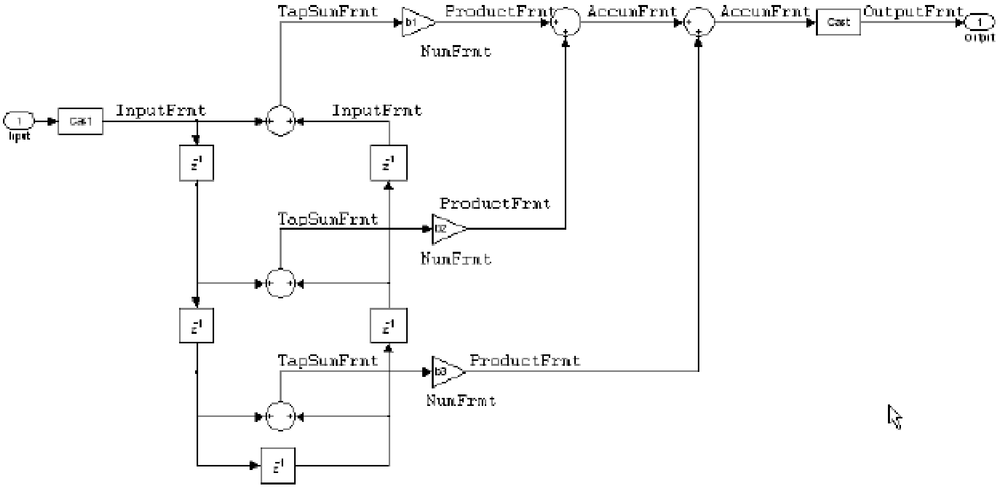
Example — Specifying an Lattice ARMA Filter

The following code specifies a fourth-order lattice ARMA filter structure for a quantized filter hq, starting from hd, a floating-point version of the filter.

```
k = [.66 .7 .44 .66];
v = [1 0 0];
hd=dfilt.latticearma(k,v);
hq.arithmetic = 'fixed';
```

Direct Form Symmetric FIR Filter Structure (Any Order)

Shown in the next figure, you see signal flow that depicts a *direct form symmetric FIR* filter structure that directly realizes a fifth-order direct form symmetric FIR filter. Filter coefficients are labeled $b(i)$, $i = 1, ..., n$, and states (used for initial and final state values in filtering) are labeled $z(i)$. Showing the filter structure used when you select fixed for the Arithmetic property value, the first figure details the properties in the filter object.



Example — Specifying an Odd-Order Direct Form Symmetric FIR Filter

By using the following code in MATLAB, you can specify a fifth-order direct form symmetric FIR filter for a fixed-point filter hq:

```
b = [-0.008 0.06 0.44 0.44 0.06 -0.008];
hd=dfilt.dfsymfir(b);
set(hq,'arithmetic','fixed');
```

Assigning Filter Coefficients

The syntax you use to assign filter coefficients for your floating-point or fixed-point filter depends on the structure you select for your filter.

Converting Filters Between Representations

Filter conversion functions in this toolbox and in Signal Processing Toolbox software let you convert filter transfer functions to other filter forms, and from other filter forms to transfer function form. Relevant conversion functions include the following functions.

Conversion Function	Description
`ca2tf`	Converts from a coupled allpass filter to a transfer function.
`cl2tf`	Converts from a lattice coupled allpass filter to a transfer function.

Conversion Function	Description
`convert`	Convert a discrete-time filter from one filter structure to another.
`sos`	Converts quantized filters to create second-order sections. We recommend this method for converting quantized filters to second-order sections.
`tf2ca`	Converts from a transfer function to a coupled allpass filter.
`tf2cl`	Converts from a transfer function to a lattice coupled allpass filter.
`tf2latc`	Converts from a transfer function to a lattice filter.
`tf2sos`	Converts from a transfer function to a second-order section form.
`tf2ss`	Converts from a transfer function to state-space form.
`tf2zp`	Converts from a rational transfer function to its factored (single section) form (zero-pole-gain form).
`zp2sos`	Converts a zero-pole-gain form to a second-order section form.
`zp2ss`	Conversion of zero-pole-gain form to a state-space form.
`zp2tf`	Conversion of zero-pole-gain form to transfer functions of multiple order sections.

Note that these conversion routines do not apply to `dfilt` objects.

The function `convert` is a special case — when you use convert to change the filter structure of a fixed-point filter, you lose all of the filter states and settings. Your new filter has default values for all properties, and it in not fixed-point.

To demonstrate the changes that occur, convert a fixed-point direct form I transposed filter to direct form II structure.

```
hd=dfilt.df1t

hd =

         FilterStructure: 'Direct-Form I Transposed'
              Arithmetic: 'double'
               Numerator: 1
             Denominator: 1
```

```
        PersistentMemory: false
                  States: Numerator:  [0x0 double]
                          Denominator:[0x0 double]

hd.arithmetic='fixed'
hd =

         FilterStructure: 'Direct-Form I Transposed'
              Arithmetic: 'fixed'
               Numerator: 1
             Denominator: 1
        PersistentMemory: false
                  States: Numerator:  [0x0 fi]
                          Denominator:[0x0 fi]

convert(hd,'df2')

Warning: Using reference filter for structure conversion.
Fixed-point attributes will not be converted.

ans =

         FilterStructure: 'Direct-Form II'
              Arithmetic: 'double'
               Numerator: 1
             Denominator: 1
        PersistentMemory: false
                  States: [0x1 double]
```

You can specify a filter with *L* sections of arbitrary order by

1. Factoring your entire transfer function with `tf2zp`. This converts your transfer function to zero-pole-gain form.
2. Using `zp2tf` to compose the transfer function for each section from the selected first-order factors obtained in step 1.

Note You are not required to normalize the leading coefficients of each section's denominator polynomial when you specify second-order sections, though `tf2sos` does.

Gain

dfilt.scalar filters have a gain value stored in the gain property. By default the gain value is one — the filter acts as a wire.

InputFracLength

InputFracLength defines the fraction length assigned to the input data for your filter. Used in tandem with InputWordLength, the pair defines the data format for input data you provide for filtering.

As with all fraction length properties in dfilt objects, the value you enter here can be any negative or positive integer, or zero. Fraction length can be larger than the associated word length, in this case InputWordLength, as well.

InputWordLength

Specifies the number of bits your filter uses to represent your input data. Your word length option is limited by the arithmetic you choose — up to 32 bits for double, float, and fixed. Setting Arithmetic to single (single-precision floating-point) limits word length to 16 bits. The default value is 16 bits.

Ladder

Included as a property in dfilt.latticearma filter objects, Ladder contains the denominator coefficients that form an IIR lattice filter object. For instance, the following code creates a high pass filter object that uses the lattice ARMA structure.

```
[b,a]=cheby1(5,.5,.5,'high')

b =

    0.0282   -0.1409    0.2817   -0.2817    0.1409   -0.0282

a =

    1.0000    0.9437    1.4400    0.9629    0.5301    0.1620

hd=dfilt.latticearma(b,a)

hd =

         FilterStructure: [1x44 char]
```

```
              Arithmetic: 'double'
                 Lattice: [1x6 double]
                  Ladder: [1 0.9437 1.4400 0.9629 0.5301 0.1620]
     PersistentMemory: false
                  States: [6x1 double]

hd.arithmetic='fixed'

hd =

         FilterStructure: [1x44 char]
              Arithmetic: 'fixed'
                 Lattice: [1x6 double]
                  Ladder: [1 0.9437 1.4400 0.9629 0.5301 0.1620]
     PersistentMemory: false
                  States: [1x1 embedded.fi]

         CoeffWordLength: 16
          CoeffAutoScale: true
                  Signed: true

         InputWordLength: 16
         InputFracLength: 15

        OutputWordLength: 16
              OutputMode: 'AvoidOverflow'

         StateWordLength: 16
         StateFracLength: 15

             ProductMode: 'FullPrecision'

         AccumWordLength: 40
           CastBeforeSum: true

               RoundMode: 'convergent'
            OverflowMode: 'wrap'
```

LadderAccumFracLength

Autoregressive, moving average lattice filter objects (`lattticearma`) use ladder coefficients to define the filter. In combination with `LadderFracLength` and `CoeffWordLength`, these three properties specify or reflect how the accumulator outputs data stored there. As with all fraction length properties, `LadderAccumFracLength` can be any integer, including integers larger than `AccumWordLength`, and positive or negative integers. The default value is 29 bits.

LadderFracLength

To let you control the way your `latticearma` filter interprets the denominator coefficients, `LadderFracLength` sets the fraction length applied to the ladder coefficients for your filter. The default value is 14 bits.

As with all fraction length properties, `LadderFracLength` can be any integer, including integers larger than `AccumWordLength`, and positive or negative integers.

Lattice

When you create a lattice-based IIR filter, your numerator coefficients (from your IIR prototype filter or the default `dfilt` lattice filter function) get stored in the `Lattice` property of the `dfilt` object. The properties `CoeffWordLength` and `LatticeFracLength` define the data format the object uses to represent the lattice coefficients. By default, lattice coefficients are in double-precision format.

LatticeAccumFracLength

Lattice filter objects (`latticeallpass`, `latticearma`, `latticemamax`, and `latticemamin`) use lattice coefficients to define the filter. In combination with `LatticeFracLength` and `CoeffWordLength`, these three properties specify how the accumulator outputs lattice coefficient-related data stored there. As with all fraction length properties, `LatticeAccumFracLength` can be any integer, including integers larger than `AccumWordLength`, and positive or negative integers. By default, the property is set to 31 bits.

LatticeFracLength

To let you control the way your filter interprets the denominator coefficients, `LatticeFracLength` sets the fraction length applied to the lattice coefficients for your lattice filter. When you create the default lattice filter, `LatticeFracLength` is 16 bits.

As with all fraction length properties, `LatticeFracLength` can be any integer, including integers larger than `CoeffWordLength`, and positive or negative integers.

MultiplicandFracLength

Each input data element for a multiply operation has both word length and fraction length to define its representation. `MultiplicandFracLength` sets the fraction length to use when the filter object performs any multiply operation during filtering. For default filters, this is set to 15 bits.

As with all word and fraction length properties, MultiplicandFracLength can be any integer, including integers larger than CoeffWordLength, and positive or negative integers.

MultiplicandWordLength

Each input data element for a multiply operation has both word length and fraction length to define its representation. MultiplicandWordLength sets the word length to use when the filter performs any multiply operation during filtering. For default filters, this is set to 16 bits. Only the df1t and df1tsos filter objects include the MultiplicandFracLength property.

Only the df1t and df1tsos filter objects include the MultiplicandWordLength property.

NumAccumFracLength

Filter structures df1, df1t, df2, and df2t that use fixed arithmetic have this property that defines the fraction length applied to numerator coefficients in output from the accumulator. In combination with AccumWordLength, the NumAccumFracLength property fully specifies how the accumulator outputs numerator-related data stored there.

As with all fraction length properties, NumAccumFracLength can be any integer, including integers larger than AccumWordLength, and positive or negative integers. 30 bits is the default value when you create the filter object. To be able to change the value for this property, set FilterInternals for the filter to SpecifyPrecision.

Numerator

The numerator coefficients for your filter, taken from the prototype you start with or from the default filter, are stored in this property. Generally this is a 1-by-N array of data in double format, where N is the length of the filter.

All of the filter objects include Numerator, except the lattice-based and second-order section filters, such as dfilt.latticema and dfilt.df1tsos.

NumFracLength

Property NumFracLength contains the value that specifies the fraction length for the numerator coefficients for your filter. NumFracLength specifies the fraction length used to interpret the numerator coefficients. Used in combination with CoeffWordLength, these two properties define the interpretation of the coefficients stored in the vector that contains the numerator coefficients.

As with all fraction length properties, the value you enter here can be any negative or positive integer, or zero. Fraction length can be larger than the associated word length, as well. By default, the value is 15 bits, with the CoeffWordLength of 16 bits.

NumProdFracLength

A property of all of the direct form IIR dfilt objects, except the ones that implement second-order sections, NumProdFracLength specifies the fraction length applied to data output from product operations the filter performs on numerator coefficients.

Looking at the signal flow diagram for the dfilt.df1t filter, for example, you see that denominators and numerators are handled separately. When you set ProductMode to SpecifyPrecision, you can change the NumProdFracLength setting manually. Otherwise, for multiplication operations that use the numerator coefficients, the filter sets the word length as defined by the ProductMode setting.

NumStateFracLength

All the variants of the direct form I structure include the property NumStateFracLength to store the fraction length applied to the numerator states for your filter object. By default, this property has the value 15 bits, with the CoeffWordLength of 16 bits, which you can change after you create the filter object.

As with all fraction length properties, the value you enter here can be any negative or positive integer, or zero. Fraction length can be larger than the associated word length, as well.

NumStateWordLength

When you look at the flow diagram for the df1sos filter object, the states associated with the numerator coefficient operations take the data format from this property and the NumStateFracLength property. In combination, these properties fully specify how the filter interprets the state it uses.

As with all fraction length properties, the value you enter here can be any negative or positive integer, or zero. Fraction length can be larger than the associated word length, as well. By default, the value is 16 bits, with the NumStateFracLength of 11 bits.

OutputFracLength

To define the output from your filter object, you need both the word and fraction lengths. `OutputFracLength` determines the fraction length applied to interpret the output data. Combining this with `OutputWordLength` fully specifies the format of the output.

Your fraction length can be any negative or positive integer, or zero. In addition, the fraction length you specify can be larger than the associated word length. Generally, the default value is 11 bits.

OutputMode

Sets the mode the filter uses to scale the filtered (output) data. You have the following choices:

- `AvoidOverflow` — directs the filter to set the property that controls the output data fraction length to avoid causing the data to overflow. In a `df2` filter, this would be the `OutputFracLength` property.
- `BestPrecision` — directs the filter to set the property that controls the output data fraction length to maximize the precision in the output data. For `df1t` filters, this is the `OutputFracLength` property. When you change the word length (`OutputWordLength`), the filter adjusts the fraction length to maintain the best precision for the new word size.
- `SpecifyPrecision` — lets you set the fraction length used by the filtered data. When you select this choice, you can set the output fraction length using the `OutputFracLength` property to define the output precision.

All filters include this property except the direct form I filter which takes the output format from the filter states.

Here is an example that changes the mode setting to `bestprecision`, and then adjusts the word length for the output.

```
hd=dfilt.df2

hd =

         FilterStructure: 'Direct-Form II'
              Arithmetic: 'double'
               Numerator: 1
             Denominator: 1
        PersistentMemory: false
                  States: [0x1 double]
```

```
hd.arithmetic='fixed'

hd =

         FilterStructure: 'Direct-Form II'
              Arithmetic: 'fixed'

      NumAccumFracLength: 29
      DenAccumFracLength: 29
           CastBeforeSum: 1
```

Changing the `OutputWordLength` to `8` bits caused the filter to change the `OutputFracLength` to `5` bits to keep the best precision for the output data.

OutputWordLength

Use the property `OutputWordLength` to set the word length used by the output from your filter. Set this property to a value that matches your intended hardware. For example, some digital signal processors use 32-bit output so you would set `OutputWordLength` to `32`.

```
[b,a] = butter(6,.5);
hd=dfilt.df1t(b,a);

set(hd,'arithmetic','fixed')

hd

hd =

         FilterStructure: 'Direct-Form I Transposed'
              Arithmetic: 'fixed'
               Numerator: [1x7 double]
             Denominator: [1 0 0.7777 0 0.1142 0 0.0018]
     PersistentMemory: false
                  States: Numerator:  [6x1 fi]

          StateAutoScale: true

             ProductMode: 'FullPrecision'

         AccumWordLength: 40
           CastBeforeSum: true

               RoundMode: 'convergent'
            OverflowMode: 'wrap'
```

When you create a filter object, this property starts with the value 16.

OverflowMode

The `OverflowMode` property is specified as one of the following two strings indicating how to respond to overflows in fixed-point arithmetic:

- `'saturate'` — saturate overflows.

  When the values of data to be quantized lie outside of the range of the largest and smallest representable numbers (as specified by the applicable word length and fraction length properties), these values are quantized to the value of either the largest or smallest representable value, depending on which is closest. `saturate` is the default value for `OverflowMode`.
- `'wrap'` — wrap all overflows to the range of representable values.

  When the values of data to be quantized lie outside of the range of the largest and smallest representable numbers (as specified by the data format properties), these values are wrapped back into that range using modular arithmetic relative to the smallest representable number. You can learn more about modular arithmetic in Fixed-Point Designer documentation.

These rules apply to the `OverflowMode` property.

- Applies to the accumulator and output data only.
- Does not apply to coefficients or input data. These always saturate the results.
- Does not apply to products. Products maintain full precision at all times. Your filters do not lose precision in the products.

Note Numbers in floating-point filters that extend beyond the dynamic range overflow to ±`inf`.

ProductFracLength

After you set `ProductMode` for a fixed-point filter to `SpecifyPrecision`, this property becomes available for you to change. `ProductFracLength` sets the fraction length the filter uses for the results of multiplication operations. Only the FIR filters such as asymmetric FIRs or lattice autoregressive filters include this dynamic property.

Your fraction length can be any negative or positive integer, or zero. In addition, the fraction length you specify can be larger than the associated word length. Generally, the default value is 11 bits.

ProductMode

This property, available when your filter is in fixed-point arithmetic mode, specifies how the filter outputs the results of multiplication operations. All `dfilt` objects include this property when they use fixed-point arithmetic.

When available, you select from one of the following values for `ProductMode`:

- `FullPrecision` — means the filter automatically chooses the word length and fraction length it uses to represent the results of multiplication operations. The setting allow the product to retain the precision provided by the inputs (multiplicands) to the operation.
- `KeepMSB` — means you specify the word length for representing product operation results. The filter sets the fraction length to discard the LSBs, keep the higher order bits in the data, and maintain the precision.
- `KeepLSB` — means you specify the word length for representing the product operation results. The filter sets the fraction length to discard the MSBs, keep the lower order bits, and maintain the precision. Compare to the `KeepMSB` option.
- `SpecifyPrecision` — means you specify the word length and the fraction length to apply to data output from product operations.

When you switch to fixed-point filtering from floating-point, you are most likely going to throw away some data bits after product operations in your filter, perhaps because you have limited resources. When you have to discard some bits, you might choose to discard the least significant bits (LSB) from a result since the resulting quantization error would be small as the LSBs carry less weight. Or you might choose to keep the LSBs because the results have MSBs that are mostly zero, such as when your values are small relative to the range of the format in which they are represented. So the options for `ProductMode` let you choose how to maintain the information you need from the accumulator.

For more information about data formats, word length, and fraction length in fixed-point arithmetic, refer to “Notes About Fraction Length, Word Length, and Precision” on page 5-26.

ProductWordLength

You use `ProductWordLength` to define the data word length used by the output from multiplication operations. Set this property to a value that matches your intended application. For example, the default value is 32 bits, but you can set any word length.

```
set(hq,'arithmetic','fixed');
set(hq,'ProductWordLength',64);
```

Note that `ProductWordLength` applies only to filters whose `Arithmetic` property value is `fixed`.

PersistentMemory

Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter object. `PersistentMemory` returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. Defaults to `false` — the filter does not retain memory about filtering operations from one to the next. Maintaining memory (setting `PersistentMemory` to `true`) lets you filter large data sets as collections of smaller subsets and get the same result.

In this example, filter `hd` first filters data `xtot` in one pass. Then you can use `hd` to filter `x` as two separate data sets. The results `ytot` and `ysec` are the same in both cases.

```
xtot=[x,x];
ytot=filter(hd,xtot)
ytot =

         0   -0.0003    0.0005   -0.0014    0.0028   -0.0054    0.0092
reset(hm1);  % Clear history of the filter
hm1.PersistentMemory='true';
ysec=[filter(hd,x) filter(hd,x)]

ysec =

         0   -0.0003    0.0005   -0.0014    0.0028   -0.0054    0.0092
```

This test verifies that `ysec` (the signal filtered by sections) is equal to `ytot` (the entire signal filtered at once).

RoundMode

The `RoundMode` property value specifies the rounding method used for quantizing numerical values. Specify the `RoundMode` property values as one of the following five strings.

RoundMode String	Description of Rounding Algorithm
`Ceiling`	Round toward positive infinity.
`Floor`	Round toward negative infinity.

RoundMode String	Description of Rounding Algorithm
`Nearest`	Round toward nearest. Ties round toward positive infinity.
`Nearest(Convergent)`	Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software.
`Round`	Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers.
`Zero`	Round toward zero.

The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.

ScaleValueFracLength

Filter structures `df1sos`, `df1tsos`, `df2sos`, and `df2tsos` that use `fixed` arithmetic have this property that defines the fraction length applied to the scale values the filter uses between sections. In combination with `CoeffWordLength`, these two properties fully specify how the filter interprets and uses the scale values stored in the property `ScaleValues`. As with fraction length properties, `ScaleValueFracLength` can be any integer, including integers larger than `CoeffWordLength`, and positive or negative integers. 15 bits is the default value when you create the filter.

ScaleValues

The `ScaleValues` property values are specified as a scalar (or vector) that introduces scaling for inputs (and the outputs from cascaded sections in the vector case) during filtering:

- When you only have a single section in your filter:
  - Specify the `ScaleValues` property value as a scalar if you only want to scale the input to your filter.
  - Specify the `ScaleValues` property as a vector of length 2 if you want to specify scaling to the input (scaled with the first entry in the vector) and the output (scaled with the last entry in the vector).

- When you have L cascaded sections in your filter:
  - Specify the `ScaleValues` property value as a scalar if you only want to scale the input to your filter.
  - Specify the value for the `ScaleValues` property as a vector of length L+1 if you want to scale the inputs to every section in your filter, along with the output:

    The first entry of your vector specifies the input scaling

    Each successive entry specifies the scaling at the output of the next section

    The final entry specifies the scaling for the filter output.

The default value for `ScaleValues` is 0.

The interpretation of this property is described as follows with diagrams in "Interpreting the ScaleValues Property" on page 5-75.

Note: The value of the `ScaleValues` property is not quantized. Data affected by the presence of a scaling factor in the filter is quantized according to the appropriate data format.

When you apply `normalize` to a fixed-point filter, the value for the `ScaleValues` property is changed accordingly.

It is good practice to choose values for this property that are either positive or negative powers of two.

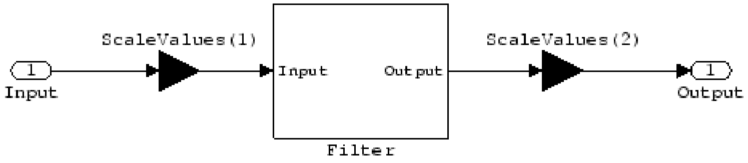
Interpreting the ScaleValues Property

When you specify the values of the `ScaleValues` property of a quantized filter, the values are entered as a vector, the length of which is determined by the number of cascaded sections in your filter:

- When you have only one section, the value of the `Scalevalues` property can be a scalar or a two-element vector.
- When you have L cascaded sections in your filter, the value of the `ScaleValues` property can be a scalar or an L+1-element vector.

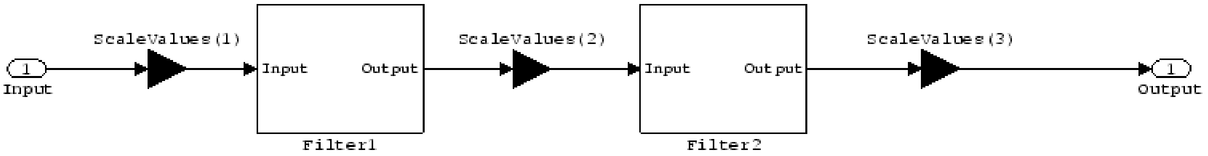
The following diagram shows how the `ScaleValues` property values are applied to a quantized filter with only one section.

Application of ScaleValues to a Single Section



The following diagram shows how the ScaleValues property values are applied to a quantized filter with two sections.

Application of ScaleValues to Multiple Sections



Signed

When you create a dfilt object for fixed-point filtering (you set the property Arithmetic to fixed, the property Signed specifies whether the filter interprets coefficients as signed or unsigned. This setting applies only to the coefficients. While the default setting is true, meaning that all coefficients are assumed to be signed, you can change the setting to false after you create the fixed-point filter.

For example, create a fixed-point direct-form II transposed filter with both negative and positive coefficients, and then change the property value for Signed from true to false to see what happens to the negative coefficient values.

```
hd=dfilt.df2t(-5:5)

hd =

         FilterStructure: 'Direct-Form II Transposed'
              Arithmetic: 'double'
               Numerator: [-5 -4 -3 -2 -1 0 1 2 3 4 5]
```

```
             Denominator: 1
        PersistentMemory: false
                  States: [10x1 double]

set(hd,'arithmetic','fixed')
hd.numerator

ans =

    -5    -4    -3    -2    -1     0
     1     2     3     4     5

set(hd,'signed',false)
hd.numerator

ans =

     0     0     0     0     0     0
     1     2     3     4     5
```

Using unsigned coefficients limits you to using only positive coefficients in your filter. `Signed` is a dynamic property — you cannot set or change it until you switch the setting for the `Arithmetic` property to `fixed`.

SosMatrix

When you convert a `dfilt` object to second-order section form, or create a second-order section filter, `sosMatrix` holds the filter coefficients as property values. Using the `double` data type by default, the matrix is in [sections coefficients per section] form, displayed as `[15-x-6]` for filters with 6 coefficients per section and 15 sections, [15 6].

To demonstrate, the following code creates an order 30 filter using second-order sections in the direct-form II transposed configuration. Notice the `sosMatrix` property contains the coefficients for all the sections.

```
d = fdesign.lowpass('n,fc',30,0.5);
hd = butter(d);

hd =

  FilterStructure: 'Direct-Form II, Second-Order Sections'
       Arithmetic: 'double'
        sosMatrix: [15x6 double]
      ScaleValues: [16x1 double]
```

```
PersistentMemory: false
          States: [2x15 double]

hd.arithmetic='fixed'

hd =

 FilterStructure: 'Direct-Form II, Second-Order Sections'
      Arithmetic: 'fixed'
       sosMatrix: [15x6 double]
     ScaleValues: [16x1 double]
PersistentMemory: false
                  States: [1x1 embedded.fi]

 CoeffWordLength: 16
  CoeffAutoScale: true
          Signed: true

 InputWordLength: 16
 InputFracLength: 15

  SectionInputWordLength: 16
   SectionInputAutoScale: true

 SectionOutputWordLength: 16
  SectionOutputAutoScale: true

        OutputWordLength: 16
              OutputMode: 'AvoidOverflow'

    1.0000    2.0000    1.0000    1.0000         0    0.2948
    1.0000    2.0000    1.0000    1.0000         0    0.2275
    1.0000    2.0000    1.0000    1.0000         0    0.1716
    1.0000    2.0000    1.0000    1.0000         0    0.1254
    1.0000    2.0000    1.0000    1.0000         0    0.0878
    1.0000    2.0000    1.0000    1.0000         0    0.0576
    1.0000    2.0000    1.0000    1.0000         0    0.0344
    1.0000    2.0000    1.0000    1.0000         0    0.0173
    1.0000    2.0000    1.0000    1.0000         0    0.0062
    1.0000    2.0000    1.0000    1.0000         0    0.0007
```

The SOS matrix is an M-by-6 matrix, where M is the number of sections in the second-order section filter. Filter `hd` has M equal to 15 as shown above (15 rows). Each row of the SOS matrix contains the numerator and denominator coefficients (b's and a's) and the scale factors of the corresponding section in the filter.

SectionInputAutoScale

Second-order section filters include this property that determines who the filter handles data in the transitions from one section to the next in the filter.

How the filter represents the data passing from one section to the next depends on the property value of `SectionInputAutoScale`. The representation the filter uses between the filter sections depends on whether the value of `SectionInputAutoScale` is `true` or `false`.

- `SectionInputAutoScale` = `true` means the filter chooses the fraction length to maintain the value of the data between sections as close to the output values from the previous section as possible. `true` is the default setting.
- `SectionInputAutoScale` = `false` removes the automatic scaling of the fraction length for the intersection data and exposes the property that controls the coefficient fraction length (`SectionInputFracLength`) so you can change it. For example, if the filter is a second-order, direct form FIR filter, setting `SectionInputAutoScale` to `false` exposes the `SectionInputFracLength` property that specifies the fraction length applied to data between the sections.

SectionInputFracLength

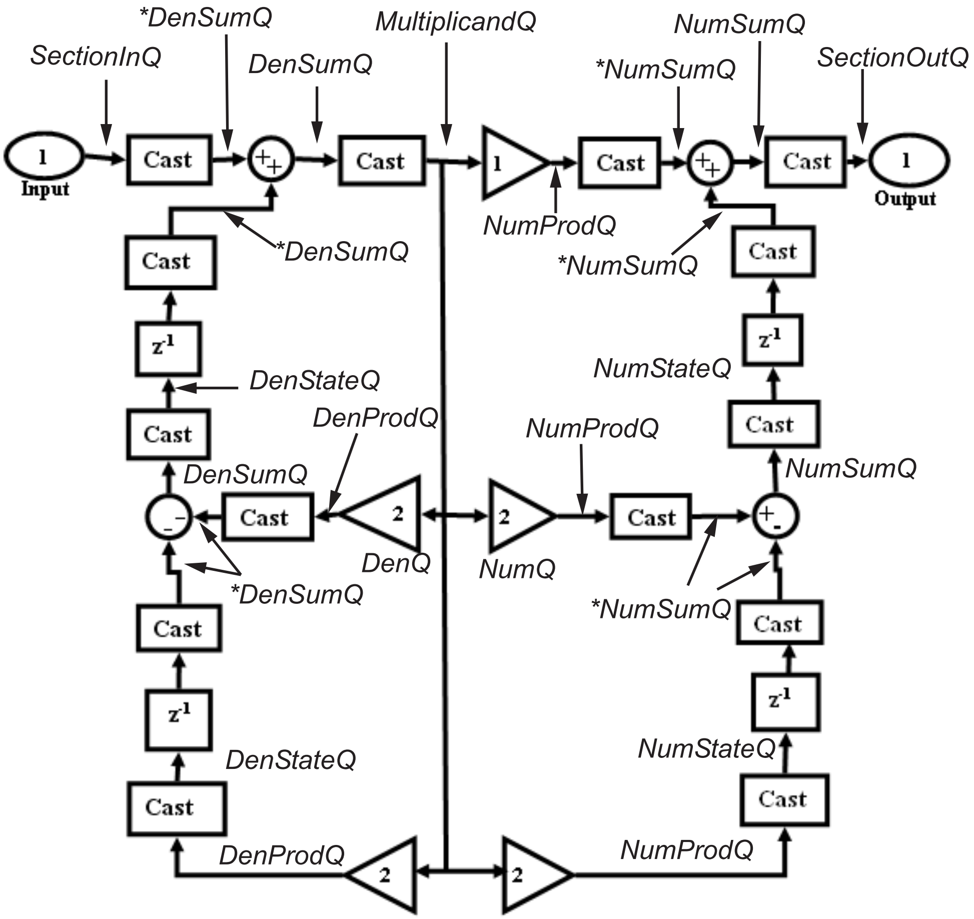
Second-order section filters use quantizers at the input to each section of the filter. The quantizers apply to the input data entering each filter section. Note that the quantizers for each section are the same. To set the fraction length for interpreting the input values, use the property value in `SectionInputFracLength`.

In combination with `CoeffWordLength`, `SectionInputFracLength` fully determines how the filter interprets and uses the state values stored in the property `States`. As with all word and fraction length properties, `SectionInputFracLength` can be any integer, including integers larger than `CoeffWordLength`, and positive or negative integers. 15 bits is the default value when you create the filter object.

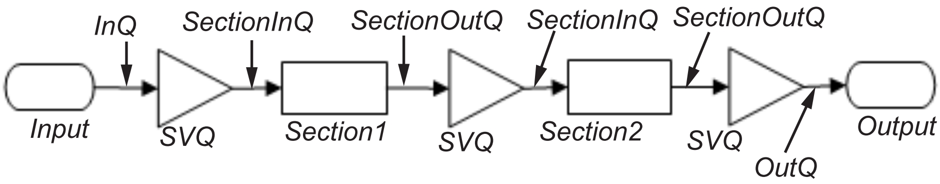
SectionInputWordLength

SOS filters are composed of sections, each one a second-order filter. Filtering data input to the filter involves passing the data through each filter section. `SectionInputWordLength` specifies the word length applied to data as it enters one filter section from the previous section. Only second-order implementations of direct-form I transposed and direct-form II transposed filters include this property.

The following diagram shows an SOS filter composed of sections (the bottom part of the diagram) and a possible internal structure of each Section (the top portion of the diagram), in this case — a direct form I transposed second order sections filter structure. Note that the output of each section is fed through a multiplier. If the gain of the multiplier `=1`, then the last Cast block of the Section is ignored, and the format of the output is NumSumQ.



* : only if CastBeforeSum is True



SectionInputWordLength defaults to 16 bits.

SectionOutputAutoScale

Second-order section filters include this property that determines who the filter handles data in the transitions from one section to the next in the filter.

How the filter represents the data passing from one section to the next depends on the property value of SectionOutputAutoScale. The representation the filter uses between the filter sections depends on whether the value of SectionOutputAutoScale is true or false.

- SectionOutputAutoScale = true means the filter chooses the fraction length to maintain the value of the data between sections as close to the output values from the previous section as possible. true is the default setting.
- SectionOutputAutoScale = false removes the automatic scaling of the fraction length for the intersection data and exposes the property that controls the coefficient fraction length (SectionOutputFracLength) so you can change it. For example, if the filter is a second-order, direct form FIR filter, setting SectionOutputAutoScale = false exposes the SectionOutputFracLength property that specifies the fraction length applied to data between the sections.

SectionOutputFracLength

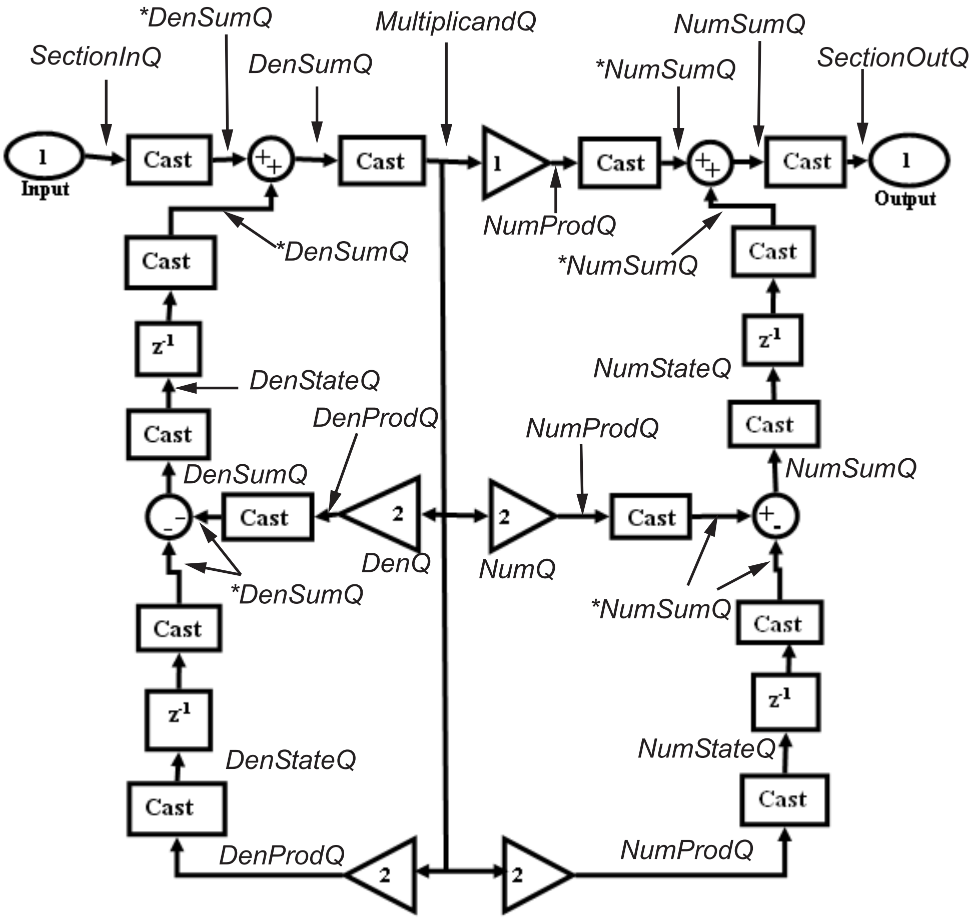
Second-order section filters use quantizers at the output from each section of the filter. The quantizers apply to the output data leaving each filter section. Note that the quantizers for each section are the same. To set the fraction length for interpreting the output values, use the property value in SectionOutputFracLength.

In combination with CoeffWordLength, SectionOutputFracLength determines how the filter interprets and uses the state values stored in the property States. As with all fraction length properties, SectionOutputFracLength can be any integer, including integers larger than CoeffWordLength, and positive or negative integers. 15 bits is the default value when you create the filter object.

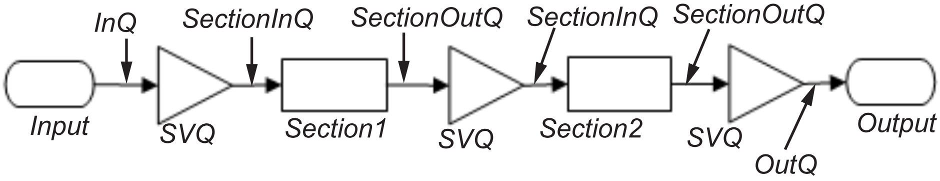
SectionOutputWordLength

SOS filters are composed of sections, each one a second-order filter. Filtering data input to the filter involves passing the data through each filter section. SectionOutputWordLength specifies the word length applied to data as it leaves one filter section to go to the next. Only second-order implementations direct-form I transposed and direct-form II transposed filters include this property.

The following diagram shows an SOS filter composed of sections (the bottom part of the diagram) and a possible internal structure of each Section (the top portion of the diagram), in this case — a direct form I transposed second order sections filter structure. Note that the output of each section is fed through a multiplier. If the gain of the multiplier =1, then the last Cast block of the Section is ignored, and the format of the output is NumSumQ.



* : only if CastBeforeSum is True



SectionOutputWordLength defaults to 16 bits.

StateAutoScale

Although all filters use states, some do not allow you to choose whether the filter automatically scales the state values to prevent overruns or bad arithmetic errors. You select either of the following settings:

- StateAutoScale = true means the filter chooses the fraction length to maintain the value of the states as close to the double-precision values as possible. When you change the word length applied to the states (where allowed by the filter structure), the filter object changes the fraction length to try to accommodate the change. true is the default setting.
- StateAutoScale = false removes the automatic scaling of the fraction length for the states and exposes the property that controls the coefficient fraction length so you can change it. For example, in a direct form I transposed SOS FIR filter, setting StateAutoScale = false exposes the NumStateFracLength and DenStateFracLength properties that specify the fraction length applied to states.

Each of the following filter structures provides the StateAutoScale property:

- df1t
- df1tsos
- df2t
- df2tsos
- dffirt

Other filter structures do not include this property.

StateFracLength

Filter states stored in the property States have both word length and fraction length. To set the fraction length for interpreting the stored filter object state values, use the property value in StateFracLength.

In combination with CoeffWordLength, StateFracLength fully determines how the filter interprets and uses the state values stored in the property States.

As with all fraction length properties, StateFracLength can be any integer, including integers larger than CoeffWordLength, and positive or negative integers. 15 bits is the default value when you create the filter object.

States

Digital filters are dynamic systems. The behavior of dynamic systems (their response) depends on the input (stimulus) to the system and the current or previous *state* of the system. You can say the system has memory or inertia. All fixed- or floating-point digital filters (as well as analog filters) have states.

Filters use the states to compute the filter output for each input sample, as well using them while filtering in loops to maintain the filter state between loop iterations. This toolbox assumes zero-valued initial conditions (the dynamic system is at rest) by default when you filter the first input sample. Assuming the states are zero initially does not mean the states are not used; they are, but arithmetically they do not have any effect.

Filter objects store the state values in the property `States`. The number of stored states depends on the filter implementation, since the states represent the delays in the filter implementation.

When you review the display for a filter object with fixed arithmetic, notice that the states return an embedded `fi` object, as you see here.

```
b = ellip(6,3,50,300/500);
hd=dfilt.dffir(b)

hd =

         FilterStructure: 'Direct-Form FIR'
              Arithmetic: 'double'
               Numerator: [0.0773 0.2938 0.5858 0.7239 0.5858 0.2938 0.0773]
        PersistentMemory: false
                  States: [6x1 double]

hd.arithmetic='fixed'

hd =

         FilterStructure: 'Direct-Form FIR'
              Arithmetic: 'fixed'
               Numerator: [0.0773 0.2938 0.5858 0.7239 0.5858 0.2938 0.0773]
        PersistentMemory: false
                  States: [1x1 embedded.fi]

         CoeffWordLength: 16
          CoeffAutoScale: 'on'
                  Signed: 'on'

         InputWordLength: 16
         InputFracLength: 15

        OutputWordLength: 16
              OutputMode: 'AvoidOverflow'

             ProductMode: 'FullPrecision'
         AccumWordLength: 40
           CastBeforeSum: 'on'

               RoundMode: 'convergent'
            OverflowMode: 'wrap'

         InheritSettings: 'off'
```

fi objects provide fixed-point support for the filters. To learn more about the details about fi objects, refer to your Fixed-Point Designer documentation.

The property States lets you use a fi object to define how the filter interprets the filter states. For example, you can create a fi object in MATLAB, then assign the object to States, as follows:

```
statefi=fi([],16,12)

statefi =

[]
   DataTypeMode = Fixed-point: binary point scaling
         Signed = true
    Wordlength = 16
Fractionlength = 12
```

This fi object does not have a value associated (notice the [] input argument to fi for the value), and it has word length of 16 bits and fraction length of 12 bit. Now you can apply statefi to the States property of the filter hd.

```
set(hd,'States',statefi);
Warning: The 'States' property will be reset to the value
specified at construction before filtering.
Set the 'PersistentMemory' flag to 'True'
to avoid changing this property value.
hd

hd =

         FilterStructure: 'Direct-Form FIR'

               Numerator: [0.0773 0.2938 0.5858 0.7239 0.5858
                           0.2938 0.0773]
        PersistentMemory: false
                  States: [1x1 embedded.fi]

         CoeffWordLength: 16
          CoeffAutoScale: 'on'
```

```
               Signed: 'on'

      InputWordLength: 16
      InputFracLength: 15

     OutputWordLength: 16
           OutputMode: 'AvoidOverflow'

          ProductMode: 'FullPrecision'
      AccumWordLength: 40
        CastBeforeSum: 'on'

            RoundMode: 'convergent'
         OverflowMode: 'wrap'
```

StateWordLength

While all filters use states, some do not allow you to directly change the state representation — the word length and fraction lengths — independently. For the others, StateWordLength specifies the word length, in bits, the filter uses to represent the states. Filters that do not provide direct state word length control include:

- df1
- dfasymfir
- dffir
- dfsymfir

For these structures, the filter derives the state format from the input format you choose for the filter — except for the df1 IIR filter. In this case, the numerator state format comes from the input format and the denominator state format comes from the output format. All other filter structures provide control of the state format directly.

TapSumFracLength

Direct-form FIR filter objects, both symmetric and antisymmetric, use this property. To set the fraction length for output from the sum operations that involve the filter tap weights, use the property value in TapSumFracLength. To enable this property, set the TapSumMode to SpecifyPrecision in your filter.

As you can see in this code example that creates a fixed-point asymmetric FIR filter, the TapSumFracLength property becomes available after you change the TapSumMode property value.

```
hd=dfilt.dfasymfir

hd =

         FilterStructure: 'Direct-Form Antisymmetric FIR'
              Arithmetic: 'double'
               Numerator: 1
        PersistentMemory: false
                  States: [0x1 double]

set(hd,'arithmetic','fixed');
hd

hd =

         FilterStructure: 'Direct-Form Antisymmetric FIR'
              Arithmetic: 'fixed'
               Numerator: 1
        PersistentMemory: false
                  States: [1x1 embedded.fi]

         CoeffWordLength: 16
          CoeffAutoScale: true
                  Signed: true

         InputWordLength: 16
         InputFracLength: 15

        OutputWordLength: 16
              OutputMode: 'AvoidOverflow'

              TapSumMode: 'KeepMSB'
        TapSumWordLength: 17

             ProductMode: 'FullPrecision'

         AccumWordLength: 40

           CastBeforeSum: true
               RoundMode: 'convergent'
            OverflowMode: 'wrap'
```

With the filter now in fixed-point mode, you can change the `TapSumMode` property value to `SpecifyPrecision`, which gives you access to the `TapSumFracLength` property.

```
set(hd,'TapSumMode','SpecifyPrecision');
hd

hd =

         FilterStructure: 'Direct-Form Antisymmetric FIR'
              Arithmetic: 'fixed'
               Numerator: 1
        PersistentMemory: false
                  States: [1x1 embedded.fi]

         CoeffWordLength: 16
          CoeffAutoScale: true
                  Signed: true

         InputWordLength: 16
         InputFracLength: 15

        OutputWordLength: 16
              OutputMode: 'AvoidOverflow'

              TapSumMode: 'SpecifyPrecision'
        TapSumWordLength: 17
        TapSumFracLength: 15

             ProductMode: 'FullPrecision'

         AccumWordLength: 40

           CastBeforeSum: true
               RoundMode: 'convergent'
            OverflowMode: 'wrap'
```

In combination with TapSumWordLength, TapSumFracLength fully determines how the filter interprets and uses the state values stored in the property States.

As with all fraction length properties, TapSumFracLength can be any integer, including integers larger than TapSumWordLength, and positive or negative integers. 15 bits is the default value when you create the filter object.

TapSumMode

This property, available only after your filter is in fixed-point mode, specifies how the filter outputs the results of summation operations that involve the filter tap weights.

Only symmetric (`dfilt.dfsymfir`) and antisymmetric (`dfilt.dfasymfir`) FIR filters use this property.

When available, you select from one of the following values:

- `FullPrecision` — means the filter automatically chooses the word length and fraction length to represent the results of the sum operation so they retain all of the precision provided by the inputs (addends).
- `KeepMSB` — means you specify the word length for representing tap sum summation results to keep the higher order bits in the data. The filter sets the fraction length to discard the LSBs from the sum operation. This is the default property value.
- `KeepLSB` — means you specify the word length for representing tap sum summation results to keep the lower order bits in the data. The filter sets the fraction length to discard the MSBs from the sum operation. Compare to the `KeepMSB` option.
- `SpecifyPrecision` — means you specify the word and fraction lengths to apply to data output from the tap sum operations.

TapSumWordLength

Specifies the word length the filter uses to represent the output from tap sum operations. The default value is 17 bits. Only `dfasymfir` and `dfsymfir` filters include this property.

Adaptive Filter Properties

In this section...

"Property Details for Adaptive Filter Properties" on page 5-96
"References for Adaptive Filters" on page 5-102

Property Summaries

The following table summarizes the adaptive filter properties and provides a brief description of each. Full descriptions of each property, in alphabetical order, are given in the subsequent section.

Property	Description
`Algorithm`	Reports the algorithm the object uses for adaptation. When you construct your adaptive filter object, this property is set automatically by the constructor, such as `adaptfilt.nlms` creating an adaptive filter that uses the normalized LMS algorithm. You cannot change the value — it is read only.
`AvgFactor`	Averaging factor used to compute the exponentially-windowed estimates of the powers in the transformed signal bins for the coefficient updates. `AvgFactor` should lie between zero and one. For default filter objects, `AvgFactor` equals (1 - `step`). `lambda` is the input argument that represents `AvgFactor`
`BkwdPredErrorPower`	Returns the minimum mean-squared prediction error. Refer to [3] in the bibliography for details about linear prediction.
`BkwdPrediction`	Returns the predicted samples generated during adaptation. Refer to [3] in the bibliography for details about linear prediction.
`Blocklength`	Block length for the coefficient updates. This must be a positive integer such that (`l/blocklength`) is also an integer. For faster execution, `blocklength` should be a power of two. `blocklength` defaults to two.

Property	Description
Coefficients	Vector containing the initial filter coefficients. It must be a length l vector where l is the number of filter coefficients. coeffs defaults to length l vector of zeros when you do not provide the argument for input.
ConversionFactor	Conversion factor defaults to the matrix [1 -1] that specifies soft-constrained initialization. This is the gamma input argument for some of the fast transversal algorithms.
Delay	Update delay given in time samples. This scalar should be a positive integer—negative delays do not work. delay defaults to 1 for most algorithms.
DesiredSignalStates	Desired signal states of the adaptive filter. dstates defaults to a zero vector with length equal to (blocklen - 1) or (swblocklen - 1) depending on the algorithm.
EpsilonStates	Vector of the epsilon values of the adaptive filter. EpsilonStates defaults to a vector of zeros with (projectord - 1) elements.
ErrorStates	Vector of the adaptive filter error states. ErrorStates defaults to a zero vector with length equal to (projectord - 1).
FFTCoefficients	Stores the discrete Fourier transform of the filter coefficients in coeffs.
FFTStates	Stores the states of the FFT of the filter coefficients during adaptation.
FilteredInputStates	Vector of filtered input states with length equal to l - 1.
FilterLength	Contains the length of the filter. Note that this is not the filter order. Filter length is 1 greater than filter order. Thus a filter with length equal to 10 has filter order equal to 9.
ForgettingFactor	Determines how the RLS adaptive filter uses past data in each iteration. You use the forgetting factor to specify whether old data carries the same weight in the algorithm as more recent data.

Property	Description
`FwdPredErrorPower`	Returns the minimum mean-squared prediction error in the forward direction. Refer to [3] in the bibliography for details about linear prediction.
`FwdPrediction`	Contains the predicted values for samples during adaptation. Compare these to the actual samples to get the error and power.
`InitFactor`	Soft-constrained initialization factor. This scalar should be positive and sufficiently large to prevent an excessive number of Kalman gain rescues. Called `delta` as an input argument, this defaults to one.
`InvCov`	Upper-triangular Cholesky (square root) factor of the input covariance matrix. Initialize this matrix with a positive definite upper triangular matrix. Dimensions are `l`-by-`l`, where `l` is the filter length.
`KalmanGain`	Empty when you construct the object, this gets populated after you run the filter.
`KalmanGainStates`	Contains the states of the Kalman gain updates during adaptation.
`Leakage`	Contains the setting for leakage in the adaptive filter algorithm. Using a leakage factor that is not 1 forces the weights to adapt even when they have found the minimum error solution. Forcing the adaptation can improve the numerical performance of the LMS algorithm.
`OffsetCov`	Contains the offset covariance matrix.
`Offset`	Specifies an optional offset for the denominator of the step size normalization term. You must specify offset to be a scalar greater than or equal to zero. Nonzero offsets can help avoid a divide-by-near-zero condition that causes errors.
`Power`	A vector of `2*l` elements, each initialized with the value `delta` from the input arguments. As you filter data, `Power` gets updated by the filter process.

Property	Description
ProjectionOrder	Projection order of the affine projection algorithm. projectord defines the size of the input signal covariance matrix and defaults to two.
ReflectionCoeffs	Coefficients determined for the reflection portion of the filter during adaptation.
ReflectionCoeffsStep	Size of the steps used to determine the reflection coefficients.
PersistentMemory	Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states and coefficients from previous filtering runs.
SecondaryPathCoeffs	A vector that contains the coefficient values of your secondary path from the output actuator to the error sensor.
SecondaryPathEstimate	An estimate of the secondary path filter model.
SecondaryPathStates	The states of the secondary path filter, the unknown system.
SqrtCov	Upper-triangular Cholesky (square root) factor of the input covariance matrix. Initialize this matrix with a positive definite upper triangular matrix.
SqrtlnvCov	Square root of the inverse of the sliding window input signal covariance matrix. This square matrix should be full-ranked.
States	Vector of the adaptive filter states. states defaults to a vector of zeros whose length depends on the chosen algorithm. Usually the length is a function of the filter length l and another input argument to the filter object, such as projectord.
StepSize	Reports the size of the step taken between iterations of the adaptive filter process. Each adaptfilt object has a default value that best meets the needs of the algorithm.
SwBlockLength	Block length of the sliding window. This integer must be at least as large as the filter length. swblocklen defaults to 16.

Like dfilt objects, adaptfilt objects have properties that govern their behavior and store some of the results of filtering operations. The following pages list, in alphabetical order, the name of every property associated with adaptfilt objects. Note that not all adaptfilt objects have all of these properties. To view the properties of a particular adaptive filter, such as an adaptfilt.bap filter, use get with the object handle, like this:

```
ha = adaptfilt.bap(32,0.5,4,1.0);
get(ha)
        PersistentMemory: false
               Algorithm: 'Block Affine Projection FIR Adaptive Filter'
            FilterLength: 32
            Coefficients: [1x32 double]
                  States: [35x1 double]
                StepSize: 0.5000
         ProjectionOrder: 4
               OffsetCov: [4x4 double]
```

get shows you the properties for ha and the values for the properties. Entering the object handle returns the same values and properties without the formatting of the list and the more familiar property names.

Property Details for Adaptive Filter Properties

Algorithm

Reports the algorithm the object uses for adaptation. When you construct you adaptive filter object, this property is set automatically. You cannot change the value—it is read only.

AvgFactor

Averaging factor used to compute the exponentially-windowed estimates of the powers in the transformed signal bins for the coefficient updates. AvgFactor should lie between zero and one. For default filter objects, AvgFactor equals (1 - step). lambda is the input argument that represent AvgFactor

BkwdPredErrorPower

Returns the minimum mean-squared prediction error in the backward direction. Refer to [3] in the bibliography for details about linear prediction.

BkwdPrediction

When you use an adaptive filter that does backward prediction, such as adaptfilt.ftf, one property of the filter contains the backward prediction coefficients for the adapted filter. With these coefficient, the forward coefficients, and the system under test, you have the full set of knowledge of how the adaptation occurred. Two values stored in properties compose the `BkwdPrediction` property:

- Coefficients, which contains the coefficients of the system under test, as determined using backward predictions process.
- Error, which is the difference between the filter coefficients determined by backward prediction and the actual coefficients of the sample filter. In this example, `adaptfilt.ftf` identifies the coefficients of an unknown FIR system.

```
x  = randn(1,500);     % Input to the filter
b  = fir1(31,0.5);     % FIR system to be identified
n  = 0.1*randn(1,500); % Observation noise signal
d  = filter(b,1,x)+n;  % Desired signal
N  = 31;               % Adaptive filter order
lam = 0.99;            % RLS forgetting factor
del = 0.1;             % Soft-constrained initialization factor
ha = adaptfilt.ftf(32,lam,del);
[y,e] = filter(ha,x,d);

ha

```

Blocklength

Block length for the coefficient updates. This must be a positive integer such that (`l/blocklen`) is also an integer. For faster execution, `blocklen` should be a power of two. `blocklen` defaults to two.

Coefficients

Vector containing the initial filter coefficients. It must be a length `l` vector where `l` is the number of filter coefficients. `coeffs` defaults to length `l` vector of zeros when you do not provide the argument for input.

ConversionFactor

Conversion factor defaults to the matrix [1 -1] that specifies soft-constrained initialization. This is the `gamma` input argument for some of the fast transversal algorithms.

Delay

Update delay given in time samples. This scalar should be a positive integer — negative delays do not work. `delay` defaults to 1 for most algorithms.

DesiredSignalStates

Desired signal states of the adaptive filter. `dstates` defaults to a zero vector with length equal to (`blocklen` - 1) or (`swblocklen` - 1) depending on the algorithm.

EpsilonStates

Vector of the epsilon values of the adaptive filter. `EpsilonStates` defaults to a vector of zeros with (`projectord` - 1) elements.

ErrorStates

Vector of the adaptive filter error states. `ErrorStates` defaults to a zero vector with length equal to (`projectord` - 1).

FFTCoefficients

Stores the discrete Fourier transform of the filter coefficients in `coeffs`.

FFTStates

Stores the states of the FFT of the filter coefficients during adaptation.

FilteredInputStates

Vector of filtered input states with length equal to `l` - 1.

FilterLength

Contains the length of the filter. Note that this is not the filter order. Filter length is 1 greater than filter order. Thus a filter with length equal to 10 has filter order equal to 9.

ForgettingFactor

Determines how the RLS adaptive filter uses past data in each iteration. You use the forgetting factor to specify whether old data carries the same weight in the algorithm as more recent data.

This is a scalar and should lie in the range (0, 1]. It defaults to 1. Setting `forgetting factor = 1` denotes infinite memory while adapting to find the new filter. Note that this is the `lambda` input argument.

FwdPredErrorPower

Returns the minimum mean-squared prediction error in the forward direction. Refer to [3] in the bibliography for details about linear prediction.

FwdPrediction

Contains the predicted values for samples during adaptation. Compare these to the actual samples to get the error and power.

InitFactor

Returns the soft-constrained initialization factor. This scalar should be positive and sufficiently large to prevent an excessive number of Kalman gain rescues. `delta` defaults to one.

InvCov

Upper-triangular Cholesky (square root) factor of the input covariance matrix. Initialize this matrix with a positive definite upper triangular matrix. Dimensions are `l`-by-`l`, where `l` is the filter length.

KalmanGain

Empty when you construct the object, this gets populated after you run the filter.

KalmanGainStates

Contains the states of the Kalman gain updates during adaptation.

Leakage

Contains the setting for leakage in the adaptive filter algorithm. Using a leakage factor that is not 1 forces the weights to adapt even when they have found the minimum error solution. Forcing the adaptation can improve the numerical performance of the LMS algorithm.

OffsetCov

Contains the offset covariance matrix.

Offset

Specifies an optional offset for the denominator of the step size normalization term. You must specify offset to be a scalar greater than or equal to zero. Nonzero offsets can help avoid a divide-by-near-zero condition that causes errors.

Use this to avoid dividing by zero or by very small numbers when input signal amplitude becomes very small, or dividing by very small numbers when any of the FFT input signal powers become very small. `offset` defaults to one.

Power

A vector of 2*`l` elements, each initialized with the value `delta` from the input arguments. As you filter data, `Power` gets updated by the filter process.

ProjectionOrder

Projection order of the affine projection algorithm. `projectord` defines the size of the input signal covariance matrix and defaults to two.

ReflectionCoeffs

For adaptive filters that use reflection coefficients, this property stores them.

ReflectionCoeffsStep

As the adaptive filter changes coefficient values during adaptation, the step size used between runs is stored here.

PersistentMemory

Determines whether the filter states and coefficients get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter.

`PersistentMemory` returns to zero any property value that the filter changes during processing. Property values that the filter does not change are not affected. Defaults to `false`.

SecondaryPathCoeffs

A vector that contains the coefficient values of your secondary path from the output actuator to the error sensor.

SecondaryPathEstimate

An estimate of the secondary path filter model.

SecondaryPathStates

The states of the secondary path filter, the unknown system.

SqrtCov

Upper-triangular Cholesky (square root) factor of the input covariance matrix. Initialize this matrix with a positive definite upper triangular matrix.

SqrtInvCov

Square root of the inverse of the sliding window input signal covariance matrix. This square matrix should be full-ranked.

States

Vector of the adaptive filter states. `states` defaults to a vector of zeros whose length depends on the chosen algorithm. Usually the length is a function of the filter length `l` and another input argument to the filter object, such as projectord.

StepSize

Reports the size of the step taken between iterations of the adaptive filter process. Each `adaptfilt` object has a default value that best meets the needs of the algorithm.

SwBlockLength

Block length of the sliding window. This integer must be at least as large as the filter length. `swblocklength` defaults to 16.

Multirate Filter Properties

In this section...
"Property Summaries" on page 5-103
"Property Details for Multirate Filter Properties" on page 5-107
"References for Multirate Filters" on page 5-117

Property Summaries

The following table summarizes the multirate filter properties and provides a brief description of each. Full descriptions of each property are given in the subsequent section.

Name	Values	Default	Description
`BlockLength`	Positive integers	100	Length of each block of data input to the FFT used in the filtering. `fftfirinterp` multirate filters include this property.
`DecimationFactor`	Any positive integer	2	Amount to reduce the input sampling rate.
`DifferentialDelay`	Any integer	1	Sets the differential delay for the filter. Usually a value of one or two is appropriate.

`FilterInternals`	`FullPrecision`,
	`MinWordlengths`,
	`SpecifyWordLengths`
	`SpecifyPrecision`
		`FullPrecision`	Controls whether the filter sets the output word and fraction lengths, and the accumulator word and fraction lengths automatically to maintain the best precision results during filtering. The default value, `FullPrecision`, sets automatic word and fraction length determination by the filter. `SpecifyPrecision` exposes the output and

Name	Values	Default	Description
			accumulator related properties so you can set your own word and fraction lengths for them.
`FilterStructure`	`mfilt` structure string	None	Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering — gains, delays, sums, products, and input/output. You cannot set this property — it is always read only and results from your choice of `mfilt` object.
`InputOffset`	Integers	0	Contains the number of input data samples processed without generating an output sample. `InputOffset = mod(length(nx),m)` where `nx` is the number of input samples that have been processed so far and m is the decimation factor.
`InterpolationFactor`	Positive integers	2	Interpolation factor for the filter. `l` specifies the amount to increase the input sampling rate.
`NumberOfSections`	Any positive integer	2	Number of sections used in the decimator, or in the comb and integrator portions of CIC filters.
`Numerator`	Array of double values	No default values	Vector containing the coefficients of the FIR lowpass filter used for interpolation.

Name	Values	Default	Description
`OverflowMode`	saturate, [wrap]	wrap	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either `saturate` (limit the output to the largest positive or negative representable value) or `wrap` (set overflowing values to the nearest representable value using modular arithmetic. The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow — they maintain full precision.
`PolyphaseAccum`	Values depend on filter type. Either double, single, or fixed-point object	0	Stores the value remaining in the accumulator after the filter processes the last input sample. The stored value for `PolyphaseAccum` affects the next output when `PersistentMemory` is `true` and `InputOffset` is not equal to 0. Always provides full precision values. Compare the `AccumWordLength` and `AccumFracLength`.

Name	Values	Default	Description
`PersistentMemory`	`false` or `true`	`false`	Determines whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. `PersistentMemory` returns to zero any state that the filter changes during processing. States that the filter does not change are not affected.
`RateChangeFactors`	[`l`,`m`]	[2,3] or [3,2]	Reports the decimation (`m`) and interpolation (`l`) factors for the filter object. Combining these factors results in the final rate change for the signal. The default changes depending on whether the filter decimates or interpolates.
`States`	Any `m`+1-by-`n` matrix of `double` values	2-by-2 matrix, `int32`	Stored conditions for the filter, including values for the integrator and comb sections. `n` is the number of filter sections and `m` is the differential delay. Stored in a `filtstates` object.
`SpecifyWordLengths`	Vector of integers	`[16 16 16 16]` bits	

Name	Values	Default	Description
WordLengthPerSection	Any integer or a vector of length 2*n	16	Defines the word length used in each section while accumulating the data in the integrator sections or while subtracting the data during the comb sections (using 'wrap' arithmetic). Enter WordLengthPerSection as a scalar or vector of length 2*n, where n is the number of sections. When WordLengthPerSection is a scalar, the scalar value is applied to each filter section. The default is 16 for each section in the decimator.

The following sections provide details about the properties that govern the way multirate filter work. Creating any multirate filter object puts in place a number of these properties. The following pages list the mfilt object properties in alphabetical order.

Property Details for Multirate Filter Properties

BitsPerSection

Any integer or a vector of length 2*n.

Defines the bits per section used while accumulating the data in the integrator sections or while subtracting the data during the comb sections (using wrap arithmetic). Enter bps as a scalar or vector of length 2*n, where n is the number of sections. When bps is a scalar, the scalar value is applied to each filter section. The default is 16 for each section in the decimator.

BlockLength

Length of each block of input data used in the filtering.

mfilt.fftfirinterp objects process data in blocks whose length is determined by the value you set for the BlockLength property. By default the property value is 100.

When you set the `BlockLength` value, try choosing a value so that [`BlockLength` + `length`(filter order)] is a power of two.

Larger block lengths generally reduce the computation time.

DecimationFactor

Decimation factor for the filter. `m` specifies the amount to reduce the sampling rate of the input signal. It must be an integer. You can enter any integer value. The default value is 2.

DifferentialDelay

Sets the differential delay for the filter. Usually a value of one or two is appropriate. While you can set any value, the default is one and the maximum is usually two.

FilterInternals

Similar to the FilterInternals pane in FDATool, this property controls whether the filter sets the output word and fraction lengths automatically, and the accumulator word and fraction lengths automatically as well, to maintain the best precision results during filtering. The default value, `FullPrecision`, sets automatic word and fraction length determination by the filter. Setting `FilterInternals` to `SpecifyPrecision` exposes the output and accumulator related properties so you can set your own word and fraction lengths for them.

About FilterInternals Mode

There are four usage modes for this that you set using the `FilterInternals` property in multirate filters.

- `FullPrecision` — All word and fraction lengths set to B_{max} + 1, called B_{accum} by Fred Harris in [2]. Full precision is the default setting.
- `MinWordLengths` — Minimum Word Lengths
- `SpecifyWordLengths` — Specify Word Lengths
- `SpecifyPrecision` — Specify Precision

Full Precision

In full precision mode, the word lengths of all sections and the output are set to B_{accum} as defined by

$$B_{accum} = ceil(N_{\sec s}(Log_2(D \times M)) + InputWordLength)$$

where N_{secs} is the number of filter sections.

Section fraction lengths and the fraction length of the output are set to the input fraction length.

Here is the display looks for this mode.

```
FilterStructure: 'Cascaded Integrator-Comb Decimator'
Arithmetic: 'fixed'
DifferentialDelay: 1
NumberOfSections: 2
DecimationFactor: 4
PersistentMemory: false

InputWordLength: 16
InputFracLength: 15

FilterInternals: 'FullPrecision'
```

Minimum Word Lengths

In minimum word length mode, you control the output word length explicitly. When the output word length is less than B_{accum}, roundoff noise is introduced at the output of the filter. Hogenauer's bit pruning theory (refer to [3] in the following References section) states that one valid design criterion is to make the word lengths of the different sections of the filter smaller than B_{accum} as well, so that the roundoff noise introduced by all sections does not exceed the roundoff noise introduced at the output.

In this mode, the design calculates the word lengths of each section to meet the Hogenauer criterion. The algorithm subtracts the number of bits computed using eq. 21 in Hogenauer's paper from B_{accum} to determine the word length each section.

To compute the fraction lengths of the different sections, the algorithm notes that the bits thrown out for this word length criterion are least significant bits (LSB), therefore each bit thrown out at a particular section decrements the fraction length of that section by one bit compared to the input fraction length. Setting the output word length for the filter automatically sets the output fraction length as well.

Here is the display for this mode:

```
FilterStructure: 'Cascaded Integrator-Comb Decimator'
```

```
Arithmetic: 'fixed'
DifferentialDelay: 1
NumberOfSections: 2
DecimationFactor: 4
PersistentMemory: false

InputWordLength: 16
InputFracLength: 15

FilterInternals: 'MinWordLengths'

OutputWordLength: 16
```

Specify Word Lengths

In this mode, the design algorithm discards the LSBs, adjusting the fraction length so that unrecoverable overflow does not occur, always producing a reasonable output.

You can specify the word lengths for all sections and the output, but you cannot control the fraction lengths for those quantities.

To specify the word lengths, you enter a vector of length 2*(NumberOfSections), where each vector element represents the word length for a section. If you specify a scalar, such as B_{accum}, the full-precision output word length, the algorithm expands that scalar to a vector of the appropriate size, applying the scalar value to each section.

The CIC design does not check that the specified word lengths are monotonically decreasing. There are some cases where the word lengths are not necessarily monotonically decreasing, for example

```
hcic=mfilt.cicdecim;
hcic.FilterInternals='minwordlengths';
hcic.Outputwordlength=14;
```

which are valid CIC filters but the word lengths do not decrease monotonically across the sections.

Here is the display looks like for the SpecifyWordLengths mode.

```
FilterStructure: 'Cascaded Integrator-Comb Decimator'
Arithmetic: 'fixed'
DifferentialDelay: 1
NumberOfSections: 2
DecimationFactor: 4
PersistentMemory: false
```

```
InputWordLength: 16
InputFracLength: 15

FilterInternals: 'SpecifyWordLengths'

SectionWordLengths: [19 18 18 17]

OutputWordLength: 16
```

Specify Precision

In this mode, you have full control over the word length and fraction lengths of all sections and the filter output.

When you elect the `SpecifyPrecision` mode, you must enter a vector of length 2*(`NumberOfSections`) with elements that represent the word length for each section. When you enter a scalar such as B_{accum}, the CIC algorithm expands that scalar to a vector of the appropriate size and applies the scalar value to each section and the output. The design does not check that this vector is monotonically decreasing.

Also, you must enter a vector of length 2*(`NumberOfSections`) with elements that represent the fraction length for each section as well. When you enter a scalar such as B_{accum}, the design applies scalar expansion as done for the word lengths.

Here is the `SpecifyPrecision` display.

```
FilterStructure: 'Cascaded Integrator-Comb Decimator'
Arithmetic: 'fixed'
DifferentialDelay: 1
NumberOfSections: 2
DecimationFactor: 4
PersistentMemory: false

InputWordLength: 16
InputFracLength: 15

FilterInternals: 'SpecifyPrecision'

SectionWordLengths: [19 18 18 17]
SectionFracLengths: [14 13 13 12]

OutputWordLength: 16
OutputFracLength: 11
```

FilterStructure

Reports the type of filter object, such as a decimator or fractional integrator. You cannot set this property — it is always read only and results from your choice of `mfilt` object. Because of the length of the names of multirate filters, `FilterStructure` often returns a vector specification for the string. For example, when you use `mfilt.firfracinterp` to design a filter, `FilterStructure` returns as [1x49 char].

```
hm=mfilt.firfracinterp

hm =

         FilterStructure: [1x49 char]
               Numerator: [1x72 double]
       RateChangeFactors: [3 2]
        PersistentMemory: false
                  States: [24x1 double]
```

InputOffset

When you decimate signals whose length is not a multiple of the decimation factor M, the last samples — (nM +1) to [(n+1)(M) -1], where *n* is an integer — are processed and used to track where the filter stopped processing input data and when to expect the next output sample. If you think of the filtering process as generating an output for a block of input data, `InputOffset` contains a count of the number of samples in the last incomplete block of input data.

Note `InputOffset` applies only when you set `PersistentMemory` to `true`. Otherwise, `InputOffset` is not available for you to use.

Two different cases can arise when you decimate a signal:

1. The input signal is a multiple of the filter decimation factor. In this case, the filter processes the input samples and generates output samples for all inputs as determined by the decimation factor. For example, processing 99 input samples with a filter that decimates by three returns 33 output samples.
2. The input signal is not a multiple of the decimation factor. When this occurs, the filter processes all of the input samples, generates output samples as determined by the decimation factor, and has one or more input samples that were processed but did not generate an output sample.

For example, when you filter 100 input samples with a filter which has decimation factor of 3, you get 33 output samples, and 1 sample that did not generate an output. In this case, `InputOffset` stores the value 1 after the filter run.

`InputOffset` equal to 1 indicates that, if you divide your input signal into blocks of data with length equal to your filter decimation factor, the filter processed one sample from a new (incomplete) block of data. Subsequent inputs to the filter are concatenated with this single sample to form the next block of length m.

One way to define the value stored in `InputOffset` is

```
InputOffset = mod(length(nx),m)
```

where `nx` is the number of input samples in the data set and `m` is the decimation factor.

Storing `InputOffset` in the filter allows you to stop filtering a signal at any point and start over from there, provided that the `PersistentMemory` property is set to `true`. Being able to resume filtering after stopping a signal lets you break large data sets in to smaller pieces for filtering. With `PersistentMemory` set to `true` and the `InputOffset` property in the filter, breaking a signal into sections of arbitrary length and filtering the sections is equivalent to filtering the entire signal at once.

```
xtot=[x,x];
ytot=filter(hm1,xtot)
ytot =

         0   -0.0003    0.0005   -0.0014    0.0028   -0.0054    0.0092
reset(hm1);  % Clear history of the filter
hm1.PersistentMemory='true';
ysec=[filter(hm1,x) filter(hm1,x)]

ysec =

         0   -0.0003    0.0005   -0.0014    0.0028   -0.0054    0.0092
```

This test verifies that `ysec` (the signal filtered by sections) is equal to `ytot` (the entire signal filtered at once).

InterpolationFactor

Amount to increase the sampling rate. Interpolation factor for the filter. It specifies the amount to increase the input sampling rate. It must be an integer. Two is the default value. You may use any positive value.

NumberOfSections

Number of sections used in the multirate filter. By default multirate filters use two sections, but any positive integer works.

OverflowMode

The `OverflowMode` property is specified as one of the following two strings indicating how to respond to overflows in fixed-point arithmetic:

- `'saturate'` — saturate overflows.

  When the values of data to be quantized lie outside of the range of the largest and smallest representable numbers (as specified by the applicable word length and fraction length properties), these values are quantized to the value of either the largest or smallest representable value, depending on which is closest.
- `'wrap'` — wrap all overflows to the range of representable values.

  When the values of data to be quantized lie outside of the range of the largest and smallest representable numbers (as specified by the data format properties), these values are wrapped back into that range using modular arithmetic relative to the smallest representable number. You can learn more about modular arithmetic in Fixed-Point Designer documentation.

These rules apply to the `OverflowMode` property.

- Applies to the accumulator and output data only.
- Does not apply to coefficients or input data. These always saturate the results.
- Does not apply to products. Products maintain full precision at all times. Your filters do not lose precision in the products.

Default value

: `'saturate'`

Note Numbers in floating-point filters that extend beyond the dynamic range overflow to ±`inf`.

PolyphaseAccum

The idea behind PolyphaseAccum and AccumWordLength/AccumFracLength is to distinguish between the adders that always work in full precision (PolyphaseAccum) from the others [the adders that are controlled by the user (through AccumWordLength and AccumFracLength) and that may introduce quantization effects when you set property FilterInternals to SpecifyPrecision.

Given a product format determined by the input word and fraction lengths, and the coefficients word and fraction lengths, doing full precision accumulation means allowing enough guard bits to avoid overflows and underflows.

Property PolyphaseAccum stores the value that was in the accumulator the last time your filter ran out of input samples to process. The default value for PolyphaseAccum affects the next output only if PersistentMemory is true and InputOffset is not equal to 0.

PolyphaseAccum stores data in the format for the filter arithmetic. Double-precision filters store doubles in PolyphaseAccum. Single-precision filter store singles in PolyphaseAccum. Fixed-point filters store fi objects in PolyphaseAccum.

PersistentMemory

Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. PersistentMemory returns to zero any state that the filter changes during processing. States that the filter does not change are not affected.

Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter object. PersistentMemory returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. Defaults to true — the filter retains memory about filtering operations from one to the next. Maintaining memory lets you filter large data sets as collections of smaller subsets and get the same result.

```
xtot=[x,x];
ytot=filter(hm1,xtot)
ytot =

         0   -0.0003    0.0005   -0.0014    0.0028   -0.0054    0.0092
reset(hm1);  % Clear history of the filter
hm1.PersistentMemory='true';
ysec=[filter(hm1,x) filter(hm1,x)]
```

```
ysec =

         0   -0.0003    0.0005   -0.0014    0.0028   -0.0054    0.0092
```

This test verifies that ysec (the signal filtered by sections) is equal to ytot (the entire signal filtered at once).

RateChangeFactors

Reports the decimation (m) and interpolation (l) factors for the filter object when you create fractional integrators and decimators, although m and l are used as arguments to both decimators and integrators, applying the same meaning. Combining these factors as input arguments to the fractional decimator or integrator results in the final rate change for the signal.

For decimating filters, the default is [2,3]. For integrators, [3,2].

States

Stored conditions for the filter, including values for the integrator and comb sections. m is the differential delay and n is the number of sections in the filter.

About the States of Multirate Filters

In the states property you find the states for both the integrator and comb portions of the filter, stored in a filtstates object. states is a matrix of dimensions m+1-by-n, with the states in CIC filters apportioned as follows:

- States for the integrator portion of the filter are stored in the first row of the state matrix.
- States for the comb portion fill the remaining rows in the state matrix.

In the state matrix, state values are specified and stored in double format.

States stores conditions for the delays between each interpolator phase, the filter states, and the states at the output of each phase in the filter, including values for the interpolator and comb states.

The number of states is (lh-1)*m+(l-1)*(lo+mo) where lh is the length of each subfilter, and l and m are the interpolation and decimation factors. lo and mo, the input and output delays between each interpolation phase, are integers from Euclid's theorem such that lo*l-mo*m = -1 (refer to the reference for more details). Use euclidfactors to get lo and mo for an mfilt.firfracdecim object.

`States` defaults to a vector of zeros that has length equal to `nstates(hm)`

Glossary

This glossary defines terms related to fixed-point data types and numbers. These terms may appear in some or all of the documents that describe MathWorks® products that have fixed-point support.

arithmetic shift

Shift of the bits of a binary word for which the sign bit is recycled for each bit shift to the right. A zero is incorporated into the least significant bit of the word for each bit shift to the left. In the absence of overflows, each arithmetic shift to the right is equivalent to a division by 2, and each arithmetic shift to the left is equivalent to a multiplication by 2.

See also binary point, binary word, bit, logical shift, most significant bit

bias

Part of the numerical representation used to interpret a fixed-point number. Along with the slope, the bias forms the scaling of the number. Fixed-point numbers can be represented as

$$\mathit{real\text{-}world\ value} = (\mathit{slope} \times \mathit{stored\ integer}) + \mathit{bias}$$

where the slope can be expressed as

$$\mathit{slope} = \mathit{fractional\ slope} \times 2^{\mathit{exponent}}$$

See also fixed-point representation, fractional slope, integer, scaling, slope, [Slope Bias]

binary number

Value represented in a system of numbers that has two as its base and that uses 1's and 0's (bits) for its notation.

See also bit

binary point

Symbol in the shape of a period that separates the integer and fractional parts of a binary number. Bits to the left of the binary point are integer bits and/or sign bits, and bits to the right of the binary point are fractional bits.

See also binary number, bit, fraction, integer, radix point

binary point-only scaling

Scaling of a binary number that results from shifting the binary point of the number right or left, and which therefore can only occur by powers of two.

See also binary number, binary point, scaling

binary word

Fixed-length sequence of bits (1's and 0's). In digital hardware, numbers are stored in binary words. The way in which hardware components or software functions interpret this sequence of 1's and 0's is described by a data type.

See also bit, data type, word

bit

Smallest unit of information in computer software or hardware. A bit can have the value 0 or 1.

ceiling (round toward)

Rounding mode that rounds to the closest representable number in the direction of positive infinity. This is equivalent to the `ceil` mode in Fixed-Point Designer software.

See also convergent rounding, floor (round toward), nearest (round toward), rounding, truncation, zero (round toward)

contiguous binary point

Binary point that occurs within the word length of a data type. For example, if a data type has four bits, its contiguous binary point must be understood to occur at one of the following five positions:

.0000
0.000
00.00
000.0
0000.

See also data type, noncontiguous binary point, word length

convergent rounding

Rounding mode that rounds to the nearest allowable quantized value. Numbers that are exactly halfway between the two nearest allowable quantized values are rounded up only if the least significant bit (after rounding) would be set to 0.

See also ceiling (round toward), floor (round toward), nearest (round toward), rounding, truncation, zero (round toward)

data type

Set of characteristics that define a group of values. A fixed-point data type is defined by its word length, its fraction length, and whether it is signed or unsigned. A floating-point data type is defined by its word length and whether it is signed or unsigned.

See also fixed-point representation, floating-point representation, fraction length, signedness, word length

data type override

Parameter in the Fixed-Point Tool that allows you to set the output data type and scaling of fixed-point blocks on a system or subsystem level.

See also data type, scaling

exponent

Part of the numerical representation used to express a floating-point or fixed-point number.

1. Floating-point numbers are typically represented as

$$real\text{ - }world\;value = mantissa \times 2^{exponent}$$

2. Fixed-point numbers can be represented as

$$real\text{-}world\;value = (slope \times stored\;integer) + bias$$

where the slope can be expressed as

$$slope = fractional\;slope \times 2^{exponent}$$

The exponent of a fixed-point number is equal to the negative of the fraction length:

$$\mathit{exponent} = -1 \times \mathit{fraction\ length}$$

See also bias, fixed-point representation, floating-point representation, fraction length, fractional slope, integer, mantissa, slope

fixed-point representation

Method for representing numerical values and data types that have a set range and precision.

1. Fixed-point numbers can be represented as

$$\mathit{real\text{-}world\ value} = (\mathit{slope} \times \mathit{stored\ integer}) + \mathit{bias}$$

where the slope can be expressed as

$$\mathit{slope} = \mathit{fractional\ slope} \times 2^{\mathit{exponent}}$$

The slope and the bias together represent the scaling of the fixed-point number.

2. Fixed-point data types can be defined by their word length, their fraction length, and whether they are signed or unsigned.

See also bias, data type, exponent, fraction length, fractional slope, integer, precision, range, scaling, slope, word length

floating-point representation

Method for representing numerical values and data types that can have changing range and precision.

1. Floating-point numbers can be represented as

$$\mathit{real\text{-}world\ value} = \mathit{mantissa} \times 2^{\mathit{exponent}}$$

2. Floating-point data types are defined by their word length.

See also data type, exponent, mantissa, precision, range, word length

floor (round toward)

Rounding mode that rounds to the closest representable number in the direction of negative infinity.

See also ceiling (round toward), convergent rounding, nearest (round toward), rounding, truncation, zero (round toward)

fraction

Part of a fixed-point number represented by the bits to the right of the binary point. The fraction represents numbers that are less than one.

See also binary point, bit, fixed-point representation

fraction length

Number of bits to the right of the binary point in a fixed-point representation of a number.

See also binary point, bit, fixed-point representation, fraction

fractional slope

Part of the numerical representation used to express a fixed-point number. Fixed-point numbers can be represented as

$$\mathit{real\text{-}world\ value} = (\mathit{slope} \times \mathit{stored\ integer}) + \mathit{bias}$$

where the slope can be expressed as

$$\mathit{slope} = \mathit{fractional\ slope} \times 2^{\mathit{exponent}}$$

The term *slope adjustment* is sometimes used as a synonym for fractional slope.

See also bias, exponent, fixed-point representation, integer, slope

full range

The broadest range available for a data type. From –∞ to ∞ for floating-point types. For integer types, the representable range is the range from the smallest to largest integer value (finite) the type can represent. For example, from `-128` to `127` for a signed 8–bit integer. Also known as representable range.

guard bits

Extra bits in either a hardware register or software simulation that are added to the high end of a binary word to ensure that no information is lost in case of overflow.

See also binary word, bit, overflow

incorrect range

A range that is too restrictive and does not include values that can actually occur in the model element. A range that is too broad is not considered incorrect because it will not lead to overflow.

See also range analysis

integer

1. Part of a fixed-point number represented by the bits to the left of the binary point. The integer represents numbers that are greater than or equal to one.

2. Also called the "stored integer." The raw binary number, in which the binary point is assumed to be at the far right of the word. The integer is part of the numerical representation used to express a fixed-point number. Fixed-point numbers can be represented as

$$real\text{-}world\ value = 2^{-fraction\ length} \times stored\ integer$$

or

$$real\text{-}world\ value = (slope \times stored\ integer) + bias$$

where the slope can be expressed as

$$slope = fractional\ slope \times 2^{exponent}$$

See also bias, fixed-point representation, fractional slope, integer, real-world value, slope

integer length

Number of bits to the left of the binary point in a fixed-point representation of a number.

See also binary point, bit, fixed-point representation, fraction length, integer

least significant bit (LSB)

Bit in a binary word that can represent the smallest value. The LSB is the rightmost bit in a big-endian-ordered binary word. The weight of the LSB is related to the fraction length according to

$$weight\ of\ LSB = 2^{-fraction\ length}$$

See also big-endian, binary word, bit, most significant bit

logical shift

Shift of the bits of a binary word, for which a zero is incorporated into the most significant bit for each bit shift to the right and into the least significant bit for each bit shift to the left.

See also arithmetic shift, binary point, binary word, bit, most significant bit

mantissa

Part of the numerical representation used to express a floating-point number. Floating-point numbers are typically represented as

$$real\text{-}world\ value = mantissa \times 2^{exponent}$$

See also exponent, floating-point representation

model element

Entities in a model that range analysis software tracks, for example, blocks, signals, parameters, block internal data (such as accumulators, products).

See also range analysis

most significant bit (MSB)

Bit in a binary word that can represent the largest value. The MSB is the leftmost bit in a big-endian-ordered binary word.

See also binary word, bit, least significant bit

nearest (round toward)

Rounding mode that rounds to the closest representable number, with the exact midpoint rounded to the closest representable number in the direction of positive infinity. This is equivalent to the `nearest` mode in Fixed-Point Designer software.

See also ceiling (round toward), convergent rounding, floor (round toward), rounding, truncation, zero (round toward)

noncontiguous binary point

Binary point that is understood to fall outside the word length of a data type. For example, the binary point for the following 4-bit word is understood to occur two bits to the right of the word length,

0000__.

thereby giving the bits of the word the following potential values:

$2^5 2^4 2^3 2^2$ __.

See also binary point, data type, word length

one's complement representation

Representation of signed fixed-point numbers. Negating a binary number in one's complement requires a bitwise complement. That is, all 0's are flipped to 1's and all 1's are flipped to 0's. In one's complement notation there are two ways to represent zero. A binary word of all 0's represents "positive" zero, while a binary word of all 1's represents "negative" zero.

See also binary number, binary word, sign/magnitude representation, signed fixed-point, two's complement representation

overflow

Situation that occurs when the magnitude of a calculation result is too large for the range of the data type being used. In many cases you can choose to either saturate or wrap overflows.

See also saturation, wrapping

padding

Extending the least significant bit of a binary word with one or more zeros.

See also least significant bit

precision

1. Measure of the smallest numerical interval that a fixed-point data type and scaling can represent, determined by the value of the number's least significant bit. The precision is given by the slope, or the number of fractional bits. The term *resolution* is sometimes used as a synonym for this definition.

2. Measure of the difference between a real-world numerical value and the value of its quantized representation. This is sometimes called quantization error or quantization noise.

See also data type, fraction, least significant bit, quantization, quantization error, range, slope

Q format

Representation used by Texas Instruments™ to encode signed two's complement fixed-point data types. This fixed-point notation takes the form

$$Qm.n$$

where

- Q indicates that the number is in Q format.
- m is the number of bits used to designate the two's complement integer part of the number.
- n is the number of bits used to designate the two's complement fractional part of the number, or the number of bits to the right of the binary point.

In Q format notation, the most significant bit is assumed to be the sign bit.

See also binary point, bit, data type, fixed-point representation, fraction, integer, two's complement

quantization

Representation of a value by a data type that has too few bits to represent it exactly.

See also bit, data type, quantization error

quantization error

Error introduced when a value is represented by a data type that has too few bits to represent it exactly, or when a value is converted from one data type to a shorter data type. Quantization error is also called quantization noise.

See also bit, data type, quantization

radix point

Symbol in the shape of a period that separates the integer and fractional parts of a number in any base system. Bits to the left of the radix point are integer and/or sign bits, and bits to the right of the radix point are fraction bits.

See also binary point, bit, fraction, integer, sign bit

range

Span of numbers that a certain data type can represent.

See also data type, full range, precision, representable range

range analysis

Static analysis of model to derive minimum and maximum range values for elements in the model. The software statically analyzes the ranges of the individual computations in the model based on specified design ranges, inputs, and the semantics of the calculation.

real-world value

Stored integer value with fixed-point scaling applied. Fixed-point numbers can be represented as

$$real\text{-}world\ value = 2^{-fraction\ length} \times stored\ integer$$

or

$$real\text{-}world\ value = (slope \times stored\ integer) + bias$$

where the slope can be expressed as

$$slope = fractional\ slope \times 2^{exponent}$$

See also integer

representable range

The broadest range available for a data type. From –∞ to ∞ for floating-point types. For integer types, the representable range is the range from the smallest to largest integer value (finite) the type can represent. For example, from `-128` to `127` for a signed 8–bit integer. Also known as full range.

resolution

See **precision**

rounding

Limiting the number of bits required to express a number. One or more least significant bits are dropped, resulting in a loss of precision. Rounding is necessary when a value cannot be expressed exactly by the number of bits designated to represent it.

See also bit, ceiling (round toward), convergent rounding, floor (round toward), least significant bit, nearest (round toward), precision, truncation, zero (round toward)

saturation

Method of handling numeric overflow that represents positive overflows as the largest positive number in the range of the data type being used, and negative overflows as the largest negative number in the range.

See also overflow, wrapping

scaled double

A double data type that retains fixed-point scaling information. For example, in Simulink and Fixed-Point Designer software you can use data type override to convert your fixed-point data types to scaled doubles. You can then simulate to determine the ideal floating-point behavior of your system. After you gather that information you can turn data type override off to return to fixed-point data types, and your quantities still have their original scaling information because it was held in the scaled double data types.

scaling

1. Format used for a fixed-point number of a given word length and signedness. The slope and bias together form the scaling of a fixed-point number.

2. Changing the slope and/or bias of a fixed-point number without changing the stored integer.

See also bias, fixed-point representation, integer, slope

shift

Movement of the bits of a binary word either toward the most significant bit ("to the left") or toward the least significant bit ("to the right"). Shifts to the right can be either logical, where the spaces emptied at the front of the word with each shift are filled in with zeros, or arithmetic, where the word is sign extended as it is shifted to the right.

See also arithmetic shift, logical shift, sign extension

sign bit

Bit (or bits) in a signed binary number that indicates whether the number is positive or negative.

See also binary number, bit

sign extension

Addition of bits that have the value of the most significant bit to the high end of a two's complement number. Sign extension does not change the value of the binary number.

See also binary number, guard bits, most significant bit, two's complement representation, word

sign/magnitude representation

Representation of signed fixed-point or floating-point numbers. In sign/magnitude representation, one bit of a binary word is always the dedicated sign bit, while the remaining bits of the word encode the magnitude of the number. Negation using sign/magnitude representation consists of flipping the sign bit from 0 (positive) to 1 (negative), or from 1 to 0.

See also binary word, bit, fixed-point representation, floating-point representation, one's complement representation, sign bit, signed fixed-point, signedness, two's complement representation

signed fixed-point

Fixed-point number or data type that can represent both positive and negative numbers.

See also data type, fixed-point representation, signedness, unsigned fixed-point

signedness

The signedness of a number or data type can be signed or unsigned. Signed numbers and data types can represent both positive and negative values, whereas unsigned numbers and data types can only represent values that are greater than or equal to zero.

See also data type, sign bit, sign/magnitude representation, signed fixed-point, unsigned fixed-point

slope

Part of the numerical representation used to express a fixed-point number. Along with the bias, the slope forms the scaling of a fixed-point number. Fixed-point numbers can be represented as

$$real\text{-}world\ value = (slope \times stored\ integer) + bias$$

where the slope can be expressed as

$$slope = fractional\ slope \times 2^{exponent}$$

See also bias, fixed-point representation, fractional slope, integer, scaling, [Slope Bias]

slope adjustment

See **fractional slope**

[Slope Bias]

Representation used to define the scaling of a fixed-point number.

See also bias, scaling, slope

stored integer

See **integer**

trivial scaling

Scaling that results in the real-world value of a number being simply equal to its stored integer value:

$$real\text{-}world\ value = stored\ integer$$

In [Slope Bias] representation, fixed-point numbers can be represented as

$$real\text{-}world\ value = (slope \times stored\ integer) + bias$$

In the trivial case, slope = 1 and bias = 0.

In terms of binary point-only scaling, the binary point is to the right of the least significant bit for trivial scaling, meaning that the fraction length is zero:

$$real\text{-}world\ value = stored\ integer \times 2^{-fraction\ length} = stored\ integer \times 2^{0}$$

Scaling is always trivial for pure integers, such as `int8`, and also for the true floating-point types `single` and `double`.

See also bias, binary point, binary point-only scaling, fixed-point representation, fraction length, integer, least significant bit, scaling, slope, [Slope Bias]

truncation

Rounding mode that drops one or more least significant bits from a number.

See also ceiling (round toward), convergent rounding, floor (round toward), nearest (round toward), rounding, zero (round toward)

two's complement representation

Common representation of signed fixed-point numbers. Negation using signed two's complement representation consists of a translation into one's complement followed by the binary addition of a one.

See also binary word, one's complement representation, sign/magnitude representation, signed fixed-point

unsigned fixed-point

Fixed-point number or data type that can only represent numbers greater than or equal to zero.

See also data type, fixed-point representation, signed fixed-point, signedness

word

Fixed-length sequence of binary digits (1's and 0's). In digital hardware, numbers are stored in words. The way hardware components or software functions interpret this sequence of 1's and 0's is described by a data type.

See also binary word, data type

word length

Number of bits in a binary word or data type.

See also binary word, bit, data type

wrapping

Method of handling overflow. Wrapping uses modulo arithmetic to cast a number that falls outside of the representable range the data type being used back into the representable range.

See also data type, overflow, range, saturation

zero (round toward)

Rounding mode that rounds to the closest representable number in the direction of zero. This is equivalent to the `fix` mode in Fixed-Point Designer software.

See also ceiling (round toward), convergent rounding, floor (round toward), nearest (round toward), rounding, truncation
