Vq = interp2(X,Y,V,Xq,Yq)
Vq = interp2(V,Xq,Yq)
Vq = interp2(V)
Vq = interp2(V,k)

Vq = interp2(____,method)
Vq = interp2(____,method,extrapval)
```

### Description

`Vq = interp2(X,Y,V,Xq,Yq)` returns interpolated values of a function of two variables at specific query points using linear interpolation. The results always pass through the original sampling of the function. `X` and `Y` contain the coordinates of the sample points. `V` contains the corresponding function values at each sample point. `Xq` and `Yq` contain the coordinates of the query points.

`Vq = interp2(V,Xq,Yq)` assumes a default grid of sample points. The default grid points cover the rectangular region, `X=1:n` and `Y=1:m`, where `[m,n] = size(V)`. Use this syntax to when you want to conserve memory and are not concerned about the absolute distances between points.

`Vq = interp2(V)` returns the interpolated values on a refined grid formed by dividing the interval between sample values once in each dimension.

`Vq = interp2(V,k)` returns the interpolated values on a refined grid formed by repeatedly dividing the intervals `k` times in each dimension.

`Vq = interp2( ____, method)` specifies an optional, trailing input argument that you can pass with any of the previous syntaxes. The `method` argument can be any of the following strings that specify alternative interpolation methods: `'linear'`, `'nearest'`, `'cubic'`, or `'spline'`. The default method is `'linear'`.

`Vq = interp2( ____, method, extrapval)` also specifies `extrapval`, a scalar value that is assigned to all queries that lie outside the domain of the sample points.

If you omit the `extrapval` argument for queries outside the domain of the sample points, then based on the `method` argument `interp2` returns one of the following:

- The extrapolated values for the `'spline'` method
- NaN values for interpolation methods other than `'spline'`

## Examples

### Interpolate Over a Grid Using Default Method

Coarsely sample the `peaks` function.

```
[X,Y] = meshgrid(-3:3);
V = peaks(X,Y);
```

Plot the coarse sampling.

```
figure
surf(X,Y,V)
title('Original Sampling');
```

Create the query grid with spacing of 0.25.

```
[Xq,Yq] = meshgrid(-3:0.25:3);
```

Interpolate at the query points.

```
Vq = interp2(X,Y,V,Xq,Yq);
```

Plot the result.

```
figure
surf(Xq,Yq,Vq);
title('Linear Interpolation Using Finer Grid');
```

### Interpolate Over a Grid Using Cubic Method

Coarsely sample the peaks function.

```
[X,Y] = meshgrid(-3:3);
V = peaks(7);
```

Plot the coarse sampling.

```
figure
surf(X,Y,V)
title('Original Sampling');
```

Create the query grid with spacing of 0.25.

```
[Xq,Yq] = meshgrid(-3:0.25:3);
```

Interpolate at the query points, and specify cubic interpolation.

```
Vq = interp2(X,Y,V,Xq,Yq,'cubic');
```

Plot the result.

```
figure
surf(Xq,Yq,Vq);
title('Cubic Interpolation Over Finer Grid');
```

### Refine Grayscale Image

Load some image data into the workspace.

```
load clown
```

Isolate a small region of the image and cast it to single.

```
V = single(X(1:124,75:225));
```

Display the image.

```
figure
imagesc(V);
```

```
colormap gray
axis image
axis off
title('Original Image');
```

Original Image

Insert interpolated values by repeatedly dividing the intervals between points of the refined grid five times in each dimension.

```
Vq = interp2(V,5);
```

Display the result.

```
figure
imagesc(Vq);
```

```
colormap gray
axis image
axis off
title('Linear Interpolation');
```

### Linear Interpolation

### Evaluate Outside the Domain of X and Y

Coarsely sample a function over the range,  $[-2, 2]$  in both dimensions.

```
[X,Y] = meshgrid(-2:0.75:2);
R = sqrt(X.^2 + Y.^2)+ eps;
V = sin(R)./(R);
```

Plot the coarse sampling.

```
figure
surf(X,Y,V)
xlim([-4 4])
ylim([-4 4])
title('Original Sampling')
```

Create the query grid that extends beyond the domain of X and Y.

```
[Xq,Yq] = meshgrid(-3:0.2:3);
```

Perform cubic interpolation within the domain of X and Y, and assign all queries that fall outside to zero.

```
Vq = interp2(X,Y,V,Xq,Yq,'cubic',0);
```

Plot the result.

```
figure
surf(Xq,Yq,Vq)
title('Cubic Interpolation with Vq=0 Outside Domain of X and Y');
```

## Input Arguments

**X, Y** — Sample grid points  
matrices | vectors

Sample grid points, specified as real matrices or vectors.

- If  $X$  and  $Y$  are matrices, then they contain the coordinates of a full grid (in `meshgrid` format). Use the `meshgrid` function to create the  $X$  and  $Y$  matrices together. Both matrices must be the same size.
- If  $X$  and  $Y$  are vectors, then they are treated as a grid vectors. The values in both vectors must be strictly monotonic and increasing.

Example: `[X,Y] = meshgrid(1:30,-10:10)`

Data Types: `single` | `double`

## **V — Sample values**

matrix

Sample values, specified as a real or complex matrix. The size requirements for  $V$  depend on the size of  $X$  and  $Y$ .

- If  $X$  and  $Y$  are matrices representing a full grid (in `meshgrid` format), then  $V$  must be the same size as  $X$  and  $Y$ .
- If  $X$  and  $Y$  are grid vectors, then  $V$  must be a matrix containing `length(Y)` rows and `length(X)` columns.

Example: `rand(10,10)`

Data Types: `single` | `double`

Complex Number Support: Yes

## **Xq, Yq — Query points**

scalars | vectors | matrices | arrays

Query points, specified as a real scalars, vectors, matrices, or arrays.

- If  $Xq$  and  $Yq$  are scalars, then they are the coordinates of a single query point.
- If  $Xq$  and  $Yq$  are vectors of different orientations, then  $Xq$  and  $Yq$  are treated as grid vectors.
- If  $Xq$  and  $Yq$  are vectors of the same size and orientation, then  $Xq$  and  $Yq$  are treated as scattered points in 2-D space.
- If  $Xq$  and  $Yq$  are matrices, then they represent either a full grid of query points (in `meshgrid` format) or scattered points.
- If  $Xq$  and  $Yq$  are N-D arrays, then they represent scattered points in 2-D space.

Example: `[Xq,Yq] = meshgrid((1:0.1:10),(-5:0.1:0))`

Data Types: `single` | `double`

**k — Refinement factor**

1 (default) | real, nonnegative, integer scalar

Refinement factor, specified as a real, nonnegative, integer scalar. This value specifies the number of times to repeatedly divide the intervals of the refined grid in each dimension. This results in  $2^k - 1$  interpolated points between sample values.

If  $k$  is 0, then  $V_q$  is the same as  $V$ .

`interp2(V, 1)` is the same as `interp2(V)`.

The following illustration shows the placement of interpolated values (in red) among nine sample values (in black) for  $k=2$ .

Example: `interp2(V, 2)`

Data Types: `single` | `double`

**method — Interpolation method**

'linear' (default) | 'nearest' | 'cubic' | 'spline'

Interpolation method, specified as a string from this table.

| Method    | Description                                                                                                                                                                                                                    | Continuity    | Comments                                                                                                                                                                                                                                                                                      |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'linear'  | The interpolated value at a query point is based on linear interpolation of the values at neighboring grid points in each respective dimension. This is the default interpolation method.                                      | $C^0$         | <ul style="list-style-type: none"> <li>Requires at least two grid points in each dimension</li> <li>Requires more memory than 'nearest'</li> </ul>                                                                                                                                            |
| 'nearest' | The interpolated value at a query point is the value at the nearest sample grid point.                                                                                                                                         | Discontinuous | <ul style="list-style-type: none"> <li>Requires two grid points in each dimension.</li> <li>Fastest computation with modest memory requirements</li> </ul>                                                                                                                                    |
| 'cubic'   | The interpolated value at a query point is based on a cubic interpolation of the values at neighboring grid points in each respective dimension. The interpolation is based on a cubic convolution.                            | $C^1$         | <ul style="list-style-type: none"> <li>Grid must have uniform spacing in each dimension, but the spacing does not have to be the same for all dimensions</li> <li>Requires at least four points in each dimension</li> <li>Requires more memory and computation time than 'linear'</li> </ul> |
| 'spline'  | The interpolated value at a query point is based on a cubic interpolation of the values at neighboring grid points in each respective dimension. The interpolation is based on a cubic spline using not-a-knot end conditions. | $C^2$         | <ul style="list-style-type: none"> <li>Requires four points in each dimension</li> <li>Requires more memory and computation time than 'cubic'</li> </ul>                                                                                                                                      |

**extrapval** — Function value outside domain of X and Y

scalar

Function value outside domain of X and Y, specified as a real or complex scalar. `interp2` returns this constant value for all points outside the domain of X and Y.

Example: 5

Example: `5+1i`

Data Types: `single` | `double`

Complex Number Support: Yes

## Output Arguments

### **Vq** — Interpolated values

`scalar` | `vector` | `matrix`

Interpolated values, returned as a real or complex scalar, vector, or matrix. The size and shape of `Vq` depends on the syntax you use and, in some cases, the size and value of the input arguments.

| Syntaxes                                                                                                                                                          | Special Conditions                                                             | Size of Vq                                                                                                           | Example                                                                                                         |

## More About

### Strictly Monotonic

A set of values that are always increasing or decreasing, without reversals. For example, the sequence,  $a = [2 \ 4 \ 6 \ 8]$  is strictly monotonic and increasing. The sequence,  $b = [2 \ 4 \ 4 \ 6 \ 8]$  is not strictly monotonic because there is no change in value between  $b(2)$  and  $b(3)$ . The sequence,  $c = [2 \ 4 \ 6 \ 8 \ 6]$  contains a reversal between  $c(4)$  and  $c(5)$ , so it is not monotonic at all.

### Full Grid (in meshgrid Format)

For `interp2`, the full grid is a pair of matrices whose elements represent a grid of points over a rectangular region. One matrix contains the  $x$ -coordinates, and the other matrix contains the  $y$ -coordinates. The values in the  $x$ -matrix are strictly monotonic and increasing along the rows. The values along its columns are constant. The values in the  $y$ -matrix are strictly monotonic and increasing along the columns. The values along its rows are constant. Use the `meshgrid` function to create a full grid that you can pass to `interp2`.

For example, the following code creates a full grid for the region,  $-1 \leq x \leq 3$  and  $1 \leq y \leq 4$ :

```
[X,Y] = meshgrid(-1:3,(1:4))
```

X =

```

-1 0 1 2 3
-1 0 1 2 3
-1 0 1 2 3
-1 0 1 2 3

```

Y =

```
 1 1 1 1 1
 2 2 2 2 2
 3 3 3 3 3
 4 4 4 4 4
```

### Grid Vectors

For `interp2`, grid vectors consist of a pair of mixed-orientation vectors that define the  $x$ - and  $y$ -coordinates in a grid. One vector is a row vector, and the other is a column vector.

For example, the following code creates the grid vectors that specify the region,  $-1 \leq x \leq 3$  and  $1 \leq y \leq 4$ :

```
x = -1:3;
y = (1:4)';
```

### Scattered Points

For `interp2`, scattered points consist of a pair of arrays that define a collection of points scattered in 2-D space. One array contains the  $x$ -coordinates, and the other contains the  $y$ -coordinates.

For example, the following code specifies the points, (2,7), (5,3), (4,1), and (10,9):

```
x = [2 5; 4 10];
y = [7 3; 1 9];
```

## interp3

Interpolation for 3-D gridded data in meshgrid format

In a future release, `interp3` will not accept mixed combinations of row and column vectors for the sample and query grids. For more information, and recommendations for updating your code, see “Functionality being removed or changed”.

### Syntax

```
Vq = interp3(X,Y,Z,V,Xq,Yq,Zq)
Vq = interp3(V,Xq,Yq,Zq)
Vq = interp3(V)
Vq = interp3(V,k)

Vq = interp3(____,method)
Vq = interp3(____,method,extrapval)
```

### Description

`Vq = interp3(X,Y,Z,V,Xq,Yq,Zq)` returns interpolated values of a function of three variables at specific query points using linear interpolation. The results always pass through the original sampling of the function. `X`, `Y`, and `Z` contain the coordinates of the sample points. `V` contains the corresponding function values at each sample point. `Xq`, `Yq`, and `Zq` contain the coordinates of the query points.

`Vq = interp3(V,Xq,Yq,Zq)` assumes a default grid of sample points. The default grid points cover the region, `X=1:n`, `Y=1:m`, `Z=1:p`, where `[m,n,p] = size(V)`. Use this syntax when you want to conserve memory and are not concerned about the absolute distances between points.

`Vq = interp3(V)` returns the interpolated values on a refined grid formed by dividing the interval between sample values once in each dimension.

`Vq = interp3(V,k)` returns the interpolated values on a refined grid formed by repeatedly dividing the intervals `k` times in each dimension.

`Vq = interp3( ____, method)` specifies an optional, trailing input argument that you can pass with any of the previous syntaxes. The `method` argument can be any of the following strings that specify alternative interpolation methods: `'linear'`, `'nearest'`, `'cubic'`, or `'spline'`. The default method is `'linear'`.

`Vq = interp3( ____, method, extrapval)` also specifies `extrapval`, a scalar value that is assigned to all queries that lie outside the domain of the sample points.

If you omit the `extrapval` argument for queries outside the domain of the sample points, then based on the `method` argument `interp3` returns one of the following:

- The extrapolated values for the `'spline'` method
- NaN values for interpolation methods other than `'spline'`

## Examples

### Interpolate Using Default Method

Load the points and values of the flow function, sampled at 10 points in each dimension.

```
[X,Y,Z,V] = flow(10);
```

The `flow` function returns the grid in the arrays, `X`, `Y`, `Z`. The grid covers the region,  $0.1 \leq X \leq 10$ ,  $-3 \leq Y \leq 3$ ,  $-3 \leq Z \leq 3$ , and the spacing is  $\Delta X = 0.5$ ,  $\Delta Y = 0.7$ , and  $\Delta Z = 0.7$ .

Now, plot slices through the volume of the sample at: `X=6`, `X=9`, `Y=2`, and `Z=0`.

```
figure
slice(X,Y,Z,V,[6 9],2,0);
shading flat
```

Create a query grid with spacing of 0.25.

```
[Xq,Yq,Zq] = meshgrid(.1:.25:10, -3:.25:3, -3:.25:3);
```

Interpolate at the points in the query grid and plot the results using the same slice planes.

```
Vq = interp3(X,Y,Z,V,Xq,Yq,Zq);
figure
slice(Xq,Yq,Zq,Vq,[6 9],2,0);
shading flat
```

### Interpolate Using Cubic Method

Load the points and values of the flow function, sampled at 10 points in each dimension.

```
[X,Y,Z,V] = flow(10);
```

The `flow` function returns the grid in the arrays, `X`, `Y`, `Z`. The grid covers the region,  $0.1 \leq X \leq 10$ ,  $-3 \leq Y \leq 3$ ,  $-3 \leq Z \leq 3$ , and the spacing is  $\Delta X = 0.5$ ,  $\Delta Y = 0.7$ , and  $\Delta Z = 0.7$ .

Plot slices through the volume of the sample at: `X=6`, `X=9`, `Y=2`, and `Z =0`.

```
figure
slice(X,Y,Z,V,[6 9],2,0);
```

shading flat

Create a query grid with spacing of 0.25.

```
[Xq,Yq,Zq] = meshgrid(.1:.25:10, -3:.25:3, -3:.25:3);
```

Interpolate at the points in the query grid using the 'cubic' interpolation method. Then plot the results.

```
Vq = interp3(X,Y,Z,V,Xq,Yq,Zq, 'cubic');
figure
slice(Xq,Yq,Zq,Vq,[6 9],2,0);
shading flat
```

### Evaluate Outside the Domain of X, Y, and Z

Create the grid vectors,  $x$ ,  $y$ , and  $z$ . These vectors define the points associated with values in  $V$ .

```
x = 1:100;
y = (1:50)';
z = 1:30;
```

Define the sample values to be a 50-by-100-by-30 random number array,  $V$ . Use the `gallery` function to create the array.

```
V = gallery('uniformdata',50,100,30,0);
```

Evaluate  $V$  at three points outside the domain of  $x$ ,  $y$ , and  $z$ . Specify `extrapval = -1`.

```
xq = [0 0 0];
yq = [0 0 51];
zq = [0 101 102];
vq = interp3(x,y,z,V,xq,yq,zq,'linear',-1)
```

```
vq =

 -1 -1 -1
```

All three points evaluate to -1 because they are outside the domain of x, y, and z.

## Input Arguments

### **X, Y, Z** — Sample grid points

arrays | vectors

Sample grid points, specified as real arrays or vectors.

- If X, Y, and Z are arrays, then they contain the coordinates of a full grid (in `meshgrid` format). Use the `meshgrid` function to create the X, Y, and Z arrays together. These arrays must be the same size.
- If X, Y, and Z are vectors, then they are treated as a grid vectors. The values in these vectors must be strictly monotonic and increasing.

Example: `[X,Y,Z] = meshgrid(1:30,-10:10,1:5)`

Data Types: `single` | `double`

### **V** — Sample values

array

Sample values, specified as a real or complex array. The size requirements for V depend on the size of X, Y, and Z.

- If X, Y, and Z are arrays representing a full grid (in `meshgrid` format), then the size of V matches the size of X, Y, or Z.
- If X, Y, and Z are grid vectors, then `size(V) = [length(Y) length(X) length(Z)]`.

Example: `rand(10,10,10)`

Data Types: `single` | `double`

Complex Number Support: Yes

### **Xq, Yq, Zq — Query points**

scalars | vectors | arrays

Query points, specified as a real scalars, vectors, or arrays.

- If Xq, Yq, and Zq are scalars, then they are the coordinates of a single query point in  $R^3$ .
- If Xq, Yq, and Zq are vectors of different orientations, then Xq, Yq, and Zq are treated as grid vectors in  $R^3$ .
- If Xq, Yq, and Zq are vectors of the same size and orientation, then Xq, Yq, and Zq are treated as scattered points in  $R^3$ .
- If Xq, Yq, and Zq are arrays of the same size, then they represent either a full grid of query points (in `meshgrid` format) or scattered points in  $R^3$ .

Example: `[Xq,Yq,Zq] = meshgrid((1:0.1:10), (-5:0.1:0), 3:5)`

Data Types: `single` | `double`

### **k — Refinement factor**

1 (default) | real, nonnegative, integer scalar

Refinement factor, specified as a real, nonnegative, integer scalar. This value specifies the number of times to repeatedly divide the intervals of the refined grid in each dimension. This results in  $2^k - 1$  interpolated points between sample values.

If k is 0, then Vq is the same as V.

`interp3(V, 1)` is the same as `interp3(V)`.

The following illustration depicts  $k=2$  in one plane of  $R^3$ . There are 72 interpolated values in red and 9 sample values in black.

Example: `interp3(V,2)`

Data Types: `single` | `double`

**method — Interpolation method**

`'linear'` (default) | `'nearest'` | `'cubic'` | `'spline'`

Interpolation method, specified as a string from this table.

| Method                 | Description                                                                                                                                                                               | Continuity    | Comments                                                                                                                                                        |
|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>'linear'</code>  | The interpolated value at a query point is based on linear interpolation of the values at neighboring grid points in each respective dimension. This is the default interpolation method. | $C^0$         | <ul style="list-style-type: none"> <li>Requires at least two grid points in each dimension</li> <li>Requires more memory than <code>'nearest'</code></li> </ul> |
| <code>'nearest'</code> | The interpolated value at a query point is the value at the nearest sample grid point.                                                                                                    | Discontinuous | <ul style="list-style-type: none"> <li>Requires two grid points in each dimension</li> <li>Fastest computation with modest memory requirements</li> </ul>       |
| <code>'cubic'</code>   | The interpolated value at a query point is based on a cubic                                                                                                                               | $C^1$         | <ul style="list-style-type: none"> <li>Grid must have uniform spacing in each dimension,</li> </ul>                                                             |

| Method   | Description                                                                                                                                                                                                                    | Continuity | Comments                                                                                                                                                                                                                                      |
|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|          | interpolation of the values at neighboring grid points in each respective dimension. The interpolation is based on a cubic convolution.                                                                                        |            | <p>but the spacing does not have to be the same for all dimensions</p> <ul style="list-style-type: none"> <li>• Requires at least four points in each dimension</li> <li>• Requires more memory and computation time than 'linear'</li> </ul> |
| 'spline' | The interpolated value at a query point is based on a cubic interpolation of the values at neighboring grid points in each respective dimension. The interpolation is based on a cubic spline using not-a-knot end conditions. | $C^2$      | <ul style="list-style-type: none"> <li>• Requires four points in each dimension</li> <li>• Requires more memory and computation time than 'cubic'</li> </ul>                                                                                  |

### **extrapval** — Function value outside domain of X, Y, and Z

scalar

Function value outside domain of X, Y, and Z, specified as a real or complex scalar. `interp3` returns this constant value for all points outside the domain of X, Y, and Z.

Example: 5

Example: 5+1i

Data Types: `single` | `double`

Complex Number Support: Yes

## Output Arguments

### **Vq** — Interpolated values

scalar | vector | array

Interpolated values, returned as a real or complex scalar, vector, or array. The size and shape of `Vq` depends on the syntax you use and, in some cases, the size and value of the input arguments.

| Syntaxes                                                                                                           | Special Conditions                                           | Size of Vq                                                                    | Example                                                                                         |
|--------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------|-------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------|
| interp3(X,Y,Z,V,Xq,Yq)<br>interp3(V,Xq,Yq,Zq)<br>and variations of these syntaxes that include method or extrapval | Xq, Yq, and Zq are scalars.                                  | Scalar                                                                        | size(Vq) = [1 1] when you pass Xq, Yq, and Zq as scalars.                                       |
| Same as above                                                                                                      | Xq, Yq, and Zq are vectors of the same size and orientation. | Vector of same size and orientation as Xq, Yq, and Zq                         | If size(Xq) = [100 1], and size(Yq) = [100 1], and size(Zq) = [100 1], then size(Vq) = [100 1]. |
| Same as above                                                                                                      | Xq, Yq, and Zq are vectors of mixed orientation.             | size(Vq) = [length(Y) length(X) length(Z)]                                    | If size(Xq) = [1 100], and size(Yq) = [50 1], and size(Zq) = [1 5], then size(Vq) = [50 100 5]. |
| Same as above                                                                                                      | Xq, Yq, and Zq are arrays of the same size.                  | Array of the same size as Xq, Yq, and Zq                                      | If size(Xq) = [50 25], and size(Yq) = [50 25], and size(Zq) = [50 25], then size(Vq) = [50 25]. |
| interp3(V,k)<br>and variations of this syntax that include method or extrapval                                     | None                                                         | Array in which the length of the ith dimension is $2^k * (size(V,i) - 1) + 1$ | If size(V) = [10 12 5], and k = 3, then size(Vq) = [73 89 33].                                  |

## More About

### Strictly Monotonic

A set of values that are always increasing or decreasing, without reversals. For example, the sequence,  $a = [2\ 4\ 6\ 8]$  is strictly monotonic and increasing. The sequence,  $b$

`b = [2 4 4 6 8]` is not strictly monotonic because there is no change in value between `b(2)` and `b(3)`. The sequence, `c = [2 4 6 8 6]` contains a reversal between `c(4)` and `c(5)`, so it is not monotonic at all.

### Full Grid (in meshgrid Format)

For `interp3`, a full grid consists of three arrays whose elements represent a grid of points that define a region in  $R^3$ . The first array contains the  $x$ -coordinates, the second array contains the  $y$ -coordinates, and the third array contains the  $z$ -coordinates.

The values in the  $x$ -array are strictly monotonic, increasing, and vary along the second dimension. The values in the  $y$ -array are strictly monotonic, increasing, and vary along the first dimension. The values in the  $z$ -array are strictly monotonic, increasing, and vary along the third dimension. Use the `meshgrid` function to create a full grid that you can pass to `interp3`.

### Grid Vectors

For `interp3`, grid vectors consist of three vectors of mixed-orientation that define the points on a grid in  $R^3$ .

For example, the following code creates the grid vectors for the region,  $1 \leq x \leq 3$ ,  $4 \leq y \leq 5$ , and  $6 \leq z \leq 8$ :

```
x = 1:3;
y = (4:5)';
z = 6:8;
```

### Scattered Points

For `interp3`, scattered points consist of three arrays or vectors, `Xq`, `Yq`, and `Zq`, that define a collection of points scattered in  $R^3$ . The  $i$ th array contains the coordinates in the  $i$ th dimension.

For example, the following code specifies the points, (1, 19, 10), (6, 40, 1), (15, 33, 22), and (0, 61, 13).

```
Xq = [1 6; 15 0];
Yq = [19 40; 33 61];
Zq = [10 1; 22 13];
```

### See Also

`interp1` | `interp2` | `interp3` | `meshgrid`

## interpft

1-D interpolation using FFT method

### Syntax

```
y = interpft(x,n)
y = interpft(x,n,dim)
```

### Description

`y = interpft(x,n)` returns the vector `y` that contains the value of the periodic function `x` resampled to `n` equally spaced points.

If `length(x) = m`, and `x` has sample interval `dx`, then the new sample interval for `y` is `dy = dx*m/n`. Note that `n` cannot be smaller than `m`.

If `X` is a matrix, `interpft` operates on the columns of `X`, returning a matrix `Y` with the same number of columns as `X`, but with `n` rows.

`y = interpft(x,n,dim)` operates along the specified dimension.

### Examples

Interpolate a triangle-like signal using an interpolation factor of 5. First, set up signal to be interpolated:

```
y = [0 .5 1 1.5 2 1.5 1 .5 0 -.5 -1 -1.5 -2 -1.5 -1 -.5 0];
N = length(y);
```

Perform the interpolation:

```
L = 5;
M = N*L;
x = 0:L:L*N-1;
xi = 0:M-1;
yi = interpft(y,M);
```

```
plot(x,y,'o',xi,yi,'*')
legend('Original data','Interpolated data')
```

## More About

### Algorithms

The `interpft` command uses the FFT method. The original vector `x` is transformed to the Fourier domain using `fft` and then transformed back with more points.

### See Also

`interp1`

## interpn

Interpolation for 1-D, 2-D, 3-D, and N-D gridded data in ndgrid format

In a future release, `interpn` will not accept mixed combinations of row and column vectors for the sample and query grids. For more information, and recommendations for updating your code, see “Functionality being removed or changed”.

### Syntax

`Vq = interpn(X1,X2,...,Xn,V,Xq1,Xq2,...,Xqn)`

`Vq = interpn(V,Xq1,Xq2,...,Xqn)`

`Vq = interpn(V)`

`Vq = interpn(V,k)`

`Vq = interpn( ____,method)`

`Vq = interpn( ____,method,extrapval)`

### Description

`Vq = interpn(X1,X2,...,Xn,V,Xq1,Xq2,...,Xqn)` returns interpolated values of a function of  $n$  variables at specific query points using linear interpolation. The results always pass through the original sampling of the function. `X1,X2,...,Xn` contain the coordinates of the sample points. `V` contains the corresponding function values at each sample point. `Xq1,Xq2,...,Xqn` contain the coordinates of the query points.

`Vq = interpn(V,Xq1,Xq2,...,Xqn)` assumes a default grid of sample points. The default grid consists of the points,  $1,2,3,\dots,n_i$  in each dimension. The value of  $n_i$  is the length of the  $i$ th dimension in `V`. Use this syntax to when you want to conserve memory and are not concerned about the absolute distances between points.

`Vq = interpn(V)` returns the interpolated values on a refined grid formed by dividing the interval between sample values once in each dimension.

`Vq = interpn(V,k)` returns the interpolated values on a refined grid formed by repeatedly dividing the intervals  $k$  times in each dimension.

`Vq = interpn( ____, method)` specifies an optional, trailing input argument that you can pass with any of the previous syntaxes. The `method` argument can be any of the following strings that specify alternative interpolation methods: `'linear'`, `'nearest'`, `'pchip'`, `'cubic'`, or `'spline'`. The default method is `'linear'`.

`Vq = interpn( ____, method, extrapolval)` also specifies `extrapolval`, a scalar value that is assigned to all queries that lie outside the domain of the sample points.

If you omit the `extrapolval` argument for queries outside the domain of the sample points, then based on the `method` argument `interpn` returns one of the following:

- The extrapolated values for the `'spline'` method
- NaN values for interpolation methods other than `'spline'`

## Examples

### 1-D Interpolation

Define the sample points and values.

```
x = [1 2 3 4 5];
v = [12 16 31 10 6];
```

Define the query points, `xq`, and interpolate.

```
xq = (1:0.1:5);
vq = interpn(x,v,xq,'cubic');
```

Plot the result.

```
figure
plot(x,v,'o',xq,vq,'-');
legend('Samples','Cubic Interpolation');
```

## 2-D Interpolation

Create a set of grid points and corresponding sample values.

```
[X1,X2] = ndgrid((-5:1:5));
R = sqrt(X1.^2 + X2.^2)+ eps;
V = sin(R)./(R);
```

Interpolate over a finer grid using `ntimes=1`.

```
Vq = interpn(V,'cubic');
mesh(Vq);
```

### Evaluate Outside Domain of 3-D Function

Create the grid vectors, `x1`, `x2`, and `x3`. These vectors define the points associated with the values in `V`.

```
x1 = 1:100;
x2 = (1:50)';
x3 = 1:30;
```

Define the sample values to be a 100-by-50-by-30 random number array, `V`. Use the `gallery` function to create the array.

```
V = gallery('uniformdata',100,50,30,0);
```

Evaluate  $V$  at three points outside the domain of  $x_1$ ,  $x_2$ , and  $x_3$ . Specify `extrapval = -1`.

```
xq1 = [0 0 0];
xq2 = [0 0 51];
xq3 = [0 101 102];
vq = interpn(x1,x2,x3,V,xq1,xq2,xq3,'linear',-1)
```

```
vq =
 -1 -1 -1
```

All three points evaluate to  $-1$  because they are outside the domain of  $x_1$ ,  $x_2$ , and  $x_3$ .

#### 4-D Interpolation

Define an anonymous function that represents  $f = te^{-x^2-y^2-z^2}$ .

```
f = @(x,y,z,t) t.*exp(-x.^2 - y.^2 - z.^2);
```

Create a grid of points in  $R^4$ . Then, pass the points through the function to create the sample values,  $V$ .

```
[x,y,z,t] = ndgrid(-1:0.2:1,-1:0.2:1,-1:0.2:1,0:2:10);
V = f(x,y,z,t);
```

Now, create the query grid.

```
[xq,yq,zq,tq] = ...
ndgrid(-1:0.05:1,-1:0.08:1,-1:0.05:1,0:0.5:10);
```

Interpolate  $V$  at the query points.

```
Vq = interpn(x,y,z,t,V,xq,yq,zq,tq);
```

Create a movie to show the results.

```
figure('renderer','zbuffer');
nframes = size(tq, 4);
for j = 1:nframes
 slice(yq(:,:,j),xq(:,:,j),zq(:,:,j),...

```

```
 Vq(:,:,j),0,0,0);
 caxis([0 10]);
 M(j) = getframe;
end
movie(M);
```

## Input Arguments

**X1, X2, ..., Xn** — Sample grid points

arrays | vectors

Sample grid points, specified as real arrays or vectors.

- If  $X_1, X_2, \dots, X_n$  are arrays, then they contain the coordinates of a full grid (in `ndgrid` format). Use the `ndgrid` function to create the  $X_1, X_2, \dots, X_n$  arrays together. These arrays must be the same size.
- If  $X_1, X_2, \dots, X_n$  are vectors, then they are treated as grid vectors. The values in these vectors must be strictly monotonic and increasing.

Example: `[X1,X2,X3] = ndgrid(1:30,-10:10,1:5)`

Data Types: `single` | `double`

### **V — Sample values**

array

Sample values, specified as a real or complex array. The size requirements for  $V$  depend on the size of  $X_1, X_2, \dots, X_n$ .

- If  $X_1, X_2, \dots, X_n$  are arrays representing a full grid (in `ndgrid` format), then the size of  $V$  matches the size of any array,  $X_1, X_2, \dots, X_n$ .
- If  $X_1, X_2, \dots, X_n$  are grid vectors, then  $V$  is an array whose  $i$ th dimension is the same length as grid vector  $X_i$ , where  $i = 1, 2, \dots, n$ .

Example: `rand(10,5,3,2)`

Data Types: `single` | `double`

Complex Number Support: Yes

### **Xq1, Xq2, ..., Xqn — Query points**

scalars | vectors | arrays

Query points, specified as a real scalars, vectors, or arrays.

- If  $X_{q1}, X_{q2}, \dots, X_{qn}$  are scalars, then they are the coordinates of a single query point in  $R^n$ .
- If  $X_{q1}, X_{q2}, \dots, X_{qn}$  are vectors of different orientations, then  $X_{q1}, X_{q2}, \dots, X_{qn}$  are treated as grid vectors in  $R^n$ .
- If  $X_{q1}, X_{q2}, \dots, X_{qn}$  are vectors of the same size and orientation, then  $X_{q1}, X_{q2}, \dots, X_{qn}$  are treated as scattered points in  $R^n$ .
- If  $X_{q1}, X_{q2}, \dots, X_{qn}$  are arrays of the same size, then they represent either a full grid of query points (in `ndgrid` format) or scattered points in  $R^n$ .

Example: `[X1,X2,X3,X4] = ndgrid(1:10,1:5,7:9,10:11)`

Data Types: `single` | `double`

### **k** — Refinement factor

1 (default) | real, nonnegative, integer scalar

Refinement factor, specified as a real, nonnegative, integer scalar. This value specifies the number of times to repeatedly divide the intervals of the refined grid in each dimension. This results in  $2^k - 1$  interpolated points between sample values.

If  $k$  is 0, then  $V_q$  is the same as  $V$ .

`interpn(V,1)` is the same as `interpn(V)`.

The following illustration depicts  $k=2$  in  $R^2$ . There are 72 interpolated values in red and 9 sample values in black.

Example: `interpn(V,2)`

Data Types: `single` | `double`

### **method** — Interpolation method

'linear' (default) | 'nearest' | 'pchip' | 'cubic' | 'spline'

Interpolation method, specified as a string from this table.

| Method    | Description                                                                                                                                                                                                   | Continuity    | Comments                                                                                                                                                                                                                                                                                      |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'linear'  | The interpolated value at a query point is based on linear interpolation of the values at neighboring grid points in each respective dimension. This is the default interpolation method.                     | $C^0$         | <ul style="list-style-type: none"> <li>Requires at least two grid points in each dimension</li> <li>Requires more memory than 'nearest'</li> </ul>                                                                                                                                            |
| 'nearest' | The interpolated value at a query point is the value at the nearest sample grid point.                                                                                                                        | Discontinuous | <ul style="list-style-type: none"> <li>Requires two grid points in each dimension.</li> <li>Fastest computation with modest memory requirements</li> </ul>                                                                                                                                    |
| 'pchip'   | Shape-preserving piecewise cubic interpolation (for 1-D only). The interpolated value at a query point is based on a shape-preserving piecewise cubic interpolation of the values at neighboring grid points. | $C^1$         | <ul style="list-style-type: none"> <li>Requires at least four points</li> <li>Requires more memory and computation time than 'linear'</li> </ul>                                                                                                                                              |
| 'cubic'   | The interpolated value at a query point is based on a cubic interpolation of the values at neighboring grid points in each respective dimension. The interpolation is based on a cubic convolution.           | $C^1$         | <ul style="list-style-type: none"> <li>Grid must have uniform spacing in each dimension, but the spacing does not have to be the same for all dimensions</li> <li>Requires at least four points in each dimension</li> <li>Requires more memory and computation time than 'linear'</li> </ul> |
| 'spline'  | The interpolated value at a query point is based on a cubic interpolation of the values at neighboring grid points in each respective dimension. The interpolation is based on a cubic                        | $C^2$         | <ul style="list-style-type: none"> <li>Requires four points in each dimension</li> <li>Requires more memory and computation time than 'cubic'</li> </ul>                                                                                                                                      |

| Method | Description                             | Continuity | Comments |
|--------|-----------------------------------------|------------|----------|
|        | spline using not-a-knot end conditions. |            |          |

**extrapval** — Function value outside domain of  $X_1, X_2, \dots, X_n$

scalar

Function value outside domain of  $X_1, X_2, \dots, X_n$ , specified as a real or complex scalar. **interp<sub>n</sub>** returns this constant value for all points outside the domain of  $X_1, X_2, \dots, X_n$ .

Example: 5

Example: 5+1i

Data Types: single | double

Complex Number Support: Yes

## Output Arguments

**V<sub>q</sub>** — Interpolated values

scalar | vector | array

Interpolated values, returned as a real or complex scalar, vector, or array. The size and shape of **V<sub>q</sub>** depends on the syntax you use and, in some cases, the size and value of the input arguments.

| Syntaxes                                                                                                                                                                 | Special Conditions                                                           | Size of V <sub>q</sub>                                           | Example                                                                                                         |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------|------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------|

## More About

### Strictly Monotonic

A set of values that are always increasing or decreasing, without reversals. For example, the sequence,  $a = [2\ 4\ 6\ 8]$  is strictly monotonic and increasing. The sequence,  $b = [2\ 4\ 4\ 6\ 8]$  is not strictly monotonic because there is no change in value between  $b(2)$  and  $b(3)$ . The sequence,  $c = [2\ 4\ 6\ 8\ 6]$  contains a reversal between  $c(4)$  and  $c(5)$ , so it is not monotonic at all.

### Full Grid (in ndgrid Format)

For `interpn`, the full grid consists of  $n$  arrays,  $X_1, X_2, \dots, X_n$ , whose elements represent a grid of points in  $R^n$ . The  $i$ th array,  $X_i$ , contains strictly monotonic, increasing values that vary most rapidly along the  $i$ th dimension.

Use the `ndgrid` function to create a full grid that you can pass to `interpn`. For example, the following code creates a full grid in  $R^2$  for the region,  $1 \leq X_1 \leq 3$ ,  $1 \leq X_2 \leq 4$ .

```
[X1,X2] = ndgrid(-1:3,(1:4))
```

$X_1 =$

```
-1 -1 -1 -1
 0 0 0 0
 1 1 1 1
 2 2 2 2
 3 3 3 3
```

$X_2 =$

```
 1 2 3 4
 1 2 3 4
 1 2 3 4
 1 2 3 4
 1 2 3 4
```

### Grid Vectors

For `interpn`, grid vectors consist of  $n$  vectors of mixed-orientation that define the points of a grid in  $R^n$ .

For example, the following code creates the grid vectors in  $R^3$  for the region,  $1 \leq x_1 \leq 3$ ,  $4 \leq x_2 \leq 5$ , and  $6 \leq x_3 \leq 8$ :

```
x1 = 1:3;
x2 = (4:5)';
x3 = 6:8;
```

**Scattered Points**

For `interpn`, scattered points consist of  $n$  arrays or vectors,  $Xq_1, Xq_2, \dots, Xq_n$ , that define a collection of points scattered in  $R^n$ . The  $i$ th array,  $X_i$ , contains the coordinates in the  $i$ th dimension.

For example, the following code specifies the points, (1, 19, 10), (6, 40, 1), (15, 33, 22), and (0, 61, 13) in  $R^3$ .

```
Xq1 = [1 6; 15 0];
Xq2 = [19 40; 33 61];
Xq3 = [10 1; 22 13];
```

# interpstreamspeed

Interpolate stream-line vertices from flow speed

## Syntax

```
interpstreamspeed(X,Y,Z,U,V,W,vertices)
interpstreamspeed(U,V,W,vertices)
interpstreamspeed(X,Y,Z,speed,vertices)
interpstreamspeed(speed,vertices)
interpstreamspeed(X,Y,U,V,vertices)
interpstreamspeed(U,V,vertices)
interpstreamspeed(X,Y,speed,vertices)
interpstreamspeed(speed,vertices)
interpstreamspeed(...,sf)
vertsout = interpstreamspeed(...)
```

## Description

`interpstreamspeed(X,Y,Z,U,V,W,vertices)` interpolates streamline vertices based on the magnitude of the vector data U, V, W.

The arrays X, Y, and Z, which define the coordinates for U, V, and W, must be monotonic, but do not need to be uniformly spaced. X, Y, and Z must have the same number of elements, as if produced by `meshgrid`.

`interpstreamspeed(U,V,W,vertices)` assumes X, Y, and Z are determined by the expression

```
[X Y Z] = meshgrid(1:n,1:m,1:p)
```

where `[m n p] = size(U)`.

`interpstreamspeed(X,Y,Z,speed,vertices)` uses the 3-D array `speed` for the speed of the vector field.

`interpstreamspeed(speed,vertices)` assumes X, Y, and Z are determined by the expression

```
[X Y Z] = meshgrid(1:n,1:m,1:p)
```

where `[m n p]=size(speed)`.

`interpstreamspeed(X,Y,U,V,vertices)` interpolates streamline vertices based on the magnitude of the vector data `U, V`.

The arrays `X` and `Y`, which define the coordinates for `U` and `V`, must be monotonic, but do not need to be uniformly spaced. `X` and `Y` must have the same number of elements, as if produced by `meshgrid`.

`interpstreamspeed(U,V,vertices)` assumes `X` and `Y` are determined by the expression

```
[X Y] = meshgrid(1:n,1:m)
```

where `[M N]=size(U)`.

`interpstreamspeed(X,Y,speed,vertices)` uses the 2-D array `speed` for the speed of the vector field.

`interpstreamspeed(speed,vertices)` assumes `X` and `Y` are determined by the expression

```
[X Y] = meshgrid(1:n,1:m)
```

where `[M,N]= size(speed)`.

`interpstreamspeed(...,sf)` uses `sf` to scale the magnitude of the vector data and therefore controls the number of interpolated vertices. For example, if `sf` is 3, then `interpstreamspeed` creates only one-third of the vertices.

`vertsout = interpstreamspeed(...)` returns a cell array of vertex arrays.

## Examples

This example draws streamlines using the vertices returned by `interpstreamspeed`. Dot markers indicate the location of each vertex. This example enables you to visualize the relative speeds of the flow data. Streamlines having widely spaced vertices indicate faster flow; those with closely spaced vertices indicate slower flow.

```
load wind
```

```

[sx sy sz] = meshgrid(80,20:1:55,5);
verts = stream3(x,y,z,u,v,w,sx,sy,sz);
iverts = interpstreamspeed(x,y,z,u,v,w,verts,0.2);
sl = streamline(iverts);
set(sl,'Marker','.')
axis tight; view(2); daspect([1 1 1])

```

This example plots streamlines whose vertex spacing indicates the value of the gradient along the streamline.

```

figure
z = membrane(6,30);
[u v] = gradient(z);
pcolor(z)

```

```
hold on
[verts averts] = streamslice(u,v);
iverts = interpstreamspeed(u,v,verts,15);
sl = streamline(iverts);
set(sl,'Marker','.')
shading interp
axis tight
view(2)
daspect([1,1,1])
hold off
```

## See Also

# intersect

Set intersection of two arrays

## Syntax

```
C = intersect(A,B)
C = intersect(A,B,'rows')
[C,ia,ib] = intersect(A,B)
[C,ia,ib] = intersect(A,B,'rows')

[C,ia,ib] = intersect(____,setOrder)

[C,ia,ib] = intersect(A,B,'legacy')
[C,ia,ib] = intersect(A,B,'rows','legacy')
```

## Description

`C = intersect(A,B)` returns the data common to both **A** and **B** with no repetitions.

- If **A** and **B** are numeric arrays, logical arrays, character arrays, categorical arrays, datetime arrays, duration arrays, or cell arrays of strings, then `intersect` returns the values common to both **A** and **B**. The values of **C** are in sorted order.
- If **A** and **B** are tables, then `intersect` returns the set of rows common to both tables. The rows of table **C** are in sorted order.

`C = intersect(A,B,'rows')` treats each row of **A** and each row of **B** as single entities and returns the rows common to both **A** and **B**. The rows of **C** are in sorted order.

The `'rows'` option does not support cell arrays, unless one of the inputs is either a categorical array or a datetime array.

`[C,ia,ib] = intersect(A,B)` also returns index vectors **ia** and **ib**.

- If **A** and **B** are numeric arrays, logical arrays, character arrays, categorical arrays, datetime arrays, duration arrays, or cell arrays of strings, then `C = A(ia)` and `C = B(ib)`.

- If A and B are tables, then `C = A(ia,:)` and `C = B(ib,:)`.

`[C,ia,ib] = intersect(A,B,'rows')` also returns index vectors `ia` and `ib`, such that `C = A(ia,:)` and `C = B(ib,:)`.

`[C,ia,ib] = intersect(____,setOrder)` returns `C` in a specific order using any of the input arguments in the previous syntaxes. `setOrder='sorted'` returns the values (or rows) of `C` in sorted order. `setOrder='stable'` returns the values (or rows) of `C` in the same order as `A`, and then `B`. If no value is specified, the default is `'sorted'`.

`[C,ia,ib] = intersect(A,B,'legacy')` and `[C,ia,ib] = intersect(A,B,'rows','legacy')` preserve the behavior of the `intersect` function from R2012b and prior releases.

The `'legacy'` option does not support categorical arrays, tables, datetime arrays, or duration arrays.

## Examples

### Intersection of Two Vectors

Define two vectors with values in common.

```
A = [7 1 7 7 4]; B = [7 0 4 4 0];
```

Find the values common to both A and B.

```
C = intersect(A,B)
```

```
C =
```

```
 4 7
```

### Intersection of Two Tables

Define two tables with rows in common.

```
A = table([1:5]', ['A'; 'B'; 'C'; 'D'; 'E'], logical([0;1;0;1;0]))
B = table([1:2:10]', ['A'; 'C'; 'E'; 'G'; 'I'], logical(zeros(5,1)))
```

```
A =
```

```

Var1 Var2 Var3
---- ---- ----
1 A false
2 B true
3 C false
4 D true
5 E false

```

B =

```

Var1 Var2 Var3
---- ---- ----
1 A false
3 C false
5 E false
7 G false
9 I false

```

Find the rows common to both A and B.

```
C = intersect(A,B)
```

C =

```

Var1 Var2 Var3
---- ---- ----
1 A false
3 C false
5 E false

```

### Intersection of Two Vectors and Their Indices

Define two vectors with values in common.

```
A = [7 1 7 7 4]; B = [7 0 4 4 0];
```

Find the values common to both A and B, as well as the index vectors `ia` and `ib`, such that `C = A(ia)` and `C = B(ib)`.

```
[C,ia,ib] = intersect(A,B)
```

C =

```
4 7
```

```
ia =
```

```
5
1
```

```
ib =
```

```
3
1
```

## Intersection of Two Tables and Their Indices

Define a table, A, of gender, age, and height for five people.

```
A = table(['M';'M';'F';'M';'F'],[27;52;31;46;35],[74;68;64;61;64],...
'VariableNames',{'Gender' 'Age' 'Height'},...
'RowNames',{'Ted' 'Fred' 'Betty' 'Bob' 'Judy'})
```

```
A =
```

|       | Gender | Age | Height |
|-------|--------|-----|--------|
|       | -----  | --- | -----  |
| Ted   | M      | 27  | 74     |
| Fred  | M      | 52  | 68     |
| Betty | F      | 31  | 64     |
| Bob   | M      | 46  | 61     |
| Judy  | F      | 35  | 64     |

Define a table, B, with rows in common with A.

```
B = table(['F';'M';'F';'F'],[31;47;35;23],[64;68;62;58],...
'VariableNames',{'Gender' 'Age' 'Height'},...
'RowNames',{'Meg' 'Joe' 'Beth' 'Amy'})
```

```
B =
```

|      | Gender | Age | Height |
|------|--------|-----|--------|
|      | -----  | --- | -----  |
| Meg  | F      | 31  | 64     |
| Joe  | M      | 47  | 68     |
| Beth | F      | 35  | 62     |

```
Amy F 23 58
```

Find the rows common to both A and B, as well as the index vectors ia and ib, such that C = A(ia,:) and C = B(ib,).

```
[C,ia,ib] = intersect(A,B)
```

```
C =
```

```
 Gender Age Height
 ----- --- -----
Betty F 31 64
```

```
ia =
```

```
3
```

```
ib =
```

```
1
```

Two rows that have the same values, but different names, are considered equal. Therefore, we discover that Betty, A(3,:), and Meg, B(1,:), have the same gender, age, and height.

### Intersection of Rows in Two Matrices

Define two matrices with rows in common.

```
A = [2 2 2; 0 0 1; 1 2 3; 1 1 1];
B = [1 2 3; 2 2 2; 2 2 0];
```

Find the rows common to both A and B as well as the index vectors ia and ib, such that C = A(ia,:) and C = B(ib,).

```
[C,ia,ib] = intersect(A,B,'rows')
```

```
C =
```

```
1 2 3
2 2 2
```

```
ia =
 3
 1
```

```
ib =
 1
 2
```

A and B do not need to have the same number of rows, but they must have the same number of columns.

### Intersection with Specified Output Order

Use the `setOrder` argument to specify the ordering of the values in C.

Specify `'stable'` if you want the values in C to have the same order as in A.

```
A = [7 1 7 7 4]; B = [7 0 4 4 0];
[C,ia,ib] = intersect(A,B,'stable')
```

```
C =
 7 4
```

```
ia =
 1
 5
```

```
ib =
 1
 3
```

Alternatively, you can specify `'sorted'` order.

```
[C,ia,ib] = intersect(A,B,'sorted')
```

```
C =
```

```

 4 7

ia =

 5
 1

ib =

 3
 1

```

### Intersection of Vectors Containing NaNs

Define two vectors containing NaN.

```
A = [5 NaN NaN]; B = [5 NaN NaN];
```

Find the values common to both A and B.

```
C = intersect(A,B)
```

```
C =

 5

```

`intersect` treats NaN values as distinct.

### Cell Array of Strings with Trailing White Space

Create a cell array of strings, A.

```
A = {'dog', 'cat', 'fish', 'horse'};
```

Create a cell array of strings, B, where some of the strings have trailing white space.

```
B = {'dog ', 'cat', 'fish ', 'horse'};
```

Find the strings common to both A and B.

```
[C,ia,ib] = intersect(A,B)
```

```
C =
```

```
'cat' 'horse'

ia =
 2
 4

ib =
 2
 4
```

`intersect` treats trailing white space in cell arrays of strings as distinct characters.

## Intersection of Arrays of Different Classes and Shapes

Create a column vector character array.

```
A = ['A'; 'B'; 'C'], class(A)
```

```
A =
A
B
C
```

```
ans =
```

```
char
```

Create a 2-by-3 matrix containing elements of numeric type double.

```
B = [65 66 67; 68 69 70], class(B)
```

```
B =
 65 66 67
 68 69 70
```

```
ans =
```

```
double
```

Find the values common to both A and B.

```
[C,ia,ib] = intersect(A,B)
```

```
C =
```

```
A
```

```
B
```

```
C
```

```
ia =
```

```
1
```

```
2
```

```
3
```

```
ib =
```

```
1
```

```
3
```

```
5
```

`intersect` interprets **B** as a character array and returns a character array, **C**.

```
class(C)
```

```
ans =
```

```
char
```

### Intersection of Char and Cell Array of Strings

Create a character array containing animal names that have three letters.

```
A = ['dog'; 'cat'; 'fox'; 'pig'];
```

```
class(A)
```

```
ans =
```

```
char
```

Create a cell array of strings containing animal names of varying lengths.

```
B = {'cat', 'dog', 'fish', 'horse'};
class(B)
```

```
ans =
```

```
cell
```

Find the strings common to both A and B.

```
C = intersect(A,B)
```

```
C =
```

```
 'cat'
 'dog'
```

The result, C, is a cell array of strings.

```
class(C)
```

```
ans =
```

```
cell
```

## Preserve Legacy Behavior of intersect

Use the 'legacy' flag to preserve the behavior of `intersect` from R2012b and prior releases in your code.

Find the intersection of A and B with the current behavior.

```
A = [7 1 7 7 4]; B = [7 0 4 4 0];
[C1,ia1,ib1] = intersect(A,B)
```

```
C1 =
```

```
 4 7
```

```
ia1 =
```

```

 5
 1

ib1 =

 3
 1

```

Find the unique elements of A and preserve the legacy behavior.

```
[C2,ia2,ib2] = intersect(A,B,'legacy')
```

```
C2 =

 4 7

```

```
ia2 =

 5 4

```

```
ib2 =

 4 1

```

## Input Arguments

### A, B — Input arrays

numeric arrays | logical arrays | character arrays | categorical arrays | datetime arrays  
| duration arrays | cell arrays of strings | tables

Input arrays, specified as numeric arrays, logical arrays, character arrays, categorical arrays, datetime arrays, duration arrays, cell arrays of strings, or tables.

A and B must be of the same class with the following exceptions:

- `logical`, `char`, and all numeric classes can combine with `double` arrays.
- Cell arrays of strings can combine with `char` arrays.

- Categorical arrays can combine with cell arrays of strings or single strings.
- Datetime arrays can combine with cell arrays of date strings or single date strings.

If **A** and **B** are both ordinal categorical arrays, they must have the same sets of categories, including their order. If neither **A** nor **B** are ordinal, they need not have the same sets of categories, and the comparison is performed using the category names. In this case, the categories of **C** are the sorted union of the categories from **A** and **B**.

If you specify the 'rows' option, **A** and **B** must have the same number of columns.

If **A** and **B** are tables, they must have the same variable names. Conversely, the row names do not matter. Two rows that have the same values, but different names, are considered equal.

If **A** and **B** are datetime arrays, they must be consistent with each other in whether they specify a time zone.

Furthermore, **A** and **B** can be objects with the following class methods:

- `sort` (or `sortrows` for the 'rows' option)
- `ne`

The object class methods must be consistent with each other. These objects include heterogeneous arrays derived from the same root class.

### **setOrder** – Order flag

'sorted' (default) | 'stable'

Order flag, specified as 'sorted' or 'stable', indicates the order of the values (or rows) in **C**.

| Order Flag | Meaning                                                                                                                                                                                                |
|------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'sorted'   | The values (or rows) in <b>C</b> return in sorted order. For example: <code>C = intersect([7 0 5],[7 1 5],'sorted')</code> returns <code>C = [5 7]</code> .                                            |
| 'stable'   | The values (or rows) in <b>C</b> return in the same order as they appear in <b>A</b> and <b>B</b> . For example: <code>C = intersect([7 0 5],[7 1 5],'stable')</code> returns <code>C = [7 5]</code> . |

## Output Arguments

### **C** — Data common to A and B

vector | matrix | table

Data common to A and B, returned as a vector, matrix, or table. If the inputs A and B are tables, the order of the variables in the resulting table, C, is the same as the order of the variables in A.

The following describes the shape of C when the inputs are vectors or matrices and when the 'legacy' flag is not specified:

- If the 'rows' flag is not specified, then C is a column vector unless both A and B are row vectors.
- If the 'rows' flag is not specified and both A and B are row vectors, then C is a row vector.
- If the 'rows' flag is specified, then C is a matrix containing the rows in common from A and B.
- If A and B have no values (or rows) in common, then C is an empty matrix.

The class of the inputs A and B determines the class of C:

- If the class of A and B are the same, then C is the same class.
- If you combine a `char` or nondouble numeric class with `double`, then C is the same class as the nondouble input.
- If you combine a `logical` class with `double`, then C is `double`.
- If you combine a cell array of strings with `char`, then C is a cell array of strings.
- If you combine a categorical array with a cell array of strings or single string, then C is a categorical array.
- If you combine a datetime array with a cell array of date strings or single date string, then C is a datetime array.

### **ia** — Index to A

column vector

Index to A, returned as a column vector when the 'legacy' flag is not specified. `ia` identifies the values (or rows) in A that are common to B. If there is a repeated value (or row) in A, then `ia` contains the index to the first occurrence of the value (or row).

## **ib** — Index to B

column vector

Index to B, returned as a column vector when the 'legacy' flag is not specified. **ib** identifies the values (or rows) in B that are common to A. If there is a repeated value (or row) in B, then **ib** contains the index to the first occurrence of the value (or row).

## **More About**

### **Tips**

- To find the intersection with respect to a subset of variables from a table, you can use column subscripting. For example, you can use `intersect(A(:,vars),B(:,vars))`, where *vars* is a positive integer, a vector of positive integers, a variable name, a cell array of variable names, or a logical vector.
- “Combine Categorical Arrays”

### **See Also**

`ismember` | `issorted` | `setdiff` | `setxor` | `sort` | `union` | `unique`

# intmax

Largest value of specified integer type

## Syntax

```
v = intmax
v = intmax('classname')
```

## Description

`v = intmax` is the largest positive value that can be represented in the MATLAB software with a 32-bit integer. Any value larger than the value returned by `intmax` saturates to the `intmax` value when cast to a 32-bit integer.

`v = intmax('classname')` is the largest positive value in the integer class `classname`. Valid values for the string `classname` are

|         |          |          |          |
|---------|----------|----------|----------|
| 'int8'  | 'int16'  | 'int32'  | 'int64'  |
| 'uint8' | 'uint16' | 'uint32' | 'uint64' |

`intmax('int32')` is the same as `intmax` with no arguments.

## Examples

Find the maximum value for a 64-bit signed integer:

```
v = intmax('int64')
v =
 9223372036854775807
```

Convert this value to a 32-bit signed integer:

```
x = int32(v)
x =
 2147483647
```

Compare the result with the default value returned by `intmax`:

```
isequal(x, intmax)
ans =
 1
```

### **See Also**

`intmin` | `realmax` | `int8` | `uint8` | `isa` | `class` | `realmin`

## intmin

Smallest value of specified integer type

### Syntax

```
v = intmin
v = intmin('classname')
```

### Description

`v = intmin` is the smallest value that can be represented in the MATLAB software with a 32-bit integer. Any value smaller than the value returned by `intmin` saturates to the `intmin` value when cast to a 32-bit integer.

`v = intmin('classname')` is the smallest positive value in the integer class `classname`. Valid values for the string `classname` are

|         |          |          |          |
|---------|----------|----------|----------|
| 'int8'  | 'int16'  | 'int32'  | 'int64'  |
| 'uint8' | 'uint16' | 'uint32' | 'uint64' |

`intmin('int32')` is the same as `intmin` with no arguments.

### Examples

Find the minimum value for a 64-bit signed integer:

```
v = intmin('int64')
v =
```

```
-9223372036854775808
```

Convert this value to a 32-bit signed integer:

```
x = int32(v)
x =
```

-2147483648

Compare the result with the default value returned by `intmin`:

```
isequal(x, intmin)
ans =
```

1

## See Also

`intmax` | `realmin` | `int8` | `uint8` | `isa` | `class` | `realmax`

# inv

Matrix inverse

## Syntax

```
Y = inv(X)
```

## Description

`Y = inv(X)` returns the inverse of the square matrix `X`. A warning message is printed if `X` is badly scaled or nearly singular.

In practice, it is seldom necessary to form the explicit inverse of a matrix. A frequent misuse of `inv` arises when solving the system of linear equations  $Ax = b$ . One way to solve this is with `x = inv(A)*b`. A better way, from both an execution time and numerical accuracy standpoint, is to use the matrix division operator `x = A\b`. This produces the solution using Gaussian elimination, without forming the inverse. See `mldivide (\)` for further information.

---

**Note:** MATLAB computes  $X^{-1}$  and `inv(X)` in the same manner, and both are subject to the same limitations.

---

## Examples

Here is an example demonstrating the difference between solving a linear system by inverting the matrix with `inv(A)*b` and solving it directly with `A\b`. A random matrix `A` of order 500 is constructed so that its condition number, `cond(A)`, is  $1.e10$ , and its norm, `norm(A)`, is 1. The exact solution `x` is a random vector of length 500 and the right-hand side is `b = A*x`. Thus the system of linear equations is badly conditioned, but consistent.

On a 300 MHz, laptop computer the statements

```
n = 500;
Q = orth(randn(n,n));
d = logspace(0,-10,n);
```

```
A = Q*diag(d)*Q';
x = randn(n,1);
b = A*x;
tic, y = inv(A)*b; toc
err = norm(y-x)
res = norm(A*y-b)
```

produce

```
elapsed_time =
 1.4320
err =
 7.3260e-006
res =
 4.7511e-007
```

while the statements

```
tic, z = A\b, toc
err = norm(z-x)
res = norm(A*z-b)
```

produce

```
elapsed_time =
 0.6410
err =
 7.1209e-006
res =
 4.4509e-015
```

It takes almost two and one half times as long to compute the solution with  $y = \text{inv}(A)*b$  as with  $z = A\b$ . Both produce computed solutions with about the same error,  $1.e-6$ , reflecting the condition number of the matrix. But the size of the residuals, obtained by plugging the computed solution back into the original equations, differs by several orders of magnitude. The direct solution produces residuals on the order of the machine accuracy, even though the system is badly conditioned.

The behavior of this example is typical. Using  $A\b$  instead of  $\text{inv}(A)*b$  is two to three times as fast and produces residuals on the order of machine accuracy, relative to the magnitude of the data.

# invhilb

Inverse of Hilbert matrix

## Syntax

```
H = invhilb(n)
```

## Description

`H = invhilb(n)` generates the exact inverse of the exact Hilbert matrix for  $n$  less than about 15. For larger  $n$ , `invhilb(n)` generates an approximation to the inverse Hilbert matrix.

## Limitations

The exact inverse of the exact Hilbert matrix is a matrix whose elements are large integers. These integers may be represented as floating-point numbers without roundoff error as long as the order of the matrix,  $n$ , is less than 15.

Comparing `invhilb(n)` with `inv(hilb(n))` involves the effects of two or three sets of roundoff errors:

- The errors caused by representing `hilb(n)`
- The errors in the matrix inversion process
- The errors, if any, in representing `invhilb(n)`

It turns out that the first of these, which involves representing fractions like  $1/3$  and  $1/5$  in floating-point, is the most significant.

## Examples

`invhilb(4)` is

```
 16 -120 240 -140
```

|      |       |       |       |
|------|-------|-------|-------|
| -120 | 1200  | -2700 | 1680  |
| 240  | -2700 | 6480  | -4200 |
| -140 | 1680  | -4200 | 2800  |

# invoke

Invoke method on COM object or interface, or display methods

## Syntax

```
S = invoke(h)
S = invoke(h, 'methodname')
S = invoke(h, 'methodname', arg1, arg2, ...)
S = invoke(h, 'custominterfacename')
```

## Description

`S = invoke(h)` returns structure array, `S`, containing a list of all methods supported by the object or interface, `h`, along with the prototypes for these methods. If `S` is empty, either there are no properties or methods in the object, or MATLAB cannot read the object's type library. Refer to the COM vendor documentation.

`S = invoke(h, 'methodname')` invokes the method specified in the string `methodname`, and returns an output value, if any, in `S`. The data type of the return value depends on the invoked method, which is determined by the control or server.

`S = invoke(h, 'methodname', arg1, arg2, ...)` invokes the method specified in the string `methodname` with input arguments `arg1`, `arg2`, etc.

`S = invoke(h, 'custominterfacename')` returns an `Interface` object `S`, which is a handle to a custom interface implemented by the COM component. The `h` argument is a handle to the COM object. The `custominterfacename` argument is a string returned by the `interfaces` function.

If the method returns a COM interface, then `invoke` returns a new MATLAB COM object that represents the interface returned. For a description of how MATLAB converts COM types, see “Handling COM Data in MATLAB Software”.

COM functions are available on Microsoft Windows systems only.

## Examples

Invoke the `Redraw` method in the `mwsamp` control.

```
f = figure('position',[100 200 200 200]);
h = actxcontrol('mwsamp.mwsampctrl.1',[0 0 200 200],f);
h.Radius = 100;
invoke(h,'Redraw');
```

Alternatively, call the method directly.

```
Redraw(h);
```

Display all `mwsamp` methods.

```
invoke(h)
ans =
 AboutBox = void AboutBox(handle)
 Beep = void Beep(handle)
 FireClickEvent = void FireClickEvent(handle)
 .
 .
```

## Getting a Custom Interface Example

Once you have created a COM server, you can query the server component to see if any custom interfaces are implemented. Use the `interfaces` function to return a list of all available custom interfaces:

```
h = actxserver('mytestenv.calculator');
customlist = interfaces(h)

customlist =
 ICalc1
 ICalc2
 ICalc3
```

To get a handle to the custom interface you want, use the `invoke` function.

```
c1 = invoke(h,'ICalc1')

c1 =
 Interface.Calc_1.0_Type_Library.ICalc_Interface
```

Use this handle with COM client functions to access the properties and methods of the object through the selected custom interface.

## ipermute

Inverse permute dimensions of N-D array

### Syntax

```
A = ipermute(B,order)
```

### Description

`A = ipermute(B,order)` is the inverse of `permute`. `ipermute` rearranges the dimensions of `B` so that `permute(A,order)` will produce `B`. `B` has the same values as `A` but the order of the subscripts needed to access any particular element are rearranged as specified by `order`. All the elements of `order` must be unique.

### Examples

Consider the 2-by-2-by-3 array `a`:

```
a = cat(3,eye(2),2*eye(2),3*eye(2))
```

```
a(:,:,1) = a(:,:,2) =
 1 0 2 0
 0 1 0 2
```

```
a(:,:,3) =
 3 0
 0 3
```

Permuting and inverse permuting `a` in the same fashion restores the array to its original form:

```
B = permute(a,[3 2 1]);
C = ipermute(B,[3 2 1]);
isequal(a,C)
ans =
```

```
1
```

## More About

### Tips

`permute` and `ipermute` are a generalization of transpose (`.'`) for multidimensional arrays.

### See Also

`permute`

**is\***

Detect state

**Description**

These functions detect the state of MATLAB entities:

|                                 |                                                                   |
|---------------------------------|-------------------------------------------------------------------|
| <code>isa</code>                | Detect object of given MATLAB class or Java class                 |
| <code>isappdata</code>          | Determine if object has specific application-defined data         |
| <code>isbetween</code>          | Array elements occurring within date and time interval            |
| <code>iscalendarduration</code> | Determine if input is duration array                              |
| <code>iscategorical</code>      | Determine whether input is categorical array                      |

| <code>isempty</code>            | Determine if input is empty array                                 |
| <code>isequal</code>            | Determine if arrays are numerically equal                         |
| <code>isequaln</code>           | Determine if arrays are numerically equal, treating NaNs as equal |
| <code>isevent</code>            | Determine if input is Component Object Model (COM) object event   |
| <code>isfield</code>            | Determine if input is MATLAB structure array field                |
| <code>isfinite</code>           | Detect finite elements of array                                   |

|             |                                                                 |
|-------------|-----------------------------------------------------------------|
| isfloat     | Determine if input is floating-point array                      |
| ishandle    | Detect valid graphics object handles                            |
| ishold      | Determine if graphics hold state is on                          |
| isinf       | Detect infinite elements of array                               |
| isinteger   | Determine if input is integer array                             |
| isinterface | Determine if input is Component Object Model (COM) interface    |
| isjava      | Determine if input is Java object                               |
| iskeyword   | Determine if input is MATLAB keyword                            |
| isletter    | Detect elements that are alphabetic letters                     |
| islogical   | Determine if input is logical array                             |
| ismac       | Determine if running MATLAB for Macintosh OS X platform         |
| ismatrix    | Determine whether input is matrix                               |
| ismember    | Detect members of specific set                                  |
| ismethod    | Determine if input is object method                             |
| ismissing   | Find table elements with missing values                         |
| isnan       | Detect elements of array that are not a number (NaN)            |
| isnumeric   | Determine if input is numeric array                             |
| isobject    | Determine if input is MATLAB object                             |
| isordinal   | Determine whether input is ordinal categorical array            |
| ispc        | Determine if running MATLAB for PC (Windows) platform           |
| isprime     | Detect prime elements of array                                  |
| isprop      | Determine if input is object property                           |
| isprotected | Determine whether categories of categorical array are protected |
| isreal      | Determine if all array elements are real numbers                |
| isrow       | Determine whether input is row vector                           |
| isscalar    | Determine if input is scalar                                    |
| issorted    | Determine if set elements are in sorted order                   |

|                          |                                                             |
|--------------------------|-------------------------------------------------------------|
| <code>isspace</code>     | Detect space characters in array                            |
| <code>issparse</code>    | Determine if input is sparse array                          |
| <code>isstrprop</code>   | Determine if string is of specified category                |
| <code>isstruct</code>    | Determine if input is MATLAB structure array                |
| <code>isstudent</code>   | Determine if Student Version of MATLAB                      |
| <code>istable</code>     | Determine whether input is table                            |
| <code>isundefined</code> | Find undefined elements in categorical array                |
| <code>isunix</code>      | Determine if running MATLAB for UNIX <sup>a</sup> platform. |
| <code>isvarname</code>   | Determine if input is valid variable name                   |
| <code>isvector</code>    | Determine if input is vector                                |
| <code>isweekend</code>   | Datetime values occurring during weekend                    |

- a. UNIX is a registered trademark of The Open Group in the United States and other countries.

## See Also

`isa` | `exist`

## isa

Determine if input is object of specified class

## Syntax

```
tf = isa(obj,ClassName)
tf = isa(obj,classCategory)
```

## Description

`tf = isa(obj,ClassName)` returns `true` if `obj` is an instance of the class specified by `ClassName`, and `false` otherwise. `isa` also returns `true` if `obj` is an instance of a class that is derived from `ClassName`.

`obj` can be any MATLAB variable.

`ClassName` can be any of the following:

- Name of any MATLAB class or fundamental type
- Name of a Java, or .NET class

## MATLAB Fundamental Types

|          |                         |
|----------|-------------------------|
| 'single' | Single-precision number |
| 'double' | Double-precision number |
| 'int8'   | Signed 8-bit integer    |
| 'int16'  | Signed 16-bit integer   |
| 'int32'  | Signed 32-bit integer   |
| 'int64'  | Signed 64-bit integer   |
| 'uint8'  | Unsigned 8-bit integer  |
| 'uint16' | Unsigned 16-bit integer |

|                   |                         |
|-------------------|-------------------------|
| 'uint32'          | Unsigned 32-bit integer |
| 'uint64'          | Unsigned 64-bit integer |
| 'logical'         | Logical true or false   |
| 'char'            | Character or string     |
| 'struct'          | Structure array         |
| 'cell'            | Cell array              |
| 'function_handle' | function handle         |

`tf = isa(obj, classCategory)` returns `true` if `obj` is an instance of any of the classes in the specified `classCategory`, and `false` otherwise. `isa` also returns true if `obj` is an instance of a class that is derived from any of the classes in `classCategory`.

`classCategory` can be `'numeric'`, `'float'`, or `'integer'`, representing a category of numeric types:

## Categories of Numeric Types

|           |                                                                                                                                                                                                                                                         |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'numeric' | Integer or floating-point array ( <code>double</code> , <code>single</code> , <code>int8</code> , <code>uint8</code> , <code>int16</code> , <code>uint16</code> , <code>int32</code> , <code>uint32</code> , <code>int64</code> , <code>uint64</code> ) |
| 'float'   | Single- or double-precision floating-point array ( <code>double</code> , <code>single</code> )                                                                                                                                                          |
| 'integer' | Signed or unsigned integer array ( <code>int8</code> , <code>uint8</code> , <code>int16</code> , <code>uint16</code> , <code>int32</code> , <code>uint32</code> , <code>int64</code> , <code>uint64</code> )                                            |

To test for a sparse array, use `issparse`. To test for a complex array, use `~isreal`.

## Examples

These examples show the values returned by `isa` when passed different types:

Determine if the value returned by the `pi` function is of class `double`:

```
isa(pi, 'double')
```

```
ans =
```

---

1

More generally, determine if the value returned by the `pi` function is a numeric value:

```
isa(pi, 'numeric')
```

```
ans =
```

1

`isa` also returns `true` for the `float` category because the class `double` is a floating-point type. However, `pi` does not return an integer type:

```
isa(pi, 'integer')
```

```
ans =
```

0

Determine if the 2-by-3 array returned by `true` is of type logical:

```
isa(true(2,3), 'logical')
```

```
ans =
```

1

Identify an instance of the MATLAB `containers.Map` class:

```
colorcodes = containers.Map({'Color', 'RGB'}, ...
 {'Yellow', uint8([255,255,0])});
isa(colorcodes, 'containers.Map')
```

```
ans =
```

1

The map key, `RGB`, references a `uint8` array:

```
isa(colorcodes('RGB'), 'integer')
```

```
ans =
```

1

Specifying a particular integer class provides more specific testing:

```
if strcmp(colorcodes('Color'),'Yellow') && ...
 isa(colorcodes('RGB'),'uint8')
 disp '''The Color is Yellow and the RGB numbers are uint8 values'''
end
'The Color is Yellow and the RGB numbers are uint8 values'
```

## See Also

`class` | `is*` | `isnumeric` | `isfloat` | `isinteger` | `exist`

# isappdata

True if application-defined data exists

## Syntax

```
isappdata(h,name)
```

## Description

`isappdata(h,name)` returns 1 if application-defined data with the specified `name` exists on the object specified by handle `h`, and returns 0 otherwise.

## More About

### Tips

Application data is data that is meaningful to or defined by your application which you attach to a figure or any GUI component (other than ActiveX controls) through its `AppData` property. Only Handle Graphics MATLAB objects use this property.

### See Also

`getappdata` | `rmapdata` | `setappdata`

## isbanded

Determine if matrix is within specific bandwidth

### Syntax

```
tf = isbanded(A,lower,upper)
```

### Description

`tf = isbanded(A,lower,upper)` returns logical 1 (`true`) if matrix `A` is within the specified lower bandwidth, `lower`, and upper bandwidth, `upper`; otherwise, it returns logical 0 (`false`).

### Examples

#### Test Square Matrix

Create a 5-by-5 square matrix.

```
A = [2 3 0 0 0 ; 1 -2 -3 0 0; 0 -1 2 3 0 ; 0 0 1 -2 -3; 0 0 0 -1 2]
```

```
A =
```

```
 2 3 0 0 0
 1 -2 -3 0 0
 0 -1 2 3 0
 0 0 1 -2 -3
 0 0 0 -1 2
```

The result is a square matrix with nonzero diagonals above and below the main diagonal.

Specify both bandwidths, `lower` and `upper`, as 1 to test if `A` is tridiagonal.

```
isbanded(A,1,1)
```

```
ans =
```

```
 1
```

The result is logical 1 (**true**).

Test if **A** has nonzero elements below the main diagonal by specifying **lower** as 0.

```
isbanded(A,0,1)
```

```
ans =
```

```
 0
```

The result is logical 0 (**false**) because **A** has nonzero elements below the main diagonal.

### Test Nonsquare Matrix

Create a 3-by-5 matrix.

```
A = [1 0 0 0 0; 2 1 0 0 0; 3 2 1 0 0]
```

```
A =
```

```
 1 0 0 0 0
 2 1 0 0 0
 3 2 1 0 0
```

The result is a rectangular matrix.

Test if **A** has nonzero elements above the main diagonal.

```
isbanded(A,2,0)
```

```
ans =
```

```
 1
```

The result is logical 1 (**true**) because the elements above the main diagonal are all zero.

### Test Sparse Block Matrix

Create a 100-by-100 sparse block matrix.

```
B = kron(speye(25),ones(4));
```

Test if **B** has a lower and upper bandwidth of 1.

```
isbanded(B,1,1)
```

```
ans =
 0
```

The result is logical 0 (**false**) because the nonzero blocks centered on the main diagonal are larger than 2-by-2.

Test if **B** has a lower and upper bandwidth of 3.

```
isbanded(B,3,3)

ans =
 1
```

The result is logical 1 (**true**). The matrix, **B**, has an upper and lower bandwidth of 3 since the nonzero diagonal blocks are 4-by-4.

## Input Arguments

### **A** — Input array

numeric array

Input array, specified as a numeric array. **isbanded** returns logical 0 (**false**) if **A** has more than two dimensions.

Data Types: `single` | `double`

Complex Number Support: Yes

### **lower** — Lower bandwidth

nonnegative integer scalar

Lower bandwidth, specified as a nonnegative integer scalar. The lower bandwidth is the number of nonzero diagonals below the main diagonal. **isbanded** returns logical 0 (**false**) if there are nonzero elements below the boundary diagonal, `diag(A, -lower)`.

### **upper** — Upper bandwidth

nonnegative integer scalar

Upper bandwidth, specified as a nonnegative integer scalar. The upper bandwidth is the number of nonzero diagonals above the main diagonal. **isbanded** returns logical 0 (**false**) if there are nonzero elements above the boundary diagonal, `diag(A, upper)`.

## More About

### Tips

- Use the `bandwidth` function to find the upper and lower bandwidths of a given matrix.
- Use `isbanded` to test for several different matrix structures by specifying appropriate upper and lower bandwidths. The table below lists some common tests.

| Lower Bandwidth        | Upper Bandwidth        | Function Call                     | Tests for               |
|------------------------|------------------------|-----------------------------------|-------------------------|
| 0                      | 0                      | <code>isbanded(A,0,0)</code>      | Diagonal matrix         |
| 1                      | 1                      | <code>isbanded(A,1,1)</code>      | Tridiagonal matrix      |
| 0                      | <code>size(A,2)</code> | <code>isbanded(A,0,size(A,</code> | Upper triangular matrix |
| <code>size(A,1)</code> | 0                      | <code>isbanded(A,size(A,1)</code> | Lower triangular matrix |
| 1                      | <code>size(A,2)</code> | <code>isbanded(A,1,size(A,</code> | Upper Hessenberg matrix |
| <code>size(A,1)</code> | 1                      | <code>isbanded(A,size(A,1)</code> | Lower Hessenberg matrix |

### See Also

`bandwidth` | `diag` | `isdiag` | `istril` | `istriu`

## isbetween

Determine elements within date and time interval

### Syntax

```
tf = isbetween(t,tlower,tupper)
```

### Description

`tf = isbetween(t,tlower,tupper)` returns an array the same size as `t` containing logical 1 (true) where the corresponding element of `t` is a datetime that lies within the closed interval specified by the corresponding elements of `tlower` and `tupper`. The output `tf` indicates which elements of `t` satisfy:

```
tlower <= t <= tupper
```

### Examples

#### Determine if Dates Occur Within Interval

Define a lower bound and an upper bound for dates.

```
tlower = datetime(2014,05,16)
```

```
tlower =
```

```
 16-May-2014
```

```
tupper = '23-May-2014'
```

```
tupper =
```

```
 23-May-2014
```

`tlower` and `tupper` can be `datetime` arrays or strings. Here, `tlower` is a `datetime` array and `tupper` is a single string.

Create an array of `datetime` values and determine if each `datetime` lies within the interval bounded by `tlower` and `tupper`.

```
t = tlower + caldays(2:2:10)
```

```
t =
```

```
 18-May-2014 20-May-2014 22-May-2014 24-May-2014 26-May-2014
```

```
tf = isbetween(t,tlower,tupper)
```

```
tf =
```

```
 1 1 1 0 0
```

## Input Arguments

### **t** — Input date and time

`datetime` array | cell array of `datetime` strings | `datetime` string

Input date and time, specified as a `datetime` array, a cell array of `datetime` strings, or a single `datetime` string.

### **tlower** — Lower bound of date and time interval

`datetime` array | cell array of `datetime` strings | `datetime` string

Lower bound of date and time interval, specified as a `datetime` array, a cell array of `datetime` strings, or a single `datetime` string.

### **tupper** — Upper bound of date and time interval

`datetime` array | cell array of date strings | `datetime` string

Upper bound of date and time interval, specified as a `datetime` array, a cell array of `datetime` strings, or a single `datetime` string.

**See Also**

# iscalendarduration

Determine if input is calendar duration array

## Syntax

```
tf = iscalendarduration(t)
```

## Description

`tf = iscalendarduration(t)` returns logical 1 (true) if `t` is a `calendarDuration` array. Otherwise, it returns logical 0 (false).

## Examples

### Determine if Array Contains Calendar Duration Values

Determine if the output of an arithmetic calculation is a `calendarDuration` array.

Add two `calendarDuration` arrays.

```
d1 = calyears(1:4);
d2 = caldays(1:4);
d = d1 + d2
```

```
d =
```

```
 1y 1d 2y 2d 3y 3d 4y 4d
```

Determine if the output is a `calendarDuration` array.

```
tf = iscalendarduration(d)
```

```
tf =
```

1

## **Input Arguments**

### **t — Input array**

scalar | vector | matrix | multidimensional array

Input array, specified as a scalar, vector, matrix, or multidimensional array. `t` can be any data type.

### **See Also**

`calendarDuration` | `isdatetime` | `isduration`

# iscategorical

Determine whether input is categorical array

## Syntax

```
tf = iscategorical(A)
```

## Description

`tf = iscategorical(A)` returns logical 1 (true) if `A` is a categorical array. Otherwise, `iscategorical` returns logical 0 (false).

## Examples

### Determine Whether Workspace Variable Is Categorical Array

Create a workspace variable, `A`.

```
A = categorical({'red' 'green' 'violet'; 'orange' 'red' 'yellow'})
```

```
A =
```

```
 red green violet
orange red yellow
```

Verify that the workspace variable, `A`, is a categorical array.

```
tf = iscategorical(A)
```

```
tf =
```

```
 1
```

A is a 2-by-3 categorical array.

## Input Arguments

### **A** — Input variable

workspace variable

Input variable, specified as a workspace variable. A can be any data type.

### See Also

`categorical` | `iscell` | `islogical` | `isnumeric` | `isobject` | `isstruct` | `istable`

# iscategory

Test for categorical array categories

## Syntax

```
tf = iscategory(A, catnames)
```

## Description

`tf = iscategory(A, catnames)` returns an array containing logical 1 (true) where the data in `catnames` is a category of `A`. Otherwise, `iscategory` returns logical 0 (false).

`tf` is the same size as `catnames`.

## Examples

### Test for Categories

Create an ordinal categorical array, `A`.

```
A = categorical({'shirt' 'pants'; 'pants' 'hat'; 'shirt' 'pants'})
```

`A =`

```
 shirt pants
 pants hat
 shirt pants
```

`A` is a 1-by-5 categorical array.

Test if the articles of clothing, `shirt`, `pants`, `socks`, and `shoes`, are categories of `A`.

```
catnames = {'shirt' 'pants' 'socks' 'shoes'};
tf = iscategory(A, catnames)
```

`tf =`

```
1 1 0 0
```

shirt and pants are categories of A, but socks, and shoes are not.

iscategory does not tell us anything about the category, hat, which we did not include in catnames.

## Test for Category with No Corresponding Data

Create a categorical array, A.

```
A = categorical({'plane' 'car' 'train' 'car' 'plane'},...
 {'boat' 'car' 'plane' 'train'})
```

```
A =
```

```
plane car train car plane
```

A is a 1-by-5 categorical array.

Test to see if boat is a category in A.

```
tf = iscategory(A, 'boat')
```

```
tf =
```

```
1
```

iscategory returns true, even though A does not contain any values from the category boat.

## Input Arguments

### A — Categorical array

vector | matrix | multidimensional array

Categorical array, specified as a vector, matrix, or multidimensional array.

### catnames — Category names

string | cell array of strings | categorical array

Category names, specified as a string, cell array of strings, or categorical array.

## **See Also**

addcats | categorical | categories | ismember | mergecats | removecats |  
renamecats | reordercats | setcats | unique

## iscell

Determine whether input is cell array

### Syntax

```
tf = iscell(A)
```

### Description

`tf = iscell(A)` returns logical 1 (**true**) if `A` is a cell array and logical 0 (**false**) otherwise.

### Examples

```
A{1,1} = [1 4 3; 0 5 8; 7 2 9];
A{1,2} = 'Anne Smith';
A{2,1} = 3+7i;
A{2,2} = -pi:pi/10:pi;
```

```
iscell(A)
```

```
ans =
```

```
 1
```

### See Also

`cell` | `istable` | `iscellstr` | `isstruct` | `isnumeric` | `islogical` | `isobject` | `isa` | `is*`

# iscellstr

Determine whether input is cell array of strings

## Syntax

```
tf = iscellstr(A)
```

## Description

`tf = iscellstr(A)` returns logical 1 (**true**) if **A** is a cell array of strings (or an empty cell array), and logical 0 (**false**) otherwise. A cell array of strings is a cell array where every element is a character array.

## Examples

```
A{1,1} = 'Thomas Lee';
A{1,2} = 'Marketing';
A{2,1} = 'Allison Jones';
A{2,2} = 'Development';
```

```
iscellstr(A)
```

```
ans =
```

```
1
```

## See Also

`cellstr` | `istable` | `iscategorical` | `iscell` | `isstrprop` | `strings` | `char` | `isstruct` | `isa` | `is*`

## ischar

Determine whether item is character array

### Syntax

```
tf = ischar(A)
```

### Description

`tf = ischar(A)` returns logical 1 (true) if `A` is a character array and logical 0 (false) otherwise.

### Examples

Given the following cell array,

```
C{1,1} = magic(3); % double array
C{1,2} = 'John Doe'; % char array
C{1,3} = 2 + 4i; % complex double
```

```
C =
```

```
 [3x3 double] 'John Doe' [2.0000+ 4.0000i]
```

`ischar` shows that only `C{1,2}` is a character array.

```
for k = 1:3
x(k) = ischar(C{1,k});
end
```

```
x
```

```
x =
```

```
 0 1 0
```

**See Also**

char | strings | isletter | isspace | isstrprop | iscellstr | isnumeric | isa | is\*

## iscolumn

Determine whether input is column vector

### Syntax

```
iscolumn(V)
```

### Description

`iscolumn(V)` returns logical 1 (**true**) if `size(V)` returns `[n 1]` with a nonnegative integer value `n`, and logical 0 (**false**) otherwise.

### Examples

Determine if a vector is a column. This example is a row so `iscolumn` returns 0:

```
V = rand(1,5);
iscolumn(V)
ans =
 0
```

Transpose the vector to make it a column. `iscolumn` returns 1:

```
V1 = V';
iscolumn(V1)
ans =
 1
```

### See Also

`ismatrix` | `isrow` | `isscalar` | `isvector`

## iscom

Determine whether input is COM or ActiveX object

### Syntax

```
tf = iscom(h)
```

### Description

`tf = iscom(h)` returns logical 1 (**true**) if handle `h` is a COM or Microsoft ActiveX object. Otherwise, returns logical 0 (**false**).

COM functions are available on Microsoft Windows systems only.

### Examples

Test an instance of a Microsoft Excel application.

```
h = actxserver('Excel.Application');
iscom(h)
```

MATLAB displays **true**, indicating object `h` is a COM object.

Test an Excel interface:

```
h = actxserver('Excel.Application');
% Create a workbooks object
w = get(h,'workbooks');
iscom(w)
```

MATLAB displays **false**, indicating object `w` is not a COM object.

### More About

- “MATLAB COM Integration”

## isdatetime

Determine if input is datetime array

### Syntax

```
tf = isdatetime(t)
```

### Description

`tf = isdatetime(t)` returns logical 1 (true) if `t` is a datetime array. Otherwise, it returns logical 0 (false).

### Examples

#### Determine if Array Contains Datetime Values

Define an array.

```
A = [datetime('now');datetime('tomorrow');'January 15, 2015']
```

```
A =
```

```
19-Sep-2014 23:57:23
20-Sep-2014 00:00:00
15-Jan-2015 00:00:00
```

Determine if the array is a `datetime` array.

```
tf = isdatetime(A)
```

```
tf =
```

```
1
```

## Input Arguments

### **t** — Input array

scalar | vector | matrix | multidimensional array

Input array, specified as a scalar, vector, matrix, or multidimensional array. **t** can be any data type.

### **See Also**

`datetime` | `iscalendarduration` | `isduration`

## isdiag

Determine if matrix is diagonal

### Syntax

```
tf = isdiag(A)
```

### Description

`tf = isdiag(A)` returns logical 1 (`true`) if `A` is a diagonal matrix; otherwise, it returns logical 0 (`false`).

### Examples

#### Test Diagonal Matrix

Create a 4-by-4 identity matrix.

```
I = eye(4)
```

```
I =
```

```
 1 0 0 0
 0 1 0 0
 0 0 1 0
 0 0 0 1
```

Test to see if the matrix is diagonal.

```
isdiag(I)
```

```
ans =
```

```
 1
```

The result is logical 1 (`true`) because all of the nonzero elements in `I` are on the main diagonal.

### Test Banded Matrix

Create a matrix with nonzero elements on the main and first diagonals.

```
A = 3*eye(4) + diag([2 2 2],1)
```

```
A =
```

```
 3 2 0 0
 0 3 2 0
 0 0 3 2
 0 0 0 3
```

Test to see if the matrix is diagonal.

```
isdiag(A)
```

```
ans =
```

```
 0
```

The matrix is not diagonal since there are nonzero elements above the main diagonal.

Create a new matrix, `B`, from the main diagonal elements of `A`.

```
B = diag(diag(A));
```

Test to see if `B` is a diagonal matrix.

```
isdiag(B)
```

```
ans =
```

```
 1
```

The result is logical 1 (`true`) because there are no nonzero elements above or below the main diagonal of `B`.

## Input Arguments

**A** — Input array

numeric array

Input array, specified as a numeric array. `isdiag` returns logical 0 (`false`) if A has more than two dimensions.

Data Types: `single` | `double`

Complex Number Support: Yes

## More About

### Diagonal Matrix

A matrix is diagonal if all elements above and below the main diagonal are zero. Any number of the elements on the main diagonal can also be zero.

For example, the 4-by-4 identity matrix,

$$I_4 = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}$$

is a diagonal matrix. Diagonal matrices are typically, but not always, square.

### Tips

- Use the `diag` function to produce diagonal matrices for which `isdiag` returns logical 1 (`true`).
- The functions `isdiag`, `istriu`, and `istril` are special cases of the function `isbanded`, which can perform all of the same tests with suitably defined upper and lower bandwidths. For example, `isdiag(A) == isbanded(A,0,0)`.

### See Also

`diag` | `istril` | `istriu` | `tril` | `triu`

## isdir

Determine whether input is folder

### Syntax

```
tf = isdir('A')
```

### Description

`tf = isdir('A')` returns logical 1 (true) if `A` is a folder. Otherwise, it returns logical 0 (false).

### Examples

Run:

```
tf=isdir('myfiles/results')
```

MATLAB returns

```
tf =
 1
```

indicating that `myfiles/results` is a folder.

### See Also

`dir` | `is*`

## isdst

Determine daylight saving time elements

### Syntax

```
tf = isdst(t)
```

### Description

`tf = isdst(t)` returns an array the same size as `t` containing logical 1 (`true`) where the corresponding element of `t` is a datetime that occurs during Daylight Saving Time, and logical 0 (`false`) otherwise. `isdst` returns `false` for all elements when the `TimeZone` property of `t` is empty (`''`).

### Examples

#### Determine If Datetime Occurs During Daylight Saving Time

```
t = datetime(2014,3,7:11,'TimeZone','America/New_York')
```

```
t =
```

```
 07-Mar-2014 08-Mar-2014 09-Mar-2014 10-Mar-2014 11-Mar-2014
```

```
tf = isdst(t)
```

```
tf =
```

```
 0 0 0 1 1
```

March 10 and March 11, 2014 in the America/New\_York time zone occur during daylight saving time.

## Input Arguments

**t** — Input date and time

`datetime` array

Input date and time, specified as a `datetime` array.

## See Also

`datetime` Properties | `isweekend` | `tzoffset`

## isduration

Determine if input is duration array

### Syntax

```
tf = isduration(t)
```

### Description

`tf = isduration(t)` returns logical 1 (true) if `t` is a duration array. Otherwise, it returns logical 0 (false).

### Examples

#### Determine if Array Contains Duration Values

Determine if the output of an arithmetic calculation is a duration array.

Subtract a `datetime` array from another.

```
t1 = datetime(2014,03,16:17);
t2 = datetime(2014,03,20);
dt = t2 - t1
```

```
dt =
```

```
 96:00:00 72:00:00
```

Determine if the output is a duration array.

```
tf = isduration(dt)
```

```
tf =
```

1

## Input Arguments

### **t** — Input array

scalar | vector | matrix | multidimensional array

Input array, specified as a scalar, vector, matrix, or multidimensional array. **t** can be any data type.

### See Also

[duration](#) | [iscalendarduration](#) | [isdatetime](#)

## isEdge

**Class:** TriRep

(Will be removed) Test if vertices are joined by edge

---

**Note:** `isEdge(TriRep)` will be removed in a future release. Use `isConnected(triangulation)` instead.

`TriRep` will be removed in a future release. Use `triangulation` instead.

---

## Syntax

`TF = isEdge(TR, V1, V2)`  
`TF = isEdge(TR, EDGE)`

## Description

`TF = isEdge(TR, V1, V2)` returns an array of 1/0 (true/false) flags, where each entry `TF(i)` is true if `V1(i), V2(i)` is an edge in the triangulation. `V1, V2` are column vectors representing the indices of the vertices in the mesh, that is, indices into the vertex coordinate arrays.

`TF = isEdge(TR, EDGE)` specifies the edge start and end indices in matrix format.

## Input Arguments

|        |                                                             |
|--------|-------------------------------------------------------------|
| TR     | Triangulation representation.                               |
| V1, V2 | Column vectors of mesh vertices.                            |
| EDGE   | Matrix of size n-by-2 where n is the number of query edges. |

## Output Arguments

TF            Array of 1/0 (true/false) flags, where each entry `TF(i)` is true if `V1(i)`, `V2(i)` is an edge in the triangulation.

## Examples

### Example 1

Load a 2-D triangulation and use `TriRep` to query the presence of an edge between pairs of points.

```
load trimesh2d
trep = TriRep(tri, x,y);
```

Test if vertices 3 and 117 are connected by an edge

```
isEdge(trep, 3, 117)
```

Test if vertices 3 and 164 are connected by an edge

```
isEdge(trep, 3, 164)
```

### Example 2

Direct query of a 3-D Delaunay triangulation created using `DelaunayTri`.

```
X = rand(10,3)
dt = DelaunayTri(X)
```

Test if vertices 2 and 7 are connected by an edge

```
isEdge(dt, 2, 7);
```

### See Also

`triangulation` | `delaunayTriangulation`

## **isempty**

Determine whether array is empty

### **Syntax**

```
TF = isempty(A)
```

### **Description**

`TF = isempty(A)` returns logical 1 (**true**) if **A** is an empty array and logical 0 (**false**) otherwise. An empty array has at least one dimension of size zero, for example, 0-by-0 or 0-by-5.

### **Examples**

```
B = rand(2,2,2);
B(:, :, :) = [];
```

```
isempty(B)
```

```
ans = 1
```

### **See Also**

`is*`

## isempty (tscollection)

Determine whether `tscollection` object is empty

### Syntax

```
isempty(tsc)
```

### Description

`isempty(tsc)` returns a logical value for `tscollection` object `tsc`, as follows:

- 1 — When `tsc` contains neither `timeseries` members nor a time vector
- 0 — When `tsc` contains either `timeseries` members or a time vector

### See Also

`timeseries` | `length (tscollection)` | `size (tscollection)` | `tscollection`

## isequal

Determine array equality

### Syntax

```
tf = isequal(A,B)
tf = isequal(A1,A2,...,An)
```

### Description

`tf = isequal(A,B)` returns logical 1 (**true**) if **A** and **B** are the same size and their contents are of equal value; otherwise, it returns logical 0 (**false**). The test compares both real and imaginary parts of numeric arrays. **isequal** ignores the data type of the values in determining whether they are equal. For cell arrays, categorical arrays, tables, or structures, the function returns logical 1 (**true**) only when all elements and properties are equal. Undefined categorical elements, NaN (Not a Number), or NaT (Not a Time) values are considered to be unequal to other elements, as well as themselves.

`tf = isequal(A1,A2,...,An)` returns logical 1 (**true**) if all the inputs are numerically equal.

### Examples

#### Compare Two Numeric Matrices

Create two numeric matrices and compare them for equality.

```
A = zeros(3,3)+1e-20;
B = zeros(3,3);
tf = isequal(A,B)
```

```
tf =
 0
```

The function returns logical 0 (`false`) because the matrices differ by a very small amount and are not *exactly* equal.

### Compare Two Structures

Create two structures and specify the fields in a different order.

```
A = struct('field1',0.005,'field2',2500);
B = struct('field2',2500,'field1',0.005);
```

Compare the structures for equality.

```
tf = isequaln(A,B)
```

```
tf =
```

```
 1
```

Even though the ordering of the fields in each structure is different, `isequal` treats them as the same because the values are equal.

### Comparing Numeric Values with Special Nonnumeric Values

Compare the logical value `true` to the double integer 1.

```
isequal(true,1)
```

```
ans =
```

```
 1
```

Notice that `isequal` does not consider data type when it tests for equality.

Similarly, compare 'A' to the ASCII-equivalent integer, 65.

```
isequal('A',65)
```

```
ans =
```

```
 1
```

The result is logical 1 (`true`) since `double('A')` equals 65.

### Compare Vectors Containing NaN Values

Create three vectors containing NaN values.

```
A1 = [1 NaN NaN];
A2 = [1 NaN NaN];
A3 = [1 NaN NaN];
```

Compare the vectors for equality.

```
tf = isequal(A1,A2,A3)
```

```
tf =

 0
```

The result is logical 0 (false) because `isequal` does not treat NaN values as equal to each other.

## Compare Two Datetime Values

Determine if midnight on January 13, 2013 in Anchorage, Alaska is equal to 11 AM on the same date in Cairo.

```
t1 = datetime(2013,1,13,0,0,0, 'TimeZone', 'America/Anchorage');
t2 = datetime(2013,1,13,11,0,0, 'TimeZone', 'Africa/Cairo');
tf = isequal(t1,t2)
```

```
tf =

 1
```

Add 8 months to the date, and compare the datetime values for equality.

```
t1 = datetime(2013,9,13,0,0,0, 'TimeZone', 'America/Anchorage');
t2 = datetime(2013,9,13,11,0,0, 'TimeZone', 'Africa/Cairo');
tf = isequal(t1,t2)
```

```
tf =

 0
```

The datetime values are no longer equal since Cairo does not observe daylight saving time.

## Input Arguments

### **A, B — Inputs to be compared**

numeric arrays | categorical arrays | cell arrays | tables | structures | ...

Inputs to be compared, specified as numeric arrays, categorical arrays, cell arrays, tables, or structures. Also, you can specify the inputs as logical arrays, character arrays, datetime arrays, duration arrays, calendarDuration arrays, or objects. The numeric types of A and B do not have to match.

You can compare a categorical array to a cell array of strings of the same size, or a single categorical element to a single string.

You can compare a datetime array to a cell array of date strings or a single date string.

If inputs A and B are *both*

- Structures -- Fields need not be in the same order as long as the contents are equal.
- Ordinal categorical arrays -- Must have the same sets of categories, including their order.
- Categorical arrays that are not ordinal -- Can have different sets of categories, and `isequal` compares the category names of each pair of elements.
- Datetime arrays -- `isequal` ignores time zone and display format when it compares points in time.
- Objects of different classes -- `isequal` returns logical 0 (`false`). This applies even when the objects have the same properties and their values match.

### **A1, A2, . . . , An — Series of inputs to be compared**

numeric arrays | categorical arrays | cell arrays | tables | structures | ...

Series of inputs to be compared, specified as numeric arrays, categorical arrays, cell arrays, tables, or structures. Also, you can specify the inputs as logical arrays, character arrays, datetime arrays, duration arrays, calendarDuration arrays, or objects. The numeric types of the inputs do not have to match.

You can compare categorical arrays to cell arrays of strings of the same size, or single categorical elements to single strings.

You can compare a datetime array to a cell array of date strings or a single date string.

If the inputs are *all*

- Structures -- Fields need not be in the same order as long as the contents are equal.
- Ordinal categorical arrays -- Must have the same sets of categories, including their order.
- Categorical arrays that are not ordinal -- Can have different sets of categories, and `isequal` compares the category names of each pair of elements.
- Datetime arrays -- `isequal` ignores time zone and display format when it compares points in time.
- Objects of different classes -- `isequal` returns logical 0 (`false`). This applies even when the objects have the same properties and their values match.

## More About

### Tips

- When comparing handle objects, use `==` to test whether objects have the same handle. Use `isequal` to determine if objects with different handles have equal property values.
- Use `isequaln` if you want to test for equality and treat NaN or NaT values as equal.

### See Also

`eq` | `is*` | `isa*` | `isequaln` | relational operators | `strcmp`

# isequaln

Determine array equality, treating NaN values as equal

## Syntax

```
tf = isequaln(A,B)
tf = isequaln(A1,A2,...,An)
```

## Description

`tf = isequaln(A,B)` returns logical 1 (**true**) if **A** and **B** are the same size and their contents are of equal value; otherwise, it returns logical 0 (**false**). The test compares both real and imaginary parts of numeric arrays. `isequaln` ignores the data type of the values in determining whether they are equal. For cell arrays, categorical arrays, tables, or structures, the function returns logical 1 (**true**) only when all elements and properties are equal. Undefined categorical elements, NaN (Not a Number), or NaT (Not a Time) values are considered to be equal to other such values.

`tf = isequaln(A1,A2,...,An)` returns logical 1 (**true**) if all the inputs are numerically equal.

## Examples

### Compare Two Numeric Matrices

Create two numeric matrices and compare them for equality.

```
A = zeros(3,3)+1e-20;
B = zeros(3,3);
tf = isequaln(A,B)
```

```
tf =
```

```
0
```

The function returns logical 0 (`false`) because the matrices differ by a very small amount and are not *exactly* equal.

### Compare Two Structures

Create two structures and specify the fields in a different order.

```
A = struct('field1',0.005,'field2',2500);
B = struct('field2',2500,'field1',0.005);
```

Compare the structures for equality.

```
tf = isequaln(A,B)
```

```
tf =
```

```
 1
```

Even though the ordering of the fields in each structure is different, `isequaln` treats them as the same because the values are equal.

### Comparing Numeric Values with Special Nonnumeric Values

Compare the logical value `true` to the double integer 1.

```
isequaln(true,1)
```

```
ans =
```

```
 1
```

Notice that `isequaln` does not consider data type when it tests for equality.

Similarly, compare 'A' to the ASCII-equivalent integer, 65.

```
isequaln('A',65)
```

```
ans =
```

```
 1
```

The result is logical 1 (`true`) since `double('A')` equals 65.

### Compare Vectors Containing NaN Values

Create three vectors containing NaN values.

```
A1 = [1 NaN NaN];
A2 = [1 NaN NaN];
A3 = [1 NaN NaN];
```

Compare the vectors for equality.

```
tf = isequaln(A1,A2,A3)
```

```
tf =
```

```
1
```

The result is logical 1 (**true**) because `isequaln` treats the NaN values as equal to each other.

## Input Arguments

### **A, B — Inputs to be compared**

numeric arrays | categorical arrays | cell arrays | tables | structures | ...

Inputs to be compared, specified as numeric arrays, categorical arrays, cell arrays, tables, or structures. Also, you can specify the inputs as logical arrays, character arrays, datetime arrays, duration arrays, calendarDuration arrays, or objects. The numeric types of **A** and **B** do not have to match.

You can compare a categorical array to a cell array of strings of the same size, or a single categorical element to a single string.

You can compare a datetime array to a cell array of date strings or a single date string.

If inputs **A** and **B** are *both*

- Structures -- Fields need not be in the same order as long as the contents are equal.
- Ordinal categorical arrays -- Must have the same sets of categories, including their order.
- Categorical arrays that are not ordinal -- Can have different sets of categories, and `isequaln` compares the category names of each pair of elements.
- Datetime arrays -- `isequal` ignores time zone and display format when it compares points in time.
- Objects of different classes -- `isequaln` returns logical 0 (**false**). This applies even when the objects have the same properties and their values match.

## **A1 , A2 , . . . , An — Series of inputs to be compared**

numeric arrays | categorical arrays | cell arrays | tables | structures | ...

Series of inputs to be compared, specified as numeric arrays, categorical arrays, cell arrays, tables, or structures. Also, you can specify the inputs as logical arrays, character arrays, datetime arrays, duration arrays, calendarDuration arrays, or objects. The numeric types of the inputs do not have to match.

You can compare categorical arrays to cell arrays of strings of the same size, or single categorical elements to single strings.

You can compare a datetime array to a cell array of date strings or a single date string.

If the inputs are *all*

- Structures -- Fields need not be in the same order as long as the contents are equal.
- Ordinal categorical arrays -- Must have the same sets of categories, including their order.
- Categorical arrays that are not ordinal -- Can have different sets of categories, and `isequaln` compares the category names of each pair of elements.
- Datetime arrays -- `isequaln` ignores time zone and display format when it compares points in time.
- Objects of different classes -- `isequaln` returns logical 0 (`false`). This applies even when the objects have the same properties and their values match.

## **More About**

### **Tips**

- When comparing handle objects, use `==` to test whether objects have the same handle. Use `isequaln` to treat NaN values as equal and determine if objects with different handles have equal property values.
- Use `isequal` if you want to test for equality and treat NaN or NaT values as unequal.

### **See Also**

`eq` | `is*` | `isa*` | `isequal` | relational operators | `strcmp`

# isequalwithequalnans

Test arrays for equality, treating NaNs as equal

---

**Note:** `isequalwithequalnans` is not recommended. Use `isequaln` instead.

---

## Syntax

```
tf = isequalwithequalnans(A, B, ...)
```

## Description

`tf = isequalwithequalnans(A, B, ...)` returns logical 1 (**true**) if the input arrays are the same type and size and hold the same contents, and logical 0 (**false**) otherwise. NaN (Not a Number) values are considered to be equal to each other. Numeric data types and structure field order do not have to match.

## Examples

Arrays containing NaNs are handled differently by `isequal` and `isequalwithequalnans`. `isequal` does not consider NaNs to be equal, while `isequalwithequalnans` does.

```
A = [32 8 -29 NaN 0 5.7];
B = A;
isequal(A, B)
ans =
 0
```

```
isequalwithequalnans(A, B)
ans =
 1
```

The position of NaN elements in the array does matter. If they are not in the same position in the arrays being compared, then `isequalwithequalnans` returns zero.

```
A = [2 4 6 NaN 8]; B = [2 4 NaN 6 8];
isequalwithequalnans(A, B)
ans =
 0
```

## More About

### Tips

`isequalwithequalnans` is the same as `isequal`, except `isequalwithequalnans` considers NaN (Not a Number) values to be equal, and `isequal` does not.

`isequalwithequalnans` recursively compares the contents of cell arrays and structures. If all the elements of a cell array or structure are numerically equal, `isequalwithequalnans` returns logical 1.

### See Also

`isequal` | `strcmp` | `isa` | `is*` | relational operators | `isequaln`

# isevent

Determine whether input is COM object event

## Syntax

```
tf = isevent(h,'eventname')
```

## Description

`tf = isevent(h,'eventname')` returns logical 1 (**true**) if `eventname` is an event recognized by COM object `h`. Otherwise, returns logical 0 (**false**). The `eventname` argument is not case-sensitive.

COM functions are available on Microsoft Windows systems only.

## Examples

This example tests events in a MATLAB sample control object.

- 1 Create an instance of the `mwsamp` control and test `Db1Click`.

```
f = figure('position',[100 200 200 200]);
h = actxcontrol('mwsamp.mwsampctrl.2',[0 0 200 200],f);
isevent(h,'Db1Click')
```

MATLAB displays **true**, indicating `Db1Click` is an event.

- 2 Try the same test on `Redraw`.

```
isevent(h,'Redraw')
```

MATLAB displays **false**, indicating `Redraw` is not an event; it is a method.

Test events in a Microsoft Excel workbook object.

- 1 Create a `Workbook` object `wb`

```
myApp = actxserver('Excel.Application');
```

```
wbs = myApp.Workbooks;
wb = Add(wbs);
```

## 2 Test Activate.

```
isevent(wb, 'Activate')
```

MATLAB displays `true`, indicating `Activate` is an event.

## 3 Test Save

```
isevent(wb, 'Save')
```

MATLAB displays `false`, indicating `Save` is not an event; it is a method.

## More About

- “Exploring Events”
- “Functions for Working with Events”

## See Also

`events (COM)` | `eventlisteners` | `registerevent`

# isfield

Determine whether input is structure array field

## Syntax

```
tf = isfield(S, 'fieldname')
tf = isfield(S, C)
```

## Description

`tf = isfield(S, 'fieldname')` examines structure `S` to see if it includes the field specified by the quoted string `'fieldname'`. Output `tf` is set to logical 1 (`true`) if `S` contains the field, or logical 0 (`false`) if not. If `S` is not a structure array, `isfield` returns `false`.

`tf = isfield(S, C)` examines structure `S` for multiple fieldnames as specified in cell array of strings `C`, and returns an array of logical values to indicate which of these fields are part of the structure. Elements of output array `tf` are set to a logical 1 (`true`) if the corresponding element of `C` holds a fieldname that belongs to structure `S`. Otherwise, logical 0 (`false`) is returned in that element. In other words, if structure `S` contains the field specified in `C{m,n}`, `isfield` returns a logical 1 (`true`) in `tf(m,n)`.

---

**Note** `isfield` returns `false` if the `field` or `fieldnames` input is empty.

---

## Examples

### Example 1 — Single Fieldname Syntax

Given the following MATLAB structure,

```
patient.name = 'John Doe';
patient.billing = 127.00;
patient.test = [79 75 73; 180 178 177.5; 220 210 205];
```

`isfield` identifies `billing` as a field of that structure.

```
isfield(patient,'billing')
ans =
 1
```

## Example 2 — Multiple Fieldname Syntax

Check structure `S` for any of four possible fieldnames. Only the first is found, so the first element of the return value is set to `true`:

```
S = struct('one', 1, 'two', 2);

fields = isfield(S, {'two', 'pi', 'One', 3.14})
fields =
 1 0 0 0
```

## More About

- “dynamic field names”

## See Also

`fieldnames` | `setfield` | `getfield` | `orderfields` | `rmfield` | `struct` | `isstruct` | `iscell` | `isa` | `is*`

# isfinite

Array elements that are finite

## Syntax

```
TF = isfinite(A)
```

## Description

`TF = isfinite(A)` returns an array the same size as `A` containing logical 1 (**true**) where the elements of the array `A` are finite and logical 0 (**false**) where they are infinite or NaN. For a complex number `z`, `isfinite(z)` returns 1 if both the real and imaginary parts of `z` are finite, and 0 if either the real or the imaginary part is infinite or NaN.

For any real `A`, exactly one of the three quantities `isfinite(A)`, `isinf(A)`, and `isnan(A)` is equal to one.

## Examples

```
a = [-2 -1 0 1 2];
isfinite(1./a)
ans =
 1 1 0 1 1
isfinite(0./a)
ans =
 1 1 0 1 1
```

## See Also

`isinf` | `isnan` | `is*`

## isfloat

Determine if input is floating-point array

### Syntax

```
tf = isfloat(A)
```

### Description

`tf = isfloat(A)` returns `true` if `A` is a floating-point array and `false` otherwise. The floating-point types are `single` and `double`, and subclasses of `single` and `double`.

### Examples

These examples show the values `isfloat` returns when passed specific types:

```
% pi returns a floating-point value
isfloat(pi)
ans =
 1

% Complex numbers are floating-point values
isfloat(3+7i)
ans =
 1

% Single-precision numbers are floating-point values
isfloat(realmax('single'))
ans =
 1

% isfloat returns a logical value
isfloat(isfloat(pi))
ans =
 0
```

### See Also

`isa` | `isinteger` | `double` | `single` | `isnumeric`

# isglobal

Determine whether input is global variable

---

**Note** `isglobal` will be removed in a future release. See “Tips” on page 1-3997 for more information.

---

## Syntax

```
tf = isglobal(A)
```

## Description

`tf = isglobal(A)` returns logical 1 (**true**) if `A` has been declared to be a global variable in the context from which `isglobal` is called, and logical 0 (**false**) otherwise.

## More About

### Tips

`isglobal` is most commonly used in conjunction with conditional global declaration. An alternate approach is to use a pair of variables, one local and one declared global.

Instead of using

```
if condition
 global x
end
```

```
x = some_value
```

```
if isglobal(x)
 do_something
end
```

You can use

```
global gx
if condition
 gx = some_value
else
 x = some_value
end
```

```
if condition
 do_something
end
```

If no other workaround is possible, you can replace the command

```
isglobal(variable)
```

with

```
~isempty(whos('global','variable'))
```

## See Also

[global](#) | [isvarname](#) | [isa](#) | [is\\*](#)

# isgraphics

True for valid graphics object handles

## Syntax

```
tf = isgraphics(H)
tf = isgraphics(H,type)
```

## Description

`tf = isgraphics(H)` returns `true` for elements of `H` that are valid graphics object and `false` where elements are not valid graphics objects.

`tf = isgraphics(H,type)` returns `true` for elements of `H` that are valid graphics objects of the type specified by the `type` argument. An object type is the string contained in the object's `Type` property.

## Examples

### Test for Valid Handles

Create a plot and return the handle array. Test array for valid handles

```
H = plot(rand(5));
isgraphics(H)
```

```
ans =
```

```
1
1
1
1
1
```

## Test for Handle Types

Create a plot and return the handle array. Concatenate with other graphics objects and test for handles that are of type line.

```
H = plot(rand(5));
a = [H;gca;gcf];
isgraphics(a,'line')
```

```
ans =
```

```
 1
 1
 1
 1
 1
 0
 0
```

## Input Arguments

**H** — Input variable or expression

graphics object array

Input variable or expression that evaluates to graphics object handles.

**type** — The object type

char

The object type, specified as a quoted string. An object's type is contained in its `Type` property.

## Output Arguments

**tf** — true or false

logical array

Logical array of 1s and 0s indicating the elements of the input array that are valid object handles or valid handles of a specific type if you specify a type argument.

## More About

- “Graphics Object Handles”

## See Also

### Functions

isa | ishghandle

## ishandle

Test for valid graphics or Java object handle

### Syntax

ishandle(H)

### Description

ishandle(H) returns an array whose elements are 1 where the elements of H are graphics or Java object handles, and 0 where they are not.

---

**Note:** You should use the most specific function for your application instead of `ishandle`, as described in the following sections.

---

### MATLAB Object Handles

Use the `isa` function to determine the class of MATLAB objects and use the `isvalid handle` class method to determine the validity of handle objects. See “Testing Handle Validity” for information on testing for MATLAB handle objects.

### Graphics Object Handles

Use `ishghandle` for graphics objects.

### Java Object Handles

Use `isjava` for Java objects.

### See Also

`isa` | `isjava` | `ishghandle`

# ishermitian

Determine if matrix is Hermitian or skew-Hermitian

## Syntax

```
tf = ishermitian(A)
tf = ishermitian(A,skewOption)
```

## Description

`tf = ishermitian(A)` returns logical 1 (true) if square matrix `A` is Hermitian; otherwise, it returns logical 0 (false).

`tf = ishermitian(A,skewOption)` specifies the type of the test. Specify `skewOption` as 'skew' to determine if `A` is skew-Hermitian.

## Examples

### Test if Symmetric Matrix Is Hermitian

Create a 3-by-3 matrix.

```
A = [1 0 1i; 0 1 0; 1i 0 1]
```

A =

```
1.0000 + 0.0000i 0.0000 + 0.0000i 0.0000 + 1.0000i
0.0000 + 0.0000i 1.0000 + 0.0000i 0.0000 + 0.0000i
0.0000 + 1.0000i 0.0000 + 0.0000i 1.0000 + 0.0000i
```

The matrix is symmetric with respect to its real-valued diagonal.

Test whether the matrix is Hermitian.

```
tf = ishermitian(A)
```

```
tf =
```

```
0
```

The result is logical 0 (**false**) because **A** is not Hermitian. In this case, **A** is equal to its transpose, **A.** ', but not its complex conjugate transpose, **A'**.

Change the element in **A(3,1)** to be **-1i**.

```
A(3,1) = -1i;
```

Determine if the modified matrix is Hermitian.

```
tf = ishermitian(A)
```

```
tf =
```

```
1
```

The matrix, **A**, is now Hermitian because it is equal to its complex conjugate transpose, **A'**.

## Test if Matrix Is Skew-Hermitian

Create a 3-by-3 matrix.

```
A = [-1i -1 1-i;1 -1i -1;-1-i 1 -1i]
```

```
A =
```

```
0.0000 - 1.0000i -1.0000 + 0.0000i 1.0000 - 1.0000i
1.0000 + 0.0000i 0.0000 - 1.0000i -1.0000 + 0.0000i
-1.0000 - 1.0000i 1.0000 + 0.0000i 0.0000 - 1.0000i
```

The matrix has pure imaginary numbers on the main diagonal.

Specify **skewOption** as **'skew'** to determine whether the matrix is skew-Hermitian.

```
tf = ishermitian(A,'skew')
```

```
tf =
```

```
1
```

The matrix,  $A$ , is skew-Hermitian since it is equal to the negation of its complex conjugate transpose,  $-A'$ .

## Input Arguments

### **A** — Input matrix

numeric matrix

Input matrix, specified as a numeric matrix. If  $A$  is not square, then `ishermitian` returns logical 0 (**false**).

Data Types: `single` | `double`

Complex Number Support: Yes

### **skewOption** — Test type

'nonskew' (default) | 'skew'

Test type, specified as 'nonskew' (default) or 'skew'. Specify 'skew' to test whether  $A$  is skew-Hermitian. Specifying `ishermitian(A, 'nonskew')` is equivalent to `ishermitian(A)`.

Data Types: `char`

## More About

### Hermitian Matrix

- A square matrix,  $A$ , is Hermitian if it is equal to its complex conjugate transpose,  $A = A'$ .

In terms of the matrix elements, this means that

$$a_{i,j} = \bar{a}_{j,i}.$$

- The entries on the diagonal of a Hermitian matrix are always real. Since real matrices are unaffected by complex conjugation, a real matrix that is symmetric is also Hermitian. For example, the matrix

$$A = \begin{bmatrix} 1 & 0 & 1 \\ 0 & 2 & 0 \\ 1 & 0 & 1 \end{bmatrix}$$

is both symmetric and Hermitian.

- The eigenvalues of a Hermitian matrix are real.

### **Skew-Hermitian Matrix**

- A square matrix,  $A$ , is skew-Hermitian if it is equal to the negation of its complex conjugate transpose,  $A = -A'$ .

In terms of the matrix elements, this means that

$$a_{i,j} = -\bar{a}_{j,i}.$$

- The entries on the diagonal of a skew-Hermitian matrix are always pure imaginary or zero. Since real matrices are unaffected by complex conjugation, a real matrix that is skew-symmetric is also skew-Hermitian. For example, the matrix

$$A = \begin{bmatrix} 0 & -1 \\ 1 & 0 \end{bmatrix}$$

is both skew-Hermitian and skew-symmetric.

- The eigenvalues of a skew-Hermitian matrix are purely imaginary or zero.

### **See Also**

`ctranspose` | `eig` | `isreal` | `issymmetric` | `transpose`

# ishghandle

True for graphics object handles

## Syntax

```
ishghandle(h)
```

## Description

`ishghandle(h)` returns an array that contains 1's where the elements of `h` are handles to existing graphic objects and 0's where they are not. Differs from `ishandle` in that Simulink objects handles return false.

## Examples

Create a plot and find the valid handles:

```
x = [1:10];
y = [1:10];
p = plot(x,y);
ishghandle(p)
```

```
ans =
```

```
1
```

## More About

- “Graphics Object Handles”

## See Also

`isa` | `isgraphics` | `gca`

## ishold

Current hold state

### Syntax

```
tf = ishold
```

### Description

`tf = ishold` returns 1 if `hold` is on, and 0 if it is off. When `hold` is on, the current plot and most axis properties are held so that subsequent graphing commands add to the existing graph.

A state of `hold` on implies that both figure and axes `NextPlot` properties are set to `add`.

### More About

- “Control Graph Display”

### See Also

`hold` | `newplot`

# isinf

Array elements that are infinite

## Syntax

```
TF = isinf(A)
```

## Description

`TF = isinf(A)` returns an array the same size as `A` containing logical 1 (**true**) where the elements of `A` are `+Inf` or `-Inf` and logical 0 (**false**) where they are not. For a complex number `z`, `isinf(z)` returns 1 if either the real or imaginary part of `z` is infinite, and 0 if both the real and imaginary parts are finite or NaN.

For any real `A`, exactly one of the three quantities `isfinite(A)`, `isinf(A)`, and `isnan(A)` is equal to one.

## Examples

```
a = [-2 -1 0 1 2];
```

```
isinf(1./a)
```

```
ans =
 0 0 1 0 0
```

```
isinf(0./a)
```

```
ans =
 0 0 0 0 0
```

## See Also

`isfinite` | `isnan` | `is*`

## **isinteger**

Determine if input is integer array

### **Syntax**

```
tf = isinteger(A)
```

### **Description**

`tf = isinteger(A)` returns `true` if the array `A` is an integer type and `false` otherwise.

An integer array is any of the following integer types and any subclasses of those types:

### **MATLAB Integer Types**

|                     |                               |
|---------------------|-------------------------------|
| <code>int8</code>   | 8-bit signed integer array    |
| <code>uint8</code>  | 8-bit unsigned integer array  |
| <code>int16</code>  | 16-bit signed integer array   |
| <code>uint16</code> | 16-bit unsigned integer array |
| <code>int32</code>  | 32-bit signed integer array   |
| <code>uint32</code> | 32-bit unsigned integer array |
| <code>int64</code>  | 64-bit signed integer array   |
| <code>uint64</code> | 64-bit unsigned integer array |

### **Examples**

These examples show the values `isinteger` returns when passed specific types:

```
% uint8 is one of the integer types
isinteger(uint8(1:255))
```

```
ans =
 1
% pi returns a double-precision value
isinteger(pi)
ans =
 0
% Constants are double-precision by default
isinteger(3)
ans =
 0
% isinteger returns a logical value
isinteger(isinteger(uint8(3)))
ans =
 0
```

## See Also

isa | isnumeric | isfloat

## isinterface

Determine whether input is COM interface

### Syntax

```
tf = isinterface(h)
```

### Description

`tf = isinterface(h)` returns logical 1 (**true**) if handle `h` is a COM interface. Otherwise, returns logical 0 (**false**).

COM functions are available on Microsoft Windows systems only.

### Examples

Test an instance of a Microsoft Excel application.

```
h = actxserver('Excel.Application');
isinterface(h)
```

MATLAB displays **false**, indicating object `h` is not an interface.

Test a `workbooks` object

```
w = get(h, 'workbooks');
isinterface(w)
```

MATLAB displays **true**, indicating object `w` is an interface.

### More About

- “Exploring Interfaces”

### See Also

`iscom` | `interfaces`

## isjava

Determine if input is Java object

### Syntax

```
tf = isjava(A)
```

### Description

`tf = isjava(A)` returns logical 1 (true) if object A is a Java object. Otherwise, it returns logical 0 (false).

### Examples

#### Test if `java.util.Date` Is Java Object

Create an instance of the Java Date class.

```
myDate = java.util.Date;
isjava(myDate)
```

```
ans =
```

```
 1
```

`myDate` is a Java object.

However, `myDate` is not a MATLAB object.

```
isobject(myDate)
```

```
ans =
```

```
 0
```

### See Also

`is*` | `isa` | `isobject` | `javaArray` | `javaMethod` | `javaObject`

## isKey

**Class:** containers.Map

**Package:** containers

Determine if `containers.Map` object contains key

## Syntax

```
tf = isKey(mapObj, keySet)
```

## Description

`tf = isKey(mapObj, keySet)` looks for the specified keys in `mapObj`, and returns logical `true` (1) for the keys that it finds, and logical `false` (0) for those it does not. `keySet` is a scalar key or a cell array of keys.

## Input Arguments

**mapObj**

Object of class `containers.Map`.

**keySet**

Scalar value, string, or cell array that specifies keys to find in `mapObj`.

## Output Arguments

**tf**

Array of logical values. If `keySet` is a scalar or a string, `tf` is a scalar. Otherwise, `tf` has the same size and dimensions as `keySet`.

## Examples

### Find Keys in a Map

Construct a map that contains rainfall data for several months:

```
months = {'Jan', 'Feb', 'Mar', 'Apr'};
rainfall = [327.2, 368.2, 197.6, 178.4];
mapObj = containers.Map(months,rainfall);
```

Determine if keys Apr, May, and Jun are in the map:

```
keySet = {'Apr','May','Jun'};
tf = isKey(mapObj,keySet)
```

This code returns 1-by-3 vector `tf`:

```
tf =
 1 0 0
```

### Find a Single Key

Determine if `mapObj` from the previous example contains key `Feb`:

```
keySet = 'Feb';
tf = isKey(mapObj,keySet)
```

This code returns scalar `tf`:

```
tf =
 1
```

### See Also

[keys](#) | [values](#) | [containers.Map](#) | [remove](#)

## iskeyword

Determine whether input is MATLAB keyword

### Syntax

```
tf = iskeyword('str')
iskeyword str
iskeyword
```

### Description

`tf = iskeyword('str')` returns logical 1 (true) if the string `str` is a keyword in the MATLAB language and logical 0 (false) otherwise. MATLAB keywords cannot be used as variable names.

`iskeyword str` uses the MATLAB command format.

`iskeyword` returns a list of all MATLAB keywords.

### Examples

To test if the word `while` is a MATLAB keyword,

```
iskeyword while
ans =
 1
```

To obtain a list of all MATLAB keywords,

```
iskeyword
 'break'
 'case'
 'catch'
 'classdef'
 'continue'
 'else'
 'elseif'
```

```
'end'
'for'
'function'
'global'
'if'
'otherwise'
'parfor'
'persistent'
'return'
'spmd'
'switch'
'try'
'while'
```

**See Also**

[isvarname](#) | [matlab.lang.makeValidName](#) | [matlab.lang.makeUniqueStrings](#) | [is\\*](#)

## isletter

Array elements that are alphabetic letters

## Syntax

```
tf = isletter('str')
```

## Description

`tf = isletter('str')` returns an array the same size as `str` containing logical 1 (true) where the elements of `str` are letters of the alphabet and logical 0 (false) where they are not.

## Examples

Find the letters in character array `s`.

```
s = 'A1,B2,C3';
```

```
isletter(s)
```

```
ans =
```

```
 1 0 0 1 0 0 1 0
```

## See Also

`ischar` | `isspace` | `isstrprop` | `iscellstr` | `isnumeric` | `char` | `strings` | `isa` | `is*`

# islogical

Determine if input is logical array

## Syntax

```
tf = islogical(A)
```

## Description

`tf = islogical(A)` returns `true` if `A` is a logical array and `false` otherwise. `islogical` also returns `true` if `A` is an instance of a class that is derived from the logical class.

## Examples

These examples show the values `islogical` returns when passed specific types:

```
% Relational operators return logical values
```

```
islogical(5<7)
ans =
 1
```

```
% true and false return logical values
```

```
islogical(true) & islogical(false)
ans =
 1
```

```
% Constants are double-precision by default
```

```
islogical(1)
ans =
 0
```

```
% logical creates logical values
```

```
islogical(logical(1))
ans =
 1
```

## **More About**

- “Determine if Arrays Are Logical”

## **See Also**

`is*` | `isa` | `logical`

## ismac

Determine if version is for Mac OS X platform

### Syntax

```
tf = ismac
```

### Description

`tf = ismac` returns logical 1 (**true**) if the version of MATLAB software is for the Apple Mac OS X platform. Otherwise, it returns logical 0 (**false**).

### More About

#### Tips

- The `isunix` function also determines if version is for Mac OS X platforms.

#### See Also

`computer` | `is*` | `ispc` | `isstudent` | `isunix`

## **ismatrix**

Determine whether input is matrix

### **Syntax**

```
ismatrix(V)
```

### **Description**

`ismatrix(V)` returns logical 1 (**true**) if `size(V)` returns `[m n]` with nonnegative integer values `m` and `n`, and logical 0 (**false**) otherwise.

### **Examples**

Create three vectors:

```
V1 = rand(5,1);
V2 = rand(5,1);
V3 = rand(5,1);
```

Concatenate the vectors and check that the result is a matrix. `ismatrix` returns 1:

```
M = cat(2,V1,V2,V3);
ismatrix(M)
ans =
 1
```

### **See Also**

`iscolumn` | `isrow` | `isscalar` | `isvector`

# ismember

Array elements that are members of set array

## Syntax

```
Lia = ismember(A,B)
Lia = ismember(A,B,'rows')
[Lia,Locb] = ismember(A,B)
[Lia,Locb] = ismember(A,B,'rows')

[Lia,Locb] = ismember(____, 'legacy')
```

## Description

`Lia = ismember(A,B)` returns an array containing **1 (true)** where the data in **A** is found in **B**. Elsewhere, it returns **0 (false)**.

- If **A** and **B** are numeric arrays, logical arrays, character arrays, categorical arrays, datetime arrays, duration arrays, or cell arrays of strings, then `ismember` returns a logical value for each element of **A**. The output, **Lia**, is an array of the same size as **A**.
- If **A** and **B** are tables, then `ismember` returns a logical value for each row of **A**. The output, **Lia**, is a column vector with the same number of rows as **A**.

`Lia = ismember(A,B,'rows')` treats each row of **A** and each row of **B** as single entities and returns a column vector containing **1 (true)** where the rows of **A** are also rows of **B**. Elsewhere, it returns **0 (false)**.

**A** and **B** must have the same number of columns when you use the `'rows'` option. Furthermore, the `'rows'` option does not support cell arrays, unless one of the inputs is either a categorical array or a datetime array.

`[Lia,Locb] = ismember(A,B)` also returns an array, **Locb**.

- If **A** and **B** are numeric arrays, logical arrays, character arrays, categorical arrays, datetime arrays, duration arrays, or cell arrays of strings, then **Locb** contains the lowest index in **B** for each value in **A** that is a member of **B**. The output array, **Locb**, contains **0** wherever **A** is not a member of **B**.

- If A and B are tables, then `Locb` contains the lowest index in B for each row in A that is also a row in B. The output vector, `Locb`, contains 0 whenever A is not a row of B.

`[Lia,Locb] = ismember(A,B,'rows')` also returns a column vector, `Locb`, containing the lowest index in B for each row in A that is also a row in B. The output vector, `Locb`, contains 0 wherever A is not a row of B.

`[Lia,Locb] = ismember( ____, 'legacy')` preserves the behavior of the `ismember` function from R2012b and prior releases using any of the input arguments in previous syntaxes.

The 'legacy' option does not support categorical arrays, tables, datetime arrays, or duration arrays.

## Examples

### Values That Are Members of Set

Define two vectors with values in common.

```
A = [5 3 4 2]; B = [2 4 4 4 6 8];
```

Determine which elements of A are also in B.

```
Lia = ismember(A,B)
```

```
Lia =
```

```
0 0 1 1
```

A(3) and A(4) are found in B.

### Table Rows Found in Another Table

Define two tables with rows in common.

```
A = table([1:5]', ['A'; 'B'; 'C'; 'D'; 'E'], logical([0;1;0;1;0]))
B = table([1:2:10]', ['A'; 'C'; 'E'; 'G'; 'I'], logical(zeros(5,1)))
```

```
A =
```

```
Var1 Var2 Var3
---- ---- -----
```

```

1 A false
2 B true
3 C false
4 D true
5 E false

```

B =

```

Var1 Var2 Var3
---- ---- -----
1 A false
3 C false
5 E false
7 G false
9 I false

```

Determine which rows of A are also in B.

```
Lia = ismember(A,B)
```

Lia =

```

1
0
1
0
1

```

A(1,:), A(3,:), and A(5,:) are found in B.

### Members of Set and Indices to Values

Define two vectors with values in common.

```
A = [5 3 4 2]; B = [2 4 4 4 6 8];
```

Determine which elements of A are also in B as well as their corresponding locations in B.

```
[Lia,Locb] = ismember(A,B)
```

Lia =

```

0 0 1 1

```

Locb =

0 0 2 1

The lowest index to A(3) is B(2).

A(4) is found in B(1).

## Rows of Another Table and Their Location

Define a table, A, of gender, age, and height for five people.

```
A = table(['M'; 'M'; 'F'; 'M'; 'F'], [27; 52; 31; 46; 35], [74; 68; 64; 61; 64], ...
'VariableNames', {'Gender' 'Age' 'Height'}, ...
'RowNames', {'Ted' 'Fred' 'Betty' 'Bob' 'Judy'})
```

A =

|       | Gender | Age | Height |
|-------|--------|-----|--------|
|       | -----  | --- | -----  |
| Ted   | M      | 27  | 74     |
| Fred  | M      | 52  | 68     |
| Betty | F      | 31  | 64     |
| Bob   | M      | 46  | 61     |
| Judy  | F      | 35  | 64     |

Define a table, B, with rows in common with A.

```
B = table(['M'; 'F'; 'F'; 'F'], [47; 31; 35; 23], [68; 64; 62; 58], ...
'VariableNames', {'Gender' 'Age' 'Height'}, ...
'RowNames', {'Joe' 'Meg' 'Beth' 'Amy'})
```

B =

|      | Gender | Age | Height |
|------|--------|-----|--------|
|      | -----  | --- | -----  |
| Meg  | F      | 31  | 64     |
| Joe  | M      | 47  | 68     |
| Beth | F      | 35  | 62     |
| Amy  | F      | 23  | 58     |

Determine which rows of A are also in B, as well as their corresponding locations in B.

```
[Lia, Locb] = ismember(A, B)
```

Lia =

```

0
0
1
0
0

```

```
Locb =
```

```

0
0
2
0
0

```

Two rows that have the same values, but different names, are considered equal. The same data for **Betty** is found in `B(2, :)`, which corresponds to **Meg**.

### Rows That Belong to a Set

Define two matrices with a row in common.

```

A = [1 3 5 6; 2 4 6 8];
B = [2 4 6 8; 1 3 5 7; 2 4 6 8];

```

Determine which rows of **A** are also in **B** as well as their corresponding locations in **B**.

```
[Lia, Locb] = ismember(A,B, 'rows')
```

```
Lia =
```

```

0
1

```

```
Locb =
```

```

0
1

```

The lowest index to `A(2, :)` is `B(1, :)`.

### Members of Set Containing NaN Values

Define two vectors containing NaN.

```
A = [5 NaN NaN]; B = [5 NaN NaN];
```

Determine which elements of A are also in B as well as their corresponding locations in B.

```
[Lia,Locb] = ismember(A,B)
```

```
Lia =
```

```
 1 0 0
```

```
Locb =
```

```
 1 0 0
```

ismember treats NaN values as distinct.

## Cell Array of Strings with Trailing White Space

Create a cell array of strings, A.

```
A = {'dog', 'cat', 'fish', 'horse'};
```

Create a cell array of strings, B, where some of the strings have trailing white space.

```
B = {'dog ', 'cat', 'fish ', 'horse'};
```

Determine which strings of A can be found in B.

```
[Lia,Locb] = ismember(A,B)
```

```
Lia =
```

```
 0 1 0 1
```

```
Locb =
```

```
 0 2 0 4
```

ismember treats trailing white space in cell arrays of strings as distinct characters.

## Members of Char and Cell Array of Strings

Create a character array, A.

```
A = ['cat'; 'dog'; 'fox'; 'pig'];
```

Create a cell array of strings, B.

```
B = {'dog', 'cat', 'fish', 'horse'};
```

Determine which strings of A can be found in B.

```
[Lia,Locb] = ismember(A,B)
```

```
Lia =
```

```
1
1
0
0
```

```
Locb =
```

```
2
1
0
0
```

### Preserve Legacy Behavior of ismember

Use the 'legacy' flag to preserve the behavior of `ismember` from R2012b and prior releases in your code.

Find the members of B with the current behavior.

```
A = [5 3 4 2]; B = [2 4 4 4 6 8];
```

```
[Lia1,Locb1] = ismember(A,B)
```

```
Lia1 =
```

```
0 0 1 1
```

```
Locb1 =
```

```
0 0 2 1
```

Find the members of B, and preserve the legacy behavior.

```
[Lia2,Locb2] = ismember(A,B, 'legacy')
```

```
Lia2 =
 0 0 1 1
Locb2 =
 0 0 4 1
```

## Input Arguments

### **A** — Query array

numeric array | logical array | character array | categorical array | datetime arrays | duration arrays | cell array of strings | table

Query array, specified as a numeric array, logical array, character array, categorical array, datetime array, duration array, cell array of strings, or a table.

**A** must belong to the same class as **B** with the following exceptions:

- `logical`, `char`, and all numeric classes can combine with `double` arrays.
- Cell arrays of strings can combine with `char` arrays.
- Categorical arrays can combine with cell arrays of strings or single strings.
- Datetime arrays can combine with cell arrays of date strings or single date strings.

If **A** and **B** are both ordinal categorical arrays, they must have the same sets of categories, including their order. If neither **A** nor **B** are ordinal, they need not have the same sets of categories, and the comparison is performed using the category names.

If you specify the `'rows'` option, **A** must have the same number of columns as **B**.

If **A** is a table, it must have the same variable names as **B**. Conversely, the row names do not matter. Two rows that have the same values, but different names, are considered equal.

If **A** and **B** are datetime arrays, they must be consistent with each other in whether they specify a time zone.

Furthermore, **A** can be an object with the following class methods:

- `sort` (or `sortrows` for the `'rows'` option)

- `eq`
- `ne`

The object class methods must be consistent with each other. These objects include heterogeneous arrays derived from the same root class.

### **B – Set array**

numeric array | logical array | character array | categorical array | datetime arrays | duration arrays | cell array of strings | table

Set array, specified as a numeric array, logical array, character array, categorical array, datetime array, duration array, cell array of strings, or a table.

**B** must belong to the same class as **A** with the following exceptions:

- `logical`, `char`, and all numeric classes can combine with `double` arrays.
- Cell arrays of strings can combine with `char` arrays.
- Categorical arrays can combine with cell arrays of strings or single strings.
- Datetime arrays can combine with cell arrays of date strings or single date strings.

If **A** and **B** are both ordinal categorical arrays, they must have the same sets of categories, including their order. If neither **A** nor **B** are ordinal, they need not have the same sets of categories, and the comparison is performed using the category names.

If you specify the `'rows'` option, **B** must have the same number of columns as **A**.

If **B** is a table, it must have the same variable names as **A**. Conversely, the row names do not matter. Two rows that have the same values, but different names, are considered equal.

If **A** and **B** are datetime arrays, they must be consistent with each other in whether they specify a time zone.

Furthermore, **B** can be an object with the following class methods:

- `sort` (or `sortrows` for the `'rows'` option)
- `eq`
- `ne`

The object class methods must be consistent with each other. These objects include heterogeneous arrays derived from the same root class.

## Output Arguments

### **Lia** — Logical index to A

vector | matrix | N-D array

Logical index to A, returned as a vector, matrix or N-D array containing 1 (true) wherever the values (or rows) in A are members of B. Elsewhere, it returns 0 (false).

Lia is an array of the same size as A, unless you specify the 'rows' flag.

If the 'rows' flag is specified or if A is a table, Lia is a column vector with the same number of rows as A.

### **Locb** — Locations in B

vector | matrix | N-D array

Locations in B, returned as a vector, matrix, or N-D array. If the 'legacy' flag is not specified, Locb contains the lowest indices to the values (or rows) in B that are found in A. Locb contains 0 wherever A is not a member of B.

Locb is an array of the same size as A unless you specify the 'rows' flag.

If the 'rows' flag is specified or if A is a table, Locb is a column vector with the same number of rows as A.

## More About

### Tips

- To find the rows from table A that are found in B with respect to a subset of variables, you can use column subscripting. For example, you can use `ismember(A(:,vars),B(:,vars))`, where *vars* is a positive integer, a vector of positive integers, a variable name, a cell array of variable names, or a logical vector.

# ismethod

Determine if method of object

## Syntax

```
tf = ismethod(obj, 'methodName')
```

## Description

`tf = ismethod(obj, 'methodName')` returns logical 1 (`true`) if the specified `methodName` is a public method of object `obj`. Otherwise, returns logical 0 (`false`).

## Examples

Determine if objects support equality testing:

```
if ismethod(obj1, 'eq') && ismethod(obj2, 'eq')
 tf = obj1 == obj2;
end
```

## See Also

`methods` | `class` | `isprop` | `isobject`

## Tutorials

- “Methods”

## ismethod (COM)

Determine whether input is COM object method

### Syntax

```
tf = ismethod(h, 'methodname')
```

### Description

`tf = ismethod(h, 'methodname')` returns logical 1 (`true`) if the specified `methodname` is a method you can call on COM object `h`. Otherwise, returns logical 0 (`false`).

COM functions are available on Microsoft Windows systems only.

### Examples

Test members of an instance of a Microsoft Excel application.

```
h = actxserver('Excel.Application');
ismethod(h, 'SaveWorkspace')
```

MATLAB returns `true`, `SaveWorkspace` is a method.

Try the same test on `UsableWidth`.

```
ismethod(h, 'UsableWidth')
```

MATLAB returns `false`, `UsableWidth` is not a method; it is a property.

# ismissing

Find table elements with missing values

## Syntax

```
TF = ismissing(A)
TF = ismissing(A,id)
```

## Description

`TF = ismissing(A)` returns a logical array, `TF`, that indicates which elements in the table `A` contain a missing value. The size of `TF` is the same as the size of `A`.

Indicators for missing data depend on the data type:

- NaN for numeric arrays
- `<undefined>` for categorical arrays
- empty string, `{ ' ' }`, for cell arrays of strings
- blank string, `[ ' ' ]`, for character arrays

`ismissing` ignores other data types.

`TF = ismissing(A,id)` treats the values in `id` as missing value indicators. You must include NaN (for floating-point variables), the empty string (for variables that are cell arrays of strings or character arrays), or the string '`<undefined>`' (for categorical variables) to have `ismissing` recognize them as missing value indicators.

## Examples

### Missing Values in Table with Various Data Types

Create a table with variables of different data types where each contains a missing value.

```
dblVar = [NaN;3;5;7;9];
singleVar = single([1;NaN;5;7;9]);
cellstrVar = {'one';'three';'';'seven';'nine'};
```

```
charVar = ['A';'C';'E';' ';'I'];
categoryVar = categorical({'red';'yellow';'blue';'violet';''});
```

```
A = table(dblVar,singleVar,cellstrVar,charVar,categoryVar)
```

```
A =
```

| <u>dblVar</u> | <u>singleVar</u> | <u>cellstrVar</u> | <u>charVar</u> | <u>categoryVar</u> |
|---------------|------------------|-------------------|----------------|--------------------|
| NaN           | 1                | 'one'             | A              | red                |
| 3             | NaN              | 'three'           | C              | yellow             |
| 5             | 5                | ' '               | E              | blue               |
| 7             | 7                | 'seven'           |                | violet             |
| 9             | 9                | 'nine'            | I              | <undefined>        |

Find the table elements with missing values.

```
TF = ismissing(A)
```

```
TF =
```

|   |   |   |   |   |
|---|---|---|---|---|
| 1 | 0 | 0 | 0 | 0 |
| 0 | 1 | 0 | 0 | 0 |
| 0 | 0 | 1 | 0 | 0 |
| 0 | 0 | 0 | 1 | 0 |
| 0 | 0 | 0 | 0 | 1 |

The size of TF is the same as the size of A.

### Specify Indicators for Missing Values in Table

Create a table where 'NA', ''-99, NaN, and Inf represent missing values.

```
dblVar = [NaN;3;Inf;7;9];
int8Var = int8([1;3;5;7;-99]);
cellstrVar = {'one';'three';'';'NA';'nine'};
charVar = ['A';'C';'E';' ';'I'];
```

```
A = table(dblVar,int8Var,cellstrVar,charVar)
```

```
A =
```

| <u>dblVar</u> | <u>int8Var</u> | <u>cellstrVar</u> | <u>charVar</u> |
|---------------|----------------|-------------------|----------------|
|---------------|----------------|-------------------|----------------|

|     |     |         |   |
|-----|-----|---------|---|
| NaN | 1   | 'one'   | A |
| 3   | 3   | 'three' | C |
| Inf | 5   | ''      | E |
| 7   | 7   | 'NA'    |   |
| 9   | -99 | 'nine'  | I |

Find the missing values in the table A.

```
id = {'NA' '' -99 NaN Inf};
TF = ismissing(A,id)
```

TF =

|   |   |   |   |
|---|---|---|---|
| 1 | 0 | 0 | 0 |
| 0 | 0 | 0 | 0 |
| 1 | 0 | 1 | 0 |
| 0 | 0 | 1 | 1 |
| 0 | 1 | 0 | 0 |

`ismissing` recognizes data in the each variable of the table, A as missing values. `ismissing` ignores trailing white space in character arrays. Therefore, since the empty string, '', is specified as a missing value indicator, `ismissing` identifies the empty string in the cell arrays of strings, A.`cellstrVar`, as well as the blank space in character array, A.`charVar` as missing values.

## Input Arguments

### A — Input table

table

Input table, specified as a table.

### id — Missing value indicators

numeric vector | string | cell array containing numeric values and strings

Missing value indicators, specified as a numeric vector, string, or cell array containing numeric values and strings. Use strings to identify categories in categorical variables that you want to treat as missing values.

You must include NaN (for floating-point variables), the empty string (for variables that are cell arrays of strings or character arrays), or the string '<undefined>' (for categorical variables) to have `ismissing` recognize them as missing value indicators.

Example: `TF = ismissing(A, -99)` recognizes only `-99` as a missing value.

Data Types: `double` | `char` | `cell`

## More About

### Tips

- You can use `A(~any(TF,2),:)` to return only complete rows from `A` and `A(:,~any(TF,1))` to return only the variables from `A` with no missing values.
- Integer variables cannot store `NaN`; therefore, you must use a special integer value (otherwise unused) to indicate missing integer data. For example, `-99`.

### Algorithms

`ismissing` treats leading and trailing white space differently for cell arrays of strings, character arrays, and categorical arrays.

- For cell arrays of strings, `ismissing` does not ignore white space. All strings must match exactly.
- For character arrays, `ismissing` ignores trailing white space. Therefore, when you specify the empty string, `' '`, as a missing value indicator, `ismissing` identifies the empty string in cell arrays of strings, `' '`, and the blank space in character arrays, `' '`, as missing values.
- For categorical arrays, `ismissing` ignores leading and trailing white space.

### See Also

`isempty` | `isnan` | `isundefined` | `standardizeMissing` | `table`

## isnan

Array elements that are NaN

### Syntax

```
TF = isnan(A)
```

### Description

`TF = isnan(A)` returns an array the same size as `A` containing logical 1 (**true**) where the elements of `A` are NaNs and logical 0 (**false**) where they are not. For a complex number `z`, `isnan(z)` returns 1 if either the real or imaginary part of `z` is NaN, and 0 if both the real and imaginary parts are finite or `Inf`.

For any real `A`, exactly one of the three quantities `isfinite(A)`, `isinf(A)`, and `isnan(A)` is equal to one.

### Examples

```
A = [-2 -1 0 1 2];
```

```
isnan(1./A)
ans =
 0 0 0 0 0
```

```
isnan(0./A)
ans =
 0 0 1 0 0
```

### See Also

```
isfinite | nan | isinf | is*
```

## isnat

Determine NaT (Not-a-Time) elements

## Syntax

```
tf = isnat(A)
```

## Description

`tf = isnat(A)` returns an array the same size as the datetime array, `A`, containing logical 1 (`true`) where the elements of `A` are Not-a-Time (NaTs) and logical 0 (`false`) where they are not. NaT represents a datetime that is undefined.

## Examples

### Determine If Array Elements are NaT

Create a datetime array from numeric values containing NaN.

```
d = datetime(2014,[1 2 NaN 4],1)
```

```
d =
```

```
 01-Jan-2014 01-Feb-2014 NaT 01-Apr-2014
```

Determine if any elements of `d` are NaT (Not-a-Time).

```
isnat(d)
```

```
ans =
```

```
 0 0 1 0
```

## Input Arguments

**A** — Input array

datetime array

Input array, specified as a datetime array.

**See Also**

isfinite | isinf

## **isnumeric**

Determine if input is numeric array

### **Syntax**

```
tf = isnumeric(A)
```

### **Description**

`tf = isnumeric(A)` returns `true` if `A` is a numeric array and `false` otherwise.

A numeric array is any of the following numeric types and any subclasses of those types:

### **MATLAB Numeric Types**

|                     |                                       |
|---------------------|---------------------------------------|
| <code>single</code> | Single-precision floating-point array |
| <code>double</code> | Double-precision floating-point array |
| <code>int8</code>   | 8-bit signed integer array            |
| <code>uint8</code>  | 8-bit unsigned integer array          |
| <code>int16</code>  | 16-bit signed integer array           |
| <code>uint16</code> | 16-bit unsigned integer array         |
| <code>int32</code>  | 32-bit signed integer array           |
| <code>uint32</code> | 32-bit unsigned integer array         |
| <code>int64</code>  | 64-bit signed integer array           |
| <code>uint64</code> | 64-bit unsigned integer array         |

### **Examples**

These examples show the values `isnumeric` returns when passed specific types:

```
% pi returns a numeric value
```

```
isnumeric(pi)
ans =
 1
% Complex numbers are numeric
isnumeric(3+7i)
ans =
 1
% Integers are numeric
isnumeric(uint8(1:255))
ans =
 1
% isnumeric returns a logical value
isnumeric(isnumeric(pi))
ans =
 0
```

## See Also

isfloat | isnan | isreal | isinteger | isprime | isfinite | isinf | isa | is\*

## **isobject**

Determine if input is MATLAB object

### **Syntax**

```
tf = isobject(A)
```

### **Description**

`tf = isobject(A)` returns `true` if `A` is an object of a MATLAB class. Otherwise, it returns `false`.

Handle Graphics objects return `false`. Use `ishandle` to test for Handle Graphics objects.

Instances of MATLAB fundamental classes return `false`. Use `isa` to test for any of these types. See “Fundamental MATLAB Classes” for more on these classes.

### **Examples**

These examples show the values `isobject` returns when passed specific types:

Define the following MATLAB class:

```
classdef button < handle
 properties
 UiHandle
 end
 methods
 function obj = button(pos)
 obj.UiHandle = uicontrol('Position',pos,...
 'Style','pushbutton');
 end
 end
end
```

Determine which objects are MATLAB objects. For example:

```
h = button([20 20 60 60]);
isobject(h)
ans =
 1
isobject(h.UiHandle)
ans =
 0
```

Use `isjava` to test for Java objects in MATLAB, where it returns `false` for MATLAB objects:

```
isjava(h)
ans =
 0
```

Create an object that is a MATLAB numeric type:

```
a = pi;
isa(a, 'double')
ans =
 1
isobject(a)
ans =
 0
```

## isocaps

Compute isosurface end-cap geometry

### Syntax

```
fvc = isocaps(X,Y,Z,V,isovalue)
fvc = isocaps(V,isovalue)
fvc = isocaps(...,'enclose')
fvc = isocaps(...,'whichplane')
[f,v,c] = isocaps(...)
isocaps(...)
```

### Description

`fvc = isocaps(X,Y,Z,V,isovalue)` computes isosurface end-cap geometry for the volume data `V` at isosurface value `isovalue`. The arrays `X`, `Y`, and `Z` define the coordinates for the volume `V`.

The struct `fvc` contains the face, vertex, and color data for the end-caps and can be passed directly to the `patch` command.

`fvc = isocaps(V,isovalue)` assumes the arrays `X`, `Y`, and `Z` are defined as `[X,Y,Z] = meshgrid(1:n,1:m,1:p)` where `[m,n,p] = size(V)`.

`fvc = isocaps(...,'enclose')` specifies whether the end-caps enclose data values above or below the value specified in `isovalue`. The string `enclose` can be either `above` (default) or `below`.

`fvc = isocaps(...,'whichplane')` specifies on which planes to draw the end-caps. Possible values for `whichplane` are `all` (default), `xmin`, `xmax`, `ymin`, `ymax`, `zmin`, or `zmax`.

`[f,v,c] = isocaps(...)` returns the face, vertex, and color data for the end-caps in three arrays instead of the struct `fvc`.

`isocaps(...)` without output arguments draws a patch with the computed faces, vertices, and colors.

## Examples

### Compute Isosurface End-Cap Geometry

This example uses a data set that is a collection of MRI slices of a human skull. It illustrates the use of `isocaps` to draw the end-caps on this cutaway volume.

The red isosurface shows the outline of the volume (skull) and the end-caps show what is inside of the volume.

The patch created from the end-cap data (`p2`) uses interpolated face coloring, which means the gray colormap and the light sources determine how it is colored. The isosurface patch (`p1`) used a flat red face color, which is affected by the lights, but does not use the colormap.

```
load mri
D = squeeze(D);
D(:,1:60,:) = [];
p1 = patch(isosurface(D, 5), 'FaceColor', 'red', ...
 'EdgeColor', 'none');
p2 = patch(isocaps(D, 5), 'FaceColor', 'interp', ...
 'EdgeColor', 'none');
view(3)
axis tight
daspect([1,1,.4])
colormap(gray(100))
camlight left
camlight
lighting gouraud
isonormals(D,p1)
```

# isocolors

Calculate isosurface and patch colors

## Syntax

```
nc = isocolors(X,Y,Z,C,vertices)
nc = isocolors(X,Y,Z,R,G,B,vertices)
nc = isocolors(C,vertices)
nc = isocolors(R,G,B,vertices)
nc = isocolors(...,PatchHandle)
isocolors(...,PatchHandle)
```

## Description

`nc = isocolors(X,Y,Z,C,vertices)` computes the colors of isosurface (patch object) `vertices` (`vertices`) using color values `C`. Arrays `X`, `Y`, `Z` define the coordinates for the color data in `C` and must be monotonic vectors that represent a Cartesian, axis-aligned grid (as if produced by `meshgrid`). The colors are returned in `nc`. `C` must be 3-D (“index colors”).

`nc = isocolors(X,Y,Z,R,G,B,vertices)` uses `R`, `G`, `B` as the red, green, and blue color arrays (“true color”).

`nc = isocolors(C,vertices)`, and `nc = isocolors(R,G,B,vertices)` assume `X`, `Y`, and `Z` are determined by the expression

```
[X Y Z] = meshgrid(1:n,1:m,1:p)
```

where `[m n p] = size(C)`.

`nc = isocolors(...,PatchHandle)` uses the vertices from the patch identified by `PatchHandle`.

`isocolors(...,PatchHandle)` sets the `FaceVertexCData` property of the patch specified by `PatchHandle` to the computed colors.

## Examples

### Indexed Color Data

This example displays an isosurface and colors it with random data using indexed color.

```
[x,y,z] = meshgrid(1:20,1:20,1:20);
data = sqrt(x.^2 + y.^2 + z.^2);
cdata = smooth3(rand(size(data)), 'box',7);
p = patch(isosurface(x,y,z,data,10));
isonormals(x,y,z,data,p)
isocolors(x,y,z,cdata,p)
p.FaceColor = 'interp';
p.EdgeColor = 'none';
view(150,30)
daspect([1 1 1])
axis tight
camlight
lighting gouraud
```

### True Color Data

This example displays an isosurface and colors it with true color (RGB) data.

```
[x,y,z] = meshgrid(1:20,1:20,1:20);
data = sqrt(x.^2 + y.^2 + z.^2);
p = patch(isosurface(x,y,z,data,20));
isonormals(x,y,z,data,p)
[r,g,b] = meshgrid(20:-1:1,1:20,1:20);
isocolors(x,y,z,r/20,g/20,b/20,p)
p.FaceColor = 'interp';
p.EdgeColor = 'none';
view(150,30)
daspect([1 1 1])
camlight
```

lighting gouraud

### Modified True Color Data

This example uses `isosurface` to calculate the true color data using the isosurface's (patch object's) vertices, but then returns the color data in a variable (`c`) in order to modify the values. It then explicitly sets the isosurface's `FaceVertexCData` to the new data (`1 - c`).

```
[x,y,z] = meshgrid(1:20,1:20,1:20);
data = sqrt(x.^2 + y.^2 + z.^2);
p = patch(isosurface(data,20));
isonormals(data,p)
```

```
[r,g,b] = meshgrid(20:-1:1,1:20,1:20);
c = isocolors(r/20,g/20,b/20,p);
p.FaceVertexCData = 1-c;
p.FaceColor = 'interp';
p.EdgeColor = 'none';
view(150,30)
daspect([1 1 1])
camlight
lighting gouraud
```

subvolume

# isonormals

Compute normals of isosurface vertices

## Syntax

```
n = isonormals(X,Y,Z,V,vertices)
n = isonormals(V,vertices)
n = isonormals(V,p)
n = isonormals(X,Y,Z,V,p)
n = isonormals(..., 'negate')
isonormals(V,p)
isonormals(X,Y,Z,V,p)
```

## Description

`n = isonormals(X,Y,Z,V,vertices)` computes the normals of the isosurface vertices from the vertex list, `vertices`, using the gradient of the data `V`. The arrays `X`, `Y`, and `Z` define the coordinates for the volume `V`. The computed normals are returned in `n`.

`n = isonormals(V,vertices)` assumes the arrays `X`, `Y`, and `Z` are defined as `[X,Y,Z] = meshgrid(1:n,1:m,1:p)` where `[m,n,p] = size(V)`.

`n = isonormals(V,p)` and `n = isonormals(X,Y,Z,V,p)` compute normals from the vertices of the patch identified by the handle `p`.

`n = isonormals(..., 'negate')` negates (reverses the direction of) the normals.

`isonormals(V,p)` and `isonormals(X,Y,Z,V,p)` set the `VertexNormals` property of the patch identified by the handle `p` to the computed normals rather than returning the values.

## Examples

### Isosurface Using Different Types of Surface Normals

Compare the effect of different surface normals on the visual appearance of lit isosurfaces. In one case, the triangles used to draw the isosurface define the normals. In

the other, the `isonormals` function uses the volume data to calculate the vertex normals based on the gradient of the data points. The latter approach generally produces a smoother-appearing isosurface.

Define a 3-D array of volume data.

```
data = cat(3,[0 .2 0; 0 .3 0; 0 0 0],...
 [.1 .2 0; 0 1 0; .2 .7 0],...
 [0 .4 .2; .2 .4 0;.1 .1 0]);
data = interp3(data,3,'cubic');
```

Draw an isosurface from the volume data and add lights. This isosurface uses triangle normals.

```
figure
subplot(1,2,1)
fv = isosurface(data,.5);
p1 = patch(fv,'FaceColor','red','EdgeColor','none');
view(3)
daspect([1,1,1])
axis tight
camlight
camlight(-80,-10)
lighting gouraud
title('Triangle Normals')
```

Draw the same lit isosurface using normals calculated from the volume data.

```
subplot(1,2,2)
fv = isosurface(data, .5);
p2 = patch(fv, 'FaceColor', 'red', 'EdgeColor', 'none');
isonormals(data,p2)
view(3)
daspect([1 1 1])
axis tight
camlight
camlight(-80,-10)
lighting gouraud
title('Data Normals')
```

These isosurfaces illustrate the difference between triangle and data normals.

# isordinal

Determine whether input is ordinal categorical array

## Syntax

```
tf = isordinal(A)
```

## Description

`tf = isordinal(A)` returns logical 1 (true) if `A` is an ordinal categorical array. Otherwise, `isordinal` returns logical 0 (false).

If a categorical array is ordinal, you can use relational operations for inequality comparisons, such as greater and less than, in addition to tests for equality.

## Examples

### Determine Whether Categorical Array Is Ordinal

Create a categorical array containing the sizes of 10 objects. Use the names `small`, `medium`, and `large` for the values 'S', 'M', and 'L'.

```
A = categorical({'M';'L';'S';'S';'M';'L';'M';'L';'M';'S'},...
 {'S','M','L'},{'small','medium','large'})
```

A =

```

medium
large
small
small
medium
large
medium
large
medium
small
```

Determine if the categories of **A** have a mathematical ordering.

```
isordinal(A)
```

```
ans =
```

```
0
```

**A** is not ordinal. You must use the `'Ordinal'`, `true` name-value pair argument in the function `categorical` to create an ordinal categorical array.

## Input Arguments

### **A** — Categorical array

vector | matrix | multidimensional array

Categorical array, specified as a vector, matrix, or multidimensional array.

## More About

### Tips

- To convert a categorical array, **A**, from nonordinal to ordinal, use `A = categorical(A, 'Ordinal', true)`.
- To convert a categorical array, **A**, from ordinal to nonordinal, use `A = categorical(A, 'Ordinal', false)`.
- “Ordinal Categorical Arrays”

### See Also

`categorical` | `categories`

# isosurface

Extract isosurface data from volume data

## Syntax

```
fv = isosurface(X,Y,Z,V,isovalue)
fv = isosurface(V,isovalue)
fvc = isosurface(...,colors)
fv = isosurface(...,'noshare')
fv = isosurface(...,'verbose')
[f,v] = isosurface(...)
[f,v,c] = isosurface(...)
isosurface(...)
```

## Description

`fv = isosurface(X,Y,Z,V,isovalue)` computes isosurface data from the volume data `V` at the isosurface value specified in `isovalue`. That is, the isosurface connects points that have the specified value much the way contour lines connect points of equal elevation.

The arrays `X`, `Y`, and `Z` represent a Cartesian, axis-aligned grid. `V` contains the corresponding values at these grid points. The coordinate arrays (`X`, `Y`, and `Z`) must be monotonic and conform to the format produced by `meshgrid`. `V` must be a 3D volume array of the same size as `X`, `Y`, and `Z`.

The struct `fv` contains the faces and vertices of the isosurface, which you can pass directly to the `patch` command.

`fv = isosurface(V,isovalue)` assumes the arrays `X`, `Y`, and `Z` are defined as `[X,Y,Z] = meshgrid(1:n,1:m,1:p)` where `[m,n,p] = size(V)`.

`fvc = isosurface(...,colors)` interpolates the array `colors` onto the scalar field and returns the interpolated values in the `facevertexcdata` field of the `fvc` structure. The size of the `colors` array must be the same as `V`. The `colors` argument enables you to control the color mapping of the isosurface with data different from that

used to calculate the isosurface (e.g., temperature data superimposed on a wind current isosurface).

`fv = isosurface(..., 'noshare')` does not create shared vertices. This is faster, but produces a larger set of vertices.

`fv = isosurface(..., 'verbose')` prints progress messages to the command window as the computation progresses.

`[f,v] = isosurface(...)` or `[f,v,c] = isosurface(...)` returns the faces and vertices (and `faceVertexCData`) in separate arrays instead of a struct.

`isosurface(...)` with no output arguments, creates a patch in the current axes with the computed faces and vertices. If no current axes exists, a new axes is created with a 3-D view.

## Special Case Behavior — `isosurface` Called with No Output Arguments

If there is no current axes and you call `isosurface` without assigning output arguments, MATLAB creates a new axes, sets it to a 3-D view, and adds lighting to the isosurface graph.

## Examples

### Example 1

This example uses the flow data set, which represents the speed profile of a submerged jet within an infinite tank (type `help flow` for more information). The isosurface is drawn at the data value of -3. The statements that follow the `patch` command prepare the isosurface for lighting by

- Recalculating the isosurface normals based on the volume data (`isonormals`)
- Setting the face and edge color (`set`, `FaceColor`, `EdgeColor`)
- Specifying the view (`daspect`, `view`)
- Adding lights (`camlight`, `lighting`)

```
[x,y,z,v] = flow;
p = patch(isosurface(x,y,z,v,-3));
```

```
isonormals(x,y,z,v,p)
p.FaceColor = 'red';
p.EdgeColor = 'none';
daspect([1,1,1])
view(3); axis tight
camlight
lighting gouraud
```

## Example 2

Visualize the same flow data as above, but color-code the surface to indicate magnitude along the X-axis. Use a sixth argument to `isosurface`, which provides a means to overlay another data set by coloring the resulting isosurface. The `colors` variable is a

vector containing a scalar value for each vertex in the isosurface, to be portrayed with the current color map. In this case, it is one of the variables that define the surface, but it could be entirely independent. You can apply a different color scheme by changing the current figure color map.

```
[x,y,z,v] = flow;
[faces,verts,colors] = isosurface(x,y,z,v,-3,x);
patch('Vertices', verts, 'Faces', faces, ...
 'FaceVertexCData', colors, ...
 'FaceColor','interp', ...
 'edgecolor', 'interp');
view(30,-15);
axis vis3d;
colormap copper
```

## More About

### Tips

You can pass the `fv` structure created by `isosurface` directly to the `patch` command, but you cannot pass the individual faces and vertices arrays (`f`, `v`) to `patch` without specifying property names. For example,

```
patch(isosurface(X,Y,Z,V,isovalue))
```

or

```
[f,v] = isosurface(X,Y,Z,V,isovalue);
patch('Faces',f,'Vertices',v)
```

- “Connecting Equal Values with Isosurfaces”

## **ispc**

Determine if version is for Windows (PC) platform

## **Syntax**

```
tf = ispc
```

## **Description**

`tf = ispc` returns logical 1 (**true**) if the version of MATLAB software is for the Microsoft Windows platform. Otherwise, it returns logical 0 (**false**).

## **See Also**

`computer` | `is*` | `ismac` | `isstudent` | `isunix`

# ispref

Test for existence of preference

## Syntax

```
ispref('group','pref')
ispref('group')
ispref('group',{'pref1','pref2',... 'prefn'})
```

## Description

`ispref('group','pref')` returns 1 if the preference specified by `group` and `pref` exists, and 0 otherwise.

`ispref('group')` returns 1 if the `GROUP` exists, and 0 otherwise.

`ispref('group',{'pref1','pref2',... 'prefn'})` returns a logical array the same length as the cell array of preference names, containing 1 where each preference exists, and 0 elsewhere.

## Examples

```
addpref('mytoolbox','version','1.0')
ispref('mytoolbox','version')
```

```
ans =
 1.0
```

## See Also

`addpref` | `rmpref` | `getpref` | `setpref` | `uigetpref` | `uisetpref`

## isprime

Determine which array elements are prime

### Syntax

```
TF = isprime(X)
```

### Description

`TF = isprime(X)` returns a logical array the same size as `X`. The value at `TF(i)` is true when `X(i)` is a prime number. Otherwise, the value is false.

### Examples

#### Determine if Double Integer Values Are Prime

```
tf = isprime([2 3 0 6 10])
```

```
tf =
```

```
 1 1 0 0 0
```

2 and 3 are prime, but 0, 6, and 10 are not.

#### Determine if Unsigned Integer Values Are Prime

```
x = uint16([333 71 99]);
```

```
tf = isprime(x)
```

```
tf =
```

```
 0 1 0
```

71 is prime, but 333 and 99 are not.

## Input Arguments

### **X** — Input values

scalar, vector, or array of real, nonnegative integer values

Input values, specified as a scalar, vector, or array of real, nonnegative integer values.

Example: 17

Example: [1 2 3 4]

Example: int16([127 255 4095])

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### **See Also**

is\* | primes

## isprop

Determine if property of object

### Syntax

```
tf = isprop(obj, 'PropertyName')
```

### Description

`tf = isprop(obj, 'PropertyName')` returns `true` if the specified `PropertyName` is a property of object `obj`. Otherwise, `isprop` returns logical `false`.

If `obj` is an array, `isprop` returns a logical array the same size as `obj`. Each `true` element of `tf` corresponds to an element of `obj` that has the property, `PropertyName`.

---

**Note:** If `obj` is an empty object or an array of empty objects, `isprop` returns an empty logical array, even if `PropertyName` is a property of `obj`.

---

While `isprop` returns `true` if the class of an object defines a property of that name, classes can control access to property values by defining property attributes. Property access can be defined as:

- Readable and writable
- Read only
- Write only
- Accessible only to certain class methods

Therefore, `isprop` might indicate that a property exists, but you might not be able to access that property. For more information, see “Getting Information About Properties”.

### Examples

This example uses `isprop` to determine if `XDataSource` is a property of object `h` before attempting to set the property value:

```
h = plot(1:10);
if isprop(h,'XDataSource')
 set(h,'XDataSource','x')
else
 error(['XDataSource not a property of class ',class(h)])
end
```

Since `XDataSource` is a property of `h`, its value is set to `'x'`.

## See Also

`properties` | `ismethod`

## Tutorials

- “Properties”

## isprop (COM)

Determine whether input is COM object property

### Syntax

```
tf = isprop(h, 'propertyname')
```

### Description

`tf = isprop(h, 'propertyname')` returns logical 1 (true) if the specified name is a property of COM object `h`. Otherwise, returns logical 0 (false).

COM functions are available on Microsoft Windows systems only.

### Examples

Test a property of an instance of a Microsoft Excel application.

```
h = actxserver('Excel.Application');
isprop(h, 'UsableWidth')
```

MATLAB returns true, `UsableWidth` is a property.

Try the same test on `SaveWorkspace`.

```
isprop(h, 'SaveWorkspace')
```

MATLAB returns false. `SaveWorkspace` is not a property; it is a method.

### More About

- “Exploring Properties”

### See Also

`inspect` | `ismethod` | `isevent`

# isprotected

Determine whether categories of categorical array are protected

## Syntax

```
tf = isprotected(A)
```

## Description

`tf = isprotected(A)` returns logical 1 (**true**) if the categories of **A** are protected. Otherwise, `isprotected` returns logical 0 (**false**).

- **true** — When you assign new values to **B**, the values must belong to one of the existing categories. Therefore, you only can combine arrays that have the same categories. To add new categories to **B**, you must use the `addcats` function.
- **false** — When you assign new values to **B**, the categories update automatically. Therefore, you can combine (nonordinal) categorical arrays that have different categories. The categories can update to include the categories from both arrays.

## Examples

### Determine Whether Categories Are Protected

Create a categorical array containing the sizes of 10 objects. Use the names `small`, `medium`, and `large` for the values `'S'`, `'M'`, and `'L'`.

```
valueset = {'S','M','L'};
catnames = {'small','medium','large'};
```

```
A = categorical({'M';'L';'S';'S';'M';'L';'M';'L';'M';'S'},...
 valueset,catnames,'Ordinal',true)
```

```
A =
```

```
 medium
 large
```

```
small
small
medium
large
medium
large
medium
small
```

A is a 10-by-1 categorical array.

Display the categories of A.

```
categories(A)
```

```
ans =
```

```
 'small'
 'medium'
 'large'
```

Determine whether the categories of A are protected.

```
tf = isprotected(A)
```

```
tf =
```

```
 1
```

Since A is an ordinal categorical array, the categories are protected. If you try to add a new value that does not belong to one of the existing categories, for example `A(11) = 'xlarge'`, then MATLAB returns an error.

First, use `addcats` to add a new category for `xlarge`.

```
A = addcats(A, 'xlarge', 'After', 'large');
```

Since A is protected, you can now add a value for `xlarge` since it has an existing category.

```
A(11) = 'xlarge'
```

```
A =
```

```
medium
```

```
large
small
small
medium
large
medium
large
medium
small
xlarge
```

A is now a 11-by-1 categorical array with four categories, such that `small < medium < large < xlarge`.

- “Work with Protected Categorical Arrays”

## Input Arguments

### **A** — Categorical array

vector | matrix | multidimensional array

Categorical array, specified as a vector, matrix, or multidimensional array.

The categories of ordinal categorical arrays are always protected.

### See Also

`categorical` | `categories`

## isreal

Determine if array is real

### Syntax

```
tf = isreal(A)
```

### Description

`tf = isreal(A)` returns logical 1 (true) if `A` does not have an imaginary part. Otherwise, it returns logical 0 (false).

If `A` has a stored imaginary part with value 0, then `isreal(A)` returns logical 0 (false).

### Examples

#### Determine If Matrix Contains All Real Values

Define a 3-by-4 matrix, `A`.

```
A = [7 3+4i 2 5i;...
 2i 1+3i 12 345;...
 52 108 78 3];
```

Determine if the array is real.

```
tf = isreal(A)
```

```
tf =
```

```
0
```

Since `A` contains complex elements, `isreal` returns false.

#### Define Complex Number with Zero-Valued Imaginary Part

Use the `complex` function to create a scalar, `A`, with zero-valued imaginary part.

```
A = complex(12)
```

```
A =
```

```
12.0000 + 0.0000i
```

Determine if A is real.

```
tf = isreal(A)
```

```
tf =
```

```
0
```

A is not real because it has an imaginary part, even though the value of the imaginary part is 0.

Determine if A contains any elements with zero-valued imaginary part.

```
~any(imag(A))
```

```
ans =
```

```
1
```

A contains elements with zero-valued imaginary part.

### **Computation Resulting in Zero-Valued Imaginary Part**

Define two complex scalars, x and y.

```
x=3+4i;
```

```
y=5-4i;
```

Determine if the addition of two complex scalars, x and y, is real.

```
A = x+y
```

```
A =
```

```
8
```

MATLAB drops the zero imaginary part.

```
isreal(A)
```

```
ans =

 1
```

A is real since it does not have an imaginary part.

## Find Real Elements in Cell Array

Create a cell array.

```
C{1,1} = pi; % double
C{2,1} = 'John Doe'; % char array
C{3,1} = 2 + 4i; % complex double
C{4,1} = ispc; % logical
C{5,1} = magic(3); % double array
C{6,1} = complex(5,0) % complex double
```

```
C =

 [3.1416]
 'John Doe'
 [2.0000 + 4.0000i]
 [1]
 [3x3 double]
 [5.0000 + 0.0000i]
```

C is a 1-by-6 cell array.

Loop over the elements of a cell array to distinguish between real and complex elements.

```
for k = 1:6
 x(k,1) = isreal(C{k,1});
end
```

```
x
```

```
x =

 1
 1
 0
 1
 1
 0
```

All but `C{3,1}` and `C{6,1}` are real arrays.

## Input Arguments

### A — Input array

scalar | vector | matrix | multidimensional array

Input array, specified as a scalar, vector, matrix, or multidimensional array.

- For numeric data types, if A does not have an imaginary part, `isreal` returns `true`; if A does have an imaginary part `isreal` returns `false`.
- For logical and char data types, `isreal` always returns `true`.
- For table, cell, struct, function\_handle, and object data types, `isreal` always returns `false`.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical | char | struct | table | cell | function\_handle  
Complex Number Support: Yes

## More About

### Tips

- `isreal(complex(A))` always returns `false`, even when the imaginary part is all zeros.
- `~isreal(x)` detects arrays that have an imaginary part, even if it is all zeros.
- “Complex Numbers”

### See Also

`complex` | `isa` | `isfinite` | `isinf` | `isnan` | `isnumeric` | `isprime`

## **isrow**

Determine whether input is row vector

### **Syntax**

```
isrow(V)
```

### **Description**

`isrow(V)` returns logical 1 (**true**) if `size(V)` returns `[1 n]` with a nonnegative integer value `n`, and logical 0 (**false**) otherwise.

### **Examples**

Determine if a vector is a row. This example is a column so `isrow` returns 0:

```
V = rand(5,1);
isrow(V)
ans =
 0
```

Transpose the vector to make it a row. `isrow` returns 1:

```
V1 = V';
isrow(V1)
ans =
 1
```

### **See Also**

`iscolumn` | `ismatrix` | `isscalar` | `isvector`

# isscalar

Determine whether input is scalar

## Syntax

```
isscalar(A)
```

## Description

`isscalar(A)` returns logical 1 (**true**) if `size(A)` returns `[1 1]`, and logical 0 (**false**) otherwise.

## Examples

Test matrix A and one element of the matrix:

```
A = rand(5);
```

```
isscalar(A)
ans =
 0
```

```
isscalar(A(3,2))
ans =
 1
```

## See Also

`isvector` | `isrow` | `ismatrix` | `iscolumn` | `islogical` | `ischar` | `isa` | `is*`

## issorted

Determine whether set elements are in sorted order

### Syntax

```
TF = issorted(A)
TF = issorted(A, 'rows')
```

### Description

`TF = issorted(A)` returns logical 1 (**true**) if the elements of `A` are in sorted order, and logical 0 (**false**) otherwise. Input `A` can be a vector or an N-by-1 or 1-by-N cell array of strings. `A` is considered to be sorted if `A` and the output of `sort(A)` are equal.

`TF = issorted(A, 'rows')` returns logical 1 (**true**) if the rows of two-dimensional matrix `A` are in sorted order, and logical 0 (**false**) otherwise. Matrix `A` is considered to be sorted if `A` and the output of `sortrows(A)` are equal.

---

**Note** Only the `issorted(A)` syntax supports `A` as a cell array of strings.

The `issorted(A, 'rows')` syntax supports `A` as a categorical array, but not as a cell array of strings.

---

### Examples

#### Example 1 — Using `issorted` on a vector

```
A = [5 12 33 39 78 90 95 107 128 131];
```

```
issorted(A)
ans =
 1
```

## Example 2 — Using issorted on a matrix

```
A = magic(5)
A =
 17 24 1 8 15
 23 5 7 14 16
 4 6 13 20 22
 10 12 19 21 3
 11 18 25 2 9
```

```
issorted(A, 'rows')
ans =
 0
```

```
B = sortrows(A)
B =
 4 6 13 20 22
 10 12 19 21 3
 11 18 25 2 9
 17 24 1 8 15
 23 5 7 14 16
```

```
issorted(B)
ans =
 1
```

## Example 3 — Using issorted on a cell array

```
x = {'one'; 'two'; 'three'; 'four'; 'five'};
issorted(x)
ans =
 0
```

```
y = sort(x)
y =
 'five'
 'four'
 'one'
 'three'
 'two'
```

```
issorted(y)
```

## More About

### Tips

For character arrays, `issorted` uses ASCII, rather than alphabetical, order.

You cannot use `issorted` on arrays of greater than two dimensions.

### See Also

`sort` | `sortrows` | `unique` | `ismember` | `intersect` | `union` | `setdiff` | `setxor` | `is*`

# isspace

Array elements that are space characters

## Syntax

```
tf = isspace('str')
```

## Description

`tf = isspace('str')` returns an array the same size as `'str'` containing logical 1 (`true`) where the elements of `str` are Unicode-represented whitespace characters, and logical 0 (`false`) where they are not.

Whitespace characters for which `isspace` returns `true` include tab, line feed, vertical tab, form feed, carriage return, and space, in addition to a number of other Unicode characters. To see all characters for which `isspace` returns `true`, enter the following command, and then look up the returned decimal codes in a Unicode reference:

```
find(isspace(char(1):char(intmax('uint16'))))
```

## Examples

```
isspace(' Find spa ces ')
Columns 1 through 13
 1 1 0 0 0 0 0 1 0 0 0 0 1 0 0
Columns 14 through 15
 0 1
```

## See Also

`isletter` | `ischar` | `isstrprop` | `strings` | `isa` | `is*`

## **issparse**

Determine whether input is sparse

### **Syntax**

TF = issparse(S)

### **Description**

TF = issparse(S) returns logical 1 (**true**) if the storage class of **S** is sparse and logical 0 (**false**) otherwise.

### **See Also**

is\* | sparse | full

## isstr

Determine whether input is character array

---

**Note:** `isstr` is not recommended. Use `ischar` instead.

---

### See Also

`ischar` | `isa` | `is*`

## isstrprop

Determine whether string is of specified category

### Syntax

```
tf = isstrprop('str', 'category')
```

### Description

`tf = isstrprop('str', 'category')` returns a logical array the same size as `str` containing logical 1 (true) where the elements of `str` belong to the specified *category*, and logical 0 (false) where they do not.

The `str` input can be a character array, cell array, or any MATLAB numeric type. If `str` is a cell array, then the return value is a cell array of the same shape as `str`.

The *category* input can be any of the strings shown in the left column below:

| Category | Description                                                                                                                                                                                                                                                                                                                                                                        |
|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| alpha    | True for those elements of <code>str</code> that are alphabetic                                                                                                                                                                                                                                                                                                                    |
| alphanum | True for those elements of <code>str</code> that are alphanumeric                                                                                                                                                                                                                                                                                                                  |
| cntrl    | True for those elements of <code>str</code> that are control characters (for example, <code>char(0:20)</code> )                                                                                                                                                                                                                                                                    |
| digit    | True for those elements of <code>str</code> that are numeric digits                                                                                                                                                                                                                                                                                                                |
| graphic  | True for those elements of <code>str</code> that are graphic characters. These are all values that represent any characters except for the following:<br><br>unassigned, space, line separator,<br>paragraph separator, control characters,<br>Unicode format control characters,<br>private user-defined characters,<br>Unicode surrogate characters,<br>Unicode other characters |
| lower    | True for those elements of <code>str</code> that are lowercase letters                                                                                                                                                                                                                                                                                                             |

| Category | Description                                                                                                                                                                                                                                                  |
|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| print    | True for those elements of <code>str</code> that are graphic characters, plus <code>char(32)</code>                                                                                                                                                          |
| punct    | True for those elements of <code>str</code> that are punctuation characters                                                                                                                                                                                  |
| wspace   | True for those elements of <code>str</code> that are white-space characters. This range includes the ANSI <sup>®</sup> C definition of white space, { <code>' ', '\t', '\n', '\r', '\v', '\f'</code> }, in addition to a number of other Unicode characters. |
| upper    | True for those elements of <code>str</code> that are uppercase letters                                                                                                                                                                                       |
| xdigit   | True for those elements of <code>str</code> that are valid hexadecimal digits                                                                                                                                                                                |

## Examples

Test for alphabetic characters in a string:

```
A = isstrprop('abc123def', 'alpha')
A =
 1 1 1 0 0 0 1 1 1
```

Test for numeric digits in a string:

```
A = isstrprop('abc123def', 'digit')
A =
 0 0 0 1 1 1 0 0 0
```

Test for hexadecimal digits in a string:

```
A = isstrprop('abcd1234efgh', 'xdigit')
A =
 1 1 1 1 1 1 1 1 1 0 0
```

Test for numeric digits in a character array:

```
A = isstrprop(char([97 98 99 49 50 51 101 102 103]), ...
 'digit')
A =
 0 0 0 1 1 1 0 0 0
```

Test for alphabetic characters in a two-dimensional cell array:

```
A = isstrprop({'abc123def'; '456ghi789'}, 'alpha')
```

```
A =
 [1x9 logical]
 [1x9 logical]
```

```
A{:,:}
ans =
 1 1 1 0 0 0 1 1 1
 0 0 0 1 1 1 0 0 0
```

Test for white-space characters in a string:

```
A = isstrprop(sprintf('a bc\n'), 'wspace')
A =
 0 1 0 0 1
```

## More About

### Tips

Numbers of type `double` are converted to `int32` according to MATLAB rules of double-to-integer conversion. Numbers of type `int64` and `uint64` bigger than `int32(inf)` saturate to `int32(inf)`.

MATLAB classifies the elements of the `str` input according to the Unicode definition of the specified category. If the numeric value of an element in the input array falls within the range that defines a Unicode character category, then this element is classified as being of that category. The set of Unicode character codes includes the set of ASCII character codes, but also covers a large number of languages beyond the scope of the ASCII set. The classification of characters is dependent on the global location of the platform on which MATLAB is installed.

Whitespace characters for which the `wspace` option returns `true` include tab, line feed, vertical tab, form feed, carriage return, and space, in addition to a number of other Unicode characters. To see all characters for which the `wspace` option returns `true`, enter the following command, and then look up the returned decimal codes in a Unicode reference:

```
find(isstrprop(char(1):char(intmax('uint16')), 'wspace'))
```

### See Also

`strings` | `ischar` | `isletter` | `isspace` | `iscellstr` | `isnumeric` | `isa` | `is*`

## isstruct

Determine whether input is structure array

### Syntax

```
tf = isstruct(A)
```

### Description

`tf = isstruct(A)` returns logical 1 (true) if `A` is a MATLAB structure and logical 0 (false) otherwise.

### Examples

```
patient.name = 'John Doe';
patient.billing = 127.00;
patient.test = [79 75 73; 180 178 177.5; 220 210 205];
```

```
isstruct(patient)
```

```
ans =
```

```
 1
```

### More About

- “dynamic field names”

### See Also

`struct` | `istable` | `iscell` | `ischar` | `isfield` | `isobject` | `isnumeric` | `islogical` | `isa` | `is*`

## **isstudent**

Determine if version is Student Version

### **Syntax**

```
tf = isstudent
```

### **Description**

`tf = isstudent` returns logical 1 (**true**) if the version of MATLAB software is the Student Version, and returns logical 0 (**false**) for commercial versions.

### **See Also**

`ver` | `version` | `license` | `ispc` | `isunix` | `is*`

# issymmetric

Determine if matrix is symmetric or skew-symmetric

## Syntax

```
tf = issymmetric(A)
tf = issymmetric(A,skewOption)
```

## Description

`tf = issymmetric(A)` returns logical 1 (**true**) if square matrix **A** is symmetric; otherwise, it returns logical 0 (**false**).

`tf = issymmetric(A,skewOption)` specifies the type of the test. Specify `skewOption` as 'skew' to determine if **A** is skew-symmetric.

## Examples

### Test if Hermitian Matrix Is Symmetric

Create a 3-by-3 matrix.

```
A = [1 0 1i; 0 1 0; -1i 0 1]
```

A =

```
1.0000 + 0.0000i 0.0000 + 0.0000i 0.0000 + 1.0000i
0.0000 + 0.0000i 1.0000 + 0.0000i 0.0000 + 0.0000i
0.0000 - 1.0000i 0.0000 + 0.0000i 1.0000 + 0.0000i
```

The matrix is Hermitian and has a real-valued diagonal.

Test whether the matrix is symmetric.

```
tf = issymmetric(A)
```

```
tf =
```

```
0
```

The result is logical 0 (**false**) because **A** is not symmetric. In this case, **A** is equal to its complex conjugate transpose, **A'**, but not its nonconjugate transpose, **A.'**

Change the element in **A(3,1)** to be **1i**.

```
A(3,1) = 1i;
```

Determine whether the modified matrix is symmetric.

```
tf = issymmetric(A)
```

```
tf =
```

```
1
```

The matrix, **A**, is now symmetric because it is equal to its nonconjugate transpose, **A.'**

## Test if Matrix Is Skew-Symmetric

Create a 4-by-4 matrix.

```
A = [0 1 -2 5; -1 0 3 -4; 2 -3 0 6; -5 4 -6 0]
```

```
A =
```

```
0 1 -2 5
-1 0 3 -4
 2 -3 0 6
-5 4 -6 0
```

The matrix is real and has a diagonal of zeros.

Specify `skewOption` as `'skew'` to determine whether the matrix is skew-symmetric.

```
tf = issymmetric(A, 'skew')
```

```
tf =
```

```
1
```

The matrix,  $A$ , is skew-symmetric since it is equal to the negation of its nonconjugate transpose,  $-A..$

## Input Arguments

### **A** — Input matrix

numeric matrix

Input matrix, specified as a numeric matrix. If  $A$  is not square, then `issymmetric` returns logical 0 (`false`).

Data Types: `single` | `double`

Complex Number Support: Yes

### **skewOption** — Test type

'nonskew' (default) | 'skew'

Test type, specified as 'nonskew' (default) or 'skew'. Specify 'skew' to test whether  $A$  is skew-symmetric. Specifying `issymmetric(A, 'nonskew')` is equivalent to `issymmetric(A)`.

Data Types: `char`

## More About

### **Symmetric Matrix**

- A square matrix,  $A$ , is symmetric if it is equal to its nonconjugate transpose,  $A = A..$

In terms of the matrix elements, this means that

$$a_{i,j} = a_{j,i}.$$

- Since real matrices are unaffected by complex conjugation, a real matrix that is symmetric is also Hermitian. For example, the matrix

$$A = \begin{bmatrix} 1 & 0 & 1 \\ 0 & 2 & 0 \\ 1 & 0 & 1 \end{bmatrix}$$

is both symmetric and Hermitian.

### **Skew-Symmetric Matrix**

- A square matrix,  $A$ , is skew-symmetric if it is equal to the negation of its nonconjugate transpose,  $A = -A^T$ .

In terms of the matrix elements, this means that

$$a_{i,j} = -a_{j,i}.$$

- Since real matrices are unaffected by complex conjugation, a real matrix that is skew-symmetric is also skew-Hermitian. For example, the matrix

$$A = \begin{bmatrix} 0 & -1 \\ 1 & 0 \end{bmatrix}$$

is both skew-symmetric and skew-Hermitian.

### **See Also**

`ctranspose` | `ishermitian` | `isreal` | `transpose`

# isTiled

**Class:** Tiff

Determine if tiled image

## Syntax

```
tf = isTiled(tiffobj)
```

## Description

`tf = isTiled(tiffobj)` returns `true` if the image has a tiled organization and `false` if the image has a stripped organization.

## Examples

### Determine if Image Has Tiled Organization

Open a Tiff object and check if the image in the TIFF file has a tiled or stripped organization.

```
t = Tiff('example.tif', 'r');
tf = isTiled(t)
```

```
tf =
```

```
1
```

The image has a tiled organization.

Close the Tiff object.

```
close(t)
```

- “Exporting Image Data and Metadata to TIFF Files”
- “Reading Image Data and Metadata from TIFF Files”

## References

This method corresponds to the `TIFFIsTiled` function in the LibTIFF C API. To use this method, you must be familiar with the TIFF specification and technical notes. View this documentation at [LibTIFF - TIFF Library and Utilities](#).

# istable

Determine whether input is table

## Syntax

```
tf = istable(T)
```

## Description

`tf = istable(T)` returns logical 1 (true) if T is a table. Otherwise, it returns logical 0 (false) otherwise.

## Examples

### Determine if Workspace Variable Is Table

Create a workspace variable, T.

```
T = table(['M';'F';'M'],[45 45;41 32;40 34],...
 {'NY';'CA';'MA'},[true;false;false])
```

T =

| Var1 | Var2 | Var3 | Var4 |
|------|------|------|------|
| M    | 45   | 45   | 'NY' |
| F    | 41   | 32   | 'CA' |
| M    | 40   | 34   | 'MA' |

Verify that the workspace variable, T, is a table.

```
istable(T)
```

```
ans =
```

```
1
```

T is a table.

### Determine if Subset of Table Is Table

Create a table, T.

```
T = table(['M';'F';'M'],[45 45;41 32;40 34],...
 {'NY';'CA';'MA'},[true;false;false])
```

T =

| Var1 | Var2 | Var3 | Var4 |       |
|------|------|------|------|-------|
| M    | 45   | 45   | 'NY' | true  |
| F    | 41   | 32   | 'CA' | false |
| M    | 40   | 34   | 'MA' | false |

Determine if the subset of table T that contains only the second and fourth variables is a table.

```
istable(T{:[2 4]})
```

ans =

0

Conversely, accessing data with curly braces, T{:[2 4]}, returns a matrix and not a table.

## Input Arguments

### T — Input variable

workspace variable

Input variable, specified as a workspace variable. T can be any data type.

### See Also

# istril

Determine if matrix is lower triangular

## Syntax

```
tf = istril(A)
```

## Description

`tf = istril(A)` returns logical 1 (true) if `A` is a lower triangular matrix; otherwise, it returns logical 0 (false).

## Examples

### Test Lower Triangular Matrix

Create a 5-by-5 matrix.

```
D = tril(magic(5))
```

D =

```
 17 0 0 0 0
 23 5 0 0 0
 4 6 13 0 0
 10 12 19 21 0
 11 18 25 2 9
```

Test `D` to see if it is lower triangular.

```
istril(D)
```

ans =

```
 1
```

The result is logical 1 (`true`) because all elements above the main diagonal are zero.

## Test Matrix of Zeros

Create a 5-by-5 matrix of zeros.

```
Z = zeros(5);
```

Test Z to see if it is lower triangular.

```
istril(Z)
```

```
ans =
```

```
1
```

The result is logical 1 (`true`) because a lower triangular matrix can have any number of zeros on its main diagonal.

## Input Arguments

### A — Input array

numeric array

Input array, specified as a numeric array. `istril` returns logical 0 (`false`) if A has more than two dimensions.

Data Types: `single` | `double`

Complex Number Support: Yes

## More About

### Lower Triangular Matrix

A matrix is lower triangular if all elements above the main diagonal are zero. Any number of the elements on the main diagonal can also be zero.

For example, the matrix

$$A = \begin{pmatrix} 1 & 0 & 0 & 0 \\ -1 & 1 & 0 & 0 \\ -2 & -2 & 1 & 0 \\ -3 & -3 & -3 & 1 \end{pmatrix}$$

is lower triangular. A diagonal matrix is both upper and lower triangular.

### Tips

- Use the `tril` function to produce lower triangular matrices for which `istril` returns logical 1 (true).
- The functions `isdiag`, `istriu`, and `istril` are special cases of the function `isbanded`, which can perform all of the same tests with suitably defined upper and lower bandwidths. For example, `istril(A) == isbanded(A, size(A,1), 0)`.

### See Also

`diag` | `isdiag` | `istriu` | `tril` | `triu`

## **istriu**

Determine if matrix is upper triangular

### **Syntax**

```
tf = istriu(A)
```

### **Description**

`tf = istriu(A)` returns logical 1 (true) if `A` is an upper triangular matrix; otherwise, it returns logical 0 (false).

### **Examples**

#### **Test Upper Triangular Matrix**

Create a 5-by-5 matrix.

```
A = triu(magic(5))
```

```
A =
```

```
 17 24 1 8 15
 0 5 7 14 16
 0 0 13 20 22
 0 0 0 21 3
 0 0 0 0 9
```

Test `A` to see if it is upper triangular.

```
istriu(A)
```

```
ans =
```

```
 1
```

The result is logical 1 (`true`) because all elements below the main diagonal are zero.

### Test Matrix of Zeros

Create a 5-by-5 matrix of zeros.

```
Z = zeros(5);
```

Test Z to see if it is upper triangular.

```
istriu(Z)
```

```
ans =
```

```
1
```

The result is logical 1 (`true`) because an upper triangular matrix can have any number of zeros on the main diagonal.

## Input Arguments

### A — Input array

numeric array

Input array, specified as a numeric array. `istriu` returns logical 0 (`false`) if A has more than two dimensions.

Data Types: `single` | `double`

Complex Number Support: Yes

## More About

### Upper Triangular Matrix

A matrix is upper triangular if all elements below the main diagonal are zero. Any number of the elements on the main diagonal can also be zero.

For example, the matrix

$$A = \begin{pmatrix} 1 & -1 & -1 & -1 \\ 0 & 1 & -2 & -2 \\ 0 & 0 & 1 & -3 \\ 0 & 0 & 0 & 1 \end{pmatrix}$$

is upper triangular. A diagonal matrix is both upper and lower triangular.

**Tips**

- Use the `triu` function to produce upper triangular matrices for which `istriu` returns logical 1 (true).
- The functions `isdiag`, `istriu`, and `istril` are special cases of the function `isbanded`, which can perform all of the same tests with suitably defined upper and lower bandwidths. For example, `istriu(A) == isbanded(A,0,size(A,2))`.

**See Also**

`diag` | `isdiag` | `istril` | `tril` | `triu`

# isundefined

Find undefined elements in categorical array

## Syntax

```
TF = isundefined(A)
```

## Description

`TF = isundefined(A)` returns a logical array, `TF`, that indicates which elements in the categorical array, `A`, contain undefined values. `isundefined` returns logical 1 (`true`) for undefined elements; otherwise it returns logical 0 (`false`). The size of `TF` is the same as the size of `A`.

Any elements in `A` without a corresponding category are undefined. Undefined values are similar to `NaN` in numeric arrays.

## Examples

### Categorical Array with Undefined Values

Create a categorical array, `A`, from numeric values where 1, 2, and 3 represent red, green, and blue respectively.

```
A = categorical([4 1; 2 3; 2 1; 3 4; 1 1],1:3,{'red','green','blue'})
```

```
A =
```

```

<undefined> red
green blue
green red
blue <undefined>
red red
```

`A` is a 5-by-2 categorical array with three categories: red, green, and blue. Array elements corresponding to the numeric value 4 in the input array to the `categorical`

function do not have a corresponding category. Therefore, they are undefined in the output categorical array, **A**.

Find undefined elements in **A**.

```
TF = isundefined(A)
```

```
TF =
```

```
 1 0
 0 0
 0 0
 0 1
 0 0
```

**A**(1,1) and **A**(4,2) are undefined.

## Input Arguments

### **A** — Categorical array

vector | matrix | multidimensional array

Categorical array, specified as a vector, matrix, or multidimensional array.

### See Also

`ismember`

## isunix

Determine if version is for UNIX platform

### Syntax

```
tf = isunix
```

### Description

`tf = isunix` returns logical 1 (**true**) if the version of MATLAB software is for the UNIX platform or the Apple Mac OS X platform. Otherwise, it returns logical 0 (**false**).

### See Also

`computer` | `is*` | `ismac` | `ispc` | `isstudent`

## isvalid (handle)

Is object valid handle class object

### Syntax

```
H1 = isvalid(Hobj)
```

### Description

`H1 = isvalid(Hobj)` returns a logical array (or scalar if `Hobj` is scalar) in which each element is `true` if the corresponding element in `Hobj` is a valid handle. This method is `Sealed`, so you cannot override it in a handle subclass.

---

**Note:** This method does not work with Handle Graphics objects. To determine the validity of a Handle Graphics object handle, use the `ishghandle` function.

---

### More About

- “Testing Handle Validity”

### See Also

`delete (handle) | handle`

## isvalid (serial)

Determine whether serial port objects are valid

### Syntax

```
out = isvalid(obj)
```

### Description

`out = isvalid(obj)` returns the logical array `out`, which contains a `0` where the elements of the serial port object, `obj` are invalid serial port objects and a `1` where the elements of `obj` are valid serial port objects.

### Examples

Suppose you create the following two serial port objects.

```
s1 = serial('COM1');
s2 = serial('COM1');
```

`s2` becomes invalid after it is deleted.

```
delete(s2)
```

`isvalid` verifies that `s1` is valid and `s2` is invalid.

```
sarray = [s1 s2];
isvalid(sarray)
```

```
ans =
 1 0
```

## More About

### Tips

`obj` becomes invalid after it is removed from memory with the `delete` function. Because you cannot connect an invalid serial port object to the device, you should remove it from the workspace with the `clear` command.

### See Also

`clear` | `delete`

## isvarname

Determine whether input is valid variable name

### Syntax

```
tf = isvarname('str')
isvarname str
```

### Description

`tf = isvarname('str')` returns logical 1 (true) if the string `str` is a valid MATLAB variable name and logical 0 (false) otherwise. A valid variable name is a character string of letters, digits, and underscores, totaling not more than `namelengthmax` characters and beginning with a letter.

MATLAB keywords are not valid variable names. Type the command `iskeyword` with no input arguments to see a list of MATLAB keywords.

`isvarname str` uses the MATLAB command format.

### Examples

This variable name is valid:

```
isvarname foo
ans =
 1
```

This one is not because it starts with a number:

```
isvarname 8th_column
ans =
 0
```

If you are building strings from various pieces, place the construction in parentheses.

```
d = date;
```

```
isvarname(['Monday_', d(1:2)])
ans =
 1
```

## See Also

[matlab.lang.makeValidName](#) | [matlab.lang.makeUniqueStrings](#) | [iskeyword](#) | [namelengthmax](#) | [is\\*](#)

## isvector

Determine whether input is vector

### Syntax

```
isvector(A)
```

### Description

`isvector(A)` returns logical 1 (**true**) if `size(A)` returns `[1 n]` or `[n 1]` with a nonnegative integer value `n`, and logical 0 (**false**) otherwise.

### Examples

Test matrix A and its row and column vectors:

```
A = rand(5);
```

```
isvector(A)
ans =
 0
```

```
isvector(A(3, :))
ans =
 1
```

```
isvector(A(:, 2))
ans =
 1
```

### See Also

`iscolumn` | `isrow` | `ismatrix` | `isscalar` | `isempty` | `isnumeric` | `islogical` | `ischar` | `isa` | `is*`

## isweekend

Determine weekend elements

### Syntax

```
tf = isweekend(t)
```

### Description

`tf = isweekend(t)` returns an array the same size as `t` containing logical 1 (`true`) where the corresponding element of `t` is a datetime that occurs on a weekend day, and logical 0 (`false`) otherwise. Weekend days are Saturday and Sunday.

### Examples

#### Determine If Date Occurs During Weekend

```
t = datetime(2014,5,2:5, 'Format', 'eee dd-MMM-yyyy')
```

```
t =
```

```
 Fri 02-May-2014 Sat 03-May-2014 Sun 04-May-2014 Mon 05-May-2014
```

```
tf = isweekend(t)
```

```
tf =
```

```
 0 1 1 0
```

May 3 and May 4, 2014 are days that fall on a weekend.

## Input Arguments

**t** — **Input date and time**

`datetime` array

Input date and time, specified as a `datetime` array.

## See Also

`day` | `isdst`

## i

Imaginary unit

### Syntax

```
1j
z = a + bj
z = x + 1j*y
```

### Description

1j returns the basic imaginary unit. j is equivalent to `sqrt(-1)`.

You can use j to enter complex numbers. You also can use the character i as the imaginary unit. To create a complex number without using i and j, use the `complex` function.

`z = a + bj` returns a complex numerical constant, z.

`z = x + 1j*y` returns a complex array, z.

### Examples

#### Complex Scalar

Create a complex scalar and use the character, j, without a multiplication sign as a suffix in forming a complex numerical constant.

```
z = 1+2j
```

```
z =
```

```
1.0000 + 2.0000i
```

#### Complex Vector

Create a complex vector from two 4-by-1 vectors of real numbers.

```
x = [1:4]';
y = [8:-2:2]';

z = x+1j*y
z =

 1.0000 + 8.0000i
 2.0000 + 6.0000i
 3.0000 + 4.0000i
 4.0000 + 2.0000i
```

z is a 4-by-1 complex vector.

### Complex Exponential

Create a complex scalar representing a complex vector with radius, *r*, and angle from the origin, *theta*.

```
r = 4;
theta = pi/4;

z = r*exp(1j*theta)
z =

 2.8284 + 2.8284i
```

## Input Arguments

### **a** — Real component of complex scalar

scalar

Real component of a complex scalar, specified as a scalar.

Data Types: `single` | `double`

### **b** — Imaginary component of complex scalar

scalar

Imaginary component of a complex scalar, specified as a scalar.

If **b** is `double`, you can use the character, `j`, without a multiplication sign as a suffix in forming the complex numerical constant.

Example: `7j`

If `b` is `single`, you must use a multiplication sign when forming the complex numerical constant.

Example: `single(7)*j`

Data Types: `single` | `double`

### **x — Real component of complex array**

scalar | vector | matrix | multidimensional array

Real component of a complex array, specified as a scalar, vector, matrix, or multidimensional array.

The size of `x` must match the size of `y`, unless one is a scalar. If either `x` or `y` is a scalar, MATLAB expands the scalar to match the size of the other input.

`single` can combine with `double`.

Data Types: `single` | `double`

### **y — Imaginary component of complex array**

scalar | vector | matrix | multidimensional array

Imaginary component of a complex array, specified as a scalar, vector, matrix, or multidimensional array.

The size of `x` must match the size of `y`, unless one is a scalar. If either `x` or `y` is a scalar, MATLAB expands the scalar to match the size of the other input.

`single` can combine with `double`.

Data Types: `single` | `double`

## Output Arguments

### **z — Complex array**

scalar | vector | matrix | multidimensional array

Complex array, returned as a scalar, vector, matrix, or multidimensional array.

The size of `z` is the same as the input arguments.

`z` is `single` if at least one input argument is `single`. Otherwise, `z` is `double`.

## More About

### Tips

- For speed and improved robustness in complex arithmetic, use `1i` and `1j` instead of `i` and `j`.
- Since `j` is a function, it can be overridden and used as a variable. However, it is best to avoid using `i` and `j` for variable names if you intend to use them in complex arithmetic.
- Use the `complex` function to create a complex output in the following cases:
  - When the names `i` and `j` might be used for other variables (and do not equal `sqrt(-1)`)
  - When the inputs are not `double` or `single`
  - When the imaginary component is all zeros
- “Complex Numbers”

`complex` | `conj` | `i` | `imag` | `real`

# javaaddpath

Add entries to dynamic Java class path

## Syntax

```
javaaddpath(dpath)
javaaddpath(dpath, '-end')
```

## Description

`javaaddpath(dpath)` adds one or more folders or Java Archive (JAR) files to the beginning of the current dynamic class path.

`javaaddpath(dpath, '-end')` adds files or folders to the end of the path.

## Examples

### Add Folder to Dynamic Class Path

Display the current dynamic path.

```
javaclasspath('-dynamic')
```

```
DYNAMIC JAVA PATH
```

```
<empty>
```

The output reflects your configuration.

Add the current folder.

```
javaaddpath(pwd)
```

Display the dynamic path.

```
p = javaclasspath
```

```
p =
```

```
'c:\work\Java'
```

The output reflects your current folder.

### Append URL to Dynamic Class Path

```
javaaddpath('http://www.example.com', '-end')
p = javaclasspath

p =
 'c:\work\Java'
 'http://www.example.com'
```

## Input Arguments

### **dpath** — Folder or JAR file

string | cell array of strings

Folder or JAR file, specified as a string or cell array of strings, to add to the dynamic path. When you add a folder to the path, MATLAB includes all files in that folder as part of the path.

Data Types: char | cell

## Limitations

- MATLAB does not support JAR files generated by the MATLAB Builder for Java<sup>®</sup> product.

## More About

### Tips

- MATLAB calls the `clear java` command whenever you change the dynamic path. This command clears the definitions of all Java classes defined by files on the dynamic class path, removes all global variables and variables from the base workspace, and removes all compiled scripts, functions, and MEX-functions from memory.

- To add folders to the static path, which MATLAB loads at startup, create a `javaclasspath.txt` file, as described in “The Static Path”.
- “Bringing Java Classes into MATLAB Workspace”

## **See Also**

`clear` | `javaclasspath` | `javarmpath`

# javaArray

Construct Java array object

## Syntax

```
ObjArr = javaArray(PackageName.ClassName,x1,...,xN)
```

## Description

ObjArr = javaArray(PackageName.ClassName,x1,...,xN) constructs an empty Java array object for objects of the specified PackageName.ClassName class.

## Examples

### Create 4-By-5 Array

Create 4-by-5 array of `java.lang.Double` type.

```
x1 = 4; x2 = 5;
dblArray = javaArray ('java.lang.Double',x1,x2);
```

Fill in values.

```
for m = 1:x1
 for n = 1:x2
 dblArray(m,n) = java.lang.Double((m*10) + n);
 end
end
```

Display results.

```
dblArray
```

```
dblArray =
java.lang.Double[][]:
 [11] [12] [13] [14] [15]
 [21] [22] [23] [24] [25]
```

[31]    [32]    [33]    [34]    [35]  
[41]    [42]    [43]    [44]    [45]

## Input Arguments

### **PackageName.ClassName** — Name of Java class

string

Name of Java class, including package name, specified as a string.

Data Types: char

### **x1, . . . , xN** — Dimensions of the array

integer

Dimensions of the array, specified as integer.

Data Types: double

## Output Arguments

### **ObjArr** — Java array

Java array

Java array with dimensions x1,...,xN.

## More About

### **Java Array Object**

A Java array object is an object with Java dimensionality.

### **Tips**

- The array created by `javaArray` is equivalent to the array created by the following Java code:

```
A = new PackageName.ClassName[x1] . . . [xN];
```

- To create an array of primitive Java types, create an array of the equivalent MATLAB type, shown in the Conversion of MATLAB Types to Java Types table. See “Conversion of MATLAB Argument Data”.
- “Working with Java Arrays”

**See Also**

`class` | `isjava` | `javaMethodEDT` | `javaObjectEDT` | `methodsview`

## javachk

Error message based on Java feature support

### Syntax

```
MSG = javachk(feature)
javachk(feature,component)
```

### Description

MSG = javachk(feature) returns a generic error message if the specified Java feature is not available in the current MATLAB session.

javachk(feature,component) also names the specified component in the error message.

### Examples

#### Generate Error

```
if isempty(javachk('jvm'))
 scalar = java.lang.Double(5);
end
% Check that JVM is available & JavaFigures are supported
error(javachk('jvm'))
error(javachk('awt'))
```

#### Generate Error in User-Defined Script

If you write a script, myFile, that displays a Java Frame and want it to error gracefully if a frame cannot be displayed, do the following:

```
error(javachk('awt','myFile'));
myFrame = java.awt.Frame;
myFrame.setVisible(1);
```

If the script cannot display a frame, it displays this error:

myFile is not supported on this platform.

## Input Arguments

### **feature** — Java feature

'awt' | 'desktop' | 'jvm' | 'swing'

Java feature, specified as one of these values:

'awt'	Java GUI components in the Abstract Window Toolkit (AWT) components are available.
'desktop'	MATLAB interactive desktop is running.
'jvm'	Java Virtual Machine software (JVM™) is running.
'swing'	Swing components (Java lightweight GUI components in the Java Foundation Classes) are available.

### **component** — Identifier

string

Identifier, specified as a string, to display in the error message.

Data Types: char

## Output Arguments

### **MSG** — Error message

structure

Error message, returned as a structure with these fields:

If it is available, javachk returns an error structure with empty **message** and **identifier** fields.

### **message** — Message

string | empty

Message, specified as a string.

**identifier – Identifier**

string | empty

Identifier, specified as a string.

**See Also**

error | usejava

# javaclasspath

Return Java class path or specify dynamic path

## Syntax

```
javaclasspath
javaclasspath(' -dynamic')
javaclasspath(' -static')

dpath = javaclasspath
spath = javaclasspath(' -static')
jpath = javaclasspath(' -all')

javaclasspath(dpath)
javaclasspath(dpath1,dpath2)

javaclasspath(statusmsg)
```

## Description

javaclasspath displays the static and dynamic segments of the Java class path.

javaclasspath(' -dynamic' ) displays the dynamic path.

javaclasspath(' -static' ) displays the static path.

dpath = javaclasspath returns the dynamic path, dpath.

spath = javaclasspath(' -static' ) returns the static path, spath.

jpath = javaclasspath(' -all' ) returns the entire path, jpath. The returned cell array contains first the static segment of the path, and then the dynamic segment.

javaclasspath(dpath) changes the dynamic path to dpath. Use this syntax to reload Java classes.

javaclasspath(dpath1,dpath2) changes the dynamic path to the concatenation of paths dpath1,dpath2.

`javaclasspath(statusmsg)` enables or disables the display of status messages.

## Examples

### Modify Path Using Cell Array

Create a cell array with two path values.

```
dpath = {'http://domain.com','http://some.domain.com/jarfile.jar'};
```

Set message flag to display class-loading messages.

```
javaclasspath('-v1')
```

Modify path.

```
javaclasspath(dpath)
```

```
Loading following class path(s) from local file system:
```

```
* http://domain.com
```

```
* http://some.domain.com/jarfile.jar
```

Display updated dynamic path.

```
javaclasspath('-dynamic')
```

```
DYNAMIC JAVA PATH
```

```
http://domain.com
```

```
http://some.domain.com/jarfile.jar
```

MATLAB adds folders from `dpath` to the existing path.

### Capture Contents of Dynamic Path

Create a cell array, `p`, with the entries of the dynamic path.

```
javaclasspath('-v0') %Suppress display of class-loading messages
```

```
p = javaclasspath
```

```
p =
```

```
{}
```

If there are no entries on the dynamic path, MATLAB creates an empty cell array.

## Input Arguments

### **dpath** — Path entries

string | cell array of strings

Path entries, specified as a string or cell array of strings, to specify for the dynamic path. Converts relative paths to absolute paths.

Example: `javaclasspath('http://domain.com')`

Data Types: char | cell

### **dpath1, dpath2** — Path entries

string | cell array of strings

Path entries, specified as a string or cell array of strings, concatenated, to specify for the dynamic path.

Data Types: char | cell

### **statusmsg** — Message flag

'-v0' (default) | '-v1'

Message flag, specified as one of these values:

- |       |                                                                                    |
|-------|------------------------------------------------------------------------------------|
| '-v0' | Does not display status messages while loading the Java path from the file system. |
| '-v1' | Displays status messages.                                                          |

Controls status message display from the `javaclasspath`, `javaaddpath`, and `javarmpath` functions.

## Output Arguments

### **dpath** — Dynamic path entries

cell array of strings

Dynamic path entries for the current path, returned as a cell array of strings. If no path entries are defined, `dpath` is an empty cell array.

### **spath** — Static path entries

cell array of strings

Static path entries for the current path, returned as a cell array of strings. If no path entries are defined, `spath` is an empty cell array.

### **jpath** — All path entries

cell array of strings

All path entries, returned as a cell array of strings. If no path entries are defined, `jpath` is an empty cell array.

## More About

### Static Path

The static path is a segment of the Java path which is loaded at the start of each MATLAB session from the MATLAB built-in Java path and the file `javaclasspath.txt`.

The static Java path offers better Java class-loading performance than the dynamic Java path. However, to modify the static Java path you need to edit the file `javaclasspath.txt` and restart MATLAB. For more information, see “The Static Path”.

### Dynamic Path

The dynamic path is a segment of the Java path which is loaded any time during a MATLAB session using the `javaclasspath` function.

You can define the dynamic path (using `javaclasspath`), modify the path (using `javaaddpath` and `javarmppath`), and refresh the Java class definitions for all classes on the dynamic path (using `clear java`) without restarting MATLAB. For more information, see “The Dynamic Path”.

### Tips

- MATLAB searches the static path before the dynamic path.

- Java classes on the static path should not have dependencies on classes on the dynamic path. Such dependencies produce run-time errors.
- MATLAB calls the `clear java` command whenever you change the dynamic path. This command clears the definitions of all Java classes defined by files on the dynamic class path, removes all global variables and variables from the base workspace, and removes all compiled scripts, functions, and MEX-functions from memory.
- MATLAB displays a warning if you add an entry to the dynamic path that is already specified on the static path.
- “The Java Class Path”

### See Also

`clear` | `javaaddpath` | `javarmpath`

## **matlab.exception.JavaException class**

**Package:** matlab.exception

Capture error information for Java exception

### **Description**

Process information from a `matlab.exception.JavaException` object to handle Java errors thrown from Java methods called from MATLAB. This class is derived from `MException`.

### **Construction**

`e = matlab.exception.JavaException(msgID, errMsg, excObj)` constructs instance `e` of `matlab.exception.JavaException` class.

### **Input Arguments**

**msgID**

message identifier

**errMsg**

error message string

**excObj**

`java.lang.Throwable` object that caused the exception

### **Output Arguments**

**e**

Instance of `matlab.exception.JavaException` class

## Properties

### ExceptionObject

Java exception object that caused the error.

## Tips

- You do not typically construct a `matlab.exception.JavaException` object explicitly. MATLAB automatically constructs a `JavaException` object whenever Java throws an exception. The `JavaException` object wraps the original Java exception.

## Copy Semantics

Handle. To learn how handle classes affect copy operations, see “Copying Objects” in the MATLAB documentation.

## Examples

```
try
 java.lang.Class.forName('foo');
catch e
 e.message
 if(isa(e, 'matlab.exception.JavaException'))
 ex = e.ExceptionObject;
 assert(isJava(ex));
 ex.printStackTrace;
 end
end
```

# javaMethod

Call Java method

## Syntax

```
javaMethod(MethodName,JavaObj,x1,...,xN)
javaMethod(StaticMethodName,ClassName,x1,...,xN)
```

## Description

`javaMethod(MethodName,JavaObj,x1,...,xN)` calls the method in the class of the Java object array with the signature matching the arguments `x1,...,xN`.

`javaMethod(StaticMethodName,ClassName,x1,...,xN)` calls the static method in class `ClassName`.

## Examples

### Call Method on Java Object

Create a `java.util.Date` object, `myDate`, and change the month to 3.

```
myDate = java.util.Date;
javaMethod('setMonth',myDate,3);
```

### Call Static Method

Call `java.lang.Double` static method, `isNaN`, to test variable `num`.

```
num = 2.2;
if javaMethod('isNaN','java.lang.Double',num)
 disp('This is not a number')
end
```

Since `num` contains a number, no message is displayed.

### Call Method Specified at Runtime

This example, searching for a text pattern in a string, uses variables for the pattern and for the search method. These variables could be set at runtime from user input.

Choose method, `startsWith`, and identify pattern, `str`.

```
fnc = 'startsWith';
str = java.lang.String('Four score');
```

Identify text to search.

```
gAddress = java.lang.String('Four score and seven years ago');
```

Search `gAddress`.

```
javaMethod(fnc,gAddress,str)
```

```
ans =
 1
```

`gAddress` starts with the words `Four score`.

## Input Arguments

### **MethodName** — Name of nonstatic Java method

string

Name of nonstatic Java method, specified as a string.

Data Types: char

### **JavaObj** — Array

Java object

Array, specified as a Java object of the class containing the method.

### **x1, ..., xN** — Java method input arguments

any type

Java method input arguments, 1 through N (if any), required by `MethodName` or `StaticMethodName`, specified by any type. The argument type is specified by the method argument list.

**StaticMethodName — Name of static Java method**

string

Name of static Java method, specified as a string.

Data Types: char

**ClassName — Name of Java class**

string

Name of Java class, specified as a string, containing `StaticMethodName`.

Data Types: char

## More About

### Tips

- In most cases, use either MATLAB or Java syntax to call methods on Java objects:

```
% MATLAB syntax
method(object, arg1, ..., argn)

/* Java syntax */
object.method(arg1, ..., argn)
```

- Use `javaMethod` to call methods having names that exceed the maximum length of a MATLAB identifier. (Call the `nameLengthmax` function to obtain the maximum identifier length.)

This is the only way you can call such a method in MATLAB. For example, if you have the following function:

```
javaMethod('DataDefinitionAndDataManipulationTransactions', T);
```

- Use `javaMethod` when you want to specify the method name as a variable, to be invoked at runtime. When calling a static method, you also can use a variable in place of the class name argument. For example, see “Call Method Specified at Runtime” on page 1-4139.

- “Calling Syntax”

## javaMethodEDT

Call Java method from Event Dispatch Thread (EDT)

### Syntax

```
javaMethodEDT (MethodName,JavaObj,x1,...,xN)
javaMethodEDT (StaticMethodName,ClassName,x1,...,xN)
```

### Description

javaMethodEDT (MethodName,JavaObj,x1,...,xN) calls the method in the class of the Java object array with the signature matching the arguments x1,...,xN from the Event Dispatch Thread (EDT)

javaMethodEDT (StaticMethodName,ClassName,x1,...,xN) calls the static method in class ClassName.

### Examples

#### Call Method from EDT

Create a `java.util.Vector` object, `v`, and add a `string` element.

```
v = java.util.Vector;
javaMethodEDT('add',v,'string');
```

### Input Arguments

#### MethodName — Name of nonstatic Java method

`string`

Name of nonstatic Java method, specified as a string.

Data Types: `char`

**JavaObj — Array**

Java object

Array, specified as a Java object of the class containing the method.

**x1, . . . , xN — Java method input arguments**

any type

Java method input arguments, 1 through N (if any), required by `MethodName` or `StaticMethodName`, specified by any type. The argument type is specified by the method argument list.

**StaticMethodName — Name of static Java method**

string

Name of static Java method, specified as a string.

Data Types: char

**ClassName — Name of Java class**

string

Name of Java class, specified as a string, containing `StaticMethodName`.

Data Types: char

## More About

**EDT**

The EDT is the Event Dispatch Thread, used in Java.

**See Also**

`import` | `isjava` | `javaMethod` | `javaObjectEDT` | `methods`

# javaObject

Call Java constructor

## Syntax

```
JavaObj = javaObject(ClassName, x1, . . . , xN)
```

## Description

JavaObj = javaObject(ClassName, x1, . . . , xN) returns Java object array, JavaObj, created by the Java constructor for the class with the argument list matching x1, . . . , xN.

## Examples

### Create Java Object

Create a Java object, strObj, of class java.lang.String.

```
strObj = javaObject('java.lang.String', 'hello');
```

## Input Arguments

### ClassName — Name of Java class

string

Name of Java class, specified as a string.

Data Types: char

### x1, . . . , xN — Java constructor input arguments

any type

Java constructor input arguments, 1 through N (if any), required by ClassName, specified by any type. The argument type is specified by the class constructor argument list.

## More About

- “Using the javaObjectEDT Function”

## See Also

`import` | `javaArray` | `javaMethod` | `javaObjectEDT` | `methods`

## javaObjectEDT

Call Java constructor on Event Dispatch Thread (EDT)

### Syntax

```
JavaObj = javaObjectEDT(ClassName, x1, . . . , xN)
```

### Description

JavaObj = javaObjectEDT(ClassName, x1, . . . , xN) returns Java object array, JavaObj, created from the EDT by the Java constructor for the class with the signature matching the arguments x1, . . . , xN.

### Examples

#### Construct Java Object Array from the EDT

```
f = javaObjectEDT('javax.swing.JFrame', 'New Title');
```

#### Call Method on Java Object

Create a JOptionPane on the EDT.

```
optPane = javaObjectEDT('javax.swing.JOptionPane');
```

Call the createDialog method on the EDT.

```
dlg = optPane.createDialog([], 'Sample Dialog');
```

### Input Arguments

#### ClassName — Name of Java class

string

Name of Java class, specified as a string.

Data Types: char

**x1, . . . , xN — Java constructor input arguments**

any type

Java constructor input arguments, 1 through N (if any), required by `ClassName`, specified by any type. The argument type is specified by the class constructor argument list.

## More About

### EDT

The EDT is the Event Dispatch Thread, used in Java.

### Tips

- MATLAB calls methods on `JavaObj` from the EDT.
- Static methods on the specified class or Java object run on the MATLAB thread unless called using the `javaMethodEDT` function.

### See Also

`import` | `javaMethodEDT` | `javaObject` | `methods`

## javarmpath

Remove entries from dynamic Java class path

### Syntax

```
javarmpath(dpath1, ..., dpathN)
```

### Description

`javarmpath(dpath1, ..., dpathN)` removes one or more files or folders from the current dynamic class path.

### Examples

#### Remove Folder from Dynamic Path

In order to preserve the state of the dynamic path on your system, this example first adds folders to the path, then removes one of these folders.

Create a variable that points to the MATLAB examples folder.

```
expath = fullfile(matlabroot, 'extern', 'examples')
```

```
expath =
```

```
C:\Program Files\MATLAB\R2012b\extern\examples
```

The path reflects the folder to your MATLAB installation.

Add two folders to the path.

```
javaclasspath({...
 expath, ...
 'http://www.example.com'})
javaclasspath('-dynamic')
```

```
DYNAMIC JAVA PATH
```

```
C:\Program Files\MATLAB\R2012b\extern\examples
http://www.example.com
```

The output displays these new folders on your existing path.

Remove one folder.

```
javarmpath(expath)
javaclasspath('-dynamic')
```

```
DYNAMIC JAVA PATH
```

```
http://www.example.com
```

The path no longer contains the examples folder.

## Input Arguments

**dpath1, ..., dpathN — Folders or JAR files**

string

Folders or JAR files, specified as strings, to remove from path.

Data Types: char

## More About

### Tips

- MATLAB calls the `clear java` command whenever you change the dynamic path. This command clears the definitions of all Java classes defined by files on the dynamic class path, removes all global variables and variables from the base workspace, and removes all compiled scripts, functions, and MEX-functions from memory.
- “Bringing Java Classes into MATLAB Workspace”

## See Also

### Functions

`clear` | `javaaddpath` | `javaclasspath`

## join

Merge two tables by matching up rows using key variables

### Syntax

```
C = join(A,B)
C = join(A,B,Name,Value)
[C,ib] = join(___)
```

### Description

`C = join(A,B)` merges tables **A** and **B** by matching up rows using all the variables with the same name as key variables. The key values must be common to both **A** and **B**, except for order.

`join` retains all the variables from **A** and appends the corresponding contents from the nonkey variables of **B**.

`C = join(A,B,Name,Value)` joins the tables with additional options specified by one or more **Name,Value** pair arguments.

For example, you can specify the variables to use as key variables.

`[C,ib] = join( ___ )` also returns an index vector, **ib**, such that each element of **ib** identifies the row in **B** that corresponds to that row in the output table, **C**. You can use this syntax with any of the input arguments of the previous syntaxes.

### Examples

#### Append Values from One Table to Another

Create a table, **A**.

```
A = table({'John','Jane','Jim','Jerry','Jill'},[1;2;1;2;1],...
 'VariableNames',{'Employee' 'Department'})
```

**A** =

Employee	Department
'John'	1
'Jane'	2
'Jim'	1
'Jerry'	2
'Jill'	1

Create a table, B, with a variable in common with A.

```
B = table([1 2]', {'Mary' 'Mike'}', ...
 'VariableNames', {'Department' 'Manager'})
```

B =

Department	Manager
1	'Mary'
2	'Mike'

Create a new table, C, containing data from tables A and B. Use the `join` function to repeat and append `Manager` data from table B to the data from table A based on the key variable, `Department`.

```
C = join(A,B)
```

C =

Employee	Department	Manager
'John'	1	'Mary'
'Jane'	2	'Mike'
'Jim'	1	'Mary'
'Jerry'	2	'Mike'
'Jill'	1	'Mary'

### Merge Tables with One Variable in Common

Create a table, A.

```
A = table([5;12;23;2;6], ...
```

```
{'cereal';'pizza';'salmon';'cookies';'pizza'},...
'VariableNames',{ 'Age', 'FavoriteFood'},...
'RowNames',{ 'Amy', 'Bobby', 'Holly', 'Harry', 'Sally'}}
```

A =

	Age	FavoriteFood
Amy	5	'cereal'
Bobby	12	'pizza'
Holly	23	'salmon'
Harry	2	'cookies'
Sally	6	'pizza'

Create a table, B, with one variable in common with A.

```
B = table({'cereal';'cookies';'pizza';'salmon';'cake'},...
[110;160;140;367;243],...
{'B';'D';'B-';'A';'C-'},...
'VariableNames',{ 'FavoriteFood', 'Calories', 'NutritionGrade'})
```

B =

FavoriteFood	Calories	NutritionGrade
'cereal'	110	'B'
'cookies'	160	'D'
'pizza'	140	'B-'
'salmon'	367	'A'
'cake'	243	'C-'

Create a new table, C, with data from tables A and B. Use FavoriteFood as a key variable to the join function.

```
C = join(A,B)
```

C =

	Age	FavoriteFood	Calories	NutritionGrade
Amy	5	'cereal'	110	'B'
Bobby	12	'pizza'	140	'B-'

Holly	23	'salmon'	367	'A'
Harry	2	'cookies'	160	'D'
Sally	6	'pizza'	140	'B-'

Table C does not include information from the last row of table B about 'cake' since there is no corresponding entry in table A.

### Merge Tables by Specifying One Key Variable

Create a table, A.

```
A = table([10;4;2;3;7],[5;4;9;6;1],[10;3;8;8;4])
```

A =

Var1	Var2	Var3
——	——	——
10	5	10
4	4	3
2	9	8
3	6	8
7	1	4

Create a table, B, giving Var2 the same contents as Var2 from table A.

```
B = table([6;1;1;6;8],[5;4;9;6;1])
```

B =

Var1	Var2
——	——
6	5
1	4
1	9
6	6
8	1

Create a new table, C, containing data from tables A and B. Use Var1 in table A and Var2 in table B as key variables to the `join` function.

```
C = join(A,B, 'Keys', 'Var2')
```

C =

Var1_A	Var2	Var3	Var1_B
10	5	10	6
4	4	3	1
2	9	8	1
3	6	8	6
7	1	4	8

`join` adds a unique suffix to the nonkey variable `Var1` to distinguish the data from tables A and B.

### Keep One Copy of Nonkey Variables

Create a new table with data from tables A and B. If any nonkey variables have the same name in both tables, keep only the copy from table A.

Create a table, A.

```
A = table([10;4;2;3;7],[5;4;9;6;1])
```

A =

Var1	Var2
10	5
4	4
2	9
3	6
7	1

Create a table, B, giving `Var2` the same contents as `Var2` from table A.

```
B = table([6;1;1;6;8],[5;4;9;6;1],[10;3;8;8;4])
```

B =

Var1	Var2	Var3
6	5	10
1	4	3

1	9	8
6	6	8
8	1	4

Create a new table, **C**, with data from tables **A** and **B**. Use **Var2** as a key variable to the **join** function and keep only the copy of **Var1** from table **A**.

```
C = join(A,B, 'Keys', 'Var2', 'KeepOneCopy', 'Var1')
```

C =

Var1	Var2	Var3
10	5	10
4	4	3
2	9	8
3	6	8
7	1	4

**C** does not contain the **Var1** data from table **B**.

### Merge Tables Using Row Names as Keys

Create a table, **A**.

```
A = table(['M';'M';'F';'F';'F'],[38;43;38;40;49],...
 'VariableNames',{ 'Gender' 'Age'},...
 'RowNames',{ 'Smith' 'Johnson' 'Williams' 'Jones' 'Brown'})
```

A =

	Gender	Age
Smith	M	38
Johnson	M	43
Williams	F	38
Jones	F	40
Brown	F	49

Create a table, **B**, such that there is a one-to-one correspondence between the rows of **A** and the rows of **B**.

```
B = table([64;69;67;71;64],...
```

```
[119;163;133;176;131],...
[122 80; 109 77; 117 75; 124 93; 125 83],...
'VariableNames',{'Height' 'Weight' 'BloodPressure'},...
'RowNames',{'Brown' 'Johnson' 'Jones' 'Smith' 'Williams'})
```

B =

	Height	Weight	BloodPressure	
	_____	_____	_____	_____
Brown	64	119	122	80
Johnson	69	163	109	77
Jones	67	133	117	75
Smith	71	176	124	93
Williams	64	131	125	83

Create a new table, C, with data from tables A and B. Use the row names as keys to the `join` function.

```
C = join(A,B, 'Keys', 'RowNames')
```

C =

	Gender	Age	Height	Weight	BloodPressure	
	_____	_____	_____	_____	_____	_____
Smith	M	38	71	176	124	93
Johnson	M	43	69	163	109	77
Williams	F	38	64	131	125	83
Jones	F	40	67	133	117	75
Brown	F	49	64	119	122	80

The rows of C are in the same order as A.

### Merge Tables Using Left and Right Keys

Create a table, A.

```
A = table([10;4;2;3;7],[5;4;9;6;1],[10;3;8;8;4])
```

A =

Var1	Var2	Var3
_____	_____	_____

10	5	10
4	4	3
2	9	8
3	6	8
7	1	4

Create a table, **B**, giving **Var2** the same contents as **Var1** from table **A**, except for order.

```
B = table([6;1;1;6;8],[2;3;4;7;10])
```

B =

Var1	Var2
6	2
1	3
1	4
6	7
8	10

Create a new table, **C**, containing data from tables **A** and **B**. Use **Var1** from table **A** with **Var2** from table **B** as key variables to the `join` function.

```
[C,ib] = join(A,B, 'LeftKeys',1, 'RightKeys',2)
```

C =

Var1_A	Var2	Var3	Var1_B
10	5	10	8
4	4	3	1
2	9	8	6
3	6	8	1
7	1	4	6

ib =

```
5
3
1
2
4
```

C is the horizontal concatenation of A and B (`ib, 2`).

## Input Arguments

### **A, B** — Input tables

tables

Input tables, specified as tables. For all key variables, each row of A must match exactly one row in B.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

Example: 'Keys', 2 uses the second variable in A and the second variable in B as key variables.

### **'Keys'** — Variables to use as keys

positive integer | vector of positive integers | variable name | cell array of variable names | logical vector | 'RowNames'

Variables to use as keys, specified as the comma-separated pair consisting of 'Keys' and a positive integer, vector of positive integers, variable name, cell array of variable names, logical vector, or 'RowNames'.

If you specify the string 'RowNames', then `join` uses the row names of A and row names of B as keys. In this case, there must be a row in B for every row in A.

You cannot use the 'Keys' name-value pair argument with the 'LeftKeys' and 'RightKeys' name-value pair arguments.

Example: 'Keys', [1 3] uses the first and third variables from A and B as a key variables.

### **'LeftKeys'** — Variables to use as keys in A

positive integer | vector of positive integers | variable name | cell array of variable names | logical vector

Variables to use as keys in A, specified as the comma-separated pair consisting of 'LeftKeys' and a positive integer, vector of positive integers, variable name, cell array of variable names, or logical vector.

You must use the 'LeftKeys' name-value pair argument in conjunction with the 'RightKeys' name-value pair argument. 'LeftKeys' and 'RightKeys' both must specify the same number of key variables. `join` pairs key values based on their order.

Example: 'LeftKeys', 1 uses only the first variable in A as a key variable.

#### **'RightKeys' — Variables to use as keys in B**

positive integer | vector of positive integers | variable name | cell array of variable names | logical vector

Variables to use as keys in B, specified as the comma-separated pair consisting of 'RightKeys' and a positive integer, vector of positive integers, variable name, cell array of variable names, or logical vector.

You must use the 'RightKeys' name-value pair argument in conjunction with the 'LeftKeys' name-value pair argument. 'LeftKeys' and 'RightKeys' both must specify the same number of key variables. `join` pairs values in A and B based on their order.

Example: 'RightKeys', 3 uses only the third variable in B as a key variable.

#### **'LeftVariables' — Variables from A to include in C**

positive integer | vector of positive integers | variable name | cell array containing one or more variable names | logical vector

Variables from A to include in C, specified as the comma-separated pair consisting of 'LeftVariables' and a positive integer, vector of positive integers, variable name, cell array of variable names, or logical vector.

You can use 'LeftVariables' to include or exclude key variables, as well as nonkey variables from the output, C.

By default, `join` includes all variables from A.

#### **'RightVariables' — Variables from B to include in C**

positive integer | vector of positive integers | variable name | cell array containing one or more variable names | logical vector

Variables from **B** to include in **C**, specified as the comma-separated pair consisting of `'RightVariables'` and a positive integer, vector of positive integers, variable name, cell array of variable names, or logical vector.

You can use `'RightVariables'` to include or exclude key variables, as well as nonkey variables from the output, **C**.

By default, `join` includes all the variables from **B** except the key variables.

### **'KeepOneCopy'** — Variables for which `join` retains only the copy from **A**

variable name | cell array containing one or more variable names

Variables for which `join` retains only the copy from **A**, specified as the comma-separated pair consisting of `'KeepOneCopy'` and a variable name or a cell array containing one or more variable names.

Key variables appear once in **C**, but if nonkey variables with identical names occur in **A** and **B**, then `join` retains both copies in **C** by default. You must use the `'KeepOneCopy'` name-value pair to retain only the copy from **A**.

Example: `'KeepOneCopy', Var2` keeps only the copy from **A** of the nonkey variable `Var2`.

## Output Arguments

### **C** — Merged data from **A** and **B**

table

Merged data from **A** and **B**, returned as a table. The table, **C**, contains one row for each row in **A**, appearing in the same order. If **A** and **B** contain nonkey variables with the same name, `join` adds a unique suffix to the corresponding variable names in **C**, unless you specify the `'KeepOneCopy'` name-value pair argument.

`join` creates **C** by horizontally concatenating `A(:, LeftVars)` and `B(ib, RightVars)`. By default, `LeftVars` is all the variables of **A**, and `RightVars` is all the nonkey variables from **B**. Otherwise, `LeftVars` consists of the variables specified by the `'LeftVariables'` name-value pair argument, and `RightVars` consists of the variables specified by the `'RightVariables'` name-value pair argument.

You can store additional metadata such as descriptions, variable units, variable names, and row names in the output table, **C**. For more information, see [Table Properties](#).

**ib — Index to B**

column vector

Index to **B**, returned as a column vector. Each element of **ib** identifies the row in **B** that corresponds to that row in the output table, **C**.

## More About

**Key Variable**

Variable used to match and combine data between the input tables, **A** and **B**.

**Key Value**

Entry in a key variable of **A**.

**Algorithms**

The `join` function first finds one or more key variables. Then, `join` uses the key variables to find the row in input table **B** that matches each row in input table **A**, and combines those rows to create a row in output table **C**.

- If there is a one-to-one mapping between key values in **A** and **B**, then `join` sorts the data in **B** and appends it to table **A**.
- If there is a many-to-one mapping between key values in **A** and **B**, then `join` sorts and repeats the data in **B** before appending it to table **A**.
- If there is data in a key variable of **B** that does not map to a key value in **A**, then `join` does not include that data in the output table, **C**.

**See Also**

`innerjoin` | `outerjoin`

# juliandate

Convert MATLAB dates and time to Julian date

## Syntax

```
d = juliandate(t)
d = juliandate(t,dateType)
```

## Description

`d = juliandate(t)` returns a **double** array containing “Julian date” on page 1-4163 equivalent to the **datetime** values in `t`. If `t` has a time zone, then `juliandate` computes `d` with respect to UTC. `juliandate` ignores leap seconds unless the time zone of `t` is `UTCLeapSeconds`.

`d = juliandate(t,dateType)` returns the type of Julian dates specified by `dateType`. For example, you can convert **datetime** values to modified Julian dates.

## Examples

### Convert Datetime Array to Julian Dates

Create a **datetime** array. Then, convert the dates to Julian dates.

```
t = datetime('today') + calmonths(1:3)

t =
 20-Oct-2014 20-Nov-2014 20-Dec-2014

d = juliandate(t)

d =
```

```
1.0e+06 *
2.4570 2.4570 2.4570
```

## Input Arguments

### **t** — Input date and time

`datetime` array

Input date and time, specified as a `datetime` array.

### **dateType** — Type of Julian date values

'juliandate' (default) | 'modifiedjuliandate'

Type of Julian date values, specified as either 'juliandate' or 'modifiedjuliandate'.

- If `dateType` is 'juliandate', then `juliandate` converts the `datetime` values in `t` to the equivalent Julian dates. A Julian date is the number of days and fractional days since noon on November 24, 4712 BCE in the proleptic Gregorian calendar, or January 1, 4713 BCE in the proleptic Julian calendar.
- If `dateType` is 'modifiedjuliandate', then `juliandate` converts the `datetime` values in `t` to the equivalent modified Julian dates. A modified Julian date is the number of days and fractional days since November 17, 1858 00:00:00.

## More About

### Julian date

A Julian date is the number of days and fractional days since noon on November 24, 4712 BCE in the proleptic Gregorian calendar, or January 1, 4713 BCE in the proleptic Julian calendar.

`datenum` | `datetime` | `exceltime` | `posixtime` | `yyyymmdd`

# keyboard

Input from keyboard

## Syntax

keyboard

## Description

`keyboard`, when placed in a program `.m` file, stops execution of the file and gives control to the keyboard. The special status is indicated by a **K** appearing before the prompt. You can examine or change variables; all MATLAB commands are valid. This keyboard mode is useful for debugging your functions.

To terminate the keyboard mode, type `return`, and then press **Enter**. To terminate keyboard mode and exit the function, type `dbquit`, and press **Enter**.

## See Also

`dbstop` | `input` | `quit` | `pause` | `return`

## keys

**Class:** `containers.Map`

**Package:** `containers`

Identify keys of `containers.Map` object

## Syntax

```
keySet = keys(mapObj)
```

## Description

`keySet = keys(mapObj)` returns cell array `keySet`, which contains all of the keys in `mapObj`.

## Input Arguments

**mapObj**

Object of class `containers.Map`.

## Output Arguments

**keySet**

1-by-n cell array, where n is the number of keys in `mapObj`.

## Examples

### Get the Keys in a Map

Create a map, and view the keys in the map:

```
myKeys = {'a', 'b', 'c'};
myValues = [1,2,3];
mapObj = containers.Map(myKeys,myValues);
```

```
keySet = keys(mapObj)
```

This code returns 1-by-3 cell array `keySet`:

```
keySet =
 'a' 'b' 'c'
```

# kron

Kronecker tensor product

## Syntax

$K = \text{kron}(A, B)$

## Description

$K = \text{kron}(A, B)$  returns the Kronecker tensor product of matrices  $A$  and  $B$ . If  $A$  is an  $m$ -by- $n$  matrix and  $B$  is a  $p$ -by- $q$  matrix, then  $\text{kron}(A, B)$  is an  $m \cdot p$ -by- $n \cdot q$  matrix formed by taking all possible products between the elements of  $A$  and the matrix  $B$ .

## Examples

### Block Diagonal Matrix

Create a block diagonal matrix.

Create a 4-by-4 identity matrix and a 2-by-2 matrix that you want to be repeated along the diagonal.

```
A = eye(4);
B = [1 -1; -1 1];
```

Use `kron` to find the Kronecker tensor product.

```
K = kron(A,B)
```

$K =$

```

 1 -1 0 0 0 0 0 0
 -1 1 0 0 0 0 0 0
 0 0 1 -1 0 0 0 0
 0 0 -1 1 0 0 0 0
 0 0 0 0 1 -1 0 0
```

```
0 0 0 0 -1 1 0 0
0 0 0 0 0 0 1 -1
0 0 0 0 0 0 -1 1
```

The result is an 8-by-8 block diagonal matrix.

## Repeat Matrix Elements

Expand the size of a matrix by repeating elements.

Create a 2-by-2 matrix of ones and a 2-by-3 matrix whose elements you want to repeat.

```
A = [1 2 3; 4 5 6];
B = ones(2);
```

Calculate the Kronecker tensor product using `kron`.

```
K = kron(A,B)
```

```
K =
```

```
1 1 2 2 3 3
1 1 2 2 3 3
4 4 5 5 6 6
4 4 5 5 6 6
```

The result is a 4-by-6 block matrix.

## Sparse Laplacian Operator Matrix

This example visualizes a sparse Laplacian operator matrix.

The matrix representation of the discrete Laplacian operator on a two-dimensional,  $n$ -by- $n$  grid is a  $n*n$ -by- $n*n$  sparse matrix. There are at most five nonzero elements in each row or column. You can generate the matrix as the Kronecker product of one-dimensional difference operators. In this example  $n = 5$ .

```
n = 5;
I = speye(n,n);
E = sparse(2:n,1:n-1,1,n,n);
D = E+E' - 2*I;
A = kron(D,I)+kron(I,D);
```

Visualize the sparsity pattern with `spy`.

```
spy(A, 'k')
```

## Input Arguments

### **A, B** — Input matrices

scalars | vectors | matrices

Input matrices, specified as scalars, vectors, or matrices. If either A or B is sparse, then kron multiplies only nonzero elements and the result is also sparse.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical

Complex Number Support: Yes

## More About

### Kronecker Tensor Product

If  $A$  is an  $m$ -by- $n$  matrix and  $B$  is a  $p$ -by- $q$  matrix, then the Kronecker tensor product of  $A$  and  $B$  is a large matrix formed by multiplying  $B$  by each element of  $A$

$$A \otimes B = \begin{bmatrix} a_{11}B & a_{12}B & \cdots & a_{1n}B \\ a_{21}B & a_{22}B & \cdots & a_{2n}B \\ \vdots & \vdots & \ddots & \vdots \\ a_{m1}B & a_{m2}B & \cdots & a_{mn}B \end{bmatrix}.$$

For example, two simple 2-by-2 matrices produce

$$A = \begin{bmatrix} 1 & -2 \\ -1 & 0 \end{bmatrix}, \quad B = \begin{bmatrix} 4 & -3 \\ 2 & 3 \end{bmatrix}$$

$$A \otimes B = \begin{bmatrix} 1 \cdot 4 & 1 \cdot -3 & -2 \cdot 4 & -2 \cdot -3 \\ 1 \cdot 2 & 1 \cdot 3 & -2 \cdot 2 & -2 \cdot 3 \\ -1 \cdot 4 & -1 \cdot -3 & 0 \cdot 4 & 0 \cdot -3 \\ -1 \cdot 2 & -1 \cdot 3 & 0 \cdot 2 & 0 \cdot 3 \end{bmatrix} = \begin{bmatrix} 4 & -3 & -8 & 6 \\ 2 & 3 & -4 & -6 \\ -4 & 3 & 0 & 0 \\ -2 & -3 & 0 & 0 \end{bmatrix}.$$

## Using KeyValueStore Objects

Store key-value pairs for use with mapreduce

The `mapreduce` function automatically creates a `KeyValueStore` object during execution and uses it to store key-value pairs added by the map and reduce functions. Although you never need to explicitly create a `KeyValueStore` object to use `mapreduce`, you do need to use the `add` and `addmulti` object functions to interact with this object in the map and reduce functions.

## Examples

### Add Key-Value Pair to KeyValueStore in Map Function

The following map function uses the `add` function to add key-value pairs one at a time to an intermediate `KeyValueStore` object (named `intermKVStore`).

```
function MeanDistMapFun(data, info, intermKVStore)
 distances = data.Distance(~isnan(data.Distance));
 sumLenKey = 'sumAndLength';
 sumLenValue = [sum(distances), length(distances)];
 add(intermKVStore, sumLenKey, sumLenValue);
end
```

### Add Multiple Key-Value Pairs to KeyValueStore in Map Function

The following map function uses `addmulti` to add several key-value pairs to an intermediate `KeyValueStore` object (named `intermKVStore`). Note that this map function collects multiple keys in the `intermKeys` variable, and multiple values in the `intermVals` variable. This prepares a single call to `addmulti` to add all of the key-value pairs at once. It is a best practice to use a single call to `addmulti` rather than using `add` in a loop.

```
function meanArrivalDelayByDayMapper(data, ~, intermKVStore)
% Mapper function for the MeanByGroupMapReduceExample.

% Copyright 2014 The MathWorks, Inc.

% Data is an n-by-2 table: first column is the DayOfWeek and the second
% is the ArrDelay. Remove missing values first.
delays = data.ArrDelay;
```

```
day = data.DayOfWeek;
notNaN = ~isnan(delays);
day = day(notNaN);
delays = delays(notNaN);

% find the unique days in this chunk
[intermKeys,~,idx] = unique(day, 'stable');

% group delays by idx and apply @grpstatsfun function to each group
intermVals = accumarray(idx,delays,size(intermKeys),@countsum);
addmulti(intermKVStore,intermKeys,intermVals);

function out = countsum(x)
n = length(x); % count
s = sum(x); % mean
out = {[n, s]};
```

## Object Functions

add addmulti

## Create Object

The `mapreduce` function automatically creates `KeyValueStore` objects during execution.

# lastDirectory

**Class:** Tiff

Determine if current IFD is last in file

## Syntax

```
tf = lastDirectory(tiffobj)
```

## Description

`tf = lastDirectory(tiffobj)` returns `true` if the current image file directory (IFD) is the last IFD in the TIFF file; otherwise, `false`. If the file contains only one image, the current IFD is the last.

## Examples

### Determine if Current Directory is the Last Directory

Open a Tiff object and determine if the current directory is the last directory in the file.

```
t = Tiff('example.tif', 'r');
tf = lastDirectory(t)
```

```
tf =
```

```
0
```

The current directory is not the last directory in the file.

Close the Tiff object.

```
close(t)
```

- “Exporting Image Data and Metadata to TIFF Files”
- “Reading Image Data and Metadata from TIFF Files”

## References

This method corresponds to the `TIFFLastDirectory` function in the LibTIFF C API. To use this method, you must be familiar with the TIFF specification and technical notes. View this documentation at [LibTIFF - TIFF Library and Utilities](#).

`Tiff.setDirectory`

# Chart Line Properties

Control chart line appearance and behavior

Chart line properties control the appearance and behavior of a chart line object. By changing property values, you can modify certain aspects of the line. Use dot notation to refer to a particular object and property:

```
h = plot(1:10);
c = h.Color;
h.Color = 'red';
```

## Line

### LineStyle — Line style

'-' (default) | '--' | ':' | '-.' | 'none'

Line style, specified as one of the line style strings listed in this table.

String	Line Style	Resulting Line
'-'	Solid line	
'--'	Dashed line	
':'	Dotted line	
'-.'	Dash-dotted line	
'none'	No line	No line

### LineWidth — Line width

0.5 (default) | positive value

Line width, specified as a positive value in point units. If the line has markers, then the line width also affects the marker edges.

Example: 0.75

### Color — Line color

[0 0 0] (default) | RGB triplet | color string | 'none'

Line color, specified as an RGB triplet, a color string, or 'none'. The default RGB triplet value of [0 0 0] corresponds to black. If you specify the Color as 'none', then the line is invisible.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0, 1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[1 1 0]
'magenta'	'm'	[1 0 1]
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black'	'k'	[0 0 0]

Example: 'blue'

Example: [0 0 1]

### **AlignVertexCenters — Sharp vertical and horizontal lines**

'off' (default) | 'on'

Sharp vertical and horizontal lines, specified as 'off' or 'on'.

If the associated figure has a GraphicsSmoothing property set to 'on' and a Renderer property set to 'opengl', then the figure applies a smoothing technique to plots. In some cases, this smoothing technique can cause vertical and horizontal lines to appear uneven in thickness or color. Use the AlignVertexCenters property to eliminate the uneven appearance.

- 'off' — Do not sharpen vertical or horizontal lines. The lines might appear uneven in thickness or color.
- 'on' — Sharpen vertical and horizontal lines to eliminate an uneven appearance.

---

**Note:** You must have a graphics card that supports this feature. To see if the feature is supported, type `opengl info`. If it is supported, then the returned fields contain the line `SupportsAlignVertexCenters: 1`.

---

## Markers

### Marker — Marker symbol

'none' (default) | marker string

Marker symbol, specified as one of the marker strings listed in this table. By default, the chart line object does not display markers. Specifying a marker symbol adds markers at each data point or vertex.

String	Marker Symbol
'o'	Circle
'+'	Plus sign
'*'	Asterisk
'.'	Point
'x'	Cross
'square' or 's'	Square
'diamond' or 'd'	Diamond
'^'	Upward-pointing triangle
'v'	Downward-pointing triangle
'>'	Right-pointing triangle
'<'	Left-pointing triangle
'pentagram' or 'p'	Five-pointed star (pentagram)
'hexagram' or 'h'	Six-pointed star (hexagram)
'none'	No markers

Example: '+'

Example: 'diamond'

### MarkerSize — Marker size

6 (default) | positive value

Marker size, specified as a positive value in point units.

Example: 10

**MarkerEdgeColor — Marker outline color**

'auto' (default) | 'none' | RGB triplet | color string

Marker outline color, specified as one of these values:

- 'auto' — Use the same color as the Color property.
- 'none' — Use no color, which makes unfilled markers invisible.
- RGB triplet or color string — Use the specified color.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0, 1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[1 1 0]
'magenta'	'm'	[1 0 1]
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black'	'k'	[0 0 0]

Example: [0.5 0.5 0.5]

Example: 'blue'

**MarkerFaceColor — Marker fill color**

'none' (default) | 'auto' | RGB triplet | color string

Marker fill color, specified as one of these values:

- 'none' — Use no color, which makes the interior invisible.

- 'auto' — Use the same color as the `Color` property for the axes.
- RGB triplet or color string — Use the specified color.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range  $[0, 1]$ , for example,  $[0.4 \ 0.6 \ 0.7]$ . This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[ 1 1 0 ]
'magenta'	'm'	[ 1 0 1 ]
'cyan'	'c'	[ 0 1 1 ]
'red'	'r'	[ 1 0 0 ]
'green'	'g'	[ 0 1 0 ]
'blue'	'b'	[ 0 0 1 ]
'white'	'w'	[ 1 1 1 ]
'black'	'k'	[ 0 0 0 ]

Example: `[0.3 0.2 0.1]`

Example: `'green'`

## Plotted Data

### **XData** — **x values**

vector

*x* values, specified as a vector.

- For 2-D line plots, if you do not specify the *x* values, then MATLAB uses the indices of `YData` as the *x* values for the plot. `XData` and `YData` must have equal lengths.
- For 3-D line plots, if you do not specify the *x* values, then MATLAB uses the indices of `ZData` as the *x* values for the plot. `XData`, `YData`, and `ZData` must have equal lengths.

Example: `[1:10]`

## **YData — y values**

vector

y values, specified as a vector. For 2-D line plots, `XData` and `YData` must have equal lengths. For 3-D line plots, `XData`, `YData`, and `ZData` must have equal lengths.

Example: `[1:10]`

## **ZData — z values**

vector

z values for the 3-D line plot, specified as a vector. `XData`, `YData`, and `ZData` must have equal lengths.

Example: `[1:10]`

## **XDataSource — Variable linked to XData**

`''` (default) | string containing MATLAB workspace variable name

Variable linked to `XData`, specified as a string containing a MATLAB workspace variable name. MATLAB evaluates the variable in the base workspace to generate the `XData`.

By default, there is no linked variable so the value is an empty string, `''`. If you link a variable, then MATLAB does not update the `XData` values immediately. To force an update of the data values, use the `refreshdata` function.

---

**Note:** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

Example: `'x'`

## **YDataSource — Variable linked to YData**

`''` (default) | string containing MATLAB workspace variable name

Variable linked to `YData`, specified as a string containing a MATLAB workspace variable name. MATLAB evaluates the variable in the base workspace to generate the `YData`.

By default, there is no linked variable so the value is an empty string, `''`. If you link a variable, then MATLAB does not update the `YData` values immediately. To force an update of the data values, use the `refreshdata` function.

---

**Note:** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

Example: 'y'

### **ZDataSource** — Variable linked to ZData

' ' (default) | string containing MATLAB workspace variable name

Variable linked to **ZData**, specified as a string containing a MATLAB workspace variable name. MATLAB evaluates the variable in the base workspace to generate the **ZData**.

By default, there is no linked variable so the value is an empty string, ' '. If you link a variable, then MATLAB does not update the **ZData** values immediately. To force an update of the data values, use the `refreshdata` function.

---

**Note:** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

Example: 'z'

### **XDataMode** — Selection mode for XData

'auto' (default) | 'manual'

Selection mode for **XData**, specified as one of these values:

- 'auto' — Use the indices of the values in **YData** (or **ZData** for 3-D plots).
- 'manual' — Use manually specified values. To specify the values, set the **XData** property or specify the input argument **X** to the plotting function.

## Visibility

### **Visible** — Visibility of chart line

'on' (default) | 'off'

Visibility of chart line, specified as one of these values:

- 'on' — Display the chart line.

- 'off' — Hide the chart line without deleting it. You still can access the properties of an invisible chart line object.

**Clipping — Clipping of chart line to axes limits**

'on' (default) | 'off'

Clipping of chart line to the axes limits, specified as one of these values:

- 'on' — Do not display parts of the chart line that are outside the axes limits.
- 'off' — Display the entire chart line, even if parts of it appear outside the axes limits. Parts of the chart line might appear outside the axes limits if you create a plot, set `hold on`, freeze the axis scaling, and then create the chart line that is larger than the original plot.

**EraseMode — (removed) Technique to draw and erase objects**

'normal' (default) | 'none' | 'xor' | 'background'

---

**Note:** `EraseMode` has been removed. You can delete code that accesses the `EraseMode` property with minimal impact. If you were using `EraseMode` to create line animations, use the `animatedline` function instead.

---

Technique to draw and erase objects, specified as one of these values:

- 'normal' — Redraw the affected region of the display, performing the three-dimensional analysis necessary to correctly render all objects. This mode produces the most accurate picture, but is the slowest. The other modes are faster, but do not perform a complete redraw and, therefore, are less accurate.
- 'none' — Do not erase the object when it is moved or destroyed. After you erase the object with `EraseMode`, 'none', it is still visible on the screen. However, you cannot print the object because MATLAB does not store any information on its former location.
- 'xor' — Draw and erase the object by performing an exclusive OR (XOR) with the color of the screen beneath it. This mode does not damage the color of the objects beneath it. However, the object color depends on the color of whatever is beneath it on the display.
- 'background' — Erase the object by redrawing it in the axes background color, or the figure background color if the axes `Color` property is 'none'. This damages objects that are behind the erased object, but properly colors the erased object.

MATLAB always prints figures as if the `EraseMode` property of all objects is set to `'normal'`. This means graphics objects created with `EraseMode` set to `'none'`, `'xor'`, or `'background'` can look different on screen than on paper. On screen, MATLAB mathematically combines layers of colors and ignores three-dimensional sorting to obtain greater rendering speed. However, MATLAB does not apply these techniques to the printed output. Use the `getframe` command or other screen capture applications to create an image of a figure containing nonnormal mode objects.

## Identifiers

### Type — Type of graphics object

`'line'`

Type of graphics object, returned as `'line'`. Use this property to find all objects of a given type within a plotting hierarchy, for example, searching for the type using `findobj`.

### Tag — User-specified tag

`''` (default) | string

Tag to associate with the chart line, specified as a string. Tags provide a way to identify graphics objects. Use this property to find all objects with a specific tag within a plotting hierarchy, for example, searching for the tag using `findobj`.

Example: `'January Data'`

### UserData — Data to associate with chart line

`[]` (default) | scalar, vector, or matrix | cell array | character array | table | structure

Data to associate with the chart line object, specified as a scalar, vector, matrix, cell array, character array, table, or structure. MATLAB does not use this data.

To associate multiple sets of data or to attach a field name to the data, use the `getappdata` and `setappdata` functions.

Example: `1:100`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `struct` | `table` | `cell`

### DisplayName — Text used by legend

`''` (default) | string

Text used by the legend, specified as a string. The text appears next to an icon of the chart line.

- If you specify text for the chart line object as an input argument to the `legend` function, then the legend uses the specified text and updates the `DisplayName`.
- If you do not specify text for the chart line object as an input argument to the `legend` function, then the legend uses the text in the `DisplayName` property. If the `DisplayName` property does not contain any text, then the legend generates a string. The string has the form `'dataN'`, where N is the number assigned to the chart line object based on its location in the list of legend entries.

If you edit interactively the string in an existing legend, then MATLAB updates the `DisplayName` to the edited string.

Example: `'Text Description'`

### **Annotation — Legend icon display style**

Annotation object

Legend icon display style, returned as an `Annotation` object. Use this object to include or exclude the chart line from a legend.

- 1 Query the `Annotation` property to get the `Annotation` object.
- 2 Query the `LegendInformation` property of the `Annotation` object to get the `LegendEntry` object.
- 3 Specify the `IconDisplayStyle` property of the `LegendEntry` object to one of these values:
  - `'on'` — Include the chart line object in the legend as one entry (default).
  - `'off'` — Do not include the chart line object in the legend.
  - `'children'` — Include only children of the chart line object as separate entries in the legend.

If a legend already exists and you change the `IconDisplayStyle` setting, then you must call `legend` to update the display.

## **Parent/Child**

### **Parent — Parent of chart line**

axes object | group object | transform object

Parent of chart line, specified as an axes, group, or transform object.

### **Children — Children of chart line**

empty `GraphicsPlaceholder` array

The chart line has no children. You cannot set this property.

### **HandleVisibility — Visibility of object handle**

'on' (default) | 'off' | 'callback'

Visibility of object handle in the `Children` property of the parent, specified as one of these values:

- 'on' — List the chart line object.
- 'off' — Do not list the chart line object. Use this option to hide object handles when a callback invokes a function that could damage the GUI, such as evaluating a user-typed string.
- 'callback' — List the chart line object in the `Children` property of the parent from within callbacks or functions invoked by callbacks, but not from within functions invoked from the command line. Use this option to protect a GUI from command-line users, while allowing callbacks to have access to objects.

If the chart line object is not listed in the `Children` property of the parent, then functions that obtain object handles by searching the object hierarchy or querying handle properties cannot return it. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

Hidden object handles are still valid. Set the root `ShowHiddenHandles` property to 'on' to list all object handles regardless of their `HandleVisibility` property setting.

## **Interactive Control**

### **ButtonDownFcn — Mouse-click callback**

' ' (default) | function handle | cell array | string

Mouse-click callback, specified as one of these values:

- Function handle

- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you click the chart line. If you specify this property using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The chart line object — You can access properties of the chart line object from within the callback function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see “Callback Definition”.

---

**Note:** If the `PickableParts` property is set to `'none'` or if the `HitTest` property is set to `'off'`, then this callback does not execute.

---

Example: `@myCallback`

Example: `{@myCallback, arg3}`

## **UIContextMenu — Context menu**

`uicontextmenu` object

Context menu, specified as a `uicontextmenu` object. Use this property to display a context menu when you right-click the chart line. Create the context menu using the `uicontextmenu` function.

---

**Note:** If the `PickableParts` property is set to `'none'` or if the `HitTest` property is set to `'off'`, then the context menu does not appear.

---

## **Selected — Selection state**

`'off'` (default) | `'on'`

Selection state, specified as one of these values:

- `'on'` — Selected. If you click the chart line when in plot edit mode, then MATLAB sets its `Selected` property to `'on'`. If the `SelectionHighlight` property also is set to `'on'`, then MATLAB displays selection handles around the chart line.
- `'off'` — Not selected.

### **SelectionHighlight** — Display of selection handles when selected

`'on'` (default) | `'off'`

Display of selection handles when selected, specified as one of these values:

- `'on'` — Display selection handles when the `Selected` property is set to `'on'`.
- `'off'` — Never display selection handles, even when the `Selected` property is set to `'on'`.

## Callback Execution Control

### **PickableParts** — Ability to capture mouse clicks

`'visible'` (default) | `'none'`

Ability to capture mouse clicks, specified as one of these values:

- `'visible'` — Can capture mouse clicks when visible. The `Visible` property must be set to `'on'` and you must click a part of the chart line that has a defined color. You cannot click a part that has an associated color property set to `'none'`. If the plot contains markers, then the entire marker is clickable if either the edge or the fill has a defined color. The `HitTest` property determines if the chart line responds to the click or if an ancestor does.
- `'none'` — Cannot capture mouse clicks. Clicking the chart line passes the click to the object below it in the current view of the figure window. The `HitTest` property of the chart line has no effect.

### **HitTest** — Response to captured mouse clicks

`'on'` (default) | `'off'`

Response to captured mouse clicks, specified as one of these values:

- `'on'` — Trigger the `ButtonDownFcn` callback of the chart line. If you have defined the `UIContextMenu` property, then invoke the context menu.

- 'off' — Trigger the callbacks for the nearest ancestor of the chart line that has a `HitTest` property set to 'on' and a `PickableParts` property value that enables the ancestor to capture mouse clicks.

---

**Note:** The `PickableParts` property determines if the chart line object can capture mouse clicks. If it cannot, then the `HitTest` property has no effect.

---

## **Interruptible — Callback interruption**

'on' (default) | 'off'

Callback interruption, specified as 'on' or 'off'. The `Interruptible` property determines if a running callback can be interrupted.

---

**Note:** There are two callback states to consider:

- The *running* callback is the currently executing callback.
  - The *interrupting* callback is a callback that tries to interrupt the running callback. Whenever MATLAB invokes a callback, that callback attempts to interrupt a running callback. The `Interruptible` property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the `BusyAction` property of the object owning the interrupting callback determines if it is discarded or put in the queue.
- 

If the `ButtonDownFcn` callback of the chart line is the running callback, then the `Interruptible` property determines if it another callback can interrupt it:

- 'on' — Interruptible. Interruption occurs at the next point where MATLAB processes the queue, such as when there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command.
  - If the running callback contains one of these commands, then MATLAB stops the execution of the callback at this point and executes the interrupting callback. MATLAB resumes executing the running callback when the interrupting callback completes. For more information, see “Interrupt Callback Execution”.
  - If the running callback does not contain one of these commands, then MATLAB finishes executing the callback without interruption.

- 'off' — Not interruptible. MATLAB finishes executing the running callback without any interruptions.

**BusyAction — Callback queuing**

'queue' (default) | 'cancel'

Callback queuing specified as 'queue' or 'cancel'. The `BusyAction` property determines how MATLAB handles the execution of interrupting callbacks.

---

**Note:** There are two callback states to consider:

- The *running* callback is the currently executing callback.
- The *interrupting* callback is a callback that tries to interrupt the running callback.

Whenever MATLAB invokes a callback, that callback attempts to interrupt a running callback. The `Interruptible` property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the `BusyAction` property of the object owning the interrupting callback determines if it is discarded or put in the queue.

---

If the `ButtonDownFcn` callback of the chart line tries to interrupt a running callback that cannot be interrupted, then the `BusyAction` property determines if it is discarded or put in the queue. Specify the `BusyAction` property as one of these values:

- 'queue' — Put the interrupting callback in a queue to be processed after the running callback finishes execution. This is the default behavior.
- 'cancel' — Discard the interrupting callback.

## Creation and Deletion Control

**CreateFcn — Creation callback**

' ' (default) | function handle | cell array | string

Creation callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments

- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you create the chart line. Setting the `CreateFcn` property on an existing chart line has no effect. You must define a default value for this property, or define this property using a `Name, Value` pair during chart line creation. MATLAB executes the callback after creating the chart line and setting all of its properties.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The chart line object — You can access properties of the chart line object from within the callback function. You also can access the chart line object through the `CallbackObject` property of the root, which can be queried using the `gcb0` function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see “Callback Definition”.

Example: `@myCallback`

Example: `{@myCallback, arg3}`

### **DeleteFcn — Deletion callback**

' ' (default) | function handle | cell array | string

Deletion callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you delete the chart line. MATLAB executes the callback before destroying the chart line so that the callback can access its property values.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The chart line object — You can access properties of the chart line object from within the callback function. You also can access the chart line object through the `CallbackObject` property of the root, which can be queried using the `gcbo` function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see “Callback Definition”.

Example: `@myCallback`

Example: `{@myCallback, arg3}`

### **BeingDeleted — Deletion status of chart line**

'off' (default) | 'on'

Deletion status of chart line, returned as 'on' or 'off'. MATLAB sets the `BeingDeleted` property to 'on' when the delete function of the chart line begins execution (see the `DeleteFcn` property). The `BeingDeleted` property remains set to 'on' until the chart line no longer exists.

Check the value of the `BeingDeleted` property to verify that the chart line is not about to be deleted before querying or modifying it.

## lasterr

Last error message

---

**Note:** `lasterr` will be removed in a future version. You can obtain information about any error that has been generated by catching an `MException`. See “Capture Information About Exceptions” in the Programming Fundamentals documentation.

---

## Syntax

```
msgstr = lasterr
[msgstr, msgid] = lasterr
lasterr('new_msgstr')
lasterr('new_msgstr', 'new_msgid')
[msgstr, msgid] = lasterr('new_msgstr', 'new_msgid')
```

## Description

`msgstr = lasterr` returns the last error message generated by the MATLAB software.

`[msgstr, msgid] = lasterr` returns the last error in `msgstr` and its message identifier in `msgid`. If the error was not defined with an identifier, `lasterr` returns an empty string for `msgid`. See “Message Identifiers” in the MATLAB Programming Fundamentals documentation for more information on the `msgid` argument and how to use it.

`lasterr('new_msgstr')` sets the last error message to a new string, `new_msgstr`, so that subsequent invocations of `lasterr` return the new error message string. You can also set the last error to an empty string with `lasterr('')`.

`lasterr('new_msgstr', 'new_msgid')` sets the last error message and its identifier to new strings `new_msgstr` and `new_msgid`, respectively. Subsequent invocations of `lasterr` return the new error message and message identifier.

`[msgstr, msgid] = lasterr('new_msgstr', 'new_msgid')` returns the last error message and its identifier, also changing these values so that subsequent

invocations of `lasterr` return the message and identifier strings specified by `new_msgstr` and `new_msgid` respectively.

## Examples

### Example 1

Here is a function that examines the `lasterr` string and displays its own message based on the error that last occurred. This example deals with two cases, each of which is an error that can result from a matrix multiply:

```
function matrix_multiply(A, B)
try
 A * B
catch
 errmsg = lasterr;
 if(strfind(errmsg, 'Inner matrix dimensions'))
 disp('** Wrong dimensions for matrix multiply')
 else
 if(strfind(errmsg, 'not defined for variables of class'))
 disp('** Both arguments must be double matrices')
 end
 end
end
end
```

If you call this function with matrices that are incompatible for matrix multiplication (e.g., the column dimension of **A** is not equal to the row dimension of **B**), MATLAB catches the error and uses `lasterr` to determine its source:

```
A = [1 2 3; 6 7 2; 0 -1 5];
B = [9 5 6; 0 4 9];

matrix_multiply(A, B)
** Wrong dimensions for matrix multiply
```

### Example 2

Specify a message identifier and error message string with `error`:

```
error('MyToolbox:angleTooLarge', ...
 'The angle specified must be less than 90 degrees.');
```

In your error handling code, use `lasterr` to determine the message identifier and error message string for the failing operation:

```
[errmsg, msgid] = lasterr
errmsg =
 The angle specified must be less than 90 degrees.
msgid =
 MyToolbox:angleTooLarge
```

## **See Also**

error | lasterror | rethrow | warning | lastwarn

---

# lasterror

Last error message and related information

---

**Note:** `lasterror` will be removed in a future version. You can obtain information about any error that has been generated by catching an `MException`. See “Capture Information About Exceptions” in the Programming Fundamentals documentation.

---

## Syntax

```
s = lasterror
s = lasterror(err)
s = lasterror('reset')
```

## Description

`s = lasterror` returns a structure `s` containing information about the most recent error issued by the MATLAB software. The return structure contains the following fields:

Fieldname	Description
<code>message</code>	Character array containing the text of the error message.
<code>identifier</code>	Character array containing the message identifier of the error message. If the last error issued by MATLAB had no message identifier, then the <code>identifier</code> field is an empty character array.
<code>stack</code>	Structure providing information on the location of the error. The structure has fields <code>file</code> , <code>name</code> , and <code>line</code> , and is the same as the structure returned by the <code>dbstack</code> function. If <code>lasterror</code> returns no stack information, <code>stack</code> is a 0-by-1 structure having the same three fields.

---

**Note** The `lasterror` return structure might contain additional fields in future versions of MATLAB.

---

The fields of the structure returned in `stack` are

Fieldname	Description
<code>file</code>	Name of the file in which the function generating the error appears. This field is the empty string if there is no file.
<code>name</code>	Name of the function in which the error occurred. If this is the primary function in the file, and the function name differs from the file name, <code>name</code> is set to the file name.
<code>line</code>	Line number of the file at which the error occurred.

See “Message Identifiers” in the MATLAB Programming Fundamentals documentation for more information on the syntax and usage of message identifiers.

`s = lasterror(err)` sets the last error information to the error message and identifier specified in the structure `err`. Subsequent invocations of `lasterror` return this new error information. The optional return structure `s` contains information on the previous error.

`s = lasterror('reset')` sets the last error information to the default state. In this state, the `message` and `identifier` fields of the return structure are empty strings, and the `stack` field is a 0-by-1 structure.

## Examples

### Example 1

Save the following MATLAB code in a file called `average.m`:

```
function y = average(x)
% AVERAGE Mean of vector elements.
% AVERAGE(X), where X is a vector, is the mean of vector elements.
% Nonvector input results in an error.
check_inputs(x)
y = sum(x)/length(x); % The actual computation

function check_inputs(x)
[m,n] = size(x);
if (~((m == 1) || (n == 1)) || (m == 1 && n == 1))
 error('AVG:NotAVector', 'Input must be a vector.')
end
```

Now run the function. Because this function requires vector input, passing a scalar value to it forces an error. The error occurs in subroutine `check_inputs`:

```
average(200)
Error using average>check_inputs (line 11)
Input must be a vector.
```

```
Error in average (line 5)
check_inputs(x)
```

Get the three fields from `lasterror`:

```
err = lasterror
err =
 message: [1x61 char]
 identifier: 'AVG:NotAVector'
 stack: [2x1 struct]
```

Display the text of the error message:

```
msg = err.message
msg =
 Error using average>check_inputs (line 11)
 Input must be a vector.
```

Display the fields containing the `stack` information. `err.stack` is a 2-by-1 structure because it provides information on the failing subroutine `check_inputs` and also the outer, primary function `average`:

```
st1 = err.stack(1,1)
st1 =
 file: 'd:\matlab_test\average.m'
 name: 'check_inputs'
 line: 11

st2 = err.stack(2,1)
st2 =
 file: 'd:\matlab_test\average.m'
 name: 'average'
 line: 5
```

---

**Note** As a rule, the name of your primary function should be the same as the name of the file that contains that function. If these names differ, MATLAB uses the file name in the `name` field of the `stack` structure.

---

## Example 2

`lasterror` is often used in conjunction with the `MException.rethrow` function in `try, catch` statements. For example,

```
try
 do_something
catch
 do_cleanup
 rethrow(lasterror)
end
```

## More About

### Tips

MathWorks is gradually transitioning MATLAB error handling to an object-oriented scheme that is based on the `MException` class. Although support for `lasterror` is expected to continue, using the static `MException.last` method of `MException` is preferable.

---

**Warning** `lasterror` and `MException.last` are not guaranteed to always return identical results. For example, `MException.last` updates its error status only on uncaught errors, where `lasterror` can update its error status on any error, whether it is caught or not.

---

### See Also

# lastwarn

Last warning message

## Syntax

```
msgstr = lastwarn
[msgstr, msgid] = lastwarn
lastwarn('new_msgstr')
lastwarn('new_msgstr', 'new_msgid')
[msgstr, msgid] = lastwarn('new_msgstr', 'new_msgid')
```

## Description

`msgstr = lastwarn` returns the last warning message generated by MATLAB, regardless of its display state.

`[msgstr, msgid] = lastwarn` returns the last warning in `msgstr` and its message identifier in `msgid`. If the warning was not defined with an identifier, `lastwarn` returns an empty string for `msgid`.

`lastwarn('new_msgstr')` sets the last warning message to a new string, `new_msgstr`, so that subsequent invocations of `lastwarn` return the new warning message string. You can also set the last warning to an empty string with `lastwarn('')`.

`lastwarn('new_msgstr', 'new_msgid')` sets the last warning message and its identifier to new strings `new_msgstr` and `new_msgid`, respectively. Subsequent invocations of `lastwarn` return the new warning message and message identifier.

`[msgstr, msgid] = lastwarn('new_msgstr', 'new_msgid')` returns the last warning message and its identifier, also changing these values so that subsequent invocations of `lastwarn` return the message and identifier strings specified by `new_msgstr` and `new_msgid`, respectively.

## Examples

Write a short function that generates a warning message. At the start of the function, enable any warnings that have a message identifier called `TestEnv:InvalidInput`:

```
function myfun(p1)
warning on TestEnv:InvalidInput;

exceedMax = find(p1 > 5000);
if any(exceedMax)
 warning('TestEnv:InvalidInput', ...
 '%d values in the "%s" array exceed the maximum.', ...
 length(exceedMax), inputname(1))
end
```

Pass an invalid value to the function:

```
dataIn = magic(10) - 2;

myfun(dataIn)
Warning: 2 values in the "dataIn" array exceed the maximum.
> In myfun at 4
```

Use `lastwarn` to determine the message identifier and error message string for the operation:

```
[warnmsg, msgid] = lastwarn
warnmsg =
 2 values in the "dataIn" array exceed the maximum.
msgid =
 TestEnv:InvalidInput
```

## More About

### Tips

`lastwarn` does not return warnings that are reported during the parsing of MATLAB commands. (Warning messages that include the failing file name and line number are parse-time warnings.)

## lcm

Least common multiple

### Syntax

```
L = lcm(A,B)
```

### Description

`L = lcm(A,B)` returns the least common multiples of the elements of `A` and `B`.

### Examples

#### Least Common Multiples of Double Array and a Scalar

```
A = [5 17; 10 60];
B = 45;
L = lcm(A,B)
```

```
L =
```

```
 45 765
 90 180
```

#### Least Common Multiples of Unsigned Integers

```
A = uint16([255 511 15]);
B = uint16([15 127 1023]);
L = lcm(A,B)
```

```
L =
```

```
 255 64897 5115
```

### Input Arguments

#### **A, B** — Input values

scalars, vectors, or arrays of real, positive integer values

Input values, specified as scalars, vectors, or arrays of real, positive integer values. A and B can be any numeric type, and they can be of different types within certain limitations:

- If A or B is of type `single`, then the other can be of type `single` or `double`.
- If A or B belongs to an integer class, then the other must belong to the same class or it must be a `double` scalar value.

A and B must be the same size or one must be a scalar.

Example: `[20 3 13],[10 6 7]`

Example: `int16([100 30 200]),int16([20 15 9])`

Example: `int16([100 30 200]),20`

Data Types: `single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64`

## Output Arguments

### **L** — Least common multiple

real, positive integer values

Least common multiple, returned as an array of real positive integer values. L is the same size as A and B, and it has the same type as A and B. If A and B are of different types, then L is returned as the `nondouble` type.

`gcd`

## ldl

Block LDL' factorization for Hermitian indefinite matrices

### Syntax

```
L = ldl(A)
[L,D] = ldl(A)
[L,D,P] = ldl(A)
[L,D,p] = ldl(A, 'vector')
[U,D,P] = ldl(A, 'upper')
[U,D,p] = ldl(A, 'upper', 'vector')
[L,D,P,S] = ldl(A)
[L,D,P,S] = LDL(A, THRESH)
[U,D,p,S] = LDL(A, THRESH, 'upper', 'vector')
```

### Description

`L = ldl(A)` returns only the "psychologically lower triangular matrix"  $L$  as in the two-output form. The permutation information is lost, as is the block diagonal factor  $D$ . By default, `ldl` references only the diagonal and lower triangle of  $A$ , and assumes that the upper triangle is the complex conjugate transpose of the lower triangle. Therefore `[L,D,P] = ldl(TRIL(A))` and `[L,D,P] = ldl(A)` both return the exact same factors. Note, this syntax is not valid for sparse  $A$ .

`[L,D] = ldl(A)` stores a block diagonal matrix  $D$  and a "psychologically lower triangular matrix" (i.e a product of unit lower triangular and permutation matrices) in  $L$  such that  $A = L*D*L'$ . The block diagonal matrix  $D$  has 1-by-1 and 2-by-2 blocks on its diagonal. Note, this syntax is not valid for sparse  $A$ .

`[L,D,P] = ldl(A)` returns unit lower triangular matrix  $L$ , block diagonal  $D$ , and permutation matrix  $P$  such that  $P'*A*P = L*D*L'$ . This is equivalent to `[L,D,P] = ldl(A, 'matrix')`.

`[L,D,p] = ldl(A, 'vector')` returns the permutation information as a vector,  $p$ , instead of a matrix. The  $p$  output is a row vector such that  $A(p,p) = L*D*L'$ .

$[U,D,P] = \text{ldl}(A, 'upper')$  references only the diagonal and upper triangle of  $A$  and assumes that the lower triangle is the complex conjugate transpose of the upper triangle. This syntax returns a unit upper triangular matrix  $U$  such that  $P' * A * P = U' * D * U$  (assuming that  $A$  is Hermitian, and not just upper triangular). Similarly,  $[L,D,P] = \text{ldl}(A, 'lower')$  gives the default behavior.

$[U,D,p] = \text{ldl}(A, 'upper', 'vector')$  returns the permutation information as a vector,  $p$ , as does  $[L,D,p] = \text{ldl}(A, 'lower', 'vector')$ .  $A$  must be a full matrix.

$[L,D,P,S] = \text{ldl}(A)$  returns unit lower triangular matrix  $L$ , block diagonal  $D$ , permutation matrix  $P$ , and scaling matrix  $S$  such that  $P' * S * A * S * P = L * D * L'$ . This syntax is only available for real sparse matrices, and only the lower triangle of  $A$  is referenced.  $\text{ldl}$  uses MA57 for sparse real symmetric  $A$ .

$[L,D,P,S] = \text{LDL}(A, \text{THRESH})$  uses  $\text{THRESH}$  as the pivot tolerance in MA57.  $\text{THRESH}$  must be a double scalar lying in the interval  $[0, 0.5]$ . The default value for  $\text{THRESH}$  is  $0.01$ . Using smaller values of  $\text{THRESH}$  may give faster factorization times and fewer entries, but may also result in a less stable factorization. This syntax is available only for real sparse matrices.

$[U,D,p,S] = \text{LDL}(A, \text{THRESH}, 'upper', 'vector')$  sets the pivot tolerance and returns upper triangular  $U$  and permutation vector  $p$  as described above.

## Examples

These examples illustrate the use of the various forms of the `ldl` function, including the one-, two-, and three-output form, and the use of the `vector` and `upper` options. The topics covered are:

- “Example 1 — Two-Output Form of `ldl`” on page 1-4206
- “Example 2 — Three Output Form of `ldl`” on page 1-4206
- “Example 3 — The Structure of  $D$ ” on page 1-4207
- “Example 4 — Using the 'vector' Option” on page 1-4207
- “Example 5 — Using the 'upper' Option” on page 1-4207
- “Example 6 — `linsolve` and the Hermitian indefinite solver” on page 1-4208

Before running any of these examples, you will need to generate the following positive definite and indefinite Hermitian matrices:

```
A = full(delsq(numgrid('L', 10)));
B = gallery('uniformdata',10,0);
M = [eye(10) B; B' zeros(10)];
```

The structure of  $M$  here is very common in optimization and fluid-flow problems, and  $M$  is in fact indefinite. Note that the positive definite matrix  $A$  must be full, as `ldl` does not accept sparse arguments.

### Example 1 — Two-Output Form of `ldl`

The two-output form of `ldl` returns  $L$  and  $D$  such that  $A - (L^*D^*L')$  is small,  $L$  is "psychologically unit lower triangular" (i.e., a permuted unit lower triangular matrix), and  $D$  is a block 2-by-2 diagonal. Note also that, because  $A$  is positive definite, the diagonal of  $D$  is all positive:

```
[LA,DA] = ldl(A);
fprintf(1, ...
'The factorization error ||A - LA*DA*LA' || is %g\n', ...
norm(A - LA*DA*LA'));
neginds = find(diag(DA) < 0)
```

Given a  $b$ , solve  $Ax=b$  using  $LA, DA$ :

```
bA = sum(A,2);
x = LA'\(DA\ (LA\bA));
fprintf(...
'The absolute error norm ||x - ones(size(bA)) || is %g\n', ...
norm(x - ones(size(bA))));
```

### Example 2 — Three Output Form of `ldl`

The three output form returns the permutation matrix as well, so that  $L$  is in fact unit lower triangular:

```
[Lm, Dm, Pm] = ldl(M);
fprintf(1, ...
'The error norm ||Pm'*M*Pm - Lm*Dm*Lm' || is %g\n', ...
norm(Pm'*M*Pm - Lm*Dm*Lm'));
fprintf(1, ...
'The difference between Lm and tril(Lm) is %g\n', ...
norm(Lm - tril(Lm)));
```

Given  $b$ , solve  $Mx=b$  using  $Lm, Dm,$  and  $Pm$ :

```

bM = sum(M,2);
x = Pm*(Lm'\(Dm\(Lm\(Pm'*bM))));
fprintf(...
'The absolute error norm ||x - ones(size(b))|| is %g\n', ...
norm(x - ones(size(bM))));

```

### Example 3 — The Structure of D

D is a block diagonal matrix with 1-by-1 blocks and 2-by-2 blocks. That makes it a special case of a tridiagonal matrix. When the input matrix is positive definite, D is almost always diagonal (depending on how definite the matrix is). When the matrix is indefinite however, D may be diagonal or it may express the block structure. For example, with A as above, DA is diagonal. But if you shift A just a bit, you end up with an indefinite matrix, and then you can compute a D that has the block structure.

```

figure; spy(DA); title('Structure of D from ldl(A)');
[Las, Das] = ldl(A - 4*eye(size(A)));
figure; spy(Das);
title('Structure of D from ldl(A - 4*eye(size(A)))');

```

### Example 4 — Using the 'vector' Option

Like the lu function, ldl accepts an argument that determines whether the function returns a permutation vector or permutation matrix. ldl returns the latter by default. When you select 'vector', the function executes faster and uses less memory. For this reason, specifying the 'vector' option is recommended. Another thing to note is that indexing is typically faster than multiplying for this kind of operation:

```

[Lm, Dm, pm] = ldl(M, 'vector');
fprintf(1, 'The error norm ||M(pm,pm) - Lm*Dm*Lm'|| is %g\n', ...
norm(M(pm,pm) - Lm*Dm*Lm'));

% Solve a system with this kind of factorization.
clear x;
x(pm,:) = Lm'\(Dm\(Lm\(bM(pm,:))));
fprintf('The absolute error norm ||x - ones(size(b))|| is %g\n', ...
norm(x - ones(size(bM))));

```

### Example 5 — Using the 'upper' Option

Like the chol function, ldl accepts an argument that determines which triangle of the input matrix is referenced, and also whether ldl returns a lower (L) or upper (L') triangular factor. For dense matrices, there are no real savings with using the upper triangular version instead of the lower triangular version:

```
Ml = tril(M);
[Lm1, Dm1, Pm1] = ld1(Ml, 'lower'); % 'lower' is default behavior.
fprintf(1, ...
'The difference between Lm1 and Lm is %g\n', norm(Lm1 - Lm));
[Umu, Dmu, pmu] = ld1(triu(M), 'upper', 'vector');
fprintf(1, ...
'The difference between Umu and Lm'' is %g\n', norm(Umu - Lm'));

% Solve a system using this factorization.
clear x;
x(pmu,:) = Umu\Dmu\((Umu'\(bM(pmu,:))));
fprintf(...
'The absolute error norm ||x - ones(size(b))|| is %g\n', ...
norm(x - ones(size(bM))));
```

When specifying both the 'upper' and 'vector' options, 'upper' must precede 'vector' in the argument list.

## Example 6 — linsolve and the Hermitian indefinite solver

When using the `linsolve` function, you may experience better performance by exploiting the knowledge that a system has a symmetric matrix. The matrices used in the examples above are a bit small to see this so, for this example, generate a larger matrix. The matrix here is symmetric positive definite, and below we will see that with each bit of knowledge about the matrix, there is a corresponding speedup. That is, the symmetric solver is faster than the general solver while the symmetric positive definite solver is faster than the symmetric solver:

```
Abig = full(delsq(numgrid('L', 30)));
bbig = sum(Abig, 2);
LSopts.POSDEF = false;
LSopts.SYM = false;
tic; linsolve(Abig, bbig, LSopts); toc;
LSopts.SYM = true;

## More About

### Algorithms

`ld1` uses the MA57 routines in the Harwell Subroutine Library (HSL) for real sparse matrices.

## **ldivide, .\**

Left array division

### **Syntax**

```
x = B.\A
x = ldivide(B,A)
```

### **Description**

`x = B.\A` divides each element of `A` by the corresponding element of `B`.

- If `A` and `B` are arrays, then they must be the same size.
- If either `A` or `B` is a scalar, then MATLAB expands the scalar value into an appropriately sized array.

`x = ldivide(B,A)` is an alternative way to divide `A` by `B`, but is rarely used. It enables operator overloading for classes.

### **Examples**

#### **Divide Two Numeric Arrays**

```
A = ones(2, 3);
B = [1 2 3; 4 5 6];
x = B.\A
```

```
x =
```

```
 1.0000 0.5000 0.3333
 0.2500 0.2000 0.1667
```

#### **Divide a Scalar by a Numeric Array**

```
C = 2;
```

```
D = [1 2 3; 4 5 6];
x = D.\C

x =

 2.0000 1.0000 0.6667
 0.5000 0.4000 0.3333
```

## Input Arguments

### A — Numerator

scalar | vector | matrix | multidimensional array

Numerator, specified as a scalar, vector, matrix or multidimensional array. If **B** is an integer data type, then **A** must be the same integer type or a scalar double.

**Data Types:** single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | duration

**Complex Number Support:** Yes

### B — Denominator

scalar | vector | matrix | multidimensional array

Denominator, specified as a scalar, vector, matrix or multidimensional array. If **A** is an integer data type, then **B** must be the same integer type or a scalar double.

**Data Types:** single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | duration

**Complex Number Support:** Yes

## Output Arguments

### x — Solution

scalar | vector | matrix | multidimensional array

Solution, returned as a scalar, vector, matrix or multidimensional array. If either **A** or **B** are integer data types, then **x** is that same integer data type.

## **More About**

### **Tips**

- MATLAB does not support complex integer division.

### **See Also**

`mldivide` | `mrdivide` | `rdivide`

## le, <=

Determine less than or equal to

### Syntax

```
A <= B
le(A,B)
```

### Description

`A <= B` returns a logical array with elements set to logical 1 (true) where A is less than or equal to B; otherwise, it returns logical 0 (false).

The test compares only the real part of numeric arrays. `le` returns logical 0 (false) where A or B have NaN or undefined categorical elements.

`le(A,B)` is an alternate way to execute `A <= B`, but is rarely used. It enables operator overloading for classes.

### Examples

#### Test Vector Elements

Find which vector elements are less than or equal to a given value.

Create a numeric vector.

```
A = [1 12 18 7 9 11 2 15];
```

Test the vector for elements that are less than or equal to 12.

```
A <= 12
```

```
ans =
```

```
 1 1 0 1 1 1 1 0
```

The result is a vector with values of logical 1 (true) where the elements of A satisfy the expression.

Use the vector of logical values as an index to view the values in A that are less than or equal to 12.

```
A(A <= 12)
```

```
ans =
```

```
 1 12 7 9 11 2
```

The result is a subset of the elements in A.

## Replace Elements of Matrix

Create a matrix.

```
A = magic(4)
```

```
A =
```

```
 16 2 3 13
 5 11 10 8
 9 7 6 12
 4 14 15 1
```

Replace all values less than or equal to 9 with the value 10.

```
A(A <= 9) = 10
```

```
A =
```

```
 16 10 10 13
 10 11 10 10
 10 10 10 12
 10 14 15 10
```

The result is a new matrix whose smallest element is 10.

## Compare Values in Categorical Array

Create an ordinal categorical array.

```
A = categorical({'large' 'medium' 'small'; 'medium' ...
```

```
'small' 'large'}},{'small' 'medium' 'large'},'Ordinal',1)
```

```
A =
```

```
 large medium small
 medium small large
```

The array has three categories: 'small', 'medium', and 'large'.

Find all values less than or equal to the category 'medium'.

```
A <= 'medium'
```

```
ans =
```

```
 0 1 1
 1 1 0
```

A value of logical 1 (`true`) indicates a value less than or equal to the category 'medium'.

Compare the rows of A.

```
A(1,:) <= A(2,:)
```

```
ans =
```

```
 0 0 1
```

The function returns logical 1 (`true`) where the first row has a category value less than or equal to the second row.

### Test Complex Numbers

Create a vector of complex numbers.

```
A = [1+i 2-2i 1+3i 1-2i 5-i];
```

Find the values that are less than or equal to 3.

```
A(A <= 3)
```

```
ans =
```

```
1.0000 + 1.0000i 2.0000 - 2.0000i 1.0000 + 3.0000i 1.0000 - 2.0000i
```

`le` compares only the real part of the elements in A.

Use `abs` to find which elements are within a radius of 3 from the origin.

```
A(abs(A) <= 3)
```

```
ans =
```

```
1.0000 + 1.0000i 2.0000 - 2.0000i 1.0000 - 2.0000i
```

The result has one less element. The element `1.0000 + 3.0000i` is not within a radius of 3 from the origin.

## Test Duration Values

Create a `duration` array.

```
d = hours(21:25) + minutes(75)
```

```
d =
```

```
22.25 hrs 23.25 hrs 24.25 hrs 25.25 hrs 26.25 hrs
```

Test the array for elements that are less than or equal to one standard day.

```
d <= 1
```

```
ans =
```

```
1 1 0 0 0
```

## Input Arguments

### A — Left array

numeric array | logical array | character array | ordinal categorical array | datetime array | duration array

Left array, specified as a numeric array, logical array, character array, categorical array, datetime array, or duration array. Inputs `A` and `B` must be the same size unless one is a scalar. A scalar input expands into an array of the same size as the other input.

If one input is an ordinal categorical array, the other input can be an ordinal categorical array, a cell array of strings, or a single string. A single string expands into a cell array of strings of the same size as the other input. If both inputs are ordinal categorical arrays, they must have the same sets of categories, including their order. See “Compare Categorical Array Elements” for more details.

If one input is a datetime array, the other input can be a datetime array, a date string, or a cell array of date strings.

If one input is a duration array, the other input can be a duration array or a numeric array. `eq` treats each numeric value as a number of standard (86400 s) days.

### **B — Right array**

numeric array | logical array | character array | ordinal categorical array | datetime array | duration array

Right array, specified as a numeric array, logical array, character array, categorical array, datetime array, or duration array. Inputs **A** and **B** must be the same size unless one is a scalar. A scalar input expands into an array of the same size as the other input.

If one input is an ordinal categorical array, the other input can be an ordinal categorical array, a cell array of strings, or a single string. A single string expands into a cell array of strings of the same size as the other input. If both inputs are ordinal categorical arrays, they must have the same sets of categories, including their order. See “Compare Categorical Array Elements” for more details.

If one input is a datetime array, the other input can be a datetime array, a date string, or a cell array of date strings.

If one input is a duration array, the other input can be a duration array or a numeric array. `eq` treats each numeric value as a number of standard (86400 s) days.

## **More About**

### **Tips**

- Some floating-point numbers cannot be represented exactly in binary form. This leads to small differences in results that the `<=` operator reflects. For more information, see “Avoiding Common Problems with Floating-Point Arithmetic”.
- “Ordinal Categorical Arrays”

# legend

Add legend to graph

## Syntax

```
legend('string1',..., 'stringN')
legend('string1',..., 'stringN', 'Location', Value)
legend(____, 'Orientation', Value)
```

```
legend(strings)
legend(strings, Name, Value)
```

```
legend(entries, ____)
```

```
legend('boxon')
legend('boxoff')
```

```
legend('hide')
legend('show')
legend('toggle')
legend('off')
```

```
legend(ax, ____)
```

```
h = legend(____)
[h, icons, plots, str] = legend(____)
```

## Description

`legend('string1', ..., 'stringN')` creates a legend in the current axes using the specified strings to label each set of data. The legend shows an icon of the associated object next to each string.

`legend('string1', ..., 'stringN', 'Location', Value)` specifies the legend location. Set `Value` to a location string such as `'northoutside'`. For a list of strings, see the `Location` property.

`legend( ____, 'Orientation', Value)` specifies the legend orientation. This option can be used with either of the input argument combinations in the previous syntaxes. Set `Value` as either `'vertical'` or `'horizontal'`. For more information, see the `Orientation` property.

`legend(strings)` creates a legend in the current axes and uses the entries in `strings` to label each set of data. Specify `strings` as either a cell array of strings or a matrix of strings.

`legend(strings, Name, Value)` specifies legend properties. Use this syntax if you want to specify `Name`, `Value` pairs other than `Location` and `Orientation` when creating a legend. For example, `'FontSize', 12` sets the font size to 12 points.

`legend(entries, ____)` displays legend entries for the objects in the graph specified by the vector `entries`. Use this syntax if you want to display legend entries for only some of the objects in the graph. The option, `entries`, can precede any of the input argument combinations in the previous syntaxes.

`legend('boxon')` displays the box around the legend.

`legend('boxoff')` removes the box around the legend.

`legend('hide')` hides the legend associated with the current axes. Hiding the legend does not delete it.

`legend('show')` makes the legend in the current axes visible. If a legend does not exist, then MATLAB creates one using the default strings.

`legend('toggle')` toggles the legend visibility. If a legend does not exist, then MATLAB creates one using the default strings.

`legend('off')` deletes the legend from the current axes.

`legend(ax, ____)` uses the axes specified by `ax` instead of the current axes (`gca`). The option, `ax`, can precede any of the previous input argument combinations.

`h = legend( ____)` returns the legend object. Use `h` to query and set properties of the legend after it is created.

---

**Note:** Starting in R2014b, the `legend` function returns a legend object. In previous releases it returns an axes object.

---

`[h,icons,plots,str] = legend( ___ )` additionally returns the objects used to create the legend icons, the objects plotted in the graph, and an array of text strings.

## Examples

### Add Legend to Graph

Create a graph of sine and cosine. Add a legend to the graph indicating the two functions.

```
x = -pi:pi/20:pi;
y1 = sin(x);
y2 = cos(x);

figure
plot(x,y1,'-ro',x,y2,'-.b')
legend('sin(x)', 'cos(x)')
```

### Specify Legend Location

Create a graph of sine and cosine. Add a legend to the top left corner of the graph by specifying the 'Location' property as 'northwest'.

```
x = -pi:pi/20:pi;
y1 = sin(x);
y2 = cos(x);
```

```
figure
plot(x,y1,'-ro',x,y2,'-.b')
legend('sin(x)', 'cos(x)', 'Location', 'northwest')
```

### Add Horizontal Legend Above Graph

Create a graph of sine and cosine. Add a horizontal legend above the axes.

```
x = -pi:pi/20:pi;
y1 = sin(x);
y2 = cos(x);
```

```
figure
plot(x,y1,'-ro',x,y2,'-.b')
legend('sin(x)', 'cos(x)', 'Location', 'northoutside', 'Orientation', 'horizontal')
```

### Change Legend Font Size

Define the data, `x`, `ydata`, and `ycos`.

```
rng default % initialize random number generator
x = linspace(0,4*pi,100);
ydata = cos(x) + 0.5*randn(1,100);
ycos = cos(x);
```

Plot `ydata` and `ycos`. Add a legend to the graph using a small, bold font. To specify Name, Value pairs when creating a legend, you must specify the legend description strings as a cell array by using curly braces, `{}`.

```
figure
```

```
plot(x,ydata,'*',x,ycos)
legend({'Collected Data','y = cos(x)'}, 'FontSize',8,'FontWeight','bold')
```

### Display Subset of Lines in Legend

Define the data.

```
x = linspace(0,3*pi);
y1 = sin(x);
y2 = sin(x - pi/4);
y3 = sin(x - pi/2);
y4 = sin(x - 3*pi/4);
y5 = sin(x - pi);
```

Plot the data and return the charting line handles.

```
figure
hLine1 = plot(x,y1);
hold all
hLine2 = plot(x,y2);
hLine3 = plot(x,y3);
hLine4 = plot(x,y4);
hLine5 = plot(x,y5);
hold off
```

Add a legend for the first and last lines by specifying their handles, hLine1 and hLine5.

```
legend([hLine1,hLine5], 'sin(x)', 'sin(x-\pi)')
```

### Specify Legend Location and Remove Border

Create a plot of sine and cosine. Add a legend to the bottom left of the axes.

```
x = linspace(0,2*pi,50);
ysin = sin(x);
ycos = cos(x);

figure
stem(x,ysin)
hold all
plot(x,ycos)
hold off

legend('sin(x)', 'cos(x)', 'Location', 'southwest')
```

Remove the legend border.

```
legend('boxoff')
```

### Specify Custom Legend Size and Location

Define the data.

```
theta = linspace(0,2*pi,100);
x1 = sin(theta);
y1 = cos(theta);
```

```
x2 = 2*sin(theta);
y2 = 2*cos(theta);
```

Create a scatter plot of two circles. Use `axis equal` to set equal scaling along both the  $x$ -axis and  $y$ -axis.

```
figure
```

```
scatter(x1,y1)
hold on
scatter(x2,y2,'*g')
hold off
axis equal
```

Add a legend to the center of the graph using the `Position` property. To set the `Position` property when creating a legend, you must define the legend strings as a cell array by using curly braces, `{}`.

```
legend({'radius = 1', 'radius = 2'}, 'Position', [0.39, 0.45, 0.25, 0.1])
```

### Delete Legend

Create a plot of sine and cosine and add a legend.

```
x = linspace(0,2*pi,50);
ysin = sin(x);
ycos = cos(x);
```

```
figure
plot(x,ysin,x,ycos)
legend('sine','cosine')
```

Delete the legend.

```
legend('off')
```

### Specify Axes for Legend

Create a figure with two subplots and return the two axes handles, `ax1` and `ax2`. Plot random data in each subplot.

```
rng default % initialize random number generator
y1 = rand(3);
y2 = rand(5);
```

```
figure
ax1 = subplot(2,1,1); % upper subplot
plot(y1)
```

```
ax2 = subplot(2,1,2); % lower subplot
```

plot(y2)

Add a legend to the upper subplot by passing its axes handle to `legend`.

```
legend(ax1, 'Line 1', 'Line 2', 'Line 3')
```

- “Include Subset of Objects in Graph Legend”
- “Specify Legend Descriptions During Line Creation”

## Input Arguments

**'string1', ..., 'stringN'** — Description for each object

comma-separated list of strings

Description for each object, specified as a comma-separated list of strings.

MATLAB sets the `String` property of the legend to the specified strings. MATLAB also sets the `DisplayName` properties of the objects to the specified strings.

If you do not specify legend strings, then `legend` uses the `DisplayName` properties of the objects instead. If an object does not have a `DisplayName` property, or if you have not defined a value for this property, then `legend` uses a string of the form `'data1'`, `'data2'`, and so on.

Example: `'Sine Function', 'Cosine Function'`

## **strings** — Description for each object

cell array of strings | matrix of strings

Description for each object, specified as a cell array of strings or a matrix of strings. If `strings` is a matrix, then the `legend` function uses each row of the matrix to label a set of data.

MATLAB sets the `String` property of the legend to the specified strings. MATLAB also sets the `DisplayName` properties of the objects to the specified strings.

If you do not specify legend strings, then `legend` uses the `DisplayName` properties of the objects instead. If an object does not have a `DisplayName` property, or if you have not defined a value for this property, then `legend` uses a string of the form `'data1'`, `'data2'`, and so on.

Example: `{'Sine Function', 'Cosine Function'}`

## **entries** — List of graphics objects to include in legend

vector

List of graphics objects to include in the legend, specified as a vector. Specifying objects is useful if you do not want to add a description for every object in the graph.

These are the graphics objects that can be included in the legend:

- `Animated line` objects
- `Area` objects
- `Bar series` objects
- `Chart line` objects
- `Chart surface` objects
- `Contour` objects
- `Errorbar series` objects
- `Group` objects

- Histogram objects
- Patch objects
- Primitive line objects
- Primitive surface objects
- Quiver series objects
- Scatter series objects
- Stair objects
- Stem series objects
- Transform objects

### **ax — Axes object**

axes object

Axes object. If you do not specify an axes, then the `legend` function adds a legend to the current axes.

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( `' '` ). You can specify several name and value pair arguments in any order as `Name1,Value1, ...,NameN,ValueN`.

The properties listed here are only a subset. For a complete list see Legend Properties.

Example: `'FontSize',12,'TextColor','blue'`

### **'Location' — Location with respect to axes**

supported location string

Location with respect to the axes, specified as one of the location strings listed in this table.

<b>Supported String</b>	<b>Resulting Location</b>
<code>'north'</code>	Inside top of axes
<code>'south'</code>	Inside bottom of axes
<code>'east'</code>	Inside right of axes
<code>'west'</code>	Inside left of axes

Supported String	Resulting Location
'northeast'	Inside top-right of axes (default for 2-D axes)
'northwest'	Inside top-left of axes
'southeast'	Inside bottom-right of axes
'southwest'	Inside bottom-left of axes
'northoutside'	Above the axes
'southoutside'	Below the axes
'eastoutside'	To the right of the axes
'westoutside'	To the left of the axes
'northeastoutside'	Outside top-right corner of the axes (default for 3-D axes)
'northwestoutside'	Outside top-left corner of the axes
'southeastoutside'	Outside bottom-right corner of the axes
'southwestoutside'	Outside bottom-left corner of the axes
'best'	Inside axes where least conflict with data in plot
'bestoutside'	To the right of the axes
'none'	Determined by <b>Position</b> property

To display the legend in a location that is not listed in the table, use the **Position** property to specify a custom location. If you set the **Position** property, then MATLAB automatically sets the **Location** property to 'none'.

Example: 'northoutside'

**'Orientation' — Orientation**

'vertical' (default) | 'horizontal'

Orientation, specified as one of these values:

- 'vertical' — Stacks the legend entries vertically. This is the default.
- 'horizontal' — Lists the legend entries side-by-side.

Example: 'horizontal'

**'Box' — Box outline**`'on' (default) | 'off'`

Box outline, specified as one of these values:

- `'on'` — Displays the box around the legend. This is the default.
- `'off'` — Removes the box around the legend.

Example: `'off'`

**'String' — Legend entry descriptions**`cell array of strings`

Legend entry descriptions, specified as a cell array of strings. If you specify strings as input to `legend`, then MATLAB sets the `String` property to the specified strings and uses these strings in the legend display. If you do not specify strings, then MATLAB uses the `DisplayName` properties of the objects, or a string of the form `'data1'`, `'data2'`, and so on. The `String` property reflects the entries in the legend.

Example: `{'Sine', 'Cosine', 'Tangent'}`

**'Interpreter' — Interpretation of text characters**`'tex' (default) | 'latex' | 'none'`

Interpretation of text characters, specified as one of these values:

- `'tex'` — Interpret text strings using a subset of TeX markup. This is the default value.
- `'latex'` — Interpret text strings using LaTeX markup.
- `'none'` — Display literal characters.

## TeX Markup

By default, MATLAB supports a subset of TeX markup. Use TeX markup to add superscripts and subscripts, modify the text type and color, and include special characters in the text string.

This table lists the supported modifiers when the `Interpreter` property is set to `'tex'`. Modifiers remain in effect until the end of the string, except for superscripts and subscripts, which only modify the next character or the text within the curly braces `{}`.

Modifier	Description	Example of String
<code>^{} </code>	Superscript	'text <sup>{superscript}</sup> '
<code>_{} </code>	Subscript	'text <sub>{subscript}</sub> '
<code>\bf</code>	Bold font	'\bf text'
<code>\it</code>	Italic font	'\it text'
<code>\sl</code>	Oblique font (usually the same as italic font)	'\sl text'
<code>\rm</code>	Normal font	'\rm text'
<code>\fontname{specifier}</code>	Font name — Set <code>specifier</code> as the name of a font family. You can use this in combination with other modifiers.	'\fontname{Courier} text'
<code>\fontsize{specifier}</code>	Font size — Set <code>specifier</code> as a numeric scalar value to change the font size.	'\fontsize{15} text'
<code>\color{specifier}</code>	Font color — Set <code>specifier</code> as one of these colors: red, green, yellow, magenta, blue, black, white, gray, darkGreen, orange, or lightBlue.	'\color{magenta} text'
<code>\color[rgb]{specifier}</code>	Custom font color — Set <code>specifier</code> as a three-element RGB triplet.	'\color[rgb]{0,0.5,0.5} text'

This table lists the supported special characters when the interpreter is set to 'tex'.

Character Sequence	Symbol	Character Sequence	Symbol	Character Sequence	Symbol

<code>\vee</code>	#	<code>\langle</code>	#	<code>\copyright</code>	©

## LaTeX Markup

To use LaTeX markup, set the `Interpreter` property to `'latex'`. The displayed text uses the default LaTeX font style. The `FontName`, `FontWeight`, and `FontAngle` properties do not have an effect. To change the font style, use LaTeX markup within the text string.

The maximum size of the string that you can use with the LaTeX interpreter is 1200 characters. For multiline strings, this reduces by about 10 characters per line.

For more information about the LaTeX system, see The LaTeX Project Web site at <http://www.latex-project.org/>.

### 'TextColor' — Text color

[0,0,0] or 'black' (default) | RGB triplet | supported color string

Text color, specified as an RGB triplet or a supported color string. The default color is black with an RGB triplet value of [0,0,0].

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0,1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[1 1 0]
'magenta'	'm'	[1 0 1]
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]

Long Name	Short Name	RGB Triplet
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black'	'k'	[0 0 0]

Example: [0,0,1]

Example: 'blue'

### 'FontSize' — Font size

9 (default) | scalar value greater than zero

Font size, specified as a scalar value greater than zero in point units. The default value is 9 points. If you change the axes font size, then MATLAB automatically sets the legend font size to 90% of the axes font size. If you manually set the legend font size, then changing the axes font size does not affect the legend.

Example: 12

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical

## Output Arguments

### **h** — Legend object

legend object

Legend object. Use `h` to modify the legend after it has been created.

### **icons** — Objects used to create legend icons and descriptions

text, patch, and line objects

Objects used to create the legend icons and descriptions, returned as text, patch, and line object.

### **plots** — Objects plotted in graph

vector of objects

Objects plotted in the graph, returned as a vector of objects.

## **str** — Text strings used in legend

cell array

Text strings used in the legend, returned as a cell array.

## **More About**

### **Tips**

- An axes can have only one legend.
- To use legend keywords, such as 'Location' or 'off' as legend descriptions, you must pass the string in a cell array to **legend**. For example, `l = legend({'Location'})` displays a legend with the entry **Location**.
- To label more than 20 objects in the legend, you must specify a string for each object. Otherwise, **legend** depicts only the first 20 objects in the graph.
- **legend** associates strings with objects in the same order that the objects are listed in the axes **Children** property.
- “Control Legend Content”

## **See Also**

### **Functions**

`hold` | `LineStyle` | `plot`

### **Properties**

Legend Properties

# Legend Properties

Control legend appearance and behavior

Legend properties control the appearance and behavior of a legend object. By changing property values, you can modify certain aspects of the legend. Use dot notation to refer to a particular object and property:

```
h = legend('show');
c = h.TextColor;
h.TextColor = 'red';
```

## Appearance

### TextColor — Text color

[0,0,0] or 'black' (default) | RGB triplet | supported color string

Text color, specified as an RGB triplet or a supported color string. The default color is black with an RGB triplet value of [0,0,0].

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0,1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[1 1 0]
'magenta'	'm'	[1 0 1]
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black'	'k'	[0 0 0]

Example: [0,0,1]

Example: 'blue'

**Color — Background color**`[1,1,1]` or `'white'` (default) | RGB triplet | supported color string

Background color, specified as an RGB triplet or a supported color string. The default color is white with an RGB triplet value of `[1,1,1]`.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
<code>'yellow'</code>	<code>'y'</code>	<code>[1 1 0]</code>
<code>'magenta'</code>	<code>'m'</code>	<code>[1 0 1]</code>
<code>'cyan'</code>	<code>'c'</code>	<code>[0 1 1]</code>
<code>'red'</code>	<code>'r'</code>	<code>[1 0 0]</code>
<code>'green'</code>	<code>'g'</code>	<code>[0 1 0]</code>
<code>'blue'</code>	<code>'b'</code>	<code>[0 0 1]</code>
<code>'white'</code>	<code>'w'</code>	<code>[1 1 1]</code>
<code>'black'</code>	<code>'k'</code>	<code>[0 0 0]</code>

Example: `[0,0,1]`

Example: `'b'`

**Box — Box outline**`'on'` (default) | `'off'`

Box outline, specified as one of these values:

- `'on'` — Displays the box around the legend. This is the default.
- `'off'` — Removes the box around the legend.

Example: `'off'`

**EdgeColor — Box outline color**`[0.15 0.15 0.15]` (default) | RGB triplet | supported color string

Box outline color, specified as an RGB triplet or a supported color string. The default color is dark gray with an RGB triplet value of `[0.15,0.15,0.15]`.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range  $[0, 1]$ , for example,  $[0.4 \ 0.6 \ 0.7]$ . This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[ 1 1 0 ]
'magenta'	'm'	[ 1 0 1 ]
'cyan'	'c'	[ 0 1 1 ]
'red'	'r'	[ 1 0 0 ]
'green'	'g'	[ 0 1 0 ]
'blue'	'b'	[ 0 0 1 ]
'white'	'w'	[ 1 1 1 ]
'black'	'k'	[ 0 0 0 ]

Example:  $[0, 1, 0]$

Example: 'g'

### **LineWidth** — Width of box outline

0.5 (default) | positive value

Width of box outline, specified as a positive value in point units. One point equals 1/72 inches.

Example: 1.5

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

## **Location and Size**

### **Location** — Location with respect to axes

supported location string

Location with respect to the axes, specified as one of the location strings listed in this table.

Supported String	Resulting Location
'north'	Inside top of axes
'south'	Inside bottom of axes
'east'	Inside right of axes
'west'	Inside left of axes
'northeast'	Inside top-right of axes (default for 2-D axes)
'northwest'	Inside top-left of axes
'southeast'	Inside bottom-right of axes
'southwest'	Inside bottom-left of axes
'northoutside'	Above the axes
'southoutside'	Below the axes
'eastoutside'	To the right of the axes
'westoutside'	To the left of the axes
'northeastoutside'	Outside top-right corner of the axes (default for 3-D axes)
'northwestoutside'	Outside top-left corner of the axes
'southeastoutside'	Outside bottom-right corner of the axes
'southwestoutside'	Outside bottom-left corner of the axes
'best'	Inside axes where least conflict with data in plot
'bestoutside'	To the right of the axes
'none'	Determined by <b>Position</b> property

To display the legend in a location that is not listed in the table, use the **Position** property to specify a custom location. If you set the **Position** property, then MATLAB automatically sets the **Location** property to 'none'.

Example: 'northoutside'

**Orientation – Orientation**

'vertical' (default) | 'horizontal'

Orientation, specified as one of these values:

- `'vertical'` — Stacks the legend entries vertically. This is the default.
- `'horizontal'` — Lists the legend entries side-by-side.

Example: `'horizontal'`

### **Position — Custom location and size**

four-element vector

Custom location and size, specified as a four-element vector of the form `[left, bottom, width, height]`. The first two values, `left` and `bottom`, specify the distance from the lower-left corner of the figure to the lower-left corner of the legend. The last two values, `width` and `height`, specify the dimensions of the legend. The `Units` property determines the position units.

If you specify the `Position` property, then MATLAB automatically changes the legend's `Location` property to `'none'`.

Example: `[0.1,0.1,0.3,0.7]`

### **Units — Position units**

`'normalized'` (default) | `'inches'` | `'centimeters'` | `'characters'` | `'points'` | `'pixels'`

Position units, specified as one of the values in this table.

<b>Units</b>	<b>Description</b>
<code>'normalized'</code> (default)	Normalized with respect to the container, which is usually the figure. The lower-left corner of the figure maps to $(0,0)$ and the upper-right corner maps to $(1,1)$ .
<code>'inches'</code>	Inches.
<code>'centimeters'</code>	Centimeters.
<code>'characters'</code>	Based on the size of characters in the default system font. The width of one character unit is the width of the letter <code>x</code> . The height of one character unit is the distance between the baselines of two lines of text.

<b>Units</b>	<b>Description</b>
'points'	Points. One point equals 1/72 inch.
'pixels'	Pixels. Pixel size depends on the screen resolution.

All units are measured from the lower-left corner of the container window.

This property affects the Position property. If you change the units, then it is good practice to return it to its default value after completing your computation to prevent affecting other functions that assume Units is the default value.

If you specify the Position and Units properties as Name, Value pairs when creating the legend, then the order of specification matters. If you want to define the position with particular units, then you must set the Units property before the Position property.

## Text

### **String** — Legend entry descriptions

cell array of strings

Legend entry descriptions, specified as a cell array of strings. If you specify strings as input to **legend**, then MATLAB sets the **String** property to the specified strings and uses these strings in the legend display. If you do not specify strings, then MATLAB uses the **DisplayName** properties of the objects, or a string of the form 'data1', 'data2', and so on. The **String** property reflects the entries in the legend.

Example: {'Sine', 'Cosine', 'Tangent'}

### **Interpreter** — Interpretation of text characters

'tex' (default) | 'latex' | 'none'

Interpretation of text characters, specified as one of these values:

- 'tex' — Interpret text strings using a subset of TeX markup. This is the default value.
- 'latex' — Interpret text strings using LaTeX markup.
- 'none' — Display literal characters.

## TeX Markup

By default, MATLAB supports a subset of TeX markup. Use TeX markup to add superscripts and subscripts, modify the text type and color, and include special characters in the text string.

This table lists the supported modifiers when the `Interpreter` property is set to `'tex'`. Modifiers remain in effect until the end of the string, except for superscripts and subscripts, which only modify the next character or the text within the curly braces `{}`.

Modifier	Description	Example of String
<code>^{ }</code>	Superscript	<code>'text^{superscript}'</code>
<code>_{ }</code>	Subscript	<code>'text_{subscript}'</code>
<code>\bf</code>	Bold font	<code>'\bf text'</code>
<code>\it</code>	Italic font	<code>'\it text'</code>
<code>\sl</code>	Oblique font (usually the same as italic font)	<code>'\sl text'</code>
<code>\rm</code>	Normal font	<code>'\rm text'</code>
<code>\fontname{specifier}</code>	Font name — Set <code>specifier</code> as the name of a font family. You can use this in combination with other modifiers.	<code>'\fontname{Courier} text'</code>
<code>\fontsize{specifier}</code>	Font size — Set <code>specifier</code> as a numeric scalar value to change the font size.	<code>'\fontsize{15} text'</code>
<code>\color{specifier}</code>	Font color — Set <code>specifier</code> as one of these colors: red, green, yellow, magenta, blue, black, white, gray, darkGreen, orange, or lightBlue.	<code>'\color{magenta} text'</code>
<code>\color[rgb]{specifier}</code>	Custom font color — Set <code>specifier</code> as a three-element RGB triplet.	<code>'\color[rgb]{0,0.5,0.5} text'</code>

This table lists the supported special characters when the interpreter is set to 'tex'.

## LaTeX Markup

To use LaTeX markup, set the **Interpreter** property to `'latex'`. The displayed text uses the default LaTeX font style. The **FontName**, **FontWeight**, and **FontAngle** properties do not have an effect. To change the font style, use LaTeX markup within the text string.

The maximum size of the string that you can use with the LaTeX interpreter is 1200 characters. For multiline strings, this reduces by about 10 characters per line.

For more information about the LaTeX system, see The LaTeX Project Web site at <http://www.latex-project.org/>.

## Font Style

### FontAngle — Character slant

`'normal'` (default) | `'italic'`

Character slant, specified as `'normal'` or `'italic'`. Not all fonts have both font styles. Therefore, the italic font might look the same as the normal font.

---

**Note:** The `'oblique'` value has been removed. Use `'italic'` instead.

---

**FontName — Font name**

'Helvetica' (default) | 'FixedWidth' | system supported font name

Font name, specified as the name of the font to use or the string 'FixedWidth'. To display and print properly, the font name must be a font that your system supports.

To use a fixed-width font that looks good in any locale, use the case-sensitive string 'FixedWidth'. This eliminates the need to hard-code the name of a fixed-width font, which might not display text properly on systems that do not use ASCII character encoding. The 'FixedWidth' value relies on the root FixedWidthFontName property. Setting the root FixedWidthFontName property causes an immediate update of the display to use the new font.

Example: 'Cambria'

**FontSize — Font size**

9 (default) | scalar value greater than zero

Font size, specified as a scalar value greater than zero in point units. The default value is 9 points. If you change the axes font size, then MATLAB automatically sets the legend font size to 90% of the axes font size. If you manually set the legend font size, then changing the axes font size does not affect the legend.

Example: 12

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical

**FontWeight — Thickness of text characters**

'normal' (default) | 'bold'

Thickness of the text characters, specified as one of these values:

- 'normal' — Default weight as defined by the particular font
- 'bold' — Thicker characters outlines than normal

MATLAB uses the FontWeight property to select a font from those available on your system. Not all fonts have a bold font weight. Therefore, specifying a bold font weight could still result in the normal font weight.

---

**Note:** The 'light' and 'demi' font weight values have been removed. Use 'normal' instead.

---

## Visibility

### Visible — Visibility of legend

'on' (default) | 'off'

Visibility of legend, specified as one of these values:

- 'on' — Display the legend.
- 'off' — Hide the legend without deleting it. You still can access the properties of an invisible legend object.

## Identifiers

### Type — Type of graphics object

'legend' (default)

Type of graphics object, returned as 'legend'. Use this property to find all objects of a given type within a plotting hierarchy.

### Tag — Tag to associate with legend

'legend' (default) | string

Tag to associate with the legend, specified as a string. Tags provide a way to identify graphics objects. Use this property to find all objects with a specific tag within a plotting hierarchy, for example, searching for the tag using `findobj`.

Example: 'January Data'

Data Types: char

### UserData — Data to associate with legend

[] (default) | scalar, vector, or matrix | cell array | character array | table | structure

Data to associate with the legend object, specified as a scalar, vector, matrix, cell array, character array, table, or structure. MATLAB does not use this data.

To associate multiple sets of data or to attach a field name to the data, use the `getappdata` and `setappdata` functions.

Example: 1:100

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `struct` | `table` | `cell`

## Parent/Child

### Parent — Parent of legend

`figure` object | `uipanel` object | `uitab` object

Parent of the legend, specified as a `figure` object, `uipanel` object, or a `uitab` object.

The legend must have the same parent as the associated axes. If you change the parent of the associated axes, then the legend automatically updates to use the same parent.

### Children — Children of legend

empty `GraphicsPlaceholder` array

The legend has no children. You cannot set this property.

### HandleVisibility — Visibility of object handle

`'on'` (default) | `'off'` | `'callback'`

Visibility of object handle in the `Children` property of the parent, specified as one of these values:

- `'on'` — List the legend object.
- `'off'` — Do not list the legend object. Use this option to hide object handles when a callback invokes a function that could damage the GUI, such as evaluating a user-typed string.
- `'callback'` — List the legend object in the `Children` property of the parent from within callbacks or functions invoked by callbacks, but not from within functions invoked from the command line. Use this option to protect a GUI from command-line users, while allowing callbacks to have access to objects.

If the legend object is not listed in the `Children` property of the parent, then functions that obtain object handles by searching the object hierarchy or querying handle properties cannot return it. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

Hidden object handles are still valid. Set the root `ShowHiddenHandles` property to `'on'` to list all object handles regardless of their `HandleVisibility` property setting.

## Interactive Control

### **ButtonDownFcn** — Callback that executes when you click the legend

@bdowncb (default) | function handle | cell array | string

Mouse-click callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you click the legend. If you specify this property using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The legend object — You can access properties of the legend object from within the callback function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see “Callback Definition”.

---

**Note:** If the PickableParts property is set to 'none' or if the HitTest property is set to 'off', then this callback does not execute.

---

Example: @myCallback

Example: {@myCallback, arg3}

### **UIContextMenu** — Context menu

uicontextmenu handle (default)

Context menu, specified as a uicontextmenu object. Use this property to display a context menu when you right-click the legend. Create the context menu using the uicontextmenu function.

---

**Note:** If the `PickableParts` property is set to `'none'` or if the `HitTest` property is set to `'off'`, then the context menu does not appear.

---

## **Selected** — Selection state

`'off'` (default) | `'on'`

Selection state, specified as one of these values:

- `'on'` — Selected. If you click the legend when in plot edit mode, then MATLAB sets its `Selected` property to `'on'`. If the `SelectionHighlight` property also is set to `'on'`, then MATLAB displays selection handles around the legend.
- `'off'` — Not selected.

## **SelectionHighlight** — Display of selection handles when selected

`'on'` (default) | `'off'`

Display of selection handles when selected, specified as one of these values:

- `'on'` — Display selection handles when the `Selected` property is set to `'on'`.
- `'off'` — Never display selection handles, even when the `Selected` property is set to `'on'`.

# Callback Execution Control

## **PickableParts** — Ability to capture mouse clicks

`'visible'` (default) | `'none'`

Ability to capture mouse clicks, specified as one of these values:

- `'visible'` — Can capture mouse clicks when visible. The `Visible` property must be set to `'on'` and you must click a part of the legend that has a defined color. You cannot click a part that has an associated color property set to `'none'`. The `HitTest` property determines if the legend responds to the click or if an ancestor does.
- `'none'` — Cannot capture mouse clicks. Clicking the legend passes the click to the object below it in the current view of the figure window. The `HitTest` property of the legend has no effect.

## **HitTest** — Response to captured mouse clicks

`'on'` (default) | `'off'`

Response to captured mouse clicks, specified as one of these values:

- 'on' — Trigger the `ButtonDownFcn` callback of the legend. If you have defined the `UIContextMenu` property, then invoke the context menu.
- 'off' — Trigger the callbacks for the nearest ancestor of the legend that has a `HitTest` property set to 'on' and a `PickableParts` property value that enables the ancestor to capture mouse clicks.

---

**Note:** The `PickableParts` property determines if the legend object can capture mouse clicks. If it cannot, then the `HitTest` property has no effect.

---

### **Interruptible — Callback interruption**

'off' (default) | 'on'

Callback interruption, specified as 'off' or 'on'. The `Interruptible` property determines if a running callback can be interrupted.

If the `ButtonDownFcn` callback of the legend is the running callback, then the `Interruptible` property determines if it can be interrupted by another callback. The `Interruptible` property has two possible values:

- 'off' — The running callback cannot be interrupted. MATLAB finishes executing the running callback without any interruptions. This is the default behavior.
- 'on' — The running callback can be interrupted. Interruption occurs at the next point where MATLAB processes the queue, such as when there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command.
  - If the running callback contains one of these commands, then MATLAB stops the execution of the callback at this point and executes the interrupting callback. MATLAB resumes executing the running callback when the interrupting callback completes. For more information, see “Interrupt Callback Execution”.
  - If the running callback does not contain one of these commands, then MATLAB finishes executing the callback without interruption.

---

**Note:** There are two callback states to consider:

- The *running* callback is the currently executing callback.
- The *interrupting* callback is a callback that tries to interrupt the running callback.

Whenever MATLAB invokes a callback, that callback attempts to interrupt a running callback. The `Interruptible` property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the `BusyAction` property of the object owning the interrupting callback determines if it is discarded or put in the queue.

---

Example: `'off'`

### **BusyAction — Callback queuing**

`'queue'` (default) | `'cancel'`

Callback queuing specified as `'queue'` or `'cancel'`. The `BusyAction` property determines how MATLAB handles the execution of interrupting callbacks.

---

**Note:** There are two callback states to consider:

- The *running* callback is the currently executing callback.
- The *interrupting* callback is a callback that tries to interrupt the running callback.

Whenever MATLAB invokes a callback, that callback attempts to interrupt a running callback. The `Interruptible` property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the `BusyAction` property of the object owning the interrupting callback determines if it is discarded or put in the queue.

---

If the `ButtonDownFcn` callback of the legend tries to interrupt a running callback that cannot be interrupted, then the `BusyAction` property determines if it is discarded or put in the queue. Specify the `BusyAction` property as one of these values:

- `'queue'` — Put the interrupting callback in a queue to be processed after the running callback finishes execution. This is the default behavior.
- `'cancel'` — Discard the interrupting callback.

## **Creation and Deletion Control**

### **CreateFcn — Creation callback**

`''` (default) | function handle | cell array | string

Creation callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you create the legend. Setting the `CreateFcn` property on an existing legend has no effect. You must define a default value for this property, or define this property using a `Name, Value` pair during legend creation. MATLAB executes the callback after creating the legend and setting all of its properties.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The legend object — You can access properties of the legend object from within the callback function. You also can access the legend object through the `CallbackObject` property of the root, which can be queried using the `gcb0` function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see “Callback Definition”.

Example: `@myCallback`

Example: `{@myCallback, arg3}`

### **DeleteFcn — Deletion callback**

' ' (default) | function handle | cell array | string

Deletion callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you delete the legend. MATLAB executes the callback before destroying the legend so that the callback can access its property values.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The legend object — You can access properties of the legend object from within the callback function. You also can access the legend object through the `CallbackObject` property of the root, which can be queried using the `gcbo` function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see “Callback Definition”.

Example: `@myCallback`

Example: `{@myCallback, arg3}`

## **BeingDeleted — Deletion status of legend**

'off' (default) | 'on'

Deletion status of legend, returned as 'on' or 'off'. MATLAB sets the `BeingDeleted` property to 'on' when the delete function of the legend begins execution (see the `DeleteFcn` property). The `BeingDeleted` property remains set to 'on' until the legend no longer exists.

Check the value of the `BeingDeleted` property to verify that the legend is not about to be deleted before querying or modifying it.

# legendre

Associated Legendre functions

## Syntax

```
P = legendre(n,X)
S = legendre(n,X,'sch')
N = legendre(n,X,'norm')
```

## Description

`P = legendre(n,X)` computes the associated Legendre functions of degree  $n$  and order  $m = 0, 1, \dots, n$ , evaluated for each element of  $X$ . Argument  $n$  must be a scalar integer, and  $X$  must contain real values in the domain  $-1 \leq x \leq 1$ .

If  $X$  is a vector, then  $P$  is an  $(n+1)$ -by- $q$  matrix, where  $q = \text{length}(X)$ . Each element  $P(m+1, i)$  corresponds to the associated Legendre function of degree  $n$  and order  $m$  evaluated at  $X(i)$ .

In general, the returned array  $P$  has one more dimension than  $X$ , and each element  $P(m+1, i, j, k, \dots)$  contains the associated Legendre function of degree  $n$  and order  $m$  evaluated at  $X(i, j, k, \dots)$ . Note that the first row of  $P$  is the Legendre polynomial evaluated at  $X$ , i.e., the case where  $m = 0$ .

`S = legendre(n,X,'sch')` computes the “Schmidt Seminormalized Associated Legendre Functions” on page 1-4265.

`N = legendre(n,X,'norm')` computes the “Fully Normalized Associated Legendre Functions” on page 1-4265.

## Examples

### Example 1

The statement `legendre(2,0:0.1:0.2)` returns the matrix

	<b>x = 0</b>	<b>x = 0.1</b>	<b>x = 0.2</b>
m = 0	-0.5000	-0.4850	-0.4400
m = 1	0	-0.2985	-0.5879
m = 2	3.0000	2.9700	2.8800

## Example 2

Given,

```
X = rand(2,4,5);
n = 2;
P = legendre(n,X)
```

then

```
size(P)
ans =
 3 2 4 5
```

and

```
P(:,1,2,3)
ans =
 -0.2475
 -1.1225
 2.4950
```

is the same as

```
legendre(n,X(1,2,3))
ans =
 -0.2475
 -1.1225
 2.49501
```

## More About

### Associated Legendre Functions

The Legendre functions are defined by

$$P_n^m(x) = (-1)^m (1-x^2)^{m/2} \frac{d^m}{dx^m} P_n(x),$$

where

$$P_n(x)$$

is the Legendre polynomial of degree  $n$ :

$$P_n(x) = \frac{1}{2^n n!} \left[ \frac{d^n}{dx^n} (x^2 - 1)^n \right]$$

### Schmidt Seminormalized Associated Legendre Functions

The Schmidt seminormalized associated Legendre functions are related to the nonnormalized associated Legendre functions  $P_n^m(x)$  by

$$P_n(x) \text{ for } m = 0,$$

$$S_n^m(x) = (-1)^m \sqrt{\frac{2(n-m)!}{(n+m)!}} P_n^m(x) \text{ for } m > 0.$$

### Fully Normalized Associated Legendre Functions

The fully normalized associated Legendre functions are normalized such that

$$\int_{-1}^1 \left( N_n^m(x) \right)^2 dx = 1$$

and are related to the unnormalized associated Legendre functions  $P_n^m(x)$  by

$$N_n^m = (-1)^m \sqrt{\frac{(n + \frac{1}{2})(n-m)!}{2(n+m)!}} P_n^m(x)$$

## Algorithms

Legendre uses a three-term backward recursion relationship in  $m$ . This recursion is on a version of the Schmidt seminormalized associated Legendre functions  $Q_n^m(x)$ , which are complex spherical harmonics. These functions are related to the standard Abramowitz and Stegun [1] functions  $P_n^m(x)$  by

$$P_n^m(x) = \sqrt{\frac{(n+m)!}{(n-m)!}} Q_n^m(x)$$

They are related to the Schmidt form given previously by

$$m = 0: S_n^m(x) = Q_n^0(x)$$

$$m > 0: S_n^m(x) = (-1)^m \sqrt{2} Q_n^m(x)$$

# length

Length of largest array dimension

## Syntax

```
L = length(X)
```

## Description

`L = length(X)` returns the length of the largest array dimension in `X`. For vectors, the length is simply the number of elements. For arrays with more dimensions, the length is `max(size(X))`. The length of an empty array is zero.

## Examples

### Number of Vector Elements

Find the length of a uniformly spaced vector in the interval `[5,10]`.

```
v = 5:10
```

```
v =
```

```
 5 6 7 8 9 10
```

```
L = length(v)
```

```
L =
```

```
 6
```

### Length of Rectangular Matrix

Find the length of a 3-by-7 matrix of zeros.

```
X = zeros(3,7);
L = length(X)
```

```
L =

 7
```

### Length of Structure Fields

Create a structure with fields for `Day` and `Month`. Use the `structfun` function to apply `length` to each field.

```
S = struct('Day',[1 13 14 26], 'Month',{'Jan','Feb', 'Mar'})
```

```
S =
```

```
 Day: [1 13 14 26]
 Month: {'Jan' 'Feb' 'Mar'}
```

```
L = structfun(@(field) length(field),S)
```

```
L =
```

```
 4
 3
```

## Input Arguments

### X — Input array

numeric array | character array | logical array | structure | cell array | categorical array | datetime array | duration array | calendarDuration array

Input array, specified as a numeric array, character array, logical array, structure, cell array, categorical array, datetime array, duration array, or calendarDuration array.

`length` does not operate on tables. To examine the dimensions of a table, use the `height`, `width`, or `size` functions.

Complex Number Support: Yes

### See Also

`ndims` | `numel` | `size`

# length

**Class:** `containers.Map`

**Package:** `containers`

Length of `containers.Map` object

## Syntax

```
mapLength = length(mapObj)
```

## Description

`mapLength = length(mapObj)` returns the number of key-value pairs in `mapObj`.

## Input Arguments

**mapObj**

Object of class `containers.Map`.

## Output Arguments

**mapLength**

Scalar numeric value that indicates the number of key-value pairs in `mapObj`. This number is equivalent to `size(mapObj, 1)` and to `mapObj.Count`.

## Examples

### Determine the Length of a Map

Create a map, and determine the number of key-value pairs:

```
myKeys = {'a', 'b', 'c'};
myValues = [1,2,3];
mapObj = containers.Map(myKeys,myValues);
```

```
mapLength = length(mapObj)
```

This code returns

```
mapLength =
 3
```

## See Also

`isKey` | `keys` | `values` | `containers.Map` | `size`

## length (serial)

Length of serial port object array

### Syntax

```
length(obj)
```

### Description

`length(obj)` returns the length of the serial port object, `obj`. It is equivalent to the command `max(size(obj))`.

### See Also

`size`

## **length (tscollection)**

Length of time vector

### **Syntax**

`length(tsc)`

### **Description**

`length(tsc)` returns an integer that represents the length of the time vector for the `tscollection` object `tsc`.

### **See Also**

`tscollection` | `isempty (tscollection)` | `size (tscollection)`

# libfunctions

Return information on functions in shared library

## Syntax

```
libfunctions libname
```

```
m = libfunctions(libname)
___ = libfunctions(___, '-full')
```

## Description

`libfunctions libname` displays names of functions defined in library, `libname`. If you called `loadlibrary` using the `alias` option, then you must use the alias name for the `libname` argument.

`m = libfunctions(libname)` returns names of functions in cell array `m`.

`___ = libfunctions( ___, '-full')` returns function signatures.

## Examples

### Display Function Signatures

Load the example library, `shrllibsample`, and list the functions.

```
if not(libisloaded('shrllibsample'))
 addpath(fullfile(matlabroot,'extern','examples','shrllib'))
 loadlibrary('shrllibsample')
end
m = libfunctions('shrllibsample','-full')

m =

 '[double, doublePtr] addDoubleRef(double, doublePtr, double)'
 'double addMixedTypes(int16, int32, double)'
 '[double, c_structPtr] addStructByRef(c_structPtr)'
 'double addStructFields(c_struct)'
```

```
'c_structPtrPtr allocateStruct(c_structPtrPtr)'
'voidPtr deallocateStruct(voidPtr)'
'lib.pointer exportedDoubleValue'
'lib.pointer getListOfStrings'
'doublePtr multDoubleArray(doublePtr, int32)'
'[lib.pointer, doublePtr] multDoubleRef(doublePtr)'
'int16Ptr multiplyShort(int16Ptr, int32)'
'doublePtr print2darray(doublePtr, int32)'
'printExportedDoubleValue'
'cstring readEnum(Enum1)'
'[cstring, cstring] stringToUpper(cstring)'
```

## Input Arguments

### **libname** — Name of shared library

string

Name of shared library, specified as a string. Do not include the path or file extension in `libname`.

If you call `loadlibrary` using the `alias` option, then you must use the alias name for the `libname` argument.

Data Types: char

## Output Arguments

### **m** — Function names

cell array

Functions names, returned as a cell array.

## Limitations

- Use with libraries that are loaded using the `loadlibrary` function.

## See Also

`calllib` | `libfunctionsview` | `loadlibrary`

# libfunctionsview

Display shared library function signatures in window

## Syntax

```
libfunctionsview libname
```

## Description

`libfunctionsview libname` displays information about functions in library, `libname`, in a new window.

## Input Arguments

**libname** — Name of shared library

string

Name of shared library, specified as a string. Do not include the path or file extension in `libname`.

If you call `loadlibrary` using the `alias` option, then you must use the alias name for the `libname` argument.

Data Types: char

## Limitations

- Use with libraries that are loaded using the `loadlibrary` function.

## Examples

**Display Function Signatures for Library libmx**

```
if not(libisloaded('libmx'))
```

```
hfile = fullfile(matlabroot, 'extern', 'include', 'matrix.h');
loadlibrary('libmx', hfile)
end
libfunctionsview libmx
```

MATLAB creates a new window displaying function signatures.

## See Also

[libfunctions](#) | [calllib](#)

# libisloaded

Determine if shared library is loaded

## Syntax

```
tf = libisloaded(libname)
```

## Description

`tf = libisloaded(libname)` returns logical 1 (`true`) if the shared library, `libname`, is loaded. Otherwise, it returns logical 0 (`false`).

## Examples

### Load Functions in Library

Load example library, `shrlibsamle`, if it is not already loaded.

```
if ~libisloaded('shrlibsamle')
 loadlibrary('shrlibsamle')
end
```

## Input Arguments

### **libname** — Name of shared library

string

Name of shared library, specified as a string. Do not include the path or file extension in `libname`.

If you call `loadlibrary` using the `alias` option, then you must use the alias name for the `libname` argument.

Data Types: char

**See Also**

loadlibrary | unloadlibrary

# libpointer

Pointer object for use with shared library

## Syntax

```
p = libpointer
p = libpointer(DataType)
p = libpointer(DataType,Value)
```

## Description

`p = libpointer` creates NULL pointer `p` of type `voidPtr`.

`p = libpointer(DataType)` creates NULL pointer of specified `DataType`.

`p = libpointer(DataType,Value)` creates pointer initialized to a copy of `Value`.

## Examples

- “Multilevel Pointers”

## Input Arguments

**DataType** — Type of pointer

string

Type of pointer, specified as a string, of any MATLAB numeric type, structure defined in the library, or enumeration defined in the library. For a list of valid MATLAB numeric types, refer to these tables in “C and MATLAB Equivalent Types”.

- MATLAB Primitive Types
- MATLAB Extended Types

Example: `'int16Ptr'`

Data Types: char

**Value — Value for pointer object**

any valid value

Value, specified as any valid value for given type.

## Limitations

- Use with libraries that are loaded using the `loadlibrary` function.

## More About

### Tips

- This is an advanced feature for experienced C programmers. MATLAB automatically converts data passed to and from external library functions to the data type expected by the external function. Use a `lib.pointer` object instead of automatic conversion in the following situations.
  - You want to modify the data in the input arguments.
  - You are passing large amounts of data, and you want to control when MATLAB makes copies of the data.
  - The library stores and uses the pointer for a period of time so you want the MATLAB function to control the lifetime of the `lib.pointer` object.
- “Working with Pointer Arguments”

### See Also

`lib.pointer` | `calllib` | `libstruct`

# lib.pointer class

**Package:** lib

Pointer object compatible with C pointer

## Description

MATLAB automatically converts arguments that are passed by reference to a function in an external library. Use a pointer object instead of automatic conversion in the following situations.

- The function modifies data in an input argument.
- You are passing large amounts of data, and you want to control when MATLAB makes copies of the data.
- The library stores and uses the pointer for a period of time so you want the MATLAB function to control the lifetime of the `lib.pointer` object.

## Construction

To create a `lib.pointer` object, use the MATLAB `libpointer` function.

A library function can return a `lib.pointer` object. Use the `setdatatype` method to manually convert the argument to use in MATLAB.

## Properties

### Data Type

Type of pointer, specified as a string, of any MATLAB numeric type, structure defined in the library, or enumeration defined in the library. For a list of valid MATLAB numeric types, refer to these tables in “C and MATLAB Equivalent Types”.

- MATLAB Primitive Types
- MATLAB Extended Types

## Value

Value, specified as any valid value for given type.

## Methods

disp	Display lib.pointer type
isNull	Points to NULL pointer
plus	+ (plus) operator for pointer arithmetic
reshape	Reshape lib.pointer array
setdatatype	Initialize type and size of lib.pointer object

## Definitions

A passed-by-reference argument in the function signature has type names ending with Ptr or PtrPtr.

## Examples

### Create Pointer

Create a pointer, pv, of type int16, initialized to 485.

```
pv = libpointer('int16Ptr',485);
```

Display the properties of pv.

```
get(pv)
```

```
Value: 485
```

DataType: 'int16Ptr'

## **See Also**

libpointer

## **More About**

- “Working with Pointer Arguments”

## disp

**Class:** lib.pointer

**Package:** lib

Display lib.pointer type

## Syntax

```
disp(h)
```

## Description

disp(h) displays type for lib.pointer object, h.

## Input Arguments

**h** — lib.pointer object.  
handle

lib.pointer object, specified as a handle.

## Examples

### Display lib.pointer Type

Create a double pointer set to 15.

```
xp = libpointer('doublePtr',15);
```

Display pointer data type.

```
disp(xp)
```

```
libpointer
```

# isNull

**Class:** lib.pointer

**Package:** lib

Points to NULL pointer

## Syntax

```
tf = isNull(h)
```

## Description

`tf = isNull(h)` returns true if `h` is a `lib.pointer` object.

## Input Arguments

**h** — **lib.pointer** object.  
handle

lib.pointer object, specified as a handle.

## Examples

### Create Null lib.pointer Object

```
nullp = libpointer('doublePtr', []);
isNull(nullp)
```

## plus

**Class:** lib.pointer

**Package:** lib

+ (plus) operator for pointer arithmetic

## Syntax

```
hout = plus(h,offset)
```

```
hout = h + offset
```

## Description

`hout = plus(h,offset)` returns pointer `hout`. Pointer `hout` is valid only as long as the original pointer, `h`, exists.

`hout = h + offset` is an alternative syntax.

## Input Arguments

**h** — **lib.pointer object.**

handle

lib.pointer object, specified as a handle.

**offset** — **Scalar increment**

uint64

Scalar increment, specified as `uint64`, from `h`.

## Related Examples

- “Iterate Through an Array”

# reshape

**Class:** lib.pointer

**Package:** lib

Reshape lib.pointer array

## Syntax

reshape(h, xdim, ydim)

## Description

reshape(h, xdim, ydim) creates an xdim-by-ydim matrix from lib.pointer object h.

## Input Arguments

**h** — **lib.pointer object.**  
handle

lib.pointer object, specified as a handle.

**xdim** — **Size of x dimension**  
double

Size of x dimension, specified as double.

**ydim** — **Size of y dimension**  
double

Size of y dimension, specified as double.

## setdatatype

**Class:** lib.pointer

**Package:** lib

Initialize type and size of lib.pointer object

### Syntax

```
setdatatype(h,type,size)
```

### Description

setdatatype(h,type,size) sets data type, type, of size, to lib.pointer, h.

### Input Arguments

**h** — **lib.pointer** object.

handle

lib.pointer object, specified as a handle.

**type** — **Data type**

string

Data type, specified as a string.

**size** — **Size**

double

Size, specified as double.

### Examples

#### Set Size and Type of lib.pointer Output Variable

Load the shrllibsample library.

```
if ~libisloaded('shrlibsample')
 addpath(fullfile(matlabroot,'extern','examples','shrlib'))
 loadlibrary('shrlibsample')
end
```

The `multDoubleRef` function takes a scalar value specified as `doubleptr`. Create variable `xp` as a `lib.pointer` object, and call the function.

```
xp = libpointer('doublePtr',99);
[xobj,xval] = calllib('shrlibsample','multDoubleRef',xp);
```

To use the variable `xobj`, set its size and data type.

```
setdatatype(xobj,'doublePtr',1,1)
xobj.Value
```

```
ans =
```

```
495
```

## libstruct

Convert MATLAB structure to C-style structure for use with shared library

### Syntax

```
S = libstruct(structtype)
S = libstruct(structtype,mlstruct)
```

### Description

`S = libstruct(structtype)` creates NULL pointer to MATLAB `libstruct` object `S`.

`S = libstruct(structtype,mlstruct)` creates pointer initialized to `mlstruct`.

### Examples

#### Call Function with `c_struct` Input Argument

Call the `addStructFields` function by creating a variable of type `c_struct`.

Load the `shrlibsample` library, which contains the `c_struct` type.

```
if ~libisloaded('shrlibsample')
 addpath(fullfile(matlabroot,'extern','examples','shrlib'))
 loadlibrary('shrlibsample')
end
```

Display function signatures for `shrlibsample` and search the list for the `addStructFields` entry.

```
libfunctionsview shrlibsample

double addStructFields(c_struct)
```

The input argument is a pointer to a `c_struct` data type.

Create a MATLAB structure, `sm`.

```
sm.p1 = 476; sm.p2 = -299; sm.p3 = 1000;
```

Construct a `libstruct` object `sc` from the `c_struct` type.

```
sc = libstruct('c_struct',sm)
```

The fields of `sc` contain the values of the MATLAB structure, `sm`.

Call the `addStructFields` function.

```
calllib('shrlibsample','addStructFields',sc)
```

```
ans =
 1177
```

To clean up, first clear the `libstruct` object, and then unload the library.

```
clear sc
unloadlibrary shrlibsample
```

## Input Arguments

### **structtype** — C structure

structure

C structure defined in shared library.

### **m1struct** — MATLAB structure

structure

MATLAB structure used to initialize the fields in `S`.

Data Types: `struct`

## Output Arguments

### **S** — Pointer

MATLAB `libstruct` object

Pointer, returned as MATLAB `libstruct` object.

## Limitations

- Use with libraries that are loaded using the `loadlibrary` function.
- You can only use the `libstruct` function on scalar structures.
- When converting a MATLAB structure to a `libstruct` object, the structure must adhere to the requirements listed in “Structure Argument Requirements”.

## More About

### Tips

- If a function in the shared library has a structure argument, use `libstruct` to create the argument. The `libstruct` function creates a C-style structure that you pass to functions in the library. You handle this structure in MATLAB as you would a true MATLAB structure.
- “Working with Structure Arguments”

# license

Return license number or perform licensing task

## Syntax

```
license
license('inuse')
S = license('inuse')
S = license('inuse', feature)
license('test',feature)
license('test',feature,toggle)
[TF errmsg] = license('checkout',feature)
```

## Description

`license` returns the license number for this MATLAB product. The return value is always a string but is not guaranteed to be a number. The following table lists text strings that `license` can return.

String	Description
'demo'	MATLAB is a demonstration version
'student'	MATLAB is the student version
'unknown'	License number cannot be determined

`license('inuse')` returns a list of licenses checked out in the current MATLAB session. In the list, products are listed alphabetically by their license feature names, i.e., the text string used to identify products in the `INCREMENT` lines in a License File (`license.dat`). Note that the feature names returned in the list contain only lower-case characters.

`S = license('inuse')` returns an array of structures, where each structure represents a checked-out license. The structures contains two fields: `feature` and `user`. The `feature` field contains the license feature name. The `user` field contains the username of the person who has the license checked out.

`S = license('inuse', feature)` checks if the product specified by the text string `feature` is checked out in the current MATLAB session. If the product is checked out, the `license` function returns the product name and the username of the person who has it checked out in the structure `S`. If the product is not currently checked out, the fields in the structure are empty.

The `feature` string must be a license feature name, spelled exactly as it appears in the `INCREMENT` lines in a License File. For example, the string `'Identification_Toolbox'` is the feature name for the System Identification Toolbox™. The `feature` string is not case-sensitive and must not exceed 27 characters.

`license('test', feature)` tests if a license exists for the product specified by the text string `feature`. The `license` command returns `1` if the license exists and `0` if the license does not exist. The `feature` string identifies a product, as described in the previous syntax.

---

**Note** Testing for a license only confirms that the license exists. It does not confirm that the license can be checked out. For example, `license` will return `1` if a license exists, even if the license has expired or if a system administrator has excluded you from using the product in an options file. The existence of a license does not indicate that the product is installed.

---

`license('test', feature, toggle)` enables or disables testing of the product specified by the text string `feature`, depending on the value of `toggle`. The parameter `toggle` can have either of two values:

`'enable'` The syntax `license('test', feature)` returns `1` if the product license exists and `0` if the product license does not exist.

`'disable'` The syntax `license('test', feature)` always returns `0` (product license does not exist) for the specified product.

---

**Note** Disabling a test for a particular product can impact other tests for the existence of the license, not just tests performed using the `license` command.

---

`[TF errmsg] = license('checkout', feature)` checks out a license for the product specified by the text string `feature`, returning `1` if it could check out a license or `0` if it could not check out a license. If you specify the optional second output argument,

`errmsg`, the `license` function returns the text of any error message encountered, or an empty string if the checkout succeeded.

## Examples

Get the license number for this MATLAB.

```
license
```

Get a list of licenses currently being used. Note that the products appear in alphabetical order by their license feature name in the list returned.

```
license('inuse')
```

```
image_toolbox
map_toolbox
matlab
```

Get a list of licenses in use with information about who is using the license.

```
S = license('inuse');
```

```
S(1)
```

```
ans =
```

```
 feature: 'image_toolbox'
 user: 'juser'
```

Determine if the license for MATLAB is currently in use.

```
S = license('inuse', 'MATLAB')
```

```
S =
```

```
 feature: 'matlab'
 user: 'jsmith'
```

Determine if a license exists for the Mapping Toolbox™.

```
license('test', 'map_toolbox')
```

```
ans =
```

1

Check out a license for the Control System Toolbox™.

```
license('checkout','control_toolbox')
```

```
ans =

# light

Create light object

## Syntax

```
light('PropertyName',propertyvalue,...)
handle = light(...)
```

## Properties

For a list of properties, see [Light Properties](#).

## Description

`light` creates a light object in the current axes. Lights affect only patch and surface objects.

`light('PropertyName',propertyvalue,...)` creates a light object using the specified values for the named properties. For a description of the properties, see [Light Properties](#). The MATLAB software parents the light to the current axes unless you specify another axes with the `Parent` property.

`handle = light(...)` returns the handle of the light object created.

## Examples

Light the `peaks` surface plot with a local light source oriented along the direction defined by the vector `[-1 0 0]`, that is, looking from 0 along the positive x-axis.

```
surf(peaks,'FaceLighting','gouraud','FaceColor','interp',...
 'AmbientStrength',0.5)
light('Position',[-1 0 0],'Style','local')
```

## Tutorials

For more information about lighting, see “Lighting Overview”.

## More About

### Tips

You cannot see a light object *per se*, but you can see the effects of the light source on patch and surface objects. You can also specify an axes-wide ambient light color that illuminates these objects. However, ambient light is visible only when at least one light object is present and visible in the axes.

You can specify properties as property name/property value pairs, structure arrays, and cell arrays (see `set` and `get` for examples of how to specify these data types).

See also the Patch Properties and Primitive Surface Properties `AmbientStrength`, `DiffuseStrength`, `SpecularStrength`, `SpecularExponent`, `SpecularColorReflectance`, and `VertexNormals` properties. Also see the `lighting` and `material` commands.

### See Also

`lighting` | `patch` | `material` | `surface`

# Light Properties

Control light appearance and behavior

Light properties control the appearance and behavior of light objects. By changing property values, you can modify certain aspects of the light. Use dot notation to refer to a particular object and property:

```
h = light;
c = h.Color;
h.Style = 'local';
```

## Color, Position, and Style

### Color — Color of light

[1 1 1] (default) | RGB triplet | color string

Color of light emanating from the light object, specified as an RGB triplet or a color string. The default RGB triplet of [1 1 1] corresponds to white.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0, 1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[1 1 0]
'magenta'	'm'	[1 0 1]
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black'	'k'	[0 0 0]

Example: 'green'

**Position — Location of light source**

[1 0 1] (default) | three-element vector of the form [x y z]

Location of light source, specified as a three-element vector of the form [x y z]. Define the vector elements in data units from the axes origin to the (x, y, z) coordinate. The actual location of the light depends on the value of the Style property.

Example: [-40 -4 140]

**Style — Type of light source**

'infinite' (default) | 'local'

Type of light source, specified as one of these values:

- 'infinite' — Place the light at infinity. Use the Position property to specify the direction from which the light shines in parallel rays.
- 'local' — Place the light at the location specified by the Position property. The light is a point source that radiates from the location in all directions.

## Visibility

**Visible — Visibility of light from light source**

'on' (default) | 'off'

Visibility of light from light source, specified as 'on' or 'off'.

## Parent and Children

**Parent — Parent of light**

axes object | group object | transform object

Parent of light, specified as an axes, group, or transform object.

**Children — Children of light**

empty GraphicsPlaceholder array

The light has no children. You cannot set this property.

**HandleVisibility — Visibility of object handle**

'on' (default) | 'off' | 'callback'

Visibility of object handle in the `Children` property of the parent, specified as one of these values:

- `'on'` — List the light object.
- `'off'` — Do not list the light object. Use this option to hide object handles when a callback invokes a function that could damage the GUI, such as evaluating a user-typed string.
- `'callback'` — List the light object in the `Children` property of the parent from within callbacks or functions invoked by callbacks, but not from within functions invoked from the command line. Use this option to protect a GUI from command-line users, while allowing callbacks to have access to objects.

If the light object is not listed in the `Children` property of the parent, then functions that obtain object handles by searching the object hierarchy or querying handle properties cannot return it. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

Hidden object handles are still valid. Set the root `ShowHiddenHandles` property to `'on'` to list all object handles regardless of their `HandleVisibility` property setting.

## Identifiers

### Type — Type of graphics object

`'light'`

Type of graphics object, returned as the string `'light'`. Use this property to find all objects of a given type within a plotting hierarchy, for example, searching for the type using `findobj`.

### Tag — Tag to associate with light

`''` (default) | string

Tag to associate with the light, specified as a string. Tags provide a way to identify graphics objects. Use this property to find all objects with a specific tag within a plotting hierarchy, for example, searching for the tag using `findobj`.

Example: `'January Data'`

### UserData — Data to associate with light

`[]` (default) | scalar, vector, or matrix | cell array | character array | table | structure

Data to associate with the light object, specified as a scalar, vector, matrix, cell array, character array, table, or structure. MATLAB does not use this data.

To associate multiple sets of data or to attach a field name to the data, use the `getappdata` and `setappdata` functions.

Example: `1:100`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `struct` | `table` | `cell`

## Creation and Deletion Control

### **CreateFcn** — Creation callback

`'` (default) | function handle | cell array | string

Creation callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you create the light. Setting the `CreateFcn` property on an existing light has no effect. You must define a default value for this property, or define this property using a `Name, Value` pair during light creation. MATLAB executes the callback after creating the light and setting all of its properties.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The light object — You can access properties of the light object from within the callback function. You also can access the light object through the `CallbackObject` property of the root, which can be queried using the `gcbo` function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see “Callback Definition”.

Example: `@myCallback`

Example: {@myCallback, arg3}

### **DeleteFcn — Deletion callback**

' ' (default) | function handle | cell array | string

Deletion callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you delete the light. MATLAB executes the callback before destroying the light so that the callback can access its property values.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The light object — You can access properties of the light object from within the callback function. You also can access the light object through the `CallbackObject` property of the root, which can be queried using the `gcbo` function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see “Callback Definition”.

Example: @myCallback

Example: {@myCallback, arg3}

### **BeingDeleted — Deletion status of light**

'off' (default) | 'on'

Deletion status of light, returned as 'on' or 'off'. MATLAB sets the `BeingDeleted` property to 'on' when the delete function of the light begins execution (see the `DeleteFcn` property). The `BeingDeleted` property remains set to 'on' until the light no longer exists.

Check the value of the `BeingDeleted` property to verify that the light is not about to be deleted before querying or modifying it.

## Unused Properties

### **ButtonDownFcn** — (unused) Mouse-click callback

' ' (default) | function handle | cell array | string

Light objects do not use this property.

### **UIContextMenu** — (unused) Context menu

uicontextmenu object

Light objects do not use this property.

### **Selected** — (unused) Selection state

'off' (default) | 'on'

Light objects do not use this property.

### **SelectionHighlight** — (unused) Display of selection handles when selected

'on' (default) | 'off'

Light objects do not use this property.

### **PickableParts** — (unused) Ability to capture mouse clicks

'visible' (default) | 'none'

Light objects do not use this property.

### **HitTest** — (unused) Response to captured mouse clicks

'on' (default) | 'off'

Light objects do not use this property.

### **Interruptible** — (unused) Callback interruption

'on' (default) | 'off'

Light objects do not use this property.

### **BusyAction** — (unused) Callback queuing

'queue' (default) | 'cancel'

Light objects do not use this property.

## **See Also**

light

## lightangle

Create or position light object in spherical coordinates

### Syntax

```
lightangle(az,e1)
light_handle = lightangle(az,e1)
lightangle(light_handle,az,e1)
[az,e1] = lightangle(light_handle)
```

### Description

`lightangle(az,e1)` creates a light at the position specified by azimuth and elevation. `az` is the azimuthal (horizontal) rotation and `e1` is the vertical elevation (both in degrees). The interpretation of azimuth and elevation is the same as that of the `view` command.

`light_handle = lightangle(az,e1)` creates a light and returns the handle of the light in `light_handle`.

`lightangle(light_handle,az,e1)` sets the position of the light specified by `light_handle`.

`[az,e1] = lightangle(light_handle)` returns the azimuth and elevation of the light specified by `light_handle`.

### Examples

```
surf(peaks)
axis vis3d
h = light;
for az = -50:10:50
 lightangle(h,az,30)
 pause(.2)
end
```

## More About

### Tips

By default, when a light is created, its style is `infinite`. If the light handle passed in to `lightangle` refers to a local light, the distance between the light and the camera target is preserved as the position is changed.

- “Lighting Overview”

`light` | `camlight` | `view`

# lighting

Specify lighting algorithm

## Syntax

```
lighting flat
lighting gouraud
lighting none
```

## Description

`lighting` selects the algorithm used to calculate the effects of `light` objects on all `surface` and `patch` objects in the current axes. In order for the `lighting` command to have any effects, however, you must create a lighting object by using the `light` function.

`lighting flat` produces uniform lighting across each of the faces of the object. Select this method to view faceted objects.

`lighting gouraud` calculates the vertex normals and interpolates linearly across the faces. Select this method to view curved surfaces.

`lighting none` turns off lighting.

## More About

### Tips

The `surf`, `mesh`, `pcolor`, `fill`, `fill3`, `surface`, and `patch` functions create graphics objects that are affected by light sources. The `lighting` command sets the `FaceLighting` and `EdgeLighting` properties of surfaces and patches appropriately for the graphics object.

- “Lighting Overview”

# lin2mu

Convert linear audio signal to mu-law

## Syntax

```
mu = lin2mu(y)
```

## Description

`mu = lin2mu(y)` converts linear audio signal amplitudes in the range `-1 # Y # 1` to mu-law encoded “flints” in the range `0 # u # 255`.

## See Also

`auwrite` | `mu2lin`

## line

Create line object

### Syntax

```
line
line(X,Y)
line(X,Y,Z)
line(X,Y,Z,'PropertyName',propertyvalue,...)
line('XData',x,'YData',y,'ZData',z,...)
h = line(...)
```

### Properties

For a list of properties, see [Primitive Line Properties](#).

### Description

`line` creates a line object in the current axes with default values `x = [0 1]` and `y = [0 1]`. You can specify the color, width, line style, and marker type, as well as other characteristics.

The `line` function has two forms:

- Automatic color and line style cycling. When you specify multiple line coordinate data as a column array using the informal syntax (i.e., the first three arguments are interpreted as the coordinates),

```
line(X,Y,Z)
```

MATLAB cycles through the axes `ColorOrder` and `LineStyleOrder` property values the way the `plot` function does. However, unlike `plot`, `line` does not call the `newplot` function.

- Purely low-level behavior. When you call `line` with only property name/property value pairs,

```
line('XData',x,'YData',y,'ZData',z)
```

MATLAB draws a line object in the current axes using the default line color (see the `colordef` function for information on color defaults). Note that you cannot specify matrix coordinate data with the low-level form of the `line` function.

`line(X,Y)` adds the line defined in vectors `X` and `Y` to the current axes. If `X` and `Y` are matrices of the same size, `line` draws one line per column.

`line(X,Y,Z)` creates lines in three-dimensional coordinates.

`line(X,Y,Z,'PropertyName',propertyvalue,...)` creates a line using the values for the property name/property value pairs specified and default values for all other properties. For a description of the properties, see Primitive Line Properties.

`line('XData',x,'YData',y,'ZData',z,...)` creates a line in the current axes using the property values defined as arguments. This is the low-level form of the `line` function, which does not accept matrix coordinate data as the other informal forms described above.

`h = line(...)` returns a column vector of primitive line handles corresponding to each line object the function creates.

## Examples

This example uses the `line` function to add a shadow to plotted data. First, plot some data and save the line's handle:

```
t = 0:pi/20:2*pi;
hline1 = plot(t,sin(t),'k');
ax = gca;
```

Next, add a shadow by offsetting the  $x$ -coordinates. Make the shadow line light gray and wider than the default `LineWidth`:

```
hline2 = line(t+.06,sin(t),...
 'LineWidth',4,...
 'Color',[.8 .8 .8],...
 'Parent',ax);
```

Finally, pull the first line to the front:

```
set(gca, 'Children', [hline1 hline2])
```

## Drawing Lines Interactively

You can use the `ginput` function to select points from a figure. For example:

```
[x,y] = ginput(5);
line(x,y)
```

### Drawing with mouse motion

You can use the axes `CurrentPoint` property and the figure `WindowButtonDownFcn` and `WindowButtonMotionFcn` properties to select a point with a mouse click and draw a line to another point by dragging the mouse, like a simple drawing program. The following example illustrates a few useful techniques for doing this type of interactive drawing.

Click to view in editor — This example enables you to click and drag the cursor to draw lines.

Click to run example — Click the left mouse button in the axes and move the cursor, left-click to define the line end point, right-click to end drawing mode.

## Input Argument Dimensions — Informal Form

This statement reuses the one-column matrix specified for `ZData` to produce two lines, each having four points.

```
line(rand(4,2),rand(4,2),rand(4,1))
```

If all the data has the same number of columns and one row each, MATLAB transposes the matrices to produce data for plotting. For example,

```
line(rand(1,4),rand(1,4),rand(1,4))
```

is changed to

```
line(rand(4,1),rand(4,1),rand(4,1))
```

This also applies to the case when just one or two matrices have one row. For example, the statement

```
line(rand(2,4),rand(2,4),rand(1,4))
```

is equivalent to

```
line(rand(4,2),rand(4,2),rand(4,1))
```

## More About

### Tips

In its informal form, the `line` function interprets the first three arguments (two for 2-D) as the X, Y, and Z coordinate data, allowing you to omit the property names. You must specify all other properties as name/value pairs. For example,

```
line(X,Y,Z,'Color','r','LineWidth',4)
```

The low-level form of the `line` function can have arguments that are only property name/property value pairs. For example,

```
line('XData',x,'YData',y,'ZData',z,...
 'Color','r','LineWidth',4)
```

Line properties control various aspects of the line object. You can also set and query property values after creating the line using dot notation or the `set` and `get` functions

Unlike high-level functions such as `plot`, `line` does not respect the settings of the figure and axes `NextPlot` properties. It simply adds line objects to the current axes. However, axes properties that are under automatic control, such as the axis limits, can change to accommodate the line within the current axes.

## Connecting the dots

The coordinate data is interpreted as vectors of corresponding x, y, and z values:

```
X = [x(1) x(2) x(3)...x(n)]
Y = [y(1) y(2) y(3)...y(n)]
Z = [z(1) z(2) z(3)...z(n)]
```

where a point is determined by the corresponding vector elements:

```
p1(x(i),y(i),z(i))
```

For example, to draw a line from the point located at  $x = .3$  and  $y = .4$  and  $z = 1$  to the point located at  $x = .7$  and  $y = .9$  and  $z = 1$ , use the following data:

```
axis([0 1 0 1])
line([.3 .7],[.4 .9],[1 1],'Marker','.', 'LineStyle','-')
```

## See Also

### Functions

[annotation](#) | [axes](#) | [loglog](#) | [plot](#) | [plot3](#)

### Properties

[Primitive Line Properties](#)

# LineSpec (Line Specification)

Line specification string syntax

## Description

Plotting functions accept *string specifiers* as arguments and modify the graph generated accordingly. Three components can be specified in the *string specifiers* along with the plotting command. They are:

- Line style
- Marker symbol
- Color

For example:

```
plot(x,y, '-.or')
```

plots *y* versus *x* using a dash-dot line (-.), places circular markers (o) at the data points, and colors both line and marker red (r). Specify the components (in any order) as a quoted string after the data arguments. Note that linespecs are single strings, not property-value pairs.

## Plotting Data Points with No Line

If you specify a marker, but not a line style, only the markers are plotted. For example:

```
plot(x,y, 'd')
```

## Line Style Specifiers

You indicate the line styles, marker types, and colors you want to display using *string specifiers*, detailed in the following tables:

Specifier	LineStyle
'-'	Solid line (default)
'--'	Dashed line

Specifier	LineStyle
'.'	Dotted line
'-.'	Dash-dot line

## Marker Specifiers

Specifier	Marker Type
'+'	Plus sign
'o'	Circle
'*'	Asterisk
'.'	Point
'x'	Cross
'square' or 's'	Square
'diamond' or 'd'	Diamond
'^'	Upward-pointing triangle
'v'	Downward-pointing triangle
'>'	Right-pointing triangle
'<'	Left-pointing triangle
'pentagram' or 'p'	Five-pointed star (pentagram)
'hexagram' or 'h'	Six-pointed star (hexagram)

---

**Note:** The point (.) marker type does not change size when the specified value is less than 5.

---

## Color Specifiers

Specifier	Color
r	Red
g	Green
b	Blue

Specifier	Color
c	Cyan
m	Magenta
y	Yellow
k	Black
w	White

## Related Properties

This page also describes how to specify the properties of lines used for plotting. MATLAB graphics give you control over these visual characteristics:

- `LineWidth` — Specifies the width (in points) of the line.
- `MarkerEdgeColor` — Specifies the color of the marker or the edge color for filled markers (circle, square, diamond, pentagram, hexagram, and the four triangles).
- `MarkerFaceColor` — Specifies the color of the face of filled markers.
- `MarkerSize` — Specifies the size of the marker in points (must be greater than 0).

In addition, you can specify the `LineStyle`, `Color`, and `Marker` properties instead of using the symbol string. This is useful if you want to specify a color that is not in the list by using RGB triplet values. See [Chart Line Properties](#) for details on these properties and [ColorSpec](#) for more information on color.

## Examples

Plot the sine function over three different ranges using different line styles, colors, and markers.

```
figure
t = 0:pi/20:2*pi;
plot(t,sin(t),'-r*')
hold on
plot(t,sin(t-pi/2),'--mo')
plot(t,sin(t-pi),':bs')
hold off
```

Create a plot illustrating how to set line properties:

```
figure
plot(t,sin(2*t),'-mo',...
 'LineWidth',2,...
 'MarkerEdgeColor','k',...
 'MarkerFaceColor',[.49 1 .63],...
 'MarkerSize',10)
```

**See Also**

[axes](#) | [line](#) | [plot](#) | [patch](#) | [set](#) | [surface](#) | [ColorSpec](#)

# linkaxes

Synchronize limits of specified 2-D axes

## Syntax

```
linkaxes(axes_handles)
linkaxes(axes_handles, 'option')
```

## Description

Use `linkaxes` to synchronize the individual axis limits across several figures or subplots within a figure. Calling `linkaxes` makes all input axes have identical limits. Linking axes is best when you want to zoom or pan in one subplot and display the same range of data in another subplot.

---

**Note:** Use `linkaxes` for axes that remain in 2-D views.

---

`linkaxes(axes_handles)` links the *x*- and *y*-axis limits of the axes specified in the vector `axes_handles`. You can link any number of existing plots or subplots. The `axes_handles` input should be a vector of the handles for each plot or subplot. Entering an array of values results in an error message.

`linkaxes(axes_handles, 'option')` links the axes' `axes_handles` according to the specified option. The *option* argument can be one of the following strings:

<code>x</code>	Link <i>x</i> -axis only.
<code>y</code>	Link <i>y</i> -axis only.
<code>xy</code>	Link <i>x</i> -axis and <i>y</i> -axis.
<code>off</code>	Remove linking.

See the `linkprop` function for more advanced capabilities that allow you to link object properties on any graphics object.

## Examples

### Create Subplots and Link Their Axes

Create three subplots and link their  $x$ -axes and  $y$ -axes so that they are always in sync.

First, create a figure with three subplots. Plot data in each subplot.

```
figure
ax1 = subplot(2,2,1);
x1 = linspace(0,6);
y1 = sin(x1);
plot(x1,y1)

ax2 = subplot(2,2,2);
x2 = linspace(0,10);
y2 = sin(2*x2);
plot(x2,y2)

ax3 = subplot(2,2,[3,4]);
x3 = linspace(0,16);
y3 = sin(6*x3);
plot(x3,y3)
```

Now link the axes for the three subplots using the `linkaxes` function. Pass the string 'xy' as an input argument to the function to link both the *x*-axes and *y*-axes. The `linkaxes` function uses the limits from the first axes passed to it.

```
linkaxes([ax1,ax2,ax3], 'xy')
```

Panning or zooming into one of the subplots displays the same range of data in the other two subplots. To remove the linking, use `linkaxes([ax1,ax2,ax3]), 'off'`.

### Use Specific Subplot to Determine Limits for All Subplots

Load the `count.dat` data set which returns a three-column array named `count`. Create a new figure with three subplots and return the axes handles. In each subplot, create a bar graph.

```
load count.dat

figure
ax1 = subplot(3,1,1);
bar(count(:,1), 'g');
```

```
ax2 = subplot(3,1,2);
bar(count(:,2), 'b');

ax3 = subplot(3,1,3);
bar(count(:,3), 'm');
```

Link the *x*-axes and *y*-axes limits using `linkaxes` with the argument `'xy'`. Base the limits on the third subplot by passing its axes handle, `ax3`, as the first input to `linkaxes`.

```
linkaxes([ax3,ax2,ax1], 'xy');
```

If you zoom in on one subplot, then the other two subplots behave in the same manner. To enable interactive zooming, use `zoom on`. To disable zooming, use `zoom off`.

### Link x-Axes And Change Axis Limits

Load the `count.dat` data set which returns a three-column array named `count`. Create a new figure with two subplots and return the axes handles. In each subplot, create a bar graph.

```
load count.dat
figure
ax1 = subplot(2,1,1);
bar(count(:,1), 'g');
```

```
ax2 = subplot(2,1,2);
bar(count(:,2), 'b');
```

Link the  $x$ -axes for the two subplots.

```
linkaxes([ax1,ax2], 'x');
```

Set the  $x$ -axis limits for the second subplot. Setting the limits overrides the limits initially set by `linkaxes`. Changing the  $x$ -axis limits effects both subplots.

```
ax2.XLim = [4.5,9.5];
```

If you pan either subplot, then both subplots pan uniformly in the  $x$ -direction, but only one subplot moves in the  $y$ -direction. To enable interactive panning, use `pan on`. To disable panning, use `pan off`.

## More About

### Tips

The first axes you supply to `linkaxes` determines the  $x$ - and  $y$ -limits for all linked axes. This can cause plots to partly or entirely disappear if their limits or scaling are very different. To override this behavior, after calling `linkaxes`, specify the limits of the axes that you want to control with the `set` command, as the third example illustrates.

---

**Note:** `linkaxes` is not designed to be transitive across multiple invocations. If you have three axes, `ax1`, `ax2`, and `ax3` and want to link them together, call `linkaxes` with `[ax1, ax2, ax3]` as the first argument. Linking `ax1` to `ax2`, then `ax2` to `ax3`, "unbinds" the `ax1-ax2` linkage.

---

# linkdata

Automatically update graphs when variables change

## Syntax

```
linkdata on
linkdata off
linkdata
linkdata(figure_handle,...)
linkobj = linkdata(figure_handle)
```

## Description

`linkdata on` turns on data linking for the current figure.

`linkdata off` turns data linking off.

`linkdata` by itself toggles the state of data linking.

`linkdata(figure_handle,...)` applies the function to the specified figure handle.

`linkobj = linkdata(figure_handle)` returns a *linkdata object* for the specified figure. The object has one read-only property, **Enable**, the string 'on' or 'off', depending on the linked state of the figure.

Data linking connects graphs in figure windows to variables in the base or a function's workspace via their **XDataSource**, **YDataSource**, and **ZDataSource** properties. When you turn on data linking for a figure, MATLAB compares variables in the current (base or function caller) workspace with the **XData**, **YData**, and **ZData** properties of graphs in the affected figure to try to match them. When a match is found, the appropriate **XDataSource**, **YDataSource** and/or **ZDataSource** for the graph are set to strings that name the matching variables.

Any subsequent changes to linked variables are reflected in graphs that use them as data sources and in the Variables editor, if the linked variables are displayed there.

Conversely, any changes to plotted data values made at the command line, in the Variables editor, or with the Brush tool (such as deleting or replacing data points), are immediately reflected in the workspace variables linked to the data points.

When a figure containing graphs is linked and any variable identified as `XDataSource`, `YDataSource`, and/or `ZDataSource` changes its values in the workspace, all graphs displaying it in that and other linked figures automatically update. This operation is equivalent to automatically calling the `refreshdata` function on the corresponding figure when a variable changes.

Linked figure windows identify themselves by the appearance of the Linked Plot information bar at the top of the window. When `linkdata` is `off` for a figure, the Linked Plot information bar is removed. If `linkdata` cannot unambiguously identify data sources for a graph in a linked figure, it reports this via the Linked Plot information bar, which gives the user an opportunity to identify data sources. The information bar displays a warning icon and a message, **No graphics have data sources** and also prompts **fix it**. Clicking **fix it** opens the Specify Data Source Properties dialog box for identifying variable names and ranges of data sources used in the graph.

## Examples

### Example 1

Create two variables, plot them as area charts, and link the plot to them:

```
x = 1:20;
y = rand(20,3);
area(x,y)
linkdata on
```

Change values for linked variable  $y$  in the workspace:

```
y(10,:) = 0;
```

The area graph immediately updates.

## Example 2

Delete a figure if it is not linked, based on a returned linkdata object:

```
fig = figure;
ld = linkdata(fig)
```

```
ld =
 graphics.linkdata
```

```
if strcmp(ld.Enable, 'off')
 delete(fig)
end
```

## Example 3

If a plotting function can display a complex variable, then you can link such plots. To do so, you need to describe the data sources as expressions to separate the real and imaginary parts of the variable. For example,

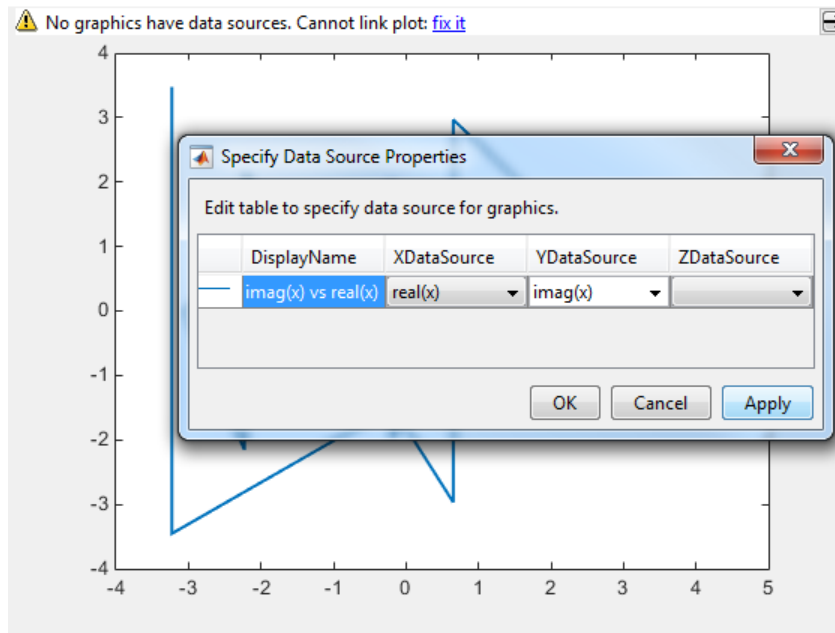

```
x = eig(randn(20,20));
whos
```

Name	Size	Bytes	Class	Attributes
x	20x1	320	double	complex

yields a complex vector. You can use `plot` to display the real portion as  $x$  and the imaginary portion as  $y$ , then link the graph to the variable:

```
plot(x)
linkdata
```

However, `linkdata` cannot unambiguously identify the graph's data sources, and you must tell it by typing `real(x)` and `imag(x)` into the Specify Data Source Properties dialog box that displays when you click **fix it** in the Linked Plot information bar.

To avoid having to type the data source names in the dialog box, you can specify them when you plot:

```
plot(x, 'XDataSource', 'real(x)', 'YDataSource', 'imag(x)')
```

If you subsequently change values of  $x$  programmatically or manually, the plot updates accordingly.

---

**Note:** Although you can use data brushing on linked plots of complex data, your brush marks only appear in the plot you are brushing, not in other plots or in the Variables editor. This is because function calls, such as `real(x)` and `imag(x)`, that you specify as data sources are not interpreted when brushing graphed data.

---

## More About

### Tips

- “Types of Variables You Can Link” on page 1-4335
- “Restoring Links that Break” on page 1-4335
- “Linking Rapidly Changing Data” on page 1-4335
- “Linking Brushed Graphs” on page 1-4336

## Types of Variables You Can Link

You can use `linkdata` to connect a graph with scalar, vector and matrix numeric variables of any class (including `complex`, if the graphing function can plot it) — essentially any data for which `isnumeric` equals `true`. See “Example 3” on page 1-4333 for instructions on linking complex variables. You can also link plots to numeric fields within structures. You can specify MATLAB expressions as data sources, for example, `sqrt(y)+1`.

## Restoring Links that Break

Refreshing data on a linked plot fails if the strings in the `XDataSource`, `YDataSource`, or `ZDataSource` properties, when evaluated, are incompatible with what is in the current workspace, such that the corresponding `XData`, `YData`, or `ZData` are unable to respond. The visual appearance of the object in the graph is not affected by such failures, so graphic objects show no indication of broken links. Instead, a warning icon and the message **Failing links** appear on the Linked Plot information bar along with an **Edit** button that opens the Specify Data Sources dialog box.

## Linking Rapidly Changing Data

`linkdata` buffers updates to data and dispatches them to plots at roughly half-second intervals. This makes data linking not suitable for smoothly animating changes in data

values unless they are updated in loops that are forced to execute two times per second or less.

One consequence of buffering link updates is that `linkdata` might not detect changes in data streams it monitors. If you are running a function that uses `assignin` or `evalin` to update workspace variables, `linkdata` can sometimes fail to process updates that change values but not the size and class of workspace variables. Such failures only happen when the function itself updates the plot.

## Linking Brushed Graphs

If you link data sources to graphs that have been brushed, their brushing marks can change or vanish. This is because the workspace variables in those graphs now dictate which, if any, observations are brushed, superseding any brushing annotations that were applied to their graphical data (`YData`, etc.). For more details, see “How Data Linking Affects Data Brushing” in the `brush` reference page.

`brush` | `linkaxes` | `linkprop` | `refreshdata`

# linkprop

Keep same value for corresponding properties of graphics objects

## Syntax

```
hlink = linkprop(obj_handles, 'PropertyName')
```

```
hlink = linkprop(obj_handles, {'PropertyName1', 'PropertyName2', ...})
```

## Description

Use `linkprop` to maintain the same values for the corresponding properties of different graphics objects.

---

**Note:** Use `linkprop` only with Handle Graphics objects.

---

`hlink = linkprop(obj_handles, 'PropertyName')` maintains the same value for the property *PropertyName* on all objects whose handles appear in `obj_handles`. `linkprop` returns the link object in `hlink`. See “About Link Objects” on page 1-4338 for more information.

`hlink = linkprop(obj_handles, {'PropertyName1', 'PropertyName2', ...})` maintains the same respective values for all properties passed as a cell array on all objects whose handles appear in `obj_handles`.

MATLAB updates the linked properties of all linked objects immediately when `linkprop` is called. The first object in the list `obj_handles` determines the property values for the other objects.

A set of graphics objects can have only one link object connecting their properties at any given time. Calling `linkprop` creates a new link object. This new link object replaces any existing link object that is associated with the objects specified in `obj_handles`. However, you can manage which properties and which objects are linked by calling methods on that object:

- To add an object to the list of linked objects, use the `addtarget` method.

- To link new properties of currently-linked objects, use the `addprop` method.
- To stop linking an object, use the `removetarget` method.
- To stop properties from linking, use the `removeprop` method.

## About Link Objects

The link object that `linkprop` returns stores the mechanism that links the properties of different graphics objects. Therefore, the link object must exist within the context where you want property linking to occur (such as in the base workspace if users are to interact with the objects from the command line or figure tools).

The following list describes ways to maintain a reference to the link object.

- Return the link object as an output argument from a function and keep it in the base workspace while interacting with the linked objects.
- Make the `hlink` variable global.
- Store the `hlink` variable in an object's `UserData` property or in application data.

## Updating a Link Object

If you want to change either the graphics objects or the properties that are linked, you need to use the link object methods designed for that purpose. These methods are functions that operate only on link objects. To use them, you must first create a link object using `linkprop`.

Method	Purpose
<code>addtarget</code>	Add specified graphics object to the link object's targets.
<code>removetarget</code>	Remove specified graphics object from the link object's targets.
<code>addprop</code>	Add specified property to the linked properties.
<code>removeprop</code>	Remove specified property from the linked properties.

## Method Syntax

```
ddtarget(hlink,obj_handles)
```

```
removetarget(hlink,obj_handles)
addprop(hlink,'PropertyName')
removeprop(hlink,'PropertyName')
```

## Method Arguments

- `hlink` — Link object returned by `linkprop`
- `obj_handles` — One or more graphic object handles
- `PropertyName` — Name of a property common to all target objects

## Examples

### Link Axes So They Rotate Simultaneously

Link properties of two axes so that rotating one axes automatically rotates the other.

Create a figure with two axes and store the axes handles. Add plots to both axes.

```
figure
ax1 = subplot(2,1,1);
[X1,Y1,Z1] = peaks;
surf(X1,Y1,Z1)

ax2 = subplot(2,1,2);
[X2,Y2,Z2] = peaks(10);
surf(X2,Y2,Z2)
```

Link the `CameraPosition` and `CameraUpVector` properties of the axes and return the link object handle. Then, enable interactive rotation and use the mouse to rotate either axes. Rotating one axes automatically rotates the other in the same manner.

```
hlink = linkprop([ax1,ax2],{'CameraPosition','CameraUpVector'});
rotate3d on
```

To disable interactive rotation, use `rotate3d off`.

Link an additional property by passing the link object handle and the property name to `addprop`.

```
addprop(hlink, 'PlotBoxAspectRatio')
```

# linsolve

Solve linear system of equations

## Syntax

```
X = linsolve(A,B)
X = linsolve(A,B,opts)
```

## Description

`X = linsolve(A,B)` solves the linear system  $A*X = B$  using LU factorization with partial pivoting when  $A$  is square and QR factorization with column pivoting otherwise. The number of rows of  $A$  must equal the number of rows of  $B$ . If  $A$  is  $m$ -by- $n$  and  $B$  is  $m$ -by- $k$ , then  $X$  is  $n$ -by- $k$ . `linsolve` returns a warning if  $A$  is square and ill conditioned or if it is not square and rank deficient.

`[X, R] = linsolve(A,B)` suppresses these warnings and returns  $R$ , which is the reciprocal of the condition number of  $A$  if  $A$  is square, or the rank of  $A$  if  $A$  is not square.

`X = linsolve(A,B,opts)` solves the linear system  $A*X = B$  or  $A'*X = B$ , using the solver that is most appropriate given the properties of the matrix  $A$ , which you specify in `opts`. For example, if  $A$  is upper triangular, you can set `opts.UT = true` to make `linsolve` use a solver designed for upper triangular matrices. If  $A$  has the properties in `opts`, `linsolve` is faster than `mldivide`, because `linsolve` does not perform any tests to verify that  $A$  has the specified properties.

---

**Notes** If  $A$  does not have the properties that you specify in `opts`, `linsolve` returns incorrect results and does not return an error message. If you are not sure whether  $A$  has the specified properties, use `mldivide` instead.

For small problems, there is no speed benefit in using `linsolve` on triangular matrices as opposed to using the `mldivide` function.

---

The `TRANSA` field of the `opts` structure specifies the form of the linear system you want to solve:

- If you set `opts.TRANSA = false`, `linsolve(A,B,opts)` solves  $A \cdot X = B$ .
- If you set `opts.TRANSA = true`, `linsolve(A,B,opts)` solves  $A' \cdot X = B$ .

The following table lists all the field of `opts` and their corresponding matrix properties. The values of the fields of `opts` must be `logical` and the default value for all fields is `false`.

Field Name	Matrix Property
LT	Lower triangular
UT	Upper triangular
UHESS	Upper Hessenberg
SYM	Real symmetric or complex Hermitian
POSDEF	Positive definite
RECT	General rectangular
TRANSA	Conjugate transpose — specifies whether the function solves $A \cdot X = B$ or $A' \cdot X = B$

The following table lists all combinations of field values in `opts` that are valid for `linsolve`. A `true/false` entry indicates that `linsolve` accepts either `true` or `false`.

LT	UT	UHESS	SYM	POSDEF	RECT	TRANSA
true	false	false	false	false	true/false	true/false
false	true	false	false	false	true/false	true/false
false	false	true	false	false	false	true/false
false	false	false	true	true/false	false	true/false
false	false	false	false	false	true/false	true/false

## Examples

The following code solves the system  $A'x = b$  for an upper triangular matrix  $A$  using both `mldivide` and `linsolve`.

```
A = triu(rand(5,3)); x = [1 1 1 0 0]'; b = A'*x;
y1 = (A')\b
```

```
opts.UT = true; opts.TRANS_A = true;
y2 = linsolve(A,b,opts)
```

```
y1 =
```

```
1.0000
1.0000
1.0000
0
0
```

```
y2 =
```

```
1.0000
1.0000
1.0000
0
0
```

---

**Note** If you are working with matrices having different properties, it is useful to create an options structure for each type of matrix, such as `opts_sym`. This way you do not need to change the fields whenever you solve a system with a different type of matrix `A`.

---

`mldivide`

# linspace

Generate linearly spaced vector

The `linspace` function generates linearly spaced vectors. It is similar to the colon operator “:” but gives direct control over the number of points and always includes the endpoints.

## Syntax

```
y = linspace(x1,x2)
y = linspace(x1,x2,N)
```

## Description

`y = linspace(x1,x2)` returns a row vector with 100 linearly spaced points in the interval `[x1,x2]`.

`y = linspace(x1,x2,N)` returns `N` linearly spaced points.

## Examples

### Create Vector of Evenly Spaced Real Numbers

Create a vector of 100 evenly spaced points in the interval `[-5,5]`.

```
y = linspace(-5,5);
```

### Create Vector with Specified Number of Values

Create a vector of 7 evenly spaced points in the interval `[-5,5]`.

```
y1 = linspace(-5,5,7)
```

```
y1 =
```

```
-5.0000 -3.3333 -1.6667 0 1.6667 3.3333 5.0000
```

### Create Vector of Evenly Spaced Complex Numbers

Create a vector of complex numbers with 8 evenly spaced points between  $1+2i$  and  $10+10i$ .

```
y = linspace(1+2i,10+10i,8)
```

```
y =
```

```
Columns 1 through 5
```

```
1.0000 + 2.0000i 2.2857 + 3.1429i 3.5714 + 4.2857i 4.8571 + 5.4286i 6.1429 +
```

```
Columns 6 through 8
```

```
7.4286 + 7.7143i 8.7143 + 8.8571i 10.0000 +10.0000i
```

## Input Arguments

### **x1, x2** — Point interval

pair of scalars

Point interval, specified as a pair of scalars.  $x1$  and  $x2$  define the interval over which `linspace` generates linearly spaced points (including the endpoints).  $x2$  can be either larger or smaller than  $x1$ . If  $x2$  is smaller than  $x1$ , then the vector contains descending values.

**Data Types:** double | single | datetime | duration

Complex Number Support: Yes

### **N** — Number of points

100 (default) | real numeric scalar

Number of points, specified as a real numeric scalar.

For best results, specify  $N$  as a positive integer to indicate the number of linearly spaced points in the interval  $[x1, x2]$ . Otherwise:

- If  $N$  is 1, then `linspace` returns  $x2$ .

- If `N` is not an integer, then `linspace` uses a number of points equal to `floor(double(N))`.
- If `N` rounds to zero or is negative, then `linspace` returns an empty 1-by-0 matrix.

## Output Arguments

### **y** — Vector of linearly spaced points

vector

Vector of linearly spaced points, returned as a vector. `y` contains `N` linearly spaced points in the interval `[x1, x2]`, including the endpoints, with the default number of points being 100.

`linspace(x1, x2, N)` uses a step size of  $(x2 - x1) / (N - 1)$ .

# RandStream.list

Random number generator algorithms

## Class

RandStream

## Syntax

RandStream.list

## Description

RandStream.list lists all the generator algorithms that may be used when creating a random number stream with RandStream or RandStream.create. The available generator algorithms and their properties are given in the following table.

Keyword	Generator	Multiple Stream and Substream Support	Approximate Period In Full Precision
mt19937ar	Mersenne twister (used by default stream at MATLAB startup)	No	$2^{19937} - 1$
mcg16807	Multiplicative congruential generator	No	$2^{31} - 2$
mlfg6331_64	Multiplicative lagged Fibonacci generator	Yes	$2^{124}$
mrg32k3a	Combined multiple recursive generator	Yes	$2^{127}$
shr3cong	Shift-register generator summed with linear	No	$2^{64}$

<b>Keyword</b>	<b>Generator</b>	<b>Multiple Stream and Substream Support</b>	<b>Approximate Period In Full Precision</b>
	congruential generator		
swb2712	Modified subtract with borrow generator	No	$2^{1492}$

See “Choosing a Random Number Generator” for details about these generator algorithms. See <http://www.math.sci.hiroshima-u.ac.jp/~m-mat/MT/emt.html> for a full description of the Mersenne twister algorithm.

# listdlg

Create and open list-selection dialog box

## Syntax

```
[Selection,ok] = listdlg('ListString',S)
```

## Description

[Selection,ok] = listdlg('ListString',S) creates a modal dialog that enables you to select one or more items from a list. **Selection** is a vector of indices of the selected strings (in single selection mode, its length is 1). **Selection** is [] when **OK** is 0. **OK** is 1 if you click the **OK** button, or 0 if you click the **Cancel** button or close the dialog box. Double-clicking on an item or pressing **Return** when multiple items are selected has the same effect as clicking the **OK** button. The dialog box has a **Select all** button (when in multiple selection mode) that enables you to select all list items.

Inputs are in parameter/value pairs:

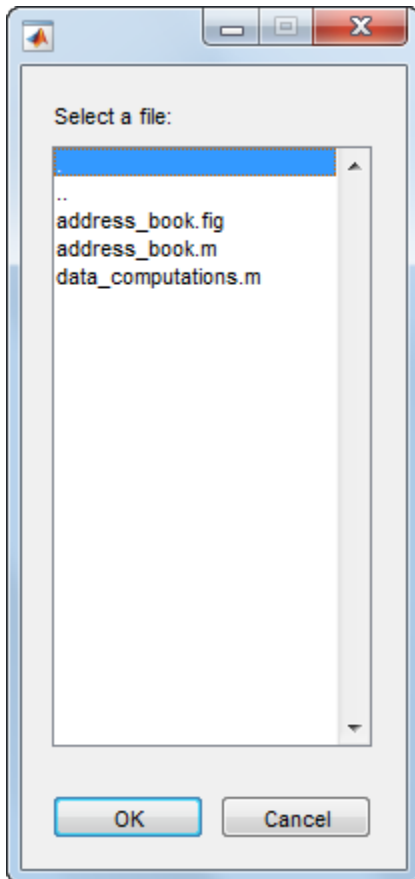

Parameter	Description
'ListString'	Cell array of strings that specify the list box items.
'SelectionMode'	String indicating whether one or many items can be selected: 'single' or 'multiple' (the default).
'ListSize'	List box size in pixels, specified as a two-element vector [width height]. Default is [160 300].
'InitialValue'	Vector of indices of the list box items that are initially selected. Default is 1, the first item.
'Name'	String for the dialog box's title. Default is ''.
'PromptString'	String matrix or cell array of strings that appears as text above the list box. Default is {}.
'OKString'	String for the OK button. Default is 'OK'.
'CancelString'	String for the Cancel button. Default is 'Cancel'.

Parameter	Description
'uh'	Uicontrol button height, in pixels. Default is 18.
'fus'	Frame/uicontrol spacing, in pixels. Default is 8.
'ffs'	Frame/figure spacing, in pixels. Default is 8.

## Examples

This example displays a dialog box that enables the user to select a file from the current directory. The function returns a vector. Its first element is the index to the selected file; its second element is 0 if no selection is made, or 1 if a selection is made.

```
d = dir;
str = {d.name};
[s,v] = listdlg('PromptString','Select a file:',...
 'SelectionMode','single',...
 'ListString',str)
```

## More About

### Modal Dialog

A window that prevents the user from interacting with other windows before responding. For more information, see the figure `WindowState` property description.

### See Also

`uigetfile` | `uigetdir` | `questdlg` | `uicontrol`

## listfonts

List available system fonts

### Syntax

```
c = listfonts
c = listfonts(h)
```

### Description

`c = listfonts` returns sorted list of available system fonts.

`c = listfonts(h)` returns sorted list of available system fonts and includes the `FontName` property of the object with handle `h`.

### Examples

#### Example 1

This example returns a list of available system fonts similar in format to the one shown.

```
list = listfonts

list =
 'Agency FB'
 'Algerian'
 'Arial'
 ...
 'ZapfChancery'
 'ZapfDingbats'
 'ZWAdobeF'
```

#### Example 2

This example returns a list of available system fonts with the value of the `FontName` property, for the object with handle `h`, included and sorted in the list.

```
h = uicontrol('Style','text','String',...
 'My Font','FontName','MyFont');
list = listfonts(h)

list =
 'Agency FB'
 'Algerian'
 'Arial'
 ...
 'MyFont'
 ...
 'ZapfChancery'
 'ZapfDingbats'
 'ZWAdobeF'
```

## More About

### Tips

Calling `listfonts` returns a list of all fonts on your system, possibly including fonts that you cannot use with MATLAB. Consider using the `uisetfont` utility (a GUI) to preview fonts to use; it only displays fonts that MATLAB can render in figures and GUIs. Like `uisetfont`, the **Custom Fonts** pane of MATLAB Preferences also previews available fonts and only shows those that MATLAB can render.

### See Also

`uisetfont`

# load

Load variables from file into workspace

## Syntax

```
load(filename)
load(filename,variables)
load(filename,'-ascii')
load(filename,'-mat')
load(filename,'-mat',variables)
```

```
S = load(___)
```

```
load filename
```

## Description

`load(filename)` loads data from `filename`.

- If `filename` is a MAT-file, then `load(filename)` loads variables in the MAT-File into the MATLAB workspace.
- If `filename` is an ASCII file, then `load(filename)` creates a double-precision array containing data from the file.

`load(filename,variables)` loads the specified variables from the MAT-file, `filename`.

`load(filename,'-ascii')` treats `filename` as an ASCII file, regardless of the file extension.

`load(filename,'-mat')` treats `filename` as a MAT-file, regardless of the file extension.

`load(filename,'-mat',variables)` loads the specified variables from `filename`.

`S = load( ___ )` loads data into `S`, using any of the input arguments in the previous syntax group.

- If `filename` is a MAT-file, then `S` is a structure array.
- If `filename` is an ASCII file, then `S` is a double-precision array containing data from the file.

`load filename` is the command form of the syntax. Command form requires fewer special characters. You do not need to type parentheses or enclose input strings in single quotes. Separate inputs with spaces instead of commas.

For example, to load a file named `durer.mat`, these statements are equivalent:

```
load durer.mat % command form
load('durer.mat') % function form
```

You can include any of the inputs described in previous syntaxes. For example, to load the variable named `X`:

```
load durer.mat X % command form
load('durer.mat','X') % function form
```

Do not use command form when any of the inputs, such as `filename`, are variables.

## Examples

### Load All Variables from MAT-File

Load all variables from the example MAT-file, `gong.mat`. Check the contents of the workspace before and after the load operation.

```
disp('Contents of workspace before loading file:')
whos
```

```
disp('Contents of gong.mat:')
whos('-file','gong.mat')
```

```
load('gong.mat')
disp('Contents of workspace after loading file:')
whos
```

You also can use command syntax to load the variables. Clear the previously loaded variables and repeat the load operation.

```
clear y Fs
```

```
load gong.mat
```

### Load Specific Variable From MAT-File

Load only variable `y` from example file `handel.mat`. If the workspace already contains variable `y`, the `load` operation overwrites it with data from the file.

```
load('handel.mat','y')
```

You also can use command syntax to load the variable, `y`.

```
load handel.mat y
```

### Use Regular Expressions to Load Specific Variables

View the contents of the example file, `accidents.mat`.

```
whos -file accidents.mat
```

Name	Size	Bytes	Class	Attributes
<code>datasources</code>	3x1	2724	cell	
<code>hwycols</code>	1x1	8	double	
<code>hwydata</code>	51x17	6936	double	
<code>hwyheaders</code>	1x17	2758	cell	
<code>hwyidx</code>	51x1	408	double	
<code>hwyrows</code>	1x1	8	double	
<code>statelabel</code>	51x1	6596	cell	
<code>ushwydata</code>	1x17	136	double	
<code>uslabel</code>	1x1	138	cell	

Use function syntax to load all variables with names not beginning with `'hwy'`, from the file.

```
load('accidents.mat', '-regexp', '^(?!hwy)...')
```

Alternatively, use command syntax to load the same variables.

```
load accidents.mat -regexp '^(?!hwy)...'
```

### Load List of Variables into Structure Array

The file, `durer.mat`, contains variables `X`, `caption`, and `map`. Create a cell array of variable names to load.

```
filename = 'durer.mat';
```

```
myVars = {'X', 'caption'};
S = load(filename, myVars{:})

S =

 X: [648x509 double]
 caption: [2x28 char]
```

Only the variables `X` and `caption` are loaded into the structure array, `S`.

### Load ASCII File

Create an ASCII file from several 4-column matrices, and load the data back into a double-precision array.

```
a = magic(4);
b = ones(2, 4) * -5.7;
c = [8 6 4 2];
save -ascii mydata.dat a b c
clear a b c
```

```
load mydata.dat -ascii
```

`load` creates an array of type `double` named `mydata`.

View information about `mydata`.

```
whos mydata
```

Name	Size	Bytes	Class	Attributes
mydata	7x4	224	double	

## Input Arguments

### **filename** — Name of file

`matlab.mat` (default) | string

Name of file, specified as a string. If you do not specify `filename`, the `load` function searches for a file named `matlab.mat`.

`filename` can include a file extension and a full or partial path. If `filename` has no extension (that is, no text after a period), `load` looks for a file named `filename.mat`. If

`filename` has an extension other than `.mat`, the `load` function treats the file as ASCII data.

When using the command form of `load`, it is unnecessary to enclose input strings in single quotes. However, if `filename` contains a space, you must enclose the argument in single quotes. For example, `load 'filename withspace.mat'`.

ASCII files must contain a rectangular table of numbers, with an equal number of elements in each row. The file delimiter (the character between elements in each row) can be a blank, comma, semicolon, or tab character. The file can contain MATLAB comments (lines that begin with a percent sign, `%`).

Example: `'myFile.mat'`

Data Types: `char`

**variables** — Names of variables to load

string

Names of variables to load, specified as one or more strings. When using the command form of `load`, you do not need to enclose input strings in single quotes. `variables` can be in one of the following forms.

Form of <code>variables</code> Input	Variables to Load
<code>var1, ..., varN</code>	Load the listed variables, specified as individual strings. Use the <code>'*'</code> wildcard to match patterns. For example, <code>load('filename.mat', 'A*')</code> or <code>load filename.mat A*</code> loads all variables in the file whose names start with A.
<code>'-regexp', expr1, ..., exprN</code>	Load only the variables or fields whose names match the “regular expressions”, specified as strings. For example, <code>load('filename.mat', '-regexp', '^Mon', '^Tues')</code> or <code>load filename.mat -regexp ^Mon ^Tues</code> loads only the variables in the file whose names begin with Mon or Tues.

Data Types: `char`

## Output Arguments

### S — Loaded variables or data

structure array | m-by-n array

Loaded variables, returned as a structure array, if `filename` is a MAT-File.

Loaded data, returned as an m-by-n array of type `double`, if `filename` is an ASCII file. `m` is equal to the number of lines in the file, and `n` is equal to the number of values on a line.

## More About

### Algorithms

If you do not specify an output for the `load` function, MATLAB creates a variable named after the loaded file (minus any file extension). For example, the command

```
load mydata.dat
```

reads data into a variable called `mydata`.

To create the variable name, `load` precedes any leading underscores or digits in `filename` with an X and replaces any other nonalphanumeric characters with underscores. For example, the command

```
load 10-May-data.dat
```

creates a variable called `X10_May_data`.

- “Supported File Formats for Import and Export”
- “Save, Load, and Delete Workspace Variables”
- “Ways to Import Text Files”
- “Loading Variables within a Function”
- “Import or Export a Sequence of Files”
- “Command vs. Function Syntax”

### See Also

`clear` | `importdata` | `matfile` | `regexp` | `save` | `uiimport` | `whos`

## load (COM)

Initialize control object from file

### Syntax

```
load(h, 'filename')
```

### Description

`load(h, 'filename')` initializes the COM object associated with the interface represented by the MATLAB COM object `h` from file specified in the string `filename`. The file must have been created previously by serializing an instance of the same control.

COM functions are available on Microsoft Windows systems only.

---

**Note** The COM `load` function is only supported for controls at this time.

---

### Examples

Create an `mwsamp` control and save its original state to the file `mwsample`:

```
f = figure('position',[100 200 200 200]);
h = actxcontrol('mwsamp.mwsampctr1.2',[0 0 200 200],f);
save(h, 'mwsample')
```

Now, alter the figure by changing its label and the radius of the circle.

```
h.Label = 'Circle';
h.Radius = 50;
Redraw(h);
```

Using the `load` function, you can restore the control to its original state.

```
load(h, 'mwsample');
get(h)
```

```
ans =
 Label: 'Label'
```

Radius: 20

### **See Also**

save (COM) | delete (COM) | actxcontrol | actxserver | release

## load (serial)

Load serial port objects and variables into MATLAB workspace

### Syntax

```
load filename
load filename obj1 obj2...
```

### Description

`load filename` returns all variables from the file specified by `filename` into the MATLAB workspace.

`load filename obj1 obj2...` returns the serial port objects specified by `obj1 obj2 ...` from the file `filename` into the MATLAB workspace.

`out = load('filename', 'obj1', 'obj2', ...)` returns the specified serial port objects from the file `filename` as a structure to `out` instead of directly loading them into the workspace. The field names in `out` match the names of the loaded serial port objects.

### Examples

---

**Note:** This example is based on a Windows platform.

---

Suppose you create the serial port objects `s1` and `s2`, configure a few properties for `s1`, and connect both objects to their instruments:

```
s1 = serial('COM1');
s2 = serial('COM2');
set(s1, 'Parity', 'mark', 'DataBits', 7);
fopen(s1);
fopen(s2);
```

Save `s1` and `s2` to the file `MyObject.mat`, and then load the objects back into the workspace:

```
save MyObject s1 s2;
load MyObject s1;
load MyObject s2;

get(s1, {'Parity', 'DataBits'})

ans =
 'mark' [7]

get(s2, {'Parity', 'DataBits'})

ans =
 'none' [8]
```

## More About

### Tips

Values for read-only properties are restored to their default values upon loading. For example, the `Status` property is restored to `closed`. To determine if a property is read-only, examine its reference pages.

### See Also

save | Status

# loadlibrary

Load C/C++ shared library into MATLAB

## Syntax

```
loadlibrary(libname,hfile)
loadlibrary(libname)
loadlibrary(libname,hfile,Name,Value)

loadlibrary(libname,@protofile)

[notfound,warnings] = loadlibrary(___)
```

## Description

`loadlibrary(libname,hfile)` loads functions from shared library, `libname`, defined in header file, `hfile`, into MATLAB.

`loadlibrary(libname)` loads the library if the name of the header file is the same as the name of the library file.

`loadlibrary(libname,hfile,Name,Value)` loads the library with one or more `Name,Value` arguments.

`loadlibrary(libname,@protofile)` uses a prototype file, `protofile`, in place of a header file.

`[notfound,warnings] = loadlibrary( ___ )` returns warning information, and can include any of the input arguments in previous syntaxes.

## Examples

### Load Functions in `shr1libsampl` Library

Add path to `examples` folder.

```
addpath(fullfile(matlabroot, 'extern', 'examples', 'shrlib'))
```

Load shrlibsample.

```
loadlibrary('shrlibsample')
```

Cleanup.

```
unloadlibrary shrlibsample
```

### Load Library Using Header File

The header file for the libmx library is `matrix.h`.

```
hfile = fullfile(matlabroot, 'extern', 'include', 'matrix.h');
loadlibrary('libmx', hfile)
```

Cleanup.

```
unloadlibrary libmx
```

### Load Library Using Multiple Header Files

Suppose that you have a library, `mylib`, with the header file, `mylib.h`. The header file contains the statement, `#include header2.h`. To use functions defined in `header2.h`, call `loadlibrary` with the `addheader` option.

```
loadlibrary('mylib', 'mylib.h', 'addheader', 'header2')
```

### Load Library Using an Alias Name

Create an alias, `lib`, for library, `shrlibsample`.

```
loadlibrary('shrlibsample', 'shrlibsample.h', 'alias', 'lib')
```

Use the alias name, `lib`, to call a function in the library.

```
str = 'This was a Mixed Case string';
calllib('lib', 'stringToUpper', str)
```

```
ans =
 THIS WAS A MIXED CASE STRING
```

Cleanup.

```
unloadlibrary lib
```

### **Search Alternative Paths for Header Files**

Add path to folder containing `shrlibsample` and its header file, `shrlibsample.h`.

```
addpath(fullfile(matlabroot, 'extern', 'examples', 'shrlib'))
```

The `shrlibsample.h` header file includes the header file, `shrhelph.h`. If `shrhelph.h` is in a different folder, for example, `c:\work`, use the `'includepath'` option to tell MATLAB where to find the file.

```
loadlibrary('shrlibsample', 'shrlibsample.h', 'includepath', 'c:\work')
```

Cleanup.

```
unloadlibrary shrlibsample
```

- “Create Alias Function Name Using Prototype File”

## **Input Arguments**

### **libname** — Name of shared library

string

Name of shared library, specified as a string. The name is case-sensitive and must match the file on your system.

On Microsoft Windows systems, `libname` refers to the name of a shared library (`.dll`) file. On Linux systems, it refers to the name of a shared object (`.so`) file. On Apple Macintosh systems, it refers to a dynamic shared library (`.dylib`). If you do not include a file extension with the `libname` argument, `loadlibrary` attempts to find the library with either the appropriate platform MEX-file extension or the appropriate platform library extension. For a list of MEX-file extensions, use `mexext`.

MATLAB extracts the name portion of the `libname` string to identify the library in other shared library functions. For example, when you call the `calllib` function, do not include the path or file extension in the library argument name.

Data Types: `char`

### **hfile** — Name of C header file

string

Name of C header file, specified as a string. The name is case-sensitive and must match the file on your system. If you do not include a file extension in the file name, `loadlibrary` uses `.h` for the extension.

Data Types: `char`

### **protofile** — Name of prototype file

`string`

Name of prototype file, specified as a string. The name is case-sensitive and must match the file on your system. The string `@protofile` specifies a function handle to the prototype file. When using a prototype file, the only valid Name,Value pair argument is **alias**.

Data Types: `char`

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as Name1,Value1, . . . ,NameN,ValueN.

Example:

### **'addheader'** — Header file

`string`

Header file, specified as the comma-separated pair consisting of 'addheader' and a string. Specify the file name without a file extension.

Each file specified by `addheader` must have a corresponding `#include` statement in the base header file. To load only the functions defined in the header file that you want to use in MATLAB, use `addheader`.

MATLAB does not verify the existence of header files and ignores any that are not needed.

### **'alias'** — Alternative name for library

`string`

Alternative name for library, specified as the comma-separated pair consisting of 'alias' and a string. Associates the specified name with the library. All subsequent calls to

MATLAB functions that reference this library must use this alias until the library is unloaded.

### **'includepath' — More search path for subordinate header files**

string

more search path for subordinate header files—header files within header files, specified as the comma-separated pair consisting of 'includepath' and a string.

### **'mfilename' — Prototype file**

string

Prototype file, specified as the comma-separated pair consisting of 'mfilename' and a string. Generates a prototype file in the current folder. The prototype file name must be different from the library name. Use this file in place of a header file when loading the library.

### **'thunkfilename' — Thunk file**

string

Thunk file, specified as the comma-separated pair consisting of 'thunkfilename' and a string. Overrides the default thunk file name.

## Output Arguments

### **notfound — Names of functions**

cell array

Names of functions found in header files but missing from the library, returned as cell array.

Data Types: cell

### **warnings — Warnings**

character array

Warnings produced while processing the header file, returned as character array.

## Limitations

- You must have a supported C compiler and Perl must be available.

- Do not call `loadlibrary` if the library is already in memory. To test this condition, call `libisloaded`.
- `loadlibrary` does not support libraries generated by the MATLAB Compiler product.
- The MATLAB Shared Library interface does not support library functions with function pointer inputs.

## More About

### Prototype File

A prototype file is a file of MATLAB commands which you can modify and use in place of a header file.

### Thunk File

A thunk file is a compatibility layer to a 64-bit library generated by MATLAB. The name of the thunk file is `BASENAME_thunk_COMPUTER.c` where *BASENAME* is either the name of the shared library or, if specified, the `mfilename` prototype name. *COMPUTER* is the string returned by the `computer` function.

MATLAB compiles this file and creates the file `BASENAME_thunk_COMPUTER.LIBEXT`, where *LIBEXT* is the platform-dependent default shared library extension, for example, `dll` on Windows.

### Tips

- If you have more than one library file of the same name, load the first using the library file name. Then load the additional libraries using the **alias** option.
- Supported and Compatible Compilers

### See Also

# loadobj

Modify load process for object

## Syntax

```
b = loadobj(a)
```

## Description

`b = loadobj(a)` is called by the `load` function if the class of `a` defines a `loadobj` method. `load` returns `b` as the value loaded from a MAT-file.

Define a `loadobj` method when objects of the class require special processing when loaded from MAT-files. If you define a `saveobj` method, then define a `loadobj` method to restore the object to the desired state. Define `loadobj` as a static method so it can accept as an argument whatever object or structure that you saved in the MAT-file. See “Implement `loadobj` as a Static Method”.

When loading a subclass object, `load` calls only the subclass `loadobj` method. If a superclass defines a `loadobj` method, the subclass inherits this method. However, it is possible that the inherited method does not perform the necessary operations to load the subclass object. Consider overriding superclass `loadobj` methods.

If any superclass in a class hierarchy defines a `loadobj` method, then the subclass `loadobj` method must ensure that the subclass and superclass objects load properly. Ensure proper loading by calling the superclass `loadobj` (or other methods) from the subclass `loadobj` method. See “Saving and Loading Objects from Class Hierarchies”.

## Input Arguments

**a**

The input argument, `a`, can be:

- The object as loaded from the MAT-file.

- A structure created by `load` (if `load` cannot resolve the object).
- A `struct` returned by the `saveobj` method.

**Default:**

# localfunctions

Function handles to all local functions in MATLAB file

## Syntax

```
fcns = localfunctions
```

## Description

`fcns = localfunctions` returns a cell array of function handles, `fcns`, to all local functions in the current file.

You cannot define local functions in the context of the command line, scripts, or anonymous functions, so when you call `localfunctions` from these contexts, you get an empty cell array. Within the cell array, `localfunctions` returns the function handles in an undefined order.

## Examples

### Display Handles to Local Functions in File

Create a new file, `fileWithLocalFunctions.m`, in your MATLAB path. In the main function, call and display the results of `localfunctions`. In the same file, create two local functions.

```
function fileWithLocalFunctions
```

```
 fcns = localfunctions;
 display(fcns)
```

```
 function alocalfunction
```

```
 function anotherlocalfunction
```

From the command line, call your function.

```
fileWithLocalFunctions
```

```
fcns =
 @localfunction
 @anotherlocalfunction
```

# log

Natural logarithm

## Syntax

$Y = \log(X)$

## Description

$Y = \log(X)$  returns the natural logarithm  $\ln(x)$  of each element in array  $X$ .

The `log` function's domain includes negative and complex numbers, which can lead to unexpected results if used unintentionally. For negative and complex numbers, `log` returns the complex logarithm

$$\log|z| + i \operatorname{atan2}(y, x).$$

Use `reallog` instead if you want negative and complex numbers to return error messages rather than return complex results.

## Examples

### Natural Logarithm of Negative Numbers

Show that the natural logarithm of -1 is *iii*.

```
log(-1)
```

```
ans =
```

```
0.0000 + 3.1416i
```

### Real-Valued Natural Logarithm

Create a vector of real numbers in the interval  $[0.25, 5]$ .

```
X = (0.25:0.25:5)';
```

Calculate the natural logarithm of the vector, X.

```
Y = log(X)
```

```
Y =
```

```

### Complex-Valued Natural Logarithm

Create two Cartesian grids for X and Y.

```
[X,Y] = meshgrid(0:0.5:1.5,-2:0.5:2);
```

Calculate the complex natural logarithm  $\ln(X + iY)$  on the grid. Use `1i` for improved speed and robustness with complex arithmetic.

```
Z = log(X + 1i*Y)
```

```
Z =
```

## Input Arguments

### **X** — Input array

scalar | vector | matrix | multidimensional array

Input array, specified as a scalar, vector, matrix, or multidimensional array.

Data Types: `single` | `double`

Complex Number Support: Yes

## Output Arguments

### **Y** — Logarithm values

scalar | vector | matrix | multidimensional array

Logarithm values, returned as a scalar, vector, matrix, or multidimensional array.

For positive real values of  $X$  in the interval  $(0, \text{Inf})$ ,  $Y$  is in the interval  $(-\text{Inf}, \text{Inf})$ . For complex and negative real values of  $X$ ,  $Y$  is complex. The data type of  $Y$  is the same as that of  $X$ .

# log10

Common logarithm (base 10)

## Syntax

$Y = \log_{10}(X)$

## Description

$Y = \log_{10}(X)$  returns the common logarithm of each element in array  $X$ . The function accepts both real and complex inputs. For real values of  $X$  in the interval  $(0, \text{Inf})$ ,  $\log_{10}$  returns real values in the interval  $(-\text{Inf}, \text{Inf})$ . For complex and negative real values of  $X$ , the  $\log_{10}$  function returns complex values.

## Examples

### Calculate Scalar Common Logarithm Values

Examine several values of the base 10 logarithm function.

Calculate the common logarithm of 1.

```
log10(1)
```

```
ans =
```

```
0
```

The result is 0, which is the x-intercept of the  $\log_{10}$  function.

Calculate the common logarithm of 10.

```
log10(10)
```

```
ans =
```

```
1
```

The result is 1 since  $10^1 = 10$ .

Calculate the common logarithm of 100.

```
log10(100)
```

```
ans =
```

```
2
```

The result is 2 since  $10^2 = 100$ .

Calculate the common logarithm of 0.

```
log10(0)
```

```
ans =
```

```
-Inf
```

The result is -Inf since  $10^{(-Inf)} = 0$ .

### **Real-Valued Common Logarithm**

Create a vector of real numbers in the interval [0.5, 10].

```
X = (0.5:0.5:10)';
```

Calculate the common logarithm of X.

```
Y = log10(X)
```

```

## Input Arguments

### X — Input array

scalar | vector | matrix | multidimensional array

Input array, specified as a scalar, vector, matrix, or multidimensional array.

Data Types: `single` | `double`  
Complex Number Support: Yes

**See Also**

`exp` | `log` | `log1p` | `log2` | `loglog` | `logm` | `reallog` | `semilogx` | `semilogy`

# log1p

Compute  $\log(1+x)$  accurately for small values of  $x$

## Syntax

$y = \log1p(x)$

## Description

$y = \log1p(x)$  computes  $\log(1+x)$ , compensating for the roundoff in  $1+x$ .  $\log1p(x)$  is more accurate than  $\log(1+x)$  for small values of  $x$ . For small  $x$ ,  $\log1p(x)$  is approximately  $x$ , whereas  $\log(1+x)$  can be zero.

## See Also

[log](#) | [expm1](#)

## log2

Base 2 logarithm and dissect floating-point numbers into exponent and mantissa

### Syntax

```
Y = log2(X)
[F,E] = log2(X)
```

### Description

$Y = \log_2(X)$  computes the base 2 logarithm of the elements of  $X$ .

$[F,E] = \log_2(X)$  returns arrays  $F$  and  $E$ . Argument  $F$  is an array of real values, usually in the range  $0.5 \leq \text{abs}(F) < 1$ . For real  $X$ ,  $F$  satisfies the equation:  $X = F \cdot 2.^E$ . Argument  $E$  is an array of integers that, for real  $X$ , satisfy the equation:  $X = F \cdot 2.^E$ .

### Examples

For IEEE arithmetic, the statement  $[F,E] = \log_2(X)$  yields the values:

X	F	E
1	1/2	1
pi	pi/4	2
-3	-3/4	2
eps	1/2	-51
realmax	1-eps/2	1024
realmin	1/2	-1021

## More About

### Tips

This function corresponds to the ANSI C function `frexp()` and the IEEE floating-point standard function `logb()`. Any zeros in `X` produce `F = 0` and `E = 0`.

### See Also

`log` | `pow2`

## logical

Convert numeric values to logicals

### Syntax

```
L = logical(A)
```

### Description

`L = logical(A)` converts numeric input `A` into an array of logical values. Any nonzero element of input `A` is converted to logical `1` (`true`) and zeros are converted to logical `0` (`false`). Complex values and NaNs cannot be converted to logical values and result in a conversion error.

### Examples

#### Pick Odd Elements from Numeric Matrix

Pick out the odd-numbered elements of a numeric matrix.

Create a numeric matrix.

```
A = [1 -3 2;5 4 7;-8 1 3];
```

Find the modulus, `mod(A,2)`, and convert it to a logical array for indexing.

```
L = logical(mod(A,2))
```

```
L =
```

```
 1 1 0
 1 0 1
 0 1 1
```

The array has logical `1` (`true`) values where `A` is odd.

Use `L` as a logical index to pick out the odd elements of `A`.

```
A(L)
ans =
 1
 5
 -3
 1
 7
 3
```

The result is a vector containing all odd elements of A.

Use the logical NOT operator, `~`, on L to find the even elements of A.

```
A(~L)
ans =
 -8
 4
 2
```

## Input Arguments

### A — Numeric input

scalar | vector | matrix | multidimensional array

Numeric input, specified as a scalar, vector, matrix, or multidimensional array.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical

## More About

### Tips

- Most arithmetic operations involving logical arrays return double values. For example, adding zero to a logical array returns a double array.
- Logical arrays also are created by the relational operators (`==`, `<`, `>`, `~`, etc.) and functions like `any`, `all`, `isnan`, `isinf`, and `isfinite`.

- “Using Logicals in Array Indexing”
- “Determine if Arrays Are Logical”

# loglog

Log-log scale plot

## Syntax

```
loglog(Y)
loglog(X1,Y1,...)
loglog(X1,Y1,LineStyle,...)
loglog(...,'PropertyName',PropertyValue,...)
h = loglog(...)
```

## Description

`loglog(Y)` plots the columns of `Y` versus their index if `Y` contains real numbers. If `Y` contains complex numbers, `loglog(Y)` and `loglog(real(Y),imag(Y))` are equivalent. `loglog` ignores the imaginary component in all other uses of this function.

`loglog(X1,Y1,...)` plots all  $Y_n$  versus  $X_n$  pairs. If only one of  $X_n$  or  $Y_n$  is a matrix, `loglog` plots the vector argument versus the rows or columns of the matrix, along the dimension of the matrix whose length matches the length of the vector. If the matrix is square, its columns plot against the vector if their lengths match.

`loglog(X1,Y1,LineStyle,...)` plots all lines defined by the  $X_n, Y_n, LineSpec$  triples, where `LineStyle` determines line type, marker symbol, and color of the plotted lines. You can mix  $X_n, Y_n, LineSpec$  triples with  $X_n, Y_n$  pairs, for example,

```
loglog(X1,Y1,X2,Y2,LineStyle,X3,Y3)
```

`loglog(...,'PropertyName',PropertyValue,...)` sets line property values for all the charting lines created. For a list of properties, see [Chart Line Properties](#).

`h = loglog(...)` returns a column vector of chart line handles, one handle per line.

If you do not specify a color when plotting more than one line, **loglog** automatically cycles through the colors and line styles in the order specified by the current axes.

If you attempt to add a **loglog**, **semilogx**, or **semilogy** plot to a linear axis mode graph with **hold on**, the axis mode remains as it is and the new data plots as linear.

## Examples

### Logarithmic Scale for Both Axes

Create a plot using a logarithmic scale for both the x-axis and the y-axis. Set the `LineStyle` string so that **loglog** plots using a line with square markers. Display the grid.

```
x = logspace(-1,2);
y = exp(x);

figure
loglog(x,y, '-s')
grid on
```

# logm

Matrix logarithm

## Syntax

```
L = logm(A)
[L, exitflag] = logm(A)
```

## Description

$L = \text{logm}(A)$  is the principal matrix logarithm of  $A$ , the inverse of  $\text{expm}(A)$ .  $L$  is the unique logarithm for which every eigenvalue has imaginary part lying strictly between  $-\pi$  and  $\pi$ . If  $A$  is singular or has any eigenvalues on the negative real axis, the principal logarithm is undefined. In this case, `logm` computes a nonprincipal logarithm and returns a warning message.

`[L, exitflag] = logm(A)` returns a scalar `exitflag` that describes the exit condition of `logm`:

- If `exitflag = 0`, the algorithm was successfully completed.
- If `exitflag = 1`, too many matrix square roots had to be computed. However, the computed value of  $L$  might still be accurate.

The input  $A$  can have class `double` or `single`.

## Limitations

For most matrices:

$$\text{logm}(\text{expm}(A)) = A = \text{expm}(\text{logm}(A))$$

These identities may fail for some  $A$ . For example, if the computed eigenvalues of  $A$  include an exact zero, then  $\text{logm}(A)$  generates infinity. Or, if the elements of  $A$  are too large,  $\text{expm}(A)$  may overflow.

## Examples

Suppose A is the 3-by-3 matrix

$$\begin{bmatrix} 1 & 1 & 0 \\ 0 & 0 & 2 \\ 0 & 0 & -1 \end{bmatrix}$$

and  $Y = \text{expm}(A)$  is

$$Y = \begin{bmatrix} 2.7183 & 1.7183 & 1.0862 \\ 0 & 1.0000 & 1.2642 \\ 0 & 0 & 0.3679 \end{bmatrix}$$

Then  $A = \text{logm}(Y)$  produces the original matrix A.

$$Y = \begin{bmatrix} 1.0000 & 1.0000 & 0.0000 \\ 0 & 0 & 2.0000 \\ 0 & 0 & -1.0000 \end{bmatrix}$$

But  $\text{log}(A)$  involves taking the logarithm of zero, and so produces

$$\text{ans} = \begin{bmatrix} 0.0000 & 0 & -35.5119 \\ -\text{Inf} & -\text{Inf} & 0.6931 \\ -\text{Inf} & -\text{Inf} & 0.0000 + 3.1416i \end{bmatrix}$$

## More About

### Tips

If A is real symmetric or complex Hermitian, then so is  $\text{logm}(A)$ .

Some matrices, like  $A = \begin{bmatrix} 0 & 1 \\ 0 & 0 \end{bmatrix}$ , do not have any logarithms, real or complex, so  $\text{logm}$  cannot be expected to produce one.

### Algorithms

The algorithm  $\text{logm}$  uses is described in [1].

# logspace

Generate logarithmically spaced vectors

## Syntax

```
y = logspace(a,b)
y = logspace(a,b,n)
y = logspace(a,pi)
```

## Description

The `logspace` function generates logarithmically spaced vectors. Especially useful for creating frequency vectors, it is a logarithmic equivalent of `linspace` and the “:” or colon operator.

`y = logspace(a,b)` generates a row vector `y` of 50 logarithmically spaced points between decades  $10^a$  and  $10^b$ .

`y = logspace(a,b,n)` generates `n` points between decades  $10^a$  and  $10^b$ .

`y = logspace(a,pi)` generates the points between  $10^a$  and  $\pi$ , which is useful for digital signal processing where frequencies over this interval go around the unit circle.

## More About

### Tips

All the arguments to `logspace` must be scalars.

### See Also

`linspace` | colon operator

## lookfor

Search for keyword in all help entries

### Alternatives

As an alternative to the `lookfor` function, use the “Function Browser”.

### Syntax

```
lookfor topic
lookfor topic -all
```

### Description

`lookfor topic` searches for the string `topic` in the first comment line (the H1 line) of the help text in all MATLAB program files found on the search path. For all files in which a match occurs, `lookfor` displays the H1 line.

`lookfor topic -all` searches the entire first comment block of a MATLAB program file looking for `topic`.

### Examples

For example:

```
lookfor inverse
```

finds at least a dozen matches, including H1 lines containing "inverse hyperbolic cosine," "two-dimensional inverse FFT," and "pseudoinverse." Contrast this with

```
which inverse
```

```
or
```

```
what inverse
```

These functions run more quickly, but probably fail to find anything because MATLAB does not have a function `inverse`.

In summary, `what` lists the functions in a given folder, `which` finds the folder containing a given function or file, and `lookfor` finds all functions in all folders that might have something to do with a given keyword.

Even more extensive than the `lookfor` function are the find features in the Current Folder browser. For example, you can look for all occurrences of a specified word in all the MATLAB program files in the current folder and its subfolders. For more information, see “Find Files and Folders”.

## lower

Convert string to lowercase

### Syntax

```
t = lower('str')
B = lower(A)
```

### Description

`t = lower('str')` returns the string formed by converting any uppercase characters in `str` to the corresponding lowercase characters and leaving all other characters unchanged.

`B = lower(A)` when `A` is a cell array of strings, returns a cell array the same size as `A` containing the result of applying `lower` to each string within `A`.

### Examples

```
lower('MathWorks') is mathworks.
```

### More About

#### Tips

Character sets supported:

- PC: Latin-1 for the Microsoft Windows operating system
- Other: ISO Latin-1 (ISO 8859-1)

`upper`

# ls

List folder contents

## Syntax

```
ls
ls name
list = ls(name)
```

## Description

`ls` lists the contents of the current folder.

`ls name` lists the files and folders in the current folder that match the specified name. You can use wildcards.

`list = ls(name)` returns the files and folders in the current folder that match the specified name to `list`.

## Input Arguments

### **name**

A string value specifying a file or folder name.

## Output Arguments

### **list**

- On UNIX platforms, `list` is a character row vector of names separated by tab and space characters.
- On Microsoft Windows platforms, `list` is an  $m$ -by- $n$  character array of names— $m$  is the number of names and  $n$  is the number of characters in the longest name. MATLAB pads names shorter than  $n$  characters with space characters.

## Examples

List all the files and folders in the current folder:

```
ls
```

List all the files and folders in the current folder that begin with the letter h:

```
ls h*
```

Return the list of all the files and folders in the current folder to `mylist`:

```
mylist = ls;
```

## Alternatives

- View files and folders in the Current Folder browser.

Open the Current Folder browser by issuing the `filebrowser` command.

## More About

### Tips

- On UNIX platforms, you can add any flags to `ls` that the operating system supports.

`dir` | `pwd`

# lscov

Least-squares solution in presence of known covariance

## Syntax

```
x = lscov(A,B)
x = lscov(A,B,w)
x = lscov(A,B,V)
x = lscov(A,B,V,alg)
[x,stdx] = lscov(...)
[x,stdx,mse] = lscov(...)
[x,stdx,mse,S] = lscov(...)
```

## Description

`x = lscov(A,B)` returns the ordinary least squares solution to the linear system of equations  $A*x = B$ , i.e.,  $x$  is the  $n$ -by-1 vector that minimizes the sum of squared errors  $(B - A*x)'*(B - A*x)$ , where  $A$  is  $m$ -by- $n$ , and  $B$  is  $m$ -by-1.  $B$  can also be an  $m$ -by- $k$  matrix, and `LSCOV` returns one solution for each column of  $B$ . When  $\text{rank}(A) < n$ , `LSCOV` sets the maximum possible number of elements of  $x$  to zero to obtain a "basic solution".

`x = lscov(A,B,w)`, where  $w$  is a vector length  $m$  of real positive weights, returns the weighted least squares solution to the linear system  $A*x = B$ , that is,  $x$  minimizes  $(B - A*x)'*diag(w)*(B - A*x)$ .  $w$  typically contains either counts or inverse variances.

`x = lscov(A,B,V)`, where  $V$  is an  $m$ -by- $m$  real symmetric positive definite matrix, returns the generalized least squares solution to the linear system  $A*x = B$  with covariance matrix proportional to  $V$ , that is,  $x$  minimizes  $(B - A*x)'*inv(V)*(B - A*x)$ .

More generally,  $V$  can be positive semidefinite, and `LSCOV` returns  $x$  that minimizes  $e'*e$ , subject to  $A*x + T*e = B$ , where the minimization is over  $x$  and  $e$ , and  $T*T' = V$ . When  $V$  is semidefinite, this problem has a solution only if  $B$  is consistent with  $A$  and  $V$  (that is,  $B$  is in the column space of  $[A \ T]$ ), otherwise `LSCOV` returns an error.

By default, `lscov` computes the Cholesky decomposition of  $V$  and, in effect, inverts that factor to transform the problem into ordinary least squares. However, if `lscov` determines that  $V$  is semidefinite, it uses an orthogonal decomposition algorithm that avoids inverting  $V$ .

`x = lscov(A,B,V,alg)` specifies the algorithm used to compute  $x$  when  $V$  is a matrix. `alg` can have the following values:

- `'chol'` uses the Cholesky decomposition of  $V$ .
- `'orth'` uses orthogonal decompositions, and is more appropriate when  $V$  is ill-conditioned or singular, but is computationally more expensive.

`[x,stdx] = lscov(...)` returns the estimated standard errors of  $x$ . When  $A$  is rank deficient, `stdx` contains zeros in the elements corresponding to the necessarily zero elements of  $x$ .

`[x,stdx,mse] = lscov(...)` returns the mean squared error. If  $B$  is assumed to have covariance matrix  $\sigma^2V$  (or  $(\sigma^2)\times\text{diag}(1/M)$ ), then `mse` is an estimate of  $\sigma^2$ .

`[x,stdx,mse,S] = lscov(...)` returns the estimated covariance matrix of  $x$ . When  $A$  is rank deficient, `S` contains zeros in the rows and columns corresponding to the necessarily zero elements of  $x$ . `lscov` cannot return `S` if it is called with multiple right-hand sides, that is, if `size(B,2) > 1`.

The standard formulas for these quantities, when  $A$  and  $V$  are full rank, are

- $x = \text{inv}(A' \cdot \text{inv}(V) \cdot A) \cdot A' \cdot \text{inv}(V) \cdot B$
- $\text{mse} = B' \cdot (\text{inv}(V) - \text{inv}(V) \cdot A \cdot \text{inv}(A' \cdot \text{inv}(V) \cdot A) \cdot A' \cdot \text{inv}(V)) \cdot B ./ (m-n)$
- $S = \text{inv}(A' \cdot \text{inv}(V) \cdot A) \cdot \text{mse}$
- $\text{stdx} = \text{sqrt}(\text{diag}(S))$

However, `lscov` uses methods that are faster and more stable, and are applicable to rank deficient cases.

`lscov` assumes that the covariance matrix of  $B$  is known only up to a scale factor. `mse` is an estimate of that unknown scale factor, and `lscov` scales the outputs `S` and `stdx` appropriately. However, if  $V$  is known to be exactly the covariance matrix of  $B$ , then that scaling is unnecessary. To get the appropriate estimates in this case, you should rescale `S` and `stdx` by  $1/\text{mse}$  and  $\text{sqrt}(1/\text{mse})$ , respectively.

## Examples

### Example 1 — Computing Ordinary Least Squares

The MATLAB backslash operator (`\`) enables you to perform linear regression by computing ordinary least-squares (OLS) estimates of the regression coefficients. You can also use `lscov` to compute the same OLS estimates. By using `lscov`, you can also compute estimates of the standard errors for those coefficients, and an estimate of the standard deviation of the regression error term:

```
x1 = [.2 .5 .6 .8 1.0 1.1]';
x2 = [.1 .3 .4 .9 1.1 1.4]';
X = [ones(size(x1)) x1 x2];
y = [.17 .26 .28 .23 .27 .34]';
```

```
a = X\y
a =
 0.1203
 0.3284
 -0.1312
```

```
[b,se_b,mse] = lscov(X,y)
b =
 0.1203
 0.3284
 -0.1312
se_b =
 0.0643
 0.2267
 0.1488
mse =
 0.0015
```

### Example 2 — Computing Weighted Least Squares

Use `lscov` to compute a weighted least-squares (WLS) fit by providing a vector of relative observation weights. For example, you might want to downweight the influence of an unreliable observation on the fit:

```
w = [1 1 1 1 1 .1]';
[bw,sew_b,msew] = lscov(X,y,w)
```

```
bw =
 0.1046
 0.4614
 -0.2621
sew_b =
 0.0309
 0.1152
 0.0814
msew =
 3.4741e-004
```

### **Example 3 — Computing General Least Squares**

Use `lscov` to compute a general least-squares (GLS) fit by providing an observation covariance matrix. For example, your data may not be independent:

```
V = .2*ones(length(x1)) + .8*diag(ones(size(x1)));
```

```
[bg,sew_b,mseg] = lscov(X,y,V)
bg =
 0.1203
 0.3284
 -0.1312
sew_b =
 0.0672
 0.2267
 0.1488
mseg =
 0.0019
```

### **Example 4 — Estimating the Coefficient Covariance Matrix**

Compute an estimate of the coefficient covariance matrix for either OLS, WLS, or GLS fits. The coefficient standard errors are equal to the square roots of the values on the diagonal of this covariance matrix:

```
[b,se_b,mse,S] = lscov(X,y);

S
S =
 0.0041 -0.0130 0.0075
 -0.0130 0.0514 -0.0328
 0.0075 -0.0328 0.0221
```

```
[se_b sqrt(diag(S))]
ans =
 0.0643 0.0643
 0.2267 0.2267
 0.1488 0.1488
```

## More About

### Algorithms

The vector  $x$  minimizes the quantity  $(A*x-B)' * \text{inv}(V) * (A*x-B)$ . The classical linear algebra solution to this problem is

$$x = \text{inv}(A' * \text{inv}(V) * A) * A' * \text{inv}(V) * B$$

but the `lskov` function instead computes the QR decomposition of  $A$  and then modifies  $Q$  by  $V$ .

# lsqnonneg

Solve nonnegative least-squares constraints problem

## Equation

Solves nonnegative least-squares curve fitting problems of the form

$$\min_x \|C \cdot x - d\|_2^2, \text{ where } x \geq 0.$$

## Syntax

```
x = lsqnonneg(C,d)
x = lsqnonneg(C,d,options)
x = lsqnonneg(problem)
[x,resnorm] = lsqnonneg(...)
[x,resnorm,residual] = lsqnonneg(...)
[x,resnorm,residual,exitflag] = lsqnonneg(...)
[x,resnorm,residual,exitflag,output] = lsqnonneg(...)
[x,resnorm,residual,exitflag,output,lambda] = lsqnonneg(...)
```

## Description

`x = lsqnonneg(C,d)` returns the vector `x` that minimizes `norm(C*x-d)` subject to `x >= 0`. `C` and `d` must be real.

`x = lsqnonneg(C,d,options)` minimizes with the optimization parameters specified in the structure `options`. You can define these parameters using the `optimset` function. `lsqnonneg` uses these `options` structure fields:

<b>Display</b>	Level of display. 'off' displays no output; 'final' displays just the final output; 'notify' (default) displays output only if the function does not converge.
<b>TolX</b>	Termination tolerance on <code>x</code> .

`x = lsqnonneg(problem)` finds the minimum for `problem`, where `problem` is a structure with the following fields:

<code>C</code>	Matrix
<code>d</code>	Vector
<code>solver</code>	'lsqnonneg'
<code>options</code>	Options structure created using <code>optimset</code>

`[x,resnorm] = lsqnonneg(...)` returns the value of the squared 2-norm of the residual:  $\text{norm}(C*x-d)^2$ .

`[x,resnorm,residual] = lsqnonneg(...)` returns the residual,  $d-C*x$ .

`[x,resnorm,residual,exitflag] = lsqnonneg(...)` returns a value `exitflag` that describes the exit condition of `lsqnonneg`:

>0	Indicates that the function converged to a solution <code>x</code> .
0	Indicates that the iteration count was exceeded. Increasing the tolerance ( <code>TolX</code> parameter in <code>options</code> ) may lead to a solution.

`[x,resnorm,residual,exitflag,output] = lsqnonneg(...)` returns a structure `output` that contains information about the operation in the following fields:

<code>algorithm</code>	'active-set'
<code>iterations</code>	The number of iterations taken
<code>message</code>	Exit message

`[x,resnorm,residual,exitflag,output,lambda] = lsqnonneg(...)` returns the dual vector (Lagrange multipliers) `lambda`, where `lambda(i) <= 0` when `x(i)` is (approximately) 0, and `lambda(i)` is (approximately) 0 when `x(i) > 0`.

## Examples

Compare the unconstrained least squares solution to the `lsqnonneg` solution for a 4-by-2 problem:

```
C = [
```

```
 0.0372 0.2869
 0.6861 0.7071
 0.6233 0.6245
 0.6344 0.6170];
d = [
 0.8587
 0.1781
 0.0747
 0.8405];
[C\d lsqnonneg(C,d)] =
 -2.5627 0
 3.1108 0.6929
[norm(C*(C\d)-d) norm(C*lsqnonneg(C,d)-d)] =
 0.6674 0.9118
```

The solution from `lsqnonneg` does not fit as well (has a larger residual), as the least squares solution. However, the nonnegative least squares solution has no negative components.

## More About

### Algorithms

`lsqnonneg` uses the algorithm described in [1]. The algorithm starts with a set of possible basis vectors and computes the associated dual vector `lambda`. It then selects the basis vector corresponding to the maximum value in `lambda` in order to swap out of the basis in exchange for another possible candidate. This continues until `lambda <= 0`.

`optimset`

# lsqr

LSQR method

## Syntax

```
x = lsqr(A,b)
lsqr(A,b,tol)
lsqr(A,b,tol,maxit)
lsqr(A,b,tol,maxit,M)
lsqr(A,b,tol,maxit,M1,M2)
lsqr(A,b,tol,maxit,M1,M2,x0)
[x,flag] = lsqr(A,b,tol,maxit,M1,M2,x0)
[x,flag,relres] = lsqr(A,b,tol,maxit,M1,M2,x0)
[x,flag,relres,iter] = lsqr(A,b,tol,maxit,M1,M2,x0)
[x,flag,relres,iter,resvec] = lsqr(A,b,tol,maxit,M1,M2,x0)
[x,flag,relres,iter,resvec,lsvec] = lsqr(A,b,tol,maxit,M1,M2,x0)
```

## Description

`x = lsqr(A,b)` attempts to solve the system of linear equations  $A*x=b$  for  $x$  if  $A$  is consistent, otherwise it attempts to solve the least squares solution  $x$  that minimizes  $\text{norm}(b-A*x)$ . The  $m$ -by- $n$  coefficient matrix  $A$  need not be square but it should be large and sparse. The column vector  $b$  must have length  $m$ . You can specify  $A$  as a function handle, `afun`, such that `afun(x, 'notransp')` returns  $A*x$  and `afun(x, 'transp')` returns  $A' * x$ .

“Parameterizing Functions” explains how to provide additional parameters to the function `afun`, as well as the preconditioner function `mfun` described below, if necessary.

If `lsqr` converges, a message to that effect is displayed. If `lsqr` fails to converge after the maximum number of iterations or halts for any reason, a warning message is printed displaying the relative residual  $\text{norm}(b-A*x) / \text{norm}(b)$  and the iteration number at which the method stopped or failed.

`lsqr(A,b,tol)` specifies the tolerance of the method. If `tol` is `[]`, then `lsqr` uses the default,  $1e-6$ .

`lsqr(A,b,tol,maxit)` specifies the maximum number of iterations.

`lsqr(A,b,tol,maxit,M)` and `lsqr(A,b,tol,maxit,M1,M2)` use n-by-n preconditioner `M` or `M = M1*M2` and effectively solve the system  $A \cdot \text{inv}(M) \cdot y = b$  for `y`, where  $y = M \cdot x$ . If `M` is `[]` then `lsqr` applies no preconditioner. `M` can be a function `mfun` such that `mfun(x, 'notransp')` returns  $M \setminus x$  and `mfun(x, 'transp')` returns  $M' \setminus x$ .

`lsqr(A,b,tol,maxit,M1,M2,x0)` specifies the n-by-1 initial guess. If `x0` is `[]`, then `lsqr` uses the default, an all zero vector.

`[x,flag] = lsqr(A,b,tol,maxit,M1,M2,x0)` also returns a convergence flag.

Flag	Convergence
0	<code>lsqr</code> converged to the desired tolerance <code>tol</code> within <code>maxit</code> iterations.
1	<code>lsqr</code> iterated <code>maxit</code> times but did not converge.
2	Preconditioner <code>M</code> was ill-conditioned.
3	<code>lsqr</code> stagnated. (Two consecutive iterates were the same.)
4	One of the scalar quantities calculated during <code>lsqr</code> became too small or too large to continue computing.

Whenever `flag` is not 0, the solution `x` returned is that with minimal norm residual computed over all the iterations. No messages are displayed if you specify the `flag` output.

`[x,flag,relres] = lsqr(A,b,tol,maxit,M1,M2,x0)` also returns an estimate of the relative residual  $\text{norm}(b-A \cdot x) / \text{norm}(b)$ . If `flag` is 0, `relres`  $\leq$  `tol`.

`[x,flag,relres,iter] = lsqr(A,b,tol,maxit,M1,M2,x0)` also returns the iteration number at which `x` was computed, where  $0 \leq \text{iter} \leq \text{maxit}$ .

`[x,flag,relres,iter,resvec] = lsqr(A,b,tol,maxit,M1,M2,x0)` also returns a vector of the residual norm estimates at each iteration, including  $\text{norm}(b-A \cdot x_0)$ .

`[x,flag,relres,iter,resvec,lsvec] = lsqr(A,b,tol,maxit,M1,M2,x0)` also returns a vector of estimates of the scaled normal equations residual at each iteration:  $\text{norm}(A \cdot \text{inv}(M)' * (B-A \cdot X)) / \text{norm}(A \cdot \text{inv}(M), 'fro')$ . Note that the estimate of  $\text{norm}(A \cdot \text{inv}(M), 'fro')$  changes, and hopefully improves, at each iteration.

## Examples

### Example 1

```
n = 100;
on = ones(n,1);
A = spdiags([-2*on 4*on -on],-1:1,n,n);
b = sum(A,2);
tol = 1e-8;
maxit = 15;
M1 = spdiags([on/(-2) on],-1:0,n,n);
M2 = spdiags([4*on -on],0:1,n,n);
```

```
x = lsqr(A,b,tol,maxit,M1,M2);
```

displays the following message:

```
lsqr converged at iteration 11 to a solution with relative
residual 3.5e-009
```

### Example 2

This example replaces the matrix **A** in Example 1 with a handle to a matrix-vector product function **afun**. The example is contained in a function **run\_lsqr** that

- Calls **lsqr** with the function handle **@afun** as its first argument.
- Contains **afun** as a nested function, so that all variables in **run\_lsqr** are available to **afun**.

The following shows the code for **run\_lsqr**:

```
function x1 = run_lsqr
n = 100;
on = ones(n,1);
A = spdiags([-2*on 4*on -on],-1:1,n,n);
b = sum(A,2);
tol = 1e-8;
maxit = 15;
M1 = spdiags([on/(-2) on],-1:0,n,n);
M2 = spdiags([4*on -on],0:1,n,n);
x1 = lsqr(@afun,b,tol,maxit,M1,M2);
```

```
function y = afun(x,transp_flag)
 if strcmp(transp_flag,'transp') % y = A'*x
 y = 4 * x;
 y(1:n-1) = y(1:n-1) - 2 * x(2:n);
 y(2:n) = y(2:n) - x(1:n-1);
 elseif strcmp(transp_flag,'notransp') % y = A*x
 y = 4 * x;
 y(2:n) = y(2:n) - 2 * x(1:n-1);
 y(1:n-1) = y(1:n-1) - x(2:n);
 end
end
end
```

When you enter

```
x1=run_lsqr;
```

MATLAB software displays the message

```
lsqr converged at iteration 11 to a solution with relative
residual 3.5e-009
```

## lt, <

Determine less than

### Syntax

```
A < B
lt(A,B)
```

### Description

`A < B` returns an array with elements set to logical 1 (`true`) where `A` is less than `B`; otherwise, it returns logical 0 (`false`).

The test compares only the real part of numeric arrays. `lt` returns logical 0 (`false`) where `A` or `B` have NaN or undefined categorical elements.

`lt(A,B)` is an alternate way to execute `A < B`, but is rarely used. It enables operator overloading for classes.

### Examples

#### Test Vector Elements

Determine if vector elements are less than a given value.

Create a numeric vector.

```
A = [1 12 18 7 9 11 2 15];
```

Test the vector for elements that are less than 12.

```
A < 12
```

```
ans =
```

```
1 0 0 1 1 1 1 0
```

The result is a vector with values of logical 1 (true) where the elements of A satisfy the expression.

Use the vector of logical values as an index to view the values in A that are less than 12.

```
A(A < 12)
```

```
ans =
```

```
 1 7 9 11 2
```

The result is a subset of the elements in A.

## Replace Elements of Matrix

Create a matrix.

```
A = magic(4)
```

```
A =
```

```
 16 2 3 13
 5 11 10 8
 9 7 6 12
 4 14 15 1
```

Replace all values less than 9 with the value 10.

```
A(A < 9) = 10
```

```
A =
```

```
 16 10 10 13
 10 11 10 10
 9 10 10 12
 10 14 15 10
```

The result is a new matrix whose smallest element is 9.

## Compare Values in Categorical Array

Create an ordinal categorical array.

```
A = categorical({'large' 'medium' 'small'; 'medium' ...
 'small' 'large'}, {'small' 'medium' 'large'}, 'Ordinal', 1)
```

```
A =
```

```
 large medium small
 medium small large
```

The array has three categories: 'small', 'medium', and 'large'.

Find all values less than the category 'medium'.

```
A < 'medium'
```

```
ans =
```

```
 0 0 1
 0 1 0
```

A value of logical 1 (true) indicates a value less than the category 'medium'.

Compare the rows of A.

```
A(1,:) < A(2,:)
```

```
ans =
```

```
 0 0 1
```

The function returns logical 1 (true) where the first row has a category value less than the second row.

### Test Complex Numbers

Create a vector of complex numbers.

```
A = [1+i 2-2i 1+3i 1-2i 5-i];
```

Find the values that are less than 3.

```
A(A < 3)
```

```
ans =
```

```
 1.0000 + 1.0000i 2.0000 - 2.0000i 1.0000 + 3.0000i 1.0000 - 2.0000i
```

It compares only the real part of the elements in A.

Use `abs` to find which elements are within a radius of 3 from the origin.

```
A(abs(A) < 3)
```

```
ans =
```

```
1.0000 + 1.0000i 2.0000 - 2.0000i 1.0000 - 2.0000i
```

The result has one less element. The element  $1.0000 + 3.0000i$  is not within a radius of 3 from the origin.

## Compare Dates

Create a vector of dates.

```
A = datetime([2014,05,01;2014,05,31])
```

```
A =
```

```
01-May-2014
31-May-2014
```

Find the dates that occur before May 10, 2014.

```
A(A < '2014-05-10')
```

```
ans =
```

```
01-May-2014
```

## Input Arguments

### A — Left array

numeric array | logical array | character array | ordinal categorical array | datetime array | duration array

Left array, specified as a numeric array, logical array, character array, categorical array, datetime array, or duration array. Inputs **A** and **B** must be the same size unless one is a scalar. A scalar input expands into an array of the same size as the other input.

If one input is an ordinal categorical array, the other input can be an ordinal categorical array, a cell array of strings, or a single string. A single string expands into a cell array of strings of the same size as the other input. If both inputs are ordinal categorical arrays, they must have the same sets of categories, including their order. See “Compare Categorical Array Elements” for more details.

If one input is a datetime array, the other input can be a datetime array, a date string, or a cell array of date strings.

If one input is a duration array, the other input can be a duration array or a numeric array. `eq` treats each numeric value as a number of standard (86400 s) days.

### **B — Right array**

numeric array | logical array | character array | ordinal categorical array | datetime array | duration array

Right array, specified as a numeric array, logical array, character array, categorical array, datetime array, or duration array. Inputs **A** and **B** must be the same size unless one is a scalar. A scalar input expands into an array of the same size as the other input.

If one input is an ordinal categorical array, the other input can be an ordinal categorical array, a cell array of strings, or a single string. A single string expands into a cell array of strings of the same size as the other input. If both inputs are ordinal categorical arrays, they must have the same sets of categories, including their order. See “Compare Categorical Array Elements” for more details.

If one input is a datetime array, the other input can be a datetime array, a date string, or a cell array of date strings.

If one input is a duration array, the other input can be a duration array or a numeric array. `eq` treats each numeric value as a number of standard (86400 s) days.

## lu

LU matrix factorization

### Syntax

```
Y = lu(A)
[L,U] = lu(A)
[L,U,P] = lu(A)
[L,U,P,Q] = lu(A)
[L,U,P,Q,R] = lu(A)
[...] = lu(A, 'vector')
[...] = lu(A, thresh)
[...] = lu(A, thresh, 'vector')
```

### Description

The `lu` function expresses a matrix  $A$  as the product of two essentially triangular matrices, one of them a permutation of a lower triangular matrix and the other an upper triangular matrix. The factorization is often called the  $LU$ , or sometimes the  $LR$ , factorization.  $A$  can be rectangular.

`Y = lu(A)` returns matrix  $Y$  that, for sparse  $A$ , contains the strictly lower triangular  $L$ , i.e., without its unit diagonal, and the upper triangular  $U$  as submatrices. That is, if `[L,U,P] = lu(A)`, then  $Y = U + L - \text{eye}(\text{size}(A))$ . For nonsparse  $A$ ,  $Y$  is the output from the LAPACK `dgetrf` or `zgetrf` routine. The permutation matrix  $P$  is not returned.

`[L,U] = lu(A)` returns an upper triangular matrix in  $U$  and a permuted lower triangular matrix in  $L$  such that  $A = L*U$ . Return value  $L$  is a product of lower triangular and permutation matrices.

`[L,U,P] = lu(A)` returns an upper triangular matrix in  $U$ , a lower triangular matrix  $L$  with a unit diagonal, and a permutation matrix  $P$ , such that  $L*U = P*A$ . The statement `lu(A, 'matrix')` returns identical output values.

`[L,U,P,Q] = lu(A)` for sparse nonempty  $A$ , returns a unit lower triangular matrix  $L$ , an upper triangular matrix  $U$ , a row permutation matrix  $P$ , and a column reordering

matrix  $Q$ , so that  $P^*A^*Q = L^*U$ . If  $A$  is empty or not sparse, `lu` displays an error message. The statement `lu(A, 'matrix')` returns identical output values.

`[L,U,P,Q,R] = lu(A)` returns unit lower triangular matrix  $L$ , upper triangular matrix  $U$ , permutation matrices  $P$  and  $Q$ , and a diagonal scaling matrix  $R$  so that  $P^*(R\backslash A)^*Q = L^*U$  for sparse non-empty  $A$ . Typically, but not always, the row-scaling leads to a sparser and more stable factorization. The statement `lu(A, 'matrix')` returns identical output values.

`[... ] = lu(A, 'vector')` returns the permutation information in two row vectors  $p$  and  $q$ . You can specify from 1 to 5 outputs. Output  $p$  is defined as  $A(p, :)=L^*U$ , output  $q$  is defined as  $A(p, q)=L^*U$ , and output  $R$  is defined as  $R(:, p)\backslash A(:, q)=L^*U$ .

`[... ] = lu(A, thresh)` controls pivoting. This syntax applies to sparse matrices only. The `thresh` input is a one- or two-element vector of type `single` or `double` that defaults to `[0.1, 0.001]`. If  $A$  is a square matrix with a mostly symmetric structure and mostly nonzero diagonal, MATLAB uses a symmetric pivoting strategy. For this strategy, the diagonal where

$$A(i, j) \geq \text{thresh}(2) * \max(\text{abs}(A(j:m, j)))$$

is selected. If the diagonal entry fails this test, a pivot entry below the diagonal is selected, using `thresh(1)`. In this case,  $L$  has entries with absolute value  $1/\min(\text{thresh})$  or less.

If  $A$  is not as described above, MATLAB uses an asymmetric strategy. In this case, the sparsest row  $i$  where

$$A(i, j) \geq \text{thresh}(1) * \max(\text{abs}(A(j:m, j)))$$

is selected. A value of 1.0 results in conventional partial pivoting. Entries in  $L$  have an absolute value of  $1/\text{thresh}(1)$  or less. The second element of the `thresh` input vector is not used when MATLAB uses an asymmetric strategy.

Smaller values of `thresh(1)` and `thresh(2)` tend to lead to sparser LU factors, but the solution can become inaccurate. Larger values can lead to a more accurate solution (but not always), and usually an increase in the total work and memory usage. The statement `lu(A, thresh, 'matrix')` returns identical output values.

`[... ] = lu(A, thresh, 'vector')` controls the pivoting strategy and also returns the permutation information in row vectors, as described above. The `thresh` input must precede `'vector'` in the input argument list.

---

**Note** In rare instances, incorrect factorization results in  $P^*A^*Q \neq L^*U$ . Increase `thresh`, to a maximum of 1.0 (regular partial pivoting), and try again.

---

## Arguments

A	Rectangular matrix to be factored.
thresh	Pivot threshold for sparse matrices. Valid values are in the interval $[0, 1]$ . If you specify the fourth output Q, the default is 0.1. Otherwise, the default is 1.0.
L	Factor of A. Depending on the form of the function, L is either a unit lower triangular matrix, or else the product of a unit lower triangular matrix with P'.
U	Upper triangular matrix that is a factor of A.
P	Row permutation matrix satisfying the equation $L^*U = P^*A$ , or $L^*U = P^*A^*Q$ . Used for numerical stability.
Q	Column permutation matrix satisfying the equation $P^*A^*Q = L^*U$ . Used to reduce fill-in in the sparse case.
R	Row-scaling matrix

## Examples

### Example 1

Start with

```
A = [1 2 3
 4 5 6
 7 8 0];
```

To see the LU factorization, call `lu` with two output arguments.

```
[L1,U] = lu(A)
```

```
L1 =
 0.1429 1.0000 0
```

$$\begin{array}{ccc}
 0.5714 & 0.5000 & 1.0000 \\
 1.0000 & 0 & 0 \\
 \\
 U = & & \\
 7.0000 & 8.0000 & 0 \\
 0 & 0.8571 & 3.0000 \\
 0 & 0 & 4.5000
 \end{array}$$

Notice that L1 is a permutation of a lower triangular matrix: if you switch rows 2 and 3, and then switch rows 1 and 2, the resulting matrix is lower triangular and has 1s on the diagonal. Notice also that U is upper triangular. To check that the factorization does its job, compute the product

$$L1*U$$

which returns the original A. The inverse of the example matrix,  $X = \text{inv}(A)$ , is actually computed from the inverses of the triangular factors

$$X = \text{inv}(U)*\text{inv}(L1)$$

Using three arguments on the left side to get the permutation matrix as well,

$$[L2,U,P] = \text{lu}(A)$$

returns a truly lower triangular L2, the same value of U, and the permutation matrix P.

$$\begin{array}{ccc}
 L2 = & & \\
 1.0000 & 0 & 0 \\
 0.1429 & 1.0000 & 0 \\
 0.5714 & 0.5000 & 1.0000 \\
 \\
 U = & & \\
 7.0000 & 8.0000 & 0 \\
 0 & 0.8571 & 3.0000 \\
 0 & 0 & 4.5000 \\
 \\
 P = & & \\
 0 & 0 & 1 \\
 1 & 0 & 0 \\
 0 & 1 & 0
 \end{array}$$

Note that  $L2 = P*L1$ .

$$P*L1$$

ans =

```

1.0000 0 0
0.1429 1.0000 0
0.5714 0.5000 1.0000

```

To verify that  $L2*U$  is a permuted version of  $A$ , compute  $L2*U$  and subtract it from  $P*A$ :

$P*A - L2*U$

ans =

```

0 0 0
0 0 0
0 0 0

```

In this case,  $\text{inv}(U) * \text{inv}(L)$  results in the permutation of  $\text{inv}(A)$  given by  $\text{inv}(P) * \text{inv}(A)$ .

The determinant of the example matrix is

$d = \det(A)$

$d = 27$

It is computed from the determinants of the triangular factors

$d = \det(L) * \det(U)$

The solution to  $Ax = b$  is obtained with matrix division

$x = A \setminus b$

The solution is actually computed by solving two triangular systems

$y = L \setminus b$

$x = U \setminus y$

## Example 2

The 1-norm of their difference is within roundoff error, indicating that  $L*U = P*B*Q$ .

Generate a 60-by-60 sparse adjacency matrix of the connectivity graph of the Buckminster-Fuller geodesic dome.

```
B = bucky;
```

Use the sparse matrix syntax with four outputs to get the row and column permutation matrices.

```
[L,U,P,Q] = lu(B);
```

Apply the permutation matrices to **B**, and subtract the product of the lower and upper triangular matrices.

```
Z = P*B*Q - L*U;
norm(Z,1)
```

```
ans =
 7.9936e-015
```

### Example 3

This example illustrates the benefits of using the 'vector' option. Note how much memory is saved by using the `lu(F, 'vector')` syntax.

```
F = gallery('uniformdata',[1000 1000],0);
g = sum(F,2);
[L,U,P] = lu(F);
[L,U,p] = lu(F,'vector');
whos P p
```

Name	Size	Bytes	Class	Attributes
P	1000x1000	8000000	double	
p	1x1000	8000	double	

The following two statements are equivalent. The first typically requires less time:

```
x = U \ (L \ (g(p,:)));
y = U \ (L \ (P*g));
```

## More About

### Tips

Most of the algorithms for computing LU factorization are variants of Gaussian elimination. The factorization is a key step in obtaining the inverse with `inv` and the

determinant with `det`. It is also the basis for the linear equation solution or matrix division obtained with `\` and `/`.

`cond` | `det` | `inv` | `ilu` | `qr` | `rref`

# Primitive Line Properties

Control primitive line appearance and behavior

Primitive line properties control the appearance and behavior of a primitive line object. By changing property values, you can modify certain aspects of the line. Use dot notation to refer to a particular object and property:

```
h = line;
s = h.LineStyle;
h.LineStyle = ':';
```

## Line

### LineStyle — Line style

'-' (default) | '--' | ':' | '-.' | 'none'

Line style, specified as one of the line style strings listed in this table.

String	Line Style	Resulting Line
'-'	Solid line	
'--'	Dashed line	
':'	Dotted line	
'-.'	Dash-dotted line	
'none'	No line	No line

### LineWidth — Line width

0.5 (default) | positive value

Line width, specified as a positive value in point units. If the line has markers, then the line width also affects the marker edges.

Example: 0.75

### Color — Line color

[0 0 0] (default) | RGB triplet | color string | 'none'

Line color, specified as an RGB triplet, a color string or 'none'. The default RGB triplet value of [0 0 0] corresponds to black. If you specify the color as 'none', then the line is invisible.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0, 1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[1 1 0]
'magenta'	'm'	[1 0 1]
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black'	'k'	[0 0 0]

Example: 'blue'

Example: [0 0 1]

### **AlignVertexCenters** — Sharp vertical and horizontal lines

'off' (default) | 'on'

Sharp vertical and horizontal lines, specified as 'off' or 'on'.

If the associated figure has a `GraphicsSmoothing` property set to 'on' and a `Renderer` property set to 'opengl', then the figure applies a smoothing technique to plots. In some cases, this smoothing technique can cause vertical and horizontal lines to appear uneven in thickness or color. Use the `AlignVertexCenters` property to eliminate the uneven appearance.

- 'off' — Do not sharpen vertical or horizontal lines. The lines might appear uneven in thickness or color.
- 'on' — Sharpen vertical and horizontal lines to eliminate an uneven appearance.

---

**Note:** You must have a graphics card that supports this feature. To see if the feature is supported, type `opengl info`. If it is supported, then the returned fields contain the line `SupportsAlignVertexCenters: 1`.

---

## Markers

### Marker — Marker symbol

'none' (default) | marker string

Marker symbol, specified as one of the marker strings listed in this table. By default, the primitive line object does not display markers. Specifying a marker symbol adds markers at each data point or vertex.

String	Marker Symbol
'o'	Circle
'+'	Plus sign
'*'	Asterisk
'.'	Point
'x'	Cross
'square' or 's'	Square
'diamond' or 'd'	Diamond
'^'	Upward-pointing triangle
'v'	Downward-pointing triangle
'>'	Right-pointing triangle
'<'	Left-pointing triangle
'pentagram' or 'p'	Five-pointed star (pentagram)
'hexagram' or 'h'	Six-pointed star (hexagram)
'none'	No markers

Example: '+'

Example: 'diamond'

### MarkerSize — Marker size

6 (default) | positive value

Marker size, specified as a positive value in point units.

Example: 10

**MarkerEdgeColor — Marker outline color**

'auto' (default) | 'none' | RGB triplet | color string

Marker outline color, specified as one of these values:

- 'auto' — Use the same color as the Color property.
- 'none' — Use no color, which makes unfilled markers invisible.
- RGB triplet or color string — Use the specified color.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0, 1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[1 1 0]
'magenta'	'm'	[1 0 1]
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black'	'k'	[0 0 0]

Example: [0.5 0.5 0.5]

Example: 'blue'

**MarkerFaceColor — Marker fill color**

'none' (default) | 'auto' | RGB triplet | color string

Marker fill color, specified as one of these values:

- 'none' — Use no color, which makes the interior invisible.
- 'auto' — Use the same color as the Color property for the axes.

- RGB triplet or color string — Use the specified color.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range  $[0, 1]$ , for example,  $[0.4 \ 0.6 \ 0.7]$ . This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[ 1 1 0 ]
'magenta'	'm'	[ 1 0 1 ]
'cyan'	'c'	[ 0 1 1 ]
'red'	'r'	[ 1 0 0 ]
'green'	'g'	[ 0 1 0 ]
'blue'	'b'	[ 0 0 1 ]
'white'	'w'	[ 1 1 1 ]
'black'	'k'	[ 0 0 0 ]

Example:  $[0.3 \ 0.2 \ 0.1]$

Example: 'green'

## Data

### XData — x values

$[0 \ 1]$  (default) | vector

x values, specified as a vector. XData and YData must have equal lengths.

Example:  $1:10$

### YData — y values

$[0 \ 1]$  (default) | vector

y values, specified as a vector. XData and YData must have equal lengths.

Example:  $1:10$

### ZData — z values

empty matrix (default) | vector

$z$  values, specified as a vector. `ZData` must have the same length as `XData` and `YData`.

Example: `1:10`

## Visibility

### **Visible** — Visibility of primitive line

'on' (default) | 'off'

Visibility of primitive line, specified as one of these values:

- 'on' — Display the primitive line.
- 'off' — Hide the primitive line without deleting it. You still can access the properties of an invisible primitive line object.

### **Clipping** — Clipping of primitive line to axes limits

'on' (default) | 'off'

Clipping of primitive line to the axes limits, specified as one of these values:

- 'on' — Do not display parts of the primitive line that are outside the axes limits.
- 'off' — Display the entire primitive line, even if parts of it appear outside the axes limits. Parts of the primitive line might appear outside the axes limits if you create a plot, set `hold on`, freeze the axis scaling, and then create the primitive line that is larger than the original plot.

### **EraseMode** — (removed) Technique to draw and erase objects

'normal' (default) | 'none' | 'xor' | 'background'

---

**Note:** `EraseMode` has been removed. You can delete code that accesses the `EraseMode` property with minimal impact. If you were using `EraseMode` to create line animations, use the `animatedline` function instead.

---

Technique to draw and erase objects, specified as one of these values:

- 'normal' — Redraw the affected region of the display, performing the three-dimensional analysis necessary to correctly render all objects. This mode produces the most accurate picture, but is the slowest. The other modes are faster, but do not perform a complete redraw and, therefore, are less accurate.

- `'none'` — Do not erase the object when it is moved or destroyed. After you erase the object with `EraseMode`, `'none'`, it is still visible on the screen. However, you cannot print the object because MATLAB does not store any information on its former location.
- `'xor'` — Draw and erase the object by performing an exclusive OR (XOR) with the color of the screen beneath it. This mode does not damage the color of the objects beneath it. However, the object color depends on the color of whatever is beneath it on the display.
- `'background'` — Erase the object by redrawing it in the axes background color, or the figure background color if the axes `Color` property is `'none'`. This damages objects that are behind the erased object, but properly colors the erased object.

MATLAB always prints figures as if the `EraseMode` property of all objects is set to `'normal'`. This means graphics objects created with `EraseMode` set to `'none'`, `'xor'`, or `'background'` can look different on screen than on paper. On screen, MATLAB mathematically combines layers of colors and ignores three-dimensional sorting to obtain greater rendering speed. However, MATLAB does not apply these techniques to the printed output. Use the `getframe` command or other screen capture applications to create an image of a figure containing nonnormal mode objects.

## Identifiers

### Type — Type of graphics object

`'line'`

Type of graphics object, returned as `'line'`. Use this property to find all objects of a given type within a plotting hierarchy, for example, searching for the type using `findobj`.

### Tag — Tag to associate with primitive line

`''` (default) | string

Tag to associate with the primitive line, specified as a string. Tags provide a way to identify graphics objects. Use this property to find all objects with a specific tag within a plotting hierarchy, for example, searching for the tag using `findobj`.

Example: `'January Data'`

### UserData — Data to associate with primitive line

`[]` (default) | scalar, vector, or matrix | cell array | character array | table | structure

Data to associate with the primitive line object, specified as a scalar, vector, matrix, cell array, character array, table, or structure. MATLAB does not use this data.

To associate multiple sets of data or to attach a field name to the data, use the `getappdata` and `setappdata` functions.

Example: `1:100`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `struct` | `table` | `cell`

### **DisplayName** — Text used by legend

`''` (default) | string

Text used by the legend, specified as a string. The text appears next to an icon of the primitive line.

- If you specify text for the primitive line object as an input argument to the `legend` function, then the legend uses the specified text and updates the `DisplayName`.
- If you do not specify text for the primitive line object as an input argument to the `legend` function, then the legend uses the text in the `DisplayName` property. If the `DisplayName` property does not contain any text, then the legend generates a string. The string has the form `'dataN'`, where N is the number assigned to the primitive line object based on its location in the list of legend entries.

If you edit interactively the string in an existing legend, then MATLAB updates the `DisplayName` to the edited string.

Example: `'Text Description'`

### **Annotation** — Legend icon display style

Annotation object

Legend icon display style, returned as an `Annotation` object. Use this object to include or exclude the primitive line from a legend.

- 1** Query the `Annotation` property to get the `Annotation` object.
- 2** Query the `LegendInformation` property of the `Annotation` object to get the `LegendEntry` object.
- 3** Specify the `IconDisplayStyle` property of the `LegendEntry` object to one of these values:

- 'on' — Include the primitive line object in the legend as one entry (default).
- 'off' — Do not include the primitive line object in the legend.
- 'children' — Include only children of the primitive line object as separate entries in the legend.

If a legend already exists and you change the `IconDisplayStyle` setting, then you must call `legend` to update the display.

## Parent/Child

### Parent — Parent of primitive line

axes object | group object | transform object

Parent of primitive line, specified as an axes, group, or transform object.

### Children — Children of primitive line

empty `GraphicsPlaceholder` array

The primitive line has no children. You cannot set this property.

### HandleVisibility — Visibility of object handle

'on' (default) | 'off' | 'callback'

Visibility of object handle in the `Children` property of the parent, specified as one of these values:

- 'on' — List the primitive line object.
- 'off' — Do not list the primitive line object. Use this option to hide object handles when a callback invokes a function that could damage the GUI, such as evaluating a user-typed string.
- 'callback' — List the primitive line object in the `Children` property of the parent from within callbacks or functions invoked by callbacks, but not from within functions invoked from the command line. Use this option to protect a GUI from command-line users, while allowing callbacks to have access to objects.

If the primitive line object is not listed in the `Children` property of the parent, then functions that obtain object handles by searching the object hierarchy or querying handle

properties cannot return it. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

Hidden object handles are still valid. Set the root `ShowHiddenHandles` property to `'on'` to list all object handles regardless of their `HandleVisibility` property setting.

## Interactive Control

### **ButtonDownFcn** — Mouse-click callback

`'` (default) | function handle | cell array | string

Mouse-click callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you click the primitive line. If you specify this property using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The primitive line object — You can access properties of the primitive line object from within the callback function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see “Callback Definition”.

---

**Note:** If the `PickableParts` property is set to `'none'` or if the `HitTest` property is set to `'off'`, then this callback does not execute.

---

Example: `@myCallback`

Example: `{@myCallback, arg3}`

### **UIContextMenu** — Context menu

`uicontextmenu` object

Context menu, specified as a `uicontextmenu` object. Use this property to display a context menu when you right-click the primitive line. Create the context menu using the `uicontextmenu` function.

---

**Note:** If the `PickableParts` property is set to `'none'` or if the `HitTest` property is set to `'off'`, then the context menu does not appear.

---

### **Selected** — Selection state

`'off'` (default) | `'on'`

Selection state, specified as one of these values:

- `'on'` — Selected. If you click the primitive line when in plot edit mode, then MATLAB sets its `Selected` property to `'on'`. If the `SelectionHighlight` property also is set to `'on'`, then MATLAB displays selection handles around the primitive line.
- `'off'` — Not selected.

### **SelectionHighlight** — Display of selection handles when selected

`'on'` (default) | `'off'`

Display of selection handles when selected, specified as one of these values:

- `'on'` — Display selection handles when the `Selected` property is set to `'on'`.
- `'off'` — Never display selection handles, even when the `Selected` property is set to `'on'`.

## Callback Execution Control

### **PickableParts** — Ability to capture mouse clicks

`'visible'` (default) | `'all'` | `'none'`

Ability to capture mouse clicks, specified as one of these values:

- `'visible'` — Can capture mouse clicks when visible. The `Visible` property must be set to `'on'` and you must click a part of the primitive line that has a defined color. You cannot click a part that has an associated color property set to `'none'`. If the plot contains markers, then the entire marker is clickable if either the edge or the fill has a defined color. The `HitTest` property determines if the primitive line responds to the click or if an ancestor does.

- 'all' — Can capture mouse clicks regardless of visibility. The Visible property can be set to 'on' or 'off' and you can click a part of the primitive line that has no color. The HitTest property determines if the primitive line responds to the click or if an ancestor does.
- 'none' — Cannot capture mouse clicks. Clicking the primitive line passes the click through it to the object below it in the current view of the figure window. The HitTest property has no effect.

### **HitTest — Response to captured mouse clicks**

'on' (default) | 'off'

Response to captured mouse clicks, specified as one of these values:

- 'on' — Trigger the ButtonDownFcn callback of the primitive line. If you have defined the UIContextMenu property, then invoke the context menu.
- 'off' — Trigger the callbacks for the nearest ancestor of the primitive line that has a HitTest property set to 'on' and a PickableParts property value that enables the ancestor to capture mouse clicks.

---

**Note:** The PickableParts property determines if the primitive line object can capture mouse clicks. If it cannot, then the HitTest property has no effect.

---

### **Interruptible — Callback interruption**

'on' (default) | 'off'

Callback interruption, specified as 'on' or 'off'. The Interruptible property determines if a running callback can be interrupted.

---

**Note:** There are two callback states to consider:

- The *running* callback is the currently executing callback.
  - The *interrupting* callback is a callback that tries to interrupt the running callback. Whenever MATLAB invokes a callback, that callback attempts to interrupt a running callback. The Interruptible property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the BusyAction property of the object owning the interrupting callback determines if it is discarded or put in the queue.
-

If the `ButtonDownFcn` callback of the primitive line is the running callback, then the `Interruptible` property determines if it another callback can interrupt it:

- `'on'` — Interruptible. Interruption occurs at the next point where MATLAB processes the queue, such as when there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command.
  - If the running callback contains one of these commands, then MATLAB stops the execution of the callback at this point and executes the interrupting callback. MATLAB resumes executing the running callback when the interrupting callback completes. For more information, see “Interrupt Callback Execution”.
  - If the running callback does not contain one of these commands, then MATLAB finishes executing the callback without interruption.
- `'off'` — Not interruptible. MATLAB finishes executing the running callback without any interruptions.

### **BusyAction — Callback queuing**

`'queue'` (default) | `'cancel'`

Callback queuing specified as `'queue'` or `'cancel'`. The `BusyAction` property determines how MATLAB handles the execution of interrupting callbacks.

---

**Note:** There are two callback states to consider:

- The *running* callback is the currently executing callback.
- The *interrupting* callback is a callback that tries to interrupt the running callback.

Whenever MATLAB invokes a callback, that callback attempts to interrupt a running callback. The `Interruptible` property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the `BusyAction` property of the object owning the interrupting callback determines if it is discarded or put in the queue.

---

If the `ButtonDownFcn` callback of the primitive line tries to interrupt a running callback that cannot be interrupted, then the `BusyAction` property determines if it is discarded or put in the queue. Specify the `BusyAction` property as one of these values:

- `'queue'` — Put the interrupting callback in a queue to be processed after the running callback finishes execution. This is the default behavior.

- 'cancel' — Discard the interrupting callback.

## Creation and Deletion Control

### **CreateFcn** — Creation callback

' ' (default) | function handle | cell array | string

Creation callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you create the primitive line. Setting the **CreateFcn** property on an existing primitive line has no effect. You must define a default value for this property, or define this property using a **Name, Value** pair during primitive line creation. MATLAB executes the callback after creating the primitive line and setting all of its properties.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The primitive line object — You can access properties of the primitive line object from within the callback function. You also can access the primitive line object through the **CallbackObject** property of the root, which can be queried using the **gcbo** function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see “Callback Definition”.

Example: @myCallback

Example: {@myCallback, arg3}

### **DeleteFcn** — Deletion callback

' ' (default) | function handle | cell array | string

Deletion callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you delete the primitive line. MATLAB executes the callback before destroying the primitive line so that the callback can access its property values.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The primitive line object — You can access properties of the primitive line object from within the callback function. You also can access the primitive line object through the `CallbackObject` property of the root, which can be queried using the `gcbo` function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see “Callback Definition”.

Example: `@myCallback`

Example: `{@myCallback, arg3}`

### **BeingDeleted** — Deletion status of primitive line

'off' (default) | 'on'

Deletion status of primitive line, returned as 'on' or 'off'. MATLAB sets the `BeingDeleted` property to 'on' when the delete function of the primitive line begins execution (see the `DeleteFcn` property). The `BeingDeleted` property remains set to 'on' until the primitive line no longer exists.

Check the value of the `BeingDeleted` property to verify that the primitive line is not about to be deleted before querying or modifying it.

# magic

Magic square

## Syntax

```
M = magic(n)
```

## Description

`M = magic(n)` returns an  $n$ -by- $n$  matrix constructed from the integers 1 through  $n^2$  with equal row and column sums. The order  $n$  must be a scalar greater than or equal to 3.

## Examples

The magic square of order 3 is

```
M = magic(3)
```

```
M =
```

```
 8 1 6
 3 5 7
 4 9 2
```

This is called a magic square because the sum of the elements in each column is the same.

```
sum(M) =
```

```
 15 15 15
```

And the sum of the elements in each row, obtained by transposing twice, is the same.

```
sum(M')' =
```

```
 15
```

```
15
15
```

This is also a special magic square because the diagonal elements have the same sum.

```
sum(diag(M)) =
```

```
15
```

The value of the characteristic sum for a magic square of order  $n$  is

```
sum(1:n^2)/n
```

which, when  $n = 3$ , is 15.

## Limitations

If you supply  $n$  less than 3, `magic` returns either a nonmagic square, or else the degenerate magic squares 1 and [ ].

## More About

### Tips

A magic square, scaled by its magic sum, is doubly stochastic.

### Algorithms

There are three different algorithms:

- $n$  odd
- $n$  even but not divisible by four
- $n$  divisible by four

To make this apparent, type

```
for n = 3:20
 A = magic(n);
 r(n) = rank(A);
end
```

For  $n$  odd, the rank of the magic square is  $n$ . For  $n$  divisible by 4, the rank is 3. For  $n$  even but not divisible by 4, the rank is  $n/2 + 2$ .

```
[(3:20)', r(3:20)']
```

```
ans =
```

3	3
4	3
5	5
6	5
7	7
8	3
9	9
10	7
11	11
12	3
13	13
14	9
15	15
16	3
17	17
18	11
19	19
20	3

Plotting  $A$  for  $n = 18, 19, 20$  shows the characteristic plot for each category.

## makehgtform

Create 4-by-4 transform matrix

### Syntax

```
M = makehgtform
M = makehgtform('translate',[tx ty tz])
M = makehgtform('scale',s)
M = makehgtform('scale',[sx,sy,sz])
M = makehgtform('xrotate',t)
M = makehgtform('yrotate',t)
M = makehgtform('zrotate',t)
M = makehgtform('axisrotate',[ax,ay,az],t)
```

### Description

Use `makehgtform` to create transform matrices for translation, scaling, and rotation of graphics objects. Apply the transform to graphics objects by assigning the transform to the `Matrix` property of a parent transform object.

`M = makehgtform` returns an identity transform.

`M = makehgtform('translate',[tx ty tz])` or `M = makehgtform('translate',tx,ty,tz)` returns a transform that translates along the *x*-axis by `tx`, along the *y*-axis by `ty`, and along the *z*-axis by `tz`.

`M = makehgtform('scale',s)` returns a transform that scales uniformly along the *x*-, *y*-, and *z*-axes.

`M = makehgtform('scale',[sx,sy,sz])` returns a transform that scales along the *x*-axis by `sx`, along the *y*-axis by `sy`, and along the *z*-axis by `sz`.

`M = makehgtform('xrotate',t)` returns a transform that rotates around the *x*-axis by `t` radians.

`M = makehgtform('yrotate',t)` returns a transform that rotates around the *y*-axis by `t` radians.

`M = makehgtform('zrotate',t)` returns a transform that rotates around the  $z$ -axis by  $t$  radians.

`M = makehgtform('axisrotate',[ax,ay,az],t)` Rotate around axis `[ax ay az]` by  $t$  radians.

Note that you can specify multiple operations in one call to `makehgtform` and the MATLAB software returns a transform matrix that is the result of concatenating all specified operations. For example,

```
m = makehgtform('xrotate',pi/2,'yrotate',pi/2);
```

is the same as

```
mx = makehgtform('xrotate',pi/2);
my = makehgtform('yrotate',pi/2);
m = mx*my;
```

# mapreduce

Programming technique for analyzing data sets that do not fit in memory

## Syntax

```
outds = mapreduce(ds,mapfun,reducefun)
outds = mapreduce(ds,mapfun,reducefun,mr)
outds = mapreduce(____,Name,Value)
```

## Description

`outds = mapreduce(ds,mapfun,reducefun)` applies map function `mapfun` to input datastore `ds`, and then passes the values associated with each unique key to reduce function `reducefun`. The output datastore is a `KeyValueDatastore` object that points to `.mat` files in the current folder.

`outds = mapreduce(ds,mapfun,reducefun,mr)` optionally specifies the runtime configuration settings for `mapreduce`. The `mr` input is the result of a call to the `mapreducer` function. Typically, this argument is used with Parallel Computing Toolbox, MATLAB Distributed Computing Server, or MATLAB Compiler. For more information, see “Speed Up and Deploy MapReduce Using Other Products”.

`outds = mapreduce( ____,Name,Value)` specifies additional options with one or more `Name,Value` pair arguments using any of the previous syntaxes. For example, you can specify `'OutputFolder'` followed by a string specifying a path to the output folder.

## Examples

- “Compute Summary Statistics by Group Using MapReduce”
- “Using MapReduce to Fit a Logistic Regression Model”
- “Tall Skinny QR (TSQR) Matrix Factorization Using MapReduce”

## Input Arguments

### **ds** — Input datastore

datastore object

Input datastore, specified as a datastore object. Use the `datastore` function to create a datastore object from your data set.

### **mapfun** — Function handle to map function

function handle

Function handle to map function. `mapfun` receives chunks from input datastore `ds`, and then uses the `add` and `addmulti` functions to add key-value pairs to an intermediate `KeyValueStore` object. The number of calls to the map function by `mapreduce` is equal to the number of chunks in the `datastore` (for example, the number of chunks is determined by the `KeyValueLimit` property for a `KeyValueDatastore`, and by the `RowsPerRead` property for a `TabularTextDatastore`).

The inputs to the map function are `data`, `info`, and `intermKVStore`, which `mapreduce` automatically creates and passes to the map function:

- The `data` and `info` inputs are the result of a call to the `read` function of `datastore`, which `mapreduce` executes automatically before each call to the map function.
- `intermKVStore` is the name of the intermediate `KeyValueStore` object to which the map function needs to add key-value pairs. If none of the calls to the map function add key-value pairs to `intermKVStore`, then `mapreduce` does not call the reduce function and the output datastore is empty.

An example of a template for the map function is

```
function myMapper(data, info, intermKVStore)
%do a calculation with the data chunk
add(intermKVStore, key, value)
end
```

Example: `@myMapper`

Data Types: `function_handle`

### **reducefun — Function handle to reduce function**

`function handle`

Function handle to reduce function. `mapreduce` calls `reducefun` once for each unique key added to the intermediate `KeyValueStore` by the map function. In each call, `mapreduce` passes the values associated with the active key to `reducefun` as a `ValueIterator` object. The `reducefun` function loops through the values for each key using the `hasnext` and `getnext` functions. Then, after performing some calculation(s), it writes key-value pairs to the final output.

The inputs to the reduce function are `intermKey`, `intermValIter`, and `outKVStore`, which `mapreduce` automatically creates and passes to the reduce function:

- `intermKey` is the active key from the intermediate `KeyValueStore` object. Each call to the reduce function by `mapreduce` specifies a new unique key from the keys in the intermediate `KeyValueStore` object.
- `intermValIter` is the `ValueIterator` associated with the active key, `intermKey`. This `ValueIterator` object contains all of the values associated with the active key. Scroll through the values using the `hasnext` and `getnext` functions.
- `outKVStore` is the name for the final `KeyValueStore` object to which the reduce function needs to add key-value pairs. `mapreduce` takes the output key-value pairs from `outKVStore` and returns them in the output datastore, `outds`, which is a `KeyValueDatastore` object by default. If none of the calls to the reduce function add final key-value pairs to `outKVStore`, then the output datastore is empty.

An example of a template for the reduce function is

```
function myReducer(intermKey, intermValIter, outKVStore)
while hasNext(intermValIter)
 X = getnext(intermValIter);
 %do a calculation with the current value, X
end
add(outKVStore, key, value)
end
```

Example: `@myReducer`

Data Types: `function_handle`

### **mr — Execution environment**

`MapReducer` object

Execution environment, specified as a MapReducer object. `mr` is the result of a call to the `mapreducer` function. The default `mr` argument is a call to `gcmr`, which uses the default global execution environment for `mapreduce` (`SerialMapReducer` in MATLAB).

---

**Note:** This setting specifies the execution environment for `mapreduce` and is not necessary to run `mapreduce` on your local computer. For more information, see “Speed Up and Deploy MapReduce Using Other Products”.

---

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( `' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `outds = mapreduce(ds, @mapfun, @reducefun, 'Display', 'off', 'OutputFolder', 'C:\Users\username\Desktop')`

### 'OutputType' — Type of datastore output

'Binary' (default) | 'TabularText'

Type of datastore output, specified as 'Binary' or 'TabularText'. The default setting of 'Binary' returns a `KeyValueDatastore` output datastore that points to `.mat` files in the output folder. The 'TabularText' option returns a `TabularTextDatastore` output datastore that points to `.txt` files in the output folder.

The `OutputType` argument affects the type of values that the reduce function can add:

- If the `OutputType` is 'Binary' (the default), then a value added by the reduce function can be any valid MATLAB object.
- If the `OutputType` is 'TabularText', then a value added by the reduce function can be a numeric scalar or string. In this case, the value cannot be NaN, complex, logical, or sparse.

### 'OutputFolder' — Destination folder of mapreduce output

`pwd` (default) | file path

Destination folder for `mapreduce` output, specified as a file path. The default output folder is the current folder, `pwd`. You can specify a different path with a fully qualified path or with a path relative to the current folder.

Example: `mapreduce(..., 'OutputFolder', 'MyOutputFolder\Results')` specifies a file path relative to the current folder for the output.

### 'Display' — Toggle for command line progress output

'on' (default) | 'off'

Toggle for command line progress output, specified as 'on' or 'off'. The default is 'on', so that `mapreduce` displays progress information in the command window during the map and reduce phases of execution.

## Output Arguments

### **outds** — Output datastore

`KeyValueDatastore` (default) | `TabularTextDatastore`

Output datastore, returned as a `KeyValueDatastore` or `TabularTextDatastore` object. By default, `outds` is a `KeyValueDatastore` object that points to `.mat` files in the current folder. Use the `Name, Value` pair arguments for 'OutputType' and 'OutputFolder' to return a `TabularTextDatastore` object or change the location of the output files, respectively.

`mapreduce` does not sort the key-value pairs in `outds`. Their order may differ when using other products with `mapreduce`.

To view the contents of `outds`, use the `preview`, `read`, or `readall` functions of `datastore`.

## More About

### Tips

- Whether you are just learning `mapreduce` or are more experienced, debugging your `mapreduce` algorithms to examine how key-value pairs move through the different phases is useful. To do this, set breakpoints in your map and reduce functions. The breakpoints stop execution of `mapreduce`, allowing you to examine the current status of relevant variables, like the `KeyValueStore` or `ValueIterator`. For more information, see “Debug MapReduce Algorithms”.

# mapreducer

Define execution environment for mapreduce

`mapreducer` is the execution configuration function for `mapreduce`. Use this function to set, change, or store the execution environment to run `mapreduce` using Parallel Computing Toolbox, MATLAB Distributed Computing Server, or MATLAB Compiler.

## Syntax

```
mapreducer
mapreducer(0)
mapreducer(mr)
mr = mapreducer(___)
mr = mapreducer(___ , 'ObjectVisibility', 'Off')
```

## Description

`mapreducer` sets the global execution environment for `mapreduce` to be the default (`SerialMapReducer` in MATLAB).

`mapreducer(0)` sets the global execution environment for `mapreduce` to be the local MATLAB session.

`mapreducer(mr)` sets the global execution environment for `mapreduce` using a previously created `MapReducer` object, `mr`.

`mr = mapreducer( ___ )` also returns a `MapReducer` object using any of the previous syntaxes. Use `mr` as a fourth input argument to `mapreduce` when you want to explicitly specify the execution environment.

`mr = mapreducer( ___ , 'ObjectVisibility', 'Off' )` toggles the visibility of the `MapReducer` object, `mr`, using any of the previous syntaxes. Use this syntax to create new `MapReducer` objects without affecting the global execution environment of `mapreduce`.

---

**Note:** In MATLAB, the `mapreduce` function automatically runs using a `SerialMapReducer`, and it is unnecessary to specify configuration settings using

mapreducer. However, if you have Parallel Computing Toolbox, MATLAB Distributed Computing Server, or MATLAB Compiler, then additional `mapreducer` configuration options are available for running in parallel or deployed environments. For more information, see the documentation in each product.

---

## Output Arguments

### **mr** — Execution environment for `mapreduce`

MapReducer object

Execution environment for `mapreduce`, returned as a MapReducer object.

If the `ObjectVisibility` property of `mr` is set to 'On' (the default), then `mr` defines the default execution environment for `mapreduce`. You can pass `mr` to the `mapreduce` function to explicitly specify the execution environment, even if its `ObjectVisibility` property is set to 'Off'.

Pass `mr` to the `mapreduce` function when using the following products:

- Parallel Computing Toolbox enables you to run `mapreduce` computations in parallel on local workers.
- MATLAB Distributed Computing Server extends Parallel Computing Toolbox, enabling you to run `mapreduce` computations on a remote cluster using Hadoop.
- MATLAB Compiler enables you to create standalone applications or deployable archives, which you can share with colleagues or deploy to production Hadoop systems.

## More About

### Tips

- If you have Parallel Computing Toolbox, see the `mapreducer` function reference page for additional information.
- If you have MATLAB Compiler, see the `mapreducer` function reference page for additional information.
- “Speed Up and Deploy MapReduce Using Other Products”

# containers.Map class

**Package:** containers

Map values to unique keys

## Description

A `Map` object is a data structure that allows you to retrieve values using a corresponding key. Keys can be real numbers or text strings and provide more flexibility for data access than array indices, which must be positive integers. Values can be scalar or nonscalar arrays.

## Construction

`mapObj = containers.Map` constructs an empty `Map` container `mapObj`.

`mapObj = containers.Map(keySet,valueSet)` constructs a `Map` that contains one or more values and a unique key for each value.

`mapObj = containers.Map(keySet,valueSet,'UniformValues',isUniform)` specifies whether all values must be uniform (either all scalars of the same data type, or all strings). Possible values for `isUniform` are logical `true` (1) or `false` (0).

`mapObj = containers.Map('KeyType',kType,'ValueType',vType)` constructs an empty `Map` object and sets the `KeyType` and `ValueType` properties. The order of the key type and value type argument pairs is not important, but both pairs are required.

## Input Arguments

### **keySet**

1-by-n array that specifies n unique keys for the map.

All keys in a `Map` object are real numeric values or all keys are strings. If  $n > 1$  and the keys are strings, `keySet` must be a cell array. The number of keys in `keySet` must equal the number of values in `valueSet`.

### **valueSet**

1-by-n array of any class that specifies n values for the map. The number of values in valueSet must equal the number of keys in keySet.

### **'UniformValues'**

Parameter string to use with the isUniform argument.

### **isUniform**

Logical value that specifies whether all values are uniform. If isUniform is true (1), all values must be scalars of the same data type, or all values must be strings. If isUniform is false (0), then containers.Map sets the ValueType to 'any'.

**Default:** true for empty Map objects, otherwise determined by the data types of values in valueSet.

### **'KeyType'**

Parameter string to use with the kType argument.

### **kType**

String that specifies the data type for the keys. Possible values are 'char', 'double', 'single', 'int32', 'uint32', 'int64', or 'uint64'.

**Default:** 'char' for empty Map objects, otherwise determined by the data types of keys in keySet. If you specify keys of different numeric types, kType is 'double'.

### **'ValueType'**

Literal string parameter to use with the vType argument.

### **vType**

String that specifies the data type for the values. Possible values are 'any', 'char', 'logical', 'double', 'single', 'int8', 'uint8', 'int16', 'uint16', 'int32', 'uint32', 'int64', or 'uint64'.

**Default:** 'any' when you create an empty Map object or when you specify values of different sizes or types, otherwise determined by the data type of valueSet.

## Properties

### Count

Unsigned 64-bit integer that represents the total number of key-value pairs contained in the `Map` object. Read only.

### KeyType

Character array that indicates the data type of all keys in the `Map` object. The default `KeyType` for empty `Map` objects is `'char'`. Otherwise, `KeyType` is determined from the data type of the `keySet` inputs. Read only.

### ValueType

Character array that indicates the data type of all values in the `Map` object. If you construct an empty `Map` object or specify values with different data types, then the value of `ValueType` is `'any'`. Otherwise, `ValueType` is determined from the data type of the `valueSet` inputs. Read only.

## Methods

<code>isKey</code>	Determine if <code>containers.Map</code> object contains key
<code>keys</code>	Identify keys of <code>containers.Map</code> object
<code>length</code>	Length of <code>containers.Map</code> object
<code>remove</code>	Remove key-value pairs from <code>containers.Map</code> object
<code>size</code>	Size of <code>containers.Map</code> object
<code>values</code>	Identify values in <code>containers.Map</code> object

## Copy Semantics

Handle. To learn how handle classes affect copy operations, see “Copying Objects” in the MATLAB documentation.

## Examples

### Construct a Map and View Properties

Construct a Map object that contains rainfall data for several months:

```
keySet = {'Jan', 'Feb', 'Mar', 'Apr'};
valueSet = [327.2, 368.2, 197.6, 178.4];
mapObj = containers.Map(keySet,valueSet)
```

This code returns a description of the map, including the property values:

```
mapObj =

 containers.Map handle
 Package: containers

 Properties:
 Count: 4
 KeyType: 'char'
 ValueType: 'double'

 Methods, Events, Superclasses
```

Get a specific property using dot notation, such as

```
mapObj.Count
```

which returns

```
ans =

 4
```

### Look Up Values in a Map

Use the map created in the previous example to find the rainfall data for February:

```
rainFeb = mapObj('Feb')
```

This code returns

```
rainFeb =
 368.2000
```

## Add a Single Value and Key to a Map

Add data for the month of May to the map created in the first example:

```
mapObj('May') = 100.0;
```

## Add Multiple Values and Keys by Concatenating Maps

Create a map that contains rainfall data for June, July, and August, and add the data to `mapObj` (from previous examples):

```
keySet = {'Jun','Jul','Aug'};
valueSet = [69.9, 32.3, 37.3];
newMap = containers.Map(keySet,valueSet);

mapObj = [mapObj; newMap];
```

Map objects only support vertical concatenation (that is, adding columns with a semicolon, `;`). When concatenating maps, the data type of all values must be consistent with the `ValueType` of the leftmost map. In this example, both maps have the a `ValueType` of `double`.

## Get the Keys or Values in a Map

Determine all the keys of `mapObj` (from previous examples) by calling the `keys` method:

```
allKeys = keys(mapObj)
```

This method returns the keys in alphabetical order:

```
allKeys =
 'Apr' 'Aug' 'Feb' 'Jan' 'Jul' 'Jun' 'Mar' 'May'
```

Get multiple values from the map by calling the `values` method. Like the `keys` method, you can request all values with the syntax `values(mapObj)`. Alternatively, request values for specific keys. For example, view the values for March, April, and May in `mapObj`:

```
springValues = values(mapObj,{'Mar','Apr','May'})
```

This method returns the values in a cell array, in the order corresponding to the specified keys:

```
springValues =
 [197.6000] [178.4000] [100]
```

## Remove Keys and Values

Remove the data for March and April from mapObj (from previous examples) by calling the remove method, and view the remaining keys:

```
remove(mapObj,{'Mar','Apr'});
keys(mapObj)
```

This code returns

```
ans =
 'Aug' 'Feb' 'Jan' 'Jul' 'Jun' 'May'
```

## Create a Map with Nonscalar Values

Map integer keys to nonscalar arrays, and view the value for one of the keys:

```
keySet = [5,10,15];
valueSet = {magic(5),magic(10),magic(15)};
mapObj = containers.Map(keySet,valueSet);
mapObj(5)
```

This code returns

```
ans =
 17 24 1 8 15
 23 5 7 14 16
 4 6 13 20 22
 10 12 19 21 3
 11 18 25 2 9
```

## Construct an Empty Map

Construct a map with no values, but set the KeyType and ValueType properties:

```
mapObj = containers.Map('KeyType','char','ValueType','int32')
```

This code returns

```
mapObj =
```

```
containers.Map handle
Package: containers
```

```
Properties:
 Count: 0
 KeyType: 'char'
 ValueType: 'int32'
```

```
Methods, Events, Superclasses
```

## Specify Whether Values Are Uniform

Construct a map with numeric values, and specify that the values do not have to be uniform:

```
keySet = {'a','b','c'};
valueSet = {1,2,3};
mapObj = containers.Map(keySet,valueSet,'UniformValues',false);
```

This map allows nonnumeric values, so

```
mapObj('d') = 'OK';
values(mapObj)
```

returns

```
ans =
 [1] [2] [3] 'OK'
```

## See Also

isKey | values | keys

## mat2cell

Convert array to cell array with potentially different sized cells

### Syntax

```
C = mat2cell(A,dim1Dist,...,dimNDist)
C = mat2cell(A,rowDist)
```

### Description

`C = mat2cell(A,dim1Dist,...,dimNDist)` divides array `A` into smaller arrays within cell array `C`. Vectors `dim1Dist,...,dimNDist` specify how to divide the rows, columns, and (when applicable) higher dimensions of `A`.

`C = mat2cell(A,rowDist)` divides array `A` into an `n`-by-1 cell array `C`, where `n == numel(rowDist)`.

### Input Arguments

#### **A**

Any type of array.

#### **dim1Dist,...,dimNDist**

Numeric vectors that describe how to divide each dimension of `A`. For example, this command

```
c = mat2cell(x, [10, 20, 30], [25, 25])
```

divides a 60-by-50 array into six arrays contained in a cell array.

For the  $k$ th dimension, `sum(dimkDist) == size(A, k)`.

If the  $k$ th dimension of  $A$  is zero, set the corresponding `dimkDist` to the empty array, `[]`. For example,

```
a = rand(3, 0, 4);
c = mat2cell(a, [1, 2], [], [2, 1, 1]);
```

### **rowDist**

Numeric vector that describes how to divide the rows of  $A$ . When you do not specify distributions for any other dimension, the `mat2cell` function creates an  $n$ -by-1 cell array  $C$ , where  $n == \text{numel}(\text{rowDist})$ .

## **Output Arguments**

### **c**

Cell array. The  $k$ th dimension of array  $C$  is given by `size(C, k) == numel(dimkDist)`. The  $k$ th dimension of the  $i$ th cell of  $C$  is given by `size(C{i}, k) == dimkDist(i)`.

## **Examples**

Divide the 5-by-4 matrix  $X$  into 2-by-3 and 2-by-2 matrices contained in a cell array.

```
X = reshape(1:20,5,4)'
```

```
C = mat2cell(X, [2 2], [3 2])
celldisp(C)
```

This code returns

```
X =
 1 2 3 4 5
 6 7 8 9 10
 11 12 13 14 15
 16 17 18 19 20

C =
 [2x3 double] [2x2 double]
 [2x3 double] [2x2 double]
```

```
C{1,1} =
 1 2 3
 6 7 8
```

```
C{2,1} =
 11 12 13
 16 17 18
```

```
C{1,2} =
 4 5
 9 10
```

```
C{2,2} =
 14 15
 19 20
```

Divide X (created in the previous example) into a 2-by-1 cell array.

```
C = mat2cell(X, [1 3])
celldisp(C)
```

This code returns

```
C =
 [1x5 double]
 [3x5 double]
```

```
C{1} =
 1 2 3 4 5
```

```
C{2} =
 6 7 8 9 10
 11 12 13 14 15
 16 17 18 19 20
```

cell2mat | num2cell

## mat2str

Convert matrix to string

### Syntax

```
str = mat2str(A)
str = mat2str(A,n)
str = mat2str(A, 'class')
str = mat2str(A, n, 'class')
```

### Description

`str = mat2str(A)` converts matrix `A` into a string. This string is suitable for input to the `eval` function such that `eval(str)` produces the original matrix to within 15 digits of precision.

`str = mat2str(A,n)` converts matrix `A` using `n` digits of precision.

`str = mat2str(A, 'class')` creates a string with the name of the class of `A` included. This option ensures that the result of evaluating `str` will also contain the class information.

`str = mat2str(A, n, 'class')` uses `n` digits of precision and includes the class information.

### Limitations

The `mat2str` function is intended to operate on scalar, vector, or rectangular array inputs only. An error will result if `A` is a multidimensional array.

### Examples

#### Example 1

Consider the matrix

```
x = [3.85 2.91; 7.74 8.99]
x =
 3.8500 2.9100
 7.7400 8.9900
```

The statement

```
A = mat2str(x)
```

produces

```
A =
 [3.85 2.91;7.74 8.99]
```

where A is a string of 21 characters, including the square brackets, spaces, and a semicolon.

`eval(mat2str(x))` reproduces x.

## Example 2

Create a 1-by-6 matrix of signed 16-bit integers, and then use `mat2str` to convert the matrix to a 1-by-33 character array, A. Note that output string A includes the class name, `int16`:

```
x1 = int16([-300 407 213 418 32 -125]);
```

```
A = mat2str(x1, 'class')
```

```
A =
 int16([-300 407 213 418 32 -125])
```

```
class(A)
```

```
ans =
 char
```

Evaluating the string A gives you an output x2 that is the same as the original `int16` matrix:

```
x2 = eval(A);
```

```
if isnumeric(x2) && isa(x2, 'int16') && all(x2 == x1)
 disp 'Conversion back to int16 worked'
end
```

Conversion back to int16 worked

**See Also**

num2str | int2str | str2num | sprintf | fprintf

# material

Control reflectance properties of surfaces and patches

## Syntax

```
material shiny
material dull
material metal
material([ka kd ks])
material([ka kd ks n])
material([ka kd ks n sc])
material default
```

## Description

`material` sets the lighting characteristics of `surface` and `patch` objects.

`material shiny` sets the reflectance properties so that the object has a high specular reflectance relative to the diffuse and ambient light, and the color of the specular light depends only on the color of the light source.

`material dull` sets the reflectance properties so that the object reflects more diffuse light and has no specular highlights, but the color of the reflected light depends only on the light source.

`material metal` sets the reflectance properties so that the object has a very high specular reflectance, very low ambient and diffuse reflectance, and the color of the reflected light depends on both the color of the light source and the color of the object.

`material([ka kd ks])` sets the ambient/diffuse/specular strength of the objects.

`material([ka kd ks n])` sets the ambient/diffuse/specular strength and specular exponent of the objects.

`material([ka kd ks n sc])` sets the ambient/diffuse/specular strength, specular exponent, and specular color reflectance of the objects.

`material default` sets the ambient/diffuse/specular strength, specular exponent, and specular color reflectance of the objects to their defaults.

## More About

### Tips

The `material` command sets the `AmbientStrength`, `DiffuseStrength`, `SpecularStrength`, `SpecularExponent`, and `SpecularColorReflectance` properties of all `surface` and `patch` objects in the axes. There must be visible `light` objects in the axes for lighting to be enabled. Look at the `material.m` file to see the actual values set (enter the command type `material`).

- “Lighting Overview”

### See Also

`lighting` | `patch` | `light` | `surface`

# matfile

Access and change variables directly in MAT-files, without loading into memory

## Syntax

```
m = matfile(filename)
m = matfile(filename, 'Writable', isWritable)
```

## Description

`m = matfile(filename)` creates a MAT-file object, `m`, connected to the MAT-file named `filename`. The object allows you to access and change variables directly in a MAT-file, without having to load the variables into memory.

The partial loading and saving that the `matfile` function provides requires less memory than the `load` and `save` commands, which always operate on entire variables.

`m = matfile(filename, 'Writable', isWritable)` enables or disables write access to the file.

## Examples

### Load Entire Variable

Load variable `topo` from the example file, `topography.mat`.

Open the example MAT-file, `topography.mat`.

```
filename = 'topography.mat';
m = matfile(filename);
```

Read the variable `topo` from the MAT-file.

```
topo = m.topo;
```

MATLAB loads the entire variable, `topo`, into the workspace.

### Save Entire Variable to Existing MAT-file

Generate a 20-by-20 example array, `x`, and save it to a MAT-file called `myFile.mat`.

```
x = magic(20);
save('myFile.mat', 'x');
```

Create a MAT-file object connected to the existing MAT-file named `myFile.mat`. Enable write access to the MAT-file by setting `Writable` to `true`.

```
m = matfile('myFile.mat', 'Writable', true);
```

Generate a 15-by-15 example array, `y`.

```
y = magic(15);
```

Save `y` to the MAT-file. Specify the variable in the MAT-file using dot notation similar to accessing fields of structure arrays.

```
m.y = y;
```

MATLAB adds a variable named `y` to the file.

Display all variables stored in the MAT-file, `myFile.mat`.

```
whos('-file', 'myFile.mat')
```

Name	Size	Bytes	Class	Attributes
x	20x20	3200	double	
y	15x15	1800	double	

### Load and Save Parts of Variables

Access specific elements of a MAT-file variable.

Open a new MAT-file, `myFile2.mat`.

```
m = matfile('myFile2.mat');
```

Save a 20-by-20 example array to part of a variable, `y`, in `myFile2.mat`. Specify the variable in the MAT-file using dot notation similar to accessing fields of structure arrays.

```
m.y(81:100,81:100) = magic(20);
```

MATLAB inserts the 20-by-20 array into the elements of `y` specified by the indices `(81:100,81:100)`.

Read a subset of array `y` into a new workspace variable, `z`.

```
z = m.y(85:94,85:94);
```

MATLAB reads the 10-by-10 subarray specified by the indices `(85:94,85:94)` from the MAT-file into workspace variable `z`.

### Determine Size of Variables

Determine the size of a variable, and then calculate the average of each column.

Open the example MAT-file, `stocks.mat`.

```
filename = 'stocks.mat';
m = matfile(filename);
```

Determine the size of the variable, `stocks`, in `stocks.mat`.

```
[nrows,ncols] = size(m,'stocks');
```

Compute the average of each column of the variable `stocks`.

```
avgs = zeros(1,ncols);
for i = 1:ncols
 avgs(i) = mean(m.stocks(:,i));
end
```

### Enable Write Access to MAT-file

Enable write access to the MAT-file, `myFile.mat`, by setting `Writable` to `true` when you open the MAT-file.

```
filename = 'myFile.mat';
m = matfile(filename,'Writable',true);
```

Alternatively, set `Properties.Writable` in a separate step after you open the MAT-file.

```
m.Properties.Writable = true;
```

## Input Arguments

### **filename** — Name of MAT-file

string

Name of a MAT-file, specified as a string. If the file is not in the current folder, **filename** must include a full or a relative path. If **filename** does not include an extension, then **matfile** appends **.mat**.

If the file does not exist, then **matfile** creates a Version 7.3 MAT-file on the first assignment to a variable.

**matfile** only supports efficient partial loading and saving for MAT-files in Version 7.3 format. If you index into a variable in a Version 7 (the current default) or earlier MAT-file, MATLAB warns and temporarily loads the entire contents of the variable.

Example: 'myFile.mat'

Data Types: char

### **isWritable** — Write access to MAT-file

true | false

Write access to the MAT-file, specified as either **true** or **false**.

- **true** enables saving to the MAT-file. If the file is read only, MATLAB changes the system permissions with the **fileattrib** function.
- **false** disables saving to the MAT-file. MATLAB does not change the system permissions.

The default value is **true** for new files, and **false** for existing files.

Data Types: logical

## Output Arguments

### **m** — MAT-file object

matlab.io.MatFile object

MAT-file object connected to a MAT-file.

Access variables in the MAT-file with dot notation similar to accessing fields of structure arrays:

- To load part of variable `varName` from the MAT-file corresponding to `m`, call:

```
loadedData = m.varName(indices);
```

- To save part of variable `varName` to the MAT-file corresponding to `m`, call:

```
m.varName(indices) = dataToSave;
```

When accessing variables, specify indices for all dimensions. Indices can be a single value, an equally spaced range of increasing values, or a colon ( `:` ); for example:

```
m.varName(100:500,200:600)
```

```
m.varName(:,501:1000)
```

```
m.varName(1:2:1000,80)
```

## Limitations

- `matfile` does not support linear indexing. You must specify indices for all dimensions.
- `matfile` does not support indexing into:
  - Variables of tables
  - Cells of cell arrays
  - Fields of structure arrays
  - User-defined classes
  - Sparse arrays
- You cannot assign complex values to an indexed portion of a real array.
- You cannot evaluate function handles using the `m` output. For example, if your MAT-file contains function handle `myfunc`, the syntax `m.myfunc()` attempts to index into the function handle, and does not invoke the function.
- Efficient partial loading and saving requires Version 7.3 MAT-files. To create a Version 7.3 MAT-file, call the `save` function with the `'-v7.3'` option. For example, to convert an existing MAT-file named `durer.mat` to Version 7.3, call:

```
load('durer.mat');
```

```
save('mycopy_durer.mat', '-v7.3');
```

## More About

### Tips

- Using the `end` keyword as part of an index causes MATLAB to load the entire variable into memory. For very large variables, this load operation results in **Out of Memory** errors. Rather than using `end`, determine the extent of a variable, `myVar`, with the `size` method, such as:

```
sizeMyVar = size(m, 'myVar')
```

- “Load Parts of Variables from MAT-Files”
- “Save Parts of Variables to MAT-Files”
- “MAT-File Versions”

### See Also

`load` | `save` | `size` | `whos`

# matlab.codetools.requiredFilesAndProducts

List dependencies of MATLAB program files

## Syntax

```
fList = matlab.codetools.requiredFilesAndProducts(files)
[fList, pList] = matlab.codetools.requiredFilesAndProducts(files)
[fList, pList] =
matlab.codetools.requiredFilesAndProducts(___, 'toponly')
```

## Description

`fList = matlab.codetools.requiredFilesAndProducts(files)` returns a list of the MATLAB program files required to run the program files specified by `files`.

`[fList, pList] = matlab.codetools.requiredFilesAndProducts(files)` also returns a list of the MathWorks products required to run the program files specified by `files`.

`[fList, pList] = matlab.codetools.requiredFilesAndProducts( ___, 'toponly')` indicates that for a file or product to be included in the output, it must be used directly by at least one file specified in `files`. The `'toponly'` input string is case insensitive.

## Examples

### Identify Required Files and Products for MATLAB Toolbox Function

Determine the required files and products for the `edge` function in the Image Processing Toolbox.

```
[fList,pList] = matlab.codetools.requiredFilesAndProducts('edge.m')
fList =
```

```
 {}

pList =
1x2 struct array with fields:
 Name
 Version
 ProductNumber
```

There are no required MATLAB files, but there are two required products.

List the required products.

```
{pList.Name} '
ans =
 'MATLAB'
 'Image Processing Toolbox'
```

## Identify Required Files and Products for Your MATLAB Program Files

In your current working folder, create a function in the file `getRandomNumber.m`.

```
function a = getRandomNumber
 rng shuffle
 a = rand;
end
```

Now, at the command line, determine the required files and products for `getRandomNumber.m`.

```
[fList,pList] = matlab.codetools.requiredFilesAndProducts('getRandomNumber.m')
fList =
 'C:\work\getRandomNumber.m'

pList =
 Name: 'MATLAB'
 Version: '8.3'
```

```
ProductNumber: 1
```

The only file required to run the `getRandomNumber` function is the function file itself. The only required MathWorks product is MATLAB.

In your current working folder, create a function in the file `displayNumber.m`.

```
function displayNumber
 a = getRandomNumber;
 disp(['Your number is ' num2str(a)])
end
```

Now, at the command line, determine the required files and products for `displayNumber.m`.

```
[fList,pList] = matlab.codetools.requiredFilesAndProducts('displayNumber.m')
```

```
fList =
```

```
 'C:\work\displayNumber.m' 'C:\work\getRandomNumber.m'
```

```
pList =
```

```
 Name: 'MATLAB'
 Version: '8.3'
 ProductNumber: 1
```

In addition to the function file itself, the `displayNumber` function requires the `getRandomNumber.m` file. The only required MathWorks product is MATLAB.

### Identify Top-Level Dependencies Only

In your current working folder, create a handle class in the file `ExampleHandle.m`.

```
classdef ExampleHandle < handle
 % class content
end
```

In your current working folder, create a class in the file `AnotherExampleHandle.m` that inherits from `ExampleHandle`.

```
classdef AnotherExampleHandle < ExampleHandle
 % class content
```

end

In your current working folder, create a function in the file `getHandles.m` that instantiates `AnotherExampleHandle` objects.

```
function [h1,h2] = getHandles()
 h1 = AnotherExampleHandle;
 h2 = AnotherExampleHandle;
end
```

Now, at the command line, determine the required files for `getHandles.m`.

```
[fList,~] = matlab.codetools.requiredFilesAndProducts('getHandles.m');
fList'
```

```
ans =
```

```
 'C:\work\AnotherExampleHandle.m'
 'C:\work\ExampleHandle.m'
 'C:\work\getHandles.m'
```

Determine the required files that are directly required for `getHandles.m`.

```
[fList,~] = matlab.codetools.requiredFilesAndProducts('getHandles.m','toponly')
```

```
fList =
```

```
 'C:\work\AnotherExampleHandle.m' 'C:\work\getHandles.m'
```

Although `AnotherExampleHandle.m` requires `ExampleHandle.m`, that file is not a direct requirement for `getHandles.m`.

## Input Arguments

### **files** — List of files for analysis

string or cell array of strings

List of files for analysis, specified as a string or cell array of strings. Each string is the name of a single MATLAB program file. For example, `files` is a list of MATLAB program files that you intend to provide to other users. The `matlab.codetools.requiredFilesAndProducts` function provides you with requirements information to pass along with your files.

To ensure an accurate dependency report, `files` and dependencies must be on the MATLAB path. `matlab.codetools.requiredFilesAndProducts` does not return information about dependent files not on the path.

Example: `'myFile.m'` or `'C:\Program Files\MATLAB\R2014a\my_work\myFile.m'`

Example: `{'myFile.m', 'myOtherFile.m'}`

Example: `cellstr(ls('*.*'))`

## Output Arguments

### **fList** — List of user-authored MATLAB program files

cell array of strings

List of user-authored MATLAB program files required by `files`, returned as a cell array of strings. Each string indicates the full path of the required file. `fList` does not include built-in MATLAB files, since these files are installed with the products listed in `pList`.

### **pList** — List of MathWorks products

structure or array of structures

List of MathWorks products required by `files`, returned as a structure or array of structures. Each required product is described by name (`Name` field), version (`Version` field) and product number (`ProductNumber` field).

The `matlab.codetools.requiredFilesAndProducts` function is intended to provide you with information to pass on to consumers of your MATLAB program files. The version numbers indicate the version of the products you have installed when you execute the function. `Version` is not an indicator of backward compatibility.

## More About

- “Identify Program Dependencies”

## matlab.io.MatFile class

**Package:** matlab.io

Load and save parts of variables in MAT-files

### Description

The `matfile` function constructs a `matlab.io.MatFile` object that corresponds to a MAT-File, such as

```
matObj = matfile('myFile.mat')
```

Access variables in the MAT-file as properties of `matObj`, with dot notation similar to accessing fields of structs. The syntax for loading and saving part of variable `varName` in the MAT-file corresponding to `matObj` is:

```
loadedData = matObj.varName(indices); % Load into workspace
matObj.varName(indices) = dataToSave; % Save to file
```

When indexing, specify indices for all dimensions. Indices can be a single value, an equally spaced range of increasing values, or a colon (:), such as

```
matObj.varName(100:500, 200:600)
matObj.varName(:, 501:1000)
matObj.varName(1:2:1000, 80)
```

### Limitations

- Using the `end` keyword as part of an index causes MATLAB to load the entire variable into memory. For very large variables, this load operation results in **Out of Memory** errors. Rather than using `end`, determine the extent of a variable with the `size` method, such as:

```
sizeMyVar = size(matObj,'myVar')
```

- `matfile` does not support linear indexing. You must specify indices for all dimensions.
- `matfile` does not support indexing into:
  - Cells of cell arrays

- Fields of structs
- User-defined classes
- Sparse arrays
- You cannot assign complex values to an indexed portion of a real array.
- You cannot evaluate function handles using a `MatFile` object. For example, if your MAT-file contains function handle `myfunc`, the syntax `matObj.myfunc()` attempts to index into the function handle, and does not invoke the function.

## Construction

`matObj = matfile(filename)` constructs a `matlab.io.MatFile` object that can load or save parts of variables in MAT-file `filename`. MATLAB does not load any data from the file into memory when creating the object.

`matObj = matfile(filename, 'Writable', isWritable)` enables or disables write access to the file for object `matObj`. Possible values for `isWritable` are logical `true` (1) or `false` (0).

## Input Arguments

### **filename**

String enclosed in single quotation marks that specifies the name of a MAT-file.

`filename` can include a full or partial path, otherwise `matfile` searches for the file along the MATLAB search path. If `filename` does not include an extension, `matfile` appends `.mat`.

If the file does not exist, `matfile` creates a Version 7.3 MAT-file on the first assignment to a variable.

`matfile` only supports partial loading and saving for MAT-files in Version 7.3 format (described in “MAT-File Versions”). If you index into a variable in a Version 7 (the current default) or earlier MAT-file, MATLAB warns and temporarily loads the entire contents of the variable.

### **'Writable'**

Parameter to use with the `isWritable` argument.

### **isWritable**

Logical value that specifies whether to allow saving to the file. Possible values:

- `true` (1) Enable saving. If the file is read only, change the system permissions with `fileattrib`.
- `false` (0) Disable saving with `matfile`. MATLAB does not change the system permissions.

**Default:** `true` for new files, `false` for existing files

## **Properties**

### **Properties.Source**

String that contains the fully qualified path to the file. Read only.

### **Properties.Writable**

Logical value that specifies whether to allow saving to the file. Possible values:

- `true` (1) Enable saving. If the file is read only, change the system permissions with `fileattrib`.
- `false` (0) Disable saving with `matfile`. MATLAB does not change the system permissions.

**Default:** `true` for new files, `false` for existing files

## **Methods**

- `size` Array dimensions
- `who` Names of variables in MAT-file
- `whos` Names, sizes, and types of variables in MAT-file

You cannot access help for these methods using the `help` command. Find help on the methods from the command line using the `doc` command, such as `doc matlab.io.MatFile/size`.

## Copy Semantics

Handle. To learn how handle classes affect copy operations, see “Copying Objects” in the MATLAB documentation.

## Examples

Create `myFile.mat` in a temporary folder and save data to part of variable `savedVar`:

```
filename = fullfile(tempdir, 'myFile.mat');
matObj = matfile(filename);
matObj.savedVar(81:100,81:100) = magic(20);
```

Load part of the data into variable `loadVar`:

```
loadVar = matObj.savedVar(85:94,85:94);
```

Load or save an entire variable by omitting the indices. For example, load variable `topo` from `topography.mat`:

```
filename = 'topography.mat';
matObj = matfile(filename);
topo = matObj.topo;
```

Determine the dimensions of a variable, and process one part of the variable at a time. In this case, calculate and store the average of each column of variable `stocks` in the example file `stocks.mat`:

```
filename = 'stocks.mat';
matObj = matfile(filename);
[nrows, ncols] = size(matObj, 'stocks');

avgs = zeros(1,ncols);
for idx = 1:ncols
 avgs(idx) = mean(matObj.stocks(:,idx));
end
```

By default, `matfile` only supports loading data from existing files. To enable saving, set `Writable` to `true` either during construction of the object,

```
filename = 'myFile.mat';
matObj = matfile(filename, 'Writable', true);
```

or in a separate step, by setting `Properties.Writable`:

```
filename = 'myFile.mat';
matObj = matfile(filename);
matObj.Properties.Writable = true;
```

## See Also

# matlab.io.fits.closeFile

Close FITS file

## Syntax

```
closeFile(fptr)
```

## Description

`closeFile(fptr)` closes an open FITS file.

This function corresponds to the `fits_close_file` (`ffclos`) function in the CFITSIO library C API.

## Examples

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits','READONLY');
fits.closeFile(fptr);
```

## See Also

[createFile](#) | [openFile](#)

## matlab.io.fits.createFile

Create FITS file

### Syntax

```
fptr = createFile(filename)
```

### Description

`fptr = createFile(filename)` creates a FITS file. An error will be returned if the specified file already exists, unless the filename is prefixed with an exclamation point (!). In that case CFITSIO will overwrite (delete) any existing file with the same name.

This function corresponds to the `fits_create_file` (`ffinit`) function in the CFITSIO library C API.

### Examples

Create a new FITS file, overwriting any existing file by the same name.

```
import matlab.io.*
fptr = fits.createFile('myfile.fits');
fits.createImg(fptr, 'uint8', [256 512]);
fits.closeFile(fptr);
fitsdisp('myfile.fits');
```

### See Also

[closeFile](#) | [createImg](#) | [createTbl](#) | [openFile](#)

# matlab.io.fits.deleteFile

Delete FITS file

## Syntax

```
deleteFile(fptr)
```

## Description

`deleteFile(fptr)` closes and deletes an open FITS file. This can be useful if a FITS file cannot be properly closed.

This function corresponds to the `fits_delete_file` (`ffdel`) function in the CFITSIO library C API.

## Examples

```
import matlab.io.*
srcFile = fullfile(matlabroot, 'toolbox', 'matlab', 'demos', 'tst0012.fits');
copyfile(srcFile, 'myfile.fits');
fileattrib('myfile.fits', '+w');
fptr = fits.openFile('myfile.fits', 'readwrite');
fits.deleteFile(fptr);
fptrs = fits.getOpenFiles()
```

## See Also

`closeFile` | `createFile`

## matlab.io.fits.fileName

Name of FITS file

### Syntax

```
name = fileName(fpPtr)
```

### Description

`name = fileName(fpPtr)` returns the name of the FITS file associated with the file handle.

This function corresponds to the `fits_file_name` (`ffflnm`) function in the CFITSIO library C API.

### Examples

```
import matlab.io.*
fpPtr = fits.openFile('tst0012.fits','READONLY');
name = fits.fileName(fpPtr);
fits.closeFile(fpPtr);
```

### See Also

[createFile](#) | [openFile](#)

# matlab.io.fits.fileMode

I/O mode of FITS file

## Syntax

```
mode = fileMode(fptr)
```

## Description

`mode = fileMode(fptr)` returns the I/O mode of the opened FITS file. Possible values returned for `mode` are 'READONLY' or 'READWRITE'.

This function corresponds to the `fits_file_mode` (`ffflmd`) function in the CFITSIO library C API.

## Examples

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
mode = fits.fileMode(fptr);
fits.closeFile(fptr);
```

## See Also

[createFile](#) | [openFile](#)

## matlab.io.fits.openFile

Open FITS file

### Syntax

```
fptr = openFile(filename)
fptr = openFile(filename,mode)
```

### Description

`fptr = openFile(filename)` opens an existing FITS file in read-only mode and returns a file pointer, `fptr`, which references the primary array (first header data unit, or "HDU").

`fptr = openFile(filename,mode)` opens an existing FITS file according to the `mode`, which describes the type of access. `mode` may be either 'READONLY' or 'READWRITE'.

This function corresponds to the `fits_open_file` (`ffopen`) function in the CFITSIO library C API.

### Examples

Open a file in read-only mode and read image data from the primary array.

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
imagedata = fits.readImg(fptr);
fits.closeFile(fptr);
```

Open a file in read-write mode and add a comment to the primary array.

```
import matlab.io.*
srcFile = fullfile(matlabroot,'toolbox','matlab','demos','tst0012.fits');
copyfile(srcFile,'myfile.fits');
fileattrib('myfile.fits','+w');
fptr = fits.openFile('myfile.fits','readwrite');
fits.writeComment(fptr,'This is just a comment.');
```

```
fits.closeFile(fptr);
```

**See Also**

[closeFile](#) | [createFile](#)

## matlab.io.fits.createImg

Create FITS image

### Syntax

```
createImg(fptr,bitpix,naxes)
```

### Description

`createImg(fptr,bitpix,naxes)` creates a new primary image or image extension with a specified datatype `bitpix` and size `naxes`. If the FITS file is currently empty then a primary array is created, otherwise a new image extension is appended to the file.

The first two elements of `naxes` correspond to the NAXIS2 and NAXIS1 keywords, while any additional elements correspond to the NAXIS3, NAXIS4 ... NAXISn keywords.

The datatype `bitpix` may be given as either a CFITSIO name or as the corresponding MATLAB datatype.

'byte_img'	'uint8'
'short_img'	'int16'
'long_img'	'int32'
'longlong_img'	'int64'
'float_img'	'single'
'double_img'	'double'

This function corresponds to the `fits_create_img11` (`ffcrim11`) function in the CFITSIO library C API.

### Examples

Create two images in a new FITS file. There are 100 rows (NAXIS2 keyword) and 200 columns (NAXIS1 keyword) in the first image, and 256 rows (NAXIS2 keyword), 512 columns (NAXIS1 keyword), and 3 planes (NAXIS3 keyword) in the second image.

```
import matlab.io.*
fptr = fits.createFile('myfile.fits');
fits.createImg(fptr, 'int16', [100 200]);
fits.createImg(fptr, 'byte_img', [256 512 3]);
fits.closeFile(fptr);
fitsdisp('myfile.fits');
```

## See Also

[createTbl](#) | [insertImg](#) | [readImg](#) | [setCompressionType](#) | [writeImg](#)

## matlab.io.fits.getImgSize

Size of image

### Syntax

```
imagesize = getImgSize(fpPtr)
```

### Description

`imagesize = getImgSize(fpPtr)` returns the number of rows and columns of an image. This function corresponds to the `fits_get_img_size` (`ffgisz`) function in the CFITSIO library C API.

### Examples

```
import matlab.io.*;
fpPtr = fits.openFile('tst0012.fits');
hdus = [1 3 4];
for j = hdus;
 htype = fits.movAbsHDU(fpPtr,j);
 sz = fits.getImgSize(fpPtr);
 fprintf('HDU %d: "%s", [' , j, htype);
 for k = 1:numel(sz)
 fprintf(' %d ', sz(k));
 end
 fprintf(']\n');
end
fits.closeFile(fpPtr);
```

### See Also

[createImg](#) | [getImgType](#)

# matlab.io.fits.getImgType

Data type of image

## Syntax

```
datatype = getImgType(fptr)
```

## Description

`datatype = getImgType(fptr)` gets the data type of an image. `datatype` can be one of the following strings:

```
'BYTE_IMG'
'SHORT_IMG'
'LONG_IMG'
'LONGLONG_IMG'
'FLOAT_IMG'
'DOUBLE_IMG'
```

This function corresponds to the `fits_get_img_type` (`ffgidt`) function in the CFITSIO library C API.

## Examples

```
fptr = fits.openFile('tst0012.fits');
hdus = [1 3 4];
for j = hdus;
 htype = fits.movAbsHDU(fptr,j);
 dtype = fits.getImgType(fptr);
 fprintf('HDU %d: "%s", "%s"\n', j, htype, dtype);
end
fits.closeFile(fptr);
```

**See Also**  
getImgSize

# matlab.io.fits.insertImg

Insert FITS image after current image

## Syntax

```
insertImage(fpPtr,bitpix,naxes)
```

## Description

`insertImage(fpPtr,bitpix,naxes)` inserts a new image extension immediately following the current HDU. If the file has just been created, a new primary array is inserted at the beginning of the file. Any following extensions in the file will be shifted down to make room for the new extension. If the current HDU is the last HDU in the file, then the new image extension will be appended to the end of the file.

This function corresponds to the `fits_insert_img11` (`ffiimg11`) function in the CFITSIO library C API.

## Examples

Create a 150x300 image between the 1st and 2nd images in a FITS file.

```
import matlab.io.*
fpPtr = fits.createFile('myfile.fits');
fits.createImg(fpPtr,'byte_img',[100 200]);
fits.createImg(fpPtr,'byte_img',[200 400]);
fits.movAbsHDU(fpPtr,1);
fits.insertImg(fpPtr,'byte_img',[150 300]);
fits.closeFile(fpPtr);
fitsdisp('myfile.fits','mode','min');
```

## See Also

`createImg`

# matlab.io.fits.readImg

Read image data

## Syntax

```
imgdata = readImg(fptr)
imgdata = readImg(fptr,fpixel,lpixel)
imgdata = readImg(fptr,fpixel,lpixel,inc)
```

## Description

`imgdata = readImg(fptr)` reads the entire current image. The number of rows in `imgdata` will correspond to the value of the NAXIS2 keyword, while the number of columns will correspond to the value of the NAXIS1 keyword. Any further dimensions of `imgdata` will correspond to NAXIS3, NAXIS4, and so on.

`imgdata = readImg(fptr,fpixel,lpixel)` reads the subimage defined by pixel coordinates `fpixel` and `lpixel`. The `fpixel` argument is the coordinate of the first pixel and `lpixel` is the coordinate of the last pixel. `fpixel` and `lpixel` are one-based.

`imgdata = readImg(fptr,fpixel,lpixel,inc)` reads the subimage defined by `fpixel`, `lpixel`, and `inc`. The `inc` argument denotes the inter- element spacing along each extent.

This function corresponds to the `fits_read_subset (ffgsv)` function in the CFITSIO library C API.

## Examples

Read an entire image.

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
data = fits.readImg(fptr);
fits.closeFile(fptr);
```

Read a 70x80 image subset.

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
img = fits.readImg(fptr,[11 11],[80 90]);
fits.closeFile(fptr);
```

## See Also

[createImg](#) | [writeImg](#)

## matlab.io.fits.setBscale

Reset image scaling

### Syntax

```
setBscale(fptr,BSCALE,BZERO)
```

### Description

`setBscale(fptr,BSCALE,BZERO)` resets the scaling factors in the primary array or image extension according to the equation

$$\text{output} = (\text{FITS array}) * \text{BSCALE} + \text{BZERO}$$

The inverse formula is used when writing data values to the FITS file.

This only affects the automatic scaling performed when the data elements are read. It does not change the BSCALE and BZERO keyword values.

### Examples

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
fits.setBscale(fptr,2.0,0.5);
data = fits.readImg(fptr);
fits.closeFile(fptr);
```

### See Also

`readImg`

# matlab.io.fits.writelmng

Write to FITS image

## Syntax

```
writeImg(fptr,data)
writeImg(fptr,data,fpixel)
```

## Description

`writeImg(fptr,data)` writes an entire image to the FITS data array. The number of rows and columns in `data` must equal the values of the NAXIS2 and NAXIS1 keywords, respectively. Any further extents must correspond to the NAXIS3, NAXIS4 ... NAXISn keywords respectively.

`writeImg(fptr,data,fpixel)` writes a subset of an image to the FITS data array. `fpixel` gives the coordinate of the first pixel in the image region.

This function corresponds to the `fits_write_subset` (`ffpss`) function in the CFITSIO library C API.

## Examples

```
import matlab.io.*
fptr = fits.createFile('myfile.fits');
fits.createImg(fptr,'long_img',[256 512]);
data = reshape(1:256*512,[256 512]);
data = int32(data);
fits.writeImg(fptr,data);
fits.closeFile(fptr);
```

Create an 80x40 uint8 image and set all but the outermost pixels to 1.

```
import matlab.io.*
fptr = fits.createFile('myfile.fits');
fits.createImg(fptr,'uint8',[80 40]);
```

```
data = ones(78,38);
fits.writeImg(fptr,data,[1 1]);
fits.closeFile(fptr);
```

## **See Also**

`createImg` | `readImg`

# matlab.io.fits.deleteKey

Delete key by name

## Syntax

```
deleteKey(fptr, keyname)
```

## Description

`deleteKey(fptr, keyname)` deletes a keyword by name.

This function corresponds to the `fits_delete_key` (`ffdrec`) function in the CFITSIO library C API.

## Examples

```
import matlab.io.*
srcFile = fullfile(matlabroot, 'toolbox', 'matlab', 'demos', 'tst0012.fits');
copyfile(srcFile, 'myfile.fits');
fileattrib('myfile.fits', '+w');
fprintf('Before key deletion...\n');
fitsdisp('myfile.fits', 'index', 1);
fptr = fits.openFile('myfile.fits', 'readwrite');
fits.deleteKey(fptr, 'DATE');
fits.closeFile(fptr);
fprintf('\n\nAfter key deletion...\n');
fitsdisp('myfile.fits', 'index', 1);
```

## See Also

`deleteRecord` | `writeKey`

## matlab.io.fits.deleteRecord

Delete key by record number

### Syntax

```
deleteRecord(fpPtr, keynum)
```

### Description

`deleteRecord(fpPtr, keynum)` deletes a keyword by record number.

This function corresponds to the `fits_delete_record` (`ffdrec`) function in the CFITSIO library C API.

### Examples

Delete the 18th keyword ("ORIGIN") in a primary array.

```
import matlab.io.*
srcFile = fullfile(matlabroot, 'toolbox', 'matlab', 'demos', 'tst0012.fits');
copyfile(srcFile, 'myfile.fits');
fileattrib('myfile.fits', '+w');
fpPtr = fits.openFile('myfile.fits', 'readwrite');
card = fits.readRecord(fpPtr, 18);
fits.deleteRecord(fpPtr, 18);
fits.closeFile(fpPtr);
```

### See Also

`deleteKey` | `readRecord`

# matlab.io.fits.getHdrSpace

Number of keywords in header

## Syntax

```
[nkeys,morekeys] = fits.getHdrSpace(fptr)
```

## Description

`[nkeys,morekeys] = fits.getHdrSpace(fptr)` returns the number of existing keywords (not counting the END keyword) and the amount of space currently available for more keywords. It returns `morekeys = -1` if the header has not yet been closed. Note that the CFITSIO library will dynamically add space if required when writing new keywords to a header so in practice there is no limit to the number of keywords that can be added to a header.

This function corresponds to the `fits_get_hdrspace` (`ffghsp`) function in the CFITSIO library C API.

## Examples

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
[nkeys,morekeys] = fits.getHdrSpace(fptr);
fits.closeFile(fptr);
```

## matlab.io.fits.readCard

Header record of keyword

### Syntax

```
card = readCard(fpPtr, keyName)
```

### Description

`card = readCard(fpPtr, keyName)` returns the entire 80-character header record of the keyword, with any trailing blank characters stripped off.

This function corresponds to the `fits_read_card` (`ffgcrd`) function in the CFITSIO library C API.

### Examples

```
import matlab.io.*
fpPtr = fits.openFile('tst0012.fits');
n = fits.getNumHDUs(fpPtr);
for j = 1:n
 fits.movAbsHdu(fpPtr, j);
 card = fits.readCard(fpPtr, 'NAXIS');
 fprintf('Hdu %d: '%s'\n', j, card);
end
fits.closeFile(fpPtr);
```

# matlab.io.fits.readKey

Keyword

## Syntax

```
[value,comment] = readKey(fptr,keyname)
```

## Description

`[value,comment] = readKey(fptr,keyname)` returns the specified key and comment. `value` is returned as a string.

This function corresponds to the `fits_read_key_str` (`ffgkys`) function in the CFITSIO library C API.

## Examples

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
n = fits.getNumHDUs(fptr);
for j = 1:n
 fits.movAbsHDU(fptr,j);
 [key,comment] = fits.readKey(fptr,'NAXIS');
 fprintf('HDU %d: NAXIS %s, "%s"\n', j, key, comment);
end
fits.closeFile(fptr);
```

```

### Description

`[value,comment] = readKeyLongLong(fptr,keyname)` returns the specified key and comment. `value` is returned as an `int64` scalar value.

This function corresponds to the `fits_read_key_lnglng` (`ffgkyjj`) function in the CFITSIO library C API.

### Examples

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
n = fits.getNumHDUs(fptr);
for j = 1:n
 fits.movAbsHDU(fptr,j);
 [key,comment] = fits.readKeyLongLong(fptr,'NAXIS');
 fprintf('HDU %d: NAXIS %d, "%s"\n', j, key, comment);
end
fits.closeFile(fptr);
```

[readKey](#) | [readKeyCmplx](#) | [readKeyDb1](#)

# matlab.io.fits.readKeyLongStr

Long string value

## Syntax

```
[value,comment] = readKeyLongStr(fptr,keyname)
```

## Description

`[value,comment] = readKeyLongStr(fptr,keyname)` returns the specified long string value and comment.

This function corresponds to the `fits_read_key_longstr` (`ffgkls`) function in the CFITSIO library C API.

## Examples

```
import matlab.io.*
idata = repmat(char(97:106),1,10);
fptr = fits.createFile('myfile.fits');
fits.createImg(fptr,'byte_img',[100 200]);
fits.writeKey(fptr,'mykey',idata);
odata1 = fits.readKey(fptr,'mykey');
odata2 = fits.readKeyLongStr(fptr,'mykey');
fits.closeFile(fptr);
```

## See Also

`readKey`

## matlab.io.fits.readKeyUnit

Physical units string from keyword

### Syntax

```
units = readKeyUnit(fptr,keywordname)
```

### Description

`units = readKeyUnit(fptr,keywordname)` returns the physical units string from an existing keyword. If no units are defined, `units` is returned as an empty string.

This function corresponds to the `fits_read_key_unit` ( `ffgunt`) function in the CFITSIO library C API.

### Examples

```
import matlab.io.*
fptr = fits.createFile('myfile.fits');
fits.createImg(fptr,'long_img',[10 20]);
fits.writeKey(fptr,'VELOCITY',12.3,'orbital speed');
fits.writeKeyUnit(fptr,'VELOCITY','km/s');
units = fits.readKeyUnit(fptr,'VELOCITY');
fits.closeFile(fptr);
```

### See Also

[readKey](#) | [writeKeyUnit](#)

# matlab.io.fits.readRecord

Header record specified by number

## Syntax

```
card = readRecord(fptr, keynum)
```

## Description

`card = readRecord(fptr, keynum)` returns the entire 80-character header record identified by the numeric `keynum`. Trailing blanks are truncated.

This function corresponds to the `fits_read_record` (`ffgrec`) function in the CFITSIO library C API.

## Examples

Read the second record in each HDU.

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
n = fits.getHdrSpace(fptr);
for j = 1:n
 card = fits.readRecord(fptr, j);
 fprintf('record %d: "%s"\n', j, card);
end
fits.closeFile(fptr);
```

## See Also

`deleteRecord` | `readCard` | `readKey`

## matlab.io.fits.writeComment

Write or append COMMENT keyword to CHU

### Syntax

```
writeComment(fptr,comment)
```

### Description

`writeComment(fptr,comment)` writes (appends) a COMMENT keyword to the CHU. The comment string will be continued over multiple keywords if it is longer than 70 characters.

This function corresponds to the `fits_write_comment` (`ffpcom`) function in the CFITSIO library C API.

### Examples

```
import matlab.io.*
fptr = fits.createFile('myfile.fits');
fits.createImg(fptr,'byte_img',[100 200]);
fits.writeComment(fptr,'this is a comment');
fits.writeComment(fptr,'this is another comment');
fits.closeFile(fptr);
fitsdisp('myfile.fits','mode','full');
```

### See Also

[writeDate](#) | [writeHistory](#)

# matlab.io.fits.writeDate

Write DATE keyword to CHU

## Syntax

```
writeDate(FPTR)
```

## Description

`writeDate(FPTR)` writes the DATE keyword to the CHU.

This function corresponds to the `fits_write_date` (`ffpdat`) function in the CFITSIO library C API.

## Examples

```
import matlab.io.*
fptr = fits.createFile('myfile.fits');
fits.createImg(fptr, 'byte_img', [100 200]);
fits.writeDate(fptr);
fits.closeFile(fptr);
fitsdisp('myfile.fits', 'mode', 'full');
```

## See Also

[writeComment](#) | [writeHistory](#)

## matlab.io.fits.writeKey

Update or add new keyword into current HDU

### Syntax

```
writeKey(fpPtr, keyName, value, comment)
writeKey(fpPtr, keyName, value, comment, decimals)
```

### Description

`writeKey(fpPtr, keyName, value, comment)` adds a new record in the current HDU, or updates it if it already exists. `comment` is optional.

`writeKey(fpPtr, keyName, value, comment, decimals)` adds a new floating point keyword in the current HDU, or updates it if it already exists. You must use this syntax to write a keyword with imaginary components. `decimals` is ignored otherwise.

If a character `value` exceeds 68 characters in length, the LONGWARN convention is automatically employed.

This function corresponds to the `fits_write_key` (`ffpky`) and `fits_update_key` (`ffuky`) family of functions in the CFITSIO library C API.

### Examples

```
import matlab.io.*
fpPtr = fits.createFile('myfile.fits');
fits.createImg(fpPtr, 'byte_img', [100 200]);
fits.writeKey(fpPtr, 'mykey1', 'a char value', 'with a comment');
fits.writeKey(fpPtr, 'mykey2', int32(1));
fits.writeKey(fpPtr, 'mykey3', 5+7*j, 'with another comment');
fits.writeKey(fpPtr, 'mykey4', 4/3, 'with yet another comment', 2);
fits.closeFile(fpPtr);
fitsdisp('myfile.fits', 'mode', 'full');
```

### See Also

[deleteKey](#) | [readKey](#) | [readRecord](#)

# matlab.io.fits.writeKeyUnit

Write physical units string

## Syntax

```
writeKeyUnit(fptr, keyname, unit)
```

## Description

`writeKeyUnit(fptr, keyname, unit)` writes a physical units string into an existing keyword.

This function corresponds to the `fits_write_key_unit` (`ffpunit`) function in the CFITSIO library C API.

## Examples

```
import matlab.io.*
fptr = fits.createFile('myFitsFile.fits');
fits.createImg(fptr, 'long_img', [10 20]);
fits.writeKey(fptr, 'VELOCITY', 12.3, 'orbital speed');
fits.writeKeyUnit(fptr, 'VELOCITY', 'km/s');
fits.closeFile(fptr);
```

## See Also

`readKeyUnit`

## matlab.io.fits.writeHistory

Write or append HISTORY keyword to CHU

### Syntax

```
writeHistory(fptr,history)
```

### Description

`writeHistory(fptr,history)` writes (appends) a HISTORY keyword to the CHU. The history string is continued over multiple keywords if it is longer than 70 characters.

This function corresponds to the `fits_write_history` (`ffphis`) function in the CFITSIO library C API.

### Examples

```
import matlab.io.*
fptr = fits.createFile('myfile.fits');
fits.createImg(fptr, 'byte_img', [100 200]);
fits.writeHistory(fptr, 'this is a history keyword');
fits.closeFile(fptr);
fitsdisp('myfile.fits', 'mode', 'full');
```

### See Also

`writeComment` | `writeDate`

# matlab.io.fits.copyHDU

Copy current HDU from one file to another

## Syntax

```
copyHDU(infptr,outfptr)
```

## Description

`copyHDU(infptr,outfptr)` copies the current HDU from the FITS file associated with `infptr` and appends it to the end of the FITS file associated with `outfptr`.

This function corresponds to the `fits_copy_hdu` (`ffcopy`) function in the CFITSIO library C API.

## Examples

Copy the first, third, and fifth HDUs from one file to another.

```
import matlab.io.*
infptr = fits.openFile('tst0012.fits');
outfptr = fits.createFile('myfile.fits');
fits.copyHDU(infptr,outfptr);
fits.movAbsHDU(infptr,3);
fits.copyHDU(infptr,outfptr);
fits.movAbsHDU(infptr,5);
fits.copyHDU(infptr,outfptr);
fits.closeFile(infptr);
fits.closeFile(outfptr);
fitsdisp('tst0012.fits','mode','min','index',[1 3 5]);
fitsdisp('myfile.fits','mode','min');
```

## See Also

`deleteHDU`

## matlab.io.fits.deleteHDU

Delete current HDU in FITS file

### Syntax

```
HDU_TYPE = deleteHDU(fpnr)
```

### Description

`HDU_TYPE = deleteHDU(fpnr)` deletes the current HDU in the FITS file. Any following HDUs will be shifted forward in the file, filling the gap created by the deleted HDU. In the case of deleting the primary array (the first HDU in the file) then the current primary array will be replaced by a null primary array containing the minimum set of required keywords and no data. If there are more HDUs in the file following the HDU being deleted, then the current HDU will be redefined to point to the following HDU. If there are no following HDUs then the current HDU will be redefined to point to the previous HDU. `HDU_TYPE` returns the type of the new current HDU.

This function corresponds to the `fits_delete_hdu` (`ffdhdu`) function in the CFITSIO library C API.

### Examples

Delete the second HDU in a FITS file.

```
import matlab.io.*
srcFile = fullfile(matlabroot, 'toolbox', 'matlab', 'demos', 'tst0012.fits');
copyfile(srcFile, 'myfile.fits');
fileattrib('myfile.fits', '+w');
fitsdisp('myfile.fits', 'mode', 'min');
fpnr = fits.openFile('myfile.fits', 'readwrite');
fits.movAbsHDU(fpnr, 2);
new_current_hdu = fits.deleteHDU(fpnr);
fits.closeFile(fpnr);
fitsdisp('myfile.fits', 'mode', 'min');
```

## See Also

copyHDU

## matlab.io.fits.getHDUnum

Number of current HDU in FITS file

### Syntax

```
N = getHDUnum(fptr)
```

### Description

`N = getHDUnum(fptr)` returns the number of the current HDU in the FITS file. The primary array has HDU number 1.

This function corresponds to the `fits_get_hdu_num` (`ffghdn`) function in the CFITSIO library C API.

### Examples

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
n = fits.getHDUnum(fptr);
fits.closeFile(fptr);
```

### See Also

`getHDUtype` | `getNumHDUs`

# matlab.io.fits.getHDUtype

Type of current HDU

## Syntax

```
htype = getHDUtype(fptr)
```

## Description

`htype = getHDUtype(fptr)` returns the type of the current HDU in the FITS file. The possible values for `htype` are:

```
'IMAGE_HDU'
'ASCII_TBL'
'BINARY_TBL'
```

This function corresponds to the `fits_get_hdu_type` (`ffghdt`) function in the CFITSIO library C API.

## Examples

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
n = fits.getNumHDUs(fptr);
for j = 1:n
 fits.getHDUtype(fptr);
end
fits.closeFile(fptr);
```

## See Also

`getHDUnum`

## matlab.io.fits.getNumHDUs

Total number of HDUs in FITS file

### Syntax

```
N = getNumHDUs(fpPtr)
```

### Description

`N = getNumHDUs(fpPtr)` returns the number of completely defined HDUs in a FITS file. If a new HDU has just been added to the FITS file, then that last HDU will only be counted if it has been closed, or if data has been written to the HDU. The current HDU remains unchanged by this routine.

This function corresponds to the `fits_get_num_hdus` (`ffthdu`) function in the CFITSIO library C API.

### Examples

```
import matlab.io.*
fpPtr = fits.openFile('tst0012.fits');
n = fits.getNumHDUs(fpPtr);
fits.closeFile(fpPtr);
```

### See Also

`getHDUenum`

# matlab.io.fits.movAbsHDU

Move to absolute HDU number

## Syntax

```
htype = fits.movAbsHDU(fpPtr,HDUNUM)
```

## Description

`htype = fits.movAbsHDU(fpPtr,HDUNUM)` moves to a specified absolute HDU number (starting with 1 for the primary array) in the FITS file. The possible values for `htype` are:

```
'IMAGE_HDU'
'ASCII_TBL'
'BINARY_TBL'
```

This function corresponds to the `fits_move_abs_hdu` function in the CFITSIO library C API.

## Examples

```
import matlab.io.*
fpPtr = fits.openFile('tst0012.fits');
n = fits.getNumHDUs(fpPtr);
for j = 1:n
 htype = fits.movAbsHDU(fpPtr,j);
 fprintf('HDU %d: "%s"\n',j,htype);
end
fits.closeFile(fpPtr);
```

## See Also

`getNumHDUs` | `movNamHDU` | `movRelHDU`

## matlab.io.fits.movNamHDU

Move to first HDU having specific type and keyword values

### Syntax

```
movNamHDU(fptr, hdutype, EXTNAME, EXTVER)
```

### Description

`movNamHDU(fptr, hdutype, EXTNAME, EXTVER)` moves to the first HDU which has the specified extension type and `EXTNAME` and `EXTVER` keyword values (or `HDUNAME` and `HDUVER` keywords).

The `hdutype` parameter may have a value of:

```
'IMAGE_HDU'
'ASCII_TBL'
'BINARY_TBL'
'ANY_HDU'
```

If `hdutype` is `'ANY_HDU'`, only the `EXTNAME` and `EXTVER` values are used to locate the correct extension. If the input value of `EXTVER` is 0, then the `EXTVER` keyword is ignored and the first HDU with a matching `EXTNAME` (or `HDUNAME`) keyword will be found.

This function corresponds to the `fits_movnam_hdu` (`ffmnhd`) function in the CFITSIO library C API.

### Examples

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
fits.movNamHDU(fptr, 'IMAGE_HDU', 'quality', 1);
fits.closeFile(fptr);
```

## See Also

[movAbsHDU](#) | [movRe1HDU](#)

## matlab.io.fits.movRelHDU

Move relative number of HDUs from current HDU

### Syntax

```
hType = moveRelHDU(fptr,nmove)
```

### Description

`hType = moveRelHDU(fptr,nmove)` moves a relative number of HDUs forward or backward from the current HDU and returns the HDU type, `hType`, of the resulting HDU. The possible values for `hType` are:

```
'IMAGE_HDU'
'ASCII_TBL'
'BINARY_TBL'
```

This function corresponds to the `fits_movrel_hdu` (`ffmrhd`) function in the CFITSIO library C API.

### Examples

Move through each HDU in succession, then move backwards twice by two HDUs.

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
n = fits.getNumHDUs(fptr);
for j = 1:n
 hType = fits.movAbsHDU(fptr,j);
 fprintf('HDU %d: "%s"\n',j,hType);
end
hType = fits.movRelHDU(fptr,-2);
n = fits.getHDUnum(fptr);
fprintf('HDU %d: "%s"\n',n,hType);
hType = fits.movRelHDU(fptr,-2);
```

```
n = fits.getHDUnum(fptr);
fprintf('HDU %d: "%s"\n',n,htype);
fits.closeFile(fptr);
```

## See Also

movAbsHDU | movNamHDU

## matlab.io.fits.writeChecksum

Compute and write checksum for current HDU

### Syntax

```
writeChecksum(fptr)
```

### Description

`writeChecksum(fptr)` computes and writes the `DATASUM` and `CHECKSUM` keyword values for the current HDU into the current header. If the keywords already exist, their values are updated only if necessary (for example, if the file has been modified since the original keyword values were computed).

This function corresponds to the `fits_write_chksum (ffpcks)` function in the CFITSIO library C API.

### Examples

```
import matlab.io.*
fptr = fits.createFile('myfile.fits');
fits.createImg(fptr, 'long_img', [10 20]);
fits.writeChecksum(fptr)
fits.closeFile(fptr);
fitsdisp('myfile.fits', 'mode', 'full');
```

### See Also

`fitsdisp`

# matlab.io.fits.imgCompress

Compress HDU from one file into another

## Syntax

```
imgCompress(infptr,outfptr)
```

## Description

`imgCompress(infptr,outfptr)` initializes the output HDU, copies all the keywords, and loops through the input image, compressing the data and writing the compressed data to the output HDU.

This function corresponds to the `fits_img_compress` function in the CFITSIO library C API.

## Examples

```
import matlab.io.*
infptr = fits.openFile('tst0012.fits');
outfptr = fits.createFile('myfile.fits');
fits.setCompressionType(outfptr,'rice');
fits.imgCompress(infptr,outfptr);
fits.closeFile(infptr);
fits.closeFile(outfptr);
```

## See Also

`setCompressionType`

## matlab.io.fits.isCompressedImg

Determine if current image is compressed

### Syntax

```
TF = isCompressedImg(fptr)
```

### Description

`TF = isCompressedImg(fptr)` returns true if the image in the current HDU is compressed.

This function corresponds to the `fits_is_compressed_image` function in the CFITSIO library C API.

### Examples

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
bool = fits.isCompressedImg(fptr);
fits.closeFile(fptr);
```

### See Also

`setCompressionType`

# matlab.io.fits.setCompressionType

Set image compression type

## Syntax

```
setCompressionType(fptr,comptype)
```

## Description

`setCompressionType(fptr,comptype)` specifies the image compression algorithm that should be used when writing a FITS image.

Supported values for `comptype` include:

```
'GZIP'
'GZIP2'
'RICE'
'PLIO'
'HCOMPRESS'
'NOCOMPRESS'
```

This function corresponds to the `fits_set_compression_type` function in the CFITSIO library C API.

## Examples

```
import matlab.io.*
fptr = fits.createFile('myfile.fits');
fits.setCompressionType(fptr,'GZIP2');
fits.createImg(fptr,'long_img',[256 512]);
data = reshape(1:256*512,[256 512]);
data = int32(data);
fits.writeImg(fptr,data);
fits.closeFile(fptr);
```

```
fitsdisp('myfile.fits','mode','full');
```

### **See Also**

createImg | setTileDim

# matlab.io.fits.setHCompScale

Set scale parameter for HCOMPRESS algorithm

## Syntax

```
setHCompScale(fptr, scale)
```

## Description

`setHCompScale(fptr, scale)` sets the scale parameter to be used with the HCOMPRESS compression algorithm. Setting the scale parameter causes the algorithm to operate in lossy mode.

This function corresponds to the `fits_set_hcomp_scale` function in the CFITSIO library C API.

## Examples

```
import matlab.io.*
data = 50*ones(256,512,'double') + 10 * rand([256 512]);
fptr = fits.createFile('myfile.fits');
fits.setCompressionType(fptr,'HCOMPRESS_1');
fits.setHCompScale(fptr,2.5);
fits.createImg(fptr,'double_img',[256 512]);
fits.writeImg(fptr,data);
fits.closeFile(fptr);
fitsdisp('myfile.fits','mode','full');
```

## See Also

`setCompressionType` | `setHCompSmooth`

# matlab.io.fits.setHCompSmooth

Set smoothing for images compressed with HCOMPRESS

## Syntax

```
setHCompSmooth(fptr,smooth)
```

## Description

`setHCompSmooth(fptr,smooth)` sets the smoothing to be used when compressing an image with the HCOMPRESS algorithm. Setting either the scale or smoothing parameter causes the algorithm to operate in lossy mode.

This function corresponds to the `fits_set_hcomp_smooth` function in the CFITSIO library C API.

## Examples

```
import matlab.io.*
data = int32(50*ones(256,512,'double') + 10 * rand([256 512]));
fptr = fits.createFile('myfile.fits');
fits.setCompressionType(fptr,'HCOMPRESS');
fits.setHCompSmooth(fptr,1);
fits.createImg(fptr,'long_img',[256 512]);
fits.writeImg(fptr,data);
fits.closeFile(fptr);
fitsdisp('myfile.fits','mode','full');
```

## See Also

`setCompressionType` | `setHCompScale`

# matlab.io.fits.setTileDim

Set tile dimensions

## Syntax

```
fits.setTileDim(fptr,tiledims)
```

## Description

`fits.setTileDim(fptr,tiledims)` specifies the size of the image compression tiles to be used when creating a compressed image.

This function corresponds to the `fits_set_tile_dim` function in the CFITSIO library C API.

## Examples

```
import matlab.io.*
fptr = fits.createFile('myfile.fits');
fits.setCompressionType(fptr,'RICE_1');
fits.setTileDim(fptr,[64 128]);
fits.createImg(fptr,'byte_img',[256 512]);
data = ones(256,512,'uint8');
fits.writeImg(fptr,data);
fits.closeFile(fptr);
fitsdisp('myfile.fits','mode','full');
```

## See Also

`setCompressionType`

## matlab.io.fits.createTbl

Create new ASCII or binary table extension

### Syntax

```
fptr = createTbl(fptr,tbltype,nrows,ttype,tform,tunit,extname)
```

### Description

`fptr = createTbl(fptr,tbltype,nrows,ttype,tform,tunit,extname)` creates a new ASCII or bintable table extension. `ttype` must be either `'binary'` or `'ascii'`. The `nrows` argument gives the initial number of rows to be created in the table and should normally be zero. `tunit` specifies the units for each column, but can be an empty cell array if no units are desired. `extname` specifies the extension name, but can be omitted.

`tform` specifies the format of the column. For binary tables, the values should be in the form of `'rt'`, where `'r'` is the repeat count and `'t'` is one of the following letters.

'A'	ASCII character
'B'	Byte or <code>uint8</code>
'C'	Complex (single precision)
'D'	Double precision
'E'	Single precision
'I'	<code>int16</code>
'J'	<code>int32</code>
'K'	<code>int64</code>
'L'	Logical
'M'	Complex (double precision)
'X'	Bit ( <code>int8</code> zeros and ones)

A column can also be specified as having variable-width if the `tform` value has the form `'1Pt'` or `'1Qt'`, where `'t'` specifies the data type as above.

For ASCII tables, the `tform` values take the form:

Iw	int16 column with width 'w'
Aw	ASCII column with width 'w'
Fww.dd	Fixed point
Eww.dd	Single precision with width 'ww' and precision 'dd'
Dww.dd	Double precision with width 'ww' and precision 'dd'

This function corresponds to the `fits_create_tbl` (`ffcrtb`) function in the CFITSIO library C API.

## Examples

Create a binary table. The first column contains strings of nine characters each. The second column contains four-element sequences of bits. The third column contains three-element sequences of `uint8` values. The fourth column contains double-precision scalars.

```
import matlab.io.*
fptr = fits.createFile('myfile.fits');
ttype = {'Col1','Col2','Col3','Col4'};
tform = {'9A','4X','3B','1D'};
tunit = {'m/s','kg','kg/m^3','candela'};
fits.createTbl(fptr,'binary',10,ttype,tform,tunit,'my-table');
fits.closeFile(fptr);
fitsdisp('myfile.fits');
```

Create a two-column table where the first column has a single double-precision value, but the second column has a variable-length double-precision value.

```
import matlab.io.*
fptr = fits.createFile('myfile2.fits');
ttype = {'Col1','Col2'};
tform = {'1D','1PD'};
fits.createTbl(fptr,'binary',0,ttype,tform);
fits.closeFile(fptr);
fitsdisp('myfile2.fits');
```

**See Also**

`createImg` | `insertATbl` | `insertBTbl` | `readCol` | `writeCol`

# matlab.io.fits.deleteCol

Delete column from table

## Syntax

```
deleteCol(fpPtr,colnum)
```

## Description

`deleteCol(fpPtr,colnum)` deletes the column from an ASCII or binary table.

This function corresponds to the `fits_delete_col` (`ffdcoll`) function in the CFITSIO library C API.

## Examples

Delete the second column in a binary table.

```
import matlab.io.*
srcFile = fullfile(matlabroot,'toolbox','matlab','demos','tst0012.fits');
copyfile(srcFile,'myfile.fits');
fileattrib('myfile.fits','+w');
fprintf('Before: '); fitsdisp('myfile.fits','index',2,'mode','min');
fpPtr = fits.openFile('myfile.fits','readwrite');
fits.movAbsHDU(fpPtr,2);
fits.deleteCol(fpPtr,2);
fits.closeFile(fpPtr);
fprintf('After : '); fitsdisp('myfile.fits','index',2,'mode','min');
```

## See Also

`deleteRows`

## matlab.io.fits.deleteRows

Delete rows from table

### Syntax

```
deleteRows(fpPtr,firstrow,nrows)
```

### Description

`deleteRows(fpPtr,firstrow,nrows)` deletes rows from an ASCII or binary table.

This function corresponds to the `fits_delete_rows` (`ffdraw`) function in the CFITSIO library C API.

### Examples

Delete the second, third, and fourth rows in a binary table (second HDU).

```
import matlab.io.*
srcFile = fullfile(matlabroot,'toolbox','matlab','demos','tst0012.fits');
copyfile(srcFile,'myfile.fits');
fileattrib('myfile.fits','+w');
fprintf('Before: '); fitsdisp('myfile.fits','index',2,'mode','min');
fpPtr = fits.openFile('myfile.fits','readwrite');
fits.movAbsHDU(fpPtr,2);
fits.deleteRows(fpPtr,2,2);
fits.closeFile(fpPtr);
fprintf('After : '); fitsdisp('myfile.fits','index',2,'mode','min');
```

### See Also

`deleteCol` | `insertRows`

# matlab.io.fits.insertRows

Insert rows into table

## Syntax

```
insertRows(fpPtr,firstrow,nrows)
```

## Description

`insertRows(fpPtr,firstrow,nrows)` inserts rows into an ASCII or binary table. `firstrow` is a one-based number.

This function corresponds to the `fits_insert_rows` (`ffifrow`) function in the CFITSIO library C API.

## Examples

Insert five rows into an empty table.

```
import matlab.io.*
fpPtr = fits.createFile('myfile.fits');
ttype = {'Col1','Col2'};
tform = {'3A','1D'};
tunit = {'m/s','candela'};
fits.createTbl(fpPtr,'binary',0,ttype,tform,tunit,'my-table');
fits.insertRows(fpPtr,1,5);
fits.closeFile(fpPtr);
fitsdisp('myfile.fits','index',2);
```

## See Also

`deleteRows` | `insertCol`

## matlab.io.fits.getAColParms

ASCII table information

### Syntax

```
[ttype,tbcol,tunit,tform,scale,zero,nulstr,tdisp] =
getAColParms(fptr,colnum)
```

### Description

```
[ttype,tbcol,tunit,tform,scale,zero,nulstr,tdisp] =
getAColParms(fptr,colnum) gets information about an existing ASCII table column.
```

This function corresponds to the `fits_get_acolparms` (`fffacl`) function in the CFITSIO library C API.

### Examples

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
fits.movAbsHDU(fptr,5);
[ttype,tbcol,tunit,tform,scale,zero,nulstr,tdisp] = fits.getAColParms(fptr,2);
fits.closeFile(fptr);
```

### See Also

`getBColParms`

# matlab.io.fits.getBColParms

Binary table information

## Syntax

```
[ttype,tunit,typechar,repeat,scale,zero,nulval,tdisp] =
getBColParms(fpPtr,colnum)
```

## Description

```
[ttype,tunit,typechar,repeat,scale,zero,nulval,tdisp] =
getBColParms(fpPtr,colnum) gets information about an existing binary table column.
```

This function corresponds to the `fits_get_bcolparms` (`ffgbcl`) function in the CFITSIO library C API.

## Examples

Get information about the second column in a binary table.

```
import matlab.io.*
fpPtr = fits.openFile('tst0012.fits');
fits.movAbsHDU(fpPtr,2);
[ttype,tunit,typechar,repeat,scale,zero,nulval,tdisp]= fits.getBColParms(fpPtr,2);
fits.closeFile(fpPtr);
```

## See Also

`getAColParms`

# matlab.io.fits.getColName

Table column name

## Syntax

```
[colnum,colname] = getColNum(fpPtr,templ,casesen)
```

## Description

`[colnum,colname] = getColNum(fpPtr,templ,casesen)` gets the table column numbers and names of the columns whose names match an input template name. If `casesen` is true, then the column name match is case-sensitive. `casesen` defaults to false.

The input column name template may be either the exact name of the column to be searched for, or it may contain wildcard characters (\*, ?, or #), or it may contain the integer number of the desired column (with the first column = 1). The '\*' wildcard character matches any sequence of characters (including zero characters) and the '?' character matches any single character. The # wildcard matches any consecutive string of decimal digits (0-9).

## Examples

Return all the columns starting with the letter 'C'.

```
import matlab.io.*
fpPtr = fits.openFile('tst0012.fits');
fits.movAbsHDU(fpPtr,2);
[nums,names] = fits.getColName(fpPtr,'C*');
fits.closeFile(fpPtr);
```

## See Also

[getAColParms](#) | [getBColParms](#)

# matlab.io.fits.getColType

Scaled column data type, repeat value, width

## Syntax

```
[dtype,repeat,width] = getColType(fptr,colnum)
```

## Description

`[dtype,repeat,width] = getColType(fptr,colnum)` returns the data type, vector repeat value, and the width in bytes of a column in an ASCII or binary table.

This function corresponds to the `fits_get_coltype11` (`ffgtc111`) function in the CFITSIO library C API.

## Examples

Get information about the 'FLUX' column in the second HDU.

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
fits.movAbsHDU(fptr,2);
[dtype,repeat,width] = fits.getColType(fptr,5);
fits.closeFile(fptr);
```

## See Also

`getEqColType`

## matlab.io.fits.getEqColType

Column data type, repeat value, width

### Syntax

```
[dtype,repeat,width] = getColType(fptr,colnum)
```

### Description

`[dtype,repeat,width] = getColType(fptr,colnum)` returns the scaled data type needed to store the scaled column data type, the vector repeat value, and the width in bytes of a column in an ASCII or binary table.

This function corresponds to the `fits_get_eqcoltype11` (`ffeqty11`) function in the CFITSIO library C API.

### Examples

Get information about the 'FLUX' column in the second HDU.

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
fits.movAbsHDU(fptr,2);
[dtype,repeat,width] = fits.getEqColType(fptr,5);
fits.closeFile(fptr);
```

### See Also

`getColType`

# matlab.io.fits.getNumCols

Number of columns in table

## Syntax

```
ncols = getNumCols(fptr)
```

## Description

`ncols = getNumCols(fptr)` gets the number of columns in the current FITS table. This function corresponds to the `fits_get_num_cols` (`ffgncl`) function in the CFITSIO library C API.

## Examples

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
fits.movAbsHDU(fptr,2);
ncols = fits.getNumCols(fptr);
nrows = fits.getNumRows(fptr);
fits.closeFile(fptr);
```

## See Also

`getNumRows`

## matlab.io.fits.getNumRows

Number of rows in table

### Syntax

```
nrows = getNumRows(fptr)
```

### Description

`nrows = getNumRows(fptr)` gets the number of rows in the current FITS table. This function corresponds to the `fits_get_num_rows11` (`ffgnrwl`) function in the CFITSIO library C API.

### Examples

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
fits.movAbsHDU(fptr,2);
ncols = fits.getNumCols(fptr);
nrows = fits.getNumRows(fptr);
fits.closeFile(fptr);
```

### See Also

`getNumCols`

# matlab.io.fits.insertCol

Insert column into table

## Syntax

```
insertCol(fptr,colnum,ttype,tform)
```

## Description

`insertCol(fptr,colnum,ttype,tform)` inserts a column into an ASCII or binary table.

This function corresponds to the `fits_insert_col` (`fficol`) function in the CFITSIO library C API.

## Examples

```
import matlab.io.*
fptr = fits.createFile('myfile.fits');
ttype = {'Col1','Col2'};
tform = {'3A','1D'};
tunit = {'m/s','candela'};
fits.createTbl(fptr,'binary',0,ttype,tform,tunit,'my-table');
fits.insertCol(fptr,3,'Col3','3D');
fits.closeFile(fptr);
fitsdisp('myfile.fits','index',2);
```

## See Also

`insertRows`

## matlab.io.fits.insertATbl

Insert ASCII table after current HDU

### Syntax

```
insertATbl(fptr, rowlen, nrows, ttype, tbc01, tform, tunit, extname)
```

### Description

`insertATbl(fptr, rowlen, nrows, ttype, tbc01, tform, tunit, extname)` inserts a new ASCII table extension immediately following the current HDU. Any following extensions are shifted down to make room for the new extension. If there are no other following extensions, then the new table extension is simply appended to the end of the file. If the FITS file is currently empty then this routine creates a dummy primary array before appending the table to it. The new extension becomes the current HDU. If `rowlen` is 0, then CFITSIO calculates the default `rowlen` based on the `tbc01` and `ttype` values.

`tform` can take the following forms. In each case, 'w' and 'ww' represent the widths of the ASCII columns.

Iw	int16 column
Aw	ASCII column
Fww.dd	Fixed point with 'dd' digits after the decimal point
Eww.dd	Single precision with 'dd' digits of precision
Dww.dd	Double precision with 'dd' digits of precision

Binary tables are recommended instead of ASCII tables.

This function corresponds to the `fits_insert_atbl (ffitab)` function in the CFITSIO library C API.

## Examples

Create an ASCII table between two images.

```
import matlab.io.*
fptr = fits.createFile('myfile.fits');
fits.createImg(fptr,'uint8',[20 30]);
fits.createImg(fptr,'int16',[30 40]);
fits.movRelHDU(fptr,-1);
ttype = {'Name','Short','Fix','Double'};
tbcol = [1 17 28 43];
tform = {'A15','I10','F14.2','D12.4'};
tunit = {'','m*2','cm','km/s'};
fits.insertATbl(fptr,0,0,ttype,tbcol,tform,tunit,'my-table');
fits.writeCol(fptr,1,1,char('abracadabra','hocus-pocus'));
fits.writeCol(fptr,2,1,int16([0; 1]));
fits.writeCol(fptr,3,1,[12.4; 4/3]);
fits.writeCol(fptr,4,1,[12.4; 4e8/3]);
fits.closeFile(fptr);
fitsdisp('myfile.fits','mode','min');
```

## See Also

[createTbl](#) | [insertBTbl](#)

## matlab.io.fits.insertBTbl

Insert binary table after current HDU

### Syntax

```
insertBTbl(fpPtr,nrows,ttype,tform,tunit,extname,pcount)
```

### Description

`insertBTbl(fpPtr,nrows,ttype,tform,tunit,extname,pcount)` inserts a new binary table extension immediately following the current HDU. Any following extensions are shifted down to make room for the new extension. If there are no other following extensions then the new table extension is simply appended to the end of the file. If the FITS file is currently empty then this routine creates a dummy primary array before appending the table to it. The new extension becomes the CHDU. If there are following extensions in the file and if the table contains variable-length array columns then `pcount` must specify the expected final size of the data heap. Otherwise, `pcount` must be zero.

This function corresponds to the `fits_insert_btbl` (`ffibin`) function in the CFITSIO library C API.

### Examples

Create a table following the primary array. Then, insert a new table just before it.

```
import matlab.io.*
fpPtr = fits.createFile('myfile.fits');
ttype = {'Col1','Col2'};
tform = {'9A','1D'};
tunit = {'m/s','candela'};
fits.createTbl(fpPtr,'binary',10,ttype,tform,tunit,'my-table');
fits.movRelHDU(fpPtr,-1);
fits.insertBTbl(fpPtr,5,ttype,tform,tunit,'my-new-table',0);
fits.closeFile(fpPtr);
fitsdisp('myfile.fits');
```

## See Also

[createTbl](#) | [insertATbl](#)

## matlab.io.fits.readATblHdr

Read header information from current ASCII table

### Syntax

```
[rowlen,nrows,ttype,tbcol,tform,tunit,exname] = readATblHdr(fptr)
```

### Description

```
[rowlen,nrows,ttype,tbcol,tform,tunit,exname] = readATblHdr(fptr)
```

reads header information for the current ASCII table.

This function corresponds to the `fits_read_atblhdr11` (`ffghtb11`) function in the CFITSIO library C API.

### Examples

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
fits.movAbsHDU(fptr,5);
[rowlen,nrows,ttype,tbcol,tform,tunit,exname] = fits.readATblHdr(fptr);
fits.closeFile(fptr);
```

### See Also

`readBTblHdr`

# matlab.io.fits.readBTblHdr

Read header information from current binary table

## Syntax

```
[nrows,ttype,tform,tunit,extname,pcount] = readBTblHdr(fptr)
```

## Description

`[nrows,ttype,tform,tunit,extname,pcount] = readBTblHdr(fptr)` reads header information for the current binary table.

This function corresponds to the `fits_read_btblhdr11` (`ffghbn11`) function in the CFITSIO library C API.

## Examples

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
fits.movAbsHDU(fptr,2);
[nrows,ttype,tform,tunit,extname,pcount] = fits.readBTblHdr(fptr);
fits.closeFile(fptr);
```

## See Also

`readATblHdr`

## matlab.io.fits.readCol

Read rows of ASCII or binary table column

### Syntax

```
[coldata,nullval] = readCol(fpPtr,colnum)
[coldata,nullval] = readCol(fpPtr,colnum,firstrow,numrows)
```

### Description

`[coldata,nullval] = readCol(fpPtr,colnum)` reads an entire column from an ASCII or binary table column. `nullval` is a logical array specifying if a particular element of `coldata` should be treated as undefined. It is the same size as `coldata`.

`[coldata,nullval] = readCol(fpPtr,colnum,firstrow,numrows)` reads a subsection of rows from an ASCII or binary table column.

The MATLAB data type returned by `readCol` corresponds to the data type returned by `getEqColType`.

This function corresponds to the `fits_read_col (ffgcv)` function in the CFITSIO library C API.

### Examples

Read an entire column.

```
import matlab.io.*
fpPtr = fits.openFile('tst0012.fits');
fits.movAbsHDU(fpPtr,2);
colnum = fits.getColName(fpPtr,'flux');
fluxdata = fits.readCol(fpPtr,colnum);
fits.closeFile(fpPtr);
```

Read the first five rows in a column.

```
import matlab.io.*
```

```
fptr = fits.openFile('tst0012.fits');
fits.movAbsHDU(fptr,2);
colnum = fits.getColName(fptr,'flux');
fluxdata = fits.readCol(fptr,colnum,1,5);
fits.closeFile(fptr);
```

## See Also

writeCol

## matlab.io.fits.setTscale

Reset image scaling

### Syntax

```
setTscale(fptr,colnum,tscale,tzero)
```

### Description

`setTscale(fptr,colnum,tscale,tzero)` resets the scaling factors for a table column according to the equation:

$$\text{output} = (\text{FITS array}) * \text{tscale} + \text{tzero}$$

The inverse formula is used when writing data values to the FITS file.

This only affects the automatic scaling performed when the data elements are read. It does not change the `tscale` and `tzero` keyword values.

### Examples

Turn off automatic scaling in a table column where the `tscale` and `tzero` keywords are present.

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
fits.movAbsHDU(fptr,2);
scaled_data = fits.readCol(fptr,3);
fits.setTscale(fptr,3,1.0,0.0);
unscaled_data = fits.readCol(fptr,3);
fits.closeFile(fptr);
```

### See Also

`readImg`

# matlab.io.fits.writeCol

Write elements into ASCII or binary table column

## Syntax

```
writeCol(fpPtr,colnum,firstrow,coldata)
```

## Description

`writeCol(fpPtr,colnum,firstrow,coldata)` writes elements into an ASCII or binary table extension column.

When writing rows of data to a variable length field, `coldata` must be a cell array.

This function corresponds to the `fits_write_col` (`ffpcol`) function in the CFITSIO library C API.

## Examples

Write to a table with ASCII, `uint8`, double-precision, and variable-length double-precision columns.

```
import matlab.io.*
fpPtr = fits.createFile('myfile.fits');
ttype = {'Col1', 'Col2', 'Col3', 'Col4'};
tform = {'3A', '3B', '1D', '1PD'};
tunit = {'m/s', 'kg/m^3', 'candela', 'parsec'};
fits.createTbl(fpPtr, 'binary', 0, ttype, tform, tunit, 'my-table');
fits.writeCol(fpPtr, 1, 1, ['dog'; 'cat']);
fits.writeCol(fpPtr, 2, 1, [0 1 2; 3 4 5; 6 7 8; 9 10 11]);
fits.writeCol(fpPtr, 3, 1, [1; 2; 3; 4]);
fits.writeCol(fpPtr, 4, 1, {1; [1 2]; [1 2 3]; [1 2 3 4]});
fits.closeFile(fpPtr);
fitsdisp('myfile.fits', 'index', 2, 'mode', 'full');
```

Write to a table with logical, bit, double precision, and variable-length complex single-precision columns.

```
import matlab.io.*
fptr = fits.createFile('myfile.fits');
ttype = {'Col1', 'Col2', 'Col3', 'Col4'};
tform = {'2L', '3X', '1D', '1PC'};
tunit = {'', 'kg/m^3', 'candela', 'parsec'};
fits.createTbl(fptr, 'binary', 0, ttype, tform, tunit, 'my-table');
fits.writeCol(fptr, 1, 1, [false false; true false]);
fits.writeCol(fptr, 2, 1, int8([0 1 1; 1 1 1; 1 1 1; 1 0 1]));
fits.writeCol(fptr, 3, 1, [1; 2; 3; 4]);
data = cell(4, 1);
data{1} = single(1);
data{2} = single(1+2j);
data{3} = single([1j 2 3+j]);
data{4} = single([1 2+3j 3 4]);
fits.writeCol(fptr, 4, 1, data);
fits.closeFile(fptr);
fitsdisp('myfile.fits', 'index', 2, 'mode', 'full');
```

## See Also

[createTbl](#) | [readCol](#)

# matlab.io.fits.getConstantValue

Numeric value of named constant

## Syntax

```
N = getConstantValue(name)
```

## Description

`N = getConstantValue(name)` returns the numeric value corresponding to the named CFITSIO constant.

## Examples

```
import matlab.io.*
n = fits.getConstantValue('BYTE_IMG');
```

## matlab.io.fits.getVersion

Revision number of the CFITSIO library

### Syntax

```
V = getVersion()
```

### Description

`V = getVersion()` returns the revision number of the CFITSIO library. This function corresponds to the `fits_get_version` (`ffvers`) function in the CFITSIO library C API.

### Examples

```
import matlab.io.*
v = fits.getVersion();
```

# matlab.io.fits.getOpenFiles

List of open FITS files

## Syntax

```
fptrs = getOpenFiles()
```

## Description

`fptrs = getOpenFiles()` returns a list of file pointers of all open FITS files.

## Examples

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
clear fptr;
fptr = fits.getOpenFiles();
fits.closeFile(fptr);
```

## See Also

## matlab.io.hdf4.sd

Interact directly with HDF4 multifile scientific data set (SD) interface

### Description

To use these MATLAB functions, you should be familiar with the HDF SD C API. In most cases, the syntax of the MATLAB function is similar to the syntax of the corresponding HDF library function. The functions are implemented as the package `matlab.io.hdf4.sd`. To use this package, prefix the function name with a package path, or use the `import` function to add the package to the current import list, prior to calling the function, for example,

```
import matlab.io.hdf4.*
sdID = sd.start('myfile.hdf','read');
```

### Access

<code>matlab.io.hdf4.sd.close</code>	Terminate access to SD interface
<code>matlab.io.hdf4.sd.endAccess</code>	Terminate access to data set
<code>matlab.io.hdf4.sd.getFilename</code>	Name of file
<code>matlab.io.hdf4.sd.select</code>	Identifier of data set with specified index
<code>matlab.io.hdf4.sd.setExternalFile</code>	Store data in external file
<code>matlab.io.hdf4.sd.start</code>	Open HDF file and initialize SD interface

### Read/Write

<code>matlab.io.hdf4.sd.create</code>	Create new data set
---------------------------------------	---------------------

matlab.io.hdf4.sd.readData	Read subsample of data
matlab.io.hdf4.sd.setFillMode	Set current fill mode of file
matlab.io.hdf4.sd.writeData	Write to data set

## **Inquiry**

matlab.io.hdf4.sd.fileInfo	Number of data sets and global attributes in file
matlab.io.hdf4.sd.getCompInfo	Information about data set compression
matlab.io.hdf4.sd.setFillValue	Fill value for data set
matlab.io.hdf4.sd.getInfo	Information about data set
matlab.io.hdf4.sd.idToRef	Reference number corresponding to data set identifier
matlab.io.hdf4.sd.idType	Type of object
matlab.io.hdf4.sd.isCoordVar	Determine if data set is a coordinate variable
matlab.io.hdf4.sd.isRecord	Determine if data set is appendable
matlab.io.hdf4.sd.nameToIndex	Index value of named data set
matlab.io.hdf4.sd.nameToIndices	List of data sets with same name
matlab.io.hdf4.sd.refToIndex	Index of data set corresponding to reference number

## Dimensions

matlab.io.hdf4.sd.dimInfo	Information about dimension
matlab.io.hdf4.sd.getDimID	Dimension identifier
matlab.io.hdf4.sd.getDimScale	Scale data for dimension
matlab.io.hdf4.sd.setDimName	Associate name with dimension
matlab.io.hdf4.sd.setDimScale	Set scale values for dimension

## User-defined Attributes

matlab.io.hdf4.sd.attrInfo	Information about attribute
matlab.io.hdf4.sd.findAttr	Index of specified attribute
matlab.io.hdf4.sd.readAttr	Read attribute value
matlab.io.hdf4.sd.setAttr	Write attribute value

## Predefined Attributes

matlab.io.hdf4.sd.getCal	Data set calibration information
matlab.io.hdf4.sd.getDataStrs	Predefined attribute strings for data set
matlab.io.hdf4.sd.getDimStrs	Predefined attribute strings for dimension

matlab.io.hdf4.sd.setFillValue	Fill value for data set
matlab.io.hdf4.sd.getRange	Maximum and minimum range values
matlab.io.hdf4.sd.setCal	Set data set calibration information
matlab.io.hdf4.sd.setDataStrs	Set predefined attributes for data set
matlab.io.hdf4.sd.setDimStrs	Set label, unit, and format attribute strings
matlab.io.hdf4.sd.setFillValue	Set fill value for data set
matlab.io.hdf4.sd.setRange	Set maximum and minimum range value for data set

## Chunking/Tiling Operations

matlab.io.hdf4.sd.getChunkInfo	Chunk size for data set
matlab.io.hdf4.sd.readChunk	Read chunk from data set
matlab.io.hdf4.sd.setChunk	Set chunk size and compression method of data set
matlab.io.hdf4.sd.writeChunk	Write chunk to data set

## Compression

matlab.io.hdf4.sd.setCompress	Set compression method of data set
-------------------------------	------------------------------------

matlab.io.hdf4.sd.setNBitDataSet

Specify nonstandard bit length for data set values

# matlab.io.hdf4.sd.attrInfo

**Package:** matlab.io.hdf4.sd

Information about attribute

## Syntax

```
[name,datatype,nelts] = attrInfo(objID,idx)
```

## Description

`[name,datatype,nelts] = attrInfo(objID,idx)` returns the name, data type, and number of elements in the specified attribute. The attribute is specified by its zero-based index value. `objID` can be either an SD interface identifier, a data set identifier, or a dimension identifier.

This function corresponds to the `SAttrinfo` function in the HDF library C API.

## Examples

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf');
idx = sd.findAttr(sdID,'creation_date');
[name,datatype,nelts] = sd.attrInfo(sdID,idx);
data = sd.readAttr(sdID,idx);
sd.close(sdID);
```

## See Also

`sd.findAttr`

## matlab.io.hdf4.sd.close

**Package:** matlab.io.hdf4.sd

Terminate access to SD interface

### Syntax

```
sd.close(sdID)
```

### Description

`sd.close(sdID)` closes the file identified by `sdID`.

This function corresponds to the `SDend` function in the HDF C API.

### Examples

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf');
idx = sd.nameToIndex(sdID, 'temperature');
sdsID = sd.select(sdID, idx);
sd.endAccess(sdsID);
sd.close(sdID);
```

### See Also

`sd.start`

# matlab.io.hdf4.sd.create

**Package:** matlab.io.hdf4.sd

Create new data set

## Syntax

```
sdsID = create(sdID,name,datatype,dims)
```

## Description

`sdsID = create(sdID,name,datatype,dims)` creates a data set with the given name `name`, data type `datatype`, and dimension sizes `dims`.

To create a data set with an unlimited dimension, the last value in `dims` should be set to 0.

This function corresponds to the `SDcreate` function in the HDF library C API, but because MATLAB uses FORTRAN-style ordering, the `dims` parameter is reversed with respect to the C library API.

## Examples

Create a 3D data set with an unlimited dimension.

```
import matlab.io.hdf4.*
sdID = sd.start('myfile.hdf','create');
sdsID = sd.create(sdID,'temperature','double',[10 20 0]);
sd.endAccess(sdsID);
sd.close(sdID);
```

## See Also

`sd.endAccess`

## matlab.io.hdf4.sd.dimInfo

**Package:** matlab.io.hdf4.sd

Information about dimension

### Syntax

```
[name,dimlen,datatype,nattrs] = dimInfo(dimID)
```

### Description

`[name,dimlen,datatype,nattrs] = dimInfo(dimID)` returns the name, length, data type, and number of attributes of the specified dimension.

This function corresponds to the `SDdiminfo` function in the HDF library C API.

### Examples

Read a 2-by-3 portion of a data set.

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf');
idx = sd.nameToIndex(sdID,'latitude');
sdsID = sd.select(sdID,idx);
dimID = sd.getDimID(sdsID,0);
[name,dimlen,datatype,nattrs] = sd.dimInfo(dimID);
sd.endAccess(sdsID);
sd.close(sdID);
```

### See Also

`sd.getDimID`

# matlab.io.hdf4.sd.endAccess

**Package:** matlab.io.hdf4.sd

Terminate access to data set

## Syntax

```
sd.endAccess(sdsID)
```

## Description

`sd.endAccess(sdsID)` terminates access to the data set identified by `sdsID`. Failing to call this function after all operations on the specified data set are complete may result in loss of data.

This function corresponds to the `SDendaccess` function in the HDF library C API.

## Examples

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf');
idx = sd.nameToIndex(sdID, 'temperature');
sdsID = sd.select(sdID, idx);
sd.endAccess(sdsID);
sd.close(sdID);
```

## See Also

`sd.close` | `sd.select`

## matlab.io.hdf4.sd.fileInfo

**Package:** matlab.io.hdf4.sd

Number of data sets and global attributes in file

### Syntax

```
[ndatasets,ngatts] = fileInfo(sdID)
```

### Description

`[ndatasets,ngatts] = fileInfo(sdID)` returns the number of data sets `ndatasets` and the number of global attributes `ngatts` in the file identified by `sdID`.

`ndatasets` includes the number of coordinate variable data sets.

This function corresponds to the `SDfileinfo` function in the HDF library C API.

### Examples

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf');
[ndatasets,ngatts] = sd.fileInfo(sdID);
sd.close(sdID);
```

`sd.getInfo`

# matlab.io.hdf4.sd.findAttr

**Package:** matlab.io.hdf4.sd

Index of specified attribute

## Syntax

```
idx = findAttr(objID,attrname)
```

## Description

`idx = findAttr(objID,attrname)` returns the index of the attribute specified by `attrname`. The `objID` input can be either an SD interface identifier, a data set identifier, or a dimension identifier.

The function corresponds to the `SDfindattr` function in the HDF library C API.

## Examples

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf');
idx = sd.findAttr(sdID,'creation_date');
data = sd.readAttr(sdID,idx);
sd.close(sdID);
```

## See Also

## matlab.io.hdf4.sd.getCal

**Package:** matlab.io.hdf4.sd

Data set calibration information

### Syntax

```
[cal,calErr,offset,offsetErr,datatype] = getCal(sdsID)
```

### Description

[cal,calErr,offset,offsetErr,datatype] = getCal(sdsID) retrieves the calibration information associated with a data set.

This function corresponds to the SDgetcal function in the HDF library C API.

### Examples

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf');
idx = sd.nameToIndex(sdID,'temperature');
sdsID = sd.select(sdID,idx);
[cal,calErr,offset,offsetErr,dtype] = sd.getCal(sdsID);
sd.endAccess(sdsID);
sd.close(sdID);
```

### See Also

sd.setCal

# matlab.io.hdf4.sd.getChunkInfo

**Package:** matlab.io.hdf4.sd

Chunk size for data set

## Syntax

```
chunkDims = getChunkInfo(sdsID)
```

## Description

`chunkDims = getChunkInfo(sdsID)` returns the chunk size for the data set specified by `sdsID`. If a data set is chunked, the dimensions of the chunks is returned in `chunkDims`. Otherwise `chunkDims` is `[]`.

This function corresponds to the `SDgetchunkinfo` function in the HDF library C API, but because MATLAB uses FORTRAN-style ordering, the `chunkDims` parameter is reversed with respect to the C library API.

## Examples

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf');
idx = sd.nameToIndex(sdID, 'temperature');
sdsID = sd.select(sdID, idx);
cdims = sd.getChunkInfo(sdsID);
sd.endAccess(sdsID);
sd.close(sdID);
```

## See Also

`sd.getCompInfo` | `sd.setChunk`

## matlab.io.hdf4.sd.getCompInfo

**Package:** matlab.io.hdf4.sd

Information about data set compression

### Syntax

```
[comptype,compparms] = getCompType(sdsID)
```

### Description

[comptype,compparms] = getCompType(sdsID) retrieves the compression type and compression information for a data set. `comptype` can be one of the following strings.

'none'	No compression
'rle'	Run-length encoding
'nbit'	NBIT compression
'skphuff'	Skipping Huffman compression
'deflate'	GZIP compression
'szip'	SZIP compression

If `comptype` is 'none' or 'rle', then `compparms` is [].

If `comptype` is 'nbit', then `compparms` is a 4-element array.

compparm(1)	sign_ext
compparm(2)	fill_one
compparm(3)	start_bit
compparm(4)	bit_len

If `comptype` is 'deflate', then `compparms` contains the deflation value, a number between 0 and 9.

If `comptype` is `'gzip'`, then `compparms` is a 5-element array. Consult the HDF Reference Manual for details on SZIP compression.

This function corresponds to the `SDgetcompinfo` function in the HDF library C API.

## Examples

```
import matlab.io.hdf4.*
sdID = sd.start('myfile.hdf','create');
sdsID = sd.create(sdID,'temperature','double',[100 50]);
sd.setCompress(sdsID,'deflate',5);
[comptype,compparm] = sd.getCompInfo(sdsID);
sd.endAccess(sdsID);
sd.close(sdID);
```

## See Also

## matlab.io.hdf4.sd.getDataStrs

**Package:** matlab.io.hdf4.sd

Predefined attribute strings for data set

### Syntax

```
[label,unit,format,coordsys] = getDataStrs(sdsID)
[label,unit,format,coordsys] = getDataStrs(sdsID,maxlen)
```

### Description

[label,unit,format,coordsys] = `getDataStrs(sdsID)` returns the label, unit, format, and coordsys attributes for the data set identified by `sdsID`.

[label,unit,format,coordsys] = `getDataStrs(sdsID,maxlen)` returns the label, unit, format, and coordsys attributes for the data set identified by `sdsID`. The `maxlen` input is the maximum length of any of the attribute strings. It defaults to 1000 if not specified.

This function corresponds to the `SDgetdatastrs` function in the HDF library C API.

### Examples

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf');
idx = sd.nameToIndex(sdID,'temperature');
sdsID = sd.select(sdID,idx);
[label,unit,fmt,coordsys] = sd.getDataStrs(sdsID);
sd.endAccess(sdsID);
sd.close(sdID);
```

### See Also

`sd.setDataStrs`

# matlab.io.hdf4.sd.getDimID

**Package:** matlab.io.hdf4.sd

Dimension identifier

## Syntax

```
dimID = getDimID(sdsID,dimnumber)
```

## Description

`dimID = getDimID(sdsID,dimnumber)` returns the identifier of the dimension given its index.

---

**Note:** MATLAB uses Fortran-style indexing while the HDF library uses C-style indexing. The order of the dimension identifiers retrieved with `sd.getDimID` are reversed from what would be retrieved via the C API.

---

This function corresponds to the `SDgetdimid` function in the HDF library C API.

## Examples

Read an entire data set.

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf');
idx = sd.nameToIndex(sdID,'temperature');
sdsID = sd.select(sdID,idx);
dimID0 = sd.getDimID(sdsID,0);
dimID1 = sd.getDimID(sdsID,1);
sd.endAccess(sdsID);
sd.close(sdID);
```

## See Also

`sd.setDimName`

# matlab.io.hdf4.sd.getDimScale

**Package:** matlab.io.hdf4.sd

Scale data for dimension

## Syntax

```
scale = getDimScale(dimID)
```

## Description

`scale = getDimScale(dimID)` returns the scale values of the dimension identified by `dimID`.

This function corresponds to the `SDgetdimscale` function in the HDF library C API.

## Examples

```
import matlab.io.hdf4.*
sdID = sd.start('myfile.hdf','create');
sdsID = sd.create(sdID,'temperature','double',20);
dimID = sd.getDimID(sdsID,0);
sd.setDimName(dimID,'x');
sd.setDimScale(dimID,0:5:95);
sd.endAccess(sdsID);
sd.close(sdID);
sdID = sd.start('myfile.hdf');
idx = sd.nameToIndex(sdID,'temperature');
sdsID = sd.select(sdID,idx);
dimID = sd.getDimID(sdsID,0);
scale = sd.getDimScale(dimID);
sd.endAccess(sdsID);
sd.close(sdID);
```

## See Also

`sd.dimInfo` | `sd.setDimScale`

**Package:** matlab.io.hdf4.sd

Predefined attribute strings for dimension

## Syntax

```
[label,unit,format] = getDimStrs(dimID)
```

## Description

`[label,unit,format] = getDimStrs(dimID)` returns the label, unit, and format attributes for the dimension identified by `dimID`.

This function corresponds to the `SDgetdimstrs` function in the HDF library C API.

## Examples

```
import matlab.io.hdf4.*
sdID = sd.start('myfile.hdf','create');
sdsID = sd.create(sdID,'temperature','double',20);
dimID = sd.getDimID(sdsID,0);
sd.setDimName(dimID,'x');
sd.setDimStrs(dimID,'xdim','none','%d');
sd.endAccess(sdsID);
sd.close(sdID);
sdID = sd.start('myfile.hdf');
idx = sd.nameToIndex(sdID,'temperature');
sdsID = sd.select(sdID,idx);
dimID = sd.getDimID(sdsID,0);
[label,unit,fmt] = sd.getDimStrs(dimID);
sd.endAccess(sdsID);
sd.close(sdID);
```

## See Also

## matlab.io.hdf4.sd.getFilename

**Package:** matlab.io.hdf4.sd

Name of file

### Syntax

```
filename = getFilename(sdID)
```

### Description

`filename = getFilename(sdID)` retrieves the name of a file previously opened with the `sd` package with identifier `sdID`.

This function corresponds to the `SDgetfilename` function in the HDF library C API.

### Examples

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf');
filename = sd.getFilename(sdID);
sd.close(sdID);
```

# matlab.io.hdf4.sd.getFillValue

**Package:** matlab.io.hdf4.sd

Fill value for data set

## Syntax

```
fillvalue = getFillValue(sdsID)
```

## Description

`fillvalue = getFillValue(sdsID)` returns the fill value for a data set.

This function corresponds to the `SDgetfillvalue` function in the HDF library C API.

## Examples

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf');
idx = sd.nameToIndex(sdID, 'temperature');
sdsID = sd.select(sdID, idx);
fillvalue = sd.getFillValue(sdsID);
sd.endAccess(sdsID);
sd.close(sdID);
```

`sd.setFillValue`

# matlab.io.hdf4.sd.getInfo

**Package:** matlab.io.hdf4.sd

Information about data set

## Syntax

```
[name,dims,datatype,nattrs] = getInfo(sdsID)
```

## Description

`[name,dims,datatype,nattrs] = getInfo(sdsID)` returns the name, extents, and number of attributes of the data set identified by `sdsID`.

This function corresponds to the `SDgetinfo` function in the HDF library C API, but because MATLAB uses FORTRAN-style ordering, the `dims` parameter is reversed with respect to the C library API.

## Examples

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf');
idx = sd.nameToIndex(sdID,'temperature');
sdsID = sd.select(sdID,idx);
[name,dims,datatype,nattrs] = sd.getInfo(sdsID);
sd.endAccess(sdsID);
sd.close(sdID);
```

## See Also

# matlab.io.hdf4.sd.getRange

**Package:** matlab.io.hdf4.sd

Maximum and minimum range values

## Syntax

```
[maxval,minval] = getRange(sdsID)
```

## Description

[maxval,minval] = getRange(sdsID) retrieves the "valid\_range" two-element attribute value.

This function corresponds to the SDgetrange function in the HDF library C API.

## Examples

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf');
idx = sd.nameToIndex(sdID,'temperature');
sdsID = sd.select(sdID,idx);
[maxval,minval] = sd.getRange(sdsID);
sd.endAccess(sdsID);
sd.close(sdID);
```

## See Also

sd.setRange

## matlab.io.hdf4.sd.idToRef

**Package:** matlab.io.hdf4.sd

Reference number corresponding to data set identifier

### Syntax

```
ref = idToRef(sdsID)
```

### Description

`ref = idToRef(sdsID)` returns the reference number corresponding to the data set.

This function corresponds to the `SDidtoref` function in the HDF library C API.

### Examples

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf');
idx = sd.nameToIndex(sdID, 'temperature');
sdsID = sd.select(sdID, idx);
ref = sd.idToRef(sdsID);
sd.endAccess(sdsID);
sd.close(sdID);
```

### See Also

`sd.refToIndex`

# matlab.io.hdf4.sd.idType

**Package:** matlab.io.hdf4.sd

Type of object

## Syntax

```
objtype = idType(objID)
```

## Description

`objtype = idType(objID)` returns the type of object that `objID` represents. Possible values for `objtype` are:

'NOT_SDAPI_ID'	The object is not an HDF SD identifier.
'SD_ID'	The object is an SD identifier (file handle) .
'SDS_ID'	The object is a data set identifier.
'DIM_ID'	The object is a dimension identifier.

This function corresponds to the `SDidtype` function in the HDF library C API.

## Examples

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf');
objType = sd.idType(sdID);
sd.close(sdID);
```

## matlab.io.hdf4.sd.isCoordVar

**Package:** matlab.io.hdf4.sd

Determine if data set is a coordinate variable

### Syntax

```
TF = isCoordVar(sdsID)
```

### Description

`TF = isCoordVar(sdsID)` returns `true` if a data set is a coordinate variable and returns `false` otherwise.

This function corresponds to the `SDiscoordvar` function in the HDF library C API.

### Examples

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf');
ndataset = sd.fileInfo(sdID);
for idx = 0:ndataset-1
 sdsID = sd.select(sdID,idx);
 sdsName = sd.getInfo(sdsID);
 fprintf('%s (index %d) ', sdsName, idx);
 if (sd.isCoordVar(sdsID))
 fprintf('is a coordinate variable.\n');
 else
 fprintf('is not a coordinate variable.\n');
 end
 sd.endAccess(sdsID);
end
sd.close(sdID);
```

### See Also

`sd.isRecord`

# matlab.io.hdf4.sd.isRecord

**Package:** matlab.io.hdf4.sd

Determine if data set is appendable

## Syntax

```
TF = isRecord(sdsID)
```

## Description

`TF = isRecord(sdsID)` determines if the data set specified by `sdsID` is appendable, meaning that the slowest changing dimension is unlimited.

This function corresponds to the `SDisrecord` function in the HDF library C API.

## Examples

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf');
ndataset = sd.fileInfo(sdID);
for idx = 0:ndataset-1
 sdsID = sd.select(sdID,idx);
 sdsName = sd.getInfo(sdsID);
 if sd.isRecord(sdsID)
 fprintf('%s is a record variable.\n',sdsName);
 else
 fprintf('%s is not a record variable.\n',sdsName);
 end
 sd.endAccess(sdsID);
end
sd.close(sdID);
```

## See Also

`sd.isCoordVar`

## matlab.io.hdf4.sd.nameToIndex

**Package:** matlab.io.hdf4.sd

Index value of named data set

### Syntax

```
idx = nameToIndex(sdID,sdsname)
```

### Description

`idx = nameToIndex(sdID,sdsname)` returns the index of the data set with the name specified by `sdsname`. If there is more than one data set with the same name, the routine returns the index of the first one.

This function corresponds to the `SDnametoindex` function in the HDF C API.

### Examples

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf','read');
idx = sd.nameToIndex(sdID,'temperature');
sd.close(sdID);
```

### See Also

`sd.select`

# matlab.io.hdf4.sd.nameToIndices

**Package:** matlab.io.hdf4.sd

List of data sets with same name

## Syntax

```
varstruct = nameToIndices(sdID,sdsname)
```

## Description

`varstruct = nameToIndices(sdID,sdsname)` returns a structure array for all data sets with the same name. Each element of `varstruct` has two fields.

'index'	Index of data set
'type'	Type of data set, either 'SDSVAR', 'COORDVAR', or 'UNKNOWN'

This function corresponds to the `SDnametoindices` function in the HDF library C API.

## Examples

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf');
varlist = sd.nameToIndices(sdID, 'latitude');
sd.close(sdID);
```

## See Also

`sd.isCoordVar` | `sd.setDimScale`

## matlab.io.hdf4.sd.readAttr

**Package:** matlab.io.hdf4.sd

Read attribute value

### Syntax

```
data = readAttr(objID,idx)
```

### Description

`data = readAttr(objID,idx)` reads the value of the attribute specified by index `idx`. The `objID` input can be an SD interface identifier, a data set identifier, or a dimension identifier. `idx` is a zero-based index.

This function corresponds to the `SDreadattr` function in the HDF library C API.

### Examples

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf');
idx = sd.findAttr(sdID,'creation_date');
data = sd.readAttr(sdID,idx);
sd.close(sdID);
```

### See Also

`sd.findAttr` | `sd.setAttr`

# matlab.io.hdf4.sd.readChunk

**Package:** matlab.io.hdf4.sd

Read chunk from data set

## Syntax

```
datachunk = readChunk(sdsID,origin)
```

## Description

`datachunk = readChunk(sdsID,origin)` reads an entire chunk of data from the data set identified by `sdsID`. The `origin` input specifies the location of the chunk in zero-based chunking coordinates, not in data set coordinates.

This function corresponds to the `SDreadchunk` function in the HDF library C API, but because MATLAB uses FORTRAN-style ordering, the `origin` parameter is reversed with respect to the C library API.

## Examples

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf');
idx = sd.nameToIndex(sdID,'temperature');
sdsID = sd.select(sdID,idx);
dataChunk = sd.readChunk(sdsID,[0 1]);
sd.endAccess(sdsID);
sd.close(sdID);
```

## See Also

`sd.writeChunk` | `sd.writeData`

## matlab.io.hdf4.sd.readData

**Package:** matlab.io.hdf4.sd

Read subsample of data

### Syntax

```
data = readData(sdsID)
data = readData(sdsID,start,count)
data = readData(sdsID,start,count,stride)
```

### Description

`data = readData(sdsID)` reads all of the data for the data set identified by `sdsID`.

`data = readData(sdsID,start,count)` reads a contiguous hyperslab of data from the data set identified by `sdsID`. The `start` input specifies the starting position from where the hyperslab is read. `count` specifies the number of values to read along each data set dimension.

`data = readData(sdsID,start,count,stride)` reads a strided hyperslab of data from the data set identified by `sdsID`.

`start`, `count`, and `stride` use zero-based indexing.

This function corresponds to the `SDreaddata` function in the HDF library C API, but because MATLAB uses FORTRAN-style ordering, the `start`, `count`, and `stride` parameters are reversed with respect to the C library API.

### Examples

Read an entire data set.

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf');
idx = sd.nameToIndex(sdID,'temperature');
```

```
sdsID = sd.select(sdID,idx);
data = sd.readData(sdsID);
sd.endAccess(sdsID);
sd.close(sdID);
```

Read a 2-by-3 portion of a data set.

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf');
idx = sd.nameToIndex(sdID,'temperature');
sdsID = sd.select(sdID,idx);
data = sd.readData(sdsID,[0 0],[2 3]);
sd.endAccess(sdsID);
sd.close(sdID);
```

## See Also

## matlab.io.hdf4.sd.refToIndex

**Package:** matlab.io.hdf4.sd

Index of data set corresponding to reference number

### Syntax

```
idx = refToIndex(sdID,ref)
```

### Description

`idx = refToIndex(sdID,ref)` returns the index of the data set identified by its reference number `ref`. The `idx` output can then be passed to `sd.select`, to obtain a data set identifier.

This function corresponds to the `SDrefToIndex` function in the HDF library C API.

### Examples

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf','read');
idx = sd.nameToIndex(sdID,'temperature');
sdsID = sd.select(sdID,idx);
ref = sd.idToRef(sdsID);
idx2 = sd.refToIndex(sdID,ref);
sd.endAccess(sdsID);
sd.close(sdID);
```

# matlab.io.hdf4.sd.select

**Package:** matlab.io.hdf4.sd

Identifier of data set with specified index

## Syntax

```
sdsID = select(sdID,IDX)
```

## Description

`sdsID = select(sdID,IDX)` returns the identifier of the data set specified by its index.

This function corresponds to the `SDselect` function in the HDF C library.

## Examples

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf','read');
idx = sd.nameToIndex(sdID,'temperature');
sdsID = sd.select(sdID,idx);
sd.endAccess(sdsID);
sd.close(sdID);
```

## See Also

`sd.endAccess` | `sd.nameToIndex`

# matlab.io.hdf4.sd.setAttr

**Package:** matlab.io.hdf4.sd

Write attribute value

## Syntax

setAttr(objID,name,value)

## Description

setAttr(objID,name,value) attaches an attribute to the object specified by objID. If objID is the SD interface identifier, then a global attribute is created. If a data identifier is specified, then the attribute is attached to the data set. If a dimension identifier is specified, then the attribute is attached to the dimension.

This function corresponds to the SDsetattr function in the HDF library C API.

## Examples

Attach attributes to a file, a data set, and to a dimension.

```
import matlab.io.hdf4.*
sdID = sd.start('myfile.hdf','create');
sd.setAttr(sdID,'creation_date',datestr(now));
sdsID = sd.create(sdID,'temperature','double',[10 20]);
sd.setAttr(sdsID,'long_name','Temperature in sunlight.');
```

```
dimID0 = sd.getDimID(sdsID,0);
sd.setAttr(dimID0,'long_name','latitude');
sd.endAccess(sdsID);
sd.close(sdID);
```

## See Also

# matlab.io.hdf4.sd.setCal

**Package:** matlab.io.hdf4.sd

Set data set calibration information

## Syntax

```
setCal(sdsID,cal,calErr,offset,offsetErr,datatype)
```

## Description

`setCal(sdsID,cal,calErr,offset,offsetErr,datatype)` sets the calibration information for a data set.

This function corresponds to the `SDsetcal` function in the HDF library C API.

## Examples

```
import matlab.io.hdf4.*
sdID = sd.start('myfile.hdf','create');
sdsID = sd.create(sdID,'temperature','double',[10 20]);
sd.setDataStrs(sdsID,'Temperature','degrees_kelvin','%.3f','spherical');
sd.setCal(sdsID,1,0,273,0,'double');
sd.endAccess(sdsID);
sd.close(sdID);
```

## See Also

`sd.getCal`

# matlab.io.hdf4.sd.setChunk

**Package:** matlab.io.hdf4.sd

Set chunk size and compression method of data set

## Syntax

```
setChunk(sdsID, chunkSize, comptype, compparm)
```

## Description

`setChunk(sdsID, chunkSize, comptype, compparm)` makes the data set specified by `sdsID` a chunked data set with chunk size given by `chunkSize` and compression specified by `comptype` and `compparm`. The `comptype` input can be one of the following strings.

'none'	No compression
'skphuff'	Skipping Huffman compression
'deflate'	GZIP compression
'rle'	Run-length encoding

- If `comptype` is 'none' or 'rle', then `compparm` need not be specified.
- If `comptype` is 'skphuff', then `compparm` is the skipping size.
- If `comptype` is 'deflate', then `compparm` is the deflate level, which must be between 0 and 9.

This function corresponds to the `SDsetchunk` function in the HDF library C API, but because MATLAB uses FORTRAN-style ordering, the `chunkSize` parameter is reversed with respect to the C library API.

## Examples

```
import matlab.io.hdf4.*
```

```
sdID = sd.start('myfile.hdf','create');
sdsID = sd.create(sdID,'temperature','double',[200 100]);
sd.setChunk(sdsID,[20 10],'skphuff',16);
sd.endAccess(sdsID);
sd.close(sdID);
```

## See Also

# matlab.io.hdf4.sd.setCompress

**Package:** matlab.io.hdf4.sd

Set compression method of data set

## Syntax

```
setCompress(sdsID,comptype,compparm)
```

## Description

`setCompress(sdsID,comptype,compparm)` sets the compression scheme for the specified data set. The compression must be done before writing the data set. `comptype` can be one of the following strings.

'none'	No compression
'skphuff'	Skipping Huffman compression
'deflate'	GZIP compression
'rle'	Run-length encoding

- If `comptype` is 'none' or 'rle', then `compparm` need not be specified.
- If `comptype` is 'skphuff', then `compparm` is the skipping size.
- If `comptype` is 'deflate', then `compparm` is the deflate level, which must be between 0 and 9.

This function corresponds to the `SDsetcompress` function in the HDF library C API.

## Examples

```
import matlab.io.hdf4.*
sdID = sd.start('myfile.hdf','create');
sdsID = sd.create(sdID,'temperature','double',[200 100]);
sd.setCompress(sdsID,'deflate',5);
data = rand(200,100);
```

```
sd.writeData(sdsID,[0 0],data);
sd.endAccess(sdsID);
sd.close(sdID);
```

**See Also**

`sd.setChunk`

## matlab.io.hdf4.sd.setDataStrs

**Package:** matlab.io.hdf4.sd

Set predefined attributes for data set

### Syntax

```
setDataStrs(sdsID,label,unit,format,coordsys)
```

### Description

`setDataStrs(sdsID,label,unit,format,coordsys)` sets the predefined attributes 'long\_name', 'units', 'format', and 'coordsys' for a data set.

This function corresponds to the `SDsetdatastrs` function in the HDF library C API.

### Examples

```
import matlab.io.hdf4.*
sdID = sd.start('myfile.hdf','create');
sdsID = sd.create(sdID,'temperature','double',[10 20]);
sd.setDataStrs(sdsID,'degrees_celsius','degrees_east','', 'geo');
sd.endAccess(sdsID);
sd.close(sdID);
```

`sd.getDataStrs` | `sd.setDimStrs`

# matlab.io.hdf4.sd.setDimName

**Package:** matlab.io.hdf4.sd

Associate name with dimension

## Syntax

```
setDimName(dimID,dimname)
```

## Description

`setDimName(dimID,dimname)` sets the name of the dimension identified by `dimID` to `dimname`.

This function corresponds to the `SDsetdimname` function in the HDF library C API.

## Examples

Create a 2D data set with dimensions 'lat' and 'lon'.

```
import matlab.io.hdf4.*
sdID = sd.start('myfile.hdf','create');
sdsID = sd.create(sdID,'temperature','double',[10 20]);
dimID = sd.getDimID(sdsID,0);
sd.setDimName(dimID,'lat');
dimID = sd.getDimID(sdsID,1);
sd.setDimName(dimID,'lon');
sd.endAccess(sdsID);
sd.close(sdID);
```

## See Also

`sd.dimInfo`

## matlab.io.hdf4.sd.setDimScale

**Package:** matlab.io.hdf4.sd

Set scale values for dimension

### Syntax

```
setDimScale(dimID,scaledata)
```

### Description

`setDimScale(dimID,scaledata)` sets the scale values for a dimension.

This function corresponds to the `SDsetdimscale` function in the HDF library C API.

### Examples

Create a 2D data set with dimensions 'lat' and 'lon'.

```
import matlab.io.hdf4.*
sdID = sd.start('myfile.hdf','create');
sdsID = sd.create(sdID,'temperature','double',[10 20]);
dimID = sd.getDimID(sdsID,0);
sd.setDimName(dimID,'lat');
sd.setDimScale(dimID,0:10:90);
dimID = sd.getDimID(sdsID,1);
sd.setDimName(dimID,'lon');
sd.setDimScale(dimID, -180:18:179);
sd.endAccess(sdsID);
sd.close(sdID);
```

### See Also

`sd.getDimScale`

# matlab.io.hdf4.sd.setDimStrs

**Package:** matlab.io.hdf4.sd

Set label, unit, and format attribute strings

## Syntax

```
setDimStrs(dimID,label,unit,format)
```

## Description

`setDimStrs(dimID,label,unit,format)` sets the label, unit, and format attributes for the dimension identified by `dimID`.

This function corresponds to the `SDsetdimstrs` function in the HDF library C API.

## Examples

```
import matlab.io.hdf4.*
sdID = sd.start('myfile.hdf','create');
sdsID = sd.create(sdID,'temperature','double',[10 20]);
dimID = sd.getDimID(sdsID,0);
sd.setDimName(dimID,'lat');
dimID = sd.getDimID(sdsID,1);
sd.setDimName(dimID,'lon');
sd.setDimStrs(dimID,'Degrees of Longitude','degrees_east','%.2f');
sd.endAccess(sdsID);
sd.close(sdID);
```

## See Also

`sd.getDimStrs`

## matlab.io.hdf4.sd.setExternalFile

**Package:** matlab.io.hdf4.sd

Store data in external file

### Syntax

```
setExternalFile(sdsID,extfile,offset)
```

### Description

`setExternalFile(sdsID,extfile,offset)` moves data values (not metadata) into the external data file `extfile` starting at the byte offset, `offset`.

Data can only be moved once for any given data set. The external file should be kept with the main file.

This function corresponds to the `SDsetexternalfile` function in the HDF library C API.

### Examples

```
import matlab.io.hdf4.*
sdID = sd.start('myfile.hdf','create');
sdsID = sd.create(sdID,'temperature','double',[10 20]);
sd.setExternalFile(sdsID,'myExternalFile.dat',0);
sd.writeData(sdsID,[0 0],rand(10,20));
sd.endAccess(sdsID);
sd.close(sdID);
```

### See Also

`sd.create` | `sd.writeData`

# matlab.io.hdf4.sd.setFillMode

**Package:** matlab.io.hdf4.sd

Set current fill mode of file

## Syntax

```
prevmode = setFillMode(sdID,fillmode)
```

## Description

`prevmode = setFillMode(sdID,fillmode)` returns the previous fill mode of a file and resets it to `fillmode`. This setting applies to all data sets contained in the file identified by `sdID`.

Possible values of `fillmode` are `'fill'`, and `'nofill'`. `'fill'` is the default mode and indicates that fill values will be written when the data set is created. `'nofill'` indicates that the fill values will not be written.

When a fixed-size data set is created, the first call to `sd.writeData` will fill the entire data set with the default or user-defined fill value if `fillmode` is `'fill'`. In data sets with an unlimited dimension, if a new write operation takes place along the unlimited dimension beyond the last location of the previous write operation, the array locations between these written areas will be initialized to the user-defined fill value, or the default fill value if a user-defined fill value has not been specified.

If it is certain that all data set values will be written before any read operation takes place, there is no need to write the fill values. Calling `sd.setFillMode` with `'nofill'` can improve performance in this case.

This function corresponds to the `SDsetfillmode` function in the HDF library C API.

## Examples

Write two partial records. Write the first in `'nofill'` mode, and the second with `'fill'` mode.

```
import matlab.io.hdf4.*
sdID = sd.start('myfile.hdf','create');
sd.setFillMode(sdID,'nofill');
sdsID = sd.create(sdID,'temperature','double',[10 10 0]);
sd.writeData(sdsID,[0 0 0], rand(5,5));
sd.setFillMode(sdID,'fill');
sd.setFillValue(sdsID,-999);
sd.writeData(sdsID,[0 0 1], rand(5,5));
sd.endAccess(sdsID);
sd.close(sdID);
```

## See Also

[sd.setFillValue](#) | [sd.setFillValue](#)

# matlab.io.hdf4.sd.setFillValue

**Package:** matlab.io.hdf4.sd

Set fill value for data set

## Syntax

```
setFillValue(sdsID,fillValue)
```

## Description

`setFillValue(sdsID,fillValue)` sets the fill value for a data set. The fill value must have the same data type as the data set.

This function corresponds to the `SDsetfillvalue` function in the HDF library C API.

## Examples

```
import matlab.io.hdf4.*
sdID = sd.start('myfile.hdf','create');
sdsID = sd.create(sdID,'temperature','double',[10 20]);
sd.setFillValue(sdsID,-999);
sd.endAccess(sdsID);
sd.close(sdID);
```

## See Also

`sd.getFillValue`

## matlab.io.hdf4.sd.setNBitDataSet

**Package:** matlab.io.hdf4.sd

Specify nonstandard bit length for data set values

### Syntax

```
setNBitDataSet(sdsID,startBit,bitlen,ext,fillone)
```

### Description

`setNBitDataSet(sdsID,startBit,bitlen,ext,fillone)` specifies that the integer data set identified by `sdsID` contains data of a non-standard length defined by `startBit` and `bitlen`.

Any length between 1 and 32 bits can be specified. After `setNBitDataset` has been called for the data set array, any read or write operation will involve conversion between the new data length of the data set array and the data length of the read or write buffer.

Bit lengths of all data types are counted from the right of the bit field starting with 0. In a bit field containing the values 01111011, bits 2 and 7 are set to 0 and all the other bits are set to 1. The least significant bit is bit 0.

The `startBit` parameter specifies the left-most position of the variable-length bit field to be written. For example, in the bit field described in the preceding paragraph a `startBit` parameter set to 4 would correspond to the fourth bit value of 1 from the right.

The parameter `bitlen` specifies the number of bits of the variable-length bit field to be written. This number includes the starting bit and the count proceeds toward the right end of the bit field - toward the lower-bit numbers. For example, starting at bit 5 and writing 4 bits of the bit field described in the preceding paragraph would result in the bit field 1110 being written to the data set. This would correspond to a `startBit` value of 5 and a `bitlen` value of 4.

The parameter `ext` specifies whether to use the left-most bit of the variable-length bit field to sign-extend to the left-most bit of the data set data. For example, if 9-bit signed integer data is extracted from bits 17-25 and the bit in position 25 is 1, then when the

data is read back from disk, bits 26-31 will be set to 1. Otherwise bit 25 will be 0 and bits 26-31 will be set to 0. The `ext` parameter can be set to `true` (or 1) or `false` (or 0); specify `true` to sign-extend.

The parameter `fillone` specifies whether to fill the "background" bits with the value 1 or 0. This parameter is also set to either `true` (or 1) or `false` (or 0).

The "background" bits of a non-standard length data set are the bits that fall outside of the non-standard length bit field stored on disk. For example, if five bits of an unsigned 16-bit integer data set located in bits 5 to 9 are written to disk with the parameter `fillone` set to `true` (or 1), then when the data is reread into memory bits 0 to 4 and 10 to 15 would be set to 1. If the same 5-bit data was written with a `fillone` value of `false` (or 0), then bits 0 to 4 and 10 to 15 would be set to 0.

The operation on `fillone` is performed before the operation on `ext`. For example, using the `ext` example above, bits 0 to 16 and 26 to 31 will first be set to the background bit value, and then bits 26 to 31 will be set to 1 or 0 based on the value of the 25th bit.

This function corresponds to the `SDsetnbitdataset` in the HDF library C API.

## Examples

```
import matlab.io.hdf4.*
sdID = sd.start('myfile.hdf','create');
sdsID = sd.create(sdID,'temperature','int32',[10 20]);
sd.setNBitDataSet(sdsID,6,4,0,0);
data = int32([1:200]);
data = reshape(data,10,20);
sd.writeData(sdsID,[0 0],data);
sd.endAccess(sdsID);
sd.close(sdID);
```

## See Also

`sd.setCompress`

# matlab.io.hdf4.sd.setRange

**Package:** matlab.io.hdf4.sd

Set maximum and minimum range value for data set

## Syntax

```
setRange(sdsID,maxval,minval)
```

## Description

`setRange(sdsID,maxval,minval)` sets the maximum and minimum range values of the data set identified by `sdsID`. These values form the "valid\_range" attribute for `sdsID`.

The actual maximum and minimum values of the data set are not computed. The "valid\_range" attribute is for informational purposes only.

This function corresponds to the `SDsetrange` function in the HDF library C interface.

## Examples

```
import matlab.io.hdf4.*
sdID = sd.start('myfile.hdf','create');
sdsID = sd.create(sdID,'temperature','double',[10 20]);
sd.setDataStrs(sdsID,'Temperature','degrees_celsius','%2f',' ');
sd.setRange(sdsID,1000,-273.15);
sd.endAccess(sdsID);
sd.close(sdID);
```

## See Also

`sd.getRange`

# matlab.io.hdf4.sd.start

**Package:** matlab.io.hdf4.sd

Open HDF file and initialize SD interface

## Syntax

```
sdID = start(filename)
sdID = start(filename,access)
```

## Description

`sdID = start(filename)` opens the file `filename` in read-only mode. This routine must be called for each file before any other `sd` calls can be made on that file.

`sdID = start(filename,access)` opens the file `filename` with the access mode specified by `access`. This routine must be called before any other SD interface operations can be made on that file. `access` can be one of the following strings:

- 'read'
- 'write'
- 'create'

`access` defaults to 'read' if not supplied.

This function corresponds to the `SDstart` function in the HDF library C API.

## Examples

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf');
sd.close(sdID);
```

## See Also

`sd.close`

# matlab.io.hdf4.sd.writeChunk

**Package:** matlab.io.hdf4.sd

Write chunk to data set

## Syntax

```
writeChunk(sdsID,origin,dataChunk)
```

## Description

`writeChunk(sdsID,origin,dataChunk)` writes an entire chunk of data to the data set identified by `sdsID`. The `origin` input specifies the location of the chunk in chunking coordinates, not in data set coordinates.

This function corresponds to the `SDwritechunk` function in the HDF library C API, but because MATLAB uses FORTRAN-style ordering, the `origin` parameter is reversed with respect to the C library API.

## Examples

Write to a 2D chunked and compressed data set. The chunked layout constitutes a 10-by-5 grid.

```
import matlab.io.hdf4.*
sdID = sd.start('myfile.hdf','create');
sdsID = sd.create(sdID,'temperature','double',[100 50]);
sd.setChunk(sdsID,[10 10],'deflate',5);
for j = 0:9
 for k = 0:4
 origin = [j k];
 data = (1:100) + k*1000 + j*10000;
 data = reshape(data,10,10);
 sd.writeChunk(sdsID,origin,data);
 end
end
```

```
sd.endAccess(sdsID);
sd.close(sdID);
```

### **See Also**

[sd.readChunk](#) | [sd.writeData](#)

## matlab.io.hdf4.sd.writeData

**Package:** matlab.io.hdf4.sd

Write to data set

### Syntax

```
writeData(sdsID,data)
writeData(sdsID,start,data)
writeData(sdsID,start,stride,data)
```

### Description

`writeData(sdsID,data)` writes all the data to the data set identified by `sdsID`.

`writeData(sdsID,start,data)` writes a contiguous hyperslab to the data set. `start` specifies the zero-based starting index. The number of values along each dimension is inferred from the size of `data`.

`writeData(sdsID,start,stride,data)` writes a strided hyperslab of data to a grid datafield. The number of elements to write along each dimension is inferred either from the size of `data` or from the data set itself.

`start` and `stride` use zero-based indexing.

This function corresponds to the `SDreadchunk` function in the HDF library C API, but because MATLAB uses FORTRAN-style ordering, the `start` and `stride` parameters are reversed with respect to the C library API.

### Examples

Write to a 2D data set.

```
import matlab.io.hdf4.*
sdID = sd.start('myfile.hdf','create');
sdsID = sd.create(sdID,'temperature','double',[10 20]);
```

```
data = rand(10,20);
sd.writeData(sdsID,[0 0],data);
sd.endAccess(sdsID);
sd.close(sdID);
```

Write to a 2D unlimited data set.

```
import matlab.io.hdf4.*
sdID = sd.start('myfile.hdf','create');
sdsID = sd.create(sdID,'temperature','double',[10 0]);
data = rand(10,20);
sd.writeData(sdsID,[0 0],data);
data = rand(10,30);
sd.writeData(sdsID,[0 20],data);
sd.endAccess(sdsID);
sd.close(sdID);
```

`sd.readData`

# matlab.io.hdfEOS.gd

Low-level access to HDF-EOS grid data

## Description

To use these MATLAB functions, you must be familiar with the HDF-EOS library C interface. In most cases, the syntax of the MATLAB function is similar to the syntax of the corresponding HDF-EOS library function. The functions are implemented as the package `matlab.io.hdfEOS.gd`. To use this package, prefix the function name with a package path, or use the `import` function to add the package to the current import list, prior to calling the function, for example,

```
import matlab.io.hdfEOS.*
gfid = gd.open(filename,'read');
```

## Access

<code>matlab.io.hdfEOS.gd.attach</code>	Attach to existing grid
<code>matlab.io.hdfEOS.gd.close</code>	Close HDF-EOS grid file
<code>matlab.io.hdfEOS.gd.detach</code>	Detach from existing grid
<code>matlab.io.hdfEOS.gd.open</code>	Open grid file

## Definition

<code>matlab.io.hdfEOS.gd.create</code>	Create new grid structure
<code>matlab.io.hdfEOS.gd.defComp</code>	Set grid field compression
<code>matlab.io.hdfEOS.gd.defDim</code>	Define new dimension within grid

matlab.io.hdfEOS.gd.defField	Define new data field within grid
matlab.io.hdfEOS.gd.defOrigin	Define origin of pixels in grid
matlab.io.hdfEOS.gd.defPixReg	Define pixel registration within grid
matlab.io.hdfEOS.gd.defProj	Define grid projection
matlab.io.hdfEOS.gd.writeBlkSomOffset	Write Block SOM offset

## Basic I/O

matlab.io.hdfEOS.gd.getFillValue	Fill value for specified field
matlab.io.hdfEOS.gd.readAttr	Read grid attribute
matlab.io.hdfEOS.gd.readField	Read data from grid field
matlab.io.hdfEOS.gd.setFillValue	Set fill value for specified field
matlab.io.hdfEOS.gd.writeAttr	Write grid attribute
matlab.io.hdfEOS.gd.writeField	Write data to grid field

## Inquiry

matlab.io.hdfEOS.gd.compInfo	Compression information for field
matlab.io.hdfEOS.gd.dimInfo	Length of dimension

<code>matlab.io.hdfeos.gd.fieldInfo</code>	Information about data field
<code>matlab.io.hdfeos.gd.gridInfo</code>	Position and size of grid
<code>matlab.io.hdfeos.gd.inqAttrs</code>	Names of grid attributes
<code>matlab.io.hdfeos.gd.inqDims</code>	Information about dimensions defined in grid
<code>matlab.io.hdfeos.gd.inqFields</code>	Information about data fields defined in grid
<code>matlab.io.hdfeos.gd.inqGrid</code>	Names of grids in file
<code>matlab.io.hdfeos.gd.nEntries</code>	Number of specified objects
<code>matlab.io.hdfeos.gd.originInfo</code>	Origin code
<code>matlab.io.hdfeos.gd.pixRegInfo</code>	Pixel registration code
<code>matlab.io.hdfeos.gd.projInfo</code>	GCTP projection information about grid
<code>matlab.io.hdfeos.gd.readBlkSomOffset</code>	Read Block SOM offset

## **Subsetting**

<code>matlab.io.hdfeos.gd.defBoxRegion</code>	Define region of interest by latitude and longitude
<code>matlab.io.hdfeos.gd.defVrtRegion</code>	Define vertical subset region
<code>matlab.io.hdfeos.gd.extractRegion</code>	Read region of interest from field

matlab.io.hdfeos.gd.getPixels	Pixel rows and columns for latitude/ longitude pairs
matlab.io.hdfeos.gd.getPixValues	Read data values for specified pixels
matlab.io.hdfeos.gd.regionInfo	Information about subsetted region

## Tiling

matlab.io.hdfeos.gd.defTile	Define tiling parameters
matlab.io.hdfeos.gd.readTile	Read single tile of data from field
matlab.io.hdfeos.gd.setTileComp	Set tiling and compression for field with fill value
matlab.io.hdfeos.gd.tileInfo	Tile size of grid field
matlab.io.hdfeos.gd.writeTile	Write tile to field

## Utility

matlab.io.hdfeos.gd.ij2ll	Convert row and column space to latitude and longitude
matlab.io.hdfeos.gd.ll2ij	Convert latitude and longitude to row and column space
matlab.io.hdfeos.gd.sphereCodeToName	Name corresponding to GCTP sphere code

matlab.io.hdfEOS.gd.sphereNameToCode

Numeric GCTP code corresponding to  
sphere name

# matlab.io.hdfeos.gd.attach

**Package:** matlab.io.hdfeos.gd

Attach to existing grid

## Syntax

```
gridID = attach(gfID,gridName)
```

## Description

`gridID = attach(gfID,gridName)` attaches to the grid dataset identified by `gridName` in the file identified by `gfID`. The `gridID` output is the identifier for the grid dataset.

This function corresponds to the `GDattach` function in the HDF-EOS library C API.

## Examples

Attach to the grid named 'PolarGrid' in the file 'grid.hdf'.

```
import matlab.io.hdfeos.*
gfID = gd.open('grid.hdf');
gridID = gd.attach(gfID,'PolarGrid');
gd.detach(gridID);
gd.close(gfID);
```

## See Also

`gd.detach` | `gd.inqGrid` | `gd.readField`

## matlab.io.hdfEOS.gd.close

**Package:** matlab.io.hdfEOS.gd

Close HDF-EOS grid file

### Syntax

```
close(gfID)
```

### Description

`close(gfID)` closes an HDF-EOS grid file identified by `gfID`.

This function corresponds to the `GDClose` function in the HDF-EOS library C API.

### Examples

```
import matlab.io.hdfEOS.*
gfID = gd.open('grid.hdf');
gd.close(gfID);
```

### See Also

`gd.create` | `gd.open`

# matlab.io.hdfEOS.gd.compInfo

**Package:** matlab.io.hdfEOS.gd

Compression information for field

## Syntax

```
[compCode,parms] = compInfo(gridID,fieldname)
```

## Description

[compCode,parms] = compInfo(gridID,fieldname) returns the compression code and compression parameters for a given field. Refer to `gd.defComp` for a description of various compression schemes and parameters.

This function corresponds to the `GDcompinfo` function in the HDF-EOS library C API.

## Examples

Get compression information for the `ice_temp` field.

```
import matlab.io.hdfEOS.*
gfid = gd.open('grid.hdf');
gridID = gd.attach(gfid,'PolarGrid');
[compCode,compParms] = gd.compInfo(gridID,'ice_temp');
gd.detach(gridID);
gd.close(gfid);
```

## See Also

`gd.defComp`

## matlab.io.hdfEOS.gd.create

**Package:** matlab.io.hdfEOS.gd

Create new grid structure

### Syntax

```
gridID = create(gfID,gridName,xdim,ydim,upLeft,lowRight)
```

### Description

`gridID = create(gfID,gridName,xdim,ydim,upLeft,lowRight)` creates a new grid structure where `gfID` is the grid file identifier. `gridName` is the name of the new grid. `xdim` and `ydim` define the size of the grid. `upLeft` is a two-element vector containing the location of the upper left pixel, and `lowRight` is a two-element vector containing the location of the lower right pixel.

---

**Note:** `upLeft` and `lowRight` are in units of meters for all GCTP projections other than the geographic and bcea projections, which should have units of packed degrees.

---

---

**Note:** For certain projections, `upLeft` and `lowRight` can be given as [ ].

- Polar Stereographic projection of an entire hemisphere.
  - Goode Homolosine projection of the entire globe.
  - Lambert Azimuthal entire polar or equatorial projection.
- 

---

**Note:** MATLAB uses Fortran-style ordering, but the HDF-EOS library uses C-style ordering.

---

This function corresponds to the `GDcreate` function in the HDF-EOS library C API.

## Examples

Create a polar stereographic grid of the northern hemisphere.

```
import matlab.io.hdfeos.*
gfid = gd.open('myfile.hdf','create');
gridID = gd.create(gfid,'PolarGrid',100,100,[],[]);
gd.detach(gridID);
gd.close(gfid);
```

Create a UTM grid bounded by 54 E to 60 E longitude and 20 N to 30 N latitude. Divide the grid into 120 bins along the x-axis and 200 bins along the y-axis.

```
import matlab.io.hdfeos.*
gfid = gd.open('myfile.hdf','create');
uplft = [210584.50041 3322395.95445];
lowrgt = [813931.10959 2214162.53278];
gridID = gd.create(gfid,'UTMGrid',120,200,uplft,lowrgt);
gd.detach(gridID);
gd.close(gfid);
```

## See Also

[gd.defProj](#) | [gd.detach](#) | [gd.gridInfo](#)

## matlab.io.hdfEOS.gd.defBoxRegion

**Package:** matlab.io.hdfEOS.gd

Define region of interest by latitude and longitude

### Syntax

```
regionID = defBoxRegion(gridID,cornerLat,cornerLon)
```

### Description

`regionID = defBoxRegion(gridID,cornerLat,cornerLon)` defines a latitude-longitude box region as a subset region for a grid. `regionID` can be used to read all the entries of a data field within the region.

This function corresponds to the `GDdefboxregion` function in the HDF-EOS library C API.

### Examples

Define a region of interest between 20 and 50 degrees latitude and between -90 and -60 degrees longitude.

```
import matlab.io.hdfEOS.*
gfid = gd.open('grid.hdf','read');
gridID = gd.attach(gfid,'PolarGrid');
cornerlat = [20 50];
cornerlon = [-90 -60];
regionID = gd.defBoxRegion(gridID,cornerlat,cornerlon);
data = gd.extractRegion(gridID,regionID,'ice_temp');
gd.detach(gridID);
gd.close(gfid);
```

### See Also

`gd.extractRegion`

# matlab.io.hdfEOS.gd.defComp

**Package:** matlab.io.hdfEOS.gd

Set grid field compression

## Syntax

```
defComp(gridID,compscheme,compparm)
```

## Description

`defComp(gridID,compscheme,compparm)` sets the HDF field compression for subsequent field definitions. The compression scheme does not apply to one-dimensional fields. `compscheme` can be one of the following strings.

'rle'	Run-length encoding
'skphuff'	Skipping Huffman
'deflate'	Gzip deflate
'none'	No compression

When the compression scheme is 'deflate', `compparm` is the deflate compression level, an integer between 0 and 9. `compparm` can be omitted for the other compression schemes.

If a field is defined with compression, it must be written with a single call to `gd.writeField`. If this is not possible, you should consider using tiling.

This function corresponds to the `GDdefcomp` function in the HDF-EOS library C API.

## Examples

Create a grid with a polar stereographic `Pressure` field using run-length encoding, and then an `Opacity` field with deflate compression.

```
import matlab.io.hdfEOS.*
```

```
gfid = gd.open('myfile.hdf','create');
gridID = gd.create(gfid,'PolarGrid',100,100,[],[]);
projparm = zeros(1,13);
projparm(6) = 90000000;
gd.defProj(gridID,'ps',[],'WGS 84',projparm);
dims = { 'XDim', 'YDim' };
gd.defComp(gridID,'rle');
gd.defField(gridID,'Pressure',dims,'float');
gd.defComp(gridID,'deflate',5);
gd.defField(gridID,'Opacity',dims,'float');
gd.detach(gridID);
gd.close(gfid);
```

## See Also

[gd.defField](#) | [gd.defTile](#)

# matlab.io.hdfEOS.gd.defDim

**Package:** matlab.io.hdfEOS.gd

Define new dimension within grid

## Syntax

```
defDim(gridID,dimname,dimlen)
```

## Description

`defDim(gridID,dimname,dimlen)` defines a new dimension named `dimname` with length `dimlen` in the grid structure identified by `gridID`.

To specify an unlimited dimension, you can use either 0 or 'unlimited' for `dimlen`.

This function corresponds to the `GDdefdim` function in the HDF-EOS library C API.

## Examples

Define a dimension 'Band' with length of 15 and an unlimited dimension 'Time'.

```
import matlab.io.hdfEOS.*
gfid = gd.open('myfile.hdf','create');
gridID = gd.create(gfid,'PolarGrid',100,100,[],[]);
gd.defDim(gridID,'Band',15);
gd.defDim(gridID,'Time',0);
gd.detach(gridID);

# matlab.io.hdfEOS.gd.defField

**Package:** matlab.io.hdfEOS.gd

Define new data field within grid

## Syntax

```
defField(gridID,fieldname,dimlist,dtype)
defField(gridID,fieldname,dimlist,dtype,mergeCode)
```

## Description

`defField(gridID,fieldname,dimlist,dtype)` defines data fields for a grid specified by `gridID`. The `fieldname` input is the name of the new field. `dimlist` is a cell array of geolocation dimensions and should be listed in FORTRAN-style order, that is, the fastest varying dimension should be listed first. `dimlist` can also be a string if there is only one dimension. `dtype` is the data type of the field.

`defField(gridID,fieldname,dimlist,dtype,mergeCode)` defines a data field with a specific merge code. `mergeCode` can be either 'nomerge' or 'automerge'. The `mergeCode` input defaults to 'nomerge' if not provided.

This function corresponds to the `GDdefField` function in the HDF library C API, but because MATLAB uses FORTRAN-style ordering, the `dimlist` parameter is reversed with respect to the C library API.

## Examples

Define a single precision grid field 'Temperature' with dimensions 'XDim' and 'YDim'. Then define a single precision field 'Spectra' with dimensions 'XDim', 'YDim', and 'Bands'.

```
import matlab.io.hdfEOS.*
gfid = gd.open('myfile.hdf','create');
xdim = 120; ydim = 200;
gridID = gd.create(gfid,'geo',xdim,ydim,[],[]);
```

```
gd.defProj(gridID,'geo',[],[],[]);
dimlist = {'XDim','YDim'};
gd.defField(gridID,'Temperature',dimlist,'single');
gd.defDim(gridID,'Bands',3);
dimlist = {'XDim','YDim','Bands'};
gd.defField(gridID,'Spectra',dimlist,'uint8');
gd.detach(gridID);
gd.close(gfid);
```

## See Also

## matlab.io.hdfEOS.gd.defOrigin

**Package:** matlab.io.hdfEOS.gd

Define origin of pixels in grid

### Syntax

```
defOrigin(gridID,originCode)
```

### Description

`defOrigin(gridID,originCode)` defines the origin of pixels in a grid. `gridID` is the identifier of the grid, and `originCode` can be one of the following four strings.

'ul'	Upper-left
'ur'	Upper-right
'll'	Lower-left
'lr'	Lower-right

You can select any corner of the grid pixel as the origin. If this routine is not invoked, the grid defaults to using the upper-left corner for the origin.

This function corresponds to the `GDdeforigin` function in the HDF-EOS library C API.

### Examples

Create a polar stereographic grid with the origin of the grid pixel in the lower right corner.

```
import matlab.io.hdfEOS.*
gfid = gd.open('myfile.hdf','create');
gridID = gd.create(gfid,'PolarGrid',100,100,[],[]);
projparm = zeros(1,13);
projparm(6) = 90000000;
gd.defProj(gridID,'ps',[],'WGS 84',projparm);
```

```
gd.defOrigin(gridID, 'lr');
gd.detach(gridID);
gd.close(gfid);
```

**See Also**

[gd.defPixReg](#) | [gd.originInfo](#)

## matlab.io.hdfEOS.gd.defPixReg

**Package:** matlab.io.hdfEOS.gd

Define pixel registration within grid

### Syntax

```
defPixReg(gridID,pixRegCode)
```

### Description

`defPixReg(gridID,pixRegCode)` defines whether the pixel center or pixel corner is used when requesting the location (longitude and latitude) of a given pixel. `pixRegCode` can be one of the following strings.

'center'	Center of pixel cell
'corner'	Corner of pixel cell

If this routine is not invoked, the pixel registration is 'center'.

This function corresponds to the `GDdefpixreg` function in the HDF-EOS library.

### Examples

Define a grid with pixel registration in the center.

```
import matlab.io.hdfEOS.*
gfid = gd.open('myfile.hdf','create');
gridID = gd.create(gfid,'PolarGrid',100,100,[],[]);
projparm = zeros(1,13);
projparm(6) = 90000000;
gd.defProj(gridID,'ps',[],'WGS 84',projparm);
gd.defPixReg(gridID,'corner');
gd.detach(gridID);
gd.close(gfid);
```

## See Also

`gd.defOrigin` | `gd.pixRegInfo`

## matlab.io.hdfeos.gd.defProj

**Package:** matlab.io.hdfeos.gd

Define grid projection

### Syntax

defProj(gridID,projCode,zoneCode,sphereCode,projParm)

### Description

defProj(gridID,projCode,zoneCode,sphereCode,projParm) defines a GCTP projection on the grid specified by gridID. The projCode argument can be one of the following strings.

'geo'	Geographic
'utm'	Universal Transverse Mercator
'albers'	Albers Canonical Equal Area
'lamcc'	Lambert Conformal Conic
'ps'	Polar Stereographic
'polyc'	Polyconic
'tm'	Transverse Mercator
'lamaz'	Lambert Azimuthal Equal Area
'snsoid'	Sinusoidal
'hom'	Hotine Oblique Mercator
'som'	Space Oblique Mercator
'good'	Interrupted Goode Homolosine
'cea'	Cylindrical Equal Area
'bcea'	Behrmann Cylindrical Equal Area
'isinus'	Integerized Sinusoidal

If `projCode` is `'geo'`, then `zoneCode`, `sphereCode`, and `projParm` should be specified as `[]`. Any other values for these parameters are ignored.

`zoneCode` is the Universal Transverse Mercator zone code. It should be specified as `-1` for other projections.

`sphereCode` is the name of the GCTP spheroid or the corresponding numeric code.

`projParm` is a vector of up to 13 elements containing projection-specific parameters. For more details about `projCode`, `zoneCode`, `sphereCode`, and `projParm`, see Chapter 6 of HDF-EOS Library Users Guide for the ECS Project, Volume 1: Overview and Examples.

This function corresponds to the `GDdefproj` function in the HDF library C API.

## Examples

Create a UTM grid bounded by 54 E to 60 E longitude and 20 N to 30 N latitude (zone 40). Divide the grid into 120 bins along the x-axis and 200 bins along the y-axis.

```
import matlab.io.hdfEOS.*
gfid = gd.open('myfile.hdf','create');
uplft = [210584.50041 3322395.95445];
lowrgt = [813931.10959 2214162.53278];
gridID = gd.create(gfid,'UTMGrid',120,200,uplft,lowrgt);
gd.defProj(gridID,'utm',40,'Clarke 1866',[]);
gd.detach(gridID);
gd.close(gfid);
```

Add a polar stereographic projection of the northern hemisphere with true scale at 90 N, 0 longitude below the pole using the WGS 84 spheroid.

```
import matlab.io.hdfEOS.*
gfid = gd.open('myfile.hdf','create');
gridID = gd.create(gfid,'PolarGrid',100,100,[],[]);
projparm = zeros(1,13);
projparm(6) = 90000000;
gd.defProj(gridID,'ps',[],'WGS 84',projparm);
gd.detach(gridID);
gd.close(gfid);
```

# matlab.io.hdfEOS.gd.defTile

**Package:** matlab.io.hdfEOS.gd

Define tiling parameters

## Syntax

```
defTile(gridID, tileDims)
```

## Description

`defTile(gridID, tileDims)` defines tiling dimensions for subsequent field definitions. If `tileDims` is `[]`, then subsequently defined fields will have no tiling.

This function corresponds to the `GDdeftile` function in the HDF-EOS library C API, but because MATLAB uses FORTRAN-style ordering, the `tileDims` parameter is reversed with respect to the C library API.

## Examples

Define a field with tiling, then a subsequent field with no tiling.

```
import matlab.io.hdfEOS.*
gfid = gd.open('myfile.hdf', 'create');
gridID = gd.create(gfid, 'GeoGrid', 120, 200, [], []);
gd.defDim(gridID, 'Bands', 3);
gd.defProj(gridID, 'geo', [], [], []);
gd.defTile(gridID, [30 50 1]);
dimlist = {'XDim', 'YDim', 'Bands'};
gd.defField(gridID, 'Spectra', dimlist, 'float');
gd.defTile(gridID, []);
dimlist = {'XDim', 'YDim'};
gd.defField(gridID, 'Temperature', dimlist, 'int32');
gd.detach(gridID);
gd.close(gfid);
```

## See Also

`gd.defField` | `gd.tileInfo`

# matlab.io.hdfEOS.gd.defVrtRegion

**Package:** matlab.io.hdfEOS.gd

Define vertical subset region

## Syntax

```
out_RID = defVrtRegion(gridID,regionID,vobj,vRange)
```

## Description

`out_RID = defVrtRegion(gridID,regionID,vobj,vRange)` defines a vertical subset region and can be used on either a monotonic field or contiguous elements of a dimension.

`regionID` should be 'noprevious' if no prior subsetting has occurred. Otherwise it should be a value as returned from a previous subsetting routine.

`vobj` is the name of either the dimension or field to subset. If `vobj` is a dimension, it should be prefixed with 'DIM: '.

`vRange` is the minimum and maximum range for the vertical subset.

This function corresponds to the `GDdefvrtregion` function in the HDF-EOS library C API.

## Examples

```
import matlab.io.hdfEOS.*
gfid = gd.open('grid.hdf');
gridID = gd.attach(gfid,'PolarGrid');
range = [333 667];
regionID = gd.defVrtRegion(gridID,'noprevious','Height',range);
data = gd.extractRegion(gridID,regionID,'pressure');
gd.detach(gridID);
gd.close(gfid);
```

```
import matlab.io.hdfeos.*
gfid = gd.open('grid.hdf');
gridID = gd.attach(gfid, 'PolarGrid');
range = [3 5];
regionID = gd.defVrtRegion(gridID, 'noprevious', 'DIM:Height', range);
data = gd.extractRegion(gridID, regionID, 'pressure');
gd.detach(gridID);
gd.close(gfid);
```

## See Also

gd.extractRegion

# matlab.io.hdfEOS.gd.detach

**Package:** matlab.io.hdfEOS.gd

Detach from existing grid

## Syntax

```
detach(gridID)
```

## Description

detach(gridID) detaches from the grid identified by gridID.

This function corresponds to the GDdetach function in the HDF-EOS library C API.

## Examples

```
import matlab.io.hdfEOS.*
gfID = gd.open('grid.hdf');
gridID = gd.attach(gfID, 'PolarGrid');
gd.detach(gridID);
gd.close(gfID);
```

## See Also

gd.attach

# matlab.io.hdfEOS.gd.dimInfo

**Package:** matlab.io.hdfEOS.gd

Length of dimension

## Syntax

```
dimlen = diminfo(gridID,dimname)
```

## Description

`dimlen = diminfo(gridID,dimname)` retrieves the length of the specified user-defined dimension.

Please note that the two extents used to create the grid are not considered user-defined dimensions. To retrieve the length of `XDim` and `YDim`, use `gd.gridInfo`. This function corresponds to the `GDdiminfo` function in the HDF-EOS library C API.

## Examples

Inquire about a 'Bands' dimension.

```
import matlab.io.hdfEOS.*
gfid = gd.open('grid.hdf');
gridID = gd.attach(gfid,'PolarGrid');
dimlen = gd.dimInfo(gridID,'Height');
gd.detach(gridID);
gd.close(gfid);
```

## See Also

## matlab.io.hdfEOS.gd.extractRegion

**Package:** matlab.io.hdfEOS.gd

Read region of interest from field

### Syntax

```
data = extractRegion(gridID,regionID,fieldname)
```

### Description

`data = extractRegion(gridID,regionID,fieldname)` extract data from a subsetting region.

This routine corresponds to the `GDextractregion` function in the HDF-EOS library C API.

### Examples

Define and extract a region of interest between 20 and 50 degrees latitude and between -90 and -60 degrees longitude.

```
import matlab.io.hdfEOS.*
gfid = gd.open('grid.hdf','read');
gridID = gd.attach(gfid,'PolarGrid');
cornerlat = [20 50];
cornerlon = [-90 -60];
regionID = gd.defBoxRegion(gridID,cornerlat,cornerlon);
data = gd.extractRegion(gridID,regionID,'ice_temp');
gd.detach(gridID);
gd.close(gfid);
```

### See Also

`gd.defBoxRegion` | `gd.defVrtRegion`

# matlab.io.hdfEOS.gd.fieldInfo

**Package:** matlab.io.hdfEOS.gd

Information about data field

## Syntax

```
[dims, ntype, dimlist] = fieldInfo(gridID, fieldname)
```

## Description

`[dims, ntype, dimlist] = fieldInfo(gridID, fieldname)` returns information about a specific geolocation or data field in the grid. `dims` is a vector containing the dimension sizes of the field. `ntype` is a string containing the HDF number type of the field. `dimlist` is a cell array of strings containing the list of dimension names.

This function corresponds to the `GDfieldinfo` function in the HDF-EOS library C API, but because MATLAB uses FORTRAN-style ordering, the `dimlist` parameter is reversed with respect to the C library API.

## Examples

```
import matlab.io.hdfEOS.*
gfid = gd.open('grid.hdf', 'read');
gridID = gd.attach(gfid, 'PolarGrid');
[dims, ntype, dimlist] = gd.fieldInfo(gridID, 'ice_temp');
gd.detach(gridID);
gd.close(gfid);
```

## See Also

`gd.defField`

## matlab.io.hdfEOS.gd.getFillValue

**Package:** matlab.io.hdfEOS.gd

Fill value for specified field

### Syntax

```
fillvalue = getFillValue(gridID,fieldname)
```

### Description

`fillvalue = getFillValue(gridID,fieldname)` retrieves the fill value for the specified field.

This function corresponds to the `GDgetfillvalue` function in the HDF-EOS library C API.

### Examples

Return the fill value for the 'ice\_temp' field in the 'PolarGrid' grid.

```
import matlab.io.hdfEOS.*
gfid = gd.open('grid.hdf');
gridID = gd.attach(gfid,'PolarGrid');
fillvalue = gd.getFillValue(gridID,'ice_temp');
gd.detach(gridID);
gd.close(gfid);
```

### See Also

`gd.setFillValue`

# matlab.io.hdfEOS.gd.getPixels

**Package:** matlab.io.hdfEOS.gd

Pixel rows and columns for latitude/longitude pairs

## Syntax

```
[row,col] = getPixels(gridID,lat,lon)
```

## Description

`[row,col] = getPixels(gridID,lat,lon)` converts latitude/longitude pairs into zero-based pixel row and column coordinates. The origin is the upper left-hand corner of the grid pixel. If the latitude/longitude pairs are outside the grid, then `row` and `col` are -1.

This function corresponds to the `GDgetpixels` function in the HDF-EOS library C API.

## Examples

```
import matlab.io.hdfEOS.*
gfid = gd.open('grid.hdf','read');
gridID = gd.attach(gfid,'PolarGrid');
cornerlat = [20 50];
cornerlon = [-90 -60];
[row,col] = gd.getPixels(gridID,cornerlat,cornerlon);
gd.detach(gridID);
gd.close(gfid);
```

## See Also

`gd.getPixValues`

# matlab.io.hdfEOS.gd.getPixValues

**Package:** matlab.io.hdfEOS.gd

Read data values for specified pixels

## Syntax

```
data = getPixValues(gridID,rows,cols,fieldname)
```

## Description

`data = getPixValues(gridID,rows,cols,fieldname)` reads data values for the pixels specified by the zero-based `rows` and `cols` coordinates. All entries along the non-geographic dimensions, i.e. NOT `XDim` and `YDim`, are returned.

This function corresponds to the `GDgetpixvalues` function in the HDF-EOS library C API.

## Examples

Read the grid field's corner values.

```
import matlab.io.hdfEOS.*
gfid = gd.open('grid.hdf','read');
gridID = gd.attach(gfid,'PolarGrid');
rows = [0 99 99 0];
cols = [0 0 99 99];
data = gd.getPixValues(gridID,rows,cols,'ice_temp');
gd.detach(gridID);
gd.close(gfid);
```

## See Also

# matlab.io.hdfEOS.gd.gridInfo

**Package:** matlab.io.hdfEOS.gd

Position and size of grid

## Syntax

```
[xDim,yDim,upLeft,lowRight] = gridInfo(gridID)
```

## Description

[xDim,yDim,upLeft,lowRight] = gridInfo(gridID) returns the size of a grid as well as the upper left and lower right corners of the grid.

---

**Note:** upLeft and lowRight are in units of meters for all GCTP projections other than the geographic and bcea projections, which will have units of packed degrees.

---

This function corresponds to the GDgridinfo function in the HDF-EOS library C API.

## Examples

```
import matlab.io.hdfEOS.*
gfid = gd.open('grid.hdf');
gridID = gd.attach(gfid,'PolarGrid');
[xdimsize,ydimsize,upleft,lowright] = gd.gridInfo(gridID);
gd.detach(gridID);
gd.close(gfid);
```

## See Also

gd.create

## matlab.io.hdfEOS.gd.ij2ll

**Package:** matlab.io.hdfEOS.gd

Convert row and column space to latitude and longitude

### Syntax

```
[lat,lon] = ij2ll(gridID,row,col)
```

### Description

`[lat,lon] = ij2ll(gridID,row,col)` converts a grid's row and column coordinates to latitude and longitude in decimal degrees.

`row` and `col` are zero-based and defined such that `col` increases monotonically with the `XDim` dimension and `row` increases monotonically with the `YDim` dimension in the HDF-EOS library.

This routine corresponds to the `GDij2ll` function in the HDF-EOS C API.

### Examples

```
import matlab.io.hdfEOS.*
gfid = gd.open('grid.hdf');
gridID = gd.attach(gfid,'PolarGrid');
[xdim,ydim] = gd.gridInfo(gridID);
r = 0:(xdim-1);
c = 0:(ydim-1);
[Col,Row] = meshgrid(c,r);
[lat,lon] = gd.ij2ll(gridID,Row,Col);
gd.detach(gridID);
gd.close(gfid);
```

**Package:** matlab.io.hdfEOS.gd

Names of grid attributes

## Syntax

```
attrList = inqAttrs(gridID)
```

## Description

`attrList = inqAttrs(gridID)` returns the list of grid attribute names. `attrList` is a cell array.

This function corresponds to the `GDinqattrs` function in the HDF-EOS library C API.

## Examples

```
import matlab.io.hdfEOS.*
gfid = gd.open('grid.hdf');
gridID = gd.attach(gfid, 'PolarGrid');
attrList = gd.inqAttrs(gridID);
gd.detach(gridID);
gd.close(gfid);
```

## See Also

# matlab.io.hdfEOS.gd.inqDims

**Package:** matlab.io.hdfEOS.gd

Information about dimensions defined in grid

## Syntax

```
[dimnames,dimlens] = inqDims(gridID)
```

## Description

[dimnames,dimlens] = inqDims(gridID) returns the names of the dimensions dimnames in a cell array and their respective lengths dimlens. This does not include the grid extent dimensions XDim and YDim.

This function corresponds to the GDinqdims function in the HDF-EOS library C API, but because MATLAB uses FORTRAN-style ordering, the dimnames and dimlens parameters are reversed with respect to the C library API.

## Examples

```
import matlab.io.hdfEOS.*
gfid = gd.open('grid.hdf','read');
gridID = gd.attach(gfid,'PolarGrid');
[dims,dimlens] = gd.inqDims(gridID);
gd.detach(gridID);
gd.close(gfid);
```

# matlab.io.hdfEOS.gd.inqFields

**Package:** matlab.io.hdfEOS.gd

Information about data fields defined in grid

## Syntax

```
[fldList,fldRank,fldType] = inqFields(gridID)
```

## Description

`[fldList,fldRank,fldType] = inqFields(gridID)` returns the list of fields `fldList` as a cell array. `fldRank` contains the rank of each data field. `fldType` is a cell array containing the data type of each data field.

This function corresponds to the `GDinqfields` function in the HDF-EOS library C API.

## Examples

```
import matlab.io.hdfEOS.*
gfid = gd.open('grid.hdf');
gridID = gd.attach(gfid,'PolarGrid');
[fldList,fldRank,fldType] = gd.inqFields(gridID);
gd.detach(gridID);
gd.close(gfid);
for j = 1:numel(fldRank)
 fprintf('%s: Rank %d, datatype %s\n', fldList{j},fldRank(j),fldType{j});
end
```

# matlab.io.hdfeos.gd.ll2ij

**Package:** matlab.io.hdfeos.gd

Convert latitude and longitude to row and column space

## Syntax

```
[row,col] = ll2ij(gridID,lat,lon)
```

## Description

`[row,col] = ll2ij(gridID,lat,lon)` converts latitude and longitude coordinates to a pre-defined grid's row and column coordinates.

`row` and `col` are zero-based and defined such that `col` increases monotonically with the `XDim` dimension and `row` increases monotonically with the `YDim` dimension in the HDF-EOS library.

This routine corresponds to the `GDll2ij` function in the HDF-EOS C API.

## Examples

```
import matlab.io.hdfeos.*
gfid = gd.open('grid.hdf');
gridID = gd.attach(gfid,'PolarGrid');
lat = [46 46 42 42];
lon = [-71 -67 -67 -71];
[row,col] = gd.ll2ij(gridID,lat,lon);
gd.detach(gridID);
gd.close(gfid);
```

## matlab.io.hdfEOS.gd.nEntries

**Package:** matlab.io.hdfEOS.gd

Number of specified objects

### Syntax

```
nentries = nEntries(gridID,entType)
```

### Description

`nentries = nEntries(gridID,entType)` returns the number of specified objects in a grid. `entType` can be either `'dims'` or `'fields'`.

This function corresponds to the `GDnentries` function in the HDF-EOS library C API.

### Examples

```
import matlab.io.hdfEOS.*
fid = gd.open('grid.hdf');
gridID = gd.attach(fid,'PolarGrid');
ndims = gd.nEntries(gridID,'dims');
nfls = gd.nEntries(gridID,'fields');
gd.detach(gridID);
gd.close(fid);
fprintf('The number of dimensions is %d.\n', ndims);
fprintf('The number of fields is %d.\n', nfls);
```

### See Also

`gd.inqGrid`

# matlab.io.hdfeos.gd.open

**Package:** matlab.io.hdfeos.gd

Open grid file

## Syntax

```
gfid = open(filename,access)
```

## Description

`gfid = open(filename,access)` opens or creates an HDF-EOS grid file identified by `filename` and returns a file ID. `access` can be one of the following string values:

'read'	Read-only
'rdwr'	Read-write
'create'	Creates a file, deleting it if it already exists

If `access` is not provided, it defaults to 'read'.

This function corresponds to the `GDopen` function in the HDF-EOS library C API.

## Examples

```
import matlab.io.hdfeos.*
gfid = gd.open('grid.hdf');
gd.close(gfid);
```

## See Also

## matlab.io.hdfEOS.gd.originInfo

**Package:** matlab.io.hdfEOS.gd

Origin code

### Syntax

```
originCode = originInfo(gridID)
```

### Description

`originCode = originInfo(gridID)` retrieves the origin code for the grid specified by `gridID`. The `originCode` output is one of the following four string values.

'ul'	Upper-left
'ur'	Upper-right
'll'	Lower-left
'lr'	Lower-right

This function corresponds to the `GDoriginInfo` routine in the HDF-EOS library.

### Examples

```
import matlab.io.hdfEOS.*
gfid = gd.open('grid.hdf');
gridID = gd.attach(gfid,'PolarGrid');
origin = gd.originInfo(gridID);
gd.detach(gridID);
gd.close(gfid);
```

## matlab.io.hdfEOS.gd.projInfo

**Package:** matlab.io.hdfEOS.gd

GCTP projection information about grid

### Syntax

```
[projCode,zoneCode,sphereName,projParm] = projInfo(gridID)
```

### Description

[projCode,zoneCode,sphereName,projParm] = projInfo(gridID) returns the GCTP projection code, zone code, spheroid, and projection parameters for the grid identified by gridID.

zoneCode is -1 if projCode is anything other than 'UTM'.

This function corresponds to the GDprojinfo function in the HDF-EOS library C API.

For details about the GCTP projection code, zone code, spheroid code, and projection parameters, please consult the HDF-EOS User's Guide.

### Examples

```
import matlab.io.hdfEOS.*
fid = gd.open('grid.hdf');
gridID = gd.attach(fid,'PolarGrid');
[projCode,zoneCode,sphereCode,projParm] = gd.projInfo(gridID);
gd.detach(gridID);
gd.close(fid);
```

# matlab.io.hdfEOS.gd.readAttr

**Package:** matlab.io.hdfEOS.gd

Read grid attribute

## Syntax

```
data = readAttr(gridID,attrname)
```

## Description

`data = readAttr(gridID,attrname)` reads a grid attribute.

This function corresponds to the `GDreadattr` function in the HDF-EOS library C API.

## Examples

```
import matlab.io.hdfEOS.*
gfid = gd.open('grid.hdf','read');
gridID = gd.attach(gfid,'PolarGrid');
data = gd.readAttr(gridID,'creation_date');
gd.detach(gridID);
gd.close(gfid);
```

## See Also

`gd.writeAttr`

# matlab.io.hdfEOS.gd.readBlkSomOffset

**Package:** matlab.io.hdfEOS.gd

Read Block SOM offset

## Syntax

```
offset = readBlkSomOffset(GID)
```

## Description

`offset = readBlkSomOffset(GID)` reads the block SOM offset values, in pixels, from a standard SOM (Space Oblique Mercator) projection. `offset` is a vector of offset values for SOM projection data. This routine can only be used with grids that use the SOM projection.

This function corresponds to the `GDbkSOMoffset` function in the HDF-EOS library C API.

## Examples

```
import matlab.io.hdfEOS.*
gfid = gd.open('myfile.hdf','create');
lowright = [30521379.68485 1152027.64253];
upleft = [-11119487.42844 8673539.24806];
gridID = gd.create(gfid,'SOM',120,60,upleft,lowright);
projparm(1) = 6378137;
projparm(2) = 0.006694348;
projparm(4) = 98096360; % 98.161 in DDDMMSSSS
projparm(5) = 87069061; % 87.112 in DDDMMSSSS
projparm(9) = 0.068585416*1440;
projparm(10) = 0.0;
projparm(12) = 6;
gd.defProj(gridID,'som',[],[],projparm);
gd.writeBlkSomOffset(gridID,[5 10 12 8 2]);
gd.detach(gridID);
```

```
gd.close(gfid);
gfid = gd.open('myfile.hdf');
gridID = gd.attach(gfid, 'SOM');
blk = gd.readBlkSomOffset(gridID);
gd.detach(gridID);
gd.close(gfid);
```

## See Also

`gd.writeBlkSomOffset`

# matlab.io.hdfEOS.gd.readField

**Package:** matlab.io.hdfEOS.gd

Read data from grid field

## Syntax

```
data = readField(gridID,fieldname)
data = readField(gridID,fieldname,start,count)
data = readField(gridID,fieldname,start,count,stride)
[data,lat,lon] = readField(___)
```

## Description

`data = readField(gridID,fieldname)` reads the entire grid field identified by `fieldname` in the grid identified by `gridID`.

`data = readField(gridID,fieldname,start,count)` reads a contiguous hyperslab of data from the field. `start` specifies the zero-based starting index of the hyperslab. `count` specifies the number of values to read along each dimension.

`data = readField(gridID,fieldname,start,count,stride)` reads a strided hyperslab of data from the field. `stride` specifies the inter-element spacing along each dimension.

`[data,lat,lon] = readField( ___ )` reads the data and the associated geocoordinates from the grid field. This syntax is only allowed when the leading two dimensions of the grid are 'XDim' and 'YDim'.

This function corresponds to the `GDreadfield` function in the HDF-EOS library C API.

## Examples

Read the data, latitude, and longitude for the 'ice\_temp' field.

```
import matlab.io.hdfEOS.*
```

```
gfid = gd.open('grid.hdf');
gridID = gd.attach(gfid, 'PolarGrid');
[data, lat, lon] = gd.readField(gridID, 'ice_temp');
gd.detach(gridID);
gd.close(gfid);
```

Read only the first 4x4 hyperslab of data, latitude, and longitude for the 'ice\_temp' field.

```
import matlab.io.hdfeos.*
gfid = gd.open('grid.hdf');
gridID = gd.attach(gfid, 'PolarGrid');
[data2, lat2, lon2] = gd.readField(gridID, 'ice_temp', [0 0], [4 4]);
gd.detach(gridID);
gd.close(gfid);
```

## See Also

`gd.writeField`

# matlab.io.hdfEOS.gd.readTile

**Package:** matlab.io.hdfEOS.gd

Read single tile of data from field

## Syntax

```
data = readTile(gridID,fieldname,tileCoords)
```

## Description

`data = readTile(gridID,fieldname,tileCoords)` reads a single of data from a field. If the data is to be read tile by tile, this routine is more efficient than `gd.readField`. In all other cases, use `gd.readField`. The `tileCoords` argument has the form `[rownum colnum]` and is defined in terms of the tile coordinates, not the data elements.

This function corresponds to the `GDreadtile` function in the HDF-EOS library C API, but because MATLAB uses FORTRAN-style ordering, the `tileCoords` parameter is reversed with respect to the C library API.

## Examples

Define a field with a 2-by-3 tiling scheme.

```
import matlab.io.hdfEOS.*
gfid = gd.open('grid.hdf','read');
gridID = gd.attach(gfid,'PolarGrid');
for h = 0:9
 data = gd.readTile(gridID,'pressure',[0 0 h]);
end
gd.detach(gridID);
gd.close(gfid);
```

## See Also

`gd.tileInfo` | `gd.writeTile`

# matlab.io.hdfEOS.gd.regionInfo

**Package:** matlab.io.hdfEOS.gd

Information about subsetted region

## Syntax

```
[dims,upLeft,lowRight] = regionInfo(gridID,regionID,fieldname)
```

## Description

`[dims,upLeft,lowRight] = regionInfo(gridID,regionID,fieldname)` returns the dimensions and corner points for the specified field of a subsetted region identified by `regionID` in the grid identified by `gridID`.

This function corresponds to the `GDregioninfo` function in the HDF-EOS library C API.

## Examples

```
import matlab.io.hdfEOS.*
gfid = gd.open('grid.hdf','read');
gridID = gd.attach(gfid,'PolarGrid');
cornerlat = [20 50];
cornerlon = [-90 -60];
regionID = gd.defBoxRegion(gridID,cornerlat,cornerlon);
[dims,upleft,lowright] = gd.regionInfo(gridID,regionID,'ice_temp');
data = gd.extractRegion(gridID,regionID,'ice_temp');
gd.detach(gridID);
gd.close(gfid);
```

## See Also

`gd.defBoxRegion` | `gd.defVrtRegion`

# matlab.io.hdfEOS.gd.setFillValue

**Package:** matlab.io.hdfEOS.gd

Set fill value for specified field

## Syntax

```
setFillValue(gridID,fieldname,fillvalue)
```

## Description

`setFillValue(gridID,fieldname,fillvalue)` sets the fill value for the specified field. The fill value should have the same data type as the field.

This function corresponds to the `GDsetfillvalue` function in the HDF-EOS library C API.

## Examples

Create a new double-precision field with a fill value of -1.

```
import matlab.io.hdfEOS.*
srcFile = fullfile(matlabroot,'toolbox','matlab','imagesci','grid.hdf');
copyfile(srcFile,'myfile.hdf');
fileattrib('myfile.hdf','+w');
gfid = gd.open('myfile.hdf','rdwr');
gridID = gd.attach(gfid,'PolarGrid');
gd.defComp(gridID,'none');
gd.defField(gridID,'newfield',{'XDim','YDim},'double');
gd.setFillValue(gridID,'newfield',-1);
gd.detach(gridID);
gd.close(gfid);
```

## See Also

`gd.getFillValue`

# matlab.io.hdfEOS.gd.setTileComp

**Package:** matlab.io.hdfEOS.gd

Set tiling and compression for field with fill value

## Syntax

```
setTileComp(gridID,fieldname,tilesize,compCode,compParm)
```

## Description

`setTileComp(gridID,fieldname,tilesize,compCode,compParm)` sets the tiling and compression for a field that had a fill value. This function must be applied after `gd.defField` and `gd.setFillValue`. The `compCode` argument can be one of the following strings.

'rle'	Run-length encoding
'skphuff'	Skipping Huffman
'deflate'	Deflate
'none'	No compression

`compParm` need only be specified when the compression scheme is 'deflate', and then must be an integer between 0 and 9.

This function corresponds to the `GDsettilecomp` function in the HDF-EOS library C API, but because MATLAB uses FORTRAN-style ordering, the `tilesize` parameter is reversed with respect to the C library API.

## Examples

Define a temperature field with a 2-by-2 tiling scheme, a fill value of -999, and deflate compression.

```
import matlab.io.hdfEOS.*
```

```
gfid = gd.open('myfile.hdf','create');
upleft = [210584.50041 3322395.95445];
lowright = [813931.10959 2214162.53278];
gridID = gd.create(gfid,'UTMGrid',120,200,upleft,lowright);
spherecode = 0; zonecode = 40;
projparm = zeros(1,13);
gd.defProj(gridID,'utm',zonecode,spherecode,projparm);
gd.defDim(gridID,'Time',10);
gd.defField(gridID,'Pollution',{'XDim','YDim','Time'],'float');
gd.setFillValue(gridID,'Pollution',single(7));
gd.setTileComp(gridID,'Pollution',[40 20 1],'deflate',5);
gd.detach(gridID);
gd.close(gfid);
```

# matlab.io.hdfEOS.gd.tileInfo

**Package:** matlab.io.hdfEOS.gd

Tile size of grid field

## Syntax

```
tileDims = tileInfo(gridID,fieldname)
```

## Description

`tileDims = tileInfo(gridID,fieldname)` returns the tile dimensions of the field specified by `fieldname` in the grid specified by `gridID`. If the field is not tiled, then `tileDims` is `[]`.

This function corresponds to the `GDtileinfo` function in the HDF-EOS library C API, but because MATLAB uses FORTRAN-style ordering, the `tileDims` parameter is reversed with respect to the C library API.

## Examples

```
import matlab.io.hdfEOS.*
gfid = gd.open('grid.hdf');
gridID = gd.attach(gfid,'PolarGrid');
tileDims = gd.tileInfo(gridID,'pressure');
gd.detach(gridID);
gd.close(gfid);
```

## See Also

`gd.defTile`

# matlab.io.hdfEOS.gd.writeAttr

**Package:** matlab.io.hdfEOS.gd

Write grid attribute

## Syntax

```
writeAttr(gridID,attrname,data)
```

## Description

`writeAttr(gridID,attrname,data)` writes an attribute to a grid. If the attribute does not exist, it is created. If the attribute exists, it can be modified in place, but it cannot be recreated with a different data type or length.

This function corresponds to the `GDwriteattr` function in the HDF-EOS library C API.

## Examples

```
import matlab.io.hdfEOS.*
srcFile = fullfile(matlabroot,'toolbox','matlab','imagesci','grid.hdf');
copyfile(srcFile,'myfile.hdf');
fileattrib('myfile.hdf','+w');
gfid = gd.open('myfile.hdf','rdwr');
gridID = gd.attach(gfid,'PolarGrid');
gd.writeAttr(gridID,'modification_date',datestr(now));
gd.detach(gridID);
gd.close(gfid);
```

## See Also

`gd.readAttr`

# matlab.io.hdfeos.gd.writeBlkSomOffset

**Package:** matlab.io.hdfeos.gd

Write Block SOM offset

## Syntax

```
writeBlkSomOffset(gridID,offset)
```

## Description

`writeBlkSomOffset(gridID,offset)` writes the block SOM offset values `n` pixels for a standard Solar Oblique Mercator (SOM) projection. `offset` is a vector of offset values for SOM projection data. This routine can only be used with grids that use the SOM projection. You must take care to use this function properly in conjunction with `gd.defProj`. The 12th element of the projection parameters must be set to the total number of blocks to be defined. `offset` starts by listing the offset to the second block, so the 12th element of the projection parameters is always one more than the length of `offset`.

All fields defined after writing the block SOM offset values will automatically include "SOMBlockDim" as the slowest varying dimension.

This function corresponds to the `GDb1kSOMoffset` function in the HDF-EOS library C API.

## Examples

```
import matlab.io.hdfeos.*
gfid = gd.open('myfile.hdf','create');
lowright = [30521379.68485 1152027.64253];
upleft = [-11119487.42844 8673539.24806];
gridID = gd.create(gfid,'SOM',120,60,upleft,lowright);
projparm(1) = 6378137;
projparm(2) = 0.006694348;
projparm(4) = 98096360; % 98.161 in DDDMMSS
```

```
projparm(5) = 87069061; % 87.112 in DDDMMSSS
projparm(9) = 0.068585416*1440;
projparm(10) = 0.0;
projparm(12) = 6;
gd.defProj(gridID, 'som', [], [], projparm);
gd.writeBlkSomOffset(gridID, [5 10 12 8 2]);
gd.detach(gridID);
gd.close(gfid);
```

## See Also

# matlab.io.hdfeos.gd.writeField

**Package:** matlab.io.hdfeos.gd

Write data to grid field

## Syntax

```
writeField(gridID,fieldname,data)
writeField(gridID,fieldname,start,data)
writeField(gridID,fieldname,start,stride,data)
```

## Description

`writeField(gridID,fieldname,data)` writes all the data to a grid field. The field is identified by `fieldname` and the grid is identified by `gridID`.

`writeField(gridID,fieldname,start,data)` writes a contiguous hyperslab to the grid field. `start` specifies the zero-based starting index.

`writeField(gridID,fieldname,start,stride,data)` writes a strided hyperslab of data to a grid data field. `stride` specifies the inter-element spacing along each dimension. The number of elements to write along each dimension is inferred from the size of `data`.

This function corresponds to the `GDwritefield` function in the HDF-EOS library C API, but because MATLAB uses FORTRAN-style ordering, the `start` and `stride` parameters are reversed with respect to the C library API.

## Examples

Write all the data to a grid field.

```
import matlab.io.hdfeos.*
srcFile = fullfile(matlabroot,'toolbox','matlab','imagesci','grid.hdf');
copyfile(srcFile,'myfile.hdf');
fileattrib('myfile.hdf','+w');
```

```
gfid = gd.open('myfile.hdf','rdwr');
gridID = gd.attach(gfid,'PolarGrid');
data = zeros(100,100,'uint16');
gd.writeField(gridID,'ice_temp',data);
gd.detach(gridID);
gd.close(gfid);
```

## See Also

# matlab.io.hdfEOS.gd.writeTile

**Package:** matlab.io.hdfEOS.gd

Write tile to field

## Syntax

```
writeTile(gridID,fieldname,tileCoords,data)
```

## Description

`writeTile(gridID,fieldname,tileCoords,data)` writes a single tile of data to a field. If the field data can be arranged tile by tile, this routine is more efficient than `gd.writeField`. In all other cases, use `gd.writeField`. The `tileCoords` argument has the form `[rownum colnum]` and is defined in terms of the tile coordinates, not the data elements.

This function corresponds to the `GDwritetile` function in the HDF-EOS library C API, but because MATLAB uses FORTRAN-style ordering, the `tileCoords` parameter is reversed with respect to the C library API.

## Examples

Define a field with a 2-by-3 tiling scheme.

```
import matlab.io.hdfEOS.*
gfid = gd.open('myfile.hdf','create');
xdim = 200; ydim = 180;
gridID = gd.create(gfid,'PolarGrid',xdim,ydim,[],[]);
zonecode = 40;
spherecode = 0;
projParm = zeros(1,13);
projParm(6) = 90000000;
gd.defProj(gridID,'ps',[],spherecode,projParm);
tileSize = [100 60];
gd.defTile(gridID,tileSize);
```

```
dimlist = {'XDim','YDim'};
gd.defField(gridID,'Pressure',dimlist,'int32');
for c = 0:2
 for r = 0:1
 data = (r+c)*ones(tileSize,'int32');
 gd.writeTile(gridID,'Pressure',[r c],data);
 end
end
gd.detach(gridID);
gd.close(gfid);
```

# matlab.io.hdfeos.sw

Low-level access to HDF-EOS swath files

## Description

To use these MATLAB functions, you must be familiar with the HDF-EOS library C interface. In most cases, the syntax of the MATLAB function is similar to the syntax of the corresponding HDF-EOS library function. The functions are implemented as the package `matlab.io.hdfeos.sw`. To use this package, prefix the function name with a package path, or use the `import` function to add the package to the current import list, prior to calling the function, for example,

```
import matlab.io.hdfeos.*
fileId = sw.open(filename);
```

## Access

<code>matlab.io.hdfeos.sw.attach</code>	Attach to swath data set
<code>matlab.io.hdfeos.sw.close</code>	Close swath file
<code>matlab.io.hdfeos.sw.create</code>	Create new swath structure
<code>matlab.io.hdfeos.sw.detach</code>	Detach from swath
<code>matlab.io.hdfeos.sw.open</code>	Open swath file

## Definition

<code>matlab.io.hdfeos.sw.defComp</code>	Set grid field compression
------------------------------------------	----------------------------

matlab.io.hdfEOS.sw.defDataField	Define new data field within swath
matlab.io.hdfEOS.sw.defDim	Define new dimension within swath

# matlab.io.hdfEOS.sw.attach

**Package:** matlab.io.hdfEOS.sw

Attach to swath data set

## Syntax

```
swathID = attach(swfid,swathname)
```

## Description

`swathID = attach(swfid,swathname)` attaches to the swath identified by `swathname` in the file identified by `swfid`. The `swathID` output is the identifier for the named swath.

This function corresponds to the `SWattach` function in the HDF-EOS library C API.

## Examples

```
import matlab.io.hdfEOS.*
swfid = sw.open('swath.hdf');
swathID = sw.attach(swfid,'Example Swath');
sw.detach(swathID);
sw.close(swfid);
```

## See Also

`sw.detach`

## matlab.io.hdfEOS.sw.close

**Package:** matlab.io.hdfEOS.sw

Close swath file

### Syntax

```
close(swfID)
```

### Description

`close(swfID)` closes an HDF-EOS swath file identified by `swfID`.

This function corresponds to the `SWclose` function in the HDF-EOS library C API.

### Examples

```
import matlab.io.hdfEOS.*
swfid = sw.open('myfile.hdf','create');
swathID = sw.create(swfid,'ExampleSwath');
sw.detach(swathID);
sw.close(swfid);
```

# matlab.io.hdfEOS.sw.compInfo

**Package:** matlab.io.hdfEOS.sw

Compression information for field

## Syntax

```
[code,parms] = compInfo(swathID,fieldname)
```

## Description

[code,parms] = compInfo(swathID,fieldname) returns the compression code and compression parameters for a given field. Refer to `sw.defComp` for a description of various compression schemes and parameters.

This function corresponds to the `SWcompinfo` function in the HDF-EOS library C API.

## Examples

```
import matlab.io.hdfEOS.*
swfid = sw.open('swath.hdf');
swathID = sw.attach(swfid,'Example Swath');
[compCode,parms] = sw.compInfo(swathID,'Spectra');
sw.detach(swathID);
sw.close(swfid);
```

## See Also

`sw.defComp`

## matlab.io.hdfEOS.sw.create

**Package:** matlab.io.hdfEOS.sw

Create new swath structure

### Syntax

```
swathID = create(swfID,swathname)
```

### Description

`swathID = create(swfID,swathname)` creates a new swath structure where `swfID` is the swath file identifier and `swathname` is the name of the new swath. The swath is created as a Vgroup with the HDF file with the name `swathname` and HDF Vgroup class 'SWATH'.

This function corresponds to the `SWcreate` function in the HDF-EOS library C API.

### Examples

```
import matlab.io.hdfEOS.*
swfid = sw.open('myfile.hdf','create');
swathID = sw.create(swfid,'ExampleSwath');
sw.detach(swathID);
sw.close(swfid);
```

### See Also

`sw.detach`

# matlab.io.hdfeos.sw.defBoxRegion

**Package:** matlab.io.hdfeos.sw

Define latitude-longitude region for swath

## Syntax

```
regionID = defBoxRegion(swathID,lat,lon,mode)
```

## Description

`regionID = defBoxRegion(swathID,lat,lon,mode)` defines a latitude-longitude box region for a swath. `lat` and `lon` are two-element arrays containing the latitude and longitude in decimal degrees of the box corners. A cross track is determined to be within the box if a condition is met according to the value of `mode`:

'MIDPOINT'	The cross track midpoint is within the box.
'ENDPOINT'	Either endpoint is within the box.
'ANYPPOINT'	Any point of the cross track is within the box.

All elements of a cross track are within the region if the condition is met. The swath must have both Longitude and Latitude (or Colatitude) defined.

`regionID` is an identifier to be used by `sw.extractRegion` to read all the entries of a data field within the region.

This function corresponds to the `SWdefboxregion` and `SWregionindex` functions in the HDF-EOS library C API.

## Examples

```
import matlab.io.hdfeos.*
swfid = sw.open('swath.hdf');
swathID = sw.attach(swfid,'Example Swath');
lat = [34 44];
```

```
lon = [16 24];
regionID = sw.defBoxRegion(swathID,lat,lon,'MIDPOINT');
data = sw.extractRegion(swathID,regionID,'Temperature');
sw.detach(swathID);
sw.close(swfid);
```

## **See Also**

sw.extractRegion

# matlab.io.hdfEOS.sw.defComp

**Package:** matlab.io.hdfEOS.sw

Set grid field compression

## Syntax

```
defComp(swathID,compscheme,compparm)
```

## Description

`defComp(swathID,compscheme,compparm)` sets the field compression for subsequent definitions. The compression scheme does not apply to one-dimensional fields. `compscheme` can be one of the following strings.

'rle'	Run-length encoding
'skphuff'	Skipping Huffman
'deflate'	Gzip compression
'none'	No compression

When the compression scheme is 'deflate', the `compparm` input is the deflate compression level, an integer between 0 and 9. `compparm` can be omitted for the other compression schemes.

Fields defined with compression must be written with a single call to `sw.writeField`.

This function corresponds to the `SWdefcomp` function in the HDF-EOS library C API.

## Examples

```
import matlab.io.hdfEOS.*
swfid = sw.open('myfile.hdf','create');
swathID = sw.create(swfid,'MySwath');
sw.defDim(swathID,'Track',4000);
```

```
sw.defDim(swathID, 'Xtrack', 2000);
sw.defDim(swathID, 'Bands', 3);
sw.defComp(swathID, 'rle');
dims = {'Xtrack', 'Track'};
sw.defDataField(swathID, 'Pressure', dims, 'float');
sw.defComp(swathID, 'deflate', 5);
sw.defDataField(swathID, 'Opacity', dims, 'float');
sw.defComp(swathID, 'skphuff');
dims = {'Xtrack', 'Track', 'Bands'};
sw.defDataField(swathID, 'Spectra', dims, 'float');
sw.defComp(swathID, 'none');
dims = {'Xtrack', 'Track'};
sw.defDataField(swathID, 'Temperature', dims, 'float');
sw.detach(swathID);
sw.close(swfid);
```

## See Also

sw.compInfo

# matlab.io.hdfEOS.sw.defDataField

**Package:** matlab.io.hdfEOS.sw

Define new data field within swath

## Syntax

```
defDataField(swathID,fieldname,dimlist,dtype)
defDataField(swathID,fieldname,dimlist,dtype,mergeCode)
```

## Description

`defDataField(swathID,fieldname,dimlist,dtype)` defines a data field to be stored in the swath identified by `swathID`. The `dimlist` input can be a cell array of dimension names, or a single char if there is only one dimension. `dtype` is the data type of the field and can be one of the following strings.

- 'double'
- 'single'
- 'int32'
- 'uint32'
- 'int16'
- 'uint16'
- 'int8'
- 'uint8'
- 'char'

`dimlist` should be ordered such that the fastest varying dimension is listed first. This is opposite from the order in which the dimensions are listed in the C API.

`defDataField(swathID,fieldname,dimlist,dtype,mergeCode)` defines a data field that can be merged with other data fields according to the value of `mergeCode`. The `mergeCode` input can be one of two strings, 'automerge' and 'nomerge'. If `mergeCode` is 'automerge', then the HDF-EOS library will attempt to merge swath

fields into a single object. This should not be done if you wish to access the swath fields individually with the another interface. By default, `mergeCode` is 'nomerge'.

---

**Note:** To assure that the fields defined by `sw.defDataField` are properly established in the file, the swath should be detached and then reattached before writing to any fields.

---

This function corresponds to the `SWdefdatafield` function in the HDF-EOS library C API, but because MATLAB uses FORTRAN-style ordering, the `dimlist` parameter is reversed with respect to the C library API.

## Examples

```
import matlab.io.hdfEOS.*
swfid = sw.open('myfile.hdf','create');
swathID = sw.create(swfid,'MySwath');
sw.defDim(swathID,'GeoTrack',2000);
sw.defDim(swathID,'GeoXtrack',1000);
sw.defDim(swathID,'DataTrack',4000);
sw.defDim(swathID,'DataXtrack',2000);
sw.defDim(swathID,'Bands',3);
sw.defDimMap(swathID,'GeoTrack','DataTrack',0,2);
sw.defDimMap(swathID,'GeoXtrack','DataXtrack',1,2);
dims = {'GeoXtrack','GeoTrack'};
sw.defGeoField(swathID,'Longitude',dims,'float');
sw.defGeoField(swathID,'Latitude',dims,'float');
dims = {'DataXtrack','DataTrack','Bands'};
sw.defDataField(swathID,'Spectra',dims,'float');
sw.detach(swathID);
sw.close(swfid);
```

## See Also

# matlab.io.hdfEOS.sw.defDim

**Package:** matlab.io.hdfEOS.sw

Define new dimension within swath

## Syntax

```
defDim(swathID,dimname,dimlen)
```

## Description

`defDim(swathID,dimname,dimlen)` defines a new dimension named `dimname` with length `dimlen` in the swath structure identified by `swathID`.

To specify an unlimited dimension, use either 0 or 'unlimited' for `dimlen`.

This function corresponds to the `SWdefdim` function in the HDF-EOS library.

## Examples

Define a dimension 'Band' with length of 15 and an unlimited dimension 'Time'.

```
import matlab.io.hdfEOS.*
swfid = sw.open('myfile.hdf','create');
swathID = sw.create(swfid,'MySwath');
sw.defDim(swathID,'GeoTrack',2000);
sw.defDim(swathID,'GeoXtrack',1000);
sw.defDim(swathID,'DataTrack',4000);
sw.defDim(swathID,'DataXtrack',2000);
sw.detach(swathID);
sw.close(swfid);
```

## See Also

`sw.dimInfo`

# matlab.io.hdfEOS.sw.defDimMap

**Package:** matlab.io.hdfEOS.sw

Define mapping between geolocation and data dimensions

## Syntax

```
defDimMap(swathID,geoDim,dataDim,offset,increment)
```

## Description

`defDimMap(swathID,geoDim,dataDim,offset,increment)` defines a monotonic mapping between the geolocation and data dimensions, which usually have differing lengths. `offset` gives the index of the data element corresponding to the first geolocation element, and `increment` gives the number of data elements to skip for each geolocation element. If the geolocation dimension begins "before" the data dimension, then `offset` is negative. Similarly, if the geolocation dimension has higher resolution than the data dimension, then `increment` is negative.

This function corresponds to the `SWdefdimmap` function in the HDF-EOS library.

## Examples

Create a dimension mapping such that the first element of the GeoTrack dimension corresponds to the first element of the DataTrack Dimension and such that the data dimension has twice the resolution as the geolocation dimension. Also create a dimension mapping such that the first element of the GeoXtrack dimension corresponds to the second element of the DataXtrack dimensions and such that the data dimension has twice the resolution as the geolocation dimension.

```
import matlab.io.hdfEOS.*
swfid = sw.open('myfile.hdf','create');
swathID = sw.create(swfid,'MySwath');
sw.defDim(swathID,'GeoTrack',2000);
sw.defDim(swathID,'GeoXtrack',1000);
sw.defDim(swathID,'DataTrack',4000);
```

```
sw.defDim(swathID, 'DataXtrack', 2000);
sw.defDimMap(swathID, 'GeoTrack', 'DataTrack', 0, 2);
sw.defDimMap(swathID, 'GeoXtrack', 'DataXtrack', 1, 2);
sw.detach(swathID);
sw.close(swfid);
```

## See Also

sw.defDim | sw.mapInfo

## matlab.io.hdfEOS.sw.defGeoField

**Package:** matlab.io.hdfEOS.sw

Define new data field within swath

### Syntax

```
defGeoField(swathID,fieldname,dimlist,dtype)
defGeoField(swathID,fieldname,dimlist,dtype,mergeCode)
```

### Description

`defGeoField(swathID,fieldname,dimlist,dtype)` defines a geolocation field to be stored in the swath identified by `swathID`. The `dimlist` argument can be a cell array of dimension names or a single char if there is only one dimension. `dtype` is the data type of the field

`dimlist` should be ordered such that the fastest varying dimension is listed first. This is opposite from the order in which the dimensions are listed in the C API.

`defGeoField(swathID,fieldname,dimlist,dtype,mergeCode)` defines a geolocation field that may be merged with other geolocation fields according to the value of `mergeCode`. The `mergeCode` argument can be one of two strings, 'automerge' and 'nomerge'. If `mergeCode` is 'automerge', then the HDF-EOS library will attempt to merge swath fields into a single object. This should not be done if you wish to access the swath fields individually with the another interface. By default, `mergeCode` is 'nomerge'.

This function corresponds to the `SWdefgeofield` function in the HDF-EOS library C API, but because MATLAB uses FORTRAN-style ordering, the `dimlist` parameter is reversed with respect to the C library API.

### Examples

```
import matlab.io.hdfEOS.*
```

```
swfid = sw.open('myfile.hdf','create');
swathID = sw.create(swfid,'MySwath');
sw.defDim(swathID,'GeoTrack',2000);
sw.defDim(swathID,'GeoXtrack',1000);
sw.defDim(swathID,'DataTrack',4000);
sw.defDim(swathID,'DataXtrack',2000);
sw.defDimMap(swathID,'GeoTrack','DataTrack',0,2);
sw.defDimMap(swathID,'GeoXtrack','DataXtrack',1,2);
dims = {'GeoXtrack','GeoTrack'};
sw.defGeoField(swathID,'Longitude',dims,'float');
sw.defGeoField(swathID,'Latitude',dims,'float');
sw.detach(swathID);
sw.close(swfid);
```

## See Also

[sw.defDataField](#) | [sw.inqGeoFields](#)

# matlab.io.hdfEOS.sw.defTimePeriod

**Package:** matlab.io.hdfEOS.sw

Define time period of interest

## Syntax

```
outpID = defTimePeriod(swathID,start,stop,mode)
```

## Description

`outpID = defTimePeriod(swathID,start,stop,mode)` defines a time period for a swath. `outpID` is a swath period ID that can be used to read all the entries of a data field within the time period. The swath structure must have the 'Time' field defined. A cross track is within a time period if a condition is met according to the value of `mode`:

'MIDPOINT'	The midpoint is within the time period.
'ENDPOINT'	Either endpoint is within the time period.

This function corresponds to the `SWdeftimeperiod` function in the HDF-EOS library C API.

## Examples

```
import matlab.io.hdfEOS.*
swfid = sw.open('swath.hdf');
swathID = sw.attach(swfid,'Example Swath');
starttime = 25;
stoptime = 425;
periodID = sw.defTimePeriod(swathID,starttime,stoptime,'MIDPOINT');
data = sw.extractPeriod(swathID,periodID,'Temperature');
sw.detach(swathID);
sw.close(swfid);
```

## See Also

# matlab.io.hdfEOS.sw.defVrtRegion

**Package:** matlab.io.hdfEOS.sw

Subset on monotonic field or dimension

## Syntax

```
regionID_out = defVrtRegion(swathID,regionID,vertObj,range)
```

## Description

`regionID_out = defVrtRegion(swathID,regionID,vertObj,range)` subsets on a monotonic field or contiguous elements of a dimension. Whereas `defBoxRegion` and `defTimePeriod` subset along the 'Track' dimension, this routine allows the user to subset along any dimension. `regionID` specifies the subsetted region from a previous call. `vertObj` specifies the dimension by which to subset. `range` specifies the minimum and maximum values for `vertObj`.

If there is no current subsetted region, `regionID` should be 'noprevious'.

`vertObj` can be either a dimension or a field. If it is a dimension, then `range` should consist of dimension indices. If `vertObj` corresponds to a field, then `range` should consist of the minimum and maximum field values. `vertObj` must be one-dimensional in this case, and its values must be monotonic.

This function corresponds to the `SWdefvrtregion` function in the HDF-EOS library C API.

## Examples

```
import matlab.io.hdfEOS.*
swfid = sw.open('swath.hdf');
swathID = sw.attach(swfid,'Example Swath');
regionID = sw.defVrtRegion(swathID,'noprevious','Bands',[450 600]);
data = sw.extractRegion(swathID,regionID,'Spectra');
sw.detach(swathID);
```

```
sw.close(swfid);
```

## matlab.io.hdfEOS.sw.nEntries

**Package:** matlab.io.hdfEOS.sw

Number of entries for specific type

### Syntax

```
nEnts = nEntries(swathID,type)
```

### Description

`nEnts = nEntries(swathID,type)` returns the number of entries in a swath. Valid inputs for `type` include:

'dims'	or 'HDFE_NENTDIM'
'maps'	or 'HDFE_NENTMAP'
'imaps'	or 'HDFE_NENTIMAP'
'geofields'	or 'HDFE_NENTGFLD'
'datafields'	or 'HDFE_NENTFLD'

This function corresponds to the `SWnentries` function in the HDF-EOS library C API.

### Examples

```
import matlab.io.hdfEOS.*
swfid = sw.open('myfile.hdf','create');
swathID = sw.create(swfid,'MySwath');
sw.defDim(swathID,'GeoTrack',2000);
sw.defDim(swathID,'GeoXtrack',1000);
sw.defDim(swathID,'DataTrack',4000);
sw.defDim(swathID,'DataXtrack',2000);
ndims = sw.nEntries(swathID,'dims');
sw.detach(swathID);
sw.close(swfid);
```

# matlab.io.hdfeos.sw.open

**Package:** matlab.io.hdfeos.sw

Open swath file

## Syntax

```
swfID = open(filename)
swfID = open(filename,access)
```

## Description

`swfID = open(filename)` opens an HDF-EOS swath file for read-only access.

`swfID = open(filename,access)` opens or creates an HDF-EOS swath file identified by `filename` and returns a file ID. `access` can be one of the following string values.

'read' (default)	Read-only
'rdwr'	Read-write
'create'	Creates a file, deleting it if it already exists

This routine corresponds to the `SWopen` function in the HDF-EOS library C API.

## Examples

```
import matlab.io.hdfeos.*
swfid = sw.open('swath.hdf');
sw.close(swfid);
```

Information about subsetted period

## Syntax

```
[datatype,dims] = periodInfo(swathID,periodID,fieldname)
```

## Description

[datatype,dims] = periodInfo(swathID,periodID,fieldname) retrieves information about the period defined for the given field. `datatype` is the data type of the field. `dims` is the dimensions of the subsetted region.

This function corresponds to the `SWperiodinfo` function in the HDF-EOS library C API, but because MATLAB uses FORTRAN-style ordering, the `dims` parameter is reversed with respect to the C library API.

## Examples

```
import matlab.io.hdfEOS.*
swfid = sw.open('swath.hdf');
swathID = sw.attach(swfid,'Example Swath');
starttime = 25;
stoptime = 425;
periodID = sw.defTimePeriod(swathID,starttime,stoptime,'MIDPOINT');
[ntype,dims] = sw.periodInfo(swathID,periodID,'Temperature');
sw.detach(swathID);
sw.close(swfid);
```

## See Also

sw.defTimePeriod | sw.extractPeriod

# matlab.io.hdfEOS.sw.readAttr

**Package:** matlab.io.hdfEOS.sw

Read swath attribute

## Syntax

```
data = readAttr(swathID,attrname)
```

## Description

`data = readAttr(swathID,attrname)` reads a swath attribute.

This function corresponds to the `SWreadAttr` function in the HDF-EOS library C API.

## Examples

```
import matlab.io.hdfEOS.*
swfid = sw.open('swath.hdf');
swathID = sw.attach(swfid,'Example Swath');
value = sw.readAttr(swathID,'creation_date');
sw.detach(swathID);
sw.close(swfid);
```

## See Also

`sw.writeAttr`

# matlab.io.hdfEOS.sw.readField

**Package:** matlab.io.hdfEOS.sw

Read data from swath field

## Syntax

```
data = readField(swathID,fieldname)
data = readField(swathID,fieldname,start,count)
data = readField(swathID,fieldname,start,count,stride)
```

## Description

`data = readField(swathID,fieldname)` reads an entire swath field.

`data = readField(swathID,fieldname,start,count)` reads a contiguous hyperslab of data from the swath field `fieldname`. The `start` input specifies the zero-based index of the first element to be read. `count` specifies the number of elements along each dimension to read.

`data = readField(swathID,fieldname,start,count,stride)` reads a strided hyperslab of data from the swath field `fieldname`. The `stride` input specifies the inter-element spacing along each dimension.

This function corresponds to the `SWreadfield` function in the HDF-EOS library C API, but because MATLAB uses FORTRAN-style ordering, the `start`, `count`, and `stride` parameters are reversed with respect to the C library API.

## Examples

```
import matlab.io.hdfEOS.*
swfid = sw.open('swath.hdf');
swathID = sw.attach(swfid,'Example Swath');
data = sw.readField(swathID,'Longitude');
sw.detach(swathID);
sw.close(swfid);
```

## See Also

`sw.writeField`

# matlab.io.hdfEOS.sw.regionInfo

**Package:** matlab.io.hdfEOS.sw

Information about subsetted region

## Syntax

```
[datatype,extent] = regionInfo(swathID,regionID,fieldname)
```

## Description

`[datatype,extent] = regionInfo(swathID,regionID,fieldname)` returns the data type and extent of a subsetted region of a field. `regionID` is the identifier for the subsetted region.

This function corresponds to the `SWregioninfo` function in the HDF-EOS library C API, but because MATLAB uses FORTRAN-style ordering, the `extent` parameter is reversed with respect to the C library API.

## Examples

```
import matlab.io.hdfEOS.*
swfid = sw.open('swath.hdf');
swathID = sw.attach(swfid,'Example Swath');
lat = [34 44];
lon = [16 24];
regionID = sw.defBoxRegion(swathID,lat,lon,'MIDPOINT');
[ntype,dims] = sw.regionInfo(swathID,regionID,'Temperature');
sw.detach(swathID);
sw.close(swfid);
```

## See Also

`sw.defBoxRegion` | `sw.defVrtRegion`

# matlab.io.hdfEOS.sw.setFillValue

**Package:** matlab.io.hdfEOS.sw

Set fill value for the specified field

## Syntax

```
setFillValue(swathID,fieldname,fillvalue)
```

## Description

`setFillValue(swathID,fieldname,fillvalue)` sets the fill value for the specified field. The field must have more than two dimensions.

This function corresponds to the `SWsetfillvalue` function in the HDF-EOS library C API.

## Examples

```
import matlab.io.hdfEOS.*
swfid = sw.open('myfile.hdf','create');
swathID = sw.create(swfid,'MySwath');
sw.defDim(swathID,'Track',400);
sw.defDim(swathID,'Xtrack',200);
dims = {'Track','Xtrack'};
sw.defDataField(swathID,'Temperature',dims,'float');
sw.setFillValue(swathID,'Temperature',single(-999));
sw.detach(swathID);
sw.close(swfid);
```

## See Also

`sw.getFillValue`

## matlab.io.hdfEOS.sw.writeAttr

**Package:** matlab.io.hdfEOS.sw

Write swath attribute

### Syntax

```
writeAttr(swathID,attrname,data)
```

### Description

`writeAttr(swathID,attrname,data)` writes an attribute to a swath. If the attribute does not exist, it is created. If the attribute exists, it can be modified in place, but it cannot be recreated with a different data type or length.

This function corresponds to the `SWwriteattr` function in the HDF-EOS library C API.

### Examples

```
import matlab.io.hdfEOS.*
swfid = sw.open('myfile.hdf','create');
swathID = sw.create(swfid,'MySwath');
sw.writeAttr(swathID,'creation_date',datestr(now));
sw.detach(swathID);
sw.close(swfid);
```

### See Also

`sw.readAttr`

# matlab.io.hdfeos.sw.writeField

**Package:** matlab.io.hdfeos.sw

Write data to swath field

## Syntax

```
writeField(swathID,fieldname,data)
writeField(swathID,fieldname,start,data)
writeField(swathID,fieldname,start,stride,data)
```

## Description

`writeField(swathID,fieldname,data)` writes an entire swath data field.

`writeField(swathID,fieldname,start,data)` writes a contiguous hyperslab to a swath field. `start` specifies the index of the first element to write. The number of elements along each dimension is inferred from either the size of `data` or from the swath field itself.

`writeField(swathID,fieldname,start,stride,data)` writes a strided hyperslab to a swath field. `stride` specifies the inter-element spacing along each dimension.

This function corresponds to the `SWwritefield` function in the HDF-EOS library C API, but because MATLAB uses FORTRAN-style ordering, the `start` and `stride` parameters are reversed with respect to the C library API.

## Examples

Write data to a geolocation field 'Longitude'.

```
lon = [-50:49];
data = repmat(lon(:),1,100);
data = single(data);
import matlab.io.hdfeos.*
srcFile = fullfile(matlabroot,'toolbox','matlab','imagesci','swath.hdf');
```

```
copyfile(srcFile, 'myfile.hdf');
fileattrib('myfile.hdf', '+w');
swfid = sw.open('myfile.hdf', 'rdwr');
swathID = sw.attach(swfid, 'Example Swath');
sw.writeField(swathID, 'Longitude', data);
sw.detach(swathID);
sw.close(swfid);
```

## See Also

sw.readField

# matlab.io.saveVariablesToScript

Save workspace variables to MATLAB script

## Syntax

```
matlab.io.saveVariablesToScript(filename)
matlab.io.saveVariablesToScript(filename,varnames)
matlab.io.saveVariablesToScript(filename,Name,Value)
[r1,r2] = matlab.io.saveVariablesToScript(filename)
```

## Description

`matlab.io.saveVariablesToScript(filename)` saves variables in the current workspace to a MATLAB script named `filename.m`. The filename can include the `.m` suffix. If you do not include it, the function adds it when it creates the file.

Variables that MATLAB cannot generate code for are saved to a MAT-file named `filename.mat`.

If a file with the same name already exists, it is overwritten.

`matlab.io.saveVariablesToScript(filename,varnames)` saves only workspace variables specified by `varnames` to the MATLAB script.

`matlab.io.saveVariablesToScript(filename,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments.

`[r1,r2] = matlab.io.saveVariablesToScript(filename)` additionally returns two cell arrays:

- `r1` for variables that were saved to the MATLAB script
- `r2` for variables that were saved to a MAT-file

## Examples

### Save Workspace Variables to MATLAB Script

Save variables from a workspace to a MATLAB script, `test.m`.

```
matlab.io.saveVariablesToScript('test.m')
```

### **Save Specific Workspace Variables to MATLAB Script**

Create and save variable `myVar` from a workspace to a MATLAB script, `test.m`.

```
myVar = 55.3;
matlab.io.saveVariablesToScript('test.m','myVar')
```

### **Append Specific Variables to Existing MATLAB Script**

Create two variables, `a` and `b`, and save them to an existing MATLAB script `abfile.m`.

```
a = 72.3;
b = pi;
matlab.io.saveVariablesToScript('abfile.m',{'a','b'},...
'SaveMode','append')
```

### **Update Specific Variables in Existing MATLAB Script**

Update and save two variables, `y` and `z`, to an existing MATLAB script `yzfile.m`.

```
y = 15.7;
z = 3 * pi;
matlab.io.saveVariablesToScript('yzfile.m',{'y','z'},...
'SaveMode','update')
```

### **Specify MATLAB Script Configuration for Saving Variable**

Update and save variable `resistance` to an existing MATLAB script `designData.m` while specifying the configuration of the script file.

```
resistance = [10 20.5 11 13.7 15.1 7.7];
matlab.io.saveVariablesToScript('designData.m','resistance',...
'SaveMode','Update','MaximumArraySize',5,...
'MaximumNestingLevel',5,'MaximumTextWidth',30)
```

### **Specify 2-D Slice for Saving 3-D Array in MATLAB Script**

Specify a 2-D slice for the output of the 3-D array `my3Dtable`, such that the 2-D slice expands along the first and third dimensions. Save the 2-D slice in the MATLAB script `sliceData.m`.

```
level1 = [1 2; 3 4];
```

```

level2 = [5 6; 7 8];
my3Dtable(:, :, 1) = level1;
my3Dtable(:, :, 2) = level2;
matlab.io.saveVariablesToScript('sliceData.m', 'MultidimensionalFormat', [1,3])

```

The resulting MATLAB code is similar to the following:

```

level1 = ...
 [1 2;
 3 4];

level2 = ...
 [5 6;
 7 8];
my3Dtable = zeros(2, 2, 2);
my3Dtable(:, 1, :) = ...
 [1 5;
 3 7];

my3Dtable(:, 2, :) = ...
 [2 6;
 4 8];

```

### Save Variables Matching a Regular Expression

Save variables that match the expression `autoL*` to a MATLAB script `autoVariables.m`.

```
matlab.io.saveVariablesToScript('autoVariables.m', 'RegExp', 'autoL*')
```

### Save Variables to Version 7.3 MATLAB Script

Create two variables, `p` and `q`, and save them to a version 7.3 MATLAB script `version73.m`.

```

p = 49;
q = 35.5;
matlab.io.saveVariablesToScript('version73.m', 'p', 'q', ...
 'MATFileVersion', 'v7.3')

```

### Return Variables Saved to MATLAB Script

Save variables that were saved to a MATLAB script to the variable `r1`, and those that were saved to a MAT-file to the variable `r2`.

```
[r1,r2] = matlab.io.saveVariablesToScript('mydata.m')
```

```
r1 =
```

```
 'level1'
 'level2'
 'level3'
 'my3Dtable'
```

```
r2 =
```

```
Empty cell array: 0-by-1
```

## Input Arguments

**filename** — Name of MATLAB script for saving variables

filename | variable

Name of MATLAB script for saving variables, specified as a string giving a file name or a variable containing the file name.

Example: `matlab.io.saveVariablesToScript('myVariables.m')`

**varnames** — Name of variables to save

string | cell array

Name of variables to save, specified as a string or a cell array.

Example: `{'X','Y','Z'}`

Data Types: char | cell

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Example: `'MaximumArraySize',500,'MATFileVersion','v4'` specifies that the maximum number of array elements to save is 500 using MATLAB version 4 syntax.

**'MATFileVersion' — MATLAB version whose syntax to use**

'v7.3' (default) | 'v4' | 'v6' | 'v7'

MATLAB version whose syntax to use for saving MAT-files, specified as the comma-separated pair consisting of 'MATFileVersion' and one of the following version numbers:

- 'v4'
- 'v6'
- 'v7'
- 'v7.3'

Example: 'MATFileVersion', 'v6'

Data Types: char

**'MaximumArraySize' — Maximum array elements to save**

1000 (default) | integer

Maximum array elements to save, specified as the comma-separated pair consisting of 'MaximumArraySize' and an integer in the range of 1 to 10,000.

Example: 'MaximumArraySize', 1050

**'MaximumNestingLevel' — Maximum number of object levels or array hierarchies to save**

20 (default) | integer

Maximum number of object levels or array hierarchies to save, specified as the comma-separated pair consisting of 'MaximumNestingLevel' and an integer in the range of 1 to 200.

Example: 'MaximumNestingLevel', 67

**'MaximumTextWidth' — Text wrap width during save**

76 (default) | integer

Text wrap width during save, specified as the comma-separated pair consisting of 'MaximumTextWidth' and an integer in the range of 32 to 256.

Example: 'MaximumTextWidth', 82

**'MultidimensionalFormat' — Dimensions of 2-D slices that represent n-D arrays of char, logic, or numeric data**

'rowvector' (default) | integer cell array

Dimensions of 2-D slices that represent n-D arrays of char, logic, or numeric data, specified as the comma-separated pair consisting of 'MultidimensionalFormat' and one of these values:

- 'rowvector' — Save multidimensional variables as a single row vector.
- integer cell array — Save a 2-D slice of multidimensional variables, where the dimensions satisfy all the following criteria:
  - Two positive integers represent dimensions.
  - The two integers are less than or equal to the dimensions of the n-D array.
  - The second integer is greater than the first.

Example: 'MultidimensionalFormat', [1,3]

### **'RegExp' — Regular expression for matching**

string

Regular expression for matching, specified as the comma-separated pair consisting of 'RegExp' and one or more expressions given as a string.

Example: 'RegExp', 'level\*'

Data Types: char

### **'SaveMode' — Mode to save MATLAB script**

'create' (default) | 'update' | 'append'

Mode to save MATLAB script, specified as the comma-separated pair consisting of SaveMode and one of these values:

- 'create' — Save variables to a new MATLAB script.
- 'update' — Only update variables that are already present in a MATLAB script.
- 'append' — Update variables that are already present in a MATLAB script and append new variables to the end of the script.

Example: 'SaveMode', 'Update'

## **Output Arguments**

**r1** — Variables that were saved to a MATLAB script

cell array

Variables that were saved to a MATLAB script, returned as a cell array of variable names.

**r2 – Variables that were saved to a MAT-file**

cell array

Variables that were saved to a MAT-file, returned as a cell array of variable names.

## Limitations

- `matlab.io.saveVariablesToScript` does not save the following variables to a MATLAB script or a MAT-file.
  - Java objects
  - .NET objects
- `matlab.io.saveVariablesToScript` saves the following variables only to a MAT-file.
  - MATLAB objects
  - Function handles
  - Anonymous functions

# matlab.lang.makeUniqueStrings

Construct unique strings from input strings

## Syntax

```
U = matlab.lang.makeUniqueStrings(S)
```

```
U = matlab.lang.makeUniqueStrings(S,excludedStrings)
```

```
U = matlab.lang.makeUniqueStrings(S,whichStrings)
```

```
U = matlab.lang.makeUniqueStrings(S, __ , maxStringLength)
```

```
[U, modified] = matlab.lang.makeUniqueStrings(__)
```

## Description

`U = matlab.lang.makeUniqueStrings(S)` constructs unique strings, `U`, from input strings, `S`, by appending an underscore and a number to duplicate strings.

`U = matlab.lang.makeUniqueStrings(S,excludedStrings)` constructs strings that are unique within `U` and with respect to `excludedStrings`. The `makeUniqueStrings` function does not check `excludedStrings` for uniqueness.

`U = matlab.lang.makeUniqueStrings(S,whichStrings)` specifies the subset of `S` to make unique within the entire set. `makeUniqueStrings` makes the strings in `S(whichStrings)` unique among themselves and with respect to the remaining strings. `makeUniqueStrings` returns the remaining strings unmodified in `U`. Use this syntax when you have an array of strings, and need to check that only some elements of the array are unique.

`U = matlab.lang.makeUniqueStrings(S, __ , maxStringLength)` specifies the maximum length, `maxStringLength`, of strings in `U`. If `makeUniqueStrings` cannot make elements in `S` unique without exceeding `maxStringLength`, it returns an error. You can use this syntax with any of the input arguments of the previous syntaxes.

`[U, modified] = matlab.lang.makeUniqueStrings( __ )` returns a logical array, `modified`, indicating modified strings.

## Examples

### Construct Unique Strings

Create an array of strings and make each element unique.

```
S = {'John' 'Sue' 'Nick' 'John' 'Campion' 'John' 'Jason'};
U = matlab.lang.makeUniqueStrings(S)
```

U =

```
'John' 'Sue' 'Nick' 'John_1' 'Campion' 'John_2' 'Jason'
```

The `makeUniqueStrings` function appends the duplicate strings in elements 3 and 5 with underscores and incrementing numbers.

### Construct Unique Strings and Specify Exclusions

Without specifying excluded strings, make the strings in `U` unique.

```
S = {'John' 'Sue' 'Nick' 'John' 'Campion' 'John' 'Jason'};
U = matlab.lang.makeUniqueStrings(S)
```

U =

```
'John' 'Sue' 'Nick' 'John_1' 'Campion' 'John_2' 'Jason'
```

Specify that the string, `'Nick'`, should be excluded from the output.

```
U = matlab.lang.makeUniqueStrings(S, 'Nick')
```

U =

```
'John' 'Sue' 'Nick_1' 'John_1' 'Campion' 'John_2' 'Jason'
```

`makeUniqueStrings` excludes `'Nick'` from `U` and instead modifies the first duplicate string, found in element 3, to be `'Nick_1'`.

Exclude workspace variables from the unique string array.

```
Sue = 42;
U = matlab.lang.makeUniqueStrings(S, who)
```

```
U =
 'John' 'Sue_1' 'Nick' 'John_1' 'Campion' 'John_2' 'Jason'
```

Since 'Sue' exists in the workspace, `makeUniqueStrings` makes this string unique by appending an underscore and number.

## Construct Unique Strings for Specified Array Elements

Create an array of strings and make only the first four elements unique.

```
S = {'quiz' 'quiz' 'quiz' 'exam' 'quiz' 'exam'};
U = matlab.lang.makeUniqueStrings(S, 1:4)
```

```
U =
 'quiz_1' 'quiz_2' 'quiz_3' 'exam_1' 'quiz' 'exam'
```

The first four elements in `U` are unique among themselves, and among the remaining strings in elements 5 and 6 ('quiz' and 'exam'). Alternatively, you can use a logical array instead of a range of linear indices to achieve the same results: `U = matlab.lang.makeUniqueStrings(S, [true true true true false false])` or `U = matlab.lang.makeUniqueStrings(S, logical([1 1 1 1 0 0]))`.

Append a duplicate 'quiz' onto the end of `S` and make the first four elements unique.

```
S{end+1} = 'quiz'
U = matlab.lang.makeUniqueStrings(S, 1:4)
```

```
S =
 'quiz' 'quiz' 'quiz' 'exam' 'quiz' 'exam' 'quiz'

U =
 'quiz_1' 'quiz_2' 'quiz_3' 'exam_1' 'quiz' 'exam' 'quiz'
```

The strings that `makeUniqueStrings` checks are still unique among themselves and among the remaining strings. Since `makeUniqueStrings` does not check any elements after element 4, duplicate strings remain.

### Construct Unique Strings with Maximum Length

Create an array from `S` where the first three elements are unique and the maximum length of each string is 5.

```
S = {'sampleData' 'sampleData' 'sampleData' 'sampleData'};
U = matlab.lang.makeUniqueStrings(S, 1:3, 5)
```

U =

```
'sampl' 'sam_1' 'sam_2' 'sampleData'
```

The first element is truncated to 5 characters. The second and third elements are truncated to 3 characters to allow `makeUniqueStrings` to append an underscore and number, and still not exceed 5 characters.

### Determine Modified Strings

```
S = {'a%name', 'name_1', '2_name'};
[N, modified] = matlab.lang.makeValidName(S)
```

N =

```
'a_name' 'name_1' 'x2_name'
```

modified =

```
1 0 1
```

`makeValidName` did not modify the second element.

## Input Arguments

### S — Input strings

string or cell array of strings

Input strings, specified as a string or cell array of strings.

**excludedStrings — Strings to exclude**

string or cell array of strings

Strings to exclude from **U**, specified as a string or cell array of strings.

Example: 'dontDuplicateThisString', {'excludeS1', 'excludeS2'}, who

**whichStrings — Subset of strings to make unique**

range of linear indices or logical array

Subset of strings, **S**, to make unique within the entire set, specified as a range of linear indices or as a logical array with the same size and shape as **S**. If there are duplicates in **S**, the `makeUniqueStrings` function only modifies those specified by `whichStrings`.

If `whichStrings` is a logical array, strings are checked for uniqueness when the array element in the same position has a value of `true`.

Example: 1:5, logical([1 0 1]), [true false true]

**maxLength — Maximum length of output strings**

integer

Maximum length of output strings in **U**, specified as an integer. If `makeUniqueStrings` cannot make elements in **S** unique without exceeding `maxLength`, it returns an error.

## Output Arguments

**U — Unique strings**

string | cell array of strings

Unique strings, returned as a string or cell array of strings. The output has the same dimension as the input, **S**.

**modified — Indicator of modified strings**

logical scalar | logical array

Indicator of modified strings, returned as a logical scalar or array and having the same dimension as the input, **S**. A value of 1 (`true`) indicates that `makeUniqueStrings`

modified the input string in the corresponding location. A value of 0 (`false`) indicates that `makeUniqueStrings` did not need to modify the input string in the corresponding location.

## More About

### Tips

- To ensure strings are valid and unique, use `matlab.lang.makeValidName` before `matlab.lang.makeUniqueStrings`.

```
S = {'my.Name', 'my_Name', 'my_Name'};
validStrings = matlab.lang.makeValidName(S)
validUniqueStrings = matlab.lang.makeUniqueStrings(validStrings, ...
 {}, nameLengthmax)
```

```
validStrings =
```

```
 'my_Name' 'my_Name' 'my_Name'
```

```
validUniqueStrings =
```

```
 'my_Name' 'my_Name_1' 'my_Name_2'
```

### See Also

`matlab.lang.makeValidName` | `nameLengthmax` | `who`

# matlab.lang.makeValidName

Construct valid MATLAB identifiers from input strings

## Syntax

```
N = matlab.lang.makeValidName(S)
N = matlab.lang.makeValidName(S,Name,Value)
[N, modified] = matlab.lang.makeValidName(___)
```

## Description

`N = matlab.lang.makeValidName(S)` constructs valid MATLAB identifiers, `N`, from input strings, `S`. The `makeValidName` function does not guarantee the strings in `N` are unique.

A valid MATLAB identifier is a string of alphanumerics (`A–Z`, `a–z`, `0–9`) and underscores, such that the first character is a letter and the length of the string is less than or equal to `namelengthmax`.

`makeValidName` deletes any whitespace characters prior to replacing any characters that are not alphanumerics or underscores. If a whitespace character is followed by a lowercase letter, `makeValidName` converts the letter to the corresponding uppercase character.

`N = matlab.lang.makeValidName(S,Name,Value)` includes additional options specified by one or more `Name,Value` pair arguments.

`[N, modified] = matlab.lang.makeValidName( ___ )` returns a logical array, `modified`, indicating modified strings. You can use this syntax with any of the input arguments of the previous syntaxes.

## Examples

### Construct Valid MATLAB Identifiers

```
S = {'Item_#', 'Price/Unit', '1st order', 'Contact'};
N = matlab.lang.makeValidName(S)
```

```
N =
 'Item__' 'Price_Unit' 'x1stOrder' 'Contact'
```

In the first and second strings, `makeValidName` replaced the invalid characters (`#` and `/`), with underscores. In the third string, `makeValidName` appended a prefix because the string doesn't begin with a letter, deleted the empty space, and capitalized the character following the deleted space.

### Construct Valid MATLAB Identifiers Using Specified Replacement Style

Replace invalid characters with the corresponding hexadecimal representation.

```
S = {'Item_#', 'Price/Unit', '1st order', 'Contact'};
N = matlab.lang.makeValidName(S, 'ReplacementStyle', 'hex')
```

```
N =
 'Item_0x23' 'Price0x2FUnit' 'x1stOrder' 'Contact'
```

In the first and second strings, `makeValidName` replaced the invalid characters (`#` and `/`), with their hexadecimal representation. In the third string, `makeValidName` appended a prefix because the string doesn't begin with a letter, deleted the empty space, and capitalized the character following the deleted space.

Delete invalid characters.

```
N = matlab.lang.makeValidName(S, 'ReplacementStyle', 'delete')
```

```
N =
 'Item_' 'PriceUnit' 'x1stOrder' 'Contact'
```

`makeValidName` deleted the invalid characters (`#` and `/`). In the third string, `makeValidName` appended a prefix because the string doesn't begin with a letter, deleted the empty space, and capitalized the character following the deleted space.

### Construct Valid MATLAB Identifiers Using Specified Prefix

```
S = {'1stMeasurement', '2ndMeasurement', 'Control'};
```

```
N = matlab.lang.makeValidName(S, 'Prefix', 'm_')

N =

 'm_1stMeasurement' 'm_2ndMeasurement' 'Control'
```

Only the strings that do not start with a letter are prepended with a prefix.

## Determine Modified Strings

```
S = {'a%name', 'name_1', '2_name'};
[N, modified] = matlab.lang.makeValidName(S)
```

```
N =

 'a_name' 'name_1' 'x2_name'
```

```
modified =

 1 0 1
```

makeValidName did not modify the second element.

## Input Arguments

### S — Input strings

string or cell array of strings

Input strings, specified as a string or cell array of strings. If **S** is a cell array of strings, it must be a 1×N or N×1 cell array.

### Name-Value Pair Arguments

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as **Name1**, **Value1**, ..., **NameN**, **ValueN**.

Example: 'ReplacementStyle', 'delete' deletes invalid characters.

### 'ReplacementStyle' — Replacement style

'underscore' (default) | 'delete' | 'hex'

Replacement style, specified as a string. The value controls how MATLAB replaces nonalphanumeric characters.

ReplacementStyle Value	Description
'underscore' (default)	Replaces all characters that are not alphanumeric or underscores with underscores. 'underscore' deletes whitespace characters and changes a lowercase letter following a whitespace to uppercase.
'hex'	Replaces each character that is not an alphanumeric or underscore with its corresponding hexadecimal representation. 'hex' deletes whitespace characters and changes a lowercase letter following a whitespace to uppercase.
'delete'	Deletes all characters that are not alphanumeric or underscores. 'delete' deletes whitespace characters and changes any lowercase letter following a whitespace to uppercase.

### 'Prefix' — Character to prefix

'x' (default) | string

Character to prefix to input strings that do not begin with a letter after `makeValidName` replaces nonalphanumeric characters, specified as a string. A valid prefix must start with a letter, contain only alphanumeric characters and underscores, and not be longer than the value of `namelengthmax`.

## Output Arguments

### N — Valid MATLAB identifiers

string | cell array of strings

Valid MATLAB identifiers, returned as a string or cell array of strings. The output has the same number of dimensions as the input, `S`.

**modified — Indicator of modified strings**

logical scalar | logical array

Indicator of modified strings, returned as a logical scalar or array and having the same number of dimensions as the input, **S**. A value of **1 (true)** indicates that `makeValidName` modified the input string in the corresponding location. A value of **0 (false)** indicates that `makeValidName` did not need to modify the input string in the corresponding location.

## More About

### Tips

- To ensure strings are valid and unique, use `matlab.lang.makeUniqueStrings` after `matlab.lang.makeValidName`.

```
S = {'my.Name', 'my_Name', 'my_Name'};
validStrings = matlab.lang.makeValidName(S)
validUniqueStrings = matlab.lang.makeUniqueStrings(validStrings, {}, ...
 namelengthmax)
```

```
validStrings =
```

```
 'my_Name' 'my_Name' 'my_Name'
```

```
validUniqueStrings =
```

```
 'my_Name' 'my_Name_1' 'my_Name_2'
```

- To customize an invalid character replacement, first use functions such as `strrep` or `regexprep` to convert to valid characters. For example, convert '@' characters in the string, **S**, to 'At' using `strrep(S, '@', 'At')`. Then, use `matlab.lang.makeValidName` to ensure that all characters in the strings are valid.

# matlabrc

Startup file for MATLAB program

## Description

At startup time, MATLAB automatically executes the file `matlabrc.m`. This function establishes the MATLAB path, sets the default figure size, and sets some uicontrol defaults.

On multiuser or networked systems, system administrators can put messages, definitions, or other code that applies to all users in their `matlabrc.m` file.

The file `matlabrc.m` invokes the `startup.m` file, if it exists on the search path MATLAB uses.

Individual users should use the `startup.m` file to customize MATLAB startup. The `matlabrc.m` file, located in the `matlabroot/toolbox/local` folder, is reserved for system administrators.

## Examples

### Turning Off the Figure Window Toolbar

If you do not want the toolbar to appear in the figure window, remove the comment marks from the following line in the `matlabrc.m` file, or create a similar line in your own `startup.m` file.

```
% set(0,'defaultfiguretoolbar','none')
```

## More About

### Tips

You can also start MATLAB using options you define at the Command Window prompt or in your Microsoft Windows shortcut for MATLAB.

## Algorithms

MATLAB invokes `matlabrc` at startup. `matlabrc.m` contains the statements

```
if exist('startup') == 2
 startup
end
```

that invokes `startup.m`, if it exists. Extend this process to create additional startup files, if required.

- “Startup Options”

## See Also

`matlabroot` | `quit` | `restoredefaultpath` | `startup`

# matlabroot

Root folder

## Syntax

```
matlabroot
mr = matlabroot
```

## Description

`matlabroot` returns the name of the folder where the MATLAB software is installed. Use `matlabroot` to create a path to MATLAB and toolbox folders that does not depend on a specific platform, MATLAB version, or installation location.

`mr = matlabroot` returns the name of the folder in which the MATLAB software is installed and assigns it to `mr`.

## Examples

Get the location where MATLAB is installed:

```
matlabroot
```

MATLAB returns:

```
C:\Program Files\MATLAB\R2009a
```

Produce a full path to the `toolbox/matlab/general` folder that is correct for the platform on which it is executed:

```
fullfile(matlabroot, 'toolbox', 'matlab', 'general')
```

Change the current folder to the MATLAB root folder:

```
cd(matlabroot)
```

To add the folder `myfiles` to the MATLAB search path, run

```
addpath([matlabroot ' /toolbox/local/myfiles'])
```

## More About

### Tips

### matlabroot as Folder Name

The term *matlabroot* also refers to the folder where MATLAB files are installed. For example, “save to *matlabroot*/toolbox/local” means save to the `toolbox/local` folder in the MATLAB root folder.

### Using \$matlabroot as a Literal

In some files, `$matlabroot` is literal. In those files, MATLAB interprets `$matlabroot` as the full path to the MATLAB root folder. For example, including the line:

```
$matlabroot/toolbox/local/myfile.jar
```

in `javaclasspath.txt`, adds `myfile.jar`, which is located in the `toolbox/local` folder, to the static Java class path.

Sometimes, particularly in older code examples, the term `$matlabroot` or `$MATLABROOT` is not meant to be interpreted literally but is used to represent the value returned by the `matlabroot` function.

### matlabroot on Macintosh Platforms

In R2008b (V7.7) and more recent versions, running `matlabroot` on Apple Macintosh platforms returns

```
/Applications/MATLAB_R2008b.app
```

In versions prior to R2008b (V7.7), such as R2008a (V7.6), running `matlabroot` on Macintosh platforms returns, for example

```
/Applications/MATLAB_R2008a
```

When you use GUIs on Macintosh platforms, you cannot directly view the contents of the MATLAB root folder. For more information, see “Navigating Within the MATLAB Root Folder on Macintosh Platforms”.

# matlabshared.supportpkg.checkForUpdate

List of support packages that can be updated

## Syntax

```
matlabshared.supportpkg.checkForUpdate
info = matlabshared.supportpkg.checkForUpdate
```

## Description

`matlabshared.supportpkg.checkForUpdate` displays information about support package updates in the MATLAB Command Window. If an update is available, use `supportPackageInstaller` to install the updates.

`info = matlabshared.supportpkg.checkForUpdate` returns a structured array of information about installed support packages.

## Examples

### Check for support package updates

```
matlabshared.supportpkg.checkForUpdate
```

```
No support packages need updates.
```

If one or more updates are available, the command line displays that information in the response.

### Get a structured array of support package updates

```
info = matlabshared.supportpkg.checkForUpdate
```

```
info =
```

```
 Name: 'Arduino'
 InstalledVersion: '3.0'
```

BaseProduct: 'Simulink'

## Output Arguments

### **info** — Return argument from function

structure created using `matlabshared.supportpkg.checkForUpdate`

Information about support package updates, returned as a structured array.

### **See Also**

`matlabshared.supportpkg.getInstalled` | `supportPackageInstaller` | `targetupdater`

# matlabshared.supportpkg.getInstalled

List of installed support packages

## Syntax

```
matlabshared.supportpkg.getInstalled
info = matlabshared.supportpkg.getInstalled
```

## Description

`matlabshared.supportpkg.getInstalled` displays information about installed support packages in the MATLAB Command Window.

`info = matlabshared.supportpkg.getInstalled` returns a structured array of information about installed support packages.

## Examples

### Get a list of installed support packages

```
matlabshared.supportpkg.getInstalled
```

```
Name Version Base Product

Arduino 3.0 Simulink
```

### Get a structured array of installed support packages

```
info = matlabshared.supportpkg.getInstalled
```

```
info =
```

```
 Name: 'Arduino'
 InstalledVersion: '3.0'
```

```
BaseProduct: 'Simulink'
```

## Output Arguments

### **info** — Return argument from function

structure created using `matlabshared.supportpkg.getInstalled`

Information about installed support packages, returned as a structured array.

### **See Also**

`matlabshared.supportpkg.checkForUpdate` | `supportPackageInstaller` | `targetupdater`

## matlab (UNIX)

Start MATLAB program from Mac or Linux system prompt

### Syntax

```
matlab
matlab helpOption
matlab envDispOption
matlab archOption
matlab dispOption
matlab modeOption
matlab -c licensefile
matlab -debug
matlab -Ddebugger options
matlab -jdb portnumber
matlab -logfile filename
matlab -mwvisual visualid
matlab -noFigureWindows
matlab -nosoftwareopengl
matlab -nosplash
matlab -nouserjavapath
matlab -r "command"
matlab -singleCompThread
matlab -softwareopengl
```

---

**Note:** You can enter more than one of these options in the same `matlab` command. If you use `-Ddebugger` to start MATLAB in debug mode, the first option in the command must be `-Ddebugger`.

---

### Description

`matlab` is a Bourne shell script that starts the MATLAB program from a Mac or Linux system prompt. (In this document, the term `matlab` refers to this script; MATLAB refers to the program). Before actually initiating the execution of MATLAB, `matlab` configures the run-time environment by:

- Determining the MATLAB root folder.
- Determining the host machine architecture.
- Processing any command-line options .
- Reading the MATLAB startup file, `.matlab7rc.sh`.
- Setting MATLAB environment variables.

There are two ways in which you can control the way the `matlab` script works:

- By specifying command-line options.
- By assigning values in the MATLAB startup file, `.matlab7rc.sh`.

## Specifying Options at the Command Line

---

**Note:** On Apple Macintosh platforms, the `matlab` script is located inside the MATLAB application package:

```
/Applications/MATLAB_R2012b.app/bin/matlab
```

To run the `matlab` command from Terminal, specify the full path, or `cd` to the `bin` folder within the application package and preface the command with `./` characters. For example:

```
./matlab -nojvm -nodisplay -nosplash -r "myfun(10,30)"
```

---

Options that you can enter at the command line are as follows:

`matlab helpOption` displays information that matches the specified `helpOption` argument without starting MATLAB. `helpOption` can be any one of the keywords shown in the following table. Enter only one `helpOption` keyword in a `matlab` command.

Values for `helpOption`

Option	Description
<b>-help</b>	Display <code>matlab</code> command usage.
<b>-h</b>	The same as <b>-help</b> .

`matlab envDispOption` displays the values of environment variables passed to MATLAB or their values when exiting MATLAB. `envDispOption` can be either one of the options shown in the following table.

Values for `envDispOption`

Option	Description
<b>-n</b>	Display all the final values of the environment variables and arguments passed to the MATLAB executable as well as other diagnostic information. Does not start MATLAB.
<b>-e</b>	Display <i>all</i> environment variables and their values before exiting. This argument must have been parsed before exiting for anything to be displayed. The last possible exiting point is just before the MATLAB image would have been executed and a status of 0 is returned. If the exit status is not 0 on return, then the variables and values might not be correct. Does not start MATLAB.

`matlab archOption` starts MATLAB and assumes that you are running on the system architecture specified by `arch`, or using the MATLAB version specified by `variant`, or both. The values for the `archOption` argument are shown in the following table. Enter only one of these options in a `matlab` command.

Values for `archOption`

Option	Description
<b>-arch</b>	Run MATLAB assuming this architecture rather than the actual architecture of the machine you are using. Replace the term <i>arch</i> with a string representing a recognized system architecture. For example:  <code>matlab -glnx86</code>
<b>v=variant</b>	Execute the version of MATLAB found in the folder <code>bin/\$ARCH/variant</code> instead of <code>bin/\$ARCH</code> . Replace the term <i>variant</i> with a string representing a MATLAB version.
<b>v=arch/variant</b>	Execute the version of MATLAB found in the folder <code>bin/arch/variant</code> instead of <code>bin/\$ARCH</code> . Replace the terms <i>arch</i> and <i>variant</i> with strings representing a specific architecture and MATLAB version.

`matlab dispOption` starts MATLAB using one of the display options shown in the following table. Enter only one of these options in a `matlab` command.

Values for `dispOption`

Option	Description
<b>-display</b> xDisp	Send X commands to X Window Server display xDisp. This option supersedes the value of the DISPLAY environment variable.  On Macintosh platforms, this option is ignored.
<b>-nodisplay</b>	Start the Oracle JVM software, but do not start the MATLAB desktop. Do not display any X commands, and ignore the DISPLAY environment variable.  On Macintosh platforms, start the JVM in headless mode, and prevent all windows from being displayed.

`matlab modeOption` starts MATLAB without its usual desktop component. Enter only one of the options shown in the following table.

Values for `modeOption`

Option	Description
<b>-desktop</b>	Allow the MATLAB desktop to be started by a process without a controlling terminal. This is usually a required command-line argument when attempting to start MATLAB from a window manager menu or desktop icon.
<b>-nodesktop</b>	Start MATLAB without bringing up the MATLAB desktop. The JVM software <i>is</i> started. To enter commands, use the current window in the operating system. Use this option to run in batch processing mode. If you pipe to MATLAB using the > constructor, the <code>nodesktop</code> option is used automatically. With <code>nodesktop</code> , MATLAB does not save statements to the Command History. With <code>nodesktop</code> , you can still use most development environment tools by starting them via a function. For

Option	Description
	example, use <code>preferences</code> to open the Preferences dialog box and <code>doc</code> to open the Help browser. Do not use <code>nodesktop</code> to provide a Command Window-only interface; instead, select <b>Desktop &gt; Desktop Layout &gt; Command Window Only</b> .
<b>-nojvm</b>	Start MATLAB without the JVM software. To enter commands, use the current window. The MATLAB desktop does not open. MATLAB graphics and any tools that require Java software, such as the desktop tools, are not supported; MATLAB displays a warning when you try to use such functionality.

`matlab -c licensefile` starts MATLAB using the specified license file. The `licensefile` argument can have the form `port@host` or it can be a colon-separated list of license filenames. This option causes the `LM_LICENSE_FILE` and `MLM_LICENSE_FILE` environment variables to be ignored.

`matlab -debug` starts MATLAB and displays debugging information that can be useful, especially for X based problems. Use this option only when working with a Technical Support Representative from The MathWorks, Inc.

`matlab -Ddebugger options` starts MATLAB in debug mode, using the named debugger (for example, `dbx`, `gdb`, `xdb`, `cvd`, `lldb`). A full path can be specified for debugger.

#### Notes for -Ddebugger Argument

- The `options` argument can include *only* those options that follow the debugger name in the syntax of the actual debug command. For most debuggers, there is a limited number of such options. Use options that would normally be passed to the MATLAB executable as parameters of a command inside the debugger (like `run`). Do not use `options` when running the `matlab matlab`.
- If any other `matlab` command options are placed before the `-Ddebugger` argument, they will be handled as if they were part of the options after the `-Ddebugger` argument and are treated as illegal options by most debuggers. The `MATLAB_DEBUG` environment variable is set to the `filename` part of the debugger argument.
- To customize your debugging session, use a startup file. See your debugger documentation for details.

- For certain debuggers like `gdb`, the `SHELL` environment variable is *always* set to `/bin/sh`.

`matlab -jdb portnumber` starts MATLAB, enabling use of the Java debugger. If you specify a port number, the Java debugger uses that port to communicate with MATLAB. You can specify any port number in the range 0-65535 that is not reserved or currently in use by another application on your system. By default, MATLAB uses port 4444. If you are running multiple MATLAB sessions and want to use the Java debugger, be sure to specify a port number.

`matlab -logfile filename` starts MATLAB and makes a copy of any output to the Command Window in file `log`. The output includes all crash reports.

`matlab -mwvisual visualid` starts MATLAB and uses `visualid` as the default X visual for figure windows. `visualid` is a hexadecimal number that can be found using `xdpyinfo`.

`matlab -noFigureWindows` starts MATLAB, but disables the display of any figure windows in MATLAB.

`matlab -nosoftwareopengl` disables auto-selection of software OpenGL when a graphics driver with known issues is detected. See `-softwareopengl` option. Not available on Mac platforms.

`matlab -nosplash` starts MATLAB but does not display the splash screen during startup.

`matlab -nouserjavapath` disables `javaclasspath.txt` and `javalibrarypath.txt` files.

`matlab -r "command"` starts MATLAB and executes the specified MATLAB `command`. Include the command in double quotation marks ("`command`"). If `command` is the name of a MATLAB function or script, do not specify the file extension. To separate multiple statements, use semicolons or commas.

`matlab -singleCompThread` limits MATLAB to a single computational thread. By default, MATLAB uses the multithreading capabilities of the computer on which it is running.

`matlab -softwareopengl` forces MATLAB to start with software OpenGL libraries. See `-nosoftwareopengl` option. Not available on Mac platforms.

## Specifying Options in the MATLAB Startup File

The `.matlab7rc.sh` shell script contains definitions for a number of variables that the `matlab` script uses. These variables are defined within the `matlab` script, but can be redefined in `.matlab7rc.sh`. When invoked, `matlab` looks for the first occurrence of `.matlab7rc.sh` in the current folder, in the home folder (`$HOME`), and in the `matlabroot/bin` folder, where the template version of `.matlab7rc.sh` is located.

You can edit the template file to redefine information used by the `matlab` script. If you do not want your changes applied system-wide, copy the edited version of the script to your current or home folder. Ensure that you edit the section that applies to your machine architecture.

The following table lists the variables defined in the `.matlab7rc.sh` file. See the comments in the `.matlab7rc.sh` file for more information about these variables.

Variable Options for Startup File

Variable	Definition and Standard Assignment Behavior
ARCH	The machine architecture.  The value ARCH passed with the <code>-arch</code> or <code>-arch/ext</code> argument to the script is tried first, then the value of the environment variable <code>MATLAB_ARCH</code> is tried next, and finally it is computed. The first one that gives a valid architecture is used.
DISPLAY	Linux platforms only. The hostname of the X Window display MATLAB uses for output.  The value of <code>Xdisplay</code> passed with the <code>-display</code> argument to the script is used; otherwise, the value in the environment is used. MATLAB ignores <code>DISPLAY</code> if the <code>-nodisplay</code> argument is passed.
LD_LIBRARY_PATH on Linux platforms.  DYLD_LIBRARY_PATH on Macintosh platforms.	Final Load library path. The name <code>LD_LIBRARY_PATH</code> is platform-dependent.  The final value is normally a colon-separated list of four sublists, each of which could be empty. The first sublist is defined in <code>.matlab7rc.sh</code> as <code>LDPATH_PREFIX</code> . The second sublist is computed in the script and includes

Variable	Definition and Standard Assignment Behavior
	<p>folders inside the MATLAB root folder and relevant Java folders. The third sublist contains any nonempty value of <code>LD_LIBRARY_PATH</code> from the environment possibly augmented in <code>.matlab7rc.sh</code>. The final sublist is defined in <code>.matlab7rc.sh</code> as <code>LDPATH_SUFFIX</code>.</p>
LM_LICENSE_FILE	<p>The FLEX lm license variable.</p> <p>The license file value passed with the <code>-c</code> argument to the script is used; otherwise it is the value set in <code>.matlab7rc.sh</code>. In general, the final value is a colon-separated list of license files and/or <code>port@host</code> entries. The shipping <code>.matlab7rc.sh</code> file starts out the value by prepending <code>LM_LICENSE_FILE</code> in the environment to a default <code>license.file</code>.</p> <p>Later in the <code>matlab</code> script, if the <code>-c</code> option is not used, the <code>matlabroot/etc</code> folder is searched for the files that start with <code>license.dat.DEMO</code>. These files are assumed to contain demo licenses and are added automatically to the end of the current list.</p>
MATLAB	<p>The MATLAB root folder.</p> <p>The default computed by the script is used unless <code>MATLABdefault</code> is reset in <code>.matlab7rc.sh</code>.</p> <p>Currently <code>MATLABdefault</code> is not reset in the shipping <code>.matlab7rc.sh</code>.</p>
MATLAB_DEBUG	<p>Normally set to the name of the debugger.</p> <p>The <code>-Ddebugger</code> argument passed to the script sets this variable. Otherwise, a nonempty value in the environment is used.</p>

Variable	Definition and Standard Assignment Behavior
MATLAB_JAVA	<p>The path to the root of the Java Runtime Environment.</p> <p>The default set in the script is used unless MATLAB_JAVA is already set. Any nonempty value from <code>.matlab7rc.sh</code> is used first, then any nonempty value from the environment. Currently there is no value set in the shipping <code>.matlab67rc.sh</code>, so that environment alone is used.</p>
MATLABPATH	<p>The MATLAB search path.</p> <p>The final value is a colon-separated list with the MATLABPATH from the environment prepended to a list of computed defaults. You can add subfolders of <code>userpath</code> to the MATLAB search path upon startup. See <code>userpath</code> for details.</p>
SHELL	<p>The shell to use when the “!” or <code>unix</code> command is issued in MATLAB. This value is taken from the environment unless SHELL is reset in <code>.matlab7rc.sh</code>.</p> <p>Another environment variable called MATLAB_SHELL takes precedence over SHELL. MATLAB checks internally for MATLAB_SHELL first and, if empty or not defined, then checks SHELL. If SHELL is also empty or not defined, MATLAB uses <code>/bin/sh</code>. Use an absolute path for the value of MATLAB_SHELL, that is, <code>/bin/sh</code>, not simply <code>sh</code>.</p> <p>Currently, the shipping <code>.matlab7rc.sh</code> file does not reset SHELL and also does not reference or set MATLAB_SHELL.</p>
TOOLBOX	<p>Path of the toolbox folder.</p> <p>A nonempty value in the environment is used first. Otherwise, <code>matlabroot/toolbox</code>, computed by the script, is used unless TOOLBOX is reset in <code>.matlab7rc.sh</code>. Currently TOOLBOX is not reset in the shipping <code>.matlab7rc.sh</code>.</p>

Variable	Definition and Standard Assignment Behavior
XAPPLRESDIR	The X application resource folder (Linux systems only).  A nonempty value in the environment is used first unless XAPPLRESDIR is reset in <code>.matlab7rc.sh</code> .
XKEYSYMDB	The X keysym database file (Linux systems only).  A nonempty value in the environment is used first unless XKEYSYMDB is reset in <code>.matlab7rc.sh</code> .

The `matlab` script determines the path of the MATLAB root folder by looking up the folder tree from the `matlabroot/bin` folder (where the `matlab` script is located). The `MATLAB` variable is then used to locate all files within the MATLAB folder tree.

You can change the definition of `MATLAB` if, for example, you want to run a different version of MATLAB or if, for some reason, the path determined by the `matlab` script is not correct. (This can happen when your system uses certain types of automounting schemes.)

`matlab` (Windows) | `mex`

## How To

- “Start MATLAB on Linux Platforms”
- “Start MATLAB on Mac Platforms”
- “Startup Options”

## matlab (Windows)

Start MATLAB program from Windows system prompt

### Syntax

```
matlab
matlab helpOption
matlab -automation
matlab -c licensefile
matlab -jdb portnumber
matlab -logfile filename
matlab -noFigureWindows
matlab -nosoftwareopengl
matlab -nosplash
matlab -nouserjavapath
matlab -r "statement"
matlab -regserver
matlab -sd "startdir"
matlab shieldOption
matlab -singleCompThread
matlab -softwareopengl
matlab -unregserver
matlab -wait
```

---

**Note** You can enter more than one of these options in the same `matlab` command.

---

### Description

`matlab` starts the MATLAB program from the Microsoft Windows system prompt. (In this document, the term `matlab` refers to the command you type, and MATLAB refers to the program). Before actually initiating the execution of MATLAB, `matlab` configures the run-time environment by:

- Determining the MATLAB root folder.

- Determining the host machine architecture.
- Selectively processing command line options with the rest passed to MATLAB.
- Setting certain MATLAB environment variables.

There are two ways in which you can control the way `matlab` works:

- By specifying command line options.
- By setting environment variables before calling the program.

## Specifying Options at the Command Line

Options that you can enter at the command line are as follows:

`matlab helpOption` displays information that matches the specified *helpOption* argument without starting MATLAB. *helpOption* can be any one of the keywords shown in the table below. Enter only one *helpOption* keyword in a `matlab` statement.

### Values for helpOption

Option	Description
<b>-help</b>	Display <code>matlab</code> command usage.
<b>-h</b>	The same as <b>-help</b> .
<b>-?</b>	The same as <b>-help</b> .

`matlab -automation` starts MATLAB as an automation server. The server window is minimized, and the MATLAB splash screen does not display on startup.

`matlab -c licensefile` starts MATLAB using the specified license file. The `licensefile` argument can have the form `port@host`. This option causes MATLAB to ignore the `LM_LICENSE_FILE` and `MLM_LICENSE_FILE` environment variables.

`matlab -jdb portnumber` starts MATLAB, enabling use of the Java debugger. If you specify a port number, the Java debugger uses that port to communicate with MATLAB. You can specify any port number in the range 0-65535 that is not reserved or currently in use by another application on your system. By default, MATLAB uses port 4444. If you are running multiple MATLAB sessions and want to use the Java debugger, be sure to specify a port number.

`matlab -logfile filename` starts MATLAB and makes a copy of any output to the Command Window in `filename`. This includes all crash reports.

`matlab -noFigureWindows` starts MATLAB, but disables the display of any figure windows in MATLAB.

`matlab -nosoftwareopengl` disables auto-selection of software OpenGL when a graphics driver with known issues is detected. See `-softwareopengl` option.

`matlab -nosplash` starts MATLAB, but does not display the splash screen during startup.

`matlab -nouserjavapath` disables `javaclasspath.txt` and `javalibrarypath.txt` files.

`matlab -r "statement"` starts MATLAB and executes the specified MATLAB statement. If `statement` is the name of a MATLAB function or script, do not specify the file extension. Any required file must be on the MATLAB search path or in the startup folder.

`matlab -regserver` registers MATLAB as a Component Object Model (COM) server.

`matlab -sd "startdir"` specifies the startup folder for MATLAB (the current folder in MATLAB after startup). The `-sd` option has been deprecated. For information about alternatives, see “MATLAB Startup Folder”.

`matlab shieldOption` provides the specified level of protection of the address space used by MATLAB during startup on Windows 32-bit platforms. It attempts to help ensure the largest contiguous block of memory available after startup, which is useful for processing large data sets. The `shieldOption` does this by ensuring resources such as DLLs, are loaded into locations that will not fragment the address space. With `shieldOption` set to a value other than `none`, address space is protected up to or after the processing of `matlabrc`. Use higher levels of protection to secure larger initial blocks of contiguous memory, however a higher level might not always provide a larger size block and might cause startup problems. Therefore, start with a lower level of protection, and if successful, try the next higher level. You can use the `memory` function after startup to see the size of the largest contiguous block of memory; this helps you determine the actual effect of the `shieldOption` setting you used. If your `matlabrc` (or `startup.m`) requires significant memory, a higher level of protection for `shieldOption` might cause startup to fail; in that event try a lower level. Values for `shieldOption` can be any one of the keywords shown in the table below.

Option	Description
<b>-shield minimum</b>	<p>This is the default setting. It protects the range 0x50000000 to 0x70000000 during MATLAB startup until just before startup processes <code>matlabrc</code>. It ensures there is at least approximately 500 MB of contiguous memory up to this point.</p> <p>Start with this, the default value. To use the default, do not specify a shield option upon startup.</p> <p>If MATLAB fails to start successfully using the default option, <b>-shield minimum</b>, instead use <b>-shield none</b>.</p> <p>If MATLAB starts successfully with the default value for <i>shieldOption</i> and you want to try to ensure an even larger contiguous block after startup, try using the <b>-shield medium</b> option.</p>
<b>-shield medium</b>	<p>This protects the same range as for minimum, 0x50000000 to 0x70000000, but protects the range until just after startup processes <code>matlabrc</code>. It ensures there is at least approximately 500 MB of contiguous memory up to this point.</p> <p>If MATLAB fails to start successfully with the <b>-shield medium</b> option, instead use the default option (<b>-shield minimum</b>).</p> <p>If MATLAB starts successfully with the <b>-shield medium</b> option and you want to try to ensure an even larger contiguous block after startup, try using the <b>-shield maximum</b> option.</p>
<b>-shield maximum</b>	<p>This protects the maximum possible range, which can be up to approximately 1.5 GB, until just after startup processes <code>matlabrc</code>.</p> <p>If MATLAB fails to start successfully with the <b>-shield maximum</b> option, instead use the <b>-shield medium</b> option.</p>

Option	Description
<b>-shield none</b>	This completely disables address shielding. Use this if MATLAB fails to start successfully with the default ( <b>-shield minimum</b> ) option.

`matlab -singleCompThread` limits MATLAB to a single computational thread. By default, MATLAB makes use of the multithreading capabilities of the computer on which it is running.

`matlab -softwareopengl` forces MATLAB to start with software OpenGL libraries. See `-nosoftwareopengl` option.

`matlab -unregserver` removes all MATLAB COM server entries from the registry.

`matlab -wait` MATLAB is started by a separate starter program which normally launches MATLAB and then immediately quits. Using this option tells the starter program not to quit until MATLAB has terminated. This option is useful when you need to process the results from MATLAB in a script. Calling MATLAB with this option blocks the script from continuing until the results are generated.

## Setting Environment Variables

You can set the following environment variables before starting MATLAB.

Variable Name	Description
LM_LICENSE_FILE	This variable specifies the License File to use. If you use the <b>-c</b> argument to specify the License File it overrides this variable. The value of this variable can be a list of License Files, separated by semi-colons, or <code>port@host</code> entries.

### How To

- “Start MATLAB on Windows Platforms”
- “Startup Options”

## max

Largest elements in array

### Syntax

$M = \max(A)$

$M = \max(A, [], \text{dim})$

$[M, I] = \max(\text{___})$

$C = \max(A, B)$

### Description

$M = \max(A)$  returns the largest elements of  $A$ .

- If  $A$  is a vector, then  $\max(A)$  returns the largest element of  $A$ .
- If  $A$  is a matrix, then  $\max(A)$  treats the columns of  $A$  as vectors and returns a row vector of largest elements.
- If  $A$  is a multidimensional array, then  $\max(A)$  treats the values along the first array dimension whose size does not equal 1 as vectors and returns an array of maximum values. The size of this dimension becomes 1 while the sizes of all other dimensions remain the same.

$M = \max(A, [], \text{dim})$  returns the largest elements along dimension  $\text{dim}$ . For example, if  $A$  is a matrix, then  $\max(A, [], 2)$  is a column vector containing the maximum value of each row.

$[M, I] = \max(\text{___})$  finds the indices of the maximum values of  $A$  and returns them in output vector  $I$ , using any of the input arguments in the previous syntaxes. If there are several identical maximum values, then  $\max$  returns the index of the first one.

$C = \max(A, B)$  returns an array the same size as  $A$  and  $B$  with the largest elements taken from  $A$  or  $B$ . The dimensions of  $A$  and  $B$  must match, or one can be a scalar.

## Examples

### Largest Element in Vector

Return the maximum value from a vector.

```
A = [23 42 37 18 52];
M = max(A)
```

```
M =

 52
```

### Single Largest Element in Array

Create a 2-by-3 matrix.

```
A = [4 8 2; 9 3 7]
```

```
A =

 4 8 2
 9 3 7
```

To find the single largest element in a matrix, you can apply the `max` function twice, `max(max(A))`. However, this does not return the index to the largest element.

Use `A(:)` to find the maximum element in the column representation of the elements from the array `A`. Also return the index to the maximum element.

```
[M,I] = max(A(:))
```

```
M =

 9
```

```
I =

 2
```

$A(:)$  is a column vector composed of all the columns from the matrix, where each column is appended to the last.  $A(2)$  returns the maximum element, 9.

### Maximum Value from Each Matrix Column

Create a 2-by-3 matrix.

$A = [2 \ 8 \ 4; \ 7 \ 3 \ 9]$

$A =$

2	8	4
7	3	9

Find the maximum of each column.

$[M, I] = \max(A)$

$M =$

7	8	9
---	---	---

$I =$

2	1	2
---	---	---

$A(I(n), n)$  contains the maximum element in the  $n$ th column of  $A$ .

### Maximum Value from Each Matrix Row

Create a 2-by-3 matrix.

$A = [1.7 \ 1.2 \ 1.5; \ 1.3 \ 1.6 \ 1.99]$

$A =$

1.7000	1.2000	1.5000
1.3000	1.6000	1.9900

Find the maximum of each row.

$[M, I] = \max(A, [], 2)$

$M =$

```
1.7000
1.9900
```

I =

```
1
3
```

$A(n, I(n))$  contains the maximum element in the  $n$ th row of A.

### Maximum Elements from Two Arrays

Create two arrays of the same size.

```
A = [1 8 3; 7 2 9]
```

```
B = [2 6 4; 5 2 7]
```

A =

```
1 8 3
7 2 9
```

B =

```
2 6 4
5 2 7
```

Find the maximum elements from A or B.

```
C = max(A,B)
```

C =

```
2 8 4
7 2 9
```

C contains the largest elements from each pair of corresponding elements in A and B.

### Maximum Elements from Array and Scalar

Compare each element of matrix A to a scalar and return the maximum.

Create a 2-by-3 matrix.

```
A = [1 7 3; 6 2 9]
```

```
A =
```

```
 1 7 3
 6 2 9
```

Compare each element of **A** to the scalar value 5.

```
B = 5;
```

```
C = max(A,B)
```

```
C =
```

```
 5 7 5
 6 5 9
```

**C** contains the larger value between each element of **A** and the scalar 5.

## Input Arguments

### **A** — Input array

scalar | vector | matrix | multidimensional array

Input array, specified as a scalar, vector, matrix, or multidimensional array. **A** can be a numeric array, logical array, ordinal categorical array, datetime array, or duration array. Complex Number Support: Yes

### **dim** — Dimension to operate along

positive integer scalar

Dimension to operate along, specified as a positive integer scalar. If no value is specified, the default is the first array dimension whose size does not equal 1.

Dimension **dim** indicates the dimension whose length reduces to 1. The `size(M, dim)` is 1, while the sizes of all other dimensions remain the same, unless `size(A, dim)` is 0. If `size(A, dim)` is 0, then `max` returns an empty array with the same dimension sizes.

Consider a two-dimensional input array, **A**:

- If `dim = 1`, then `max(A, [], 1)` returns a row vector containing the largest element in each column.

$\max(A, [], 1)$

- If  $\text{dim} = 2$ , then  $\max(A, [], 2)$  returns a column vector containing the largest element in each row.

$\max(A, [], 2)$

$\max$  returns  $A$  if  $\text{dim}$  is greater than  $\text{ndims}(A)$ .

**B – Second input array**

scalar | vector | matrix | multidimensional array

Second input array, specified as a scalar, vector, matrix, or multidimensional array.  $B$  can be a numeric array, logical array, ordinal categorical array, datetime array, or duration array.

The dimensions of  $A$  and  $B$  must match, or one can be a scalar.

If  $A$  and  $B$  are ordinal categorical arrays, they must have the same sets of categories, including their order.

A and B can be the same data type or one can be `double` and combine with `single`, any integer data type, or `duration`.

Complex Number Support: Yes

## Output Arguments

### **M** — Maximum values

scalar | vector | matrix | multidimensional array

Maximum values, returned as scalar, vector, matrix, or multidimensional array.

The `size(M,dim)` is 1, while the sizes of all other dimensions match the size of the corresponding dimension in A, unless `size(A,dim)` is 0. If `size(A,dim)` is 0, then M is an empty array with the same dimension sizes as A.

### **I** — Index to A

array the same size as A

Index to A, returned as an array the same size as A. If the largest element occurs more than once, then I contains the index to the first occurrence of the value.

### **C** — Maximum elements from A or B

array

Maximum elements from A or B, returned as an array.

The size of C is as follows:

- If A and B are arrays of the same size, then the size of C matches the size of A and B.
- If either A or B is a scalar, then the size of C matches the size of the nonscalar input array.

The data type of C is as follows:

- If A and B are the same data type, then C matches the data type of A and B.
- If either A or B is `single`, then C is `single`.
- If A and B are an integer data type and a scalar `double`, then C is the same integer data type.

## More About

### Algorithms

The `max` function ignores NaNs. When all elements in `A` are NaNs, then `max` returns the first one as the maximum. Undefined values in categorical arrays and NaT values in datetime arrays are similar to NaNs in numeric arrays.

When `A` is complex, the `max` function returns the complex number with the largest complex modulus (magnitude). If magnitudes are equal, then `max` returns the value with the largest magnitude and the largest phase angle.

When you use `max(A,B)` with an empty array and a scalar, then `max` returns an empty array.

# MaximizeCommandWindow

Open Automation server window

## Syntax

### IDL Method Signature

```
HRESULT MaximizeCommandWindow(void)
```

### Microsoft Visual Basic Client

```
MaximizeCommandWindow
```

### MATLAB Client

```
MaximizeCommandWindow(h)
```

## Description

`MaximizeCommandWindow(h)` displays the window for the server attached to handle `h`, and makes it the currently active window on the desktop.

`MaximizeCommandWindow` restores the window to the size it had at the time it was minimized, not to the maximum size on the desktop. If the server window was not previously in a minimized state, `MaximizeCommandWindow` does nothing.

## Examples

From a Visual Basic .NET client, modify the size of the command window in a MATLAB Automation server.

```
Dim Matlab As Object
Matlab = CreateObject("matlab.application")
```

Matlab.MinimizeCommandWindow

'Now return the server window to its former state on  
'the desktop and make it the currently active window.

Matlab.MaximizeCommandWindow

## **See Also**

MinimizeCommandWindow

# maxNumCompThreads

Control maximum number of computational threads

---

**Note:** maxNumCompThreads will be removed in a future version. You can set the -singleCompThread option when starting MATLAB to limit MATLAB to a single computational thread. By default, MATLAB makes use of the multithreading capabilities of the computer on which it is running.

---

## Syntax

```
N = maxNumCompThreads
LASTN = maxNumCompThreads(N)
LASTN = maxNumCompThreads('automatic')
```

## Description

N = maxNumCompThreads returns the current maximum number of computational threads N.

LASTN = maxNumCompThreads(N) sets the maximum number of computational threads to N, and returns the previous maximum number of computational threads, LASTN.

LASTN = maxNumCompThreads('automatic') sets the maximum number of computational threads using what the MATLAB software determines to be the most desirable. It additionally returns the previous maximum number of computational threads, LASTN.

Currently, the maximum number of computational threads is equal to the number of computational cores on your machine.

---

**Note** Setting the maximum number of computational threads using maxNumCompThreads does not propagate to your next MATLAB session.

---

## mean

Average or mean value of array

### Syntax

```
M = mean(A)
M = mean(A,dim)
M = mean(____, type)
```

### Description

`M = mean(A)` returns the mean value along the first array dimension of `A` whose size does not equal 1.

- If `A` is a vector, then `mean(A)` returns the mean of the elements.
- If `A` is a nonempty, nonvector matrix, then `mean(A)` treats the columns of `A` as vectors and returns a row vector whose elements are the mean of each column.
- If `A` is an empty 0-by-0 matrix, then `mean(A)` returns NaN.
- If `A` is a multidimensional array, then `mean(A)` treats the values along the first array dimension whose size does not equal 1 as vectors and returns an array of row vectors. The size of this dimension becomes 1 while the sizes of all other dimensions remain the same.

`M = mean(A,dim)` returns the mean along dimension `dim`. For example, if `A` is a matrix, then `mean(A,2)` is a column vector containing the mean of each row.

`M = mean( ____, type)` returns the mean in the class specified by `type`, using any of the input arguments in the previous syntaxes. `type` can be `'double'`, `'native'`, or `'default'`.

The `type` option does not support datetime arrays or duration arrays.

## Examples

### Mean of Matrix Columns

Define a 4-by-3 matrix.

```
A = [0 1 1; 2 3 2; 1 3 2; 4 2 2]
```

```
A =
```

```

0 1 1
2 3 2
1 3 2
4 2 2
```

Find the mean value of each column.

```
M = mean(A)
```

```
M =
```

```

1.7500 2.2500 1.7500
```

### Mean of Matrix Rows

Define a 2-by-3 matrix.

```
A = [0 1 1; 2 3 2]
```

```
A =
```

```

0 1 1
2 3 2
```

Find the mean value of each row.

```
M = mean(A,2)
```

```
M =
```

```

0.6667
2.3333
```

### Mean of 3-D array

Create a 1-by-3-by-4 array of integers between 1 and 10.

```
A = gallery('integerdata',10,[1,3,4],1)
```

A(:, :, 1) =

10 8 10

A(:, :, 2) =

6 9 5

A(:, :, 3) =

9 6 1

A(:, :, 4) =

4 9 5

Find the mean values of this 3-D array along the second dimension.

M = mean(A)

M(:, :, 1) =

9.3333

M(:, :, 2) =

6.6667

M(:, :, 3) =

5.3333

M(:, :, 4) =

6

This operation produces a 1-by-1-by-4 array by computing the mean of the three values along the second dimension. The size of the second dimension is reduced to 1.

Compute the mean along the first dimension of A.

```
M = mean(A,1);
isequal(A,M)
```

```
ans =
 1
```

This operation returns the same array as A because the size of the first dimension is 1.

### Mean of 8-bit Integer Array

Define a 1-by-4 vector of 8-bit integers.

```
A = int8(1:4)
```

```
A =
 1 2 3 4
```

Compute the mean value.

```
M = mean(A),
class(M)
```

```
M =
 2.5000
```

```
ans =
double
```

M is the mean value returned as `double`. This operation returns the same result as `M = mean(A, 'default')`.

Specify type as `'native'` to return the mean value as an 8-bit integer.

```
M = mean(A, 'native'),
class(M)
```

```
M =
```

3

ans =

int8

## Input Arguments

### **A** — Input array

vector | matrix | multidimensional array

Input array, specified as a vector, matrix, or multidimensional array.

If **A** contains NaN or NaT (Not a Time), then **M** returns NaN or NaT.

**Data Types:** single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | datetime | duration

### **dim** — Dimension to operate along

positive integer scalar

Dimension to operate along, specified as a positive integer scalar. If no value is specified, the default is the first array dimension whose size does not equal 1.

Dimension **dim** indicates the dimension whose length reduces to 1. The **size(M, dim)** is 1, while the sizes of all other dimensions remain the same.

Consider a two-dimensional input array, **A**.

- If **dim** = 1, then **mean(A, 1)** returns a row vector containing the mean of the elements in each column.
- If **dim** = 2, then **mean(A, 2)** returns a column vector containing the mean of the elements in each row.

`mean` returns `A` if `dim` is greater than `ndims(A)`.

Data Types: `double` | `single` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

#### type – Output class

'default' (default) | 'double' | 'native'

Output class, specified as 'default', 'double', or 'native', and which defines the data type of the output, `M`.

type	Output data type
'default'	<code>double</code> , unless the input data type is <code>single</code> . In which case, the output data type is <code>single</code> .
'double'	<code>double</code>
'native'	same data type as the input array, <code>A</code>

#### See Also

# median

Median value of array

## Syntax

`M = median(A)`  
`M = median(A,dim)`

## Description

`M = median(A)` returns the median value of `A`.

- If `A` is a vector, then `median(A)` returns the median value of `A`.
- If `A` is a nonempty matrix, then `median(A)` treats the columns of `A` as vectors and returns a row vector of median values.
- If `A` is an empty 0-by-0 matrix, `median(A)` returns `NaN`.
- If `A` is a multidimensional array, then `median(A)` treats the values along the first array dimension whose size does not equal 1 as vectors and returns an array of median values. The size of this dimension becomes 1 while the sizes of all other dimensions remain the same.

`median` computes natively in the numeric class of `A`, such that `class(M) = class(A)`.

`M = median(A,dim)` returns the median of elements along dimension `dim`. For example, if `A` is a matrix, then `median(A,2)` is a column vector containing the median value of each row.

## Examples

### Median of Matrix Columns

Define a 4-by-3 matrix.

```
A = [0 1 1; 2 3 2; 1 3 2; 4 2 2]
```

```
A =
```

```

0 1 1
2 3 2
1 3 2
4 2 2

```

Find the median value of each column.

```
M = median(A)
```

```
M =
```

```

1.5000 2.5000 2.0000

```

For each column, the median value is the mean of the middle two numbers in sorted order.

### Median of Matrix Rows

Define a 2-by-3 matrix.

```
A = [0 1 1; 2 3 2]
```

```
A =
```

```

0 1 1
2 3 2

```

Find the median value of each row.

```
M = median(A,2)
```

```
M =
```

```

1
2

```

For each row, the median value is the middle number in sorted order.

### Median of 3-D Array

Create a 1-by-3-by-4 array of integers between 1 and 10.

```
A = gallery('integerdata',10,[1,3,4],1)
```

```
A(:,:,1) =
```

```

10 8 10

```

```
A(:,:,2) =
```

```
 6 9 5
```

```
A(:,:,3) =
```

```
 9 6 1
```

```
A(:,:,4) =
```

```
 4 9 5
```

Find the median values of this 3-D array along the second dimension.

```
M = median(A)
```

```
M(:,:,1) =
```

```
 10
```

```
M(:,:,2) =
```

```
 6
```

```
M(:,:,3) =
```

```
 6
```

```
M(:,:,4) =
```

```
 5
```

This operation produces a 1-by-1-by-4 array by computing the median of the three values along the second dimension. The size of the second dimension is reduced to 1.

Compute the median along the first dimension of A.

```
M = median(A,1);
```

```
isequal(A,M)
```

```
ans =
```

```
1
```

This returns the same array as `A` because the size of the first dimension is 1.

### Median of 8-bit Integer Array

Define a 1-by-4 vector of 8-bit integers.

```
A = int8(1:4)
```

```
A =
```

```
1 2 3 4
```

Compute the median value.

```
M = median(A),
class(M)
```

```
M =
```

```
3
```

```
ans =
```

```
int8
```

`M` is the mean of the middle two numbers in sorted order returned as an 8-bit integer.

## Input Arguments

### A — Input array

vector | matrix | multidimensional array

Input array, specified as a vector, matrix, or multidimensional array. `A` can be a numeric array, ordinal categorical array, datetime array, or duration array.

If `A` contains NaN or NaT (Not a Time), then `median` returns NaN or NaT. Undefined values in categorical arrays are similar to NaNs in numeric arrays.

**dim — Dimension to operate along**

positive integer scalar

Dimension to operate along, specified as a positive integer scalar. If no value is specified, the default is the first array dimension whose size does not equal 1.

Dimension `dim` indicates the dimension whose length reduces to 1. The `size(M,dim)` is 1, while the sizes of all other dimensions remain the same.

Consider a two-dimensional input array, `A`.

- If `dim = 1`, then `median(A,1)` returns a row vector containing the median of the elements in each column.
- If `dim = 2`, then `median(A,2)` returns a column vector containing the median of the elements in each row.

`median` returns `A` if `dim` is greater than `ndims(A)`.

## More About

### Algorithms

For ordinal categorical arrays, MATLAB interprets the median of an even number of elements as follows:

If the number of categories between the middle two values is ...	Then the median is ...
zero (values are from consecutive categories)	larger of the two middle values

<b>If the number of categories between the middle two values is ...</b>	<b>Then the median is ...</b>
an odd number	value from category occurring midway between the two middle values
an even number	value from larger of the two categories occurring midway between the two middle values

### See Also

corrcoef | cov | max | mean | min | mode | std | var

# memmapfile

Create memory map to a file

## Syntax

```
m = memmapfile(filename)
m = memmapfile(filename,Name,Value)
```

## Description

`m = memmapfile(filename)` maps an existing file, `filename`, to memory and returns the memory map, `m`.

Memory-mapping is a mechanism that maps a portion of a file, or an entire file, on disk to a range of memory addresses within the MATLAB address space. Then, MATLAB can access files on disk in the same way it accesses dynamic memory, accelerating file reading and writing. Memory-mapping allows you to work with data in a file as if it were a MATLAB array.

`m = memmapfile(filename,Name,Value)` specifies the properties of `m` using one or more name-value pair arguments. For example, you can specify the format of the data in the file.

## Examples

### Map Entire File of uint8 Data

At the command prompt, create a sample file in your current folder called `records.dat`, containing 10 `uint8` values.

```
myData = uint8(1:10)';

fileID = fopen('records.dat','w');
fwrite(fileID, myData,'uint8');
fclose(fileID);
```

Create a map for `records.dat`. When using `memmapfile`, the default data format is `uint8` so the file name is the only required input argument in this case.

```
m = memmapfile('records.dat')

m =

 Filename: 'd:\matlab\records.dat'
 Writable: false
 Offset: 0
 Format: 'uint8'
 Repeat: Inf
 Data: 10x1 uint8 array
```

MATLAB maps the entire `records.dat` file to memory, setting all properties of the memory map to their default values. The memory map is assigned to the variable, `m`. In this example, the command maps the entire file as a sequence of unsigned 8-bit integers and gives the caller read-only access to its contents.

View the mapped data by accessing the `Data` property of `m`.

```
m.Data

ans =

 1
 2
 3
 4
 5
 6
 7
 8
 9
 10
```

### Map Entire File of Double-Precision Data

Create a memory map for double-precision data. The syntax is similar when specifying other data types.

At the command prompt, create a sample file in your current folder called `records.dat`, containing 10 double values.

```
myData = (1:10)';
```

```
fileID = fopen('records.dat','w');
fwrite(fileID,myData,'double');
fclose(fileID);
```

Create a memory map for `records.dat`, and set the `Format` property for the output to `'double'`.

```
m = memmapfile('records.dat','Format','double')
```

```
m =
```

```
 Filename: 'd:\matlab\records.dat'
 Writable: false
 Offset: 0
 Format: 'double'
 Repeat: Inf
 Data: 10x1 double array
```

The `Data` property contains the 10 double-precision values in `records.dat`.

## Map and Change Part of a File

Create a memory map for a large array of `int32` data. Specify write access, and nondefault `Format` and `Offset` values.

At the command prompt, create a sample file in your current folder called `records.dat`, containing 10,000 `int32` values.

```
myData = int32([1:10000]);
```

```
fileID = fopen('records.dat','w');
fwrite(fileID,myData,'int32');
fclose(fileID);
```

Create a memory map for `records.dat`, and set the `Format` property for the output to `int32`. Also, set the `Offset` property to disregard the first 9000 bytes in the file, and the `Writable` property to permit write access.

```
m = memmapfile('records.dat',...
 'Offset',9000,...
 'Format','int32',...
 'Writable',true);
```

An `Offset` value of 9000 indicates that the first 9000 bytes of `records.dat` are not mapped.

Type the name of the memory map to see the current settings for all properties.

```
m
m =
 Filename: 'd:\matlab\records.dat'
 Writable: true
 Offset: 9000
 Format: 'int32'
 Repeat: Inf
 Data: 7750x1 int32 array
```

The `Format` property indicates that any read or write operation made via the memory map reads and writes the file contents as a sequence of signed 32-bit integers. The `Data` property contains only 7750 elements because the first 9000 bytes of `records.dat`, representing the first 2250 values in the file, are not mapped.

View the first five elements of the mapped data by accessing the `Data` property of `m`.

```
m.Data(1:5)
```

```
ans =
 2251
 2252
 2253
 2254
 2255
```

### Map Region of File to Specific Array Shape

Create a memory map for a region of a file containing 100 double-precision values.

At the command prompt, create a sample file in your current folder called `mybinary.bin`, containing 100 double-precision values.

```
randData = gallery('uniformdata',[100,1],0,'double');

fileID = fopen('mybinary.bin','w');
fwrite(fileID,randData,'double');
fclose(fileID);
```

Map the first 75 values in `mybinary.bin` to a 5-by-5-by-3 array of double-precision values that can be referenced in the structure of the memory map using the field name `x`. Specify these parameters with the `Format` name-value pair argument.

```
m = memmapfile('mybinary.bin',...
 'Format',{ 'double' ,[5 5 3] ,'x'})

m =

 Filename: 'd:\matlab\mybinary.bin'
 Writable: false
 Offset: 0
 Format: { 'double' [5 5 3] 'x' }
 Repeat: Inf
 Data: 1x1 struct array with fields:
 x
```

The `Data` property is a structure array that contains the mapped values in the field, `x`.

Assign the mapped data to a variable, `A`. Because the `Data` property is a structure array, you must index into the field, `x`, to access the data.

```
A = m.Data.x;
```

View information about `A`.

```
whos A
```

Name	Size	Bytes	Class	Attributes
A	5x5x3	600	double	

### Map Segments of File to Multiple Arrays

Map segments of a file with different array shapes and data types to memory.

At the command prompt, create a sample file in your current folder called `mybinary.bin`. Write `uint16` data and double-precision data representing sample pressure, temperature, and volume values into the file. In this case, each of the `uint16` arrays are 50-by-1 and the double-precision arrays are 5-by-10. `k` is a sample scaling factor.

```
k = 8.21;
[pres1,temp1] = gallery('integerdata',[1,300],[50,1],0,'uint16');
vol1 = double(reshape(k*temp1./pres1,5,10));
```

```
[pres2,temp2] = gallery('integerdata',[5,500],[50,1],5,'uint16');
vol2 = double(reshape(k*temp2./pres2,5,10));
```

```
fileID = fopen('mybinary.bin','w');
fwrite(fileID,pres1,'uint16');
fwrite(fileID,temp1,'uint16');
fwrite(fileID,vol1,'double');
fwrite(fileID,pres2,'uint16');
fwrite(fileID,temp2,'uint16');
fwrite(fileID,vol2,'double');
fclose(fileID);
```

Map the file to arrays accessible by unique names. Define a field, `pressure`, containing a 50-by-1 array of `uint16` values, followed by a field, `temperature`, containing 50-by-1 `uint16` values. Define a field, `volume`, containing a 5-by-10 array of double-precision values. Use a cell array to define the format of the mapped region and repeat the pattern twice.

```
m = memmapfile('mybinary.bin',...
'Format',{'uint16',[50 1],'pressure';...
'uint16',[50,1],'temperature';...
'double',[5,10],'volume'},'Repeat',2)
```

```
m =
```

```
Filename: 'd:\matlab\mybinary.bin'
Writable: false
Offset: 0
Format: {'uint16' [50 1] 'pressure'
 'uint16' [50 1] 'temperature'
 'double' [5 10] 'volume'}
Repeat: 2
Data: 2x1 struct array with fields:
 pressure
 temperature
 volume
```

The `Data` property of the memory map, `m`, is a 2-by-1 structure array because the `Format` is applied twice.

Copy the `Data` property to a variable, `A`. Then, view the last block of `double` data, which you can access using the field name, `volume`.

```
A = m.Data;
```

```
myVolume = A(2).volume
```

```
myVolume =
```

```
 2 13 32 5 5 16 4 22 3 8
 2 9 53 38 13 19 23 85 2 120
 29 10 6 1 2 5 6 58 20 11
 7 15 4 1 5 18 1 4 14 8
 9 8 4 2 0 9 8 6 3 3
```

- “Map File to Memory”

## Input Arguments

**filename** — Name of file to map

string

Name of the file to map including the file extension, specified as a string. The **filename** argument cannot include any wildcard characters (for example, \* or ?).

Example: 'myFile.dat'

Data Types: char

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Example: `m = memmapfile('myFile.dat','Format','int32','Offset',255)` maps int32 data in the file, myFile.dat, to memory starting from the 256th byte.

**'Writable'** — Type of access allowed to mapped region

false (default) | true

Type of access allowed to the mapped region, specified as the comma-separated pair consisting of 'Writable' and either true or false. If the **Writable** property is set to false, the mapped region is read-only. If true, then write access is allowed.

Example: 'Writable',true

Data Types: `logical`

**'Offset' — Number of bytes from start of file to start of mapped region**

0 (default) | nonnegative integer

Number of bytes from the start of the file to the start of the mapped region, specified as the comma-separated pair consisting of `'Offset'` and a nonnegative integer. This value is zero-based. That is, an `Offset` value of 0 represents the start of the file.

Example: `'Offset', 1024`

Data Types: `double`

**'Format' — Format of mapped region**

`'uint8'` (default) | string | n-by-3 cell array

Format of the mapped region contents, specified as the comma-separated pair consisting of `'Format'` and a single string or an n-by-3 cell array.

- If the file region you are mapping contains data of only one type, specify the `Format` value as a string identifying that type.  
**Example:** `'int16'`
- To specify an array shape to apply to the data read or written to the mapped file, and a field name to reference this array, specify the `Format` value as a 1-by-3 cell array. The first cell contains a string identifying the data type to apply to the mapped region. The second cell contains the array dimensions to apply to the region. The third cell contains a string specifying the field name to use in the `Data` structure array of the memory map.  
**Example:** `{'uint64', [30 4 10], 'x'}`
- If the region you are mapping is composed of segments of varying data types or array shapes, you can specify an individual format for each segment using an n-by-3 cell array, where n is the number of segments.  
**Example:** `{'uint64', [30 4 10], 'x'; 'uint32', [30 4 6], 'y'}`

You can use any of the following data types when you specify a `Format` value:

- `'int8'`
- `'int16'`
- `'int32'`
- `'int64'`

- 'uint8'
- 'uint16'
- 'uint32'
- 'uint64'
- 'single'
- 'double'

Data Types: char | cell

### 'Repeat' — Number of times to apply Format parameter

Inf (default) | positive integer

Number of times to apply the `Format` parameter to the mapped region of the file, specified as the comma-separated pair consisting of 'Repeat' and a positive integer. If the value of `Repeat` is `Inf`, then `memmapfile` applies the `Format` parameter until the end of the file.

Example: 'Repeat', 2000

Data Types: double

## Output Arguments

### **m** — Memory map

`memmapfile` object

Memory map, returned as a `memmapfile` object with the following properties.

Property	Description
Filename	Path and name of the mapped file
Writable	Type of access allowed to the mapped region
Offset	Number of bytes from the start of the file to the start of the mapped region
Format	Format of the contents of the mapped region, including data type, array size, and field name by which to access the data

Property	Description
Repeat	Number of times to apply the pattern specified by the <code>Format</code> property to the mapped region of the file
Data	Memory-mapped data from the file. <code>Data</code> can be a numeric array or a structure array with field names specified in the <code>Format</code> property

The values for any property (except for `Data`) are set at the time you call `memmapfile`, using name-value pair arguments.

Access any property of `m` with dot notation similar to accessing fields of a structure array. For example, to access the memory-mapped data in the `Data` property, do one of the following:

- If `Data` is a numeric array, call `m.Data`.
- If `Data` is a scalar (1-by-1) structure array, call `m.Data.fieldname`, where *fieldname* is the name of a field.
- If `Data` is a nonscalar structure array, call `m.Data(index).fieldname` where *index* is the index for the element in the structure array, and *fieldname* is the name of a field. For example, to access the file data in the `temperature` field of the first element of `Data`, call `m.Data(1).temperature`.

After you create a memory map, `m`, you can change the value of any of its properties, except for `Data`. To assign a new value, use dot notation. For example, to set a new `Offset` value for `m`, type:

```
m.Offset = 2048;
```

## More About

### Tips

- You can map only an existing file. You cannot create a new file and map that file to memory in one operation. Use the MATLAB file I/O functions to create the file before attempting to map it to memory.
- After `memmapfile` locates the file, MATLAB stores the file's absolute pathname internally, and then uses this stored path to locate the file from that point on. As

a result, you can work in other directories outside your current work directory and retain access to the mapped file.

- `memmapfile` does not expand or append to a mapped file. Use instead standard file I/O functions like `fopen` and `fwrite`.

## Algorithms

The actual mapping of a file to the MATLAB address space does not take place when you construct a `memmapfile` object. A memory map, based on the information currently stored in the mapped object, is generated the first time you reference or modify the `Data` property for that object.

- “Overview of Memory-Mapping”

# memory

Display memory information

## Syntax

```
memory
userview = memory
[userview systemview] = memory
```

## Limitations

- The `memory` function is available only on Microsoft Windows systems. Results are dependant on your computer hardware and the load on your computer.

## Description

`memory` displays information showing how much memory is available and how much the MATLAB software is currently using. The information displayed at your computer screen includes the following items, each of which is described in a section below:

- “Maximum Possible Array” on page 1-4820
- “Memory Available for All Arrays” on page 1-4821
- “Memory Used By MATLAB” on page 1-4822
- “Total Physical Memory (RAM)” on page 1-4822

`userview = memory` returns user-focused information on memory use in structure `userview`. The information returned in `userview` includes the following items, each of which is described in a section below:

- “Maximum Possible Array” on page 1-4820
- “Memory Available for All Arrays” on page 1-4821
- “Memory Used By MATLAB” on page 1-4822

`[userview systemview] = memory` returns both user- and system-focused information on memory use in structures `userview` and `systemview`, respectively.

The `userview` structure is described in the command syntax above. The information returned in `systemview` includes the following items, each of which is described in a section below:

- “Virtual Address Space” on page 1-4822
- “System Memory” on page 1-4823
- “Physical Memory” on page 1-4823

## Output Arguments

Each of the sections below describes a value that is displayed or returned by the `memory` function.

### Maximum Possible Array

Maximum Possible Array is the size of the largest contiguous free memory block. As such, it is an upper bound on the largest single array MATLAB can create at this time.

MATLAB derives this number from the smaller of the following two values:

- The largest contiguous memory block found in the MATLAB virtual address space
- The total available system memory

To see how many array elements this number represents, divide by the number of bytes in the array class. For example, for a `double` array, divide by 8. The actual number of elements MATLAB can create is always fewer than this number.

When you enter the `memory` command without assigning its output, MATLAB displays this information as a string. When you do assign the output, MATLAB returns the information in a structure field. See the table below.

Command	Returned in
<code>memory</code>	String labelled Maximum possible array:
<code>user = memory</code>	Structure field <code>user.MaxPossibleArrayBytes</code>

All values are double-precision and in units of bytes.

## Footnotes

When you enter the `memory` command without specifying any outputs, MATLAB may also display one of the following footnotes. 32-bit systems show either the first or second footnote; 64-bit systems show only the second footnote:

Limited by contiguous virtual address space available.

There is sufficient system memory to allow mapping of all virtual addresses in the largest available block of the MATLAB process. The maximum amount of total MATLAB virtual address space is either 2 GB or 3 GB, depending on whether the `/3GB` switch is in effect or not.

Limited by System Memory (physical + swap file) available.

There is insufficient system memory to allow mapping of all virtual addresses in the largest available block of the MATLAB process.

## Memory Available for All Arrays

Memory Available for All Arrays is the total amount of memory available to hold data. The amount of memory available is guaranteed to be at least as large as this field.

MATLAB derives this number from the smaller of the following two values:

- The total available MATLAB virtual address space
- The total available system memory

When you enter the `memory` command without assigning its output, MATLAB displays this information as a string. When you do assign the output, MATLAB returns the information in a structure field. See the table below.

Command	Returned in
<code>memory</code>	String labelled Memory available for all arrays:
<code>user = memory</code>	Structure field <code>user.MemAvailableAllArrays</code>

## Footnotes

When you enter the `memory` command without specifying any outputs, MATLAB may also display one of the following footnotes. 32-bit systems show either the first or second footnote; 64-bit systems show only the latter footnote:

Limited by virtual address space available.

There is sufficient system memory to allow mapping of all available virtual addresses in the MATLAB process virtual address space to system memory. The maximum amount of total MATLAB virtual address space is either 2 GB or 3 GB, depending on whether the /3GB switch is in effect or not.

Limited by System Memory (physical + swap file) available.

There is insufficient system memory to allow mapping of all available virtual addresses in the MATLAB process.

## Memory Used By MATLAB

Memory Used By MATLAB is the total amount of system memory reserved for the MATLAB process. It is the sum of the physical memory and potential swap file usage.

When you enter the `memory` command without assigning its output, MATLAB displays this information as a string. When you do assign the output, MATLAB returns the information in a structure field. See the table below.

Command	Returned in
<code>memory</code>	String labelled <code>Memory used by MATLAB:</code>
<code>user = memory</code>	Structure field <code>user.MemUsedMATLAB</code>

## Total Physical Memory (RAM)

Physical Memory (RAM) is the total physical memory (or RAM) in the computer.

When you enter the `memory` command without assigning its output, MATLAB displays this information as a string. See the table below.

Command	Returned in
<code>memory</code>	String labelled <code>Physical Memory (RAM):</code>

## Virtual Address Space

Virtual Address Space is the amount of available and total virtual memory for the MATLAB process. MATLAB returns the information in two fields of the return structure: `Available` and `Total`.

Command	Return Value	Returned in Structure Field
[user,sys] = memory	Available memory	sys.VirtualAddressSpace.Available
	Total memory	sys.VirtualAddressSpace.Total

You can monitor the difference:

```
VirtualAddressSpace.Total - VirtualAddressSpace.Available
```

as the Virtual Bytes counter in the Windows Performance program. (e.g., Windows XP Control Panel/Administrative Tool/Performance program).

## System Memory

System Memory is the amount of available system memory on your computer system. This number includes the amount of available physical memory and the amount of available swap file space on the computer running MATLAB. MATLAB returns the information in the `SystemMemory` field of the return structure.

Command	Return Value	Returned in Structure Field
[user,sys] = memory	Available memory	sys.SystemMemory

This is the same as the difference:

```
limit - total (in bytes)
```

found in the Windows Task Manager: Performance/Commit Charge.

## Physical Memory

Physical Memory is the available and total amounts of physical memory (RAM) on the computer running MATLAB. MATLAB returns the information in two fields of the return structure: `Available` and `Total`.

Command	Value	Returned in Structure Field
[user,sys] = memory	Available memory	sys.PhysicalMemory.Available
	Total memory	sys.PhysicalMemory.Total

Available physical memory is the same as:

```
Available (in bytes)
```

found in the Windows Task Manager: Performance/Physical Memory

The total physical memory is the same as

Total (in bytes)

found in the Windows Task Manager: Performance/Physical Memory

You can use the amount of available physical memory as a measure of how much data you can access quickly.

## Examples

Display memory statistics on a 32-bit Windows system:

```
memory
```

```
Maximum possible array: 677 MB (7.101e+008 bytes) *
Memory available for all arrays: 1601 MB (1.679e+009 bytes) **
Memory used by MATLAB: 446 MB (4.681e+008 bytes)
Physical Memory (RAM): 3327 MB (3.489e+009 bytes)
```

\* Limited by contiguous virtual address space available.

\*\* Limited by virtual address space available.

Return in the structure `userview`, information on the largest array MATLAB can create at this time, how much memory is available to hold data, and the amount of memory currently being used by your MATLAB process:

```
userview = memory
```

```
userview =
 MaxPossibleArrayBytes: 710127616
 MemAvailableAllArrays: 1.6792e+009
 MemUsedMATLAB: 468127744
```

Assign the output to two structures, `user` and `sys`, to obtain the information shown here:

```
[user sys] = memory;

% --- Largest array MATLAB can create ---
user.MaxPossibleArrayBytes
ans =
```

```
710127616

% --- Memory available for data ---
user.MemAvailableAllArrays
ans =
 1.6797e+009

% --- Memory used by MATLAB process ---
user.MemUsedMATLAB
ans =
 467603456

% --- Virtual memory for MATLAB process ---
sys.VirtualAddressSpace
ans =
 Available: 1.6797e+009
 Total: 2.1474e+009

% --- Physical memory and paging file ---
sys.SystemMemory
ans =
 Available: 4.4775e+009

% --- Computer's physical memory ---
sys.PhysicalMemory
ans =
 Available: 2.3941e+009
 Total: 3.4889e+009
```

## More About

### Tips

### Details on Memory Used By MATLAB

MATLAB computes the value for Memory Used By MATLAB by walking the MATLAB process memory structures and summing all the sections that have physical storage allocated in memory or in the paging file on disk.

Using the Windows Task Manager, you have for the MATLAB.exe image:

Mem Usage < MemUsedMATLAB < Mem Usage + VM Size (in bytes)

where both of the following are true:

- `Mem Usage` is the working set size in kilobytes.
- `VM Size` is the page file usage, or private bytes, in kilobytes.

The working set size is the portion of the MATLAB virtual address space that is *currently* resident in RAM and can be referenced without a memory page fault. The page file usage gives the portion of the MATLAB virtual address space that requires a backup that doesn't already exist. Another name for page file usage is *private bytes*. It includes all MATLAB variables and workspaces. Since some of the pages in the page file may also be part of the working set, this sum is an overestimate of `MemUseMATLAB`. Note that there are virtual pages in the MATLAB process space that already have a backup. For example, code loaded from EXEs and DLLs and memory-mapped files. If any part of those files is in memory when the memory builtin is called, that memory will be counted as part of `MemUsedMATLAB`.

## Reserved Addresses

Reserved addresses are addresses sets aside in the process virtual address space for some specific future use. These reserved addresses reduce the size of `MemAvailableAllArrays` and can reduce the size of the current or future value of `MaxPossibleArrayBytes`.

### Example 1 — Java Virtual Machine (JVM)

At MATLAB startup, part of the MATLAB virtual address space is reserved by the Java Virtual Machine (JVM) and cannot be used for storing MATLAB arrays.

### Example 2 — Standard Windows Heap Manager

MATLAB, by default, uses the standard Windows heap manager except for a set of small preselected allocation sizes. One characteristic of this heap manager is that its behavior depends upon whether the requested allocation is less than or greater than the fixed number of 524,280 bytes. For, example, if you create a sequence of MATLAB arrays, each less than 524,280 bytes, and then clear them all, the `MemUsedMATLAB` value before and after shows little change, and the `MemAvailableAllArrays` value is now smaller by the total space allocated.

The result is that, instead of globally freeing the extra memory, the memory becomes reserved. It can *only* be reused for arrays less than 524,280 bytes. You cannot reclaim this memory for a larger array except by restarting MATLAB.

## menu

Generate menu of choices for user input

### Syntax

```
choice = menu('mtitle','opt1','opt2',...,'optn')
choice = menu('mtitle',options)
```

### Description

`choice = menu('mtitle','opt1','opt2',...,'optn')` displays the menu whose title is in the string variable 'mtitle' and whose choices are string variables 'opt1', 'opt2', and so on. The menu opens in a modal dialog box. `menu` returns the number of the selected menu item, or 0 if the user clicks the close button on the window.

`choice = menu('mtitle',options)` , where options is a 1-by-N cell array of strings containing the menu choices.

If the user's terminal provides a graphics capability, `menu` displays the menu items as push buttons in a figure window (Example 1). Otherwise, they will be given as a numbered list in the Command Window (Example 2).

## Examples

### Example 1

On a system with a display, `menu` displays choices as buttons in a dialog box:

```
choice = menu('Choose a color','Red','Blue','Green')
displays the following dialog box.
```

The number entered by the user in response to the prompt is returned as `choice` (i.e., `choice = 2` implies that the user selected `Blue`).

After input is accepted, the dialog box closes, returning the output in `choice`. You can use `choice` to control the color of a graph:

```
t = 0:.1:60;
s = sin(t);
color = ['r','b','g']
plot(t,s,color(choice))
```

## Example 2

On a system without a display, `menu` displays choices in the Command Window:

```
choice = menu('Choose a color','Red','Blue','Green')
```

displays the following text.

```
----- Choose a color -----
1) Red
2) Blue
3) Green
Select a menu number:
```

## **More About**

### **Tips**

To call `menu` from a `uicontrol` or other ui object, set that object's `Interruptible` property to `'on'`. For more information, see [Uicontrol Properties](#).

# mergecats

Merge categories in categorical array

## Syntax

```
B = mergecats(A,oldcats)
B = mergecats(A,oldcats,newcat)
```

## Description

`B = mergecats(A,oldcats)` merges two or more categories in `A` into the first category, `oldcats(1)`. Any values in `A` from `oldcats` become `oldcats(1)` in `B`.

`B = mergecats(A,oldcats,newcat)` merges `oldcats` into a single new category, `newcat`. Any values in `A` from `oldcats` become `newcat` in `B`.

## Examples

### Merge Two Categories into One

Create a categorical array containing various colors.

```
A = categorical({'red','blue','pink','red','blue','red'})
```

A =

```
red
blue
pink
red
blue
red
```

A is a 6-by-1 categorical array.

Display the categories of A.

```
categories(A)
```

```
ans =
 'blue'
 'pink'
 'red'
```

The three categories are in alphabetical order.

Merge the categories `red` and `pink` into the category `red`. Specify `red` first in `oldcats` to use it as the merged category.

```
oldcats = {'red', 'pink'};
B = mergecats(A, oldcats)
```

```
B =
 red
 blue
 red
 red
 blue
 red
```

`mergetcats` replaces the value `pink` from `A(3)` with `red`.

Display the categories of `B`.

```
categories(B)
```

```
ans =
 'blue'
 'red'
```

`B` has two categories instead of three.

## Merge Alphabetically Listed Categories

Create a categorical array containing various items.

```
A = categorical({'shirt' 'pants'; 'shoes' 'shirt'; 'dress' 'belt'})
```

```
A =
 shirt pants
 shoes shirt
```

```
dress belt
```

Display the categories of **A**.

```
categories(A)
```

```
ans =
```

```
'belt'
'dress'
'pants'
'shirt'
'shoes'
```

The five categories are in alphabetical order.

Merge the categories **belt** and **shoes** into a new category called **other**.

```
B = mergocats(A,{'belt' 'shoes'}, 'other')
```

```
B =
```

```
shirt pants
other shirt
dress other
```

The value **other** replaces all instances of **belt** and **shoes**.

Display the categories of **B**.

```
categories(B)
```

```
ans =
```

```
'other'
'dress'
'pants'
'shirt'
```

**B** has four categories and the order is no longer alphabetical. **other** appears in place of **belt**.

### Merge Categories of Ordinal Categorical Array

Create an ordinal categorical array.

```
A = categorical([1 2 3 2 1],1:3,{'poor','fair','good'},'Ordinal',true)
```

```
A =
 poor fair good fair poor
```

Display the categories of A.

```
categories(A)
```

```
ans =
```

```
 'poor'
 'fair'
 'good'
```

Since A is ordinal, the categories have the mathematical ordering `poor < fair < good`.

Consider all `fair` or `poor` values to be `bad`. Since A is ordinal, the categories to merge must be consecutive.

```
B = mergecats(A, {'fair' 'poor'}, 'bad')
```

```
B =
```

```
 bad bad good bad bad
```

The value `bad` replaces all instances of `fair` and `poor`.

Display the categories of B.

```
categories(B)
```

```
ans =
```

```
 'bad'
 'good'
```

B has two categories with the mathematical ordering: `bad < good`.

## Input Arguments

### A — Categorical array

vector | matrix | multidimensional array

Categorical array, specified as a vector, matrix, or multidimensional array.

**oldcats — Categories to merge**

cell array of strings

Categories to merge, specified as a cell array of strings. If *A* is ordinal, the categories to merge must be consecutive.

**newcat — New category**

oldcats(1) (default) | string

New category, specified as a string.

**See Also**

addcats | categories | iscategory | removecats | renamecats | reordercats  
| setcats

# mesh

Mesh plot

## Syntax

```
mesh(X,Y,Z)
mesh(Z)
mesh(...,C)
mesh(...,'PropertyName',PropertyValue,...)
mesh(axes_handles,...)
h = mesh(...)
```

## Description

`mesh(X,Y,Z)` draws a wireframe mesh with color determined by `Z`, so color is proportional to surface height. If `X` and `Y` are vectors, `length(X) = n` and `length(Y) = m`, where `[m,n] = size(Z)`. In this case,  $(X(j), Y(i), Z(i,j))$  are the intersections of the wireframe grid lines; `X` and `Y` correspond to the columns and rows of `Z`, respectively. If `X` and `Y` are matrices,  $(X(i,j), Y(i,j), Z(i,j))$  are the intersections of the wireframe grid lines.

`mesh(Z)` draws a wireframe mesh using `X = 1:n` and `Y = 1:m`, where `[m,n] = size(Z)`. The height, `Z`, is a single-valued function defined over a rectangular grid. Color is proportional to surface height.

`mesh(...,C)` draws a wireframe mesh with color determined by matrix `C`. MATLAB performs a linear transformation on the data in `C` to obtain colors from the current colormap. If `X`, `Y`, and `Z` are matrices, they must be the same size as `C`.

`mesh(...,'PropertyName',PropertyValue,...)` sets the value of the specified surface property. Multiple property values can be set with a single statement.

`mesh(axes_handles, ...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`h = mesh(...)` returns a handle to a Chart Surface Properties graphics object.

## Examples

### Create Mesh Plot of Sinc Function

Create a mesh plot of the sinc function,  $z = \sin(r)/r$ .

```
[X,Y] = meshgrid(-8:.5:8);
R = sqrt(X.^2 + Y.^2) + eps;
Z = sin(R)./R;
```

```
figure
mesh(Z)
```

### **Specify Color for Mesh Plot**

Specify a color matrix for a mesh plot.

```
[X,Y] = meshgrid(-8:.5:8);
R = sqrt(X.^2 + Y.^2) + eps;
Z = sin(R)./R;
C = gradient(Z);
```

```
figure
mesh(X,Y,Z,C)
```

### Change Lighting and Line Width for Mesh Plot

Change the lighting and the line width for a mesh plot using Name, Value pair arguments.

```
[X,Y] = meshgrid(-8:.5:8);
R = sqrt(X.^2 + Y.^2) + eps;
Z = sin(R)./R;
C = del2(Z);
```

```
figure
mesh(X,Y,Z,C, 'FaceLighting', 'gouraud', 'LineWidth', 0.3)
```

## More About

### Tips

`mesh` does not accept complex inputs.

A mesh is drawn as a `Surfaceplot` graphics object with the viewpoint specified by `view(3)`. The face color is the same as the background color (to simulate a wireframe with hidden-surface elimination), or `none` when drawing a standard see-through wireframe. The current colormap determines the edge color. The `hidden` command controls the simulation of hidden-surface elimination in the mesh, and the `shading` command controls the shading model.

Chart Surface Properties

## meshc

Plot a contour graph under mesh graph

## Syntax

```
meshc(X,Y,Z)
meshc(Z)
meshc(...,C)
meshc(axes_handles,...)
h = meshc(...)
```

## Description

`meshc(X,Y,Z)` draws a wireframe mesh and a contour plot under it with color determined by `Z`, so color is proportional to surface height. If `X` and `Y` are vectors, `length(X) = n` and `length(Y) = m`, where `[m,n] = size(Z)`. In this case, `(X(j), Y(i), Z(i,j))` are the intersections of the wireframe grid lines; `X` and `Y` correspond to the columns and rows of `Z`, respectively. If `X` and `Y` are matrices, `(X(i,j), Y(i,j), Z(i,j))` are the intersections of the wireframe grid lines.

`meshc(Z)` draws a contour plot under wireframe mesh using `X = 1:n` and `Y = 1:m`, where `[m,n] = size(Z)`. The height, `Z`, is a single-valued function defined over a rectangular grid. Color is proportional to surface height.

`meshc(...,C)` draws a `meshc` graph with color determined by matrix `C`. MATLAB performs a linear transformation on the data in `C` to obtain colors from the current colormap. If `X`, `Y`, and `Z` are matrices, they must be the same size as `C`.

`meshc(axes_handles,...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`h = meshc(...)` returns handles to the Chart Surface Properties and Contour Properties graphics object.

## Examples

### Display Contour Plot Under Mesh Plot

Use `meshc` to display a combination of a mesh plot and a contour plot of the `peaks` function.

```
figure
[X,Y] = meshgrid(-3:.125:3);
Z = peaks(X,Y);
meshc(Z)
```

## More About

### Tips

`meshc` does not accept complex inputs.

A mesh is drawn as a `Surfaceplot` graphics object with the viewpoint specified by `view(3)`. The face color is the same as the background color (to simulate a wireframe with hidden-surface elimination), or `none` when drawing a standard see-through wireframe. The current colormap determines the edge color. The `hidden` command controls the simulation of hidden-surface elimination in the mesh, and the `shading` command controls the shading model.

## Algorithms

The range of *X*, *Y*, and *Z*, or the current settings of the axes `XLimMode`, `YLimMode`, and `ZLimMode` properties, determine the axis limits. `axis` sets these properties.

The range of *C*, or the current settings of the axes `CLim` and `CLimMode` properties (also set by the `caxis` function), determine the color scaling. Use the scaled color values are used as indices into the current colormap.

The mesh rendering functions produce color values by mapping the *z* data values (or an explicit color array) onto the current colormap. The MATLAB default behavior is to compute the color limits automatically using the minimum and maximum data values (also set using `caxis auto`). The minimum data value maps to the first color value in the colormap and the maximum data value maps to the last color value in the colormap. MATLAB performs a linear transformation on the intermediate values to map them to the current colormap.

`meshc` calls `mesh`, turns `hold` on, and then calls `contour` and positions the contour on the *x-y* plane. For additional control over the appearance of the contours, issue these commands directly. You can combine other types of graphs in this manner, for example `surf` and `pcolor` plots.

`meshc` assumes that *X* and *Y* are monotonically increasing. If *X* or *Y* is irregularly spaced, `contour3` calculates contours using a regularly spaced contour grid, and then it transforms the data to *X* or *Y*.

## meshz

Plot a curtain around mesh plot

### Syntax

```
meshz(X,Y,Z)
meshz(Z)
meshz(...,C)
meshz(axes_handles,...)
h = meshz(...)
```

### Description

`meshz(X,Y,Z)` draws a curtain around the wireframe mesh with color determined by `Z`, so color is proportional to surface height. If `X` and `Y` are vectors, `length(X) = n` and `length(Y) = m`, where `[m,n] = size(Z)`. In this case, `(X(j), Y(i), Z(i,j))` are the intersections of the wireframe grid lines; `X` and `Y` correspond to the columns and rows of `Z`, respectively. If `X` and `Y` are matrices, `(X(i,j), Y(i,j), Z(i,j))` are the intersections of the wireframe grid lines.

`meshz(Z)` draws a curtain around the wireframe mesh using `X = 1:n` and `Y = 1:m`, where `[m,n] = size(Z)`. The height, `Z`, is a single-valued function defined over a rectangular grid. Color is proportional to surface height.

`meshz(...,C)` draws a `meshz` graph with color determined by matrix `C`. MATLAB performs a linear transformation on the data in `C` to obtain colors from the current colormap. If `X`, `Y`, and `Z` are matrices, they must be the same size as `C`.

`meshz(axes_handles,...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`h = meshz(...)` returns a handle to a Chart Surface Properties graphics object.

## Examples

### Curtain Plot of Peaks Function

Generate a curtain plot of the `peaks` function using `meshz`.

```
figure
[X,Y] = meshgrid(-3:.125:3);
Z = peaks(X,Y);
meshz(Z)
```

### Specify Color for Curtain Plot

Specify a color matrix for a curtain plot.

```
[X,Y] = meshgrid(-3:.125:3);
Z = peaks(X,Y);
C = gradient(Z);
```

```
figure
meshz(X,Y,Z,C)
```

## More About

### Tips

meshz does not accept complex inputs.

A mesh is drawn as a chart surface graphics object with the viewpoint specified by `view(3)`. The face color is the same as the background color (to simulate a wireframe with hidden-surface elimination), or `none` when drawing a standard see-through wireframe. The current colormap determines the edge color. The `hidden` command controls the simulation of hidden-surface elimination in the mesh, and the `shading` command controls the shading model.

### Functions

`axis` | `caxis` | `colormap` | `contour` | `hidden` | `hold` | `mesh` | `meshc` | `meshgrid` | `shading` | `surf` | `surface` | `surfc` | `surf1` | `view` | `waterfall`

### Properties

Chart Surface Properties

# meshgrid

Rectangular grid in 2-D and 3-D space

## Syntax

```
[X,Y] = meshgrid(xgv,ygv)
[X,Y,Z] = meshgrid(xgv,ygv,zgv)
[X,Y] = meshgrid(gv)
[X,Y,Z] = meshgrid(gv)
```

## Description

`[X,Y] = meshgrid(xgv,ygv)` replicates the grid vectors `xgv` and `ygv` to produce a full grid. This grid is represented by the output coordinate arrays `X` and `Y`. The output coordinate arrays `X` and `Y` contain copies of the grid vectors `xgv` and `ygv` respectively. The sizes of the output arrays are determined by the length of the grid vectors. For grid vectors `xgv` and `ygv` of length `M` and `N` respectively, `X` and `Y` will have `N` rows and `M` columns.

`[X,Y,Z] = meshgrid(xgv,ygv,zgv)` produces three-dimensional coordinate arrays. The output coordinate arrays `X`, `Y`, and `Z` contain copies of the grid vectors `xgv`, `ygv`, and `zgv` respectively. The sizes of the output arrays are determined by the length of the grid vectors. For grid vectors `xgv`, `ygv`, and `zgv` of length `M`, `N`, and `P` respectively, `X`, `Y`, and `Z` will have `N` rows, `M` columns, and `P` pages.

`[X,Y] = meshgrid(gv)` is the same as `[X,Y] = meshgrid(gv,gv)`. In other words, you can reuse the same grid vector in each respective dimension. The dimensionality of the output arrays is determined by the number of output arguments.

`[X,Y,Z] = meshgrid(gv)` is the same as `[X,Y,Z] = meshgrid(gv,gv,gv)`. Again, the dimensionality of the output arrays is determined by the number of output arguments.

The output coordinate arrays are typically used to evaluate functions of two or three variables. They are also frequently used to create surface and volumetric plots.

## Input Arguments

**xgv, ygv, zgv**

Grid vectors specifying a series of grid point coordinates in the x, y and z directions, respectively.

**gv**

Generic grid vector specifying a series of point coordinates.

## Output Arguments

**X, Y, Z**

Output arrays that specify the full grid.

## Examples

### 2-D Grid From Vectors

Create a full grid from two monotonically increasing grid vectors:

```
[X,Y] = meshgrid(1:3,10:14)
```

```
X =
```

```
 1 2 3
 1 2 3
 1 2 3
 1 2 3
 1 2 3
```

```
Y =
```

```
 10 10 10
 11 11 11
 12 12 12
 13 13 13
 14 14 14
```

### Plot 3-D Functional Surface

Use `meshgrid` to create a gridded  $(X, Y)$  domain.

```
[X,Y] = meshgrid(-2:.2:2, -2:.2:2);
```

Evaluate the function  $z(x, y) = xe^{-x^2-y^2}$  over this domain and generate a surface plot of the results.

```
Z = X .* exp(-X.^2 - Y.^2);
surf(X,Y,Z)
```

## More About

### Tips

The `meshgrid` function is similar to `ndgrid`, however `meshgrid` is restricted to 2-D and 3-D while `ndgrid` supports 1-D to N-D. The coordinates output by each function are the same, but the shape of the output arrays in the first two dimensions are different. For grid vectors `x1gv`, `x2gv` and `x3gv` of length `M`, `N` and `P` respectively, `meshgrid(x1gv, x2gv)` will output arrays of size `N-by-M` while `ndgrid(x1gv, x2gv)` outputs arrays of size `M-by-N`. Similarly, `meshgrid(x1gv, x2gv, x3gv)` will output arrays of size `N-by-M-by-P` while `ndgrid(x1gv, x2gv, x3gv)` outputs arrays of size `M-by-N-by-P`.

See “Grid Representation” in the MATLAB Mathematics documentation for more information.

# meta.class

`meta.class` class describes MATLAB classes

## Description

Instances of the `meta.class` class contains information about MATLAB classes. The read/write properties of the `meta.class` class correspond to class attributes and are set only from within class definitions on the `classdef` line. You can query the read-only properties of the `meta.class` object to obtain information that is specified syntactically by the class (for example, to obtain the name of the class).

You cannot instantiate a `meta.class` object directly. You can construct a `meta.class` object from an instance of a class or using the class name:

- `metaclass` — returns a `meta.class` object representing the object passed as an argument.
- `?ClassName` — returns a `meta.class` object representing the named class.
- `fromName` — static method returns a `meta.class` object representing the named class.

For example, the `metaclass` function returns the `meta.class` object representing `MyClass`.

```
ob = MyClass;
obmeta = metaclass(ob);
obmeta.Name
ans =
MyClass
```

You can use the class name to obtain the `meta.class` object:

```
obmeta = ?MyClass;
```

You can also use the `fromName` static method:

```
obmeta = meta.class.fromName('MyClass');
```

## Properties

Property	Purpose
Abstract attribute, default = false	If <code>true</code> , this class is an abstract class (cannot be instantiated).  See “Defining Abstract Classes” for more information.
AllowedSubclasses attribute, write only from <code>classdef</code> statement	List classes that can subclass this class. Specify subclasses as <code>meta.class</code> objects in the form: <ul style="list-style-type: none"> <li>• A single <code>meta.class</code> object</li> <li>• A cell array of <code>meta.class</code> objects</li> </ul> Specify <code>meta.class</code> objects using the <code>?ClassName</code> syntax only.
ConstructOnLoad attribute, default = false	If <code>true</code> , MATLAB calls the class constructor automatically when loading an object from a MAT-file. Therefore, the construction must be implemented so that calling it with no arguments does not produce an error.  See “Tips for Saving and Loading”
ContainingPackage read only	A <code>meta.package</code> object describing the package within which this class is contained, or an empty object if this class is not in a package.  See “Packages Create Namespaces”.
Description read only	Currently not used
DetailedDescription read only	Currently not used
Enumeration attribute, default = false	If <code>true</code> , this class is an enumeration class. See “Working with Enumerations”.
EventList read only	An array of <code>meta.event</code> objects describing each event defined by this class, including all inherited events.  See “Events”.
Events read only	A cell array of <code>meta.event</code> objects describing each event defined by this class, including all inherited events.

Property	Purpose
Use <code>EventList</code> instead	
<code>EnumerationMemberList</code>	An array of <code>meta.EnumeratedValue</code> objects describing the member names defined by an enumeration class.  See “Enumerations” for more information on enumeration classes.
<code>EnumeratedValues</code> read only  Use <code>EnumeratedMemberList</code> instead	A cell array of <code>meta.EnumeratedValue</code> objects describing the member names defined by an enumeration class.  See “Enumerations” for more information on enumeration classes.
<code>Hidden</code> attribute, default = <code>false</code>	If set to <code>true</code> , the class does not appear in the output of MATLAB commands or tools that display class names.
<code>InferiorClasses</code> attribute, default = <code>{}</code>	A cell array of <code>meta.class</code> objects defining the precedence of classes represented by the list as inferior to this class.  See “Class Precedence”
<code>MethodList</code> read only	An array of <code>meta.method</code> objects describing each method defined by this class, including all inherited public and protected methods.  See “How to Use Methods”.
<code>Methods</code> read only  Use <code>MethodList</code> instead	A cell array of <code>meta.method</code> objects describing each method defined by this class, including all inherited public and protected methods.
<code>Name</code> read only	Name of the class associated with this <code>meta.class</code> object (char array)
<code>PropertyList</code> read only	An array of <code>meta.property</code> objects describing each property defined by this class, including all inherited public and protected properties.  See “Properties”.

Property	Purpose
<b>Properties</b> read only Use <code>PropertyList</code> instead	A cell array of <code>meta.property</code> objects describing each property defined by this class, including all inherited public and protected properties.  See “Properties”.
<b>Sealed</b> attribute, default = <code>false</code>	If <code>true</code> , the class cannot be subclassed.
<b>SuperClassList</b> read only	An array of <code>meta.class</code> objects describing each direct superclass from which this class is derived.  See “Creating Subclasses — Syntax and Techniques”.
<b>SuperClasses</b> read only Use <code>SuperClassList</code> instead	A cell array of <code>meta.class</code> objects describing each direct superclass from which this class is derived.

## Methods

Method	Purpose
<code>fromName</code>	Returns the <code>meta.class</code> object associated with the specified class name.
<code>tf = eq(Cls)</code>	Equality function ( <code>a == b</code> ). Use to test if two variables refer to equal classes (classes that contain exactly the same list of elements).
<code>tf = ne(Cls)</code>	Not equal function ( <code>a ~= b</code> ). Use to test if two variables refer to different meta-classes.
<code>tf = lt(ClsA,ClsB)</code>	Less than function ( <code>ClsA &lt; ClsB</code> ). Use to determine if <code>ClsA</code> is a strict subclass of <code>ClsB</code> (i.e., a strict subclass means <code>ClsX &lt; ClsX</code> is <code>false</code> ).
<code>tf = le(ClsA,ClsB)</code>	Less than or equal to function ( <code>ClsA &lt;= ClsB</code> ). Use to determine if <code>ClsA</code> is a subclass of <code>ClsB</code> .
<code>tf = gt(ClsA,ClsB)</code>	Greater than function ( <code>ClsB &gt; ClsA</code> ). Use to determine if <code>ClsB</code> is a strict superclass of <code>ClsA</code> (i.e., a strict superclass means <code>ClsX &gt; ClsX</code> is <code>false</code> ).

Method	Purpose
<code>tf = ge(ClsA, ClsB)</code>	Greater than or equal to function ( <code>ClsB &gt;= ClsA</code> ). Use to determine if <code>ClsB</code> is a superclass of <code>ClsA</code> .

## Events

Event	Purpose
<code>InstanceCreated</code>	If the class is a handle class, this event occurs every time a new instance of this handle class is created, including new instances of any subclasses. The event occurs immediately after all constructor functions finish executing.
<code>InstanceDestroyed</code>	If the class is a handle class, this event occurs every time an instance of this handle class is destroyed, including all subclasses. The event occurs immediately before any destructor functions execute.

## Examples

Find property attributes using the `handle` class `findobj` method and the `audioplayer` `meta.class` object. Determine if a class defines the property named `SampleRate` and does it have public set access.

```
mc = ?audioplayer;
mp = findobj(mc.PropertyList, 'Name', 'SampleRate');
strcmp(mp.SetAccess, 'public')
...
```

## More About

- “Getting Information About Classes and Objects”

## See Also

`fromName` | `meta.property` | `meta.method` | `meta.event` | `meta.package`

## **meta.class.fromName**

Return `meta.class` object associated with named class

### **Syntax**

```
mcls = meta.class.fromName('ClassName')
```

### **Description**

`mcls = meta.class.fromName('ClassName')` is a static method that returns the `meta.class` object associated with the class *ClassName*. Note that you can also use the `?` operator to obtain the `meta.class` object for a class name:

```
mcls = ?ClassName;
```

The equivalent call to `meta.class.fromName` is:

```
mcls = meta.class.fromName('ClassName');
```

Use `meta.class.fromName` when using a `char` variable for the class name:

```
function mcls = getMetaClass(cname)
 % Do error checking
 mcls = meta.class.fromName(cname);
 ...
end
```

### **See Also**

`meta.class`

# meta.DynamicProperty

`meta.DynamicProperty` class describes dynamic property of MATLAB object

## Description

The `meta.DynamicProperty` class contains descriptive information about dynamic properties that you have added to an instance of a MATLAB classes. The MATLAB class must be a subclass of `dynamicprops`. The properties of the `meta.DynamicProperty` class correspond to property attributes that you specify from within class definitions. Dynamic properties are not defined in `classdef` blocks, but you can set their attributes by setting the `meta.DynamicProperty` object properties.

You add a dynamic property to an object using the `addprop` method of the `dynamicprops` class. The `addprop` method returns a `meta.DynamicProperty` instance representing the new dynamic property. You can modify the properties of the `meta.DynamicProperty` object to set the attributes of the dynamic property or to add set and get access methods, which would be defined in the `classdef` for regular properties.

You cannot instantiate the `meta.DynamicProperty` class. You must use `addprop` to obtain a `meta.DynamicProperty` object.

To remove the dynamic property, call the `delete` handle class method on the `meta.DynamicProperty` object.

Obtain a `meta.DynamicProperty` object from the `addprops` method, which returns an array of `meta.DynamicProperty` objects, one for each dynamic property.

See “Dynamic Properties — Adding Properties to an Instance” for more information.

## Properties

Property	Purpose
Name	Name of the property.
Description	Currently not used
DetailedDescription	Currently not used

Property	Purpose
AbortSet	If <code>true</code> , and this property belongs to a handle class, then MATLAB does not set the property value if the new value is the same as the current value. This approach prevents the triggering of property <code>PreSet</code> and <code>PostSet</code> events.
Abstract attribute, default = <code>false</code>	<p>If <code>true</code>, the property has no implementation, but a concrete subclass must redefine this property without <code>Abstract</code> being set to <code>true</code>.</p> <ul style="list-style-type: none"> <li>• Abstract properties cannot define set or get access methods. See “Property Access Methods”</li> <li>• Abstract properties cannot define initial values. “Assigning a Default Value”</li> <li>• All subclasses must specify the same values as the superclass for the property <code>SetAccess</code> and <code>GetAccess</code> attributes.</li> <li>• <code>Abstract=true</code> should be used with the class attribute <code>Sealed=false</code> (the default).</li> </ul>
Access	<p><code>public</code> – unrestricted access</p> <p><code>protected</code> – access from class or subclasses</p> <p><code>private</code> – access by class members only (not subclasses)</p> <p>List of classes that have get and set access to this property. Specify classes as <code>meta.class</code> objects in the form:</p> <ul style="list-style-type: none"> <li>• A single <code>meta.class</code> object</li> <li>• A cell array of <code>meta.class</code> objects. An empty cell array, <code>{}</code>, is the same as <code>private</code> access.</li> </ul> <p>Use <code>Access</code> to set both <code>SetAccess</code> and <code>GetAccess</code> to the same value. Query the values of <code>SetAccess</code> and <code>GetAccess</code> directly (not <code>Access</code>).</p>

Property	Purpose
<code>Constant</code> attribute, default = <code>false</code>	<p>Set to <code>true</code> if you want only one value for this property in all instances of the class.</p> <ul style="list-style-type: none"> <li>Subclasses inherit constant properties, but cannot change them.</li> <li>Constant properties cannot be <code>Dependent</code></li> <li><code>SetAccess</code> is ignored.</li> </ul> <p>See “Properties with Constant Values”</p>
<code>DefaultValue</code>	Querying this property returns an error because dynamic properties cannot define default values.
<code>DefiningClass</code>	The <code>meta.class</code> object representing the class that defines this property.
<code>GetAccess</code> attribute, default = <code>public</code>	<p><code>public</code> – unrestricted access</p> <p><code>protected</code> – access from class or subclasses</p> <p><code>private</code> – access by class members only</p>
<code>SetAccess</code> attribute, default = <code>public</code>	<p><code>public</code> – unrestricted access</p> <p><code>protected</code> – access from class or subclasses</p> <p><code>private</code> – access by class members only</p>
<code>Dependent</code> attribute, default = <code>false</code>	<p>If <code>false</code>, property value is stored in object. If <code>true</code>, property value is not stored in object and the set and get functions cannot access the property by indexing into the object using the property name.</p> <p>See “Property Get Methods”</p>
<code>Transient</code> attribute, default = <code>false</code>	If <code>true</code> , property value is not saved when object is saved to a file. See “Understanding the Save and Load Process” for more about saving objects.
<code>Hidden</code> attribute, default = <code>false</code>	Determines whether the property should be shown in a property list (e.g., Property Inspector, call to <code>properties</code> , etc.).

Property	Purpose
GetObservable attribute, default = false	If true, and it is a handle class property, then listeners can be created for access to this property. The listeners are called whenever property values are queried. See “Property-Set and Query Events”
SetObservable attribute, default = false	If true, and it is a handle class property, then listeners can be created for access to this property. The listeners are called whenever property values are modified. See “Property-Set and Query Events”
GetMethod	Function handle of the get method associated with this property. Empty if there is no get method specified. See “Get Method Syntax”
SetMethod	Function handle of the set method associated with this property. Empty if there is no set method specified. See “Property Set Methods”
HasDefault	Always false. Dynamic properties cannot define default values.

## Events

See “Listen for Changes to Property Values” for information on using property events.

Event Name	Purpose
PreGet	Event occurs just before property is queried.
PostGet	Event occurs just after property has been queried
PreSet	Event occurs just before this property is modified
PostSet	Event occurs just after this property has been modified
ObjectBeingDestroyed	Inherited from handle

# meta.EnumeratedValue

Describes enumeration members of MATLAB class

## Description

The `meta.EnumeratedValue` class contains information about enumeration members defined by MATLAB classes. The properties of a `meta.EnumeratedValue` object correspond to the attributes of the enumeration member being described.

All `meta.EnumeratedValue` properties are read-only. Query the `meta.EnumeratedValue` object to obtain information about the enumeration member it describes.

Obtain a `meta.EnumeratedValue` object from the `EnumerationMemberList` property of the `meta.class` object. `EnumerationMemberList` is an array of `Meta.EnumeratedValue` instances, one per enumeration member.

The `meta.EnumeratedValue` class is a subclass of the `handle` class.

## Example

To access the `meta.EnumeratedValue` objects for a class, first create a `meta.class` object for that class. For example, give the following `OnOff` class definition:

```
classdef OnOff < logical
 enumeration
 On (true)
 Off (false)
 end
end
```

Obtain a `meta.EnumeratedValue` object from the `EnumerationMemberList` property of the `meta.class` object:

```
% Obtain the meta.class instance for the OnOff class
mc = ?OnOff;
% Get the array of EnumerateValue objects
enumList = mc.EnumerationMemberList;
% Access the Name property of the first object in the array
```

```
enumList(1).Name =
ans =
On
```

## Properties

Property	Purpose
Name read only	Name of the enumeration member associated with this <code>meta.EnumeratedValue</code> object
Description read only	This property is not used
DetailedDescription read only	This property is not used

## Methods

See the `handle` superclass for inherited methods.

## Events

See the `handle` superclass for inherited events.

## More About

- “Working with Enumerations”
- “Getting Information About Classes and Objects”

## See Also

## meta.event

meta.event class describes MATLAB class events

### Description

The `meta.event` class provides information about MATLAB class events. The read/write properties of the `meta.event` class correspond to event attributes and are specified only from within class definitions.

You can query the read-only properties of the `meta.event` object to obtain information that is specified syntactically by the class (for example, to obtain the name of the class defining the event).

You cannot instantiate a `meta.event` object directly. Obtain a `meta.event` object from the `meta.class` `EventList` property, which contains an array of `meta.event` objects, one for each event defined by the class. For example, replace *ClassName* with the name of the class whose events you want to query:

```
mco = ?ClassName;
elist = mco.EventList;
elist(1).Name; % name of first event in list
```

Use the `metaclass` function to obtain a `meta.class` object from a class instance:

```
mco = metaclass(obj);
```

### Properties

Property	Purpose
Name read only	Name of the event.
Description read only	Currently not used
DetailedDescription read only	Currently not used
Hidden	If <code>true</code> , the event does not appear in the list of events returned by the <code>events</code> function (or other event listing functions or viewers)
ListenAccess	Determines where you can create listeners for the event.

Property	Purpose
	<ul style="list-style-type: none"> <li>• <b>public</b> — unrestricted access</li> <li>• <b>protected</b> — access from methods in class or subclasses</li> <li>• <b>private</b> — access by class methods only (not from subclasses)</li> <li>• List classes that have listen access to this event. Specify classes as <code>meta.class</code> objects in the form:               <ul style="list-style-type: none"> <li>• A single <code>meta.class</code> object</li> <li>• A cell array of <code>meta.class</code> objects. An empty cell array, <code>{}</code>, is the same as <b>private</b> access.</li> </ul> </li> </ul> <p style="text-align: center;">See “Controlling Access to Class Members”</p>
NotifyAccess	<p>Determines where code can trigger the event.</p> <ul style="list-style-type: none"> <li>• <b>public</b> — any code can trigger event</li> <li>• <b>protected</b> — can trigger event from methods in class or subclasses</li> <li>• <b>private</b> — can trigger event by class methods only (not from subclasses)</li> <li>• List classes that have notify access to this event. Specify classes as <code>meta.class</code> objects in the form:               <ul style="list-style-type: none"> <li>• A single <code>meta.class</code> object</li> <li>• A cell array of <code>meta.class</code> objects. An empty cell array, <code>{}</code>, is the same as <b>private</b> access.</li> </ul> </li> </ul> <p style="text-align: center;">See “Controlling Access to Class Members”</p>
DefiningClass	<p>The <code>meta.class</code> object representing the class that defines this event.</p>

`meta.property` | `meta.class` | `meta.method` | `metaclass`

## meta.MetaData class

**Package:** meta

**Superclasses:** matlab.mixin.Heterogeneous

Superclass for MATLAB object metadata

### Description

The `meta.MetaData` class of objects represent MATLAB class definitions and the constituent parts of those definitions, such as properties and methods. Metadata enable a program to get information about a class definition.

The `meta.MetaData` class forms the root of the metadata class hierarchy, which enables the formation of arrays of metadata objects belonging to different specific classes.

MATLAB uses instances of the `meta.MetaData` class as the default object to fill in missing array elements.

`findobj` and `findprop`, can search the metadata hierarchy and return an array of different metadata objects. These function require the ability to form heterogeneous arrays containing various metaclass objects.

See the `matlab.mixin.Heterogeneous` class for more information on heterogeneous hierarchies.

### Construction

You cannot create an instance of the `meta.MetaData` class directly. MATLAB constructs instances of this class as required.

### Copy Semantics

Handle. To learn how handle classes affect copy operations, see “Copying Objects” in the MATLAB documentation.

## Examples

This example shows how the `meta.Metadata` class facilitates working with metaclasses.

Create a `meta.class` instance representing the MATLAB `timeseries` class:

```
>> mc = ?timeseries;
```

MATLAB uses `meta.Metadata` objects to fill empty array elements:

```
>> m(2) = mc
>> class(m(1))
```

```
ans =
```

```
meta.Metadata
>> class(m(2))
```

```
ans =
```

```
meta.class
```

Use `findobj` to find all properties and methods that have protected access:

```
>> protectedMembers = findobj(mc,{'Access','protected'},...
'-or',{'SetAccess','protected'},...
'-or',{'GetAccess','protected'});
```

The `timeseries` class defines both properties and methods that have protected access. Therefore, `findobj` returns a heterogeneous array of class `meta.Metadata`. This array contains both `meta.property` and `meta.method` objects.

```
>> protectedMembers
```

```
protectedMembers =
```

```
 1x1 heterogeneous meta.Metadata (meta.property, meta.method)
 handle with no properties.
 Package: meta
>> class(protectedMembers(1))
```

```
ans =
```

```
meta.property
```

```
>> protectedMembers(1).Name
```

```
ans =

Length
>> protectedMembers(1).SetAccess

ans =

protected
>> protectedMembers(1).GetAccess

ans =

public
```

## How To

- “Class Attributes”
- “Property Attributes”
- “Getting Information About Classes and Objects”

# meta.method

meta.method class describes MATLAB class methods

## Description

The `meta.method` class provides information about the methods of MATLAB classes. The read/write properties of the `meta.method` class correspond to method attributes and are specified only from within class definitions.

You can query the read-only properties of the `meta.method` object to obtain information that is specified syntactically by the class (for example, to obtain the name of the class defining a method).

You cannot instantiate a `meta.method` object directly. Obtain a `meta.method` object from the `meta.class.MethodList` property, which contains an array of `meta.method` objects, one for each class method. For example, replace *ClassName* with the name of the class whose methods you want to query:

```
mco = ?ClassName;
mlist = mco.MethodList;
mlist(1).Name; % name of first method in the list
```

Use the `metaclass` function to obtain a `meta.class` object from a class instance:

```
mco = metaclass(obj);
```

## Properties

Property	Purpose
Abstract	<p>If <code>true</code>, the method has no implementation. The method has a syntax line that can include arguments, which subclasses use when implementing the method.</p> <ul style="list-style-type: none"> <li>Subclasses are not required to define the same number of input and output arguments.</li> <li>The method can have comments after the function line</li> </ul>

Property	Purpose
	<ul style="list-style-type: none"> <li>Does not contain <code>function</code> or <code>end</code> keywords, only the function syntax (e.g., <code>[ a, b ] = myMethod(x, y)</code>)</li> </ul>
Access attribute, default = <code>public</code>	<p>Determines what code can call this method.</p> <ul style="list-style-type: none"> <li><code>public</code> — unrestricted access</li> <li><code>protected</code> — access from methods in class or subclasses</li> <li><code>private</code> — access by class methods only (not from subclasses)</li> </ul>
DefiningClass	The <code>meta.class</code> object representing the class that defines this method.
Description read only	Currently not used
DetailedDescription read only	Currently not used
Hidden attribute, default = <code>false</code>	When <code>false</code> , the method name shows in the list of methods displayed using the <code>methods</code> or <code>methodsview</code> commands. If set to <code>true</code> , the method name is not included in these listings.
Name read only	Name of the method.
Sealed attribute, default = <code>false</code>	If <code>true</code> , the method cannot be redefined in a subclass. Attempting to define a method with the same name in a subclass causes an error.
Static attribute, default = <code>false</code>	<p>Set to <code>true</code> to define a method that does not depend on an object of the class and does not require an object argument. Call static methods using the class name in place of the object:</p> <pre><i>classname.methodname()</i></pre> <p>Or with an instance of the class, like any method:</p> <pre><i>o.methodname()</i></pre> <p>See “Static Methods”</p>

## meta.package

`meta.package` class describes MATLAB packages

### Description

The `meta.package` class contains information about MATLAB packages.

You cannot instantiate a `meta.package` object directly. Obtain a `meta.package` object from the `meta.class` `ContainingPackage` property, which contains a `meta.package` object, or an empty object, if the class is not in a package.

### Properties

Property	Purpose
Name read only	Name of the package associated with this <code>meta.package</code> object
ClassList read only	List of classes that are scoped to this package. An object array of <code>meta.class</code> objects.
Classes read only Use ClassList instead	List of classes that are scoped to this package. A cell array of <code>meta.class</code> objects.
FunctionList read only	List of functions that are scoped to this package. An object array of function handles.
Functions read only Use FunctionList instead	List of functions that are scoped to this package. A cell array of function handles.
PackageList read only	List of packages that are scoped to this package. An object array of <code>meta.package</code> objects.
Packages read only Use PackageList instead	List of packages that are scoped to this package. A cell array of <code>meta.package</code> objects.

Property	Purpose
ContainingPackage read only	A <code>meta.package</code> object describing the package within which this package is contained, or an empty object if this package is not nested.

## Methods

Method	Purpose
<code>fromName</code>	Static method returns a <code>meta.package</code> object for a specified package name.
<code>getAllPackages</code>	Static method returns a cell array of <code>meta.package</code> objects representing all top-level packages.

## meta.abstractDetails

**Package:** meta

Find abstract methods and properties

### Syntax

```
meta.abstractDetails(ClassName)
meta.abstractDetails(mc)
absMembers = meta.abstractDetails(___)
```

### Description

`meta.abstractDetails(ClassName)` displays a list of abstract methods and properties for the class with name `ClassName`. Use the fully specified name for classes in packages. MATLAB displays all public and protected abstract methods and properties, including those declared `Hidden`.

`meta.abstractDetails(mc)` displays a list of abstract methods and properties for the class represented by the `meta.class` object `mc`.

`absMembers = meta.abstractDetails( ___ )` returns an array of the metaclass objects corresponding to the abstract members of the class, and can include any of the input arguments in previous syntaxes. If the class has both abstract methods and abstract properties, `absMembers` is a heterogeneous array of class `meta.MetaData` containing `meta.method` and `meta.property` objects.

A class can be abstract without defining any abstract methods or properties if it declares the `Abstract` class attribute. In this case, `meta.abstractDetails` returns no abstract members for that class, but the class is abstract. See “Determine If a Class Is Abstract” for more information.

### Input Arguments

#### **ClassName**

Name of the class specified as a character string (for example, 'MyClass')

**mc**

meta.class object representing the class (for example, ?MyClass)

## Output Arguments

**absMembers**

Array of metaclass objects representing abstract class members

## Examples

### Display Abstract Member Names

Define the class, AbsBase, with an abstract property:

```
classdef AbsBase
 properties (Abstract)
 Prop1
 end
 methods(AbsBase)
 result = methodOne(obj)
 output = methodTwo(obj)
 end
end
```

Pass the class name (AbsBase) as a string:

```
meta.abstractDetails('AbsBase')
```

meta.abstractDetails displays the names of the abstract properties and methods defined in the class AbsBase.

```
Abstract methods for class AbsBase:
 methodTwo % defined in AbsBase
 methodOne % defined in AbsBase
```

```
Abstract properties for class AbsBase:
```

```
Prop1 % defined in AbsBase
```

## Return Abstract Member Metaclass Objects

Pass a `meta.class` object representing the `AbsBase` class and return the metaclass objects for the abstract members. Use the definition of the `AbsBase` class from the previous example.

```
mc = ?AbsBase;
absMembers = meta.abstractDetails(mc);
```

`absMembers` is a heterogeneous array containing a `meta.property` object for the `Prop1` abstract property and `meta.method` objects for the `methodOne` and `methodTwo` abstract methods.

List the names of the metaclass objects.

```
for k=1:length(absMembers)
 disp(absMembers(k).Name)
end
```

```
methodTwo
methodOne
Prop1
```

## Find Inherited Abstract Members

Derive the `SubAbsBase` class from `AbsBase`, which is defined in a previous example.

```
classdef SubAbsBase < AbsBase
 properties
 SubProp = 1;
 end
 methods
 function result = methodOne(obj)
 result = obj.SubProp + 1;
 end
 end
end
```

Display the names of the abstract members inherited by `SubAbsBase`.

```
meta.abstractDetails('SubAbsBase')
```

```
Abstract methods for class SubAbsBase:
```

```
methodTwo % defined in AbsBase
```

```
Abstract properties for class SubAbsBase:
 Prop1 % defined in AbsBase
```

To make SubAbsBase a concrete class, you need to implement concrete versions of methodTwo and Prop1 in the subclass.

`meta.class` | `meta.class.forName`

## meta.package.fromName

Return `meta.package` object for specified package

### Syntax

```
mpkg = meta.package.fromName('pkgname')
```

### Description

`mpkg = meta.package.fromName('pkgname')` is a static method that returns the `meta.package` object associated with the named package. If `pkgname` is a nested package, then you must provide the fully qualified name (e.g., `'pkgname1.pkgname2'`).

### Examples

List the classes in the `event` package:

```
mev = meta.package.fromName('event');
for k=1:length(mev.Classes)
 disp(mev.Classes{k}.Name)
end
event.EventData
event.PropertyEvent
event.listener
event.propListener
```

### See Also

`meta.package` | `meta.package.getAllPackages`

# meta.package.getAllPackages

Get all top-level packages

## Syntax

P = meta.package.getAllPackages

## Description

P = meta.package.getAllPackages is a static method that returns a cell array of meta.package objects representing all the top-level packages that are visible on the MATLAB path or defined as top-level built-in packages. You can access subpackages using the Packages property of each meta.package object.

Note that the time required to find all the packages on the path might be excessively long in some cases. You should therefore avoid using this method in any code where execution time is a consideration. getAllPackages is generally intended for interactive use only.

## See Also

meta.package | meta.package.fromName

## meta.property

`meta.property` class describes MATLAB class properties

### Description

The `meta.property` class provides information about the properties of MATLAB classes. The read/write properties of the `meta.property` class correspond to property attributes and are specified only from within your class definitions.

You can query the read-only properties of the `meta.property` object to obtain information that is specified syntactically by the class (for example, to obtain the function handle of a property's set access method).

You cannot instantiate a `meta.property` object directly. Obtain a `meta.property` object from the `meta.class` `PropertyList` property, which contains an array of `meta.property` objects, one for each class property. For example, replace `ClassName` with the name of the class whose properties you want to query:

```
mco = ?ClassName;
plist = mco.PropertyList;
plist(1).Name; % name of first property
```

Use the `metaclass` function to obtain a `meta.class` object from a class instance:

```
mco = metaclass(obj);
```

### Properties

Property	Purpose
Name read only	Name of the property.
Description read only	Currently not used
DetailedDescription read only	Currently not used
AbortSet attribute, default = false	If true, and this property belongs to a handle class, then MATLAB does not set the property value if the new

Property	Purpose
	<p>value is the same as the current value. This prevents the triggering of property <code>PreSet</code> and <code>PostSet</code> events.</p> <p>See “Listen for Changes to Property Values”</p>
<p><b>Abstract</b> attribute, default = <code>false</code></p>	<p>If <code>true</code>, the property has no implementation, but a concrete subclass must redefine this property without <b>Abstract</b> being set to <code>true</code>.</p> <ul style="list-style-type: none"> <li>• Abstract properties cannot define set or get access methods. See “Property Access Methods”</li> <li>• Abstract properties cannot define initial values. “Assigning a Default Value”</li> <li>• All subclasses must specify the same values as the superclass for the property <code>SetAccess</code> and <code>GetAccess</code> attributes.</li> <li>• <b>Abstract=true</b> should be used with the class attribute <code>Sealed=false</code> (the default).</li> </ul>
<p><b>Access</b></p>	<p><code>public</code> – unrestricted access</p> <p><code>protected</code> – access from class or subclasses</p> <p><code>private</code> – access by class members only (not subclasses)</p> <p>List of classes that have get and set access to this property. Specify classes as <code>meta.class</code> objects in the form:</p> <ul style="list-style-type: none"> <li>• A single <code>meta.class</code> object</li> <li>• A cell array of <code>meta.class</code> objects. An empty cell array, <code>{}</code>, is the same as <code>private</code> access.</li> </ul> <p>Use <b>Access</b> to set both <code>SetAccess</code> and <code>GetAccess</code> to the same value. Query the values of <code>SetAccess</code> and <code>GetAccess</code> directly (not <b>Access</b>).</p>

Property	Purpose
<p><b>Constant</b> attribute, default = <b>false</b></p>	<p>Set to <b>true</b> if you want only one value for this property in all instances of the class.</p> <ul style="list-style-type: none"> <li>• Subclasses inherit constant properties, but cannot change them.</li> <li>• <b>Constant</b> properties cannot be <b>Dependent</b></li> <li>• <b>SetAccess</b> is ignored.</li> </ul> <p>See “Properties with Constant Values”</p>
<p><b>DefaultValue</b></p>	<p>Property default value (if specified in class definition). See also <b>HasDefault</b> property. Abstract, dependent and dynamic properties cannot specify default values.</p>
<p><b>DefiningClass</b></p>	<p>The <b>meta.class</b> object representing the class that defines this property.</p>
<p><b>GetAccess</b> attribute, default = <b>public</b></p>	<p><b>public</b> – unrestricted access</p> <p><b>protected</b> – access from class or subclasses</p> <p><b>private</b> – access by class members only</p> <p>List classes that have get access to this property. Specify classes as <b>meta.class</b> objects in the form:</p> <ul style="list-style-type: none"> <li>• A single <b>meta.class</b> object</li> <li>• A cell array of <b>meta.class</b> objects. An empty cell array, {}, is the same as <b>private</b> access.</li> </ul> <p>See “Controlling Access to Class Members”</p>
<p><b>Dependent</b> attribute, default = <b>false</b></p>	<p>If <b>false</b>, property value is stored in object. If <b>true</b>, property value is not stored in object and the set and get functions cannot access the property by indexing into the object using the property name.</p> <p>See “Property Get Methods”</p>

Property	Purpose
<code>Transient</code> attribute, default = <code>false</code>	If <code>true</code> , property value is not saved when object is saved to a file. See “Understanding the Save and Load Process” for more about saving objects.
<code>GetMethod</code> read only	Function handle of the get method associated with this property. Empty if there is no get method specified. See “Get Method Syntax”
<code>GetObservable</code> attribute, default = <code>false</code>	If <code>true</code> , and it is a handle class property, then listeners can be created for access to this property. The listeners are called whenever property values are queried. See “Property-Set and Query Events”
<code>HasDefault</code>	Property contains a boolean value indicating if the property defines a default value. Test <code>HasDefault</code> before querying the <code>DefaultValue</code> property to avoid a <code>MATLAB:class:NoDefaultDefined</code> error.
<code>Hidden</code> attribute, default = <code>false</code>	Determines whether the property should be shown in a property list (e.g., Property Inspector, call to <code>properties</code> , etc.).
<code>SetAccess</code> attribute, default = <code>public</code>	<p><code>public</code> – unrestricted access</p> <p><code>protected</code> – access from class or subclasses</p> <p><code>private</code> – access by class members only</p> <p><code>immutable</code> — property can be set only in the constructor.</p> <p>See “Mutable and Immutable Properties”</p> <p>List classes that have set access to this property. Specify classes as <code>meta.class</code> objects in the form:</p> <ul style="list-style-type: none"> <li>• A single <code>meta.class</code> object</li> <li>• A cell array of <code>meta.class</code> objects. An empty cell array, <code>{}</code>, is the same as <code>private</code> access.</li> </ul> <p>See “Controlling Access to Class Members”</p>

Property	Purpose
SetMethod read only	Function handle of the set method associated with this property. Empty if there is no set method specified. See “Property Set Methods”
SetObservable attribute, default = false	If true, and it is a handle class property, then listeners can be created for access to this property. The listeners are called whenever property values are modified. See “Property-Set and Query Events”

## Events

See “Listen for Changes to Property Values” for information on using property events.

Event Name	Purpose
PreGet	Event occurs just before property is queried.
PostGet	Event occurs just after property has been queried
PreSet	Event occurs just before this property is modified
PostSet	Event occurs just after this property has been modified

`meta.method` | `meta.class` | `meta.event` | `metaclass`

# metaclass

Obtain `meta.class` object

## Syntax

```
mc = metaclass(object)
mc = ?ClassName
```

## Description

`mc = metaclass(object)` returns the `meta.class` object for the class of `object`. The `object` input argument can be a scalar or an array of objects. However, `metaclass` always returns a scalar `meta.class` object.

`mc = ?ClassName` returns the `meta.class` object for the class with name, *ClassName*. The `?` operator works only with a class name, not an object.

If you pass a class name as a string to the `metaclass` function, it returns the `meta.class` object for the `char` class. Use the `?` operator or the `meta.class.fromName` method to obtain the `meta.class` object from a class name. Use this method if you want to pass the class name in a string variable.

## Examples

Return the `meta.class` object for an instance of the `MException` class:

```
obj = MException('Msg:ID', 'MsgTxt');
mc = metaclass(obj);
```

Use the `?` operator to get the `meta.class` object for the `matlab.mixin.SetGet` class:

```
mc = ?matlab.mixin.SetGet;
```

## See Also

`meta.class` | `meta.class.fromName`

## **Tutorials**

- “Class Metadata”

# methods

Class method names

## Syntax

```
methods('classname')
methods(..., '-full')
m = methods(...)
```

## Description

`methods('classname')` displays the names of the methods for the class *classname*. If *classname* is a MATLAB or Java class, then `methods` displays only public methods, including those methods inherited from superclasses.

`methods(..., '-full')` displays a full description of the methods, including inheritance information and, for MATLAB and Java methods, method attributes and signatures. `methods` does not remove duplicate method names with different signatures. Do not use this option with classes defined before MATLAB 7.6.

`m = methods(...)` returns the method names in a cell array of strings.

`methods` is also a MATLAB class-definition keyword. See `classdef` for more information on class-definition keywords.

This function does not show generic methods from classes based on the Microsoft .NET Framework. Use your product documentation to get information on generic methods.

## Examples

Retrieve the names of the static methods in class `MException`:

```
methods('MException')
```

Methods for class `MException`:

addCause      getReport      ne      throw  
eq            isequal        rethrow     throwAsCaller

Static methods:

last

## See Also

methodsvew | properties | events | what | which

## Tutorials

- “Methods”

# methodsview

View class methods

## Syntax

```
methodsview packagename.classname
methodsview classname
methodsview(object)
```

## Description

`methodsview packagename.classname` displays information about the methods in the class, `classname`. If the class is in a package, include `packagename`. If `classname` is a MATLAB or Java class, `methodsview` lists only public methods, including those methods inherited from superclasses.

`methodsview classname` displays information describing the class `classname`.

`methodsview(object)` displays information about the methods of the class of `object`.

`methodsview` creates a window that displays the methods defined in the specified class. `methodsview` provides additional information like arguments, returned values, and superclasses. It also includes method qualifiers (for example, `abstract` or `synchronized`) and possible exceptions thrown.

## Examples

List information on all methods in the `java.awt.MenuItem` class:

```
methodsview java.awt.MenuItem
```

MATLAB displays this information in a new window.

## See Also

`methods` | `import` | `class` | `javaArray`

## mex

Build MEX-function from C/C++ or Fortran source code

## Syntax

```
mex filenames
mex option1 ... optionN filenames

mex -setup lang
```

## Description

`mex filenames` compiles and links one or more C, C++, or Fortran source files into a binary MEX-file, callable from MATLAB. `filenames` specify the source files. Also builds executable files for standalone MATLAB engine and MAT-file applications.

MATLAB automatically selects a compiler, if installed, based on the language of the `filenames` arguments.

`mex option1 ... optionN filenames` builds with the specified build options. The `option1 ... optionN` arguments supplement or override the default `mex` build configuration.

`mex -setup lang` selects a compiler for the given `lang`. Use this option when you want to change the default compiler for the given language.

## Examples

### Build C MEX-File

Build a single C program, `yprime.c`, into a MEX-file.

Each example is based on MEX examples in the `matlabroot/extern/examples` subfolders. To build the example code, copy the source file to a writable folder on your path, such as `c:\work`. Set the current folder to `c:\work`.

```
[s,msg,msgid] = mkdir('c:\work');
if (isempty(msgid))
 mkdir('c:\work')
end
cd c:\work
```

Copy the source code, `yprime.c`.

```
copyfile(fullfile(matlabroot,'extern','examples','mex',...
 'yprime.c'),'.','f');
```

Build the MEX-file.

```
mex yprime.c
```

```
Building with 'Microsoft Visual C++ 2010 (C)'.
MEX completed successfully.
```

The output displays information specific to your compiler.

Test.

```
T=1; Y=1:4;
yprime(T,Y)
```

```
ans =
 2.0000 8.9685 4.0000 -1.0947
```

### Build MEX-File from Multiple Source Files

The MEX-file example, `fulltosparse`, consists of two Fortran source files, `loadsparse.F` and `fulltosparse.F`.

To run this example, you need a supported Fortran compiler installed on your system.

Copy the source files to the current folder.

```
copyfile(fullfile(matlabroot,'extern','examples','refbook',...
 'loadsparse.F'),'.','f');
copyfile(fullfile(matlabroot,'extern','examples','refbook',...
 'fulltosparse.F'),'.','f');
```

Build the `fulltosparse` MEX-file.

```
mex -largeArrayDims fulltosparse.F loadsparse.F
```

The MEX-file name is `fulltosparse` because `fulltosparse.F` is the first file on the command line.

Test.

```
full = eye(5);
spar = fulltosparse(full)
```

```
spar =
 (1,1) 1
 (2,2) 1
 (3,3) 1
 (4,4) 1
 (5,5) 1
```

## Preview Build Commands

To preview the build command details without executing the commands, use the `-n` option.

```
mex -n yprime.c
```

The output displays information specific to your platform and compiler.

## Display Detailed Build and Troubleshooting Information

To display the compile and link commands and other information useful for troubleshooting, use verbose mode.

```
mex -v -compatibleArrayDims yprime.c
```

The output displays information specific to your platform and compiler.

## Create and Link to Separate Object Files

You can link to object files that you compile separately from your source MEX-files.

The MEX-file example, `fulltosparse`, consists of two Fortran source files, `loadsparse.F` and `fulltosparse.F`. The `fulltosparse` file is the gateway routine (contains the `mexFunction` subroutine) and `loadsparse` contains the computational routine.

To run this example, you need a supported Fortran compiler installed on your system.

Copy the computational subroutine to your current folder.

```
copyfile(fullfile(matlabroot, 'extern', 'examples', 'refbook', ...
 'loadparse.F'), '.', 'f');
```

Compile the subroutine and place the object file in a separate folder, `c:\objfiles`.

```
mkdir c:\objfiles
mex -largeArrayDims -c -outdir c:\objfiles loadparse.F
```

Copy the gateway subroutine to your current folder. Compile and link with the `loadparse` object file.

```
copyfile(fullfile(matlabroot, 'extern', 'examples', 'refbook', ...
 'fulltospars.F'), '.', 'f');
mex -largeArrayDims fulltospars.F c:\objfiles\loadparse.obj
```

### Specify Path to Include File

Use the `-I` option to specify the path to include the MATLAB LAPACK library subroutines for handling complex number routines. To use these subroutines, your MEX-file must access the header file, `fort.h`.

Copy the `matrixDivideComplex.c` example to the current folder.

```
copyfile(fullfile(matlabroot, 'extern', 'examples', 'refbook', ...
 'matrixDivideComplex.c'), '.', 'f');
```

Create the `-I` argument by concatenating `'-I'` with the path to `fort.h` file.

```
ipath = ['-I' fullfile(matlabroot, 'extern', 'examples', 'refbook')];
```

Create variables for the names and paths to the LAPACK library file and the file, `fort.c`, containing the complex number handling routines.

```
lapacklib = fullfile(matlabroot, ...
 'extern', 'lib', computer('arch'), 'microsoft', 'libmwlpack.lib');
fortfile = fullfile(matlabroot, 'extern', 'examples', ...
 'refbook', 'fort.c');
```

Build the MEX-file.

```
mex('-v', '-largeArrayDims', ipath, ...
 'matrixDivideComplex.c', fortfile, lapacklib)
```

### Specify Path to Library File

Build the `matrixDivide.c` example on a Windows platform.

Use the `-L` and `-l` options to specify the `libmwlapack.lib` library, located in the folder, `matlabroot\extern\lib\arch\microsoft`.

Copy the `matrixDivide.c` example to the current folder.

```
copyfile(fullfile(matlabroot, 'extern', 'examples', 'refbook', 'matrixDivide.c'), ...
 '.', 'f');
```

Capture the value of `matlabroot`.

```
matlabroot
```

```
ans =
```

```
C:\Program Files\MATLAB\R2014a
```

Capture the value of `arch`.

```
arch
```

```
ans =
```

```
win64
```

To build the MEX-file, copy the values of `matlabroot` and `arch` into the `mex` command, as shown in the following statement.

```
mex -largeArrayDims '-LC:\Program Files\MATLAB\R2014a\extern\lib\win64\microsoft'...
 -llibmwlapack matrixDivide.c
```

You must use the `'` characters because `\Program Files` in the path includes a space.

## Define Directive

Define the character to use between strings in a matrix.

The MATLAB example, `mxcreatecharmatrixfromstr.c`, uses a `#define` symbol, `SPACE_PADDING`, to determine what character to use between strings in a matrix. To set the value, build the MEX-file with the `-D` option.

Copy the `mxcreatecharmatrixfromstr.c` example to the current folder.

```
copyfile(fullfile(matlabroot, 'extern', 'examples', 'mx', ...
 'mxcreatecharmatrixfromstr.c'), '.', 'f');
```

Set the `SPACE_PADDING` directive to add a space between strings.

```
mex mxcreatecharmatrixfromstr.c -DSPACE_PADDING
```

### Override Default Compiler Switch Option

Build the `yprime.c` MEX-file by appending the value `-Wall` to the existing compiler flag. Because the value includes a space character, you must delineate the string; the character you use depends on the platform.

At the MATLAB prompt, use MATLAB single quotes (`'`).

```
mex -v COMPFLAGS='$COMPFLAGS -Wall' yprime.c
```

At the Windows Command Prompt, use double quotes (`"`).

```
mex -v COMPFLAGS="$COMPFLAGS -Wall" yprime.c
```

At the shell command line on Mac and Linux, use single quotes (`'`).

```
mex -v CFLAGS='$CFLAGS -Wall' yprime.c
```

### Build Engine Application

Copy the `engwindemo.c` engine example to the current folder.

```
copyfile(fullfile(matlabroot,...
 'extern','examples','eng_mat','engwindemo.c'),'.','f');
```

```
mex -client engine engwindemo.c
```

Run the example.

```
!engwindemo
```

### Select C Compiler

```
mex -setup
```

MATLAB displays the options for your version and system based on the list of Supported and Compatible Compilers.

- “Table of MEX-File Source Code Files”

## Input Arguments

**filenames** — One or more file names

string

One or more file names, including name and file extension, specified as a string. If the file is not in the current folder, specify the full path to the file. File names can be any combination of:

- C, C++, or Fortran language source files
- Simulink S-function files
- object files
- library files

The first file listed in filenames is the name of the binary MEX-file. To override this naming convention, use the ' -output ' option.

Data Types: char

**option1 ... optionN — One or more build options**

strings corresponding to valid option flags

One or more build options, specified as one of these values. Options can appear in any order on any platform, except where indicated.

Option	Description
@rspfile	Uses Windows RSP file. An RSP file is a text file containing command-line options.
-c	Compiles an object file only. Does not build a binary MEX-file.
-client engine	Build engine application.
-compatibleArrayDims (default) -largeArrayDims	Links with the specified MATLAB array-handling API. <ul style="list-style-type: none"> <li>• -compatibleArrayDims — Uses the MATLAB Version 7.2 array-handling API, which limits arrays to 2<sup>31</sup>-1 elements. Default option.</li> <li>• -largeArrayDims — Uses the MATLAB large-array-handling API. This API handles arrays with more than 2<sup>31</sup>-1 elements. Must use this option when calling LAPACK or BLAS functions.</li> </ul> <p>In verbose mode (-v option), if you do not specify either the -compatibleArrayDims or the -largeArrayDims</p>

Option	Description
	option, MATLAB displays a message showing the default option.
<p>-D<i>symbolname</i> - D<i>symbolname=symbolvalue</i> -U<i>symbolname</i></p>	<p>The -D options define C preprocessor macros. Equivalent to the following in the source file:</p> <ul style="list-style-type: none"> <li>• #define <i>symbolname</i></li> <li>• #define <i>symbolname symbolvalue</i></li> </ul> <p>The -U option removes any initial definition of the C preprocessor macro, <i>symbolname</i>. Inverse of the -D option.</p> <p>Do not add a space between <b>D</b> or <b>U</b> and <i>symbolname</i>. Do not add spaces around the = sign.</p> <p>Example: “Define Directive” on page 1-4898</p>
-f <i>filepath</i>	<p>To build engine applications, use the -client engine option.</p> <p>Specifies name and location of the mex configuration file. Overrides the default compiler selection. For information about using a non-default compiler, see “Changing Default Compiler”. <i>filepath</i> is the name and full path of the configuration file, specified as a string.</p>
-g	Adds symbolic information and disables optimizing built object code. Use for debugging. To debug with optimization, add the -O option.
-h[elp]	Displays help for mex. Use from an operating system prompt.
-I <i>pathname</i>	<p>Adds <i>pathname</i> to the list of folders to search for #include files.</p> <p>Do not add a space between <b>I</b> and <i>pathname</i>.</p> <p>Example: “Specify Path to Include File” on page 1-4897</p>
-llibname -Llibfolder -llibname	Links with object library <i>libname</i> in (optional) <i>libfolder</i> .

Option	Description
	<p>MATLAB expands <i>libname</i> to:</p> <ul style="list-style-type: none"> <li>• <i>libname.lib</i> or <i>liblibname.lib</i> — Windows systems</li> <li>• <i>liblibname.dylib</i> — Mac systems</li> <li>• <i>liblibname.so</i> — Linux systems</li> </ul> <p>If used, the <code>-L</code> option must precede the <code>-l</code> option. When using the <code>-L</code> option on Linux or Mac systems, you also must set the runtime library path, as explained in “Setting Run-Time Library Path”.</p> <p>Do not add a space between <code>l</code> and <i>libname</i> or between <code>L</code> and <i>libfolder</i>.</p> <p>Specify the <code>-l</code> option with the lowercase letter <code>L</code>.</p> <p>Example: “Specify Path to Library File” on page 1-4897</p>
<p><code>-largeArrayDims</code>  <code>-compatibleArrayDims</code>            (default)</p>	<p>Links with the specified MATLAB array-handling API.</p> <ul style="list-style-type: none"> <li>• <code>-compatibleArrayDims</code> — Uses the MATLAB Version 7.2 array-handling API, which limits arrays to <math>2^{31}-1</math> elements. Default option.</li> <li>• <code>-largeArrayDims</code> — Uses the MATLAB large-array-handling API. This API handles arrays with more than <math>2^{31}-1</math> elements. Must use this option when calling LAPACK or BLAS functions.</li> </ul> <p>In verbose mode (<code>-v</code> option), if you do not specify either the <code>-compatibleArrayDims</code> or the <code>-largeArrayDims</code> option, MATLAB displays a message showing the default option.</p>
<p><code>-n</code></p>	<p>Displays, but does not execute, commands that <code>mex</code> would execute.</p> <p>Example: “Preview Build Commands” on page 1-4896</p>

Option	Description
-O	<p>Optimizes the object code. Use this option to compile with optimization.</p> <p>Optimization is enabled by default. Optimization is disabled when the -g option appears without the -O option.</p> <p>Specify this option with the capital letter <b>O</b>.</p>
-outdir <i>dirname</i>	<p>Places all output files in folder <i>dirname</i>.</p> <p>Example: “Create and Link to Separate Object Files” on page 1-4896</p>
-output <i>mexname</i>	<p>Overrides the default MEX-file naming mechanism. Creates binary MEX-file named <i>mexname</i> with the appropriate MEX-file extension.</p>
-setup <i>lang</i>	<p>Change the default compiler to build <i>lang</i> language MEX-files. When you use this option, all other command-line options are ignored.</p>
-silent	<p>Suppresses informational messages. The <code>mex</code> function still reports errors and warnings, even when you specify <code>-silent</code>.</p>
-U <i>symbolname</i>	<p>Removes any initial definition of the C preprocessor macro <i>symbolname</i>. (Inverse of the -D option.)</p> <p>Do not add a space between <b>U</b> and <i>symbolname</i>.</p>
-v	<p>Buils in verbose mode. Displays values for internal variables after all command-line arguments are considered. Displays each compile and link step fully evaluated.</p> <p>Example: “Display Detailed Build and Troubleshooting Information” on page 1-4896</p>
<i>varname=varvalue</i>	<p>Overrides default setting for variable <i>varname</i>. This option is processed after all command-line arguments are considered.</p> <p>Example: “Override Default Compiler Switch Option” on page 1-4899.</p>

**lang — Language**

C (default) | C++ | CPP | Fortran

Language, specified as one of these values.

C	C compilers, including C++.
C++ or CPP	C++ compilers.
Fortran	Fortran compilers.

## More About

### Tips

- You can run `mex` from:
  - MATLAB Command Window
  - Windows system prompt
  - Mac Terminal
  - Linux shell

For command-line usage outside of MATLAB, the `mex` program is located in the folder specified by `[matlabroot ' /bin ' ]`.

- The MEX-file has a platform-dependent extension. You can place binary MEX-files for different platforms in the same folder.

Platform	Binary MEX-File Extension
Linux (64-bit)	<code>mexa64</code>
Apple Mac (64-bit)	<code>mexmaci64</code>
Microsoft Windows (32-bit)	<code>mexw32</code>
Windows (64-bit)	<code>mexw64</code>

To identify the MEX-file extension, use the `mexext` function.

- To use `mex` to build executable files for standalone MATLAB engine and MAT-file applications, use the `-client engine` option.

- “Build MEX-File”
- “Changing Default Compiler”
- Supported and Compatible Compilers

## mex.getCompilerConfigurations

Get compiler configuration information for building MEX-files

### Syntax

```
cc = mex.getCompilerConfigurations
cc = mex.getCompilerConfigurations(lang)
cc = mex.getCompilerConfigurations(lang,list)
```

### Description

`cc = mex.getCompilerConfigurations` returns an object `cc` containing information about the default compiler configurations used by the `mex` command. There is one configuration for each supported language.

`cc = mex.getCompilerConfigurations(lang)` returns an array of objects for the given language, `lang`.

`cc = mex.getCompilerConfigurations(lang,list)` returns information about the set of configurations, `list`.

### Examples

#### Display Information for C Compiler

```
myCCompiler = mex.getCompilerConfigurations('C','Selected')
```

```
myCCompiler =
```

```
 CompilerConfiguration with properties:
```

```
 Name: 'Microsoft Visual C++ 2010 (C)'
 Manufacturer: 'Microsoft'
 Language: 'C'
 Version: '10.0'
 Location: 'c:\Program Files (x86)\Microsoft Visual Studio 10.0'
 ShortName: 'MSVC100'
```

```

 Priority: 'A'
 Details: [1x1 mex.CompilerConfigurationDetails]
 LinkerName: 'link'
 LinkerVersion: ''
 MexOpt: 'C:\Users\user\AppData\Roaming\MathWorks\MATLAB\R2014a\mex_C_win64

```

MATLAB displays information depending on your architecture and your version of MATLAB.

### Display Number of Supported C Compilers

```

cLanguageCC = mex.getCompilerConfigurations('C','Supported');
length(cLanguageCC)

```

```

ans =
 10

```

The number of compilers for your version of MATLAB might be different.

## Input Arguments

### lang — Language

'Any' (default) | 'C' | 'C++' | 'CPP' | 'Fortran'

Language, specified as one of these values.

'Any'	All supported languages. This is the default value.
'C'	All C compiler configurations, including C++ configurations.
'C++' or 'CPP'	All C++ compiler configurations.
'Fortran'	All Fortran compiler configurations.

### list — Set of configurations

'Selected' (default) | 'Installed' | 'Supported'

Set of configurations, specified as one of these values.

'Selected'	The default compiler for each language.
'Installed'	All supported compilers <code>mex</code> finds installed on your system.

'Supported'

All compilers supported in the current release.

## Output Arguments

### **cc** — Compiler information

`mex.CompilerConfiguration` object or array of objects

Compiler information, specified as a `mex.CompilerConfiguration` object or array of `mex.CompilerConfiguration` objects. The `mex.CompilerConfiguration` class contains the following read-only properties.

Property	Purpose
Name	Compiler name.
ShortName	Character string used to identify options file for the compiler.
Manufacturer	Name of the manufacturer of the compiler.
Language	Compiler language.
Version	(Windows platforms only) Version of the compiler.
Location	(Windows platforms only) Folder where compiler is installed.
Details	More read-only properties about the compiler configuration. These properties might differ across compilers, platforms, and releases of MATLAB.
LinkerName	Linker name.
LinkerVersion	(Windows platforms only) Version of the linker.
MexOpt	Name and full path to options file.
Priority	The priority of this compiler.

`mex`

# MException class

Capture error information

## Description

Any MATLAB code that detects an error and throws an exception must construct an `MException` object. This class contains retrievable information about errors. MATLAB can throw either predefined exceptions or exceptions that you construct.

## Construction

`ME = MException(msgID,msgtext)` captures information about a specific error and stores it in the `MException` object, `ME`. The `MException` object is constructed with a message identifier, `msgID`, and an error message string, `msgtext`.

`ME = MException(msgID,msgtext,A1,...,An)` allows formatting of the error message string using text or numeric values, `A1,...,An`, to replace conversion specifiers in `msgtext` at run time.

## Input Arguments

### **msgID** — Identifier for error

string

Identifier for the error, specified as a string. Use the message identifier with exception handling to better identify the source of the error or to control a selected subset of the exceptions in your program.

The message identifier includes a component and mnemonic. The identifier must always contain a colon and follows a simple format: `component:mnemonic`. The component and mnemonic fields must each begin with a letter. The remaining characters can be alphanumeric (A–Z, a–z, 0–9) and underscores. No white space characters can appear anywhere in `msgID`. For more information, see “Message Identifiers”.

Example: `'MyComponent:noSuchVariable'`

**msgtext — Information about cause of error**

string

Information about the cause of the error and how you might correct it, specified as a string. To format the string, use escape sequences, such as `\t` or `\n`. You also can use any format specifiers supported by the `sprintf` function, such as `%s` or `%d`. Specify values for the conversion specifiers via the `A1, . . . , An` input arguments. For more information, see “Formatting Strings”.

Example: 'Error opening file.'

Example: 'Error on line %d.'

**A1, . . . , An — Numeric or character arrays**

scalar | vector | matrix | multidimensional array

Numeric or character arrays, specified as a scalar, vector, matrix, or multidimensional array. This input argument provides the values that correspond to and replace the conversion specifiers in `msgtext`.

## Properties

**identifier — Unique identifier of error**

string

String that uniquely identifies the error, specified as a string by the `msgID` input argument. This property is read only. For more information, see “Message Identifiers”.

**message — Error message**

string

String that contains the error message that is displayed when MATLAB throws the exception, specified by the `msgtext` and `A1, . . . , An` input arguments. This property is read only. For more information, see “Text of the Error Message”.

**stack — Stack trace information**

array of structures

Structure array that contains stack trace information including the file name (`file`), function name (`name`), and line number (`line`) where MATLAB throws the exception. If the error occurs in a called function, the `stack` property also contains the file name,

function name, and line number for each of the called functions. MATLAB generates the stack only when it throws the exception.

`stack` is an N-by-1 `struct` array, where N represents the depth of the call stack. This property is read only. For more information, see “The Call Stack”.

### **cause — Cause of the exception**

cell array of MException objects

Cell array of MException objects that caused MATLAB to create this exception. Use the `addCause` method to add an exception to the `cause` field of the another exception. For more information, see “The Cause Array”.

## Methods

<code>addCause</code>	Record additional causes of exception
<code>getReport</code>	Get error message for exception
<code>last</code>	Return last uncaught exception
<code>rethrow</code>	Rethrow previously caught exception
<code>throw</code>	Throw exception
<code>throwAsCaller</code>	Throw exception as if occurs within calling function

## Copy Semantics

Value. To learn how value classes affect copy operations, see “Copying Objects” in the MATLAB documentation.

## Examples

### Create MException Object

```
msgID = 'myComponent:inputError';
msgtext = 'Input does not have the expected format.';

ME = MException(msgID,msgtext)

ME =

MException with properties:

 identifier: 'myComponent:inputError'
 message: 'Input does not have the expected format.'
 cause: {}
 stack: [0x1 struct]
```

### Create MException with Formatted Error Message

```
msgID = 'MATLAB:test';
msgtext = 'There are %d errors on this page';
A1 = 10;

ME = MException(msgID,msgtext,A1)

ME =

MException with properties:

 identifier: 'MATLAB:test'
 message: 'There are 10 errors on this page'
 cause: {}
 stack: [0x1 struct]
```

### Create and Throw MException Object

Throw an exception if an input variable name does not exist in the workspace.

```
str = input('Type a variable name: ','s');
if ~exist(str,'var')
```

```

 ME = MException('MyComponent:noSuchVariable', ...
 'Variable %s not found',str);
 throw(ME)
end

```

At the input prompt, enter any variable that does not exist in your workspace. For example, enter `notaVariable`.

```
Variable notaVariable not found
```

Since `notVariable` doesn't exist in your workspace, MATLAB creates an `MException` object, and then throws it.

### Use try/catch to Capture Exception

Catch the exception generated by calling a nonexistent function, `notaFunction`. If the function is not defined, issue a warning and assign the output a value of 0.

```

try
 a = notaFunction(5,6);
catch ME
 if strcmp(ME.identifier,'MATLAB:UndefinedFunction')
 warning('Function is undefined. Assigning a value of 0.');
```

```

 else
 rethrow(ME)
 end
end
end

```

```
Warning: Function is undefined. Assigning a value of 0.
```

By itself, the call to `notaFunction` results in an error. Using `try` and `catch`, this code catches the undefined function exception and repackages it as a warning, allowing MATLAB to continue executing subsequent commands. If the caught exception has a different error identifier, MATLAB rethrows the exception.

## addCause

**Class:** MException

Record additional causes of exception

### Syntax

```
baseException = addCause(baseException,causeException)
```

### Description

`baseException = addCause(baseException,causeException)` modifies the existing `MException` object `baseException` by appending `causeException` to its `cause` property. Catching the resulting exception in a `try/catch` statement makes the base exception, along with all of the appended cause records, available to help diagnose the error.

### Input Arguments

**baseException — Primary exception**

MException object

Primary exception containing the primary cause and location of an error, specified as an `MException` object.

**causeException — Related exception**

MException object

Related exception containing the cause and location of an error related to `baseException`, specified as an `MException` object.

### Examples

**Add Causes to Exception**

Create an array, and an index into it with a logical array.

```
A = [13 42; 7 20];
idx = [1 0 1; 0 1 0];
```

Create an exception that provides general information about an error. Test the index array and add exceptions with more detailed information about the source of the failure.

```
try
 A(idx);
catch
 msgID = 'MYFUN:BadIndex';
 msg = 'Unable to index into array.';
 baseException = MException(msgID,msg);

 try
 assert(islogical(idx),'MYFUN:notLogical',...
 'Indexing array is not logical.')
 catch causeException
 baseException = addCause(baseException,causeException);
 end

 if any(size(idx) > size(A))
 msgID = 'MYFUN:incorrectSize';
 msg = 'Indexing array is too large.';
 causeException2 = MException(msgID,msg);
 baseException = addCause(baseException,causeException2);
 end
 throw(baseException)
end
```

```
Unable to index into array.
```

```
Caused by:
 Indexing array is not logical.
 Indexing array is too large.
```

Examine the `baseException` object.

```
baseException
```

```
baseException =
```

```
MException with properties:
```

```
 identifier: 'MYFUN:BadIndex'
 message: 'Unable to index into array.'
```

```
cause: {2x1 cell}
stack: [0x1 struct]
```

The value of the `cause` property is a 2x1 cell array.

Examine the first cause of the exception.

```
baseException.cause{1}
```

```
ans =
```

```
MException with properties:
```

```
identifier: 'MYFUN:notLogical'
message: 'Indexing array is not logical.'
cause: {0x1 cell}
stack: [0x1 struct]
```

Examine the second cause of the exception.

```
baseException.cause{2}
```

```
ans =
```

```
MException with properties:
```

```
identifier: 'MYFUN:incorrectSize'
message: 'Indexing array is too large.'
cause: {}
stack: [0x1 struct]
```

## See Also

`MException` | `MException.throw` | `MException.rethrow` |

# getReport

**Class:** MException

Get error message for exception

## Syntax

```
msgString = getReport(exception)
msgString = getReport(exception,type)
msgString = getReport(exception,type,'hyperlinks',hlink)
```

## Description

`msgString = getReport(exception)` gets the error message for an exception and returns it as a formatted string, `msgString`. The message string is the value of the `message` property of the `MException` object, `exception`. It is the same string that MATLAB displays when it throws the exception.

`msgString = getReport(exception,type)` returns the error message using the indicated level of detail, specified by `type`.

`msgString = getReport(exception,type,'hyperlinks',hlink)` uses the value of `hlink` to determine whether to include active hyperlinks to the failing lines of code within the error message.

## Input Arguments

**exception** — Exception object that provides error message

MException object

Exception object that provides the error message, specified as a scalar `MException` object.

**type** — Detail indicator of message string

'extended' (default) | 'basic'

Detail indicator of the message string returned, specified as 'extended' or 'basic'.

type Value	msgString Detail Level
'extended' (default)	msgString includes the line number, error message, cause, and stack summary. To display the proper stack, MATLAB first must throw an exception.
'basic'	msgString includes the error message.

**hlink — Hyperlink indicator of message string**

'on' (default) | 'off' | 'default'

Hyperlink indicator of the message string that includes active hyperlinks to the failing lines of code, specified as 'on', 'off', or 'default'.

hlink Value	Action
'on'	Display hyperlinks to failing lines of code.
'off'	Do not display hyperlinks to failing lines of code.
'default'	Use the default for the Command Window to determine whether or not to use hyperlinks in the error message.

## Examples

**Get Error Message from Exception**

Cause MATLAB to throw an exception.

```
plus
```

```
Error using ±
Not enough input arguments.
```

Get the error message from the exception.

```
exception = MException.last;
msgString = getReport(exception)
```

```
msgString =
```

```
Error using ±
```

Not enough input arguments.

### Specify Detail Level in Error Message

In a file in your current working folder, create the following function in `testFunc.m`.

```
function a = testFunc
try
 a = notaFunction(5,6);
catch a

end
```

Since the function, `notaFunction`, does not exist, `testFunc` returns an `mException` object.

At the command prompt, call `testFunc` and get the error message.

```
m = testFunc;
msgString = getReport(m)

msgString =

Undefined function 'notaFunction' for input arguments of type 'double'.

Error in testFunc (line 3)
 a = notaFunction(5,6);
```

Specify that the error message only contains the error message and not the stack information.

```
msgString = getReport(m, 'basic')

msgString =

Undefined function 'notaFunction' for input arguments of type 'double'.
```

### Turn Off Hyperlinks in Error Message

Cause MATLAB to throw an exception.

```
try
 surf
catch exception
end
```

Get the error message from the exception.

```
msgString = getReport(exception)
```

```
msgString =
```

```
Error using surf (line 49)
Not enough input arguments.
```

Get the error message without active hyperlinks to `surf.m`.

```
msgString = getReport(exception, 'extended', 'hyperlinks', 'off')
```

```
msgString =
```

```
Error using surf (line 49)
Not enough input arguments.
```

# MException.last

**Class:** MException

Return last uncaught exception

## Syntax

```
exception = MException.last
MException.last('reset')
```

## Description

`exception = MException.last` returns the contents of the most recently thrown, uncaught MException object. `MException.last` is not set if the last exception is caught by a try/catch statement. `MException.last` is a static method of the MException class.

`MException.last('reset')` clears the properties of the exception returned from `MException.last`. It sets the `MException.identifier` and `message` properties to an empty string, the `stack` property to a 0-by-1 structure, and the `cause` property to an empty cell array.

## Tips

- Use `MException.last` only from the Command Window, not within a function.

## Examples

### Get Last Uncaught Exception

Cause MATLAB to throw, but not catch, an exception.

```
A = 25;
A(2)
```

Index exceeds matrix dimensions.

Get the uncaught exception.

```
exception = MException.last
```

```
exception =
```

```
MException with properties:
```

```
 identifier: 'MATLAB:badsubscript'
 message: 'Index exceeds matrix dimensions.'
 cause: {}
 stack: [0x1 struct]
```

## **Reset Last Uncaught Exception**

Call the `surf` function with no input arguments.

```
surf
```

```
Error using surf (line 49)
Not enough input arguments.
```

Get the uncaught exception.

```
exception = MException.last
```

```
exception =
```

```
MException with properties:
```

```
 identifier: 'MATLAB:nargchk:notEnoughInputs'
 message: 'Not enough input arguments.'
 cause: {0x1 cell}
 stack: [1x1 struct]
```

Get the last, uncaught exception.

```
MException.last('reset')
exception = MException.last
```

```
exception =
```

```
MException with properties:
```

```
identifier: ''
message: ''
 cause: {0x1 cell}
 stack: [0x1 struct]
```

## See Also

MException.addCause | MException.getReport | MException.rethrow |  
MException.throw | MException.throwAsCaller | MException | assert | error  
| try, catch

## rethrow

**Class:** MException

Rethrow previously caught exception

### Syntax

```
rethrow(exception)
```

### Description

`rethrow(exception)` rethrows a previously caught exception, `exception`. MATLAB typically responds to errors by terminating the currently running program. However, you can use a `try/catch` block to catch the exception. This interrupts the program termination so you can execute your own error handling procedures. End the `catch` block with a `rethrow` statement to terminate the program and redisplay the exception.

`rethrow` handles the stack trace differently from `error`, `assert`, and `throw`. Instead of creating the stack from where MATLAB executes the method, `rethrow` preserves the original exception information and enables you to retrace the source of the original error.

### Input Arguments

**exception** — Exception containing cause and location of error

MException object

Exception containing the cause and location of an error, specified as a scalar MException object.

### Examples

#### Catch and Rethrow Exception

Cause MATLAB to throw an error by calling `surf` with no inputs. Catch the exception, display the error identifier, and rethrow the exception.

```

try
 surf
catch ME
 disp(['ID: ' ME.identifier])
 rethrow(ME)
end

```

```

ID: MATLAB:nargchk:notEnoughInputs
Error using surf (line 49)
Not enough input arguments.

```

### Compare Behavior of throw and rethrow

Create a function, `combineArrays`, in your working folder.

```

function C = combineArrays(A,B)
try
 C = catAlongDim1(A,B); % Line 3
catch exception
 throw(exception) % Line 5
end
end

function V = catAlongDim1(V1,V2)
V = cat(1,V1,V2); % Line 10
end

```

Call the `combineArrays` function with arrays of different sizes.

```

A = 1:5;
B = 1:4;

```

```
combineArrays(A,B)
```

```

Error using combineArrays (line 5)
Dimensions of matrices being concatenated are not consistent.

```

The stack refers to line 5 where MATLAB throws the exception.

Replace `throw(exception)` with `rethrow(exception)` on line 5 of the `combineArrays` function, and call the function again.

```
combineArrays(A,B)
```

```
Error using cat
```

Dimensions of matrices being concatenated are not consistent.

Error in combineArrays>catAlongDim1 (line 10)

```
V = cat(1,V1,V2); % Line 10
```

Error in combineArrays (line 3)

```
 C = catAlongDim1(A,B); % Line 3
```

The `rethrow` method maintains the original stack and indicates the error is on line 3.

## See Also

`MException.addCause` | `MException.getReport` | `MException.last` |  
`MException.throw` | `MException.throwAsCaller` | `MException` | `assert` | `error`  
| `try, catch`

# throw

**Class:** MException

Throw exception

## Syntax

```
throw(exception)
```

## Description

`throw(exception)` throws an exception based on the information contained in the `MException` object, `exception`. The exception terminates the currently running function and returns control either to the keyboard or to an enclosing `catch` block. When you throw an exception from outside a `try/catch` statement, MATLAB displays the error message in the Command Window.

The `throw` method, unlike the `throwAsCaller` and `rethrow` methods, creates the stack trace from the location where MATLAB executes the method.

You can access the `MException` object via a `try/catch` statement or the `MException.last` method.

## Input Arguments

**exception** — Exception containing cause and location of error

`MException` object

Exception containing the cause and location of an error, specified as a scalar `MException` object.

## Examples

### Create and Throw MException Object

Throw an exception if an input variable name does not exist in the workspace.

```
str = input('Type a variable name: ','s');
if ~exist(str,'var')
 ME = MException('MyComponent:noSuchVariable', ...
 'Variable %s not found',str);
 throw(ME)
end
```

At the input prompt, enter any variable that does not exist in your workspace. For example, enter `notaVariable`.

```
Variable notaVariable not found
```

Since `notaVariable` doesn't exist in your workspace, MATLAB creates an `MException` object, and then throws it.

### Compare Behavior of `throw` and `rethrow`

Create a function, `combineArrays`, in your working folder.

```
function C = combineArrays(A,B)
try
 C = catAlongDim1(A,B); % Line 3
catch exception
 throw(exception) % Line 5
end
end

function V = catAlongDim1(V1,V2)
V = cat(1,V1,V2); % Line 10
end
```

Call the `combineArrays` function with arrays of different sizes.

```
A = 1:5;
B = 1:4;
```

```
combineArrays(A,B)
```

```
Error using combineArrays (line 5)
Dimensions of matrices being concatenated are not consistent.
```

The stack refers to line 5 where MATLAB throws the exception.

Replace `throw(exception)` with `rethrow(exception)` on line 5 of the `combineArrays` function, and call the function again.

```
combineArrays(A,B)
```

```
Error using cat
```

```
Dimensions of matrices being concatenated are not consistent.
```

```
Error in combineArrays>catAlongDim1 (line 10)
```

```
V = cat(1,V1,V2); % Line 10
```

```
Error in combineArrays (line 3)
```

```
 C = catAlongDim1(A,B); % Line 3
```

The `rethrow` method maintains the original stack and indicates the error is on line 3.

`MException` | `MException.rethrow` | `MException.throwAsCaller` |

`MException.addCause` | `MException.getReport` | `MException.last` | | `error` |

`try`, `catch`

## throwAsCaller

**Class:** MException

Throw exception as if occurs within calling function

### Syntax

```
throwAsCaller(exception)
```

### Description

`throwAsCaller(exception)` throws an exception as if it occurs within the calling function. The exception terminates the currently running function and returns control to the keyboard or an enclosing `catch` block. When you throw an exception from outside a `try/catch` statement, MATLAB displays the error message in the Command Window.

You can access the `MException` object via a `try/catch` statement or the `MException.last` method.

In some cases, it is more informative for the error to point to the location in the calling function that results in the exception rather than pointing to the function that actually throws the exception. You can use `throwAsCaller` to simplify the error display.

### Input Arguments

**exception** — Exception containing cause and location of error

MException object

Exception containing the cause and location of an error, specified as a scalar `MException` object.

### Examples

#### Compare Behavior of `throw` and `throwAsCaller`

Create a function, `sayHello`, in your working folder.

```
function sayHello(N)
 checkInput(N)
 str = ['Hello, ' N '!'];
 disp(str)

function checkInput(N)
 if ~ischar(N)
 ME = MException('sayHello:inputError','Input must be char. ');
 throw(ME)
 end
```

At the command prompt, call the function with a numeric input.

```
sayHello(42)
```

```
Error using sayHello>checkInput (line 9)
Input must be char.
```

```
Error in sayHello (line 2)
checkInput(N)
```

The top of the stack refers to line 9 because this is where MATLAB throws the exception. After the initial stack frame, MATLAB displays information from the calling function.

Replace `throw(ME)` with `throwAsCaller(ME)` in line 9 of `sayHello.m` and call the function again.

```
sayHello(42)
```

```
Error using sayHello (line 2)
Input must be char.
```

The top of the stack refers to line 2 because that is the location of the error in the calling function.

## mexext

Binary MEX-file-name extension

### Syntax

```
ext = mexext
extlist = mexext('all')
```

### Description

`ext = mexext` returns the file-name extension for the current platform.

`extlist = mexext('all')` returns the extensions for all platforms.

### Examples

#### Display File Extension for Your Computer

Find the MEX-file extension for the system you are currently working on.

```
ext = mexext

ext =
 mexw32
```

Your results reflect your system.

#### Find File Extension for Specific Platform

Find the MEX-file extension for the Apple Macintosh systems.

Get the list for supported platforms.

```
extlist = mexext('all');
```

The `mex` function identifies a platform by its `arch` value, which is the output of the `computer('arch')` command. For Macintosh platforms, the value is `maci64`.

Search the `arch` field in the results, `extlist`, for `'maci64'`, and display the corresponding `ext` field.

```
for k=1:length(extlist)
 if strcmp(extlist(k).arch, 'maci64')
 disp(sprintf('Arch: %s Ext: %s', ...
 extlist(k).arch, extlist(k).ext))
 end, end
```

```
Arch: maci64 Ext: mexmaci64
```

The file extension is `mexmaci64`.

## Output Arguments

### **ext** — File-name extension

mexa64 | mexmaci64 | mexw32 | mexw64

File-name extension for MEX-file, returned as one of these values.

Platform	Binary MEX-File Extension
Linux (64-bit)	mexa64
Apple Mac (64-bit)	mexmaci64
Microsoft Windows (32-bit)	mexw32
Windows (64-bit)	mexw64

### **extlist** — All file-name extensions

structure

All file-name extensions, returned as a structure with these fields:

#### **arch** — Platform

string

Platform, specified as a string. The name of the platform is the output of the `computer('arch')` command.

#### **ext** — File extension

string

File extension, specified as a string.

## More About

### Tips

- To use the MEX-file-name extension in makefiles or scripts outside MATLAB, type one of the following from the system command prompt. The script is located in the *matlabroot*\bin folder.
  - `mexext.bat`—Windows platform.
  - `mexext.sh`—UNIX platform.

For example, the following commands are in a GNU<sup>®</sup> makefile.

```
ext = $(shell mexext)
yprime.$(ext) : yprime.c
 mex yprime.c
```

- MATLAB continues to execute a MEX-file with a `.dll` extension, but future versions of MATLAB will not support this extension.

### See Also

`computer` | `mex`

# mfilename

File name of currently running function

## Syntax

```
mfilename
p = mfilename('fullpath')
c = mfilename('class')
```

## Description

`mfilename` returns a string containing the file name of the most recently invoked function. When called from within the file, it returns the name of that file. This allows a function to determine its name, even if the file name has been changed.

`p = mfilename('fullpath')` returns the full path and name of the file in which the call occurs, not including the filename extension.

`c = mfilename('class')` in a method, returns the class of the method, not including the leading @ sign. If called from a nonmethod, it yields the empty string.

## More About

### Tips

If `mfilename` is called with any argument other than the above two, it behaves as if it were called with no argument.

When called from the command line, `mfilename` returns an empty string.

To get the names of the callers of a MATLAB function file, use `dbstack` with an output argument.

`dbstack` | `nargin` | `function` | `nargout` | `inputname`

## mget

**Class:** FTP

Download files from FTP server

## Syntax

```
mget(ftpobj, contents)
mget(ftpobj, contents, target)
```

## Description

`mget(ftpobj, contents)` retrieves the file or folder specified by `contents` from an FTP server into the MATLAB current folder.

`mget(ftpobj, contents, target)` retrieves the file or folder into the local folder specified by `target`, which includes an absolute or relative path.

## Input Arguments

### **ftpobj**

FTP object created by `ftp`.

### **contents**

String enclosed in single quotation marks that specifies either a file name or a folder name. Can include a wildcard character (\*).

### **target**

String enclosed in single quotation marks that specifies the absolute or relative path of the local folder to contain the downloaded contents.

## Examples

Connect to an FTP server and retrieve the file `README` into the current MATLAB folder:

```
mw = ftp('ftp.mathworks.com');
mget(mw, 'README');
close(mw);
```

**See Also**

mput | cd | ftp

## min

Smallest elements in array

### Syntax

$M = \min(A)$

$M = \min(A, [], \text{dim})$

$[M, I] = \min(\_\_\_)$

$C = \min(A, B)$

### Description

$M = \min(A)$  returns the smallest elements of  $A$ .

- If  $A$  is a vector, then  $\min(A)$  returns the smallest element of  $A$ .
- If  $A$  is a matrix, then  $\min(A)$  treats the columns of  $A$  as vectors and returns a row vector of smallest elements.
- If  $A$  is a multidimensional array, then  $\min(A)$  treats the values along the first array dimension whose size does not equal 1 as vectors. The size of this dimension becomes 1 while the sizes of all other dimensions remain the same.

$M = \min(A, [], \text{dim})$  returns the smallest elements along dimension  $\text{dim}$ . For example, if  $A$  is a matrix, then  $\min(A, [], 2)$  is a column vector containing the minimum value of each row.

$[M, I] = \min(\_\_\_)$  finds the indices of the minimum values of  $A$  and returns them in output vector  $I$ , using any of the input arguments in the previous syntaxes. If there are several identical minimum values, then  $\min$  returns the index of the first one.

$C = \min(A, B)$  returns an array the same size as  $A$  and  $B$  with the smallest elements taken from  $A$  or  $B$ .

The dimensions of  $A$  and  $B$  must match, or one can be a scalar.

## Examples

### Smallest Element in Vector

Return the minimum value from a vector.

```
A = [23 42 37 18 52];
M = min(A)
```

```
M =
```

```
 18
```

### Single Smallest Element in Array

Create a 2-by-3 matrix.

```
A = [4 8 2; 9 3 7]
```

```
A =
```

```
 4 8 2
 9 3 7
```

To find the single smallest element in a matrix, you can apply the `min` function twice, `min(min(A))`. However, this does not return the index to the smallest element.

Use `A(:)` to find the minimum element in the column representation of the elements from the array `A`. Also return the index to the smallest element.

```
[M,I] = min(A(:))
```

```
M =
```

```
 2
```

```
I =
```

```
 5
```

$A(:)$  is a column vector composed of all the columns from the matrix, where each column is appended to the last.  $A(5)$  returns the minimum element, 2.

### Minimum Value from Each Matrix Column

Create a 2-by-3 matrix.

```
A = [2 8 4; 7 3 9]
```

```
A =
```

```
 2 8 4
 7 3 9
```

Find the minimum of each column.

```
[M,I] = min(A)
```

```
M =
```

```
 2 3 4
```

```
I =
```

```
 1 2 1
```

$A(I(n),n)$  contains the minimum element in the  $n$ th column of  $A$ .

### Minimum Value from Each Matrix Row

Create a 2-by-3 matrix.

```
A = [1.7 1.2 1.5; 1.3 1.6 1.99]
```

```
A =
```

```
 1.7000 1.2000 1.5000
 1.3000 1.6000 1.9900
```

Find the minimum of each row.

```
[M,I] = min(A,[],2)
```

```
M =
```

```

1.2000
1.3000

```

I =

```

2
1

```

$A(n, I(n))$  contains the minimum element in the  $n$ th row of A.

### Minimum Elements from Two Arrays

Create two arrays of the same size.

```
A = [1 8 3; 7 2 9]
```

```
B = [2 6 4; 5 2 7]
```

A =

```

1 8 3
7 2 9

```

B =

```

2 6 4
5 2 7

```

Find the minimum elements from A or B.

```
C = min(A,B)
```

C =

```

1 6 3
5 2 7

```

C contains the smallest elements from each pair of corresponding elements in A and B.

### Minimum Elements from Array and Scalar

Compare each element of matrix A to a scalar and return the minimum.

Create a 2-by-3 matrix.

```
A = [1 7 3; 6 2 9]
```

```
A =
```

```
 1 7 3
 6 2 9
```

Compare each element of **A** to the scalar value 5.

```
B = 5;
C = min(A,B)
```

```
C =
```

```
 1 5 3
 5 2 5
```

**C** contains the smaller value between each element of **A** and the scalar 5.

## Input Arguments

### **A** — Input array

scalar | vector | matrix | multidimensional array

Input array, specified as a scalar, vector, matrix, or multidimensional array. **A** can be a numeric array, logical array, ordinal categorical array, datetime array, or duration array. Complex Number Support: Yes

### **dim** — Dimension to operate along

positive integer scalar

Dimension to operate along, specified as a positive integer scalar. If no value is specified, the default is the first array dimension whose size does not equal 1.

Dimension **dim** indicates the dimension whose length reduces to 1. The `size(M, dim)` is 1, while the sizes of all other dimensions remain the same, unless `size(A, dim)` is 0. If `size(A, dim)` is 0, then `min` returns an empty array with the same dimension sizes.

Consider a two-dimensional input array, **A**:

- If `dim = 1`, then `min(A, [], 1)` returns a row vector containing the smallest element in each column.

- If  $\text{dim} = 2$ , then  $\min(A,[],2)$  returns a column vector containing the smallest element in each row.

`min` returns `A` if `dim` is greater than `ndims(A)`.

### **B — Second input array**

scalar | vector | matrix | multidimensional array

Second input array, specified as a scalar, vector, matrix, or multidimensional array. `B` can be a numeric array, logical array, ordinal categorical array, datetime array, or duration array.

The dimensions of `A` and `B` must match, or one can be a scalar.

If `A` and `B` are ordinal categorical arrays, they must have the same sets of categories, including their order.

A and B can be the same data type or one can be `double` and combine with `single`, any integer data type, or `duration`.

Complex Number Support: Yes

## Output Arguments

### **M** — Minimum values

scalar | vector | matrix | multidimensional array

Minimum values, returned as scalar, vector, matrix, or multidimensional array.

`size(M, dim)` is 1, while the sizes of all other dimensions match the size of the corresponding dimension in A, unless `size(A, dim)` is 0. If `size(A, dim)` is 0, then M is an empty array with the same dimension sizes as A.

### **I** — Index to A

array the same size as A

Index to A, returned as an array the same size as A. If the smallest element occurs more than once, then I contains the index to the first occurrence of the value.

### **C** — Minimum elements from A or B

array

Minimum elements from A or B, returned as an array.

The size of C is as follows:

- If A and B are arrays of the same size, then the size of C matches the size of A and B.
- If either A or B is a scalar, then the size of C matches the size of the nonscalar input array.

The data type of C is as follows:

- If A and B are the same data type, then C matches the data type of A and B.
- If either A or B is `single`, then C is `single`.
- If A and B are an integer data type and a scalar `double`, then C is the same integer data type.

---

## More About

### Algorithms

The `min` function ignores NaNs. When all elements in `A` are NaNs, then `min` returns the first one as the minimum. Undefined values in categorical arrays and `NaN` values in datetime arrays are similar to NaNs in numeric arrays.

When `A` is complex, the `min` function returns the complex number with the smallest complex modulus (magnitude). If magnitudes are equal, then `min` returns the value with the smallest magnitude and the smallest phase angle.

When you use `min(A,B)` with an empty array and a scalar, then `min` returns an empty array.

- “Matrix Indexing”

`isnan` | `max` | `mean` | `median` | `sort`

# MinimizeCommandWindow

Minimize size of Automation server window

## Syntax

### IDL Method Signature

```
HRESULT MinimizeCommandWindow(void)
```

### Microsoft Visual Basic Client

```
MinimizeCommandWindow
```

### MATLAB Client

```
MinimizeCommandWindow(h)
```

## Description

`MinimizeCommandWindow(h)` minimizes the window for the server attached to handle `h`, and makes it inactive.

If the server window was already in a minimized state, `MinimizeCommandWindow` does nothing.

## Examples

From a Visual Basic .NET client, modify the size of the command window in a MATLAB Automation server.

```
Dim Matlab As Object
```

```
Matlab = CreateObject("matlab.application")
Matlab.MinimizeCommandWindow
```

'Now return the server window to its former state on  
'the desktop and make it the currently active window.

Matlab.MaximizeCommandWindow

## **See Also**

MaximizeCommandWindow

## minres

Minimum residual method

### Syntax

```
x = minres(A,b)
minres(A,b,tol)
minres(A,b,tol,maxit)
minres(A,b,tol,maxit,M)
minres(A,b,tol,maxit,M1,M2)
minres(A,b,tol,maxit,M1,M2,x0)
[x,flag] = minres(A,b,...)
[x,flag,relres] = minres(A,b,...)
[x,flag,relres,iter] = minres(A,b,...)
[x,flag,relres,iter,resvec] = minres(A,b,...)
[x,flag,relres,iter,resvec,resveccg] = minres(A,b,...)
```

### Description

`x = minres(A,b)` attempts to find a minimum norm residual solution  $x$  to the system of linear equations  $A*x=b$ . The  $n$ -by- $n$  coefficient matrix  $A$  must be symmetric but need not be positive definite. It should be large and sparse. The column vector  $b$  must have length  $n$ . You can specify  $A$  as a function handle, `afun`, such that `afun(x)` returns  $A*x$ .

“Parameterizing Functions” explains how to provide additional parameters to the function `afun`, as well as the preconditioner function `mfun` described below, if necessary.

If `minres` converges, a message to that effect is displayed. If `minres` fails to converge after the maximum number of iterations or halts for any reason, a warning message is printed displaying the relative residual  $\text{norm}(b-A*x)/\text{norm}(b)$  and the iteration number at which the method stopped or failed.

`minres(A,b,tol)` specifies the tolerance of the method. If `tol` is `[]`, then `minres` uses the default,  $1e-6$ .

`minres(A,b,tol,maxit)` specifies the maximum number of iterations. If `maxit` is `[]`, then `minres` uses the default,  $\min(n,20)$ .

`minres(A,b,tol,maxit,M)` and `minres(A,b,tol,maxit,M1,M2)` use symmetric positive definite preconditioner `M` or `M = M1*M2` and effectively solve the system  $\text{inv}(\text{sqrt}(M)) * A * \text{inv}(\text{sqrt}(M)) * y = \text{inv}(\text{sqrt}(M)) * b$  for `y` and then return  $x = \text{inv}(\text{sqrt}(M)) * y$ . If `M` is `[]` then `minres` applies no preconditioner. `M` can be a function handle `mfun`, such that `mfun(x)` returns  $M \backslash x$ .

`minres(A,b,tol,maxit,M1,M2,x0)` specifies the initial guess. If `x0` is `[]`, then `minres` uses the default, an all-zero vector.

`[x,flag] = minres(A,b,...)` also returns a convergence flag.

Flag	Convergence
0	<code>minres</code> converged to the desired tolerance <code>tol</code> within <code>maxit</code> iterations.
1	<code>minres</code> iterated <code>maxit</code> times but did not converge.
2	Preconditioner <code>M</code> was ill-conditioned.
3	<code>minres</code> stagnated. (Two consecutive iterates were the same.)
4	One of the scalar quantities calculated during <code>minres</code> became too small or too large to continue computing.

Whenever `flag` is not 0, the solution `x` returned is that with minimal norm residual computed over all the iterations. No messages are displayed if the `flag` output is specified.

`[x,flag,relres] = minres(A,b,...)` also returns the relative residual  $\text{norm}(b - A*x) / \text{norm}(b)$ . If `flag` is 0, `relres <= tol`.

`[x,flag,relres,iter] = minres(A,b,...)` also returns the iteration number at which `x` was computed, where  $0 \leq \text{iter} \leq \text{maxit}$ .

`[x,flag,relres,iter,resvec] = minres(A,b,...)` also returns a vector of estimates of the `minres` residual norms at each iteration, including  $\text{norm}(b - A*x_0)$ .

`[x,flag,relres,iter,resvec,resveccg] = minres(A,b,...)` also returns a vector of estimates of the Conjugate Gradients residual norms at each iteration.

## Examples

### Using minres with a Matrix Input

```
n = 100; on = ones(n,1);
A = spdiags([-2*on 4*on -2*on],-1:1,n,n);
b = sum(A,2);
tol = 1e-10;
maxit = 50;
M1 = spdiags(4*on,0,n,n);

x = minres(A,b,tol,maxit,M1);
minres converged at iteration 49 to a solution with relative
residual 4.7e-014
```

### Using minres with a Function Handle

This example replaces the matrix `A` in the previous example with a handle to a matrix-vector product function `afun`. The example is contained in a file `run_minres` that

- Calls `minres` with the function handle `@afun` as its first argument.
- Contains `afun` as a nested function, so that all variables in `run_minres` are available to `afun`.

The following shows the code for `run_minres`:

```
function x1 = run_minres
n = 100;
on = ones(n,1);
A = spdiags([-2*on 4*on -2*on],-1:1,n,n);
b = sum(A,2);
tol = 1e-10;
maxit = 50;
M = spdiags(4*on,0,n,n);
x1 = minres(@afun,b,tol,maxit,M);

 function y = afun(x)
 y = 4 * x;
 y(2:n) = y(2:n) - 2 * x(1:n-1);
 y(1:n-1) = y(1:n-1) - 2 * x(2:n);
 end
end
```

When you enter

```
x1=run_minres;
```

MATLAB software displays the message

```
minres converged at iteration 49 to a solution with relative
residual 4.7e-014
```

## Using minres instead of pcg

Use a symmetric indefinite matrix that fails with `pcg`.

```
A = diag([20:-1:1, -1:-1:-20]);
b = sum(A,2); % The true solution is the vector of all ones.
x = pcg(A,b); % Errors out at the first iteration.
```

displays the following message:

```
pcg stopped at iteration 1 without converging to the desired
tolerance 1e-006 because a scalar quantity became too small or
too large to continue computing.
The iterate returned (number 0) has relative residual 1
```

However, `minres` can handle the indefinite matrix `A`.

```
x = minres(A,b,1e-6,40);
minres converged at iteration 39 to a solution with relative
residual 1.3e-007
```

## minus, -

Subtraction

### Syntax

```
C = A - B
C = minus(A,B)
```

### Description

`C = A - B` subtracts array `B` from array `A` and returns the result in `C`.

`C = minus(A,B)` is an alternate way to execute `A - B`, but is rarely used. It enables operator overloading for classes.

### Examples

#### Subtract Scalar from Array

Create an array, `A`, and subtract a scalar value from it.

```
A = [2 1; 3 5];
C = A - 2
```

```
C =
```

```
 0 -1
 1 3
```

The scalar is subtracted from each entry of `A`.

#### Subtract Two Arrays

Create two arrays, `A` and `B`, and subtract the second, `B`, from the first, `A`.

```
A = [1 0; 2 4];
B = [5 9; 2 1];
```

```
C = A - B
```

```
C =
```

```
 -4 -9
 0 3
```

The elements of **B** are subtracted from the corresponding elements of **A**.

Use the syntax `-C` to negate the elements of **C**.

```
-C
```

```
ans =
```

```
 4 9
 0 -3
```

## Input Arguments

### **A** — Input array

scalar | vector | matrix | multidimensional array

Input array, specified as a scalar, vector, matrix, or multidimensional array. **A** can be a numeric array, logical array, character array, datetime array, duration array, or calendar duration array. Inputs **A** and **B** must be the same size unless one is a scalar. You can add a scalar value to any other value.

If one input is a datetime array, duration array, or calendar duration array, then numeric values in the other input are treated as a number of 24-hour days.

If one input is a datetime array, then the other input also can be a date string or a cell array containing date strings.

Complex Number Support: Yes

### **B** — Input array

scalar | vector | matrix | multidimensional array

Input array, specified as a scalar, vector, matrix, or multidimensional array. **B** can be a numeric array, logical array, character array, datetime array, duration array, or calendar duration array. Inputs **A** and **B** must be the same size unless one is a scalar. You can add a scalar value to any other value.

If one input is a datetime array, duration array, or calendar duration array, then numeric values in the other input are treated as a number of 24-hour days.

If one input is a datetime array, then the other input also can be a date string or a cell array containing date strings.

Complex Number Support: Yes

## **See Also**

`diff` | `plus` | `uminus`

# minute

Minute number

## Syntax

```
m = minute(t)
```

## Description

`m = minute(t)` returns the minute numbers of the datetime values in `t`. The `m` output is a double array the same size as `t` and contains integer values from 0 to 59.

The `minute` function returns the minute numbers of datetime values. To assign minute values to a datetime array, `t`, use `t.Minute` and modify the `Minute` property.

## Examples

### Find Minute Number of Datetime Values

```
t1 = datetime('now');
t = t1 + minutes(2:4)
```

```
t =
```

```
 20-Sep-2014 00:10:17 20-Sep-2014 00:11:17 20-Sep-2014 00:12:17
```

```
m = minute(t)
```

```
m =
```

```
 10 11 12
```

## Input Arguments

**t** — **Input date and time**  
datetime array

Input date and time, specified as a `datetime` array.

## See Also

`datetime` Properties | `hms` | `hour` | `second` | `timeofday`

# minutes

Duration in minutes

## Syntax

```
M = minutes(X)
```

## Description

`M = minutes(X)` returns an array of minutes equivalent to the values in `X`.

- If `X` is a numeric array, then `M` is a **duration** array in units of minutes.
- If `X` is a **duration** array, then `M` is a **double** array with each element equal to the number of minutes in the corresponding element of `X`.

## Examples

### Create Duration Array of Minutes

```
X = magic(4);
M = minutes(X)
```

M =

```
16 mins 2 mins 3 mins 13 mins
5 mins 11 mins 10 mins 8 mins
9 mins 7 mins 6 mins 12 mins
4 mins 14 mins 15 mins 1 min
```

### Convert Durations to Numeric Array of Minutes

Create a **duration** array.

```
X = hours(2:10:38) + minutes(30)
```

```
X =
 2.5 hrs 12.5 hrs 22.5 hrs 32.5 hrs
```

Convert each duration in `X` to a number of minutes.

```
M = minutes(X)
```

```
M =
 150 750 1350 1950
```

View the data type of `M`.

```
whos M
```

Name	Size	Bytes	Class	Attributes
M	1x4	32	double	

## Input Arguments

### **X** — Input array

numeric array | duration array | logical array

Input array, specified as a numeric array, duration array, or logical array.

### See Also

`duration`

# mislocked

Determine if function is locked in memory

## Syntax

```
mislocked
mislocked(fun)
```

## Description

`mislocked` by itself returns logical 1 (**true**) if the currently running function is locked in memory, and logical 0 (**false**) otherwise. Functions that are locked cannot be removed with the `clear` function unless you first unlock them using the `munlock` function. You can use locking on functions that reside in MATLAB `.m` files or `.mex` files.

`mislocked(fun)` returns logical 1 (**true**) if the function named *fun* is locked in memory, and logical 0 (**false**) otherwise.

## See Also

`mlock` | `munlock` | `inmem`

# mkdir

Make new folder

## Syntax

```
mkdir('folderName')
mkdir('parentFolder','folderName')
status = mkdir(____)
[status,message,messageid] = mkdir(____)
```

## Description

`mkdir('folderName')` creates the folder `folderName`, where `folderName` can be an absolute or a relative path.

`mkdir('parentFolder','folderName')` creates the folder `folderName` in `parentFolder`, where `parentFolder` is an absolute or relative path. If `parentFolder` does not exist, MATLAB attempts to create it. See the Tips section.

`status = mkdir(____)` creates the specified folder. When the operation is successful, it returns a `status` of logical 1. When the operation is unsuccessful, it returns logical 0.

`[status,message,messageid] = mkdir(____)` creates the specified folder, and returns the status, message string, and MATLAB message ID. The value given to `status` is logical 1 for success, and logical 0 for error.

## Examples

### Creating a Subfolder in the Current Folder

Create a subfolder called `newdir` in the current folder:

```
mkdir('newdir')
```

## Creating a Subfolder in the Specified Parent Folder

Create a subfolder called `newFolder` in the folder `testdata`, using a relative path, where `newFolder` is at the same level as the current folder:

```
mkdir('../testdata','newFolder')
```

## Returning Status When Creating a Folder

In this example, the first attempt to create `newFolder` succeeds, returning a status of 1, and no error or warning message or message identifier:

```
[s, mess, messid] = mkdir('../testdata', 'newFolder')
s =
 1
mess =
 ''
messid =
 ''
```

Attempt to create the same folder again. `mkdir` again returns a success status, and also a warning and message identifier informing you that the folder exists:

```
[s,mess,messid] = mkdir('../testdata','newFolder')
s =
 1
mess =
 Directory "newFolder" already exists.
messid =
 MATLAB:MKDIR:DirectoryExists
```

## More About

### Tips

If an argument specifies a path that includes one or more nonexistent folders, MATLAB attempts to create the nonexistent folder. For example, for

```
mkdir('myFolder\folder1\folder2\targetFolder')
```

if `folder1` does not exist, MATLAB creates `folder1`, creates `folder2` within `folder1`, and creates `targetFolder` within `folder2`.

---

# mkdir

**Class:** FTP

Create folder on FTP server

## Syntax

```
mkdir(ftpobj, folder)
```

## Description

`mkdir(ftpobj, folder)` creates the specified folder on the FTP server associated with `ftpobj`.

## Input Arguments

### **ftpobj**

FTP object created by `ftp`.

### **folder**

String enclosed in single quotation marks that specifies a path relative to the current folder on the FTP server.

## Examples

Suppose that a hypothetical host, `ftp.testsite.com`, contains a folder named `testfolder`. Connect to the server and add a subfolder:

```
test=ftp('ftp.testsite.com');
mkdir(test, 'testfolder/newfolder');
close(test);
```

**See Also**

`rmdir` | `dir` | `ftp`

# mkpp

Make piecewise polynomial

## Syntax

```
pp = mkpp(breaks,coefs)
pp = mkpp(breaks,coefs,d)
```

## Description

`pp = mkpp(breaks,coefs)` builds a piecewise polynomial `pp` from its breaks and coefficients. `breaks` is a vector of length `L+1` with strictly increasing elements which represent the start and end of each of `L` intervals. `coefs` is an `L`-by-`k` matrix with each row `coefs(i,:)` containing the coefficients of the terms, from highest to lowest exponent, of the order `k` polynomial on the interval `[breaks(i),breaks(i+1)]`.

`pp = mkpp(breaks,coefs,d)` indicates that the piecewise polynomial `pp` is `d`-vector valued, i.e., the value of each of its coefficients is a vector of length `d`. `breaks` is an increasing vector of length `L+1`. `coefs` is a `d`-by-`L`-by-`k` array with `coefs(r,i,:)` containing the `k` coefficients of the `i`th polynomial piece of the `r`th component of the piecewise polynomial.

Use `ppval` to evaluate the piecewise polynomial at specific points. Use `unmkpp` to extract details of the piecewise polynomial.

**Note.** The *order* of a polynomial tells you the number of coefficients used in its description. A *k*th order polynomial has the form

$$c_1x^{k-1} + c_2x^{k-2} + \dots + c_{k-1}x + c_k$$

It has *k* coefficients, some of which can be 0, and maximum exponent *k* - 1. So the order of a polynomial is usually one greater than its degree. For example, a cubic polynomial is of order 4.

## Examples

### Construct and Plot Piecewise Polynomial

The first plot shows the quadratic polynomial

$$1 - \left(\frac{x}{2} - 1\right)^2 = \frac{-x^2}{4} + x$$

shifted to the interval [-8,-4]. The second plot shows its negative

$$\left(\frac{x}{2} - 1\right)^2 - 1 = \frac{x^2}{4} - x$$

but shifted to the interval [-4,0].

The last plot shows a piecewise polynomial constructed by alternating these two quadratic pieces over four intervals. It also shows its first derivative, which was constructed after breaking the piecewise polynomial apart using `unmkpp`.

```
subplot(2,2,1)
cc = [-1/4 1 0];
pp1 = mkpp([-8 -4],cc);
xx1 = -8:0.1:-4;
plot(xx1,ppval(pp1,xx1),'k-')

subplot(2,2,2)
pp2 = mkpp([-4 0],-cc);
xx2 = -4:0.1:0;
plot(xx2,ppval(pp2,xx2),'k-')

subplot(2,1,2)
pp = mkpp([-8 -4 0 4 8],[cc;-cc;cc;-cc]);
xx = -8:0.1:8;
plot(xx,ppval(pp,xx),'k-')
[breaks,coefs,l,k,d] = unmkpp(pp);
dpp = mkpp(breaks, repmat(k-1:-1:1,d*1,1).*coefs(:,1:k-1),d);
hold on, plot(xx,ppval(dpp,xx),'r-'), hold off
```

**See Also**

ppval | spline | unmkpp

## **mldivide, \**

Solve systems of linear equations  $Ax = B$  for  $x$

### **Syntax**

```
x = A\B
x = mldivide(A,B)
```

### **Description**

$x = A\B$  solves the system of linear equations  $A*x = B$ . The matrices  $A$  and  $B$  must have the same number of rows. MATLAB displays a warning message if  $A$  is badly scaled or nearly singular, but performs the calculation regardless.

- If  $A$  is a scalar, then  $A\B$  is equivalent to  $A.\B$ .
- If  $A$  is a square  $n$ -by- $n$  matrix and  $B$  is a matrix with  $n$  rows, then  $x = A\B$  is a solution to the equation  $A*x = B$ , if it exists.
- If  $A$  is a rectangular  $m$ -by- $n$  matrix with  $m \sim n$ , and  $B$  is a matrix with  $m$  rows, then  $A\B$  returns a least-squares solution to the system of equations  $A*x = B$ .

$x = \text{mldivide}(A,B)$  is an alternative way to execute  $x = A\B$ , but is rarely used. It enables operator overloading for classes.

### **Examples**

#### **System of Equations**

Solve a simple system of linear equations,  $A*x = B$ .

```
A = magic(3);
B = [15; 15; 15];
x = A\B
```

```
x =

 1.0000
 1.0000
```

```
1.0000
```

### Linear System with Singular Matrix

Solve a linear system of equations  $A*x = b$  involving a singular matrix,  $A$ .

```
A = magic(4);
b = [34; 34; 34; 34];
x = A\b
```

```
Warning: Matrix is close to singular or badly scaled. Results may be inaccurate. RCOND
1.306145e-17.
```

```
x =
```

```
1.5000
2.5000
-0.5000
0.5000
```

When `rcond` is between 0 and `eps`, MATLAB issues a nearly singular warning, but proceeds with the calculation. When working with ill-conditioned matrices, an unreliable solution can result even though the residual ( $b - A*x$ ) is relatively small. In this particular example, the norm of the residual is zero, and an exact solution is obtained, although `rcond` is small.

When `rcond` is equal to 0, the singular warning appears.

```
A = [1 0; 0 0];
b = [1; 1];
x = A\b
```

```
Warning: Matrix is singular to working precision.
```

```
x =
```

```
1
Inf
```

In this case, division by zero leads to computations with `Inf` and/or `NaN`, making the computed result unreliable.

### Least-Squares Solution of Underdetermined System

Solve a system of linear equations,  $A*x = b$ .

```
A = [1 2 0; 0 4 3];
b = [8; 18];
x = A\b
```

```
ans =
```

```
 0
 4.0000
 0.6667
```

## Linear System with Sparse Matrix

Solve a simple system of linear equations using sparse matrices.

Consider the matrix equation  $A*x = B$ .

```
A = sparse([0 2 0 1 0; 4 -1 -1 0 0; 0 0 0 3 -6; -2 0 0 0 2; 0 0 4 2 0]);
B = sparse([8; -1; -18; 8; 20]);
x = A\b
```

```
x =
```

```
(1,1) 1.0000
(2,1) 2.0000
(3,1) 3.0000
(4,1) 4.0000
(5,1) 5.0000
```

## Input Arguments

### A — Coefficient matrix

vector | full matrix | sparse matrix

Coefficient matrix, specified as a vector, full matrix, or sparse matrix. If A has  $m$  rows, then B must have  $m$  rows.

Data Types: `single` | `double`

Complex Number Support: Yes

### B — Right-hand side

vector | full matrix | sparse matrix

Right-hand side, specified as a vector, full matrix, or sparse matrix. If B has  $m$  rows, then A must have  $m$  rows.

Data Types: `single` | `double`  
Complex Number Support: Yes

## Output Arguments

### **x** — Solution

vector | full matrix | sparse matrix

Solution, returned as a vector, full matrix, or sparse matrix. If  $A$  is an  $m$ -by- $n$  matrix and  $B$  is an  $m$ -by- $p$  matrix, then  $x$  is an  $n$ -by- $p$  matrix, including the case when  $p=1$ .

If  $A$  has full storage,  $x$  is also full. If  $A$  is sparse, then  $x$  has the same storage as  $B$ .

## More About

### Tips

- If  $A$  is a square matrix,  $A \setminus B$  is roughly equal to `inv(A)*B`, but MATLAB processes  $A \setminus B$  differently and more robustly.
- If the rank of  $A$  is less than the number of columns in  $A$ , then  $x = A \setminus B$  is not necessarily the minimum norm solution. The more computationally expensive  $x = \text{pinv}(A) * B$  computes the minimum norm least-squares solution.
- For full singular inputs, you can compute the least-squares solution using the function `linsolve`.

### Algorithms

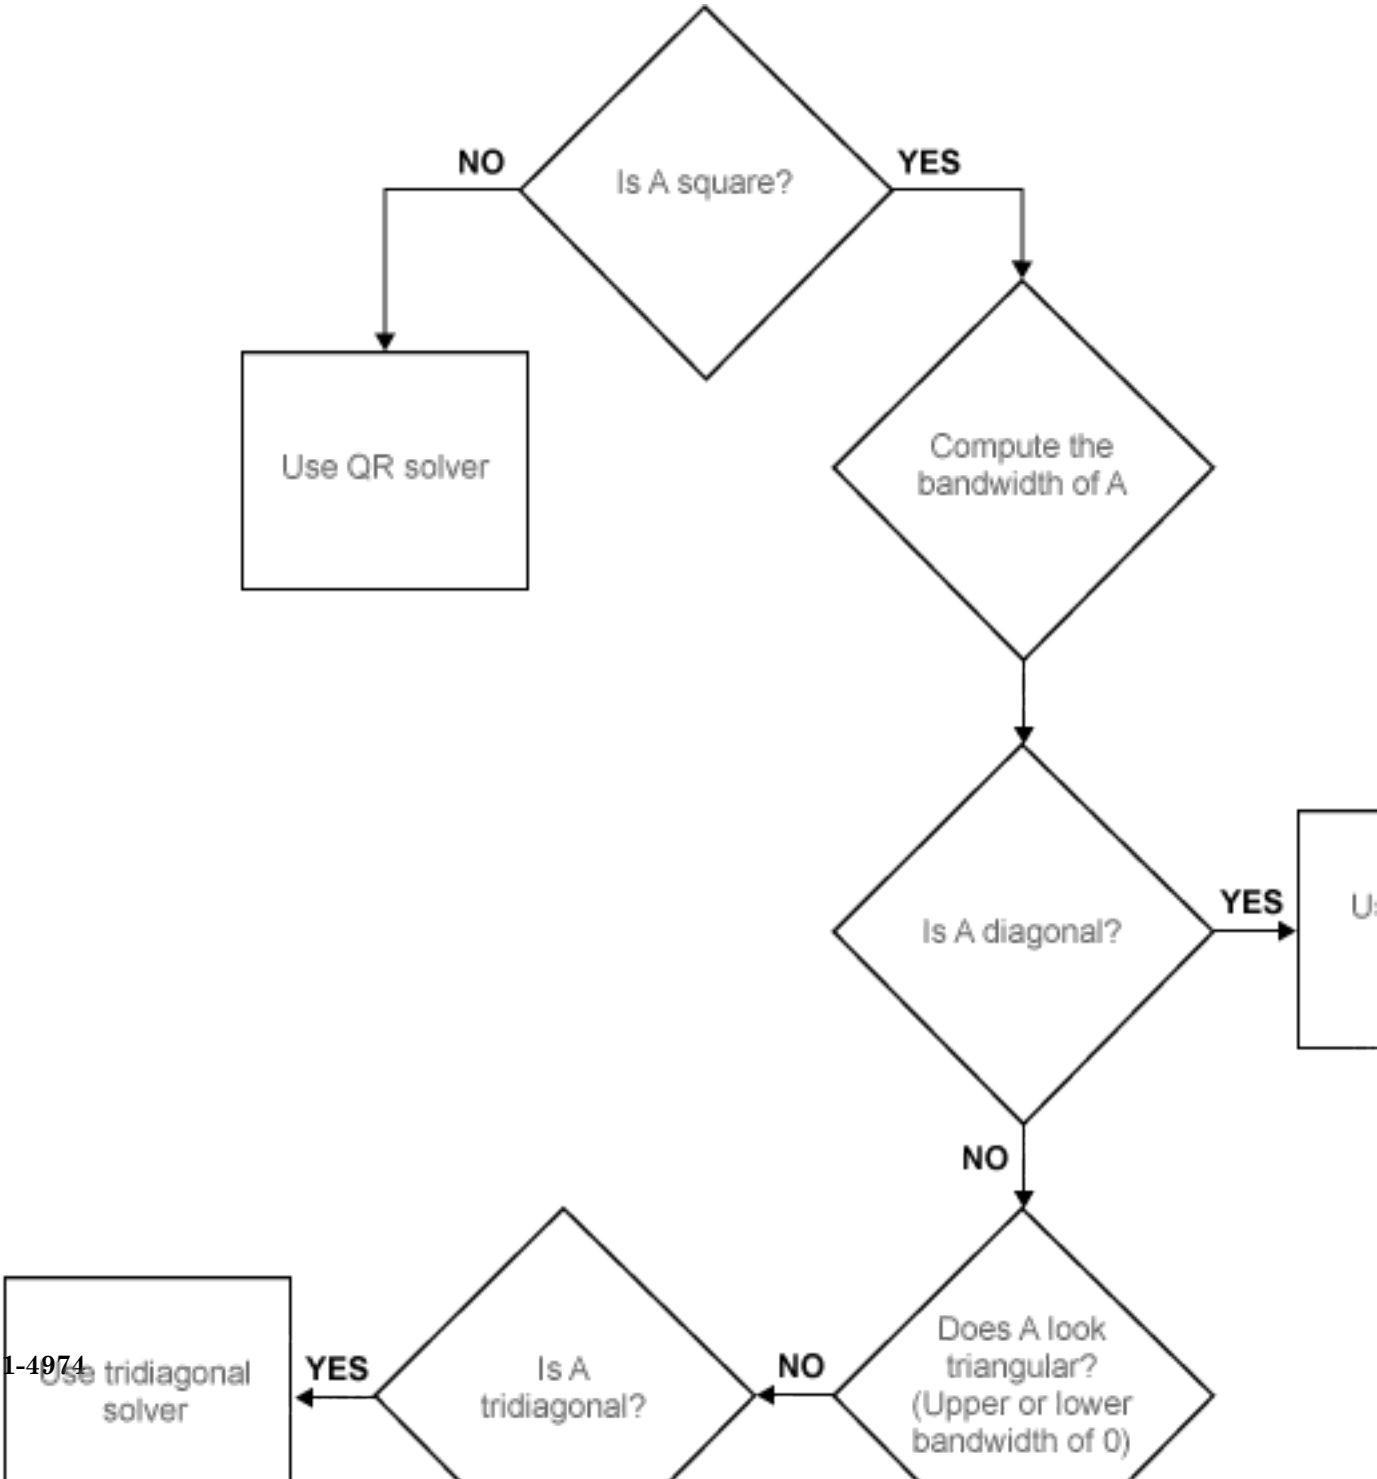

The versatility of `mldivide` in solving linear systems stems from its ability to take advantage of symmetries in the problem by dispatching to an appropriate solver. This approach aims to minimize computation time. The first distinction the function makes is between *full* (also called “*dense*”) and *sparse* input arrays.

## Algorithm for Full Inputs

The flow chart below shows the algorithm path when inputs  $A$  and  $B$  are **full**.

## mrdivide, /

Solve systems of linear equations  $xA = B$  for  $x$

### Syntax

```
x = B/A
x = mrdivide(B,A)
```

### Description

$x = B/A$  solves the system of linear equations  $x*A = B$  for  $x$ . The matrices  $A$  and  $B$  must contain the same number of columns. MATLAB displays a warning message if  $A$  is badly scaled or nearly singular, but performs the calculation regardless.

- If  $A$  is a scalar, then  $B/A$  is equivalent to  $B ./ A$ .
- If  $A$  is a square  $n$ -by- $n$  matrix and  $B$  is a matrix with  $n$  columns, then  $x = B/A$  is a solution to the equation  $x*A = B$ , if it exists.
- If  $A$  is a rectangular  $m$ -by- $n$  matrix with  $m \approx n$ , and  $B$  is a matrix with  $n$  columns, then  $x = B/A$  returns a least-squares solution of the system of equations  $x*A = B$ .

$x = \text{mrdivide}(B,A)$  is an alternative way to execute  $x = B/A$ , but is rarely used. It enables operator overloading for classes.

### Examples

#### System of Equations

Solve a system of equations that has a unique solution,  $x*A = B$ .

```
A = [1 1 3; 2 0 4; -1 6 -1];
B = [2 19 8];
x = B/A
```

```
x =
```

```
1.0000 2.0000 3.0000
```

### Least-Squares on an Underdetermined System

Solve an underdetermined system,  $x \cdot C = D$ .

```
C = [1 0; 2 0; 1 0];
```

```
D = [1 2];
```

```
x = D/C
```

```
Warning: Rank deficient, rank = 1, tol = 6.280370e-16.
```

```
x =
```

```
0 0.5000 0
```

MATLAB issues a warning but proceeds with calculation.

Verify that  $x$  is not an exact solution.

```
x*C-D
```

```
ans =
```

```
0 -2
```

## Input Arguments

### A — Coefficient matrix

vector | full matrix | sparse matrix

Coefficient matrix, specified as a vector, full matrix, or sparse matrix. If A has  $n$  columns, then B must have  $n$  columns.

Data Types: `single` | `double`

Complex Number Support: Yes

### B — Right-hand side

vector | full matrix | sparse matrix

Right-hand side, specified as a vector, full matrix, or sparse matrix. If B has  $n$  columns, then A must have  $n$  columns.

Data Types: `single` | `double`

Complex Number Support: Yes

## Output Arguments

### **x — Solution**

vector | full matrix | sparse matrix

Solution, returned as a vector, full matrix, or sparse matrix. If  $A$  is an  $m$ -by- $n$  matrix and  $B$  is a  $p$ -by- $n$  matrix, then  $x$  is a  $p$ -by- $m$  matrix.

$x$  is sparse only if both  $A$  and  $B$  are sparse matrices.

## More About

### Tips

- The operators `/` and `\` are related to each other by the equation  $B/A = (A' \setminus B')'$ .
- If  $A$  is a square matrix,  $B/A$  is roughly equal to  $B * \text{inv}(A)$ , but MATLAB processes  $B/A$  differently and more robustly.
- “Systems of Linear Equations”

### See Also

# mlint

Check MATLAB code files for possible problems

---

**Note:** `mlint` is not recommended. Use `checkcode` instead.

---

## Alternatives

For information on using the graphical user interface to the Code Analyzer, see “Check Code for Errors and Warnings”.

## Syntax

```
mlint('filename')
mlint('filename','-config=settings.txt')
mlint('filename','-config=factory')
inform=mlint('filename','-struct')
msg=mlint('filename','-string')
[inform,filepaths]=mlint('filename')
inform=mlint('filename','-id')
inform=mlint('filename','-fullpath')
inform=mlint('filename','-notok')
mlint('filename','-cyc')
mlint('filename','-codegen')
mlint('filename','-eml')
```

## Description

`mlint('filename')` displays Code Analyzer messages about `filename`, where the message reports potential problems and opportunities for code improvement. The line number in the message is a hyperlink that opens the file in the Editor, scrolled to that line. If `filename` is a cell array, information is displayed for each file. For `mlint(F1,F2,F3,...)`, where each input is a character array, MATLAB software

displays information about each input file name. You cannot combine cell arrays and character arrays of file names. Note that the exact text of the `mlint` messages is subject to some change between versions.

`mlint('filename', '-config=settings.txt')` overrides the default active settings file with the settings that enable or suppress messages as indicated in the specified `settings.txt` file.

---

**Note:** If used, you must specify the full path to the `settings.txt` file specified with the `-config` option.

---

For information about creating a `settings.txt` file, see “Save and Reuse Code Analyzer Message Settings”. If you specify an invalid file, `mlint` returns a message indicating that it cannot open or read the file you specified. In that case, `mlint` uses the factory default settings.

`mlint('filename', '-config=factory')` ignores all settings files and uses the factory default preference settings.

`inform=mlint('filename', '-struct')` returns the information in a structure array whose length is the number of messages found. The structure has the fields that follow.

Field	Description
<code>message</code>	Message describing the suspicious construct that code analysis caught.
<code>line</code>	Vector of file line numbers to which the message refers.
<code>column</code>	Two-column array of file columns (column extents) to which the message applies. The first column of the array specifies the column in the Editor where the message begins. The second column of the array specifies the column in the Editor where the message ends. There is one row in the two-column array for each occurrence of a message.

If you specify multiple file names as input, or if you specify a cell array as input, `inform` contains a cell array of structures.

`msg=mlint('filename', '-string')` returns the information as a string to the variable `msg`. If you specify multiple file names as input, or if you specify a cell array as

input, `msg` contains a string where each file's information is separated by 10 equal sign characters (=), a space, the file name, a space, and 10 equal sign characters.

If you omit the **-struct** or **-string** argument and you specify an output argument, the default behavior is **-struct**. If you omit the argument and there are no output arguments, the default behavior is to display the information to the command line.

`[inform,filepath]=mlint('filename')` additionally returns `filepath`s, the absolute paths to the file names, in the same order as you specified them.

`inform=mlint('filename','-id')` requests the message ID, where ID is a string of the form ABC... When returned to a structure, the output also has the `id` field, which is the ID associated with the message.

`inform=mlint('filename','-fullpath')` assumes that the input file names are absolute paths, so that `mlint` does not try to locate them.

`inform=mlint('filename','-notok')` runs `mlint` for all lines in `filename`, even those lines that end with the `mlint` suppression directive, `%#ok`.

`mlint('filename','-cyc')` displays the McCabe complexity (also referred to as cyclomatic complexity) of each function in the file. Higher McCabe complexity values indicate higher complexity, and there is some evidence to suggest that programs with higher complexity values are more likely to contain errors. Frequently, you can lower the complexity of a function by dividing it into smaller, simpler functions. In general, smaller complexity values indicate programs that are easier to understand and modify. Some people advocate splitting up programs that have a complexity rating over 10.

`mlint('filename','-codegen')` enables code generation messages for display in the Command Window.

`mlint('filename','-eml')` '-eml' is not recommended. Use '-codegen' instead.

## Examples

The following examples use `lengthofline.m`, which is a sample file with MATLAB code that can be improved. You can find it in `matlabroot/help/techdoc/matlab_env/examples`. If you want to run the examples, save a copy of `lengthofline.m` to a location on your MATLAB path.

## Running mlint on a File with No Options

To run `mlint` on the example file, `lengthofline.m`, run

```
mlint('lengthofline')
```

MATLAB displays the M-Lint messages for `lengthofline.m` in the Command Window:

```
L 22 (C 1-9): The value assigned here to variable 'nohandle' might never be used.
L 23 (C 12-15): NUMEL(x) is usually faster than PROD(SIZE(x)).
L 24 (C 5-11): 'notline' might be growing inside a loop. Consider preallocating for speed.
L 24 (C 44-49): Use STRCMP(str1,str2) instead of using LOWER in a call to STRCMP.
L 28 (C 12-15): NUMEL(x) is usually faster than PROD(SIZE(x)).
L 34 (C 13-16): 'data' might be growing inside a loop. Consider preallocating for speed.
L 34 (C 24-31): Use dynamic fieldnames with structures instead of GETFIELD.
 Type 'doc struct' for more information.
L 38 (C 29): Use || instead of | as the OR operator in (scalar) conditional statements.
L 39 (C 47): Use || instead of | as the OR operator in (scalar) conditional statements.
L 40 (C 47): Use || instead of | as the OR operator in (scalar) conditional statements.
L 42 (C 13-16): 'data' might be growing inside a loop. Consider preallocating for speed.
L 43 (C 13-15): 'dim' might be growing inside a loop. Consider preallocating for speed.
L 45 (C 13-15): 'dim' might be growing inside a loop. Consider preallocating for speed.
L 48 (C 52): There may be a parenthesis imbalance around here.
L 48 (C 53): There may be a parenthesis imbalance around here.
L 48 (C 54): There may be a parenthesis imbalance around here.
L 48 (C 55): There may be a parenthesis imbalance around here.
L 49 (C 17): Terminate statement with semicolon to suppress output (in functions).
L 49 (C 23): Use of brackets [] is unnecessary. Use parentheses to group, if needed.
```

For details about these messages and how to improve the code, see “Changing Code Based on Code Analyzer Messages” in the MATLAB Desktop Tools and Development Environment documentation.

## Running mlint with Options to Show IDs and Return Results to a Structure

To store the results to a structure and include message IDs, run

```
inform=mlint('lengthofline', '-id')
```

MATLAB returns

```
inform =
```

```
19x1 struct array with fields:
 message
 line
 column
 id
```

To see values for the first message, run

```
inform(1)
```

MATLAB displays

```
ans =
```

```
message: 'The value assigned here to variable 'nohandle' might never be used.'
line: 22
column: [1 9]
id: 'NASGU'
```

Here, the message is for the value that appears on line 22 that extends from column 1–9 in the file.NASGU is the ID for the message 'The value assigned here to variable 'nohandle' might never be used.'.

## Displaying McCabe Complexity with mlint

To display the McCabe complexity of a MATLAB code file, run `mlint` with the `-cyc` option, as shown in the following example (assuming you have saved `lengthofline.m` to a local folder).

```
mlint lengthofline.m -cyc
```

Results displayed in the Command Window show the McCabe complexity of the file, followed by the M-Lint messages, as shown here:

```
L 1 (C 23-34): The McCabe complexity of 'lengthofline' is 12.
L 22 (C 1-9): The value assigned here to variable 'nohandle' might never be used.
L 23 (C 12-15): NUMEL(x) is usually faster than PROD(SIZE(x)).
L 24 (C 5-11): 'notline' might be growing inside a loop. Consider preallocating for speed.
L 24 (C 44-49): Use STRCMPI(str1,str2) instead of using UPPER/LOWER in a call to STRCMP.
L 28 (C 12-15): NUMEL(x) is usually faster than PROD(SIZE(x)).
L 34 (C 13-16): 'data' might be growing inside a loop. Consider preallocating for speed.
L 34 (C 24-31): Use dynamic fieldnames with structures instead of GETFIELD. Type 'doc struct' for more information.
L 38 (C 29): Use || instead of | as the OR operator in (scalar) conditional statements.
L 39 (C 47): Use || instead of | as the OR operator in (scalar) conditional statements.
L 40 (C 47): Use || instead of | as the OR operator in (scalar) conditional statements.
L 42 (C 13-16): 'data' might be growing inside a loop. Consider preallocating for speed.
L 43 (C 13-15): 'dim' might be growing inside a loop. Consider preallocating for speed.
L 45 (C 13-15): 'dim' might be growing inside a loop. Consider preallocating for speed.
L 48 (C 52): There may be a parenthesis imbalance around here.
L 48 (C 53): There may be a parenthesis imbalance around here.
L 48 (C 54): There may be a parenthesis imbalance around here.
L 48 (C 55): There may be a parenthesis imbalance around here.
L 49 (C 17): Terminate statement with semicolon to suppress output (in functions).
L 49 (C 23): Use of brackets [] is unnecessary. Use parentheses to group, if needed.
```

## See Also

`mlintrpt`, `profile`

## How To

- For information on the suppression directive, `%#0k`, and suppressing messages from within your program, see “Adjust Code Analyzer Message Indicators and Messages”.

# mlintrpt

Run `checkcode` for file or folder, reporting results in browser

## Syntax

```
mlintrpt
mlintrpt('filename','file')
mlintrpt('dirname','dir')
mlintrpt('filename','file','settings.txt')
mlintrpt('dirname','dir','settings.txt')
```

## Description

`mlintrpt` scans all files with an `.m` file extension in the current folder for Code Analyzer messages and reports the results in a MATLAB Web browser.

`mlintrpt('filename','file')` scans `filename` for Code Analyzer messages and reports results. You can omit `'file'` in this form of the syntax because it is the default.

`mlintrpt('dirname','dir')` scans the specified folder. Here, `dirname` can be in the current folder or can be a full path.

`mlintrpt('filename','file','settings.txt')` applies the Code Analyzer preference settings to enable or suppress messages as indicated in the specified `settings.txt` file.

`mlintrpt('dirname','dir','settings.txt')` applies the settings indicated in the specified `settings.txt` file.

---

**Note:** If you specify a `settings.txt` file, you must specify the full path to the file.

---

## Examples

`lengthofline.m` is an example file with code that can be improved. It is found in `matlabroot/matlab/help/techdoc/matlab_env/examples`.

## Run Report for All Files in a Folder

Run

```
mlintrpt(fullfile(matlabroot,'help','techdoc','matlab_env','examples'),'dir')
```

and MATLAB displays a report of potential problems and improvements for all files with an `.m` file extension in the `examples` folder.

For details about these messages and how to improve the code, see “Changing Code Based on Code Analyzer Messages”.

## Run Report Using Code Analyzer Preference Settings

You can save preference settings to a text file by clicking the **Preferences** button in the **Environment** section on the **Home** tab and selecting **Code Analyzer** in the left pane.

To save a preferences file, select **Save as** under the  drop-down list. To apply those settings when you run `mlintrpt`, use the `file` option and supply the full path to the settings file name as shown in this example:

```
mlintrpt('lengthofline.m', 'file', ...
'C:\WINNT\Profiles\me\Application Data\MathWorks\MATLAB\R2012b\mymlint.txt')
```

Alternatively, use `fullfile` if the settings file is stored in the preferences folder:

```
mlintrpt('lengthofline.m', 'file', fullfile(prefdir,'mymlint.txt'))
```

Assuming that in that example `mymlint.txt` file, the setting for **Terminate statement with semicolon to suppress output** has been disabled, the results of `mlintrpt` for `lengthofline` do not show that message for line 49.

When `mlintrpt` cannot locate the settings file, the first message in the report is

```
O: Unable to open or read the configuration file 'mymlint.txt'--using default settings.
```

`checkcode`

# mlock

Prevent clearing function from memory

## Syntax

```
mlock
```

## Description

`mlock` locks the currently running function in memory so that subsequent `clear` functions do not remove it. Locking a function in memory also prevents any persistent variables defined in the file from getting reinitialized.

Use the `munlock` function to return the file to its normal, clearable state.

## Examples

The function `testfun` begins with an `mlock` statement.

```
function testfun
mlock
:
```

When you execute this function, it becomes locked in memory. You can check this using the `mislocked` function.

```
testfun

mislocked('testfun')
ans =
 1
```

Using `munlock`, you unlock the `testfun` function in memory. Checking its status with `mislocked` shows that it is indeed unlocked at this point.

```
munlock('testfun')
```

```
mislocked('testfun')
ans =
 0
```

## **See Also**

`mislocked` | `inmem` | `munlock` | `persistent`

# mmfileinfo

Information about multimedia file

## Syntax

```
info = mmfileinfo(filename)
```

## Description

*info* = mmfileinfo(*filename*) returns a structure, *info*, with fields containing information about the contents of the multimedia file identified by *filename*. The *filename* input is a string enclosed in single quotation marks.

If *filename* is a URL, mmfileinfo might take a long time to return because it must first download the file. For large files, downloading can take several minutes. To avoid blocking the MATLAB command line while this processing takes place, download the file before calling mmfileinfo.

The *info* structure contains the following fields, listed in the order they appear in the structure.

Field	Description
Filename	String indicating the name of the file.
Path	String indicating the absolute path to the file.
Duration	Length of the file in seconds.
Audio	Structure containing information about the audio data in the file. See “Audio Data” on page 1-4990 for more information about this data structure.
Video	Structure containing information about the video data in the file. See “Video Data” on page 1-4990 for more information about this data structure.

## Audio Data

The `Audio` structure contains the following fields, listed in the order they appear in the structure. If the file does not contain audio data, the fields in the structure are empty.

Field	Description
Format	Text string, indicating the audio format.
NumberOfChannels	Number of audio channels.

## Video Data

The `Video` structure contains the following fields, listed in the order they appear in the structure. If the file does not contain video data, the fields in the structure are empty.

Field	Description
Format	Text string, indicating the video format.
Height	Height of the video frame.
Width	Width of the video frame.

## Examples

Display information about the example file `xylophone.mpg`:

```
info = mmfileinfo('xylophone.mpg')
audio = info.Audio
video = info.Video
```

MATLAB returns:

```
info =
 Filename: 'xylophone.mpg'
 Path: 'matlabroot\toolbox\matlab\audiovideo'
 Duration: 4.7020
 Audio: [1x1 struct]
 Video: [1x1 struct]

audio =
 Format: 'MPEG'
```

NumberOfChannels: 2

video =

Format: 'MPEG1'

Height: 240

Width: 320

where `Path` is system-dependent.

## See Also

`get` | `VideoReader`

## mmreader class

Create object for reading video files

---

**Note:** `mmreader` has been removed. Use `VideoReader` instead.

---

### Description

Use `mmreader` with the `read` method to read video data from a multimedia file into the MATLAB workspace.

The file formats that `mmreader` supports vary by platform, as follows (with no restrictions on file extensions):

All Platforms	Motion JPEG 2000 (.mj2)
Windows	AVI (.avi), MPEG-1 (.mpg), Windows Media Video (.wmv, .asf, .asx), and any format supported by Microsoft DirectShow.
Macintosh	AVI (.avi), MPEG-1 (.mpg), MPEG-4 (.mp4, .m4v), Apple QuickTime Movie (.mov), and any format supported by QuickTime as listed on <a href="http://support.apple.com/kb/HT3775">http://support.apple.com/kb/HT3775</a> .
Linux	Any format supported by your installed plug-ins for GStreamer 0.10 or above, as listed on <a href="http://gstreamer.freedesktop.org/documentation/plugins.html">http://gstreamer.freedesktop.org/documentation/plugins.html</a> , including AVI (.avi) and Ogg Theora (.ogg).

For more information, see “Supported Video File Formats” in the MATLAB Data Import and Export documentation.

## Construction

`obj = mmreader(filename)` constructs `obj` to read video data from the file named `filename`. The `mmreader` constructor searches for the file on the MATLAB path. If it cannot construct the object for any reason, `mmreader` generates an error.

`obj = mmreader(filename, 'PropertyName', PropertyValue)` constructs the object using options, specified as property name/value pairs. Property name/value pairs can be in any format that the `set` method supports: name/value string pairs, structures, or name/value cell array pairs.

## Properties

### **BitsPerPixel**

Bits per pixel of the video data. (Read-only)

### **Duration**

Total length of the file in seconds. (Read-only)

### **FrameRate**

Frame rate of the video in frames per second. (Read-only)

### **Height**

Height of the video frame in pixels. (Read-only)

### **Name**

Name of the file associated with the object. (Read-only)

### **NumberOfFrames**

Total number of frames in the video stream. (Read-only)

Some files store video at a variable frame rate, including many Windows Media Video files. For these files, `mmreader` cannot determine the number of frames until you read the last frame. When you construct the object, `mmreader` returns a warning and does not set the `NumberOfFrames` property.

To count the number of frames in a variable frame rate file, use the `read` method to read the last frame of the file. For example:

```
vidObj = mmreader('varFrameRateFile.wmv');
lastFrame = read(vidObj, inf);
numFrames = vidObj.NumberOfFrames;
```

## **Path**

String containing the full path to the file associated with the reader. (Read-only)

## **Tag**

User-defined string to identify the object.

**Default:** ''

## **Type**

Class name of the object: 'mmreader'. (Read-only)

## **UserData**

Generic field for user-defined data.

**Default:** []

## **VideoFormat**

String indicating the MATLAB representation of the video format, such as 'RGB24'. (Read-only)

## **Width**

Width of the video frame in pixels. (Read-only)

## **Methods**

For backward compatibility, `mmreader` supports the following `VideoReader` methods:

`get`

Query property values for video reader object

<code>getFileFormats</code>	File formats that <code>VideoReader</code> supports
<code>hasFrame</code>	Determine if frame available to read
<code>read</code>	Read video frame data from file
<code>readFrame</code>	Read video frame from video file
<code>set</code>	Set property values for video reader object

## Copy Semantics

Handle. To learn how handle classes affect copy operations, see “Copying Objects” in the MATLAB Programming Fundamentals documentation.

## Examples

Construct an `mmreader` object for the example movie file `xylophone.mpg` and view its properties:

```
xyloObj = mmreader('xylophone.mpg', 'Tag', 'My reader object');
get(xyloObj)
```

Read and play back the movie file `xylophone.mpg`:

```
xyloObj = mmreader('xylophone.mpg');

nFrames = xyloObj.NumberOfFrames;
vidHeight = xyloObj.Height;
vidWidth = xyloObj.Width;

% Preallocate movie structure.
mov(1:nFrames) = ...
 struct('cdata', zeros(vidHeight, vidWidth, 3, 'uint8'),...
 'colormap', []);

% Read one frame at a time.
```

```
for k = 1 : nFrames
 mov(k).cdata = read(xyloObj, k);
end

% Size a figure based on the video's width and height.
hf = figure;
set(hf, 'position', [150 150 vidWidth vidHeight])

% Play back the movie once at the video's frame rate.
movie(hf, mov, 1, xyloObj.FrameRate);
```

- “Read Video Files”

# mod

Remainder after division (modulo operation)

## Syntax

```
b = mod(a,m)
```

## Description

`b = mod(a,m)` returns the remainder after division of `a` by `m`, where `a` is the dividend and `m` is the divisor. This function is often called the modulo operation and is computed using `b = a - a.*floor(a./m)`. The `mod` function follows the convention that `mod(a,0)` returns `a`.

## Examples

### Remainder After Division of Scalar

Compute 23 modulo 5.

```
b = mod(23,5)
```

```
b =
```

```
3
```

### Remainder After Division of Vector

Find the remainder after division for a vector of integers and the divisor 3.

```
a = 1:5;
m = 3;
b = mod(a,m)
```

```
b =
```

1 2 0 1 2

### Remainder After Division for Positive and Negative Values

Find the remainder after division for a set of integers including both positive and negative values. Note that nonzero results are always positive if the divisor is positive.

```
a = [-4 -1 7 9];
m = 3;
b = mod(a,m)
```

b =

2 2 1 0

### Remainder After Division for Negative Divisor

Find the remainder after division by a negative divisor for a set of integers including both positive and negative values. Note that nonzero results are always negative if the divisor is negative.

```
a = [-4 -1 7 9];
m = -3;
b = mod(a,m)
```

b =

-1 -1 -2 0

### Remainder After Division for Floating-Point Values

Find the remainder after division for several angles using a modulus of  $2\pi$ . Note that mod attempts to compensate for floating-point round-off effects to produce exact integer results when possible.

```
theta = [0.0 3.5 5.9 6.2 9.0 4*pi];
m = 2*pi;
b = mod(theta,m)
```

b =

0 3.5000 5.9000 6.2000 2.7168 0

## Input Arguments

### **a** — Dividend

scalar | vector | matrix | multidimensional array

Dividend, specified as a scalar, vector, matrix, or multidimensional array. **a** must be a real-valued array of any numerical type. Inputs **a** and **m** must be the same size unless one is a scalar **double**. If one input has an integer data type, then the other input must be of the same integer data type or be a scalar **double**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **m** — Divisor

scalar | vector | matrix | multidimensional array

Divisor (or modulus), specified as a scalar, vector, matrix, or multidimensional array. **m** must be a real-valued array of any numerical type. Inputs **a** and **m** must be the same size unless one is a scalar **double**. If one input has an integer data type, then the other input must be of the same integer data type or be a scalar **double**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

## More About

### Differences Between `mod` and `rem`

The concept of remainder after division is not uniquely defined, and the two functions `mod` and `rem` each compute a different variation. The `mod` function produces a result that is either zero or has the same sign as the divisor. The `rem` function produces a result that is either zero or has the same sign as the dividend.

Another difference is the convention when the divisor is zero. The `mod` function follows the convention that `mod(a, 0)` returns **a**, whereas the `rem` function follows the convention that `rem(a, 0)` returns NaN.

Both variants have their uses. For example, in signal processing, the `MOD` function is useful in the context of periodic signals because its output is periodic (with period equal to the divisor).

## Congruence Relationships

The `MOD` function is useful for congruence relationships: `a` and `b` are congruent (mod `m`) if and only if `MOD(a, m) == MOD(b, m)`. For example, 23 and 13 are congruent (mod 5).

`rem`

# mode

Most frequent values in array

## Syntax

`M = mode(X)`

`M = mode(X,dim)`

`[M,F] = mode( ___ )`

`[M,F,C] = mode( ___ )`

## Description

`M = mode(X)` returns the sample mode of `X`, which is the most frequently occurring value in `X`. When there are multiple values occurring equally frequently, `mode` returns the smallest of those values. For complex inputs, the smallest value is the first value in a sorted list.

- If `X` is a vector, then `mode(X)` returns the most frequent value of `X`.
- If `X` is a nonempty matrix, then `mode(X)` returns a row vector containing the mode of each column of `X`.
- If `X` is an empty 0-by-0 matrix, `mode(X)` returns `NaN`.
- If `X` is a multidimensional array, then `mode(X)` treats the values along the first array dimension whose size does not equal 1 as vectors and returns an array of most frequent values. The size of this dimension becomes 1 while the sizes of all other dimensions remain the same.

`M = mode(X,dim)` returns the mode of elements along dimension `dim`. For example, if `X` is a matrix, then `mode(X,2)` is a column vector containing the most frequent value of each row

`[M,F] = mode( ___ )` also returns a frequency array `F`, using any of the input arguments in the previous syntaxes. `F` is the same size as `M`, and each element of `F` represents the number of occurrences of the corresponding element of `M`.

`[M,F,C] = mode( ___ )` also returns a cell array `C` of the same size as `M` and `F`. Each element of `C` is a sorted vector of all values that have the same frequency as the corresponding element of `M`.

## Examples

### Mode of Matrix Columns

Define a 3-by-4 matrix.

```
X = [3 3 1 4; 0 0 1 1; 0 1 2 4]
```

X =

```
 3 3 1 4
 0 0 1 1
 0 1 2 4
```

Find the most frequent value of each column.

```
M = mode(X)
```

M =

```
 0 0 1 4
```

### Mode of Matrix Rows

Define a 3-by-4 matrix.

```
X = [3 3 1 4; 0 0 1 1; 0 1 2 4]
```

X =

```
 3 3 1 4
 0 0 1 1
 0 1 2 4
```

Find the most frequent value of each row.

```
M = mode(X,2)
```

M =

```
3
0
0
```

### Mode of 3-D Array

Create a 1-by-3-by-4 array of integers between 1 and 10.

```
X = gallery('integerdata',10,[1,3,4],1)
```

```
X(:,:,1) =
```

```
 10 8 10
```

```
X(:,:,2) =
```

```
 6 9 5
```

```
X(:,:,3) =
```

```
 9 6 1
```

```
X(:,:,4) =
```

```
 4 9 5
```

Find the most frequent values of this 3-D array along the second dimension.

```
M = mode(X)
```

```
M(:,:,1) =
```

```
 10
```

```
M(:,:,2) =
```

```
 5
```

```
M(:,:,3) =
```

1

```
M(:, :, 4) =
```

4

This operation produces a 1-by-1-by-4 array by finding the most frequent value along the second dimension. The size of the second dimension reduces to 1.

Compute the mode along the first dimension of X.

```
M = mode(X, 1);
```

```
isequal(X, M)
```

```
ans =
```

1

This returns the same array as X because the size of the first dimension is 1.

## Mode of Matrix Columns with Frequency Information

Define a 3-by-4 matrix.

```
X = [3 3 1 4; 0 0 1 1; 0 1 2 4]
```

```
X =
```

```
3 3 1 4
0 0 1 1
0 1 2 4
```

Find the most frequent value of each column, as well as how often it occurs.

```
[M, F] = mode(X)
```

```
M =
```

```
0 0 1 4
```

```
F =
```

```

2 1 2 2

```

$F(1)$  is 2 since  $M(1)$  occurs twice in the first column.

### Mode of Matrix Rows with Frequency and Multiplicity Information

Define a 3-by-4 matrix.

```
X = [3 3 1 4; 0 0 1 1; 0 1 2 4]
```

```
X =
```

```

3 3 1 4
0 0 1 1
0 1 2 4

```

Find the most frequent value of each row, how often it occurs, and which values in that row occur with the same frequency.

```
[M,F,C] = mode(X,2)
```

```
M =
```

```

3
0
0

```

```
F =
```

```

2
2
1

```

```
C =
```

```

[3]
[2x1 double]
[4x1 double]

```

$C\{2\}$  is the 2-by-1 vector  $[0;1]$  since values 0 and 1 in the second row occur with frequency  $F(2)$ .

$C\{3\}$  is the 4-by-1 vector `[0;1;2;4]` since all values in the third row occur with frequency  $F(3)$ .

## Mode of 16-bit Unsigned Integer Array

Define a 1-by-4 vector of 16-bit unsigned integers.

```
X = gallery('integerdata',10,[1,4],3,'uint16')
```

```
X =
```

```
 6 3 2 3
```

Find the most frequent value, as well as the number of times it occurs.

```
[M,F] = mode(X),
class(M)
```

```
M =
```

```
 3
```

```
F =
```

```
 2
```

```
ans =
```

```
uint16
```

M is the same class as the input, X.

## Input Arguments

### X — Input array

vector | matrix | multidimensional array

Input array, specified as a vector, matrix, or multidimensional array. X can be a numeric array, categorical array, datetime array, or duration array.

NaN or NaT (Not a Time) values in the input array, X, are ignored. Undefined values in categorical arrays are similar to NaNs in numeric arrays.

**dim — Dimension to operate along**

positive integer scalar

Dimension to operate along, specified as a positive integer scalar. If no value is specified, the default is the first array dimension whose size does not equal 1.

Dimension `dim` indicates the dimension whose length reduces to 1. The `size(M, dim)` is 1, while the sizes of all other dimensions remain the same.

Consider a two-dimensional input array, `X`.

- If `dim = 1`, then `mode(X, 1)` returns a row vector containing the most frequent value in each column.
- If `dim = 2`, then `mode(X, 2)` returns a column vector containing the most frequent value in each row.

`mode` returns `X` if `dim` is greater than `ndims(X)`.

Data Types: `double` | `single` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

## Output Arguments

**M — Most frequent values**

scalar | vector | matrix | multidimensional array

Most frequent values returned as a scalar, vector, matrix, or multidimensional array. When there are multiple values occurring equally frequently, `mode` returns the smallest of those values. For complex inputs, this is taken to be the first value in a sorted list of values.

The class of `M` is the same as the class of the input array, `X`.

## **F — Frequency array**

scalar | vector | matrix | multidimensional array

Frequency array returned as a scalar, vector, matrix, or multidimensional array. The size of `F` is the same as the size of `M`, and each element of `F` represents the number of occurrences of the corresponding element of `M`.

The class of `F` is always `double`.

## **C — Most frequent values with multiplicity**

cell array

Most frequent values with multiplicity returned as a cell array. The size of `C` is the same as the size of `M` and `F`, and each element of `C` is a sorted column vector of all values that have the same frequency as the corresponding element of `M`.

## **More About**

### **Tips**

- The `mode` function is most useful with discrete or coarsely rounded data. The mode for a continuous probability distribution is defined as the peak of its density function. Applying the `mode` function to a sample from that distribution is unlikely to provide a good estimate of the peak; it would be better to compute a histogram or density estimate and calculate the peak of that estimate. Also, the `mode` function is not suitable for finding peaks in distributions having multiple modes.

### **See Also**

`hist` | `histc` | `mean` | `median` | `sort`

# month

Month number and name

## Syntax

```
m = month(t)
m = month(t,monthType)
```

## Description

`m = month(t)` returns the month numbers of the datetime values in `t`. The `m` output contains integer values from 1 to 12.

`m = month(t,monthType)` returns the type of month number or name specified by `monthType`.

The `month` function returns the month numbers or names of datetime values. To assign month numbers to datetime array `t`, use `t.Month` and modify the `Month` property.

## Examples

### Extract Month Number from Dates

Extract the month numbers from an array of dates.

```
t = datetime(2014,05,31):caldays(35):datetime(2014,10,15)
```

```
t =
```

```
 31-May-2014 05-Jul-2014 09-Aug-2014 13-Sep-2014
```

```
m = month(t)
```

```
m =
 5 7 8 9
```

## Find Month Names of Dates

Get the month names from an array of dates.

```
t = datetime(2013,01,01):calweeks(12):datetime(2013,12,31)
```

```
t =
 01-Jan-2013 26-Mar-2013 18-Jun-2013 10-Sep-2013 03-Dec-2013
```

```
m = month(t, 'name')
```

```
m =
 'January' 'March' 'June' 'September' 'December'
```

## Input Arguments

### **t** — Input date and time

`datetime` array

Input date and time, specified as a `datetime` array.

### **monthType** — Type of month values

'monthofyear' (default) | 'name' | 'shortname'

Type of month values, specified as one of the following strings.

Value of monthType	Description
'monthofyear'	Month-of-year number
'name'	Full month names, for example, August or September.

Value of monthType	Description
'shortname'	Abbreviated month names, for example, Aug or Sep.

## Output Arguments

### **m** — Month number or name

double array | cell array of strings

Month number or name, returned as a numeric array of type `double`, or a cell array of strings. `m` is the same size as `t`.

## See Also

`datetime Properties` | `day` | `quarter` | `week` | `year` | `ymd`

## more

Control paged output for Command Window

### Syntax

```
more on
more off
more(n)
A = more(state)
```

### Description

`more on` enables paging of the output in the MATLAB Command Window. MATLAB displays output one page at a time. Use the keys defined in the table below to control paging.

`more off` disables paging of the output in the MATLAB Command Window.

`more(n)` defines the length of a page to be *n* lines.

`A = more(state)` returns in *A* the number of lines that are currently defined to be a page. The *state* input can be one of the quoted strings 'on' or 'off', or the number of lines to set as the new page length.

By default, the length of a page is equal to the number of lines available for display in the MATLAB Command Window. Manually changing the size of the command window adjusts the page length accordingly.

If you set the page length to a specific value, MATLAB uses that value for the page size, regardless of the size of the command window. To have MATLAB return to matching page size to window size, type `more off` followed by `more on`.

To see the status of `more`, type `get(0, 'More')`. MATLAB returns either `on` or `off`, indicating the `more` status.

When you have enabled `more` and are examining output, you can do the following.

---

Press the...	To...
Return key	Advance to the next line of output.
Space bar	Advance to the next page of output.
Q (for quit) key	Terminate display of the text. Do not use <b>Ctrl+C</b> to terminate <b>more</b> or you might generate error messages in the Command Window.

**more** is in the **off** state, by default.

diary

## morebins

Increase number of histogram bins

### Syntax

```
N = morebins(h)
```

### Description

`N = morebins(h)` increases the number of bins in histogram `h` by 10% (rounded up to the nearest integer) and returns the new number of bins.

### Examples

#### Increase Number of Histogram Bins

Plot a histogram of 1,000 random numbers and return a handle to the histogram object.

```
x = randn(1000,1);
h = histogram(x)
```

```
h =
```

```
 Histogram with properties:
```

```
 Data: [1000x1 double]
 Values: [1x23 double]
 NumBins: 23
 BinEdges: [1x24 double]
 BinWidth: 0.3000
 BinLimits: [-3.3000 3.6000]
 Normalization: 'count'
 FaceColor: 'auto'
 EdgeColor: [0 0 0]
```

Use GET to show all properties

Use `morebins` to increase the number of bins in the histogram.

```
morebins(h);
morebins(h)
```

```
ans =
```

```
29
```

## Input Arguments

### **h** — Input histogram

histogram object

Input histogram, specified as a histogram object. For more information, see Using histogram Objects.

## Output Arguments

### **N** — Number of bins

scalar

Number of bins, returned as a scalar. N is the new number of bins for the histogram after increase.

## More About

- [Using histogram Objects](#)
- [Histogram Properties](#)

## See Also

[fewerbins](#) | [histcounts](#) | [histogram](#)

## move

Move or resize control in parent window

### Syntax

```
V = move(h,position)
```

### Description

`V = move(h,position)` moves the control to the position specified by the `position` argument. When you use `move` with only the handle argument, `h`, it returns a four-element vector indicating the current position of the control.

The position argument is a four-element vector specifying the position and size of the control in the parent figure window. The elements of the vector are:

```
[x, y, width, height]
```

where `x` and `y` are offsets, in pixels, from the bottom left corner of the figure window to the same corner of the control, and `width` and `height` are the size of the control itself.

### Examples

This example moves the control.

```
f = figure('Position',[100 100 200 200]);
h = actxcontrol('mwsamp.mwsampctrl.1',[0 0 200 200],f);
pos = move(h,[50 50 200 200])

pos =
 50 50 200 200
```

The next example resizes the control to always be centered in the figure as you resize the figure window. Start by creating the script `resizectrl.m` that contains:

```
% Get the new position and size of the figure window
fpos = get(gcbo,'position');
```

```
% Resize the control accordingly
move(h,[0 0 fpos(3) fpos(4)]);
```

Now execute the following:

```
f = figure('Position',[100 100 200 200]);
h = actxcontrol('mwsamp.mwsampctrl.1',[0 0 200 200]);
set(f,'ResizeFcn','resizectl');
```

As you resize the figure window, notice that the circle moves so that it is always positioned in the center of the window.

set (COM) | get (COM)

# movefile

Move file or folder

## Syntax

```
movefile('source')
movefile('source','destination')
movefile('source','destination','f')
[status,message,messageid] = movefile(___)
```

## Description

`movefile('source')` moves the file or folder named `source` to the current folder, where `source` is the absolute or relative path name for the folder or file. To move multiple files or folders, use one or more wildcard characters (\*) after the last file separator in `source`. The `source` argument permits a wildcard character in a path string. `movefile` does not preserve the archive attribute of `source`.

`movefile('source','destination')` moves the file or folder named `source` to the location `destination`, where `source` and `destination` are the absolute or relative paths for the folder or file. To move multiple files or folders, you can use one or more wildcard characters (\*) after the last file separator in `source`. You cannot use a wildcard character in `destination`. To rename a file or folder when moving it, make `destination` a different name than `source`, and specify only one file for `source`. When `source` and `destination` have the same location, `movefile` renames `source` to `destination`.

`movefile('source','destination','f')` moves the file or folder named `source` to the location `destination`, regardless of the read-only attribute of `destination`.

`[status,message,messageid] = movefile( ___ )` moves the file or folder named `source` to the location `destination`, returning the status, a message, and the MATLAB message ID. Here, `status` is logical 1 for success or logical 0 for error. `movefile` requires only one output argument.

## Examples

### Moving a File to the Current Folder

Assuming `myfiles` is a subfolder within the current folder, move the file `myfunction.m` to the current folder:

```
movefile('myfiles/myfunction.m')
```

Assuming `projects/testcases` is the current folder, move `projects/myfiles` and its contents to the current folder:

```
movefile('../myfiles')
```

### Renaming a File in the Current Folder

In the current folder, rename `oldname.m` to `newname.m`:

```
movefile('oldname.m','newname.m')
```

### Using a Wildcard to Move All Matching Files

Assuming `myfiles` is a subfolder of the current folder, move all files whose names that begin with `my` from the `myfiles` folder, to the current folder:

```
movefile('myfiles/my*')
```

### Moving a File to a Different Folder

Assuming `projects` and the current folder are at the same level, move the file `myfunction.m` from the current folder to the folder `projects`:

```
movefile('myfunction.m','../projects')
```

### Moving a Folder Down One Level

Assuming `projects` is a subfolder of the current folder, move the folder `projects/testcases` and all its contents down a level in `projects` into `projects/myfiles`:

```
movefile('projects/testcases','projects/myfiles/')
```

## Moving a File to a Read-Only Folder and Renaming the File

Move the file `myfile.m` from the current folder to `d:/work/restricted`, assigning it the name `test1.m`, where `restricted` is a read-only folder:

```
movefile('myfile.m','d:/work/restricted/test1.m','f')
```

The read-only file `myfile.m` is no longer in the current folder. The file `test1.m` is in `d:/work/restricted` and is read only.

## Returning Status When Moving Files

Move all files in the folder `myfiles` whose names start with `new` to the current folder, when there is an error. You mistype `new*` as `nex*` and no items in the current folder start with `nex*`:

```
[s,mess,messid] = movefile('myfiles/nex*')
```

```
s =
 0
```

```
mess =
```

```
No matching files were found.
```

```
messid =
```

```
MATLAB:MOVEFILE:FileDoesNotExist
```

## More About

# movegui

Move GUI figure to specified location on screen

## Syntax

```
movegui(h, 'position')
movegui(position)
movegui(h)
movegui
```

## Description

`movegui(h, 'position')` moves the figure identified by handle `h` to the specified screen location, preserving the figure's size. The `position` argument is either a string or a two-element vector, as defined in the tables that follow.

`movegui(position)` moves the callback figure (`gcbf`) or the current figure (`gcf`) to the specified position.

`movegui(h)` moves the figure identified by the handle `h` to the onscreen position.

`movegui` moves the callback figure (`gcbf`) or the current figure (`gcf`) to the onscreen position. You can specify `'movegui'` as a `CreateFcn` callback for a figure. Doing so ensures after you save a figure, that figure appears on screen when you reload it, regardless of its saved position. See the following example.

When it is a string, `position` is one of the following descriptors.

Position String	Description
north	Top center edge of screen
south	Bottom center edge of screen
east	Right center edge of screen
west	Left center edge of screen
northeast	Top right corner of screen

Position String	Description
northwest	Top left corner of screen
southeast	Bottom right corner of screen
southwest	Bottom left corner
center	Centered on screen
onscreen	Nearest location to current location that is entirely on screen

You can also specify the *position* argument as a two-element vector,  $[h, v]$ . Depending on sign,  $h$  specifies the figure's offset from the left or right edge of the screen, and  $v$  specifies the figure's offset from the top or bottom of the screen, in pixels. The following table summarizes the possible values.

$h$ (for $h \geq 0$ )	Offset of left side from left edge of screen
$h$ (for $h < 0$ )	Offset of right side from right edge of screen
$v$ (for $v \geq 0$ )	Offset of bottom edge from bottom of screen
$v$ (for $v < 0$ )	Offset of top edge from top of screen

Applying `movegui` to a maximized figure window moves the window towards the task bar and creates a gap on the opposite side of the screen about as wide as the task bar. The window might shrink in size by a few pixels. If you use the `onscreen` option with a maximized figure window, then `movegui` creates a gap on both the left and upper sides of the screen so that the top-left corner of the figure is visible.

`GUIDE` and `openfig` call `movegui` when loading figures to ensure they are visible.

## Examples

Ensure that a saved GUI appears on screen when you reload it, regardless of the target computer screen size and resolution. Create a figure that is off the screen, assign `movegui` as its `CreateFcn` callback, save the figure, and then reload it.

```
f = figure('Position',[10000,10000,400,300]);
% The figure does not display because
% it is created offscreen.
```

```
f.CreateFcn = @movegui;
hgsave(f, 'onscreenfig');
close(f);
f2 = hgload('onscreenfig');
% The reloaded figure is now visible
```

Move a figure to the bottom left corner of the screen.

```
f = figure;
movegui(f, 'southwest');
```

Move a figure so that it is offset 100 pixels from the bottom and left side of the screen.

```
f = figure;
movegui(f, [100, 100]);
```

## movie

Play recorded movie frames

### Syntax

```
movie(M)
movie(M,n)
movie(M,n,fps)
movie(h,...)
movie(h,M,n,fps,loc)
```

### Description

The `movie` function plays the movie defined by a matrix whose columns are movie frames (usually produced by `getframe`).

`movie(M)` plays the movie in matrix `M` once, using the current axes as the default target. If you want to play the movie in the figure instead of the axes, specify the figure handle (or `gcf`) as the first argument: `movie(figure_handle, ...)`. `M` must be an array of movie frames (usually from `getframe`).

`movie(M,n)` plays the movie `n` times. If `n` is negative, each cycle is shown forward then backward. If `n` is a vector, the first element is the number of times to play the movie, and the remaining elements make up a list of frames to play in the movie.

For example, if `M` has four frames then `n = [10 4 4 2 1]` plays the movie ten times, and the movie consists of frame 4 followed by frame 4 again, followed by frame 2 and finally frame 1.

`movie(M,n,fps)` plays the movie at `fps` frames per second. The default is 12 frames per second. Computers that cannot achieve the specified speed play as fast as possible.

`movie(h, ...)` plays the movie centered in the figure or axes identified by the handle `h`. Specifying the figure or axes enables MATLAB to fit the movie to the available size.

`movie(h,M,n,fps,loc)` specifies `loc`, a four-element location vector, `[x y 0 0]`, where the lower left corner of the movie frame is anchored (only the first two elements in

the vector are used). The location is relative to the lower left corner of the figure or axes specified by handle `h` and in units of pixels, regardless of the object's `Units` property.

## Examples

### Record Frames and Play Movie

Use the `getframe` function in a loop to record frames of the `peaks` function vibrating. Preallocate an array to store the movie frames.

```
figure
Z = peaks;
surf(Z)
axis tight manual
ax = gca;
ax.NextPlot = 'replaceChildren';

loops = 40;
F(loops) = struct('cdata',[],'colormap',[]);
for j = 1:loops
 X = sin(j*pi/10)*Z;
 surf(X,Z)
 drawnow
 F(j) = getframe;
end
```

To play the movie two times, use `movie(F,2)`.

## More About

### Tips

The `movie` function uses a default figure size of 560-by-420 and does not resize figures to fit movies with larger or smaller frames. To accommodate other frame sizes, you can resize the figure to fit the movie, as shown in the second example below.

`movie` only accepts 8-bit image frames; it does not accept 16-bit grayscale or 24-bit truecolor image frames.

Buffering the movie places all frames in memory. As a result, on Microsoft Windows and perhaps other platforms, a long movie (on the order of several hundred frames) can exhaust memory, depending on system resources. In such cases an error message is issued:

```
??? Error using ==> movie
Could not create movie frame
```

You can abort a movie by typing **Ctrl-C**.

`movie` is not a built-in function. Therefore, you cannot call `movie` using the `builtin` function.

## Limitations with Renderer on Windows Systems

Setting the figure `Renderer` property to `painters` works around limitations of using `getframe` with the OpenGL renderer on some Windows systems.

- “Record Animation for Playback”

`getframe` | `frame2im` | `im2frame` | `VideoReader` | `VideoWriter`

## movie2avi

Create Audio/Video Interleaved (AVI) file from MATLAB movie

---

**Note:** `movie2avi` will be removed in a future release. Use `VideoWriter` instead.

---

### Syntax

```
movie2avi(mov, filename)
movie2avi(mov, filename, ParameterName, ParameterValue)
```

### Description

`movie2avi(mov, filename)` creates the AVI file `filename` from the MATLAB movie `mov`. The `filename` input is a string. The `mov` input is a 1-by- $n$  structure array, where  $n$  is the number of frames. Each frame is a structure with two fields: `cdata` and `colormap`. For more information, see `getframe`.

`movie2avi(mov, filename, ParameterName, ParameterValue)` accepts one or more comma-separated parameter name/value pairs. The following table lists the available parameters and values.

Parameter Name	Value	Default
'colormap'	An $m$ -by-3 matrix defining the colormap for indexed AVI movies, where $m$ is no more than 256 (236 for Indeo compression).  Valid only when the 'compression' is 'MSVC', 'RLE', or 'None'.	No default
'compression'	A text string specifying the compression codec to use. To create an uncompressed file, specify a value of 'None'.  On UNIX operating systems, the only valid value is 'None'.	'Indeo5' on Windows systems.  'None' on UNIX systems.

Parameter Name	Value	Default
	<p>On Windows systems, valid values include:</p> <ul style="list-style-type: none"> <li>• 'MSVC'</li> <li>• 'RLE'</li> <li>• 'Cinepak' on 32-bit systems.</li> <li>• 'Indeo3' or 'Indeo5' on 32-bit Windows XP systems.</li> </ul> <p>Alternatively, specify a custom compression codec on Windows systems using the four-character code that identifies the codec (typically included in the codec documentation). If MATLAB cannot find the specified codec, it returns an error.</p>	
'fps'	A scalar value specifying the speed of the AVI movie in frames per second (fps).	15 fps
'keyframe'	For compressors that support temporal compression, the number of key frames per second.	2.1429 key frames per second
'quality'	<p>A number from 0 through 100. Higher quality numbers result in higher video quality and larger file sizes. Lower quality numbers result in lower video quality and smaller file sizes.</p> <p>Valid only for compressed movies.</p>	75
'videoname'	A descriptive name for the video stream, no more than 64 characters.	<i>filename</i>

## Examples

Create a movie and write to an uncompressed AVI file, `myPeaks.avi`:

```
nFrames = 20;

% Preallocate movie structure.
mov(1:nFrames) = struct('cdata', [],...
 'colormap', []);
```

```
% Create movie.
Z = peaks; surf(Z);
axis tight manual
set(gca,'nextplot','replacechildren');
for k = 1:nFrames
 surf(sin(2*pi*k/20)*Z,Z)
 mov(k) = getframe(gcf);
end

% Create AVI file.
movie2avi(mov, 'myPeaks.avi', 'compression', 'None');
```

## More About

### Tips

- On some Windows systems, including all 64-bit systems, the default Indeo 5 codec is not available. MATLAB issues a warning, and creates an uncompressed file.
- On 32-bit Windows XP systems, MATLAB can create AVI files compressed with Indeo 3 and Indeo 5 codecs. However, Microsoft Windows XP Service Pack 3 (SP3) with Security Update 954157 disables playback of Indeo 3 and Indeo 5 codecs in Windows Media Player and Internet Explorer. Consider specifying a `compression` value of `'None'`.

# mpower, ^

Matrix power

## Syntax

```
C = A^B
C = mpower(A,B)
```

## Description

$C = A^B$  computes  $A$  to the  $B$  power and returns the result in  $C$ .

$C = \text{mpower}(A,B)$  is an alternate way to execute  $A^B$ , but is rarely used. It enables operator overloading for classes.

## Examples

### Square a Matrix

Create a 2-by-2 matrix and square it.

```
A = [1 2; 3 4];
C = A^2
```

```
C =
```

```
 7 10
 15 22
```

The syntax  $A^2$  is equivalent to  $A*A$ .

### Matrix Exponents

Create a 2-by-2 matrix and use it as the exponent for a scalar.

```
B = [0 1; 1 0];
```

$C = 2^B$

$C =$

```
1.2500 0.7500
0.7500 1.2500
```

Compute  $C$  by first finding the eigenvalues  $D$  and eigenvectors  $V$  of the matrix  $B$ .

$[V,D] = \text{eig}(B)$

$V =$

```
-0.7071 0.7071
0.7071 0.7071
```

$D =$

```
-1 0
0 1
```

Next, use the formula  $2^B = V \cdot 2^D / V$  to compute the power.

$C = V \cdot 2^D / V$

$C =$

```
1.2500 0.7500
0.7500 1.2500
```

## Input Arguments

### A — Base

scalar | matrix

Base, specified as a scalar or matrix. Inputs  $A$  and  $B$  must be one of the following:

- Base  $A$  is a square matrix and exponent  $B$  is a scalar. If  $B$  is a positive integer, the power is computed by repeated squaring. For other values of  $B$  the calculation involves eigenvalues and eigenvectors.
- Base  $A$  is a scalar and exponent  $B$  is a square matrix. The calculation uses eigenvalues and eigenvectors.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical | char

Complex Number Support: Yes

### **B — Exponent**

scalar | matrix

Exponent, specified as a scalar or matrix. Inputs **A** and **B** must be one of the following:

- Base **A** is a square matrix and exponent **B** is a scalar. If **B** is a positive integer, the power is computed by repeated squaring. For other values of **B** the calculation involves eigenvalues and eigenvectors.
- Base **A** is a scalar and exponent **B** is a square matrix. The calculation uses eigenvalues and eigenvectors.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical | char

Complex Number Support: Yes

### **See Also**

## **mput**

**Class:** FTP

Upload file or folder to FTP server

## **Syntax**

```
mput(ftpobj, contents)
paths = mput(ftpobj, contents)
```

## **Description**

`mput(ftpobj, contents)` uploads the file or folder specified by `contents` to the current folder on an FTP server.

`paths = mput(ftpobj, contents)` returns a cell array that lists the paths to the uploaded files on the server.

## **Input Arguments**

### **ftpobj**

FTP object created by `ftp`.

### **contents**

String enclosed in single quotation marks that specifies either a file name or a folder name. Can include a wildcard character (\*).

## **Output Arguments**

### **paths**

Cell array that includes the paths to the uploaded files on the server.

## Examples

Suppose that your current MATLAB folder contains files `myfile1.m` through `myfile10.m`, and that you want to upload to a hypothetical FTP server, `ftp.testsite.com`. Connect to the server and upload the files:

```
test = ftp('ftp.testsite.com');
mput(test, 'myfile*.m');
close(test);
```

## See Also

`mkdir` | `mget` | `ftp` | `rename`

# msgbox

Create and open message dialog box

## Syntax

```
h = msgbox(Message)
h = msgbox(Message,Title)
h = msgbox(Message,Title,Icon)
h = msgbox(Message,Title,'custom',IconData,IconCMap)
h = msgbox(____,CreateMode)
```

## Description

`h = msgbox(Message)` creates a message dialog box that automatically wraps `Message` to fit an appropriately sized figure.

`h = msgbox(Message,Title)` specifies the title of the message box.

`h = msgbox(Message,Title,Icon)` specifies which built-in icon to display in the message dialog box.

`h = msgbox(Message,Title,'custom',IconData,IconCMap)` specifies a custom icon to include in the message dialog box. `IconData` is the image data that defines the icon. `IconCMap` is the colormap used for the image. If `IconData` is a true-color image, you do not need to specify an `IconCMap`.

`h = msgbox( ____,CreateMode)` specifies whether the message box is modal. Additionally, you can specify a TeX interpreter for `Message` and `Title`.

## Examples

### Simple Message Dialog Box

Specify the text you want displayed in the message dialog box.

```
h = msgbox('Operation Completed');
```

### Message Dialog Box Text with Line Breaks

Specify the message dialog box text using a cell array of strings to insert line breaks between the display of each string in the cell array.

```
h = msgbox({'Operation' 'Completed'});
```

### Message Dialog Box with a Title

Specify the message dialog box text and give the dialog box a title, Success.

```
h = msgbox('Operation Completed', 'Success');
```

### Message Dialog Box that Uses a Built-in Icon

Include a built-in error icon with an error message in a message dialog box entitled Error.

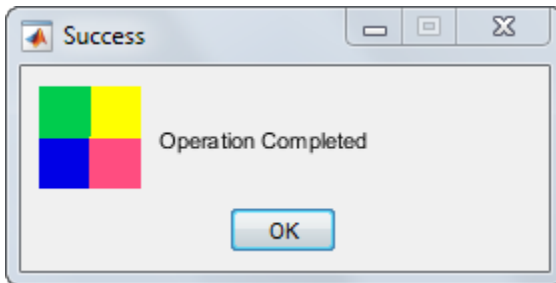

```
h = msgbox('Invalid Value', 'Error', 'error');
```

### Message Dialog Box that Uses a True-Color Custom Icon

Create a 4-by-4-by-3 array containing RGB values. Then, specify it as a custom icon in the dialog box.

```
myicon(:,:,1) = [0 1; 0 1];
myicon(:,:,2) = [.8 1; 0 .3];
myicon(:,:,3) = [.3 0; .9 .5];
h=msgbox('Operation Completed', 'Success', 'custom', myicon);
```

Alternatively, you can read an RGB image file into MATLAB using the `imread` function. Then, you can specify the resulting image array to be the custom icon.

### Message Dialog Box that Uses an Indexed Custom Icon

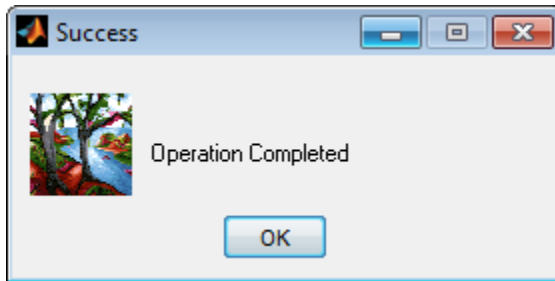

Use `trees.tiff` (which is on the MATLAB path) as an icon in your message dialog box. Because `.tiff` images use a colormap to define the colors, you must specify a colormap. Change the colormap to change the image colors.

Determine the value to specify for IconData by passing the image file to `imread`.

```
[cdata,map] = imread('trees.tif');
```

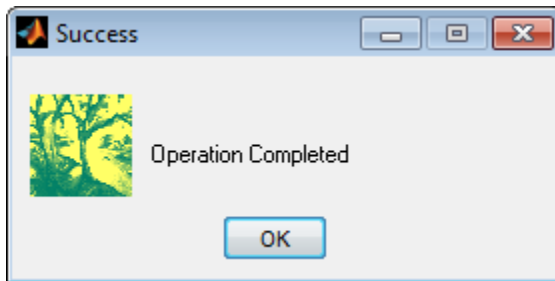

Create the message dialog box, including the custom icon.

```
h=msgbox('Operation Completed',...
 'Success','custom',cdata,map);
```

Adjust the image colors by specifying a different colormap. For instance, specify the MATLAB built-in colormap, `summer`

```
h=msgbox('Operation Completed','Success','custom',...
 cdata,summer);
```

### Modal Message Dialog Box

Create a modal message dialog box, wrapping the call to `msgbox` with `uiwait` to make the message dialog box block MATLAB execution until the user responds to the message dialog box.

```
uiwait(msgbox('Operation Completed','Success','modal'));
```

## Modal Message Dialog Box that Uses a TeX Formatted Message

Create a structure to specify that the user must click OK before interacting with another window and that MATLAB interpret the message text as TeX format.

```
CreateStruct.Interpreter = 'tex';
CreateStruct.WindowStyle = 'modal';
```

Create the message dialog box.

```
h=msgbox('Z = X^2 + Y^2', 'Value', CreateStruct);
```

## Input Arguments

### Message — Message dialog box text

string vector | string matrix | cell array

Dialog box text specified as a string vector, string matrix, or cell array.

Example: 'Operation Completed'

Example: ['Operation ', 'Completed']

Example: {'Operation', 'Completed'}

### Title — Message dialog box title bar text

string vector

Dialog box title bar text specified as a string vector.

Example: 'Success'

### **Icon** — Icon to include in message dialog box

'none' (default) | 'error' | 'help' | 'warn' | 'custom'

Icon to include in message dialog box specified as a string.

Built-in icons appear as follows:

-  Error
-  Help
-  Warn

### **IconData** — Image data defining a custom icon

matrix

Image data defining a custom icon specified as a matrix. Each element of the matrix specifies the color of a rectangular segment in the image. Use `imread` to get the `IconData` value for an image that you want to use as a message dialog box icon.

Example: `[1:64]*[1:64]/64`

### **IconCMap** — Colormap for a custom icon that is not true-color

m-by-3 matrix | built-in colormap

Colormap for a custom icon that is not true-color, specified as a m-by-3 matrix of real numbers between 0.0 and 1.0, or as a MATLAB built-in colormap. Use `imread` to get the `IconCMap` value for an image that you want to use as a message dialog box icon.

Example: `[0.5 0.5 0.5]`

Example: `hot(64)`

### **CreateMode** — Message dialog box mode

'nonmodal' (default) | structure | 'modal' | 'replace'

Mode in which message dialog box is created, specified as a string or a structure.

- If `CreateMode` is a structure, it can have the fields `WindowStyle` and `Interpreter`. The `WindowStyle` field must be one of the strings listed in the list items that

follow this one. The `Interpreter` field must be the string `'tex'` or `'none'`. If the `Interpreter` value is `'tex'`, MATLAB interprets the `Message` and `Title` values as TeX. The default value for `Interpreter` is `'none'`.

- If `CreateMode` is `'nonmodal'`, MATLAB creates a new nonmodal message box with the specified parameters. Existing message boxes with the same `Title` remain.
- If `CreateMode` is `'modal'`, MATLAB replaces the existing message box with the specified `Title` that was last created or clicked on with the specified modal dialog box. MATLAB deletes all other message boxes with the same title. The replaced message box can be either modal or nonmodal.
- If `CreateMode` is `'replace'`, MATLAB replaces the message box having the specified `Title` that was last created or clicked on with a nonmodal message box as specified. MATLAB deletes all other message boxes with the same title. The replaced message box can be either modal or nonmodal.

Example: `CreateStruct.Interpreter='tex';`

## Output Arguments

### **h** — Message dialog box handle

scalar

Message dialog box handle returned as a scalar. This is a unique identifier, which you can use to query and modify the properties of a specific message dialog box.

## More About

### **modal dialog box**

A modal dialog box prevents a user from interacting with other windows before responding to the modal dialog box.

For more information about modal dialog boxes, see `WindowStyle` in the `Figure Properties` topic.

### **Tips**

- Program execution continues even when a modal dialog box is active. To block MATLAB program execution until the user responds to the modal dialog box, use the `uiwait` function.

- If you open a dialog box with `errordlg`, `msgbox`, or `warndlg` using `'CreateMode', 'modal'` and a nonmodal dialog box that was created with any of these functions is already present and *has the same title as the modal dialog box*, then the nonmodal dialog box closes when the modal one opens.
- “Reading Image Data”

`errordlg` | `helpdlg` | `imread` | `warndlg`

## **mtimes, \***

Matrix Multiplication

### **Syntax**

```
C = A*B
C = mtimes(A,B)
```

### **Description**

$C = A*B$  is the matrix product of  $A$  and  $B$ . If  $A$  is an  $m$ -by- $p$  and  $B$  is a  $p$ -by- $n$  matrix, then  $C$  is an  $m$ -by- $n$  matrix defined by

$$C(i, j) = \sum_{k=1}^p A(i, k)B(k, j).$$

This definition says that  $C(i, j)$  is the inner product of the  $i$ th row of  $A$  with the  $j$ th column of  $B$ . You can write this definition using the MATLAB colon operator as

```
C(i, j) = A(i, :)*B(:, j)
```

For nonscalar  $A$  and  $B$ , the number of columns of  $A$  must equal the number of rows of  $B$ . Matrix multiplication is *not* universally commutative for nonscalar inputs. That is,  $A*B$  is typically not equal to  $B*A$ . If at least one input is scalar, then  $A*B$  is equivalent to  $A.*B$  and is commutative.

$C = \text{mtimes}(A, B)$  is an alternative way to execute  $A*B$ , but is rarely used. It enables operator overloading for classes.

### **Examples**

#### **Multiply Two Vectors**

Create a 1-by-4 row vector,  $A$ , and a 4-by-1 column vector,  $B$ .

```
A = [1 1 0 0];
B = [1; 2; 3; 4];
```

Multiply A times B.

```
C = A*B
```

```
C =
```

```
3
```

The result is a 1-by-1 scalar, also called the *dot product* or *inner product* of the vectors A and B. Alternatively, you can calculate the dot product  $A \cdot B$  with the syntax `dot(A,B)`.

Multiply B times A.

```
C = B*A
```

```
C =
```

```
1 1 0 0
2 2 0 0
3 3 0 0
4 4 0 0
```

The result is a 4-by-4 matrix, also called the *outer product* of the vectors A and B. The outer product of two vectors, `A # B`, returns a matrix.

### Multiply Two Arrays

Create two arrays, A and B.

```
A = [1 3 5; 2 4 7];
B = [-5 8 11; 3 9 21; 4 0 8];
```

Calculate the product of A and B.

```
C = A*B
```

```
C =
```

```
24 35 114
30 52 162
```

Calculate the inner product of the second row of A and the third column of B.

```
A(2,:) * B(:,3)
```

```
ans =
```

```
162
```

This answer is the same as `C(2,3)`.

## Input Arguments

### A — Left Array

scalar | vector | matrix

Left Array, specified as a scalar, vector, or matrix. For nonscalar inputs, the number of columns in *A* must be equal to the number of rows in *B*.

**Data Types:** single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical | char | cell | duration | calendarDuration

**Complex Number Support:** Yes

### B — Right Array

scalar | vector | matrix

Right Array, specified as a scalar, vector, or matrix. For nonscalar inputs, the number of columns in *A* must be equal to the number of rows in *B*.

**Data Types:** single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical | char | cell | duration | calendarDuration

**Complex Number Support:** Yes

## Output Arguments

### C — Product Array

scalar | vector | matrix

Product Array, returned as a scalar, vector, or matrix. Array *C* has the same number of rows as input *A* and the same number of columns as input *B*. For example, if *A* is an *m*-by-0 empty matrix and *B* is a 0-by-*n* empty matrix, then *A*\**B* is an *m*-by-*n* matrix of zeros.

## See Also

colon | cross | dot | times

## **mu2lin**

Convert mu-law audio signal to linear

### **Syntax**

```
y = mu2lin(mu)
```

### **Description**

`y = mu2lin(mu)` converts mu-law encoded 8-bit audio signals, stored as “flints” in the range  $0 \leq \mu \leq 255$ , to linear signal amplitude in the range  $-s < Y < s$  where  $s = 32124/32768 \approx .9803$ . The input `mu` is often obtained using `fread(..., 'uchar')` to read byte-encoded audio files. “Flints” are MATLAB integers — floating-point numbers whose values are integers.

# multibandread

Read band-interleaved data from binary file

## Syntax

```
X = multibandread(filename, size, precision, offset, interleave,
byteorder)
X = multibandread(...,subset1,subset2,subset3)
```

## Description

`X = multibandread(filename, size, precision, offset, interleave, byteorder)` reads band-sequential (BSQ), band-interleaved-by-line (BIL), or band-interleaved-by-pixel (BIP) data from the binary file `filename`. The `filename` input is a string enclosed in single quotes. This function defines *band* as the third dimension in a 3-D array, as shown in this figure.

You can use the parameters to `multibandread` to specify many aspects of the read operation, such as which bands to read. See “Parameters” on page 1-5052 for more information.

`X` is a 2-D array if only one band is read; otherwise it is 3-D. `X` is returned as an array of data type `double` by default. Use the `precision` parameter to map the data to a different data type.

`X = multibandread(...,subset1,subset2,subset3)` reads a subset of the data in the file. You can use up to three subsetting parameters to specify the data subset along row, column, and band dimensions. See “Subsetting Parameters” on page 1-5053 for more information.

---

**Note:** In addition to BSQ, BIL, and BIP files, multiband imagery may be stored using the TIFF file format. In that case, use the `imread` function to import the data.

---

## Parameters

This table describes the arguments accepted by `multibandread`.

Argument	Description
<code>filename</code>	String containing the name of the file to be read.
<code>size</code>	<p>Three-element vector of integers consisting of <code>[height, width, N]</code>, where</p> <ul style="list-style-type: none"> <li><code>height</code> is the total number of rows</li> <li><code>width</code> is the total number of elements in each row</li> <li><code>N</code> is the total number of bands.</li> </ul> <p>This will be the dimensions of the data if it is read in its entirety.</p>
<code>precision</code>	<p>String specifying the format of the data to be read, such as <code>'uint8'</code>, <code>'double'</code>, <code>'integer*4'</code>, or any of the other precisions supported by the <code>fread</code> function.</p> <p>Note: You can also use the <code>precision</code> parameter to specify the format of the output data. For example, to read <code>uint8</code> data and output a <code>uint8</code> array, specify a precision of <code>'uint8=&gt;uint8'</code> (or <code>'*uint8'</code>). To read <code>uint8</code> data and output it in the MATLAB software in single precision, specify <code>'uint8=&gt;single'</code>. See <code>fread</code> for more information.</p>
<code>offset</code>	Scalar specifying the zero-based location of the first data element in the file. This value represents the number of bytes from the beginning of the file to where the data begins.
<code>interleave</code>	String specifying the format in which the data is stored

Argument	Description
	<ul style="list-style-type: none"> <li>• 'bsq' — Band-Sequential</li> <li>• 'bil' — Band-Interleaved-by-Line</li> <li>• 'bip' — Band-Interleaved-by-Pixel</li> </ul> <p>For more information about these interleave methods, see the <code>multibandwrite</code> reference page.</p>
<code>byteorder</code>	<p>String specifying the byte ordering (machine format) in which the data is stored, such as</p> <ul style="list-style-type: none"> <li>• 'ieee-le' — Little-endian</li> <li>• 'ieee-be' — Big-endian</li> </ul> <p>See <code>fopen</code> for a complete list of supported formats.</p>

## Subsetting Parameters

You can specify up to three subsetting parameters. Each subsetting parameter is a three-element cell array, `{dim, method, index}`, where

Parameter	Description
<i>dim</i>	<p>Text string specifying the dimension to subset along. It can have any of these values:</p> <ul style="list-style-type: none"> <li>• 'Column'</li> <li>• 'Row'</li> <li>• 'Band'</li> </ul>
<i>method</i>	<p>Text string specifying the subsetting method. It can have either of these values:</p> <ul style="list-style-type: none"> <li>• 'Direct'</li> <li>• 'Range'</li> </ul> <p>If you leave out this element of the subset cell array, <code>multibandread</code> uses 'Direct' as the default.</p>

Parameter	Description
index	<p>If method is 'Direct', index is a vector specifying the indices to read along the Band dimension.</p> <p>If method is 'Range', index is a three-element vector of [start, increment, stop] specifying the range and step size to read along the dimension specified in dim. If index is a two-element vector, multibandread assumes that the value of increment is 1.</p>

## Examples

### Example 1

Setup initial parameters for a data set.

```
rows=3; cols=3; bands=5;
filename = tempname;
```

Define the data set.

```
fid = fopen(filename, 'w', 'ieee-le');
fwrite(fid, 1:rows*cols*bands, 'double');
fclose(fid);
```

Read every other band of the data using the Band-Sequential format.

```
im1 = multibandread(filename, [rows cols bands], ...
 'double', 0, 'bsq', 'ieee-le', ...
 {'Band', 'Range', [1 2 bands]})
```

Read the first two rows and columns of data using Band-Interleaved-by-Pixel format.

```
im2 = multibandread(filename, [rows cols bands], ...
 'double', 0, 'bip', 'ieee-le', ...
 {'Row', 'Range', [1 2]}, ...
 {'Column', 'Range', [1 2]})
```

Read the data using Band-Interleaved-by-Line format.

```
im3 = multibandread(filename, [rows cols bands], ...
```

```
'double', 0, 'bil', 'ieee-le')
```

Delete the file created in this example.

```
delete(filename);
```

## Example 2

Read `int16` BIL data from the FITS file `tst0012.fits`, starting at byte 74880.

```
im4 = multibandread('tst0012.fits', [31 73 5], ...
 'int16', 74880, 'bil', 'ieee-be', ...
 {'Band', 'Range', [1 3]});
im5 = double(im4)/max(max(max(im4)));
imagesc(im5);
```

## See Also

`fread` | `fwrite` | `imread` | `memmapfile` | `multibandwrite`

## multibandwrite

Write band-interleaved data to file

### Syntax

```
multibandwrite(data,filename,interleave)
multibandwrite(data,filename,interleave,start,totalsize)
multibandwrite(...,param,value...)
```

### Description

`multibandwrite(data,filename,interleave)` writes `data`, a two- or three-dimensional numeric or logical array, to the binary file specified by `filename`. The `filename` input is a string enclosed in single quotes. The length of the third dimension of `data` determines the number of bands written to the file. The bands are written to the file in the form specified by `interleave`. See “Interleave Methods” on page 1-5057 for more information about this argument.

If `filename` already exists, `multibandwrite` overwrites it unless you specify the optional `offset` parameter. See the last alternate syntax for `multibandwrite` for information about other optional parameters.

`multibandwrite(data,filename,interleave,start,totalsize)` writes `data` to the binary file `filename` in chunks. In this syntax, `data` is a subset of the complete data set.

`start` is a 1-by-3 array [`firstrow firstcolumn firstband`] that specifies the location to start writing data. `firstrow` and `firstcolumn` specify the location of the upper left image pixel. `firstband` gives the index of the first band to write. For example, `data(I,J,K)` contains the data for the pixel at [`firstrow+I-1, firstcolumn+J-1`] in the (`firstband+K-1`)-th band.

`totalsize` is a 1-by-3 array, [`totalrows,totalcolumns,totalbands`], which specifies the full, three-dimensional size of the data to be written to the file.

---

**Note** In this syntax, you must call `multibandwrite` multiple times to write all the data to the file. The first time it is called, `multibandwrite` writes the complete file,

using the fill value for all values outside the data subset. In each subsequent call, `multibandwrite` overwrites these fill values with the data subset in `data`. The parameters `filename`, `interleave`, `offset`, and `totalsize` must remain constant throughout the writing of the file.

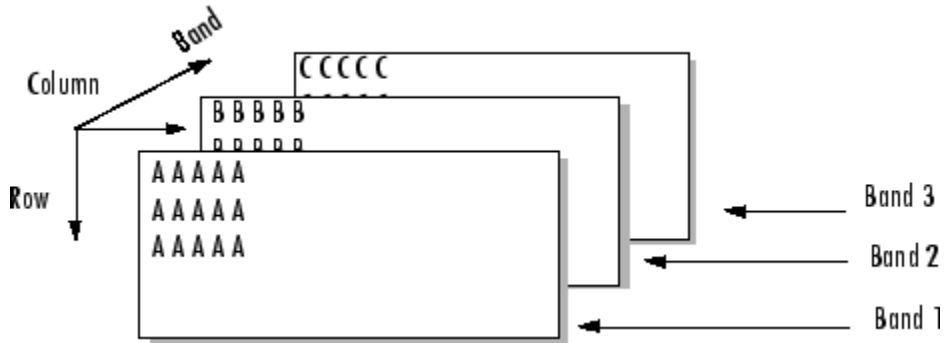

`multibandwrite(..., param, value...)` writes the multiband data to a file, specifying any of these optional parameter/value pairs.

Parameter	Description
'precision'	String specifying the form and size of each element written to the file. See the help for <code>fwrite</code> for a list of valid values. The default precision is the class of the data.
'offset'	The number of bytes to skip before the first data element. If the file does not already exist, <code>multibandwrite</code> writes ASCII null values to fill the space. To specify a different fill value, use the parameter 'fillvalue'.  This option is useful when you are writing a header to the file before or after writing the data. When writing the header to the file after the data is written, open the file with <code>fopen</code> using 'r+' permission.
'machfmt'	String to control the format in which the data is written to the file. Typical values are 'ieee-le' for little endian and 'ieee-be' for big endian. See the help for <code>fopen</code> for a complete list of available formats. The default machine format is the local machine format.
'fillvalue'	A number specifying the value to use in place of missing data. 'fillvalue' can be a single number, specifying the fill value for all missing data, or a 1-by-Number-of-bands vector of numbers specifying the fill value for each band. This value is used to fill space when data is written in chunks.

## Interleave Methods

`interleave` is a string that specifies how `multibandwrite` interleaves the bands as it writes data to the file. If `data` is two-dimensional, `multibandwrite` ignores the

interleave argument. The following table lists the supported methods and uses this example multiband file to illustrate each method.

Supported methods of interleaving bands include those listed below.

Method	String	Description	Example
Band-Interleaved-by-Line	'bil'	Write an entire row from each band	AAAAABBBBBCCCC AAAAABBBBBCCCC AAAAABBBBBCCCC
Band-Interleaved-by-Pixel	'bip'	Write a pixel from each band	ABCABCABCABC...
Band-Sequential	'bsq'	Write each band in its entirety	AAAA AAAA AAAA BBBB BBBB BBBB CCCC CCCC CCCC

## Examples

**Note** To run these examples successfully, you must be in a writable directory.

### Example 1

Write all data (interleaved by line) to the file in one call.

```
data = reshape(uint16(1:600), [10 20 3]);
multibandwrite(data, 'data.bil', 'bil');
```

## Example 2

Write a single-band tiled image with one call for each tile. This is only useful if a subset of each band is available at each call to `multibandwrite`.

```
numBands = 1;
dataDims = [1024 1024 numBands];
data = reshape(uint32(1:(1024 * 1024 * numBands)), dataDims);

for band = 1:numBands
 for row = 1:2
 for col = 1:2

 subsetRows = ((row - 1) * 512 + 1):(row * 512);
 subsetCols = ((col - 1) * 512 + 1):(col * 512);

 upperLeft = [subsetRows(1), subsetCols(1), band];
 multibandwrite(data(subsetRows, subsetCols, band), ...
 'banddata.bsq', 'bsq', upperLeft, dataDims);

 end
 end
end
```

## See Also

`multibandread` | `fwrite` | `fread`

## **munlock**

Allow clearing functions from memory

### **Syntax**

```
munlock
munlock fun
munlock('fun')
```

### **Description**

`munlock` unlocks the currently running `.m` or `.mex` function in memory so that subsequent `clear` functions can remove it.

`munlock fun` unlocks the `.m` or `.mex` file named `fun` from memory. By default, these files are unlocked so that changes to the file are picked up. Calls to `munlock` are needed only to unlock `.m` or `.mex` functions that have been locked with `mlock`.

`munlock('fun')` is the function form of `munlock`.

### **Examples**

The function `testfun` begins with an `mlock` statement.

```
function testfun
mlock
 :
 :
```

When you execute this function, it becomes locked in memory. You can check this using the `mislocked` function.

```
testfun

mislocked testfun
ans =
```

1

Using `munlock`, you unlock the `testfun` function in memory. Checking its status with `mislocked` shows that it is indeed unlocked at this point.

```
munlock testfun
```

```
mislocked testfun
```

```
ans =
```

```
0
```

### **See Also**

`mlock` | `mislocked` | `inmem` | `persistent`

## **namelengthmax**

Maximum identifier length

### **Syntax**

```
len = namelengthmax
```

### **Description**

`len = namelengthmax` returns the maximum length allowed for MATLAB identifiers, which include:

- Variable names
- Structure field names
- Script, function, and class names
- Model names

Rather than hard-coding a specific maximum name length into your programs, use the `namelengthmax` function. This saves you the trouble of having to update these limits should the identifier length change in some future MATLAB release.

### **Examples**

Call `namelengthmax` to get the maximum identifier length:

```
maxid = namelengthmax
maxid =
 63
```

### **See Also**

`isvarname` | `matlab.lang.makeValidName` | `matlab.lang.makeUniqueStrings`

# NaN

Not-a-Number

## Syntax

NaN

`N = NaN(n)`

`N = NaN(sz1, ..., szN)`

`N = NaN(sz)`

`N = NaN(classname)`

`N = NaN(n, classname)`

`N = NaN(sz1, ..., szN, classname)`

`N = NaN(sz, classname)`

`N = NaN('like', p)`

`N = NaN(n, 'like', p)`

`N = NaN(sz1, ..., szN, 'like', p)`

`N = NaN(sz, 'like', p)`

## Description

NaN returns the IEEE arithmetic representation for Not-a-Number (NaN). These values result from operations which have undefined numerical results.

`N = NaN(n)` is an  $n$ -by- $n$  matrix of NaN values.

`N = NaN(sz1, ..., szN)` is a  $sz1$ -by-...-by- $szN$  array of NaN values where  $sz1, \dots, szN$  indicates the size of each dimension. For example, `NaN(3, 4)` returns a 3-by-4 array of NaN values.

`N = NaN(sz)` is an array of NaN values where the size vector, `sz`, defines `size(N)`. For example, `NaN([3, 4])` returns a 3-by-4 array of NaN values.

---

**Note** The size inputs `sz1, \dots, szN`, as well as the elements of the size vector `sz`, should be nonnegative integers. Negative integers are treated as 0.

---

`N = NaN(classname)` returns a NaN value where the string, `classname`, specifies the data type. `classname` can be either `'single'` or `'double'`.

`N = NaN(n,classname)` returns an `n`-by-`n` array of NaN values of data type `classname`.

`N = NaN(sz1,...,szN,classname)` returns a `sz1`-by-...-by-`szN` array of NaN values of data type `classname`.

`N = NaN(sz,classname)` returns an array of NaN values where the size vector, `SZ`, defines `size(N)` and `classname` defines `class(N)`.

`N = NaN('like',p)` returns a NaN value of the same data type, sparsity, and complexity (real or complex) as the numeric variable, `p`.

`N = NaN(n,'like',p)` returns an `n`-by-`n` array of NaN values like `p`.

`N = NaN(sz1,...,szN,'like',p)` returns a `sz1`-by-...-by-`szN` array of NaN values like `p`.

`N = NaN(sz,'like',p)` returns an array of NaN values like `p` where the size vector, `SZ`, defines `size(N)`.

## Examples

These operations produce NaN:

- Any arithmetic operation on a NaN, such as `sqrt(NaN)`
- Addition or subtraction, such as magnitude subtraction of infinities as `(+Inf)+(-Inf)`
- Multiplication, such as `0*Inf`
- Division, such as `0/0` and `Inf/Inf`
- Remainder, such as `rem(x,y)` where `y` is zero or `x` is infinity

## More About

### Tips

Because two NaNs are not equal to each other, logical operations involving NaNs always return false, except `~=` (not equal). Consequently,

```
NaN ~= NaN
ans =
 1
NaN == NaN
ans =
 0
```

and the NaNs in a vector are treated as different unique elements.

```
unique([1 1 NaN NaN])
ans =
 1 NaN NaN
```

Use the `isnan` function to detect NaNs in an array.

```
isnan([1 1 NaN NaN])
ans =
 0 0 1 1
```

- “Class Support for Array-Creation Functions”

## See Also

`inf` | `isfinite` | `isfloat` | `isnan`

# nargchk

Validate number of input arguments

---

**Note:** nargchk will be removed in a future version. Use narginchk instead.

---

## Syntax

```
msgstring = nargchk(minargs, maxargs, numargs)
msgstring = nargchk(minargs, maxargs, numargs, 'string')
msgstruct = nargchk(minargs, maxargs, numargs, 'struct')
```

## Description

Use `nargchk` inside a function to check that the desired number of input arguments is specified in the call to that function.

`msgstring = nargchk(minargs, maxargs, numargs)` returns an error message string `msgstring` if the number of inputs specified in the call `numargs` is less than `minargs` or greater than `maxargs`. If `numargs` is between `minargs` and `maxargs` (inclusive), `nargchk` returns an empty matrix.

It is common to use the `nargin` function to determine the number of input arguments specified in the call.

`msgstring = nargchk(minargs, maxargs, numargs, 'string')` is essentially the same as the command shown above, as `nargchk` returns a string by default.

`msgstruct = nargchk(minargs, maxargs, numargs, 'struct')` returns an error message structure `msgstruct` instead of a string. The fields of the return structure contain the error message string and a message identifier. If `numargs` is between `minargs` and `maxargs` (inclusive), `nargchk` returns an empty structure.

When too few inputs are supplied, the message string and identifier are

```
message: 'Not enough input arguments.'
```

```
identifier: 'MATLAB:nargchk:notEnoughInputs'
```

When too many inputs are supplied, the message string and identifier are

```
message: 'Too many input arguments.'
identifier: 'MATLAB:nargchk:tooManyInputs'
```

## Examples

Given the function `CheckInputs`,

```
function CheckInputs(x, y, z)
error(nargchk(2, 3, nargin))
```

Then typing `CheckInputs(1)` produces

```
Not enough input arguments.
```

## More About

### Tips

`nargchk` is often used together with the `error` function. The `error` function accepts either type of return value from `nargchk`: a message string or message structure. For example, this command provides the `error` function with a message string and identifier regarding which error was caught:

```
error(nargchk(2, 4, nargin, 'struct'))
```

If `nargchk` detects no error, it returns an empty string or structure. When `nargchk` is used with the `error` function, as shown here, this empty string or structure is passed as an input to `error`. When `error` receives an empty string or structure, it simply returns and no error is generated.

### See Also

`narginchk` | `nargin` | `nargoutchk` | `nargout` | `varargin` | `varargout` | `error`

## nargin

Number of function input arguments

### Syntax

```
nargin
nargin(fx)
```

### Description

`nargin` returns the number of input arguments passed in the call to the currently executing function. Use this `nargin` syntax only in the body of a function.

`nargin(fx)` returns the number of input arguments that appear in the definition statement for function `fx`. If the function includes `varargin` in its definition, then `nargin` returns the negative of the number of inputs. For example, if function `foo` declares inputs `a`, `b`, and `varargin`, then `nargin('foo')` returns `-3`.

### Input Arguments

**fx**

Either a function handle or a string in single quotes that specifies the name of a function.

### Examples

#### Inputs to Current Function

Create a function in a file named `addme.m` that accepts up to two inputs, and identify the number of inputs with `nargin`.

```
function c = addme(a,b)

switch nargin
 case 2
```

```

 c = a + b;
 case 1
 c = a + a;
 otherwise
 c = 0;
end

```

### Inputs Defined for a Function

Determine how many inputs a function can accept.

The function `addme` created in the previous example has two inputs in its declaration statement (`a` and `b`).

```

fx = 'addme';
nargin(fx)

ans =
 2

```

### Function with varargin Input

Determine how many inputs a function that uses `varargin` can accept.

Define a function in a file named `mynewplot.m` that accepts numeric inputs `x` and `y` and any number of additional plot inputs using `varargin`.

```

function mynewplot(x,y,varargin)
 figure
 plot(x,y,varargin{:})
 title('My New Plot')

```

At the command line, query how many inputs `newplot` can accept.

```

fx = 'mynewplot';
nargin(fx)

ans =
 -3

```

The minus sign indicates that the third input is `varargin`. The `mynewplot` function can accept an indeterminate number of additional input arguments.

### See Also

`nargout` | `narginchk` | `nargoutchk` | `varargin` | `varargout` | `inputname`

## narginchk

Validate number of input arguments

### Syntax

```
narginchk(minargs, maxargs)
```

### Description

`narginchk(minargs, maxargs)` throws an error if the number of inputs specified in the call to the currently executing function is less than `minargs` or greater than `maxargs`. If the number of inputs is between `minargs` and `maxargs` (inclusive), `narginchk` does nothing.

When too few inputs are supplied, the message identifier and message are:

```
identifier: 'MATLAB:narginchk:notEnoughInputs'
message: 'Not enough input arguments.'
```

When too many inputs are supplied, the message identifier and message are:

```
identifier: 'MATLAB:narginchk:tooManyInputs'
message: 'Too many input arguments.'
```

### Examples

This function uses `narginchk` to verify that a minimum of 2 and maximum of 5 input arguments are received from the calling function:

```
function check_inputs(A, B, varargin)
minargs=2; maxargs=5;

% Number of inputs must be >=minargs and <=maxargs.
narginchk(minargs, maxargs)

fprintf('Received 2 required, %d optional inputs.\n\n', ...
 size(varargin, 2))
```

Call the example function, passing 1 input argument:

```
check_inputs(23)
Error using check_inputs
Not enough input arguments.
```

Call the function, passing 5 arguments:

```
check_inputs(23, 9, 15, 34, 62)
Received 2 required, 3 optional inputs.
```

Call the function, passing 6 arguments:

```
check_inputs(23, 9, 15, 34, 62, 6)
Error using check_inputs
Too many input arguments.
```

## More About

### Tips

- To verify that there are a minimum of N arguments, specify `inf` as `maxargs`. For example: `narginchk(5,inf)` throws an error when there are not at least five inputs.

### See Also

`nargin` | `nargoutchk` | `nargout` | `varargin` | `varargout`

## nargout

Number of function output arguments

### Syntax

nargout  
nargout (fx)

### Description

nargout returns the number of output arguments specified in the call to the currently executing function. Use this nargout syntax only in the body of a function.

nargout (fx) returns the number of outputs that appear in the definition statement of function fx. If the function includes varargout in its definition, then nargout returns the negative of the number of outputs. For example, if function foo declares outputs a, b, and varargout, then nargout ( 'foo' ) returns -3.

### Input Arguments

fx

Either a function handle or a string in single quotes that specifies the name of a function.

### Examples

#### Outputs for Current Function

Create a function in a file named `subtract.m` that calculates a second return value only when requested.

```
function [dif,absdif] = subtract(y,x)
```

```
dif = y - x;
if nargout > 1
 disp('Calculating absolute value')
 absdif = abs(dif);
end
```

### Outputs Defined for a Function

Determine how many outputs a function can return.

The function named `subtract` created in the previous example has two outputs in its declaration statement (`dif` and `absdif`).

```
fx = 'subtract';
nargout(fx)
```

```
ans =
 2
```

### Function with varargout Output

Determine how many outputs a function that uses `varargout` can return.

Define a function in a file named `mysize.m` that returns a vector of dimensions from the `size` function and the individual dimensions using `varargout`.

```
function [sizeVector,varargout] = mysize(x)
 sizeVector = size(x);
 varargout = cell(1,nargout-1);
 for k = 1:length(varargout)
 varargout{k} = sizeVector(k);
 end
```

At the command line, query how many outputs `mysize` can return.

```
fx = 'mysize';
nargout(fx)
```

```
ans =
 -2
```

The minus sign indicates that the second output is `varargout`. The `mysize` function can return an indeterminate number of additional outputs.

## More About

### Tips

- When you use a function as part of an expression, MATLAB calls the function with one output argument, so `nargout` within the function returns 1. For example, given the following `if` statement and the `subtract` function defined in the Examples section, the value of `nargout` within the `subtract` function is 1.

```
a = 1;
b = 2;
if subtract(a,b) < 0
 disp('Result is negative')
end
```

### See Also

[nargin](#) | [nargoutchk](#) | [narginchk](#) | [varargout](#) | [varargin](#) | [inputname](#)

# nargoutchk

Validate number of output arguments

## Syntax

```
nargoutchk(minargs, maxargs)
```

## Description

`nargoutchk(minargs, maxargs)` throws an error if the number of outputs specified in the call is less than `minargs` or greater than `maxargs`. If the number of outputs is between `minargs` and `maxargs` (inclusive), `nargoutchk` does nothing.

When too few outputs are supplied, the identifier and message are:

```
identifier: 'MATLAB:nargoutchk:notEnoughOutputs'
message: 'Not enough output arguments.'
```

When too many outputs are supplied, the identifier and message are:

```
identifier: 'MATLAB:nargoutchk:tooManyOutputs'
message: 'Too many output arguments.'
```

## Examples

This function uses `nargoutchk` to verify that a minimum of 2 and maximum of 5 input arguments are passed back to the calling function:

```
function [varargout] = check_outputs(array_in)
minargs=2; maxargs=5;

% Number of outputs must be >=minargs and <=maxargs.
nargoutchk(minargs, maxargs)

for k=1:nargout
 varargout{k} = array_in(k)*3;
end
```

Initialize input array X to a vector of 6 elements:

```
X = 5:7:40
X =
 5 12 19 26 33 40
```

Call the example function with 1 output argument. This is less than the minimum (2) that was specified by `nargoutchk` and results in an error:

```
A = check_outputs(X);
```

```
Error using check_outputs
Not enough output arguments.
```

Call the function with 4 output arguments. This is within the allowable bounds (2 to 5) specified by `nargoutchk`:

```
[A, B, C, D] = check_outputs(X);
```

```
[A, B, C, D]
ans =
 15 36 57 78
```

Call the function with 6 output arguments. This exceeds the maximum (5) that was specified by `nargoutchk` and results in an error:

```
[A, B, C, D, E, F] = check_outputs(X);
```

```
Error using check_outputs
Too many output arguments.
```

## More About

### Tips

- To verify that there are a minimum of N arguments, specify `inf` as `maxargs`. For example: `nargoutchk(5, inf)` throws an error when there are not at least five outputs.

# native2unicode

Convert numeric bytes to Unicode character representation

## Syntax

```
unicodestr = native2unicode(bytes)
unicodestr = native2unicode(bytes, encoding)
```

## Description

`unicodestr = native2unicode(bytes)` converts a numeric vector, `bytes`, from the user default encoding to Unicode character representation. `bytes` is treated as a stream of 8-bit bytes, and each value must be in the range [0,255]. Return value `unicodestr` is a `char` vector having the same general array shape as `bytes`.

`unicodestr = native2unicode(bytes, encoding)` converts `bytes` to Unicode representation assuming that the byte stream is in the character encoding scheme specified by the string `encoding`. `encoding` must be the empty string ( `' '` ) or a name or alias for an encoding scheme. Some examples are `'UTF-8'`, `'latin1'`, `'US-ASCII'`, and `'Shift_JIS'`. If `encoding` is unspecified or is the empty string ( `' '` ), the default encoding scheme is used.

---

**Note** If `bytes` is a `char` vector, it is returned unchanged.

---

## Examples

This example begins with a vector of bytes in an unknown character encoding scheme. The user-written function `detect_encoding` determines the encoding scheme. If successful, it returns the encoding scheme name or alias as a string. If unsuccessful, it throws an error represented by an `MException` object, `ME`. The example calls `native2unicode` to convert the bytes to Unicode representation:

```
try
 enc = detect_encoding(bytes);
```

```
 str = native2unicode(bytes, enc);
 disp(str);
 catch ME
 rethrow(ME);
 end
```

Note that the computer must be configured to display text in a language represented by the detected encoding scheme for the output of `disp(str)` to be correct.

## **See Also**

`unicode2native`

# nchoosek

Binomial coefficient or all combinations

## Syntax

`b = nchoosek(n,k)`  
`C = nchoosek(v,k)`

## Description

`b = nchoosek(n,k)` returns the binomial coefficient, defined as  $n!/((n-k)! k!)$ . This is the number of combinations of  $n$  items taken  $k$  at a time.

`C = nchoosek(v,k)` returns a matrix containing all possible combinations of the elements of vector  $v$  taken  $k$  at a time. Matrix  $C$  has  $k$  columns and  $n!/((n-k)! k!)$  rows, where  $n$  is `length(v)`.

## Examples

### Binomial Coefficient, "5 Choose 4"

`b = nchoosek(5,4)`

`b =`

5

### All Combinations of Five Numbers Taken Four at a Time

`v = 2:2:10;`

`C = nchoosek(v,4)`

`C =`

2	4	6	8
2	4	6	10
2	4	8	10

```
2 6 8 10
4 6 8 10
```

### All Combinations of Three Unsigned Integers Taken Two at a Time

```
v = uint16([10 20 30]);
C = nchoosek(v,uint16(2))
```

C =

```
10 20
10 30
20 30
```

## Input Arguments

### **n** — Number of possible choices

scalar, real, nonnegative value

Number of possible choices, specified as a scalar value of any numeric type that is real and nonnegative.

Example: 10

Example: `int16(10)`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **k** — Number of selected choices

scalar, real, nonnegative value

Number of selected choices, specified as a scalar value that is real and nonnegative. **k** can be any numeric type. However, `nchoosek(n,k)` requires that **n** and **k** be the same type or that at least one of them be of type `double`.

There are no restrictions on combining inputs of different types for `nchoosek(v,k)`.

Example: 3

Example: `int16(3)`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**v — Set of all choices**

vector of numeric, logical, or char values

Set of all choices, specified as a vector of numeric, logical, or char values.

Example: [1 2 3 4 5]

Example: [1+1i 2+1i 3+1i 4+1i]

Example: int16([1 2 3 4 5])

Example: [true false true false]

Example: ['abcd']

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 |  
uint32 | uint64 | logical | char

Complex Number Support: Yes

## Output Arguments

**b — Binomial coefficient**

nonnegative scalar value

Binomial coefficient, returned as a nonnegative scalar value. **b** is the same type as **n** and **k**. If **n** and **k** are of different types, then **b** is returned as the nondouble type.

**C — All combinations of v**

matrix

All combinations of **v**, returned as a matrix of the same type as **v**. Matrix **C** has **k** columns and  $n!/((n-k)! k!)$  rows, where  $n$  is `length(v)`.

Each row of **C** contains a combination of **k** items chosen from **v**. The elements in each row of **C** are listed in the same order as they appear in **v**.

## Limitations

- When  $b = \text{nchoosek}(n, k)$  is sufficiently large, `nchoosek` displays a warning that the result might not be exact. In this case, the result is only accurate to 15 digits for double-precision inputs, or 8 digits for single-precision inputs.

- $C = \text{nchoosek}(v, k)$  is only practical for situations where  $\text{length}(v)$  is less than about 15.

**See Also**  
perms

# ndgrid

Rectangular grid in N-D space

## Syntax

```
[X1,X2,X3,...,Xn] = ndgrid(x1gv,x2gv,x3gv,...,xngv)
[X1,X2,...,Xn] = ndgrid(xgv)
```

## Description

`[X1,X2,X3,...,Xn] = ndgrid(x1gv,x2gv,x3gv,...,xngv)` replicates the grid vectors `x1gv,x2gv,x3gv,...,xngv` to produce a full grid. This grid is represented by the output coordinate arrays `X1,X2,X3,...,Xn`. The *i*th dimension of any output array `Xi` contains copies of the grid vector `xigv`.

`[X1,X2,...,Xn] = ndgrid(xgv)` is the same as `[X1,X2,...,Xn] = ndgrid(xgv,xgv,...,xgv)`. In other words, you can reuse the same grid vector in each respective dimension. The dimensionality of the output arrays is determined by the number of output arguments.

The coordinate arrays `[X1,X2,X3,...,Xn]` are typically used to evaluate functions of several variables and to create surface and volumetric plots.

## Input Arguments

### **xigv**

Grid vector specifying a series of grid point coordinates in the *i*th dimension.

### **xgv**

Generic grid vector specifying a series of point coordinates.

## Output Arguments

### **$X_i$**

The  $i$ th dimension of the output array  $X_i$  are copies of elements of the grid vector  $x_{igv}$ . The output arrays specify the full grid.

## Examples

### **Evaluate Function Over Gridded Domain**

Evaluate the function  $x_1 e^{-x_1^2 - x_2^2}$  over the gridded domain  $-2 < x_1 < 2$  and  $-2 < x_2 < 2$ .

Create a grid of values for the domain.

```
[X1,X2] = ndgrid(-2:.2:2, -2:.2:2);
```

Evaluate the function over the domain.

```
Z = X1 .* exp(-X1.^2 - X2.^2);
```

Generate a mesh plot of the function.

```
mesh(X1,X2,Z)
```

## More About

### Tips

The `ndgrid` function is similar to `meshgrid`, however `ndgrid` supports 1-D to N-D while `meshgrid` is restricted to 2-D and 3-D. The coordinates output by each function are the same, but the shape of the output arrays in the first two dimensions are different. For grid vectors `x1gv`, `x2gv` and `x3gv` of length `M`, `N` and `P` respectively, `ndgrid(x1gv, x2gv)` will output arrays of size `M-by-N` while `meshgrid(x1gv, x2gv)` outputs arrays of size `N-by-M`. Similarly, `ndgrid(x1gv, x2gv, x3gv)` will output arrays of size `M-by-N-by-P` while `meshgrid(x1gv, x2gv, x3gv)` outputs arrays of size `N-by-M-by-P`.

See “Grid Representation” in the MATLAB Mathematics documentation for more information.

- “Interpolating Gridded Data”

`griddedInterpolant` | `meshgrid` | `mesh` | `surf`

# ndims

Number of array dimensions

## Syntax

```
N = ndims(A)
```

## Description

`N = ndims(A)` returns the number of dimensions in the array `A`. The number of dimensions is always greater than or equal to 2. The function ignores trailing singleton dimensions, for which `size(A,dim) = 1`.

## Examples

### Find Dimensions of Vector

Create a row vector.

```
A = 1:5;
```

Find the number of dimensions in the vector.

```
ndims(A)
```

```
ans =
```

```
2
```

The result is 2 because the vector has a size of 1-by-5.

### Find Dimensions of Cell Array

Create a cell array of strings.

```
C{1,1,1} = 'cell_1';
C{1,1,2} = 'cell_2';
C{1,1,3} = 'cell_3'
```

```
C(:,:,1) =
 'cell_1'

C(:,:,2) =
 'cell_2'

C(:,:,3) =
 'cell_3'
```

Find the number of dimensions of the cell array.

```
ndims(A)

ans =

 3
```

The result is **3** because the cell array has a size of 1-by-1-by-3.

## Input Arguments

### **A** — Input array

scalar | vector | matrix | multidimensional array

Input array, specified as a scalar, vector, matrix, or multidimensional array. This includes numeric arrays, logical arrays, character arrays, categorical arrays, datetime arrays, duration arrays, calendarDuration arrays, tables, structure arrays, cell arrays, and object arrays.

## More About

### Algorithms

The number of dimensions in an array is the same as the length of the size vector of the array. In other words, `ndims(A) = length(size(A))`.

## See Also

length | size

## **ne, ~=**

Determine inequality

### **Syntax**

```
A ~= B
ne(A,B)
```

### **Description**

`A ~= B` returns a logical array with elements set to logical 1 (**true**) where arrays `A` and `B` are not equal; otherwise, it returns logical 0 (**false**). The test compares both real and imaginary parts of numeric arrays. `ne` returns logical 1 (**true**) where `A` or `B` have NaN or undefined categorical elements.

`ne(A,B)` is an alternative way to execute `A ~= B`, but is rarely used. It enables operator overloading for classes.

### **Examples**

#### **Inequality of Two Vectors**

Create two vectors containing both real and imaginary numbers.

```
A = [1+i 3 2 4+i];
B = [1 3+i 2 4+i];
```

Compare the two vectors for inequality.

```
A ~= B
```

```
ans =
```

```
 1 1 0 0
```

The `ne` function tests both real and imaginary parts for inequality, and returns logical 1 (`true`) where one or both parts are not equal.

### Find Characters in String

Create a string of characters.

```
M = 'masterpiece';
```

Test the string for the presence of a specific character using `~=`.

```
M ~= 'n'
```

```
ans =
```

```
 1 1 1 1 1 1 1 1 1 1 1
```

The value of logical 1 (`true`) in the vector indicates the absence of the character `'n'`. The character is not present in the string.

### Find Values in Categorical Array

Create a categorical array.

```
A = categorical({'heads' 'heads' 'tails'; 'tails' 'heads' 'tails'})
```

```
A =
```

```
 heads heads tails
 tails heads tails
```

The array has two categories: `'heads'` and `'tails'`.

Find all values not in the `'heads'` category.

```
A ~= 'heads'
```

```
ans =
```

```
 0 0 1
 1 0 1
```

A value of logical 1 (`true`) indicates a value not in the category. Since `A` only has two categories, `A ~= 'heads'` returns the same answer as `A == 'tails'`.

Compare the rows of **A** for inequality.

```
A(1,:) ~= A(2,:)
```

```
ans =
```

```
1 0 0
```

The function returns logical 1 (**true**) where the rows have unequal category values.

### **Compare Floating-Point Numbers**

Some floating-point numbers cannot be represented exactly in binary form. This leads to small differences in results that the `~=` operator reflects.

Perform a few subtraction operations on a floating-point number and store the result in **C**.

```
C = 0.5-0.4-0.1
```

```
C =
```

```
-2.7756e-17
```

Intuitively, **C** should be equal to *exactly* 0. Its small value is due to the nature of floating-point arithmetic.

Compare **C** to zero for inequality.

```
C ~= 0
```

```
ans =
```

```
1
```

The result is logical 1 (**true**).

Compare floating-point numbers using a tolerance, **tol**, instead of `~=`.

```
tol = eps;
```

```
abs(C-0) > tol
```

```
ans =
```

```
0
```

The two numbers, C and 0, are closer to one another than two consecutive floating-point numbers. They are essentially equal.

### Inequality of Two Datetime Arrays

Compare the elements of two `datetime` arrays for inequality.

Create two `datetime` arrays in different time zones.

```
t1 = [2014,04,14,9,0,0;2014,04,14,10,0,0];
A = datetime(t1,'TimeZone','America/Los_Angeles');
A.Format = 'd-MMM-y HH:mm:ss Z'
```

A =

```
14-Apr-2014 09:00:00 -0700
14-Apr-2014 10:00:00 -0700
```

```
t2 = [2014,04,14,12,0,0;2014,04,14,12,30,0];
B = datetime(t2,'TimeZone','America/New_York');
B.Format = 'd-MMM-y HH:mm:ss Z'
```

B =

```
14-Apr-2014 12:00:00 -0400
14-Apr-2014 12:30:00 -0400
```

Check where elements in A and B are not equal.

A~=B

ans =

```
0
1
```

## Input Arguments

### A — Left array

numeric array | logical array | character array | categorical array | datetime array | duration array

Left array, specified as a numeric array, logical array, character array, categorical array, datetime array, or duration array. Inputs **A** and **B** must be the same size unless one is a scalar. A scalar input expands into an array of the same size as the other input.

If one input is a categorical array, the other input can be a categorical array, a cell array of strings, or a single string. A single string expands into a cell array of strings of the same size as the other input. If both inputs are ordinal categorical arrays, they must have the same sets of categories, including their order. If both inputs are categorical arrays that are not ordinal, they can have different sets of categories. See “Compare Categorical Array Elements” for more details.

If one input is a datetime array, the other input can be a datetime array, a date string, or a cell array of date strings.

If one input is a duration array, the other input can be a duration array or a numeric array. `eq` treats each numeric value as a number of standard (86400 s) days.

Complex Number Support: Yes

### B — Right array

numeric array | logical array | character array | categorical array | datetime array | duration array

Right array, specified as a numeric array, logical array, character array, or categorical array. Inputs **A** and **B** must be the same size unless one is a scalar. A scalar input expands into an array of the same size as the other input.

If one input is a categorical array, the other input can be a categorical array, a cell array of strings, or a single string. A single string expands into a cell array of strings of the same size as the other input. If both inputs are ordinal categorical arrays, they must have the same sets of categories, including their order. If both inputs are categorical arrays that are not ordinal, they can have different sets of categories. See “Compare Categorical Array Elements” for more details.

---

If one input is a datetime array, the other input can be a datetime array, a date string, or a cell array of date strings.

If one input is a duration array, the other input can be a duration array or a numeric array. `eq` treats each numeric value as a number of standard (86400 s) days.

Complex Number Support: Yes

### **See Also**

`eq` | `ge` | `gt` | `le` | `lt`

## nearestNeighbor

**Class:** DelaunayTri

(Will be removed) Point closest to specified location

---

**Note:** `nearestNeighbor(DelaunayTri)` will be removed in a future release. Use `nearestNeighbor(triangulation)` instead.

`DelaunayTri` will be removed in a future release. Use `delaunayTriangulation` instead.

---

### Syntax

```
PI = nearestNeighbor(DT,QX)
PI = nearestNeighbor(DT,QX,QY)
PI = nearestNeighbor(DT,QX,QY,QZ)
[PI,D] = nearestNeighbor(DT,QX,...)
```

### Description

`PI = nearestNeighbor(DT,QX)` returns the index of the nearest point in `DT.X` for each query point location in `QX`.

`PI = nearestNeighbor(DT,QX,QY)` and `PI = nearestNeighbor(DT,QX,QY,QZ)` allow the query points to be specified in column vector format when working in 2-D and 3-D.

`[PI,D] = nearestNeighbor(DT,QX,...)` returns the index of the nearest point in `DT.X` for each query point location in `QX`. The corresponding Euclidean distances between the query points and their nearest neighbors are returned in `D`.

---

**Note:** `nearestNeighbor` is not supported for 2-D triangulations that have constrained edges.

---

## Input Arguments

- DT** Delaunay triangulation.
- QX** The matrix **QX** is of size **mpts**-by-**ndim**, **mpts** being the number of query points and **ndim** the dimension of the space where the points reside.

## Output Arguments

- PI** **PI** is a column vector of point indices that index into the points **DT.X**. The length of **PI** is equal to the number of query points **mpts**.
- D** **D** is a column vector of length **mpts**.

## Examples

Create a Delaunay triangulation:

```
x = rand(10,1);
y = rand(10,1);
dt = DelaunayTri(x,y);
Create query points:
```

```
qrypts = [0.25 0.25; 0.5 0.5];
Find the nearest neighbors to the query points:
```

```
pid = nearestNeighbor(dt, qrypts)
```

## See Also

delaunayTriangulation | pointLocation | triangulation

## neighbors

**Class:** TriRep

(Will be removed) Simplex neighbor information

---

**Note:** `neighbors(TriRep)` will be removed in a future release. Use `neighbors(triangulation)` instead.

---

TriRep will be removed in a future release. Use `triangulation` instead.

---

### Syntax

SN = neighbors(TR, SI)

### Description

SN = neighbors(TR, SI) returns the simplex neighbor information for the specified simplices SI.

### Input Arguments

TR	Triangulation representation.
SI	SI is a column vector of simplex indices that index into the triangulation matrix <code>TR.Triangulation</code> . If SI is not specified the neighbor information for the entire triangulation is returned, where the neighbors associated with simplex <code>i</code> are defined by the <code>i</code> 'th row of SN.

### Output Arguments

SN	SN is an <code>m</code> -by- <code>n</code> matrix, where <code>m = length(SI)</code> , the number of specified simplices, and <code>n</code> is the number of neighbors per simplex. Each row <code>SN(i, :)</code> represents the neighbors of the simplex <code>SI(i)</code> .
----	-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

By convention, the simplex opposite `vertex(j)` of simplex `SI(i)` is `SN(i,j)`. If a simplex has one or more boundary facets, the nonexistent neighbors are represented by `NaN`.

## Definitions

A *simplex* is a triangle/tetrahedron or higher-dimensional equivalent. A *facet* is an edge of a triangle or a face of a tetrahedron.

## Examples

### Example 1

Load a 3-D triangulation and use `TriRep` to compute the neighbors of all tetrahedra.

```
load tetmesh
trep = TriRep(tet, X)
nbrs = neighbors(trep)
```

### Example 2

Query a 2-D triangulation created using `DelaunayTri`.

```
x = rand(10,1)
y = rand(10,1)
dt = DelaunayTri(x,y)
Find the neighbors of the first triangle:

n1 = neighbors(dt, 1)
```

# NET

Summary of functions in MATLAB .NET interface

## Description

Use the following functions to bring assemblies from the Microsoft .NET Framework into the MATLAB environment. The functions are implemented as a package called NET. To use these functions, prefix the function name with package name NET.

BeginInvoke	Initiate asynchronous .NET delegate call
cell	Create cell array
Combine	Convenience function for static .NET System.Delegate Combine method
enableNETfromNetworkDrive	Enable access to .NET commands from network drive
EndInvoke	Retrieve result of asynchronous call initiated by .NET System.Delegate BeginInvoke method
NET.addAssembly	Make .NET assembly visible to MATLAB
NET.Assembly	Members of .NET assembly
NET.convertArray	Convert numeric MATLAB array to .NET array
NET.createArray	Array for nonprimitive .NET types
NET.createGeneric	Create instance of specialized .NET generic type

---

NET.disableAutoRelease	Lock .NET object representing a RunTime Callable Wrapper (COM Wrapper) so that MATLAB does not release COM object
NET.enableAutoRelease	Unlock .NET object representing a RunTime Callable Wrapper (COM Wrapper) so that MATLAB releases COM object
NET.GenericClass	Represent parameterized generic type definitions
NET.invokeGenericMethod	Invoke generic method of object
NET.isNETSupported	Check for supported Microsoft .NET Framework
NET.NetException	Capture error information for .NET exception
NET.setStaticProperty	Static property or field name
Remove	Convenience function for static .NET System.Delegate Remove method
RemoveAll	Convenience function for static .NET System.Delegate RemoveAll method

## More About

- “Call .NET Libraries”

# NET.addAssembly

**Package:** NET

Make .NET assembly visible to MATLAB

## Syntax

```
asmInfo = NET.addAssembly(globalName)
asmInfo = NET.addAssembly(privateName)
```

## Description

`asmInfo = NET.addAssembly(globalName)` loads a global .NET assembly into MATLAB.

`asmInfo = NET.addAssembly(privateName)` loads a private .NET assembly.

## Limitations

- `NET.addAssembly` does not support assemblies generated by the MATLAB Builder NE product.

## Input Arguments

### **globalName**

One of the following:

- String representing the name of a global assembly.
- Instance of `System.Reflection.AssemblyName` class.

### **Default:**

### **privateName**

String representing the full path of a private assembly.

Default:

## Output Arguments

### asmInfo

NET.Assembly object containing names of the members of the assembly.

## Examples

Display today's date using `System.DateTime` in the `microsoft.VisualBasic` assembly.

```
System.DateTime.Now.ToLongDateString
```

Call the `System.Windows.Forms.MessageBox.Show` method in the global assembly `System.Windows.Forms`.

```
asm = NET.addAssembly('System.Windows.Forms');
import System.Windows.Forms.*;
MessageBox.Show('Simple Message Box')
```

Display classes in the private assembly `NetSample.dll`.

```
asm = NET.addAssembly('c:\work\NetSample.dll');
asm.Classes
```

## More About

### Tips

- MATLAB dynamically loads the `microsoft.VisualBasic.dll` and `System.dll` assemblies from the .NET Framework class library the first time you type "NET." or "System.". You do not need to call `NET.addAssembly` to access classes in these assemblies.
- Refer to your .NET product documentation for the name of the assembly and its deployment type (global or private).
- “Assembly is Library of .NET Classes”
- MSDN AssemblyName Class

**See Also**

NET.Assembly

# NET.Assembly class

**Package:** NET

Members of .NET assembly

## Description

NET.Assembly object returns names of the members of an assembly.

## Construction

The NET.addAssembly function creates an instance of this class.

## Properties

### AssemblyHandle

Instance of System.Reflection.Assembly class of the added assembly.

### Classes

nClassx1 cell array of class names of the assembly, where nClass is the number of classes

### Enums

nEnumx1 cell array of enums of the assembly, where nEnum is the number of enums

### Structures

nStructx1 cell array of structures of the assembly, where nStruct is the number of structures

### GenericTypes

nGenTypex1 cell array of generic types of the assembly, where nGenType is the number of generic types

## **Interfaces**

nInterfacex1 cell array of interface names of the assembly, where nInterface is the number of interfaces

## **Delegates**

nDelegatex1 cell array of delegates of the assembly, where nDelegate is the number of delegates

## **See Also**

NET.addAssembly

## **How To**

- “What Classes Are in a .NET Assembly?”

# NET.convertArray

**Package:** NET

Convert numeric MATLAB array to .NET array

---

**Note:** MATLAB automatically converts arrays to .NET types. For information, see “Using Arrays with .NET Applications”.

---

## Syntax

```
arrObj = NET.convertArray(V, 'arrType', [m,n])
```

## Description

`arrObj = NET.convertArray(V, 'arrType', [m,n])` converts a MATLAB array `V` to a .NET array. Optional value `arrType` is a string representing a namespace-qualified .NET array type. To convert a MATLAB vector to a two-dimensional .NET array (either 1-by-n or m-by-1), use optional values `m`, `n`. If `V` is a MATLAB vector and you do not specify the number of dimensions and their sizes, the output `arrObj` is a one-dimensional .NET array.

If you do not specify `arrType`, MATLAB converts the type according to the MATLAB Primitive Type Conversion Table. See “Pass Primitive .NET Types”.

## Examples

Create a list `aList` of random `System.Int32` integers using the `System.Collections.Generic.List` class, and then sort the results:

```
% Create array R of random integers
nInt = 5;
R = randi(100,1,nInt);
%Create .NET array A
```

```
A = NET.convertArray(R, 'System.Int32');
%Put A into aList, a generic collections list
aList = NET.createGeneric(...
 'System.Collections.Generic.List',...
 {'System.Int32'},A.Length);
aList.AddRange(A);
%Sort the values in aList
aList.Sort;
```

## See Also

NET.createArray

# NET.createArray

**Package:** NET

Array for nonprimitive .NET types

## Syntax

```
array = NET.createArray(typeName, [m, n, p, ...])
array = NET.createArray(typeName, m, n, p, ...)
```

## Description

`array = NET.createArray(typeName, [m, n, p, ...])` creates an m-by-n-by-p-by-... array of type `typeName`, which is either a fully qualified .NET array type name (namespace and array type name) or an instance of the `NET.GenericClass` class, in case of arrays of generic type. `m, n, p, ...` are the number of elements in each dimension of the array.

`array = NET.createArray(typeName, m, n, p, ...)` alternative syntax for creating an array.

You cannot specify the lower bound of an array.

## Examples

### Create .NET Array of Generic Type

This example creates a .NET array of `List<Int32>` generic type.

```
genType = NET.GenericClass('System.Collections.Generic.List', ...
 'System.Int32');
arr = NET.createArray(genType, 5)

arr =
```

```
List<System*Int32>[] with properties:
```

```
 Length: 5
 LongLength: 5
 Rank: 1
 SyncRoot: [1x1 System.Collections.Generic.List<System*Int32>[]]
 IsReadOnly: 0
 IsFixedSize: 1
 IsSynchronized: 0
```

## Create and Initialize Jagged Array

This example creates a jagged .NET array of 3 elements.

```
jaggedArray = NET.createArray('System.Double[]', 3)
```

```
jaggedArray =
```

```
 Double[][] with properties
```

```
 Length: 3
 LongLength: 3
 Rank: 1
 SyncRoot: [1x1 System.Double[][]]
 IsReadOnly: 0
 IsFixedSize: 1
 IsSynchronized: 0
```

Assign values:

```
jaggedArray(1) = [1, 3, 5, 7, 9];
```

```
jaggedArray(2) = [0, 2, 4, 6];
```

```
jaggedArray(3) = [11, 22];
```

Access first value of 3rd array:

```
jaggedArray(3,1)
```

```
ans =
 11
```

## Create Jagged Array of Generic Type

This example creates a jagged array of List<Double> generic type.

```
genCls = NET.GenericClass('System.Collections.Generic.List[]',...
 'System.Double');
```

Create the array, genArr.

```
genArr = NET.createArray(genCls,3)
```

```
genArr =
```

```
List<System*Double>[][] with properties:
```

```
 Length: 3
 LongLength: 3
 Rank: 1
 SyncRoot: [1x1 System.Collections.Generic.List`1[][]]
 IsReadOnly: 0
 IsFixedSize: 1
 IsSynchronized: 0
```

## Create Nested Jagged Array

This command creates a jagged array of type `System.Double[][][]`.

```
netArr = NET.createArray('System.Double[][]', 3)
```

```
netArr =
```

```
Double[][][] with properties:
```

```
 Length: 3
 LongLength: 3
 Rank: 1
 SyncRoot: [1x1 System.Double[][][]]
 IsReadOnly: 0
 IsFixedSize: 1
 IsSynchronized: 0
```

## NET.createGeneric

**Package:** NET

Create instance of specialized .NET generic type

### Syntax

```
genObj = createGeneric(className,paramTypes,varargin ctorArgs)
```

### Description

genObj = createGeneric(className,paramTypes,varargin ctorArgs) creates an instance genObj of generic type className.

### Input Arguments

className	Fully qualified string with the generic type name.
paramTypes	Allowed cell types are: strings with fully qualified parameter type names and instances of the NET.GenericClass class when parameterization with another parameterized type is needed.
ctorArgs	Optional, variable length (0 to N) list of constructor arguments matching the arguments of the .NET generic class constructor intended to be invoked.

### Output Arguments

genObj	Handle to the specialized generic class instance.
--------	---------------------------------------------------

### Examples

#### Create a List of System.Double Objects

Create a strongly typed list dblLst of objects of type System.Double:

```
t = NET.createGeneric('System.Collections.Generic.List',...
 {'System.Double'},10);
```

### Create a List with Key/Value Pairs

Create the `kvpType` generic association where `Key` is of `System.Int32` type and `Value` is a `System.String`:

```
pe = NET.GenericClass('System.Collections.Generic.KeyValuePair',...
 'System.Int32', 'System.String');
```

Create the list `kvpList` with initial storage capacity for 10 key-value pairs:

```
st = NET.createGeneric('System.Collections.Generic.List',...
 {kvpType},10);
```

### Add an Item to the List

Create a `KeyValuePair` item.

```
kvpItem = NET.createGeneric('System.Collections.Generic.KeyValuePair',...
 {'System.Int32', 'System.String'},42, 'myString');
```

Add this item to the list `kvpList`.

```
kvpList.Add(kvpItem);
```

## See Also

NET.GenericClass

# NET.disableAutoRelease

**Package:** NET

Lock .NET object representing a RunTime Callable Wrapper (COM Wrapper) so that MATLAB does not release COM object

## Syntax

A = NET.disableAutoRelease(obj)

## Description

A = NET.disableAutoRelease(obj) locks a .NET object representing a RunTime Callable Wrapper (COM Wrapper) so that MATLAB does not release the COM object. obj is a .NET object representing a COM Wrapper.

Before passing a .NET object representing a COM Wrapper to another process, lock the object using this function so that MATLAB does not release it. After using the object, call NET.enableAutoRelease to release the COM object.

## Examples

The following user-defined function, `GetComApp.m`, has access to a COM object defined in the **pseudo-class** `ComNamespace.ComClass`. One of its methods is `readData`, with the signature:

```
System.StringRetVal readData(ComNamespace.ComClass this, System.String strIn)
```

The input argument is defined in the **pseudo-class** `NetDocTest.MyClass`, which has a property named `MyApp`.

```
function GetComApp(obj)
comObj = ComNamespace.ComClass;
obj.MyApp = comObj;
% To pass a COM object to another process, lock the object
NET.disableAutoRelease(comObj);
end
```

The example in `NET.enableAutoRelease` shows how to call the `GetComApp` function.

## More About

- “How MATLAB Handles System.\_\_ComObject”

## See Also

`NET.enableAutoRelease`

# NET.enableAutoRelease

**Package:** NET

Unlock .NET object representing a RunTime Callable Wrapper (COM Wrapper) so that MATLAB releases COM object

## Syntax

```
A = NET.enableAutoRelease(obj)
```

## Description

`A = NET.enableAutoRelease(obj)` releases the COM wrapper when the object goes out of scope, where `obj` is a .NET object representing a COM Wrapper.

Call this function only if the object was locked using `NET.disableAutoRelease`.

## Examples

The following **pseudo-code** shows how to call a function (`GetComApp.m`, described in `NET.disableAutoRelease`) which returns a COM object. The object, `mainObj` of type `NetDocTest.MyClass`, has a property, `MyApp`. Call `GetComApp` to get a COM object, and use its `readData` method.

```
mainObj = NetDocTest.MyClass;
GetComApp(mainObj);
app = mainObj.MyApp;
app.readData('hello');
% Unlock the COM object
NET.enableAutoRelease(mainObj.MyApp);
```

## More About

- “How MATLAB Handles System.\_\_ComObject”

NET.disableAutoRelease

## NET.GenericClass class

**Package:** NET

Represent parameterized generic type definitions

### Description

The `NET.createGeneric` function uses instances of this class to create a generic specialization that requires parameterization with another parameterized type.

### Construction

```
genType = NET.GenericClass (className, paramTypes)
```

### Input Arguments

**className**

Fully qualified string containing the generic type name.

**Default:**

**paramTypes**

Optional, variable length (1 to N) list of types for the generic class parameterization. Allowed argument types are:

- Fully qualified string containing the generic type name.
- Instance of the `NET.GenericClass` class when deeper nested parameterization with another parameterized type is needed.

**Default:**

### Examples

Create an instance of `System.Collections.Generic.List` of `System.Collections.Generic.KeyValuePair` generic associations where `Key` is of

System.Int32 type and Value is a System.String class with initial storage capacity for 10 key-value pairs.

```
kvpType = NET.GenericClass(...
 'System.Collections.Generic.KeyValuePair',...
 'System.Int32', 'System.String');
kvpList = NET.createGeneric('System.Collections.Generic.List',...
 { kvpType }, 10);
```

## How To

- “.NET Generic Classes”

# NET.invokeGenericMethod

**Package:** NET

Invoke generic method of object

## Syntax

```
[varargout] = NET.invokeGenericMethod(obj, 'genericMethodName',
paramTypes, args, ...)
```

## Description

[varargout] = NET.invokeGenericMethod(obj, 'genericMethodName', paramTypes, args, ...) calls instance or static generic method *genericMethodName*.

## Input Arguments

- |                          |                                                                                                                                                                                                                                                                                                                                  |
|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| obj                      | Allowed argument types are: <ul style="list-style-type: none"><li>• Instances of class containing the generic method</li><li>• Strings with fully qualified class name, if calling static generic methods</li><li>• Instances of NET.GenericClass definitions, if calling static generic methods of a generic class</li></ul>    |
| <i>genericMethodName</i> | Generic method name to invoke                                                                                                                                                                                                                                                                                                    |
| paramTypes               | Cell vector (1 to N) with the types for generic method parameterization, where allowed cell types are: <ul style="list-style-type: none"><li>• Strings with fully qualified parameter type name.</li><li>• Instances of NET.GenericClass definitions, if using nested parameterization with another parameterized type</li></ul> |
| args                     | Optional, variable length (0 to N) list of method arguments                                                                                                                                                                                                                                                                      |

## Output Arguments

`varargout` Variable-length output argument list, `varargout`, from method `genericMethodName`

## Examples

The following syntax calls a generic method that takes two parameterized types and returns a parameterized type:

```
a = NET.invokeGenericMethod(obj, ...
 'myGenericSwapMethod', ...
 {'System.Double', 'System.Double'}, ...
 5, 6);
```

To display generic methods in MATLAB, see the example “Display .NET Generic Methods Using Reflection”.

## More About

- “Call .NET Generic Methods”

## See Also

`NET.GenericClass` | `NET.createGeneric` | `varargout`

## **NET.isNETSupported**

Check for supported Microsoft .NET Framework

### **Syntax**

```
tf = NET.isNETSupported
```

### **Description**

`tf = NET.isNETSupported` returns logical **1 (true)** if a supported version of the Microsoft .NET Framework is found. Otherwise, it returns logical **0 (false)** and you cannot use the .NET Framework in MATLAB.

# NET.NetException class

**Package:** NET

Capture error information for .NET exception

## Description

Process information from a NET.NetException object to handle .NET errors. This class is derived from MException.

## Construction

`e = NET.NetException(msgID, errMsg, netObj)` constructs instance `e` of NET.NetException class.

## Input Arguments

**msgID**

message identifier

**errMsg**

error message string

**netObj**

System.Exception object that caused the exception

## Properties

**ExceptionObject**

System.Exception class causing the error.

## Methods

### Inherited Methods

See the methods of the base class `MException`.

### Examples

Display error information after trying to load an unknown assembly:

```
try
 NET.addAssembly('C:\Work\invalidfile.dll')
catch e
 e.message;
 if(isa(e, 'NET.NetException'))
 eObj = e.ExceptionObject
 end
end

ans =

- “Property Attributes”

# NET.setStaticProperty

**Package:** NET

Static property or field name

## Syntax

```
NET.setStaticProperty('propName', value)
```

## Description

NET.setStaticProperty('propName', value) sets the static property or field name specified in the string propName to the given value.

## Examples

To set the myStaticProperty in the given class and namespace, use the syntax:

```
NET.setStaticProperty('MyTestObject.MyClass.myStaticProperty', 5);
```

## nccreate

Create variable in NetCDF file

### Syntax

```
nccreate(filename,varname)
nccreate(filename,varname,Name,Value)
```

### Description

`nccreate(filename,varname)` creates a scalar double variable named `varname` in the NetCDF file `filename`. If `filename` does not exist, `nccreate` creates the file using the `netcdf4_classic` format. To create a nonscalar variable, use the `Dimensions` argument.

`nccreate(filename,varname,Name,Value)` creates a variable named `varname` with additional options specified by one or more `Name,Value` pair arguments.

### Input Arguments

#### **filename**

Text string specifying a NetCDF file, or the name you want to assign to a new NetCDF file.

#### **Default:**

#### **varname**

Text string specifying the name you want to assign to a variable in a NetCDF file.

#### **Default:**

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single

quotes ( ' '). You can specify several name and value pair arguments in any order as Name1,Value1, . . . ,NameN,ValueN.

**'Dimensions'**

Cell array specifying dimensions for the variable in the NetCDF file. The cell array lists the dimension name as a string followed by its numerical length: {dname1,dlength1,dname2,dlength2, . . . }. If a dimension exists, specifying its length is optional. Use Inf to specify an unlimited dimension.

All formats other than netcdf4 format files can have only one unlimited dimension per file and it has to be the last in the list specified. A netcdf4 format file can have any number of unlimited dimensions in any order.

A single-dimension variable is always treated as a column vector.

**Default:**

**'Datatype'**

Text string specifying a MATLAB data type. When nccreate creates the variable in the NetCDF file, it uses a corresponding NetCDF datatype. The following table describes how MATLAB datatypes map to NetCDF datatypes.

<b>MATLAB Data Type</b>	<b>Corresponding NetCDF Variable Type</b>
double	NC_DOUBLE
single	NC_FLOAT
int64	NC_INT64*
uint64	NC_UINT64*
int32	NC_INT
uint32	NC_UINT*
int16	NC_SHORT
uint16	NC_USHORT*
int8	NC_BYTE
uint8	NC_UBYTE*
char	NC_CHAR

\* These data types are only available when the file is a `netcdf4` format file.

**Default:**

**'Format'**

Text string specifying the type of NetCDF file you want to create.

Format String	Description
<code>classic</code>	NetCDF 3
<code>64bit</code>	NetCDF 3, with 64-bit offsets
<code>netcdf4_classic</code>	NetCDF 4 classic model
<code>netcdf4</code>	NetCDF 4 model (Use this to enable group hierarchy)

If `varname` specifies a group (e.g., `/grid3/temperature`), `nccreate` sets the value of `format` to `'netcdf4'`.

**Default:** `netcdf4_classic`

**'FillValue'**

A scalar specifying the value to use for missing values. To disable fill values, set `FillValue` to the text string `'disable'`. (Available for `netcdf4` or `netcdf4_classic` formats only.)

**Default:** Value specified by the NetCDF library

**'ChunkSize'**

Vector specifying the size of the chunk along each dimension, `[num_rows, num_cols, ..., num_ndims]`. (Available for `netcdf4` or `netcdf4_classic` formats only.)

**Default:** Set by the NetCDF library

**'DeflateLevel'**

Numeric value between 0 (least) and 9 (most) specifying the compression setting for the deflate filter, or the text string `disable`. (Available for `netcdf4` or `netcdf4_classic` formats only.)

**Default:** Disabled

**'Shuffle'**

Boolean flag to turn on the shuffle filter. (Available for `netcdf4` or `netcdf4_classic` formats only.)

**Default:** False

## Examples

Create a new 2–D variable in a classic format file. Write data to this variable

```
nccreate('myncclassic.nc','peaks',...
 'Dimensions',{ 'r' 200 'c' 200},...
 'Format','classic');
ncwrite('myncclassic.nc','peaks', peaks(200));
ncdisp('myncclassic.nc');
```

# ncdisp

Display contents of NetCDF data source in Command Window

## Syntax

```
ncdisp(source)
ncdisp(source,location)
ncdisp(source,location,dispFormat)
```

## Description

`ncdisp(source)` displays all the groups, dimensions, variable definitions, and all attributes in the NetCDF data source, `source`, as text in the Command Window.

`ncdisp(source,location)` displays information about the variable or group specified by `location`.

`ncdisp(source,location,dispFormat)` displays the contents of the NetCDF data source, in the display format specified by `dispFormat`.

## Examples

### Display Contents of NetCDF File

Display the contents of the example NetCDF file, `example.nc`.

```
ncdisp('example.nc')
```

Source:

```
matlabroot\toolbox\matlab\demos\example.nc
```

Format:

```
netcdf4
```

Global Attributes:

```
creation_date = '29-Mar-2010'
```

Dimensions:

```
x = 50
```

```
y = 50
```

```
z = 5
```

```
Variables:
 avagadros_number
 Size: 1x1
 Dimensions:
 Datatype: double
 Attributes:
 description = 'this variable has no dimensions'

 temperature
 Size: 50x1
 Dimensions: x
 Datatype: int16
 Attributes:
 scale_factor = 1.8
 add_offset = 32
 units = 'degrees_fahrenheit'

 peaks
 Size: 50x50
 Dimensions: x,y
 Datatype: int16
 Attributes:
 description = 'z = peaks(50);'

Groups:
 /grid1/
 Attributes:
 description = 'This is a group attribute.'
 Dimensions:
 x = 360
 y = 180
 time = 0 (UNLIMITED)
 Variables:
 temp
 Size: []
 Dimensions: x,y,time
 Datatype: int16

 /grid2/
 Attributes:
 description = 'This is another group attribute.'
 Dimensions:
 x = 360
 y = 180
 time = 0 (UNLIMITED)
 Variables:
 temp
```

```

Size: []
Dimensions: x,y,time
Datatype: int16

```

MATLAB displays all the groups, dimensions, and variable definitions in `example.nc`.

### Display Contents of NetCDF Variable

Display the contents of the variable `peaks` in the file, `example.nc`.

```

ncdisp('example.nc', 'peaks')
Source:
 matlabroot\toolbox\matlab\demos\example.nc
Format:
 netcdf4
Dimensions:
 x = 50
 y = 50
Variables:
 peaks
 Size: 50x50
 Dimensions: x,y
 Datatype: int16
 Attributes:
 description = 'z = peaks(50);'

```

### Display Contents of NetCDF File and Hide Attributes

Display only the group hierarchy and variable definitions of the example file, `example.nc`.

```

ncdisp('example.nc', '/', 'min')
Source:
 matlabroot\toolbox\matlab\demos\example.nc
Format:
 netcdf4
Variables:
 avagadros_number
 Size: 1x1
 Dimensions:
 Datatype: double
 temperature
 Size: 50x1
 Dimensions: x

```

```
 Datatype: int16
peaks Size: 50x50
 Dimensions: x,y
 Datatype: int16
Groups:
 /grid1/
 Variables:
 temp
 Size: []
 Dimensions: x,y,time
 Datatype: int16

 /grid2/
 Variables:
 temp
 Size: []
 Dimensions: x,y,time
 Datatype: int16
```

## Input Arguments

### **source** — Name of NetCDF file

string

Name of a NetCDF file, specified as a string. **source** also can be the URL of an OPeNDAP NetCDF data source that resolves to a NetCDF file or a variable in a NetCDF file.

Example: 'myNetCDFfile.nc'

Data Types: char

### **location** — Location of variable or group

'/' (default) | string

Location of a variable or group in the NetCDF file, specified as a string. Set **location** to '/' (forward slash) to display the entire contents of the file.

Data Types: char

### **dispFormat** — Display format

'full' (default) | 'min'

Display format, specified as one of the following strings.

'full'	Display group hierarchy with dimensions, attributes, and variable definitions.
'min'	Display group hierarchy and variable definitions.

Data Types: char

## More About

### Tips

- If source is an OPeNDAP URL with string constraints, use the syntax, `ncdisp(source)` with no other input arguments.
- “Importing NetCDF Files and OPeNDAP Data”

### See Also

`ncinfo` | `ncread` | `ncreadatt` | `ncwrite` | `netcdf`

## ncinfo

Return information about NetCDF data source

### Syntax

```
finfo = ncinfo(source)
vinfo = ncinfo(source,varname)
ginfo = ncinfo(source,groupname)
```

### Description

`finfo = ncinfo(source)` returns information in the structure `finfo` about the entire NetCDF data source specified by `source`, where `source` can be the name of a NetCDF file or the URL of an OPeNDAP NetCDF data source.

`vinfo = ncinfo(source,varname)` returns information in the structure `vinfo` about the variable `varname` in `source`.

`ginfo = ncinfo(source,groupname)` returns information in the structure `ginfo` about the group `groupname` in `source` (only NetCDF4 data sources).

---

**Note:** Use `ncdisp` for visual inspection of a NetCDF source.

---

### Input Arguments

#### **source**

Text string specifying the name of a NetCDF file or the URL of an OPeNDAP NetCDF data source.

#### **Default:**

#### **varname**

Text string specifying the name of a variable in a NetCDF file or OPeNDAP data source.

**Default:**

**groupname**

Text string specifying the name of a group in a NetCDF file or OPeNDAP data source.

**Default:**

## Output Arguments

**finfo**

A structure with the following fields.

Field	Description	
Filename	NetCDF file name or OPeNDAP URL	
Name	' / ', indicating the full file	
Dimensions	An array of structures with these fields:	
	Name	Dimension name
	Length	Current length of dimension
	Unlimited	Boolean flag, true for unlimited dimensions
Variables	An array of structures with these fields:	
	Name	Variable name
	Dimensions	Associated dimensions
	Size	Current variable size
	Datatype	MATLAB datatype
	Attributes	Associated variable attributes
	ChunkSize	Chunk size, if defined. [ ] otherwise
	FillValue	Fill value of the variable.
	DeflateLevel	Deflate filter level, if enabled.
	Shuffle	Shuffle filter enabled flag

Field	Description
Attributes	An array of global attributes with these fields:
	Name Attribute name
	Value Attribute value
Groups	An array of groups present in the file, for <code>netcdf4</code> files; An empty array ( <code>[]</code> ) for all other NetCDF file formats.
Format	The format of the NetCDF file

**vinfo**

A structure containing only the variable fields from `finfo`.

Field	Description
Filename	NetCDF file name
Name	Name of the variable
Dimensions	Dimensions of the variable
Size	Size of the current variable
Datatype	MATLAB datatype
Attributes	Attributes associated with the variable
ChunkSize	Chunk size, if defined. <code>[]</code> otherwise.
FillValue	Fill value used in the variable.
DeflateLevel	Deflate filter level, if enabled.
Shuffle	Shuffle filter enabled flag
Format	The format of the NetCDF file

**ginfo**

A structure containing only the group fields from `finfo`.

Field	Description
Filename	NetCDF file name
Name	Name of the group
Dimensions	Only dimensions defined in the specified group

Field	Description
Variables	Only variables defined in the specified group
Attributes	Attributes associated with the variable
Groups	Names of groups, if defined. [ ] otherwise.
Format	The format of the NetCDF file

## Examples

Search for dimensions with names that start with the character x in the file.

```

finfo = ncinfo('example.nc');
disp(finfo);
dimNames = {finfo.Dimensions.Name};
dimMatch = strncmpi(dimNames,'x',1);
disp(finfo.Dimensions(dimMatch));

```

Obtain the size of a variable and check if it has any unlimited dimensions.

```

vinfo = ncinfo('example.nc','peaks');
varSize = vinfo.Size;
disp(vinfo);
hasUnLimDim = any([vinfo.Dimensions.Unlimited]);

```

Find all unlimited dimensions defined in a group.

```

ginfo = ncinfo('example.nc','/grid2/');
unlimDims = [ginfo.Dimensions.Unlimited];
disp(ginfo.Dimensions(unlimDims));

```

## Tutorials

- “Importing NetCDF Files and OPeNDAP Data”

## ncread

Read data from variable in NetCDF data source

### Syntax

```
vardata = ncread(source, varname)
vardata = ncread(source, varname, start, count, stride)
```

### Description

`vardata = ncread(source, varname)` reads data from the variable `varname` in `source`, which can be either the name of a NetCDF file or an OPeNDAP NetCDF data source.

`vardata = ncread(source, varname, start, count, stride)` reads data from the variable `varname` in `source` beginning at the location given by `start`. `count` specifies the number of elements to read along the corresponding dimension. The optional argument `stride` specifies the inter-element spacing along each dimension.

### Input Arguments

#### **source**

Text string specifying the name of a NetCDF file or the URL of an OPeNDAP NetCDF data source.

#### **Default:**

#### **varname**

Text string specifying the name of a variable in the NetCDF file or OPeNDAP NetCDF data source.

#### **Default:**

**start**

For an  $N$ -dimensional variable, **start** is a vector of length  $N$  of indices specifying the starting location. Indices are 1-based.

**count**

Vector of length  $N$  specifying the number of elements to read along the corresponding dimensions. If a particular element of **count** is `Inf`, **ncread** reads data until the end of the corresponding dimension.

**stride**

Optional argument that specifies the inter-element spacing along each dimension.

**Default:** Vector of 1s (ones)

## Output Arguments

**vardata**

The data in the variable. **ncread** uses the MATLAB datatype that is the closest type to the corresponding NetCDF datatype, except when at least one of `_FillValue`, `scale_offset`, and `add_offset` variables attribute is present. **ncread** applies the following attribute conventions, in sequence, to **vardata** if the corresponding attribute exists for this variable:

- If the `_FillValue` attribute exists, **ncread** replaces values in **vardata** equal to the value of `_FillValue` with NaNs. If the `_FillValue` attribute does not exist, **ncread** queries the NetCDF library for the variable's fill value.
- If the `scale_factor` attribute exists, **ncread** multiplies **vardata** by the value of the `scale_factor` attribute.
- If the `add_offset` attribute exists, **ncread** adds the value of the `add_offset` attribute to **vardata**.

## Examples

Read and display the data in the `peaks` variable in the example file.

```
ncdisp('example.nc','peaks');
peaksData = ncread('example.nc','peaks');
peaksDesc = ncreadatt('example.nc','peaks','description');
surf(double(peaksData));
title(peaksDesc);
```

Subsample the peaks data by a factor of 2 (read every other value along each dimension).

```
subsetdata = ncread('example.nc','peaks',...
 [1 1], [Inf Inf], [2 2]);
surf(double(subsetdata));
```

## See Also

## Tutorials

- “Importing NetCDF Files and OPeNDAP Data”

# ncreadatt

Read attribute value from NetCDF data source

## Syntax

```
attvalue = ncreadatt(source,location,attname)
```

## Description

`attvalue = ncreadatt(source,location,attname)` reads the attribute `attname` from the group or variable specified by `location` in `source`, where `source` is the name of a NetCDF file or the URL of a NetCDF data source.

## Input Arguments

### **source**

Text string specifying the name of a NetCDF file or the URL of an OPeNDAP NetCDF data source.

### **location**

Text string specifying a group or variable in the NetCDF data source. To read global attributes, set `location` to `'/'` (forward slash).

### **attname**

Text string specifying the name of an attribute that you want to read in the NetCDF data source.

## Output Arguments

### **attvalue**

Data associated with the attribute.

## Examples

Read a global attribute.

```
creation_date = ncreadatt('example.nc', '/', 'creation_date');
disp(creation_date);
```

Read an attribute associated with a variable.

```
scale_factor = ncreadatt('example.nc', 'temperature', 'scale_factor');
disp(scale_factor);
```

Read an attribute associated with a group (netcdf4 format files only).

```
desc_value = ncreadatt('example.nc', '/grid2', 'description');
disp(desc_value);
```

# ncwrite

Write data to NetCDF file

## Syntax

```
ncwrite(filename, varname, vardata)
ncwrite(filename, varname, vardata, start, stride)
```

## Description

`ncwrite(filename, varname, vardata)` writes the numerical or char data in `vardata` to an existing variable `varname` in the NetCDF file `filename`. `ncwrite` writes the data in `vardata` starting at the beginning of the variable and extends unlimited dimensions automatically, if needed.

If the NetCDF file or the variable do not exist, use `nccreate` to create them first.

`ncwrite(filename, varname, vardata, start, stride)` writes `vardata` to an existing variable `varname` in file `filename` beginning at the location given by `start`. `stride` is an optional argument that specifies the inter-element spacing of the data written. Use this syntax to append data to an existing variable or write partial data.

## Input Arguments

### **filename**

Text string specifying the name of a NetCDF file. If the file does not exist, use `nccreate` to create it first.

### **Default:**

### **varname**

Text string specifying the name of a variable in a NetCDF file. If the variable does not exist, use `nccreate` to create it first.

**vardata**

Data to write to the variable in the NetCDF file.

**start**

For an  $N$ -dimensional variable, **start** is a vector of indices of length  $N$  specifying the starting location. Indices are 1-based.

**stride**

(Optional) Vector of length  $N$ , specifying the inter-element spacing.

**Default:** Vector of ones

## Examples

Create a new `netcdf4_classic` file, and write a scalar variable with no dimensions. Add the creation time as a global attribute.

```
nccreate('myfile.nc','pi');
ncwrite('myfile.nc','pi',3.1);
ncwriteatt('myfile.nc','/','creation_time',datestr(now));
% overwrite existing data
ncwrite('myfile.nc','pi',3.1416);
ncdisp('myfile.nc');
```

Create a `netcdf4_classic` file with a variable defined on an unlimited dimension. Write data incrementally to the variable.

```
nccreate('mynctest.nc','vmark',...
 'Dimensions', {'time', inf, 'cols', 6},...
 'ChunkSize', [3 3],...
 'DeflateLevel', 2);
ncwrite('mynctest.nc','vmark', eye(3),[1 1]);
varData = ncread('mynctest.nc','vmark');
disp(varData);
ncwrite('mynctest.nc','vmark',fliplr(eye(3)),[1 4]);
varData = ncread('mynctest.nc','vmark');
disp(varData);
```

## More About

### Tips

- If the variable `varname` already exists, `ncwrite` expects the datatype of `vardata` to match the NetCDF variable data type.
- If the variable `varname` has a `_FillValue`, `scale_factor` or `add_offset` attribute, `ncwrite` expects data in `double` format and casts `vardata` to the NetCDF data type, after applying the following attribute conventions in sequence:
  - 1 Subtract the value of the `add_offset` attribute from `vardata`.
  - 2 Divide `vardata` by the value of the `scale_factor` attribute.
  - 3 Replace NaNs in `vardata` by the value of the `_FillValue` attribute. If this attribute does not exist, `ncwrite` tries to use the fill value for this variable as reported by the NetCDF library.

`ncdisp` | `ncread` | `ncinfo` | `netcdf` | `ncwriteatt` | `nccreate`

### Tutorials

- “Exporting to NetCDF Files”

## ncwriteatt

Write attribute to NetCDF file

### Syntax

```
ncwriteatt(filename,location,attname,attvalue)
```

### Description

`ncwriteatt(filename,location,attname,attvalue)` creates or modifies the attribute specified by `attname` in the group or variable specified by `location`, in the NetCDF file specified by `filename`. `attvalue` can be a numeric vector or a string.

### Input Arguments

#### **filename**

Text string specifying the name of a NetCDF file

#### **location**

Text string specifying a group or variable in the NetCDF file. To write global attributes, set `location` to `'/'` (forward slash).

#### **attname**

Text string specifying the name of an existing attribute in a NetCDF file or the name of the attribute that you want to create.

#### **attvalue**

Numeric vector or a string.

### Examples

Create a global attribute.

```
copyfile(which('example.nc'),'myfile.nc');
fileattrib('myfile.nc','+w');
ncdisp('myfile.nc');
ncwriteatt('myfile.nc','/', 'creation_date',datestr(now));
ncdisp('myfile.nc');
```

Modify an existing attribute.

```
copyfile(which('example.nc'),'myfile.nc');
fileattrib('myfile.nc','+w');
ncdisp('myfile.nc','peaks');
ncwriteatt('myfile.nc','peaks','description','Output of PEAKS');
ncdisp('myfile.nc','peaks');
```

## See Also

[ncdisp](#) | [ncreadatt](#) | [ncwrite](#) | [ncread](#) | [nccreate](#) | [netcdf](#)

## Tutorials

- “Exporting to NetCDF Files”

## ncwritschema

Add NetCDF schema definitions to NetCDF file

### Syntax

```
ncwritschema(filename, schema)
```

### Description

`ncwritschema(filename, schema)` creates or adds attributes, dimensions, variable definitions and group structure defined in `schema` to the file `filename`.

Use `ncwritschema` in combination with `ncinfo` to create a new NetCDF file based on the schema of an existing file. You can also use `ncwritschema` to add variable definitions, attributes, dimensions, or group structure to an existing file.

---

**Note:** `ncwritschema` does not write variable data. Use `ncwrite` to write data to the created variables. Created unlimited dimensions will have an initial size of 0 until you write data.

---

---

**Note:** `ncwritschema` cannot change the format of an existing file. It cannot redefine existing variables and dimensions in `filename`. If your schema contains attributes, dimensions, variable definitions, or a group structure that already exist in the file, `writschema` issues a warning but continues processing.

---

### Input Arguments

#### **filename**

Text string specifying the name of a NetCDF file. If `filename` does not exist, `ncwritschema` creates a new file using the `netcdf4_classic` format, unless the `Format` field in `schema` specifies another format.

**Default:****schema**

A structure, or array of structures, representing either a dimension, variable, an entire NetCDF file, or a `netcdf4` group. A group or file schema can contain a dimension or variable schema, or both. You can use the output returned by `ncinfo` as a `schema` structure. The following table lists the fields in the various types of schema structures. Optional fields are marked with asterisk (\*).

Schema Type	Structure Field	Description
Group/File Schema	Name	Text string identifying the group name. Use ' / ' to indicate the entire file.
	Dimensions*	Dimension schema
	Variables*	Variable schema
	Attributes*	Structure array of group/global attributes with Name and Value fields
	Format*	Text string identifying a NetCDF file format
Dimension schema	Name	Text string identifying the dimension
	Length	Length of the dimension. Can be <code>Inf</code> .
	Unlimited*	Boolean flag indicating if the dimension is unlimited
	Format*	Text string identifying a NetCDF file format
Variable schema	Name	Text string identifying a variable name
	Dimensions	Variable's dimension schema
	Datatype	Text string identifying a MATLAB datatype
	Attributes*	Structure array of variable attributes with Name and Value fields
	ChunkSize*	Numeric value specifying chunk size of the variable
	FillValue*	Character or numeric fill value

Schema Type	Structure Field	Description
	DeflateValue*	Deflate compression level
	Shuffle*	Boolean flag to turn on the Shuffle filter
	Format*	Text string identifying a NetCDF file format

**Default:**

## Examples

Create a classic format file with two dimension definitions.

```
mySchema.Name = '/';
mySchema.Format = 'classic';
mySchema.Dimensions(1).Name = 'time';
mySchema.Dimensions(1).Length = Inf;
mySchema.Dimensions(2).Name = 'rows';
mySchema.Dimensions(2).Length = 10;
ncwritescema('emptyFile.nc', mySchema);
ncdisp('emptyFile.nc');
```

Create a `netcdf4_classic` format file to store a single variable from an existing file. First use `ncinfo` to get the schema of the peaks variable from the file. Then use `ncwritescema` to create a NetCDF file, defining the peaks variable. Use `ncread` to get the data associated with the peaks variable and then use `ncwrite` to write the data to the variable in the new NetCDF file.

```
myVarSchema = ncinfo('example.nc','peaks');
ncwritescema('peaksFile.nc',myVarSchema);
peaksData = ncread('example.nc','peaks');
ncwrite('peaksFile.nc','peaks',peaksData);
ncdisp('peaksFile.nc');
```

## Tutorials

- “Exporting to NetCDF Files”

# netcdf

Summary of MATLAB Network Common Data Form (NetCDF) capabilities

## Description

MATLAB provides both high- and low-level access to NetCDF files:

- High-level access functions make it easy to read a data set from a NetCDF file or write a variable from the MATLAB workspace into a NetCDF file
- Low-level access functions provide interfaces to dozens of functions in the NetCDF library

---

**Note:** For information about MATLAB support for the Common Data Format (CDF), which is a completely separate and incompatible format, see `cdflib`.

---

## High-Level Access

These functions provide high-level access to NetCDF files.

<code>nccreate</code>	Create variable in NetCDF file
<code>ncinfo</code>	Return information about NetCDF data source
<code>ncread</code>	Read data from variable in NetCDF data source
<code>ncreadatt</code>	Read attribute value from NetCDF data source
<code>ncwrite</code>	Write data to NetCDF file
<code>ncwriteatt</code>	Write attribute to NetCDF file

ncwritescema

Add NetCDF schema definitions to NetCDF file

## Low-Level Access

The MATLAB low-level functions provide an API that you can use to enable reading data from and writing data to NetCDF files (known as *data sets* in NetCDF terminology). To use these functions, you should be familiar with the information about NetCDF contained in the NetCDF C Interface Guide.

MATLAB supports NetCDF version 4.1.3.

In most cases, the syntax of the MATLAB function matches the syntax of the NetCDF library function. The functions are implemented as a package called `netcdf`. To use these functions, prefix the function name with package name `netcdf`. For example, to call the NetCDF library routine used to open existing NetCDF files, use the following MATLAB syntax:

```
ncid = netcdf.open(ncfile, mode);
```

## Library Functions

`netcdf`

Summary of MATLAB Network Common Data Form (NetCDF) capabilities

`netcdf.getChunkCache`

Retrieve chunk cache settings for NetCDF library

`netcdf.inqLibVers`

Return NetCDF library version information

`netcdf.setChunkCache`

Set default chunk cache settings for NetCDF library

`netcdf.setDefaultFormat`

Change default netCDF file format

**File Operations**

netcdf.abort	Revert recent netCDF file definitions
netcdf.close	Close netCDF file
netcdf.create	Create new NetCDF dataset
netcdf.endDef	End netCDF file define mode
netcdf.inq	Return information about netCDF file
netcdf.inqFormat	Determine format of NetCDF file
netcdf.inqGrps	Retrieve array of child group IDs
netcdf.inqUnlimDims	Return list of unlimited dimensions in group
netcdf.open	Open NetCDF data source
netcdf.reDef	Put open netCDF file into define mode
netcdf.setFill	Set netCDF fill mode
netcdf.sync	Synchronize netCDF file to disk

**Dimensions**

netcdf.defDim	Create netCDF dimension
netcdf.inqDim	Return netCDF dimension name and length

netcdf.inqDimID	Return dimension ID
netcdf.renameDim	Change name of netCDF dimension
<b>Variables</b>	
netcdf.defVar	Create NetCDF variable
netcdf.defVarChunking	Define chunking behavior for NetCDF variable
netcdf.defVarDeflate	Define compression parameters for NetCDF variable
netcdf.defVarFill	Define fill parameters for NetCDF variable
netcdf.defVarFletcher32	Define checksum parameters for NetCDF variable
netcdf.getVar	Return data from netCDF variable
netcdf.inqVarChunking	Determine chunking settings for NetCDF variable
netcdf.inqVarDeflate	Determine compression settings for NetCDF variable
netcdf.inqVarFill	Determine values of fill parameters for NetCDF variable
netcdf.inqVarFletcher32	Fletcher32 checksum setting for NetCDF variable
netcdf.inqVar	Information about variable

netcdf.inqVarID	Return ID associated with variable name
netcdf.putVar	Write data to netCDF variable
netcdf.renameVar	Change name of netCDF variable

### **Attributes**

netcdf.copyAtt	Copy attribute to new location
netcdf.delAtt	Delete netCDF attribute
netcdf.getAtt	Return netCDF attribute
netcdf.inqAtt	Return information about netCDF attribute
netcdf.inqAttID	Return ID of netCDF attribute
netcdf.inqAttName	Return name of netCDF attribute
netcdf.putAtt	Write netCDF attribute
netcdf.renameAtt	Change name of attribute

### **Utilities**

netcdf.getConstant	Return numeric value of named constant
netcdf.getConstantNames	Return list of constants known to netCDF library

## netcdf.abort

Revert recent netCDF file definitions

### Syntax

```
netcdf.abort(ncid)
```

### Description

`netcdf.abort(ncid)` reverts a netCDF file to its previous state, backing out any definitions made since the file last entered define mode. A file enters define mode when you create it (using `netcdf.create`) or when you explicitly enter define mode (using `netcdf.redef`). Once you leave define mode (using `netcdf.endDef`), you cannot revert the definitions you made while in define mode. `ncid` is a netCDF file identifier returned by `netcdf.create` or `netcdf.open`. A call to `netcdf.abort` closes the file.

This function corresponds to the `nc_abort` function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

### Examples

This example creates a new file, performs an operation on the file, and then reverts the file back to its original state. To run this example, you must have write permission in your current directory.

```
% Create a netCDF file
ncid = netcdf.create('foo.nc', 'NC_NOGLOBBER');

% Perform an operation, such as defining a dimension.
dimid = netcdf.defDim(ncid, 'lat', 50);

% Revert the file back to its previous state.
netcdf.abort(ncid)

% Verify that the file is now closed.
```

```
dimid = netcdf.defDim(ncid, 'lat', 50); % should fail
??? Error using ==> netcdflib
NetCDF: Not a valid ID
```

```
Error in ==> defDim at 22
dimid = netcdflib('def_dim', ncid,dimname,dimlen);
```

## See Also

[netcdf.create](#) | [netcdf.endDef](#) | [netcdf.reDef](#)

## netcdf.close

Close netCDF file

### Syntax

```
netcdf.close(ncid)
```

### Description

`netcdf.close(ncid)` terminates access to the netCDF file identified by `ncid`.

`ncid` is a netCDF file identifier returned by `netcdf.create` or `netcdf.open`.

This function corresponds to the `nc_close` function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

### Examples

This example creates a new netCDF file, and then closes the file. You must have write permission in your current directory to run this example.

```
ncid = netcdf.open('foo.nc', 'NC_WRITE')
netcdf.close(ncid)
```

### See Also

`netcdf.create` | `netCDF.open`

# netcdf.copyAtt

Copy attribute to new location

## Syntax

```
netcdf.copyAtt(ncid_in,varid_in,attname,ncid_out,varid_out)
```

## Description

`netcdf.copyAtt(ncid_in,varid_in,attname,ncid_out,varid_out)` copies an attribute from one variable to another, possibly across files. `ncid_in` and `ncid_out` are netCDF file identifiers returned by `netcdf.create` or `netcdf.open`. `varid_in` identifies the variable with an attribute that you want to copy. `varid_out` identifies the variable to which you want to associate a copy of the attribute.

This function corresponds to the `nc_copy_att` function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

## Examples

This example makes a copy of the attribute associated with the first variable in the netCDF example file, `example.nc`, in a new file. To run this example, you must have write permission in your current directory.

```
% Open example file.
ncid = netcdf.open('example.nc','NC_NOWRITE');

% Get identifier for a variable in the file.
varid = netcdf.inqVarID(ncid,'avagadros_number');

% Create new netCDF file.
ncid2 = netcdf.create('foo.nc','NC_NOCLlobber');

% Define a dimension in the new file.
dimid2 = netcdf.defDim(ncid2,'x',50);
```

```
% Define a variable in the new file.
varid2 = netcdf.defVar(ncid2,'myvar','double',dimid2);

% Copy the attribute named 'description' into the new file,
% associating the attribute with the new variable.
netcdf.copyAtt(ncid,varid,'description',ncid2,varid2);
%
% Check the name of the attribute in new file.
attname = netcdf.inqAttName(ncid2,varid2,0)

attname =

description
```

## See Also

[netcdf.inqAtt](#) | [netcdf.inqAttID](#) | [netcdf.inqAttName](#) | [netcdf.putAtt](#) | [netcdf.renameAtt](#)

# netcdf.create

Create new NetCDF dataset

## Syntax

```
ncid = netcdf.create(filename,mode)
[chunksize_out,ncid] = netcdf.create(filename,mode,initsz,chunksize)
```

## Description

`ncid = netcdf.create(filename,mode)` creates a new NetCDF file according to the file creation mode. The return value `ncid` is a file ID. The `mode` parameter is a text string that describes the type of file access, which can have any of the following values.

Value	Description
NOCLOBBER	Prevent overwriting of existing file with the same name.
CLOBBER	Overwrite any existing file with the same name.
SHARE	Allow synchronous file updates.
64BIT_OFFSET	Allow easier creation of files and variables which are larger than two gigabytes.
NETCDF4	Create a NetCDF-4/HDF5 file
CLASSIC_MODEL	Enforce the classic model; has no effect unless used in a bitwise-or with NETCDF4

---

**Note:** You can specify the mode as a numeric value, retrieved using the `netcdf.getConstant` function. To specify more than one mode, use a bitwise-OR of the numeric values of the modes.

---

`[chunksize_out,ncid] = netcdf.create(filename,mode,initsz,chunksize)` creates a new netCDF file, but with additional performance tuning parameters. `initsz` sets the initial size of the file. `chunksize` can affect I/O performance. The actual value chosen by the NetCDF library might not correspond to the input value.

This function corresponds to the `nc_create` and `nc__create` functions in the NetCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

## Examples

This example creates a netCDF dataset named `foo.nc`, only if no other file with the same name exists in the current directory. To run this example, you must have write permission in your current directory.

```
ncid = netcdf.create('foo.nc', 'NOCLOBBER');
```

This example creates a netCDF-4 file that uses the classic model.

```
mode = netcdf.getConstant('NETCDF4');
mode = bitor(mode, netcdf.getConstant('CLASSIC_MODEL'));
ncid = netcdf.create('myfile.nc', mode);
netcdf.close(ncid);
```

## See Also

`netcdf.getConstant` | `netcdf.open`

# netcdf.defDim

Create netCDF dimension

## Syntax

```
dimid = netcdf.defDim(ncid,dimname,dimlen)
```

## Description

`dimid = netcdf.defDim(ncid,dimname,dimlen)` creates a new dimension in the netCDF file specified by `ncid`, where `dimname` is a character string that specifies the name of the dimension and `dimlen` is a numeric value that specifies its length. To define an unlimited dimension, specify the predefined constant `'NC_UNLIMITED'` for `dimlen`, using `netcdf.getConstant` to retrieve the value.

`netcdf.defDim` returns `dimid`, a numeric ID corresponding to the new dimension.

This function corresponds to the `nc_def_dim` function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

For copyright information, read the `netcdfcopyright.txt` and `mexnccopyright.txt` files.

## Examples

Create a new file and define two dimensions in the file. One dimension is an unlimited dimension. To run this example, you must have write permission in your current folder.

```
% Create a netCDF file.
ncid = netcdf.create('foo.nc','NC_NOCLlobber')

% Define a dimension.
lat_dimID = netcdf.defDim(ncid,'latitude',360);

% Define an unlimited dimension.
```

```
long_dimID = netcdf.defDim(ncid, 'longitude', ...
 netcdf.getConstant('NC_UNLIMITED'));
```

## **See Also**

`netcdf.getConstant`

# netcdf.defGrp

Create group in NetCDF file

## Syntax

```
childGrpID = netcdf.defGrp(parentGroupId,childGroupName)
```

## Description

`childGrpID = netcdf.defGrp(parentGroupId,childGroupName)` creates a child group with the name specified by `childGroupName`, that is the child of the parent group specified by `parentGroupId`

## Input Arguments

### **parentGroupId**

Identifier of NetCDF file, returned by `netcdf.create` or `netcdf.open`, or of a NetCDF group, returned by `netcdf.defGrp`.

**Default:**

### **childGroupName**

Text string specifying the name that you want to assign to the group.

**Default:**

## Output Arguments

### **childGrpID**

Identifier of a NetCDF group.

## Examples

This example creates a NetCDF dataset and then defines a group.

```
ncid = netcdf.create('myfile.nc', 'netcdf4');
childGroupId = netcdf.defGrp(ncid, 'mygroup');
netcdf.close(ncid);
```

## References

This function corresponds to the `nc_def_grp` function in the NetCDF library C API.

For copyright information, read the files `netcdfcopyright.txt` and `mexnccopyright.txt`.

## See Also

`netcdf` | `netcdf.inqGrps`

# netcdf.defVar

Create NetCDF variable

## Syntax

```
varid = netcdf.defVar(ncid,varname,xtype,dimids)
```

## Description

`varid = netcdf.defVar(ncid,varname,xtype,dimids)` creates a new variable in the dataset identified by `ncid`.

`varname` is a character string that specifies the name of the variable. `xtype` can be either a character string specifying the data type of the variable, such as `'double'`, or it can be the numeric equivalent returned by the `netcdf.getConstant` function. `dimids` specifies a list of dimension IDs.

`netcdf.defVar` returns `varid`, a numeric identifier for the new variable.

This function corresponds to the `nc_def_var` function in the NetCDF library C API. Because MATLAB uses FORTRAN-style ordering, the fastest-varying dimension comes first and the slowest comes last. Any unlimited dimension is therefore last in the list of dimension IDs. This ordering is the reverse of that found in the C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

## Examples

This example creates a new netCDF file, defines a dimension in the file, and then defines a variable on that dimension. (In netCDF files, you must create a dimension before you can create a variable.) To run this example, you must have write permission in your current directory.

```
% Create netCDF file.
ncid = netcdf.create('foo.nc', 'NC_NOCLOBBER');
%
```

```
% Define a dimension in the new file.
dimid = netcdf.defDim(ncid,'x',50);

% Define a variable in the new file.
varid = netcdf.defVar(ncid,'myvar','double',dimid)
```

## **See Also**

`netCDF.getConstant` | `netCDF.inqVar` | `netCDF.putVar`

# netcdf.defVarChunking

Define chunking behavior for NetCDF variable

## Syntax

```
netcdf.defVarChunking(ncid, varid, storage, chunkDims)
```

## Description

`netcdf.defVarChunking(ncid, varid, storage, chunkDims)`. sets the chunk settings for the variable specified by `varid`. Chunking is a technique to improve performance. `storage` specifies the type of chunking to use and `chunkDims` specifies the extents of the chunk size. You must specify the chunk size used with a variable after creating the variable but before you write data to the variable.

You cannot specify the chunk size for variables in a NetCDF file created with the netCDF-3 mode (`CLASSIC_MODEL`).

## Input Arguments

### **ncid**

Identifier of NetCDF file, returned by `netcdf.create` or `netcdf.open`, or of a NetCDF group, returned by `netcdf.defGrp`.

### **Default:**

### **varid**

Identifier of a NetCDF variable, returned by `netcdf.defVar`.

### **Default:**

### **storage**

Text string specifying whether NetCDF should break the variable into chunks when writing to a file. If set to `CHUNKED`, NetCDF breaks the variable into chunks; if set to `CONTIGUOUS`, NetCDF does not break the data into chunks.

**Default:****chunkDims**

Array specifying the dimensions of the chunk.

Because MATLAB uses FORTRAN-style ordering, the order of dimensions in `chunkdims` is reversed relative to what would be in the C API.

If storage is `CONTIGUOUS`, you can omit `chunkDims`.

**Default:** Chunk size determined by the NetCDF library.

## Examples

This example creates a NetCDF file and specifies the chunking behavior of a variable.

```
ncid = netcdf.create('myfile.nc','NETCDF4');
latdimid = netcdf.defDim(ncid,'lat',1800);
londimid = netcdf.defDim(ncid,'col',3600);
varid = netcdf.defVar(ncid,'earthgrid','double',[latdimid londimid]);
netcdf.defVarChunking(ncid,varid,'CHUNKED',[180 360]);
netcdf.close(ncid);
```

## References

This function corresponds to the `nc_def_var_chunking` function in the NetCDF library C API.

For copyright information, read the `netcdfcopyright.txt` and `mexnccopyright.txt` files.

## See Also

`netcdf` | `netcdf.inqVarChunking`

# netcdf.defVarDeflate

Define compression parameters for NetCDF variable

## Syntax

```
netcdf.defVarDeflate(ncid, varid, shuffle, deflate, deflateLevel)
```

## Description

`netcdf.defVarDeflate(ncid, varid, shuffle, deflate, deflateLevel)` sets the compression parameters for the NetCDF variable specified by `varid` in the location specified by `ncid`.

## Input Arguments

### **ncid**

Identifier of NetCDF file, returned by `netcdf.create` or `netcdf.open`, or of a NetCDF group, returned by `netcdf.defGrp`.

### **Default:**

### **varid**

Identifier of a NetCDF variable, returned by `netcdf.defVar`.

### **Default:**

### **shuffle**

Boolean value. To turn on the shuffle filter, set this argument to `true`. The shuffle filter can assist with the compression of integer data by changing the byte order in the data stream.

### **Default:**

## **deflate**

Boolean value. To turn on compression, set this argument to `true` and set the `deflateLevel` argument to the desired compression level.

**Default:**

## **deflateLevel**

Numeric value between `0` and `9` specifying the amount of compression, where `0` is no compression and `9` is the most compression.

**Default:**

## **Examples**

This example create a variable with dimensions [1800 3600] and a compression level of 5. This results in a chunked layout that is a 10-by-10 grid.

```
ncid = netcdf.create('myfile.nc','NETCDF4');
latdimid = netcdf.defDim(ncid,'lat',1800);
londimid = netcdf.defDim(ncid,'col',3600);
varid = netcdf.defVar(ncid,'earthgrid','double',[latdimid londimid]);
netcdf.defVarDeflate(ncid,varid,true,true,5);
netcdf.close(ncid);
```

## **References**

This function corresponds to the `nc_def_var_deflate` function in the netCDF library C API.

For copyright information, read the `netcdfcopyright.txt` and `mexnccopyright.txt` files.

## **See Also**

`netcdf` | `netcdf.inqVarDeflate`

# netcdf.defVarFill

Define fill parameters for NetCDF variable

## Syntax

```
netcdf.defVarFill(ncid, varid, noFillMode, fillValue)
```

## Description

`netcdf.defVarFill(ncid, varid, noFillMode, fillValue)` sets the fill parameters for the NetCDF variable identified by `varid`. `ncid` specifies the location.

For netCDF-4 files, you can only specify fill values when the NetCDF is in definition mode (before calling `netcdf.endDef`). For NetCDF files in classic and 64-bit offset modes, you can turn no-fill mode on and off at any time.

## Input Arguments

### **ncid**

Identifier of a NetCDF file, returned by `netcdf.create` or `netcdf.open`, or of a NetCDF group, returned by `netcdf.defGrp`.

### **Default:**

### **varid**

Identifier of a NetCDF variable, returned by `netcdf.defVar`.

### **Default:**

### **noFillMode**

Boolean value. When set to `true`, turns off use of fill values for the variable, which can be helpful in high performance applications. When `true`, `netcdf.defVarFill` ignores the value of the `fillValue` argument. To use the fill value, set this to `false`.

**Default:**

## **fillValue**

Specifies the value to use in the variable when no other value is specified. The data type must be the same data type as the variable.

**Default:**

## **Examples**

This example creates a NetCDF file and defines a fill value for a variable.

```
ncid = netcdf.create('myfile.nc', 'NETCDF4');
dimid = netcdf.defDim(ncid, 'latitude', 180);
varid = netcdf.defVar(ncid, 'latitude', 'double', dimid);
netcdf.defVarFill(ncid, varid, false, -999);
netcdf.close(ncid);
```

## **References**

This function corresponds to the `nc_def_var_fill` function in the NetCDF library C API.

For copyright information, read the `netcdfcopyright.txt` and `mexnccopyright.txt` files.

## **See Also**

`netcdf` | `netcdf.setFill` | `netcdf.inqVarFill`

# netcdf.defVarFletcher32

Define checksum parameters for NetCDF variable

## Syntax

```
netcdf.defVarFletcher32(ncid, varid, setting)
```

## Description

`netcdf.defVarFletcher32(ncid, varid, setting)` defines the checksum settings for the NetCDF variable specified by `varid` in the file specified by `ncid`.

## Input Arguments

### **ncid**

Identifier of NetCDF file, returned by `netcdf.create` or `netcdf.open`, or of a NetCDF group, returned by `netcdf.defGrp`.

**Default:**

### **varid**

Identifier of a NetCDF variable, returned by `netcdf.defVar`.

**Default:**

### **setting**

Text string specifying whether Fletcher32 checksum error detection is used with the variable. To turn on Fletcher32 checksum, specify the value `FLETCHER32`. To turn off the use of checksum error detection, specify the value `NOCHECKSUM`.

**Default:**

## Examples

This example creates a NetCDF dataset and turns on the Fletcher32 checksum for a variable.

```
ncid = netcdf.create('myfile.nc', 'NETCDF4');
latdimid = netcdf.defDim(ncid, 'lat', 1800);
londimid = netcdf.defDim(ncid, 'col', 3600);
varid = netcdf.defVar(ncid, 'earthgrid', 'double', [latdimid londimid]);
netcdf.defVarFletcher32(ncid, varid, 'FLETCHER32');
netcdf.close(ncid);
```

## References

This function corresponds to the `nc_def_var_fletcher32` function in the NetCDF library C API.

For copyright information, read the files `netcdfcopyright.txt` and `mexnccopyright.txt`.

## See Also

`netcdf` | `netcdf.inqVarFletcher32`

# netcdf.delAtt

Delete netCDF attribute

## Syntax

```
netcdf.delAtt(ncid,varid,attName)
```

## Description

`netcdf.delAtt(ncid,varid,attName)` deletes the attribute identified by the text string `attName`.

`ncid` is a netCDF file identifier returned by `netcdf.create` or `netcdf.open`.

`varid` is a numeric value that identifies the variable. To delete a global attribute, use `netcdf.getConstant('GLOBAL')` for the `varid`. You must be in define mode to delete an attribute.

This function corresponds to the `nc_del_att` function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

## Examples

This example opens a local copy of the example netCDF file included with MATLAB, `example.nc`.

```
% Open a netCDF file.
ncid = netcdf.open('my_example.nc','NC_WRITE')

% Determine number of global attributes in file.
[numdims numvars numatts unlimdimID] = netcdf.inq(ncid);

numatts =
```

1

```
% Get name of attribute; it is needed for deletion.
attname = netcdf.inqAttName(ncid,netcdf.getConstant('NC_GLOBAL'),0)

% Put file in define mode to delete an attribute.
netcdf.reDef(ncid);

% Delete the global attribute in the netCDF file.
netcdf.delAtt(ncid,netcdf.getConstant('GLOBAL'),attname);

% Verify that the global attribute was deleted.
[numdims numvars numatts unlimdimID] = netcdf.inq(ncid);

numatts =

 0
```

## See Also

`netcdf.getConstant` | `netcdf.inqAttName`

# netcdf.endDef

End netCDF file define mode

## Syntax

```
netcdf.endDef(ncid)
netcdf.endDef(ncid,h_minfree,v_align,v_minfree,r_align)
```

## Description

`netcdf.endDef(ncid)` takes a netCDF file out of define mode and into data mode. `ncid` is a netCDF file identifier returned by `netcdf.create` or `netcdf.open`.

`netcdf.endDef(ncid,h_minfree,v_align,v_minfree,r_align)` takes a netCDF file out of define mode, specifying four additional performance tuning parameters. For example, one reason for using the performance parameters is to reserve extra space in the netCDF file header using the `h_minfree` parameter:

```
ncid = netcdf.endDef(ncid,20000,4,0,4);
```

This reserves 20,000 bytes in the header, which can be used later when adding attributes. This can be extremely efficient when working with very large netCDF 3 files. To understand how to use these performance tuning parameters, see the netCDF library documentation.

This function corresponds to the `nc_enddef` and `nc__enddef` functions in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

## Examples

### Take File out of Define Mode

When you create a file using `netcdf.create`, the functions opens the file in define mode. This example uses `netcdf.endDef` to take the file out of define mode.

Create a netCDF file.

```
ncid = netcdf.create('foo.c', 'NC_NOCLIBBER');
```

Define a dimension.

```
dimid = netcdf.defDim(ncid, 'lat', 50);
```

Leave define mode.

```
netcdf.endDef(ncid)
```

Test if still in define mode.

```
dimid = netcdf.defDim(ncid, 'lon', 50);
```

Error using netcdflib

The NetCDF library encountered an error during execution of 'defDim' function - 'Operat  
(NC\_ENOTINDEFINE)'.

Error in netcdf.defDim (line 25)

```
dimid = netcdflib('defDim', ncid, dimname, dimlen);
```

netcdf.defDim errors, as expected.

## See Also

[netcdf.create](#) | [netcdf.reDef](#)

# netcdf.getAtt

Return netCDF attribute

## Syntax

```
attrvalue = netcdf.getAtt(ncid,varid,attname)
attrvalue = netcdf.getAtt(ncid,varid,attname,output_datatype)
```

## Description

`attrvalue = netcdf.getAtt(ncid,varid,attname)` returns `attrvalue`, the value of the attribute specified by the text string `attname`. When it chooses the data type of `attrvalue`, MATLAB attempts to match the netCDF class of the attribute. For example, if the attribute has the netCDF data type `NC_INT`, MATLAB uses the `int32` class for the output data. If an attribute has the netCDF data type `NC_BYTE`, the class of the output data is `int8` value.

`attrvalue = netcdf.getAtt(ncid,varid,attname,output_datatype)` returns `attrvalue`, the value of the attribute specified by the text string `attname`, using the output class specified by `output_datatype`. You can specify any of the following strings for the output data type.

'int'	'double'	'int16'
'short'	'single'	'int8'
'float'	'int32'	'uint8'

This function corresponds to several attribute I/O functions in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

## Examples

This example opens the example netCDF file included with MATLAB, `example.nc`, and gets the value of the attribute associated with the first variable. The example also gets the value of the global variable in the file.

```
% Open a netCDF file.
ncid = netcdf.open('example.nc','NC_NOWRITE');

% Get name of first variable.
[varname vartype vardimIDs varatts] = netcdf.inqVar(ncid,0);

% Get ID of variable, given its name.
varid = netcdf.inqVarID(ncid,varname);

% Get attribute name, given variable id.
attname = netcdf.inqAttName(ncid,varid,0);

% Get value of attribute.
attval = netcdf.getAtt(ncid,varid,attname);

% Get name of global attribute
gattname = netcdf.inqAttName(ncid,netcdf.getConstant('NC_GLOBAL'),0);

% Get value of global attribute.
gattval = netcdf.getAtt(ncid,netcdf.getConstant('NC_GLOBAL'),gattname)

gattval =

09-Jun-2008
```

## See Also

[netcdf.inqAtt](#) | [netcdf.putAtt](#)

# netcdf.getChunkCache

Retrieve chunk cache settings for NetCDF library

## Syntax

```
[csize, nelems, premp] = netcdf.getChunkCache()
```

## Description

[csize, nelems, premp] = netcdf.getChunkCache() returns the default chunk cache settings.

## Output Arguments

### **csize**

Scalar double specifying the total size of the raw data chunk cache in bytes.

### **nelems**

Scalar double specifying the number of chunk slots in the raw data chunk cache hash table.

### **premp**

Double, between 0 and 1, inclusive, that specifies how the library handles preempting fully read chunks in the chunk cache. A value of zero means fully read chunks are treated no differently than other chunks, that is, preemption occurs solely based on the Least Recently Used (LRU) algorithm. A value of 1 means fully read chunks are always preempted before other chunks.

## Examples

Determine information about the chunk cache size used by the NetCDF library.

```
[csize, nelems, premp] = netcdf.getChunkCache();
```

## References

This function corresponds to the `nc_get_chunk_cache` function in the NetCDF library C API.

For copyright information, read the `netcdfcopyright.txt` and `mexnccopyright.txt` files.

## See Also

`netcdf` | `netcdf.setChunkCache`

# netcdf.getConstant

Return numeric value of named constant

## Syntax

```
val = netcdf.getConstant(param_name)
```

## Description

`val = netcdf.getConstant(param_name)` returns the numeric value corresponding to the name of a constant defined by the netCDF library. For example, `netcdf.getConstant('NC_NOCLONER')` returns the numeric value corresponding to the netCDF constant `NC_NOCLONER`.

The value for `param_name` can be either upper- or lowercase, and does not need to include the leading three characters `'NC_'`. To retrieve a list of all the names defined by the netCDF library, use the `netcdf.getConstantNames` function.

This function has no direct equivalent in the netCDF C interface. To find out more about NetCDF, see `netcdf`.

## Examples

This example opens the example netCDF file included with MATLAB, `example.nc`.

```
% Open example file.
ncid = netcdf.open('example.nc','NC_NOWRITE');

% Determine contents of the file.
[ndims nvars natts dimm] = netcdf.inq(ncid);

% Get name of global attribute.
% Note: You must use netcdf.getConstant to specify NC_GLOBAL.
attname = netcdf.inqattname(ncid,netcdf.getConstant('NC_GLOBAL'),0)

attname =
```

creation\_date

**See Also**

netcdf.getConstantNames

# netcdf.getConstantNames

Return list of constants known to netCDF library

## Syntax

```
val = netcdf.getConstantNames(param_name)
```

## Description

`val = netcdf.getConstantNames(param_name)` returns a list of names of netCDF library constants, definitions, and enumerations. When these strings are supplied as actual parameters to MATLAB netCDF package functions, the functions automatically convert the constant to the appropriate numeric value.

This MATLAB function has no direct equivalent in the netCDF C interface. To find out more about netCDF, see `netcdf`.

## Examples

```
nc_constants = netcdf.getConstantNames
```

```
nc_constants =

 'NC2_ERR'
 'NC_64BIT_OFFSET'
 'NC_BYTE'
 'NC_CHAR'
 'NC_CLOBBER'
 'NC_DOUBLE'
 'NC_EBADDIM'
 'NC_EBADID'
 'NC_EBADNAME'
 'NC_EBADTYPE'
 ...
```

## See Also

`netcdf.getConstantNames`

## netcdf.getVar

Return data from netCDF variable

### Syntax

```
data = netcdf.getVar(ncid,varid)
data = netcdf.getVar(ncid,varid,start)
data = netcdf.getVar(ncid,varid,start,count)
data = netcdf.getVar(ncid,varid,start,count,stride)
data = netcdf.getVar(...,output_type)
```

### Description

`data = netcdf.getVar(ncid,varid)` returns `data`, the value of the variable specified by `varid`. MATLAB attempts to match the class of the output data to netCDF class of the variable.

`ncid` is a netCDF file identifier returned by `netcdf.create` or `netcdf.open`.

`data = netcdf.getVar(ncid,varid,start)` returns a single value starting at the specified index, `start`.

`data = netcdf.getVar(ncid,varid,start,count)` returns a contiguous section of a variable. `start` specifies the starting point and `count` specifies the amount of data to return.

`data = netcdf.getVar(ncid,varid,start,count,stride)` returns a subset of a section of a variable. `start` specifies the starting point, `count` specifies the extent of the section, and `stride` specifies which values to return.

`data = netcdf.getVar(...,output_type)` specifies the data type of the return value `data`. You can specify any of the following strings for the output data type.

'int8'
'uint8'
'int16'

'int32'
'single'
'double'

This function corresponds to several functions in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

## Examples

Open the example netCDF file and get the value of a variable in the file.

```
% Open example file.
ncid = netcdf.open('example.nc', 'NC_NOWRITE');

% Get the name of the first variable.
[varname, xtype, varDimIDs, varAtts] = netcdf.inqVar(ncid,0);

% Get variable ID of the first variable, given its name.
varid = netcdf.inqVarID(ncid,varname);

% Get the value of the first variable, given its ID.
data = netcdf.getVar(ncid,varid)

data =

 6.0221e+023

% Determine the data type of the output value
whos data
 Name Size Bytes Class Attributes

 data 1x1 8 double

% Get the value again, this time specifying the output data type
data = netcdf.getVar(ncid,varid,'single');

% Determine the data type of the output value
whos data
 Name Size Bytes Class Attributes
```

data      1x1                      4   single

## netcdf.inq

Return information about netCDF file

### Syntax

```
[ndims,nvars,ngatts,unlimdimid] = netcdf.inq(ncid)
```

### Description

`[ndims,nvars,ngatts,unlimdimid] = netcdf.inq(ncid)` returns the number of dimensions, variables, and global attributes in a netCDF file. The function also returns the ID of the dimension defined with unlimited length, if one exists.

`ncid` is a netCDF file identifier returned by `netcdf.create` or `netcdf.open`. You can call `netcdf.inq` in either define mode or data mode.

This function corresponds to the `nc_inq` function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

### Examples

This example opens the example netCDF file included with MATLAB, `example.nc`, and uses the `netcdf.inq` function to get information about the contents of the file.

```
% Open netCDF example file.
ncid = netcdf.open('example.nc','NC_NOWRITE')

% Get information about the contents of the file.
[numdims, numvars, numglobalatts, unlimdimID] = netcdf.inq(ncid)

numdims =
```

4

```
numvars =
```

```
4
```

```
numglobalatts =
```

```
1
```

```
unlimdimID =
```

```
3
```

## **See Also**

## netcdf.inqDimIDs

Retrieve list of dimension identifiers in group

### Syntax

```
dimIDs = netcdf.inqDimIDs(ncid)
dimIDs = netcdf.inqDimIDs(ncid,includeParents)
```

### Description

`dimIDs = netcdf.inqDimIDs(ncid)` returns a list of dimension identifiers in the group specified by `ncid`.

`dimIDs = netcdf.inqDimIDs(ncid,includeParents)` includes all dimensions in all parent groups if `includeParents` is true.

### Input Arguments

#### **ncid**

Identifier of a NetCDF file, returned by `netcdf.create` or `netcdf.open`, or of a NetCDF group, returned by `netcdf.defGrp`.

**Default:**

#### **includeParents**

Boolean value. If set to true, `netcdf.inqDimIDs` includes the dimensions of all parent groups.

**Default:** false

### Output Arguments

#### **dimIDs**

Array of dimension IDs

## Examples

This example opens the NetCDF sample file and gets the IDs of all the dimensions.

```
ncid = netcdf.open('example.nc', 'NOWRITE');
gid = netcdf.inqNcid(ncid, 'grid1');
dimids = netcdf.inqDimIDs(gid);
dimids_all = netcdf.inqDimIDS(gid, true);
netcdf.close(ncid);
```

## References

This function corresponds to the `nc_inq_dimids` function in the NetCDF library C API.

For copyright information, read the `netcdfcopyright.txt` and `mexnccopyright.txt` files.

# netcdf.inqFormat

Determine format of NetCDF file

## Syntax

```
format = netcdf.inqFormat(ncid)
```

## Description

`format = netcdf.inqFormat(ncid)` returns the format for the file specified by NetCDF file identifier, `ncid`.

## Input Arguments

### `ncid`

Identifier of a NetCDF file, returned by `netcdf.create` or `netcdf.open`, or of a NetCDF group, returned by `netcdf.defGrp`.

**Default:**

## Output Arguments

### `format`

Text string that specifies the format of the NetCDF file. Values include:

Format String	Description
FORMAT_CLASSIC	Classic format — Original NetCDF format, used by all NetCDF files created between 1989 and 2004
FORMAT_64BIT	Classic format, 64-bit — Original format with 64-bit addressing capability to allow creation and access of much larger files.

<b>Format String</b>	<b>Description</b>
FORMAT_NETCDF4	Enhanced model, HDF5-based — Introduced in 2008, NetCDF, version 4, extends the classic model and is based on HDF5.
FORMAT_NETCDF4_CLASSIC	Classic model, HDF5-based — Introduced in 2008, NetCDF, version 4, implements classic model but is based on HDF5.

## Examples

This example opens the sample NetCDF file and determines the format.

```
ncid = netcdf.open('example.nc', 'NOWRITE');
fmt = netcdf.inqFormat(ncid)

format =

FORMAT_NETCDF4

netcdf.close(ncid);
```

## References

This function corresponds to the `nc_inq_format` function in the NetCDF library C API.

For copyright information, read the `netcdfcopyright.txt` and `mexnccopyright.txt` files.

`netcdf.getConstant` | `netcdf`

# netcdf.inqGrpName

Retrieve name of group

## Syntax

```
groupName = netcdf.inqGrpName(ncid)
```

## Description

`groupName = netcdf.inqGrpName(ncid)` returns the name of a group specified by `ncid`.

## Input Arguments

### **ncid**

Identifier of NetCDF file, returned by `netcdf.create` or `netcdf.open`, or of a NetCDF group, returned by `netcdf.defGrp`.

**Default:**

## Output Arguments

### **groupName**

Text string specifying name of a group. The root group has the name `'/'`.

## Examples

This example opens the NetCDF sample file and gets the names of groups in the dataset.

```
ncid = netcdf.open('example.nc', 'nowrite');
name = netcdf.inqGrpName(ncid);
```

```
netcdf.close(ncid);
```

## References

This function corresponds to the `nc_inq_grpname` function in the NetCDF library C API.

For copyright information, read the `netcdfcopyright.txt` and `mexnccopyright.txt` files.

## See Also

`netcdf` | `netcdf.inqGrpNameFull`

# netcdf.inqGrpNameFull

Complete pathname of group

## Syntax

```
groupName = netcdf.inqGrpNameFull(ncid)
```

## Description

`groupName = netcdf.inqGrpNameFull(ncid)` returns the complete pathname of the group specified by `ncid`.

## Input Arguments

### **ncid**

Identifier of NetCDF file, returned by `netcdf.create` or `netcdf.open`, or of a NetCDF group, returned by `netcdf.defGrp`.

**Default:**

## Output Arguments

### **groupName**

Text string specifying complete path of group.

The root group has the name `' / '`. The names of parent groups and child groups use the forward slash `' / '` separator, as in UNIX folder names, for example, `/group1/subgrp2/subsubgrp3`.

## Examples

Open the NetCDF sample dataset and retrieve the names of all groups.

```
ncid = netcdf.open('example.nc', 'NOWRITE');
gid = netcdf.inqNcid(ncid, 'grid2');
fullName = netcdf.inqGrpNameFull(gid);
netcdf.close(ncid);
```

## References

This function corresponds to the `nc_inq_grpname_full` function in the netCDF library C API.

For copyright information, read the `netcdfcopyright.txt` and `mexnccopyright.txt` files.

## See Also

`netcdf` | `netcdf.inqGrpName`

## netcdf.inqGrpParent

Retrieve ID of parent group.

### Syntax

```
parentGroupID = netcdf.inqGrpParent(ncid)
```

### Description

`parentGroupID = netcdf.inqGrpParent(ncid)` returns the ID of the parent group given the location of the child group, specified by `ncid`.

### Input Arguments

#### **ncid**

Identifier of a NetCDF file, returned by `netcdf.create` or `netcdf.open`, or of a NetCDF group, returned by `netcdf.defGrp`.

**Default:**

### Output Arguments

#### **parentGroupID**

Identifier of the NetCDF group or file that is the parent of the specified file or group.

### Examples

This example opens the NetCDF sample file and gets the full path of the parent of the specified group.

```
ncid = netcdf.open('example.nc', 'NOWRITE');
```

```
gid = netcdf.inqNcid(ncid,'grid2');
parentId = netcdf.inqGrpParent(gid);
fullName = netcdf.inqGrpNameFull(parentId);
netcdf.close(ncid);
```

## References

This function corresponds to the `nc_inq_grp_parent` function in the NetCDF library C API.

For copyright information, read the `netcdfcopyright.txt` and `mexnccopyright.txt` files.

`netcdf` | `netcdf.inqGrps`

## netcdf.inqGrps

Retrieve array of child group IDs

### Syntax

```
childGrps = netcdf.inqGrps(ncid)
```

### Description

`childGrps = netcdf.inqGrps(ncid)` returns all the child group IDs in the parent group, specified by `ncid`.

### Input Arguments

#### **ncid**

Identifier of NetCDF file, returned by `netcdf.create` or `netcdf.open`, or of a NetCDF group, returned by `netcdf.defGrp`.

**Default:**

### Output Arguments

#### **childGrps**

Array containing identifiers of child groups in the specified NetCDF file or group.

### Examples

This example opens the sample NetCDF file and then gets information about the groups it contains.

```
ncid = netcdf.open('example.nc', 'nowrite');
```

```
childGroups = netcdf.inqGrps(ncid);
netcdf.close(ncid);
```

This function corresponds to the `nc_inq_grps` function in the netCDF library C API.

For copyright information, read the `netcdfcopyright.txt` and `mexnccopyright.txt` files.

## See Also

`netcdf` | `netcdf.inqNcid`

## netcdf.inqNcid

Return ID of named group

### Syntax

```
childGroupId = netcdf.inqNcid(ncid,childGroupName)
```

### Description

`childGroupId = netcdf.inqNcid(ncid,childGroupName)` returns the ID of the child group, specified by the name `childGroupName`, in the file or group specified by `ncid`.

### Input Arguments

#### **ncid**

Identifier of a NetCDF file, returned by `netcdf.create` or `netcdf.open`, or of a NetCDF group, returned by `netcdf.defGrp`.

**Default:**

#### **childGroupName**

Text string specifying the name of a NetCDF group.

**Default:**

### Output Arguments

#### **childGroupID**

Identifier of a NetCDF group.

## Examples

This example opens the sample NetCDF dataset and then gets the ID of a group in the dataset.

```
ncid = netcdf.open('example.nc', 'nowrite');
gid = netcdf.inqNcid(ncid, 'grid1');
netcdf.close(ncid);
```

## netcdf.inqUnlimDims

Return list of unlimited dimensions in group

### Syntax

```
unlimdimIDs = netcdf.inqUnlimDims(ncid)
```

### Description

`unlimdimIDs = netcdf.inqUnlimDims(ncid)` returns the IDs of all unlimited dimensions in the group specified by `ncid`.

### Input Arguments

#### **ncid**

Identifier of a NetCDF file, returned by `netcdf.create` or `netcdf.open`, or group, returned by `netcdf.defGrp`.

**Default:**

### Output Arguments

#### **unlimDimIDs**

An array containing the identifiers of each unlimited dimension. `unlimDimIDs` is empty if there are no unlimited dimensions.

### Examples

This example opens the NetCDF sample dataset and gets the IDs of all the unlimited dimensions.

```
ncid = netcdf.open('example.nc','NOWRITE');
dimids = netcdf.inqUnlimDims(ncid)

dimids =

 []

netcdf.close(ncid);
```

## References

This function corresponds to the `nc_inq_unlim_dims` function in the NetCDF library C API.

For copyright information, read the `netcdfcopyright.txt` and `mexnccopyright.txt` files.

## See Also

## netcdf.inqVarIDs

IDs of all variables in group

### Syntax

```
varids = netcdf.inqVarIDs(ncid)
```

### Description

`varids = netcdf.inqVarIDs(ncid)` returns IDs of the all the variables in the group specified by `ncid`.

### Input Arguments

#### **ncid**

Identifier of NetCDF file, returned by `netcdf.create` or `netcdf.open`, or of a NetCDF group, returned by `netcdf.defGrp`.

**Default:**

### Output Arguments

#### **varids**

Array containing identifiers of variables in a NetCDF file or group.

### Examples

This example opens the NetCDF sample file and gets the IDs of all the variables in a group.

```
ncid = netcdf.open('example.nc', 'NOWRITE');
```

```
gid = netcdf.inqNcid(ncid,'grid1');
varids = netcdf.inqVarIDs(gid);
netcdf.close(ncid);
```

## References

This function corresponds to the `nc_inq_varids` function in the NetCDF library C API.

For copyright information, read the `netcdfcopyright.txt` and `mexnccopyright.txt` files.

## See Also

`netcdf` | `netcdf.inqDimIDs` | `netcdf.inqVarID`

# netcdf.inqVarChunking

Determine chunking settings for NetCDF variable

## Syntax

```
[storage,chunkSizes] = netcdf.inqVarChunking(ncid,varid)
```

## Description

`[storage,chunkSizes] = netcdf.inqVarChunking(ncid,varid)` returns the type of chunking and the dimensions of a chunk for the NetCDF variable specified by `varid`, in the file or group specified by `ncid`.

## Input Arguments

### **ncid**

Identifier of NetCDF file, returned by `netcdf.create` or `netcdf.open`, or of a NetCDF group, returned by `netcdf.defGrp`.

**Default:**

### **varid**

Identifier of NetCDF variable, returned by `netcdf.defVar`.

**Default:**

## Output Arguments

### **storage**

Text string specifying if NetCDF breaks the data into chunks when writing to a file. `CHUNKED` indicates the data is chunked; `CONTIGUOUS` indicates that the data is not chunked.

## **chunkSizes**

Array specifying the dimensions of the chunk.

Because MATLAB uses FORTRAN-style ordering, the order of dimensions in `chunkdims` is reversed relative to what would be in the NetCDF C API.

If the storage type specified is `CONTIGUOUS`, `netcdf.inqVarChunking` returns an empty array, `[]`.

## **Examples**

This example opens the NetCDF sample dataset and gets the values of chunking parameters associated with a variable.

```
ncid = netcdf.open('example.nc','NOWRITE');
groupid = netcdf.inqNcid(ncid,'grid1');
varid = netcdf.inqVarID(groupid,'temp');
[storage,chunkSize] = netcdf.inqVarChunking(groupid,varid);
netcdf.close(ncid);
```

## **References**

This function corresponds to the `nc_inq_var_chunking` function in the netCDF library C API.

For copyright information, read the `netcdfcopyright.txt` and `mexnccopyright.txt` files.

## **See Also**

`netcdf` | `netcdf.defVar` | `netcdf.defVarChunking`

# netcdf.inqVarDeflate

Determine compression settings for NetCDF variable

## Syntax

```
[shuffle,deflate,deflateLevel] = netcdf.inqVarDeflate(ncid,varid)
```

## Description

```
[shuffle,deflate,deflateLevel] = netcdf.inqVarDeflate(ncid,varid)
```

returns the compression parameters for the NetCDF variable specified by `varid` in the location specified by `ncid`.

## Input Arguments

### **ncid**

Identifier of a NetCDF file, returned by `netcdf.create` or `netcdf.open`, or of a NetCDF group, returned by `netcdf.defGrp`.

**Default:**

### **varid**

Identifier of NetCDF variable, returned by `netcdf.defVar`.

**Default:**

## Output Arguments

### **shuffle**

Boolean value. `true` indicates that the shuffle filter is enabled for the specified variable. The shuffle filter can assist with the compression of integer data by changing the byte order in the data stream.

**deflate**

Boolean value. `true` indicates that compression is enabled for this variable. The `deflateLevel` argument specifies the level of compression.

**deflateLevel**

Scalar value between 0 and 9 specifying the amount of compression, where 0 is no compression and 9 is the most compression

## Examples

This example opens the NetCDF sample file and gets information about variable compression.

```
ncid = netcdf.open('example.nc', 'NOWRITE');
groupid = netcdf.inqNcid(ncid, 'grid1');
varid = netcdf.inqVarID(groupid, 'temp');
[shuffle, deflate, deflateLevel] = netcdf.inqVarDeflate(groupid, varid);
netcdf.close(ncid);
```

## References

This function corresponds to the `nc_inq_var_deflate` function in the netCDF library C API.

# netcdf.inqVarFill

Determine values of fill parameters for NetCDF variable

## Syntax

```
[noFillMode,fillValue] = netcdf.inqVarFill(ncid,varid)
```

## Description

[noFillMode,fillValue] = netcdf.inqVarFill(ncid,varid) returns the fill mode and the fill value for the variable `varid` in the file or group specified by `ncid`.

## Input Arguments

### **ncid**

Identifier of a NetCDF file, returned by `netcdf.create` or `netcdf.open`, or a NetCDF group, returned by `netcdf.defGrp`.

**Default:**

### **varid**

Identifier of NetCDF variable.

**Default:**

## Output Arguments

### **noFillMode**

Boolean value. `true` indicates that use of the fill values for the variable has been disabled.

## **fillValue**

Specifies the value to use in the variable when no other value is specified and use of fill values has been enabled.

## **Examples**

This example opens the NetCDF sample dataset and gets the fill mode and fill value used with a variable.

```
ncid = netcdf.open('example.nc','NOWRITE');
varid = netcdf.inqVarID(ncid,'temperature');
[noFillMode,fillValue] = netcdf.inqVarFill(ncid,varid);
netcdf.close(ncid);
```

## **References**

This function corresponds to the `nc_inq_var_fill` function in the netCDF library C API.

For copyright information, read the `netcdfcopyright.txt` and `mexnccopyright.txt` files.

# netcdf.inqVarFletcher32

Fletcher32 checksum setting for NetCDF variable

## Syntax

```
setting = netcdf.inqVarFletcher32(ncid,varid)
```

## Description

`setting = netcdf.inqVarFletcher32(ncid,varid)` returns the Fletcher32 checksum setting for the NetCDF variable specified by `varid` in the file or group specified by `ncid`.

## Input Arguments

### **ncid**

Identifier for NetCDF file, returned by `netcdf.create` or `netcdf.open`, or group, returned by `netcdf.defGrp`.

### **Default:**

### **varid**

Identifier of NetCDF variable.

### **Default:**

## Output Arguments

### **setting**

Text string specifying whether the Fletcher32 checksum is turned on for the specified variable. `netcdf.inqVarFletcher32` returns the text string `FLETCHER32` if the checksum is turned on for the variable; otherwise, `NOCHECKSUM`.

## Examples

This example opens the sample NetCDF file and gets information about the checksum setting for a variable.

```
ncid = netcdf.open('example.nc', 'NOWRITE');
varid = netcdf.inqVarID(ncid, 'temperature');
setting = netcdf.inqVarFletcher32(ncid, varid);
netcdf.close(ncid);
```

## References

This function corresponds to the `nc_inq_var_fletcher32` function in the netCDF library C API.

# netcdf.inqAtt

Return information about netCDF attribute

## Syntax

```
[xtype,attlen] = netcdf.inqAtt(ncid,varid,attname)
```

## Description

`[xtype,attlen] = netcdf.inqAtt(ncid,varid,attname)` returns the data type, `xtype`, and length, `attlen`, of the attribute identified by the text string `attname`.

`ncid` is a netCDF file identifier returned by `netcdf.create` or `netcdf.open`.

`varid` identifies the variable that the attribute is associated with. To get information about a global attribute, specify `netcdf.getConstant('NC_GLOBAL')` in place of `varid`.

This function corresponds to the `nc_inq_att` function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

## Examples

This example opens the example netCDF file included with MATLAB, `example.nc`, and gets information about an attribute in the file.

```
% Open netCDF example file.
ncid = netcdf.open('example.nc','NOWRITE');

% Get identifier of a variable in the file, given its name.
varid = netcdf.inqVarID(ncid,'avagadros_number');

% Get attribute name, given variable id and attribute number.
attname = netcdf.inqAttName(ncid,varid,0);
```

```
% Get information about the attribute.
[xtype,attlen] = netcdf.inqAtt(ncid,varid,'description')

xtype =

 2

attlen =

 31

% Get name of global attribute
gattname = netcdf.inqAttName(ncid,netcdf.getConstant('NC_GLOBAL'),0);

% Get information about global attribute.
[gxtype gattlen] = netcdf.inqAtt(ncid,netcdf.getConstant('NC_GLOBAL'),gattname)

gxtype =

 2

gattlen =

 11
```

## See Also

[netcdf.inqAttID](#) | [netcdf.inqAttName](#)

# netcdf.inqAttID

Return ID of netCDF attribute

## Syntax

```
attnum = netcdf.inqAttID(ncid,varid,attname)
```

## Description

`attnum = netcdf.inqAttID(ncid,varid,attname)` retrieves `attnum`, the identifier of the attribute specified by the text string `attname`.

`varid` specifies the variable the attribute is associated with.

`ncid` is a netCDF file identifier returned by `netcdf.create` or `netcdf.open`.

This function corresponds to the `nc_inq_attid` function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

## Examples

This example opens the netCDF example file included with MATLAB, `example.nc`.

```
% Open the netCDF example file.
ncid = netcdf.open('example.nc','NC_NOWRITE');

% Get the identifier of a variable in the file.
varid = netcdf.inqVarID(ncid,'avagadros_number');

% Retrieve the identifier of the attribute associated with the variable.
attid = netcdf.inqAttID(ncid,varid,'description');
```

## See Also

`netcdf.inqAtt` | `netcdf.inqAttName`

## netcdf.inqAttName

Return name of netCDF attribute

### Syntax

```
attname = netcdf.inqAttName(ncid,varid,attnum)
```

### Description

`attname = netcdf.inqAttName(ncid,varid,attnum)` returns `attname`, a text string specifying the name of an attribute.

`ncid` is a netCDF file identifier returned by `netcdf.create` or `netcdf.open`.

`varid` is a numeric identifier of a variable in the file. If you want to get the name of a global attribute in the file, use `netcdf.getConstant('NC_GLOBAL')` in place of `attnum` is a zero-based numeric value specifying the attribute, with 0 indicating the first attribute, 1 the second attribute, and so on.

This function corresponds to the `nc_inq_attname` function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

### Examples

This example opens the example netCDF file included with MATLAB, `example.nc`.

```
% Open netCDF example file.
ncid = netcdf.open('example.nc','NC_NOWRITE');

% Get identifier of a variable in the file.
varid = netcdf.inqVarID(ncid,'avagadros_number')

% Get the name of the attribute associated with the variable.
attname = netcdf.inqAttName(ncid,varid,0)
```

```
attname =
description
% Get the name of the global attribute associated with the variable.
gattname = netcdf.inqAttName(ncid,netcdf.getConstant('NC_GLOBAL'),0)
gattname =
creation_date
```

**See Also**

netcdf.inqAtt | netcdf.inqAttID

## netcdf.inqDim

Return netCDF dimension name and length

### Syntax

```
[dimname, dimlen] = netcdf.inqDim(ncid,dimid)
```

### Description

`[dimname, dimlen] = netcdf.inqDim(ncid,dimid)` returns the name, `dimname`, and length, `dimlen`, of the dimension specified by `dimid`. If `ndims` is the number of dimensions defined for a netCDF file, each dimension has an ID between 0 and `ndims-1`. For example, the dimension identifier of the first dimension is 0, the second dimension is 1, and so on.

`ncid` is a netCDF file identifier returned by `netcdf.create` or `netcdf.open`.

This function corresponds to the `nc_inq_dim` function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

### Examples

The example opens the example netCDF file include with MATLAB, `example.nc`.

```
ncid = netcdf.open('example.nc','NC_NOWRITE');
```

```
% Get name and length of first dimension
[dimname, dimlen] = netcdf.inqDim(ncid,0)
```

```
dimname =
```

```
x
```

```
dimlen =
```

50

**See Also**

netcdf.inqDimID

## netcdf.inqDimID

Return dimension ID

### Syntax

```
dimid = netcdf.inqDimID(ncid,dimname)
```

### Description

`dimid = netcdf.inqDimID(ncid,dimname)` returns `dimid`, the identifier of the dimension specified by the character string `dimname`. You can use the `netcdf.inqDim` function to retrieve the dimension name. `ncid` is a netCDF file identifier returned by `netcdf.create` or `netcdf.open`.

This function corresponds to the `nc_inq_dimid` function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

### Examples

This example opens the example netCDF file included with MATLAB, `example.nc`.

```
% Open netCDF example file.
ncid = netcdf.open('example.nc','NC_NOWRITE');

% Get name and length of first dimension
[dimname, dimlen] = netcdf.inqDim(ncid,0);

% Retrieve identifier of dimension.
dimid = netcdf.inqDimID(ncid,dimname)

dimid =

 0
```

### See Also

`netcdf.inqDim`

## netcdf.inqLibVers

Return NetCDF library version information

### Syntax

```
libvers = netcdf.inqLibVers
```

### Description

`libvers = netcdf.inqLibVers` returns a string identifying the version of the NetCDF library.

This function corresponds to the `nc_inq_libvers` function in the NetCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

### Examples

```
libvers = netcdf.inqLibVers
```

```
libvers =
```

```
4.1.3
```

## netcdf.inqVar

Information about variable

### Syntax

```
[varname,xtype,dimids,natts] = netcdf.inqVar(ncid,varid)
```

### Description

`[varname,xtype,dimids,natts] = netcdf.inqVar(ncid,varid)` returns information about the variable identified by `varid`. The argument, `ncid`, is a netCDF file identifier returned by `netcdf.create` or `netcdf.open`.

The output argument, `varname`, is the name of the variable. `xtype` is the data type, `dimids` is the dimension IDs, and `natts` is the number of attributes associated with the variable. Dimension IDs are zero-based.

This function corresponds to the `nc_inq_var` function in the netCDF library C API. Because MATLAB uses FORTRAN-style ordering, however, the order of the dimension IDs is reversed relative to what would be obtained from the C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

### Examples

Open the example netCDF file included with MATLAB, `example.nc`, and get information about a variable in the file.

```
% Open the example netCDF file.
ncid = netcdf.open('example.nc','NC_NOWRITE');

% Get information about third variable in the file.
[varname, xtype, dimids, numatts] = netcdf.inqVar(ncid,2)

varname =
```

```
peaks
```

```
xtype =
```

```
 5
```

```
dimids =
```

```
 0 1
```

```
numatts =
```

```
 1 1
```

### **See Also**

[netcdf.create](#) | [netcdf.inqVarID](#) | [netcdf.open](#)

## netcdf.inqVarID

Return ID associated with variable name

### Syntax

```
varid = netcdf.inqVarID(ncid,varname)
```

### Description

`varid = netcdf.inqVarID(ncid,varname)` returns `varid`, the ID of a netCDF variable specified by the text string, `varname`.

`ncid` is a netCDF file identifier returned by `netcdf.create` or `netcdf.open`.

This function corresponds to the `nc_inq_varid` function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

### Examples

This example opens the example netCDF file included with MATLAB, `example.nc`, and uses several inquiry functions to get the ID of the first variable.

```
ncid = netcdf.open('example.nc','NC_NOWRITE');

% Get information about first variable in the file.
[varname, xtype, dimids, atts] = netcdf.inqVar(ncid,0);

% Get variable ID of the first variable, given its name
varid = netcdf.inqVarID(ncid,varname)

varid =

 0
```

### See Also

`netcdf.create` | `netcdf.inqVar` | `netcdf.open`

# netcdf.open

Open NetCDF data source

## Syntax

```
ncid = netcdf.open(source)
ncid = netcdf.open(source,mode)
[chosen_chunksize, ncid] = netcdf.open(source,mode,chunksize)
```

## Description

`ncid = netcdf.open(source)` opens `source`, which can be the name of a NetCDF file or the URL of an OPeNDAP NetCDF data source, for read-only access. Returns a NetCDF ID in `ncid`.

`ncid = netcdf.open(source,mode)` opens `source` with the type of access specified by `mode`, which can have any of the following values.

Value	Description
'WRITE '	Read-write access
'SHARE '	Synchronous file updates
'NOWRITE '	Read-only access (Default)

You can also specify `mode` as a numeric value that can be retrieved using `netcdf.getConstant`. Use these numeric values when you want to specify a bitwise-OR of several modes.

`[chosen_chunksize, ncid] = netcdf.open(source,mode,chunksize)` opens `source`, an existing netCDF data source, specifying the additional I/O performance tuning parameter, `chunksize`. The actual value used by the NetCDF library might not correspond to the input value you specify.

This function corresponds to the `nc_open` and `nc__open` functions in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

## Examples

This example opens the example NetCDF file included with MATLAB, `example.nc`.

```
ncid = netcdf.open('example.nc','NOWRITE');
netcdf.close(ncid);
```

## See Also

`netcdf.close` | `netcdf` | `netcdf.getConstant`

# netcdf.putAtt

Write netCDF attribute

## Syntax

```
netcdf.putAtt(ncid,varid,attrname,attrvalue)
```

## Description

`netcdf.putAtt(ncid,varid,attrname,attrvalue)` writes the attribute named `attrname` with value `attrvalue` to the netCDF variable specified by `varid`. To specify a global attribute, use `netcdf.getConstant('NC_GLOBAL')` for `varid`.

`ncid` is a netCDF file identifier returned by `netCDF.create` or `netCDF.open`.

---

**Note:** You cannot use `netcdf.putAtt` to set the `'_FillValue'` attribute of NetCDF4 files. Use the `netcdf.defVarFill` function to set the fill value for a variable.

---

This function corresponds to several attribute I/O functions in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

## Examples

This example creates a new netCDF file, defines a dimension and a variable, adds data to the variable, and then creates an attribute associated with the variable. To run this example, you must have writer permission in your current directory.

```
% Create a variable in the workspace.
my_vardata = linspace(0,50,50);

% Create a netCDF file.
ncid = netcdf.create('foo.nc','NC_WRITE');
```

```
% Define a dimension in the file.
dimid = netcdf.defDim(ncid,'my_dim',50);

% Define a new variable in the file.
varid = netcdf.defVar(ncid,'my_var','double',dimid);

% Leave define mode and enter data mode to write data.
netcdf.endDef(ncid);

% Write data to variable.
netcdf.putVar(ncid,varid,my_vardata);

% Re-enter define mode.
netcdf.reDef(ncid);

% Create an attribute associated with the variable.
netcdf.putAtt(ncid,0,'my_att',10);

% Verify that the attribute was created.
[xtype xlen] = netcdf.inqAtt(ncid,0,'my_att')

xtype =

 6

xlen =

 1
```

This example creates a new netCDF file, specifies a global attribute, and assigns a value to the attribute.

```
ncid = netcdf.create('myfile.nc','CLOBBER');
varid = netcdf.getConstant('GLOBAL');
netcdf.putAtt(ncid,varid,'creation_date',datestr(now));
netcdf.close(ncid);
```

## See Also

[netcdf.getAtt](#) | [netcdf.defVarFill](#) | [netcdf.getConstant](#)

# netcdf.putVar

Write data to netCDF variable

## Syntax

```
netcdf.putVar(ncid, varid, data)
netcdf.putVar(ncid, varid, start, data)
netcdf.putVar(ncid, varid, start, count, data)
netcdf.putVar(ncid, varid, start, count, stride, data)
```

## Description

`netcdf.putVar(ncid, varid, data)` writes data to a netCDF variable identified by `varid`.

`ncid` is a netCDF file identifier returned by `netcdf.create` or `netcdf.open`.

`netcdf.putVar(ncid, varid, start, data)` writes a single data value into the variable at the index specified by `start`.

`netcdf.putVar(ncid, varid, start, count, data)` writes a section of values into the netCDF variable at the index specified by the vector `start` to the extent specified by the vector `count`, along each dimension of the specified variable.

`netcdf.putVar(ncid, varid, start, count, stride, data)` writes the subsection specified by sampling interval, `stride`, of the values in the section of the variable beginning at the index `start` and to the extent specified by `count`.

This function corresponds to several variable I/O functions in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

## Examples

### Write Variable to New netCDF File

Create a new netCDF file and write a variable to the file.

Create a 50 element vector for a variable.

```
my_vardata = linspace(0,50,50);
```

Open the netCDF file.

```
ncid = netcdf.create('foo.nc', 'NOCLlobber');
```

Define the dimensions of the variable.

```
dimid = netcdf.defDim(ncid, 'my_dim', 50);
```

Define a new variable in the file.

```
my_varID = netcdf.defVar(ncid, 'my_var', 'double', dimid);
```

Leave define mode and enter data mode to write data.

```
netcdf.endDef(ncid);
```

Write data to variable.

```
netcdf.putVar(ncid, my_varID, my_vardata);
```

Verify that the variable was created.

```
[varname xtype dimid natts] = netcdf.inqVar(ncid, 0)
```

```
varname =
```

```
my_var
```

```
xtype =
```

```
6
```

```
dimid =
```

```
0
```

```
natts =
```

```
0
```

Close the file.

```
netcdf.close(ncid)
```

### **Write Elements of Variable**

Write to the first ten elements of the example `temperature` variable.

```
srcFile = fullfile(matlabroot, 'toolbox', 'matlab', 'demos', 'example.nc');
copyfile(srcFile, 'myfile.nc');
fileattrib('myfile.nc', '+w');
ncid = netcdf.open('myfile.nc', 'WRITE');
varid = netcdf.inqVarID(ncid, 'temperature');
data = [100:109];
netcdf.putVar(ncid, varid, 0, 10, data);
netcdf.close(ncid);
```

### **See Also**

`netcdf.getVar`

## netcdf.reDef

Put open netCDF file into define mode

### Syntax

```
netcdf.reDef(ncid)
```

### Description

`netcdf.reDef(ncid)` puts an open netCDF file into define mode so that dimensions, variables, and attributes can be added or renamed. Attributes can also be deleted in define mode. `ncid` is a valid NetCDF file ID, returned from a previous call to `netcdf.open` or `netcdf.create`.

This function corresponds to the `nc_redef` function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

### Examples

This example opens a local copy of the example netCDF file included with MATLAB, `example.nc`.

```
% Open a netCDF file.
ncid = netcdf.open('my_example.nc','NC_WRITE')

% Try to define a dimension.
dimid = netcdf.defdim(ncid, 'lat', 50); % should fail.
??? Error using ==> netcdflib
NetCDF: Operation not allowed in data mode

Error in ==> defDim at 22
dimid = netcdflib('def_dim', ncid,dimname,dimlen);

% Put file in define mode.
netcdf.reDef(ncid);
```

```
% Try to define a dimension again. Should succeed.
dimid = netcdf.defDim(ncid, 'lat', 50);
```

**See Also**

[netcdf.create](#) | [netcdf.endDef](#) | [netcdf.open](#)

## **netcdf.renameAtt**

Change name of attribute

### **Syntax**

```
netcdf.renameAtt(ncid, varid, oldName, newName)
```

### **Description**

`netcdf.renameAtt(ncid, varid, oldName, newName)` changes the name of the attribute specified by the character string `oldName`.

`newName` is a character string that specifies the new name.

`ncid` is a netCDF file identifier returned by `netcdf.create` or `netcdf.open`.

`varid` identifies the variable to which the attribute is associated. To specify a global attribute, use `netcdf.getConstant('NC_GLOBAL')` for `varid`.

This function corresponds to the `nc_rename_att` function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

### **Examples**

This example modifies a local copy of the example netCDF file included with MATLAB, `example.nc`.

```
% Open netCDF file.
ncid = netcdf.open('my_example.nc', 'NC_WRITE')

% Get the ID of a variable the attribute is associated with.
varID = netcdf.inqVarID(ncid, 'avagadros_number')

% Rename the attribute.
netcdf.renameAtt(ncid, varID, 'description', 'Description');
```

```
% Verify that the name changed.
attname = netcdf.inqAttName(ncid,varID,0)
```

```
attname =
```

```
Description
```

### **See Also**

```
netcdf.inqAttName
```

## netcdf.renameDim

Change name of netCDF dimension

### Syntax

```
netcdf.renameDim(ncid,dimid,newName)
```

### Description

`netcdf.renameDim(ncid,dimid,newName)` renames the dimension identified by the dimension identifier, `dimid`.

`newName` is a character string specifying the new name. `ncid` is a netCDF file identifier returned by `netcdf.create` or `netcdf.open`

This function corresponds to the `nc_rename_dim` function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

### Examples

This examples modifies a local copy of the example netCDF file included with MATLAB, `example.nc`.

```
% Open netCDF file.
ncid = netcdf.open('my_example.nc','NC_WRITE')

% Put file is define mode.
netcdf.reDef(ncid)

% Get the identifier of a dimension to rename.
dimid = netcdf.inqDimID(ncid,'x');

% Rename the dimension.
netcdf.renameDim(ncid,dimid,'Xdim')
```

```
% Verify that the name changed.
data = netcdf.inqDim(ncid,dimid)
```

```
data =
```

```
Xdim
```

## **See Also**

netcdf.defDim

## **netcdf.renameVar**

Change name of netCDF variable

### **Syntax**

```
netcdf.renameVar(ncid,varid,newName)
```

### **Description**

`netcdf.renameVar(ncid,varid,newName)` renames the variable identified by `varid` in the netCDF file identified by `ncid`. `newName` is a character string specifying the new name.

This function corresponds to the `nc_rename_var` function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

### **Examples**

This example modifies a local copy of the example netCDF file included with MATLAB, `example.nc`.

```
% Open netCDF file.
ncid = netcdf.open('my_example.nc','NC_WRITE')

% Put file in define mode.
netcdf.redef(ncid)

% Get name of first variable
[varname, xtype, varDimIDs, varAtts] = netcdf.inqVar(ncid,0);

varname

varname =

avagadros_number
```

```
% Rename the variable, using a capital letter to start the name.
netcdf.renameVar(ncid,0,'Avagadros_number')

% Verify that the name of the variable changed.
[varname, xtype, varDimIDs, varAtts] = netcdf.inqVar(ncid,0);

varname

varname =

Avagadros_number
```

### **See Also**

netCDF.defVar | netCDF.inqVar | netCDF.putVar

## netcdf.setChunkCache

Set default chunk cache settings for NetCDF library

### Syntax

```
netcdf.setChunkCache(csize,nelems,premp)
```

### Description

`netcdf.setChunkCache(csize,nelems,premp)` sets the default chunk cache settings used by the NetCDF library.

Settings apply for subsequent file open or create operations, for the remainder of the MATLAB session or until you issue a `clear mex` call. This function does not change the chunk cache settings of files already open.

### Input Arguments

#### **csize**

Scalar double specifying the total size of the raw data chunk cache in bytes.

**Default:**

#### **nelems**

Scalar double specifying the number of chunk slots in the raw data chunk cache hash table.

**Default:**

#### **premp**

Scalar double, between 0 and 1, inclusive, that specifies how the library handles preempting fully read chunks in the chunk cache. A value of 0 means fully read chunks are treated no differently than other chunks, that is, preemption occurs solely based

on the Least Recently Used (LRU) algorithm. A value of 1 means fully read chunks are always preempted before other chunks.

**Default:**

## Examples

This example sets the cache chunk size used by the NetCDF library.

```
netcdf.setChunkCache(32000000, 2003, .75)
```

## References

This function corresponds to the `nc_set_chunk_cache` function in the NetCDF library C API.

For copyright information, read the `netcdfcopyright.txt` and `mexnccopyright.txt` files.

## See Also

`netcdf` | `netcdf.getChunkCache`

## netcdf.setDefaultFormat

Change default netCDF file format

### Syntax

```
oldFormat = netcdf.setDefaultFormat(newFormat)
```

### Description

`oldFormat = netcdf.setDefaultFormat(newFormat)` changes the default format used by `netCDF.create` when creating new netCDF files, and returns the value of the old format. You can use this function to change the format used by a netCDF file without having to change the creation mode flag used in each call to `netCDF.create`.

`newFormat` can be either of the following values.

Value	Description
'NC_FORMAT_CLASSIC'	Original netCDF file format
'NC_FORMAT_64BIT'	64-bit offset format; relaxes limitations on creating very large files

You can also specify the numeric equivalent of these values, as retrieved by `netcdf.getConstant`.

This function corresponds to the `nc_set_default_format` function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

### Examples

```
oldFormat = netcdf.setDefaultFormat('NC_FORMAT_64BIT');
```

### See Also

`netcdf.create`

## netcdf.setFill

Set netCDF fill mode

### Syntax

```
old_mode = netcdf.setFill(ncid,new_mode)
```

### Description

`old_mode = netcdf.setFill(ncid,new_mode)` sets the fill mode for a netCDF file identified by `ncid`.

`new_mode` can be either 'FILL' or 'NOFILL' or their numeric equivalents, as retrieved by `netcdf.getConstant`. The default mode is 'FILL'. netCDF pre-fills data with fill values. Specifying 'NOFILL' can be used to enhance performance, because it avoids the duplicate writes that occur when the netCDF writes fill values that are later overwritten with data.

This function corresponds to the `nc_set_fill` function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

### Examples

This example creates a new file and specifies the fill mode used by netCDF with the file.

```
ncid = netcdf.open('foo.nc','NC_WRITE');

% Set filling behavior
old_mode = netcdf.setFill(ncid,'NC_NOFILL');
```

### See Also

`netcdf.getConstant`

## netcdf.sync

Synchronize netCDF file to disk

### Syntax

```
netcdf.sync(ncid)
```

### Description

`netcdf.sync(ncid)` synchronizes the state of a netCDF file to disk. The netCDF library normally buffers accesses to the underlying netCDF file, unless you specify the `NC_SHARE` mode when you opened the file with `netcdf.open` or `netcdf.create`. To call `netcdf.sync`, the netCDF file must be in data mode.

This function corresponds to the `nc_sync` function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

### Examples

This example creates a new netCDF file for write access, performs an operation on the file, takes the file out of define mode, and then synchronizes the file to disk.

```
% Create a netCDF file.
ncid = netcdf.create('foo.nc', 'NC_WRITE');

% Perform an operation.
dimid = netcdf.defDim(ncid, 'Xdim', 50);

% Take file out of define mode.
netcdf.endDef(ncid);

% Synchronize the file to disk.
netcdf.sync(ncid)
```

### See Also

`netcdf.close` | `netcdf.create` | `netcdf.open` | `netcdf.endDef`

# newplot

Determine where to draw graphics objects

## Syntax

```
newplot
h = newplot
h = newplot(hsave)
```

## Description

`newplot` prepares a figure and axes for subsequent graphics commands.

`h = newplot` prepares a figure and axes for subsequent graphics commands and returns a handle to the current axes.

`h = newplot(hsave)` prepares and returns an axes, but does not delete any objects whose handles you have assigned to the `hsave` argument, which can be a vector of handles. If `hsave` is not empty, the figure and axes containing `hsave` are prepared for plotting instead of the current axes of the current figure. If `hsave` is empty, `newplot` behaves as if it were called without any inputs.

## More About

### Tips

To create a simple 2-D plot, use the `plot` function instead.

Use `newplot` at the beginning of high-level graphics code to determine which figure and axes to target for graphics output. Calling `newplot` can change the current figure and current axes. Basically, there are three options when you are drawing graphics in existing figures and axes:

- Add the new graphics without changing any properties or deleting any objects.
- Delete all existing objects whose handles are not hidden before drawing the new objects.

- Delete all existing objects regardless of whether or not their handles are hidden, and reset most properties to their defaults before drawing the new objects (refer to the following table for specific information).

The figure and axes `NextPlot` properties determine how `newplot` behaves. The following two tables describe this behavior with various property values.

First, `newplot` reads the current figure's `NextPlot` property and acts accordingly.

<b>NextPlot</b>	<b>What Happens</b>
<code>new</code>	Create a new figure and use it as the current figure.
<code>add</code>	Draw to the current figure without clearing any graphics objects already present.
<code>replacechildren</code>	Remove all child objects whose <code>HandleVisibility</code> property is set to <code>on</code> and reset figure <code>NextPlot</code> property to <code>add</code> .  This clears the current figure and is equivalent to issuing the <code>clf</code> command.
<code>replace</code>	Remove all child objects (regardless of the setting of the <code>HandleVisibility</code> property) and reset figure properties to their defaults, except  <code>NextPlot</code> is reset to <code>add</code> regardless of user-defined defaults.  • <code>Position</code> , <code>Units</code> , <code>PaperPosition</code> , and <code>PaperUnits</code> are not reset.  This clears and resets the current figure and is equivalent to issuing the <code>clf reset</code> command.

After `newplot` establishes which figure to draw in, it reads the current axes' `NextPlot` property and acts accordingly.

<b>NextPlot</b>	<b>Description</b>
<code>add</code>	Draw into the current axes, retaining all graphics objects already present.

NextPlot	Description
replacechildren	Remove all child objects whose <code>HandleVisibility</code> property is set to <code>on</code> , but do not reset axes properties. This clears the current axes like the <code>cla</code> command.
replace	Remove all child objects (regardless of the setting of the <code>HandleVisibility</code> property) and reset axes properties to their defaults, except <code>Position</code> and <code>Units</code> .  This clears and resets the current axes like the <code>cla reset</code> command.

- “Control Graph Display”

## nextDirectory

**Class:** Tiff

Make next IFD current IFD

### Syntax

```
nextDirectory(tiffobj)
```

### Description

`nextDirectory(tiffobj)` makes the next image file directory (IFD) in the file the current IFD. `Tiff` object methods operate on the current IFD. Use this method to navigate among IFDs in a TIFF file containing multiple images.

### Examples

#### Make Next Directory the Current Directory

Open a `Tiff` object and change the current IFD to the next IFD in the file.

```
t = Tiff('example.tif', 'r');
nextDirectory(t);
close(t);
```

- “Exporting Image Data and Metadata to TIFF Files”
- “Reading Image Data and Metadata from TIFF Files”

### References

This method corresponds to the `TIFFReadDirectory` function in the LibTIFF C API. To use this method, you must be familiar with the TIFF specification and technical notes. View this documentation at [LibTIFF - TIFF Library and Utilities](#).

## **See Also**

Tiff.setDirectory

## nextpow2

Exponent of next higher power of 2

### Syntax

`P = nextpow2(A)`

### Description

`P = nextpow2(A)` returns the exponents for the smallest powers of two that satisfy

$$2^p \geq |A|$$

for each element in `A`.

You can use `nextpow2` to pad the signal you pass to `fft`. Doing so can speed up the computation of the FFT when the signal length is not an exact power of 2.

### Examples

#### Next Power of 2 of Double Integer Values

Define a vector of `double` integer values and calculate the exponents for the next power of 2 higher than those values.

```
a = [1 -2 3 -4 5 9 519];
p = nextpow2(a)
```

```
p =
```

```
0 1 2 2 3 4 10
```

Calculate the positive next powers of 2.

```
np2 = 2.^p
```

```
np2 =
 1 2 4 4 8 16 1024
```

Preserve the sign of the original input values.

```
np2.*sign(a)
ans =
 1 -2 4 -4 8 16 1024
```

### Next Power of 2 of Unsigned Integer Values

Define a vector of unsigned integers and calculate the exponents for the next power of 2 higher than those values.

```
a = uint32([1020 4000 32700]);
p = nextpow2(a)
```

```
p =
 10 12 15
```

Calculate the next powers of 2 higher than the values in **a**.

```
2.^p
ans =
 1024 4096 32768
```

### Optimize FFT with Padding

Use `nextpow2` to increase the performance of `fft` when the length of your signal is not a power of 2.

Create a 1-D vector containing 8191 sample values.

```
x = gallery('uniformdata',[1,8191],0);
```

Calculate the next power of 2 higher than 8191.

```
p = nextpow2(8191);
n = 2^p
```

n =

8192

Pass the signal and the next power of 2 to the `fft` function.

```
y = fft(x,n);
```

## Input Arguments

### A — Input values

scalar, vector, or array of real numbers

Input values, specified as a scalar, vector, or array of real numbers of any numeric type.

Example: 15

Example: [-15.123 32.456 63.111]

Example: `int16([-15 32 63])`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### See Also

`fft` | `log2` | `pow2`

## nnz

Number of nonzero matrix elements

### Syntax

```
n = nnz(X)
```

### Description

`n = nnz(X)` returns the number of nonzero elements in matrix `X`.

The density of a sparse matrix is `nnz(X)/prod(size(X))`.

### Examples

The matrix

```
w = sparse(wilkinson(21));
```

is a tridiagonal matrix with 20 nonzeros on each of three diagonals, so `nnz(w) = 60`.

### See Also

`find` | `isa` | `nonzeros` | `nzmax` | `size` | `whos`

## noanimate

Change EraseMode of all objects to normal

---

**Note:** noanimate has been removed.

---

### Syntax

```
noanimate(state,fig_handle)
noanimate(state)
```

### Description

`noanimate(state,fig_handle)` sets the `EraseMode` of all image, line, patch, surface, and text graphics objects in the specified figure to `normal`. `state` can be the following strings:

- 'save' — Set the values of the `EraseMode` properties to `normal` for all the appropriate objects in the designated figure.
- 'restore' — Restore the `EraseMode` properties to the previous values (i.e., the values before calling `noanimate` with the 'save' argument).

`noanimate(state)` operates on the current figure.

`noanimate` is useful if you want to print the figure to a TIFF or JPEG format.

### See Also

`print`

## nonzeros

Nonzero matrix elements

### Syntax

```
s = nonzeros(A)
```

### Description

`s = nonzeros(A)` returns a full column vector of the nonzero elements in `A`, ordered by columns.

This gives the `s`, but not the `i` and `j`, from `[i,j,s] = find(A)`. Generally,

```
length(s) = nnz(A) <= nzmax(A) <= prod(size(A))
```

### See Also

`find` | `isa` | `nnz` | `nzmax` | `size` | `whos`

## norm

Vector and matrix norms

### Syntax

```
n = norm(X)
n = norm(X,p)
```

### Description

`n = norm(X)` returns the 2-norm of input `X` and is equivalent to `norm(X,2)`. If `X` is a vector, `norm(X)` is the Euclidean distance. If `X` is a matrix, `norm(X)` is the largest singular value of `X`.

`n = norm(X,p)` returns the  $p$ -norm of input `X`.

### Examples

#### 1- and 2- Norm of Vector

Calculate the 2-norm of a vector corresponding to the point (-2,3,-1) in 3-D space. The 2-norm is equal to the Euclidean length of the vector.

```
X = [-2 3 -1];
n = norm(X)
```

```
n =
```

```
3.7417
```

Calculate the 1-norm of the vector, which is the sum of the element magnitudes.

```
n = norm(X,1)
```

```
n =
```

6

## 2-Norm of Matrix

Calculate the 2-norm of a matrix, which is the largest singular value.

```
X = [2 0 1; -1 1 0; -3 3 0];
n = norm(X)
```

```
n =
```

```
4.7234
```

## Frobenius Norm of Sparse Matrix

Use 'fro' to calculate the Frobenius norm of a sparse matrix, which calculates the 2-norm of the column vector,  $S(:)$ .

```
S = sparse(1:25,1:25,1);
n = norm(S, 'fro')
```

```
n =
```

```
5
```

# Input Arguments

### **X** — Numeric array

scalar | vector | matrix

Numeric array, specified as a scalar, vector, or matrix. Use `norm(X, 'fro')` when  $X$  is sparse.

Data Types: `single` | `double`

Complex Number Support: Yes

### **p** — Norm type

2 (default) | positive integer scalar | `Inf` | `-Inf` | `'fro'`

Norm type, specified as 2 (default), a positive integer scalar, `Inf`, `-Inf`, or `'fro'`. Whether  $X$  is a matrix or vector determines the allowed values of  $p$  (and what they return). This table lists the calculated values for each allowed value of  $p$ .

**Note:** The table does not reflect the actual algorithms used in calculations.

---

<b>p</b>	<b>Matrix</b>	<b>Vector</b>
1	$\max(\text{sum}(\text{abs}(X)))$	$\text{sum}(\text{abs}(X))$
2	$\max(\text{svd}(X))$	$\text{sum}(\text{abs}(X).^2)^{(1/2)}$
positive, real-valued numeric p	–	$\text{sum}(\text{abs}(X).^p)^{(1/p)}$
Inf	$\max(\text{sum}(\text{abs}(X')))$	$\max(\text{abs}(X))$
-Inf	–	$\min(\text{abs}(X))$
'fro'	$\text{sqrt}(\text{sum}(\text{diag}(X'*X)))$	$\text{norm}(X)$

## Output Arguments

**n** — Matrix or vector norm

scalar

Matrix or vector norm, returned as a scalar. The norm gives a measure of the magnitude of the elements. By convention, `norm` returns NaN if the input contains NaN values.

## See Also

`cond` | `condest` | `hypot` | `normest` | `rcond`

# normest

2-norm estimate

## Syntax

```
nrm = normest(S)
nrm = normest(S,tol)
[nrm,count] = normest(...)
```

## Description

This function is intended primarily for sparse matrices, although it works correctly and may be useful for large, full matrices as well.

`nrm = normest(S)` returns an estimate of the 2-norm of the matrix **S**.

`nrm = normest(S,tol)` uses relative error `tol` instead of the default tolerance `1.e-6`. The value of `tol` determines when the estimate is considered acceptable.

`[nrm,count] = normest(...)` returns an estimate of the 2-norm and also gives the number of power iterations used.

## More About

### Algorithms

The power iteration involves repeated multiplication by the matrix **S** and its transpose, **S'**. The iteration is carried out until two successive estimates agree to within the specified relative tolerance.

### See Also

`cond` | `condest` | `norm` | `rcond` | `svd`

## **not, ~**

Find logical NOT

### **Syntax**

`~A`  
`not(A)`

### **Description**

`~A` performs a logical NOT of input array `A`, and returns an array containing elements set to either logical 1 (**true**) or logical 0 (**false**). An element of the output array is set to 1 if the input array contains a zero value element at that same array location. Otherwise, that element is set to 0.

The input of the expression can be an array or can be a scalar value. If the input is an array, then the output is an array of the same dimensions. If the input is scalar, then the output is scalar.

`not(A)` is called for the syntax `~A` when `A` is an object.

### **Examples**

If matrix `A` is

0	29	0	36	0
23	34	35	0	39
0	24	31	27	0
0	29	0	0	34

then

`~A`  
ans =

1	0	1	0	1
0	0	0	1	0

1	0	0	0	1
1	0	1	1	0

## notebook

Open MATLAB Notebook in Microsoft Word software (on Microsoft Windows platforms)

### Syntax

```
notebook
notebook('filename')
notebook('-setup')
```

### Description

`notebook` starts Microsoft Word software and creates a new MATLAB Notebook titled Document 1.

`notebook('filename')` starts Microsoft Word and opens the notebook `filename`, where `filename` is either in the MATLAB current folder or is a full path. If `filename` does not exist, MATLAB creates a new notebook titled `filename`. If the file name extension is not specified, MATLAB assumes `.doc`.

`notebook('-setup')` runs an interactive setup function for MATLAB Notebook. It copies the notebook template, `m-book.dot`, to the Microsoft Word template folder, whose location MATLAB automatically determines from the Windows system registry. Upon completion, MATLAB displays a message indicating whether or not the setup was successful.

### More About

- “Create a MATLAB Notebook with Microsoft Word”

# notify (handle)

Notify listeners that event is occurring

## Syntax

```
notify(Hobj, 'EventName')
notify(Hobj, 'EventName', evtData)
```

## Description

`notify(Hobj, 'EventName')` notifies listeners that the specified event is taking place on the specified handle objects.

`notify(Hobj, 'EventName', evtData)` includes user-defined event data.

## Input Arguments

**Hobj**

Array of handle objects triggering the specified event.

**EventName**

Name of the event.

**evtData**

An `event.EventData` object encapsulating information about the event. When you trigger an event using `notify`, MATLAB assigns values to the properties of the `event.EventData` object that is passed to the listener callback function.

Listener callbacks should not reuse the same event data object in subsequent calls to `notify`. Always create a new event data object to pass to `notify`.

You can define custom event data by subclassing `event.EventData` and passing an instance of your subclass as the `data` argument. See “Defining Event-Specific Data” for information on defining event data.

## See Also

See “Events and Listeners — Syntax and Techniques”

handle, addlistener

## now

Current date and time as serial date number

## Syntax

```
t = now
```

## Description

`t = now` returns the current date and time as a serial date number. A serial date number represents the whole and fractional number of days from a fixed, preset date (January 0, 0000).

`floor(now)` returns the current date as a serial date number, and `rem(now, 1)` returns the current time as a serial date number. `datestr(now)` returns the current date and time as a string.

## Examples

```
t1 = now, t2 = rem(now, 1)
```

```
t1 =
```

```
7.2908e+05
```

```
t2 =
```

```
0.4013
```

## More About

### Tips

- To return a datetime scalar representing the current date and time, type:

```
t = datetime('now')
```

**See Also**

clock | date | datenum | datestr | datetime

# nthroot

Real nth root of real numbers

## Syntax

`Y = nthroot(X,N)`

## Description

`Y = nthroot(X,N)` returns the real nth root of the elements of X. Both X and N must be real scalars or arrays of the same size. If an element in X is negative, then the corresponding element in N must be an odd integer.

## Examples

### Calculate Real Root of Negative Number

Find the real cube root of -27.

```
nthroot(-27, 3)
```

```
ans =
```

```
-3
```

For comparison, also calculate  $(-27)^{(1/3)}$ .

```
(-27)^(1/3)
```

```
ans =
```

```
1.5000 + 2.5981i
```

The result is the complex cube root of -27.

### Calculate Several Real Roots of Scalar

Create a vector of roots to calculate, N.

$$N = [5 \ 3 \ -1];$$

Use `nthroot` to calculate several real roots of `-8`.

$$Y = \text{nthroot}(-8,N)$$

Y =

$$\begin{array}{ccc} -1.5157 & -2.0000 & -0.1250 \end{array}$$

The result is a vector of the same size as N.

### **Elementwise Roots of Matrix**

Create a matrix of bases, X, and a matrix of nth roots, N.

$$X = [-2 \ -2 \ -2; \ 4 \ -3 \ -5]$$

$$N = [1 \ -1 \ 3; \ 1/2 \ 5 \ 3]$$

X =

$$\begin{array}{ccc} -2 & -2 & -2 \\ 4 & -3 & -5 \end{array}$$

N =

$$\begin{array}{ccc} 1.0000 & -1.0000 & 3.0000 \\ 0.5000 & 5.0000 & 3.0000 \end{array}$$

Each element in X corresponds to an element in N.

Calculate the real nth roots of the elements in X.

$$Y = \text{nthroot}(X,N)$$

Y =

$$\begin{array}{ccc} -2.0000 & -0.5000 & -1.2599 \\ 16.0000 & -1.2457 & -1.7100 \end{array}$$

Except for the signs (which are treated separately), the result is comparable to  $\text{abs}(X)^{(1./N)}$ . By contrast, you can calculate the complex roots using  $X^{(1./N)}$ .

## Input Arguments

### **X** — Input array

scalar | vector | matrix | multidimensional array

Input array, specified as a scalar, vector, matrix, or multidimensional array. X can be either a scalar or an array of the same size as N. The elements of X must be real.

Data Types: single | double

### **N** — Roots to calculate

scalar | array of same size as X

Roots to calculate, specified as a scalar or array of the same size as X. The elements of N must be real. If an element in X is negative, the corresponding element in N must be an odd integer.

Data Types: single | double

## More About

### Tips

- While `power` is a more efficient function for computing the roots of numbers, in cases where both real and complex roots exist, `power` returns only the complex roots. In these cases, use `nthroot` to obtain the real roots.

### See Also

`power` | `sqrt`

# null

Null space

## Syntax

```
Z = null(A)
Z = null(A, 'r')
```

## Description

`Z = null(A)` is an orthonormal basis for the null space of `A` obtained from the singular value decomposition. That is, `A*Z` has negligible elements, `size(Z,2)` is the nullity of `A`, and `Z'*Z = I`.

`Z = null(A, 'r')` is a “rational” basis for the null space obtained from the reduced row echelon form. `A*Z` is zero, `size(Z,2)` is an estimate for the nullity of `A`, and, if `A` is a small matrix with integer elements, the elements of the reduced row echelon form (as computed using `rref`) are ratios of small integers.

The orthonormal basis is preferable numerically, while the rational basis may be preferable pedagogically.

## Examples

### Example 1

Compute the orthonormal basis for the null space of a matrix `A`.

```
A = [1 2 3
 1 2 3
 1 2 3];
```

```
Z = null(A);
A*Z
```

```
ans =
 1.0e-015 *
 0.2220 0.2220
 0.2220 0.2220
 0.2220 0.2220
```

```
Z' * Z
```

```
ans =
 1.0000 -0.0000
 -0.0000 1.0000
```

## Example 2

Compute the 1-norm of the matrix  $A*Z$  and determine that it is within a small tolerance.

```
norm(A*Z,1) < 1e-12
ans =
 1
```

## Example 3

Compute the rational basis for the null space of the same matrix  $A$ .

```
ZR = null(A, 'r')
```

```
ZR =
 -2 -3
 1 0
 0 1
```

```
A*ZR
```

```
ans =
 0 0
 0 0
 0 0
```

## See Also

[orth](#) | [rank](#) | [rref](#) | [svd](#)

## num2cell

Convert array to cell array with consistently sized cells

### Syntax

```
C = num2cell(A)
C = num2cell(A,dim)
```

### Description

`C = num2cell(A)` converts array `A` into cell array `C` by placing each element of `A` into a separate cell in `C`. Array `A` need not be numeric.

`C = num2cell(A,dim)` splits the contents of `A` into separate cells of `C`, where `dim` specifies which dimensions of `A` to include in each cell. `dim` can be a scalar or a vector of dimensions. For example, if `A` has 2 rows and 3 columns, then:

- `num2cell(A,1)` creates a 1-by-3 cell array `C`, where each cell contains a 2-by-1 column of `A`.
- `num2cell(A,2)` creates a 2-by-1 cell array `C`, where each cell contains a 1-by-3 row of `A`.
- `num2cell(A,[1 2])` creates a 1-by-1 cell array `C`, where the cell contains the entire array `A`.

### Examples

#### Convert Arrays to Cell Array

Place all elements of a numeric array into separate cells.

```
a = magic(3)
c = num2cell(a)
```

```
a =
```

```

8 1 6
3 5 7
4 9 2

```

```
c =
```

```

[8] [1] [6]
[3] [5] [7]
[4] [9] [2]

```

Place individual letters of a word into separate cells of an array.

```

a = ['four'; 'five'; 'nine']
c = num2cell(a)

```

```
a =
```

```

four
five
nine

```

```
c =
```

```

'f' 'o' 'u' 'r'
'f' 'i' 'v' 'e'
'n' 'i' 'n' 'e'

```

### Create Cell Array of Numeric Arrays

Generate a 4-by-3-by-2 numeric array, and then create a 1-by-3-by-2 cell array of 4-by-1 column vectors.

```

A = reshape(1:12,4,3);
A(:,:,2) = A*10
C = num2cell(A,1)

```

```
A(:,:,1) =
```

```
1 5 9
2 6 10
3 7 11
4 8 12
```

```
A(:, :, 2) =
```

```
10 50 90
20 60 100
30 70 110
40 80 120
```

```
C(:, :, 1) =
```

```
[4x1 double] [4x1 double] [4x1 double]
```

```
C(:, :, 2) =
```

```
[4x1 double] [4x1 double] [4x1 double]
```

Each 4-by-1 vector contains elements from along the *first* dimension of A:

```
C{1}
```

```
ans =
```

```
1
2
3
4
```

Create a 4-by-1-by-2 cell array of 1-by-3 numeric arrays.

```
C = num2cell(A, 2)
```

```
C(:, :, 1) =
```

```
[1x3 double]
```

```
[1x3 double]
[1x3 double]
[1x3 double]
```

```
C(:, :, 2) =
```

```
[1x3 double]
[1x3 double]
[1x3 double]
[1x3 double]
```

Each 1-by-3 row vector contains elements from along the *second* dimension of A:

```
C{1}
```

```
ans =
```

```
1 5 9
```

Finally, create a 4-by-3 cell array of 1-by-1-by-2 numeric arrays.

```
C = num2cell(A, 3)
```

```
C =
```

```
[1x1x2 double] [1x1x2 double] [1x1x2 double]
[1x1x2 double] [1x1x2 double] [1x1x2 double]
[1x1x2 double] [1x1x2 double] [1x1x2 double]
[1x1x2 double] [1x1x2 double] [1x1x2 double]
```

Each 1-by-1-by-2 vector contains elements from along the *third* dimension of A:

```
C{1}
```

```
ans(:, :, 1) =
```

```
1
```

```
ans(:,:,2) =
```

```
10
```

## Combine Across Multiple Dimensions

Create a cell array by combining elements into numeric arrays along several dimensions.

```
A = reshape(1:12,4,3);
A(:,:,2) = A*10
c = num2cell(A,[1 3])
```

```
A(:,:,1) =
```

```
1 5 9
2 6 10
3 7 11
4 8 12
```

```
A(:,:,2) =
```

```
10 50 90
20 60 100
30 70 110
40 80 120
```

```
c =
```

```
[4x1x2 double] [4x1x2 double] [4x1x2 double]
```

Each 4-by-1-by-2 array contains elements from along the first and third dimension of A:

```
c{1}
```

```
ans(:,:,1) =
```

```
1
2
```

```

 3
 4

ans(:,:,2) =

 10
 20
 30
 40

c = num2cell(A,[2 3])

c =

 [1x3x2 double]
 [1x3x2 double]
 [1x3x2 double]
 [1x3x2 double]

```

## Input Arguments

### A — Input

any type of multidimensional array

Input, specified as any type of multidimensional array.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `struct` | `cell` | `function_handle`

### dim — Dimension of A

positive integer | positive vector of integers

Dimension of A, specified as a positive integer or a vector of positive integers. `dim` must be between 1 and `ndims(A)`.

Elements need not be in numeric order. However, `num2cell` permutes the dimensions of the arrays in each cell of C to match the order of the specified dimensions.

Data Types: `double`

## Output Arguments

### C — Resulting array

cell array

Resulting array, returned as a cell array. The size of **C** depends on the size of **A** and the values of **dim**.

- If **dim** is not specified, then **C** is the same size as **A**.
- If **dim** is a scalar, then **C** contains  $\text{numel}(\mathbf{A}) / \text{size}(\mathbf{A}, \text{dim})$  cells. If **dim** is 1 or 2, then each cell contains a column or row vector, respectively. If **dim** > 2, then each cell contains an array whose **dim**th dimensional length is  $\text{size}(\mathbf{A}, \text{dim})$ , and whose other dimensions are all singletons.

For example, given a 4-by-7-by-3 array, **A**, this figure shows how `num2cell` creates cells corresponding to **dim** values of 1, 2, and 3.

- If **dim** is a vector containing **N** values, then **C** has  $\text{numel}(\mathbf{A}) / \text{prod}([\text{size}(\mathbf{A}, \text{dim}(1)), \dots, \text{size}(\mathbf{A}, \text{dim}(\mathbf{N}))])$  cells. Each cell contains an array whose **dim**(**i**)th dimension has a length of  $\text{size}(\mathbf{A}, \text{dim}(\mathbf{i}))$  and whose other dimensions are singletons.

For example, given a 4-by-7-by-3 array, you can specify **dim** as an positive integer vector to create cell arrays of different dimensions.

## num2hex

Convert singles and doubles to IEEE hexadecimal strings

### Syntax

num2hex(X)

### Description

If X is a single or double precision array with n elements, num2hex(X) is an n-by-8 or n-by-16 char array of the hexadecimal floating-point representation. The same representation is printed with format hex.

### Examples

```
num2hex([1 0 0.1 -pi Inf NaN])
```

returns

ans =

```
3ff0000000000000

## num2str

Convert number to string

### Syntax

```
str = num2str(A)
str = num2str(A,precision)
str = num2str(A,formatSpec)
```

### Description

`str = num2str(A)` converts array `A` into a string representation `str`. The output format depends upon the magnitude of the original values and sometimes includes exponents. `num2str` is useful for labeling and titling plots with numeric values.

`str = num2str(A,precision)` returns a string representation with the maximum number of digits specified by `precision`.

`str = num2str(A,formatSpec)` applies a format specified by `formatSpec` to all elements of `A`.

### Examples

#### Default Conversions of Floating-Point Values

Convert `pi` and `eps` to text strings.

```
str = num2str(pi)
```

```
str =
```

```
3.1416
```

```
str = num2str(eps)
```

```
str =
2.2204e-16
```

### Specifying Precision

Specify the number of significant digits for floating-point values.

```
A = gallery('normaldata',[2,2],0);
precision = 3;
str = num2str(A,precision)
```

```
str =
-0.433 0.125
-1.67 0.288
```

### Specifying Formatting

Specify the width, precision, and other formatting for an array of floating-point values.

```
A = gallery('uniformdata',[2,3],0) * 9999;
formatSpec = '%10.5e\n';
str = num2str(A,formatSpec)
```

```
str =
9.50034e+03
6.06782e+03
8.91210e+03
2.31115e+03
4.85934e+03
7.62021e+03
```

The format `'%10.5e'` prints each value in exponential format with five decimal places, and `'\n'` prints a new line character.

## Input Arguments

### **A** — Input array

scalar | vector | matrix | multidimensional array

Input array, specified as a scalar, vector, matrix, or multidimensional array of real or complex numbers.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

### **precision** — Numeric precision

positive integer

Numeric precision of the output string, specified as a positive integer. This is the maximum number of digits in the output string.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **formatSpec** — Format of the output fields

string

Format of the output fields, specified as a string.

The string can include a percent sign followed by a conversion character. The following table lists the available conversion characters and subtypes.

Value Type	Conversion	Details
Integer, signed	<code>%d</code> or <code>%i</code>	Base 10
Integer, unsigned	<code>%u</code>	Base 10
	<code>%o</code>	Base 8 (octal)
	<code>%x</code>	Base 16 (hexadecimal), lowercase letters <code>a–f</code>
	<code>%X</code>	Same as <code>%x</code> , uppercase letters <code>A–F</code>

Value Type	Conversion	Details
Floating-point number	%f	Fixed-point notation
	%e	Exponential notation, such as 3.141593e+00
	%E	Same as %e, but uppercase, such as 3.141593E+00
	%g	The more compact of %e or %f, with no trailing zeros
	%G	The more compact of %E or %f, with no trailing zeros
	%bx or %bX %bo %bu	Double-precision hexadecimal, octal, or decimal value Example: %bx prints pi as 400921fb54442d18
	%tx or %tX %to %tu	Single-precision hexadecimal, octal, or decimal value Example: %tx prints pi as 40490fdb
Characters	%c	Single character
	%s	String of characters

The string can include optional operators, which appear in the following order (includes spaces for clarity):

Optional operators include:

- Identifier

Order for processing inputs. Use the syntax  $n\$$ , where  $n$  represents the position of the value in the input list.

For example, '%3\$s %2\$s %1\$s %2\$s' prints inputs 'A', 'B', 'C' as follows: C B A B.

- Flags

- '-' Left-justify. Example: % -5.2f
- '+' Print sign character (+) for positive values. Example: %+5.2f
- ' ' Pad to field width with spaces before the value. Example: % 5.2f
- '0' Pad to field width with zeros. Example: %05.2f
- '#' Modify selected numeric conversions:
  - For %o, %x, or %X, print 0, 0x, or 0X prefix.
  - For %f, %e, or %E, print decimal point even when precision is 0.
  - For %g or %G, do not remove trailing zeros or decimal point.

Example: %#5.0f

- Field width

Minimum number of characters to print. Can be a number, or an asterisk (\*) to refer to an argument in the input list. For example, the input list ('%12d', intmax) is equivalent to ('%\*d', 12, intmax).

- Precision

For %f, %e, or %E:                      Number of digits to the right of the decimal point.  
Example: '%6.4f' prints pi as '3.1416'

For %g or %G                              Number of significant digits.  
Example: '%6.4g' prints pi as ' 3.142'

Can be a number, or an asterisk (\*) to refer to an argument in the input list. For example, the input list ('%6.4f', pi) is equivalent to ('%\*.4f', 6, 4, pi).

The string can also include combinations of the following:

- Literal text to print. To print a single quotation mark, include '' in formatSpec.
- Control characters, including:

%%                      Percent character

<code>\\</code>	Backslash
<code>\a</code>	Alarm
<code>\b</code>	Backspace
<code>\f</code>	Form feed
<code>\n</code>	New line
<code>\r</code>	Carriage return
<code>\t</code>	Horizontal tab
<code>\v</code>	Vertical tab
<code>\xN</code>	Character whose ASCII code is the hexadecimal number, <i>N</i>
<code>\N</code>	Character whose ASCII code is the octal number, <i>N</i>

The following limitations apply to conversions:

- Numeric conversions print only the real component of complex numbers.
- If you specify a conversion that does not fit the data, such as a string conversion for a numeric value, MATLAB overrides the specified conversion, and uses `%e`.
- If you apply a string conversion (`%s`) to integer values, MATLAB converts values that correspond to valid character codes to characters. For example, `'%s'` converts `[65 66 67]` to `ABC`.

## Output Arguments

**str** — String representation of input array

character array

String representation of the input array, *A*, returned as a character array.

## More About

### Algorithms

`num2str` trims any leading spaces from a string, even when `formatSpec` includes a space character flag. For example, `num2str(42.67, '% 10.2f')` returns a 1-by-5 character array `'42.67'`.

# numberOfStrips

**Class:** Tiff

Total number of strips in image

## Syntax

```
numStrips = numberOfStrips(tiffobj)
```

## Description

`numStrips = numberOfStrips(tiffobj)` returns the total number of strips in the image.

## Examples

### Determine Number of Strips in Image

Determine the number of strips in the second image of a file.

Create a Tiff object associated with the example file, `example.tif`.

```
t = Tiff('example.tif', 'r');
```

When the Tiff object is created, the first image in the file is the current image file directory.

Make the second image the current directory.

```
nextDirectory(t)
```

Get the number of strips in the image if the image has a stripped organization.

```
if ~isTiled(t)
 numStrips = numberOfStrips(t)
end
```

```
numStrips =
```

7

The image has 7 strips.

Close the `Tiff` object.

```
close(t)
```

`Tiff.numberOfTiles` | `Tiff.isTiled`

# numberOfTiles

**Class:** Tiff

Total number of tiles in image

## Syntax

```
numTiles = numberOfTiles(tiffobj)
```

## Description

`numTiles = numberOfTiles(tiffobj)` returns the total number of tiles in the image.

## Examples

### Determine Number of Tiles in Image

Create a Tiff object associated with the example file, `example.tif`. Get the number of tiles in the image if the image has a tiled organization.

```
t = Tiff('example.tif','r');
if isTiled(t)
 nTiles = numberOfTiles(t)
end
```

```
nTiles =
```

```
 110
```

The image has 110 tiles.

Close the Tiff object.

```
close(t)
```

- “Exporting Image Data and Metadata to TIFF Files”
- “Reading Image Data and Metadata from TIFF Files”

# numel

Number of array elements

## Syntax

```
n = numel(A)
```

## Description

`n = numel(A)` returns the number of elements, `n`, in array `A`, equivalent to `prod(size(A))`.

## Examples

### Number of Elements in 3-D Matrix

Create a 4-by-4-by-2 matrix.

```
A = magic(4);
A(:,:,2) = A'
```

```
A(:,:,1) =
 16 2 3 13
 5 11 10 8
 9 7 6 12
 4 14 15 1
```

```
A(:,:,2) =
 16 5 9 4
 2 11 7 14
 3 10 6 15
 13 8 12 1
```

`numel` counts 32 elements in the matrix.

```
n = numel(A)
```

```
n =
 32
```

## Number of Elements in Cell Array of Strings

Create a cell array of strings.

```
A = {'dog', 'cat', 'fish', 'horse'};
```

`numel` counts 4 string elements in the array.

```
n = numel(A)
```

```
n =
 4
```

## Number of Elements in Table

Create a table with four variables listing patient information for five people.

```
LastName = {'Smith'; 'Johnson'; 'Williams'; 'Jones'; 'Brown'};
Age = [38; 43; 38; 40; 49];
Height = [71; 69; 64; 67; 64];
Weight = [176; 163; 131; 133; 119];
BloodPressure = [124 93; 109 77; 125 83; 117 75; 122 80];
```

```
A = table(Age, Height, Weight, BloodPressure, 'RowNames', LastName)
```

```
A =
```

	Age	Height	Weight	BloodPressure	
	---	-----	-----	-----	-----
Smith	38	71	176	124	93
Johnson	43	69	163	109	77
Williams	38	64	131	125	83
Jones	40	67	133	117	75
Brown	49	64	119	122	80

Find the number of elements in the table.

```
n = numel(A)
```

n =

20

`numel` returns a value equivalent to `prod(size(A))` corresponding to the 5 rows and 4 variables.

## Input Arguments

### **A** — Input array

scalar | vector | matrix | multidimensional array

Input array, specified as a scalar, vector, matrix, or multidimensional array. This includes numeric arrays, logical arrays, character arrays, categorical arrays, datetime arrays, duration arrays, `calendarDuration` arrays, tables, structure arrays, cell arrays, and object arrays.

## Limitations

- If `A` is a table, `numel` returns the number of elements in the table, `A`, equivalent to `prod(size(A))`. Variables in a table can have multiple columns, but `numel(A)` only accounts for the number of rows and number of variables.

## More About

- “`numel`, `subsref`, and `subsasgn` — Considerations for Overloading”

## See Also

`prod` | `size` | `subsref`

## **nzmax**

Amount of storage allocated for nonzero matrix elements

### **Syntax**

`n = nzmax(S)`

### **Description**

`n = nzmax(S)` returns the amount of storage allocated for nonzero elements.

If `S` is a sparse matrix...      `nzmax(S)` is the number of storage locations allocated for the nonzero elements in `S`.

If `S` is a full matrix...      `nzmax(S) = prod(size(S))`.

Often, `nnz(S)` and `nzmax(S)` are the same. But if `S` is created by an operation which produces fill-in matrix elements, such as sparse matrix multiplication or sparse LU factorization, more storage may be allocated than is actually required, and `nzmax(S)` reflects this. Alternatively, `sparse(i,j,s,m,n,nzmax)` or its simpler form, `spalloc(m,n,nzmax)`, can set `nzmax` in anticipation of later fill-in.

# matlab.lang.ObjectUpdateFailure class

**Package:** matlab.lang

Class representing objects that cannot be updated to new class definition

## Description

MATLAB converts objects to instances of `matlab.lang.ObjectUpdateFailure` when a class definition changes, but existing objects of that class cannot be updated to conform to the new definition. When objects cannot be updated, the automatic update process replaces existing objects of the class with `matlab.lang.ObjectUpdateFailure` objects.

Typical cases where objects are converted to `matlab.lang.ObjectUpdateFailure` objects include cases where a class:

- Is made abstract
- Is converted to an enumeration class
- Changes its heterogeneous root
- Inherits `suboref`, `subsasgn`, `cat`, `vertcat`, or `horzcat` methods

## Attributes

<code>Sealed</code>	<code>true</code>
<code>HandleCompatible</code>	<code>true</code>

To learn about attributes of classes, see “Class Attributes” in the MATLAB Object-Oriented Programming documentation.

## More About

- “Automatic Updates for Modified Classes”
- “Class Attributes”

## ode15i

Solve fully implicit differential equations, variable order method

### Syntax

```
[T,Y] = ode15i(odefun,tspan,y0,yp0)
[T,Y] = ode15i(odefun,tspan,y0,yp0,options)
[T,Y,TE,YE,IE] = ode15i(odefun,tspan,y0,yp0,options...)
sol = ode15i(odefun,[t0 tfinal],y0,yp0,...)
```

### Arguments

The following table lists the input arguments for `ode15i`.

<code>odefun</code>	A function handle that evaluates the left side of the differential equations, which are of the form $f(t,y,y') = 0$ .
<code>tspan</code>	A vector specifying the interval of integration, <code>[t0,tf]</code> . To obtain solutions at specific times (all increasing or all decreasing), use <code>tspan = [t0,t1,...,tf]</code> .
<code>y0, yp0</code>	Vectors of initial conditions for $y$ and $y'$ respectively.
<code>options</code>	Optional integration argument created using the <code>odeset</code> function. See <code>odeset</code> for details.

The following table lists the output arguments for `ode15i`.

<code>T</code>	Column vector of time points
<code>Y</code>	Solution array. Each row in $y$ corresponds to the solution at a time returned in the corresponding row of $t$ .

### Description

`[T,Y] = ode15i(odefun,tspan,y0,yp0)` with `tspan = [t0 tf]` integrates the system of differential equations  $f(t,y,y') = 0$  from time `t0` to `tf` with initial conditions `y0` and `yp0`. `odefun` is a function handle. Function `ode15i` solves ODEs and DAEs of index 1. The initial conditions must be consistent, meaning that  $f(t_0,y_0,y_0') = 0$ . You

can use the function `decic` to compute consistent initial conditions close to guessed values. Function `odefun(t,y,yp)`, for a scalar `t` and column vectors `y` and `yp`, must return a column vector corresponding to  $f(t,y,y')$ . Each row in the solution array `Y` corresponds to a time returned in the column vector `T`. To obtain solutions at specific times `t0,t1,...,tf` (all increasing or all decreasing), use `tspan = [t0,t1,...,tf]`.

“Parameterizing Functions” explains how to provide additional parameters to the function `odefun`, if necessary.

`[T,Y] = ode15i(odefun,tspan,y0,yp0,options)` solves as above with default integration parameters replaced by property values specified in `options`, an argument created with the `odeset` function. Commonly used options include a scalar relative error tolerance `RelTol` ( $1e-3$  by default) and a vector of absolute error tolerances `AbsTol` (all components  $1e-6$  by default). See `odeset` for details.

`[T,Y,TE,YE,IE] = ode15i(odefun,tspan,y0,yp0,options...)` with the 'Events' property in `options` set to a function `events`, solves as above while also finding where functions of  $(t,y,y')$ , called event functions, are zero. The function `events` is of the form `[value,isterminal,direction] = events(t,y,yp)` and includes the necessary event functions. Code the function `events` so that the `i`th element of each output vector corresponds to the `i`th event. For the `i`th event function in `events`:

- `value(i)` is the value of the function.
- `isterminal(i) = 1` if the integration is to terminate at a zero of this event function and 0 otherwise.
- `direction(i) = 0` if all zeros are to be computed (the default), `+1` if only the zeros where the event function increases, and `-1` if only the zeros where the event function decreases.

Output `TE` is a column vector of times at which events occur. Rows of `YE` are the corresponding solutions, and indices in vector `IE` specify which event occurred. See “Integrator Options” in the MATLAB Mathematics documentation for more information.

`sol = ode15i(odefun,[t0 tfinal],y0,yp0,...)` returns a structure that can be used with `deval` to evaluate the solution at any point between `t0` and `tfinal`. The structure `sol` always includes these fields:

- |                    |                                                                                                                                                                                               |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>sol.x</code> | Steps chosen by the solver. If you specify the <code>Events</code> option and a terminal event is detected, <code>sol.x(end)</code> contains the end of the step at which the event occurred. |
| <code>sol.y</code> | Each column <code>sol.y(:,i)</code> contains the solution at <code>sol.x(i)</code> .                                                                                                          |

If you specify the `Events` option and events are detected, `sol` also includes these fields:

<code>sol.xe</code>	Points at which events, if any, occurred. <code>sol.xe(end)</code> contains the exact point of a terminal event, if any.
<code>sol.ye</code>	Solutions that correspond to events in <code>sol.xe</code> .
<code>sol.ie</code>	Indices into the vector returned by the function specified in the <code>Events</code> option. The values indicate which event the solver detected.

## Options

`ode15i` accepts the following parameters in `options`. For more information, see `odeset` and “Changing ODE Integration Properties” in the MATLAB Mathematics documentation.

Error control	<code>RelTol</code> , <code>AbsTol</code> , <code>NormControl</code>
Solver output	<code>OutputFcn</code> , <code>OutputSel</code> , <code>Refine</code> , <code>Stats</code>
Event location	<code>Events</code>
Step size	<code>MaxStep</code> , <code>InitialStep</code>
Jacobian matrix	<code>Jacobian</code> , <code>JPattern</code> , <code>Vectorized</code>

## Solver Output

If you specify an output function as the value of the `OutputFcn` property, the solver calls it with the computed solution after each time step. Four output functions are provided: `odeplot`, `odephas2`, `odephas3`, `odeprint`. When you call the solver with no output arguments, it calls the default `odeplot` to plot the solution as it is computed. `odephas2` and `odephas3` produce two- and three-dimensional phase plane plots, respectively. `odeprint` displays the solution components on the screen. By default, the ODE solver passes all components of the solution to the output function. You can pass only specific components by providing a vector of indices as the value of the `OutputSel` property. For example, if you call the solver with no output arguments and set the value of `OutputSel` to `[1,3]`, the solver plots solution components 1 and 3 as they are computed.

## Jacobian Matrices

The Jacobian matrices  $\partial f/\partial y$  and  $\partial f/\partial y'$  are critical to reliability and efficiency. You can provide these matrices as one of the following:

- Function of the form  $[dfdy, dfdyp] = FJAC(t, y, yp)$  that computes the Jacobian matrices. If FJAC returns an empty matrix  $[]$  for either  $dfdy$  or  $dfdyp$ , then `ode15i` approximates that matrix by finite differences.
- Cell array of two constant matrices  $\{dfdy, dfdyp\}$ , either of which could be empty.

Use `odeset` to set the `Jacobian` option to the function or cell array. If you do not set the `Jacobian` option, `ode15i` approximates both Jacobian matrices by finite differences.

For `ode15i`, `Vectorized` is a two-element cell array. Set the first element to 'on' if `odefun(t, [y1, y2, ...], yp)` returns `[odefun(t, y1, yp), odefun(t, y2, yp), ...]`. Set the second element to 'on' if `odefun(t, y, [yp1, yp2, ...])` returns `[odefun(t, y, yp1), odefun(t, y, yp2), ...]`. The default value of `Vectorized` is `{'off', 'off'}`.

For `ode15i`, `JPattern` is also a two-element sparse matrix cell array. If  $\partial f/\partial y$  or  $\partial f/\partial y'$  is a sparse matrix, set `JPattern` to the sparsity patterns,  $\{SPDY, SPDYP\}$ . A sparsity pattern of  $\partial f/\partial y$  is a sparse matrix `SPDY` with `SPDY(i, j) = 1` if component  $i$  of  $f(t, y, yp)$  depends on component  $j$  of  $y$ , and 0 otherwise. Use `SPDY = []` to indicate that  $\partial f/\partial y$  is a full matrix. Similarly for  $\partial f/\partial y'$  and `SPDYP`. The default value of `JPattern` is  $\{[], []\}$ .

## Examples

### Solve Weissinger Implicit ODE

This example uses a helper function, `decic`, to hold fixed the initial value for  $y(t_0)$  and compute a consistent initial value for  $y'(t_0)$  for the Weissinger implicit ODE. The Weissinger function evaluates the residual of the implicit ODE.

```
t0 = 1;
y0 = sqrt(3/2);
yp0 = 0;
[y0, yp0] = decic(@weissinger, t0, y0, 1, yp0, 0);
```

Use `ode15i` to solve the ODE, and then plot the numerical solution, `y`, against the analytical solution, `ytrue`.

```
[t, y] = ode15i(@weissinger, [1 10], y0, yp0);
ytrue = sqrt(t.^2 + 0.5);
plot(t, y, t, ytrue, 'o')
```

## Other Examples

The files, `ihb1dae.m` and `iburgersode.m`, are examples of implicit ODEs.

## See Also

`decic` | `deval` | `odeget` | `odeset` | `function_handle` | `ode45` | `ode23` | `ode113` | `ode15s` | `ode23s` | `ode23t` | `ode23tb`

## ode15s

Solve stiff differential equations and DAEs; variable order method

### Syntax

```
[T,Y] = solver(odefun,tspan,y0)
[T,Y] = solver(odefun,tspan,y0,options)
[T,Y,TE,YE,IE] = solver(odefun,tspan,y0,options)
sol = solver(odefun,[t0 tf],y0...)
```

This page contains an overview of the solver functions: `ode23`, `ode45`, `ode113`, `ode15s`, `ode23s`, `ode23t`, and `ode23tb`. You can call any of these solvers by substituting the placeholder, `solver`, with any of the function names.

### Arguments

The following table describes the input arguments to the solvers.

<code>odefun</code>	A function handle that evaluates the right side of the differential equations. All solvers solve systems of equations in the form $y' = f(t,y)$ or problems that involve a mass matrix, $M(t,y)y' = f(t,y)$ . The <code>ode23s</code> solver can solve only equations with constant mass matrices. <code>ode15s</code> and <code>ode23t</code> can solve problems with a mass matrix that is singular, i.e., differential-algebraic equations (DAEs).
<code>tspan</code>	A vector specifying the interval of integration, <code>[t0,tf]</code> . The solver imposes the initial conditions at <code>tspan(1)</code> , and integrates from <code>tspan(1)</code> to <code>tspan(end)</code> . To obtain solutions at specific times (all increasing or all decreasing), use <code>tspan = [t0,t1,...,tf]</code> .  For <code>tspan</code> vectors with two elements <code>[t0 tf]</code> , the solver returns the solution evaluated at every integration step. For <code>tspan</code> vectors with more than two elements, the solver returns solutions evaluated at the given time points. The time values must be in order, either increasing or decreasing.

Specifying `tspan` with more than two elements does not affect the internal time steps that the solver uses to traverse the interval from `tspan(1)` to `tspan(end)`. All solvers in the ODE suite obtain output values by means of continuous extensions of the basic formulas. Although a solver does not necessarily step precisely to a time point specified in `tspan`, the solutions produced at the specified time points are of the same order of accuracy as the solutions computed at the internal time points.

Specifying `tspan` with more than two elements has little effect on the efficiency of computation, but for large systems, affects memory management.

`y0` A vector of initial conditions.

`options` Structure of optional parameters that change the default integration properties. This is the fourth input argument.

```
[t,y] = solver(odefun,tspan,y0,options)
```

You can create options using the `odeset` function. See `odeset` for details.

The following table lists the output arguments for the solvers.

<code>T</code>	Column vector of time points.
<code>Y</code>	Solution array. Each row in <code>Y</code> corresponds to the solution at a time returned in the corresponding row of <code>T</code> .
<code>TE</code>	The time at which an event occurs.
<code>YE</code>	The solution at the time of the event.
<code>IE</code>	The index <code>i</code> of the event function that vanishes.
<code>sol</code>	Structure to evaluate the solution.

## Description

`[T,Y] = solver(odefun,tspan,y0)` with `tspan = [t0 tf]` integrates the system of differential equations  $y' = f(t,y)$  from time `t0` to `tf` with initial conditions `y0`. The first

input argument, `odefun`, is a function handle. The function,  $f = \text{odefun}(t, y)$ , for a scalar  $t$  and a column vector  $y$ , must return a column vector  $f$  corresponding to  $f(t, y)$ . Each row in the solution array  $Y$  corresponds to a time returned in column vector  $T$ . To obtain solutions at the specific times  $t_0, t_1, \dots, t_f$  (all increasing or all decreasing), use `tspan = [t0, t1, ..., tf]`.

“Parameterizing Functions” explains how to provide additional parameters to the function `fun`, if necessary.

`[T, Y] = solver(odefun, tspan, y0, options)` solves as above with default integration parameters replaced by “property values” specified in `options`, an argument created with the `odeset` function. Commonly used properties include a scalar relative error tolerance `RelTol` ( $1e-3$  by default) and a vector of absolute error tolerances `Abstol` (all components are  $1e-6$  by default). If certain components of the solution must be nonnegative, use the `odeset` function to set the `NonNegative` property to the indices of these components. See `odeset` for details.

`[T, Y, TE, YE, IE] = solver(odefun, tspan, y0, options)` solves as above while also finding where functions of  $(t, y)$ , called event functions, are zero. For each event function, you specify whether the integration is to terminate at a zero and whether the direction of the zero crossing matters. Do this by setting the 'Events' property to a function, e.g., `events` or `@events`, and creating a function `[value, isterminal, direction] = events(t, y)`. For the  $i$ th event function in `events`,

- `value(i)` is the value of the function.
- `isterminal(i) = 1`, if the integration is to terminate at a zero of this event function and 0 otherwise.
- `direction(i) = 0` if all zeros are to be computed (the default), `+1` if only the zeros where the event function increases, and `-1` if only the zeros where the event function decreases.

Corresponding entries in `TE`, `YE`, and `IE` return, respectively, the time at which an event occurs, the solution at the time of the event, and the index  $i$  of the event function that vanishes.

`sol = solver(odefun, [t0 tf], y0...)` returns a structure that you can use with `deval` to evaluate the solution at any point on the interval `[t0, tf]`. You must pass `odefun` as a function handle. The structure `sol` always includes these fields:

`sol.x`                                      Steps chosen by the solver.

`sol.y` Each column `sol.y(:,i)` contains the solution at `sol.x(i)`.  
`sol.solver` Solver name.

If you specify the `Events` option and events are detected, `sol` also includes these fields:

`sol.xe` Points at which events, if any, occurred. `sol.xe(end)` contains the exact point of a terminal event, if any.  
`sol.ye` Solutions that correspond to events in `sol.xe`.  
`sol.ie` Indices into the vector returned by the function specified in the `Events` option. The values indicate which event the solver detected.

If you specify an output function as the value of the `OutputFcn` property, the solver calls it with the computed solution after each time step. Four output functions are provided: `odeplot`, `odephas2`, `odephas3`, `odeprint`. When you call the solver with no output arguments, it calls the default `odeplot` to plot the solution as it is computed. `odephas2` and `odephas3` produce two- and three-dimensional phase plane plots, respectively. `odeprint` displays the solution components on the screen. By default, the ODE solver passes all components of the solution to the output function. You can pass only specific components by providing a vector of indices as the value of the `OutputSel` property. For example, if you call the solver with no output arguments and set the value of `OutputSel` to `[1,3]`, the solver plots solution components 1 and 3 as they are computed.

For the stiff solvers `ode15s`, `ode23s`, `ode23t`, and `ode23tb`, the Jacobian matrix  $\partial f/\partial y$  is critical to reliability and efficiency. Use `odeset` to set `Jacobian` to `@FJAC` if `FJAC(T,Y)` returns the Jacobian  $\partial f/\partial y$  or to the matrix  $\partial f/\partial y$  if the Jacobian is constant. If the `Jacobian` property is not set (the default),  $\partial f/\partial y$  is approximated by finite differences. Set the `Vectorized` property 'on' if the ODE function is coded so that `odefun(T,[Y1,Y2 ...])` returns `[odefun(T,Y1),odefun(T,Y2) ...]`. If  $\partial f/\partial y$  is a sparse matrix, set the `JPattern` property to the sparsity pattern of  $\partial f/\partial y$ , i.e., a sparse matrix `S` with `S(i,j) = 1` if the *i*th component of  $f(t,y)$  depends on the *j*th component of *y*, and 0 otherwise.

The solvers of the ODE suite can solve problems of the form  $M(t,y)y' = f(t,y)$ , with time- and state-dependent mass matrix *M*. (The `ode23s` solver can solve only equations with constant mass matrices.) If a problem has a mass matrix, create a function `M = MASS(t,y)` that returns the value of the mass matrix, and use `odeset` to set the `Mass` property to `@MASS`. If the mass matrix is constant, the matrix should be used as the value of the `Mass` property. Problems with state-dependent mass matrices are more difficult:

- If the mass matrix does not depend on the state variable  $y$  and the function `MASS` is to be called with one input argument,  $t$ , set the `MStateDependence` property to 'none'.
- If the mass matrix depends weakly on  $y$ , set `MStateDependence` to 'weak' (the default); otherwise, set it to 'strong'. In either case, the function `MASS` is called with the two arguments  $(t,y)$ .

If there are many differential equations, it is important to exploit sparsity:

- Return a sparse  $M(t,y)$ .
- Supply the sparsity pattern of  $\partial f/\partial y$  using the `JPattern` property or a sparse  $\partial f/\partial y$  using the `Jacobian` property.
- For strongly state-dependent  $M(t,y)$ , set `MvPattern` to a sparse matrix  $S$  with  $S(i,j) = 1$  if for any  $k$ , the  $(i,k)$  component of  $M(t,y)$  depends on component  $j$  of  $y$ , and 0 otherwise.

If the mass matrix  $M$  is singular, then  $M(t,y)y' = f(t,y)$  is a system of differential algebraic equations. DAEs have solutions only when  $y_0$  is consistent, that is, if there is a vector  $yp_0$  such that  $M(t_0,y_0)yp_0 = f(t_0,y_0)$ . The `ode15s` and `ode23t` solvers can solve DAEs of index 1 provided that  $y_0$  is sufficiently close to being consistent. If there is a mass matrix, you can use `odeset` to set the `MassSingular` property to 'yes', 'no', or 'maybe'. The default value of 'maybe' causes the solver to test whether the problem is a DAE. You can provide  $yp_0$  as the value of the `InitialSlope` property. The default is the zero vector. If a problem is a DAE, and  $y_0$  and  $yp_0$  are not consistent, the solver treats them as guesses, attempts to compute consistent values that are close to the guesses, and continues to solve the problem. When solving DAEs, it is very advantageous to formulate the problem so that  $M$  is a diagonal matrix (a semi-explicit DAE).

Solver	Problem Type	Order of Accuracy	When to Use
ode45	Nonstiff	Medium	Most of the time. This should be the first solver you try.
ode23	Nonstiff	Low	For problems with crude error tolerances or for solving moderately stiff problems.
ode113	Nonstiff	Low to high	For problems with stringent error tolerances or for solving computationally intensive problems.

Solver	Problem Type	Order of Accuracy	When to Use
ode15s	Stiff	Low to medium	If ode45 is slow because the problem is stiff.
ode23s	Stiff	Low	If using crude error tolerances to solve stiff systems and the mass matrix is constant.
ode23t	Moderately Stiff	Low	For moderately stiff problems if you need a solution without numerical damping.
ode23tb	Stiff	Low	If using crude error tolerances to solve stiff systems.

The algorithms used in the ODE solvers vary according to order of accuracy [6] and the type of systems (stiff or nonstiff) they are designed to solve. See “Algorithms” on page 1-5322 for more details.

## Options

Different solvers accept different parameters in the options list. For more information, see `odeset` and “Integrator Options” in the MATLAB Mathematics documentation.

Parameters	ode45	ode23	ode113	ode15s	ode23s	ode23t	ode23tb
RelTol, AbsTol, NormControl	√	√	√	√	√	√	√
OutputFcn, OutputSel, Refine, Stats	√	√	√	√	√	√	√
NonNegative	√	√	√	√ *	—	√ *	√ *
Events	√	√	√	√	√	√	√
MaxStep, InitialStep	√	√	√	√	√	√	√

Parameters	ode45	ode23	ode113	ode15s	ode23s	ode23t	ode23tb
Jacobian, JPattern, Vectorized	—	—	—	√	√	√	√
Mass	√	√	√	√	√	√	√
MStateDependence	√	√	√	√	—	√	√
MvPattern	—	—	—	√	—	√	√
MassSingular	—	—	—	√	—	√	—
InitialSlope	—	—	—	√	—	√	—
MaxOrder, BDF	—	—	—	√	—	—	—

**Note** You can use the `NonNegative` parameter with `ode15s`, `ode23t`, and `ode23tb` only for those problems for which there is no mass matrix.

## Examples

### Example 1

An example of a nonstiff system is the system of equations describing the motion of a rigid body without external forces.

$$\begin{aligned} y_1' &= y_2 y_3 & y_1(0) &= 0 \\ y_2' &= -y_1 y_3 & y_2(0) &= 1 \\ y_3' &= -0.51 y_1 y_2 & y_3(0) &= 1 \end{aligned}$$

To simulate this system, create a function `rigid` containing the equations

```
function dy = rigid(t,y)
dy = zeros(3,1); % a column vector
dy(1) = y(2) * y(3);
dy(2) = -y(1) * y(3);
dy(3) = -0.51 * y(1) * y(2);
```

In this example we change the error tolerances using the `odeset` command and solve on a time interval `[0 12]` with an initial condition vector `[0 1 1]` at time 0.

```
options = odeset('RelTol',1e-4,'AbsTol',[1e-4 1e-4 1e-5]);
[T,Y] = ode45(@rigid,[0 12],[0 1 1],options);
```

Plotting the columns of the returned array Y versus T shows the solution

```
plot(T,Y(:,1),'-',T,Y(:,2),'-.',T,Y(:,3),'.');
```

## Example 2

An example of a stiff system is provided by the van der Pol equations in relaxation oscillation. The limit cycle has portions where the solution components change slowly and the problem is quite stiff, alternating with regions of very sharp change where it is not stiff.

$$\begin{aligned}y_1' &= y_2 & y_1(0) &= 2 \\y_2' &= 1000(1 - y_1^2)y_2 - y_1 & y_2(0) &= 0\end{aligned}$$

To simulate this system, create a function `vdp1000` containing the equations

```
function dy = vdp1000(t,y)
dy = zeros(2,1); % a column vector
dy(1) = y(2);
dy(2) = 1000*(1 - y(1)^2)*y(2) - y(1);
```

For this problem, we will use the default relative and absolute tolerances ( $1e-3$  and  $1e-6$ , respectively) and solve on a time interval of `[0 3000]` with initial condition vector `[2 0]` at time 0.

```
[T,Y] = ode15s(@vdp1000,[0 3000],[2 0]);
```

Plotting the first column of the returned matrix `Y` versus `T` shows the solution

```
plot(T,Y(:,1),'-o')
```

### Example 3

This example solves an ordinary differential equation with time-dependent terms.

Consider the following ODE, with time-dependent parameters defined only through the set of data points given in two vectors:

$$y'(t) + f(t)y(t) = g(t)$$

The initial condition is  $y(1) = 1$ , where the function  $f(t)$  is defined by the  $n$ -by-1 vector  $f$  evaluated at times  $ft$ , and the function  $g(t)$  is defined by the  $m$ -by-1 vector  $g$  evaluated at times  $gt$ .

First, define the time-dependent parameters  $f(t)$  and  $g(t)$  as the following:

```
ft = linspace(0,5,25); % Generate t for f
f = ft.^2 - ft - 3; % Generate f(t)
gt = linspace(1,6,25); % Generate t for g
g = 3*sin(gt-0.25); % Generate g(t)
```

Write a function to interpolate the data sets specified above to obtain the value of the time-dependent terms at the specified time:

```
function dydt = myode(t,y,ft,f,gt,g)
f = interp1(ft,f,t); % Interpolate the data set (ft,f) at time t
g = interp1(gt,g,t); % Interpolate the data set (gt,g) at time t
dydt = -f.*y + g; % Evaluate ODE at time t
Call the derivative function myode.m within the MATLAB ode45 function specifying
time as the first input argument :
```

```
Tspan = [1 5]; % Solve from t=1 to t=5
IC = 1; % y(t=1) = 1
[T Y] = ode45(@(t,y) myode(t,y,ft,f,gt,g),Tspan,IC); % Solve ODE
Plot the solution y(t) as a function of time:
```

```
plot(T, Y);
title('Plot of y as a function of time');
xlabel('Time');
ylabel('Y(t)');
```

## More About

### Algorithms

`ode45` is based on an explicit Runge-Kutta (4,5) formula, the Dormand-Prince pair. It is a *one-step* solver – in computing  $y(t_n)$ , it needs only the solution at the immediately preceding time point,  $y(t_{n-1})$ . In general, `ode45` is the best function to apply as a *first try* for most problems. [3]

`ode23` is an implementation of an explicit Runge-Kutta (2,3) pair of Bogacki and Shampine. It may be more efficient than `ode45` at crude tolerances and in the presence of moderate stiffness. Like `ode45`, `ode23` is a one-step solver. [2]

`ode113` is a variable order Adams-Bashforth-Moulton PECE solver. It may be more efficient than `ode45` at stringent tolerances and when the ODE file function is particularly expensive to evaluate. `ode113` is a *multistep* solver — it normally needs the solutions at several preceding time points to compute the current solution. [7]

The above algorithms are intended to solve nonstiff systems. If they appear to be unduly slow, try using one of the stiff solvers below.

`ode15s` is a variable order solver based on the numerical differentiation formulas (NDFs). Optionally, it uses the backward differentiation formulas (BDFs, also known as Gear's method) that are usually less efficient. Like `ode113`, `ode15s` is a multistep solver. Try `ode15s` when `ode45` fails, or is very inefficient, and you suspect that the problem is stiff, or when solving a differential-algebraic problem. [9], [10]

`ode23s` is based on a modified Rosenbrock formula of order 2. Because it is a one-step solver, it may be more efficient than `ode15s` at crude tolerances. It can solve some kinds of stiff problems for which `ode15s` is not effective. [9]

`ode23t` is an implementation of the trapezoidal rule using a “free” interpolant. Use this solver if the problem is only moderately stiff and you need a solution without numerical damping. `ode23t` can solve DAEs. [10]

`ode23tb` is an implementation of TR-BDF2, an implicit Runge-Kutta formula with a first stage that is a trapezoidal rule step and a second stage that is a backward differentiation formula of order two. By construction, the same iteration matrix is used in evaluating both stages. Like `ode23s`, this solver may be more efficient than `ode15s` at crude tolerances. [8], [1]

# ode23

Solve nonstiff differential equations; low order method

## Syntax

```
[T,Y] = solver(odefun,tspan,y0)
[T,Y] = solver(odefun,tspan,y0,options)
[T,Y,TE,YE,IE] = solver(odefun,tspan,y0,options)
sol = solver(odefun,[t0 tf],y0...)
```

This page contains an overview of the solver functions: `ode23`, `ode45`, `ode113`, `ode15s`, `ode23s`, `ode23t`, and `ode23tb`. You can call any of these solvers by substituting the placeholder, `solver`, with any of the function names.

## Arguments

The following table describes the input arguments to the solvers.

<code>odefun</code>	A function handle that evaluates the right side of the differential equations. All solvers solve systems of equations in the form $y' = f(t,y)$ or problems that involve a mass matrix, $M(t,y)y' = f(t,y)$ . The <code>ode23s</code> solver can solve only equations with constant mass matrices. <code>ode15s</code> and <code>ode23t</code> can solve problems with a mass matrix that is singular, i.e., differential-algebraic equations (DAEs).
<code>tspan</code>	A vector specifying the interval of integration, <code>[t0,tf]</code> . The solver imposes the initial conditions at <code>tspan(1)</code> , and integrates from <code>tspan(1)</code> to <code>tspan(end)</code> . To obtain solutions at specific times (all increasing or all decreasing), use <code>tspan = [t0,t1,...,tf]</code> .

For `tspan` vectors with two elements `[t0 tf]`, the solver returns the solution evaluated at every integration step. For `tspan` vectors with more than two elements, the solver returns solutions evaluated at the given time points. The time values must be in order, either increasing or decreasing.

Specifying `tspan` with more than two elements does not affect the internal time steps that the solver uses to traverse the interval from `tspan(1)` to `tspan(end)`. All solvers in the ODE suite obtain output values by means of continuous extensions of the basic formulas. Although a solver does not necessarily step precisely to a time point specified in `tspan`, the solutions produced at the specified time points are of the same order of accuracy as the solutions computed at the internal time points.

Specifying `tspan` with more than two elements has little effect on the efficiency of computation, but for large systems, affects memory management.

`y0` A vector of initial conditions.

`options` Structure of optional parameters that change the default integration properties. This is the fourth input argument.

`[t,y] = solver(odefun,tspan,y0,options)`

You can create options using the `odeset` function. See `odeset` for details.

The following table lists the output arguments for the solvers.

<code>T</code>	Column vector of time points.
<code>Y</code>	Solution array. Each row in <code>Y</code> corresponds to the solution at a time returned in the corresponding row of <code>T</code> .
<code>TE</code>	The time at which an event occurs.
<code>YE</code>	The solution at the time of the event.
<code>IE</code>	The index <code>i</code> of the event function that vanishes.
<code>sol</code>	Structure to evaluate the solution.

## Description

`[T,Y] = solver(odefun,tspan,y0)` with `tspan = [t0 tf]` integrates the system of differential equations  $y' = f(t,y)$  from time `t0` to `tf` with initial conditions `y0`. The first

input argument, `odefun`, is a function handle. The function,  $f = \text{odefun}(t, y)$ , for a scalar  $t$  and a column vector  $y$ , must return a column vector  $f$  corresponding to  $f(t, y)$ . Each row in the solution array  $Y$  corresponds to a time returned in column vector  $T$ . To obtain solutions at the specific times  $t_0, t_1, \dots, t_f$  (all increasing or all decreasing), use `tspan = [t0, t1, ..., tf]`.

“Parameterizing Functions” explains how to provide additional parameters to the function `fun`, if necessary.

`[T, Y] = solver(odefun, tspan, y0, options)` solves as above with default integration parameters replaced by “property values” specified in `options`, an argument created with the `odeset` function. Commonly used properties include a scalar relative error tolerance `RelTol` ( $1e-3$  by default) and a vector of absolute error tolerances `Abstol` (all components are  $1e-6$  by default). If certain components of the solution must be nonnegative, use the `odeset` function to set the `NonNegative` property to the indices of these components. See `odeset` for details.

`[T, Y, TE, YE, IE] = solver(odefun, tspan, y0, options)` solves as above while also finding where functions of  $(t, y)$ , called event functions, are zero. For each event function, you specify whether the integration is to terminate at a zero and whether the direction of the zero crossing matters. Do this by setting the 'Events' property to a function, e.g., `events` or `@events`, and creating a function `[value, isterminal, direction] = events(t, y)`. For the  $i$ th event function in `events`,

- `value(i)` is the value of the function.
- `isterminal(i) = 1`, if the integration is to terminate at a zero of this event function and 0 otherwise.
- `direction(i) = 0` if all zeros are to be computed (the default), +1 if only the zeros where the event function increases, and -1 if only the zeros where the event function decreases.

Corresponding entries in `TE`, `YE`, and `IE` return, respectively, the time at which an event occurs, the solution at the time of the event, and the index  $i$  of the event function that vanishes.

`sol = solver(odefun, [t0 tf], y0...)` returns a structure that you can use with `deval` to evaluate the solution at any point on the interval `[t0, tf]`. You must pass `odefun` as a function handle. The structure `sol` always includes these fields:

`sol.x`                      Steps chosen by the solver.

`sol.y` Each column `sol.y(:,i)` contains the solution at `sol.x(i)`.  
`sol.solver` Solver name.

If you specify the `Events` option and events are detected, `sol` also includes these fields:

`sol.xe` Points at which events, if any, occurred. `sol.xe(end)` contains the exact point of a terminal event, if any.  
`sol.ye` Solutions that correspond to events in `sol.xe`.  
`sol.ie` Indices into the vector returned by the function specified in the `Events` option. The values indicate which event the solver detected.

If you specify an output function as the value of the `OutputFcn` property, the solver calls it with the computed solution after each time step. Four output functions are provided: `odeplot`, `odephas2`, `odephas3`, `odeprint`. When you call the solver with no output arguments, it calls the default `odeplot` to plot the solution as it is computed. `odephas2` and `odephas3` produce two- and three-dimensional phase plane plots, respectively. `odeprint` displays the solution components on the screen. By default, the ODE solver passes all components of the solution to the output function. You can pass only specific components by providing a vector of indices as the value of the `OutputSel` property. For example, if you call the solver with no output arguments and set the value of `OutputSel` to `[1,3]`, the solver plots solution components 1 and 3 as they are computed.

For the stiff solvers `ode15s`, `ode23s`, `ode23t`, and `ode23tb`, the Jacobian matrix  $\partial f/\partial y$  is critical to reliability and efficiency. Use `odeset` to set `Jacobian` to `@FJAC` if `FJAC(T,Y)` returns the Jacobian  $\partial f/\partial y$  or to the matrix  $\partial f/\partial y$  if the Jacobian is constant. If the `Jacobian` property is not set (the default),  $\partial f/\partial y$  is approximated by finite differences. Set the `Vectorized` property 'on' if the ODE function is coded so that `odefun(T,[Y1,Y2 ...])` returns `[odefun(T,Y1),odefun(T,Y2) ...]`. If  $\partial f/\partial y$  is a sparse matrix, set the `JPattern` property to the sparsity pattern of  $\partial f/\partial y$ , i.e., a sparse matrix `S` with `S(i,j) = 1` if the *i*th component of  $f(t,y)$  depends on the *j*th component of  $y$ , and 0 otherwise.

The solvers of the ODE suite can solve problems of the form  $M(t,y)y' = f(t,y)$ , with time- and state-dependent mass matrix  $M$ . (The `ode23s` solver can solve only equations with constant mass matrices.) If a problem has a mass matrix, create a function `M = MASS(t,y)` that returns the value of the mass matrix, and use `odeset` to set the `Mass` property to `@MASS`. If the mass matrix is constant, the matrix should be used as the value of the `Mass` property. Problems with state-dependent mass matrices are more difficult:

- If the mass matrix does not depend on the state variable  $y$  and the function `MASS` is to be called with one input argument,  $t$ , set the `MStateDependence` property to 'none'.
- If the mass matrix depends weakly on  $y$ , set `MStateDependence` to 'weak' (the default); otherwise, set it to 'strong'. In either case, the function `MASS` is called with the two arguments  $(t,y)$ .

If there are many differential equations, it is important to exploit sparsity:

- Return a sparse  $M(t,y)$ .
- Supply the sparsity pattern of  $\partial f/\partial y$  using the `JPattern` property or a sparse  $\partial f/\partial y$  using the `Jacobian` property.
- For strongly state-dependent  $M(t,y)$ , set `MvPattern` to a sparse matrix  $S$  with  $S(i,j) = 1$  if for any  $k$ , the  $(i,k)$  component of  $M(t,y)$  depends on component  $j$  of  $y$ , and 0 otherwise.

If the mass matrix  $M$  is singular, then  $M(t,y)y' = f(t,y)$  is a system of differential algebraic equations. DAEs have solutions only when  $y_0$  is consistent, that is, if there is a vector  $yp_0$  such that  $M(t_0,y_0)yp_0 = f(t_0,y_0)$ . The `ode15s` and `ode23t` solvers can solve DAEs of index 1 provided that  $y_0$  is sufficiently close to being consistent. If there is a mass matrix, you can use `odeset` to set the `MassSingular` property to 'yes', 'no', or 'maybe'. The default value of 'maybe' causes the solver to test whether the problem is a DAE. You can provide  $yp_0$  as the value of the `InitialSlope` property. The default is the zero vector. If a problem is a DAE, and  $y_0$  and  $yp_0$  are not consistent, the solver treats them as guesses, attempts to compute consistent values that are close to the guesses, and continues to solve the problem. When solving DAEs, it is very advantageous to formulate the problem so that  $M$  is a diagonal matrix (a semi-explicit DAE).

Solver	Problem Type	Order of Accuracy	When to Use
ode45	Nonstiff	Medium	Most of the time. This should be the first solver you try.
ode23	Nonstiff	Low	For problems with crude error tolerances or for solving moderately stiff problems.
ode113	Nonstiff	Low to high	For problems with stringent error tolerances or for solving computationally intensive problems.

Solver	Problem Type	Order of Accuracy	When to Use
ode15s	Stiff	Low to medium	If ode45 is slow because the problem is stiff.
ode23s	Stiff	Low	If using crude error tolerances to solve stiff systems and the mass matrix is constant.
ode23t	Moderately Stiff	Low	For moderately stiff problems if you need a solution without numerical damping.
ode23tb	Stiff	Low	If using crude error tolerances to solve stiff systems.

The algorithms used in the ODE solvers vary according to order of accuracy [6] and the type of systems (stiff or nonstiff) they are designed to solve. See “Algorithms” on page 1-5336 for more details.

## Options

Different solvers accept different parameters in the options list. For more information, see `odeset` and “Integrator Options” in the MATLAB Mathematics documentation.

Parameters	ode45	ode23	ode113	ode15s	ode23s	ode23t	ode23tb
RelTol, AbsTol, NormControl	√	√	√	√	√	√	√
OutputFcn, OutputSel, Refine, Stats	√	√	√	√	√	√	√
NonNegative	√	√	√	√ *	—	√ *	√ *
Events	√	√	√	√	√	√	√
MaxStep, InitialStep	√	√	√	√	√	√	√

Parameters	ode45	ode23	ode113	ode15s	ode23s	ode23t	ode23tb
Jacobian, JPattern, Vectorized	—	—	—	√	√	√	√
Mass	√	√	√	√	√	√	√
MStateDependence	√	√	√	√	—	√	√
MvPattern	—	—	—	√	—	√	√
MassSingular	—	—	—	√	—	√	—
InitialSlope	—	—	—	√	—	√	—
MaxOrder, BDF	—	—	—	√	—	—	—

**Note** You can use the `NonNegative` parameter with `ode15s`, `ode23t`, and `ode23tb` only for those problems for which there is no mass matrix.

## Examples

### Example 1

An example of a nonstiff system is the system of equations describing the motion of a rigid body without external forces.

$$\begin{aligned}
 y_1' &= y_2 y_3 & y_1(0) &= 0 \\
 y_2' &= -y_1 y_3 & y_2(0) &= 1 \\
 y_3' &= -0.51 y_1 y_2 & y_3(0) &= 1
 \end{aligned}$$

To simulate this system, create a function `rigid` containing the equations

```
function dy = rigid(t,y)
dy = zeros(3,1); % a column vector
dy(1) = y(2) * y(3);
dy(2) = -y(1) * y(3);
dy(3) = -0.51 * y(1) * y(2);
```

In this example we change the error tolerances using the `odeset` command and solve on a time interval `[0 12]` with an initial condition vector `[0 1 1]` at time 0.

```
options = odeset('RelTol',1e-4,'AbsTol',[1e-4 1e-4 1e-5]);
[T,Y] = ode45(@rigid,[0 12],[0 1 1],options);
```

Plotting the columns of the returned array Y versus T shows the solution

```
plot(T,Y(:,1),'-',T,Y(:,2),'-.',T,Y(:,3),'.');
```

## Example 2

An example of a stiff system is provided by the van der Pol equations in relaxation oscillation. The limit cycle has portions where the solution components change slowly and the problem is quite stiff, alternating with regions of very sharp change where it is not stiff.

$$\begin{aligned}y_1' &= y_2 & y_1(0) &= 2 \\y_2' &= 1000(1 - y_1^2)y_2 - y_1 & y_2(0) &= 0\end{aligned}$$

To simulate this system, create a function `vdp1000` containing the equations

```
function dy = vdp1000(t,y)
dy = zeros(2,1); % a column vector
dy(1) = y(2);
dy(2) = 1000*(1 - y(1)^2)*y(2) - y(1);
```

For this problem, we will use the default relative and absolute tolerances ( $1e-3$  and  $1e-6$ , respectively) and solve on a time interval of `[0 3000]` with initial condition vector `[2 0]` at time 0.

```
[T,Y] = ode15s(@vdp1000,[0 3000],[2 0]);
```

Plotting the first column of the returned matrix `Y` versus `T` shows the solution

```
plot(T,Y(:,1),'-o')
```

### Example 3

This example solves an ordinary differential equation with time-dependent terms.

Consider the following ODE, with time-dependent parameters defined only through the set of data points given in two vectors:

$$y'(t) + f(t)y(t) = g(t)$$

The initial condition is  $y(1) = 1$ , where the function  $f(t)$  is defined by the  $n$ -by-1 vector  $f$  evaluated at times  $ft$ , and the function  $g(t)$  is defined by the  $m$ -by-1 vector  $g$  evaluated at times  $gt$ .

First, define the time-dependent parameters  $f(t)$  and  $g(t)$  as the following:

```
ft = linspace(0,5,25); % Generate t for f
f = ft.^2 - ft - 3; % Generate f(t)
gt = linspace(1,6,25); % Generate t for g
g = 3*sin(gt-0.25); % Generate g(t)
```

Write a function to interpolate the data sets specified above to obtain the value of the time-dependent terms at the specified time:

```
function dydt = myode(t,y,ft,f,gt,g)
f = interp1(ft,f,t); % Interpolate the data set (ft,f) at time t
g = interp1(gt,g,t); % Interpolate the data set (gt,g) at time t
dydt = -f.*y + g; % Evaluate ODE at time t
Call the derivative function myode.m within the MATLAB ode45 function specifying
time as the first input argument :
```

```
Tspan = [1 5]; % Solve from t=1 to t=5
IC = 1; % y(t=1) = 1
[T Y] = ode45(@(t,y) myode(t,y,ft,f,gt,g),Tspan,IC); % Solve ODE
Plot the solution y(t) as a function of time:
```

```
plot(T, Y);
title('Plot of y as a function of time');
xlabel('Time');
ylabel('Y(t)');
```

## More About

### Algorithms

`ode45` is based on an explicit Runge-Kutta (4,5) formula, the Dormand-Prince pair. It is a *one-step* solver – in computing  $y(t_n)$ , it needs only the solution at the immediately preceding time point,  $y(t_{n-1})$ . In general, `ode45` is the best function to apply as a *first try* for most problems. [3]

`ode23` is an implementation of an explicit Runge-Kutta (2,3) pair of Bogacki and Shampine. It may be more efficient than `ode45` at crude tolerances and in the presence of moderate stiffness. Like `ode45`, `ode23` is a one-step solver. [2]

`ode113` is a variable order Adams-Bashforth-Moulton PECE solver. It may be more efficient than `ode45` at stringent tolerances and when the ODE file function is particularly expensive to evaluate. `ode113` is a *multistep* solver — it normally needs the solutions at several preceding time points to compute the current solution. [7]

The above algorithms are intended to solve nonstiff systems. If they appear to be unduly slow, try using one of the stiff solvers below.

`ode15s` is a variable order solver based on the numerical differentiation formulas (NDFs). Optionally, it uses the backward differentiation formulas (BDFs, also known as Gear's method) that are usually less efficient. Like `ode113`, `ode15s` is a multistep solver. Try `ode15s` when `ode45` fails, or is very inefficient, and you suspect that the problem is stiff, or when solving a differential-algebraic problem. [9], [10]

`ode23s` is based on a modified Rosenbrock formula of order 2. Because it is a one-step solver, it may be more efficient than `ode15s` at crude tolerances. It can solve some kinds of stiff problems for which `ode15s` is not effective. [9]

`ode23t` is an implementation of the trapezoidal rule using a “free” interpolant. Use this solver if the problem is only moderately stiff and you need a solution without numerical damping. `ode23t` can solve DAEs. [10]

`ode23tb` is an implementation of TR-BDF2, an implicit Runge-Kutta formula with a first stage that is a trapezoidal rule step and a second stage that is a backward differentiation formula of order two. By construction, the same iteration matrix is used in evaluating both stages. Like `ode23s`, this solver may be more efficient than `ode15s` at crude tolerances. [8], [1]

## ode23s

Solve stiff differential equations; low order method

### Syntax

```
[T,Y] = solver(odefun,tspan,y0)
[T,Y] = solver(odefun,tspan,y0,options)
[T,Y,TE,YE,IE] = solver(odefun,tspan,y0,options)
sol = solver(odefun,[t0 tf],y0...)
```

This page contains an overview of the solver functions: `ode23`, `ode45`, `ode113`, `ode15s`, `ode23s`, `ode23t`, and `ode23tb`. You can call any of these solvers by substituting the placeholder, `solver`, with any of the function names.

### Arguments

The following table describes the input arguments to the solvers.

<code>odefun</code>	A function handle that evaluates the right side of the differential equations. All solvers solve systems of equations in the form $y' = f(t,y)$ or problems that involve a mass matrix, $M(t,y)y' = f(t,y)$ . The <code>ode23s</code> solver can solve only equations with constant mass matrices. <code>ode15s</code> and <code>ode23t</code> can solve problems with a mass matrix that is singular, i.e., differential-algebraic equations (DAEs).
<code>tspan</code>	A vector specifying the interval of integration, <code>[t0,tf]</code> . The solver imposes the initial conditions at <code>tspan(1)</code> , and integrates from <code>tspan(1)</code> to <code>tspan(end)</code> . To obtain solutions at specific times (all increasing or all decreasing), use <code>tspan = [t0,t1,...,tf]</code> .  For <code>tspan</code> vectors with two elements <code>[t0 tf]</code> , the solver returns the solution evaluated at every integration step. For <code>tspan</code> vectors with more than two elements, the solver returns solutions evaluated at the given time points. The time values must be in order, either increasing or decreasing.

Specifying `tspan` with more than two elements does not affect the internal time steps that the solver uses to traverse the interval from `tspan(1)` to `tspan(end)`. All solvers in the ODE suite obtain output values by means of continuous extensions of the basic formulas. Although a solver does not necessarily step precisely to a time point specified in `tspan`, the solutions produced at the specified time points are of the same order of accuracy as the solutions computed at the internal time points.

Specifying `tspan` with more than two elements has little effect on the efficiency of computation, but for large systems, affects memory management.

`y0`

A vector of initial conditions.

`options`

Structure of optional parameters that change the default integration properties. This is the fourth input argument.

`[t,y] = solver(odefun,tspan,y0,options)`

You can create options using the `odeset` function. See `odeset` for details.

The following table lists the output arguments for the solvers.

<code>T</code>	Column vector of time points.
<code>Y</code>	Solution array. Each row in <code>Y</code> corresponds to the solution at a time returned in the corresponding row of <code>T</code> .
<code>TE</code>	The time at which an event occurs.
<code>YE</code>	The solution at the time of the event.
<code>IE</code>	The index <code>i</code> of the event function that vanishes.
<code>sol</code>	Structure to evaluate the solution.

## Description

`[T,Y] = solver(odefun,tspan,y0)` with `tspan = [t0 tf]` integrates the system of differential equations  $y' = f(t,y)$  from time `t0` to `tf` with initial conditions `y0`. The first

input argument, `odefun`, is a function handle. The function, `f = odefun(t,y)`, for a scalar `t` and a column vector `y`, must return a column vector `f` corresponding to  $f(t,y)$ . Each row in the solution array `Y` corresponds to a time returned in column vector `T`. To obtain solutions at the specific times `t0, t1, ..., tf` (all increasing or all decreasing), use `tspan = [t0,t1, ..., tf]`.

“Parameterizing Functions” explains how to provide additional parameters to the function `fun`, if necessary.

`[T,Y] = solver(odefun,tspan,y0,options)` solves as above with default integration parameters replaced by “property values” specified in `options`, an argument created with the `odeset` function. Commonly used properties include a scalar relative error tolerance `RelTol` (`1e-3` by default) and a vector of absolute error tolerances `Abstol` (all components are `1e-6` by default). If certain components of the solution must be nonnegative, use the `odeset` function to set the `NonNegative` property to the indices of these components. See `odeset` for details.

`[T,Y,TE,YE,IE] = solver(odefun,tspan,y0,options)` solves as above while also finding where functions of  $(t,y)$ , called event functions, are zero. For each event function, you specify whether the integration is to terminate at a zero and whether the direction of the zero crossing matters. Do this by setting the 'Events' property to a function, e.g., `events` or `@events`, and creating a function `[value,isterminal,direction] = events(t,y)`. For the `i`th event function in `events`,

- `value(i)` is the value of the function.
- `isterminal(i) = 1`, if the integration is to terminate at a zero of this event function and `0` otherwise.
- `direction(i) = 0` if all zeros are to be computed (the default), `+1` if only the zeros where the event function increases, and `-1` if only the zeros where the event function decreases.

Corresponding entries in `TE`, `YE`, and `IE` return, respectively, the time at which an event occurs, the solution at the time of the event, and the index `i` of the event function that vanishes.

`sol = solver(odefun,[t0 tf],y0...)` returns a structure that you can use with `deval` to evaluate the solution at any point on the interval `[t0,tf]`. You must pass `odefun` as a function handle. The structure `sol` always includes these fields:

`sol.x`                      Steps chosen by the solver.

`sol.y` Each column `sol.y(:,i)` contains the solution at `sol.x(i)`.  
`sol.solver` Solver name.

If you specify the `Events` option and events are detected, `sol` also includes these fields:

`sol.xe` Points at which events, if any, occurred. `sol.xe(end)` contains the exact point of a terminal event, if any.  
`sol.ye` Solutions that correspond to events in `sol.xe`.  
`sol.ie` Indices into the vector returned by the function specified in the `Events` option. The values indicate which event the solver detected.

If you specify an output function as the value of the `OutputFcn` property, the solver calls it with the computed solution after each time step. Four output functions are provided: `odeplot`, `odephas2`, `odephas3`, `odeprint`. When you call the solver with no output arguments, it calls the default `odeplot` to plot the solution as it is computed. `odephas2` and `odephas3` produce two- and three-dimensional phase plane plots, respectively. `odeprint` displays the solution components on the screen. By default, the ODE solver passes all components of the solution to the output function. You can pass only specific components by providing a vector of indices as the value of the `OutputSel` property. For example, if you call the solver with no output arguments and set the value of `OutputSel` to `[1,3]`, the solver plots solution components 1 and 3 as they are computed.

For the stiff solvers `ode15s`, `ode23s`, `ode23t`, and `ode23tb`, the Jacobian matrix  $\partial f/\partial y$  is critical to reliability and efficiency. Use `odeset` to set `Jacobian` to `@FJAC` if `FJAC(T,Y)` returns the Jacobian  $\partial f/\partial y$  or to the matrix  $\partial f/\partial y$  if the Jacobian is constant. If the `Jacobian` property is not set (the default),  $\partial f/\partial y$  is approximated by finite differences. Set the `Vectorized` property 'on' if the ODE function is coded so that `odefun(T,[Y1,Y2 ...])` returns `[odefun(T,Y1),odefun(T,Y2) ...]`. If  $\partial f/\partial y$  is a sparse matrix, set the `JPattern` property to the sparsity pattern of  $\partial f/\partial y$ , i.e., a sparse matrix `S` with `S(i,j) = 1` if the *i*th component of  $f(t,y)$  depends on the *j*th component of  $y$ , and 0 otherwise.

The solvers of the ODE suite can solve problems of the form  $M(t,y)y' = f(t,y)$ , with time- and state-dependent mass matrix  $M$ . (The `ode23s` solver can solve only equations with constant mass matrices.) If a problem has a mass matrix, create a function `M = MASS(t,y)` that returns the value of the mass matrix, and use `odeset` to set the `Mass` property to `@MASS`. If the mass matrix is constant, the matrix should be used as the value of the `Mass` property. Problems with state-dependent mass matrices are more difficult:

- If the mass matrix does not depend on the state variable  $y$  and the function `MASS` is to be called with one input argument,  $t$ , set the `MStateDependence` property to 'none'.
- If the mass matrix depends weakly on  $y$ , set `MStateDependence` to 'weak' (the default); otherwise, set it to 'strong'. In either case, the function `MASS` is called with the two arguments  $(t,y)$ .

If there are many differential equations, it is important to exploit sparsity:

- Return a sparse  $M(t,y)$ .
- Supply the sparsity pattern of  $\partial f/\partial y$  using the `JPattern` property or a sparse  $\partial f/\partial y$  using the `Jacobian` property.
- For strongly state-dependent  $M(t,y)$ , set `MvPattern` to a sparse matrix  $S$  with  $S(i,j) = 1$  if for any  $k$ , the  $(i,k)$  component of  $M(t,y)$  depends on component  $j$  of  $y$ , and 0 otherwise.

If the mass matrix  $M$  is singular, then  $M(t,y)y' = f(t,y)$  is a system of differential algebraic equations. DAEs have solutions only when  $y_0$  is consistent, that is, if there is a vector  $yp_0$  such that  $M(t_0,y_0)yp_0 = f(t_0,y_0)$ . The `ode15s` and `ode23t` solvers can solve DAEs of index 1 provided that  $y_0$  is sufficiently close to being consistent. If there is a mass matrix, you can use `odeset` to set the `MassSingular` property to 'yes', 'no', or 'maybe'. The default value of 'maybe' causes the solver to test whether the problem is a DAE. You can provide  $yp_0$  as the value of the `InitialSlope` property. The default is the zero vector. If a problem is a DAE, and  $y_0$  and  $yp_0$  are not consistent, the solver treats them as guesses, attempts to compute consistent values that are close to the guesses, and continues to solve the problem. When solving DAEs, it is very advantageous to formulate the problem so that  $M$  is a diagonal matrix (a semi-explicit DAE).

Solver	Problem Type	Order of Accuracy	When to Use
ode45	Nonstiff	Medium	Most of the time. This should be the first solver you try.
ode23	Nonstiff	Low	For problems with crude error tolerances or for solving moderately stiff problems.
ode113	Nonstiff	Low to high	For problems with stringent error tolerances or for solving computationally intensive problems.

Solver	Problem Type	Order of Accuracy	When to Use
ode15s	Stiff	Low to medium	If ode45 is slow because the problem is stiff.
ode23s	Stiff	Low	If using crude error tolerances to solve stiff systems and the mass matrix is constant.
ode23t	Moderately Stiff	Low	For moderately stiff problems if you need a solution without numerical damping.
ode23tb	Stiff	Low	If using crude error tolerances to solve stiff systems.

The algorithms used in the ODE solvers vary according to order of accuracy [6] and the type of systems (stiff or nonstiff) they are designed to solve. See “Algorithms” on page 1-5350 for more details.

## Options

Different solvers accept different parameters in the options list. For more information, see `odeset` and “Integrator Options” in the MATLAB Mathematics documentation.

Parameters	ode45	ode23	ode113	ode15s	ode23s	ode23t	ode23tb
RelTol, AbsTol, NormControl	√	√	√	√	√	√	√
OutputFcn, OutputSel, Refine, Stats	√	√	√	√	√	√	√
NonNegative	√	√	√	√ *	—	√ *	√ *
Events	√	√	√	√	√	√	√
MaxStep, InitialStep	√	√	√	√	√	√	√

Parameters	ode45	ode23	ode113	ode15s	ode23s	ode23t	ode23tb
Jacobian, JPattern, Vectorized	—	—	—	√	√	√	√
Mass	√	√	√	√	√	√	√
MStateDependence	√	√	√	√	—	√	√
MvPattern	—	—	—	√	—	√	√
MassSingular	—	—	—	√	—	√	—
InitialSlope	—	—	—	√	—	√	—
MaxOrder, BDF	—	—	—	√	—	—	—

**Note** You can use the `NonNegative` parameter with `ode15s`, `ode23t`, and `ode23tb` only for those problems for which there is no mass matrix.

## Examples

### Example 1

An example of a nonstiff system is the system of equations describing the motion of a rigid body without external forces.

$$\begin{aligned} y_1' &= y_2 y_3 & y_1(0) &= 0 \\ y_2' &= -y_1 y_3 & y_2(0) &= 1 \\ y_3' &= -0.51 y_1 y_2 & y_3(0) &= 1 \end{aligned}$$

To simulate this system, create a function `rigid` containing the equations

```
function dy = rigid(t,y)
dy = zeros(3,1); % a column vector
dy(1) = y(2) * y(3);
dy(2) = -y(1) * y(3);
dy(3) = -0.51 * y(1) * y(2);
```

In this example we change the error tolerances using the `odeset` command and solve on a time interval `[0 12]` with an initial condition vector `[0 1 1]` at time 0.

```
options = odeset('RelTol',1e-4,'AbsTol',[1e-4 1e-4 1e-5]);
[T,Y] = ode45(@rigid,[0 12],[0 1 1],options);
```

Plotting the columns of the returned array Y versus T shows the solution

```
plot(T,Y(:,1),'-',T,Y(:,2),'-.',T,Y(:,3),'.');
```

## Example 2

An example of a stiff system is provided by the van der Pol equations in relaxation oscillation. The limit cycle has portions where the solution components change slowly and the problem is quite stiff, alternating with regions of very sharp change where it is not stiff.

$$\begin{aligned}y_1' &= y_2 & y_1(0) &= 2 \\y_2' &= 1000(1 - y_1^2)y_2 - y_1 & y_2(0) &= 0\end{aligned}$$

To simulate this system, create a function `vdp1000` containing the equations

```
function dy = vdp1000(t,y)
dy = zeros(2,1); % a column vector
dy(1) = y(2);
dy(2) = 1000*(1 - y(1)^2)*y(2) - y(1);
```

For this problem, we will use the default relative and absolute tolerances ( $1e-3$  and  $1e-6$ , respectively) and solve on a time interval of `[0 3000]` with initial condition vector `[2 0]` at time 0.

```
[T,Y] = ode15s(@vdp1000,[0 3000],[2 0]);
```

Plotting the first column of the returned matrix `Y` versus `T` shows the solution

```
plot(T,Y(:,1),'-o')
```

### Example 3

This example solves an ordinary differential equation with time-dependent terms.

Consider the following ODE, with time-dependent parameters defined only through the set of data points given in two vectors:

$$y'(t) + f(t)y(t) = g(t)$$

The initial condition is  $y(1) = 1$ , where the function  $f(t)$  is defined by the  $n$ -by-1 vector  $f$  evaluated at times  $ft$ , and the function  $g(t)$  is defined by the  $m$ -by-1 vector  $g$  evaluated at times  $gt$ .

First, define the time-dependent parameters  $f(t)$  and  $g(t)$  as the following:

```
ft = linspace(0,5,25); % Generate t for f
f = ft.^2 - ft - 3; % Generate f(t)
gt = linspace(1,6,25); % Generate t for g
g = 3*sin(gt-0.25); % Generate g(t)
```

Write a function to interpolate the data sets specified above to obtain the value of the time-dependent terms at the specified time:

```
function dydt = myode(t,y,ft,f,gt,g)
f = interp1(ft,f,t); % Interpolate the data set (ft,f) at time t
g = interp1(gt,g,t); % Interpolate the data set (gt,g) at time t
dydt = -f.*y + g; % Evaluate ODE at time t
```

Call the derivative function `myode.m` within the MATLAB `ode45` function specifying time as the first input argument :

```
Tspan = [1 5]; % Solve from t=1 to t=5
IC = 1; % y(t=1) = 1
[T Y] = ode45(@(t,y) myode(t,y,ft,f,gt,g),Tspan,IC); % Solve ODE
Plot the solution y (t) as a function of time:
```

```
plot(T, Y);
title('Plot of y as a function of time');
xlabel('Time');
ylabel('Y(t)');
```

## More About

### Algorithms

`ode45` is based on an explicit Runge-Kutta (4,5) formula, the Dormand-Prince pair. It is a *one-step* solver – in computing  $y(t_n)$ , it needs only the solution at the immediately preceding time point,  $y(t_{n-1})$ . In general, `ode45` is the best function to apply as a *first try* for most problems. [3]

`ode23` is an implementation of an explicit Runge-Kutta (2,3) pair of Bogacki and Shampine. It may be more efficient than `ode45` at crude tolerances and in the presence of moderate stiffness. Like `ode45`, `ode23` is a one-step solver. [2]

`ode113` is a variable order Adams-Bashforth-Moulton PECE solver. It may be more efficient than `ode45` at stringent tolerances and when the ODE file function is particularly expensive to evaluate. `ode113` is a *multistep* solver — it normally needs the solutions at several preceding time points to compute the current solution. [7]

The above algorithms are intended to solve nonstiff systems. If they appear to be unduly slow, try using one of the stiff solvers below.

`ode15s` is a variable order solver based on the numerical differentiation formulas (NDFs). Optionally, it uses the backward differentiation formulas (BDFs, also known as Gear's method) that are usually less efficient. Like `ode113`, `ode15s` is a multistep solver. Try `ode15s` when `ode45` fails, or is very inefficient, and you suspect that the problem is stiff, or when solving a differential-algebraic problem. [9], [10]

`ode23s` is based on a modified Rosenbrock formula of order 2. Because it is a one-step solver, it may be more efficient than `ode15s` at crude tolerances. It can solve some kinds of stiff problems for which `ode15s` is not effective. [9]

`ode23t` is an implementation of the trapezoidal rule using a “free” interpolant. Use this solver if the problem is only moderately stiff and you need a solution without numerical damping. `ode23t` can solve DAEs. [10]

`ode23tb` is an implementation of TR-BDF2, an implicit Runge-Kutta formula with a first stage that is a trapezoidal rule step and a second stage that is a backward differentiation formula of order two. By construction, the same iteration matrix is used in evaluating both stages. Like `ode23s`, this solver may be more efficient than `ode15s` at crude tolerances. [8], [1]

## ode23t

Solve moderately stiff ODEs and DAEs; trapezoidal rule

### Syntax

```
[T,Y] = solver(odefun,tspan,y0)
[T,Y] = solver(odefun,tspan,y0,options)
[T,Y,TE,YE,IE] = solver(odefun,tspan,y0,options)
sol = solver(odefun,[t0 tf],y0...)
```

This page contains an overview of the solver functions: `ode23`, `ode45`, `ode113`, `ode15s`, `ode23s`, `ode23t`, and `ode23tb`. You can call any of these solvers by substituting the placeholder, `solver`, with any of the function names.

### Arguments

The following table describes the input arguments to the solvers.

<code>odefun</code>	A function handle that evaluates the right side of the differential equations. All solvers solve systems of equations in the form $y' = f(t,y)$ or problems that involve a mass matrix, $M(t,y)y' = f(t,y)$ . The <code>ode23s</code> solver can solve only equations with constant mass matrices. <code>ode15s</code> and <code>ode23t</code> can solve problems with a mass matrix that is singular, i.e., differential-algebraic equations (DAEs).
<code>tspan</code>	A vector specifying the interval of integration, <code>[t0,tf]</code> . The solver imposes the initial conditions at <code>tspan(1)</code> , and integrates from <code>tspan(1)</code> to <code>tspan(end)</code> . To obtain solutions at specific times (all increasing or all decreasing), use <code>tspan = [t0,t1,...,tf]</code> .  For <code>tspan</code> vectors with two elements <code>[t0 tf]</code> , the solver returns the solution evaluated at every integration step. For <code>tspan</code> vectors with more than two elements, the solver returns solutions evaluated at the given time points. The time values must be in order, either increasing or decreasing.

Specifying `tspan` with more than two elements does not affect the internal time steps that the solver uses to traverse the interval from `tspan(1)` to `tspan(end)`. All solvers in the ODE suite obtain output values by means of continuous extensions of the basic formulas. Although a solver does not necessarily step precisely to a time point specified in `tspan`, the solutions produced at the specified time points are of the same order of accuracy as the solutions computed at the internal time points.

Specifying `tspan` with more than two elements has little effect on the efficiency of computation, but for large systems, affects memory management.

`y0`

A vector of initial conditions.

`options`

Structure of optional parameters that change the default integration properties. This is the fourth input argument.

```
[t,y] = solver(odefun,tspan,y0,options)
```

You can create options using the `odeset` function. See `odeset` for details.

The following table lists the output arguments for the solvers.

<code>T</code>	Column vector of time points.
<code>Y</code>	Solution array. Each row in <code>Y</code> corresponds to the solution at a time returned in the corresponding row of <code>T</code> .
<code>TE</code>	The time at which an event occurs.
<code>YE</code>	The solution at the time of the event.
<code>IE</code>	The index <code>i</code> of the event function that vanishes.
<code>sol</code>	Structure to evaluate the solution.

## Description

`[T,Y] = solver(odefun,tspan,y0)` with `tspan = [t0 tf]` integrates the system of differential equations  $y' = f(t,y)$  from time `t0` to `tf` with initial conditions `y0`. The first

input argument, `odefun`, is a function handle. The function,  $f = \text{odefun}(t, y)$ , for a scalar  $t$  and a column vector  $y$ , must return a column vector  $f$  corresponding to  $f(t, y)$ . Each row in the solution array  $Y$  corresponds to a time returned in column vector  $T$ . To obtain solutions at the specific times  $t_0, t_1, \dots, t_f$  (all increasing or all decreasing), use `tspan = [t0, t1, ..., tf]`.

“Parameterizing Functions” explains how to provide additional parameters to the function `fun`, if necessary.

`[T, Y] = solver(odefun, tspan, y0, options)` solves as above with default integration parameters replaced by “property values” specified in `options`, an argument created with the `odeset` function. Commonly used properties include a scalar relative error tolerance `RelTol` ( $1e-3$  by default) and a vector of absolute error tolerances `Abstol` (all components are  $1e-6$  by default). If certain components of the solution must be nonnegative, use the `odeset` function to set the `NonNegative` property to the indices of these components. See `odeset` for details.

`[T, Y, TE, YE, IE] = solver(odefun, tspan, y0, options)` solves as above while also finding where functions of  $(t, y)$ , called event functions, are zero. For each event function, you specify whether the integration is to terminate at a zero and whether the direction of the zero crossing matters. Do this by setting the 'Events' property to a function, e.g., `events` or `@events`, and creating a function `[value, isterminal, direction] = events(t, y)`. For the  $i$ th event function in `events`,

- `value(i)` is the value of the function.
- `isterminal(i) = 1`, if the integration is to terminate at a zero of this event function and `0` otherwise.
- `direction(i) = 0` if all zeros are to be computed (the default), `+1` if only the zeros where the event function increases, and `-1` if only the zeros where the event function decreases.

Corresponding entries in `TE`, `YE`, and `IE` return, respectively, the time at which an event occurs, the solution at the time of the event, and the index  $i$  of the event function that vanishes.

`sol = solver(odefun, [t0 tf], y0...)` returns a structure that you can use with `deval` to evaluate the solution at any point on the interval `[t0, tf]`. You must pass `odefun` as a function handle. The structure `sol` always includes these fields:

`sol.x`                                      Steps chosen by the solver.

`sol.y` Each column `sol.y(:,i)` contains the solution at `sol.x(i)`.  
`sol.solver` Solver name.

If you specify the `Events` option and events are detected, `sol` also includes these fields:

`sol.xe` Points at which events, if any, occurred. `sol.xe(end)` contains the exact point of a terminal event, if any.  
`sol.ye` Solutions that correspond to events in `sol.xe`.  
`sol.ie` Indices into the vector returned by the function specified in the `Events` option. The values indicate which event the solver detected.

If you specify an output function as the value of the `OutputFcn` property, the solver calls it with the computed solution after each time step. Four output functions are provided: `odeplot`, `odephas2`, `odephas3`, `odeprint`. When you call the solver with no output arguments, it calls the default `odeplot` to plot the solution as it is computed. `odephas2` and `odephas3` produce two- and three-dimensional phase plane plots, respectively. `odeprint` displays the solution components on the screen. By default, the ODE solver passes all components of the solution to the output function. You can pass only specific components by providing a vector of indices as the value of the `OutputSel` property. For example, if you call the solver with no output arguments and set the value of `OutputSel` to `[1,3]`, the solver plots solution components 1 and 3 as they are computed.

For the stiff solvers `ode15s`, `ode23s`, `ode23t`, and `ode23tb`, the Jacobian matrix  $\partial f/\partial y$  is critical to reliability and efficiency. Use `odeset` to set `Jacobian` to `@FJAC` if `FJAC(T,Y)` returns the Jacobian  $\partial f/\partial y$  or to the matrix  $\partial f/\partial y$  if the Jacobian is constant. If the `Jacobian` property is not set (the default),  $\partial f/\partial y$  is approximated by finite differences. Set the `Vectorized` property 'on' if the ODE function is coded so that `odefun(T,[Y1,Y2 ...])` returns `[odefun(T,Y1),odefun(T,Y2) ...]`. If  $\partial f/\partial y$  is a sparse matrix, set the `JPattern` property to the sparsity pattern of  $\partial f/\partial y$ , i.e., a sparse matrix `S` with `S(i,j) = 1` if the *i*th component of  $f(t,y)$  depends on the *j*th component of *y*, and 0 otherwise.

The solvers of the ODE suite can solve problems of the form  $M(t,y)y' = f(t,y)$ , with time- and state-dependent mass matrix *M*. (The `ode23s` solver can solve only equations with constant mass matrices.) If a problem has a mass matrix, create a function `M = MASS(t,y)` that returns the value of the mass matrix, and use `odeset` to set the `Mass` property to `@MASS`. If the mass matrix is constant, the matrix should be used as the value of the `Mass` property. Problems with state-dependent mass matrices are more difficult:

- If the mass matrix does not depend on the state variable  $y$  and the function `MASS` is to be called with one input argument,  $t$ , set the `MStateDependence` property to 'none'.
- If the mass matrix depends weakly on  $y$ , set `MStateDependence` to 'weak' (the default); otherwise, set it to 'strong'. In either case, the function `MASS` is called with the two arguments  $(t,y)$ .

If there are many differential equations, it is important to exploit sparsity:

- Return a sparse  $M(t,y)$ .
- Supply the sparsity pattern of  $\partial f/\partial y$  using the `JPattern` property or a sparse  $\partial f/\partial y$  using the `Jacobian` property.
- For strongly state-dependent  $M(t,y)$ , set `MvPattern` to a sparse matrix  $S$  with  $S(i,j) = 1$  if for any  $k$ , the  $(i,k)$  component of  $M(t,y)$  depends on component  $j$  of  $y$ , and 0 otherwise.

If the mass matrix  $M$  is singular, then  $M(t,y)y' = f(t,y)$  is a system of differential algebraic equations. DAEs have solutions only when  $y_0$  is consistent, that is, if there is a vector  $yp_0$  such that  $M(t_0,y_0)yp_0 = f(t_0,y_0)$ . The `ode15s` and `ode23t` solvers can solve DAEs of index 1 provided that  $y_0$  is sufficiently close to being consistent. If there is a mass matrix, you can use `odeset` to set the `MassSingular` property to 'yes', 'no', or 'maybe'. The default value of 'maybe' causes the solver to test whether the problem is a DAE. You can provide  $yp_0$  as the value of the `InitialSlope` property. The default is the zero vector. If a problem is a DAE, and  $y_0$  and  $yp_0$  are not consistent, the solver treats them as guesses, attempts to compute consistent values that are close to the guesses, and continues to solve the problem. When solving DAEs, it is very advantageous to formulate the problem so that  $M$  is a diagonal matrix (a semi-explicit DAE).

Solver	Problem Type	Order of Accuracy	When to Use
ode45	Nonstiff	Medium	Most of the time. This should be the first solver you try.
ode23	Nonstiff	Low	For problems with crude error tolerances or for solving moderately stiff problems.
ode113	Nonstiff	Low to high	For problems with stringent error tolerances or for solving computationally intensive problems.

Solver	Problem Type	Order of Accuracy	When to Use
ode15s	Stiff	Low to medium	If ode45 is slow because the problem is stiff.
ode23s	Stiff	Low	If using crude error tolerances to solve stiff systems and the mass matrix is constant.
ode23t	Moderately Stiff	Low	For moderately stiff problems if you need a solution without numerical damping.
ode23tb	Stiff	Low	If using crude error tolerances to solve stiff systems.

The algorithms used in the ODE solvers vary according to order of accuracy [6] and the type of systems (stiff or nonstiff) they are designed to solve. See “Algorithms” on page 1-5364 for more details.

## Options

Different solvers accept different parameters in the options list. For more information, see `odeset` and “Integrator Options” in the MATLAB Mathematics documentation.

Parameters	ode45	ode23	ode113	ode15s	ode23s	ode23t	ode23tb
RelTol, AbsTol, NormControl	√	√	√	√	√	√	√
OutputFcn, OutputSel, Refine, Stats	√	√	√	√	√	√	√
NonNegative	√	√	√	√ *	—	√ *	√ *
Events	√	√	√	√	√	√	√
MaxStep, InitialStep	√	√	√	√	√	√	√

Parameters	ode45	ode23	ode113	ode15s	ode23s	ode23t	ode23tb
Jacobian, JPattern, Vectorized	—	—	—	√	√	√	√
Mass	√	√	√	√	√	√	√
MStateDependence	√	√	√	√	—	√	√
MvPattern	—	—	—	√	—	√	√
MassSingular	—	—	—	√	—	√	—
InitialSlope	—	—	—	√	—	√	—
MaxOrder, BDF	—	—	—	√	—	—	—

**Note** You can use the `NonNegative` parameter with `ode15s`, `ode23t`, and `ode23tb` only for those problems for which there is no mass matrix.

## Examples

### Example 1

An example of a nonstiff system is the system of equations describing the motion of a rigid body without external forces.

$$\begin{aligned}
 y_1' &= y_2 y_3 & y_1(0) &= 0 \\
 y_2' &= -y_1 y_3 & y_2(0) &= 1 \\
 y_3' &= -0.51 y_1 y_2 & y_3(0) &= 1
 \end{aligned}$$

To simulate this system, create a function `rigid` containing the equations

```
function dy = rigid(t,y)
dy = zeros(3,1); % a column vector
dy(1) = y(2) * y(3);
dy(2) = -y(1) * y(3);
dy(3) = -0.51 * y(1) * y(2);
```

In this example we change the error tolerances using the `odeset` command and solve on a time interval `[0 12]` with an initial condition vector `[0 1 1]` at time 0.

```
options = odeset('RelTol',1e-4,'AbsTol',[1e-4 1e-4 1e-5]);
[T,Y] = ode45(@rigid,[0 12],[0 1 1],options);
```

Plotting the columns of the returned array Y versus T shows the solution

```
plot(T,Y(:,1),'-',T,Y(:,2),'-.',T,Y(:,3),'.'
```

## Example 2

An example of a stiff system is provided by the van der Pol equations in relaxation oscillation. The limit cycle has portions where the solution components change slowly and the problem is quite stiff, alternating with regions of very sharp change where it is not stiff.

$$\begin{aligned}y_1' &= y_2 & y_1(0) &= 2 \\y_2' &= 1000(1 - y_1^2)y_2 - y_1 & y_2(0) &= 0\end{aligned}$$

To simulate this system, create a function `vdp1000` containing the equations

```
function dy = vdp1000(t,y)
dy = zeros(2,1); % a column vector
dy(1) = y(2);
dy(2) = 1000*(1 - y(1)^2)*y(2) - y(1);
```

For this problem, we will use the default relative and absolute tolerances ( $1e-3$  and  $1e-6$ , respectively) and solve on a time interval of `[0 3000]` with initial condition vector `[2 0]` at time 0.

```
[T,Y] = ode15s(@vdp1000,[0 3000],[2 0]);
```

Plotting the first column of the returned matrix `Y` versus `T` shows the solution

```
plot(T,Y(:,1),'-o')
```

### Example 3

This example solves an ordinary differential equation with time-dependent terms.

Consider the following ODE, with time-dependent parameters defined only through the set of data points given in two vectors:

$$y'(t) + f(t)y(t) = g(t)$$

The initial condition is  $y(1) = 1$ , where the function  $f(t)$  is defined by the  $n$ -by-1 vector  $f$  evaluated at times  $ft$ , and the function  $g(t)$  is defined by the  $m$ -by-1 vector  $g$  evaluated at times  $gt$ .

First, define the time-dependent parameters  $f(t)$  and  $g(t)$  as the following:

```
ft = linspace(0,5,25); % Generate t for f
f = ft.^2 - ft - 3; % Generate f(t)
gt = linspace(1,6,25); % Generate t for g
g = 3*sin(gt-0.25); % Generate g(t)
```

Write a function to interpolate the data sets specified above to obtain the value of the time-dependent terms at the specified time:

```
function dydt = myode(t,y,ft,f,gt,g)
f = interp1(ft,f,t); % Interpolate the data set (ft,f) at time t
g = interp1(gt,g,t); % Interpolate the data set (gt,g) at time t
dydt = -f.*y + g; % Evaluate ODE at time t
```

Call the derivative function `myode.m` within the MATLAB `ode45` function specifying time as the first input argument :

```
Tspan = [1 5]; % Solve from t=1 to t=5
IC = 1; % y(t=1) = 1
[T Y] = ode45(@(t,y) myode(t,y,ft,f,gt,g),Tspan,IC); % Solve ODE
Plot the solution y(t) as a function of time:
```

```
plot(T, Y);
title('Plot of y as a function of time');
xlabel('Time');
ylabel('Y(t)');
```

## More About

### Algorithms

`ode45` is based on an explicit Runge-Kutta (4,5) formula, the Dormand-Prince pair. It is a *one-step* solver – in computing  $y(t_n)$ , it needs only the solution at the immediately preceding time point,  $y(t_{n-1})$ . In general, `ode45` is the best function to apply as a *first try* for most problems. [3]

`ode23` is an implementation of an explicit Runge-Kutta (2,3) pair of Bogacki and Shampine. It may be more efficient than `ode45` at crude tolerances and in the presence of moderate stiffness. Like `ode45`, `ode23` is a one-step solver. [2]

`ode113` is a variable order Adams-Bashforth-Moulton PECE solver. It may be more efficient than `ode45` at stringent tolerances and when the ODE file function is particularly expensive to evaluate. `ode113` is a *multistep* solver — it normally needs the solutions at several preceding time points to compute the current solution. [7]

The above algorithms are intended to solve nonstiff systems. If they appear to be unduly slow, try using one of the stiff solvers below.

`ode15s` is a variable order solver based on the numerical differentiation formulas (NDFs). Optionally, it uses the backward differentiation formulas (BDFs, also known as Gear's method) that are usually less efficient. Like `ode113`, `ode15s` is a multistep solver. Try `ode15s` when `ode45` fails, or is very inefficient, and you suspect that the problem is stiff, or when solving a differential-algebraic problem. [9], [10]

`ode23s` is based on a modified Rosenbrock formula of order 2. Because it is a one-step solver, it may be more efficient than `ode15s` at crude tolerances. It can solve some kinds of stiff problems for which `ode15s` is not effective. [9]

`ode23t` is an implementation of the trapezoidal rule using a “free” interpolant. Use this solver if the problem is only moderately stiff and you need a solution without numerical damping. `ode23t` can solve DAEs. [10]

`ode23tb` is an implementation of TR-BDF2, an implicit Runge-Kutta formula with a first stage that is a trapezoidal rule step and a second stage that is a backward differentiation formula of order two. By construction, the same iteration matrix is used in evaluating both stages. Like `ode23s`, this solver may be more efficient than `ode15s` at crude tolerances. [8], [1]

## ode23tb

Solve stiff differential equations; low order method

### Syntax

```
[T,Y] = solver(odefun,tspan,y0)
[T,Y] = solver(odefun,tspan,y0,options)
[T,Y,TE,YE,IE] = solver(odefun,tspan,y0,options)
sol = solver(odefun,[t0 tf],y0...)
```

This page contains an overview of the solver functions: `ode23`, `ode45`, `ode113`, `ode15s`, `ode23s`, `ode23t`, and `ode23tb`. You can call any of these solvers by substituting the placeholder, `solver`, with any of the function names.

### Arguments

The following table describes the input arguments to the solvers.

<code>odefun</code>	A function handle that evaluates the right side of the differential equations. All solvers solve systems of equations in the form $y' = f(t,y)$ or problems that involve a mass matrix, $M(t,y)y' = f(t,y)$ . The <code>ode23s</code> solver can solve only equations with constant mass matrices. <code>ode15s</code> and <code>ode23t</code> can solve problems with a mass matrix that is singular, i.e., differential-algebraic equations (DAEs).
<code>tspan</code>	A vector specifying the interval of integration, <code>[t0,tf]</code> . The solver imposes the initial conditions at <code>tspan(1)</code> , and integrates from <code>tspan(1)</code> to <code>tspan(end)</code> . To obtain solutions at specific times (all increasing or all decreasing), use <code>tspan = [t0,t1,...,tf]</code> .  For <code>tspan</code> vectors with two elements <code>[t0 tf]</code> , the solver returns the solution evaluated at every integration step. For <code>tspan</code> vectors with more than two elements, the solver returns solutions evaluated at the given time points. The time values must be in order, either increasing or decreasing.

Specifying `tspan` with more than two elements does not affect the internal time steps that the solver uses to traverse the interval from `tspan(1)` to `tspan(end)`. All solvers in the ODE suite obtain output values by means of continuous extensions of the basic formulas. Although a solver does not necessarily step precisely to a time point specified in `tspan`, the solutions produced at the specified time points are of the same order of accuracy as the solutions computed at the internal time points.

Specifying `tspan` with more than two elements has little effect on the efficiency of computation, but for large systems, affects memory management.

`y0`

A vector of initial conditions.

`options`

Structure of optional parameters that change the default integration properties. This is the fourth input argument.

`[t,y] = solver(odefun,tspan,y0,options)`

You can create options using the `odeset` function. See `odeset` for details.

The following table lists the output arguments for the solvers.

<code>T</code>	Column vector of time points.
<code>Y</code>	Solution array. Each row in <code>Y</code> corresponds to the solution at a time returned in the corresponding row of <code>T</code> .
<code>TE</code>	The time at which an event occurs.
<code>YE</code>	The solution at the time of the event.
<code>IE</code>	The index <code>i</code> of the event function that vanishes.
<code>sol</code>	Structure to evaluate the solution.

## Description

`[T,Y] = solver(odefun,tspan,y0)` with `tspan = [t0 tf]` integrates the system of differential equations  $y' = f(t,y)$  from time `t0` to `tf` with initial conditions `y0`. The first

input argument, `odefun`, is a function handle. The function,  $f = \text{odefun}(t, y)$ , for a scalar  $t$  and a column vector  $y$ , must return a column vector  $f$  corresponding to  $f(t, y)$ . Each row in the solution array  $Y$  corresponds to a time returned in column vector  $T$ . To obtain solutions at the specific times  $t_0, t_1, \dots, t_f$  (all increasing or all decreasing), use `tspan = [t0, t1, ..., tf]`.

“Parameterizing Functions” explains how to provide additional parameters to the function `fun`, if necessary.

`[T, Y] = solver(odefun, tspan, y0, options)` solves as above with default integration parameters replaced by “property values” specified in `options`, an argument created with the `odeset` function. Commonly used properties include a scalar relative error tolerance `RelTol` ( $1e-3$  by default) and a vector of absolute error tolerances `Abstol` (all components are  $1e-6$  by default). If certain components of the solution must be nonnegative, use the `odeset` function to set the `NonNegative` property to the indices of these components. See `odeset` for details.

`[T, Y, TE, YE, IE] = solver(odefun, tspan, y0, options)` solves as above while also finding where functions of  $(t, y)$ , called event functions, are zero. For each event function, you specify whether the integration is to terminate at a zero and whether the direction of the zero crossing matters. Do this by setting the 'Events' property to a function, e.g., `events` or `@events`, and creating a function `[value, isterminal, direction] = events(t, y)`. For the  $i$ th event function in `events`,

- `value(i)` is the value of the function.
- `isterminal(i) = 1`, if the integration is to terminate at a zero of this event function and 0 otherwise.
- `direction(i) = 0` if all zeros are to be computed (the default), +1 if only the zeros where the event function increases, and -1 if only the zeros where the event function decreases.

Corresponding entries in `TE`, `YE`, and `IE` return, respectively, the time at which an event occurs, the solution at the time of the event, and the index  $i$  of the event function that vanishes.

`sol = solver(odefun, [t0 tf], y0...)` returns a structure that you can use with `deval` to evaluate the solution at any point on the interval `[t0, tf]`. You must pass `odefun` as a function handle. The structure `sol` always includes these fields:

`sol.x`                                      Steps chosen by the solver.

`sol.y` Each column `sol.y(:,i)` contains the solution at `sol.x(i)`.  
`sol.solver` Solver name.

If you specify the `Events` option and events are detected, `sol` also includes these fields:

`sol.xe` Points at which events, if any, occurred. `sol.xe(end)` contains the exact point of a terminal event, if any.  
`sol.ye` Solutions that correspond to events in `sol.xe`.  
`sol.ie` Indices into the vector returned by the function specified in the `Events` option. The values indicate which event the solver detected.

If you specify an output function as the value of the `OutputFcn` property, the solver calls it with the computed solution after each time step. Four output functions are provided: `odeplot`, `odephas2`, `odephas3`, `odeprint`. When you call the solver with no output arguments, it calls the default `odeplot` to plot the solution as it is computed. `odephas2` and `odephas3` produce two- and three-dimensional phase plane plots, respectively. `odeprint` displays the solution components on the screen. By default, the ODE solver passes all components of the solution to the output function. You can pass only specific components by providing a vector of indices as the value of the `OutputSel` property. For example, if you call the solver with no output arguments and set the value of `OutputSel` to `[1,3]`, the solver plots solution components 1 and 3 as they are computed.

For the stiff solvers `ode15s`, `ode23s`, `ode23t`, and `ode23tb`, the Jacobian matrix  $\partial f/\partial y$  is critical to reliability and efficiency. Use `odeset` to set `Jacobian` to `@FJAC` if `FJAC(T,Y)` returns the Jacobian  $\partial f/\partial y$  or to the matrix  $\partial f/\partial y$  if the Jacobian is constant. If the `Jacobian` property is not set (the default),  $\partial f/\partial y$  is approximated by finite differences. Set the `Vectorized` property 'on' if the ODE function is coded so that `odefun(T,[Y1,Y2 ...])` returns `[odefun(T,Y1),odefun(T,Y2) ...]`. If  $\partial f/\partial y$  is a sparse matrix, set the `JPattern` property to the sparsity pattern of  $\partial f/\partial y$ , i.e., a sparse matrix `S` with `S(i,j) = 1` if the *i*th component of  $f(t,y)$  depends on the *j*th component of *y*, and 0 otherwise.

The solvers of the ODE suite can solve problems of the form  $M(t,y)y' = f(t,y)$ , with time- and state-dependent mass matrix *M*. (The `ode23s` solver can solve only equations with constant mass matrices.) If a problem has a mass matrix, create a function `M = MASS(t,y)` that returns the value of the mass matrix, and use `odeset` to set the `Mass` property to `@MASS`. If the mass matrix is constant, the matrix should be used as the value of the `Mass` property. Problems with state-dependent mass matrices are more difficult:

- If the mass matrix does not depend on the state variable  $y$  and the function `MASS` is to be called with one input argument,  $t$ , set the `MStateDependence` property to 'none'.
- If the mass matrix depends weakly on  $y$ , set `MStateDependence` to 'weak' (the default); otherwise, set it to 'strong'. In either case, the function `MASS` is called with the two arguments  $(t,y)$ .

If there are many differential equations, it is important to exploit sparsity:

- Return a sparse  $M(t,y)$ .
- Supply the sparsity pattern of  $\partial f/\partial y$  using the `JPattern` property or a sparse  $\partial f/\partial y$  using the `Jacobian` property.
- For strongly state-dependent  $M(t,y)$ , set `MvPattern` to a sparse matrix  $S$  with  $S(i,j) = 1$  if for any  $k$ , the  $(i,k)$  component of  $M(t,y)$  depends on component  $j$  of  $y$ , and 0 otherwise.

If the mass matrix  $M$  is singular, then  $M(t,y)y' = f(t,y)$  is a system of differential algebraic equations. DAEs have solutions only when  $y_0$  is consistent, that is, if there is a vector  $yp_0$  such that  $M(t_0,y_0)yp_0 = f(t_0,y_0)$ . The `ode15s` and `ode23t` solvers can solve DAEs of index 1 provided that  $y_0$  is sufficiently close to being consistent. If there is a mass matrix, you can use `odeset` to set the `MassSingular` property to 'yes', 'no', or 'maybe'. The default value of 'maybe' causes the solver to test whether the problem is a DAE. You can provide  $yp_0$  as the value of the `InitialSlope` property. The default is the zero vector. If a problem is a DAE, and  $y_0$  and  $yp_0$  are not consistent, the solver treats them as guesses, attempts to compute consistent values that are close to the guesses, and continues to solve the problem. When solving DAEs, it is very advantageous to formulate the problem so that  $M$  is a diagonal matrix (a semi-explicit DAE).

Solver	Problem Type	Order of Accuracy	When to Use
ode45	Nonstiff	Medium	Most of the time. This should be the first solver you try.
ode23	Nonstiff	Low	For problems with crude error tolerances or for solving moderately stiff problems.
ode113	Nonstiff	Low to high	For problems with stringent error tolerances or for solving computationally intensive problems.

Solver	Problem Type	Order of Accuracy	When to Use
ode15s	Stiff	Low to medium	If ode45 is slow because the problem is stiff.
ode23s	Stiff	Low	If using crude error tolerances to solve stiff systems and the mass matrix is constant.
ode23t	Moderately Stiff	Low	For moderately stiff problems if you need a solution without numerical damping.
ode23tb	Stiff	Low	If using crude error tolerances to solve stiff systems.

The algorithms used in the ODE solvers vary according to order of accuracy [6] and the type of systems (stiff or nonstiff) they are designed to solve. See “Algorithms” on page 1-5378 for more details.

## Options

Different solvers accept different parameters in the options list. For more information, see `odeset` and “Integrator Options” in the MATLAB Mathematics documentation.

Parameters	ode45	ode23	ode113	ode15s	ode23s	ode23t	ode23tb
RelTol, AbsTol, NormControl	√	√	√	√	√	√	√
OutputFcn, OutputSel, Refine, Stats	√	√	√	√	√	√	√
NonNegative	√	√	√	√ *	—	√ *	√ *
Events	√	√	√	√	√	√	√
MaxStep, InitialStep	√	√	√	√	√	√	√

Parameters	ode45	ode23	ode113	ode15s	ode23s	ode23t	ode23tb
Jacobian, JPattern, Vectorized	—	—	—	√	√	√	√
Mass	√	√	√	√	√	√	√
MStateDependence	√	√	√	√	—	√	√
MvPattern	—	—	—	√	—	√	√
MassSingular	—	—	—	√	—	√	—
InitialSlope	—	—	—	√	—	√	—
MaxOrder, BDF	—	—	—	√	—	—	—

**Note** You can use the `NonNegative` parameter with `ode15s`, `ode23t`, and `ode23tb` only for those problems for which there is no mass matrix.

## Examples

### Example 1

An example of a nonstiff system is the system of equations describing the motion of a rigid body without external forces.

$$\begin{aligned} y_1' &= y_2 y_3 & y_1(0) &= 0 \\ y_2' &= -y_1 y_3 & y_2(0) &= 1 \\ y_3' &= -0.51 y_1 y_2 & y_3(0) &= 1 \end{aligned}$$

To simulate this system, create a function `rigid` containing the equations

```
function dy = rigid(t,y)
dy = zeros(3,1); % a column vector
dy(1) = y(2) * y(3);
dy(2) = -y(1) * y(3);
dy(3) = -0.51 * y(1) * y(2);
```

In this example we change the error tolerances using the `odeset` command and solve on a time interval `[0 12]` with an initial condition vector `[0 1 1]` at time 0.

```
options = odeset('RelTol',1e-4,'AbsTol',[1e-4 1e-4 1e-5]);
[T,Y] = ode45(@rigid,[0 12],[0 1 1],options);
```

Plotting the columns of the returned array Y versus T shows the solution

```
plot(T,Y(:,1),'-',T,Y(:,2),'-.',T,Y(:,3),'.'
```

## Example 2

An example of a stiff system is provided by the van der Pol equations in relaxation oscillation. The limit cycle has portions where the solution components change slowly and the problem is quite stiff, alternating with regions of very sharp change where it is not stiff.

$$\begin{aligned}y_1' &= y_2 & y_1(0) &= 2 \\y_2' &= 1000(1 - y_1^2)y_2 - y_1 & y_2(0) &= 0\end{aligned}$$

To simulate this system, create a function `vdp1000` containing the equations

```
function dy = vdp1000(t,y)
dy = zeros(2,1); % a column vector
dy(1) = y(2);
dy(2) = 1000*(1 - y(1)^2)*y(2) - y(1);
```

For this problem, we will use the default relative and absolute tolerances ( $1e-3$  and  $1e-6$ , respectively) and solve on a time interval of `[0 3000]` with initial condition vector `[2 0]` at time 0.

```
[T,Y] = ode15s(@vdp1000,[0 3000],[2 0]);
```

Plotting the first column of the returned matrix `Y` versus `T` shows the solution

```
plot(T,Y(:,1),'-o')
```

### Example 3

This example solves an ordinary differential equation with time-dependent terms.

Consider the following ODE, with time-dependent parameters defined only through the set of data points given in two vectors:

$$y'(t) + f(t)y(t) = g(t)$$

The initial condition is  $y(1) = 1$ , where the function  $f(t)$  is defined by the  $n$ -by-1 vector  $f$  evaluated at times  $ft$ , and the function  $g(t)$  is defined by the  $m$ -by-1 vector  $g$  evaluated at times  $gt$ .

First, define the time-dependent parameters  $f(t)$  and  $g(t)$  as the following:

```
ft = linspace(0,5,25); % Generate t for f
f = ft.^2 - ft - 3; % Generate f(t)
gt = linspace(1,6,25); % Generate t for g
g = 3*sin(gt-0.25); % Generate g(t)
```

Write a function to interpolate the data sets specified above to obtain the value of the time-dependent terms at the specified time:

```
function dydt = myode(t,y,ft,f,gt,g)
f = interp1(ft,f,t); % Interpolate the data set (ft,f) at time t
g = interp1(gt,g,t); % Interpolate the data set (gt,g) at time t
dydt = -f.*y + g; % Evaluate ODE at time t
```

Call the derivative function `myode.m` within the MATLAB `ode45` function specifying time as the first input argument :

```
Tspan = [1 5]; % Solve from t=1 to t=5
IC = 1; % y(t=1) = 1
[T Y] = ode45(@(t,y) myode(t,y,ft,f,gt,g),Tspan,IC); % Solve ODE
Plot the solution y (t) as a function of time:
```

```
plot(T, Y);
title('Plot of y as a function of time');
xlabel('Time');
ylabel('Y(t)');
```

## More About

### Algorithms

`ode45` is based on an explicit Runge-Kutta (4,5) formula, the Dormand-Prince pair. It is a *one-step* solver – in computing  $y(t_n)$ , it needs only the solution at the immediately preceding time point,  $y(t_{n-1})$ . In general, `ode45` is the best function to apply as a *first try* for most problems. [3]

`ode23` is an implementation of an explicit Runge-Kutta (2,3) pair of Bogacki and Shampine. It may be more efficient than `ode45` at crude tolerances and in the presence of moderate stiffness. Like `ode45`, `ode23` is a one-step solver. [2]

`ode113` is a variable order Adams-Bashforth-Moulton PECE solver. It may be more efficient than `ode45` at stringent tolerances and when the ODE file function is particularly expensive to evaluate. `ode113` is a *multistep* solver — it normally needs the solutions at several preceding time points to compute the current solution. [7]

The above algorithms are intended to solve nonstiff systems. If they appear to be unduly slow, try using one of the stiff solvers below.

`ode15s` is a variable order solver based on the numerical differentiation formulas (NDFs). Optionally, it uses the backward differentiation formulas (BDFs, also known as Gear's method) that are usually less efficient. Like `ode113`, `ode15s` is a multistep solver. Try `ode15s` when `ode45` fails, or is very inefficient, and you suspect that the problem is stiff, or when solving a differential-algebraic problem. [9], [10]

`ode23s` is based on a modified Rosenbrock formula of order 2. Because it is a one-step solver, it may be more efficient than `ode15s` at crude tolerances. It can solve some kinds of stiff problems for which `ode15s` is not effective. [9]

`ode23t` is an implementation of the trapezoidal rule using a “free” interpolant. Use this solver if the problem is only moderately stiff and you need a solution without numerical damping. `ode23t` can solve DAEs. [10]

`ode23tb` is an implementation of TR-BDF2, an implicit Runge-Kutta formula with a first stage that is a trapezoidal rule step and a second stage that is a backward differentiation formula of order two. By construction, the same iteration matrix is used in evaluating both stages. Like `ode23s`, this solver may be more efficient than `ode15s` at crude tolerances. [8], [1]

# ode45

Solve nonstiff differential equations; medium order method

## Syntax

```
[T,Y] = solver(odefun,tspan,y0)
[T,Y] = solver(odefun,tspan,y0,options)
[T,Y,TE,YE,IE] = solver(odefun,tspan,y0,options)
sol = solver(odefun,[t0 tf],y0...)
```

This page contains an overview of the solver functions: `ode23`, `ode45`, `ode113`, `ode15s`, `ode23s`, `ode23t`, and `ode23tb`. You can call any of these solvers by substituting the placeholder, `solver`, with any of the function names.

## Arguments

The following table describes the input arguments to the solvers.

<code>odefun</code>	A function handle that evaluates the right side of the differential equations. All solvers solve systems of equations in the form $y' = f(t,y)$ or problems that involve a mass matrix, $M(t,y)y' = f(t,y)$ . The <code>ode23s</code> solver can solve only equations with constant mass matrices. <code>ode15s</code> and <code>ode23t</code> can solve problems with a mass matrix that is singular, i.e., differential-algebraic equations (DAEs).
<code>tspan</code>	A vector specifying the interval of integration, <code>[t0,tf]</code> . The solver imposes the initial conditions at <code>tspan(1)</code> , and integrates from <code>tspan(1)</code> to <code>tspan(end)</code> . To obtain solutions at specific times (all increasing or all decreasing), use <code>tspan = [t0,t1,...,tf]</code> .

For `tspan` vectors with two elements `[t0 tf]`, the solver returns the solution evaluated at every integration step. For `tspan` vectors with more than two elements, the solver returns solutions evaluated at the given time points. The time values must be in order, either increasing or decreasing.

Specifying `tspan` with more than two elements does not affect the internal time steps that the solver uses to traverse the interval from `tspan(1)` to `tspan(end)`. All solvers in the ODE suite obtain output values by means of continuous extensions of the basic formulas. Although a solver does not necessarily step precisely to a time point specified in `tspan`, the solutions produced at the specified time points are of the same order of accuracy as the solutions computed at the internal time points.

Specifying `tspan` with more than two elements has little effect on the efficiency of computation, but for large systems, affects memory management.

`y0`

A vector of initial conditions.

`options`

Structure of optional parameters that change the default integration properties. This is the fourth input argument.

`[t,y] = solver(odefun,tspan,y0,options)`

You can create options using the `odeset` function. See `odeset` for details.

The following table lists the output arguments for the solvers.

<code>T</code>	Column vector of time points.
<code>Y</code>	Solution array. Each row in <code>Y</code> corresponds to the solution at a time returned in the corresponding row of <code>T</code> .
<code>TE</code>	The time at which an event occurs.
<code>YE</code>	The solution at the time of the event.
<code>IE</code>	The index <code>i</code> of the event function that vanishes.
<code>sol</code>	Structure to evaluate the solution.

## Description

`[T,Y] = solver(odefun,tspan,y0)` with `tspan = [t0 tf]` integrates the system of differential equations  $y' = f(t,y)$  from time `t0` to `tf` with initial conditions `y0`. The first

input argument, `odefun`, is a function handle. The function,  $f = \text{odefun}(t, y)$ , for a scalar  $t$  and a column vector  $y$ , must return a column vector  $f$  corresponding to  $f(t, y)$ . Each row in the solution array  $Y$  corresponds to a time returned in column vector  $T$ . To obtain solutions at the specific times  $t_0, t_1, \dots, t_f$  (all increasing or all decreasing), use `tspan = [t0, t1, ..., tf]`.

“Parameterizing Functions” explains how to provide additional parameters to the function `fun`, if necessary.

`[T, Y] = solver(odefun, tspan, y0, options)` solves as above with default integration parameters replaced by “property values” specified in `options`, an argument created with the `odeset` function. Commonly used properties include a scalar relative error tolerance `RelTol` ( $1e-3$  by default) and a vector of absolute error tolerances `Abstol` (all components are  $1e-6$  by default). If certain components of the solution must be nonnegative, use the `odeset` function to set the `NonNegative` property to the indices of these components. See `odeset` for details.

`[T, Y, TE, YE, IE] = solver(odefun, tspan, y0, options)` solves as above while also finding where functions of  $(t, y)$ , called event functions, are zero. For each event function, you specify whether the integration is to terminate at a zero and whether the direction of the zero crossing matters. Do this by setting the `'Events'` property to a function, e.g., `events` or `@events`, and creating a function `[value, isterminal, direction] = events(t, y)`. For the  $i$ th event function in `events`,

- `value(i)` is the value of the function.
- `isterminal(i) = 1`, if the integration is to terminate at a zero of this event function and 0 otherwise.
- `direction(i) = 0` if all zeros are to be computed (the default), +1 if only the zeros where the event function increases, and -1 if only the zeros where the event function decreases.

Corresponding entries in `TE`, `YE`, and `IE` return, respectively, the time at which an event occurs, the solution at the time of the event, and the index  $i$  of the event function that vanishes.

`sol = solver(odefun, [t0 tf], y0...)` returns a structure that you can use with `deval` to evaluate the solution at any point on the interval `[t0, tf]`. You must pass `odefun` as a function handle. The structure `sol` always includes these fields:

`sol.x`                                      Steps chosen by the solver.

`sol.y` Each column `sol.y(:,i)` contains the solution at `sol.x(i)`.  
`sol.solver` Solver name.

If you specify the `Events` option and events are detected, `sol` also includes these fields:

`sol.xe` Points at which events, if any, occurred. `sol.xe(end)` contains the exact point of a terminal event, if any.  
`sol.ye` Solutions that correspond to events in `sol.xe`.  
`sol.ie` Indices into the vector returned by the function specified in the `Events` option. The values indicate which event the solver detected.

If you specify an output function as the value of the `OutputFcn` property, the solver calls it with the computed solution after each time step. Four output functions are provided: `odeplot`, `odephas2`, `odephas3`, `odeprint`. When you call the solver with no output arguments, it calls the default `odeplot` to plot the solution as it is computed. `odephas2` and `odephas3` produce two- and three-dimensional phase plane plots, respectively. `odeprint` displays the solution components on the screen. By default, the ODE solver passes all components of the solution to the output function. You can pass only specific components by providing a vector of indices as the value of the `OutputSel` property. For example, if you call the solver with no output arguments and set the value of `OutputSel` to `[1,3]`, the solver plots solution components 1 and 3 as they are computed.

For the stiff solvers `ode15s`, `ode23s`, `ode23t`, and `ode23tb`, the Jacobian matrix  $\partial f/\partial y$  is critical to reliability and efficiency. Use `odeset` to set `Jacobian` to `@FJAC` if `FJAC(T,Y)` returns the Jacobian  $\partial f/\partial y$  or to the matrix  $\partial f/\partial y$  if the Jacobian is constant. If the `Jacobian` property is not set (the default),  $\partial f/\partial y$  is approximated by finite differences. Set the `Vectorized` property 'on' if the ODE function is coded so that `odefun(T,[Y1,Y2 ...])` returns `[odefun(T,Y1),odefun(T,Y2) ...]`. If  $\partial f/\partial y$  is a sparse matrix, set the `JPattern` property to the sparsity pattern of  $\partial f/\partial y$ , i.e., a sparse matrix `S` with `S(i,j) = 1` if the *i*th component of  $f(t,y)$  depends on the *j*th component of *y*, and 0 otherwise.

The solvers of the ODE suite can solve problems of the form  $M(t,y)y' = f(t,y)$ , with time- and state-dependent mass matrix *M*. (The `ode23s` solver can solve only equations with constant mass matrices.) If a problem has a mass matrix, create a function `M = MASS(t,y)` that returns the value of the mass matrix, and use `odeset` to set the `Mass` property to `@MASS`. If the mass matrix is constant, the matrix should be used as the value of the `Mass` property. Problems with state-dependent mass matrices are more difficult:

- If the mass matrix does not depend on the state variable  $y$  and the function `MASS` is to be called with one input argument,  $t$ , set the `MStateDependence` property to 'none'.
- If the mass matrix depends weakly on  $y$ , set `MStateDependence` to 'weak' (the default); otherwise, set it to 'strong'. In either case, the function `MASS` is called with the two arguments  $(t,y)$ .

If there are many differential equations, it is important to exploit sparsity:

- Return a sparse  $M(t,y)$ .
- Supply the sparsity pattern of  $\partial f/\partial y$  using the `JPattern` property or a sparse  $\partial f/\partial y$  using the `Jacobian` property.
- For strongly state-dependent  $M(t,y)$ , set `MvPattern` to a sparse matrix  $S$  with  $S(i,j) = 1$  if for any  $k$ , the  $(i,k)$  component of  $M(t,y)$  depends on component  $j$  of  $y$ , and  $0$  otherwise.

If the mass matrix  $M$  is singular, then  $M(t,y)y' = f(t,y)$  is a system of differential algebraic equations. DAEs have solutions only when  $y_0$  is consistent, that is, if there is a vector  $yp_0$  such that  $M(t_0,y_0)yp_0 = f(t_0,y_0)$ . The `ode15s` and `ode23t` solvers can solve DAEs of index 1 provided that  $y_0$  is sufficiently close to being consistent. If there is a mass matrix, you can use `odeset` to set the `MassSingular` property to 'yes', 'no', or 'maybe'. The default value of 'maybe' causes the solver to test whether the problem is a DAE. You can provide  $yp_0$  as the value of the `InitialSlope` property. The default is the zero vector. If a problem is a DAE, and  $y_0$  and  $yp_0$  are not consistent, the solver treats them as guesses, attempts to compute consistent values that are close to the guesses, and continues to solve the problem. When solving DAEs, it is very advantageous to formulate the problem so that  $M$  is a diagonal matrix (a semi-explicit DAE).

Solver	Problem Type	Order of Accuracy	When to Use
ode45	Nonstiff	Medium	Most of the time. This should be the first solver you try.
ode23	Nonstiff	Low	For problems with crude error tolerances or for solving moderately stiff problems.
ode113	Nonstiff	Low to high	For problems with stringent error tolerances or for solving computationally intensive problems.

Solver	Problem Type	Order of Accuracy	When to Use
ode15s	Stiff	Low to medium	If ode45 is slow because the problem is stiff.
ode23s	Stiff	Low	If using crude error tolerances to solve stiff systems and the mass matrix is constant.
ode23t	Moderately Stiff	Low	For moderately stiff problems if you need a solution without numerical damping.
ode23tb	Stiff	Low	If using crude error tolerances to solve stiff systems.

The algorithms used in the ODE solvers vary according to order of accuracy [6] and the type of systems (stiff or nonstiff) they are designed to solve. See “Algorithms” on page 1-5392 for more details.

## Options

Different solvers accept different parameters in the options list. For more information, see `odeset` and “Integrator Options” in the MATLAB Mathematics documentation.

Parameters	ode45	ode23	ode113	ode15s	ode23s	ode23t	ode23tb
RelTol, AbsTol, NormControl	√	√	√	√	√	√	√
OutputFcn, OutputSel, Refine, Stats	√	√	√	√	√	√	√
NonNegative	√	√	√	√ *	—	√ *	√ *
Events	√	√	√	√	√	√	√
MaxStep, InitialStep	√	√	√	√	√	√	√

Parameters	ode45	ode23	ode113	ode15s	ode23s	ode23t	ode23tb
Jacobian, JPattern, Vectorized	—	—	—	√	√	√	√
Mass	√	√	√	√	√	√	√
MStateDependence	√	√	√	√	—	√	√
MvPattern	—	—	—	√	—	√	√
MassSingular	—	—	—	√	—	√	—
InitialSlope	—	—	—	√	—	√	—
MaxOrder, BDF	—	—	—	√	—	—	—

**Note** You can use the `NonNegative` parameter with `ode15s`, `ode23t`, and `ode23tb` only for those problems for which there is no mass matrix.

## Examples

### Example 1

An example of a nonstiff system is the system of equations describing the motion of a rigid body without external forces.

$$\begin{aligned} y_1' &= y_2 y_3 & y_1(0) &= 0 \\ y_2' &= -y_1 y_3 & y_2(0) &= 1 \\ y_3' &= -0.51 y_1 y_2 & y_3(0) &= 1 \end{aligned}$$

To simulate this system, create a function `rigid` containing the equations

```
function dy = rigid(t,y)
dy = zeros(3,1); % a column vector
dy(1) = y(2) * y(3);
dy(2) = -y(1) * y(3);
dy(3) = -0.51 * y(1) * y(2);
```

In this example we change the error tolerances using the `odeset` command and solve on a time interval `[0 12]` with an initial condition vector `[0 1 1]` at time 0.

```
options = odeset('RelTol',1e-4,'AbsTol',[1e-4 1e-4 1e-5]);
[T,Y] = ode45(@rigid,[0 12],[0 1 1],options);
```

Plotting the columns of the returned array Y versus T shows the solution

```
plot(T,Y(:,1),'-',T,Y(:,2),'-.',T,Y(:,3),'.');
```

## Example 2

An example of a stiff system is provided by the van der Pol equations in relaxation oscillation. The limit cycle has portions where the solution components change slowly and the problem is quite stiff, alternating with regions of very sharp change where it is not stiff.

$$\begin{aligned}y_1' &= y_2 & y_1(0) &= 2 \\y_2' &= 1000(1 - y_1^2)y_2 - y_1 & y_2(0) &= 0\end{aligned}$$

To simulate this system, create a function `vdp1000` containing the equations

```
function dy = vdp1000(t,y)
dy = zeros(2,1); % a column vector
dy(1) = y(2);
dy(2) = 1000*(1 - y(1)^2)*y(2) - y(1);
```

For this problem, we will use the default relative and absolute tolerances ( $1e-3$  and  $1e-6$ , respectively) and solve on a time interval of `[0 3000]` with initial condition vector `[2 0]` at time 0.

```
[T,Y] = ode15s(@vdp1000,[0 3000],[2 0]);
```

Plotting the first column of the returned matrix `Y` versus `T` shows the solution

```
plot(T,Y(:,1),'-o')
```

### Example 3

This example solves an ordinary differential equation with time-dependent terms.

Consider the following ODE, with time-dependent parameters defined only through the set of data points given in two vectors:

$$y'(t) + f(t)y(t) = g(t)$$

The initial condition is  $y(1) = 1$ , where the function  $f(t)$  is defined by the  $n$ -by-1 vector  $f$  evaluated at times  $ft$ , and the function  $g(t)$  is defined by the  $m$ -by-1 vector  $g$  evaluated at times  $gt$ .

First, define the time-dependent parameters  $f(t)$  and  $g(t)$  as the following:

```
ft = linspace(0,5,25); % Generate t for f
f = ft.^2 - ft - 3; % Generate f(t)
gt = linspace(1,6,25); % Generate t for g
g = 3*sin(gt-0.25); % Generate g(t)
```

Write a function to interpolate the data sets specified above to obtain the value of the time-dependent terms at the specified time:

```
function dydt = myode(t,y,ft,f,gt,g)
f = interp1(ft,f,t); % Interpolate the data set (ft,f) at time t
g = interp1(gt,g,t); % Interpolate the data set (gt,g) at time t
dydt = -f.*y + g; % Evaluate ODE at time t
```

Call the derivative function `myode.m` within the MATLAB `ode45` function specifying time as the first input argument :

```
Tspan = [1 5]; % Solve from t=1 to t=5
IC = 1; % y(t=1) = 1
[T Y] = ode45(@(t,y) myode(t,y,ft,f,gt,g),Tspan,IC); % Solve ODE
Plot the solution y(t) as a function of time:
```

```
plot(T, Y);
title('Plot of y as a function of time');
xlabel('Time');
ylabel('Y(t)');
```

## More About

### Algorithms

`ode45` is based on an explicit Runge-Kutta (4,5) formula, the Dormand-Prince pair. It is a *one-step* solver – in computing  $y(t_n)$ , it needs only the solution at the immediately preceding time point,  $y(t_{n-1})$ . In general, `ode45` is the best function to apply as a *first try* for most problems. [3]

`ode23` is an implementation of an explicit Runge-Kutta (2,3) pair of Bogacki and Shampine. It may be more efficient than `ode45` at crude tolerances and in the presence of moderate stiffness. Like `ode45`, `ode23` is a one-step solver. [2]

`ode113` is a variable order Adams-Bashforth-Moulton PECE solver. It may be more efficient than `ode45` at stringent tolerances and when the ODE file function is particularly expensive to evaluate. `ode113` is a *multistep* solver — it normally needs the solutions at several preceding time points to compute the current solution. [7]

The above algorithms are intended to solve nonstiff systems. If they appear to be unduly slow, try using one of the stiff solvers below.

`ode15s` is a variable order solver based on the numerical differentiation formulas (NDFs). Optionally, it uses the backward differentiation formulas (BDFs, also known as Gear's method) that are usually less efficient. Like `ode113`, `ode15s` is a multistep solver. Try `ode15s` when `ode45` fails, or is very inefficient, and you suspect that the problem is stiff, or when solving a differential-algebraic problem. [9], [10]

`ode23s` is based on a modified Rosenbrock formula of order 2. Because it is a one-step solver, it may be more efficient than `ode15s` at crude tolerances. It can solve some kinds of stiff problems for which `ode15s` is not effective. [9]

`ode23t` is an implementation of the trapezoidal rule using a “free” interpolant. Use this solver if the problem is only moderately stiff and you need a solution without numerical damping. `ode23t` can solve DAEs. [10]

`ode23tb` is an implementation of TR-BDF2, an implicit Runge-Kutta formula with a first stage that is a trapezoidal rule step and a second stage that is a backward differentiation formula of order two. By construction, the same iteration matrix is used in evaluating both stages. Like `ode23s`, this solver may be more efficient than `ode15s` at crude tolerances. [8], [1]

# ode113

Solve nonstiff differential equations; variable order method

## Syntax

```
[T,Y] = solver(odefun,tspan,y0)
[T,Y] = solver(odefun,tspan,y0,options)
[T,Y,TE,YE,IE] = solver(odefun,tspan,y0,options)
sol = solver(odefun,[t0 tf],y0...)
```

This page contains an overview of the solver functions: `ode23`, `ode45`, `ode113`, `ode15s`, `ode23s`, `ode23t`, and `ode23tb`. You can call any of these solvers by substituting the placeholder, `solver`, with any of the function names.

## Arguments

The following table describes the input arguments to the solvers.

<code>odefun</code>	A function handle that evaluates the right side of the differential equations. All solvers solve systems of equations in the form $y' = f(t,y)$ or problems that involve a mass matrix, $M(t,y)y' = f(t,y)$ . The <code>ode23s</code> solver can solve only equations with constant mass matrices. <code>ode15s</code> and <code>ode23t</code> can solve problems with a mass matrix that is singular, i.e., differential-algebraic equations (DAEs).
<code>tspan</code>	A vector specifying the interval of integration, <code>[t0,tf]</code> . The solver imposes the initial conditions at <code>tspan(1)</code> , and integrates from <code>tspan(1)</code> to <code>tspan(end)</code> . To obtain solutions at specific times (all increasing or all decreasing), use <code>tspan = [t0,t1,...,tf]</code> .  For <code>tspan</code> vectors with two elements <code>[t0 tf]</code> , the solver returns the solution evaluated at every integration step. For <code>tspan</code> vectors with more than two elements, the solver returns solutions evaluated at the given time points. The time values must be in order, either increasing or decreasing.

Specifying `tspan` with more than two elements does not affect the internal time steps that the solver uses to traverse the interval from `tspan(1)` to `tspan(end)`. All solvers in the ODE suite obtain output values by means of continuous extensions of the basic formulas. Although a solver does not necessarily step precisely to a time point specified in `tspan`, the solutions produced at the specified time points are of the same order of accuracy as the solutions computed at the internal time points.

Specifying `tspan` with more than two elements has little effect on the efficiency of computation, but for large systems, affects memory management.

`y0` A vector of initial conditions.

`options` Structure of optional parameters that change the default integration properties. This is the fourth input argument.

```
[t,y] = solver(odefun,tspan,y0,options)
```

You can create options using the `odeset` function. See `odeset` for details.

The following table lists the output arguments for the solvers.

<code>T</code>	Column vector of time points.
<code>Y</code>	Solution array. Each row in <code>Y</code> corresponds to the solution at a time returned in the corresponding row of <code>T</code> .
<code>TE</code>	The time at which an event occurs.
<code>YE</code>	The solution at the time of the event.
<code>IE</code>	The index <code>i</code> of the event function that vanishes.
<code>sol</code>	Structure to evaluate the solution.

## Description

`[T,Y] = solver(odefun,tspan,y0)` with `tspan = [t0 tf]` integrates the system of differential equations  $y' = f(t,y)$  from time `t0` to `tf` with initial conditions `y0`. The first

input argument, `odefun`, is a function handle. The function,  $f = \text{odefun}(t, y)$ , for a scalar  $t$  and a column vector  $y$ , must return a column vector  $f$  corresponding to  $f(t, y)$ . Each row in the solution array  $Y$  corresponds to a time returned in column vector  $T$ . To obtain solutions at the specific times  $t_0, t_1, \dots, t_f$  (all increasing or all decreasing), use `tspan = [t0, t1, ..., tf]`.

“Parameterizing Functions” explains how to provide additional parameters to the function `fun`, if necessary.

`[T, Y] = solver(odefun, tspan, y0, options)` solves as above with default integration parameters replaced by “property values” specified in `options`, an argument created with the `odeset` function. Commonly used properties include a scalar relative error tolerance `RelTol` ( $1e-3$  by default) and a vector of absolute error tolerances `Abstol` (all components are  $1e-6$  by default). If certain components of the solution must be nonnegative, use the `odeset` function to set the `NonNegative` property to the indices of these components. See `odeset` for details.

`[T, Y, TE, YE, IE] = solver(odefun, tspan, y0, options)` solves as above while also finding where functions of  $(t, y)$ , called event functions, are zero. For each event function, you specify whether the integration is to terminate at a zero and whether the direction of the zero crossing matters. Do this by setting the 'Events' property to a function, e.g., `events` or `@events`, and creating a function `[value, isterminal, direction] = events(t, y)`. For the  $i$ th event function in `events`,

- `value(i)` is the value of the function.
- `isterminal(i) = 1`, if the integration is to terminate at a zero of this event function and 0 otherwise.
- `direction(i) = 0` if all zeros are to be computed (the default), +1 if only the zeros where the event function increases, and -1 if only the zeros where the event function decreases.

Corresponding entries in `TE`, `YE`, and `IE` return, respectively, the time at which an event occurs, the solution at the time of the event, and the index  $i$  of the event function that vanishes.

`sol = solver(odefun, [t0 tf], y0...)` returns a structure that you can use with `deval` to evaluate the solution at any point on the interval `[t0, tf]`. You must pass `odefun` as a function handle. The structure `sol` always includes these fields:

`sol.x`                      Steps chosen by the solver.

`sol.y` Each column `sol.y(:,i)` contains the solution at `sol.x(i)`.  
`sol.solver` Solver name.

If you specify the `Events` option and events are detected, `sol` also includes these fields:

`sol.xe` Points at which events, if any, occurred. `sol.xe(end)` contains the exact point of a terminal event, if any.  
`sol.ye` Solutions that correspond to events in `sol.xe`.  
`sol.ie` Indices into the vector returned by the function specified in the `Events` option. The values indicate which event the solver detected.

If you specify an output function as the value of the `OutputFcn` property, the solver calls it with the computed solution after each time step. Four output functions are provided: `odeplot`, `odephas2`, `odephas3`, `odeprint`. When you call the solver with no output arguments, it calls the default `odeplot` to plot the solution as it is computed. `odephas2` and `odephas3` produce two- and three-dimensional phase plane plots, respectively. `odeprint` displays the solution components on the screen. By default, the ODE solver passes all components of the solution to the output function. You can pass only specific components by providing a vector of indices as the value of the `OutputSel` property. For example, if you call the solver with no output arguments and set the value of `OutputSel` to `[1,3]`, the solver plots solution components 1 and 3 as they are computed.

For the stiff solvers `ode15s`, `ode23s`, `ode23t`, and `ode23tb`, the Jacobian matrix  $\partial f/\partial y$  is critical to reliability and efficiency. Use `odeset` to set `Jacobian` to `@FJAC` if `FJAC(T,Y)` returns the Jacobian  $\partial f/\partial y$  or to the matrix  $\partial f/\partial y$  if the Jacobian is constant. If the `Jacobian` property is not set (the default),  $\partial f/\partial y$  is approximated by finite differences. Set the `Vectorized` property 'on' if the ODE function is coded so that `odefun(T,[Y1,Y2 ...])` returns `[odefun(T,Y1),odefun(T,Y2) ...]`. If  $\partial f/\partial y$  is a sparse matrix, set the `JPattern` property to the sparsity pattern of  $\partial f/\partial y$ , i.e., a sparse matrix `S` with `S(i,j) = 1` if the *i*th component of  $f(t,y)$  depends on the *j*th component of *y*, and 0 otherwise.

The solvers of the ODE suite can solve problems of the form  $M(t,y)y' = f(t,y)$ , with time- and state-dependent mass matrix *M*. (The `ode23s` solver can solve only equations with constant mass matrices.) If a problem has a mass matrix, create a function `M = MASS(t,y)` that returns the value of the mass matrix, and use `odeset` to set the `Mass` property to `@MASS`. If the mass matrix is constant, the matrix should be used as the value of the `Mass` property. Problems with state-dependent mass matrices are more difficult:

- If the mass matrix does not depend on the state variable  $y$  and the function `MASS` is to be called with one input argument,  $t$ , set the `MStateDependence` property to 'none'.
- If the mass matrix depends weakly on  $y$ , set `MStateDependence` to 'weak' (the default); otherwise, set it to 'strong'. In either case, the function `MASS` is called with the two arguments  $(t,y)$ .

If there are many differential equations, it is important to exploit sparsity:

- Return a sparse  $M(t,y)$ .
- Supply the sparsity pattern of  $\partial f/\partial y$  using the `JPattern` property or a sparse  $\partial f/\partial y$  using the `Jacobian` property.
- For strongly state-dependent  $M(t,y)$ , set `MvPattern` to a sparse matrix  $S$  with  $S(i,j) = 1$  if for any  $k$ , the  $(i,k)$  component of  $M(t,y)$  depends on component  $j$  of  $y$ , and 0 otherwise.

If the mass matrix  $M$  is singular, then  $M(t,y)y' = f(t,y)$  is a system of differential algebraic equations. DAEs have solutions only when  $y_0$  is consistent, that is, if there is a vector  $yp_0$  such that  $M(t_0,y_0)yp_0 = f(t_0,y_0)$ . The `ode15s` and `ode23t` solvers can solve DAEs of index 1 provided that  $y_0$  is sufficiently close to being consistent. If there is a mass matrix, you can use `odeset` to set the `MassSingular` property to 'yes', 'no', or 'maybe'. The default value of 'maybe' causes the solver to test whether the problem is a DAE. You can provide  $yp_0$  as the value of the `InitialSlope` property. The default is the zero vector. If a problem is a DAE, and  $y_0$  and  $yp_0$  are not consistent, the solver treats them as guesses, attempts to compute consistent values that are close to the guesses, and continues to solve the problem. When solving DAEs, it is very advantageous to formulate the problem so that  $M$  is a diagonal matrix (a semi-explicit DAE).

Solver	Problem Type	Order of Accuracy	When to Use
ode45	Nonstiff	Medium	Most of the time. This should be the first solver you try.
ode23	Nonstiff	Low	For problems with crude error tolerances or for solving moderately stiff problems.
ode113	Nonstiff	Low to high	For problems with stringent error tolerances or for solving computationally intensive problems.

Solver	Problem Type	Order of Accuracy	When to Use
ode15s	Stiff	Low to medium	If ode45 is slow because the problem is stiff.
ode23s	Stiff	Low	If using crude error tolerances to solve stiff systems and the mass matrix is constant.
ode23t	Moderately Stiff	Low	For moderately stiff problems if you need a solution without numerical damping.
ode23tb	Stiff	Low	If using crude error tolerances to solve stiff systems.

The algorithms used in the ODE solvers vary according to order of accuracy [6] and the type of systems (stiff or nonstiff) they are designed to solve. See “Algorithms” on page 1-5406 for more details.

## Options

Different solvers accept different parameters in the options list. For more information, see `odeset` and “Integrator Options” in the MATLAB Mathematics documentation.

Parameters	ode45	ode23	ode113	ode15s	ode23s	ode23t	ode23tb
RelTol, AbsTol, NormControl	√	√	√	√	√	√	√
OutputFcn, OutputSel, Refine, Stats	√	√	√	√	√	√	√
NonNegative	√	√	√	√ *	—	√ *	√ *
Events	√	√	√	√	√	√	√
MaxStep, InitialStep	√	√	√	√	√	√	√

Parameters	ode45	ode23	ode113	ode15s	ode23s	ode23t	ode23tb
Jacobian, JPattern, Vectorized	—	—	—	√	√	√	√
Mass	√	√	√	√	√	√	√
MStateDependence	√	√	√	√	—	√	√
MvPattern	—	—	—	√	—	√	√
MassSingular	—	—	—	√	—	√	—
InitialSlope	—	—	—	√	—	√	—
MaxOrder, BDF	—	—	—	√	—	—	—

**Note** You can use the `NonNegative` parameter with `ode15s`, `ode23t`, and `ode23tb` only for those problems for which there is no mass matrix.

## Examples

### Example 1

An example of a nonstiff system is the system of equations describing the motion of a rigid body without external forces.

$$\begin{aligned} y_1' &= y_2 y_3 & y_1(0) &= 0 \\ y_2' &= -y_1 y_3 & y_2(0) &= 1 \\ y_3' &= -0.51 y_1 y_2 & y_3(0) &= 1 \end{aligned}$$

To simulate this system, create a function `rigid` containing the equations

```
function dy = rigid(t,y)
dy = zeros(3,1); % a column vector
dy(1) = y(2) * y(3);
dy(2) = -y(1) * y(3);
dy(3) = -0.51 * y(1) * y(2);
```

In this example we change the error tolerances using the `odeset` command and solve on a time interval `[0 12]` with an initial condition vector `[0 1 1]` at time 0.

```
options = odeset('RelTol',1e-4,'AbsTol',[1e-4 1e-4 1e-5]);
[T,Y] = ode45(@rigid,[0 12],[0 1 1],options);
```

Plotting the columns of the returned array Y versus T shows the solution

```
plot(T,Y(:,1),'-',T,Y(:,2),'-.',T,Y(:,3),'.'
```

## Example 2

An example of a stiff system is provided by the van der Pol equations in relaxation oscillation. The limit cycle has portions where the solution components change slowly and the problem is quite stiff, alternating with regions of very sharp change where it is not stiff.

$$\begin{aligned}y_1' &= y_2 & y_1(0) &= 2 \\y_2' &= 1000(1 - y_1^2)y_2 - y_1 & y_2(0) &= 0\end{aligned}$$

To simulate this system, create a function `vdp1000` containing the equations

```
function dy = vdp1000(t,y)
dy = zeros(2,1); % a column vector
dy(1) = y(2);
dy(2) = 1000*(1 - y(1)^2)*y(2) - y(1);
```

For this problem, we will use the default relative and absolute tolerances ( $1e-3$  and  $1e-6$ , respectively) and solve on a time interval of `[0 3000]` with initial condition vector `[2 0]` at time 0.

```
[T,Y] = ode15s(@vdp1000,[0 3000],[2 0]);
```

Plotting the first column of the returned matrix `Y` versus `T` shows the solution

```
plot(T,Y(:,1),'-o')
```

### Example 3

This example solves an ordinary differential equation with time-dependent terms.

Consider the following ODE, with time-dependent parameters defined only through the set of data points given in two vectors:

$$y'(t) + f(t)y(t) = g(t)$$

The initial condition is  $y(1) = 1$ , where the function  $f(t)$  is defined by the  $n$ -by-1 vector  $f$  evaluated at times  $ft$ , and the function  $g(t)$  is defined by the  $m$ -by-1 vector  $g$  evaluated at times  $gt$ .

First, define the time-dependent parameters  $f(t)$  and  $g(t)$  as the following:

```
ft = linspace(0,5,25); % Generate t for f
f = ft.^2 - ft - 3; % Generate f(t)
gt = linspace(1,6,25); % Generate t for g
g = 3*sin(gt-0.25); % Generate g(t)
```

Write a function to interpolate the data sets specified above to obtain the value of the time-dependent terms at the specified time:

```
function dydt = myode(t,y,ft,f,gt,g)
f = interp1(ft,f,t); % Interpolate the data set (ft,f) at time t
g = interp1(gt,g,t); % Interpolate the data set (gt,g) at time t
dydt = -f.*y + g; % Evaluate ODE at time t
Call the derivative function myode.m within the MATLAB ode45 function specifying
time as the first input argument :
```

```
Tspan = [1 5]; % Solve from t=1 to t=5
IC = 1; % y(t=1) = 1
[T Y] = ode45(@(t,y) myode(t,y,ft,f,gt,g),Tspan,IC); % Solve ODE
Plot the solution y(t) as a function of time:
```

```
plot(T, Y);
title('Plot of y as a function of time');
xlabel('Time');
ylabel('Y(t)');
```

## More About

### Algorithms

`ode45` is based on an explicit Runge-Kutta (4,5) formula, the Dormand-Prince pair. It is a *one-step* solver – in computing  $y(t_n)$ , it needs only the solution at the immediately preceding time point,  $y(t_{n-1})$ . In general, `ode45` is the best function to apply as a *first try* for most problems. [3]

`ode23` is an implementation of an explicit Runge-Kutta (2,3) pair of Bogacki and Shampine. It may be more efficient than `ode45` at crude tolerances and in the presence of moderate stiffness. Like `ode45`, `ode23` is a one-step solver. [2]

`ode113` is a variable order Adams-Bashforth-Moulton PECE solver. It may be more efficient than `ode45` at stringent tolerances and when the ODE file function is particularly expensive to evaluate. `ode113` is a *multistep* solver — it normally needs the solutions at several preceding time points to compute the current solution. [7]

The above algorithms are intended to solve nonstiff systems. If they appear to be unduly slow, try using one of the stiff solvers below.

`ode15s` is a variable order solver based on the numerical differentiation formulas (NDFs). Optionally, it uses the backward differentiation formulas (BDFs, also known as Gear's method) that are usually less efficient. Like `ode113`, `ode15s` is a multistep solver. Try `ode15s` when `ode45` fails, or is very inefficient, and you suspect that the problem is stiff, or when solving a differential-algebraic problem. [9], [10]

`ode23s` is based on a modified Rosenbrock formula of order 2. Because it is a one-step solver, it may be more efficient than `ode15s` at crude tolerances. It can solve some kinds of stiff problems for which `ode15s` is not effective. [9]

`ode23t` is an implementation of the trapezoidal rule using a “free” interpolant. Use this solver if the problem is only moderately stiff and you need a solution without numerical damping. `ode23t` can solve DAEs. [10]

`ode23tb` is an implementation of TR-BDF2, an implicit Runge-Kutta formula with a first stage that is a trapezoidal rule step and a second stage that is a backward differentiation formula of order two. By construction, the same iteration matrix is used in evaluating both stages. Like `ode23s`, this solver may be more efficient than `ode15s` at crude tolerances. [8], [1]

# odeget

Ordinary differential equation options parameters

## Syntax

```
o = odeget(options,'name')
o = odeget(options,'name',default)
```

## Description

`o = odeget(options,'name')` extracts the value of the property specified by string `'name'` from integrator options structure `options`, returning an empty matrix if the property value is not specified in `options`. It is only necessary to type the leading characters that uniquely identify the property name. Case is ignored for property names.

`o = odeget(options,'name',default)` returns `o = default` if the named property is not specified in `options`.

The empty matrix `[]` is a valid `options` argument, and the syntax `odeget([], 'name', default)` always returns `default`.

## Examples

Having constructed an ODE options structure,

```
options = odeset('RelTol',1e-4,'AbsTol',[1e-3 2e-3 3e-3]);
```

you can view these property settings with `odeget`.

```
odeget(options,'RelTol')
ans =
```

```
1.0000e-04
```

```
odeget(options,'AbsTol')
ans =
```

0.0010    0.0020    0.0030

```
odeget([], 'RelTol', 1e-3)
ans =
```

1.0000e-03

**See Also**

odeset

# odeset

Create or alter options structure for ordinary differential equation solvers

## Syntax

```
options = odeset('name1',value1,'name2',value2,...)
options = odeset(olddopts,'name1',value1,...)
options = odeset(olddopts,newopts)
odeset
```

## Description

The `odeset` function lets you adjust the integration parameters of the following ODE solvers.

For solving fully implicit differential equations:  
`ode15i`

For solving initial value problems:  
`ode23`, `ode45`, `ode113`, `ode15s`, `ode23s`, `ode23t`, `ode23tb`

See below for information about the integration parameters.

`options = odeset('name1',value1,'name2',value2,...)` creates an options structure that you can pass as an argument to any of the ODE solvers. In the resulting structure, `options`, the named properties have the specified values. For example, `'name1'` has the value `value1`. Any unspecified properties have default values. It is sufficient to type only the leading characters that uniquely identify a property name. Case is ignored for property names.

`options = odeset(olddopts,'name1',value1,...)` alters an existing options structure `olddopts`. This sets `options` equal to the existing structure `olddopts`, overwrites any values in `olddopts` that are respecified using name/value pairs, and adds any new pairs to the structure. The modified structure is returned as an output argument.

`options = odeset(oldopts,newopts)` alters an existing options structure `oldopts` by combining it with a new options structure `newopts`. Any new options not equal to the empty matrix overwrite corresponding options in `oldopts`.

`odeset` with no input arguments displays all property names as well as their possible and default values.

## ODE Properties

The following sections describe the properties that you can set using `odeset`. The available properties depend on the ODE solver you are using. There are several categories of properties:

- “Error Control Properties” on page 1-5412
- “Solver Output Properties” on page 1-5414
- “Step-Size Properties” on page 1-5416
- “Event Location Property” on page 1-5418
- “Jacobian Matrix Properties” on page 1-5419
- “Mass Matrix and DAE Properties” on page 1-5422
- “ode15s and ode15i-Specific Properties” on page 1-5424

---

**Note** This reference page describes the ODE properties for MATLAB, Version 7. The Version 5 properties are supported only for backward compatibility. For information on the Version 5 properties, type at the MATLAB command line: `more on`, `type odeset`, `more off`.

---

## Error Control Properties

At each step, the solver estimates the local error  $e$  in the  $i$ th component of the solution. This error must be less than or equal to the acceptable error, which is a function of the specified relative tolerance, `RelTol`, and the specified absolute tolerance, `AbsTol`.

$$|e(i)| \leq \max(\text{RelTol} * \text{abs}(y(i)), \text{AbsTol}(i))$$

For routine problems, the ODE solvers deliver accuracy roughly equivalent to the accuracy you request. They deliver less accuracy for problems integrated over "long" intervals and problems that are moderately unstable. Difficult problems may require

tighter tolerances than the default values. For relative accuracy, adjust **RelTol**. For the absolute error tolerance, the scaling of the solution components is important: if  $|y|$  is somewhat smaller than **AbsTol**, the solver is not constrained to obtain any correct digits in  $y$ . You might have to solve a problem more than once to discover the scale of solution components.

Roughly speaking, this means that you want **RelTol** correct digits in all solution components except those smaller than thresholds **AbsTol(i)**. Even if you are not interested in a component  $y(i)$  when it is small, you may have to specify **AbsTol(i)** small enough to get some correct digits in  $y(i)$  so that you can accurately compute more interesting components.

The following table describes the error control properties. Further information on each property is given following the table.

Property	Value	Description
<b>RelTol</b>	Positive scalar {1e-3}	Relative error tolerance that applies to all components of the solution vector $y$ .
<b>AbsTol</b>	Positive scalar or vector {1e-6}	Absolute error tolerances that apply to the individual components of the solution vector.
<b>NormControl</b>	on   {off}	Control error relative to norm of solution.

## Description of Error Control Properties

**RelTol** — This tolerance is a measure of the error relative to the size of each solution component. Roughly, it controls the number of correct digits in all solution components, except those smaller than thresholds **AbsTol(i)**.

The default,  $1e-3$ , corresponds to 0.1% accuracy.

**AbsTol** — **AbsTol(i)** is a threshold below which the value of the  $i$ th solution component is unimportant. The absolute error tolerances determine the accuracy when the solution approaches zero.

If **AbsTol** is a vector, the length of **AbsTol** must be the same as the length of the solution vector  $y$ . If **AbsTol** is a scalar, the value applies to all components of  $y$ .

**NormControl** — Set this property **on** to request that the solvers control the error in each integration step with  $\text{norm}(e) \leq \max(\text{RelTol} \cdot \text{norm}(y), \text{AbsTol})$ . By default the solvers use a more stringent componentwise error control.

## Solver Output Properties

The following table lists the solver output properties that control the output that the solvers generate. Further information on each property is given following the table.

Property	Value	Description
NonNegative	Vector of integers	Specifies which components of the solution vector must be nonnegative. The default value is [ ].
OutputFcn	Function handle	A function for the solver to call after every successful integration step.
OutputSel	Vector of indices	Specifies which components of the solution vector are to be passed to the output function.
Refine	Positive integer	Increases the number of output points by a factor of <code>Refine</code> .
Stats	on   {off}	Determines whether the solver should display statistics about its computations. By default, <code>Stats</code> is off.

### Description of Solver Output Properties

**NonNegative** — The `NonNegative` property is not available in `ode23s`, `ode15i`. In `ode15s`, `ode23t`, and `ode23tb`, `NonNegative` is not available for problems where there is a mass matrix.

**OutputFcn** — To specify an output function, set '`OutputFcn`' to a function handle. For example,

```
options = odeset('OutputFcn',@myfun)
```

sets '`OutputFcn`' to `@myfun`, a handle to the function `myfun`. See the `function_handle` reference page for more information.

The output function must be of the form

```
status = myfun(t,y,flag)
```

“Parameterizing Functions” explains how to provide additional parameters to `myfun`, if necessary.

The solver calls the specified output function with the following flags. Note that the syntax of the call differs with the flag. The function must respond appropriately:

Flag	Description
init	The solver calls <code>myfun(tspan,y0,'init')</code> before beginning the integration to allow the output function to initialize. <code>tspan</code> and <code>y0</code> are the input arguments to the ODE solver.
{[]}	The solver calls <code>status = myfun(t,y,[])</code> after each integration step on which output is requested. <code>t</code> contains points where output was generated during the step, and <code>y</code> is the numerical solution at the points in <code>t</code> . If <code>t</code> is a vector, the <code>i</code> th column of <code>y</code> corresponds to the <code>i</code> th element of <code>t</code> .  When <code>length(tspan) &gt; 2</code> the output is produced at every point in <code>tspan</code> . When <code>length(tspan) = 2</code> the output is produced according to the <code>Refine</code> option.  <code>myfun</code> must return a <code>status</code> output value of 0 or 1. If <code>status = 1</code> , the solver halts integration. You can use this mechanism, for instance, to implement a <b>Stop</b> button.
done	The solver calls <code>myfun([],[],'done')</code> when integration is complete to allow the output function to perform any cleanup chores.

You can use these general purpose output functions or you can edit them to create your own. Type `help function` at the command line for more information.

- `odeplot` — Time series plotting (default when you call the solver with no output arguments and you have not specified an output function)
- `odephas2` — Two-dimensional phase plane plotting
- `odephas3` — Three-dimensional phase plane plotting
- `odeprint` — Print solution as it is computed

---

**Note** If you call the solver with no output arguments, the solver does not allocate storage to hold the entire solution history.

---

**OutputSel** — Use `OutputSel` to specify which components of the solution vector you want passed to the output function. For example, if you want to use the `odeplot` output

function, but you want to plot only the first and third components of the solution, you can do this using

```
options = ...
odeset('OutputFcn',@odeplot,'OutputSel',[1 3]);
```

By default, the solver passes all components of the solution to the output function.

**Refine** — If **Refine** is 1, the solver returns solutions only at the end of each time step. If **Refine** is  $n > 1$ , the solver subdivides each time step into  $n$  smaller intervals and returns solutions at each time point. **Refine** does not apply when `length(tspan) > 2` or the ODE solver returns the solution as a structure.

---

**Note** In all the solvers, the default value of **Refine** is 1. Within `ode45`, however, the default is 4 to compensate for the solver's large step sizes. To override this and see only the time steps chosen by `ode45`, set **Refine** to 1.

---

The extra values produced for **Refine** are computed by means of continuous extension formulas. These are specialized formulas used by the ODE solvers to obtain accurate solutions between computed time steps without significant increase in computation time.

**Stats** — By default, **Stats** is *off*. If it is *on*, after solving the problem the solver displays

- Number of successful steps
- Number of failed attempts
- Number of times the ODE function was called to evaluate  $f(t,y)$

Solvers based on implicit methods, including `ode23s`, `ode23t`, `ode15s`, and `ode15i`, also display

- Number of times that the partial derivatives matrix  $\partial f/\partial x$  was formed
- Number of LU decompositions
- Number of solutions of linear systems

## Step-Size Properties

The step-size properties specify the size of the first step the solver tries, potentially helping it to better recognize the scale of the problem. In addition, you can specify bounds on the sizes of subsequent time steps.

The following table describes the step-size properties. Further information on each property is given following the table.

Property	Value	Description
<code>InitialStep</code>	Positive scalar	Suggested initial step size.
<code>MaxStep</code>	Positive scalar { $0.1 * \text{abs}(t_0 - t_f)$ }	Upper bound on solver step size.

## Description of Step-Size Properties

**InitialStep** — `InitialStep` sets an upper bound on the magnitude of the first step size the solver tries. If you do not set `InitialStep`, the initial step size is based on the slope of the solution at the initial time `tspan(1)`, and if the slope of all solution components is zero, the procedure might try a step size that is much too large. If you know this is happening or you want to be sure that the solver resolves important behavior at the start of the integration, help the code start by providing a suitable `InitialStep`.

**MaxStep** — If the differential equation has periodic coefficients or solutions, it might be a good idea to set `MaxStep` to some fraction (such as 1/4) of the period. This guarantees that the solver does not enlarge the time step too much and step over a period of interest. Do *not* reduce `MaxStep` for any of the following purposes:

- To produce more output points. This can significantly slow down solution time. Instead, use `Refine` to compute additional outputs by continuous extension at very low cost.
- When the solution does not appear to be accurate enough. Instead, reduce the relative error tolerance `RelTol`, and use the solution you just computed to determine appropriate values for the absolute error tolerance vector `AbsTol`. See “Error Control Properties” on page 1-5412 for a description of the error tolerance properties.
- To make sure that the solver doesn't step over some behavior that occurs only once during the simulation interval. If you know the time at which the change occurs, break the simulation interval into two pieces and call the solver twice. If you do not

know the time at which the change occurs, try reducing the error tolerances `RelTol` and `AbSTol`. Use `MaxStep` as a last resort.

## Event Location Property

In some ODE problems the times of specific events are important, such as the time at which a ball hits the ground, or the time at which a spaceship returns to the earth. While solving a problem, the ODE solvers can detect such events by locating transitions to, from, or through zeros of user-defined functions.

The following table describes the `Events` property. Further information on each property is given following the table.

### ODE Events Property

String	Value	Description
<code>Events</code>	Function handle	Handle to a function that includes one or more event functions.

## Description of Event Location Properties

**Events** — The function is of the form

```
[value, isterminal, direction] = events(t, y)
```

`value`, `isterminal`, and `direction` are vectors for which the `i`th element corresponds to the `i`th event function:

- `value(i)` is the value of the `i`th event function.
- `isterminal(i) = 1` if the integration is to terminate at a zero of this event function, otherwise, `0`.
- `direction(i) = 0` if all zeros are to be located (the default), `+1` if only zeros where the event function is increasing, and `-1` if only zeros where the event function is decreasing.

If you specify an events function and events are detected, the solver returns three additional outputs:

- A column vector of times at which events occur

- Solution values corresponding to these times
- Indices into the vector returned by the events function. The values indicate which event the solver detected.

If you call the solver as

```
[T,Y,TE,YE,IE] = solver(odefun,tspan,y0,options)
```

the solver returns these outputs as TE, YE, and IE respectively. If you call the solver as

```
sol = solver(odefun,tspan,y0,options)
```

the solver returns these outputs as `sol.xe`, `sol.ye`, and `sol.ie`, respectively.

For examples that use an event function, see “Event Location” and “Advanced Event Location” in the MATLAB Mathematics documentation.

## Jacobian Matrix Properties

The stiff ODE solvers often execute faster if you provide additional information about the Jacobian matrix  $\partial f/\partial y$ , a matrix of partial derivatives of the function that defines the differential equations.

$$\frac{\partial f}{\partial y} = \begin{bmatrix} \frac{\partial f_1}{\partial y_1} & \frac{\partial f_1}{\partial y_2} & \cdots \\ \frac{\partial f_2}{\partial y_1} & \frac{\partial f_2}{\partial y_2} & \cdots \\ \vdots & \vdots & \ddots \end{bmatrix}$$

The Jacobian matrix properties pertain only to those solvers for stiff problems (`ode15s`, `ode23s`, `ode23t`, `ode23tb`, and `ode15i`) for which the Jacobian matrix  $\partial f/\partial y$  can be critical to reliability and efficiency. If you do not provide a function to calculate the Jacobian, these solvers approximate the Jacobian numerically using finite differences. In this case, you might want to use the `Vectorized` or `JPattern` properties.

The following table describes the Jacobian matrix properties for all implicit solvers except `ode15i`. Further information on each property is given following the table. See [Jacobian Properties for ode15i](#) for `ode15i`-specific information.

**Jacobian Properties for All Implicit Solvers Except ode15i**

Property	Value	Description
Jacobian	Function handle   constant matrix	Matrix or function that evaluates the Jacobian.
JPattern	Sparse matrix of {0,1}	Generates a sparse Jacobian matrix numerically.
Vectorized	on   {off}	Allows the solver to reduce the number of function evaluations required.

**Description of Jacobian Properties**

**Jacobian** — Supplying an analytical Jacobian often increases the speed and reliability of the solution for stiff problems. Set this property to a function `FJac`, where `FJac(t,y)` computes  $\partial f/\partial y$ , or to the constant value of  $\partial f/\partial y$ .

The Jacobian for the “van der Pol Equation (Stiff)”, described in the MATLAB Mathematics documentation, can be coded as

```
function J = vdp1000jac(t,y)
J = [0 1
 (-2000*y(1)*y(2)-1) (1000*(1-y(1)^2))];
```

**JPattern** — `JPattern` is a sparsity pattern with 1s where there might be nonzero entries in the Jacobian.

---

**Note** If you specify `Jacobian`, the solver ignores any setting for `JPattern`.

---

Set this property to a sparse matrix  $S$  with  $S(i,j) = 1$  if component  $i$  of  $f(t,y)$  depends on component  $j$  of  $y$ , and 0 otherwise. The solver uses this sparsity pattern to generate a sparse Jacobian matrix numerically. If the Jacobian matrix is large and sparse, this can greatly accelerate execution. For an example using the `JPattern` property, see “Example: Large, Stiff, Sparse Problem” in the MATLAB Mathematics documentation.

**Vectorized** — The `Vectorized` property allows the solver to reduce the number of function evaluations required to compute all the columns of the Jacobian matrix, and might significantly reduce solution time.

Set `on` to inform the solver that you have coded the ODE function `F` so that `F(t, [y1 y2 ...])` returns `[F(t,y1) F(t,y2) ...]`. This allows the solver to reduce the number of function evaluations required to compute all the columns of the Jacobian matrix, and might significantly reduce solution time.

---

**Note** If you specify `Jacobian`, the solver ignores a setting of `'on'` for `'Vectorized'`.

---

With the MATLAB array notation, it is typically an easy matter to vectorize an ODE function. For example, you can vectorize the “van der Pol Equation (Stiff)”, described in the MATLAB Mathematics documentation, by introducing colon notation into the subscripts and by using the array power (`.^`) and array multiplication (`.*`) operators.

```
function dydt = vdp1000(t,y)
dydt = [y(2,:); 1000*(1-y(1,:).^2).*y(2,:)-y(1,:)];
```

---

**Note** Vectorization of the ODE function used by the ODE solvers differs from the vectorization used by the boundary value problem (BVP) solver, `bvp4c`. For the ODE solvers, the ODE function is vectorized only with respect to the second argument, while `bvp4c` requires vectorization with respect to the first and second arguments.

---

The following table describes the Jacobian matrix properties for `ode15i`.

### Jacobian Properties for `ode15i`

Property	Value	Description
Jacobian	Function handle   Cell array of constant values	Function that evaluates the Jacobian or a cell array of constant values.
JPattern	Sparse matrices of {0,1}	Generates a sparse Jacobian matrix numerically.
Vectorized	on   {off}	Vectorized ODE function

### Description of Jacobian Properties for `ode15i`

**Jacobian** — Supplying an analytical Jacobian often increases the speed and reliability of the solution for stiff problems. Set this property to a function

```
[dFdy,dFdp] = Fjac(t,y,yp)
```

or to a cell array of constant values  $[\partial F/\partial y, (\partial F/\partial y)']$ .

**JPattern** —

**JPattern** is a sparsity pattern with 1's where there might be nonzero entries in the Jacobian.

Set this property to  $\{\text{dFdypPattern}, \text{dFdyPattern}\}$ , the sparsity patterns of  $\partial F/\partial y$  and  $\partial F/\partial y'$ , respectively.

**Vectorized** —

Set this property to  $\{\text{yVect}, \text{ypVect}\}$ . Setting **yVect** to 'on' indicates that

$F(t, [y1\ y2\ \dots], yp)$

returns

$[F(t, y1, yp), F(t, y2, yp)\ \dots]$

Setting **ypVect** to 'on' indicates that

$F(t, y, [yp1\ yp2\ \dots])$

returns

$[F(t, y, yp1)\ F(t, y, yp2)\ \dots]$

## Mass Matrix and DAE Properties

This section describes mass matrix and differential-algebraic equation (DAE) properties, which apply to all the solvers except `ode15i`. These properties are not applicable to `ode15i` and their settings do not affect its behavior.

The solvers of the ODE suite can solve ODEs of the form

$$M(t, y)y' = f(t, y)$$

with a mass matrix  $M(t, y)$  that can be sparse.

When  $M(t, y)$  is nonsingular, the equation above is equivalent to  $y' = M^{-1} f(t, y)$  and the ODE has a solution for any initial values  $y_0$  at  $t_0$ . The more general form (Equation 1-3)

is convenient when you express a model naturally in terms of a mass matrix. For large, sparse  $M(t,y)$ , solving Equation 1-3 directly reduces the storage and run-time needed to solve the problem.

When  $M(t,y)$  is singular, then  $M(t,y)$  times  $M(t,y)y' = f(t,y)$  is a DAE. A DAE has a solution only when  $y_0$  is consistent; that is, there exists an initial slope  $yp_0$  such that  $M(t_0,y_0)yp_0 = f(t_0,y_0)$ . If  $y_0$  and  $yp_0$  are not consistent, the solver treats them as guesses, attempts to compute consistent values that are close to the guesses, and continues to solve the problem. For DAEs of index 1, solving an initial value problem with consistent initial conditions is much like solving an ODE.

The `ode15s` and `ode23t` solvers can solve DAEs of index 1. For examples of DAE problems, see “Example: Differential-Algebraic Problem”, in the MATLAB Mathematics documentation, and the examples `amp1dae` and `hb1dae`.

The following table describes the mass matrix and DAE properties. Further information on each property is given following the table.

### Mass Matrix and DAE Properties (Solvers Other Than `ode15i`)

Property	Value	Description
Mass	Matrix   function handle	Mass matrix or a function that evaluates the mass matrix $M(t,y)$ .
MStateDependence	none   {weak}   strong	Dependence of the mass matrix on $y$ .
MvPattern	Sparse matrix	$\partial(M(t,y)v)/\partial y$ sparsity pattern.
MassSingular	yes   no   {maybe}	Indicates whether the mass matrix is singular.
InitialSlope	Vector {zero vector}	Vector representing the consistent initial slope $yp_0$ .

### Description of Mass Matrix and DAE Properties

**Mass** — For problems of the form  $M(t)y' = f(t,y)$ , set 'Mass' to a mass matrix  $M$ .

For problems of the form  $M(t)y' = f(t,y)$ , set 'Mass' to a function handle `@Mfun`, where `Mfun(t,y)` evaluates the mass matrix  $M(t,y)$ . The `ode23s` solver can only solve problems with a constant mass matrix  $M$ . When solving DAEs, using `ode15s` or `ode23t`, it is advantageous to formulate the problem so that  $M$  is a diagonal matrix (a semiexplicit DAE).

For example problems, see “Finite Element Discretization” in the MATLAB Mathematics documentation, or the examples `fem2ode` or `batonode`.

**MStateDependence** — Set this property to `none` for problems  $M(t)y' = f(t, y)$ .

Both `weak` and `strong` indicate  $M(t, y)$ , but `weak` results in implicit solvers using approximations when solving algebraic equations.

**MvPattern** — Set this property to a sparse matrix  $S$  with  $S(i, j) = 1$  if, for any  $k$ , the  $(i, k)$  component of  $M(t, y)$  depends on component  $j$  of  $y$ , and 0 otherwise. For use with the `ode15s`, `ode23t`, and `ode23tb` solvers when `MStateDependence` is `strong`. See `burgersode` as an example.

**MassSingular** — Set this property to `no` if the mass matrix is not singular and you are using either the `ode15s` or `ode23t` solver. The default value of `maybe` causes the solver to test whether the problem is a DAE, by testing whether  $M(t_0, y_0)$  is singular.

**InitialSlope** — Vector representing the consistent initial slope  $yp_0$ , where  $yp_0$  satisfies  $M(t_0, y_0) \cdot yp_0 = f(t_0, y_0)$ . The default is the zero vector.

This property is for use with the `ode15s` and `ode23t` solvers when solving DAEs.

## ode15s and ode15i-Specific Properties

`ode15s` is a variable-order solver for stiff problems. It is based on the numerical differentiation formulas (NDFs). The NDFs are generally more efficient than the closely related family of backward differentiation formulas (BDFs), also known as Gear's methods. The `ode15s` properties let you choose among these formulas, as well as specifying the maximum order for the formula used.

`ode15i` solves fully implicit differential equations of the form

$$f(t, y, y') = 0$$

using the variable order BDF method.

The following table describes the `ode15s` and `ode15i`-specific properties. Further information on each property is given following the table. Use `odeset` to set these properties.

### ode15s and ode15i-Specific Properties

Property	Value	Description
MaxOrder	1   2   3   4   {5}	Maximum order formula used to compute the solution.
BDF (ode15s only)	on   {off}	Specifies whether you want to use the BDFs instead of the default NDFs.

### Description of ode15s and ode15i-Specific Properties

**MaxOrder** — Maximum order formula used to compute the solution.

**BDF** (ode15s only) — Set **BDF** on to have **ode15s** use the BDFs.

For both the NDFs and BDFs, the formulas of orders 1 and 2 are A-stable (the stability region includes the entire left half complex plane). The higher order formulas are not as stable, and the higher the order the worse the stability. There is a class of stiff problems (stiff oscillatory) that is solved more efficiently if **MaxOrder** is reduced (for example to 2) so that only the most stable formulas are used.

## odextend

Extend solution of initial value problem for ordinary differential equation

### Syntax

```
solext = odextend(sol, odefun, tfinal)
solext = odextend(sol, [], tfinal)
solext = odextend(sol, odefun, tfinal, yinit)
solext = odextend(sol, odefun, tfinal, [yinit, ypinit])
solext = odextend(sol, odefun, tfinal, yinit, options)
```

### Description

`solext = odextend(sol, odefun, tfinal)` extends the solution stored in `sol` to an interval with upper bound `tfinal` for the independent variable. Specify `odefun` as a function handle. Specify `sol` as an ODE solution structure created using an ODE solver. The lower bound for the independent variable in `solext` is the same as in `sol`. If you created `sol` with an ODE solver other than `ode15i`, the function `odefun` computes the right-hand side of the ODE equation, which is of the form  $y' = f(t,y)$ . If you created `sol` using `ode15i`, the function `odefun` computes the left-hand side of the ODE equation, which is of the form  $f(t,y,y') = 0$ .

“Parameterizing Functions” explains how to provide additional parameters to the function `odefun`, if necessary.

`odextend` extends the solution by integrating `odefun` from the upper bound for the independent variable in `sol` to `tfinal`, using the same ODE solver that created `sol`. By default, `odextend` uses

- The initial conditions `y = sol.y(:,end)` for the subsequent integration
- The same integration properties and additional input arguments the ODE solver originally used to compute `sol`. This information is stored as part of the solution structure `sol` and is subsequently passed to `solext`. Unless you want to change these values, you do not need to pass them to `odextend`.

`solext = odextend(sol, [], tfinal)` uses the same ODE function that the ODE solver uses to compute `sol` to extend the solution. It is not necessary to pass in `odefun` explicitly unless it differs from the original ODE function.

`solext = odextend(sol, odefun, tfinal, yinit)` uses the column vector `yinit` as new initial conditions for the subsequent integration, instead of the vector `sol.y(end)`.

---

**Note** To extend solutions obtained with `ode15i`, use the following syntax, in which the column vector `ypinit` is the initial derivative of the solution:

---

```
solext = odextend(sol, odefun, tfinal, [yinit, ypinit])
```

---

`solext = odextend(sol, odefun, tfinal, yinit, options)` uses the integration properties specified in `options` instead of the options the ODE solver originally used to compute `sol`. The new options are then stored within the structure `solext`. See `odeset` for details on setting `options` properties. Set `yinit = []` as a placeholder to specify the default initial conditions.

## Examples

The following command

```
sol=ode45(@vdp1,[0 10],[2 0]);
```

uses `ode45` to solve the system  $y' = \text{vdp1}(t, y)$ , where `vdp1` is an example of an ODE function provided with MATLAB software, on the interval `[0 10]`. Then, the commands

```
sol=odextend(sol,@vdp1,20);
plot(sol.x,sol.y(1,:));
```

extend the solution to the interval `[0 20]` and plot the first component of the solution on `[0 20]`.

## onCleanup

Cleanup tasks upon function completion

### Syntax

```
cleanupObj = onCleanup(cleanupFun)
```

### Description

`cleanupObj = onCleanup(cleanupFun)` creates an object that, when destroyed, executes the function `cleanupFun`. MATLAB implicitly clears all local variables at the termination of a function, whether by normal completion, or a forced exit, such as an error, or **Ctrl+C**.

If you reference or pass `cleanupObj` outside your function, then `cleanupFun` does not run when that function terminates. Instead, it runs whenever MATLAB destroys the object.

### Examples

#### Close a Figure After Executing Function

Save the following code in `action.m` and type `action` in the Command Window.

```
function [] = action()
f = figure;
finishup = onCleanup(@() myCleanupFun(f));
disp('Display Figure')
end
```

```
function myCleanupFun(f)
close(f)
disp('Close Figure')
end
```

```
Display Figure
```

Close Figure

### Switch Directories After Executing Function

Pass your own script to the `onCleanup` object so that it executes when MATLAB destroys the cleanup object.

Save the following code in `cleanup.m`.

```
cd(tempdir)
disp('You are now in the temporary folder')
```

Save the following code in `youraction.m` and type `youraction` in the Command Window.

```
function [] = youraction
 changeup = onCleanup(@cleanup);
 disp('Execute Code')
end
```

```
Execute Code
You are now in the temporary folder
```

## Input Arguments

**cleanupFun** — Clean-up task  
function handle

Clean-up task, specified as a handle to a function.

You can declare any number of `onCleanup` objects in a program file. However, if the clean-up tasks depend on the order of execution, then you should define only one object that calls a script or function, containing the relevant clean-up commands.

You should use an anonymous function handle to call your clean-up task. This allows you to pass arguments to your clean-up function.

Example: `@() fclose('file.m')`

Example: `@() user_script`

Example: `@() function(input)`

Data Types: `function_handle`

## More About

### Tips

- Avoid using nested functions during cleanup. MATLAB can clear variables used in nested functions before the clean-up function tries to read from them.
- If your program contains multiple cleanup objects, MATLAB does not guarantee the order that it destroys these objects.
- If the order of your cleanup functions matters, define one `onCleanup` object for all the tasks.
  - “Clean Up When Functions Complete”
  - “Object Lifecycle”
  - “Function Handles”
  - “What Are Anonymous Functions?”

## ones

Create array of all ones

### Syntax

```
X = ones
X = ones(n)
X = ones(sz1, ..., szN)
X = ones(sz)

X = ones(classname)
X = ones(n, classname)
X = ones(sz1, ..., szN, classname)
X = ones(sz, classname)

X = ones('like', p)
X = ones(n, 'like', p)
X = ones(sz1, ..., szN, 'like', p)
X = ones(sz, 'like', p)
```

### Description

`X = ones` returns the scalar 1.

`X = ones(n)` returns an  $n$ -by- $n$  matrix of ones.

`X = ones(sz1, ..., szN)` returns an  $sz1$ -by-...-by- $szN$  array of ones where  $sz1, \dots, szN$  indicates the size of each dimension. For example, `ones(2,3)` returns a 2-by-3 array of ones.

`X = ones(sz)` returns an array of ones where the size vector, `SZ`, defines `size(X)`. For example, `ones([2,3])` returns a 2-by-3 array of ones.

`X = ones(classname)` returns a scalar 1 where the string, `classname`, specifies the data type. For example, `ones('int8')` returns a scalar, 8-bit integer 1.

`X = ones(n, classname)` returns an  $n$ -by- $n$  array of ones of data type `classname`.

`X = ones(sz1, ..., szN, classname)` returns an `sz1`-by-...-by-`szN` array of ones of data type `classname`.

`X = ones(sz, classname)` returns an array of ones where the size vector, `SZ`, defines `size(X)` and `classname` defines `class(X)`.

`X = ones('like', p)` returns a scalar `1` with the same data type, sparsity, and complexity (real or complex) as the numeric variable, `p`.

`X = ones(n, 'like', p)` returns an `n`-by-`n` array of ones like `p`.

`X = ones(sz1, ..., szN, 'like', p)` returns an `sz1`-by-...-by-`szN` array of ones like `p`.

`X = ones(sz, 'like', p)` returns an array of ones like `p` where the size vector, `SZ`, defines `size(X)`.

## Examples

### Square Array of Ones

Create a 4-by-4 array of ones.

```
X = ones(4)
```

```
X =
```

```
 1 1 1 1
 1 1 1 1
 1 1 1 1
 1 1 1 1
```

### 3-D Array of Ones

Create a 2-by-3-by-4 array of ones.

```
X = ones(2,3,4);
```

```
size(X)
```

```
ans =
```

```

 2 3 4

```

### Size Defined by Existing Array

Define a 3-by-2 array A.

```
A = [1 4 ; 2 5 ; 3 6];
```

```
sz = size(A)
```

```
sz =
```

```

 3 2

```

Create an array of ones that is the same size as A

```
X = ones(sz)
```

```
X =
```

```

 1 1
 1 1
 1 1

```

### Nondefault Numeric Data Type

Create a 1-by-3 vector of ones whose elements are 16-bit unsigned integers.

```
X = ones(1,3,'uint16'),
class(X)
```

```
X =
```

```

 1 1 1

```

```
ans =
```

```
uint16
```

### Complex One

Create a scalar 1 that is not real valued, but instead is complex like an existing array.

Define a complex vector.

```
p = [1+2i 3i];
```

Create a scalar `1` that is complex like `p`.

```
X = ones('like',p)
X =
 1.0000 + 0.0000i
```

### Size and Numeric Data Type of Defined by Existing Array

Define a 2-by-3 array of 8-bit unsigned integers.

```
p = uint8([1 3 5 ; 2 4 6]);
```

Create an array of ones that is the same size and data type as `p`.

```
X = ones(size(p), 'like', p),
class(X)
X =
 1 1 1
 1 1 1
```

```
ans =
```

```
uint8
```

## Input Arguments

### **n** — Size of square matrix

integer value

Size of square matrix, specified as an integer value, defines the output as a square, n-by-n matrix of ones.

- If `n` is 0, then `X` is an empty matrix.
- If `n` is negative, then it is treated as 0.

Data Types: `double` | `single` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**sz1, ..., szN — Size of each dimension**

two or more integer values

Size of each dimension, specified as two or more integer values, defines X as a sz1-by...-by-szN array.

- If the size of any dimension is 0, then X is an empty array.
- If the size of any dimension is negative, then it is treated as 0.
- If any trailing dimensions greater than 2 have a size of 1, then the output, X, does not include those dimensions.

Data Types: double | single | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**sz — Output size**

row vector of integer values

Output size, specified as a row vector of integer values. Each element of this vector indicates the size of the corresponding dimension.

- If the size of any dimension is 0, then X is an empty array.
- If the size of any dimension is negative, then it is treated as 0.
- If any trailing dimensions greater than 2 have a size of 1, then the output, X, does not include those dimensions.

Example: `sz = [2,3,4]` defines X as a 2-by-3-by-4 array.

Data Types: double | single | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**classname — Output class**

'double' (default) | 'single' | 'int8' | 'uint8' | ...

Output class, specified as 'double', 'single', 'int8', 'uint8', 'int16', 'uint16', 'int32', 'uint32', 'int64', or 'uint64'.

Data Types: char

**p — Prototype**

numeric variable

Prototype, specified as a numeric variable.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Complex Number Support: Yes

## More About

`complex` | `eye` | `false` | `rand` | `randn` | `size` | `zeros`

## open

Open file in appropriate application

### Syntax

```
open(name)
output = open(name)
```

### Description

`open(name)` opens the specified file or variable in the appropriate application.

`output = open(name)` returns an empty *output* (`[]`) for most cases. If opening a MAT-file, *output* is a structure that contains the variables in the file. If opening a figure, *output* is a handle to that figure.

### Input Arguments

#### **name**

Name of file or variable to open. If *name* does not include an extension, the `open` function:

- 1 Searches for a variable named *name*. If the variable exists, `open` opens it in the Variables editor.
- 2 Searches the MATLAB path for *name*.mdl, *name*.slx, or *name*.m. If *name*.mdl or *name*.slx exists, then `open` opens the model in Simulink. If only *name*.m exists, `open` opens the file in the MATLAB Editor.

If more than one file named *name* exists on the MATLAB path, the `open` function opens the file returned by `which(name)`.

The `open` function performs the following actions based on the file extension:

<code>.m</code>	Open in MATLAB Editor.
<code>.mat</code>	Return variables in structure <code>st</code> when called with the syntax:  <code>st = open(name)</code>
<code>.fig</code>	Open figure in Handle Graphics.
<code>.mdl</code> or <code>.slx</code>	Open model in Simulink.
<code>.prj</code>	Open project in the MATLAB Compiler Deployment Tool.
<code>.doc*</code>	Open document in Microsoft Word.
<code>.exe</code>	Run executable file (only on Windows systems).
<code>.pdf</code>	Open document in Adobe® Acrobat®.
<code>.ppt*</code>	Open document in Microsoft PowerPoint.
<code>.xls*</code>	Start MATLAB Import Wizard.
<code>.htm</code> or <code>.html</code>	Open document in MATLAB browser.
<code>.url</code>	Open file in your default Web browser.

## Examples

Open `Contents.m` in the MATLAB Editor by typing:

```
open Contents.m
```

Generally, MATLAB opens `matlabroot\toolbox\matlab\general\Contents.m`. However, if you have a file called `Contents.m` in a directory that is before `toolbox\matlab\general` on the MATLAB path, then `open` opens that file instead.

Open a file not on the MATLAB path by including the complete file specification:

```
open('D:\temp\data.mat')
```

If the file does not exist, MATLAB displays an error message.

Create a function called `opentxt` to handle files with extension `.txt`:

```
function opentxt(filename)
 fprintf('You have requested file: %s\n', filename);
```

```
wh = which(filename);
if exist(filename, 'file') == 2
 fprintf('Opening in MATLAB Editor: %s\n', filename);
 edit(filename);
elseif ~isempty(wh)
 fprintf('Opening in MATLAB Editor: %s\n', wh);
 edit(wh);
else
 warning('MATLAB:fileNotFound', ...
 'File was not found: %s', filename);
end

end
```

Open the file `ngc6543a.txt` (a description of `ngc6543a.jpg`, located in `matlabroot\toolbox\matlab\demos`):

```
photo_text = 'ngc6543a.txt';
open(photo_text)
```

`open` calls your function with the following syntax:

```
opentxt(photo_text)
```

## More About

### Tips

The `open` function opens files based on their extension. You can extend the functionality of `open` by defining your own file handling function of the form `openxxx`, where `xxx` is a file extension. For example, if you create a function `openlog`, the `open` function calls `openlog` to process any files with the `.log` extension. The `open` function returns any single *output* defined by your function.

### See Also

`edit` | `load` | `openfig` | `openvar` | `path` | `uiopen` | `which` | `winopen`

## open

**Class:** VideoWriter

Open file for writing video data

## Syntax

```
open(writerObj)
```

## Description

`open(writerObj)` opens the file associated with `writerObj` for writing. When you open the file, all properties of the object become read only. `open` discards any existing contents of the file.

## Input Arguments

**writerObj**

VideoWriter object created by the `VideoWriter` function.

## Examples

Open a new AVI file:

```
myObj = VideoWriter('newfile.avi');
open(myObj);
```

## See Also

`close` | `writeVideo` | `VideoWriter`

# openfig

Open new copy or raise existing copy of saved figure

## Syntax

```
openfig('filename.fig')
openfig('filename.fig','new')
openfig('filename.fig','reuse')
openfig('filename.fig','new','invisible')
openfig('filename.fig','reuse','invisible')
openfig('filename.fig','new','visible')
openfig('filename.fig','reuse','visible')
figure_handle = openfig(...)
```

## Description

`openfig('filename.fig')` and `openfig('filename.fig','new')` opens the figure contained in the FIG-file, `filename.fig`, and ensures it is visible and positioned completely on screen. You do not have to specify the full path to the FIG-file as long as it is on your MATLAB path. The `.fig` extension is optional.

`openfig('filename.fig','reuse')` opens the figure contained in the FIG-file only if a copy of the figure is not currently open. Otherwise, `openfig` brings the existing copy forward, making sure it is still visible and completely on screen.

`openfig('filename.fig','new','invisible')` or `openfig('filename.fig','reuse','invisible')` opens the figure as in the preceding syntax, while forcing the figure to be invisible.

`openfig('filename.fig','new','visible')` or `openfig('filename.fig','reuse','visible')` opens the figure, while forcing the figure to be visible.

`figure_handle = openfig(...)` returns the handle to the figure.

## More About

### Tips

Use `openfig` to load `.fig` files `.openfig`:

- Provides compatibility with different screen sizes and resolutions by ensuring the figure displays on screen
- Controls if MATLAB displays one or multiple instances of a figure at any given time. The `reuse` option is useful if the figure contains a graphical user interface.
- Returns the handle of the figure created, which is typically hidden for graphical user interface figures.

If the `.fig` file contains an invisible figure, `openfig` returns its handle and leaves it invisible. The caller can make the figure visible when appropriate.

Do not use `openfig` or double-click a `.fig` file to open a GUI created with GUIDE. Instead open the GUI code file by typing its name in the command window or by right-clicking its name in the Current Folder Browser and selecting **Run File**. To open a GUIDE GUI, for example one called `guifile.m`, in an invisible state, specify the `Visible` property in your command:

```
guifile('Visible','off')
```

Your code can then make the figure visible at an appropriate time.

### See Also

`open` | `savefig` | `save`

# opengl

Control OpenGL rendering

The `autoselect`, `neverselect`, `advise`, `quiet`, `verbose`, and `DriverBugWorkaround` inputs have been removed in R2014b. For more information about the behavior of these syntaxes in previous releases, see `opengl` for R2014a.

## Syntax

```
opengl info
d = opengl('data')
```

```
opengl software
opengl hardware
```

```
opengl('save', 'software')
opengl('save', 'hardware')
```

## Description

`opengl info` prints information about the OpenGL library on your system, such as the version, vendor, and graphics features that it supports. The returned fields might change in future releases as graphics features change. Using this command loads the OpenGL library.

`d = opengl('data')` returns the same data provided with `opengl info`, but stores it in a structure.

`opengl software` uses the software version of OpenGL built into MATLAB to render subsequent graphics. This command works only on Windows systems. To use software OpenGL on Linux systems, start MATLAB with the `-softwareopengl` flag. Macintosh systems do not support software OpenGL.

`opengl hardware` uses the version of OpenGL on your operating system to render subsequent graphics. Use this option if you have graphics hardware that supports

hardware-accelerated OpenGL. This command works only on Windows systems. To use hardware OpenGL on Linux systems, start MATLAB with the `-nosoftwareopengl` flag.

`opengl('save','software')` sets your preferences so that future sessions of MATLAB on this computer use software OpenGL. This command does not affect the current session.

`opengl('save','hardware')` uses the version of OpenGL on your operating system. This command does not affect the current session.

## Examples

### Display Information About OpenGL

Display information about the OpenGL library on your system, such as the vendor, the version, and the MATLAB graphics features that it supports. Also display whether MATLAB is using a hardware-accelerated implementation or a software implementation of OpenGL.

```
opengl info
```

```
 Version: '3.3.0'
 Vendor: 'NVIDIA Corporation'
 Renderer: 'Quadro 400/PCIe/SSE2'
 MaxTextureSize: 8192
 Visual: 'Visual 0x07, (RGBA 32 bits (8 8 8 8), ...'
 Software: 'false'
 SupportsGraphicsSmoothing: 1
 SupportsDepthPeelTransparency: 1
 SupportsAlignVertexCenters: 1
 Extensions: {251x1 cell}
 MaxFrameBufferSize: 8192
```

### Determine Graphics Hardware

Determine your graphics hardware by checking the `Vendor` and `Renderer` fields returned by the `opengl info` command.

```
opengl info
```

```
Version: '3.3.0'
Vendor: 'NVIDIA Corporation'
Renderer: 'Quadro 400/PCI/SSE2'
MaxTextureSize: 8192
Visual: 'Visual 0x07, (RGBA 32 bits (8 8 8 8), Z depth 24 b
Software: 'false'
SupportsGraphicsSmoothing: 1
SupportsDepthPeelTransparency: 1
SupportsAlignVertexCenters: 1
Extensions: {235x1 cell}
MaxFrameBufferSize: 8192
```

If you are using software OpenGL, then the name listed in the **Vendor** field is not your graphics hardware vendor. The line **Software: 'true'** indicates that you are using software OpenGL.

If you are using software OpenGL on Windows systems, determine your graphics hardware by closing all figures, switching to hardware OpenGL, and reissuing the `opengl info` command. Then, switch back to software OpenGL.

```
close all
opengl hardware
opengl info
opengl software
```

If you are using software OpenGL on Linux systems, determine your graphics hardware by starting MATLAB with the `-nosoftwareopengl` flag. Then, issue the `opengl info` command.

Mac OS X systems do not support software OpenGL, so the **Vendor** field always lists the name of your graphics hardware vendor.

## Use Software OpenGL for Current Session

Switch to using software OpenGL to render graphics in the current session.

```
opengl software
```

## Use Software OpenGL for Future Sessions

Set your preferences so that MATLAB uses software OpenGL to render graphics in all future sessions. This command does not affect the current session.

```
opengl(save, 'software')
```

## More About

### Tips

- By default, MATLAB uses your graphics hardware if it supports hardware-accelerated OpenGL. If it is not available or if you are using a virtual machine, a Linux VNC, or a graphics driver with known issues, then MATLAB uses software OpenGL instead. For more information on graphics renderers, see the figure `Renderer` property.
- For the best results with graphics, upgrade your graphics drivers to the latest version available. For more information, see “System Requirements for Graphics”.

`matlabunix` | `matlabwindows`

## openvar

Open workspace variable in Variables editor or other graphical editing tool

### Syntax

```
openvar(varname)
```

### Description

`openvar(varname)` opens the workspace variable named by the string, `varname`, in the Variables editor for graphical editing. Changes that you make to variables in the Variables editor occur in the workspace as soon as you enter them.

In some toolboxes, `openvar` opens a tool appropriate for viewing or editing objects indicated by `varname` instead of opening the Variables editor.

MATLAB does not impose any limitation on the size of a variable that you can open in the Variables editor. However, your operating system or the amount of physical memory installed on your computer can impose such limits.

### Examples

#### Identify Outliers in a Linked Graph

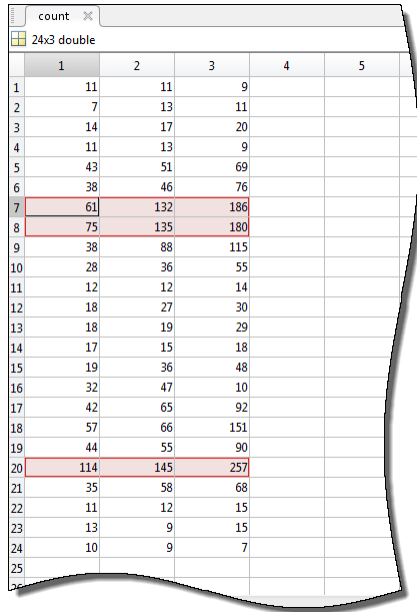

Use data brushing to identify observations in a vector or matrix that might warrant further analysis.

Make a scatter plot of data in the sample MAT-file `count.dat`, and open the variable `count` in the Variables editor.

```
load count.dat
scatter(count(:,1),count(:,2))
openvar('count')
```

Right-click a cell in the Variables editor and select **Brushing > Brushing On**. This turns on data brushing in the Variables editor.

Select the rows 7, 8, and 20. (Select noncontiguous rows by holding down the **Ctrl** key and clicking in each row.)

	1	2	3	4	5
1	11	11	9		
2	7	13	11		
3	14	17	20		
4	11	13	9		
5	43	51	69		
6	38	46	76		
7	61	132	186		
8	75	135	180		
9	38	88	115		
10	28	36	55		
11	12	12	14		
12	18	27	30		
13	18	19	29		
14	17	15	18		
15	19	36	48		
16	32	47	10		
17	42	65	92		
18	57	66	151		
19	44	55	90		
20	114	145	257		
21	35	58	68		
22	11	12	15		
23	13	9	15		
24	10	9	7		
25					
26					

In the Figure window with the scatter plot, click **Brush/Select Data**  to enable data brushing, and **Link Plot**  to enable data linking.

The data observations you brushed in the Variables editor appear highlighted in the scatter plot.

As long as data linking is enabled in the figure, observations that you brush in the scatter plot are highlighted in the Variables editor. When a figure is not linked to its data sources, you can still brush its graphs and you can brush the same data in the Variables editor, but only the display that you brush responds by highlighting.

## Input Arguments

**varname** — Variable name

string

Variable name, specified as a string. The named variable can be an array, character string, cell array, structure, or an object and its properties. If the named variable is a multidimensional array, then you can only view the array in the Variables editor, and not edit it.

Example: 'myVariable'

Example: 'A'

## More About

### Tips

- As an alternative to the `openvar` function, double-click a variable in the “Workspace browser”.
- “View, Edit, and Copy Variables”
- “Making Graphs Responsive with Data Linking”

# optimget

Optimization options values

## Syntax

```
val = optimget(options,'param')
val = optimget(options,'param',default)
```

## Description

`val = optimget(options,'param')` returns the value of the specified parameter in the optimization options structure `options`. You need to type only enough leading characters to define the parameter name uniquely. Case is ignored for parameter names.

`val = optimget(options,'param',default)` returns `default` if the specified parameter is not defined in the optimization options structure `options`. Note that this form of the function is used primarily by other optimization functions.

## Examples

This statement returns the value of the `Display` optimization options parameter in the structure called `my_options`.

```
val = optimget(my_options,'Display')
```

This statement returns the value of the `Display` optimization options parameter in the structure called `my_options` (as in the previous example) except that if the `Display` parameter is not defined, it returns the value `'final'`.

```
optnew = optimget(my_options,'Display','final');
```

## See Also

`optimset` | `fminbnd` | `fminsearch` | `fzero` | `lsqnonneg`

## optimset

Create or edit optimization options structure

### Syntax

```
options = optimset('param1',value1,'param2',value2,...)
optimset
options = optimset
options = optimset(optimfun)
options = optimset(olddopts,'param1',value1,...)
options = optimset(olddopts,newopts)
```

### Description

The function `optimset` creates an `options` structure that you can pass as an input argument to the following four MATLAB optimization functions:

- `fminbnd`
- `fminsearch`
- `fzero`
- `lsqnonneg`

You can use the `options` structure to change the default parameters for these functions.

---

**Note** If you have an Optimization Toolbox™ license, you can also use `optimset` to create an expanded `options` structure containing additional options specifically designed for the functions provided in that toolbox. For more information about these additional options, see the reference page for the enhanced Optimization Toolbox `optimset` function.

---

`options = optimset('param1',value1,'param2',value2,...)` creates an optimization options structure called `options`, in which the specified parameters (`param`) have specified values. Any unspecified parameters are set to `[]` (parameters with value `[]` indicate to use the default value for that parameter when `options`

is passed to the optimization function). It is sufficient to type only enough leading characters to define the parameter name uniquely. Case is ignored for parameter names.

`optimset` with no input or output arguments displays a complete list of parameters with their valid values.

`options = optimset` (with no input arguments) creates an options structure `options` where all fields are set to `[]`.

`options = optimset(optimfun)` creates an options structure `options` with all parameter names and default values relevant to the optimization function `optimfun`.

`options = optimset(olddopts, 'param1', value1, ...)` creates a copy of `olddopts`, modifying the specified parameters with the specified values.

`options = optimset(olddopts, newopts)` combines an existing options structure `olddopts` with a new options structure `newopts`. Any parameters in `newopts` with nonempty values overwrite the corresponding old parameters in `olddopts`.

## Options

The following table lists the available options for the MATLAB optimization functions.

Option	Value	Description	Solvers
Display	'off'   'iter'   {'final'}   'notify'	Level of display. 'off' displays no output; 'iter' displays output at each iteration (not available for <code>lsqnonneg</code> ); 'final' displays just the final output; 'notify' displays output only if the function does not converge.	fminbnd, fminsearch,fzero, lsqnonneg
FunValChec	{'off'}   'on'	Check whether objective function values are valid. 'on' displays an error when the objective function returns a value that is <code>complex</code> or <code>NaN</code> . 'off' displays no error.	fminbnd, fminsearch,fzero

Option	Value	Description	Solvers
MaxFunEval	positive integer	Maximum number of function evaluations allowed.	fminbnd, fminsearch
MaxIter	positive integer	Maximum number of iterations allowed.	fminbnd, fminsearch
OutputFcn	function   {[ ]}	User-defined function that an optimization function calls at each iteration. See “Output Functions”.	fminbnd, fminsearch, fzero
PlotFcns	function   {[ ]}	User-defined or built-in plot function that an optimization function calls at each iteration. Built-in functions: <ul style="list-style-type: none"> <li>• @optimplotx plots the current point</li> <li>• @optimplotfval plots the function value</li> <li>• @optimplotfunccount plots the function count (not available for fzero)</li> </ul> See “Plot Functions”.	fminbnd, fminsearch, fzero
TolFun	positive scalar	Termination tolerance on the function value. See “Tolerances and Stopping Criteria”.	fminsearch
TolX	positive scalar	Termination tolerance on $x$ , the current point. See “Tolerances and Stopping Criteria”.	fminbnd, fminsearch, fzero, lsqnonneg

## Examples

This statement creates an optimization options structure called `options` in which the `Display` parameter is set to `'iter'` and the `TolFun` parameter is set to `1e-8`.

```
options = optimset('Display','iter','TolFun',1e-8)
```

This statement makes a copy of the options structure called `options`, changing the value of the `TolX` parameter and storing new values in `optnew`.

```
optnew = optimset(options,'TolX',1e-4);
```

This statement returns an optimization options structure that contains all the parameter names and default values relevant to the function `fminbnd`.

```
optimset('fminbnd')
```

## See Also

## or, |

Find logical OR

### Syntax

A | B | ...  
or(A, B)

### Description

A | B | ... performs a logical OR of all input arrays A, B, etc., and returns an array containing elements set to either logical 1 (**true**) or logical 0 (**false**). An element of the output array is set to 1 if any input arrays contain a nonzero element at that same array location. Otherwise, that element is set to 0.

Each input of the expression can be an array or can be a scalar value. All nonscalar input arrays must have equal dimensions. If one or more inputs are an array, then the output is an array of the same dimensions. If all inputs are scalar, then the output is scalar.

If the expression contains both scalar and nonscalar inputs, then each scalar input is treated as if it were an array having the same dimensions as the other input arrays. In other words, if input A is a 3-by-5 matrix and input B is the number 1, then B is treated as if it were a 3-by-5 matrix of ones.

or(A, B) is called for the syntax A | B when either A or B is an object.

---

**Note** The symbols | and || perform different operations in a MATLAB application. The element-wise OR operator described here is |. The short-circuit OR operator is ||.

---

### Examples

If matrix A is

0.4235	0.5798	0	0.7942	0
0.5155	0	0	0	0.8744

0	0	0	0.4451	0.0150
0.4329	0.6405	0.6808	0	0

and matrix B is

0	1	0	1	0
1	1	0	0	1
0	0	0	1	0
0	1	0	0	1

then

A   B				
ans =				
1	1	0	1	0
1	1	0	0	1
0	0	0	1	1
1	1	1	0	1

## ordeig

Eigenvalues of quasitriangular matrices

### Syntax

```
E = ordeig(T)
E = ordeig(AA, BB)
```

### Description

`E = ordeig(T)` takes a quasitriangular Schur matrix `T`, typically produced by `schur`, and returns the vector `E` of eigenvalues in their order of appearance down the diagonal of `T`.

`E = ordeig(AA, BB)` takes a quasitriangular matrix pair `AA` and `BB`, typically produced by `qz`, and returns the generalized eigenvalues in their order of appearance down the diagonal of `AA-#*BB`.

`ordeig` is an order-preserving version of `eig` for use with `ordschur` and `ordqz`. It is also faster than `eig` for quasitriangular matrices.

### Examples

#### Example 1

```
T=diag([1 -1 3 -5 2]);
```

`ordeig(T)` returns the eigenvalues of `T` in the same order they appear on the diagonal.

```
ordeig(T)
```

```
ans =
```

```
 1
 -1
 3
```

```
-5
 2
```

`eig(T)`, on the other hand, returns the eigenvalues in order of increasing magnitude.

```
eig(T)
```

```
ans =
```

```
-5
-1
 1
 2
 3
```

## Example 2

```
A = rand(10);
[U, T] = schur(A);
abs(ordeig(T))
```

```
ans =
```

```

# orderfields

Order fields of structure array

## Syntax

```
s = orderfields(s1)
s = orderfields(s1, s2)
s = orderfields(s1, c)
s = orderfields(s1, perm)
[s, perm] = orderfields(...)
```

## Description

`s = orderfields(s1)` orders the fields in `s1` so that the new structure array `s` has field names in ASCII dictionary order.

`s = orderfields(s1, s2)` orders the fields in `s1` so that the new structure array `s` has field names in the same order as those in `s2`. Structures `s1` and `s2` must have the same fields.

`s = orderfields(s1, c)` orders the fields in `s1` so that the new structure array `s` has field names in the same order as those in the cell array of field name strings `c`. Structure `s1` and cell array `c` must contain the same field names.

`s = orderfields(s1, perm)` orders the fields in `s1` so that the new structure array `s` has fieldnames in the order specified by the indices in permutation vector `perm`.

If `s1` has `N` fieldnames, the elements of `perm` must be an arrangement of the numbers from 1 to `N`. This is particularly useful if you have more than one structure array that you would like to reorder in the same way.

`[s, perm] = orderfields(...)` returns a permutation vector representing the change in order performed on the fields of the structure array that results in `s`.

## Examples

Create a structure `s`. Then create a new structure from `s`, but with the fields ordered alphabetically:

```
s = struct('b', 2, 'c', 3, 'a', 1)
s =
 b: 2
 c: 3
 a: 1
```

```
snew = orderfields(s)
snew =
 a: 1
 b: 2
 c: 3
```

Arrange the fields of `s` in the order specified by the second (cell array) argument of `orderfields`. Return the new structure in `snew` and the permutation vector used to create it in `perm`:

```
[snew, perm] = orderfields(s, {'b', 'a', 'c'})
snew =
 b: 2
 a: 1
 c: 3
perm =
 1
 3
 2
```

Now create a new structure, `s2`, having the same fieldnames as `s`. Reorder the fields using the permutation vector returned in the previous operation:

```
s2 = struct('b', 3, 'c', 7, 'a', 4)
s2 =
 b: 3
 c: 7
 a: 4

snew = orderfields(s2, perm)
snew =
 b: 3
 a: 4
```

c: 7

## More About

### Tips

`orderfields` only orders top-level fields. It is not recursive.

## ordqz

Reorder eigenvalues in QZ factorization

### Syntax

```
[AAS,BBS,QS,ZS] = ordqz(AA,BB,Q,Z,select)
[...] = ordqz(AA,BB,Q,Z,keyword)
[...] = ordqz(AA,BB,Q,Z,clusters)
```

### Description

[AAS,BBS,QS,ZS] = ordqz(AA,BB,Q,Z,select) reorders the QZ factorizations  $Q^*A^*Z = AA$  and  $Q^*B^*Z = BB$  produced by the qz function for a matrix pair (A,B). It returns the reordered pair (AAS,BBS) and the cumulative orthogonal transformations QS and ZS such that  $QS^*A^*ZS = AAS$  and  $QS^*B^*ZS = BBS$ . In this reordering, the selected cluster of eigenvalues appears in the leading (upper left) diagonal blocks of the quasitriangular pair (AAS,BBS), and the corresponding invariant subspace is spanned by the leading columns of ZS. The logical vector `select` specifies the selected cluster as  $E(\text{select})$  where E is the vector of eigenvalues as they appear along the diagonal of  $AA- \#*BB$ .

---

**Note** To extract E from AA and BB, use `ordeig(BB)`, instead of `eig`. This ensures that the eigenvalues in E occur in the same order as they appear on the diagonal of  $AA- \#*BB$ .

---

[...] = ordqz(AA,BB,Q,Z,keyword) sets the selected cluster to include all eigenvalues in the region specified by keyword:

keyword	Selected Region
'lhp'	Left-half plane ( $\text{real}(E) < 0$ )
'rhp'	Right-half plane ( $\text{real}(E) > 0$ )
'udi'	Interior of unit disk ( $\text{abs}(E) < 1$ )
'udo'	Exterior of unit disk ( $\text{abs}(E) > 1$ )

[...] = `ordqz(AA, BB, Q, Z, clusters)` reorders multiple clusters at once. Given a vector `clusters` of cluster indices commensurate with `E = ordeig(AA, BB)`, such that all eigenvalues with the same `clusters` value form one cluster, `ordqz` sorts the specified clusters in descending order along the diagonal of `(AAS, BBS)`. The cluster with highest index appears in the upper left corner.

### See Also

`ordeig` | `ordschur` | `qz`

## ordschur

Reorder eigenvalues in Schur factorization

### Syntax

```
[US,TS] = ordschur(U,T,select)
[US,TS] = ordschur(U,T,keyword)
[US,TS] = ordschur(U,T,clusters)
```

### Description

[US,TS] = ordschur(U,T,select) reorders the Schur factorization  $X = U*TS*U'$  produced by the `schur` function and returns the reordered Schur matrix `TS` and the cumulative orthogonal transformation `US` such that  $X = US*TS*US'$ . In this reordering, the selected cluster of eigenvalues appears in the leading (upper left) diagonal blocks of the quasitriangular Schur matrix `TS`, and the corresponding invariant subspace is spanned by the leading columns of `US`. The logical vector `select` specifies the selected cluster as `E(select)` where `E` is the vector of eigenvalues as they appear along `T`'s diagonal.

---

**Note** To extract `E` from `T`, use `E = ordeig(T)`, instead of `eig`. This ensures that the eigenvalues in `E` occur in the same order as they appear on the diagonal of `TS`.

---

[US,TS] = ordschur(U,T,keyword) sets the selected cluster to include all eigenvalues in one of the following regions:

keyword	Selected Region
'lhp'	Left-half plane ( $\text{real}(E) < 0$ )
'rhp'	Right-half plane ( $\text{real}(E) > 0$ )
'udi'	Interior of unit disk ( $\text{abs}(E) < 1$ )
'udo'	Exterior of unit disk ( $\text{abs}(E) > 1$ )

`[US,TS] = ordschur(U,T,clusters)` reorders multiple clusters at once. Given a vector `clusters` of cluster indices, commensurate with `E = ordeig(T)`, and such that all eigenvalues with the same `clusters` value form one cluster, `ordschur` sorts the specified clusters in descending order along the diagonal of `TS`, the cluster with highest index appearing in the upper left corner.

## orient

Hardcopy paper orientation

### Alternatives

Use **File** → **Print Preview** on the figure window menu to directly manipulate print layout, paper size, headers, fonts and other properties when printing figures. For details, see “Using Print Preview” in the MATLAB Graphics documentation.

### Syntax

```
orient
orient landscape
orient portrait
orient tall
orient(fig_handle)
orient(simulink_model)
orient(fig_handle,orientation)
orient(simulink_model,orientation)
```

### Description

`orient` returns a string with the current paper orientation: `portrait`, `landscape`, or `tall`.

`orient landscape` sets the paper orientation of the current figure to full-page landscape, orienting the longest page dimension horizontally. The figure is centered on the page and scaled to fit the page with a 0.25 inch border.

`orient portrait` sets the paper orientation of the current figure to portrait, orienting the longest page dimension vertically. The `portrait` option returns the page orientation to the MATLAB default. (Note that the result of using the `portrait` option is affected by changes you make to figure properties. See the "Algorithm" section for more specific information.)

`orient tall` maps the current figure to the entire page in portrait orientation, leaving a 0.25 inch border.

`orient(fig_handle)` returns the current orientation of the specified figure.

`orient(simulink_model)` returns the current orientation of the Simulink model.

`orient(fig_handle,orientation)` sets the orientation for the specified figure to the specified orientation (`landscape`, `portrait`, or `tall`).

`orient(simulink_model,orientation)` sets the orientation for the Simulink model.

## More About

### Algorithms

`orient` sets the `PaperOrientation`, `PaperPosition`, and `PaperUnits` properties of the current figure. Subsequent print operations use these properties. The result of using the `portrait` option can be affected by default property values as follows:

- If the current figure `PaperType` is the same as the default figure `PaperType` and the default figure `PaperOrientation` has been set to `landscape`, then the `orient portrait` command uses the current values of `PaperOrientation` and `PaperPosition` to place the figure on the page.
- If the current figure `PaperType` is the same as the default figure `PaperType` and the default figure `PaperOrientation` has been set to `landscape`, then the `orient portrait` command uses the default figure `PaperPosition` with the `x`, `y` and `width`, `height` values reversed (i.e., `[y,x,height,width]`) to position the figure on the page.
- If the current figure `PaperType` is different from the default figure `PaperType`, then the `orient portrait` command uses the current figure `PaperPosition` with the `x`, `y` and `width`, `height` values reversed (i.e., `[y,x,height,width]`) to position the figure on the page.

`print` | `printpreview` | `set`

## orth

Orthonormal basis for range of matrix

### Syntax

```
Q = orth(A)
```

### Description

`Q = orth(A)` returns an orthonormal basis for the range of **A**. The columns of **Q** are vectors, which span the range of **A**. The number of columns in **Q** is equal to the rank of **A**.

### Examples

#### Basis for Full Rank Matrix

Calculate and verify the orthonormal basis vectors for the range of a full rank matrix.

Define a matrix and find the rank.

```
A = [1 0 1; -1 -2 0; 0 1 -1];
```

```
r = rank(A)
```

```
r =
```

```
3
```

Since **A** is a square matrix of full rank, the orthonormal basis calculated by `orth(A)` matches the matrix **U** calculated in the singular value decomposition, `[U,S] = svd(A, 'econ')`. This is because the singular values of **A** are all nonzero.

Calculate the orthonormal basis for the range of **A** using `orth`.

```
Q = orth(A)
```

```
Q =
```

```

-0.1200 -0.8097 0.5744
 0.9018 0.1531 0.4042
-0.4153 0.5665 0.7118

```

The number of columns in  $Q$  is equal to  $\text{rank}(A)$ . Since  $A$  is of full rank,  $Q$  and  $A$  are the same size.

Verify that the basis,  $Q$ , is orthogonal and normalized within a reasonable error range.

```
E = norm(eye(r) - Q' * Q, 'fro')
```

```
E =
```

```
9.6228e-16
```

The error is on the order of `eps`.

### Basis for Rank Deficient Matrix

Calculate and verify the orthonormal basis vectors for the range of a rank deficient matrix.

Define a singular matrix and find the rank.

```
A = [1 0 1; 0 1 0; 1 0 1];
r = rank(A)
```

```
r =
```

```
2
```

Since  $A$  is rank deficient, the orthonormal basis calculated by `orth(A)` matches only the first  $r = 2$  columns of matrix  $U$  calculated in the singular value decomposition,  $[U, S] = \text{svd}(A, 'econ')$ . This is because the singular values of  $A$  are *not* all nonzero.

Calculate the orthonormal basis for the range of  $A$  using `orth`.

```
Q = orth(A)
```

```
Q =
```

```

-0.7071 0
 0 1.0000
-0.7071 0

```

Since  $A$  is rank deficient,  $Q$  contains one fewer column than  $A$ .

## Input Arguments

### **A** — Input matrix

scalar | vector | matrix

Input matrix, specified as a scalar, vector, or matrix.

Data Types: `single` | `double`

Complex Number Support: Yes

## More About

### Range

The column space, or *range*, of a matrix  $A$  is the collection of all linear combinations of the columns of  $A$ . Any vector,  $\mathbf{b}$ , that is a solution to the linear equation,  $A\mathbf{x} = \mathbf{b}$ , is included in the range of  $A$  since you can also write it as a linear combination of the columns of  $A$ .

### Rank

The rank of a matrix is equal to the dimension of the range.

### Algorithms

`orth` is obtained from  $U$  in the singular value decomposition,  $[U,S] = \text{svd}(A, 'econ')$ . If  $r = \text{rank}(A)$ , the first  $r$  columns of  $U$  form an orthonormal basis for the range of  $A$ .

### See Also

`null` | `rank` | `svd`

# outerjoin

Outer join between two tables

## Syntax

```
C = outerjoin(A,B)
C = outerjoin(A,B,Name,Value)
[C,ia,ib] = outerjoin(___)
```

## Description

`C = outerjoin(A,B)` creates the table, `C`, as the outer join between the tables `A` and `B` by matching up rows using all the variables with the same name as key variables.

The outer join includes the rows that match between `A` and `B`, and also unmatched rows from either `A` or `B`, all with respect to the key variables. `C` contains all variables from both `A` and `B`, including the key variables.

`C = outerjoin(A,B,Name,Value)` performs the outer-join operation with additional options specified by one or more `Name,Value` pair arguments.

`[C,ia,ib] = outerjoin( ___ )` also returns index vectors, `ia` and `ib`, indicating the correspondence between rows in `C` and those in `A` and `B` respectively. You can use this syntax with any of the input arguments in the previous syntaxes.

## Examples

### Outer-Join Operation of Tables with One Variable in Common

Create a table, `A`.

```
A = table([5;12;23;2;15;6],...
 {'cheerios';'pizza';'salmon';'oreos';'lobster';'pizza'},...
 'VariableNames',{'Age','FavoriteFood'},...
 'RowNames',{'Amy','Bobby','Holly','Harry','Marty','Sally'})
```

A =

	Age	FavoriteFood
Amy	5	'cheerios'
Bobby	12	'pizza'
Holly	23	'salmon'
Harry	2	'oreos'
Marty	15	'lobster'
Sally	6	'pizza'

Create a table, B, with one variable in common with A, called FavoriteFood.

```
B = table({'cheerios';'oreos';'pizza';'salmon';'cake'},...
[110;160;140;367;243],...
{'A-';'D';'B';'B';'C-'},...
'VariableNames',{'FavoriteFood','Calories','NutritionGrade'})
```

B =

FavoriteFood	Calories	NutritionGrade
'cheerios'	110	'A-'
'oreos'	160	'D'
'pizza'	140	'B'
'salmon'	367	'B'
'cake'	243	'C-'

Use the `outerjoin` function to create a new table, C, with data from tables A and B.

```
C = outerjoin(A,B)
```

C =

Age	FavoriteFood_A	FavoriteFood_B	Calories	NutritionGrade
NaN	' '	'cake'	243	'C-'
5	'cheerios'	'cheerios'	110	'A-'
15	'lobster'	' '	NaN	' '
2	'oreos'	'oreos'	160	'D'
12	'pizza'	'pizza'	140	'B'
6	'pizza'	'pizza'	140	'B'

```
23 'salmon' 'salmon' 367 'B'
```

Table C contains a separate variable for the key variable from A, called `FavoriteFood_A`, and the key variable from B, called `FavoriteFood_B`.

### Merge Key Variable Pair to Single Variable

Create a table, A.

```
A = table({'a' 'b' 'c' 'e' 'h'},[1 2 3 11 17]',...
 'VariableNames',{ 'Key1' 'Var1'})
```

A =

Key1	Var1
'a'	1
'b'	2
'c'	3
'e'	11
'h'	17

Create a table, B, with common values in the variable `Key1` between tables A and B, but also containing rows with values of `Key1` not present in A.

```
B = table({'a' 'b' 'd' 'e'},[4;5;6;7]',...
 'VariableNames',{ 'Key1' 'Var2'})
```

B =

Key1	Var2
'a'	4
'b'	5
'd'	6
'e'	7

Use the `outerjoin` function to create a new table, C, with data from tables A and B. Merge the key values into a single variable in the output table, C.

```
C = outerjoin(A,B, 'MergeKeys', true)
```

C =

Key1	Var1	Var2
'a'	1	4
'b'	2	5
'c'	3	NaN
'd'	NaN	6
'e'	11	7
'h'	17	NaN

Variables in table C that came from A contain null values in the rows that have no match from B. Similarly, variables in C that came from B contain null values in those rows that had no match from A.

## Outer-Join Operation of Tables and Indices to Values

Create a table, A.

```
A = table({'a' 'b' 'c' 'e' 'h'},[1 2 3 11 17]',...
 'VariableNames',{ 'Key1' 'Var1'})
```

A =

Key1	Var1
'a'	1
'b'	2
'c'	3
'e'	11
'h'	17

Create a table, B, with common values in the variable Key1 between tables A and B, but also containing rows with values of Key1 not present in A.

```
B = table({'a' 'b' 'd' 'e'},[4;5;6;7],...
 'VariableNames',{ 'Key1' 'Var2'})
```

B =

Key1	Var2
------	------

```
'a' 4
'b' 5
'd' 6
'e' 7
```

Use the `outerjoin` function to create a new table, **C**, with data from tables **A** and **B**. Match up rows with common values in the key variable, **Key1**, but also retain rows whose key values don't have a match.

Also, return index vectors, **ia** and **ib** indicating the correspondence between rows in **C** and rows in **A** and **B** respectively.

```
[C,ia,ib] = outerjoin(A,B)
```

```
C =
```

Key1_A	Var1	Key1_B	Var2
'a'	1	'a'	4
'b'	2	'b'	5
'c'	3	''	NaN
''	NaN	'd'	6
'e'	11	'e'	7
'h'	17	''	NaN

```
ia =
```

```
1
2
3
0
4
5
```

```
ib =
```

```
1
2
0
3
4
0
```

The index vectors `ia` and `ib` contain zeros to indicate the rows in table `C` that do not correspond to rows in tables `A` or `B`, respectively.

### Left Outer-Join Operation of Tables and Indices to Values

Create a table, `A`.

```
A = table({'a' 'b' 'c' 'e' 'h'},[1 2 3 11 17]',...
 'VariableNames',{ 'Key1' 'Var1'})
```

`A =`

Key1	Var1
'a'	1
'b'	2
'c'	3
'e'	11
'h'	17

Create a table, `B`, with common values in the variable `Key1` between tables `A` and `B`, but also containing rows with values of `Key1` not present in `A`.

```
B = table({'a' 'b' 'd' 'e'},[4;5;6;7],...
 'VariableNames',{ 'Key1' 'Var2'})
```

`B =`

Key1	Var2
'a'	4
'b'	5
'd'	6
'e'	7

Use the `outerjoin` function to create a new table, `C`, with data from tables `A` and `B`. Ignore rows in `B` whose key values do not match any rows in `A`.

Also, return index vectors, `ia` and `ib` indicating the correspondence between rows in `C` and rows in `A` and `B` respectively.

```
[C,ia,ib] = outerjoin(A,B,'Type','left')
```

```
C =
```

Key1_A	Var1	Key1_B	Var2
'a'	1	'a'	4
'b'	2	'b'	5
'c'	3	''	NaN
'e'	11	'e'	7
'h'	17	''	NaN

```
ia =
```

```
1
2
3
4
5
```

```
ib =
```

```
1
2
0
4
0
```

All values of `ia` are nonzero indicating that all rows in `C` have corresponding rows in `A`.

## Input Arguments

**A, B** — Input tables  
tables

Input tables, specified as tables.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single

quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'Keys', 2` uses the second variable in A and the second variable in B as key variables.

### **'Keys' — Variables to use as keys**

positive integer | vector of positive integers | variable name | cell array of variable names | logical vector

Variables to use as keys, specified as the comma-separated pair consisting of `'Keys'` and a positive integer, vector of positive integers, variable name, cell array of variable names, or logical vector.

You cannot use the `'Keys'` name-value pair argument with the `'LeftKeys'` and `'RightKeys'` name-value pair arguments.

Example: `'Keys', [1 3]` uses the first and third variables in A and B as a key variables.

### **'LeftKeys' — Variables to use as keys in A**

positive integer | vector of positive integers | variable name | cell array of variable names | logical vector

Variables to use as keys in A, specified as the comma-separated pair consisting of `'LeftKeys'` and a positive integer, vector of positive integers, variable name, cell array of variable names, or logical vector.

You must use the `'LeftKeys'` name-value pair argument in conjunction with the `'RightKeys'` name-value pair argument. `'LeftKeys'` and `'RightKeys'` both must specify the same number of key variables. `outerjoin` pairs key values based on their order.

Example: `'LeftKeys', 1` uses only the first variable in A as a key variable.

### **'RightKeys' — Variables to use as keys in B**

positive integer | vector of positive integers | variable name | cell array of variable names | logical vector

Variables to use as keys in B, specified as the comma-separated pair consisting of `'RightKeys'` and a positive integer, vector of positive integers, variable name, cell array of variable names, or logical vector.

You must use the `'RightKeys'` name-value pair argument in conjunction with the `'LeftKeys'` name-value pair argument. `'LeftKeys'` and `'RightKeys'` both must

specify the same number of key variables. `outerjoin` pairs key values based on their order.

Example: `'RightKeys', 3` uses only the third variable in B as a key variable.

### **'MergeKeys' — Merge keys flag**

false (default) | true | 0 | 1

Merge keys flag, specified as the comma-separated pair consisting of `'MergeKeys'` and either `false`, `true`, 0 or 1.

`false` `outerjoin` includes two separate variables in the output table, C, for each key variable pair from tables A and B.

This is the default behavior.

`true` `outerjoin` includes a single variable in the output table, C, for each key variable pair from tables A and B.

`outerjoin` creates the single variable by merging the key values from A and B, taking values from A where a corresponding row exists in A, and taking values from B otherwise.

If you specify, `'MergeKeys', true`, then `outerjoin` includes all key variables in the output table, C, and overrides the inclusion or exclusion of key variables specified via the `'LeftVariables'` and `'RightVariables'` name-value pair arguments.

### **'LeftVariables' — Variables from A to include in C**

positive integer | vector of positive integers | variable name | cell array containing one or more variable names | logical vector

Variables from A to include in C, specified as the comma-separated pair consisting of `'LeftVariables'` and a positive integer, vector of positive integers, variable name, cell array of variable names, or logical vector.

You can use `'LeftVariables'` to include or exclude key variables as well as nonkey variables from the output, C.

By default, `outerjoin` includes all variables from A.

### **'RightVariables' — Variables from B to include in C**

positive integer | vector of positive integers | variable name | cell array containing one or more variable names | logical vector

Variables from **B** to include in **C**, specified as the comma-separated pair consisting of `'RightVariables'` and a positive integer, vector of positive integers, variable name, cell array of variable names, or logical vector.

You can use `'RightVariables'` to include or exclude key variables as well as nonkey variables from the output, **C**.

By default, `outerjoin` includes all the variables from **B**.

### **'Type' — Type of outer join operation**

`'full'` (default) | `'left'` | `'right'`

Type of outer-join operation, specified as the comma-separated pair consisting of `'Type'` and either `'full'`, `'left'`, or `'right'`.

- For a left outer join, **C** contains rows corresponding to key values in **A** that do not match any values in **B**, but not vice-versa.
- For a right outer join, **C** contains rows corresponding to key values in **B** that do not match any values in **A**, but not vice-versa.

By default, `outerjoin` does a full outer join and includes unmatched rows from both **A** and **B**.

## **Output Arguments**

### **C — Outer join from A and B**

table

Outer join from **A** and **B**, returned as a table. The output table, **C**, contains one row for each pair of rows in tables **A** and **B** that share the same combination of key values. If **A** and **B** contain variables with the same name, `outerjoin` adds a unique suffix to the corresponding variable names in **C**. Variables in **C** that came from **A** contain null values in those rows that had no match from **B**. Similarly, variables in **C** that came from **B** contain null values in those rows that had no match from **A**.

In general, if there are  $m$  rows in table **A** and  $n$  rows in table **B** that all contain the same combination of values in the key variables, table **C** contains  $m*n$  rows for that combination. **C** also contains rows corresponding to key value combinations in one input table that do not match any row the other input table.

**C** contains the horizontal concatenation of **A(ia,LeftVars)** and **B(ib,RightVars)** sorted by the values in the key variables. By default, **LeftVars** consists of all the variables of **A**, and **RightVars** consists of all the from **B**. Otherwise, **LeftVars** consists of the variables specified by the '**LeftVariables**' name-value pair argument, and **RightVars** consists of the variables specified by the '**RightVariables**' name-value pair argument.

You can store additional metadata such as descriptions, variable units, variable names, and row names in the table. For more information, see [Table Properties](#).

### **ia** — Index to A

column vector

Index to **A**, returned as a column vector. Each element of **ia** identifies the row in table **A** that corresponds to that row in the output table, **C**. The vector **ia** contains zeros to indicate the rows in **C** that do not correspond to rows in **A**.

### **ib** — Index to B

column vector

Index to **B**, returned as a column vector. Each element of **ib** identifies the row in table **B** that corresponds to that row in the output table, **C**. The vector **ib** contains zeros to indicate the rows in **C** that do not correspond to rows in **B**.

## More About

### Key Variable

Variable used to match and combine data between the input tables, **A** and **B**.

### See Also

[join](#) | [outerjoin](#)

## pack

Consolidate workspace memory

### Syntax

```
pack
pack filename
pack('filename')
```

### Description

`pack` frees up needed space by reorganizing information so that it only uses the minimum memory required. All variables from your base and global workspaces are preserved. Any persistent variables that are defined at the time are set to their default value (the empty matrix, `[]`).

The MATLAB software temporarily stores your workspace data in a file called `tp#####.mat` (where `#####` is a numeric value) that is located in your temporary folder. (You can use the command `dir(tempdir)` to see the files in this folder).

`pack filename` frees space in memory, temporarily storing workspace data in a file specified by `filename`. This file resides in your current working folder and, unless specified otherwise, has a `.mat` file extension.

`pack('filename')` is the function form of `pack`.

### Examples

Change the current folder to one that is writable, run `pack`, and return to the previous folder.

```
cwd = pwd;
cd(tempdir);
pack
cd(cwd)
```

## More About

### Tips

You can only run `pack` from the MATLAB command line.

If you specify a `filename` argument, that file must reside in a folder for which you have write permission.

The `pack` function does not affect the amount of memory allocated to the MATLAB process. You must quit MATLAB to free up this memory.

Since MATLAB uses a heap method of memory management, extended MATLAB sessions may cause memory to become fragmented. When memory is fragmented, there may be plenty of free space, but not enough contiguous memory to store a new large variable.

If you get the `Out of memory` message from MATLAB, the `pack` function may find you some free memory without forcing you to delete variables.

The `pack` function frees space by

- Saving all variables in the base and global workspaces to a temporary file.
- Clearing all variables and functions from memory.
- Reloading the base and global workspace variables back from the temporary file and then deleting the file.

If you use `pack` and there is still not enough free memory to proceed, you must clear some variables. If you run out of memory often, you can allocate larger matrices earlier in the MATLAB session and use these system-specific tips:

- When running MATLAB on The Open Group UNIX platforms, ask your system manager to increase your swap space.
- On Microsoft Windows platforms, increase virtual memory using the Windows Control Panel.

To maintain persistent variables when you run `pack`, use `mlock` in the function.

`clear` | `memory`

## padecoeff

Padé approximation of time delays

### Syntax

```
[num,den] = padecoeff(T,N)
```

### Description

`[num,den] = padecoeff(T,N)` returns the Nth-order Padé approximation of the continuous-time delay  $T$  in transfer function form. The row vectors `num` and `den` contain the numerator and denominator coefficients in descending powers of  $s$ . Both are Nth-order polynomials.

Class support for input  $T$ :

float: double, single

### Class Support

Input  $T$  support floating-point values of type `single` or `double`.

# pagesetupdlg

Page setup dialog box

## Syntax

```
dlg = pagesetupdlg(fig)
```

---

**Note:** pagesetupdlg is no longer supported. Use `printpreview` instead.

---

## Description

`dlg = pagesetupdlg(fig)` creates a dialog box from which a set of page layout properties for the figure window, `fig`, can be set.

`pagesetupdlg` implements the "Page Setup..." option in the **Figure File Menu**.

`pagesetupdlg` supports setting the layout for a single figure. `fig` must be a single figure handle, not a vector of figures or a Simulink diagram.

## See Also

`printdlg` | `printpreview` | `printopt`

## pan

Pan view of graph interactively

### Syntax

```
pan on
pan xon
pan yon
pan off
pan
pan(figure_handle, ...)
h = pan(figure_handle)
```

### Description

`pan on` turns on mouse-based panning in the current figure.

`pan xon` turns on panning only in the *x* direction in the current figure.

`pan yon` turns on panning only in the *y* direction in the current figure.

`pan off` turns panning off in the current figure.

`pan` toggles the pan state in the current figure `on` or `off`.

`pan(figure_handle, ...)` sets the pan state in the specified figure.

`h = pan(figure_handle)` returns the figure's pan *mode object* for the figure `figure_handle` for you to customize the mode's behavior.

### Using Pan Mode Objects

Access the following properties of pan mode objects.

- *Enable* 'on' | 'off' — Specifies whether this figure mode is currently enabled on the figure
- *Motion* 'horizontal' | 'vertical' | 'both' — The type of panning enabled for the figure

- **FigureHandle** <handle> — The associated figure handle, a read-only property that cannot be set

## Pan Mode Callbacks

You can program the following callbacks for pan mode operations.

- **ButtonDownFilter** <function\_handle> — Function to intercept **ButtonDown** events

The application can inhibit the panning operation under circumstances the programmer defines, depending on what the callback returns. The input function handle should reference a function with two implicit arguments (similar to Handle Graphics object callbacks):

```
function [res] = myfunction(obj,event_obj)
% obj handle to the object clicked on
% event_obj event data (empty in this release)
% res [output] a logical flag to determine whether the pan
% operation should take place(for 'res' set to 'false')
% or the 'ButtonDownFcn' property of the object should
% take precedence (when 'res' is 'true')
```

- **ActionPreCallback** <function\_handle> — Function to execute before panning

Set this callback to if you need to execute code when a pan operation begins. The function handle should reference a function with two implicit arguments (similar to Handle Graphics object callbacks):

```
function myfunction(obj,event_obj)
% obj handle to the figure that has been clicked on
% event_obj object containing struct of event data
```

The event data struct has the following field:

<b>Axes</b>	The handle of the axes that is being panned
-------------	---------------------------------------------

- **ActionPostCallback** <function\_handle> — Function to execute after panning

Set this callback if you need to execute code when a pan operation ends. The function handle should reference a function with two implicit arguments (similar to Handle Graphics object callbacks):

```
function myfunction(obj,event_obj)
```

```
% obj handle to the figure that has been clicked on
% event_obj object containing struct of event data
% (same as the event data of the
% 'ActionPreCallback' callback)
```

## Pan Mode Utility Functions

The following functions in pan mode query and set certain of its properties.

- `flags = isAllowAxesPan(h, axes)` — Function querying permission to pan axes

Calling the function `isAllowAxesPan` on the pan object, `h`, with a vector of axes handles, `axes`, as input returns a logical array of the same dimension as the axes handle vector, which indicates whether a pan operation is permitted on the axes objects.

- `setAllowAxesPan(h, axes, flag)` — Function to set permission to pan axes

Calling the function `setAllowAxesPan` on the pan object, `h`, with a vector of axes handles, `axes`, and a logical scalar, `flag`, either allows or disallows a pan operation on the axes objects.

- `info = getAxesPanMotion(h, axes)` — Function to get style of pan operations

Calling the function `getAxesPanMotion` on the pan object, `h`, with a vector of axes handles, `axes`, as input will return a character cell array of the same dimension as the axes handle vector, which indicates the type of pan operation for each axes. Possible values for the type of operation are 'horizontal', 'vertical' or 'both'.

- `setAxesPanMotion(h, axes, style)` — Function to set style of pan operations

Calling the function `setAxesPanMotion` on the pan object, `h`, with a vector of axes handles, `axes`, and a character array, `style`, sets the style of panning on each axes.

## Examples

### Example 1 — Entering Pan Mode

Plot a graph and turn on Pan mode:

```
plot(magic(10));
pan on
```

```
% pan on the plot
```

## Example 2 — Constrained Pan

Constrain pan to  $x$ -axis using `set`:

```
plot(magic(10));
h = pan;
h.Motion = 'horizontal';
h.Enable = 'on';
% pan on the plot in the horizontal direction.
```

## Example 3 — Constrained Pan in Subplots

Create four axes as subplots and give each one a different panning behavior:

```
ax1 = subplot(2,2,1);
plot(1:10);
h = pan;
ax2 = subplot(2,2,2);
plot(rand(3));
setAllowAxesPan(h,ax2,false);
ax3 = subplot(2,2,3);
plot(peaks);
setAxesPanMotion(h,ax3,'horizontal');
ax4 = subplot(2,2,4);
contour(peaks);
setAxesPanMotion(h,ax4,'vertical');
% pan on the plots.
```

## Example 4 — Coding a ButtonDown Callback

Create a `buttonDown` callback for pan mode objects to trigger. Copy the following code to a new file, execute it, and observe panning behavior:

```
function demo
% Allow a line to have its own 'ButtonDownFcn' callback.
hLine = plot(rand(1,10));
hLine.ButtonDownFcn = 'disp(''This executes'')';
hLine.Tag = 'DoNotIgnore';
h = pan;
h.ButtonDownFilter = @mycallback;
h.Enable = 'on';
```

```
% mouse click on the line
%
function [flag] = mycallback(obj,event_obj)
% If the tag of the object is 'DoNotIgnore', then
% return true.

% Indicate what the target is.
disp(['Clicked ' obj.Type ' object'])
objTag = obj.Tag;
if strcmpi(objTag,'DoNotIgnore')
 flag = true;
else
 flag = false;
end
```

## Example 5 — Coding Pre- and Post-Callback Behavior

Create callbacks for pre- and post-ButtonDown events for pan mode objects to trigger. Copy the following code to a new file, execute it, and observe panning behavior:

```
function demo
% Listen to pan events
plot(1:10);
h = pan;
h.ActionPreCallback = @myprecallback;
h.ActionPostCallback = @mypostcallback;
h.Enable = 'on';
%
function myprecallback(obj, evd)
disp('A pan is about to occur.');
```

```
%
function mypostcallback(obj, evd)
newLim = evd.Axes.XLim;
msgbox(sprintf('The new X-Limits are [%f,%f].',newLim));
```

## Example 6 — Creating a Context Menu for Pan Mode

Coding a context menu that lets the user to switch to Zoom mode by right-clicking:

```
figure
plot(magic(10));
hCM = uicontextmenu;
hMenu = uimenu('Parent',hCM,'Label','Switch to zoom',...
```

```

 'Callback', 'zoom(gcf, 'on')');
hPan = pan(gcf);
hPan.UIContextMenu = hCM;
pan('on')

```

You cannot add items to the built-in pan context menu, but you can replace it with your own.

## Alternatives

Use the Pan tool  on the figure toolbar to enable and disable pan mode on a plot, or select **Pan** from the figure's **Tools** menu. For details, see “Panning — Shifting Your View of the Graph”.

## More About

### Tips

You can create a pan mode object once and use it to customize the behavior of different axes, as Example 3 illustrates. You can also change its callback functions on the fly.

---

**Note: Do not change figure callbacks within an interactive mode.** While a mode is active (when panning, zooming, etc.), you will receive a warning if you attempt to change any of the figure's callbacks and the operation will not succeed. The one exception to this rule is the figure `WindowButtonMotionFcn` callback, which can be changed from within a mode. Therefore, if you are creating a GUI that updates a figure's callbacks, the GUI should some keep track of which interactive mode is active, if any, before attempting to do this.

---

When you assign different pan behaviors to different `subplot` axes via a mode object and then link them using the `linkaxes` function, the behavior of the axes you manipulate with the mouse carries over to the linked axes, regardless of the behavior you previously set for the other axes.

## matlab.unittest.parameters

Summary of classes associated with MATLAB Unit Test parameters

### Description

The `matlab.unittest.parameters` package consists of the following classes used in parameterized testing.

<code>matlab.unittest.parameters.EmptyParameter</code>	Empty parameter implementation
<code>matlab.unittest.parameters.ClassSetupParameter</code>	Specification of Class Setup Parameter
<code>matlab.unittest.parameters.TestParameter</code>	Specification of Test Parameter
<code>matlab.unittest.parameters.MethodSetupParameter</code>	Specification of Method Setup Parameter

### See Also

`matlab.unittest.TestSuite.selectIf`

### Related Examples

- “Create Basic Parameterized Test”
- “Create Advanced Parameterized Test”

# matlab.unittest.parameters.EmptyParameter class

**Package:** matlab.unittest.parameters

Empty parameter implementation

## Description

The `matlab.unittest.parameters.EmptyParameter` class is a `Parameter` implementation that provides no parameter information. There is no need for test authors to interact with this `Parameter` directly. This class provides an empty parameter instance to the `Parameterization` property of a nonparameterized test element.

## Properties

### Property

String indicating the name of the property that defines the Empty Parameter.

### Name

String indicating the name that uniquely identifies a particular value for a Empty Parameter.

### Value

Value of the Empty Parameter. The `Value` property holds the data that the Test Runner uses for parameterized testing.

## Copy Semantics

Value. To learn how value classes affect copy operations, see “Copying Objects” in the MATLAB documentation.

## See Also

`matlab.unittest.TestCase`

# matlab.unittest.parameters.ClassSetupParameter class

**Package:** matlab.unittest.parameters

Specification of Class Setup Parameter

## Description

The `matlab.unittest.parameters.ClassSetupParameter` class holds information about a single value of a Class Setup Parameter.

## Properties

### Property

String indicating the name of the property that defines the Class Setup Parameter.

### Name

String indicating the name that uniquely identifies a particular value for a Class Setup Parameter.

### Value

Value of the Class Setup Parameter. The `Value` property holds the data that the Test Runner uses for parameterized testing.

## Copy Semantics

`Value`. To learn how value classes affect copy operations, see “Copying Objects” in the MATLAB documentation.

## pareto

Pareto chart

## Syntax

```
pareto(Y)
pareto(Y, names)
pareto(Y, X)
H = pareto(...)
```

## Description

Pareto charts display the values in the vector  $Y$  as bars drawn in descending order. Values in  $Y$  must be nonnegative and not include NaNs. Only the first 95% of the cumulative distribution is displayed.

`pareto(Y)` labels each bar with its element index in  $Y$  and also plots a line displaying the cumulative sum of  $Y$ .

`pareto(Y, names)` labels each bar with the associated name in the string matrix or cell array `names`.

`pareto(Y, X)` labels each bar with the associated value from  $X$ .

`pareto(ax, ...)` plots into the axes `ax` rather than the current axes, `gca`.

`H = pareto(...)` returns handles to the primitive line and bar series objects created.

## Examples

### Create Pareto Chart

Create a Pareto chart of vector `y`.

```
y = [90,75,30,60,5,40,40,5];
figure
pareto(y)
```

`pareto` displays the elements in `y` as bars in descending order and labels each bar with its index in `y`. Since `pareto` displays only the first 95% of the cumulative distribution, some elements in `y` are not displayed.

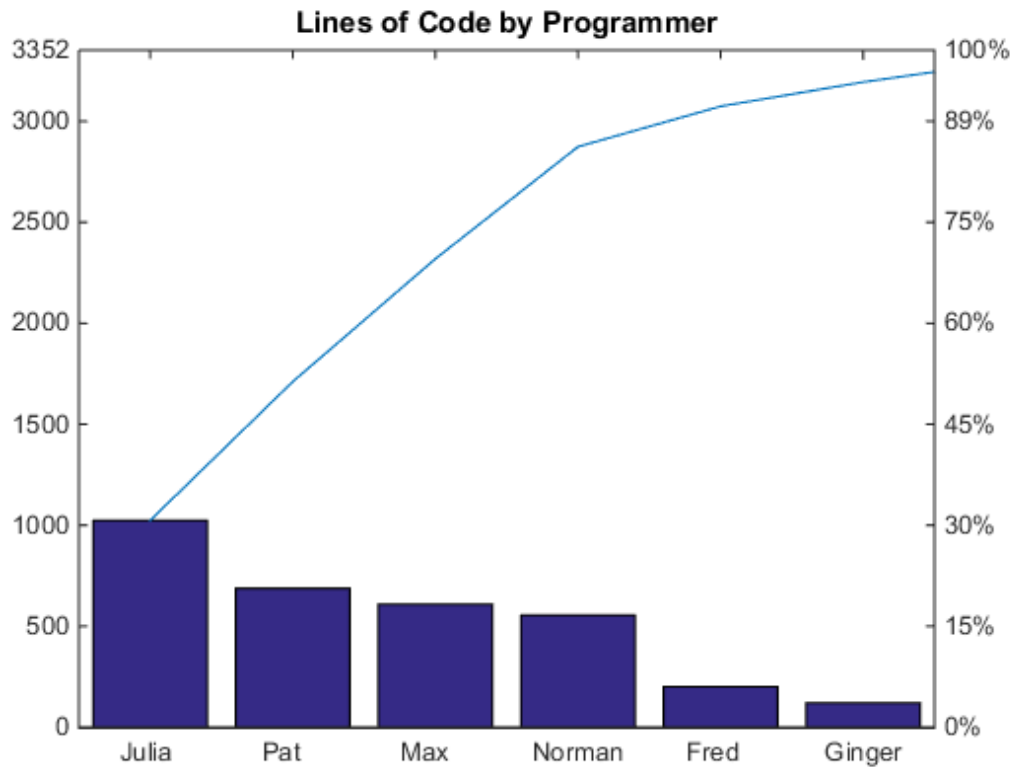

### Label Bars in Pareto Chart

Examine the cumulative productivity of a group of programmers to see how normal its distribution is. Label each bar with the name of the programmer.

```
codelines = [200 120 555 608 1024 101 57 687];
```

```
coders = {'Fred', 'Ginger', 'Norman', 'Max', 'Julia', 'Wally', 'Heidi', 'Pat'};

figure
pareto(codelines, coders)
title('Lines of Code by Programmer')
```

## More About

### Tips

You can use `pareto` to display the output of `hist`, even for vectors that include negative numbers. Because only the first 95 percent of values are displayed, one or more of the

smallest bars may not appear. If you extend the `XLim` of your chart, you can display all the values, but the new bars will not be labeled.

You cannot place datatips (use the `Datacursor` tool) on graphs created with `pareto`.

# parfor

Parallel for loop

## Syntax

```
parfor loopvar = initval:endval; statements; end
parfor (loopvar = initval:endval, M); statements; end
```

## Description

`parfor loopvar = initval:endval; statements; end` executes a series of MATLAB statements for values of `loopvar` between `initval` and `endval`, inclusive, which specify a vector of increasing integer values. The loop runs in parallel when you have the Parallel Computing Toolbox or when you create a MEX function with MATLAB Coder. Unlike a traditional `for`-loop, iterations are not executed in a guaranteed order.

`parfor (loopvar = initval:endval, M); statements; end` executes statements in a loop using a maximum of `M` workers or threads, where `M` is a nonnegative integer.

## Examples

Perform three large eigenvalue computations using three workers or cores with Parallel Computing Toolbox software:

```
parpool(3)
parfor i=1:3, c(:,i) = eig(rand(1000)); end
```

## More About

### Tips

- If you have Parallel Computing Toolbox software, see the function reference pages for `parfor` and `parpool` for additional information.

- If you have MATLAB Coder software, see the `parfor` function reference page for additional information.

for

## parse

**Class:** inputParser

Parse function inputs

## Syntax

```
parse(p, argList)
```

## Description

`parse(p, argList)` parses and validates the inputs in `argList`.

## Input Arguments

**p**

Object of class `inputParser`.

**argList**

Comma separated list of inputs to parse and validate for your custom function. The class of each input depends upon your function definition.

## Examples

### Input Parsing

Parse and validate required and optional function inputs.

Create a custom function with required and optional inputs in the file `findArea.m`.

```
function a = findArea(width,varargin)
 p = inputParser;
 defaultHeight = 1;
```

```
defaultUnits = 'inches';
defaultShape = 'rectangle';
expectedShapes = {'square', 'rectangle', 'parallelogram'};

addRequired(p, 'width', @isnumeric);
addOptional(p, 'height', defaultHeight, @isnumeric);
addParameter(p, 'units', defaultUnits);
addParameter(p, 'shape', defaultShape, ...
 @(x) any(validatestring(x, expectedShapes)));

parse(p, width, varargin{:});
a = p.Results.width .* p.Results.height;
```

The input parser checks whether `width` and `height` are numeric, and whether the `shape` matches a string in cell array `expectedShapes`. `@` indicates a function handle, and the syntax `@(x)` creates an anonymous function with input `x`.

Call the function with inputs that do not match the scheme. For example, specify a nonnumeric value for the `width` input:

```
findArea('text')
```

```
Error using findArea (line 14)
The value of 'width' is invalid. It must satisfy the function: isnumeric.
```

Specify an unsupported value for `shape`:

```
findArea(4, 'shape', 'circle')
```

```
Error using findArea (line 14)
The value of 'shape' is invalid. Expected input to match one of these strings:

square, rectangle, parallelogram

The input, 'circle', did not match any of the valid strings.
```

# parseSoapResponse

Convert response string from SOAP (Simple Object Access Protocol) server into MATLAB types

## Compatibility

parseSoapResponse will be removed in a future release. Use `matlab.wsd1.createWSDLCient` instead.

## Syntax

```
data = parseSoapResponse(response)
```

## Description

`data = parseSoapResponse(response)` extracts data from SOAP server response and converts to MATLAB types.

## Examples

### Retrieve Book Information from Library Database

This example assumes the library is on a local intranet and does not use an actual endpoint; therefore, you cannot run it.

Retrieve the name of the author of a book titled “In the Fall.” The relative path of the library service is `urn:LibraryCatalog`. To get the author's name, use the `getAuthor` function, which takes the book name as the input value. The `getAuthor` parameter is `nameToLookUp`. The XML data type for title is `{http://www.w3.org/2001/XMLSchema}string`. The SOAP message style is `rpc` by default.

Create the SOAP message.

```
message = createSoapMessage(...
```

```
'urn:LibraryCatalog',...
'getAuthor',...
{'In the Fall'},...
{'nameToLookUp'},...
{'{http://www.w3.org/2001/XMLSchema}string'})

message =

[#document: null]
```

This response does not necessarily indicate that the message is valid, although certain input problems produce error messages.

Send the message to the server for processing, and get the author's name back. The server endpoint is `http://test/soap/services/LibraryCatalog`. The server method is `urn:LibraryCatalog#getAuthor`.

```
response = callSoapService(...
 'http://test/soap/services/LibraryCatalog',...
 'urn:LibraryCatalog#getAuthor',...
 message)

<?xml version="1.0" encoding="utf-8"?>
<soapenv:Envelope
xmlns:soapenv="http://schemas.xmlsoap.org/soap/envelope/"
xmlns:xsd="http://www.w3.org/2001/XMLSchema"
xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
<soapenv:Body>
<getAuthorResponse xmlns="urn:LibraryCatalog">
<ns1:getAuthorReturn xmlns:ns1="http://latestversion.soap.test">
Kate Alvin
</ns1:getAuthorReturn>
</getAuthorResponse>
</soapenv:Body>
</soapenv:Envelope>
```

MATLAB returns the message in a single line, displayed here on separate lines for legibility.

Extract the author's name.

```
author = parseSoapResponse(response)

author = Kate Alvin
```

MATLAB automatically converted the XML string data type to `char`.

## Input Arguments

### **response** — Data from SOAP server

string

Data from SOAP server, specified as a string. `response` is the output from the `callSoapService` function.

## Output Arguments

### **data** — Output of SOAP service call

cell array of any valid MATLAB type

Output of SOAP service call, returned as a cell array of any valid MATLAB type. For information about `data`, see the documentation for the SOAP service used in the `callSoapService` function.

# pascal

Pascal matrix

## Syntax

```
A = pascal(n)
A = pascal(n,1)
A = pascal(n,2)
```

## Description

`A = pascal(n)` returns a “Pascal’s Matrix” on page 1-5515 of order  $n$ : a symmetric positive definite matrix with integer entries taken from Pascal’s triangle. The inverse of  $A$  has integer entries.

`A = pascal(n,1)` returns the lower triangular Cholesky factor (up to the signs of the columns) of the Pascal matrix. It is *involutary*, that is, it is its own inverse.

`A = pascal(n,2)` returns a transposed and permuted version of `pascal(n,1)`.  $A$  is a cube root of the identity matrix.

## Examples

`pascal(4)` returns

```
1 1 1 1
1 2 3 4
1 3 6 10
1 4 10 20
```

`A = pascal(3,2)` produces

```
A =
 1 1 1
 -2 -1 0
 1 0 0
```

## More About

### Pascal's Matrix

Pascal's triangle is a triangle formed by rows of numbers. The first row has entry 1. Each succeeding row is formed by adding adjacent entries of the previous row, substituting a 0 where there is no adjacent entry. Pascal's matrix is generated by selecting the portion of Pascal's triangle that corresponds to the specified matrix dimensions, as outlined in the graphic. The matrix outlined corresponds to the MATLAB command `pascal(4)`.

# patch

Create one or more filled polygons

## Syntax

```
patch(X,Y,C)
patch(X,Y,Z,C)
patch(FV)
patch(X,Y,C,'PropertyName',propertyvalue...)
patch('PropertyName',propertyvalue,...)
handle = patch(...)
```

## Properties

For a list of properties, see Patch Properties.

## Description

`patch(X,Y,C)` adds a filled 2-D patch object to the current axes. A patch object is one or more polygons defined by the coordinates of its vertices. The elements of `X` and `Y` specify the vertices of a polygon. If `X` and `Y` are `m`-by-`n` matrices, MATLAB draws `n` polygons with `m` vertices. `C` determines the color of the patch. For more information on color input requirements, see “Coloring Patches” on page 1-5521.

MATLAB does not require each face to have the same number of vertices. In cases where they do not, pad the end of the `FACES` matrix with `NaNs`. To define a patch with faces that do not close, add one or more `NaNs` to the row in the `Vertices` matrix that defines the vertex you do not want connected.

See “Introduction to Patch Objects” for more information on using patch objects.

`patch(X,Y,Z,C)` creates a patch in 3-D coordinates. If the coordinate data does not define closed polygons, `patch` closes the polygons. The data can define concave or intersecting polygons. However, if the edges of an individual patch face intersect themselves, the resulting face might be only partly filled. In that case, it is better to divide the face into smaller polygons.

`patch(FV)` creates a patch using structure `FV`, which contains the fields `vertices`, `faces`, and optionally `facevertexcdata`. These fields correspond to the `Vertices`, `Faces`, and `FaceVertexCData` patch properties. Specifying only unique vertices and their connection matrix can reduce the size of the data for patches having many faces. For an example of how to specify patches with this method, see “Specifying Patch Object Shapes” on page 1-5518.

`patch(X,Y,C,'PropertyName',propertyvalue...)` follows the `X`, `Y`, (`Z`), and `C` arguments with property name/property value pairs to specify additional patch properties. For a description of the properties, see Patch Properties. You can specify properties as property name/property value pairs, structure arrays, and cell arrays (see the `set` and `get` reference pages for examples of how to specify these data types).

`patch('PropertyName',propertyvalue,...)` specifies all properties using property name/property value pairs. This form lets you omit the color specification because MATLAB uses the default face color and edge color unless you explicitly assign a value to the `FaceColor` and `EdgeColor` properties. This form also lets you specify the patch using the `Faces` and `Vertices` properties instead of `x`-, `y`-, and `z`-coordinates. See “Specifying Patch Object Shapes” on page 1-5518 for more information.

`handle = patch(...)` returns the handle of the patch object it creates.

Unlike high-level area creation functions, such as `fill` or `area`, `patch` does not check the settings of the figure and axes `NextPlot` properties. It simply adds the patch object to the current axes.

## Examples

### Define a Square Patch

Create a square patch with red face color and black edges using `x`- and `y`-coordinates:

```
x = [0 1 1 0];
y = [0 0 1 1];
patch(x,y,'red')
```

Create a square patch with red face color and black edges using vertices and faces:

```
vert = [0 0;1 0;1 1;0 1]; % x and y vertex coordinates
fac = [1 2 3 4]; % vertices to connect to make square
```

```
patch('Faces',fac,'Vertices',vert,'FaceColor','red')
```

Specify colors for each vertex and interpolate the face color:

```
fvc = [1 0 0;0 1 0;0 0 1;0 0 0];
patch('Faces',fac,'Vertices',vert,...
'FaceVertexCData',fvc,'FaceColor','interp')
```

## Specifying Patch Object Shapes

The next two examples create a patch object using two methods:

- Specifying  $x$ -,  $y$ -, and  $z$ -coordinates and color data (XData, YData, ZData, and CData properties)

- Specifying vertices, the connection matrix, and color data (Vertices, Faces, and FaceVertexCData properties)

Create five triangular faces, each having three vertices, by specifying the  $x$ -,  $y$ -, and  $z$ -coordinates of each vertex:

```
xdata = [2 2 0 2 5;
 2 8 2 4 5;
 8 8 2 4 8];
ydata = [4 4 4 2 0;
 8 4 6 2 2;
 4 0 4 0 0];
zdata = ones(3,5);

% Red numbers denote the vertex indices.
% For this example:
% xindices = [1 4 7 10 13;
% 2 5 8 11 14;
% 3 6 9 12 15];
% Blue numbers denote the face numbers.
patch(xdata,ydata,zdata,'w')
```

Create the five triangular faces, specifying faces and vertices:

```
% The Vertices property contains the coordinates of each
% unique vertex defining the patch. The Faces property
% specifies how to connect these vertices to form each
% face of the patch. More than one face may
% use a given vertex.
% For this example, five triangles have 11 total vertices,
% instead of 15. Each row contains
% the x- and y-coordinates
% of each vertex.
verts = [2 4; ...
 2 8; ...
 8 4; ...
 8 0; ...
 0 4; ...
 2 6; ...
 2 2; ...
 4 2; ...
 4 0; ...
 5 2; ...
 5 0];

% There are five faces, defined by connecting the
% vertices in the order indicated.
faces = [...
 1 2 3; ...
 1 3 4; ...
 5 6 1; ...
 7 8 9; ...
 11 10 4];

% Create the patch by specifying the Faces, Vertices,
% and FaceVertexCData properties as well as the
% FaceColor property. Red numbers denote the vertex
% numbers, as defined in faces. Blue indicate face numbers.
p = patch('Faces',faces,'Vertices',verts,'FaceColor','w');
```

```
% Using the previous values for verts and faces, you can
% create the same patch object using a structure:
patchinfo.Vertices = verts;
patchinfo.Faces = faces;
patchinfo.FaceColor = 'w';
```

```
patch(patchinfo);
```

## Coloring Patches

There are many ways to customize your patch objects using colors. The appropriate input depends on:

- Whether you want to change the edge colors
- How you specified the patch faces:
  - Using face/vertex values
  - Using  $x$ -,  $y$ -, and  $z$ -coordinates

The following sections present the various options available.

## Specifying Edge Colors

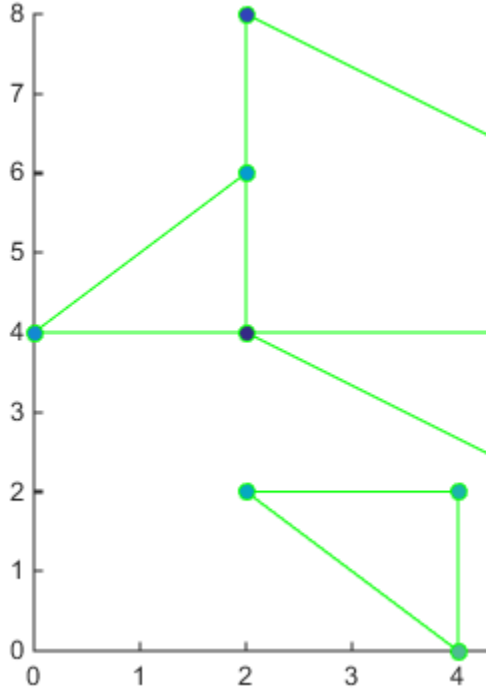

The following options apply to the edge colors of your patch object. The settings are independent of the face colors, but the colors themselves depend on the colors specified at each vertex. Markers show the color at each vertex. Specify the colors using the `EdgeColor` property. Explore the options using the Sample Code in the following table. Create a base patch object with this code:

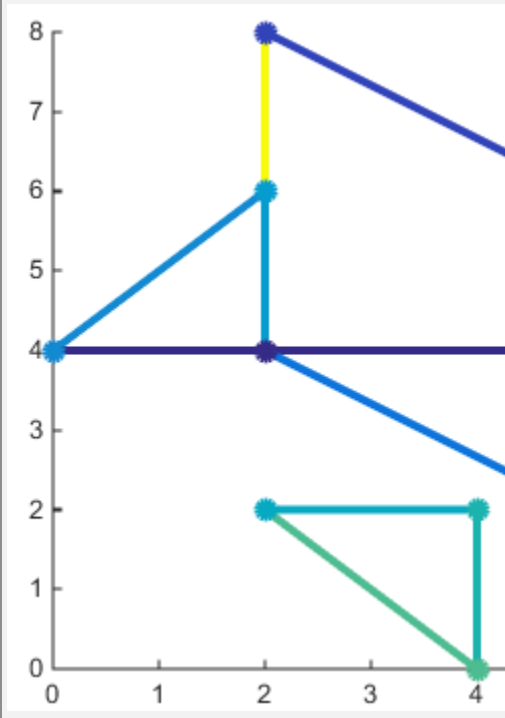

```
xdata = [2 2 0 2 5;
 2 8 2 4 5;
 8 8 2 4 8];
ydata = [4 4 4 2 0;
 8 4 6 2 2;
 4 0 4 0 0];
cdata = [15 0 4 6 10;
 1 2 5 7 9;
 2 3 0 8 3];
p = patch(xdata,ydata,cdata,'Marker','o',...
 'MarkerFaceColor','flat',...
 'FaceColor','none')
```

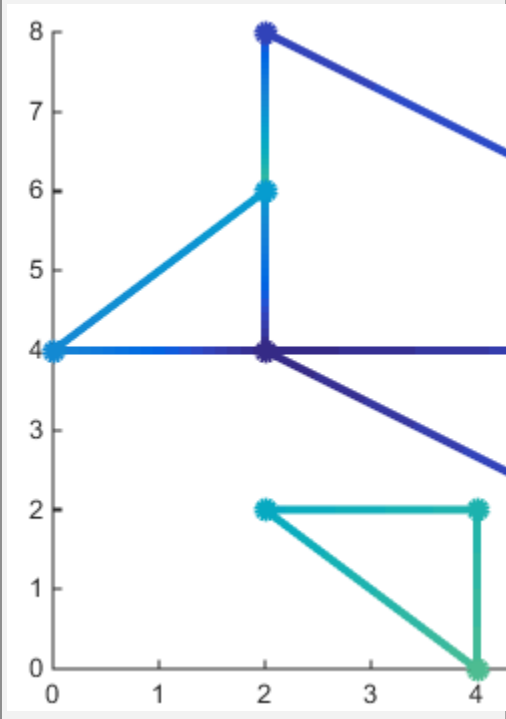

For more detailed information on how the `EdgeColor` property works, see the [Patch Properties](#) property page.

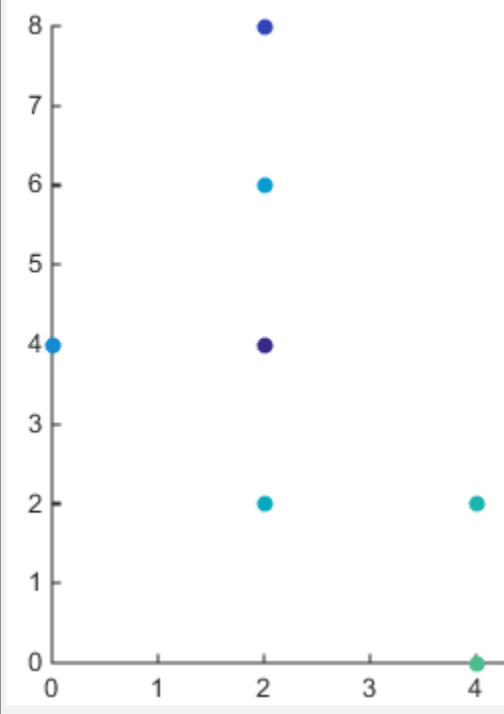

Desired Look	EdgeColor Value	Sample Code
All edges have the same color, around all faces. This option does not rely on the <code>FaceColor</code> value.	MATLAB color specifier. <code>EdgeColor</code>	<code>set(p,'EdgeColor','g')</code>

Desired Look	EdgeColor Value	Sample Code
 <p>The plot shows a 2D coordinate system with x-axis from 0 to 4 and y-axis from 0 to 8. A patch is defined by vertices at (0,4), (2,4), (2,8), (4,8), (4,2), (2,2), and (4,0). The edges are colored green.</p>		

Desired Look	EdgeColor Value	Sample Code
<p>Each edge corresponds to the color of the vertex that precedes the edge, with one color per edge. This option requires that the <code>FaceColor</code> property be <code>flat</code> or <code>interp</code>. By default, if you specify <code>CData</code> when creating the patch object, its <code>FaceColor</code> property is <code>interp</code>.</p> 	<p>'flat'</p>	<pre>set(p, 'EdgeColor', 'flat', ...       'LineWidth', 3)</pre>

Desired Look	EdgeColor Value	Sample Code
<p>Each edge corresponds to the vertex colors, interpolated between vertices. This option requires that the <code>FaceColor</code> property be <code>flat</code> or <code>interp</code>. By default, if you specify <code>CData</code> when creating the patch object, its <code>FaceColor</code> property is <code>interp</code>.</p> 	'interp'	<pre>set(p, 'EdgeColor', 'interp')</pre>

Desired Look	EdgeColor Value	Sample Code
<p>Edges have no color. This option does not rely on the FaceColor value. If set, markers retain vertex colors.</p> 	'none'	<pre>set(p, 'EdgeColor', 'none')</pre>

### Specifying Face Colors Using Face/Vertex Input Matrices

The following options apply to the face colors of your patch object when you specify the faces using face/vertex input matrices. To explore the options, start with a base patch object:

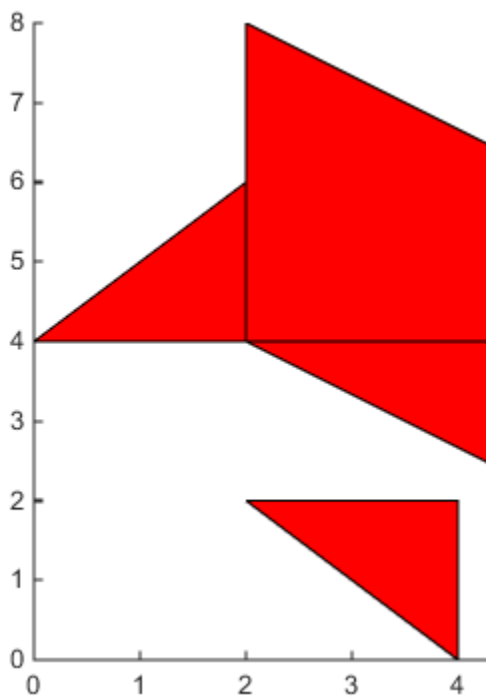

```
% For this example, there are five triangles (m = 5)
% sharing eleven unique vertices (k = 11).
verts = [2 4; ...
 2 8; ...
 8 4; ...
 8 0; ...
```

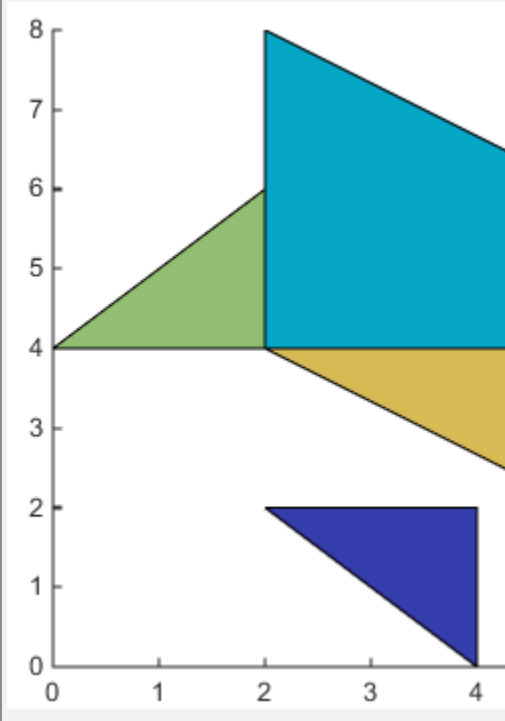

```

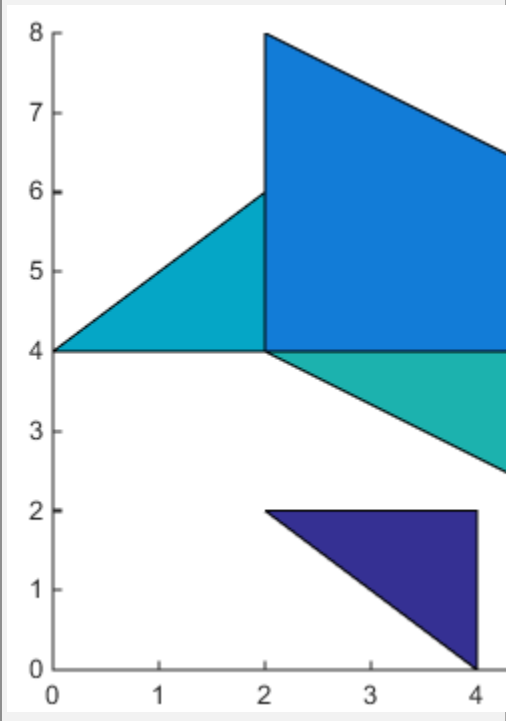

0 4; ...
2 6; ...
2 2; ...
4 2; ...
4 0; ...
5 2; ...
5 0];
faces = [1 2 3; ...
 1 3 4; ...
 5 6 1; ...
 7 8 9; ...
 11 10 4];
p = patch('Faces',faces,'Vertices',verts,'FaceColor','b');

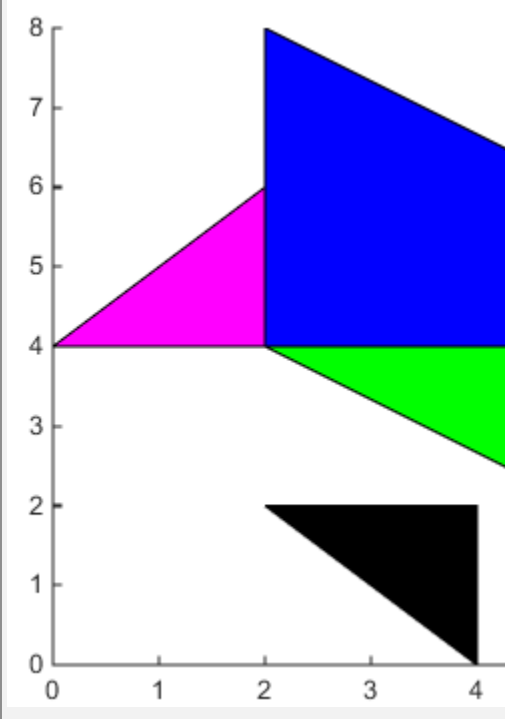

```

For more information on the relevant properties, see `FaceColor`, `FaceVertexCData`, and `CDataMapping`.

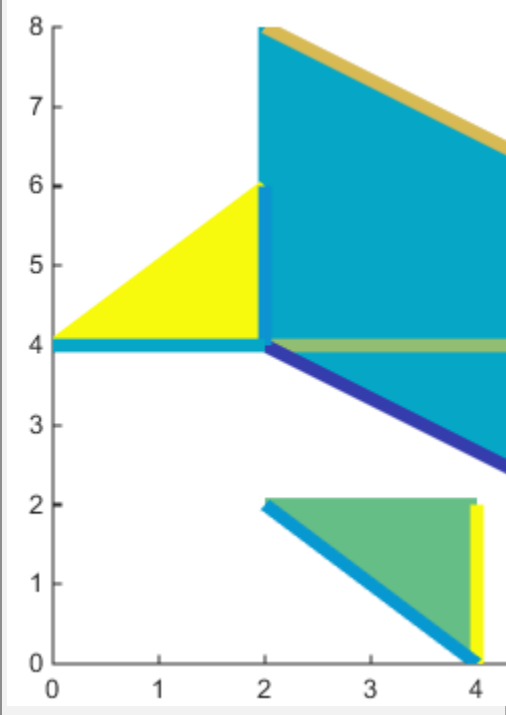

Desired Look	Parameter Values	Sample Code
<p>All faces have the same color.</p> 	<ul style="list-style-type: none"> <li>• <code>FaceColor</code></li> <li>• <code>FaceVertexCData</code>: <code>[]</code> (no input)</li> </ul> <p>An empty array is the default value, and <code>patch</code> ignores any input until you set <code>FaceColor</code> to <code>'flat'</code> or <code>'interp'</code>.</p> <ul style="list-style-type: none"> <li>• Color source: <code>truecolor</code></li> <li>• <code>CDataMapping</code>: <code>'direct'</code> or <code>'scaled'</code>.</li> </ul> <p><code>'scaled'</code> is the default value, but neither affects the outcome.</p>	<pre>set(p,'FaceColor','r') </pre> <p>or</p> <pre>set(p,'FaceColor',[1 0 0]) </pre>

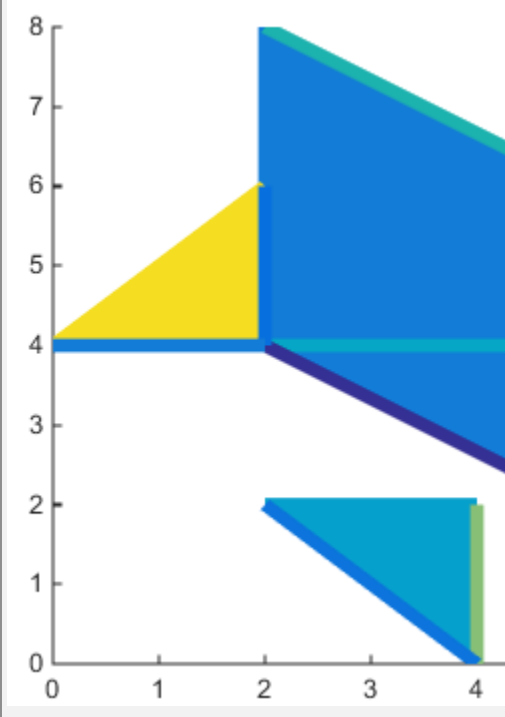

Desired Look	Parameter Values	Sample Code
<p>Each face has a single, unique color, indexed from a selected section of the colormap.</p> 	<ul style="list-style-type: none"> <li>• <b>FaceColor:</b> 'flat'</li> <li>• <b>FaceVertexCData:</b> m-by-1 matrix of index values</li> <li>• <b>Color source:</b> A selected portion of the colormap</li> <li>• <b>CDataMapping:</b> 'scaled'</li> </ul>	<pre>clear cdata set(gca,'CLim',[0 40]) cdata = [15 30 25 2 60]'; set(p,'FaceColor','flat',... 'FaceVertexCData',cdata,... 'CDataMapping','scaled')</pre>

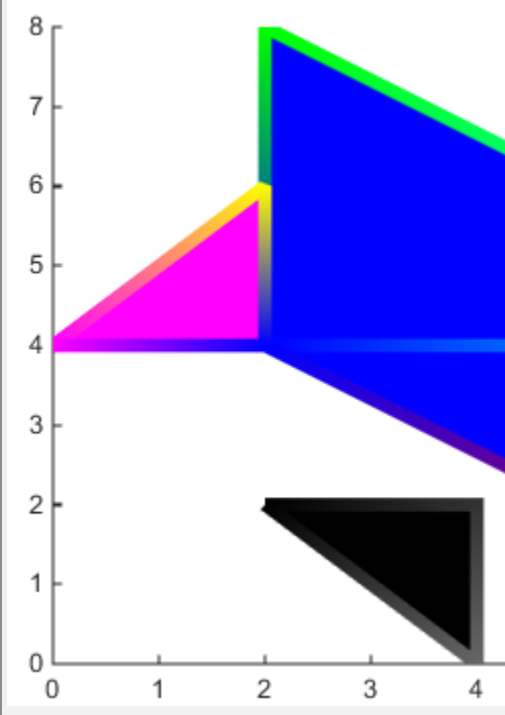

Desired Look	Parameter Values	Sample Code
<p>Each face has a single, unique color, indexed from the whole colormap.</p> 	<ul style="list-style-type: none"> <li>• <b>FaceColor:</b> 'flat'</li> <li>• <b>FaceVertexCData:</b> m-by-1 matrix of index values</li> <li>• <b>Color source:</b> colormap</li> <li>• <b>CDataMapping:</b> 'direct'</li> </ul> <p>'scaled' is the default value when you input CData values. If you want to change the axes CLim property, but want your patch object to index the entire colormap, use 'CDataMapping', 'dire</p>	<pre>clear cdata set(gca,'CLim',[0 40]) cdata = [15 30 25 2 60]'; set(p,'FaceColor','flat',... 'FaceVertexCData',cdata,... 'CDataMapping','direct')</pre>

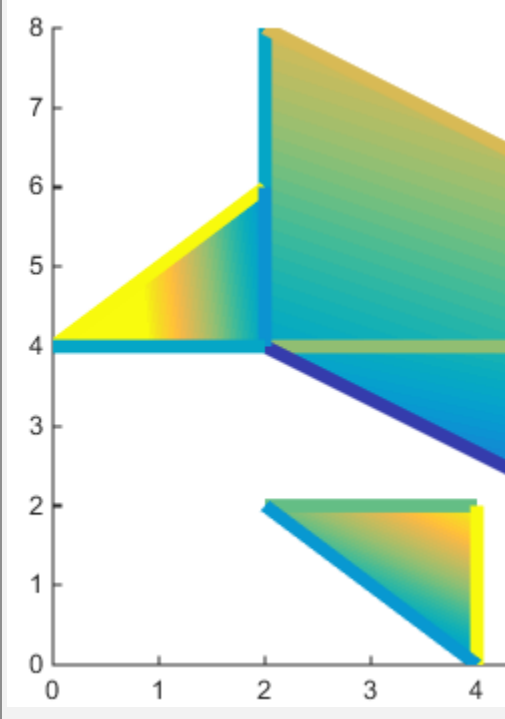

Desired Look	Parameter Values	Sample Code
<p>Each face has a single, unique color, determined by truecolor value input.</p> 	<ul style="list-style-type: none"> <li>• <b>FaceColor:</b> 'flat'</li> <li>• <b>FaceVertexCData:</b> m-by-3 matrix of truecolor values, from 0 to 1</li> <li>• <b>Color source:</b> truecolor</li> <li>• <b>CDataMapping:</b> 'direct' or 'scaled'.</li> </ul> <p>'scaled' is the default value, but neither affects the outcome.</p>	<pre>clear cdata cdata = [0 0 1 0 0.8;          0 1 0 0 0.8;          1 0 1 0 0.8]'; set(p,'FaceColor','flat',...     'FaceVertexCData',cdata)</pre>

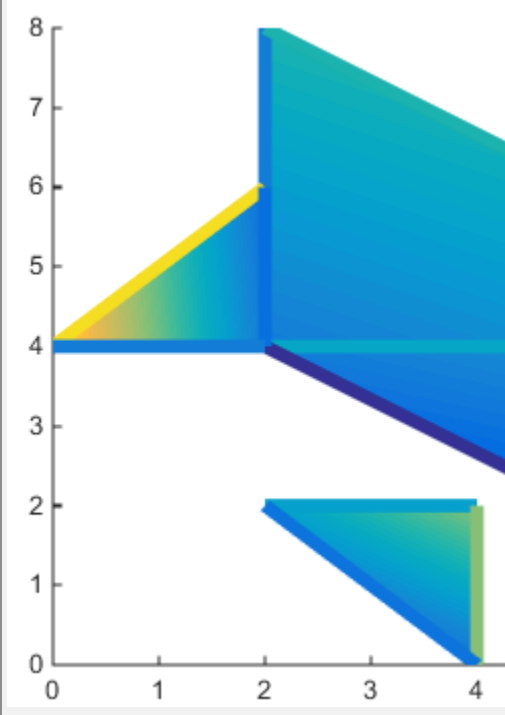

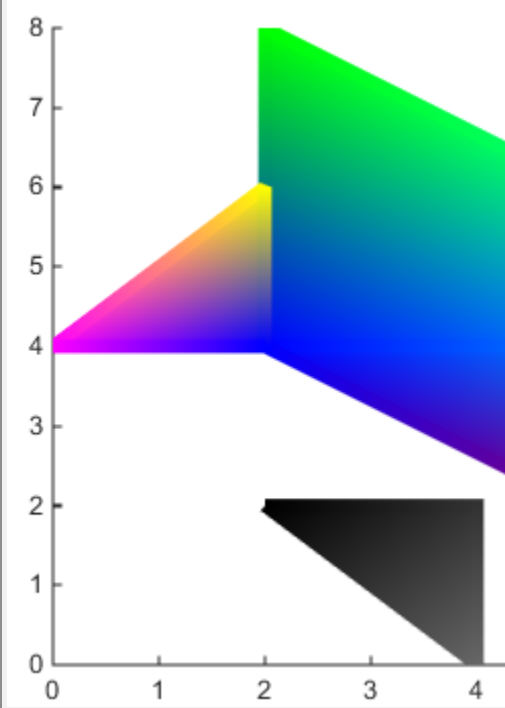

Desired Look	Parameter Values	Sample Code
<p>Each unique vertex has a single, unique color, indexed from a selected section of the colormap. Faces each have a single, unique color, but edges may have 'flat' or 'interp' color.</p> 	<ul style="list-style-type: none"> <li>• <b>FaceColor:</b> 'flat'</li> <li>• <b>FaceVertexCData:</b> k-by-1 matrix of index values</li> <li>• <b>Color source:</b> A selected portion of the colormap</li> <li>• <b>CDataMapping:</b> 'scaled'</li> </ul>	<pre>clear cdata set(gca,'CLim',[0 40]) cdata = [15 30 25 2 ... 60 12 23 40 13 26 24]'; set(p,'FaceColor','flat',... 'FaceVertexCData',cdata,... 'EdgeColor','flat',... 'LineWidth',5,... 'CDataMapping','scaled')</pre>

Desired Look	Parameter Values	Sample Code
<p>Each unique vertex has a single, unique color, indexed from the whole colormap. Faces each have a single, unique color, but edges may have 'flat' or 'interp' color.</p> 	<ul style="list-style-type: none"> <li>• <b>FaceColor:</b> 'flat'</li> <li>• <b>FaceVertexCData:</b> k-by-1 matrix of index values</li> <li>• <b>Color source:</b> colormap</li> <li>• <b>CDataMapping:</b> 'direct'</li> </ul> <p>'scaled' is the default value when you input CData values. If you want to change the axes CLim property, but want your patch object to index the entire colormap, use 'CDataMapping', 'dire</p>	<pre>clear cdata set(gca,'CLim',[0 40]) cdata = [15 30 25 2 ... 60 12 23 40 13 26 24]'; set(p,'FaceColor','flat',... 'FaceVertexCData',cdata,...     'EdgeColor','interp',...     'LineWidth',5)</pre>

### Specifying Face Colors Using x-, y-, and z-Coordinate Input

The following options apply to the face colors of your patch object when you specify the faces using x-, y-, and z-coordinates. To explore the options, start with a base patch object:

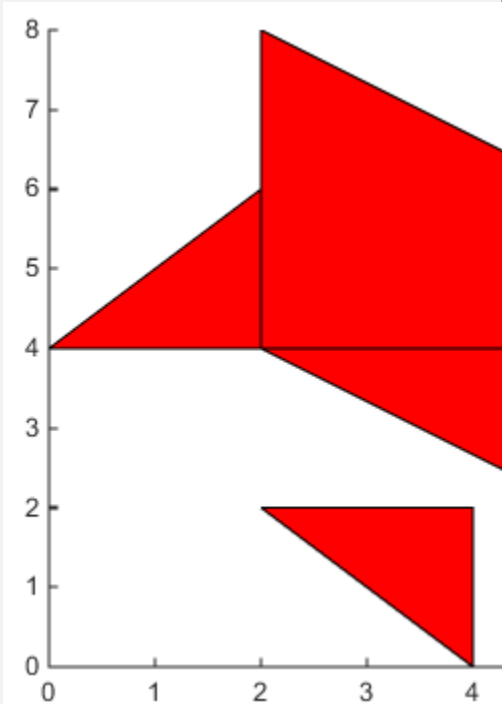

```
% For this example, there are five (m=5) triangles (n=3).
% The total number of vertices is mxn, or k = 15.
xdata = [2 2 0 2 5;
 2 8 2 4 5;
 8 8 2 4 8];
```

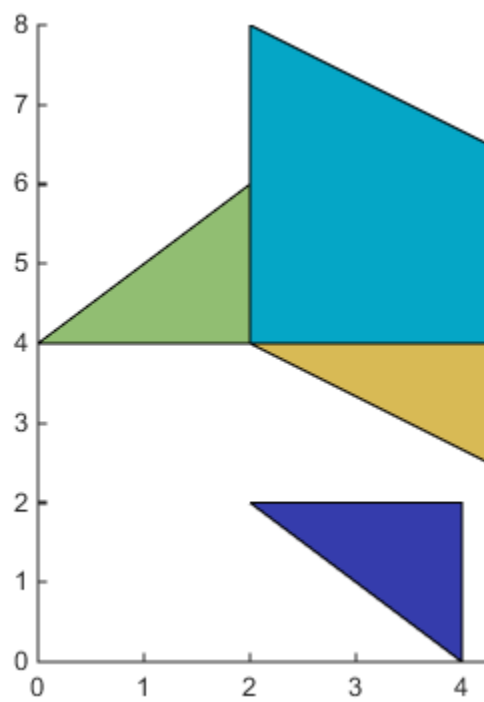

```

ydata = [4 4 4 2 0;
 8 4 6 2 2;
 4 0 4 0 0];
zdata = ones(3,5);
p = patch(xdata,ydata,zdata,'b')

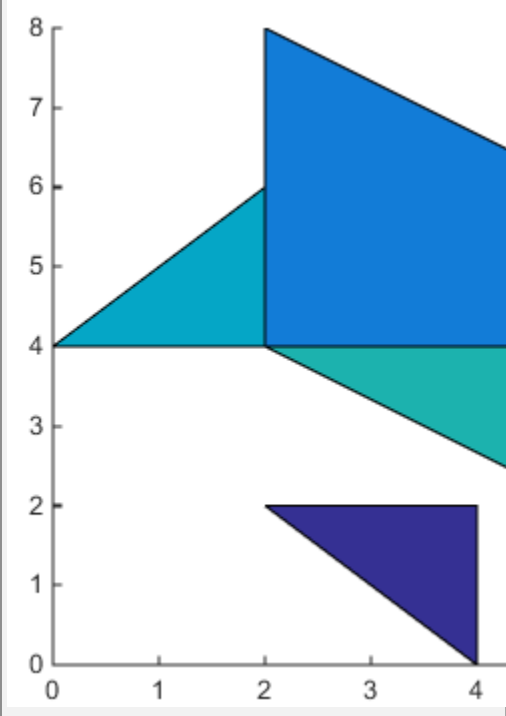

```

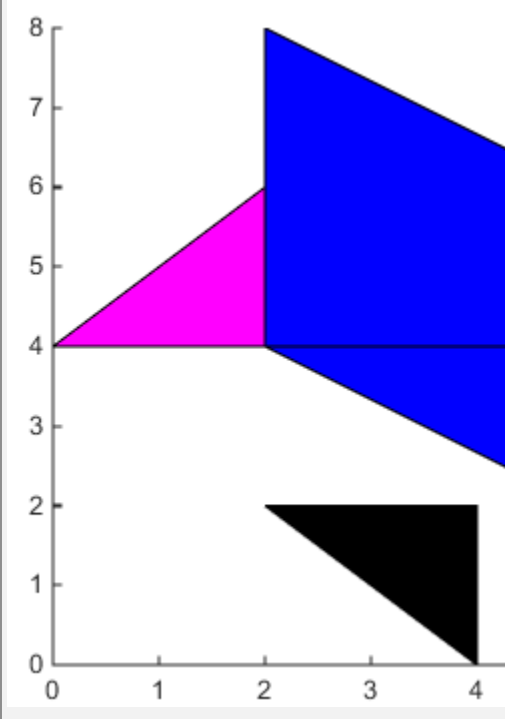

For more information on the relevant properties, see `FaceColor`, `CData`, and `CDataMapping`.

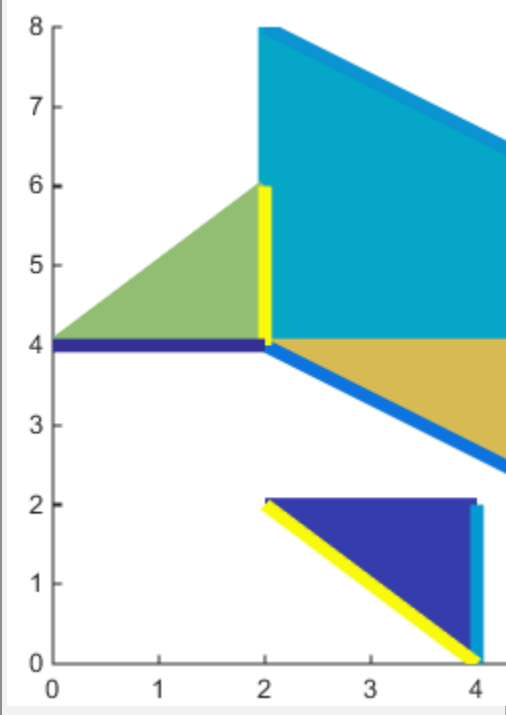

Desired Look	Parameter Values	Sample Code
<p>All faces have the same color.</p> 	<ul style="list-style-type: none"> <li>• <code>FaceColor</code>: <code>ColorSpec</code></li> <li>• <code>CData</code>: <code>[]</code> (no input)</li> <li>• Color source: <code>truecolor</code></li> <li>• <code>CDataMapping</code>: <code>'direct'</code> or <code>'scaled'</code>.</li> </ul> <p><code>'scaled'</code> is the default value, but neither affects the outcome.</p>	<pre> set(p,'FaceColor','r')  or  set(p,'FaceColor',[1 0 0]) </pre>
<p>Each face has a single, unique color, indexed from a selected section of the colormap.</p>	<ul style="list-style-type: none"> <li>• <code>FaceColor</code>: <code>'flat'</code></li> <li>• <code>CData</code>: m-by-1 matrix of index values</li> <li>• Color source: A selected portion of the colormap</li> </ul>	<pre> clear cdata set(gca,'CLim',[0 40]) cdata = [15 30 25 2 60]; set(p,'FaceColor','flat',... # Patch Properties

Control patch appearance and behavior

Patch properties control the appearance and behavior of patch objects. By changing property values, you can modify certain aspects of the patch. Use dot notation to refer to a particular object and property:

```
h = patch;
c = h.CData;
h.CDataMapping = 'scaled';
```

## Faces

### FaceColor — Face color

[0 0 0] (default) | 'none' | 'flat' | 'interp' | RGB triplet or color string

Face color, specified as one of these values:

- 'none' — Do not draw the faces.
- 'flat' — Uniform face colors. Use the CData values. The color data at the first vertex determines the color for the entire face. You must first specify CData or FaceVertexCData as an array containing one value per face.
- 'interp' — Vary the color across each face. Use a bilinear interpolation of the CData values at each vertex. You must first specify CData or FaceVertexCData as an array containing one value per vertex.
- RGB triplet or color string — Same color for all of the faces.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0, 1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[1 1 0]
'magenta'	'm'	[1 0 1]
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]

Long Name	Short Name	RGB Triplet
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black'	'k'	[0 0 0]

### FaceAlpha — Face transparency

1 (default) | scalar in range [0,1] | 'flat' | 'interp'

Face transparency, specified as one of these values:

- Scalar in range [0, 1] — Use the same transparency value for all of the faces. A value of 1 is fully opaque and 0 is completely transparent.
- 'flat' — Use uniform transparency across each face. The alpha data at the first vertex determines the transparency for the entire face. You must first specify the FaceVertexAlphaData property as an array containing one alpha value per face.
- 'interp' — Vary the transparency across each face. Bilinear interpolation of the AlphaData values at each vertex determines the transparency values. You must first specify the FaceVertexAlphaData property as an array containing one alpha value per vertex.

### FaceLighting — Effect of light objects on faces

'flat' (default) | 'gouraud' | 'none'

Effect of light objects on faces, specified as one of these values:

- 'flat' — Apply light uniformly across the faces. Use this value to view faceted objects.
- 'gouraud' — Vary the light across the faces. Calculate the light at the vertices and then linearly interpolate the light across the faces. Use this value to view curved surfaces.
- 'none' — Do not apply light from light objects to the faces.

---

**Note:** The 'phong' value has been removed. Use 'gouraud' instead.

---

### BackFaceLighting — Face lighting when normals point away from camera

'reverslit' (default) | 'unlit' | 'lit'

Face lighting when the vertex normals point away from camera, specified as one of these values:

- `'reverslit'` — Light the face as if the vertex normal pointed towards the camera.
- `'unlit'` — Do not light the face.
- `'lit'` — Light the face according to the vertex normal.

Use this property to discriminate between the internal and external surfaces of an object. For an example, see “Back Face Lighting”.

## Edges

### EdgeColor — Edge color of the patch faces

[0 0 0] (default) | `'none'` | `'flat'` | `'interp'` | RGB triplet or color string

Color of the edges of the patch faces, specified as one of these values:

- `'none'` — Do not draw edges.
- `'flat'` — Use the color of each vertex to set the color of the edge that follows it. This means that the edge coloring is dependent on the order in which you specify the vertices:

- `'interp'` — Linearly interpolate the `CData` or `FaceVertexCData` values at the vertices determines the edge color.
- RGB triplet or a color string — Use the same color for all edges.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0, 1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[ 1 1 0 ]
'magenta'	'm'	[ 1 0 1 ]
'cyan'	'c'	[ 0 1 1 ]
'red'	'r'	[ 1 0 0 ]
'green'	'g'	[ 0 1 0 ]
'blue'	'b'	[ 0 0 1 ]
'white'	'w'	[ 1 1 1 ]
'black'	'k'	[ 0 0 0 ]

Example: 'flat'

**LineStyle — Line style**

'-' (default) | '--' | ':' | '-.' | 'none'

Line style, specified as one of the line style strings listed in this table.

String	Line Style	Resulting Line
'-'	Solid line	
'--'	Dashed line	
':'	Dotted line	
'-.'	Dash-dotted line	
'none'	No line	No line

**LineWidth — Line width**

0.5 (default) | positive value

Line width, specified as a positive value in point units. If the line has markers, then the line width also affects the marker edges.

Example: 0.75

**EdgeAlpha — Transparency of patch face edges**

1 (default) | scalar value in range [0,1] | 'flat' | 'interp'

Transparency of patch face edges, specified as one of these values:

- Scalar value in range  $[0, 1]$  — Use the same transparency value for all of the edges.. A value of 1 is fully opaque and 0 is completely transparent.
- 'flat' — Uniform transparency along each edge. Before you set `EdgeAlpha` to 'flat', you must first define `FaceVertexAlphaData` as an array containing one alpha value per face. The alpha data of each vertex controls the transparency of the edge that follows it.
- 'interp' — Vary the transparency along edge segment. Before you set `EdgeAlpha` to 'interp', you must first define `FaceVertexAlphaData` as an array containing one alpha value per vertex. Linear interpolation of the alpha data at each vertex determines the transparency of the edge connecting those vertices.

### **EdgeLighting — Effect of light objects on edges**

'none' (default) | 'flat' | 'gouraud'

Effect of light objects on edges, specified as one of these values:

- 'flat' — Apply light uniformly across the each edges.
- 'none' — Do not apply lights from light objects to the edges.
- 'gouraud' — Calculate the light at the vertices, and then linearly interpolate across the edges.

---

**Note:** The 'phong' value has been removed. Use 'gouraud' instead.

---

### **AlignVertexCenters — Sharp vertical and horizontal lines**

'off' (default) | 'on'

Sharp vertical and horizontal lines, specified as 'off' or 'on'.

If the associated figure has a `GraphicsSmoothing` property set to 'on' and a `Renderer` property set to 'opengl', then the figure applies a smoothing technique to plots. In some cases, this smoothing technique can cause vertical and horizontal lines to appear uneven in thickness or color. Use the `AlignVertexCenters` property to eliminate the uneven appearance.

- 'off' — Do not sharpen vertical or horizontal lines. The lines might appear uneven in thickness or color.
- 'on' — Sharpen vertical and horizontal lines to eliminate an uneven appearance.

---

**Note:** You must have a graphics card that supports this feature. To see if the feature is supported, type `opengl info`. If it is supported, then the returned fields contain the line `SupportsAlignVertexCenters: 1`.

---

## Markers

### Marker — Marker symbol

'none' (default) | marker string

Marker symbol, specified as one of the marker strings listed in this table. By default, the patch object does not display markers. Specifying a marker symbol adds markers at each data point or vertex.

String	Marker Symbol
'o'	Circle
'+'	Plus sign
'*'	Asterisk
'.'	Point
'x'	Cross
'square' or 's'	Square
'diamond' or 'd'	Diamond
'^'	Upward-pointing triangle
'v'	Downward-pointing triangle
'>'	Right-pointing triangle
'<'	Left-pointing triangle
'pentagram' or 'p'	Five-pointed star (pentagram)
'hexagram' or 'h'	Six-pointed star (hexagram)
'none'	No markers

Example: '+'

Example: 'diamond'

### MarkerEdgeColor — Marker outline color

'auto' (default) | 'none' | 'flat' | RGB triplet or color string

Marker outline color, specified as specified as one of these values:

- 'auto' — Use the same color as the EdgeColor property.
- 'none' — Use no color, which makes unfilled markers invisible.
- 'flat' — Use the CData value at the vertex to set the color.
- RGB triplet or color string — Use the specified color.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0, 1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[1 1 0]
'magenta'	'm'	[1 0 1]
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black'	'k'	[0 0 0]

Example: [0.5 0.5 0.5]

Example: 'blue'

#### **MarkerFaceColor** — Marker fill color

'none' (default) | 'auto' | 'flat' | RGB triplet or color string

Marker fill color, specified as one of these values:

- 'none' — Use no color, which allows the background to show through.
- 'auto' — Use the same color as the Color property for the axes.
- 'flat' — Use the CData value of the vertex to set the color.
- RGB triplet or color string — Use the specified color.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range

[0, 1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[1 1 0]
'magenta'	'm'	[1 0 1]
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black'	'k'	[0 0 0]

This property affects only the circle, square, diamond, pentagram, hexagram, and the four triangle marker types.

Example: [0.3 0.2 0.1]

Example: 'green'

Example:

### **MarkerSize** — Marker size

6 (default) | positive value

Marker size, specified as a positive value in point units.

Example: 10

## Face and Vertex Normals

### **FaceNormals** — Face normal vectors

m-by-n-by-3 array (default) | array of normal vectors

Face normal vectors, specified as an array of normal vectors with one normal vector one per patch face. Define one normal per patch face, as determined by the size of the Faces property value. Face normals determine the orientation of each patch face. This data is used for lighting calculations.

Specifying values for this property sets the associated mode to manual. If you do not specify normal vectors, then the patch generates this data when the axes contains light objects. The patch computes face normals using Newell's method.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **VertexNormals** — Vertex normal vectors

`m-by-n-by-3` array (default) | array of normal vectors

Vertex normal vectors, specified as an array of normal vectors with one normal vector one per patch vertex. Define one normal per patch vertex, as determined by the size of the Vertices property value. Vertex normals determine the shape and orientation of the patch. This data is used for lighting calculations.

Specifying values for this property sets the associated mode to manual. If you do not specify normal vectors, then the patch generates this data when the axes contains light objects.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **FaceNormalsMode** — Selection mode for FaceNormals

`'auto'` (default) | `'manual'`

Selection mode for `FaceNormals`, specified as one of these values:

- `'auto'` — The `patch` function calculates face normals when you add a light to the scene.
- `'manual'` — Use the face normal data specified by the `FaceNormals` property. Assigning values to the `FaceNormals` property sets `FaceNormalsMode` to `'manual'`.

### **VertexNormalsMode** — Selection mode for VertexNormals

`'auto'` (default) | `'manual'`

Selection mode for `VertexNormals`, specified as one of these values:

- `'auto'` — The `patch` function calculates vertex normals when you add a light to the scene.
- `'manual'` — Use the vertex normal data specified by the `VertexNormals` property. Assigning values to the `VertexNormals` property sets `VertexNormalsMode` to `'manual'`.

## Ambient Lighting

### **AmbientStrength** — Strength of ambient light

0.3 (default) | scalar in range [0, 1]

Strength of ambient light, specified as a scalar value in the range [0, 1]. Ambient light is a nondirectional light that illuminates the entire scene. There must be at least one visible light object in the axes for the ambient light to be visible.

The `AmbientLightColor` property for the axes sets the color of the ambient light. The color is the same for all objects in the axes.

Example: 0.5

Data Types: double

### **DiffuseStrength** — Strength of diffuse light

0.6 (default) | scalar in range [0, 1]

Strength of diffuse light, specified as a scalar value in the range [0, 1]. Diffuse light is the nonspecular reflectance from light objects in the axes.

Example: 0.3

Data Types: double

### **SpecularStrength** — Strength of specular reflection

0.9 (default) | scalar in range [0, 1]

Strength of specular reflection, specified as a scalar value in the range [0, 1]. Specular reflections are the bright spots on the surface from light objects in the axes.

Example: 0.3

Data Types: double

### **SpecularColorReflectance** — Color of specular reflections

1 (default) | scalar between 0 and 1 inclusive

Color of specular reflections, specified as a scalar between 0 and 1 inclusive.

- 0 — The color of the specular reflection depends on both the color of the object from which it reflects and the color of the light source.

- 1 — The color of the specular reflection depends only on the color of the light source (that is, the light object `Color` property).

The contributions from the light source color and the patch color to the specular reflection color vary linearly for values between 0 and 1.

Example: 0.5

Data Types: `single` | `double`

### **SpecularExponent** — Expansiveness of specular reflection

10 (default) | scalar value greater than 0

Expansiveness of specular reflection, specified as a scalar value greater than 0. `SpecularExponent` controls the size of the specular reflection spot. Greater values produce less specular reflection.

Most materials have exponents in the range of 5 to 20.

Example: 17

Data Types: `double`

## Color and Transparency Mapping

### **FaceVertexAlphaData** — Face and vertex transparency data

[] (default) | single transparency value | column vector of transparency values

Face and vertex transparency data, specified in one of these forms:

- A single transparency value, which applies the same transparency to the entire patch. The `FaceAlpha` property must be set to `'flat'`.
- An m-by-1 array (where m is the number of rows in the `Faces` property), which specifies one transparency value per face. The `FaceAlpha` property must be set to `'flat'`.
- An m-by-1 array (where m is the number of rows in the `Vertices` property), which specifies one transparency value per vertex. The `FaceAlpha` property must be set to `'interp'`.

The `AlphaDataMapping` property determines how MATLAB interprets the `FaceVertexAlphaData` property values.

**AlphaDataMapping — Transparency mapping method**`'scaled'` (default) | `'direct'` | `'none'`

Transparency mapping method, specified as one of these values:

- `'none'` — Clamps the elements of `FaceVertexAlphaData` to the region between 0 and 1. A value of 1 or greater means completely opaque, a value of 0 or less means completely transparent, and a value between 0 and 1 means semitransparent.
- `'scaled'` — Transforms the `FaceVertexAlphaData` to span the portion of the figure alphamap indicated by the axes `ALim` property, linearly mapping data values to alpha values.
- `'direct'` — Uses the `FaceVertexAlphaData` as indices directly into the figure alphamap, which is determined by the figure `Alphamap` property. Values with a decimal portion are fixed to the nearest lower integer. MATLAB maps values less than 1 to the first value in the alphamap and values greater than `length(alphamap)` to the last value in the alphamap. If `FaceVertexAlphaData` is an array of `uint8` integers, then the indexing begins at 0 (that is, MATLAB maps a value of 0 to the first alpha value in the alphamap).

**FaceVertexCData — Face and vertex colors**`[]` (default) | single color for entire patch | one color per face | one color per vertex

Face and vertex colors, specified as a single color for the entire patch, one color per face, or one color per vertex for interpolated face color.

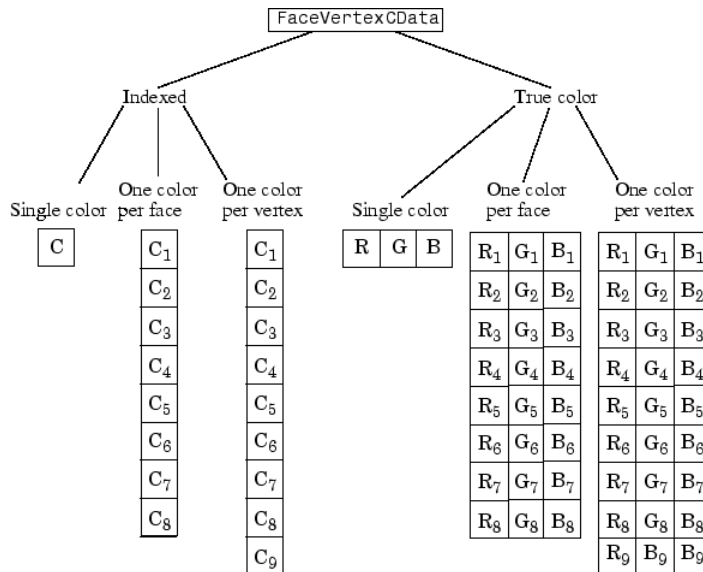

If you want to use indexed colors, then specify `FaceVertexCData` in one of these forms:

- For one color for the entire patch, use a single value.
- For one color per face, use an `m`-by-1 column vector, where `m` is the number of rows in the `Faces` property.
- For interpolated face color, use an `m`-by-1 column vector where `m` is the number of rows in the `Vertices` property.

If you want to use true colors, then specify `FaceVertexCData` in one of these forms:

- For one color for the entire patch, use a three-element row vector defining an RGB triplet.
- For one color per face, use an `m`-by-3 array of RGB triplets, where `m` is the number of rows in the `Faces` property.
- For interpolated face color, use an `m`-by-3 array, where `m` is the number of rows in the `Vertices` property.

The following diagram illustrates the various forms of the FaceVertexCData property for a patch having eight faces and nine vertices. The CDataMapping property determines how MATLAB interprets the FaceVertexCData property when you specify indexed colors.

### CData — Patch color data

single color for entire patch | one color per face | one color per vertex

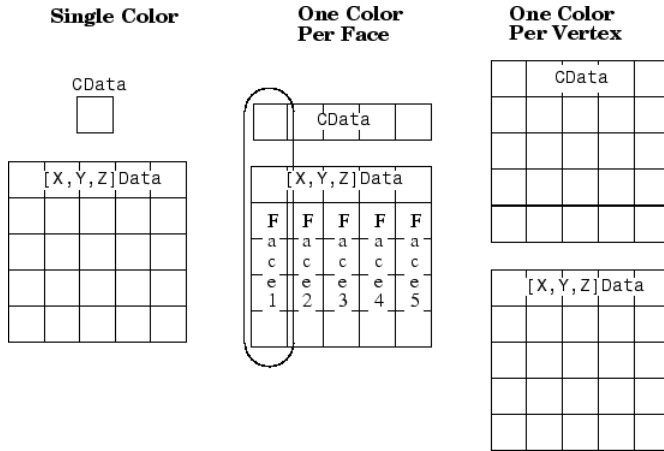

Patch color data, specified as a single color for the entire patch, one color per face, or one color per vertex.

The way the `patch` function interprets CData depends on the type of data supplied. Specify CData in one of these forms:

- Numeric values that are scaled to map linearly into the current colormap.
- Integer values that are used directly as indices into the current colormap.
- Arrays of RGB triplets. RGB triplets are not mapped into the current colormap, but interpreted as the colors defined.

The following diagrams illustrate the dimensions of CData with respect to the arrays in the XData, YData, and ZData properties.

These diagrams illustrates the use of indexed color.

These diagrams illustrates the use of true color. True color requires either a single RGB triplet or an array of RGB triplets.

If CData contains NaNs, then patch does not color the faces.

An alternative method for defining patches uses the Faces, Vertices, and FaceVertexCData properties.

Example: [ 1, 0, 0]

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **CDataMapping** — Direct or scaled color data mapping

'scaled' (default) | 'direct'

Direct or scaled color data mapping, specified as 'scaled' (the default) or 'direct'. The `CData` and `FaceVertexCData` properties contains color data. If you use true color specification for `CData` or `FaceVertexCData`, then this property has no effect.

- 'direct' — Interpret the values as indices into the current colormap. Values with a decimal portion are fixed to the nearest lower integer.
  - If the values are of type `double` or `single`, then values of 1 or less map to the first color in the colormap. Values equal to or greater than the length of the colormap map to the last color in the colormap.
  - If the values are of type `uint8`, `uint16`, `uint32`, `uint64`, `int8`, `int16`, `int32`, or `int64`, then values of 0 or less map to the first color in the colormap. Values equal to or greater than the length of the colormap map to the last color in the colormap (or up to the range limits of the type).
  - If the values are of type `logical`, then values of 0 map to the first color in the colormap and values of 1 map to the second color in the colormap.
- 'scaled' — Scale the values to range between the minimum and maximum color limits. The `CLim` property of the axes contains the color limits.

## **Data**

### **XData** — x-coordinates of the patch vertices

vector | matrix

The *x*-coordinates of the patch vertices, specified as a vector or a matrix. If `XData` is a matrix, then each column represents the *x*-coordinates of a single face of the patch. In this case, `XData`, `YData`, and `ZData` must have the same dimensions.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **YData** — y-coordinates of the patch vertices

vector | matrix

The *y*-coordinates defining the patch, specified as a vector or a matrix. If YData is a matrix, then each column represents the *y*-coordinates of a single face of the patch. In this case, XData, YData, and ZData must have the same dimensions.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **ZData — z-coordinates of the patch vertices**

`vector` | `matrix`

The *z*-coordinates of the patch vertices, specified as a vector or a matrix. If ZData is a matrix, then each column represents the *z*-coordinates of a single face of the patch. In this case, XData, YData, and ZData must have the same dimensions.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **Faces — Vertex connection defining each face**

`vector` | `matrix`

Vertex connection defining each face, specified as a vector or a matrix defining the vertices in the Vertices property that are to be connected to form each face. The Faces and Vertices properties provide an alternative way to specify a patch that can be more efficient than using XData, YData, and ZData coordinates in most cases.

Each row in the faces array designates the connections for a single face, and the number of elements in that row that are not NaN defines the number of vertices for that face. Therefore, an *m*-by-*n* Faces array defines *m* faces with up to *n* vertices each.

For example, consider the following patch. It is composed of eight triangular faces defined by nine vertices. The corresponding Faces and Vertices properties are shown to the right of the patch. Note how some faces share vertices with other faces. For example, the fifth vertex (V5) is used six times, once each by faces one, two, three, six, seven, and eight. Without sharing vertices, this same patch requires 24 vertex definitions.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### Vertices — Vertex coordinates

vector | matrix

Vertex coordinates, specified as a vector or a matrix defining the  $(x,y,z)$  coordinates of each vertex. The Faces and Vertices properties provide an alternative way to specify a patch that can be more efficient than using XData, YData, and ZData coordinates in most cases. See the **FACES** property for a description of how the vertex data is used.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

## Visibility

### Visible — Visibility of patch

'on' (default) | 'off'

Visibility of patch, specified as one of these values:

- 'on' — Display the patch.
- 'off' — Hide the patch without deleting it. You still can access the properties of an invisible patch object.

### Clipping — Clipping of patch to axes limits

'on' (default) | 'off'

Clipping of patch to the axes limits, specified as one of these values:

- 'on' — Do not display parts of the patch that are outside the axes limits.
- 'off' — Display the entire patch, even if parts of it appear outside the axes limits. Parts of the patch might appear outside the axes limits if you create a plot, set `hold on`, freeze the axis scaling, and then create the patch that is larger than the original plot.

**EraseMode — (removed) Technique to draw and erase objects**

'normal' (default) | 'none' | 'xor' | 'background'

---

**Note:** `EraseMode` has been removed. You can delete code that accesses the `EraseMode` property with minimal impact. If you were using `EraseMode` to create line animations, use the `animatedline` function instead.

---

Technique to draw and erase objects, specified as one of these values:

- 'normal' — Redraw the affected region of the display, performing the three-dimensional analysis necessary to correctly render all objects. This mode produces the most accurate picture, but is the slowest. The other modes are faster, but do not perform a complete redraw and, therefore, are less accurate.
- 'none' — Do not erase the object when it is moved or destroyed. After you erase the object with `EraseMode`, 'none', it is still visible on the screen. However, you cannot print the object because MATLAB does not store any information on its former location.
- 'xor' — Draw and erase the object by performing an exclusive OR (XOR) with the color of the screen beneath it. This mode does not damage the color of the objects beneath it. However, the object color depends on the color of whatever is beneath it on the display.
- 'background' — Erase the object by redrawing it in the axes background color, or the figure background color if the axes `Color` property is 'none'. This damages objects that are behind the erased object, but properly colors the erased object.

MATLAB always prints figures as if the `EraseMode` property of all objects is set to 'normal'. This means graphics objects created with `EraseMode` set to 'none', 'xor', or 'background' can look different on screen than on paper. On screen, MATLAB mathematically combines layers of colors and ignores three-dimensional sorting to obtain greater rendering speed. However, MATLAB does not apply these techniques to the

printed output. Use the `getframe` command or other screen capture applications to create an image of a figure containing nonnormal mode objects.

## Parent/Child

### Parent — Parent of patch

axes object | group object | transform object

Parent of patch, specified as an axes, group, or transform object.

### Children — Children of patch

empty `GraphicsPlaceholder` array

The patch has no children. You cannot set this property.

### HandleVisibility — Visibility of object handle

'on' (default) | 'off' | 'callback'

Visibility of object handle in the `Children` property of the parent, specified as one of these values:

- 'on' — List the patch object.
- 'off' — Do not list the patch object. Use this option to hide object handles when a callback invokes a function that could damage the GUI, such as evaluating a user-typed string.
- 'callback' — List the patch object in the `Children` property of the parent from within callbacks or functions invoked by callbacks, but not from within functions invoked from the command line. Use this option to protect a GUI from command-line users, while allowing callbacks to have access to objects.

If the patch object is not listed in the `Children` property of the parent, then functions that obtain object handles by searching the object hierarchy or querying handle properties cannot return it. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

Hidden object handles are still valid. Set the root `ShowHiddenHandles` property to 'on' to list all object handles regardless of their `HandleVisibility` property setting.

## Identifiers

### **Type — Type of graphics object**

'patch'

Type of graphics object, returned as 'patch'. Use this property to find all objects of a given type within a plotting hierarchy, for example, searching for the type using `findobj`.

### **Tag — User-specified tag**

'' (default) | string

Tag to associate with the patch, specified as a string. Tags provide a way to identify graphics objects. Use this property to find all objects with a specific tag within a plotting hierarchy, for example, searching for the tag using `findobj`.

Example: 'January Data'

### **UserData — Data to associate with patch**

[] (default) | scalar, vector, or matrix | cell array | character array | table | structure

Data to associate with the patch object, specified as a scalar, vector, matrix, cell array, character array, table, or structure. MATLAB does not use this data.

To associate multiple sets of data or to attach a field name to the data, use the `getappdata` and `setappdata` functions.

Example: `1:100`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `struct` | `table` | `cell`

### **DisplayName — Text used by legend**

'' (default) | string

Text used by the legend, specified as a string. The text appears next to an icon of the patch.

- If you specify text for the patch object as an input argument to the `legend` function, then the legend uses the specified text and updates the `DisplayName`.
- If you do not specify text for the patch object as an input argument to the `legend` function, then the legend uses the text in the `DisplayName` property. If the `DisplayName` property does not contain any text, then the legend generates a string.

The string has the form 'dataN', where N is the number assigned to the patch object based on its location in the list of legend entries.

If you edit interactively the string in an existing legend, then MATLAB updates the `DisplayName` to the edited string.

Example: 'Text Description'

### **Annotation — Legend icon display style**

Annotation object

Legend icon display style, returned as an `Annotation` object. Use this object to include or exclude the patch from a legend.

- 1 Query the `Annotation` property to get the `Annotation` object.
- 2 Query the `LegendInformation` property of the `Annotation` object to get the `LegendEntry` object.
- 3 Specify the `IconDisplayStyle` property of the `LegendEntry` object to one of these values:
  - 'on' — Include the patch object in the legend as one entry (default).
  - 'off' — Do not include the patch object in the legend.
  - 'children' — Include only children of the patch object as separate entries in the legend.

If a legend already exists and you change the `IconDisplayStyle` setting, then you must call `legend` to update the display.

## **Interactive Control**

### **ButtonDownFcn — Mouse-click callback**

' ' (default) | function handle | cell array | string

Mouse-click callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you click the patch. If you specify this property using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The patch object — You can access properties of the patch object from within the callback function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see “Callback Definition”.

---

**Note:** If the `PickableParts` property is set to `'none'` or if the `HitTest` property is set to `'off'`, then this callback does not execute.

---

Example: `@myCallback`

Example: `{@myCallback, arg3}`

## **UIContextMenu — Context menu**

`uicontextmenu` object

Context menu, specified as a `uicontextmenu` object. Use this property to display a context menu when you right-click the patch. Create the context menu using the `uicontextmenu` function.

---

**Note:** If the `PickableParts` property is set to `'none'` or if the `HitTest` property is set to `'off'`, then the context menu does not appear.

---

## **Selected — Selection state**

`'off'` (default) | `'on'`

Selection state, specified as one of these values:

- `'on'` — Selected. If you click the patch when in plot edit mode, then MATLAB sets its `Selected` property to `'on'`. If the `SelectionHighlight` property also is set to `'on'`, then MATLAB displays selection handles around the patch.
- `'off'` — Not selected.

**SelectionHighlight** — Display of selection handles when selected

'on' (default) | 'off'

Display of selection handles when selected, specified as one of these values:

- 'on' — Display selection handles when the Selected property is set to 'on'.
- 'off' — Never display selection handles, even when the Selected property is set to 'on'.

## Creation and Deletion Control

**CreateFcn** — Creation callback

' ' (default) | function handle | cell array | string

Creation callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you create the patch. Setting the `CreateFcn` property on an existing patch has no effect. You must define a default value for this property, or define this property using a `Name, Value` pair during patch creation. MATLAB executes the callback after creating the patch and setting all of its properties.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The patch object — You can access properties of the patch object from within the callback function. You also can access the patch object through the `CallbackObject` property of the root, which can be queried using the `gcbo` function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see “Callback Definition”.

Example: @myCallback

Example: {@myCallback, arg3}

**DeleteFcn — Deletion callback**

' ' (default) | function handle | cell array | string

Deletion callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you delete the patch. MATLAB executes the callback before destroying the patch so that the callback can access its property values.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The patch object — You can access properties of the patch object from within the callback function. You also can access the patch object through the `CallbackObject` property of the root, which can be queried using the `gcbo` function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see “Callback Definition”.

Example: @myCallback

Example: {@myCallback, arg3}

**BeingDeleted — Deletion status of patch**

'off' (default) | 'on'

Deletion status of patch, returned as 'on' or 'off'. MATLAB sets the `BeingDeleted` property to 'on' when the delete function of the patch begins execution (see the `DeleteFcn` property). The `BeingDeleted` property remains set to 'on' until the patch no longer exists.

Check the value of the `BeingDeleted` property to verify that the patch is not about to be deleted before querying or modifying it.

## Callback Execution Control

### PickableParts — Ability to capture mouse clicks

'visible' (default) | 'all' | 'none'

Ability to capture mouse clicks, specified as one of these values:

- 'visible' — Can capture mouse clicks when visible. The Visible property must be set to 'on' and you must click a part of the patch that has a defined color. You cannot click a part that has an associated color property set to 'none'. If the plot contains markers, then the entire marker is clickable if either the edge or the fill has a defined color. The HitTest property determines if the patch responds to the click or if an ancestor does.
- 'all' — Can capture mouse clicks regardless of visibility. The Visible property can be set to 'on' or 'off' and you can click a part of the patch that has no color. The HitTest property determines if the patch responds to the click or if an ancestor does.
- 'none' — Cannot capture mouse clicks. Clicking the patch passes the click through it to the object below it in the current view of the figure window. The HitTest property has no effect.

### HitTest — Response to captured mouse clicks

'on' (default) | 'off'

Response to captured mouse clicks, specified as one of these values:

- 'on' — Trigger the ButtonDownFcn callback of the patch. If you have defined the UIContextMenu property, then invoke the context menu.
- 'off' — Trigger the callbacks for the nearest ancestor of the patch that has a HitTest property set to 'on' and a PickableParts property value that enables the ancestor to capture mouse clicks.

---

**Note:** The PickableParts property determines if the patch object can capture mouse clicks. If it cannot, then the HitTest property has no effect.

---

### Interruptible — Callback interruption

'on' (default) | 'off'

Callback interruption, specified as 'on' or 'off'. The Interruptible property determines if a running callback can be interrupted.

---

**Note:** There are two callback states to consider:

- The *running* callback is the currently executing callback.
  - The *interrupting* callback is a callback that tries to interrupt the running callback. Whenever MATLAB invokes a callback, that callback attempts to interrupt a running callback. The `Interruptible` property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the `BusyAction` property of the object owning the interrupting callback determines if it is discarded or put in the queue.
- 

If the `ButtonDownFcn` callback of the patch is the running callback, then the `Interruptible` property determines if it another callback can interrupt it:

- 'on' — Interruptible. Interruption occurs at the next point where MATLAB processes the queue, such as when there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command.
  - If the running callback contains one of these commands, then MATLAB stops the execution of the callback at this point and executes the interrupting callback. MATLAB resumes executing the running callback when the interrupting callback completes. For more information, see “Interrupt Callback Execution”.
  - If the running callback does not contain one of these commands, then MATLAB finishes executing the callback without interruption.
- 'off' — Not interruptible. MATLAB finishes executing the running callback without any interruptions.

### **BusyAction — Callback queuing**

'queue' (default) | 'cancel'

Callback queuing specified as 'queue' or 'cancel'. The `BusyAction` property determines how MATLAB handles the execution of interrupting callbacks.

---

**Note:** There are two callback states to consider:

- The *running* callback is the currently executing callback.
- The *interrupting* callback is a callback that tries to interrupt the running callback.

Whenever MATLAB invokes a callback, that callback attempts to interrupt a running callback. The `Interruptible` property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the `BusyAction` property of the object owning the interrupting callback determines if it is discarded or put in the queue.

---

If the `ButtonDownFcn` callback of the patch tries to interrupt a running callback that cannot be interrupted, then the `BusyAction` property determines if it is discarded or put in the queue. Specify the `BusyAction` property as one of these values:

- `'queue'` — Put the interrupting callback in a queue to be processed after the running callback finishes execution. This is the default behavior.
- `'cancel'` — Discard the interrupting callback.

## path

View or change search path

### Alternatives

As an alternative to the `path` function, use the Set Path dialog box.

### Syntax

```
path
path('newpath')
path(path, 'newpath')
path('newpath', path)
p = path
```

### Description

`path` displays the MATLAB search path, which is stored in `pathdef.m`.

`path('newpath')` changes the search path to `newpath`, where `newpath` is a string array of folders.

`path(path, 'newpath')` adds the `newpath` folder to the end of the search path. If `newpath` is already on the search path, then `path(path, 'newpath')` moves `newpath` to the end of the search path.

`path('newpath', path)` adds the `newpath` folder to the top of the search path. If `newpath` is already on the search path, then `path('newpath', path)` moves `newpath` to the top of the search path. To add multiple folders in one statement, instead use `addpath`.

`p = path` returns the search path to string variable `p`.

### Examples

Display the search path:

path

MATLAB returns, for example

MATLABPATH

```
H:\My Documents\MATLAB
C:\Program Files\MATLAB\R200nn\toolbox\matlab\general
C:\Program Files\MATLAB\R200nn\toolbox\matlab\ops
C:\Program Files\MATLAB\R200nn\toolbox\matlab\lang
C:\Program Files\MATLAB\R200nn\toolbox\matlab\elmat
C:\Program Files\MATLAB\R200nn\toolbox\matlab\elfun
...
```

R200nn represents the folder for the MATLAB release, for example, R2009b.

Add a new folder to the search path on Microsoft Windows platforms:

```
path(path, 'c:/tools/goodstuff')
```

Add a new folder to the search path on UNIX<sup>3</sup> platforms:

```
path(path, '/home/tools/goodstuff')
```

Temporarily add the folder `my_files` to the search path, run `my_function` in `my_files`, then restore the previous search path:

```
p = path
path(p, 'my_files')
my_function
path(p)
```

## **path2rc**

Save current search path to `pathdef.m` file

### **Syntax**

`path2rc`

### **Description**

`path2rc` runs `savepath`. The `savepath` function is replacing `path2rc`. Use `savepath` instead of `path2rc` and replace instances of `path2rc` with `savepath`.

# pathsep

Search path separator for current platform

## Syntax

```
c = pathsep
```

## Description

`c = pathsep` returns the search path separator character for this platform. The search path separator is the character that separates path names in the `pathdef.m` file, as returned by the `path` function. The character is a semicolon (;). For versions of MATLAB software earlier than version 7.7 (R2008b), the character on UNIX<sup>4</sup> platforms was a colon (:). Use `pathsep` to work programmatically with the content of the search path file.

# pathtool

Open Set Path dialog box to view and change search path

## Syntax

pathtool

## Description

pathtool opens the Set Path dialog box, a graphical user interface you use to view and modify the MATLAB search path.

## More About

- “What Is the MATLAB Search Path?”

## See Also

## pause

Halt execution temporarily

### Syntax

```
pause
pause(n)
pause on
pause off
pause query
state = pause('query')
oldstate = pause(newstate)
```

### Description

`pause`, by itself, causes the currently executing function to stop and wait for you to press any key before continuing. Pausing must be enabled for this to take effect. (See `pause on`, below). `pause` without arguments also blocks execution of Simulink models, but not repainting of them.

`pause(n)` pauses execution for `n` seconds before continuing, where `n` is any nonnegative real number. Pausing must be enabled for this to take effect.

Typing `pause(inf)` puts you into an infinite loop. To return to the MATLAB prompt, type **Ctrl+C**.

`pause on` enables the pausing of MATLAB execution via the `pause` and `pause(n)` commands. Pausing remains enabled until you enter `pause off` in your function or at the command line.

`pause off` disables the pausing of MATLAB execution via the `pause` and `pause(n)` commands. This allows normally interactive scripts to run unattended. Pausing remains disabled until you enter `pause on` in your function or at the command line, or start a new MATLAB session.

`pause query` displays 'on' if pausing is currently enabled. Otherwise, it displays 'off'.

`state = pause('query')` returns 'on' in character array `state` if pausing is currently enabled. Otherwise, the value of `state` is 'off'.

`oldstate = pause(newstate)`, enables or disables pausing, depending on the 'on' or 'off' value in `newstate`, and returns the former setting (also either 'on' or 'off') in character array `oldstate`.

## More About

### Tips

The accuracy of `pause` is subject to the scheduling resolution of the operating system you are using, and also to other system activity. It cannot be guaranteed with 100% confidence. Asking for finer resolutions shows higher relative error.

While MATLAB is paused, the following continue to execute:

- Repainting of figure windows, Simulink block diagrams, and Java windows
- HG callbacks from figure windows
- Event handling from Java windows

# **pbaspect**

Set or query plot box aspect ratio

## **Syntax**

```
pbaspect
pbaspect([aspect_ratio])
pbaspect('mode')
pbaspect('auto')
pbaspect('manual')
pbaspect(axes_handle,...)
```

## **Description**

The plot box aspect ratio determines the relative size of the  $x$ -,  $y$ -, and  $z$ -axes.

`pbaspect` with no arguments returns the plot box aspect ratio of the current axes.

`pbaspect([aspect_ratio])` sets the plot box aspect ratio in the current axes to the specified value. Specify the aspect ratio as three relative values representing the ratio of the  $x$ -,  $y$ -, and  $z$ -axes size. For example, a value of `[1 1 1]` (the default) means the plot box is a cube (although with stretch-to-fill enabled, it may not appear as a cube). See [Tips](#).

`pbaspect('mode')` returns the current value of the plot box aspect ratio mode, which can be either `auto` (the default) or `manual`. See [Remarks](#).

`pbaspect('auto')` sets the plot box aspect ratio mode to `auto`.

`pbaspect('manual')` sets the plot box aspect ratio mode to `manual`.

`pbaspect(axes_handle,...)` performs the set or query on the axes identified by the first argument, `axes_handle`. If you do not specify an axes handle, `pbaspect` operates on the current axes.

## Examples

### Query Plot Box Aspect Ratio

Plot the function  $z = xe^{-x^2-y^2}$  over the range  $-2 \leq x \leq 2$  and  $-2 \leq y \leq 2$ .

```
[x,y] = meshgrid([-2:.2:2]);
z = x.*exp(-x.^2 - y.^2);
surf(x,y,z)
```

Query the plot box aspect ratio to show that the plot box is square.

```
plotboxaspect = pbaspect
```

```
plotboxaspect =
 1.0000 0.9419 0.8518
```

Change the data aspect ratio.

```
daspect([1,1,1])
```

Query the plot box aspect ratio to show how it changes to accommodate the specified data aspect ratio.

```
plotboxaspect = pbaspect
```

```
plotboxaspect =
```

```
4 4 1
```

Make the plot box square again by changing the plot box aspect ratio to `[1, 1, 1]`.

```
pbaspect([1,1,1])
```

## More About

### Tips

`pbaspect` sets or queries values of the axes object `PlotBoxAspectRatio` and `PlotBoxAspectRatioMode` properties.

When the plot box aspect ratio mode is `auto`, the MATLAB software sets the ratio to `[1 1 1]`, but may change it to accommodate manual settings of the data aspect ratio, camera view angle, or axis limits. See the axes `DataAspectRatio` property for a table listing the interactions between various properties.

Setting a value for the plot box aspect ratio or setting the plot box aspect ratio mode to `manual` disables the MATLAB stretch-to-fill feature (stretching of the axes to fit the window). This means setting the plot box aspect ratio to its current value,

```
pbaspect(pbaspect)
```

can cause a change in the way the graphs look. See the Remarks section of the `axes` reference description, “Axes Aspect Ratio Properties” in the 3-D Visualization manual, and “Setting Aspect Ratio” in the MATLAB Graphics manual for a discussion of stretch-to-fill.

## pcg

Preconditioned conjugate gradients method

### Syntax

```
x = pcg(A,b)
pcg(A,b,tol)
pcg(A,b,tol,maxit)
pcg(A,b,tol,maxit,M)
pcg(A,b,tol,maxit,M1,M2)
pcg(A,b,tol,maxit,M1,M2,x0)
[x,flag] = pcg(A,b,...)
[x,flag,relres] = pcg(A,b,...)
[x,flag,relres,iter] = pcg(A,b,...)
[x,flag,relres,iter,resvec] = pcg(A,b,...)
```

### Description

`x = pcg(A,b)` attempts to solve the system of linear equations  $A^*x=b$  for  $x$ . The  $n$ -by- $n$  coefficient matrix  $A$  must be symmetric and positive definite, and should also be large and sparse. The column vector  $b$  must have length  $n$ . You also can specify  $A$  to be a function handle, `aFun`, such that `aFun(x)` returns  $A^*x$ .

“Parameterizing Functions” explains how to provide additional parameters to the function `aFun`, as well as the preconditioner function `mFun` described below, if necessary.

If `pcg` converges, a message to that effect is displayed. If `pcg` fails to converge after the maximum number of iterations or halts for any reason, a warning message is printed displaying the relative residual  $\text{norm}(b-A^*x)/\text{norm}(b)$  and the iteration number at which the method stopped or failed.

`pcg(A,b,tol)` specifies the tolerance of the method. If `tol` is `[]`, then `pcg` uses the default,  $1e-6$ .

`pcg(A,b,tol,maxit)` specifies the maximum number of iterations. If `maxit` is `[]`, then `pcg` uses the default,  $\min(n,20)$ .

`pcg(A,b,tol,maxit,M)` and `pcg(A,b,tol,maxit,M1,M2)` use symmetric positive definite preconditioner `M` or `M = M1*M2` and effectively solve the system  $\text{inv}(M) * A * x = \text{inv}(M) * b$  for `x`. If `M` is `[]` then `pcg` applies no preconditioner. `M` can be a function handle `mfun` such that `mfun(x)` returns `M \ x`.

`pcg(A,b,tol,maxit,M1,M2,x0)` specifies the initial guess. If `x0` is `[]`, then `pcg` uses the default, an all-zero vector.

`[x,flag] = pcg(A,b,...)` also returns a convergence flag.

Flag	Convergence
0	<code>pcg</code> converged to the desired tolerance <code>tol</code> within <code>maxit</code> iterations.
1	<code>pcg</code> iterated <code>maxit</code> times but did not converge.
2	Preconditioner <code>M</code> was ill-conditioned.
3	<code>pcg</code> stagnated. (Two consecutive iterates were the same.)
4	One of the scalar quantities calculated during <code>pcg</code> became too small or too large to continue computing.

Whenever `flag` is not 0, the solution `x` returned is that with minimal norm residual computed over all the iterations. No messages are displayed if the `flag` output is specified.

`[x,flag,relres] = pcg(A,b,...)` also returns the relative residual  $\text{norm}(b-A*x) / \text{norm}(b)$ . If `flag` is 0, `relres <= tol`.

`[x,flag,relres,iter] = pcg(A,b,...)` also returns the iteration number at which `x` was computed, where  $0 \leq \text{iter} \leq \text{maxit}$ .

`[x,flag,relres,iter,resvec] = pcg(A,b,...)` also returns a vector of the residual norms at each iteration including  $\text{norm}(b-A*x0)$ .

## Examples

### Using `pcg` with Large Matrices

This example shows how to use `pcg` with a matrix input and with a function handle.

```

n1 = 21;
A = gallery('moler',n1);
b1 = sum(A,2);
tol = 1e-6;
maxit = 15;
M1 = spdiags((1:n1)',0,n1,n1);
[x1,flag1,rr1,iter1,rv1] = pcg(A,b1,tol,maxit,M1);

```

Alternatively, you can use the following function in place of the matrix A:

```

function y = applyMoler(x)
y = x;
y(end-1:-1:1) = y(end-1:-1:1) - cumsum(y(end:-1:2));
y(2:end) = y(2:end) - cumsum(y(1:end-1));

```

By using this function, you can solve larger systems more efficiently as there is no need to store the entire matrix A:

```

n2 = 21;
b2 = applyMoler(ones(n2,1));
tol = 1e-6;
maxit = 15;
M2 = spdiags((1:n2)',0,n2,n2);
[x2,flag2,rr2,iter2,rv2] = pcg(@applyMoler,b2,tol,maxit,M2);

```

## Using pcg with a Preconditioner

This example demonstrates how to use a preconditioner matrix with `pcg`.

Create an input matrix and try to solve the system with `pcg`.

```

A = delsq(numgrid('S',100));
b = ones(size(A,1),1);
[x0,f10,rr0,it0,rv0] = pcg(A,b,1e-8,100);

```

`f10` is 1 because `pcg` does not converge to the requested tolerance of  $1e-8$  within the requested maximum 100 iterations. A preconditioner can make the system converge more quickly.

Use `ichol` with only one input argument to construct an incomplete Cholesky factorization with zero fill.

```

L = ichol(A);

```

```
[x1,f11,rr1,it1,rv1] = pcg(A,b,1e-8,100,L,L');
```

`f11` is 0 because `pcg` drives the relative residual to  $9.8e-09$  (the value of `rr1`) which is less than the requested tolerance of  $1e-8$  at the seventy-seventh iteration (the value of `it1`) when preconditioned by the zero-fill incomplete Cholesky factorization. `rv1(1) = norm(b)` and `rv1(78) = norm(b-A*x1)`.

The previous matrix represents the discretization of the Laplacian on a 100x100 grid with Dirichlet boundary conditions. This means that a modified incomplete Cholesky preconditioner might perform even better.

Use the `michol` option to create a modified incomplete Cholesky preconditioner.

```
L = ichol(A,struct('michol','on'));
[x2,f12,rr2,it2,rv2] = pcg(A,b,1e-8,100,L,L');
```

In this case you attain convergence in only forty-seven iterations.

You can see how the preconditioners affect the rate of convergence of `pcg` by plotting each of the residual histories starting from the initial estimate (iterate number 0).

```
figure;
semilogy(0:it0,rv0/norm(b),'b. ');
hold on;
semilogy(0:it1,rv1/norm(b),'r. ');
semilogy(0:it2,rv2/norm(b),'k. ');
legend('No Preconditioner','IC(0)','MIC(0)');
xlabel('iteration number');
ylabel('relative residual');
hold off;
```

## pchip

Piecewise Cubic Hermite Interpolating Polynomial (PCHIP)

### Syntax

```
yi = pchip(x,y,xi)
pp = pchip(x,y)
```

### Description

`yi = pchip(x,y,xi)` returns vector `yi` containing elements corresponding to the elements of `xi` and determined by piecewise cubic interpolation within vectors `x` and `y`. The vector `x` specifies the points at which the data `y` is given. If `y` is a matrix, then the interpolation is performed for each column of `y` and `yi` is `length(xi)-by-size(y,2)`.

`pp = pchip(x,y)` returns a piecewise polynomial structure for use by `ppval`. `x` can be a row or column vector. `y` is a row or column vector of the same length as `x`, or a matrix with `length(x)` columns.

`pchip` finds values of an underlying interpolating function  $P(x)$  at intermediate points, such that:

- On each subinterval  $x_k \leq x \leq x_{k+1}$ ,  $P(x)$  is the cubic Hermite interpolant to the given values and certain slopes at the two endpoints.
- $P(x)$  interpolates  $y$ , i.e.,  $P(x_j) = y_j$ , and the first derivative  $\frac{dP}{dx}$  is continuous. The second derivative  $\frac{d^2P}{dx^2}$  is probably not continuous; there may be jumps at the  $x_j$ .
- The slopes at the  $x_j$  are chosen in such a way that  $P(x)$  preserves the shape of the data and respects monotonicity. This means that, on intervals where the data are monotonic, so is  $P(x)$ ; at points where the data has a local extremum, so does  $P(x)$ .

---

**Note** If  $y$  is a matrix,  $P(x)$  satisfies the above for each column of  $y$ .

---

## Examples

### Data Interpolation Using `spline` and `pchip`

```
x = -3:3;
y = [-1 -1 -1 0 1 1 1];
t = -3:.01:3;
p = pchip(x,y,t);
s = spline(x,y,t);
plot(x,y,'o',t,p,'- ',t,s,'- .')
legend('data', 'pchip', 'spline',4)
```

## More About

### Tips

`spline` constructs  $S(x)$  in almost the same way `pchip` constructs  $P(x)$ . However, `spline` chooses the slopes at the  $x_j$  differently, namely to make even  $S''(x)$  continuous.

This has the following effects:

- `spline` produces a smoother result, i.e.  $S''(x)$  is continuous.
- `spline` produces a more accurate result if the data consists of values of a smooth function.

- pchip has no overshoots and less oscillation if the data are not smooth.
- pchip is less expensive to set up.
- The two are equally expensive to evaluate.

## **pcode**

Create protected function file

### **Syntax**

```
pcode(fun)
pcode(fun1,...,funN)
pcode(fun,'-inplace')
```

### **Description**

`pcode(fun)` obfuscates the code in `fun.m` and produces a file called `fun.p`, known as a P-file. If `fun` is a folder, then all the script or function files in that folder are obfuscated in P-files. MATLAB creates the P-files in the current folder. The original `.m` file or folder can be anywhere on the search path.

`pcode(fun1,...,funN)` creates `N` P-files from the listed files. If any inputs are folders, then MATLAB creates a P-file for every `.m` file the folders contain.

`pcode(fun,'-inplace')` creates P-files in the same folder as the script or function files.

---

**Note:** The `pcode` function *obfuscates* your `.m` files, it does not *encrypt* them. While the content in a `.p` file is difficult to understand, it should not be considered secure. It is not recommended that you P-code files to protect your intellectual property.

---

### **Input Arguments**

#### **fun**

MATLAB file or directory containing MATLAB files. If `fun` resides within a package and/or class folder, then `pcode` creates the same package and/or class structure to house the resulting P-files.

An input argument with no file extension and that is not a folder must be a function in the MATLAB path or in the current folder.

When using wild cards \*, pcode ignores all files with extensions other than .m.

**Default:**

## Examples

### P-Coding Multiple Files

Convert selected files from the sparfun folder into P-files.

Create a temporary folder and define an existing path to .m files.

```
tmp = tempname;
mkdir(tmp)
cd(tmp)
fun = fullfile(matlabroot, 'toolbox', 'matlab', 'sparfun', 'spr*.m');
```

Create the P-files.

```
pcode(fun)
dir(tmp)

. .. sprand.p sprandn.p sprandsym.p sprank.p
```

The temporary folder now contains encoded P-files.

### P-Coding Files That Belong to a Package and/or Class

Generate P-files from input files that are part of a package and/or class. This example uses an existing MATLAB example class.

Define funclass as an existing a class folder that contains .m files.

```
funclass = fullfile(docroot, 'techdoc', 'matlab_oop', ...
 'examples', '@BankAccount')
dir(funclass)
```

```
funclass =
```

```
C:\Program Files\MATLAB\R2013a\help\techdoc\matlab_oop\examples\@BankAccount
```

```
. .. BankAccount.m
```

Create a temporary folder. This folder has no package or class structure at this time.

```
tmp = tempname;
mkdir(tmp);
cd(tmp);
dir(tmp)
```

```
. ..
```

Create a P-file for every `.m` file in the path `funclass`. Because the input files are part of a package and/or class, MATLAB creates a folder structure so that the output file belongs to the same package and/or class.

```
pcode(funclass)
dir(tmp)
```

```
. .. @BankAccount
```

You see that the P-file resides in the same folder structure.

```
dir('@BankAccount')
```

```
. .. BankAccount.p
```

## P-Coding In Place

Generate P-files in the same folder as the input files using the option `inplace`

Copy several MATLAB files to a temporary folder.

```
fun = fullfile(matlabroot, 'toolbox', 'matlab', 'sparfun', 'spr*.m');
tmp = tempname;
mkdir(tmp);
copyfile(fun, tmp)
dir(tmp)
```

```
. .. sprand.m sprandn.m sprandsym.m sprank.m
```

Create P-files in the same folder as the original `.m` files.

```
pcode(tmp, '-inplace')
dir(tmp)
```

```
. sprand.m sprandn.m sprandsym.m sprank.m
```

.. sprand.p sprandn.p sprandsym.p sprank.p

## More About

### Tips

- The `pcode` algorithm was redesigned in MATLAB 7.5 (Release R2007b). You can run older P-files in any current version of MATLAB; however, upcoming releases will not run P-files created before version 7.5. Files generated in 7.5, or later versions, cannot run in MATLAB 7.4 or earlier.
- When obfuscating all files in a folder, `pcode` does not obfuscate any files within subfolders.
- A P-file takes precedence over the corresponding `.m` file for execution, even after modifications to the `.m` file.
- MATLAB does not display any of the help comments that might be in the original `.m` file.
- “Protect Your Source Code”

## **pcolor**

Pseudocolor (checkerboard) plot

### **Syntax**

```
pcolor(C)
pcolor(X,Y,C)
pcolor(axes_handles,...)
h = pcolor(...)
```

### **Description**

A pseudocolor plot is a rectangular array of cells with colors determined by **C**. MATLAB creates a pseudocolor plot using each set of four adjacent points in **C** to define a surface rectangle (i.e., cell).

The default **shading** is **faceted**, which colors each cell with a single color. The last row and column of **C** are not used in this case. With **shading interp**, each cell is colored by bilinear interpolation of the colors at its four vertices, using all elements of **C**.

The minimum and maximum elements of **C** are assigned the first and last colors in the colormap. Colors for the remaining elements in **C** are determined by a linear mapping from value to colormap element.

**pcolor(C)** draws a pseudocolor plot. The elements of **C** are linearly mapped to an index into the current colormap. The mapping from **C** to the current colormap is defined by **colormap** and **caxis**.

**pcolor(X,Y,C)** draws a pseudocolor plot of the elements of **C** at the locations specified by **X** and **Y**. The plot is a logically rectangular, two-dimensional grid with vertices at the points  $[X(i,j), Y(i,j)]$ . **X** and **Y** are vectors or matrices that specify the spacing of the grid lines. If **X** and **Y** are vectors, **X** corresponds to the columns of **C** and **Y** corresponds to the rows. If **X** and **Y** are matrices, they must be the same size as **C**.

**pcolor(axes\_handles,...)** plots into the axes with handle **axes\_handle** instead of the current axes (**gca**).

**h = pcolor(...)** returns a handle to a **surface** graphics object.

## Examples

### Pseudocolor Plot of Hadamard Matrix

A Hadamard matrix has elements that are +1 and -1. A colormap with only two entries is appropriate when displaying a pseudocolor plot of this matrix.

```
pcolor(hadamard(20))
colormap(gray(2))
axis ij
axis square
```

### Polar Coordinate System

A simple color wheel illustrates a polar coordinate system.

```
n = 6;
r = (0:n)'/n;
theta = pi*(-n:n)/n;
X = r*cos(theta);
Y = r*sin(theta);
C = r*cos(2*theta);
pcolor(X,Y,C)
axis equal tight
```

## More About

### Tips

A pseudocolor plot is a flat surface plot viewed from above. `pcolor(X,Y,C)` is the same as viewing `surf(X,Y,zeros(size(X)),C)` using `view([0 90])`.

When you use `shading faceted` or `shading flat`, the constant color of each cell is the color associated with the corner having the smallest  $x$ - $y$  coordinates. Therefore, `C(i,j)` determines the color of the cell in the  $i$ th row and  $j$ th column. The last row and column of `C` are not used.

When you use `shading interp`, each cell's color results from a bilinear interpolation of the colors at its four vertices, and all elements of `C` are used.

## Algorithms

Use the `pcolor`, `image`, or `imagesc` function to display image data. Each function displays a rectangular array of cells and uses `C` to determine the colors.

- `pcolor(C)` uses the values in `C` to define the vertex colors by scaling the values to map to the full range of the colormap. The size of `C` determines the number of vertices. `pcolor` determines the cell colors using the colors defined at the cell vertices.
- `image(C)` uses `C` to define the cell colors by mapping the values directly into the colormap. The size of `C` determines the number of cells.
- `imagesc(C)` uses `C` to define the cell colors by scaling the values to map to the full range of the colormap. The size of `C` determines the number of cells.

`pcolor(X,Y,C)` can produce parametric grids, which is not possible with `image` or `imagesc`.

## See Also

`caxis` | `image` | `mesh` | `shading` | `surf` | `view`

## pdepe

Solve initial-boundary value problems for parabolic-elliptic PDEs in 1-D

### Syntax

```
sol = pdepe(m,pdefun,icfun,bcfun,xmesh,tspan)
sol = pdepe(m,pdefun,icfun,bcfun,xmesh,tspan,options)
[sol,tsol,sole,te,ie] =
pdepe(m,pdefun,icfun,bcfun,xmesh,tspan,options)
```

### Arguments

<code>m</code>	A parameter corresponding to the symmetry of the problem. <code>m</code> can be <code>slab = 0</code> , <code>cylindrical = 1</code> , or <code>spherical = 2</code> .
<code>pdefun</code>	A handle to a function that defines the components of the PDE.
<code>icfun</code>	A handle to a function that defines the initial conditions.
<code>bcfun</code>	A handle to a function that defines the boundary conditions.
<code>xmesh</code>	A vector [ <code>x0</code> , <code>x1</code> , ..., <code>xn</code> ] specifying the points at which a numerical solution is requested for every value in <code>tspan</code> . The elements of <code>xmesh</code> must satisfy <code>x0 &lt; x1 &lt; ... &lt; xn</code> . The length of <code>xmesh</code> must be <code>&gt;= 3</code> .
<code>tspan</code>	A vector [ <code>t0</code> , <code>t1</code> , ..., <code>tf</code> ] specifying the points at which a solution is requested for every value in <code>xmesh</code> . The elements of <code>tspan</code> must satisfy <code>t0 &lt; t1 &lt; ... &lt; tf</code> . The length of <code>tspan</code> must be <code>&gt;= 3</code> .
<code>options</code>	Some options of the underlying ODE solver are available in <code>pdepe</code> : <code>RelTol</code> , <code>AbsTol</code> , <code>NormControl</code> , <code>InitialStep</code> , <code>MaxStep</code> , and <code>Events</code> . In most cases, default values for these options provide satisfactory solutions. See <code>odeset</code> for details.

### Description

`sol = pdepe(m,pdefun,icfun,bcfun,xmesh,tspan)` solves initial-boundary value problems for systems of parabolic and elliptic PDEs in the one space variable  $x$  and time

$t$ . `pdefun`, `icfun`, and `bcfun` are function handles. See the `function_handle` reference page for more information. The ordinary differential equations (ODEs) resulting from discretization in space are integrated to obtain approximate solutions at times specified in `tspan`. The `pdepe` function returns values of the solution on a mesh provided in `xmesh`.

“Parameterizing Functions” explains how to provide additional parameters to the functions `pdefun`, `icfun`, or `bcfun`, if necessary.

`pdepe` solves PDEs of the form:

$$c\left(x,t,u,\frac{\partial u}{\partial x}\right)\frac{\partial u}{\partial t} = x^{-m}\frac{\partial}{\partial x}\left(x^m f\left(x,t,u,\frac{\partial u}{\partial x}\right)\right) + s\left(x,t,u,\frac{\partial u}{\partial x}\right)$$

The PDEs hold for  $t_0 \leq t \leq t_f$  and  $a \leq x \leq b$ . The interval  $[a,b]$  must be finite.  $m$  can be 0, 1, or 2, corresponding to slab, cylindrical, or spherical symmetry, respectively. If  $m > 0$ , then  $a$  must be  $\geq 0$ .

In Equation 1-4,  $f(x,t,u,\partial u/\partial x)$  is a flux term and  $s(x,t,u,\partial u/\partial x)$  is a source term. The coupling of the partial derivatives with respect to time is restricted to multiplication by a diagonal matrix  $c(x,t,u,\partial u/\partial x)$ . The diagonal elements of this matrix are either identically zero or positive. An element that is identically zero corresponds to an elliptic equation and otherwise to a parabolic equation. There must be at least one parabolic equation. An element of  $c$  that corresponds to a parabolic equation can vanish at isolated values of  $x$  if those values of  $x$  are mesh points. Discontinuities in  $c$  and/or  $s$  due to material interfaces are permitted provided that a mesh point is placed at each interface.

For  $t = t_0$  and all  $x$ , the solution components satisfy initial conditions of the form

$$u(x,t_0) = u_0(x)$$

For all  $t$  and either  $x = a$  or  $x = b$ , the solution components satisfy a boundary condition of the form

$$p(x,t,u) + q(x,t)f\left(x,t,u,\frac{\partial u}{\partial x}\right) = 0$$

Elements of  $q$  are either identically zero or never zero. Note that the boundary conditions are expressed in terms of the flux  $f$  rather than  $\partial u/\partial x$ . Also, of the two coefficients, only  $p$  can depend on  $u$ .

In the call `sol = pdepe(m,pdefun,icfun,bcfun,xmesh,tspan)`:

- `m` corresponds to  $m$ .
- `xmesh(1)` and `xmesh(end)` correspond to  $a$  and  $b$ .
- `tspan(1)` and `tspan(end)` correspond to  $t_0$  and  $t_f$ .
- `pdefun` computes the terms  $c$ ,  $f$ , and  $s$  (Equation 1-4). It has the form

$$[c,f,s] = \text{pdefun}(x,t,u,dudx)$$

The input arguments are scalars  $x$  and  $t$  and vectors  $u$  and  $dudx$  that approximate the solution  $u$  and its partial derivative with respect to  $x$ , respectively.  $c$ ,  $f$ , and  $s$  are column vectors.  $c$  stores the diagonal elements of the matrix  $c$  (Equation 1-4).

- `icfun` evaluates the initial conditions. It has the form

$$u = \text{icfun}(x)$$

When called with an argument  $x$ , `icfun` evaluates and returns the initial values of the solution components at  $x$  in the column vector  $u$ .

- `bcfun` evaluates the terms  $p$  and  $q$  of the boundary conditions (Equation 1-6). It has the form

$$[p1,q1,pr,qr] = \text{bcfun}(x1,u1,xr,ur,t)$$

$u1$  is the approximate solution at the left boundary  $x1 = a$  and  $ur$  is the approximate solution at the right boundary  $xr = b$ .  $p1$  and  $q1$  are column vectors corresponding to  $p$  and  $q$  evaluated at  $x1$ , similarly  $pr$  and  $qr$  correspond to  $xr$ . When  $m > 0$  and  $a = 0$ , boundedness of the solution near  $x = 0$  requires that the flux  $f$  vanish at  $a = 0$ . `pdepe` imposes this boundary condition automatically and it ignores values returned in  $p1$  and  $q1$ .

`pdepe` returns the solution as a multidimensional array `sol`.  $u_i = ui = \text{sol}(:, :, i)$  is an approximation to the  $i$ th component of the solution vector  $u$ . The element  $ui(j,k) = \text{sol}(j,k,i)$  approximates  $u_i$  at  $(t,x) = (\text{tspan}(j), \text{xmesh}(k))$ .

$ui = \text{sol}(j, :, i)$  approximates component  $i$  of the solution at time  $\text{tspan}(j)$  and mesh points  $\text{xmesh}(:)$ . Use `pdeval` to compute the approximation and its partial derivative  $\partial u_i / \partial x$  at points not included in `xmesh`. See `pdeval` for details.

`sol = pdepe(m,pdefun,icfun,bcfun,xmesh,tspan,options)` solves as above with default integration parameters replaced by values in `options`, an argument created

with the `odeset` function. Only some of the options of the underlying ODE solver are available in `pdepe`: `RelTol`, `AbsTol`, `NormControl`, `InitialStep`, and `MaxStep`. The defaults obtained by leaving off the input argument options will generally be satisfactory. See `odeset` for details.

`[sol,tsol,sole,te,ie] = pdepe(m,pdefun,icfun,bcfun,xmesh,tspan,options)` with the 'Events' property in `options` set to a function handle `Events`, solves as above while also finding where event functions  $g(t,u(x,t))$  are zero. For each function you specify whether the integration is to terminate at a zero and whether the direction of the zero crossing matters. Three column vectors are returned by `events`: `[value,isterminal,direction] = events(m,t,xmesh,umesh)`. `xmesh` contains the spatial mesh and `umesh` is the solution at the mesh points. Use `pdeval` to evaluate the solution between mesh points. For the  $I$ -th event function, `value(i)` is the value of the function, `ISTERMINAL(I) = 1` if the integration is to terminate at a zero of this event function and 0 otherwise. `direction(i) = 0` if all zeros are to be computed (the default), +1 if only zeros where the event function is increasing, and -1 if only zeros where the event function is decreasing. Output `tsol` is a column vector of times specified in `tspan`, prior to first terminal event. `SOL(j,:,:) =` the solution at `T(j)`. `TE` is a vector of times at which events occur. `SOLE(j,:,:) =` the solution at `TE(j)` and indices in vector `IE` specify which event occurred.

If `UI = SOL(j,:,i)` approximates component  $i$  of the solution at time `TSPAN(j)` and mesh points `XMESH`, `pdeval` evaluates the approximation and its partial derivative  $\partial u_i / \partial x$  at the array of points `XOUT` and returns them in `UOUT` and `DUOUTDX`: `[UOUT,DUOUTDX] = PDEVAL(M, XMESH, UI, XOUT)`

---

**Note:** The partial derivative  $\partial u_i / \partial x$  is evaluated here rather than the flux. The flux is continuous, but at a material interface the partial derivative may have a jump.

---

## Examples

**Example 1.** This example illustrates the straightforward formulation, computation, and plotting of the solution of a single PDE.

$$\pi^2 \frac{\partial u}{\partial t} = \frac{\partial}{\partial x} \left( \frac{\partial u}{\partial x} \right)$$

This equation holds on an interval  $0 \leq x \leq 1$  for times  $t \geq 0$ .

The PDE satisfies the initial condition

$$u(x,0) = \sin \pi x$$

and boundary conditions

$$u(0,t) \equiv 0$$

$$\pi e^{-t} + \frac{\partial u}{\partial x}(1,t) = 0$$

It is convenient to use local functions to place all the functions required by pdepe in a single function.

```
function pdex1

m = 0;
x = linspace(0,1,20);
t = linspace(0,2,5);

sol = pdepe(m,@pdex1pde,@pdex1ic,@pdex1bc,x,t);
% Extract the first solution component as u.
u = sol(:,:,1);

% A surface plot is often a good way to study a solution.
surf(x,t,u)
title('Numerical solution computed with 20 mesh points.')
xlabel('Distance x')
ylabel('Time t')

% A solution profile can also be illuminating.
figure
plot(x,u(end,:))
title('Solution at t = 2')
xlabel('Distance x')
ylabel('u(x,2)')
% -----
function [c,f,s] = pdex1pde(x,t,u,DuDx)
c = pi^2;
f = DuDx;
```

```
s = 0;
% -----
function u0 = pdex1ic(x)
u0 = sin(pi*x);
% -----
function [pl,q1,pr,qr] = pdex1bc(xl,ul,xr,ur,t)
pl = ul;
q1 = 0;
pr = pi * exp(-t);
qr = 1;
```

In this example, the PDE, initial condition, and boundary conditions are coded in local functions `pdex1pde`, `pdex1ic`, and `pdex1bc`.

The surface plot shows the behavior of the solution.

The following plot shows the solution profile at the final value of  $t$  (i.e.,  $t = 2$ ).

**Example 2.** This example illustrates the solution of a system of PDEs. The problem has boundary layers at both ends of the interval. The solution changes rapidly for small  $t$ .

The PDEs are

$$\frac{\partial u_1}{\partial t} = 0.024 \frac{\partial^2 u_1}{\partial x^2} - F(u_1 - u_2)$$

$$\frac{\partial u_2}{\partial t} = 0.170 \frac{\partial^2 u_2}{\partial x^2} + F(u_1 - u_2)$$

where  $F(y) = \exp(5.73y) - \exp(-11.46y)$ .

This equation holds on an interval  $0 \leq x \leq 1$  for times  $t \geq 0$ .

The PDE satisfies the initial conditions

$$u_1(x, 0) \equiv 1$$

$$u_2(x, 0) \equiv 0$$

and boundary conditions

$$\begin{aligned} \frac{\partial u_1}{\partial x}(0, t) &\equiv 0 \\ u_2(0, t) &\equiv 0 \\ u_1(1, t) &\equiv 1 \\ \frac{\partial u_2}{\partial x}(1, t) &\equiv 0 \end{aligned}$$

In the form expected by `pdepe`, the equations are

$$\begin{bmatrix} 1 \\ 1 \end{bmatrix} \cdot * \frac{\partial}{\partial t} \begin{bmatrix} u_1 \\ u_2 \end{bmatrix} = \frac{\partial}{\partial x} \begin{bmatrix} 0.024(\partial u_1 / \partial x) \\ 0.170(\partial u_2 / \partial x) \end{bmatrix} + \begin{bmatrix} -F(u_1 - u_2) \\ F(u_1 - u_2) \end{bmatrix}$$

The boundary conditions on the partial derivatives of  $u$  have to be written in terms of the flux. In the form expected by `pdepe`, the left boundary condition is

$$\begin{bmatrix} 0 \\ u_2 \end{bmatrix} + \begin{bmatrix} 1 \\ 0 \end{bmatrix} \cdot * \begin{bmatrix} 0.024(\partial u_1 / \partial x) \\ 0.170(\partial u_2 / \partial x) \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

and the right boundary condition is

$$\begin{bmatrix} u_1 - 1 \\ 0 \end{bmatrix} + \begin{bmatrix} 0 \\ 1 \end{bmatrix} \cdot * \begin{bmatrix} 0.024(\partial u_1 / \partial x) \\ 0.170(\partial u_2 / \partial x) \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The solution changes rapidly for small  $t$ . The program selects the step size in time to resolve this sharp change, but to see this behavior in the plots, the example must select the output times accordingly. There are boundary layers in the solution at both ends of  $[0, 1]$ , so the example places mesh points near 0 and 1 to resolve these sharp changes. Often some experimentation is needed to select a mesh that reveals the behavior of the solution.

function `pdex4`

```

m = 0;
x = [0 0.005 0.01 0.05 0.1 0.2 0.5 0.7 0.9 0.95 0.99 0.995 1];
t = [0 0.005 0.01 0.05 0.1 0.5 1 1.5 2];

sol = pdepe(m,@pdex4pde,@pdex4ic,@pdex4bc,x,t);
u1 = sol(:,:,1);
u2 = sol(:,:,2);

figure
surf(x,t,u1)
title('u1(x,t)')
xlabel('Distance x')
ylabel('Time t')

figure
surf(x,t,u2)
title('u2(x,t)')
xlabel('Distance x')
ylabel('Time t')
% -----
function [c,f,s] = pdex4pde(x,t,u,DuDx)
c = [1; 1];
f = [0.024; 0.17] .* DuDx;
y = u(1) - u(2);
F = exp(5.73*y)-exp(-11.47*y);
s = [-F; F];
% -----
function u0 = pdex4ic(x);
u0 = [1; 0];
% -----
function [pl,q1,pr,qr] = pdex4bc(xl,ul,xr,ur,t)
pl = [0; ul(2)];
q1 = [1; 0];
pr = [ur(1)-1; 0];
qr = [0; 1];

```

In this example, the PDEs, initial conditions, and boundary conditions are coded in local functions `pdex4pde`, `pdex4ic`, and `pdex4bc`.

The surface plots show the behavior of the solution components.

## More About

### Tips

- The arrays `xmesh` and `tspan` play different roles in `pdepe`.

**tspan** – The `pdepe` function performs the time integration with an ODE solver that selects both the time step and formula dynamically. The elements of `tspan` merely specify where you want answers and the cost depends weakly on the length of `tspan`.

**xmesh** – Second order approximations to the solution are made on the mesh specified in `xmesh`. Generally, it is best to use closely spaced mesh points where the solution changes rapidly. `pdepe` does *not* select the mesh in  $x$  automatically. You must provide an appropriate fixed mesh in `xmesh`. The cost depends strongly on the length of `xmesh`. When  $m > 0$ , it is not necessary to use a fine mesh near  $x = 0$  to account for the coordinate singularity.

- The time integration is done with `ode15s`. `pdepe` exploits the capabilities of `ode15s` for solving the differential-algebraic equations that arise when Equation 1-4 contains elliptic equations, and for handling Jacobians with a specified sparsity pattern.
- After discretization, elliptic equations give rise to algebraic equations. If the elements of the initial conditions vector that correspond to elliptic equations are not "consistent" with the discretization, `pdepe` tries to adjust them before beginning the time integration. For this reason, the solution returned for the initial time may have a discretization error comparable to that at any other time. If the mesh is sufficiently fine, `pdepe` can find consistent initial conditions close to the given ones. If `pdepe` displays a message that it has difficulty finding consistent initial conditions, try refining the mesh.

No adjustment is necessary for elements of the initial conditions vector that correspond to parabolic equations.

# pdeval

Evaluate numerical solution of PDE using output of pdepe

## Syntax

```
[uout,duoutdx] = pdeval(m,x,ui,xout)
```

## Arguments

m	Symmetry of the problem: slab = 0, cylindrical = 1, spherical = 2. This is the first input argument used in the call to pdepe.
x	A vector [x0, x1, ..., xn] specifying the points at which the elements of ui were computed. This is the same vector with which pdepe was called.
ui	A vector sol(j, :, i) that approximates component i of the solution at time $t_f$ and mesh points xmesh, where sol is the solution returned by pdepe.
xout	A vector of points from the interval [x0,xn] at which the interpolated solution is requested.

## Description

[uout,duoutdx] = pdeval(m,x,ui,xout) approximates the solution  $u_i$  and its partial derivative  $\partial u_i / \partial x$  at points from the interval [x0,xn]. The pdeval function returns the computed values in uout and duoutdx, respectively.

---

**Note** pdeval evaluates the partial derivative  $\partial u_i / \partial x$  rather than the flux  $f$ . Although the flux is continuous, the partial derivative may have a jump at a material interface.

pdepe

## peaks

Example function of two variables

### Syntax

```
Z = peaks;
Z = peaks(n);
Z = peaks(V);
Z = peaks(X,Y);
peaks(...)
[X,Y,Z] = peaks(...);
```

### Description

**peaks** is a function of two variables, obtained by translating and scaling Gaussian distributions, which is useful for demonstrating **mesh**, **surf**, **pcolor**, **contour**, and so on.

**Z = peaks;** returns a 49-by-49 matrix.

**Z = peaks(n);** returns an *n*-by-*n* matrix.

**Z = peaks(V);** returns an *n*-by-*n* matrix, where *n* = **length(V)**.

**Z = peaks(X,Y);** evaluates **peaks** at the given *X* and *Y* (which must be the same size) and returns a matrix the same size.

**peaks(...)** (with no output argument) plots the peaks function with **surf**. Use any of the input argument combinations in the previous syntaxes.

**[X,Y,Z] = peaks(...);** returns two additional matrices, *X* and *Y*, for parametric plots, for example, **surf(X,Y,Z,del2(Z))**. If not given as input, the underlying matrices *X* and *Y* are

```
[X,Y] = meshgrid(V,V)
```

where  $V$  is a given vector, or  $V$  is a vector of length  $n$  with elements equally spaced from  $-3$  to  $3$ . If no input argument is given, the default  $n$  is 49.

## Examples

### Peaks Surface

Create a 5-by-5 matrix of peaks and display the surface.

```
figure
peaks(5);
```

```
z = 3*(1-x).^2.*exp(-(x.^2) - (y+1).^2) ...
 - 10*(x/5 - x.^3 - y.^5).*exp(-x.^2-y.^2) ...
 - 1/3*exp(-(x+1).^2 - y.^2)
```

**See Also**

meshgrid | surf

# perl

Call Perl script using appropriate operating system executable

## Syntax

```
perl('perlfile')
perl('perlfile',arg1,arg2,...)
result = perl(...)
[result, status] = perl(...)
```

## Description

`perl('perlfile')` calls the Perl script `perlfile`, using the appropriate operating system Perl executable. Perl is included with the MATLAB software on Microsoft Windows systems, and thus MATLAB users can run user-created MATLAB functions containing the `perl` function. On Linux and Macintosh systems, MATLAB calls the Perl interpreter available with the operating system.

`perl('perlfile',arg1,arg2,...)` calls the Perl script `perlfile`, using the appropriate operating system Perl executable, and passes the arguments `arg1`, `arg2`, and so on, to `perlfile`.

`result = perl(...)` returns the results of attempted Perl call to `result`.

`[result, status] = perl(...)` returns the results of attempted Perl call to `result` and its exit status to `status`.

It is sometimes beneficial to use Perl scripts instead of MATLAB code. The `perl` function allows you to run those scripts from MATLAB. Specific examples where you might choose to use a Perl script include:

- Perl script already exists
- Perl script preprocesses data quickly, formatting it in a way more easily read by MATLAB
- Perl has features not supported by MATLAB

## Examples

Given the Perl script, `hello.pl`:

```
$input = $ARGV[0];
print "Hello $input."
```

At the MATLAB command line, type:

```
perl('hello.pl', 'World')

ans =
Hello World.
```

`dos` | `regexp` | `system` | `unix` | “! (exclamation point)”

## perms

All possible permutations

### Syntax

`P = perms(v)`

### Description

`P = perms(v)` returns a matrix containing all permutations of the elements of vector `v` in reverse lexicographic order. Each row of `P` contains a different permutation of the  $n$  elements in `v`. Matrix `P` has the same data type as `v`, and it has  $n!$  rows and  $n$  columns.

### Examples

#### All Permutations of Double Integers

```
v = [2 4 6];
P = perms(v)
```

P =

```

 6 4 2
 6 2 4
 4 6 2
 4 2 6
 2 4 6
 2 6 4
```

#### All Permutations of Unsigned Integers

```
v = uint16([1023 4095 65535]);
P = perms(v)
```

P =

```

65535 4095 1023
65535 1023 4095
```

```
4095 65535 1023
4095 1023 65535
1023 4095 65535
1023 65535 4095
```

## All Permutations of Complex Numbers

```
v = [1+1i 2+1i 3+1i];
```

```
P = perms(v)
```

```
P =
```

```
3.0000 + 1.0000i 2.0000 + 1.0000i 1.0000 + 1.0000i
3.0000 + 1.0000i 1.0000 + 1.0000i 2.0000 + 1.0000i
2.0000 + 1.0000i 3.0000 + 1.0000i 1.0000 + 1.0000i
2.0000 + 1.0000i 1.0000 + 1.0000i 3.0000 + 1.0000i
1.0000 + 1.0000i 2.0000 + 1.0000i 3.0000 + 1.0000i
1.0000 + 1.0000i 3.0000 + 1.0000i 2.0000 + 1.0000i
```

## Input Arguments

### **v** — Set of items

vector of numeric, logical, or char values

Set of items, specified as a vector of numeric, logical, or char values.

Example: [1 2 3 4]

Example: [1+1i 2+1i 3+1i 4+1i]

Example: int16([1 2 3 4])

Example: ['abcd']

Example: [true false true false]

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 |  
uint32 | uint64 | logical | char

Complex Number Support: Yes

## Limitations

perms(v) is practical when length(v) is less than about 10.

## See Also

nchoosek | permute | randperm

## permute

Rearrange dimensions of N-D array

### Syntax

```
B = permute(A,order)
```

### Description

`B = permute(A,order)` rearranges the dimensions of `A` so that they are in the order specified by the vector `order`. `B` has the same values of `A` but the order of the subscripts needed to access any particular element is rearranged as specified by `order`. All the elements of `order` must be unique, real, positive, integer values.

### Examples

Given any matrix `A`, the statement

```
permute(A,[2 1])
```

is the same as `A.'`.

For example:

```
A = [1 2; 3 4]; permute(A,[2 1])
ans =
 1 3
 2 4
```

The following code permutes a three-dimensional array:

```
X = rand(12,13,14);
Y = permute(X,[2 3 1]);
size(Y)
ans =
 13 14 12
```

## More About

### Tips

`permute` and `ipermute` are a generalization of transpose (`.'`) for multidimensional arrays.

## **persistent**

Define persistent variable

### **Syntax**

```
persistent X Y Z
```

### **Description**

`persistent X Y Z` defines X, Y, and Z as variables that are local to the function in which they are declared; yet their values are retained in memory between calls to the function. Persistent variables are similar to global variables because the MATLAB software creates permanent storage for both. They differ from global variables in that persistent variables are known only to the function in which they are declared. This prevents persistent variables from being changed by other functions or from the MATLAB command line.

Whenever you clear or modify a function that is in memory, MATLAB also clears all persistent variables declared by that function. To keep a function in memory until MATLAB quits, use `mlock`.

If the persistent variable does not exist the first time you issue the `persistent` statement, it is initialized to the empty matrix.

It is an error to declare a variable persistent if a variable with the same name exists in the current workspace. MATLAB also errors if you declare any of a function's input or output arguments as persistent within that same function. For example, the following persistent declaration is invalid:

```
function myfun(argA, argB, argC)
persistent argB
```

### **Examples**

This function writes a large array to a spreadsheet file and then reads several rows from the same file. Because you only need to write the array to the spreadsheet one time, the

program tests whether an array can be read from the file and, if so, does not waste time in repeating that task. By defining the `dblArray` variable as persistent, you can easily check whether the array has been read from the spreadsheet file.

Here is the `arrayToXLS` function:

```
function arrayToXLS(A, xlsfile, x1, x2)
persistent dblArray;

if isempty(dblArray)
 disp 'Writing spreadsheet file ...'
 xlswrite(xlsfile, A);
end

disp 'Reading array from spreadsheet ...'
dblArray = xlsread(xlsfile, 'Sheet1', [x1 ':' x2])
fprintf('\n');
```

Run the function three times and observe the time elapsed for each run. The second and third run take approximately one tenth the time of the first run in which the function must create the spreadsheet:

```
largeArray = rand(4000, 200);

tic, arrayToXLS(largeArray, 'myTest.xls', 'E254', 'J256'), toc
Writing spreadsheet file ...
Reading array from spreadsheet ...
dblArray =
 0.0982 0.3783 0.1264 0.7880 0.1902 0.5811
 0.2251 0.2704 0.5682 0.7271 0.8028 0.2834
 0.6453 0.5568 0.8254 0.4961 0.9096 0.5402
```

Elapsed time is 8.990525 seconds.

```

## More About

### Tips

There is no function form of the `persistent` command (i.e., you cannot use parentheses and quote the variable names).

### See Also

`global` | `clear` | `mislocked` | `mlock` | `munlock` | `isempty`

## pi

Ratio of circle's circumference to its diameter

## Syntax

pi

## Description

pi returns the floating-point number nearest the value of  $\pi$ . The expressions `4*atan(1)` and `imag(log(-1))` provide the same value.

## Examples

Find the sine of  $\pi$ :

```
sin(pi)
```

returns

```
ans =
```

```
1.2246e-16
```

The expression `sin(pi)` is not exactly zero because `pi` is not exactly  $\pi$ .

## pie

Pie chart

### Syntax

```
pie(X)
pie(X,explode)
pie(X,labels)
pie(X,explode,labels)
```

```
pie(ax, ___)
```

```
p = pie(___)
```

### Description

`pie(X)` draws a pie chart using the data in `X`. Each slice of the pie chart represents an element in `X`.

- If  $\text{sum}(X) \neq 1$ , then the values in `X` directly specify the areas of the pie slices. `pie` draws only a partial pie if  $\text{sum}(X) < 1$ .
- If  $\text{sum}(X) > 1$ , then `pie` normalizes the values by  $X/\text{sum}(X)$  to determine the area of each slice of the pie.
- If `X` is of data type `categorical`, the slices correspond to categories. The area of each slice is the number of elements in the category divided by the number of elements in `X`.

`pie(X,explode)` offsets slices from the pie. `explode` is a vector or matrix of zeros and nonzeros that correspond to `X`. The `pie` function offsets slices for the nonzero elements only in `explode`.

If `X` is of data type `categorical`, then `explode` can be a vector of zeros and nonzeros corresponding to categories, or a cell array of the names of categories to offset.

`pie(X,labels)` specifies text labels for the slices. The number of labels must equal the number of slices. `X` must be numeric.

`pie(X, explode, labels)` specifies text labels for the slices. The number of labels must equal the number of slices.

`pie(ax, ___)` plots into the axes specified by `ax` instead of into the current axes (`gca`). The option `ax` can precede any of the input argument combinations in the previous syntaxes.

`p = pie(___)` returns a vector of patch and text graphics objects. The input can be any of the input argument combinations in the previous syntaxes.

## Examples

### Create Pie Chart with Offset Slices

Create a pie chart of vector `X`.

```
X = [1 3 0.5 2.5 2];
pie(X)
```

Offset the second and fourth pie slices by setting the corresponding `explode` elements to 1.

```
explode = [0 1 0 1 0];
pie(X,explode)
```

### Specify Text Labels for Pie Chart

Create a pie chart of vector X and label the slices.

```
X = 1:3;
labels = {'Taxes', 'Expenses', 'Profit'};
pie(X, labels)
```

### Modify Text Label for Pie Chart

Create a labeled pie chart, and then modify the color and font size of the text labels.

```
X = 1:3;
labels = {'Taxes', 'Expenses', 'Profit'};
p = pie(X, labels)
```

p =

1x6 graphics array:

Patch Text Patch Text Patch Text

Get the text object for the label 'Profit'. Change its color and font size.

```
t = p(6);
t.BackgroundColor = 'cyan';
t.EdgeColor = 'red';
t.FontSize = 14;
```

### Plot Partial Pie Chart

Create a pie chart of vector X where the sum of the elements is less than 1.

```
X = [0.19 0.22 0.41];
pie(X)
```

`pie` draws a partial pie because the sum of the elements is less than 1.

### Plot Multiple Pie Charts

Create two vectors of data and plot and label each one in its own pie chart.

```
X = [0.2 0.4 0.4];
labels = {'Taxes', 'Expenses', 'Profit'};
ax1 = subplot(1,2,1);
pie(ax1,X,labels)
title(ax1, '2012');
```

```
Y = [0.24 0.46 0.3];
ax2 = subplot(1,2,2);
```

```
pie(ax2,Y,labels)
title(ax2,'2013');
```

### Plot Categorical Pie Chart with Offsets

Plot a categorical pie chart with offset slices corresponding to categories.

```
X = categorical({'North','South','North','East','South','West'});
explode = {'North','South'};
pie(X,explode)
```

Now, use a logical vector to offset the same slices.

```
explode = [0 1 1 0];
pie(X,explode)
```

### Plot Categorical Pie Chart with Labels

Plot a categorical pie chart without any offset slices and label the slices. When `X` is of data type `categorical` you must specify the input argument `explode`. To specify labels without any offset slices, specify `explode` as an empty cell array, and `labels` as the labels.

```
X = categorical({'North','South','North','East','South','West'});
explode = {};
labels = {'E','N','S','W'};
pie(X,explode,labels)
```

Now, offset a slice and label all slices.

```
X = categorical({'North', 'South', 'North', 'East', 'South', 'West'});
explode = {'West'};
labels = {'E', 'N', 'S', 'W'};
pie(X, explode, labels)
```

- “Offset Pie Slice with Greatest Contribution”
- “Label Pie Chart With Text and Percent Values”

## Input Arguments

**X** — Input array

vector or matrix

Input vector or matrix.

- If X is numeric, then all values in X must be finite. `pie` ignores nonpositive values.
- If X is categorical, then `pie` ignores undefined elements.

**Data Types:** double | logical | categorical

### **explode** — Offset slices

vector or matrix

Offset slices, specified as a vector or matrix.

- If  $X$  is numeric, then **explode** must be a logical or numeric vector or matrix of zeros and nonzeros that correspond to  $X$ . A true (nonzero) value offsets the corresponding slice from the center of the pie chart, so that  $X(i, j)$  is offset from the center if **explode**( $i, j$ ) is nonzero. **explode** must be the same size as  $X$ .
- If  $X$  is categorical, then **explode** can be a cell array of strings that are category names. **pie** offsets slices corresponding to categories in **explode**.
- If  $X$  is categorical, then **explode** also can be a logical or numeric vector with elements that correspond to each category in  $X$ . The **pie** function offsets slices corresponding to true (nonzero) in category order.

### **labels** — Text labels

cell array of strings

Text labels for slices, specified as a cell array of strings.

### **ax** — Axes

axes object

Axes object. Use **ax** to plot the pie chart in a specific axes instead of the current axes (**gca**).

## Output Arguments

### **p** — Patch and text objects

vector

Patch and text objects, returned as a vector.

## See Also

[pie3](#)

## pie3

3-D pie chart

## Syntax

```
pie3(X)
pie3(X,explode)
pie3(...,labels)
pie3(axes_handle,...)
h = pie3(...)
```

## Description

`pie3(X)` draws a three-dimensional pie chart using the data in `X`. Each element in `X` is represented as a slice in the pie chart.

- If `sum(X) # 1`, then the values in `X` directly specify the area of the pie slices. `pie3` draws only a partial pie if `sum(X) < 1`.
- If the sum of the elements in `X` is greater than one, then `pie3` normalizes the values by `X/sum(X)` to determine the area of each slice of the pie.

`pie3(X,explode)` specifies whether to offset a slice from the center of the pie chart. `X(i,j)` is offset from the center of the pie chart if `explode(i,j)` is nonzero. `explode` must be the same size as `X`.

`pie3(...,labels)` specifies text labels for the slices. The number of labels must equal the number of elements in `X`.

`pie3(axes_handle,...)` plots into the axes with the handle `axes_handle` instead of into the current axes (`gca`).

`h = pie3(...)` returns a vector of handles to patch, surface, and text graphics objects.

## Examples

### Create 3-D Pie Chart

Create a 3-D pie chart of vector `x`.

```
x = [1,3,0.5,2.5,2];
figure
pie3(x)
```

To offset the second pie slice, set the corresponding `explode` element to 1.

```
explode = [0,1,0,0,0];
figure
pie3(x,explode)
```

### Specify Text Labels for 3-D Pie Chart

Create a 3-D pie chart and specify the text labels.

```
x = 1:3;
labels = {'Taxes','Expenses','Profit'};

figure
pie3(x,labels)
```

**See Also**  
pie

## **pinv**

Moore-Penrose pseudoinverse of matrix

### **Syntax**

```
B = pinv(A)
B = pinv(A,tol)
```

### **Definitions**

The Moore-Penrose pseudoinverse is a matrix **B** of the same dimensions as **A'** satisfying four conditions:

```
A*B*A = A
B*A*B = B
A*B is Hermitian
B*A is Hermitian
```

The computation is based on `svd(A)` and any singular values less than `tol` are treated as zero.

### **Description**

`B = pinv(A)` returns the Moore-Penrose pseudoinverse of **A**.

`B = pinv(A,tol)` returns the Moore-Penrose pseudoinverse and overrides the default tolerance, `max(size(A))*norm(A)*eps`.

### **Examples**

If **A** is square and not singular, then `pinv(A)` is an expensive way to compute `inv(A)`. If **A** is not square, or is square and singular, then `inv(A)` does not exist. In these cases, `pinv(A)` has some of, but not all, the properties of `inv(A)`.

If  $A$  has more rows than columns and is not of full rank, then the overdetermined least squares problem

`minimize norm(A*x-b)`

does not have a unique solution. Two of the infinitely many solutions are

`x = pinv(A)*b`

and

`y = A\b`

These two are distinguished by the facts that  $\text{norm}(x)$  is smaller than the norm of any other solution and that  $y$  has the fewest possible nonzero components.

For example, the matrix generated by

`A = magic(8); A = A(:,1:6)`

is an 8-by-6 matrix that happens to have  $\text{rank}(A) = 3$ .

```
A =
 64 2 3 61 60 6
 9 55 54 12 13 51
 17 47 46 20 21 43
 40 26 27 37 36 30
 32 34 35 29 28 38
 41 23 22 44 45 19
 49 15 14 52 53 11
 8 58 59 5 4 62
```

The right-hand side is `b = 260*ones(8,1)`,

```
b =
 260
 260
 260
 260
 260
 260
 260
 260
```

The scale factor 260 is the 8-by-8 magic sum. With all eight columns, one solution to  $A*x = b$  would be a vector of all 1's. With only six columns, the equations are still consistent,

so a solution exists, but it is not all 1's. Since the matrix is rank deficient, there are infinitely many solutions. Two of them are

$$x = \text{pinv}(A)*b$$

which is

$$x = \begin{bmatrix} 1.1538 \\ 1.4615 \\ 1.3846 \\ 1.3846 \\ 1.4615 \\ 1.1538 \end{bmatrix}$$

and

$$y = A \setminus b$$

which produces this result.

Warning: Rank deficient, rank = 3 tol = 1.8829e-013.

$$y = \begin{bmatrix} 4.0000 \\ 5.0000 \\ 0 \\ 0 \\ 0 \\ -1.0000 \end{bmatrix}$$

Both of these are exact solutions in the sense that  $\text{norm}(A*x-b)$  and  $\text{norm}(A*y-b)$  are on the order of roundoff error. The solution  $x$  is special because

$$\text{norm}(x) = 3.2817$$

is smaller than the norm of any other solution, including

$$\text{norm}(y) = 6.4807$$

On the other hand, the solution  $y$  is special because it has only three nonzero components.

# planerot

Givens plane rotation

## Syntax

```
[G,y] = planerot(x)
```

## Description

`[G,y] = planerot(x)` where  $x$  is a 2-component column vector, returns a 2-by-2 orthogonal matrix  $G$  so that  $y = G*x$  has  $y(2) = 0$ .

## Examples

```
x = [3 4];
[G,y] = planerot(x')
```

```
G =
 0.6000 0.8000
 -0.8000 0.6000
```

```
y =
 5
 0
```

# play

Play audio from `audioplayer` object

## Syntax

```
play(playerObj)
play(playerObj, start)
play(playerObj, [start, stop])
```

## Description

`play(playerObj)` plays the audio associated with `audioplayer` object `playerObj` from beginning to end.

`play(playerObj, start)` plays audio from the sample indicated by `start` to the end.

`play(playerObj, [start, stop])` plays audio from the sample indicated by `start` to the sample indicated by `stop`.

## Examples

### Play with and without Blocking

Play two audio samples with and without blocking using the `play` and `playblocking` methods.

Load data from example files `chirp.mat` and `gong.mat`.

```
chirpData = load('chirp.mat');
chirpObj = audioplayer(chirpData.y, chirpData.Fs);
```

```
gongData = load('gong.mat');
gongObj = audioplayer(gongData.y, gongData.Fs);
```

Play the samples with blocking, one after the other.

```
playblocking(chirpObj);
```

```
playblocking(gongObj);
```

Play without blocking. The audio can overlap.

```
play(chirpObj);
play(gongObj);
```

### Starting Sample

Play audio from the example file `handel.mat` starting 4 seconds from the beginning.

```
load handel.mat;
playerObj = audioplayer(y,Fs);
start = playerObj.SampleRate * 4;

play(playerObj,start);
```

### Sample Range

Play the first 3 seconds of audio from the example file `handel.mat`.

```
load handel.mat;
playerObj = audioplayer(y,Fs);
start = 1;
stop = playerObj.SampleRate * 3;

play(playerObj,[start,stop]);
```

### See Also

[audioplayer](#) | [playblocking](#)

### How To

- “Play Audio”

## play

Play audio from audiorecorder object

### Syntax

```
player = play(recObj)
player = play(recObj, start)
player = play(recObj, [start stop])
```

### Description

*player* = play(*recObj*) plays the audio associated with audiorecorder object *recObj* from beginning to end, and returns an audioplayer object.

*player* = play(*recObj*, *start*) plays audio from the sample indicated by *start* to the end.

*player* = play(*recObj*, [*start stop*]) plays audio from the sample indicated by *start* to the sample indicated by *stop*.

### Examples

Record 5 seconds of your speech with a microphone, and play it back. Display the properties of the audioplayer object.

```
myVoice = audiorecorder;

disp('Start speaking. ');
recordblocking(myVoice, 5);
disp('End of recording. Playing back ... ');

playerObj = play(myVoice);

disp('Properties of playerObj: ');
get(playerObj)
```

Play back only the first 3 seconds of the speech recorded in the previous example:

```
play(myVoice, [1 myVoice.SampleRate*3]);
```

### **See Also**

[audioplayer](#) | [audiorecorder](#)

## playblocking

Play audio from `audioplayer` object, holding control until playback completes

### Syntax

```
playblocking(playerObj)
playblocking(playerObj, start)
playblocking(playerObj, [start, stop])
```

### Description

`playblocking(playerObj)` plays the audio associated with `audioplayer` object `playerObj` from beginning to end. `playblocking` does not return control until playback completes.

`playblocking(playerObj, start)` plays audio from the sample indicated by `start` to the end.

`playblocking(playerObj, [start, stop])` plays audio from the sample indicated by `start` to the sample indicated by `stop`.

### Examples

#### Play with and without Blocking

Play two audio samples with and without blocking using the `play` and `playblocking` methods.

Load data from example files `chirp.mat` and `gong.mat`.

```
chirpData = load('chirp.mat');
chirpObj = audioplayer(chirpData.y, chirpData.Fs);
```

```
gongData = load('gong.mat');
gongObj = audioplayer(gongData.y, gongData.Fs);
```

Play the samples with blocking, one after the other.

```
playblocking(chirpObj);
playblocking(gongObj);
```

Play without blocking. The audio can overlap.

```
play(chirpObj);
play(gongObj);
```

### Starting Sample

Play audio from the example file `handel.mat` starting 4 seconds from the beginning.

```
load handel.mat;
playerObj = audioplayer(y,Fs);
start = playerObj.SampleRate * 4;

playblocking(playerObj,start);
beep;
```

### Sample Range

Play the first 3 seconds of audio from the example file `handel.mat`.

```
load handel.mat;
playerObj = audioplayer(y,Fs);
start = 1;
stop = playerObj.SampleRate * 3;

playblocking(playerObj,[start,stop]);
beep;
```

# plot

2-D line plot

## Syntax

```
plot(X,Y)
plot(X,Y,LineStyle)
plot(X1,Y1,...,Xn,Yn)
plot(X1,Y1,LineStyle1,...,Xn,Yn,LineStylen)
```

```
plot(Y)
plot(Y,LineStyle)
```

```
plot(____,Name,Value)
plot(ax, ____)
```

```
h = plot(____)
```

## Description

`plot(X,Y)` creates a 2-D line plot of the data in `Y` versus the corresponding values in `X`.

- If `X` and `Y` are both vectors, then they must have equal length. The `plot` function plots `Y` versus `X`.
- If `X` and `Y` are both matrices, then they must have equal size. The `plot` function plots columns of `Y` versus columns of `X`.
- If one of `X` or `Y` is a vector and the other is a matrix, then the matrix must have dimensions such that one of its dimensions equals the vector length. If the number of matrix rows equals the vector length, then the `plot` function plots each matrix column versus the vector. If the number of matrix columns equals the vector length, then the function plots each matrix row versus the vector. If the matrix is square, then the function plots each column versus the vector.
- If one of `X` or `Y` is a scalar and the other is a vector, then the `plot` function plots the vector as discrete points at the scalar value.

`plot(X,Y,LineStyle)` sets the line style, marker symbol, and color.

`plot(X1,Y1,...,Xn,Yn)` plots multiple X, Y pairs using the same axes for all lines.

`plot(X1,Y1,LineStyle1,...,Xn,Yn,LineStylen)` sets the line style, marker type, and color for each line. You can mix X, Y, LineSpec triplets with X, Y pairs. For example, `plot(X1,Y1,X2,Y2,LineStyle2,X3,Y3)`.

`plot(Y)` creates a 2-D line plot of the data in Y versus the index of each value.

- If Y is a vector, then the x-axis scale ranges from 1 to `length(Y)`.
- If Y is a matrix, then the `plot` function plots the columns of Y versus their row number. The x-axis scale ranges from 1 to the number of rows in Y.
- If Y is complex, then the `plot` function plots the imaginary part of Y versus the real part of Y, such that `plot(Y)` is equivalent to `plot(real(Y), imag(Y))`.

`plot(Y,LineStyle)` sets the line style, marker symbol, and color.

`plot( ____, Name, Value)` specifies line properties using one or more Name, Value pair arguments. Use this option with any of the input argument combinations in the previous syntaxes. Name, Value pair settings apply to all the lines plotted. You cannot specify different Name, Value pairs for each line using this syntax.

`plot(ax, ____)` plots into the axes specified by ax instead of into the current axes (`gca`). The option, ax can precede any of the input combinations in the previous syntaxes.

`h = plot( ____)` returns a column vector of chart line objects. Use h to modify a specific chart lines after it is created.

## Examples

### Create Line Plot

Define x as a vector of linearly spaced values between 0 and  $2\pi$ . Use an increment of  $\pi/100$  between the values. Define y as sine values of x.

```
x = 0:pi/100:2*pi;
y = sin(x);
```

Create a line plot of the data.

```
figure % opens new figure window
plot(x,y)
```

## Plot Multiple Lines

Define  $x$  as 100 linearly spaced values between  $-2\pi$  and  $2\pi$ . Define  $y1$  and  $y2$  as sine and cosine values of  $x$ . Create a line plot of both sets of data.

```
x = linspace(-2*pi,2*pi);
y1 = sin(x);
y2 = cos(x);
```

```
figure
plot(x,y1,x,y2)
```

### Create Line Plot From Matrix

Define Y as the 4-by-4 matrix returned by the `magic` function.

```
Y = magic(4)
```

Y =

16	2	3	13
5	11	10	8
9	7	6	12

4 14 15 1

Create a 2-D line plot of Y. MATLAB® plots each matrix column as a separate line.

```
figure
plot(Y)
```

### Specify Line Style

Plot three sine curves with a small phase shift between each line. Use the default line style for the first line. Specify a dashed line style for the second line and a dotted line style for the third line.

```
x = 0:pi/100:2*pi;
```

```
y1 = sin(x);
y2 = sin(x-0.25);
y3 = sin(x-0.5);

figure
plot(x,y1,x,y2,'-o',x,y3,'*')
```

MATLAB® cycles the line color through the default color order.

### Specify Line Style, Color, and Marker

Plot three sine curves with a small phase shift between each line. Use a green line with no markers for the first sine curve. Use a blue dashed line with circle markers for the second sine curve. Use only cyan star markers for the third sine curve.

```
x = 0:pi/10:2*pi;
y1 = sin(x);
y2 = sin(x-0.25);
y3 = sin(x-0.5);
```

```
figure
plot(x,y1, 'g',x,y2, 'b--o',x,y3, 'c*')
```

### Specify Line Width, Marker Size, and Marker Color

Create a line plot and use the `LineStyleSpec` option to specify a dashed green line with square markers. Use `Name, Value` pairs to specify the line width, marker size, and marker colors. Set the marker edge color to blue and set the marker face color using an RGB color value.

```
x = -pi:pi/10:pi;
y = tan(sin(x)) - sin(tan(x));

figure
plot(x,y,'--gs',...
 'LineWidth',2,...
 'MarkerSize',10,...
 'MarkerEdgeColor','b',...
 'MarkerFaceColor',[0.5,0.5,0.5])
```

### Add Title and Axis Labels

Use the `linspace` function to define  $x$  as a vector of 150 values between 0 and 10. Define  $y$  as cosine values of  $x$ .

```
x = linspace(0,10,150);
y = cos(5*x);
```

Create a 2-D line plot of the cosine curve. Change the line color to a shade of blue-green using an RGB color value. Add a title and axis labels to the graph using the `title`, `xlabel`, and `ylabel` functions.

```
figure
plot(x,y, 'Color',[0,0.7,0.9])

title('2-D Line Plot')
xlabel('x')
ylabel('cos(5x)')
```

### Plot Durations and Specify Tick Format

Define `t` as seven linearly spaced duration values between 0 and 3 minutes. Plot random data and specify the format of the duration tick marks using the 'DurationTickFormat' name-value pair argument.

```
t = 0:seconds(30):minutes(3);
y = rand(1,7);

plot(t,y,'DurationTickFormat','mm:ss')
```

## Specify Axes for Line Plot

Create a figure with two subplots and return the handle to each subplot axes, `ax1` and `ax2`.

```
figure % new figure
ax1 = subplot(2,1,1); % top subplot
ax2 = subplot(2,1,2); % bottom subplot
```

Create a 2-D line plot in each axes by referring to the axes handles. Add a title and y-axis label to each axes by passing the axes handles to the `title` and `ylabel` functions.

```
x = linspace(0,3);
y1 = sin(5*x);
y2 = sin(15*x);

plot(ax1,x,y1)
title(ax1,'Top Subplot')
ylabel(ax1,'sin(5x)')

plot(ax2,x,y2)
title(ax2,'Bottom Subplot')
ylabel(ax2,'sin(15x)')
```

### Change Line Properties Using Handles

Define  $x$  as 100 linearly spaced values between  $-2\pi$  and  $2\pi$ . Define  $y1$  and  $y2$  as sine and cosine values of  $x$ . Create a line plot of both sets of data and return the handles of the two lines in  $h$ .

```
x = linspace(-2*pi,2*pi);
y1 = sin(x);
y2 = cos(x);
```

```
figure
h = plot(x,y1,x,y2);
```

Use the handle of the first line, `h(1)`, to change the line width to 2. Use the handle of the second line, `h(2)`, to add star markers to the plotted line.

```
h(1).LineWidth = 2;
h(2).Marker = '*';
```

## Input Arguments

### Y — y values

scalar | vector | matrix

y values, specified as a scalar, a vector, or a matrix. Y can be a numeric array, logical array, datetime array, or duration array. To plot against specific *x* values you must also specify X.

### X — x values

scalar | vector | matrix

$x$  values, specified as a scalar, a vector, or a matrix.  $X$  can be a numeric array, logical array, datetime array, or duration array.

### **LineStyleSpec** — Line style, marker symbol, and color

string

Line style, marker symbol, and color, specified as a string. The elements of the string can appear in any order, and you can omit one or more options from the string specifier. If you omit the line style and specify the marker character, then the plot shows only the marker and no line.

If  $Y$  is a matrix and you specify a color with **LineStyleSpec**, then all the lines use the specified color. If you specify a marker type or line style and do not specify a color, then the lines cycle through the color order.

Example: `'- -or'` is a red dashed line with circle markers

Specifier	Line Style
-	Solid line (default)
- -	Dashed line
:	Dotted line
- .	Dash-dot line

Specifier	Marker
o	Circle
+	Plus sign
*	Asterisk
.	Point
x	Cross
s	Square
d	Diamond
^	Upward-pointing triangle
v	Downward-pointing triangle
>	Right-pointing triangle
<	Left-pointing triangle

Specifier	Marker
p	Pentagram
h	Hexagram

Specifier	Color
y	yellow
m	magenta
c	cyan
r	red
g	green
b	blue
w	white
k	black

**ax — Axes object**

axes object

Axes object. If you do not specify an axes, then the `plot` function uses the current axes.

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1, ...,NameN,ValueN`.

The chart line properties listed here are only a submit. For a complete list, see Chart Line Properties.

Example: `'Marker', 'o', 'MarkerFaceColor', 'red'`

**'Color' — Line color**

`[0 0.4470 0.7410]` (default) | RGB triplet | color string | 'none'

Line color, specified as an RGB triplet, a color string, or 'none'. If you specify the `Color` as 'none', then the line is invisible.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range  $[0, 1]$ , for example,  $[0.4 \ 0.6 \ 0.7]$ . This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[ 1 1 0 ]
'magenta'	'm'	[ 1 0 1 ]
'cyan'	'c'	[ 0 1 1 ]
'red'	'r'	[ 1 0 0 ]
'green'	'g'	[ 0 1 0 ]
'blue'	'b'	[ 0 0 1 ]
'white'	'w'	[ 1 1 1 ]
'black'	'k'	[ 0 0 0 ]

Example: 'blue'

Example: [0 0 1]

### 'DatetimeTickFormat' — Format for datetime tick labels

string

Format for `datetime` tick labels, specified as the comma-separated pair consisting of `'DatetimeTickFormat'` and a string. Use the letters A-Z and a-z to construct a custom string value. These letters correspond to the Unicode Locale Data Markup Language (LDML) standard for dates. You can include non-ASCII letter characters such as a hyphen, space, or colon to separate the fields.

If you do not specify a value for `'DatetimeTickFormat'`, then `plot` automatically optimizes and updates the tick labels based on the axis limits.

Example: `'DatetimeTickFormat','eeee, MMMM d, yyyy HH:mm:ss'` displays a date and time such as Saturday, April 19, 2014 21:41:06.

The following table shows several common display formats and examples of the formatted output for the date, Saturday, April 19, 2014 at 9:41:06 PM in New York City.

Value of <code>DatetimeTickFormat</code>	Example
'yyyy-MM-dd'	2014-04-19

Value of <code>DatetimeTickFormat</code>	Example
'dd/MM/yyyy'	19/04/2014
'dd.MM.yyyy'	19.04.2014
'yyyy# MM# dd#'	2014# 04# 19#
'MMMM d, yyyy'	April 19, 2014
'eeee, MMMM d, yyyy HH:mm:ss'	Saturday, April 19, 2014 21:41:06
'MMMM d, yyyy HH:mm:ss Z'	April 19, 2014 21:41:06 -0400

For a complete list of valid letter identifiers, see the `Format` property for `datetime` arrays.

`DatetimeTickFormat` is not a chart line property. You must set the tick format using the name-value pair argument when creating a plot.

**'DurationTickFormat' – Format for duration tick labels**

string

Format for `duration` tick labels, specified as the comma-separated pair consisting of `'DurationTickFormat'` and a string.

If you do not specify a value for `'DurationTickFormat'`, then `plot` automatically optimizes and updates the tick labels based on the axis limits.

To display a duration as a single number that includes a fractional part, for example, 1.234 hours, specify one of the following strings.

Value of <code>DurationTickFormat</code>	Description
'y'	Number of exact fixed-length years. A fixed-length year is equal to 365.2425 days.
'd'	Number of exact fixed-length days. A fixed-length day is equal to 24 hours.
'h'	Number of hours
'm'	Number of minutes
's'	Number of seconds

Example: `'DurationTickFormat', 'h'` displays duration values in terms of fixed-length days.

To display a duration in the form of a digital timer, specify one of the following strings.

- `'dd:hh:mm:ss'`
- `'hh:mm:ss'`
- `'mm:ss'`
- `'hh:mm'`

In addition, you can display up to nine fractional second digits by appending up to nine `S` characters.

Example: `'DurationTickFormat', 'hh:mm:ss.SSS'` displays the milliseconds of a duration value to three digits.

`DurationTickFormat` is not a chart line property. You must set the tick format using the name-value pair argument when creating a plot.

#### **'LineStyle' — Line style**

`'-'` (default) | `'--'` | `':'` | `'-.'` | `'none'`

Line style, specified as one of the line style strings listed in this table.

String	Line Style	Resulting Line
<code>'-'</code>	Solid line	
<code>'--'</code>	Dashed line	
<code>':'</code>	Dotted line	
<code>'-.'</code>	Dash-dotted line	
<code>'none'</code>	No line	No line

#### **'LineWidth' — Line width**

0.5 (default) | positive value

Line width, specified as a positive value in point units. If the line has markers, then the line width also affects the marker edges.

Example: 0.75

#### **'Marker' — Marker symbol**

`'none'` (default) | string

Marker symbol, specified as one of the marker strings in this table. By default, a chart line does not have markers. Add markers at each data point along the line by specifying a marker symbol.

String	Marker Symbol
'o'	Circle
'+'	Plus sign
'*'	Asterisk
'.'	Point
'x'	Cross
'square' or 's'	Square
'diamond' or 'd'	Diamond
'^'	Upward-pointing triangle
'v'	Downward-pointing triangle
'>'	Right-pointing triangle
'<'	Left-pointing triangle
'pentagram' or 'p'	Five-pointed star (pentagram)
'hexagram' or 'h'	Six-pointed star (hexagram)
'none'	No markers

Example: 'Marker', '+'

Example: 'Marker', 'diamond'

**'MarkerEdgeColor' — Marker outline color**

'auto' (default) | 'none' | RGB triplet | color string

Marker outline color, specified as one of these values:

- 'auto' — Use the same color as the Color property.
- 'none' — Use no color, which makes unfilled markers invisible.
- RGB triplet or color string — Use the specified color.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range

[0, 1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[1 1 0]
'magenta'	'm'	[1 0 1]
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black'	'k'	[0 0 0]

Example: [0.5 0.5 0.5]

Example: 'blue'

### 'MarkerFaceColor' — Marker fill color

'none' (default) | 'auto' | RGB triplet | color string

Marker fill color, specified as one of these values:

- 'none' — Use no color, which makes the interior invisible.
- 'auto' — Use the same color as the `Color` property for the axes.
- RGB triplet or color string — Use the specified color.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0, 1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[1 1 0]
'magenta'	'm'	[1 0 1]
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]

Long Name	Short Name	RGB Triplet
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black'	'k'	[0 0 0]

Example: [0.3 0.2 0.1]

Example: 'green'

### 'MarkerSize' — Marker size

6 (default) | positive value

Marker size, specified as a positive value in point units.

Example: 10

## Output Arguments

### **h** — One or more chart line objects

scalar | vector

One or more chart line objects, returned as a scalar or a vector. These are unique identifiers, which you can use to query and modify properties of a specific chart line.

## More About

### Tips

- `plot` uses colors and line styles based on the `ColorOrder` and `LineStyleOrder` properties for the current axes. `plot` cycles through the colors with the first line style. Then, it cycles through the colors again with each additional line style.

To change the colors and line styles for the current axes, set the `ColorOrder` and `LineStyleOrder` properties. For example, to set the line style order for the current axes to a solid line with asterisk markers, a dotted line, and circle markers with no line, use this command:

```
ax = gca;
ax.LineStyleOrder = '-*|:|o|';
```

- Use NaN and Inf values to create breaks in the lines. For example, this code plots the first two elements, skips the third element, and draws another line using the last two elements: `plot([1,2,NaN,4,5])`.

### Properties

Chart Line Properties

# plot3

3-D line plot

## Syntax

```
plot3(X1,Y1,Z1,...)
plot3(X1,Y1,Z1,LineStyle,...)
plot3(...,'PropertyName',PropertyValue,...)
plot3(axes_handle,...)
h = plot3(...)
```

## Description

The `plot3` function displays a three-dimensional plot of a set of data points.

`plot3(X1,Y1,Z1,...)`, where `X1`, `Y1`, `Z1` are vectors or matrices, plots one or more lines in three-dimensional space through the points whose coordinates are the elements of `X1`, `Y1`, and `Z1`.

`plot3(X1,Y1,Z1,LineStyle,...)` creates and displays all lines defined by the `Xn,Yn,Zn,LineStyle` quads, where `LineStyle` is a line specification that determines line style, marker symbol, and color of the plotted lines.

`plot3(...,'PropertyName',PropertyValue,...)` sets line properties to the specified property values for all the charting lines created by `plot3`. See [Chart Line Properties](#) for a description of the properties you can set.

`plot3(axes_handle,...)` plots into the axes specified by `axes_handle` instead of into the current axes (`gca`). The option, `axes_handle` can precede any of the input combinations in the previous syntaxes.

`h = plot3(...)` returns a column vector of charting line handles, with one handle per object.

## Examples

### Plot 3-D Helix

Define `t` as values between 0 and  $10\pi$ . Define `st` and `ct` as vectors of sine and cosine values. Plot a 3-D helix.

```
t = 0:pi/50:10*pi;
st = sin(t);
ct = cos(t);
```

```
figure
plot3(st,ct,t)
```

## More About

### Tips

If one or more of  $X_1, Y_1, Z_1$  is a vector, the vectors are plotted versus the rows or columns of the matrix, depending whether the vectors' lengths equal the number of rows or the number of columns.

You can mix  $X_n, Y_n, Z_n$  triples with  $X_n, Y_n, Z_n, \text{LineSpec}$  quads, for example,

```
plot3(X1,Y1,Z1,X2,Y2,Z2,LineSpec,X3,Y3,Z3)
```

See `LineSpec` and `plot` for information on line types and markers.

**Properties**

Chart Line Properties

# plotbrowser

Show or hide figure **Plot Browser**

## Syntax

```
plotbrowser('on')
plotbrowser('off')
plotbrowser
plotbrowser(figure_handle,...)
```

## Description

`plotbrowser('on')` displays the Plot Browser on the current figure.

`plotbrowser('off')` hides the Plot Browser on the current figure.

`plotbrowser` toggles the visibility of the Plot Browser on the current figure. You can use `plotbrowser('toggle')` instead for the same functionality.

`plotbrowser(figure_handle,...)` shows or hides the Plot Browser on the figure specified by `figure_handle`.

## Examples

### Open Plot Browser

Plot a 5-by-5 matrix of random numbers. Then, open the plot browser.

```
plot(rand(5))
plotbrowser('on')
```

## Alternatives

To collectively enable Plotting Tools, use the large Plotting Tool icon  on the figure toolbar. To collectively disable the Plotting Tools, use the smaller icon . Open or close the **Plot Browser** tool from the figure's **View** menu.

## **More About**

### **Tips**

If you call `plotbrowser` in a MATLAB program and subsequent lines depend on the Plot Browser being fully initialized, follow it by `drawnow` to ensure complete initialization.

### **See Also**

`plottools` | `figurepalette` | `propertyeditor`

# plottedit

Interactively edit and annotate plots

## Syntax

```
plottedit on
plottedit off
plottedit
plottedit(h)
plottedit(state)
plottedit(h,state)
```

## Description

`plottedit on` starts plot edit mode for the current figure, allowing you to use a graphical interface to annotate and edit plots easily. In plot edit mode, you can label axes, change line styles, and add text, line, and arrow annotations.

`plottedit off` ends plot mode for the current figure.

`plottedit` toggles the plot edit mode for the current figure.

`plottedit(h)` toggles the plot edit mode for the figure specified by figure handle `h`.

`plottedit(state)` specifies the `plottedit` state for the current figure. Values for `state` can be as shown.

Value for state	Description
'on'	Starts plot edit mode
'off'	Ends plot edit mode
'showtoolsmenu'	Displays the <b>Tools</b> menu in the menu bar
'hidetoolsmenu'	Removes the <b>Tools</b> menu from the menu bar

---

**Note** 'hidetoolsmenu' is intended for GUI developers who do not want the **Tools** menu to appear in applications that use the figure window.

---

`plottedit(h, state)` specifies the `plottedit` state for figure handle `h`.

## Examples

Start plot edit mode for figure 2.

```
plottedit(2)
```

End plot edit mode for figure 2.

```
plottedit(2, 'off')
```

Hide the **Tools** menu for the current figure:

```
plottedit('hidetoolsmenu')
```

## See Also

# plotmatrix

Scatter plot matrix

## Syntax

```
plotmatrix(X,Y)
plotmatrix(X)
plotmatrix(____,LineStyleSpec)

[H,AX,BigAx,P,PAX] = plotmatrix(____)
```

## Description

`plotmatrix(X,Y)` creates a matrix of subaxes containing scatter plots of the columns of *X* against the columns of *Y*. If *X* is *p*-by-*n* and *Y* is *p*-by-*m*, then `plotmatrix` produces an *n*-by-*m* matrix of subaxes.

`plotmatrix(X)` is the same as `plotmatrix(X,X)` except that the subaxes along the diagonal are replaced with histogram plots of the data in the corresponding column of *X*. For example, the subaxes along the diagonal in the *i*th column is replaced by `hist(X(:,i))`.

`plotmatrix( ____,LineStyleSpec)` specifies the line style, marker symbol, and color for the scatter plots. The option `LineStyleSpec` can be preceded by any of the input argument combinations in the previous syntaxes.

`[H,AX,BigAx,P,PAX] = plotmatrix( ____)` returns handles to the graphic objects created as follows:

- `H` – Matrix of handles to the line objects used to create the scatter plots
- `AX` – Matrix of handles to the individual subaxes
- `BigAx` – Handle to the big axes that frames the subaxes
- `P` – Vector of handles for the patch objects that create the histogram plots
- `PAX` – Vector of handles to the invisible histogram axes

`BigAx` is left as the current axes (`gca`) so that a subsequent `title`, `xlabel`, or `ylabel` command will center text with respect to the big axes.

## Examples

### Create Scatter Plot Matrix with Two Matrix Inputs

Initialize the random-number generator to make the output of `randn` repeatable. Define `X` as a matrix of normally distributed pseudorandom data and `Y` as a matrix of integer values.

```
rng default
X = randn(50,3);
Y = reshape(1:150,50,3);
```

Create a scatter plot matrix of the columns of `X` against the columns of `Y`.

```
figure
plotmatrix(X,Y)
```

The subplot in the  $i$ th row,  $j$ th column of the figure is a scatter plot of the  $i$ th column of  $Y$  against the  $j$ th column of  $X$ .

### Create Scatter Plot Matrix with One Matrix Input

Initialize the random-number generator to make the output of `randn` repeatable and generate a matrix of normally distributed pseudorandom data

```
rng default
X = randn(50,3);
```

Create a scatter plot matrix.

```
figure
plotmatrix(X)
```

The subplot in the  $i$ th row,  $j$ th column of the matrix is a scatter plot of the  $i$ th column of  $X$  against the  $j$ th column of  $X$ . Along the diagonal, `plotmatrix` creates a histogram plot of each column of  $X$ .

### Specify Marker Type and Color

Initialize the random-number generator to make the output of `randn` repeatable. Generate a matrix of normally distributed pseudorandom data.

```
rng(0, 'twister');
X = randn(50,3);
```

Create a scatter plot matrix and specify the marker type and the color for the scatter plots.

```
figure
plotmatrix(X, '*r')
```

The `LineStyle` option sets properties for the scatter plots. To set properties for the histogram plots, use the patch object handles.

### Set Plotmatrix Properties Using Handles

Initialize the random-number generator to make the output of `randn` repeatable. Generate a matrix of normally distributed pseudorandom data.

```
rng default
X = randn(50,3);
```

Create a scatter plot matrix and return the object handles and the axes handles.

```
figure
[H,AX,BigAx,P,PAX] = plotmatrix(X);
```

To set properties for the scatter plots, use the handles in H. To set properties for the histograms, use the patch handles in P. To set axes properties, use the axes handles, AX, BigAx, and PAX.

Set the color and marker type for the scatter plot in the lower left corner.

```
H(3).Color = 'g';
H(3).Marker = '*';
```

Set the color for the histogram plot in the lower right corner. Use the `title` command to title the figure.

```
P(3).EdgeColor = 'k';
P(3).FaceColor = 'g';
title(BigAx, 'A Comparison of Data Sets')
```

## Input Arguments

### X — Data to display

matrix

Data to display, specified as a matrix.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

### Y — Data to plot against X

matrix

Data to plot against X, specified as a matrix.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

### **LineStyle** — Line style, marker symbol, and color for scatter plots

string

Line style, marker symbol, and color for the scatter plots, specified as a string. For more information on line style, marker symbol, and color options see `LineStyle`.

Example: `'*r'`

Data Types: `char`

## Output Arguments

### **H** — Line object handles

matrix

Line object handles, returned as a matrix. This is a unique identifier, which you can use to query and modify the properties of a specific line object. The line objects are used to create the scatter plots.

### **AX** — Subaxes handles

matrix

Subaxes handles, returned as a matrix. This is a unique identifier, which you can use to query and modify the properties of a specific subaxes.

### **BigAX** — Big axes handle

scalar

Big axes handle, returned as a scalar. This is a unique identifier, which you can use to query and modify properties of the big axes. `BigAX` is left as the current axes (`gca`) so that a subsequent `title`, `xlabel`, or `ylabel` command will center text with respect to the big axes.

### **P** — Patch object handles

vector | []

Patch object handles, returned as a vector or []. If histogram plots are created, then `P` is returned as a vector of patch object handles for the histogram plots. These are unique

identifiers, which you can use to query and modify the properties of a specific patch object. If no histogram plots are created, then **P** is returned as empty brackets.

## **PAX — Handle to invisible histogram axes**

vector | []

Handle to invisible histogram axes, returned as a vector or []. If histogram plots are created, then **PAX** is returned as a vector of histogram axes handles. These are unique identifiers, which you can use to query and modify the properties of a specific axes, such as the axes scale. If no histogram plots are created, then **PAX** is returned as empty brackets.

## **See Also**

scatter | scatter3

# plottools

Show or hide plot tools

## Syntax

```
plottools('on')
plottools('off')
plottools
plottools(figure_handle,...)
plottools(...,'tool')
```

## Description

`plottools('on')` displays the Figure Palette, Plot Browser, and Property Editor on the current figure, configured as you last used them.

`plottools('off')` hides the Figure Palette, Plot Browser, and Property Editor on the current figure.

`plottools` with no arguments, is the same as `plottools('on')`

`plottools(figure_handle,...)` displays or hides the plot tools on the specified figure instead of on the current figure.

`plottools(...,'tool')` operates on the specified tool only. *tool* can be one of the following strings:

- `figurepalette`
- `plotbrowser`
- `propertyeditor`

---

**Note:** The first time you open the plotting tools, all three of them appear, grouped around the current figure as shown above. If you close, move, or undock any of the tools, MATLAB remembers the configuration you left them in and restores it when you invoke the tools for subsequent figures, both within and across MATLAB sessions.

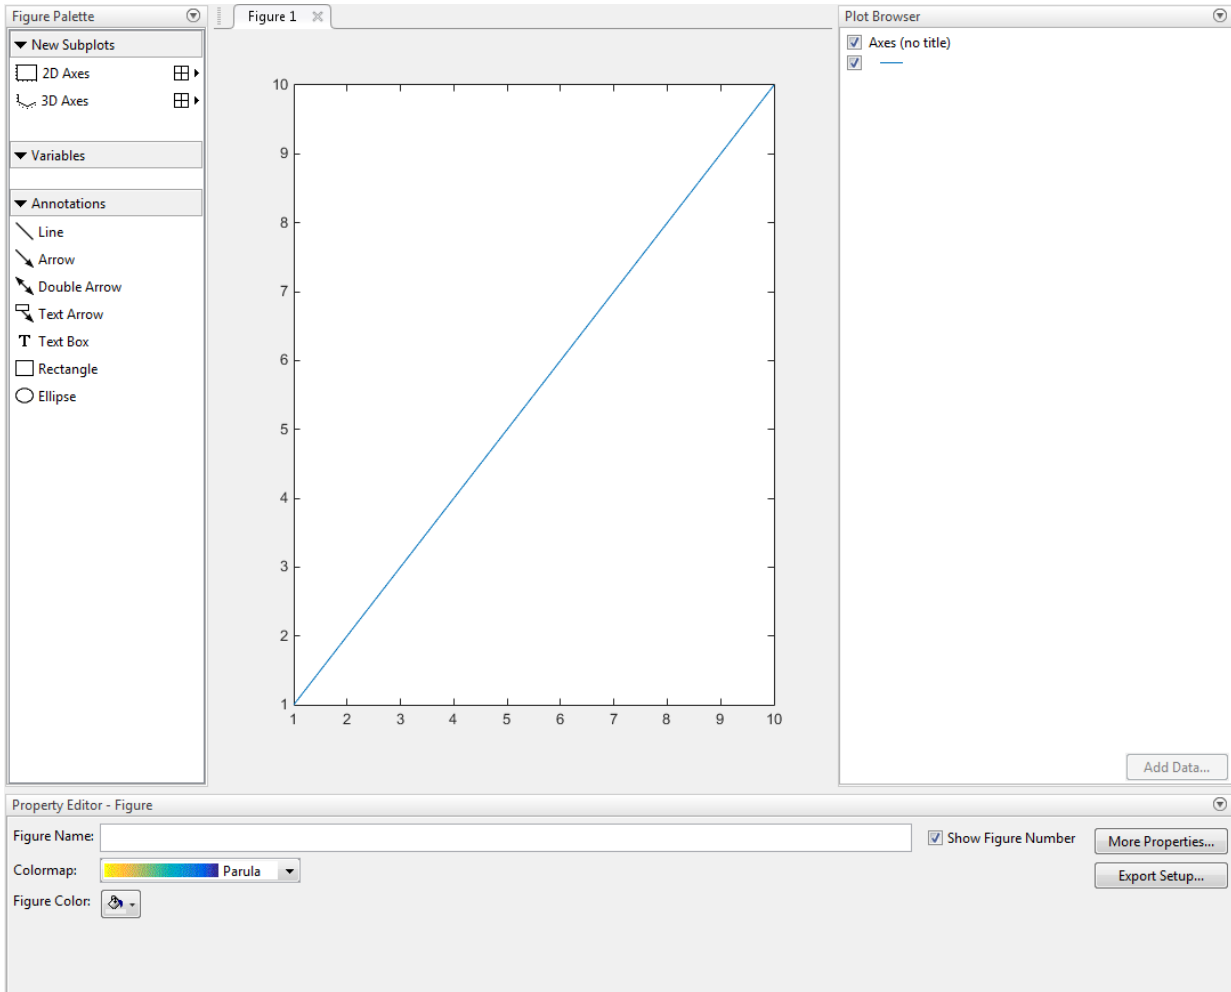

---

## Examples

### Open Plot Tools

Create a line plot and open the plot tools.

```
plot(1:10);
plottools('on')
```

## Alternatives

Click the larger **Plotting Tools** icon  on the figure toolbar to collectively enable plotting tools, and the smaller icon  to collectively disable them. Individually select

the **Figure Palette**, **Plot Browser**, and **Property Editor** tools from the figure's **View** menu. For details, see “Customize Graph Using Plot Tools”.

**See Also**

figurepalette | plotbrowser | propertyeditor

# plotyy

2-D line plots with y-axes on both left and right side

## Syntax

```
plotyy(X1,Y1,X2,Y2)
plotyy(X1,Y1,X2,Y2,function)
plotyy(X1,Y1,X2,Y2,'function1','function2')
[AX,H1,H2] = plotyy(...)
```

## Description

`plotyy(X1,Y1,X2,Y2)` plots Y1 versus X1 with y-axis labeling on the left and plots Y2 versus X2 with y-axis labeling on the right.

`plotyy(X1,Y1,X2,Y2,function)` uses the specified plotting function to produce the graph.

`function` can be either a function handle or a string specifying `plot`, `semilogx`, `semilogy`, `loglog`, `stem`, or any MATLAB function that accepts the syntax

```
h = function(x,y)
```

For example,

```
plotyy(x1,y1,x2,y2,@loglog) % function handle
plotyy(x1,y1,x2,y2,'loglog') % string
```

Function handles enable you to access user-defined local functions and can provide other advantages. See `@` for more information on using function handles.

`plotyy(X1,Y1,X2,Y2,'function1','function2')` uses `function1(X1,Y1)` to plot the data for the left axis and `function2(X2,Y2)` to plot the data for the right axis.

`[AX,H1,H2] = plotyy(...)` returns the handles of the two axes created in `AX` and the handles of the graphics objects from each plot in `H1` and `H2`. `AX(1)` is the left axes and `AX(2)` is the right axes.

## Examples

### Plot Two Data Sets with Different y-Axes

Plot two data sets on one graph using two *y*-axes.

```
x = 0:0.01:20;
y1 = 200*exp(-0.05*x).*sin(x);
y2 = 0.8*exp(-0.5*x).*sin(10*x);
```

```
figure % new figure
plotyy(x,y1,x,y2)
```

### Add Title and Axis Labels

Plot two data sets using a graph with two y-axes. Add a title and axis labels.

```
x = 0:0.01:20;
y1 = 200*exp(-0.05*x).*sin(x);
y2 = 0.8*exp(-0.5*x).*sin(10*x);

figure % new figure
[hAx,hLine1,hLine2] = plotyy(x,y1,x,y2);

title('Multiple Decay Rates')
xlabel('Time (\musec)')

ylabel(hAx(1),'Slow Decay') % left y-axis
```

```
ylabel(hAx(2), 'Fast Decay') % right y-axis
```

### Change Line Styles

Plot two data sets using a graph with two  $y$ -axes. Change the line styles.

```
x = 0:0.01:20;
y1 = 200*exp(-0.05*x).*sin(x);
y2 = 0.8*exp(-0.5*x).*sin(10*x);

figure % new figure
[hAx,hLine1,hLine2] = plotyy(x,y1,x,y2);

hLine1.LineStyle = '--';
```

```
hLine2.LineStyle = ':';
```

### Combine Different Types of Plots

Plot two data sets using a graph with two y-axes. Use a line plot for the data associated with the left y-axis. Use a stem plot for the data associated with the right y-axis.

```
x = 0:0.1:10;
y1 = 200*exp(-0.05*x).*sin(x);
y2 = 0.8*exp(-0.5*x).*sin(10*x);
```

```
figure
plotyy(x,y1,x,y2,'plot','stem')
```

### Use Right y-Axis for Two Data Sets

Plot three data sets using a graph with two  $y$ -axes. Plot one set of data associated with the left  $y$ -axis. Plot two sets of data associated with the right  $y$ -axis by using two-column matrices.

```
x = linspace(0,10);
y1 = 200*exp(-0.05*x).*sin(x);
y2 = 0.8*exp(-0.5*x).*sin(10*x);
y3 = 0.2*exp(-0.5*x).*sin(10*x);
```

```
figure
[hAx,hLine1,hLine2] = plotyy(x,y1,['x','x'],[y2',y3']');
```

# matlab.unittest.plugins

Summary of classes in MATLAB Plugins Interface

## Description

Plugins customize a `TestRunner` object. The `matlab.unittest.plugins` package consists of the following customized MATLAB plugins.

<code>matlab.unittest.plugins.CodeCoveragePlugin</code>	Plugin that produces a code coverage report
<code>matlab.unittest.plugins.DiagnosticsValidationPlugin</code>	Plugin to help validate diagnostic code
<code>matlab.unittest.plugins.FailureDiagnosticsPlugin</code>	Plugin to show diagnostics on failure
<code>matlab.unittest.plugins.LoggingPlugin</code>	Plugin to report diagnostic messages
<code>matlab.unittest.plugins.OutputStream</code>	Interface that determines where to send text output
<code>matlab.unittest.plugins.StopOnFailuresPlugin</code>	Plugin to debug test failures
<code>matlab.unittest.plugins.TAPPlugin</code>	Plugin that produces Test Anything Protocol stream
<code>matlab.unittest.plugins.ToFile</code>	Output stream to write text output to file
<code>matlab.unittest.plugins.ToStandardOutput</code>	Output stream to display text information to screen
<code>matlab.unittest.plugins.TestRunnerPlugin</code>	Plugin interface for extending <code>TestRunner</code>
<code>matlab.unittest.plugins.TestRunProgressPlugin</code>	Plugin that reports test run progress

# matlab.unittest.plugins.CodeCoveragePlugin class

**Package:** matlab.unittest.plugins

Plugin that produces a code coverage report

## Description

Add the `CodeCoveragePlugin` to the `TestRunner` to produce a line coverage report for MATLAB source code. The testing framework runs the tests, and the resulting coverage report indicates the executed lines of code. The coverage report is based on source code located in one or more folders or packages.

The `CodeCoveragePlugin` uses the MATLAB profiler to determine which lines of code the tests execute. The tests and source code should not interact with the profiler. Prior to running a suite of tests, the plugin clears any data collected by the profiler.

## Construction

`matlab.unittest.plugins.CodeCoveragePlugin.forFolder(folder)` creates a plugin that produces a code coverage report for one or more folders. The plugin reports on the source code inside `folder`.

`matlab.unittest.plugins.CodeCoveragePlugin.forPackage(package)` creates a plugin that produces a code coverage report for one or more packages. The plugin reports on the source code contained in `package`.

## Input Arguments

**folder** — Location(s) of folder containing source code

string | cell array of strings

Location(s) of folder containing source code, specified as a string or cell array of strings. `folder` is the absolute or relative path to one or more folders. If you specify multiple folders, MATLAB opens a profile coverage report for each folder.

Example: `'C:\projects\myproj'`

Example: `pwd`

Example: `{'C:\projects\myprojA', 'myprojB'}`

### **package** — Name(s) of package containing source code

string | cell array of strings

Name(s) of package containing source code, specified as a string or cell array of strings. If you specify multiple packages, MATLAB opens a profile coverage report for each package.

Example: `'myproject.controller'`

Example: `{'myprojA', 'myprojB'}`

## Copy Semantics

Handle. To learn how handle classes affect copy operations, see “Copying Objects” in the MATLAB documentation.

## Examples

### Generate Code Coverage Report

In an new file, `quadraticSolver.m`, in your working folder, create the following function.

```
function roots = quadraticSolver(a,b,c)
% quadraticSolver returns solutions to the
% quadratic equation a*x^2 + b*x + c = 0.

checkInputs

roots(1) = (-b + sqrt(b^2 - 4*a*c)) / (2*a);
roots(2) = (-b - sqrt(b^2 - 4*a*c)) / (2*a);

function checkInputs
 if ~isa(a,'numeric') || ~isa(b,'numeric') || ~isa(c,'numeric')
 error('quadraticSolver:InputMustBeNumeric', ...
 'Coefficients must be numeric.')
 end
```

```
end
end
```

Create a test for the quadratic solver. In a `tests` subfolder, create `SolverTest.m` containing the following test class.

```
classdef SolverTest < matlab.unittest.TestCase
 % SolverTest tests solutions to the quadratic equation
 % $a*x^2 + b*x + c = 0$

 methods (Test)
 function testRealSolution(testCase)
 actSolution = quadraticSolver(1,-3,2);
 expSolution = [2,1];
 testCase.verifyEqual(actSolution,expSolution)
 end
 function testImaginarySolution(testCase)
 actSolution = quadraticSolver(1,2,10);
 expSolution = [-1+3i, -1-3i];
 testCase.verifyEqual(actSolution,expSolution)
 end
 end
end
```

At the command prompt, create a test suite from the `tests` folder.

```
import matlab.unittest.TestSuite
import matlab.unittest.TestRunner
import matlab.unittest.plugins.CodeCoveragePlugin

suite = TestSuite.fromFolder('tests');
```

Create a test runner.

```
runner = TestRunner.withTextOutput;
```

Add `CodeCoveragePlugin` to the runner and run the tests. Specify that the source code folder is your current working folder. If you have other source code files in your current working folder, they will show up in the coverage report.

```
runner.addPlugin(CodeCoveragePlugin.forFolder(pwd))
result = runner.run(suite);
```

```
Running SolverTest
```

```
..
Done SolverTest
```

MATLAB opens a Profiler Coverage Report for the quadratic solver function.

## Profiler Coverage Report

Run the Coverage Report after you run the Profiler to identify how much of a file ran when it was profiled ([Learn More](#)).

Report for folder C:\myWork

<a href="#">quadraticSolver.m</a>	 Total coverage: 75.0%
<a href="#">quadraticSolver</a>	<a href="#">Coverage</a> : 100.0% Total time: 0.0 seconds Total lines: 4
<a href="#">quadraticSolver&gt;checkInputs</a>	<a href="#">Coverage</a> : 50.0% Total time: 0.0 seconds Total lines: 4

The `checkInputs` nested function does not have complete code coverage. Since the tests in `SolverTest.m` do not pass nonnumeric input to `quadraticSolver`, MATLAB does not exercise the code that throws an error if the inputs are not numeric. To address the missing coverage, add a test method to test the error condition.

`matlab.unittest.plugins.TestRunnerPlugin` | `profile`

# matlab.unittest.plugins.DiagnosticsValidationPlugin class

**Package:** matlab.unittest.plugins

Plugin to help validate diagnostic code

## Description

The `DiagnosticsValidationPlugin` creates a plugin to help validate diagnostic code.

Add the `DiagnosticsValidationPlugin` to the `TestRunner` to confirm that user-supplied diagnostics execute correctly. This plugin is useful because typically tests do not encounter failure conditions. A failure can result in unexercised diagnostic code. If a programming error exists in this diagnostic code, the error is not evident unless the test fails. However, at this point in the testing process, the diagnostics for the failure condition are lost due to the error in the diagnostic code.

Use this plugin to unconditionally evaluate the diagnostics supplied by the test writer, regardless of whether the test results in a passing or failing condition. This approach helps you to confirm that all of the diagnostic code is free from programming errors.

The diagnostic analysis can reduce the test performance and can result in very verbose text output. Be aware of these impacts before using this plugin for routine testing.

## Construction

`matlab.unittest.plugins.DiagnosticsValidationPlugin` creates a plugin to help validate diagnostic code.

`matlab.unittest.plugins.DiagnosticsValidationPlugin(stream)` redirects all the text output to the output stream, `stream`. If you do not specify the output stream, the plugin uses the default `ToStandardOutput` stream.

## Input Arguments

### stream

Location where the plugin directs text output, specified as an `OutputStream`.

**Default:** `ToStandardOutput`

## Copy Semantics

Handle. To learn how handle classes affect copy operations, see “Copying Objects” in the MATLAB documentation.

## Examples

### Add Plugin to TestRunner

In your working folder, create a file, `ExampleTest.m`, containing the following test class. In this example, the `testThree` method has an intentional error. The method should use a function handle to the `dir` function as a `FunctionHandleDiagnostic`, but `dir` is misspelled.

```
classdef ExampleTest < matlab.unittest.TestCase
 methods(Test)
 function testOne(testCase)
 % test code
 end
 function testTwo(testCase)
 % test code
 end
 function testThree(testCase)
 % The following should use @dir as a function handle,
 % but there is a typo
 testCase.verifyEqual('myfile', 'myfile', @dri)
 end
 end
end
```

All of the tests in `ExampleTest.m` result in a passing condition, but there is an error in the diagnostic.

At the command prompt, create a test suite from the `ExampleTest` class.

```
import matlab.unittest.TestRunner
import matlab.unittest.TestSuite
import matlab.unittest.plugins.DiagnosticsValidationPlugin

suite = TestSuite.fromClass(?ExampleTest);
```

Create a test runner with no plugins. This code creates a silent runner and provides you with complete control over the installed plugins.

```
runner = TestRunner.withTextOutput;
```

Run the tests.

```
result1 = runner.run(suite);
```

```
Running ExampleTest
...
Done ExampleTest
```

---

No diagnostic output is displayed because all the tests passed. The testing framework does not encounter the bug in the `FunctionHandleDiagnostic` of `testThree`.

Add `DiagnosticsValidationPlugin` to the runner and run the tests.

```
runner.addPlugin(DiagnosticsValidationPlugin)
result2 = runner.run(suite);
```

```
Running ExampleTest
..

Validation of Test Diagnostic:

Error occurred while capturing diagnostics:
Error using evalc
Undefined function or variable 'dri'.

Error in ExampleTest/testThree (line 12)
 testCase.verifyEqual('myfile','myfile', @dri);

.
Done ExampleTest
```

---

The framework executes the diagnostic provided by the `FunctionHandleDiagnostic`, even though none of the tests fails. Without this plugin, the test framework only encounters the bug if the test fails.

### **See Also**

`matlab.unittest.diagnostics` | `matlab.unittest.plugins` | `OutputStream` | `ToStandardOutput`

# matlab.unittest.plugins.FailureDiagnosticsPlugin class

**Package:** matlab.unittest.plugins

Plugin to show diagnostics on failure

## Description

The `FailureDiagnosticsPlugin` creates a plugin to show diagnostics upon encountering a test failure. Add it to the `TestRunner` to output test failure diagnostics to the Command Window. This plugin is used by default when you construct a test runner using `TestRunner.withTextOutput`.

## Construction

`matlab.unittest.plugins.FailureDiagnosticsPlugin` creates a plugin to show diagnostics upon encountering a test failure.

`matlab.unittest.plugins.DFailureDiagnosticsPlugin(stream)` redirects all the text output to the output stream, `stream`. If you do not specify the output stream, the plugin uses the `ToStandardOutput` stream.

## Input Arguments

### **stream**

Location where the plugin directs text output, specified as an `OutputStream`.

**Default:** `ToStandardOutput`

## Copy Semantics

Handle. To learn how handle classes affect copy operations, see “Copying Objects” in the MATLAB documentation.

## Examples

### Add Plugin to TestRunner

In your working folder, create a file, `ExampleTest.m`, containing the following test class.

```
classdef ExampleTest < matlab.unittest.TestCase
 methods(Test)
 function testPathAdd(testCase)
 % test code
 end
 function testOne(testCase) % Test fails
 testCase.verifyEqual(5, 4, 'Testing 5==4')
 end
 function testTwo(testCase) % Test passes
 testCase.verifyEqual(5, 5, 'Testing 5==5')
 end
 end
end
```

The `verifyEqual` qualification in `testOne` causes a test failure. The qualifications in `testOne` and `testTwo` include an instance of a `matlab.unittest.diagnostics.StringDiagnostic`.

At the command prompt, create a test suite from the `ExampleTest` class.

```
import matlab.unittest.TestRunner
import matlab.unittest.TestSuite
import matlab.unittest.plugins.FailureDiagnosticsPlugin

suite = TestSuite.fromClass(?ExampleTest);
```

Create a test runner with no plugins. This code creates a silent runner and provides you with complete control over the installed plugins.

```
runner = TestRunner.withNoPlugins;
```

Run the tests.

```
result1 = runner.run(suite);
```

No output is displayed, but `result1` contains information about the failed test.

Add FailureDiagnosticsPlugin to the runner and run the tests.

```
runner.addPlugin(FailureDiagnosticsPlugin)
result2 = runner.run(suite);
```

```
=====
Verification failed in ExampleTest/testOne.
```

```

Test Diagnostic:

Testing 5==4
```

```

Framework Diagnostic:

verifyEqual failed.
```

```
--> The values are not equal using "isequaln".
--> Failure table:
```

Index	Actual	Expected	Error	RelativeError
1	5	4	1	0.25

```
Actual Value:
```

```
5
```

```
Expected Value:

# matlab.unittest.plugins.LoggingPlugin class

**Package:** matlab.unittest.plugins

Plugin to report diagnostic messages

## Description

The `LoggingPlugin` creates a plugin to report diagnostic messages that are created by the `log` method of a `TestCase` or `Fixture`.

## Construction

Instantiate a `LoggingPlugin` using one of its static methods.

Use the `withVerbosity` static method to configure a plugin to respond to messages of a particular verbosity. Also, the `withVerbosity` method accepts a number of name/value pairs to configure the format for reporting logged messages.

## Properties

### Description — Logged diagnostic message description

'Diagnostic logged' (default) | string

Logged diagnostic message description, specified as a string. The value of this property is printed alongside each logged diagnostic message. `Description` is read only, and its value is set during construction.

### HideLevel — Indicator to display verbosity level

false (default) | true

Indicator to display the verbosity level alongside each logged diagnostic, specified as `false` (logical(0)) or `true` (logical(1)). By default, this property is `false` and the test framework displays the verbosity level. `HideLevel` is read only, and its value is set during construction.

### HideTimestamp — Indicator to display timestamp

false (default) | true

Indicator to display the timestamp from when the test framework generates the logged message alongside each logged diagnostic, specified as `false` (`logical(0)`) or `true` (`logical(1)`). By default, this property is `false` and the test framework displays the timestamp. `HideTimestamp` is read only, and its value is set during construction.

### **NumStackFrames** — Number of stack frames to display

0 (default) | integer value | `Inf`

Number of stack frames to display after each logged diagnostic message, specified as an integer value. By default, this property is 0, and the test framework does not display stack information. If `NumStackFrames` is `Inf`, the test framework displays all available stack frames. `NumStackFrames` is read only, and its value is set during construction.

### **Verbosity** — Verbosity levels supported by plugin instance

array of `matlab.unittest.Verbosity` instances

Verbosity levels supported by plugin instance, specified as an array of `matlab.unittest.Verbosity` instances. The plugin reacts to diagnostics that are logged at a verbosity level listed in this array. `Verbosity` is read only, and its value is set during construction.

## Methods

`withVerbosity`

Construct `LoggingPlugin` for messages of specified verbosity

## Copy Semantics

Handle. To learn how handle classes affect copy operations, see “Copying Objects” in the MATLAB documentation.

## See Also

`matlab.unittest.Verbosity` | `matlab.unittest.fixtures.Fixture.log` | `matlab.unittest.TestCase.log`

# matlab.unittest.plugins.LoggingPlugin.withVerbosity

**Class:** matlab.unittest.plugins.LoggingPlugin

**Package:** matlab.unittest.plugins

Construct LoggingPlugin for messages of specified verbosity

## Syntax

matlab.unittest.plugins.LoggingPlugin.withVerbosity(v)

matlab.unittest.plugins.LoggingPlugin.withVerbosity(v,stream)

matlab.unittest.plugins.LoggingPlugin.withVerbosity(v,Name,Value)

## Description

matlab.unittest.plugins.LoggingPlugin.withVerbosity(v) constructs a LoggingPlugin for messages of the specified verbosity.

matlab.unittest.plugins.LoggingPlugin.withVerbosity(v,stream) redirects the text output to the output stream.

matlab.unittest.plugins.LoggingPlugin.withVerbosity(v,Name,Value) includes additional options specified by one or more Name,Value pair arguments.

## Input Arguments

**v** — **Verbosity levels supported by plugin instance**

1 | 2 | 3 | 4 | matlab.unittest.Verbosity enumeration

Verbosity levels supported by the plugin instance, specified as an integer value between 1 and 4 or a matlab.unittest.Verbosity enumeration object. The plugin reacts to diagnostics that are logged at this level and lower. Integer values correspond to the members of the matlab.unittest.Verbosity enumeration.

Numeric Representation	Corresponding Enumeration Object	Verbosity Description
1	matlab.unittest.Verbosity.Ter	minimal amount of information

Numeric Representation	Corresponding Enumeration Object	Verbosity Description
2	matlab.unittest.Verbosity.Con	typical amount of information
3	matlab.unittest.Verbosity.Det	supplemental amount of information
4	matlab.unittest.Verbosity.Ver	surplus of information

### **stream** — Location where plugin directs text output

ToStandardOutput instance (default) | OutputStream instance

Location where the plugin directs text output, specified as an OutputStream instance. By default, the plugin uses the OutputStream subclass ToStandardOutput as the stream.

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

### **'Description'** — Logged diagnostic message description

'Diagnostic logged' (default) | string

Logged diagnostic message description, specified as a string. This value is printed alongside each logged diagnostic message. If the value is an empty string, the test framework does not display a description.

### **'ExcludingLowerLevels'** — Indicator to display messages logged at levels lower than the verbosity level

false (default) | true

Indicator to display messages logged at levels lower than the verbosity level, v, specified as false or true (logical(0) or logical(1)). By default, the value is false and the plugin reacts to all messages logged at level v or lower. If the value is true, the plugin reacts only to messages logged at level v.

### **'HideLevel1'** — Indicator to display verbosity level

false (default) | true

Indicator to display the verbosity level alongside each logged diagnostic, specified as `false` or `true` (`logical(0)` or `logical(1)`). By default, the value is `false` and the test framework displays the verbosity level.

**'HideTimestamp' — Indicator to display timestamp**

`false` (default) | `true`

Indicator to display the timestamp from when the test framework generates the logged message alongside each logged diagnostic, specified as `false` or `true` (`logical(0)` or `logical(1)`). By default, the value is `false` and the test framework displays the timestamp.

**'NumStackFrames' — Number of stack frames to display**

0 (default) | integer value | `Inf`

Number of stack frames to display after each logged diagnostic message, specified as an integer value. By default, the value is 0, and the test framework does not display stack information. If `NumStackFrames` is `Inf`, the test framework displays all available stack frames.

## Examples

### Create Logging Plugin

Create a function-based test in a file, `sampleLogTest.m`, in your working folder.

```
function tests = sampleLogTest
tests = functiontests(localfunctions);

function svdTest(testCase)
import matlab.unittest.Verbosity

log(testCase, 'Generating matrix. ');
m = rand(1000);

log(testCase, 1, 'About to call SVD. ');
[U,S,V] = svd(m);

log(testCase, Verbosity.Terse, 'SVD finished. ');

verifyEqual(testCase, U*S*V', m, 'AbsTol', 1e-6)
```

At the command prompt, run the test.

```
results = run(sampleLogTest);

Running sampleLogTest
 [Terse] Diagnostic logged (2014-04-14T14:20:59): About to call SVD.
 [Terse] Diagnostic logged (2014-04-14T14:20:59): SVD finished.
.
Done sampleLogTest
```

The default runner reports the diagnostics at level 1 (Terse).

Create a test runner to report the diagnostics at levels 1 and 2, and rerun the test.

```
import matlab.unittest.TestRunner
import matlab.unittest.plugins.LoggingPlugin

runner = TestRunner.withNoPlugins;
p = LoggingPlugin.withVerbosity(2);
runner.addPlugin(p);

results = runner.run(sampleLogTest);

[Concise] Diagnostic logged (2014-04-14T14:28:14): Generating matrix.
 [Terse] Diagnostic logged (2014-04-14T14:28:14): About to call SVD.
 [Terse] Diagnostic logged (2014-04-14T14:28:15): SVD finished.
```

## Configure Logged Message Output

Create the following class In a file in your current working folder, `ExampleLogTest.m`.

```
classdef ExampleLogTest < matlab.unittest.TestCase
 methods(Test)
 function testOne(testCase) % Test fails
 log(testCase,3,'Starting Test')
 log(testCase,'Testing 5==4')
 testCase.verifyEqual(5,4)
 log(testCase,4,'Test Complete')
 end
 function testTwo(testCase) % Test passes
 log(testCase,matlab.unittest.Verbosity.Detailed,'Starting Test')
 log(testCase,'Testing 5==5')
 testCase.verifyEqual(5,5)
 log(testCase,matlab.unittest.Verbosity.Verbose,'Test Complete')
```

```
 end
 end
end
```

The log messages in `testTwo` uses `Verbosity` enumerations instead of the corresponding integers.

At the command prompt, create the test suite and a runner at verbosity level 4, and then run the test.

```
import matlab.unittest.TestSuite
import matlab.unittest.TestRunner
import matlab.unittest.plugins.LoggingPlugin
suite = TestSuite.fromClass(?ExampleLogTest);
```

```
runner = TestRunner.withNoPlugins;
p = LoggingPlugin.withVerbosity(4);
runner.addPlugin(p);
```

```
results = runner.run(suite);
```

```
[Detailed] Diagnostic logged (2014-04-14T15:24:03): Starting Test
[Concise] Diagnostic logged (2014-04-14T15:24:03): Testing 5==4
[Verbose] Diagnostic logged (2014-04-14T15:24:03): Test Complete
[Detailed] Diagnostic logged (2014-04-14T15:24:03): Starting Test
[Concise] Diagnostic logged (2014-04-14T15:24:03): Testing 5==5
[Verbose] Diagnostic logged (2014-04-14T15:24:03): Test Complete
```

Create a new plugin to direct the output to a file, `myOutput.log`, and rerun the tests.

```
import matlab.unittest.plugins.ToFile
outFile = 'myOutput.log';

runner = TestRunner.withNoPlugins;
p = LoggingPlugin.withVerbosity(4,ToFile(outFile));
runner.addPlugin(p);
```

```
results = runner.run(suite);
```

Observe the contents in the file created by the plugin.

```
disp(fileread(outFile))
```

```
[Detailed] Diagnostic logged (2014-04-14T15:27:44): Starting Test
[Concise] Diagnostic logged (2014-04-14T15:27:44): Testing 5==4
```

```
[Verbose] Diagnostic logged (2014-04-14T15:27:44): Test Complete
[Detailed] Diagnostic logged (2014-04-14T15:27:44): Starting Test
[Concise] Diagnostic logged (2014-04-14T15:27:44): Testing 5==5
[Verbose] Diagnostic logged (2014-04-14T15:27:44): Test Complete
```

Create a new plugin that does not display level 4 messages. Do not display the verbosity level or timestamp. Rerun the tests.

```
runner = TestRunner.withNoPlugins;
p = LoggingPlugin.withVerbosity(matlab.unittest.Verbosity.Detailed,...
 'HideLevel',true,'HideTimestamp',true);
runner.addPlugin(p);
```

```
results = runner.run(suite);
```

```
Diagnostic logged: Starting Test
Diagnostic logged: Testing 5==4
Diagnostic logged: Starting Test
Diagnostic logged: Testing 5==5
```

## See Also

# matlab.unittest.plugins.OutputStream class

**Package:** matlab.unittest.plugins

Interface that determines where to send text output

## Description

The `OutputStream` interface is an abstract interface class that you can use as a base class to specify where plugins direct their text output. To create a custom output stream, implement a `print` method that correctly handles the formatted text information the testing framework passes to it. Many text-oriented plugins accept an `OutputStream` to redirect the text they produce in a configurable manner.

## Methods

`print`

Print string to output stream

## Copy Semantics

Handle. To learn how handle classes affect copy operations, see “Copying Objects” in the MATLAB documentation.

## Examples

### Create Custom Output Stream

In a file in your working directory, create a new output stream class in the file `ToFigure.m`. This class allows plugin output to be redirected to a figure.

```
classdef ToFigure < matlab.unittest.plugins.OutputStream
 properties (SetAccess=private)
```

```

 Figure
 end
 properties(Access=private)
 ListBox
 end

```

This class uses two properties. `Figure` is the figure that receives and displays the output. `ListBox` is a handle to the list box that displays the text.

In the same file, add the following methods block.

```

methods
 function print(stream,formatSpec,varargin)
 % Create the figure
 if isempty(stream.Figure) || ~ishghandle(stream.Figure)
 stream.createFigure
 end
 newStr = sprintf(formatSpec,varargin{:});
 oldStr = strjoin(stream.ListBox.String', '\n');

 % Create the full string
 fullStr = [oldStr,newStr];
 fullStrCell = strsplit(fullStr,'\n','CollapseDelimiters',false);

 % Set the string and selection
 stream.ListBox.String = fullStrCell';
 stream.ListBox.Value = numel(fullStrCell);
 drawnow
 end
end

```

You must implement the `print` method for any subclass of `OutputStream`. In this example, the method creates a new figure (if necessary), formats the incoming text, and then adds it to the output stream.

In the same file, add the following methods block containing a helper function to create the figure.

```

methods(Access=private)
 function createFigure(stream)
 stream.Figure = figure(...
 'Name', 'Unit Test Output', ...
 'WindowStyle', 'docked');
 end
end

```

```
 stream.ListBox = uicontrol(...
 'Parent', stream.Figure, ...
 'Style', 'listbox', ...
 'String', {}, ...
 'Units', 'normalized', ...
 'Position', [.05 .05 .9 .9], ...
 'Max', 2, ...
 'FontName', 'Monospaced', ...
 'FontSize', 13);
 end
end
end
```

In an new file in your working folder, create `ExampleTest.m` containing the following test class.

```
classdef ExampleTest < matlab.unittest.TestCase
 methods(Test)
 function testOne(testCase) % Test fails
 testCase.verifyEqual(5, 4, 'Testing 5==4');
 end
 function testTwo(testCase) % Test passes
 testCase.verifyEqual(5, 5, 'Testing 5==5');
 end
 function testThree(testCase)
 % test code
 end
 end
end
```

The `verifyEqual` qualification in `testOne` causes a test failure. The qualifications in `testOne` and `testTwo` include an instance of a `matlab.unittest.diagnostics.StringDiagnostic`.

At the command prompt, create a test suite from the `ExampleTest` class.

```
import matlab.unittest.TestSuite
import matlab.unittest.TestRunner
import matlab.unittest.plugins.DiagnosticsValidationPlugin

suite = TestSuite.fromClass(?ExampleTest);
```

Create a test runner that displays output to the command window.

```
runner = TestRunner.withTextOutput;
```

Create a `DiagnosticsValidationPlugin` that explicitly specifies that its output should go to a figure via the `ToFigure` output stream.

```
plugin = DiagnosticsValidationPlugin(ToFigure);
```

Add the plugin to the `TestRunner` and run the suite.

```
runner.addPlugin(plugin)
result = runner.run(suite);
```

```

Done ExampleTest
```

Failure Summary:

Name	Failed	Incomplete	Reason(s)
ExampleTest/testOne	X		Failed by verification.

Only the test failures produce output to the screen. By default, `TestRunner.withTextOutput` uses a `FailureDiagnosticsPlugin` to display output on the screen.

In addition to the default text output being displayed on the screen, the `DiagnosticsValidationPlugin` output is directed to a docked figure. The figure shows the following text.

```

Validation of Test Diagnostic:

Testing 5==4

Validation of Test Diagnostic:

Testing 5==5
```

The `DiagnosticsValidationPlugin` displays the diagnostic information regardless of whether the tests encounter failure conditions.

## See Also

`matlab.unittest.plugins.OutputStream` | `fprintf` |  
`matlab.unittest.plugins`

# print

**Class:** matlab.unittest.plugins.OutputStream

**Package:** matlab.unittest.plugins

Print string to output stream

## Syntax

```
print(stream,formatSpec,A1,...,An)
```

## Description

`print(stream,formatSpec,A1,...,An)` formats the data in arrays `A1,...,An` according to `formatSpec`, and sends the result to the output stream, `stream`. Assign `formatSpec` and `A1,...,An` using the same interface that you use for `sprintf` and `fprintf`.

## Input Arguments

### **stream**

Output stream, specified as an instance of the `OutputStream` class

### **formatSpec**

Format of text in output stream, specified as a string. For information on the construction of `formatSpec` string, see the input argument entry on the `fprintf` or `sprintf` reference pages.

### **A**

Numeric or character arrays, specified as a scalar, vector, matrix, or multidimensional array.

## See Also

`fprintf` | `sprintf`

# matlab.unittest.plugins.StopOnFailuresPlugin class

**Package:** matlab.unittest.plugins

Plugin to debug test failures

## Description

The `StopOnFailuresPlugin` class provides a plugin to help debug test failures. Adding `StopOnFailuresPlugin` to the test runner pauses execution of a test if it encounters a qualification failure or uncaught error and puts MATLAB into debug mode.

If `StopOnFailuresPlugin` encounters a qualification failure or uncaught error in a test, you can use MATLAB debugging commands, such as `dbup`, `dbstep`, `dbcont`, and `dbquit`, to investigate the cause of the test failure.

If `StopOnFailuresPlugin` encounters an uncaught error in a test, you cannot use `dbup` to shift context to the source of the error because the error disrupts the stack.

## Construction

`matlab.unittest.plugins.StopOnFailuresPlugin` creates a plugin to debug test failures.

`matlab.unittest.plugins.StopOnFailuresPlugin('IncludingAssumptionFailures', tf)` indicates whether to react to assumption failures. By default, `StopOnFailuresPlugin` reacts to only uncaught errors and verification, assertion, and fatal assertion qualification errors. However, when `'IncludingAssumptionFailures'` is set to `true`, the plugin also reacts to assumption failures.

## Input Arguments

**tf** — Indicator to react to assumption failures

FALSE (default) | TRUE

Indicator to react to assumption failures, specified as logical `false` or `true`. When this value is `true`, the test runner reacts to assumption failures. When the value is `false`, the plugin ignores assumption failures.

## Properties

### IncludeAssumptionFailures

When this property value is `true`, the instance reacts to assumption failures. When the value is `false`, the instance ignores assumption failures. The `IncludeAssumptionFailures` property is `false` by default. To specify the property as `true`, use the `InlcudingAssumptionFailures` input when you construct the instance.

## Copy Semantics

Handle. To learn how handle classes affect copy operations, see “Copying Objects” in the MATLAB documentation.

## Examples

### Add Plugin to TestRunner

In your working folder, create the file `ExampleTest.m` containing the following test class.

```
classdef ExampleTest < matlab.unittest.TestCase
 methods(Test)
 function testOne(testCase) % Test fails
 act = 3.1416;
 exp = pi;
 testCase.verifyEqual(act, exp)
 end
 function testTwo(testCase) % Test does not complete
 testCase.assertEqual(5, 4)
 end
 end
end
```

At the command prompt, create a test suite from the `ExampleTest` class and a test runner.

```
import matlab.unittest.TestRunner
import matlab.unittest.TestSuite
import matlab.unittest.plugins.StopOnFailuresPlugin
```

```
suite = TestSuite.fromClass(?ExampleTest);
runner = TestRunner.withTextOutput;
```

Run the tests.

```
result = runner.run(suite);
```

Running ExampleTest

```

## matlab.unittest.plugins.TAPPlugin class

**Package:** matlab.unittest.plugins

Plugin that produces Test Anything Protocol stream

### Description

The `TAPPlugin` creates a plugin that produces a Test Anything Protocol (TAP) stream. Using this plugin, you can integrate MATLAB Unit Test results into third-party systems that recognize the TAP protocol. For example, you can integrate test results with continuous integration systems like Jenkins™ or TeamCity®.

### Construction

`matlab.unittest.plugins.TAPPlugin.producingOriginalFormat` creates a plugin that produces output in the form of the original TAP format (version 12). By default, the plugin displays the output to the screen. In this case, other output sent to the screen can invalidate the TAP stream. To avoid this, redirect the output to a different output stream, such as the `ToFile` stream.

`matlab.unittest.plugins.TAPPlugin.producingOriginalFormat(stream)` redirects all the text output to the output stream, `stream`. If you do not specify the output stream, the plugin uses the `ToStandardOutput` stream.

### Input Arguments

**stream**

Location where the plugin directs text output, specified as an `OutputStream`.

**Default:** `ToStandardOutput`

### Copy Semantics

Handle. To learn how handle classes affect copy operations, see “Copying Objects” in the MATLAB documentation.

## Examples

### Create TAP Plugin

In a new file in your working folder, create `ExampleTest.m` containing the following test class.

```
classdef ExampleTest < matlab.unittest.TestCase
 methods(Test)
 function testOne(testCase) % Test fails
 testCase.verifyEqual(5, 4, 'Testing 5==4')
 end
 function testTwo(testCase) % Test passes
 testCase.verifyEqual(5, 5, 'Testing 5==5')
 end
 function testThree(testCase)
 % test code
 end
 end
end
```

At the command prompt, create a test suite from the `ExampleTest` class.

```
import matlab.unittest.TestRunner
import matlab.unittest.TestSuite
import matlab.unittest.plugins.TAPPlugin
import matlab.unittest.plugins.ToFile
```

```
suite = TestSuite.fromClass(?ExampleTest);
```

Create a test runner that displays output to the command window using the default plugin.

```
runner = TestRunner.withTextOutput;
```

Create a `TAPPlugin` that explicitly specifies that its output should go to the file `MyTapOutput.tap`.

```
tapFile = 'MyTAPOutput.tap';
plugin = TAPPlugin.producingOriginalFormat(ToFile(tapFile));
```

Add the plugin to the `TestRunner` and run the suite.

```
runner.addPlugin(plugin)
```

```
result = runner.run(suite);
```

```
Running ExampleTest
```

```
=====
Verification failed in ExampleTest/testOne.
```

```

Test Diagnostic:

Testing 5==4
```

```

Framework Diagnostic:

verifyEqual failed.
--> The values are not equal using "isequaln".
--> Failure table:
```

Index	Actual	Expected	Error	RelativeError
1	5	4	1	0.25

```

## matlab.unittest.plugins.ToFile class

**Package:** matlab.unittest.plugins

**Superclasses:** matlab.unittest.plugins.OutputStream

Output stream to write text output to file

### Description

The `ToFile` class creates an output stream that writes text output to a file. Whenever text prints to this stream, the output stream opens the file, appends the text, and closes the file.

### Construction

`matlab.unittest.plugins.ToFile(fname)` creates an `OutputStream` that writes text output to the file, `fname`.

### Input Arguments

#### **fname**

Name of file to write the output text, specified as a string. If `fname` exists, the text from the stream is appended to the file.

### Properties

#### **Filename**

Name of file to redirect text output from the plugin, specified in the input argument, `fname`.

### Copy Semantics

Handle. To learn how handle classes affect copy operations, see “Copying Objects” in the MATLAB documentation.

## Examples

### Direct TAPPlugin Output Text to Separate File

In your working folder, create the file `ExampleTest.m` containing the following test class.

```
classdef ExampleTest < matlab.unittest.TestCase
 methods(Test)
 function testOne(testCase) % Test fails
 testCase.verifyEqual(5, 4, 'Testing 5==4')
 end
 function testTwo(testCase) % Test passes
 testCase.verifyEqual(5, 5, 'Testing 5==5')
 end
 function testThree(testCase)
 % test code
 end
 end
end
```

The `verifyEqual` qualification in `testOne` causes a test failure. The qualifications in `testOne` and `testTwo` include an instance of a `matlab.unittest.diagnostics.StringDiagnostic`.

At the command prompt, create a test suite from the `ExampleTest` class.

```
import matlab.unittest.TestRunner
import matlab.unittest.TestSuite
import matlab.unittest.plugins.TAPPlugin
import matlab.unittest.plugins.ToFile

suite = TestSuite.fromClass(?ExampleTest);
```

Create a test runner that displays output to the command window.

```
runner = TestRunner.withTextOutput;
```

Create a `TAPPlugin` that explicitly specifies that its output should go to the file, `MyTapOutput.tap`.

```
filename = 'MyTapOutput.tap';
plugin = TAPPlugin.producingOriginalFormat(ToFile(filename));
```

Add the plugin to the TestRunner and run the suite.

```
runner.addPlugin(plugin)
result = runner.run(suite);
```

Running ExampleTest

```

`matlab.unittest.plugins`

# matlab.unittest.plugins.ToStandardOutput class

**Package:** matlab.unittest.plugins

**Superclasses:** matlab.unittest.plugins.OutputStream

Output stream to display text information to screen

## Description

The `ToStandardOutput` class creates an output stream to display text output to the screen. Many plugins that accept an output stream use `ToStandardOutput` as their default stream.

## Construction

`matlab.unittest.plugins.ToStandardOutput` creates an `OutputStream` that prints text output to the screen.

## Copy Semantics

Handle. To learn how handle classes affect copy operations, see “Copying Objects” in the MATLAB documentation.

## Examples

### Direct Plugin Output Text to Standard Output

In your working folder, create the file `ExampleTest.m` containing the following test class.

```
classdef ExampleTest < matlab.unittest.TestCase
 methods(Test)
 function testOne(testCase) % Test fails
 testCase.verifyEqual(5, 4, 'Testing 5==4')
 end
 end
end
```

```

 function testTwo(testCase) % Test passes
 testCase.verifyEqual(5, 5, 'Testing 5==5')
 end
 function testThree(testCase)
 % test code
 end
 end
end
end

```

The `verifyEqual` qualification in `testOne` causes a test failure. The qualifications in `testOne` and `testTwo` include an instance of a `matlab.unittest.diagnostics.StringDiagnostic`.

At the command prompt, create a test suite from the `ExampleTest` class.

```

import matlab.unittest.TestRunner
import matlab.unittest.TestSuite
import matlab.unittest.plugins.FailureDiagnosticsPlugin
import matlab.unittest.plugins.ToStandardOutput

```

```

suite = TestSuite.fromClass(?ExampleTest);

```

Create a test runner with no plugins. This code creates a silent runner and provides you with complete control over the installed plugins.

```

runner = TestRunner.withNoPlugins;

```

Create a `FailureDiagnosticsPlugin` that explicitly specifies that its output should go to the screen.

```

plugin = FailureDiagnosticsPlugin(ToStandardOutput);

```

Add the plugin to the `TestRunner` and run the suite.

```

runner.addPlugin(plugin)
result = runner.run(suite);

```

```

matlab.unittest.plugins

# matlab.unittest.plugins.TestRunnerPlugin class

**Package:** matlab.unittest.plugins

Plugin interface for extending TestRunner

## Description

The `TestRunnerPlugin` interface enables extension of the `matlab.unittest.TestRunner`. To customize a test run, create a subclass of `TestRunnerPlugin` and override select methods. `TestRunnerPlugin` provides you with a default implementation, so override only methods necessary to achieve your required customization. Every method you implement must invoke its corresponding superclass method, passing along the same instance of `pluginData` that it receives.

To run tests with this extension, add the custom `TestRunnerPlugin` to the `TestRunner` using the `addPlugin` method of `TestRunner`.

## Methods

<code>runTestSuite</code>	Extend running of TestSuite array
<code>createSharedTestFixture</code>	Extend creation of shared test fixture instances
<code>setupSharedTestFixture</code>	Extend setting up shared test fixture
<code>runTestClass</code>	Extend running of TestSuite array from same class or function
<code>createTestClassInstance</code>	Extend creation of class-level TestCase instances
<code>setupTestClass</code>	Extend setting up test class

<code>runTest</code>	Extend running of single <code>TestSuite</code> element
<code>createTestMethodInstance</code>	Extend creation of method-level <code>TestCase</code> instances
<code>setupTestMethod</code>	Extend setting up of test method
<code>runTestMethod</code>	Extend running of single <code>Test</code> method
<code>teardownTestMethod</code>	Extend tearing down of test method
<code>teardownTestClass</code>	Extend tearing down of test class
<code>teardownSharedTestFixture</code>	Extend tearing down shared test fixture

## Copy Semantics

Handle. To learn how handle classes affect copy operations, see “Copying Objects” in the MATLAB documentation.

# runTestSuite

**Class:** matlab.unittest.plugins.TestRunnerPlugin

**Package:** matlab.unittest.plugins

Extend running of TestSuite array

## Syntax

```
runTestSuite(plugin,pluginData)
```

## Description

`runTestSuite(plugin,pluginData)` extends the running of the original `TestSuite` array that the test framework hands to the `TestRunner`.

## Input Arguments

### **plugin**

Instance of `matlab.unittest.plugins.TestRunnerPlugin`.

### **pluginData**

Test suite information, specified as an instance of `matlab.unittest.plugins.plugindata.TestSuiteRunPluginData`. The test framework uses this information to introspect into the test content.

## Examples

### Implement runTestSuite Method

```
classdef ExamplePlugin < matlab.unittest.plugins.TestRunnerPlugin
 methods (Access = protected)
 function runTestSuite(plugin, pluginData)
```

```
% Introspect into pluginData to get TestSuite size
suiteSize = numel(pluginData.TestSuite);
fprintf('### Running a total of %d tests\n', suiteSize)

% Invoke the super class method
runTestSuite@matlab.unittest.plugins.TestRunnerPlugin(plugin, pluginData)
end
end
end
```

matlab.unittest.plugins.pluginData.TestSuiteRunPluginData |  
matlab.unittest.TestResult

# createSharedTestFixture

**Class:** matlab.unittest.plugins.TestRunnerPlugin

**Package:** matlab.unittest.plugins

Extend creation of shared test fixture instances

## Syntax

```
f = createSharedTestFixture(plugin,pluginData)
```

## Description

`f = createSharedTestFixture(plugin,pluginData)` extends the creation of shared test fixtures and returns the modified `Fixture` instance, `f`. The testing framework uses the fixture instance to customize running tests that use shared fixtures. The testing framework evaluates this method within the scope of the `runTestSuite` method of the `TestRunnerPlugin` for each shared test fixture it needs to set up. A typical implementation of this method is to add listeners to various events originating from the shared test fixture instance. Since the `Fixture` inherits from the `handle` class, add listeners by calling the `addlistener` method from within the `createSharedTestFixture` method.

## Input Arguments

### **plugin**

Instance of `matlab.unittest.plugins.TestRunnerPlugin`.

### **pluginData**

Shared test fixture creation information, specified as an instance of `matlab.unittest.plugins.pluginData.PluginData`. The test framework uses this information to introspect into the test content.

## Examples

### Extend Creation of Shared Test Fixture Instances

Extend the running of tests to count the number of shared test fixture assertion failures.

```
classdef ExamplePlugin < matlab.unittest.plugins.TestRunnerPlugin

 properties (SetAccess = private)
 FixtureAssertionFailureData = {};
 end

 methods (Access = protected)
 function fixture = createSharedTestFixture(plugin, pluginData)
 % Invoke the super class method
 fixture = createSharedTestFixture@...
 matlab.unittest.plugins.TestRunnerPlugin(plugin, pluginData);

 % Get the fixture name
 fixtureName = pluginData.Name;

 % Add a listener to fixture assertion failures
 % and capture the qualification failure information
 fixture.addListener('AssertionFailed', @(~,evd) ...
 plugin.captureFixtureAssertionFailureData(evd, fixtureName))
 end
 end

 methods (Access = private)
 function captureFixtureAssertionFailureData(plugin, eventData, fixtureName)
 plugin.FixtureAssertionFailureData{end+1} = struct(...
 'FixtureName', fixtureName, ...
 'ActualValue', eventData.ActualValue, ...
 'Constraint', eventData.Constraint, ...
 'Stack', eventData.Stack);
 end
 end
end
```

## setupSharedTestFixture

**Class:** matlab.unittest.plugins.TestRunnerPlugin

**Package:** matlab.unittest.plugins

Extend setting up shared test fixture

### Syntax

```
setupSharedTestFixture(plugin,pluginData)
```

### Description

`setupSharedTestFixture(plugin,pluginData)` extends the setting up of a shared test fixture. This method defines how the `TestRunner` performs shared fixture setup. The test framework evaluates this method one time for each shared test fixture, within the scope of the `runTestSuite` method of the `TestRunnerPlugin`.

### Input Arguments

#### **plugin**

Instance of `matlab.unittest.plugins.TestRunnerPlugin`.

#### **pluginData**

Shared test fixture setup information, specified as an instance of `matlab.unittest.plugins.plugindata.SharedTestFixturePluginData`. The test framework uses this information to introspect into the test content.

### Examples

#### **Implement setupSharedTestFixture Method**

Display the shared test fixture name at setup time.

```
classdef ExamplePlugin < matlab.unittest.plugins.TestRunnerPlugin

 methods (Access = protected)
 function setupSharedTestFixture(plugin, pluginData)
 fprintf('### Setting up: %s\n', pluginData.Name)
 setupSharedTestFixture@matlab.unittest.plugins.TestRunnerPlugin...
 (plugin, pluginData);
 end
 end
end
```

createSharedTestFixture

## runTestClass

**Class:** matlab.unittest.plugins.TestRunnerPlugin

**Package:** matlab.unittest.plugins

Extend running of TestSuite array from same class or function

### Syntax

```
runTestClass(plugin,pluginData)
```

### Description

`runTestClass(plugin,pluginData)` extends the running of tests that belong to the same test class, function, or script. This method applies to a subset of the full `TestSuite` being run by the `TestRunner`. The test framework evaluates this method within the scope of the `runTestSuite` method of the `TestRunnerPlugin`. It evaluates this method between setting up and tearing down the shared test fixture (`setupSharedTestFixture` and `teardownSharedTestFixture`). Provided the test framework completes shared test fixture setup, it invokes this method one time per test class.

### Input Arguments

**plugin**

Instance of `matlab.unittest.plugins.TestRunnerPlugin`.

**pluginData**

Test suite information, specified as an instance of `matlab.unittest.plugins.pluginData.TestSuiteRunPluginData`. The test framework uses this information to introspect into the test content.

## Examples

### Extend runTestClass method

Print the label of the test content element at run time.

```
classdef ExamplePlugin < matlab.unittest.plugins.TestRunnerPlugin
 methods (Access = protected)
 function runTestClass(plugin, pluginData)
 fprintf('### Running test class: %s\n', pluginData.Name)

 runTestClass@matlab.unittest.plugins.TestRunnerPlugin(...
 plugin, pluginData);
 end
 end
end
```

matlab.unittest.TestResult

## createTestClassInstance

**Class:** matlab.unittest.plugins.TestRunnerPlugin

**Package:** matlab.unittest.plugins

Extend creation of class-level `TestCase` instances

### Syntax

```
tc = createTestClassInstance(plugin,pluginData)
```

### Description

`tc = createTestClassInstance(plugin,pluginData)` extends the creation of class-level `TestCase` instances, and returns the modified `TestCase` instance, `tc`. The test framework uses the `TestCase` instance to customize running tests that belong to the same test class. The test framework evaluates this method within the scope of the `runTestClass` method of the `TestRunnerPlugin`. A typical implementation of this method is to add listeners to various events originating from the class level instance. Since the `TestCase` inherits from the `handle` class, add listeners by calling the `addListener` method from within the `createTestClassInstance` method. For each class, the test framework passes the instance to any method with the `TestClassSetup` or `TestClassTeardown` attribute.

### Input Arguments

#### **plugin**

Instance of `matlab.unittest.plugins.TestRunnerPlugin`.

#### **pluginData**

Class-level `TestCase` creation information, specified as an instance of `matlab.unittest.plugins.pluginData.PluginData`. The test framework uses this information to introspect into the test content.

## Examples

### Extend Creation of Class-Level TestCase Instances

Extend the running of tests to count the number of class-level assumption failures.

```
classdef ExamplePlugin < matlab.unittest.plugins.TestRunnerPlugin

 properties (SetAccess = private)
 TestClassAssumptionFailureData = {};
 end

 methods (Access = protected)
 function testCase = createTestClassInstance(plugin,pluginData)
 % Invoke super class method
 testCase = createTestClassInstance@...
 matlab.unittest.plugins.TestRunnerPlugin(plugin,pluginData);

 % Get the test class name
 instanceName = pluginData.Name;

 % Add a listener to capture assumption failures
 testCase.addlistener('AssumptionFailed', @(~,evd) ...
 plugin.captureClassLevelAssumptionFailureData(evd,instanceName))
 end
 end

 methods (Access = private)
 function captureClassLevelAssumptionFailureData(plugin,eventData,instanceName)
 plugin.TestClassAssumptionFailureData{end+1} = struct(...
 'InstanceName', instanceName, ...
 'ActualValue' , eventData.ActualValue, ...
 'Constraint' , eventData.Constraint, ...
 'Stack' , eventData.Stack);
 end
 end
end
```

# setupTestClass

**Class:** matlab.unittest.plugins.TestRunnerPlugin

**Package:** matlab.unittest.plugins

Extend setting up test class

## Syntax

```
setupTestClass(plugin,pluginData)
```

## Description

`setupTestClass(plugin,pluginData)` extends the setting up of a test class. This method defines how the `TestRunner` performs test class setup. The test framework evaluates this method within the scope of the `runTestClass` method of the `TestRunnerPlugin`. If the test class contains properties with the `ClassSetupParameter` attribute, the test framework evaluates the `setupTestClass` method as many times as the class setup parameterization dictates.

## Input Arguments

### **plugin**

Instance of `matlab.unittest.plugins.TestRunnerPlugin`.

### **pluginData**

Test class setup information, specified as an instance of `matlab.unittest.plugins.plugindata.PluginData`. The test framework uses this information to introspect into the test content.

## Examples

### **Implement setupTestClass Method**

Display the test class name at setup time.

```
classdef ExamplePlugin < matlab.unittest.plugins.TestRunnerPlugin

 methods (Access = protected)
 function setupTestClass(plugin, pluginData)
 fprintf('### Setting up: %s\n', pluginData.Name)
 setupTestClass@matlab.unittest.plugins.TestRunnerPlugin...
 (plugin, pluginData);
 end
 end
end
```

matlab.unittest.plugins.plugindata.PluginData |  
createTestClassInstance

# runTest

**Class:** matlab.unittest.plugins.TestRunnerPlugin

**Package:** matlab.unittest.plugins

Extend running of single TestSuite element

## Syntax

```
runTest(plugin,pluginData)
```

## Description

`runTest(plugin,pluginData)` extends the running of a single `TestSuite` element. This method allows the test author to override the method that runs a scalar test element in the `TestSuite` array, including the creation of the `TestCase`, and the `TestMethodSetup` and `TestMethodTeardown` routines. Provided the test framework completes all fixture setup, it invokes this method one time per test element.

## Input Arguments

### **plugin**

Instance of `matlab.unittest.plugins.TestRunnerPlugin`.

### **pluginData**

Test element information, specified as an instance of `matlab.unittest.plugins.plugindata.TestSuiteRunPluginData`. The test framework uses this information to introspect into the test content.

## Examples

### **Extend runTest method**

Print the label of the test content element at run time.

```
classdef ExamplePlugin < matlab.unittest.plugins.TestRunnerPlugin
 methods (Access = protected)
 function runTest(plugin, pluginData)
 fprintf('### Running test: %s\n', pluginData.Name)
 runTest@matlab.unittest.plugins.TestRunnerPlugin(...
 plugin, pluginData);
 end
 end
end
```

- “Write Plugins to Extend TestRunner”
- “Create Custom Plugin”

# createTestMethodInstance

**Class:** matlab.unittest.plugins.TestRunnerPlugin

**Package:** matlab.unittest.plugins

Extend creation of method-level `TestCase` instances

## Syntax

```
tc = createTestMethodInstance(plugin,pluginData)
```

## Description

`tc = createTestMethodInstance(plugin,pluginData)` extends the creation of method-level `TestCase` instances, and returns the modified `TestCase` instance, `tc`. The test framework evaluates this method within the scope of the `runTest` method of the `TestRunnerPlugin`. A typical implementation of this method is to add listeners to various events originating from the method level instance. Since the `TestCase` inherits from the `handle` class, add listeners by calling the `addlistener` method from within the `createTestMethodInstance` method. The test framework creates instances for every element of the `matlab.unittest.Test` array and passes each instance to its corresponding `Test` methods and to any method with the `TestMethodSetup` or `TestMethodTeardown` attribute.

## Input Arguments

### **plugin**

Instance of `matlab.unittest.plugins.TestRunnerPlugin`.

### **pluginData**

Method-level `TestCase` creation information, specified as an instance of `matlab.unittest.plugins.pluginData.PluginData`. The test framework uses this information to introspect into the test content.

## Examples

### Implement createMethodInstance Method

Add a listener to listen for assumption failures. Use the helper function, `captureMethodLevelAssumptionFailureData`, to populate the `TestMethodAssumptionFailureData` property.

```
classdef ExamplePlugin < matlab.unittest.plugins.TestRunnerPlugin

 properties (SetAccess = private)
 TestMethodAssumptionFailureData = {};
 end

 methods (Access = protected)
 function testCase = createTestMethodInstance(plugin, pluginData)
 testCase = createTestMethodInstance@...
 matlab.unittest.plugins.TestRunnerPlugin(plugin, pluginData);

 instanceName = pluginData.Name;
 testCase.addListener('AssumptionFailed', @(~,evd) ...
 plugin.captureMethodLevelAssumptionFailureData(evd,instanceName))
 end
 end

 methods (Access = private)
 function captureMethodLevelAssumptionFailureData(...
 plugin, eventData, instanceName)
 plugin.TestMethodAssumptionFailureData{end+1} = struct(...
 'InstanceName', instanceName, ...
 'ActualValue' , eventData.ActualValue, ...
 'Constraint' , eventData.Constraint, ...
 'Stack' , eventData.Stack);
 end
 end
end
```

## setupTestMethod

**Class:** matlab.unittest.plugins.TestRunnerPlugin

**Package:** matlab.unittest.plugins

Extend setting up of test method

### Syntax

```
setupTestMethod(plugin,pluginData)
```

### Description

`setupTestMethod(plugin,pluginData)` extends the setting up of a test method. This method defines how the `TestRunner` performs test method setup for the single test suite element. The test framework evaluates this method within the scope of the `runTest` method of the `TestRunnerPlugin`.

### Input Arguments

#### **plugin**

Instance of `matlab.unittest.plugins.TestRunnerPlugin`.

#### **pluginData**

Test method setup information, specified as an instance of `matlab.unittest.plugins.pluginData.PluginData`. The test framework uses this information to introspect into the test content.

### Examples

#### **Implement setupTestMethod**

```
classdef ExamplePlugin < matlab.unittest.plugins.TestRunnerPlugin
```

```
methods (Access = protected)
 function setupTestMethod(plugin, pluginData)
 fprintf('### Setting up: %s\n', pluginData.Name)
 setupTestMethod@matlab.unittest.plugins.TestRunnerPlugin...
 (plugin, pluginData);
 end
end
end
```

## runTestMethod

**Class:** matlab.unittest.plugins.TestRunnerPlugin

**Package:** matlab.unittest.plugins

Extend running of single Test method

### Syntax

```
runTestMethod(plugin,pluginData)
```

### Description

`runTestMethod(plugin,pluginData)` extends the running of a single `Test` method. The test framework evaluates this method within the scope of the `runTest` method of the `TestRunnerPlugin`. It evaluates this method between setting up and tearing down the scalar `TestSuite` element (`setupTestMethod` and `teardownTestMethod`).

### Input Arguments

#### **plugin**

Instance of `matlab.unittest.plugins.TestRunnerPlugin`.

#### **pluginData**

Test method information, specified as an instance of `matlab.unittest.plugins.plugindata.TestSuiteRunPluginData`. The test framework uses this information to introspect into the test content.

### Examples

#### **Extend runTestMethod method**

Print the time taken to evaluate the test method.

```
classdef ExamplePlugin < matlab.unittest.plugins.TestRunnerPlugin
 methods (Access = protected)
 function runTestMethod(plugin, pluginData)
 tic

 runTestMethod@matlab.unittest.plugins.TestRunnerPlugin(...
 plugin, pluginData);

 fprintf('### %s ran in %f seconds excluding fixture time.',...
 pluginData.Name, toc)
 end
 end
end
```

# teardownTestMethod

**Class:** matlab.unittest.plugins.TestRunnerPlugin

**Package:** matlab.unittest.plugins

Extend tearing down of test method

## Syntax

```
teardownTestMethod(plugin,pluginData)
```

## Description

`teardownTestMethod(plugin,pluginData)` extends the tearing down of a test method. This method defines how the `TestRunner` performs test method teardown for the single test suite element. The test framework evaluates this method within the scope of the `runTest` method of the `TestRunnerPlugin`.

## Input Arguments

### **plugin**

Instance of `matlab.unittest.plugins.TestRunnerPlugin`.

### **pluginData**

Test method teardown information, specified as an instance of `matlab.unittest.plugins.pluginData.PluginData`. The test framework uses this information to introspect into the test content.

## Examples

### **Implement teardownTestMethod Method**

Display the test method name at teardown time.

```
classdef ExamplePlugin < matlab.unittest.plugins.TestRunnerPlugin
 methods (Access = protected)
 function teardownTestMethod(plugin, pluginData)
 fprintf('### Tearing down: %s\n', pluginData.Name)
 teardownTestMethod@matlab.unittest.plugins.TestRunnerPlugin...
 (plugin, pluginData);
 end
 end
end
```

## teardownTestClass

**Class:** matlab.unittest.plugins.TestRunnerPlugin

**Package:** matlab.unittest.plugins

Extend tearing down of test class

### Syntax

```
teardownTestClass(plugin,pluginData)
```

### Description

`teardownTestClass(plugin,pluginData)` extends the tearing down of a test class. This method defines how the `TestRunner` performs test class teardown. The test framework evaluates this method within the scope of the `runTestClass` method of the `TestRunnerPlugin`. If the test class contains properties with the `ClassSetupParameter` attribute, the test framework evaluates the `teardownTestClass` method as many times as the class setup parameterization dictates.

### Input Arguments

#### **plugin**

Instance of `matlab.unittest.plugins.TestRunnerPlugin`.

#### **pluginData**

Test class teardown information, specified as an instance of `matlab.unittest.plugins.pluginData.PluginData`. The test framework uses this information to introspect into the test content.

## Examples

### Implement `teardownTestClass` Method

Display the test class name at teardown time.

```
classdef ExamplePlugin < matlab.unittest.plugins.TestRunnerPlugin

 methods (Access = protected)
 function teardownTestClass(plugin, pluginData)
 fprintf('### Tearing down: %s\n', pluginData.Name)
 teardownTestClass@matlab.unittest.plugins.TestRunnerPlugin...
 (plugin, pluginData);
 end
 end
end
```

- “Write Plugins to Extend TestRunner”
- “Create Custom Plugin”

## teardownSharedTestFixture

**Class:** matlab.unittest.plugins.TestRunnerPlugin

**Package:** matlab.unittest.plugins

Extend tearing down shared test fixture

### Syntax

```
teardownSharedTestFixture(plugin,pluginData)
```

### Description

`teardownSharedTestFixture(plugin,pluginData)` extends the tearing down of a shared test fixture. This method defines how the `TestRunner` performs shared fixture teardown. The test framework evaluates this method one time for each shared test fixture, within the scope of the `runTestSuite` method of the `TestRunnerPlugin`.

### Input Arguments

#### **plugin**

Instance of `matlab.unittest.plugins.TestRunnerPlugin`.

#### **pluginData**

Shared test fixture teardown information, specified as an instance of `matlab.unittest.plugins.pluginData.SharedTestFixturePluginData`. The test framework uses this information to introspect into the test content.

### Examples

#### **Implement teardownSharedTestFixture Method**

Display the shared test fixture name at teardown time.

```
classdef ExamplePlugin < matlab.unittest.plugins.TestRunnerPlugin

 methods (Access = protected)
 function teardownSharedTestFixture(plugin, pluginData)
 fprintf('### Setting up: %s\n', pluginData.Name)
 teardownSharedTestFixture@matlab.unittest.plugins.TestRunnerPlugin...
 (plugin, pluginData);
 end
 end
end
```

createSharedTestFixture

# matlab.unittest.plugins.TestRunProgressPlugin class

**Package:** matlab.unittest.plugins

Plugin that reports test run progress

## Description

The `TestRunProgressPlugin` creates a plugin that reports on test run progress.

## Construction

`matlab.unittest.plugins.TestRunProgressPlugin.withVerbosity(v)` constructs a `TestRunProgressPlugin` for the specified verbosity.

`matlab.unittest.plugins.TestRunProgressPlugin.withVerbosity(v, stream)` redirects the text output to the output stream.

## Input Arguments

**v** — Verbosity level

1 | 2 | 3 | 4 | `matlab.unittest.Verbosity` enumeration

Verbosity level, specified as an integer value between 1 and 4 or a `matlab.unittest.Verbosity` enumeration object. Integer values correspond to the members of the `matlab.unittest.Verbosity` enumeration.

Numeric Representation	Corresponding Enumeration Object	Verbosity Description
1	<code>matlab.unittest.Verbosity.Ter</code>	Minimal amount of information
2	<code>matlab.unittest.Verbosity.Con</code>	Typical amount of information
3	<code>matlab.unittest.Verbosity.Det</code>	Supplemental amount of information
4	<code>matlab.unittest.Verbosity.Ver</code>	Surplus of information

**stream — Location where plugin directs text output**

ToStandardOutput instance (default) | OutputStream instance

Location where the plugin directs text output, specified as an `OutputStream` instance. By default, the plugin uses the `OutputStream` subclass `ToStandardOutput` as the stream.

## Copy Semantics

Handle. To learn how handle classes affect copy operations, see “Copying Objects” in the MATLAB documentation.

## Examples

### Create Test Run Progress Plugin

Create a function-based test called `cylinderPlotTest` in a file in your working folder.

```
function tests = cylinderPlotTest
tests = functiontests(localfunctions);
end

function setupOnce(testCase)
testCase.TestData.Figure = figure;
addTeardown(testCase,@close,testCase.TestData.Figure)
end

function setup(testCase)
testCase.TestData.Axes = axes('Parent',testCase.TestData.Figure);
addTeardown(testCase,@clf,testCase.TestData.Figure)
cylinder(testCase.TestData.Axes,10)
end

function testXLim(testCase)
xlim = testCase.TestData.Axes.XLim;
verifyLessThanOrEqual(testCase,xlim(1),-10,'Minimum x-limit too large')
verifyGreaterThanOrEqual(testCase,xlim(2),10,'Maximum x-limit too small')
end
```

```
function zdataTest(testCase)
s = findobj(testCase.TestData.Axes, 'Type', 'surface');
verifyEqual(testCase, min(s.ZData(:)), 0, 'Min cylinder value is incorrect')
verifyEqual(testCase, max(s.ZData(:)), 1, 'Max cylinder value is incorrect')
end
```

At the command prompt, run the test.

```
results = run(cylinderPlotTest);
```

```
Running cylinderPlotTest
..
Done cylinderPlotTest
```

---

By default, the test runner uses verbosity level 2.

Create a test runner to report the diagnostics at level 1, and rerun the test.

```
import matlab.unittest.TestRunner
import matlab.unittest.plugins.TestRunProgressPlugin

runner = TestRunner.withNoPlugins;
p = TestRunProgressPlugin.withVerbosity(1);
runner.addPlugin(p);

results = runner.run(cylinderPlotTest);

..
```

Create a test runner to report the diagnostics at level 4, and rerun the test.

```
runner = TestRunner.withNoPlugins;
p = TestRunProgressPlugin.withVerbosity(4);
runner.addPlugin(p);

results = runner.run(cylinderPlotTest);

Running cylinderPlotTest
Setting up cylinderPlotTest
Evaluating TestClassSetup: setupOnce
Done setting up cylinderPlotTest in 0.067649 seconds
Running cylinderPlotTest/testXLim
Evaluating TestMethodSetup: setup
Evaluating Test: testXLim
Evaluating TestMethodTeardown: teardown
```

```

 Evaluating addTeardown function: clf
Done cylinderPlotTest/testXLim in 0.053834 seconds
Running cylinderPlotTest/zdataTest
 Evaluating TestMethodSetup: setup
 Evaluating Test: zdataTest
 Evaluating TestMethodTeardown: teardown
 Evaluating addTeardown function: clf
Done cylinderPlotTest/zdataTest in 0.037715 seconds
Tearing down cylinderPlotTest
 Evaluating TestClassTeardown: teardownOnce
 Evaluating addTeardown function: close
Done tearing down cylinderPlotTest in 0.022783 seconds
Done cylinderPlotTest in 0.18198 seconds

```

### Configure Progress Message Output

Create a class named `ExampleProgressTest` in a file in your current working folder.

```

classdef ExampleProgressTest < matlab.unittest.TestCase
 methods(Test)
 function testOne(testCase) % Test fails
 testCase.verifyEqual(5,4)
 end
 function testTwo(testCase) % Test passes
 testCase.verifyEqual(5,5)
 end
 end
end
end

```

At the command prompt, create the test suite and a runner at verbosity level 3, and then run the test.

```

import matlab.unittest.TestSuite
import matlab.unittest.TestRunner
import matlab.unittest.plugins.TestRunProgressPlugin

suite = TestSuite.fromClass(?ExampleProgressTest);

runner = TestRunner.withNoPlugins;
p = TestRunProgressPlugin.withVerbosity(3);
runner.addPlugin(p);
results = runner.run(suite);

Running ExampleProgressTest

```

```
Setting up ExampleProgressTest
Done setting up ExampleProgressTest in 0 seconds
Running ExampleProgressTest/testOne
Done ExampleProgressTest/testOne in 0.0049988 seconds
Running ExampleProgressTest/testTwo
Done ExampleProgressTest/testTwo in 0.0044541 seconds
Tearing down ExampleProgressTest
Done tearing down ExampleProgressTest in 0 seconds
Done ExampleProgressTest in 0.0094529 seconds
```

---

Create a new plugin to direct the output to a file named `myOutput.log`, and rerun the tests.

```
import matlab.unittest.plugins.ToFile
outFile = 'myOutput.log';

runner = TestRunner.withNoPlugins;
p = TestRunProgressPlugin.withVerbosity(3,ToFile(outFile));
runner.addPlugin(p);

results = runner.run(suite);
```

Observe the contents of the file created by the plugin.

```
disp(fileread(outFile))
```

```
Running ExampleProgressTest
Setting up ExampleProgressTest
Done setting up ExampleProgressTest in 0 seconds
Running ExampleProgressTest/testOne
Done ExampleProgressTest/testOne in 0.0050172 seconds
Running ExampleProgressTest/testTwo
Done ExampleProgressTest/testTwo in 0.0049449 seconds
Tearing down ExampleProgressTest
Done tearing down ExampleProgressTest in 0 seconds
Done ExampleProgressTest in 0.009962 seconds
```

---

| `matlab.unittest.plugins.OutputStream` |  
`matlab.unittest.plugins.ToStandardOutput` | `matlab.unittest.Verbosity`

# matlab.unittest.plugins.TestSuiteProgressPlugin class

**Package:** matlab.unittest.plugins

(Not recommended) Plugin that outputs progress information as text

---

**Note:** `TestSuiteProgressPlugin` is not recommended. Use `TestRunProgressPlugin` instead. To construct a plugin with the same level of detail, use `TestRunProgressPlugin.withVerbosity(2)`.

---

## Description

The `TestSuiteProgressPlugin` class creates a plugin to output progress information as text. `TestSuiteProgressPlugin` is added to the `TestRunner` to show the progress of the testing to the Command Window. This plugin is used by default when you construct a test runner with `TestRunner.withTextOutput`.

## Construction

`matlab.unittest.plugins.TestSuiteProgressPlugin` creates a plugin to output progress information as text.

`matlab.unittest.plugins.TestSuiteProgressPlugin(stream)` redirects all the text output to the output stream, `stream`. If you do not specify the output stream, the plugin uses the `ToStandardOutput` stream.

## Input Arguments

**stream**

Location where the plugin directs text output, specified as an `OutputStream`.

**Default:** `ToStandardOutput`

## Copy Semantics

Handle. To learn how handle classes affect copy operations, see “Copying Objects” in the MATLAB documentation.

## Examples

### Add Plugin to TestRunner

In your working folder, create the file `ExampleTest.m` containing the following test class.

```
classdef ExampleTest < matlab.unittest.TestCase
 methods(Test)
 function testOne(testCase)
 % test code
 end
 function testTwo(testCase) % Test fails
 % test code
 end
 function testThree(testCase) % Test passes
 % test code
 end
 end
end
```

At the command prompt, create a test suite from the `ExampleTest` class.

```
import matlab.unittest.TestRunner
import matlab.unittest.TestSuite
import matlab.unittest.plugins.TestSuiteProgressPlugin

suite = TestSuite.fromClass(?ExampleTest);
```

Create a test runner with no plugins. This code creates a silent runner and provides you with complete control over the installed plugins.

```
runner = TestRunner.withNoPlugins;
```

Run the tests.

```
result1 = runner.run(suite);
```

No output is displayed.

Add `TestSuiteProgressPlugin` to the runner and run the tests.

```
runner.addPlugin(TestSuiteProgressPlugin)
result2 = runner.run(suite);
```

```
Running ExampleTest
```

```
...
```

```
Done ExampleTest
```

---

# matlab.unittest.plugins.plugindata

Summary of classes in MATLAB Plugin Data Interface

## Description

The `plugindata` classes store information about test content for use by the plugins and plugin methods. The `TestRunner` passes instances of these classes to various plugin methods. The `matlab.unittest.plugins.plugindata` package consists of the following MATLAB plugin data classes.

- `matlab.unittest.plugins.plugindata.PluginData`  
Data object passed to `TestRunnerPlugin` methods
- `matlab.unittest.plugins.plugindata.SharedTestFixturePluginData`  
Plugin data containing shared test fixture information
- `matlab.unittest.plugins.plugindata.TestSuiteRunPluginData`  
Plugin data containing selected test information

## See Also

`matlab.unittest.plugins | TestRunnerPlugin`

# matlab.unittest.plugins.plugindata.PluginData class

**Package:** matlab.unittest.plugins.plugindata

Data object passed to TestRunnerPlugin methods

## Description

The `PluginData` class defines the data the `TestRunner` passes to various plugin methods. It is created by the `TestRunner`, so there is no need for test plugin authors to construct this class directly.

## Properties

### Name

Label of test content executed by the test runner within the scope of a plugin method, represented as a string. Use the `Name` property for informational, labeling, and display purposes. Do not use `Name` programmatically to introspect into the content.

### See Also

`TestRunnerPlugin`

# matlab.unittest.plugins.plugindata.SharedTestFixturePluginData class

**Package:** matlab.unittest.plugins.plugindata

Plugin data containing shared test fixture information

## Description

The `SharedTestFixturePluginData` defines the data the `TestRunner` passes to plugin methods related to shared test fixtures. The `TestRunner` creates this, so there is no need for test plugin authors to construct this class directly.

## Properties

### Name

Label of shared test fixture, represented as a string. Use the `Name` property for informational, labeling, and display purposes. Do not use `Name` programmatically to introspect into the content.

### Description

Description of action performed during setup and teardown of a shared text fixture, represented as a string

### See Also

matlab.unittest.fixtures.Fixture | TestRunnerPlugin

# matlab.unittest.plugins.plugindata.TestSuiteRunPluginData class

**Package:** matlab.unittest.plugins.plugindata

Plugin data containing selected test information

## Description

The `TestSuiteRunPluginData` defines the data the `TestRunner` passes to plugin methods related to running tests from the suite. The `TestRunner` creates this, so there is no need for test plugin authors to construct this class directly.

## Properties

### Name

Name corresponding to the portion of the test suite the runner executes within a plugin method, represented as a string. Use the `Name` property for informational, labeling, and display purposes. Do not use `Name` programmatically to introspect into the content.

### TestSuite

Select test methods, represented as a `matlab.unittest.TestSuite` instance

### TestResult

Results from running select test methods listed in `TestSuite`, represented as a `matlab.unittest.TestResult` array

## See Also

`matlab.unittest.TestSuite` | `matlab.unittest.TestResult` | `TestRunnerPlugin`

## plus, +

Addition

### Syntax

```
C = A + B
C = plus(A,B)
```

### Description

`C = A + B` adds arrays `A` and `B` and returns the result in `C`.

`C = plus(A,B)` is an alternate way to execute `A + B`, but is rarely used. It enables operator overloading for classes.

### Examples

#### Add Scalar to Array

Create an array, `A`, and add a scalar value to it.

```
A = [0 1; 1 0];
C = A + 2
```

```
C =
```

```
 2 3
 3 2
```

The scalar value is added to each entry of `A`.

#### Add Two Arrays

Create two arrays, `A` and `B`, and add them together.

```
A = [1 0; 2 4];
B = [5 9; 2 1];
```

$$C = A + B$$
$$C =$$
$$\begin{array}{cc} 6 & 9 \\ 4 & 5 \end{array}$$

The elements of **A** are added to the corresponding elements of **B**.

## Input Arguments

### **A** — Input array

scalar | vector | matrix | multidimensional array

Input array, specified as a scalar, vector, matrix, or multidimensional array. **A** can be a numeric array, logical array, character array, datetime array, duration array, or calendar duration array. Inputs **A** and **B** must be the same size unless one is a scalar. You can add a scalar value to any other value.

If one input is a datetime array, duration array, or calendar duration array, then numeric values in the other input are treated as a number of 24-hour days.

Complex Number Support: Yes

### **B** — Input array

scalar | vector | matrix | multidimensional array

Input array, specified as a scalar, vector, matrix, or multidimensional array. **B** can be a numeric array, logical array, character array, datetime array, duration array, or calendar duration array. Inputs **A** and **B** must be the same size unless one is a scalar. You can add a scalar value to any other value.

If one input is a datetime array, duration array, or calendar duration array, then numeric values in the other input are treated as a number of 24-hour days.

Complex Number Support: Yes

## pointLocation

**Class:** DelaunayTri

(Will be removed) Simplex containing specified location

---

**Note:** `pointLocation(DelaunayTri)` will be removed in a future release. Use `pointLocation(triangulation)` instead.

`DelaunayTri` will be removed in a future release. Use `delaunayTriangulation` instead.

---

## Syntax

```
SI = pointLocation(DT,QX)
SI = pointLocation(DT,QX,QY)
SI = pointLocation(DT,QX,QY,QZ)
[SI, BC] = pointLocation(DT,...)
```

## Description

`SI = pointLocation(DT,QX)` returns the indices `SI` of the enclosing simplex (triangle/tetrahedron) for each query point location in `QX`. The enclosing simplex for point `QX(k,:)` is `SI(k)`. `pointLocation` returns `NaN` for all points outside the convex hull.

`SI = pointLocation(DT,QX,QY)` and `SI = pointLocation(DT,QX,QY,QZ)` allow the query point locations to be specified in alternative column vector format when working in 2-D and 3-D.

`[SI, BC] = pointLocation(DT,...)` returns the barycentric coordinates `BC`.

## Input Arguments

`DT` Delaunay triangulation.

**QX** Matrix of size `mpts-by-ndim`, `mpts` being the number of query points.

## Output Arguments

**SI** Column vector of length `mpts` containing the indices of the enclosing simplex for each query point. `mpts` is the number of query points.

**BC** `BC` is a `mpts-by-ndim` matrix, each row `BC(i,:)` represents the barycentric coordinates of `QX(i,:)` with respect to the enclosing simplex `SI(i)`.

## Examples

### Example 1

Create a 2-D Delaunay triangulation:

```
X = rand(10,2);
dt = DelaunayTri(X);
```

Find the triangles that contain specified query points:

```
qrypts = [0.25 0.25; 0.5 0.5];
triids = pointLocation(dt, qrypts)
```

### Example 2

Create a 3-D Delaunay triangulation:

```
x = rand(10,1);
y = rand(10,1);
z = rand(10,1);
dt = DelaunayTri(x,y,z);
```

Find the triangles that contain specified query points and evaluate the barycentric coordinates:

```
qrypts = [0.25 0.25 0.25; 0.5 0.5 0.5];
```

```
[tetids, bcs] = pointLocation(dt, qrypts)
```

# pol2cart

Transform polar or cylindrical coordinates to Cartesian

## Syntax

```
[X,Y] = pol2cart(THETA,RHO)
[X,Y,Z] = pol2cart(THETA,RHO,Z)
```

## Description

`[X,Y] = pol2cart(THETA,RHO)` transforms the polar coordinate data stored in corresponding elements of `THETA` and `RHO` to two-dimensional Cartesian, or  $xy$ , coordinates. The arrays `THETA` and `RHO` must be the same size (or either can be scalar). The values in `THETA` must be in radians.

`[X,Y,Z] = pol2cart(THETA,RHO,Z)` transforms the cylindrical coordinate data stored in corresponding elements of `THETA`, `RHO`, and `Z` to three-dimensional Cartesian, or  $xyz$  coordinates. The arrays `THETA`, `RHO`, and `Z` must be the same size (or any can be scalar). The values in `THETA` must be in radians.

## More About

### Algorithms

The mapping from polar and cylindrical coordinates to Cartesian coordinates is:

**Polar to Cartesian Mapping**

$$x = \text{rho} * \cos(\text{theta})$$
$$y = \text{rho} * \sin(\text{theta})$$

**Polar to Cartesian Mapping**

$$x = \text{rho} * \cos(\text{theta})$$
$$y = \text{rho} * \sin(\text{theta})$$
$$z = z$$

**See Also**

# polar

Polar coordinate plot

## Syntax

```
polar(theta,rho)
polar(theta,rho,LineStyle)
polar(axes_handle,...)
h = polar(...)
```

## Description

The `polar` function accepts polar coordinates, plots them in a Cartesian plane, and draws the polar grid on the plane.

`polar(theta,rho)` creates a polar coordinate plot of the angle `theta` versus the radius `rho`. `theta` is the angle from the  $x$ -axis to the radius vector specified in radians; `rho` is the length of the radius vector specified in dataspace units.

`polar(theta,rho,LineStyle)` `LineStyle` specifies the line type, plot symbol, and color for the lines drawn in the polar plot.

`polar(axes_handle,...)` plots into the axes with the handle `axes_handle` instead of into the current axes (`gca`).

`h = polar(...)` returns the handle of a line object in `h`.

## Examples

### Simple Polar Plot

Create a simple polar plot using a dashed red line.

```
theta = 0:0.01:2*pi;
rho = sin(2*theta).*cos(2*theta);
```

```
figure
polar(theta,rho,'--r')
```

## More About

### Tips

Negative  $r$  values reflect through the origin, rotating by  $\pi$  (since  $(\theta, r)$  transforms to  $(r \cdot \cos(\theta), r \cdot \sin(\theta))$ ). If you want different behavior, you can

manipulate  $r$  prior to plotting. For example, you can make  $r$  equal to  $\max(0, r)$  or  $\text{abs}(r)$ .

**See Also**

## poly

Polynomial with specified roots

### Syntax

```
p = poly(A)
p = poly(r)
```

### Description

`p = poly(A)` where  $A$  is an  $n$ -by- $n$  matrix returns an  $n+1$  element row vector whose elements are the coefficients of the characteristic polynomial,  $\det(\lambda I - A)$ . The coefficients are ordered in descending powers: if a vector  $c$  has  $n+1$  components, the polynomial it represents is  $c_1\lambda^n + c_2\lambda^{n-1} + \dots + c_n\lambda + c_{n+1}$

`p = poly(r)` where  $r$  is a vector returns a row vector whose elements are the coefficients of the polynomial whose roots are the elements of  $r$ .

### Examples

MATLAB displays polynomials as row vectors containing the coefficients ordered by descending powers. The characteristic equation of the matrix

$A =$

```
 1 2 3
 4 5 6
 7 8 0
```

is returned in a row vector by `poly`:

```
p = poly(A)
```

```
p =
 1 -6 -72 -27
```

The roots of this polynomial (eigenvalues of matrix **A**) are returned in a column vector by **roots**:

```
r = roots(p)
```

```
r =
```

```
 12.1229
 -5.7345
 -0.3884
```

## More About

### Tips

Note the relationship of this command to

```
r = roots(p)
```

which returns a column vector whose elements are the roots of the polynomial specified by the coefficients row vector **p**. For vectors, **roots** and **poly** are inverse functions of each other, up to ordering, scaling, and roundoff error.

### Algorithms

The algorithms employed for **poly** and **roots** illustrate an interesting aspect of the modern approach to eigenvalue computation. **poly(A)** generates the characteristic polynomial of **A**, and **roots(poly(A))** finds the roots of that polynomial, which are the eigenvalues of **A**. But both **poly** and **roots** use **eig**, which is based on similarity transformations. The classical approach, which characterizes eigenvalues as roots of the characteristic polynomial, is actually reversed.

If **A** is an  $n$ -by- $n$  matrix, **poly(A)** produces the coefficients **c(1)** through **c(n+1)**, with **c(1) = 1**, in

$$\det(\lambda I - A) = c_1 \lambda^n + \dots + c_n \lambda + c_{n+1}$$

The algorithm is

```
z = eig(A);
c = zeros(n+1,1); c(1) = 1;
```

```
for j = 1:n
 c(2:j+1) = c(2:j+1) - z(j)*c(1:j);
end
```

This recursion is easily derived by expanding the product.

$$(\lambda - \lambda_1)(\lambda - \lambda_2)\dots(\lambda - \lambda_n)$$

It is possible to prove that `poly(A)` produces the coefficients in the characteristic polynomial of a matrix within roundoff error of `A`. This is true even if the eigenvalues of `A` are badly conditioned. The traditional algorithms for obtaining the characteristic polynomial, which do not use the eigenvalues, do not have such satisfactory numerical properties.

`conv` | `polyval` | `roots` | `residue`

# polyarea

Area of polygon

## Syntax

```
A = polyarea(X,Y)
A = polyarea(X,Y,dim)
```

## Description

`A = polyarea(X,Y)` returns the area of the polygon specified by the vertices in the vectors `X` and `Y`.

If `X` and `Y` are matrices of the same size, then `polyarea` returns the area of polygons defined by the columns `X` and `Y`.

If `X` and `Y` are multidimensional arrays, `polyarea` returns the area of the polygons in the first nonsingleton dimension of `X` and `Y`.

`A = polyarea(X,Y,dim)` operates along the dimension specified by scalar `dim`.

## Examples

### Find Area of Polygon

```
L = linspace(0,2.*pi,9);
xv = 1.2*cos(L)';
yv = 1.2*sin(L)';

xv = [xv ; xv(1)];
yv = [yv ; yv(1)];

A = polyarea(xv,yv)
```

```
A =
```

4.0729

```
plot(xv,yv);
title(['Area = ' num2str(A)])
axis image
```

# polyder

Polynomial derivative

## Syntax

```
k = polyder(p)
k = polyder(a,b)
[q,d] = polyder(b,a)
```

## Description

The `polyder` function calculates the derivative of polynomials, polynomial products, and polynomial quotients. The operands `a`, `b`, and `p` are vectors whose elements are the coefficients of a polynomial in descending powers.

`k = polyder(p)` returns the derivative of the polynomial `p`.

`k = polyder(a,b)` returns the derivative of the product of the polynomials `a` and `b`.

`[q,d] = polyder(b,a)` returns the numerator `q` and denominator `d` of the derivative of the polynomial quotient `b/a`.

## Examples

The derivative of the product

$$(3x^2 + 6x + 9)(x^2 + 2x)$$

is obtained with

```
a = [3 6 9];
b = [1 2 0];
k = polyder(a,b)
k =
 12 36 42 18
```

This result represents the polynomial

$$12x^3 + 36x^2 + 42x + 18$$

conv | deconv

# polyeig

Polynomial eigenvalue problem

## Syntax

```
[X,e] = polyeig(A0,A1,...Ap)
e = polyeig(A0,A1,..,Ap)
[X, e, s] = polyeig(A0,A1,..,AP)
```

## Description

`[X,e] = polyeig(A0,A1,...Ap)` solves the polynomial eigenvalue problem of degree  $p$

$$(A_0 + \lambda A_1 + \dots + \lambda^p A_p)x = 0$$

where polynomial degree  $p$  is a non-negative integer, and  $A_0, A_1, \dots, A_p$  are input matrices of order  $n$ . The output consists of a matrix  $X$  of size  $n$ -by- $n \cdot p$  whose columns are the eigenvectors, and a vector  $e$  of length  $n \cdot p$  containing the eigenvalues.

If  $\lambda$  is the  $j$ th eigenvalue in  $e$ , and  $x$  is the  $j$ th column of eigenvectors in  $X$ , then  $(A_0 + \lambda A_1 + \dots + \lambda^p A_p) \cdot x$  is approximately 0.

`e = polyeig(A0,A1,...,Ap)` is a vector of length  $n \cdot p$  whose elements are the eigenvalues of the polynomial eigenvalue problem.

`[X, e, s] = polyeig(A0,A1,..,AP)` also returns a vector  $s$  of length  $p \cdot n$  containing condition numbers for the eigenvalues. At least one of  $A_0$  and  $A_p$  must be nonsingular. Large condition numbers imply that the problem is close to a problem with multiple eigenvalues.

## More About

### Tips

Based on the values of  $p$  and  $n$ , `polyeig` handles several special cases:

- $p = 0$ , or `polyeig(A)` is the standard eigenvalue problem: `eig(A)`.
- $p = 1$ , or `polyeig(A,B)` is the generalized eigenvalue problem: `eig(A, -B)`.
- $n = 1$ , or `polyeig(a0,a1,...ap)` for scalars  $a_0, a_1 \dots, a_p$  is the standard polynomial problem: `roots([ap ... a1 a0])`.

If both  $A_0$  and  $A_p$  are singular the problem is potentially ill-posed. Theoretically, the solutions might not exist or might not be unique. Computationally, the computed solutions might be inaccurate. If one, but not both, of  $A_0$  and  $A_p$  is singular, the problem is well posed, but some of the eigenvalues might be zero or infinite.

Note that scaling  $A_0, A_1, \dots, A_p$  to have  $\text{norm}(A_i)$  roughly equal 1 may increase the accuracy of `polyeig`. In general, however, this cannot be achieved. (See Tisseur [3] for more detail.)

### Algorithms

The `polyeig` function uses the QZ factorization to find intermediate results in the computation of generalized eigenvalues. It uses these intermediate results to determine if the eigenvalues are well-determined. See the descriptions of `eig` and `qz` for more on this.

# polyfit

Polynomial curve fitting

## Syntax

```
p = polyfit(x,y,n)
[p,S] = polyfit(x,y,n)
[p,S,mu] = polyfit(x,y,n)
```

## Description

`p = polyfit(x,y,n)` returns the coefficients for a polynomial  $p(x)$  of degree  $n$  that is a best fit (in a least-squares sense) for the data in  $y$ . The coefficients in  $p$  are in descending powers, and the length of  $p$  is  $n+1$

$$p(x) = p_1x^n + p_2x^{n-1} + \dots + p_nx + p_{n+1}.$$

`[p,S] = polyfit(x,y,n)` also returns a structure  $S$  that can be used as an input to `polyval` to obtain error estimates.

`[p,S,mu] = polyfit(x,y,n)` also returns  $\mu$ , which is a two-element vector with centering and scaling values.  $\mu(1)$  is `mean(x)`, and  $\mu(2)$  is `std(x)`. Using these values, `polyfit` centers  $x$  at zero and scales it to have unit standard deviation

$$\hat{x} = \frac{x - \bar{x}}{\sigma_x}.$$

This centering and scaling transformation improves the numerical properties of both the polynomial and the fitting algorithm.

## Examples

### Fit Polynomial to Trigonometric Function

Generate 10 points equally spaced along a sine curve in the interval  $[0, 4\pi]$ .

```
x = linspace(0,4*pi,10);
y = sin(x);
```

Use `polyfit` to fit a 7th-degree polynomial to the points.

```
p = polyfit(x,y,7);
```

Evaluate the polynomial on a finer grid and plot the results.

```
x1 = linspace(0,4*pi);
y1 = polyval(p,x1);
figure
plot(x,y, 'o')
hold on
plot(x1,y1)
hold off
```

### Fit Polynomial to Set of Points

Create a vector of 5 equally spaced points in the interval  $[0, 1]$ , and evaluate  $y(x) = (1+x)^{-1}$  at those points.

```
x = linspace(0,1,5);
y = 1./(1+x);
```

Fit a polynomial of degree 4 to the 5 points. In general, for  $n$  points, you can fit a polynomial of degree  $n-1$  to exactly pass through the points.

```
p = polyfit(x,y,4);
```

Evaluate the original function and the polynomial fit on a finer grid of points between 0 and 2.

```
x1 = linspace(0,2);
y1 = 1./(1+x1);
f1 = polyval(p,x1);
```

Plot the function values and the polynomial fit in the wider interval  $[0, 2]$ , with the points used to obtain the polynomial fit highlighted as circles. The polynomial fit is good in the original  $[0, 1]$  interval, but quickly diverges from the fitted function outside of that interval.

```
figure
plot(x,y,'o')
hold on
plot(x1,y1)
plot(x1,f1,'r--')
legend('y','y1','f1')
```

### Fit Polynomial to Error Function

First generate a vector of  $x$  points, equally spaced in the interval  $[0, 2.5]$ , and then evaluate  $\text{erf}(x)$  at those points.

```
x = (0:0.1:2.5)';
y = erf(x);
```

Determine the coefficients of the approximating polynomial of degree 6.

```
p = polyfit(x,y,6)
```

```
p =
```

0.0084   -0.0983   0.4217   -0.7435   0.1471   1.1064   0.0004

To see how good the fit is, evaluate the polynomial at the data points and generate a table showing the data, fit, and error.

```
f = polyval(p,x);
T = table(x,y,f,y-f, 'VariableNames', {'X', 'Y', 'Fit', 'FitError'})
```

T =

X	Y	Fit	FitError
0	0	0.00044117	-0.00044117
0.1	0.11246	0.11185	0.00060836

0.9	0.79691	0.79654	0.00036515
1	0.8427	0.84238	0.0003164
1.1	0.88021	0.88005	0.00015948
1.2	0.91031	0.91035	-3.9919e-05
1.3	0.93401	0.93422	-0.000211
1.4	0.95229	0.95258	-0.00029933
1.5	0.96611	0.96639	-0.00028097
1.6	0.97635	0.97652	-0.00016704
1.7	0.98379	0.98379	8.3306e-07
1.8	0.98909	0.98893	0.00016278
1.9	0.99279	0.99253	0.00025791
2	0.99532	0.99508	0.00024347
2.1	0.99702	0.99691	0.0001131
2.2	0.99814	0.99823	-8.8548e-05
2.3	0.99886	0.99911	-0.00025673
2.4	0.99931	0.99954	-0.00022451
2.5	0.99959	0.99936	0.00023151

In this interval, the interpolated values and the actual values agree fairly closely. Create a plot to show how outside this interval, the extrapolated values quickly diverge from the actual data.

```
x1 = (0:0.1:5)';
y1 = erf(x1);
f1 = polyval(p,x1);
figure
plot(x,y, 'o')
hold on
plot(x1,y1, '-')
plot(x1,f1, 'r--')
axis([0 5 0 2])
hold off
```

### Use Centering and Scaling to Improve Numerical Properties

Create a table of population data for the years 1750 - 2000 and plot the data points.

```
year = (1750:25:2000)';
pop = 1e6*[791 856 978 1050 1262 1544 1650 2532 6122 8170 11560]';
T = table(year, pop)
plot(year,pop,'o')
```

T =

year	pop
_____	_____

1750	7.91e+08
1775	8.56e+08
1800	9.78e+08
1825	1.05e+09
1850	1.262e+09
1875	1.544e+09
1900	1.65e+09
1925	2.532e+09
1950	6.122e+09
1975	8.17e+09
2000	1.156e+10

Use `polyfit` with three outputs to fit a 5th-degree polynomial using centering and scaling, which improves the numerical properties of the problem. `polyfit` centers the

data in `year` at 0 and scales it to have a standard deviation of 1, which avoids an ill-conditioned Vandermonde matrix in the fit calculation.

```
[p,~,mu] = polyfit(T.year, T.pop, 5);
```

Use `polyval` with four inputs to evaluate `p` with the scaled years,  $(\text{year} - \mu(1)) / \mu(2)$ . Plot the results against the original years.

```
f = polyval(p,year,[],mu);
hold on
plot(year,f)
hold off
```

## Input Arguments

### **x** — Query points

vector

Query points, specified as a vector. The points in **x** correspond to the fitted function values contained in **y**.

Warning messages result when **x** has repeated (or nearly repeated) points or if **x** might need centering and scaling.

Data Types: `single` | `double`

Complex Number Support: Yes

**y — Fitted values at query points**  
vector

Fitted values at query points, specified as a vector. The values in **y** correspond to the query points contained in **x**.

Data Types: `single` | `double`  
Complex Number Support: Yes

**n — Degree of polynomial fit**  
positive integer scalar

Degree of polynomial fit, specified as a positive integer scalar. **n** specifies the polynomial power of the left-most coefficient in **p**.

A warning message results if **n** is greater than or equal to `length(x)`.

## Output Arguments

**p — Least-squares fit polynomial coefficients**  
vector

Least-squares fit polynomial coefficients, returned as a vector. **p** has length  $n+1$  and contains the polynomial coefficients in descending powers with the highest power being **n**.

Use `polyval` to evaluate **p** at query points.

**S — Error estimation structure**  
structure

Error estimation structure. This optional output structure is primarily used as an input to the `polyval` function to obtain error estimates. **S** contains the following fields:

Field	Description
R	Triangular factor from a QR decomposition of the Vandermonde matrix of <b>x</b>
df	Degrees of freedom

Field	Description
normr	Norm of the residuals

If the data in `y` is random, then an estimate of the covariance matrix of `p` is  $(R_{inv} * R_{inv}') * normr^2 / df$ , where `Rinv` is the inverse of `R`.

If the errors in the data in `y` are independent and normal with constant variance, then `[y,delta] = polyval(...)` produces error bounds that contain at least 50% of the predictions. That is, `y ± delta` contains at least 50% of the predictions of future observations at `x`.

### **mu — Centering and scaling values**

two element vector

Centering and scaling values, returned as a two element vector. `mu(1)` is `mean(x)`, and `mu(2)` is `std(x)`. These values center the query points in `x` at zero with unit standard deviation.

Use `mu` as the fourth input to `polyval` to evaluate `p` at the scaled points,  $(x - mu(1)) / mu(2)$ .

## Limitations

- In problems with many points, increasing the degree of the polynomial fit using `polyfit` does not always result in a better fit. High-order polynomials can be oscillatory between the data points, leading to a *poorer* fit to the data. In those cases, you might use a low-order polynomial fit (which tends to be smoother between points) or a different technique, depending on the problem.
- Polynomials are unbounded, oscillatory functions by nature. Therefore, they are not well-suited to extrapolating bounded data or monotonic (increasing or decreasing) data.

## More About

### Algorithms

`polyfit` uses `x` to form Vandermonde matrix `V` with `n+1` columns, resulting in the linear system

$$\begin{pmatrix} x_1^{n+1} & x_1^n & \cdots & 1 \\ x_2^{n+1} & x_2^n & \cdots & 1 \\ \vdots & \vdots & \ddots & \vdots \\ x_n^{n+1} & x_n^n & \cdots & 1 \end{pmatrix} \begin{pmatrix} p_1 \\ p_2 \\ \vdots \\ p_n \end{pmatrix} = \begin{pmatrix} y_1 \\ y_2 \\ \vdots \\ y_n \end{pmatrix},$$

which `polyfit` solves with  $\mathbf{p} = \mathbf{V} \backslash \mathbf{y}$ . Since the columns in the Vandermonde matrix are powers of the vector  $\mathbf{x}$ , the condition number of  $\mathbf{V}$  is often large for high-order fits, resulting in a singular coefficient matrix. In those cases centering and scaling can improve the numerical properties of the system to produce a more reliable fit.

- “Programmatic Fitting”

# polyint

Integrate polynomial analytically

## Syntax

```
polyint(p,k)
polyint(p)
```

## Description

`polyint(p,k)` returns a polynomial representing the integral of polynomial `p`, using a scalar constant of integration `k`. Specify `p` and `k` as type `double` or `single`.

`polyint(p)` assumes a constant of integration `k=0`.

## See Also

`polyder` | `polyval` | `polyvalm` | `polyfit`

# polyval

Polynomial evaluation

## Syntax

```
y = polyval(p,x)
[y,delta] = polyval(p,x,S)
y = polyval(p,x,[],mu)
[y,delta] = polyval(p,x,S,mu)
```

## Description

`y = polyval(p,x)` returns the value of a polynomial of degree  $n$  evaluated at  $x$ . The input argument `p` is a vector of length  $n+1$  whose elements are the coefficients in descending powers of the polynomial to be evaluated.

$$y = p_1x^n + p_2x^{n-1} + \dots + p_nx + p_{n+1}$$

`x` can be a matrix or a vector. In either case, `polyval` evaluates `p` at each element of `x`.

`[y,delta] = polyval(p,x,S)` uses the optional output structure `S` generated by `polyfit` to generate error estimates `delta`. `delta` is an estimate of the standard deviation of the error in predicting a future observation at  $x$  by  $p(x)$ . If the coefficients in `p` are least squares estimates computed by `polyfit`, and the errors in the data input to `polyfit` are independent, normal, and have constant variance, then `y±delta` contains at least 50% of the predictions of future observations at  $x$ .

`y = polyval(p,x,[],mu)` or `[y,delta] = polyval(p,x,S,mu)` use  $\hat{x} = (x - \mu_1) / \mu_2$  in place of  $x$ . In this equation,  $\mu_1 = \text{mean}(x)$  and  $\mu_2 = \text{std}(x)$ . The centering and scaling parameters `mu = [mu1,mu2]` are optional output computed by `polyfit`.

## Examples

The polynomial  $p(x) = 3x^2 + 2x + 1$  is evaluated at  $x = 5, 7,$  and  $9$  with

```
p = [3 2 1];
polyval(p,[5 7 9])
```

which results in

```
ans =
```

```
86 162 262
```

For another example, see `polyfit`.

## More About

### Tips

The `polyvalm(p,x)` function, with `x` a matrix, evaluates the polynomial in a matrix sense. See `polyvalm` for more information.

### See Also

`polyfit` | `polyvalm` | `polyder` | `polyint`

## polyvalm

Matrix polynomial evaluation

### Syntax

```
Y = polyvalm(p,X)
```

### Description

`Y = polyvalm(p,X)` evaluates a polynomial in a matrix sense. This is the same as substituting matrix `X` in the polynomial `p`.

Polynomial `p` is a vector whose elements are the coefficients of a polynomial in descending powers, and `X` must be a square matrix.

### Examples

The Pascal matrices are formed from Pascal's triangle of binomial coefficients. Here is the Pascal matrix of order 4.

```
X = pascal(4)
```

```
X =
```

```
 1 1 1 1
 1 2 3 4
 1 3 6 10
 1 4 10 20
```

Its characteristic polynomial can be generated with the `poly` function.

```
p = poly(X)
```

```
p =
```

```
 1 -29 72 -29 1
```

This represents the polynomial  $x^4 - 29x^3 + 72x^2 - 29x + 1$ .

Pascal matrices have the curious property that the vector of coefficients of the characteristic polynomial is palindromic; it is the same forward and backward.

Evaluating this polynomial at each element is not very interesting.

```
polyval(p,X)
ans =
 16 16 16 16
 16 15 -140 -563
 16 -140 -2549 -12089
 16 -563 -12089 -43779
```

But evaluating it in a matrix sense is interesting.

```
polyvalm(p,X)
ans =
 0 0 0 0
 0 0 0 0
 0 0 0 0
 0 0 0 0
```

The result is the zero matrix. This is an instance of the Cayley-Hamilton theorem: a matrix satisfies its own characteristic equation.

## See Also

[polyfit](#) | [polyval](#)

## posixtime

Convert MATLAB dates and time to POSIX time

### Syntax

```
p = posixtime(t)
```

### Description

`p = posixtime(t)` returns the POSIX<sup>®</sup> time equivalent to the datetime values in `t`. The POSIX time is the number of seconds (including fractional seconds) elapsed since 00:00:00 1-Jan-1970 UTC, ignoring leap seconds. `p` is a **double** array.

### Examples

#### Convert Datetime Array to POSIX Time

Create a datetime array. Then, convert the dates to the equivalent POSIX<sup>®</sup> time.

```
t = datetime('now') + calmonths(1:3)
```

```
t =
```

```
 20-Oct-2014 00:18:06 20-Nov-2014 00:18:06 20-Dec-2014 00:18:06
```

```
format longG
```

```
p = posixtime(t)
```

```
p =
```

```
 1413764286.647
```

```
 1416442686.647
```

```
 1419034686.647
```

## Input Arguments

**t** — **Input date and time**  
datetime array

Input date and time, specified as a `datetime` array.

## See Also

`datenum` | `datetime` | `exceltime` | `juliandate` | `yyyymmdd`

## pow2

Base 2 power and scale floating-point numbers

### Syntax

```
X = pow2(Y)
X = pow2(F,E)
```

### Description

`X = pow2(Y)` returns an array `X` whose elements are 2 raised to the power `Y`.

`X = pow2(F,E)` computes  $x = f * 2^e$  for corresponding elements of `F` and `E`. The result is computed quickly by simply adding `E` to the floating-point exponent of `F`. Arguments `F` and `E` are real and integer arrays, respectively.

### Examples

For IEEE arithmetic, the statement `X = pow2(F,E)` yields the values:

F	E	X
1/2	1	1
pi/4	2	pi
-3/4	2	-3
1/2	-51	eps
1-eps/2	1024	realmax
1/2	-1021	realmin

### More About

#### Tips

This function corresponds to the ANSI C function `ldexp()` and the IEEE floating-point standard function `scalbn()`.

## See Also

`exp` | `hex2num` | `log2` | `mpower` | `power` | `realmax` | `realmin`

## power, .^

Element-wise power

### Syntax

```
C = A.^B
C = power(A,B)
```

### Description

$C = A.^B$  raises each element of  $A$  to the corresponding power in  $B$ .

$C = \text{power}(A,B)$  is an alternate way to execute  $A.^B$ , but is rarely used. It enables operator overloading for classes.

### Examples

#### Square Each Element of Vector

Create a vector,  $A$ , and square each element.

```
A = 1:5;
C = A.^2
```

```
C =
```

```
 1 4 9 16 25
```

#### Find Inverse of Each Matrix Element

Create a matrix,  $A$ , and take the inverse of each element.

```
A = [1 2 3; 4 5 6; 7 8 9];
C = A.^-1
```

```
C =
```

```

1.0000 0.5000 0.3333
0.2500 0.2000 0.1667
0.1429 0.1250 0.1111

```

An inversion of the elements is not equal to the inverse of the matrix, which is instead written  $A^{-1}$  or `inv(A)`.

### Find Roots of Number

Calculate the roots of -1 to the 1/3 power.

```

A = -1;
B = 1/3;
C = A.^B

```

```
C =
```

```
0.5000 + 0.8660i
```

For negative base  $A$  and noninteger  $B$ , if `abs(B)` is less than 1, the `power` function returns the complex roots of  $A$ .

Use the `nthroot` function to obtain the real roots.

```
C = nthroot(A,3)
```

```
C =
```

```
-1
```

## Input Arguments

### A — Base

scalar | vector | matrix | multidimensional array

Base, specified as a scalar, vector, matrix, or multidimensional array. Inputs  $A$  and  $B$  must be the same size unless one is a scalar. A scalar value expands into an array of the same size as the other input.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char`

Complex Number Support: Yes

**B — Exponent**

scalar | vector | matrix | multidimensional array

Exponent, specified as a scalar, vector, matrix, or multidimensional array. Inputs **A** and **B** must be the same size unless one is a scalar. A scalar value expands into an array of the same size as the other input.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical | char

Complex Number Support: Yes

**See Also**

mpower | nthroot | realpow

# ppval

Evaluate piecewise polynomial

## Syntax

```
v = ppval(pp,xx)
```

## Description

`v = ppval(pp,xx)` returns the value of the piecewise polynomial  $f$ , contained in `pp`, at the entries of `xx`. You can construct `pp` using the functions `pchip`, `spline`, or the spline utility `mkpp`.

`v` is obtained by replacing each entry of `xx` by the value of  $f$  there. If  $f$  is scalar-valued, `v` is of the same size as `xx`. `xx` may be  $N$ -dimensional.

If `pp` was constructed by `pchip`, `spline`, or `mkpp` using the orientation of non-scalar function values specified for those functions, then:

If  $f$  is  $[D1, \dots, Dr]$ -valued, and `xx` is a vector of length  $N$ , then `V` has size  $[D1, \dots, Dr, N]$ , with `V(:, ..., :, J)` the value of  $f$  at `xx(J)`.

If  $f$  is  $[D1, \dots, Dr]$ -valued, and `xx` has size  $[N1, \dots, Ns]$ , then `V` has size  $[D1, \dots, Dr, N1, \dots, Ns]$ , with `V(:, ..., :, J1, ..., Js)` the value of  $f$  at `xx(J1, ..., Js)`.

## Examples

Compare the result of integrating  $\cos(x)$  between 0 and 10 to the result of integrating a piece-wise polynomial approximation of the same function.

```
a = 0; b = 10;
int1 = integral(@cos,a,b)
```

```
int1 =
 -0.5440
```

Create a piece-wise polynomial approximation of  $\cos(x)$  and integrate over the same interval.

```
x = a:b;
y = cos(x);
pp = spline(x,y);
int2 = integral(@(x)ppval(pp,x),a,b)
```

```
int2 =
 -0.5485
```

## See Also

mkpp | spline | unmkpp

# prefdir

Folder containing preferences, history, and layout files

## Syntax

```
prefdir
folder = prefdir
folder = prefdir(1)
```

## Description

`prefdir` returns the folder that contains

- Preferences for MATLAB and related products (`matlab.prf`)
- Command history file (`History.xml`)
- MATLAB shortcuts (`shortcuts_2.xml`)
- MATLAB desktop layout files (`MATLABDesktop.xml` and `Your_Saved_LayoutMATLABLayout.xml`)
- Other related files

`folder = prefdir` assigns to `folder` the name of the folder containing preferences and related files.

`folder = prefdir(1)` creates a folder for preferences and related files if one does not exist. If the folder does exist, the name is assigned to `folder`.

## Examples

View the location of the preferences folder:

```
prefdir
```

Make the preferences folder become the current folder:

```
cd(prefdir)
```

```
% Then, view the files for customizing MathWorks products:
dir
```

On Windows platforms, go directly to the preferences folder in Microsoft Windows Explorer

```
winopen(prefdir)
```

## More About

### Tips

- You must have write access to the preferences folder. Otherwise, MATLAB generates an error in the Command Window when you try to change preferences. This can happen if the folder is hidden, for example: `myname/.matlab/R2009a`.
- “Preferences Folder and Files MATLAB Uses When Multiple MATLAB Releases Are Installed”

### See Also

`preferences` | `getpref` | `setpref`

# preferences

Open Preferences dialog box

## Syntax

preferences

## Description

preferences displays the Preferences dialog box, from which you can make changes to options for MATLAB and related products.

## More About

- “Preferences”

## See Also

prefdir

## primes

Prime numbers less than or equal to input value

### Syntax

```
p = primes(n)
```

### Description

`p = primes(n)` returns a row vector containing all the prime numbers less than or equal to `n`. The data type of `p` is the same as that of `n`.

### Examples

#### Primes Less Than or Equal to 25

```
p = primes(25)
```

```
p =
```

```
 2 3 5 7 11 13 17 19 23
```

#### Primes Less Than or Equal to an Unsigned Integer

```
n = uint16(12);
```

```
p = primes(n)
```

```
p =
```

```
 2 3 5 7 11
```

### Input Arguments

**n** — Input value

scalar, real integer value

Input value, specified as a scalar that is a real integer value.

Example: 10

Example: `int16(32)`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **See Also**

`factor` | `isprime`

## print

Print figure or save to file

### Contents

Syntax

“Description” on page 1-5854

“Printer Drivers” on page 1-5856

“Graphics File Formats” on page 1-5857

“Printing Options” on page 1-5860

“Paper Sizes” on page 1-5862

“Printing Tips” on page 1-5863

“Examples” on page 1-5866

“Alternatives” on page 1-5868

### Syntax

```
print
print('argument1', 'argument2', ...)
print(handle, 'filename')
print argument1 argument2 ... argumentn
cdata = print('-RGBImage')
cdata = print(fig, '-RGBImage')
```

### Description

`print` sends the contents of the current figure, including bitmap representations of any user interface controls, to the printer using the device and system printing command defined by `printopt`.

`print('argument1', 'argument2', ...)` is the function form of `print`. It enables you to pass variables for any input arguments. This form is useful for passing file names and handles (for example, `print(handle, 'filename')`). See “Batch Processing” on page 1-5867 for an example. Also see “Specifying the Figure to Print” on page 1-5866 for further examples.

---

**Note:** Print input only takes string variables and object handles as inputs. Strings passed in as cell array or structure inputs are not accepted.

---

`print argument1 argument2 ... argumentn` prints the figure using the specified arguments.

`cdata = print('-RGBImage')` return RGB image data for the current figure. Use the quoted string, `'-RGBImage'`, in parentheses for this syntax.

`cdata = print(fig, '-RGBImage')` return RGB image data for the specified figure. Use the quoted string, `'-RGBImage'` in parentheses.

Using the `'-RGBImage'` option differs from screen captures in that all printing features apply to the output, such as setting the resolution or using `InvertHardcopy`.

The following arguments apply to both the function and the command form:

Argument	Description
<code>handle</code>	Print the specified object.
<code>filename</code>	Direct the output to the PostScript file designated by <code>filename</code> . If <code>filename</code> does not include an extension, <code>print</code> appends an appropriate extension.
<code>-ddriver</code>	Print the figure using the specified printer <i>driver</i> , (such as color PostScript). If you omit <code>-ddriver</code> , <code>print</code> uses the default value stored in <code>printopt.m</code> . The table in “Printer Drivers” on page 1-5856 lists all supported device types.
<code>-dformat</code>	Copy the figure to the system Clipboard (Microsoft Windows platforms only). To be valid, the <i>format</i> for this operation must be either <code>-dmeta</code> (Windows Enhanced Metafile) or <code>-dbitmap</code> (Windows Bitmap).

Argument	Description
<code>-dformat filename</code>	Export the figure to the specified file using the specified graphics <i>format</i> (such as TIFF). The table of “Graphics File Formats” on page 1-5857 lists all supported graphics file formats.
<code>-smodelname</code>	Print the current Simulink model <i>modename</i> .
<code>-options</code>	Specify print options that modify the action of the <code>print</code> command. (For example, the <code>-noui</code> option suppresses printing of user interface controls.) “Printing Options” on page 1-5860 lists available options.

## Printer Drivers

The following table shows the more widely used printer drivers supported by MATLAB software. If you do not specify a driver, the default setting shown in the previous table is used. For a list of all supported printer drivers, type `print -d` at the MATLAB prompt. Some things to remember:

- As indicated in “Description” on page 1-5854 the `-d` switch specifies a printer driver or a graphics file format:
  - Specifying a printer driver without a file name or printer name (the `-P` option) sends the output formatted by the specified driver to your default printer, which may not be what you want to do.

---

**Note:** On Windows systems, when you use the `-P` option to identify a printer, if you specify any driver other than `-dwin` or `-dwinc`, MATLAB writes the output to a file with an appropriate extension but does not send it to the printer.

However, if you setup a shared network printer and specify the printer with the network path in the `print` command, then you can print to that printer.

- Specifying a `-dmeta` or a `-dbitmap` graphics format without a file name places the graphic on the system Clipboard, if possible (Windows platforms only).
- Specifying any other graphics format without a file name creates a file in the current folder with a name such as `figureN.fmt`, where `N` is 1, 2, 3, ... and `fmt` indicates the format type, for example, `eps` or `png`.

- Not all drivers are supported on all platforms. Support is noted in the first column of the table.
- If you specify a particular printer with the `-P` option and do not specify a driver, a default driver for that printer is selected, either by the operating system or by MATLAB, depending on the platform:
  - On Windows, the driver associated with this particular printing device is used.
  - On Macintosh and UNIX platforms, the driver specified in `printopt.m` is used

See “Selecting the Printer” in the Graphics documentation for more information.

Printer Driver	Print Command Option String
PostScript Level 3 black and white	<code>-dps</code>
PostScript Level 3 color	<code>-dpssc</code>
PostScript Level 2 black and white	<code>-dps2</code>
PostScript Level 2 color	<code>-dpssc2</code>
Windows color (Windows only)	<code>-dwinc</code>
Windows monochrome (Windows only)	<code>-dwin</code>

## Graphics File Formats

To save a figure in a standard graphics format, specify a format option and file name. To set the resolution of the output file for a built-in MATLAB format, use the `-r` switch. (For example, `-r300` sets the output resolution to 300 dots per inch.) The `-r` switch is also supported for Windows Enhanced Metafiles, JPEG, TIFF and PNG files.

For more information, see “Printing and Exporting Without a Display” on page 1-5859 and “Resolution Considerations” on page 1-5861.

---

**Note:** When you print to a file, the file name must have fewer than 128 characters, including path name. When you print to a file in your current folder, the filename must have fewer than 126 characters, because MATLAB places `'./'` or `'.\'` at the beginning of the filename when referring to it.

---

The following table shows the supported output formats for exporting from figures and the option settings to use. All formats except for EMF are supported on both Windows and UNIX platforms.

<b>Graphics Format</b>	<b>Bitmap or Vector</b>	<b>Print Command Option String</b>
<b>BMP</b> monochrome BMP	Bitmap	-dbmpmono
<b>BMP</b> 24-bit BMP	Bitmap	-dbmp16m
<b>BMP</b> 8-bit (256-color) BMP (this format uses a fixed colormap)	Bitmap	-dbmp256
<b>BMP</b> 24-bit	Bitmap	-dbmp
<b>EMF</b>	Vector	-dmeta
<b>EPS</b> Level 3 black and white	Vector	-deps
<b>EPS</b> Level 3 color	Vector	-depssc
<b>EPS</b> Level 2 black and white	Vector	-deps2
<b>EPS</b> Level 2 color	Vector	-depssc2
<b>HDF</b> 24-bit	Bitmap	-dhdf
<b>JPEG</b> 24-bit	Bitmap	-djpeg
<b>PBM</b> (plain format) 1-bit	Bitmap	-dpbm
<b>PBM</b> (raw format) 1-bit	Bitmap	-dpbmraw
<b>PCX</b> 1-bit	Bitmap	-dpcxmono
<b>PCX</b> 24-bit color PCX file format, three 8-bit planes	Bitmap	-dpcx24b
<b>PCX</b> 8-bit newer color PCX file format (256-color)	Bitmap	-dpcx256
<b>PCX</b> Older color PCX file format (EGA/VGA, 16-color)	Bitmap	-dpcx16
<b>PDF</b> Color PDF file format	Vector	-dpdf
<b>PGM</b> Portable Graymap (plain format)	Bitmap	-dpgm
<b>PGM</b> Portable Graymap (raw format)	Bitmap	-dpgmraw
<b>PNG</b> 24-bit	Bitmap	-dpng

Graphics Format	Bitmap or Vector	Print Command Option String
PPM Portable Pixmap (plain format)	Bitmap	-dppm
PPM Portable Pixmap (raw format)	Bitmap	-dppmraw
SVG Scalable Vector Graphics (For Simulink Models Only)	Vector	-dsvg
TIFF 24-bit	Bitmap	-dtiff or -dtiffn
TIFF preview for EPS files	Bitmap	-tiff

The TIFF image format is supported on all platforms by most word processors for importing images. The `-dtiffn` variant writes an uncompressed TIFF. JPEG is a lossy, highly compressed format that is supported on all platforms for image processing and for inclusion into HTML documents on the Web. To create these formats, MATLAB renders the figure using the `opengl` rendering method and the resulting bitmap is then saved to the specified file.

## Printing and Exporting Without a Display

On a UNIX platform, where you can start in MATLAB `-nodisplay` mode (`matlab -nodisplay`), you can print using most of the drivers you can use with a display and export to most of the same file formats.

All the PostScript devices function in `-nodisplay` mode on UNIX platforms. The graphic devices `-djpeg`, `-dpng`, `-dtiff` (compressed TIFF bitmaps), and `-tiff` (EPS with TIFF preview) work.

The same is true for the `-noFigureWindows` startup option which suppresses figures on all platforms. On Windows platforms the `-dwin`, `-dwinc`, and `-dsetup` options operate as usual under `-noFigureWindows`. However, the `printpreview` GUI does not function in this mode. Naturally, the Windows only `-dwin` and `-dwinc` output formats cannot be used on UNIX or Mac platforms with or without a display.

The formats which you cannot generate in `nodisplay` mode on UNIX and Mac platforms are:

- `bitmap (-dbitmap)` — Windows bitmap file
- `bmp (-dbmp . . .)` — Monochrome and color bitmaps

- `hdf (-dhdf)` — Hierarchical Data Format
- `svg (-dsvg)` — Scalable Vector Graphics file
- `tiffn (-dtiffn)` — TIFF image file, no compression

When you start MATLAB in `-nodisplay` or `-noFigureWindows` mode on any platform, MATLAB:

- Does not print or export `uicontrols`.
- Always uses the `painters` renderer, even if you specify the `-opengl` option with the `print` command.

## Printing Options

This table summarizes options that you can specify for `print`. The second column links to tutorials that provide operational details. Also see “Resolution Considerations” on page 1-5861 for information on controlling output resolution.

Option	Description
<code>-append</code>	PostScript devices only (' <code>-dps</code> ', ' <code>-dpvc</code> ', ' <code>-dpvc2</code> ', and ' <code>-dpvc2</code> '). Append figure to existing PostScript file.
<code>-cmyk</code>	PostScript devices only. Print with CMYK colors instead of RGB. See ““Setting CMYK Color””.
<code>-ddriver</code>	Printing only. Printer driver to use. See “Printer Drivers” on page 1-5856 table.
<code>-dformat</code>	Exporting only. Graphics format to use. See “Graphics Format Files” table.
<code>-fhandle</code>	Handle of figure to print. Note that you cannot specify both this option and the <code>-swindowtitle</code> option. See ““Which Figure Is Printed””.
<code>-loose</code>	PostScript printing only. Use loose bounding box for PostScript output. See ““Producing Uncropped Figures””.
<code>-noui</code>	Suppress printing of user interface controls. See ““Excluding User Interface Controls””.
<code>-opengl</code>	Render using the OpenGL renderer. Use this renderer when exporting to a bit-mapped format.

Option	Description
	You cannot specify this method in conjunction with <code>-painters</code> .
<code>-painters</code>	Render using the Painter's algorithm. Use this renderer when exporting to a vector format, such as PostScript, PDF, and scalable vector graphics.  Note that you cannot specify this method in conjunction with <code>-opengl</code> .
<code>-Pprinter</code>	Specify name of printer to use. On Macintosh computers, printer names shown in the print dialog might not work when specified at the command line using the <code>-P</code> option. See ““Selecting the Printer”” for more information.
<code>-rnumber</code>	PostScript and built-in raster formats only. Specify resolution in dots per inch. Defaults to <b>90</b> for Simulink, <b>150</b> for figures in image formats and OpenGL, screen resolution for metafiles, and <b>864</b> otherwise. Use <code>-r0</code> to specify screen resolution. For details, see “Resolution Considerations” on page 1-5861 and ““Setting the Resolution””.
<code>-swindowtitle</code>	Specify name of Simulink system window to print. Note that you cannot specify both this option and the <code>-fhandle</code> option. See ““Which Figure Is Printed””.
<code>-v</code>	Display the Java Print dialog on all platforms.

## Resolution Considerations

Use `-rnumber` to specify the resolution of the generated output. In general, using a higher value yields higher quality output but at the cost of larger output files. Resolution affects the resolution and output size of all MATLAB built-in *raster* formats.

---

**Note:** In headless (`nodisplay`) mode, writing to certain image formats is not done by built-in drivers, as it is when a display is being used. These formats are `-djpeg`, `-dtiff`, and `-dpng`. Furthermore, the `-dhdf` and `-dbmp` formats cannot be generated in headless mode (but you can substitute `-dbmp16m` for `-dbmp`). See “Printing and Exporting Without a Display” on page 1-5859 for details on printing when not using a display.

---

The effect of the `-r` option on output quality can be subtle at ordinary magnification when using the OpenGL renderer and writing to one of the MATLAB built-in raster formats, or when generating vector output that contains an embedded raster image (for example, PostScript or PDF). The effect of specifying higher resolution is more apparent when viewing the output at higher magnification or when printed, since a larger `-r` setting provides more data to use when scaling the image.

When generating fully vectorized output (as when using the painters renderer to output a vector format such as PostScript or PDF), the resolution setting affects the degree of detail of the output; setting resolution higher generates crisper output (but small changes in the resolution may have no observable effect). For example, the gap widths of lines that do not use a solid ( ' - ' ) linestyle can be affected.

## Paper Sizes

MATLAB printing supports a number of standard paper sizes. You can select from the following list by setting the `PaperType` property of the figure or selecting a supported paper size from the Print dialog box.

Property Value	Size (Width by Height)
usletter	8.5 by 11 inches
uslegal	8.5 by 14 inches
tabloid	11 by 17 inches
A0	841 by 1189 mm
A1	594 by 841 mm
A2	420 by 594 mm
A3	297 by 420 mm
A4	210 by 297 mm
A5	148 by 210 mm
B0	1029 by 1456 mm
B1	728 by 1028 mm
B2	514 by 728 mm
B3	364 by 514 mm
B4	257 by 364 mm

Property Value	Size (Width by Height)
B5	182 by 257 mm
arch-A	9 by 12 inches

## Printing Tips

### Setting Default Printer

You can edit the file `printopt.m` to set the default printer type and destination. If you want to set up a new printer, use the operating system printer management utilities. Restart MATLAB if you do not see a printer which is already setup.

### Figures with Resize Functions

The `print` command produces a warning when you print a figure having a callback routine defined for the figure `ResizeFcn`. To avoid the warning, set the figure `PaperPositionMode` property to `auto` or select **Auto (Actual Size, Centered)** in the **File > Print Preview** dialog box.

### Troubleshooting Microsoft Windows Printing

If you encounter problems such as segmentation violations, general protection faults, or application errors, or the output does not appear as you expect when using Microsoft printer drivers, try the following:

- If your printer is PostScript compatible, print with one of the MATLAB built-in PostScript drivers. There are various PostScript device options that you can use with `print`, which all start with `-dps`.
- The behavior you are experiencing might occur only with certain versions of the print driver. Contact the print driver vendor for information on how to obtain and install a different driver.
- Copy the figure as a Windows Enhanced Metafile using the **Edit > Copy Figure** menu item on the figure window menu or the `print -dmeta` option at the command line. You can then import the file into another application for printing.

You can set copy options in the figure's **File > Preferences > Copying Options** dialog box. The Windows Enhanced Metafile Clipboard format produces a better quality image than Windows Bitmap.

## Printing MATLAB GUIs

You can generally obtain better results when printing a figure window that contains MATLAB `uicontrols` by setting these key properties:

- Set the figure `PaperPositionMode` property to `auto`. This ensures that the printed version is the same size as the on-screen version. With `PaperPositionMode` set to `auto` MATLAB, does not resize the figure to fit the current value of the `PaperPosition` figure property value. This is particularly important if you have specified a figure `ResizeFcn`, because if MATLAB resizes the figure during the print operation, `ResizeFcn` is automatically called.

To set `PaperPositionMode` on the current figure, use the command:

```
set(gcf, 'PaperPositionMode', 'auto')
```

- Set the figure `InvertHardcopy` property to `off`. By default, MATLAB changes the figure background color of printed output to white, but does not change the color of `uicontrols`. If you have set the background color, for example, to match the gray of the GUI devices, you must set `InvertHardcopy` to `off` to preserve the color scheme.

To set `InvertHardcopy` on the current figure, use the command:

```
set(gcf, 'InvertHardcopy', 'off')
```

- Use a color device if you want lines and text that are in color on the screen to be written to the output file as colored objects. Black and white devices convert colored

lines and text to black or white to provide the best contrast with the background and to avoid dithering.

- Use the `print` command's `-loose` option to keep a bounding box from being too tightly wrapped around objects contained in the figure. This is important if you have intentionally used space between `uicontrols` or axes and the edge of the figure and you want to maintain this appearance in the printed output. PDF output ignores the `-loose` option.

If you print or export in `nodisplay` mode, none of the `uicontrols` the figure has will be visible. If you run code that adds `uicontrols` to a figure when the figure is invisible, the controls will not print until the figure is made visible.

## Printing Interpolated Shading with PostScript Drivers

You can print MATLAB surface objects (such as graphs created with `surf` or `mesh`) using interpolated colors. However, only patch objects that are composed of triangular faces can be printed using interpolated shading.

Printed output is always interpolated in RGB space, not in the colormap colors. This means that if you are using indexed color and interpolated face coloring, the printed output can look different from what is displayed on screen.

PostScript files generated for interpolated shading contain the color information of the graphics object's vertices and require the printer to perform the interpolation calculations. This can take an excessive amount of time and in some cases, printers might time out before finishing the print job. One solution to this problem is to interpolate the data and generate a greater number of faces, which can then be flat shaded.

To obtain higher resolution (for example, to make text look better), use the `-r` option to increase the resolution. There is, however, a tradeoff between the resolution and the size of the created PostScript file, which can be quite large at higher resolutions. The default resolution of 150 dpi generally produces good results. You can reduce the size of the output file by making the figure smaller before printing it and setting the figure `PaperPositionMode` to `auto`, or by just setting the `PaperPosition` property to a smaller size.

## Examples

### Export Figure at Screen Size and Resolution

This example exports a surface plot to a `.png` file. Setting the current figure's (`gcf`) `PaperPositionMode` to `'auto'` enables you to resize the figure window and print it at the size you see on the screen.

```
surf(peaks)
set(gcf, 'PaperPositionMode', 'auto')
print('-dpng', '-r0', 'PeaksSurface')
```

For additional details, see ““Printing Images”” in the MATLAB Graphics documentation.

### Export to a Vector Format

Export a figure in a vector format using the `painters` renderer:

```
bar(1:10)
print -depssc -painters BarPlot
```

### Specifying the Figure to Print

Pass a figure handle as a variable to the function form of `print`. For example:

```
h = figure;
plot(1:4, 5:8)
print(h)
```

Save the figure with the handle `h` to a PostScript file named `Figure2`, which can be printed later:

```
print(h, '-dps', 'Figure2.ps')
```

Pass in a file name as a variable:

```
filename = 'mydata';
print(h, '-dpssc', filename);
```

(Because a file name is specified, the figure will be printed to a file.)

## Specifying the Model to Print

Print a noncurrent Simulink model using the `-s` option with the title of the window (in this case, `f14`):

```
print('-sf14')
```

If the window title includes any spaces, you must call the function form rather than the command form of `print`. For example, this command saves the Simulink window title `Thruster Control`:

```
print('-sThruster Control')
```

To print the current system, use:

```
print('-s')
```

For information about issues specific to printing Simulink windows, see the Simulink documentation.

## Return Image RGB Data for Figure

Create an RGB image of the figure.

```
surf(peaks)
cData = print('-RGBImage');
```

Display the image data at full resolution using `imshow`.

```
imshow(cData)
```

## Batch Processing

Use the function form of `print` to pass variables containing file names. For example, this `for` loop uses file names stored in a cell array to create a series of graphs and prints each one with a different file name:

```
fnames = {'file1', 'file2', 'file3'};
for k=1:length(fnames)
 surf(peaks)
 print('-dtiff', '-r200', fnames{k})
end
```

fnames is a cell of string arrays so each element is a string.

## Tiff Preview

The command

```
print('-depsc', '-tiff', '-r300', 'picture1')
```

saves the current figure at 300 dpi, in a color Encapsulated PostScript file named `picture1.eps`. The `-tiff` option creates a 72 dpi TIFF preview, which many word processor applications can display on screen after you import the EPS file. This enables you to view the picture on screen within your word processor and print the document to a PostScript printer using a resolution of 300 dpi.

## Alternatives

Select **File > Print** from the figure window to open the Print dialog box and **File > Print Preview** to open the Print Preview GUI. For details, see “How to Print or Export”.

# printopt

Configure printer defaults

## Syntax

```
[pcmd,dev] = printopt
```

## Description

[pcmd,dev] = printopt returns strings containing the current system-dependent printing command and output device. `printopt` is a file used by `print` to produce the hard-copy output. You can edit the file `printopt.m` to set your default printer type and destination.

`pcmd` and `dev` are platform-dependent strings. `pcmd` contains the command that `print` uses to send a file to the printer. `dev` contains the printer driver or graphics format option for the `print` command. Their defaults are platform dependent.

Platform	Print Command	Driver or Format
Mac and UNIX	<code>lpr -r</code>	<code>-dps2</code>
Windows	<code>COPY /B %s LPT1:</code>	<code>-dwin</code>

`printdlg` | `print`

## printdlg

Print dialog box

---

**Note:** The `-crossplatform` and `-setup` input arguments have been removed in R2014b. They no longer have any effect.

---

## Syntax

```
printdlg
printdlg(fig)
```

## Description

`printdlg` prints the current figure.

`printdlg(fig)` creates a modal dialog box from which you can print the figure window identified by the handle `fig`. Uimenu's do not print.

## More About

### Tips

If you want to set up a new printer, use the operating system printer management utilities. Restart MATLAB if you do not see the printer which is already setup.

# printpreview

Preview figure to print

## Contents

- “Description” on page 1-5871
- “Right Pane Controls” on page 1-5872
- “The Layout Tab” on page 1-5873
- “The Lines/Text Tab” on page 1-5874
- “The Color Tab” on page 1-5876
- “The Advanced Tab” on page 1-5878
- “Alternatives” on page 1-5879

## Syntax

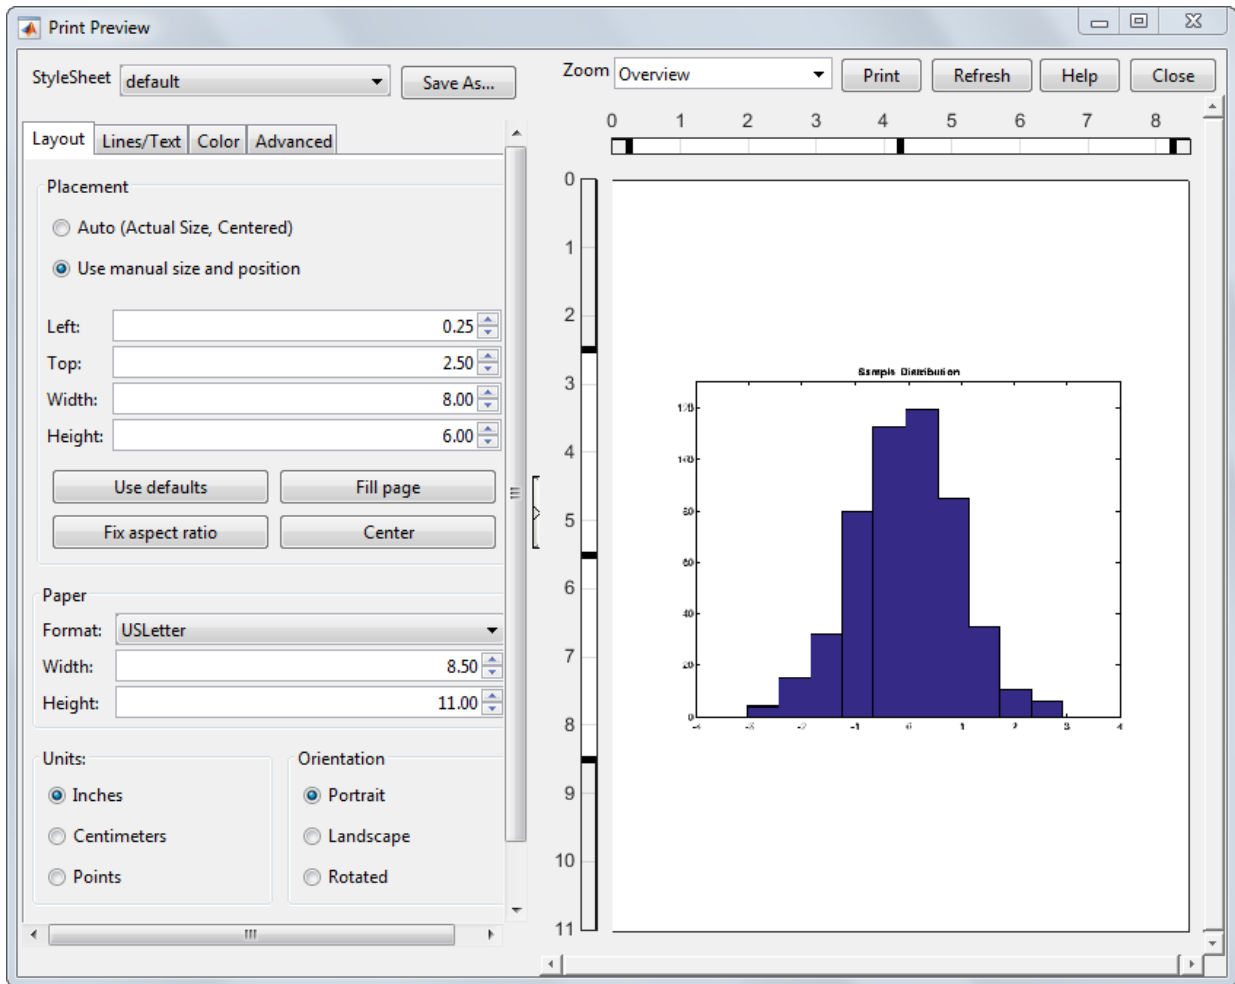

```
printpreview
printpreview(f)
```

## Description

`printpreview` displays a dialog box showing the figure in the currently active figure window as it will print. A scaled version of the figure displays in the right-hand pane of the GUI.

`printpreview(f)` displays a dialog box showing the figure having the handle `f` as it will print.

Use the Print Preview dialog box, shown below, to control the layout and appearance of figures before sending them to a printer or print file. Controls are grouped into four tabbed panes: **Layout**, **Lines/Text**, **Color**, and **Advanced**.

## Right Pane Controls

You can position and scale plots on the printed page using the rulers in the right-hand pane of the Print Preview dialog. Use the outer ruler handlebars to change margins. Moving them changes plot proportions. Use the center ruler handlebars to change the position of the plot on the page. Plot proportions do not change, but you can move portions of the plot off the paper. The buttons on that pane let you refresh the plot, close the dialog (preserving all current settings), print the page immediately, or obtain context-

sensitive help. Use the **Zoom** box and scroll bars to view and position page elements more precisely.

## The Layout Tab

Use the **Layout** tab, shown above, to control the paper format and placement of the plot on printed pages. The following table summarizes the **Layout** options:

Group	Option	Description
Placement	<b>Auto</b>	Let MATLAB decide placement of plot on page <sup>*</sup>
	<b>Use manual...</b>	Specify position parameters for plot on page <sup>*</sup>
	<b>Top, Left, Width, Height</b>	Standard position parameters in current units
	<b>Use defaults</b>	Revert to default position
	<b>Fill page</b>	Expand figure to fill printable area (see note below)
	<b>Fix aspect ratio</b>	Correct height/width ratio
	<b>Center</b>	Center plot on printed page
Paper	<b>Format</b>	U.S. and ISO <sup>®</sup> sheet size selector
	<b>Width, Height</b>	Sheet size in current units
Units	<b>Inches</b>	Use inches as units for dimensions and positions
	<b>Centimeters</b>	Use centimeters as units for dimensions and positions
	<b>Points</b>	Use points as units for dimensions and positions
Orientation	<b>Portrait</b>	Upright paper orientation
	<b>Landscape</b>	Sideways paper orientation
	<b>Rotated</b>	Currently the same as <b>Landscape</b>

<sup>\*</sup> Selecting **Auto** in the Placement group sets the figure `PaperPositionMode` to 'auto' and disables the controls in that panel. Selecting **Use manual size and position** sets the figure `PaperPositionMode` to 'manual' and enables the controls. If you set

PaperPositionMode programmatically, the print preview Placement controls respond accordingly.

---

**Note:** Selecting the **Fill page** option changes the PaperPosition property to fill the page, allowing objects in normalized units to expand to fill the space. If an object within the figure has an absolute size, for example a table, it can overflow the page when objects with normalized units expand. To avoid having objects fall off the page, do not use **Fill page** under such circumstances.

---

## The Lines/Text Tab

Use the **Lines/Text** tab, shown below, to control the line weights, font characteristics, and headers for printed pages. The following table summarizes the **Lines/Text** options:

Layout Lines/Text Color Advanced

**Lines**

Line Width  Default  
 Scale By  %  
 Custom  points

Min Width  Default  
 Custom

**Text**

Font Name  Default  
 Custom

Font Size  Default  
 Scale By  %  
 Custom  points

Font Weight

Font Angle

**Header**

Header Text

Date Style

Group	Option	Description
Lines	<b>Line Width</b>	Scale all lines by a percentage from 0 upward (100 being no change), print lines at a specified point size, or default line widths used on the plot
	<b>Min Width</b>	Smallest line width (in points) to use when printing; defaults to 0.5 point
Text	<b>Font Name</b>	Select a system font for all text on plot, or default to fonts currently used on the plot

<b>Group</b>	<b>Option</b>	<b>Description</b>
	<b>Font Size</b>	Scale all text by a percentage from 0 upward (100 being no change), print text at a specified point size, or default to this used on the plot
	<b>Font Weight</b>	Select <b>Normal ... Bold</b> font styling for all text from drop-down menu or default to the font weights used on the plot
	<b>Font Angle</b>	Select <b>Normal, Italic</b> or <b>Oblique</b> font styling for all text from drop-down menu or default to the font angles used on the plot
Header	<b>Header Text</b>	Type the text to appear on the header at the upper left of printed pages, or leave blank for no header
	<b>Date Style</b>	Select a date format to have today's date appear at the upper left of printed pages, or <b>none</b> for no date

## The Color Tab

Use the **Color** tab, shown below, to control how colors are printed for lines and backgrounds. The following table summarizes the **Color** options:

Layout Lines/Text **Color** Advanced

**Color Scale**

Black and White (Lines and Text only)

Gray Scale

Color

RGB

CMYK

**Background color**

Same as figure

Custom white

Group	Option	Description
Color Scale	<b>Black and White</b>	Select to print lines and text in black and white, but use color for patches and other objects
	<b>Gray Scale</b>	Convert colors to shades of gray on printed pages
	<b>Color</b>	Print everything in color, matching colors on plot; select <b>RGB</b> (default) or <b>CMYK</b> color model for printing

Group	Option	Description
Background Color	<b>Same as figure</b>	Print the figure's background color as it is
	<b>Custom</b>	Select a color name, or type a colorspec for the background; <code>white</code> (default) implies no background color, even on colored paper.

## The Advanced Tab

Use the **Advanced** tab, shown below, to control finer details of printing, such as limits and ticks, renderer, resolution, and the printing of UIControls. The following table summarizes the **Advanced** options:

Group	Option	Description
Axes limits and ticks	<b>Recompute limits and ticks</b>	Redraw $x$ - and $y$ -axes ticks and limits based on printed plot size (default)
	<b>Keep limits and ticks</b>	Use the $x$ - and $y$ -axes ticks and limits shown on the plot when printing the previewed figure
Miscellaneous	<b>Renderer</b>	Select a rendering algorithm for printing: <code>painters</code> , <code>opengl</code> , or <code>auto</code> (default)

Group	Option	Description
	<b>Resolution</b>	Select resolution to print at in dots per inch: 150, 300, 600, or auto (default), or type in any other positive value
	<b>Print UIControls</b>	Print all visible UIControls in the figure (default), or uncheck to exclude them from being printed

## Alternatives

Use **File > Print Preview** on the figure window menu to access the Print Preview dialog box, described below. For details, see “Using Print Preview”.

# prod

Product of array elements

## Syntax

`B = prod(A)`  
`B = prod(A,dim)`  
`B = prod( ____,type)`

## Description

`B = prod(A)` returns the product of the array elements of `A`.

- If `A` is a vector, then `prod(A)` returns the product of the elements.
- If `A` is a nonempty matrix, then `prod(A)` treats the columns of `A` as vectors and returns a row vector of the products of each column.
- If `A` is an empty 0-by-0 matrix, `prod(A)` returns 1.
- If `A` is a multidimensional array, then `prod(A)` acts along the first nonsingleton dimension and returns an array of products. The size of this dimension reduces to 1 while the sizes of all other dimensions remain the same.

`prod` computes and returns `B` as `single` if the input, `A`, is `single`. For all other numeric and logical data types, `prod` computes and returns `B` as `double`.

`B = prod(A,dim)` returns the products along dimension `dim`. For example, if `A` is a matrix, `prod(A,2)` is a column vector containing the products of each row.

`B = prod( ____,type)` multiplies in and returns an array in the class specified by `type`, using any of the input arguments in the previous syntaxes. `type` can be `'double'` or `'native'`.

## Examples

### Product of Elements in Each Column

Create a 3-by-3 array whose elements correspond to their linear indices.

```
A=[1:3:7;2:3:8;3:3:9]
```

```
A =
```

```
 1 4 7
 2 5 8
 3 6 9
```

Find the product of the elements in each column.

```
B = prod(A)
```

```
B =
```

```
 6 120 504
```

The length of the first dimension is 1 , and the length of the second dimension matches `size(A,2)`.

### Logical Input with Double Output

Create an array of logical values.

```
A = [true false; true true]
```

```
A =
```

```
 1 0
 1 1
```

Find the product of the elements in each column.

```
B = prod(A)
```

```
B =
```

```
 1 0
```

The output is `double`.

```
class(B)
```

```
ans =
```

double

**Product of Elements in Each Row**

Create a 3-by-3 array whose elements correspond to their linear indices.

```
A=[1:3:7;2:3:8;3:3:9]
```

A =

```
 1 4 7
 2 5 8
 3 6 9
```

Find the product of the elements in each row and reduce the length of the second dimension to 1.

```
dim = 2;
B = prod(A,dim)
```

B =

```
 28
 80
 162
```

The length of the first dimension matches `size(A,1)`, and the length of the second dimension is 1.

**Product of Elements in Each Plane**

Create a 3-by-3-by-2 array whose elements correspond to their linear indices.

```
A=[1:3:7;2:3:8;3:3:9];
A(:,:,2)=[10:3:16;11:3:17;12:3:18]
```

A(:,:,1) =

```
 1 4 7
 2 5 8
 3 6 9
```

A(:,:,2) =

```
 10 13 16
```

```

11 14 17
12 15 18

```

Find the product of each element in the first plane with its corresponding element in the second plane.

```

dim = 3;
B = prod(A,dim)

```

B =

```

10 52 112
22 70 136
36 90 162

```

The length of the first dimension matches `size(A,1)`, the length of the second dimension matches `size(A,2)`, and the length of the third dimension is 1.

### Single-Precision Input treated as Double

Create a 3-by-3 array of single-precision values.

```

A = single([1200 1500 1800; 1300 1600 1900; 1400 1700 2000])

```

A =

```

1200 1500 1800
1300 1600 1900
1400 1700 2000

```

Find the product of the elements in each row by performing the multiplication in double precision.

```

B = prod(A,2, 'double')

```

B =

```

1.0e+09 *
3.2400
3.9520
4.7600

```

The output is double precision.

```

class(B)

```

```
ans =
double
```

## Integer Data Type for Input and Output

Create a 3-by-3 array of 8-bit unsigned integers.

```
A = uint8([1:3:7;2:3:8;3:3:9])
```

```
A =
```

```
 1 4 7
 2 5 8
 3 6 9
```

Find the product of the elements in each column natively in `uint8`.

```
B = prod(A, 'native')
```

```
B =
```

```
 6 120 255
```

The result is an array of 8-bit unsigned integers.

```
class(B)
```

```
ans =
```

```
uint8
```

## Input Arguments

### A — Input array

vector | matrix | multidimensional array

Input array, specified as a vector, matrix, or multidimensional array.

Data Types: `double` | `single` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

Complex Number Support: Yes

### **dim** – Dimension to operate along

positive integer scalar

Dimension to operate along, specified as a positive integer scalar. If no value is specified, the default is the first array dimension whose size does not equal 1.

Dimension `dim` indicates the dimension whose length reduces to 1. The `size(B, dim)` is 1, while the sizes of all other dimensions remain the same.

Consider a two-dimensional input array, `A`.

- If `dim = 1`, then `prod(A, 1)` returns a row vector containing the product of the elements in each column.
- If `dim = 2`, then `prod(A, 2)` returns a column vector containing the product of the elements in each row.

`prod` returns `A` if `dim` is greater than `ndims(A)`.

Data Types: `double` | `single` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **type** – Output class

'double' | 'native'

Output class, specified as 'double' or 'native', defines the data type that the operation is performed in and output in.

- If `type` is 'double', then `prod` computes and returns a double precision array, regardless of the input data type. For example, if `A` is `single`, then `prod` multiplies in and returns in `double`.

- If `type` is `'native'`, `prod` multiplies natively and returns an array with the same data type as the input array `A`. For example, if `A` is an 8-bit unsigned integer, `prod` multiplies natively and returns `B` with data type `uint8`.

Data Types: `char`

## Output Arguments

### **B** — Product array

scalar | vector | matrix | multidimensional array

Product array, returned as a scalar, vector, matrix, or multidimensional array.

The class of `B` is as follows:

- If the `type` argument is not used and the input is not `single`, then the output is `double`.
- If the `type` argument is not used and the input is `single`, then the output is `single`.
- If the `type` argument specifies `'double'`, then the output is `double` regardless of the input data type.
- If the `type` argument specifies `'native'`, then the output is the same data type as the input.

## More About

### First Nonsingleton Dimension

The first nonsingleton dimension is the first dimension of an array whose size is not equal to 1.

For example:

- If `X` is a 1-by-`n` row vector, then the second dimension is the first nonsingleton dimension of `X`.
- If `X` is a 1-by-0-by-`n` empty array, then the second dimension is the first nonsingleton dimension of `X`.
- If `X` is a 1-by-1-by-3 array, then the third dimension is the first nonsingleton dimension of `X`.

# profile

Profile execution time for function

## Syntax

```
profile on
profile -history
profile -nohistory
profile -history -historysize integer
profile -timer clock
profile -history -historysize integer -timer clock
profile off
profile resume
profile clear
profile viewer
S = profile('status')
stats = profile('info')
```

## Description

The `profile` function helps you debug and optimize MATLAB code files by tracking their execution time. For each MATLAB function, MATLAB local function, or MEX-function in the file, `profile` records information about execution time, number of calls, parent functions, child functions, code line hit count, and code line execution time. Some people use `profile` simply to see the child functions; see also `matlab.codetools.requiredFilesAndProducts` for that purpose. To open the Profiler graphical user interface, use the `profile viewer` syntax. By default, Profiler time is CPU time. The total time reported by the Profiler is not the same as the time reported using the `tic` and `toc` functions or the time you would observe using a stopwatch.

---

**Note:** If your system uses Intel multi-core chips, you may want to restrict the active number of CPUs to 1 for the most accurate and efficient profiling. See “Multi-Core Processors — Setting for Most Accurate Profiling on Windows Systems” or “Multi-Core

---

Processors — Setting for Most Accurate Profiling on Linux Systems” for details on how to do this.

---

`profile on` starts the Profiler, clearing previously recorded profile statistics. Note the following:

- You can specify all, none, or a subset, of the `-history`, `-historysize` and `-timer` options with the `profile on` syntax.
- You can specify options in any order, including before or after `on`.
- If the Profiler is currently on and you specify `profile` with one of the options, MATLAB software returns an error message and the option has no effect. For example, if you specify `profile -timer real`, MATLAB returns the following error: The profiler has already been started. TIMER cannot be changed.
- To change options, first specify `profile off`, and then specify `profile on` or `profile resume` with new options.

`profile -history` records the exact sequence of function calls. The `profile` function records, by default, up to 1,000,000 function entry and exit events. For more than 1,000,000 events, `profile` continues to record other profile statistics, but not the sequence of calls. To change the number of function entry and exit events that the `profile` function records, use the `-historysize` option. By default, the `history` option is not enabled.

`profile -nohistory` disables further recording of the history (exact sequence of function calls). Use the `-nohistory` option after having previously set the `-history` option. All other profiling statistics continue to be collected.

`profile -history -historysize integer` specifies the number of function entry and exit events to record. By default, `historysize` is set to 1,000,000.

`profile -timer clock` specifies the type of time to use. Valid values for `clock` are:

- 'cpu' — The Profiler uses computer time (the default).
- 'real' — The Profiler uses wall-clock time.

For example, `cpu` time for the `pause` function is typically small, but `real` time accounts for the actual time paused, and therefore would be larger.

`profile -history -historysize integer -timer clock` specifies all of the options. Any order is acceptable, as is a subset.

`profile off` stops the Profiler.

`profile resume` restarts the Profiler without clearing previously recorded statistics.

`profile clear` clears the statistics recorded by `profile`.

`profile viewer` stops the Profiler and displays the results in the Profiler window. For more information, see “Profiling for Improving Performance” in the Desktop Tools and Development Environment documentation.

`S = profile('status')` returns a structure containing information about the current status of the Profiler. The table lists the fields in the order that they appear in the structure.

Field	Values	Default Value
ProfilerStatus	'on' or 'off'	off
DetailLevel	'mmex'	'mmex'
Timer	'cpu' or 'real'	'cpu'
HistoryTracking	'on' or 'off'	'off'
HistorySize	integer	1000000

`stats = profile('info')` stops the Profiler and displays a structure containing the results. Use this function to access the data generated by `profile`. The table lists the fields in the order that they appear in the structure.

Field	Description
FunctionTable	Structure array containing statistics about each function called
FunctionHistory	Array containing function call history
ClockPrecision	Precision of the <code>profile</code> function's time measurement
ClockSpeed	Estimated clock speed of the CPU
Name	Name of the profiler

The `FunctionTable` field is an array of structures, where each structure contains information about one of the functions or local functions called during execution. The following table lists these fields in the order that they appear in the structure.

Field	Description
<code>CompleteName</code>	Full path to <code>FunctionName</code> , including local functions
<code>FunctionName</code>	Function name; includes local functions
<code>FileName</code>	Full path to <code>FunctionName</code> , with file extension, excluding local functions
<code>Type</code>	MATLAB functions, MEX-functions, and many other types of functions including MATLAB local functions, nested functions, and anonymous functions
<code>NumCalls</code>	Number of times the function was called
<code>TotalTime</code>	Total time spent in the function and its child functions
<code>TotalRecursiveTime</code>	No longer used.
<code>Children</code>	<code>FunctionTable</code> indices to child functions
<code>Parents</code>	<code>FunctionTable</code> indices to parent functions
<code>ExecutedLines</code>	Array containing line-by-line details for the function being profiled.  Column 1: Number of the line that executed. If a line was not executed, it does not appear in this matrix.  Column 2: Number of times the line was executed  Column 3: Total time spent on that line. Note: The sum of Column 3 entries does not necessarily add up to the function's <code>TotalTime</code> .
<code>IsRecursive</code>	BOOLEAN value: Logical 1 (true) if recursive, otherwise logical 0 (false)
<code>PartialData</code>	BOOLEAN value: Logical 1 (true) if function was modified during profiling, for example by being edited or cleared. In that event, data was collected only up until the point when the function was modified.

## Examples

### Profile, View Results, and Save Profile Data as HTML

This example profiles the MATLAB `magic` command and then displays the results in the Profiler window. The example then retrieves the profile data on which the HTML display is based and uses the `profsave` command to save the profile data in HTML form.

```
profile on
plot(magic(35))
profile viewer
p = profile('info');
profsave(p, 'profile_results')
```

### Profile, Save Profile Data to a MAT-File, and View Results

Another way to save profile data is to store it in a MAT-file. This example stores the profile data in a MAT-file, clears the profile data from memory, and then loads the profile data from the MAT-file. This example also shows a way to bring the reloaded profile data into the Profiler graphical interface as live profile data, not as a static HTML page.

```
p = profile('info');
save myprofiledata p
clear p
load myprofiledata
profview(0,p)
```

### Profile and Show Results Including History

This example illustrates an effective way to view the results of profiling when the `history` option is enabled. The history data describes the sequence of functions entered and exited during execution. The `profile` command returns history data in the `FunctionHistory` field of the structure it returns. The history data is a 2-by-*n* array. The first row contains Boolean values, where 0 means entrance into a function and 1 means exit from a function. The second row identifies the function being entered or exited by its index in the `FunctionTable` field. This example reads the history data and displays it in the MATLAB Command Window.

```
profile on -history
plot(magic(4));
p = profile('info');
```

```
for n = 1:size(p.FunctionHistory,2)
 if p.FunctionHistory(1,n)==0
 str = 'entering function: ';
 else
 str = 'exiting function: ';
 end
 disp([str p.FunctionTable(p.FunctionHistory(2,n)).FunctionName])
end
```

## profsave

Save profile report in HTML format

### Syntax

```
profsave
profsave(profinfo)
profsave(profinfo,dirname)
```

### Description

`profsave` executes the `profile('info')` function and saves the results in HTML format. `profsave` creates a separate HTML file for each function listed in the `FunctionTable` field of the structure returned by `profile`. By default, `profsave` stores the HTML files in a subfolder of the current folder named `profile_results`.

`profsave(profinfo)` saves the profiling results, `profinfo`, in HTML format. `profinfo` is a structure of profiling information returned by the `profile('info')` function.

`profsave(profinfo,dirname)` saves the profiling results, `profinfo`, in HTML format. `profsave` creates a separate HTML file for each function listed in the `FunctionTable` field of `profinfo` and stores them in the folder specified by `dirname`.

### Examples

Run `profile` and save the results.

```
profile on
plot(magic(5))
profile off
profsave(profile('info'),'myprofile_results')
```

profile

## propedit

Open Property Editor

## Syntax

```
propedit
propedit(handle_list)
```

## Description

`propedit` starts the Property Editor, a graphical user interface to the properties of graphics objects. If no current figure exists, `propedit` will create one.

`propedit(handle_list)` edits the properties for the object (or objects) in `handle_list`.

Starting the Property Editor enables plot editing mode for the figure.

## See Also

`inspect` | `plottedit` | `propertyeditor`

## propedit (COM)

Open built-in property page for control

### Syntax

```
propedit(h)
```

### Description

`propedit(h)` requests the control to display its built-in property page. Note that some controls do not have a built-in property page. For those controls, this command fails.

COM functions are available on Microsoft Windows systems only.

### See Also

`get (COM)` | `inspect`

## properties

Class property names

### Syntax

```
properties('classname')
properties(obj)
p = properties(...)
```

### Description

`properties('classname')` displays the names of the public properties for the MATLAB class named by `classname`. The `properties` function also displays inherited properties.

`properties(obj)` `obj` can be either a scalar object or an array of objects. When `obj` is scalar, `properties` also returns dynamic properties. See “Dynamic Properties — Adding Properties to an Instance” for information on using dynamic properties.

`p = properties(...)` returns the property names in a cell array of strings.

### Definitions

A property is public when its `GetAccess` attribute value is `public` and its `Hidden` attribute value is `false` (default values for these attributes). See “Property Attributes” for a complete list of attributes.

`properties` is also a MATLAB class-definition keyword. See `classdef` for more information on class definition keywords.

### Examples

Retrieve the names of the public properties of class `memmapfile` and store the result in a cell array of strings:

```
p = properties('memmapfile');
p
ans =

 'writable'
 'offset'
 'format'
 'repeat'
 'filename'
```

Construct an instance of the `MException` class and get its properties names:

```
me = MException('Msg:ID','MsgText');
properties(me)
Properties for class MException:

 identifier
 message
 cause
 stack
```

## See Also

# propertyeditor

Show or hide **Property Editor**

## Syntax

```
propertyeditor('on')
propertyeditor('off')
propertyeditor
propertyeditor(figure_handle,...)
```

## Description

`propertyeditor('on')` displays the Property Editor tool on the current figure.

`propertyeditor('off')` hides the Property Editor on the current figure.

`propertyeditor` toggles the visibility of the Property Editor on the current figure. You can also use `propertyeditor('toggle')` instead for the same functionality.

`propertyeditor(figure_handle,...)` displays or hides the Property Editor on the figure specified by `figure_handle`.

## Examples

### Open Property Editor

Create a simple plot and open the property editor.

```
plot(1:10)
propertyeditor
```

## Alternatives

To collectively enable Plotting Tools, use the large Plotting Tool icon  on the figure toolbar. To collectively disable the Plotting Tools, use the smaller icon . Open or close

the **Property Editor** tool from the figure's **View** menu. For details, see “Customize Objects in Graph”.

## More About

### Tips

If you call `propertyeditor` in a MATLAB program and subsequent lines depend on the Property Editor being fully initialized, follow it by `drawnow` to ensure complete initialization.

# matlab.mixin.util.PropertyGroup class

**Package:** matlab.mixin.util

Custom property list for object display

## Description

Use the `PropertyGroup` class to create custom property display lists for class derived from `matlab.mixin.CustomDisplay`.

## Construction

`P = matlab.mixin.util.PropertyGroup(propertyList)` constructs a property group with the supplied `propertyList`.

`P = matlab.mixin.util.PropertyGroup(propertyList,title)` displays `title` above the list of properties.

## Input Arguments

### **propertyList**

The `propertyList` is either a cell array of property names, or a scalar `struct` with property name-value pairs.

### **title**

Text to display above properties.

## Properties

### **NumProperties**

The number of properties in the `PropertyList`.

**Attributes:**

Dependent	true
GetAccess	public
GetObservable	true
SetAccess	private
Transient	true

## **PropertyList**

The list of properties to display, stored as a scalar struct or a cell array of strings.

### **Attributes:**

GetAccess	public
GetObservable	true
SetAccess	public
SetObservable	true

### **Title**

An optional Title for the PropertyGroup.

### **Attributes:**

GetAccess	public
GetObservable	true
SetAccess	public
SetObservable	true

## **Copy Semantics**

Value. To learn how value classes affect copy operations, see “Copying Objects” in the MATLAB documentation.

### **See Also**

`matlab.mixin.CustomDisplay`

## psi

Psi (polygamma) function

### Syntax

```
Y = psi(X)
Y = psi(k,X)
```

### Description

`Y = psi(X)` evaluates the  $\psi$  function for each element of array `X`. `X` must be real and nonnegative. The  $\psi$  function, also known as the digamma function, is the logarithmic derivative of the gamma function

$$\begin{aligned}\psi(x) &= \text{digamma}(x) \\ &= \frac{d(\log(\Gamma(x)))}{dx} \\ &= \frac{d(\Gamma(x)) / dx}{\Gamma(x)}\end{aligned}$$

`Y = psi(k,X)` evaluates the  $k$ th derivative of  $\psi$  at the elements of `X`. `psi(0,X)` is the digamma function, `psi(1,X)` is the trigamma function, `psi(2,X)` is the tetragamma function, etc.

## Examples

### Example 1

Use the `psi` function to calculate Euler's constant,  $\gamma$ .

```
format long
-psi(1)
ans =
 0.57721566490153
```

```
-psi(0,1)
ans =
 0.57721566490153
```

## Example 2

The trigamma function of 2,  $\text{psi}(1, 2)$ , is the same as  $(\pi^2/6) - 1$ .

```
format long
psi(1,2)
ans =
 0.64493406684823
```

```
pi^2/6 - 1
ans =
 0.64493406684823
```

# publish

Generate view of MATLAB file in specified format

## Syntax

```
publish(file)
publish(file,format)
```

```
publish(file,Name,Value)
publish(file,options)
```

```
my_doc = publish(file, ___)
```

## Description

`publish(file)` generates a view of a MATLAB file in HTML format for sharing your code. For example, `publish('myfile.m')` executes the code in `myfile.m` using the base workspace and saves the formatted code and results in `/html/myfile.html`. The `html` subfolder is relative to the `file` folder.

When MATLAB publishes a file, it can delete existing files from the output folder that start with the same name as `file`.

`publish(file,format)` generates a view of a MATLAB file in the specified file format. The resulting files save to the `html` subfolder for all file formats.

`publish(file,Name,Value)` generates a view of the MATLAB file, `file`, with options specified by one or more name-value pair arguments.

`publish(file,options)` uses the options structure to customize the output, which is useful when you want to preconfigure and save your options for repeated use. The options structure fields and values correspond to names and values of name-value pair arguments, respectively.

`my_doc = publish(file, ___ )` generates a view of the MATLAB file `file`, and returns a string indicating the path of the resulting output file. It can include any of the input arguments in previous syntaxes.

## Examples

### Generate HTML View of MATLAB Script

Generate an HTML view of the code, MATLAB results, and comments in a MATLAB script.

Copy the example file, `fourier_demo2.m`, to your current folder.

```
copyfile(fullfile(matlabroot, 'help', 'techdoc', ...
'matlab_env', 'examples', 'fourier_demo2.m'), '.', 'f')
```

Generate an HTML view of the MATLAB file.

```
publish('fourier_demo2.m');
```

The `publish` command executes the code for each cell in `fourier_demo2.m`, and saves the file to `/html/fourier_demo2.html`.

View the HTML file.

```
web('html/fourier_demo2.html')
```

### Generate View of MATLAB Script in Microsoft Word Format

Generate a Microsoft Word view of the code, MATLAB results, and comments in a MATLAB script.

Copy the example file to your current folder.

```
copyfile(fullfile(matlabroot, 'help', 'techdoc', ...
'matlab_env', 'examples', 'fourier_demo2.m'), '.', 'f')
```

Publish the file in Microsoft Word format.

```
publish('fourier_demo2.m', 'doc');
```

View the published output.

```
winopen('html/fourier_demo2.doc')
```

### Publish MATLAB Script Using Name-Value Pairs to Customize Output

Generate an HTML view of the code, MATLAB results, and comments in a MATLAB script. Use name-value pair arguments to include window decorations in the published output.

Copy the example file to your current folder.

```
copyfile(fullfile(matlabroot,'help','techdoc',...
'matlab_env','examples','fourier_demo2.m'),'.','f')
```

Publish the example MATLAB file to HTML format.

```
publish('fourier_demo2.m','figureSnapMethod','entireFigureWindow')
```

The 'figureSnapMethod','entireFigureWindow' name-value pair argument specifies to include the window decorations in the figures, and to match the figure background color to the screen color.

View the published output.

```
web('html/fourier_demo2.html')
```

## Customize publish Output Using Options Structure

Generate a Microsoft Word view of the code, MATLAB results, and comments in a MATLAB script. Use a structure to customize the published output.

Specifying options as a structure is useful when you want to preconfigure and save your options for repeated use.

Copy the example file to your current folder.

```
copyfile(fullfile(matlabroot,'help','techdoc',...
'matlab_env','examples','fourier_demo2.m'),'.','f')
```

Define options to customize the published output as a structure, `options_doc_nocode`.

```
options_doc_nocode.format = 'doc';
options_doc_nocode.showCode = false;
```

Publish the file, specifying the options structure.

```
publish('fourier_demo2.m',options_doc_nocode);
```

## Save File Path of Published Script to Variable

Generate an HTML view of a MATLAB script, and save the path of the published HTML file to a variable.

This example assumes that the current folder is `C:\my_MATLAB_files`.

Copy the example file to your current folder.

```
copyfile(fullfile(matlabroot,'help','techdoc',...
'matlab_env','examples','fourier_demo2.m'),'.','f')
```

Publish the MATLAB file, and save the path of the resulting published HTML file to an output variable.

```
mydoc = publish('fourier_demo2.m')

mydoc =

C:\my_MATLAB_files\html\fourier_demo2.html
```

## Input Arguments

### **file** — MATLAB file

string

Full or partial path of the MATLAB file for which you want to generate a presentation view, specified as a string.

Example: `'myfile.m'`

### **format** — Output format of published file

'html' (default) | 'doc' | 'latex' | 'ppt' | 'xml' | 'pdf'

Output format of published MATLAB file, specified as one of the following string values.

Output Format	String Value
Hypertext Markup Language	'html' (default)
Microsoft Word	'doc'
LaTeX	'latex'
Microsoft PowerPoint	'ppt'
Extensible Markup Language	'xml'
Portable Document Format	'pdf'

Example: `publish('myfile.m','ppt');`

### **options** — Options for published output

MATLAB structure

Options for published output, specified as a structure. Use the options structure instead of name-value pair arguments when you want to reuse the same configuration for publishing multiple MATLAB code files.

The options structure field and values correspond to names and values of the name-value pair arguments, respectively.

For example, to specify the PDF output format and the output folder C:\myPublishedOutput, use:

```
options = struct('format','pdf','outputDir','C:\myPublishedOutput')
```

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Example: 'format','latex','showCode',false specifies LaTeX output file format and excludes the code from the output.

## **Output Options**

### **'format'** — Published output file format

'html' (default) | 'doc' | 'latex' | 'ppt' | 'xml' | 'pdf'

Published output file format, specified as the comma-separated pair consisting of 'format' and one of the following string values.

<b>Output Format</b>	<b>String Value</b>
Hypertext Markup Language	'html' (default)

Output Format	String Value
Microsoft Word	'doc'
LaTeX	'latex'
Microsoft PowerPoint	'ppt'
Extensible Markup Language	'xml'
Portable Document Format	'pdf'

### 'outputDir' – Output folder

' ' (default) | full path

Output folder to which the published document is saved, specified as the comma-separated pair consisting of 'outputDir' and the full path. You must specify the full path as a string, for example 'C:\myPublishedOutput'.

The default value, ' ', specifies the html subfolder of the current folder.

### 'stylesheet' – Extensible Stylesheet language (XSL) file

' ' (default) | full path to XSL file name

Extensible Stylesheet Language (XSL) file to use when publishing MATLAB code to HTML, XML, or LaTeX format, specified as the comma-separated pair consisting of 'stylesheet' and the full path to the XSL file. The full path must be a string, for example, 'C:\myStylesheet\stylesheet.xml'

The default value, ' ', specifies the MATLAB default style sheet.

## Figure Options

### 'createThumbnail' – Thumbnail image creation

true (default) | false

Thumbnail image creation for the published document, specified as the comma-separated pair consisting of 'createThumbnail' and either true or false. You can use this thumbnail to represent your file in HTML pages.

### 'figureSnapMethod' – Published figure window appearance

'entireGUIWindow' (default) | 'print' | 'getframe' | 'entireFigureWindow'

Appearance of published figure windows, including window decorations and background color, specified as the comma-separated pair consisting of 'figureSnapMethod' and one of the following string values.

String Value	Window Decorations		Background Color	
	GUIs	Figures	GUIs	Figures
'entireGUIWindow' (default)	Included	Excluded	Matches screen	White
'print'	Excluded	Excluded	White	White
'getframe'	Excluded	Excluded	Matches screen	Matches screen
'entireFigureWindow'	Included	Included	Matches screen	Matches screen

**'imageFormat' — Published image file format**

'png' | 'eps2' | 'jpg' | ...

Published image file format, specified as the comma-separated pair consisting of 'imageFormat' and one of the following string values.

'format' Value	Valid 'imageFormat' Value	Default 'imageFormat' Value
'doc'	Any image format that your installed version of Microsoft Office can import, including 'png', 'jpg', 'bmp', and 'tiff'. If the 'figureSnapMethod' is 'print', then you can also specify 'eps', 'eps2', 'ill', 'meta', and 'pdf'.	'png'
'html'	Any format publishes successfully. Ensure that the tools you use to view and process the output files can display the output format you specify.	'png'
'latex'	Any format publishes successfully. Ensure that the tools you use to	'eps2', except when 'figureSnapMethod'

	view and process the output files can display the output format you specify.	is any one of the following: <ul style="list-style-type: none"> <li>• 'getframe'</li> <li>• 'entireFigureWindow'</li> <li>• 'entireGUIWindow'</li> </ul> and the snapped window is a GUI window  In these cases the default is 'png'
'pdf'	'bmp' or 'jpg'.	'bmp'
'ppt'	Any format that your installed version of Microsoft Office can import, including 'png', 'jpg', 'bmp', and 'tiff'.	'png'
'xml'	Any format publishes successfully. Ensure that the tools you use to view and process the output files can display the output format you specify.	'png'

### 'maxHeight' — Maximum height of published images

[ ] (default) | positive integer value

Maximum height of published images that the code generates, specified as the comma-separated pair consisting of 'maxHeight' and one of the following values:

- [ ] (default)—Unrestricted height. This value is always used when the 'format' value is 'pdf'.
- Positive integer value that specifies the image height in pixels.

### 'maxWidth' — Maximum width of published images

' ' (default) | positive integer value

Maximum width of an image that the code generates, specified as the comma-separated pair consisting of 'maxWidth' and one of the following values:

- [ ] (default)—Unrestricted width. This value is always used when the 'format' value is 'pdf'.

- Positive integer value that specifies the image width in pixels.

**'useNewFigure' — Create new figure**

true (default) | false

A logical value that determines if MATLAB creates a new Figure window for figures that the code generates, specified as the comma-separated pair consisting of 'useNewFigure' and one of the following:

- **true** (default)—If the code generates a figure, then MATLAB creates a Figure window with a white background, and at the default size before publishing.
- **false**—MATLAB does not create a figure window.

This value enables you to use a figure with different properties for publishing. For example, open a Figure window, change the size and background color, and then publish your code. Figures in your published document use the characteristics of the figure you opened before publishing.

## Code Options

**'evalCode' — Option to run code**

true (default) | false

Option to evaluate code and include the MATLAB output in the published view, specified as a logical value.

**'catchError' — Error handling during publishing**

true (default) | false

Error handling during publishing, specified as the comma-separated pair consisting of 'catchError' and one of the following logical values:

- **true** (default)—MATLAB continues publishing and includes the error in the published file.
- **false**—MATLAB displays the error at the command line and does not produce a published file.

**'codeToEvaluate' — Additional code to evaluate during publishing**

string

Additional code to evaluate during publishing, specified as the comma-separated pair consisting of `'codeToEvaluate'` and the string with the corresponding code. Use this option to specify code that does not appear in the MATLAB file, for example to set the value of an input argument for a function being published.

If this option is unspecified, MATLAB evaluates only the code in the MATLAB file you are publishing.

**'maxOutputLines' — Maximum number of lines**

`Inf` (default) | nonnegative integer value

Maximum number of lines in MATLAB output per cell evaluated during publishing, specified as the comma-separated pair consisting of `'maxOutputLines'` and one of the following values:

- `Inf` (default)—MATLAB includes all output lines in the published output.
- Nonnegative integer—MATLAB truncates the number of lines in the output at the number of lines you specify.

**'showCode' — Option to include code in published file**

`true` (default) | `false`

Option to include code in published file, specified as the comma-separated pair consisting of `'showCode'` and a logical value.

## More About

### Window Decorations

Window decorations include window title bar, toolbar, menu bar, and window border.

### Syntax Highlighting

Syntax highlighting colors various elements in code to help you identify these elements while reading or editing code. By default, keywords are blue, strings are purple, and unterminated strings are maroon.

MATLAB does not preserve syntax highlighting when you set `'format'` to `'latex'` or `'ppt'`.

## Tips

- If `'format` is `'html'`, MATLAB includes the code being published at the end of the published HTML file as comments, even when you set the `'showCode'` option to `false`. Because MATLAB includes the code as comments, this code does not display in a Web browser. This enables you to use the `grabcode` function to extract the MATLAB code from an HTML file, even when the file does not display the code.
- “Publishing MATLAB Code”
- “Publishing Markup”

# PutCharArray

Store character array in Automation server

## Syntax

### IDL Method Signature

```
PutCharArray([in] BSTR varname, [in] BSTR workspace,
 [in] BSTR string)
```

### Microsoft Visual Basic Client

```
PutCharArray(varname As String, workspace As String,
 string As String)
```

### MATLAB Client

```
PutCharArray(h, 'varname', 'workspace', 'string')
```

## Description

`PutCharArray(h, 'varname', 'workspace', 'string')` stores the character array in `string` in the specified `workspace` of the server attached to handle `h`, assigning to it the variable `varname`. The values for `workspace` are `base` or `global`. The function name is case-sensitive.

## Examples

### Visual Basic .NET Client

This example uses the Visual Basic `MsgBox` command to control flow between MATLAB and the Visual Basic Client.

```
Dim Matlab As Object
```

Try

```
Matlab = GetObject(, "matlab.application")
Catch e As Exception
 Matlab = CreateObject("matlab.application")
End Try
MsgBox("MATLAB window created; now open it...")
```

Open the MATLAB window, then click **Ok**.

```
Matlab.PutCharArray("str", "base", _
 "He jests at scars that never felt a wound.")
MsgBox("In MATLAB, type" & vbCrLf _
 & "str")
```

In the MATLAB window type `str`; MATLAB displays:

```
str =
He jests at scars that never felt a wound.
```

Click **Ok**.

```
MsgBox("closing MATLAB window...")
```

Click **Ok** to close and terminate MATLAB.

```
Matlab.Quit()
```

## More About

### Tips

The character array specified in the `string` argument can have any dimensions. However, `PutCharArray` changes the dimensions to a 1-by-n column-wise representation, where n is the number of characters in the array. Executing the following commands in MATLAB illustrates this behavior:

```
h = actxserver('matlab.application');
chArr = ['abc'; 'def'; 'ghk']
chArr =
abc
def
ghk
```

```
PutCharArray(h, 'Foo', 'base', chArr)
tstArr = GetCharArray(h, 'Foo', 'base')
tstArr =
adgbehcfk
```

**See Also**

[GetCharArray](#) | [PutWorkspaceData](#) | [GetWorkspaceData](#) | [Execute](#)

## PutFullMatrix

Matrix in Automation server workspace

### Syntax

#### IDL Method Signature

```
PutFullMatrix([in] BSTR varname, [in] BSTR workspace,
[in] SAFEARRAY(double) xreal, [in] SAFEARRAY(double) ximag)
```

#### Microsoft Visual Basic Client

```
PutFullMatrix([in] varname As String, [in] workspace As String,
[in] xreal As Double, [in] ximag As Double)
```

#### MATLAB Client

```
PutFullMatrix(h, 'varname', 'workspace', xreal, ximag)
```

### Description

`PutFullMatrix(h, 'varname', 'workspace', xreal, ximag)` stores a matrix in the specified *workspace* of the server attached to handle `h` and assigns it to variable `varname`. Use `xreal` and `ximag` for the real and imaginary parts of the matrix. The matrix cannot be a scalar, an empty array, or have more than two dimensions. The values for *workspace* are `base` or `global`.

For VBScript clients, use the `GetWorkspaceData` and `PutWorkspaceData` functions to pass numeric data to and from the MATLAB workspace. These functions use the variant data type instead of `safearray`, which VBScript does not support.

### Examples

This example uses a Visual Basic .NET client to write a matrix to the base workspace of the server:

```
Dim MatLab As Object
Dim XReal(4, 4) As Double
Dim XImag(4, 4) As Double
Dim ZReal(4, 4) As Double
Dim ZImag(4, 4) As Double
Dim i, j As Integer

For i = 0 To 4
 For j = 0 To 4
 XReal(i, j) = Rnd() * 6
 XImag(i, j) = 0
 Next j
Next i

Matlab = CreateObject("matlab.application")
MatLab.PutFullMatrix("M", "base", XReal, XImag)
MatLab.GetFullMatrix("M", "base", ZReal, ZImag)
```

Use a Visual Basic .NET client to write a matrix to the global workspace of the server:

```
Dim MatLab As Object
Dim XReal(1,2) As Double
Dim XImag(1,2) As Double
Dim result As String
Dim i,j As Integer

For i = 0 To 1
 For j = 0 To 2
 XReal(i,j) = (j * 2 + 1) + i
 XImag(i,j) = 1
 Next j
Next i

Matlab = CreateObject("matlab.application")
MatLab.PutFullMatrix("X", "global", XReal, XImag)
result = Matlab.Execute("whos global")
MsgBox(result)
```

# PutWorkspaceData

Data in Automation server workspace

## Syntax

### IDL Method Signature

```
PutWorkspaceData([in] BSTR varname, [in] BSTR workspace,
[in] VARIANT data)
```

### Microsoft Visual Basic Client

```
PutWorkspaceData(varname As String, workspace As String,
data As Object)
```

### MATLAB Client

```
PutWorkspaceData(h, 'varname', 'workspace', data)
```

## Description

`PutWorkspaceData(h, 'varname', 'workspace', data)` stores data in the *workspace* of the server attached to handle `h` and assigns it to `varname`. The values for *workspace* are `base` or `global`.

Use `PutWorkspaceData` to pass numeric and character array data respectively to the server. Do *not* use `PutWorkspaceData` on sparse arrays, structures, or function handles. Use the `Execute` method for these data types.

The `GetWorkspaceData` and `PutWorkspaceData` functions pass numeric data as a variant data type. These functions are especially useful for VBScript clients as VBScript does not support the `safearray` data type used by `GetFullMatrix` and `PutFullMatrix`.

## Examples

Create an array in a Visual Basic .NET client and put it in the base workspace of the MATLAB Automation server:

- 1 Create the Visual Basic application. Use the `MsgBox` command to control flow between MATLAB and the application:

```
Dim Matlab As Object
Dim data(6) As Double
Dim i As Integer
Matlab = CreateObject("matlab.application")
For i = 0 To 6
 data(i) = i * 15
Next i
Matlab.PutWorkspaceData("A","base",data)
MsgBox("In MATLAB, type" & vbCrLf & "A")
```

- 2 Open the MATLAB window and type A. MATLAB displays:

```
A =
 0 15 30 45 60 75 90
```

- 3 Click **Ok** to close and terminate MATLAB.

# pwd

Identify current folder

## Syntax

```
pwd
currentFolder = pwd
```

## Description

pwd displays the MATLAB current folder.

currentFolder = pwd returns the current folder as a string to currentFolder.

## Alternatives

- Use the Current Folder toolbar.

## See Also

cd | dir

## pyargs

Create keyword argument for Python function

### Syntax

```
kwa = pyargs(argKey, argValue)
```

### Description

`kwa = pyargs(argKey, argValue)` creates a `pyargs` keyword argument to pass to a Python<sup>®</sup> function.

### Examples

#### Use Keyword Argument to Modify the Display of Calendar Month

Create a calendar.

```
cal = py.calendar.TextCalendar;
```

Display calendar for December, 2014.

```
formatmonth(cal, int32(2014), int32(12))
```

```
ans =
```

```
 Python str with no properties.
```

```
 December 2014
Mo Tu We Th Fr Sa Su
 1 2 3 4 5 6 7
 8 9 10 11 12 13 14
15 16 17 18 19 20 21
22 23 24 25 26 27 28
29 30 31
```

Read the function signature from the Python documentation for the `calendar.TextCalendar.formatmonth` function.

```
py.help('calendar.TextCalendar.formatmonth')
```

```
Help on method formatmonth in calendar.TextCalendar:
```

```
calendar.TextCalendar.formatmonth = formatmonth(self, theyear, themonth, w=0, l=0) unbound method TextCalendar.formatmonth
 Return a month's calendar string (multi-line).
```

Arguments `w` and `l` are optional, with default values of `0`.

Read the function signature in MATLAB.

```
methods(cal, '-full')
```

```
lhs formatmonth(self, theyear, themonth, w, l, pyargs)
```

Search the output for the `formatmonth` function signature. You can use the `pyargs` argument instead of the optional `w` and `l` arguments.

Change the line spacing, `l`, using a `pyargs` argument.

```
formatmonth(cal,int32(2014),int32(12),pyargs('l',int32(2)))
```

```
ans =
```

```
 Python str with no properties.
```

```
 December 2014
```

```
Mo Tu We Th Fr Sa Su
```

```
 1 2 3 4 5 6 7
```

```
 8 9 10 11 12 13 14
```

```
15 16 17 18 19 20 21
```

```
22 23 24 25 26 27 28
```

```
29 30 31
```

## Input Arguments

**argKey, argValue** — Python function arguments  
keyword and value arguments

Python function keyword arguments specified as one or more comma-separated pairs of `argKey`,`argValue` arguments. `argKey` is the Python function key name and is a string. `argValue` is the argument value, represented by any type. Use the function argument list to identify `argKey` and `argValue`. You can specify several key and value pair arguments in any order as `argKey1`,`argValue1`, . . . ,`argKeyN`,`argValueN`.

Example: `'length',int32(2)`

# matlab.exception.PyException class

**Package:** matlab.exception

Capture error information for Python exception

## Description

Process information from a `matlab.exception.PyException` object to handle Python errors thrown from Python methods called from MATLAB. This class is derived from `MException`.

## Construction

`e = matlab.exception.PyException(msgID, errMsg, excObj)` constructs instance `e` of `matlab.exception.PyException` class.

## Input Arguments

**msgID** — Message identifier

string

Message identifier, specified as a string.

**errMsg** — Error message

string

Error message, specified as a string.

**excObj** — Exception object

pythonclass

Exception object, specified as the `pythonclass` that caused the exception.

## Output Arguments

**e** — Exception object

exception object

Instance of `matlab.exception.PyException` class

## Properties

### **ExceptionObject** – Object

exception object

Python exception object that caused the error.

## Tips

- Typically, you do not construct a `matlab.exception.PyException` object explicitly. MATLAB automatically constructs a `PyException` object whenever Python throws an exception. The `PyException` object wraps the original Python exception.

## Examples

### **Catch Python Exception**

Generate a Python exception and display information.

```
try
 py.list('x','y',1)
catch e
 e.message
 if(isa(e, ''))
 e.ExceptionObject
 end
end
```

```
ans =
```

```
Python Error: list() takes at most 1 argument (3 given)
```

When MATLAB displays a message containing the text `Python Error`, refer to your Python documentation for more information.

## More About

- “Capture Information About Exceptions”

- “Throw an Exception”

## **External Web Sites**

## pyversion

Change default version of Python interpreter

### Syntax

```
pyversion
[version, executable, isloaded] = pyversion
```

```
___ = pyversion version
___ = pyversion executable
```

### Description

`pyversion` displays details about the current Python version.

`[version, executable, isloaded] = pyversion` returns Python version information.

`___ = pyversion version` changes the default Python version on Microsoft Windows platforms. The setting is persistent across MATLAB sessions.

You cannot change the version after MATLAB loads Python, which happens when you type any `py.` command. Use `isloaded` to determine the status. To change the version if Python is loaded already, restart MATLAB, and then call `pyversion`.

`___ = pyversion executable` specifies full path to Python executable. Use on any platform or for repackaged CPython implementation downloads.

### Examples

#### Display Python Version

```
pyversion

 version: '2.7'
executable: 'C:\Python27\python.exe'
```

```
library: 'C:\windows\system32\python27.dll'
home: 'C:\Python27'
isloaded: 0
```

### Use Python Version 2.7

```
[v, e, loaded] = pyversion;
if loaded
 disp('To change the Python version, restart MATLAB, then call pyversion.')
else
 pyversion 2.7
end
```

## Input Arguments

### **version** — Python version number

string

Python version number, specified as a string. Version must contain the major and minor version numbers separated by a period. Windows platform only.

`pyversion` looks for the version in the Windows registry. If you download from [www.python.org/downloads](http://www.python.org/downloads), the installation automatically adds the version to the registry. If you download the Python application from a different source, either add it to the registry, or use the `pyversion(executable)` syntax to change the version.

Example: 3.3

### **executable** — Name of existing Python executable file

string

Name of an existing Python executable file, specified as a string. This argument must contain the name of the Python executable file and it can contain the full path.

Example: C:\Python33\python.exe

## Output Arguments

### **version** — Python version number

string

Python version number, specified as a string.

**executable** — Name of Python executable file

string

Name of Python executable file, specified as a string.

**isloaded** — Indicates if specified version is loaded

logical

Indicates if specified version is loaded, specified as logical.

## qmr

Quasi-minimal residual method

### Syntax

```
x = qmr(A,b)
qmr(A,b,tol)
qmr(A,b,tol,maxit)
qmr(A,b,tol,maxit,M)
qmr(A,b,tol,maxit,M1,M2)
qmr(A,b,tol,maxit,M1,M2,x0)
[x,flag] = qmr(A,b,...)
[x,flag,relres] = qmr(A,b,...)
[x,flag,relres,iter] = qmr(A,b,...)
[x,flag,relres,iter,resvec] = qmr(A,b,...)
```

### Description

`x = qmr(A,b)` attempts to solve the system of linear equations  $A^*x=b$  for  $x$ . The  $n$ -by- $n$  coefficient matrix  $A$  must be square and should be large and sparse. The column vector  $b$  must have length  $n$ . You can specify  $A$  as a function handle, `afun`, such that `afun(x, 'notransp')` returns  $A^*x$  and `afun(x, 'transp')` returns  $A' * x$ .

“Parameterizing Functions” explains how to provide additional parameters to the function `afun`, as well as the preconditioner function `mfun` described below, if necessary.

If `qmr` converges, a message to that effect is displayed. If `qmr` fails to converge after the maximum number of iterations or halts for any reason, a warning message is printed displaying the relative residual  $\text{norm}(b-A^*x)/\text{norm}(b)$  and the iteration number at which the method stopped or failed.

`qmr(A,b,tol)` specifies the tolerance of the method. If `tol` is `[]`, then `qmr` uses the default,  $1e-6$ .

`qmr(A,b,tol,maxit)` specifies the maximum number of iterations. If `maxit` is `[]`, then `qmr` uses the default,  $\min(n,20)$ .

`qmr(A,b,tol,maxit,M)` and `qmr(A,b,tol,maxit,M1,M2)` use preconditioners `M` or `M = M1*M2` and effectively solve the system  $\text{inv}(M)*A*x = \text{inv}(M)*b$  for `x`. If `M` is `[]` then `qmr` applies no preconditioner. `M` can be a function handle `mfun` such that `mfun(x, 'notransp')` returns `M\x` and `mfun(x, 'transp')` returns `M'\x`.

`qmr(A,b,tol,maxit,M1,M2,x0)` specifies the initial guess. If `x0` is `[]`, then `qmr` uses the default, an all zero vector.

`[x,flag] = qmr(A,b,...)` also returns a convergence flag.

Flag	Convergence
0	<code>qmr</code> converged to the desired tolerance <code>tol</code> within <code>maxit</code> iterations.
1	<code>qmr</code> iterated <code>maxit</code> times but did not converge.
2	Preconditioner <code>M</code> was ill-conditioned.
3	The method stagnated. (Two consecutive iterates were the same.)
4	One of the scalar quantities calculated during <code>qmr</code> became too small or too large to continue computing.

Whenever `flag` is not 0, the solution `x` returned is that with minimal norm residual computed over all the iterations. No messages are displayed if the `flag` output is specified.

`[x,flag,relres] = qmr(A,b,...)` also returns the relative residual  $\text{norm}(b-A*x) / \text{norm}(b)$ . If `flag` is 0, `relres <= tol`.

`[x,flag,relres,iter] = qmr(A,b,...)` also returns the iteration number at which `x` was computed, where  $0 \leq \text{iter} \leq \text{maxit}$ .

`[x,flag,relres,iter,resvec] = qmr(A,b,...)` also returns a vector of the residual norms at each iteration, including  $\text{norm}(b-A*x_0)$ .

## Examples

### Using `qmr` with a Matrix Input

This example shows how to use `qmr` with a matrix input. The code:

```

n = 100;
on = ones(n,1);
A = spdiags([-2*on 4*on -on],-1:1,n,n);
b = sum(A,2);
tol = 1e-8; maxit = 15;
M1 = spdiags([on/(-2) on],-1:0,n,n);
M2 = spdiags([4*on -on],0:1,n,n);
x = qmr(A,b,tol,maxit,M1,M2);

```

displays the message:

```

qmr converged at iteration 9 to a solution...
with relative residual
5.6e-009

```

## Using qmr with a Function Handle

This example replaces the matrix *A* in the previous example with a handle to a matrix-vector product function *afun*. The example is contained in a file *run\_qmr* that

- Calls *qmr* with the function handle *@afun* as its first argument.
- Contains *afun* as a nested function, so that all variables in *run\_qmr* are available to *afun*.

The following shows the code for *run\_qmr*:

```

function x1 = run_qmr
n = 100;
on = ones(n,1);
A = spdiags([-2*on 4*on -on],-1:1,n,n);
b = sum(A,2);
tol = 1e-8;
maxit = 15;
M1 = spdiags([on/(-2) on],-1:0,n,n);
M2 = spdiags([4*on -on],0:1,n,n);
x1 = qmr(@afun,b,tol,maxit,M1,M2);

function y = afun(x,transp_flag)
 if strcmp(transp_flag,'transp') % y = A'*x
 y = 4 * x;
 y(1:n-1) = y(1:n-1) - 2 * x(2:n);
 y(2:n) = y(2:n) - x(1:n-1);
 else
 y = A * x;
 end

```

```
 elseif strcmp(transp_flag,'notransp') % y = A*x
 y = 4 * x;
 y(2:n) = y(2:n) - 2 * x(1:n-1);
 y(1:n-1) = y(1:n-1) - x(2:n);
 end
 end
end
```

When you enter

```
x1=run_qmr;
```

MATLAB software displays the message

```
qmr converged at iteration 9 to a solution with relative residual
5.6e-009
```

## Using qmr with a Preconditioner

This example demonstrates the use of a preconditioner.

Load `A = west0479`, a real 479-by-479 nonsymmetric sparse matrix.

```
load west0479;
A = west0479;
```

Define `b` so that the true solution is a vector of all ones.

```
b = full(sum(A,2));
```

Set the tolerance and maximum number of iterations.

```
tol = 1e-12;
maxit = 20;
```

Use `qmr` to find a solution at the requested tolerance and number of iterations.

```
[x0,f10,rr0,it0,rv0] = qmr(A,b,tol,maxit);
```

`f10` is 1 because `qmr` does not converge to the requested tolerance `1e-12` within the requested 20 iterations. The seventeenth iterate is the best approximate solution and is the one returned as indicated by `it0 = 17`. MATLAB stores the residual history in `rv0`.

Plot the behavior of qmr.

```
semilogy(0:maxit,rv0/norm(b),'-o');
xlabel('Iteration number');
ylabel('Relative residual');
```

The plot shows that the solution does not converge. You can use a preconditioner to improve the outcome.

Create the preconditioner with `ilu`, since the matrix  $A$  is nonsymmetric.

```
[L,U] = ilu(A,struct('type','ilutp','droptol',1e-5));
```

Error using `ilu`

There is a pivot equal to zero. Consider decreasing the drop tolerance or consider using the 'udiag' option.

MATLAB cannot construct the incomplete LU as it would result in a singular factor, which is useless as a preconditioner.

You can try again with a reduced drop tolerance, as indicated by the error message.

```
[L,U] = ilu(A,struct('type','ilutp','droptol',1e-6));
[x1,f11,rr1,it1,rv1] = qmr(A,b,tol,maxit,L,U);
```

f11 is 0 because qmr drives the relative residual to  $4.1410e-014$  (the value of rr1). The relative residual is less than the prescribed tolerance of  $1e-12$  at the sixth iteration (the value of it1) when preconditioned by the incomplete LU factorization with a drop tolerance of  $1e-6$ . The output rv1(1) is norm(b), and the output rv1(7) is norm(b-A\*x2).

You can follow the progress of qmr by plotting the relative residuals at each iteration starting from the initial estimate (iterate number 0).

```
semilogy(0:it1,rv1/norm(b),'-o');
xlabel('Iteration number');
ylabel('Relative residual');
```

# qr

Orthogonal-triangular decomposition

## Syntax

```
[Q,R] = qr(A)
[Q,R] = qr(A,0)
[Q,R,E] = qr(A)
[Q,R,E] = qr(A,'matrix')
[Q,R,e] = qr(A,'vector')
[Q,R,e] = qr(A,0)
X = qr(A)
X = qr(A,0)
R = qr(A)
R = qr(A,0)
[C,R] = qr(A,B)
[C,R,E] = qr(A,B)
[C,R,E] = qr(A,B,'matrix')
[C,R,e] = qr(A,B,'vector')
[C,R] = qr(A,B,0)
[C,R,e] = qr(A,B,0)
```

## Description

$[Q,R] = \text{qr}(A)$ , where  $A$  is  $m$ -by- $n$ , produces an  $m$ -by- $n$  upper triangular matrix  $R$  and an  $m$ -by- $m$  unitary matrix  $Q$  so that  $A = Q \cdot R$ .

$[Q,R] = \text{qr}(A,0)$  produces the economy-size decomposition. If  $m > n$ , only the first  $n$  columns of  $Q$  and the first  $n$  rows of  $R$  are computed. If  $m \leq n$ , this is the same as  $[Q,R] = \text{qr}(A)$ .

If  $A$  is full:

$[Q,R,E] = \text{qr}(A)$  or  $[Q,R,E] = \text{qr}(A, 'matrix')$  produces unitary  $Q$ , upper triangular  $R$  and a permutation matrix  $E$  so that  $A \cdot E = Q \cdot R$ . The column permutation  $E$  is chosen so that  $\text{abs}(\text{diag}(R))$  is decreasing.

$[Q,R,e] = \text{qr}(A, 'vector')$  returns the permutation information as a vector instead of a matrix. That is,  $e$  is a row vector such that  $A(:,e) = Q^*R$ .

$[Q,R,e] = \text{qr}(A,0)$  produces an economy-size decomposition in which  $e$  is a permutation vector, so that  $A(:,e) = Q^*R$ .

$X = \text{qr}(A)$  and  $X = \text{qr}(A,0)$  return a matrix  $X$  such that  $\text{triu}(X)$  is the upper triangular factor  $R$ .

If  $A$  is sparse:

$R = \text{qr}(A)$  computes a  $Q$ -less QR decomposition and returns the upper triangular factor  $R$ . Note that  $R = \text{chol}(A^*A)$ . Since  $Q$  is often nearly full, this is preferred to  $[Q,R] = \text{QR}(A)$ .

$R = \text{qr}(A,0)$  produces economy-size  $R$ . If  $m > n$ ,  $R$  has only  $n$  rows. If  $m \leq n$ , this is the same as  $R = \text{qr}(A)$ .

$[Q,R,E] = \text{qr}(A)$  or  $[Q,R,E] = \text{qr}(A, 'matrix')$  produces unitary  $Q$ , upper triangular  $R$  and a permutation matrix  $E$  so that  $A^*E = Q^*R$ . The column permutation  $E$  is chosen to reduce fill-in in  $R$ .

$[Q,R,e] = \text{qr}(A, 'vector')$  returns the permutation information as a vector instead of a matrix. That is,  $e$  is a row vector such that  $A(:,e) = Q^*R$ .

$[Q,R,e] = \text{qr}(A,0)$  produces an economy-size decomposition in which  $e$  is a permutation vector, so that  $A(:,e) = Q^*R$ .

$[C,R] = \text{qr}(A,B)$ , where  $B$  has as many rows as  $A$ , returns  $C = Q^*B$ . The least-squares solution to  $A^*X = B$  is  $X = R \setminus C$ .

$[C,R,E] = \text{qr}(A,B)$  or  $[C,R,E] = \text{qr}(A,B, 'matrix')$ , also returns a fill-reducing ordering. The least-squares solution to  $A^*X = B$  is  $X = E^*(R \setminus C)$ .

$[C,R,e] = \text{qr}(A,B, 'vector')$  returns the permutation information as a vector instead of a matrix. That is, the least-squares solution to  $A^*X = B$  is  $X(e,:) = R \setminus C$ .

$[C,R] = \text{qr}(A,B,0)$  produces economy-size results. If  $m > n$ ,  $C$  and  $R$  have only  $n$  rows. If  $m \leq n$ , this is the same as  $[C,R] = \text{qr}(A,B)$ .

$[C,R,e] = \text{qr}(A,B,0)$  additionally produces a fill-reducing permutation vector  $e$ . In this case, the least-squares solution to  $A^*X = B$  is  $X(e,:) = R \setminus C$ .

## Examples

Find the least squares approximate solution to  $A*x = b$  with the Q-less QR decomposition and one step of iterative refinement:

```
if issparse(A), R = qr(A);
else R = triu(qr(A)); end
x = R \ (R' \ (A' * b));
r = b - A * x;
err = R \ (R' \ (A' * r));
x = x + err;
```

## qrdelete

Remove column or row from QR factorization

### Syntax

```
[Q1,R1] = qrdelete(Q,R,j)
[Q1,R1] = qrdelete(Q,R,j,'col')
[Q1,R1] = qrdelete(Q,R,j,'row')
```

### Description

`[Q1,R1] = qrdelete(Q,R,j)` returns the QR factorization of the matrix  $A_1$ , where  $A_1$  is  $A$  with the column  $A(:,j)$  removed and  $[Q,R] = \text{qr}(A)$  is the QR factorization of  $A$ .

`[Q1,R1] = qrdelete(Q,R,j,'col')` is the same as `qrdelete(Q,R,j)`.

`[Q1,R1] = qrdelete(Q,R,j,'row')` returns the QR factorization of the matrix  $A_1$ , where  $A_1$  is  $A$  with the row  $A(j,:)$  removed and  $[Q,R] = \text{qr}(A)$  is the QR factorization of  $A$ .

### Examples

```
A = magic(5);
[Q,R] = qr(A);
j = 3;
[Q1,R1] = qrdelete(Q,R,j,'row');
```

```
Q1 =
 0.5274 -0.5197 -0.6697 -0.0578
 0.7135 0.6911 0.0158 0.1142
 0.3102 -0.1982 0.4675 -0.8037
 0.3413 -0.4616 0.5768 0.5811
```

```
R1 =
 32.2335 26.0908 19.9482 21.4063 23.3297
 0 -19.7045 -10.9891 0.4318 -1.4873
```

```

0 0 22.7444 5.8357 -3.1977
0 0 0 -14.5784 3.7796

```

returns a valid QR factorization, although possibly different from

```

A2 = A;
A2(j,:) = [];
[Q2,R2] = qr(A2)

```

```

Q2 =
-0.5274 0.5197 0.6697 -0.0578
-0.7135 -0.6911 -0.0158 0.1142

## More About

### Algorithms

The `qrdelete` function uses a series of Givens rotations to zero out the appropriate elements of the factorization.

### See Also

`planerot` | `qr` | `qrinsert`

## qrinsert

Insert column or row into QR factorization

### Syntax

```
[Q1,R1] = qrinsert(Q,R,j,x)
[Q1,R1] = qrinsert(Q,R,j,x,'col')
[Q1,R1] = qrinsert(Q,R,j,x,'row')
```

### Description

`[Q1,R1] = qrinsert(Q,R,j,x)` returns the QR factorization of the matrix  $A_1$ , where  $A_1$  is  $A = Q \cdot R$  with the column  $x$  inserted before  $A(:,j)$ . If  $A$  has  $n$  columns and  $j = n + 1$ , then  $x$  is inserted after the last column of  $A$ .

`[Q1,R1] = qrinsert(Q,R,j,x,'col')` is the same as `qrinsert(Q,R,j,x)`.

`[Q1,R1] = qrinsert(Q,R,j,x,'row')` returns the QR factorization of the matrix  $A_1$ , where  $A_1$  is  $A = Q \cdot R$  with an extra row,  $x$ , inserted before  $A(j,:)$ .

### Examples

```
A = magic(5);
[Q,R] = qr(A);
j = 3;
x = 1:5;
[Q1,R1] = qrinsert(Q,R,j,x,'row')
```

```
Q1 =
 0.5231 0.5039 -0.6750 0.1205 0.0411 0.0225
 0.7078 -0.6966 0.0190 -0.0788 0.0833 -0.0150

## qrupdate

Rank 1 update to QR factorization

### Syntax

```
[Q1,R1] = qrupdate(Q,R,u,v)
```

### Description

`[Q1,R1] = qrupdate(Q,R,u,v)` when `[Q,R] = qr(A)` is the original QR factorization of `A`, returns the QR factorization of `A + u*v'`, where `u` and `v` are column vectors of appropriate lengths.

### Examples

The matrix

```
mu = sqrt(eps)
```

```
mu =
```

```
1.4901e-08
```

```
A = [ones(1,4); mu*eye(4)];
```

is a well-known example in least squares that indicates the dangers of forming  $A' * A$ . Instead, we work with the QR factorization – orthonormal `Q` and upper triangular `R`.

```
[Q,R] = qr(A);
```

As we expect, `R` is upper triangular.

```
R =
```

```
-1.0000 -1.0000 -1.0000 -1.0000
 0 0.0000 0.0000 0.0000
 0 0 0.0000 0.0000
```

```

 0 0 0 0.0000
 0 0 0 0

```

In this case, the upper triangular entries of  $R$ , excluding the first row, are on the order of  $\sqrt{\text{eps}}$ .

Consider the update vectors

```
u = [-1 0 0 0 0]'; v = ones(4,1);
```

Instead of computing the rather trivial QR factorization of this rank one update to  $A$  from scratch with

```
[QT,RT] = qr(A + u*v')
```

QT =

```

 0 0 0 0 1
 -1 0 0 0 0
 0 -1 0 0 0
 0 0 -1 0 0
 0 0 0 -1 0

```

RT =

1.0e-007 \*

```

 -0.1490 0 0 0
 0 -0.1490 0 0
 0 0 -0.1490 0
 0 0 0 -0.1490
 0 0 0 0

```

we may use `qrupdate`.

```
[Q1,R1] = qrupdate(Q,R,u,v)
```

Q1 =

```

 -0.0000 -0.0000 -0.0000 -0.0000 1.0000
 1.0000 -0.0000 -0.0000 -0.0000 0.0000
 0.0000 1.0000 -0.0000 -0.0000 0.0000
 0.0000 0.0000 1.0000 -0.0000 0.0000
 -0.0000 -0.0000 -0.0000 1.0000 0.0000

```

```
R1 =

1.0e-007 *
0.1490 0.0000 0.0000 0.0000
0 0.1490 0.0000 0.0000
0 0 0.1490 0.0000
0 0 0 0.1490
0 0 0 0
```

Note that both factorizations are correct, even though they are different.

## More About

### Tips

`qrupdate` works only for full matrices.

### Algorithms

`qrupdate` uses the algorithm in section 12.5.1 of the third edition of *Matrix Computations* by Golub and van Loan. `qrupdate` is useful since, if we take  $N = \max(m, n)$ , then computing the new QR factorization from scratch is roughly an  $O(N^3)$  algorithm, while simply updating the existing factors in this way is an  $O(N^2)$  algorithm.

# quad

Numerically evaluate integral, adaptive Simpson quadrature

## Compatibility

quad will be removed in a future release. Use `integral` instead.

## Syntax

```
q = quad(fun,a,b)
q = quad(fun,a,b,tol)
q = quad(fun,a,b,tol,trace)
[q,fcnt] = quad(...)
```

## Description

*Quadrature* is a numerical method used to find the area under the graph of a function, that is, to compute a definite integral.

$$q = \int_a^b f(x) dx$$

`q = quad(fun,a,b)` tries to approximate the integral of function `fun` from `a` to `b` to within an error of `1e-6` using recursive adaptive Simpson quadrature. `fun` is a function handle. Limits `a` and `b` must be finite. The function `y = fun(x)` should accept a vector argument `x` and return a vector result `y`, the integrand evaluated at each element of `x`.

“Parameterizing Functions” explains how to provide additional parameters to the function `fun`, if necessary.

`q = quad(fun,a,b,tol)` uses an absolute error tolerance `tol` instead of the default which is `1.0e-6`. Larger values of `tol` result in fewer function evaluations and faster computation, but less accurate results. In MATLAB version 5.3 and earlier, the `quad` function used a less reliable algorithm and a default relative tolerance of `1.0e-3`.

`q = quad(fun,a,b,tol,trace)` with non-zero `trace` shows the values of `[fcnt a b-a Q]` during the recursion.

`[q,fcnt] = quad(...)` returns the number of function evaluations.

The function `quadl` may be more efficient with high accuracies and smooth integrands.

The list below contains information to help you determine which quadrature function in MATLAB to use:

- The `quad` function may be most efficient for low accuracies with nonsmooth integrands.
- The `quadl` function may be more efficient than `quad` at higher accuracies with smooth integrands.
- The `quadgk` function may be most efficient for high accuracies and oscillatory integrands. It supports infinite intervals and can handle moderate singularities at the endpoints. It also supports contour integration along piecewise linear paths.
- The `quadv` function vectorizes `quad` for an array-valued `fun`.
- If the interval is infinite, `[a, Inf)`, then for the integral of `fun(x)` to exist, `fun(x)` must decay as `x` approaches infinity, and `quadgk` requires it to decay rapidly. Special methods should be used for oscillatory functions on infinite intervals, but `quadgk` can be used if `fun(x)` decays fast enough.
- The `quadgk` function will integrate functions that are singular at finite endpoints if the singularities are not too strong. For example, it will integrate functions that behave at an endpoint `c` like `log|x-c|` or `|x-c|^p` for `p >= -1/2`. If the function is singular at points inside `(a,b)`, write the integral as a sum of integrals over subintervals with the singular points as endpoints, compute them with `quadgk`, and add the results.

## Examples

To compute the integral

$$\int_0^2 \frac{1}{x^3 - 2x - 5} dx,$$

write a function `myfun` that computes the integrand:

```
function y = myfun(x)
y = 1./(x.^3-2*x-5);
```

Then pass `@myfun`, a function handle to `myfun`, to `quad`, along with the limits of integration, 0 to 2:

```
Q = quad(@myfun,0,2)
```

```
Q =
```

```
-0.4605
```

Alternatively, you can pass the integrand to `quad` as an anonymous function handle `F`:

```
F = @(x)1./(x.^3-2*x-5);
Q = quad(F,0,2);
```

## Diagnostics

`quad` may issue one of the following warnings:

'Minimum step size reached' indicates that the recursive interval subdivision has produced a subinterval whose length is on the order of roundoff error in the length of the original interval. A nonintegrable singularity is possible.

'Maximum function count exceeded' indicates that the integrand has been evaluated more than 10,000 times. A nonintegrable singularity is likely.

'Infinite or Not-a-Number function value encountered' indicates a floating point overflow or division by zero during the evaluation of the integrand in the interior of the interval.

## More About

### Algorithms

`quad` implements a low order method using an adaptive recursive Simpson's rule.

# quad2d

Numerically evaluate double integral, tiled method

## Syntax

```
q = quad2d(fun,a,b,c,d)
[q,errbnd] = quad2d(...)
q = quad2d(fun,a,b,c,d,param1,val1,param2,val2,...)
```

## Description

`q = quad2d(fun,a,b,c,d)` approximates the integral of `fun(x,y)` over the planar region  $a \leq x \leq b$  and  $c(x) \leq y \leq d(x)$ . `fun` is a function handle, `c` and `d` may each be a scalar or a function handle.

All input functions must be vectorized. The function `Z=fun(X,Y)` must accept 2-D matrices `X` and `Y` of the same size and return a matrix `Z` of corresponding values. The functions `ymin=c(X)` and `ymax=d(X)` must accept matrices and return matrices of the same size with corresponding values.

`[q,errbnd] = quad2d(...)`. `errbnd` is an approximate upper bound on the absolute error,  $|Q - I|$ , where `I` denotes the exact value of the integral.

`q = quad2d(fun,a,b,c,d,param1,val1,param2,val2,...)` performs the integration as above with specified values of optional parameters:

<code>AbsTol</code>	absolute error tolerance
<code>RelTol</code>	relative error tolerance

`quad2d` attempts to satisfy `ERRBND <= max(AbsTol,RelTol*|Q|)`. This is absolute error control when  $|Q|$  is sufficiently small and relative error control when  $|Q|$  is larger. A default tolerance value is used when a tolerance is not specified. The default value of `AbsTol` is `1e-5`. The default value of `RelTol` is `100*eps(class(Q))`. This is also the minimum value of `RelTol`. Smaller `RelTol` values are automatically increased to the default value.

<b>MaxFunEvals</b>	Maximum allowed number of evaluations of <code>fun</code> reached.
--------------------	--------------------------------------------------------------------

The `MaxFunEvals` parameter limits the number of vectorized calls to `fun`. The default is 2000.

<b>FailurePlot</b>	Generate a plot if <code>MaxFunEvals</code> is reached.
--------------------	---------------------------------------------------------

Setting `FailurePlot` to `true` generates a graphical representation of the regions needing further refinement when `MaxFunEvals` is reached. No plot is generated if the integration succeeds before reaching `MaxFunEvals`. These (generally) 4-sided regions are mapped to rectangles internally. Clusters of small regions indicate the areas of difficulty. The default is `false`.

<b>Singular</b>	Problem may have boundary singularities
-----------------	-----------------------------------------

With `Singular` set to `true`, `quad2d` will employ transformations to weaken boundary singularities for better performance. The default is `true`. Setting `Singular` to `false` will turn these transformations off, which may provide a performance benefit on some smooth problems.

## Examples

### Example 1

Integrate  $y \sin(x) + x \cos(y)$  over  $\pi \leq x \leq 2\pi$ ,  $0 \leq y \leq \pi$ . The true value of the integral is  $-\pi^2$ .

```
Q = quad2d(@(x,y) y.*sin(x)+x.*cos(y),pi,2*pi,0,pi)
```

### Example 2

Integrate  $[(x+y)^{1/2}(1+x+y)^2]^{-1}$  over the triangle  $0 \leq x \leq 1$  and  $0 \leq y \leq 1-x$ . The integrand is infinite at (0,0). The true value of the integral is  $\pi / 4 - 1 / 2$ .

```
fun = @(x,y) 1./(sqrt(x + y) .* (1 + x + y).^2)
```

In Cartesian coordinates:

```
ymin = @(x) 1 - x;
Q = quad2d(fun,0,1,0,ymin)
```

In polar coordinates:

```
polarfun = @(theta,r) fun(r.*cos(theta),r.*sin(theta)).*r;
rmax = @(theta) 1./(sin(theta) + cos(theta));
Q = quad2d(polarfun,0,pi/2,0,rmax)
```

## Limitations

quad2d begins by mapping the region of integration to a rectangle. Consequently, it may have trouble integrating over a region that does not have four sides or has a side that cannot be mapped smoothly to a straight line. If the integration is unsuccessful, some helpful tactics are leaving `Singular` set to its default value of `true`, changing between Cartesian and polar coordinates, or breaking the region of integration into pieces and adding the results of integration over the pieces.

For instance:

```
fun = @(x,y)abs(x.^2 + y.^2 - 0.25);
c = @(x)-sqrt(1 - x.^2);
d = @(x)sqrt(1 - x.^2);
quad2d(fun, -1,1,c,d, 'AbsTol',1e-8,...
 'FailurePlot',true, 'Singular',false);
```

Warning: Reached the maximum number of function evaluations (2000). The result fails the global error test.

The failure plot shows two areas of difficulty, near the points  $(-1, 0)$  and  $(1, 0)$  and near the circle  $x^2 + y^2 = 0.25$ .

Changing the value of `Singular` to `true` will cope with the geometric singularities at  $(-1, 0)$  and  $(1, 0)$ . The larger shaded areas may need refinement but are probably not areas of difficulty.

```
Q = quad2d(fun, -1, 1, c, d, 'AbsTol', 1e-8, ...
 'FailurePlot', true, 'Singular', true);
```

Warning: Reached the maximum number of function evaluations (2000). The result passes the global error test.

From here you can take advantage of symmetry:

```
Q = 4*quad2d(fun,0,1,0,d,'Abstol',1e-8,...
 'Singular',true,'FailurePlot',true)
```

Q =

0.9817

However, the code is still working very hard near the singularity. It may not be able to provide higher accuracy:

```
Q = 4*quad2d(fun,0,1,0,d,'Abstol',1e-10,...
```

```
'Singular',true,'FailurePlot',true);
```

Warning: Reached the maximum number of function evaluations (2000). The result passes the global error test.

At higher accuracy, a change in coordinates may work better.

```
polarfun = @(theta,r) fun(r.*cos(theta),r.*sin(theta)).*r;
Q = 4*quad2d(polarfun,0,pi/2,0,1,'AbsTol',1e-10);
```

It is best to put the singularity on the boundary by splitting the region of integration into two parts:

```
Q1 = 4*quad2d(polarfun,0,pi/2,0,0.5,'AbsTol',5e-11);
Q2 = 4*quad2d(polarfun,0,pi/2,0.5,1,'AbsTol',5e-11);
```

$Q = Q1 + Q2;$

# quadgk

Numerically evaluate integral, adaptive Gauss-Kronrod quadrature

## Syntax

```
q = quadgk(fun,a,b)
[q,errbnd] = quadgk(fun,a,b)
[q,errbnd] = quadgk(fun,a,b,param1,val1,param2,val2,...)
```

## Description

`q = quadgk(fun,a,b)` attempts to approximate the integral of a scalar-valued function `fun` from `a` to `b` using high-order global adaptive quadrature and default error tolerances. The function `y = fun(x)` should accept a vector argument `x` and return a vector result `y`, where `y` is the integrand evaluated at each element of `x`. `fun` must be a function handle. Limits `a` and `b` can be `-Inf` or `Inf`. If both are finite, they can be complex. If at least one is complex, the integral is approximated over a straight line path from `a` to `b` in the complex plane.

“Parameterizing Functions” explains how to provide additional parameters to the function `fun`, if necessary.

`[q,errbnd] = quadgk(fun,a,b)` returns an approximate upper bound on the absolute error,  $|Q - I|$ , where `I` denotes the exact value of the integral.

`[q,errbnd] = quadgk(fun,a,b,param1,val1,param2,val2,...)` performs the integration with specified values of optional parameters. The available parameters are

Parameter	Description	
'AbsTol'	Absolute error tolerance.  The default value of 'AbsTol' is <code>1.e-10</code> (double), <code>1.e-5</code> (single).	<code>quadgk</code> attempts to satisfy <code>errbnd &lt;= max(AbsTol, RelTol* Q )</code> . This is absolute error control when <code> Q </code> is sufficiently small and relative error control when <code> Q </code> is larger. For pure absolute error control use 'AbsTol'
'RelTol'	Relative error tolerance.	

Parameter	Description	
	The default value of 'RelTol' is 1.e-6 (double), 1.e-4 (single).	> 0 and 'RelTol' = 0. For pure relative error control use 'AbsTol' = 0. Except when using pure absolute error control, the minimum relative tolerance is 'RelTol' >= 100*eps(class(Q)).
'Waypoints'	Vector of integration waypoints.	<p>If <math>\text{fun}(x)</math> has discontinuities in the interval of integration, the locations should be supplied as a <code>Waypoints</code> vector. When <code>a</code>, <code>b</code>, and the waypoints are all real, only the waypoints between <code>a</code> and <code>b</code> are used, and they are used in sorted order. Note that waypoints are not intended for singularities in <math>\text{fun}(x)</math>. Singular points should be handled by making them endpoints of separate integrations and adding the results.</p> <p>If <code>a</code>, <code>b</code>, or any entry of the waypoints vector is complex, the integration is performed over a sequence of straight line paths in the complex plane, from <code>a</code> to the first waypoint, from the first waypoint to the second, and so forth, and finally from the last waypoint to <code>b</code>.</p>

Parameter	Description	
'MaxIntervalCount'	Maximum number of intervals allowed.  The default value is 650.	The 'MaxIntervalCount' parameter limits the number of intervals that <code>quadgk</code> uses at any one time after the first iteration. A warning is issued if <code>quadgk</code> returns early because of this limit. Routinely increasing this value is not recommended, but it may be appropriate when <code>errbnd</code> is small enough that the desired accuracy has nearly been achieved.

The list below contains information to help you determine which quadrature function in MATLAB to use:

- The `quad` function may be most efficient for low accuracies with nonsmooth integrands.
- The `quadl` function may be more efficient than `quad` at higher accuracies with smooth integrands.
- The `quadgk` function may be most efficient for high accuracies and oscillatory integrands. It supports infinite intervals and can handle moderate singularities at the endpoints. It also supports contour integration along piecewise linear paths.
- The `quadv` function vectorizes `quad` for an array-valued `fun`.
- If the interval is infinite,  $[a, \text{Inf})$ , then for the integral of `fun(x)` to exist, `fun(x)` must decay as `x` approaches infinity, and `quadgk` requires it to decay rapidly. Special methods should be used for oscillatory functions on infinite intervals, but `quadgk` can be used if `fun(x)` decays fast enough.
- The `quadgk` function will integrate functions that are singular at finite endpoints if the singularities are not too strong. For example, it will integrate functions that behave at an endpoint `c` like  $\log|x-c|$  or  $|x-c|^p$  for  $p \geq -1/2$ . If the function is singular at points inside  $(a, b)$ , write the integral as a sum of integrals over subintervals with the singular points as endpoints, compute them with `quadgk`, and add the results.

## Examples

### Integrand with a singularity at an integration end point

Write a function `myfun` that computes the integrand:

```
function y = myfun(x)
y = exp(x).*log(x);
```

Then pass `@myfun`, a function handle to `myfun`, to `quadgk`, along with the limits of integration, 0 to 1:

```
q = quadgk(@myfun,0,1)

q =

 -1.3179
```

Alternatively, you can pass the integrand to `quadgk` as an anonymous function handle `F`:

```
f = @(x)exp(x).*log(x);
q = quadgk(f,0,1);
```

### Oscillatory integrand on a semi-infinite interval

Integrate over a semi-infinite interval with specified tolerances, and return the approximate error bound:

```
f = @(x)x.^5.*exp(-x).*sin(x);
[q,errbnd] = quadgk(f,0,inf,'RelTol',1e-8,'AbsTol',1e-12)

q =

 -15.0000

errbnd =

 9.4386e-009
```

### Contour integration around a pole

Use `Waypoints` to integrate around a pole using a piecewise linear contour:

```
f = @(z)1./(2*z - 1);
```

```
q = quadgk(f,-1-i,-1-i,'Waypoints',[1-i,1+i,-1+i])
```

```
q =
```

```
0.0000 + 3.1416i
```

## Diagnostics

quadgk may issue one of the following warnings:

'Minimum step size reached' indicates that interval subdivision has produced a subinterval whose length is on the order of roundoff error in the length of the original interval. A nonintegrable singularity is possible.

'Reached the limit on the maximum number of intervals in use' indicates that the integration was terminated before meeting the tolerance requirements and that continuing the integration would require more than `MaxIntervalCount` subintervals. The integral may not exist, or it may be difficult to approximate numerically. Increasing `MaxIntervalCount` usually does not help unless the tolerance requirements were nearly met when the integration was previously terminated.

'Infinite or Not-a-Number function value encountered' indicates a floating point overflow or division by zero during the evaluation of the integrand in the interior of the interval.

## More About

### Algorithms

quadgk implements adaptive quadrature based on a Gauss-Kronrod pair (15<sup>th</sup> and 7<sup>th</sup> order formulas).

# quadl

Numerically evaluate integral, adaptive Lobatto quadrature

## Compatibility

quadl will be removed in a future release. Use `integral` instead.

## Syntax

```
q = quadl(fun,a,b)
q = quadl(fun,a,b,tol)
quadl(fun,a,b,tol,trace)
[q,fcnt] = quadl(...)
```

## Description

`q = quadl(fun,a,b)` approximates the integral of function `fun` from `a` to `b`, to within an error of  $10^{-6}$  using recursive adaptive Lobatto quadrature. `fun` is a function handle. It accepts a vector `x` and returns a vector `y`, the function `fun` evaluated at each element of `x`. Limits `a` and `b` must be finite.

“Parameterizing Functions” explains how to provide additional parameters to the function `fun`, if necessary.

`q = quadl(fun,a,b,tol)` uses an absolute error tolerance of `tol` instead of the default, which is `1.0e-6`. Larger values of `tol` result in fewer function evaluations and faster computation, but less accurate results.

`quadl(fun,a,b,tol,trace)` with non-zero `trace` shows the values of [`fcnt` `a` `b` `a` `q`] during the recursion.

`[q,fcnt] = quadl(...)` returns the number of function evaluations.

Use array operators `.*`, `./` and `.^` in the definition of `fun` so that it can be evaluated with a vector argument.

The function `quad` might be more efficient with low accuracies or nonsmooth integrands.

The list below contains information to help you determine which quadrature function in MATLAB to use:

- The `quad` function might be most efficient for low accuracies with nonsmooth integrands.
- The `quadl` function might be more efficient than `quad` at higher accuracies with smooth integrands.
- The `quadgk` function might be most efficient for high accuracies and oscillatory integrands. It supports infinite intervals and can handle moderate singularities at the endpoints. It also supports contour integration along piecewise linear paths.
- The `quadv` function vectorizes `quad` for an array-valued `fun`.
- If the interval is infinite, `[a, Inf)`, then for the integral of `fun(x)` to exist, `fun(x)` must decay as `x` approaches infinity, and `quadgk` requires it to decay rapidly. Special methods should be used for oscillatory functions on infinite intervals, but `quadgk` can be used if `fun(x)` decays fast enough.
- The `quadgk` function will integrate functions that are singular at finite endpoints if the singularities are not too strong. For example, it will integrate functions that behave at an endpoint `c` like `log|x-c|` or `|x-c|^p` for `p >= -1/2`. If the function is singular at points inside `(a,b)`, write the integral as a sum of integrals over subintervals with the singular points as endpoints, compute them with `quadgk`, and add the results.

## Examples

Pass the function handle, `@myfun`, to `quadl`:

```
Q = quadl(@myfun,0,2);
```

where the function `myfun.m` is:

```
function y = myfun(x)
y = 1./(x.^3-2*x-5);
```

Pass anonymous function handle `F` to `quadl`:

```
F = @(x) 1./(x.^3-2*x-5);
Q = quadl(F,0,2);
```

## Diagnostics

quad1 might issue one of the following warnings:

'Minimum step size reached' indicates that the recursive interval subdivision has produced a subinterval whose length is on the order of roundoff error in the length of the original interval. A nonintegrable singularity is possible.

'Maximum function count exceeded' indicates that the integrand has been evaluated more than 10,000 times. A nonintegrable singularity is likely.

'Infinite or Not-a-Number function value encountered' indicates a floating point overflow or division by zero during the evaluation of the integrand in the interior of the interval.

## More About

### Algorithms

quad1 implements a high order method using an adaptive Gauss/Lobatto quadrature rule.
