An n -by-2 cell array of the categories used at branches in tree, where n is the number of nodes. For each branch node i based on a categorical predictor variable x , the left child is chosen if x is among the categories listed in `CutCategories{i,1}`, and the right child is chosen if x is among those listed in `CutCategories{i,2}`. Both columns of `CutCategories` are empty for branch nodes based on continuous predictors and for leaf nodes.

`CutPoint` contains the cut points for 'continuous' cuts, and `CutCategories` contains the set of categories.

CutPoint

An n -element vector of the values used as cut points in tree, where n is the number of nodes. For each branch node i based on a continuous predictor variable x , the left child is chosen if `CutPoint < v(i)` and the right child is chosen if `x >= CutPoint(i)`. `CutPoint` is NaN for branch nodes based on categorical predictors and for leaf nodes.

CutType

An n -element cell array indicating the type of cut at each node in tree, where n is the number of nodes. For each node i , `CutType{i}` is:

- 'continuous' — If the cut is defined in the form $x < v$ for a variable x and cut point v .
- 'categorical' — If the cut is defined by whether a variable x takes a value in a set of categories.
- '' — If i is a leaf node.

`CutPoint` contains the cut points for 'continuous' cuts, and `CutCategories` contains the set of categories.

CutPredictor

An n -element cell array of the names of the variables used for branching in each node in tree, where n is the number of nodes. These variables are sometimes known as *cut variables*. For leaf nodes, `CutPredictor` contains an empty string.

`CutPoint` contains the cut points for 'continuous' cuts, and `CutCategories` contains the set of categories.

IsBranchNode

An n -element logical vector `ib` that is `true` for each branch node and `false` for each leaf node of tree.

NodeError

An n -element vector `e` of the errors of the nodes in tree, where n is the number of nodes. `e(i)` is the misclassification probability for node `i`.

NodeMean

An n -element numeric array with mean values in each node of tree, where n is the number of nodes in the tree. Every element in `NodeMean` is the average of the true `Y` values over all observations in the node.

NodeProbability

An n -element vector `p` of the probabilities of the nodes in tree, where n is the number of nodes. The probability of a node is computed as the proportion of observations from the original data that satisfy the conditions for the node. This proportion is adjusted for any prior probabilities assigned to each class.

NodeRisk

An n -element vector of the risk of the nodes in the tree, where n is the number of nodes. The risk for each node is the node error weighted by the node probability.

NodeSize

An n -element vector `sizes` of the sizes of the nodes in tree, where n is the number of nodes. The size of a node is defined as the number of observations from the data used to create the tree that satisfy the conditions for the node.

NumNodes

The number of nodes n in tree.

Parent

An n -element vector \mathbf{p} containing the number of the parent node for each node in tree, where n is the number of nodes. The parent of the root node is 0.

PredictorNames

A cell array of names for the predictor variables, in the order in which they appear in X .

PruneAlpha

Numeric vector with one element per pruning level. If the pruning level ranges from 0 to M , then `PruneAlpha` has $M + 1$ elements sorted in ascending order. `PruneAlpha(1)` is for pruning level 0 (no pruning), `PruneAlpha(2)` is for pruning level 1, and so on.

PruneList

An n -element numeric vector with the pruning levels in each node of tree, where n is the number of nodes. The pruning levels range from 0 (no pruning) to M , where M is the distance between the deepest leaf and the root node.

ResponseName

Name of the response variable Y , a string.

ResponseTransform

Function handle for transforming the raw response values (mean squared error). The function handle should accept a matrix of response values and return a matrix of the same size. The default string 'none' means $@(x)x$, or no transformation.

Add or change a `ResponseTransform` function using dot notation:

```
ctree.ResponseTransform = @function
```

SurrogateCutCategories

An n -element cell array of the categories used for surrogate splits in tree, where n is the number of nodes in tree. For each node k , `SurrogateCutCategories{k}` is a cell array. The length of `SurrogateCutCategories{k}` is equal to the number of surrogate predictors found at this node. Every element of `SurrogateCutCategories{k}` is either

an empty string for a continuous surrogate predictor, or is a two-element cell array with categories for a categorical surrogate predictor. The first element of this two-element cell array lists categories assigned to the left child by this surrogate split, and the second element of this two-element cell array lists categories assigned to the right child by this surrogate split. The order of the surrogate split variables at each node is matched to the order of variables in `SurrogateCutPredictor`. The optimal-split variable at this node does not appear. For nonbranch (leaf) nodes, `SurrogateCutCategories` contains an empty cell.

SurrogateCutFlip

An n -element cell array of the numeric cut assignments used for surrogate splits in tree, where n is the number of nodes in tree. For each node k , `SurrogateCutFlip{k}` is a numeric vector. The length of `SurrogateCutFlip{k}` is equal to the number of surrogate predictors found at this node. Every element of `SurrogateCutFlip{k}` is either zero for a categorical surrogate predictor, or a numeric cut assignment for a continuous surrogate predictor. The numeric cut assignment can be either -1 or $+1$. For every surrogate split with a numeric cut C based on a continuous predictor variable Z , the left child is chosen if $Z < C$ and the cut assignment for this surrogate split is $+1$, or if $Z \geq C$ and the cut assignment for this surrogate split is -1 . Similarly, the right child is chosen if $Z \geq C$ and the cut assignment for this surrogate split is $+1$, or if $Z < C$ and the cut assignment for this surrogate split is -1 . The order of the surrogate split variables at each node is matched to the order of variables in `SurrogateCutPredictor`. The optimal-split variable at this node does not appear. For nonbranch (leaf) nodes, `SurrogateCutFlip` contains an empty array.

SurrogateCutPoint

An n -element cell array of the numeric values used for surrogate splits in tree, where n is the number of nodes in tree. For each node k , `SurrogateCutPoint{k}` is a numeric vector. The length of `SurrogateCutPoint{k}` is equal to the number of surrogate predictors found at this node. Every element of `SurrogateCutPoint{k}` is either NaN for a categorical surrogate predictor, or a numeric cut for a continuous surrogate predictor. For every surrogate split with a numeric cut C based on a continuous predictor variable Z , the left child is chosen if $Z < C$ and `SurrogateCutFlip` for this surrogate split is $+1$, or if $Z \geq C$ and `SurrogateCutFlip` for this surrogate split is -1 . Similarly, the right child is chosen if $Z \geq C$ and `SurrogateCutFlip` for this surrogate split is $+1$, or if $Z < C$ and `SurrogateCutFlip` for this surrogate split is -1 . The order of the surrogate split variables at each node is matched to the order of variables returned by `SurrogateCutVar`. The optimal-split variable at this node does not appear. For nonbranch (leaf) nodes, `SurrogateCutPoint` contains an empty cell.

SurrogateCutType

An n -element cell array indicating types of surrogate splits at each node in tree, where n is the number of nodes in tree. For each node k , `SurrogateCutType{k}` is a cell array with the types of the surrogate split variables at this node. The variables are sorted by the predictive measure of association with the optimal predictor in the descending order, and only variables with the positive predictive measure are included. The order of the surrogate split variables at each node is matched to the order of variables in `SurrogateCutPredictor`. The optimal-split variable at this node does not appear. For nonbranch (leaf) nodes, `SurrogateCutType` contains an empty cell. A surrogate split type can be either 'continuous' if the cut is defined in the form $Z < V$ for a variable Z and cut point V or 'categorical' if the cut is defined by whether Z takes a value in a set of categories.

SurrogateCutPredictor

An n -element cell array of the names of the variables used for surrogate splits in each node in tree, where n is the number of nodes in tree. Every element of `SurrogateCutPredictor` is a cell array with the names of the surrogate split variables at this node. The variables are sorted by the predictive measure of association with the optimal predictor in the descending order, and only variables with the positive predictive measure are included. The optimal-split variable at this node does not appear. For nonbranch (leaf) nodes, `SurrogateCutPredictor` contains an empty cell.

SurrogatePredictorAssociation

An n -element cell array of the predictive measures of association for surrogate splits in tree, where n is the number of nodes in tree. For each node k , `SurrogatePredictorAssociation{k}` is a numeric vector. The length of `SurrogatePredictorAssociation{k}` is equal to the number of surrogate predictors found at this node. Every element of `SurrogatePredictorAssociation{k}` gives the predictive measure of association between the optimal split and this surrogate split. The order of the surrogate split variables at each node is the order of variables in `SurrogateCutPredictor`. The optimal-split variable at this node does not appear. For nonbranch (leaf) nodes, `SurrogatePredictorAssociation` contains an empty cell.

Methods

loss

Regression error

surrogateAssociation	Mean predictive measure of association for surrogate splits in decision tree
predict	Predict response of regression tree
predictorImportance	Estimates of predictor importance
view	View tree

Copy Semantics

Value. To learn how value classes affect copy operations, see “Copying Objects” in the MATLAB documentation.

Examples

Construct and Compact a Regression Tree

Load the sample data.

```
load carsmall
```

Construct a regression tree for the sample data.

```
tree = fitrtree([Weight, Cylinders],MPG,...
    'MinParentSize',20,...
    'PredictorNames',{'W','C'});
```

Make a compact version of the tree.

```
ctree = compact(tree);
```

Compare the size of the compact tree to that of the full tree.

```
t = whos('tree'); % t.bytes = size of tree in bytes
c = whos('ctree'); % c.bytes = size of ctree in bytes
[c.bytes t.bytes]
```

```
ans =  
    4972    8173
```

The compact tree is smaller than the full tree.

CompactTreeBagger class

Compact ensemble of decision trees grown by bootstrap aggregation

Description

CompactTreeBagger class is a lightweight class that contains the trees grown using TreeBagger. CompactTreeBagger does not preserve any information about how TreeBagger grew the decision trees. It does not contain the input data used for growing trees, nor does it contain training parameters such as minimal leaf size or number of variables sampled for each decision split at random. You can only use CompactTreeBagger for predicting the response of the trained ensemble given new data X , and other related functions.

CompactTreeBagger lets you save the trained ensemble to disk, or use it in any other way, while discarding training data and various parameters of the training configuration irrelevant for predicting response of the fully grown ensemble. This reduces storage and memory requirements, especially for ensembles trained on large data sets.

Construction

<code>.CompactTreeBagger</code>	Create CompactTreeBagger object
---------------------------------	---------------------------------

Methods

<code>combine</code>	Combine two ensembles
<code>error</code>	Error (misclassification probability or MSE)
<code>margin</code>	Classification margin

<code>mdsProx</code>	Multidimensional scaling of proximity matrix
<code>meanMargin</code>	Mean classification margin
<code>outlierMeasure</code>	Outlier measure for data
<code>predict</code>	Predict response
<code>proximity</code>	Proximity matrix for data
<code>setDefaultYfit</code>	Set default value for <code>predict</code>

Properties

ClassNames

The `ClassNames` property is a cell array containing the class names for the response variable `Y` supplied to `TreeBagger`. This property is empty for regression trees.

DeltaCritDecisionSplit

The `DeltaCritDecisionSplit` property is a numeric array of size 1-by-`Nvars` of changes in the split criterion summed over splits on each variable, averaged across the entire ensemble of grown trees.

See also `TreeBagger.DeltaCritDecisionSplit`, `ClassificationTree.predictorImportance`, and `RegressionTree.predictorImportance`

DefaultYfit

The `DefaultYfit` property controls what predicted value `CompactTreeBagger` returns when no prediction is possible, for example when the `predict` method needs to predict for an observation which has only false values in the matrix supplied through `'useifort'` argument.

For classification, you can set this property to either '' or 'MostPopular'. If you choose 'MostPopular' (default), the property value becomes the name of the most probable class in the training data.

For regression, you can set this property to any numeric scalar. The default is the mean of the response for the training data.

See also `predict`, `setDefaultYfit`, `TreeBagger.DefaultYfit`.

Method

The `Method` property is 'classification' for classification ensembles and 'regression' for regression ensembles.

NTrees

The `NTrees` property is a scalar equal to the number of decision trees in the ensemble.

NVarSplit

The `NVarSplit` property is a numeric array of size 1-by-*Nvars*, where every element gives a number of splits on this predictor summed over all trees.

Trees

The `Trees` property is a cell array of size `NTrees`-by-1 containing the trees in the ensemble.

VarAssoc

The `VarAssoc` property is a matrix of size *Nvars*-by-*Nvars* with predictive measures of variable association, averaged across the entire ensemble of grown trees. If you grew the ensemble setting 'surrogate' to 'on', this matrix for each tree is filled with predictive measures of association averaged over the surrogate splits. If you grew the ensemble setting 'surrogate' to 'off' (default), `VarAssoc` is diagonal.

See also `ClassificationTree.surrogateAssociation`, `RegressionTree.surrogateAssociation`.

VarNames

The `VarNames` property is a cell array containing the names of the predictor variables (features). These names are taken from the optional 'names' parameter that supplied to `TreeBagger`. The default names are 'x1', 'x2', etc.

Copy Semantics

Value. To learn how this affects your use of the class, see “Comparing Handle and Value Classes” in the MATLAB Object-Oriented Programming documentation.

CompactTreeBagger

Class: CompactTreeBagger

Create CompactTreeBagger object

Description

When you use the `TreeBagger` constructor to grow trees, it creates a `CompactTreeBagger` object. You can obtain the compact object from the full `TreeBagger` object using the `TreeBagger/compact` method. You do not create an instance of `CompactTreeBagger` directly.

compare

Class: GeneralizedLinearMixedModel

Compare generalized linear mixed-effects models

Syntax

```
results = compare(glme, altglme)
results = compare(glme, altglme, Name, Value)
```

Description

`results = compare(glme, altglme)` returns the results of a likelihood ratio test that compares the generalized linear mixed-effects models `glme` and `altglme`. To conduct a valid likelihood ratio test, both models must use the same response vector in the fit, and `glme` must be nested in `altglme`. Always input the smaller model first, and the larger model second.

`compare` tests the following null and alternate hypotheses:

- H_0 : Observed response vector is generated by `glme`.
- H_1 : Observed response vector is generated by model `altglme`.

`results = compare(glme, altglme, Name, Value)` returns the results of a likelihood ratio test using additional options specified by one or more `Name, Value` pair arguments. For example, you can check if the first input model, `glme`, is nested in the second input model, `altglme`.

Input Arguments

glme — Generalized linear mixed-effects model

GeneralizedLinearMixedModel object

Generalized linear mixed-effects model, specified as a `GeneralizedLinearMixedModel` object. For properties and methods of this object, see `GeneralizedLinearMixedModel`.

You can create a `GeneralizedLinearMixedModel` object by fitting a generalized linear mixed-effects model to your sample data using `fitglme`. To conduct a valid likelihood ratio test on two models that have response distributions other than normal, you must fit both models using the `'ApproximateLaplace'` or `'Laplace'` fit method. Models with response distributions other than normal that are fitted using `'MPL'` or `'REML'` cannot be compared using a likelihood ratio test.

altglme — Alternative generalized linear mixed-effects model

`GeneralizedLinearMixedModel` object

Alternative generalized linear mixed-effects model, specified as a `GeneralizedLinearMixedModel` object. `altglme` must fit to the same response vector as `glme`, but with different model specifications. `glme` must be nested in `altglme`, such that you can obtain `glme` from `altglme` by setting some of the model parameters of `altglme` to fixed values such as 0.

You can create a `GeneralizedLinearMixedModel` object by fitting a generalized linear mixed-effects model to your sample data using `fitglme`. To conduct a valid likelihood ratio test on two models that have response distributions other than normal, you must fit both models using the `'ApproximateLaplace'` or `'Laplace'` fit method. Models with response distributions other than normal that are fitted using `'MPL'` or `'REML'` cannot be compared using a likelihood ratio test.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

'CheckNesting' — Indicator to check nesting between two models

`true` (default) | `false`

Indicator to check nesting between two models, specified as the comma-separated pair consisting of `'CheckNesting'` and either `true` or `false`. If `'CheckNesting'` is `true`, then `compare` checks if the smaller model `glme` is nested in the larger model `altglme`. If the nesting requirements are not satisfied, then `compare` returns an error. If `'CheckNesting'` is `false`, then `compare` does not perform this check.

Example: `'CheckNesting',true`

Output Arguments

results — Results of likelihood ratio test

table

Results of the likelihood ratio test, returned as a table with two rows. The first row is for `glme`, and the second row is for `altglme`. The columns of results contain the following.

<code>Model</code>	Name of the model
<code>DF</code>	Degrees of freedom
<code>AIC</code>	Akaike information criterion for the model
<code>BIC</code>	Bayesian information criterion for the model
<code>LogLik</code>	Maximized log likelihood for the model
<code>LRStat</code>	Likelihood ratio test statistic for comparing <code>altglme</code> and <code>glme</code>
<code>deltaDF</code>	DF for <code>altglme</code> minus DF for <code>glme</code>
<code>pValue</code>	p -value for the likelihood ratio test

Definitions

Likelihood Ratio Test

A *likelihood ratio test* compares the specifications of two nested models by assessing the significance of restrictions to an extended model with unrestricted parameters. Under the null hypothesis H_0 , the likelihood ratio test statistic has an approximate chi-squared reference distribution with degrees of freedom `deltaDF`.

When comparing two models, `compare` computes the p -value for the likelihood ratio test by comparing the observed likelihood ratio test statistic with this chi-squared reference distribution. A small p -value leads to a rejection of H_0 in favor of H_1 , and acceptance of the alternate model `altglme`. On the other hand, a large p -value indicates that we cannot reject H_0 , and reflects insufficient evidence to accept the model `altglme`.

The p -values obtained using the likelihood ratio test can be conservative when testing for the presence or absence of random-effects terms, and anti-conservative when testing

for the presence or absence of fixed-effects terms. Instead, use the `fixedEffects` or `coefTest` methods to test for fixed effects.

To conduct a valid likelihood ratio test on GLME models, both models must be fitted using a Laplace or approximate Laplace fit method. Models fitted using a maximum pseudo likelihood (MPL) or restricted maximum pseudo likelihood (REMP) method cannot be compared using a likelihood ratio test. When comparing models fitted using MPL, the maximized log likelihood of the pseudodata from the final pseudo likelihood iteration is used in the likelihood ratio test. If you compare models with non-normal distributions fitted using MPL, then `compare` gives a warning that the likelihood ratio test is using maximized log likelihood of pseudodata from the final pseudo likelihood iteration. To use the true maximized log likelihood in the likelihood ratio test, fit both `glme` and `altglme` using approximate Laplace or Laplace prior to model comparison.

Nesting Requirements

To conduct a valid likelihood ratio test, `glme` must be nested in `altglme`. The `'CheckNesting'`, `true` name-value pair argument checks the following requirements, and returns an error if any are not satisfied:

- You must fit both models (`glme` and `altglme`) using the `'ApproximateLaplace'` or `'Laplace'` fit method. You cannot compare GLME models fitted using `'MPL'` or `'REMP'` using a likelihood ratio test.
- You must fit both models using the same response vector, response distribution, and link function.
- The smaller model (`glme`) must be nested within the larger model (`altglme`), such that you can obtain `glme` from `altglme` by setting some of the model parameters of `altglme` to fixed values such as 0.
- The maximized log likelihood of the larger model (`altglme`) must be greater than or equal to the maximized log likelihood of the smaller model (`glme`).
- The weight vectors used to fit `glme` and `altglme` must be identical.
- The random-effects design matrix of the larger model (`altglme`) must contain the random-effects design matrix of the smaller model (`glme`).
- The fixed-effects design matrix of the larger model (`altglme`) must contain the fixed-effects design matrix of the smaller model (`glme`).

Akaike and Bayesian Information Criteria

The *Akaike information criterion* (AIC) is $AIC = -2\log L_M + 2(\text{param})$.

$\log L_M$ depends on the method used to fit the model.

- If you use 'Laplace' or 'ApproximateLaplace', then $\log L_M$ is the maximized log likelihood.
- If you use 'MPL', then $\log L_M$ is the maximized log likelihood of the pseudo data from the final pseudo likelihood iteration.
- If you use 'REML', then $\log L_M$ is the maximized restricted log likelihood of the pseudo data from the final pseudo likelihood iteration.

$param$ is the total number of parameters estimated in the model. For most GLME models, $param$ is equal to $nc + p + 1$, where nc is the total number of parameters in the random-effects covariance, excluding the residual variance, and p is the number of fixed-effects coefficients. However, if the dispersion parameter is fixed at 1.0 for binomial or Poisson distributions, then $param$ is equal to $(nc + p)$.

The *Bayesian information criterion* (BIC) is $BIC = -2 * \log L_M + \ln(n_{eff})(param)$.

$\log L_M$ depends on the method used to fit the model.

- If you use 'Laplace' or 'ApproximateLaplace', then $\log L_M$ is the maximized log likelihood.
- If you use 'MPL', then $\log L_M$ is the maximized log likelihood of the pseudo data from the final pseudo likelihood iteration.
- If you use 'REML', then $\log L_M$ is the maximized restricted log likelihood of the pseudo data from the final pseudo likelihood iteration.

n_{eff} is the effective number of observations.

- If you use 'MPL', 'Laplace', or 'ApproximateLaplace', then $n_{eff} = n$, where n is the number of observations.
- If you use 'REML', then $n_{eff} = n - p$.

$param$ is the total number of parameters estimated in the model. For most GLME models, $param$ is equal to $nc + p + 1$, where nc is the total number of parameters in the random-effects covariance, excluding the residual variance, and p is the number of fixed-effects coefficients. However, if the dispersion parameter is fixed at 1.0 for binomial or Poisson distributions, then $param$ is equal to $(nc + p)$.

A lower value of deviance indicates a better fit. As the value of deviance decreases, both AIC and BIC tend to decrease. Both AIC and BIC also include penalty terms based on

the number of parameters estimated, p . So, when the number of parameters increase, the values of AIC and BIC tend to increase as well. When comparing different models, the model with the lowest AIC or BIC value is considered as the best fitting model.

For models fitted using 'MPL' and 'REML', AIC and BIC are based on the log likelihood (or restricted log likelihood) of pseudo data from the final pseudo likelihood iteration. Therefore, a direct comparison of AIC and BIC values between models fitted using 'MPL' and 'REML' is not appropriate.

Examples

Compare Mixed-Effects Models

Navigate to the folder containing the sample data. Load the sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

```
load mfr
```

This simulated data is from a manufacturing company that operates 50 factories across the world, with each factory running a batch process to create a finished product. The company wants to decrease the number of defects in each batch, so it developed a new manufacturing process. To test the effectiveness of the new process, the company selected 20 of its factories at random to participate in an experiment: Ten factories implemented the new process, while the other ten continued to run the old process. In each of the 20 factories, the company ran five batches (for a total of 100 batches) and recorded the following data:

- Flag to indicate whether the batch used the new process (`newprocess`)
- Processing time for each batch, in hours (`time`)
- Temperature of the batch, in degrees Celsius (`temp`)
- Categorical variable indicating the supplier of the chemical used in the batch (`supplier`)
- Number of defects in the batch (`defects`)

The data also includes `time_dev` and `temp_dev`, which represent the absolute deviation of time and temperature, respectively, from the process standard of 3 hours at 20 degrees Celsius.

Fit a fixed-effects-only model using `newprocess`, `time_dev`, `temp_dev`, and `supplier` as fixed-effects predictors. Specify the response distribution as Poisson, the link function as log, and the fit method as Laplace. Specify the dummy variable encoding as 'effects', so the dummy variable coefficients sum to 0.

```
FEglme = fitglme(mfr, 'defects ~ 1 + newprocess + time_dev + temp_dev + supplier', 'Dist
```

Fit a second model that uses the same fixed-effects predictors, response distribution, link function, and fit method. This time, include a random-effects intercept grouped by `factory`, to account for quality differences that might exist due to factory-specific variations.

The number of defects can be modeled using a Poisson distribution

$$defects_{ij} \sim \text{Poisson}(\mu_{ij})$$

This corresponds to the generalized linear mixed-effects model

$$\log(\mu_{ij}) = \beta_0 + \beta_1 newprocess_{ij} + \beta_2 time_dev_{ij} + \beta_3 temp_dev_{ij} + \beta_4 supplier_C_{ij} + \beta_5 supplier_B_{ij} +$$

where

- $defects_{ij}$ is the number of defects observed in the batch produced by factory i during batch j .
- μ_{ij} is the mean number of defects corresponding to factory i (where $i = 1, 2, \dots, 20$) during batch j (where $j = 1, 2, \dots, 5$).
- $newprocess_{ij}$, $time_dev_{ij}$, and $temp_dev_{ij}$ are the measurements for each variable that correspond to factory i during batch j . For example, $newprocess_{ij}$ indicates whether the batch produced by factory i during batch j used the new process.
- $supplier_C_{ij}$ and $supplier_B_{ij}$ are dummy variables that use effects (sum-to-zero) coding to indicate whether company **C** or **B**, respectively, supplied the process chemicals for the batch produced by factory i during batch j .
- $b_i \sim N(0, \sigma_b^2)$ is a random-effects intercept for each factory i that accounts for factory-specific variation in quality.

```
glme = fitglme(mfr, 'defects ~ 1 + newprocess + time_dev + temp_dev + supplier + (1|fact
```

Compare the two models using a theoretical likelihood ratio test. Specify 'CheckNesting' as true, so `compare` returns a warning if the nesting requirements are not satisfied.

```
results = compare(FEglme,glme,'CheckNesting',true)
```

```
results =
```

Theoretical Likelihood Ratio Test

Model	DF	AIC	BIC	LogLik	LRStat	deltaDF
FEglme	6	431.02	446.65	-209.51		
glme	7	416.35	434.58	-201.17	16.672	1

```
pValue
```

```
4.4435e-05
```

Since `compare` did not return an error, the nesting requirements are satisfied. The small p -value indicates that `compare` rejects the null hypothesis that the observed response vector is generated by the model `FEglme`, and instead accepts the alternate model `glme`. The smaller AIC and BIC values for `glme` also support the conclusion that `glme` provides a better fitting model for the response.

compare

Class: LinearMixedModel

Compare linear mixed-effects models

Syntax

```
results = compare(lme,altlme)
results = compare( ____,Name,Value)

[results,siminfo] = compare(lme,altlme,'NSim',nsim)
[results,siminfo] = compare( ____,Name,Value)
```

Description

`results = compare(lme,altlme)` returns the results of a likelihood ratio test that compares the linear mixed-effects models `lme` and `altlme`. Both models must use the same response vector in the fit and `lme` must be nested in `altlme` for a valid theoretical likelihood ratio test. Always input the smaller model first, and the larger model second.

`compare` tests the following null and alternate hypotheses:

H_0 : Observed response vector is generated by `lme`.

H_1 : Observed response vector is generated by model `altlme`.

It is recommended that you fit `lme` and `altlme` using the maximum likelihood (ML) method prior to model comparison. If you use the restricted maximum likelihood (REML) method, then both models must have the same fixed-effects design matrix.

To test for fixed effects, use `compare` with the simulated likelihood ratio test when `lme` and `altlme` are fit using ML or use the `fixedEffects`, `anova`, or `coefTest` methods.

`results = compare(____,Name,Value)` also returns the results of a likelihood ratio test that compares linear mixed-effects models `lme` and `altlme` with additional options specified by one or more `Name,Value` pair arguments.

For example, you can check if the first input model is nested in the second input model.

```
[results,siminfo] = compare(lme,altlme,'NSim',nsim)
```

returns the results of a simulated likelihood ratio test that compares linear mixed-effects models `lme` and `altlme`.

You can fit `lme` and `altlme` using ML or REML. Also, `lme` does not have to be nested in `altlme`. If you use the restricted maximum likelihood (REML) method to fit the models, then both models must have the same fixed-effects design matrix.

```
[results,siminfo] = compare( ___,Name,Value)
```

also returns the results of a simulated likelihood ratio test that compares linear mixed-effects models `lme` and `altlme` with additional options specified by one or more `Name,Value` pair arguments.

For example, you can change the options for performing the simulated likelihood ratio test, or change the confidence level of the confidence interval for the p -value.

Input Arguments

lme — Linear mixed-effects model

LinearMixedModel object

Linear mixed-effects model, returned as a `LinearMixedModel` object.

For properties and methods of this object, see `LinearMixedModel`.

altlme — Alternative linear mixed-effects model

LinearMixedModel object

Alternative linear mixed-effects model fit to the same response vector but with different model specifications, specified as a `LinearMixedModel` object. `lme` must be nested in `altlme`, that is, `lme` should be obtained from `altlme` by setting some parameters to fixed values, such as 0. You can create a linear mixed-effects object using `fitlme` or `fitlmematrix`.

nsim — Number of replications for simulations

positive integer number

Number of replications for simulations in the simulated likelihood ratio test, specified as a positive integer number. You must specify `nsim` to do a simulated likelihood ratio test.

Example: `'NSim',1000`

Data Types: `double` | `single`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

'Alpha' — Confidence level

0.05 (default) | scalar value in the range 0 to 1

Confidence level, specified as the comma-separated pair consisting of 'Alpha' and a scalar value in the range 0 to 1. For a value α , the confidence level is $100*(1-\alpha)\%$.

For example, for 99% confidence intervals, you can specify the confidence level as follows.

Example: 'Alpha', 0.01

Data Types: `single` | `double`

'Options' — Options for performing simulated likelihood ratio test

structure

Options for performing the simulated likelihood ratio test, specified as the comma-separated pair consisting of 'Options', and a structure created by `statset('LinearMixedModel')`.

`compare` uses the following fields.

'UseParallel'

- False for serial computation. Default.
- True for parallel computation.

'UseSubstreams'

- False for not using a separate substream of the random number generator for each iteration. Default.
- True for using a separate substream of the random number generator for each iteration. You can only use this option with random stream types that support substreams.

'Streams'

- If 'UseSubstreams' is True, then 'Streams' must be a single random number stream, or a scalar cell array containing a single stream.
- If 'UseSubstreams' is False and
 - 'UseParallel' is False, then 'Streams' must be a single random number stream, or a scalar cell array containing a single stream.
 - 'UseParallel' is True, then 'Streams' must be equal to the number of processors used. If a parallel pool is open, then the 'Streams' is the same length as the size of the parallel pool. If 'UseParallel' is True, a parallel pool might open up for you. But since 'Streams' must be equal to the number of processors used, it is best to open a pool explicitly using the `parpool` command, before calling `compare` with the 'UseParallel', 'True' option.

For information on parallel statistical computing at the command line, enter

`help parallelstats`

Data Types: struct

'CheckNesting' — Indicator to check nesting between two models

false (default) | true

Indicator to check nesting between two models, specified as the comma-separated pair consisting of 'CheckNesting' and one of the following.

false

Default. No checks.

true

`compare` checks if the smaller model `lme` is nested in the bigger model `altlme`.

`lme` must be nested in the alternate model `altlme` for a valid theoretical likelihood ratio test. `compare` returns an error message if the nesting requirements are not satisfied.

Although valid for both tests, the nesting requirements are weaker for the simulated likelihood ratio test.

Example: `'CheckNesting', true`

Data Types: `single` | `double`

Output Arguments

results — Results of likelihood ratio test or simulated likelihood ratio test

dataset array

Results of the likelihood ratio test or simulated likelihood ratio test, returned as a dataset array with two rows. The first row is for `lme`, and the second row is for `altlme`. The columns of `results` depend on whether the test is a likelihood ratio or a simulated likelihood ratio test.

- If you use the likelihood ratio test, then `results` contains the following columns.

<code>Model</code>	Name of the model
<code>DF</code>	Degrees of freedom, that is, the number of free parameters in the model
<code>AIC</code>	Akaike information criterion for the model
<code>BIC</code>	Bayesian information criterion for the model
<code>LogLik</code>	Maximized log likelihood for the model
<code>LRStat</code>	Likelihood ratio test statistic for comparing <code>altlme</code> versus <code>lme</code>
<code>deltaDF</code>	DF for <code>altlme</code> minus DF for <code>lme</code>
<code>pValue</code>	<i>p</i> -value for the likelihood ratio test

- If you use the simulated likelihood ratio test, then `results` contains the following columns.

<code>Model</code>	Name of the model
--------------------	-------------------

DF	Degrees of freedom, that is, the number of free parameters in the model
LogLik	Maximized log likelihood for the model
LRStat	Likelihood ratio test statistic for comparing <code>altlme</code> versus <code>lme</code>
pValue	<i>p</i> -value for the likelihood ratio test
Lower	Lower limit of the confidence interval for pValue
Upper	Upper limit of the confidence interval for pValue

siminfo — Simulation output

structure

Simulation output, returned as a structure with the following fields.

<code>nsim</code>	Value set for <code>nsim</code> .
<code>alpha</code>	Value set for 'Alpha'.
<code>pValueSim</code>	Simulation-based <i>p</i> -value.
<code>pValueSimCI</code>	Confidence interval for <code>pValueSim</code> . The first element of the vector is the lower limit and the second element of the vector contains the upper limit.
<code>deltaDF</code>	The number of free parameters in <code>altlme</code> minus the number of free parameters in <code>lme</code> . DF for <code>altlme</code> minus DF for <code>lme</code> .
<code>TH0</code>	A vector of simulated likelihood ratio test statistics under the null hypothesis that the model <code>lme</code> generated the observed response vector <code>y</code> .

Examples

Test for Random Effects

Load the sample data.

```
load flu
```

The `flu` dataset array has a `Date` variable, and 10 variables containing estimated influenza rates (in 9 different regions, estimated from Google searches, plus a nationwide estimate from the CDC).

To fit a linear-mixed effects model, your data must be in a properly formatted dataset array. To fit a linear mixed-effects model with the influenza rates as the responses and region as the predictor variable, combine the nine columns corresponding to the regions into a tall array. The new dataset array, `flu2`, must have the response variable, `FluRate`, the nominal variable, `Region`, that shows which region each estimate is from, and the grouping variable `Date`.

```
flu2 = stack(flu,2:10,'NewDataVarName','FluRate',...  
            'IndVarName','Region');  
flu2.Date = nominal(flu2.Date);
```

Fit a linear mixed-effects model, with a varying intercept and varying slope for each region, grouped by `Date`.

```
altlme = fitlme(flu2,'FluRate ~ 1 + Region + (1 + Region|Date)');
```

Fit a linear mixed-effects model with fixed effects for the region and a random intercept that varies by `Date`.

```
lme = fitlme(flu2,'FluRate ~ 1 + Region + (1|Date)');
```

Compare the two models. Also check if `lme2` is nested in `lme`.

```
compare(lme,altlme,'CheckNesting',true)
```

```
ans =
```

```
Theoretical Likelihood Ratio Test
```

Model	DF	AIC	BIC	LogLik	LRStat	deltaDF	pValue
<code>lme</code>	11	318.71	364.35	-148.36			
<code>altlme</code>	55	-305.51	-77.346	207.76	712.22	44	0

The small p -value of 0 indicates that model `altlme` is significantly better than the simpler model `lme`.

Test for Fixed and Random Effects

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load fertilizer
```

The dataset array includes data from a split-plot experiment, where soil is divided into three blocks based on the soil type: sandy, silty, and loamy. Each block is divided into five plots, where five different types of tomato plants (cherry, heirloom, grape, vine, and plum) are randomly assigned to these plots. The tomato plants in the plots are then divided into subplots, where each subplot is treated by one of four fertilizers. This is simulated data.

Store the data in a dataset array called `ds`, for practical purposes, and define `Tomato`, `Soil`, and `Fertilizer` as categorical variables.

```
ds = fertilizer;
ds.Tomato = nominal(ds.Tomato);
ds.Soil = nominal(ds.Soil);
ds.Fertilizer = nominal(ds.Fertilizer);
```

Fit a linear mixed-effects model, where `Fertilizer` and `Tomato` are the fixed-effects variables, and the mean yield varies by the block (soil type) and the plots within blocks (tomato types within soil types) independently.

```
lmeBig = fitlme(ds, 'Yield ~ Fertilizer * Tomato + (1|Soil) + (1|Soil:Tomato)');
```

Refit the model after removing the interaction term `Tomato:Fertilizer` and the random-effects term `(1 | Soil)`.

```
lmeSmall = fitlme(ds, 'Yield ~ Fertilizer + Tomato + (1|Soil:Tomato)');
```

Compare the two models using the simulated likelihood ratio test with 1000 replications. You must use this test to test for both fixed- and random-effect terms. Note that both models are fit using the default fitting method, ML. That's why, there is no restriction on the fixed-effects design matrices. If you use restricted maximum likelihood (REML) method, both models must have identical fixed-effects design matrices.

```
[table, siminfo] = compare(lmeSmall, lmeBig, 'nsim', 1000)
```

```
table =
```

Simulated Likelihood Ratio Test: Nsim = 1000, Alpha = 0.05

Model	DF	AIC	BIC	LogLik	LRStat	pValue	Lower	Upper
lme2	10	511.06	532	-245.53				
lme	23	522.57	570.74	-238.29	14.491	0.54845	0.51702	0.5796

```
siminfo =
    nsim: 1000
    alpha: 0.0500
    pvalueSim: 0.5485
    pvalueSimCI: [0.5170 0.5796]
    deltaDF: 13
    TH0: [1000x1 double]
```

The high p -value 0.5485 suggests that the larger model, `lme` is not significantly better than the smaller model, `lme2`. The smaller values of AIC and BIC for `lme2` also support this.

Models with Correlated and Uncorrelated Random Effects

Load the sample data.

```
load carbig
```

Fit a linear mixed-effects model for miles per gallon (MPG), with fixed effects for acceleration, horsepower, and the cylinders, and potentially correlated random effects for intercept and acceleration grouped by model year.

First, prepare the design matrices.

```
X = [ones(406,1) Acceleration Horsepower];
Z = [ones(406,1) Acceleration];
Model_Year = nominal(Model_Year);
G = Model_Year;
```

Now, fit the model using `fitlmematrix` with the defined design matrices and grouping variables.

```
lme = fitlmematrix(X,MPG,Z,G,'FixedEffectPredictors',...
    {'Intercept','Acceleration','Horsepower'},'RandomEffectPredictors',...
    {'{Intercept','Acceleration'}},'RandomEffectGroups',{'Model_Year'});
```

Refit the model with uncorrelated random effects for intercept and acceleration. First prepare the random effects design and the random effects grouping variables.

```
Z = {ones(406,1),Acceleration};
G = {Model_Year,Model_Year};

lme2 = fitlmematrix(X,MPG,Z,G,'FixedEffectPredictors',...
{'Intercept','Acceleration','Horsepower'},'RandomEffectPredictors',...
{{'Intercept'}},{ 'Acceleration' }},'RandomEffectGroups',...
{'Model_Year','Model_Year'});
```

Compare lme and lme2 using the simulated likelihood ratio test.

```
compare(lme2,lme,'CheckNesting',true,'NSim',1000)
```

```
ans =
```

```
Simulated Likelihood Ratio Test: Nsim = 1000, Alpha = 0.05
```

Model	DF	AIC	BIC	LogLik	LRStat	pValue	Lower	Upper
lme2	6	2194.5	2218.3	-1091.3				
lme	7	2193.5	2221.3	-1089.7	3.0323	0.095904	0.078373	0.103437

The high p -value of 0.095904 indicates that lme2 is not a significantly better fit than lme.

Simulated Likelihood Ratio Test Using Parallel Computing

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load fertilizer
```

The dataset array includes data from a split-plot experiment, where soil is divided into three blocks based on the soil type: sandy, silty, and loamy. Each block is divided into five plots, where five different types of tomato plants (cherry, heirloom, grape, vine, and plum) are randomly assigned to these plots. The tomato plants in the plots are then divided into subplots, where each subplot is treated by one of four fertilizers. This is simulated data.

Store the data in a dataset array called `ds`, for practical purposes, and define `Tomato`, `Soil`, and `Fertilizer` as categorical variables.

```
ds = fertilizer;  
ds.Tomato = nominal(ds.Tomato);  
ds.Soil = nominal(ds.Soil);  
ds.Fertilizer = nominal(ds.Fertilizer);
```

Fit a linear mixed-effects model, where `Fertilizer` and `Tomato` are the fixed-effects variables, and the mean yield varies by the block (soil type), and the plots within blocks (tomato types within soil types) independently.

```
lme = fitlme(ds, 'Yield ~ Fertilizer * Tomato + (1|Soil) + (1|Soil:Tomato)');
```

Refit the model after removing the interaction term `Tomato:Fertilizer` and the random-effects term `(1|Soil)`.

```
lme2 = fitlme(ds, 'Yield ~ Fertilizer + Tomato + (1|Soil:Tomato)');
```

Create the options structure for `LinearMixedModel`.

```
opt = statset('LinearMixedModel')
```

```
opt =
```

```

Compare `lme2` and `lme` using the simulated likelihood ratio test with 1000 replications and parallel computing.

```
compare(lme2,lme,'nsim',1000,'Options',opt)
```

```
ans =
```

```
Simulated Likelihood Ratio Test: Nsim = 1000, Alpha = 0.05
```

Model	DF	AIC	BIC	LogLik	LRStat	pValue	Lower	Upper
lme2	10	511.06	532	-245.53				
lme	23	522.57	570.74	-238.29	14.491	0.54845	0.51702	0.579

The high p -value, 0.5485 suggests that the larger model, `lme` is not significantly better than the smaller model, `lme2`. The smaller values of AIC and BIC for `lme2` also support this.

Definitions

Likelihood Ratio Test

Under the null hypothesis H_0 , the observed likelihood ratio test statistic has an approximate chi-squared reference distribution with degrees of freedom `deltaDF`. When

comparing two models, `compare` computes the p -value for the likelihood ratio test by comparing the observed likelihood ratio test statistic with this chi-squared reference distribution.

The p -values obtained using the likelihood ratio test can be conservative when testing for the presence or absence of random-effects terms and anticonservative when testing for the presence or absence of fixed-effects terms. Hence, use the `fixedEffects`, `anova`, or `coefTest` method or the simulated likelihood ratio test while testing for fixed effects.

Simulated Likelihood Ratio Test

To perform the simulated likelihood ratio test, `compare` first generates the reference distribution of the likelihood ratio test statistic under the null hypothesis. Then, it assesses the statistical significance of the alternate model by comparing the observed likelihood ratio test statistic to this reference distribution.

`compare` produces the simulated reference distribution of the likelihood ratio test statistic under the null hypothesis as follows:

- Generate random data `ysim` from the fitted model `lme`.
- Fit the model specified in `lme` and alternate model `altlme` to the simulated data `ysim`.
- Calculate the likelihood ratio test statistic using results from step 2 and store the value.
- Repeat step 1 to 3 `nsim` times.

Then, `compare` computes the p -value for the simulated likelihood ratio test by comparing the observed likelihood ratio test statistic with the simulated reference distribution. The p -value estimate is the ratio of the number of times the simulated likelihood ratio test statistic is equal to or exceeds the observed value plus one, to the number of replications plus one.

Suppose the observed likelihood ratio statistic is T , and the simulated reference distribution is stored in vector T_{H_0} . Then,

$$p\text{-value} = \frac{\left[\sum_{j=1}^{nsim} I(T_{H_0}(j) \geq T) \right] + 1}{nsim + 1}.$$

To account for the uncertainty in the simulated reference distribution, `compare` computes a $100*(1 - \alpha)\%$ confidence interval for the true p -value.

You can use the simulated likelihood ratio test to compare arbitrary linear mixed-effects models. That is, when you are using the simulated likelihood ratio test, `lme` does not have to be nested within `altlme`, and you can fit `lme` and `altlme` using either maximum likelihood (ML) or restricted maximum likelihood (REML) methods. If you use the restricted maximum likelihood (REML) method to fit the models, then both models must have the same fixed-effects design matrix.

Nesting Requirements

The 'CheckNesting','True' name-value pair argument checks the following requirements.

For a simulated likelihood ratio test:

- You must use the same method to fit both models (`lme` and `altlme`). `compare` cannot compare a model fit using ML to a model fit using REML.
- You must fit both models to the same response vector.
- If you use REML to fit `lme` and `altlme`, then both models must have the same fixed-effects design matrix.
- The maximized log likelihood or restricted log likelihood of the bigger model (`altlme`) must be greater than or equal to that of the smaller model (`lme`).

For a theoretical test, 'CheckNesting', 'True' checks all the requirements listed for a simulated likelihood ratio test and the following:

- Weight vectors you use to fit `lme` and `altlme` must be identical.
- If you use ML to fit `lme` and `altlme`, the fixed-effects design matrix of the bigger model (`altlme`) must contain that of the smaller model (`lme`).
- The random-effects design matrix of the bigger model (`altlme`) must contain that of the smaller model (`lme`).

Akaike and Bayesian Information Criteria

Akaike information criterion (AIC) is $AIC = -2*\log L_M + 2*(nc + p + 1)$, where $\log L_M$ is the maximized log likelihood (or maximized restricted log likelihood) of the model, and $nc + p + 1$ is the number of parameters estimated in the model. p is the number of fixed-effects

coefficients, and nc is the total number of parameters in the random-effects covariance excluding the residual variance.

Bayesian information criterion (BIC) is $BIC = -2 \cdot \log L_M + \ln(n_{eff}) \cdot (nc + p + 1)$, where $\log L_M$ is the maximized log likelihood (or maximized restricted log likelihood) of the model, n_{eff} is the effective number of observations, and $(nc + p + 1)$ is the number of parameters estimated in the model.

- If the fitting method is maximum likelihood (ML), then $n_{eff} = n$, where n is the number of observations.
- If the fitting method is restricted maximum likelihood (REML), then $n_{eff} = n - p$.

A lower value of deviance indicates a better fit. As the value of deviance decreases, both AIC and BIC tend to decrease. Both AIC and BIC also include penalty terms based on the number of parameters estimated, p . So, when the number of parameters increase, the values of AIC and BIC tend to increase as well. When comparing different models, the model with the lowest AIC or BIC value is considered as the best fitting model.

Deviance

`LinearMixedModel` computes the deviance of model M as minus two times the loglikelihood of that model. Let L_M denote the maximum value of the likelihood function for model M . Then, the deviance of model M is

$$-2 \cdot \log L_M.$$

A lower value of deviance indicates a better fit. Suppose M_1 and M_2 are two different models, where M_1 is nested in M_2 . Then, the fit of the models can be assessed by comparing the deviances Dev_1 and Dev_2 of these models. The difference of the deviances is

$$Dev = Dev_1 - Dev_2 = 2(\log LM_2 - \log LM_1).$$

Usually, the asymptotic distribution of this difference has a chi-square distribution with degrees of freedom v equal to the number of parameters that are estimated in one model but fixed (typically at 0) in the other. That is, it is equal to the difference in the number of parameters estimated in M_1 and M_2 . You can get the p -value for this test using `1 - chi2cdf(Dev, v)`, where $Dev = Dev_2 - Dev_1$.

However, in mixed-effects models, when some variance components fall on the boundary of the parameter space, the asymptotic distribution of this difference is more complicated. For example, consider the hypotheses

$H_0: D = \begin{pmatrix} D_{11} & 0 \\ 0 & 0 \end{pmatrix}$, D is a q -by- q symmetric positive semidefinite matrix.

$H_1: D$ is a $(q+1)$ -by- $(q+1)$ symmetric positive semidefinite matrix.

That is, H_1 states that the last row and column of D are different from zero. Here, the bigger model M_2 has $q + 1$ parameters and the smaller model M_1 has q parameters. And Dev has a 50:50 mixture of χ^2_q and $\chi^2_{(q+1)}$ distributions (Stram and Lee, 1994).

ComputeOOBPrediction property

Class: TreeBagger

Flag to compute out-of-bag predictions

Description

The `ComputeOOBPrediction` property is a logical flag specifying whether out-of-bag predictions for training observations should be computed. The default is `false`.

If this flag is true, the following properties are available:

- `OOBIndices`
- `OOBInstanceWeight`

If this flag is true, the following methods can be called:

- `oobError`
- `oobMargin`
- `oobMeanMargin`

See Also

`OOBIndices` | `oobMargin` | `oobError` | `OOBInstanceWeight` | `oobMeanMargin`

ComputeOOBVarImp property

Class: TreeBagger

Flag to compute out-of-bag variable importance

Description

The `ComputeOOBVarImp` property is a logical flag specifying whether `TreeBagger` should compute out-of-bag estimates of variable importance. The default is false.

If this flag is true, the following properties are available:

- `OOBPermutedVarDeltaError`
- `OOBPermutedVarDeltaMeanMargin`
- `OOBPermutedVarCountRaiseMargin`

See Also

`oobMeanMargin` | `ComputeOOBPrediction` | `OOBPermutedVarDeltaError` | `OOBPermutedVarDeltaMeanMargin` | `OOBPermutedVarCountRaiseMargin` | `TreeBagger`

confusionmat

Confusion matrix

Syntax

```
C = confusionmat(group,grouphat)
C = confusionmat(group,grouphat, 'order',grouporder)
[C,order] = confusionmat(...)
```

Description

`C = confusionmat(group,grouphat)` returns the confusion matrix `C` determined by the known and predicted groups in `group` and `grouphat`, respectively. `group` and `grouphat` are grouping variables with the same number of observations, as described in “Grouping Variables” on page 2-52. Input vectors must be of the same type. `C` is a square matrix with size equal to the total number of distinct elements in `group` and `grouphat`. `C(i, j)` is a count of observations known to be in group `i` but predicted to be in group `j`. Group indices and their order are the same for the rows and columns of `C`, computed by `grp2idx` using `grp2idx(group;grouphat)`. NaN, empty, or 'undefined' groups are not counted.

`C = confusionmat(group,grouphat, 'order',grouporder)` uses `grouporder` to order the rows and columns of `C`. `grouporder` is a grouping variable containing all of the distinct elements in `group` and `grouphat`. If `grouporder` contains elements that are not in `group` or `grouphat`, the corresponding entries in `C` will be 0.

`[C,order] = confusionmat(...)` also returns the order of the rows and columns of `C` in a variable `order` the same type as `group` and `grouphat`.

Examples

Example 1

Display the confusion matrix for data with two misclassifications and one missing classification:

```

g1 = [1 1 2 2 3 3]'; % Known groups
g2 = [1 1 2 3 4 NaN]'; % Predicted groups

[C,order] = confusionmat(g1,g2)
C =
     2     0     0     0
     0     1     1     0
     0     0     0     1
     0     0     0     0
order =
     1
     2
     3
     4

```

Example 2

Randomize the measurements and groups in Fisher's iris data:

```

load fisheriris
numObs = length(species);
p = randperm(numObs);
meas = meas(p,:);
species = species(p);

```

Use `classify` to classify measurements in the second half of the data, using the first half of the data for training:

```

half = floor(numObs/2);
training = meas(1:half,:);
trainingSpecies = species(1:half);
sample = meas(half+1:end,:);
grouphat = classify(sample,training,trainingSpecies);

```

Display the confusion matrix for the resulting classification:

```

group = species(half+1:end);
[C,order] = confusionmat(group,grouphat)
C =
    22     0     0
     2    22     0
     0     0    29
order =
    'virginica'

```

```
'versicolor'  
'setosa'
```

`crosstab` | `grp2idx`

controlchart

Shewhart control charts

Syntax

```
controlchart(X)
controlchart(x,group)
controlchart(X,group)
[stats,plotdata] = controlchart(x,[group])
controlchart(x,group,'name',value)
```

Description

`controlchart(X)` produces an xbar chart of the measurements in matrix `X`. Each row of `X` is considered to be a subgroup of measurements containing replicate observations taken at the same time. The rows should be in time order. If `X` is a time series object, the time samples should contain replicate observations.

The chart plots the means of the subgroups in time order, a center line (CL) at the average of the means, and upper and lower control limits (UCL, LCL) at three standard errors from the center line. The standard error is the estimated process standard deviation divided by the square root of the subgroup size. Process standard deviation is estimated from the average of the subgroup standard deviations. Out of control measurements are marked as violations and drawn with a red circle. Data cursor mode is enabled, so clicking any data point displays information about that point.

`controlchart(x,group)` accepts a grouping variable `group` for a vector of measurements `x`. `group` is a categorical variable, vector, string array, or cell array of strings the same length as `x`. Consecutive measurements `x(n)` sharing the same value of `group(n)` for $1 \leq n \leq \text{length}(x)$ are defined to be a subgroup. Subgroups can have different numbers of observations.

`controlchart(X,group)` accepts a grouping variable `group` for a matrix of measurements in `X`. In this case, `group` is only used to label the time axis; it does not change the default grouping by rows.

`[stats,plotdata] = controlchart(x,[group])` returns a structure `stats` of subgroup statistics and parameter estimates, and a structure `plotdata` of plotted values. `plotdata` contains one record for each chart.

The fields in `stats` and `plotdata` depend on the chart type.

The fields in `stats` are selected from the following:

- `mean` — Subgroup means
- `std` — Subgroup standard deviations
- `range` — Subgroup ranges
- `n` — Subgroup size, or total inspection size or area
- `i` — Individual data values
- `ma` — Moving averages
- `mr` — Moving ranges
- `count` — Count of defects or defective items
- `mu` — Estimated process mean
- `sigma` — Estimated process standard deviation
- `p` — Estimated proportion defective
- `m` — Estimated mean defects per unit

The fields in `plotdata` are the following:

- `pts` — Plotted point values
- `cl` — Center line
- `lcl` — Lower control limit
- `ucl` — Upper control limit
- `se` — Standard error of plotted point
- `n` — Subgroup size
- `ooc` — Logical that is true for points that are out of control

`controlchart(x,group,'name',value)` specifies one or more of the following optional parameter name/value pairs, with *name* in single quotes:

- `charttype` — The name of a chart type chosen from among the following:
 - `'xbar'` — Xbar or mean

- 's' — Standard deviation
- 'r' — Range
- 'ewma' — Exponentially weighted moving average
- 'i' — Individual observation
- 'mr' — Moving range of individual observations
- 'ma' — Moving average of individual observations
- 'p' — Proportion defective
- 'np' — Number of defectives
- 'u' — Defects per unit
- 'c' — Count of defects

Alternatively, a parameter can be a cell array listing multiple compatible chart types. There are four sets of compatible types:

- 'xbar', 's', 'r', and 'ewma'
- 'i', 'mr', and 'ma'
- 'p' and 'np'
- 'u' and 'c'
- **display** — Either 'on' (default) to display the control chart, or 'off' to omit the display
- **label** — A string array or cell array of strings, one per subgroup. This label is displayed as part of the data cursor for a point on the plot.
- **lambda** — A parameter between 0 and 1 controlling how much the current prediction is influenced by past observations in an EWMA plot. Higher values of 'lambda' give less weight to past observations and more weight to the current observation. The default is 0.4.
- **limits** — A three-element vector specifying the values of the lower control limit, center line, and upper control limits. Default is to estimate the center line and to compute control limits based on the estimated value of sigma. Not permitted if there are multiple chart types.
- **mean** — Value for the process mean, or an empty value (default) to estimate the mean from X. This is the μ parameter for **p** and **np** charts, the mean defects per unit for **u** and **c** charts, and the normal μ parameter for other charts.

- **nsigma** — The number of sigma multiples from the center line to a control limit. Default is 3.
- **parent** — The handle of the axes to receive the control chart plot. Default is to create axes in a new figure. Not permitted if there are multiple chart types.
- **rules** — The name of a control rule, or a cell array containing multiple control rule names. These rules, together with the control limits, determine if a point is marked as out of control. The default is to apply no control rules, and to use only the control limits to decide if a point is out of control. See **controlrules** for more information. Control rules are applied to charts that measure the process level (**xbar**, **i**, **c**, **u**, **p**, and **np**) rather than the variability (**r**, **s**), and they are not applied to charts based on moving statistics (**ma**, **mr**, **ewma**).
- **sigma** — Either a value for sigma, or a method of estimating sigma chosen from among **'std'** (the default) to use the average within-subgroup standard deviation, **'range'** to use the average subgroup range, and **'variance'** to use the square root of the pooled variance. When creating **i**, **mr**, or **ma** charts for data not in subgroups, the estimate is always based on a moving range.
- **specs** — A vector specifying specification limits. Typically this is a two-element vector of lower and upper specification limits. Since specification limits typically apply to individual measurements, this parameter is primarily suitable for **i** charts. These limits are not plotted on **r**, **s**, or **mr** charts.
- **unit** — The total number of inspected items for **p** and **np** charts, and the size of the inspected unit for **u** and **c** charts. In both cases **X** must be the count of the number of defects or defectives found. Default is 1 for **u** and **c** charts. This argument is required (no default) for **p** and **np** charts.
- **width** — The width of the window used for computing the moving ranges and averages in **mr** and **ma** charts, and for computing the sigma estimate in **i**, **mr**, and **ma** charts. Default is 5.

Examples

XBar and R Charts

Load the sample data.

```
load parts
```

Create xbar and r control charts for the data.

```
st = controlchart(runout, 'chart', {'xbar' 'r'});
```

Display the process mean and standard deviation.

```
fprintf('Parameter estimates: mu = %g, sigma = %g\n',st.mu,st.sigma);
```

```
Parameter estimates: mu = -0.0863889, sigma = 0.130215
```

controlrules

controlrules

Western Electric and Nelson control rules

Syntax

```
R = controlrules('rules',x,cl,se)
[R,RULES] = controlrules('rules',x,cl,se)
```

Description

`R = controlrules('rules',x,cl,se)` determines which points in the vector `x` violate the control rules in `rules`. `cl` is a vector of center-line values. `se` is a vector of standard errors. (Typically, control limits on a control chart are at the values `cl - 3*se` and `cl + 3*se`.) `rules` is the name of a control rule, or a cell array containing multiple control rule names, from the list below. If `x` has n values and `rules` contains m rules, then `R` is an n -by- m logical array, with `R(i, j)` assigned the value 1 if point `i` violates rule `j`, 0 if it does not.

The following are accepted values for `rules` (specified inside single quotes):

- `we1` — 1 point above `cl + 3*se`
- `we2` — 2 of 3 above `cl + 2*se`
- `we3` — 4 of 5 above `cl + se`
- `we4` — 8 of 8 above `cl`
- `we5` — 1 below `cl - 3*se`
- `we6` — 2 of 3 below `cl - 2*se`
- `we7` — 4 of 5 below `cl - se`
- `we8` — 8 of 8 below `cl`
- `we9` — 15 of 15 between `cl - se` and `cl + se`
- `we10` — 8 of 8 below `cl - se` or above `cl + se`
- `n1` — 1 point below `cl - 3*se` or above `cl + 3*se`
- `n2` — 9 of 9 on the same side of `cl`

- n3 — 6 of 6 increasing or decreasing
- n4 — 14 alternating up/down
- n5 — 2 of 3 below $c1 - 2*se$ or above $c1 + 2*se$, same side
- n6 — 4 of 5 below $c1 - se$ or above $c1 + se$, same side
- n7 — 15 of 15 between $c1 - se$ and $c1 + se$
- n8 — 8 of 8 below $c1 - se$ or above $c1 + se$, either side
- we — All Western Electric rules
- n — All Nelson rules

For multi-point rules, a rule violation at point i indicates that the set of points ending at point i triggered the rule. Point i is considered to have violated the rule only if it is one of the points violating the rule's condition.

Any points with NaN as their x , $c1$, or se values are not considered to have violated rules, and are not counted in the rules for other points.

Control rules can be specified in the `controlchart` function as values for the 'rules' parameter.

`[R,RULES] = controlrules('rules',x,c1,se)` returns a cell array of text strings RULES listing the rules applied.

Examples

Use Western Electric Control Rule

Load the sample data.

```
load parts;
```

Create an Xbar chart using the `we2` rule to mark out of control measurements.

```
st = controlchart(runout,'rules','we2');
x = st.mean;
c1 = st.mu;
se = st.sigma./sqrt(st.n);
hold on
plot(c1+2*se,'m')
```

You can see the out of control points marked with a red circle.

Use `controlrules` to identify the measurements that violate the control rule.

```
R = controlrules('we2',x,c1,se);
I = find(R)
```

I =

```
21
23
24
25
26
```

controlchart

Converged property

Class: `gmdistribution`

Determine if algorithm converged

Description

Logical `true` if the algorithm has converged; logical `false` if the algorithm has not converged.

Note: This property applies only to `gmdistribution` objects constructed with `fitgmdist`.

cophenet

Cophenetic correlation coefficient

Syntax

```
c = cophenet(Z,Y)
[c,d] = cophenet(Z,Y)
```

Description

`c = cophenet(Z,Y)` computes the cophenetic correlation coefficient for the hierarchical cluster tree represented by `Z`. `Z` is the output of the `linkage` function. `Y` contains the distances or dissimilarities used to construct `Z`, as output by the `pdist` function. `Z` is a matrix of size $(m-1)$ -by-3, with distance information in the third column. `Y` is a vector of size $m*(m-1)/2$.

`[c,d] = cophenet(Z,Y)` returns the cophenetic distances `d` in the same lower triangular distance vector format as `Y`.

The cophenetic correlation for a cluster tree is defined as the linear correlation coefficient between the cophenetic distances obtained from the tree, and the original distances (or dissimilarities) used to construct the tree. Thus, it is a measure of how faithfully the tree represents the dissimilarities among observations.

The cophenetic distance between two observations is represented in a dendrogram by the height of the link at which those two observations are first joined. That height is the distance between the two subclusters that are merged by that link.

The output value, `c`, is the cophenetic correlation coefficient. The magnitude of this value should be very close to 1 for a high-quality solution. This measure can be used to compare alternative cluster solutions obtained using different algorithms.

The cophenetic correlation between `Z(:,3)` and `Y` is defined as

$$c = \frac{\sum_{i < j} (Y_{ij} - y)(Z_{ij} - z)}{\sqrt{\sum_{i < j} (Y_{ij} - y)^2 \sum_{i < j} (Z_{ij} - z)^2}}$$

where:

- Y_{ij} is the distance between objects i and j in Y .
- Z_{ij} is the cophenetic distance between objects i and j , from $Z(:,3)$.
- y and z are the average of Y and $Z(:,3)$, respectively.

Examples

```
X = [rand(10,3); rand(10,3)+1; rand(10,3)+2];
Y = pdist(X);
Z = linkage(Y, 'average');

% Compute Spearman's rank correlation between the
% dissimilarities and the cophenetic distances
[c,D] = cophenet(Z,Y);
r = corr(Y',D', 'type', 'spearman')
r =
    0.8279
```

copulacdf

Copula cumulative distribution function

Syntax

```
Y = copulacdf('Gaussian',U,rho)
Y = copulacdf('t',U,rho,NU)
Y = copulacdf('family',U,alpha)
```

Description

`Y = copulacdf('Gaussian',U,rho)` returns the cumulative probability of the Gaussian copula with linear correlation parameters `rho`, evaluated at the points in `U`. `U` is an n -by- p matrix of values in $[0, 1]$, representing n points in the p -dimensional unit hypercube. `rho` is a p -by- p correlation matrix. If `U` is an n -by-2 matrix, `rho` may also be a scalar correlation coefficient.

`Y = copulacdf('t',U,rho,NU)` returns the cumulative probability of the `t` copula with linear correlation parameters `rho` and degrees of freedom parameter `NU`, evaluated at the points in `U`. `U` is an n -by- p matrix of values in $[0, 1]$. `rho` is a p -by- p correlation matrix. If `U` is an n -by-2 matrix, `rho` may also be a scalar correlation coefficient.

`Y = copulacdf('family',U,alpha)` returns the cumulative probability of the bivariate Archimedean copula determined by `family`, with scalar parameter `alpha`, evaluated at the points in `U`. `family` is Clayton, Frank, or Gumbel. `U` is an n -by-2 matrix of values in $[0, 1]$.

Examples

Compute the Gaussian Copula cdf

Compute and plot the cdf of a Gaussian copula.

```
u = linspace(0,1,10);
[U1,U2] = meshgrid(u,u);
```

```
F = copulacdf('Clayton',[U1(:) U2(:)],1);  
surf(U1,U2,reshape(F,10,10))  
xlabel('u1')  
ylabel('u2')
```

See Also

[copulapdf](#) | [copularnd](#) | [copulastat](#) | [copulaparam](#)

copulafit

Fit copula to data

Syntax

```
RHOHAT = copulafit('Gaussian',U)
[RHOHAT,nuhat] = copulafit('t',U)
[RHOHAT,nuhat,nuci] = copulafit('t',U)
paramhat = copulafit('family',U)
[paramhat,paramci] = copulafit('family',U)
[...] = copulafit(...,'alpha',alpha)
[...] = copulafit('t',U,'Method','ApproximateML')
[...] = copulafit(...,'Options',options)
```

Description

`RHOHAT = copulafit('Gaussian',U)` returns an estimate `RHOHAT` of the matrix of linear correlation parameters for a Gaussian copula, given data in `U`. `U` is an n -by- p matrix of values in the open interval $(0,1)$ representing n points in the p -dimensional unit hypercube.

`[RHOHAT,nuhat] = copulafit('t',U)` returns an estimate `RHOHAT` of the matrix of linear correlation parameters for a t copula and an estimate `nuhat` of the degrees of freedom parameter, given data in `U`. `U` is an n -by- p matrix of values in the open interval $(0,1)$ representing n points in the p -dimensional unit hypercube.

`[RHOHAT,nuhat,nuci] = copulafit('t',U)` also returns an approximate 95% confidence interval `nuci` for the degrees of freedom parameter estimated in `nuhat`.

`paramhat = copulafit('family',U)` returns an estimate `paramhat` of the copula parameter for an Archimedean copula specified by `family`, given data in `U`. `U` is an n -by-2 matrix of values in the open interval $(0,1)$ representing n points in the unit square. `family` is one of Clayton, Frank, or Gumbel.

`[paramhat,paramci] = copulafit('family',U)` also returns an approximate 95% confidence interval `paramci` for the copula parameter estimated in `paramhat`.

[...] = copulafit(...,'alpha',alpha) returns approximate $100*(1-\alpha)\%$ confidence intervals in nuci or paramci.

Note: By default, copulafit uses maximum likelihood to fit a copula to U. When U contains data transformed to the unit hypercube by parametric estimates of their marginal cumulative distribution functions, this is known as the *Inference Functions for Margins (IFM)* method. When U contains data transformed by the empirical cdf (see ecdf), this is known as *Canonical Maximum Likelihood (CML)*.

[...] = copulafit('t',U,'Method','ApproximateML') fits a *t* copula for large samples U by maximizing an objective function that approximates the profile log-likelihood for the degrees of freedom parameter (see [1]). This method can be significantly faster than maximum likelihood, but the estimates and confidence limits may not be accurate for small to moderate sample sizes.

[...] = copulafit(...,'Options',options) specifies control parameters for the iterative parameter estimation algorithm using an options structure options as created by statset. Type statset('copulafit') at the command prompt for fields and default values used by copulafit. This argument is not applicable to the 'Gaussian' family.

Examples

Fit a Gaussian Copula

Load and plot simulated stock return data.

```
load stockreturns
x = stocks(:,1);
y = stocks(:,2);

figure;
scatterhist(x,y)
```

Transform the data to the copula scale (unit square) using a kernel estimator of the cumulative distribution function.

```
u = ksdensity(x,x,'function','cdf');  
v = ksdensity(y,y,'function','cdf');
```

```
figure;  
scatterhist(u,v)  
xlabel('u')  
ylabel('v')
```

Fit a t copula.

```
[Rho,nu] = copulafit('t',[u v], 'Method','ApproximateML')
```

Rho =

```
1.0000    0.7220
0.7220    1.0000
```

nu =

```
2.6133e+06
```

Generate a random sample from the t copula.

```
r = copularnd('t',Rho,nu,1000);
u1 = r(:,1);
v1 = r(:,2);

figure;
scatterhist(u1,v1)
xlabel('u')
ylabel('v')
set(get(gca,'children'),'marker','.')
```

Transform the random sample back to the original scale of the data.

```
x1 = ksdensity(x,u1,'function','icdf');
```

```
y1 = ksdensity(y,v1,'function','icdf');  
  
figure;  
scatterhist(x1,y1)  
set(get(gca,'children'),'marker','.')
```

copulaparam

Copula parameters as function of rank correlation

Syntax

```
rho = copulaparam('Gaussian',R)
rho = copulaparam('t',R,NU)
alpha = copulaparam(family,R)
[...] = copulaparam(...,'type',type)
```

Description

`rho = copulaparam('Gaussian',R)` returns the linear correlation parameters `rho` corresponding to a Gaussian copula having Kendall's rank correlation `R`. If `R` is a scalar correlation coefficient, `rho` is a scalar correlation coefficient corresponding to a bivariate copula. If `R` is a `p`-by-`p` correlation matrix, `rho` is a `p`-by-`p` correlation matrix.

`rho = copulaparam('t',R,NU)` returns the linear correlation parameters `rho` corresponding to a `t` copula having Kendall's rank correlation `R` and degrees of freedom `NU`. If `R` is a scalar correlation coefficient, `rho` is a scalar correlation coefficient corresponding to a bivariate copula. If `R` is a `p`-by-`p` correlation matrix, `rho` is a `p`-by-`p` correlation matrix.

`alpha = copulaparam(family,R)` returns the copula parameter `alpha` corresponding to a bivariate Archimedean copula having Kendall's rank correlation `R`. `R` is a scalar. `family` is one of 'Clayton', 'Frank', or 'Gumbel'.

`[...] = copulaparam(...,'type',type)` assumes `R` is the specified type of rank correlation. `type` is 'Kendall' for Kendall's tau or 'Spearman' for Spearman's rho.

`copulaparam` uses an approximation to Spearman's rank correlation for copula families when no analytic formula exists. The approximation is based on a smooth fit to values computed at discrete values of the copula parameters. For a `t` copula, the approximation is accurate for degrees of freedom larger than 0.05.

Examples

Get the linear correlation coefficient corresponding to a bivariate Gaussian copula having a rank correlation of -0.5.

```
tau = -0.5
rho = copulaparam('gaussian',tau)
rho =
    -0.7071
```

```
% Generate dependent beta random values using that copula
u = copularnd('gaussian',rho,100);
b = betainv(u,2,2);
```

```
% Verify that the sample has a rank correlation
% approximately equal to tau
tau_sample = corr(b,'type','k')
tau_sample =
    1.0000    -0.4638
   -0.4638    1.0000
```

copulapdf

Copula probability density function

Syntax

```
Y = copulapdf('Gaussian',U,rho)
Y = copulapdf('t',U,rho,NU)
Y = copulapdf('family',U,alpha)
```

Description

`Y = copulapdf('Gaussian',U,rho)` returns the probability density of the Gaussian copula with linear correlation parameters `rho`, evaluated at the points in `U`. `U` is an n -by- p matrix of values in $[0, 1]$, representing n points in the p -dimensional unit hypercube. `rho` is a p -by- p correlation matrix. If `U` is an n -by-2 matrix, `rho` may also be a scalar correlation coefficient.

`Y = copulapdf('t',U,rho,NU)` returns the probability density of the t copula with linear correlation parameters `rho` and degrees of freedom parameter `NU`, evaluated at the points in `U`. `U` is an n -by- p matrix of values in $[0, 1]$. `rho` is a p -by- p correlation matrix. If `U` is an n -by-2 matrix, `rho` may also be a scalar correlation coefficient.

`Y = copulapdf('family',U,alpha)` returns the probability density of the bivariate Archimedean copula determined by `family`, with scalar parameter `alpha`, evaluated at the points in `U`. `family` is Clayton, Frank, or Gumbel. `U` is an n -by-2 matrix of values in $[0, 1]$.

Examples

Compute the Gaussian Copula pdf

Compute and plot the pdf of a Gaussian copula.

```
u = linspace(0,1,10);
[U1,U2] = meshgrid(u,u);
```

```
F = copulapdf('Clayton',[U1(:) U2(:)],1);  
surf(U1,U2,reshape(F,10,10))  
xlabel('u1')  
ylabel('u2')
```

[copulacdf](#) | [copulaparam](#) | [copularnd](#) | [copulastat](#)

copulastat

Copula rank correlation

Syntax

```
R = copulastat('Gaussian',rho)
R = copulastat('t',rho,NU)
R = copulastat(family,alpha)
R = copulastat(...,'type',type)
```

Description

`R = copulastat('Gaussian',rho)` returns the Kendall's rank correlation `R` that corresponds to a Gaussian copula having linear correlation parameters `rho`. If `rho` is a scalar correlation coefficient, `R` is a scalar correlation coefficient corresponding to a bivariate copula. If `rho` is a `p`-by-`p` correlation matrix, `R` is a `p`-by-`p` correlation matrix.

`R = copulastat('t',rho,NU)` returns the Kendall's rank correlation `R` that corresponds to a `t` copula having linear correlation parameters `rho` and degrees of freedom `NU`. If `rho` is a scalar correlation coefficient, `R` is a scalar correlation coefficient corresponding to a bivariate copula. If `rho` is a `p`-by-`p` correlation matrix, `R` is a `p`-by-`p` correlation matrix.

`R = copulastat(family,alpha)` returns the Kendall's rank correlation `R` that corresponds to a bivariate Archimedean copula with scalar parameter `alpha`. `family` is one of 'Clayton', 'Frank', or 'Gumbel'.

`R = copulastat(...,'type',type)` returns the specified type of rank correlation. `type` is 'Kendall' to compute Kendall's tau, or 'Spearman' to compute Spearman's rho.

`copulastat` uses an approximation to Spearman's rank correlation for copula families when no analytic formula exists. The approximation is based on a smooth fit to values computed at discrete values of the copula parameters. For a `t` copula, the approximation is accurate for degrees of freedom larger than 0.05.

Examples

Compute the Gaussian Copula Rank Correlation

Compute the rank correlation for a Gaussian copula with the specified linear correlation parameter `rho`.

```
rho = -.7071;  
tau = copulastat('gaussian',rho)
```

```
tau =  
  
    -0.5000
```

Generate dependent beta random values using that copula.

```
u = copularnd('gaussian',rho,100);  
b = betainv(u,2,2);
```

Verify that the sample has a rank correlation approximately equal to `tau`.

```
tau_sample = corr(b,'type','k')
```

```
tau_sample =  
  
    1.0000    -0.5135  
   -0.5135    1.0000
```

copularnd

Copula random numbers

Syntax

```
U = copularnd('Gaussian',rho,N)
U = copularnd('t',rho,NU,N)
U = copularnd('family',alpha,N)
```

Description

`U = copularnd('Gaussian',rho,N)` returns N random vectors generated from a Gaussian copula with linear correlation parameters `rho`. If `rho` is a p -by- p correlation matrix, `U` is an n -by- p matrix. If `rho` is a scalar correlation coefficient, `copularnd` generates `U` from a bivariate Gaussian copula. Each column of `U` is a sample from a `Uniform(0,1)` marginal distribution.

`U = copularnd('t',rho,NU,N)` returns N random vectors generated from a t copula with linear correlation parameters `rho` and degrees of freedom `NU`. If `rho` is a p -by- p correlation matrix, `U` is an n -by- p matrix. If `rho` is a scalar correlation coefficient, `copularnd` generates `U` from a bivariate t copula. Each column of `U` is a sample from a `Uniform(0,1)` marginal distribution.

`U = copularnd('family',alpha,N)` returns N random vectors generated from the bivariate Archimedean copula determined by `family`, with scalar parameter `alpha`. `family` is Clayton, Frank, or Gumbel. `U` is an n -by-2 matrix. Each column of `U` is a sample from a `Uniform(0,1)` marginal distribution.

Examples

Determine the linear correlation parameter corresponding to a bivariate Gaussian copula having a rank correlation of `-0.5`.

```
tau = -0.5
rho = copulaparam('gaussian',tau)
```

```
rho =  
    -0.7071  
  
% Generate dependent beta random values using that copula  
u = copularnd('gaussian',rho,100);  
b = betainv(u,2,2);  
  
% Verify that the sample has a rank correlation  
% approximately equal to tau  
tau_sample = corr(b,'type','kendall')  
tau_sample =  
    1.0000    -0.4537  
   -0.4537    1.0000
```

cordexch

Coordinate exchange

Syntax

```
dCE = cordexch(nfactors, nruns)
[dCE, X] = cordexch(nfactors, nruns)
[dCE, X] = cordexch(nfactors, nruns, 'model')
[dCE, X] = cordexch(..., 'name', value)
```

Description

`dCE = cordexch(nfactors, nruns)` uses a coordinate-exchange algorithm to generate a D -optimal design `dCE` with `nruns` runs (the rows of `dCE`) for a linear additive model with `nfactors` factors (the columns of `dCE`). The model includes a constant term.

`[dCE, X] = cordexch(nfactors, nruns)` also returns the associated design matrix `X`, whose columns are the model terms evaluated at each treatment (row) of `dCE`.

`[dCE, X] = cordexch(nfactors, nruns, 'model')` uses the linear regression model specified in `model`. `model` is one of the following strings, specified inside single quotes:

- `linear` — Constant and linear terms. This is the default.
- `interaction` — Constant, linear, and interaction terms
- `quadratic` — Constant, linear, interaction, and squared terms
- `purequadratic` — Constant, linear, and squared terms

The order of the columns of `X` for a full quadratic model with n terms is:

- 1 The constant term
- 2 The linear terms in order 1, 2, ..., n
- 3 The interaction terms in order (1, 2), (1, 3), ..., (1, n), (2, 3), ..., ($n - 1$, n)
- 4 The squared terms in order 1, 2, ..., n

Other models use a subset of these terms, in the same order.

Alternatively, *model* can be a matrix specifying polynomial terms of arbitrary order. In this case, *model* should have one column for each factor and one row for each term in the model. The entries in any row of *model* are powers for the factors in the columns. For example, if a model has factors X1, X2, and X3, then a row [0 1 2] in *model* specifies the term $(X1.^0) \cdot (X2.^1) \cdot (X3.^2)$. A row of all zeros in *model* specifies a constant term, which can be omitted.

[dCE,X] = cordexch(..., 'name', value) specifies one or more optional name/value pairs for the design. Valid parameters and their values are listed in the following table. Specify *name* inside single quotes.

name	Value
bounds	Lower and upper bounds for each factor, specified as a 2-by-nfactors matrix. Alternatively, this value can be a cell array containing nfactors elements, each element specifying the vector of allowable values for the corresponding factor.
categorical	Indices of categorical predictors.
display	Either 'on' or 'off' to control display of the iteration counter. The default is 'on'.
excludefun	Handle to a function that excludes undesirable runs. If the function is <i>f</i> , it must support the syntax $b = f(S)$, where <i>S</i> is a matrix of treatments with nfactors columns and <i>b</i> is a vector of Boolean values with the same number of rows as <i>S</i> . <i>b</i> (<i>i</i>) is true if the method should exclude <i>i</i> th row <i>S</i> .
init	Initial design as a nruns-by-nfactors matrix. The default is a randomly selected set of points.
levels	Vector of number of levels for each factor. Not used when bounds is specified as a cell array.
maxiter	Maximum number of iterations. The default is 10.
tries	Number of times to try to generate a design from a new starting point. The algorithm uses random points for each try, except possibly the first. The default is 1.
options	A structure that specifies whether to run in parallel, and specifies the random stream or streams. Create the options structure with statset. Option fields:

name	Value
	<ul style="list-style-type: none"> • UseParallel — Set to <code>true</code> to compute in parallel. Default is <code>false</code>. • UseSubstreams — Set to <code>true</code> to compute in parallel in a reproducible fashion. Default is <code>false</code>. To compute reproducibly, set Streams to a type allowing substreams: <code>'mlfg6331_64'</code> or <code>'mrg32k3a'</code>. • Streams — A <code>RandStream</code> object or cell array of such objects. If you do not specify Streams, <code>cordexch</code> uses the default stream or streams. If you choose to specify Streams, use a single object except in the case <ul style="list-style-type: none"> • You have an open Parallel pool • UseParallel is <code>true</code> • UseSubstreams is <code>false</code> <p>In that case, use a cell array the same size as the Parallel pool.</p>

Examples

Suppose you want a design to estimate the parameters in the following three-factor, seven-term interaction model:

$$y = \beta_0 + \beta_1 x_1 + \beta_2 x_2 + \beta_3 x_3 + \beta_{12} x_1 x_2 + \beta_{13} x_1 x_3 + \beta_{23} x_2 x_3 + \varepsilon$$

Use `cordexch` to generate a *D*-optimal design with seven runs:

```

nfactors = 3;
nruns = 7;
[dCE,X] = cordexch(nfactors,nruns,'interaction','tries',10)
dCE =
    -1     1     1
    -1    -1    -1
     1     1     1
    -1     1    -1
     1    -1     1
     1    -1    -1
    -1    -1     1

```

```

X =
  1  -1  1  1  -1  -1  1
  1  -1  -1  -1  1  1  1
  1  1  1  1  1  1  1
  1  -1  1  -1  -1  1  -1
  1  1  -1  1  -1  1  -1
  1  1  -1  -1  -1  -1  1
  1  -1  -1  1  1  -1  -1

```

Columns of the design matrix X are the model terms evaluated at each row of the design dCE. The terms appear in order from left to right: constant term, linear terms (1, 2, 3), interaction terms (12, 13, 23). Use X to fit the model, as described in “Linear Regression” on page 9-11, to response data measured at the design points in dCE.

More About

Algorithms

Both `cordexch` and `rowexch` use iterative search algorithms. They operate by incrementally changing an initial design matrix X to increase $D = |X^T X|$ at each step. In both algorithms, there is randomness built into the selection of the initial design and into the choice of the incremental changes. As a result, both algorithms may return locally, but not globally, D -optimal designs. Run each algorithm multiple times and select the best result for your final design. Both functions have a 'tries' parameter that automates this repetition and comparison.

Unlike the row-exchange algorithm used by `rowexch`, `cordexch` does not use a candidate set. (Or rather, the candidate set is the entire design space.) At each step, the coordinate-exchange algorithm exchanges a single element of X with a new element evaluated at a neighboring point in design space. The absence of a candidate set reduces demands on memory, but the smaller scale of the search means that the coordinate-exchange algorithm is more likely to become trapped in a local minimum.

corr

Linear or rank correlation

Syntax

```
RHO = corr(X)
RHO = corr(X,Y)
[RHO,PVAL] = corr(X,Y)
[RHO,PVAL] = corr(X,Y, 'name', value)
```

Description

`RHO = corr(X)` returns a p -by- p matrix containing the pairwise linear correlation coefficient between each pair of columns in the n -by- p matrix X .

`RHO = corr(X, Y)` returns a $p1$ -by- $p2$ matrix containing the pairwise correlation coefficient between each pair of columns in the n -by- $p1$ and n -by- $p2$ matrices X and Y .

The difference between `corr(X, Y)` and the MATLAB function `corrcoef(X, Y)` is that `corrcoef(X, Y)` returns a matrix of correlation coefficients for the two column vectors X and Y . If X and Y are not column vectors, `corrcoef(X, Y)` converts them to column vectors.

`[RHO, PVAL] = corr(X, Y)` also returns `PVAL`, a matrix of p -values for testing the hypothesis of no correlation against the alternative that there is a nonzero correlation. Each element of `PVAL` is the p value for the corresponding element of `RHO`. If `PVAL(i, j)` is small, say less than 0.05, then the correlation `RHO(i, j)` is significantly different from zero.

`[RHO, PVAL] = corr(X, Y, 'name', value)` specifies one or more optional name/value pairs. Specify *name* inside single quotes. The following table lists valid parameters and their values.

Parameter	Values
type	<ul style="list-style-type: none">'Pearson' (the default) computes Pearson's linear correlation coefficient

Parameter	Values
	<ul style="list-style-type: none"> 'Kendall' computes Kendall's tau 'Spearman' computes Spearman's rho
rows	<ul style="list-style-type: none"> 'all' (the default) uses all rows regardless of missing values (NaNs) 'complete' uses only rows with no missing values 'pairwise' computes $RHO(i, j)$ using rows with no missing values in column i or j
tail — The alternative hypothesis against which to compute p -values for testing the hypothesis of no correlation	<ul style="list-style-type: none"> 'both' — Correlation is not zero (the default) 'right' — Correlation is greater than zero 'left' — Correlation is less than zero

Using the 'pairwise' option for the rows parameter may return a matrix that is not positive definite. The 'complete' option always returns a positive definite matrix, but in general the estimates are based on fewer observations.

corr computes p -values for Pearson's correlation using a Student's t distribution for a transformation of the correlation. This correlation is exact when X and Y are normal. corr computes p -values for Kendall's tau and Spearman's rho using either the exact permutation distributions (for small sample sizes), or large-sample approximations.

corr computes p -values for the two-tailed test by doubling the more significant of the two one-tailed p -values.

Examples

Find Correlation Between Two Matrices

Find the correlation between two matrices and compare to the correlation between two column vectors.

Generate sample data.

```
rng('default')
x = randn(30,4);
y = randn(30,4);
y(:,4) = sum(x,2); % introduce correlation
```

Calculate the correlation between columns of X and Y.

```
[r,p] = corr(x,y)
```

r =

```
-0.1686   -0.0363    0.2278    0.6901
 0.3022    0.0332   -0.0866    0.2617
-0.3632   -0.0987   -0.0200    0.3504
-0.1365   -0.1804    0.0853    0.4908
```

p =

```
0.3731    0.8489    0.2260    0.0000
0.1045    0.8619    0.6491    0.1624
0.0485    0.6039    0.9166    0.0577
0.4721    0.3400    0.6539    0.0059
```

Calculate the correlation between X and Y using `corrcoef`.

```
[r,p] = corrcoef(x,y)
```

r =

```
1.0000    0.1252
0.1252    1.0000
```

p =

```
1.0000    0.1729
0.1729    1.0000
```

MATLAB function `corrcoef` converts X and Y into column vectors before computing the correlation between them.

corrcoef | corrcov | tiedrank | partialcorr

corrcoef

Convert covariance matrix to correlation matrix

Syntax

```
R = corrcoef(C)
[R,sigma] = corrcoef(C)
```

Description

`R = corrcoef(C)` computes the correlation matrix `R` corresponding to the covariance matrix `C`. `C` must be square, symmetric, and positive semi-definite.

`[R,sigma] = corrcoef(C)` also computes the vector of standard deviations `sigma`.

Examples

Use `cov` and `corrcoef` to compute covariances and correlations, respectively, for sample data on weight and blood pressure (systolic, diastolic) in `hospital.mat`:

```
load hospital
X = [hospital.Weight hospital.BloodPressure];
C = cov(X)
C =
    706.0404    27.7879    41.0202
    27.7879    45.0622    23.8194
    41.0202    23.8194    48.0590
R = corrcoef(X)
R =
    1.0000    0.1558    0.2227
    0.1558    1.0000    0.5118
    0.2227    0.5118    1.0000
```

Compare `R` with the correlation matrix computed from `C` by `corrcoef`:

```
corrcoef(C)
ans =
```

1.0000	0.1558	0.2227
0.1558	1.0000	0.5118
0.2227	0.5118	1.0000

Cost property

Class: TreeBagger

Misclassification costs

Description

The `Cost` property is a matrix with misclassification costs. This property is empty for ensembles of regression trees.

See Also

`ClassificationTree` | `RegressionTree` | `TreeBagger` | `fitctree` | `fitrtree`

covarianceParameters

Class: GeneralizedLinearMixedModel

Extract covariance parameters of generalized linear mixed-effects model

Syntax

```
psi = covarianceParameters(glme)
[psi,dispersion] = covarianceParameters(glme)
[psi,dispersion,stats] = covarianceParameters(glme)
[ ___ ] = covarianceParameters(glme,Name,Value)
```

Description

`psi = covarianceParameters(glme)` returns the estimated prior covariance parameters of random-effects predictors in the generalized linear mixed-effects model `glme`.

`[psi,dispersion] = covarianceParameters(glme)` also returns an estimate of the dispersion parameter.

`[psi,dispersion,stats] = covarianceParameters(glme)` also returns a cell array `stats` containing the covariance parameter estimates and related statistics.

`[___] = covarianceParameters(glme,Name,Value)` returns any of the above output arguments using additional options specified by one or more `Name,Value` pair arguments. For example, you can specify the confidence level for the confidence limits of covariance parameters.

Input Arguments

glme — Generalized linear mixed-effects model

GeneralizedLinearMixedModel object

Generalized linear mixed-effects model, specified as a `GeneralizedLinearMixedModel` object. For properties and methods of this object, see `GeneralizedLinearMixedModel`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

'Alpha' — Confidence level

0.05 (default) | scalar value in the range [0,1]

Confidence level, specified as the comma-separated pair consisting of 'Alpha' and a scalar value in the range [0,1]. For a value α , the confidence level is $100 \times (1 - \alpha)\%$.

For example, for 99% confidence intervals, you can specify the confidence level as follows.

Example: 'Alpha', 0.01

Data Types: single | double

Output Arguments

psi — Estimated prior covariance parameters

cell array

Estimated prior covariance parameters for the random-effects predictors, returned as a cell array of length R , where R is the number of grouping variables used in the model. `psi{r}` contains the covariance matrix of random effects associated with grouping variable g_r , where $r = 1, 2, \dots, R$. The order of grouping variables in `psi` is the same as the order entered when fitting the model. For more information on grouping variables, see “Grouping Variables” on page 2-52.

dispersion — Dispersion parameter

scalar value

Dispersion parameter, returned as a scalar value.

stats — Covariance parameter estimates and related statistics

cell array

Covariance parameter estimates and related statistics, returned as a cell array of length $(R + 1)$, where R is the number of grouping variables used in the model. The first R cells of `stats` each contain a dataset array with the following columns.

Group	Grouping variable name
Name1	Name of the first predictor variable
Name2	Name of the second predictor variable
Type	If Name1 and Name2 are the same, then Type is <code>std</code> (standard deviation). If Name1 and Name2 are different, then Type is <code>corr</code> (correlation).
Estimate	If Name1 and Name2 are the same, then Estimate is the standard deviation of the random effect associated with predictor Name1 or Name2. If Name1 and Name2 are different, then Estimate is the correlation between the random effects associated with predictors Name1 and Name2.
Lower	Lower limit of the confidence interval for the covariance parameter
Upper	Upper limit of the confidence interval for the covariance parameter

Cell $R + 1$ contains related statistics for the dispersion parameter.

It is recommended that the presence or absence of covariance parameters in `glme` be tested using the `compare` method, which uses a likelihood ratio test.

When fitting a GLME model using `fitglme` and one of the maximum likelihood fit methods ('Laplace' or 'ApproximateLaplace'), `covarianceParameters` derives the confidence intervals in `stats` based on a Laplace approximation to the log likelihood of the generalized linear mixed-effects model.

When fitting a GLME model using `fitglme` and one of the pseudo likelihood fit methods ('MPL' or 'REMP'), `covarianceParameters` derives the confidence intervals in `stats` based on the fitted linear mixed-effects model from the final pseudo likelihood iteration.

Examples

Obtain Estimated Covariance Parameters

Navigate to the folder containing the sample data. Load the sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')

load mfr
```

This simulated data is from a manufacturing company that operates 50 factories across the world, with each factory running a batch process to create a finished product. The company wants to decrease the number of defects in each batch, so it developed a new manufacturing process. To test the effectiveness of the new process, the company selected 20 of its factories at random to participate in an experiment: Ten factories implemented the new process, while the other ten continued to run the old process. In each of the 20 factories, the company ran five batches (for a total of 100 batches) and recorded the following data:

- Flag to indicate whether the batch used the new process (**newprocess**)
- Processing time for each batch, in hours (**time**)
- Temperature of the batch, in degrees Celsius (**temp**)
- Categorical variable indicating the supplier (A, B, or C) of the chemical used in the batch (**supplier**)
- Number of defects in the batch (**defects**)

The data also includes **time_dev** and **temp_dev**, which represent the absolute deviation of time and temperature, respectively, from the process standard of 3 hours at 20 degrees Celsius.

Fit a generalized linear mixed-effects model using **newprocess**, **time_dev**, **temp_dev**, and **supplier** as fixed-effects predictors. Include a random-effects term for intercept grouped by **factory**, to account for quality differences that might exist due to factory-specific variations. The response variable **defects** has a Poisson distribution, and the appropriate link function for this model is log. Use the Laplace fit method to estimate the coefficients. Specify the dummy variable encoding as **'effects'**, so the dummy variable coefficients sum to 0.

The number of defects can be modeled using a Poisson distribution

$$defects_{ij} \sim \text{Poisson}(\mu_{ij})$$

This corresponds to the generalized linear mixed-effects model

$$\log(\mu_{ij}) = \beta_0 + \beta_1 newprocess_{ij} + \beta_2 time_dev_{ij} + \beta_3 temp_dev_{ij} + \beta_4 supplier_C_{ij} + \beta_5 supplier_B_{ij} +$$

where

- $defects_{ij}$ is the number of defects observed in the batch produced by factory i during batch j .
- μ_{ij} is the mean number of defects corresponding to factory i (where $i = 1, 2, \dots, 20$) during batch j (where $j = 1, 2, \dots, 5$).
- $newprocess_{ij}$, $time_dev_{ij}$, and $temp_dev_{ij}$ are the measurements for each variable that correspond to factory i during batch j . For example, $newprocess_{ij}$ indicates whether the batch produced by factory i during batch j used the new process.
- $supplier_C_{ij}$ and $supplier_B_{ij}$ are dummy variables that use effects (sum-to-zero) coding to indicate whether company C or B, respectively, supplied the process chemicals for the batch produced by factory i during batch j .
- $b_i \sim N(0, \sigma_b^2)$ is a random-effects intercept for each factory i that accounts for factory-specific variation in quality.

```
glme = fitglme(mfr, 'defects ~ 1 + newprocess + time_dev + temp_dev + supplier + (1|factory)')
```

Compute and display the estimate of the prior covariance parameter for the random-effects predictor.

```
[psi, dispersion, stats] = covarianceParameters(glme);
psi{1}
```

```
ans =
```

```
0.0985
```

`psi{1}` is an estimate of the prior covariance matrix of the first grouping variable. In this example, there is only one grouping variable (`factory`), so `psi{1}` is an estimate of σ_b^2 .

Display the dispersion parameter.

```
dispersion
```

```
dispersion =
```

```
1
```

Display the estimated standard deviation of the random effect associated with the predictor. The first cell of `stats` contains statistics for `factory`, while the second cell contains statistics for the dispersion parameter.

```
stats{1}
```

```
ans =
```

```
Covariance Type: Isotropic
```

Group	Name1	Name2	Type	Estimate
factory	'(Intercept)'	'(Intercept)'	'std'	0.31381
Lower	Upper			
0.19253	0.51148			

The estimated standard deviation of the random effect associated with the predictor is 0.31381. The 95% confidence interval is [0.19253 , 0.51148]. Because the confidence interval does not contain 0, the random intercept is significant at the 5% significance level.

`GeneralizedLinearMixedModel` | `compare` | `fitglme` | `fixedEffects` | `randomEffects`

covarianceParameters

Class: LinearMixedModel

Extract covariance parameters of linear mixed-effects model

Syntax

```
psi = covarianceParameters(lme)
[psi,mse] = covarianceParameters(lme)
[psi,mse,stats] = covarianceParameters(lme)
[psi,mse,stats] = covarianceParameters(lme,Name,Value)
```

Description

`psi = covarianceParameters(lme)` returns the estimated covariance parameters that parameterize the prior covariance of random effects.

`[psi,mse] = covarianceParameters(lme)` also returns an estimate of the residual variance.

`[psi,mse,stats] = covarianceParameters(lme)` also returns a cell array, `stats`, containing the covariance parameters and related statistics.

`[psi,mse,stats] = covarianceParameters(lme,Name,Value)` returns the covariance parameters and related statistics in `stats` with additional options specified by one or more Name,Value pair arguments.

For example, you can specify the confidence level for the confidence limits of covariance parameters.

Input Arguments

lme — Linear mixed-effects model

LinearMixedModel object

Linear mixed-effects model, returned as a `LinearMixedModel` object.

For properties and methods of this object, see `LinearMixedModel`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

'Alpha' — Confidence level

0.05 (default) | scalar value in the range 0 to 1

Confidence level, specified as the comma-separated pair consisting of 'Alpha' and a scalar value in the range 0 to 1. For a value α , the confidence level is $100 \cdot (1 - \alpha)\%$.

For example, for 99% confidence intervals, you can specify the confidence level as follows.

Example: 'Alpha', 0.01

Data Types: `single` | `double`

Output Arguments

`psi` — Estimate of covariance parameters

cell array

Estimate of covariance parameters that parameterize the prior covariance of the random effects, returned as a cell array of length R , such that `psi{r}` contains the covariance matrix of random effects associated with grouping variable g_r , $r = 1, 2, \dots, R$. The order of grouping variables is the same order you enter when you fit the model.

`mse` — Residual variance estimate

scalar value

Residual variance estimate, returned as a scalar value.

`stats` — Covariance parameter estimates and related statistics

cell array

Covariance parameter estimates and related statistics, returned as a cell array of length $(R + 1)$ containing dataset arrays with the following columns.

Group	Grouping variable name
Name1	Name of the first predictor variable
Name2	Name of the second predictor variable
Type	std (standard deviation), if Name1 and Name2 are the same
	corr (correlation), if Name1 and Name2 are different
Estimate	Standard deviation of the random effect associated with predictor Name1 or Name2, if Name1 and Name2 are the same
	Correlation between the random effects associated with predictors Name1 and Name2, if Name1 and Name2 are different
Lower	Lower limit of a 95% confidence interval for the covariance parameter
Upper	Upper limit of a 95% confidence interval for the covariance parameter

`stats{r}` is a dataset array containing statistics on covariance parameters for the r th grouping variable, $r = 1, 2, \dots, R$. `stats{R+1}` contains statistics on the residual standard deviation. The dataset array for the residual error has the fields `Group`, `Name`, `Estimate`, `Lower`, and `Upper`.

Examples

Two Random-Effects Terms for Intercept

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load fertilizer
```

The dataset array includes data from a split-plot experiment, where soil is divided into three blocks based on the soil type: sandy, silty, and loamy. Each block is divided into five plots, where five different types of tomato plants (cherry, heirloom, grape, vine, and plum) are randomly assigned to these plots. The tomato plants in the plots are then divided into subplots, where each subplot is treated by one of four fertilizers. This is simulated data.

Store the data in a dataset array called `ds`, for practical purposes, and define `Tomato`, `Soil`, and `Fertilizer` as categorical variables.

```
ds = fertilizer;
ds.Tomato = nominal(ds.Tomato);
ds.Soil = nominal(ds.Soil);
ds.Fertilizer = nominal(ds.Fertilizer);
```

Fit a linear mixed-effects model, where `Fertilizer` is the fixed-effects variable, and the mean yield varies by the block (soil type), and the plots within blocks (tomato types within soil types) independently. This model corresponds to

$$y_{ijk} = \beta_0 + \sum_{j=2}^5 \beta_{2,j} I[T]_{ij} + b_{0k} S_k + b_{0jk} (S * T)_{jk} + \varepsilon_{ijk},$$

where $i = 1, 2, \dots, 60$ corresponds to the observations, $j = 2, \dots, 5$ corresponds to the tomato types, and $k = 1, 2, 3$ corresponds to the blocks (soil). S_k represents the k th soil type, and $(S * T)_{jk}$ represents the j th tomato type nested in the k th soil type. $I[T]_{ij}$ is the dummy variable representing the level j of the tomato type.

The random effects and observation error have the following prior distributions:

$b_{0k} \sim N(0, \sigma_S^2)$, $b_{0jk} \sim N(0, \sigma_{S*T}^2)$, and $\varepsilon_{ijk} \sim N(0, \sigma^2)$.

```
lme = fitlme(ds, 'Yield ~ Fertilizer + (1|Soil) + (1|Soil:Tomato)');
```

Compute the covariance parameter estimates (estimates of σ_S^2 and σ_{S*T}^2) of the random-effects terms.

```
psi = covarianceParameters(lme)
```

```
psi =
```

```
[ 4.4026e-17]
[ 352.8481]
```

Compute the residual variance (σ^2).

```
[~,mse] = covarianceParameters(lme)
```

```
mse =
```

```
151.9007
```

Potentially Correlated Random-Effects Terms

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load weight
```

`weight` contains data from a longitudinal study, where 20 subjects are randomly assigned to 4 exercise programs, and their weight loss is recorded over six 2-week time periods. This is simulated data.

Store the data in a dataset array. Define `Subject` and `Program` as categorical variables.

```
ds = dataset(InitialWeight,Program,Subject,Week,y);
ds.Subject = nominal(ds.Subject);
ds.Program = nominal(ds.Program);
```

Fit a linear mixed-effects model where the initial weight, type of program, week, and the interaction between the week and type of program are the fixed effects. The intercept and week vary by subject.

For 'reference' dummy variable coding, `fitlme` uses Program A as reference and creates the necessary dummy variables $I_{[.]}$. This model corresponds to

$$y_{im} = \beta_0 + \beta_1 IW_i + \beta_2 Week_i + \beta_3 I[PB]_i + \beta_4 I[PC]_i + \beta_5 I[PD]_i \\ + b_{0m} + b_{1m} Week_{im} + \varepsilon_{im},$$

where i corresponds to the observation number, $i = 1, 2, \dots, 120$, and m corresponds to the subject number, $m = 1, 2, \dots, 20$. β_j are the fixed-effects coefficients, $j = 0, 1, \dots, 8$, and b_{0m} and b_{1m} are random effects. IW stands for initial weight and $I[\cdot]$ is a dummy variable representing a type of program. For example, $I[PB]_i$ is the dummy variable representing Program B.

The random effects and observation error have the following prior

distributions:
$$\begin{pmatrix} b_{0m} \\ b_{1m} \end{pmatrix} \sim N \left(0, \begin{pmatrix} \sigma_0^2 & \sigma_{0,1} \\ \sigma_{0,1} & \sigma_1^2 \end{pmatrix} \right) \text{ and } \varepsilon_{im} \sim N(0, \sigma^2).$$

```
lme = fitlme(ds, 'y ~ InitialWeight + Program + (Week|Subject)');
```

Compute the estimates of covariance parameters for the random effects.

```
[psi,mse,stats] = covarianceParameters(lme)
psi =
    [2x2 double]
mse =
    0.0105
stats =
    [3x7 classreg.regr.lmeutils.titledataset]
    [1x5 dataset]
```

`mse` is the estimated residual variance. It is the estimate for σ^2 .

To see the covariance parameters estimates for the random-effects terms (σ_0^2 , σ_1^2 , and $\sigma_{0,1}^2$), index into `psi`.

```
psi{1}
ans =
    0.0572    0.0490
    0.0490    0.0624
```

The estimate of the variance of the random effects term for the intercept, σ_0^2 , is 0.0572. The estimate of the variance of the random effects term for week, σ_1^2 , is 0.0624. The estimate for the covariance of the random effects terms for the intercept and week, $\sigma_{0,1}$, is 0.0490.

`stats` is a 2-by-1 cell array. The first cell of `stats` contains the confidence intervals for the standard deviation of the random effects and the correlation between the random effects for intercept and week. To display them, index into `stats`.

```
stats{1}
```

```
ans =
```

```
Covariance Type: FullCholesky
```

Group	Name1	Name2	Type	Estimate	Lower	Upper
Subject	'(Intercept)'	'(Intercept)'	'std'	0.23927	0.18	0.30
Subject	'Week'	'(Intercept)'	'corr'	0.81971	0.38	0.98
Subject	'Week'	'Week'	'std'	0.2497	0.18	0.30

The display shows the name of the grouping parameter (**Group**), the random-effects variables (**Name1**, **Name2**), the type of the covariance parameters (**Type**), the estimate (**Estimate**) for each parameter, and the 95% confidence intervals for the parameters (**Lower**, **Upper**). The estimates in this table are related to the estimates in `psi` as follows.

The standard deviation of the random-effects term for intercept is $0.23927 = \sqrt{0.0572}$. Likewise, the standard deviation of the random effects term for week is $0.2497 = \sqrt{0.0624}$. Finally, the correlation between the random-effects terms of intercept and week is $0.81971 = 0.0490 / (0.23927 * 0.2497)$.

Note that this display also shows which covariance pattern you use when fitting the model. In this case, the covariance pattern is `FullCholesky`. To change the covariance pattern for the random-effects terms, you must use the `'CovariancePattern'` name-value pair argument when fitting the model.

The second cell of `stats` includes similar statistics for the residual standard deviation. Display the contents of the second cell.

```
stats{2}
```

```
ans =
```

Group	Name	Estimate	Lower	Upper
Error	'Res Std'	0.10261	0.087882	0.11981

The estimate for residual standard deviation is the square root of `mse`, $0.10261 = \sqrt{0.0105}$.

Two Grouping Variables

Load the sample data.

```
load carbig
```

Fit a linear mixed-effects model for miles per gallon (MPG), with fixed effects for acceleration and weight, a potentially correlated random effect for intercept and acceleration grouped by model year, and an independent random effect for weight, grouped by the origin of the car. This model corresponds to

$$MPG_{imk} = \beta_0 + \beta_1 Acc_i + \beta_2 Weight_i + b_{10m} + b_{11m} Acc_i + b_{21k} Weight_i + \varepsilon_{imk},$$

$$m = 1, 2, \dots, 13, \quad k = 1, 2, \dots, 8,$$

where m represents the levels for the variable `Model_Year`, and k represents the levels for the variable `Origin`. MPG_{imk} is the miles per gallon for the i th observation, m th model year, and k th origin that correspond to the i th observation. The random-effects terms and the observation error have the following prior distributions:

$$b_{1m} = \begin{pmatrix} b_{10m} \\ b_{11m} \end{pmatrix} \sim N \left(0, \begin{pmatrix} \sigma_{10}^2 & \sigma_{10,11} \\ \sigma_{10,11} & \sigma_{11}^2 \end{pmatrix} \right),$$

$$b_{2k} \sim N(0, \sigma_2^2),$$

$$\varepsilon_{imk} \sim N(0, \sigma^2).$$

Here, the random-effects term b_{1m} represents the first random effect at level m of the first grouping variable. The random-effects term b_{10m} corresponds to the first random effects term (1), for the intercept (0), at the m th level (m) of the first grouping variable. Likewise b_{11m} is the level m for the first predictor (1) in the first random-effects term (1).

Similarly, b_{2k} stands for the second random effects-term at level k of the second grouping variable.

σ_{10}^2 is the variance of the random-effects term for the intercept, σ_{11}^2 is the variance of the random effects term for the predictor acceleration, and $\sigma_{10,11}$ is the covariance of the random-effects terms for the intercept and the predictor acceleration. σ_2^2 is the variance of the second random-effects term, and σ^2 is the residual variance.

First, prepare the design matrices for fitting the linear mixed-effects model.

```
X = [ones(406,1) Acceleration Weight];
Z = {[ones(406,1) Acceleration],[Weight]};
Model_Year = nominal(Model_Year);
Origin = nominal(Origin);
G = {Model_Year,Origin};
```

Fit the model using the design matrices.

```
lme = fitlmematrix(X,MPG,Z,G,'FixedEffectPredictors',...
{'Intercept','Acceleration','Weight'},'RandomEffectPredictors',...
{{'Intercept','Acceleration'},{'Weight'}},'RandomEffectGroups',{'Model_Year','Origin'});
```

Compute the estimates of covariance parameters for the random effects.

```
[psi,mse,stats] = covarianceParameters(lme)
```

```
psi =
```

```
    [2x2 double]
    [6.7989e-08]
```

```
mse =
```

```
    9.0755
```

```
stats =
```

```
    [3x7 classreg.regr.lmeutils.titledataset]
    [1x7 classreg.regr.lmeutils.titledataset]
    [1x5 dataset                               ]
```

The residual variance `mse` is 9.0755. `psi` is a 2-by-1 cell array, and `stats` is a 3-by-1 cell array. To see the contents, you must index into these cell arrays.

First, index into the first cell of `psi`.

```
psi{1}
```

```
ans =
```

```
    8.5160    -0.8387
   -0.8387    0.1087
```

The first cell of `psi` contains the covariance parameters for the correlated random effects for intercept σ^2_{10} as 8.5160, and for acceleration σ^2_{11} as 0.1087. The estimate for the covariance of the random-effects terms for the intercept and acceleration $\sigma_{10,11}$ is -0.8387 .

Now, index into the second cell of `psi`.

```
psi{2}
```

```
ans =
```

```
6.7989e-08
```

The second cell of `psi` contains the estimate for the variance of the random-effects term for weight σ^2_2 .

Index into the first cell of `stats`.

```
stats{1}
```

```
ans =
```

```
Covariance Type: FullCholesky
```

Group	Name1	Name2	Type	Estimate
Model_Year	'Intercept'	'Intercept'	'std'	2.9182
Model_Year	'Acceleration'	'Intercept'	'corr'	-0.87172
Model_Year	'Acceleration'	'Acceleration'	'std'	0.32968

This table shows the standard deviation estimates for the random-effects terms for intercept and acceleration. Note that the standard deviations estimates are the square roots of the diagonal elements in the first cell of `psi`. Specifically, $2.9182 = \text{sqrt}(8.5160)$ and $0.32968 = \text{sqrt}(0.1087)$. The correlation is a function of the covariance of intercept and acceleration, and the standard deviations of intercept and acceleration. The covariance of intercept and acceleration is the off-diagonal value in the first cell of `psi`, -0.8387 . So, the correlation is $-0.8387 / (0.32968 * 2.92182) = -0.87$.

The grouping variable for intercept and acceleration is `Model_Year`.

Index into the second cell of `stats`.

```
stats{2}
```

```
ans =
```

```
Covariance Type: FullCholesky
```

Group	Name1	Name2	Type	Estimate	Lower
Origin	'Weight'	'Weight'	'std'	0.00026075	9.2158e-05

The second cell of `stats` has the standard deviation estimate and the 95% confidence limits for the standard deviation of the random-effects term for `Weight`. The grouping variable is `Origin`.

Index into the third cell of `stats`.

```
stats{3}
```

```
ans =
```

Group	Name	Estimate	Lower	Upper
Error	'Res Std'	3.0126	2.8028	3.238

The third cell of `stats` contains the estimate for residual standard deviation and the 95% confidence limits. The estimate for residual standard deviation is the square root of `mse`, $\text{sqrt}(9.0755) = 3.0126$.

Construct 99% confidence intervals for the covariance parameters.

```
[~,~,stats] = covarianceParameters(lme, 'Alpha', 0.01);  
stats{1}
```

```
ans =
```

```
Covariance Type: FullCholesky
```

Group	Name1	Name2	Type	Estimate
Model_Year	'Intercept'	'Intercept'	'std'	2.9182

CovarianceType property

Class: gmdistribution

Type of covariance matrices

Description

The string 'diagonal' if the covariance matrices are restricted to be diagonal; the string 'full' otherwise.

coxphfit

Cox proportional hazards regression

Syntax

```
b = coxphfit(X,T)
b = coxphfit(X,T,Name,Value)
[b,logl,H,stats] = coxphfit( ___ )
```

Description

`b = coxphfit(X,T)` returns a p -by-1 vector, `b`, of coefficient estimates for a Cox proportional hazards regression of the observed responses in an n -by-1 vector, `T`, on the predictors in an n -by- p matrix `X`.

The model does not include a constant term, and `X` cannot contain a column of 1s.

`b = coxphfit(X,T,Name,Value)` returns a vector of coefficient estimates, with additional options specified by one or more `Name,Value` pair arguments.

`[b,logl,H,stats] = coxphfit(___)` also returns the loglikelihood, `logl`, a structure, `stats`, that contains additional statistics, and a two-column matrix, `H`, that contains the `T` values in the first column and the estimated baseline cumulative hazard, in the second column. You can use any of the input arguments in the previous syntaxes.

Examples

Lifetime of Light Bulbs

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load lightbulb
```

The first column of the light bulb data has the lifetime (in hours) of two different types of bulbs. The second column has the binary variable indicating whether the bulb is fluorescent or incandescent. 0 indicates that the bulb is incandescent, and 1 indicates that it is fluorescent. The third column contains the censorship information, where 0 indicates the bulb was observed until failure, and 1 indicates the bulb was censored.

Fit a Cox proportional hazards model for the lifetime of the light bulbs, also accounting for censoring. The predictor variable is the type of bulb.

```
b = coxphfit(lightbulb(:,2),lightbulb(:,1),...
'censoring',lightbulb(:,3))
```

```
b =
```

```
4.7262
```

The estimate of the hazard ratio is $\exp(b) = 112.8646$. This means that the hazard for the incandescent bulbs is 112.86 times the hazard for the fluorescent bulbs.

Change the Algorithm Parameters

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load lightbulb
```

The first column of the data has the lifetime (in hours) of two types of bulbs. The second column has the binary variable indicating whether the bulb is fluorescent or incandescent. 0 indicates that the bulb is incandescent, and 1 indicates that it is fluorescent. The third column contains the censorship information, where 0 indicates the bulb is observed until failure, and 1 indicates the item (bulb) is censored.

Fit a Cox proportional hazards model, also accounting for censoring. The predictor variable is the type of bulb.

```
b = coxphfit(lightbulb(:,2),lightbulb(:,1),...
'censoring',lightbulb(:,3))
```

```
b =
```

4.7262

Display the default control parameters for the algorithm `coxphfit` uses to estimate the coefficients.

```
statset('coxphfit')  
  
ans =  
  
    Display: 'off'  
    MaxFunEvals: 200  
    MaxIter: 100  
    TolBnd: 1.0000e-06  
    TolFun: 1.0000e-08  
    TolTypeFun: []  
    TolX: 1.0000e-08  
    TolTypeX: []  
    GradObj: []  
    Jacobian: []  
    DerivStep: []  
    FunValCheck: []  
    Robust: []  
    RobustWgtFun: []  
    WgtFun: []  
    Tune: []  
    UseParallel: []  
    UseSubstreams: []  
    Streams: {}  
    OutputFcn: []
```

Save the options under a different name and change how the results will be displayed and the maximum number of iterations, `Display` and `MaxIter`.

```
coxphopt = statset('coxphfit');  
coxphopt.Display = 'final';  
coxphopt.MaxIter = 50;
```

Run `coxphfit` with the new algorithm parameters.

```
b = coxphfit(lightbulb(:,2),lightbulb(:,1),...  
'censoring',lightbulb(:,3),'options',coxphopt)
```

```
Successful convergence: Norm of gradient less than OPTIONS.TolFun
```

```
b =
```

4.7262

coxphfit displays a report on the final iteration. Changing the maximum number of iterations did not affect the coefficient estimate.

Fit and Compare Cox and Weibull Survivor Functions

Generate Weibull data depending on predictor X.

```
rng('default') % for reproducibility
X = 4*rand(100,1);
A = 50*exp(-0.5*X);
B = 2;
y = wblrnd(A,B);
```

The response values are generated from a Weibull distribution with a shape parameter depending on the predictor variable X and a scale parameter of 2.

Fit a Cox proportional hazards model.

```
[b,logL,H,stats] = coxphfit(X,y);
[b logL]
```

ans =

```
0.9409 -331.1479
```

The coefficient estimate is 0.9409 and the log likelihood value is -331.1479.

Request the model statistics.

```
stats
```

```
stats =
```

```
covb: 0.0158
beta: 0.9409
se: 0.1256
z: 7.4889
p: 6.9462e-14
```

The covariance matrix of the coefficient estimates, `covb`, contains only one value, which is equal to the variance of the coefficient estimate in this example. The coefficient estimate, `beta`, is the same as `b` and is equal to 0.9409. The standard error of the coefficient estimate, `se`, is 0.1256, which is the square root of the variance 0.0158. The z -

statistic, z , is $\text{beta}/\text{se} = 0.9409/0.1256 = 7.4880$. The p -value, p , indicates that the effect of X is significant.

Plot the Cox estimate of the baseline survivor function together with the known Weibull function.

```
stairs(H(:,1),exp(-H(:,2)),'LineWidth',2)
xx = linspace(0,100);
line(xx,1-wblcdf(xx,50*exp(-0.5*mean(X)),B),'color','r','LineWidth',2)
xlim([0,50])
legend('Estimated Survivor Function','Weibull Survivor Function')
```

The fitted model gives a close estimate to the survivor function of the actual distribution.

- “Survivor Functions for Two Groups” on page 12-25

- “Cox Proportional Hazards Model for Censored Data” on page 12-33

Input Arguments

X — Observations on predictor variables

matrix

Observations on predictor variables, specified as an n -by- p matrix of p predictors for each of n observations.

The model does not include a constant term, thus X cannot contain a column of 1s.

Data Types: `single` | `double`

T — Time-to-event data

vector

Time-to-event data, specified as an n -by-1 vector.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1`, `Value1`, ..., `NameN`, `ValueN`.

Example: `'baseline',0,'censoring',censoreddata,'frequency',freq` specifies that `coxphfit` calculates the baseline hazard rate relative to 0, considering the censoring information in the vector `censoreddata`, and the frequency of observations on T and X given in the vector `freq`.

'baseline' — X values at which to compute the baseline hazard

`mean(X)` (default) | scalar value

X values at which to compute the baseline hazard, specified as the comma-separated pair consisting of `'baseline'` and a scalar value.

The default is `mean(X)`, so the hazard rate at X is $h(t) \cdot \exp((X - \text{mean}(X)) \cdot b)$. Enter 0 to compute the baseline relative to 0, so the hazard rate at X is $h(t) \cdot \exp(X \cdot b)$.

Changing the baseline does not affect the coefficient estimates, but the hazard ratio changes.

Example: `'baseline',0`

Data Types: `single` | `double`

'censoring' — Indicator for censoring

array of 0s (default) | array of 0s and 1s

Indicator for censoring, specified as the comma-separated pair consisting of `'censoring'` and a Boolean array of the same size as `T`. Use 1 for observations that are right censored and 0 for observations that are fully observed. The default is all observations are fully observed.

Example: `'censoring',cens`

Data Types: `logical`

'frequency' — Frequency of observations

array of 1s (default) | vector of nonnegative integer counts

Frequency of observations, specified as the comma-separated pair consisting of `'frequency'` and an array that is the same size as `T` containing nonnegative integer counts.

The j^{th} element of this vector gives the number of times the method observes the j^{th} element of `T` and the j^{th} row of `X`. The default is one observation per row of `X` and `T`.

Example: `'frequency',freq`

Data Types: `single` | `double`

'init' — Initial values for estimated coefficients

vector

Initial values for estimated coefficients, specified as the comma-separated pair consisting of `'init'` and a vector containing the coefficient initial values.

Example: `'init',initcoef`

Data Types: `single` | `double`

'options' — Algorithm control parameters

structure

Algorithm control parameters for the iterative algorithm used to estimate b , specified as the comma-separated pair consisting of 'options' and a structure. A call to `statset` creates this argument. For parameter names and default values, type `statset('coxphfit')`. You can set the options under a new name and use that in the name-value pair argument.

Example: `'options',statset('coxphfit')`

Data Types: char

Output Arguments

b — Coefficient estimates

vector

Coefficient estimates for a Cox proportional hazards regression, returned as a p -by-1 vector.

logl — Loglikelihood

scalar

Loglikelihood of the fitted model, returned as a scalar.

You can use log likelihood values to compare different models and assess the significance of effects of terms in the model.

H — Estimated baseline cumulative hazard

two-column matrix

Estimated baseline cumulative hazard rate evaluated at T values, returned as a two-column matrix. The first column of the matrix contains T values, and the second column contains cumulative hazard rate estimates.

stats — Coefficient statistics

structure

Coefficient statistics, returned as a structure that contains the following fields.

beta	Coefficient estimates (same as b)
se	Standard errors of coefficient estimates, b

z	z-statistics for b (that is, b divided by standard error)
p	p-values for b
covb	Estimated covariance matrix for b

More About

Cox Proportional Hazards Regression

Cox proportional hazards regression is a semiparametric method for adjusting survival rate estimates to remove the effect of confounding variables and to quantify the effect of predictor variables. The method represents the effects of explanatory and confounding variables as a multiplier of a common baseline hazard function, $h_0(t)$.

For a baseline relative to 0, this model corresponds to

$$h_X(t) = h_0(t)e^{\sum_i X_i b_i},$$

where $h_X(t)$ is the hazard rate at X and $h_0(t)$ is the baseline hazard rate function. The baseline hazard function is the nonparametric part of the Cox proportional hazards regression function, whereas the impact of the predictor variables is a loglinear regression. The assumption is that the baseline hazard function depends on time, t , but the predictor variables do not depend on time.

Prior property

Class: NaiveBayes

Class priors

Description

The `Prior` property is a vector of length `NClasses` containing the class priors. The priors for empty classes are zero.

createns

Create object to use in k -nearest neighbors search

Syntax

```
NS = createns(X)
NS = createns(X, 'Name', Value)
```

Description

`NS = createns(X)` uses the data observations in an $m \times n$ matrix X to create an object `NS`. Rows of X correspond to observations and columns correspond to variables. `NS` is either an `ExhaustiveSearcher` or a `KDTreeSearcher` object which you can use to find nearest neighbors in X for desired query points. When `NS` is an `ExhaustiveSearcher` object, `knnsearch` uses the exhaustive search algorithm to find nearest neighbors. When `NS` is a `KDTreeSearcher`, `createns` creates and saves a kd -tree based on X in `NS`. `knnsearch` uses the kd -tree to find nearest neighbors. For information on these search methods, see “ k -Nearest Neighbor Search and Radius Search” on page 16-11.

`NS = createns(X, 'Name', Value)` accepts one or more optional name/value pairs. Specify *Name* inside single quotes. Specify `NSMethod` to determine which type of object to create. The object's properties save the information when you specify other arguments. For more information on the objects' properties, see `ExhaustiveSearcher` and `KDTreeSearcher`.

Input Arguments

Name-Value Pair Arguments

'NSMethod'

Nearest neighbors search method, used to define the type of object created. Value is either:

- `'kdtree'` — Create a `KDTreeSearcher` object. If you do not specify `NSMethod`, this is the default value when the number of columns of `X` is less than 10, `X` is not sparse, and the distance measure is one of the following measures:
 - `'euclidean'` (default)
 - `'cityblock'`
 - `'minkowski'`
 - `'chebychev'`
- `'exhaustive'` — Create an `ExhaustiveSearcher` object. If you do not specify `NSMethod`, this is the default value when the default criteria for `'kdtree'` do not apply.

'Distance'

A string or a function handle specifying the default distance metric used when you call the `knnsearch` method to find nearest neighbors for future query points. If you specify a distance metric but not an `NSMethod`, this input determines the type of object `createns` creates, according to the default values described in `NSMethod`.

For both `KDTreeSearcher` and `ExhaustiveSearcher` objects, the following options apply:

- `'euclidean'` (default) — Euclidean distance.
- `'cityblock'` — City block distance.
- `'chebychev'` — Chebychev distance (maximum coordinate difference).
- `'minkowski'` — Minkowski distance.

The following options apply only to `ExhaustiveSearcher` objects:

- `'seuclidean'` — Standardized Euclidean distance. Each coordinate difference between rows in `X` and the query matrix is scaled by dividing by the corresponding element of the standard deviation computed from `X`, `S=nanstd(X)`. To specify another value for `S`, use the `Scale` argument.
- `'mahalanobis'` — Mahalanobis distance, which is computed using a positive definite covariance matrix `C`. The default value of `C` is the sample covariance matrix of `X`, as computed by `nancov(X)`. To change the value of `C`, use the `Cov` parameter.
- `'cosine'` — One minus the cosine of the included angle between observations (treated as vectors).

- `'correlation'` — One minus the sample linear correlation between observations (treated as sequences of values).
- `'spearman'` — One minus the sample Spearman's rank correlation between observations (treated as sequences of values).
- `'hamming'` — Hamming distance, which is percentage of coordinates that differ.
- `'jaccard'` — One minus the Jaccard coefficient, which is the percentage of nonzero coordinates that differ.
- `custom distance function` — A distance function specified using `@` (for example, `@distfun`). A distance function must be of the form `function D2 = distfun(ZI, ZJ)`, taking as arguments a 1-by- n vector `ZI` containing a single row from `X` or from the query points `Y`, and an $m2$ -by- n matrix `ZJ` containing multiple rows of `X` or `Y`, and returning an $m2$ -by-1 vector of distances $d2$, whose j th element is the distance between the observations `ZI` and `ZJ(j, :)`.

'P'

A positive scalar, p , indicating the exponent of the Minkowski distance. This parameter is only valid when `Distance` is `'minkowski'`. Default is 2.

'Cov'

A positive definite matrix indicating the covariance matrix when computing the Mahalanobis distance. This parameter is only valid when `Distance` is `'mahalanobis'`. Default is `nancov(X)`.

'Scale'

A vector `S` with the length equal to the number of columns in `X`. Each coordinate of `X` and each query point is scaled by the corresponding element of `S` when computing the standardized Euclidean distance. This parameter is only valid when `Distance` is `'seuclidean'`. Default is `nanstd(X)`.

'BucketSize'

A positive integer, indicating the maximum number of data points in each leaf node of the kd -tree. This argument is only meaningful when using the kd -tree search method. Default is 50.

Examples

Create a *kd*-tree with a Minkowski distance metric and a *P* value of 5:

```
load fisheriris
x = meas(:,3:4);
% Since x has only two columns and the Distance is Minkowski,
% createns creates a KDTreeSearcher object by default:
knnobj = createns(x,'Distance','minkowski','P',5)

knnobj =

KDTreeSearcher

Properties:
    BucketSize: 50
              X: [150x2 double]
    Distance: 'minkowski'
    DistParameter: 5
```

[knnsearch](#) | [knnsearch](#) | [ExhaustiveSearcher](#) | [KDTreeSearcher](#)

crosstab

Cross-tabulation

Syntax

```
table = crosstab(x1,x2)
table = crosstab(x1,...,xn)
[table,chi2,p] = crosstab(____)
[table,chi2,p,labels] = crosstab(____)
```

Description

`table = crosstab(x1,x2)` returns a cross-tabulation, `table`, of two vectors of the same length, `x1` and `x2`.

`table = crosstab(x1,...,xn)` returns a multi-dimensional cross-tabulation, `table`, of data for multiple input vectors, `x1`, `x2`, ..., `xn`.

`[table,chi2,p] = crosstab(____)` also returns the chi-square statistic, `chi2`, and its *p*-value, `p`, for a test that `table` is independent in each dimension. You can use any of the previous syntaxes.

`[table,chi2,p,labels] = crosstab(____)` also returns a cell array, `labels`, which contains one column of labels for each input argument, `x1 ... xn`.

Examples

Cross-Tabulate Two Data Vectors

Create two sample data vectors, containing three and four distinct values, respectively.

```
x = [1 1 2 3 1];
y = [1 2 5 3 1];
```

Cross-tabulate `x` and `y`.

```
table = crosstab(x,y)
```

```
table =
```

```
    2    1    0    0
    0    0    0    1
    0    0    1    0
```

The rows in `table` correspond to the three distinct values in `x`, and the columns correspond to the four distinct values in `y`.

Cross-Tabulate Independent Data Vectors

Generate two independent vectors, `x1` and `x2`, each containing 50 discrete uniform random numbers in the range `1:3`.

```
rng default; % for reproducibility
x1 = unidrnd(3,50,1);
x2 = unidrnd(3,50,1);
```

Cross-tabulate `x1` and `x2`.

```
[table,chi2,p] = crosstab(x1,x2)
```

```
table =
```

```
    1    6    7
    5    5    2
   11    7    6
```

```
chi2 =
```

```
    7.5449
```

```
p =
```

```
    0.1097
```

The returned p value of 0.1097 indicates that, at the 5% significance level, `crosstab` fails to reject the null hypothesis that `table` is independent in each dimension.

Cross-Tabulate Grouped Data

Load the sample data, which contains measurements of large model cars during the years 1970-1982.

```
load carbig
```

Cross-tabulate the data of four-cylinder cars (`cyl4`) based on model year (`when`) and country of origin (`org`).

```
[table,chi2,p,labels] = crosstab(cyl4,when,org);
```

Use `labels` to determine the index location in `table` for the number of four-cylinder cars made in the USA during the late period of the data.

```
labels
```

```
labels =
```

```

'Other'   'Early'   'USA'
'Four'    'Mid'     'Europe'
[]        'Late'    'Japan'
```

The first column of `labels` corresponds to the data in `cyl4`, and indicates that row 2 of `table` contains data on cars with four cylinders. The second column of `labels` corresponds to the data in `when`, and indicates that column 3 of `table` contains data on cars made during the late period. The third column of `labels` corresponds to the data in `org`, and indicates that location 1 of the third dimension of `table` contains data on cars made in the USA.

Therefore, `table(2,3,1)` contains the number of four-cylinder cars made in the USA during the late period.

```
table(2,3,1)
```

```
ans =
```

```
38
```

The data contains 38 four-cylinder cars made in the USA during the late period.

Generate Contingency Table Using `crosstab`

Load the hospital data.

```
load hospital
```

The `hospital` dataset array contains data on 100 hospital patients, including last name, gender, age, weight, smoking status, and systolic and diastolic blood pressure measurements.

To determine whether smoking status is independent of gender, use `crosstab` to create a 2-by-2 contingency table of smokers and nonsmokers, grouped by gender.

```
[tbl,chi2,p,labels] = crosstab(hospital.Sex, hospital.Smoker)
```

```
tbl =
```

```
    40    13
    26    21
```

```
chi2 =
```

```
    4.5083
```

```
p =
```

```
    0.0337
```

```
labels =
```

```
    'Female'    '0'
    'Male'      '1'
```

The rows of the resulting contingency table `tbl` correspond to the patient's gender, with row 1 containing data for females and row 2 containing data for males. The columns correspond to the patient's smoking status, with column 1 containing data for nonsmokers and column 2 containing data for smokers. The returned result `chi2` =

4.5083 is the value of the chi-squared test statistic for a Pearson's chi-squared test of independence. The returned value $p = 0.0337$ is an approximate p -value based on the chi-squared distribution.

Input Arguments

x1 — Input vector

vector of grouping variables

Input vector, specified as a vector of grouping variables. All input vectors, including x_1 , x_2 , ..., x_n , must be the same length.

Data Types: `single` | `double` | `char` | `logical`

x2 — Input vector

vector of grouping variables

Input vector, specified as a vector of grouping variables. All input vectors, including x_1 , x_2 , ..., x_n , must be the same length.

Data Types: `single` | `double` | `char` | `logical`

x1, ..., xn — Input vectors

vectors of grouping variables

Input vectors, specified as vectors of grouping variables. If you use this syntax to specify more than two input vectors, then `crosstab` generates a multi-dimensional cross-tabulation table. All input vectors, including x_1 , x_2 , ..., x_n , must be the same length.

Data Types: `single` | `double` | `char` | `logical`

Output Arguments

table — Cross-tabulation table

matrix of integer values

Cross-tabulation table, returned as a matrix of integer values.

If you specify two input vectors, x_1 and x_2 , then `table` is an m -by- n matrix, where m is the number of distinct values in x_1 and n is the number of distinct values in x_2 .

If you specify three or more input vectors, then `table(i, j, ..., n)` is a count of indices where `grp2idx(x1)` is `i`, `grp2idx(x2)` is `j`, `grp2idx(x3)` is `k`, and so on.

chi2 — Chi-square statistic

positive scalar value

Chi-square statistic, returned as a positive scalar value. The null hypothesis is that the proportion in any entry of `table` is the product of the proportions in each dimension.

p — p-Value

scalar value in the range `[0, 1]`

p-value for the chi-square test statistic, returned as a scalar value in the range `[0, 1]`. `crosstab` tests that `table` is independent in each dimension.

labels — Data labels

cell array

Data labels, returned as a cell array. The entries in the first column are labels for the rows of `table`, the entries in the second column are labels for the columns, and so on, for a multi-dimensional `table`.

More About

Algorithms

`crosstab` uses `grp2idx` to assign a positive integer to each distinct value. `table(i, j)` is a count of indices where `grp2idx(x1)` is `i` and `grp2idx(x2)` is `j`. The numerical order of `grp2idx(x1)` and `grp2idx(x2)` order rows and columns of `table`, respectively.

In this case, the returned value of `table(i, j, ..., n)` is a count of indices where `grp2idx(x1)` is `i`, `grp2idx(x2)` is `j`, `grp2idx(x3)` is `k`, and so on.

`grp2idx` | `tabulate`

crossval

Loss estimate using cross validation

Syntax

```
vals = crossval(fun,X)
vals = crossval(fun,X,Y,...)
mse = crossval('mse',X,y,'Predfun',predfun)
mcr = crossval('mcr',X,y,'Predfun',predfun)
val = crossval(criterion,X1,X2,...,y,'Predfun',predfun)
vals = crossval(...,'name',value)
```

Description

`vals = crossval(fun,X)` performs 10-fold cross validation for the function `fun`, applied to the data in `X`.

`fun` is a function handle to a function with two inputs, the training subset of `X`, `XTRAIN`, and the test subset of `X`, `XTEST`, as follows:

```
testval = fun(XTRAIN,XTEST)
```

Each time it is called, `fun` should use `XTRAIN` to fit a model, then return some criterion `testval` computed on `XTEST` using that fitted model.

`X` can be a column vector or a matrix. Rows of `X` correspond to observations; columns correspond to variables or features. Each row of `vals` contains the result of applying `fun` to one test set. If `testval` is a non-scalar value, `CROSSVAL` converts it to a row vector using linear indexing and stored in one row of `vals`.

`vals = crossval(fun,X,Y,...)` is used when data are stored in separate variables `X`, `Y`, All variables (column vectors, matrices, or arrays) must have the same number of rows. `fun` is called with the training subsets of `X`, `Y`, ... , followed by the test subsets of `X`, `Y`, ... , as follows:

```
testvals = fun(XTRAIN,YTRAIN,...,XTEST,YTEST,...)
```

`mse = crossval('mse',X,y,'Predfun',predfun)` returns `mse`, a scalar containing a 10-fold cross validation estimate of mean-squared error for the function `predfun`. `X` can

be a column vector, matrix, or array of predictors. y is a column vector of response values. X and y must have the same number of rows.

`predfun` is a function handle called with the training subset of X , the training subset of y , and the test subset of X as follows:

```
yfit = predfun(XTRAIN,ytrain,XTEST)
```

Each time it is called, `predfun` should use `XTRAIN` and `ytrain` to fit a regression model and then return fitted values in a column vector `yfit`. Each row of `yfit` contains the predicted values for the corresponding row of `XTEST`. `crossval` computes the squared errors between `yfit` and the corresponding response test set, and returns the overall mean across all test sets.

`mcr = crossval('mcr',X,y,'Predfun',predfun)` returns `mcr`, a scalar containing a 10-fold cross validation estimate of misclassification rate (the proportion of misclassified samples) for the function `predfun`. The matrix X contains predictor values and the vector y contains class labels. `predfun` should use `XTRAIN` and `YTRAIN` to fit a classification model and return `yfit` as the predicted class labels for `XTEST`. `crossval` computes the number of misclassifications between `yfit` and the corresponding response test set, and returns the overall misclassification rate across all test sets.

`val = crossval(criterion,X1,X2,...,y,'Predfun',predfun)`, where *criterion* is 'mse' or 'mcr', returns a cross validation estimate of mean-squared error (for a regression model) or misclassification rate (for a classification model) with predictor values in $X1$, $X2$, ... and, respectively, response values or class labels in y . $X1$, $X2$, ... and y must have the same number of rows. `predfun` is a function handle called with the training subsets of $X1$, $X2$, ..., the training subset of y , and the test subsets of $X1$, $X2$, ..., as follows:

```
yfit=predfun(X1TRAIN,X2TRAIN,...,ytrain,X1TEST,X2TEST,...)
```

`yfit` should be a column vector containing the fitted values.

`vals = crossval(...,'name',value)` specifies one or more optional parameter name/value pairs from the following table. Specify *name* inside single quotes.

Name	Value
holdout	A scalar specifying the ratio or the number of observations p for holdout cross validation. When $0 < p < 1$, approximately $p*n$ observations for the test set are randomly selected. When

Name	Value
	p is an integer, p observations for the test set are randomly selected.
<code>kfold</code>	A scalar specifying the number of folds k for k -fold cross validation.
<code>leaveout</code>	Specifies leave-one-out cross validation. The value must be 1.
<code>mcreps</code>	A positive integer specifying the number of Monte-Carlo repetitions for validation. If the first input of <code>crossval</code> is 'mse' or 'mcr', <code>crossval</code> returns the mean of mean-squared error or misclassification rate across all of the Monte-Carlo repetitions. Otherwise, <code>crossval</code> concatenates the values <code>vals</code> from all of the Monte-Carlo repetitions along the first dimension.
<code>partition</code>	An object <code>c</code> of the <code>cvpartition</code> class, specifying the cross validation type and partition.
<code>stratify</code>	A column vector <code>group</code> specifying groups for stratification. Both training and test sets have roughly the same class proportions as in <code>group</code> . NaNs or empty strings in <code>group</code> are treated as missing values, and the corresponding rows of the data are ignored.
<code>options</code>	A structure that specifies whether to run in parallel, and specifies the random stream or streams. Create the <code>options</code> structure with <code>statset</code> . Option fields: <ul style="list-style-type: none"> • <code>UseParallel</code> — Set to <code>true</code> to compute in parallel. Default is <code>false</code>. • <code>UseSubstreams</code> — Set to <code>true</code> to compute in parallel in a reproducible fashion. Default is <code>false</code>. To compute reproducibly, set <code>Streams</code> to a type allowing substreams: 'mlfg6331_64' or 'mrg32k3a'. • <code>Streams</code> — A <code>RandStream</code> object or cell array consisting of one such object. If you do not specify <code>Streams</code>, <code>crossval</code> uses the default stream.

Only one of `kfold`, `holdout`, `leaveout`, or `partition` can be specified, and `partition` cannot be specified with `stratify`. If both `partition` and `mcreps` are specified,

the first Monte-Carlo repetition uses the partition information in the `cvpartition` object, and the `repartition` method is called to generate new partitions for each of the remaining repetitions. If no cross validation type is specified, the default is 10-fold cross validation.

Note: When using cross validation with classification algorithms, stratification is preferred. Otherwise, some test sets may not include observations from all classes.

Examples

Example 1

Compute mean-squared error for regression using 10-fold cross validation:

```
load('fisheriris');
y = meas(:,1);
X = [ones(size(y,1),1),meas(:,2:4)];

regf=@(XTRAIN,ytrain,XTEST)(XTEST*regress(ytrain,XTRAIN));

cvMse = crossval('mse',X,y,'predfun',regf)
cvMse =
    0.1015
```

Example 2

Compute misclassification rate using stratified 10-fold cross validation:

```
load('fisheriris');
y = species;
X = meas;
cp = cvpartition(y,'k',10); % Stratified cross-validation

classf = @(XTRAIN, ytrain,XTEST)(classify(XTEST,XTRAIN,...
ytrain));

cvMCR = crossval('mcr',X,y,'predfun',classf,'partition',cp)
cvMCR =
    0.0200
```

Example 3

Compute the confusion matrix using stratified 10-fold cross validation:

```
load('fisheriris');
y = species;
X = meas;
order = unique(y); % Order of the group labels
cp = cvpartition(y,'k',10); % Stratified cross-validation

f = @(xtr,ytr,xte,yte)confusionmat(yte,...
classfify(xte,xtr,ytr),'order',order);

cfMat = crossval(f,X,y,'partition',cp);
cfMat = reshape(sum(cfMat),3,3)
cfMat =
    50     0     0
     0    48     2
     0     1    49
```

cfMat is the summation of 10 confusion matrices from 10 test sets.

See Also

cvpartition

crossval

Class: ClassificationDiscriminant

Cross-validated discriminant analysis classifier

Syntax

```
cvmodel = crossval(obj)
cvmodel = crossval(obj,Name,Value)
```

Description

`cvmodel = crossval(obj)` creates a partitioned model from `obj`, a fitted discriminant analysis classifier. By default, `crossval` uses 10-fold cross validation on the training data to create `cvmodel`.

`cvmodel = crossval(obj,Name,Value)` creates a partitioned model with additional options specified by one or more `Name,Value` pair arguments.

Tips

- Assess the predictive performance of `obj` on cross-validated data using the “kfold” methods and properties of `cvmodel`, such as `kfoldLoss`.

Input Arguments

obj

Discriminant analysis classifier, produced using `fitcdiscr`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single

quotes (' '). You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

'CVPartition'

Object of class `cvpartition`, created by the `cvpartition` function. `crossval` splits the data into subsets with `cvpartition`.

Use only one of these options at a time: 'CVPartition', 'Holdout', 'KFold', or 'Leaveout'.

Default: []

'Holdout'

Holdout validation tests the specified fraction of the data, and uses the rest of the data for training. Specify a numeric scalar from 0 to 1. Use only one of these options at a time: 'CVPartition', 'Holdout', 'KFold', or 'Leaveout'.

'KFold'

Number of folds to use in a cross-validated classifier, a positive integer.

Use only one of these options at a time: 'CVPartition', 'Holdout', 'KFold', or 'Leaveout'.

Default: 10

'Leaveout'

Set to 'on' for leave-one-out cross validation.

Use only one of these options at a time: 'CVPartition', 'Holdout', 'KFold', or 'Leaveout'.

Examples

Create a classification model for the Fisher iris data, and then create a cross-validation model. Evaluate the quality the model using `kfoldLoss`.

```
load fisheriris
```

```
obj = fitcdiscr(meas,species);  
cvmodel = crossval(obj);  
L = kfoldLoss(cvmodel)
```

```
L =  
    0.0200
```

Alternatives

You can create a cross-validation classifier directly from the data, instead of creating a discriminant analysis classifier followed by a cross-validation classifier. To do so, include one of these options in `fitcdiscr`: `'CrossVal'`, `'CVPartition'`, `'Holdout'`, `'KFold'`, or `'Leaveout'`.

See Also

`kfoldEdge` | `kfoldfun` | `kfoldLoss` | `kfoldMargin` | `fitcdiscr` | `crossval` | `kfoldPredict`

How To

- “Discriminant Analysis” on page 15-3

crossval

Class: ClassificationECOC

Cross-validated, error-correcting output code multiclass model

Syntax

```
CVMdl = crossval(Mdl)
CVMdl = crossval(Mdl,Name,Value)
```

Description

`CVMdl = crossval(Mdl)` returns a cross-validated (partitioned), error-correcting output codes (ECOC) multiclass model (`CVMdl`) from a trained ECOC model (`Mdl`).

By default, `crossval` uses 10-fold cross validation on the training data to create `CVMdl`.

`CVMdl = crossval(Mdl,Name,Value)` returns a partitioned ECOC model with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify the number of folds or a holdout sample proportion.

Tips

Assess the predictive performance of `Mdl` on cross-validated data using the `kfold` functions and properties of `CVMdl`, such as `kfoldLoss`.

Input Arguments

Mdl — ECOC multiclass model

ClassificationECOC model

ECOC multiclass model, specified as a `ClassificationECOC` model returned by `fitcecoc`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

'CVPartition' — Cross-validation partition

[] (default) | `cvpartition` partition object

Cross-validation partition, specified as the comma-separated pair consisting of 'CVPartition' and a `cvpartition` partition object as created by `cvpartition`. The partition object specifies the type of cross-validation, and also the indexing for training and validation sets.

If you specify `CVPartition`, then you cannot specify any of `Holdout`, `KFold`, or `Leaveout`.

'Holdout' — Fraction of data for holdout validation

scalar value in the range (0,1)

Fraction of data used for holdout validation, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range (0,1). If you specify 'Holdout', p , then the software:

- 1 Randomly reserves $p*100\%$ of the data as validation data, and trains the model using the rest of the data
- 2 Stores the compact, trained model in `CVMdl.Trained`

If you specify `Holdout`, then you cannot specify any of `CVPartition`, `KFold`, or `Leaveout`.

Example: 'Holdout', 0.1

Data Types: `double` | `single`

'KFold' — Number of folds

10 (default) | positive integer value

Number of folds to use in a cross-validated classifier, specified as the comma-separated pair consisting of 'KFold' and a positive integer value. If you specify, e.g., 'KFold', k , then the software:

- 1 Randomly partitions the data into k sets

- 2 For each set, reserves the set as validation data, and trains the model using the other $k - 1$ sets
- 3 Stores the k compact, trained models in the cells of a k -by-1 cell vector in `CVMdl.Trained`

If you specify `KFold`, then you cannot specify any of `CVPartition`, `Holdout`, or `Leaveout`.

Example: `'KFold',8`

Data Types: `double`

'Leaveout' — Leave-one-out cross-validation flag

'off' (default) | 'on'

Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of 'Leaveout' and 'on' or 'off'. If you specify 'Leaveout', 'on', then, for each of the n observations, where n is `size(Mdl.X,1)`, the software:

- 1 Reserves the observation as validation data, and trains the model using the other $n - 1$ observations
- 2 Stores the n compact, trained models in `CVMdl.Trained`

If you specify `Leaveout`, then you cannot specify `CVPartition`, `Holdout`, or `KFold`.

Example: `'Leaveout','on'`

Data Types: `char`

'Options' — Estimation options

[] (default) | structure array returned by `statset`

Estimation options, specified as the comma-separated pair consisting of 'Options' and a structure array returned by `statset`.

To invoke parallel computing:

- You need a Parallel Computing Toolbox license.
- Specify `'Options',statset('UseParallel',1)`.

Output Arguments

CVMdl — Cross-validated ECOC model

ClassificationPartitionedECOC model

Cross-validated ECOC model, returned as a `ClassificationPartitionedECOC` model.

Examples

Cross Validate an ECOC Classifier

Train a one-versus-one ECOC classifier using binary SVM learners.

Load Fisher's iris data set.

```
load fisheriris
X = meas;
Y = species;
rng(1); % For reproducibility
```

Create an SVM template. It is good practice to standardize the predictors.

```
t = templateSVM('Standardize',1)
```

```
t =
```

Fit template for classification SVM.

```
          Alpha: [0x1 double]
BoxConstraint: []
      CacheSize: []
   CachingMethod: ''
DeltaGradientTolerance: []
      GapTolerance: []
      KKTolerance: []
   IterationLimit: []
   KernelFunction: ''
      KernelScale: []
      KernelOffset: []
KernelPolynomialOrder: []
          NumPrint: []
              Nu: []
   OutlierFraction: []
ShrinkagePeriod: []
          Solver: ''
StandardizeData: 1
   VerbosityLevel: []
```

```
Method: 'SVM'
Type: 'classification'
```

`t` is an SVM template. All of its properties are empty, except for `StandardizedData`, `Method`, and `Type`. When the software trains the ECOC classifier, it sets the applicable properties to their default values.

Train the ECOC classifier. It is good practice to specify the class order.

```
Mdl = fitcecoc(X,Y,'Learners',t,...
    'ClassNames',{'setosa','versicolor','virginica'});
```

`Mdl` is a `ClassificationECOC` classifier. You can access its properties using dot notation.

Cross validate `Mdl` using 10-fold cross validation.

```
CVMD1 = crossval(Mdl);
```

`CVMD1` is a `ClassificationPartitionedECOC` cross-validated ECOC classifier.

Estimate the generalization error.

```
oosLoss = kfoldLoss(CVMD1)
```

```
oosLoss =
    0.0400
```

The out-of-sample classification error is 4%, which indicates that the ECOC classifier generalizes fairly well.

Cross Validate an ECOC Classifier Using Parallel Computing

Consider the `arrhythmia` data set. There are 16 classes in the study, 13 of which are represented in the data. The first class indicates that the subject did not have arrhythmia, and the last class indicates that the subject's arrhythmia state was not recorded. Suppose that the other classes are ordinal levels indicating the severity of arrhythmia.

Train an ECOC classifier with a custom coding design specified by the description of the classes.

Load the arrhythmia data set.

```
load arrhythmia
Y = categorical(Y);
K = unique(Y); % Number of distinct classes
```

Construct a coding matrix that describes the nature of the classes.

```
OrdMat = designecoc(11,'ordinal');
nOM = size(OrdMat);
class1VSOrd = [1; -ones(11,1); 0];
class1VSClass16 = [1; zeros(11,1); -1];
OrdVSClass16 = [0; ones(11,1); -1];
Coding = [class1VSOrd class1VSClass16 OrdVSClass16,...
          [zeros(1,nOM(2)); OrdMat; zeros(1,nOM(2))]];

```

Train an ECOC classifier using the custom coding design (Coding) and parallel computing. Specify to use an ensemble of 50 classification trees boosted using GentleBoost.

```
t = templateEnsemble('GentleBoost',50,'Tree');
options = statset('UseParallel',1);
Mdl = fitcecoc(X,Y,'Coding',Coding,'Learners',t,'Options',options);
```

Mdl is a ClassificationECOC model. You can access its properties using dot notation.

Cross validate Mdl using 8-fold cross validation and parallel computing.

```
rng(1); % For reproducibility
CVMdl = crossval(Mdl,'Options',options,'KFold',8);
```

Warning: One or more folds do not contain points from all the groups.

Since some of the classes have low relative frequency, some of the folds do not train using observations from those classes. CVMdl is a ClassificationPartitionedECOC cross-validated ECOC model.

Estimate the generalization error using parallel computing.

```
oosLoss = kfoldLoss(CVMdl,'Options',options)

oosLoss =

    0.3208
```

The out-of-sample classification error is 32%, which indicates that this model does not generalize well. To improve the model, try training using a different boosting method, such as RobustBoost, or a different algorithm altogether, such as SVM.

- “Quick Start Parallel Computing for Statistics Toolbox” on page 20-2

Alternatives

Instead of training an ECOC model and then cross validating it, you can create a cross-validated ECOC model directly using `fitcecoc` and by specifying any of these name-value pair arguments: `CrossVal`, `CVPartition`, `Holdout`, `Leaveout`, or `KFold`.

crossval

Class: ClassificationEnsemble

Cross validate ensemble

Syntax

```
cvens = crossval(ens)
cvens = crossval(ens,Name,Value)
```

Description

`cvens = crossval(ens)` creates a cross-validated ensemble from `ens`, a classification ensemble. Default is 10-fold cross validation.

`cvens = crossval(ens,Name,Value)` creates a cross-validated ensemble with additional options specified by one or more `Name,Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Input Arguments

ens

A classification ensemble created with `fitensemble`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

'cvpartition'

A partition of class `cvpartition`. Sets the partition for cross validation.

Use no more than one of the name-value pairs `cvpartition`, `holdout`, `kfold`, or `leaveout`.

'holdout'

Holdout validation tests the specified fraction of the data, and uses the rest of the data for training. Specify a numeric scalar from 0 to 1. You can only use one of these four options at a time for creating a cross-validated tree: `'kfold'`, `'holdout'`, `'leaveout'`, or `'cvpartition'`.

'kfold'

Number of folds for cross validation, a numeric positive scalar.

Use no more than one of the name-value pairs `'kfold'`, `'holdout'`, `'leaveout'`, or `'cvpartition'`.

'leaveout'

If `'on'`, use leave-one-out cross validation.

Use no more than one of the name-value pairs `'kfold'`, `'holdout'`, `'leaveout'`, or `'cvpartition'`.

'nprint'

Printout frequency, a positive integer scalar. Use this parameter to observe the training of cross-validation folds.

Default: `'off'`, meaning no printout

Output Arguments

`cvens`

A cross-validated classification ensemble of class `ClassificationPartitionedEnsemble`.

Alternatives

You can create a cross-validation ensemble directly from the data, instead of creating an ensemble followed by a cross-validation ensemble. To do so, include one of these

five options in `fitensemble`: 'crossval', 'kfold', 'holdout', 'leaveout', or 'cvpartition'.

Examples

Create a cross-validated classification model for the Fisher iris data, and assess its quality using the `kfoldLoss` method.

```
load fisheriris
ens = fitensemble(meas,species,'AdaBoostM2',100,'Tree');
cvens = crossval(ens);
L = kfoldLoss(cvens)

L =
    0.0467
```

[ClassificationPartitionedEnsemble](#) | [cvpartition](#)

crossval

Class: ClassificationKNN

Cross-validated k -nearest neighbor classifier

Syntax

```
cvmodel = crossval mdl
cvmodel = crossval mdl, Name, Value
```

Description

`cvmodel = crossval(mdl)` creates a partitioned model from `mdl`, a fitted KNN classification model. By default, `CROSSVAL` uses 10-fold cross validation on the training data to create `cvmodel`.

`cvmodel = crossval(mdl, Name, Value)` creates a partitioned model with additional options specified by one or more `Name, Value` pair arguments.

Tips

- Assess the predictive performance of `mdl` on cross-validated data using the “kfold” methods and properties of `cvmodel`, such as `kfoldLoss`.

Input Arguments

mdl — Classifier model

classifier model object

k -nearest neighbor classifier model, returned as a classifier model object.

Note that using the 'CrossVal', 'Kfold', 'Holdout', 'Leaveout', or 'CVPartition' options results in a model of class

`ClassificationPartitionedModel`. You cannot use a partitioned tree for prediction, so this kind of tree does not have a `predict` method.

Otherwise, `mdl` is of class `ClassificationKNN`, and you can use the `predict` method to make predictions.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

'CVPartition'

Object of class `cvpartition`, created by the `cvpartition` function. `crossval` splits the data into subsets with `cvpartition`.

Use only one of these four options at a time: `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'`.

'Holdout'

Holdout validation tests the specified fraction of the data, and uses the remaining data for training. Specify a numeric scalar from 0 to 1. Use only one of these four options at a time: `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'`.

'KFold'

Number of folds to use in a cross-validated tree, a positive integer.

Use only one of these four options at a time: `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'`.

Default: 10

'Leaveout'

Set to `'on'` for leave-one-out cross validation.

Use only one of these four options at a time: `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'`.

Output Arguments

cvmodel

Partitioned model of class `ClassificationPartitionedModel`.

Examples

Cross-Validated *K*-Nearest Neighbor Model

Construct a cross-validated *k*-nearest neighbor model, and assess classification performance using the model.

Load the data.

```
load fisheriris
X = meas;
Y = species;
```

Construct a classifier for nearest neighbors.

```
mdl = fitcknn(X,Y);
```

Construct a cross-validated classifier.

```
cvmdl = crossval(mdl)
```

```
cvmdl =
```

```
classreg.learning.partition.ClassificationPartitionedModel:
  CrossValidatedModel: 'KNN'
  PredictorNames: {'x1' 'x2' 'x3' 'x4'}
  CategoricalPredictors: []
  ResponseName: 'Y'
  NumObservations: 150
  KFold: 10
  Partition: [1x1 cvpartition]
  ClassNames: {'setosa' 'versicolor' 'virginica'}
  ScoreTransform: 'none'
```

Find the cross-validated loss of the classifier.

```
cvmdlloss = kfoldLoss(cvmdl)
```

```
cvmdlloss =  
    0.0400
```

The cross-validated loss is less than 5%. You can expect `mdl` to have a similar error rate.

- “Examine the Quality of a KNN Classifier” on page 16-29
- “Modify a KNN Classifier” on page 16-30

Alternatives

You can create a cross-validated model directly from the data, instead of creating a model followed by a cross-validated model. To do so, include one of these options in `fitcknn`: 'CrossVal', 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'.

crossval

Class: ClassificationNaiveBayes

Cross-validated naive Bayes classifier

Syntax

```
CVMD1 = crossval(Mdl)
CVMD1 = crossval(Mdl,Name,Value)
```

Description

`CVMD1 = crossval(Mdl)` returns a partitioned naive Bayes classifier (`CVSMdl`) from a trained naive Bayes classifier (`Mdl`).

By default, `crossval` uses 10-fold cross validation on the training data to create `CVMD1`.

`CVMD1 = crossval(Mdl,Name,Value)` returns a partitioned naive Bayes classifier with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify a holdout sample proportion.

Tips

Assess the predictive performance of `Mdl` on cross-validated data using the “kfold” function and properties of `CVMD1`, such as `kfoldLoss`.

Input Arguments

Mdl — Fully trained naive Bayes classifier

ClassificationNaiveBayes model

A fully trained naive Bayes classifier, specified as a `ClassificationNaiveBayes` model trained by `fitcnb`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

'CVPartition' — Cross-validation partition

[] (default) | `cvpartition` partition object

Cross-validation partition, specified as the comma-separated pair consisting of 'CVPartition' and a `cvpartition` partition object as created by `cvpartition`. The partition object specifies the type of cross-validation, and also the indexing for training and validation sets.

If you specify `CVPartition`, then you cannot specify any of `Holdout`, `KFold`, or `Leaveout`.

'Holdout' — Fraction of data for holdout validation

scalar value in the range (0,1)

Fraction of data used for holdout validation, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range (0,1). If you specify 'Holdout', p , then the software:

- 1 Randomly reserves $p*100\%$ of the data as validation data, and trains the model using the rest of the data
- 2 Stores the compact, trained model in `CVMdl.Trained`

If you specify `Holdout`, then you cannot specify any of `CVPartition`, `KFold`, or `Leaveout`.

Example: 'Holdout', 0.1

Data Types: `double` | `single`

'KFold' — Number of folds

10 (default) | positive integer value

Number of folds to use in a cross-validated classifier, specified as the comma-separated pair consisting of 'KFold' and a positive integer value. If you specify, e.g., 'KFold', k , then the software:

- 1 Randomly partitions the data into k sets

- 2 For each set, reserves the set as validation data, and trains the model using the other $k - 1$ sets
- 3 Stores the k compact, trained models in the cells of a k -by-1 cell vector in `CVMdl.Trained`

If you specify `KFold`, then you cannot specify any of `CVPartition`, `Holdout`, or `Leaveout`.

Example: `'KFold', 8`

Data Types: `double`

'Leaveout' — Leave-one-out cross-validation flag

`'off'` (default) | `'on'`

Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of `'Leaveout'` and `'on'` or `'off'`. If you specify `'Leaveout', 'on'`, then, for each of the n observations, where n is `size(Mdl.X, 1)`, the software:

- 1 Reserves the observation as validation data, and trains the model using the other $n - 1$ observations
- 2 Stores the n compact, trained models in `CVMdl.Trained`

If you specify `Leaveout`, then you cannot specify `CVPartition`, `Holdout`, or `KFold`.

Example: `'Leaveout', 'on'`

Data Types: `char`

Output Arguments

CVMdl — Cross-validated naive Bayes classifier

`ClassificationPartitionedModel` model

Cross-validated naive Bayes classifier, returned as a `ClassificationPartitionedModel` model.

Examples

Cross Validate a Naive Bayes Classifier Using `crossval`

Load the ionosphere data set.

```
load ionosphere
X = X(:,3:end); % Remove first two predictors for stability
rng(1);        % For reproducibility
```

Train a naive Bayes classifier. It is good practice to define the class order. Assume that each predictor is conditionally, normally distributed given its label.

```
Mdl = fitcnb(X,Y,'ClassNames',{'b','g'});
```

Mdl is a trained `ClassificationNaiveBayes` classifier. 'b' is the negative class and 'g' is the positive class.

Cross validate the classifier using 10-fold cross validation.

```
CVMdl = crossval(Mdl)
FirstModel = CVMdl.Trained{1}
```

```
CVMdl =
```

```
classreg.learning.partition.ClassificationPartitionedModel
  CrossValidatedModel: 'NaiveBayes'
  PredictorNames: {1x32 cell}
  ResponseName: 'Y'
  NumObservations: 351
  KFold: 10
  Partition: [1x1 cvpartition]
  ClassNames: {'b' 'g'}
  ScoreTransform: 'none'
```

```
FirstModel =
```

```
classreg.learning.classif.CompactClassificationNaiveBayes
  PredictorNames: {1x32 cell}
  ResponseName: 'Y'
  ClassNames: {'b' 'g'}
  ScoreTransform: 'none'
  DistributionNames: {1x32 cell}
  DistributionParameters: {2x32 cell}
```

`CVMD1` is a `ClassificationPartitionedModel` cross-validated classifier. The software:

- 1 Randomly partitions the data into 10, equally sized sets.
- 2 Trains a naive Bayes classifier on nine of the sets.
- 3 Repeats steps 1 and 2 $k = 10$ times. It excludes one partition each time, and trains on the other nine partitions.
- 4 Combines generalization statistics for each fold.

`FirstModel` is the first of the 10 trained classifiers. It is a `CompactClassificationNaiveBayes` model.

You can estimate the generalization error by passing `CVMD1` to `kfoldLoss`.

Specify a Holdout-Sample Proportion for Naive Bayes Cross Validation

By default, `crossval` uses 10-fold cross validation to cross validate a naive Bayes classifier. You have several other options, such as specifying a different number of folds or holdout-sample proportion. This example shows how to specify a holdout-sample proportion.

Load the `ionosphere` data set.

```
load ionosphere
X = X(:,3:end); % Remove first two predictors for stability
rng(1);        % For reproducibility
```

Train a naive Bayes classifier. Assume that each predictor is conditionally, normally distributed given its label. It is good practice to define the class order.

```
Mdl = fitcnb(X,Y,'ClassNames',{'b','g'});
```

`Mdl` is a trained `ClassificationNaiveBayes` classifier. 'b' is the negative class and 'g' is the positive class.

Cross validate the classifier by specifying a 30% holdout sample.

```
CVMD1 = crossval(Mdl,'Holdout',0.30)
TrainedModel = CVMD1.Trained{1}
```

```
CVMD1 =
```

```
classreg.learning.partition.ClassificationPartitionedModel
  CrossValidatedModel: 'NaiveBayes'
  PredictorNames: {1x32 cell}
  ResponseName: 'Y'
  NumObservations: 351
  KFold: 1
  Partition: [1x1 cvpartition]
  ClassNames: {'b' 'g'}
  ScoreTransform: 'none'
```

```
TrainedModel =
```

```
classreg.learning.classif.CompactClassificationNaiveBayes
  PredictorNames: {1x32 cell}
  ResponseName: 'Y'
  ClassNames: {'b' 'g'}
  ScoreTransform: 'none'
  DistributionNames: {1x32 cell}
  DistributionParameters: {2x32 cell}
```

`CVMD1` is a `ClassificationPartitionedModel`. `TrainedModel` is a `CompactClassificationNaiveBayes` classifier trained using 70% of the data.

Estimate the generalization error.

```
kfoldLoss(CVMD1)
```

```
ans =
```

```
0.02571
```

The out-of-sample misclassification error is approximately 2.6%.

Alternatives

Instead of creating a naive Bayes classifier followed by a cross-validation classifier, create a cross-validated classifier directly using `fitcnb` and by specifying any of these

name-value pair arguments: 'CrossVal', 'CVPartition', 'Holdout', 'Leaveout', or 'KFold'.

ClassificationNaiveBayes | ClassificationPartitionedModel |
CompactClassificationNaiveBayes | fitcnb | kfoldLoss

crossval

Class: ClassificationSVM

Cross-validated support vector machine classifier

Syntax

```
CVSVMModel = crossval(SVMModel)
```

```
CVSVMModel = crossval(SVMModel, Name, Value)
```

Description

`CVSVMModel = crossval(SVMModel)` returns a cross-validated (partitioned) support vector machine classifier (`CVSVMModel`) from a trained SVM classifier (`SVMModel`).

By default, `crossval` uses 10-fold cross validation on the training data to create `CVSVMModel`.

`CVSVMModel = crossval(SVMModel, Name, Value)` returns a partitioned SVM classifier with additional options specified by one or more `Name, Value` pair arguments.

For example, you can specify the number of folds or holdout sample proportion.

Tips

Assess the predictive performance of `SVMModel` on cross-validated data using the “kfold” methods and properties of `CVSVMModel`, such as `kfoldLoss`.

Input Arguments

SVMModel — Full, trained SVM classifier

ClassificationSVM classifier

Full, trained SVM classifier, specified as a `ClassificationSVM` model trained using `fitcsvm`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

'CVPartition' — Cross-validation partition

[] (default) | `cvpartition` partition object

Cross-validation partition, specified as the comma-separated pair consisting of 'CVPartition' and a `cvpartition` partition object as created by `cvpartition`. The partition object specifies the type of cross-validation, and also the indexing for training and validation sets.

If you specify `CVPartition`, then you cannot specify any of `Holdout`, `KFold`, or `Leaveout`.

'Holdout' — Fraction of data for holdout validation

scalar value in the range (0,1)

Fraction of data used for holdout validation, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range (0,1). If you specify 'Holdout', p , then the software:

- 1 Randomly reserves $p*100\%$ of the data as validation data, and trains the model using the rest of the data
- 2 Stores the compact, trained model in `CVMdl.Trained`

If you specify `Holdout`, then you cannot specify any of `CVPartition`, `KFold`, or `Leaveout`.

Example: 'Holdout', 0.1

Data Types: `double` | `single`

'KFold' — Number of folds

10 (default) | positive integer value

Number of folds to use in a cross-validated classifier, specified as the comma-separated pair consisting of 'KFold' and a positive integer value. If you specify, e.g., 'KFold', k , then the software:

- 1 Randomly partitions the data into k sets

- 2 For each set, reserves the set as validation data, and trains the model using the other $k - 1$ sets
- 3 Stores the k compact, trained models in the cells of a k -by-1 cell vector in `CVMdl.Trained`

If you specify `KFold`, then you cannot specify any of `CVPartition`, `Holdout`, or `Leaveout`.

Example: `'KFold', 8`

Data Types: `double`

'Leaveout' — Leave-one-out cross-validation flag

`'off'` (default) | `'on'`

Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of `'Leaveout'` and `'on'` or `'off'`. If you specify `'Leaveout', 'on'`, then, for each of the n observations, where n is `size(Mdl.X, 1)`, the software:

- 1 Reserves the observation as validation data, and trains the model using the other $n - 1$ observations
- 2 Stores the n compact, trained models in `CVMdl.Trained`

If you specify `Leaveout`, then you cannot specify `CVPartition`, `Holdout`, or `KFold`.

Example: `'Leaveout', 'on'`

Data Types: `char`

Output Arguments

CVSVMModel — Cross-validated SVM classifier

`ClassificationPartitionedModel` classifier

Cross-validated SVM classifier, returned as a `ClassificationPartitionedModel` classifier.

Examples

Cross Validate an SVM Classifier Using crossval

Load the ionosphere data set.

```
load ionosphere
rng(1); % For reproducibility
```

Train an SVM classifier. It is good practice to standardize the predictors and define the class order.

```
SVMModel = fitcsvm(X,Y,'Standardize',true,'ClassNames',{'b','g'});
```

SVMModel is a trained ClassificationSVM classifier. 'b' is the negative class and 'g' is the positive class.

Cross validate the classifier using 10-fold cross validation.

```
CVSVMModel = crossval(SVMModel)
FirstModel = CVSVMModel.Trained{1}
```

```
CVSVMModel =
```

```
classreg.learning.partition.ClassificationPartitionedModel
  CrossValidatedModel: 'SVM'
  PredictorNames: {1x34 cell}
  ResponseName: 'Y'
  NumObservations: 351
  KFold: 10
  Partition: [1x1 cvpartition]
  ClassNames: {'b' 'g'}
  ScoreTransform: 'none'
```

```
FirstModel =
```

```
classreg.learning.classif.CompactClassificationSVM
  PredictorNames: {1x34 cell}
  ResponseName: 'Y'
  ClassNames: {'b' 'g'}
  ScoreTransform: 'none'
  Alpha: [78x1 double]
  Bias: -0.2209
  KernelParameters: [1x1 struct]
    Mu: [1x34 double]
    Sigma: [1x34 double]
  SupportVectors: [78x34 double]
```

```
SupportVectorLabels: [78x1 double]
```

`CVSVMModel` is a `ClassificationPartitionedModel` cross-validated classifier. The software:

- 1 Randomly partitions the data into 10, equally sized sets.
- 2 Trains an SVM classifier on nine of the sets.
- 3 Repeats steps 1 and 2 $k = 10$ times. It leaves out one of the partitions each time, and trains on the other nine partitions.
- 4 Combines generalization statistics for each fold.

`FirstModel` is the first of the 10 trained classifiers. It is a `CompactClassificationSVM` classifier.

You can estimate the generalization error by passing `CVSVMModel` to `kfoldLoss`.

Specify a Holdout-Sample Proportion for SVM Cross Validation

By default, `crossval` uses 10-fold cross validation to cross validate an SVM classifier. You have several other options, such as specifying a different number of folds or holdout sample proportion. This example shows how to specify a holdout-sample proportion.

Load the `ionosphere` data set.

```
load ionosphere
rng(1); % For reproducibility
```

Train an SVM classifier. It is good practice to standardize the predictors and define the class order.

```
SVMModel = fitcsvm(X,Y,'Standardize',true,'ClassNames',{'b','g'});
```

`SVMModel` is a trained `ClassificationSVM` classifier. 'b' is the negative class and 'g' is the positive class.

Cross validate the classifier by specifying a 15% holdout sample.

```
CVSVMModel = crossval(SVMModel,'Holdout',0.15)
TrainedModel = CVSVMModel.Trained{1}
```

```
CVSVMModel =  
  
classreg.learning.partition.ClassificationPartitionedModel  
  CrossValidatedModel: 'SVM'  
  PredictorNames: {1x34 cell}  
  ResponseName: 'Y'  
  NumObservations: 351  
  KFold: 1  
  Partition: [1x1 cvpartition]  
  ClassNames: {'b' 'g'}  
  ScoreTransform: 'none'
```

```
TrainedModel =  
  
classreg.learning.classif.CompactClassificationSVM  
  PredictorNames: {1x34 cell}  
  ResponseName: 'Y'  
  ClassNames: {'b' 'g'}  
  ScoreTransform: 'none'  
  Alpha: [74x1 double]  
  Bias: -0.2952  
  KernelParameters: [1x1 struct]  
  Mu: [1x34 double]  
  Sigma: [1x34 double]  
  SupportVectors: [74x34 double]  
  SupportVectorLabels: [74x1 double]
```

CVSVMModel is a `ClassificationPartitionedModel`. TrainedModel is a `CompactClassificationSVM` classifier trained using 85% of the data.

Estimate the generalization error.

```
kfoldLoss(CVSVMModel)
```

```
ans =
```

```
0.0769
```

The out-of-sample misclassification error is approximately 8%.

Alternatives

Instead of training an SVM classifier and then cross-validating it, you can create a cross-validated classifier directly using `fitcsvm` and by specifying any of these name-value pair arguments: 'CrossVal', 'CVPartition', 'Holdout', 'Leaveout', or 'Kfold'.

`ClassificationPartitionedModel` | `ClassificationSVM` |
`CompactClassificationSVM` | `cvpartition` | `fitcsvm`

crossval

Class: ClassificationTree

Cross-validated decision tree

Syntax

```
cvmodel = crossval(model)
cvmodel = crossval(model,Name,Value)
```

Description

`cvmodel = crossval(model)` creates a partitioned model from `model`, a fitted classification tree. By default, `crossval` uses 10-fold cross validation on the training data to create `cvmodel`.

`cvmodel = crossval(model,Name,Value)` creates a partitioned model with additional options specified by one or more `Name,Value` pair arguments.

Tips

- Assess the predictive performance of `model` on cross-validated data using the “kfold” methods and properties of `cvmodel`, such as `kfoldLoss`.

Input Arguments

`model`

A classification model, produced using `fitctree`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

'CVPartition'

Object of class `cvpartition`, created by the `cvpartition` function. `crossval` splits the data into subsets with `cvpartition`.

Use only one of these four options at a time: `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'`.

'Holdout'

Holdout validation tests the specified fraction of the data, and uses the remaining data for training. Specify a numeric scalar from 0 to 1. Use only one of these four options at a time: `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'`.

'KFold'

Number of folds to use in a cross-validated tree, a positive integer.

Use only one of these four options at a time: `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'`.

Default: 10

'Leaveout'

Set to `'on'` for leave-one-out cross validation.

Use only one of these four options at a time: `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'`.

Output Arguments

`cvmodel`

Partitioned model of class `ClassificationPartitionedModel`.

Examples

Create a Cross-Validation Model

Create a classification model for the ionosphere data, then create a cross-validation model. Evaluate the quality the model using `kfoldLoss`.

```
load ionosphere
tree = fitctree(X,Y);
cvmodel = crossval(tree);
L = kfoldLoss(cvmodel)

L =
    0.1168
```

Alternatives

You can create a cross-validation tree directly from the data, instead of creating a decision tree followed by a cross-validation tree. To do so, include one of these five options in `fitctree`: 'CrossVal', 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'.

See Also

`fitctree` | `crossval`

crossval

Class: RegressionEnsemble

Cross validate ensemble

Syntax

```
cvens = crossval(ens)
cvens = crossval(ens,Name,Value)
```

Description

`cvens = crossval(ens)` creates a cross-validated ensemble from `ens`, a regression ensemble. Default is 10-fold cross validation.

`cvens = crossval(ens,Name,Value)` creates a cross-validated ensemble with additional options specified by one or more `Name,Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Input Arguments

ens

A regression ensemble created with `fitensemble`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

'cvpartition'

A partition of class `cvpartition`. Sets the partition for cross validation.

Use no more than one of the name-value pairs `cvpartition`, `holdout`, `kfold`, and `leaveout`.

'holdout'

Holdout validation tests the specified fraction of the data, and uses the rest of the data for training. Specify a numeric scalar from 0 to 1. You can only use one of these four options at a time for creating a cross-validated tree: `'kfold'`, `'holdout'`, `'leaveout'`, or `'cvpartition'`.

'kfold'

Number of folds for cross validation, a numeric positive scalar.

Use no more than one of the name-value pairs `'kfold'`, `'holdout'`, `'leaveout'`, or `'cvpartition'`.

'leaveout'

If `'on'`, use leave-one-out cross-validation.

Use no more than one of the name-value pairs `'kfold'`, `'holdout'`, `'leaveout'`, or `'cvpartition'`.

'nprint'

Printout frequency, a positive integer scalar. Use this parameter to observe the training of cross-validation folds.

Default: `'off'`, meaning no printout

Output Arguments

`cvens`

A cross-validated classification ensemble of class `RegressionPartitionedEnsemble`.

Alternatives

You can create a cross-validation ensemble directly from the data, instead of creating an ensemble followed by a cross-validation ensemble. To do so, include one of these

five options in `fitensemble`: 'crossval', 'kfold', 'holdout', 'leaveout', or 'cvpartition'.

Examples

Create a cross-validated classification model for the `carsmall` data, and assess its quality using the `kfoldLoss` method:

```
X = [Acceleration Displacement Horsepower Weight];  
rens = fitensemble(X,MPG,'LSBoost',100,'Tree');  
cvens = crossval(rens);  
L = kfoldLoss(cvens)
```

```
L =  
    21.9868
```

See Also

`RegressionPartitionedEnsemble` | `cvpartition`

crossval

Class: RegressionTree

Cross-validated decision tree

Syntax

```
cvmodel = crossval(model)
cvmodel = crossval(model,Name,Value)
```

Description

`cvmodel = crossval(model)` creates a partitioned model from `model`, a fitted regression tree. By default, `crossval` uses 10-fold cross validation on the training data to create `cvmodel`.

`cvmodel = crossval(model,Name,Value)` creates a partitioned model with additional options specified by one or more `Name,Value` pair arguments.

Tips

- Assess the predictive performance of `model` on cross-validated data using the “kfold” methods and properties of `cvmodel`, such as `kfoldLoss`.

Input Arguments

`model`

A regression model, produced using `fitrtree`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

'CVPartition'

Object of class `cvpartition`, created by the `cvpartition` function. `crossval` splits the data into subsets with `cvpartition`.

Use only one of these four options at a time: `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'`.

Default: `[]`

'Holdout'

Holdout validation tests the specified fraction of the data, and uses the rest of the data for training. Specify a numeric scalar from 0 to 1. You can only use one of these four options at a time for creating a cross-validated tree: `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'`.

'KFold'

Number of folds to use in a cross-validated tree, a positive integer.

Use only one of these four options at a time: `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'`.

Default: 10

'Leaveout'

Set to `'on'` for leave-one-out cross-validation.

Output Arguments

`cvmodel`

A partitioned model of class `RegressionPartitionedModel`.

Examples

Create a regression model of the `carsmall` data, and assess its accuracy with `kfoldLoss`:

```
load carsmall
X = [Acceleration Displacement Horsepower Weight];
tree = fitrtree(X,MPG);
cvtree = crossval(tree);
L = kfoldLoss(cvtree)

L =
    25.2432
```

Alternatives

You can create a cross-validation tree directly from the data, instead of creating a decision tree followed by a cross-validation tree. To do so, include one of these five options in `fitrtree`: 'CrossVal', 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'.

`fitrtree` | `crossval`

cutcategories

Class: classregtree

Cut categories

Syntax

```
C = cutcategories(t)
C = cutcategories(t,nodes)
```

Description

`C = cutcategories(t)` returns an n -by-2 cell array `C` of the categories used at branches in the decision tree `t`, where n is the number of nodes. For each branch node i based on a categorical predictor variable x , the left child is chosen if x is among the categories listed in `C{i,1}`, and the right child is chosen if x is among those listed in `C{i,2}`. Both columns of `C` are empty for branch nodes based on continuous predictors and for leaf nodes.

`C = cutcategories(t,nodes)` takes a vector `nodes` of node numbers and returns the categories for the specified nodes.

Examples

Create a classification tree for car data:

```
load carsmall

t = classregtree([MPG Cylinders],Origin,...
                'names',{'MPG' 'Cyl'},'cat',2)
t =
Decision tree for classification

classregtree | cuttype | cutpoint | cutvar

cutpoint

Class: classregtree

Decision tree cut point values

Syntax

```
v = cutpoint(t)
v = cutpoint(t,nodes)
```

Description

`v = cutpoint(t)` returns an n -element vector v of the values used as cut points in the decision tree t , where n is the number of nodes. For each branch node i based on a continuous predictor variable x , the left child is chosen if $x < v(i)$ and the right child is chosen if $x \geq v(i)$. v is NaN for branch nodes based on categorical predictors and for leaf nodes.

`v = cutpoint(t,nodes)` takes a vector `nodes` of node numbers and returns the cut points for the specified nodes.

Examples

Create a classification tree for car data:

```
load carsmall
t = classregtree([MPG Cylinders],Origin,...
                'names',{'MPG' 'Cyl'},'cat',2)
t =

`classregtree` | `cuttype` | `cutcategories` | `cutvar`

cuttype

Class: classregtree

Cut types

Syntax

```
c = cuttype(t)
c = cuttype(t,nodes)
```

Description

`c = cuttype(t)` returns an n -element cell array `c` indicating the type of cut at each node in the tree `t`, where n is the number of nodes. For each node `i`, `c{i}` is:

- `'continuous'` — If the cut is defined in the form $x < v$ for a variable `x` and cut point `v`.
- `'categorical'` — If the cut is defined by whether a variable `x` takes a value in a set of categories.
- `''` — If `i` is a leaf node.

`cutvar` returns the cut points for `'continuous'` cuts, and `cutcategories` returns the set of categories.

`c = cuttype(t,nodes)` takes a vector `nodes` of node numbers and returns the cut types for the specified nodes.

Examples

Create a classification tree for car data:

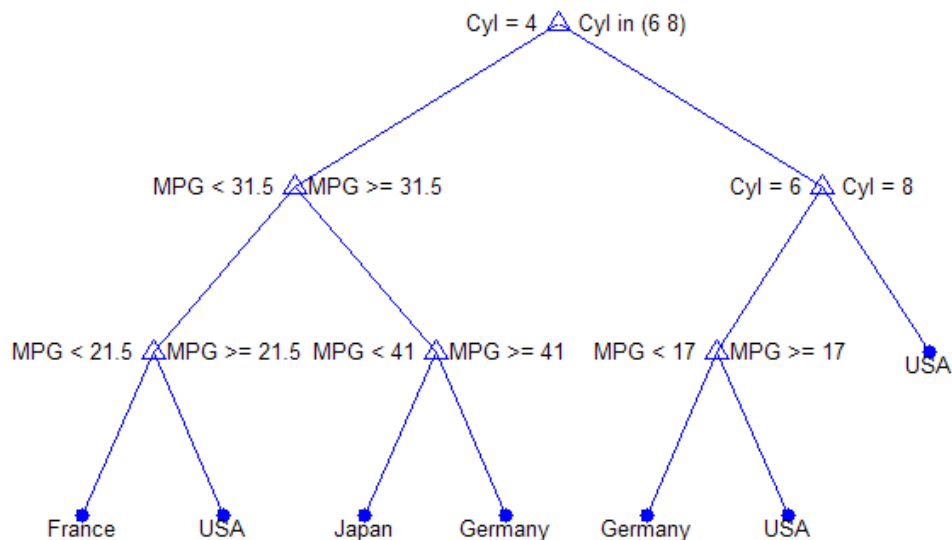

```
load carsmall
t = classregtree([MPG Cylinders],Origin,...
                'names',{'MPG' 'Cyl'},'cat',2)
t =

`classregtree` | `cutvar` | `numnodes` | `cutcategories`

cutvar

Class: classregtree

Cut variable names

Syntax

```
v = cutvar(t)
v = cutvar(t,nodes)
[v,num] = cutvar(...)
```

Description

`v = cutvar(t)` returns an n -element cell array `v` of the names of the variables used for branching in each node of the tree `t`, where n is the number of nodes. These variables are sometimes known as *cut variables*. For leaf nodes, `v` contains an empty string.

`v = cutvar(t,nodes)` takes a vector `nodes` of node numbers and returns the cut variables for the specified nodes.

`[v,num] = cutvar(...)` also returns a vector `num` containing the number of each variable.

Examples

Create a classification tree for car data:

```
load carsmall

t = classregtree([MPG Cylinders],Origin,...
                'names',{'MPG' 'Cyl'},'cat',2)

classregtree | children | numnodes

cvloss

Class: ClassificationTree

Classification error by cross validation

Syntax

```
E = cvloss(tree)
[E,SE] = cvloss(tree)
[E,SE,Nleaf] = cvloss(tree)
[E,SE,Nleaf,BestLevel] = cvloss(tree)
[E,...] = cvloss(tree,Name,Value)
```

Description

`E = cvloss(tree)` returns the cross-validated classification error (loss) for `tree`, a classification tree.

`[E,SE] = cvloss(tree)` returns the standard error of `E`.

`[E,SE,Nleaf] = cvloss(tree)` returns the number of leaves of `tree`.

`[E,SE,Nleaf,BestLevel] = cvloss(tree)` returns the optimal pruning level for `tree`.

`[E,...] = cvloss(tree,Name,Value)` cross validates with additional options specified by one or more `Name,Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Input Arguments

tree

A classification tree produced by `fitctree`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

'Subtrees'

Vector of pruning levels, with 0 representing the full, unpruned tree. tree must include a pruning sequence as created either by `fitctree` with 'Prune' set to 'on', or by the `prune` method. The returned E, SE, and Nleaf are vectors of the same length as Subtrees; BestLevel is a scalar. If you set Subtrees to 'all', cvloss uses the entire pruning sequence.

Default: 0

'TreeSize'

One of the following strings:

- 'se' — cvloss uses the smallest tree whose cost is within one standard error of the minimum cost.
- 'min' — cvloss uses the minimal cost tree.

Default: 'se'

'kfold'

Number of cross-validation samples, a positive integer.

Default: 10

Output Arguments

E

The cross-validation classification error (loss). A vector or scalar depending on the setting of the Subtrees name-value pair.

SE

The standard error of E. A vector or scalar depending on the setting of the `Subtrees` name-value pair.

Nleaf

Number of leaf nodes in tree. Leaf nodes are terminal nodes, which give classifications, not splits. A vector or scalar depending on the setting of the `Subtrees` name-value pair.

BestLevel

By default, a scalar representing the largest pruning level that achieves a value of E within SE of the minimum error. If you set `TreeSize` to 'min', `BestLevel` is the smallest value in `Subtrees`.

Examples

Compute the Cross-Validation Error

Compute the cross-validation error for the default classification tree for the `ionosphere` data.

```
load ionosphere
tree = fitctree(X,Y);
[E,SE,Nleaf,BestLevel] = cvloss(tree)
```

```
E =
    0.1282
```

```
SE =
    0.0178
```

```
Nleaf =
    19
```

```
BestLevel =
    0
```

Find the best level by using the `Subtrees` name-value pair.

```
[~,~,~,BestLevel] = cvloss(tree, 'Subtrees', 'all')
```

```
BestLevel =  
  6
```

Alternatives

You can construct a cross-validated tree model with `crossval`, and call `kfoldLoss` instead of `cvloss`. The alternative can save time if you are going to examine the cross-validated tree more than once.

However, unlike `cvloss`, `kfoldLoss` does not return `SE`, `Nleaf`, or `BestLevel`. `kfoldLoss` also does not allow you to examine any error other than classification error.

See Also

`fitctree` | `crossval` | `kfoldLoss` | `loss`

cvloss

Class: RegressionTree

Regression error by cross validation

Syntax

```
E = cvloss(tree)
[E,SE] = cvloss(tree)
[E,SE,Nleaf] = cvloss(tree)
[E,SE,Nleaf,BestLevel] = cvloss(tree)
[E,...] = cvloss(tree,Name,Value)
```

Description

`E = cvloss(tree)` returns the cross-validated regression error (loss) for `tree`, a regression tree.

`[E,SE] = cvloss(tree)` returns the standard error of `E`.

`[E,SE,Nleaf] = cvloss(tree)` returns the number of leaves (terminal nodes) in `tree`.

`[E,SE,Nleaf,BestLevel] = cvloss(tree)` returns the optimal pruning level for `tree`.

`[E,...] = cvloss(tree,Name,Value)` cross validates with additional options specified by one or more `Name,Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Input Arguments

tree

A regression tree produced by `fitrtree`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

'Subtrees'

Vector of pruning levels, with 0 representing the full, unpruned tree. `tree` must include a pruning sequence as created either by `fitctree` with 'prune' set to 'on', or by the `prune` method. The returned `E`, `SE`, and `Nleaf` are vectors of the same length as `Subtrees`; `BestLevel` is a scalar. If you set `Subtrees` to 'all', `cvloss` uses the entire pruning sequence.

Default: 0

'TreeSize'

One of the following strings:

- 'se' — `cvloss` uses the smallest tree whose cost is within one standard error of the minimum cost.
- 'min' — `cvloss` uses the minimal cost tree.

Default: 'se'

'kfold'

Number of cross-validation samples, a positive integer.

Default: 10

Output Arguments

E

The cross-validation mean squared error (loss). A vector or scalar depending on the setting of the `Subtrees` name-value pair.

SE

The standard error of E. A vector or scalar depending on the setting of the `Subtrees` name-value pair.

Nleaf

Number of leaf nodes in tree. Leaf nodes are terminal nodes, which give responses, not splits. A vector or scalar depending on the setting of the `Subtrees` name-value pair.

BestLevel

By default, a scalar representing the largest pruning level that achieves a value of E within SE of the minimum error. If you set `TreeSize` to 'min', `BestLevel` is the smallest value in `Subtrees`.

Examples

Compute the cross-validation error for the default classification tree for the `carsmall` data:

```
load carsmall
X = [Displacement Horsepower Weight];
tree = fitrtree(X,MPG);
[E,SE,Nleaf,BestLevel] = cvloss(tree)
```

```
E =
    30.7558
```

```
SE =
     6.0651
```

```
Nleaf =
     19
```

```
BestLevel =
     0
```

Find the best level by using the `Subtrees` name-value pair:

```
[~,~,~,BestLevel] = cvloss(tree,'Subtrees','all')
```

```
BestLevel =  
    15
```

Alternatives

You can construct a cross-validated tree model with `crossval`, and call `kfoldLoss` instead of `cvloss`. The alternative can save time if you are going to examine the cross-validated tree more than once.

However, unlike `cvloss`, `kfoldLoss` does not return `SE`, `Nleaf`, or `BestLevel`.

cvpartition class

Data partitions for cross validation

Description

An object of the `cvpartition` class defines a random partition on a set of data of a specified size. Use this partition to define test and training sets for validating a statistical model using cross validation.

Construction

`.cvpartition` Create cross validation partition for data

Methods

`disp` Display `cvpartition` object

`display` Display `cvpartition` object

`repartition` Repartition data for cross-validation

`test` Test indices for cross-validation

`training` Training indices for cross-validation

Properties

`NumObservations` Number of observations (including observations with missing `group` values)

NumTestSets	Number of test sets
TestSize	Size of each test set
TrainSize	Size of each training set
Type	Type of partition

Copy Semantics

Value. To learn how this affects your use of the class, see “Comparing Handle and Value Classes” in the MATLAB Object-Oriented Programming documentation.

Examples

Use a 10-fold stratified cross validation to compute the misclassification error for `classify` on iris data.

```
load('fisheriris');
CVO = cvpartition(species,'k',10);
err = zeros(CVO.NumTestSets,1);
for i = 1:CVO.NumTestSets
    trIdx = CVO.training(i);
    teIdx = CVO.test(i);
    ytest = classify(meas(teIdx,:),meas(trIdx,:),...
        species(trIdx,:));
    err(i) = sum(~strcmp(ytest,species(teIdx)));
end
cvErr = sum(err)/sum(CVO.TestSize);
```

How To

- “Grouping Variables” on page 2-52

cvpartition

Class: cvpartition

Create cross validation partition for data

Syntax

```
c = cvpartition(n, 'Kfold', k)
c = cvpartition(group, 'Kfold', k)
c = cvpartition(n, 'HoldOut', p)
c = cvpartition(group, 'HoldOut', p)
c = cvpartition(n, 'LeaveOut')
c = cvpartition(n, 'resubstitution')
```

Description

`c = cvpartition(n, 'Kfold', k)` constructs an object `c` of the `cvpartition` class defining a random partition for k -fold cross validation on n observations. The partition divides the observations into k disjoint subsamples (or *folds*), chosen randomly but with roughly equal size. The default value of k is 10.

`c = cvpartition(group, 'Kfold', k)` creates a random partition for a stratified k -fold cross validation. `group` is a numeric vector, categorical array, string array, or cell array of strings indicating the class of each observation. Each subsample has roughly equal size and roughly the same class proportions as in `group`. `cvpartition` treats NaNs or empty strings in `group` as missing values.

`c = cvpartition(n, 'HoldOut', p)` creates a random partition for holdout validation on n observations. This partition divides the observations into a training set and a test (or *holdout*) set. The parameter `p` must be a scalar. When $0 < p < 1$, `cvpartition` randomly selects approximately $p \cdot n$ observations for the test set. When `p` is an integer, `cvpartition` randomly selects `p` observations for the test set. The default value of `p` is 1/10.

`c = cvpartition(group, 'HoldOut', p)` randomly partitions observations into a training set and a test set with stratification, using the class information in `group`; that is, both training and test sets have roughly the same class proportions as in `group`.

`c = cvpartition(n, 'LeaveOut')` creates a random partition for leave-one-out cross validation on `n` observations. Leave-one-out is a special case of 'KFold', in which the number of folds equals the number of observations.

`c = cvpartition(n, 'resubstitution')` creates an object `c` that does not partition the data. Both the training set and the test set contain all of the original `n` observations.

Examples

Use stratified 10-fold cross validation to compute misclassification rate:

```
load fisheriris;
y = species;
c = cvpartition(y, 'k', 10);

fun = @(xT,yT,xt,yt)(sum(~strcmp(yt,classify(xt,xT,yT))));

rate = sum(crossval(fun,meas,y,'partition',c))...
      /sum(c.TestSize)
rate =
    0.0200
```

See Also

`crossval` | `repartition`

How To

- “Grouping Variables” on page 2-52

cvshrink

Class: ClassificationDiscriminant

Cross-validate regularization of linear discriminant

Syntax

```
err = cvshrink(obj)
[err,gamma] = cvshrink(obj)
[err,gamma,delta] = cvshrink(obj)
[err,gamma,delta,numpred] = cvshrink(obj)
[err,...] = cvshrink(obj,Name,Value)
```

Description

`err = cvshrink(obj)` returns a vector of cross-validated classification error values for differing values of the regularization parameter Gamma.

`[err,gamma] = cvshrink(obj)` also returns the vector of Gamma values.

`[err,gamma,delta] = cvshrink(obj)` also returns the vector of Delta values.

`[err,gamma,delta,numpred] = cvshrink(obj)` returns the vector of number of nonzero predictors for each setting of the parameters Gamma and Delta.

`[err,...] = cvshrink(obj,Name,Value)` cross validates with additional options specified by one or more Name,Value pair arguments.

Tips

- Examine the `err` and `numpred` outputs to see the tradeoff between cross-validated error and number of predictors. When you find a satisfactory point, set the corresponding `gamma` and `delta` properties in the model using dot notation. For example, if `(i,j)` is the location of the satisfactory point, set

```
obj.Gamma = gamma(i);
```

```
obj.Delta = delta(i,j);
```

Input Arguments

obj

Discriminant analysis classifier, produced using `fitcdiscr`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

'delta'

- Scalar `delta` — `cvshrink` uses this value of `delta` with every value of `gamma` for regularization.
- Row vector `delta` — For each `i` and `j`, `cvshrink` uses `delta(j)` with `gamma(i)` for regularization.
- Matrix `delta` — The number of rows of `delta` must equal the number of elements in `gamma`. For each `i` and `j`, `cvshrink` uses `delta(i,j)` with `gamma(i)` for regularization.

Default: 0

'gamma'

Vector of Gamma values for cross-validation.

Default: 0:0.1:1

'NumDelta'

Number of Delta intervals for cross-validation. For every value of Gamma, `cvshrink` cross-validates the discriminant using `NumDelta + 1` values of Delta, uniformly spaced from zero to the maximal Delta at which all predictors are eliminated for this value of Gamma. If you set `delta`, `cvshrink` ignores `NumDelta`.

Default: 0

'NumGamma'

Number of Gamma intervals for cross-validation. `cvshrink` cross-validates the discriminant using `NumGamma + 1` values of Gamma, uniformly spaced from `MinGamma` to 1. If you set `gamma`, `cvshrink` ignores `NumGamma`.

Default: 10

'verbose'

Verbosity level, an integer from 0 to 2. Higher values give more progress messages.

Default: 0

Output Arguments

err

Numeric vector or matrix of errors. `err` is the misclassification error rate, meaning the average fraction of misclassified data over all folds.

- If `delta` is a scalar (default), `err(i)` is the misclassification error rate for `obj` regularized with `gamma(i)`.
- If `delta` is a vector, `err(i,j)` is the misclassification error rate for `obj` regularized with `gamma(i)` and `delta(j)`.
- If `delta` is a matrix, `err(i,j)` is the misclassification error rate for `obj` regularized with `gamma(i)` and `delta(i,j)`.

gamma

Vector of Gamma values used for regularization. See “Gamma and Delta” on page 21-799.

delta

Vector or matrix of Delta values used for regularization. See “Gamma and Delta” on page 21-799.

- If you give a scalar for the `delta` name-value pair, the output `delta` is a row vector the same size as `gamma`, with entries equal to the input scalar.
- If you give a row vector for the `delta` name-value pair, the output `delta` is a matrix with the same number of columns as the row vector, and with the number of rows equal to the number of elements of `gamma`. The output `delta(i, j)` is equal to the input `delta(j)`.
- If you give a matrix for the `delta` name-value pair, the output `delta` is the same as the input matrix. The number of rows of `delta` must equal the number of elements in `gamma`.

numpred

Numeric vector or matrix containing the number of predictors in the model at various regularizations. `numpred` has the same size as `err`.

- If `delta` is a scalar (default), `numpred(i)` is the number of predictors for `obj` regularized with `gamma(i)` and `delta`.
- If `delta` is a vector, `numpred(i, j)` is the number of predictors for `obj` regularized with `gamma(i)` and `delta(j)`.
- If `delta` is a matrix, `numpred(i, j)` is the number of predictors for `obj` regularized with `gamma(i)` and `delta(i, j)`.

Definitions

Gamma and Delta

Regularization is the process of finding a small set of predictors that yield an effective predictive model. For linear discriminant analysis, there are two parameters, γ and δ , that control regularization as follows. `cvshrink` helps you select appropriate values of the parameters.

Let Σ represent the covariance matrix of the data X , and let \hat{X} be the centered data (the data X minus the mean by class). Define

$$D = \text{diag}(\hat{X}^T * \hat{X}).$$

The regularized covariance matrix $\tilde{\Sigma}$ is

$$\tilde{\Sigma} = (1 - \gamma)\Sigma + \gamma D.$$

Whenever $\gamma \geq \text{MinGamma}$, $\tilde{\Sigma}$ is nonsingular.

Let μ_k be the mean vector for those elements of X in class k , and let μ_0 be the global mean vector (the mean of the rows of X). Let C be the correlation matrix of the data X , and let \tilde{C} be the regularized correlation matrix:

$$\tilde{C} = (1 - \gamma)C + \gamma I,$$

where I is the identity matrix.

The linear term in the regularized discriminant analysis classifier for a data point x is

$$(x - \mu_0)^T \tilde{\Sigma}^{-1} (\mu_k - \mu_0) = \left[(x - \mu_0)^T D^{-1/2} \right] \left[\tilde{C}^{-1} D^{-1/2} (\mu_k - \mu_0) \right].$$

The parameter δ enters into this equation as a threshold on the final term in square brackets. Each component of the vector $\left[\tilde{C}^{-1} D^{-1/2} (\mu_k - \mu_0) \right]$ is set to zero if it is smaller in magnitude than the threshold δ . Therefore, for class k , if component j is thresholded to zero, component j of x does not enter into the evaluation of the posterior probability.

The `DeltaPredictor` property is a vector related to this threshold. When $\delta \geq \text{DeltaPredictor}(\mathbf{i})$, all classes k have

$$\left| \tilde{C}^{-1} D^{-1/2} (\mu_k - \mu_0) \right| \leq \delta.$$

Therefore, when $\delta \geq \text{DeltaPredictor}(\mathbf{i})$, the regularized classifier does not use predictor \mathbf{i} .

Examples

Regularize Data with Many Predictors

Regularize a discriminant analysis classifier, and view the tradeoff between the number of predictors in the model and the classification accuracy.

Create a linear discriminant analysis classifier for the `ovariancancer` data. Set the `SaveMemory` and `FillCoeffs` options to keep the resulting model reasonably small.

```
load ovariancancer
obj = fitcdiscr(obs,grp,...
    'SaveMemory','on','FillCoeffs','off');
```

Use 10 levels of `Gamma` and 10 levels of `Delta` to search for good parameters. This search is time-consuming. Set `Verbose` to 1 to view the progress.

```
rng('default') % for reproducibility
[err,gamma,delta,numpred] = cvshrink(obj,...
    'NumGamma',9,'NumDelta',9,'Verbose',1);
```

```
Done building cross-validated model.
Processing Gamma step 1 out of 10.
Processing Gamma step 2 out of 10.
Processing Gamma step 3 out of 10.
Processing Gamma step 4 out of 10.
Processing Gamma step 5 out of 10.
Processing Gamma step 6 out of 10.
Processing Gamma step 7 out of 10.
Processing Gamma step 8 out of 10.
Processing Gamma step 9 out of 10.
Processing Gamma step 10 out of 10.
```

Plot the classification error rate against the number of predictors.

```
plot(err,numpred,'k.')
xlabel('Error rate');
ylabel('Number of predictors');
```

cvshrink

Class: RegressionEnsemble

Cross validate shrinking (pruning) ensemble

Syntax

```
vals = cvshrink(ens)
[vals,nlearn] = cvshrink(ens)
[vals,nlearn] = cvshrink(ens,Name,Value)
```

Description

`vals = cvshrink(ens)` returns an L-by-T matrix with cross-validated values of the mean squared error. L is the number of `lambda` values in the `ens.Regularization` structure. T is the number of threshold values on weak learner weights. If `ens` does not have a `Regularization` property filled in by the `regularize` method, pass a `lambda` name-value pair.

`[vals,nlearn] = cvshrink(ens)` returns an L-by-T matrix of the mean number of learners in the cross-validated ensemble.

`[vals,nlearn] = cvshrink(ens,Name,Value)` cross validates with additional options specified by one or more `Name,Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Input Arguments

ens

A regression ensemble, created with `fitensemble`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single

quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

'cvpartition'

A partition created with `cvpartition` to use in a cross-validated tree. You can only use one of these four options at a time: `'kfold'`, `'holdout'`, `'leaveout'`, or `'cvpartition'`.

'holdout'

Holdout validation tests the specified fraction of the data, and uses the rest of the data for training. Specify a numeric scalar from 0 to 1. You can only use one of these four options at a time for creating a cross-validated tree: `'kfold'`, `'holdout'`, `'leaveout'`, or `'cvpartition'`.

'kfold'

Number of folds to use in a cross-validated tree, a positive integer. If you do not supply a cross-validation method, `cvshrink` uses 10-fold cross validation. You can only use one of these four options at a time: `'kfold'`, `'holdout'`, `'leaveout'`, or `'cvpartition'`.

Default: 10

'lambda'

Vector of nonnegative regularization parameter values for lasso. If empty, `cvshrink` does not perform cross validation.

Default: []

'leaveout'

Use leave-one-out cross validation by setting to `'on'`. You can only use one of these four options at a time: `'kfold'`, `'holdout'`, `'leaveout'`, or `'cvpartition'`.

'threshold'

Numeric vector with lower cutoffs on weights for weak learners. `cvshrink` discards learners with weights below `threshold` in its cross-validation calculation.

Default: 0

Output Arguments

vals

L-by-T matrix with cross-validated values of the mean squared error. L is the number of values of the regularization parameter 'lambda', and T is the number of 'threshold' values on weak learner weights.

nlearn

L-by-T matrix with cross-validated values of the mean number of learners in the cross-validated ensemble. L is the number of values of the regularization parameter 'lambda', and T is the number of 'threshold' values on weak learner weights.

Examples

Create a regression ensemble for predicting mileage from the carsmall data. Cross validate the ensemble for three values each of lambda and threshold.

```
load carsmall
X = [Displacement Horsepower Weight];
ens = fitensemble(X,MPG,'bag',100,'Tree',...
    'type','regression');
[vals nlearn] = cvshrink(ens,'lambda',[.01 .1 1],...
    'threshold',[0 .01 .1])

vals =
    20.0949    19.9007    131.6316
    20.0924    19.8431    128.0989
    19.9759    19.7987    119.5574

nlearn =
    13.3000    11.6000     3.5000
    13.2000    11.5000     3.6000
    13.4000    11.4000     3.9000
```

Clearly, setting a threshold of 0.1 leads to unacceptable errors, while a threshold of 0.01 gives similar errors to a threshold of 0. The mean number of learners with a threshold of 0.1 is about 11.5, whereas the mean number is about 13.2 when the threshold is 0.

regularize | shrink

datasample

Randomly sample from data, with or without replacement

Syntax

```
y = datasample(data,k)
y = datasample(data,k,dim)
[y,idx] = datasample(data,k,...)
[y,...] = datasample(s,data,k,...)
[y,...] = datasample(data,k,Name,Value)
[y,...] = datasample(data,k,dim,Name,Value)
```

Description

`y = datasample(data,k)` returns k observations sampled uniformly at random, with replacement, from the data in `data`.

`y = datasample(data,k,dim)` returns a sample taken along dimension `dim` of `data`.

`[y,idx] = datasample(data,k,...)` returns an index vector indicating which values `datasample` sampled from `data`.

`[y,...] = datasample(s,data,k,...)` uses the random number stream `s` to generate random numbers.

`[y,...] = datasample(data,k,Name,Value)` or `[y,...] = datasample(data,k,dim,Name,Value)` samples with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

data

Vector, matrix, N -dimensional array, table, or dataset array representing the data from which to sample. By default, `datasample` regards the rows of a `data` matrix, or the first

nonsingleton dimension of a `data` array, as data elements. Change this behavior with the `dim` argument.

k

Positive integer, the number of samples.

dim

Integer specifying the dimension on which to take samples. For example, if `data` is a matrix and `dim` is 2, `y` contains a selection of columns in `data`. If `data` is a table or dataset array and `dim` is 2, `y` contains a selection of variables in `data`. Use `dim` to ensure sampling along a specific dimension regardless of whether `data` is a vector, matrix or N -dimensional array.

Default: 1

s

Random number stream. Create `s` using `rng` or `RandStream`.

Default: The global random number stream

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`,`Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1`,`Value1`, . . . ,`NameN`,`ValueN`.

'Replace'

Select the sample with replacement if `Replace` is `true`, or without replacement if `Replace` is `false`. If `Replace` is `false`, `k` must not be larger than the number of data elements in `data`.

Default: `true`

'Weights'

Vector with the same number of elements as data elements in `data`, and with nonnegative elements. Sample with probability proportional to the elements of `Weights`.

Default: `ones(datasize,1)`, where `datasize` is the number of data elements in `data`

Output Arguments

y

- If `data` is a vector, `y` is a vector containing `k` elements selected from `data`.
- If `data` is a matrix, `y` is a matrix containing `k` rows selected from `data`. Or, if `dim = 2`, `y` is a matrix containing `k` columns selected from `data`
- If `data` is an N -dimensional array, `datasample` samples along its first non-singleton dimension. Or, if you give a `dim` name-value pair, `datasample` samples along the dimension `dim`.

When the sample is taken with replacement (default), `y` can contain repeated observations from `data`. Set the `Replace` name-value pair to `false` to sample without replacement.

idx

Vector of indices indicating which elements `datasample` chose from `data` to create `y`. For example:

- If `data` is a vector, `y = data(idx)`.
- If `data` is a matrix, `y = data(idx,:)`.

Examples

Draw five unique values from the integers `1:10`.

```
y = datasample(1:10,5,'Replace',false)
```

```
y =
     6     3     7     8     5
```

Generate a random sequence of the characters `ACGT`, with replacement, according to specified probabilities.

```
seq = datasample('ACGT',48,'Weights',[0.15 0.35 0.35 0.15])
```

```
seq =
```

```
CTTCGACTGTGAGTGGGCGCGACAAGGCTACCGGCCCGGGCGGCACTC
```

Select a random subset of columns from a data matrix.

```
X = randn(10,1000);  
Y = datasample(X,5,2,'Replace',false)
```

```
Y =  
    0.7007    0.3382    2.1298   -0.1891    0.5026  
    0.6520   -0.6693   -0.1961   -0.9915    1.9107  
    0.1785    0.6640    2.3247   -1.1735   -1.0020  
    1.6760    2.6102   -0.8902   -0.7735    1.8676  
   -0.3251   -0.6415   -0.2572   -0.1629   -1.0523  
    0.1011    0.9323   -1.3088   -0.4477    0.8036  
   -0.5767   -0.5778   -0.8556    0.8672   -0.0727  
   -0.0615   -0.9084    0.9020   -0.4185   -1.9520  
    0.7256   -1.1228    0.7558    1.2691    2.4997  
   -1.2273    0.5754   -0.8755   -0.8224   -1.2066
```

Resample observations from a dataset array to create a bootstrap replicate dataset.

```
load hospital  
y = datasample(hospital,size(hospital,1));
```

Use the second output to sample “in parallel” from two data vectors.

```
x1 = randn(100,1);  
x2 = randn(100,1);  
[y1,idx] = datasample(x1,10);  
y2 = x2(idx);
```

Alternatives

You can use `randi` or `randperm` to generate indices for random sampling with or without replacement, respectively. However, `datasample` can be more convenient because it samples directly from your data. `datasample` also allows weighted sampling.

More About

Tips

- To sample random integers with replacement from a range, use `randi`.

- To sample random integers without replacement, use `randperm` or `datasample`.
- To randomly sample from data, with or without replacement, use `datasample`.

Algorithms

`datasample` uses `randperm`, `rand`, or `randi` to generate random values. Therefore, `datasample` changes the state of the MATLAB global random number generator. Control the random number generator using `rng`.

For selecting weighted samples without replacement, `datasample` uses the algorithm of Wong and Easton [1].

dataset class

Arrays for statistical data

Compatibility

The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

Description

Dataset arrays are used to collect heterogeneous data and metadata including variable and observation names into a single container variable. Dataset arrays are suitable for storing column-oriented or tabular data that are often stored as columns in a text file or in a spreadsheet, and can accommodate variables of different types, sizes, units, etc.

Dataset arrays can contain different kinds of variables, including numeric, logical, character, categorical, and cell. However, a dataset array is a different class than the variables that it contains. For example, even a dataset array that contains only variables that are double arrays cannot be operated on as if it were itself a double array. However, using dot subscripting, you can operate on variable in a dataset array as if it were a workspace variable.

You can subscript dataset arrays using parentheses much like ordinary numeric arrays, but in addition to numeric and logical indices, you can use variable and observation names as indices.

Construction

Use the `dataset` constructor to create a dataset array from variables in the MATLAB workspace. You can also create a dataset array by reading data from a text or spreadsheet file. You can access each variable in a dataset array much like fields in a structure, using dot subscripting. See the following section for a list of operations available for dataset arrays.

.dataset

Construct dataset array

Methods

cat

get

Access dataset array properties

horzcat

Horizontal concatenation for dataset arrays

intersect

Set intersection for dataset array observations

<code>isempty</code>	True for empty dataset array
<code>ismember</code>	Dataset array elements that are members of set
<code>ismissing</code>	Find dataset array elements with missing values
<code>join</code>	Merge observations
<code>length</code>	Length of dataset array
<code>ndims</code>	Number of dimensions of dataset array
<code>numel</code>	Number of elements in dataset array
<code>replacedata</code>	Replace dataset variables
<code>replaceWithMissing</code>	Insert missing data indicators into a dataset array
<code>set</code>	Set and display properties
<code>setdiff</code>	Set difference for dataset array observations
<code>setxor</code>	Set exclusive or for dataset array observations
<code>single</code>	Convert dataset variables to single array
<code>size</code>	Size of dataset array
<code>sortrows</code>	Sort rows of dataset array

stack	Stack data from multiple variables into single variable
subsasgn	Subscripted assignment to dataset array
subsref	Subscripted reference for dataset array
summary	Print summary of dataset array
union	Set union for dataset array observations
unique	Unique observations in dataset array
unstack	Unstack data from single variable into multiple variables
vertcat	Vertical concatenation for dataset arrays

Properties

A dataset array `D` has properties that store metadata (information about your data). Access or assign to a property using `P = D.Properties.PropName` or `D.Properties.PropName = P`, where `PropName` is one of the following:

Description	String describing data set
DimNames	Two-element cell array of strings giving names of dimensions of data set
ObsNames	Cell array of nonempty, distinct strings giving names of observations in data set
Units	Units of variables in data set

UserData	Variable containing additional information associated with data set
VarDescription	Cell array of strings giving descriptions of variables in data set
VarNames	Cell array giving names of variables in data set

Copy Semantics

Value. To learn how this affects your use of the class, see “Comparing Handle and Value Classes” in the MATLAB Object-Oriented Programming documentation.

Examples

Load a dataset array from a .mat file and create some simple subsets:

```
load hospital
h1 = hospital(1:10,:)
h2 = hospital(:, {'LastName' 'Age' 'Sex' 'Smoker'})

% Access and modify metadata
hospital.Properties.Description
hospital.Properties.VarNames{4} = 'Wgt'

% Create a new dataset variable from an existing one
hospital.AtRisk = hospital.Smoker | (hospital.Age > 40)

% Use individual variables to explore the data
boxplot(hospital.Age, hospital.Sex)
h3 = hospital(hospital.Age < 30, ...
    {'LastName' 'Age' 'Sex' 'Smoker'})

% Sort the observations based on two variables
h4 = sortrows(hospital, {'Sex', 'Age'})
```

How To

- “Dataset Arrays” on page 2-132

dataset

Class: dataset

Construct dataset array

Compatibility

The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

Syntax

```
A = dataset(varspec, 'ParamName', Value)
A = dataset('File', filename, 'ParamName', Value)
A = dataset('XLSFile', filename, 'ParamName', Value)
A = dataset('XPTFile', xptfilename, 'ParamName', Value)
```

Description

`A = dataset(varspec, 'ParamName', Value)` creates dataset array `A` using the workspace variable input method `varspec` and one or more optional name/value pairs (see Parameter Name/Value Pairs).

The input method `varspec` can be one or more of the following:

- `VAR` — a workspace variable. `dataset` uses the workspace name for the variable name in `A`. To include multiple variables, specify `VAR_1, VAR_2, ..., VAR_N`. Variables can be arrays of any size, but all variables must have the same number of rows. `VAR` can also be an expression. In this case, `dataset` creates a default name automatically.
- `{VAR, name}` — a workspace variable, `VAR` and a variable name, `name`. `dataset` uses `name` as the variable name. To include multiple variables and names, specify `{VAR_1, name_1}, {VAR_2, name_2}, ..., {VAR_N, name_N}`.

- $\{VAR, name_1, \dots, name_m\}$ — an m -columned workspace variable, VAR . `dataset` uses the names $name_1, \dots, name_m$ as variable names. You must include a name for every column in VAR . Each column becomes a separate variable in A .

You can combine these input methods to include as many variables and names as needed. Names must be valid, unique MATLAB identifier strings. For example input combinations, see Examples. For optional name/value pairs see Inputs.

To convert numeric arrays, cell arrays, structure arrays, or tables to dataset arrays, you can also use (respectively):

- `mat2dataset`
- `cell2dataset`
- `struct2dataset`
- `table2dataset`

Note: Dataset arrays may contain built-in types or array objects as variables. Array objects must implement each of the following:

- Standard MATLAB parenthesis indexing of the form `var(i, ...)`, where i is a numeric or logical vector corresponding to rows of the variable
 - A `size` method with a `dim` argument
 - A `vertcat` method
-

`A = dataset('File', filename, 'ParamName', Value)` creates dataset array A from column-oriented data in the text file specified by the string `filename`. Variables in A are of type `double` if data in the corresponding column of the file, following the column header, are entirely numeric; otherwise the variables in A are cell arrays of strings. `dataset` converts empty fields to either `NaN` (for a numeric variable) or the empty string (for a string-valued variable). `dataset` ignores insignificant white space in the file. You cannot specify both a file and workspace variables as input. See Name/Value Pairs for more information.

`A = dataset('XLSFile', filename, 'ParamName', Value)` creates dataset array A from column-oriented data in the Excel spreadsheet specified by the string `filename`. Variables in A are of type `double` if data in the corresponding column of the spreadsheet, following the column header, are entirely numeric; otherwise the variables in A are cell arrays of strings. See Name/Value Pairs for more information.

`A = dataset('XPTfile', xptfilename, 'ParamName', Value)` creates a dataset array from a SAS® XPORT format file. Variable names from the XPORT format file are preserved. Numeric data types in the XPORT format file are preserved but all other data types are converted to cell arrays of strings. The XPORT format allows for 28 missing data types. `dataset` represents these in the file by an upper case letter, '.' or '_'. `dataset` converts all missing data to NaN values in `A`. See Name/Value Pairs for more information.

Parameter Name/Value Pairs

Specify one or more of the following name/value pairs when constructing a dataset:

'VarNames'

A cell array `{name_1, ..., name_m}` naming the `m` variables in `A` with the specified variable names. Names must be valid, unique MATLAB identifier strings. The number of names must equal the number of variables in `A`. You cannot use the `VarNames` parameter if you provide names for individual variables using `{VAR, name}` pairs. To specify `VarNames` when using a file as input, set `ReadVarNames` to `false`.

'ObsNames'

A cell array `{name_1, ..., name_n}` naming the `n` observations in `A` with the specified observation names. The names need not be valid MATLAB identifier strings, but must be unique. The number of names must equal the number of observations (rows) in `A`. To specify `ObsNames` when using a file as input, set `ReadObsNames` to `false`.

Name/value pairs available when using text files as inputs:

'Delimiter'

A string indicating the character separating columns in the file. Values are

- '\t' (tab, the default when no `format` is specified)
- ' ' (space, the default when a `format` is specified)
- ',' (comma)
- ';' (semicolon)
- '|' (bar)

'Format'

A format string, as accepted by `textscan`. `dataset` reads the file using `textscan`, and creates variables in `A` according to the conversion specifiers in the format string. You may also provide any name/value pairs accepted by `textscan`. Using the `Format` parameter is much faster for large files. If `ReadObsNames` is `true`, the format string should include a format specifier for the first column of the file.

'HeaderLines'

Numeric value indicating the number of lines to skip at the beginning of a file.

Default: 0

'TreatAsEmpty'

Specifies strings to treat as the empty string in a numeric column. Values may be a character string or a cell array of strings. The parameter applies only to numeric columns in the file; `dataset` does not accept numeric literals such as `'-99'`.

Name/value pairs available when using text files or Excel spreadsheets as inputs:

'ReadVarNames'

A logical value indicating whether (`true`) or not (`false`) to read variable names from the first row of the file. The default is `true`. If `ReadVarNames` is `true`, variable names in the column headers of the file or range (if using an Excel spreadsheet) cannot be empty.

'ReadObsNames'

A logical value indicating whether (`true`) or not (`false`) to read observation names from the first column of the file or range (if using an Excel spreadsheet). The default is `false`. If `ReadObsNames` and `ReadVarNames` are both `true`, `dataset` saves the header of the first column in the file or range as the name of the first dimension in `A.Properties.DimNames`.

When reading from an XPT format file, the `ReadObsNames` parameter name/value pair determines whether or not to try to use the first variable in the file as observation names. Specify as a logical value (default `false`). If the contents of the first variable are not valid observation names then `dataset` reads the variable into a variable of the dataset array and does not set the observation names.

Name/value pairs available when using Excel spreadsheets as input:**'Sheet'**

A positive scalar value of type `double` indicating the sheet number, or a quoted string indicating the sheet name.

'Range'

A string of the form `'C1:C2'` where `C1` and `C2` are the names of cells at opposing corners of a rectangular region to be read, as for `xlsread`. By default, the rectangular region extends to the right-most column containing data. If the spreadsheet contains empty columns between columns of data, or if the spreadsheet contains figures or other non-tabular information, specify a range that contains only data.

Examples

Create a dataset array from workspace variables, including observation names:

```
load cereal
cereal = dataset(Calories,Protein,Fat,Sodium,Fiber,Carbo,...
    Sugars,'ObsNames',Name)
cereal.Properties.VarDescription = Variables(4:10,2);
```

Create a dataset array from a single, multi-columned workspace variable, designating variable names for each column:

```
load cities
categories = cellstr(categories);
cities = dataset({ratings,categories{:}},...
    'ObsNames',cellstr(names))
```

Load data from a text or spreadsheet file

```
patients = dataset('File','hospital.dat',...
    'Delimiter',' ','ReadObsNames',true)
patients2 = dataset('XLSFile','hospital.xls',...
    'ReadObsNames',true)
```

- 1 Load patient data from the CSV file `hospital.dat` and store the information in a `dataset` array with observation names given by the first column in the data (patient identification):

```
patients = dataset('file','hospital.dat', ...
                  'format','%S%S%S%f%f%f%f%f%f%f', ...
                  'Delimiter',' ',' ','ReadObsNames',true);
```

You can also load the data without specifying a format string. `dataset` will automatically create `dataset` variables that are either `double` arrays or cell arrays of strings, depending on the contents of the file:

```
patients = dataset('file','hospital.dat',...
                  'delimiter',' ','...',
                  'ReadObsNames',true);
```

- 2 Make the {0,1}-valued variable `smoke` nominal, and change the labels to 'No' and 'Yes':

```
patients.smoke = nominal(patients.smoke,{'No','Yes'});
```

- 3 Add new levels to `smoke` as placeholders for more detailed histories of smokers:

```
patients.smoke = addlevels(patients.smoke,...
                          {'0-5 Years','5-10 Years','LongTerm'});
```

- 4 Assuming the nonsmokers have never smoked, relabel the 'No' level:

```
patients.smoke = setlabels(patients.smoke,'Never','No');
```

- 5 Drop the undifferentiated 'Yes' level from `smoke`:

```
patients.smoke = droplevels(patients.smoke,'Yes');
```

Warning: OLDLEVELS contains categorical levels that were present in A, caused some array elements to have undefined levels.

Note that smokers now have an undefined level.

- 6 Set each smoker to one of the new levels, by observation name:

```
patients.smoke('YPL-320') = '5-10 Years';
```

dataset2cell

Class: dataset

Convert dataset array to cell array

Compatibility

The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

Syntax

```
C = dataset2cell(D)
```

Description

`C = dataset2cell(D)` converts the dataset array `D` to a cell array `C`. Each variable of `D` becomes a column in `C`. If `D` is an `M`-by-`N` array, then `C` is $(M+1)$ -by-`N`, with the variable names of `D` in the first row. If `D` contains observation names, then `C` is $(M+1)$ -by- $(N+1)$, with the observation names in the first column.

dataset2struct

Class: dataset

Convert dataset array to structure

Compatibility

The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

Syntax

```
S = dataset2struct(D)
S = dataset2struct(D, 'AsScalar', true)
```

Description

`S = dataset2struct(D)` converts a dataset array to a structure array. Each variable of `D` becomes a field in `S`. If `D` is an M -by- N dataset array, then `S` is M -by-1 and has N fields. If `D` contains observation names, then `S` contains those names in the additional field `ObsNames`.

`S = dataset2struct(D, 'AsScalar', true)` converts a dataset array to a scalar structure. Each variable of `D` becomes a field in `S`. If `D` is an M -by- N dataset array, then `S` has N fields, each of which as M rows. If `D` contains observation names, then `S` contains those names in the additional field `ObsNames`.

Input Arguments

D

M -by- N dataset array.

Output Arguments

S

M -by-1 structure array, with N fields. If the input dataset array contains observation names, then **S** has an additional field **ObsNames**.

If you specify `'AsScalar', true`, then **S** is a scalar structure, with N fields, each with M rows.

Examples

Convert Dataset Array to Structure Array

Load sample dataset array.

```
load('hospital')
```

Create a dataset array, **D**, that has only a subset of the observations and variables.

```
D = hospital(1:8, {'LastName', 'Sex', 'Age'});
size(D)
```

```
ans =
```

```
     8     3
```

The dataset array **D** has 8 observations and 3 variables.

Convert **D** to a structure array.

```
S = dataset2struct(D)
```

```
S =
```

```
8x1 struct array with fields:
    ObsNames
    LastName
    Sex
    Age
```

The structure is **8x1**, corresponding to the 8 observations in the dataset array. **S** also has the field **ObsNames**, since **D** had observation names.

Display the field data for the first element of `S`.

```
S(1)
ans =
    ObsNames: 'YPL-320'
    LastName: 'SMITH'
           Sex: [1x1 nominal]
           Age: 38
```

This information corresponds to the first observation (row) of the dataset array.

Convert Dataset Array to Scalar Structure

Load sample dataset array.

```
load('hospital')
```

Create a dataset array, `D`, that has only a subset of the observations and variables.

```
D = hospital(1:8,{'LastName','Sex','Age'});
size(D)
ans =
     8     3
```

The dataset array `D` has 8 observations and 3 variables.

Convert `D` to a scalar structure array.

```
S = dataset2struct(D, 'AsScalar', true)
S =
    ObsNames: {8x1 cell}
    LastName: {8x1 cell}
           Sex: [8x1 nominal]
           Age: [8x1 double]
```

The data in the fields of the scalar structure is `8x1`, corresponding to the 8 observations in the dataset array. `S` also has the field `ObsNames`, since `D` had observation names.

Display the data for the field `LastName`.

```
S.LastName
```

```
ans =
```

```
    'SMITH'  
    'JOHNSON'  
    'WILLIAMS'  
    'JONES'  
    'BROWN'  
    'DAVIS'  
    'MILLER'  
    'WILSON'
```

The structure field `LastName` contains all of the data that was in the original dataset array variable, `LastName`.

dataset2table

Convert dataset array to table

Syntax

```
t = dataset2table(ds)
```

Description

`t = dataset2table(ds)` converts a dataset array to a table.

Examples

Convert a Dataset Array to a Table

Load the sample data, which contains nutritional information for 77 cereals.

```
load cereal;
```

Create a dataset array containing the calorie, protein, fat, and name data for the first five cereals. Label the variables.

```
Calories = Calories(1:5);  
Protein = Protein(1:5);  
Fat = Fat(1:5);  
Name = Name(1:5);
```

```
cereal = dataset(Calories,Protein,Fat,'ObsNames',Name)  
cereal.Properties.VarDescription = Variables(4:6,2);
```

```
cereal =
```

	Calories	Protein	Fat
100% Bran	70	4	1
100% Natural Bran	120	3	5
All-Bran	70	4	1
All-Bran with Extra Fiber	50	4	0
Almond Delight	110	2	2

Convert the dataset array to a table.

```
t = dataset2table(cereal)
```

```
t =
```

	Calories	Protein	Fat
	-----	-----	---
100% Bran	70	4	1
100% Natural Bran	120	3	5
All-Bran	70	4	1
All-Bran with Extra Fiber	50	4	0
Almond Delight	110	2	2

Input Arguments

ds — Input dataset array

dataset array

Input dataset array to convert to a table, specified as a dataset array. Each variable in `ds` becomes a variable in the output table `t`.

Output Arguments

t — Output table

table

Output table, returned as a table. The table can store metadata such as descriptions, variable units, variable names, and row names. For more information, see [Table Properties](#).

dataset | table

datasetfun

Class: dataset

Apply function to dataset array variables

Compatibility

The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

Syntax

```
b = datasetfun(fun,A)
[b,c,...] = datasetfun(fun,A)
[b,...] = datasetfun(fun,A,...,'UniformOutput',false)
[b,...] = datasetfun(fun,A,...,'DatasetOutput',true)
[b,...] = datasetfun(fun,A,...,'DataVars',vars)
[b,...] = datasetfun(fun,A,...,'ObsNames',obsnames)
[b,...] = datasetfun(fun,A,...,'ErrorHandler',efun)
```

Description

`b = datasetfun(fun,A)` applies the function specified by `fun` to each variable of the dataset array `A`, and returns the results in the vector `b`. The *i*th element of `b` is equal to `fun` applied to the *i*th dataset variable of `A`. `fun` is a function handle to a function that takes one input argument and returns a scalar value. `fun` must return values of the same class each time it is called, and `datasetfun` concatenates them into the vector `b`. The outputs from `fun` must be one of the following types: numeric, logical, character, structure, or cell.

To apply functions that return results that are nonscalar or of different sizes and types, use the `'UniformOutput'` or `'DatasetOutput'` parameters described below.

Do not rely on the order in which `datasetfun` computes the elements of `b`, which is unspecified.

If `fun` is bound to more than one built-in function or file, (that is, if it represents a set of overloaded functions), `datasetfun` follows MATLAB dispatching rules in calling the function. (See “Function Precedence Order”.)

`[b,c,...] = datasetfun(fun,A)`, where `fun` is a function handle to a function that returns multiple outputs, returns vectors `b`, `c`, ..., each corresponding to one of the output arguments of `fun`. `datasetfun` calls `fun` each time with as many outputs as there are in the call to `datasetfun`. `fun` may return output arguments having different classes, but the class of each output must be the same each time `fun` is called.

`[b,...] = datasetfun(fun,A,...,'UniformOutput',false)` allows you to specify a function `fun` that returns values of different sizes or types. `datasetfun` returns a cell array (or multiple cell arrays), where the *i*th cell contains the value of `fun` applied to the *i*th dataset variable of `A`. Setting `'UniformOutput'` to `true` is equivalent to the default behavior.

`[b,...] = datasetfun(fun,A,...,'DatasetOutput',true)` specifies that the output(s) of `fun` are returned as variables in a dataset array (or multiple dataset arrays). `fun` must return values with the same number of rows each time it is called, but it may return values of any type. The variables in the output dataset array(s) have the same names as the variables in the input. Setting `'DatasetOutput'` to `false` (the default) specifies that the type of the output(s) from `datasetfun` is determined by `'UniformOutput'`.

`[b,...] = datasetfun(fun,A,...,'DataVars',vars)` allows you to apply `fun` only to the dataset variables in `A` specified by `vars`. `vars` is a positive integer, a vector of positive integers, a variable name, a cell array containing one or more variable names, or a logical vector.

`[b,...] = datasetfun(fun,A,...,'ObsNames',obsnames)` specifies observation names for the dataset output when `'DatasetOutput'` is `true`.

`[b,...] = datasetfun(fun,A,...,'ErrorHandler',efun)`, where `efun` is a function handle, specifies the MATLAB function to call if the call to `fun` fails. The error-handling function is called with the following input arguments:

- A structure with the fields `identifier`, `message`, and `index`, respectively containing the identifier of the error that occurred, the text of the error message, and the linear index into the input array(s) at which the error occurred

- The set of input arguments at which the call to the function failed

The error-handling function should either re-throw an error, or return the same number of outputs as `fun`. These outputs are then returned as the outputs of `datasetfun`. If `'UniformOutput'` is true, the outputs of the error handler must also be scalars of the same type as the outputs of `fun`. For example, the following code could be saved in a file as the error-handling function:

```
function [A,B] = errorFunc(S,varargin)

warning(S.identifier,S.message);
A = NaN;
B = NaN;
```

If an error-handling function is not specified, the error from the call to `fun` is rethrown.

Examples

Work With Datasets Using Function Handles

Use function handles to compute the mean and plot a histogram of selected variables in a dataset array.

Load the sample data.

```
load hospital
```

Use `datasetfun` to compute the means of the `Weight` and `BloodPressure` variables, and store the results in a dataset array.

```
stats = datasetfun(@mean,hospital,...
    'DataVars',{'Weight','BloodPressure'},...
    'UniformOutput',false)
```

```
stats =

    [154]    [1x2 double]
```

The variable `BloodPressure` contains two columns: One for the systolic measurement, and one for the diastolic measurement.

Display the mean of the blood pressure variable.

```
stats{2}
```

```
ans =
```

```
122.7800  82.9600
```

Plot a histogram of the blood pressure variable.

```
datasetfun(@hist,hospital,...  
           'DataVars','BloodPressure',...  
           'UniformOutput',false);  
title('\bf Blood Pressure')  
legend('Systolic','Diastolic','Location','N')
```

grpstats

daugment

D-optimal augmentation

Syntax

```
dCE2 = daugment(dCE, mruns)
[dCE2, X] = daugment(dCE, mruns)
[dCE2, X] = daugment(dCE, mruns, model)
[dCE2, X] = daugment(..., param1, val1, param2, val2, ...)
```

Description

`dCE2 = daugment(dCE, mruns)` uses a coordinate-exchange algorithm to *D*-optimally add `mruns` runs to an existing experimental design `dCE` for a linear additive model.

`[dCE2, X] = daugment(dCE, mruns)` also returns the design matrix `X` associated with the augmented design.

`[dCE2, X] = daugment(dCE, mruns, model)` uses the linear regression model specified in `model`. `model` is one of the following strings:

- 'linear' — Constant and linear terms. This is the default.
- 'interaction' — Constant, linear, and interaction terms
- 'quadratic' — Constant, linear, interaction, and squared terms
- 'purequadratic' — Constant, linear, and squared terms

The order of the columns of `X` for a full quadratic model with n terms is:

- 1 The constant term
- 2 The linear terms in order 1, 2, ..., n
- 3 The interaction terms in order (1, 2), (1, 3), ..., (1, n), (2, 3), ..., ($n - 1$, n)
- 4 The squared terms in order 1, 2, ..., n

Other models use a subset of these terms, in the same order.

Alternatively, `model` can be a matrix specifying polynomial terms of arbitrary order. In this case, `model` should have one column for each factor and one row for each term in

the model. The entries in any row of *model* are powers for the factors in the columns. For example, if a model has factors X_1 , X_2 , and X_3 , then a row $[0 \ 1 \ 2]$ in *model* specifies the term $(X_1.^0) \cdot (X_2.^1) \cdot (X_3.^2)$. A row of all zeros in *model* specifies a constant term, which can be omitted.

`[dCE2,X] = daugment(...,param1,val1,param2,val2,...)` specifies additional parameter/value pairs for the design. Valid parameters and their values are listed in the following table.

Parameter	Value
'bounds'	Lower and upper bounds for each factor, specified as a 2-by-nfactors matrix, where nfactors is the number of factors. Alternatively, this value can be a cell array containing nfactors elements, each element specifying the vector of allowable values for the corresponding factor.
'categorical'	Indices of categorical predictors.
'display'	Either 'on' or 'off' to control display of the iteration counter. The default is 'on'.
'excludefun'	Handle to a function that excludes undesirable runs. If the function is f , it must support the syntax $b = f(S)$, where S is a matrix of treatments with nfactors columns, where nfactors is the number of factors, and b is a vector of Boolean values with the same number of rows as S . $b(i)$ is true if the i th row S should be excluded.
'init'	Initial design as an mruns-by-nfactors matrix, where nfactors is the number of factors. The default is a randomly selected set of points.
'levels'	Vector of number of levels for each factor.
'maxiter'	Maximum number of iterations. The default is 10.
'options'	The value is a structure that contains options specifying whether to compute multiple tries in parallel, and specifying how to use random numbers when generating the starting points for the tries. Create the options structure with <code>statset</code> . Applicable <code>statset</code> parameters are: <ul style="list-style-type: none"> 'UseParallel' — If true and if a parpool of the Parallel Computing Toolbox is open, compute in parallel. If the Parallel

Parameter	Value
	<p>Computing Toolbox is not installed, or a <code>parpool</code> is not open, computation occurs in serial mode. Default is <code>false</code>, meaning serial computation.</p> <ul style="list-style-type: none"> • <code>UseSubstreams</code> — Set to <code>true</code> to compute in parallel in a reproducible fashion. Default is <code>false</code>. To compute reproducibly, set <code>Streams</code> to a type allowing substreams: <code>'mlfg6331_64'</code> or <code>'mrg32k3a'</code>. • <code>Streams</code> — A <code>RandStream</code> object or cell array of such objects. If you do not specify <code>Streams</code>, <code>daugment</code> uses the default stream or streams. If you choose to specify <code>Streams</code>, use a single object except in the case <ul style="list-style-type: none"> • You have an open Parallel pool • <code>UseParallel</code> is <code>true</code> • <code>UseSubstreams</code> is <code>false</code> <p>In that case, use a cell array the same size as the Parallel pool.</p>
<code>'tries'</code>	Number of times to try to generate a design from a new starting point. The algorithm uses random points for each try, except possibly the first. The default is 1.

Note: The `daugment` function augments an existing design using a coordinate-exchange algorithm; the `'start'` parameter of the `candexch` function provides the same functionality using a row-exchange algorithm.

Examples

The following eight-run design is adequate for estimating main effects in a four-factor model:

```
dCEmain = cordexch(4,8)
dCEmain =
     1     -1     -1     1
    -1     -1     1     1
    -1     1     -1     1
     1     1     1    -1
```

```
1      1      1      1
-1     1     -1     -1
1     -1     -1     -1
-1    -1      1     -1
```

To estimate the six interaction terms in the model, augment the design with eight additional runs:

```
dCEinteraction = daugment(dCEmain,8,'interaction')
dCEinteraction =
 1     -1     -1      1
-1     -1      1      1
-1      1     -1      1
 1      1      1     -1
 1      1      1      1
-1      1     -1     -1
 1     -1     -1     -1
-1     -1      1     -1
-1      1      1      1
-1     -1     -1     -1
 1     -1      1     -1
 1      1     -1      1
-1      1      1     -1
 1      1     -1     -1
 1     -1      1      1
 1      1      1     -1
```

The augmented design is full factorial, with the original eight runs in the first eight rows.

dcovary | cordexch | candexch

dcovary

D-optimal design with fixed covariates

Syntax

```
dcv = dcovary(nfactors, fixed)
[dcv, X] = dcovary(nfactors, fixed)
[dcv, X] = dcovary(nfactors, fixed, model)
[dcv, X] = daugment(..., param1, val1, param2, val2, ...)
```

Description

`dcv = dcovary(nfactors, fixed)` uses a coordinate-exchange algorithm to generate a *D*-optimal design for a linear additive model with `nfactors` factors, subject to the constraint that the model include the fixed covariate factors in `fixed`. The number of runs in the design is the number of rows in `fixed`. The design `dcv` augments `fixed` with initial columns for treatments of the model terms.

`[dcv, X] = dcovary(nfactors, fixed)` also returns the design matrix `X` associated with the design.

`[dcv, X] = dcovary(nfactors, fixed, model)` uses the linear regression model specified in `model`. `model` is one of the following strings:

- 'linear' — Constant and linear terms. This is the default.
- 'interaction' — Constant, linear, and interaction terms
- 'quadratic' — Constant, linear, interaction, and squared terms
- 'purequadratic' — Constant, linear, and squared terms

The order of the columns of `X` for a full quadratic model with n terms is:

- 1 The constant term
- 2 The linear terms in order 1, 2, ..., n
- 3 The interaction terms in order (1, 2), (1, 3), ..., (1, n), (2, 3), ..., ($n - 1$, n)

4 The squared terms in order 1, 2, ..., n

Other models use a subset of these terms, in the same order.

Alternatively, *model* can be a matrix specifying polynomial terms of arbitrary order. In this case, *model* should have one column for each factor and one row for each term in the model. The entries in any row of *model* are powers for the factors in the columns. For example, if a model has factors X_1 , X_2 , and X_3 , then a row $[0 \ 1 \ 2]$ in *model* specifies the term $(X_1.^0) .* (X_2.^1) .* (X_3.^2)$. A row of all zeros in *model* specifies a constant term, which can be omitted.

`[dCV,X] = daugment(...,param1,val1,param2,val2,...)` specifies additional parameter/value pairs for the design. Valid parameters and their values are listed in the following table.

Parameter	Value
'bounds'	Lower and upper bounds for each factor, specified as a 2-by-nfactors matrix. Alternatively, this value can be a cell array containing nfactors elements, each element specifying the vector of allowable values for the corresponding factor.
'categorical'	Indices of categorical predictors.
'display'	Either 'on' or 'off' to control display of the iteration counter. The default is 'on'.
'excludedefun'	Handle to a function that excludes undesirable runs. If the function is f , it must support the syntax $b = f(S)$, where S is a matrix of treatments with nfactors columns and b is a vector of Boolean values with the same number of rows as S . $b(i)$ is true if the i th row S should be excluded.
'init'	Initial design as an mruns-by-nfactors matrix. The default is a randomly selected set of points.
'levels'	Vector of number of levels for each factor.
'maxiter'	Maximum number of iterations. The default is 10.
'options'	The value is a structure that contains options specifying whether to compute multiple tries in parallel, and specifying how to use random numbers when generating the starting points for the tries. Create the options structure with <code>statset</code> . Applicable <code>statset</code> parameters are:

Parameter	Value
	<ul style="list-style-type: none"> • 'UseParallel' — If <code>true</code> and if a parpool of the Parallel Computing Toolbox is open, compute in parallel. If the Parallel Computing Toolbox is not installed, or a parpool is not open, computation occurs in serial mode. Default is <code>false</code>, meaning serial computation. • UseSubstreams — Set to <code>true</code> to compute in parallel in a reproducible fashion. Default is <code>false</code>. To compute reproducibly, set <code>Streams</code> to a type allowing substreams: 'mlfg6331_64' or 'mrg32k3a'. • Streams — A RandStream object or cell array of such objects. If you do not specify <code>Streams</code>, <code>dcovary</code> uses the default stream or streams. If you choose to specify <code>Streams</code>, use a single object except in the case <ul style="list-style-type: none"> • You have an open Parallel pool • UseParallel is <code>true</code> • UseSubstreams is <code>false</code> <p>In that case, use a cell array the same size as the Parallel pool.</p>
'tries'	Number of times to try to generate a design from a new starting point. The algorithm uses random points for each try, except possibly the first. The default is 1.

Examples

Example 1

Suppose you want a design to estimate the parameters in a three-factor linear additive model, with eight runs that necessarily occur at different times. If the process experiences temporal linear drift, you may want to include the run time as a variable in the model. Produce the design as follows:

```
time = linspace(-1,1,8)';
[dCV1,X] = dcovary(3,time,'linear')
dCV1 =
    -1.0000    1.0000    1.0000   -1.0000
```

```
    1.0000   -1.0000   -1.0000   -0.7143
   -1.0000   -1.0000   -1.0000   -0.4286
    1.0000   -1.0000    1.0000   -0.1429
    1.0000    1.0000   -1.0000    0.1429
   -1.0000    1.0000   -1.0000    0.4286
    1.0000    1.0000    1.0000    0.7143
   -1.0000   -1.0000    1.0000    1.0000
X =
    1.0000   -1.0000    1.0000    1.0000   -1.0000
    1.0000    1.0000   -1.0000   -1.0000   -0.7143
    1.0000   -1.0000   -1.0000   -1.0000   -0.4286
    1.0000    1.0000   -1.0000    1.0000   -0.1429
    1.0000    1.0000    1.0000   -1.0000    0.1429
    1.0000   -1.0000    1.0000   -1.0000    0.4286
    1.0000    1.0000    1.0000    1.0000    0.7143
    1.0000   -1.0000   -1.0000    1.0000    1.0000
```

The column vector `time` is a fixed factor, normalized to values between ± 1 . The number of rows in the fixed factor specifies the number of runs in the design. The resulting design `dCV` gives factor settings for the three controlled model factors at each time.

Example 2

The following example uses the `dummyvar` function to block an eight-run experiment into 4 blocks of size 2 for estimating a linear additive model with two factors:

```
fixed = dummyvar([1 1 2 2 3 3 4 4]);
dCV2 = dcovary(2, fixed(:, 1:3), 'linear')
dCV2 =
    1    1    1    0    0
   -1   -1    1    0    0
   -1    1    0    1    0
    1   -1    0    1    0
    1    1    0    0    1
   -1   -1    0    0    1
   -1    1    0    0    0
    1   -1    0    0    0
```

The first two columns of `dCV2` contain the settings for the two factors; the last three columns are dummy variable codings for the four blocks.

`daugment` | `cordexch` | `dummyvar`

DefaultYfit property

Class: TreeBagger

Default value returned by `predict` and `oobPredict`

Description

The `DefaultYfit` property controls what predicted value `TreeBagger` returns when no prediction is possible, for example when the `oobPredict` method needs to predict for an observation that is in-bag for all trees in the ensemble.

For classification, you can set this property to either `' '` or `'MostPopular'`. If you choose `'MostPopular'` (default), the property value becomes the name of the most probable class in the training data.

For regression, you can set this property to any numeric scalar. The default is the mean of the response for the training data.

If you set this property to `' '` for classification or `NaN` for regression, `TreeBagger` excludes the in-bag observations from computation of the out-of-bag error and margin.

See Also

`Predict` | `oobPredict` | `OOBIndices`

delete

Class: grandstream

Delete handle object

Syntax

```
delete(h)
```

Description

`delete(h)` deletes the handle object `h`, where `h` is a scalar handle. The `delete` method deletes a handle object but does not clear the handle from the workspace. A deleted handle is no longer valid.

See Also

`clear` | `isvalid` | `grandstream`

DeltaCritDecisionSplit property

Class: TreeBagger

Split criterion contributions for each predictor

Description

The `DeltaCritDecisionSplit` property is a numeric array of size 1-by-Nvars of changes in the split criterion summed over splits on each variable, averaged across the entire ensemble of grown trees.

See Also

`ClassificationTree` | `RegressionTree` | `TreeBagger` | `fitctree` | `fitrtree`

dendrogram

Dendrogram plot

Syntax

```
dendrogram(tree)  
dendrogram(tree, Name, Value)
```

```
dendrogram(tree, P)  
dendrogram(tree, P, Name, Value)
```

```
H = dendrogram( ___ )  
[H, T, outperm] = dendrogram( ___ )
```

Description

`dendrogram(tree)` generates a dendrogram plot of the hierarchical binary cluster tree. A dendrogram consists of many *U*-shaped lines that connect data points in a hierarchical tree. The height of each *U* represents the distance between the two data points being connected.

- If there are 30 or fewer data points in the original data set, then each leaf in the dendrogram corresponds to one data point.
- If there are more than 30 data points, then `dendrogram` collapses lower branches so that there are 30 leaf nodes. As a result, some leaves in the plot correspond to more than one data point.

`dendrogram(tree, Name, Value)` uses additional options specified by one or more name-value pair arguments.

`dendrogram(tree, P)` generates a dendrogram plot with no more than *P* leaf nodes. If there are more than *P* data points in the original data set, then `dendrogram` collapses the lower branches of the tree. As a result, some leaves in the plot correspond to more than one data point.

`dendrogram(tree, P, Name, Value)` uses additional options specified by one or more name-value pair arguments.

`H = dendrogram(___)` generates a dendrogram plot and returns a vector of line handles. You can use any of the input arguments from the previous syntaxes.

`[H,T,outperm] = dendrogram(___)` also returns a vector containing the leaf node number for each object in the original data set, `T`, and a vector giving the order of the node labels of the leaves as shown in the dendrogram, `outperm`.

- It is useful to return `T` when the number of leaf nodes, `P`, is less than the total number of data points, so that some leaf nodes in the display correspond to multiple data points.
- The order of the node labels given in `outperm` is from left to right for a horizontal dendrogram, and from bottom to top for a vertical dendrogram.

Examples

Plot Dendrogram

Generate sample data.

```
rng('default') % For reproducibility
X = rand(10,3);
```

Create a hierarchical binary cluster tree using `linkage`. Then, plot the dendrogram using the default options.

```
tree = linkage(X,'average');

figure()
dendrogram(tree)
```

Specify Dendrogram Leaf Node Order

Generate sample data.

```
rng('default') % For reproducibility  
X = rand(10,3);
```

Create a hierarchical binary cluster tree using linkage.

```
tree = linkage(X, 'average');
```

```
D = pdist(X);  
leafOrder = optimalleaforder(tree,D)
```

```
leafOrder =
```

```
3 7 6 1 4 9 5 8 10 2
```

Plot the dendrogram using an optimal leaf order.

```
figure()
```

```
dendrogram(tree, 'Reorder', leafOrder)
```

The order of the leaf nodes in the dendrogram plot corresponds—from left to right—to the permutation in `leafOrder`.

Specify Number of Nodes in Dendrogram Plot

Generate sample data.

```
rng('default') % For reproducibility
X = rand(100,2);
```

There are 100 data points in the original data set, `X`.

Create a hierarchical binary cluster tree using `linkage`. Then, plot the dendrogram for the complete tree (100 leaf nodes) by setting the input argument `P` equal to `0`.

```
tree = linkage(X, 'average');
```

```
figure()  
dendrogram(tree,0)
```

Now, plot the dendrogram with only 25 leaf nodes. Return the mapping of the original data points to the leaf nodes shown in the plot.

```
figure()  
[~,T] = dendrogram(tree,25);
```

List the original data points that are in leaf node 7 of the dendrogram plot.

```
find(T==7)
```

```
ans =
```

```

7
33
60
70
74
76
86
```

Change Dendrogram Orientation and Line Width

Generate sample data.

```
rng('default') % For reproducibility
X = rand(10,3);
```

Create a hierarchical binary cluster tree using `linkage`. Then, plot the dendrogram with a vertical orientation, using the default color threshold. Return handles to the lines so you can change the dendrogram line widths.

```
tree = linkage(X, 'average');

figure()
H = dendrogram(tree, 'Orientation', 'left', 'ColorThreshold', 'default');
set(H, 'LineWidth', 2)
```

Input Arguments

tree — Hierarchical binary cluster tree

matrix returned by `linkage`

Hierarchical binary cluster tree, specified as an $(M - 1)$ -by-3 matrix that you generate using `linkage`, where M is the number of data points in the original data set.

P — Maximum number of leaf nodes

30 (default) | positive integer value

Maximum number of leaf nodes to include in the dendrogram plot, specified as a positive integer value.

- If there are P or fewer data points in the original data set, then each leaf in the dendrogram corresponds to one data point.
- If there are more than P data points, then `dendrogram` collapses lower branches so that there are P leaf nodes. As a result, some leaves in the plot correspond to more than one data point.

If you do not specify P , then `dendrogram` uses 30 as the maximum number of leaf nodes. To display the complete tree, set P equal to 0.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`,`Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Orientation','left','Reorder',myOrder`, specifies a vertical dendrogram with leaves in the order specified by `myOrder`.

'Reorder' — Order of leaf nodes

vector

Order of leaf nodes in the dendrogram plot, specified as the comma-separated pair consisting of `'Reorder'` and a vector giving the order of nodes in the complete tree. The order vector must be a permutation of the vector `1:M`, where M is the number of data points in the original data set. Specify the order from left to right for horizontal dendrograms, and from bottom to top for vertical dendrograms.

If M is greater than the number of leaf nodes in the dendrogram plot, P (by default, P is 30), then you can only specify a permutation vector that does not separate the groups of leaves that correspond to collapsed nodes.

Example:

Data Types: `single` | `double`

'CheckCrossing' — Indicator for whether to check for crossing branches

`true` (default) | `false`

Indicator for whether to check for crossing branches in the dendrogram plot, specified as the comma-separated pair consisting of `'CheckCrossing'` and either `true` or `false`. This option is only useful when you specify a value for `Reorder`.

When `CheckCrossing` has the value `true`, `dendrogram` issues a warning if the order of the leaf nodes causes crossing branches in the plot. If the dendrogram plot does not show a complete tree (because the number of data points in the original data set is greater than `P`), `dendrogram` only issues a warning when the order of the leaf nodes causes branch to cross in the dendrogram as shown in the plot. That is, there is no warning if the order causes crossing branches in the complete tree but not in the dendrogram as shown in the plot.

Data Types: `logical`

'ColorThreshold' — Threshold for unique colors

`'default'` | scalar value in the range $(0, \max(\text{tree}(:,3)))$

Threshold for unique colors in the dendrogram plot, specified as the comma-separated pair consisting of `'ColorThreshold'` and either the string `'default'` or a scalar value in the range $(0, \max(\text{tree}(:,3)))$. If `ColorThreshold` has the value T , then `dendrogram` assigns a unique color to each group of nodes in the dendrogram whose linkage is less than T .

- If `ColorThreshold` has the value `'default'`, then the threshold, T , is 70% of the maximum linkage, $0.7 * \max(\text{tree}(:,3))$.
- If you do not specify a value for `ColorThreshold`, or if you specify a threshold outside the range $(0, \max(\text{tree}(:,3)))$, then `dendrogram` uses only one color for the dendrogram plot.

'Orientation' — Orientation of dendrogram

`'top'` (default) | `'bottom'` | `'left'` | `'right'`

Orientation of the dendrogram in the figure window, specified as the comma-separated pair consisting of `'Orientation'` and one of these strings:

<code>'top'</code>	Top to bottom
--------------------	---------------

'bottom'	Bottom to top
'left'	Left to right
'right'	Right to left

Data Types: char

'Labels' — Label for each data point

character array | cell array of strings

Label for each data point in the original data set, specified as the comma-separated pair consisting of 'Labels' and a character array or cell array of strings. `dendrogram` labels any leaves in the dendrogram plot containing a single data point with that data point's label.

Data Types: char | cell

Output Arguments

H — Handles to lines

vector

Handles to lines in the dendrogram plot, returned as a vector.

T — Leaf node numbers

column vector

Leaf node numbers for each data point in the original data set, returned as a column vector of length M , where M is the number of data points in the original data set.

When there are fewer than P data points in the original data (P is 30, by default), all data points are displayed in the dendrogram, with each node containing a single data point. In this case, T is the identity map, $T = (1:M)'$.

T is useful when P is less than the total number of data points. That is, when some leaf nodes in the dendrogram display correspond to multiple data points. For example, to find out which data points are contained in leaf node k of the dendrogram plot, use `find(T==k)`.

outperm — Permutation of node labels

vector

Permutation of the node labels of the leaves of the dendrogram as shown in the plot, returned as a row vector. `outperm` gives the order from left to right for a horizontal dendrogram, and from bottom to top for a vertical dendrogram. If there are P leaves in the dendrogram plot, `outperm` is a permutation of the vector $1:P$.

`cluster` | `clusterdata` | `cophenet` | `inconsistent` | `linkage` | `pdist` | `silhouette`

Description property

Class: dataset

String describing data set

Compatibility

The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

Description

Description is a string describing the data set. The default is an empty string.

designecoc

Coding matrix for reducing error-correcting output code to binary

Syntax

```
M = designecoc(K,name)
M = designecoc(K,name,Name,Value)
```

Description

`M = designecoc(K,name)` returns the coding matrix `M` that reduces the error-correcting output code (ECOC) design specified by `name` and `K` classes to a binary problem. `M` has `K` rows and `L` columns, with each row corresponding to a class and each column corresponding to a binary learner. `name` and `K` determine the value of `L`.

You can view or customize `M`, and then specify it as the coding matrix for training an ECOC multiclass classifier using `fitcecoc`.

`M = designecoc(K,name,Name,Value)` returns the coding matrix with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify the number of trials when generating a dense or sparse, random coding matrix.

Examples

Train ECOC Classifiers Using a Custom Coding Design

Consider the `arrhythmia` data set. There are 16 classes in the study, 13 of which are represented in the data. The first class indicates that the subject did not have arrhythmia, and the last class indicates that the subject's arrhythmia state was not recorded. Suppose that the other classes are ordinal levels indicating the severity of arrhythmia. Train an ECOC classifier using a custom coding design specified by the description of the classes.

Load the arrhythmia data set.

```
load arrhythmia
K = 13; % Number of distinct classes
```

Construct a coding matrix that describes the nature of the classes.

```
OrdMat = designecoc(11,'ordinal');
nOM = size(OrdMat);
class1VSOrd = [1; -ones(11,1); 0];
class1VSClass16 = [1; zeros(11,1); -1];
OrdVSClass16 = [0; ones(11,1); -1];
Coding = [class1VSOrd class1VSClass16 OrdVSClass16,...
          [zeros(1,nOM(2)); OrdMat; zeros(1,nOM(2))]]
```

Coding =

1	1	0	0	0	0	0	0	0	0	0	0	0
-1	0	1	-1	-1	-1	-1	-1	-1	-1	-1	-1	-1
-1	0	1	1	-1	-1	-1	-1	-1	-1	-1	-1	-1
-1	0	1	1	1	-1	-1	-1	-1	-1	-1	-1	-1
-1	0	1	1	1	1	-1	-1	-1	-1	-1	-1	-1
-1	0	1	1	1	1	1	-1	-1	-1	-1	-1	-1
-1	0	1	1	1	1	1	1	-1	-1	-1	-1	-1
-1	0	1	1	1	1	1	1	1	-1	-1	-1	-1
-1	0	1	1	1	1	1	1	1	1	-1	-1	-1
-1	0	1	1	1	1	1	1	1	1	1	-1	-1
-1	0	1	1	1	1	1	1	1	1	1	1	-1
-1	0	1	1	1	1	1	1	1	1	1	1	1
0	-1	-1	0	0	0	0	0	0	0	0	0	0

Train an ECOC classifier using the custom coding design Coding.

```
Mdl = fitcecoc(X,Y,'Coding',Coding);
```

Estimate the in-sample classification error.

```
genErr = resubLoss(Mdl)
```

genErr =

```
0.3518
```

The in-sample classification error is quite large. One course of action is to reconsider the coding design.

Choose Among Several Random Coding Designs

If you request a random coding matrix by specifying `sparserandom` or `denserandom`, then, by default, `designecoc` generates 10,000 random matrices. Then, it chooses the matrix with the largest, minimal, pair-wise row distances based on the Hamming measure. You can specify to generate more matrices to increase the chance of obtaining a better one, or you can generate several coding matrices, and then see which performs best.

Load the `arrhythmia` data set. Reserve the observations classified into class 16 (i.e., those that do not have an arrhythmia classification) as new data.

```
load arrhythmia
oosIdx = Y == 16;
isIdx = ~oosIdx;
Y = categorical(Y(isIdx));
tabulate(Y)
K = numel(unique(Y));
```

Value	Count	Percent
1	245	56.98%
2	44	10.23%
3	15	3.49%
4	15	3.49%
5	13	3.02%
6	25	5.81%
7	3	0.70%
8	2	0.47%
9	9	2.09%
10	50	11.63%
14	4	0.93%
15	5	1.16%

Generate four random coding design matrices such that the first two are dense and the second two are sparse. Specify to find the best out of 20,000 variates.

```
rng(1); % For reproducibility

Coding = cell(4,1); % Preallocate for coding matrices
CodingTypes = {'denserandom', 'denserandom', 'sparserandom', 'sparserandom'};
for j = 1:4;
    Coding{j} = designecoc(K, CodingTypes{j}, 'NumTrials', 2e4);
```

```
end
```

Coding is a 4-by-1 cell array, where each cell is a coding design matrix. The matrices have K rows, but the number of columns (i.e., binary learners) might vary.

Train and cross validate ECOC classifiers using the 15-fold cross validation. Specify that each ECOC classifier be trained using a classification tree, and the random coding matrix stored in Coding.

```
Mdl = cell(4,1); % Preallocate for the ECOC classifiers
for j = 1:4;
    Mdl{j} = fitcecoc(X(isIdx,:),Y,'Learners','tree',...
        'Coding',Coding{j},'KFold',15);
end
```

```
Warning: One or more folds do not contain points from all the groups.
Warning: One or more folds do not contain points from all the groups.
Warning: One or more folds do not contain points from all the groups.
Warning: One or more folds do not contain points from all the groups.
```

Mdl is a 4-by-1 cell array of **ClassificationPartitionedECOC** models. Several classes have low relative frequency in the data, and so there is a chance that, during cross validation, some in-sample folds will not train using observations from those classes.

Estimate the 15-fold classification error for each classifier.

```
genErr = nan(4,1);
for j = 1:4;
    genErr(j) = kfoldLoss(Mdl{j});
end
```

```
genErr
```

```
genErr =
    0.2279
    0.2163
    0.2116
    0.2256
```

Though the generalization error is still high, the best performing model, based solely on the out-of-sample classification error, is the model that used the coding design Coding{3}.

You can try to improve the generalization error by tuning some parameters of the binary learners. For example, you can specify to use the twoing rule or deviance for the split criterion, rather than the default Gini's diversity index. You might also specify to use surrogate splits since there are missing values in the data.

Input Arguments

K — Number of classes

positive integer

Number of classes, specified as a positive integer.

K specifies the number of rows of the coding matrix M.

Data Types: `single` | `double`

name — Coding design name

'binarycomplete' | 'denserandom' | 'onevsall' | 'onevsone' |
'sparserandom' | ...

Coding design name, specified as a string. This table summarizes the available coding schemes.

Value	Number of Binary Learners	Description
'allpairs' and 'onevsone'	$K(K-1)/2$	For each binary learner, one class is positive, another is negative, and the software ignores the rest. This design exhausts all combinations of class pair assignments.
'binarycomplete'	$2^{(K-1)} - 1$	This design partitions the classes into all binary combinations, and does not ignore any classes. That is, for each binary learner, all class assignments are -1 and 1 with at least one positive and negative class in the assignment.

Value	Number of Binary Learners	Description
'denserandom'	Random, but approximately $10 \log_2 K$	For each binary learner, the software randomly assigns classes into positive or negative classes, with at least one of each type. For more details, see “Random Coding Design Matrices” on page 21-1292.
'onevsall'	K	For each binary learner, one class is positive and the rest are negative. This design exhausts all combinations of positive class assignments.
'ordinal'	$K - 1$	For the first binary learner, the first class is negative, and the rest positive. For the second binary learner, the first two classes are negative, and the rest positive, and so on.
'sparserandom'	Random, but approximately $15 \log_2 K$	For each binary learner, the software randomly assigns classes as positive or negative with probability 0.25 for each, and ignores classes with probability 0.5. For more details, see “Random Coding Design Matrices” on page 21-1292.
'ternarycomplete'	$(3^K - 2^{(K+1)} + 1) / 2$	This design partitions the classes into all ternary combinations. That is, all class assignments are 0, -1, and 1 with at least one positive and one negative class in the assignment.

Data Types: char

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Example: 'NumTrials',1000 specifies to generate 1000 random matrices.

'NumTrials' — Number of random coding matrices to generate
10000 (default) | positive integer

Number of random coding matrices to generate, specified as the comma-separated pair consisting of 'NumTrials' and a positive integer.

The software:

- Generates NumTrials matrices, and selects the one with the maximal, pair-wise row distance.
- Ignores NumTrials for all values of name except 'denserandom' and 'sparserandom'.

Example: 'NumTrials',1000

Data Types: single | double

Output Arguments

M — Coding matrix
numeric matrix

Coding matrix that reduces an ECOC scheme to binary, returned as a numeric matrix. M has K rows and L columns, where L is the number of binary learners. Each row corresponds to a class and each column corresponds to a binary learner.

The elements of M are -1, 0, or 1, and the value corresponds to a dichotomous class assignment. This table describes the meaning of $M(i, j)$, that is, the class that learner j assigns to observations in class i.

Value	Dichotomous Class Assignment
- 1	Negative class
0	Learner j removes observations in class i from the data set before training.
1	Positive class

The binary learners for designs `denserandom`, `binarycomplete`, and `onevsall` do not assign 0 to observations in any class.

More About

Tips

- The number of binary learners grows with the number of classes. For a problem with many classes, the `binarycomplete` and `ternarycomplete` coding designs are not efficient. However:
 - If $K \leq 4$, then use `ternarycomplete` coding design rather than `sparserandom`.
 - If $K \leq 5$, then use `binarycomplete` coding design rather than `denserandom`.

You can display the coding design matrix of a trained ECOC classifier by entering `Mdl.CodingMatrix` into the Command Window.

- You should form a coding matrix using intimate knowledge of the application, and taking into account computational constraints. If you have sufficient computational power and time, then try several coding matrices and choose the one with the best performance (e.g., check the confusion matrices for each model using `confusionmat`).

Algorithms

Custom Coding Design Matrices

Custom coding matrices must have a certain form. The software validates custom coding matrices by ensuring:

- Every element is -1, 0, or 1.
- Every column contains at least one -1 and one 1.
- For all distinct column vectors u and v , $u \neq v$ and $u \neq -v$.

- All rows vectors are unique.
- The matrix can separate any two classes. That is, you can travel from any row to any other row following these rules:
 - You can move vertically from 1 to -1 or -1 to 1.
 - You can move horizontally from a nonzero element to another nonzero element.
 - You can use a column of the matrix for a vertical move only once.

If it is not possible to move from row i to row j using these rules, then classes i and j cannot be separated by the design. For example, in the coding design

$$\begin{bmatrix} 1 & 0 \\ -1 & 0 \\ 0 & 1 \\ 0 & -1 \end{bmatrix}$$

classes 1 and 2 cannot be separated from classes 3 and 4 (that is, you cannot move horizontally from the -1 in row 2 to column 2 since there is a 0 in that position). Therefore, the software rejects this coding design.

Random Coding Design Matrices

For a given number of classes, e.g., K , the software generates random coding design matrices as follows.

- 1 The software generates one of the following:
 - a Dense random — The software sets each element of the K -by- L_d coding design matrix with a 1 or a -1 with equal probability, where $L_d \approx \lceil 10 \log_2 K \rceil$.
 - b Sparse random — The software sets each element of the K -by- L_s coding design matrix with a 1, with probability 0.25, a -1 with probability 0.25, and a 0 with probability 0.5, where $L_s \approx \lceil 15 \log_2 K \rceil$.
- 2 If a column does not contain at least one 1 and at least one -1, then the software removes that column.
- 3 For distinct columns u and v , if $u = v$ or $u \neq -v$, then the software removes v from the coding design matrix.

The software randomly generates 10,000 matrices by default, and retains the matrix with the largest, minimal pair-wise row distance based on the Hamming measure ([4]) given by

$$\Delta(k_1, k_2) = 0.5 \sum_{l=1}^L |m_{k_1, l} - m_{k_2, l}|,$$

where $m_{k,l}$ is an element of coding design matrix j .

devianceTest

Class: GeneralizedLinearModel

Analysis of deviance

Syntax

```
tbl = devianceTest mdl)
```

Description

`tbl = devianceTest(mdl)` returns an analysis of deviance table for the `mdl` generalized linear model. `tbl` gives the result of a test of whether the fitted model fits significantly better than a constant model.

Input Arguments

mdl

Generalized linear model, as constructed by `fitglm` or `stepwiseglm`.

Output Arguments

tbl

Table containing two rows and four columns.

- The first row relates to a constant model.
- The second row relates to the full model in `mdl`.
- The columns are:

Deviance

Deviance is twice the difference between the log likelihoods of the corresponding

	model (mdl or constant) and the saturated model. The test statistic for the deviance test is twice the difference between the log likelihoods of the tested model mdl and the constant model. For more information, see Deviance.
DFE	Error degrees of freedom. It is the number of observations minus the number of parameters in the corresponding model.
chi2Stat	F statistic or Chi-squared statistic, depending on whether the dispersion is estimated (F statistic) or not (Chi-squared statistic) <ul style="list-style-type: none"> • <i>Chi-squared statistic</i> is the difference between the deviance of the constant model and the deviance of the full model. • <i>F statistic</i> is the difference between the deviance of the constant model and the deviance of the full model, divided by the estimated dispersion.
pValue	<i>p</i> -value associated with the test. It is the Chi-squared statistic with (number of coefficients in the model minus one) degrees of freedom, or <i>F</i> statistic with (number of coefficients in the model minus one) numerator degrees of freedom, and DFE denominator degrees of freedom.

Definitions

Deviance

Deviance of a model M_1 is twice the difference between the loglikelihood of that model and the saturated model, M_S . The saturated model is the model with the maximum number of parameters that can be estimated. For example, if there are n observations y_i ,

$i = 1, 2, \dots, n$, with potentially different values for $X_i^T\beta$, then you can define a saturated model with n parameters. Let $L(b,y)$ denote the maximum value of the likelihood function for a model. Then the deviance of model M_1 is

$$-2(\log L(b_1, y) - \log L(b_S, y)),$$

where b_1 are the estimated parameters for model M_1 and b_S are the estimated parameters for the saturated model. The deviance has a chi-square distribution with $n - p$ degrees of freedom, where n is the number of parameters in the saturated model and p is the number of parameters in model M_1 .

If M_1 and M_2 are two different generalized linear models, then the fit of the models can be assessed by comparing the deviances D_1 and D_2 of these models. The difference of the deviances is

$$\begin{aligned} D &= D_2 - D_1 = -2(\log L(b_2, y) - \log L(b_S, y)) + 2(\log L(b_1, y) - \log L(b_S, y)) \\ &= -2(\log L(b_2, y) - \log L(b_1, y)). \end{aligned}$$

Asymptotically, this difference has a chi-square distribution with degrees of freedom v equal to the number of parameters that are estimated in one model but fixed (typically at 0) in the other. That is, it is equal to the difference in the number of parameters estimated in M_1 and M_2 . You can get the p -value for this test using `1 - chi2cdf(D, V)`, where $D = D_2 - D_1$.

Examples

Deviance Test

Perform a deviance test on a generalized linear model.

Construct a generalized linear model.

```
rng('default') % for reproducibility
X = randn(100,5);
mu = exp(X(:, [1 4 5]) * [.4; .2; .3]);
y = poissrnd(mu);
mdl = fitglm(X,y, 'linear', 'Distribution', 'poisson');
```

Test whether the model differs from a constant in a statistically significant way.

```
tbl = devianceTest mdl)
```

```
tbl =
```

	Deviance	DFE
log(y) ~ 1	128.58	99
log(y) ~ 1 + x1 + x2 + x3 + x4 + x5	83.726	94

	chi2Stat
log(y) ~ 1	
log(y) ~ 1 + x1 + x2 + x3 + x4 + x5	44.858

	pValue
log(y) ~ 1	
log(y) ~ 1 + x1 + x2 + x3 + x4 + x5	1.5502e-08

The p -value is very small, indicating that the model significantly differs from a constant.

designMatrix

Class: GeneralizedLinearMixedModel

Fixed- and random-effects design matrices

Syntax

```
D = designMatrix(glme)
D = designMatrix(glme, 'Fixed')

D = designMatrix(glme, 'Random')
Dsub = designMatrix(glme, 'Random', gnumbers)
[Dsub, gnames] = designMatrix(glme, 'Random', gnumbers)
```

Description

`D = designMatrix(glme)` or `D = designMatrix(glme, 'Fixed')` returns the fixed-effects design matrix for the generalized linear mixed-effects model `glme`.

`D = designMatrix(glme, 'Random')` returns the random-effects design matrix for the generalized linear mixed-effects model `glme`.

`Dsub = designMatrix(glme, 'Random', gnumbers)` returns a subset of the random-effects design matrix for the generalized linear mixed-effects model `glme` that corresponds to the grouping variables indicated by `gnumbers`.

`[Dsub, gnames] = designMatrix(glme, 'Random', gnumbers)` also returns the grouping variable names that correspond to `gnumbers`.

Input Arguments

glme — Generalized linear mixed-effects model

GeneralizedLinearMixedModel object

Generalized linear mixed-effects model, specified as a `GeneralizedLinearMixedModel` object. For properties and methods of this object, see `GeneralizedLinearMixedModel`.

gnumbers — Grouping variable numbers

array of integer values

Grouping variable numbers, specified as an array of integer values containing elements in the range $[1, R]$, where R is the length of the cell array that contains the grouping variables for the generalized linear mixed-effects model `glme`.

For example, you can specify the grouping variables `g1`, `g3`, and `gr` as `[1, 3, r]`.

Data Types: `single` | `double`

Output Arguments

D — Design matrix

matrix

Design matrix of a generalized linear mixed-effects model `glme` returned as one of the following:

- Fixed-effects design matrix — n -by- p matrix consisting of the fixed-effects design matrix of `glme`, where n is the number of observations and p is the number of fixed-effects terms.
- Random-effects design matrix — n -by- k matrix, consisting of the random-effects design matrix of `glme`. Here, k is equal to `length(B)`, where `B` is the random-effects coefficients vector of generalized linear mixed-effects model `glme`. The random-effects design matrix is returned as a sparse matrix. For more information about sparse matrices, see “Full and Sparse Matrices”.

If `glme` has R grouping variables `g1`, `g2`, ..., `gR`, with levels m_1 , m_2 , ..., m_R , respectively, and if q_1 , q_2 , ..., q_R are the lengths of the random-effects vectors that are associated with `g1`, `g2`, ..., `gR`, respectively, then `B` is a column vector of length $q_1 * m_1 + q_2 * m_2 + \dots + q_R * m_R$.

`B` is made by concatenating the empirical Bayes predictors of random effects vectors corresponding to each level of each grouping variable as `[g1level1; g1level2; ...; g1levelm1; g2level1; g2level2; ...; g2levelm2; ...; gRlevel1; gRlevel2; ...; gRlevelmR]`'.

Data Types: `single` | `double`

Dsub — Submatrix of random-effects design matrix

matrix

Submatrix of random-effects design matrix that corresponds to the grouping variables specified by `gnumbers`, returned as an n -by- k matrix, where k is length of the column vector `Bsub`.

`Bsub` contains the concatenated empirical Bayes predictors of random-effects vectors, corresponding to each level of the grouping variables, specified by `gnumbers`.

If, for example, `gnumbers` is `[1,3,r]`, this corresponds to the grouping variables g_1 , g_3 , and g_r . Then, `Bsub` contains the empirical Bayes predictors of random-effects vectors corresponding to each level of the grouping variables g_1 , g_3 , and g_r , such as

```
[g1level1; g1level2; ...; g1levelm1; g3level1; g3level2; ...; g3levelm3;  
grlevel1; grlevel2; ...; grlevelmr]'.
```

Thus, `Dsub*Bsub` represents the contribution of all random effects corresponding to grouping variables g_1 , g_3 , and g_r to the response of `glme`.

If `gnumbers` is empty, then `Dsub` is the full random-effects design matrix.

Data Types: `single` | `double`**gnames — Names of grouping variables** k -by-1 cell array

Names of grouping variables corresponding to the integers in `gnumbers` if the design type is 'Random', returned as a k -by-1 cell array. If the design type is 'Fixed', then `gnames` is an empty matrix `[]`.

Data Types: `cell`

Examples

Obtain Fixed- and Random-Effects Design Matrices

Navigate to the folder containing the sample data. Load the sample data.

```
cd(matlabroot)  
cd('help/toolbox/stats/examples')
```

```
load mfr
```

This simulated data is from a manufacturing company that operates 50 factories across the world, with each factory running a batch process to create a finished product. The company wants to decrease the number of defects in each batch, so it developed a new manufacturing process. To test the effectiveness of the new process, the company selected 20 of its factories at random to participate in an experiment: Ten factories implemented the new process, while the other ten continued to run the old process. In each of the 20 factories, the company ran five batches (for a total of 100 batches) and recorded the following data:

- Flag to indicate whether the batch used the new process (**newprocess**)
- Processing time for each batch, in hours (**time**)
- Temperature of the batch, in degrees Celsius (**temp**)
- Categorical variable indicating the supplier (A, B, or C) of the chemical used in the batch (**supplier**)
- Number of defects in the batch (**defects**)

The data also includes **time_dev** and **temp_dev**, which represent the absolute deviation of time and temperature, respectively, from the process standard of 3 hours at 20 degrees Celsius.

Fit a generalized linear mixed-effects model using **newprocess**, **time_dev**, **temp_dev**, and **supplier** as fixed-effects predictors. Include a random-effects term for intercept grouped by **factory**, to account for quality differences that might exist due to factory-specific variations. The response variable **defects** has a Poisson distribution, and the appropriate link function for this model is log. Use the Laplace fit method to estimate the coefficients. Specify the dummy variable encoding as 'effects', so the dummy variable coefficients sum to 0.

The number of defects can be modeled using a Poisson distribution

$$defects_{ij} \sim \text{Poisson}(\mu_{ij})$$

This corresponds to the generalized linear mixed-effects model

$$\log(\mu_{ij}) = \beta_0 + \beta_1 \text{newprocess}_{ij} + \beta_2 \text{time_dev}_{ij} + \beta_3 \text{temp_dev}_{ij} + \beta_4 \text{supplier_C}_{ij} + \beta_5 \text{supplier_B}_{ij} +$$

where

- $defects_{ij}$ is the number of defects observed in the batch produced by factory i during batch j .
- μ_{ij} is the mean number of defects corresponding to factory i (where $i = 1, 2, \dots, 20$) during batch j (where $j = 1, 2, \dots, 5$).
- $newprocess_{ij}$, $time_dev_{ij}$, and $temp_dev_{ij}$ are the measurements for each variable that correspond to factory i during batch j . For example, $newprocess_{ij}$ indicates whether the batch produced by factory i during batch j used the new process.
- $supplier_C_{ij}$ and $supplier_B_{ij}$ are dummy variables that use effects (sum-to-zero) coding to indicate whether company C or B, respectively, supplied the process chemicals for the batch produced by factory i during batch j .
- $b_i \sim N(0, \sigma_b^2)$ is a random-effects intercept for each factory i that accounts for factory-specific variation in quality.

```
glme = fitglme(mfr, 'defects ~ 1 + newprocess + time_dev + temp_dev + supplier + (1|fact
```

Extract the fixed-effects design matrix and display rows 1 through 10.

```
Dfe = designMatrix(glme, 'Fixed');
disp(Dfe(1:10,:))
```

```

designMatrix

Class: LinearMixedModel

Fixed- and random-effects design matrices

Syntax

```
D = designMatrix(lme)
D = designMatrix(lme, 'Fixed')

D = designMatrix(lme, 'Random')
Dsub = designMatrix(lme, 'Random', gnumbers)
[Dsub, gnames] = designMatrix(lme, 'Random', gnumbers)
```

Description

`D = designMatrix(lme)` or `D = designMatrix(lme, 'Fixed')` returns the fixed-effects design matrix for the linear mixed-effects model `lme`.

`D = designMatrix(lme, 'Random')` returns the random-effects design matrix for the linear mixed-effects model `lme`.

`Dsub = designMatrix(lme, 'Random', gnumbers)` returns a subset of the random-effects design matrix for the linear mixed-effects model `lme` corresponding to the grouping variables indicated by the integers in `gnumbers`.

`[Dsub, gnames] = designMatrix(lme, 'Random', gnumbers)` also returns the grouping variable names corresponding to the integers in `gnumbers`.

Input Arguments

lme — Linear mixed-effects model

LinearMixedModel object

Linear mixed-effects model, returned as a LinearMixedModel object.

For properties and methods of this object, see `LinearMixedModel`.

gnumbers — Grouping variable numbers

integer array

Grouping variable numbers, specified as an integer array, where R is the length of the cell array that contains the grouping variables for the linear mixed-effects model `lme`.

For example, you can specify the grouping variables g_1 , g_3 , and g_r as follows.

Example: `[1,3,r]`

Data Types: `double` | `single`

Output Arguments

D — Design matrix

matrix

Design matrix of a linear mixed-effects model `lme` returned as one of the following:

- Fixed-effects design matrix — n -by- p matrix consisting of the fixed-effects design of `lme`, where n is the number of observations and p is the number of fixed-effects terms.
- Random-effects design matrix — n -by- k matrix, consisting of the random-effects design matrix of `lme`. Here, k is equal to `length(B)`, where `B` is the random-effects coefficients vector of linear mixed-effects model `lme`.

If `lme` has R grouping variables g_1, g_2, \dots, g_R , with levels m_1, m_2, \dots, m_R , respectively, and if q_1, q_2, \dots, q_R are the lengths of the random-effects vectors that are associated with g_1, g_2, \dots, g_R , respectively, then `B` is a column vector of length $q_1 * m_1 + q_2 * m_2 + \dots + q_R * m_R$.

`B` is made by concatenating the best linear unbiased predictors of random-effects vectors corresponding to each level of each grouping variable as `[g1level1; g1level2; ...; g1level m_1 ; g2level1; g2level2; ...; g2level m_2 ; ...; gRlevel1; gRlevel2; ...; gRlevel m_R]'`.

Data Types: `single` | `double`

Dsub — Submatrix of random-effects design matrix

matrix

Submatrix of random-effects design matrix corresponding to the grouping variables indicated by the integers in `gnumbers`, returned as an n -by- k matrix, where k is length of the column vector `Bsub`.

`Bsub` contains the concatenated best linear unbiased predictors (BLUPs) of random-effects vectors, corresponding to each level of the grouping variables, specified by `gnumbers`.

If, for example, `gnumbers` is `[1,3,r]`, this corresponds to the grouping variables `g1`, `g3`, and `gr`. Then, `Bsub` contains the concatenated BLUPs of random-effects vectors corresponding to each level of the grouping variables `g1`, `g3`, and `gr`, such as

```
[g1level1; g1level2; ...; g1levelm1; g3level1; g3level2; ...; g3levelm3;  
grlevel1; grlevel2; ...; grlevelmr]'.
```

Thus, `Dsub*Bsub` represents the contribution of all random effects corresponding to grouping variables `g1`, `g3`, and `gr` to the response of `lme`.

If `gnumbers` is empty, then `Dsub` is the full random-effects design matrix.

Data Types: `single` | `double`

gnames — Names of grouping variables

k -by-1 cell array

Names of grouping variables corresponding to the integers in `gnumbers` if the design type is `'Random'`, returned as a k -by-1 cell array. If the design type is `'Fixed'`, then `gnames` is an empty matrix `[]`.

Data Types: `cell`

Examples

Display Fixed- and Random-Effects Design Matrices

Navigate to a folder containing sample data.

```
cd(matlabroot)  
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load shift
```

The data shows the deviations from the target quality characteristic measured from the products that 5 operators manufacture during three different shifts, morning, evening, and night. This is a randomized block design, where the operators are the blocks. The experiment is designed to study the impact of the time of shift on the performance. The performance measure is the deviation of the quality characteristics from the target value. This is simulated data.

Shift and Operator are nominal variables.

```
shift.Shift = nominal(shift.Shift);
shift.Operator = nominal(shift.Operator);
```

Fit a linear mixed-effects model with a random intercept grouped by operator to assess if performance significantly differs according to the time of the shift.

```
lme = fitlme(shift, 'QCDev ~ Shift + (1|Operator)');
```

Display the fixed-effects design matrix.

```
designMatrix(lme)
```

```
ans =
```

```

1      1      0
1      0      0
1      0      1
1      1      0
1      0      0
1      0      1
1      1      0
1      0      0
1      0      1
1      1      0
1      0      0
1      0      1
1      1      0
1      0      0
1      0      1
```

The column of 1s represents the constant term in the model. `fitlme` takes the evening shift as the reference group and creates two dummy variables to represent the morning and night shifts, respectively.

Display the random-effects design matrix.

```
designMatrix(lme, 'random')
```

```
ans =
```

```
(1,1)      1
(2,1)      1
(3,1)      1
(4,2)      1
(5,2)      1
(6,2)      1

0 0 0 0 1
```

Each column corresponds to a level of the grouping variable, `Operator`.

Random-Effects Design Matrix of Multiple Grouping Variables

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load fertilizer
```

The dataset array includes data from a split-plot experiment, where soil is divided into three blocks based on the soil type: sandy, silty, and loamy. Each block is divided into five plots, where five different types of tomato plants (cherry, heirloom, grape, vine, and plum) are randomly assigned to these plots. The tomato plants in the plots are then divided into subplots, where each subplot is treated by one of four fertilizers. This is simulated data.

Store the data in a dataset array called `ds`, for practical purposes, and define `Tomato`, `Soil`, and `Fertilizer` as categorical variables.

```
ds = fertilizer;
ds.Tomato = nominal(ds.Tomato);
ds.Soil = nominal(ds.Soil);
ds.Fertilizer = nominal(ds.Fertilizer);
```

Fit a linear mixed-effects model, where `Fertilizer` and `Tomato` are the fixed-effects variables, and the mean yield varies by the block (soil type), and the plots within blocks (tomato types within soil types) independently.

```
lme = fitlme(ds, 'Yield ~ Fertilizer * Tomato + (1|Soil) + (1|Soil:Tomato)');
```

Store and examine the full random-effects design matrix.

```
D = full(designMatrix(lme, 'random'));
```

The first three columns of matrix `D` contain the indicator variables `fitlme` creates for the three levels (`Loamy`, `Silty`, `Sandy`, respectively) of the first grouping variable, `Soil`. The next 15 columns contain the indicator variables created for the second grouping variable, `Tomato` nested under `Soil`. These are basically the elementwise

products of the dummy variables representing the levels of Soil (Loamy, Silty, and Sandy, respectively) and the levels of Tomato (Cherry, Grape, Heirloom, Plum, Vine, respectively).

Subset of the Random-Effects Design Matrix

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load fertilizer
```

dfittool

Open Distribution Fitting app

Syntax

```
dfittool  
dfittool(y)  
dfittool(y,cens)  
dfittool(y,cens,freq)  
dfittool(y,cens,freq,dsname)
```

Description

`dfittool` opens the Distribution Fitting app or brings focus to the app if it is already open. Use the Distribution Fitting app to import data from the workspace, fit distributions to the data, and display the fitted distribution over plots of the empirical distributions.

`dfittool(y)` displays the Distribution Fitting app and creates a data set with data specified by the vector `y`.

`dfittool(y,cens)` uses the vector `cens` to specify whether the observation `y(j)` is censored, (`cens(j)==1`) and/or observed, exactly (`cens(j)==0`). If `cens` is omitted or empty, no `y` values are censored.

`dfittool(y,cens,freq)` uses the vector `freq` to specify the frequency of each element of `y`. If `freq` is omitted or empty, all `y` values have a frequency of 1.

`dfittool(y,cens,freq,dsname)` creates a data set with the name `dsname` using the data vector `y`, censoring indicator `cens`, and frequency vector `freq`.

Dimensions property

Class: grandset

Number of dimensions

Description

Number of dimensions in the point set. The `Dimensions` property of a point set contains a positive integer that indicates the number of dimensions for which the points have values. For example, a point set with `Dimensions=5` produces points that each have five values.

Set this property by specifying the number of dimensions when constructing a new point set. After construction, you cannot change the value. The default number of dimensions is 2.

DimNames property

Class: dataset

Two-element cell array of strings giving names of dimensions of data set

Compatibility

The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

Description

A two-element cell array of strings giving the names of the two dimensions of the data set. The default is `{'Observations' 'Variables'}`.

disp

Class: classregtree

Display classregtree object

Syntax

```
display(t)
```

Description

`display(t)` prints the classregtree object `t`.

See Also

`classregtree` | `view`

disp

Class: cvpartition

Display cvpartition object

Syntax

disp(c)

Description

disp(c) prints the cvpartition object c.

See Also

cvpartition

disp

Class: dataset

Display dataset array

Compatibility

The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

Syntax

`disp(ds)`

Description

`disp(ds)` prints the dataset array `ds`, including variable names and observation names (if present), without printing the dataset name. In all other ways it's the same as leaving the semicolon off an expression.

For numeric or categorical variables that are 2-D and have three or fewer columns, `disp` prints the actual data using either short `g`, long `g`, or bank format, depending on the current command line setting. Otherwise, `disp` prints the size and type of each dataset element.

For character variables that are 2-D and 10 or fewer characters wide, `disp` prints quoted strings. Otherwise, `disp` prints the size and type of each dataset element.

For cell variables that are 2-D and have three or fewer columns, `disp` prints the contents of each cell (or its size and type if too large). Otherwise, `disp` prints the size of each dataset element.

For time series variables, `disp` prints columns for both the time and the data. If the variable is 2-D and has three or fewer columns, `disp` prints the actual data. Otherwise, `disp` prints the size and type of each dataset element.

For other types of variables, `disp` prints the size and type of each dataset element.

Class: GeneralizedLinearModel

Display generalized linear regression model

Syntax

```
disp mdl
```

Description

`disp(mdl)` displays the `mdl` linear model.

Input Arguments

mdl

Generalized linear model, as constructed by `fitglm` or `stepwiseglm`.

Examples

Display a Generalized Linear Regression Model

Create and display a generalized linear regression model.

Create a generalized linear regression model of Poisson data.

```
X = 2 + randn(100,1);  
mu = exp(1 + X/2);  
y = poissrnd(mu);  
mdl = fitglm(X,y,...  
    'y ~ x1', 'distr', 'poisson');
```

Display the model.

```
disp(mdl)
```

Generalized Linear regression model:

$\log(y) \sim 1 + x1$

Distribution = Poisson

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	0.9581	0.090294	10.611	2.6519e-26
x1	0.51027	0.033738	15.124	1.1179e-51

100 observations, 98 error degrees of freedom

Dispersion: 1

Chi²-statistic vs. constant model: 221, p-value = 5.77e-50

Alternatives

Enter *mdl* at the command line to obtain a display, where *mdl* is the name of your model.

Class: GeneralizedLinearMixedModel

Display generalized linear mixed-effects model

Syntax

```
disp(glme)
```

Description

`disp(glme)` displays fitted generalized linear mixed-effects model `glme`.

Input Arguments

glme — Generalized linear mixed-effects model

GeneralizedLinearMixedModel object

Generalized linear mixed-effects model, specified as a GeneralizedLinearMixedModel object. For properties and methods of this object, see GeneralizedLinearMixedModel.

Definitions

Akaike and Bayesian Information Criteria

The *Akaike information criterion* (AIC) is $AIC = -2\log L_M + 2(\text{param})$.

$\log L_M$ depends on the method used to fit the model.

- If you use 'Laplace' or 'ApproximateLaplace', then $\log L_M$ is the maximized log likelihood.
- If you use 'MPL', then $\log L_M$ is the maximized log likelihood of the pseudo data from the final pseudo likelihood iteration.
- If you use 'REMPLE', then $\log L_M$ is the maximized restricted log likelihood of the pseudo data from the final pseudo likelihood iteration.

$param$ is the total number of parameters estimated in the model. For most GLME models, $param$ is equal to $nc + p + 1$, where nc is the total number of parameters in the random-effects covariance, excluding the residual variance, and p is the number of fixed-effects coefficients. However, if the dispersion parameter is fixed at 1.0 for binomial or Poisson distributions, then $param$ is equal to $(nc + p)$.

The *Bayesian information criterion* (BIC) is $BIC = -2 * \log L_M + \ln(n_{eff})(param)$.

$\log L_M$ depends on the method used to fit the model.

- If you use 'Laplace' or 'ApproximateLaplace', then $\log L_M$ is the maximized log likelihood.
- If you use 'MPL', then $\log L_M$ is the maximized log likelihood of the pseudo data from the final pseudo likelihood iteration.
- If you use 'REML', then $\log L_M$ is the maximized restricted log likelihood of the pseudo data from the final pseudo likelihood iteration.

n_{eff} is the effective number of observations.

- If you use 'MPL', 'Laplace', or 'ApproximateLaplace', then $n_{eff} = n$, where n is the number of observations.
- If you use 'REML', then $n_{eff} = n - p$.

$param$ is the total number of parameters estimated in the model. For most GLME models, $param$ is equal to $nc + p + 1$, where nc is the total number of parameters in the random-effects covariance, excluding the residual variance, and p is the number of fixed-effects coefficients. However, if the dispersion parameter is fixed at 1.0 for binomial or Poisson distributions, then $param$ is equal to $(nc + p)$.

A lower value of deviance indicates a better fit. As the value of deviance decreases, both AIC and BIC tend to decrease. Both AIC and BIC also include penalty terms based on the number of parameters estimated, p . So, when the number of parameters increase, the values of AIC and BIC tend to increase as well. When comparing different models, the model with the lowest AIC or BIC value is considered as the best fitting model.

For models fitted using 'MPL' and 'REML', AIC and BIC are based on the log likelihood (or restricted log likelihood) of pseudo data from the final pseudo likelihood iteration. Therefore, a direct comparison of AIC and BIC values between models fitted using 'MPL' and 'REML' is not appropriate.

Examples

Display a Generalized Linear Mixed-Effects Model

Navigate to the folder containing the sample data. Load the sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')

load mfr
```

This simulated data is from a manufacturing company that operates 50 factories across the world, with each factory running a batch process to create a finished product. The company wants to decrease the number of defects in each batch, so it developed a new manufacturing process. To test the effectiveness of the new process, the company selected 20 of its factories at random to participate in an experiment: Ten factories implemented the new process, while the other ten continued to run the old process. In each of the 20 factories, the company ran five batches (for a total of 100 batches) and recorded the following data:

- Flag to indicate whether the batch used the new process (**newprocess**)
- Processing time for each batch, in hours (**time**)
- Temperature of the batch, in degrees Celsius (**temp**)
- Categorical variable indicating the supplier of the chemical used in the batch (**supplier**)
- Number of defects in the batch (**defects**)

The data also includes **time_dev** and **temp_dev**, which represent the absolute deviation of time and temperature, respectively, from the process standard of 3 hours at 20 degrees Celsius.

Fit a generalized linear mixed-effects model using **newprocess**, **time_dev**, **temp_dev**, and **supplier** as fixed-effects predictors. Include a random-effects term for intercept grouped by **factory**, to account for quality differences that might exist due to factory-specific variations. The response variable **defects** has a Poisson distribution, and the appropriate link function for this model is log. Use the Laplace fit method to estimate the coefficients. Specify the dummy variable encoding as **'effects'**, so the dummy variable coefficients sum to 0.

The number of defects can be modeled using a Poisson distribution

$$defects_{ij} \sim \text{Poisson}(\mu_{ij})$$

This corresponds to the generalized linear mixed-effects model

$$\log(\mu_{ij}) = \beta_0 + \beta_1 newprocess_{ij} + \beta_2 time_dev_{ij} + \beta_3 temp_dev_{ij} + \beta_4 supplier_C_{ij} + \beta_5 supplier_B_{ij} + b_i$$

where

- $defects_{ij}$ is the number of defects observed in the batch produced by factory i during batch j .
- μ_{ij} is the mean number of defects corresponding to factory i (where $i = 1, 2, \dots, 20$) during batch j (where $j = 1, 2, \dots, 5$).
- $newprocess_{ij}$, $time_dev_{ij}$, and $temp_dev_{ij}$ are the measurements for each variable that correspond to factory i during batch j . For example, $newprocess_{ij}$ indicates whether the batch produced by factory i during batch j used the new process.
- $supplier_C_{ij}$ and $supplier_B_{ij}$ are dummy variables that use effects (sum-to-zero) coding to indicate whether company **C** or **B**, respectively, supplied the process chemicals for the batch produced by factory i during batch j .
- $b_i \sim N(0, \sigma_b^2)$ is a random-effects intercept for each factory i that accounts for factory-specific variation in quality.

```
glme = fitglme(mfr, 'defects ~ 1 + newprocess + time_dev + temp_dev + supplier + (1|factory)
```

Display the model.

Group: factory (20 Levels)

Name1	Name2	Type	Estimate
'(Intercept)'	'(Intercept)'	'std'	0.31381

Group: Error

Name	Estimate
'sqrt(Dispersion)'	1

The **Model information** table displays the total number of observations in the sample data (100), the number of fixed- and random-effects coefficients (6 and 20, respectively), and the number of covariance parameters (1). It also indicates that the response variable has a **Poisson** distribution, the link function is **Log**, and the fit method is **Laplace**.

Formula indicates the model specification using Wilkinson's notation.

The `Model fit statistics` table displays statistics used to assess the goodness of fit of the model. This includes the Akaike information criterion (AIC), Bayesian information criterion (BIC) values, log likelihood (LogLikelihood), and deviance (Deviance) values.

The `Fixed effects coefficients` table indicates that `fitglme` returned 95% confidence intervals. It contains one row for each fixed-effects predictor, and each column contains statistics corresponding to that predictor. Column 1 (`Name`) contains the name of each fixed-effects coefficient, column 2 (`Estimate`) contains its estimated value, and column 3 (`SE`) contains the standard error of the coefficient. Column 4 (`tStat`) contains the *t*-statistic for a hypothesis test that the coefficient is equal to 0. Column 5 (`DF`) and column 6 (`pValue`) contain the degrees of freedom and *p*-value that correspond to the *t*-statistic, respectively. The last two columns (`Lower` and `Upper`) display the lower and upper limits, respectively, of the 95% confidence interval for each fixed-effects coefficient.

`Random effects covariance parameters` displays a table for each grouping variable (here, only `factory`), including its total number of levels (20), and the type and estimate of the covariance parameter. Here, `std` indicates that `fitglme` returns the standard deviation of the random effect associated with the `factory` predictor, which has an estimated value of 0.31381. It also displays a table containing the error parameter type (here, the square root of the dispersion parameter), and its estimated value of 1.

The standard display generated by `fitglme` does not provide confidence intervals for the random-effects parameters. To compute and display these values, use `covarianceParameters`.

Class: LinearMixedModel

Display linear mixed-effects model

Syntax

```
display(lme)
```

Description

`display(lme)` displays the fitted linear mixed-effects model `lme`.

Input Arguments

lme — Linear mixed-effects model

LinearMixedModel object

Linear mixed-effects model, returned as a LinearMixedModel object.

For properties and methods of this object, see LinearMixedModel.

Examples

Randomized Block Design

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load shift
```

The dataset array shows the absolute deviations from the target quality characteristic measured from the products that five operators manufacture during three shifts, morning, evening, and night. This is a randomized block design, where the operators are the blocks. The experiment is designed to study the impact of the time of shift on the performance. The performance measure is the absolute deviation of the quality characteristics from the target value. This is simulated data.

Shift and Operator are nominal variables.

```
shift.Shift = nominal(shift.Shift);
shift.Operator = nominal(shift.Operator);
```

Fit a linear mixed-effects model with a random intercept grouped by operator to assess if performance significantly differs according to the time of the shift.

```
lme = fitlme(shift, 'QCDev ~ Shift + (1|Operator)');
```

Display the model.

```
disp(lme)
```

Linear mixed-effects model fit by ML

Model information:

Number of observations	15

Group: Error					
Name	Estimate	Lower	Upper		
'Res Std'	0.76439	0.49315	1.1848		

This display includes the model performance statistics, Akaike information criterion (AIC), Bayesian information criterion (BIC), loglikelihood, and deviance.

The fixed-effects coefficients table includes the names and estimates of the coefficients in the first two columns. The third column **SE** shows the standard errors of the coefficients. The column **tStat** includes the *t*-statistic values that correspond to each coefficient. **DF** is the residual degrees of freedom, and the **pValue** is the *p*-value that corresponds to the corresponding *t*-statistic value. The columns **Lower** and **Upper** display the lower and upper limits of a 95% confidence interval for each fixed-effects coefficient.

The first table for the random effects shows the types and the estimates of the random effects covariance parameters, with the lower and upper limits of a 95% confidence interval for each parameter. The display also shows the name of the grouping variable, operator, and the total number of levels, 5.

The second table for the random effects shows the estimate of the observation error, with the lower and upper limits of a 95% confidence interval.

Definitions

Akaike and Bayesian Information Criteria

Akaike information criterion (AIC) is $AIC = -2 \cdot \log L_M + 2 \cdot (nc + p + 1)$, where $\log L_M$ is the maximized log likelihood (or maximized restricted log likelihood) of the model, and $nc + p + 1$ is the number of parameters estimated in the model. p is the number of fixed-effects coefficients, and nc is the total number of parameters in the random-effects covariance excluding the residual variance.

Bayesian information criterion (BIC) is $BIC = -2 \cdot \log L_M + \ln(n_{eff}) \cdot (nc + p + 1)$, where $\log L_M$ is the maximized log likelihood (or maximized restricted log likelihood) of the model, n_{eff} is the effective number of observations, and $(nc + p + 1)$ is the number of parameters estimated in the model.

- If the fitting method is maximum likelihood (ML), then $n_{eff} = n$, where n is the number of observations.
- If the fitting method is restricted maximum likelihood (REML), then $n_{eff} = n - p$.

A lower value of deviance indicates a better fit. As the value of deviance decreases, both AIC and BIC tend to decrease. Both AIC and BIC also include penalty terms based on the number of parameters estimated, p . So, when the number of parameters increase, the values of AIC and BIC tend to increase as well. When comparing different models, the model with the lowest AIC or BIC value is considered as the best fitting model.

Deviance

`LinearMixedModel` computes the deviance of model M as minus two times the loglikelihood of that model. Let L_M denote the maximum value of the likelihood function for model M . Then, the deviance of model M is

$$-2 * \log L_M.$$

A lower value of deviance indicates a better fit. Suppose M_1 and M_2 are two different models, where M_1 is nested in M_2 . Then, the fit of the models can be assessed by comparing the deviances Dev_1 and Dev_2 of these models. The difference of the deviances is

$$Dev = Dev_1 - Dev_2 = 2(\log LM_2 - \log LM_1).$$

Usually, the asymptotic distribution of this difference has a chi-square distribution with degrees of freedom v equal to the number of parameters that are estimated in one model but fixed (typically at 0) in the other. That is, it is equal to the difference in the number of parameters estimated in M_1 and M_2 . You can get the p -value for this test using `1 - chi2cdf(Dev, V)`, where $Dev = Dev_2 - Dev_1$.

However, in mixed-effects models, when some variance components fall on the boundary of the parameter space, the asymptotic distribution of this difference is more complicated. For example, consider the hypotheses

$$H_0: D = \begin{pmatrix} D_{11} & 0 \\ 0 & 0 \end{pmatrix}, \text{ } D \text{ is a } q\text{-by-}q \text{ symmetric positive semidefinite matrix.}$$

H_1 : D is a $(q+1)$ -by- $(q+1)$ symmetric positive semidefinite matrix.

That is, H_1 states that the last row and column of D are different from zero. Here, the bigger model M_2 has $q + 1$ parameters and the smaller model M_1 has q parameters. And Dev has a 50:50 mixture of χ^2_q and $\chi^2_{(q+1)}$ distributions (Stram and Lee, 1994).

disp

Class: NaiveBayes

Display NaiveBayes classifier object

Syntax

```
disp(nb)
```

Description

`disp(nb)` prints a text representation of the `NaiveBayes` object `nb`, without printing the object name. In all other ways it's the same as leaving the semicolon off an expression.

See Also

`NaiveBayes` | `display`

disp

Class: NonLinearModel

Display nonlinear regression model

Syntax

```
disp mdl
```

Description

`disp(mdl)` displays the `mdl` nonlinear model at the command line.

Input Arguments

mdl

Nonlinear regression model, constructed by `fitnlm`.

Examples

Display a Nonlinear Regression Model

Create and display a nonlinear regression model.

Load the `reaction` data, and specify both a model function and starting values for the iterations.

```
load reaction
modelfun = 'rate~(b1*x2-x3/b5)/(1+b2*x1+b3*x2+b4*x3)';
beta0 = [1 .05 .02 .1 2];
```

Create a model of the data.

```
mdl = fitnlm(reactants,rate,modelfun,beta0);
```

Display the model.

```
disp(md1)
```

```
Nonlinear regression model:
```

```
rate ~ (b1*x2 - x3/b5)/(1 + b2*x1 + b3*x2 + b4*x3)
```

```
Estimated Coefficients:
```

	Estimate	SE	tStat	pValue
b1	1.2526	0.86701	1.4447	0.18654
b2	0.062776	0.043561	1.4411	0.18753
b3	0.040048	0.030885	1.2967	0.23089
b4	0.11242	0.075157	1.4957	0.17309
b5	1.1914	0.83671	1.4239	0.1923

```
Number of observations: 13, Error degrees of freedom: 8
```

```
Root Mean Squared Error: 0.193
```

```
R-Squared: 0.999, Adjusted R-Squared 0.998
```

```
F-statistic vs. constant model: 1.81e+03, p-value = 7.36e-12
```

Alternatives

Enter *md1* at the command line to obtain a display, where *md1* is the name of your model.

- “Nonlinear Regression” on page 11-2

disp

Class: `piecwisedistribution`

Display `piecwisedistribution` object

Syntax

```
disp(A)
```

Description

`disp(A)` prints a text representation of the `piecwisedistribution` object `A`, without printing the object name. In all other ways it's the same as leaving the semicolon off an expression.

See Also

`piecwisedistribution`

disp

Class: grandset

Display grandset object

Syntax

`disp(p)`

Description

`disp(p)` displays the properties of the quasi-random point set `s`, without printing the variable name. `disp` prints out the number of dimensions and points in the point-set, and follows this with the list of all property values for the object.

See Also

grandset

disp

Class: grandstream

Display grandstream object

Syntax

disp(q)

Description

disp(q) displays the quasi-random stream **q**, without printing the variable name. **disp** prints the type and number of dimensions in the stream, and follows it with the list of point set properties.

See Also

grandstream

display

Class: `classregtree`

Display `classregtree` object

Syntax

```
display(t)  
display(A)
```

Description

`display(t)` prints the `classregtree` object `t`. `classregtree` calls `display` when a you do not use a semicolon to terminate a statement.

`display(A)` prints the categorical array `A`. `categorical` calls `display` when a you do not use a semicolon to terminate a statement.

See Also

`classregtree` | `prune` | `test` | `eval`

display

Class: `cvpartition`

Display `cvpartition` object

Syntax

`display(c)`

Description

`display(c)` prints the `cvpartition` object `c`. `cvpartition` calls `display` when a you do not use a semicolon to terminate a statement.

See Also

`cvpartition`

display

Class: dataset

Display dataset array

Compatibility

The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

Syntax

`display(ds)`

Description

`display(ds)` prints the dataset array `ds`, including variable names and observation names (if present). `dataset` calls `display` when you do not use a semicolon to terminate a statement

For numeric or categorical variables that are 2-D and have three or fewer columns, `display` prints the actual data. Otherwise, `display` prints the size and type of each dataset element.

For character variables that are 2-D and 10 or fewer characters wide, `display` prints quoted strings. Otherwise, `display` prints the size and type of each dataset element.

For cell variables that are 2-D and have three or fewer columns, `display` prints the contents of each cell (or its size and type if too large). Otherwise, `display` prints the size of each dataset element.

For time series variables, `display` prints columns for both the time and the data. If the variable is 2-D and has three or fewer columns, `display` prints the actual data. Otherwise, `display` prints the size and type of each dataset element.

For other types of variables, `display` prints the size and type of each dataset element.

See Also

`dataset` | `display` | `format`

display

Class: `gmdistribution`

Display Gaussian mixture distribution object

Syntax

```
display(obj)
```

Description

`display(obj)` prints a text representation of the `gmdistribution` object `obj`. `gmdistribution` calls `display` when a you do not use a semicolon to terminate a statement.

See Also

`gmdistribution` | `disp`

display

Class: NaiveBayes

Display NaiveBayes classifier object

Syntax

```
display(nb)
```

Description

`display(nb)` prints a text representation of the `NaiveBayes` object `nb`. `NaiveBayes` calls `display` when a you do not use a semicolon to terminate a statement.

See Also

`piecwisedistribution`

DistName property

Class: ProbDist

Read-only string containing probability distribution name of ProbDist object

Description

DistName is a read-only property of the ProbDist class. DistName is a string containing the type of distribution used to create the object.

Values

Possible values are:

- 'kernel'
- 'beta'
- 'binomial'
- 'birnbaumsaunders'
- 'exponential'
- 'extreme value'
- 'gamma'
- 'generalized extreme value'
- 'generalized pareto'
- 'inversegaussian'
- 'logistic'
- 'loglogistic'
- 'lognormal'
- 'nakagami'
- 'negative binomial'
- 'normal'
- 'poisson'

- 'rayleigh'
- 'rician'
- 'tlocationscale'
- 'weibull'

Use this information to view and compare the type of distribution used to create distribution objects.

Dist property

Class: NaiveBayes

Distribution names

Description

The `Dist` property is a string or a 1-by-`NDims` cell array of strings indicating the types of distributions for all the features. If all the features use the same type of distribution, `Dist` is a single string. Otherwise `Dist(j)` indicates the distribution type used for the `j`th feature.

The valid strings for this property are the following:

'normal'	Normal distribution.
'kernel'	Kernel smoothing density estimate.
'mvmn'	Multivariate multinomial distribution.
'mn'	Multinomial bag-of-tokens model.

DistributionName property

Class: `gmdistribution`

Type of distribution

Description

The string `'gaussian mixture distribution'`.

disttool

Interactive density and distribution plots

Syntax

```
disttool
```

Description

`disttool` is a graphical interface for exploring the effects of changing parameters on the plot of a cdf or pdf.

See Also

`randtool` | `dfittool`

double

Class: dataset

Convert dataset variables to double array

Compatibility

The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

Syntax

```
b = double(A)
b = double(a,vars)
```

Description

`b = double(A)` returns the contents of the dataset `A`, converted to one double array. The classes of the variables in the dataset must support the conversion.

`b = double(a,vars)` returns the contents of the dataset variables specified by `vars`. `vars` is a positive integer, a vector of positive integers, a variable name, a cell array containing one or more variable names, or a logical vector.

See Also

`dataset` | `single` | `replacedata`

droplevels

Drop levels from a nominal or ordinal array

Compatibility

The `nominal` and `ordinal` array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the MATLAB categorical data type instead.

Syntax

```
B = droplevels(A)
B = droplevels(A,oldlevels)
```

Description

`B = droplevels(A)` drops unused levels from the nominal or ordinal array `A`. The array `B` has the same size, type, and values as `A`, but has a list of potential levels that includes only those present in some element of `A`.

`B = droplevels(A,oldlevels)` removes the specified levels `oldlevels` from `A`.

`droplevels` removes levels, but does not remove elements. Elements of `B` that correspond to elements of `A` having levels in `oldlevels` all have an undefined level.

Examples

Drop Levels From an Ordinal Array

Bin patient ages into ordinal levels corresponding to 10-year intervals.

```
load hospital
edges = 0:10:100;
labels = strcat(num2str((0:10:90)', '%d'), {'s'});
```

```
A = ordinal(hospital.Age,labels,[],edges);
getlabels(A)
```

```
ans =
```

```
Columns 1 through 8
```

```
'0s'    '10s'    '20s'    '30s'    '40s'    '50s'    '60s'    '70s'
```

```
Columns 9 through 10
```

```
'80s'    '90s'
```

Drop any levels that have no patients in them.

```
A = droplevels(A);
getlabels(A)
```

```
ans =
```

```
'20s'    '30s'    '40s'    '50s'
```

- “Add and Drop Category Levels” on page 2-21

Input Arguments

A — Nominal or ordinal array

nominal array | ordinal array

Nominal or ordinal array, specified as a `nominal` or `ordinal` array object created using `nominal` or `ordinal`.

oldlevels — Levels to remove

cell array of strings | 2-D character matrix

Levels to remove from the `nominal` or `ordinal` array, specified as a cell array of strings or 2-D character matrix.

Data Types: `char` | `cell`

Output Arguments

B — Nominal or ordinal array

`nominal array` | `ordinal array`

Nominal or ordinal array, returned as a `nominal` or `ordinal` array object.

More About

- Using nominal Objects
- Using ordinal Objects

See Also

`addlevels` | `mergelevels` | `nominal` | `ordinal` | `reorderlevels`

dummyvar

Create dummy variables

Syntax

```
D = dummyvar(group)
```

Description

`D = dummyvar(group)` returns a matrix `D` containing zeros and ones, whose columns are dummy variables for the grouping variable `group`. Columns of `group` represent categorical predictor variables, with values indicating categorical levels. Rows of `group` represent observations across variables.

`group` can be a numeric vector or categorical column vector representing levels within a single variable, a cell array containing one or more grouping variables, or a numeric matrix or cell array of categorical column vectors representing levels within multiple variables. If `group` is a numeric vector or matrix, values in any column must be positive integers in the range from 1 to the number of levels for the corresponding variable. In this case, `dummyvars` treats each column as a separate numeric grouping variable. With multiple grouping variables, the sets of dummy variable columns are in the same order as the grouping variables in `group`.

The order of the dummy variable columns in `D` matches the order of the groups defined by `group`. When `group` is a categorical vector, the groups and their order match the output of the `getlabels(group)` method. When `group` is a numeric vector, `dummyvar` assumes that the groups and their order are `1:max(group)`. In this respect, `dummyvars` treats a numeric grouping variable differently than `grp2idx`.

If `group` is n -by- p , `D` is n -by- S , where S is the sum of the number of levels in each of the columns of `group`. The number of levels s in any column of `group` is the maximum positive integer in the column or the number of categorical levels. Levels are considered distinct if they appear in different columns of `group`, even if they have the same value. Columns of `D` are, from left to right, dummy variables created from the first column of `group`, followed by dummy variables created from the second column of `group`, etc.

`dummyvar` treats NaN values or undefined categorical levels in `group` as missing data and returns NaN values in `D`.

Dummy variables are used in regression analysis and ANOVA to indicate values of categorical predictors.

Note: If a column of 1s is introduced in the matrix `D`, the resulting matrix $X = [\text{ones}(\text{size}(D, 1), 1) \ D]$ will be rank deficient. The matrix `D` itself will be rank deficient if `group` has multiple columns. This is because dummy variables produced from any column of `group` always sum to a column of 1s. Regression and ANOVA calculations often address this issue by eliminating one dummy variable (implicitly setting the coefficients for dropped columns to zero) from each group of dummy variables produced by a column of `group`.

Examples

Suppose you are studying the effects of two machines and three operators on a process. Use `group` to organize predictor data on machine-operator combinations:

```
machine = [1 1 1 1 2 2 2 2]';
operator = [1 2 3 1 2 3 1 2]';
group = [machine operator]
group =
     1     1
     1     2
     1     3
     1     1
     2     2
     2     3
     2     1
     2     2
```

Use `dummyvar` to create dummy variables for a regression or ANOVA calculation:

```
D = dummyvar(group)
D =
     1     0     1     0     0
     1     0     0     1     0
     1     0     0     0     1
     1     0     1     0     0
     0     1     0     1     0
```

0	1	0	0	1
0	1	1	0	0
0	1	0	1	0

The first two columns of **D** represent observations of machine 1 and machine 2, respectively; the remaining columns represent observations of the three operators.

dwtest

Durbin-Watson test

Syntax

```
p = dwtest(r,x)
p = dwtest(r,x,Name,Value)
[p,d] = dwtest( ___ )
```

Description

`p = dwtest(r,x)` returns the p -value for the Durbin-Watson test of the null hypothesis that the residuals from a linear regression are uncorrelated. The alternative hypothesis is that there is autocorrelation among the residuals.

`p = dwtest(r,x,Name,Value)` returns the p -value for the Durbin-Watson test with additional options specified by one or more name-value pair arguments. For example, you can conduct a one-sided test or calculate the p -value using a normal approximation.

`[p,d] = dwtest(___)` also returns the Durbin-Watson test statistic, d , using any of the input arguments from the previous syntaxes.

Examples

Test Residuals For Correlation

Load the sample census data.

```
load census
```

Create a design matrix using the census date (`cdate`) as the predictor. Add a column of 1 values to include a constant term.

```
n = length(cdate);
x = [ones(n,1),cdate];
```

Fit a linear regression to the data.

```
[b,bint,r] = regress(pop,x);
```

Test the null hypothesis that there is no autocorrelation among the residuals, r .

```
[p,d] = dwtest(r,x)
```

```
p =
```

```
0
```

```
d =
```

```
0.1308
```

The returned value $p = 0$ indicates rejection of the null hypothesis at the 5% significance level.

One-Sided Hypothesis Test

Load the sample census data.

```
load census
```

Create a design matrix using the census date (`cdate`) as the predictor. Add a column of 1 values to include a constant term.

```
n = length(cdate);  
x = [ones(n,1),cdate];
```

Fit a linear regression to the data.

```
[b,bint,r] = regress(pop,x);
```

Test the null hypothesis that there is no autocorrelation among regression residuals, against the alternative hypothesis that the autocorrelation is greater than zero.

```
[p,d] = dwtest(r,x,'Tail','right')
```

```
p =
```

```
0
```

```
d =  
    0.1308
```

The returned value $p = 0$ indicates rejection of the null hypothesis at the 5% significance level, in favor of the alternative hypothesis that the autocorrelation among residuals is greater than zero.

Input Arguments

x — Design matrix
matrix

Design matrix for a linear regression, specified as a matrix. Include a column of 1 values in the design matrix so the model contains a constant term.

Data Types: `single` | `double`

r — Regression residuals
vector

Regression residuals, specified as a vector. Obtain `r` by performing a linear regression using a function such as `regress`, or by using the backslash operator.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Tail','right','Method','approximate'` specifies a right-tailed hypothesis test and calculates the p-value using a normal approximation.

'Method' — Computation method for p-value
'exact' | 'approximate'

Computation method for the p -value, specified as the comma-separated pair consisting of 'Method' and one of the following.

- 'exact' Calculate an exact p -value using the Pan algorithm. This is the default if the sample size is less than 400.
- 'approximate' Calculate the p -value using a normal approximation. This is the default if the sample size is 400 or larger.

Example: 'Method', 'exact'

'Tail' — Type of alternative hypothesis

'both' (default) | 'right' | 'left'

Type of alternative hypothesis to evaluate, specified as the comma-separated pair consisting of 'Tail' and one of the following.

- 'both' Test the alternate hypothesis that autocorrelation among the residuals is not zero.
- 'right' Test the alternative hypothesis that autocorrelation among the residuals is greater than zero.
- 'left' Test the alternative hypothesis that autocorrelation among the residuals is less than zero.

Example: 'Tail', 'right'

Output Arguments

p — p -value

scalar value in the range [0,1]

p -value of the test, returned as a scalar value in the range [0,1]. p is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. Small values of p cast doubt on the validity of the null hypothesis.

d — Test statistic

nonnegative scalar value

Test statistic of the hypothesis test, returned as a nonnegative scalar value.

More About

Durbin-Watson Test

The Durbin-Watson test is used to test the null hypothesis that linear regression residuals are uncorrelated, against the alternative that autocorrelation exists.

The test statistic for the Durbin-Watson test is

$$d = \frac{\sum_{t=2}^T (e_t - e_{t-1})^2}{\sum_{t=1}^T e_t^2},$$

where T is the number of observations, and e_t is the residual at time t .

The p -value of the Durbin-Watson test is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. A significantly small p -value casts doubt on the validity of the null hypothesis and indicates correlation among residuals. The p -value can be calculated exactly using the Pan algorithm. Alternatively, the p -value can be estimated using a normal approximation.

See Also

regress

dwtest

Class: LinearModel

Durbin-Watson test of linear model

Syntax

```
P = dwtest mdl
[P,DW] = dwtest mdl
[P,DW] = dwtest mdl,method
[P,DW] = dwtest mdl,method,tail
```

Description

`P = dwtest(mdl)` returns the p -value of the Durbin-Watson test on the `mdl` linear model.

`[P,DW] = dwtest(mdl)` returns the Durbin-Watson statistic.

`[P,DW] = dwtest(mdl,method)` specifies the method `dwtest` uses to compute the p -value.

`[P,DW] = dwtest(mdl,method,tail)` specifies the alternative hypothesis.

Input Arguments

mdl

Linear model, as constructed by `fitlm` or `stepwiselm`.

method

Algorithm for computing the p -value:

- `'exact'` — Calculates an exact p -value using Pan's algorithm.
- `'approximate'` — Calculates the p -value using a normal approximation.

Default: `'exact'` when the sample size is less than 400, `'approximate'` otherwise

tail

`dwtest` tests whether `mdl` has no serial correlation against one of these alternative hypotheses:

Tail	Alternative Hypothesis
'both'	Serial correlation is not 0.
'right'	Serial correlation is greater than 0 (right-tailed test).
'left'	Serial correlation is less than 0 (left-tailed test).

Default: 'both'

Output Arguments

P

p-value of the test, a scalar. `dwtest` tests if the residuals are uncorrelated, against the alternative that there is autocorrelation among them. Small values of **P** indicate that the residuals are correlated.

DW

Value of the Durbin-Watson statistic, a scalar.

Definitions

Durbin-Watson Statistic

Let r be the vector of residuals (in `mdl.residuals.response`). The Durbin-Watson statistic is

$$DW = \frac{\sum_{i=1}^{n-1} (r_{i+1} - r_i)^2}{\sum_{i=1}^n r_i^2}.$$

Examples

Test Residuals for Autocorrelation

Examine whether the residuals from a fitted model of census data over time have autocorrelated residuals.

Load the census data and create a linear model.

```
load census
mdl = fitlm(cdate, pop);
```

Find the p -value of the Durbin-Watson autocorrelation test.

```
P = dwtest(mdl)
```

```
P =
```

```
0
```

There is significant autocorrelation in the residuals.

Algorithms

Approximate calculation of the p -value uses a normal approximation [1]. Exact calculation uses Pan's algorithm [2].

LinearModel

How To

- “Linear Regression” on page 9-11

ecdf

Empirical cumulative distribution function

Syntax

```
[f,x] = ecdf(y)
[f,x] = ecdf(y,Name,Value)
[f,x,flo,fup] = ecdf( ___ )
```

```
ecdf( ___ )
ecdf(ax, ___ )
```

Description

`[f,x] = ecdf(y)` returns the empirical cumulative distribution function (cdf), `f`, evaluated at the points in `x`, using the data in the vector `y`.

In survival and reliability analysis, this empirical cdf is called the Kaplan-Meier estimate. And the data might correspond to survival or failure times.

`[f,x] = ecdf(y,Name,Value)` returns the empirical function values, `f`, evaluated at the points in `x`, with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify the type of function to evaluate or which data is censored.

`[f,x,flo,fup] = ecdf(___)` also returns the 95% lower and upper confidence bounds for the evaluated function values. You can use any of the input arguments in the previous syntaxes.

`ecdf` computes the confidence bounds using Greenwood's formula. They are not simultaneous confidence bounds.

`ecdf(___)` plots the evaluated function.

`ecdf(ax, ___)` plots the evaluated function using axes with the handle, `ax`, instead of the current axes returned by `gca`.

Examples

Compute Empirical Cumulative Distribution Function

Compute the Kaplan-Meier estimate of the cumulative distribution function (cdf) for simulated survival data.

Generate survival data from a Weibull distribution with parameters 3 and 1.

```
rng default; % for reproducibility
failuretime = random('wbl',3,1,15,1);
```

Compute the Kaplan-Meier estimate of the cdf for survival data.

```
[f,x] = ecdf(failuretime);
[f,x]
```

```
ans =
```

Plot the estimated cdf.

```
figure()
plot(x,f)
```

Empirical Hazard Function of Right-Censored Data

Compute and plot the hazard function of simulated right-censored survival data.

Generate failure times from a Birnbaum-Saunders distribution.

```
rng default % for reproducibility
failuretime = random('birnbaumsaunders',0.3,1,100,1);
```

Assuming that the end of the study is at time 0.9, generate a logical array that indicates simulated failure times that are larger than 0.9 as censored data, and store this information in a vector.

```
T = 0.9;
```

```
cens = (failuretime>T);
```

Plot the empirical hazard function for the data.

```
ecdf(failuretime,'function','cumulative hazard',...
'censoring',cens,'bounds','on');
```

Compare Empirical Cumulative Distribution Function (CDF) with Known CDF

Generate right-censored survival data and compare the empirical cumulative distribution function (cdf) with the known cdf.

Generate failure times from an exponential distribution with mean failure time of 15.

```
rng default % for reproducibility
y = exprnd(15,75,1);
```

Generate drop-out times from an exponential distribution with mean failure time of 30.

```
d = exprnd(30,75,1);
```

Generate the observed failure times. They are the minimum of the generated failure times and the drop-out times.

```
t = min(y,d);
```

Create a logical array that indicates generated failure times that are larger than the drop-out times. The data for which this is true are censored.

```
censored = (y>d);
```

Compute the empirical cdf and confidence bounds.

```
[f,x,flo,fup] = ecdf(t,'censoring',censored);
```

Plot the cdf and confidence bounds.

```
figure()
ecdf(t,'censoring',censored,'bounds','on');
hold on
```

Superimpose a plot of the known population cdf.

```
xx = 0:.1:max(t);
yy = 1-exp(-xx/15);
plot(xx,yy,'g-','LineWidth',2)
axis([0 50 0 1])
legend('Empirical','LCB','UCB','Population',...
       'Location','SE')
hold off
```

Empirical Survivor Function with 99% Confidence Bounds

Generate survival data and plot the empirical survivor function with 99% confidence bounds.

Generate lifetime data from a Weibull distribution with parameters 100 and 2.

```
rng default % for reproducibility
R = wblrnd(100,2,100,1);
```

Plot the survivor function for the data with 99% confidence bounds.

```
ecdf(R, 'function', 'survivor', 'alpha', 0.01, 'bounds', 'on')
hold on
```

Fit the Weibull survivor function.

```
x = 1:1:250;
wblsurv = 1-cdf('weibull',x,100,2);
plot(x,wblsurv,'g-','LineWidth',2)
legend('Empirical','LCB','UCB','Population',...
'Location','NE')
```

The survivor function based on the actual distribution is within the confidence bounds.

Input Arguments

y — Input data

column vector

Input data, specified as a column vector. For example, in survival or reliability analysis, data might be survival or failure times for each item or individual.

Data Types: `single` | `double`

ax — Axes handle

handle

Axes handle for the figure `ecdf` plots to, specified as a handle.

For instance, if `h` is a handle for a figure, then `ecdf` can plot to that figure as follows.

Example: `ecdf(h,x)`

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Example: `'censoring',c,'function','cumulative hazard','alpha',0.025,'bounds','on'` specifies that `ecdf` returns the cumulative hazard function and plots the 97.5% confidence bounds, accounting for the censored data specified by vector `c`.

'censoring' — Indicator of censored data

array of 0s (default) | vector of 0s and 1s

Indicator of censored data, specified as the comma-separated pair including `'censoring'` and a Boolean array of the same size as `x`. Enter 1 for observations that are right-censored and 0 for observations that are fully observed. Default is all observations are fully observed.

For instance, if vector `cdata` stores the censored data information, you can enter the censoring information as follows.

Example: `'censoring',cdata`

Data Types: `logical`

'frequency' — Frequency of observations

array of 1s (default) | vector of nonnegative scalars

Frequency of observations, specified as the comma-separated pair consisting of `'frequency'` and a vector containing nonnegative integer counts. This vector is the same size as the vector `x`. The `j`th element of this vector gives the number of times the `j`th element of `x` was observed. Default is one observation per element of `x`.

For instance, if `failurefreq` is a vector of frequencies, then you can enter it as follows.

Example: `'frequency', failurefreq`

Data Types: `single | double`

'alpha' — Confidence level

0.05 (default) | scalar value in the range (0,1)

Confidence level for the confidence interval of the evaluated function, specified as the comma-separated pair consisting of `'alpha'` and a scalar value between in the range (0,1). Default is 0.05 for 95% confidence. For a given value `alpha`, the confidence level is $100(1 - \alpha)\%$.

For instance, for a 99% confidence interval, you can specify the alpha value as follows.

Example: `'alpha', 0.01`

Data Types: `single | double`

'function' — Type of function returned

`'cdf'` (default) | `'survivor'` | `'cumulative hazard'`

Type of function that `ecdf` evaluates and returns, specified as the comma-separated pair consisting of `'function'` and one of the following.

<code>'cdf'</code>	Default. Cumulative distribution function.
<code>'survivor'</code>	Survivor function.
<code>'cumulative hazard'</code>	Cumulative hazard function.

Example: `'function', 'cumulative hazard'`

Data Types: `char`

'bounds' — Indicator for including bounds

`'off'` (default) | `'on'`

Indicator for including bounds, specified as the comma-separated pair consisting of `'bounds'` and one of the following.

<code>'off'</code>	Default. Specify to omit bounds.
<code>'on'</code>	Specify to include bounds.

Note: This name-value argument is used only for plotting.

Example: 'bounds', 'on'

Data Types: char

Output Arguments

f — Function values

column vector

Function values evaluated at the points in **x**, returned as a column vector.

x — Distinct observed points

column vector

Distinct observed points in data vector **y**, returned as a column vector.

f1o — Lower confidence bound

column vector

Lower confidence bound for the evaluated function, returned as a column vector. **ecdf** computes the confidence bounds using Greenwood's formula. They are not simultaneous confidence bounds.

fup — Upper confidence bound

column vector

Upper confidence bound for the evaluated function, returned as a column vector. **ecdf** computes the confidence bounds using Greenwood's formula. They are not simultaneous confidence bounds.

More About

Greenwood's Formula

Approximation for the variance of Kaplan-Meier estimator.

The variance estimate is given by

$$V(S(t)) = S^2(t) \sum_{t_i < T} \frac{d_i}{r_i(r_i - d_i)},$$

where r_i is the number at risk at time t_i , and d_i is the number of failures at time t_i .

`cdfplot` | `ecdfhist`

ecdfhist

Histogram based on empirical cumulative distribution function

Syntax

```
[n,c] = ecdfhist(f,x)
[n,c] = ecdfhist(f,x,m)

n = ecdfhist(f,x,centers)

ecdfhist( ___ )
```

Description

`[n,c] = ecdfhist(f,x)` returns the heights, `n`, of histogram bars for 10 equally spaced bins and the position of the bin centers, `c`.

`ecdfhist` computes the bar heights from the increases in the empirical cumulative distribution function, `f`, at evaluation points, `x`. It normalizes the bar heights so that the area of the histogram is equal to 1. In contrast, `hist` produces bars with heights representing bin counts.

`[n,c] = ecdfhist(f,x,m)` returns the histogram bars using `m` bins.

`n = ecdfhist(f,x,centers)` returns the heights of the histogram bars with bin centers specified by `centers`.

`ecdfhist(___)` plots the histogram bars.

Examples

Return Histogram Bar Heights and Bin Centers

Compute the histogram bar heights based on the empirical cumulative distribution function.

Generate failure times from a Birnbaum-Saunders distribution.

```
rng('default') % for reproducibility
failuretime = random('birnbaumsaunders',0.3,1,100,1);
```

Assuming that the end of the study is at time 0.9, mark the generated failure times that are larger than 0.9 as censored data and store that information in a vector.

```
T = 0.9;
cens = (failuretime>T);
```

Compute the empirical cumulative distribution function for the data.

```
[f,x] = ecdf(failuretime,'censoring',cens);
```

Now, find the bar heights of the histogram using the cumulative distribution function estimate.

```
[n,c] = ecdfhist(f,x);
[n' c']
```

```
ans =
```

0.9412    0.6665
0.2353    0.7515
0.2353    0.8365
```

Return Bar Heights and Bin Centers for a Given Number of Bins

Compute the bar heights for six bins using the empirical cumulative distribution function and also return the bin centers.

Generate failure times from a Birnbaum-Saunders distribution.

```
rng('default') % for reproducibility
```

```
failuretime = random('birnbaumsaunders',0.3,1,100,1);
```

Assuming that the end of the study is at time 0.9, mark the generated failure times that are larger than 0.9 as censored data and store that information in a vector.

```
T = 0.9;
cens = (failuretime>T);
```

First, compute the empirical cumulative distribution function for the data.

```
[f,x] = ecdf(failuretime,'censoring',cens);
```

Now, estimate the histogram with six bins using the cumulative distribution function estimate.

```
[n,c] = ecdfhist(f,x,6);
[n' c']
```

```
ans =
```

```
1.9764    0.0998
1.7647    0.2415

0.4235    0.5248
0.7764    0.6665
0.2118    0.8081
```

Draw Histogram for Given Bin Centers

Draw the histogram of the empirical cumulative distribution histogram for specified bin centers.

Generate failure times from a Birnbaum-Saunders distribution.

```
rng default; % For reproducibility
failuretime = random('birnbaumsaunders',0.3,1,100,1);
```

Assuming that the end of the study is at time 0.9, mark the generated failure times that are larger than 0.9 as censored data and store that information in a vector.

```
T = 0.9;
cens = (failuretime>T);
```

Define bin centers.

```
centers = 0.1:0.1:1;
```

Compute the empirical cumulative distribution function for the data and draw the histogram for specified bin centers.

```
[f,x] = ecdf(failuretime,'censoring',cens);  
ecdfhist(f,x,centers)  
axis([0 1 0 2.5])
```

Compare Histogram with Known Probability Distribution Function

Generate right-censored survival data and compare the histogram from cumulative distribution function with the known probability distribution function.

Generate failure times from an exponential distribution with mean failure time of 15.

```
rng default; % For reproducibility  
y = exprnd(15,75,1);
```

Generate drop-out times from an exponential distribution with mean failure time of 30.

```
d = exprnd(30,75,1);
```

Record the minimum of these times as the observed failure times.

```
t = min(y,d);
```

Generate censoring by finding the generated failure times that are greater than the drop-out times.

```
censored = (y>d);
```

Calculate the empirical cdf and plot a histogram using the empirical cumulative distribution function.

```
[f,x] = ecdf(t,'censoring',censored);  
ecdfhist(f,x)  
h = findobj(gca,'Type','patch');  
h.FaceColor = [.8 .8 1];  
hold on
```

Superimpose a plot of the known population pdf.

```
xx = 0:.1:max(t);  
yy = exp(-xx/15)/15;  
plot(xx,yy,'r-','LineWidth',2)  
hold off
```

Input Arguments

f — Empirical cdf values

vector

Empirical cdf values at given evaluation points, **x**, specified as a vector.

For instance, you can use `ecdf` to obtain the empirical cdf values and enter them in `ecdfhist` as follows.

```
Example: [f,x] = ecdf(failure); ecdfhist(f,x);
```

Data Types: single | double

x — Evaluation points

vector

Evaluation points at which empirical cdf values, `f`, are calculated, specified as a vector.

For instance, you can use `ecdf` to obtain the empirical cdf values and enter them in `ecdfhist` as follows.

```
Example: [f,x] = ecdf(failure); ecdfhist(f,x);
```

Data Types: `single` | `double`

m — Number of bins

scalar

Number of bins, specified as a scalar.

For instance, you can draw a histogram with 8 bins as follows.

```
Example: ecdfhist(f,x,8)
```

Data Types: `single` | `double`

centers — Center points of bins

vector

Center points of bins, specified as a vector.

```
Example: centers = 2:2:10; ecdfhist(f,x,centers);
```

Data Types: `single` | `double`

Output Arguments

n — Heights of histogram bars

row vector

Heights of histogram bars `ecdfhist` calculates based on the empirical cdf values, returned as a row vector.

c — Position of bin centers

row vector

Position of bin centers, returned as a row vector.

edge

Class: ClassificationKNN

Edge of k -nearest neighbor classifier

Syntax

```
E = edge(md1, X, Y)
E = edge(md1, X, Y, Name, Value)
```

Description

`E = edge(md1, X, Y)` returns the classification edge for `md1` with data `X` and classification `Y`.

`E = edge(md1, X, Y, Name, Value)` computes the edge with additional options specified by one or more `Name, Value` pair arguments.

Input Arguments

md1 — Classifier model
classifier model object

k -nearest neighbor classifier model, returned as a classifier model object.

Note that using the `'CrossVal'`, `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'` options results in a model of class `ClassificationPartitionedModel`. You cannot use a partitioned tree for prediction, so this kind of tree does not have a `predict` method.

Otherwise, `md1` is of class `ClassificationKNN`, and you can use the `predict` method to make predictions.

X — Matrix of predictor values
matrix

Matrix of predictor values. Each column of X represents one variable, and each row represents one observation.

Y — Categorical variables

categorical array | cell array of strings | character array | logical vector | numeric vector

A categorical array, cell array of strings, character array, logical vector, or a numeric vector with the same number of rows as X . Each row of Y represents the classification of the corresponding row of X .

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

'weights'

Observation weights, a numeric vector of length `size(X,1)`. If you supply `weights`, `edge` computes weighted classification edge.

Default: `ones(size(X,1))`

Output Arguments

E

Classification edge, a scalar that is the mean classification margin (see “Margin” on page 21-970).

Definitions

Edge

The *edge* is the mean value of the classification *margin*.

Margin

The classification *margin* is the difference between the classification *score* for the true class and maximal classification score for the false classes.

Margin is a column vector with the same number of rows as X .

Score

The *score* of a classification is the posterior probability of the classification. The posterior probability is the number of neighbors that have that classification, divided by the number of neighbors. For a more detailed definition that includes weights and prior probabilities, see “Posterior Probability” on page 21-3315.

Examples

Edge Calculation

Construct a k -nearest neighbor classifier for the Fisher iris data, where $k = 5$.

Load the data.

```
load fisheriris
X = meas;
Y = species;
```

Construct a classifier for five-nearest neighbors.

```
mdl = fitcknn(X,Y,'NumNeighbors',5);
```

Examine the edge of the classifier for minimum, mean, and maximum observations classified 'setosa', 'versicolor', and 'virginica' respectively.

```
NewX = [min(X);mean(X);max(X)];
Y = {'setosa';'versicolor';'virginica'};
E = edge(mdl,NewX,Y)
```

```
E =
```

```
1
```

The classifier has no doubt that the Y entries are correct classifications (all five nearest neighbors of each NewX point classify as the corresponding Y entry).

See Also

`ClassificationKNN` | `fitcknn` | `loss` | `margin`

More About

- “Classification Using Nearest Neighbors” on page 16-8

edge

Class: CompactClassificationDiscriminant

Classification edge

Syntax

`E = edge(obj, X, Y)`

`E = edge(obj, X, Y, Name, Value)`

Description

`E = edge(obj, X, Y)` returns the classification edge for `obj` with data `X` and classification `Y`.

`E = edge(obj, X, Y, Name, Value)` computes the edge with additional options specified by one or more `Name, Value` pair arguments.

Input Arguments

`obj`

Discriminant analysis classifier of class `ClassificationDiscriminant` or `CompactClassificationDiscriminant`, typically constructed with `fitcdiscr`.

`X`

Matrix where each row represents an observation, and each column represents a predictor. The number of columns in `X` must equal the number of predictors in `obj`.

`Y`

Class labels, with the same data type as exists in `obj`. The number of elements of `Y` must equal the number of rows of `X`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

'weights'

Observation weights, a numeric vector of length `size(X,1)`. If you supply weights, `edge` computes the weighted classification edge.

Default: `ones(size(X,1))`

Output Arguments

E

Edge, a scalar representing the weighted average value of the margin.

Definitions

Edge

The *edge* is the weighted mean value of the classification *margin*. The weights are class prior probabilities. If you supply additional weights, those weights are normalized to sum to the prior probabilities in the respective classes, and are then used to compute the weighted average.

Margin

The classification *margin* is the difference between the classification *score* for the true class and maximal classification score for the false classes.

The classification margin is a column vector with the same number of rows as in the matrix `X`. A high value of margin indicates a more reliable prediction than a low value.

Score (discriminant analysis)

For discriminant analysis, the *score* of a classification is the posterior probability of the classification. For the definition of posterior probability in discriminant analysis, see “Posterior Probability” on page 15-7.

Examples

Compute the classification edge and margin for the Fisher iris data, trained on its first two columns of data, and view the last 10 entries:

```
load fisheriris
X = meas(:,1:2);
obj = fitcdiscr(X,species);
E = edge(obj,X,species)
```

```
E =
    0.4980
```

```
M = margin(obj,X,species);
M(end-10:end)
```

```
ans =
    0.6551
    0.4838
    0.6551
   -0.5127
    0.5659
    0.4611
    0.4949
    0.1024
    0.2787
   -0.1439
   -0.4444
```

The classifier trained on all the data is better:

```
obj = fitcdiscr(meas,species);
E = edge(obj,meas,species)
```

```
E =
    0.9454
```

```
M = margin(obj,meas,species);  
M(end-10:end)
```

```
ans =  
    0.9983  
    1.0000  
    0.9991  
    0.9978  
    1.0000  
    1.0000  
    0.9999  
    0.9882  
    0.9937  
    1.0000  
    0.9649
```

How To

- “Discriminant Analysis” on page 15-3

edge

Class: CompactClassificationECOC

Classification edge for error-correcting output code multiclass classifiers

Syntax

```
e = edge(Mdl,X,Y)
e = edge(Mdl,X,Y,Name,Value)
```

Description

`e = edge(Mdl,X,Y)` returns the classification edge (**e**) for the error-correcting output code (ECOC) multiclass classifier `Mdl` using predictor data `X` and class labels `Y`. Each row of `X` and `Y` is an observation.

`e = edge(Mdl,X,Y,Name,Value)` computes the classification edge with additional options specified by one or more `Name,Value` pair arguments.

For example, specify a decoding scheme, binary learner loss function, or verbosity level.

Input Arguments

Mdl — ECOC multiclass classifier

ClassificationECOC model | CompactClassificationECOC model

ECOC multiclass classifier, specified as a `ClassificationECOC` or `CompactClassificationECOC` model. You can create a:

- `ClassificationECOC` model by training the ECOC classifier using `fitcecoc`
- `CompactClassificationECOC` model by passing a `ClassificationECOC` classifier to `compact`

X — Predictor data

numeric matrix

Predictor data, specified as a numeric matrix.

Each row of X corresponds to one observation (also called an instance or example), and each column corresponds to one variable (also known as a feature). The variables composing the columns of X should be the same as the variables that trained the `Mdl` classifier.

The length of Y and the number of rows of X must be equal.

If you trained `Mdl` specifying to standardize the predictor data, then the software standardizes the columns of X using the corresponding means and standard deviations that the software stored in `Mdl.BinaryLearner{j}.Mu` and `Mdl.BinaryLearner{j}.Sigma` for learner j .

Data Types: `double` | `single`

Y — Class labels

categorical array | character array | logical vector | vector of numeric values | cell array of strings

Class labels, specified as a categorical or character array, logical or numeric vector, or cell array of strings. Y must be the same as the data type of `Mdl.ClassNames`.

The length of Y and the number of rows of X must be equal.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

'BinaryLoss' — Binary learner loss function

function handle | 'hamming' | 'linear' | 'exponential' | 'binodeviance' | 'hinge' | 'quadratic'

Binary learner loss function, specified as the comma-separated pair consisting of `'BinaryLoss'` and a function handle or string.

- If the value is a string, then it must correspond to a built-in function. This table summarizes the built-in functions, where y_j is a class label for a particular binary learner (in the set $\{-1, 1, 0\}$), s_j is the score for observation j , and $g(y_j, s_j)$ is the binary loss formula.

Value	Description	Score Domain	$g(y_i, s_i)$
'binodeviance'	Binomial deviance	$(-\infty, \infty)$	$\log[1 + \exp(-2y_i s_i)] / [2\log(2)]$
'exponential'	Exponential	$(-\infty, \infty)$	$\exp(-y_i s_i) / 2$
'hamming'	Hamming	$\{-1, 1\}$	$[1 - \text{sign}(y_i s_i)] / 2$
'hinge'	Hinge	$(-\infty, \infty)$	$\max(0, 1 - y_i s_i) / 2$
'linear'	Linear	$(-\infty, \infty)$	$(1 - y_i s_i) / 2$
'quadratic'	Quadratic	$[0, 1]$	$[1 - y_i(2s_i - 1)]^2 / 2$

The software normalizes the binary losses such that the loss is 0.5 when $y_j = 0$. Also, the software calculates the mean binary loss for each class.

- For a custom binary loss function, e.g., `customFunction`, specify its function handle `'BinaryLoss', @customFunction`.

`customFunction` should have this form

```
bLoss = customFunction(M,s)
```

where:

- M is the K -by- L coding matrix stored in `Mdl.CodingMatrix`.
- s is the 1-by- L row vector of classification scores.
- `bLoss` is the classification loss. This scalar aggregates the binary losses for every learner in a particular class. For example, you can use the mean binary loss to aggregate the loss over the learners for each class.
- K is the number of classes.
- L is the number of binary learners.

For an example on passing a custom binary loss function, see “Predict Test-Sample Labels of ECOC Models Using Custom Binary Loss Function”.

This list describes the default values of `BinaryLoss`. If all binary learners are:

- SVMs, then `BinaryLoss` is `'hinge'`
- Ensembles trained by `AdaboostM1` or `GentleBoost`, then `BinaryLoss` is `'exponential'`

- Ensembles trained by `LogitBoost`, then `BinaryLoss` is `'binodeviance'`
- Predicting class posterior probabilities (i.e., set `'FitPosterior',1` in `fitcecoc`), then `BinaryLoss` is `'quadratic'`

Otherwise, the default `BinaryLoss` is `'hamming'`.

Example: `'BinaryLoss','binodeviance'`

Data Types: `char` | `function_handle`

'Decoding' — Decoding scheme

`'lossweighted'` (default) | `'lossbased'`

Decoding scheme that aggregates the “binary losses”, specified as the comma-separated pair consisting of `'Decoding'` and `'lossweighted'` or `'lossbased'`.

Example: `'Decoding','lossbased'`

Data Types: `char`

'Options' — Estimation options

`[]` (default) | structure array returned by `statset`

Estimation options, specified as the comma-separated pair consisting of `'Options'` and a structure array returned by `statset`.

To invoke parallel computing:

- You need a Parallel Computing Toolbox license.
- Specify `'Options',statset('UseParallel',1)`.

'Verbose' — Verbosity level

`0` (default) | `1`

Verbosity level, specified as the comma-separated pair consisting of `'Verbose'` and `0` or `1`. `Verbose` controls the amount of diagnostic messages that the software displays in the Command Window.

If `Verbose` is `0`, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: `'Verbose',1`

Data Types: `single` | `double`

'Weights' — Observation weights`ones(size(X,1))` (default) | numeric vector

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and a numeric vector. `Weights` need the same length as the number of rows of `X`, i.e., `size(X,1)`. The software normalizes `Weights` to sum up to the value of the prior probability in the respective class.

If you supply weights, `edge` computes the weighted classification edge.

Output Arguments

e — Classification edge

scalar

Classification edge, returned as a scalar. `e` represents the (weighted) mean of the classification margins.

Definitions

Classification Edge

The *classification edge* is the weighted mean of the *classification margins*.

One way to choose among multiple classifiers, e.g., to perform feature selection, is to choose the classifier that yields the highest edge.

Classification Margin

The *classification margins* are, for each observation, the difference between the negative loss for the positive class and maximal negative loss among the negative classes. If the margins are on the same scale, then they serve as a classification confidence measure, i.e., among multiple classifiers, those that yield larger margins are better “[4]”.

Binary Loss

A *binary loss* is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Let:

- m_{kj} be element (k,j) of the coding design matrix M (i.e., the code corresponding to class k of binary learner j)
- s_j be the score of binary learner j for an observation
- g be the binary loss function
- \hat{k} be the predicted class for the observation

In *loss-based decoding* [3], the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j).$$

In *loss-weighted decoding* [3], the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \frac{\sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j)}{\sum_{j=1}^L |m_{kj}|}.$$

Allwein et al. [1] suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where y_j is a class label for a particular binary learner (in the set $\{-1,1,0\}$), s_j is the score for observation j , and $g(y_j, s_j)$.

Value	Description	Score Domain	$g(y_j, s_j)$
'binodeviance'	Binomial deviance	$(-\infty, \infty)$	$\log[1 + \exp(-2y_j s_j)] / [2\log(2)]$
'exponential'	Exponential	$(-\infty, \infty)$	$\exp(-y_j s_j) / 2$

Value	Description	Score Domain	$g(y_j, s_j)$
'hamming'	Hamming	$\{-1, 1\}$	$[1 - \text{sign}(y_j s_j)]/2$
'hinge'	Hinge	$(-\infty, \infty)$	$\max(0, 1 - y_j s_j)/2$
'linear'	Linear	$(-\infty, \infty)$	$(1 - y_j s_j)/2$
'quadratic'	Quadratic	$[0, 1]$	$[1 - y_j(2s_j - 1)]^2/2$

The software normalizes the binary losses such that the loss is 0.5 when $y_j = 0$, and aggregates using the average of the binary learners [1].

Do not confuse the binary loss with the overall classification loss (specified by the LossFun name-value pair argument of `predict` and `loss`), e.g., classification error, which measures how well an ECOC classifier performs as a whole.

Examples

Estimate the Test-Sample Edge of ECOC Models

Load Fisher's iris data set.

```
load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y); % Class order
rng(1); % For reproducibility
```

Train an ECOC model using SVM binary classifiers and specify a 30% holdout sample. It is good practice to standardize the predictors and define the class order. Specify to standardize the predictors using an SVM template.

```
t = templateSVM('Standardize', 1);
CVMdl = fitcecoc(X, Y, 'Holdout', 0.30, 'Learners', t, 'ClassNames', classOrder);
CMdl = CVMdl.Trained{1}; % Extract trained, compact classifier
testInds = test(CVMdl.Partition); % Extract the test indices
XTest = X(testInds, :);
YTest = Y(testInds, :);
```

CVMdl is a `ClassificationPartitionedECOC` model. It contains the property `Trained`, which is a 1-by-1 cell array holding a `CompactClassificationECOC` model that the software trained using the training set.

Estimate the test-sample edge.

```
e = edge(CMdl,XTest,YTest)
```

```
e =
```

```
0.4573
```

The estimated test sample margin average is approximately 0.45.

Estimate the Test-Sample Weighted Margin Mean of ECOC Models

Load Fisher's iris data set.

```
load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y); % Class order
rng(1); % For reproducibility
```

Suppose that the observations were measured sequentially, and that the last 75 observations were better quality due to a technology upgrade. One way to incorporate this advancement is to weigh the better quality observations more than the other observations.

Define a weight vector that weighs the better quality observations two times the other observations.

```
n = size(X,1);
weights = [ones(n-75,1);2*ones(75,1)];
```

Train an ECOC model using SVM binary classifiers and specify a 30% holdout sample and the weighting scheme. It is good practice to standardize the predictors and define the class order. Specify to standardize the predictors using an SVM template.

```
t = templateSVM('Standardize',1);
CMdl = fitcecoc(X,Y,'Holdout',0.30,'Learners',t,...
'Weights',weights,'ClassNames',classOrder);
CMdl = CMdl.Trained{1}; % Extract trained, compact classifier
testInds = test(CMdl.Partition); % Extract the test indices
XTest = X(testInds,:);
YTest = Y(testInds,:);
wTest = weights(testInds,:);
```

`CVMD1` is a trained `ClassificationPartitionedECOC` model. It contains the property `Trained`, which is a 1-by-1 cell array holding a `CompactClassificationECOC` classifier that the software trained using the training set.

Estimate the test-sample weighted edge using the weighting scheme.

```
e = edge(CMD1,XTest,YTest,'Weights',wTest)
```

```
e =
```

```
0.4798
```

The test sample weighted average margin is approximately 0.48.

Select ECOC Model Features by Comparing Test-Sample Edges

The classifier edge measures the average of the classifier margins. One way to perform feature selection is to compare test-sample edges from multiple models. Based solely on this criterion, the classifier with the highest edge is the best classifier.

Load Fisher's iris data set.

```
load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y); % Class order
rng(1); % For reproducibility
```

Partition the data set into training and test sets. Specify a 30% holdout sample for testing.

```
Partition = cvpartition(Y,'Holdout',0.30);
testInds = test(Partition); % Indices for the test set
XTest = X(testInds,:);
YTest = Y(testInds,:);
```

`Partition` defines the data set partition.

Define these two data sets:

- `fullX` contains all predictors.
- `partX` contains the petal dimensions.

```
fullX = X;
```

```
partX = X(:,3:4);
```

Train an ECOC model using SVM binary classifiers for each predictor set, and specify the partition definition. It is good practice to standardize the predictors and define the class order. Specify to standardize the predictors using an SVM template.

```
t = templateSVM('Standardize',1);
CVMdl = fitcecoc(fullX,Y,'CVPartition',Partition,'Learners',t,...
    'ClassNames',classOrder);
PCVMdl = fitcecoc(partX,Y,'CVPartition',Partition,'Learners',t,...
    'ClassNames',classOrder);
CMdl = CVMdl.Trained{1};
PCMdl = PCVMdl.Trained{1};
```

CVMdl and PCVMdl are `ClassificationPartitionedECOC` models. They contain the property `Trained`, which is a 1-by-1 cell array holding a `CompactClassificationECOC` model that the software trained using the training set.

Estimate the test sample edge for each classifier.

```
fullEdge = edge(CMdl,XTest,YTest)
partEdge = edge(PCMdl,XTest(:,3:4),YTest)
```

```
fullEdge =
```

```
    0.4573
```

```
partEdge =
```

```
    0.4839
```

PCMdl achieves an edge that resembles the more complex model CMdl.

- “Quick Start Parallel Computing for Statistics Toolbox” on page 20-2

Tip

To compare margins or edges of several classifiers, use template objects to specify a common score transform function among the classifiers when you train them using `fitcecoc`.

edge

Class: CompactClassificationEnsemble

Classification edge

Syntax

`E = edge(ens, X, Y)`

`E = edge(ens, X, Y, Name, Value)`

Description

`E = edge(ens, X, Y)` returns the classification edge for `ens` with data `X` and classification `Y`.

`E = edge(ens, X, Y, Name, Value)` computes the edge with additional options specified by one or more `Name, Value` pair arguments.

Input Arguments

ens

A classification ensemble constructed with `fitensemble`, or a compact classification ensemble constructed with `compact`.

X

A matrix where each row represents an observation, and each column represents a predictor. The number of columns in `X` must equal the number of predictors in `ens`.

Y

Class labels, with the same data type as exists in `ens`. The number of elements of `Y` must equal the number of rows of `X`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

'learners'

Indices of weak learners in the ensemble ranging from 1 to `ens.NumTrained`. `edge` uses only these learners for calculating loss.

Default: `1:NumTrained`

'mode'

String representing the meaning of the output `E`:

- 'ensemble' — `E` is a scalar value, the edge for the entire ensemble.
- 'individual' — `E` is a vector with one element per trained learner.
- 'cumulative' — `E` is a vector in which element `J` is obtained by using learners `1:J` from the input list of learners.

Default: 'ensemble'

'UseObsForLearner'

A logical matrix of size `N`-by-`T`, where:

- `N` is the number of rows of `X`.
- `T` is the number of weak learners in `ens`.

When `UseObsForLearner(i, j)` is true, learner `j` is used in predicting the class of row `i` of `X`.

Default: `true(N,T)`

'weights'

Observation weights, a numeric vector of length `size(X,1)`. If you supply weights, `edge` computes weighted classification edge.

Default: `ones(size(X,1))`

Output Arguments

E

The classification edge, a vector or scalar depending on the setting of the `mode` name-value pair. Classification edge is weighted average classification margin.

Definitions

Margin

The classification *margin* is the difference between the classification *score* for the true class and maximal classification score for the false classes. Margin is a column vector with the same number of rows as in the matrix X .

Score (ensemble)

For ensembles, a classification *score* represents the confidence of a classification into a class. The higher the score, the higher the confidence.

Different ensemble algorithms have different definitions for their scores. Furthermore, the range of scores depends on ensemble type. For example:

- AdaBoostM1 scores range from $-\infty$ to ∞ .
- Bag scores range from 0 to 1.

Edge

The *edge* is the weighted mean value of the classification margin. The weights are the class probabilities in `ens.Prior`. If you supply weights in the `weights` name-value pair, those weights are used instead of class probabilities.

Examples

Make a boosted ensemble classifier for the `ionosphere` data, and find the classification edge for the last few rows:

```
load ionosphere
ens = fitensemble(X,Y,'AdaboostM1',100,'Tree');
E = edge(ens,X(end-10:end,:),Y(end-10:end))
```

```
E =
    8.3310
```

See Also

margin | edge

edge

Class: CompactClassificationNaiveBayes

Classification edge for naive Bayes classifiers

Syntax

```
e = edge(Mdl, X, Y)
e = edge(Mdl, X, Y, Name, Value)
```

Description

`e = edge(Mdl, X, Y)` returns the classification edge (**e**) for the naive Bayes classifier `Mdl` using predictor data `X` and class labels `Y`.

`e = edge(Mdl, X, Y, Name, Value)` computes the classification edge with additional options specified by one or more `Name, Value` pair arguments.

Input Arguments

Mdl — Naive Bayes classifier

`ClassificationNaiveBayes model` | `CompactClassificationNaiveBayes model`

Naive Bayes classifier, specified as a `ClassificationNaiveBayes` model or `CompactClassificationNaiveBayes` model returned by `fitcnb` or `compact`, respectively.

X — Predictor data

`numeric matrix`

Predictor data, specified as a numeric matrix.

Each row of `X` corresponds to one observation (also known as an instance or example), and each column corresponds to one variable (also known as a feature). The variables making up the columns of `X` should be the same as the variables that trained `Mdl`.

The length of `Y` and the number of rows of `X` must be equal.

Data Types: `double` | `single`

Y — Class labels

categorical array | character array | logical vector | vector of numeric values | cell array of strings

Class labels, specified as a categorical or character array, logical or numeric vector, or cell array of strings. `Y` must be the same as the data type of `Mdl.ClassNames`.

The length of `Y` and the number of rows of `X` must be equal.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

'Weights' — Observation weights

`ones(size(X,1),1)` (default) | numeric vector

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and a numeric vector.

The size of `Weights` must be equal to the number of rows of `X`. The software weighs the observations in each row of `X` with the corresponding weight in `Weights`.

If you do not specify your own loss function, then the software normalizes `Weights` to add up to 1.

Data Types: `double`

Output Arguments

e — Classification edge

scalar

“Classification edge”, returned as a scalar. If you supply `Weights`, then `e` is the weighted classification edge.

Definitions

Classification Edge

The *classification edge* is the weighted mean of the classification margins.

If you supply weights, then the software normalizes them to sum to the prior probability of their respective class. The software uses the normalized weights to compute the weighted mean.

One way to choose among multiple classifiers, e.g., to perform feature selection, is to choose the classifier that yields the highest edge.

Classification Margins

The *classification margins* are, for each observation, the difference between the score for the true class and maximal score for the false classes. Provided that they are on the same scale, margins serve as a classification confidence measure, i.e., among multiple classifiers, those that yield larger margins are better “[2]”.

Posterior Probability

The *posterior probability* is the probability that an observation belongs in a particular class, given the data.

For naive Bayes, the posterior probability that a classification is k for a given observation (x_1, \dots, x_p) is

$$\hat{P}(Y = k | x_1, \dots, x_p) = \frac{P(X_1, \dots, X_p | y = k) \pi(Y = k)}{P(X_1, \dots, X_p)},$$

where:

- $P(X_1, \dots, X_p | y = k)$ is the conditional joint density of the predictors given they are in class k . `Mdl.DistributionNames` stores the distribution names of the predictors.
- $\pi(Y = k)$ is the class prior probability distribution. `Mdl.Prior` stores the prior distribution.

- $P(X_1, \dots, X_P)$ is the joint density of the predictors. The classes are discrete, so

$$P(X_1, \dots, X_P) = \sum_{k=1}^K P(X_1, \dots, X_P | y = k) \pi(Y = k).$$

Prior Probability

The *prior probability* is the believed relative frequency that observations from a class occur in the population for each class.

Score

The naive Bayes *score* is the class posterior probability given the observation.

Examples

Estimate the Test Sample Edge of Naive Bayes Classifiers

Load Fisher's iris data set.

```
load fisheriris
X = meas;      % Predictors
Y = species;  % Response
rng(1);       % For reproducibility
```

Train a naive Bayes classifier. Specify a 30% holdout sample for testing. It is good practice to specify the class order. Assume that each predictor is conditionally, normally distributed given its label.

```
CVMD1 = fitcnb(X, Y, 'Holdout', 0.30, ...
    'ClassNames', {'setosa', 'versicolor', 'virginica'});
CMD1 = CVMD1.Trained{1};           % Extract trained, compact classifier
testInds = test(CVMD1.Partition); % Extract the test indices
XTest = X(testInds, :);
YTest = Y(testInds);
```

CVMD1 is a `ClassificationPartitionedModel` classifier. It contains the property `Trained`, which is a 1-by-1 cell array holding a `CompactClassificationNaiveBayes` classifier that the software trained using the training set.

Estimate the test sample edge.

```
e = edge(CMdl,XTest,YTest)
```

```
e =
```

```
0.8244
```

The estimated test sample margin average is approximately 0.82. This indicates that, on average, the test sample difference between the estimated posterior probability for the predicted class and the posterior probability for the class with the next lowest posterior probability is approximately 0.82. This indicates that the classifier labels with high confidence.

Estimate the Test Sample Weighted Margin Mean of Naive Bayes Classifiers

Load Fisher's iris data set.

```
load fisheriris
X = meas; % Predictors
Y = species; % Response
rng(1);
```

Suppose that the setosa iris measurements are lower quality because they were measured with an older technology. One way to incorporate this is to weigh the setosa iris measurements less than the other observations.

Define a weight vector that weighs the better quality observations twice the other observations.

```
n = size(X,1);
idx = strcmp(Y,'setosa');
weights = ones(size(X,1),1);
weights(idx) = 0.5;
```

Train a naive Bayes classifier. Specify the weighting scheme and a 30% holdout sample for testing. It is good practice to specify the class order. Assume that each predictor is conditionally, normally distributed given its label.

```
CVMDL = fitcnb(X,Y,'Weights',weights,'Holdout',0.30,...
    'ClassNames',{'setosa','versicolor','virginica'});
CMdl = CVMDL.Trained{1}; % Extract trained, compact classifier
testInds = test(CVMDL.Partition); % Extract the test indices
XTest = X(testInds,:);
```

```
YTest = Y(testInds);  
wTest = weights(testInds);
```

CVMdl is a `ClassificationPartitionedModel` classifier. It contains the property `Trained`, which is a 1-by-1 cell array holding a `CompactClassificationNaiveBayes` classifier that the software trained using the training set.

Estimate the test sample weighted edge using the weighting scheme.

```
e = edge(CMdl,XTest,YTest,'Weights',wTest)
```

```
e =  
  
    0.7893
```

The test sample weighted average margin is approximately 0.79. This indicates that, on average, the test sample difference between the estimated posterior probability for the predicted class and the posterior probability for the class with the next lowest posterior probability is approximately 0.79. This indicates that the classifier labels with high confidence.

Select Naive Bayes Classifier Features by Comparing Test Sample Edges

The classifier edge measures the average of the classifier margins. One way to perform feature selection is to compare test sample edges from multiple models. Based solely on this criterion, the classifier with the highest edge is the best classifier.

Load Fisher's iris data set.

```
load fisheriris  
X = meas;    % Predictors  
Y = species; % Response  
rng(1);
```

Partition the data set into training and test sets. Specify a 30% holdout sample for testing.

```
Partition = cvpartition(Y,'Holdout',0.30);  
testInds = test(Partition); % Indices for the test set  
XTest = X(testInds,:);  
YTest = Y(testInds,:);
```

Partition defines the data set partition.

Define these two data sets:

- `fullX` contains all predictors.
- `partX` contains the last two predictors.

```
fullX = X;
partX = X(:,3:4);
```

Train naive Bayes classifiers for each predictor set. Specify the partition definition.

```
FCVMdl = fitcnb(fullX,Y,'CVPartition',Partition);
PCVMdl = fitcnb(partX,Y,'CVPartition',Partition);
FCMdl = FCVMdl.Trained{1};
PCMdl = PCVMdl.Trained{1};
```

`FCVMdl` and `PCVMdl` are `ClassificationPartitionedModel` classifiers. They contain the property `Trained`, which is a 1-by-1 cell array holding a `CompactClassificationNaiveBayes` classifier that the software trained using the training set.

Estimate the test sample edge for each classifier.

```
fullEdge = edge(FCMdl,XTest,YTest)
partEdge = edge(PCMdl,XTest(:,3:4),YTest)
```

```
fullEdge =
    0.8244
```

```
partEdge =
    0.8420
```

The test-sample edges of the classifiers are nearly the same. However, the model trained using two predictors (`PCMdl`) is less complex.

edge

Class: CompactClassificationSVM

Classification edge for support vector machine classifiers

Syntax

```
e = edge(SVMModel, X, Y)
e = edge(SVMModel, X, Y, Name, Value)
```

Description

`e = edge(SVMModel, X, Y)` returns the classification edge (**e**) for the support vector machine (SVM) classifier `SVMModel` using predictor data `X` and class labels `Y`.

`e = edge(SVMModel, X, Y, Name, Value)` computes the classification edge with additional options specified by one or more `Name, Value` pair arguments.

Input Arguments

SVMModel — SVM classifier

ClassificationSVM classifier | CompactClassificationSVM classifier

SVM classifier, specified as a `ClassificationSVM` classifier or `CompactClassificationSVM` classifier returned by `fitcsvm` or `compact`, respectively.

X — Predictor data

numeric matrix

Predictor data, specified as a numeric matrix.

Each row of `X` corresponds to one observation (also known as an instance or example), and each column corresponds to one variable (also known as a feature). The variables making up the columns of `X` should be the same as the variables that trained the `SVMModel` classifier.

The length of `Y` and the number of rows of `X` must be equal.

If you set `'Standardize', true` in `fitcsvm` to train `SVMModel`, then the software standardizes the columns of `X` using the corresponding means in `SVMModel.Mu` and standard deviations in `SVMModel.Sigma`.

Data Types: `double` | `single`

Y — Class labels

categorical array | character array | logical vector | vector of numeric values | cell array of strings

Class labels, specified as a categorical or character array, logical or numeric vector, or cell array of strings. `Y` must be the same as the data type of `SVMModel.ClassNames`.

The length of `Y` and the number of rows of `X` must be equal.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

'Weights' — Observation weights

`ones(size(X,1))` (default) | numeric vector

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and a numeric vector. `Weights` must have the same length as the number of rows of `X`, i.e., `size(X,1)`.

If you supply weights, `edge` computes the weighted classification edge.

Output Arguments

e — Classification edge

scalar

Classification edge, returned as a scalar. `e` represents the (weighted) mean of the classification margins.

Definitions

Classification Edge

The *edge* is the weighted mean of the *classification margins*.

The weights are the prior class probabilities. If you supply weights, then the software normalizes them to sum to the prior probabilities in the respective classes. The software uses the renormalized weights to compute the weighted mean.

One way to choose among multiple classifiers, e.g., to perform feature selection, is to choose the classifier that yields the highest edge.

Classification Margins

The *classification margins* are, for each observation, the difference between the score for the true class and maximal score for the false classes. Provided that they are on the same scale, margins serve as a classification confidence measure, i.e., among multiple classifiers, those that yield larger margins are better “[2]”.

Score

The SVM *score* for classifying observation x is the signed distance from x to the decision boundary ranging from $-\infty$ to $+\infty$. A positive score for a class indicates that x is predicted to be in that class, a negative score indicates otherwise.

The score is also the numerical, predicted response for x , $f(x)$, computed by the trained SVM classification function

$$f(x) = \sum_{j=1}^n \alpha_j y_j G(x_j, x) + b,$$

where $(\alpha_1, \dots, \alpha_n, b)$ are the estimated SVM parameters, $G(x_j, x)$ is the dot product in the predictor space between x and the support vectors, and the sum includes the training set observations.

Examples

Estimate the Test Sample Edge of SVM Classifiers

Load the `ionosphere` data set.

```
load ionosphere
rng(1); % For reproducibility
```

Train an SVM classifier. Specify a 15% holdout sample for testing. It is good practice to specify the class order and standardize the data.

```
CVSVMModel = fitcsvm(X,Y,'Holdout',0.15,'ClassNames',{'b','g'},...
    'Standardize',true);
CompactSVMModel = CVSVMModel.Trained{1}; % Extract trained, compact classifier
testInds = test(CVSVMModel.Partition); % Extract the test indices
XTest = X(testInds,:);
YTest = Y(testInds,:);
```

`CVSVMModel` is a `ClassificationPartitionedModel` classifier. It contains the property `Trained`, which is a 1-by-1 cell array holding a `CompactClassificationSVM` classifier that the software trained using the training set.

Estimate the test sample edge.

```
e = edge(CompactSVMModel,XTest,YTest)
```

```
e =
    5.0765
```

The estimated test sample margin average is approximately 5.

Estimate the Test Sample Weighted Margin Mean of SVM Classifiers

Load the `ionosphere` data set.

```
load ionosphere
rng(1); % For reproducibility
```

Suppose that the observations were measured sequentially, and that the last 150 observations were better quality due to a technology upgrade. One way to incorporate

this advancement is to weigh the better quality observations more than the other observations.

Define a weight vector that weighs the better quality observations two times the other observations.

```
n = size(X,1);
weights = [ones(n-150,1);2*ones(150,1)];
```

Train an SVM classifier. Specify the weighting scheme and a 15% holdout sample for testing. It is good practice to specify the class order and standardize the data.

```
CVSVMModel = fitcsvm(X,Y,'Weights',weights,'Holdout',0.15,...
    'ClassNames',{'b','g'],'Standardize',true);
CompactSVMModel = CVSVMModel.Trained{1};
testInds = test(CVSVMModel.Partition); % Extract the test indices
XTest = X(testInds,:);
YTest = Y(testInds,:);
wTest = weights(testInds,:);
```

CVSVMModel is a trained `ClassificationPartitionedModel` classifier. It contains the property `Trained`, which is a 1-by-1 cell array holding a `CompactClassificationSVM` classifier that the software trained using the training set.

Estimate the test sample weighted edge using the weighting scheme.

```
e = edge(CompactSVMModel,XTest,YTest,'Weights',wTest)
```

```
e =
```

```
4.8341
```

The test sample weighted average margin is approximately 5.

Select SVM Classifier Features by Comparing Test Sample Edges

The classifier edge measures the average of the classifier margins. One way to perform feature selection is to compare test sample edges from multiple models. Based solely on this criterion, the classifier with the highest edge is the best classifier.

Load the ionosphere data set.

```
load ionosphere
```

```
rng(1); % For reproducibility
```

Partition the data set into training and test sets. Specify a 15% holdout sample for testing.

```
Partition = cvpartition(Y, 'Holdout', 0.15);  
testInds = test(Partition); % Indices for the test set  
XTest = X(testInds,:);  
YTest = Y(testInds,:);
```

Partition defines the data set partition.

Define these two data sets:

- `fullX` contains all predictors (except the removed column of 0s).
- `partX` contains the last 20 predictors.

```
fullX = X;  
partX = X(:, end-20:end);
```

Train SVM classifiers for each predictor set. Specify the partition definition.

```
FullCVSVMModel = fitcsvm(fullX, Y, 'CVPartition', Partition);  
PartCVSVMModel = fitcsvm(partX, Y, 'CVPartition', Partition);  
FCSVMModel = FullCVSVMModel.Trained{1};  
PCSVMModel = PartCVSVMModel.Trained{1};
```

`FullCVSVMModel` and `PartCVSVMModel` are `ClassificationPartitionedModel` classifiers. They contain the property `Trained`, which is a 1-by-1 cell array holding a `CompactClassificationSVM` classifier that the software trained using the training set.

Estimate the test sample edge for each classifier.

```
fullEdge = edge(FCSVMModel, XTest, YTest)  
partEdge = edge(PCSVMModel, XTest(:, end-20:end), YTest)
```

```
fullEdge =  
  
    2.8319
```

```
partEdge =
```

1.5540

The edge for the classifier trained on the complete data set is greater, suggesting that the classifier trained using all of the predictors is better.

Algorithms

For binary classification, the software defines the margin for observation j , m_j , as

$$m_j = 2y_j f(x_j),$$

where $y_j \in \{-1, 1\}$, and $f(x_j)$ is the predicted score of observation j for the positive class. However, the literature commonly uses $m_j = y_j f(x_j)$ to define the margin.

edge

Class: CompactClassificationTree

Classification edge

Syntax

`E = edge(tree,X,Y)`

`E = edge(tree,X,Y,Name,Value)`

Description

`E = edge(tree,X,Y)` returns the classification edge for `tree` with data `X` and classification `Y`.

`E = edge(tree,X,Y,Name,Value)` computes the edge with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

tree

A classification tree created by `fitctree`, or a compact classification tree created by `compact`.

X

A matrix where each row represents an observation, and each column represents a predictor. The number of columns in `X` must equal the number of predictors in `tree`.

Y

Class labels, with the same data type as exists in `tree`. The number of elements of `Y` must equal the number of rows of `X`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

'weights'

Observation weights, a numeric vector of length `size(X,1)`. If you supply weights, `edge` computes weighted classification edge.

Default: `ones(size(X,1))`

Output Arguments

E

The edge, a scalar representing the weighted average value of the margin.

Definitions

Margin

The classification *margin* is the difference between the classification *score* for the true class and maximal classification score for the false classes. Margin is a column vector with the same number of rows as the matrix `X`.

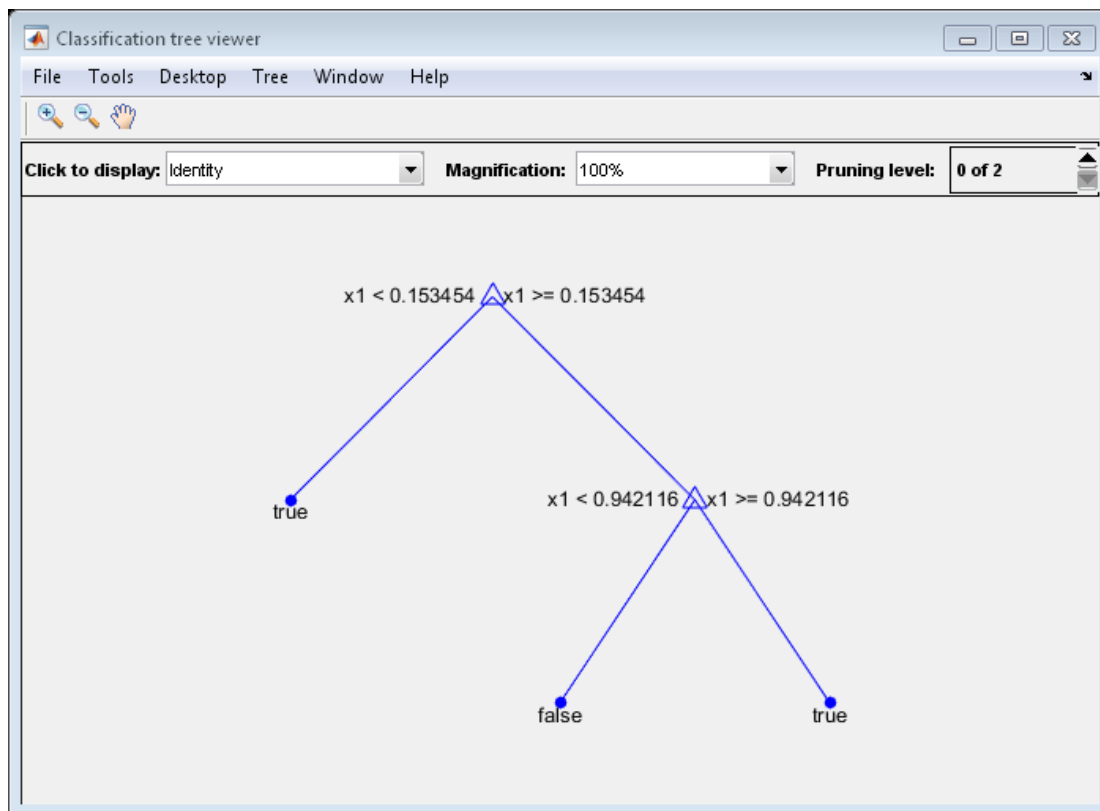

Score (tree)

For trees, the *score* of a classification of a leaf node is the posterior probability of the classification at that node. The posterior probability of the classification at a node is the number of training sequences that lead to that node with the classification, divided by the number of training sequences that lead to that node.

For example, consider classifying a predictor `X` as `true` when `X < 0.15` or `X > 0.95`, and `X` is false otherwise.

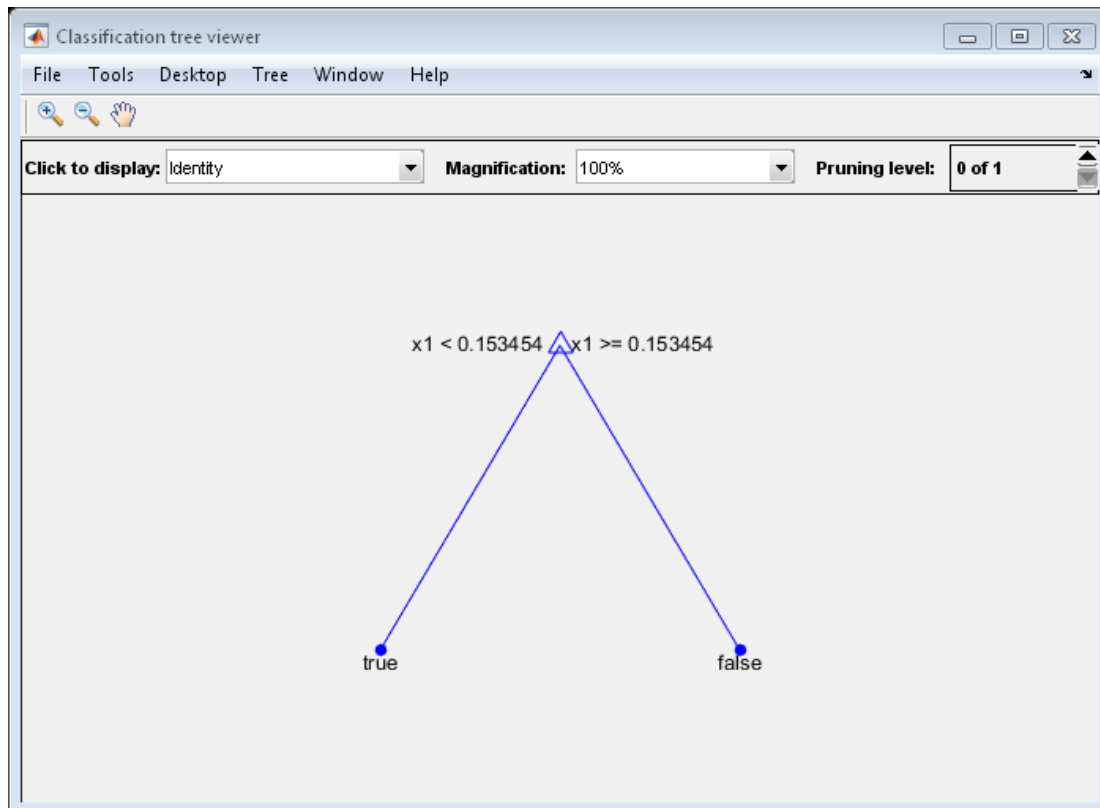

Generate 100 random points and classify them:

```
rng(0,'twister') % for reproducibility
X = rand(100,1);
Y = (abs(X - .55) > .4);
tree = fitctree(X,Y);
view(tree,'Mode','Graph')
```

Prune the tree:

```
tree1 = prune(tree,'Level',1);
view(tree1,'Mode','Graph')
```

The pruned tree correctly classifies observations that are less than 0.15 as **true**. It also correctly classifies observations from .15 to .94 as **false**. However, it incorrectly classifies observations that are greater than .94 as **false**. Therefore, the score for observations that are greater than .15 should be about $.05/.85=.06$ for **true**, and about $.8/.85=.94$ for **false**.

Compute the prediction scores for the first 10 rows of X:

```
[~,score] = predict(tree1,X(1:10));
[score X(1:10,:)]
```

ans =

```
0.9059    0.0941    0.8147
```

```
0.9059    0.0941    0.9058
         0    1.0000    0.1270
0.9059    0.0941    0.9134
0.9059    0.0941    0.6324
         0    1.0000    0.0975
0.9059    0.0941    0.2785
0.9059    0.0941    0.5469
0.9059    0.0941    0.9575
0.9059    0.0941    0.9649
```

Indeed, every value of X (the right-most column) that is less than 0.15 has associated scores (the left and center columns) of 0 and 1, while the other values of X have associated scores of 0.91 and 0.09. The difference (score 0.09 instead of the expected .06) is due to a statistical fluctuation: there are 8 observations in X in the range (.95, 1) instead of the expected 5 observations.

Edge

The *edge* is the weighted mean value of the classification margin. The weights are the class probabilities in `tree.Prior`. If you supply weights in the `weights` name-value pair, those weights are normalized to sum to the prior probabilities in the respective classes, and are then used to compute the weighted average.

Examples

Compute the classification margin and edge for the Fisher iris data, trained on its first two columns of data, and view the last 10 entries:

```
load fisheriris
X = meas(:,1:2);
tree = fitctree(X,species);
E = edge(tree,X,species)

E =
    0.6299

M = margin(tree,X,species);
M(end-10:end)

ans =
```

```
0.1111
0.1111
0.1111
-0.2857
0.6364
0.6364
0.1111
0.7500
1.0000
0.6364
0.2000
```

The classification tree trained on all the data is better.

```
tree = fitctree(meas,species);
E = edge(tree,meas,species)
```

```
E =
    0.9384
```

```
M = margin(tree,meas,species);
M(end-10:end)
```

```
ans =
    0.9565
    0.9565
    0.9565
    0.9565
    0.9565
    0.9565
    0.9565
    0.9565
    0.9565
    0.9565
```

end

Class: dataset

Last index in indexing expression for dataset array

Compatibility

The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

Syntax

`end(A, k, n)`

Description

`end(A, k, n)` is called for indexing expressions involving the dataset `A` when `end` is part of the `k`-th index out of `n` indices. For example, the expression `A(end-1, :)` calls `A`'s `end` method with `end(A, 1, 2)`.

See Also

`size`

end

Class: grandset

Last index in indexing expression for point set

Syntax

`end(p, k, n)`

Description

`end(p, k, n)` is called for indexing expressions involving the point set `p` when `end` is part of the `k`-th index out of `n` indices. For example, the expression `p(end-1, :)` calls `p`'s `end` method with `end(p, 1, 2)`.

See Also

grandset

epsilon

Class: RepeatedMeasuresModel

Epsilon adjustment for repeated measures anova

Syntax

```
tbl = epsilon(rm)
tbl = epsilon(rm,C)
```

Description

`tbl = epsilon(rm)` returns the epsilon adjustment factors for repeated measures model `rm`.

`tbl = epsilon(rm,C)` returns the epsilon adjustment factors for the test based on the contrast matrix `C`.

Tips

- The `mauchly` method tests for sphericity.
- The `ranova` method contains p -values based on each epsilon value.

Input Arguments

rm — Repeated measures model
RepeatedMeasuresModel object

Repeated measures model, returned as a `RepeatedMeasuresModel` object.

For properties and methods of this object, see `RepeatedMeasuresModel`.

C — Contrasts
matrix

Contrasts, specified as a matrix. The default value of `C` is the `Q` factor in a QR decomposition of the matrix `M`, where `M` is defined so that `Y*M` is the difference between all successive pairs of columns of the repeated measures matrix `Y`.

Data Types: `single` | `double`

Output Arguments

tbl — Epsilon adjustment factors

table

Epsilon adjustment factors for the repeated measures model `rm`, returned as a table. `tbl` contains four different adjustments for `epsilon`.

Correction	Definition
Uncorrected	No adjustments, <code>epsilon = 1</code>
Greenhouse-Geiser	Greenhouse-Geiser approximation
Huynh-Feldt	Huynh-Feldt approximation
Lower bound	Lower bound on the p -value

For details, see “Compound Symmetry Assumption and Epsilon Corrections” on page 8-52.

Data Types: `table`

Examples

Epsilon Corrections for Repeated Measures ANOVA

Load the sample data.

```
load fisheriris
```

The column vector, `species` consists of iris flowers of three different species: `setosa`, `versicolor`, `virginica`. The double matrix `meas` consists of four types of measurements on the flowers: the length and width of sepals and petals in centimeters, respectively.

Store the data in a table array.

```
t = table(species,meas(:,1),meas(:,2),meas(:,3),meas(:,4),...
```

```
'VariableNames',{ 'species', 'meas1', 'meas2', 'meas3', 'meas4' });
Meas = dataset([1 2 3 4]', 'VarNames', {'Measurements'});
```

Fit a repeated measures model, where the measurements are the responses and the species is the predictor variable.

```
rm = fitrm(t, 'meas1-meas4~species', 'WithinDesign', Meas);
```

Perform repeated measures analysis of variance.

```
ranovatbl = ranova(rm)
```

```
ranovatbl =
```

	SumSq	DF	MeanSq	F	pValue	pValue
Measurements	1656.3	3	552.09	6873.3	0	0
species:Measurements	282.47	6	47.078	586.1	1.4271e-206	0
Error	35.423	441	0.080324			

`ranova` computes the last three p -values using Greenhouse-Geisser, Huynh-Feldt, and lower bound corrections, respectively.

Display the epsilon correction values.

```
epsilon(rm)
```

```
ans =
```

	epsilon
Uncorrected	1
Greenhouse-Geisser	0.75179
Huynh-Feldt	0.77448
Lower bound	0.33333

You can check the compound symmetry (sphericity) assumption using the `mauchly` method.

Algorithms

`ranova` computes the regular p -value (in the `pValue` column of the `rmanova` table) using the F -statistic cumulative distribution function:

$$p\text{-value} = 1 - \text{fcdf}(F, v_1, v_2).$$

When the compound symmetry assumption is not satisfied, `ranova` uses a correction factor ϵ , to compute the corrected p -values as follows:

$$p\text{-value_corrected} = 1 - \text{fcdf}(F, \epsilon^*v_1, \epsilon^*v_2).$$

The `epsilon` method returns the epsilon adjustment values.

evcdf

Extreme value cumulative distribution function

Syntax

```
p = evcdf(x,mu,sigma)
[p,plo,pup] = evcdf(x,mu,sigma,pcov,alpha)
[p,plo,pup] = evcdf( ____, 'upper' )
```

Description

`p = evcdf(x,mu,sigma)` returns the cumulative distribution function (cdf) for the type 1 extreme value distribution, with location parameter `mu` and scale parameter `sigma`, at each of the values in `x`. `x`, `mu`, and `sigma` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array of the same size as the other inputs. The default values for `mu` and `sigma` are 0 and 1, respectively.

`[p,plo,pup] = evcdf(x,mu,sigma,pcov,alpha)` returns confidence bounds for `p` when the input parameters `mu` and `sigma` are estimates. `pcov` is a 2-by-2 covariance matrix of the estimated parameters. `alpha` has a default value of 0.05, and specifies 100(1 - `alpha`)% confidence bounds. `plo` and `pup` are arrays of the same size as `p`, containing the lower and upper confidence bounds.

`[p,plo,pup] = evcdf(____, 'upper')` returns the complement of the type 1 extreme value distribution cdf at each value in `x`, using an algorithm that more accurately computes the extreme upper tail probabilities. You can use the 'upper' argument with any of the previous syntaxes.

The function `evcdf` computes confidence bounds for `P` using a normal approximation to the distribution of the estimate

$$\frac{X - \hat{\mu}}{\hat{\sigma}}$$

and then transforming those bounds to the scale of the output `P`. The computed bounds give approximately the desired confidence level when you estimate `mu`, `sigma`, and `pcov`

from large samples, but in smaller samples other methods of computing the confidence bounds might be more accurate.

The type 1 extreme value distribution is also known as the Gumbel distribution. The version used here is suitable for modeling minima; the mirror image of this distribution can be used to model maxima by negating X and subtracting the resulting distribution values from 1. See “Extreme Value Distribution” on page B-36 for more details. If x has a Weibull distribution, then $X = \log(x)$ has the type 1 extreme value distribution.

evfit

Extreme value parameter estimates

Syntax

```
parmhat = evfit(data)
[parmhat,parmci] = evfit(data)
[parmhat,parmci] = evfit(data,alpha)
[...] = evfit(data,alpha,censoring)
[...] = evfit(data,alpha,censoring,freq)
[...] = evfit(data,alpha,censoring,freq,options)
```

Description

`parmhat = evfit(data)` returns maximum likelihood estimates of the parameters of the type 1 extreme value distribution given the data in the vector `data`. `parmhat(1)` is the location parameter, μ , and `parmhat(2)` is the scale parameter, σ .

`[parmhat,parmci] = evfit(data)` returns 95% confidence intervals for the parameter estimates on the μ and σ parameters in the 2-by-2 matrix `parmci`. The first column of the matrix of the extreme value fit contains the lower and upper confidence bounds for the parameter μ , and the second column contains the confidence bounds for the parameter σ .

`[parmhat,parmci] = evfit(data,alpha)` returns $100(1 - \text{alpha})\%$ confidence intervals for the parameter estimates, where `alpha` is a value in the range `[0 1]` specifying the width of the confidence intervals. By default, `alpha` is `0.05`, which corresponds to 95% confidence intervals.

`[...] = evfit(data,alpha,censoring)` accepts a Boolean vector, `censoring`, of the same size as `data`, which is 1 for observations that are right-censored and 0 for observations that are observed exactly.

`[...] = evfit(data,alpha,censoring,freq)` accepts a frequency vector, `freq` of the same size as `data`. Typically, `freq` contains integer frequencies for the corresponding elements in `data`, but can contain any nonnegative values. Pass in `[]` for `alpha`, `censoring`, or `freq` to use their default values.

[...] = `evfit(data,alpha,censoring,freq,options)` accepts a structure, `options`, that specifies control parameters for the iterative algorithm the function uses to compute maximum likelihood estimates. You can create `options` using the function `statset`. Enter `statset('evfit')` to see the names and default values of the parameters that `evfit` accepts in the `options` structure. See the reference page for `statset` for more information about these options.

The type 1 extreme value distribution is also known as the Gumbel distribution. The version used here is suitable for modeling minima; the mirror image of this distribution can be used to model maxima by negating X . See “Extreme Value Distribution” on page B-36 for more details. If x has a Weibull distribution, then $X = \log(x)$ has the type 1 extreme value distribution.

evinv

Extreme value inverse cumulative distribution function

Syntax

```
X = evinv(P,mu,sigma)
[X,XLO,XUP] = evinv(P,mu,sigma,pcov,alpha)
```

Description

`X = evinv(P,mu,sigma)` returns the inverse cumulative distribution function (cdf) for a type 1 extreme value distribution with location parameter `mu` and scale parameter `sigma`, evaluated at the values in `P`. `P`, `mu`, and `sigma` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array of the same size as the other inputs. The default values for `mu` and `sigma` are 0 and 1, respectively.

`[X,XLO,XUP] = evinv(P,mu,sigma,pcov,alpha)` produces confidence bounds for `X` when the input parameters `mu` and `sigma` are estimates. `pcov` is the covariance matrix of the estimated parameters. `alpha` is a scalar that specifies $100(1 - \text{alpha})\%$ confidence bounds for the estimated parameters, and has a default value of 0.05. `XLO` and `XUP` are arrays of the same size as `X` containing the lower and upper confidence bounds.

The function `evinv` computes confidence bounds for `P` using a normal approximation to the distribution of the estimate

$$\hat{\mu} + \hat{\sigma} q$$

where q is the P th quantile from an extreme value distribution with parameters $\mu = 0$ and $\sigma = 1$. The computed bounds give approximately the desired confidence level when you estimate `mu`, `sigma`, and `pcov` from large samples, but in smaller samples other methods of computing the confidence bounds might be more accurate.

The type 1 extreme value distribution is also known as the Gumbel distribution. The version used here is suitable for modeling minima; the mirror image of this distribution can be used to model maxima by negating `X`. See “Extreme Value Distribution” on page

B-36 for more details. If x has a Weibull distribution, then $X = \log(x)$ has the type 1 extreme value distribution.

eq

Class: grandstream

Test handle equality

Syntax

```
h1 == h2  
tf = eq(h1, h2)
```

Description

`h1 == h2` performs element-wise comparisons between handle arrays `h1` and `h2`. `h1` and `h2` must be of the same dimensions unless one is a scalar. The result is a logical array of the same dimensions, where each element is an element-wise equality result. If one of `h1` or `h2` is scalar, scalar expansion is performed and the result will match the dimensions of the array that is not scalar.

`tf = eq(h1, h2)` stores the result in a logical array of the same dimensions.

See Also

grandstream | gt | le | ne | ge | lt

error

Class: CompactTreeBagger

Error (misclassification probability or MSE)

Syntax

```
err = error(B,X,Y)
err = error(B,X,Y, 'param1',val1, 'param2',val2, ...)
```

Description

`err = error(B,X,Y)` computes the misclassification probability (for classification trees) or mean squared error (MSE, for regression trees) for each tree, for predictors `X` given true response `Y`. For classification, `Y` can be either a numeric vector, character matrix, cell array of strings, categorical vector or logical vector. For regression, `Y` must be a numeric vector. `err` is a vector with one error measure for each of the `NTrees` trees in the ensemble `B`.

`err = error(B,X,Y, 'param1',val1, 'param2',val2, ...)` specifies optional parameter name/value pairs:

<code>'mode'</code>	String indicating how the method computes errors. If set to <code>'cumulative'</code> (default), <code>error</code> computes cumulative errors and <code>err</code> is a vector of length <code>NTrees</code> , where the first element gives error from <code>trees(1)</code> , second element gives error from <code>trees(1:2)</code> etc, up to <code>trees(1:NTrees)</code> . If set to <code>'individual'</code> , <code>err</code> is a vector of length <code>NTrees</code> , where each element is an error from each tree in the ensemble. If set to <code>'ensemble'</code> , <code>err</code> is a scalar showing the cumulative error for the entire ensemble.
<code>'trees'</code>	Vector of indices indicating what trees to include in this calculation. By default, this argument is set to <code>'all'</code> and the method uses all trees. If <code>'trees'</code> is a numeric vector, the method returns a vector of length <code>NTrees</code> for <code>'cumulative'</code> and <code>'individual'</code> modes, where <code>NTrees</code> is the number of elements in the input vector, and a scalar for <code>'ensemble'</code> mode. For example, in the <code>'cumulative'</code>

- mode, the first element gives error from `trees(1)`, the second element gives error from `trees(1:2)` etc.
- '`treeweights`' Vector of tree weights. This vector must have the same length as the '`trees`' vector. The method uses these weights to combine output from the specified trees by taking a weighted average instead of the simple non-weighted majority vote. You cannot use this argument in the '`individual`' mode.
- '`useifort`' Logical matrix of size `Nobs`-by-`NTrees` indicating which trees should be used to make predictions for each observation. By default the method uses all trees for all observations.

See Also

`TreeBagger.error`

error

Class: TreeBagger

Error (misclassification probability or MSE)

Syntax

```
err = error(B,X,Y)
err = error(B,X,Y, 'param1',val1, 'param2',val2, ...)
```

Description

`err = error(B,X,Y)` computes the misclassification probability for classification trees or mean squared error (MSE) for regression trees for each tree, for predictors `X` given true response `Y`. For classification, `Y` can be either a numeric vector, character matrix, cell array of strings, categorical vector or logical vector. For regression, `Y` must be a numeric vector. `err` is a vector with one error measure for each of the `NTrees` trees in the ensemble `B`.

`err = error(B,X,Y, 'param1',val1, 'param2',val2, ...)` specifies optional parameter name/value pairs:

<code>'mode'</code>	String indicating how the method computes errors. If set to <code>'cumulative'</code> (default), <code>error</code> computes cumulative errors and <code>err</code> is a vector of length <code>NTrees</code> , where the first element gives error from <code>trees(1)</code> , second element gives error from <code>trees(1:2)</code> etc, up to <code>trees(1:NTrees)</code> . If set to <code>'individual'</code> , <code>err</code> is a vector of length <code>NTrees</code> , where each element is an error from each tree in the ensemble. If set to <code>'ensemble'</code> , <code>err</code> is a scalar showing the cumulative error for the entire ensemble.
<code>'trees'</code>	Vector of indices indicating what trees to include in this calculation. By default, this argument is set to <code>'all'</code> and the method uses all trees. If <code>'trees'</code> is a numeric vector, the method returns a vector of length <code>NTrees</code> for <code>'cumulative'</code> and <code>'individual'</code> modes, where <code>NTrees</code> is the number of elements in the input vector, and a scalar for <code>'ensemble'</code> mode. For example, in the <code>'cumulative'</code>

- mode, the first element gives error from `trees(1)`, the second element gives error from `trees(1:2)` etc.
- '`treeweights`' Vector of tree weights. This vector must have the same length as the '`trees`' vector. The method uses these weights to combine output from the specified trees by taking a weighted average instead of the simple non-weighted majority vote. You cannot use this argument in the '`individual`' mode.
- '`useifort`' Logical matrix of size `Nobs`-by-`NTrees` indicating which trees should be used to make predictions for each observation. By default the method uses all trees for all observations.

`CompactTreeBagger.error`

eval

Class: classregtree

Predicted responses

Syntax

```
yfit = eval(t,X)
yfit = eval(t,X,s)
[yfit,nodes] = eval(...)
[yfit,nodes,cnums] = eval(...)
[...] = t(X)
[...] = t(X,s)
```

Description

`yfit = eval(t,X)` takes a classification or regression tree `t` and a matrix `X` of predictors, and produces a vector `yfit` of predicted response values. For a regression tree, `yfit(i)` is the fitted response value for a point having the predictor values `X(i,:)`. For a classification tree, `yfit(i)` is the class into which the tree assigns the point with data `X(i,:)`.

`yfit = eval(t,X,s)` takes an additional vector `s` of pruning levels, with 0 representing the full, unpruned tree. `t` must include a pruning sequence as created by `classregtree` or by `prune`. If `s` has k elements and `X` has n rows, the output `yfit` is an n -by- k matrix, with the j th column containing the fitted values produced by the `s(j)` subtree. `s` must be sorted in ascending order.

To compute fitted values for a tree that is not part of the optimal pruning sequence, first use `prune` to prune the tree.

`[yfit,nodes] = eval(...)` also returns a vector `nodes` the same size as `yfit` containing the node number assigned to each row of `X`. Use `view` to display the node numbers for any node you select.

`[yfit,nodes,cnums] = eval(...)` is valid only for classification trees. It returns a vector `cnum` containing the predicted class numbers.

NaN values in X are treated as missing. If `eval` encounters a missing value when it attempts to evaluate the split rule at a branch node, it cannot determine whether to proceed to the left or right child node. Instead, it sets the corresponding fitted value equal to the fitted value assigned to the branch node.

`[...] = t(X)` or `[...] = t(X,s)` also invoke `eval`.

Examples

Create a classification tree for Fisher's iris data:

```
load fisheriris;

t = classregtree(meas,species,...
                'names',{'SL' 'SW' 'PL' 'PW'})
t =
Decision tree for classification

evalclusters

Evaluate clustering solutions

Syntax

```
eva = evalclusters(x,clust,criterion)
eva = evalclusters(x,clust,criterion,Name,Value)
```

Description

`eva = evalclusters(x,clust,criterion)` creates a clustering evaluation object containing data used to evaluate the optimal number of data clusters.

`eva = evalclusters(x,clust,criterion,Name,Value)` creates a clustering evaluation object using additional options specified by one or more name-value pair arguments.

Examples

Evaluate the Clustering Solution Using Calinski-Harabasz Criterion

Evaluate the optimal number of clusters using the Calinski-Harabasz clustering evaluation criterion.

Load the sample data.

```
load fisheriris;
```

The data contains length and width measurements from the sepals and petals of three species of iris flowers.

Evaluate the optimal number of clusters using the Calinski-Harabasz criterion. Cluster the data using `kmeans`.

```
rng('default'); % For reproducibility
eva = evalclusters(meas,'kmeans','CalinskiHarabasz','KList',[1:6])

eva =
```

```
CalinskiHarabaszEvaluation with properties:
```

```
NumObservations: 150
  InspectedK: [1 2 3 4 5 6]
CriterionValues: [1x6 double]
  OptimalK: 3
```

The `OptimalK` value indicates that, based on the Calinski-Harabasz criterion, the optimal number of clusters is three.

Evaluate a Matrix of Clustering Solutions

Use an input matrix of proposed clustering solutions to evaluate the optimal number of clusters.

Load the sample data.

```
load fisheriris;
```

The data contains length and width measurements from the sepals and petals of three species of iris flowers.

Use `kmeans` to create an input matrix of proposed clustering solutions for the sepal length measurements, using 1, 2, 3, 4, 5, and 6 clusters.

```
clust = zeros(size(meas,1),6);
for i=1:6
clust(:,i) = kmeans(meas,i,'emptyaction','singleton',...
  'replicate',5);
end
```

Each row of `clust` corresponds to one sepal length measurement. Each of the six columns corresponds to a clustering solution containing 1 to 6 clusters.

Evaluate the optimal number of clusters using the Calinski-Harabasz criterion.

```
eva = evalclusters(meas,clust,'CalinskiHarabasz')
eva =
```

```
CalinskiHarabaszEvaluation with properties:
```

```
NumObservations: 150
  InspectedK: [1 2 3 4 5 6]
CriterionValues: [NaN 513.9245 561.6278 530.7658 459.5058 473.6577]
```

```
OptimalK: 3
```

The `OptimalK` value indicates that, based on the Calinski-Harabasz criterion, the optimal number of clusters is three.

Specify Clustering Algorithm with a Function Handle

Use a function handle to specify the clustering algorithm, then evaluate the optimal number of clusters.

Load the sample data.

```
load fisheriris;
```

The data contains length and width measurements from the sepals and petals of three species of iris flowers.

Use a function handle to specify the clustering algorithm.

```
myfunc = @(X,K)(kmeans(X, K, 'emptyaction','singleton',...
    'replicate',5));
```

Evaluate the optimal number of clusters for the sepal length data using the Calinski-Harabasz criterion.

```
eva = evalclusters(meas,myfunc,'CalinskiHarabasz',...
    'klist',[1:6])
```

```
eva =
```

```
CalinskiHarabaszEvaluation with properties:
```

```
NumObservations: 150
InspectedK: [1 2 3 4 5 6]
CriterionValues: [NaN 513.9245 561.6278 530.7658 459.5058 473.6577]
OptimalK: 3
```

The `OptimalK` value indicates that, based on the Calinski-Harabasz criterion, the optimal number of clusters is three.

Input Arguments

x — Input data
matrix

Input data, specified as an N -by- P matrix. N is the number of observations, and P is the number of variables.

Data Types: `single` | `double`

clust — Clustering algorithm

'kmeans' | 'linkage' | 'gmdistribution' | matrix of clustering solutions | function handle

Clustering algorithm, specified as one of the following.

'kmeans'	Cluster the data in <code>x</code> using the <code>kmeans</code> clustering algorithm, with 'EmptyAction' set to 'singleton' and 'Replicates' set to 5.
'linkage'	Cluster the data in <code>x</code> using the <code>clusterdata</code> agglomerative clustering algorithm, with 'Linkage' set to 'ward'.
'gmdistribution'	Cluster the data in <code>x</code> using the <code>gmdistribution</code> Gaussian mixture distribution algorithm, with 'SharedCov' set to true and 'Replicates' set to 5.

If `Criterion` is 'CalinskHarabasz', 'DaviesBouldin', or 'silhouette', you can specify a clustering algorithm using the `function_handle` (@) operator. The function must be of the form `C = clustfun(DATA,K)`, where `DATA` is the data to be clustered, and `K` is the number of clusters. The output of `clustfun` must be one of the following:

- A vector of integers representing the cluster index for each observation in `DATA`. There must be `K` unique values in this vector.
- A numeric n -by- K matrix of score for n observations and K classes. In this case, the cluster index for each observation is determined by taking the largest score value in each row.

If `Criterion` is 'CalinskHarabasz', 'DaviesBouldin', or 'silhouette', you can also specify `clust` as a n -by- K matrix containing the proposed clustering solutions. n is the number of observations in the sample data, and K is the number of proposed clustering solutions. Column j contains the cluster indices for each of the N points in the j th clustering solution.

criterion — Clustering evaluation criterion

'CalinskiHarabasz' | 'DaviesBouldin' | 'gap' | 'silhouette'

Clustering evaluation criterion, specified as one of the following.

'CalinskiHarabasz'	Create a <code>CalinskiHarabaszEvaluation</code> clustering evaluation object containing Calinski-Harabasz index values.
'DaviesBouldin'	Create a <code>DaviesBouldinEvaluation</code> cluster evaluation object containing Davies-Bouldin index values.
'gap'	Create a <code>GapEvaluation</code> cluster evaluation object containing gap criterion values.
'silhouette'	Create a <code>SilhouetteEvaluation</code> cluster evaluation object containing silhouette values.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'KList', [1:5], 'Distance', 'cityblock'` specifies to test 1, 2, 3, 4, and 5 clusters using the sum of absolute differences distance measure.

For All Criteria

'KList' — List of number of clusters to evaluate

vector

List of number of clusters to evaluate, specified as the comma-separated pair consisting of `'KList'` and a vector of positive integer values. You must specify `KList` when `clust` is a clustering algorithm name string or a function handle. When `criterion` is `'gap'`, `clust` must be a string or a function handle, and you must specify `KList`.

Example: `'KList', [1:6]`

For Silhouette and Gap

'Distance' — Distance metric

'sqEuclidean' (default) | 'Euclidean' | 'cityblock' | vector | function | ...

Distance metric used for computing the criterion values, specified as the comma-separated pair consisting of 'Distance' and one of the following.

'sqEuclidean'	Squared Euclidean distance
'Euclidean'	Euclidean distance
'cityblock'	Sum of absolute differences
'cosine'	One minus the cosine of the included angle between points (treated as vectors)
'correlation'	One minus the sample correlation between points (treated as sequences of values)
'Hamming'	Percentage of coordinates that differ
'Jaccard'	Percentage of nonzero coordinates that differ

For detailed information about each distance metric, see `pdist`.

You can also specify a function for the distance metric by using the `function_handle` (`@`) operator. The distance function must be of the form `d2 = distfun(XI,XJ)`, where `XI` is a 1-by- n vector corresponding to a single row of the input matrix `X`, and `XJ` is an m_2 -by- n matrix corresponding to multiple rows of `X`. `distfun` must return an m_2 -by-1 vector of distances `d2`, whose k th element is the distance between `XI` and `XJ(k,:)`.

If `Criterion` is 'silhouette', you can also specify `Distance` as the output vector output created by the function `pdist`.

When `Clust` a string representing a built-in clustering algorithm, `evalclusters` uses the distance metric specified for `Distance` to cluster the data, except for the following:

- If `Clust` is 'linkage', and `Distance` is either 'sqEuclidean' or 'Euclidean', then the clustering algorithm uses Euclidean distance and Ward linkage.
- If `Clust` is 'linkage' and `Distance` is any other metric, then the clustering algorithm uses the specified distance metric and average linkage.

In all other cases, the distance metric specified for `Distance` must match the distance metric used in the clustering algorithm to obtain meaningful results.

Example: 'Distance', 'Euclidean'

For Silhouette Only

'ClusterPriors' — Prior probabilities for each cluster

'empirical' (default) | 'equal'

Prior probabilities for each cluster, specified as the comma-separated pair consisting of 'ClusterPriors' and one of the following.

'empirical'	Compute the overall silhouette value for the clustering solution by averaging the silhouette values for all points. Each cluster contributes to the overall silhouette value proportionally to its size.
'equal'	Compute the overall silhouette value for the clustering solution by averaging the silhouette values for all points within each cluster, and then averaging those values across all clusters. Each cluster contributes equally to the overall silhouette value, regardless of its size.

Example: 'ClusterPriors', 'empirical'

For Gap Only

'B' — Number of reference data sets

100 (default) | positive integer value

Number of reference data sets generated from the reference distribution ReferenceDistribution, specified as the comma-separated pair consisting of 'B' and a positive integer value.

Example: 'B', 150

'ReferenceDistribution' — Reference data generation method

'PCA' (default) | 'uniform'

Reference data generation method, specified as the comma-separated pair consisting of 'ReferenceDistributions' and one of the following.

- 'PCA' Generate reference data from a uniform distribution over a box aligned with the principal components of the data matrix x .
- 'uniform' Generate reference data uniformly over the range of each feature in the data matrix x .

Example: 'ReferenceDistribution', 'uniform'

'SearchMethod' — Method for selecting optimal number of clusters

'globalMaxSE' (default) | 'firstMaxSE'

Method for selecting the optimal number of clusters, specified as the comma-separated pair consisting of 'SearchMethod' and one of the following.

- 'globalMaxSE' Evaluate each proposed number of clusters in KList and select the smallest number of clusters satisfying

$$\text{Gap}(K) \geq \text{GAPMAX} - \text{SE}(\text{GAPMAX}),$$

where K is the number of clusters, $\text{Gap}(K)$ is the gap value for the clustering solution with K clusters, GAPMAX is the largest gap value, and $\text{SE}(\text{GAPMAX})$ is the standard error corresponding to the largest gap value.

- 'firstMaxSE' Evaluate each proposed number of clusters in KList and select the smallest number of clusters satisfying

$$\text{Gap}(K) \geq \text{Gap}(K + 1) - \text{SE}(K + 1),$$

where K is the number of clusters, $\text{Gap}(K)$ is the gap value for the clustering solution with K clusters, and $\text{SE}(K + 1)$ is the standard error of the clustering solution with $K + 1$ clusters.

Example: 'SearchMethod', 'globalMaxSE'

Output Arguments

eva — Clustering evaluation data

clustering evaluation object

Clustering evaluation data, returned as a clustering evaluation object.

evlike

Extreme value negative log-likelihood

Syntax

```
nlogL = evlike(params,data)
[nlogL,AVAR] = evlike(params,data)
[...] = evlike(params,data,censoring)
[...] = evlike(params,data,censoring,freq)
```

Description

`nlogL = evlike(params,data)` returns the negative of the log-likelihood for the type 1 extreme value distribution. `params(1)` is the tail location parameter, μ , and `params(2)` is the scale parameter, σ . `nlogL` is a scalar.

`[nlogL,AVAR] = evlike(params,data)` returns the inverse of Fisher's information matrix, `AVAR`. If the input parameter values in `params` are the maximum likelihood estimates, the diagonal elements of `AVAR` are their asymptotic variances. `AVAR` is based on the observed Fisher's information, not the expected information.

`[...] = evlike(params,data,censoring)` accepts a Boolean vector of the same size as `data`, which is 1 for observations that are right-censored and 0 for observations that are observed exactly.

`[...] = evlike(params,data,censoring,freq)` accepts a frequency vector of the same size as `data`. `freq` typically contains integer frequencies for the corresponding elements in `data`, but can contain any nonnegative values. Pass in `[]` for `censoring` to use its default value.

The type 1 extreme value distribution is also known as the Gumbel distribution. The version used here is suitable for modeling minima; the mirror image of this distribution can be used to model maxima by negating `data`. See “Extreme Value Distribution” on page B-36 for more details. If x has a Weibull distribution, then $X = \log(x)$ has the type 1 extreme value distribution.

More About

- “Extreme Value Distribution” on page B-36

evfit | evpdf | evcdf | evinv | evstat | evrnd

evpdf

Extreme value probability density function

Syntax

```
Y = evpdf(X,mu,sigma)
```

Description

`Y = evpdf(X,mu,sigma)` returns the pdf of the type 1 extreme value distribution with location parameter `mu` and scale parameter `sigma`, evaluated at the values in `X`. `X`, `mu`, and `sigma` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array of the same size as the other inputs. The default values for `mu` and `sigma` are 0 and 1, respectively.

The type 1 extreme value distribution is also known as the Gumbel distribution. The version used here is suitable for modeling minima; the mirror image of this distribution can be used to model maxima by negating `X`. See “Extreme Value Distribution” on page B-36 for more details. If x has a Weibull distribution, then $X = \log(x)$ has the type 1 extreme value distribution.

evrnd

Extreme value random numbers

Syntax

```
R = evrnd(mu, sigma)
R = evrnd(mu, sigma, m, n, ...)
R = evrnd(mu, sigma, [m, n, ...])
```

Description

`R = evrnd(mu, sigma)` generates random numbers from the extreme value distribution with parameters specified by location parameter `mu` and scale parameter `sigma`. `mu` and `sigma` can be vectors, matrices, or multidimensional arrays that have the same size, which is also the size of `R`. A scalar input for `mu` or `sigma` is expanded to a constant array with the same dimensions as the other input.

`R = evrnd(mu, sigma, m, n, ...)` or `R = evrnd(mu, sigma, [m, n, ...])` generates an `m`-by-`n`-by-... array containing random numbers from the extreme value distribution with parameters `mu` and `sigma`. `mu` and `sigma` can each be scalars or arrays of the same size as `R`.

The type 1 extreme value distribution is also known as the Gumbel distribution. The version used here is suitable for modeling minima; the mirror image of this distribution can be used to model maxima by negating `R`. See “Extreme Value Distribution” on page B-36 for more details. If x has a Weibull distribution, then $X = \log(x)$ has the type 1 extreme value distribution.

evstat

Extreme value mean and variance

Syntax

```
[M,V] = evstat(mu,sigma)
```

Description

`[M,V] = evstat(mu,sigma)` returns the mean of and variance for the type 1 extreme value distribution with location parameter `mu` and scale parameter `sigma`. `mu` and `sigma` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array of the same size as the other input. The default values for `mu` and `sigma` are 0 and 1, respectively.

The type 1 extreme value distribution is also known as the Gumbel distribution. The version used here is suitable for modeling minima; the mirror image of this distribution can be used to model maxima. See “Extreme Value Distribution” on page B-36 for more details. If x has a Weibull distribution, then $X = \log(x)$ has the type 1 extreme value distribution.

prob.ExponentialDistribution class

Package: prob

Superclasses: prob.ToolboxFittableParametricDistribution

Exponential probability distribution object

Description

`prob.ExponentialDistribution` is an object consisting of parameters, a model description, and sample data for an exponential probability distribution.

Create a probability distribution object with specified parameter values using `makedist`. Alternatively, fit a distribution to data using `fitdist` or the Distribution Fitting app.

Construction

`pd = makedist('Exponential')` creates an exponential probability distribution object using the default parameter values.

`pd = makedist('Exponential', 'mu', mu)` creates an exponential probability distribution object using the specified parameter value.

Input Arguments

mu — Mean

1 (default) | positive scalar value

Mean of the exponential distribution, specified as a positive scalar value.

Data Types: `single` | `double`

Properties

mu — Mean

positive scalar value

Mean of the exponential distribution, stored as a positive scalar value.

Data Types: `single` | `double`

DistributionName — Probability distribution name

probability distribution name string

Probability distribution name, stored as a valid probability distribution name string. This property is read-only.

Data Types: `char`

InputData — Data used for distribution fitting

structure

Data used for distribution fitting, stored as a structure containing the following:

- **data**: Data vector used for distribution fitting.
- **cens**: Censoring vector, or empty if none.
- **freq**: Frequency vector, or empty if none.

This property is read-only.

Data Types: `struct`

IsTruncated — Logical flag for truncated distribution

0 | 1

Logical flag for truncated distribution, stored as a logical value. If `IsTruncated` equals 0, the distribution is not truncated. If `IsTruncated` equals 1, the distribution is truncated. This property is read-only.

Data Types: `logical`

NumParameters — Number of parameters

positive integer value

Number of parameters for the probability distribution, stored as a positive integer value. This property is read-only.

Data Types: `single` | `double`

ParameterCovariance — Covariance matrix of the parameter estimates

matrix of scalar values

Covariance matrix of the parameter estimates, stored as a p -by- p matrix, where p is the number of parameters in the distribution. The (i,j) element is the covariance between

the estimates of the i th parameter and the j th parameter. The (i,i) element is the estimated variance of the i th parameter. If parameter i is fixed rather than estimated by fitting the distribution to data, then the (i,i) elements of the covariance matrix are 0. This property is read-only.

Data Types: `single` | `double`

ParameterDescription — Distribution parameter descriptions

cell array of strings

Distribution parameter descriptions, stored as a cell array of strings. Each cell contains a short description of one distribution parameter. This property is read-only.

Data Types: `char`

ParameterIsFixed — Logical flag for fixed parameters

array of logical values

Logical flag for fixed parameters, stored as an array of logical values. If 0, the corresponding parameter in the `ParameterNames` array is not fixed. If 1, the corresponding parameter in the `ParameterNames` array is fixed. This property is read-only.

Data Types: `logical`

ParameterNames — Distribution parameter names

cell array of strings

Distribution parameter names, stored as a cell array of strings. This property is read-only.

Data Types: `char`

ParameterValues — Distribution parameter values

vector of scalar values

Distribution parameter values, stored as a vector. This property is read-only.

Data Types: `single` | `double`

Truncation — Truncation interval

vector of scalar values

Truncation interval for the probability distribution, stored as a vector containing the lower and upper truncation boundaries. This property is read-only.

Data Types: `single` | `double`

Methods

Inherited Methods

<code>cdf</code>	Cumulative distribution function of probability distribution object

var	Variance of probability distribution object

Definitions

Exponential Distribution

The exponential distribution is used to model events that occur randomly over time, and its main application area is studies of lifetimes. It is a special case of the gamma distribution with the shape parameter $\alpha = 1$.

The exponential distribution uses the following parameters.

Parameter	Description	Support
mu	Mean	$\mu > 0$

The probability density function (pdf) is

$$f(x | \mu) = \frac{1}{\mu} e^{-\frac{x}{\mu}} \quad ; \quad x \geq 0.$$

Examples

Create an Exponential Distribution Object Using Default Parameters

Create an exponential distribution object using the default parameter values.

```
pd = makedist('Exponential')
```

```
pd =  
    ExponentialDistribution  
    Exponential distribution  
    mu = 1
```

Create an Exponential Distribution Object Using Specified Parameters

Create an exponential distribution object by specifying the parameter values.

```
pd = makedist('Exponential', 'mu', 2)
```

```
pd =  
    ExponentialDistribution  
    Exponential distribution  
    mu = 2
```

Compute the variance of the distribution.

```
v = var(pd)
```

```
v =  
    4
```

- “Property Attributes”

expcdf

Exponential cumulative distribution function

Syntax

```
p = expcdf(x,mu)
[p,plo,pup] = expcdf(x,mu,pcov,alpha)
[p,plo,pup] = expcdf( ____, 'upper' )
```

Description

`p = expcdf(x,mu)` computes the exponential cdf at each of the values in `x` using the corresponding mean parameter `mu`. `x` and `mu` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other input. The parameters in `mu` must be positive.

`[p,plo,pup] = expcdf(x,mu,pcov,alpha)` produces confidence bounds for `Pp` when the input mean parameter `mu` is an estimate. `pcov` is the variance of the estimated `mu`. `alpha` specifies 100(1 - `alpha`)% confidence bounds. The default value of `alpha` is 0.05. `plo` and `pup` are arrays of the same size as `p` containing the lower and upper confidence bounds. The bounds are based on a normal approximation for the distribution of the log of the estimate of `mu`. If you estimate `mu` from a set of data, you can get a more accurate set of bounds by applying `expfit` to the data to get a confidence interval for `mu`, and then evaluating `expinv` at the lower and upper endpoints of that interval.

`[p,plo,pup] = expcdf(____, 'upper')` returns the complement of the exponential cdf at each value in `x`, using an algorithm that more accurately computes the extreme upper tail probabilities. You can use the `'upper'` argument with any of the prior syntaxes.

The exponential cdf is

$$p = F(x | u) = \int_0^x \frac{1}{\mu} e^{-\frac{t}{\mu}} dt = 1 - e^{-\frac{x}{\mu}}$$

The result, p , is the probability that a single observation from an exponential distribution will fall in the interval $[0 x]$.

Examples

Compute the Exponential CDF

The following code shows that the median of the exponential distribution is $\mu \log(2)$.

```
mu = 10:10:60;
p = expcdf(log(2)*mu,mu)

p =
    0.5000    0.5000    0.5000    0.5000    0.5000    0.5000
```

What is the probability that an exponential random variable is less than or equal to the mean, μ ?

```
mu = 1:6;
x = mu;
p = expcdf(x,mu)

p =
    0.6321    0.6321    0.6321    0.6321    0.6321    0.6321
```

More About

- “Exponential Distribution” on page B-33

See Also

`cdf` | `exppdf` | `expinv` | `expstat` | `expfit` | `explike` | `expnrd`

expfit

Exponential parameter estimates

Syntax

```
muhat = expfit(data)
[muhat,muci] = expfit(data)
[muhat,muci] = expfit(data,alpha)
[...] = expfit(data,alpha,censoring)
[...] = expfit(data,alpha,censoring,freq)
```

Description

`muhat = expfit(data)` estimates the mean of an exponentially distributed sample data. Each entry of `muhat` corresponds to the data in a column of `data`.

`[muhat,muci] = expfit(data)` returns 95% confidence intervals for the mean parameter estimates in matrix `muci`. The first row of `muci` contains the lower bounds of the confidence intervals, and the second row contains the upper bounds.

`[muhat,muci] = expfit(data,alpha)` returns $100(1 - \alpha)\%$ confidence intervals for the parameter estimates, where `alpha` is a value in the range `[0 1]` specifying the width of the confidence intervals. By default, `alpha` is `0.05`, which corresponds to 95% confidence intervals.

`[...] = expfit(data,alpha,censoring)` accepts a Boolean vector, `censoring`, of the same size as `data`, which is 1 for observations that are right-censored and 0 for observations that are observed exactly. `data` must be a vector in order to pass in the argument `censoring`.

`[...] = expfit(data,alpha,censoring,freq)` accepts a frequency vector, `freq` of the same size as `data`. Typically, `freq` contains integer frequencies for the corresponding elements in `data`, but can contain any nonnegative values. Pass in `[]` for `alpha`, `censoring`, or `freq` to use their default values.

Examples

The following estimates the mean μ of exponentially distributed data, and returns a 95% confidence interval for the estimate:

```
mu = 3;  
data = exprnd(mu,100,1); % Simulated data
```

```
[muhat,muci] = expfit(data)  
muhat =  
    2.7511  
muci =  
    2.2826  
    3.3813
```

ExhaustiveSearcher class

Superclasses: NeighborSearcher

Nearest neighbors search using exhaustive search

Description

An ExhaustiveSearcher object performs *k*NN (*k*-nearest neighbor) search using exhaustive search. Search objects store information about the data used, and the distance metric and parameters. The search performance for this object, compared with the KDTreeSearcher object, tends to be better for larger dimensions (10 or more) and worse for smaller dimensions. For details on search objects, see “What Are Search Objects?”.

Construction

`NS = ExhaustiveSearcher(X, 'Name', Value)` constructs an ExhaustiveSearcher object based on *X*, where rows of *X* correspond to observations and columns correspond to variables, using one or more optional name-value pair arguments. You can then use this object to find neighbors in *X* nearest to the query points.

`NS = createns(X, 'NSMethod', 'exhaustive', 'Name', Value)` creates an ExhaustiveSearcher object based on *X* using `createns`, where rows of *X* correspond to observations and columns correspond to variables, using one or more optional name-value pair arguments. You can use this object to find neighbors in *X* nearest to the query points.

Name-Value Pair Arguments

The ExhaustiveSearcher and the createns functions accept one or more of the following optional name-value pair arguments as input.

'Distance'

A string or function handle specifying the default distance metric used when you call the `knnsearch` method.

- 'euclidean' — Euclidean distance (default).
- 'seuclidean' — Standardized Euclidean distance. Each coordinate difference between rows in X and the query matrix is scaled by dividing by the corresponding element of the standard deviation computed from X , $S=\text{nanstd}(X)$. To specify another value for S , use the `Scale` argument.
- 'cityblock' — City block distance.
- 'chebychev' — Chebychev distance (maximum coordinate difference).
- 'minkowski' — Minkowski distance.
- 'mahalanobis' — Mahalanobis distance, computed using a positive definite covariance matrix C . The default value of C is $\text{nancov}(X)$. To change the value of C , use the `Cov` parameter.
- 'cosine' — One minus the cosine of the included angle between observations (treated as vectors).
- 'correlation' — One minus the sample linear correlation between observations (treated as sequences of values).
- 'spearman' — One minus the sample Spearman's rank correlation between observations (treated as sequences of values).
- 'hamming' — Hamming distance, percentage of coordinates that differ.
- 'jaccard' — One minus the Jaccard coefficient, the percentage of nonzero coordinates that differ.
- custom distance function — A distance function specified using `@` (for example, `@distfun`). A custom distance function must
 - Have the form `function D2 = distfun(ZI, ZJ)`
 - Take as arguments:
 - A 1-by- n vector ZI containing a single row from X or from the query points Y
 - An $m2$ -by- n matrix ZJ containing multiple rows of X or Y
 - Return an $m2$ -by-1 vector of distances $D2$, whose j th element is the distance between the observations ZI and $ZJ(j, :)$

For details on these distance metrics, see “Distance Metrics”.

'p'

A positive scalar indicating the exponent of the Minkowski distance. This parameter is only valid when `Distance` is 'minkowski'. Default is 2.

'Cov'

A positive definite matrix indicating the covariance matrix when computing the Mahalanobis distance. This parameter is only valid when `Distance` is `'mahalanobis'`. Default is `nancov(X)`.

'Scale'

A vector `S` with the length equal to the number of columns in `X`. Each coordinate of `X` and each query point is scaled by the corresponding element of `S` when computing the standardized Euclidean distance. This parameter is only valid when `Distance` is `'seuclidean'`. Default is `nanstd(X)`.

Properties

X

A matrix used to create the object.

Distance

A string specifying a built-in distance metric or a function handle that you provide when you create the object. This property is the default distance metric used when you call the `knnsearch` method to find nearest neighbors for future query points.

DistParameter

Specifies the additional parameter for the chosen distance metric. The value is:

- If `'Distance'` is `'minkowski'`: A positive scalar indicating the exponent of the Minkowski distance.
- If `'Distance'` is `'mahalanobis'`: A positive definite matrix representing the covariance matrix used for computing the Mahalanobis distance.
- If `'Distance'` is `'seuclidean'`: A vector representing the scale value of the data when computing the `'seuclidean'` distance.
- Otherwise: Empty.

Methods

knnsearch

Find k -nearest neighbors using ExhaustiveSearcher object

rangesearch

Find all neighbors within specified distance using ExhaustiveSearcher object

Examples

Train a k -Nearest Neighbors Searcher

You can create an ExhaustiveSearcher model in two ways.

Load Fisher's iris data. Focus on the petal dimensions.

```
load fisheriris
X = meas(:, [3 4]); % Predictors
```

Prepare an exhaustive, nearest neighbors searcher using ExhaustiveSearcher and the predictors. Use the Minkowski distance metric.

```
ESMd11 = ExhaustiveSearcher(X, 'Distance', 'Minkowski')
```

```
ESMd11 =
```

```
ExhaustiveSearcher with properties:
```

```
    Distance: 'minkowski'
  DistParameter: 2
           X: [150x2 double]
```

ESMd11 is an ExhaustiveSearcher model. Access properties of ESMd11 using dot notation. For example, use ESMd11.DistParameter to access the Minkowski distance exponent.

Prepare an exhaustive, nearest neighbors searcher using createns and by specifying that the nearest neighbors search method is exhaustive.

```
ESMd12 = createns(X, 'NsMethod', 'exhaustive', ...  
    'Distance', 'minkowski')
```

```
ESMd12 =
```

```
ExhaustiveSearcher with properties:
```

```
    Distance: 'minkowski'  
    DistParameter: 2  
         X: [150x2 double]
```

ESMd12 is also an ExhaustiveSearcher model, and it is equivalent to ESMd11.

You can pass new data and either of the models to:

- “knnsearch (ExhaustiveSearcher)” to find indices and distances of nearest neighbors.
- “rangearch (ExhaustiveSearcher)” to find indices of all nearest neighbors within a distance that you specify.

For more in-depth examples using the knnsearch, see “”.

How To

- “*k*-Nearest Neighbor Search and Radius Search” on page 16-11
- “Distance Metrics”

expinv

Exponential inverse cumulative distribution function

Syntax

```
X = expinv(P,mu)
[X,XLO,XUP] = expinv(X,mu,pcov,alpha)
```

Description

`X = expinv(P,mu)` computes the inverse of the exponential cdf with parameters specified by mean parameter `mu` for the corresponding probabilities in `P`. `P` and `mu` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other input. The parameters in `mu` must be positive and the values in `P` must lie on the interval `[0 1]`.

`[X,XLO,XUP] = expinv(X,mu,pcov,alpha)` produces confidence bounds for `X` when the input mean parameter `mu` is an estimate. `pcov` is the variance of the estimated `mu`. `alpha` specifies `100(1 - alpha)%` confidence bounds. The default value of `alpha` is 0.05. `XLO` and `XUP` are arrays of the same size as `X` containing the lower and upper confidence bounds. The bounds are based on a normal approximation for the distribution of the log of the estimate of `mu`. If you estimate `mu` from a set of data, you can get a more accurate set of bounds by applying `expfit` to the data to get a confidence interval for `mu`, and then evaluating `expinv` at the lower and upper end points of that interval.

The inverse of the exponential cdf is

$$x = F^{-1}(p | \mu) = -\mu \ln(1 - p)$$

The result, `x`, is the value such that an observation from an exponential distribution with parameter `mu` will fall in the range `[0 x]` with probability `p`.

Examples

Let the lifetime of light bulbs be exponentially distributed with $\mu = 700$ hours. What is the median lifetime of a bulb?

```
expinv(0.50,700)
ans =
  485.2030
```

Suppose you buy a box of “700 hour” light bulbs. If 700 hours is the mean life of the bulbs, half of them will burn out in less than 500 hours.

More About

- “Exponential Distribution” on page B-33

`icdf` | `expcdf` | `exppdf` | `expstat` | `expfit` | `explike` | `exprnd`

explike

Exponential negative log-likelihood

Syntax

```
nlogL = explike(param,data)
[nlogL,avar] = explike(param,data)
[...] = explike(param,data,censoring)
[...] = explike(param,data,censoring,freq)
```

Description

`nlogL = explike(param,data)` returns the negative of the log-likelihood for the exponential distribution. `param` is the mean parameter, `mu`. `nlogL` is a scalar.

`[nlogL,avar] = explike(param,data)` returns the inverse of Fisher's information, `avar`, a scalar. If the input parameter value in `param` is the maximum likelihood estimate, `avar` is its asymptotic variance. `avar` is based on the observed Fisher's information, not the expected information.

`[...] = explike(param,data,censoring)` accepts a Boolean vector, `censoring`, of the same size as `data`, which is 1 for observations that are right-censored and 0 for observations that are observed exactly.

`[...] = explike(param,data,censoring,freq)` accepts a frequency vector, `freq`, of the same size as `data`. The vector `freq` typically contains integer frequencies for the corresponding elements in `data`, but can contain any nonnegative values. Pass in `[]` for `censoring` to use its default value.

export

Class: dataset

Write dataset array to file

Compatibility

The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

Syntax

```
export(DS,'file',filename)
export(DS)
export(DS,'file',filename,'Delimiter',delim)
export(DS,'XLSfile',filename)
export(DS,'XPTfile',filename)
export(DS,...,'WriteVarNames',false)
export(DS,...,'WriteObsNames',false)
```

Description

`export(DS,'file',filename)` writes the dataset array `DS` to a tab-delimited text file, including variable names and observation names, if present. If the observation names exist, the name in the first column of the first line of the file is the first dimension name for the dataset (by default, `'Observations'`). `export` overwrites any existing file named `filename`.

`export(DS)` writes to a text file whose default name is the name of the dataset array `DS` appended by `'.txt'`. If `export` cannot construct the file name from the dataset array input, it writes to the file `'dataset.txt'`. `export` overwrites any existing file.

`export(DS,'file',filename,'Delimiter',delim)` writes the dataset array `DS` to a text file using the delimiter `delim`. `delim` must be one of the following:

- ' ' or 'space'
- '\t' or 'tab'
- ',' or 'comma'
- ';' or 'semi'
- '|' or 'bar'

`export(DS, 'XLSfile', filename)` writes the dataset array `DS` to a Microsoft® Excel spreadsheet file, including variable names and observation names (if present). You can specify the 'Sheet' and 'Range' parameter name/value pairs, with parameter values as accepted by the `xlsread` function.

`export(DS, 'XPTfile', filename)` writes the dataset array `DS` to a SAS XPORT format file. When writing to an XPORT format file, variables must be scalar valued. `export` saves observation names to a variable called `obsnames`, unless the `WriteObsNames` parameter described below is `false`. The XPORT format restricts the length of variable names to eight characters; longer variable names are truncated.

`export(DS, ..., 'WriteVarNames', false)` does not write the variable names to the text file. `export(DS, ..., 'WriteVarNames', true)` is the default, writing the names as column headings in the first line of the file.

`export(DS, ..., 'WriteObsNames', false)` does not write the observation names to the text file. `export(DS, ..., 'WriteObsNames', true)` is the default, writing the names as the first column of the file.

In some cases, `export` creates a text file that does not represent `A` exactly, as described below. If you use `dataset` to read the file back into MATLAB, the new dataset array may not have exactly the same contents as the original dataset array. Save `A` as a MAT-file if you need to import it again as a dataset array.

`export` writes out numeric variables using long g format, and categorical or character variables as unquoted strings.

For non-character variables with more than one column, `export` writes out multiple delimiter-separated fields on each line, and constructs suitable column headings for the first line of the file.

`export` writes out variables that have more than two dimensions as a single empty field in each line of the file.

For cell-valued variables, `export` writes out the contents of each cell only when the cell contains a single row, and writes out a single empty field otherwise.

In some cases, `export` creates a file that cannot be read back into MATLAB using `dataset`. Writing a dataset array that contains a cell-valued variable whose cell contents are not scalars results in a mismatch in the file between the number of fields on each line and the number of column headings on the first line. Writing a dataset array that contains a cell-valued variable whose cell contents are not all the same length results in a different number of fields on each line in the file. Therefore, if you might need to import a dataset array again, save it as a `.mat` file.

Examples

Move data between external text files and dataset arrays in the MATLAB workspace:

```
A = dataset('file','sat2.dat','delimiter',' ','')
```

```
A =  
    Test          Gender          Score  
    'Verbal'      'Male'          470  
    'Verbal'      'Female'        530  
    'Quantitative' 'Male'          520  
    'Quantitative' 'Female'        480
```

```
export(A(A.Score > 500,:), 'file', 'HighScores.txt')
```

```
B = dataset('file', 'HighScores.txt', 'delimiter', '\t')
```

```
B =  
    Test          Gender          Score  
    'Verbal'      'Female'        530  
    'Quantitative' 'Male'          520
```

See Also

`dataset`

exppdf

Exponential probability density function

Syntax

```
Y = exppdf(X,mu)
```

Description

`Y = exppdf(X,mu)` returns the pdf of the exponential distribution with mean parameter `mu`, evaluated at the values in `X`. `X` and `mu` can be vectors, matrices, or multidimensional arrays that have the same size. A scalar input is expanded to a constant array with the same dimensions as the other input. The parameters in `mu` must be positive.

The exponential pdf is

$$y = f(x | \mu) = \frac{1}{\mu} e^{-\frac{x}{\mu}}$$

The exponential pdf is the gamma pdf with its first parameter equal to 1.

The exponential distribution is appropriate for modeling waiting times when the probability of waiting an additional period of time is independent of how long you have already waited. For example, the probability that a light bulb will burn out in its next minute of use is relatively independent of how many minutes it has already burned.

Examples

```
y = exppdf(5,1:5)
y =
    0.0067    0.0410    0.0630    0.0716    0.0736

y = exppdf(1:5,1:5)
```

y =
0.3679 0.1839 0.1226 0.0920 0.0736

pdf | expcdf | expinv | expstat | expfit | explike | exprnd

exprnd

Exponential random numbers

Syntax

```
R = exprnd(mu)
R = exprnd(mu,m,n,...)
R = exprnd(mu,[m,n,...])
```

Description

`R = exprnd(mu)` generates random numbers from the exponential distribution with mean parameter `mu`. `mu` can be a vector, a matrix, or a multidimensional array. The size of `R` is the size of `mu`.

`R = exprnd(mu,m,n,...)` or `R = exprnd(mu,[m,n,...])` generates an `m`-by-`n`-by-... array containing random numbers from the exponential distribution with mean parameter `mu`. `mu` can be a scalar or an array of the same size as `R`.

Examples

```
n1 = exprnd(5:10)
n1 =
    7.5943    18.3400    2.7113    3.0936    0.6078    9.5841

n2 = exprnd(5:10,[1 6])
n2 =
    3.2752    1.1110    23.5530    23.4303    5.7190    3.9876

n3 = exprnd(5,2,3)
n3 =

expstat

Exponential mean and variance

Syntax

```
[m,v] = expstat(mu)
```

Description

`[m,v] = expstat(mu)` returns the mean of and variance for the exponential distribution with parameters `mu`. `mu` can be a vectors, matrix, or multidimensional array. The mean of the exponential distribution is μ , and the variance is μ^2 .

Examples

```
[m,v] = expstat([1 10 100 1000])  
m =  
    1    10    100    1000  
v =  
    1    100   10000  1000000
```

prob.ExtremeValueDistribution class

Package: prob

Superclasses: prob.ToolboxFittableParametricDistribution

Extreme value probability distribution object

Description

`prob.ExtremeValueDistribution` is an object consisting of parameters, a model description, and sample data for an extreme value probability distribution.

Create a probability distribution object with specified parameter values using `makedist`. Alternatively, fit a distribution to data using `fitdist` or the Distribution Fitting app.

Construction

`pd = makedist('ExtremeValue')` creates an extreme value probability distribution object using the default parameter values.

`pd = makedist('ExtremeValue', 'mu', mu, 'sigma', sigma)` creates an extreme value probability distribution object using the specified parameter values.

Input Arguments

mu — Location parameter

0 (default) | scalar value

Location parameter of the extreme value distribution, specified as a scalar value.

Data Types: `single` | `double`

sigma — Scale parameter

1 (default) | nonnegative scalar value

Scale parameter of the extreme value distribution, specified as a nonnegative scalar value.

Data Types: `single` | `double`

Properties

mu — Location parameter

scalar value

Location parameter of the extreme value distribution, stored as a scalar value.

Data Types: `single` | `double`

sigma — Scale parameter

nonnegative scalar value

Scale parameter of the extreme value distribution, stored as a nonnegative scalar value.

Data Types: `single` | `double`

DistributionName — Probability distribution name

probability distribution name string

Probability distribution name, stored as a valid probability distribution name string. This property is read-only.

Data Types: `char`

InputData — Data used for distribution fitting

structure

Data used for distribution fitting, stored as a structure containing the following:

- **data**: Data vector used for distribution fitting.
- **cens**: Censoring vector, or empty if none.
- **freq**: Frequency vector, or empty if none.

This property is read-only.

Data Types: `struct`

IsTruncated — Logical flag for truncated distribution

0 | 1

Logical flag for truncated distribution, stored as a logical value. If `IsTruncated` equals 0, the distribution is not truncated. If `IsTruncated` equals 1, the distribution is truncated. This property is read-only.

Data Types: logical

NumParameters — Number of parameters

positive integer value

Number of parameters for the probability distribution, stored as a positive integer value. This property is read-only.

Data Types: single | double

ParameterCovariance — Covariance matrix of the parameter estimates

matrix of scalar values

Covariance matrix of the parameter estimates, stored as a p -by- p matrix, where p is the number of parameters in the distribution. The (i, j) element is the covariance between the estimates of the i th parameter and the j th parameter. The (i, i) element is the estimated variance of the i th parameter. If parameter i is fixed rather than estimated by fitting the distribution to data, then the (i, i) elements of the covariance matrix are 0. This property is read-only.

Data Types: single | double

ParameterDescription — Distribution parameter descriptions

cell array of strings

Distribution parameter descriptions, stored as a cell array of strings. Each cell contains a short description of one distribution parameter. This property is read-only.

Data Types: char

ParameterIsFixed — Logical flag for fixed parameters

array of logical values

Logical flag for fixed parameters, stored as an array of logical values. If 0, the corresponding parameter in the `ParameterNames` array is not fixed. If 1, the corresponding parameter in the `ParameterNames` array is fixed. This property is read-only.

Data Types: logical

ParameterNames — Distribution parameter names

cell array of strings

Distribution parameter names, stored as a cell array of strings. This property is read-only.

Data Types: char

ParameterValues — Distribution parameter values

vector of scalar values

Distribution parameter values, stored as a vector. This property is read-only.

Data Types: single | double

Truncation — Truncation interval

vector of scalar values

Truncation interval for the probability distribution, stored as a vector containing the lower and upper truncation boundaries. This property is read-only.

Data Types: single | double

Methods

Inherited Methods

cdf

Cumulative distribution function of probability distribution object

icdf

Inverse cumulative distribution function of probability distribution object

iqr

Interquartile range of probability distribution object

median

Median of probability distribution object

pdf	Probability density function of probability distribution object
random	Generate random numbers from probability distribution object
truncate	Truncate probability distribution object
mean	Mean of probability distribution object
negloglik	Negative loglikelihood of probability distribution object
paramci	Confidence intervals for probability distribution parameters
proflik	Profile likelihood function for probability distribution object
std	Standard deviation of probability distribution object
var	Variance of probability distribution object

Definitions

Extreme Value Distribution

The extreme value distribution is appropriate for modeling the smallest value from a distribution whose tails decay exponentially fast, for example, the normal distribution. It can also model the largest value from a distribution, such as the normal or exponential distributions, by using the negative of the original values.

The extreme value distribution uses the following parameters.

Parameter	Description	Support
mu	Location parameter	$-\infty < \mu < \infty$
sigma	Scale parameter	$\sigma \geq 0$

The probability density function (pdf) is

$$f(x | \mu, \sigma) = \sigma^{-1} \exp\left(\frac{x - \mu}{\sigma}\right) \exp\left(-\exp\left(\frac{x - \mu}{\sigma}\right)\right) ; \quad -\infty < x < \infty.$$

This form of the probability density function is suitable for modeling the minimum value. To model the maximum value, use the negative of the original values.

Examples

Create an Extreme Value Distribution Object Using Default Parameters

Create an extreme value distribution object using the default parameter values.

```
pd = makedist('ExtremeValue')
pd =
    ExtremeValueDistribution

    Extreme Value distribution
    mu = 0
    sigma = 1
```

Create an Extreme Value Distribution Object Using Specified Parameters

Create an extreme value distribution object by specifying the parameter values.

```
pd = makedist('ExtremeValue', 'mu', -1, 'sigma', 2)
pd =
    ExtremeValueDistribution

    Extreme Value distribution
    mu = -1
```

```
sigma = 2
```

Compute the standard deviation for the distribution.

```
s = std(pd)
```

```
s =
```

```
2.5651
```

factoran

Factor analysis

Syntax

```
lambda = factoran(X,m)
[lambda,psi] = factoran(X,m)
[lambda,psi,T] = factoran(X,m)
[lambda,psi,T,stats] = factoran(X,m)
[lambda,psi,T,stats,F] = factoran(X,m)
[...] = factoran(...,param1,val1,param2,val2,...)
```

Definitions

`factoran` computes the maximum likelihood estimate (MLE) of the factor loadings matrix Λ in the factor analysis model

$$x = \mu + \Lambda f + e$$

where x is a vector of observed variables, μ is a constant vector of means, Λ is a constant d -by- m matrix of factor loadings, f is a vector of independent, standardized common factors, and e is a vector of independent specific factors. x , μ , and e are of length d . f is of length m .

Alternatively, the factor analysis model can be specified as

$$\text{cov}(x) = \Lambda\Lambda^T + \Psi$$

where $\Psi = \text{cov}(e)$ is a d -by- d diagonal matrix of specific variances.

Description

`lambda = factoran(X,m)` returns the maximum likelihood estimate, `lambda`, of the factor loadings matrix, in a common factor analysis model with m common factors. X is an n -by- d matrix where each row is an observation of d variables. The (i, j) th

element of the d -by- m matrix `lambda` is the coefficient, or loading, of the j th factor for the i th variable. By default, `factoran` calls the function `rotatefactors` to rotate the estimated factor loadings using the `'varimax'` option.

`[lambda,psi] = factoran(X,m)` also returns maximum likelihood estimates of the specific variances as a column vector `psi` of length d .

`[lambda,psi,T] = factoran(X,m)` also returns the m -by- m factor loadings rotation matrix `T`.

`[lambda,psi,T,stats] = factoran(X,m)` also returns a structure `stats` containing information relating to the null hypothesis, H_0 , that the number of common factors is m . `stats` includes the following fields:

Field	Description
<code>loglike</code>	Maximized log-likelihood value
<code>dfe</code>	Error degrees of freedom = $((d-m)^2 - (d+m))/2$
<code>chisq</code>	Approximate chi-squared statistic for the null hypothesis
<code>p</code>	Right-tail significance level for the null hypothesis

`factoran` does not compute the `chisq` and `p` fields unless `dfe` is positive and all the specific variance estimates in `psi` are positive (see “Heywood Case” on page 21-1091 below). If `X` is a covariance matrix, then you must also specify the `'nobs'` parameter if you want `factoran` to compute the `chisq` and `p` fields.

`[lambda,psi,T,stats,F] = factoran(X,m)` also returns, in `F`, predictions of the common factors, known as factor scores. `F` is an n -by- m matrix where each row is a prediction of m common factors. If `X` is a covariance matrix, `factoran` cannot compute `F`. `factoran` rotates `F` using the same criterion as for `lambda`.

`[...] = factoran(...,param1,val1,param2,val2,...)` enables you to specify optional parameter name/value pairs to control the model fit and the outputs. The following are the valid parameter/value pairs.

Parameter	Value	
<code>'xtype'</code>	Type of input in the matrix <code>X</code> . <code>'xtype'</code> can be one of:	
	<code>'data'</code>	Raw data (default)
	<code>'covariance'</code>	Positive definite covariance or correlation matrix

Parameter	Value	
'scores'	Method for predicting factor scores. 'scores' is ignored if X is not raw data.	
	'wls' 'Bartlett'	Synonyms for a weighted least-squares estimate that treats F as fixed (default)
	'regression' 'Thomson'	Synonyms for a minimum mean squared error prediction that is equivalent to a ridge regression
'start'	Starting point for the specific variances ψ_i in the maximum likelihood optimization. Can be specified as:	
	'random'	Chooses d uniformly distributed values on the interval [0,1].
	'Rsquared'	Chooses the starting vector as a scale factor times $\text{diag}(\text{inv}(\text{corrcoef}(X)))$ (default). For examples, see Jöreskog [2].
	Positive integer	Performs the given number of maximum likelihood fits, each initialized as with 'random'. <code>factoran</code> returns the fit with the highest likelihood.
	Matrix	Performs one maximum likelihood fit for each column of the specified matrix. The i th optimization is initialized with the values from the i th column. The matrix must have d rows.
'rotate'	Method used to rotate factor loadings and scores. 'rotate' can have the same values as the 'Method' parameter of <code>rotatefactors</code> . See the reference page for <code>rotatefactors</code> for a full description of the available methods.	
	'none'	Performs no rotation.
	'equamax'	Special case of the orthomax rotation. Use the 'normalize', 'reltol', and 'maxit' parameters to control the details of the rotation.

Parameter	Value	
	'orthomax'	<p>Orthogonal rotation that maximizes a criterion based on the variance of the loadings.</p> <p>Use the 'coeff', 'normalize', 'reitol', and 'maxit' parameters to control the details of the rotation.</p>
	'parsimax'	<p>Special case of the orthomax rotation (default). Use the 'normalize', 'reitol', and 'maxit' parameters to control the details of the rotation.</p>
	'pattern'	<p>Performs either an oblique rotation (the default) or an orthogonal rotation to best match a specified pattern matrix. Use the 'type' parameter to choose the type of rotation. Use the 'target' parameter to specify the pattern matrix.</p>
	'procrustes'	<p>Performs either an oblique (the default) or an orthogonal rotation to best match a specified target matrix in the least squares sense.</p> <p>Use the 'type' parameter to choose the type of rotation. Use 'target' to specify the target matrix.</p>
	'promax'	<p>Performs an oblique procrustes rotation to a target matrix determined by factoran as a function of an orthomax solution.</p> <p>Use the 'power' parameter to specify the exponent for creating the target matrix. Because 'promax' uses 'orthomax' internally, you can also specify the parameters that apply to 'orthomax'.</p>
	'quartimax'	<p>Special case of the orthomax rotation (default). Use the 'normalize', 'reitol', and 'maxit' parameters to control the details of the rotation.</p>

Parameter	Value
	<p>'varimax'</p> <p>Special case of the orthomax rotation (default). Use the 'normalize', 'reltol', and 'maxit' parameters to control the details of the rotation.</p>
	<p>Function</p> <p>Function handle to rotation function of the form</p> <pre>[B,T] = myrotation(A,...)</pre> <p>where A is a d-by-m matrix of unrotated factor loadings, B is a d-by-m matrix of rotated loadings, and T is the corresponding m-by-m rotation matrix.</p> <p>Use the <code>factoran</code> parameter 'userargs' to pass additional arguments to this rotation function. See “User-Defined Rotation Function” on page 21-1090.</p>
'coeff'	<p>Coefficient, often denoted as γ, defining the specific 'orthomax' criterion. Must be from 0 to 1. The value 0 corresponds to quartimax, and 1 corresponds to varimax. Default is 1.</p>
'normalize'	<p>Flag indicating whether the loading matrix should be row-normalized (1) or left unnormalized (0) for 'orthomax' or 'varimax' rotation. Default is 1.</p>
'reltol'	<p>Relative convergence tolerance for 'orthomax' or 'varimax' rotation. Default is <code>sqrt(eps)</code>.</p>
'maxit'	<p>Iteration limit for 'orthomax' or 'varimax' rotation. Default is 250.</p>
'target'	<p>Target factor loading matrix for 'procrustes' rotation. Required for 'procrustes' rotation. No default value.</p>
'type'	<p>Type of 'procrustes' rotation. Can be 'oblique' (default) or 'orthogonal'.</p>
'power'	<p>Exponent for creating the target matrix in the 'promax' rotation. Must be ≥ 1. Default is 4.</p>

Parameter	Value
'userargs'	Denotes the beginning of additional input values for a user-defined rotation function. factoran appends all subsequent values, in order and without processing, to the rotation function argument list, following the unrotated factor loadings matrix A . See “User-Defined Rotation Function” on page 21-1090.
'nobs'	If X is a covariance or correlation matrix, indicates the number of observations that were used in its estimation. This allows calculation of significance for the null hypothesis even when the original data are not available. There is no default. 'nobs' is ignored if X is raw data.
'delta'	Lower bound for the specific variances psi during the maximum likelihood optimization. Default is 0.005.
'optimopts'	Structure that specifies control parameters for the iterative algorithm the function uses to compute maximum likelihood estimates. Create this structure with the function statset . Enter statset('factoran') to see the names and default values of the parameters that factoran accepts in the options structure. See the reference page for statset for more information about these options.

Examples

Estimate and Plot Factor Loadings

Load the sample data.

```
load carbig
```

Define the variable matrix.

```
X = [Acceleration Displacement Horsepower MPG Weight];
X = X(all(~isnan(X),2),:);
```

Estimate the factor loadings using a minimum mean squared error prediction for a factor analysis with two common factors.

```
[Lambda,Psi,T,stats,F] = factoran(X,2,'scores','regression');
```

```

inv(T'*T); % Estimated correlation matrix of F, == eye(2)
Lambda*Lambda' + diag(Psi); % Estimated correlation matrix
Lambda*inv(T); % Unrotate the loadings
F*T'; % Unrotate the factor scores

```

Create biplot of two factors.

```
biplot(Lambda, 'LineWidth', 2, 'MarkerSize', 20)
```

Estimate the factor loadings using the covariance (or correlation) matrix.

```

[Lambda,Psi,T] = factoran(cov(X),2,'xtype','cov')
% [Lambda,Psi,T] = factoran(corrcoef(X),2,'xtype','cov')

```

Lambda =

```
-0.2432  -0.8500
 0.8773   0.3871
 0.7618   0.5930
-0.7978  -0.2786
 0.9692   0.2129
```

Psi =

```
0.2184
0.0804
0.0680
0.2859
0.0152
```

T =

```
0.9476   0.3195
0.3195  -0.9476
```

Although the estimates are the same, the use of a covariance matrix rather than raw data doesn't let you request scores or significance level.

Use promax rotation.

```
[Lambda,Psi,T,stats,F] = factoran(X,2,'rotate','promax',...
                                   'powerpm',4);
inv(T'*T)                          % Estimated correlation of F,
                                   % no longer eye(2)
Lambda*inv(T'*T)*Lambda'+diag(Psi) % Estimated correlation of X
```

ans =

```
1.0000  -0.6391
-0.6391   1.0000
```

ans =

```
1.0000  -0.5424  -0.6893   0.4309  -0.4167
```

```
-0.5424    1.0000    0.8979   -0.8078    0.9328
-0.6893    0.8979    1.0000   -0.7730    0.8647
 0.4309   -0.8078   -0.7730    1.0000   -0.8326
-0.4167    0.9328    0.8647   -0.8326    1.0000
```

Plot the unrotated variables with oblique axes superimposed.

```
invT = inv(T);
Lambda0 = Lambda*invT;
figure()
line([-invT(1,1) invT(1,1) NaN -invT(2,1) invT(2,1)], ...
      [-invT(1,2) invT(1,2) NaN -invT(2,2) invT(2,2)], ...
      'Color','r','linewidth',2)
grid on
hold on
biplot(Lambda0,'LineWidth',2,'MarkerSize',20)
xlabel('Loadings for unrotated Factor 1')
ylabel('Loadings for unrotated Factor 2')
```

Plot the rotated variables against the oblique axes.

```
figure()  
biplot(Lambda, 'LineWidth',2, 'MarkerSize',20)
```

User-Defined Rotation Function

Syntax for passing additional arguments to a user-defined rotation function:

[Lambda,Psi,T] = ...

```
factoran(X,2,'rotate',@myrotation,'userargs',1,'two');
```

More About

Tips

Observed Data Variables

The variables in the observed data matrix X must be linearly independent, i.e., $\text{cov}(X)$ must have full rank, for maximum likelihood estimation to succeed. `factoran` reduces both raw data and a covariance matrix to a correlation matrix before performing the fit.

`factoran` standardizes the observed data X to zero mean and unit variance before estimating the loadings λ . This does not affect the model fit, because MLEs in this model are invariant to scale. However, λ and ψ are returned in terms of the standardized variables, i.e., $\lambda \lambda' + \text{diag}(\psi)$ is an estimate of the correlation matrix of the original data X (although not after an oblique rotation). See “Estimate and Plot Factor Loadings” on page 21-1085 and “User-Defined Rotation Function” on page 21-1090.

Heywood Case

If elements of ψ are equal to the value of the `'delta'` parameter (i.e., they are essentially zero), the fit is known as a Heywood case, and interpretation of the resulting estimates is problematic. In particular, there can be multiple local maxima of the likelihood, each with different estimates of the loadings and the specific variances. Heywood cases can indicate overfitting (i.e., m is too large), but can also be the result of underfitting.

Rotation of Factor Loadings and Scores

Unless you explicitly specify no rotation using the `'rotate'` parameter, `factoran` rotates the estimated factor loadings, λ , and the factor scores, F . The output matrix T is used to rotate the loadings, i.e., $\lambda = \lambda_0 T$, where λ_0 is the initial (unrotated) MLE of the loadings. T is an orthogonal matrix for orthogonal rotations, and the identity matrix for no rotation. The inverse of T is known as the primary axis rotation matrix, while T itself is related to the reference axis rotation matrix. For orthogonal rotations, the two are identical.

`factoran` computes factor scores that have been rotated by `inv(T')`, i.e., $F = F0 * \text{inv}(T')$, where `F0` contains the unrotated predictions. The estimated covariance of `F` is `inv(T'*T)`, which, for orthogonal or no rotation, is the identity matrix. Rotation of factor loadings and scores is an attempt to create a more easily interpretable structure in the loadings matrix after maximum likelihood estimation.

FBoot property

Class: TreeBagger

Fraction of in-bag observations

Description

The `FBoot` property is the fraction of observations to be randomly selected with replacement for each bootstrap replica. The size of each replica is given by $n \cdot \text{FBoot}$, where n is the number of observations in the training set. The default value is 1.

fcdf

F cumulative distribution function

Syntax

```
p = fcdf(x, v1, v2)
p = fcdf(x, v1, Vv2, 'upper')
```

Description

`p = fcdf(x, v1, v2)` computes the F cdf at each of the values in x using the corresponding numerator degrees of freedom $v1$ and denominator degrees of freedom $v2$. x , $v1$, and $v2$ can be vectors, matrices, or multidimensional arrays that are all the same size. A scalar input is expanded to a constant matrix with the same dimensions as the other inputs. $v1$ and $v2$ parameters must contain real positive values.

`p = fcdf(x, v1, Vv2, 'upper')` returns the complement of the F cdf at each value in x , using an algorithm that more accurately computes the extreme upper tail probabilities.

The F cdf is

$$p = F(x | v_1, v_2) = \int_0^x \frac{\Gamma\left(\frac{v_1 + v_2}{2}\right)}{\Gamma\left(\frac{v_1}{2}\right)\Gamma\left(\frac{v_2}{2}\right)} \left(\frac{v_1}{v_2}\right)^{\frac{v_1}{2}} \frac{t^{\frac{v_1-2}{2}}}{\left[1 + \left(\frac{v_1}{v_2}\right)t\right]^{\frac{v_1+v_2}{2}}} dt$$

The result, p , is the probability that a single observation from an F distribution with parameters v_1 and v_2 will fall in the interval $[0, x]$.

Examples

Compute F Distribution CDF

The following illustrates a useful mathematical identity for the F distribution.

```
nu1 = 1:5;  
nu2 = 6:10;  
x = 2:6;
```

```
F1 = fcdf(x,nu1,nu2)
```

```
F1 =  
    0.7930    0.8854    0.9481    0.9788    0.9919
```

```
F2 = 1 - fcdf(1./x,nu2,nu1)
```

```
F2 =  
    0.7930    0.8854    0.9481    0.9788    0.9919
```

feval

Class: GeneralizedLinearModel

Evaluate generalized linear regression model prediction

Syntax

```
ypred = feval(md1,Xnew1,Xnew2,...,Xnewn)
```

Description

`ypred = feval(md1,Xnew1,Xnew2,...,Xnewn)` returns the predicted response of `md1` to the input `[Xnew1,Xnew_2,...,Xnewn]`.

Tips

- `feval` allows you to easily evaluate predictions of a model when the model was fitted using a table or dataset array. `predict` requires a table or dataset array with the same predictor names, but you can use simple arrays of scalars with `feval`.

Input Arguments

md1

Generalized linear model, as constructed by `fitglm` or `stepwiseglm`.

Xnew1,Xnew2,...,Xnewn

Predictor components. `Xnewi` can be one of:

- Scalar
- Vector
- Array

Each nonscalar component must have the same size (number of elements in each dimension).

If you pass just one `Xnew` array, `Xnew` can be a table, dataset array, or an array of doubles, where each column of the array represents one predictor.

Output Arguments

`ypred`

Predicted mean values at `Xnew`. `ypred` is the same size as each component of `Xnew`.

For binomial models, `feval` uses 1 as the `BinomialSize` parameter, so `ypred` is predicted probabilities.

For models with an offset, `feval` uses 0 as the offset value.

Examples

Predict Responses Using `feval`

Generate a generalized linear model, and plot its responses to a range of input data.

Generate artificial data for the model, Poisson random numbers with two underlying predictors `X(1)` and `X(2)`.

```
rng('default') % for reproducibility
rndvars = randn(100,2);
X = [2+rndvars(:,1),rndvars(:,2)];
mu = exp(1 + X*[1;2]);
y = poissrnd(mu);
```

Create a generalized linear regression model of Poisson data.

```
mdl = fitglm(X,y,'y ~ x1 + x2','distr','poisson');
```

Generate a range of values for `X(1)` and `X(2)`, and plot the model predictions at those values.

```
[Xtest1 Xtest2] = meshgrid(-1:.5:3,-2:.5:2);
```

```
Z = feval mdl, Xtest1, Xtest2);  
surf(Xtest1, Xtest2, Z)
```

- “feval” on page 10-35

Alternatives

`predict` gives the same predictions, but uses a single input array with one observation in each row, rather than one component in each input argument.

`random` predicts with added noise.

See Also

`GeneralizedLinearModel` | `predict` | `random`

More About

- “Generalized Linear Models” on page 10-12

feval

Class: LinearModel

Evaluate linear regression model prediction

Syntax

```
ypred = feval(md1,Xnew1,Xnew2,...,Xnewn)
```

Description

`ypred = feval(md1,Xnew1,Xnew2,...,Xnewn)` returns the predicted response of `md1` to the input `[Xnew1,Xnew2,...,Xnewn]`.

Input Arguments

md1

Linear model, as constructed by `fitlm` or `stepwiselm`.

Xnew1,Xnew2,...,Xnewn

Predictor components. `Xnewi` can be one of:

- Scalar
- Vector
- Array

Each nonscalar component must have the same size (number of elements in each dimension).

If you pass just one `Xnew` array, `Xnew` can be a table, dataset array, or an array of doubles, where each column of the array represents one predictor.

Output Arguments

ypred

Predicted mean values at `Xnew`. `ypred` is the same size as each component of `Xnew`.

For models with an offset, `feval` uses 0 as the offset value.

Examples

Plot Different Categorical Levels

Fit a mileage model to the `smallcar` data, including the `Year` categorical predictor. Superimpose fitted curves on a scatter plot of the data.

Load the data and fit a model.

```
load carsmall
tbl = table(MPG,Weight);
tbl.Year = ordinal(Model_Year);
mdl = fitlm(tbl,'MPG ~ Year + Weight^2');
```

Create a scatter plot of the mileage versus weight.

```
gscatter(tbl.Weight,tbl.MPG,tbl.Year);
```

Use `feval` to plot curves of the model predictions for the various years and weights.

```
w = linspace(min(tbl.Weight),max(tbl.Weight))';  
line(w,feval mdl,w,'70'),'Color','r')  
line(w,feval mdl,w,'76'),'Color','g')  
line(w,feval mdl,w,'82'),'Color','b')
```

- “feval” on page 9-38
- “Linear Regression Workflow” on page 9-41

Alternatives

`predict` gives the same predictions, but uses a single input array with one observation in each row, rather than one component in each input argument. `predict` also gives confidence intervals on its predictions.

`random` predicts with added noise.

See Also

`predict` | `LinearModel` | `random`

How To

- “Linear Regression” on page 9-11

feval

Class: NonLinearModel

Evaluate nonlinear regression model prediction

Syntax

```
yPred = feval(md1,Xnew1,Xnew2,...,Xnewn)
```

Description

`yPred = feval(md1,Xnew1,Xnew2,...,Xnewn)` returns the predicted response of `md1` to the input `[Xnew1,Xnew2,...,Xnewn]`.

Input Arguments

md1

Nonlinear regression model, constructed by `fitnlm`.

Xnew1,Xnew2,...,Xnewn

Predictor components. `Xnewi` can be one of:

- Scalar
- Vector
- Array

Each nonscalar component must have the same size (number of elements in each dimension).

If you pass just one `Xnew` array, `Xnew` can be a table, dataset array, or an array of doubles, where each column of the array represents one predictor.

Output Arguments

`ypred`

Predicted mean values at `Xnew`. `ypred` is the same size as each component of `Xnew`.

Examples

Predict a Nonlinear Model from a Table

Create a nonlinear model for auto mileage based on the `carbig` data. Predict the mileage of an average automobile.

Load the data and create a nonlinear model.

```
load carbig
tbl = table(Horsepower,Weight,MPG);
modelfun = @(b,x)b(1) + b(2)*x(:,1).^b(3) + ...
    b(4)*x(:,2).^b(5);
beta0 = [-50 500 -1 500 -1];
mdl = fitnlm(tbl,modelfun,beta0);
```

Find the predicted mileage of an average auto. The data contain some observations with NaN, so compute the mean using `nanmean`.

```
Xnew = nanmean([Horsepower Weight]);
MPGnew = feval(mdl,Xnew)
```

```
MPGnew =
```

```
    21.8073
```

- “Predict or Simulate Responses Using a Nonlinear Model” on page 11-10

Alternatives

`predict` gives the same predictions, but uses a single input array with one observation in each row, rather than one component in each input argument. `predict` also gives confidence intervals on its predictions.

random predicts with added noise.

ff2n

Two-level full factorial design

Syntax

```
dFF2 = ff2n(n)
```

Description

dFF2 = ff2n(n) gives factor settings dFF2 for a two-level full factorial design with n factors. dFF2 is m -by- n , where m is the number of treatments in the full-factorial design. Each row of dFF2 corresponds to a single treatment. Each column contains the settings for a single factor, with values of 0 and 1 for the two levels.

Examples

```
dFF2 = ff2n(3)
```

```
dFF2 =
```

```
 0  0  0
 0  0  1
 0  1  0
 0  1  1
 1  0  0
 1  0  1
 1  1  0
 1  1  1
```

fullfact

fillProximities

Class: TreeBagger

Proximity matrix for training data

Syntax

```
B = fillProximities(B)
B = fillProximities(B, 'param1', val1, 'param2', val2, ...)
```

Description

`B = fillProximities(B)` computes a proximity matrix for the training data and stores it in the `Properties` field of `B`.

`B = fillProximities(B, 'param1', val1, 'param2', val2, ...)` specifies optional parameter name/value pairs:

<code>'trees'</code>	Either <code>'all'</code> or a vector of indices of the trees in the ensemble to be used in computing the proximity matrix. Default is <code>'all'</code> .
<code>'nprint'</code>	Number of training cycles (grown trees) after which <code>TreeBagger</code> displays a diagnostic message showing training progress. Default is no diagnostic messages.

See Also

`CompactTreeBagger.outlierMeasure` | `CompactTreeBagger.proximity`

findobj

Class: grandstream

Find objects matching specified conditions

Syntax

```
hm = findobj(h, 'conditions')
```

Description

The `findobj` method of the `handle` class follows the same syntax as the MATLAB `findobj` command, except that the first argument must be an array of handles to objects.

`hm = findobj(h, 'conditions')` searches the handle object array `h` and returns an array of handle objects matching the specified conditions. Only the public members of the objects of `h` are considered when evaluating the conditions.

See Also

`findobj` | `grandstream`

findprop

Class: grandstream

Find property of MATLAB handle object

Syntax

```
p = findprop(h, 'propname')
```

Description

`p = findprop(h, 'propname')` finds and returns the `meta.property` object associated with property name `propname` of scalar handle object `h`. `propname` must be a string. It can be the name of a property defined by the class of `h` or a dynamic property added to scalar object `h`.

If no property named `propname` exists for object `h`, an empty `meta.property` array is returned.

See Also

`dynamicprops` | `findobj` | `meta.property` | `grandstream`

finv

F inverse cumulative distribution function

Syntax

`X = finv(P,V1,V2)`

Description

`X = finv(P,V1,V2)` computes the inverse of the *F* cdf with numerator degrees of freedom `V1` and denominator degrees of freedom `V2` for the corresponding probabilities in `P`. `P`, `V1`, and `V2` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs.

`V1` and `V2` parameters must contain real positive values, and the values in `P` must lie on the interval [0 1].

The *F* inverse function is defined in terms of the *F* cdf as

$$x = F^{-1}(p | v_1, v_2) = \{x : F(x | v_1, v_2) = p\}$$

where

$$p = F(x | v_1, v_2) = \int_0^x \frac{\Gamma\left(\frac{v_1 + v_2}{2}\right)}{\Gamma\left(\frac{v_1}{2}\right)\Gamma\left(\frac{v_2}{2}\right)} \left(\frac{v_1}{v_2}\right)^{\frac{v_1}{2}} \frac{t^{\frac{v_1}{2}-2}}{\left[1 + \left(\frac{v_1}{v_2}\right)t\right]^{\frac{v_1 + v_2}{2}}} dt$$

Examples

Find a value that should exceed 95% of the samples from an *F* distribution with 5 degrees of freedom in the numerator and 10 degrees of freedom in the denominator.

```
x = finv(0.95,5,10)
x =
    3.3258
```

You would observe values greater than 3.3258 only 5% of the time by chance.

fishertest

Fisher's exact test

Syntax

```
h = fishertest(x)
[h,p,stats] = fishertest(x)
[ ___ ] = fishertest(x,Name,Value)
```

Description

`h = fishertest(x)` returns a test decision for Fisher's exact test of the null hypothesis that there are no nonrandom associations between the two categorical variables in `x`, against the alternative that there is a nonrandom association. The result `h` is `1` if the test rejects the null hypothesis at the 5% significance level, or `0` otherwise.

`[h,p,stats] = fishertest(x)` also returns the significance level `p` of the test and a structure `stats` containing additional test results, including the odds ratio and its asymptotic confidence interval.

`[___] = fishertest(x,Name,Value)` returns a test decision using additional options specified by one or more name-value pair arguments. For example, you can change the significance level of the test or conduct a one-sided test.

Examples

Conduct Fisher's Exact Test

In a small survey, a researcher asked 17 individuals if they received a flu shot this year, and whether they caught the flu this winter. The results indicate that, of the nine people who did not receive a flu shot, three got the flu and six did not. Of the eight people who received a flu shot, one got the flu and seven did not.

Create a 2-by-2 contingency table containing the survey data. Row 1 contains data for the individuals who did not receive a flu shot, and row 2 contains data for the individuals

who received a flu shot. Column 1 contains the number of individuals who got the flu, and column 2 contains the number of individuals who did not.

```
x = table([3;1],[6;7], 'VariableNames', {'Flu', 'NoFlu'}, 'RowNames', {'NoShot', 'Shot'})
x =
```

	Flu	NoFlu
NoShot	3	6
Shot	1	7

Use Fisher's exact test to determine if there is a nonrandom association between receiving a flu shot and getting the flu.

```
h = fishertest(x)
```

```
h =
    0
```

The returned test decision $h = 0$ indicates that `fishertest` does not reject the null hypothesis of no nonrandom association between the categorical variables at the default 5% significance level. Therefore, based on the test results, individuals who do not get a flu shot do not have different odds of getting the flu than those who got the flu shot.

Conduct a One-Sided Fisher's Exact Test

In a small survey, a researcher asked 17 individuals if they received a flu shot this year, and whether they caught the flu. The results indicate that, of the nine people who did not receive a flu shot, three got the flu and six did not. Of the eight people who received a flu shot, one got the flu and seven did not.

```
x = [3,6;1,7];
```

Use a right-tailed Fisher's exact test to determine if the odds of getting the flu is higher for individuals who did not receive a flu shot than for individuals who did. Conduct the test at the 1% significance level.

```
[h,p,stats] = fishertest(x, 'Tail', 'right', 'Alpha', 0.01)
```

```
h =
    0
```

```
p =  
  0.3353  
  
stats =  
      OddsRatio: 3.5000  
      ConfidenceInterval: [0.1289 95.0408]
```

The returned test decision `h = 0` indicates that `fishertest` does not reject the null hypothesis of no nonrandom association between the categorical variables at the 1% significance level. Since this is a right-tailed hypothesis test, the conclusion is that individuals who do not get a flu shot do not have greater odds of getting the flu than those who got the flu shot.

Generate a Contingency Table Using `crosstab`

Load the hospital data.

```
load hospital
```

The `hospital` dataset array contains data on 100 hospital patients, including last name, gender, age, weight, smoking status, and systolic and diastolic blood pressure measurements.

To determine if smoking status is independent of gender, use `crosstab` to create a 2-by-2 contingency table of smokers and nonsmokers, grouped by gender.

```
[tbl,chi2,p,labels] = crosstab(hospital.Sex,hospital.Smoker)  
  
tbl =  
    40    13  
    26    21  
  
chi2 =  
    4.5083  
  
p =
```

```
0.0337
```

```
labels =
```

```
  'Female'  '0'
  'Male'    '1'
```

The rows of the resulting contingency table `tbl` correspond to the patient's gender, with row 1 containing data for females and row 2 containing data for males. The columns correspond to the patient's smoking status, with column 1 containing data for nonsmokers and column 2 containing data for smokers. The returned result `chi2 = 4.5083` is the value of the chi-squared test statistic for a chi-squared test of independence. The returned value `p = 0.0337` is an approximate p -value based on the chi-squared distribution.

Use the contingency table generated by `crosstab` to perform Fisher's exact test on the data.

```
[h,p,stats] = fishertest(tbl)
```

```
h =
```

```
1
```

```
p =
```

```
0.0375
```

```
stats =
```

```
      OddsRatio: 2.4852
ConfidenceInterval: [1.0624 5.8135]
```

The result `h = 1` indicates that `fishertest` rejects the null hypothesis of nonassociation between smoking status and gender at the 5% significance level. In other words, there is an association between gender and smoking status. The odds ratio indicates that the male patients have about 2.5 times greater odds of being smokers than the female patients.

The returned p -value of the test, `p = 0.0375`, is close to, but not exactly the same as, the result obtained by `crosstab`. This is because `fishertest` computes an exact p -

value using the sample data, while `crosstab` uses a chi-squared approximation to compute the p -value.

Input Arguments

x — Contingency table

2-by-2 matrix of nonnegative integer values | 2-by-2 table of nonnegative integer values

Contingency table, specified as a 2-by-2 matrix or table containing nonnegative integer values. A contingency table contains the frequency distribution of the variables in the sample data. You can use `crosstab` to generate a contingency table from sample data.

Example: `[4,0;0,4]`

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`,`Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Alpha',0.01,'Tail','right'` specifies a right-tailed hypothesis test at the 1% significance level.

'Alpha' — Significance level

0.05 (default) | scalar value in the range (0,1)

Significance level of the hypothesis test, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the range (0,1).

Example: `'Alpha',0.01`

Data Types: `single` | `double`

'Tail' — Type of alternative hypothesis

`'both'` (default) | `'right'` | `'left'`

Type of alternative hypothesis, specified as the comma-separated pair consisting of `'Tail'` and one of the following.

'both'	Two-tailed test. The alternative hypothesis is that there is a nonrandom association between the two variables in <code>x</code> , and the odds ratio is not equal to 1.
'right'	Right-tailed test. The alternative hypothesis is that the odds ratio is greater than 1.
'left'	Left-tailed test. The alternative hypothesis is that the odds ratio is less than 1.

Example: 'Tail', 'right'

Output Arguments

h — Hypothesis test result

1 | 0

Hypothesis test result, returned as a logical value.

- If `h` is 1, then `fishertest` rejects the null hypothesis at the Alpha significance level.
- If `h` is 0, then `fishertest` fails to reject the null hypothesis at the Alpha significance level.

p — *p*-value

scalar value in the range [0,1]

p-value of the test, returned as a scalar value in the range [0,1]. *p* is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. Small values of *p* cast doubt on the validity of the null hypothesis.

stats — Test data

structure

Test data, returned as a structure with the following fields:

- **OddsRatio** — A measure of association between the two variables.
- **ConfidenceInterval** — Asymptotic confidence interval for the odds ratio. If any of the cell frequencies in `x` are 0, then `fishertest` does not compute a confidence interval and instead displays `[-Inf Inf]`.

More About

Fisher's Exact Test

Fisher's exact test is a nonparametric statistical test used to test the null hypothesis that no nonrandom associations exist between two categorical variables, against the alternative that there is a nonrandom association between the variables.

Fisher's exact test provides an alternative to the chi-squared test for small samples, or samples with very uneven marginal distributions. Unlike the chi-squared test, Fisher's exact test does not depend on large-sample distribution assumptions, and instead calculates an exact p -value based on the sample data. Although Fisher's exact test is valid for samples of any size, it is not recommended for large samples because it is computationally intensive. If all of the frequency counts in the contingency table are greater than or equal to $1e7$, then `fishertest` errors. For contingency tables that contain large count values or are well-balanced, use `crosstab` or `chi2gof` instead.

`fishertest` accepts a 2-by-2 contingency table as input, and computes the p -value of the test as follows:

- 1 Calculate the sums for each row, column, and total number of observations in the contingency table.
- 2 Using a multivariate generalization of the hypergeometric probability function, calculate the conditional probability of observing the exact result in the contingency table if the null hypothesis were true, given its row and column sums. The conditional probability is

$$P_{cutoff} = \frac{(R_1!R_2!)(C_1!C_2!)}{N! \prod_{i,j} n_{ij}!},$$

where R_1 and R_2 are the row sums, C_1 and C_2 are the column sums, N is the total number of observations in the contingency table, and n_{ij} is the value in the i th row and j th column of the table.

- 3 Find all possible matrices of nonnegative integers consistent with the row and column sums. For each matrix, calculate the associated conditional probability using the equation for P_{cutoff} .
- 4 Use these values to calculate the p -value of the test, based on the alternative hypothesis of interest.

- For a two-sided test, sum all of the conditional probabilities less than or equal to P_{cutoff} for the observed contingency table. This represents the probability of observing a result as extreme as, or more extreme than, the actual outcome if the null hypothesis were true. Small p -values cast doubt on the validity of the null hypothesis, in favor of the alternative hypothesis of association between the variables.
- For a left-sided test, sum the conditional probabilities of all the matrices with a (1,1) cell frequency less than or equal to n_{11} .
- For a right-sided test, sum the conditional probabilities of all the matrices with a (1,1) cell frequency greater than or equal to n_{11} in the observed contingency table.

The odds ratio is

$$OR = \frac{n_{11}n_{22}}{n_{21}n_{12}} .$$

The null hypothesis of conditional independence is equivalent to the hypothesis that the odds ratio equals 1. The left-sided alternative is equivalent to an odds ratio less than 1, and the right-sided alternative is equivalent to an odds ratio greater than 1.

The asymptotic $100(1 - \alpha)\%$ confidence interval for the odds ratio is

$$CI = \left[\exp\left(L - \Phi^{-1}\left(\frac{1-\alpha}{2}\right)SE\right), \exp\left(L + \Phi^{-1}\left(\frac{1-\alpha}{2}\right)SE\right) \right],$$

where L is the log odds ratio, $\Phi^{-1}(\cdot)$ is the inverse of the normal inverse cumulative distribution function, and SE is the standard error for the log odds ratio. If the $100(1 - \alpha)\%$ confidence interval does not contain the value 1, then the association is significant at the α significance level. If any of the four cell frequencies are 0, then `fishertest` does not compute the confidence interval and instead displays `[- Inf Inf]`.

`fishertest` only accepts 2-by-2 contingency tables as input. To test the independence of categorical variables with more than two levels, use the chi-squared test provided by `crosstab`.

`chi2gof` | `crosstab`

ClassificationDiscriminant.fit

Class: ClassificationDiscriminant

Fit discriminant analysis classifier (to be removed)

Compatibility

ClassificationDiscriminant.fit will be removed in a future release. Use fitcdiscr instead.

Syntax

```
obj = ClassificationDiscriminant.fit(x,y)
obj = ClassificationDiscriminant.fit(x,y,Name,Value)
```

Description

obj = ClassificationDiscriminant.fit(x,y) returns a discriminant analysis classifier based on the input variables (also known as predictors, features, or attributes) x and output (response) y.

obj = ClassificationDiscriminant.fit(x,y,Name,Value) fits a classifier with additional options specified by one or more Name,Value pair arguments. If you use one of the following five options, obj is of class ClassificationPartitionedModel: 'CrossVal', 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'. Otherwise, obj is of class ClassificationDiscriminant.

Input Arguments

x — Predictor values

matrix of numeric values

Predictor values, specified as a matrix of numeric values. Each column of x represents one variable, and each row represents one observation.

`ClassificationDiscriminant.fit` considers NaN values in `x` as missing values. `ClassificationDiscriminant.fit` does not use observations with missing values for `x` in the fit.

Example:

Data Types: `single` | `double`

y — Classification values

numeric vector | categorical vector | logical vector | character array | cell array of strings

Classification values, specified as a numeric vector, categorical vector (nominal or ordinal), logical vector, character array, or cell array of strings. Each row of `y` represents the classification of the corresponding row of `x`.

`ClassificationDiscriminant.fit` considers NaN values in `y` to be missing values. `ClassificationDiscriminant.fit` does not use observations with missing values for `y` in the fit.

Data Types: `single` | `double` | `logical` | `char` | `cell`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

'ClassNames' — Class names

array

Class names, specified as the comma-separated pair consisting of `'ClassNames'` and an array. Use the data type that exists in `y`. The default is the class names that exist in `y`. Use `ClassNames` to order the classes or to select a subset of classes for training.

Data Types: `single` | `double` | `logical` | `char`

'Cost' — Cost of misclassification

square matrix | structure

Cost of misclassification, specified as the comma-separated pair consisting of `'Cost'` and a square matrix, where `Cost(i, j)` is the cost of classifying a point into class

j if its true class is i . Alternatively, `Cost` can be a structure `S` having two fields: `S.ClassNames` containing the group names as a variable of the same type as y , and `S.ClassificationCosts` containing the cost matrix.

The default is `Cost(i, j)=1` if $i \neq j$, and `Cost(i, j)=0` if $i=j$.

Data Types: `single` | `double` | `struct`

'CrossVal' — Flag to train cross-validated classifier

'off' (default) | 'on'

Flag to train a cross-validated classifier, specified as the comma-separated pair consisting of 'CrossVal' and either 'on' or 'off'.

If you specify 'on', then `ClassificationDiscriminant.fit` creates a cross-validated classifier with 10 folds.

You can override this cross-validation setting using one of the 'KFold', 'Holdout', 'Leaveout', or 'CVPartition' name-value pair arguments.

You can only use one of these four options at a time to create a cross-validated model: 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'.

Alternatively, cross validate `obj` later using the `crossval` method.

Example: 'CrossVal', 'on'

'CVPartition' — Cross-validated model partition

`cvpartition` object

Cross-validated model partition, specified as the comma-separated pair consisting of 'CVPartition' and an object created using `cvpartition`. You can only use one option at a time for creating a cross-validated model: 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'.

'Delta' — Linear coefficient threshold

0 (default) | nonnegative scalar value

Linear coefficient threshold, specified as the comma-separated pair consisting of 'Delta' and a nonnegative scalar value. If a coefficient of `obj` has magnitude smaller than `Delta`, `obj` sets this coefficient to 0, and you can eliminate the corresponding predictor from the model. Set `Delta` to a higher value to eliminate more predictors.

Delta must be 0 for quadratic discriminant models.

Data Types: single | double

'DiscrimType' — Discriminant type

'linear' (default) | 'quadratic' | 'diagLinear' | 'diagQuadratic' |
'pseudoLinear' | 'pseudoQuadratic'

Discriminant type, specified as the comma-separated pair consisting of 'DiscrimType' and one of the following:

- 'linear'
- 'quadratic'
- 'diagLinear'
- 'diagQuadratic'
- 'pseudoLinear'
- 'pseudoQuadratic'

Example: 'DiscrimType', 'quadratic'

'FillCoeffs' — Coeffs property flag

'on' | 'off'

Coeffs property flag, specified as the comma-separated pair consisting of 'FillCoeffs' and 'on' or 'off'. Setting the flag to 'on' populates the Coeffs property in the classifier object. This can be computationally intensive, especially when cross validating. The default is 'on', unless you specify a cross validation name-value pair, in which case the flag is set to 'off' by default.

Example: 'FillCoeffs', 'off'

'Gamma' — Regularization parameter

scalar value in the range [0, 1]

Parameter for regularizing the correlation matrix of predictors, specified as the comma-separated pair consisting of 'Gamma' and a scalar value in the range [0, 1].

- Linear discriminant — Scalar value in the range [0, 1].
 - If you pass a value strictly between 0 and 1, fitcdiscr sets the discriminant type to 'Linear'.

- If you pass 0 for Gamma and 'Linear' for DiscrimType, and if the correlation matrix is singular, fitcdiscr sets Gamma to the minimal value required for inverting the covariance matrix.
- If you set Gamma to 1, fitcdiscr sets the discriminant type to 'DiagLinear'.
- Quadratic discriminant — Either 0 or 1.
 - If you pass 0 for Gamma and 'Quadratic' for DiscrimType, and if one of the classes has a singular covariance matrix, fitcdiscr errors.
 - If you set Gamma to 1, fitcdiscr sets the discriminant type to 'DiagQuadratic'.
 - If you set Gamma to a value between 0 and 1 for a quadratic discriminant, fitcdiscr errors.

Example: 'Gamma', 1

Data Types: single | double

'Holdout' — Fraction of data for holdout validation

scalar value in the range (0,1)

Fraction of data used for holdout validation, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range (0,1). If you specify 'Holdout', p , then the software:

- 1 Randomly reserves $p*100\%$ of the data as validation data, and trains the model using the rest of the data
- 2 Stores the compact, trained model in CVMdl.Trained

If you specify Holdout, then you cannot specify any of CVPartition, KFold, or Leaveout.

Example: 'Holdout', 0.1

Data Types: double | single

'KFold' — Number of folds

10 (default) | positive integer value

Number of folds to use in a cross-validated classifier, specified as the comma-separated pair consisting of 'KFold' and a positive integer value.

You can only use one of these four options at a time to create a cross-validated model: 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'.

Example: 'KFold',8

Data Types: single | double

'Leaveout' — Leave-one-out cross-validation flag

'off' (default) | 'on'

Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of 'Leaveout' and either 'on' or 'off'. If you specify 'on', then the software implements leave-one-out cross validation.

If you use 'Leaveout', you cannot use these 'CVPartition', 'Holdout', or 'KFold' name-value pair arguments.

Example: 'Leaveout', 'on'

Data Types: char

'PredictorNames' — Predictor variable names

{'x1', 'x2', ...} (default) | cell array of strings

Predictor variable names, specified as the comma-separated pair consisting of 'PredictorNames' and a cell array of strings containing the names for the predictor variables, in the order in which they appear in x.

Data Types: cell

'Prior' — Prior probabilities

'empirical' (default) | 'uniform' | vector of scalar values | structure

Prior probabilities for each class, specified as the comma-separated pair consisting of 'Prior' and one of the following.

- A string:
 - 'empirical' determines class probabilities from class frequencies in y. If you pass observation weights, they are used to compute the class probabilities.
 - 'uniform' sets all class probabilities equal.
- A vector containing one scalar value for each class.
- A structure S with two fields:
 - S.ClassNames containing the class names as a variable of the same type as y
 - S.ClassProbs containing a vector of corresponding probabilities

Example: 'Prior', 'uniform'

Data Types: single | double | struct

'ResponseName' — Response variable name

'Y' (default) | string

Response variable name, specified as the comma-separated pair consisting of 'ResponseName' and a string containing the name of the response variable *y*.

Example: 'ResponseName', 'Response'

Data Types: char

'SaveMemory' — Flag to save covariance matrix

'off' (default) | 'on'

Flag to save covariance matrix, specified as the comma-separated pair consisting of 'SaveMemory' and either 'on' or 'off'. If you specify 'on', then `fitcdiscr` does not store the full covariance matrix, but instead stores enough information to compute the matrix. The `predict` method computes the full covariance matrix for prediction, and does not store the matrix. If you specify 'off', then `fitcdiscr` computes and stores the full covariance matrix in `obj`.

Specify `SaveMemory` as 'on' when the input matrix contains thousands of predictors.

Example: 'SaveMemory', 'on'

'ScoreTransform' — Score transform function

'none' (default) | valid score transform string | function handle

Score transform function, specified as the comma-separated pair consisting of 'ScoreTransform' and one of the following.

String	Formula
'doublelogit'	$1/(1 + e^{-2x})$
'invlogit'	$\log(x / (1-x))$
'ismax'	Set the score for the class with the largest score to 1, and scores for all other classes to 0.
'logit'	$1/(1 + e^{-x})$
'none'	x (no transformation)

String	Formula
'sign'	-1 for $x < 0$ 0 for $x = 0$ 1 for $x > 0$
'symmetric'	$2x - 1$
'symmetriclogit'	$2/(1 + e^{-x}) - 1$
'symmetricismax'	Set the score for the class with the largest score to 1, and scores for all other classes to -1.

Alternatively, you can use your own function handle for transforming scores. Your function should accept a matrix (the original scores) and return a matrix of the same size (the transformed scores).

Example: 'ScoreTransform', 'logit'

Data Types: function_handle

'Weights' — Observation weights

`ones(size(X,1),1)` (default) | vector of scalar values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a vector of scalar values. The length of `Weights` is the number of rows in `x`. `fitcdiscr` normalizes the weights to sum to 1.

Data Types: single | double

Output Arguments

obj — Discriminant analysis classifier

classifier object

Discriminant analysis classifier, returned as a classifier object.

Note that using the 'CrossVal', 'KFold', 'Holdout', 'Leaveout', or 'CVPartition' options results in a tree of class `ClassificationPartitionedModel`. You cannot use a partitioned tree for prediction, so this kind of tree does not have a `predict` method.

Otherwise, `obj` is of class `ClassificationDiscriminant`, and you can use the `predict` method to predict the response of new data.

Definitions

Discriminant Classification

The model for discriminant analysis is:

- Each class (Y) generates data (X) using a multivariate normal distribution. That is, the model assumes X has a Gaussian mixture distribution (`gmdistribution`).
- For linear discriminant analysis, the model has the same covariance matrix for each class, only the means vary.
- For quadratic discriminant analysis, both means and covariances of each class vary.

`predict` classifies so as to minimize the expected classification cost:

$$\hat{y} = \arg \min_{y=1, \dots, K} \sum_{k=1}^K \hat{P}(k | x) C(y | k),$$

where

- \hat{y} is the predicted classification.
- K is the number of classes.
- $\hat{P}(k | x)$ is the posterior probability of class k for observation x .
- $C(y | k)$ is the cost of classifying an observation as y when its true class is k .

For details, see “How the `predict` Method Classifies” on page 15-6.

Examples

Construct a Discriminant Analysis Classifier

Load the sample data.

```
load fisheriris
```

Construct a discriminant analysis classifier using the sample data.

```
obj = ClassificationDiscriminant.fit(meas,species)
```

```
obj =
```

```
ClassificationDiscriminant
  PredictorNames: {'x1' 'x2' 'x3' 'x4'}
  ResponseName: 'Y'
  ClassNames: {'setosa' 'versicolor' 'virginica'}
  ScoreTransform: 'none'
  NumObservations: 150
  DiscrimType: 'linear'
    Mu: [3x4 double]
    Coeffs: [3x3 struct]
```

Properties, Methods

Alternatives

The `classify` function also performs discriminant analysis. `classify` is usually more awkward to use:

- `classify` requires you to fit the classifier every time you make a new prediction.
- `classify` does not perform cross validation.
- `classify` requires you to fit the classifier when changing prior probabilities.

How To

- “Discriminant Analysis” on page 15-3

ClassificationKNN.fit

Class: ClassificationKNN

Fit k -nearest neighbor classifier (to be removed)

Compatibility

`ClassificationKNN.fit` will be removed in a future release. Use `fitcknn` instead.

Syntax

```
mdl = ClassificationKNN.fit(X,y)
mdl = ClassificationKNN.fit(X,y,Name,Value)
```

Description

`mdl = ClassificationKNN.fit(X,y)` returns a classification model based on the input variables (also known as predictors, features, or attributes) `X` and output (response) `y`.

`mdl = ClassificationKNN.fit(X,y,Name,Value)` fits a model with additional options specified by one or more `Name,Value` pair arguments.

If you use one of these options, `mdl` is of class `ClassificationPartitionedModel`: 'CrossVal', 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'. Otherwise, `mdl` is of class `ClassificationKNN`.

Input Arguments

X — Predictor values

numeric matrix

Predictor values, specified as a numeric matrix. Each column of `X` represents one variable, and each row represents one observation.

Data Types: `single` | `double`

y — Classification values

numeric vector | categorical vector | logical vector | character array | cell array of strings

Classification values, specified as a numeric vector, categorical vector, logical vector, character array, or cell array of strings, with the same number of rows as `X`. Each row of `y` represents the classification of the corresponding row of `X`.

Data Types: `single` | `double` | `cell` | `logical` | `char`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

'BreakTies' — Tie-breaking algorithm

`'smallest'` (default) | `'nearest'` | `'random'`

Tie-breaking algorithm used by the `predict` method if multiple classes have the same smallest cost, specified as the comma-separated pair consisting of `'BreakTies'` and one of the following:

- `'smallest'` — Use the smallest index among tied groups.
- `'nearest'` — Use the class with the nearest neighbor among tied groups.
- `'random'` — Use a random tiebreaker among tied groups.

By default, ties occur when multiple classes have the same number of nearest points among the `K` nearest neighbors.

Example: `'BreakTies', 'nearest'`

'BucketSize' — Maximum data points in node

50 (default) | positive integer value

Maximum number of data points in the leaf node of the *kd*-tree, specified as the comma-separated pair consisting of `'BucketSize'` and a positive integer value. This argument is meaningful only when `NSMethod` is `'kdtree'`.

Example: `'BucketSize',40`

Data Types: `single` | `double`

'CategoricalPredictors' — Categorical predictor flag

`[]` (default) | `'all'`

Categorical predictor flag, specified as the comma-separated pair consisting of `'CategoricalPredictors'` and one of the following:

- `'all'` — All predictors are categorical.
- `[]` — No predictors are categorical.

When you set `CategoricalPredictors` to `'all'`, the default `Distance` is `'hamming'`.

Example: `'CategoricalPredictors','all'`

'ClassNames' — Class names

`numeric vector` | `categorical vector` | `logical vector` | `character array` | `cell array of strings`

Class names, specified as the comma-separated pair consisting of `'ClassNames'` and an array representing the class names. Use the same data type as the values that exist in `y`.

Use `ClassNames` to order the classes or to select a subset of classes for training. The default is the class names in `y`.

Data Types: `single` | `double` | `char` | `logical` | `cell`

'Cost' — Cost of misclassification

`square matrix` | `structure`

Cost of misclassification of a point, specified as the comma-separated pair consisting of `'Cost'` and one of the following:

- Square matrix, where `Cost(i,j)` is the cost of classifying a point into class `j` if its true class is `i`.
- Structure `S` having two fields: `S.ClassNames` containing the group names as a variable of the same type as `y`, and `S.ClassificationCosts` containing the cost matrix.

The default is `Cost(i,j)=1` if `i~=j`, and `Cost(i,j)=0` if `i=j`.

Data Types: `single` | `double` | `struct`

'Cov' — Covariance matrix

`nancov(X)` (default) | positive definite matrix of scalar values

Covariance matrix, specified as the comma-separated pair consisting of `'Cov'` and a positive definite matrix of scalar values representing the covariance matrix when computing the Mahalanobis distance. This argument is only valid when `'Distance'` is `'mahalanobis'`.

You cannot simultaneously specify `'Standardize'` and either of `'Scale'` or `'Cov'`.

Data Types: `single` | `double`

'CrossVal' — Cross-validation flag

`'off'` (default) | `'on'`

Cross-validation flag, specified as the comma-separated pair consisting of `'CrossVal'` and either `'on'` or `'off'`. If `'on'`, `fitcknn` creates a cross-validated model with 10 folds. Use the `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'` parameters to override this cross-validation setting. You can only use one parameter at a time to create a cross-validated model.

Alternatively, cross validate mdl later using the `crossval` method.

Example: `'Crossval', 'on'`

'CVPartition' — Cross-validated model partition

`cvpartition` object

Cross-validated model partition, specified as the comma-separated pair consisting of `'CVPartition'` and an object created using `cvpartition`. You can only use one of these four options at a time to create a cross-validated model: `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'`.

'Distance' — Distance metric

valid distance metric string | function handle

Distance metric, specified as the comma-separated pair consisting of `'Distance'` and a valid distance metric string or function handle. The allowable strings depend on the `NSMethod` parameter, which you set in `fitcknn`, and which exists as a field in

`ModelParameters`. If you specify `CategoricalPredictors` as `'all'`, then the default distance metric is `'hamming'`. Otherwise, the default distance metric is `'euclidean'`.

NSMethod	Distance Metric Names
<code>exhaustive</code>	Any distance metric of <code>ExhaustiveSearcher</code>
<code>kdtree</code>	<code>'cityblock'</code> , <code>'chebychev'</code> , <code>'euclidean'</code> , or <code>'minkowski'</code>

For definitions, see “Distance Metrics”.

This table includes valid distance metrics of `ExhaustiveSearcher`.

Value	Description
<code>'cityblock'</code>	City block distance.
<code>'chebychev'</code>	Chebychev distance (maximum coordinate difference).
<code>'correlation'</code>	One minus the sample linear correlation between observations (treated as sequences of values).
<code>'cosine'</code>	One minus the cosine of the included angle between observations (treated as vectors).
<code>'euclidean'</code>	Euclidean distance.
<code>'hamming'</code>	Hamming distance, percentage of coordinates that differ.
<code>'jaccard'</code>	One minus the Jaccard coefficient, the percentage of nonzero coordinates that differ.
<code>'mahalanobis'</code>	Mahalanobis distance, computed using a positive definite covariance matrix <code>C</code> . The default value of <code>C</code> is the sample covariance matrix of <code>X</code> , as computed by <code>nancov(X)</code> . To specify a different value for <code>C</code> , use the <code>'Cov'</code> name-value pair argument.
<code>'minkowski'</code>	Minkowski distance. The default exponent is 2. To specify a different exponent, use the <code>'Exponent'</code> name-value pair argument.
<code>'seuclidean'</code>	Standardized Euclidean distance. Each coordinate difference between <code>X</code> and a query point is scaled, meaning divided by a scale value <code>S</code> . The default value of <code>S</code> is the standard deviation computed from <code>X</code> , <code>S = nanstd(X)</code> . To specify another value for <code>S</code> , use the <code>Scale</code> name-value pair argument.

Value	Description
'spearman'	One minus the sample Spearman's rank correlation between observations (treated as sequences of values).
@ <i>distfun</i>	Distance function handle. <i>distfun</i> has the form <pre>function D2 = DISTFUN(ZI,ZJ) % calculation of distance ... where</pre> <ul style="list-style-type: none"> • ZI is a 1-by-N vector containing one row of X or y. • ZJ is an M2-by-N matrix containing multiple rows of X or y. • D2 is an M2-by-1 vector of distances, and D2(k) is the distance between observations ZI and ZJ(J,:).

Example: 'Distance', 'minkowski'

Data Types: function_handle

'DistanceWeight' — Distance weighting function

'equal' (default) | 'inverse' | 'squaredinverse' | function handle

Distance weighting function, specified as the comma-separated pair consisting of 'DistanceWeight' and either a function handle or one of the following strings specifying the distance weighting function.

DistanceWeight	Meaning
'equal'	No weighting
'inverse'	Weight is 1/distance
'squaredinverse'	Weight is 1/distance ²
@ <i>fcn</i>	<i>fcn</i> is a function that accepts a matrix of nonnegative distances, and returns a matrix the same size containing nonnegative distance weights. For example, 'squaredinverse' is equivalent to @(d)d.^(-2).

Example: 'DistanceWeight', 'inverse'

Data Types: `function_handle`

'Exponent' — Minkowski distance exponent

2 (default) | positive scalar value

Minkowski distance exponent, specified as the comma-separated pair consisting of 'Exponent' and a positive scalar value. This argument is only valid when 'Distance' is 'minkowski'.

Example: 'Exponent',3

Data Types: `single` | `double`

'Holdout' — Fraction of data for holdout validation

0 (default) | scalar value in the range [0,1]

Fraction of data used for holdout validation, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range [0,1]. Holdout validation tests the specified fraction of the data, and uses the remaining data for training.

If you use `Holdout`, you cannot use any of the 'CVPartition', 'KFold', or 'Leaveout' name-value pair arguments.

Example: 'Holdout',0.1

Data Types: `single` | `double`

'IncludeTies' — Tie inclusion flag

false (default) | true

Tie inclusion flag, specified as the comma-separated pair consisting of 'IncludeTies' and a logical value indicating whether `predict` includes all the neighbors whose distance values are equal to the Kth smallest distance. If `IncludeTies` is true, `predict` includes all these neighbors. Otherwise, `predict` uses exactly K neighbors.

Example: 'IncludeTies',true

Data Types: `logical`

'KFold' — Number of folds

10 (default) | positive integer value

Number of folds to use in a cross-validated model, specified as the comma-separated pair consisting of 'KFold' and a positive integer value.

If you use 'KFold', you cannot use any of the 'CVPartition', 'Holdout', or 'Leaveout' name-value pair arguments.

Example: 'KFold',8

Data Types: single | double

'Leaveout' — Leave-one-out cross-validation flag

'off' (default) | 'on'

Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of 'Leaveout' and either 'on' or 'off'. Specify 'on' to use leave-one-out cross validation.

If you use 'Leaveout', you cannot use any of the 'CVPartition', 'Holdout', or 'KFold' name-value pair arguments.

Example: 'Leaveout', 'on'

'NSMethod' — Nearest neighbor search method

'kdtree' | 'exhaustive'

Nearest neighbor search method, specified as the comma-separated pair consisting of 'NSMethod' and 'kdtree' or 'exhaustive'.

- 'kdtree' — Create and use a *kd*-tree to find nearest neighbors. 'kdtree' is valid when the distance metric is one of the following:
 - 'euclidean'
 - 'cityblock'
 - 'minkowski'
 - 'chebyshev'
- 'exhaustive' — Use the exhaustive search algorithm. The distance values from all points in X to each point in y are computed to find nearest neighbors.

The default is 'kdtree' when X has 10 or fewer columns, X is not sparse, and the distance metric is a 'kdtree' type; otherwise, 'exhaustive'.

Example: 'NSMethod', 'exhaustive'

'NumNeighbors' — Number of nearest neighbors to find

1 (default) | positive integer value

Number of nearest neighbors in X to find for classifying each point when predicting, specified as the comma-separated pair consisting of `'NumNeighbors'` and a positive integer value.

Example: `'NumNeighbors',3`

Data Types: `single` | `double`

'PredictorNames' — Predictor variable names

`{'x1','x2',...}` (default) | cell array of strings

Predictor variable names, specified as the comma-separated pair consisting of `'PredictorNames'` and a cell array of strings containing the names for the predictor variables, in the order in which they appear in X .

Data Types: `cell`

'Prior' — Prior probabilities

`'empirical'` (default) | `'uniform'` | vector of scalar values | structure

Prior probabilities for each class, specified as the comma-separated pair consisting of `'Prior'` and one of the following.

- A string:
 - `'empirical'` determines class probabilities from class frequencies in y . If you pass observation weights, they are used to compute the class probabilities.
 - `'uniform'` sets all class probabilities equal.
- A vector (one scalar value for each class).
- A structure S with two fields:
 - `S.ClassNames` containing the class names as a variable of the same type as y
 - `S.ClassProbs` containing a vector of corresponding probabilities

If you set values for both `Weights` and `Prior`, the weights are renormalized to add up to the value of the prior probability in the respective class.

Example: `'Prior','uniform'`

Data Types: `single` | `double` | `struct`

'ResponseName' — Response variable name

`'Y'` (default) | string

Response variable name, specified as the comma-separated pair consisting of 'ResponseName' and a string containing the name of the response variable y.

Example: 'ResponseName', 'Response'

Data Types: char

'Scale' — Distance scale

nanstd(X) (default) | vector of nonnegative scalar values

Distance scale, specified as the comma-separated pair consisting of 'Scale' and a vector containing nonnegative scalar values with length equal to the number of columns in X. Each coordinate difference between X and a query point is scaled by the corresponding element of Scale. This argument is only valid when 'Distance' is 'seuclidean'.

You cannot simultaneously specify 'Standardize' and either of 'Scale' or 'Cov'.

Data Types: single | double

'Weights' — Observation weights

ones(size(X,1),1) (default) | vector of scalar values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a vector of scalar values. The length of Weights is the number of rows in X.

The software normalizes the weights in each class to add up to the value of the prior probability of the class.

Data Types: single | double

Output Arguments

mdl — Classifier model

classifier model object

k-nearest neighbor classifier model, returned as a classifier model object.

Note that using the 'CrossVal', 'Kfold', 'Holdout', 'Leaveout', or 'CVPartition' options results in a model of class ClassificationPartitionedModel. You cannot use a partitioned tree for prediction, so this kind of tree does not have a predict method.

Otherwise, `mdl` is of class `ClassificationKNN`, and you can use the `predict` method to make predictions.

Definitions

Prediction

`ClassificationKNN` predicts the classification of a point `Xnew` using a procedure equivalent to this:

- 1 Find the `NumNeighbors` points in the training set `X` that are nearest to `Xnew`.
- 2 Find the `NumNeighbors` response values `Y` to those nearest points.
- 3 Assign the classification label `Ynew` that has the largest posterior probability among the values in `Y`.

For details, see “Posterior Probability” on page 21-3315 in the `predict` documentation.

Examples

Train a *k*-Nearest Neighbor Classifier

Construct a *k*-nearest neighbor classifier for Fisher's iris data, where *k*, the number of nearest neighbors in the predictors, is 5.

Load Fisher's iris data.

```
load fisheriris
X = meas;
Y = species;
```

`X` is a numeric matrix that contains four petal measurements for 150 irises. `Y` is a cell array of strings that contains the corresponding iris species.

Train a 5-nearest neighbors classifier. It is good practice to standardize noncategorical predictor data.

```
Mdl = fitcknn(X,Y,'NumNeighbors',5,'Standardize',1)
```

```

Mdl =

ClassificationKNN
  PredictorNames: {'x1' 'x2' 'x3' 'x4'}
  ResponseName: 'Y'
  ClassNames: {'setosa' 'versicolor' 'virginica'}
  ScoreTransform: 'none'
  NumObservations: 150
  Distance: 'euclidean'
  NumNeighbors: 5

```

Mdl is a trained `ClassificationKNN` classifier, and some of its properties display in the Command Window.

To access the properties of Mdl, use dot notation.

```

Mdl.ClassNames
Mdl.Prior

```

```

ans =

    'setosa'
    'versicolor'
    'virginica'

ans =

    0.3333    0.3333    0.3333

```

`Mdl.Prior` contains the class prior probabilities, which are settable using the name-value pair argument `'Prior'` in `fitcknn`. The order of the class prior probabilities corresponds to the order of the classes in `Mdl.ClassNames`. By default, the prior probabilities are the respective relative frequencies of the classes in the data.

You can also reset the prior probabilities after training. For example, set the prior probabilities to 0.5, 0.2, and 0.3 respectively.

```

Mdl.Prior = [0.5 0.2 0.3];

```

You can pass `Mdl` to, for example, “`predict (ClassificationKNN)`” to label new measurements, or “`crossval (ClassificationKNN)`” to cross validate the classifier.

Train a *k*-Nearest Neighbor Classifier Using the Minkowski Metric

Load Fisher's iris data set.

```
load fisheriris
X = meas;
Y = species;
```

`X` is a numeric matrix that contains four petal measurements for 150 irises. `Y` is a cell array of strings that contains the corresponding iris species.

Train a 3-nearest neighbors classifier using the Minkowski metric. To use the Minkowski metric, you must use an exhaustive searcher. It is good practice to standardize noncategorical predictor data.

```
Mdl = fitcknn(X,Y,'NumNeighbors',3,...
    'NSMethod','exhaustive','Distance','minkowski',...
    'Standardize',1);
```

`Mdl` is a `ClassificationKNN` classifier.

You can examine the properties of `Mdl` by double-clicking `Mdl` in the Workspace window. This opens the Variable Editor.

The screenshot shows the MATLAB Workspace window with a table of variables. The table has four columns: Name, Value, Min, and Max. The variable `Mdl` is highlighted with a mouse cursor. The other variables are `meas`, `species`, `X`, and `Y`.

Name	Value	Min	Max
<code>Mdl</code>	<code>1x1 ClassificationKNN</code>		
<code>meas</code>	<code>150x4 double</code>	0.1000	7.9
<code>species</code>	<code>150x1 cell</code>		
<code>X</code>	<code>150x4 double</code>	0.1000	7.9
<code>Y</code>	<code>150x1 cell</code>

ClassificationTree.fit

Class: ClassificationTree

Fit classification tree (to be removed)

Compatibility

ClassificationTree.fit will be removed in a future release. Use fitctree instead.

Syntax

```
tree = ClassificationTree.fit(x,y)
tree = ClassificationTree.fit(x,y,Name,Value)
```

Description

`tree = ClassificationTree.fit(x,y)` returns a classification tree based on the input variables (also known as predictors, features, or attributes) `x` and output (response) `y`. `tree` is a binary tree, where each branching node is split based on the values of a column of `x`.

`tree = ClassificationTree.fit(x,y,Name,Value)` fits a tree with additional options specified by one or more `Name,Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Note that using the `'CrossVal'`, `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'` options results in a tree of class `ClassificationPartitionedModel`. You cannot use a partitioned tree for prediction, so this kind of tree does not have a `predict` method.

Otherwise, `tree` is of class `ClassificationTree`, and you can use the `predict` method to make predictions.

Input Arguments

x — Predictor values

matrix of floating point values

Predictor values, specified as a matrix of floating point values.

`ClassificationTree.fit` considers NaN values in `x` as missing values.

`ClassificationTree.fit` does not use observations with all missing values for `x` in the fit. `ClassificationTree.fit` uses observations with some missing values for `x` to find splits on variables for which these observations have valid values.

Data Types: `single` | `double`

y — predictor values

numeric vector | categorical vector | logical vector | character array | cell array of strings

Predictor values, specified as a numeric vector, categorical vector, logical vector, character array, or cell array of strings.

Each row of `y` represents the classification of the corresponding row of `x`. For numeric `y`, consider using `fitrtree` instead. `ClassificationTree.fit` considers NaN values in `y` to be missing values.

`ClassificationTree.fit` does not use observations with missing values for `y` in the fit.

Data Types: `single` | `double` | `char` | `logical` | `cell`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1`, `Value1`, ..., `NameN`, `ValueN`.

'AlgorithmForCategorical' — Algorithm for best split on categorical predictor
'Exact' | 'PullLeft' | 'PCA' | 'OVAbyClass'

Algorithm to find the best split on a categorical predictor with L levels for data with $K \geq 3$ classes, specified as the comma-separated pair consisting of `'AlgorithmForCategorical'` and one of the following.

'Exact'	Consider all $2^{L-1} - 1$ combinations
'PullLeft'	Pull left by purity
'PCA'	Principal component-based partition
'OVByClass'	One versus all by class

`ClassificationTree.fit` selects the optimal subset of algorithms for each split using the known number of classes and levels of a categorical predictor. For $K = 2$ classes, `ClassificationTree.fit` always performs the exact search.

Example: `'AlgorithmForCategorical', 'PCA'`

'CategoricalPredictors' — Categorical predictors list

numeric or logical vector | cell array of strings | character matrix | 'all'

Categorical predictors list, specified as the comma-separated pair consisting of `'CategoricalPredictors'` and one of the following.

- A numeric vector with indices from 1 to p , where p is the number of columns of x .
- A logical vector of length p , where a `true` entry means that the corresponding column of x is a categorical variable.
- A cell array of strings, where each element in the array is the name of a predictor variable. The names must match entries in `PredictorNames` values.
- A character matrix, where each row of the matrix is a name of a predictor variable. The names must match entries in `PredictorNames` values. Pad the names with extra blanks so each row of the character matrix has the same length.
- `'all'`, meaning all predictors are categorical.

Example: `'CategoricalPredictors', 'all'`

Data Types: `single` | `double` | `char`

'ClassNames' — Class names

numeric vector | categorical vector | logical vector | character array | cell array of strings

Class names, specified as the comma-separated pair consisting of `'ClassNames'` and an array representing the class names. Use the same data type as the values that exist in y .

Use `ClassNames` to order the classes or to select a subset of classes for training. The default is the class names that exist in y .

Data Types: `single` | `double` | `char` | `logical` | `cell`

'Cost' — Cost of misclassification

square matrix | structure

Cost of misclassification a point, specified as the comma-separated pair consisting of `'Cost'` and one of the following.

- Square matrix, where `Cost(i, j)` is the cost of classifying a point into class `j` if its true class is `i`.
- Structure `S` having two fields: `S.ClassNames` containing the group names as a variable of the same type as `y`, and `S.ClassificationCosts` containing the cost matrix.

The default is `Cost(i, j)=1` if `i~j`, and `Cost(i, j)=0` if `i=j`

Data Types: `single` | `double` | `struct`

'CrossVal' — Flag to grow cross-validated tree

`'off'` (default) | `'on'`

Flag to grow a cross-validated decision tree, specified as the comma-separated pair consisting of `'CrossVal'` and either `'on'` or `'off'`.

If `'on'`, `ClassificationTree.fit` grows a cross-validated decision tree with 10 folds. You can override this cross-validation setting using one of the `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'` name-value pair arguments. Note that you can only use one of these four options (`'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'`) at a time when creating a cross-validated tree.

Alternatively, cross-validate tree later using the `crossval` method.

Example: `'CrossVal', 'on'`

'CVPartition' — Partition for cross-validation tree

`cvpartition` object

Partition to use in a cross-validated tree, specified as the comma-separated pair consisting of `'CVPartition'` and an object of the `cvpartition` class created using `cvpartition`.

Note that if you use `'CVPartition'`, you cannot use any of the `'KFold'`, `'Holdout'`, or `'Leaveout'` name-value pair arguments.

'Holdout' — Fraction of data for holdout validation

1 (default) | scalar value in the range (0,1]

Fraction of data used for holdout validation, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range [0,1]. Holdout validation tests the specified fraction of the data, and uses the rest of the data for training.

Note that if you use 'Holdout', you cannot use any of the 'CVPartition', 'KFold', or 'Leaveout' name-value pair arguments.

Example: 'Holdout',0.1

Data Types: single | double

'KFold' — Number of folds

10 (default) | positive integer value

Number of folds to use in a cross-validated tree, specified as the comma-separated pair consisting of 'KFold' and a positive integer value.

Note that if you use 'KFold', you cannot use any of the 'CVPartition', 'Holdout', or 'Leaveout' name-value pair arguments.

Example: 'KFold',8

Data Types: single | double

'Leaveout' — Leave-one-out cross validation flag

'off' (default) | 'on'

Leave-one-out cross validation flag, specified as the comma-separated pair consisting of 'Leaveout' and either 'on' or 'off'. Use leave-one-out cross validation by setting to 'on'.

Note that if you use 'Leaveout', you cannot use any of the 'CVPartition', 'Holdout', or 'KFold' name-value pair arguments.

Example: 'Leaveout','on'

'MaxCat' — Maximum category levels

10 (default) | nonnegative scalar value

Maximum category levels, specified as the comma-separated pair consisting of 'MaxCat' and a nonnegative scalar value. `ClassificationTree.fit` splits a categorical predictor using the exact search algorithm if the predictor has at most `MaxCat` levels in

the split node. Otherwise, `ClassificationTree.fit` finds the best categorical split using one of the inexact algorithms.

Note that passing a small value can lead to loss of accuracy and passing a large value can lead to long computation time and memory overload.

Example: `'MaxCat',8`

'MergeLeaves' — Leaf merge flag

`'on'` (default) | `'off'`

Leaf merge flag, specified as the comma-separated pair consisting of `'MergeLeaves'` and either `'on'` or `'off'`. When `'on'`, `ClassificationTree.fit` merges leaves that originate from the same parent node, and that give a sum of risk values greater or equal to the risk associated with the parent node. When `'off'`, `ClassificationTree.fit` does not merge leaves.

Example: `'MergeLeaves','off'`

'MinLeaf' — Minimum number of leaf node observations

1 (default) | positive integer value

Minimum number of leaf node observations, specified as the comma-separated pair consisting of `'MinLeaf'` and a positive integer value. Each leaf has at least `MinLeaf` observations per tree leaf. If you supply both `MinParent` and `MinLeaf`, `ClassificationTree.fit` uses the setting that gives larger leaves: `MinParent=max(MinParent,2*MinLeaf)`.

Example: `'MinLeaf',3`

Data Types: `single` | `double`

'MinParent' — Minimum number of branch node observations

10 (default) | positive integer value

Minimum number of branch node observations, specified as the comma-separated pair consisting of `'MinParent'` and a positive integer value. Each branch node in the tree has at least `MinParent` observations. If you supply both `MinParent` and `MinLeaf`, `ClassificationTree.fit` uses the setting that gives larger leaves: `MinParent=max(MinParent,2*MinLeaf)`.

Example: `'MinParent',8`

Data Types: `single` | `double`

'NVarToSample' — Number of predictors for split`'all'` | positive integer value

Number of predictors to select at random for each split, specified as the comma-separated pair consisting of `'NVarToSample'` and a positive integer value. You can also specify `'all'` to use all available predictors.

Example: `'NVarToSample',3`

Data Types: `single` | `double`

'PredictorNames' — Predictor variable names`{'x1','x2',...}` (default) | cell array of strings

Predictor variable names, specified as the comma-separated pair consisting of `'PredictorNames'` and a cell array of strings containing the names for the predictor variables, in the order in which they appear in `x`.

'Prior' — Prior probabilities`'empirical'` (default) | `'uniform'` | vector of scalar values | structure

Prior probabilities for each class, specified as the comma-separated pair consisting of `'Prior'` and one of the following.

- A string:
 - `'empirical'` determines class probabilities from class frequencies in `y`. If you pass observation weights, they are used to compute the class probabilities.
 - `'uniform'` sets all class probabilities equal.
- A vector (one scalar value for each class)
- A structure `S` with two fields:
 - `S.ClassNames` containing the class names as a variable of the same type as `y`
 - `S.ClassProbs` containing a vector of corresponding probabilities

If you set values for both `weights` and `prior`, the weights are renormalized to add up to the value of the prior probability in the respective class.

Example: `'Prior','uniform'`

'Prune' — Pruning flag`'on'` (default) | `'off'`

Pruning flag, specified as the comma-separated pair consisting of 'Prune' and either 'on' or 'off'. When 'on', `ClassificationTree.fit` grows the classification tree, and computes the optimal sequence of pruned subtrees. When 'off' `ClassificationTree.fit` grows the classification tree without pruning.

Example: 'Prune', 'off'

'PruneCriterion' — Pruning criterion

'error' (default) | 'impurity'

Pruning criterion, specified as the comma-separated pair consisting of 'PruneCriterion' and either 'error' or 'impurity'.

Example: 'PruneCriterion', 'impurity'

'ResponseName' — Response variable name

'Y' (default) | string

Response variable name, specified as the comma-separated pair consisting of 'ResponseName' and a string representing the name of the response variable y.

Example: 'ResponseName', 'Response'

'ScoreTransform' — Score transform function

'none' | 'symmetric' | 'invlogit' | 'ismax' | function handle | ...

Score transform function, specified as the comma-separated pair consisting of 'ScoreTransform' and a function handle for transforming scores. Your function should accept a matrix (the original scores) and return a matrix of the same size (the transformed scores).

Alternatively, you can specify one of the following strings representing a built-in transformation function.

String	Formula
'doublelogit'	$1/(1 + e^{-2x})$
'invlogit'	$\log(x / (1-x))$
'ismax'	Set the score for the class with the largest score to 1, and scores for all other classes to 0.
'logit'	$1/(1 + e^{-x})$

String	Formula
'none'	x (no transformation)
'sign'	-1 for $x < 0$ 0 for $x = 0$ 1 for $x > 0$
'symmetric'	$2x - 1$
'symmetriclogit'	$2/(1 + e^{-x}) - 1$
'symmetricismax'	Set the score for the class with the largest score to 1, and scores for all other classes to -1.

Example: 'ScoreTransform', 'logit'

'SplitCriterion' — Split criterion

'gdi' (default) | 'twoing' | 'deviance'

Split criterion, specified as the comma-separated pair consisting of 'SplitCriterion' and 'gdi' (Gini's diversity index), 'twoing' for the twoing rule, or 'deviance' for maximum deviance reduction (also known as cross entropy).

Example: 'SplitCriterion', 'deviance'

'Surrogate' — Surrogate decision splits flag

'off' | 'on' | 'all' | positive integer value

Surrogate decision splits flag, specified as the comma-separated pair consisting of 'Surrogate' and 'on', 'off', 'all', or a positive integer value.

- When set to 'on', `ClassificationTree.fit` finds at most 10 surrogate splits at each branch node.
- When set to a positive integer value, `ClassificationTree.fit` finds at most the specified number of surrogate splits at each branch node.
- When set to 'all', `ClassificationTree.fit` finds all surrogate splits at each branch node. The 'all' setting can use much time and memory.

Use surrogate splits to improve the accuracy of predictions for data with missing values. The setting also enables you to compute measures of predictive association between predictors.

Example: 'Surrogate', 'on'

'Weights' — Observation weights`ones(size(x,1),1) (default) | vector of scalar values`

Vector of observation weights, specified as the comma-separated pair consisting of `'Weights'` and a vector of scalar values. The length of `Weights` is equal to the number of rows in `x`. `ClassificationTree.fit` normalizes the weights in each class to add up to the value of the prior probability of the class.

Data Types: `single` | `double`

Output Arguments

tree — Classification tree`classification tree object`

Classification tree object, returned as a classification tree object.

Note that using the `'CrossVal'`, `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'` options results in a tree of class `ClassificationPartitionedModel`. You cannot use a partitioned tree for prediction, so this kind of tree does not have a `predict` method. Instead, use `kfoldpredict` to predict responses for observations not used for training.

Otherwise, `tree` is of class `ClassificationTree`, and you can use the `predict` method to make predictions.

Definitions

Impurity and Node Error

`ClassificationTree` splits nodes based on either *impurity* or *node error*.

Impurity means one of several things, depending on your choice of the `SplitCriterion` name-value pair argument:

- Gini's Diversity Index (`gdi`) — The Gini index of a node is

$$1 - \sum_i p^2(i),$$

where the sum is over the classes i at the node, and $p(i)$ is the observed fraction of classes with class i that reach the node. A node with just one class (a *pure* node) has Gini index 0; otherwise the Gini index is positive. So the Gini index is a measure of node impurity.

- Deviance ('deviance') — With $p(i)$ defined the same as for the Gini index, the deviance of a node is

$$-\sum_i p(i) \log p(i).$$

A pure node has deviance 0; otherwise, the deviance is positive.

- Twoing rule ('twoing') — Twoing is not a purity measure of a node, but is a different measure for deciding how to split a node. Let $L(i)$ denote the fraction of members of class i in the left child node after a split, and $R(i)$ denote the fraction of members of class i in the right child node after a split. Choose the split criterion to maximize

$$P(L)P(R) \left(\sum_i |L(i) - R(i)| \right)^2,$$

where $P(L)$ and $P(R)$ are the fractions of observations that split to the left and right respectively. If the expression is large, the split made each child node purer. Similarly, if the expression is small, the split made each child node similar to each other, and hence similar to the parent node, and so the split did not increase node purity.

- Node error — The node error is the fraction of misclassified classes at a node. If j is the class with the largest number of training samples at a node, the node error is $1 - p(j)$.

Examples

Construct a Classification Tree

Construct a classification tree for the data in `ionosphere.mat`.

```
load ionosphere
tc = ClassificationTree.fit(X,Y)

tc =

ClassificationTree
    PredictorNames: {1x34 cell}
    ResponseName: 'Y'
    ClassNames: {'b' 'g'}
    ScoreTransform: 'none'
    CategoricalPredictors: []
    NumObservations: 351
```

GeneralizedLinearModel.fit

Class: GeneralizedLinearModel

Create generalized linear regression model

Compatibility

GeneralizedLinearModel.fit will be removed in a future release. Use fitglm instead.

Syntax

```
mdl = GeneralizedLinearModel.fit(tbl)
mdl = GeneralizedLinearModel.fit(X,y)
mdl = GeneralizedLinearModel.fit(...,modelspec)
mdl = GeneralizedLinearModel.fit(...,Name,Value)
mdl = GeneralizedLinearModel.fit(...,modelspec,Name,Value)
```

Description

`mdl = GeneralizedLinearModel.fit(tbl)` creates a generalized linear model of a table or dataset array `tbl`.

`mdl = GeneralizedLinearModel.fit(X,y)` creates a generalized linear model of the responses `y` to a data matrix `X`.

`mdl = GeneralizedLinearModel.fit(...,modelspec)` creates a generalized linear model as specified by `modelspec`.

`mdl = GeneralizedLinearModel.fit(...,Name,Value)` or `mdl = GeneralizedLinearModel.fit(...,modelspec,Name,Value)` creates a generalized linear model with additional options specified by one or more `Name,Value` pair arguments.

Tips

- The generalized linear model `mdl` is a standard linear model unless you specify otherwise with the `Distribution` name-value pair.
- For other methods such as `devianceTest`, or properties of the `GeneralizedLinearModel` object, see `GeneralizedLinearModel`.

Input Arguments

tbl — Input data

table | dataset array

Input data, specified as a table or dataset array. When `modelspec` is a `formula`, it specifies the variables to be used as the predictors and response. Otherwise, if you do not specify the predictor and response variables, the last variable is the response variable and the others are the predictor variables by default.

Predictor variables and response variables can be numeric, or any grouping variable type, such as logical or categorical (see “Grouping Variables” on page 2-52).

To set a different column as the response variable, use the `ResponseVar` name-value pair argument. To use a subset of the columns as predictors, use the `PredictorVars` name-value pair argument.

Data Types: `single` | `double` | `logical`

X — Predictor variables

matrix

Predictor variables, specified as an n -by- p matrix, where n is the number of observations and p is the number of predictor variables. Each column of `X` represents one variable, and each row represents one observation.

By default, there is a constant term in the model, unless you explicitly remove it, so do not include a column of 1s in `X`.

Data Types: `single` | `double` | `logical`

y — Response variable

vector

Response variable, specified as an n -by-1 vector, where n is the number of observations. Each entry in y is the response for the corresponding row of X .

modelspec — Model specification

string specifying the model | t -by- $(p+1)$ terms matrix | string of the form ' $Y \sim \text{terms}$ '

Model specification, which is the starting model for `stepwiseglm`, specified as one of the following:

- String specifying the type of model.

String	Model Type
'constant'	Model contains only a constant (intercept) term.
'linear'	Model contains an intercept and linear terms for each predictor.
'interactions'	Model contains an intercept, linear terms, and all products of pairs of distinct predictors (no squared terms).
'purequadratic'	Model contains an intercept, linear terms, and squared terms.
'quadratic'	Model contains an intercept, linear terms, interactions, and squared terms.
'polyijk'	Model is a polynomial with all terms up to degree i in the first predictor, degree j in the second predictor, etc. Use numerals 0 through 9. For example, 'poly2111' has a constant plus all linear and product terms, and also contains terms with predictor 1 squared.

- t -by- $(p+1)$ matrix, namely terms matrix, specifying terms to include in model, where t is the number of terms and p is the number of predictor variables, and plus one is for the response variable.
- String representing a formula in the form ' $Y \sim \text{terms}$ ', where the **terms** are in “Wilkinson Notation” on page 21-1171.

Example: 'quadratic'

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

'**BinomialSize**' — Number of trials for binomial distribution

1 (default) | scalar value | vector

Number of trials for binomial distribution, that is the sample size, specified as the comma-separated pair consisting of a scalar value or a vector of the same length as the response. This is the parameter `n` for the fitted binomial distribution. `BinomialSize` applies only when the `Distribution` parameter is 'binomial'.

If `BinomialSize` is a scalar value, that means all observations have the same number of trials.

As an alternative to `BinomialSize`, you can specify the response as a two-column vector with counts in column 1 and `BinomialSize` in column 2.

Data Types: single | double

'**CategoricalVars**' — Categorical variables

cell array of strings | logical or numeric index vector

Categorical variables in the fit, specified as the comma-separated pair consisting of 'CategoricalVars' and either a cell array of strings of the names of the categorical variables in the table or dataset array `tbl`, or a logical or numeric index vector indicating which columns are categorical.

- If data is in a table or dataset array `tbl`, then the default is to treat all categorical or logical variables, character arrays, or cell arrays of strings as categorical variables.
- If data is in matrix `X`, then the default value of this name-value pair argument is an empty matrix `[]`. That is, no variable is categorical unless you specify it.

For example, you can specify the observations 2 and 3 out of 6 as categorical using either of the following examples.

Example: 'CategoricalVars', [2,3]

Example: 'CategoricalVars', logical([0 1 1 0 0 0])

Data Types: single | double | logical

'DispersionFlag' — Indicator to compute dispersion parameter

false for 'binomial' and 'poisson' distributions (default) | true

Indicator to compute dispersion parameter for 'binomial' and 'poisson' distributions, specified as the comma-separated pair consisting of 'DispersionFlag' and one of the following.

true	Estimate a dispersion parameter when computing standard errors
false	Default. Use the theoretical value when computing standard errors

The fitting function always estimates the dispersion for other distributions.

Example: 'DispersionFlag', true

'Distribution' — Distribution of the response variable

'normal' (default) | 'binomial' | 'poisson' | 'gamma' | 'inverse gaussian'

Distribution of the response variable, specified as the comma-separated pair consisting of 'Distribution' and one of the following.

'normal'	Normal distribution
'binomial'	Binomial distribution
'poisson'	Poisson distribution
'gamma'	Gamma distribution
'inverse gaussian'	Inverse Gaussian distribution

Example: 'Distribution', 'gamma'

'Exclude' — Observations to exclude

logical or numeric index vector

Observations to exclude from the fit, specified as the comma-separated pair consisting of 'Exclude' and a logical or numeric index vector indicating which observations to exclude from the fit.

For example, you can exclude observations 2 and 3 out of 6 using either of the following examples.

Example: 'Exclude', [2,3]

Example: 'Exclude', logical([0 1 1 0 0 0])

Data Types: `single` | `double` | `logical`

'Intercept' — Indicator for constant term

`true` (default) | `false`

Indicator the for constant term (intercept) in the fit, specified as the comma-separated pair consisting of `'Intercept'` and either `true` to include or `false` to remove the constant term from the model.

Use `'Intercept'` only when specifying the model using a string, not a formula or matrix.

Example: `'Intercept', false`

'Link' — Link function

The canonical link function (default) | scalar value | structure

Link function to use in place of the canonical link function, specified as the comma-separated pair consisting of `'Link'` and one of the following.

Link Function Name	Link Function	Mean (Inverse) Function
<code>'identity'</code>	$f(\mu) = \mu$	$\mu = Xb$
<code>'log'</code>	$f(\mu) = \log(\mu)$	$\mu = \exp(Xb)$
<code>'logit'</code>	$f(\mu) = \log(\mu/(1-\mu))$	$\mu = \exp(Xb) / (1 + \exp(Xb))$
<code>'probit'</code>	$f(\mu) = \Phi^{-1}(\mu)$	$\mu = \Phi(Xb)$
<code>'comploglog'</code>	$f(\mu) = \log(-\log(1 - \mu))$	$\mu = 1 - \exp(-\exp(Xb))$
<code>'reciprocal'</code>	$f(\mu) = 1/\mu$	$\mu = 1/(Xb)$
<code>p</code> (a number)	$f(\mu) = \mu^p$	$\mu = Xb^{1/p}$
<code>S</code> (a structure) with three fields. Each field holds a function handle that accepts a vector of inputs and returns a vector of the same size: <ul style="list-style-type: none"> <code>S.Link</code> — The link function <code>S.Inverse</code> — The inverse link function 	$f(\mu) = S.Link(\mu)$	$\mu = S.Inverse(Xb)$

Link Function Name	Link Function	Mean (Inverse) Function
• S.Derivative — The derivative of the link function		

The link function defines the relationship $f(\mu) = X^*b$ between the mean response μ and the linear combination of predictors X^*b .

For more information on the canonical link functions, see [Definitions](#).

Example: 'Link', 'probit'

'Offset' — Offset variable

[] (default) | vector | string

Offset variable in the fit, specified as the comma-separated pair consisting of 'Offset' and a vector or name of a variable with the same length as the response.

`fitglm` and `stepwiseglm` use `Offset` as an additional predictor, with a coefficient value fixed at 1.0. In other words, the formula for fitting is $\mu \sim \text{Offset} + (\text{terms involving real predictors})$

with the `Offset` predictor having coefficient 1.

For example, consider a Poisson regression model. Suppose the number of counts is known for theoretical reasons to be proportional to a predictor A. By using the log link function and by specifying `log(A)` as an offset, you can force the model to satisfy this theoretical constraint.

Data Types: single | double | char

'PredictorVars' — Predictor variables

cell array of strings | logical or numeric index vector

Predictor variables to use in the fit, specified as the comma-separated pair consisting of 'PredictorVars' and either a cell array of strings of the variable names in the table or dataset array `tbl`, or a logical or numeric index vector indicating which columns are predictor variables.

The strings should be among the names in `tbl`, or the names you specify using the 'VarNames' name-value pair argument.

The default is all variables in `X`, or all variables in `tbl` except for `ResponseVar`.

For example, you can specify the second and third variables as the predictor variables using either of the following examples.

Example: `'PredictorVars',[2,3]`

Example: `'PredictorVars',logical([0 1 1 0 0 0])`

Data Types: `single | double | logical | cell`

'ResponseVar' — Response variable

`last column in tbl (default) | string for variable name | logical or numeric index vector`

Response variable to use in the fit, specified as the comma-separated pair consisting of `'ResponseVar'` and either a string of the variable name in the table or dataset array `tbl`, or a logical or numeric index vector indicating which column is the response variable. You typically need to use `'ResponseVar'` when fitting a table or dataset array `tbl`.

For example, you can specify the fourth variable, say `yield`, as the response out of six variables, in one of the following ways.

Example: `'ResponseVar','yield'`

Example: `'ResponseVar',[4]`

Example: `'ResponseVar',logical([0 0 0 1 0 0])`

Data Types: `single | double | logical | char`

'VarNames' — Names of variables in fit

`{'x1','x2',...,'xn','y'} (default) | cell array of strings`

Names of variables in fit, specified as the comma-separated pair consisting of `'VarNames'` and a cell array of strings including the names for the columns of `X` first, and the name for the response variable `y` last.

`'VarNames'` is not applicable to variables in a table or dataset array, because those variables already have names.

For example, if in your data, horsepower, acceleration, and model year of the cars are the predictor variables, and miles per gallon (MPG) is the response variable, then you can name the variables as follows.

Example: `'VarNames',{'Horsepower','Acceleration','Model_Year','MPG'}`

Data Types: `cell`

'Weights' — Observation weights

`ones(n,1)` (default) | n -by-1 vector of nonnegative scalar values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and an n -by-1 vector of nonnegative scalar values, where n is the number of observations.

Data Types: `single` | `double`

Output Arguments

mdl — Generalized linear model

`GeneralizedLinearModel` object

Generalized linear model representing a least-squares fit of the link of the response to the data, returned as a `GeneralizedLinearModel` object.

For properties and methods of the generalized linear model object, `mdl`, see the `GeneralizedLinearModel` class page.

Definitions

Terms Matrix

A terms matrix is a t -by- $(p + 1)$ matrix specifying terms in a model, where t is the number of terms, p is the number of predictor variables, and plus one is for the response variable.

The value of $T(i, j)$ is the exponent of variable j in term i . Suppose there are three predictor variables A , B , and C :

```
[0 0 0 0] % Constant term or intercept
[0 1 0 0] % B; equivalently, A^0 * B^1 * C^0
[1 0 1 0] % A*C
[2 0 0 0] % A^2
[0 1 2 0] % B*(C^2)
```

The 0 at the end of each term represents the response variable. In general,

- If you have the variables in a table or dataset array, then 0 must represent the response variable depending on the position of the response variable. The following example illustrates this.

Load the sample data and define the dataset array.

```
load hospital
ds = dataset(hospital.Sex,hospital.BloodPressure(:,1),hospital.Age,...
hospital.Smoker,'VarNames',{'Sex','BloodPressure','Age','Smoker'});
```

Represent the linear model 'BloodPressure ~ 1 + Sex + Age + Smoker' in a terms matrix. The response variable is in the second column of the dataset array, so there must be a column of 0s for the response variable in the second column of the terms matrix.

```
T = [0 0 0 0;1 0 0 0;0 0 1 0;0 0 0 1]
```

```
T =
```

```

0     0     0     0
1     0     0     0
0     0     1     0
0     0     0     1
```

Redefine the dataset array.

```
ds = dataset(hospital.BloodPressure(:,1),hospital.Sex,hospital.Age,...
hospital.Smoker,'VarNames',{'BloodPressure','Sex','Age','Smoker'});
```

Now, the response variable is the first term in the dataset array. Specify the same linear model, 'BloodPressure ~ 1 + Sex + Age + Smoker', using a terms matrix.

```
T = [0 0 0 0;0 1 0 0;0 0 1 0;0 0 0 1]
```

```
T =
```

```

0     0     0     0
0     1     0     0
0     0     1     0
0     0     0     1
```

- If you have the predictor and response variables in a matrix and column vector, then you must include 0 for the response variable at the end of each term. The following example illustrates this.

Load the sample data and define the matrix of predictors.

```
load carsmall
X = [Acceleration,Weight];
```

Specify the model 'MPG ~ Acceleration + Weight + Acceleration:Weight + Weight^2' using a term matrix and fit the model to the data. This model includes the main effect and two-way interaction terms for the variables, Acceleration and Weight, and a second-order term for the variable, Weight.

```
T = [0 0 0;1 0 0;0 1 0;1 1 0;0 2 0]
```

```
T =
```

```

0    0    0
1    0    0
0    1    0
1    1    0
0    2    0
```

Fit a linear model.

```
mdl = fitlm(X,MPG,T)
```

```
mdl =
```

```
Linear regression model:
y ~ 1 + x1*x2 + x2^2
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	48.906	12.589	3.8847	0.00019665
x1	0.54418	0.57125	0.95261	0.34337
x2	-0.012781	0.0060312	-2.1192	0.036857
x1:x2	-0.00010892	0.00017925	-0.6076	0.545
x2^2	9.7518e-07	7.5389e-07	1.2935	0.19917

Number of observations: 94, Error degrees of freedom: 89

Root Mean Squared Error: 4.1

R-squared: 0.751, Adjusted R-Squared 0.739

F-statistic vs. constant model: 67, p-value = 4.99e-26

Only the intercept and x2 term, which correspond to the Weight variable, are significant at the 5% significance level.

Now, perform a stepwise regression with a constant model as the starting model and a linear model with interactions as the upper model.

```
T = [0 0 0;1 0 0;0 1 0;1 1 0];  
mdl = stepwiselm(X,MPG,[0 0 0], 'upper',T)
```

1. Adding x2, FStat = 259.3087, pValue = 1.643351e-28

```
mdl =
```

Linear regression model:

```
y ~ 1 + x2
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	49.238	1.6411	30.002	2.7015e-49
x2	-0.0086119	0.0005348	-16.103	1.6434e-28

Number of observations: 94, Error degrees of freedom: 92

Root Mean Squared Error: 4.13

R-squared: 0.738, Adjusted R-Squared 0.735

F-statistic vs. constant model: 259, p-value = 1.64e-28

The results of the stepwise regression are consistent with the results of `fitlm` in the previous step.

Formula

A formula for model specification is a string of the form ' $Y \sim terms$ '

where

- Y is the response name.
- $terms$ contains
 - Variable names
 - + means include the next variable
 - - means do not include the next variable
 - : defines an interaction, a product of terms
 - * defines an interaction **and all lower-order terms**
 - ^ raises the predictor to a power, exactly as in * repeated, so ^ includes lower order terms as well
 - () groups terms

Note: Formulas include a constant (intercept) term by default. To exclude a constant term from the model, include -1 in the formula.

For example,

'Y ~ A + B + C' means a three-variable linear model with intercept.

'Y ~ A + B + C - 1' is a three-variable linear model without intercept.

'Y ~ A + B + C + B^2' is a three-variable model with intercept and a B^2 term.

'Y ~ A + B^2 + C' is the same as the previous example because B^2 includes a B term.

'Y ~ A + B + C + A:B' includes an A*B term.

'Y ~ A*B + C' is the same as the previous example because $A*B = A + B + A:B$.

'Y ~ A*B*C - A:B:C' has all interactions among A, B, and C, except the three-way interaction.

'Y ~ A*(B + C + D)' has all linear terms, plus products of A with each of the other variables.

Wilkinson Notation

Wilkinson notation describes the factors present in models. The notation relates to factors present in models, not to the multipliers (coefficients) of those factors.

Wilkinson Notation	Factors in Standard Notation
1	Constant (intercept) term
A^k , where k is a positive integer	A, A^2, \dots, A^k
A + B	A, B
A*B	A, B, A*B
A:B	A*B only
-B	Do not include B
A*B + C	A, B, C, A*B
A + B + C + A:B	A, B, C, A*B
A*B*C - A:B:C	A, B, C, A*B, A*C, B*C
A*(B + C)	A, B, C, A*B, A*C

Statistics Toolbox notation always includes a constant term unless you explicitly remove the term using -1.

Canonical Link Function

The default link function for a generalized linear model is the *canonical link function*.

Canonical Link Functions for Generalized Linear Models

Distribution	Link Function Name	Link Function	Mean (Inverse) Function
'normal'	'identity'	$f(\mu) = \mu$	$\mu = Xb$
'binomial'	'logit'	$f(\mu) = \log(\mu/(1-\mu))$	$\mu = \exp(Xb) / (1 + \exp(Xb))$
'poisson'	'log'	$f(\mu) = \log(\mu)$	$\mu = \exp(Xb)$
'gamma'	-1	$f(\mu) = 1/\mu$	$\mu = 1/(Xb)$
'inverse gaussian'	-2	$f(\mu) = 1/\mu^2$	$\mu = (Xb)^{-1/2}$

Examples

Fit a Generalized Linear Model

Make a logistic binomial model of the probability of smoking as a function of age, weight, and sex, using a two-way interactions model.

Load the `hospital` dataset array.

```
load hospital
ds = hospital; % just to use the ds name
```

Specify the model using a formula that allows up to two-way interactions.

```
modelspec = 'Smoker ~ Age*Weight*Sex - Age:Weight:Sex';
```

Create the generalized linear model.

```
mdl = fitglm(ds,modelspec,'Distribution','binomial')
```

```
mdl =
```

```
Generalized Linear regression model:
  logit(Smoker) ~ 1 + Sex*Age + Sex*Weight + Age*Weight
  Distribution = Binomial
```

```
Estimated Coefficients:
```

	Estimate	SE	tStat	pValue
(Intercept)	-6.0492	19.749	-0.3063	0.75938
Sex_Male	-2.2859	12.424	-0.18399	0.85402
Age	0.11691	0.50977	0.22934	0.81861
Weight	0.031109	0.15208	0.20455	0.83792
Sex_Male:Age	0.020734	0.20681	0.10025	0.92014
Sex_Male:Weight	0.01216	0.053168	0.22871	0.8191
Age:Weight	-0.00071959	0.0038964	-0.18468	0.85348

100 observations, 93 error degrees of freedom
 Dispersion: 1
 Chi^2-statistic vs. constant model: 5.07, p-value = 0.535

The large p -value indicates the model might not differ statistically from a constant.

- “Generalized Linear Model Workflow” on page 10-39

Alternatives

You can also construct a generalized linear model using `fitglm`.

Use `stepwiseglm` to select a model specification automatically. Use `step`, `addTerms`, or `removeTerms` to adjust a fitted model.

More About

- “Generalized Linear Models” on page 10-12

gmdistribution.fit

Class: gmdistribution

Gaussian mixture parameter estimates

Note: `fit` will be removed in a future release. Use `fitgmdist` instead.

Syntax

```
obj = gmdistribution.fit(X,k)
obj = gmdistribution.fit(...,param1,val1,param2,val2,...)
```

Description

`obj = gmdistribution.fit(X,k)` uses an Expectation Maximization (EM) algorithm to construct an object `obj` of the `gmdistribution` class containing maximum likelihood estimates of the parameters in a Gaussian mixture model with `k` components for data in the n -by- d matrix `X`, where n is the number of observations and d is the dimension of the data.

`gmdistribution` treats NaN values as missing data. Rows of `X` with NaN values are excluded from the fit.

`obj = gmdistribution.fit(...,param1,val1,param2,val2,...)` provides control over the iterative EM algorithm. Parameters and values are listed below.

Parameter	Value
'Start'	Method used to choose initial component parameters. One of the following: <ul style="list-style-type: none">'randSample' — To select <code>k</code> observations from <code>X</code> at random as initial component means. The mixing proportions are uniform.

Parameter	Value
	<p>The initial covariance matrices for all components are diagonal, where the element j on the diagonal is the variance of $X(:, j)$. This is the default.</p> <ul style="list-style-type: none"> • 'plus' — The software selects k observations from X using the kmeans++ algorithm. The initial mixing proportions are uniform. The initial covariance matrices for all components are diagonal, where the element j on the diagonal is the variance of $X(:, j)$. • S — A structure array with fields <code>mu</code>, <code>Sigma</code>, and <code>PComponents</code>. See <code>gmdistribution</code> for descriptions of values. • s — A vector of length n containing an initial guess of the component index for each point.
'Replicates'	A positive integer giving the number of times to repeat the EM algorithm, each time with a new set of parameters. The solution with the largest likelihood is returned. A value larger than 1 requires the 'randSample' start method. The default is 1.
'CovType'	'diagonal' if the covariance matrices are restricted to be diagonal; 'full' otherwise. The default is 'full'.
'SharedCov'	Logical <code>true</code> if all the covariance matrices are restricted to be the same (pooled estimate); logical <code>false</code> otherwise.
'Regularize'	A nonnegative regularization number added to the diagonal of covariance matrices to make them positive-definite. The default is 0.
'Options'	Options structure for the iterative EM algorithm, as created by <code>statset.gmdistribution.fit</code> uses the parameters 'Display' with a default value of 'off', 'MaxIter' with a default value of 100, and 'TolFun' with a default value of $1e-6$.

In some cases, `gmdistribution` may converge to a solution where one or more of the components has an ill-conditioned or singular covariance matrix.

The following issues may result in an ill-conditioned covariance matrix:

- The number of dimension of your data is relatively high and there are not enough observations.
- Some of the features (variables) of your data are highly correlated.
- Some or all the features are discrete.

- You tried to fit the data to too many components.

In general, you can avoid getting ill-conditioned covariance matrices by using one of the following precautions:

- Pre-process your data to remove correlated features.
- Set 'SharedCov' to `true` to use an equal covariance matrix for every component.
- Set 'CovType' to 'diagonal'.
- Use 'Regularize' to add a very small positive number to the diagonal of every covariance matrix.
- Try another set of initial values.

In other cases `gmdistribution` may pass through an intermediate step where one or more of the components has an ill-conditioned covariance matrix. Trying another set of initial values may avoid this issue without altering your data or model.

Examples

Generate data from a mixture of two bivariate Gaussian distributions using the `mvnrnd` function:

```
MU1 = [1 2];  
SIGMA1 = [2 0; 0 .5];  
MU2 = [-3 -5];  
SIGMA2 = [1 0; 0 1];  
X = [mvnrnd(MU1,SIGMA1,1000);mvnrnd(MU2,SIGMA2,1000)];  
  
scatter(X(:,1),X(:,2),10,'.')  
hold on
```

Next, fit a two-component Gaussian mixture model:

```
options = statset('Display','final');  
obj = gmdistribution.fit(X,2,'Options',options);  
10 iterations, log-likelihood = -7046.78  
  
h = ezcontour(@(x,y)pdf(obj,[x y]),[-8 6],[-8 6]);
```

Among the properties of the fit are the parameter estimates:

```
ComponentMeans = obj.mu
ComponentMeans =
    0.9391    2.0322
   -2.9823   -4.9737

ComponentCovariances = obj.Sigma
ComponentCovariances(:,:,1) =
    1.7786   -0.0528
   -0.0528    0.5312
ComponentCovariances(:,:,2) =
    1.0491   -0.0150
   -0.0150    0.9816
```

```
MixtureProportions = obj.PComponents
MixtureProportions =
    0.5000    0.5000
```

The Akaike information is minimized by the two-component model:

```
AIC = zeros(1,4);
obj = cell(1,4);
for k = 1:4
    obj{k} = gmdistribution.fit(X,k);
    AIC(k) = obj{k}.AIC;
end
```

```
[minAIC,numComponents] = min(AIC);
numComponents
numComponents =
    2
```

```
model = obj{2}
model =
Gaussian mixture distribution
with 2 components in 2 dimensions
Component 1:
Mixing proportion: 0.500000
Mean:    0.9391    2.0322
Component 2:
Mixing proportion: 0.500000
Mean:    -2.9823   -4.9737
```

Both the Akaike and Bayes information are negative log-likelihoods for the data with penalty terms for the number of estimated parameters. They are often used to determine an appropriate number of components for a model when the number of components is unspecified.

LinearModel.fit

Class: LinearModel

Create linear regression model

Compatibility

LinearModel.fit will be removed in a future release. Use fitlm instead.

Syntax

```
mdl = LinearModel.fit(tbl)
mdl = LinearModel.fit(X,y)
mdl = LinearModel.fit(...,modelspec)
mdl = LinearModel.fit(...,Name,Value)
mdl = LinearModel.fit(...,modelspec,Name,Value)
```

Description

mdl = LinearModel.fit(tbl) creates a linear model of a table or dataset array tbl.

mdl = LinearModel.fit(X,y) creates a linear model of the responses y to a data matrix X.

mdl = LinearModel.fit(...,modelspec) creates a linear model of the specified type.

mdl = LinearModel.fit(...,Name,Value) or mdl = LinearModel.fit(...,modelspec,Name,Value) creates a linear model with additional options specified by one or more Name,Value pair arguments.

Tips

- Use robust fitting (RobustOpts name-value pair) to reduce the effect of outliers automatically.

- Do not use robust fitting when you want to subsequently adjust a model using `step`.
- For other methods or properties of the `LinearModel` object, see `LinearModel`.

Input Arguments

tbl — Input data

table | dataset array

Input data, specified as a table or dataset array. When `modelspec` is a `formula`, it specifies the variables to be used as the predictors and response. Otherwise, if you do not specify the predictor and response variables, the last variable is the response variable and the others are the predictor variables by default.

Predictor variables can be numeric, or any grouping variable type, such as logical or categorical (see “Grouping Variables” on page 2-52). The response must be numeric or logical.

To set a different column as the response variable, use the `ResponseVar` name-value pair argument. To use a subset of the columns as predictors, use the `PredictorVars` name-value pair argument.

Data Types: `single` | `double` | `logical`

X — Predictor variables

matrix

Predictor variables, specified as an n -by- p matrix, where n is the number of observations and p is the number of predictor variables. Each column of `X` represents one variable, and each row represents one observation.

By default, there is a constant term in the model, unless you explicitly remove it, so do not include a column of 1s in `X`.

Data Types: `single` | `double` | `logical`

y — Response variable

vector

Response variable, specified as an n -by-1 vector, where n is the number of observations. Each entry in `y` is the response for the corresponding row of `X`.

Data Types: `single` | `double`

modelspec — Model specification

string naming the model | t -by- $(p + 1)$ terms matrix | string of the form 'Y ~ terms'

Model specification, specified as one of the following. The choice is the starting model for `stepwiselm`.

- A string naming the model.

String	Model Type
'constant'	Model contains only a constant (intercept) term.
'linear'	Model contains an intercept and linear terms for each predictor.
'interactions'	Model contains an intercept, linear terms, and all products of pairs of distinct predictors (no squared terms).
'purequadratic'	Model contains an intercept, linear terms, and squared terms.
'quadratic'	Model contains an intercept, linear terms, interactions, and squared terms.
'polyijk'	Model is a polynomial with all terms up to degree i in the first predictor, degree j in the second predictor, etc. Use numerals 0 through 9. For example, 'poly2111' has a constant plus all linear and product terms, and also contains terms with predictor 1 squared.

- t -by- $(p + 1)$ matrix, namely terms matrix, specifying terms to include in the model, where t is the number of terms and p is the number of predictor variables, and plus 1 is for the response variable.
- A string representing a formulain the form 'Y ~ terms', where the **terms** are in “Wilkinson Notation” on page 21-1191.

Example: `'quadratic'`

Example: `'y ~ X1 + X2^2 + X1:X2'`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

'CategoricalVars' — Categorical variables

cell array of strings | logical or numeric index vector

Categorical variables in the fit, specified as the comma-separated pair consisting of 'CategoricalVars' and either a cell array of strings of the names of the categorical variables in the table or dataset array `tbl`, or a logical or numeric index vector indicating which columns are categorical.

- If data is in a table or dataset array `tbl`, then the default is to treat all categorical or logical variables, character arrays, or cell arrays of strings as categorical variables.
- If data is in matrix `X`, then the default value of this name-value pair argument is an empty matrix `[]`. That is, no variable is categorical unless you specify it.

For example, you can specify the observations 2 and 3 out of 6 as categorical using either of the following examples.

Example: 'CategoricalVars', [2,3]

Example: 'CategoricalVars', logical([0 1 1 0 0 0])

Data Types: single | double | logical

'Exclude' — Observations to exclude

logical or numeric index vector

Observations to exclude from the fit, specified as the comma-separated pair consisting of 'Exclude' and a logical or numeric index vector indicating which observations to exclude from the fit.

For example, you can exclude observations 2 and 3 out of 6 using either of the following examples.

Example: 'Exclude', [2,3]

Example: 'Exclude', logical([0 1 1 0 0 0])

Data Types: single | double | logical

'Intercept' — Indicator for constant term

true (default) | false

Indicator the for constant term (intercept) in the fit, specified as the comma-separated pair consisting of **'Intercept'** and either **true** to include or **false** to remove the constant term from the model.

Use **'Intercept'** only when specifying the model using a string, not a formula or matrix.

Example: `'Intercept',false`

'PredictorVars' — Predictor variables

cell array of strings | logical or numeric index vector

Predictor variables to use in the fit, specified as the comma-separated pair consisting of **'PredictorVars'** and either a cell array of strings of the variable names in the table or dataset array `tbl`, or a logical or numeric index vector indicating which columns are predictor variables.

The strings should be among the names in `tbl`, or the names you specify using the **'VarNames'** name-value pair argument.

The default is all variables in `X`, or all variables in `tbl` except for `ResponseVar`.

For example, you can specify the second and third variables as the predictor variables using either of the following examples.

Example: `'PredictorVars',[2,3]`

Example: `'PredictorVars',logical([0 1 1 0 0 0])`

Data Types: `single` | `double` | `logical` | `cell`

'ResponseVar' — Response variable

last column in `tbl` (default) | string for variable name | logical or numeric index vector

Response variable to use in the fit, specified as the comma-separated pair consisting of **'ResponseVar'** and either a string of the variable name in the table or dataset array `tbl`, or a logical or numeric index vector indicating which column is the response variable. You typically need to use **'ResponseVar'** when fitting a table or dataset array `tbl`.

For example, you can specify the fourth variable, say `yield`, as the response out of six variables, in one of the following ways.

Example: 'ResponseVar', 'yield'

Example: 'ResponseVar', [4]

Example: 'ResponseVar', logical([0 0 0 1 0 0])

Data Types: single | double | logical | char

'RobustOpts' — Indicator of robust fitting type

'off' (default) | 'on' | string | structure with string or function handle

Indicator of the robust fitting type to use, specified as the comma-separated pair consisting of 'RobustOpts' and one of the following.

- 'off' — No robust fitting. `fitlm` uses ordinary least squares.
- 'on' — Robust fitting. When you use robust fitting, 'bisquare' weight function is the default.
- String — Name of the robust fitting weight function from the following table. `fitlm` uses the corresponding default tuning constant in the table.
- Structure with the string `RobustWgtFun` containing the name of the robust fitting weight function from the following table and optional scalar `Tune` fields — `fitlm` uses the `RobustWgtFun` weight function and `Tune` tuning constant from the structure. You can choose the name of the robust fitting weight function from this table. If you do not supply a `Tune` field, the fitting function uses the corresponding default tuning constant.

Weight Function	Equation	Default Tuning Constant
'andrews'	$w = (\text{abs}(r) < \pi) .* \sin(r) ./ r$	1.339
'bisquare' (default)	$w = (\text{abs}(r) < 1) .* (1 - r.^2).^2$	4.685
'cauchy'	$w = 1 ./ (1 + r.^2)$	2.385
'fair'	$w = 1 ./ (1 + \text{abs}(r))$	1.400
'huber'	$w = 1 ./ \max(1, \text{abs}(r))$	1.345
'logistic'	$w = \tanh(r) ./ r$	1.205
'ols'	Ordinary least squares (no weighting function)	None
'talwar'	$w = 1 * (\text{abs}(r) < 1)$	2.795

Weight Function	Equation	Default Tuning Constant
'welsch'	$w = \exp(- (r.^2))$	2.985

The value r in the weight functions is

$$r = \text{resid} / (\text{tune} * s * \text{sqrt}(1-h)),$$

where `resid` is the vector of residuals from the previous iteration, `h` is the vector of leverage values from a least-squares fit, and `s` is an estimate of the standard deviation of the error term given by

$$s = \text{MAD} / 0.6745.$$

MAD is the median absolute deviation of the residuals from their median. The constant 0.6745 makes the estimate unbiased for the normal distribution. If there are p columns in X , the smallest p absolute deviations are excluded when computing the median.

Default tuning constants give coefficient estimates that are approximately 95% as statistically efficient as the ordinary least-squares estimates, provided the response has a normal distribution with no outliers. Decreasing the tuning constant increases the downweight assigned to large residuals; increasing the tuning constant decreases the downweight assigned to large residuals.

- Structure with the function handle `RobustWgtFun` and optional scalar `Tune` fields — You can specify a custom weight function. `fitlm` uses the `RobustWgtFun` weight function and `Tune` tuning constant from the structure. Specify `RobustWgtFun` as a function handle that accepts a vector of residuals, and returns a vector of weights the same size. The fitting function scales the residuals, dividing by the tuning constant (default 1) and by an estimate of the error standard deviation before it calls the weight function.

Example: `'RobustOpts', 'andrews'`

'VarNames' — Names of variables in fit

`{'x1', 'x2', ..., 'xn', 'y'}` (default) | cell array of strings

Names of variables in fit, specified as the comma-separated pair consisting of `'VarNames'` and a cell array of strings including the names for the columns of X first, and the name for the response variable y last.

'VarNames' is not applicable to variables in a table or dataset array, because those variables already have names.

For example, if in your data, horsepower, acceleration, and model year of the cars are the predictor variables, and miles per gallon (MPG) is the response variable, then you can name the variables as follows.

Example: 'VarNames', {'Horsepower', 'Acceleration', 'Model_Year', 'MPG'}

Data Types: cell

'Weights' — Observation weights

ones(*n*, 1) (default) | *n*-by-1 vector of nonnegative scalar values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and an *n*-by-1 vector of nonnegative scalar values, where *n* is the number of observations.

Data Types: single | double

Output Arguments

mdl — Linear model

LinearModel object

Linear model representing a least-squares fit of the response to the data, returned as a LinearModel object.

If the value of the 'RobustOpts' name-value pair is not [] or 'ols', the model is not a least-squares fit, but uses the robust fitting function.

For properties and methods of the linear model object, mdl, see the LinearModel class page.

Definitions

Terms Matrix

A terms matrix is a *t*-by- $(p + 1)$ matrix specifying terms in a model, where *t* is the number of terms, *p* is the number of predictor variables, and plus one is for the response variable.

The value of $T(i, j)$ is the exponent of variable j in term i . Suppose there are three predictor variables A , B , and C :

```
[0 0 0 0] % Constant term or intercept
[0 1 0 0] % B; equivalently, A^0 * B^1 * C^0
[1 0 1 0] % A*C
[2 0 0 0] % A^2
[0 1 2 0] % B*(C^2)
```

The 0 at the end of each term represents the response variable. In general,

- If you have the variables in a table or dataset array, then 0 must represent the response variable depending on the position of the response variable. The following example illustrates this.

Load the sample data and define the dataset array.

```
load hospital
ds = dataset(hospital.Sex,hospital.BloodPressure(:,1),hospital.Age,...
hospital.Smoker,'VarNames',{'Sex','BloodPressure','Age','Smoker'});
```

Represent the linear model 'BloodPressure ~ 1 + Sex + Age + Smoker' in a terms matrix. The response variable is in the second column of the dataset array, so there must be a column of 0s for the response variable in the second column of the terms matrix.

```
T = [0 0 0 0;1 0 0 0;0 0 1 0;0 0 0 1]
```

```
T =
```

```
    0    0    0    0
    1    0    0    0
    0    0    1    0
    0    0    0    1
```

Redefine the dataset array.

```
ds = dataset(hospital.BloodPressure(:,1),hospital.Sex,hospital.Age,...
hospital.Smoker,'VarNames',{'BloodPressure','Sex','Age','Smoker'});
```

Now, the response variable is the first term in the dataset array. Specify the same linear model, 'BloodPressure ~ 1 + Sex + Age + Smoker', using a terms matrix.

```
T = [0 0 0 0;0 1 0 0;0 0 1 0;0 0 0 1]
```

```
T =
    0     0     0     0
    0     1     0     0
    0     0     1     0
    0     0     0     1
```

- If you have the predictor and response variables in a matrix and column vector, then you must include 0 for the response variable at the end of each term. The following example illustrates this.

Load the sample data and define the matrix of predictors.

```
load carsmall
X = [Acceleration,Weight];
```

Specify the model 'MPG ~ Acceleration + Weight + Acceleration:Weight + Weight^2' using a term matrix and fit the model to the data. This model includes the main effect and two-way interaction terms for the variables, `Acceleration` and `Weight`, and a second-order term for the variable, `Weight`.

```
T = [0 0 0;1 0 0;0 1 0;1 1 0;0 2 0]
```

```
T =
    0     0     0
    1     0     0
    0     1     0
    1     1     0
    0     2     0
```

Fit a linear model.

```
mdl = fitlm(X,MPG,T)
```

```
mdl =
```

```
Linear regression model:
y ~ 1 + x1*x2 + x2^2
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	48.906	12.589	3.8847	0.00019665
x1	0.54418	0.57125	0.95261	0.34337

x2	-0.012781	0.0060312	-2.1192	0.036857
x1:x2	-0.00010892	0.00017925	-0.6076	0.545
x2^2	9.7518e-07	7.5389e-07	1.2935	0.19917

Number of observations: 94, Error degrees of freedom: 89
 Root Mean Squared Error: 4.1
 R-squared: 0.751, Adjusted R-Squared 0.739
 F-statistic vs. constant model: 67, p-value = 4.99e-26

Only the intercept and x2 term, which correspond to the `Weight` variable, are significant at the 5% significance level.

Now, perform a stepwise regression with a constant model as the starting model and a linear model with interactions as the upper model.

```
T = [0 0 0;1 0 0;0 1 0;1 1 0];
mdl = stepwiselm(X,MPG,[0 0 0], 'upper',T)
```

1. Adding x2, FStat = 259.3087, pValue = 1.643351e-28

mdl =

Linear regression model:
 $y \sim 1 + x2$

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	49.238	1.6411	30.002	2.7015e-49
x2	-0.0086119	0.0005348	-16.103	1.6434e-28

Number of observations: 94, Error degrees of freedom: 92
 Root Mean Squared Error: 4.13
 R-squared: 0.738, Adjusted R-Squared 0.735
 F-statistic vs. constant model: 259, p-value = 1.64e-28

The results of the stepwise regression are consistent with the results of `fitlm` in the previous step.

Formula

A formula for model specification is a string of the form `'Y ~ terms'`

where

- Y is the response name.
- *terms* contains
 - Variable names
 - + means include the next variable
 - - means do not include the next variable
 - : defines an interaction, a product of terms
 - * defines an interaction **and all lower-order terms**
 - ^ raises the predictor to a power, exactly as in * repeated, so ^ includes lower order terms as well
 - () groups terms

Note: Formulas include a constant (intercept) term by default. To exclude a constant term from the model, include - 1 in the formula.

For example,

' $Y \sim A + B + C$ ' means a three-variable linear model with intercept.

' $Y \sim A + B + C - 1$ ' is a three-variable linear model without intercept.

' $Y \sim A + B + C + B^2$ ' is a three-variable model with intercept and a B^2 term.

' $Y \sim A + B^2 + C$ ' is the same as the previous example because B^2 includes a B term.

' $Y \sim A + B + C + A:B$ ' includes an $A*B$ term.

' $Y \sim A*B + C$ ' is the same as the previous example because $A*B = A + B + A:B$.

' $Y \sim A*B*C - A:B:C$ ' has all interactions among A , B , and C , except the three-way interaction.

' $Y \sim A*(B + C + D)$ ' has all linear terms, plus products of A with each of the other variables.

Wilkinson Notation

Wilkinson notation describes the factors present in models. The notation relates to factors present in models, not to the multipliers (coefficients) of those factors.

Wilkinson Notation	Factors in Standard Notation
1	Constant (intercept) term

Wilkinson Notation	Factors in Standard Notation
A^k , where k is a positive integer	A, A^2, \dots, A^k
$A + B$	A, B
$A*B$	$A, B, A*B$
$A:B$	$A*B$ only
$-B$	Do not include B
$A*B + C$	$A, B, C, A*B$
$A + B + C + A:B$	$A, B, C, A*B$
$A*B*C - A:B:C$	$A, B, C, A*B, A*C, B*C$
$A*(B + C)$	$A, B, C, A*B, A*C$

Statistics Toolbox notation always includes a constant term unless you explicitly remove the term using `-1`.

Examples

Linear Regression Model of Matrix Data

Fit a linear model of the Hald data.

Load the data.

```
load hald
X = ingredients; % Predictor variables
y = heat; % Response
```

Fit a default linear model to the data.

```
mdl = fitlm(X,y)
```

```
mdl =
```

```
Linear regression model:
y ~ 1 + x1 + x2 + x3 + x4
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	62.405	70.071	0.8906	0.39913
x1	1.5511	0.74477	2.0827	0.070822
x2	0.51017	0.72379	0.70486	0.5009
x3	0.10191	0.75471	0.13503	0.89592
x4	-0.14406	0.70905	-0.20317	0.84407

Number of observations: 13, Error degrees of freedom: 8

Root Mean Squared Error: 2.45

R-squared: 0.982, Adjusted R-Squared 0.974

F-statistic vs. constant model: 111, p-value = 4.76e-07

Linear Regression with Categorical Predictor and Nonlinear Model

Fit a model of a table that contains a categorical predictor. Use a nonlinear response formula.

Load the `carsmall` data.

```
load carsmall
```

Construct a table containing continuous predictor variable `Weight`, nominal predictor variable `Year`, and response variable `MPG`.

```
tbl = table(MPG,Weight);
tbl.Year = nominal(Model_Year);
```

Create a fitted model of `MPG` as a function of `Year`, `Weight`, and `Weight2`. (You don't have to include `Weight` explicitly in your formula because it is a lower-order term of `Weight2`.)

```
mdl = fitlm(tbl,'MPG ~ Year + Weight^2')
```

```
mdl =
```

```
Linear regression model:
MPG ~ 1 + Weight + Year + Weight^2
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	54.206	4.7117	11.505	2.6648e-19
Weight	-0.016404	0.0031249	-5.2493	1.0283e-06
Year_76	2.0887	0.71491	2.9215	0.0044137
Year_82	8.1864	0.81531	10.041	2.6364e-16
Weight^2	1.5573e-06	4.9454e-07	3.149	0.0022303

Number of observations: 94, Error degrees of freedom: 89
 Root Mean Squared Error: 2.78
 R-squared: 0.885, Adjusted R-Squared 0.88
 F-statistic vs. constant model: 172, p-value = 5.52e-41

`fitlm` creates two dummy (indicator) variables for the nominal variate, `Year`. The dummy variable `Year_76` takes the value 1 if model year is 1976 and takes the value 0 if it is not. The dummy variable `Year_82` takes the value 1 if model year is 1982 and takes the value 0 if it is not. And the year 1970 is the reference year. The corresponding model is

$$M\hat{P}G = 54.206 - 0.0164(\textit{Weight}) + 2.0887(\textit{Year_76}) + 8.1864(\textit{Year_82}) + (1.557e - 06)(\textit{Weight})^2$$

Simultaneously Specify the Variables and Use Formula

Simultaneously identify response and predictor variables and specify the model using formula in linear regression.

Load sample data.

```
load hospital
```

Fit a linear model with interaction terms to the data.

```
mdl = fitlm(hospital, 'Weight~1+Age*Sex*Smoker-Age:Sex:Smoker', 'ResponseVar', 'Weight', 'F
```

```
mdl =
```

Linear regression model:

```
Weight ~ 1 + Sex*Age + Sex*Smoker + Age*Smoker
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	118.7	7.0718	16.785	6.821e-30
Sex_Male	68.336	9.7153	7.0339	3.3386e-10
Age	0.31068	0.18531	1.6765	0.096991
Smoker_1	3.0425	10.446	0.29127	0.77149
Sex_Male:Age	-0.49094	0.24764	-1.9825	0.050377
Sex_Male:Smoker_1	0.9509	3.8031	0.25003	0.80312
Age:Smoker_1	-0.07288	0.26275	-0.27737	0.78211

Number of observations: 100, Error degrees of freedom: 93
 Root Mean Squared Error: 8.75
 R-squared: 0.898, Adjusted R-Squared 0.892
 F-statistic vs. constant model: 137, p-value = 6.91e-44

The weight of the patients do not seem to differ significantly according to age, or the status of smoking, or interaction of these factors with gender at the 5% significance level.

Robust Linear Regression Model

Fit a linear regression model of the Hald data using robust fitting.

Load the data.

```
load hald
X = ingredients; % predictor variables
y = heat; % response
```

Fit a robust linear model to the data.

```
mdl = fitlm(X,y,'linear','RobustOpts','on')
```

```
mdl =
```

```
Linear regression model (robust fit):
  y ~ 1 + x1 + x2 + x3 + x4
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	60.09	75.818	0.79256	0.4509
x1	1.5753	0.80585	1.9548	0.086346
x2	0.5322	0.78315	0.67957	0.51596
x3	0.13346	0.8166	0.16343	0.87424
x4	-0.12052	0.7672	-0.15709	0.87906

Number of observations: 13, Error degrees of freedom: 8
 Root Mean Squared Error: 2.65
 R-squared: 0.979, Adjusted R-Squared 0.969
 F-statistic vs. constant model: 94.6, p-value = 9.03e-07

Algorithms

The main fitting algorithm is QR decomposition. For robust fitting, the algorithm is `robustfit`.

Alternatives

You can also construct a linear model using `fitlm`.

You can construct a model in a range of possible models using `stepwiselm`. However, you cannot use robust regression and stepwise regression together.

`predict` | `stepwiselm` | `LinearModel`

How To

- “Linear Regression” on page 9-11

LinearMixedModel.fit

Class: LinearMixedModel

Fit linear mixed-effects model using tables

Compatibility

LinearMixedModel.fit will be removed in a future release. Use fitlme instead.

Syntax

```
lme = LinearMixedModel.fit(tbl,formula)
```

```
lme = LinearMixedModel.fit(tbl,formula,Name,Value)
```

Description

`lme = LinearMixedModel.fit(tbl,formula)` returns a linear mixed-effects model, specified by `formula`, fitted to the variables in the table or dataset array `tbl`.

`lme = LinearMixedModel.fit(tbl,formula,Name,Value)` returns a linear mixed-effects model with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify the covariance pattern of the random-effects terms, the method to use in estimating the parameters, or options for the optimization algorithm.

Tips

- If your model is not easily described using a formula, you can create matrices to define the fixed and random effects, and fit the model using `fitlmematrix`.

Input Arguments

tbl — Input data

table | dataset array

Input data, which includes the response variable, predictor variables, and grouping variables, specified as a table or `dataset` array. The predictor variables can be continuous or grouping variables (see “Grouping Variables” on page 2-52). You must specify the model for the variables using formula.

Data Types: `single` | `double` | `char` | `cell`

formula — Formula for model specification

string of the form `'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)'`

Formula for model specification, specified as a string of the form `'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)'`. For full description, see “Formula” on page 21-1215.

Example: `'y ~ treatment +(1|block)'`

Data Types: `char`

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

'CovariancePattern' — Pattern of covariance matrix

`'FullCholesky'` (default) | `string` | square symmetric logical matrix | cell array of strings or logical matrices

Pattern of the covariance matrix of the random effects, specified as the comma-separated pair consisting of `'CovariancePattern'` and a string, a square symmetric logical matrix, or a cell array of strings or logical matrices.

If there are R random-effects terms, then the value of `'CovariancePattern'` must be a cell array of length R , where each element r of this cell array specifies the pattern of the covariance matrix of the random-effects vector associated with the r th random-effects term. The options for each element follow.

`'FullCholesky'`

Default. Full covariance matrix using the Cholesky parameterization. `fitlme` estimates all elements of the covariance matrix.

'Full'

Full covariance matrix, using the log-Cholesky parameterization. `fitlme` estimates all elements of the covariance matrix.

'Diagonal'

Diagonal covariance matrix. That is, off-diagonal elements of the covariance matrix are constrained to be 0.

$$\begin{pmatrix} \sigma_{b1}^2 & 0 & 0 \\ 0 & \sigma_{b2}^2 & 0 \\ 0 & 0 & \sigma_{b3}^2 \end{pmatrix}$$

'Isotropic'

Diagonal covariance matrix with equal variances. That is, off-diagonal elements of the covariance matrix are constrained to be 0, and the diagonal elements are constrained to be equal. For example, if there are three random-effects terms with an isotropic covariance structure, this covariance matrix looks like

$$\begin{pmatrix} \sigma_b^2 & 0 & 0 \\ 0 & \sigma_b^2 & 0 \\ 0 & 0 & \sigma_b^2 \end{pmatrix}$$

where σ_b^2 is the common variance of the random-effects terms.

'CompSymm'

Compound symmetry structure. That is, common variance along diagonals and equal correlation between all random effects. For example, if there are three random-effects terms with a covariance matrix having a compound symmetry structure, this covariance matrix looks like

$$\begin{pmatrix} \sigma_{b1}^2 & \sigma_{b1,b2} & \sigma_{b1,b2} \\ \sigma_{b1,b2} & \sigma_{b1}^2 & \sigma_{b1,b2} \\ \sigma_{b1,b2} & \sigma_{b1,b2} & \sigma_{b1}^2 \end{pmatrix}$$

where σ_{b1}^2 is the common variance of the random-effects terms and $\sigma_{b1,b2}$ is the common covariance between any two random-effects term .

PAT

Square symmetric logical matrix. If 'CovariancePattern' is defined by the matrix PAT, and if `PAT(a, b) = false`, then the (a, b) element of the corresponding covariance matrix is constrained to be 0.

Example: 'CovariancePattern', 'Diagonal'

Example: 'CovariancePattern', {'Full', 'Diagonal'}

'FitMethod' — Method for estimating parameters

'ML' (default) | 'REML'

Method for estimating parameters of the linear mixed-effects model, specified as the comma-separated pair consisting of 'FitMethod' and either of the following.

'ML'

Default. Maximum likelihood estimation

'REML'

Restricted maximum likelihood estimation

Example: 'FitMethod', 'REML'

'Weights' — Observation weights

vector of scalar values

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and a vector of length n , where n is the number of observations.

Data Types: `single` | `double`**'Exclude' — Indices for rows to exclude**

use all rows without NaNs (default) | vector of integer or logical values

Indices for rows to exclude from the linear mixed-effects model in the data, specified as the comma-separated pair consisting of `'Exclude'` and a vector of integer or logical values.

For example, you can exclude the 13th and 67th rows from the fit as follows.

Example: `'Exclude', [13,67]`Data Types: `single` | `double` | `logical`**'DummyVarCoding' — Coding to use for dummy variables**`'reference'` (default) | `'effects'` | `'full'`

Coding to use for dummy variables created from the categorical variables, specified as the comma-separated pair consisting of `'DummyVarCoding'` and one of the following.

<code>'reference'</code>	Default. Coefficient for first category set to 0.
<code>'effects'</code>	Coefficients sum to 0.
<code>'full'</code>	One dummy variable for each category.

Example: `'DummyVarCoding', 'effects'`**'Optimizer' — Optimization algorithm**`'quasnewton'` (default) | `'fminunc'`

Optimization algorithm, specified as the comma-separated pair consisting of `'Optimizer'` and either of the following.

<code>'quasnewton'</code>	Default. Uses a trust region based quasi-Newton optimizer. Change
---------------------------	---

'fminunc'

the options of the algorithm using `statset('LinearMixedModel')`. If you don't specify the options, then `LinearMixedModel` uses the default options of `statset('LinearMixedModel')`.

You must have Optimization Toolbox to specify this option. Change the options of the algorithm using `optimoptions('fminunc')`. If you don't specify the options, then `LinearMixedModel` uses the default options of `optimoptions('fminunc')` with 'Algorithm' set to 'quasi-newton'.

Example: 'Optimizer', 'fminunc'

'OptimizerOptions' — Options for optimization algorithm

structure returned by `statset` | object returned by `optimoptions`

Options for the optimization algorithm, specified as the comma-separated pair consisting of 'OptimizerOptions' and a structure returned by `statset('LinearMixedModel')` or an object returned by `optimoptions('fminunc')`.

- If 'Optimizer' is 'fminunc', then use `optimoptions('fminunc')` to change the options of the optimization algorithm. See `optimoptions` for the options 'fminunc' uses. If 'Optimizer' is 'fminunc' and you do not supply 'OptimizerOptions', then the default for `LinearMixedModel` is the default options created by `optimoptions('fminunc')` with 'Algorithm' set to 'quasi-newton'.
- If 'Optimizer' is 'quasi-newton', then use `statset('LinearMixedModel')` to change the optimization parameters. If you don't change the optimization parameters, then `LinearMixedModel` uses the default options created by `statset('LinearMixedModel')`:

The 'quasi-newton' optimizer uses the following fields in the structure created by `statset('LinearMixedModel')`.

'To1Fun' — Relative tolerance on gradient of objective function

1e-6 (default) | positive scalar value

Relative tolerance on the gradient of the objective function, specified as a positive scalar value.

'ToIX' — Absolute tolerance on step size

1e-12 (default) | positive scalar value

Absolute tolerance on the step size, specified as a positive scalar value.

'MaxIter' — Maximum number of iterations allowed

10000 (default) | positive scalar value

Maximum number of iterations allowed, specified as a positive scalar value.

'Display' — Level of display

'off' (default) | 'iter' | 'final'

Level of display, specified as one of 'off', 'iter', or 'final'.

'StartMethod' — Method to start iterative optimization

'default' (default) | 'random'

Method to start iterative optimization, specified as the comma-separated pair consisting of 'StartMethod' and either of the following.

'default'	Default. An internally defined default value.
'random'	A random initial value.

Example: 'StartMethod', 'random'

'Verbose' — Indicator to display optimization process on screen

false (default) | true

Indicator to display the optimization process on screen, specified as the comma-separated pair consisting of 'Verbose' and either false or true. Default is false.

The setting for 'Verbose' overrides the field 'Display' in 'OptimizerOptions'.

Example: 'Verbose', true

'CheckHessian' — Indicator to check positive definiteness of Hessian

false (default) | true

Indicator to check the positive definiteness of the Hessian of the objective function with respect to unconstrained parameters at convergence, specified as the comma-separated pair consisting of 'CheckHessian' and either `false` or `true`. Default is `false`.

Specify 'CheckHessian' as `true` to verify optimality of the solution or to determine if the model is overparameterized in the number of covariance parameters.

Example: 'CheckHessian',`true`

Output Arguments

lme — Linear mixed-effects model

LinearMixedModel object

Linear mixed-effects model, returned as a `LinearMixedModel` object.

For properties and methods of this object, see `LinearMixedModel`.

Examples

Random-Intercept Model

Load the sample data.

```
load flu
```

The `flu` dataset array has a `Date` variable, and 10 variables containing estimated influenza rates (in 9 different regions, estimated from Google searches, plus a nationwide estimate from the CDC).

To fit a linear-mixed effects model, your data must be in a properly formatted dataset array. To fit a linear mixed-effects model with the influenza rates as the responses, combine the nine columns corresponding to the regions into a tall array. The new dataset array, `flu2`, must have the response variable `FluRate`, the nominal variable `Region` that shows which region each estimate is from, the nationwide estimate `WtdILI`, and the grouping variable `Date`.

```
flu2 = stack(flu,2:10,'NewDataVarName','FluRate',...  
            'IndVarName','Region');  
flu2.Date = nominal(flu2.Date);
```

Fit a linear mixed-effects model with the nationwide a random intercept that varies by Date. The model corresponds to

$$y_{im} = \beta_0 + \beta_1 \text{WtdILI}_{im} + b_{0m} + \varepsilon_{im}, \quad i = 1, 2, \dots, 468, \quad m = 1, 2, \dots, 52,$$

where y_{im} is the observation i for level m of grouping variable **Date**. b_{0m} is the random effect for level m of the grouping variable **Date** and ε_{im} is the observation error for observation i . The random effect has the prior distribution, $b \sim N(0, \sigma_b^2)$ and the error term has the distribution, $\varepsilon \sim N(0, \sigma^2)$.

```
lme = LinearMixedModel.fit(flu2, 'FluRate ~ 1 + WtdILI + (1|Date)')
```

```
lme =
```

```
Linear mixed-effects model fit by ML
```

```
Model information:
```

Number of observations	468
Fixed effects coefficients	2
Random effects coefficients	52
Covariance parameters	2

```
Formula:
```

```
FluRate ~ 1 + WtdILI + (1 | Date)
```

```
Model fit statistics:
```

AIC	BIC	LogLikelihood	Deviance
286.24	302.83	-139.12	278.24

```
Fixed effects coefficients (95% CIs):
```

Name	Estimate	SE	tStat	DF	pValue	Lower	Upper
'(Intercept)'	0.16385	0.057525	2.8484	466	0.0045885	0.0508	0.2769
'WtdILI'	0.7236	0.032219	22.459	466	3.0502e-76	0.6602	0.7869

```
Random effects covariance parameters (95% CIs):
```

```
Group: Date (52 Levels)
```

Name1	Name2	Type	Estimate	Lower	Upper
'(Intercept)'	'(Intercept)'	'std'	0.17146	0.13227	0.22265

```
Group: Error
```

Name	Estimate	Lower	Upper
'Res Std'	0.30201	0.28217	0.32324

The confidence limits for the standard deviation of the random-effects term, σ_b^2 , do not include 0 (0.13227, 0.22226), which indicates that the random-effects term is significant. You can also test the significance of the random-effects terms using the `compare` method.

The estimated value of an observation is the sum of the fixed effects and the random-effect value at the grouping variable level corresponding to that observation. For example, the estimated flu rate for observation 28 is

$$\begin{aligned}\hat{y}_{28} &= \hat{\beta}_0 + \hat{\beta}_1 \text{WtdILI}_{28} + \hat{b}_{10/30/2005} \\ &= 0.1639 + 0.7236 * (1.343) + 0.3318 \\ &= 1.46749,\end{aligned}$$

where \hat{b} is the BLUP of the random effects for the intercept. You can compute this value in the following way.

```
beta = fixedEffects(lme);
[~,~,STATS] = randomEffects(lme); % Compute the random-effects statistics (STATS)
STATS.Level = nominal(STATS.Level1);
y_hat = beta(1) + beta(2)*flu2.WtdILI(28) + STATS.Estimate(STATS.Level=='10/30/2005')
y_hat =
    1.4674
```

You can display the fitted value using the `fitted` method.

```
F = fitted(lme);
F(28)
ans =
    1.4674
```

Randomized-Block Design

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load shift
```

The dataset array shows the absolute deviations from the target quality characteristic measured from the products each of five operators manufacture over three different shifts, morning, evening, and night. This is a randomized block design, where the operators are the blocks. The experiment is designed to study the impact of the time of shift on the performance. The performance measure is the absolute deviations of the quality characteristics from the target value. This is simulated data.

Fit a linear mixed-effects model with a random intercept grouped by operator, to assess if there is significant difference in the performance according to the time of the shift. Use the restricted maximum likelihood method and 'effects' contrasts.

'effects' contrasts mean that the coefficients sum to 0, and `LinearMixedModel.fit` creates a matrix called a 'fixed effects design matrix' to describe the effect of Shift. This matrix has two columns, *Shift_Evening* and *Shift_Morning*, where

$$\text{Shift_Evening} = \begin{cases} 0, & \text{if Morning} \\ 1, & \text{if Evening} \\ -1, & \text{if Night} \end{cases} \quad \text{and} \quad \text{Shift_Morning} = \begin{cases} 1, & \text{if Morning} \\ 0, & \text{if Evening} \\ -1, & \text{if Night} \end{cases} .$$

The model corresponds to

$$\text{Morning Shift: } QCDev_{im} = \beta_0 + \beta_2 \text{Shift_Morning}_i + b_{0m} + \varepsilon_{im}, \quad m = 1, 2, \dots, 5,$$

$$\text{Evening Shift: } QCDev_{im} = \beta_0 + \beta_1 \text{Shift_Evening}_i + b_{0m} + \varepsilon_{im},$$

$$\text{Night Shift: } QCDev_{im} = \beta_0 - \beta_1 \text{Shift_Evening}_i - \beta_2 \text{Shift_Morning}_i + b_{0m} + \varepsilon_{im},$$

where $b \sim N(0, \sigma_b^2)$ and $\varepsilon \sim N(0, \sigma^2)$.

```
lme = LinearMixedModel.fit(shift, 'QCDev ~ Shift + (1|Operator)', ...
'FitMethod', 'REML', 'DummyVarCoding', 'effects')
```

```
lme =
```

```
Linear mixed-effects model fit by REML
```

  'Res Std' 0.85462      0.52357    1.395

```

Compute the best linear unbiased predictor (BLUP) estimates of random effects.

```
B = randomEffects(lme)
```

```
B =
```

```

0.5775
1.1757
-2.1715
2.3655
-1.9472

```

The estimated absolute deviation from the target quality characteristics for the third operator working in the evening shift is

$$\begin{aligned}
 \hat{y}_{Evening, Operator3} &= \hat{\beta}_0 + \hat{\beta}_1 Shift_Evening + \hat{b}_{03} \\
 &= 3.6525 - 0.53293 - 2.1715 \\
 &= 0.94807.
 \end{aligned}$$

You can also display this value as follows.

```

F = fitted(lme);
F(shift.Shift=='Evening' & shift.Operator=='3')

```

```
ans =
    0.9481
```

Similarly, you can calculate the estimated absolute deviation from the target quality characteristics for the third operator working in the morning shift is

$$\begin{aligned}\hat{y}_{Morning,Operator3} &= \hat{\beta}_0 + \hat{\beta}_2 Shift_Morning + \hat{b}_{03} \\ &= 3.6525 - 0.91973 - 2.1715 \\ &= 0.56127.\end{aligned}$$

You can also display this value in the following way.

```
F(shift.Shift=='Morning' & shift.Operator=='3')
ans =
    0.5613
```

The operator tends to make a smaller magnitude of error in the morning shift.

Split-Plot Experiment

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load fertilizer
```

The dataset array includes data from a split-plot experiment, where soil is divided into three blocks based on the soil type: sandy, silty, and loamy. Each block is divided into five plots, where five types of tomato plants, (cherry, heirloom, grape, vine, and plum) are randomly assigned to these plots. Then, the tomato plants in the plots are divided into subplots, where each subplot is treated by one of the four fertilizers. This is simulated data.

Store the data in a dataset array called `ds`, for practical purposes, and define `Tomato`, `Soil`, and `Fertilizer` as categorical variables.

```
ds = fertilizer;
ds.Tomato = nominal(ds.Tomato);
ds.Soil = nominal(ds.Soil);
```

```
ds.Fertilizer = nominal(ds.Fertilizer);
```

Fit a linear mixed-effects model, where `Fertilizer` and `Tomato` are the fixed-effects variables, and the mean yield varies by the block (soil type) and the plots within blocks (tomato types within soil types) independently.

This model corresponds to

$$y_{imjk} = \beta_0 + \sum_{m=2}^4 \beta_{1m} I[F]_{im} + \sum_{j=2}^5 \beta_{2j} I[T]_{ij} + \sum_{j=2}^5 \sum_{m=2}^4 \beta_{3mj} I[F]_{im} I[T]_{ij} + b_{0k} S_k + b_{0jk} (S^* T)_{jk} + \varepsilon_{imjk},$$

where $i = 1, 2, \dots, 60$, the index m corresponds to the fertilizer types, j corresponds to the tomato types, and $k = 1, 2, 3$ corresponds to the blocks (soil). S_k represents the k th soil type, and $(S^* T)_{jk}$ represents the j th tomato type nested in the k th soil type. $I[F]_{im}$ is the dummy variable representing level m of the fertilizer. Similarly, $I[T]_{ij}$ is the dummy variable representing the level j of the tomato type.

The random effects and observation error have the following prior distributions:

$b_{0k} \sim N(0, \sigma_S^2)$, $b_{0jk} \sim N(0, \sigma_{S^*T}^2)$, and $\varepsilon_{imjk} \sim N(0, \sigma^2)$.

```
lme = LinearMixedModel.fit(ds, 'Yield ~ Fertilizer * Tomato + (1|Soil) + (1|Soil:Tomato)');
```

```
lme =
```

```
Linear mixed-effects model fit by ML
```

```

Name	Estimate	Lower	Upper
'Res Std'	10.499	8.5389	12.908

The p -values corresponding to the last 12 rows in the fixed-effects coefficients display (0.82701 to 0.47881) indicate that interaction coefficients between the tomato and fertilizer types are not significant. To test for the overall interaction between tomato and fertilizer, use the `anova` method after refitting the model using `'effects'` contrasts.

The confidence interval for the standard deviations of the random-effects terms (σ^2_s), where the intercept is grouped by soil is very large. This term does not appear significant.

Refit the model after removing the interaction term `Tomato:Fertilizer` and the random-effects term (`1 | Soil`).

```
lme = LinearMixedModel.fit(ds, 'Yield ~ Fertilizer + Tomato + (1|Soil:Tomato)')
```

```
lme =

You can compare the two models using the `compare` method with the simulated likelihood ratio test since both a fixed-effect and a random-effect term will be tested.

Longitudinal Study with a Covariate

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load weight
```

`weight` contains data from a longitudinal study, where 20 subjects are randomly assigned to 4 exercise programs (A, B, C, D), and their weight loss is recorded over six two-week time periods. This is simulated data.

Store the data in a table. Define `Subject` and `Program` as categorical variables.

```
tbl = table(InitialWeight,Program,Subject,Week,y);
tbl.Subject = nominal(tbl.Subject);
tbl.Program = nominal(tbl.Program);
```

Fit a linear mixed-effects model where the initial weight, type of program, week, and the interaction between the week and type of program are the fixed effects. The intercept and week vary by subject.

`LinearMixedModel.fit` uses Program A as a reference and creates the necessary dummy variables $I[\cdot]$. Since the model already has an intercept, `LinearMixedModel.fit` only creates dummy variables for program types B, C, D. This is also known as the 'reference' method of coding dummy variables. This model corresponds to

$$\begin{aligned}
 y_{im} = & \beta_0 + \beta_1 IW_i + \beta_2 Week_i + \beta_3 I[PB]_i + \beta_4 I[PC]_i + \beta_5 I[PD]_i \\
 & + \beta_6 (Week_i * I[PB]_i) + \beta_7 (Week_i * I[PC]_i) + \beta_8 (Week_i * I[PD]_i) \\
 & + b_{0m} + b_{1m} Week_{im} + \varepsilon_{im},
 \end{aligned}$$

where $i = 1, 2, \dots, 120$, and $m = 1, 2, \dots, 20$. β_j are the fixed-effects coefficients, $j = 0, 1, \dots, 8$, and b_{1m} and b_{0m} are random effects. IW stands for initial weight and $I[\cdot]$ is a

dummy variable representing a type of program. For example, $I[PB]_i$ is the dummy variable representing program type B. The random effects and observation error have the following prior distributions: $b_{0m} \sim N(0, \sigma_0^2)$, $b_{1m} \sim N(0, \sigma_1^2)$, and $\varepsilon_{im} \sim N(0, \sigma^2)$.

```
lme = LinearMixedModel.fit(tbl, 'y ~ InitialWeight + Program*Week + (Week|Subject)')

0.15033	0.11004	0.20537

Group: Error

Name	Estimate	Lower	Upper
'Res Std'	0.10261	0.087882	0.11981

The p -values 0.022863 and 0.011567 indicate significant effects of subject initial weights and time in the amount of weight lost. The weight loss of subjects who are in Program B is significantly different relative to the weight loss of subjects who are in Program A. The lower and upper limits of the covariance parameters for the random effects do not include 0, thus they are significant. You can also test the significance of the random effects using the `compare` method.

Definitions

Formula

In general, a formula for model specification is a string of the form `'y ~ terms'`. For the linear mixed-effects models, this formula is in the form `'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)'`, where `fixed` and `random` contain the fixed-effects and the random-effects terms.

Suppose a table `tbl` contains the following:

- A response variable, y
- Predictor variables, X_j , which can be continuous or grouping variables

- Grouping variables, g_1, g_2, \dots, g_R ,

where the grouping variables in X_j and g_r can be categorical, logical, character arrays, or cell arrays of strings.

Then, in a formula of the form, 'y ~ fixed + (random₁|g₁) + ... + (random_R|g_R)', the term **fixed** corresponds to a specification of the fixed-effects design matrix X , **random₁** is a specification of the random-effects design matrix Z_1 corresponding to grouping variable g_1 , and similarly **random_R** is a specification of the random-effects design matrix Z_R corresponding to grouping variable g_R . You can express the **fixed** and **random** terms using Wilkinson notation.

Wilkinson notation describes the factors present in models. The notation relates to factors present in models, not to the multipliers (coefficients) of those factors.

Wilkinson Notation	Factors in Standard Notation
1	Constant (intercept) term
X ^k , where k is a positive integer	X, X ² , ..., X ^k
X1 + X2	X1, X2
X1*X2	X1, X2, X1.*X2 (elementwise multiplication of X1 and X2)
X1:X2	X1.*X2 only
- X2	Do not include X2
X1*X2 + X3	X1, X2, X3, X1*X2
X1 + X2 + X3 + X1:X2	X1, X2, X3, X1*X2
X1*X2*X3 - X1:X2:X3	X1, X2, X3, X1*X2, X1*X3, X2*X3
X1*(X2 + X3)	X1, X2, X3, X1*X2, X1*X3

Statistics Toolbox notation always includes a constant term unless you explicitly remove the term using -1. Here are some examples for linear mixed-effects model specification.

Examples:

Formula	Description
'y ~ X1 + X2'	Fixed effects for the intercept, X1 and X2. This is equivalent to 'y ~ 1 + X1 + X2'.

Formula	Description
'y ~ -1 + X1 + X2'	No intercept and fixed effects for X1 and X2. The implicit intercept term is suppressed by including -1.
'y ~ 1 + (1 g1)'	Fixed effects for the intercept plus random effect for the intercept for each level of the grouping variable g1.
'y ~ X1 + (1 g1)'	Random intercept model with a fixed slope.
'y ~ X1 + (X1 g1)'	Random intercept and slope, with possible correlation between them. This is equivalent to 'y ~ 1 + X1 + (1 + X1 g1)'
'y ~ X1 + (1 g1) + (-1 + X1 g1)'	Independent random effects terms for intercept and slope.
'y ~ 1 + (1 g1) + (1 g2) + (1 g1:g2)'	Random intercept model with independent main effects for g1 and g2, plus an independent interaction effect.

Cholesky Parameterization

One of the assumptions of linear mixed-effects models is that the random effects have the following prior distribution.

$$b \sim N(0, \sigma^2 D(\theta)),$$

where D is a q -by- q symmetric and positive semidefinite matrix, parameterized by a variance component vector θ , q is the number of variables in the random-effects term, and σ^2 is the observation error variance. Since the covariance matrix of the random effects, D , is symmetric, it has $q(q+1)/2$ free parameters. Suppose L is the lower triangular Cholesky factor of $D(\theta)$ such that

$$D(\theta) = L(\theta)L(\theta)^T,$$

then the $q^*(q+1)/2$ -by-1 unconstrained parameter vector θ is formed from elements in the lower triangular part of L .

For example, if

$$L = \begin{bmatrix} L_{11} & 0 & 0 \\ L_{21} & L_{22} & 0 \\ L_{31} & L_{32} & L_{33} \end{bmatrix},$$

then

$$\theta = \begin{bmatrix} L_{11} \\ L_{21} \\ L_{31} \\ L_{22} \\ L_{32} \\ L_{33} \end{bmatrix}.$$

Log-Cholesky Parameterization

When the diagonal elements of L in Cholesky parameterization are constrained to be positive, then the solution for L is unique. Log-Cholesky parameterization is the same as Cholesky parameterization except that the logarithm of the diagonal elements of L are used to guarantee unique parameterization.

For example, for the 3-by-3 example in Cholesky parameterization, enforcing $L_{ii} \geq 0$,

$$\theta = \begin{bmatrix} \log(L_{11}) \\ L_{21} \\ L_{31} \\ \log(L_{22}) \\ L_{32} \\ \log(L_{33}) \end{bmatrix}.$$

Alternatives

You can also construct a linear mixed-effects model using `fitlme`. If your data is in matrix format, then use `fitlmematrix`.

fit

Class: NaiveBayes

Create Naive Bayes classifier object by fitting training data

Syntax

```
nb = NaiveBayes.fit(training, class)
nb = NaiveBayes.fit(..., 'param1',val1, 'param2',val2, ...)
```

Note: `fit` will be removed in a future release. Use `fitNaiveBayes` instead.

Description

`nb = NaiveBayes.fit(training, class)` builds a `NaiveBayes` classifier object `nb`. `training` is an N-by-D numeric matrix of training data. Rows of `training` correspond to observations; columns correspond to features. `class` is a classing variable for `training` taking K distinct levels. Each element of `class` defines which class the corresponding row of `training` belongs to. `training` and `class` must have the same number of rows.

`nb = NaiveBayes.fit(..., 'param1',val1, 'param2',val2, ...)` specifies one or more of the following name/value pairs:

- `'Distribution'` – a string or a 1-by-D cell vector of strings, specifying which distributions `fit` uses to model the data. If the value is a string, `fit` models all the features using one type of distribution. `fit` can also model different features using different types of distributions. If the value is a cell vector, its *j*th element specifies the distribution `fit` uses for the *j*th feature. The available types of distributions are:

<code>'normal'</code> (default)	Normal (Gaussian) distribution.
<code>'kernel'</code>	Kernel smoothing density estimate.
<code>'mvnm'</code>	Multivariate multinomial distribution for discrete data. <code>fit</code> assumes each individual feature follows a multinomial model within a class. The parameters for a feature include

the probabilities of all possible values that the corresponding feature can take.

'mn' Multinomial distribution for classifying the count-based data such as the bag-of-tokens model. In the bag-of-tokens model, the value of the *j*th feature is the number of occurrences of the *j*th token in this observation, so it must be a nonnegative integer. When 'mn' is used, `fit` considers each observation as multiple trials of a multinomial distribution, and considers each occurrence of a token as one trial. The number of categories (bins) in this multinomial model is the number of distinct tokens, i.e., the number of columns of `training`.

If you specify `mn`, then all features are components of a multinomial distribution. Therefore, you cannot include 'mn' as an element of a cell array of strings.

- 'Prior' – The prior probabilities for the classes, specified as one of the following:

'empirical'
(default)

`fit` estimates the prior probabilities from the relative frequencies of the classes in `training`.

'uniform'
vector

The prior probabilities are equal for all classes.

vector

A numeric vector of length *K* specifying the prior probabilities in the class order of `class`.

structure

A structure `S` containing class levels and their prior probabilities. `S` must have two fields:

- `S.prob`: A numeric vector of prior probabilities.
- `S.class`: A vector of the same type as `class`, containing unique class levels indicating the class for the corresponding element of `prob`. `S.class` must contain all the *K* levels in `class`. It can also contain classes that do not appear in `class`. This can be useful if `training` is a subset of a larger training set. `fit` ignores any classes that appear in `S.class` but not in `class`.

If the prior probabilities don't sum to one, `fit` will normalize them.

- 'KSWidth' – The bandwidth of the kernel smoothing window. The default is to select a default bandwidth automatically for each combination of feature and class, using a

value that is optimal for a Gaussian distribution. You can specify the value as one of the following:

- | | |
|---------------|---|
| scalar | Width for all features in all classes. |
| row vector | 1-by-D vector where the j th element is the bandwidth for the j th feature in all classes. |
| column vector | K-by-1 vector where the i th element specifies the bandwidth for all features in the i th class. K represents the number of class levels. |
| matrix | K-by-D matrix M where $M(i, j)$ specifies the bandwidth for the j th feature in the i th class. |
| structure | A structure S containing class levels and their bandwidths. S must have two fields: <ul style="list-style-type: none">• S.width – A numeric array of bandwidths specified as a row vector, or a matrix with D columns.• S.class – A vector of the same type as class, containing unique class levels indicating the class for the corresponding row of width. |
- 'KSSupport' – The regions where the density can be applied. It can be a string, a two-element vector as shown below, or a 1-by-D cell array of these values:

'unbounded' (default)	The density can extend over the whole real line.
'positive'	The density is restricted to positive values.
[L,U]	A two-element vector specifying the finite lower bound L and upper bound U for the support of the density.
 - 'KSType' – The type of kernel smoother to use. It can be a string or a 1-by-D cell array of strings. Each string can be 'normal' (default), 'box', 'triangle', or 'epanechnikov'.

How To

- “Naive Bayes Classification” on page 15-34
- “Grouping Variables” on page 2-52

NonLinearModel.fit

Class: NonLinearModel

Fit nonlinear regression model

Compatibility

NonLinearModel.fit will be removed in a future release. Use fitnlm instead.

Syntax

```
mdl = NonLinearModel.fit(tbl,modelfun,beta0)
mdl = NonLinearModel.fit(X,y,modelfun,beta0)
mdl = NonLinearModel.fit(...,modelfun,beta0,Name,Value)
```

Description

`mdl = NonLinearModel.fit(tbl,modelfun,beta0)` fits the model specified by `modelfun` to variables in the table or dataset array `tbl`, and returns the nonlinear model `mdl`. `NonLinearModel.fit` estimates model coefficients using an iterative procedure starting from the initial values in `beta0`.

`mdl = NonLinearModel.fit(X,y,modelfun,beta0)` fits a nonlinear regression model using the column vector `y` as a response variable and the columns of the matrix `X` as predictor variables.

`mdl = NonLinearModel.fit(...,modelfun,beta0,Name,Value)` fits a nonlinear regression model with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

tbl — Input data

table | dataset array

Input data, specified as a table or dataset array. If you do not specify the predictor and response variables, the last variable is the response variable and the others are the predictor variables by default.

Predictor variables and response variable must be numeric.

To set a different column as the response variable, use the `ResponseVar` name-value pair argument. To use a subset of the columns as predictors, use the `PredictorVars` name-value pair argument.

Data Types: `single` | `double` | `logical`

X — Predictor variables

matrix

Predictor variables, specified as an n -by- p matrix, where n is the number of observations and p is the number of predictor variables. Each column of `X` represents one variable, and each row represents one observation.

By default, there is a constant term in the model, unless you explicitly remove it, so do not include a column of 1s in `X`.

Data Types: `single` | `double` | `logical`

y — Response variable

vector

Response variable, specified as an n -by-1 vector, where n is the number of observations. Each entry in `y` is the response for the corresponding row of `X`.

Data Types: `single` | `double`

modelfun — Functional form of the model

function handle | string of the form ' $y \sim f(b_1, b_2, \dots, b_j, x_1, x_2, \dots, x_k)$ '

Functional form of the model, specified as either of the following.

- Function handle `@modelfun` or `@(b,x)modelfun`, where
 - `b` is a coefficient vector with the same number of elements as `beta0`.
 - `x` is a matrix with the same number of columns as `X` or the number of predictor variable columns of `tbl`.

`modelfun(b,x)` returns a column vector that contains the same number of rows as `x`. Each row of the vector is the result of evaluating `modelfun` on the corresponding row of `x`. In other words, `modelfun` is a vectorized function, one that operates on all data rows and returns all evaluations in one function call. `modelfun` should return real numbers to obtain meaningful coefficients.

- String of the form `'y ~ f(b1,b2,...,bj,x1,x2,...,xk)'`, where `f` represents a scalar function of the scalar coefficient variables `b1,...,bj` and the scalar data variables `x1,...,xk`.

beta0 – Coefficients

numeric vector

Coefficients for the nonlinear model, specified as a numeric vector. `NonLinearModel` starts its search for optimal coefficients from `beta0`.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

'CoefficientNames' – Names of the model coefficients

`{'b1','b2',...,'bk'}` (default) | cell array of strings

Names of the model coefficients, specified as a cell array of strings.

Data Types: `char`

'ErrorModel' – Form of the error variance model

`'constant'` (default) | `'proportional'` | `'combined'`

Form of the error variance model, specified as one of the following. Each model defines the error using a standard mean-zero and unit-variance variable e in combination with independent components: the function value f , and one or two parameters a and b

`'constant'` (default) $y = f + ae$

'proportional' $y = f + bfe$

'combined' $y = f + (a + b|f|)e$

The only allowed error model when using Weights is 'constant'.

Note: options.RobustWgtFun must have value [] when using an error model other than 'constant'.

Example: 'ErrorModel', 'proportional'

'ErrorParameters' — Initial estimates of the error model parameters

numeric array

Initial estimates of the error model parameters for the chosen ErrorModel, specified as a numeric array.

Error Model	Parameters	Default Values
'constant'	a	1
'proportional'	b	1
'combined'	a, b	[1, 1]

You can only use the 'constant' error model when using Weights.

Note: options.RobustWgtFun must have value [] when using an error model other than 'constant'.

For example, if 'ErrorModel' has the value 'combined', you can specify the starting value 1 for a and the starting value 2 for b as follows.

Example: 'ErrorParameters', [1,2]

Data Types: char

'Exclude' — Observations to exclude

logical or numeric index vector

Observations to exclude from the fit, specified as the comma-separated pair consisting of 'Exclude' and a logical or numeric index vector indicating which observations to exclude from the fit.

For example, you can exclude observations 2 and 3 out of 6 using either of the following examples.

Example: 'Exclude', [2,3]

Example: 'Exclude', logical([0 1 1 0 0 0])

Data Types: single | double | logical

'Options' — Options for controlling the iterative fitting procedure

[] (default) | structure

Options for controlling the iterative fitting procedure, specified as a structure created by `statset`. The relevant fields are the nonempty fields in the structure returned by the call `statset('nlinfit')`.

Option	Meaning	Default
DerivStep	Relative difference used in finite difference derivative calculations. A positive scalar, or a vector of positive scalars the same size as the vector of parameters estimated by the Statistics Toolbox function using the options structure.	$\text{eps}^{(1/3)}$
Display	Amount of information displayed by the fitting algorithm. <ul style="list-style-type: none"> 'off' — Displays no information. 'final' — Displays the final output. 'iter' — Displays iterative output to the Command Window. 	'off'
FunValCheck	String indicating to check for invalid values, such as NaN or Inf, from the model function.	'on'
MaxIter	Maximum number of iterations allowed. Positive integer.	200
RobustWgtFun	Weight function for robust fitting. Can also be a function handle that accepts a normalized residual as input and returns the robust weights as output.	[]

Option	Meaning	Default
	If you use a function handle, give a Tune constant. See “Robust Options” on page 21-1556	
Tune	Tuning constant used in robust fitting to normalize the residuals before applying the weight function. A positive scalar. Required if the weight function is specified as a function handle.	See “Robust Options” on page 21-1556 for the default, which depends on RobustWgtFun.
TolFun	Termination tolerance for the objective function value. Positive scalar.	1e-8
TolX	Termination tolerance for the parameters. Positive scalar.	1e-8

Data Types: struct

'PredictorVars' — Predictor variables

cell array of strings | logical or numeric index vector

Predictor variables to use in the fit, specified as the comma-separated pair consisting of 'PredictorVars' and either a cell array of strings of the variable names in the table or dataset array `tbl`, or a logical or numeric index vector indicating which columns are predictor variables.

The strings should be among the names in `tbl`, or the names you specify using the 'VarNames' name-value pair argument.

The default is all variables in `X`, or all variables in `tbl` except for `ResponseVar`.

For example, you can specify the second and third variables as the predictor variables using either of the following examples.

Example: 'PredictorVars', [2,3]

Example: 'PredictorVars', logical([0 1 1 0 0 0])

Data Types: single | double | logical | cell

'ResponseVar' — Response variable

last column in `tbl` (default) | string for variable name | logical or numeric index vector

Response variable to use in the fit, specified as the comma-separated pair consisting of 'ResponseVar' and either a string of the variable name in the table or dataset

array `tbl`, or a logical or numeric index vector indicating which column is the response variable. You typically need to use `'ResponseVar'` when fitting a table or dataset array `tbl`.

For example, you can specify the fourth variable, say `yield`, as the response out of six variables, in one of the following ways.

Example: `'ResponseVar', 'yield'`

Example: `'ResponseVar', [4]`

Example: `'ResponseVar', logical([0 0 0 1 0 0])`

Data Types: `single` | `double` | `logical` | `char`

'VarNames' — Names of variables in fit

`{'x1', 'x2', ..., 'xn', 'y'}` (default) | cell array of strings

Names of variables in fit, specified as the comma-separated pair consisting of `'VarNames'` and a cell array of strings including the names for the columns of `X` first, and the name for the response variable `y` last.

`'VarNames'` is not applicable to variables in a table or dataset array, because those variables already have names.

For example, if in your data, horsepower, acceleration, and model year of the cars are the predictor variables, and miles per gallon (MPG) is the response variable, then you can name the variables as follows.

Example: `'VarNames', {'Horsepower', 'Acceleration', 'Model_Year', 'MPG'}`

Data Types: `cell`

'Weights' — Observation weights

`ones(n, 1)` (default) | vector of nonnegative scalar values | function handle

Observation weights, specified as a vector of nonnegative scalar values or function handle.

- If you specify a vector, then it must have n elements, where n is the number of rows in `tbl` or `y`.
- If you specify a function handle, then the function must accept a vector of predicted response values as input, and return a vector of real positive weights as output.

Given weights, W , `NonLinearModel` estimates the error variance at observation i by $MSE * (1/W(i))$, where MSE is the mean squared error.

Data Types: `single` | `double` | `function_handle`

Output Arguments

`mdl` — Nonlinear model

`NonLinearModel` object

Nonlinear model representing a least-squares fit of the response to the data, returned as a `NonLinearModel` object.

If the `Options` structure contains a nonempty `RobustWgtFun` field, the model is not a least-squares fit, but uses the `RobustWgtFun` robust fitting function.

For properties and methods of the nonlinear model object, `mdl`, see the `NonLinearModel` class page.

Definitions

Robust Options

Weight Function	Equation	Default Tuning Constant
'andrews'	$w = (\text{abs}(r) < \pi) .* \sin(r) ./ r$	1.339
'bisquare' (default)	$w = (\text{abs}(r) < 1) .* (1 - r.^2).^2$	4.685
'cauchy'	$w = 1 ./ (1 + r.^2)$	2.385

Examples

Nonlinear Model from a Table

Create a nonlinear model for auto mileage based on the `carbig` data.

Load the data and create a nonlinear model.

```
load carbig
tbl = table(Horsepower,Weight,MPG);
modelfun = @(b,x)b(1) + b(2)*x(:,1).^b(3) + ...
    b(4)*x(:,2).^b(5);
beta0 = [-50 500 -1 500 -1];
mdl = NonLinearModel.fit(tbl,modelfun,beta0)

mdl =
```

Nonlinear regression model:

$$\text{MPG} \sim b_1 + b_2 \cdot \text{Horsepower}^{b_3} + b_4 \cdot \text{Weight}^{b_5}$$

Estimated	Coefficients:			
	Estimate	SE	tStat	pValue
b1	-49.383	119.97	-0.41164	0.68083
b2	376.43	567.05	0.66384	0.50719
b3	-0.78193	0.47168	-1.6578	0.098177
b4	422.37	776.02	0.54428	0.58656
b5	-0.24127	0.48325	-0.49926	0.61788

Number of observations: 392, Error degrees of freedom: 387

Root Mean Squared Error: 3.96

R-Squared: 0.745, Adjusted R-Squared 0.743

F-statistic vs. constant model: 283, p-value = 1.79e-113

Nonlinear Model from Matrix Data

Create a nonlinear model for auto mileage based on the `carbig` data.

Load the data and create a nonlinear model.

```
load carbig
X = [Horsepower,Weight];
```

```
y = MPG;
modelfun = @(b,x)b(1) + b(2)*x(:,1).^b(3) + ...
    b(4)*x(:,2).^b(5);
beta0 = [-50 500 -1 500 -1];
mdl = NonLinearModel.fit(X,y,modelfun,beta0)

mdl =
```

```
Nonlinear regression model:
    y ~ b1 + b2*x1^b3 + b4*x2^b5
```

```
Estimated Coefficients:
```

	Estimate	SE	tStat	pValue
b1	-49.383	119.97	-0.41164	0.68083
b2	376.43	567.05	0.66384	0.50719
b3	-0.78193	0.47168	-1.6578	0.098177
b4	422.37	776.02	0.54428	0.58656
b5	-0.24127	0.48325	-0.49926	0.61788

```
Number of observations: 392, Error degrees of freedom: 387
Root Mean Squared Error: 3.96
R-Squared: 0.745, Adjusted R-Squared 0.743
F-statistic vs. constant model: 283, p-value = 1.79e-113
```

Adjust Fitting Options in the Nonlinear Model

Create a nonlinear model for auto mileage based on the `carbig` data. Strive for more accuracy by lowering the `TolFun` option, and observe the iterations by setting the `Display` option.

Load the data and create a nonlinear model.

```
load carbig
X = [Horsepower,Weight];
y = MPG;
modelfun = @(b,x)b(1) + b(2)*x(:,1).^b(3) + ...
    b(4)*x(:,2).^b(5);
beta0 = [-50 500 -1 500 -1];
```

Create options to lower `TolFun` and to report iterative display, and create a model using the options.

```
opts = statset('Display','iter','TolFun',1e-10);
```

```
mdl = NonLinearModel.fit(X,y,modelfun,beta0,'Options',opts);
```

Iteration	SSE	Norm of Gradient	Norm of Step
0	1.82248e+06		
1	678600	788810	1691.07
2	616716	6.12739e+06	45.4738

%% Many iterations deleted %%

122	6068.48	1.56393	0.629325
123	6068.48	1.13809	0.432543
124	6068.48	0.295962	0.297511

Iterations terminated: relative change in SSE less than OPTIONS.TolFun

Specify Nonlinear Regression Using Model String Syntax

Specify a nonlinear regression model for estimation using a function handle or model string syntax.

Load sample data.

```
S = load('reaction');
X = S.reactants;
y = S.rate;
beta0 = S.beta;
```

Use a function handle to specify the Hougen-Watson model for the rate data.

```
mdl = NonLinearModel.fit(X,y,@hougen,beta0)
```

```
mdl =
```

```
Nonlinear regression model:
y ~ hougen(b,X)
```

```
Estimated Coefficients:
```

	Estimate	SE	tStat	pValue
b1	1.2526	0.86701	1.4447	0.18654
b2	0.062776	0.043561	1.4411	0.18753
b3	0.040048	0.030885	1.2967	0.23089
b4	0.11242	0.075157	1.4957	0.17309
b5	1.1914	0.83671	1.4239	0.1923

```
Number of observations: 13, Error degrees of freedom: 8
Root Mean Squared Error: 0.193
```

R-Squared: 0.999, Adjusted R-Squared 0.998
F-Statistic vs. zero model: 3.91e+03, p-value = 2.54e-13

Alternatively, you can use a string expression to specify the Hougen-Watson model for the rate data.

```
myfun = 'y~(b1*x2-x3/b5)/(1+b2*x1+b3*x2+b4*x3)';  
mdl2 = NonLinearModel.fit(X,y,myfun,beta0)
```

```
mdl2 =
```

Nonlinear regression model:

$$y \sim (b_1 x_2 - x_3/b_5)/(1 + b_2 x_1 + b_3 x_2 + b_4 x_3)$$

Estimated Coefficients:

	Estimate	SE	tStat	pValue
b1	1.2526	0.86701	1.4447	0.18654
b2	0.062776	0.043561	1.4411	0.18753
b3	0.040048	0.030885	1.2967	0.23089
b4	0.11242	0.075157	1.4957	0.17309
b5	1.1914	0.83671	1.4239	0.1923

Number of observations: 13, Error degrees of freedom: 8
Root Mean Squared Error: 0.193
R-Squared: 0.999, Adjusted R-Squared 0.998
F-Statistic vs. zero model: 3.91e+03, p-value = 2.54e-13

Estimate Nonlinear Regression Using Robust Fitting Options

Generate sample data from the nonlinear regression model

$$y = b_1 + b_2 \exp\{-b_3 x\} + \varepsilon,$$

where b_1 , b_2 , and b_3 are coefficients, and the error term is normally distributed with mean 0 and standard deviation 0.5.

```
modelfun = @(b,x)(b(1)+b(2)*exp(-b(3)*x));
```

```
rng('default') % for reproducibility  
b = [1;3;2];  
x = exprnd(2,100,1);  
y = modelfun(b,x) + normrnd(0,0.5,100,1);
```

Set robust fitting options.

```
opts = statset('nlinfit');
opts.RobustWgtFun = 'bisquare';
```

Fit the nonlinear model using the robust fitting options. Here, use a string expression to specify the model.

```
b0 = [2;2;2];
modelstr = 'y ~ b1 + b2*exp(-b3*x)';

mdl = NonLinearModel.fit(x,y,modelstr,b0,'Options',opts)

mdl =
```

```
Nonlinear regression model (robust fit):
  y ~ b1 + b2*exp( - b3*x)
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
b1	1.0218	0.07202	14.188	2.1344e-25
b2	3.6619	0.25429	14.401	7.974e-26
b3	2.9732	0.38496	7.7232	1.0346e-11

```
Number of observations: 100, Error degrees of freedom: 97
Root Mean Squared Error: 0.501
R-Squared: 0.807, Adjusted R-Squared 0.803
F-statistic vs. constant model: 203, p-value = 2.34e-35
```

Fit Nonlinear Regression Model Using Weights Function Handle

Load sample data.

```
S = load('reaction');
X = S.reactants;
y = S.rate;
beta0 = S.beta;
```

Specify a function handle for observation weights. The function accepts the model fitted values as input, and returns a vector of weights.

```
a = 1; b = 1;
weights = @(yhat) 1./((a + b*abs(yhat)).^2);
```

Fit the Hougen-Watson model to the rate data using the specified observation weights function.

```
mdl = NonLinearModel.fit(X,y,@hougen,beta0,'Weights',weights)
```

```
mdl =
```

```
Nonlinear regression model:
```

```
y ~ hougen(b,X)
```

```
Estimated Coefficients:
```

	Estimate	SE	tStat	pValue
b1	0.83085	0.58224	1.427	0.19142
b2	0.04095	0.029663	1.3805	0.20477
b3	0.025063	0.019673	1.274	0.23842
b4	0.080053	0.057812	1.3847	0.20353
b5	1.8261	1.281	1.4256	0.19183

```
Number of observations: 13, Error degrees of freedom: 8
```

```
Root Mean Squared Error: 0.037
```

```
R-Squared: 0.998, Adjusted R-Squared 0.998
```

```
F-statistic vs. zero model: 1.14e+03, p-value = 3.49e-11
```

Nonlinear Regression Model Using Nonconstant Error Model

Load sample data.

```
S = load('reaction');
```

```
X = S.reactants;
```

```
y = S.rate;
```

```
beta0 = S.beta;
```

Fit the Hougen-Watson model to the rate data using the combined error variance model.

```
mdl = NonLinearModel.fit(X,y,@hougen,beta0,'ErrorModel','combined')
```

```
mdl =
```

```
Nonlinear regression model:
```

```
y ~ hougen(b,X)
```

```
Estimated Coefficients:
```

	Estimate	SE	tStat	pValue
b1	1.2526	0.86702	1.4447	0.18654
b2	0.062776	0.043561	1.4411	0.18753
b3	0.040048	0.030885	1.2967	0.23089
b4	0.11242	0.075158	1.4957	0.17309
b5	1.1914	0.83671	1.4239	0.1923

Number of observations: 13, Error degrees of freedom: 8
 Root Mean Squared Error: 1.27
 R-Squared: 0.999, Adjusted R-Squared 0.998
 F-statistic vs. zero model: 3.91e+03, p-value = 2.54e-13

- “Nonlinear Regression Workflow” on page 11-14

Algorithms

`NonLinearModel.fit` uses the same fitting algorithm as `nlinfit`.

Alternatives

You can also construct a nonlinear model using `fitnlm`.

RegressionTree.fit

Class: RegressionTree

Binary decision tree for regression (to be removed)

Compatibility

RegressionTree.fit will be removed in a future release. Use fitrtree instead.

Syntax

```
tree = RegressionTree.fit(x,y)
tree = RegressionTree.fit(x,y,Name,Value)
```

Description

`tree = RegressionTree.fit(x,y)` returns a regression tree based on the input variables (also known as predictors, features, or attributes) `x` and output (response) `y`. `tree` is a binary tree where each branching node is split based on the values of a column of `x`.

`tree = RegressionTree.fit(x,y,Name,Value)` fits a tree with additional options specified by one or more `Name,Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Note that using the `'CrossVal'`, `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'` options results in a tree of class `RegressionPartitionedModel`. You cannot use a partitioned tree for prediction, so this kind of tree does not have a `predict` method.

Otherwise, `tree` is of class `RegressionTree`, and you can use the `predict` method to make predictions.

Input Arguments

x — Predictor values

matrix of scalar values

Predictor values, specified as a matrix of scalar values. Each column of **x** represents one variable, and each row represents one observation.

`RegressionTree.fit` considers NaN values in **x** as missing values.

`RegressionTree.fit` does not use observations with all missing values for **x** the fit.

`RegressionTree.fit` uses observations with some missing values for **x** to find splits on variables for which these observations have valid values.

Data Types: `single` | `double`

y — Response values

vector of scalar values

Response values, specified as a vector of scalar values with the same number of rows as **x**. Each entry in **y** is the response to the data in the corresponding row of **x**.

`RegressionTree.fit` considers NaN values in **y** to be missing values.

`RegressionTree.fit` does not use observations with missing values for **y** in the fit.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of **Name**,**Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

'CategoricalPredictors' — Categorical predictors list

numeric or logical vector | cell array of strings | character matrix | 'all'

Categorical predictors list, specified as the comma-separated pair consisting of 'CategoricalPredictors' and one of the following.

- A numeric vector with indices from 1 to **p**, where **p** is the number of columns of **x**.

- A logical vector of length `p`, where a `true` entry means that the corresponding column of `x` is a categorical variable.
- A cell array of strings, where each element in the array is the name of a predictor variable. The names must match entries in the `PredictorNames` property.
- A character matrix, where each row of the matrix is a name of a predictor variable. Pad the names with extra blanks so each row of the character matrix has the same length.
- `'all'`, meaning all predictors are categorical.

Example:

Data Types: `single` | `double` | `logical` | `char` | `struct` | `cell`

'CrossVal' — Cross-validation flag

`'off'` (default) | `'on'`

Cross-validation flag, specified as the comma-separated pair consisting of `'CrossVal'` and either `'on'` or `'off'`.

If `'on'`, `RegressionTree.fit` grows a cross-validated decision tree with 10 folds. You can override this cross-validation setting using one of the `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'` name-value pair arguments. Note that you can only use one of these four options (`'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'`) at a time when creating a cross-validated tree.

Alternatively, cross-validate tree later using the `crossval` method.

Example: `'CrossVal', 'on'`

'CVPartition' — Partition for cross-validation tree

`cvpartition` object

Partition for cross-validated tree, specified as the comma-separated pair consisting of `'CVPartition'` and an object of the `cvpartition` class created using `cvpartition`.

Note that if you use `'CVPartition'`, you cannot use any of the `'KFold'`, `'Holdout'`, or `'Leaveout'` name-value pair arguments.

Example:

'Holdout' — Fraction of data for holdout validation

scalar value in the range `[0, 1]`

Fraction of data used for holdout validation, specified as the comma-separated pair consisting of `'Holdout'` and a scalar value in the range `[0,1]`. Holdout validation tests the specified fraction of the data, and uses the rest of the data for training.

Note that if you use `'Holdout'`, you cannot use any of the `'CVPartition'`, `'KFold'`, or `'Leaveout'` name-value pair arguments.

Example: `'Holdout',0.1`

Data Types: `single` | `double`

'KFold' — Number of folds

10 (default) | positive integer value

Number of folds to use in a cross-validated tree, specified as the comma-separated pair consisting of `'KFold'` and a positive integer value.

Note that if you use `'KFold'`, you cannot use any of the `'CVPartition'`, `'Holdout'`, or `'Leaveout'` name-value pair arguments.

Example: `'KFold',8`

Data Types: `single` | `double`

'Leaveout' — Leave-one-out cross-validation flag

`'off'` (default) | `'on'`

Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of `'Leaveout'` and either `'on'` or `'off'`. Use leave-one-out cross validation by setting to `'on'`.

Note that if you use `'Leaveout'`, you cannot use any of the `'CVPartition'`, `'Holdout'`, or `'KFold'` name-value pair arguments.

Example: `'Leaveout','on'`

'MergeLeaves' — Leaf merge flag

`'on'` (default) | `'off'`

Leaf merge flag, specified as the comma-separated pair consisting of `'MergeLeaves'` and either `'on'` or `'off'`. When `'on'`, `RegressionTree.fit` merges leaves that originate from the same parent node, and that give a sum of risk values greater or equal to the risk associated with the parent node. When `'off'`, `RegressionTree.fit` does not merge leaves.

Example: 'MergeLeaves', 'off'

'MinLeaf' — Minimum number of leaf node observations

1 (default) | positive integer value

Minimum number of leaf node observations, specified as the comma-separated pair consisting of 'MinLeaf' and a positive integer value. Each leaf has at least MinLeaf observations per tree leaf. If you supply both MinParent and MinLeaf, RegressionTree.fit uses the setting that gives larger leaves: $\text{MinParent} = \max(\text{MinParent}, 2 * \text{MinLeaf})$.

Example: 'MinLeaf', 3

Data Types: single | double

'MinParent' — Minimum number of branch node observations

10 (default) | positive integer value

Minimum number of branch node observations, specified as the comma-separated pair consisting of 'MinParent' and a positive integer value. Each branch node in the tree has at least MinParent observations. If you supply both MinParent and MinLeaf, RegressionTree.fit uses the setting that gives larger leaves: $\text{MinParent} = \max(\text{MinParent}, 2 * \text{MinLeaf})$.

Example: 'MinParent', 8

Data Types: single | double

'NVarToSample' — Number of predictors for split

'all' (default) | positive integer value

Number of predictors to select at random for each split, specified as the comma-separated pair consisting of 'NVarToSample' and a positive integer value. You can also specify 'all' to use all available predictors.

Example: 'NVarToSample', 3

Data Types: single | double

'PredictorNames' — Predictor variable names

{ 'x1', 'x2', ... } (default) | cell array of strings

Predictor variable names, specified as the comma-separated pair consisting of 'PredictorNames' and a cell array of strings containing the names for the predictor variables, in the order in which they appear in x.

Example:

Data Types: cell

'Prune' — Pruning flag

'on' (default) | 'off'

Pruning flag, specified as the comma-separated pair consisting of 'Prune' and either 'on' or 'off'. When 'on', `RegressionTree.fit` computes the full tree and the optimal sequence of pruned subtrees. When 'off', `RegressionTree.fit` computes the full tree without pruning.

Example: 'Prune', 'off'

'PruneCriterion' — Pruning criterion

'mse' (default)

Pruning criterion, specified as the comma-separated pair consisting of 'PruneCriterion' and 'mse'.

Example: 'PruneCriterion', 'mse'

'QEToler' — Quadratic error tolerance

1e-6 (default) | positive scalar value

Quadratic error tolerance per node, specified as the comma-separated pair consisting of 'QEToler' and a positive scalar value. Splitting nodes stops when quadratic error per node drops below $QEToler * QED$, where QED is the quadratic error for the entire data computed before the decision tree is grown.

Example: 'QEToler', 1e4

'ResponseName' — Response variable name

'Y' (default) | string

Response variable name, specified as the comma-separated pair consisting of 'ResponseName' and a string containing the name of the response variable in y .

Example: 'ResponseName', 'Response'

Data Types: char

'ResponseTransform' — Response transform function

'none' (default) | function handle

Response transform function for transforming the raw response values, specified as the comma-separated pair consisting of 'ResponseTransform' and either a function handle or 'none'. The function handle should accept a matrix of response values and return a matrix of the same size. The default string 'none' means $@(x)x$, or no transformation.

Add or change a ResponseTransform function using dot notation:

```
tree.ResponseTransform = @function
```

Example:

Data Types: function_handle

'SplitCriterion' — Split criterion

'MSE' (default)

Split criterion, specified as the comma-separated pair consisting of 'SplitCriterion' and 'MSE', meaning mean squared error.

Example: 'SplitCriterion', 'MSE'

'Surrogate' — Surrogate decision splits flag

'off' | 'on' | 'all' | positive integer value

Surrogate decision splits flag, specified as the comma-separated pair consisting of 'Surrogate' and 'on', 'off', 'all', or a positive integer value.

- When 'on', RegressionTree.fit finds at most 10 surrogate splits at each branch node.
- When set to a positive integer value, RegressionTree.fit finds at most the specified number of surrogate splits at each branch node.
- When set to 'all', RegressionTree.fit finds all surrogate splits at each branch node. The 'all' setting can use much time and memory.

Use surrogate splits to improve the accuracy of predictions for data with missing values. The setting also enables you to compute measures of predictive association between predictors.

Example: 'Surrogate', 'on'

Data Types: single | double

'Weights' — Observation weights

ones(size(X,1),1) (default) | vector of scalar values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a vector of scalar values. The length of `Weights` is the number of rows in `x`.

Example:

Data Types: `single` | `double`

Output Arguments

tree — Regression tree

regression tree object

Regression tree, returned as a regression tree object. Note that using the 'Crossval', 'Kfold', 'Holdout', 'Leaveout', or 'CVPartition' options results in a tree of class `RegressionPartitionedModel`. You cannot use a partitioned tree for prediction, so this kind of tree does not have a `predict` method.

Otherwise, `tree` is of class `RegressionTree`, and you can use the `predict` method to make predictions.

Examples

Predict Values Using a Regression Tree

Load the sample data.

```
load carsmall
```

Construct a regression tree to predict the mileage of cars based on their weights and numbers of cylinders.

```
tree = RegressionTree.fit([Weight, Cylinders],MPG,...
    'MinParent',20,...
    'PredictorNames',{ 'W', 'C' })
```

```
tree =
```

```
RegressionTree
    PredictorNames: { 'W' 'C' }
    ResponseName: 'Y'
    ResponseTransform: 'none'
```

```
CategoricalPredictors: []  
  NumObservations: 94
```

Predict the mileage of a car that weighs 2200 lbs and has four cylinders.

```
predict(tree, [2200, 4])
```

```
ans =  
  29.6111
```

How To

- “Splitting Categorical Predictors” on page 16-57

fitcdiscr

Fit discriminant analysis classifier

Syntax

```
obj = fitcdiscr(x,y)
obj = fitcdiscr(x,y,Name,Value)
```

Description

`obj = fitcdiscr(x,y)` returns a discriminant analysis classifier based on the input variables (also known as predictors, features, or attributes) `x` and output (response) `y`.

`obj = fitcdiscr(x,y,Name,Value)` fits a classifier with additional options specified by one or more name-value pair arguments. For example, you can specify the cost of misclassification, prior probabilities for each class, or observation weights.

Examples

Construct a Discriminant Analysis Classifier

Construct a discriminant analysis classifier for the Fisher iris data.

```
load fisheriris
obj = fitcdiscr(meas,species)

obj =

    ClassificationDiscriminant
    PredictorNames: {'x1' 'x2' 'x3' 'x4'}
    ResponseName: 'Y'
    ClassNames: {'setosa' 'versicolor' 'virginica'}
    ScoreTransform: 'none'
    NumObservations: 150
    DiscrimType: 'linear'
        Mu: [3x4 double]
        Coeffs: [3x3 struct]
```

Properties, Methods

Input Arguments

x — Predictor values

matrix of numeric values

Predictor values, specified as a matrix of numeric values. Each column of **x** represents one variable, and each row represents one observation.

`fitcdiscr` considers NaN values in **x** as missing values. `fitcdiscr` does not use observations with missing values for **x** in the fit.

Data Types: `single` | `double`

y — Classification values

numeric vector | categorical vector | logical vector | character array | cell array of strings

Classification values, specified as a categorical or character array, logical or numeric vector, or cell array of strings. Each row of **y** represents the classification of the corresponding row of **x**.

`fitcdiscr` considers NaN values in **y** to be missing values. `fitcdiscr` does not use observations with missing values for **y** in the fit.

Data Types: `single` | `double` | `logical` | `char` | `cell`

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Example: `'DiscrimType','quadratic','SaveMemory','on'` specifies a quadratic discriminant classifier and does not store the covariance matrix in the output object.

'ClassNames' — Class names

array

Class names, specified as the comma-separated pair consisting of `'ClassNames'` and an array. Use the data type that exists in `y`. The default is the class names that exist in `y`. Use `ClassNames` to order the classes or to select a subset of classes for training.

Data Types: `single` | `double` | `logical` | `char`

'Cost' — Cost of misclassification

`square matrix` | `structure`

Cost of misclassification, specified as the comma-separated pair consisting of `'Cost'` and a square matrix, where `Cost(i, j)` is the cost of classifying a point into class `j` if its true class is `i`. Alternatively, `Cost` can be a structure `S` having two fields: `S.ClassNames` containing the group names as a variable of the same type as `y`, and `S.ClassificationCosts` containing the cost matrix.

The default is `Cost(i, j)=1` if `i~j`, and `Cost(i, j)=0` if `i=j`.

Data Types: `single` | `double` | `struct`

'CrossVal' — Flag to train cross-validated classifier

`'off'` (default) | `'on'`

Flag to train a cross-validated classifier, specified as the comma-separated pair consisting of `'CrossVal'` and either `'on'` or `'off'`.

If you specify `'on'`, then `fitcdiscr` creates a cross-validated classifier with 10 folds.

You can override this cross-validation setting using one of the `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'` name-value pair arguments.

You can only use one of these four options at a time to create a cross-validated model: `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'`.

Alternatively, cross validate `obj` later using the `crossval` method.

Example: `'CrossVal', 'on'`

'CVPartition' — Cross-validated model partition

`cvpartition object`

Cross-validated model partition, specified as the comma-separated pair consisting of `'CVPartition'` and an object created using `cvpartition`. You can only use one option

at a time for creating a cross-validated model: 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'.

'Delta' — Linear coefficient threshold

0 (default) | nonnegative scalar value

Linear coefficient threshold, specified as the comma-separated pair consisting of 'Delta' and a nonnegative scalar value. If a coefficient of `Obj` has magnitude smaller than `Delta`, `Obj` sets this coefficient to 0, and you can eliminate the corresponding predictor from the model. Set `Delta` to a higher value to eliminate more predictors.

`Delta` must be 0 for quadratic discriminant models.

Data Types: single | double

'DiscrimType' — Discriminant type

'linear' (default) | 'quadratic' | 'diagLinear' | 'diagQuadratic' | 'pseudoLinear' | 'pseudoQuadratic'

Discriminant type, specified as the comma-separated pair consisting of 'DiscrimType' and one of the following:

- 'linear'
- 'quadratic'
- 'diagLinear'
- 'diagQuadratic'
- 'pseudoLinear'
- 'pseudoQuadratic'

Example: 'DiscrimType', 'quadratic'

'FillCoeffs' — Coeffs property flag

'on' | 'off'

`Coeffs` property flag, specified as the comma-separated pair consisting of 'FillCoeffs' and 'on' or 'off'. Setting the flag to 'on' populates the `Coeffs` property in the classifier object. This can be computationally intensive, especially when cross validating. The default is 'on', unless you specify a cross validation name-value pair, in which case the flag is set to 'off' by default.

Example: 'FillCoeffs', 'off'

'Gamma' — Regularization parameter

scalar value in the range [0, 1]

Parameter for regularizing the correlation matrix of predictors, specified as the comma-separated pair consisting of 'Gamma' and a scalar value in the range [0, 1].

- Linear discriminant — Scalar value in the range [0, 1].
 - If you pass a value strictly between 0 and 1, `fitcdiscr` sets the discriminant type to 'Linear'.
 - If you pass 0 for Gamma and 'Linear' for `DiscrimType`, and if the correlation matrix is singular, `fitcdiscr` sets Gamma to the minimal value required for inverting the covariance matrix.
 - If you set Gamma to 1, `fitcdiscr` sets the discriminant type to 'DiagLinear'.
- Quadratic discriminant — Either 0 or 1.
 - If you pass 0 for Gamma and 'Quadratic' for `DiscrimType`, and if one of the classes has a singular covariance matrix, `fitcdiscr` errors.
 - If you set Gamma to 1, `fitcdiscr` sets the discriminant type to 'DiagQuadratic'.
 - If you set Gamma to a value between 0 and 1 for a quadratic discriminant, `fitcdiscr` errors.

Example: 'Gamma', 1

Data Types: single | double

'Holdout' — Fraction of data for holdout validation

scalar value in the range (0,1)

Fraction of data used for holdout validation, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range (0,1). If you specify 'Holdout', p , then the software:

- 1 Randomly reserves $p*100\%$ of the data as validation data, and trains the model using the rest of the data
- 2 Stores the compact, trained model in `CVMdl.Trained`

If you specify `Holdout`, then you cannot specify any of `CVPartition`, `KFold`, or `Leaveout`.

Example: 'Holdout', 0.1

Data Types: double | single

'KFold' — Number of folds

10 (default) | positive integer value

Number of folds to use in a cross-validated classifier, specified as the comma-separated pair consisting of 'KFold' and a positive integer value.

You can only use one of these four options at a time to create a cross-validated model: 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'.

Example: 'KFold',8

Data Types: single | double

'Leaveout' — Leave-one-out cross-validation flag

'off' (default) | 'on'

Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of 'Leaveout' and either 'on' or 'off'. If you specify 'on', then the software implements leave-one-out cross validation.

If you use 'Leaveout', you cannot use these 'CVPartition', 'Holdout', or 'KFold' name-value pair arguments.

Example: 'Leaveout', 'on'

Data Types: char

'PredictorNames' — Predictor variable names

{'x1', 'x2', ...} (default) | cell array of strings

Predictor variable names, specified as the comma-separated pair consisting of 'PredictorNames' and a cell array of strings containing the names for the predictor variables, in the order in which they appear in x.

Data Types: cell

'Prior' — Prior probabilities

'empirical' (default) | 'uniform' | vector of scalar values | structure

Prior probabilities for each class, specified as the comma-separated pair consisting of 'Prior' and one of the following.

- A string:

- `'empirical'` determines class probabilities from class frequencies in `y`. If you pass observation weights, they are used to compute the class probabilities.
- `'uniform'` sets all class probabilities equal.
- A vector containing one scalar value for each class.
- A structure `S` with two fields:
 - `S.ClassNames` containing the class names as a variable of the same type as `y`.
 - `S.ClassProbs` containing a vector of corresponding probabilities

Example: `'Prior', 'uniform'`

Data Types: `single` | `double` | `struct`

'ResponseName' — Response variable name

`'Y'` (default) | `string`

Response variable name, specified as the comma-separated pair consisting of `'ResponseName'` and a string containing the name of the response variable `y`.

Example: `'ResponseName', 'Response'`

Data Types: `char`

'SaveMemory' — Flag to save covariance matrix

`'off'` (default) | `'on'`

Flag to save covariance matrix, specified as the comma-separated pair consisting of `'SaveMemory'` and either `'on'` or `'off'`. If you specify `'on'`, then `fitcdiscr` does not store the full covariance matrix, but instead stores enough information to compute the matrix. The `predict` method computes the full covariance matrix for prediction, and does not store the matrix. If you specify `'off'`, then `fitcdiscr` computes and stores the full covariance matrix in `obj`.

Specify `SaveMemory` as `'on'` when the input matrix contains thousands of predictors.

Example: `'SaveMemory', 'on'`

'ScoreTransform' — Score transform function

`'none'` (default) | valid score transform string | function handle

Score transform function, specified as the comma-separated pair consisting of `'ScoreTransform'` and one of the following.

String	Formula
'doublelogit'	$1/(1 + e^{-2x})$
'invlogit'	$\log(x / (1-x))$
'ismax'	Set the score for the class with the largest score to 1, and scores for all other classes to 0.
'logit'	$1/(1 + e^{-x})$
'none'	x (no transformation)
'sign'	-1 for $x < 0$ 0 for $x = 0$ 1 for $x > 0$
'symmetric'	$2x - 1$
'symmetriclogit'	$2/(1 + e^{-x}) - 1$
'symmetricismax'	Set the score for the class with the largest score to 1, and scores for all other classes to -1.

Alternatively, you can use your own function handle for transforming scores. Your function should accept a matrix (the original scores) and return a matrix of the same size (the transformed scores).

Example: 'ScoreTransform', 'logit'

Data Types: function_handle

'Weights' — Observation weights

ones(size(X,1),1) (default) | vector of scalar values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a vector of scalar values. The length of Weights is the number of rows in x. fitcdiscr normalizes the weights to sum to 1.

Data Types: single | double

Output Arguments

obj — Discriminant analysis classifier

classifier object

Discriminant analysis classifier, returned as a classifier object.

Note that using the 'CrossVal', 'Kfold', 'Holdout', 'Leaveout', or 'CVPartition' options results in a tree of class `ClassificationPartitionedModel`. You cannot use a partitioned tree for prediction, so this kind of tree does not have a `predict` method.

Otherwise, `obj` is of class `ClassificationDiscriminant`, and you can use the `predict` method to predict the response of new data.

Alternative Functionality

Functions

The `classify` function also performs discriminant analysis. `classify` is usually more awkward to use.

- `classify` requires you to fit the classifier every time you make a new prediction.
- `classify` does not perform cross validation.
- `classify` requires you to fit the classifier when changing prior probabilities.

More About

Discriminant Classification

The model for discriminant analysis is:

- Each class (Y) generates data (X) using a multivariate normal distribution. That is, the model assumes X has a Gaussian mixture distribution (`gmdistribution`).
 - For linear discriminant analysis, the model has the same covariance matrix for each class, only the means vary.
 - For quadratic discriminant analysis, both means and covariances of each class vary.

`predict` classifies so as to minimize the expected classification cost:

$$\hat{y} = \operatorname{argmin}_{y=1,\dots,K} \sum_{k=1}^K \hat{P}(k|x)C(y|k),$$

where

- \hat{y} is the predicted classification.
- K is the number of classes.
- $\hat{P}(k|x)$ is the posterior probability of class k for observation x .
- $C(y|k)$ is the cost of classifying an observation as y when its true class is k .

For details, see “How the predict Method Classifies” on page 15-6.

- “Discriminant Analysis” on page 15-3

fitcecoc

Fit multiclass models for support vector machines or other classifiers

Syntax

```
Mdl = fitcecoc(X,Y)
Mdl = fitcecoc(X,Y,Name,Value)
```

Description

`Mdl = fitcecoc(X,Y)` returns a full, trained error-correcting output codes (ECOC) multiclass model using the predictors `X` and the class labels `Y`. By default, `fitcecoc` uses $K(K-1)/2$ binary support vector machine (SVM) models using the one-versus-one coding design, where K is the number of unique class labels (levels). `Mdl` is a `ClassificationECOC` model.

`Mdl = fitcecoc(X,Y,Name,Value)` returns an ECOC model with additional options specified by one or more `Name,Value` pair arguments.

For example, specify different binary learners, a different coding design, or to cross validate. It is good practice to cross validate using the `Kfold Name,Value` pair argument. The cross-validation results determine how well the ECOC classifier generalizes.

Examples

Train a Multiclass Model Using SVM Learners

Train an error-correcting output codes (ECOC) multiclass model using support vector machine (SVM) binary learners.

Load Fisher's iris data set.

```
load fisheriris
X = meas;
Y = species;
```

Train an ECOC multiclass model using the default options.

```
Mdl = fitcecoc(X,Y)
```

```
Mdl =
```

```
ClassificationECOC
  PredictorNames: {'x1' 'x2' 'x3' 'x4'}
  ResponseName: 'Y'
  ClassNames: {'setosa' 'versicolor' 'virginica'}
  ScoreTransform: 'none'
  BinaryLearners: {3x1 cell}
  CodingName: 'onevsone'
```

Mdl is a **ClassificationECOC** model. By default, **fitcecoc** uses SVM binary learners, and uses a one-versus-one coding design. You can access Mdl properties using dot notation.

Display the coding design matrix.

```
Mdl.ClassNames
CodingMat = Mdl.CodingMatrix
```

```
ans =
```

```
'setosa'
'versicolor'
'virginica'
```

```
CodingMat =
```

```
 1    1    0
-1    0    1
 0   -1   -1
```

A one-versus-one coding design on three classes yields three binary learners. Columns of **CodingMat** correspond to learners and rows correspond to classes. The class order corresponds to the order in **Mdl.ClassNames**. For example, **CodingMat(:,1)** is **[1; -1; 0]**, and indicates that the software trains the first SVM binary learner using all observations classified as 'setosa' and 'versicolor'. Since 'setosa' corresponds

to 1, it is the positive class, and since 'versicolor' corresponds to -1, it is the negative class.

You can access each binary learner using cell indexing and dot notation.

```
Mdl.BinaryLearners{1} % The first binary learner
Mdl.BinaryLearners{1}.SupportVectors % Support vector indices
```

```
ans =
```

```
classreg.learning.classif.CompactClassificationSVM
  PredictorNames: {'x1' 'x2' 'x3' 'x4'}
  ResponseName: 'Y'
  ClassNames: [-1 1]
  ScoreTransform: 'none'
  Alpha: [3x1 double]
  Bias: 1.4505
  KernelParameters: [1x1 struct]
  SupportVectors: [3x4 double]
  SupportVectorLabels: [3x1 double]
```

```
ans =
```

```
5.1000    3.3000    1.7000    0.5000
4.5000    2.3000    1.3000    0.3000
5.1000    2.5000    3.0000    1.1000
```

Compute the in-sample classification error.

```
isLoss = resubLoss(Mdl)
```

```
isLoss =
```

```
0.0067
```

The classification error is small, but the classifier might have been overfit. You can cross validate the classifier using `crossval`.

Cross Validate an ECOC Classifier

Train a one-versus-one ECOC classifier using binary SVM learners.

Load Fisher's iris data set.

```
load fisheriris
X = meas;
Y = species;
rng(1); % For reproducibility
```

Create an SVM template. It is good practice to standardize the predictors.

```
t = templateSVM('Standardize',1)
```

```
t =
```

Fit template for classification SVM.

```
          Alpha: [0x1 double]
      BoxConstraint: []
          CacheSize: []
      CachingMethod: ''
DeltaGradientTolerance: []
          GapTolerance: []
          KKTolerance: []
      IterationLimit: []
      KernelFunction: ''
          KernelScale: []
          KernelOffset: []
KernelPolynomialOrder: []
          NumPrint: []
              Nu: []
      OutlierFraction: []
      ShrinkagePeriod: []
          Solver: ''
StandardizeData: 1
      VerbosityLevel: []
          Method: 'SVM'
          Type: 'classification'
```

`t` is an SVM template. All of its properties are empty, except for `StandardizeData`, `Method`, and `Type`. When the software trains the ECOC classifier, it sets the applicable properties to their default values.

Train the ECOC classifier. It is good practice to specify the class order.

```
Mdl = fitcecoc(X,Y,'Learners',t,...  
             'ClassNames',{'setosa','versicolor','virginica'});
```

`Mdl` is a `ClassificationECOC` classifier. You can access its properties using dot notation.

Cross validate `Mdl` using 10-fold cross validation.

```
CVMdl = crossval(Mdl);
```

`CVMdl` is a `ClassificationPartitionedECOC` cross-validated ECOC classifier.

Estimate the generalization error.

```
oosLoss = kfoldLoss(CVMdl)
```

```
oosLoss =  
  
    0.0400
```

The out-of-sample classification error is 4%, which indicates that the ECOC classifier generalizes fairly well.

Estimate Posterior Probabilities Using ECOC Classifiers

Load Fisher's iris data set. Train the classifier using the petal dimensions as predictors.

```
load fisheriris  
X = meas(:,3:4);  
Y = species;  
rng(1); % For reproducibility
```

Create an SVM template, and specify the Gaussian kernel. It is good practice to standardize the predictors.

```
t = templateSVM('Standardize',1,'KernelFunction','gaussian');
```

`t` is an SVM template. Most of its properties are empty. When the software trains the ECOC classifier, it sets the applicable properties to their default values.

Train the ECOC classifier using the SVM template. Transform classification scores to class posterior probabilities (which are returned by `predict` or `resubPredict`) using the 'FitPosterior' name-value pair argument. Display diagnostic messages during the training using the 'Verbose' name-value pair argument. It is good practice to specify the class order.

```
Mdl = fitcecoc(X,Y,'Learners',t,'FitPosterior',1,...
    'ClassNames',{'setosa','versicolor','virginica'},...
    'Verbose',2);
```

```
Training binary learner 1 (SVM) out of 3 with 50 negative and 50 positive observations
Negative class indices: 2
Positive class indices: 1
```

```
Fitting posterior probabilities for learner 1 (SVM).
Training binary learner 2 (SVM) out of 3 with 50 negative and 50 positive observations
Negative class indices: 3
Positive class indices: 1
```

```
Fitting posterior probabilities for learner 2 (SVM).
Training binary learner 3 (SVM) out of 3 with 50 negative and 50 positive observations
Negative class indices: 3
Positive class indices: 2
```

```
Fitting posterior probabilities for learner 3 (SVM).
```

`Mdl` is a `ClassificationECOC` model. The same SVM template applies to each binary learner, but you can adjust options for each binary learner by passing in a cell vector of templates.

Predict the in-sample labels and class posterior probabilities. Display diagnostic messages during the computation of labels and class posterior probabilities using the 'Verbose' name-value pair argument.

```
[label,~,~,Posterior] = resubPredict(Mdl,'Verbose',1);
Mdl.BinaryLoss
```

```
Predictions from all learners have been computed.
Loss for all observations has been computed.
```

```
Computing posterior probabilities...
```

```
ans =
```

```
quadratic
```

The software assigns an observation to the class that yields the smallest average binary loss. Since all binary learners are computing posterior probabilities, the binary loss function is `quadratic`.

Display a random set of results.

```
idx = randsample(size(X,1),10,1);
Mdl.ClassNames
table(Y(idx),label(idx),Posterior(idx,:),...
    'VariableNames',{ 'TrueLabel', 'PredLabel', 'Posterior'})
```

```
ans =
```

```
'setosa'
'versicolor'
'virginica'
```

```
ans =
```

TrueLabel	PredLabel	Posterior		
'virginica'	'virginica'	0.0039321	0.0039869	0.99208
'virginica'	'virginica'	0.017067	0.018263	0.96467
'virginica'	'virginica'	0.014948	0.015856	0.9692
'versicolor'	'versicolor'	2.2197e-14	0.87317	0.12683
'setosa'	'setosa'	0.999	0.00025091	0.00074639
'versicolor'	'virginica'	2.2195e-14	0.059429	0.94057
'versicolor'	'versicolor'	2.2194e-14	0.97001	0.029986
'setosa'	'setosa'	0.999	0.0002499	0.00074741
'versicolor'	'versicolor'	0.0085646	0.98259	0.008849
'setosa'	'setosa'	0.999	0.00025013	0.00074718

The columns of `Posterior` correspond to the class order of `Mdl.ClassNames`.

Define a grid of values in the observed predictor space. Predict the posterior probabilities for each instance in the grid.

```
xMax = max(X);
xMin = min(X);

x1Pts = linspace(xMin(1),xMax(1));
x2Pts = linspace(xMin(2),xMax(2));
[x1Grid,x2Grid] = meshgrid(x1Pts,x2Pts);

[~,~,~,PosteriorRegion] = predict(Mdl,[x1Grid(:),x2Grid(:)]);
```

For each coordinate on the grid, plot the maximum class posterior probability among all classes.

```
figure;
contourf(x1Grid,x2Grid,...
         reshape(max(PosteriorRegion,[],2),size(x1Grid,1),size(x1Grid,2)));
h = colorbar;
h.YLabel.String = 'Maximum posterior';
h.YLabel.FontSize = 15;
hold on
gh = gscatter(X(:,1),X(:,2),Y,'krk','*xd',8);
gh(2).LineWidth = 2;
gh(3).LineWidth = 2;

title 'Iris Petal Measurements and Maximum Posterior';
xlabel 'Petal length (cm)';
ylabel 'Petal width (cm)';
axis tight
legend(gh,'Location','NorthWest')
hold off
```

Train ECOC Classifiers Using Ensembles and Parallel Computing

Train a one-versus-all ECOC classifier using a GentleBoost ensemble of decision trees with surrogate splits. Estimate the classification error using 10-fold cross validation.

Load and inspect the arrhythmia data set.

```
load arrhythmia
[n,p] = size(X)
isLabels = unique(Y);
nLabels = numel(isLabels)
tabulate(categorical(Y))
```

n =

```

452

p =

    279

nLabels =

    13

    Value    Count    Percent
    1         245     54.20%
    2          44     9.73%
    3          15     3.32%
    4          15     3.32%
    5          13     2.88%
    6          25     5.53%
    7           3     0.66%
    8           2     0.44%
    9           9     1.99%
   10          50    11.06%
   14           4     0.88%
   15           5     1.11%
   16          22     4.87%

```

There are 279 predictors, and a relatively small sample size of 452. There are 16 distinct labels, but only 13 are represented in the response (Y), and each label describes various degrees of arrhythmia. 54.20% of the observations are in class 1.

Create an ensemble template. You must specify at least three arguments: a method, a number of learners, and the type of learner. For this example, specify 'GentleBoost' for the method, 100 for the number of learners, and a decision tree template that uses surrogate splits since there are missing observations.

```

tTree = templateTree('surrogate','on');
tEnsemble = templateEnsemble('GentleBoost',100,tTree);

```

tEnsemble is a template object. Most of its properties are empty, but the software fills them with their default values during training.

Train a one-versus-all ECOC classifier using the ensembles of decision trees as binary learners. If you have a Parallel Computing Toolbox license, then you can speed up the

computation by specifying to use parallel computing. This sends each binary learner to a worker in the pool (the number of workers depends on your system configuration). Also, specify that the prior probabilities are $1/K$, where $K = 13$, which is the number of distinct classes.

```
pool = parpool; % Invoke workers
options = statset('UseParallel',1);
Mdl = fitcecoc(X,Y,'Coding','onevsall','Learners',tEnsemble,...
    'Prior','uniform','Options',options);
```

Starting parallel pool (parpool) using the 'local' profile ... connected to 2 workers.

Mdl is a `ClassificationECOC` model.

Cross validate the ECOC classifier using 10-fold cross validation.

```
CVMD1 = crossval(Mdl,'Options',options);
```

Warning: One or more folds do not contain points from all the groups.

CVMD1 is a `ClassificationPartitionedECOC` model. The warning indicates that some classes are not represented while the software trains at least one fold. Therefore, those folds cannot predict labels for the missing classes. You can inspect the results of a fold using cell indexing and dot notation, e.g., access the results of the first fold by entering `CVMD1.Trained{1}`. Your results might vary.

Use the cross-validated ECOC classifier to predict out-of-fold labels. You can compute the confusion matrix using `confusionmat`. However, if you have a Neural Network Toolbox license, you can plot the confusion matrix using `plotconfusion`. The input arguments of `plotconfusion` are not vectors of the true and predicted labels like `confusionmat`, but indicator matrices of the true and predicted labels. Both start as K -by- n matrices of 0s. If observation j has label index k (or has predicted label k), then element (k,j) of the true label indicator matrix (or predicted label indicator matrix) is 1. You can convert label indices returned by `predict`, `resubPredict`, or `kfoldPredict` to label indicator matrices using linear indexing. For details on linear indexing, see `sub2ind` and `ind2sub`.

```
oofLabel = kfoldPredict(CVMD1,'Options',options);
ConfMat = confusionmat(Y,oofLabel);
```

```
% Convert the integer label vector to a class-identifier matrix.
[~,grp] = ismember(oofLabel,isLabels);
oofLabelMat = zeros(nLabels,n);
idxLinear = sub2ind([nLabels n],grp,(1:n)');
```

```
oofLabelMat(idLinear) = 1; % Flags the row corresponding to the class
YMat = zeros(nLabels,n);
idLinearY = sub2ind([nLabels n],grp,(1:n)');
YMat(idLinearY) = 1;

figure;
plotconfusion(YMat,oofLabelMat);
h = gca;
h.XTickLabel = [num2cell(isLabels); {' '}];
h.YTickLabel = [num2cell(isLabels); {' '}];
```

														Target Class

- “Quick Start Parallel Computing for Statistics Toolbox” on page 20-2

Input Arguments

X — Predictor data

numeric matrix

Predictor data, specified as a numeric matrix.

Each row of X corresponds to one observation (also known as an instance or example), and each column corresponds to one variable (also known as a feature).

The length of Y and the number of rows of X must be equal.

It is good practice to standardize the continuous predictor variables. For k NN and SVM binary classifiers, set 'Standardize', 1 in the template functions `templateKNN` or `templateSVM`, respectively.

Data Types: `double` | `single`

Y – Class labels

categorical array | character array | logical vector | vector of numeric values | cell array of strings

Class labels to which the ECOC model is trained, specified as a categorical or character array, logical or numeric vector, or cell array of strings.

If Y is a character array, then each element must correspond to one row of the array.

The length of Y and the number of rows of X must be equal.

It is good practice to specify the class order using the `ClassNames` name-value pair argument.

Note: The software treats NaN, empty string (' '), and <undefined> elements as missing data. The software removes rows of X corresponding to missing values in Y . However, the treatment of missing values in X varies among binary learners. For details, see the training functions for your binary learners: `fitcdiscr`, `fitcknn`, `fitcnb`, `fitcsvm`, `fitctree`, or `fitensemb`. Removing observations decreases the effective training or cross-validation sample size.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example: 'Learners', 'tree', 'Coding', 'onevsone', 'CrossVal', 'on' specifies to use decision trees for all binary learners, a one-versus-one coding design, and to implement 10-fold cross validation.

ECOC Classifier Options

'Coding' — Coding design

'onevsall' (default) | 'allpairs' | 'binarycomplete' | 'denserandom' | 'onevsone' | 'ordinal' | 'sparserandom' | 'ternarycomplete' | numeric matrix

Coding design name, specified as the comma-separated pair consisting of 'Coding' and a numeric matrix or string.

This table summarizes the available, built-in coding designs.

Value	Number of Binary Learners	Description
'allpairs' and 'onevsone'	$K(K-1)/2$	For each binary learner, one class is positive, another is negative, and the software ignores the rest. This design exhausts all combinations of class pair assignments.
'binarycomplete'	$2^{(K-1)} - 1$	This design partitions the classes into all binary combinations, and does not ignore any classes. That is, for each binary learner, all class assignments are -1 and 1 with at least one positive and negative class in the assignment.
'denserandom'	Random, but approximately $10 \log_2 K$	For each binary learner, the software randomly assigns classes into positive or negative classes, with at least one of each type. For more details, see "Random

Value	Number of Binary Learners	Description
		Coding Design Matrices” on page 21-1292.
'onevsall'	K	For each binary learner, one class is positive and the rest are negative. This design exhausts all combinations of positive class assignments.
'ordinal'	$K - 1$	For the first binary learner, the first class is negative, and the rest positive. For the second binary learner, the first two classes are negative, and the rest positive, and so on.
'sparsestrandom'	Random, but approximately $15 \log_2 K$	For each binary learner, the software randomly assigns classes as positive or negative with probability 0.25 for each, and ignores classes with probability 0.5. For more details, see “Random Coding Design Matrices” on page 21-1292.
'ternarycomplete'	$(3^K - 2^{(K+1)} + 1)/2$	This design partitions the classes into all ternary combinations. That is, all class assignments are 0, -1, and 1 with at least one positive and one negative class in the assignment.

You can also specify a coding design using a custom coding matrix. The custom coding matrix is a K -by- L matrix, where each row corresponds to a class and each column corresponds to a binary learner. The class order (rows) corresponds to the order in `ClassNames`. You must compose the matrix by following these guidelines:

- Every element of the custom coding matrix must be -1, 0, or 1, and the value corresponds to a dichotomous class assignment. This table describes the meaning of `Coding(i, j)`, that is, the class that learner `j` assigns to observations in class `i`.

Value	Dichotomous Class Assignment
-1	Negative class
0	Learner <code>j</code> removes observations in class <code>i</code> from the data set before training.
1	Positive class

- Every column must contain at least one -1 or 1.
- For all column indices `i, j` such that `i ≠ j`, `Coding(:, i)` cannot equal `Coding(:, j)` and `Coding(:, i)` cannot equal `-Coding(:, j)`.
- All rows of the custom coding matrix must be different.

For more details on the form of custom coding design matrices, see “Custom Coding Design Matrices” on page 21-1290.

Example: `'Coding', 'ternarycomplete'`

Data Types: `char | double | single | int16 | int32 | int64 | int8`

'FitPosterior' — Flag indicating whether to transform scores to posterior probabilities
false or 0 (default) | true or 1

Flag indicating whether to transform scores to posterior probabilities, specified as the comma-separated pair consisting of `'FitPosterior'` and a true (1) or false (0).

If `FitPosterior` is true, then the software transforms binary-learner classification scores to posterior probabilities. You can obtain posterior probabilities by using `kfoldPredict`, `predict`, or `resubPredict`.

Ensemble methods that do not fit posterior probabilities are `AdaBoostM2`, `LPBoost`, `RUSBoost`, `RobustBoost`, and `TotalBoost`. Therefore, if any binary learner is an ensemble that uses any of these methods, then the software throws an error.

Example: `'FitPosterior', 1`

Data Types: `logical`

'Learners' — Binary learner templates

'svm' (default) | 'discriminant' | 'knn' | 'tree' | template object | cell vector of template objects

Binary learner templates, specified as the comma-separated pair consisting of 'Learners' and a string, template object, or cell vector of template objects. Specifically, you can specify binary classifiers such as SVM and the ensembles that use GentleBoost, LogitBoost, and RobustBoost to solve multiclass problems. However, fitcecoc also supports multiclass models as binary classifiers.

- If **Learners** is a string, then the software trains each binary learner using the default values of the algorithm corresponding to the string. This table summarizes the available strings.

Value	Description
'discriminant'	Discriminant analysis. For default options, see <code>templateDiscriminant</code> .
'knn'	k -nearest neighbors. For default options, see <code>templateKNN</code> .
'naivebayes'	Naive Bayes. For default options, see <code>templateNaiveBayes</code> .
'svm'	SVM. For default options, see <code>templateSVM</code> .
'tree'	Classification trees. For default options, see <code>templateTree</code> .

- If **Learners** is a template object, then each binary learner trains according to the options stored therein. You can create a template object using:
 - `templateDiscriminant`, for discriminant analysis.
 - `templateEnsemble`, for ensemble learning. You must at least specify the learning method (`Method`), the number of learners (`NLearn`), and the type of learner (`Learners`). You cannot use the `AdaBoostM2` ensemble method for binary learning.
 - `templateKNN`, for k -nearest neighbors.
 - `templateNaiveBayes`, for naive Bayes.
 - `templateSVM`, for SVM.

- `templateTree`, for classification trees.
- If `Learners` is cell vector of template objects, then:
 - Cell j corresponds to binary learner j (in other words, column j of the coding design matrix), and the cell vector must have length L , where L is the number of columns in the coding design matrix. For details, see `Coding`.
 - To use one of the built-in loss functions for prediction, then all binary learners must return a score in the same range. For example, you cannot include default SVM binary learners with default naive Bayes binary learners because the former returns a score in the range $(-\infty, \infty)$, and the latter returns a posterior probability as a score. Otherwise, you must provide a custom loss as a function handle to functions such as `predict` and `loss`.

By default, the software trains using default SVM templates for all learners.

Cross-Validation Options

'CrossVal' — Flag to train cross-validated classifier

'off' (default) | 'on'

Flag to train a cross-validated classifier, specified as the comma-separated pair consisting of 'Crossval' and 'on' or 'off'.

If you specify 'on', then the software trains a cross-validated classifier with 10 folds.

You can override this cross-validation setting using one of the 'KFold', 'Holdout', 'Leaveout', or 'CVPartition' name-value pair arguments.

You can only use one of these four options at a time to create a cross-validated model: 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'.

Alternatively, cross-validate `Mdl` later by passing it to `crossval`.

Example: 'Crossval', 'on'

Data Types: char

'CVPartition' — Cross-validation partition

[] (default) | `cvpartition` partition object

Cross-validation partition, specified as the comma-separated pair consisting of 'CVPartition' and a `cvpartition` partition object as created by `cvpartition`. The partition object specifies the type of cross-validation, and also the indexing for training and validation sets.

If you specify `CVPartition`, then you cannot specify any of `Holdout`, `KFold`, or `Leaveout`.

'Holdout' — Fraction of data for holdout validation

scalar value in the range (0,1)

Fraction of data used for holdout validation, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range (0,1). If you specify 'Holdout', p , then the software:

- 1 Randomly reserves $p*100\%$ of the data as validation data, and trains the model using the rest of the data
- 2 Stores the compact, trained model in `CVMdl.Trained`

If you specify `Holdout`, then you cannot specify any of `CVPartition`, `KFold`, or `Leaveout`.

Example: 'Holdout', 0.1

Data Types: `double` | `single`

'KFold' — Number of folds

10 (default) | positive integer value

Number of folds to use in a cross-validated classifier, specified as the comma-separated pair consisting of 'KFold' and a positive integer value.

You can only use one of these four options at a time to create a cross-validated model: 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'.

Example: 'KFold', 8

Data Types: `single` | `double`

'Leaveout' — Leave-one-out cross-validation flag

'off' (default) | 'on'

Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of 'Leaveout' and either 'on' or 'off'. If you specify 'on', then the software implements leave-one-out cross validation.

If you use `'Leaveout'`, you cannot use these `'CVPartition'`, `'Holdout'`, or `'KFold'` name-value pair arguments.

Example: `'Leaveout','on'`

Data Types: `char`

Other Classification Options

'CategoricalPredictors' — Categorical predictors list

character array | logical vector | numeric vector | cell array of strings | `'all'`

Categorical predictors list, specified as the comma-separated pair consisting of `'CategoricalPredictors'` and one of the following:

- A numeric vector with indices from 1 through p , where p is the number of columns of X .
- A logical vector of length p , where a `true` entry means that the corresponding column of X is a categorical variable.
- A cell array of strings, where each element in the array is the name of a predictor variable. The names must match the entries in `PredictorNames`.
- A character matrix, where each row of the matrix is a name of a predictor variable. The names must match the entries in `PredictorNames`. Pad the names with extra blanks so each row of the character matrix has the same length.
- `'all'`, meaning all predictors are categorical.

Specification of `CategoricalPredictors` is appropriate if:

- At least one predictor is categorical and all binary learners are classification trees, naive Bayes learners, or ensembles of classification trees.
- All predictors are categorical and at least one binary learner is k NN.

If you specify `CategoricalPredictors` for any other case, then the software warns that it cannot train that binary learner. For example, the software cannot train SVM learners using categorical predictors.

The default is `[]`, which indicates that there are no categorical predictors.

Example: `'CategoricalPredictors','all'`

Data Types: `single` | `double` | `char`

'ClassNames' — Class names

categorical array | character array | logical vector | vector of numeric values | cell array of strings

Class names, specified as the comma-separated pair consisting of **'ClassNames'** and a categorical or character array, logical or numeric vector, or cell array of strings. You must set **ClassNames** using the data type of **Y**.

The default is the distinct class names in **Y**.

If **Y** is a character array, then each element must correspond to one *row* of the array.

Use **ClassNames** to order the classes or to select a subset of classes for training.

Example: `'ClassNames',{'setosa','virginica','versicolor'}`

'Cost' — Misclassification cost

square matrix | structure array

Misclassification cost, specified as the comma-separated pair consisting of **'Cost'** and a square matrix or structure. If you specify:

- The square matrix **Cost**, then $\text{Cost}(i, j)$ is the cost of classifying a point into class j if its true class is i
- The structure **S**, then it must have two fields:
 - **S.ClassNames**, which contains the class names as a variable of the same data type as **Y**
 - **S.ClassificationCosts**, which contains the cost matrix with rows and columns ordered as in **S.ClassNames**

The default is $\text{Cost}(i, j) = 1$ if $i \neq j$, and $\text{Cost}(i, j) = 0$ if $i = j$.

Example: `'Cost',[0 1 2 ; 1 0 2; 2 2 0]`

Data Types: double | single | struct

'Options' — Parallel computing options

`[]` (default) | structure array returned by `statset`

Parallel computing options, specified as the comma-separated pair consisting of **'Options'** and a structure array returned by `statset`. These options require Parallel Computing Toolbox. `fitcecoc` uses **'Streams'**, **'UseParallel'**, and **'UseSubstreams'** fields.

This table summarizes the available options.

Option	Description
'Streams'	<p>A <code>RandStream</code> object or cell array of such objects. If you do not specify <code>Streams</code>, the software uses the default stream or streams. If you specify <code>Streams</code>, use a single object except when the following are true:</p> <ul style="list-style-type: none"> • You have an open parallel pool. • <code>UseParallel</code> is <code>true</code>. • <code>UseSubstreams</code> is <code>false</code>. <p>In that case, use a cell array the same size as the parallel pool. If a parallel pool is not open, then the software tries to open one (depending on your preferences), and <code>Streams</code> must supply a single random number stream.</p>
'UseParallel'	<p>If you have Parallel Computing Toolbox, then you can invoke a pool of workers by setting <code>'UseParallel', 1</code>.</p>
'UseSubstreams'	<p>Set to <code>true</code> to compute in parallel using the stream specified by <code>'Streams'</code>. Default is <code>false</code>. For example, set <code>Streams</code> to a type allowing substreams, such as <code>'mlfg6331_64'</code> or <code>'mrg32k3a'</code>.</p>

A best practice to ensure more predictable results is to use `parpool` and explicitly create a parallel pool before you invoke parallel computing using `fitcecoc`.

Example: `'Options', statset('UseParallel', 1)`

'PredictorNames' — Predictor variable names

`{'x1', 'x2', ...}` (default) | cell array of strings

Predictor variable names, specified as the comma-separated pair consisting of `'PredictorNames'` and a cell array of strings containing the names for the predictor variables, in the order in which they appear in `X`.

Example: `'PredictorNames', {'PedalWidth', 'PedalLength'}`

Data Types: `cell`

'Prior' — Prior probabilities

'empirical' (default) | 'uniform' | numeric vector | structure

Prior probabilities for each class, specified as the comma-separated pair consisting of 'Prior' and a string, numeric vector, or a structure.

This table summarizes the available options for setting prior probabilities.

Value	Description
'empirical'	The class prior probabilities are the class relative frequencies in Y .
'uniform'	All class prior probabilities are equal to $1/K$, where K is the number of classes.
numeric vector	Each element is a class prior probability. Order the elements according to <code>Mdl.ClassNames</code> or specify the order using the <code>ClassNames</code> name-value pair argument. The software normalizes the elements such that they sum to 1.
structure	A structure S with two fields: <ul style="list-style-type: none"> <code>S.ClassNames</code> contains the class names as a variable of the same type as Y. <code>S.ClassProbs</code> contains a vector of corresponding prior probabilities. The software normalizes the elements such that they sum to 1.

For more details on how the software incorporates class prior probabilities, see “Prior Probabilities and Cost” on page 21-1291.

Example: `struct('ClassNames', {'setosa', 'versicolor'}, 'ClassProbs', [1,2])`

'ResponseName' — Response variable name

'Y' (default) | string

Response variable name, specified as the comma-separated pair consisting of 'ResponseName' and a string containing the name of the response variable Y.

Example: 'ResponseName', 'IrisType'

Data Types: char

'Verbose' — Verbosity level

0 (default) | 1 | 2

Verbosity level, specified as the comma-separated pair consisting of 'Verbose' and 0, 1, or 2. **Verbose** controls the amount of diagnostic information per binary learner that the software displays in the Command Window.

This table summarizes the available verbosity level options.

Value	Description
0	The software does not display diagnostic information.
1	The software displays diagnostic messages every time it trains a new binary learner.
2	The software displays extra diagnostic messages every time it trains a new binary learner.

Example: 'Verbose', 1

Data Types: double | single

'Weights' — Observation weights

ones(size(X,1),1) (default) | numeric vector

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a numeric vector.

The size of **Weights** must equal the number of rows of X. The software weighs the observations in each row of X with the corresponding weight in **Weights**.

The software normalizes **Weights** to sum up to the value of the prior probability in the respective class.

Data Types: double | single

Output Arguments

Mdl — Trained ECOC model

ClassificationECOC model | ClassificationPartitionedECOC cross-validated model

Trained ECOC classifier, returned as a **ClassificationECOC** model or **ClassificationPartitionedECOC** cross-validated model.

If you set any of the name-value pair arguments **KFold**, **Holdout**, **Leaveout**, **CrossVal**, or **CVPartition**, then **Mdl** is a **ClassificationPartitionedECOC** cross-validated model. Otherwise, **Mdl** is a **ClassificationECOC** model.

To reference properties of **Mdl**, use dot notation. For example, enter **Mdl.BinaryLearners** in the Command Window to display a cell vector of trained binary learner models.

More About

Binary Loss

A *binary loss* is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Let:

- m_{kj} be element (k,j) of the coding design matrix M (i.e., the code corresponding to class k of binary learner j)
- s_j be the score of binary learner j for an observation
- g be the binary loss function
- \hat{k} be the predicted class for the observation

In *loss-based decoding* [3], the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \underset{k}{\operatorname{argmin}} \sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j).$$

In *loss-weighted decoding* [3], the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \underset{k}{\operatorname{argmin}} \frac{\sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j)}{\sum_{j=1}^L |m_{kj}|}.$$

Allwein et al. [1] suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where y_j is a class label for a particular binary learner (in the set $\{-1, 1, 0\}$), s_j is the score for observation j , and $g(y_j, s_j)$.

Value	Description	Score Domain	$g(y_j, s_j)$
'binodeviance'	Binomial deviance	$(-\infty, \infty)$	$\log[1 + \exp(-2y_j s_j)] / [2\log(2)]$
'exponential'	Exponential	$(-\infty, \infty)$	$\exp(-y_j s_j) / 2$
'hamming'	Hamming	$\{-1, 1\}$	$[1 - \operatorname{sign}(y_j s_j)] / 2$
'hinge'	Hinge	$(-\infty, \infty)$	$\max(0, 1 - y_j s_j) / 2$
'linear'	Linear	$(-\infty, \infty)$	$(1 - y_j s_j) / 2$
'quadratic'	Quadratic	$[0, 1]$	$[1 - y_j(2s_j - 1)]^2 / 2$

The software normalizes the binary losses such that the loss is 0.5 when $y_j = 0$, and aggregates using the average of the binary learners [1].

Do not confuse the binary loss with the overall classification loss (specified by the LossFun name-value pair argument of `predict` and `loss`), e.g., classification error, which measures how well an ECOC classifier performs as a whole.

Coding Design

A *coding design* is a matrix where elements direct which classes are trained by each binary learner, that is, how the multiclass problem is reduced to a series of binary problems.

Each row of the coding design corresponds to a distinct class, and each column corresponds to a binary learner. In a ternary coding design (adopted by the software), for a particular column (or binary learner):

- Rows containing a 1 indicate to the binary learner to group all observations in the corresponding classes into a positive class.
- Rows containing a -1 indicate to the binary learner to group all observations in the corresponding classes into a negative class.
- Rows containing a 0 indicate to the binary learner to ignore all observations in the corresponding classes.

Coding matrices with large, minimal, pair-wise row distances based on the Hamming measure are desirable. For details on the pair-wise row distance measure, see “Random Coding Design Matrices” on page 21-1292 and [4].

This table describes popular coding designs. For the example, suppose K (the number of distinct classes) is 3.

Coding Design	Description	Number of Learners	Minimal Pair-Wise Row Distance
one-versus-all (OVA)	For each binary learner, one class is positive and the rest are negative. This design exhausts all combinations of positive class assignments.	K	2
one-versus-one (OVO)	For each binary learner, one class is positive, another is negative, and the rest are ignored. This design exhausts all combinations of class pair assignments.	$K(K - 1)/2$	1
binary complete	This design partitions the classes	$2^{K-1} - 1$	2^{K-2}

Coding Design	Description	Number of Learners	Minimal Pair-Wise Row Distance
	into all binary combinations, and does not ignore any classes. That is, all class assignments are - 1 and 1 with at least one positive and negative class in the assignment for each binary learner.		
ternary complete	This design partitions the classes into all ternary combinations. That is, all class assignments are 0, - 1, and 1 with at least one positive and negative class in the assignment for each binary learner.	$(3^K - 2^{K+1} + 1)/2$	3^{K-2}
ordinal	For the first binary learner, the first class is negative, and the rest positive. For the second binary learner, the first two classes are negative, and the rest positive, and so on.	$K - 1$	1

Coding Design	Description	Number of Learners	Minimal Pair-Wise Row Distance
dense random	For each binary learner, the software randomly assigns classes into positive or negative classes, with at least one of each type. For more details, see “Random Coding Design Matrices” on page 21-1292.	Random, but approximately $10 \log_2 K$	Variable
sparse random	For each binary learner, the software randomly assigns classes as positive or negative with probability 0.25 for each, and ignores classes with probability 0.5. For more details, see “Random Coding Design Matrices” on page 21-1292.	Random, but approximately $15 \log_2 K$	Variable

This plot compares the number of binary learners for the coding designs with increasing K .

Error-Correcting Output Code Multiclass Model

An *error-correcting output code multiclass model* (ECOC) reduces the problem of classification with three or more classes to a set of binary classifiers.

ECOC classification requires a coding design, which determines the classes that the binary learners train on, and a decoding scheme, which determines how the results (predictions) of the binary classifiers are aggregated. Suppose that there are three classes, the coding design is one-versus-one, the decoding scheme uses loss g , and the learners are SVMs. To build this classification model, ECOC follows these steps.

1

A one-versus-one coding design is

	Learner 1	Learner 2	Learner 3
Class 1	1	1	0
Class 2	-1	0	1
Class 3	0	-1	-1

Learner 1 trains on observations having Class 1 and Class 2, and treats Class 1 as the positive class and Class 2 as the negative class. The other learners are trained similarly. Let M be the coding design matrix with elements m_{kl} , and s_l be the predicted classification score for the positive class of learner l .

- 2 A new observation is assigned to the class (\hat{k}) that minimizes the aggregation of the losses for the L binary learners. That is,

$$\hat{k} = \underset{k}{\operatorname{argmin}} \frac{\sum_{l=1}^L |m_{kl}| g(m_{kl}, s_l)}{\sum_{l=1}^L |m_{kl}|}.$$

ECOC models can improve classification accuracy, even compared to other multiclass models [2].

Tips

- The number of binary learners grows with the number of classes. For a problem with many classes, the `binarycomplete` and `ternarycomplete` coding designs are not efficient. However:
 - If $K \leq 4$, then use `ternarycomplete` coding design rather than `sparserandom`.
 - If $K \leq 5$, then use `binarycomplete` coding design rather than `denserandom`.

You can display the coding design matrix of a trained ECOC classifier by entering `Mdl.CodingMatrix` into the Command Window.

- You should form a coding matrix using intimate knowledge of the application, and taking into account computational constraints. If you have sufficient computational power and time, then try several coding matrices and choose the one with the best performance (e.g., check the confusion matrices for each model using `confusionmat`).

Algorithms

Custom Coding Design Matrices

Custom coding matrices must have a certain form. The software validates custom coding matrices by ensuring:

- Every element is -1, 0, or 1.
- Every column contains at least one -1 and one 1.
- For all distinct column vectors u and v , $u \neq v$ and $u \neq -v$.
- All rows vectors are unique.
- The matrix can separate any two classes. That is, you can travel from any row to any other row following these rules:
 - You can move vertically from 1 to -1 or -1 to 1.
 - You can move horizontally from a nonzero element to another nonzero element.
 - You can use a column of the matrix for a vertical move only once.

If it is not possible to move from row i to row j using these rules, then classes i and j cannot be separated by the design. For example, in the coding design

$$\begin{bmatrix} 1 & 0 \\ -1 & 0 \\ 0 & 1 \\ 0 & -1 \end{bmatrix}$$

classes 1 and 2 cannot be separated from classes 3 and 4 (that is, you cannot move horizontally from the -1 in row 2 to column 2 since there is a 0 in that position). Therefore, the software rejects this coding design.

Parallel Computing

If you use parallel computing (see Options), then `fitcecoc` trains binary learners in parallel.

Prior Probabilities and Cost

- **Prior probabilities** — The software normalizes the specified class prior probabilities (Prior) for each binary learner. Let M be the coding design matrix and $I(A,c)$ be an indicator matrix. The indicator matrix has the same dimensions as A , and has elements equaling one if the corresponding element of A is c , and zero otherwise. Let M_{+1} and M_{-1} be K -by- L matrices such that:
 - $M_{+1} = M \circ I(M,1)$, where \circ is element-wise multiplication (that is, `Mplus = M.*(M == 1)`). Also, let $m_l^{(+1)}$ be column vector l of M_{+1} .
 - $M_{-1} = -M \circ I(M,-1)$ (that is, `Mminus = -M.*(M == -1)`). Also, let $m_l^{(-1)}$ be column vector l of M_{-1} .

Let $\pi_l^{+1} = m_l^{(+1)} \circ \pi$ and $\pi_l^{-1} = m_l^{(-1)} \circ \pi$, where π is the vector of specified, class prior probabilities (Prior).

Then, the positive and negative, scalar class prior probabilities for binary learner l are

$$\hat{\pi}_l^{(j)} = \frac{\|\pi_l^{(j)}\|_1}{\|\pi_l^{(+1)}\|_1 + \|\pi_l^{(-1)}\|_1},$$

where $j = \{-1,1\}$ and $\|a\|_1$ is the one-norm of a .

- **Cost** — The software normalizes the K -by- K cost matrix C (Cost) for each binary learner. For binary learner l , the cost of classifying a negative-class observation into the positive class is

$$c_l^{-+} = \left(\pi_l^{(-1)} \right) C \pi_l^{(+1)}.$$

Similarly, the cost of classifying a positive-class observation into the negative class is

$$c_l^{+-} = \left(\pi_l^{(+1)} \right) C \pi_l^{(-1)}.$$

The cost matrix for binary learner l is

$$C_l = \begin{bmatrix} 0 & c_l^{-+} \\ c_l^{+-} & 0 \end{bmatrix}.$$

ECOC models accommodate misclassification costs by incorporating them with class prior probabilities. If you specify `Prior` and `Cost`, then the software adjusts the class prior probabilities as follows:

$$\bar{\pi}_l^{-1} = \frac{c_l^{-+} \hat{\pi}_l^{-1}}{c_l^{-+} \hat{\pi}_l^{-1} + c_l^{+-} \hat{\pi}_l^{+1}}$$

$$\bar{\pi}_l^{+1} = \frac{c_l^{+-} \hat{\pi}_l^{+1}}{c_l^{-+} \hat{\pi}_l^{-1} + c_l^{+-} \hat{\pi}_l^{+1}}.$$

Random Coding Design Matrices

For a given number of classes, e.g., K , the software generates random coding design matrices as follows.

- 1 The software generates one of the following:
 - a Dense random — The software sets each element of the K -by- L_d coding design matrix with a 1 or a -1 with equal probability, where $L_d \approx \lceil 10 \log_2 K \rceil$.
 - b Sparse random — The software sets each element of the K -by- L_s coding design matrix with a 1, with probability 0.25, a -1 with probability 0.25, and a 0 with probability 0.5, where $L_s \approx \lceil 15 \log_2 K \rceil$.
- 2 If a column does not contain at least one 1 and at least one -1, then the software removes that column.
- 3 For distinct columns u and v , if $u = v$ or $u \neq -v$, then the software removes v from the coding design matrix.

The software randomly generates 10,000 matrices by default, and retains the matrix with the largest, minimal pair-wise row distance based on the Hamming measure ([4]) given by

$$\Delta(k_1, k_2) = 0.5 \sum_{l=1}^L |m_{k_1, l} - m_{k_2, l}|,$$

where $m_{k,l}$ is an element of coding design matrix j .

fitcknn

Fit k -nearest neighbor classifier

Syntax

```
mdl = fitcknn(X,y)
mdl = fitcknn(X,y,Name,Value)
```

Description

`mdl = fitcknn(X,y)` returns a classification model based on the input variables (also known as predictors, features, or attributes) X and output (response) y .

`mdl = fitcknn(X,y,Name,Value)` fits a model with additional options specified by one or more name-value pair arguments. For example, you can specify the tie-breaking algorithm, distance metric, or observation weights.

Examples

Train a k -Nearest Neighbor Classifier

Construct a k -nearest neighbor classifier for Fisher's iris data, where k , the number of nearest neighbors in the predictors, is 5.

Load Fisher's iris data.

```
load fisheriris
X = meas;
Y = species;
```

X is a numeric matrix that contains four petal measurements for 150 irises. Y is a cell array of strings that contains the corresponding iris species.

Train a 5-nearest neighbors classifier. It is good practice to standardize noncategorical predictor data.

```
Mdl = fitcknn(X,Y,'NumNeighbors',5,'Standardize',1)
```

```
Mdl =  
  
ClassificationKNN  
  PredictorNames: {'x1' 'x2' 'x3' 'x4'}  
  ResponseName: 'Y'  
  ClassNames: {'setosa' 'versicolor' 'virginica'}  
  ScoreTransform: 'none'  
  NumObservations: 150  
  Distance: 'euclidean'  
  NumNeighbors: 5
```

Mdl is a trained **ClassificationKNN** classifier, and some of its properties display in the Command Window.

To access the properties of Mdl, use dot notation.

```
Mdl.ClassNames  
Mdl.Prior
```

```
ans =  
  
    'setosa'  
    'versicolor'  
    'virginica'  
  
ans =  
  
    0.3333    0.3333    0.3333
```

Mdl.Prior contains the class prior probabilities, which are settable using the name-value pair argument '**Prior**' in **fitcknn**. The order of the class prior probabilities corresponds to the order of the classes in **Mdl.ClassNames**. By default, the prior probabilities are the respective relative frequencies of the classes in the data.

You can also reset the prior probabilities after training. For example, set the prior probabilities to 0.5, 0.2, and 0.3 respectively.

```
Mdl.Prior = [0.5 0.2 0.3];
```

You can pass `Mdl` to, for example, “`predict (ClassificationKNN)`” to label new measurements, or “`crossval (ClassificationKNN)`” to cross validate the classifier.

Train a *k*-Nearest Neighbor Classifier Using the Minkowski Metric

Load Fisher's iris data set.

```
load fisheriris
X = meas;
Y = species;
```

`X` is a numeric matrix that contains four petal measurements for 150 irises. `Y` is a cell array of strings that contains the corresponding iris species.

Train a 3-nearest neighbors classifier using the Minkowski metric. To use the Minkowski metric, you must use an exhaustive searcher. It is good practice to standardize noncategorical predictor data.

```
Mdl = fitcknn(X,Y,'NumNeighbors',3,...
    'NSMethod','exhaustive','Distance','minkowski',...
    'Standardize',1);
```

`Mdl` is a `ClassificationKNN` classifier.

You can examine the properties of `Mdl` by double-clicking `Mdl` in the Workspace window. This opens the Variable Editor.

The screenshot shows the MATLAB Workspace window with a table of variables. The table has four columns: Name, Value, Min, and Max. The variable `Mdl` is highlighted with a mouse cursor. The other variables are `meas`, `species`, `X`, and `Y`.

Name	Value	Min	Max
<code>Mdl</code>	<code>1x1 ClassificationKNN</code>		
<code>meas</code>	<code>150x4 double</code>	0.1000	7.9
<code>species</code>	<code>150x1 cell</code>		
<code>X</code>	<code>150x4 double</code>	0.1000	7.9
<code>Y</code>	<code>150x1 cell</code>		

Property ▲	Value	Min	Max
NumNeighbors	3	3	3
Distance	'minkowski'		
DistParameter	2	2	2
IncludeTies	0		
DistanceWeight	'equal'		
BreakTies	'smallest'		
NSMethod	'exhaustive'		

Train a k -Nearest Neighbor Classifier Using a Custom Distance Metric

Train a k -nearest neighbor classifier using the chi-square distance.

Load Fisher's iris data set.

```
load fisheriris
X = meas;    % Predictors
Y = species; % Response
```

The chi-square distance between j -dimensional points x and z is

$$\chi(x, z) = \sqrt{\sum_{j=1}^J w_j (x_j - z_j)^2},$$

where w_j is a weight associated with dimension j .

Specify the chi-square distance function. The distance function must:

- Take one row of X , e.g., x , and the matrix Z .
- Compare x to each row of Z .
- Return a vector D of length n_z , where n_z is the number of rows of Z . Each element of D is the distance between the observation corresponding to x and the observations corresponding to each row of Z .

```
chiSqrDist = @(x,Z,wt) sqrt((bsxfun(@minus,x,Z).^2)*wt);
```

This example uses arbitrary weights for illustration.

Train a 3-nearest neighbor classifier. It is good practice to standardize noncategorical predictor data.

```
k = 3;
w = [0.3; 0.3; 0.2; 0.2];
KNNMdl = fitcknn(X,Y,'Distance',@(x,Z)chiSqrDist(x,Z,w),...
    'NumNeighbors',k,'Standardize',1);
```

KNNMdl is a “ClassificationKNN class” classifier.

Cross validate the KNN classifier using the default 10-fold cross validation. Examine the classification error.

```
rng(1); % For reproducibility
CVKNNMdl = crossval(KNNMdl);
classError = kfoldLoss(CVKNNMdl)
```

```
classError =
    0.0600
```

CVKNNMdl is a “ClassificationPartitionedModel class” classifier. The 10-fold classification error is 4%.

Compare the classifier with one that uses a different weighting scheme.

```
w2 = [0.2; 0.2; 0.3; 0.3];  
CVKNNMdl2 = fitcknn(X,Y, 'Distance',@(x,Z)chiSqrDist(x,Z,w2),...  
    'NumNeighbors',k, 'KFold',10, 'Standardize',1);  
classError2 = kfoldLoss(CVKNNMdl2)
```

```
classError2 =  
  
    0.0400
```

The second weighting scheme yields a classifier that has better out-of-sample performance.

- “Construct a KNN Classifier” on page 16-28
- “Modify a KNN Classifier” on page 16-30

Input Arguments

X — Predictor values

numeric matrix

Predictor values, specified as a numeric matrix. Each column of X represents one variable, and each row represents one observation.

Data Types: single | double

y — Classification values

numeric vector | categorical vector | logical vector | character array | cell array of strings

Classification values, specified as a numeric vector, categorical vector, logical vector, character array, or cell array of strings, with the same number of rows as X. Each row of y represents the classification of the corresponding row of X.

Data Types: `single` | `double` | `cell` | `logical` | `char`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example:

```
'NumNeighbors',3,'NSMethod','exhaustive','Distance','minkowski'
```

specifies a classifier for three-nearest neighbors using the nearest neighbor search method and the Minkowski metric.

'BreakTies' — Tie-breaking algorithm

`'smallest'` (default) | `'nearest'` | `'random'`

Tie-breaking algorithm used by the `predict` method if multiple classes have the same smallest cost, specified as the comma-separated pair consisting of `'BreakTies'` and one of the following:

- `'smallest'` — Use the smallest index among tied groups.
- `'nearest'` — Use the class with the nearest neighbor among tied groups.
- `'random'` — Use a random tiebreaker among tied groups.

By default, ties occur when multiple classes have the same number of nearest points among the `K` nearest neighbors.

Example: `'BreakTies','nearest'`

'BucketSize' — Maximum data points in node

50 (default) | positive integer value

Maximum number of data points in the leaf node of the *kd*-tree, specified as the comma-separated pair consisting of `'BucketSize'` and a positive integer value. This argument is meaningful only when `NSMethod` is `'kdtree'`.

Example: `'BucketSize',40`

Data Types: `single` | `double`

'CategoricalPredictors' — Categorical predictor flag

`[]` (default) | `'all'`

Categorical predictor flag, specified as the comma-separated pair consisting of 'CategoricalPredictors' and one of the following:

- 'all' — All predictors are categorical.
- [] — No predictors are categorical.

When you set `CategoricalPredictors` to 'all', the default `Distance` is 'hamming'.

Example: 'CategoricalPredictors', 'all'

'ClassNames' — Class names

numeric vector | categorical vector | logical vector | character array | cell array of strings

Class names, specified as the comma-separated pair consisting of 'ClassNames' and an array representing the class names. Use the same data type as the values that exist in `y`.

Use `ClassNames` to order the classes or to select a subset of classes for training. The default is the class names in `y`.

Data Types: single | double | char | logical | cell

'Cost' — Cost of misclassification

square matrix | structure

Cost of misclassification of a point, specified as the comma-separated pair consisting of 'Cost' and one of the following:

- Square matrix, where $\text{Cost}(i, j)$ is the cost of classifying a point into class `j` if its true class is `i`.
- Structure `S` having two fields: `S.ClassNames` containing the group names as a variable of the same type as `y`, and `S.ClassificationCosts` containing the cost matrix.

The default is $\text{Cost}(i, j) = 1$ if $i \neq j$, and $\text{Cost}(i, j) = 0$ if $i = j$.

Data Types: single | double | struct

'Cov' — Covariance matrix

nancov(X) (default) | positive definite matrix of scalar values

Covariance matrix, specified as the comma-separated pair consisting of 'Cov' and a positive definite matrix of scalar values representing the covariance matrix when

computing the Mahalanobis distance. This argument is only valid when 'Distance' is 'mahalanobis'.

You cannot simultaneously specify 'Standardize' and either of 'Scale' or 'Cov'.

Data Types: `single` | `double`

'CrossVal' — Cross-validation flag

'off' (default) | 'on'

Cross-validation flag, specified as the comma-separated pair consisting of 'CrossVal' and either 'on' or 'off'. If 'on', `fitcknn` creates a cross-validated model with 10 folds. Use the 'KFold', 'Holdout', 'Leaveout', or 'CVPartition' parameters to override this cross-validation setting. You can only use one parameter at a time to create a cross-validated model.

Alternatively, cross validate mdl later using the `crossval` method.

Example: 'Crossval', 'on'

'CVPartition' — Cross-validated model partition

`cvpartition` object

Cross-validated model partition, specified as the comma-separated pair consisting of 'CVPartition' and an object created using `cvpartition`. You can only use one of these four options at a time to create a cross-validated model: 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'.

'Distance' — Distance metric

valid distance metric string | function handle

Distance metric, specified as the comma-separated pair consisting of 'Distance' and a valid distance metric string or function handle. The allowable strings depend on the `NSMethod` parameter, which you set in `fitcknn`, and which exists as a field in `ModelParameters`. If you specify `CategoricalPredictors` as 'all', then the default distance metric is 'hamming'. Otherwise, the default distance metric is 'euclidean'.

<code>NSMethod</code>	Distance Metric Names
<code>exhaustive</code>	Any distance metric of <code>ExhaustiveSearcher</code>
<code>kdtree</code>	'cityblock', 'chebychev', 'euclidean', or 'minkowski'

For definitions, see “Distance Metrics”.

This table includes valid distance metrics of `ExhaustiveSearcher`.

Value	Description
'cityblock'	City block distance.
'chebychev'	Chebychev distance (maximum coordinate difference).
'correlation'	One minus the sample linear correlation between observations (treated as sequences of values).
'cosine'	One minus the cosine of the included angle between observations (treated as vectors).
'euclidean'	Euclidean distance.
'hamming'	Hamming distance, percentage of coordinates that differ.
'jaccard'	One minus the Jaccard coefficient, the percentage of nonzero coordinates that differ.
'mahalanobis'	Mahalanobis distance, computed using a positive definite covariance matrix C . The default value of C is the sample covariance matrix of X , as computed by <code>nancov(X)</code> . To specify a different value for C , use the ' <code>Cov</code> ' name-value pair argument.
'minkowski'	Minkowski distance. The default exponent is 2. To specify a different exponent, use the ' <code>Exponent</code> ' name-value pair argument.
'seuclidean'	Standardized Euclidean distance. Each coordinate difference between X and a query point is scaled, meaning divided by a scale value S . The default value of S is the standard deviation computed from X , <code>S = nanstd(X)</code> . To specify another value for S , use the ' <code>Scale</code> ' name-value pair argument.
'spearman'	One minus the sample Spearman's rank correlation between observations (treated as sequences of values).
@ <i>distfun</i>	Distance function handle. <i>distfun</i> has the form <pre>function D2 = DISTFUN(ZI,ZJ) % calculation of distance ...</pre>

Value	Description
	<p>where</p> <ul style="list-style-type: none"> • ZI is a 1-by-N vector containing one row of X or y. • ZJ is an M2-by-N matrix containing multiple rows of X or y. • D2 is an M2-by-1 vector of distances, and D2(k) is the distance between observations ZI and ZJ(J, :).

Example: 'Distance', 'minkowski'

Data Types: function_handle

'DistanceWeight' — Distance weighting function

'equal' (default) | 'inverse' | 'squaredinverse' | function handle

Distance weighting function, specified as the comma-separated pair consisting of 'DistanceWeight' and either a function handle or one of the following strings specifying the distance weighting function.

DistanceWeight	Meaning
'equal'	No weighting
'inverse'	Weight is 1/distance
'squaredinverse'	Weight is 1/distance ²
@fcn	fcn is a function that accepts a matrix of nonnegative distances, and returns a matrix the same size containing nonnegative distance weights. For example, 'squaredinverse' is equivalent to @(d)d.^(-2).

Example: 'DistanceWeight', 'inverse'

Data Types: function_handle

'Exponent' — Minkowski distance exponent

2 (default) | positive scalar value

Minkowski distance exponent, specified as the comma-separated pair consisting of 'Exponent' and a positive scalar value. This argument is only valid when 'Distance' is 'minkowski'.

Example: 'Exponent',3

Data Types: single | double

'Holdout' — Fraction of data for holdout validation

0 (default) | scalar value in the range [0,1]

Fraction of data used for holdout validation, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range [0,1]. Holdout validation tests the specified fraction of the data, and uses the remaining data for training.

If you use Holdout, you cannot use any of the 'CVPartition', 'Kfold', or 'Leaveout' name-value pair arguments.

Example: 'Holdout',0.1

Data Types: single | double

'IncludeTies' — Tie inclusion flag

false (default) | true

Tie inclusion flag, specified as the comma-separated pair consisting of 'IncludeTies' and a logical value indicating whether predict includes all the neighbors whose distance values are equal to the Kth smallest distance. If IncludeTies is true, predict includes all these neighbors. Otherwise, predict uses exactly K neighbors.

Example: 'IncludeTies',true

Data Types: logical

'Kfold' — Number of folds

10 (default) | positive integer value

Number of folds to use in a cross-validated model, specified as the comma-separated pair consisting of 'Kfold' and a positive integer value.

If you use 'Kfold', you cannot use any of the 'CVPartition', 'Holdout', or 'Leaveout' name-value pair arguments.

Example: 'Kfold',8

Data Types: single | double

'Leaveout' — Leave-one-out cross-validation flag

'off' (default) | 'on'

Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of 'Leaveout' and either 'on' or 'off'. Specify 'on' to use leave-one-out cross validation.

If you use 'Leaveout', you cannot use any of the 'CVPartition', 'Holdout', or 'Kfold' name-value pair arguments.

Example: 'Leaveout', 'on'

'NSMethod' — Nearest neighbor search method

'kdtree' | 'exhaustive'

Nearest neighbor search method, specified as the comma-separated pair consisting of 'NSMethod' and 'kdtree' or 'exhaustive'.

- 'kdtree' — Create and use a *kd*-tree to find nearest neighbors. 'kdtree' is valid when the distance metric is one of the following:
 - 'euclidean'
 - 'cityblock'
 - 'minkowski'
 - 'chebyshev'
- 'exhaustive' — Use the exhaustive search algorithm. The distance values from all points in X to each point in y are computed to find nearest neighbors.

The default is 'kdtree' when X has 10 or fewer columns, X is not sparse, and the distance metric is a 'kdtree' type; otherwise, 'exhaustive'.

Example: 'NSMethod', 'exhaustive'

'NumNeighbors' — Number of nearest neighbors to find

1 (default) | positive integer value

Number of nearest neighbors in X to find for classifying each point when predicting, specified as the comma-separated pair consisting of 'NumNeighbors' and a positive integer value.

Example: 'NumNeighbors', 3

Data Types: single | double

'PredictorNames' — Predictor variable names

{ 'x1', 'x2', ... } (default) | cell array of strings

Predictor variable names, specified as the comma-separated pair consisting of `'PredictorNames'` and a cell array of strings containing the names for the predictor variables, in the order in which they appear in `X`.

Data Types: `cell`

'Prior' — Prior probabilities

`'empirical'` (default) | `'uniform'` | vector of scalar values | structure

Prior probabilities for each class, specified as the comma-separated pair consisting of `'Prior'` and one of the following.

- A string:
 - `'empirical'` determines class probabilities from class frequencies in `y`. If you pass observation weights, they are used to compute the class probabilities.
 - `'uniform'` sets all class probabilities equal.
- A vector (one scalar value for each class).
- A structure `S` with two fields:
 - `S.ClassNames` containing the class names as a variable of the same type as `y`
 - `S.ClassProbs` containing a vector of corresponding probabilities

If you set values for both `Weights` and `Prior`, the weights are renormalized to add up to the value of the prior probability in the respective class.

Example: `'Prior','uniform'`

Data Types: `single` | `double` | `struct`

'ResponseName' — Response variable name

`'Y'` (default) | `string`

Response variable name, specified as the comma-separated pair consisting of `'ResponseName'` and a string containing the name of the response variable `y`.

Example: `'ResponseName','Response'`

Data Types: `char`

'Scale' — Distance scale

`nanstd(X)` (default) | vector of nonnegative scalar values

Distance scale, specified as the comma-separated pair consisting of 'Scale' and a vector containing nonnegative scalar values with length equal to the number of columns in X. Each coordinate difference between X and a query point is scaled by the corresponding element of Scale. This argument is only valid when 'Distance' is 'seuclidean'.

You cannot simultaneously specify 'Standardize' and either of 'Scale' or 'Cov'.

Data Types: single | double

'ScoreTransform' — Score transform function

'none' (default) | 'doublelogit' | 'invlogit' | 'ismax' | 'logit' | 'sign' | 'symmetric' | 'symmetriclogit' | 'symmetricismax' | function handle

Score transform function, specified as the comma-separated pair consisting of 'ScoreTransform' and a string or function handle.

- If the value is a string, then it must correspond to a built-in function. This table summarizes the available, built-in functions.

String	Formula
'doublelogit'	$1/(1 + e^{-2x})$
'invlogit'	$\log(x / (1-x))$
'ismax'	Set the score for the class with the largest score to 1, and scores for all other classes to 0.
'logit'	$1/(1 + e^{-x})$
'none'	x (no transformation)
'sign'	-1 for $x < 0$ 0 for $x = 0$ 1 for $x > 0$
'symmetric'	$2x - 1$
'symmetriclogit'	$2/(1 + e^{-x}) - 1$
'symmetricismax'	Set the score for the class with the largest score to 1, and scores for all other classes to -1.

- For a MATLAB function, or a function that you define, enter its function handle.

Mdl.ScoreTransform = @function;

`function` should accept a matrix (the original scores) and return a matrix of the same size (the transformed scores).

Example: `'ScoreTransform', 'sign'`

Data Types: `char | function_handle`

'Standardize' — Flag to standardize predictors

`false` (default) | `true`

Flag to standardize the predictors, specified as the comma-separated pair consisting of `'Standardize'` and `true` (1) or `false` (0).

If you set `'Standardize', true`, then the software centers and scales each column of the predictor data (X) by the column mean and standard deviation, respectively.

The software does not standardize categorical predictors, and throws an error if all predictors are categorical.

You cannot simultaneously specify `'Standardize', 1` and either of `'Scale'` or `'Cov'`.

It is good practice to standardize the predictor data.

Example: `'Standardize', true`

Data Types: `logical`

'Weights' — Observation weights

`ones(size(X,1),1)` (default) | vector of scalar values

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and a vector of scalar values. The length of `Weights` is the number of rows in X.

The software normalizes the weights in each class to add up to the value of the prior probability of the class.

Data Types: `single | double`

Output Arguments

mdl — Classifier model

classifier model object

k -nearest neighbor classifier model, returned as a classifier model object.

Note that using the 'CrossVal', 'Kfold', 'Holdout', 'Leaveout', or 'CVPartition' options results in a model of class `ClassificationPartitionedModel`. You cannot use a partitioned tree for prediction, so this kind of tree does not have a `predict` method.

Otherwise, `mdl` is of class `ClassificationKNN`, and you can use the `predict` method to make predictions.

Alternatives

Although `fitcknn` can train a multiclass KNN classifier, you can reduce a multiclass learning problem to a series of KNN binary learners using `fitcecoc`.

More About

Prediction

`ClassificationKNN` predicts the classification of a point X_{new} using a procedure equivalent to this:

- 1 Find the `NumNeighbors` points in the training set X that are nearest to X_{new} .
- 2 Find the `NumNeighbors` response values Y to those nearest points.
- 3 Assign the classification label Y_{new} that has the largest posterior probability among the values in Y .

For details, see “Posterior Probability” on page 21-3315 in the `predict` documentation.

Algorithms

- NaNs or `<undefined>`s indicate missing observations. The following describes the behavior of `fitcknn` when the data set or weights contain missing observations.
 - If any value of y or any weight is missing, then `fitcknn` removes those values from y , the weights, and the corresponding rows of X from the data. The software renormalizes the weights to sum to 1.

- If you specify to standardize predictors ('Standardize', 1) or the standardized Euclidean distance ('Distance', 'seuclidean') without a scale, then `fitcknn` removes missing observations from individual predictors before computing the mean and standard deviation. In other words, the software implements `nanmean` and `nanstd` on each predictor.
- If you specify the Mahalanobis distance ('Distance', 'mahalanobis') without its covariance matrix, then `fitcknn` removes rows of X that contain at least one missing value. In other words, the software implements `nancov` on the predictor matrix X .
- Suppose that you set 'Standardize', 1.
 - If you also specify `Prior` or `Weights`, then the software takes the observation weights into account. Specifically, the weighted mean of predictor j is

$$\bar{x}_j = \sum_{B_j} w_k x_{jk}$$

and the weighted standard deviation is

$$s_j = \sum_{B_j} w_k (x_{jk} - \bar{x}_j),$$

where B_j is the set of indices k for which x_{jk} and w_k are not missing.

- If you also set 'Distance', 'mahalanobis' or 'Distance', 'seuclidean', then you cannot specify `Scale` or `Cov`. Instead, the software:
 - 1 Computes the means and standard deviations of each predictor
 - 2 Standardizes the data using the results of step 1
 - 3 Computes the distance parameter values using their respective default.
- If you specify `Scale` and either of `Prior` or `Weights`, then the software scales observed distances by the weighted standard deviations.
- If you specify `Cov` and either of `Prior` or `Weights`, then the software applies the weighted covariance matrix to the distances. In other words,

$$\text{Cov} = \frac{\sum_B w_j}{\left(\sum_B w_j\right)^2 - \sum_B w_j^2} \sum_B w_j (x_j - \bar{x}) (x_j - \bar{x}),$$

where B is the set of indices j for which the observation x_j does not have any missing values and w_j is not missing.

- “Classification Using Nearest Neighbors” on page 16-8

fitcnb

Train multiclass naive Bayes model

Syntax

```
Mdl = fitcnb(X,Y)
Mdl = fitcnb(X,Y,Name,Value)
```

Description

`Mdl = fitcnb(X,Y)` returns a multiclass naive Bayes model (`Mdl`), trained by predictors `X` and class labels `Y`.

Predict labels for new data by passing the data and `Mdl` to `predict`.

`Mdl = fitcnb(X,Y,Name,Value)` returns a naive Bayes classifier with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify a distribution to model the data, prior probabilities for the classes, or the kernel smoothing window bandwidth.

Examples

Train a Naive Bayes Classifier

Load Fisher's iris data set.

```
load fisheriris
X = meas(:,3:4);
Y = species;
tabulate(Y)
```

Value	Count	Percent
setosa	50	33.33%
versicolor	50	33.33%
virginica	50	33.33%

The software can classify data with more than two classes using naive Bayes methods.

Train a naive Bayes classifier. It is good practice to specify the class order.

```
Mdl = fitcnb(X,Y,...
    'ClassNames',{'setosa','versicolor','virginica'})

Mdl =

    ClassificationNaiveBayes
        PredictorNames: {'x1' 'x2'}
        ResponseName: 'Y'
        ClassNames: {'setosa' 'versicolor' 'virginica'}
        ScoreTransform: 'none'
        NumObservations: 150
        DistributionNames: {'normal' 'normal'}
        DistributionParameters: {3x2 cell}
```

Mdl is a trained `ClassificationNaiveBayes` classifier.

By default, the software models the predictor distribution within each class using a Gaussian distribution having some mean and standard deviation. Use dot notation to display the parameters of a particular Gaussian fit, e.g., display the fit for the first feature within `setosa`.

```
setosaIndex = strcmp(Mdl.ClassNames,'setosa');
estimates = Mdl.DistributionParameters{setosaIndex,1}
```

```
estimates =

    1.4620
    0.1737
```

The mean is 1.4620 and the standard deviation is 0.1737.

Plot the Gaussian contours.

```
figure
gscatter(X(:,1),X(:,2),Y);
h = gca;
xylim = [h.XLim h.YLim]; % Get current axis limits
```

```

hold on
Params = cell2mat(Mdl.DistributionParameters);
Mu = Params(2*(1:3)-1,1:2); % Extract the means
Sigma = zeros(2,2,3);
for j = 1:3
    Sigma(:,:,j) = diag(Params(2*j,:)); % Extract the standard deviations
    ezcontour(@(x1,x2)mvnpdf([x1,x2],Mu(j,:),Sigma(:,:,j)),...
        xylim+0.5*[-1,1,-1,1]) ...
    % Draw contours for the multivariate normal distributions
end
title('Naive Bayes Classifier -- Fisher's Iris Data')
xlabel('Petal Length (cm)')
ylabel('Petal Width (cm)')
hold off

```

You can change the default distribution using the name-value pair argument 'DistributionNames'. For example, if some predictors are categorical, then you can specify that they are multivariate, multinomial random variables using 'DistributionNames', 'mvnm'.

Specify Prior Probabilities When Training Naive Bayes Classifiers

Construct a naive Bayes classifier for Fisher's iris data set. Also, specify prior probabilities during training.

Load Fisher's iris data set.

```
load fisheriris
X = meas;
Y = species;
classNames = {'setosa', 'versicolor', 'virginica'}; % Class order
```

X is a numeric matrix that contains four petal measurements for 150 irises. Y is a cell array of strings that contains the corresponding iris species.

By default, the prior class probability distribution is the relative frequency distribution of the classes in the data set, which in this case is 33% for each species. However, suppose you know that in the population 50% of the irises are setosa, 20% are versicolor, and 30% are virginica. You can incorporate this information by specifying this distribution as a prior probability during training.

Train a naive Bayes classifier. Specify the class order and prior class probability distribution.

```
prior = [0.5 0.2 0.3];
Mdl = fitcnb(X,Y, 'ClassNames', classNames, 'Prior', prior)
```

```
Mdl =
```

```
ClassificationNaiveBayes
    PredictorNames: {'x1' 'x2' 'x3' 'x4'}
    ResponseName: 'Y'
    ClassNames: {'setosa' 'versicolor' 'virginica'}
    ScoreTransform: 'none'
    NumObservations: 150
    DistributionNames: {'normal' 'normal' 'normal' 'normal'}
    DistributionParameters: {3x4 cell}
```

Mdl is a trained `ClassificationNaiveBayes` classifier, and some of its properties appear in the Command Window. The software treats the predictors as independent given a class, and, by default, fits them using normal distributions.

The naive Bayes algorithm does not use the prior class probabilities during training. Therefore, you can specify prior class probabilities after training using dot notation. For example, suppose that you want to see the difference in performance between a model that uses the default prior class probabilities and a model that uses `prior`.

Create a new naive Bayes model based on Mdl, and specify that the prior class probability distribution is an empirical class distribution.

```
defaultPriorMdl = Mdl;
FreqDist = cell2table(tabulate(Y));
defaultPriorMdl.Prior = FreqDist{:,3};
```

The software normalizes the prior class probabilities to sum to 1.

Estimate the cross-validation error for both models using 10-fold cross validation.

```
rng(1); % For reproducibility
defaultCVMdl = crossval(defaultPriorMdl);
defaultLoss = kfoldLoss(defaultCVMdl)
CVMdl = crossval(Mdl);
Loss = kfoldLoss(CVMdl)
```

```
defaultLoss =
```

```
    0.0533
```

```
Loss =
```

```
    0.0340
```

Mdl performs better than `defaultPriorMdl`.

Specify Predictor Distributions for Naive Bayes Classifiers

Load Fisher's iris data set.

```
load fisheriris
X = meas;
```

```
Y = species;
```

Train a naive Bayes classifier using every predictor. It is good practice to specify the class order.

```
Mdl1 = fitcnb(X,Y,...  
             'ClassNames',{'setosa','versicolor','virginica'})  
Mdl1.DistributionParameters  
Mdl1.DistributionParameters{1,2}
```

```
Mdl1 =
```

```
ClassificationNaiveBayes  
    PredictorNames: {'x1' 'x2' 'x3' 'x4'}  
    ResponseName: 'Y'  
    ClassNames: {'setosa' 'versicolor' 'virginica'}  
    ScoreTransform: 'none'  
    NumObservations: 150  
    DistributionNames: {'normal' 'normal' 'normal' 'normal'}  
    DistributionParameters: {3x4 cell}
```

```
ans =
```

```
    [2x1 double]    [2x1 double]    [2x1 double]    [2x1 double]  
    [2x1 double]    [2x1 double]    [2x1 double]    [2x1 double]  
    [2x1 double]    [2x1 double]    [2x1 double]    [2x1 double]
```

```
ans =
```

```
    3.4280  
    0.3791
```

By default, the software models the predictor distribution within each class as a Gaussian with some mean and standard deviation. There are four predictors and three class levels. Each cell in `Mdl1.DistributionParameters` corresponds to a numeric vector containing the mean and standard deviation of each distribution, e.g., the mean and standard deviation for setosa iris sepal widths are 3.4280 and 0.3791, respectively.

Estimate the confusion matrix for `Mdl1`.

```
isLabels1 = resubPredict(Mdl1);
ConfusionMat1 = confusionmat(Y,isLabels1)
```

```
ConfusionMat1 =
```

```
    50     0     0
     0    47     3
     0     3    47
```

Element (j, k) of `ConfusionMat1` represents the number of observations that the software classifies as k , but are truly in class j according to the data.

Retrain the classifier using the Gaussian distribution for predictors 1 and 2 (the sepal lengths and widths), and the default normal kernel density for predictors 3 and 4 (the petal lengths and widths).

```
Mdl2 = fitcnb(X,Y,...
    'Distribution',{'normal','normal','kernel','kernel'},...
    'ClassNames',{'setosa','versicolor','virginica'});
Mdl2.DistributionParameters{1,2}
```

```
ans =
```

```
    3.4280
    0.3791
```

The software does not train parameters to the kernel density. Rather, the software chooses an optimal width. However, you can specify a width using the `'Width'` name-value pair argument.

Estimate the confusion matrix for `Mdl2`.

```
isLabels2 = resubPredict(Mdl2);
ConfusionMat2 = confusionmat(Y,isLabels2)
```

```
ConfusionMat2 =
```

```
    50     0     0
     0    47     3
     0     3    47
```

Based on the confusion matrices, the two classifiers perform similarly in the training sample.

Compare Classifiers Using Cross Validation

Load Fisher's iris data set.

```
load fisheriris
X = meas;
Y = species;
rng(1); % For reproducibility
```

Train and cross validate a naive Bayes classifier using the default options and k -fold cross validation. It is good practice to specify the class order.

```
CVMd11 = fitcnb(X,Y,...
    'ClassNames',{'setosa','versicolor','virginica'},...
    'CrossVal','on');
```

By default, the software models the predictor distribution within each class as a Gaussian with some mean and standard deviation. CVMd11 is a `ClassificationPartitionedModel` model.

Create a default naive Bayes binary classifier template, and train an error-correcting, output codes multiclass model.

```
t = templateNaiveBayes();
CVMd12 = fitcecoc(X,Y,'CrossVal','on','Learners',t);
```

CVMd12 is a `ClassificationPartitionedECOC` model. You can specify options for the naive Bayes binary learners using the same name-value pair arguments as for `fitcnb`.

Compare the out-of-sample k -fold classification error (proportion of misclassified observations).

```
classErr1 = kfoldLoss(CVMd11,'LossFun','ClassifErr')
classErr2 = kfoldLoss(CVMd12,'LossFun','ClassifErr')
```

```
classErr1 =
    0.0533
```

```
classErr2 =
```

0.0467

Mdl2 has a lower generalization error.

Train Naive Bayes Classifiers Using Multinomial Predictors

Some spam filters classify an incoming email as spam based on how many times a word or punctuation (called tokens) occurs in an email. The predictors are the frequencies of particular words or punctuations in an email. Therefore, the predictors compose multinomial random variables.

This example illustrates classification using naive Bayes and multinomial predictors.

Create Training Data

Suppose you observed 1000 emails and classified them as spam or not spam. Do this by randomly assigning -1 or 1 to y for each email.

```
n = 1000; % Sample size
rng(1); % For reproducibility
Y = randsample([-1 1],n,true); % Random labels
```

To build the predictor data, suppose that there are five tokens in the vocabulary, and 20 observed tokens per email. Generate predictor data from the five tokens by drawing random, multinomial deviates. The relative frequencies for tokens corresponding to spam emails should differ from emails that are not spam.

```
tokenProbs = [0.2 0.3 0.1 0.15 0.25;... % Token relative frequencies
              0.4 0.1 0.3 0.05 0.15]; % Fixed for convenience
tokensPerEmail = 20;
X = zeros(n,5);
X(Y == 1,:) = mnrnd(tokensPerEmail,tokenProbs(1,:),sum(Y == 1));
X(Y == -1,:) = mnrnd(tokensPerEmail,tokenProbs(2,:),sum(Y == -1));
```

Train the Classifier

Train a naive Bayes classifier. Specify that the predictors are multinomial.

```
Mdl = fitcnb(X,Y,'Distribution','mn');
```

Mdl is a trained `ClassificationNaiveBayes` classifier.

Assess the in-sample performance of Mdl by estimating the misclassification error.

```
isGenRate = resubLoss(Mdl,'LossFun','ClassifErr')
```

```
isGenRate =  
    0.0200
```

The in-sample misclassification rate is 2%.

Create New Data

Randomly generate deviates that represent a new batch of emails.

```
newN = 500;  
newY = randsample([-1 1],newN,true);  
newX = zeros(newN,5);  
newX(newY == 1,:) = mnrnd(tokensPerEmail,tokenProbs(1,:),...  
    sum(newY == 1));  
newX(newY == -1,:) = mnrnd(tokensPerEmail,tokenProbs(2,:),...  
    sum(newY == -1));
```

Assess Classifier Performance

Classify the new emails using the trained naive Bayes classifier `Md1`, and determine whether the algorithm generalizes.

```
oosGenRate = loss(Md1,newX,newY)
```

```
oosGenRate =  
    0.0261
```

The out-of-sample misclassification rate is 2.6% indicating that the classifier generalizes fairly well.

Input Arguments

X — Predictor data

matrix of numeric values

Predictor data to which the naive Bayes classifier is trained, specified as a matrix of numeric values.

Each row of X corresponds to one observation (also known as an instance or example), and each column corresponds to one variable (also known as a feature).

The length of Y and the number of rows of X must be equivalent.

Data Types: `double`

Y – Class labels

categorical array | character array | logical vector | vector of numeric values | cell array of strings

Class labels to which the naive Bayes classifier is trained, specified as a categorical or character array, logical or numeric vector, or cell array of strings. Each element of Y defines the class membership of the corresponding row of X . Y supports K class levels.

If Y is a character array, then each row must correspond to one class label.

The length of Y and the number of rows of X must be equivalent.

Data Types: `cell` | `char` | `double` | `logical`

Note: The software treats NaN, empty string (' '), and `<undefined>` elements as missing values.

- If Y contains missing values, then the software removes them and the corresponding rows of X .
- If X contains any rows composed entirely of missing values, then the software removes those rows and the corresponding elements of Y .
- If X contains missing values and you set '`Distribution`', '`mn`', then the software removes those rows of X and the corresponding elements of Y .
- If a predictor is not represented in a class, that is, if all of its values are NaN within a class, then the software returns an error.

Removing rows of X and corresponding elements of Y decreases the effective training or cross-validation sample size.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single

quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Distribution','mn','Prior','uniform','KSWidth',0.5` specifies that the data distribution is multinomial, the prior probabilities for all classes are equal, and the kernel smoothing window bandwidth for all classes is 0.5 units.

Naive Bayes Options

'DistributionNames' — Data distributions

'kernel' | 'mn' | 'mvmn' | 'normal' | cell array of strings

Data distributions `fitcnb` uses to model the data, specified as the comma-separated pair consisting of 'DistributionNames' and a string or cell array of strings.

This table summarizes the available distributions.

Value	Description
'kernel'	Kernel smoothing density estimate.
'mn'	Multinomial distribution. If you specify <code>mn</code> , then all features are components of a multinomial distribution. Therefore, you cannot include 'mn' as an element of a cell array of strings. For details, see “Algorithms”.
'mvmn'	Multivariate multinomial distribution. For details, see “Algorithms”.
'normal'	Normal (Gaussian) distribution.

If you specify a string, then the software models all the features using that distribution. If you specify a 1-by- P cell array of strings, then the software models feature j using the distribution in element j of the cell array.

By default, the software sets all predictors specified as categorical predictors (using the `CategoricalPredictors` name-value pair argument) to 'mvmn'. Otherwise, the default distribution is 'normal'.

You must specify that at least one predictor has distribution 'kernel' to additionally specify Kernel, Support, or Width.

Example: 'Distribution', 'mn'

Data Types: cell | char

'Kernel' – Kernel smoother type

'normal' (default) | 'box' | 'epanechnikov' | 'triangle' | cell array of strings

Kernel smoother type, specified as the comma-separated pair consisting of 'Kernel' and a string or cell array of strings.

This table summarizes the available options for setting the kernel smoothing density region. Let $I\{u\}$ denote the indicator function.

Value	Kernel	Formula
'box'	Box (uniform)	$f(x) = 0.5I\{ x \leq 1\}$
'epanechni	Epanechnikov	$f(x) = 0.75(1 - x^2)I\{ x \leq 1\}$
'normal'	Gaussian	$f(x) = \frac{1}{\sqrt{2\pi}} \exp(-0.5x^2)$
'triangle'	Triangular	$f(x) = (1 - x)I\{ x \leq 1\}$

If you specify a 1-by- P cell array, with each cell containing any value in the table, then the software trains the classifier using the kernel smoother type in cell j for feature j in X . The software ignores cells of **Kernel** not corresponding to a predictor whose distribution is 'kernel'.

You must specify that at least one predictor has distribution 'kernel' to additionally specify **Kernel**, **Support**, or **Width**.

Example: 'Kernel', {'epanechnikov', 'normal'}

Data Types: cell | char

'Support' – Kernel smoothing density support

'unbounded' (default) | 'positive' | cell array | numeric row vector

Kernel smoothing density support, specified as the comma-separated pair consisting of 'Support' and 'positive', 'unbounded', a cell array, or a numeric row vector. The software applies the kernel smoothing density to the specified region.

This table summarizes the available options for setting the kernel smoothing density region.

Value	Description
1-by-2 numeric row vector	For example, $[L, U]$, where L and U are the finite lower and upper bounds, respectively, for the density support.
'positive'	The density support is all positive real values.
'unbounded'	The density support is all real values.

If you specify a 1-by- P cell array, with each cell containing any value in the table, then the software trains the classifier using the kernel support in cell j for feature j in X . The software ignores cells of `Kernel` not corresponding to a predictor whose distribution is 'kernel'.

You must specify that at least one predictor has distribution 'kernel' to additionally specify `Kernel`, `Support`, or `Width`.

Example: 'KSSupport', {[-10,20], 'unbounded' }

Data Types: cell | char | double

'Width' — Kernel smoothing window width

matrix of numeric values | numeric column vector | numeric row vector | scalar

Kernel smoothing window width, specified as the comma-separated pair consisting of 'Width' and a matrix of numeric values, numeric column vector, numeric row vector, or scalar.

Suppose there are K class levels and P predictors. This table summarizes the available options for setting the kernel smoothing window width.

Value	Description
K -by- P matrix of numeric values	Element (k,j) specifies the width for predictor j in class k .
K -by-1 numeric column vector	Element k specifies the width for all predictors in class k .
1-by- P numeric row vector	Element j specifies the width in all class levels for predictor j .

Value	Description
scalar	Specifies the bandwidth for all features in all classes.

By default, the software selects a default width automatically for each combination of predictor and class by using a value that is optimal for a Gaussian distribution. If you specify `Width` and it contains NaNs, then the software selects widths for the elements containing NaNs.

You must specify that at least one predictor has distribution `'kernel'` to additionally specify `Kernel`, `Support`, or `Width`.

Example: `'Width', [NaN NaN]`

Data Types: `double` | `struct`

Cross-Validation Options

'CrossVal' — Cross-validation flag

`'off'` (default) | `'on'`

Cross-validation flag, specified as the comma-separated pair consisting of `'CrossVal'` and either `'on'` or `'off'`. If `'on'`, `fitcknn` creates a cross-validated model with 10 folds. Use the `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'` parameters to override this cross-validation setting. You can only use one parameter at a time to create a cross-validated model.

Alternatively, cross validate `Mdl` after training using the `crossval` method.

Example: `'Crossval', 'on'`

'CVPartition' — Cross-validated model partition

`cvpartition` object

Cross-validated model partition, specified as the comma-separated pair consisting of `'CVPartition'` and an object created using `cvpartition`. You can only use one of these four options at a time to create a cross-validated model: `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'`.

'Holdout' — Fraction of data for holdout validation

0 (default) | scalar value in the range `[0, 1]`

Fraction of data used for holdout validation, specified as the comma-separated pair consisting of `'Holdout'` and a scalar value in the range $[0, 1]$. Holdout validation tests the specified fraction of the data, and uses the remaining data for training.

If you use `Holdout`, you cannot use any of the `'CVPartition'`, `'KFold'`, or `'Leaveout'` name-value pair arguments.

Example: `'Holdout', 0.1`

Data Types: `single` | `double`

'KFold' — Number of folds

10 (default) | positive integer value

Number of folds to use in a cross-validated model, specified as the comma-separated pair consisting of `'KFold'` and a positive integer value.

If you use `'KFold'`, you cannot use any of the `'CVPartition'`, `'Holdout'`, or `'Leaveout'` name-value pair arguments.

Example: `'KFold', 8`

Data Types: `single` | `double`

'Leaveout' — Leave-one-out cross-validation flag

'off' (default) | 'on'

Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of `'Leaveout'` and either `'on'` or `'off'`. Specify `'on'` to use leave-one-out cross validation.

If you use `'Leaveout'`, you cannot use any of the `'CVPartition'`, `'Holdout'`, or `'KFold'` name-value pair arguments.

Example: `'Leaveout', 'on'`

Other Classification Options

'CategoricalPredictors' — Categorical predictors list

[] (default) | 'all' | cell array of strings | character array | logical vector | numeric vector

Categorical predictors list, specified as the comma-separated pair consisting of `'CategoricalPredictors'` and one of the following:

- A numeric vector with indices from 1 through `p`, where `p` is the number of columns of `X`.
- A logical vector of length `p`, where a `true` entry means that the corresponding column of `X` is a categorical variable.
- A cell array of strings, where each element in the array is the name of a predictor variable. The names must match entries in `PredictorNames` values.
- A character matrix, where each row of the matrix is a name of a predictor variable. The names must match entries in `PredictorNames` values. Pad the names with extra blanks so each row of the character matrix has the same length.
- `'all'`, meaning all predictors are categorical.

By default, no predictors are categorical.

Example: `'CategoricalPredictors','all'`

Data Types: `single` | `double` | `char` | `cell`

'ClassNames' — Class names

numeric vector | categorical vector | logical vector | character array | cell array of strings

Class names, specified as the comma-separated pair consisting of `'ClassNames'` and an array representing the class names. Use the same data type as the values that exist in `Y`.

Use `ClassNames` to order the classes or to select a subset of classes for training.

The default is the class names in `Y`.

Example: `'ClassNames',{'b','g'}`

Data Types: `single` | `double` | `char` | `logical` | `cell`

'Cost' — Cost of misclassification

square matrix | structure

Cost of misclassification of a point, specified as the comma-separated pair consisting of `'Cost'` and one of the following:

- Square matrix, where `Cost(i,j)` is the cost of classifying a point into class `j` if its true class is `i`.

- Structure **S** having two fields: **S.ClassNames** containing the group names as a variable of the same type as **Y**, and **S.ClassificationCosts** containing the cost matrix.

The default is $\text{Cost}(i, j) = 1$ if $i \neq j$, and $\text{Cost}(i, j) = 0$ if $i = j$.

Example: `'Cost', struct('ClassNames', {'b', 'g'}, 'ClassificationCosts', [0 0.5; 1 0])`

Data Types: `single | double | struct`

'PredictorNames' — Predictor variable names

`{'x1', 'x2', ...}` (default) | cell array of strings

Predictor variable names, specified as the comma-separated pair consisting of **'PredictorNames'** and a cell array of strings containing the names for the predictor variables, in the order in which they appear in **X**.

Data Types: `cell`

'Prior' — Prior probabilities

`'empirical'` (default) | `'uniform'` | vector of scalar values | structure

Prior probabilities for each class, specified as the comma-separated pair consisting of **'Prior'** and one of the following.

- A string:
 - `'empirical'` determines class probabilities from class frequencies in **Y**.
 - `'uniform'` sets all class probabilities equal.
- A vector (one scalar value for each class).
- A structure **S** with two fields:
 - **S.ClassNames** containing the class names as a variable of the same type as **Y**
 - **S.ClassProbs** containing a vector of corresponding probabilities

The software normalizes the values of **Prior** so that they sum to 1. If you set values for both **Weights** and **Prior**, the weights are renormalized to sum to the value of the prior probability in their respective class.

Example: `'Prior', 'uniform'`

Data Types: `single | double | struct`

'ResponseName' — Response variable name`'Y'` (default) | string

Response variable name, specified as the comma-separated pair consisting of `'ResponseName'` and a string containing the name of the response variable Y.

Example: `'ResponseName', 'Response'`

Data Types: char

'ScoreTransform' — Score transform function
`'none'` (default) | `'doublelogit'` | `'invlogit'` | `'ismax'` | `'logit'` | `'sign'` | `'symmetric'` | `'symmetriclogit'` | `'symmetricismax'` | function handle

Score transform function, specified as the comma-separated pair consisting of `'ScoreTransform'` and a string or function handle.

- If the value is a string, then it must correspond to a built-in function. This table summarizes the available, built-in functions.

String	Formula
<code>'doublelogit'</code>	$1/(1 + e^{-2x})$
<code>'invlogit'</code>	$\log(x / (1-x))$
<code>'ismax'</code>	Set the score for the class with the largest score to 1, and scores for all other classes to 0.
<code>'logit'</code>	$1/(1 + e^{-x})$
<code>'none'</code>	x (no transformation)
<code>'sign'</code>	-1 for $x < 0$ 0 for $x = 0$ 1 for $x > 0$
<code>'symmetric'</code>	$2x - 1$
<code>'symmetriclogit'</code>	$2/(1 + e^{-x}) - 1$
<code>'symmetricismax'</code>	Set the score for the class with the largest score to 1, and scores for all other classes to -1.

- For a MATLAB function, or a function that you define, enter its function handle.

```
Mdl.ScoreTransform = @function;
```

function should accept a matrix (the original scores) and return a matrix of the same size (the transformed scores).

Example: 'ScoreTransform', 'sign'

Data Types: char | function_handle

'Weights' — Observation weights

ones(size(X,1),1) (default) | vector of scalar values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a vector of scalar values. The length of `Weights` is the number of rows in `X`.

The software normalizes the weights in each class to add up to the value of the prior probability of the class.

Data Types: single | double

Output Arguments

Md1 — Trained naive Bayes classifier

ClassificationNaiveBayes classifier

Trained naive Bayes classifier, returned as a `ClassificationNaiveBayes` classifier.

More About

Bag-of-Tokens Model

In the bag-of-tokens model, the value of predictor j is the nonnegative number of occurrences of token j in this observation. The number of categories (bins) in this multinomial model is the number of distinct tokens, that is, the number of predictors.

Naive Bayes

Naive Bayes is a classification algorithm that applies density estimation to the data.

The algorithm leverages Bayes theorem, and (naively) assumes that the predictors are conditionally independent, given the class. Though the assumption is usually violated

in practice, naive Bayes classifiers tend to yield posterior distributions that are robust to biased class density estimates, particularly where the posterior is 0.5 (the decision boundary) “[1]”.

Naive Bayes classifiers assign observations to the most probable class (in other words, the *maximum a posteriori* decision rule). Explicitly, the algorithm:

- 1 Estimates the densities of the predictors within each class.
- 2 Models posterior probabilities according to Bayes rule. That is, for all $k = 1, \dots, K$,

$$\hat{P}(Y = k | X_1, \dots, X_P) = \frac{\pi(Y = k) \prod_{j=1}^P P(X_j | Y = k)}{\sum_{k=1}^K \pi(Y = k) \prod_{j=1}^P P(X_j | Y = k)},$$

where:

- Y is the random variable corresponding to the class index of an observation.
 - X_1, \dots, X_P are the random predictors of an observation.
 - $\pi(Y = k)$ is the prior probability that a class index is k .
- 3 Classifies an observation by estimating the posterior probability for each class, and then assigns the observation to the class yielding the maximum posterior probability.

If the predictors compose a multinomial distribution, then the posterior probability $\hat{P}(Y = k | X_1, \dots, X_P) \propto \pi(Y = k) P_{mn}(X_1, \dots, X_P | Y = k)$, where

$P_{mn}(X_1, \dots, X_P | Y = k)$ is the probability mass function of a multinomial distribution.

Tips

For classifying count-based data, such as the bag-of-tokens model, use the multinomial distribution (e.g., set 'Distribution', 'mn').

Algorithms

- If you specify 'Distribution', 'mn' when training Mdl using `fitcnb`, then the software fits a multinomial distribution using the “bag-of-tokens model”. The

software stores the probability that token j appears in class k in the property `DistributionParameters{k,j}`. Using additive smoothing “[2]”, the estimated probability is

$$P(\text{token } j \mid \text{class } k) = \frac{1 + c_{jk}}{P + c_k},$$

where:

- $$c_{j|k} = n_k \frac{\sum_{i: y_i \in \text{class } k} x_{ij} w_i}{\sum_{i: y_i \in \text{class } k} w_i};$$
 which is the weighted number of occurrences of token j in class k .
- n_k is the number of observations in class k .
- w_i is the weight for observation i . The software normalizes weights within a class such that they sum to the prior probability for that class.
- $$c_k = \sum_{j=1}^P c_{j|k};$$
 which is the total weighted number of occurrences of all tokens in class k .
- If you specify 'Distribution', 'mvnm' when training Mdl using `fitcnb`, then:
 - 1 For each predictor, the software collects a list of the unique levels, stores the sorted list in `CategoricalLevels`, and considers each level a bin. Each predictor/class combination is a separate, independent multinomial random variable.
 - 2 For predictor j in class k , the software counts instances of each categorical level using the list stored in `CategoricalLevels{j}`.
 - 3 The software stores the probability that predictor j , in class k , has level L in the property `DistributionParameters{k,j}`, for all levels in `CategoricalLevels{j}`. Using additive smoothing “[2]”, the estimated probability is

$$P(\text{predictor } j = L \mid \text{class } k) = \frac{1 + m_{j|k}(L)}{m_j + m_k},$$

where:

$$m_{j|k}(L) = n_k \frac{\sum_{i: y_i \in \text{class } k} I\{x_{ij} = L\} w_i}{\sum_{i: y_i \in \text{class } k} w_i};$$

which is the weighted number of

observations for which predictor j equals L in class k .

- n_k is the number of observations in class k .
 - $I\{x_{ij} = L\} = 1$ if $x_{ij} = L$, 0 otherwise.
 - w_i is the weight for observation i . The software normalizes weights within a class such that they sum to the prior probability for that class.
 - m_j is the number of distinct levels in predictor j .
 - m_k is the weighted number of observations in class k .

fitcsvm

Train binary support vector machine classifier

Syntax

```
SVMMModel = fitcsvm(X,Y)
SVMMModel = fitcsvm(X,Y,Name,Value)
```

Description

`SVMMModel = fitcsvm(X,Y)` returns a support vector machine classifier `SVMMModel`, trained by predictors `X` and class labels `Y` for one- or two-class classification.

`SVMMModel = fitcsvm(X,Y,Name,Value)` returns a support vector machine classifier with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify the type of cross validation, the cost for misclassification, or the type of score transformation function.

Examples

Train a Support Vector Machine Classifier

Load Fisher's iris data set. Remove the sepal lengths and widths, and all observed setosa irises.

```
load fisheriris
inds = ~strcmp(species,'setosa');
X = meas(inds,3:4);
y = species(inds);
```

Train an SVM classifier using the processed data set.

```
SVMMModel = fitcsvm(X,y)
```

```

SVMModel =

  ClassificationSVM
    PredictorNames: {'x1' 'x2'}
    ResponseName: 'Y'
    ClassNames: {'versicolor' 'virginica'}
    ScoreTransform: 'none'
    NumObservations: 100
        Alpha: [24x1 double]
        Bias: -14.4149
    KernelParameters: [1x1 struct]
    BoxConstraints: [100x1 double]
    ConvergenceInfo: [1x1 struct]
    IsSupportVector: [100x1 logical]
    Solver: 'SMO'

```

The Command Window shows that `SVMModel` is a trained `ClassificationSVM` classifier and a property list. Display the properties of `SVMModel`, for example, to determine the class order, by using dot notation.

```
classOrder = SVMModel.ClassNames
```

```

classOrder =

    'versicolor'
    'virginica'

```

The first class ('`versicolor`') is the negative class, and the second ('`virginica`') is the positive class. You can change the class order during training by using the '`ClassNames`' name-value pair argument.

Plot a scatter diagram of the data and circle the support vectors.

```

sv = SVMModel.SupportVectors;
figure
gscatter(X(:,1),X(:,2),y)
hold on
plot(sv(:,1),sv(:,2),'ko','MarkerSize',10)
legend('versicolor','virginica','Support Vector')

```

```
hold off
```

The support vectors are observations that occur on or beyond their estimated class boundaries.

You can adjust the boundaries (and therefore the number of support vectors) by setting a box constant during training using the 'BoxConstraint' name-value pair argument.

Train and Cross Validate an SVM Classifier

Load the `ionosphere` data set.

```
load ionosphere
```

```
rng(1); % For reproducibility
```

Train an SVM classifier using the radial basis kernel. Let the software find a scale value for the kernel function. It is good practice to standardize the predictors.

```
SVMMModel = fitcsvm(X,Y,'Standardize',true,'KernelFunction','RBF',...
    'KernelScale','auto');
```

SVMMModel is a trained ClassificationSVM classifier.

Cross validate the SVM classifier. By default, the software uses 10-fold cross validation.

```
CVSVMMModel = crossval(SVMMModel);
```

CVSVMMModel is a ClassificationPartitionedModel cross-validated classifier.

Estimate the out-of-sample misclassification rate.

```
classLoss = kfoldLoss(CVSVMMModel)
```

```
classLoss =
    0.0484
```

The generalization rate is approximately 5%.

Detect Outliers Using SVM and One-Class Learning

Load Fisher's iris data set. Remove the petal lengths and widths. Treat all irises as coming from the same class.

```
load fisheriris
X = meas(:,1:2);
y = ones(size(X,1),1);
```

Train an SVM classifier using the processed data set. Assume that 5% of the observations are outliers. It is good practice to standardize the predictors.

```
rng(1);
SVMMModel = fitcsvm(X,y,'KernelScale','auto','Standardize',true,...
    'OutlierFraction',0.05);
```

`SVMModel` is a trained `ClassificationSVM` classifier. By default, the software uses the Gaussian kernel for one-class learning.

Plot the observations and the decision boundary. Flag the support vectors and potential outliers.

```
svInd = SVMModel.IsSupportVector;
h = 0.02; % Mesh grid step size
[X1,X2] = meshgrid(min(X(:,1)):h:max(X(:,1)),...
    min(X(:,2)):h:max(X(:,2)));
[~,score] = predict(SVMModel,[X1(:),X2(:)]);
scoreGrid = reshape(score,size(X1,1),size(X2,2));

figure
plot(X(:,1),X(:,2),'k.')
hold on
plot(X(svInd,1),X(svInd,2),'ro','MarkerSize',10)
contour(X1,X2,scoreGrid)
colorbar;
title('{\bf Iris Outlier Detection via One-Class SVM}')
xlabel('Sepal Length (cm)')
ylabel('Sepal Width (cm)')
legend('Observation','Support Vector')
hold off
```

The boundary separating the outliers from the rest of the data occurs where the contour value is 0.

Verify that the fraction of observations with negative scores in the cross-validated data is close to 5%.

```
CVSVMModel = crossval(SVMModel);
[~,scorePred] = kfoldPredict(CVSVMModel);
outlierRate = mean(scorePred<0)
```

```
outlierRate =
```

```
0.0467
```

Find Multiple Class Boundaries Using Binary SVM

Load Fisher's iris data set. Use the petal lengths and widths.

```
load fisheriris
X = meas(:,3:4);
Y = species;
```

Examine a scatter plot of the data.

```
figure
gscatter(X(:,1),X(:,2),Y);
title('\bf Scatter Diagram of Iris Measurements');
xlabel('Petal Length (cm)');
ylabel('Petal Width (cm)');
legend('Location','Northwest');
lims = get(gca,{'XLim','YLim'}); % Extract the _x_ and _y_ axis limits
```

There are three classes, one of which is linearly separable from the others.

For each class:

- 1 Create a logical vector (`indx`) indicating whether an observation is a member of the class.
- 2 Train an SVM classifier using the predictor data and `indx`.
- 3 Store the classifier in a cell of a cell array.

`% It is good practice to define the class order and standardize the
% predictors.`

```
SVMModels = cell(3,1);
classes = unique(Y);
rng(1); % For reproducibility
```

```

for j = 1:numel(classes);
    indx = strcmp(Y,classes(j)); % Create binary classes for each classifier
    SVMModels{j} = fitcsvm(X,indx,'ClassNames',[false true],'Standardize',true,...
        'KernelFunction','rbf','BoxConstraint',1);
end

```

`SVMModels` is a 3-by-1 cell array, with each cell containing a `ClassificationSVM` classifier. For each cell, the positive class is setosa, versicolor, and virginica, respectively.

Define a fine grid within the plot, and treat the coordinates as new observations from the distribution of the training data. Estimate the score of the new observations using each classifier.

```

d = 0.02;
[x1Grid,x2Grid] = meshgrid(min(X(:,1)):d:max(X(:,1)),...
    min(X(:,2)):d:max(X(:,2)));
xGrid = [x1Grid(:),x2Grid(:)];
N = size(xGrid,1);
Scores = zeros(N,numel(classes));

for j = 1:numel(classes);
    [~,score] = predict(SVMModels{j},xGrid);
    Scores(:,j) = score(:,2); % Second column contains positive-class scores
end

```

Each row of `Scores` contains three scores. The index of the element with the largest score is the index of the class to which the new class observation most likely belongs.

Associate each new observation with the classifier that gives it the maximum score.

```
[~,maxScore] = max(Scores,[],2);
```

Color in the regions of the plot based on which class the corresponding new observation belongs.

```

figure
h(1:3) = gscatter(xGrid(:,1),xGrid(:,2),maxScore,...
    [0.1 0.5 0.5; 0.5 0.1 0.5; 0.5 0.5 0.1]);
hold on
h(4:6) = gscatter(X(:,1),X(:,2),Y);
title({'\bf Iris Classification Regions'});
xlabel('Petal Length (cm)');
ylabel('Petal Width (cm)');
legend(h,{'setosa region','versicolor region','virginica region'},...

```

```

    'observed setosa', 'observed versicolor', 'observed virginica'}, ...
    'Location', 'Northwest');
axis tight
hold off

```

Input Arguments

X — Predictor data

matrix of numeric values

Predictor data to which the SVM classifier is trained, specified as a matrix of numeric values.

Each row of `X` corresponds to one observation (also known as an instance or example), and each column corresponds to one predictor.

The length of `Y` and the number of rows of `X` must be equal.

It is good practice to:

- Cross validate using the `KFold` name-value pair argument. The cross-validation results determine how well the SVM classifier generalizes.
- Standardize the predictor variables using the `Standardize` name-value pair argument.

To specify the names of the predictors in the order of their appearance in `X`, use the `PredictorNames` name-value pair argument.

Data Types: `double` | `single`

Y — Class labels

categorical array | character array | logical vector | vector of numeric values | cell array of strings

Class labels to which the SVM classifier is trained, specified as a categorical or character array, logical or numeric vector, or cell array of strings.

If `Y` is a character array, then each element must correspond to one row of the array.

The length of `Y` and the number of rows of `X` must be equal.

It is good practice to specify the order of the classes using the `ClassNames` name-value pair argument.

To specify the response variable name, use the `ResponseName` name-value pair argument.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single

quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'KFold',10,'Cost',[0 2;1 0],'ScoreTransform','sign'` specifies to perform 10-fold cross validation, apply double the penalty to false positives compared to false negatives, and transform the scores using the sign function.

'Alpha' — Initial estimates of alpha coefficients

vector of nonnegative real values

Initial estimates of alpha coefficients, specified as the comma-separated pair consisting of 'Alpha' and a vector of nonnegative real values. The length of Alpha must be equal to the number of rows of X.

- Each element of Alpha corresponds to an observation in X.
- Alpha cannot contain any NaNs.
- If you specify Alpha and any of the cross-validation name-value pair arguments ('CrossVal', 'CVPartition', 'Holdout', 'KFold', or 'Leaveout'), then the software returns an error.

The defaults are:

- `0.5*ones(size(X,1),1)` for one-class learning
- `zeros(size(X,1),1)` for two-class learning

Example: `'Alpha',0.1*ones(size(X,1),1)`

Data Types: double | single

'BoxConstraint' — Box constraint

1 (default) | positive scalar

Box constraint, specified as the comma-separated pair consisting of 'BoxConstraint' and a positive scalar.

For one-class learning, the software always sets the box constraint to 1.

Example: `'BoxConstraint',100`

Data Types: double | single

'CacheSize' — Cache size

1000 (default) | 'maximal' | positive scalar

Cache size, specified as the comma-separated pair consisting of `'CacheSize'` and `'maximal'` or a positive scalar.

If `CacheSize` is `'maximal'`, then the software reserves enough disk space to hold the entire n -by- n Gram matrix.

If `CacheSize` is a positive scalar, then the software reserves `CacheSize` megabytes of disk space for training the classifier.

Example: `'CacheSize','maximal'`

Data Types: `double` | `char` | `single`

'ClassNames' — Class names

categorical array | character array | logical vector | vector of numeric values | cell array of strings

Class names, specified as the comma-separated pair consisting of `'ClassNames'` and categorical or character array, logical or numeric vector, or cell array of strings. You must set `ClassNames` using the data type of `Y`.

The default is the distinct class names of `Y`.

If `Y` is a character array, then each element must correspond to one *row* of the array.

Use `ClassNames` to order the classes or to select a subset of classes for training.

Example: `'ClassNames',logical([0,1])`

'Cost' — Misclassification cost

square matrix | structure array

Misclassification cost, specified as the comma-separated pair consisting of `'Cost'` and a square matrix or structure. If you specify:

- The square matrix `Cost`, then `Cost(i,j)` is the cost of classifying a point into class `j` if its true class is `i`
- The structure `S`, then it must have two fields:
 - `S.ClassNames`, which contains the class names as a variable of the same data type as `Y`
 - `S.ClassificationCosts`, which contains the cost matrix with rows and columns ordered as in `S.ClassNames`

For two-class learning, if you specify a cost matrix, then the software updates the prior probabilities by incorporating the penalties described in the cost matrix. Subsequently, the cost matrix resets to the default. For more details, see “Algorithms” on page 21-1365.

The defaults are:

- For one-class learning, `Cost = 0`.
- For two-class learning, `Cost(i,j) = 1` if $i \neq j$, and `Cost(i,j) = 0` if $i = j$.

Example: `'Cost', [0,1;2,0]`

Data Types: `double` | `single` | `struct`

'Crossval' — Flag to train cross-validated classifier

`'off'` (default) | `'on'`

Flag to train a cross-validated classifier, specified as the comma-separated pair consisting of `'Crossval'` and a string.

If you specify `'on'`, then the software trains a cross-validated classifier with 10 folds.

You can override this cross-validation setting using one of the `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'` name-value pair arguments.

You can only use one of these four options at a time for creating a cross-validated model: `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'`.

Alternatively, cross-validate `SVMModel` later by passing it to `crossval`.

Example: `'Crossval', 'on'`

Data Types: `char`

'CVPartition' — Cross-validation partition

`[]` (default) | `cvpartition` partition object

Cross-validation partition, specified as the comma-separated pair consisting of `'CVPartition'` and a `cvpartition` partition object as created by `cvpartition`. The partition object specifies the type of cross-validation, and also the indexing for training and validation sets.

If you specify `CVPartition`, then you cannot specify any of `Holdout`, `KFold`, or `Leaveout`.

'DeltaGradientTolerance' — Tolerance for gradient difference

nonnegative scalar

Tolerance for the gradient difference between upper and lower violators obtained by Sequential Minimal Optimization (SMO) or Iterative Single Data Algorithm (ISDA), specified as the comma-separated pair consisting of `'DeltaGradientTolerance'` and a nonnegative scalar.

If `DeltaGradientTolerance` is 0, then the software does not use the tolerance for the gradient difference to check for optimization convergence.

The defaults are:

- `1e-3` if the solver is SMO (for example, you set `'Solver', 'SMO'`)
- `0` if the solver is ISDA (for example, you set `'Solver', 'ISDA'`)

Example: `'DeltaGapTolerance', 1e-2`

Data Types: `double` | `single`

'GapTolerance' — Feasibility gap tolerance`0` (default) | nonnegative scalar

Feasibility gap tolerance obtained by SMO or ISDA, specified as the comma-separated pair consisting of `'GapTolerance'` and a nonnegative scalar.

If `GapTolerance` is 0, then the software does not use the feasibility gap tolerance to check for optimization convergence.

Example: `'GapTolerance', 1e-2`

Data Types: `double` | `single`

'Holdout' — Fraction of data for holdout validation

scalar value in the range (0,1)

Fraction of data used for holdout validation, specified as the comma-separated pair consisting of `'Holdout'` and a scalar value in the range (0,1). If you specify `'Holdout', p`, then the software:

- 1 Randomly reserves $p*100\%$ of the data as validation data, and trains the model using the rest of the data
- 2 Stores the compact, trained model in `CVMdl.Trained`

If you specify `Holdout`, then you cannot specify any of `CVPartition`, `KFold`, or `Leaveout`.

Example: `'Holdout', 0.1`

Data Types: `double` | `single`

'IterationLimit' — Maximal number of numerical optimization iterations

1e6 (default) | positive integer

Maximal number of numerical optimization iterations, specified as the comma-separated pair consisting of `'IterationLimit'` and a positive integer.

The software returns a trained classifier regardless of whether the optimization routine successfully converges.

Example: `'IterationLimit', 1e8`

Data Types: `double` | `single`

'KernelFunction' — Kernel function

string

Kernel function used to compute the Gram matrix, specified as the comma-separated pair consisting of `'KernelFunction'` and a string.

This table summarizes the available options for setting a kernel function.

Value	Description	Formula
<code>'gaussian'</code> or <code>'rbf'</code>	Gaussian or Radial Basis Function (RBF) kernel, default for one-class learning	$G(x_1, x_2) = \exp\left(-\ x_1 - x_2\ ^2\right)$
<code>'linear'</code>	Linear kernel, default for two-class learning	$G(x_1, x_2) = x_1'x_2$
<code>'polynomial'</code>	Polynomial kernel. Use <code>'PolynomialOrder'</code> , <code>polyOrder</code> to specify a polynomial kernel of order <code>polyOrder</code> .	$G(x_1, x_2) = (1 + x_1'x_2)^p$

You can set your own kernel function, for example, `kernel`, by setting `'KernelFunction', 'kernel'`. `kernel` must have the following form:

```
function G = kernel(U,V)
```

where:

- U is an m -by- p matrix.
- V is an n -by- p matrix.
- G is an m -by- n Gram matrix of the rows of U and V.

And `kernel.m` must be on the MATLAB path.

It is good practice to avoid using generic names for kernel functions. For example, call a sigmoid kernel function `'mysigmoid'` rather than `'sigmoid'`.

Example: `'KernelFunction', 'gaussian'`

Data Types: `char`

'KernelOffset' — Kernel offset parameter

nonnegative scalar

Kernel offset parameter, specified as the comma-separated pair consisting of `'KernelOffset'` and a nonnegative scalar.

The software adds `KernelOffset` to each element of the Gram matrix.

The defaults are:

- 0 if the solver is SMO (for example, you set `'Solver', 'SMO'`)
- 0.1 if the solver is ISDA (for example, you set `'Solver', 'ISDA'`)

Example: `'KernelOffset', 0`

Data Types: `double` | `single`

'KernelScale' — Kernel scale parameter

1 (default) | `'auto'` | positive scalar

Kernel scale parameter, specified as the comma-separated pair consisting of `'KernelScale'` and `'auto'` or a positive scalar.

- If `KernelFunction` is `'gaussian'` (`'rbf'`), `'linear'`, or `'polyomial'`, then the software divides all elements of the predictor matrix X by the value of `KernelScale`. Then, the software applies the appropriate kernel norm to compute the Gram matrix.

- If you specify 'auto', then the software uses a heuristic procedure to select the scale value. The heuristic procedure uses subsampling. Therefore, to reproduce results, set a random number seed using `rng` before training the classifier.
- If you specify `KernelScale` and your own kernel function, for example, `kernel`, using 'KernelFunction', 'kernel', then the software displays an error. You must apply scaling within `kernel`.

Example: 'KernelScale', 'auto'

Data Types: double | single | char

'KFold' — Number of folds

10 (default) | positive integer value

Number of folds to use in a cross-validated classifier, specified as the comma-separated pair consisting of 'KFold' and a positive integer value.

You can only use one of these four options at a time to create a cross-validated model: 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'.

Example: 'KFold', 8

Data Types: single | double

'KKTolerance' — Karush-Kuhn-Tucker complementarity conditions violation tolerance

nonnegative scalar

Karush-Kuhn-Tucker (KKT) complementarity conditions violation tolerance, specified as the comma-separated pair consisting of 'KKTolerance' and a nonnegative scalar.

If `KKTolerance` is 0, then the software does not use the KKT complementarity conditions violation tolerance to check for optimization convergence.

The defaults are:

- 0 if the solver is SMO (for example, you set 'Solver', 'SMO')
- 1e-3 if the solver is ISDA (for example, you set 'Solver', 'ISDA')

Example: 'KKTolerance', 1e-2

Data Types: double | single

'Leaveout' — Leave-one-out cross-validation flag

'off' (default) | 'on'

Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of `'Leaveout'` and either `'on'` or `'off'`. If you specify `'on'`, then the software implements leave-one-out cross validation.

If you use `'Leaveout'`, you cannot use these `'CVPartition'`, `'Holdout'`, or `'KFold'` name-value pair arguments.

Example: `'Leaveout','on'`

Data Types: `char`

'Nu' — # parameter for one-class learning

0.5 (default) | positive scalar

`ν` parameter for one-class learning, specified as the comma-separated pair consisting of `'Nu'` and a positive scalar. `NU` must be greater than 0 and at most 1.

Set `Nu` to control the tradeoff between ensuring most training examples are in the positive class and minimizing the weights in the score function.

Example: `'Nu',0.25`

Data Types: `double` | `single`

'NumPrint' — Number of iterations between optimization diagnostic message output

1000 (default) | nonnegative integer

Number of iterations between optimization diagnostic message output, specified as the comma-separated pair consisting of `'NumPrint'` and a nonnegative integer.

If you use `'Verbose',1` and `'NumPrint',numprint`, then the software displays all optimization diagnostic messages from SMO and ISDA every `numprint` iterations in the Command Window.

Example: `'NumPrint',500`

Data Types: `double` | `single`

'OutlierFraction' — Expected proportion of outliers in training data

0 (default) | nonnegative scalar

Expected proportion of outliers in the training data, specified as the comma-separated pair consisting of `'OutlierFraction'` and a nonnegative scalar. `OutlierFraction` must be at least 0 and less than 1.

If you set `'OutlierFraction'`, `outlierfraction`, where `outlierfraction` is a value greater than 0, then:

- For two-class learning, the software implements *robust learning*. In other words, the software attempts to remove $100 \times \text{outlierfraction}\%$ of the observations when the optimization algorithm converges. The removed observations correspond to gradients that are large in magnitude.
- For one-class learning, the software finds an appropriate bias term such that `outlierfraction` of the observations in the training set have negative scores.

Example: `'OutlierFraction',0.01`

Data Types: `double` | `single`

'PolynomialOrder' — Polynomial kernel function order

3 (default) | positive integer

Polynomial kernel function order, specified as the comma-separated pair consisting of `'PolynomialOrder'` and a positive integer.

If you set `'PolynomialOrder'` and `KernelFunction` is not `'polynomial'`, then the software displays an error.

Example: `'PolynomialOrder',2`

Data Types: `double` | `single`

'PredictorNames' — Predictor variable names

`{'x1','x2',...}` (default) | cell array of strings

Predictor variable names, specified as the comma-separated pair consisting of `'PredictorNames'` and a cell array of strings containing the names for the predictor variables, in the order in which they appear in `X`.

Example: `'PredictorNames',{'PedalWidth','PedalLength'}`

Data Types: `cell`

'Prior' — Prior probabilities

`'empirical'` (default) | `'uniform'` | numeric vector | structure

Prior probabilities for each class, specified as the comma-separated pair consisting of `'Prior'` and a string, numeric vector, or a structure.

This table summarizes the available options for setting prior probabilities.

Value	Description
'empirical'	The class prior probabilities are the class relative frequencies in Y .
'uniform'	All class prior probabilities are equal to $1/K$, where K is the number of classes.
numeric vector	Each element is a class prior probability. Order the elements according to <code>SVMModel.ClassNames</code> or specify the order using the <code>ClassNames</code> name-value pair argument. The software normalizes the elements such that they sum to 1.
structure	A structure S with two fields: <ul style="list-style-type: none"> • <code>S.ClassNames</code> contains the class names as a variable of the same type as Y. • <code>S.ClassProbs</code> contains a vector of corresponding prior probabilities. The software normalizes the elements such that they sum to 1.

For two-class learning, if you specify a cost matrix, then the software updates the prior probabilities by incorporating the penalties described in the cost matrix. For more details, see “Algorithms” on page 21-1365.

Example: `struct('ClassNames',{{'setosa','versicolor'}},'ClassProbs',[1,2])`

Data Types: char | double | single | struct

'ResponseName' — Response variable name

'Y' (default) | string

Response variable name, specified as the comma-separated pair consisting of 'ResponseName' and a string containing the name of the response variable Y .

Example: `'ResponseName','IrisType'`

Data Types: char

'ScoreTransform' — Score transform function

'none' (default) | 'doublelogit' | 'invlogit' | 'ismax' | 'logit' | 'sign' | 'symmetric' | 'symmetriclogit' | 'symmetricismax' | function handle

Score transform function, specified as the comma-separated pair consisting of 'ScoreTransform' and a string or function handle.

- If the value is a string, then it must correspond to a built-in function. This table summarizes the available, built-in functions.

String	Formula
'doublelogit'	$1/(1 + e^{-2x})$
'invlogit'	$\log(x / (1-x))$
'ismax'	Set the score for the class with the largest score to 1, and scores for all other classes to 0.
'logit'	$1/(1 + e^{-x})$
'none'	x (no transformation)
'sign'	-1 for $x < 0$ 0 for $x = 0$ 1 for $x > 0$
'symmetric'	$2x - 1$
'symmetriclogit'	$2/(1 + e^{-x}) - 1$
'symmetricismax'	Set the score for the class with the largest score to 1, and scores for all other classes to -1.

- For a MATLAB function, or a function that you define, enter its function handle.

```
SVMModel.ScoreTransform = @function;
```

function should accept a matrix (the original scores) and return a matrix of the same size (the transformed scores).

Example: 'ScoreTransform', 'sign'

Data Types: char | function_handle

'ShrinkagePeriod' — Number of iterations between movement of observations from active to inactive set

0 (default) | nonnegative integer

Number of iterations between the movement of observations from the active to inactive set, specified as the comma-separated pair consisting of 'ShrinkagePeriod' and a nonnegative integer.

If you set 'ShrinkagePeriod',0, then the software does not shrink the active set.

Example: 'ShrinkagePeriod',1000

Data Types: double | single

'Solver' — Optimization routine

'ISDA' | 'L1QP' | 'SMO'

Optimization routine, specified as a string.

This table summarizes the available optimization routine options.

Value	Description
'ISDA'	Iterative Single Data Algorithm
'L1QP'	Uses quadprog to implement <i>L1</i> soft-margin minimization by quadratic programming. This option requires an Optimization Toolbox license.
'SMO'	Sequential Minimal Optimization

The defaults are:

- 'ISDA' if you set 'OutlierFraction' to a positive value and for two-class learning
- 'SMO' otherwise

Example: 'Solver','ISDA'

Data Types: char

'Standardize' — Flag to standardize predictors

false (default) | true

Flag to standardize the predictors, specified as the comma-separated pair consisting of `'Standardize'` and `true` (1) or `false` (0).

If you set `'Standardize', true`, then the software centers and scales each column of the predictor data (X) by the column mean and standard deviation, respectively. It is good practice to standardize the predictor data.

Example: `'Standardize', true`

Data Types: `logical`

'Verbose' — Verbosity level

0 (default) | 1 | 2

Verbosity level, specified as the comma-separated pair consisting of `'Verbose'` and either 0, 1, or 2. `Verbose` controls the amount of optimization information that the software displays in the Command Window and saves as a structure to `SVMModel.ConvergenceInfo.History`.

This table summarizes the available verbosity level options.

Value	Description
0	The software does not display or save convergence information.
1	The software displays diagnostic messages and saves convergence criteria every <code>numprint</code> iterations, where <code>numprint</code> is the value of the name-value pair argument <code>'NumPrint'</code> .
2	The software displays diagnostic messages and saves convergence criteria at every iteration.

Example: `'Verbose', 1`

Data Types: `double` | `single`

'Weights' — Observation weights

`ones(size(X,1),1)` (default) | numeric vector

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and a numeric vector.

The size of `Weights` must equal the number of rows of `X`. The software weighs the observations in each row of `X` with the corresponding weight in `Weights`.

The software normalizes `Weights` to sum up to the value of the prior probability in the respective class.

Data Types: `double` | `single`

Output Arguments

SVMMODEL — Trained SVM classifier

`ClassificationSVM` classifier | `ClassificationPartitionedModel` cross-validated classifier

Trained SVM classifier, returned as a `ClassificationSVM` classifier or `ClassificationPartitionedModel` cross-validated classifier.

If you set any of the name-value pair arguments `KFold`, `Holdout`, `Leaveout`, `CrossVal`, or `CVPartition`, then `SVMMODEL` is a `ClassificationPartitionedModel` cross-validated classifier. Otherwise, `SVMMODEL` is a `ClassificationSVM` classifier.

To reference properties of `SVMMODEL`, use dot notation. For example, enter `SVMMODEL.Alpha` in the Command Window to display the trained Lagrange multipliers.

Limitations

- The software trains SVM classifiers for one- or two-class learning applications.

More About

Box Constraint

A parameter that controls the maximum penalty imposed on margin-violating observations, and aids in preventing overfitting (regularization).

If you increase the box constraint, then the SVM classifier assigns fewer support vectors. However, increasing the box constraint can lead to longer training times.

Gram Matrix

The Gram matrix of a set of n vectors $\{x_1, \dots, x_n; x_j \in R^p\}$ is an n -by- n matrix with element (j, k) defined as $G(x_j, x_k) = \langle \#(x_j), \#(x_k) \rangle$, an inner product of the transformed predictors using the kernel function $\#$.

For nonlinear SVM, the algorithm forms a Gram matrix using the predictor matrix columns. The dual formalization replaces the inner product of the predictors with corresponding elements of the resulting Gram matrix (called the “kernel trick”). Subsequently, nonlinear SVM operates in the transformed predictor space to find a separating hyperplane.

Karush-Kuhn-Tucker Complementarity Conditions

KKT complementarity conditions are optimization constraints required for optimal nonlinear programming solutions.

In SVM, the KKT complementarity conditions are

$$\begin{cases} \alpha_j [y_j (w' \phi(x_j) + b) - 1 + \xi_j] = 0 \\ \xi_j (C - \alpha_j) = 0 \end{cases}$$

for all $j = 1, \dots, n$, where w_j is a weight, $\#$ is a kernel function (see “Gram matrix”), and ξ_j is a slack variable. If the classes are perfectly separable, then $\xi_j = 0$ for all $j = 1, \dots, n$.

One-Class Learning

One-class learning, or unsupervised SVM, aims at separating data from the origin in the high-dimensional, predictor space (not the original predictor space), and is an algorithm used for outlier detection.

The algorithm resembles that of “SVM for binary classification”. The objective is to minimize dual expression

$$0.5 \sum_{j,k} \alpha_j \alpha_k G(x_j, x_k)$$

with respect to $\alpha_1, \dots, \alpha_n$, subject to

$$\sum \alpha_j = n\nu$$

and $0 \leq \alpha_j \leq 1$ for all $j = 1, \dots, n$. $G(x_j, x_k)$ is element (j, k) of the “Gram matrix”.

A small value of ν leads to fewer support vectors, and, therefore, a smooth, crude decision boundary. A large value of ν leads to more support vectors, and therefore, a curvy, flexible decision boundary. The optimal value of ν should be large enough to capture the data complexity and small enough to avoid overtraining. Also, $0 < \nu \leq 1$.

For more details, see “[3]”.

Support Vector

Support vectors are observations corresponding to strictly positive estimates of $\alpha_1, \dots, \alpha_n$.

SVM classifiers that yield fewer support vectors for a given training set are more desirable.

Support Vector Machines for Binary Classification

The SVM binary classification algorithm searches for an optimal hyperplane that separates the data into two classes. For separable classes, the optimal hyperplane maximizes a *margin* (space that does not contain any observations) surrounding itself, which creates boundaries for the positive and negative classes. For inseparable classes, the objective is the same, but the algorithm imposes a penalty on the length of the margin for every observation that is on the wrong side of its class boundary.

The linear SVM score function is

$$f(x) = x'\beta + \beta_0,$$

where:

- x is an observation (corresponding to a row of X).

- The vector β contains the coefficients that define an orthogonal vector to the hyperplane (corresponding to `SVMModel.Beta`). For separable data, the optimal margin length is $2 / \|\beta\|$.
- β_0 is the bias term (corresponding to `SVMModel.Bias`).

The root of $f(x)$ for particular coefficients defines a hyperplane. For a particular hyperplane, $f(z)$ is the distance from point z to the hyperplane.

An SVM classifier searches for the maximum margin length, while keeping observations in the positive ($y = 1$) and negative ($y = -1$) classes separate. Therefore:

- For separable classes, the objective is to minimize $\|\beta\|$ with respect to the β and β_0 subject to $y_j f(x_j) \geq 1$, for all $j = 1, \dots, n$. This is the *primal* formalization for separable classes.
- For inseparable classes, SVM uses slack variables (ξ_j) to penalize the objective function for observations that cross the margin boundary for their class. $\xi_j = 0$ for observations that do not cross the margin boundary for their class, otherwise $\xi_j \geq 0$.

The objective is to minimize $0.5\|\beta\|^2 + C\sum \xi_j$ with respect to the β , β_0 , and ξ_j subject to $y_j f(x_j) \geq 1 - \xi_j$ and $\xi_j \geq 0$ for all $j = 1, \dots, n$, and for a positive scalar “box constraint” C . This is the primal formalization for inseparable classes.

SVM uses the Lagrange multipliers method to optimize the objective. This introduces n coefficients a_1, \dots, a_n (corresponding to `SVMModel.Alpha`). The dual formalizations for linear SVM are:

- For separable classes, minimize

$$0.5 \sum_{j=1}^n \sum_{k=1}^n \alpha_j \alpha_k y_j y_k x_j' x_k - \sum_{j=1}^n \alpha_j$$

with respect to a_1, \dots, a_n , subject to $\sum \alpha_j y_j = 0$, $a_j \geq 0$ for all $j = 1, \dots, n$, and “Karush-Kuhn-Tucker (KKT) complementarity conditions”.

- For inseparable classes, the objective is the same as for separable classes, except for the additional condition $0 \leq \alpha_j \leq C$ for all $j = 1, \dots, n$.

The resulting score function is

$$f(x) = \sum_{j=1}^n \alpha_j y_j x' x_j + b.$$

The score function is free of the estimate of β as a result of the primal formalization.

In some cases, there is a nonlinear boundary separating the classes. *Nonlinear SVM* works in a transformed predictor space to find an optimal, separating hyperplane.

The dual formalization for nonlinear SVM is

$$0.5 \sum_{j=1}^n \sum_{k=1}^n \alpha_j \alpha_k y_j y_k G(x_j, x_k) - \sum_{j=1}^n \alpha_j$$

with respect to $\alpha_1, \dots, \alpha_n$, subject to $\sum \alpha_j y_j = 0$, $0 \leq \alpha_j \leq C$ for all $j = 1, \dots, n$, and the KKT complementarity conditions. $G(x_k, x_j)$ are elements of the “Gram matrix”. The resulting score function is

$$f(x) = \sum_{j=1}^n \alpha_j y_j G(x, x_j) + b.$$

For more details, see “Understanding Support Vector Machines”, “[1]”, and “[2]”.

Tips

- For one-class learning:
 - The default setting for the name-value pair argument 'Alpha' can lead to long training times. To speed up training, set Alpha to a vector mostly composed of 0s.
 - Set the name-value pair argument Nu to a value closer to 0 to yield fewer support vectors, and, therefore, a smoother, but crude decision boundary
- Sparsity in support vectors is a desirable property of an SVM classifier. To decrease the number of support vectors, set BoxConstraint to a large value. This also increases the training time.

- For large data sets, try optimizing the cache size. This can have a significant impact on the training speed.
- If the support vector set is much less than the number of observations in the training set, then you might significantly speed up convergence by shrinking the active-set using the name-value pair argument 'ShrinkagePeriod'. It is good practice to use 'ShrinkagePeriod', 1000.

Algorithms

- All solvers implement $L1$ soft-margin minimization.
- `fitcsvm` and `svmtrain` use, among other algorithms, SMO for optimization. The software implements SMO differently between the two functions, but numerical studies show that there is sensible agreement in the results.
- For one-class learning, the software estimates the Lagrange multipliers, $\alpha_1, \dots, \alpha_n$, such that

$$\sum_{j=1}^n \alpha_j = nv.$$

- For two-class learning, if you specify a cost matrix C , then the software updates the class prior probabilities (p) to p_c by incorporating the penalties described in C . The formula for the updated prior probability vector is

$$p_c = \frac{p'C}{\sum p'C}.$$

Subsequently, the software resets the cost matrix to the default:

$$C = \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}.$$

- If you set 'Standardize', true when you train the SVM classifier using `fitcsvm`, then the software trains the classifier using the standardized predictor matrix, but stores the unstandardized data in the classifier property X . However, if you standardize the data, then the data size in memory doubles until optimization ends.
- If you set 'Standardize', true and any of 'Cost', 'Prior', or 'Weights', then the software standardizes the predictors using their corresponding weighted means and weighted standard deviations.

- Let p be the proportion of outliers you expect in the training data. If you use 'OutlierFraction', p when you train the SVM classifier using `fitcsvm`, then:
 - For one-class learning, the software trains the bias term such that 100 p % of the observations in the training data have negative scores.
 - The software implements *robust learning* for two-class learning. In other words, the software attempts to remove 100 p % of the observations when the optimization algorithm converges. The removed observations correspond to gradients that are large in magnitude.

fitctree

Fit classification tree

Syntax

```
tree = fitctree(X,Y)
tree = fitctree(X,Y,Name,Value)
```

Description

`tree = fitctree(X,Y)` returns a classification tree based on the input variables (also known as predictors, features, or attributes) `X` and output (response or labels) `Y`. The returned tree is a binary tree, where each branching node is split based on the values of a column of `X`.

`tree = fitctree(X,Y,Name,Value)` fits a tree with additional options specified by one or more name-value pair arguments. For example, you can specify the algorithm used to find the best split on a categorical predictor, grow a cross-validated tree, or hold out a fraction of the input data for validation.

Examples

Grow a Classification Tree

Construct a classification tree using sample data.

Construct a classification tree using the `ionosphere` data set.

```
load ionosphere
tc = fitctree(X,Y)
```

```
tc =
    ClassificationTree
        PredictorNames: {1x34 cell}
        ResponseName: 'Y'
```

```
      ClassNames: {'b' 'g'}
      ScoreTransform: 'none'
      CategoricalPredictors: []
      NumObservations: 351
```

Input Arguments

X — Predictor values

matrix of floating-point values

Predictor values, specified as a matrix of floating-point values.

`fitctree` considers NaN values in X as missing values. `fitctree` does not use observations with all missing values for X in the fit. `fitctree` uses observations with some missing values for X to find splits on variables for which these observations have valid values.

Data Types: `single` | `double`

Y — Class labels

numeric vector | categorical vector | logical vector | character array | cell array of strings

Class labels, specified as a numeric vector, categorical vector, logical vector, character array, or cell array of strings.

Each row of X represents the classification of the corresponding row of X. For numeric Y, consider using `fitrtree` instead. `fitctree` considers NaN, '' (empty string), and <undefined> values in Y to be missing values.

`fitctree` does not use observations with missing values for Y in the fit.

Data Types: `single` | `double` | `char` | `logical` | `cell`

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Example: `'CrossVal', 'on', 'MinLeafSize', 40` specifies a cross-validated classification tree with a minimum of 40 observations per leaf.

'AlgorithmForCategorical' — Algorithm for best categorical predictor split

`'Exact' | 'PullLeft' | 'PCA' | 'OVAbyClass'`

Algorithm to find the best split on a categorical predictor with C categories for data and $K \geq 3$ classes, specified as the comma-separated pair consisting of `'AlgorithmForCategorical'` and one of the following.

`'Exact'`

Consider all $2^{C-1} - 1$ combinations.

`'PullLeft'`

Start with all C categories on the right branch. Consider moving each category to the left branch as it achieves the minimum impurity for the K classes among the remaining categories. From this sequence, choose the split that has the lowest impurity.

`'PCA'`

Compute a score for each category using the inner product between the first principal component of a weighted covariance matrix (of the centered class probability matrix) and the vector of class probabilities for that category. Sort the scores in ascending order, and consider all $C - 1$ splits.

`'OVAbyClass'`

Start with all C categories on the right branch. For each class, order the categories based on their probability for that class. For the first class, consider moving each category to the left branch in order, recording the impurity criterion at each move. Repeat for the remaining classes. From this sequence, choose the split that has the minimum impurity.

`fitctree` automatically selects the optimal subset of algorithms for each split using the known number of classes and levels of a categorical predictor. For $K = 2$ classes, `fitctree` always performs the exact search. Use the `'AlgorithmForCategorical'` name-value pair argument to specify a particular algorithm.

Example: 'AlgorithmForCategorical', 'PCA'

'CategoricalPredictors' — Categorical predictors list

numeric or logical vector | cell array of strings | character matrix | 'all'

Categorical predictors list, specified as the comma-separated pair consisting of 'CategoricalPredictors' and one of the following:

- A numeric vector with indices from 1 through p , where p is the number of columns of X .
- A logical vector of length p , where a `true` entry means that the corresponding column of X is a categorical variable.
- A cell array of strings, where each element in the array is the name of a predictor variable. The names must match entries in `PredictorNames` values.
- A character matrix, where each row of the matrix is a name of a predictor variable. The names must match entries in `PredictorNames` values. Pad the names with extra blanks so each row of the character matrix has the same length.
- 'all', meaning all predictors are categorical.

Example: 'CategoricalPredictors', 'all'

Data Types: single | double | char

'ClassNames' — Class names

numeric vector | categorical vector | logical vector | character array | cell array of strings

Class names, specified as the comma-separated pair consisting of 'ClassNames' and an array representing the class names. Use the same data type as the values that exist in Y .

Use `ClassNames` to order the classes or to select a subset of classes for training. The default is the class names that exist in Y .

Data Types: single | double | char | logical | cell

'Cost' — Cost of misclassification

square matrix | structure

Cost of misclassification of a point, specified as the comma-separated pair consisting of 'Cost' and one of the following:

- Square matrix, where $\text{Cost}(i, j)$ is the cost of classifying a point into class j if its true class is i .

- Structure `S` having two fields: `S.ClassNames` containing the group names as a variable of the same data type as `Y`, and `S.ClassificationCosts` containing the cost matrix.

The default is $\text{Cost}(i, j) = 1$ if $i \neq j$, and $\text{Cost}(i, j) = 0$ if $i = j$.

Data Types: `single` | `double` | `struct`

'CrossVal' — Flag to grow cross-validated decision tree

'off' (default) | 'on'

Flag to grow a cross-validated decision tree, specified as the comma-separated pair consisting of 'CrossVal' and 'on' or 'off'.

If 'on', `fitctree` grows a cross-validated decision tree with 10 folds. You can override this cross-validation setting using one of the 'KFold', 'Holdout', 'Leaveout', or 'CVPartition' name-value pair arguments. Note that you can only use one of these four arguments at a time when creating a cross-validated tree.

Alternatively, cross validate tree later using the `crossval` method.

Example: 'CrossVal', 'on'

'CVPartition' — Partition for cross-validated tree

`cvpartition` object

Partition to use in a cross-validated tree, specified as the comma-separated pair consisting of 'CVPartition' and an object created using `cvpartition`.

If you use 'CVPartition', you cannot use any of the 'KFold', 'Holdout', or 'Leaveout' name-value pair arguments.

'Holdout' — Fraction of data for holdout validation

0 (default) | scalar value in the range [0, 1]

Fraction of data used for holdout validation, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range [0, 1]. Holdout validation tests the specified fraction of the data, and uses the rest of the data for training.

If you use 'Holdout', you cannot use any of the 'CVPartition', 'KFold', or 'Leaveout' name-value pair arguments.

Example: 'Holdout', 0.1

Data Types: `single` | `double`

'KFold' — Number of folds

10 (default) | positive integer value

Number of folds to use in a cross-validated tree, specified as the comma-separated pair consisting of 'KFold' and a positive integer value.

If you use 'KFold', you cannot use any of the 'CVPartition', 'Holdout', or 'Leaveout' name-value pair arguments.

Example: 'KFold',8

Data Types: `single` | `double`

'Leaveout' — Leave-one-out cross-validation flag

'off' (default) | 'on'

Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of 'Leaveout' and 'on' or 'off'. Specify 'on' to use leave-one-out cross-validation.

If you use 'Leaveout', you cannot use any of the 'CVPartition', 'Holdout', or 'KFold' name-value pair arguments.

Example: 'Leaveout', 'on'

'MaxNumCategories' — Maximum category levels

10 (default) | nonnegative scalar value

Maximum category levels, specified as the comma-separated pair consisting of 'MaxNumCategories' and a nonnegative scalar value. `fitctree` splits a categorical predictor using the exact search algorithm if the predictor has at most `MaxNumCategories` levels in the split node. Otherwise, `fitctree` finds the best categorical split using one of the inexact algorithms.

Passing a small value can lead to loss of accuracy and passing a large value can increase computation time and memory overload.

Example: 'MaxNumCategories',8

'MergeLeaves' — Leaf merge flag

'on' (default) | 'off'

Leaf merge flag, specified as the comma-separated pair consisting of 'MergeLeaves' and 'on' or 'off'.

If `MergeLeaves` is 'on', then `fitctree`:

- Merges leaves that originate from the same parent node, and that yields a sum of risk values greater or equal to the risk associated with the parent node
- Estimates the optimal sequence of pruned subtrees, but does not prune the classification tree

Otherwise, `fitctree` does not merge leaves.

Example: 'MergeLeaves', 'off'

'MinLeafSize' — Minimum number of leaf node observations

1 (default) | positive integer value

Minimum number of leaf node observations, specified as the comma-separated pair consisting of 'MinLeafSize' and a positive integer value. Each leaf has at least `MinLeafSize` observations per tree leaf. If you supply both `MinParentSize` and `MinLeafSize`, `fitctree` uses the setting that gives larger leaves: `MinParentSize = max(MinParentSize, 2*MinLeafSize)`.

Example: 'MinLeafSize', 3

Data Types: single | double

'MinParentSize' — Minimum number of branch node observations

10 (default) | positive integer value

Minimum number of branch node observations, specified as the comma-separated pair consisting of 'MinParentSize' and a positive integer value. Each branch node in the tree has at least `MinParentSize` observations. If you supply both `MinParentSize` and `MinLeafSize`, `fitctree` uses the setting that gives larger leaves: `MinParentSize = max(MinParentSize, 2*MinLeafSize)`.

Example: 'MinParentSize', 8

Data Types: single | double

'NumVariablesToSample' — Number of predictors for split

'all' | positive integer value

Number of predictors to select at random for each split, specified as the comma-separated pair consisting of 'NumVariablesToSample' and a positive integer value. You can also specify 'all' to use all available predictors.

Example: `'NumVariablesToSample',3`

Data Types: `single` | `double`

'PredictorNames' — Predictor variable names

`{'x1','x2',...}` (default) | cell array of strings

Predictor variable names, specified as the comma-separated pair consisting of `'PredictorNames'` and a cell array of strings containing the names for the predictor variables, in the order in which they appear in `X`.

'Prior' — Prior probabilities

`'empirical'` (default) | `'uniform'` | vector of scalar values | structure

Prior probabilities for each class, specified as the comma-separated pair consisting of `'Prior'` and one of the following.

- A string:
 - `'empirical'` determines class probabilities from class frequencies in `Y`. If you pass observation weights, `fitctree` uses the weights to compute the class probabilities.
 - `'uniform'` sets all class probabilities equal.
- A vector (one scalar value for each class)
- A structure `S` with two fields:
 - `S.ClassNames` containing the class names as a variable of the same type as `Y`
 - `S.ClassProbs` containing a vector of corresponding probabilities

If you set values for both `weights` and `prior`, the weights are renormalized to add up to the value of the prior probability in the respective class.

Example: `'Prior','uniform'`

'Prune' — Flag to estimate optimal sequence of pruned subtrees

`'on'` (default) | `'off'`

Flag to estimate the optimal sequence of pruned subtrees, specified as the comma-separated pair consisting of `'Prune'` and `'on'` or `'off'`.

If `Prune` is `'on'`, then `fitctree` grows the classification tree and estimates the optimal sequence of pruned subtrees, but does not prune the classification tree. Otherwise,

`fitctree` grows the classification tree without estimating the optimal sequence of pruned subtrees.

To prune a trained classification tree, pass the classification tree to `prune`.

Example: `'Prune', 'off'`

'PruneCriterion' — Pruning criterion

`'error'` (default) | `'impurity'`

Pruning criterion, specified as the comma-separated pair consisting of `'PruneCriterion'` and `'error'` or `'impurity'`.

Example: `'PruneCriterion', 'impurity'`

'ResponseName' — Response variable name

`'Y'` (default) | string

Response variable name, specified as the comma-separated pair consisting of `'ResponseName'` and a string representing the name of the response variable Y.

Example: `'ResponseName', 'Response'`

'ScoreTransform' — Score transform function

`'none'` | `'symmetric'` | `'invlogit'` | `'ismax'` | function handle | ...

Score transform function, specified as the comma-separated pair consisting of `'ScoreTransform'` and a function handle for transforming scores. Your function should accept a matrix (the original scores) and return a matrix of the same size (the transformed scores).

Alternatively, you can specify one of the following strings representing a built-in transformation function.

String	Formula
<code>'doublelogit'</code>	$1/(1 + e^{-2x})$
<code>'invlogit'</code>	$\log(x / (1-x))$
<code>'ismax'</code>	Set the score for the class with the largest score to 1, and scores for all other classes to 0.
<code>'logit'</code>	$1/(1 + e^{-x})$
<code>'none'</code>	x (no transformation)

String	Formula
'sign'	-1 for $x < 0$ 0 for $x = 0$ 1 for $x > 0$
'symmetric'	$2x - 1$
'symmetriclogit'	$2/(1 + e^{-x}) - 1$
'symmetricismax'	Set the score for the class with the largest score to 1, and scores for all other classes to -1.

Example: 'ScoreTransform', 'logit'

'SplitCriterion' — Split criterion

'gdi' (default) | 'twoing' | 'deviance'

Split criterion, specified as the comma-separated pair consisting of 'SplitCriterion' and 'gdi' (Gini's diversity index), 'twoing' for the twoing rule, or 'deviance' for maximum deviance reduction (also known as cross entropy).

Example: 'SplitCriterion', 'deviance'

'Surrogate' — Surrogate decision splits flag

'off' | 'on' | 'all' | positive integer value

Surrogate decision splits flag, specified as the comma-separated pair consisting of 'Surrogate' and 'on', 'off', 'all', or a positive integer value.

- When set to 'on', `fitctree` finds at most 10 surrogate splits at each branch node.
- When set to 'all', `fitctree` finds all surrogate splits at each branch node. The 'all' setting can use considerable time and memory.
- When set to a positive integer value, `fitctree` finds at most the specified number of surrogate splits at each branch node.

Use surrogate splits to improve the accuracy of predictions for data with missing values. The setting also lets you compute measures of predictive association between predictors.

Example: 'Surrogate', 'on'

'Weights' — Observation weights

`ones(size(x,1),1)` (default) | vector of scalar values

Vector of observation weights, specified as the comma-separated pair consisting of 'Weights' and a vector of scalar values. The length of `Weights` equals the number of rows in `X`. `fitctree` normalizes the weights in each class to add up to the value of the prior probability of the class.

Data Types: `single` | `double`

Output Arguments

tree — Classification tree

classification tree object

Classification tree, returned as a classification tree object.

Using the 'CrossVal', 'KFold', 'Holdout', 'Leaveout', or 'CVPartition' options results in a tree of class `ClassificationPartitionedModel`. You cannot use a partitioned tree for prediction, so this kind of tree does not have a `predict` method. Instead, use `kfoldpredict` to predict responses for observations not used for training.

Otherwise, `tree` is of class `ClassificationTree`, and you can use the `predict` method to make predictions.

More About

Impurity and Node Error

`ClassificationTree` splits nodes based on either *impurity* or *node error*.

Impurity means one of several things, depending on your choice of the `SplitCriterion` name-value pair argument:

- Gini's Diversity Index (`gdi`) — The Gini index of a node is

$$1 - \sum_i p^2(i),$$

where the sum is over the classes i at the node, and $p(i)$ is the observed fraction of classes with class i that reach the node. A node with just one class (a *pure* node) has

Gini index 0; otherwise the Gini index is positive. So the Gini index is a measure of node impurity.

- Deviance ('deviance') — With $p(i)$ defined the same as for the Gini index, the deviance of a node is

$$-\sum_i p(i) \log p(i).$$

A pure node has deviance 0; otherwise, the deviance is positive.

- Twoing rule ('twoing') — Twoing is not a purity measure of a node, but is a different measure for deciding how to split a node. Let $L(i)$ denote the fraction of members of class i in the left child node after a split, and $R(i)$ denote the fraction of members of class i in the right child node after a split. Choose the split criterion to maximize

$$P(L)P(R) \left(\sum_i |L(i) - R(i)| \right)^2,$$

where $P(L)$ and $P(R)$ are the fractions of observations that split to the left and right respectively. If the expression is large, the split made each child node purer. Similarly, if the expression is small, the split made each child node similar to each other, and hence similar to the parent node, and so the split did not increase node purity.

- Node error — The node error is the fraction of misclassified classes at a node. If j is the class with the largest number of training samples at a node, the node error is $1 - p(j)$.

Tips

By default, Prune is 'on'. However, this specification does not prune the classification tree. To prune a trained classification tree, pass the classification tree to `prune`.

Algorithms

If MergeLeaves is 'on' and PruneCriterion is 'error' (which are the default values for these name-value pair arguments), then the software applies pruning only to the leaves and by using classification error. This specification amounts to merging leaves that share the most popular class per leaf.

fitglm

Create generalized linear regression model

Syntax

```
mdl = fitglm(tbl)
mdl = fitglm(X,y)
mdl = fitglm( ____,modelspec)
mdl = fitglm( ____,Name,Value)
```

Description

`mdl = fitglm(tbl)` returns a generalized linear model fit to variables in the table or dataset array `tbl`. By default, `fitglm` takes the last variable as the response variable.

`mdl = fitglm(X,y)` returns a generalized linear model of the responses `y`, fit to the data matrix `X`.

`mdl = fitglm(____,modelspec)` returns a generalized linear model of the type you specify in `modelspec`.

`mdl = fitglm(____,Name,Value)` returns a generalized linear model with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify which variables are categorical, the distribution of the response variable, and the link function to use.

Examples

Fit a Logistic Regression Model

Make a logistic binomial model of the probability of smoking as a function of age, weight, and sex, using a two-way interactions model.

Load the `hospital` dataset array.

```
load hospital
```

```
ds = hospital; % just to use the ds name
```

Specify the model using a formula that allows up to two-way interactions between the variables age, weight, and sex. Smoker is the response variable.

```
modelspec = 'Smoker ~ Age*Weight*Sex - Age:Weight:Sex';
```

Fit a logistic binomial model.

```
mdl = fitglm(ds,modelspec,'Distribution','binomial')
```

```
mdl =
```

```
Generalized Linear regression model:
logit(Smoker) ~ 1 + Sex*Age + Sex*Weight + Age*Weight
Distribution = Binomial
```

```
Estimated Coefficients:
```

	Estimate	SE	tStat	pValue
(Intercept)	-6.0492	19.749	-0.3063	0.75938
Sex_Male	-2.2859	12.424	-0.18399	0.85402
Age	0.11691	0.50977	0.22934	0.81861
Weight	0.031109	0.15208	0.20455	0.83792
Sex_Male:Age	0.020734	0.20681	0.10025	0.92014
Sex_Male:Weight	0.01216	0.053168	0.22871	0.8191
Age:Weight	-0.00071959	0.0038964	-0.18468	0.85348

```
100 observations, 93 error degrees of freedom
Dispersion: 1
Chi^2-statistic vs. constant model: 5.07, p-value = 0.535
```

All of the p-values (under pValue) are large. This means none of the coefficients are significant. The large p -value for the test of the model, 0.535, indicates that this model might not differ statistically from a constant model.

GLM for Poisson Response

Create sample data with 20 predictors, and Poisson response using just three of the predictors, plus a constant.

```
rng('default') % for reproducibility
X = randn(100,7);
mu = exp(X(:,[1 3 6])*[.4;.2;.3] + 1);
y = poissrnd(mu);
```

Fit a generalized linear model using the Poisson distribution.

```
mdl = fitglm(X,y,'linear','Distribution','poisson')
```

```
mdl =
```

```
Generalized Linear regression model:
log(y) ~ 1 + x1 + x2 + x3 + x4 + x5 + x6 + x7
Distribution = Poisson
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	0.88723	0.070969	12.502	7.3149e-36
x1	0.44413	0.052337	8.4858	2.1416e-17
x2	0.0083388	0.056527	0.14752	0.88272
x3	0.21518	0.063416	3.3932	0.00069087
x4	-0.058386	0.065503	-0.89135	0.37274
x5	-0.060824	0.073441	-0.8282	0.40756
x6	0.34267	0.056778	6.0352	1.5878e-09
x7	0.04316	0.06146	0.70225	0.48252

```
100 observations, 92 error degrees of freedom
Dispersion: 1
Chi^2-statistic vs. constant model: 119, p-value = 1.55e-22
```

The p -values of 2.14e-17, 0.00069, and 1.58e-09 indicate that the coefficients of the variables x_1 , x_3 , and x_6 are statistically significant.

- “Generalized Linear Model Workflow” on page 10-39

Input Arguments

tbl — Input data

table | dataset array

Input data, specified as a table or dataset array. When `modelspec` is a formula, it specifies the variables to be used as the predictors and response. Otherwise, if you do not specify the predictor and response variables, the last variable is the response variable and the others are the predictor variables by default.

Predictor variables and response variables can be numeric, or any grouping variable type, such as logical or categorical (see “Grouping Variables” on page 2-52).

To set a different column as the response variable, use the `ResponseVar` name-value pair argument. To use a subset of the columns as predictors, use the `PredictorVars` name-value pair argument.

Data Types: single | double | logical

X — Predictor variables

matrix

Predictor variables, specified as an n -by- p matrix, where n is the number of observations and p is the number of predictor variables. Each column of X represents one variable, and each row represents one observation.

By default, there is a constant term in the model, unless you explicitly remove it, so do not include a column of 1s in X .

Data Types: `single` | `double` | `logical`

y — Response variable

vector

Response variable, specified as an n -by-1 vector, where n is the number of observations. Each entry in y is the response for the corresponding row of X .

modelspec — Model specification

string specifying the model | t -by- $(p+1)$ terms matrix | string of the form ' $Y \sim \text{terms}$ '

Model specification, which is the starting model for `stepwiseglm`, specified as one of the following:

- String specifying the type of model.

String	Model Type
'constant'	Model contains only a constant (intercept) term.
'linear'	Model contains an intercept and linear terms for each predictor.
'interactions'	Model contains an intercept, linear terms, and all products of pairs of distinct predictors (no squared terms).
'purequadratic'	Model contains an intercept, linear terms, and squared terms.
'quadratic'	Model contains an intercept, linear terms, interactions, and squared terms.
'polyijk'	Model is a polynomial with all terms up to degree i in the first predictor, degree j in the second predictor, etc. Use numerals 0 through 9. For example, 'poly2111' has a constant plus all linear and product terms, and also contains terms with predictor 1 squared.

- t -by- $(p+1)$ matrix, namely “Terms Matrix” on page 21-1390, specifying terms to include in model, where t is the number of terms and p is the number of predictor variables, and plus one is for the response variable.
- String representing a “Formula” on page 21-1393 in the form `'Y ~ terms'`, where the `terms` are in “Wilkinson Notation” on page 21-1394.

Example: `'quadratic'`

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Distribution','normal','link','probit','Exclude',[23,59]` specifies that the distribution of the response is normal, and instructs `fitglm` to use the probit link function and exclude the 23rd and 59th observations from the fit.

'BinomialSize' — Number of trials for binomial distribution

1 (default) | scalar value | vector

Number of trials for binomial distribution, that is the sample size, specified as the comma-separated pair consisting of a scalar value or a vector of the same length as the response. This is the parameter n for the fitted binomial distribution. **BinomialSize** applies only when the **Distribution** parameter is `'binomial'`.

If **BinomialSize** is a scalar value, that means all observations have the same number of trials.

As an alternative to **BinomialSize**, you can specify the response as a two-column vector with counts in column 1 and **BinomialSize** in column 2.

Data Types: `single` | `double`

'CategoricalVars' — Categorical variables

cell array of strings | logical or numeric index vector

Categorical variables in the fit, specified as the comma-separated pair consisting of `'CategoricalVars'` and either a cell array of strings of the names of the categorical

variables in the table or dataset array `tbl`, or a logical or numeric index vector indicating which columns are categorical.

- If data is in a table or dataset array `tbl`, then the default is to treat all categorical or logical variables, character arrays, or cell arrays of strings as categorical variables.
- If data is in matrix `X`, then the default value of this name-value pair argument is an empty matrix `[]`. That is, no variable is categorical unless you specify it.

For example, you can specify the observations 2 and 3 out of 6 as categorical using either of the following examples.

Example: `'CategoricalVars',[2,3]`

Example: `'CategoricalVars',logical([0 1 1 0 0 0])`

Data Types: `single` | `double` | `logical`

'DispersionFlag' — Indicator to compute dispersion parameter

`false` for 'binomial' and 'poisson' distributions (default) | `true`

Indicator to compute dispersion parameter for 'binomial' and 'poisson' distributions, specified as the comma-separated pair consisting of 'DispersionFlag' and one of the following.

<code>true</code>	Estimate a dispersion parameter when computing standard errors
<code>false</code>	Default. Use the theoretical value when computing standard errors

The fitting function always estimates the dispersion for other distributions.

Example: `'DispersionFlag',true`

'Distribution' — Distribution of the response variable

`'normal'` (default) | `'binomial'` | `'poisson'` | `'gamma'` | `'inverse gaussian'`

Distribution of the response variable, specified as the comma-separated pair consisting of 'Distribution' and one of the following.

<code>'normal'</code>	Normal distribution
<code>'binomial'</code>	Binomial distribution

'poisson' Poisson distribution
 'gamma' Gamma distribution
 'inverse gaussian' Inverse Gaussian distribution

Example: 'Distribution', 'gamma'

'Exclude' — Observations to exclude

logical or numeric index vector

Observations to exclude from the fit, specified as the comma-separated pair consisting of 'Exclude' and a logical or numeric index vector indicating which observations to exclude from the fit.

For example, you can exclude observations 2 and 3 out of 6 using either of the following examples.

Example: 'Exclude', [2,3]

Example: 'Exclude', logical([0 1 1 0 0 0])

Data Types: single | double | logical

'Intercept' — Indicator for constant term

true (default) | false

Indicator the for constant term (intercept) in the fit, specified as the comma-separated pair consisting of 'Intercept' and either **true** to include or **false** to remove the constant term from the model.

Use 'Intercept' only when specifying the model using a string, not a formula or matrix.

Example: 'Intercept', false

'Link' — Link function

The canonical link function (default) | scalar value | structure

Link function to use in place of the canonical link function, specified as the comma-separated pair consisting of 'Link' and one of the following.

Link Function Name	Link Function	Mean (Inverse) Function
'identity'	$f(\mu) = \mu$	$\mu = Xb$

Link Function Name	Link Function	Mean (Inverse) Function
'log'	$f(\mu) = \log(\mu)$	$\mu = \exp(Xb)$
'logit'	$f(\mu) = \log(\mu/(1-\mu))$	$\mu = \exp(Xb) / (1 + \exp(Xb))$
'probit'	$f(\mu) = \Phi^{-1}(\mu)$	$\mu = \Phi(Xb)$
'comprologlog'	$f(\mu) = \log(-\log(1 - \mu))$	$\mu = 1 - \exp(-\exp(Xb))$
'reciprocal'	$f(\mu) = 1/\mu$	$\mu = 1/(Xb)$
p (a number)	$f(\mu) = \mu^p$	$\mu = Xb^{1/p}$
S (a structure) with three fields. Each field holds a function handle that accepts a vector of inputs and returns a vector of the same size: <ul style="list-style-type: none"> S.Link — The link function S.Inverse — The inverse link function S.Derivative — The derivative of the link function 	$f(\mu) = S.Link(\mu)$ $\mu = S.Inverse(Xb)$	

The link function defines the relationship $f(\mu) = X^*b$ between the mean response μ and the linear combination of predictors X^*b .

For more information on the canonical link functions, see [Definitions](#).

Example: 'Link', 'probit'

'Offset' — Offset variable

[] (default) | vector | string

Offset variable in the fit, specified as the comma-separated pair consisting of 'Offset' and a vector or name of a variable with the same length as the response.

`fitglm` and `stepwiseglm` use `Offset` as an additional predictor, with a coefficient value fixed at 1.0. In other words, the formula for fitting is $\mu \sim \text{Offset} + (\text{terms involving real predictors})$

with the `Offset` predictor having coefficient 1.

For example, consider a Poisson regression model. Suppose the number of counts is known for theoretical reasons to be proportional to a predictor `A`. By using the log link function and by specifying `log(A)` as an offset, you can force the model to satisfy this theoretical constraint.

Data Types: `single` | `double` | `char`

'PredictorVars' — Predictor variables

cell array of strings | logical or numeric index vector

Predictor variables to use in the fit, specified as the comma-separated pair consisting of `'PredictorVars'` and either a cell array of strings of the variable names in the table or dataset array `tbl`, or a logical or numeric index vector indicating which columns are predictor variables.

The strings should be among the names in `tbl`, or the names you specify using the `'VarNames'` name-value pair argument.

The default is all variables in `X`, or all variables in `tbl` except for `ResponseVar`.

For example, you can specify the second and third variables as the predictor variables using either of the following examples.

Example: `'PredictorVars',[2,3]`

Example: `'PredictorVars',logical([0 1 1 0 0 0])`

Data Types: `single` | `double` | `logical` | `cell`

'ResponseVar' — Response variable

last column in `tbl` (default) | string for variable name | logical or numeric index vector

Response variable to use in the fit, specified as the comma-separated pair consisting of `'ResponseVar'` and either a string of the variable name in the table or dataset array `tbl`, or a logical or numeric index vector indicating which column is the response variable. You typically need to use `'ResponseVar'` when fitting a table or dataset array `tbl`.

For example, you can specify the fourth variable, say `yield`, as the response out of six variables, in one of the following ways.

Example: `'ResponseVar','yield'`

Example: 'ResponseVar',[4]

Example: 'ResponseVar',logical([0 0 0 1 0 0])

Data Types: single | double | logical | char

'VarNames' — Names of variables in fit

{'x1','x2',...,'xn','y'} (default) | cell array of strings

Names of variables in fit, specified as the comma-separated pair consisting of 'VarNames' and a cell array of strings including the names for the columns of X first, and the name for the response variable y last.

'VarNames' is not applicable to variables in a table or dataset array, because those variables already have names.

For example, if in your data, horsepower, acceleration, and model year of the cars are the predictor variables, and miles per gallon (MPG) is the response variable, then you can name the variables as follows.

Example: 'VarNames',{'Horsepower','Acceleration','Model_Year','MPG'}

Data Types: cell

'Weights' — Observation weights

ones(n,1) (default) | n -by-1 vector of nonnegative scalar values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and an n -by-1 vector of nonnegative scalar values, where n is the number of observations.

Data Types: single | double

Output Arguments

mdl — Generalized linear model

GeneralizedLinearModel object

Generalized linear model representing a least-squares fit of the link of the response to the data, returned as a GeneralizedLinearModel object.

For properties and methods of the generalized linear model object, mdl, see the GeneralizedLinearModel class page.

Alternative Functionality

Use `stepwiseglm` to select a model specification automatically. Use `step`, `addTerms`, or `removeTerms` to adjust a fitted model.

More About

Terms Matrix

A terms matrix is a t -by- $(p + 1)$ matrix specifying terms in a model, where t is the number of terms, p is the number of predictor variables, and plus one is for the response variable.

The value of $T(i, j)$ is the exponent of variable j in term i . Suppose there are three predictor variables A, B, and C:

```
[0 0 0 0] % Constant term or intercept
[0 1 0 0] % B; equivalently, A^0 * B^1 * C^0
[1 0 1 0] % A*C
[2 0 0 0] % A^2
[0 1 2 0] % B*(C^2)
```

The 0 at the end of each term represents the response variable. In general,

- If you have the variables in a table or dataset array, then 0 must represent the response variable depending on the position of the response variable. The following example illustrates this.

Load the sample data and define the dataset array.

```
load hospital
ds = dataset(hospital.Sex, hospital.BloodPressure(:,1), hospital.Age, ...
hospital.Smoker, 'VarNames', {'Sex', 'BloodPressure', 'Age', 'Smoker'});
```

Represent the linear model `'BloodPressure ~ 1 + Sex + Age + Smoker'` in a terms matrix. The response variable is in the second column of the dataset array, so there must be a column of 0s for the response variable in the second column of the terms matrix.

```
T = [0 0 0 0; 1 0 0 0; 0 0 1 0; 0 0 0 1]
```

```
T =
```

```

0    0    0    0
1    0    0    0
0    0    1    0
0    0    0    1

```

Redefine the dataset array.

```

ds = dataset(hospital.BloodPressure(:,1),hospital.Sex,hospital.Age,...
hospital.Smoker, 'VarNames',{ 'BloodPressure', 'Sex', 'Age', 'Smoker' });

```

Now, the response variable is the first term in the dataset array. Specify the same linear model, 'BloodPressure ~ 1 + Sex + Age + Smoker', using a terms matrix.

```
T = [0 0 0 0;0 1 0 0;0 0 1 0;0 0 0 1]
```

```
T =
```

```

0    0    0    0
0    1    0    0
0    0    1    0
0    0    0    1

```

- If you have the predictor and response variables in a matrix and column vector, then you must include 0 for the response variable at the end of each term. The following example illustrates this.

Load the sample data and define the matrix of predictors.

```

load carsmall
X = [Acceleration,Weight];

```

Specify the model 'MPG ~ Acceleration + Weight + Acceleration:Weight + Weight^2' using a term matrix and fit the model to the data. This model includes the main effect and two-way interaction terms for the variables, Acceleration and Weight, and a second-order term for the variable, Weight.

```
T = [0 0 0;1 0 0;0 1 0;1 1 0;0 2 0]
```

```
T =
```

```

0    0    0
1    0    0
0    1    0
1    1    0

```

```
0 2 0
```

Fit a linear model.

```
mdl = fitlm(X,MPG,T)
```

```
mdl =
```

Linear regression model:

```
y ~ 1 + x1*x2 + x2^2
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	48.906	12.589	3.8847	0.00019665
x1	0.54418	0.57125	0.95261	0.34337
x2	-0.012781	0.0060312	-2.1192	0.036857
x1:x2	-0.00010892	0.00017925	-0.6076	0.545
x2^2	9.7518e-07	7.5389e-07	1.2935	0.19917

Number of observations: 94, Error degrees of freedom: 89

Root Mean Squared Error: 4.1

R-squared: 0.751, Adjusted R-Squared 0.739

F-statistic vs. constant model: 67, p-value = 4.99e-26

Only the intercept and x2 term, which correspond to the `Weight` variable, are significant at the 5% significance level.

Now, perform a stepwise regression with a constant model as the starting model and a linear model with interactions as the upper model.

```
T = [0 0 0;1 0 0;0 1 0;1 1 0];
```

```
mdl = stepwiselm(X,MPG,[0 0 0], 'upper', T)
```

1. Adding x2, FStat = 259.3087, pValue = 1.643351e-28

```
mdl =
```

Linear regression model:

```
y ~ 1 + x2
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	49.238	1.6411	30.002	2.7015e-49
x2	-0.0086119	0.0005348	-16.103	1.6434e-28

Number of observations: 94, Error degrees of freedom: 92
 Root Mean Squared Error: 4.13
 R-squared: 0.738, Adjusted R-Squared 0.735
 F-statistic vs. constant model: 259, p-value = 1.64e-28

The results of the stepwise regression are consistent with the results of `fitlm` in the previous step.

Formula

A formula for model specification is a string of the form ' $Y \sim terms$ '

where

- Y is the response name.
- $terms$ contains
 - Variable names
 - $+$ means include the next variable
 - $-$ means do not include the next variable
 - $:$ defines an interaction, a product of terms
 - $*$ defines an interaction **and all lower-order terms**
 - $^$ raises the predictor to a power, exactly as in $*$ repeated, so $^$ includes lower order terms as well
 - $()$ groups terms

Note: Formulas include a constant (intercept) term by default. To exclude a constant term from the model, include -1 in the formula.

For example,

' $Y \sim A + B + C$ ' means a three-variable linear model with intercept.

' $Y \sim A + B + C - 1$ ' is a three-variable linear model without intercept.

' $Y \sim A + B + C + B^2$ ' is a three-variable model with intercept and a B^2 term.

' $Y \sim A + B^2 + C$ ' is the same as the previous example because B^2 includes a B term.

' $Y \sim A + B + C + A:B$ ' includes an $A*B$ term.

' $Y \sim A*B + C$ ' is the same as the previous example because $A*B = A + B + A:B$.

'Y ~ A*B*C - A:B:C' has all interactions among A, B, and C, except the three-way interaction.

'Y ~ A*(B + C + D)' has all linear terms, plus products of A with each of the other variables.

Wilkinson Notation

Wilkinson notation describes the factors present in models. The notation relates to factors present in models, not to the multipliers (coefficients) of those factors.

Wilkinson Notation	Factors in Standard Notation
1	Constant (intercept) term
A ^k , where k is a positive integer	A, A ² , ..., A ^k
A + B	A, B
A*B	A, B, A*B
A:B	A*B only
-B	Do not include B
A*B + C	A, B, C, A*B
A + B + C + A:B	A, B, C, A*B
A*B*C - A:B:C	A, B, C, A*B, A*C, B*C
A*(B + C)	A, B, C, A*B, A*C

Statistics Toolbox notation always includes a constant term unless you explicitly remove the term using -1.

Canonical Link Function

The default link function for a generalized linear model is the *canonical link function*.

Canonical Link Functions for Generalized Linear Models

Distribution	Link Function Name	Link Function	Mean (Inverse) Function
'normal'	'identity'	$f(\mu) = \mu$	$\mu = Xb$
'binomial'	'logit'	$f(\mu) = \log(\mu/(1-\mu))$	$\mu = \exp(Xb) / (1 + \exp(Xb))$
'poisson'	'log'	$f(\mu) = \log(\mu)$	$\mu = \exp(Xb)$
'gamma'	-1	$f(\mu) = 1/\mu$	$\mu = 1/(Xb)$

Distribution	Link Function Name	Link Function	Mean (Inverse) Function
'inverse gaussian'	-2	$f(\mu) = 1/\mu^2$	$\mu = (Xb)^{-1/2}$

Tips

- The generalized linear model `mdl` is a standard linear model unless you specify otherwise with the **Distribution** name-value pair.
- For methods such as `plotResiduals` or `devianceTest`, or properties of the `GeneralizedLinearModel` object, see `GeneralizedLinearModel`.
- “Generalized Linear Models” on page 10-12

fitglme

Fit generalized linear mixed-effects model

Syntax

```
glme = fitglme(tbl,formula)
glme = fitglme(tbl,formula,Name,Value)
```

Description

`glme = fitglme(tbl,formula)` returns a generalized linear mixed-effects model, `glme`. The model is specified by `formula` and fitted to the predictor variables in the table or dataset array, `tbl`.

`glme = fitglme(tbl,formula,Name,Value)` returns a generalized linear mixed-effects model using additional options specified by one or more `Name,Value` pair arguments. For example, you can specify the distribution of the response, the link function, or the covariance pattern of the random-effects terms.

Examples

Fit a Generalized Linear Mixed-Effects Model

Navigate to the folder containing the sample data. Load the sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

```
load mfr
```

This simulated data is from a manufacturing company that operates 50 factories across the world, with each factory running a batch process to create a finished product. The company wants to decrease the number of defects in each batch, so it developed a new manufacturing process. To test the effectiveness of the new process, the company selected 20 of its factories at random to participate in an experiment: Ten factories implemented the new process, while the other ten continued to run the old process. In each of the

20 factories, the company ran five batches (for a total of 100 batches) and recorded the following data:

- Flag to indicate whether the batch used the new process (**newprocess**)
- Processing time for each batch, in hours (**time**)
- Temperature of the batch, in degrees Celsius (**temp**)
- Categorical variable indicating the supplier of the chemical used in the batch (**supplier**)
- Number of defects in the batch (**defects**)

The data also includes **time_dev** and **temp_dev**, which represent the absolute deviation of time and temperature, respectively, from the process standard of 3 hours at 20 degrees Celsius.

Fit a generalized linear mixed-effects model using **newprocess**, **time_dev**, **temp_dev**, and **supplier** as fixed-effects predictors. Include a random-effects term for intercept grouped by **factory**, to account for quality differences that might exist due to factory-specific variations. The response variable **defects** has a Poisson distribution, and the appropriate link function for this model is log. Use the Laplace fit method to estimate the coefficients. Specify the dummy variable encoding as 'effects', so the dummy variable coefficients sum to 0.

The number of defects can be modeled using a Poisson distribution

$$defects_{ij} \sim \text{Poisson}(\mu_{ij})$$

This corresponds to the generalized linear mixed-effects model

$$\log(\mu_{ij}) = \beta_0 + \beta_1 newprocess_{ij} + \beta_2 time_dev_{ij} + \beta_3 temp_dev_{ij} + \beta_4 supplier_C_{ij} + \beta_5 supplier_B_{ij} +$$

where

- $defects_{ij}$ is the number of defects observed in the batch produced by factory i during batch j .
- μ_{ij} is the mean number of defects corresponding to factory i (where $i = 1, 2, \dots, 20$) during batch j (where $j = 1, 2, \dots, 5$).
- $newprocess_{ij}$, $time_dev_{ij}$, and $temp_dev_{ij}$ are the measurements for each variable that correspond to factory i during batch j . For example, $newprocess_{ij}$ indicates whether the batch produced by factory i during batch j used the new process.

- $supplier_C_{ij}$ and $supplier_B_{ij}$ are dummy variables that use effects (sum-to-zero) coding to indicate whether company C or B, respectively, supplied the process chemicals for the batch produced by factory i during batch j .
- $b_i \sim N(0, \sigma_b^2)$ is a random-effects intercept for each factory i that accounts for factory-specific variation in quality.

```
glme = fitglme(mfr, 'defects ~ 1 + newprocess + time_dev + temp_dev + supplier + (1|fact
```

Display the model.

```
disp(glme)
```

```
glme =
```

Generalized linear mixed-effects model fit by ML

Model information:

Number of observations	100

-1.7395	1.5505
-2.1926	1.6263
-0.22679	0.083051
-0.082588	0.22473

Random effects covariance parameters:

Group: factory (20 Levels)

Name1	Name2	Type	Estimate
'(Intercept)'	'(Intercept)'	'std'	0.31381

Group: Error

Name	Estimate
'sqrt(Dispersion)'	1

The **Model information** table displays the total number of observations in the sample data (100), the number of fixed- and random-effects coefficients (6 and 20, respectively), and the number of covariance parameters (1). It also indicates that the response variable has a **Poisson** distribution, the link function is **Log**, and the fit method is **Laplace**.

Formula indicates the model specification using Wilkinson's notation.

The **Model fit statistics** table displays statistics used to assess the goodness of fit of the model. This includes the Akaike information criterion (**AIC**), Bayesian information criterion (**BIC**) values, log likelihood (**LogLikelihood**), and deviance (**Deviance**) values.

The **Fixed effects coefficients** table indicates that **fitglm** returned 95% confidence intervals. It contains one row for each fixed-effects predictor, and each column contains statistics corresponding to that predictor. Column 1 (**Name**) contains the name of each fixed-effects coefficient, column 2 (**Estimate**) contains its estimated value, and column 3 (**SE**) contains the standard error of the coefficient. Column 4 (**tStat**) contains the *t*-statistic for a hypothesis test that the coefficient is equal to 0. Column 5 (**DF**) and column 6 (**pValue**) contain the degrees of freedom and *p*-value that correspond to the *t*-statistic, respectively. The last two columns (**Lower** and **Upper**) display the lower and upper limits, respectively, of the 95% confidence interval for each fixed-effects coefficient.

Random effects covariance parameters displays a table for each grouping variable (here, only **factory**), including its total number of levels (20), and the type and estimate of the covariance parameter. Here, **std** indicates that **fitglm** returns the standard deviation of the random effect associated with the **factory** predictor, which has an estimated value of 0.31381. It also displays a table containing the error parameter type (here, the square root of the dispersion parameter), and its estimated value of 1.

The standard display generated by `fitglme` does not provide confidence intervals for the random-effects parameters. To compute and display these values, use `covarianceParameters`.

- “Fit a Generalized Linear Mixed-Effects Model” on page 10-79

Input Arguments

tbl — Input data

table | dataset array

Input data, which includes the response variable, predictor variables, and grouping variables, specified as a table or dataset array. The predictor variables can be continuous or grouping variables (see “Grouping Variables” on page 2-52). You must specify the model for the variables using formula.

Data Types: `single` | `double` | `char` | `cell`

formula — Formula for model specification

string of the form `'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)'`

Formula for model specification, specified as a string of the form `'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)'`. The string is case sensitive. For a full description, see “Formula” on page 21-1412.

Example: `'y ~ treatment + (1|block)'`

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example:

`'Distribution','Poisson','Link','log','FitMethod','Laplace','DummyVarCoding',` specifies the response variable distribution as Poisson, the link function as log, the fit method as Laplace, and dummy variable coding where the coefficients sum to 0.

'BinomialSize' — Number of trials for binomial distribution

1 (default) | scalar value | vector | variable name

Number of trials for binomial distribution, that is the sample size, specified as the comma-separated pair consisting of a scalar value, a vector of the same length as the response, or the name of a variable in the input table. If you specify the name of a variable, then the variable must be of the same length as the response. `BinomialSize` applies only when the `Distribution` parameter is `'binomial'`.

If `BinomialSize` is a scalar value, that means all observations have the same number of trials.

Data Types: `single` | `double`

'CheckHessian' — Indicator to check positive definiteness of Hessian

`false` (default) | `true`

Indicator to check the positive definiteness of the Hessian of the objective function with respect to unconstrained parameters at convergence, specified as the comma-separated pair consisting of `'CheckHessian'` and either `false` or `true`. Default is `false`.

Specify `'CheckHessian'` as `true` to verify optimality of the solution or to determine if the model is overparameterized in the number of covariance parameters.

If you specify `'FitMethod'` as `'MPL'` or `'REML'`, then the covariance of the fixed effects and the covariance parameters is based on the fitted linear mixed-effects model from the final pseudo likelihood iteration.

Example: `'CheckHessian', true`

'CovarianceMethod' — Method to compute covariance of estimated parameters

`'conditional'` (default) | `'JointHessian'`

Method to compute covariance of estimated parameters, specified as the comma-separated pair consisting of `'CovarianceMethod'` and either `'conditional'` or `'JointHessian'`. If you specify `'conditional'`, then `fitglme` computes a fast approximation to the covariance of fixed effects given the estimated covariance parameters. It does not compute the covariance of covariance parameters. If you specify `'JointHessian'`, then `fitglme` computes the joint covariance of fixed effects and covariance parameters via the observed information matrix using the Laplacian loglikelihood.

If you specify `'FitMethod'` as `'MPL'` or `'REML'`, then the covariance of the fixed effects and the covariance parameters is based on the fitted linear mixed-effects model from the final pseudo likelihood iteration.

Example: `'CovarianceMethod', 'JointHessian'`

'CovariancePattern' — Pattern of covariance matrix

'FullCholesky' | 'Isotropic' | 'Full' | 'Diagonal' | 'CompSymm' | square symmetric logical matrix | cell array of strings or logical matrices

Pattern of the covariance matrix of the random effects, specified as the comma-separated pair consisting of 'CovariancePattern' and a string, a square symmetric logical matrix, or a cell array containing strings or logical matrices.

If there are R random-effects terms, then the value of 'CovariancePattern' must be a cell array of length R , where each element r of this cell array specifies the pattern of the covariance matrix of the random-effects vector associated with the r th random-effects term. The options for each element follow.

'FullCholesky'

Full covariance matrix using the Cholesky parameterization. `fitglm` estimates all elements of the covariance matrix.

'Isotropic'

Diagonal covariance matrix with equal variances. That is, off-diagonal elements of the covariance matrix are constrained to be 0, and the diagonal elements are constrained to be equal. For example, if there are three random-effects terms with an isotropic covariance structure, this covariance matrix looks like

$$\begin{pmatrix} \sigma_b^2 & 0 & 0 \\ 0 & \sigma_b^2 & 0 \\ 0 & 0 & \sigma_b^2 \end{pmatrix}$$

where σ_b^2 is the common variance of the random-effects terms.

'Full'

Full covariance matrix, using the log-Cholesky parameterization. `fitlme` estimates all elements of the covariance matrix.

'Diagonal'

Diagonal covariance matrix. That is, off-diagonal elements of the covariance matrix are constrained to be 0.

$$\begin{pmatrix} \sigma_{b1}^2 & 0 & 0 \\ 0 & \sigma_{b2}^2 & 0 \\ 0 & 0 & \sigma_{b3}^2 \end{pmatrix}$$

'CompSymm'

Compound symmetry structure. That is, common variance along diagonals and equal correlation between all random effects. For example, if there are three random-effects terms with a covariance matrix having a compound symmetry structure, this covariance matrix looks like

$$\begin{pmatrix} \sigma_{b1}^2 & \sigma_{b1,b2} & \sigma_{b1,b2} \\ \sigma_{b1,b2} & \sigma_{b1}^2 & \sigma_{b1,b2} \\ \sigma_{b1,b2} & \sigma_{b1,b2} & \sigma_{b1}^2 \end{pmatrix}$$

where σ_{b1}^2 is the common variance of the random-effects terms and $\sigma_{b1,b2}$ is the common covariance between any two random-effects term .

PAT

Square symmetric logical matrix. If 'CovariancePattern' is defined by the matrix PAT, and if $\text{PAT}(a, b) = \text{false}$, then the (a,b) element of the corresponding covariance matrix is constrained to be 0.

For scalar random-effects terms, the default is 'Isotropic'. Otherwise, the default is 'FullCholesky'.

Example: 'CovariancePattern', 'Diagonal'

Example: 'CovariancePattern', {'Full', 'Diagonal'}

'DispersionFlag' — Indicator to compute dispersion parameter

false for 'binomial' and 'poisson' distributions (default) | true

Indicator to compute dispersion parameter for 'binomial' and 'poisson' distributions, specified as the comma-separated pair consisting of 'DispersionFlag' and one of the following.

true	Estimate a dispersion parameter when computing standard errors
false	Use the theoretical value of 1.0 when computing standard errors

'DispersionFlag' only applies if 'FitMethod' is 'MPL' or 'REML'.

The fitting function always estimates the dispersion for other distributions.

Example: 'DispersionFlag', true

'Distribution' — Distribution of the response variable

'Normal' (default) | 'Binomial' | 'Poisson' | 'Gamma' | 'InverseGaussian'

Distribution of the response variable, specified as the comma-separated pair consisting of 'Distribution' and one of the following.

'Normal'	Normal distribution
'Binomial'	Binomial distribution
'Poisson'	Poisson distribution
'Gamma'	Gamma distribution
'InverseGaussian'	Inverse Gaussian distribution

Example: 'Distribution', 'Binomial'

'DummyVarCoding' — Coding to use for dummy variables

'reference' (default) | 'effects' | 'full'

Coding to use for dummy variables created from the categorical variables, specified as the comma-separated pair consisting of 'DummyVarCoding' and one of the following.

'reference'	Default. Coefficient for first category set to 0.
'effects'	Coefficients sum to 0.

'full' One dummy variable for each category.

Example: 'DummyVarCoding', 'effects'

'EBMethod' — Method used to approximate empirical Bayes estimates of random effects

'Auto' (default) | 'LineSearchNewton' | 'TrustRegion2D' | 'fsolve'

Method used to approximate empirical Bayes estimates of random effects, specified as the comma-separated pair consisting of 'EBMethod' and one of the following.

- 'Auto'
- 'LineSearchNewton'
- 'TrustRegion2D'
- 'fsolve'

'Auto' is similar to 'LineSearchNewton' but uses a different convergence criterion and does not display iterative progress. 'Auto' and 'LineSearchNewton' may fail for non-canonical link functions. For non-canonical link functions, 'TrustRegion2D' or 'fsolve' are recommended. You must have Optimization Toolbox to use 'fsolve'.

Example: 'EBMethod', 'LineSearchNewton'

'EBOptions' — Options for empirical Bayes optimization

structure

Options for empirical Bayes optimization, specified as the comma-separated pair consisting of 'EBOptions' and a structure containing the following.

'TolFun'	Relative tolerance on the gradient norm. Default is 1e-6.
'TolX'	Absolute tolerance on the step size. Default is 1e-8.
'MaxIter'	Maximum number of iterations. Default is 100.
'Display'	'off', 'iter', or 'final'. Default is 'off'.

If EBMethod is 'Auto' and 'FitMethod' is 'Laplace', TolFun is the relative tolerance on the linear predictor of the model, and the 'Display' option does not apply.

If `'EBMethod'` is `'fsolve'`, then `'EBOptions'` must be specified as an object created by `optimoptions('fsolve')`.

Data Types: `struct`

'Exclude' — Indices for rows to exclude

use all rows without NaNs (default) | vector of integer or logical values

Indices for rows to exclude from the generalized linear mixed-effects model in the data, specified as the comma-separated pair consisting of `'Exclude'` and a vector of integer or logical values.

For example, you can exclude the 13th and 67th rows from the fit as follows.

Example: `'Exclude', [13,67]`

Data Types: `single` | `double` | `logical`

'FitMethod' — Method for estimating model parameters

`'MPL'` (default) | `'REML'` | `'Laplace'` | `'ApproximateLaplace'`

Method for estimating model parameters, specified as the comma-separated pair consisting of `'FitMethod'` and one of the following.

- `'MPL'` — Maximum pseudo likelihood
- `'REML'` — Restricted maximum pseudo likelihood
- `'Laplace'` — Maximum likelihood using Laplace approximation
- `'ApproximateLaplace'` — Maximum likelihood using approximate Laplace approximation with fixed effects profiled out

Example: `'FitMethod', 'REML'`

'InitPLIterations' — Initial number of pseudo likelihood iterations

10 (default) | integer value in the range [1, Inf)

Initial number of pseudo likelihood iterations used to initialize parameters for `ApproximateLaplace` and `Laplace` fit methods, specified as the comma-separated pair consisting of `'InitPLIterations'` and an integer value greater than or equal to 1.

Data Types: `single` | `double`

'Link' — Link function

`'identity'` | `'log'` | `'logit'` | `'probit'` | `'comploglog'` | `'reciprocal'` | scalar value | structure

Link function, specified as the comma-separated pair consisting of 'Link' and one of the following.

'identity'	$g(\mu) = \mu$	This is the default for the normal distribution.
'log'	$g(\mu) = \log(\mu)$	This is the default for the Poisson distribution.
'logit'	$g(\mu) = \log(\mu/(1-\mu))$	This is the default for the binomial distribution.
'loglog'	$g(\mu) = \log(-\log(\mu))$	
'probit'	$g(\mu) = \text{norminv}(\mu)$	
'comploglog'	$g(\mu) = \log(-\log(1-\mu))$	
'reciprocal'	$g(\mu) = \mu.^{-1}$	
Scalar value P	$g(\mu) = \mu.^P$	
Structure S		A structure containing four fields whose values are function handles with the following names: <ul style="list-style-type: none"> • S.Link — Link function • S.Derivative — Derivative • S.SecondDerivative — Second derivative • S.Inverse — Inverse of link <p>Specification of S.SecondDerivative can be omitted if FitMethod is MPL or REMP, or if S is the canonical link for the specified distribution.</p>

The default link function used by `fitglm` is the canonical link that depends on the distribution of the response.

```
'Normal'           'identity'  
'Binomial'        'logit'  
'Poisson'         'log'  
'Gamma'           -1  
'InverseGaussian' -2
```

Example: 'Link', 'log'

Data Types: single | double | struct

'MuStart' — Starting value for conditional mean

scalar value

Starting value for conditional mean, specified as the comma-separated pair consisting of 'MuStart' and a scalar value. Valid values are as follows.

Distribution	Values
'Normal'	(-Inf, Inf)
'Binomial'	(0, 1)
'Poisson'	(0, Inf)
'Gamma'	(0, Inf)
'InverseGaussian'	(0, Inf)

Data Types: single | double

'Offset' — Offset

zeros(*n*, 1) (default) | *n*-by-1 vector of scalar values

Offset, specified as the comma-separated pair consisting of 'Offset' and an *n*-by-1 vector of scalar values, where *n* is the length of the response vector. You can also specify the variable name of an *n*-by-1 vector of scalar values. 'Offset' is used as an additional predictor that has a coefficient value fixed at 1.0.

Data Types: single | double

'Optimizer' — Optimization algorithm

'quasnewton' (default) | 'fminsearch' | 'fminunc'

Optimization algorithm, specified as the comma-separated pair consisting of 'Optimizer' and either of the following.

'quasnewton'	Uses a trust region based quasi-Newton optimizer. You can change the options of the algorithm using <code>statset('fitglm')</code> . If you do not specify the options, then <code>fitglm</code> uses the default options of <code>statset('fitglm')</code> .
'fminsearch'	Uses a derivative-free Nelder-Mead method. You can change the options of the algorithm using <code>optimset('fminsearch')</code> . If you do not specify the options, then <code>fitglm</code> uses the default options of <code>optimset('fminsearch')</code> .
'fminunc'	Uses a line search-based quasi-Newton method. You must have Optimization Toolbox to specify this option. You can change the options of the algorithm using <code>optimoptions('fminunc')</code> . If you do not specify the options, then <code>fitglm</code> uses the default options of <code>optimoptions('fminunc')</code> with 'Algorithm' set to 'quasi-newton'.

Example: 'Optimizer', 'fminsearch'

'OptimizerOptions' — Options for optimization algorithm

structure returned by `statset` | structure returned by `optimset` | object returned by `optimoptions`

Options for the optimization algorithm, specified as the comma-separated pair consisting of 'OptimizerOptions' and a structure returned by `statset('fitglm')`, a structure created by `optimset('fminsearch')`, or an object returned by `optimoptions('fminunc')`.

- If 'Optimizer' is 'fminsearch', then use `optimset('fminsearch')` to change the options of the algorithm. If 'Optimizer' is 'fminsearch' and you do not supply 'OptimizerOptions', then the defaults used in `fitglm` are the default options created by `optimset('fminsearch')`.
- If 'Optimizer' is 'fminunc', then use `optimoptions('fminunc')` to change the options of the optimization algorithm. See `optimoptions` for the

options 'fminunc' uses. If 'Optimizer' is 'fminunc' and you do not supply 'OptimizerOptions', then the defaults used in `fitglm` are the default options created by `optimoptions('fminunc')` with 'Algorithm' set to 'quasi-newton'.

- If 'Optimizer' is 'quasi-newton', then use `statset('fitglm')` to change the optimization parameters. If 'Optimizer' is 'quasi-newton' and you do not change the optimization parameters using `statset`, then `fitglm` uses the default options created by `statset('fitglm')`.

The 'quasi-newton' optimizer uses the following fields in the structure created by `statset('fitglm')`.

'ToIFun' — Relative tolerance on gradient of objective function

1e-6 (default) | positive scalar value

Relative tolerance on the gradient of the objective function, specified as a positive scalar value.

'ToIX' — Absolute tolerance on step size

1e-12 (default) | positive scalar value

Absolute tolerance on the step size, specified as a positive scalar value.

'MaxIter' — Maximum number of iterations allowed

10000 (default) | positive scalar value

Maximum number of iterations allowed, specified as a positive scalar value.

'Display' — Level of display

'off' (default) | 'iter' | 'final'

Level of display, specified as one of 'off', 'iter', or 'final'.

'PLIterations' — Maximum number of pseudo likelihood iterations

100 (default) | positive integer value

Maximum number of pseudo likelihood (PL) iterations, specified as the comma-separated pair consisting of 'PLIterations' and a positive integer value. PL is used for fitting the model if 'FitMethod' is 'MPL' or 'REMP'. For other 'FitMethod' values, PL iterations are used to initialize parameters for subsequent optimization.

Example: 'PLIterations',200

Data Types: `single` | `double`

'PLTolerance' — Relative tolerance factor for pseudo likelihood iterations

`1e-08` (default) | positive scalar value

Relative tolerance factor for pseudo likelihood iterations, specified as the comma-separated pair consisting of `'PLTolerance'` and a positive scalar value.

Example: `'PLTolerance', 1e-06`

Data Types: `single` | `double`

'StartMethod' — Method to start iterative optimization

`'default'` (default) | `'random'`

Method to start iterative optimization, specified as the comma-separated pair consisting of `'StartMethod'` and either of the following.

<code>'default'</code>	Default. An internally defined default value.
<code>'random'</code>	A random initial value.

Example: `'StartMethod', 'random'`

'UseSequentialFitting' — Initial fitting type

`false` (default) | `true`

, specified as the comma-separated pair consisting of `'UseSequentialFitting'` and either `false` or `true`. If `'UseSequentialFitting'` is `false`, all maximum likelihood methods are initialized using one or more pseudo likelihood iterations. If `'UseSequentialFitting'` is `true`, the initial values from pseudo likelihood iterations are refined using `'ApproximateLaplace'` for `'Laplace'` fitting.

Example: `'UseSequentialFitting', true`

'Verbose' — Indicator to display optimization process on screen

`0` (default) | `1` | `2`

Indicator to display the optimization process on screen, specified as the comma-separated pair consisting of `'Verbose'` and 0, 1, or 2. If `'Verbose'` is specified as 1 or 2, then `fitglm` displays the progress of the iterative model-fitting process. Specifying `'Verbose'` as 2 displays iterative optimization information from the individual pseudo likelihood iterations. Specifying `'Verbose'` as 1 omits this display.

The setting for `'Verbose'` overrides the field `'Display'` in `'OptimizerOptions'`.

Example: `'Verbose', true`

'Weights' — Observation weights

vector of nonnegative scalar values

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and an n -by-1 vector of nonnegative scalar values, where n is the number of observations. If the response distribution is binomial or Poisson, then `'Weights'` must be a vector of positive integers.

Data Types: `single` | `double`

Output Arguments

g1me — Generalized linear mixed-effects model

`GeneralizedLinearMixedModel` object

Generalized linear mixed-effects model, specified as a `GeneralizedLinearMixedModel` object. For properties and methods of this object, see `GeneralizedLinearMixedModel`.

More About

Formula

In general, a formula for model specification is a string of the form `'y ~ terms'`. For the generalized linear mixed-effects models, this formula is in the form `'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)'`, where `fixed` and `random` contain the fixed-effects and the random-effects terms.

Suppose a table `tbl` contains the following:

- A response variable, y
- Predictor variables, X_j , which can be continuous or grouping variables
- Grouping variables, g_1, g_2, \dots, g_R ,

where the grouping variables in X_j and g_r can be categorical, logical, character arrays, or cell arrays of strings.

Then, in a formula of the form, $y \sim \text{fixed} + (\text{random}_1 | g_1) + \dots + (\text{random}_R | g_R)$, the term **fixed** corresponds to a specification of the fixed-effects design matrix X , **random₁** is a specification of the random-effects design matrix Z_1 corresponding to grouping variable g_1 , and similarly **random_R** is a specification of the random-effects design matrix Z_R corresponding to grouping variable g_R . You can express the **fixed** and **random** terms using Wilkinson notation.

Wilkinson notation describes the factors present in models. The notation relates to factors present in models, not to the multipliers (coefficients) of those factors.

Wilkinson Notation	Factors in Standard Notation
1	Constant (intercept) term
X^k , where k is a positive integer	X, X^2, \dots, X^k
$X1 + X2$	$X1, X2$
$X1 * X2$	$X1, X2, X1.*X2$ (elementwise multiplication of $X1$ and $X2$)
$X1 : X2$	$X1.*X2$ only
$- X2$	Do not include $X2$
$X1 * X2 + X3$	$X1, X2, X3, X1 * X2$
$X1 + X2 + X3 + X1 : X2$	$X1, X2, X3, X1 * X2$
$X1 * X2 * X3 - X1 : X2 : X3$	$X1, X2, X3, X1 * X2, X1 * X3, X2 * X3$
$X1 * (X2 + X3)$	$X1, X2, X3, X1 * X2, X1 * X3$

Statistics Toolbox notation always includes a constant term unless you explicitly remove the term using -1 . Here are some examples for generalized linear mixed-effects model specification.

Examples:

Formula	Description
$y \sim X1 + X2$	Fixed effects for the intercept, $X1$ and $X2$. This is equivalent to $y \sim 1 + X1 + X2$.
$y \sim -1 + X1 + X2$	No intercept and fixed effects for $X1$ and $X2$. The implicit intercept term is suppressed by including -1 .

Formula	Description
'y ~ 1 + (1 g1)'	Fixed effects for the intercept plus random effect for the intercept for each level of the grouping variable g1.
'y ~ X1 + (1 g1)'	Random intercept model with a fixed slope.
'y ~ X1 + (X1 g1)'	Random intercept and slope, with possible correlation between them. This is equivalent to 'y ~ 1 + X1 + (1 + X1 g1)'
'y ~ X1 + (1 g1) + (-1 + X1 g1)'	Independent random effects terms for intercept and slope.
'y ~ 1 + (1 g1) + (1 g2) + (1 g1:g2)'	Random intercept model with independent main effects for g1 and g2, plus an independent interaction effect.

GeneralizedLinearMixedModel

fitgmdist

Fit Gaussian mixture distribution to data

Syntax

```
GMMModel = fitgmdist(X,k)
GMMModel = fitgmdist(X,k,Name,Value)
```

Description

`GMMModel = fitgmdist(X,k)` returns a Gaussian mixture distribution model (`GMMModel`) with `k` components fitted to data (`X`).

`GMMModel = fitgmdist(X,k,Name,Value)` returns a Gaussian mixture distribution model with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify a regularization value or the covariance type.

Examples

Cluster Data Using a Gaussian Mixture Model

Generate data from a mixture of two bivariate Gaussian distributions.

```
mu1 = [1 2];
Sigma1 = [2 0; 0 0.5];
mu2 = [-3 -5];
Sigma2 = [1 0; 0 1];
rng(1); % For reproducibility
X = [mvnrnd(mu1,Sigma1,1000);mvnrnd(mu2,Sigma2,1000)];
```

Fit a Gaussian mixture model. Specify that there are two components.

```
GMMModel = fitgmdist(X,2);
```

Plot the data over the fitted Gaussian mixture model contours.

```
figure
```

```

y = [zeros(1000,1);ones(1000,1)];
h = gscatter(X(:,1),X(:,2),y);
hold on
ezcontour(@(x1,x2)pdf(GMMModel,[x1 x2]),get(gca,{'XLim','YLim'}))
title('\bf Scatter Plot and Fitted Gaussian Mixture Contours')
legend(h, 'Model 0', 'Model1')
hold off

```

Regularize Gaussian Mixture Model Estimation

Generate data from a mixture of two bivariate Gaussian distributions. Create a third predictor that is the sum of the first and second predictors.

```
mu1 = [1 2];
```

```

Sigma1 = [1 0; 0 1];
mu2 = [3 4];
Sigma2 = [0.5 0; 0 0.5];
rng(1); % For reproducibility
X1 = [mvnrnd(mu1,Sigma1,100);mvnrnd(mu2,Sigma2,100)];
X = [X1,X1(:,1)+X1(:,2)];

```

The columns of X are linearly dependent. This can cause ill-conditioned covariance estimates.

Fit a Gaussian mixture model to the data. You can use `try / catch` statements to help manage error messages.

```

rng(1); % Reset seed for common start values
try
    GMMModel = fitgmdist(X,2)
catch exception
    disp('There was an error fitting the Gaussian mixture model')
    error = exception.message
end

```

```

There was an error fitting the Gaussian mixture model

```

```

error =

```

```

Ill-conditioned covariance created at iteration 2.

```

The covariance estimates are ill-conditioned. Subsequently, optimization stops and an error appears.

Fit a Gaussian mixture model again, but use regularization.

```

rng(1); % Reset seed for common start values
GMMModel = fitgmdist(X,2,'RegularizationValue',0.1)

```

```

GMMModel =

```

```

Gaussian mixture distribution with 2 components in 3 dimensions

```

```

Component 1:

```

```

Mixing proportion: 0.507057

```

```

Mean:    0.9767    2.0130    2.9897

```

```
Component 2:  
Mixing proportion: 0.492943  
Mean:      3.1030    3.9544    7.0574
```

In this case, the algorithm converges to a solution due to regularization.

Select the Number of Gaussian Mixture Model Components Using PCA

Gaussian mixture models require that you specify a number of components before being fit to data. For many applications, it might be difficult to know the appropriate number of components. This example shows how to explore the data, and try to get an initial guess at the number of components using principal component analysis.

Load Fisher's iris data set.

```
load fisheriris  
classes = unique(species)
```

```
classes =  
  
    'setosa'  
    'versicolor'  
    'virginica'
```

The data set contains three classes of iris species. The analysis proceeds as if this is unknown.

Use principal component analysis to reduce the dimension of the data to two dimensions for visualization.

```
[~,score] = pca(meas, 'NumComponents',2);
```

Fit three Gaussian mixture models to the data by specifying 1, 2, and 3 components. Increase the number of optimization iterations to 1000. Use dot notation to store the final parameter estimates. By default, the software fits full and different covariances for each component.

```
GMMModels = cell(3,1); % Preallocation  
options = statset('MaxIter',1000);
```

```
rng(1); % For reproducibility
for j = 1:3
    GMModels{j} = fitgmdist(score,j,'Options',options);
    fprintf('\n GM Mean for %i Component(s)\n',j)
    Mu = GMModels{j}.mu
end
```

```
GM Mean for 1 Component(s)
```

```
Mu =
    1.0e-14 *
   -0.2805   -0.0931
```

```
GM Mean for 2 Component(s)
```

```
Mu =
    1.3212   -0.0954
   -2.6424    0.1909
```

```
GM Mean for 3 Component(s)
```

```
Mu =
    1.9642    0.0062
   -2.6424    0.1909
    0.4750   -0.2292
```

`GMModels` is a cell array containing three, fitted `gmdistribution` models. The means in the three component models are different, suggesting that the model distinguishes among the three iris species.

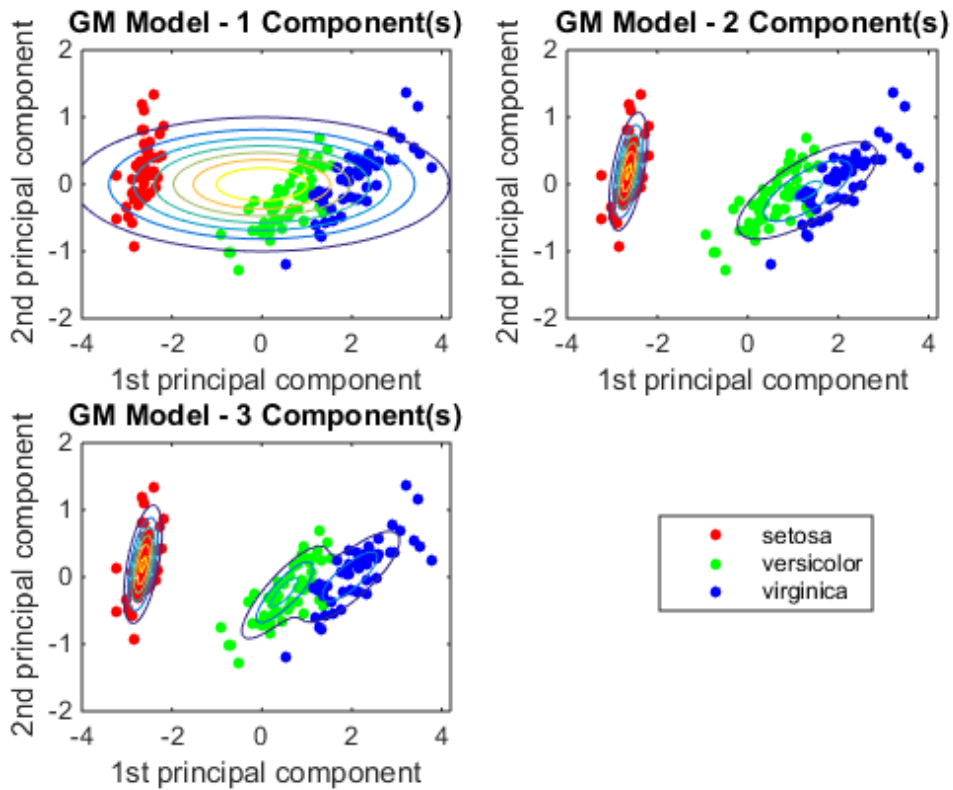

Plot the scores over the fitted Gaussian mixture model contours. Since the data set includes labels, use `gscatter` to distinguish between the true number of components.

```
figure
for j = 1:3
    subplot(2,2,j)
```

```

gscatter(score(:,1),score(:,2),species)
hold on
ezcontour(@(x1,x2)pdf(GMModels{j},[x1 x2]),...
    cell2mat(get(gca,{'XLim','YLim'})),100)
title(sprintf('GM Model - %i Component(s)',j));
xlabel('1st principal component');
ylabel('2nd principal component');
if(j ~= 3)
    legend off;
end
hold off
end
g = legend;
set(g,'Position',[0.7,0.25,0.1,0.1])

```

The three-component Gaussian mixture model, in conjunction with PCA, looks like it distinguishes between the three iris species.

There are other options you can use to help select the appropriate number of components for a Gaussian mixture model. For example,

- Compare multiple models with varying numbers of components using information criteria, e.g., AIC or BIC.
- Estimate the number of clusters using `evalclusters`, which supports, the Calinski-Harabasz criterion and the gap statistic, or other criteria.

Determine the Best Gaussian Mixture Fit Using AIC

Gaussian mixture models require that you specify a number of components before being fit to data. For many applications, it might be difficult to know the appropriate number of components. This example uses the AIC fit statistic to help you choose the best fitting Gaussian mixture model over varying numbers of components.

Generate data from a mixture of two bivariate Gaussian distributions.

```
mu1 = [1 1];
Sigma1 = [0.5 0; 0 0.5];
mu2 = [2 4];
Sigma2 = [0.2 0; 0 0.2];
rng(1);
X = [mvnrnd(mu1,Sigma1,1000);mvnrnd(mu2,Sigma2,1000)];

plot(X(:,1),X(:,2),'ko')
title('Scatter Plot')
xlim([min(X(:)) max(X(:))]) % Make axes have the same scale
ylim([min(X(:)) max(X(:))])
```

Supposing that you do not know the underlying parameter values, the scatter plots suggests:

- There are two components.
- The variances between the clusters are different.
- The variance within the clusters is the same.
- There is no covariance within the clusters.

Fit a two-component Gaussian mixture model. Based on the scatter plot inspection, specify that the covariance matrices are diagonal. Print the final iteration and loglikelihood statistic to the Command Window by passing a `statset` structure as the value of the `Options` name-value pair argument.

```
options = statset('Display','final');
GMMModel = fitgmdist(X,2,'CovarianceType','diagonal','Options',options);
```

```
10 iterations, log-likelihood = -4787.38
```

GMMModel is a fitted gmdistribution model.

Examine the AIC over varying numbers of components.

```
AIC = zeros(1,4);
GMMModels = cell(1,4);
options = statset('MaxIter',500);
for k = 1:4
    GMMModels{k} = fitgmdist(X,k,'Options',options,'CovarianceType','diagonal');
    AIC(k) = GMMModels{k}.AIC;
end
```

```
[minAIC,numComponents] = min(AIC);
numComponents
```

```
BestModel = GMMModels{numComponents}
```

```
numComponents =
```

```
2
```

```
BestModel =
```

```
Gaussian mixture distribution with 2 components in 2 dimensions
```

```
Component 1:
```

```
Mixing proportion: 0.501736
```

```
Mean:    1.9824    4.0013
```

```
Component 2:
```

```
Mixing proportion: 0.498264
```

```
Mean:    0.9879    1.0511
```

The smallest AIC occurs when the software fits the two-component Gaussian mixture model.

Set Initial Values When Fitting Gaussian Mixture Models

Gaussian mixture model parameter estimates might vary with different initial values. This example shows how to control initial values when you fit Gaussian mixture models using `fitgmdist`.

Load Fisher's iris data set. Use the petal lengths and widths as predictors.

```
load fisheriris
X = meas(:,3:4);
```

Fit a Gaussian mixture model to the data using default initial values. There are three iris species, so specify $k = 3$ components.

```
rng(10); % For reproducibility
GMMModel1 = fitgmdist(X,3);
```

By default, the software:

- 1 Randomly chooses $k = 3$ data points
- 2 Treats the chosen data points as initial means for each component
- 3 Sets the initial covariance matrices as diagonal, where element (j, j) is the variance of $X(:, j)$
- 4 Treats the initial mixing proportions as uniform

Fit a Gaussian mixture model by connecting each observation to its label.

```
y = ones(size(X,1),1);
y(strcmp(species,'setosa')) = 2;
y(strcmp(species,'virginica')) = 3;

GMMModel2 = fitgmdist(X,3,'Start',y);
```

Fit a Gaussian mixture model by explicitly specifying the initial means, covariance matrices, and mixing proportions.

```
Mu = [1 1; 2 2; 3 3];
Sigma(:,:,1) = [1 1; 1 2];
Sigma(:,:,2) = 2*[1 1; 1 2];
```

```

Sigma(:,:,3) = 3*[1 1; 1 2];
PComponents = [1/2,1/4,1/4];
S = struct('mu',Mu,'Sigma',Sigma,'ComponentProportion',PComponents);

GMMModel3 = fitgmdist(X,3,'Start',S);

```

Use `gscatter` to plot a scatter diagram that distinguishes between the iris species. For each model, plot the fitted Gaussian mixture model contours.

```

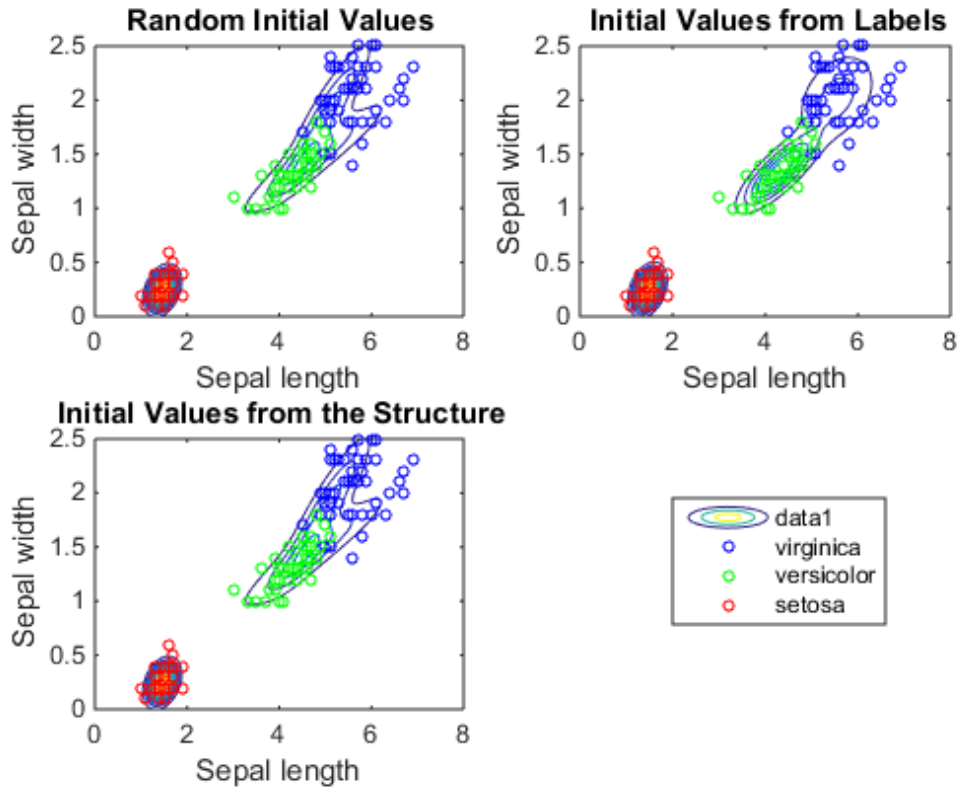

figure
subplot(2,2,1)
h = gscatter(X(:,1),X(:,2),species,[],'o',4);
haxis = gca;
xlim = haxis.XLim;
ylim = haxis.YLim;
d = (max([xlim ylim])-min([xlim ylim]))/1000;
[X1Grid,X2Grid] = meshgrid(xlim(1):d:xlim(2),ylim(1):d:ylim(2));
hold on
contour(X1Grid,X2Grid,reshape(pdf(GMMModel1,[X1Grid(:) X2Grid(:)]),...
    size(X1Grid,1),size(X1Grid,2)),20)
uistack(h,'top')
title('{\bf Random Initial Values}');
xlabel('Sepal length');
ylabel('Sepal width');
legend off;
hold off
subplot(2,2,2)
h = gscatter(X(:,1),X(:,2),species,[],'o',4);
hold on
contour(X1Grid,X2Grid,reshape(pdf(GMMModel2,[X1Grid(:) X2Grid(:)]),...
    size(X1Grid,1),size(X1Grid,2)),20)
uistack(h,'top')
title('{\bf Initial Values from Labels}');
xlabel('Sepal length');
ylabel('Sepal width');
legend off
hold off
subplot(2,2,3)
h = gscatter(X(:,1),X(:,2),species,[],'o',4);
hold on
contour(X1Grid,X2Grid,reshape(pdf(GMMModel3,[X1Grid(:) X2Grid(:)]),...
    size(X1Grid,1),size(X1Grid,2)),20)
uistack(h,'top')
title('{\bf Initial Values from the Structure}');
xlabel('Sepal length');

```

```

ylabel('Sepal width');
legend('Location',[0.7,0.25,0.1,0.1]);
hold off

```

According to the counters, `GMMModel2` seems to suggest a slight trimodality, while the others suggest bimodal distributions.

Display the estimated component means.

```

table(GMMModel1.mu,GMMModel2.mu,GMMModel3.mu,'VariableNames',...
      {'Model1','Model2','Model3'})

```

```
ans =
```

Model1		Model2		Model3	
5.0241	1.8658	4.2857	1.3339	1.4604	0.2429
4.7471	1.4616	1.462	0.246	4.7509	1.4629
1.4605	0.24306	5.5507	2.0316	5.0158	1.8592

GMMModel2 seems to distinguish between the iris species the best.

- “Cluster with Gaussian Mixtures”
- “Soft Clustering Using Gaussian Mixture Distributions”
- “Assign New Data to Clusters”

Input Arguments

X — Data

numeric matrix

Data to which the Gaussian mixture model is fit, specified as a numeric matrix.

The rows of **X** correspond to observations, and columns correspond to variables.

NaNs indicate missing values. The software removes rows of **X** containing at least one NaN before fitting, which decreases the effective sample size.

Data Types: `double`

k — Number of components

positive integer

Number of components to use when fitting Gaussian mixture model, specified as a positive integer. For example, if you specify **k** = **3**, then the software fits a Gaussian mixture model with three distinct means, covariances matrices, and component proportions to the data (**X**).

Name-Value Pair Arguments

Specify optional comma-separated pairs of **Name**,**Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single

quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'RegularizationValue', 0.1, 'CovarianceType', 'diagonal'` specifies a regularization parameter value of 0.1 and to fit diagonal covariance matrices.

'CovarianceType' — Type of covariance matrix

`'full'` (default) | `'diagonal'`

Type of covariance matrix to fit to the data, specified as the comma-separated pair consisting of `'CovarianceType'` and either `'diagonal'` or `'full'`.

If you set `'diagonal'`, then the software fits diagonal covariance matrices. In this case, the software estimates $k \cdot d$ covariance parameters, where d is the number of columns in X (i.e., $d = \text{size}(X, 2)$).

Otherwise, the software fits full covariance matrices. In this case, the software estimates $k \cdot d \cdot (d + 1) / 2$ covariance parameters.

Example: `'CovarianceType', 'diagonal'`

Data Types: char

'Options' — Iterative EM algorithm optimization options

`statset options structure`

Iterative EM algorithm optimization options, specified as the comma-separated pair consisting of `'Options'` and a `statset options structure`.

This table describes the available name-value pair arguments.

Name	Value
'Display'	<p><code>'final'</code>: Display the final output.</p> <p><code>'iter'</code>: Display iterative output to the Command Window for some functions; otherwise display the final output.</p> <p><code>'off'</code>: Do not display optimization information.</p>
'MaxIter'	Positive integer indicating the maximum number of iterations allowed. The default is 100

Name	Value
'TolFun'	Positive scalar indicating the termination tolerance for the loglikelihood function value. The default is $1e-6$.

Example:

```
'Options',statset('Display','final','MaxIter',1500,'TolFun',1e-5)
```

'RegularizationValue' — Regularization parameter value

0 (default) | nonnegative scalar

Regularization parameter value, specified as the comma-separated pair consisting of 'RegularizationValue' and a nonnegative scalar.

Set `RegularizationValue` to a small positive scalar to ensure that the estimated covariance matrices are positive definite.

Example: 'RegularizationValue',0.01

Data Types: double

'Replicates' — Number of times to repeat EM algorithm

1 (default) | positive integer

Number of times to repeat the EM algorithm using a new set of initial values, specified as the comma-separated pair consisting of 'Replicates' and a positive integer.

If `Replicates` is greater than 1, then:

- The name-value pair argument `Start` must be `randSample` (which is the default value) or `plus`.
- `GMMModel` is the fit with the largest loglikelihood.

Example: 'Replicates',10

Data Types: double

'SharedCovariance' — Flag indicating whether all covariance matrices are identical

logical false (default) | logical true

Flag indicating whether all covariance matrices are identical (i.e., fit a pooled estimate), specified as the comma-separated pair consisting of 'SharedCovariance' and either logical value `false` or `true`.

If `SharedCovariance` is `true`, then all `k` covariance matrices are equal, and the number of covariance parameters is scaled down by a factor of `k`.

'Start' — Initial value setting method

'randSample' (default) | 'plus' | vector of integers | structure array

Initial value setting method, specified as the comma-separated pair consisting of 'Start' and 'randSample', 'plus', a vector of integers, or a structure array.

The value of `Start` determines the initial values required by the optimization routine for each Gaussian component parameter — mean, covariance, and mixing proportion. This table summarizes the available options.

Value	Description
'randSample'	The software selects <code>k</code> observations from <code>X</code> at random as initial component means. The mixing proportions are uniform. The initial covariance matrices for all components are diagonal, where the element <code>j</code> on the diagonal is the variance of <code>X(:,j)</code> .
'plus'	The software selects <code>k</code> observations from <code>X</code> using the <code>kmeans++</code> algorithm. The initial mixing proportions are uniform. The initial covariance matrices for all components are diagonal, where the element <code>j</code> on the diagonal is the variance of <code>X(:,j)</code> .
Vector of integers	A vector of length <code>n</code> (the number of observations) containing an initial guess of the component index for each point. That is, each element is an integer from 1 to <code>k</code> , which corresponds to a component. The software collects all observations corresponding to the same component, computes means, covariances, and mixing proportions for each, and sets the initial values to these statistics.
Structure array	Suppose that there are <code>d</code> variables (i.e., <code>d = size(X,2)</code>). The structure array, e.g., <code>S</code> , must have three fields: <ul style="list-style-type: none"> <code>S.mu</code>: A <code>k</code>-by-<code>d</code> matrix specifying the initial mean of each component <code>S.Sigma</code>: A numeric array specifying the covariance matrix of each component. <code>Sigma</code> is one of the following: <ul style="list-style-type: none"> A <code>d</code>-by-<code>d</code>-by-<code>k</code> array. <code>Sigma(:, :, j)</code> is the initial covariance matrix of component <code>j</code>. A 1-by-<code>d</code>-by-<code>k</code> array. <code>diag(Sigma(:, :, j))</code> is the initial covariance matrix of component <code>j</code>.

Value	Description
	<ul style="list-style-type: none"> • A d-by-d matrix. <code>Sigma</code> is the initial covariance matrix for all components. • A 1-by-d vector. <code>diag(Sigma)</code> is the initial covariance matrix for all components. • <code>S.ComponentProportion</code>: A 1-by-k vector of scalars specifying the initial mixing proportions of each component. The default is uniform.

Example: `'Start',ones(n,1))`

Data Types: `char` | `double` | `struct`

Output Arguments

GMMModel — Fitted Gaussian mixture model

`gmdistribution` model

Fitted Gaussian mixture model, returned as a `gmdistribution` model.

Access properties of `GMMModel` using dot notation. For example, display the AIC by entering `GMMModel.AIC`.

More About

Tips

`gmdistribution` might:

- Converge to a solution where one or more of the components has an ill-conditioned or singular covariance matrix.

The following issues might result in an ill-conditioned covariance matrix:

- The number of dimensions of your data is relatively high and there are not enough observations.
- Some of the predictors (variables) of your data are highly correlated.

- Some or all the features are discrete.
- You tried to fit the data to too many components.

In general, you can avoid getting ill-conditioned covariance matrices by using one of the following precautions:

- Preprocess your data to remove correlated features.
 - Set `'SharedCovariance'` to `true` to use an equal covariance matrix for every component.
 - Set `'CovarianceType'` to `'diagonal'`.
 - Use `'RegularizationValue'` to add a very small positive number to the diagonal of every covariance matrix.
 - Try another set of initial values.
- Pass through an intermediate step where one or more of the components has an ill-conditioned covariance matrix. Try another set of initial values to avoid this issue without altering your data or model.

Algorithms

Gaussian Mixture Model Likelihood Optimization

The software optimizes the Gaussian mixture model likelihood using the iterative Expectation-Maximization (EM) algorithm.

k-means++ Algorithm for Initialization

The *k*-means++ algorithm uses an heuristic to find centroid seeds for *k*-means clustering. `fitgmdist` can apply the same principle to initialize the EM algorithm by using the *k*-means++ algorithm to select the initial parameter values for a fitted Gaussian mixture model.

The *k*-means++ algorithm assumes the number of clusters is *k* and chooses the initial parameter values as follows.

1

Select the component mixture probability to be the uniform probability $p_i = \frac{1}{k}$,

where $i = 1, \dots, k$.

- 2 Select the covariance matrices to be diagonal and identical, where $\sigma_i = \text{diag}(a_1, a_2, \dots, a_k)$ and $a_j = \text{var}(X_j)$.
- 3 Select the first initial component center μ_1 uniformly from all data points in X .
- 4 To choose center j :
 - a Compute the Mahalanobis distances from each observation to each centroid, and assign each observation to its closest centroid.
 - b For $m = 1, \dots, n$ and $p = 1, \dots, j - 1$, select centroid j at random from X with probability

$$\frac{d^2(x_m, \mu_p)}{\sum_{h; x_h \in M_p} d^2(x_h, \mu_p)}$$

where $d(x_m, \mu_p)$ is the distance between observation m and μ_p , and M_p is the set of all observations closest to centroid μ_p and x_m belongs to M_p .

That is, select each subsequent center with a probability proportional to the distance from itself to the closest center that you already chose.

- 5 Repeat step 4 until k centroids are chosen.

fitlm

Create linear regression model

Syntax

```
mdl = fitlm(tbl)
mdl = fitlm(tbl,modelspec)

mdl = fitlm(X,y)
mdl = fitlm(X,y,modelspec)

mdl = fitlm( ____,Name,Value)
```

Description

`mdl = fitlm(tbl)` returns a linear model fit to variables in the table or dataset array `tbl`. By default, `fitlm` takes the last variable as the response variable.

`mdl = fitlm(tbl,modelspec)` returns a linear model of the type you specify in `modelspec` fit to variables in the table or dataset array `tbl`.

`mdl = fitlm(X,y)` returns a linear model of the responses `y`, fit to the data matrix `X`.

`mdl = fitlm(X,y,modelspec)` returns a linear model of the type you specify in `modelspec` for the responses `y`, fit to the data matrix `X`.

`mdl = fitlm(____,Name,Value)` returns a linear model with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify which variables are categorical, perform robust regression, or use observation weights.

Examples

Linear Regression with Categorical Predictor and Quadratic Term

Fit a quadratic linear regression model to variables in a table. The data includes continuous and categorical predictor variables.

Load the sample data.

```
load carsmall
```

Construct a table containing continuous predictor variable `Weight` and response variable `MPG`. Add the nominal predictor variable `Year`.

```
tbl = table(MPG,Weight);
tbl.Year = nominal(Model_Year);
```

Create a fitted model of `MPG` as a function of `Year`, `Weight`, and `Weight2`. You don't have to include `Weight` explicitly in your formula because it is a lower-order term of `Weight2`. For details, see “Formula” on page 21-1447.

```
mdl = fitlm(tbl, 'MPG ~ Year + Weight^2')
```

```
mdl =
```

```
Linear regression model:
```

```
MPG ~ 1 + Weight + Year + Weight^2
```

```
Estimated Coefficients:
```

	Estimate	SE	tStat
(Intercept)	54.206	4.7117	11.505
Weight	-0.016404	0.0031249	-5.2493
Year_76	2.0887	0.71491	2.9215
Year_82	8.1864	0.81531	10.041
Weight^2	1.5573e-06	4.9454e-07	3.149

```
pValue
```

(Intercept)	2.6648e-19
Weight	1.0283e-06
Year_76	0.0044137
Year_82	2.6364e-16
Weight^2	0.0022303

```
Number of observations: 94, Error degrees of freedom: 89
```

```
Root Mean Squared Error: 2.78
```

```
R-squared: 0.885, Adjusted R-Squared 0.88
```

```
F-statistic vs. constant model: 172, p-value = 5.52e-41
```

`fitlm` creates two dummy (indicator) variables for the nominal variables, `Year`. The dummy variable `Year_76` takes the value 1 if the model year is 1976 and takes the value 0 if it is not. The dummy variable `Year_82` takes the value 1 if model year is 1982 and takes the value 0 if it is not. 1970 is the reference year (for details on dummy variables, see “Dummy Indicator Variables” on page 2-55). The fitted model is

$$\hat{MPG} = 54.206 - 0.0164(\text{Weight}) + 2.0887(\text{Year}_76) + 8.1864(\text{Year}_82) + (1.557e - 06)(\text{Weight})^2$$

Simultaneously Specify the Variables and Use Formula

Simultaneously identify response and predictor variables and specify the model using a formula in linear regression.

Load sample data.

```
load hospital
```

Fit a linear model with interaction terms to the data. Indicate which variable is the response variable and identify the continuous and categorical predictors using name-value pair arguments.

```
mdl = fitlm(hospital, 'Weight~1+Age*Sex*Smoker-Age:Sex:Smoker', 'ResponseVar', 'Weight', 'F
```

```
mdl =
```

Linear regression model:

```
Weight ~ 1 + Sex*Age + Sex*Smoker + Age*Smoker
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	118.7	7.0718	16.785	6.821e-30
Sex_Male	68.336	9.7153	7.0339	3.3386e-10
Age	0.31068	0.18531	1.6765	0.096991
Smoker_1	3.0425	10.446	0.29127	0.77149
Sex_Male:Age	-0.49094	0.24764	-1.9825	0.050377
Sex_Male:Smoker_1	0.9509	3.8031	0.25003	0.80312
Age:Smoker_1	-0.07288	0.26275	-0.27737	0.78211

Number of observations: 100, Error degrees of freedom: 93

Root Mean Squared Error: 8.75

R-squared: 0.898, Adjusted R-Squared 0.892

F-statistic vs. constant model: 137, p-value = 6.91e-44

The t -statistics in `tStat` and corresponding p -values in `pValue` indicate that patient weights do not seem to differ significantly according to age, or the status of smoking, or the interaction of these factors with gender at the 5% significance level.

Robust Linear Regression Model

Fit a linear regression model of the Hald data using robust fitting.

Load the data.

```
load hald
X = ingredients; % Predictor variables
y = heat; % Response
```

Fit a robust linear model to the data.

```
mdl = fitlm(X,y,'linear','RobustOpts','on')
```

```
mdl =
```

Linear regression model (robust fit):

$$y \sim 1 + x1 + x2 + x3 + x4$$

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	60.09	75.818	0.79256	0.4509
x1	1.5753	0.80585	1.9548	0.086346
x2	0.5322	0.78315	0.67957	0.51596
x3	0.13346	0.8166	0.16343	0.87424
x4	-0.12052	0.7672	-0.15709	0.87906

Number of observations: 13, Error degrees of freedom: 8

Root Mean Squared Error: 2.65

R-squared: 0.979, Adjusted R-Squared 0.969

F-statistic vs. constant model: 94.6, p-value = 9.03e-07

Input Arguments

tbl — Input data

table | dataset array

Input data, specified as a table or dataset array. When `modelspec` is a `formula`, it specifies the variables to be used as the predictors and response. Otherwise, if you do not specify the predictor and response variables, the last variable is the response variable and the others are the predictor variables by default.

Predictor variables can be numeric, or any grouping variable type, such as logical or categorical (see “Grouping Variables” on page 2-52). The response must be numeric or logical.

To set a different column as the response variable, use the `ResponseVar` name-value pair argument. To use a subset of the columns as predictors, use the `PredictorVars` name-value pair argument.

Data Types: `single` | `double` | `logical`

X — Predictor variables

matrix

Predictor variables, specified as an n -by- p matrix, where n is the number of observations and p is the number of predictor variables. Each column of `X` represents one variable, and each row represents one observation.

By default, there is a constant term in the model, unless you explicitly remove it, so do not include a column of 1s in `X`.

Data Types: `single` | `double` | `logical`

y — Response variable

vector

Response variable, specified as an n -by-1 vector, where n is the number of observations. Each entry in `y` is the response for the corresponding row of `X`.

Data Types: `single` | `double`

modelspec — Model specification

'linear' (default) | string naming the model | t -by- $(p + 1)$ terms matrix | string of the form 'Y ~ terms'

Model specification, specified as one of the following. The choice is the starting model for `stepwiselm`. Default is `'linear'`.

- A string naming the model.

String	Model Type
<code>'constant'</code>	Model contains only a constant (intercept) term.
<code>'linear'</code>	Model contains an intercept and linear terms for each predictor.
<code>'interactions'</code>	Model contains an intercept, linear terms, and all products of pairs of distinct predictors (no squared terms).
<code>'purequadratic'</code>	Model contains an intercept, linear terms, and squared terms.
<code>'quadratic'</code>	Model contains an intercept, linear terms, interactions, and squared terms.
<code>'polyijk'</code>	Model is a polynomial with all terms up to degree i in the first predictor, degree j in the second predictor, etc. Use numerals 0 through 9. For example, <code>'poly2111'</code> has a constant plus all linear and product terms, and also contains terms with predictor 1 squared.

- t -by- $(p + 1)$ matrix, namely terms matrix, specifying terms to include in the model, where t is the number of terms and p is the number of predictor variables, and plus 1 is for the response variable.
- A string representing a formula in the form `'Y ~ terms'`, where the `terms` are in Wilkinson Notation.

Example: `'quadratic'`

Example: `'y ~ X1 + X2^2 + X1:X2'`

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'Intercept',false,'PredictorVars',[1,3],'ResponseVar',5,'RobustOpts','logistic'` specifies a robust regression model with no constant term, where the algorithm uses the logistic weighting function with the default tuning constant, first and third variables are the predictor variables, and fifth variable is the response variable.

'CategoricalVars' — Categorical variables

cell array of strings | logical or numeric index vector

Categorical variables in the fit, specified as the comma-separated pair consisting of `'CategoricalVars'` and either a cell array of strings of the names of the categorical variables in the table or dataset array `tbl`, or a logical or numeric index vector indicating which columns are categorical.

- If data is in a table or dataset array `tbl`, then the default is to treat all categorical or logical variables, character arrays, or cell arrays of strings as categorical variables.
- If data is in matrix `X`, then the default value of this name-value pair argument is an empty matrix `[]`. That is, no variable is categorical unless you specify it.

For example, you can specify the observations 2 and 3 out of 6 as categorical using either of the following examples.

Example: `'CategoricalVars',[2,3]`

Example: `'CategoricalVars',logical([0 1 1 0 0 0])`

Data Types: `single` | `double` | `logical`

'Exclude' — Observations to exclude

logical or numeric index vector

Observations to exclude from the fit, specified as the comma-separated pair consisting of `'Exclude'` and a logical or numeric index vector indicating which observations to exclude from the fit.

For example, you can exclude observations 2 and 3 out of 6 using either of the following examples.

Example: `'Exclude',[2,3]`

Example: `'Exclude',logical([0 1 1 0 0 0])`

Data Types: `single` | `double` | `logical`

'Intercept' — Indicator for constant term

true (default) | false

Indicator the for constant term (intercept) in the fit, specified as the comma-separated pair consisting of 'Intercept' and either **true** to include or **false** to remove the constant term from the model.

Use 'Intercept' only when specifying the model using a string, not a formula or matrix.

Example: 'Intercept',false

'PredictorVars' — Predictor variables

cell array of strings | logical or numeric index vector

Predictor variables to use in the fit, specified as the comma-separated pair consisting of 'PredictorVars' and either a cell array of strings of the variable names in the table or dataset array `tbl`, or a logical or numeric index vector indicating which columns are predictor variables.

The strings should be among the names in `tbl`, or the names you specify using the 'VarNames' name-value pair argument.

The default is all variables in `X`, or all variables in `tbl` except for `ResponseVar`.

For example, you can specify the second and third variables as the predictor variables using either of the following examples.

Example: 'PredictorVars',[2,3]

Example: 'PredictorVars',logical([0 1 1 0 0 0])

Data Types: single | double | logical | cell

'ResponseVar' — Response variable

last column in `tbl` (default) | string for variable name | logical or numeric index vector

Response variable to use in the fit, specified as the comma-separated pair consisting of 'ResponseVar' and either a string of the variable name in the table or dataset array `tbl`, or a logical or numeric index vector indicating which column is the response variable. You typically need to use 'ResponseVar' when fitting a table or dataset array `tbl`.

For example, you can specify the fourth variable, say `yield`, as the response out of six variables, in one of the following ways.

Example: 'ResponseVar', 'yield'

Example: 'ResponseVar', [4]

Example: 'ResponseVar', logical([0 0 0 1 0 0])

Data Types: single | double | logical | char

'RobustOpts' — Indicator of robust fitting type

'off' (default) | 'on' | string | structure with string or function handle

Indicator of the robust fitting type to use, specified as the comma-separated pair consisting of 'RobustOpts' and one of the following.

- 'off' — No robust fitting. `fitlm` uses ordinary least squares.
- 'on' — Robust fitting. When you use robust fitting, 'bisquare' weight function is the default.
- String — Name of the robust fitting weight function from the following table. `fitlm` uses the corresponding default tuning constant in the table.
- Structure with the string `RobustWgtFun` containing the name of the robust fitting weight function from the following table and optional scalar `Tune` fields — `fitlm` uses the `RobustWgtFun` weight function and `Tune` tuning constant from the structure. You can choose the name of the robust fitting weight function from this table. If you do not supply a `Tune` field, the fitting function uses the corresponding default tuning constant.

Weight Function	Equation	Default Tuning Constant
'andrews'	$w = (\text{abs}(r) < \pi) .* \sin(r) ./ r$	1.339
'bisquare' (default)	$w = (\text{abs}(r) < 1) .* (1 - r.^2).^2$	4.685
'cauchy'	$w = 1 ./ (1 + r.^2)$	2.385
'fair'	$w = 1 ./ (1 + \text{abs}(r))$	1.400
'huber'	$w = 1 ./ \max(1, \text{abs}(r))$	1.345
'logistic'	$w = \tanh(r) ./ r$	1.205
'ols'	Ordinary least squares (no weighting function)	None
'talwar'	$w = 1 * (\text{abs}(r) < 1)$	2.795

Weight Function	Equation	Default Tuning Constant
'welsch'	$w = \exp(- (r.^2))$	2.985

The value r in the weight functions is

$$r = \text{resid} / (\text{tune} * s * \text{sqrt}(1-h)),$$

where `resid` is the vector of residuals from the previous iteration, `h` is the vector of leverage values from a least-squares fit, and `s` is an estimate of the standard deviation of the error term given by

$$s = \text{MAD} / 0.6745.$$

MAD is the median absolute deviation of the residuals from their median. The constant 0.6745 makes the estimate unbiased for the normal distribution. If there are p columns in X , the smallest p absolute deviations are excluded when computing the median.

Default tuning constants give coefficient estimates that are approximately 95% as statistically efficient as the ordinary least-squares estimates, provided the response has a normal distribution with no outliers. Decreasing the tuning constant increases the downweight assigned to large residuals; increasing the tuning constant decreases the downweight assigned to large residuals.

- Structure with the function handle `RobustWgtFun` and optional scalar `Tune` fields — You can specify a custom weight function. `fitlm` uses the `RobustWgtFun` weight function and `Tune` tuning constant from the structure. Specify `RobustWgtFun` as a function handle that accepts a vector of residuals, and returns a vector of weights the same size. The fitting function scales the residuals, dividing by the tuning constant (default 1) and by an estimate of the error standard deviation before it calls the weight function.

Example: `'RobustOpts', 'andrews'`

'VarNames' — Names of variables in fit

`{'x1', 'x2', ..., 'xn', 'y'}` (default) | cell array of strings

Names of variables in fit, specified as the comma-separated pair consisting of `'VarNames'` and a cell array of strings including the names for the columns of X first, and the name for the response variable y last.

'VarNames' is not applicable to variables in a table or dataset array, because those variables already have names.

For example, if in your data, horsepower, acceleration, and model year of the cars are the predictor variables, and miles per gallon (MPG) is the response variable, then you can name the variables as follows.

Example: 'VarNames', {'Horsepower', 'Acceleration', 'Model_Year', 'MPG'}

Data Types: cell

'Weights' — Observation weights

ones(*n*, 1) (default) | *n*-by-1 vector of nonnegative scalar values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and an *n*-by-1 vector of nonnegative scalar values, where *n* is the number of observations.

Data Types: single | double

Output Arguments

mdl — Linear model

LinearModel object

Linear model representing a least-squares fit of the response to the data, returned as a LinearModel object.

If the value of the 'RobustOpts' name-value pair is not [] or 'ols', the model is not a least-squares fit, but uses the robust fitting function.

For properties and methods of the linear model object, mdl, see the LinearModel class page.

More About

Terms Matrix

A terms matrix is a *t*-by-(*p* + 1) matrix specifying terms in a model, where *t* is the number of terms, *p* is the number of predictor variables, and plus one is for the response variable.

The value of $T(i, j)$ is the exponent of variable j in term i . Suppose there are three predictor variables A , B , and C :

```
[0 0 0 0] % Constant term or intercept
[0 1 0 0] % B; equivalently, A^0 * B^1 * C^0
[1 0 1 0] % A*C
[2 0 0 0] % A^2
[0 1 2 0] % B*(C^2)
```

The 0 at the end of each term represents the response variable. In general,

- If you have the variables in a table or dataset array, then 0 must represent the response variable depending on the position of the response variable. The following example illustrates this.

Load the sample data and define the dataset array.

```
load hospital
ds = dataset(hospital.Sex,hospital.BloodPressure(:,1),hospital.Age,...
hospital.Smoker, 'VarNames', {'Sex', 'BloodPressure', 'Age', 'Smoker'});
```

Represent the linear model 'BloodPressure ~ 1 + Sex + Age + Smoker' in a terms matrix. The response variable is in the second column of the dataset array, so there must be a column of 0s for the response variable in the second column of the terms matrix.

```
T = [0 0 0 0;1 0 0 0;0 0 1 0;0 0 0 1]
```

```
T =
```

```
    0    0    0    0
    1    0    0    0
    0    0    1    0
    0    0    0    1
```

Redefine the dataset array.

```
ds = dataset(hospital.BloodPressure(:,1),hospital.Sex,hospital.Age,...
hospital.Smoker, 'VarNames', {'BloodPressure', 'Sex', 'Age', 'Smoker'});
```

Now, the response variable is the first term in the dataset array. Specify the same linear model, 'BloodPressure ~ 1 + Sex + Age + Smoker', using a terms matrix.

```
T = [0 0 0 0;0 1 0 0;0 0 1 0;0 0 0 1]
```

```
T =  
  
    0    0    0    0  
    0    1    0    0  
    0    0    1    0  
    0    0    0    1
```

- If you have the predictor and response variables in a matrix and column vector, then you must include 0 for the response variable at the end of each term. The following example illustrates this.

Load the sample data and define the matrix of predictors.

```
load carsmall  
X = [Acceleration,Weight];
```

Specify the model 'MPG ~ Acceleration + Weight + Acceleration:Weight + Weight^2' using a term matrix and fit the model to the data. This model includes the main effect and two-way interaction terms for the variables, `Acceleration` and `Weight`, and a second-order term for the variable, `Weight`.

```
T = [0 0 0;1 0 0;0 1 0;1 1 0;0 2 0]
```

```
T =  
  
    0    0    0  
    1    0    0  
    0    1    0  
    1    1    0  
    0    2    0
```

Fit a linear model.

```
mdl = fitlm(X,MPG,T)
```

```
mdl =
```

```
Linear regression model:  
y ~ 1 + x1*x2 + x2^2
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	48.906	12.589	3.8847	0.00019665
x1	0.54418	0.57125	0.95261	0.34337

x2	-0.012781	0.0060312	-2.1192	0.036857
x1:x2	-0.00010892	0.00017925	-0.6076	0.545
x2^2	9.7518e-07	7.5389e-07	1.2935	0.19917

Number of observations: 94, Error degrees of freedom: 89
 Root Mean Squared Error: 4.1
 R-squared: 0.751, Adjusted R-Squared 0.739
 F-statistic vs. constant model: 67, p-value = 4.99e-26

Only the intercept and x2 term, which correspond to the `Weight` variable, are significant at the 5% significance level.

Now, perform a stepwise regression with a constant model as the starting model and a linear model with interactions as the upper model.

```
T = [0 0 0;1 0 0;0 1 0;1 1 0];
mdl = stepwiselm(X,MPG,[0 0 0], 'upper',T)
```

1. Adding x2, FStat = 259.3087, pValue = 1.643351e-28

mdl =

Linear regression model:

$$y \sim 1 + x2$$

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	49.238	1.6411	30.002	2.7015e-49
x2	-0.0086119	0.0005348	-16.103	1.6434e-28

Number of observations: 94, Error degrees of freedom: 92
 Root Mean Squared Error: 4.13
 R-squared: 0.738, Adjusted R-Squared 0.735
 F-statistic vs. constant model: 259, p-value = 1.64e-28

The results of the stepwise regression are consistent with the results of `fitlm` in the previous step.

Formula

A formula for model specification is a string of the form ' $Y \sim terms$ '

where

- Y is the response name.

- *terms* contains
 - Variable names
 - + means include the next variable
 - - means do not include the next variable
 - : defines an interaction, a product of terms
 - * defines an interaction **and all lower-order terms**
 - ^ raises the predictor to a power, exactly as in * repeated, so ^ includes lower order terms as well
 - () groups terms

Note: Formulas include a constant (intercept) term by default. To exclude a constant term from the model, include - 1 in the formula.

For example,

'Y ~ A + B + C' means a three-variable linear model with intercept.

'Y ~ A + B + C - 1' is a three-variable linear model without intercept.

'Y ~ A + B + C + B^2' is a three-variable model with intercept and a B^2 term.

'Y ~ A + B^2 + C' is the same as the previous example because B^2 includes a B term.

'Y ~ A + B + C + A:B' includes an A*B term.

'Y ~ A*B + C' is the same as the previous example because $A*B = A + B + A:B$.

'Y ~ A*B*C - A:B:C' has all interactions among A, B, and C, except the three-way interaction.

'Y ~ A*(B + C + D)' has all linear terms, plus products of A with each of the other variables.

Wilkinson Notation

Wilkinson notation describes the factors present in models. The notation relates to factors present in models, not to the multipliers (coefficients) of those factors.

Wilkinson Notation	Factors in Standard Notation
1	Constant (intercept) term
A^k , where k is a positive integer	A, A^2, \dots, A^k

Wilkinson Notation	Factors in Standard Notation
$A + B$	A, B
$A*B$	A, B, $A*B$
$A:B$	$A*B$ only
$-B$	Do not include B
$A*B + C$	A, B, C, $A*B$
$A + B + C + A:B$	A, B, C, $A*B$
$A*B*C - A:B:C$	A, B, C, $A*B$, $A*C$, $B*C$
$A*(B + C)$	A, B, C, $A*B$, $A*C$

Statistics Toolbox notation always includes a constant term unless you explicitly remove the term using -1 .

fitlme

Fit linear mixed-effects model

Syntax

```
lme = fitlme(tbl,formula)
lme = fitlme(tbl,formula,Name,Value)
```

Description

`lme = fitlme(tbl,formula)` returns a linear mixed-effects model, specified by `formula`, fitted to the variables in the table or dataset array `tbl`.

`lme = fitlme(tbl,formula,Name,Value)` returns a linear mixed-effects model with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify the covariance pattern of the random-effects terms, the method to use in estimating the parameters, or options for the optimization algorithm.

Examples

Fit Linear Mixed-Effects Model

Load the sample data.

```
load imports-85
```

Store the variables in a table.

```
tbl = table(X(:,12),X(:,14),X(:,24),'VariableNames',{ 'Horsepower', 'CityMPG', 'EngineType
```

Display the first five rows of the table.

```
tbl(1:5,:)
```

```
ans =
```

Horsepower	CityMPG	EngineType
------------	---------	------------

111	21	13
111	21	13
154	19	37
102	24	35
115	18	35

Fit a linear mixed-effects model for miles per gallon in the city, with fixed effects for horsepower, and uncorrelated random effect for intercept and horsepower grouped by the engine type.

```
lme = fitlme(tbl, 'CityMPG~Horsepower+(1|EngineType)+(Horsepower-1|EngineType)');
```

In this model, `CityMPG` is the response variable, `horsepower` is the predictor variable, and engine type is the grouping variable. The fixed-effects portion of the model corresponds to `1 + Horsepower`, because the intercept is included by default.

Since the random-effect terms for intercept and horsepower are uncorrelated, these terms are specified separately. Because the second random-effect term is only for horsepower, you must include a `-1` to eliminate the intercept from the second random-effect term.

Display the model.

```
lme
```

```
lme =
```

```
Linear mixed-effects model fit by ML
```

```
Model information:
```

Number of observations	203
Fixed effects coefficients	2
Random effects coefficients	14
Covariance parameters	3

```
Formula:
```

```
CityMPG ~ 1 + Horsepower + (1 | EngineType) + (Horsepower | EngineType)
```

```
Model fit statistics:
```

AIC	BIC	LogLikelihood	Deviance
1099.5	1116	-544.73	1089.5

```
Fixed effects coefficients (95% CIs):
```

Name	Estimate	SE	tStat	DF	pValue	Lower
'(Intercept)'	37.276	2.8556	13.054	201	1.3147e-28	31.64
'Horsepower'	-0.12631	0.02284	-5.53	201	9.8848e-08	-0.1713

Random effects covariance parameters (95% CIs):

Group: EngineType (7 Levels)

Name1	Name2	Type	Estimate	Lower	Upper
'(Intercept)'	'(Intercept)'	'std'	5.7338	2.3773	13.82

Group: EngineType (7 Levels)

Name1	Name2	Type	Estimate	Lower	Upper
'Horsepower'	'Horsepower'	'std'	0.050357	0.02307	0.1099

Group: Error

Name	Estimate	Lower	Upper
'Res Std'	3.226	2.9078	3.5789

Note that the random-effects covariance parameters for intercept and horsepower are separate in the display.

Now, fit a linear mixed-effects model for miles per gallon in the city, with the same fixed-effects term and potentially correlated random effect for intercept and horsepower grouped by the engine type.

```
lme2 = fitlme(tbl, 'CityMPG~Horsepower+(Horsepower|EngineType)');
```

Because the random-effect term includes the intercept by default, you do not have to add 1, the random effect term is equivalent to (1 + Horsepower|EngineType).

Display the model.

```
lme2
```

```
lme2 =
```

```
Linear mixed-effects model fit by ML
```

```
Model information:
```

```

Name	Estimate	SE	tStat	DF	pValue	Lower
'(Intercept)'	33.824	4.0181	8.4178	201	7.1678e-15	25.90
'Horsepower'	-0.1087	0.032912	-3.3029	201	0.0011328	-0.173

```
Random effects covariance parameters (95% CIs):
```

```
Group: EngineType (7 Levels)
```

Name1	Name2	Type	Estimate	Lower	Upper
'(Intercept)'	'(Intercept)'	'std'	9.4952	4.7022	14.2882
'Horsepower'	'(Intercept)'	'corr'	-0.96843	-0.99568	-0.94118
'Horsepower'	'Horsepower'	'std'	0.078874	0.039917	0.117831

```
Group: Error
```

Name	Estimate	Lower	Upper
'Res Std'	3.1845	2.8774	3.5243

Note that the random effects covariance parameters for intercept and horsepower are together in the display, and it includes the correlation ('corr') between the intercept and horsepower.

Random Intercept Model

Load the sample data.

```
load flu
```

The `flu` dataset array has a `Date` variable, and 10 variables containing estimated influenza rates (in 9 different regions, estimated from Google searches, plus a nationwide estimate from the Centers for Disease Control and Prevention, CDC).

To fit a linear-mixed effects model, your data must be in a properly formatted dataset array. To fit a linear mixed-effects model with the influenza rates as the responses, combine the nine columns corresponding to the regions into a tall array. The new dataset array, `flu2`, must have the new response variable `FluRate`, the nominal variable `Region` that shows which region each estimate is from, the nationwide estimate `WtdILI`, and the grouping variable `Date`.

```
flu2 = stack(flu,2:10, 'NewDataVarName', 'FluRate', ...
```

```
'IndVarName', 'Region');
flu2.Date = nominal(flu2.Date);
```

Display the first six rows of `flu2`.

```
flu2(1:6, :)
```

```
ans =
```

Date	WtdILI	Region	FluRate
10/9/2005	1.182	NE	0.97
10/9/2005	1.182	MidAtl	1.025
10/9/2005	1.182	ENCentral	1.232
10/9/2005	1.182	WNCentral	1.286
10/9/2005	1.182	SAtl	1.082
10/9/2005	1.182	ESCentral	1.457

Fit a linear mixed-effects model with a fixed-effects term for the nationwide estimate, `WtdILI`, and a random intercept that varies by `Date`. The model corresponds to

$$y_{im} = \beta_0 + \beta_1 WtdILI_{im} + b_{0m} + \varepsilon_{im}, \quad i = 1, 2, \dots, 468, \quad m = 1, 2, \dots, 52,$$

where y_{im} is the observation i for level m of grouping variable `Date`. b_{0m} is the random effect for level m of the grouping variable `Date` and ε_{im} is the observation error for observation i . The random effect has the prior distribution, $b \sim N(0, \sigma_b^2)$ and the error term has the distribution, $\varepsilon \sim N(0, \sigma^2)$.

```
lme = fitlme(flu2, 'FluRate ~ 1 + WtdILI + (1|Date)')
```

```
lme =
```

Linear mixed-effects model fit by ML

Model information:

Number of observations	468
Fixed effects coefficients	2
Random effects coefficients	52
Covariance parameters	2

Formula:

```
FluRate ~ 1 + WtdILI + (1 | Date)
```

Model fit statistics:

AIC	BIC	LogLikelihood	Deviance

Random effects covariance parameters (95% CIs):

Group: Date (52 Levels)

Name1	Name2	Type	Estimate	Lower	Upper
'(Intercept)'	'(Intercept)'	'std'	0.17146	0.13227	0.22226

Group: Error

Name	Estimate	Lower	Upper
'Res Std'	0.30201	0.28217	0.32324

Estimated covariance parameters are displayed in the section titled "Random effects covariance parameters". The estimated value of σ_b is 0.17146 and its 95% confidence interval is [0.13227, 0.22226]. Since this interval does not include 0, the random-effects term is significant. You can formally test the significance of any random-effects term using a likelihood ratio test via the `compare` method.

The estimated response at an observation is the sum of the fixed effects and the random-effect value at the grouping variable level corresponding to that observation. For example, the estimated flu rate for observation 28 is

$$\begin{aligned}\hat{y}_{28} &= \hat{\beta}_0 + \hat{\beta}_1 \text{WtdILI}_{28} + \hat{b}_{10/30/2005} \\ &= 0.1639 + 0.7236 * (1.343) + 0.3318 \\ &= 1.46749,\end{aligned}$$

where \hat{b} is the estimated best linear unbiased predictor (BLUP) of the random effects for the intercept. You can compute this value as follows.

```
beta = fixedEffects(lme);
[~,~,STATS] = randomEffects(lme); % Compute the random-effects statistics (STATS)
STATS.Level = nominal(STATS.Level1);
y_hat = beta(1) + beta(2)*flu2.WtdILI(28) + STATS.Estimate(STATS.Level=='10/30/2005')
y_hat =
    1.4674
```

You can display the fitted value using the `fitted` method.

```
F = fitted(lme);  
F(28)  
  
ans =  
  
    1.4674
```

Randomized Block Design

Navigate to a folder containing sample data.

```
cd(matlabroot)  
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load shift
```

The data shows the absolute deviations from the target quality characteristic measured from the products each of five operators manufacture during three shifts: morning, evening, and night. This is a randomized block design, where the operators are the blocks. The experiment is designed to study the impact of the time of shift on the performance. The performance measure is the absolute deviations of the quality characteristics from the target value. This is simulated data.

Fit a linear mixed-effects model with a random intercept grouped by operator to assess if performance significantly differs according to the time of the shift. Use the restricted maximum likelihood method and 'effects' contrasts.

'effects' contrasts mean that the coefficients sum to 0, and `fitlme` creates a matrix called a “fixed effects design matrix” to describe the effect of shift. This matrix has two columns, *Shift_Evening* and *Shift_Morning*, where

$$\text{Shift_Evening} = \begin{cases} 0, & \text{if Morning} \\ 1, & \text{if Evening} \\ -1, & \text{if Night} \end{cases} \quad \text{and} \quad \text{Shift_Morning} = \begin{cases} 1, & \text{if Morning} \\ 0, & \text{if Evening} \\ -1, & \text{if Night} \end{cases}.$$

The model corresponds to

$$\text{Morning Shift: } QCDev_{im} = \beta_0 + \beta_2 \text{Shift_Morning}_i + b_{0m} + \varepsilon_{im}, \quad m = 1, 2, \dots, 5,$$

$$\text{Evening Shift: } QCDev_{im} = \beta_0 + \beta_1 \text{Shift_Evening}_i + b_{0m} + \varepsilon_{im},$$

$$\text{Night Shift: } QCDev_{im} = \beta_0 - \beta_1 \text{Shift_Evening}_i - \beta_2 \text{Shift_Morning}_i + b_{0m} + \varepsilon_{im},$$

where $b \sim N(0, \sigma_b^2)$ and $\varepsilon \sim N(0, \sigma^2)$.

```
lme = fitlme(shift, 'QCDev ~ Shift + (1|Operator)', ...
  'FitMethod', 'REML', 'DummyVarCoding', 'effects')
```

```
lme =
```

```
Linear mixed-effects model fit by REML
```

```
Model information:

'Shift_Evening'	-0.53293	0.31206	-1.7078	12	0.11339	-1.212
'Shift_Morning'	-0.91973	0.31206	-2.9473	12	0.012206	-1.599

```
Random effects covariance parameters (95% CIs):
```

```
Group: Operator (5 Levels)
```

Name1	Name2	Type	Estimate	Lower	Upper
'(Intercept)'	'(Intercept)'	'std'	2.0457	0.98207	4.26

```
Group: Error
```

Name	Estimate	Lower	Upper
'Res Std'	0.85462	0.52357	1.395

Compute the best linear unbiased predictor (BLUP) estimates of random effects.

```
B = randomEffects(lme)
```

```
B =
```

```
0.5775
```

```
1.1757  
-2.1715  
2.3655  
-1.9472
```

The estimated absolute deviation from the target quality characteristics for the third operator working the evening shift is

$$\begin{aligned}\hat{y}_{\text{Evening,Operator3}} &= \hat{\beta}_0 + \hat{\beta}_1 \text{Shift_Evening} + \hat{b}_{03} \\ &= 3.6525 - 0.53293 - 2.1715 \\ &= 0.94807.\end{aligned}$$

You can also display this value as follows.

```
F = fitted(lme);  
F(shift.Shift=='Evening' & shift.Operator=='3')
```

```
ans =
```

```
0.9481
```

Similarly, you can calculate the estimated absolute deviation from the target quality characteristics for the third operator working the morning shift as

$$\begin{aligned}\hat{y}_{\text{Morning,Operator3}} &= \hat{\beta}_0 + \hat{\beta}_2 \text{Shift_Morning} + \hat{b}_{03} \\ &= 3.6525 - 0.91973 - 2.1715 \\ &= 0.56127.\end{aligned}$$

You can also display this value as follows.

```
F(shift.Shift=='Morning' & shift.Operator=='3')
```

```
ans =
```

```
0.5613
```

The operator tends to make a smaller magnitude of error during the morning shift.

Split-Plot Experiment

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load fertilizer
```

The dataset array includes data from a split-plot experiment, where soil is divided into three blocks based on the soil type: sandy, silty, and loamy. Each block is divided into five plots, where five types of tomato plants (cherry, heirloom, grape, vine, and plum) are randomly assigned to these plots. The tomato plants in the plots are then divided into subplots, where each subplot is treated by one of four fertilizers. This is simulated data.

Store the data in a dataset array called `ds`, and define `Tomato`, `Soil`, and `Fertilizer` as categorical variables.

```
ds = fertilizer;
ds.Tomato = nominal(ds.Tomato);
ds.Soil = nominal(ds.Soil);
ds.Fertilizer = nominal(ds.Fertilizer);
```

Fit a linear mixed-effects model, where `Fertilizer` and `Tomato` are the fixed-effects variables, and the mean yield varies by the block (soil type) and the plots within blocks (tomato types within soil types) independently.

This model corresponds to

$$y_{imjk} = \beta_0 + \sum_{m=2}^4 \beta_{1m} I[F]_{im} + \sum_{j=2}^5 \beta_{2j} I[T]_{ij} + \sum_{j=2}^5 \sum_{m=2}^4 \beta_{3mj} I[F]_{im} I[T]_{ij} + b_{0k} S_k + b_{0jk} (S^* T)_{jk} + \varepsilon_{imjk},$$

where $i = 1, 2, \dots, 60$, index m corresponds to the fertilizer types, j corresponds to the tomato types, and $k = 1, 2, 3$ corresponds to the blocks (soil). S_k represents the k th soil type, and $(S^* T)_{jk}$ represents the j th tomato type nested in the k th soil type. $I[F]_{im}$ is the dummy variable representing level m of the fertilizer. Similarly, $I[T]_{ij}$ is the dummy variable representing level j of the tomato type.

The random effects and observation error have these prior distributions: $b_{0k} \sim N(0, \sigma^2_S)$, $b_{0jk} \sim N(0, \sigma^2_{S^*T})$, and $\varepsilon_{imjk} \sim N(0, \sigma^2)$.

```
lme = fitlme(ds, 'Yield ~ Fertilizer * Tomato + (1|Soil) + (1|Soil:Tomato)')
lme =
```

Linear mixed-effects model fit by ML

Model information:

The p -values corresponding to the last 12 rows in the fixed-effects coefficients display (0.82701 to 0.47881) indicate that interaction coefficients between the tomato and fertilizer types are not significant. To test for the overall interaction between tomato and fertilizer, use the `anova` method after refitting the model using `'effects'` contrasts.

The confidence interval for the standard deviations of the random-effects terms (σ^2_s), where the intercept is grouped by soil, is very large. This term does not appear significant.

Refit the model after removing the interaction term `Tomato:Fertilizer` and the random-effects term (`1 | Soil`).

Random effects covariance parameters (95% CIs):

Group: Soil:Tomato (15 Levels)

Name1	Name2	Type	Estimate	Lower	Upper
'(Intercept)'	'(Intercept)'	'std'	10.02	6.0812	16.5008

Group: Error

Name	Estimate	Lower	Upper
'Res Std'	12.325	10.024	15.153

You can compare the two models using the `compare` method with the simulated likelihood ratio test since both a fixed-effect and a random-effect term are tested.

Longitudinal Study with a Covariate

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load weight
```

`weight` contains data from a longitudinal study, where 20 subjects are randomly assigned to 4 exercise programs (A, B, C, D), and their weight loss is recorded over six 2-week time periods. This is simulated data.

Store the data in a table. Define `Subject` and `Program` as categorical variables.

```
tbl = table(InitialWeight,Program,Subject,Week,y);
tbl.Subject = nominal(tbl.Subject);
tbl.Program = nominal(tbl.Program);
```

Fit a linear mixed-effects model where the initial weight, type of program, week, and the interaction between the week and type of program are the fixed effects. The intercept and week vary by subject.

`fitlme` uses program A as a reference and creates the necessary dummy variables $I[.]$. Since the model already has an intercept, `fitlme` only creates dummy variables for programs B, C, and D. This is also known as the 'reference' method of coding dummy variables. This model corresponds to

$$y_{im} = \beta_0 + \beta_1 IW_i + \beta_2 Week_i + \beta_3 I[PB]_i + \beta_4 I[PC]_i + \beta_5 I[PD]_i \\ + \beta_6 (Week_i * I[PB]_i) + \beta_7 (Week_i * I[PC]_i) + \beta_8 (Week_i * I[PD]_i) \\ + b_{0m} + b_{1m} Week_{im} + \varepsilon_{im},$$

where $i = 1, 2, \dots, 120$, and $m = 1, 2, \dots, 20$. β_j are the fixed-effects coefficients, $j = 0, 1, \dots, 8$, and b_{0m} and b_{1m} are random effects. IW stands for initial weight and $I[.]$ is a dummy variable representing a type of program. For example, $I[PB]_i$ is the dummy variable representing program B. The random effects and observation error have these prior distributions: $b_{0m} \sim N(0, \sigma^2_0)$, $b_{1m} \sim N(0, \sigma^2_1)$, and $\varepsilon_{im} \sim N(0, \sigma^2)$.

```
lme = fitlme(tbl, 'y ~ InitialWeight + Program*Week + (Week|Subject)')
```

```
lme =

Random effects covariance parameters (95% CIs):

Group: Subject (20 Levels)

Name1	Name2	Type	Estimate	Lower	Upper
'(Intercept)'	'(Intercept)'	'std'	0.18407	0.12281	0.22533
'Week'	'(Intercept)'	'corr'	0.66841	0.21076	0.88606
'Week'	'Week'	'std'	0.15033	0.11004	0.20062

Group: Error

Name	Estimate	Lower	Upper
'Res Std'	0.10261	0.087882	0.11981

The p -values 0.022863 and 0.011567 indicate significant effects of subject initial weights and time in the amount of weight lost. The weight loss of subjects who are in program B is significantly different relative to the weight loss of subjects who are in program A. The lower and upper limits of the covariance parameters for the random effects do not include 0, thus they are significant. You can also test the significance of the random effects using the `compare` method.

Input Arguments

tbl — Input data

table | dataset array

Input data, which includes the response variable, predictor variables, and grouping variables, specified as a table or `dataset` array. The predictor variables can be continuous or grouping variables (see “Grouping Variables” on page 2-52). You must specify the model for the variables using formula.

Data Types: single | double | char | cell

formula — Formula for model specification

string of the form 'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)'

Formula for model specification, specified as a string of the form 'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)'. The string is case sensitive. For a full description, see “Formula” on page 21-1471.

Example: `'y ~ treatment + (1|block)'`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example:

`'CovariancePattern', 'Diagonal', 'Optimizer', 'fminunc', 'OptimizerOptions', opt` specifies a model, where the random-effects terms have a diagonal covariance matrix structure, and `fitlme` uses the `fminunc` optimization algorithm with the custom optimization parameters defined in variable `opt`.

'CovariancePattern' — Pattern of covariance matrix

`'FullCholesky'` (default) | string | square symmetric logical matrix | cell array of strings or logical matrices

Pattern of the covariance matrix of the random effects, specified as the comma-separated pair consisting of `'CovariancePattern'` and a string, a square symmetric logical matrix, or a cell array of strings or logical matrices.

If there are R random-effects terms, then the value of `'CovariancePattern'` must be a cell array of length R , where each element r of this cell array specifies the pattern of the covariance matrix of the random-effects vector associated with the r th random-effects term. The options for each element follow.

`'FullCholesky'`

Default. Full covariance matrix using the Cholesky parameterization. `fitlme` estimates all elements of the covariance matrix.

`'Full'`

Full covariance matrix, using the log-Cholesky parameterization. `fitlme` estimates all elements of the covariance matrix.

`'Diagonal'`

Diagonal covariance matrix. That is, off-diagonal elements of the covariance matrix are constrained to be 0.

'Isotropic'

$$\begin{pmatrix} \sigma_{b1}^2 & 0 & 0 \\ 0 & \sigma_{b2}^2 & 0 \\ 0 & 0 & \sigma_{b3}^2 \end{pmatrix}$$

Diagonal covariance matrix with equal variances. That is, off-diagonal elements of the covariance matrix are constrained to be 0, and the diagonal elements are constrained to be equal. For example, if there are three random-effects terms with an isotropic covariance structure, this covariance matrix looks like

$$\begin{pmatrix} \sigma_b^2 & 0 & 0 \\ 0 & \sigma_b^2 & 0 \\ 0 & 0 & \sigma_b^2 \end{pmatrix}$$

where σ_b^2 is the common variance of the random-effects terms.

'CompSymm'

Compound symmetry structure. That is, common variance along diagonals and equal correlation between all random effects. For example, if there are three random-effects terms with a covariance matrix having a compound symmetry structure, this covariance matrix looks like

$$\begin{pmatrix} \sigma_{b1}^2 & \sigma_{b1,b2} & \sigma_{b1,b2} \\ \sigma_{b1,b2} & \sigma_{b1}^2 & \sigma_{b1,b2} \\ \sigma_{b1,b2} & \sigma_{b1,b2} & \sigma_{b1}^2 \end{pmatrix}$$

where σ_{b1}^2 is the common variance of the random-effects terms and $\sigma_{b1,b2}$ is the common covariance between any two random-effects term .

PAT

Square symmetric logical matrix. If 'CovariancePattern' is defined by the matrix PAT, and if `PAT(a,b) = false`, then the (a,b) element of the corresponding covariance matrix is constrained to be 0.

Example: 'CovariancePattern', 'Diagonal'

Example: 'CovariancePattern', {'Full', 'Diagonal'}

'FitMethod' — Method for estimating parameters

'ML' (default) | 'REML'

Method for estimating parameters of the linear mixed-effects model, specified as the comma-separated pair consisting of 'FitMethod' and either of the following.

'ML'

Default. Maximum likelihood estimation

'REML'

Restricted maximum likelihood estimation

Example: 'FitMethod', 'REML'

'Weights' — Observation weights

vector of scalar values

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and a vector of length n , where n is the number of observations.

Data Types: `single` | `double`**'Exclude' — Indices for rows to exclude**

use all rows without NaNs (default) | vector of integer or logical values

Indices for rows to exclude from the linear mixed-effects model in the data, specified as the comma-separated pair consisting of `'Exclude'` and a vector of integer or logical values.

For example, you can exclude the 13th and 67th rows from the fit as follows.

Example: `'Exclude', [13,67]`Data Types: `single` | `double` | `logical`**'DummyVarCoding' — Coding to use for dummy variables**`'reference'` (default) | `'effects'` | `'full'`

Coding to use for dummy variables created from the categorical variables, specified as the comma-separated pair consisting of `'DummyVarCoding'` and one of the following.

<code>'reference'</code>	Default. Coefficient for first category set to 0.
<code>'effects'</code>	Coefficients sum to 0.
<code>'full'</code>	One dummy variable for each category.

Example: `'DummyVarCoding', 'effects'`**'Optimizer' — Optimization algorithm**`'quasnewton'` (default) | `'fminunc'`

Optimization algorithm, specified as the comma-separated pair consisting of `'Optimizer'` and either of the following.

<code>'quasnewton'</code>	Default. Uses a trust region based quasi-Newton optimizer. Change
---------------------------	---

'fminunc'

the options of the algorithm using `statset('LinearMixedModel')`. If you don't specify the options, then `LinearMixedModel` uses the default options of `statset('LinearMixedModel')`.

You must have Optimization Toolbox to specify this option. Change the options of the algorithm using `optimoptions('fminunc')`. If you don't specify the options, then `LinearMixedModel` uses the default options of `optimoptions('fminunc')` with 'Algorithm' set to 'quasi-newton'.

Example: 'Optimizer', 'fminunc'

'OptimizerOptions' — Options for optimization algorithm

structure returned by `statset` | object returned by `optimoptions`

Options for the optimization algorithm, specified as the comma-separated pair consisting of 'OptimizerOptions' and a structure returned by `statset('LinearMixedModel')` or an object returned by `optimoptions('fminunc')`.

- If 'Optimizer' is 'fminunc', then use `optimoptions('fminunc')` to change the options of the optimization algorithm. See `optimoptions` for the options 'fminunc' uses. If 'Optimizer' is 'fminunc' and you do not supply 'OptimizerOptions', then the default for `LinearMixedModel` is the default options created by `optimoptions('fminunc')` with 'Algorithm' set to 'quasi-newton'.
- If 'Optimizer' is 'quasi-newton', then use `statset('LinearMixedModel')` to change the optimization parameters. If you don't change the optimization parameters, then `LinearMixedModel` uses the default options created by `statset('LinearMixedModel')`:

The 'quasi-newton' optimizer uses the following fields in the structure created by `statset('LinearMixedModel')`.

'To1Fun' — Relative tolerance on gradient of objective function

1e-6 (default) | positive scalar value

Relative tolerance on the gradient of the objective function, specified as a positive scalar value.

'ToIX' — Absolute tolerance on step size

1e-12 (default) | positive scalar value

Absolute tolerance on the step size, specified as a positive scalar value.

'MaxIter' — Maximum number of iterations allowed

10000 (default) | positive scalar value

Maximum number of iterations allowed, specified as a positive scalar value.

'Display' — Level of display

'off' (default) | 'iter' | 'final'

Level of display, specified as one of 'off', 'iter', or 'final'.

'StartMethod' — Method to start iterative optimization

'default' (default) | 'random'

Method to start iterative optimization, specified as the comma-separated pair consisting of 'StartMethod' and either of the following.

'default' Default. An internally defined default value.

'random' A random initial value.

Example: 'StartMethod', 'random'

'Verbose' — Indicator to display optimization process on screen

false (default) | true

Indicator to display the optimization process on screen, specified as the comma-separated pair consisting of 'Verbose' and either false or true. Default is false.

The setting for 'Verbose' overrides the field 'Display' in 'OptimizerOptions'.

Example: 'Verbose', true

'CheckHessian' — Indicator to check positive definiteness of Hessian

false (default) | true

Indicator to check the positive definiteness of the Hessian of the objective function with respect to unconstrained parameters at convergence, specified as the comma-separated pair consisting of 'CheckHessian' and either `false` or `true`. Default is `false`.

Specify 'CheckHessian' as `true` to verify optimality of the solution or to determine if the model is overparameterized in the number of covariance parameters.

Example: 'CheckHessian',`true`

Output Arguments

lme — Linear mixed-effects model

`LinearMixedModel` object

Linear mixed-effects model, returned as a `LinearMixedModel` object.

For properties and methods of this object, see `LinearMixedModel`.

Alternatives

If your model is not easily described using a formula, you can create matrices to define the fixed and random effects, and fit the model using `fitlmematrix(X,y,Z,G)`.

More About

Formula

In general, a formula for model specification is a string of the form '`y ~ terms`'. For the linear mixed-effects models, this formula is in the form '`y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)`', where `fixed` and `random` contain the fixed-effects and the random-effects terms.

Suppose a table `tbl` contains the following:

- A response variable, `y`
- Predictor variables, X_j , which can be continuous or grouping variables

- Grouping variables, g_1, g_2, \dots, g_R ,

where the grouping variables in X_j and g_r can be categorical, logical, character arrays, or cell arrays of strings.

Then, in a formula of the form, `'y ~ fixed + (random1|g1) + ... + (randomR|gR)'`, the term `fixed` corresponds to a specification of the fixed-effects design matrix X , `random1` is a specification of the random-effects design matrix Z_1 corresponding to grouping variable g_1 , and similarly `randomR` is a specification of the random-effects design matrix Z_R corresponding to grouping variable g_R . You can express the `fixed` and `random` terms using Wilkinson notation.

Wilkinson notation describes the factors present in models. The notation relates to factors present in models, not to the multipliers (coefficients) of those factors.

Wilkinson Notation	Factors in Standard Notation
1	Constant (intercept) term
X^k , where k is a positive integer	X, X^2, \dots, X^k
$X1 + X2$	$X1, X2$
$X1 * X2$	$X1, X2, X1.*X2$ (elementwise multiplication of $X1$ and $X2$)
$X1 : X2$	$X1.*X2$ only
$- X2$	Do not include $X2$
$X1 * X2 + X3$	$X1, X2, X3, X1 * X2$
$X1 + X2 + X3 + X1 : X2$	$X1, X2, X3, X1 * X2$
$X1 * X2 * X3 - X1 : X2 : X3$	$X1, X2, X3, X1 * X2, X1 * X3, X2 * X3$
$X1 * (X2 + X3)$	$X1, X2, X3, X1 * X2, X1 * X3$

Statistics Toolbox notation always includes a constant term unless you explicitly remove the term using `-1`. Here are some examples for linear mixed-effects model specification.

Examples:

Formula	Description
<code>'y ~ X1 + X2'</code>	Fixed effects for the intercept, $X1$ and $X2$. This is equivalent to <code>'y ~ 1 + X1 + X2'</code> .

Formula	Description
'y ~ -1 + X1 + X2'	No intercept and fixed effects for X1 and X2. The implicit intercept term is suppressed by including -1.
'y ~ 1 + (1 g1)'	Fixed effects for the intercept plus random effect for the intercept for each level of the grouping variable g1.
'y ~ X1 + (1 g1)'	Random intercept model with a fixed slope.
'y ~ X1 + (X1 g1)'	Random intercept and slope, with possible correlation between them. This is equivalent to 'y ~ 1 + X1 + (1 + X1 g1)'
'y ~ X1 + (1 g1) + (-1 + X1 g1)'	Independent random effects terms for intercept and slope.
'y ~ 1 + (1 g1) + (1 g2) + (1 g1:g2)'	Random intercept model with independent main effects for g1 and g2, plus an independent interaction effect.

Cholesky Parameterization

One of the assumptions of linear mixed-effects models is that the random effects have the following prior distribution.

$$b \sim N(0, \sigma^2 D(\theta)),$$

where D is a q -by- q symmetric and positive semidefinite matrix, parameterized by a variance component vector θ , q is the number of variables in the random-effects term, and σ^2 is the observation error variance. Since the covariance matrix of the random effects, D , is symmetric, it has $q(q+1)/2$ free parameters. Suppose L is the lower triangular Cholesky factor of $D(\theta)$ such that

$$D(\theta) = L(\theta)L(\theta)^T,$$

then the $q^*(q+1)/2$ -by-1 unconstrained parameter vector θ is formed from elements in the lower triangular part of L .

For example, if

$$L = \begin{bmatrix} L_{11} & 0 & 0 \\ L_{21} & L_{22} & 0 \\ L_{31} & L_{32} & L_{33} \end{bmatrix},$$

then

$$\theta = \begin{bmatrix} L_{11} \\ L_{21} \\ L_{31} \\ L_{22} \\ L_{32} \\ L_{33} \end{bmatrix}.$$

Log-Cholesky Parameterization

When the diagonal elements of L in Cholesky parameterization are constrained to be positive, then the solution for L is unique. Log-Cholesky parameterization is the same as Cholesky parameterization except that the logarithm of the diagonal elements of L are used to guarantee unique parameterization.

For example, for the 3-by-3 example in Cholesky parameterization, enforcing $L_{ii} \geq 0$,

$$\theta = \begin{bmatrix} \log(L_{11}) \\ L_{21} \\ L_{31} \\ \log(L_{22}) \\ L_{32} \\ \log(L_{33}) \end{bmatrix}.$$

LinearMixedModel | fitlmematrix

fitlmematrix

Fit linear mixed-effects model

Syntax

```
lme = fitlmematrix(X,y,Z,[])  
lme = fitlmematrix(X,y,Z,G)  
lme = fitlmematrix( ____,Name,Value)
```

Description

`lme = fitlmematrix(X,y,Z,[])` creates a linear mixed-effects model of the responses `y` using the fixed-effects design matrix `X` and random-effects design matrix or matrices in `Z`.

`[]` implies that there is one group. That is, the grouping variable `G` is `ones(n,1)`, where n is the number of observations. Using `fitlmematrix(X,Y,Z,[])` without a specified covariance pattern most likely results in a nonidentifiable model. This syntax is recommended only if you build the grouping information into the random effects design `Z` and specify a covariance pattern for the random effects using the 'CovariancePattern' name-value pair argument.

`lme = fitlmematrix(X,y,Z,G)` creates a linear mixed-effects model of the responses `y` using the fixed-effects design matrix `X` and random-effects design matrix `Z` or matrices in `Z`, and the grouping variable or variables in `G`.

`lme = fitlmematrix(____,Name,Value)` also creates a linear mixed-effects model with additional options specified by one or more `Name,Value` pair arguments, using any of the previous input arguments.

For example, you can specify the names of the response, predictor, and grouping variables. You can also specify the covariance pattern, fitting method, or the optimization algorithm.

Examples

No Grouping Variable Specified

Load the sample data.

```
load carsmall
```

Fit a linear mixed-effects model, where miles per gallon (MPG) is the response, weight is the predictor variable, and the intercept varies by model year. First, define the design matrices. Then, fit the model using the specified design matrices.

```
y = MPG;
X = [ones(size(Weight)), Weight];
Z = ones(size(y));
lme = fitlmematrix(X,y,Z,Model_Year)

lme =
```

Linear mixed-effects model fit by ML

Model information:

Number of observations	94
Fixed effects coefficients	2
Random effects coefficients	3
Covariance parameters	2

Formula:

```
y ~ x1 + x2 + (z11 | g1)
```

Model fit statistics:

Longitudinal Study with a Covariate

Navigate to a folder containing sample data.

```
cd(matlabroot)
```

```
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load weight
```

`weight` contains data from a longitudinal study, where 20 subjects are randomly assigned 4 exercise programs (A, B, C, D) and their weight loss is recorded over six 2-week time periods. This is simulated data.

Define `Subject` and `Program` as categorical variables. Create the design matrices for a linear mixed-effects model, with the initial weight, type of program, week, and the interaction between the week and type of program as the fixed effects. The intercept and coefficient of week vary by subject.

This model corresponds to

$$\begin{aligned}
 y_{im} = & \beta_0 + \beta_1 IW_i + \beta_2 Week_i + \beta_3 I[PB]_i + \beta_4 I[PC]_i + \beta_5 I[PD]_i \\
 & + \beta_6 (Week_i * I[PB]_i) + \beta_7 (Week_i * I[PC]_i) + \beta_8 (Week_i * I[PD]_i) \\
 & + b_{0m} + b_{1m} Week_{im} + \varepsilon_{im},
 \end{aligned}$$

where $i = 1, 2, \dots, 120$, and $m = 1, 2, \dots, 20$. β_j are the fixed-effects coefficients, $j = 0, 1, \dots, 8$, and b_{0m} and b_{1m} are random effects. IW stands for initial weight and $I[\cdot]$ is a dummy variable representing a type of program. For example, $I[PB]_i$ is the dummy variable representing program type B. The random effects and observation error have these prior distributions: $b_{0m} \sim N(0, \sigma^2_0)$, $b_{1m} \sim N(0, \sigma^2_1)$, and $\varepsilon_{im} \sim N(0, \sigma^2)$.

```
Subject = nominal(Subject);
Program = nominal(Program);
D = dummyvar(Program); % Create dummy variables for Program
X = [ones(120,1), InitialWeight, D(:,2:4), Week, ...
     D(:,2).*Week, D(:,3).*Week, D(:,4).*Week];
Z = [ones(120,1), Week];
G = Subject;
```

Since the model has an intercept, you only need the dummy variables for programs B, C, and D. This is also known as the 'reference' method of coding dummy variables.

Fit the model using `fitlmematrix` with the defined design matrices and grouping variables.

```
lme = fitlmematrix(X,y,Z,G,'FixedEffectPredictors',...

Random effects covariance parameters (95% CIs):

Group: Subject (20 Levels)

Name1	Name2	Type	Estimate	Lower	Upper
'Intercept'	'Intercept'	'std'	0.18407	0.12281	0.27587
'Week'	'Intercept'	'corr'	0.66841	0.21076	0.88573
'Week'	'Week'	'std'	0.15033	0.11004	0.20537

Group: Error

Name	Estimate	Lower	Upper
'Res Std'	0.10261	0.087882	0.11981

The *p*-values 0.0228 and 0.0115 indicate significant effects of the initial weights of the subjects and the time factor in the amount of weight lost. The weight loss of subjects who

are in program B is significantly different relative to the weight loss of subjects who are in program A. The lower and upper limits of the covariance parameters for the random effects do not include zero, thus they seem significant. You can also test the significance of the random-effects using the `compare` method.

Random Intercept Model

Load the sample data.

```
load flu
```

The `flu` dataset array has a `Date` variable, and 10 variables for estimated influenza rates (in 9 different regions, estimated from Google searches, plus a nationwide estimate from the Centers for Disease Control and Prevention, CDC).

To fit a linear-mixed effects model, where the influenza rates are the responses, combine the nine columns corresponding to the regions into a tall array that has a single response variable, `FluRate`, and a nominal variable, `Region`, the nationwide estimate `WtdILI`, that shows which region each estimate is from, and the grouping variable `Date`.

```
flu2 = stack(flu,2:10,'NewDataVarName','FluRate',...
    'IndVarName','Region');
flu2.Date = nominal(flu2.Date);
```

Define the design matrices for a random-intercept linear mixed-effects model, where the intercept varies by `Date`. The corresponding model is

$$y_{im} = \beta_0 + \beta_1 WtdILLI_{im} + b_{0m} + \varepsilon_{im}, \quad i = 1, 2, \dots, 468, \quad m = 1, 2, \dots, 52,$$

where y_{im} is the observation i for level m of grouping variable `Date`. b_{0m} is the random effect for level m of the grouping variable `Date` and ε_{im} is the observation error for observation i . The random effect has the prior distribution, $b_{0m} \sim N(0, \sigma_{FR}^2)$ and the error term has the distribution, $\varepsilon_{im} \sim N(0, \sigma^2)$.

```
y = flu2.FluRate;
X = [ones(468,1) flu2.WtdILI];
Z = [ones(468,1)];
G = flu2.Date;
```

Fit the linear mixed-effects model.

```
lme = fitlmematrix(X,y,Z,G, 'FixedEffectPredictors', {'Intercept', 'NationalRate'}, ...
  'RandomEffectPredictors', {'Intercept'}, 'RandomEffectGroups', {'Date'})
```

```
lme =
```

```
Linear mixed-effects model fit by ML
```

```
Model information:
```

```
Number of observations      468
Fixed effects coefficients    2
Random effects coefficients  52
Covariance parameters        2
```

```
Formula:
```

```
y ~ Intercept + NationalRate + (Intercept | Date)
```

```
Model fit statistics:
```

```
AIC      BIC      LogLikelihood  Deviance
286.24   302.83   -139.12      278.24
```

```
Fixed effects coefficients (95% CIs):
```

Name	Estimate	SE	tStat	DF	pValue	Lower	Upper
'Intercept'	0.16385	0.057525	2.8484	466	0.0045885	0.0508	0.2769
'NationalRate'	0.7236	0.032219	22.459	466	3.0502e-76	0.660	0.7872

```
Random effects covariance parameters (95% CIs):
```

```
Group: Date (52 Levels)
```

Name1	Name2	Type	Estimate	Lower	Upper
'Intercept'	'Intercept'	'std'	0.17146	0.13227	0.22226

```
Group: Error
```

Name	Estimate	Lower	Upper
'Res Std'	0.30201	0.28217	0.32324

The confidence limits of the standard deviation of the random-effects term $\sigma_{b_{0m}}^2$, do not include zero (0.13227, 0.22226), which indicates that the random-effects term is significant. You can also test the significance of the random-effects using `compare` method.

The estimated value of an observation is the sum of the fixed-effects values and value of the random effect at the grouping variable level corresponding to that observation. For example, the estimated flu rate for observation 28

$$\begin{aligned}\hat{y}_{28} &= \hat{\beta}_0 + \hat{\beta}_1 \text{WtdILI}_{28} + \hat{b}_{10/30/2005} \\ &= 0.1639 + 0.7236 * (1.343) + 0.3318 \\ &= 1.46749,\end{aligned}$$

where \hat{b} is the best linear unbiased predictor (BLUP) of the random effects for the intercept. You can compute this value as follows.

```
beta = fixedEffects(lme);
[~,~,STATS] = randomEffects(lme); % compute the random effects statistics STATS
STATS.Level = nominal(STATS.Level);
y_hat = beta(1) + beta(2)*flu2.WtdILI(28) + STATS.Estimate(STATS.Level=='10/30/2005')

y_hat =

    1.4674
```

You can simply display the fitted value using the `fitted(lme)` method.

```
F = fitted(lme);
F(28)

ans =

    1.4674
```

Randomized Block Design

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load shift
```

The data shows the deviations from the target quality characteristic measured from the products that five operators manufacture during three shifts: morning, evening, and night. This is a randomized block design, where the operators are the blocks. The experiment is designed to study the impact of the time of shift on the performance. The performance measure is the deviations of the quality characteristics from the target value. This is simulated data.

Define the design matrices for a linear mixed-effects model with a random intercept grouped by operator, and shift as the fixed effects. Use the 'effects' contrasts. 'effects' contrasts mean that the coefficients sum to 0. You need to create two contrast coded variables in the fixed-effects design matrix, X1 and X2, where

$$Shift_Evening = \begin{cases} 0, & \text{if Morning} \\ 1, & \text{if Evening} \\ -1, & \text{if Night} \end{cases} \quad \text{and} \quad Shift_Morning = \begin{cases} 1, & \text{if Morning} \\ 0, & \text{if Evening} \\ -1, & \text{if Night} \end{cases}.$$

The model corresponds to

$$\text{Morning Shift: } QCDev_{im} = \beta_0 + \beta_2 Shift_Morning_i + b_{0m} + \varepsilon_{im}, \quad m = 1, 2, \dots, 5,$$

$$\text{Evening Shift: } QCDev_{im} = \beta_0 + \beta_1 Shift_Evening_i + b_{0m} + \varepsilon_{im},$$

$$\text{Night Shift: } QCDev_{im} = \beta_0 - \beta_1 Shift_Evening_i - \beta_2 Shift_Morning_i + b_{0m} + \varepsilon_{im},$$

where i represents the observations, and m represents the operators, $i = 1, 2, \dots, 15$, and $m = 1, 2, \dots, 5$. The random effects and the observation error have these distributions: $b_{0m} \sim N(0, \sigma^2_{b_{0m}})$ and $\varepsilon_{im} \sim N(0, \sigma^2)$.

```
S = shift.Shift;
X1 = (S=='Morning') - (S=='Night');
X2 = (S=='Evening') - (S=='Night');
X = [ones(15,1), X1, X2];
y = shift.QCDev;
Z = ones(15,1);
G = shift.Operator;
```

Fit a linear mixed-effects model using the specified design matrices and restricted maximum likelihood method.

```
lme = fitlmematrix(X,y,Z,G,'FitMethod','REML','FixedEffectPredictors',...
{'Intercept','S_Morning','S_Evening'},'RandomEffectPredictors',{{'Intercept'}},...
'RandomEffectGroups',{'Operator'},'DummyVarCoding','effects')
```

```
lme =

'Res Std'	0.85462	0.52357	1.395

Compute the best linear unbiased predictor (BLUP) estimates of random effects.

```
B = randomEffects(lme)
```

```
B =
```

```

0.5775
1.1757
-2.1715
2.3655
-1.9472

```

The estimated deviation from the target quality characteristics for the third operator working the evening shift is

$$\begin{aligned}
 \hat{y}_{Evening, Operator3} &= \hat{\beta}_0 + \hat{\beta}_1 Shift_Evening + \hat{b}_{03} \\
 &= 3.6525 - 0.53293 - 2.1715 \\
 &= 0.94807.
 \end{aligned}$$

You can also display this value as follows.

```
F = fitted(lme);
F(shift.Shift=='Evening' & shift.Operator=='3')

ans =

    0.9481
```

Correlated and Uncorrelated Random-Effects Terms

Load the sample data.

```
load carbig
```

Fit a linear mixed-effects model for miles per gallon (MPG), with fixed effects for acceleration and horsepower, and uncorrelated random effect for intercept and acceleration grouped by the model year. This model corresponds to

$$MPG_{im} = \beta_0 + \beta_1 Acc_i + \beta_2 HP + b_{0m} + b_{1m} Acc_{im} + \varepsilon_{im}, \quad m = 1, 2, 3,$$

with the random-effects terms having these distributions: $b_{0m} \sim N(0, \sigma_0^2)$, and $b_{1m} \sim N(0, \sigma_1^2)$. m represents the model year.

First, prepare the design matrices for fitting the linear mixed-effects model.

```
X = [ones(406,1) Acceleration Horsepower];
Z = {ones(406,1), Acceleration};
G = {Model_Year, Model_Year};
Model_Year = nominal(Model_Year);
```

Now, fit the model using `fitlmematrix` with the defined design matrices and grouping variables.

```
lme = fitlmematrix(X, MPG, Z, G, 'FixedEffectPredictors', ...
{'Intercept', 'Acceleration', 'Horsepower'}, 'RandomEffectPredictors', ...
{{'Intercept'}, {'Acceleration'}}}, 'RandomEffectGroups', {'Model_Year', 'Model_Year'})

lme =

Linear mixed-effects model fit by ML
```

Model information:

Number of observations	392
Fixed effects coefficients	3
Random effects coefficients	26
Covariance parameters	3

Formula:

$$y \sim \text{Intercept} + \text{Acceleration} + \text{Horsepower} + (\text{Intercept} \mid \text{Model_Year}) + (\text{Acceleration} \mid \text{Model_Year})$$

Model fit statistics:

AIC	BIC	LogLikelihood	Deviance
2194.5	2218.3	-1091.3	2182.5

Fixed effects coefficients (95% CIs):

Name	Estimate	SE	tStat	DF	pValue	Lower	Upper
'Intercept'	49.839	2.0518	24.291	389	5.6168e-80	44.735	54.943
'Acceleration'	-0.58565	0.10846	-5.3995	389	1.1652e-07	-0.8027	-0.3686
'Horsepower'	-0.16534	0.0071227	-23.213	389	1.9755e-75	-0.1796	-0.1511

Random effects covariance parameters (95% CIs):

Group: Model_Year (13 Levels)

Name1	Name2	Type	Estimate	Lower	Upper
'Intercept'	'Intercept'	'std'	8.0669e-07	NaN	NaN

Group: Model_Year (13 Levels)

Name1	Name2	Type	Estimate	Lower	Upper
'Acceleration'	'Acceleration'	'std'	0.18783	0.12523	0.25043

Group: Error

Name	Estimate	Lower	Upper
'Res Std'	3.7258	3.4698	4.0007

Note that the random effects covariance parameters for intercept and acceleration are separate in the display. The standard deviation of the random effect for the intercept does not seem significant.

Refit the model with potentially correlated random effects for intercept and acceleration. In this case, the random-effects terms has this prior distribution

$$b_m = \begin{pmatrix} b_{0m} \\ b_{1m} \end{pmatrix} \sim N \left(0, \begin{pmatrix} \sigma_0^2 & \sigma_{0,1} \\ \sigma_{0,1} & \sigma_1^2 \end{pmatrix} \right),$$

where m represents the model year.

First, prepare the random-effects design matrix and grouping variable.

```
Z = [ones(406,1) Acceleration];
G = Model_Year;

lme = fitlmematrix(X,MPG,Z,G,'FixedEffectPredictors',...
{'Intercept','Acceleration','Horsepower'},'RandomEffectPredictors',...
{{'Intercept','Acceleration'}},'RandomEffectGroups',{'Model_Year'})

lme =
```

Linear mixed-effects model fit by ML

Model information:

Number of observations	392
Fixed effects coefficients	3
Random effects coefficients	26
Covariance parameters	4

Formula:

```
y ~ Intercept + Acceleration + Horsepower + (Intercept + Acceleration | Model_Year)
```

Model fit statistics:

AIC	BIC	LogLikelihood	Deviance
2193.5	2221.3	-1089.7	2179.5

Fixed effects coefficients (95% CIs):

Name	Estimate	SE	tStat	DF	pValue	Lower	Upper
'Intercept'	50.133	2.2652	22.132	389	7.7727e-71	45.601	54.665
'Acceleration'	-0.58327	0.13394	-4.3545	389	1.7075e-05	-0.8511	-0.3154
'Horsepower'	-0.16954	0.0072609	-23.35	389	5.188e-76	-0.2047	-0.1344

Random effects covariance parameters (95% CIs):

Group: Model_Year (13 Levels)

Name1	Name2	Type	Estimate	Lower	Upper
'Intercept'	'Intercept'	'std'	3.3475	1.2862	5.4088
'Acceleration'	'Intercept'	'corr'	-0.87971	-0.98501	-0.77441
'Acceleration'	'Acceleration'	'std'	0.33789	0.1825	0.51328

Group: Error

Name	Estimate	Lower	Upper
'Res Std'	3.6874	3.4298	3.9644

Note that the random effects covariance parameters for intercept and acceleration are together in the display, with an addition of the correlation between the intercept and acceleration. The confidence intervals for the standard deviations and the correlation between the random effects for intercept and acceleration do not include 0s, hence they seem significant. You can compare these two models using the `compare` method.

Specify the Covariance Pattern

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load weight
```

`weight` contains data from a longitudinal study, where 20 subjects are randomly assigned 4 exercise programs, and their weight loss is recorded over six 2-week time periods. This is simulated data.

Define `Subject` and `Program` as categorical variables.

```
Subject = nominal(Subject);
Program = nominal(Program);
```

Create the design matrices for a linear mixed-effects model, with the initial weight, type of program, and week as the fixed effects.

```
D = dummyvar(Program);
X = [ones(120,1), InitialWeight, D(:,2:4), Week];
Z = [ones(120,1) Week];
G = Subject;
```

This model corresponds to

$$y_{im} = \beta_0 + \beta_1 IW_i + \beta_2 Week_i + \beta_3 I[PB]_i + \beta_4 I[PC]_i + \beta_5 I[PD]_i \\ + b_{0m} + b_{1m} Week2_{im} + b_{2m} Week4_{im} + b_{3m} Week6_{im} + b_{4m} Week8_{im} \\ + b_{5m} Week10_{im} + b_{6m} Week12_{im} + \varepsilon_{im},$$

where $i = 1, 2, \dots, 120$, and $m = 1, 2, \dots, 20$.

β_j are the fixed-effects coefficients, $j = 0, 1, \dots, 8$, and b_{1m} and b_{1m} are random effects. IW stands for initial weight and $I[.]$ is a dummy variable representing a type of program. For

example, $I[PB]_i$ is the dummy variable representing program type B. The random effects and observation error have these prior distributions: $b_{0m} \sim N(0, \sigma_0^2)$, $b_{1m} \sim N(0, \sigma_1^2)$, and $\varepsilon_{im} \sim N(0, \sigma^2)$.

Fit the model using `fitlmematrix` with the defined design matrices and grouping variables. Assume the repeated observations collected on a subject have common variance along diagonals.

```
lme = fitlmematrix(X,y,Z,G, 'FixedEffectPredictors',...
{'Intercept', 'InitWeight', 'PrgB', 'PrgC', 'PrgD', 'Week'},...
'RandomEffectPredictors', {{'Intercept', 'Week'}},...
'RandomEffectGroups', {'Subject'}, 'CovariancePattern', 'Isotropic')
```

```
lme =

Input Arguments

X — Fixed-effects design matrix

n-by-*p* matrix

Fixed-effects design matrix, specified as an *n*-by-*p* matrix, where *n* is the number of observations, and *p* is the number of fixed-effects predictor variables. Each row of **X** corresponds to one observation, and each column of **X** corresponds to one variable.

Data Types: `single` | `double`

y — Response values

n-by-1 vector

Response values, specified as an *n*-by-1 vector, where *n* is the number of observations.

Data Types: `single` | `double`

Z — Random-effects design

n-by-*q* matrix | cell array of *R* *n*-by-*q*(*r*) matrices, *r* = 1, 2, ..., *R*

Random-effects design, specified as either of the following.

- If there is one random-effects term in the model, then **Z** must be an *n*-by-*q* matrix, where *n* is the number of observations and *q* is the number of variables in the random-effects term.
- If there are *R* random-effects terms, then **Z** must be a cell array of length *R*. Each cell of **Z** contains an *n*-by-*q*(*r*) design matrix $Z\{\mathbf{r}\}$, *r* = 1, 2, ..., *R*, corresponding to each random-effects term. Here, *q*(*r*) is the number of random effects term in the *r*th random effects design matrix, $Z\{\mathbf{r}\}$.

Data Types: `single` | `double` | `cell`

G — Grouping variable or variables

n-by-1 vector | cell array of *R* *n*-by-1 vectors

Grouping variable or variables, specified as either of the following.

- If there is one random-effects term, then **G** must be an n -by-1 vector corresponding to a single grouping variable with M levels or groups.

G can be a categorical vector, numeric vector, character array, or cell array of strings.

- If there are multiple random-effects terms, then **G** must be a cell array of length R . Each cell of **G** contains a grouping variable **G**{ r }, $r = 1, 2, \dots, R$, with $M(r)$ levels.

G{ r } can be a categorical vector, numeric vector, character array, or cell array of strings.

Data Types: `single` | `double` | `char` | `cell`

Name-Value Pair Arguments

Specify optional comma-separated pairs of **Name**,**Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as **Name1**,**Value1**, . . . ,**NameN**,**ValueN**.

Example:

`'CovariancePattern', 'Diagonal', 'DummyVarCoding', 'full', 'Optimizer', 'fminunc'` specifies a random-effects covariance pattern with zero off-diagonal elements, creates a dummy variable for each level of a categorical variable, and uses the `fminunc` optimization algorithm.

'FixedEffectPredictors' — Names of columns in fixed-effects design matrix

{`'x1'`, `'x2'`, . . . , `'xP'`} (default) | cell array of length p

Names of columns in the fixed-effects design matrix **X**, specified as the comma-separated pair consisting of `'FixedEffectPredictors'` and a cell array of length p .

For example, if you have a constant term and two predictors, say **TimeSpent** and **Gender**, where **Female** is the reference level for **Gender**, as the fixed effects, then you can specify the names of your fixed effects in the following way. **Gender_Male** represents the dummy variable you must create for category **Male**. You can choose different names for these variables.

Example: `'FixedEffectPredictors',`
{`'Intercept'`, `'TimeSpent'`, `'Gender_Male'`},

Data Types: `cell`

'RandomEffectPredictors' — Names of columns in random-effects design matrix or cell array

cell array of length q | cell array of length R with elements of length $q(r)$, $r = 1, 2, \dots, R$

Names of columns in the random-effects design matrix or cell array Z , specified as the comma-separated pair consisting of **'RandomEffectPredictors'** and either of the following:

- A cell array of length q when Z is an n -by- q design matrix. In this case, the default is `{'z1', 'z2', ..., 'zQ'}`.
- A cell array of length R , when Z is a cell array of length R with each element $Z\{r\}$ of length $q(r)$, $r = 1, 2, \dots, R$. In this case, the default is `{'z11', 'z12', ..., 'z1Q(1)', ..., {'zr1', 'zr2', ..., 'zrQ(r)'}}`.

For example, suppose you have correlated random effects for intercept and a variable named `Acceleration`. Then, you can specify the random-effects predictor names as follows.

Example: `'RandomEffectPredictors', {'Intercept', 'Acceleration'}`

If you have two random effects terms, one for the intercept and the variable `Acceleration` grouped by variable `g1`, and the second for the intercept, grouped by the variable `g2`, then you specify the random-effects predictor names as follows.

Example: `'RandomEffectPredictors', {{'Intercept', 'Acceleration'}}, {'Intercept'}}`

Data Types: `cell`

'ResponseVarName' — Name of response variable

`'y'` (default) | `string`

Name of response variable, specified as the comma-separated pair consisting of **'ResponseVarName'** and a string.

For example, if your response variable name is `score`, then you can specify it as follows.

Example: `'ResponseVarName', 'score'`

Data Types: `char`

'RandomEffectGroups' — Names of random effects grouping variables

`'g'` or `{'g1', 'g2', ..., 'gR'}` (default) | `string` | cell array of strings

Names of random effects grouping variables, specified as the comma-separated pair 'RandomEffectGroups' and either of the following:

- String — If there is only one random-effects term, that is, if G is a vector, then the value of 'RandomEffectGroups' is a string containing the name for the grouping variable G . The default is 'g'.
- Cell array of strings — If there are multiple random-effects terms, that is, if G is a cell array of length R , then the value of 'RandomEffectGroups' is a cell array of length R , where each cell contains the name for the grouping variable $G\{r\}$. The default is {'g1', 'g2', ..., 'gR'}.

For example, if you have two random-effects terms, $z1$ and $z2$, grouped by the grouping variables `sex` and `subject`, then you can specify the names of your grouping variables as follows.

Example: 'RandomEffectGroups', {'sex', 'subject'}

Data Types: char | cell

'CovariancePattern' — Pattern of covariance matrix

'FullCholesky' (default) | string | square symmetric logical matrix | cell array of strings or logical matrices

Pattern of the covariance matrix of the random effects, specified as the comma-separated pair consisting of 'CovariancePattern' and a string, a square symmetric logical matrix, or a cell array of strings or logical matrices.

If there are R random-effects terms, then the value of 'CovariancePattern' must be a cell array of length R , where each element r of this cell array specifies the pattern of the covariance matrix of the random-effects vector associated with the r th random-effects term. The options for each element follow.

'FullCholesky'

Default. Full covariance matrix using the Cholesky parameterization. `fitlme` estimates all elements of the covariance matrix.

'Full'

Full covariance matrix, using the log-Cholesky parameterization. `fitlme` estimates all elements of the covariance matrix.

'Diagonal'

Diagonal covariance matrix. That is, off-diagonal elements of the covariance matrix are constrained to be 0.

$$\begin{pmatrix} \sigma_{b1}^2 & 0 & 0 \\ 0 & \sigma_{b2}^2 & 0 \\ 0 & 0 & \sigma_{b3}^2 \end{pmatrix}$$

'Isotropic'

Diagonal covariance matrix with equal variances. That is, off-diagonal elements of the covariance matrix are constrained to be 0, and the diagonal elements are constrained to be equal. For example, if there are three random-effects terms with an isotropic covariance structure, this covariance matrix looks like

$$\begin{pmatrix} \sigma_b^2 & 0 & 0 \\ 0 & \sigma_b^2 & 0 \\ 0 & 0 & \sigma_b^2 \end{pmatrix}$$

where σ_b^2 is the common variance of the random-effects terms.

`'CompSymm'`

Compound symmetry structure. That is, common variance along diagonals and equal correlation between all random effects. For example, if there are three random-effects terms with a covariance matrix having a compound symmetry structure, this covariance matrix looks like

$$\begin{pmatrix} \sigma_{b1}^2 & \sigma_{b1,b2} & \sigma_{b1,b2} \\ \sigma_{b1,b2} & \sigma_{b1}^2 & \sigma_{b1,b2} \\ \sigma_{b1,b2} & \sigma_{b1,b2} & \sigma_{b1}^2 \end{pmatrix}$$

where σ_{b1}^2 is the common variance of the random-effects terms and $\sigma_{b1,b2}$ is the common covariance between any two random-effects term .

`PAT`

Square symmetric logical matrix. If `'CovariancePattern'` is defined by the matrix `PAT`, and if `PAT(a, b) = false`, then the `(a, b)` element of the corresponding covariance matrix is constrained to be 0.

Example: `'CovariancePattern', 'Diagonal'`

Example: `'CovariancePattern', {'Full', 'Diagonal'}`

'FitMethod' — Method for estimating parameters

`'ML'` (default) | `'REML'`

Method for estimating parameters of the linear mixed-effects model, specified as the comma-separated pair consisting of `'FitMethod'` and either of the following.

`'ML'`

Default. Maximum likelihood estimation

`'REML'`

Restricted maximum likelihood estimation

Example: `'FitMethod', 'REML'`

'Weights' — Observation weights

vector of scalar values

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and a vector of length n , where n is the number of observations.

Data Types: `single` | `double`

'Exclude' — Indices for rows to exclude

use all rows without NaNs (default) | vector of integer or logical values

Indices for rows to exclude from the linear mixed-effects model in the data, specified as the comma-separated pair consisting of `'Exclude'` and a vector of integer or logical values.

For example, you can exclude the 13th and 67th rows from the fit as follows.

Example: `'Exclude', [13,67]`

Data Types: `single` | `double` | `logical`

'DummyVarCoding' — Coding to use for dummy variables

`'reference'` (default) | `'effects'` | `'full'`

Coding to use for dummy variables created from the categorical variables, specified as the comma-separated pair consisting of `'DummyVarCoding'` and one of the following.

<code>'reference'</code>	Default. Coefficient for first category set to 0.
<code>'effects'</code>	Coefficients sum to 0.
<code>'full'</code>	One dummy variable for each category.

Example: `'DummyVarCoding', 'effects'`

'Optimizer' — Optimization algorithm

`'quasnewton'` (default) | `'fminunc'`

Optimization algorithm, specified as the comma-separated pair consisting of `'Optimizer'` and either of the following.

<code>'quasnewton'</code>	Default. Uses a trust region based quasi-Newton optimizer. Change
---------------------------	---

'fminunc'

the options of the algorithm using `statset('LinearMixedModel')`. If you don't specify the options, then `LinearMixedModel` uses the default options of `statset('LinearMixedModel')`.

You must have Optimization Toolbox to specify this option. Change the options of the algorithm using `optimoptions('fminunc')`. If you don't specify the options, then `LinearMixedModel` uses the default options of `optimoptions('fminunc')` with 'Algorithm' set to 'quasi-newton'.

Example: 'Optimizer', 'fminunc'

'OptimizerOptions' — Options for optimization algorithm

structure returned by `statset` | object returned by `optimoptions`

Options for the optimization algorithm, specified as the comma-separated pair consisting of 'OptimizerOptions' and a structure returned by `statset('LinearMixedModel')` or an object returned by `optimoptions('fminunc')`.

- If 'Optimizer' is 'fminunc', then use `optimoptions('fminunc')` to change the options of the optimization algorithm. See `optimoptions` for the options 'fminunc' uses. If 'Optimizer' is 'fminunc' and you do not supply 'OptimizerOptions', then the default for `LinearMixedModel` is the default options created by `optimoptions('fminunc')` with 'Algorithm' set to 'quasi-newton'.
- If 'Optimizer' is 'quasi-newton', then use `statset('LinearMixedModel')` to change the optimization parameters. If you don't change the optimization parameters, then `LinearMixedModel` uses the default options created by `statset('LinearMixedModel')`:

The 'quasi-newton' optimizer uses the following fields in the structure created by `statset('LinearMixedModel')`.

'To1Fun' — Relative tolerance on gradient of objective function

1e-6 (default) | positive scalar value

Relative tolerance on the gradient of the objective function, specified as a positive scalar value.

'ToIX' — Absolute tolerance on step size

1e-12 (default) | positive scalar value

Absolute tolerance on the step size, specified as a positive scalar value.

'MaxIter' — Maximum number of iterations allowed

10000 (default) | positive scalar value

Maximum number of iterations allowed, specified as a positive scalar value.

'Display' — Level of display

'off' (default) | 'iter' | 'final'

Level of display, specified as one of 'off', 'iter', or 'final'.

'StartMethod' — Method to start iterative optimization

'default' (default) | 'random'

Method to start iterative optimization, specified as the comma-separated pair consisting of 'StartMethod' and either of the following.

'default'	Default. An internally defined default value.
'random'	A random initial value.

Example: 'StartMethod', 'random'

'Verbose' — Indicator to display optimization process on screen

false (default) | true

Indicator to display the optimization process on screen, specified as the comma-separated pair consisting of 'Verbose' and either false or true. Default is false.

The setting for 'Verbose' overrides the field 'Display' in 'OptimizerOptions'.

Example: 'Verbose', true

'CheckHessian' — Indicator to check positive definiteness of Hessian`false (default) | true`

Indicator to check the positive definiteness of the Hessian of the objective function with respect to unconstrained parameters at convergence, specified as the comma-separated pair consisting of 'CheckHessian' and either `false` or `true`. Default is `false`.

Specify 'CheckHessian' as `true` to verify optimality of the solution or to determine if the model is overparameterized in the number of covariance parameters.

Example: `'CheckHessian', true`

Output Arguments

lme — Linear mixed-effects model`LinearMixedModel` object

Linear mixed-effects model, returned as a `LinearMixedModel` object.

For properties and methods of this object, see `LinearMixedModel`.

Alternative Functionality

You can also fit a linear mixed-effects model using `fitlme(tbl, formula)`, where `tbl` is a table or dataset array containing the response `y`, the predictor variables `X`, and the grouping variables, and `formula` is of the form `'y ~ fixed + (random1|g1) + ... + (randomR|gR)'`.

More About

Cholesky Parameterization

One of the assumptions of linear mixed-effects models is that the random effects have the following prior distribution.

$$b \sim N(0, \sigma^2 D(\theta)),$$

where D is a q -by- q symmetric and positive semidefinite matrix, parameterized by a variance component vector θ , q is the number of variables in the random-effects term, and σ^2 is the observation error variance. Since the covariance matrix of the random effects, D , is symmetric, it has $q(q+1)/2$ free parameters. Suppose L is the lower triangular Cholesky factor of $D(\theta)$ such that

$$D(\theta) = L(\theta)L(\theta)^T,$$

then the $q^*(q+1)/2$ -by-1 unconstrained parameter vector θ is formed from elements in the lower triangular part of L .

For example, if

$$L = \begin{bmatrix} L_{11} & 0 & 0 \\ L_{21} & L_{22} & 0 \\ L_{31} & L_{32} & L_{33} \end{bmatrix},$$

then

$$\theta = \begin{bmatrix} L_{11} \\ L_{21} \\ L_{31} \\ L_{22} \\ L_{32} \\ L_{33} \end{bmatrix}.$$

Log-Cholesky Parameterization

When the diagonal elements of L in Cholesky parameterization are constrained to be positive, then the solution for L is unique. Log-Cholesky parameterization is the same as Cholesky parameterization except that the logarithm of the diagonal elements of L are used to guarantee unique parameterization.

For example, for the 3-by-3 example in Cholesky parameterization, enforcing $L_{ii} \geq 0$,

$$\theta = \begin{bmatrix} \log(L_{11}) \\ L_{21} \\ L_{31} \\ \log(L_{22}) \\ L_{32} \\ \log(L_{33}) \end{bmatrix}.$$

fitrm

Fit repeated measures model

Syntax

```
rm = fitrm(t,modelspec)
rm = fitrm(t,modelspec,Name,Value)
```

Description

`rm = fitrm(t,modelspec)` returns a repeated measures model, specified by `modelspec`, fitted to the variables in the table or dataset array `t`.

`rm = fitrm(t,modelspec,Name,Value)` returns a repeated measures model, with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify the hypothesis for the within-subject factors.

Examples

Fit a Repeated Measures Model

Load the sample data.

```
load fisheriris
```

The column vector `species` consists of iris flowers of three different species: `setosa`, `versicolor`, and `virginica`. The double matrix `meas` consists of four types of measurements on the flowers: the length and width of sepals and petals in centimeters, respectively.

Store the data in a table array.

```
t = table(species,meas(:,1),meas(:,2),meas(:,3),meas(:,4),...
'VariableNames',{'species','meas1','meas2','meas3','meas4'});
Meas = table([1 2 3 4'],'VariableNames',{'Measurements'});
```

Fit a repeated measures model, where the measurements are the responses and the `species` is the predictor variable.

```

rm = fitrm(t, 'meas1-meas4~species', 'WithinDesign', Meas)
rm =
  RepeatedMeasuresModel with properties:
  Between Subjects:
    BetweenDesign: [150x5 table]
    ResponseNames: {'meas1' 'meas2' 'meas3' 'meas4'}
    BetweenFactorNames: {'species'}
    BetweenModel: '1 + species'
  Within Subjects:
    WithinDesign: [4x1 table]
    WithinFactorNames: {'Measurements'}
    WithinModel: 'separatemeans'
  Estimates:
    Coefficients: [3x4 table]
    Covariance: [4x4 table]

```

Display the coefficients.

```
rm.Coefficients
```

```
ans =
```

	meas1	meas2	meas3	meas4
(Intercept)	5.8433	3.0573	3.758	1.1993
species_setosa	-0.83733	0.37067	-2.296	-0.95333
species_versicolor	0.092667	-0.28733	0.502	0.12667

`fitrm` uses the 'effects' contrasts which means that the coefficients sum to 0. The `rm.DesignMatrix` has one column of 1s for the intercept, and two other columns `species_setosa` and `species_versicolor`, which are as follows:

$$\text{species_setosa} = \begin{cases} 1, & \text{if } setosa \\ 0, & \text{if } versicolor \\ -1, & \text{if } virginica \end{cases} \quad \text{and} \quad \text{species_versicolor} = \begin{cases} 0, & \text{if } setosa \\ 1, & \text{if } versicolor \\ -1, & \text{if } virginica \end{cases}$$

Display the covariance matrix.

```
rm.Covariance
```

```
ans =
```

	meas1	meas2	meas3	meas4
meas1	0.26501	0.092721	0.16751	0.038401
meas2	0.092721	0.11539	0.055244	0.03271
meas3	0.16751	0.055244	0.18519	0.042665
meas4	0.038401	0.03271	0.042665	0.041882

Specify the Within-Subject Hypothesis

Navigate to the folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load('longitudinalData')
```

The matrix Y contains response data for 16 individuals. The response is the blood level of a drug measured at five time points (time = 0, 2, 4, 6, and 8). Each row of Y corresponds to an individual, and each column corresponds to a time point. The first eight subjects are female, and the second eight subjects are male. This is simulated data.

Define a variable that stores gender information.

```
Gender = ['F' 'F' 'F' 'F' 'F' 'F' 'F' 'F' 'M' 'M' 'M' 'M' 'M' 'M' 'M' 'M'];
```

Store the data in a proper table array format to conduct repeated measures analysis.

```
t = table(Gender,Y(:,1),Y(:,2),Y(:,3),Y(:,4),Y(:,5),...
'VariableNames',{'Gender','t0','t2','t4','t6','t8'});
```

Define the within-subjects variable.

```
Time = [0 2 4 6 8]';
```

Fit a repeated measures model, where blood levels are the responses and gender is the predictor variable. Also define the hypothesis for within-subject factors.

```
rm = fitrm(t,'t0-t8 ~ Gender','WithinDesign',Time,'WithinModel','orthogonalcontrasts')
```

```
rm =  
  
RepeatedMeasuresModel with properties:  
  
Between Subjects:  
  BetweenDesign: [16x6 table]  
  ResponseNames: {'t0' 't2' 't4' 't6' 't8'}  
  BetweenFactorNames: {'Gender'}  
  BetweenModel: '1 + Gender'  
  
Within Subjects:  
  WithinDesign: [5x1 table]  
  WithinFactorNames: {'Time'}  
  WithinModel: 'orthogonalcontrasts'  
  
Estimates:  
  Coefficients: [2x5 table]  
  Covariance: [5x5 table]
```

Fit a Model with Covariates

Load the sample data.

```
load repeatedmeas
```

The table `between` includes the eight repeated measurements `y1–y8` as responses and the between-subject factors `Group`, `Gender`, `IQ`, and `Age`. `IQ` and `Age` as continuous variables. The table `within` includes the within-subject factors `w1` and `w2`.

Fit a repeated measures model, where `age`, `IQ`, and `group`, `gender` are the predictor variables, and the model includes the interaction effect of `group` and `gender`. Also define the within-subject factors.

```
rm = fitrm(between, 'y1-y8 ~ Group*Gender+Age+IQ', 'WithinDesign', within)
```

```
rm =  
  
RepeatedMeasuresModel with properties:  
  
Between Subjects:  
  BetweenDesign: [30x12 table]  
  ResponseNames: {'y1' 'y2' 'y3' 'y4' 'y5' 'y6' 'y7' 'y8'}  
  BetweenFactorNames: {'Age' 'IQ' 'Group' 'Gender'}  
  BetweenModel: '1 + Age + IQ + Group*Gender'
```

```

Within Subjects:
  WithinDesign: [8x2 table]
  WithinFactorNames: {'w1' 'w2'}
  WithinModel: 'separatemeans'

```

```

Estimates:
  Coefficients: [8x8 table]
  Covariance: [8x8 table]

```

Display the coefficients.

```
rm.Coefficients
```

```
ans =
```

	y1	y2	y3	y4	y5
(Intercept)	141.38	195.25	9.8663	-49.154	157.77
Age	0.32042	-4.7672	-1.2748	0.6216	-1.0621
IQ	-1.2671	-1.1653	0.05862	0.4288	-1.4518
Group_A	-1.2195	-9.6186	22.532	15.303	12.602
Group_B	2.5186	1.417	-2.2501	0.50181	8.0907

Group_A:Gender_Female	4.1046	10.064	-7.3053	-3.3085	4.6751
Group_B:Gender_Female	-0.48486	-2.9202	1.1222	0.69715	-0.065945

The display shows the coefficients for fitting the repeated measures as a function of the terms in the between-subjects model.

Input Arguments

t — Input data

table

Input data, which includes the values of the response variables and the between-subject factors to use as predictors in the repeated measures model, specified as a table.

Data Types: table

modelspec — Formula for model specification

string of the form 'y1-yk ~ terms'

Formula for model specification, specified as a string of the form `'y1-yk ~ terms'`. The responses and terms are specified using Wilkinson notation. `fitrm` treats the variables used in model terms as categorical if they are categorical (nominal or ordinal), logical, char arrays, or a cell arrays of strings.

For example, if you have four repeated measures as responses and the factors `x1`, `x2`, and `x3` as the predictor variables, then you can define a repeated measures model as follows.

Example: `'y1-y4 ~ x1 + x2 * x3'`

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'WithinDesign','W','WithinModel','w1+w2'` specifies the matrix `w` as the design matrix for within-subject factors, and the model for within-subject factors `w1` and `w2` is `'w1+w2'`.

'WithinDesign' — Design for within-subject factors

numeric vector of length r (default) | r -by- k numeric matrix | r -by- k table

Design for within-subject factors, specified as the comma-separated pair consisting of `'WithinDesign'` and one of the following:

- Numeric vector of length r , where r is the number of repeated measures.

In this case, `fitrm` treats the values in the vector as continuous, and these are typically time values.

- r -by- k numeric matrix of the values of the k within-subject factors, w_1, w_2, \dots, w_k .

In this case, `fitrm` treats all k variables as continuous.

- r -by- k table that contains the values of the k within-subject factors.

In this case, `fitrm` treats all numeric variables as continuous, and all categorical variables as categorical.

For example, if the table `weeks` contains the values of the within-subject factors, then you can define the design table as follows.

Example: `'WithinDesign', weeks`

Data Types: `single | double | table`

'WithinModel' — Model specifying within-subject hypothesis test

`'separatemeans'` (default) | `'orthogonalcontrasts'` | string that defines a model

Model specifying the within-subject hypothesis test, specified as the comma-separated pair consisting of `'WithinModel'` and one of the following:

- `'separatemeans'` — Compute a separate mean for each group.
- `'orthogonalcontrasts'` — This is valid only when the within-subject model has a single numeric factor T . Responses are the average, the slope of centered T , and, in general, all orthogonal contrasts for a polynomial up to $T^{(p-1)}$, where p is the number of rows in the within-subject model.
- A string that defines a model specification in the within-subject factors. You can define the model based on the rules for the `terms` in `modelspec`.

For example, if there are three within-subject factors `w1`, `w2`, and `w3`, then you can specify a model for the within-subject factors as follows.

Example: `'WithinModel', 'w1+w2+w2*w3'`

Data Types: `single | double`

Output Arguments

rm — Repeated measures model

`RepeatedMeasuresModel` object

Repeated measures model, returned as a `RepeatedMeasuresModel` object.

For properties and methods of this object, see `RepeatedMeasuresModel`.

More About

Model Specification Using Wilkinson Notation

Wilkinson notation describes the factors present in models. It does not describe the multipliers (coefficients) of those factors.

The following rules specify the responses in modelspec.

Wilkinson Notation	Meaning
Y1, Y2, Y3	Specific list of variables
Y1 - Y5	All table variables from Y1 through Y5

The following rules specify terms in modelspec.

Wilkinson notation	Factors in Standard Notation
1	Constant (intercept) term
X^k , where k is a positive integer	X, X^2, \dots, X^k
$X1 + X2$	$X1, X2$
$X1 * X2$	$X1, X2, X1 * X2$
$X1 : X2$	$X1 * X2$ only
$-X2$	Do not include $X2$
$X1 * X2 + X3$	$X1, X2, X3, X1 * X2$
$X1 + X2 + X3 + X1 : X2$	$X1, X2, X3, X1 * X2$
$X1 * X2 * X3 - X1 : X2 : X3$	$X1, X2, X3, X1 * X2, X1 * X3, X2 * X3$
$X1 * (X2 + X3)$	$X1, X2, X3, X1 * X2, X1 * X3$

Statistics Toolbox notation always includes a constant term unless you explicitly remove the term using -1.

RepeatedMeasuresModel

fitdist

Fit probability distribution object to data

Syntax

```
pd = fitdist(x,distname)
pd = fitdist(x,distname,Name,Value)

[pdca,gn,gl] = fitdist(x,distname,'By',groupvar)
[pdca,gn,gl] = fitdist(x,distname,'By',groupvar,Name,Value)
```

Description

`pd = fitdist(x,distname)` creates a probability distribution object by fitting the distribution specified by `distname` to the data in column vector `x`.

`pd = fitdist(x,distname,Name,Value)` creates the probability distribution object with additional options specified by one or more name-value pair arguments. For example, you can indicate censored data or specify control parameters for the iterative fitting algorithm.

`[pdca,gn,gl] = fitdist(x,distname,'By',groupvar)` creates probability distribution objects by fitting the distribution specified by `distname` to the data in `x` based on the grouping variable `groupvar`. It returns a cell array of fitted probability distribution objects, `pdca`, a cell array of group labels, `gn`, and a cell array of grouping variable levels, `gl`.

`[pdca,gn,gl] = fitdist(x,distname,'By',groupvar,Name,Value)` returns the above output arguments using additional options specified by one or more name-value pair arguments. For example, you can indicate censored data or specify control parameters for the iterative fitting algorithm.

Examples

Fit a Normal Distribution to Data

Load the sample data. Create a vector containing the patients' weight data.

```
load hospital
x = hospital.Weight;
```

Create a normal distribution object by fitting it to the data.

```
pd = fitdist(x, 'Normal')
```

```
pd =
```

```
NormalDistribution
```

```
Normal distribution
```

```
mu = 154 [148.728, 159.272]
sigma = 26.5714 [23.3299, 30.8674]
```

Plot the pdf of the distribution.

```
x_values = 50:1:250;
y = pdf(pd,x_values);
plot(x_values,y, 'LineWidth',2)
```

Fit a Kernel Distribution to Data

Load the sample data. Create a vector containing the patients' weight data.

```
load hospital
x = hospital.Weight;
```

Create a kernel distribution object by fitting it to the data. Use the Epanechnikov kernel function.

```
pd = fitdist(x,'Kernel','Kernel','epanechnikov')
```

```
pd =
```

```
KernelDistribution
```

```
Kernel = epanechnikov  
Bandwidth = 14.3792  
Support = unbounded
```

Plot the pdf of the distribution.

```
x_values = 50:1:250;  
y = pdf(pd,x_values);  
plot(x_values,y)
```

Fit Normal Distributions to Grouped Data

Load the sample data. Create a vector containing the patients' weight data.

```
load hospital
x = hospital.Weight;
```

Create normal distribution objects by fitting them to the data, grouped by patient gender.

```
gender = hospital.Sex;
[pdca,gn,gl] = fitdist(x,'Normal','By',gender)
```

```
pdca =
```

```
        [1x1 prob.NormalDistribution]    [1x1 prob.NormalDistribution]

gn =

    'Female'
    'Male'

gl =

    'Female'
    'Male'
```

The cell array `pdca` contains two probability distribution objects, one for each gender group. The cell array `gn` contains two strings of the group labels. The cell array `gl` contains two strings of the group levels.

View each distribution in the cell array `pdca` to compare the mean, `mu`, and the standard deviation, `sigma`, grouped by patient gender.

```
female = pdca{1} % Distribution for females
```

```
female =

    NormalDistribution

    Normal distribution
        mu = 130.472    [128.183, 132.76]
        sigma = 8.30339    [6.96947, 10.2736]
```

```
male = pdca{2} % Distribution for males
```

```
male =

    NormalDistribution

    Normal distribution
        mu = 180.532    [177.833, 183.231]
```

```
sigma = 9.19322 [7.63933, 11.5466]
```

Compute the pdf of each distribution.

```
x_values = 50:1:250;  
femalepdf = pdf(female,x_values);  
malepdf = pdf(male,x_values);
```

Plot the pdfs for a visual comparison of weight distribution by gender.

```
figure  
plot(x_values,femalepdf,'LineWidth',2)  
hold on  
plot(x_values,malepdf,'Color','r','LineStyle',':','LineWidth',2)  
legend(gn,'Location','NorthEast')  
hold off
```

Fit Kernel Distributions to Grouped Data

Load the sample data. Create a vector containing the patients' weight data.

```
load hospital
x = hospital.Weight;
```

Create kernel distribution objects by fitting them to the data, grouped by patient gender. Use a triangular kernel function.

```
gender = hospital.Sex;
[pdca,gn,gl] = fitdist(x,'Kernel','By',gender,'Kernel','triangle');
```

View each distribution in the cell array `pdca` to see the kernel distributions for each gender.

```
female = pdca{1} % Distribution for females
```

```
female =
```

```
KernelDistribution
```

```
Kernel = triangle  
Bandwidth = 4.25894  
Support = unbounded
```

```
male = pdca{2} % Distribution for males
```

```
male =
```

```
KernelDistribution
```

```
Kernel = triangle  
Bandwidth = 5.08961  
Support = unbounded
```

Compute the pdf of each distribution.

```
x_values = 50:1:250;  
femalepdf = pdf(female,x_values);  
malepdf = pdf(male,x_values);
```

Plot the pdfs for a visual comparison of weight distribution by gender.

```
figure  
plot(x_values,femalepdf,'LineWidth',2)  
hold on  
plot(x_values,malepdf,'Color','r','LineStyle',':','LineWidth',2)  
legend(gn,'Location','NorthEast')  
hold off
```

Input Arguments

x — Input data

column vector

Input data, specified as a column vector. `fitdist` ignores NaN values in `x`. Additionally, any NaN values in the censoring vector or frequency vector causes `fitdist` to ignore the corresponding values in `x`.

Data Types: `single` | `double`

distname — Distribution name

string

Distribution name, specified as one of the following strings. The distribution specified by `distname` determines the class type of the returned probability distribution object.

Distribution Name	Description	Distribution Class
'Beta'	Beta distribution	prob.BetaDistribution
'Binomial'	Binomial distribution	prob.BinomialDistribution
'BirnbauSaunders'	Birnbau-Saunders distribution	prob.BirnbauSaundersDistribution
'Burr'	Burr distribution	prob.BurrDistribution
'Exponential'	Exponential distribution	prob.ExponentialDistribution
'ExtremeValue'	Extreme Value distribution	prob.ExtremeValueDistribution
'Gamma'	Gamma distribution	prob.GammaDistribution
'GeneralizedExtremeValue'	Generalized Extreme Value distribution	prob.GeneralizedExtremeValueDistribution
'GeneralizedPareto'	Generalized Pareto distribution	prob.GeneralizedParetoDistribution
'InverseGaussian'	Inverse Gaussian distribution	prob.InverseGaussianDistribution
'Kernel'	Kernel distribution	prob.KernelDistribution
'Logistic'	Logistic distribution	prob.LogisticDistribution
'Loglogistic'	Loglogistic distribution	prob.LoglogisticDistribution
'Lognormal'	Lognormal distribution	prob.LognormalDistribution
'Multinomial'	Multinomial distribution	prob.MultinomialDistribution
'Nakagami'	Nakagami distribution	prob.NakagamiDistribution
'NegativeBinomial'	Negative Binomial distribution	prob.NegativeBinomialDistribution
'Normal'	Normal distribution	prob.NormalDistribution
'Poisson'	Poisson distribution	prob.PoissonDistribution
'Rayleigh'	Rayleigh distribution	prob.RayleighDistribution
'Rician'	Rician distribution	prob.RicianDistribution
'tLocationScale'	t Location-Scale distribution	prob.tLocationScaleDistribution

Distribution Name	Description	Distribution Class
'Weibull'	Weibull distribution	prob.WeibullDistribution

groupvar — Grouping variable

categorical array | logical or numeric vector | cell array of strings

Grouping variable, specified as a categorical array, logical or numeric vector, or cell array of strings. Each unique value in a grouping variable defines a group.

For example, if `Gender` is a cell array of strings with values `'Male'` and `'Female'`, you can use `Gender` as a grouping variable to fit a distribution to your data by gender.

More than one grouping variable can be used by specifying a cell array of grouping variable names. Observations are placed in the same group if they have common values of all specified grouping variables.

For example, if `Smoker` is a logical vector with values `0` for nonsmokers and `1` for smokers, then specifying the cell array `{Gender,Smoker}` divides observations into four groups: Male Smoker, Male Nonsmoker, Female Smoker, and Female Nonsmoker.

Example: `{Gender,Smoker}`

Data Types: `single` | `double` | `logical` | `cell` | `char`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `fitdist(x,'Kernel','Kernel','triangle')` fits a kernel distribution object to the data in `x` using a triangular kernel function.

'Censoring' — Logical flag for censored data

0 (default) | vector of logical values

Logical flag for censored data, specified as the comma-separated pair consisting of `'Censoring'` and a vector of logical values that is the same size as input vector `x`. The value is `1` when the corresponding element in `x` is a right-censored observation and `0`

when the corresponding element is an exact observation. The default is a vector of 0s, indicating that all observations are exact.

`fitdist` ignores any NaN values in this censoring vector. Additionally, any NaN values in `x` or the frequency vector causes `fitdist` to ignore the corresponding values in the censoring vector.

Data Types: `logical`

'Frequency' — Observation frequency

1 (default) | vector of nonnegative integer values

Observation frequency, specified as the comma-separated pair consisting of 'Frequency' and a vector of nonnegative integer values that is the same size as input vector `x`. Each element of the frequency vector specifies the frequencies for the corresponding elements in `x`. The default is a vector of 1s, indicating that each value in `x` only appears once.

`fitdist` ignores any NaN values in this frequency vector are ignored by the fitting calculations. Additionally, any NaN values in `x` or the censoring vector causes `fitdist` to ignore the corresponding values in the frequency vector.

Data Types: `logical`

'Options' — Control parameters

structure

Control parameters for the iterative fitting algorithm, specified as the comma-separated pair consisting of 'Options' and a structure you create using `statset`.

Data Types: `struct`

'NTrials' — Number of trials

positive integer value

Number of trials for the binomial distribution, specified as the comma-separated pair consisting of 'NTrials' and a positive integer value. You must specify `distname` as 'Binomial' to use this option.

Data Types: `single` | `double`

'Theta' — Threshold parameter

0 (default) | scalar value

Threshold parameter for the generalized Pareto distribution, specified as the comma-separated pair consisting of `'Theta'` and a scalar value. You must specify `distname` as `'GeneralizedPareto'` to use this option.

Data Types: `single` | `double`

'Kernel' — Kernel smoother type

`'normal'` (default) | `'box'` | `'triangle'` | `'epanechnikov'`

Kernel smoother type, specified as the comma-separated pair consisting of `'Kernel'` and one of the following:

- `'normal'`
- `'box'`
- `'triangle'`
- `'epanechnikov'`

You must specify `distname` as `'Kernel'` to use this option.

'Support' — Kernel density support

`'unbounded'` (default) | `'positive'` | two-element vector

Kernel density support, specified as the comma-separated pair consisting of `'Support'` and a string or two-element vector. The string must be one of the following.

<code>'unbounded'</code>	Density can extend over the whole real line.
<code>'positive'</code>	Density is restricted to positive values.

Alternatively, you can specify a two-element vector giving finite lower and upper limits for the support of the density.

You must specify `distname` as `'Kernel'` to use this option.

Data Types: `single` | `double`

'Width' — Bandwidth of kernel smoothing window

scalar value

Bandwidth of the kernel smoothing window, specified as the comma-separated pair consisting of `'Width'` and a scalar value. The default value used by `fitdist` is optimal for estimating normal densities, but you might want to choose a smaller value to reveal

features such as multiple modes. You must specify `distname` as 'Kernel' to use this option.

Data Types: `single` | `double`

Output Arguments

pd — Probability distribution

probability distribution object

Probability distribution, returned as a probability distribution object. The distribution specified by `distname` determines the class type of the returned probability distribution object.

pdca — Probability distribution objects

cell array

Probability distribution objects of the type specified by `distname`, returned as a cell array.

gn — Group labels

cell array of strings

Group labels, returned as a cell array of strings.

g1 — Grouping variable levels

cell array of strings

Grouping variable levels, returned as a cell array of strings containing one column for each grouping variable.

Alternative Functionality

App

The Distribution Fitting app opens a graphical user interface for you to import data from the workspace and interactively fit a probability distribution to that data. You can then save the distribution to the workspace as a probability distribution object. Open the Distribution Fitting app using `dfittool`, or click Distribution Fitting on the Apps tab.

More About

Algorithms

The `fitdlist` function fits most distributions using maximum likelihood estimation. Two exceptions are the normal and lognormal distributions with uncensored data.

- For the uncensored normal distribution, the estimated value of the sigma parameter is the square root of the unbiased estimate of the variance.
- For the uncensored lognormal distribution, the estimated value of the sigma parameter is the square root of the unbiased estimate of the variance of the log of the data.

fitensemble

Fitted ensemble for classification or regression

Syntax

```
Ensemble = fitensemble(X,Y,Method,NLearn,Learners)
Ensemble = fitensemble(X,Y,Method,NLearn,Learners,Name,Value)
```

Description

`Ensemble = fitensemble(X,Y,Method,NLearn,Learners)` creates an ensemble model that predicts responses to data. The ensemble consists of models listed in `Learners`.

`Ensemble = fitensemble(X,Y,Method,NLearn,Learners,Name,Value)` creates an ensemble model with additional options specified by one or more `Name,Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Input Arguments

X

Matrix of predictor values. Each column of `X` represents one variable, and each row represents one observation.

Y

For classification, `Y` is a categorical variable, character array, or cell array of strings. Each row of `Y` represents the classification of the corresponding row of `X`.

For regression, `Y` is a numeric column vector with the same number of rows as `X`. Each entry in `Y` is the response to the data in the corresponding row of `X`.

Method

Case-insensitive string consisting of one of the following.

- For classification with two classes:
 - 'AdaBoostM1'
 - 'LogitBoost'
 - 'GentleBoost'
 - 'RobustBoost' (requires an Optimization Toolbox license)
 - 'LPBoost' (requires an Optimization Toolbox license)
 - 'TotalBoost' (requires an Optimization Toolbox license)
 - 'RUSBoost'
 - 'Subspace'
 - 'Bag'
- For classification with three or more classes:
 - 'AdaBoostM2'
 - 'LPBoost' (requires an Optimization Toolbox license)
 - 'TotalBoost' (requires an Optimization Toolbox license)
 - 'RUSBoost'
 - 'Subspace'
 - 'Bag'
- For regression:
 - 'LSBoost'
 - 'Bag'

'Bag' applies to all methods. So when you use 'Bag', indicate whether you want a classifier or regressor with the `type` name-value pair set to 'classification' or 'regression'.

NLearn

Number of ensemble learning cycles, a positive integer (or the string 'AllPredictorCombinations', see the next paragraph). At every training cycle, `fitensemble` loops over all learner templates in `Learners` and trains one weak learner for every template. The total number of trained learners in `Ensemble` is `NLearn*numel(Learners)`.

If you set `Method` to `'Subspace'`, you can set `NLearn` to `'AllPredictorCombinations'`. With this setting, `fitensemble` constructs learners for all possible combinations of predictors taken `NPredToSample` at a time. This gives a total of `nchoosek(size(X,2),NPredToSample)` learners in the ensemble. You can use only one learner template for this setting.

`NLearn` for ensembles can vary from a few dozen to a few thousand. Usually, an ensemble with a good predictive power needs from a few hundred to a few thousand weak learners. You do not have to train an ensemble for that many cycles at once. You can start by growing a few dozen learners, inspect the ensemble performance and, if necessary, train more weak learners using the `resume` method of the ensemble.

Learners

One of the following:

- A string with the name of a weak learner:
 - `'Discriminant'` recommended for `'Subspace'`
 - `'KNN'` (applies only to `'Subspace'`)
 - `'Tree'` (applies to all methods except `'Subspace'`)
- A single weak learner template you create with `templateTree`, `templateKNN`, or `templateDiscriminant`.
- A cell array of weak learner templates. Usually you should supply only one weak learner template.

Ensemble performance depends on the parameters of the weak learners, and you can get poor performance using weak learners with default parameters. Specify the parameters for the weak learners in the template. Specify parameters for the ensemble in the `fitensemble` name-value pairs.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

All Ensembles

'CategoricalPredictors'

List of categorical predictors. Pass `CategoricalPredictors` as one of:

- A numeric vector with indices from 1 to `p`, where `p` is the number of columns of `X`.
- A logical vector of length `p`, where a `true` entry means that the corresponding column of `X` is a categorical variable.
- `'All'`, meaning all predictors are categorical.
- A cell array of strings, where each element in the array is the name of a predictor variable. The names must match entries in the `PredictorNames` property.
- A character matrix, where each row of the matrix is the name of a predictor variable. The names must match entries in the `PredictorNames` property. Pad the names with extra blanks so each row of the character matrix has the same length.

You can set `CategoricalPredictors` for these learners:

- `'Tree'`
- `'KNN'`, when all predictors are categorical

Default: `[]`

'CrossVal'

If `'On'`, grows a cross-validated learner with 10 folds. You can use `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'` parameters to override this cross-validation setting. You can only use one of these four parameters (`'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'`) at a time when creating a cross-validated learner.

Default: `'Off'`

'CVPartition'

Partition created with `cvpartition` to use in a cross-validated learner. You can only use one of these four options at a time: `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'`.

'FResample'

Fraction of the training set to be selected by resampling for every weak learner. A numeric scalar from 0 through 1. This parameter has no effect unless you grow an

ensemble by bagging or set `'Resample'` to `'on'`. The default setting is the one used most often for an ensemble grown by resampling.

Default: 1

'Holdout'

Holdout validation tests the specified fraction of the data, and uses the remaining data for training. Specify a numeric scalar from 0 to 1. You can only use one of these four options at a time for creating a cross-validated learner: `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'`.

'KFold'

Number of folds to use in a cross-validated learner, a positive integer. You can only use one of these four options at a time: `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'`.

Default: 10

'Leaveout'

Use leave-one-out cross validation by setting to `'on'`. You can only use one of these four options at a time: `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'`.

'NPredToSample'

Number of predictors in each random subspace learner, a positive integer from 1 to `size(X,2)`.

Default: 1

'NPrint'

Printout frequency, a positive integer scalar. Set to `'Off'` for no printout. Use this parameter to track how many weak learners have been trained so far. This is useful when you train ensembles with many learners on large data sets. If you use one of the cross-validation options, this parameter defines the printout frequency per number of cross-validation folds.

Default: `'Off'`

'PredictorNames'

Cell array of names for the predictor variables, in the order in which they appear in X .

Default: {'x1', 'x2', ...}

'Replace'

'On' or 'Off'. If 'On', sample with replacement. If 'Off', sample without replacement. This parameter has no effect unless you grow an ensemble by bagging or set `Resample` to 'On'. If you set `Resample` to 'On' and `Replace` to 'Off', `fitensemble` samples training observations assuming uniform weights, and boosts by reweighting observations.

Default: 'On'

'Resample'

'On' or 'Off'. If 'On', grow an ensemble by resampling, with the resampling fraction given by `FResample`, and sampling with or without replacement given by `Replace`.

- Boosting — When 'Off', the boosting algorithm reweights observations at every learning iteration. When 'On', the algorithm samples training observations using updated weights as the multinomial sampling probabilities.
- Bagging — You can use only the default value of this parameter ('On').

Default: 'Off' for boosting, 'On' for bagging

'ResponseName'

Name of the response variable Y , a string.

Default: 'Y'

'Type'

String, either 'Classification' or 'Regression'. Specify `Type` when the `Method` is 'Bag'.

'Weights'

Vector of observation weights. The length of `Weights` is the number of rows in X .

Default: `ones(size(X,1),1)`

Classification Ensembles

'ClassNames'

Array of class names. Specify a data type the same as exists in Y .

Default: Class names that exist in Y

'Cost'

Square matrix C , where $C(i, j)$ is the cost of classifying a point into class j if its true class is i . Alternatively, `cost` can be a structure S having two fields:

- S .ClassNames containing the group names as a categorical variable, character array, or cell array of strings
- S .ClassificationCosts containing the cost matrix C

If `Method` is `Bag`, `Type` is `Classification`, and `Cost` is highly skewed, then, for in-bag samples, the software oversamples unique observations from the class that has a large penalty. For smaller sample sizes, this might cause a very low relative frequency of out-of-bag observations from the class that has a large penalty. Therefore, the estimated out-of-bag error is highly variable, and might be difficult to interpret.

Default: $C(i, j) = 1$ if $i \neq j$, and $C(i, j) = 0$ if $i = j$

'Prior'

Prior probabilities for each class. Specify as one of:

- A string:
 - 'Empirical' determines class probabilities from class frequencies in Y . If you pass observation weights, they are used to compute the class probabilities.
 - 'Uniform' sets all class probabilities equal.
- A vector (one scalar value for each class)
- A structure S with two fields:
 - S .ClassNames containing the class names as a categorical variable, character array, or cell array of strings
 - S .ClassProbs containing a vector of corresponding probabilities

If you set values for both `Weights` and `Prior`, the weights are renormalized to add up to the value of the prior probability in the respective class.

If `Method` is `Bag`, `Type` is `Classification`, and `Prior` is highly skewed, then, for in-bag samples, the software oversamples unique observations from the class that has a large prior probability. For smaller sample sizes, this might cause a very low relative frequency of out-of-bag observations from the class that has a large prior probability. Therefore, the estimated out-of-bag error is highly variable, and might be difficult to interpret.

Default: `'Empirical'`

AdaBoostM1, AdaBoostM2, LogitBoost, GentleBoost, RUSBoost, and LSBoost

'LearnRate'

Learning rate for shrinkage, a numeric scalar from 0 to 1. If you set the learning rate to less than 1, the ensemble requires more learning iterations but often achieves a better accuracy. 0.1 is a popular choice for an ensemble grown with shrinkage.

Default: 1

RUSBoost

'RatioToSmallest'

Either a numeric scalar or vector with K elements when there are K classes. Every element of this vector is the sampling proportion for this class with respect to the class with fewest observations in Y . If you pass a scalar, the software uses this sampling proportion for all classes. For example, suppose you have class A with 100 observations and class B with 10 observations. If you pass `[2 1]` for `'RatioToSmallest'`, every learner in the ensemble is trained on 20 observations of class A and 10 observations of class B. If you pass 2 or `[2 2]`, every learner is trained on 20 observations of class A and 20 observations of class B. If you specify class names by using the `ClassNames` name-value pair argument of the fitting function, then the software matches elements in the array of class names to elements in this vector.

Default: ones(K,1)

LPBoost and TotalBoost

'MarginPrecision'

Margin precision, a numeric scalar between 0 and 1. `MarginPrecision` affects the number of boosting iterations required for conversion. Use a small value to grow an ensemble with many learners, and use a large value to grow an ensemble with few learners.

Default: 0.01

RobustBoost

'RobustErrorGoal'

Target classification error for `RobustBoost`, a numeric scalar from 0 through 1. Usually there is an optimal range for this parameter for your training data. If you set the error goal too low or too high, `RobustBoost` can produce a model with poor classification accuracy.

Default: 0.1

'RobustMarginSigma'

Spread of the distribution of classification margins over the training set for `RobustBoost`, a numeric positive scalar. You should consult literature on `RobustBoost` before setting this parameter

Default: 0.1

'RobustMaxMargin'

Maximal classification margin for `RobustBoost` in the training set, a nonnegative numeric scalar. `RobustBoost` minimizes the number of observations in the training set with classification margins below `RobustMaxMargin`.

Default: 0

Output Arguments

Ensemble

Ensemble object for predicting characteristics. The class of Ensemble depends on settings. In the following table, cross-validation names are `CrossVal`, `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'`.

Settings	Class
Resample name-value pair is <code>'Off'</code> , and you don't set a cross-validation name-value pair argument.	<code>ClassificationEnsemble</code>
Resample name-value pair is <code>'Off'</code> , and you don't set a cross-validation name-value pair argument.	<code>RegressionEnsemble</code>
Resample name-value pair is <code>'On'</code> , type is <code>'classification'</code> , and you don't set a cross-validation name-value pair argument.	<code>ClassificationBaggedEnsemble</code>
Resample name-value pair is <code>'On'</code> , type is <code>'regression'</code> , and you don't set a cross-validation name-value pair argument.	<code>RegressionBaggedEnsemble</code>
Method is a classification method, and you set a cross-validation name-value pair argument.	<code>ClassificationPartitionedEnsemble</code>
Method is a regression method, and you set a cross-validation name-value pair argument.	<code>RegressionPartitionedEnsemble</code>

Examples

Estimate the Resubstitution Loss of a Boosting Ensemble

Estimate the resubstitution loss of a trained, boosting classification ensemble of decision trees.

Load the `ionosphere` data set.

```
load ionosphere;
```

Train a decision tree ensemble using AdaBoost, 100 learning cycles, and the entire data set.

```
ClassTreeEns = fitensemble(X,Y, 'AdaBoostM1', 100, 'Tree');
```

`ClassTreeEns` is a trained `ClassificationEnsemble` ensemble classifier.

Determine the cumulative resubstitution losses (i.e., the cumulative misclassification error of the labels in the training data).

```
rsLoss = resubLoss(ClassTreeEns, 'Mode', 'Cumulative');
```

`rsLoss` is a 100-by-1 vector, where element k contains the resubstitution loss after the first k learning cycles.

Plot the cumulative resubstitution loss over the number of learning cycles.

```
plot(rsLoss);  
xlabel('Number of Learning Cycles');  
ylabel('Resubstitution Loss');
```

In general, as the number of decision trees in the trained classification ensemble increases, the resubstitution loss decreases.

A decrease in resubstitution loss might indicate that the software trained the ensemble sensibly. However, you cannot infer the predictive power of the ensemble by this decrease. To measure the predictive power of an ensemble, estimate the generalization error by:

- 1 Randomly partitioning the data into training and cross-validation sets. Do this by specifying `'holdout'`, `holdoutProportion` when you train the ensemble using `fitensemble`.

- 2 Passing the trained ensemble to `kfoldLoss`, which estimates the generalization error.

Train a Regression Ensemble

Use a trained, boosted regression tree ensemble to predict the fuel economy of a car. Choose the number of cylinders, volume displaced by the cylinders, horsepower, and weight as predictors.

Load the `carsmall` data set. Set the predictors to `X`.

```
load carsmall
X = [Cylinders,Displacement,Horsepower,Weight];
xnames = {'Cylinders','Displacement','Horsepower','Weight'};
```

Specify a regression tree template that uses surrogate splits to improve predictive accuracy in the presence of NaN values.

```
RegTreeTemp = templateTree('Surrogate','On');
```

Train the regression tree ensemble using `LSBoost` and 100 learning cycles.

```
RegTreeEns = fitensemble(X,MPG,'LSBoost',100,RegTreeTemp,...
    'PredictorNames',xnames);
```

`RegTreeEns` is a trained `RegressionEnsemble` regression ensemble.

Use the trained regression ensemble to predict the fuel economy for a four-cylinder car with a 200-cubic inch displacement, 150 horsepower, and weighing 3000 lbs.

```
predMPG = predict(RegTreeEns,[4 200 150 3000])
```

```
predMPG =
    21.7781
```

The average fuel economy of a car with these specifications is 21.78 mpg.

Estimate the Generalization Error of a Boosting Ensemble

Estimate the generalization error of a trained, boosting classification ensemble of decision trees.

Load the `ionosphere` data set.

```
load ionosphere;
```

Train a decision tree ensemble using `AdaBoostM1`, 100 learning cycles, and half of the data chosen randomly. The software validates the algorithm using the remaining half.

```
rng(2); % For reproducibility
ClassTreeEns = fitensemble(X,Y,'AdaBoostM1',100,'Tree',...
    'Holdout',0.5);
```

`ClassTreeEns` is a trained `ClassificationEnsemble` ensemble classifier.

Determine the cumulative generalization error, i.e., the cumulative misclassification error of the labels in the validation data).

```
genError = kfoldLoss(ClassTreeEns,'Mode','Cumulative');
```

`genError` is a 100-by-1 vector, where element k contains the generalization error after the first k learning cycles.

Plot the generalization error over the number of learning cycles.

```
plot(genError);
xlabel('Number of Learning Cycles');
ylabel('Generalization Error');
```

The cumulative generalization error decreases to approximately 7% when 25 weak learners compose the ensemble classifier.

More About

Tips

Avoid large estimated out-of-bag error variances by setting a more balanced misclassification cost matrix or a less skewed prior probability vector. This is particularly important if you train using a small sample size.

Algorithms

- For details of boosting and bagging algorithms, see “Ensemble Algorithms” on page 16-146.
- `fitensemble` generates in-bag samples by oversampling classes with large misclassification costs and undersampling classes with small misclassification costs. Consequently, out-of-bag samples have fewer observations from classes with large misclassification costs and more observations from classes with small misclassification costs. If you train a classification ensemble using a small data set and a highly skewed cost matrix, then the number of out-of-bag observations per class might be very low. Therefore, the estimated out-of-bag error might have a large variance and might be difficult to interpret. The same phenomenon can occur for classes with large prior probabilities.

fitnlm

Fit nonlinear regression model

Syntax

```
mdl = fitnlm(tbl,modelfun,beta0)
mdl = fitnlm(X,y,modelfun,beta0)
mdl = fitnlm( ____,modelfun,beta0,Name,Value)
```

Description

`mdl = fitnlm(tbl,modelfun,beta0)` fits the model specified by `modelfun` to variables in the table or dataset array `tbl`, and returns the nonlinear model `mdl`.

`fitnlm` estimates model coefficients using an iterative procedure starting from the initial values in `beta0`.

`mdl = fitnlm(X,y,modelfun,beta0)` fits a nonlinear regression model using the column vector `y` as a response variable and the columns of the matrix `X` as predictor variables.

`mdl = fitnlm(____,modelfun,beta0,Name,Value)` fits a nonlinear regression model with additional options specified by one or more `Name,Value` pair arguments.

Examples

Nonlinear Model from a Table

Create a nonlinear model for auto mileage based on the `carbig` data.

Load the data and create a nonlinear model.

```
load carbig
tbl = table(Horsepower,Weight,MPG);
modelfun = @(b,x)b(1) + b(2)*x(:,1).^b(3) + ...
```

```
b(4)*x(:,2).^b(5);  
beta0 = [-50 500 -1 500 -1];  
mdl = fitnlm(tbl,modelfun,beta0)
```

```
mdl =
```

Nonlinear regression model:

MPG ~ b1 + b2*Horsepower^b3 + b4*Weight^b5

Estimated Coefficients:

	Estimate	SE	tStat	pValue
b1	-49.383	119.97	-0.41164	0.68083
b2	376.43	567.05	0.66384	0.50719
b3	-0.78193	0.47168	-1.6578	0.098177
b4	422.37	776.02	0.54428	0.58656
b5	-0.24127	0.48325	-0.49926	0.61788

Number of observations: 392, Error degrees of freedom: 387

Root Mean Squared Error: 3.96

R-Squared: 0.745, Adjusted R-Squared 0.743

F-statistic vs. constant model: 283, p-value = 1.79e-113

Nonlinear Model from Matrix Data

Create a nonlinear model for auto mileage based on the `carbig` data.

Load the data and create a nonlinear model.

```
load carbig  
X = [Horsepower,Weight];  
y = MPG;  
modelfun = @(b,x)b(1) + b(2)*x(:,1).^b(3) + ...  
    b(4)*x(:,2).^b(5);  
beta0 = [-50 500 -1 500 -1];  
mdl = fitnlm(X,y,modelfun,beta0)
```

```
mdl =
```

Nonlinear regression model:

y ~ b1 + b2*x1^b3 + b4*x2^b5

Estimated Coefficients:

	Estimate	SE	tStat	pValue
b1	-49.383	119.97	-0.41164	0.68083
b2	376.43	567.05	0.66384	0.50719
b3	-0.78193	0.47168	-1.6578	0.098177
b4	422.37	776.02	0.54428	0.58656
b5	-0.24127	0.48325	-0.49926	0.61788

Number of observations: 392, Error degrees of freedom: 387

Root Mean Squared Error: 3.96

R-Squared: 0.745, Adjusted R-Squared 0.743

F-statistic vs. constant model: 283, p-value = 1.79e-113

Adjust Fitting Options in the Nonlinear Model

Create a nonlinear model for auto mileage based on the `carbig` data. Strive for more accuracy by lowering the `TolFun` option, and observe the iterations by setting the `Display` option.

Load the data and create a nonlinear model.

```
load carbig
X = [Horsepower,Weight];
y = MPG;
modelfun = @(b,x)b(1) + b(2)*x(:,1).^b(3) + ...
    b(4)*x(:,2).^b(5);
beta0 = [-50 500 -1 500 -1];
```

Create options to lower `TolFun` and to report iterative display, and create a model using the options.

```
opts = statset('Display','iter','TolFun',1e-10);
mdl = fitnlm(X,y,modelfun,beta0,'Options',opts);
```

Iteration	SSE	Norm of Gradient	Norm of Step
0	1.82248e+06		
1	678600	788810	1691.07
2	616716	6.12739e+06	45.4738
%%%	Many iterations deleted	%%%	
122	6068.48	1.56393	0.629325
123	6068.48	1.13809	0.432543
124	6068.48	0.295962	0.297511

Iterations terminated: relative change in SSE less than OPTIONS.ToIFun

Specify Nonlinear Regression Using Model String Syntax

Specify a nonlinear regression model for estimation using a function handle or model string syntax.

Load sample data.

```
S = load('reaction');  
X = S.reactants;  
y = S.rate;  
beta0 = S.beta;
```

Use a function handle to specify the Hougen-Watson model for the rate data.

```
mdl = fitnlm(X,y,@hougen,beta0)
```

```
mdl =
```

Nonlinear regression model:

```
y ~ hougen(b,X)
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
b1	1.2526	0.86701	1.4447	0.18654
b2	0.062776	0.043561	1.4411	0.18753
b3	0.040048	0.030885	1.2967	0.23089
b4	0.11242	0.075157	1.4957	0.17309
b5	1.1914	0.83671	1.4239	0.1923

Number of observations: 13, Error degrees of freedom: 8

Root Mean Squared Error: 0.193

R-Squared: 0.999, Adjusted R-Squared 0.998

F-statistic vs. zero model: 3.91e+03, p-value = 2.54e-13

Alternatively, you can use a string expression to specify the Hougen-Watson model for the rate data.

```
myfun = 'y~(b1*x2-x3/b5)/(1+b2*x1+b3*x2+b4*x3)';  
mdl2 = fitnlm(X,y,myfun,beta0)
```

```
mdl2 =
```

Nonlinear regression model:

$$y \sim (b1*x2 - x3/b5)/(1 + b2*x1 + b3*x2 + b4*x3)$$

Estimated Coefficients:

	Estimate	SE	tStat	pValue
b1	1.2526	0.86701	1.4447	0.18654
b2	0.062776	0.043561	1.4411	0.18753
b3	0.040048	0.030885	1.2967	0.23089
b4	0.11242	0.075157	1.4957	0.17309
b5	1.1914	0.83671	1.4239	0.1923

Number of observations: 13, Error degrees of freedom: 8

Root Mean Squared Error: 0.193

R-Squared: 0.999, Adjusted R-Squared 0.998

F-statistic vs. zero model: 3.91e+03, p-value = 2.54e-13

Estimate Nonlinear Regression Using Robust Fitting Options

Generate sample data from the nonlinear regression model

$$y = b_1 + b_2 \exp\{-b_3 x\} + \varepsilon,$$

where b_1 , b_2 , and b_3 are coefficients, and the error term is normally distributed with mean 0 and standard deviation 0.5.

```
modelfun = @(b,x)(b(1)+b(2)*exp(-b(3)*x));
```

```
rng('default') % for reproducibility
```

```
b = [1;3;2];
```

```
x = exprnd(2,100,1);
```

```
y = modelfun(b,x) + normrnd(0,0.5,100,1);
```

Set robust fitting options.

```
opts = statset('nlinfit');
```

```
opts.RobustWgtFun = 'bisquare';
```

Fit the nonlinear model using the robust fitting options. Here, use a string expression to specify the model.

```
b0 = [2;2;2];
```

```
modelstr = 'y ~ b1 + b2*exp(-b3*x)';
```

```
mdl = fitnlm(x,y,modelstr,b0,'Options',opts)
mdl =
```

```
Nonlinear regression model (robust fit):
y ~ b1 + b2*exp( - b3*x)
```

```
Estimated Coefficients:
```

	Estimate	SE	tStat	pValue
b1	1.0218	0.07202	14.188	2.1344e-25
b2	3.6619	0.25429	14.401	7.974e-26
b3	2.9732	0.38496	7.7232	1.0346e-11

```
Number of observations: 100, Error degrees of freedom: 97
Root Mean Squared Error: 0.501
R-Squared: 0.807, Adjusted R-Squared 0.803
F-statistic vs. constant model: 203, p-value = 2.34e-35
```

Fit Nonlinear Regression Model Using Weights Function Handle

Load sample data.

```
S = load('reaction');
X = S.reactants;
y = S.rate;
beta0 = S.beta;
```

Specify a function handle for observation weights. The function accepts the model fitted values as input, and returns a vector of weights.

```
a = 1; b = 1;
weights = @(yhat) 1./((a + b*abs(yhat)).^2);
```

Fit the Hougen-Watson model to the rate data using the specified observation weights function.

```
mdl = fitnlm(X,y,@hougen,beta0,'Weights',weights)
mdl =
```

```
Nonlinear regression model:
y ~ hougen(b,X)
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
b1	0.83085	0.58224	1.427	0.19142
b2	0.04095	0.029663	1.3805	0.20477
b3	0.025063	0.019673	1.274	0.23842
b4	0.080053	0.057812	1.3847	0.20353
b5	1.8261	1.281	1.4256	0.19183

Number of observations: 13, Error degrees of freedom: 8
 Root Mean Squared Error: 0.037
 R-Squared: 0.998, Adjusted R-Squared 0.998
 F-statistic vs. zero model: 1.14e+03, p-value = 3.49e-11

Nonlinear Regression Model Using Nonconstant Error Model

Load sample data.

```
S = load('reaction');
X = S.reactants;
y = S.rate;
beta0 = S.beta;
```

Fit the Hougen-Watson model to the rate data using the combined error variance model.

```
mdl = fitnlm(X,y,@hougen,beta0,'ErrorModel','combined')
```

```
mdl =
```

Nonlinear regression model:

$y \sim \text{hougen}(b,X)$

Estimated Coefficients:

	Estimate	SE	tStat	pValue
b1	1.2526	0.86702	1.4447	0.18654
b2	0.062776	0.043561	1.4411	0.18753
b3	0.040048	0.030885	1.2967	0.23089
b4	0.11242	0.075158	1.4957	0.17309
b5	1.1914	0.83671	1.4239	0.1923

Number of observations: 13, Error degrees of freedom: 8
 Root Mean Squared Error: 1.27
 R-Squared: 0.999, Adjusted R-Squared 0.998

F-statistic vs. zero model: 3.91e+03, p-value = 2.54e-13

- “Examine Quality and Adjust the Fitted Nonlinear Model” on page 11-7
- “Predict or Simulate Responses Using a Nonlinear Model” on page 11-10
- “Nonlinear Regression Workflow” on page 11-14

Input Arguments

tbl — Input data

table | dataset array

Input data, specified as a table or dataset array. If you do not specify the predictor and response variables, the last variable is the response variable and the others are the predictor variables by default.

Predictor variables and response variable must be numeric.

You specify the response and predictor names in your model string. If you do not provide a model string, you can set a different column as the response variable by using the `ResponseVar` name-value pair argument. You can select a subset of the columns as predictors by using the `PredictorVars` name-value pair argument.

Data Types: `single` | `double` | `logical`

X — Predictor variables

matrix

Predictor variables, specified as an n -by- p matrix, where n is the number of observations and p is the number of predictor variables. Each column of X represents one variable, and each row represents one observation.

Data Types: `single` | `double` | `logical`

y — Response variable

vector

Response variable, specified as an n -by-1 vector, where n is the number of observations. Each entry in y is the response for the corresponding row of X .

Data Types: `single` | `double`

modelfun — Functional form of the model

function handle | string of the form ' $y \sim f(b_1, b_2, \dots, b_j, x_1, x_2, \dots, x_k)$ '

Functional form of the model, specified as either of the following.

- Function handle `@modelfun` or `@(b,x)modelfun`, where
 - `b` is a coefficient vector with the same number of elements as `beta0`.
 - `x` is a matrix with the same number of columns as `X` or the number of predictor variable columns of `tbl`.

`modelfun(b,x)` returns a column vector that contains the same number of rows as `x`. Each row of the vector is the result of evaluating `modelfun` on the corresponding row of `x`. In other words, `modelfun` is a vectorized function, one that operates on all data rows and returns all evaluations in one function call. `modelfun` should return real numbers to obtain meaningful coefficients.

- String of the form `'y ~ f(b1,b2,...,bj,x1,x2,...,xk)'`, where `f` represents a scalar function of the scalar coefficient variables `b1,...,bj` and the scalar data variables `x1,...,xk`.

beta0 – Coefficients

numeric vector

Coefficients for the nonlinear model, specified as a numeric vector. `NonLinearModel` starts its search for optimal coefficients from `beta0`.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'ErrorModel','combined','Exclude',2,'Options',opt` specifies the error model as the combined model, excludes the second observation from the fit, and uses the options defined in the structure `opt` to control the iterative fitting procedure.

'CoefficientNames' – Names of the model coefficients

`{'b1','b2',...,'bk'}` (default) | cell array of strings

Names of the model coefficients, specified as a cell array of strings.

Data Types: `char`

'ErrorModel' — Form of the error variance model`'constant'` (default) | `'proportional'` | `'combined'`

Form of the error variance model, specified as one of the following. Each model defines the error using a standard mean-zero and unit-variance variable e in combination with independent components: the function value f , and one or two parameters a and b

<code>'constant'</code> (default)	$y = f + ae$
<code>'proportional'</code>	$y = f + bfe$
<code>'combined'</code>	$y = f + (a + b f)e$

The only allowed error model when using `Weights` is `'constant'`.

Note: `options.RobustWgtFun` must have value `[]` when using an error model other than `'constant'`.

Example: `'ErrorModel', 'proportional'`

'ErrorParameters' — Initial estimates of the error model parameters`numeric array`

Initial estimates of the error model parameters for the chosen `ErrorModel`, specified as a numeric array.

Error Model	Parameters	Default Values
<code>'constant'</code>	a	1
<code>'proportional'</code>	b	1
<code>'combined'</code>	a, b	[1, 1]

You can only use the `'constant'` error model when using `Weights`.

Note: `options.RobustWgtFun` must have value `[]` when using an error model other than `'constant'`.

For example, if 'ErrorModel' has the value 'combined', you can specify the starting value 1 for a and the starting value 2 for b as follows.

Example: 'ErrorParameters', [1,2]

Data Types: single | double

'Exclude' — Observations to exclude

logical or numeric index vector

Observations to exclude from the fit, specified as the comma-separated pair consisting of 'Exclude' and a logical or numeric index vector indicating which observations to exclude from the fit.

For example, you can exclude observations 2 and 3 out of 6 using either of the following examples.

Example: 'Exclude', [2,3]

Example: 'Exclude', logical([0 1 1 0 0 0])

Data Types: single | double | logical

'Options' — Options for controlling the iterative fitting procedure

[] (default) | structure

Options for controlling the iterative fitting procedure, specified as a structure created by `statset`. The relevant fields are the nonempty fields in the structure returned by the call `statset('fitnlm')`.

Option	Meaning	Default
DerivStep	Relative difference used in finite difference derivative calculations. A positive scalar, or a vector of positive scalars the same size as the vector of parameters estimated by the Statistics Toolbox function using the options structure.	$\text{eps}^{(1/3)}$
Display	Amount of information displayed by the fitting algorithm. <ul style="list-style-type: none"> 'off' — Displays no information. 'final' — Displays the final output. 'iter' — Displays iterative output to the Command Window. 	'off'

Option	Meaning	Default
FunValCheck	String indicating to check for invalid values, such as NaN or Inf, from the model function.	'on'
MaxIter	Maximum number of iterations allowed. Positive integer.	200
RobustWgtFun	Weight function for robust fitting. Can also be a function handle that accepts a normalized residual as input and returns the robust weights as output. If you use a function handle, give a Tune constant. See “Robust Options” on page 21-1556	[]
Tune	Tuning constant used in robust fitting to normalize the residuals before applying the weight function. A positive scalar. Required if the weight function is specified as a function handle.	See “Robust Options” on page 21-1556 for the default, which depends on RobustWgtFun.
TolFun	Termination tolerance for the objective function value. Positive scalar.	1e-8
TolX	Termination tolerance for the parameters. Positive scalar.	1e-8

Data Types: struct

'PredictorVars' — Predictor variables

cell array of strings | logical or numeric index vector

Predictor variables to use in the fit, specified as the comma-separated pair consisting of 'PredictorVars' and either a cell array of strings of the variable names in the table or dataset array `tbl`, or a logical or numeric index vector indicating which columns are predictor variables.

The strings should be among the names in `tbl`, or the names you specify using the 'VarNames' name-value pair argument.

The default is all variables in `X`, or all variables in `tbl` except for `ResponseVar`.

For example, you can specify the second and third variables as the predictor variables using either of the following examples.

Example: 'PredictorVars', [2,3]

Example: `'PredictorVars',logical([0 1 1 0 0 0])`

Data Types: `single` | `double` | `logical` | `cell`

'ResponseVar' — Response variable

last column of `tbl` (default) | string for variable name | logical or numeric index vector

Response variable to use in the fit, specified as the comma-separated pair consisting of `'ResponseVar'` and either a string of the variable name in the table or dataset array `tbl`, or a logical or numeric index vector indicating which column is the response variable.

If you supply a model string, it specifies the response variable. Otherwise, when fitting a table or dataset array, `'ResponseVar'` indicates which variable `fitnlm` should use as the response.

For example, you can specify the fourth variable, say `yield`, as the response out of six variables, in one of the following ways.

Example: `'ResponseVar','yield'`

Example: `'ResponseVar',[4]`

Example: `'ResponseVar',logical([0 0 0 1 0 0])`

Data Types: `single` | `double` | `logical` | `char`

'VarNames' — Names of variables in fit

`{'x1','x2',..., 'xn','y'}` (default) | cell array of strings

Names of variables in fit, specified as the comma-separated pair consisting of `'VarNames'` and a cell array of strings including the names for the columns of `X` first, and the name for the response variable `y` last.

`'VarNames'` is not applicable to variables in a table or dataset array, because those variables already have names.

For example, if in your data, horsepower, acceleration, and model year of the cars are the predictor variables, and miles per gallon (MPG) is the response variable, then you can name the variables as follows.

Example: `'VarNames',{'Horsepower','Acceleration','Model_Year','MPG'}`

Data Types: `cell`

'Weights' — Observation weights

`ones(n,1)` (default) | vector of nonnegative scalar values | function handle

Observation weights, specified as a vector of nonnegative scalar values or function handle.

- If you specify a vector, then it must have n elements, where n is the number of rows in `tbl` or `y`.
- If you specify a function handle, then the function must accept a vector of predicted response values as input, and return a vector of real positive weights as output.

Given weights, `W`, `NonLinearModel` estimates the error variance at observation `i` by $\text{MSE} * (1/W(i))$, where `MSE` is the mean squared error.

Data Types: `single` | `double` | `function_handle`

Output Arguments

mdl — Nonlinear model

`NonLinearModel` object

Nonlinear model representing a least-squares fit of the response to the data, returned as a `NonLinearModel` object.

If the `Options` structure contains a nonempty `RobustWgtFun` field, the model is not a least-squares fit, but uses the `RobustWgtFun` robust fitting function.

For properties and methods of the nonlinear model object, `mdl`, see the `NonLinearModel` class page.

nlinfit | NonLinearModel

LinearMixedModel.fitmatrix

Class: LinearMixedModel

Fit linear mixed-effects model using design matrices

Compatibility

LinearMixedModel.fitmatrix will be removed in a future release. Use fitlmematrix instead.

Syntax

```
lme = LinearMixedModel.fitmatrix(X,y,Z,[])  
lme = LinearMixedModel.fitmatrix(X,y,Z,G)  
lme = LinearMixedModel.fitmatrix( ____,Name,Value)
```

Description

`lme = LinearMixedModel.fitmatrix(X,y,Z,[])` creates a linear mixed-effects model of the responses `y` using the fixed-effects design matrix `X` and random-effects design matrix or matrices in `Z`.

`[]` implies that there is one group. That is, the grouping variable `G` is `ones(n,1)`, where `n` is the number of observations. Using `LinearMixedModel.fitmatrix(X,Y,Z,[])` without a specified covariance pattern most likely will result in a non-identifiable model. This syntax is recommended only if you build the grouping information into the random effects design `Z` and specify a covariance pattern for the random effects using 'CovariancePattern' name-value pair argument.

`lme = LinearMixedModel.fitmatrix(X,y,Z,G)` creates a linear mixed-effects model of the responses `y` using the fixed-effects design matrix `X` and random-effects design matrix `Z` or matrices in `Z`, and the grouping variable or variables in `G`.

`lme = LinearMixedModel.fitmatrix(____,Name,Value)` also creates a linear mixed-effects model with additional options specified by one or more `Name,Value` pair arguments, using any of the previous input arguments.

For example, you can specify the names of the response, predictor, and grouping variables. You can also specify the covariance pattern, fitting method, or the optimization algorithm.

Tips

- If your model is not easily described using a formula, you can create matrices to define the fixed and random effects, and fit the model using `fitlmematrix`.

Input Arguments

X — Fixed-effects design matrix

n-by-*p* matrix

Fixed-effects design matrix, specified as an *n*-by-*p* matrix, where *n* is the number of observations, and *p* is the number of fixed-effects predictor variables. Each row of **X** corresponds to one observation, and each column of **X** corresponds to one variable.

Data Types: `single` | `double`

y — Response values

n-by-1 vector

Response values, specified as an *n*-by-1 vector, where *n* is the number of observations.

Data Types: `single` | `double`

Z — Random-effects design

n-by-*q* matrix | cell array of *R* *n*-by-*q*(*r*) matrices, *r* = 1, 2, ..., *R*

Random-effects design, specified as either of the following.

- If there is one random-effects term in the model, then **Z** must be an *n*-by-*q* matrix, where *n* is the number of observations and *q* is the number of variables in the random-effects term.
- If there are *R* random-effects terms, then **Z** must be a cell array of length *R*. Each cell of **Z** contains an *n*-by-*q*(*r*) design matrix $Z\{r\}$, *r* = 1, 2, ..., *R*, corresponding to each random-effects term. Here, *q*(*r*) is the number of random effects term in the *r*th random effects design matrix, $Z\{r\}$.

Data Types: `single` | `double` | `cell`

G — Grouping variable or variables

n -by-1 vector | cell array of R n -by-1 vectors

Grouping variable or variables, specified as either of the following.

- If there is one random-effects term, then **G** must be an n -by-1 vector corresponding to a single grouping variable with M levels or groups.

G can be a categorical vector, numeric vector, character array, or cell array of strings.

- If there are multiple random-effects terms, then **G** must be a cell array of length R . Each cell of **G** contains a grouping variable $G\{r\}$, $r = 1, 2, \dots, R$, with $M(r)$ levels.

$G\{r\}$ can be a categorical vector, numeric vector, character array, or cell array of strings.

Data Types: `single` | `double` | `char` | `cell`

Name-Value Pair Arguments

Specify optional comma-separated pairs of **Name**,**Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as **Name1**,**Value1**, ..., **NameN**,**ValueN**.

'FixedEffectPredictors' — Names of columns in fixed-effects design matrix

{'x1', 'x2', ..., 'xP'} (default) | cell array of length p

Names of columns in the fixed-effects design matrix X , specified as the comma-separated pair consisting of **'FixedEffectPredictors'** and a cell array of length p .

For example, if you have a constant term and two predictors, say **TimeSpent** and **Gender**, where **Female** is the reference level for **Gender**, as the fixed effects, then you can specify the names of your fixed effects in the following way. **Gender_Male** represents the dummy variable you must create for category **Male**. You can choose different names for these variables.

Example: `'FixedEffectPredictors'`,
{'Intercept', 'TimeSpent', 'Gender_Male'},

Data Types: `cell`

'RandomEffectPredictors' — Names of columns in random-effects design matrix or cell array

cell array of length q | cell array of length R with elements of length $q(r)$, $r = 1, 2, \dots, R$

Names of columns in the random-effects design matrix or cell array Z , specified as the comma-separated pair consisting of **'RandomEffectPredictors'** and either of the following:

- A cell array of length q when Z is an n -by- q design matrix. In this case, the default is `{'z1', 'z2', ..., 'zQ'}`.
- A cell array of length R , when Z is a cell array of length R with each element $Z\{r\}$ of length $q(r)$, $r = 1, 2, \dots, R$. In this case, the default is `{'z11', 'z12', ..., 'z1Q(1)'}, ..., {'zr1', 'zr2', ..., 'zrQ(r)'}`.

For example, suppose you have correlated random effects for intercept and a variable named `Acceleration`. Then, you can specify the random-effects predictor names as follows.

Example: `'RandomEffectPredictors', {'Intercept', 'Acceleration'}`

If you have two random effects terms, one for the intercept and the variable `Acceleration` grouped by variable `g1`, and the second for the intercept, grouped by the variable `g2`, then you specify the random-effects predictor names as follows.

Example: `'RandomEffectPredictors', {{'Intercept', 'Acceleration'}}, {'Intercept'}}`

Data Types: `cell`

'ResponseVarName' — Name of response variable

`'y'` (default) | `string`

Name of response variable, specified as the comma-separated pair consisting of **'ResponseVarName'** and a string.

For example, if your response variable name is `score`, then you can specify it as follows.

Example: `'ResponseVarName', 'score'`

Data Types: `char`

'RandomEffectGroups' — Names of random effects grouping variables

`'g'` or `{'g1', 'g2', ..., 'gR'}` (default) | `string` | cell array of strings

Names of random effects grouping variables, specified as the comma-separated pair 'RandomEffectGroups' and either of the following:

- String — If there is only one random-effects term, that is, if G is a vector, then the value of 'RandomEffectGroups' is a string containing the name for the grouping variable G . The default is 'g'.
- Cell array of strings — If there are multiple random-effects terms, that is, if G is a cell array of length R , then the value of 'RandomEffectGroups' is a cell array of length R , where each cell contains the name for the grouping variable $G\{r\}$. The default is {'g1', 'g2', ..., 'gR'}.

For example, if you have two random-effects terms, $z1$ and $z2$, grouped by the grouping variables `sex` and `subject`, then you can specify the names of your grouping variables as follows.

Example: 'RandomEffectGroups', {'sex', 'subject'}

Data Types: char | cell

'CovariancePattern' — Pattern of covariance matrix

'FullCholesky' (default) | string | square symmetric logical matrix | cell array of strings or logical matrices

Pattern of the covariance matrix of the random effects, specified as the comma-separated pair consisting of 'CovariancePattern' and a string, a square symmetric logical matrix, or a cell array of strings or logical matrices.

If there are R random-effects terms, then the value of 'CovariancePattern' must be a cell array of length R , where each element r of this cell array specifies the pattern of the covariance matrix of the random-effects vector associated with the r th random-effects term. The options for each element follow.

'FullCholesky'

Default. Full covariance matrix using the Cholesky parameterization. `fitlme` estimates all elements of the covariance matrix.

'Full'

Full covariance matrix, using the log-Cholesky parameterization. `fitlme` estimates all elements of the covariance matrix.

'Diagonal'

Diagonal covariance matrix. That is, off-diagonal elements of the covariance matrix are constrained to be 0.

$$\begin{pmatrix} \sigma_{b1}^2 & 0 & 0 \\ 0 & \sigma_{b2}^2 & 0 \\ 0 & 0 & \sigma_{b3}^2 \end{pmatrix}$$

'Isotropic'

Diagonal covariance matrix with equal variances. That is, off-diagonal elements of the covariance matrix are constrained to be 0, and the diagonal elements are constrained to be equal. For example, if there are three random-effects terms with an isotropic covariance structure, this covariance matrix looks like

$$\begin{pmatrix} \sigma_b^2 & 0 & 0 \\ 0 & \sigma_b^2 & 0 \\ 0 & 0 & \sigma_b^2 \end{pmatrix}$$

where σ_b^2 is the common variance of the random-effects terms.

'CompSymm'

Compound symmetry structure. That is, common variance along diagonals and equal correlation between all random effects. For example, if there are three random-effects terms with a covariance matrix having a compound symmetry structure, this covariance matrix looks like

$$\begin{pmatrix} \sigma_{b1}^2 & \sigma_{b1,b2} & \sigma_{b1,b2} \\ \sigma_{b1,b2} & \sigma_{b1}^2 & \sigma_{b1,b2} \\ \sigma_{b1,b2} & \sigma_{b1,b2} & \sigma_{b1}^2 \end{pmatrix}$$

where σ_{b1}^2 is the common variance of the random-effects terms and $\sigma_{b1,b2}$ is the common covariance between any two random-effects term .

PAT

Square symmetric logical matrix. If 'CovariancePattern' is defined by the matrix PAT, and if `PAT(a, b) = false`, then the (a, b) element of the corresponding covariance matrix is constrained to be 0.

Example: 'CovariancePattern', 'Diagonal'

Example: 'CovariancePattern', {'Full', 'Diagonal'}

'FitMethod' — Method for estimating parameters

'ML' (default) | 'REML'

Method for estimating parameters of the linear mixed-effects model, specified as the comma-separated pair consisting of 'FitMethod' and either of the following.

'ML'

Default. Maximum likelihood estimation

'REML'

Restricted maximum likelihood estimation

Example: 'FitMethod', 'REML'

'Weights' — Observation weights

vector of scalar values

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and a vector of length n , where n is the number of observations.

Data Types: `single` | `double`**'Exclude' — Indices for rows to exclude**

use all rows without NaNs (default) | vector of integer or logical values

Indices for rows to exclude from the linear mixed-effects model in the data, specified as the comma-separated pair consisting of `'Exclude'` and a vector of integer or logical values.

For example, you can exclude the 13th and 67th rows from the fit as follows.

Example: `'Exclude', [13,67]`Data Types: `single` | `double` | `logical`**'DummyVarCoding' — Coding to use for dummy variables**`'reference'` (default) | `'effects'` | `'full'`

Coding to use for dummy variables created from the categorical variables, specified as the comma-separated pair consisting of `'DummyVarCoding'` and one of the following.

<code>'reference'</code>	Default. Coefficient for first category set to 0.
<code>'effects'</code>	Coefficients sum to 0.
<code>'full'</code>	One dummy variable for each category.

Example: `'DummyVarCoding', 'effects'`**'Optimizer' — Optimization algorithm**`'quasinevton'` (default) | `'fminunc'`

Optimization algorithm, specified as the comma-separated pair consisting of `'Optimizer'` and either of the following.

<code>'quasinevton'</code>	Default. Uses a trust region based quasi-Newton optimizer. Change
----------------------------	---

'fminunc'

the options of the algorithm using `statset('LinearMixedModel')`. If you don't specify the options, then `LinearMixedModel` uses the default options of `statset('LinearMixedModel')`.

You must have Optimization Toolbox to specify this option. Change the options of the algorithm using `optimoptions('fminunc')`. If you don't specify the options, then `LinearMixedModel` uses the default options of `optimoptions('fminunc')` with 'Algorithm' set to 'quasi-newton'.

Example: 'Optimizer', 'fminunc'

'OptimizerOptions' — Options for optimization algorithm

structure returned by `statset` | object returned by `optimoptions`

Options for the optimization algorithm, specified as the comma-separated pair consisting of 'OptimizerOptions' and a structure returned by `statset('LinearMixedModel')` or an object returned by `optimoptions('fminunc')`.

- If 'Optimizer' is 'fminunc', then use `optimoptions('fminunc')` to change the options of the optimization algorithm. See `optimoptions` for the options 'fminunc' uses. If 'Optimizer' is 'fminunc' and you do not supply 'OptimizerOptions', then the default for `LinearMixedModel` is the default options created by `optimoptions('fminunc')` with 'Algorithm' set to 'quasi-newton'.
- If 'Optimizer' is 'quasi-newton', then use `statset('LinearMixedModel')` to change the optimization parameters. If you don't change the optimization parameters, then `LinearMixedModel` uses the default options created by `statset('LinearMixedModel')`:

The 'quasi-newton' optimizer uses the following fields in the structure created by `statset('LinearMixedModel')`.

'To1Fun' — Relative tolerance on gradient of objective function

1e-6 (default) | positive scalar value

Relative tolerance on the gradient of the objective function, specified as a positive scalar value.

'ToIX' — Absolute tolerance on step size

1e-12 (default) | positive scalar value

Absolute tolerance on the step size, specified as a positive scalar value.

'MaxIter' — Maximum number of iterations allowed

10000 (default) | positive scalar value

Maximum number of iterations allowed, specified as a positive scalar value.

'Display' — Level of display

'off' (default) | 'iter' | 'final'

Level of display, specified as one of 'off', 'iter', or 'final'.

'StartMethod' — Method to start iterative optimization

'default' (default) | 'random'

Method to start iterative optimization, specified as the comma-separated pair consisting of 'StartMethod' and either of the following.

'default'	Default. An internally defined default value.
'random'	A random initial value.

Example: 'StartMethod', 'random'

'Verbose' — Indicator to display optimization process on screen

false (default) | true

Indicator to display the optimization process on screen, specified as the comma-separated pair consisting of 'Verbose' and either false or true. Default is false.

The setting for 'Verbose' overrides the field 'Display' in 'OptimizerOptions'.

Example: 'Verbose', true

'CheckHessian' — Indicator to check positive definiteness of Hessian

false (default) | true

Indicator to check the positive definiteness of the Hessian of the objective function with respect to unconstrained parameters at convergence, specified as the comma-separated pair consisting of 'CheckHessian' and either `false` or `true`. Default is `false`.

Specify 'CheckHessian' as `true` to verify optimality of the solution or to determine if the model is overparameterized in the number of covariance parameters.

Example: 'CheckHessian', `true`

Output Arguments

lme — Linear mixed-effects model

`LinearMixedModel` object

Linear mixed-effects model, returned as a `LinearMixedModel` object.

For properties and methods of this object, see `LinearMixedModel`.

Examples

No Grouping Variable Specified

Load the sample data.

```
load carsmall
```

Fit a linear mixed-effects model, where MPG is the response, weight is the predictor variable, and the intercept varies by model year. First, define the design matrices. Then, fit the model using the specified design matrices.

```
y = MPG;  
X = [ones(size(Weight)), Weight];  
Z = ones(size(y));  
lme = LinearMixedModel.fitmatrix(X,y,Z,Model_Year)
```

```
lme =

Longitudinal Study with Covariate

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load weight
```

`weight` contains data from a longitudinal study, where 20 subjects are randomly assigned 4 exercise programs (A, B, C, D) and their weight loss is recorded over six two-week time periods. This is simulated data.

Define `Subject` and `Program` as categorical variables. Create the design matrices for a linear mixed-effects model, with the initial weight, type of program, week, and the interaction between the week and type of program as the fixed effects. The intercept and coefficient of week vary by subject.

This model corresponds to

$$\begin{aligned}
 y_{im} = & \beta_0 + \beta_1 IW_i + \beta_2 Week_i + \beta_3 I[PB]_i + \beta_4 I[PC]_i + \beta_5 I[PD]_i \\
 & + \beta_6 (Week_i * I[PB]_i) + \beta_7 (Week_i * I[PC]_i) + \beta_8 (Week_i * I[PD]_i) \\
 & + b_{0m} + b_{1m} Week_{im} + \varepsilon_{im},
 \end{aligned}$$

where $i = 1, 2, \dots, 120$, and $m = 1, 2, \dots, 20$. β_j are the fixed-effects coefficients, $j = 0, 1, \dots, 8$, and b_{0m} and b_{1m} are random effects. IW stands for initial weight and $I[\cdot]$ is a dummy variable representing a type of program. For example, $I[PB]_i$ is the dummy variable representing program type B. The random effects and observation error have the following prior distributions: $b_{0m} \sim N(0, \sigma_0^2)$, $b_{1m} \sim N(0, \sigma_1^2)$, and $\varepsilon_{im} \sim N(0, \sigma^2)$.

```
Subject = nominal(Subject);
Program = nominal(Program);
D = dummyvar(Program); % Create dummy variables for Program
X = [ones(120,1), InitialWeight, D(:,2:4), Week, ...
     D(:,2).*Week, D(:,3).*Week, D(:,4).*Week];
Z = [ones(120,1), Week];
G = Subject;
```

Since the model has an intercept, you only need the dummy variables for programs B, C, and D. This is also known as the 'reference' method of coding dummy variables.

Fit the model using `LinearMixedModel.fitmatrix` with the defined design matrices and grouping variables.

```
lme = LinearMixedModel.fitmatrix(X,y,Z,G,'FixedEffectPredictors',...
{'Intercept','InitWeight','PrgB','PrgC','PrgD','Week','Week_PrgB','Week_PrgC','Week_PrgD',
'RandomEffectPredictors',{{'Intercept','Week'}},'RandomEffectGroups',{'Subject'})
```

```
lme =

'Week_PrgD'	0.033114	0.095394	0.34713	111	0.72915	-0

Random effects covariance parameters (95% CIs):

Group: Subject (20 Levels)

Name1	Name2	Type	Estimate	Lower	Upper
'Intercept'	'Intercept'	'std'	0.18407	0.12281	0.27587
'Week'	'Intercept'	'corr'	0.66841	0.21076	0.88573
'Week'	'Week'	'std'	0.15033	0.11004	0.20537

Group: Error

Name	Estimate	Lower	Upper
'Res Std'	0.10261	0.087882	0.11981

The p -values 0.0228 and 0.0115 indicate significant effects of the initial weights of the subjects and the time factor in the amount of weight lost. The weight loss of subjects that are in program B is significantly different relative to the weight loss of subjects that are in program A. The lower and upper limits of the covariance parameters for the random effects do not include zero, thus they seem significant. You can also test the significance of the random-effects using the `compare` method.

Random-Intercept Model

Load the sample data.

```
load flu
```

`flu` dataset array has a `Date` variable, and 10 variables for estimated influenza rates (in 9 different regions, estimated from Google searches, plus a nationwide estimate from the CDC).

To fit a linear-mixed effects model, where the influenza rates are the responses, combine the nine columns corresponding to the regions into a tall array that has a single response variable, `FluRate`, and a nominal variable, `Region`, the nationwide estimate `WtdILI`, that shows which region each estimate is from, and the grouping variable `Date`.

```
flu2 = stack(flu,2:10, 'NewDataVarName', 'FluRate', ...
```

```
'IndVarName', 'Region');
flu2.Date = nominal(flu2.Date);
```

Define the design matrices for a random-intercept linear mixed-effects model, where the intercept varies by `Date`. The corresponding model is

$$y_{im} = \beta_0 + \beta_1 \text{WtdILI}_{im} + b_{0m} + \varepsilon_{im}, \quad i = 1, 2, \dots, 468, \quad m = 1, 2, \dots, 52,$$

where y_{im} is the observation i for level m of grouping variable `Date`. b_{0m} is the random effect for level m of the grouping variable `Date` and ε_{im} is the observation error for observation i . The random effect has the prior distribution, $b_{0m} \sim N(0, \sigma_{FR}^2)$ and the error term has the distribution, $\varepsilon_{im} \sim N(0, \sigma^2)$.

```
y = flu2.FluRate;
X = [ones(468,1) flu2.WtdILI];
Z = [ones(468,1)];
G = flu2.Date;
```

Fit the linear mixed-effects model.

```
lme = LinearMixedModel.fitmatrix(X,y,Z,G, 'FixedEffectPredictors', {'Intercept', 'NationalRate'},
'RandomEffectPredictors', {'Intercept'}, 'RandomEffectGroups', {'Date'})
```

```
lme =
```

```
Linear mixed-effects model fit by ML
```

```
Model information:
```

Number of observations	468
Fixed effects coefficients	2
Random effects coefficients	52
Covariance parameters	2

```
Formula:
```

```
y ~ Intercept + NationalRate + (Intercept | Date)
```

```
Model fit statistics:
```

AIC	BIC	LogLikelihood	Deviance
286.24	302.83	-139.12	278.24

```
Fixed effects coefficients (95% CIs):
```

Name	Estimate	SE	tStat	DF	pValue	Lower	Upper
------	----------	----	-------	----	--------	-------	-------

'Intercept'	0.16385	0.057525	2.8484	466	0.0045885	0.0500
'NationalRate'	0.7236	0.032219	22.459	466	3.0502e-76	0.6600

Random effects covariance parameters (95% CIs):

Group: Date (52 Levels)

Name1	Name2	Type	Estimate	Lower	Upper
'Intercept'	'Intercept'	'std'	0.17146	0.13227	0.22226

Group: Error

Name	Estimate	Lower	Upper
'Res Std'	0.30201	0.28217	0.32324

The confidence limits of the standard deviation of the random-effects term $\sigma_{b_{0m}}^2$, do not include zero (0.13227, 0.22226), which indicates that the random-effects term is significant. You can also test the significance of the random-effects using `compare` method.

The estimated value of an observation is the sum of the fixed-effects values and value of the random effect at the grouping variable level corresponding to that observation. For example, the estimated flu rate for observation 28

$$\begin{aligned}\hat{y}_{28} &= \hat{\beta}_0 + \hat{\beta}_1 \text{WtdILI}_{28} + \hat{b}_{10/30/2005} \\ &= 0.1639 + 0.7236 * (1.343) + 0.3318 \\ &= 1.46749,\end{aligned}$$

where \hat{b} is the BLUP of the random effects for the intercept. You can compute this value in the following way.

```
beta = fixedEffects(lme);
[~,~,STATS] = randomEffects(lme); % compute the random effects statistics STATS
STATS.Level = nominal(STATS.Level1);
y_hat = beta(1) + beta(2)*flu2.WtdILI(28) + STATS.Estimate(STATS.Level=='10/30/2005')
y_hat =
    1.4674
```

You can simply display the fitted value using the `fitted(lme)` method.

```
F = fitted(lme);
F(28)
```

```
ans =
```

```
1.4674
```

Randomized-Block Design

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load shift
```

The data set shows the deviations from the target quality characteristic measured from the products each of five operators manufacture over three different shifts, morning, evening, and night. This is a randomized block design, where the operators are the blocks. The experiment is designed to study the impact of the time of shift on the performance. The performance measure is the deviations of the quality characteristics from the target value. This is simulated data.

Define the design matrices for a linear mixed-effects model with a random intercept grouped by operator, and shift as the fixed effects. Use the 'effects' contrasts. 'effects' contrasts mean that the coefficients sum to zero. You need to create two contrast coded variables in the fixed-effects design matrix, $X1$ and $X2$, where

$$Shift_Evening = \begin{cases} 0, & \text{if Morning} \\ 1, & \text{if Evening} \\ -1, & \text{if Night} \end{cases} \quad \text{and} \quad Shift_Morning = \begin{cases} 1, & \text{if Morning} \\ 0, & \text{if Evening} \\ -1, & \text{if Night} \end{cases}.$$

The model corresponds to

$$\begin{aligned} \text{Morning Shift: } QCDev_{im} &= \beta_0 + \beta_2 Shift_Morning_i + b_{0m} + \varepsilon_{im}, \quad m = 1, 2, \dots, 5, \\ \text{Evening Shift: } QCDev_{im} &= \beta_0 + \beta_1 Shift_Evening_i + b_{0m} + \varepsilon_{im}, \\ \text{Night Shift: } QCDev_{im} &= \beta_0 - \beta_1 Shift_Evening_i - \beta_2 Shift_Morning_i + b_{0m} + \varepsilon_{im}, \end{aligned}$$

where i represents the observations, and m represents the operators, $i = 1, 2, \dots, 15$, and $m = 1, 2, \dots, 5$. The random effects and the observation error have the following distributions: $b_{0m} \sim N(0, \sigma_{b_{0m}}^2)$ and $\varepsilon_{im} \sim N(0, \sigma^2)$.

```

S = shift.Shift;
X1 = (S=='Morning') - (S=='Night');
X2 = (S=='Evening') - (S=='Night');
X = [ones(15,1), X1, X2];
y = shift.QCDev;
Z = ones(15,1);
G = shift.Operator;

```

Fit a linear mixed-effects model using the specified design matrices and restricted maximum likelihood method.

```

lme = LinearMixedModel.fitmatrix(X,y,Z,G,'FitMethod','REML','FixedEffectPredictors',...
{'Intercept','S_Morning','S_Evening'},'RandomEffectPredictors',{{'Intercept'}},...
'RandomEffectGroups',{'Operator'},'DummyVarCoding','effects')

```

The estimated deviation from the target quality characteristics for the third operator working in the evening shift is

$$\begin{aligned}\hat{y}_{Evening,Operator3} &= \hat{\beta}_0 + \hat{\beta}_1 Shift_Evening + \hat{b}_{03} \\ &= 3.6525 - 0.53293 - 2.1715 \\ &= 0.94807.\end{aligned}$$

You can also display this value in the following way.

```
F = fitted(lme);
F(shift.Shift=='Evening' & shift.Operator=='3')
```

```
ans =
```

```
0.9481
```

Correlated and Uncorrelated Random-Effects Terms

Load the sample data.

```
load carbig
```

Fit a linear mixed-effects model for miles per gallon (MPG), with fixed effects for acceleration, horsepower and the cylinders, and uncorrelated random-effect for intercept and acceleration grouped by the model year. This model corresponds to

$$MPG_{im} = \beta_0 + \beta_1 Acc_i + \beta_2 HP + b_{0m} + b_{1m} Acc_{im} + \varepsilon_{im}, \quad m = 1, 2, 3,$$

with the random-effects terms having the following prior distributions: $b_{0m} \sim N(0, \sigma^2_0)$, and $b_{1m} \sim N(0, \sigma^2_1)$. m represents the model year.

First, prepare the design matrices for fitting the linear mixed-effects model.

```
X = [ones(406,1) Acceleration Horsepower];
Z = {ones(406,1), Acceleration};
G = {Model_Year, Model_Year};
Model_Year = nominal(Model_Year);
```

Now, fit the model using `LinearMixedModel.fitmatrix` with the defined design matrices and grouping variables.

```
lme = LinearMixedModel.fitmatrix(X, MPG, Z, G, 'FixedEffectPredictors', ...
{'Intercept', 'Acceleration', 'Horsepower'}, 'RandomEffectPredictors', ...
{'Intercept'}, {'Acceleration'}}, 'RandomEffectGroups', {'Model_Year', 'Model_Year'})
```

```
lme =
```

```
Linear mixed-effects model fit by ML
```

```
Model information:
```

Number of observations	392
Fixed effects coefficients	3
Random effects coefficients	26
Covariance parameters	3

```
Formula:
```

```
y ~ Intercept + Acceleration + Horsepower + (Intercept | Model_Year) + (Acceleration
```

```
Model fit statistics:
```

AIC	BIC	LogLikelihood	Deviance
2194.5	2218.3	-1091.3	2182.5

```
Fixed effects coefficients (95% CIs):
```

'Intercept'	49.839	2.0518	24.291	389	5.6168e-80	44.735	54.943
'Acceleration'	-0.58565	0.10846	-5.3995	389	1.1652e-07	-0.8027	-0.3686
'Horsepower'	-0.16534	0.0071227	-23.213	389	1.9755e-75	-0.1796	-0.1511

```
Random effects covariance parameters (95% CIs):
```

```
Group: Model_Year (13 Levels)
```

Name1	Name2	Type	Estimate	Lower	Upper
-------	-------	------	----------	-------	-------

	'Intercept'	'Intercept'	'std'	8.0669e-07	NaN	NaN
Group: Model_Year (13 Levels)						
	Name1	Name2	Type	Estimate	Lower	Upper
	'Acceleration'	'Acceleration'	'std'	0.18783	0.12523	0.25043
Group: Error						
	Name	Estimate	Lower	Upper		
	'Res Std'	3.7258	3.4698	4.0007		

The standard deviation of the random effect for the intercept does not seem significant.

Refit the model with potentially correlated random effects for intercept and acceleration. In this case the random-effects terms have the following prior distribution

$$b_m = \begin{pmatrix} b_{0m} \\ b_{1m} \end{pmatrix} \sim N \left(0, \begin{pmatrix} \sigma_0^2 & \sigma_{0,1} \\ \sigma_{0,1} & \sigma_1^2 \end{pmatrix} \right),$$

where m represents the model year.

First prepare the random-effects design matrix and grouping variable.

```
Z = [ones(406,1) Acceleration];
G = Model_Year;
```

```
lme = LinearMixedModel.fitmatrix(X,MPG,Z,G,'FixedEffectPredictors',...
{'Intercept','Acceleration','Horsepower'},'RandomEffectPredictors',...
{'Intercept','Acceleration'}},'RandomEffectGroups',{'Model_Year'})
```

```
lme =
```

Linear mixed-effects model fit by ML

Model information:

Number of observations	392
Fixed effects coefficients	3
Random effects coefficients	26
Covariance parameters	4

Formula:

```
y ~ Intercept + Acceleration + Horsepower + (Intercept + Acceleration | Model_Year)
```

Model fit statistics:

AIC	BIC	LogLikelihood	Deviance
2193.5	2221.3	-1089.7	2179.5

Fixed effects coefficients (95% CIs):

Name	Estimate	SE	tStat	DF	pValue	Lower
'Intercept'	50.133	2.2652	22.132	389	7.7727e-71	45.601
'Acceleration'	-0.58327	0.13394	-4.3545	389	1.7075e-05	-0.8511
'Horsepower'	-0.16954	0.0072609	-23.35	389	5.188e-76	-0.1836

Random effects covariance parameters (95% CIs):

Group: Model_Year (13 Levels)

Name1	Name2	Type	Estimate	Lower	Upper
'Intercept'	'Intercept'	'std'	3.3475	1.2862	5.4088
'Acceleration'	'Intercept'	'corr'	-0.87971	-0.98501	-0.77441
'Acceleration'	'Acceleration'	'std'	0.33789	0.1825	0.51328

Group: Error

Name	Estimate	Lower	Upper
'Res Std'	3.6874	3.4298	3.9644

The confidence intervals for the standard deviations and the correlation between the random effects for intercept and acceleration do not include zeros, hence they seem significant. You can compare these two models using the `compare` method.

Specify the Covariance Pattern

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load weight
```

`weight` contains data from a longitudinal study, where 20 subjects are randomly assigned 4 exercise programs, and their weight loss is recorded over six two-week time periods. This is simulated data.

Define `Subject` and `Program` as categorical variables.

```
Subject = nominal(Subject);
Program = nominal(Program);
```

Create the design matrices for a linear mixed-effects model, with the initial weight, type of program, and week are the fixed effects.

```
D = dummyvar(Program);
X = [ones(120,1), InitialWeight, D(:,2:4), Week];
Z = [ones(120,1) Week];
G = Subject;
```

This model corresponds to

$$y_{im} = \beta_0 + \beta_1 IW_i + \beta_2 Week_i + \beta_3 I[PB]_i + \beta_4 I[PC]_i + \beta_5 I[PD]_i \\ + b_{0m} + b_{1m} Week2_{im} + b_{2m} Week4_{im} + b_{3m} Week6_{im} + b_{4m} Week8_{im} \\ + b_{5m} Week10_{im} + b_{6m} Week12_{im} + \varepsilon_{im},$$

where $i = 1, 2, \dots, 120$, and $m = 1, 2, \dots, 20$.

β_j are the fixed-effects coefficients, $j = 0, 1, \dots, 8$, and b_{1m} and b_{1m} are random effects. IW stands for initial weight and $I[\cdot]$ is a dummy variable representing a type of program. For example, $I[PB]_i$ is the dummy variable representing program type B. The random effects and observation error have the following prior distributions: $b_{0m} \sim N(0, \sigma_0^2)$, $b_{1m} \sim N(0, \sigma_1^2)$, and $\varepsilon_{im} \sim N(0, \sigma^2)$.

Fit the model using `LinearMixedModel.fitmatrix` with the defined design matrices and grouping variables. Assume the repeated observations collected on a subject have common variance along diagonals.

```
lme = LinearMixedModel.fitmatrix(X,y,Z,G, 'FixedEffectPredictors', ...
{'Intercept', 'InitWeight', 'PrgB', 'PrgC', 'PrgD', 'Week'}, ...
'RandomEffectPredictors', {{'Intercept', 'Week'}}, ...
'RandomEffectGroups', {'Subject'}, 'CovariancePattern', 'Isotropic')
```

```
lme =
```

Definitions

Cholesky Parameterization

One of the assumptions of linear mixed-effects models is that the random effects have the following prior distribution.

$$b \sim N(0, \sigma^2 D(\theta)),$$

where D is a q -by- q symmetric and positive semidefinite matrix, parameterized by a variance component vector θ , q is the number of variables in the random-effects term, and σ^2 is the observation error variance. Since the covariance matrix of the random effects, D , is symmetric, it has $q(q+1)/2$ free parameters. Suppose L is the lower triangular Cholesky factor of $D(\theta)$ such that

$$D(\theta) = L(\theta)L(\theta)^T,$$

then the $q^*(q+1)/2$ -by-1 unconstrained parameter vector θ is formed from elements in the lower triangular part of L .

For example, if

$$L = \begin{bmatrix} L_{11} & 0 & 0 \\ L_{21} & L_{22} & 0 \\ L_{31} & L_{32} & L_{33} \end{bmatrix},$$

then

$$\theta = \begin{bmatrix} L_{11} \\ L_{21} \\ L_{31} \\ L_{22} \\ L_{32} \\ L_{33} \end{bmatrix}.$$

Log-Cholesky Parameterization

When the diagonal elements of L in Cholesky parameterization are constrained to be positive, then the solution for L is unique. Log-Cholesky parameterization is the same as Cholesky parameterization except that the logarithm of the diagonal elements of L are used to guarantee unique parameterization.

For example, for the 3-by-3 example in Cholesky parameterization, enforcing $L_{ii} \geq 0$,

$$\theta = \begin{bmatrix} \log(L_{11}) \\ L_{21} \\ L_{31} \\ \log(L_{22}) \\ L_{32} \\ \log(L_{33}) \end{bmatrix}.$$

Alternatives

You can also fit a linear mixed-effects model using `fitlme(tbl, formula)`, where `tbl` is a table or dataset array containing the response `y`, the predictor variables `X`, and the grouping variables, and `formula` is of the form `'y ~ fixed + (random1|g1) + ... + (randomR|gR)'`.

If your model is not easily described using a formula, you can create matrices to define the fixed and random effects, and fit the model using `fitlmematrix(X,y,Z,G)`.

`fitlme` | `LinearMixedModel`

fitNaiveBayes

Train naive Bayes classifier

Syntax

```
NBModel = fitNaiveBayes(X,Y)
NBModel = fitNaiveBayes(X,Y,Name,Value)
```

Description

`NBModel = fitNaiveBayes(X,Y)` returns a naive Bayes classifier `NBModel`, trained by predictors `X` and class labels `Y` for K -level classification.

Predict labels for new data by passing the data and `NBModel` to `predict`.

`NBModel = fitNaiveBayes(X,Y,Name,Value)` returns a naive Bayes classifier with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify a distribution to model the data, prior probabilities for the classes, or the kernel smoothing window bandwidth.

Examples

Train a Naive Bayes Classifier

Load Fisher's iris data set.

```
load fisheriris
X = meas(:,3:4);
Y = species;
tabulate(Y)
```

Value	Count	Percent
setosa	50	33.33%
versicolor	50	33.33%
virginica	50	33.33%

The software can classify data with more than two classes using naive Bayes methods.

Train a naive Bayes classifier.

```
NBModel = fitNaiveBayes(X,Y)
```

```
NBModel =
```

```
Naive Bayes classifier with 3 classes for 2 dimensions.  
Feature Distribution(s):normal  
Classes:setosa, versicolor, virginica
```

NBModel is a trained NaiveBayes classifier.

By default, the software models the predictor distribution within each class using a Gaussian distribution having some mean and standard deviation. Use dot notation to display the parameters of a particular Gaussian fit, e.g., display the fit for the first feature within `setosa`.

```
setosaIndex = strcmp(NBModel.ClassLevels, 'setosa');  
estimates = NBModel.Params{setosaIndex,1}
```

```
estimates =
```

```
    1.4620  
    0.1737
```

The mean is 1.4620 and the standard deviation is 0.1737.

Plot the Gaussian contours.

```
figure  
gscatter(X(:,1),X(:,2),Y);  
xlim = cell2mat(get(gca,{'Xlim','Ylim'})); % Gets current axis limits  
hold on  
Params = cell2mat(NBModel.Params);  
Mu = Params(2*(1:3)-1,1:2); % Extracts the means  
Sigma = zeros(2,2,3);  
for j = 1:3  
    Sigma(:,:,j) = diag(Params(2*j,:)); % Extracts the standard deviations  
    ezcontour(@(x1,x2)mvnpdf([x1,x2],Mu(j,:),Sigma(:,:,j)),...  
        xlim+0.5*[-1,1,-1,1]) ...  
    % Draws contours for the multivariate normal distributions
```

```

end
title('Naive Bayes Classifier -- Fisher's Iris Data')
xlabel('Petal Length (cm)')
ylabel('Petal Width (cm)')
hold off

```

You can change the default distribution using the name-value pair argument 'Distribution'. For example, If some predictors are count based, then you can specify that they are multinomial random variables using 'Distribution', 'mn'.

Specify Predictor Distributions for Naive Bayes Classifiers

Load Fisher's iris data set.

```
load fisheriris
```

```
X = meas;  
Y = species;
```

Train a naive Bayes classifier using every predictor.

```
NBModel1 = fitNaiveBayes(X,Y);  
NBModel1.ClassLevels % Display the class order  
NBModel1.Params  
NBModel1.Params{1,2}
```

```
ans =
```

```
'setosa'  
'versicolor'  
'virginica'
```

```
ans =
```

```
[2x1 double] [2x1 double] [2x1 double] [2x1 double]  
[2x1 double] [2x1 double] [2x1 double] [2x1 double]  
[2x1 double] [2x1 double] [2x1 double] [2x1 double]
```

```
ans =
```

```
3.4280  
0.3791
```

By default, the software models the predictor distribution within each class as a Gaussian with some mean and standard deviation. There are four predictors and three class levels. Each cell in `NBModel1.Params` corresponds to a numeric vector containing the mean and standard deviation of each distribution, e.g., the mean and standard deviation for setosa iris sepal widths are `3.4280` and `0.3791`, respectively.

Estimate the confusion matrix for `NBModel1`.

```
predictLabels1 = predict(NBModel1,X);  
[ConfusionMat1,labels] = confusionmat(Y,predictLabels1)
```

```
ConfusionMat1 =
```

```

50    0    0
  0   47   3
  0    3  47

```

```

labels =
  'setosa'
  'versicolor'
  'virginica'

```

Element (j, k) of `ConfusionMat1` represents the number of observations that the software classifies as k , but the data show as being in class j .

Retrain the classifier using the Gaussian distribution for predictors 1 and 2 (the sepal lengths and widths), and the default normal kernel density for predictors 3 and 4 (the petal lengths and widths).

```

NBModel2 = fitNaiveBayes(X,Y,...
  'Distribution',{ 'normal', 'kernel', 'normal', 'kernel'});
NBModel2.Params{1,2}

```

```

ans =
  KernelDistribution
  Kernel = normal
  Bandwidth = 0.179536
  Support = unbounded

```

The software does not train parameters to the kernel density. Rather, the software chooses an optimal width. However, you can specify a width using the `'KSWidth'` name-value pair argument.

Estimate the confusion matrix for `NBModel2`.

```

predictLabels2 = predict(NBModel2,X);
ConfusionMat2 = confusionmat(Y,predictLabels2)

```

```

ConfusionMat2 =

```

```
50    0    0
  0   47   3
  0    3  47
```

Based on the confusion matrices, the two classifiers perform similarly in the training sample.

Train Naive Bayes Classifiers Using Multinomial Predictors

Some spam filters classify an incoming email as spam based on how many times a word or punctuation (called tokens) occurs in an email. The predictors are the frequencies of particular words or punctuations in an email. Therefore, the predictors compose multinomial random variables.

This example illustrates classification using naive Bayes and multinomial predictors.

Suppose you observed 1000 emails and classified them as spam or not spam. Do this by randomly assigning -1 or 1 to y for each email.

```
n = 1000; % Sample size
rng(1); % For reproducibility
y = randsample([-1 1],n,true); % Random labels
```

To build the predictor data, suppose that there are five tokens in the vocabulary, and 20 observed tokens per email. Generate predictor data from the five tokens by drawing multinomial deviates. The relative frequencies for tokens corresponding to spam emails should differ from emails that are not spam.

```
tokenProbs = [0.2 0.3 0.1 0.15 0.25;... % Token relative frequencies
              0.4 0.1 0.3 0.05 0.15];
tokensPerEmail = 20;
X = zeros(n,5);
X(y == 1,:) = mnrnd(tokensPerEmail,tokenProbs(1,:),sum(y == 1));
X(y == -1,:) = mnrnd(tokensPerEmail,tokenProbs(2,:),sum(y == -1));
```

Train a naive Bayes classifier. Specify that the predictors are multinomial.

```
NBModel = fitNaiveBayes(X,y,'Distribution','mn');
```

NBModel is a trained NaiveBayes classifier.

Assess the in-sample performance of NBModel by estimating the misclassification rate.

```
predSpam = predict(NBModel,X);
misclass = sum(y'~=predSpam)/n
```

```

misclass =
    0.0200

```

The in-sample misclassification rate is 2%.

Randomly generate deviates that represent a new batch of emails.

```

nOut = 500;
yOut = randsample([-1 1],nOut,true);
XOut = zeros(nOut,5);
XOut(yOut == 1,:) = mnrnd(tokensPerEmail,tokenProbs(1,:),...
    sum(yOut == 1));
XOut(yOut == -1,:) = mnrnd(tokensPerEmail,tokenProbs(2,:),...
    sum(yOut == -1));

```

Classify the new emails using the trained naive Bayes classifier `NBModel`, and determine whether the algorithm generalizes.

```

predSpamOut = predict(NBModel,XOut);
genRate = sum(yOut'~=predSpamOut)/nOut

```

```

genRate =
    0.0260

```

The out-of-sample misclassification rate is 2.6% indicating that the classifier generalizes fairly well.

Input Arguments

X — Predictor data

matrix of numeric values

Predictor data to which the naive Bayes classifier is trained, specified as a matrix of numeric values.

Each row of `X` corresponds to one observation (also known as an instance or example), and each column corresponds to one variable (also known as a feature).

The length of `Y` and the number of rows of `X` must be equivalent.

Data Types: `double`

Y — Class labels

categorical array | character array | logical vector | vector of numeric values | cell array of strings

Class labels to which the naive Bayes classifier is trained, specified as a categorical or character array, logical or numeric vector, or cell array of strings. Each element of `Y` defines the class membership of the corresponding row of `X`. `Y` supports K class levels.

If `Y` is a character array, then each row must correspond to one class label.

The length of `Y` and the number of rows of `X` must be equivalent.

Data Types: `cell` | `char` | `double` | `logical`

Note: The software treats NaN, empty string (' '), and `<undefined>` elements as missing values.

- If `Y` contains missing values, then the software removes them and the corresponding rows of `X`.
- If `X` contains any rows composed entirely of missing values, then the software removes those rows and the corresponding elements of `Y`.
- If `X` contains missing values and you set `'Distribution', 'mn'`, then the software removes those rows of `X` and the corresponding elements of `Y`.
- If a predictor is not represented in a class, that is, if all of its values are NaN within a class, then the software returns an error.

Removing rows of `X` and corresponding elements of `Y` decreases the effective training or cross-validation sample size.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1, ...,NameN,ValueN`.

Example: 'Distribution', 'mn', 'Prior', 'uniform', 'KSWidth', 0.5 specifies the following: the data distribution is multinomial, the prior probabilities for all classes are equal, and the kernel smoothing window bandwidth for all classes is 0.5 units.

'Distribution' — Data distributions

'normal' (default) | 'kernel' | 'mn' | 'mvmn' | cell array of strings

Data distributions `fitNaiveBayes` uses to model the data, specified as the comma-separated pair consisting of 'Distribution' and a string or cell array of strings.

This table summarizes the available distributions.

Value	Description
'kernel'	Kernel smoothing density estimate.
'mn'	Multinomial distribution. If you specify <code>mn</code> , then all features are components of a multinomial distribution. Therefore, you cannot include 'mn' as an element of a cell array of strings. For details, see “Algorithms” on page 21-1597.
'mvmn'	Multivariate multinomial distribution. For details, see “Algorithms” on page 21-1597.
'normal'	Normal (Gaussian) distribution.

If you specify a string, then the software models all the features using that distribution. If you specify a 1-by- D cell array of strings, then the software models feature j using the distribution in element j of the cell array.

Example: 'Distribution', {'kernel', 'normal'}

Data Types: cell | char

'KSSupport' — Kernel smoothing density support

'unbounded' (default) | 'positive' | cell array | numeric row vector

Kernel smoothing density support, specified as the comma-separated pair consisting of 'KSSupport' and a numeric row vector, a string, or a cell array. The software applies the kernel smoothing density to this region.

If you do not specify 'Distribution', 'kernel', then the software ignores the values of 'KSSupport', 'KSType', and 'KSWidth'.

This table summarizes the available options for setting the kernel smoothing density region.

Value	Description
1-by-2 numeric row vector	For example, [L,U], where L and U are the finite lower and upper bounds, respectively, for the density support.
'positive'	The density support is all positive real values.
'unbounded'	The density support is all real values.

If you specify a 1-by-*D* cell array, with each cell containing any value in the table, then the software trains the classifier using the kernel support in cell *j* for feature *j* in *X*.

Example: 'KSSupport', {[-10,20], 'unbounded' }

Data Types: cell | char | double

'KSType' — Kernel smoother type

'normal' (default) | 'box' | 'epanechnikov' | 'triangle' | cell array of strings

Kernel smoother type, specified as the comma-separated pair consisting of 'KSType' and a string or cell array of strings.

If you do not specify 'Distribution', 'kernel', then the software ignores the values of 'KSSupport', 'KSType', and 'KSWidth'.

This table summarizes the available options for setting the kernel smoothing density region. Let $I\{u\}$ denote the indicator function.

Value	Kernel	Formula
'box'	Box (uniform)	$f(x) = 0.5I\{ x \leq 1\}$
'epanechni	Epanechnikov	$f(x) = 0.75(1 - x^2)I\{ x \leq 1\}$
'normal'	Gaussian	$f(x) = \frac{1}{\sqrt{2\pi}} \exp(-0.5x^2)$
'triangle'	Triangular	$f(x) = (1 - x)I\{ x \leq 1\}$

If you specify a 1-by- D cell array, with each cell containing any value in the table, then the software trains the classifier using the kernel smoother type in cell j for feature j in X .

Example: 'KSType', {'epanechnikov', 'normal'}

Data Types: cell | char

'KSWidth' — Kernel smoothing window bandwidth

matrix of numeric values (default) | numeric column vector | numeric row vector | scalar | structure array

Kernel smoothing window bandwidth, specified as the comma-separated pair consisting of 'KSWidth' and a matrix of numeric values, numeric row vector, numeric column vector, scalar, or structure array.

If you do not specify 'Distribution', 'kernel', then the software ignores the values of 'KSSupport', 'KSType', and 'KSWidth'.

Suppose there are K class levels and D predictors. This table summarizes the available options for setting the kernel smoothing window bandwidth.

Value	Description
K -by- D matrix of numeric values	Element (k,d) specifies the bandwidth for predictor d in class k .
K -by-1 numeric column vector	Element k specifies the bandwidth for all predictors in class k .
1-by- D numeric row vector	Element d specifies the bandwidth in all class levels for predictor d .
scalar	Specifies the bandwidth for all features in all classes.
structure array	<p>A structure array S containing class levels and their bandwidths. S must have two fields:</p> <ul style="list-style-type: none"> • S.width: A numeric row vector of bandwidths, or a matrix of numeric values with D columns. • S.group: A vector of the same type as Y, containing unique class levels indicating the class for the corresponding element of S.width.

By default, the software selects a default bandwidth automatically for each combination of feature and class by using a value that is optimal for a Gaussian distribution.

Example: `'KSWidth', struct('width', [0.5, 0.25], 'group', {'b'; 'g'})`

Data Types: `double` | `struct`

'Prior' — Class prior probabilities

`'empirical'` (default) | `'uniform'` | numeric vector | structure array

Class prior probabilities, specified as the comma-separated pair consisting of `'Prior'` and a numeric vector, structure array, or string.

This table summarizes the available options for setting prior probabilities.

Value	Description
<code>'empirical'</code>	The software uses the class relative frequencies distribution for the prior probabilities.
numeric vector	A numeric vector of length K specifying the prior probabilities for each class. The order of the elements of <code>Prior</code> should correspond to the order of the class levels. For details on the order of the classes, see “Algorithms” on page 21-1597. The software normalizes prior probabilities to sum to 1.
structure array	A structure array <code>S</code> containing class levels and their prior probabilities. <code>S</code> must have two fields: <ul style="list-style-type: none"> • <code>S.prob</code>: A numeric vector of prior probabilities. The software normalizes prior probabilities to sum to 1. • <code>S.group</code>: A vector of the same type as <code>Y</code> containing unique class levels indicating the class for the corresponding element of <code>S.prob</code>. <code>S.class</code> must contain all the K levels in <code>Y</code>. It can also contain classes that do not appear in <code>Y</code>. This can be useful if <code>X</code> is a subset of a larger training set. The software ignores any classes that appear in <code>S.group</code> but not in <code>Y</code>.
<code>'uniform'</code>	The prior probabilities are equal for all classes.

Example: `'Prior', struct('prob', [1, 2], 'group', {'b'; 'g'})`

Data Types: `char` | `double` | `struct`

Output Arguments

NBModel — Trained naive Bayes classifier

NaiveBayes classifier

Trained naive Bayes classifier, returned as a `NaiveBayes` classifier.

More About

Bag-of-Tokens Model

In the bag-of-tokens model, the value of predictor j is the nonnegative number of occurrences of token j in this observation. The number of categories (bins) in this multinomial model is the number of distinct tokens, that is, the number of predictors.

Tips

- For classifying count-based data, such as the bag-of-tokens model, use the multinomial distribution (e.g., set `'Distribution', 'mn'`).
- This list defines the order of the classes. It is useful when you specify prior probabilities by setting `'Prior', prior`, where `prior` is a numeric vector.
 - If `Y` is a categorical array, then the order of the class levels matches the output of `categories(Y)`.
 - If `Y` is a numeric or logical vector, then the order of the class levels matches the output of `sort(unique(Y))`.
 - For cell arrays of string and character arrays, the order of the class labels is the order which each label appears in `Y`.

Algorithms

- If you specify `'Distribution', 'mn'`, then the software considers each observation as multiple trials of a multinomial distribution, and considers each occurrence of a token as one trial (see “Bag-of-Tokens Model” on page 21-1597).
- If you specify `'Distribution', 'mvmn'`, then the software assumes each individual predictor follows a multinomial model within a class. The parameters for a predictor include the probabilities of all possible values that the corresponding feature can take.
- “Naive Bayes Classification” on page 15-34

- “Grouping Variables” on page 2-52

NaiveBayes | posterior | predict

fitPosterior

Class: ClassificationSVM

Fit posterior probabilities

Syntax

```
ScoreSVMModel = fitPosterior(SVMModel)
[ScoreSVMModel,ScoreTransform] = fitPosterior(SVMModel)
[ScoreSVMModel,ScoreTransform] = fitPosterior(SVMModel,Name,Value)
```

Description

`ScoreSVMModel = fitPosterior(SVMModel)` returns a trained support vector machine (SVM) classifier `ScoreSVMModel` containing the optimal score-to-posterior-probability transformation function for two-class learning.

The software fits the appropriate score-to-posterior-probability transformation function using the SVM classifier `SVMModel`, and by conducting 10-fold cross validation using the stored predictor data (`SVMModel.X`) and the class labels (`SVMModel.Y`) as outlined in [1]. The transformation function computes the posterior probability that an observation is classified into the positive class (`SVMModel.Classnames(2)`).

- If the classes are inseparable, then the transformation function is the “sigmoid function”.
- If the classes are perfectly separable, then the transformation function is the “step function”.
- In two-class learning, if one of the two classes has a relative frequency of 0, then the transformation function is the “constant function”. `fitPosterior` is not appropriate for one-class learning.
- The software stores the optimal score transformation function in `ScoreSVMModel.ScoreTransform`.

`[ScoreSVMModel,ScoreTransform] = fitPosterior(SVMModel)` additionally returns the optimal score-to-posterior-probability transformation function parameters (`ScoreTransform`).

`[ScoreSVMModel,ScoreTransform] = fitPosterior(SVMModel,Name,Value)`
returns the optimal score-to-posterior-probability transformation function and its parameters with additional options specified by one or more Name,Value pair arguments.

Tips

Here is one way to predict positive class posterior probabilities.

- 1 Train an SVM classifier by passing the data to `fitcsvm`. The result is a trained SVM classifier, such as, `SVMModel`, that stores the data. The software sets the score transformation function property (`SVMModel.ScoreTransformation`) to `none`.
- 2 Pass the trained SVM classifier `SVMModel` to `fitSVMPosterior` or `fitPosterior`. The result, for example, `ScoreSVMModel`, is the same, trained SVM classifier as `SVMModel`, except the software sets `ScoreSVMModel.ScoreTransformation` to the optimal score transformation function.

If you skip step 2, then `predict` returns the positive class score rather than the positive class posterior probability.

- 3 Pass the trained SVM classifier containing the optimal score transformation function (`ScoreSVMModel`) and predictor data matrix to `predict`. The second column of the second output argument stores the positive class posterior probabilities corresponding to each row of the predictor data matrix.

Input Arguments

SVMModel — Trained SVM classifier

`ClassificationSVM` classifier

Trained SVM classifier, specified as a `ClassificationSVM`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

'CVPartition' — Cross-validation partition

[] (default) | cvpartition partition

Cross-validation partition used to compute the transformation function, specified as the comma-separated pair consisting of 'CVPartition' and a cvpartition partition as created by cvpartition. You can use only one of these four options at a time for creating a cross-validated model: 'Kfold', 'Holdout', 'Leaveout', or 'CVPartition'.

crossval splits the data into subsets using cvpartition.

'Holdout' — Fraction of data for holdout validation

scalar value in the range (0,1)

Fraction of data for holdout validation used to compute the transformation function, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range (0,1). Holdout validation tests the specified fraction of the data, and uses the remaining data for training.

You can use only one of these four options at a time for creating a cross-validated model: 'Kfold', 'Holdout', 'Leaveout', or 'CVPartition'.

Example: 'Holdout', 0.1

Data Types: double | single

'Kfold' — Number of folds

10 (default) | positive integer value

Number of folds to use when computing the transformation function, specified as the comma-separated pair consisting of 'Kfold' and a positive integer value.

You can use only one of these four options at a time for creating a cross-validated model: 'Kfold', 'Holdout', 'Leaveout', or 'CVPartition'.

Example: 'Kfold', 8

Data Types: single | double

'Leaveout' — Leave-one-out cross-validation flag

'off' (default) | 'on'

Leave-one-out cross-validation flag indicating whether to use leave-one-out cross validation to compute the transformation function, specified as the comma-separated

pair consisting of 'Leaveout' and 'on' or 'off'. Use leave-one-out cross validation by using 'on'.

You can use only one of these four options at a time for creating a cross-validated model: 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'.

Example: 'Leaveout', 'on'

Output Arguments

ScoreSVMModel — Trained SVM classifier

ClassificationSVM classifier

Trained SVM classifier containing the estimated score-to-posterior-probability transformation function, returned as a ClassificationSVM classifier.

To estimate posterior probabilities for the training set observations, pass ScoreSVMModel to resubPredict.

To estimate posterior probabilities for new observations, then pass them and ScoreSVMModel to predict. If you set 'Standardize', true in fitcsvm to train SVMModel, then predict standardizes the columns of X using the corresponding means in SVMModel.Mu and standard deviations in SVMModel.Sigma.

ScoreTransform — Optimal score transformation function parameters

structure array

Optimal score-to-posterior-probability transformation function parameters, returned as a structure array.

- If field Type is sigmoid, then ScoreTransform has the following other fields:
 - Slope: The value of A in the “sigmoid function”
 - Intercept: The value of B in the sigmoid function
- If field Type is step, then ScoreTransform has the following other fields:
 - PositiveClassProbability: The value of π in the “step function”. It represents the probability that an observation is in the positive class. Also, the posterior probability that an observation is in the positive class given that its score is in the interval (LowerBound,UpperBound).

- **LowerBound:** The value $\max_{y_n=-1} s_n$ in the step function. It represents the lower bound of the score interval that assigns observations with scores in the interval the posterior probability of being in the positive class `PositiveClassProbability`. Any observation with a score less than `LowerBound` has the posterior probability of being the positive class 0.
- **UpperBound:** The value $\min_{y_n=+1} s_n$ in the step function. It represents the upper bound of the score interval that assigns observations with scores in the interval the posterior probability of being in the positive class `PositiveClassProbability`. Any observation with a score greater than `UpperBound` has the posterior probability of being the positive class 1.
- If field `Type` is constant, then `ScoreTransform.PredictedClass` contains the name of the class prediction.

This result is the same as `SVMModel.ClassNames`. The posterior probability of an observation being in `ScoreTransform.PredictedClass` is always 1.

Definitions

Sigmoid Function

The sigmoid function that maps score s_j corresponding to observation j to the positive class posterior probability is

$$P(s_j) = \frac{1}{1 + \exp(As_j + B)}.$$

If the output argument `ScoreTransform.Type` is `sigmoid`, then parameters A and B correspond to the fields `Scale` and `Intercept` of `ScoreTransform`, respectively.

Step Function

The step function that maps score s_j corresponding to observation j to the positive class posterior probability is

$$P(s_j) = \begin{cases} 0; & s < \max_{y_k=-1} s_k \\ \pi; & \max_{y_k=-1} s_k \leq s_j \leq \min_{y_k=+1} s_k, \\ 1; & s_j > \min_{y_k=+1} s_k \end{cases}$$

where:

- s_j the score of observation j .
- $+1$ and -1 denote the positive and negative classes, respectively.
- π is the prior probability that an observation is in the positive class.

If the output argument `ScoreTransform.Type` is `step`, then the quantities $\max_{y_k=-1} s_k$

and $\min_{y_k=+1} s_k$ correspond to the fields `LowerBound` and `UpperBound` of `ScoreTransform`, respectively.

Constant Function

The constant function maps all scores in a sample to posterior probabilities 1 or 0.

If all observations have posterior probability 1, then they are expected to come from the positive class.

If all observations have posterior probability 0, then they are not expected to come from the positive class.

Examples

Estimate In-Sample Posterior Probabilities of SVM Classifiers

Load the `ionosphere` data set.

```
load ionosphere
```

Train an SVM classifier. It is good practice to specify the class order and standardize the data.

```
SVMModel = fitcsvm(X,Y,'ClassNames',{'b','g'},'Standardize',true);
```

SVMModel is a ClassificationSVM classifier. The positive class is 'g'.

Fit the optimal score-to-posterior-probability transformation function.

```
rng(1); % For reproducibility
ScoreSVMModel = fitPosterior(SVMModel)
```

```
ScoreSVMModel =
```

```
ClassificationSVM
  PredictorNames: {1x34 cell}
   ResponseName: 'Y'
   ClassNames: {'b' 'g'}
  ScoreTransform: '@(S)sigmoid(S,-9.481802e-01,-1.218745e-01)'
```

NumObservations: 351

```
   Alpha: [90x1 double]
   Bias: -0.1343
KernelParameters: [1x1 struct]
   Mu: [1x34 double]
   Sigma: [1x34 double]
  BoxConstraints: [351x1 double]
ConvergenceInfo: [1x1 struct]
IsSupportVector: [351x1 logical]
   Solver: 'SMO'
```

Since the classes are inseparable, the score transformation function (ScoreSVMModel.ScoreTransform) is the sigmoid function.

Estimate scores and positive class posterior probabilities for the training data. Display the results for the first 10 observations.

```
[label,scores] = resubPredict(SVMModel);
[~,postProbs] = resubPredict(ScoreSVMModel);
table(Y(1:10),label(1:10),scores(1:10,2),postProbs(1:10,2),'VariableNames',...
      {'TrueLabel','PredictedLabel','Score','PosteriorProbability'})
```

```
ans =
```

TrueLabel	PredictedLabel	Score	PosteriorProbability
'g'	'g'	1.4861	0.82215
'b'	'b'	-1.0004	0.30436
'g'	'g'	1.8685	0.86916
'b'	'b'	-2.6458	0.084183
'g'	'g'	1.2805	0.79184
'b'	'b'	-1.4617	0.22028
'g'	'g'	2.1672	0.89814
'b'	'b'	-5.7085	0.0050122
'g'	'g'	2.4797	0.92223
'b'	'b'	-2.7811	0.074805

Plot Posterior Probability Contours for Multiple Classes Using SVM

This example steps through the process of one-versus-all (OVA) classification to train a multiclass SVM classifier, and then plots probability contours for each class. To implement OVA directly, see “fitcecoc”.

Load Fisher's iris data set. Use the petal lengths and widths.

```
load fisheriris
X = meas(:,3:4);
Y = species;
```

Examine a scatter plot of the data.

```
figure
gscatter(X(:,1),X(:,2),Y);
title('\bf Scatter Diagram of Iris Measurements');
xlabel('Petal length');
ylabel('Petal width');
legend('Location', 'Northwest');
axis tight
```

Train three binary SVM classifiers that separate each type of iris from the others. Assume that a radial basis function is an appropriate kernel for each, and allow the algorithm to choose a kernel scale. It is good practice to define the class order and standardize the predictors.

```

classNames = {'setosa'; 'virginica'; 'versicolor'};
numClasses = size(classNames,1);
inds = cell(3,1); % Preallocation
SVMModel = cell(3,1);

rng(1); % For reproducibility
for j = 1:numClasses
    inds{j} = strcmp(Y,classNames{j}); % OVA classification
    SVMModel{j} = fitcsvm(X,inds{j},'ClassNames',[false true],...

```

```
        'Standardize',true,'KernelFunction','rbf','KernelScale','auto');  
end
```

fitcsvm uses a heuristic procedure that involves subsampling to compute the value of the kernel scale.

Fit the optimal score-to-posterior-probability transformation function for each classifier.

```
for j = 1:numClasses  
    SVMModel{j} = fitPosterior(SVMModel{j});  
end
```

Warning: Classes are perfectly separated. The optimal score-to-posterior transformation is a step function.

Define a grid to plot the posterior probability contours. Estimate the posterior probabilities over the grid for each classifier.

```
d = 0.02;  
[x1Grid,x2Grid] = meshgrid(min(X(:,1)):d:max(X(:,1)),...  
    min(X(:,2)):d:max(X(:,2)));  
xGrid = [x1Grid(:),x2Grid(:)];
```

```
posterior = cell(3,1);  
for j = 1:numClasses  
    [~,posterior{j}] = predict(SVMModel{j},xGrid);  
end
```

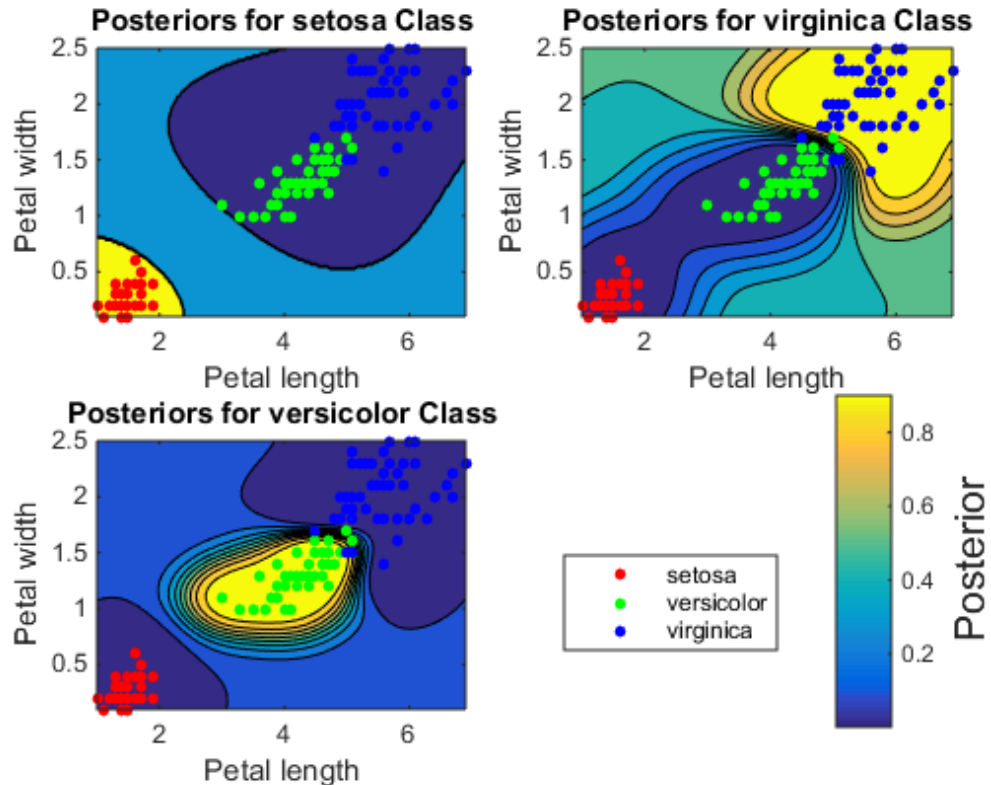

For each SVM classifier, plot the posterior probability contour under the scatter plot of the data.

```
figure  
h = zeros(numClasses + 1,1); % Preallocation for graphics handles  
for j = 1:numClasses  
    subplot(2,2,j)  
    contourf(x1Grid,x2Grid,reshape(posterior{j}(:,2),size(x1Grid,1),size(x1Grid,2)));  
    hold on  
    h(1:numClasses) = gscatter(X(:,1),X(:,2),Y);  
    title(sprintf('Posteriors for %s Class',classNames{j}));  
    xlabel('Petal length');  
    ylabel('Petal width');  
    legend off  
    axis tight  
    hold off  
end  
h(numClasses + 1) = colorbar('Location','EastOutside',...
```

```

'Position',[0.8,0.1,0.05,0.4]);
set(get(h(numClasses + 1),'YLabel'),'String','Posterior','FontSize',16);
legend(h(1:numClasses),'Location',[0.6,0.2,0.1,0.1]);

```

Fit Optimal Posterior Probability Function Using Holdout Cross Validation

Platt (2000) outlines a bias-reducing method of estimating the score-to-posterior-probability transformation function. This method estimates the transformation function after the SVM classifier is trained, and uses cross validation to reduce bias. By default, `fitPosterior` and `fitSVMPosterior` use 10-fold cross validation when they estimate the transformation function. To reduce run time for larger data sets, you can specify to use holdout cross validation instead.

Load the ionosphere data set.

```
load ionosphere
```

Train an SVM classifier. It is good practice to specify the class order and standardize the data.

```
SVMModel = fitcsvm(X,Y,'ClassNames',{ 'b', 'g'},'Standardize',true);
```

SVMModel is a `ClassificationSVM` classifier. The positive class is 'g'.

Fit the optimal score-to-posterior-probability transformation function. For comparison, use 10-fold cross validation (default) and specify a 10% holdout test sample.

```
rng(1); % For reproducibility

tic; % Start the stopwatch
SVMModel_10FCV = fitPosterior(SVMModel);
toc % Stop the stopwatch and display the run time

tic;
SVMModel_HO = fitPosterior(SVMModel,'Holdout',0.10);
toc
```

```
Elapsed time is 0.670387 seconds.
```

```
Elapsed time is 0.121654 seconds.
```

Though both runtimes are short because the data set is relatively small, SVMModel_HO fitted the score transformation function much faster than SVMModel_10FCV.

Algorithms

If you reestimate the score-to-posterior-probability transformation function, that is, if you pass an SVM classifier to `fitPosterior` or `fitSVMPosterior` and its `ScoreTransform` property is not `none`, then the software:

- Displays a warning
- Resets the original transformation function to 'none' before estimating the new one

Alternatives

You can also fit the posterior probability function using `fitSVMPosterior`. This function is similar to `fitPosterior`, except it is more broad since it accepts a wider range of SVM classifier types.

`ClassificationSVM` | `fitcsvm` | `fitSVMPosterior` | `predict`

fitPosterior

Class: CompactClassificationSVM

Fit posterior probabilities

Syntax

```
ScoreSVMModel = fitPosterior(SVMModel,X,Y)
[ScoreSVMModel,ScoreTransform] = fitPosterior(SVMModel,X,Y)
```

Description

`ScoreSVMModel = fitPosterior(SVMModel,X,Y)` returns a trained support vector machine (SVM) classifier `ScoreSVMModel` containing the optimal score-to-posterior-probability transformation function for two-class learning.

The software fits the appropriate score-to-posterior-probability transformation function using the SVM classifier `SVMModel`, and by conducting 10-fold cross validation using the stored predictor data (`SVMModel.X`) and the class labels (`SVMModel.Y`) as outlined in [1]. The transformation function computes the posterior probability that an observation is classified into the positive class (`SVMModel.Classnames(2)`).

- If the classes are inseparable, then the transformation function is the “sigmoid function”.
- If the classes are perfectly separable, the transformation function is the “step function”.
- In two-class learning, if one of the two classes has a relative frequency of 0, then the transformation function is the “constant function”. `fitPosterior` is not appropriate for one-class learning.
- The software stores the optimal score-to-posterior-probability transformation function in `ScoreSVMModel.ScoreTransform`.

`[ScoreSVMModel,ScoreTransform] = fitPosterior(SVMModel,X,Y)` additionally returns the optimal score-to-posterior-probability transformation function parameters (`ScoreTransform`)

Tips

Here is one way to predict positive class posterior probabilities.

- 1 Train an SVM classifier by passing the data to `fitsvm`. The result is a trained SVM classifier, such as, `SVMMODEL`, that stores the data. The software sets the score transformation function property (`SVMMODEL.ScoreTransformation`) to `none`.
- 2 Pass the trained SVM classifier `SVMMODEL` to `fitSVMPosterior` or `fitPosterior`. The result, for example, `ScoreSVMMODEL`, is the same, trained SVM classifier as `SVMMODEL`, except the software sets `ScoreSVMMODEL.ScoreTransformation` to the optimal score transformation function.

If you skip step 2, then `predict` returns the positive class score rather than the positive class posterior probability.

- 3 Pass the trained SVM classifier containing the optimal score transformation function (`ScoreSVMMODEL`) and predictor data matrix to `predict`. The second column of the second output argument stores the positive class posterior probabilities corresponding to each row of the predictor data matrix.

Input Arguments

SVMMODEL — Trained, compact SVM classifier

`CompactClassificationSVM` classifier

Trained, compact SVM classifier, specified as a `CompactClassificationSVM`.

X — Predictor data

matrix

Predictor data used to estimate the score-to-posterior-probability transformation function, specified as a matrix.

Each row of `X` corresponds to one observation (also known as an instance or example), and each column corresponds to one variable (also known as a feature).

The length of `Y` and the number of rows of `X` must be equal.

If you set `'Standardize', true` in `fitsvm` to train `SVMMODEL`, then the software standardizes the columns of `X` using the corresponding means in `SVMMODEL.Mu` and

standard deviations in `SVMMODEL.Sigma`. If the software fits the transformation-function parameter estimates using standardized data, then the estimates might differ from estimation without standardized data.

Data Types: `double` | `single`

Y — Class labels

categorical array | character array | logical vector | vector of numeric values | cell array of strings

Class labels used to estimate the score-to-posterior-probability transformation function, specified as a categorical or character array, logical or numeric vector, or cell array of strings.

If Y is a character array, then each element must correspond to one class label.

The length of Y and the number of rows of X must be equal.

Output Arguments

ScoreSVMMODEL — Trained, compact SVM classifier

`CompactClassificationSVM` classifier

Trained, compact SVM classifier containing the estimated score-to-posterior-probability transformation function, returned as a `CompactClassificationSVM` classifier.

To estimate posterior probabilities, pass `ScoreSVMMODEL` and predictor data to `predict`. If you set `'Standardize', true` in `fitsvm` to train `SVMMODEL`, then `predict` standardizes the columns of X using the corresponding means in `SVMMODEL.Mu` and standard deviations in `SVMMODEL.Sigma`.

ScoreTransform — Optimal score transformation function parameters

structure array

Optimal score-to-posterior-probability transformation function parameters, returned as a structure array.

- If field `Type` is `sigmoid`, then `ScoreTransform` has the following other fields:
 - **Slope:** The value of A in the “sigmoid function”
 - **Intercept:** The value of B in the sigmoid function

- If field `Type` is `step`, then `ScoreTransform` has the following other fields:
 - **PositiveClassProbability**: The value of π in the “step function”. It represents the probability that an observation is in the positive class. Also, the posterior probability that an observation is in the positive class given that its score is in the interval `(LowerBound,UpperBound)`.
 - **LowerBound**: The value $\max_{y_n=-1} s_n$ in the step function. It represents the lower bound of the score interval that assigns observations with scores in the interval the posterior probability of being in the positive class `PositiveClassProbability`. Any observation with a score less than `LowerBound` has the posterior probability of being the positive class `0`.
 - **UpperBound**: The value $\min_{y_n=+1} s_n$ in the step function. It represents the upper bound of the score interval that assigns observations with scores in the interval the posterior probability of being in the positive class `PositiveClassProbability`. Any observation with a score greater than `UpperBound` has the posterior probability of being the positive class `1`.
- If field `Type` is `constant`, then `ScoreTransform.PredictedClass` contains the name of the class prediction.

This result is the same as `SVMModel.ClassNames`. The posterior probability of an observation being in `ScoreTransform.PredictedClass` is always `1`.

Definitions

Sigmoid Function

The sigmoid function that maps score s_j corresponding to observation j to the positive class posterior probability is

$$P(s_j) = \frac{1}{1 + \exp(As_j + B)}$$

If the output argument `ScoreTransform.Type` is `sigmoid`, then parameters A and B correspond to the fields `Scale` and `Intercept` of `ScoreTransform`, respectively.

Step Function

The step function that maps score s_j corresponding to observation j to the positive class posterior probability is

$$P(s_j) = \begin{cases} 0; & s < \max_{y_k=-1} s_k \\ \pi; & \max_{y_k=-1} s_k \leq s_j \leq \min_{y_k=+1} s_k, \\ 1; & s_j > \min_{y_k=+1} s_k \end{cases}$$

where:

- s_j the score of observation j .
- $+1$ and -1 denote the positive and negative classes, respectively.
- π is the prior probability that an observation is in the positive class.

If the output argument `ScoreTransform.Type` is `step`, then the quantities $\max_{y_k=-1} s_k$

and $\min_{y_k=+1} s_k$ correspond to the fields `LowerBound` and `UpperBound` of `ScoreTransform`, respectively.

Constant Function

The constant function maps all scores in a sample to posterior probabilities 1 or 0.

If all observations have posterior probability 1, then they are expected to come from the positive class.

If all observations have posterior probability 0, then they are not expected to come from the positive class.

Examples

Estimate Posterior Probabilities for New Data When Classes Are Inseparable

Load the `ionosphere` data set. Reserve 20 random observations of the data, and consider this set new data.

```
load ionosphere
n = size(X,1);
rng(1); % For reproducibility

indx = ~ismember([1:n],randsample(n,20)); % Indices for the training data
```

The classes of this data set are inseparable.

Train an SVM classifier using the training data. It is good practice to specify the class order and standardize the data.

```
SVMModel = fitcsvm(X(indx,:),Y(indx),'ClassNames',{'b','g'},...
    'Standardize',true);
```

SVMModel is a ClassificationSVM classifier.

Use the new data set to estimate the optimal score-to-posterior-probability transformation function for mapping scores to the posterior probability of an observation being classified as g. For efficiency, make a compact version of the SVM classifier SVMModel, and pass it and the new data to fitPosterior.

```
CompactSVMModel = compact(SVMModel);
[ScoreCSVMModel,ScoreParameters] = fitPosterior(CompactSVMModel,...
    X(~indx,:),Y(~indx));
```

```
ScoreTransform = ScoreCSVMModel.ScoreTransform
ScoreParameters
```

```
ScoreTransform =
```

```
@(S) sigmoid(S, -1.098922e+00, 4.519963e-01)
```

```
ScoreParameters =
```

```
    Type: 'sigmoid'
    Slope: -1.0989
    Intercept: 0.4520
```

ScoreTransform is the optimal score transform function. ScoreParameters is a structure array having three fields: the score transformation function name (Type), the sigmoid slope (Slope) and sigmoid intercept (Intercept) estimates.

Alternatively, you can pass `SVMModel` and the new data to `fitSVMPosterior`, but this does not have the benefit of efficiency.

Estimate the posterior probabilities that the observations in the new data are in class `g`.

```
[labels,postProbs] = predict(ScoreCSVMModel,X(~indx,:));
table(Y(~indx),labels,postProbs(:,2),...
      'VariableNames',{'TrueLabel','PredictedLabel','PosteriorProbability'})
```

ans =

TrueLabel	PredictedLabel	PosteriorProbability
'g'	'g'	0.78437
'b'	'b'	0.024588
'g'	'g'	0.82399
'b'	'b'	0.0061637
'b'	'b'	3.6118e-06
'b'	'b'	0.15688
'b'	'g'	0.9622
'b'	'b'	6.1348e-09
'b'	'b'	0.0019646
'g'	'g'	0.7251
'g'	'g'	0.70263
'b'	'b'	0.075298
'g'	'g'	0.90691
'g'	'g'	0.82849
'b'	'b'	0.051193
'g'	'g'	0.95331
'b'	'b'	0.0031877
'b'	'b'	0.16015
'g'	'g'	0.92008
'g'	'g'	0.91349

Estimate Posterior Probabilities for New Data When Classes Are Separable

Load Fisher's iris data set. Use the petal lengths and widths, and remove the virginica species from the data. Reserve 10 random observations of the data, and consider this set new data.

```
load fisheriris
```

```
classKeep = ~strcmp(species,'virginica');
X = meas(classKeep,3:4);
Y = species(classKeep);

rng(1); % For reproducibility
indx1 = 1:numel(species);
indx2 = indx1(classKeep);
indx = ~ismember(indx2,randsample(indx2,10)); % Indices for the training data

gscatter(X(indx,1),X(indx,2),Y(indx));
title('Scatter Diagram of Iris Measurements')
xlabel('Petal length')
ylabel('Petal width')
legend('Setosa','Versicolor')
```

The classes are perfectly separable. Therefore, the score-to-posterior-probability transformation function is a step function.

Train an SVM classifier. It is good practice to specify the class order and standardize the data.

```
SVMMModel = fitcsvm(X(indx,:),Y(indx),...  
    'ClassNames',{'setosa','versicolor'}, 'Standardize',true);
```

SVMMModel is a ClassificationSVM classifier.

Use the new data set to estimate the optimal score-to-posterior-probability transformation function for mapping scores to the posterior probability of an observation being classified as `versicolor`. For efficiency, make a compact version of the SVM classifier SVMMModel, and pass it and the new data to `fitPosterior`.

```
CompactSVMMModel = compact(SVMMModel);  
[ScoreCSVMMModel,ScoreParameters] = fitPosterior(CompactSVMMModel,...  
    X(~indx,:),Y(~indx));
```

```
ScoreTransform = ScoreCSVMMModel.ScoreTransform
```

```
Warning: Classes are perfectly separated. The optimal score-to-posterior  
transformation is a step function.
```

```
ScoreTransform =
```

```
@(S)step(S, -1.338450e+00,2.012495e+00,5.333333e-01)
```

`fitPosterior` displays a warning whenever the classes are separable, and stores the step function in `ScoreSVMMModel.ScoreTransform`.

Display the score function type and its estimated values.

```
ScoreParameters
```

```
ScoreParameters =
```

```
    Type: 'step'  
LowerBound: -1.3385  
UpperBound: 2.0125
```

```
PositiveClassProbability: 0.5333
```

`ScoreParameters` is a structure array having four fields:

- The score transformation function type (`Type`)
- The score corresponding to negative class boundary (`LowerBound`)
- The score corresponding to positive class boundary (`UpperBound`)
- The positive class probability (`PositiveClassProbability`)

Alternatively, you can pass `SVMModel` and the new data to `fitSVMPosterior`, but this does not have the benefit of efficiency.

Estimate the posterior probabilities that the observations in the new data are versicolor irises.

```
[labels,postProbs] = predict(ScoreCSVMModel,X(~indx,:));
table(Y(~indx),labels,postProbs(:,2),...
      'VariableNames',{'TrueLabel','PredictedLabel','PosteriorProbability'})
```

ans =

TrueLabel	PredictedLabel	PosteriorProbability
'setosa'	'setosa'	0
'setosa'	'setosa'	0
'setosa'	'setosa'	0
'setosa'	'setosa'	0
'setosa'	'setosa'	0
'setosa'	'setosa'	0
'setosa'	'setosa'	0
'setosa'	'setosa'	0
'versicolor'	'versicolor'	1
'versicolor'	'versicolor'	1

Since the classes are separable, the step function transforms the positive-class score to:

- 0, if the score is less than `ScoreParameters.LowerBound`
- 1, if the score is greater than `ScoreParameters.UpperBound`

- `ScoreParameters.PositiveClassProbability`, if the score is in the interval [`ScoreParameters.LowerBound` , `ScoreParameters.LowerBound`]

Algorithms

If you reestimate the score-to-posterior-probability transformation function, that is, if you pass an SVM classifier to `fitPosterior` or `fitSVMPosterior` and its `ScoreTransform` property is not `none`, then the software:

- Displays a warning
- Resets the original transformation function to 'none' before estimating the new one

Alternatives

You can also estimate the optimal score-to-posterior-probability function using `fitSVMPosterior`. This function is similar to `fitPosterior`, except it is more broad since it accepts a wider range of SVM classifier types.

`CompactClassificationSVM` | `fitcsvm` | `fitSVMPosterior` | `predict`

fitree

Binary decision tree for regression

Syntax

```
tree = fitrtree(x,y)
tree = fitrtree(x,y,Name,Value)
```

Description

`tree = fitrtree(x,y)` returns a regression tree based on the input variables (also known as predictors, features, or attributes) `x` and output (response) `y`. The returned tree is a binary tree where each branching node is split based on the values of a column of `x`.

`tree = fitrtree(x,y,Name,Value)` fits a tree with additional options specified by one or more name-value pair arguments. For example, you can grow a cross-validated tree, hold out a fraction of data for validation, or specify observation weights.

Examples

Grow a Classification Tree

Construct a classification tree using sample data.

Construct a classification tree using the `ionosphere` data set.

```
load ionosphere
tc = fitctree(X,Y)
```

```
tc =
    ClassificationTree
        PredictorNames: {1x34 cell}
        ResponseName: 'Y'
        ClassNames: {'b' 'g'}
```

```
ScoreTransform: 'none'  
CategoricalPredictors: []  
NumObservations: 351
```

Input Arguments

x — Predictor values

matrix of scalar values

Predictor values, specified as a matrix of scalar values. Each column of **x** represents one variable, and each row represents one observation.

`fitrtree` considers NaN values in **x** as missing values. `fitrtree` does not use observations with all missing values for **x** in the fit. `fitrtree` uses observations with some missing values for **x** to find splits on variables for which these observations have valid values.

Data Types: `single` | `double`

y — Response values

vector of scalar values

Response values, specified as a vector of scalar values with the same number of rows as **x**. Each entry in **y** is the response to the data in the corresponding row of **x**.

`fitrtree` considers NaN values in **y** to be missing values. `fitrtree` does not use observations with missing values for **y** in the fit.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of **Name**,**Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as **Name1**,**Value1**, . . . ,**NameN**,**ValueN**.

Example: `'CrossVal','on','MinParentSize',30` specifies a cross-validated regression tree with a minimum of 30 observations per branch node.

'CategoricalPredictors' — Categorical predictors list

numeric or logical vector | cell array of strings | character matrix | 'all'

Categorical predictors list, specified as the comma-separated pair consisting of 'CategoricalPredictors' and one of the following:

- A numeric vector with indices from 1 through p , where p is the number of columns of x .
- A logical vector of length p , where a `true` entry means that the corresponding column of x is a categorical variable.
- A cell array of strings, where each element in the array is the name of a predictor variable. The names must match entries in the `PredictorNames` property.
- A character matrix, where each row of the matrix is a name of a predictor variable. Pad the names with extra blanks so each row of the character matrix has the same length.
- 'all', meaning all predictors are categorical.

Data Types: single | double | logical | char | cell

'CrossVal' — Cross-validation flag

'off' (default) | 'on'

Cross-validation flag, specified as the comma-separated pair consisting of 'CrossVal' and either 'on' or 'off'.

If 'on', `fitree` grows a cross-validated decision tree with 10 folds. You can override this cross-validation setting using one of the 'KFold', 'Holdout', 'Leaveout', or 'CVPartition' name-value pair arguments. You can only use one of these arguments at a time when creating a cross-validated tree.

Alternatively, cross validate tree later using the `crossval` method.

Example: 'CrossVal', 'on'

'CVPartition' — Partition for cross-validated tree

cvpartition object

Partition for cross-validated tree, specified as the comma-separated pair consisting of 'CVPartition' and an object created using `cvpartition`.

If you use 'CVPartition', you cannot use any of the 'KFold', 'Holdout', or 'Leaveout' name-value pair arguments.

'Holdout' — Fraction of data for holdout validation

0 (default) | scalar value in the range [0,1]

Fraction of data used for holdout validation, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range [0,1]. Holdout validation tests the specified fraction of the data, and uses the rest of the data for training.

If you use 'Holdout', you cannot use any of the 'CVPartition', 'KFold', or 'Leaveout' name-value pair arguments.

Example: 'Holdout',0.1

Data Types: single | double

'KFold' — Number of folds

10 (default) | positive integer value

Number of folds to use in a cross-validated tree, specified as the comma-separated pair consisting of 'KFold' and a positive integer value.

If you use 'KFold', you cannot use any of the 'CVPartition', 'Holdout', or 'Leaveout' name-value pair arguments.

Example: 'KFold',8

Data Types: single | double

'Leaveout' — Leave-one-out cross-validation flag

'off' (default) | 'on'

Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of 'Leaveout' and either 'on' or 'off'. Specify 'on' to use leave-one-out cross validation.

If you use 'Leaveout', you cannot use any of the 'CVPartition', 'Holdout', or 'KFold' name-value pair arguments.

Example: 'Leaveout','on'

'MergeLeaves' — Leaf merge flag

'on' (default) | 'off'

Leaf merge flag, specified as the comma-separated pair consisting of 'MergeLeaves' and either 'on' or 'off'.

If `MergeLeaves` is 'on', then `fitree` merges leaves that originate from the same parent node, and that give a sum of risk values greater or equal to the risk associated with the parent node. Otherwise, `fitree` does not merge leaves.

Example: `'MergeLeaves', 'off'`

'MinLeafSize' — Minimum number of leaf node observations

1 (default) | positive integer value

Minimum number of leaf node observations, specified as the comma-separated pair consisting of `'MinLeafSize'` and a positive integer value. Each leaf has at least `MinLeafSize` observations per tree leaf. If you supply both `MinParentSize` and `MinLeafSize`, `fitree` uses the setting that gives larger leaves: `MinParentSize = max(MinParentSize, 2*MinLeafSize)`.

Example: `'MinLeafSize', 3`

Data Types: `single` | `double`

'MinParentSize' — Minimum number of branch node observations

10 (default) | positive integer value

Minimum number of branch node observations, specified as the comma-separated pair consisting of `'MinParentSize'` and a positive integer value. Each branch node in the tree has at least `MinParentSize` observations. If you supply both `MinParentSize` and `MinLeafSize`, `fitree` uses the setting that gives larger leaves: `MinParentSize = max(MinParentSize, 2*MinLeafSize)`.

Example: `'MinParentSize', 8`

Data Types: `single` | `double`

'NumVariablesToSample' — Number of predictors for split

'all' (default) | positive integer value

Number of predictors to select at random for each split, specified as the comma-separated pair consisting of `'NumVariablesToSample'` and a positive integer value. You can also specify `'all'` to use all available predictors.

Example: `'NumVariablesToSample', 3`

Data Types: `single` | `double`

'PredictorNames' — Predictor variable names

{ 'x1', 'x2', ... } (default) | cell array of strings

Predictor variable names, specified as the comma-separated pair consisting of `'PredictorNames'` and a cell array of strings containing the names for the predictor variables, in the order in which they appear in `x`.

Data Types: `cell`

'Prune' — Flag to estimate the optimal sequence of pruned subtrees

`'on'` (default) | `'off'`

Flag to estimate the optimal sequence of pruned subtrees, specified as the comma-separated pair consisting of `'Prune'` and either `'on'` or `'off'`.

If `Prune` is `'on'`, then `fitrtree` grows the regression tree and estimates the optimal sequence of pruned subtrees, but does not prune the regression tree. Otherwise, `fitrtree` grows the regression tree without estimating the optimal sequence of pruned subtrees.

To prune a trained regression tree, pass the regression tree to `prune`.

Example: `'Prune', 'off'`

'PruneCriterion' — Pruning criterion

`'mse'`

Pruning criterion, specified as the comma-separated pair consisting of `'PruneCriterion'` and `'mse'`.

Example: `'PruneCriterion', 'mse'`

'QuadraticErrorTolerance' — Quadratic error tolerance

`1e-6` (default) | positive scalar value

Quadratic error tolerance per node, specified as the comma-separated pair consisting of `'QuadraticErrorTolerance'` and a positive scalar value. Splitting nodes stops when the quadratic error per node drops below `QuadraticErrorTolerance*QED`, where `QED` is the quadratic error for all data computed before the decision tree is grown.

Example: `'QuadraticErrorTolerance', 1e-4`

'ResponseName' — Response variable name

`'Y'` (default) | string

Response variable name, specified as the comma-separated pair consisting of `'ResponseName'` and a string containing the name of the response variable in `y`.

Example: 'ResponseName', 'Response'

Data Types: char

'ResponseTransform' — Response transform function

'none' (default) | function handle

Response transform function for transforming the raw response values, specified as the comma-separated pair consisting of 'ResponseTransform' and either a function handle or 'none'. The function handle should accept a matrix of response values and return a matrix of the same size. The default string 'none' means $@(x)x$, or no transformation.

Add or change a ResponseTransform function using dot notation:

```
tree.ResponseTransform = @function
```

Data Types: function_handle

'SplitCriterion' — Split criterion

'MSE'

Split criterion, specified as the comma-separated pair consisting of 'SplitCriterion' and 'MSE', meaning mean squared error.

Example: 'SplitCriterion', 'MSE'

'Surrogate' — Surrogate decision splits flag

'off' | 'on' | 'all' | positive integer value

Surrogate decision splits flag, specified as the comma-separated pair consisting of 'Surrogate' and one of 'on', 'off', 'all', or a positive integer value.

- When 'on', `fitrtree` finds at most 10 surrogate splits at each branch node.
- When set to a positive integer value, `fitrtree` finds at most the specified number of surrogate splits at each branch node.
- When set to 'all', `fitrtree` finds all surrogate splits at each branch node. The 'all' setting can use considerable time and memory.

Use surrogate splits to improve the accuracy of predictions for data with missing values. The setting also lets you compute measures of predictive association between predictors.

Example: 'Surrogate', 'on'

Data Types: `single` | `double`

'Weights' — Observation weights

`ones(size(X,1),1)` (default) | vector of scalar values

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and a vector of scalar values. The length of `Weights` is the number of rows in `x`.

Data Types: `single` | `double`

Output Arguments

tree — Regression tree

regression tree object

Regression tree, returned as a regression tree object. Note that using the `'Crossval'`, `'Kfold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'` options results in a tree of class `RegressionPartitionedModel`. You cannot use a partitioned tree for prediction, so this kind of tree does not have a `predict` method.

Otherwise, `tree` is of class `RegressionTree`, and you can use the `predict` method to make predictions.

More About

Tips

By default, `Prune` is `'on'`. However, this specification does not prune the regression tree. To prune a trained regression tree, pass the regression tree to `prune`.

fitSVMPosterior

Fit posterior probabilities

Syntax

```
ScoreSVMModel = fitSVMPosterior(SVMModel)
ScoreSVMModel = fitSVMPosterior(SVMModel,Name,Value)
ScoreSVMModel = fitSVMPosterior(SVMModel,X,Y)
[ScoreSVMModel,ScoreTransform] = fitSVMPosterior( ___ )
```

Description

`ScoreSVMModel = fitSVMPosterior(SVMModel)` returns `ScoreSVMModel`, which is a trained, support vector machine (SVM) classifier containing the optimal score-to-posterior-probability transformation function for two-class learning.

The software fits the appropriate score-to-posterior-probability transformation function using the SVM classifier `SVMModel`, and by cross validation using the stored predictor data (`SVMModel.X`) and the class labels (`SVMModel.Y`). The transformation function computes the posterior probability that an observation is classified into the positive class (`SVMModel.Classnames(2)`).

- If the classes are inseparable, then the transformation function is the sigmoid function.
- If the classes are perfectly separable, the transformation function is the step function.
- In two-class learning, if one of the two classes has a relative frequency of 0, then the transformation function is the constant function. `fitSVMPosterior` is not appropriate for one-class learning.
- If `SVMModel` is a `ClassificationSVM` classifier, then the software estimates the optimal transformation function by 10-fold cross validation as outlined in [1]. Otherwise, `SVMModel` must be a `ClassificationPartitionedModel` classifier. `SVMModel` specifies the cross-validation method.
- The software stores the optimal transformation function in `ScoreSVMModel.ScoreTransform`.

`ScoreSVMModel = fitSVMPosterior(SVMModel,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments provided `SVMModel` is a `ClassificationSVM` classifier.

For example, you can specify the number of folds to use in k -fold cross validation.

`ScoreSVMModel = fitSVMPosterior(SVMModel,X,Y)` returns a trained, support vector classifier containing the transformation function from the trained, compact SVM classifier `SVMModel`. The software estimates the score transformation function using predictor data `X` and class labels `Y`.

`[ScoreSVMModel,ScoreTransform] = fitSVMPosterior(___)` additionally returns the transformation function parameters (`ScoreTransform`) using any of the input arguments in the previous syntaxes.

Examples

Fit the Score-to-Posterior Probability Function for Separable Classes

Load Fisher's iris data set. Train the classifier using the petal lengths and widths, and remove the virginica species from the data.

```
load fisheriris
classKeep = ~strcmp(species,'virginica');
X = meas(classKeep,3:4);
y = species(classKeep);

gscatter(X(:,1),X(:,2),y);
title('Scatter Diagram of Iris Measurements')
xlabel('Petal length')
ylabel('Petal width')
legend('Setosa','Versicolor')
```

The classes are perfectly separable. Therefore, the score transformation function is a step function.

Train an SVM classifier using the data. Cross validate the classifier using 10-fold cross validation (the default).

```
rng(1);
CVSVMModel = fitcsvm(X,y,'CrossVal','on');
```

CVSVMModel is a trained `ClassificationPartitionedModel` SVM classifier.

Estimate the step function that transforms scores to posterior probabilities.

```
[ScoreCVSVMModel,ScoreParameters] = fitSVMPosterior(CVSVMModel);
```

Warning: Classes are perfectly separated. The optimal score-to-posterior transformation is a step function.

`fitSVMPosterior` does the following:

- Uses the data that the software stored in `CVSVMModel` to fit the transformation function
- Warns whenever the classes are separable
- Stores the step function in `ScoreCSVMModel.ScoreTransform`

Display the score function type and its parameter values.

`ScoreParameters`

```
ScoreParameters =  
  
                Type: 'step'  
        LowerBound: -0.8431  
        UpperBound: 0.6897  
PositiveClassProbability: 0.5000
```

`ScoreParameters` is a structure array with four fields:

- The score transformation function type (`Type`)
- The score corresponding to the negative class boundary (`LowerBound`)
- The score corresponding to the positive class boundary (`UpperBound`)
- The positive class probability (`PositiveClassProbability`)

Since the classes are separable, the step function transforms the score to either 0 or 1, which is the posterior probability that an observation is a versicolor iris.

Fit the Score-to-Posterior Probability Function for Inseparable Classes

Load the `ionosphere` data set.

```
load ionosphere
```

The classes of this data set are not separable.

Train an SVM classifier. Cross validate using 10-fold cross validation (the default). It is good practice to standardize the predictors and specify the class order.

```

rng(1) % For reproducibility
CVSVMModel = fitcsvm(X,Y,'ClassNames',{ 'b', 'g'}, 'Standardize', true, ...
    'CrossVal', 'on');
ScoreTransform = CVSVMModel.ScoreTransform

```

```
ScoreTransform =
```

```
none
```

CVSVMModel is a trained ClassificationPartitionedModel SVM classifier. The positive class is 'g'. The ScoreTransform property is none.

Estimate the optimal score function for mapping observation scores to posterior probabilities of an observation being classified as 'g'.

```

[ScoreCVSVMModel, ScoreParameters] = fitSVMPosterior(CVSVMModel);
ScoreTransform = ScoreCVSVMModel.ScoreTransform
ScoreParameters

```

```
ScoreTransform =
```

```
@(S) sigmoid(S, -9.481576e-01, -1.218300e-01)
```

```
ScoreParameters =
```

```

    Type: 'sigmoid'
    Slope: -0.9482
    Intercept: -0.1218

```

ScoreTransform is the optimal score transform function. ScoreParameters contains the score transformation function, slope estimate, and the intercept estimate.

You can estimate test-sample, posterior probabilities by passing ScoreCVSVMModel to kfoldPredict.

Estimate Posterior Probabilities for Test Samples

Estimate positive class posterior probabilities for the test set of an SVM algorithm.

Load the `ionosphere` data set.

```
load ionosphere
```

Train an SVM classifier. Specify a 20% holdout sample. It is good practice to standardize the predictors and specify the class order.

```
rng(1) % For reproducibility
CVSVMModel = fitcsvm(X,Y,'Holdout',0.2,'Standardize',true,...
    'ClassNames',{'b','g'});
```

`CVSVMModel` is a trained `ClassificationPartitionedModel` cross-validated classifier.

Estimate the optimal score function for mapping observation scores to posterior probabilities of an observation being classified as 'g'.

```
ScoreCVSVMModel = fitSVMPosterior(CVSVMModel);
```

`ScoreSVMModel` is a trained `ClassificationPartitionedModel` cross-validated classifier containing the optimal score transformation function estimated from the training data.

Estimate the out-of-sample positive class posterior probabilities. Display the results for the first 10 out-of-sample observations.

```
[~,OOSPostProbs] = kfoldPredict(ScoreCVSVMModel);
indx = ~isnan(OOSPostProbs(:,2));
hoObs = find(indx); % Holdout observation numbers
OOSPostProbs = [hoObs, OOSPostProbs(indx,2)];
table(OOSPostProbs(1:10,1),OOSPostProbs(1:10,2),...
    'VariableNames',{'ObservationIndex','PosteriorProbability'})
```

```
ans =
```

ObservationIndex	PosteriorProbability
6	0.17378
7	0.89637
8	0.0076609
9	0.91602
16	0.026718

22	4.6081e-06
23	0.9024
24	2.4129e-06
38	0.00042697
41	0.86427

Input Arguments

SVMMoDel — Trained SVM classifier

ClassificationSVM classifier | CompactClassificationSVM classifier | ClassificationPartitionedModel classifier

Trained SVM classifier, specified as a **ClassificationSVM**, **CompactClassificationSVM**, or **ClassificationPartitionedModel** classifier.

If **SVMMoDel** is a **ClassificationSVM** classifier, then you can set optional name-value pair arguments.

If **SVMMoDel** is a **CompactClassificationSVM** classifier, then you must input predictor data **X** and class labels **Y**.

X — Predictor data

matrix

Predictor data used to estimate the score-to-posterior-probability transformation function, specified as a matrix.

Each row of **X** corresponds to one observation (also known as an instance or example), and each column corresponds to one variable (also known as a feature).

The length of **Y** and the number of rows of **X** must be equal.

If you set **'Standardize'**, **true** in **fitcsvm** to train **SVMMoDel**, then the software standardizes the columns of **X** using the corresponding means in **SVMMoDel.Mu** and standard deviations in **SVMMoDel.Sigma**. If the software fits the transformation-function parameter estimates using standardized data, then the estimates might differ from estimation without standardized data.

Data Types: double | single

Y — Class labels

categorical array | character array | logical vector | vector of numeric values | cell array of strings

Class labels used to estimate the score-to-posterior-probability transformation function, specified as a categorical or character array, logical or numeric vector, or cell array of strings.

If Y is a character array, then each element must correspond to one class label.

The length of Y and the number of rows of X must be equal.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Example: 'KFold',8 performs 8-fold cross validation when SVMModel is a ClassificationSVM classifier.

'CVPartition' — Cross-validation partition

[] (default) | cvpartition partition

Cross-validation partition used to compute the transformation function, specified as the comma-separated pair consisting of 'CVPartition' and a cvpartition partition as created by cvpartition. You can use only one of these four options at a time for creating a cross-validated model: 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'.

crossval splits the data into subsets using cvpartition.

'Holdout' — Fraction of data for holdout validation

scalar value in the range (0,1)

Fraction of data for holdout validation used to compute the transformation function, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range (0,1). Holdout validation tests the specified fraction of the data, and uses the remaining data for training.

You can use only one of these four options at a time for creating a cross-validated model: 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'.

Example: 'Holdout', 0.1

Data Types: double | single

'KFold' — Number of folds

10 (default) | positive integer value

Number of folds to use when computing the transformation function, specified as the comma-separated pair consisting of 'KFold' and a positive integer value.

You can use only one of these four options at a time for creating a cross-validated model: 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'.

Example: 'KFold', 8

Data Types: single | double

'Leaveout' — Leave-one-out cross-validation flag

'off' (default) | 'on'

Leave-one-out cross-validation flag indicating whether to use leave-one-out cross validation to compute the transformation function, specified as the comma-separated pair consisting of 'Leaveout' and 'on' or 'off'. Use leave-one-out cross validation by using 'on'.

You can use only one of these four options at a time for creating a cross-validated model: 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'.

Example: 'Leaveout', 'on'

Output Arguments

ScoreSVMModel1 — Trained SVM classifier

ClassificationSVM classifier | CompactClassificationSVM classifier | ClassificationPartitionedModel classifier

Trained SVM classifier containing the estimated score transformation function, returned as a ClassificationSVM, CompactClassificationSVM, or ClassificationPartitionedModel classifier.

The `ScoreSVMModel` classifier type is the same as the `SVMModel` classifier type.

To estimate posterior probabilities, pass `ScoreSVMModel` and predictor data to `predict`. If you set `'Standardize', true` in `fitsvm` to train `SVMModel`, then `predict` standardizes the columns of `X` using the corresponding means in `SVMModel.Mu` and standard deviations in `SVMModel.Sigma`.

ScoreTransform — Optimal score-to-posterior-probability transformation function parameters

structure array

Optimal score-to-posterior-probability transformation function parameters, specified as a structure array. If field `Type` is:

- `sigmoid`, then `ScoreTransform` has these fields:
 - `Slope` — The value of `A` in the sigmoid function
 - `Intercept` — The value of `B` in the sigmoid function
- `step`, then `ScoreTransform` has these fields:
 - `PositiveClassProbability`: the value of π in the step function. π represents:
 - The probability that an observation is in the positive class.
 - The posterior probability that a score is in the interval `(LowerBound,UpperBound)`.
 - `LowerBound`: the value $\max_{y_n=-1} s_n$ in the step function. It represents the lower bound of the interval that assigns the posterior probability of being in the positive class `PositiveClassProbability` to scores. Any observation with a score less than `LowerBound` has posterior probability of being the positive class `0`.
 - `UpperBound`: the value $\min_{y_n=+1} s_n$ in the step function. It represents the upper bound of the interval that assigns the posterior probability of being in the positive class `PositiveClassProbability`. Any observation with a score greater than `UpperBound` has posterior probability of being the positive class `1`.
- `constant`, then `ScoreTransform.PredictedClass` contains the name of the class prediction.

This result is the same as `SVMModel.ClassNames`. The posterior probability of an observation being in `ScoreTransform.PredictedClass` is always `1`.

More About

Sigmoid Function

The sigmoid function that maps score s_j corresponding to observation j to the positive class posterior probability is

$$P(s_j) = \frac{1}{1 + \exp(As_j + B)}.$$

If the output argument `ScoreTransform.Type` is `sigmoid`, then parameters A and B correspond to the fields `Scale` and `Intercept` of `ScoreTransform`, respectively.

Step Function

The step function that maps score s_j corresponding to observation j to the positive class posterior probability is

$$P(s_j) = \begin{cases} 0; & s < \max_{y_k=-1} s_k \\ \pi; & \max_{y_k=-1} s_k \leq s_j \leq \min_{y_k=+1} s_k, \\ 1; & s_j > \min_{y_k=+1} s_k \end{cases}$$

where:

- s_j the score of observation j .
- $+1$ and -1 denote the positive and negative classes, respectively.
- π is the prior probability that an observation is in the positive class.

If the output argument `ScoreTransform.Type` is `step`, then the quantities $\max_{y_k=-1} s_k$

and $\min_{y_k=+1} s_k$ correspond to the fields `LowerBound` and `UpperBound` of `ScoreTransform`, respectively.

Constant Function

The constant function maps all scores in a sample to posterior probabilities 1 or 0.

If all observations have posterior probability 1, then they are expected to come from the positive class.

If all observations have posterior probability 0, then they are not expected to come from the positive class.

Tips

Here is one way to predict positive class posterior probabilities.

- 1 Train an SVM classifier by passing the data to `fitcsvm`. The result is a trained SVM classifier, such as `SVMModel`, that stores the data. The software sets the score transformation function property (`SVMModel.ScoreTransformation`) to `none`.
- 2 Pass the trained SVM classifier `SVMModel` to `fitSVMPosterior` or `fitPosterior`. The result, for example, `ScoreSVMModel`, is the same, trained SVM classifier as `SVMModel`, except the software sets `ScoreSVMModel.ScoreTransformation` to the optimal score transformation function.

If you skip step 2, then `predict` returns the positive class score rather than the positive class posterior probability.

- 3 Pass the trained SVM classifier containing the optimal score transformation function (`ScoreSVMModel`) and predictor data matrix to `predict`. The second column of the second output argument stores the positive class posterior probabilities corresponding to each row of the predictor data matrix.

Algorithms

If you reestimate the score-to-posterior-probability transformation function, that is, if you pass an SVM classifier to `fitPosterior` or `fitSVMPosterior` and its `ScoreTransform` property is not `none`, then the software:

- Displays a warning
- Resets the original transformation function to 'none' before estimating the new one

fitted

Class: `GeneralizedLinearMixedModel`

Fitted responses from generalized linear mixed-effects model

Syntax

```
mufit = fitted(glme)
mufit = fitted(glme, Name, Value)
```

Description

`mufit = fitted(glme)` returns the fitted conditional response of the generalized linear mixed-effects model `glme`.

`mufit = fitted(glme, Name, Value)` returns the fitted response with additional options specified by one or more name-value pair arguments. For example, you can specify to compute the marginal fitted response.

Input Arguments

glme — Generalized linear mixed-effects model

`GeneralizedLinearMixedModel` object

Generalized linear mixed-effects model, specified as a `GeneralizedLinearMixedModel` object. For properties and methods of this object, see `GeneralizedLinearMixedModel`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

'Conditional' — Indicator for conditional response

true (default) | false

Indicator for conditional response, specified as the comma-separated pair consisting of 'Conditional' and one of the following.

true	Contributions from both fixed effects and random effects (conditional)
false	Contribution from only fixed effects (marginal)

To obtain fitted marginal response values, `fitted` computes the conditional mean of the response with the empirical Bayes predictor vector of random effects b set equal to 0. For more information, see “Conditional and Marginal Response” on page 21-1645

Example: 'Conditional', false

Output Arguments

mufit — Fitted response values n -by-1 vector

Fitted response values, returned as an n -by-1 vector, where n is the number of observations.

Definitions

Conditional and Marginal Response

A *conditional response* includes contributions from both fixed- and random-effects predictors. A *marginal response* includes contribution from only fixed effects.

Suppose the generalized linear mixed-effects model `glme` has an n -by- p fixed-effects design matrix X and an n -by- q random-effects design matrix Z . Also, suppose the estimated p -by-1 fixed-effects vector is $\hat{\beta}$, and the q -by-1 empirical Bayes predictor vector of random effects is \hat{b} .

The fitted conditional response corresponds to the 'Conditional', true name-value pair argument, and is defined as

$$\hat{\mu}_{cond} = g^{-1}(\hat{\eta}_{ME}),$$

where $\hat{\eta}_{ME}$ is the linear predictor including the fixed- and random-effects of the generalized linear mixed-effects model

$$\hat{\eta}_{ME} = X\hat{\beta} + Z\hat{b} + \delta.$$

The fitted marginal response corresponds to the 'Conditional', false name-value pair argument, and is defined as

$$\hat{\mu}_{mar} = g^{-1}(\hat{\eta}_{FE}),$$

where $\hat{\eta}_{FE}$ is the linear predictor including only the fixed-effects portion of the generalized linear mixed-effects model

$$\hat{\eta}_{FE} = X\hat{\beta} + \delta.$$

Examples

Plot Observed Versus Fitted Values

Navigate to the folder containing the sample data. Load the sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
load mfr
```

This simulated data is from a manufacturing company that operates 50 factories across the world, with each factory running a batch process to create a finished product. The

company wants to decrease the number of defects in each batch, so it developed a new manufacturing process. To test the effectiveness of the new process, the company selected 20 of its factories at random to participate in an experiment: Ten factories implemented the new process, while the other ten continued to run the old process. In each of the 20 factories, the company ran five batches (for a total of 100 batches) and recorded the following data:

- Flag to indicate whether the batch used the new process (**newprocess**)
- Processing time for each batch, in hours (**time**)
- Temperature of the batch, in degrees Celsius (**temp**)
- Categorical variable indicating the supplier (A, B, or C) of the chemical used in the batch (**supplier**)
- Number of defects in the batch (**defects**)

The data also includes **time_dev** and **temp_dev**, which represent the absolute deviation of time and temperature, respectively, from the process standard of 3 hours at 20 degrees Celsius.

Fit a generalized linear mixed-effects model using **newprocess**, **time_dev**, **temp_dev**, and **supplier** as fixed-effects predictors. Include a random-effects term for intercept grouped by **factory**, to account for quality differences that might exist due to factory-specific variations. The response variable **defects** has a Poisson distribution, and the appropriate link function for this model is log. Use the Laplace fit method to estimate the coefficients. Specify the dummy variable encoding as 'effects', so the dummy variable coefficients sum to 0.

The number of defects can be modeled using a Poisson distribution

$$defects_{ij} \sim \text{Poisson}(\mu_{ij})$$

This corresponds to the generalized linear mixed-effects model

$$\log(\mu_{ij}) = \beta_0 + \beta_1 \text{newprocess}_{ij} + \beta_2 \text{time_dev}_{ij} + \beta_3 \text{temp_dev}_{ij} + \beta_4 \text{supplier_C}_{ij} + \beta_5 \text{supplier_B}_{ij} +$$

where

- $defects_{ij}$ is the number of defects observed in the batch produced by factory i during batch j .
- μ_{ij} is the mean number of defects corresponding to factory i (where $i = 1, 2, \dots, 20$) during batch j (where $j = 1, 2, \dots, 5$).
- $newprocess_{ij}$, $time_dev_{ij}$, and $temp_dev_{ij}$ are the measurements for each variable that correspond to factory i during batch j . For example, $newprocess_{ij}$ indicates whether the batch produced by factory i during batch j used the new process.
- $supplier_C_{ij}$ and $supplier_B_{ij}$ are dummy variables that use effects (sum-to-zero) coding to indicate whether company C or B, respectively, supplied the process chemicals for the batch produced by factory i during batch j .
- $b_i \sim N(0, \sigma_b^2)$ is a random-effects intercept for each factory i that accounts for factory-specific variation in quality.

```
glme = fitglme(mfr, 'defects ~ 1 + newprocess + time_dev + temp_dev + supplier + (1|facto
```

Generate the fitted conditional mean values for the model.

```
mufit = fitted(glme);
```

Create a scatterplot of the observed values versus fitted values.

```

fitted

Class: LinearMixedModel

Fitted responses from a linear mixed-effects model

Syntax

```
yfit = fitted(lme)
yfit = fitted(lme,Name,Value)
```

Description

`yfit = fitted(lme)` returns the fitted conditional response from the linear mixed-effects model `lme`.

`yfit = fitted(lme,Name,Value)` returns the fitted response from the linear mixed-effects model `lme` with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify if you want to compute the fitted marginal response.

Input Arguments

lme — Linear mixed-effects model

LinearMixedModel object

Linear mixed-effects model, returned as a LinearMixedModel object.

For properties and methods of this object, see LinearMixedModel.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single

quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

'Conditional' — Indicator for conditional response

True (default) | False

Indicator for conditional response, specified as the comma-separated pair consisting of 'Conditional' and either of the following.

True	Contribution from both fixed effects and random effects (conditional)
False	Contribution from only fixed effects (marginal)

Example: `'Conditional, 'False'`

Output Arguments

yfit — Fitted response values

n-by-1 vector

Fitted response values, returned as an *n*-by-1 vector, where *n* is the number of observations.

Examples

Compute Fitted Conditional and Marginal Responses

Load the sample data.

```
load flu
```

The `flu` dataset array has a `Date` variable, and 10 variables containing estimated influenza rates (in 9 different regions, estimated from Google searches, plus a nationwide estimate from the Center for Disease Control and Prevention, CDC).

To fit a linear-mixed effects model, your data must be in a properly formatted dataset array. To fit a linear mixed-effects model with the influenza rates as the responses and region as the predictor variable, combine the nine columns corresponding to the regions into a tall array. The new dataset array, `flu2`, must have the response variable, `FluRate`, the nominal variable, `Region`, that shows which region each estimate is from, and the grouping variable `Date`.

```
flu2 = stack(flu,2:10,'NewDataVarName','FluRate',...
            'IndVarName','Region');
flu2.Date = nominal(flu2.Date);
```

Fit a linear mixed-effects model with fixed effects for region and a random intercept that varies by `Date`.

`Region` is a categorical variable. You can specify the contrasts for categorical variables using the `DummyVarCoding` name-value pair argument when fitting the model. When you do not specify the contrasts, `fitlme` uses the 'reference' contrast by default. Because the model has an intercept, `fitlme` takes the first region, NE, as the reference and creates eight dummy variables representing the other eight regions. For example, `I[MidAtl]` is the dummy variable representing the region `MidAtl`. For details, see “Dummy Indicator Variables” on page 2-55.

The corresponding model is

$$y_{im} = \beta_0 + \beta_1 I[\text{MidAtl}]_i + \beta_2 I[\text{ENCentral}]_i + \beta_3 I[\text{WNCentral}]_i + \beta_4 I[\text{SAtl}]_i \\ + \beta_5 I[\text{ESCentral}]_i + \beta_6 I[\text{WSCentral}]_i + \beta_7 I[\text{Mtn}]_i + \beta_8 I[\text{Pac}]_i + b_{0m} + \varepsilon_{im}, \quad m = 1, 2, \dots, 52,$$

where y_{im} is the observation i for level m of grouping variable `Date`, β_j , $j = 0, 1, \dots, 8$, are the fixed-effects coefficients, with β_0 being the coefficient for region NE. b_{0m} is the random effect for level m of the grouping variable `Date`, and ε_{im} is the observation error for observation i . The random effect has the prior distribution, $b_{0m} \sim N(0, \sigma_b^2)$ and the error term has the distribution, $\varepsilon_{im} \sim N(0, \sigma^2)$.

```
lme = fitlme(flu2,'FluRate ~ 1 + Region + (1|Date)')
```

Linear mixed-effects model fit by ML

Model information:

Number of observations	468
Fixed effects coefficients	9
Random effects coefficients	52
Covariance parameters	2

Formula:

FluRate ~ 1 + Region + (1|Date)

Model fit statistics:

AIC	BIC	LogLikelihood	Deviance
318.71	364.35	-148.36	296.71

Fixed effects coefficients (95% CIs):

Name	Estimate	SE	tStat	DF	pValue
'(Intercept)'	1.2233	0.096678	12.654	459	1.085e-31
'Region_MidAtl'	0.010192	0.052221	0.19518	459	0.84534
'Region_ENCentral'	0.051923	0.052221	0.9943	459	0.3206
'Region_WNCentral'	0.23687	0.052221	4.5359	459	7.3324e-06
'Region_SAtl'	0.075481	0.052221	1.4454	459	0.14902
'Region_ESCentral'	0.33917	0.052221	6.495	459	2.1623e-10
'Region_WSCentral'	0.069	0.052221	1.3213	459	0.18705
'Region_Mtn'	0.046673	0.052221	0.89377	459	0.37191
'Region_Pac'	-0.16013	0.052221	-3.0665	459	0.0022936

Random effects covariance parameters (95% CIs):

Group: Date (52 Levels)

Name1	Name2	Type	Estimate	Lower	Upper
'(Intercept)'	'(Intercept)'	'std'	0.6443	0.5297	0.78368

Group: Error

Name	Estimate	Lower	Upper
'Res Std'	0.26627	0.24878	0.285

The p -values 7.3324e-06 and 2.1623e-10 respectively show that the fixed effects of the flu rates in regions `WNCentral` and `ESCentral` are significantly different relative to the flu rates in region `NE`.

The confidence limits for the standard deviation of the random-effects term, σ_b^2 , do not include 0 (0.5297, 0.78368), which indicates that the random-effects term is significant. You can also test the significance of the random-effects terms using the `compare` method.

The conditional fitted response from the model at a given observation includes contributions from fixed and random effects. For example, the estimated best linear unbiased predictor (BLUP) of the flu rate for region `WNCentral` in week 10/9/2005 is

$$\begin{aligned}\hat{y}_{WNCentral,10/9/2005} &= \hat{\beta}_0 + \hat{\beta}_3 I[WNCentral] + \hat{b}_{10/9/2005} \\ &= 1.2233 + 0.23687 - 0.1718 \\ &= 1.28837.\end{aligned}$$

This is the fitted conditional response, since it includes contributions to the estimate from both the fixed and random effects. You can compute this value as follows.

```
beta = fixedEffects(lme);
[~,~,STATS] = randomEffects(lme); % Compute the random-effects statistics (STATS)
STATS.Level = nominal(STATS.Level);
y_hat = beta(1) + beta(4) + STATS.Estimate(STATS.Level=='10/9/2005')

y_hat =

    1.2884
```

In the previous calculation, `beta(1)` corresponds to the estimate for β_0 and `beta(4)` corresponds to the estimate for β_3 . You can simply display the fitted value using the `fitted` method.

```
F = fitted(lme);
F(flu2.Date == '10/9/2005' & flu2.Region == 'WNCentral')

ans =

    1.2884
```

The estimated marginal response for region `WNCentral` in week `10/9/2005` is

$$\begin{aligned}\hat{y}_{WNCentral,10/9/2005}^{(\text{marginal})} &= \hat{\beta}_0 + \hat{\beta}_3 I[WNCentral] \\ &= 1.2233 + 0.23687 \\ &= 1.46017.\end{aligned}$$

Compute the fitted marginal response.

```
F = fitted(lme,'Conditional',false);
F(flu2.Date == '10/9/2005' & flu2.Region == 'WNCentral')
```

```
ans =  
  
    1.4602
```

Plot Residuals vs. Fitted Values

Navigate to a folder containing sample data.

```
cd(matlabroot)  
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load weight
```

`weight` contains data from a longitudinal study, where 20 subjects are randomly assigned to 4 exercise programs, and their weight loss is recorded over six 2-week time periods. This is simulated data.

Store the data in a table. Define `Subject` and `Program` as categorical variables.

```
tbl = table(InitialWeight,Program,Subject,Week,y);  
tbl.Subject = nominal(tbl.Subject);  
tbl.Program = nominal(tbl.Program);
```

Fit a linear mixed-effects model where the initial weight, type of program, week, and the interaction between the week and type of program are the fixed effects. The intercept and week vary by subject.

```
lme = fitlme(tbl,'y ~ InitialWeight + Program*Week + (Week|Subject)');
```

Compute the fitted values and raw residuals.

```
F = fitted(lme);  
R = residuals(lme);
```

Plot the residuals versus the fitted values.

```
plot(F,R,'bx')  
xlabel('Fitted Values')  
ylabel('Residuals')
```

Now, plot the residuals versus the fitted values, grouped by program.

```
figure();  
gscatter(F,R,Program)
```

Definitions

Fitted Conditional and Marginal Response

A conditional response includes contributions from both fixed and random effects, whereas a marginal response includes contribution from only fixed effects.

Suppose the linear mixed-effects model, lme , has an n -by- p fixed-effects design matrix X and an n -by- q random-effects design matrix Z . Also, suppose the p -by-1 estimated

fixed-effects vector is $\hat{\beta}$, and the q -by-1 estimated best linear unbiased predictor (BLUP) vector of random effects is \hat{b} . The fitted conditional response is

$$\hat{y}_{Cond} = X\hat{\beta} + Z\hat{b},$$

and the fitted marginal response is

$$\hat{y}_{Mar} = X\hat{\beta}.$$

See Also

`LinearMixedModel` | `residuals` | `response`

fixedEffects

Class: GeneralizedLinearMixedModel

Estimates of fixed effects and related statistics

Syntax

```
beta = fixedEffects(glme)
[beta,betaname] = fixedEffects(glme)
[beta,betaname,stats] = fixedEffects(glme)
[ ___ ] = fixedEffects(glme,Name,Value)
```

Description

`beta = fixedEffects(glme)` returns the estimated fixed-effects coefficients, `beta`, of the generalized linear mixed-effects model `glme`.

`[beta,betaname] = fixedEffects(glme)` also returns the names of estimated fixed-effects coefficients in `betaname`. Each name corresponds to a fixed-effects coefficient in `beta`.

`[beta,betaname,stats] = fixedEffects(glme)` also returns a table of statistics, `stats`, related to the estimated fixed-effects coefficients of `glme`.

`[___] = fixedEffects(glme,Name,Value)` returns any of the output arguments in previous syntaxes using additional options specified by one or more `Name,Value` pair arguments. For example, you can specify the confidence level, or the method for computing the approximate degrees of freedom for the *t*-statistic.

Input Arguments

glme — Generalized linear mixed-effects model

GeneralizedLinearMixedModel object

Generalized linear mixed-effects model, specified as a `GeneralizedLinearMixedModel` object. For properties and methods of this object, see `GeneralizedLinearMixedModel`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

'Alpha' — Confidence level

0.05 (default) | scalar value in the range [0,1]

Confidence level, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the range [0,1]. For a value α , the confidence level is $100 \times (1 - \alpha)\%$.

For example, for 99% confidence intervals, you can specify the confidence level as follows.

Example: `'Alpha', 0.01`

Data Types: `single` | `double`

'DFMethod' — Method for computing approximate degrees of freedom

`'residual'` (default) | `'none'`

Method for computing approximate degrees of freedom, specified as the comma-separated pair consisting of `'DFMethod'` and one of the following.

`'residual'`

The degrees of freedom are assumed to be constant and equal to $n - p$, where n is the number of observations and p is the number of fixed effects.

`'none'`

All degrees of freedom are set to infinity.

Example: `'DFMethod', 'none'`

Output Arguments

beta — Estimated fixed-effects coefficients

vector

Estimated fixed-effects coefficients of the fitted generalized linear mixed-effects model `glme`, returned as a vector.

betanames — Names of fixed-effects coefficients

table

Names of fixed-effects coefficients in beta, returned as a table.

stats — Fixed-effects estimates and related statistics

dataset array

Fixed-effects estimates and related statistics, returned as a dataset array that has one row for each of the fixed effects and one column for each of the following statistics.

Name	Name of the fixed-effects coefficient
Estimate	Estimated coefficient value
SE	Standard error of the estimate
tStat	<i>t</i> -statistic for a test that the coefficient is 0
DF	Estimated degrees of freedom for the <i>t</i> -statistic
pValue	<i>p</i> -value for the <i>t</i> -statistic
Lower	Lower limit of a 95% confidence interval for the fixed-effects coefficient
Upper	Upper limit of a 95% confidence interval for the fixed-effects coefficient

When fitting a model using `fitglme` and one of the maximum likelihood fit methods ('Laplace' or 'ApproximateLaplace'), if you specify the 'CovarianceMethod' name-value pair argument as 'conditional', then SE does not account for the uncertainty in estimating the covariance parameters. To account for this uncertainty, specify 'CovarianceMethod' as 'JointHessian'.

When fitting a GLME model using `fitglme` and one of the pseudo likelihood fit methods ('MPL' or 'REMP'), `fixedEffects` bases the fixed effects estimates and related statistics on the fitted linear mixed-effects model from the final pseudo likelihood iteration.

Examples

Estimate Fixed-Effects Coefficients

Navigate to the folder containing the sample data. Load the sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')

load mfr
```

This simulated data is from a manufacturing company that operates 50 factories across the world, with each factory running a batch process to create a finished product. The company wants to decrease the number of defects in each batch, so it developed a new manufacturing process. To test the effectiveness of the new process, the company selected 20 of its factories at random to participate in an experiment: Ten factories implemented the new process, while the other ten continued to run the old process. In each of the 20 factories, the company ran five batches (for a total of 100 batches) and recorded the following data:

- Flag to indicate whether the batch used the new process (**newprocess**)
- Processing time for each batch, in hours (**time**)
- Temperature of the batch, in degrees Celsius (**temp**)
- Categorical variable indicating the supplier (A, B, or C) of the chemical used in the batch (**supplier**)
- Number of defects in the batch (**defects**)

The data also includes **time_dev** and **temp_dev**, which represent the absolute deviation of time and temperature, respectively, from the process standard of 3 hours at 20 degrees Celsius.

Fit a generalized linear mixed-effects model using **newprocess**, **time_dev**, **temp_dev**, and **supplier** as fixed-effects predictors. Include a random-effects term for intercept grouped by **factory**, to account for quality differences that might exist due to factory-specific variations. The response variable **defects** has a Poisson distribution, and the appropriate link function for this model is log. Use the Laplace fit method to estimate the coefficients. Specify the dummy variable encoding as **'effects'**, so the dummy variable coefficients sum to 0.

The number of defects can be modeled using a Poisson distribution

$$defects_{ij} \sim \text{Poisson}(\mu_{ij})$$

This corresponds to the generalized linear mixed-effects model

$$\log(\mu_{ij}) = \beta_0 + \beta_1 \text{newprocess}_{ij} + \beta_2 \text{time_dev}_{ij} + \beta_3 \text{temp_dev}_{ij} + \beta_4 \text{supplier_C}_{ij} + \beta_5 \text{supplier_B}_{ij} + b_i$$

where

- defects_{ij} is the number of defects observed in the batch produced by factory i during batch j .
- μ_{ij} is the mean number of defects corresponding to factory i (where $i = 1, 2, \dots, 20$) during batch j (where $j = 1, 2, \dots, 5$).
- newprocess_{ij} , time_dev_{ij} , and temp_dev_{ij} are the measurements for each variable that correspond to factory i during batch j . For example, newprocess_{ij} indicates whether the batch produced by factory i during batch j used the new process.
- supplier_C_{ij} and supplier_B_{ij} are dummy variables that use effects (sum-to-zero) coding to indicate whether company C or B, respectively, supplied the process chemicals for the batch produced by factory i during batch j .
- $b_i \sim N(0, \sigma_b^2)$ is a random-effects intercept for each factory i that accounts for factory-specific variation in quality.

```
glme = fitglme(mfr, 'defects ~ 1 + newprocess + time_dev + temp_dev + supplier + (1|factory)')
```

Compute and display the estimated fixed-effects coefficient values and related statistics.

```
[beta, betanames, stats] = fixedEffects(glme);
stats
```

```
stats =
```

```
Fixed effect coefficients: DFMethod = 'residual', Alpha = 0.05
```

Name	Estimate	SE	tStat	DF
'(Intercept)'	1.4689	0.15988	9.1875	94
'newprocess'	-0.36766	0.17755	-2.0708	94
'time_dev'	-0.094521	0.82849	-0.11409	94
'temp_dev'	-0.28317	0.9617	-0.29444	94
'supplier_C'	-0.071868	0.078024	-0.9211	94
'supplier_B'	0.071072	0.07739	0.91836	94

pValue	Lower	Upper
9.8194e-15	1.1515	1.7864

0.041122	-0.72019	-0.015134
0.90941	-1.7395	1.5505
0.76907	-2.1926	1.6263
0.35936	-0.22679	0.083051
0.36078	-0.082588	0.22473

The returned results indicate, for example, that the estimated coefficient for `temp_dev` is -0.28317 . Its large p -value, `0.76907`, indicates that it is not a statistically significant predictor at the 5% significance level. Additionally, the confidence interval boundaries `Lower` and `Upper` indicate that the 95% confidence interval for the coefficient for `temp_dev` is $[-0.2.1926, 1.6263]$. This interval contains 0, which supports the conclusion that `temp_dev` is not statistically significant at the 5% significance level.

fixedEffects

Class: LinearMixedModel

Estimates of fixed effects and related statistics

Syntax

```
beta = fixedEffects(lme)
[beta,betaname] = fixedEffects(lme)
[beta,betaname,stats] = fixedEffects(lme)
[beta,betaname,stats] = fixedEffects(lme,Name,Value)
```

Description

`beta = fixedEffects(lme)` returns the estimated fixed-effects coefficients, `beta`, of the linear mixed-effects model `lme`.

`[beta,betaname] = fixedEffects(lme)` also returns the names of estimated fixed-effects coefficients in `betaname`. Each name corresponds to a fixed-effects coefficient in `beta`.

`[beta,betaname,stats] = fixedEffects(lme)` also returns the estimated fixed-effects coefficients of the linear mixed-effects model `lme` and related statistics in `stats`.

`[beta,betaname,stats] = fixedEffects(lme,Name,Value)` also returns the estimated fixed-effects coefficients of the linear mixed-effects model `lme` and related statistics with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

lme — Linear mixed-effects model

LinearMixedModel object

Linear mixed-effects model, returned as a LinearMixedModel object.

For properties and methods of this object, see LinearMixedModel.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

'Alpha' — Confidence level

0.05 (default) | scalar value in the range 0 to 1

Confidence level, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the range 0 to 1. For a value α , the confidence level is $100*(1-\alpha)\%$.

For example, for 99% confidence intervals, you can specify the confidence level as follows.

Example: `'Alpha', 0.01`

Data Types: `single` | `double`

'DFMethod' — Method for computing approximate degrees of freedom

'Residual' (default) | 'Satterthwaite' | 'None'

Method for computing approximate degrees of freedom for the t -statistic that tests the fixed-effects coefficients against 0, specified as the comma-separated pair consisting of `'DFMethod'` and one of the following.

`'Residual'`

Default. The degrees of freedom are assumed to be constant and equal to $n - p$, where n is the number of observations and p is the number of fixed effects.

`'Satterthwaite'`

Satterthwaite approximation.

`'None'`

All degrees of freedom are set to infinity.

For example, you can specify the Satterthwaite approximation as follows.

Example: `'DFMethod', 'Satterthwaite'`

Output Arguments

beta — Fixed-effects coefficients estimates

vector

Fixed-effects coefficients estimates of the fitted linear mixed-effects model `lme`, returned as a vector.

betanames — Names of fixed-effects coefficients

table

Names of fixed-effects coefficients in beta, returned as a table.

stats — Fixed-effects estimates and related statistics

dataset array

Fixed-effects estimates and related statistics, returned as a dataset array that has one row for each of the fixed effects and one column for each of the following statistics.

Name	Name of the fixed effect coefficient
Estimate	Estimated coefficient value
SE	Standard error of the estimate
tStat	<i>t</i> -statistic for a test that the coefficient is zero
DF	Estimated degrees of freedom for the <i>t</i> -statistic
pValue	<i>p</i> -value for the <i>t</i> -statistic
Lower	Lower limit of a 95% confidence interval for the fixed-effect coefficient
Upper	Upper limit of a 95% confidence interval for the fixed-effect coefficient

Examples

Display Fixed-Effects Coefficient Estimates and Names

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

load `weight`

The data set `weight` contains data from a longitudinal study, where 20 subjects are randomly assigned to 4 exercise programs, and their weight loss is recorded over six 2-week time periods. This is simulated data.

Store the data in a table. Define `Subject` and `Program` as categorical variables.

```
tbl = tbl(InitWeight,Program,Subject,Week,y);
tbl.Subject = nominal(tbl.Subject);
tbl.Program = nominal(tbl.Program);
```

Fit a linear mixed-effects model where the initial weight, type of program, week, and the interaction between week and program are the fixed effects. The intercept and week vary by subject.

```
lme = fitlme(tbl,'y ~ InitWeight + Program*Week + (Week|Subject)');
```

Display the fixed-effects coefficient estimates and corresponding fixed-effects names.

```
[beta,betaname] = fixedEffects(lme);
```

```
beta =
```

```
    0.6610
    0.0032
    0.3608
   -0.0333
    0.1132
    0.1732
    0.0388
    0.0305
    0.0331
```

```
betaname =
```

```
    Name
    '(Intercept) '
    'InitWeight '
    'Program_B '
    'Program_C '
    'Program_D '
    'Week '
    'Program_B:Week '
```

```
'Program_C:Week'
'Program_D:Week'
```

Compute Coefficient Estimates and Related Statistics

Load the sample data.

```
load carbig
```

Fit a linear mixed-effects model for miles per gallon (MPG), with fixed effects for acceleration and horsepower, and potentially correlated random effects for intercept and acceleration grouped by model year. First, store the data in a table.

```
tbl = table(Acceleration,Horsepower,Model_Year,MPG);
```

Fit the model.

```
lme = fitlme(tbl, 'MPG ~ Acceleration + Horsepower + (Acceleration|Model_Year)');
```

Compute the fixed-effects coefficients estimates and related statistics.

```
[~,~,stats] = fixedEffects(lme)
```

```
stats =
```

```
Fixed effect coefficients: DFMethod = 'Residual', Alpha = 0.05
```

Name	Estimate	SE	tStat	DF	pValue	Lower
'(Intercept)'	50.133	2.2652	22.132	389	7.7727e-71	44.599
'Acceleration'	-0.58327	0.13394	-4.3545	389	1.7075e-05	-0.85111
'Horsepower'	-0.16954	0.0072609	-23.35	389	5.188e-76	-0.20835

The small p -values (under `pValue`) indicate that all fixed-effects coefficients are significant.

Compute Confidence Intervals with Specified Options

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load shift
```

The data shows the deviations from the target quality characteristic measured from the products that five operators manufacture during three shifts: morning, evening, and night. This is a randomized block design, where the operators are the blocks. The experiment is designed to study the impact of the time of shift on the performance. The performance measure is the deviation of the quality characteristics from the target value. This is simulated data.

`Shift` and `Operator` are nominal variables.

```
shift.Shift = nominal(shift.Shift);
shift.Operator = nominal(shift.Operator);
```

Fit a linear mixed-effects model with a random intercept grouped by operator to assess if performance significantly differs according to the time of the shift.

```
lme = fitlme(shift, 'QCDev ~ Shift + (1|Operator)');
```

Compute the 99% confidence intervals for fixed-effects coefficients, using the residual method to compute the degrees of freedom. This is the default method.

```
[~,~,stats] = fixedEffects(lme, 'alpha', 0.01)
```

```
stats =
```

```
Fixed effect coefficients: DFMethod = 'Residual', Alpha = 0.01
```

Name	Estimate	SE	tStat	DF	pValue	Lower
'(Intercept)'	3.1196	0.88681	3.5178	12	0.0042407	0.4108
'Shift_Morning'	-0.3868	0.48344	-0.80009	12	0.43921	-1.863
'Shift_Night'	1.9856	0.48344	4.1072	12	0.0014535	0.508

Compute the 99% confidence intervals for fixed-effects coefficients, using the Satterthwaite approximation to compute the degrees of freedom.

```
[~,~,stats] = fixedEffects(lme, 'DFMethod', 'Satterthwaite', 'alpha', 0.01)
```

```
stats =
```

```
Fixed effect coefficients: DFMethod = 'Satterthwaite', Alpha = 0.01
```

Name	Estimate	SE	tStat	DF	pValue	Lower
'(Intercept)'	3.1196	0.88681	3.5178	6.123	0.01214	-0.14
'Shift_Morning'	-0.3868	0.48344	-0.80009	10	0.44225	-1

'Shift_Night'	1.9856	0.48344	4.1072	10	0.00212	0.4
---------------	--------	---------	--------	----	---------	-----

The Satterthwaite approximation usually produces smaller DF values than the residual method. That is why it produces larger p -values (`pValue`) and larger confidence intervals (see `Lower` and `Upper`).

fpdf

F probability density function

Syntax

`Y = fpdf(X, V1, V2)`

Description

`Y = fpdf(X, V1, V2)` computes the *F* pdf at each of the values in `X` using the corresponding numerator degrees of freedom `V1` and denominator degrees of freedom `V2`. `X`, `V1`, and `V2` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs. `V1` and `V2` parameters must contain real positive values, and the values in `X` must lie on the interval $[0, \infty)$.

The probability density function for the *F* distribution is

$$y = f(x | v_1, v_2) = \frac{\Gamma\left(\frac{v_1 + v_2}{2}\right)}{\Gamma\left(\frac{v_1}{2}\right)\Gamma\left(\frac{v_2}{2}\right)} \left(\frac{v_1}{v_2}\right)^{\frac{v_1}{2}} \frac{x^{\frac{v_1-2}{2}}}{\left[1 + \left(\frac{v_1}{v_2}\right)x\right]^{\frac{v_1+v_2}{2}}}$$

Examples

```
y = fpdf(1:6,2,2)
y =
    0.2500    0.1111    0.0625    0.0400    0.0278    0.0204

z = fpdf(3,5:10,5:10)
z =
    0.0689    0.0659    0.0620    0.0577    0.0532    0.0487
```

fracfact

Fractional factorial design

Syntax

```
X = fracfact(gen)
[X,conf] = fracfact(gen)
[X,conf] = fracfact(gen,Name,Value)
```

Description

`X = fracfact(gen)` creates the two-level fractional factorial design defined by the generator string `gen`.

`[X,conf] = fracfact(gen)` returns a cell array of strings containing the confounding pattern for the design.

`[X,conf] = fracfact(gen,Name,Value)` creates a fractional factorial designs with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

gen

Either a cell array of strings where each cell contains one “word,” or a string consisting of “words” separated by spaces. “Words” consist of case-sensitive letters or groups of letters, where 'a' represents string 1, 'b' represents string 2, ..., 'A' represents string 27, ..., 'Z' represents string 52.

Each word defines how the corresponding factor’s levels are defined as products of generators from a 2^K full-factorial design. K is the number of letters of the alphabet in `gen`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single

quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

'FactorNames'

Cell array specifying the name for each factor.

Default: { 'X1', 'X2', . . . }

'MaxInt'

Positive integer setting the maximum level of interaction to include in the confounding output.

Default: 2

Output Arguments

X

The two-level fractional factorial design. X is a matrix of size N-by-P, where

- $N = 2^K$, where K is the number of letters of the alphabet in gen.
- P is the number of words in gen.

Because X is a two-level design, the components of X are ± 1 . For the meaning of X, see “Fractional Factorial Designs” on page 18-5.

conf

Cell array of strings containing the confounding pattern for the design.

Examples

Generate a fractional factorial design for four variables, where the fourth variable is the product of the first three:

```
x = fracfact('a b c abc')
```

```
x =
    -1    -1    -1    -1
    -1    -1     1     1
```

```
-1    1    -1    1
-1    1    1    -1
 1    -1   -1    1
 1    -1    1    -1
 1    1    -1   -1
 1    1    1    1
```

Find generators for a six-factor design that uses four factors and achieves resolution IV using `fracfactgen`. Use the result to specify the design:

```
generators = fracfactgen('a b c d e f',4, ... % 4 factors
 4) % resolution 4
```

```
generators =
  'a'
  'b'
  'c'
  'd'
  'bcd'
  'acd'
```

```
x = fracfact(generators)
```

```
x =
-1    -1    -1    -1    -1    -1
-1    -1    -1    1    1    1
-1    -1    1    -1    1    1
-1    -1    1    1    -1    -1
-1    1    -1    -1    1    -1
-1    1    -1    1    -1    1
-1    1    1    -1    -1    1
-1    1    1    1    1    -1
 1    -1    -1    -1    -1    1
 1    -1    -1    1    1    -1
 1    -1    1    -1    1    -1
 1    -1    1    1    -1    1
 1    1    -1    -1    1    1
 1    1    -1    1    -1    -1
 1    1    1    -1    -1    -1
 1    1    1    1    1    1
```

ff2n | fracfactgen | fullfact | hadamard

fracfactgen

Fractional factorial design generators

Syntax

```
generators = fracfactgen(terms)
generators = fracfactgen(terms,k)
generators = fracfactgen(terms,k,R)
generators = fracfactgen(terms,k,R,basic)
```

Description

`generators = fracfactgen(terms)` uses the Franklin-Bailey algorithm to find generators for the smallest two-level fractional-factorial design for estimating linear model terms specified by `terms`. `terms` is a string consisting of words formed from the 52 case-sensitive letters a-Z, separated by spaces. Use 'a' - 'z' for the first 26 factors, and, if necessary, 'A' - 'Z' for the remaining factors. For example, `terms = 'a b c ab ac'`. Single-character words indicate main effects to be estimated; multiple-character words indicate interactions. Alternatively, `terms` is an m -by- n matrix of 0s and 1s where m is the number of model terms to be estimated and n is the number of factors. For example, if `terms` contains rows `[0 1 0 0]` and `[1 0 0 1]`, then the factor `b` and the interaction between factors `a` and `d` are included in the model. `generators` is a cell array of strings with one generator per cell. Pass `generators` to `fracfact` to produce the fractional-factorial design and corresponding confounding pattern.

`generators = fracfactgen(terms,k)` returns generators for a two-level fractional-factorial design with 2^k -runs, if possible. If `k` is `[]`, `fracfactgen` finds the smallest design.

`generators = fracfactgen(terms,k,R)` finds a design with resolution `R`, if possible. The default resolution is 3.

A design of *resolution R* is one in which no n -factor interaction is confounded with any other effect containing less than $R - n$ factors. Thus a resolution III design does not confound main effects with one another but may confound them with two-way interactions, while a resolution IV design does not confound either main effects or two-way interactions but may confound two-way interactions with each other.

If `fracfactgen` is unable to find a design at the requested resolution, it tries to find a lower-resolution design sufficient to calibrate the model. If it is successful, it returns the generators for the lower-resolution design along with a warning. If it fails, it returns an error.

`generators = fracfactgen(terms,k,R,basic)` also accepts a vector `basic` specifying the indices of factors that are to be treated as basic. These factors receive full-factorial treatments in the design. The default includes factors that are part of the highest-order interaction in `terms`.

Examples

Suppose you wish to determine the effects of four two-level factors, for which there may be two-way interactions. A full-factorial design would require $2^4 = 16$ runs. The `fracfactgen` function finds generators for a resolution IV (separating main effects) fractional-factorial design that requires only $2^3 = 8$ runs:

```
generators = fracfactgen('a b c d',3,4)
generators =
  'a'
  'b'
  'c'
  'abc'
```

The more economical design and the corresponding confounding pattern are returned by `fracfact`:

```
[dfF,confounding] = fracfact(generators)
dfF =
  -1  -1  -1  -1
  -1  -1   1   1
  -1   1  -1   1
  -1   1   1  -1
   1  -1  -1   1
   1  -1   1  -1
   1   1  -1  -1
   1   1   1   1
confounding =
  'Term'      'Generator'    'Confounding'
  'X1'        'a'            'X1'
  'X2'        'b'            'X2'
```

'X3'	'c'	'X3'
'X4'	'abc'	'X4'
'X1*X2'	'ab'	'X1*X2 + X3*X4'
'X1*X3'	'ac'	'X1*X3 + X2*X4'
'X1*X4'	'bc'	'X1*X4 + X2*X3'
'X2*X3'	'bc'	'X1*X4 + X2*X3'
'X2*X4'	'ac'	'X1*X3 + X2*X4'
'X3*X4'	'ab'	'X1*X2 + X3*X4'

The confounding pattern shows, for example, that the two-way interaction between X1 and X2 is confounded by the two-way interaction between X3 and X4.

friedman

Friedman's test

Syntax

```
p = friedman(x, reps)
p = friedman(x, reps, displayopt)
[p, table] = friedman( ___ )
[p, table, stats] = friedman( ___ )
```

Description

`p = friedman(x, reps)` returns the p -value for the nonparametric Friedman's test to compare column effects in a two-way layout. `friedman` tests the null hypothesis that the column effects are all the same against the alternative that they are not all the same.

`p = friedman(x, reps, displayopt)` enables the ANOVA table display when `displayopt` is 'on' (default) and suppresses the display when `displayopt` is 'off'.

`[p, table] = friedman(___)` returns the ANOVA table (including column and row labels) in cell array `table`.

`[p, table, stats] = friedman(___)` also returns a structure `stats` that you can use to perform a follow-up multiple comparison test.

Examples

Test For Column Effects Using Friedman's Test

This example shows how to test for column effects in a two-way layout using Friedman's test.

Load the sample data.

```
load popcorn
```

```
popcorn
```

```
popcorn =
```

```
  5.5000  4.5000  3.5000
  5.5000  4.5000  4.0000
  6.0000  4.0000  3.0000
  6.5000  5.0000  4.0000
  7.0000  5.5000  5.0000
  7.0000  5.0000  4.5000
```

This data comes from a study of popcorn brands and popper type (Hogg 1987). The columns of the matrix `popcorn` are brands (Gourmet, National, and Generic). The rows are popper type (Oil and Air). The study popped a batch of each brand three times with each popper. The values are the yield in cups of popped popcorn.

Use Friedman's test to determine whether the popcorn brand affects the yield of popcorn.

```
p = friedman(popcorn,3)
```

```
p =
```

```
  0.0010
```

Friedman's ANOVA Table					
Source	SS	df	MS	Chi-sq	Prob>Chi-sq
Columns	99.75	2	49.875	13.76	0.001
Interaction	0.0833	2	0.0417		
Error	16.1667	12	1.3472		
Total	116	17			

Test for column effects after row effects are removed

The small value of $p = 0.001$ indicates the popcorn brand affects the yield of popcorn.

Input Arguments

x — Sample data

matrix

Sample data for the hypothesis test, specified as a matrix. The columns of **x** represent changes in a factor A. The rows represent changes in a blocking factor B. If there is more than one observation for each combination of factors, input **reps** indicates the number of replicates in each “cell,” which must be constant.

Data Types: `single` | `double`

reps — Number of replicates per cell

1 (default) | positive integer value

Number of replicates per cell, specified as a positive integer value.

Data Types: `single` | `double`

displayopt — ANOVA table display option

'off' (default) | 'on'

ANOVA table display option, specified as 'off' or 'on'.

If `displayopt` is 'on', then `friedman` displays a figure showing an ANOVA table, which divides the variability of the ranks into two or three parts:

- The variability due to the differences among the column effects
- The variability due to the interaction between rows and columns (if `reps` is greater than its default value of 1)
- The remaining variability not explained by any systematic source

The ANOVA table has six columns:

- The first shows the source of the variability.
- The second shows the Sum of Squares (SS) due to each source.
- The third shows the degrees of freedom (df) associated with each source.
- The fourth shows the Mean Squares (MS), which is the ratio SS/df .
- The fifth shows Friedman's chi-square statistic.
- The sixth shows the p value for the chi-square statistic.

You can copy a text version of the ANOVA table to the clipboard by selecting `Copy Text` from the **Edit** menu.

Output Arguments

p — p -value

scalar value in the range [0, 1]

p -value of the test, returned as a scalar value in the range [0, 1]. p is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. Small values of p cast doubt on the validity of the null hypothesis.

table — ANOVA table

cell array

ANOVA table, including column and row labels, returned as a cell array. The ANOVA table has six columns:

- The first shows the source of the variability.
- The second shows the Sum of Squares (SS) due to each source.
- The third shows the degrees of freedom (df) associated with each source.
- The fourth shows the Mean Squares (MS), which is the ratio SS/df.
- The fifth shows Friedman's chi-square statistic.
- The sixth shows the p value for the chi-square statistic.

You can copy a text version of the ANOVA table to the clipboard by selecting **Copy Text** from the **Edit** menu.

stats — Test data

structure

Test data, returned as a structure. `friedman` evaluates the hypothesis that the column effects are all the same against the alternative that they are not all the same. However, sometimes it is preferable to perform a test to determine which pairs of column effects are significantly different, and which are not. You can use the `multcompare` function to perform such tests by supplying `stats` as the input value.

More About

Friedman's Test

Friedman's test is similar to classical balanced two-way ANOVA, but it tests only for column effects after adjusting for possible row effects. It does not test for row effects or interaction effects. Friedman's test is appropriate when columns represent treatments that are under study, and rows represent nuisance effects (blocks) that need to be taken into account but are not of any interest.

The different columns of X represent changes in a factor A. The different rows represent changes in a blocking factor B. If there is more than one observation for each combination of factors, input `reps` indicates the number of replicates in each "cell," which must be constant.

The matrix below illustrates the format for a set-up where column factor A has three levels, row factor B has two levels, and there are two replicates (`reps=2`). The subscripts indicate row, column, and replicate, respectively.

$$\begin{bmatrix} x_{111} & x_{121} & x_{131} \\ x_{112} & x_{122} & x_{132} \\ x_{211} & x_{221} & x_{231} \\ x_{212} & x_{222} & x_{232} \end{bmatrix}$$

Friedman's test assumes a model of the form

$$x_{ijk} = \mu + \alpha_i + \beta_j + \varepsilon_{ijk}$$

where μ is an overall location parameter, α_i represents the column effect, β_j represents the row effect, and ε_{ijk} represents the error. This test ranks the data within each level of B, and tests for a difference across levels of A. The `p` that `friedman` returns is the p value for the null hypothesis that $\alpha_i = 0$. If the p value is near zero, this casts doubt on the null hypothesis. A sufficiently small p value suggests that at least one column-sample median is significantly different than the others; i.e., there is a main effect due to factor A. The choice of a critical p value to determine whether a result is “statistically significant” is left to the researcher. It is common to declare a result significant if the p value is less than 0.05 or 0.01.

Friedman's test makes the following assumptions about the data in X:

- All data come from populations having the same continuous distribution, apart from possibly different locations due to column and row effects.
- All observations are mutually independent.

The classical two-way ANOVA replaces the first assumption with the stronger assumption that data come from normal distributions.

frnd

F random numbers

Syntax

```
R = frnd(V1,V2)
R = frnd(V1,V2,m,n,...)
R = frnd(V1,V2,[m,n,...])
```

Description

`R = frnd(V1,V2)` generates random numbers from the *F* distribution with numerator degrees of freedom *V1* and denominator degrees of freedom *V2*. *V1* and *V2* can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input for *V1* or *V2* is expanded to a constant array with the same dimensions as the other input.

`R = frnd(V1,V2,m,n,...)` or `R = frnd(V1,V2,[m,n,...])` generates an *m*-by-*n*-by-... array containing random numbers from the *F* distribution with parameters *V1* and *V2*. *V1* and *V2* can each be scalars or arrays of the same size as *R*.

Examples

```
n1 = frnd(1:6,1:6)
n1 =
    0.0022    0.3121    3.0528    0.3189    0.2715    0.9539
```

```
n2 = frnd(2,2,[2 3])
n2 =
    0.3186    0.9727    3.0268
    0.2052  148.5816    0.2191
```

```
n3 = frnd([1 2 3;4 5 6],1,2,3)
n3 =
    0.6233    0.2322    31.5458
    2.5848    0.2121    4.4955
```

random | fpdf | fcdf | finv | fstat

fstat

F mean and variance

Syntax

```
[M,V] = fstat(V1,V2)
```

Description

[M,V] = fstat(V1,V2) returns the mean of and variance for the *F* distribution with numerator degrees of freedom V1 and denominator degrees of freedom V2. V1 and V2 can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of M and V. A scalar input for V1 or V2 is expanded to a constant arrays with the same dimensions as the other input.

The mean of the *F* distribution for values of ν_2 greater than 2 is

$$\frac{\nu_2}{\nu_2 - 2}$$

The variance of the *F* distribution for values of ν_2 greater than 4 is

$$\frac{2\nu_2^2(\nu_1 + \nu_2 - 2)}{\nu_1(\nu_2 - 2)^2(\nu_2 - 4)}$$

The mean of the *F* distribution is undefined if ν_2 is less than 3. The variance is undefined for ν_2 less than 5.

Examples

fstat returns NaN when the mean and variance are undefined.

```
[m,v] = fstat(1:5,1:5)
```

```
m =  
NaN NaN 3.0000 2.0000 1.6667  
v =  
NaN NaN NaN NaN 8.8889
```

fsurfht

Interactive contour plot

Syntax

```
fsurfht(fun,xlims,ylim)  
fsurfht(fun,xlims,ylim,p1,p2,p3,p4,p5)
```

Description

`fsurfht(fun,xlims,ylim)` is an interactive contour plot of the function specified by the text variable `fun`. The x -axis limits are specified by `xlims` in the form `[xmin xmax]`, and the y -axis limits are specified by `ylim` in the form `[ymin ymax]`.

`fsurfht(fun,xlims,ylim,p1,p2,p3,p4,p5)` allows for five optional parameters that you can supply to the function `fun`.

The intersection of the vertical and horizontal reference lines on the plot defines the current x value and y value. You can drag these reference lines and watch the calculated z -values (at the top of the plot) update simultaneously. Alternatively, you can type the x value and y value into editable text fields on the x -axis and y -axis.

Examples

Plot the Gaussian likelihood function for the `gas.mat` data.

```
load gas
```

Create a function containing the following commands, and name it `gauslike.m`.

```
function z = gauslike(mu,sigma,p1)  
n = length(p1);  
z = ones(size(mu));  
for i = 1:n  
z = z .* (normpdf(p1(i),mu,sigma));  
end
```

The `gauslike` function calls `normpdf`, treating the data sample as fixed and the parameters μ and σ as variables. Assume that the gas prices are normally distributed, and plot the likelihood surface of the sample.

```
fsurfht('gauslike',[112 118],[3 5],price1)
```

The sample mean is the x value at the maximum, but the sample standard deviation is *not* the y value at the maximum.

```
mumax = mean(price1)
mumax =
    115.1500
sigmamax = std(price1)*sqrt(19/20)
sigmamax =
```

3.7719

fullfact

Full factorial design

Syntax

```
dFF = fullfact(levels)
```

Description

`dFF = fullfact(levels)` gives factor settings `dFF` for a full factorial design with n factors, where the number of levels for each factor is given by the vector `levels` of length n . `dFF` is m -by- n , where m is the number of treatments in the full-factorial design. Each row of `dFF` corresponds to a single treatment. Each column contains the settings for a single factor, with integer values from one to the number of levels.

Examples

The following generates an eight-run full-factorial design with two levels in the first factor and four levels in the second factor:

```
dFF = fullfact([2 4])
dFF =
  1  1
  2  1
  1  2
  2  2
  1  3
  2  3
  1  4
  2  4
```

See Also

`ff2n`

gagerr

Gage repeatability and reproducibility study

Syntax

```
gagerr(y, {part, operator})  
gagerr(y, GROUP)  
gagerr(y, part)  
gagerr(..., param1, val1, param2, val2, ...)  
[TABLE, stats] = gagerr(...)
```

Description

`gagerr(y, {part, operator})` performs a gage repeatability and reproducibility study on measurements in `y` collected by `operator` on `part`. `y` is a column vector containing the measurements on different parts. `part` and `operator` are categorical variables, numeric vectors, character matrices, or cell arrays of strings. The number of elements in `part` and `operator` should be the same as in `y`.

`gagerr` prints a table in the command window in which the decomposition of variance, standard deviation, study var (5.15 x standard deviation) are listed with respective percentages for different sources. Summary statistics are printed below the table giving the number of distinct categories (NDC) and the percentage of Gage R&R of total variations (PRR).

`gagerr` also plots a bar graph showing the percentage of different components of variations. Gage R&R, repeatability, reproducibility, and part-to-part variations are plotted as four vertical bars. Variance and study var are plotted as two groups.

To determine the capability of a measurement system using NDC, use the following guidelines:

- If $NDC > 5$, the measurement system is capable.
- If $NDC < 2$, the measurement system is not capable.
- Otherwise, the measurement system may be acceptable.

To determine the capability of a measurement system using PRR, use the following guidelines:

- If $PRR < 10\%$, the measurement system is capable.
- If $PRR > 30\%$, the measurement system is not capable.
- Otherwise, the measurement system may be acceptable.

`gagerr(y, GROUP)` performs a gage R&R study on measurements in `y` with `part` and `operator` represented in `GROUP`. `GROUP` is a numeric matrix whose first and second columns specify different parts and operators, respectively. The number of rows in `GROUP` should be the same as the number of elements in `y`.

`gagerr(y, part)` performs a gage R&R study on measurements in `y` without operator information. The assumption is that all variability is contributed by `part`.

`gagerr(..., param1, val1, param2, val2, ...)` performs a gage R&R study using one or more of the following parameter name/value pairs:

- `'spec'` — A two-element vector that defines the lower and upper limit of the process, respectively. In this case, summary statistics printed in the command window include Precision-to-Tolerance Ratio (PTR). Also, the bar graph includes an additional group, the percentage of tolerance.

To determine the capability of a measurement system using PTR, use the following guidelines:

- If $PTR < 0.1$, the measurement system is capable.
- If $PTR > 0.3$, the measurement system is not capable.
- Otherwise, the measurement system may be acceptable.
- `'printtable'` — A string with a value `'on'` or `'off'` that indicates whether the tabular output should be printed in the command window or not. The default value is `'on'`.
- `'printgraph'` — A string with a value `'on'` or `'off'` that indicates whether the bar graph should be plotted or not. The default value is `'on'`.
- `'randomoperator'` — A logical value, `true` or `false`, that indicates whether the effect of `operator` is random or not. The default value is `true`.
- `'model'` — The model to use, specified by one of:
 - `'linear'` — Main effects only (default)
 - `'interaction'` — Main effects plus two-factor interactions
 - `'nested'` — Nest operator in part

The default value is 'linear'.

[TABLE, stats] = gagerr(...) returns a 6-by-5 matrix TABLE and a structure stats. The columns of TABLE, from left to right, represent variance, percentage of variance, standard deviations, study var, and percentage of study var. The rows of TABLE, from top to bottom, represent different sources of variations: gage R&R, repeatability, reproducibility, operator, operator and part interactions, and part. stats is a structure containing summary statistics for the performance of the measurement system. The fields of stats are:

- ndc — Number of distinct categories
- prr — Percentage of gage R&R of total variations
- ptr — Precision-to-tolerance ratio. The value is NaN if the parameter 'spec' is not given.

Examples

Gage R&R Study

Simulate a measurement system by randomly generating the operators, parts, and the measurements, y, operators do on the parts.

```
rng(1234, 'twister')           % for reproducibility
y = randn(100,1);              % measurements
part = ceil(3*rand(100,1));     % parts
operator = ceil(4*rand(100,1)); % operators
```

Conduct a gage R&R study for this system using a mixed ANOVA model without interactions.

```
gagerr(y, {part, operator}, 'randomoperator', true)
```

Columns 1 through 4

gamcdf

Gamma cumulative distribution function

Syntax

```
gamcdf(x, a, b)
[p, plo, pup] = gamcdf(x, a, b, pcov, alpha)
[p, plo, pup] = gamcdf( ____, 'upper' )
```

Description

`gamcdf(x, a, b)` returns the gamma cdf at each of the values in `x` using the corresponding shape parameters in `a` and scale parameters in `b`. `x`, `a`, and `b` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs. The parameters in `a` and `b` must be positive.

`[p, plo, pup] = gamcdf(x, a, b, pcov, alpha)` produces confidence bounds for `p` when the input parameters `a` and `b` are estimates. `pcov` is a 2-by-2 matrix containing the covariance matrix of the estimated parameters. `alpha` has a default value of 0.05, and specifies $100(1 - \alpha)\%$ confidence bounds. `plo` and `pup` are arrays of the same size as `p` containing the lower and upper confidence bounds.

`[p, plo, pup] = gamcdf(____, 'upper')` returns the complement of the gamma cdf at each value in `x`, using an algorithm that more accurately computes the extreme upper tail probabilities. You can use the 'upper' argument with any of the previous syntaxes.

The gamma cdf is

$$p = F(x | a, b) = \frac{1}{b^a \Gamma(a)} \int_0^x t^{a-1} e^{-\frac{t}{b}} dt$$

The result, p , is the probability that a single observation from a gamma distribution with parameters a and b will fall in the interval $[0, x]$.

`gammainc` is the gamma distribution with b fixed at 1.

Examples

Compute Gamma Distribution CDF

The mean of the gamma distribution is the product of the parameters, ab . In this example, the mean approaches the median as it increases (i.e., the distribution becomes more symmetric).

```
a = 1:6;  
b = 5:10;  
prob = gamcdf(a.*b,a,b)  
  
prob =  
    0.6321    0.5940    0.5768    0.5665    0.5595    0.5543
```

More About

gamfit

Gamma parameter estimates

Syntax

```
phat = gamfit(data)
[phat,pci] = gamfit(data)
[phat,pci] = gamfit(data,alpha)
[...] = gamfit(data,alpha,censoring,freq,options)
```

Description

`phat = gamfit(data)` returns the maximum likelihood estimates (MLEs) for the parameters of the gamma distribution given the data in vector `data`.

`[phat,pci] = gamfit(data)` returns MLEs and 95% percent confidence intervals. The first row of `pci` is the lower bound of the confidence intervals; the last row is the upper bound.

`[phat,pci] = gamfit(data,alpha)` returns $100(1 - \alpha)\%$ confidence intervals. For example, `alpha = 0.01` yields 99% confidence intervals.

`[...] = gamfit(data,alpha,censoring)` accepts a Boolean vector of the same size as `data` that is 1 for observations that are right-censored and 0 for observations that are observed exactly.

`[...] = gamfit(data,alpha,censoring,freq)` accepts a frequency vector of the same size as `data`. `freq` typically contains integer frequencies for the corresponding elements in `data`, but may contain any nonnegative values.

`[...] = gamfit(data,alpha,censoring,freq,options)` accepts a structure, `options`, that specifies control parameters for the iterative algorithm the function uses to compute maximum likelihood estimates. The gamma fit function accepts an `options` structure which can be created using the function `statset`. Enter `statset('gamfit')` to see the names and default values of the parameters that `gamfit` accepts in the `options` structure.

Examples

Fit a gamma distribution to random data generated from a specified gamma distribution:

```
a = 2; b = 4;  
data = gamrnd(a,b,100,1);
```

```
[p,ci] = gamfit(data)
```

```
p =  
 2.1990  3.7426
```

```
ci =  
 1.6840  2.8298  
 2.7141  4.6554
```

prob.GammaDistribution class

Package: prob

Superclasses: prob.ToolboxFittableParametricDistribution

Gamma probability distribution object

Description

`prob.GammaDistribution` is an object consisting of parameters, a model description, and sample data for a gamma probability distribution.

Create a probability distribution object with specified parameter values using `makedist`. Alternatively, fit a distribution to data using `fitdist` or the Distribution Fitting app.

Construction

`pd = makedist('Gamma')` creates a gamma probability distribution object using the default parameter values.

`pd = makedist('Gamma', 'a', a, 'b', b)` creates a gamma probability distribution object using the specified parameter values.

Input Arguments

a — Shape parameter

1 (default) | positive scalar value

Shape parameter for the gamma distribution, specified as a positive scalar value.

Data Types: `single` | `double`

b — Scale parameter

1 (default) | nonnegative scalar value

Scale parameter for the gamma distribution, specified as a nonnegative scalar value.

Data Types: `single` | `double`

Properties

a — Shape parameter

positive scalar value

Shape parameter for the gamma distribution, stored as a positive scalar value.

Data Types: `single` | `double`

b — Scale parameter

nonnegative scalar value

Scale parameter for the gamma distribution, stored as a nonnegative scalar value.

Data Types: `single` | `double`

DistributionName — Probability distribution name

probability distribution name string

Probability distribution name, stored as a valid probability distribution name string. This property is read-only.

Data Types: `char`

InputData — Data used for distribution fitting

structure

Data used for distribution fitting, stored as a structure containing the following:

- **data**: Data vector used for distribution fitting.
- **cens**: Censoring vector, or empty if none.
- **freq**: Frequency vector, or empty if none.

This property is read-only.

Data Types: `struct`

IsTruncated — Logical flag for truncated distribution

0 | 1

Logical flag for truncated distribution, stored as a logical value. If **IsTruncated** equals 0, the distribution is not truncated. If **IsTruncated** equals 1, the distribution is truncated. This property is read-only.

Data Types: `logical`

NumParameters — Number of parameters

positive integer value

Number of parameters for the probability distribution, stored as a positive integer value. This property is read-only.

Data Types: `single` | `double`

ParameterCovariance — Covariance matrix of the parameter estimates

matrix of scalar values

Covariance matrix of the parameter estimates, stored as a p -by- p matrix, where p is the number of parameters in the distribution. The (i,j) element is the covariance between the estimates of the i th parameter and the j th parameter. The (i,i) element is the estimated variance of the i th parameter. If parameter i is fixed rather than estimated by fitting the distribution to data, then the (i,i) elements of the covariance matrix are 0. This property is read-only.

Data Types: `single` | `double`

ParameterDescription — Distribution parameter descriptions

cell array of strings

Distribution parameter descriptions, stored as a cell array of strings. Each cell contains a short description of one distribution parameter. This property is read-only.

Data Types: `char`

ParameterIsFixed — Logical flag for fixed parameters

array of logical values

Logical flag for fixed parameters, stored as an array of logical values. If 0, the corresponding parameter in the `ParameterNames` array is not fixed. If 1, the corresponding parameter in the `ParameterNames` array is fixed. This property is read-only.

Data Types: `logical`

ParameterNames — Distribution parameter names

cell array of strings

Distribution parameter names, stored as a cell array of strings. This property is read-only.

Data Types: char

ParameterValues — Distribution parameter values

vector of scalar values

Distribution parameter values, stored as a vector. This property is read-only.

Data Types: single | double

Truncation — Truncation interval

vector of scalar values

Truncation interval for the probability distribution, stored as a vector containing the lower and upper truncation boundaries. This property is read-only.

Data Types: single | double

Methods

Inherited Methods

cdf	Cumulative distribution function of probability distribution object
icdf	Inverse cumulative distribution function of probability distribution object

proflik	Profile likelihood function for probability distribution object
std	Standard deviation of probability distribution object
var	Variance of probability distribution object

Definitions

Gamma Distribution

The gamma distribution is a two-parameter family of distributions used to model sums of exponentially distributed random variables. The chi-square and the exponential distributions, which are children of the gamma distribution, are one-parameter distributions that fix one of the two gamma parameters.

The gamma distribution uses the following parameters.

Parameter	Description	Support
a	Shape parameter	$a > 0$
b	Scale parameter	$b \geq 0$

The probability density function (pdf) is

$$f(x | a, b) = \frac{1}{b^a \Gamma(a)} x^{a-1} e^{-\frac{x}{b}} \quad ; \quad x > 0,$$

where $\Gamma(\cdot)$ is the Gamma function.

Examples

Create a Gamma Distribution Object Using Default Parameters

Create a gamma distribution object using the default parameter values.

```
pd = makedist('Gamma')
```

```
pd =
```

```
GammaDistribution
```

```
Gamma distribution
```

```
  a = 1
```

```
  b = 1
```

Create a Gamma Distribution Object Using Specified Parameters

Create a gamma distribution object by specifying the parameter values.

```
pd = makedist('Gamma', 'a', 2, 'b', 4)
```

```
pd =
```

```
GammaDistribution
```

```
Gamma distribution
```

```
  a = 2

gaminv

Gamma inverse cumulative distribution function

Syntax

```
X = gaminv(P,A,B)
[X,XLO,XUP] = gamcdf(P,A,B,pcov,alpha)
```

Description

`X = gaminv(P,A,B)` computes the inverse of the gamma cdf with shape parameters in **A** and scale parameters in **B** for the corresponding probabilities in **P**. **P**, **A**, and **B** can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs. The parameters in **A** and **B** must all be positive, and the values in **P** must lie on the interval [0 1].

The gamma inverse function in terms of the gamma cdf is

$$x = F^{-1}(p | a, b) = \{x : F(x | a, b) = p\}$$

where

$$p = F(x | a, b) = \frac{1}{b^a \Gamma(a)} \int_0^x t^{a-1} e^{-\frac{t}{b}} dt$$

`[X,XLO,XUP] = gamcdf(P,A,B,pcov,alpha)` produces confidence bounds for **P** when the input parameters **A** and **B** are estimates. **pcov** is a 2-by-2 matrix containing the covariance matrix of the estimated parameters. **alpha** has a default value of 0.05, and specifies 100(1 - **alpha**)% confidence bounds. **PLO** and **PUP** are arrays of the same size as **P** containing the lower and upper confidence bounds.

Examples

This example shows the relationship between the gamma cdf and its inverse function.

```
a = 1:5;  
b = 6:10;  
x = gaminv(gamcdf(1:5,a,b),a,b)  
x =  
    1.0000    2.0000    3.0000    4.0000    5.0000
```

More About

Algorithms

There is no known analytical solution to the integral equation above. `gaminv` uses an iterative approach (Newton's method) to converge on the solution.

gamlike

Gamma negative log-likelihood

Syntax

```
nlogL = gamlike(params,data)
[nlogL,AVAR] = gamlike(params,data)
```

Description

`nlogL = gamlike(params,data)` returns the negative of the gamma log-likelihood of the parameters, `params`, given `data`. `params(1)=A`, shape parameters, and `params(2)=B`, scale parameters.

`[nlogL,AVAR] = gamlike(params,data)` also returns `AVAR`, which is the asymptotic variance-covariance matrix of the parameter estimates when the values in `params` are the maximum likelihood estimates. `AVAR` is the inverse of Fisher's information matrix. The diagonal elements of `AVAR` are the asymptotic variances of their respective parameters.

`[...] = gamlike(params,data,censoring)` accepts a Boolean vector of the same size as `data` that is 1 for observations that are right-censored and 0 for observations that are observed exactly.

`[...] = gamfit(params,data,censoring,freq)` accepts a frequency vector of the same size as `data`. `freq` typically contains integer frequencies for the corresponding elements in `data`, but may contain any non-negative values.

`gamlike` is a utility function for maximum likelihood estimation of the gamma distribution. Since `gamlike` returns the negative gamma log-likelihood function, minimizing `gamlike` using `fminsearch` is the same as maximizing the likelihood.

Examples

Compute the negative log-likelihood of parameter estimates computed by the `gamfit` function:

```
a = 2; b = 3;
r = gamrnd(a,b,100,1);

[nlogL,AVAR] = gamlike(gamfit(r),r)
nlogL =
    267.5648
AVAR =
    0.0788  -0.1104
   -0.1104  0.1955
```

gamfit | gampdf | gamcdf | gaminv | gamstat | gamrnd

gampdf

Gamma probability density function

Syntax

```
Y = gampdf(X,A,B)
```

Description

`Y = gampdf(X,A,B)` computes the gamma pdf at each of the values in `X` using the corresponding shape parameters in `A` and scale parameters in `B`. `X`, `A`, and `B` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs. The parameters in `A` and `B` must all be positive, and the values in `X` must lie on the interval $[0 \infty)$.

The gamma pdf is

$$y = f(x | a, b) = \frac{1}{b^a \Gamma(a)} x^{a-1} e^{-\frac{x}{b}}$$

The gamma probability density function is useful in reliability models of lifetimes. The gamma distribution is more flexible than the exponential distribution in that the probability of a product surviving an additional period may depend on its current age. The exponential and χ^2 functions are special cases of the gamma function.

Examples

The exponential distribution is a special case of the gamma distribution.

```
mu = 1:5;
```

```
y = gampdf(1,1,mu)  
y =
```

```
0.3679 0.3033 0.2388 0.1947 0.1637
```

```
y1 = exppdf(1,mu)
```

```
y1 =
```

```
0.3679 0.3033 0.2388 0.1947 0.1637
```

gamrnd

Gamma random numbers

Syntax

```
R = gamrnd(A,B)
R = gamrnd(A,B,m,n,...)
R = gamrnd(A,B,[m,n,...])
```

Description

`R = gamrnd(A,B)` generates random numbers from the gamma distribution with shape parameters in `A` and scale parameters in `B`. `A` and `B` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input for `A` or `B` is expanded to a constant array with the same dimensions as the other input.

`R = gamrnd(A,B,m,n,...)` or `R = gamrnd(A,B,[m,n,...])` generates an `m`-by-`n`-by-... array containing random numbers from the gamma distribution with parameters `A` and `B`. `A` and `B` can each be scalars or arrays of the same size as `R`.

Examples

```
n1 = gamrnd(1:5,6:10)
n1 =
    9.1132  12.8431  24.8025  38.5960 106.4164
```

```
n2 = gamrnd(5,10,[1 5])
n2 =
    30.9486  33.5667  33.6837  55.2014  46.8265
```

```
n3 = gamrnd(2:6,3,1,5)
n3 =
    12.8715  11.3068  3.0982  15.6012  21.6739
```

gamstat

Gamma mean and variance

Syntax

```
[M,V] = gamstat(A,B)
```

Description

`[M,V] = gamstat(A,B)` returns the mean of and variance for the gamma distribution with shape parameters in **A** and scale parameters in **B**. **A** and **B** can be vectors, matrices, or multidimensional arrays that have the same size, which is also the size of **M** and **V**. A scalar input for **A** or **B** is expanded to a constant array with the same dimensions as the other input.

The mean of the gamma distribution with parameters a and b is ab . The variance is ab^2 .

Examples

```
[m,v] = gamstat(1:5,1:5)
```

```
m =  
    1    4    9   16   25  
v =  
    1    8   27   64  125
```

```
[m,v] = gamstat(1:5,1./(1:5))
```

```
m =  
    1    1    1    1    1  
v =  
    1.0000    0.5000    0.3333    0.2500    0.2000
```

ge

Class: grandstream

Greater than or equal relation for handles

Syntax

`h1 >= h2`

Description

`h1 >= h2` performs element-wise comparisons between handle arrays `h1` and `h2`. `h1` and `h2` must be of the same dimensions unless one is a scalar. The result is a logical array of the same dimensions, where each element is an element-wise `>=` result.

If one of `h1` or `h2` is scalar, scalar expansion is performed and the result will match the dimensions of the array that is not scalar.

`tf = ge(h1, h2)` stores the result in a logical array of the same dimensions.

prob.GeneralizedExtremeValueDistribution class

Package: prob

Superclasses: prob.ToolboxFittableParametricDistribution

Generalized extreme value probability distribution object

Description

`prob.GeneralizedExtremeValueDistribution` is an object consisting of parameters, a model description, and sample data for a generalized extreme value probability distribution.

Create a probability distribution object with specified parameter values using `makedist`. Alternatively, fit a distribution to data using `fitdist` or the Distribution Fitting app.

Construction

`pd = makedist('GeneralizedExtremeValue')` creates a generalized extreme value probability distribution object using the default parameter values.

`pd = makedist('GeneralizedExtremeValue', 'k', k, 'sigma', sigma, 'mu', mu)` creates a generalized extreme value probability distribution object using the specified parameter values.

Input Arguments

k — Shape parameter

0 (default) | scalar value

Shape parameter for the generalized extreme value distribution, specified as a scalar value.

Data Types: `single` | `double`

sigma — Scale parameter

1 (default) | nonnegative scalar value

Scale parameter for the generalized extreme value distribution, specified as a nonnegative scalar value.

Data Types: `single` | `double`

mu — Location parameter

0 (default) | scalar value

Location parameter for the generalized extreme value distribution, specified as a scalar value.

Data Types: `single` | `double`

Properties

k — Shape parameter

scalar value

Shape parameter of the generalized extreme value distribution, stored as a scalar value.

Data Types: `single` | `double`

sigma — Scale parameter

nonnegative scalar value

Scale parameter of the generalized extreme value distribution, stored as a nonnegative scalar value.

Data Types: `single` | `double`

mu — Location parameter

scalar value

Location parameter of the generalized extreme value distribution, stored as a scalar value.

Data Types: `single` | `double`

DistributionName — Probability distribution name

probability distribution name string

Probability distribution name, stored as a valid probability distribution name string. This property is read-only.

Data Types: `char`

InputData — Data used for distribution fitting

structure

Data used for distribution fitting, stored as a structure containing the following:

- **data**: Data vector used for distribution fitting.
- **cens**: Censoring vector, or empty if none.
- **freq**: Frequency vector, or empty if none.

This property is read-only.

Data Types: `struct`

IsTruncated — Logical flag for truncated distribution

0 | 1

Logical flag for truncated distribution, stored as a logical value. If **IsTruncated** equals 0, the distribution is not truncated. If **IsTruncated** equals 1, the distribution is truncated. This property is read-only.

Data Types: `logical`

NumParameters — Number of parameters

positive integer value

Number of parameters for the probability distribution, stored as a positive integer value. This property is read-only.

Data Types: `single` | `double`

ParameterCovariance — Covariance matrix of the parameter estimates

matrix of scalar values

Covariance matrix of the parameter estimates, stored as a p -by- p matrix, where p is the number of parameters in the distribution. The (i, j) element is the covariance between the estimates of the i th parameter and the j th parameter. The (i, i) element is the estimated variance of the i th parameter. If parameter i is fixed rather than estimated by fitting the distribution to data, then the (i, i) elements of the covariance matrix are 0. This property is read-only.

Data Types: `single` | `double`

ParameterDescription — Distribution parameter descriptions

cell array of strings

Distribution parameter descriptions, stored as a cell array of strings. Each cell contains a short description of one distribution parameter. This property is read-only.

Data Types: char

ParameterIsFixed — Logical flag for fixed parameters

array of logical values

Logical flag for fixed parameters, stored as an array of logical values. If 0, the corresponding parameter in the `ParameterNames` array is not fixed. If 1, the corresponding parameter in the `ParameterNames` array is fixed. This property is read-only.

Data Types: logical

ParameterNames — Distribution parameter names

cell array of strings

Distribution parameter names, stored as a cell array of strings. This property is read-only.

Data Types: char

ParameterValues — Distribution parameter values

vector of scalar values

Distribution parameter values, stored as a vector. This property is read-only.

Data Types: single | double

Truncation — Truncation interval

vector of scalar values

Truncation interval for the probability distribution, stored as a vector containing the lower and upper truncation boundaries. This property is read-only.

Data Types: single | double

Methods

Inherited Methods

`cdf`

Cumulative distribution function of probability distribution object

icdf	Inverse cumulative distribution function of probability distribution object
iqr	Interquartile range of probability distribution object
median	Median of probability distribution object
pdf	Probability density function of probability distribution object
random	Generate random numbers from probability distribution object
truncate	Truncate probability distribution object
mean	Mean of probability distribution object
negloglik	Negative loglikelihood of probability distribution object
paramci	Confidence intervals for probability distribution parameters
proflik	Profile likelihood function for probability distribution object
std	Standard deviation of probability distribution object
var	Variance of probability distribution object

Definitions

Generalized Extreme Value Distribution

The generalized extreme value distribution is often used to model the smallest or largest value among a large set of independent, identically distributed random values representing measurements or observations. It combines three simpler distributions into a single form, allowing a continuous range of possible shapes that include all three of the simpler distributions.

The three distribution types correspond to the limiting distribution of block maxima from different classes of underlying distributions:

- Type 1 — Distributions whose tails decrease exponentially, such as the normal distribution
- Type 2 — Distributions whose tails decrease as a polynomial, such as Student's t distribution
- Type 3 — Distributions whose tails are finite, such as the beta distribution

The generalized extreme value distribution uses the following parameters.

Parameter	Description	Support
k	Shape parameter	$-\infty \leq k \leq \infty$
σ	Scale parameter	$\sigma \geq 0$
μ	Location parameter	$-\infty \leq \mu \leq \infty$

The probability density function (pdf) for a Type 1 distribution, where shape parameter $k = 0$, is

$$f(x | 0, \mu, \sigma) = \left(\frac{1}{\sigma} \right) \exp \left(-\exp \left(-\frac{(x - \mu)}{\sigma} \right) - \frac{(x - \mu)}{\sigma} \right) ; \quad -\infty < x < \infty.$$

When $k \neq 0$, the pdf is

$$f(x | k, \mu, \sigma) = \left(\frac{1}{\sigma}\right) \exp \left(- \left(1 + k \frac{(x - \mu)}{\sigma} \right)^{-\frac{1}{k}} \right) \left(1 + k \frac{(x - \mu)}{\sigma} \right)^{-1 - \frac{1}{k}}$$

for

$$1 + k \frac{(x - \mu)}{\sigma} > 0.$$

For the Type 2 case, $k > 0$ and $x \geq \mu - \frac{\sigma}{k}$. For the Type 3 case, $k < 0$ and $x < \mu - \frac{\sigma}{k}$.

Examples

Create a Generalized Extreme Value Distribution Object Using Default Parameters

Create a generalized extreme value distribution object using the default parameter values.

```
pd = makedist('GeneralizedExtremeValue')
```

```
pd =
```

```
GeneralizedExtremeValueDistribution
```

```
Generalized Extreme Value distribution
```

```
    k = 0
```

```
    sigma = 1
```

```
    mu = 0
```

Create a Generalized Extreme Value Distribution Object Using Specified Parameters

Create a generalized extreme value distribution object by specifying values for the parameters.

```
pd = makedist('GeneralizedExtremeValue', 'k', 0, 'sigma', 2, 'mu', 1)
```

```
pd =
```

```
GeneralizedExtremeValueDistribution
```

```
Generalized Extreme Value distribution
```

```
    k = 0  
    sigma = 2  
    mu = 1
```

Compute the mean of the distribution.

```
m = mean(pd)
```

```
m =
```

```
    2.1544
```

- “Property Attributes”

GeneralizedLinearMixedModel class

Generalized linear mixed-effects model class

Description

A `GeneralizedLinearMixedModel` object represents a regression model of a response variable that contains both fixed and random effects. The object comprises data, a model description, fitted coefficients, covariance parameters, design matrices, residuals, residual plots, and other diagnostic information for a generalized linear mixed-effects (GLME) model. You can predict model responses with the `predict` function and generate random data at new design points using the `random` function.

Construction

You can fit a generalized linear mixed-effects (GLME) model to sample data using `fitglme(tbl, formula)`. For more information, see `fitglme`.

Input Arguments

tbl — Input data

table | dataset array

Input data, which includes the response variable, predictor variables, and grouping variables, specified as a table or dataset array. The predictor variables can be continuous or grouping variables (see “Grouping Variables” on page 2-52). You must specify the model for the variables using `formula`.

Data Types: `table`

formula — Formula for model specification

string of the form `'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)'`

Formula for model specification, specified as a string of the form `'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)'`. For a full description, see `Formula`.

Example: 'y ~ treatment +(1|block)'

Properties

Coefficients — Estimates of fixed-effects coefficients

dataset array

Estimates of fixed-effects coefficients and related statistics, stored as a dataset array that has one row for each coefficient and the following columns:

- **Name** — Name of the coefficient
- **Estimate** — Estimated coefficient value
- **SE** — Standard error of the estimate
- **tStat** — *t*-statistic for a test that the coefficient is equal to 0
- **DF** — Degrees of freedom associated with the *t* statistic
- **pValue** — *p*-value for the *t*-statistic
- **Lower** — Lower confidence limit
- **Upper** — Upper confidence limit

To obtain any of these columns as a vector, index into the property using dot notation.

Use the `coefTest` method to perform other tests on the coefficients.

CoefficientCovariance — Covariance of estimated fixed-effects vector

matrix

Covariance of estimated fixed-effects vector, stored as a matrix.

Data Types: `single` | `double`

CoefficientNames — Names of fixed-effects coefficients

cell array of strings

Names of fixed-effects coefficients, stored as a cell array of strings. The label for the coefficient of the constant term is (`Intercept`). The labels for other coefficients indicate the terms that they multiply. When the term includes a categorical predictor, the label also indicates the level of that predictor.

Data Types: `cell`

DFE — Degrees of freedom for error

positive integer value

Degrees of freedom for error, stored as a positive integer value. DFE is the number of observations minus the number of estimated coefficients.

DFE contains the degrees of freedom corresponding to the 'Residual' method of calculating denominator degrees of freedom for hypothesis tests on fixed-effects coefficients. If n is the number of observations and p is the number of fixed-effects coefficients, then DFE is equal to $n - p$.

Data Types: `double`

Dispersion — Model dispersion parameter

scalar value

Model dispersion parameter, stored as a scalar value. The dispersion parameter defines the conditional variance of the response.

For observation i , the conditional variance of the response y_i , given the conditional mean μ_i and the dispersion parameter σ^2 , in a generalized linear mixed-effects model is

$$\text{var}(y_i | \mu_i, \sigma^2) = \frac{\sigma^2}{w_i} v(\mu_i),$$

where w_i is the i th observation weight and v is the variance function for the specified conditional distribution of the response. The **Dispersion** property contains an estimate of σ^2 for the specified GLME model. The value of **Dispersion** depends on the specified conditional distribution of the response. For binomial and Poisson distributions, the theoretical value of **Dispersion** is equal to $\sigma^2 = 1.0$.

- If **FitMethod** is `MPL` or `REMP` and the 'DispersionFlag' name-value pair argument in `fitglme` is `true`, then a dispersion parameter is estimated from data for all distributions, including binomial and Poisson distributions.
- If **FitMethod** is `ApproximateLaplace` or `Laplace`, then the 'DispersionFlag' name-value pair argument in `fitglme` does not apply, and the dispersion parameter is fixed at 1.0 for binomial and Poisson distributions. For all other distributions, **Dispersion** is estimated from data.

Data Types: double

DispersionEstimated — Flag indicating if dispersion parameter was estimated

true | false

Flag indicating estimated dispersion parameter, stored as a logical value.

- If `FitMethod` is `ApproximateLaplace` or `Laplace`, then the dispersion parameter is fixed at its theoretical value of 1.0 for binomial and Poisson distributions, and `DispersionEstimated` is `false`. For other distributions, the dispersion parameter is estimated from the data, and `DispersionEstimated` is `true`.
- If `FitMethod` is `MPL` or `REMP`, and the `'DispersionFlag'` name-value pair argument in `fitglm` is specified as `true`, then the dispersion parameter is estimated for all distributions, including binomial and Poisson distributions, and `DispersionEstimated` is `true`.
- If `FitMethod` is `MPL` or `REMP`, and the `'DispersionFlag'` name-value pair argument in `fitglm` is specified as `false`, then the dispersion parameter is fixed at its theoretical value for binomial and Poisson distributions, and `DispersionEstimated` is `false`. For distributions other than binomial and Poisson, the dispersion parameter is estimated from the data, and `DispersionEstimated` is `true`.

Data Types: logical

Distribution — Response distribution name

'Normal' | 'Binomial' | 'Poisson' | 'Gamma' | 'InverseGaussian'

Response distribution name, stored as one of the following:

- `'Normal'` — Normal distribution
- `'Binomial'` — Binomial distribution
- `'Poisson'` — Poisson distribution
- `'Gamma'` — Gamma distribution
- `'InverseGaussian'` — Inverse Gaussian distribution

FitMethod — Method used to fit the model

'MPL' | 'REMP' | 'ApproximateLaplace' | 'Laplace'

Method used to fit the model, stored as one of the following.

- 'MPL' — Maximum pseudo likelihood
- 'REMP' — Restricted maximum pseudo likelihood
- 'ApproximateLaplace' — Maximum likelihood using the approximate Laplace method, with fixed effects profiled out
- 'Laplace' — Maximum likelihood using the Laplace method

Formula — Model specification formula

object

Model specification formula, stored as an object. The model specification formula uses Wilkinson's notation to describe the relationship between the fixed-effects terms, random-effects terms, and grouping variables in the GLME model. For more information see Formula.

Link — Link function characteristics

structure

Link function characteristics, stored as a structure containing the following fields. The link is a function G that links the distribution parameter MU to the linear predictor ETA as follows: $G(MU) = ETA$.

Name	Name of the link function
Link	Function that defines G
Derivative	Derivative of G
SecondDerivative	Second derivative of G
Inverse	Inverse of G

Data Types: struct

LogLikelihood — Log of likelihood function

scalar value

Log of likelihood function evaluated at the estimated coefficient values, stored as a scalar value. LogLikelihood depends on the method used to fit the model.

- If you use 'Laplace' or 'ApproximateLaplace', then LogLikelihood is the maximized log likelihood.

- If you use 'MPL', then `LogLikelihood` is the maximized log likelihood of the pseudo data from the final pseudo likelihood iteration.
- If you use 'REML', then `LogLikelihood` is the maximized restricted log likelihood of the pseudo data from the final pseudo likelihood iteration.

Data Types: double

ModelCriterion — Model criterion

table

Model criterion to compare fitted generalized linear mixed-effects models, stored as a table with the following fields.

AIC	Akaike information criterion
BIC	Bayesian information criterion
LogLikelihood	<ul style="list-style-type: none">• For a model fit using 'Laplace' or 'ApproximateLaplace', <code>LogLikelihood</code> is the maximized log likelihood.• For a model fit using 'MPL', <code>LogLikelihood</code> is the maximized log likelihood of the pseudo data from the final pseudo likelihood iteration.• For a model fit using 'REML', <code>LogLikelihood</code> is the maximized restricted log likelihood of the pseudo data from the final pseudo likelihood iteration.
Deviance	-2 times <code>LogLikelihood</code>

NumCoefficients — Number of fixed-effects coefficients

positive integer value

Number of fixed-effects coefficients in the fitted generalized linear mixed-effects model, stored as a positive integer value.

Data Types: double

NumEstimatedCoefficients — Number of estimated fixed-effects coefficients

positive integer value

Number of estimated fixed-effects coefficients in the fitted generalized linear mixed-effects model, stored as a positive integer value.

Data Types: double

NumObservations — Number of observations

positive integer value

Number of observations used in the fit, stored as a positive integer value. **NumObservations** is the number of rows in the table or dataset array **tbl**, minus rows excluded using the 'Exclude' name-value pair of **fitglme** or rows containing NaN values.

Data Types: double

NumPredictors — Number of predictors

positive integer value

Number of variables used as predictors in the generalized linear mixed-effects model, stored as a positive integer value.

Data Types: double

NumVariables — Total number of variables

positive integer value

Total number of variables, including the response and predictors, stored as a positive integer value. If the sample data is in a table or dataset array **tbl**, then **NumVariables** is the total number of variables in **tbl**, including the response variable. **NumVariables** includes variables, if any, that are not used as predictors or as the response.

Data Types: double

ObservationInfo — Information about the observations

table

Information about the observations used in the fit, stored as a table.

ObservationInfo has one row for each observation and the following columns.

Weights

The weight value for the observation. The default value is 1.

Excluded	If the observation was excluded from the fit using the 'Exclude' name-value pair argument in <code>fitglme</code> , then Excluded is <code>true</code> , or 1. Otherwise, Excluded is <code>false</code> , or 0.
Missing	If the observation was excluded from the fit because any response or predictor value is missing, then Missing is <code>true</code> . Otherwise, Missing is <code>false</code> . Missing values include NaN for numeric variables, empty cells for cell arrays, blank rows for character arrays, and the <code><undefined></code> value for categorical arrays.
Subset	If the observation was used in the fit, then Subset is <code>true</code> . If the observation was not used in the fit because it is missing or excluded, then Subset is <code>false</code> .
BinomSize	Binomial size for each observation. This column only applies when fitting a binomial distribution.

Data Types: `table`

ObservationNames — Names of observations

cell array of strings

Names of observations used in the fit, stored as a cell array of strings.

- If the data is in a table or dataset array `tbl` that contains observation names, then **ObservationNames** uses those names.
- If the data is provided in matrices, or in a table or dataset array without observation names, then **ObservationNames** is an empty cell array.

Data Types: `cell`

PredictorNames — Names of predictors

cell array of strings

Names of the variables used as predictors in the fit, stored as a cell array of strings that has the same length as `NumPredictors`.

Data Types: `cell`

ResponseName — Name of response variable

character string

Name of the variable used as the response variable in the fit, stored as a character string.

Data Types: `char`

Rsquared — Proportion of variability in the response explained by the fitted model

structure

Proportion of variability in the response explained by the fitted model, stored as a structure. **Rsquared** contains the *R*-squared value of the fitted model, also known as the multiple correlation coefficient. **Rsquared** contains the following fields.

Ordinary

R-squared value, stored as a scalar value in a structure.

`Rsquared.Ordinary = 1 - SSE./SST`

Adjusted

R-squared value adjusted for the number of fixed-effects coefficients, stored as a scalar value in a structure.

`Rsquared.Adjusted = 1 - (SSE./SST)*(DFT./DFE)`,

where $DFE = n - p$, $DFT = n - 1$, n is the total number of observations, and p is the number of fixed-effects coefficients.

Data Types: `struct`

SSE — Error sum of squares

positive scalar value

Error sum of squares, stored as a positive scalar value. **SSE** is the weighted sum of the squared conditional residuals, and is calculated as

$$SSE = \sum_{i=1}^n w_i^{eff} (y_i - f_i)^2,$$

where n is the number of observations, w_i^{eff} is the i th effective weight, y_i is the i th response, and f_i is the i th fitted value.

The i th effective weight is calculated as

$$w_i^{\text{eff}} = \left\{ \frac{w_i}{v_i(\mu_i(\hat{\beta}, \hat{b}))} \right\},$$

where v_i is the variance term for the i th observation, $\hat{\beta}$ and \hat{b} are estimated values of β and b , respectively.

The i th fitted value is calculated as

$$f_i = g^{-1}(x_i^T \hat{\beta} + z_i^T \hat{b} + \delta_i),$$

where x_i^T is the i th row of the fixed-effects design matrix X , and z_i^T is the i th row of the random-effects design matrix Z . δ_i is the i th offset value.

Data Types: double

SSR — Regression sum of squares

positive scalar value

Regression sum of squares, stored as a positive scalar value. **SSR** is the sum of squares explained by the generalized linear mixed-effects regression, or equivalently the weighted sum of the squared deviations of the conditional fitted values from their weighted mean. **SSR** is calculated as

$$SSR = \sum_{i=1}^N w_i^{\text{eff}} (f_i - \bar{f})^2,$$

where n is the number of observations, w_i^{eff} is the i th effective weight, f_i is the i th fitted value, and \bar{f} is a weighted average of the fitted values.

The i th effective weight is calculated as

$$w_i^{eff} = \left\{ \frac{w_i}{v_i(\mu_i(\hat{\beta}, \hat{b}))} \right\},$$

where $\hat{\beta}$ and \hat{b} are estimated values of β and b , respectively.

The i th fitted value is calculated as

$$f_i = g^{-1}(x_i^T \hat{\beta} + z_i^T \hat{b} + \delta_i),$$

where x_i^T is the i th row of the fixed-effects design matrix X , and z_i^T is the i th row of the random-effects design matrix Z . δ_i is the i th offset value.

The weighted average of fitted values is calculated as

$$\bar{f} = \frac{\left[\sum_{i=1}^n w_i^{eff} f_i \right]}{\sum_{i=1}^n w_i^{eff}}.$$

Data Types: double

SST — Total sum of squares

positive scalar value

Total sum of squares, stored as a positive scalar value. For a GLME model, SST is defined as $SST = SSE + SSR$.

Data Types: double

VariableInfo — Information about the variables

table

Information about the variables used in the fit, stored as a table. `VariableInfo` has one row for each variable and contains the following columns.

<code>Class</code>	Class of the variable ('double', 'cell', 'nominal', and so on).
<code>Range</code>	Value range of the variable. <ul style="list-style-type: none">• For a numerical variable, <code>Range</code> is a two-element vector of the form <code>[min,max]</code>.• For a cell or categorical variable, <code>Range</code> is a cell or categorical array containing all unique values of the variable.
<code>InModel</code>	If the variable is a predictor in the fitted model, <code>InModel</code> is <code>true</code> . If the variable is not in the fitted model, <code>InModel</code> is <code>false</code> .
<code>IsCategorical</code>	If the variable type is treated as a categorical predictor (such as cell, logical, or categorical), then <code>IsCategorical</code> is <code>true</code> . If the variable is a continuous predictor, then <code>IsCategorical</code> is <code>false</code> .

Data Types: `table`

VariableNames — Names of the variables

cell array of strings

Names of all the variables contained in the table or dataset array `tbl`, stored as a cell array of strings.

Data Types: `cell`

Variables — Variables

table

Variables, stored as a table. If the fit is based on a table or dataset array `tbl`, then `Variables` is identical to `tbl`.

Data Types: `table`

Methods

<code>anova</code>	Analysis of variance for generalized linear mixed-effects model
<code>coefCI</code>	Confidence intervals for coefficients of generalized linear mixed-effects model
<code>coefTest</code>	Hypothesis test on fixed and random effects of generalized linear mixed-effects model
<code>compare</code>	Compare generalized linear mixed-effects models
<code>covarianceParameters</code>	Extract covariance parameters of generalized linear mixed-effects model
<code>designMatrix</code>	Fixed- and random-effects design matrices
<code>fitted</code>	Fitted responses from generalized linear mixed-effects model
<code>fixedEffects</code>	Estimates of fixed effects and related statistics
<code>plotResiduals</code>	Plot residuals of generalized linear mixed-effects model
<code>predict</code>	Predict response of generalized linear mixed-effects model

random	Generate random responses from fitted generalized linear mixed-effects model
randomEffects	Estimates of random effects and related statistics
refit	Refit generalized linear mixed-effects model
residuals	Residuals of fitted generalized linear mixed-effects model
response	Response vector of generalized linear mixed-effects model

Definitions

Formula

In general, a formula for model specification is a string of the form `'y ~ terms'`. For generalized linear mixed-effects models, this formula is in the form `'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)'`, where `fixed` and `random` contain the fixed-effects and the random-effects terms, respectively, and `R` is the number of grouping variables in the model.

Suppose a table `tbl` contains the following:

- A response variable, `y`
- Predictor variables, `Xj`, which can be continuous or grouping variables
- Grouping variables, `g1`, `g2`, ..., `gR`,

where the grouping variables in `Xj` and `gr` can be categorical, logical, character arrays, or cell arrays of strings.

Then, in a formula of the form, `'y ~ fixed + (random1|g1) + ... + (randomR|gR)'`, the term `fixed` corresponds to a specification of the fixed-effects design matrix

X , `random1` is a specification of the random-effects design matrix Z_1 corresponding to grouping variable g_1 , and similarly `randomR` is a specification of the random-effects design matrix Z_R corresponding to grouping variable g_R . You can express the `fixed` and `random` terms using Wilkinson notation.

Wilkinson notation describes the factors present in models. The notation relates to factors present in models, not to the multipliers (coefficients) of those factors.

Wilkinson Notation	Factors in Standard Notation
1	Constant (intercept) term
X^k , where k is a positive integer	X, X^2, \dots, X^k
$X1 + X2$	$X1, X2$
$X1 * X2$	$X1, X2, X1.*X2$ (elementwise multiplication of $X1$ and $X2$)
$X1 : X2$	$X1.*X2$ only
$- X2$	Do not include $X2$
$X1 * X2 + X3$	$X1, X2, X3, X1 * X2$
$X1 + X2 + X3 + X1 : X2$	$X1, X2, X3, X1 * X2$
$X1 * X2 * X3 - X1 : X2 : X3$	$X1, X2, X3, X1 * X2, X1 * X3, X2 * X3$
$X1 * (X2 + X3)$	$X1, X2, X3, X1 * X2, X1 * X3$

Statistics Toolbox notation always includes a constant term unless you explicitly remove the term using `-1`. Here are some examples for linear mixed-effects model specification.

Examples:

Formula	Description
' $y \sim X1 + X2$ '	Fixed effects for the intercept, $X1$ and $X2$. This is equivalent to ' $y \sim 1 + X1 + X2$ '.
' $y \sim -1 + X1 + X2$ '	No intercept and fixed effects for $X1$ and $X2$. The implicit intercept term is suppressed by including <code>-1</code> .
' $y \sim 1 + (1 g1)$ '	Fixed effects for the intercept plus random effect for the intercept for each level of the grouping variable $g1$.

Formula	Description
'y ~ X1 + (1 g1)'	Random intercept model with a fixed slope.
'y ~ X1 + (X1 g1)'	Random intercept and slope, with possible correlation between them. This is equivalent to 'y ~ 1 + X1 + (1 + X1 g1)'
'y ~ X1 + (1 g1) + (-1 + X1 g1)'	Independent random effects terms for intercept and slope.
'y ~ 1 + (1 g1) + (1 g2) + (1 g1:g2)'	Random intercept model with independent main effects for g1 and g2, plus an independent interaction effect.

Examples

Fit a Generalized Linear Mixed-Effects Model

Navigate to the folder containing the sample data. Load the sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

```
load mfr
```

This simulated data is from a manufacturing company that operates 50 factories across the world, with each factory running a batch process to create a finished product. The company wants to decrease the number of defects in each batch, so it developed a new manufacturing process. To test the effectiveness of the new process, the company selected 20 of its factories at random to participate in an experiment: Ten factories implemented the new process, while the other ten continued to run the old process. In each of the 20 factories, the company ran five batches (for a total of 100 batches) and recorded the following data:

- Flag to indicate whether the batch used the new process (`newprocess`)
- Processing time for each batch, in hours (`time`)
- Temperature of the batch, in degrees Celsius (`temp`)
- Categorical variable indicating the supplier of the chemical used in the batch (`supplier`)

- Number of defects in the batch (**defects**)

The data also includes `time_dev` and `temp_dev`, which represent the absolute deviation of time and temperature, respectively, from the process standard of 3 hours at 20 degrees Celsius.

Fit a generalized linear mixed-effects model using `newprocess`, `time_dev`, `temp_dev`, and `supplier` as fixed-effects predictors. Include a random-effects term for intercept grouped by `factory`, to account for quality differences that might exist due to factory-specific variations. The response variable `defects` has a Poisson distribution, and the appropriate link function for this model is log. Use the Laplace fit method to estimate the coefficients. Specify the dummy variable encoding as `'effects'`, so the dummy variable coefficients sum to 0.

The number of defects can be modeled using a Poisson distribution

$$defects_{ij} \sim \text{Poisson}(\mu_{ij})$$

This corresponds to the generalized linear mixed-effects model

$$\log(\mu_{ij}) = \beta_0 + \beta_1 newprocess_{ij} + \beta_2 time_dev_{ij} + \beta_3 temp_dev_{ij} + \beta_4 supplier_C_{ij} + \beta_5 supplier_B_{ij} +$$

where

- $defects_{ij}$ is the number of defects observed in the batch produced by factory i during batch j .
- μ_{ij} is the mean number of defects corresponding to factory i (where $i = 1, 2, \dots, 20$) during batch j (where $j = 1, 2, \dots, 5$).
- $newprocess_{ij}$, $time_dev_{ij}$, and $temp_dev_{ij}$ are the measurements for each variable that correspond to factory i during batch j . For example, $newprocess_{ij}$ indicates whether the batch produced by factory i during batch j used the new process.
- $supplier_C_{ij}$ and $supplier_B_{ij}$ are dummy variables that use effects (sum-to-zero) coding to indicate whether company **C** or **B**, respectively, supplied the process chemicals for the batch produced by factory i during batch j .
- $b_i \sim N(0, \sigma_b^2)$ is a random-effects intercept for each factory i that accounts for factory-specific variation in quality.

```
glme = fitglme(mfr, 'defects ~ 1 + newprocess + time_dev + temp_dev + supplier + (1|fact
```

Display the model.

```

```

Random effects covariance parameters:
Group: factory (20 Levels)
      Name1          Name2          Type          Estimate
      '(Intercept)'  '(Intercept)'  'std'        0.31381

Group: Error
      Name          Estimate
      'sqrt(Dispersion)'  1

```

The **Model information** table displays the total number of observations in the sample data (100), the number of fixed- and random-effects coefficients (6 and 20, respectively), and the number of covariance parameters (1). It also indicates that the response variable has a **Poisson** distribution, the link function is **Log**, and the fit method is **Laplace**.

Formula indicates the model specification using Wilkinson's notation.

The **Model fit statistics** table displays statistics used to assess the goodness of fit of the model. This includes the Akaike information criterion (**AIC**), Bayesian information criterion (**BIC**) values, log likelihood (**LogLikelihood**), and deviance (**Deviance**) values.

The **Fixed effects coefficients** table indicates that **fitglm** returned 95% confidence intervals. It contains one row for each fixed-effects predictor, and each column contains statistics corresponding to that predictor. Column 1 (**Name**) contains the name of each fixed-effects coefficient, column 2 (**Estimate**) contains its estimated value, and column 3 (**SE**) contains the standard error of the coefficient. Column 4 (**tStat**) contains the *t*-statistic for a hypothesis test that the coefficient is equal to 0. Column 5 (**DF**) and column 6 (**pValue**) contain the degrees of freedom and *p*-value that correspond to the *t*-statistic, respectively. The last two columns (**Lower** and **Upper**) display the lower and upper limits, respectively, of the 95% confidence interval for each fixed-effects coefficient.

Random effects covariance parameters displays a table for each grouping variable (here, only **factory**), including its total number of levels (20), and the type and estimate of the covariance parameter. Here, **std** indicates that **fitglm** returns the standard deviation of the random effect associated with the factory predictor, which has an estimated value of 0.31381. It also displays a table containing the error parameter type (here, the square root of the dispersion parameter), and its estimated value of 1.

The standard display generated by **fitglm** does not provide confidence intervals for the random-effects parameters. To compute and display these values, use **covarianceParameters**.

More About

- “Generalized Linear Mixed-Effects Models” on page 10-64

GeneralizedLinearModel class

Generalized linear regression model class

Description

An object comprising training data, model description, diagnostic information, and fitted coefficients for a generalized linear regression. Predict model responses with the `predict` or `feval` methods.

Construction

`mdl = fitglm(tbl)` or `mdl = fitglm(X,y)` creates a generalized linear model of a table or dataset array `tbl`, or of the responses `y` to a data matrix `X`. For details, see `fitglm`.

`mdl = stepwiseglm(tbl)` or `mdl = stepwiseglm(X,y)` creates a generalized linear model of a table or dataset array `tbl`, or of the responses `y` to a data matrix `X`, with unimportant predictors excluded. For details, see `stepwiseglm`.

Input Arguments

tbl — Input data

table | dataset array

Input data, specified as a table or dataset array. When `modelspec` is a `formula`, it specifies the variables to be used as the predictors and response. Otherwise, if you do not specify the predictor and response variables, the last variable is the response variable and the others are the predictor variables by default.

Predictor variables can be numeric, or any grouping variable type, such as logical or categorical (see “Grouping Variables” on page 2-52). The response must be numeric or logical.

To set a different column as the response variable, use the `ResponseVar` name-value pair argument. To use a subset of the columns as predictors, use the `PredictorVars` name-value pair argument.

Data Types: `single` | `double` | `logical`

X — Predictor variables

matrix

Predictor variables, specified as an n -by- p matrix, where n is the number of observations and p is the number of predictor variables. Each column of **X** represents one variable, and each row represents one observation.

By default, there is a constant term in the model, unless you explicitly remove it, so do not include a column of 1s in **X**.

Data Types: `single` | `double` | `logical`

y — Response variable

vector

Response variable, specified as an n -by-1 vector, where n is the number of observations. Each entry in **y** is the response for the corresponding row of **X**.

Data Types: `single` | `double`

Properties

CoefficientCovariance

Covariance matrix of coefficient estimates.

CoefficientNames

Cell array of strings containing a label for each coefficient.

Coefficients

Coefficient values stored as a table. **Coefficients** has one row for each coefficient and these columns:

- **Estimate** — Estimated coefficient value
- **SE** — Standard error of the estimate
- **tStat** — t statistic for a test that the coefficient is zero
- **pValue** — p -value for the t statistic

To obtain any of these columns as a vector, index into the property using dot notation. For example, in **mdl** the estimated coefficient vector is

```
beta = mdl.Coefficients.Estimate
```

Use `coefTest` to perform other tests on the coefficients.

Deviance

Deviance of the fit. It is useful for comparing two models when one is a special case of the other. The difference between the deviance of the two models has a chi-square distribution with degrees of freedom equal to the difference in the number of estimated parameters between the two models. For more information on deviance, see “Deviance” on page 21-1765.

DFE

Degrees of freedom for error (residuals), equal to the number of observations minus the number of estimated coefficients.

Diagnostics

Table with diagnostics helpful in finding outliers and influential observations. The table contains the following fields:

Field	Meaning	Utility
Leverage	Diagonal elements of <code>HatMatrix</code>	Leverage indicates to what extent the predicted value for an observation is determined by the observed value for that observation. A value close to 1 indicates that the prediction is largely determined by that observation, with little contribution from the other observations. A value close to 0 indicates the fit is largely determined by the other observations. For a model with p coefficients and n observations, the average value of <code>Leverage</code> is p/n . An observation with <code>Leverage</code> larger than $2*p/n$ can be an outlier.
<code>CooksDistance</code>	Cook's measure of scaled change in fitted values	<code>CooksDistance</code> is a measure of scaled change in fitted values. An observation with <code>CooksDistance</code> larger than three times the mean Cook's distance can be an outlier.
<code>HatMatrix</code>	Projection matrix to compute fitted from observed responses	<code>HatMatrix</code> is an n -by- n matrix such that <code>Fitted = HatMatrix*Y</code> , where <code>Y</code> is the response vector and <code>Fitted</code> is the vector of fitted response values.

All of these quantities are computed on the scale of the linear predictor. So, for example, in the equation that defines the hat matrix,

```
Yfit = glm.Fitted.LinearPredictor
Y = glm.Fitted.LinearPredictor + glm.Residuals.LinearPredictor
```

Dispersion

Scale factor of the variance of the response. **Dispersion** multiplies the variance function for the distribution.

For example, the variance function for the binomial distribution is $p(1-p)/n$, where p is the probability parameter and n is the sample size parameter. If **Dispersion** is near 1, the variance of the data appears to agree with the theoretical variance of the binomial distribution. If **Dispersion** is larger than 1, the data are “overdispersed” relative to the binomial distribution.

DispersionEstimated

Logical value indicating whether `fitglm` used the **Dispersion** property to compute standard errors for the coefficients in **Coefficients.SE**. If **DispersionEstimated** is false, `fitglm` used the theoretical value of the variance.

- **DispersionEstimated** can be false only for 'binomial' or 'poisson' distributions.
- Set **DispersionEstimated** by setting the **DispersionFlag** name-value pair in `fitglm`.

Distribution

Structure with the following fields relating to the generalized distribution:

Field	Description
Name	Name of the distribution, one of 'normal', 'binomial', 'poisson', 'gamma', or 'inverse gamma'.
DevianceFunction	Function that computes the components of the deviance as a function of the fitted parameter values and the response values.
VarianceFunction	Function that computes the theoretical variance for the distribution as a function of the fitted parameter values. When DispersionEstimated is true, Dispersion multiplies the variance function in the computation of the coefficient standard errors.

Fitted

Table of predicted (fitted) values based on the training data, a table with one row for each observation and the following columns.

Field	Description
Response	Predicted values on the scale of the response.
LinearPredictor	Predicted values on the scale of the linear predictor. These are the same as the link function applied to the Response fitted values.
Probability	Fitted probabilities (this column is included only with the binomial distribution).

To obtain any of the columns as a vector, index into the property using dot notation. For example, in the model `mdl`, the vector `f` of fitted values on the response scale is

```
f = mdl.Fitted.Response
```

Use `predict` to compute predictions for other predictor values, or to compute confidence bounds on `Fitted`.

Formula

Object containing information about the model.

Link

Structure with fields relating to the link function. The link is a function f that links the distribution parameter μ to the fitted linear combination Xb of the predictors:

$$f(\mu) = Xb.$$

The structure has the following fields.

Field	Description
Name	Name of the link function, or '' if you specified the link as a function handle rather than a string.
LinkFunction	The function that defines f , a function handle.
DevianceFunction	Derivative of f , a function handle.

Field	Description
VarianceFunction	Inverse of f , a function handle.

LogLikelihood

Log likelihood of the model distribution at the response values, with mean fitted from the model, and other parameters estimated as part of the model fit.

ModelCriterion

AIC and other information criteria for comparing models. A structure with fields:

- **AIC** — Akaike information criterion
- **AICc** — Akaike information criterion corrected for sample size
- **BIC** — Bayesian information criterion
- **CAIC** — Consistent Akaike information criterion

To obtain any of these values as a scalar, index into the property using dot notation. For example, in a model `mdl`, the AIC value `aic` is:

```
aic = mdl.ModelCriterion.AIC
```

NumCoefficients

Number of coefficients in the model, a positive integer. **NumCoefficients** includes coefficients that are set to zero when the model terms are rank deficient.

NumEstimatedCoefficients

Number of estimated coefficients in the model, a positive integer. **NumEstimatedCoefficients** does not include coefficients that are set to zero when the model terms are rank deficient. **NumEstimatedCoefficients** is the degrees of freedom for regression.

NumObservations

Number of observations the fitting function used in fitting. This is the number of observations supplied in the original table, dataset, or matrix, minus any excluded rows (set with the **Excluded** name-value pair) or rows with missing values.

NumPredictors

Number of variables `fitlm` used as predictors for fitting.

NumVariables

Number of variables in the data. **NumVariables** is the number of variables in the original table or dataset, or the total number of columns in the predictor matrix and response vector when the fit is based on those arrays. It includes variables, if any, that are not used as predictors or as the response.

ObservationInfo

Table with the same number of rows as the input data (`tbl` or `X`).

Field	Description
Weights	Observation weights. Default is all 1.
Excluded	Logical value, 1 indicates an observation that you excluded from the fit with the <code>Exclude</code> name-value pair.
Missing	Logical value, 1 indicates a missing value in the input. Missing values are not used in the fit.
Subset	Logical value, 1 indicates the observation is not excluded or missing, so is used in the fit.

ObservationNames

Cell array of strings containing the names of the observations used in the fit.

- If the fit is based on a table or dataset containing observation names, **ObservationNames** uses those names.
- Otherwise, **ObservationNames** is an empty cell array

Offset

Vector with the same length as the number of rows in the data, passed from `fitglm` or `stepwiseglm` in the `Offset` name-value pair. The fitting function used `Offset` as a predictor variable, but with the coefficient set to exactly 1. In other words, the formula for fitting was

$\mu \sim \text{Offset} + (\text{terms involving real predictors})$

with the `Offset` predictor having coefficient 1.

For example, consider a Poisson regression model. Suppose the number of counts is known for theoretical reasons to be proportional to a predictor `A`. By using the log link function and by specifying `log(A)` as an offset, you can force the model to satisfy this theoretical constraint.

PredictorNames

Cell array of strings, the names of the predictors used in fitting the model.

Residuals

Table containing residuals, with one row for each observation and these variables.

Field	Description
Raw	Observed minus fitted values.
LinearPredictor	Residuals on the linear predictor scale, equal to the adjusted response value minus the fitted linear combination of the predictors.
Pearson	Raw residuals divided by the estimated standard deviation of the response.
Anscombe	Residuals defined on transformed data with the transformation chosen to remove skewness.
Deviance	Residuals based on the contribution of each observation to the deviance.

To obtain any of these columns as a vector, index into the property using dot notation. For example, in a model `mdl`, the ordinary raw residual vector `r` is:

```
r = mdl.Residuals.Raw
```

Rows not used in the fit because of missing values (in `ObservationInfo.Missing`) contain NaN values.

Rows not used in the fit because of excluded values (in `ObservationInfo.Excluded`) contain NaN values, with the following exceptions:

- `raw` contains the difference between the observed and predicted values.
- `standardized` is the residual, standardized in the usual way.
- `studentized` matches the standardized values because this residual is not used in the estimate of the residual standard deviation.

ResponseName

String giving naming the response variable.

Rsquared

Proportion of total sum of squares explained by the model. The ordinary R-squared value relates to the `SSR` and `SST` properties:

$$\text{Rsquared} = \text{SSR}/\text{SST} = 1 - \text{SSE}/\text{SST}.$$

For a linear or nonlinear model, `Rsquared` is a structure with two fields:

- `Ordinary` — Ordinary (unadjusted) R-squared
- `Adjusted` — R-squared adjusted for the number of coefficients

For a generalized linear model, `Rsquared` is a structure with five fields:

- `Ordinary` — Ordinary (unadjusted) R-squared
- `Adjusted` — R-squared adjusted for the number of coefficients
- `LLR` — Log-likelihood ratio
- `Deviance` — Deviance
- `AdjGeneralized` — Adjusted generalized R-squared

To obtain any of these values as a scalar, index into the property using dot notation. For example, the adjusted R-squared value in `mdl` is

```
r2 = mdl.Rsquared.Adjusted
```

SSE

Sum of squared errors (residuals).

The Pythagorean theorem implies

$$SST = SSE + SSR.$$

SSR

Regression sum of squares, the sum of squared deviations of the fitted values from their mean.

The Pythagorean theorem implies

$$SST = SSE + SSR.$$

SST

Total sum of squares, the sum of squared deviations of y from $\text{mean}(y)$.

The Pythagorean theorem implies

$$SST = SSE + SSR.$$

Steps

Structure that is empty unless `stepwiselm` constructed the model.

Field	Description
Start	Formula representing the starting model
Lower	Formula representing the lower bound model, these terms that must remain in the model
Upper	Formula representing the upper bound model, model cannot contain more terms than <code>Upper</code>
Criterion	Criterion used for the stepwise algorithm, such as 'sse'
PEnter	Value of the parameter, such as 0.05
PRemove	Value of the parameter, such as 0.10
History	Table representing the steps taken in the fit

The `History` table has one row for each step including the initial fit, and the following variables (columns).

Field	Description
Action	Action taken during this step, one of: <ul style="list-style-type: none"> 'Start' — First step

Field	Description
	<ul style="list-style-type: none"> 'Add' — A term is added 'Remove' — A term is removed
TermName	<ul style="list-style-type: none"> 'Start' step: The starting model specification 'Add' or 'Remove' steps: The term moved in that step
Terms	Terms matrix (see <code>modelspec</code> of <code>fitlm</code>)
DF	Regression degrees of freedom after this step
delDF	Change in regression degrees of freedom from previous step (negative for steps that remove a term)
Deviance	Deviance (residual sum of squares) at that step
FStat	F statistic that led to this step
PValue	p -value of the F statistic

VariableInfo

Table containing metadata about `Variables`. There is one row for each term in the model, and the following columns.

Field	Description
Class	String giving variable class, such as 'double'
Range	Cell array giving variable range: <ul style="list-style-type: none"> Continuous variable — Two-element vector $[min, max]$, the minimum and maximum values Categorical variable — Cell array of distinct variable values
InModel	Logical vector, where <code>true</code> indicates the variable is in the model
IsCategorical	Logical vector, where <code>true</code> indicates a categorical variable

VariableNames

Cell array of strings containing names of the variables in the fit.

- If the fit is based on a table or dataset, this property provides the names of the variables in that table or dataset.

- If the fit is based on a predictor matrix and response vector, `VariableNames` is the values in the `VarNames` name-value pair of the fitting method.
- Otherwise the variables have the default fitting names.

Variables

Table containing the data, both observations and responses, that the fitting function used to construct the fit. If the fit is based on a table or dataset array, `Variables` contains all of the data from that table or dataset array. Otherwise, `Variables` is a table created from the input data matrix X and response vector y .

Methods

<code>addTerms</code>	Add terms to generalized linear model
<code>coefCI</code>	Confidence intervals of coefficient estimates of generalized linear model
<code>coefTest</code>	Linear hypothesis test on generalized linear regression model coefficients
<code>devianceTest</code>	Analysis of deviance
<code>disp</code>	Display generalized linear regression model
<code>feval</code>	Evaluate generalized linear regression model prediction
<code>fit</code>	Create generalized linear regression model
<code>plotDiagnostics</code>	Plot diagnostics of generalized linear regression model
<code>plotResiduals</code>	Plot residuals of generalized linear regression model

plotSlice	Plot of slices through fitted generalized linear regression surface
predict	Predict response of generalized linear regression model
random	Simulate responses for generalized linear regression model
removeTerms	Remove terms from generalized linear model
step	Improve generalized linear regression model by adding or removing terms
stepwise	Create generalized linear regression model by stepwise regression

Definitions

Canonical Link Function

The default link function for a generalized linear model is the *canonical link function*.

Canonical Link Functions for Generalized Linear Models

Distribution	Link Function Name	Link Function	Mean (Inverse) Function
'normal'	'identity'	$f(\mu) = \mu$	$\mu = Xb$
'binomial'	'logit'	$f(\mu) = \log(\mu/(1-\mu))$	$\mu = \exp(Xb) / (1 + \exp(Xb))$
'poisson'	'log'	$f(\mu) = \log(\mu)$	$\mu = \exp(Xb)$
'gamma'	-1	$f(\mu) = 1/\mu$	$\mu = 1/(Xb)$
'inverse gaussian'	-2	$f(\mu) = 1/\mu^2$	$\mu = (Xb)^{-1/2}$

Hat Matrix

The *hat matrix* H is defined in terms of the data matrix X and a diagonal weight matrix W :

$$H = X(X^T W X)^{-1} X^T W^T.$$

W has diagonal elements w_i :

$$w_i = \frac{g'(\mu_i)}{\sqrt{V(\mu_i)}},$$

where

- g is the link function mapping y_i to $x_i b$.
- g' is the derivative of the link function g .
- V is the variance function.
- μ_i is the i th mean.

The diagonal elements H_{ii} satisfy

$$0 \leq h_{ii} \leq 1$$

$$\sum_{i=1}^n h_{ii} = p,$$

where n is the number of observations (rows of X), and p is the number of coefficients in the regression model.

Leverage

The *leverage* of observation i is the value of the i th diagonal term, h_{ii} , of the hat matrix H . Because the sum of the leverage values is p (the number of coefficients in the regression model), an observation i can be considered to be an outlier if its leverage substantially exceeds p/n , where n is the number of observations.

Cook's Distance

The Cook's distance D_i of observation i is

$$D_i = w_i \frac{e_i^2}{p\hat{\phi}} \frac{h_{ii}}{(1-h_{ii})^2},$$

where

- $\hat{\phi}$ is the dispersion parameter (estimated or theoretical).
- e_i is the linear predictor residual, $g(y_i) - x_i\hat{\beta}$, where
 - g is the link function.
 - y_i is the observed response.
 - x_i is the observation.
 - $\hat{\beta}$ is the estimated coefficient vector.
- p is the number of coefficients in the regression model.
- h_{ii} is the i th diagonal element of the Hat Matrix H .

Deviance

Deviance of a model M_1 is twice the difference between the loglikelihood of that model and the saturated model, M_S . The saturated model is the model with the maximum number of parameters that can be estimated. For example, if there are n observations y_i , $i = 1, 2, \dots, n$, with potentially different values for $X_i^T\beta$, then you can define a saturated model with n parameters. Let $L(b,y)$ denote the maximum value of the likelihood function for a model. Then the deviance of model M_1 is

$$-2(\log L(b_1, y) - \log L(b_S, y)),$$

where b_1 are the estimated parameters for model M_1 and b_S are the estimated parameters for the saturated model. The deviance has a chi-square distribution with $n - p$ degrees of freedom, where n is the number of parameters in the saturated model and p is the number of parameters in model M_1 .

If M_1 and M_2 are two different generalized linear models, then the fit of the models can be assessed by comparing the deviances D_1 and D_2 of these models. The difference of the deviances is

$$\begin{aligned} D &= D_2 - D_1 = -2(\log L(b_2, y) - \log L(b_S, y)) + 2(\log L(b_1, y) - \log L(b_S, y)) \\ &= -2(\log L(b_2, y) - \log L(b_1, y)). \end{aligned}$$

Asymptotically, this difference has a chi-square distribution with degrees of freedom v equal to the number of parameters that are estimated in one model but fixed (typically at 0) in the other. That is, it is equal to the difference in the number of parameters estimated in M_1 and M_2 . You can get the p -value for this test using `1 - chi2cdf(D, V)`, where $D = D_2 - D_1$.

Copy Semantics

Value. To learn how value classes affect copy operations, see “Copying Objects” in the MATLAB documentation.

Examples

Fit a Generalized Linear Model

Fit a logistic regression model of probability of smoking as a function of age, weight, and sex, using a two-way interactions model.

Load the `hospital` dataset array.

```
load hospital
ds = hospital; % just to use the ds name
```

Specify the model using a formula that allows up to two-way interactions.

```
modelspec = 'Smoker ~ Age*Weight*Sex - Age:Weight:Sex';
```

Create the generalized linear model.

```
mdl = fitglm(ds, modelspec, 'Distribution', 'binomial')
mdl =
```

```
Generalized Linear regression model:
logit(Smoker) ~ 1 + Sex*Age + Sex*Weight + Age*Weight
Distribution = Binomial
```

```

Estimated Coefficients:
              Estimate      SE      tStat      pValue
(Intercept)   -6.0492     19.749   -0.3063   0.75938
Sex_Male      -2.2859     12.424   -0.18399  0.85402
Age           0.11691     0.50977  0.22934  0.81861
Weight        0.031109     0.15208  0.20455  0.83792
Sex_Male:Age  0.020734     0.20681  0.10025  0.92014
Sex_Male:Weight 0.01216     0.053168 0.22871  0.8191
Age:Weight    -0.00071959     0.0038964 -0.18468  0.85348

```

```

100 observations, 93 error degrees of freedom
Dispersion: 1
Chi^2-statistic vs. constant model: 5.07, p-value = 0.535

```

The large p -value indicates the model might not differ statistically from a constant.

Create a Generalized Linear Model Stepwise

Create response data using just three of 20 predictors, and create a generalized linear model stepwise to see if it uses just the correct predictors.

Create data with 20 predictors, and Poisson response using just three of the predictors, plus a constant.

```

rng('default') % for reproducibility
X = randn(100,20);
mu = exp(X(:,[5 10 15])*[.4;.2;.3] + 1);
y = poissrnd(mu);

```

Fit a generalized linear model using the Poisson distribution.

```

mdl = stepwiseglm(X,y,...
    'constant','upper','linear','Distribution','poisson')

```

```

1. Adding x5, Deviance = 134.439, Chi2Stat = 52.24814, PValue = 4.891229e-13
2. Adding x15, Deviance = 106.285, Chi2Stat = 28.15393, PValue = 1.1204e-07
3. Adding x10, Deviance = 95.0207, Chi2Stat = 11.2644, PValue = 0.000790094

```

```
mdl =
```

```

Generalized Linear regression model:
log(y) ~ 1 + x5 + x10 + x15
Distribution = Poisson

```

```

Estimated Coefficients:
              Estimate      SE      tStat      pValue
(Intercept)   1.0115     0.064275  15.737   8.4217e-56
x5            0.39508     0.066665  5.9263  3.0977e-09
x10           0.18863     0.05534  3.4085  0.0006532
x15           0.29295     0.053269  5.4995  3.8089e-08

```

```
100 observations, 96 error degrees of freedom
```

Dispersion: 1
Chi²-statistic vs. constant model: 91.7, p-value = 9.61e-20

prob.GeneralizedParetoDistribution class

Package: prob

Superclasses: prob.ToolboxFittableParametricDistribution

Generalized Pareto probability distribution object

Description

`prob.GeneralizedParetoDistribution` is an object consisting of parameters, a model description, and sample data for a generalized Pareto probability distribution.

Create a probability distribution object with specified parameter values using `makedist`. Alternatively, fit a distribution to data using `fitdist` or the Distribution Fitting app.

Construction

`pd = makedist('GeneralizedParetoDistribution')` creates a generalized Pareto probability distribution object using default parameter values.

`pd = makedist('GeneralizedParetoDistribution','k',k,'sigma',sigma,'theta',theta)` creates a generalized Pareto probability distribution object using the specified parameter values.

Input Arguments

k — Shape parameter

1 (default) | scalar value

Shape parameter for the generalized Pareto distribution, specified as a scalar value.

Data Types: `single` | `double`

sigma — Scale parameter

1 (default) | nonnegative scalar value

Scale parameter for the generalized Pareto distribution, specified as a nonnegative scalar value.

Data Types: `single` | `double`

theta — Location parameter

1 (default) | scalar value

Location parameter for the generalized Pareto distribution, specified as a scalar value.

Data Types: `single` | `double`

Properties

k — Shape parameter

scalar value

Shape parameter for the generalized Pareto distribution, stored as a scalar value.

Data Types: `single` | `double`

sigma — Scale parameter

nonnegative scalar value

Scale parameter for the generalized Pareto distribution, stored as a nonnegative scalar value.

Data Types: `single` | `double`

theta — Location parameter

scalar value

Location parameter for the generalized Pareto distribution, stored as a scalar value.

Data Types: `single` | `double`

DistributionName — Probability distribution name

probability distribution name string

Probability distribution name, stored as a valid probability distribution name string. This property is read-only.

Data Types: `char`

InputData — Data used for distribution fitting

structure

Data used for distribution fitting, stored as a structure containing the following:

- **data**: Data vector used for distribution fitting.
- **cens**: Censoring vector, or empty if none.
- **freq**: Frequency vector, or empty if none.

This property is read-only.

Data Types: `struct`

IsTruncated — Logical flag for truncated distribution

0 | 1

Logical flag for truncated distribution, stored as a logical value. If **IsTruncated** equals 0, the distribution is not truncated. If **IsTruncated** equals 1, the distribution is truncated. This property is read-only.

Data Types: `logical`

NumParameters — Number of parameters

positive integer value

Number of parameters for the probability distribution, stored as a positive integer value. This property is read-only.

Data Types: `single` | `double`

ParameterCovariance — Covariance matrix of the parameter estimates

matrix of scalar values

Covariance matrix of the parameter estimates, stored as a p -by- p matrix, where p is the number of parameters in the distribution. The (i, j) element is the covariance between the estimates of the i th parameter and the j th parameter. The (i, i) element is the estimated variance of the i th parameter. If parameter i is fixed rather than estimated by fitting the distribution to data, then the (i, i) elements of the covariance matrix are 0. This property is read-only.

Data Types: `single` | `double`

ParameterDescription — Distribution parameter descriptions

cell array of strings

Distribution parameter descriptions, stored as a cell array of strings. Each cell contains a short description of one distribution parameter. This property is read-only.

Data Types: char

ParameterIsFixed — Logical flag for fixed parameters

array of logical values

Logical flag for fixed parameters, stored as an array of logical values. If 0, the corresponding parameter in the `ParameterNames` array is not fixed. If 1, the corresponding parameter in the `ParameterNames` array is fixed. This property is read-only.

Data Types: logical

ParameterNames — Distribution parameter names

cell array of strings

Distribution parameter names, stored as a cell array of strings. This property is read-only.

Data Types: char

ParameterValues — Distribution parameter values

vector of scalar values

Distribution parameter values, stored as a vector. This property is read-only.

Data Types: single | double

Truncation — Truncation interval

vector of scalar values

Truncation interval for the probability distribution, stored as a vector containing the lower and upper truncation boundaries. This property is read-only.

Data Types: single | double

Methods

Inherited Methods

`cdf`

Cumulative distribution function of probability distribution object

Definitions

Generalized Pareto Distribution

The generalized Pareto distribution is used to model the tails of another distribution. It allows a continuous range of possible shapes that include both the exponential and Pareto distributions as special cases. It has three basic forms, each corresponding to a limiting distribution of exceedence data from a different class of underlying distributions.

- Distributions whose tails decrease exponentially, such as the normal, lead to a generalized Pareto shape parameter of zero.
- Distributions whose tails decrease polynomially, such as the Student's t , lead to a positive shape parameter.
- Distributions whose tails are finite, such as the beta, lead to a negative shape parameter.

The generalized Pareto distribution uses the following parameters.

Parameter	Description	Support
k	Shape parameter	$-\infty < k < \infty$
σ	Scale parameter	$\sigma \geq 0$
θ	Location parameter	$-\infty < \theta < \infty$

The probability density function (pdf) of the generalized Pareto distribution with shape parameter $k \neq 0$ is

$$f(x | k, \sigma, \theta) = \left(\frac{1}{\sigma} \right) \left(1 + k \frac{(x - \theta)}{\sigma} \right)^{-1 - \frac{1}{k}}$$

for $x > \theta$, when $k > 0$, or for $\theta < x < -\frac{\sigma}{k}$, when $k < 0$.

For $k = 0$, the pdf is

$$y = f(x | 0, \sigma, \theta) = \left(\frac{1}{\sigma}\right) \exp\left(-\frac{(x - \theta)}{\sigma}\right)$$

for $x > \theta$.

If $k = 0$ and $\theta = 0$, the generalized Pareto distribution is equivalent to the exponential

distribution. If $k > 0$ and $\theta = \frac{\sigma}{k}$, the generalized Pareto distribution is equivalent to the Pareto distribution.

Examples

Create a Generalized Pareto Distribution Object Using Default Parameters

Create a generalized Pareto distribution object using the default parameter values.

```
pd = makedist('GeneralizedPareto')
```

```
pd =
```

```
GeneralizedParetoDistribution
```

```
Generalized Pareto distribution
```

```
    k = 1
```

```
    sigma = 1
```

```
    theta = 1
```

Create a Generalized Pareto Distribution Object Using Specified Parameters

Create a generalized Pareto distribution object by specifying parameter values.

```
pd = makedist('GeneralizedPareto', 'k', 0, 'sigma', 2, 'theta', 1)
```

```
pd =
```

```
GeneralizedParetoDistribution
```

```
Generalized Pareto distribution
```

```
    k = 0
```

```
    sigma = 2
```

```
theta = 1
```

Compute the mean of the distribution.

```
m = mean(pd)
```

```
m =
```

```
2.1544
```

geocdf

Geometric cumulative distribution function

Syntax

```
y = geocdf(x,p)
y = geocdf(x,p,'upper')
```

Description

`y = geocdf(x,p)` returns the cumulative distribution function (cdf) of the geometric distribution at each value in `x` using the corresponding probabilities in `p`. `x` and `p` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other input. The parameters in `p` must lie on the interval `[0,1]`.

`y = geocdf(x,p,'upper')` returns the complement of the geometric distribution cdf at each value in `x`, using an algorithm that more accurately computes the extreme upper tail probabilities.

Examples

Compute Geometric Distribution cdf

Suppose you toss a fair coin repeatedly, and a "success" occurs when the coin lands with heads facing up. What is the probability of observing three or fewer tails ("failures") before tossing a heads?

To solve, determine the value of the cumulative distribution function (cdf) for the geometric distribution at `x` equal to 3. The probability of success (tossing a heads) `p` in any given trial is 0.5.

```
x = 3;
p = 0.5;
y = geocdf(x,p)
```

$y =$
 0.9375

The returned value of y indicates that the probability of observing three or fewer tails before tossing a heads is 0.9375.

More About

Geometric Distribution cdf

The cumulative distribution function (cdf) of the geometric distribution is

$$y = F(x | p) = 1 - (1 - p)^{x+1} ; x = 0, 1, 2, \dots,$$

where p is the probability of success, and x is the number of failures before the first success. The result y is the probability of observing up to x trials before a success, when the probability of success in any given trial is p .

- “Geometric Distribution” on page B-59

See Also

geopdf | geoinv | geostat | geornd | cdf | mle

geoinv

Geometric inverse cumulative distribution function

Syntax

```
x = geoinv(y,p)
```

Description

`x = geoinv(y,p)` returns the inverse cumulative distribution function (icdf) of the geometric distribution at each value in `y` using the corresponding probabilities in `p`.

`geoinv` returns the smallest positive integer `x` such that the geometric cdf evaluated at `x` is equal to or exceeds `y`. You can think of `y` as the probability of observing `x` successes in a row in independent trials, where `p` is the probability of success in each trial.

`y` and `p` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input for `p` or `y` is expanded to a constant array with the same dimensions as the other input. The values in `p` and `y` must lie on the interval `[0, 1]`.

Examples

Compute Geometric Distribution icdf

Suppose the probability of a five-year-old car battery not starting in cold weather is 0.03. If we want no more than a ten percent chance that the car does not start, what is the maximum number of days in a row that we should try to start the car?

To solve, compute the inverse cdf of the geometric distribution. In this example, a "success" means the car does not start, while a "failure" means the car does start. The probability of success for each trial `p` equals 0.03, while the probability of observing `x` failures in a row before observing a success `y` equals 0.1.

```
y = 0.1;  
p = 0.03;  
x = geoinv(y,p)
```

```
x =  
    3
```

The returned result indicates that if we start the car three times, there is at least a ten percent chance that it will not start on one of those tries. Therefore, if we want no greater than a ten percent chance that the car will not start, we should only attempt to start it for a maximum of two days in a row.

We can confirm this result by evaluating the cdf at values of x equal to 2 and 3, given the probability of success for each trial p equal to 0.03.

```
y2 = geocdf(2,p) % cdf for x = 2  
y3 = geocdf(3,p) % cdf for x = 3
```

```
y2 =  
    0.0873
```

```
y3 =  
    0.1147
```

The returned results indicate an 8.7% chance of the car not starting if we try two days in a row, and an 11.5% chance of not starting if we try three days in a row.

geomean

Geometric mean

Syntax

```
m = geomean(x)
geomean(X,dim)
```

Description

`m = geomean(x)` calculates the geometric mean of a sample. For vectors, `geomean(x)` is the geometric mean of the elements in `x`. For matrices, `geomean(X)` is a row vector containing the geometric means of each column. For N-dimensional arrays, `geomean` operates along the first nonsingleton dimension of `X`.

`geomean(X,dim)` takes the geometric mean along the dimension `dim` of `X`.

The geometric mean is

$$m = \left[\prod_{i=1}^n x_i \right]^{\frac{1}{n}}$$

Examples

The arithmetic mean is greater than or equal to the geometric mean.

```
x = exprnd(1,10,6);
```

```
geometric = geomean(x)
```

```
geometric =
```

```
0.7466 0.6061 0.6038 0.2569 0.7539 0.3478
```

```
average = mean(x)
```

```
average =
```

1.3509 1.1583 0.9741 0.5319 1.0088 0.8122

More About

- “Geometric Distribution” on page B-59

mean | median | harmmean | trimmean

geopdf

Geometric probability density function

Syntax

```
y = geopdf(x,p)
```

Description

`y = geopdf(x,p)` returns the probability density function (pdf) of the geometric distribution at each value in `x` using the corresponding probabilities in `p`. `x` and `p` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other input. The parameters in `p` must lie on the interval $[0, 1]$.

Examples

Compute Geometric Distribution pdf

Suppose you toss a fair coin repeatedly, and a "success" occurs when the coin lands with heads facing up. What is the probability of observing exactly three tails ("failures") before tossing a heads?

To solve, determine the value of the probability density function (pdf) for the geometric distributon at x equal to 3. The probability of success (tossing a heads) p in any given trial is 0.5.

```
x = 3;  
p = 0.5;  
y = geopdf(x,p)
```

```
y =
```

```
0.0625
```

The returned value of y indicates that the probability of observing exactly three tails before tossing a heads is 0.0625.

More About

Geometric Distribution pdf

The probability distribution function (pdf) of the geometric distribution is

$$y = f(x | p) = p(1 - p)^x \quad ; \quad x = 0, 1, 2, \dots,$$

where p is the probability of success, and x is the number of failures before the first success. The result y is the probability of observing exactly x trials before a success, when the probability of success in any given trial is p . For discrete distributions, the probability distribution function is also known as the probability mass function (pmf).

geornd

Geometric random numbers

Syntax

```
r = geornd(p)
r = geornd(p,m,n,...)
r = geornd(p,[m,n,...])
```

Description

`r = geornd(p)` generates random numbers from a geometric distribution with probability parameter `p`. `p` can be a vector, a matrix, or a multidimensional array. The size of `r` is equal to the size of `p`. The parameters in `p` must lie in the interval `[0,1]`.

`r = geornd(p,m,n,...)` or `r = geornd(p,[m,n,...])` generates a multidimensional `m`-by-`n`-by-... array containing random numbers from the geometric distribution with probability parameter `p`. `p` can be a scalar or an array of the same size as `r`.

The geometric distribution is useful to model the number of failures before one success in a series of independent trials, where each trial results in either success or failure, and the probability of success in any individual trial is the constant `p`.

Examples

Generate Random Numbers from Geometric Distribution

Generate a single random number from a geometric distribution with probability parameter `p` equal to 0.01.

```
rng default % For reproducibility
p = 0.01;
r1 = geornd(0.01)
```

```
r1 =  
    20
```

The returned random number represents a single experiment in which 20 failures were observed before a success, where each independent trial has a probability of success p equal to 0.01.

Generate a 1-by-5 array of random numbers from a geometric distribution with probability parameter p equal to 0.01.

```
r2 = geornd(p,1,5)  
  
r2 =  
     9    205     9    45    231
```

Each random number in the returned array represents the result of an experiment to determine the number of failures observed before a success, where each independent trial has a probability of success p equal to 0.01.

Generate a 1-by-3 array containing one random number from each of the three geometric distributions corresponding to the parameters in the 1-by-3 array of probabilities p .

```
p = [0.01 0.1 0.5];  
r3 = geornd(p,[1 3])
```

```
r3 =  
    127     5     0
```

Each element of the returned 1-by-3 array `r3` contains one random number generated from the geometric distribution described by the corresponding parameter in `P`. For example, the first element in `r3` represents an experiment in which 127 failures were observed before a success, where each independent trial has a probability of success p equal to 0.01. The second element in `r3` represents an experiment in which 5 failures were observed before a success, where each independent trial has a probability of success p equal to 0.1. The third element in `r3` represents an experiment in which zero failures

were observed before a success - in other words, the first attempt was a success - where each independent trial has a probability of success p equal to 0.5.

geostat

Geometric mean and variance

Syntax

```
[m,v] = geostat(p)
```

Description

`[m,v] = geostat(p)` returns the mean `m` and variance `v` of a geometric distribution with corresponding probability parameters in `p`. `p` can be a vector, a matrix, or a multidimensional array. The parameters in `p` must lie in the interval `[0,1]`.

Examples

Compute Mean and Variance of Geometric Distribution

Define a probability vector that contains six different parameter values.

```
p = 1./(1:6)
```

```
p =
```

```
1.0000    0.5000    0.3333    0.2500    0.2000    0.1667
```

Compute the mean and variance of the geometric distribution that corresponds to each value contained in probability vector.

```
[m,v] = geostat(1./(1:6))
```

```
m =
```

```
0    1.0000    2.0000    3.0000    4.0000    5.0000
```

v =

0 2.0000 6.0000 12.0000 20.0000 30.0000

The returned values indicate that, for example, the mean of a geometric distribution with probability parameter p equal to 1/3 is 2, and its variance is 6.

More About

Geometric Distribution Mean and Variance

The mean of the geometric distribution is

$$\text{mean} = \frac{1-p}{p},$$

and the variance of the geometric distribution is

$$\text{var} = \frac{1-p}{p^2},$$

where p is the probability of success.

clustering.evaluation.GapEvaluation class

Package: clustering.evaluation

Superclasses: clustering.evaluation.ClusterCriterion

Gap criterion clustering evaluation object

Description

`clustering.evaluation.GapEvaluation` is an object consisting of sample data, clustering data, and gap criterion values used to evaluate the optimal number of clusters. Create a gap criterion clustering evaluation object using `evalclusters`.

Construction

`eva = evalclusters(x, clust, 'Gap')` creates a gap criterion clustering evaluation object.

`eva = evalclusters(x, clust, 'Gap', Name, Value)` creates a gap criterion clustering evaluation object using additional options specified by one or more name-value pair arguments.

Input Arguments

x — Input data

matrix

Input data, specified as an N -by- P matrix. N is the number of observations, and P is the number of variables.

Data Types: `single` | `double`

clust — Clustering algorithm

`'kmeans'` | `'linkage'` | `'gmdistribution'` | matrix of clustering solutions | function handle

Clustering algorithm, specified as one of the following.

'kmeans'	Cluster the data in <code>x</code> using the <code>kmeans</code> clustering algorithm, with <code>'EmptyAction'</code> set to <code>'singleton'</code> and <code>'Replicates'</code> set to 5.
'linkage'	Cluster the data in <code>x</code> using the <code>clusterdata</code> agglomerative clustering algorithm, with <code>'Linkage'</code> set to <code>'ward'</code> .
'gmdistribution'	Cluster the data in <code>x</code> using the <code>gmdistribution</code> Gaussian mixture distribution algorithm, with <code>'SharedCov'</code> set to <code>true</code> and <code>'Replicates'</code> set to 5.

If `Criterion` is `'CalinskHarabasz'`, `'DaviesBouldin'`, or `'silhouette'`, you can specify a clustering algorithm using the `function_handle` (@) operator. The function must be of the form `C = clustfun(DATA,K)`, where `DATA` is the data to be clustered, and `K` is the number of clusters. The output of `clustfun` must be one of the following:

- A vector of integers representing the cluster index for each observation in `DATA`. There must be `K` unique values in this vector.
- A numeric n -by- K matrix of score for n observations and K classes. In this case, the cluster index for each observation is determined by taking the largest score value in each row.

If `Criterion` is `'CalinskHarabasz'`, `'DaviesBouldin'`, or `'silhouette'`, you can also specify `clust` as a n -by- K matrix containing the proposed clustering solutions. n is the number of observations in the sample data, and K is the number of proposed clustering solutions. Column j contains the cluster indices for each of the N points in the j th clustering solution.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'KList',[1:5],'Distance','cityblock'` specifies to test 1, 2, 3, 4, and 5 clusters using the sum of absolute differences distance measure.

'B' — Number of reference data sets

100 (default) | positive integer value

Number of reference data sets generated from the reference distribution `ReferenceDistribution`, specified as the comma-separated pair consisting of `'B'` and a positive integer value.

Example: `'B', 150`

'Distance' — Distance metric

`'sqEuclidean'` (default) | `'Euclidean'` | `'cityblock'` | function | ...

Distance metric used for computing the criterion values, specified as the comma-separated pair consisting of `'Distance'` and one of the following.

<code>'sqEuclidean'</code>	Squared Euclidean distance
<code>'Euclidean'</code>	Euclidean distance
<code>'cityblock'</code>	Sum of absolute differences
<code>'cosine'</code>	One minus the cosine of the included angle between points (treated as vectors)
<code>'correlation'</code>	One minus the sample correlation between points (treated as sequences of values)
<code>'Hamming'</code>	Percentage of coordinates that differ
<code>'Jaccard'</code>	Percentage of nonzero coordinates that differ

For detailed information about each distance metric, see `pdist`.

You can also specify a function for the distance metric by using the `function_handle` (`@`) operator. The distance function must be of the form

```
d2 = distfun(XI,XJ),
```

where `XI` is a 1-by- n vector corresponding to a single row of the input matrix `X`, and `XJ` is an m_2 -by- n matrix corresponding to multiple rows of `X`. `distfun` must return an m_2 -by-1 vector of distances `d2`, whose k th element is the distance between `XI` and `XJ(k,:)`.

If `Criterion` is `'silhouette'`, you can also specify `Distance` as the output vector output created by the function `pdist`.

When `Clust` a string representing a built-in clustering algorithm, `evalclusters` uses the distance metric specified for `Distance` to cluster the data, except for the following:

- If `Clust` is `'linkage'`, and `Distance` is either `'sqEuclidean'` or `'Euclidean'`, then the clustering algorithm uses Euclidean distance and Ward linkage.

- If `Clust` is 'linkage' and `Distance` is any other metric, then the clustering algorithm uses the specified distance metric and average linkage.

In all other cases, the distance metric specified for `Distance` must match the distance metric used in the clustering algorithm to obtain meaningful results.

Example: 'Distance', 'Euclidean'

'KList' — List of number of clusters to evaluate

vector

List of number of clusters to evaluate, specified as the comma-separated pair consisting of 'KList' and a vector of positive integer values. You must specify `KList` when `clust` is a clustering algorithm name string or a function handle. When `criterion` is 'gap', `clust` must be a string or a function handle, and you must specify `KList`.

Example: 'KList', [1:6]

'ReferenceDistribution' — Reference data generation method

'PCA' (default) | 'uniform'

Reference data generation method, specified as the comma-separated pair consisting of 'ReferenceDistributions' and one of the following.

'PCA'	Generate reference data from a uniform distribution over a box aligned with the principal components of the data matrix x .
'uniform'	Generate reference data uniformly over the range of each feature in the data matrix x .

Example: 'ReferenceDistribution', 'uniform'

'SearchMethod' — Method for selecting optimal number of clusters

'globalMaxSE' (default) | 'firstMaxSE'

Method for selecting the optimal number of clusters, specified as the comma-separated pair consisting of 'SearchMethod' and one of the following.

'globalMaxSE'	Evaluate each proposed number of clusters in <code>KList</code> and select the smallest number of clusters satisfying
---------------	---

$$\text{Gap}(K) \geq \text{GAPMAX} - \text{SE}(\text{GAPMAX}),$$

where K is the number of clusters, $\text{Gap}(K)$ is the gap value for the clustering solution with K clusters, GAPMAX is the largest gap value, and $\text{SE}(\text{GAPMAX})$ is the standard error corresponding to the largest gap value.

'firstMaxSE'

Evaluate each proposed number of clusters in `KList` and select the smallest number of clusters satisfying

$$\text{Gap}(K) \geq \text{Gap}(K + 1) - \text{SE}(K + 1),$$

where K is the number of clusters, $\text{Gap}(K)$ is the gap value for the clustering solution with K clusters, and $\text{SE}(K + 1)$ is the standard error of the clustering solution with $K + 1$ clusters.

Example: 'SearchMethod', 'globalMaxSE'

Properties

B

Number of data sets generated from the reference distribution, stored as a positive integer value.

ClusteringFunction

Clustering algorithm used to cluster the input data, stored as a valid clustering algorithm name string or function handle. If the clustering solutions are provided in the input, `ClusteringFunction` is empty.

CriterionName

Name of the criterion used for clustering evaluation, stored as a valid criterion name string.

CriterionValues

Criterion values corresponding to each proposed number of clusters in `InspectedK`, stored as a vector of numerical values.

Distance

Distance measure used for clustering data, stored as a valid distance measure name string.

ExpectedLogW

Expectation of the natural logarithm of W based on the generated reference data, stored as a vector of scalar values. W is the within-cluster dispersion computed using the distance measurement **Distance**.

InspectedK

List of the number of proposed clusters for which to compute criterion values, stored as a vector of positive integer values.

LogW

Natural logarithm of W based on the input data, stored as a vector of scalar values. W is the within-cluster dispersion computed using the distance measurement **Distance**.

Missing

Logical flag for excluded data, stored as a column vector of logical values. If **Missing** equals **true**, then the corresponding value in the data matrix X is not used in the clustering solution.

NumObservations

Number of observations in the data matrix X , minus the number of missing (NaN) values in X , stored as a positive integer value.

OptimalK

Optimal number of clusters, stored as a positive integer value.

OptimalY

Optimal clustering solution corresponding to **OptimalK**, stored as a column vector of positive integer values. If the clustering solutions are provided in the input, **OptimalY** is empty.

ReferenceDistribution

Reference data generation method, stored as a valid reference distribution name string.

SE

Standard error of the natural logarithm of W with respect to the reference data for each number of clusters in `InspectedK`, stored as a vector of scalar values. W is the within-cluster dispersion computed using the distance measurement `Distance`.

SearchMethod

Method for determining the optimal number of clusters, stored as a valid search method name string.

StdLogW

Standard deviation of the natural logarithm of W with respect to the reference data for each number of clusters in `InspectedK`. W is the within-cluster dispersion computed using the distance measurement `Distance`.

X

Data used for clustering, stored as a matrix of numerical values.

Methods

increaseB

Increase reference data sets

Inherited Methods

addK

Evaluate additional numbers of clusters

plot

Plot clustering evaluation object criterion values

compact

Compact clustering evaluation object

Definitions

Gap Value

A common graphical approach to cluster evaluation involves plotting an error measurement versus several proposed numbers of clusters, and locating the “elbow” of this plot. The “elbow” occurs at the most dramatic decrease in error measurement. The gap criterion formalizes this approach by estimating the “elbow” location as the number of clusters with the largest gap value. Therefore, under the gap criterion, the optimal number of clusters occurs at the solution with the largest local or global gap value within a tolerance range.

The gap value is defined as

$$Gap_n(k) = E_n^* \{ \log(W_k) \} - \log(W_k),$$

where n is the sample size, k is the number of clusters being evaluated, and W_k is the pooled within-cluster dispersion measurement

$$W_k = \sum_{r=1}^k \frac{1}{2n_r} D_r,$$

where n_r is the number of data points in cluster r , and D_r is the sum of the pairwise distances for all points in cluster r .

The expected value $E_n^* \{ \log(W_k) \}$ is determined by Monte Carlo sampling from a reference distribution, and $\log(W_k)$ is computed from the sample data.

The gap value is defined even for clustering solutions that contain only one cluster, and can be used with any distance metric. However, the gap criterion is more computationally

expensive than other cluster evaluation criteria, because the clustering algorithm must be applied to the reference data for each proposed clustering solution.

Examples

Evaluate the Clustering Solution Using Gap Criterion

Evaluate the optimal number of clusters using the gap clustering evaluation criterion.

Load the sample data.

```
load fisheriris;
```

The data contains sepal and petal measurements from three species of iris flowers.

Evaluate the number of clusters based on the gap criterion values. Cluster the data using `kmeans`.

```
rng('default'); % For reproducibility
eva = evalclusters(meas,'kmeans','gap','KList',[1:6])
```

```
eva =
```

```
GapEvaluation with properties:
```

```
NumObservations: 150
InspecteK: [1 2 3 4 5 6]
CriterionValues: [1x6 double]
OptimalK: 4
```

The `OptimalK` value indicates that, based on the gap criterion, the optimal number of clusters is four.

Plot the gap criterion values for each number of clusters tested.

```
figure;
plot(eva);
```

Based on the plot, the maximum value of the gap criterion occurs at five clusters. However, the value at four clusters is within one standard error of the maximum, so the suggested optimal number of clusters is four.

Create a grouped scatter plot to examine the relationship between petal length and width. Group the data by suggested clusters.

```
figure;  
PetalLength = meas(:,3);  
PetalWidth = meas(:,4);  
ClusterGroup = eva.OptimalY;  
figure;  
gscatter(PetalLength,PetalWidth,ClusterGroup,'rbgk','xod^');
```

The plot shows cluster 1 in the lower-left corner, completely separated from the other three clusters. Cluster 1 contains flowers with the smallest petal widths and lengths. Cluster 4 is in the upper-right corner, and contains flowers with the largest petal widths and lengths. Clusters 2 and 3 are near the center of the plot, and contain flowers with measurements between the two extremes.

- “Property Attributes”

get

Class: dataset

Access dataset array properties

Compatibility

The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

Syntax

```
get(A)
s = get(A)
p = get(A,PropertyName)
p = get(A,{PropertyName1,PropertyName2,...})
```

Description

`get(A)` displays a list of property/value pairs for the dataset array `A`.

`s = get(A)` returns the values in a scalar structure `s` with field names given by the properties.

`p = get(A,PropertyName)` returns the value of the property specified by the string `PropertyName`.

`p = get(A,{PropertyName1,PropertyName2,...})` allows multiple property names to be specified and returns their values in a cell array.

Examples

Create a dataset array from Fisher's iris data and access the information.

```
load fisheriris
NumObs = size(meas,1);
NameObs = strcat({'Obs'},num2str((1:NumObs)','%-d'));
iris = dataset({nominal(species),'species'},...
              {meas,'SL','SW','PL','PW'},...
              'ObsNames',NameObs);

get(iris)
  Description: ''
  Units: {}
  DimNames: {'Observations' 'Variables'}
  UserData: []
  ObsNames: {150x1 cell}
  VarNames: {'species' 'SL' 'SW' 'PL' 'PW'}

ON = get(iris,'ObsNames');
ON(1:3)
ans =
    'Obs1'
    'Obs2'
    'Obs3'
```

set | summary

getlabels

Access categorical array labels

Compatibility

The `nominal` and `ordinal` array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the MATLAB categorical data type instead.

Syntax

```
labels = getlabels(A)
```

Description

`labels = getlabels(A)` returns the labels of the levels in the nominal or ordinal array `A` as a cell array of strings, `labels`. If `A` is an ordinal array, `getlabels` returns the labels in the order of the levels.

Examples

- “Change Category Labels” on page 2-9

Input Arguments

A — Nominal or ordinal array

nominal array | ordinal array

Nominal or ordinal array, specified as a `nominal` or `ordinal` array object created using `nominal` or `ordinal`.

More About

- Using nominal Objects

- Using ordinal Objects

See Also

getlevels | nominal | ordinal

getlevels

Access categorical array levels

Compatibility

The `nominal` and `ordinal` array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the MATLAB categorical data type instead.

Syntax

```
L = getlevels(A)
```

Description

`L = getlevels(A)` returns the levels in the nominal or ordinal array `A` in `L`, a vector with the same type as `A`.

Examples

- “Add and Drop Category Levels” on page 2-21
- “Merge Category Levels” on page 2-19
- “Reorder Category Levels” on page 2-11

Input Arguments

A — Nominal or ordinal array

`nominal` array | `ordinal` array

Nominal or ordinal array, specified as a `nominal` or `ordinal` array object created using `nominal` or `ordinal`.

More About

- Using nominal Objects
- Using ordinal Objects

`getlabels` | `nominal` | `ordinal`

gevcdf

Generalized extreme value cumulative distribution function

Syntax

```
p = gevcdf(x,k,sigma,mu)
p = gevcdf(x,k,sigma,mu,'upper')
```

Description

`p = gevcdf(x,k,sigma,mu)` returns the cdf of the generalized extreme value (GEV) distribution with shape parameter `k`, scale parameter `sigma`, and location parameter, `mu`, evaluated at the values in `x`. The size of `p` is the common size of the input arguments. A scalar input functions as a constant matrix of the same size as the other inputs.

`p = gevcdf(x,k,sigma,mu,'upper')` returns the complement of the cdf of the GEV distribution, using an algorithm that more accurately computes the extreme upper tail probabilities.

Default values for `k`, `sigma`, and `mu` are 0, 1, and 0, respectively.

When $k < 0$, the GEV is the type III extreme value distribution. When $k > 0$, the GEV distribution is the type II, or Frechet, extreme value distribution. If w has a Weibull distribution as computed by the `wblcdf` function, then $-w$ has a type III extreme value distribution and $1/w$ has a type II extreme value distribution. In the limit as k approaches 0, the GEV is the mirror image of the type I extreme value distribution as computed by the `evcdf` function.

The mean of the GEV distribution is not finite when $k \geq 1$, and the variance is not finite when $k \geq 1/2$. The GEV distribution has positive density only for values of X such that $k*(X-\mu)/\sigma > -1$.

`cdf` | `gevpdf` | `gevinv` | `gevstat` | `gevfit` | `gevlike` | `gevrnd`

gevfit

Generalized extreme value parameter estimates

Syntax

```
parmhat = gevfit(X)
[parmhat,parmci] = gevfit(X)
[parmhat,parmci] = gevfit(X,alpha)
[...] = gevfit(X,alpha,options)
```

Description

`parmhat = gevfit(X)` returns maximum likelihood estimates of the parameters for the generalized extreme value (GEV) distribution given the data in `X`. `parmhat(1)` is the shape parameter, `k`, `parmhat(2)` is the scale parameter, `sigma`, and `parmhat(3)` is the location parameter, `mu`.

`[parmhat,parmci] = gevfit(X)` returns 95% confidence intervals for the parameter estimates.

`[parmhat,parmci] = gevfit(X,alpha)` returns $100(1-\text{alpha})\%$ confidence intervals for the parameter estimates.

`[...] = gevfit(X,alpha,options)` specifies control parameters for the iterative algorithm used to compute ML estimates. This argument can be created by a call to `statset`. See `statset('gevfit')` for parameter names and default values. Pass in `[]` for `alpha` to use the default values.

When $k < 0$, the GEV is the type III extreme value distribution. When $k > 0$, the GEV distribution is the type II, or Frechet, extreme value distribution. If w has a Weibull distribution as computed by the `wblfit` function, then $-w$ has a type III extreme value distribution and $1/w$ has a type II extreme value distribution. In the limit as k approaches 0, the GEV is the mirror image of the type I extreme value distribution as computed by the `evfit` function.

The mean of the GEV distribution is not finite when $k \geq 1$, and the variance is not finite when $k \geq 1/2$. The GEV distribution is defined for $k*(X-\text{mu})/\text{sigma} > -1$.

mle | gevlike | gevpdf | gevCDF | gevinv | gevstat | gevrnd

gevinv

Generalized extreme value inverse cumulative distribution function

Syntax

```
X = gevinv(P,k,sigma,mu)
```

Description

`X = gevinv(P,k,sigma,mu)` returns the inverse cdf of the generalized extreme value (GEV) distribution with shape parameter `k`, scale parameter `sigma`, and location parameter `mu`, evaluated at the values in `P`. The size of `X` is the common size of the input arguments. A scalar input functions as a constant matrix of the same size as the other inputs.

Default values for `k`, `sigma`, and `mu` are 0, 1, and 0, respectively.

When $k < 0$, the GEV is the type III extreme value distribution. When $k > 0$, the GEV distribution is the type II, or Frechet, extreme value distribution. If w has a Weibull distribution as computed by the `wblinv` function, then $-w$ has a type III extreme value distribution and $1/w$ has a type II extreme value distribution. In the limit as k approaches 0, the GEV is the mirror image of the type I extreme value distribution as computed by the `evinv` function.

The mean of the GEV distribution is not finite when $k \geq 1$, and the variance is not finite when $k \geq 1/2$. The GEV distribution has positive density only for values of X such that $k*(X-\mu)/\sigma > -1$.

gevlike

Generalized extreme value negative log-likelihood

Syntax

```
nlogL = gevlike(params,data)
[nlogL,ACOV] = gevlike(params,data)
```

Description

`nlogL = gevlike(params,data)` returns the negative of the log-likelihood `nlogL` for the generalized extreme value (GEV) distribution, evaluated at parameters `params`. `params(1)` is the shape parameter, `k`, `params(2)` is the scale parameter, `sigma`, and `params(3)` is the location parameter, `mu`.

`[nlogL,ACOV] = gevlike(params,data)` returns the inverse of Fisher's information matrix, `ACOV`. If the input parameter values in `params` are the maximum likelihood estimates, the diagonal elements of `ACOV` are their asymptotic variances. `ACOV` is based on the observed Fisher's information, not the expected information.

When $k < 0$, the GEV is the type III extreme value distribution. When $k > 0$, the GEV distribution is the type II, or Frechet, extreme value distribution. If w has a Weibull distribution as computed by the `wbllike` function, then $-w$ has a type III extreme value distribution and $1/w$ has a type II extreme value distribution. In the limit as k approaches 0, the GEV is the mirror image of the type I extreme value distribution as computed by the `evlike` function.

The mean of the GEV distribution is not finite when $k \geq 1$, and the variance is not finite when $k \geq 1/2$. The GEV distribution has positive density only for values of X such that $k*(X-\mu)/\sigma > -1$.

gevpdf

Generalized extreme value probability density function

Syntax

`Y = gevpdf(X,k,sigma,mu)`

Description

`Y = gevpdf(X,k,sigma,mu)` returns the pdf of the generalized extreme value (GEV) distribution with shape parameter `k`, scale parameter `sigma`, and location parameter, `mu`, evaluated at the values in `X`. The size of `Y` is the common size of the input arguments. A scalar input functions as a constant matrix of the same size as the other inputs.

Default values for `k`, `sigma`, and `mu` are 0, 1, and 0, respectively.

When $k < 0$, the GEV is the type III extreme value distribution. When $k > 0$, the GEV distribution is the type II, or Frechet, extreme value distribution. If w has a Weibull distribution as computed by the `wblpdf` function, then $-w$ has a type III extreme value distribution and $1/w$ has a type II extreme value distribution. In the limit as k approaches 0, the GEV is the mirror image of the type I extreme value distribution as computed by the `evcdf` function.

The mean of the GEV distribution is not finite when $k \geq 1$, and the variance is not finite when $k \geq 1/2$. The GEV distribution has positive density only for values of X such that $k*(X-mu)/sigma > -1$.

gevrnd

Generalized extreme value random numbers

Syntax

```
R = gevrnd(k, sigma, mu)
R = gevrnd(k, sigma, mu, m, n, ...)
R = gevrnd(k, sigma, mu, [m, n, ...])
```

Description

`R = gevrnd(k, sigma, mu)` returns an array of random numbers chosen from the generalized extreme value (GEV) distribution with shape parameter `k`, scale parameter `sigma`, and location parameter, `mu`. The size of `R` is the common size of the input arguments if all are arrays. If any parameter is a scalar, the size of `R` is the size of the other parameters.

`R = gevrnd(k, sigma, mu, m, n, ...)` or `R = gevrnd(k, sigma, mu, [m, n, ...])` generates an `m`-by-`n`-by-... array containing random numbers from the GEV distribution with parameters `k`, `sigma`, and `mu`. The `k`, `sigma`, `mu` parameters can each be scalars or arrays of the same size as `R`.

When $k < 0$, the GEV is the type III extreme value distribution. When $k > 0$, the GEV distribution is the type II, or Frechet, extreme value distribution. If w has a Weibull distribution as computed by the `wblrnd` function, then $-w$ has a type III extreme value distribution and $1/w$ has a type II extreme value distribution. In the limit as k approaches 0, the GEV is the mirror image of the type I extreme value distribution as computed by the `evrnd` function.

The mean of the GEV distribution is not finite when $k \geq 1$, and the variance is not finite when $k \geq 1/2$. The GEV distribution has positive density only for values of X such that $k*(X-\mu)/\sigma > -1$.

gevstat

Generalized extreme value mean and variance

Syntax

```
[M,V] = gevstat(k,sigma,mu)
```

Description

`[M,V] = gevstat(k,sigma,mu)` returns the mean of and variance for the generalized extreme value (GEV) distribution with shape parameter `k`, scale parameter `sigma`, and location parameter, `mu`. The sizes of `M` and `V` are the common size of the input arguments. A scalar input functions as a constant matrix of the same size as the other inputs.

Default values for `k`, `sigma`, and `mu` are 0, 1, and 0, respectively.

When $k < 0$, the GEV is the type III extreme value distribution. When $k > 0$, the GEV distribution is the type II, or Frechet, extreme value distribution. If w has a Weibull distribution as computed by the `wblstat` function, then $-w$ has a type III extreme value distribution and $1/w$ has a type II extreme value distribution. In the limit as k approaches 0, the GEV is the mirror image of the type I extreme value distribution as computed by the `evstat` function.

The mean of the GEV distribution is not finite when $k \geq 1$, and the variance is not finite when $k \geq 1/2$. The GEV distribution has positive density only for values of X such that $k*(X-mu)/sigma > -1$.

gline

Interactively add line to plot

Syntax

```
gline(h)
gline
hline = gline(...)
```

Description

`gline(h)` allows you to draw a line segment in the figure with handle `h` by clicking the pointer at the two endpoints. A rubber-band line tracks the pointer movement.

`gline` with no input arguments defaults to `h = gcf` and draws in the current figure.

`hline = gline(...)` returns the handle `hline` to the line.

Examples

Use `gline` to connect two points in a plot:

```
x = 1:10;

y = x + randn(1,10);
scatter(x,y,25,'b','*')

lsline

mu = mean(y);
hold on
plot([1 10],[mu mu],'ro')

hline = gline; % Connect circles
set(hline,'Color','r')
```

**See Also**

refline | refcurve | lsline

glmfit

Generalized linear model regression

Syntax

```
b = glmfit(X,y,distr)
b = glmfit(X,y,distr,param1,val1,param2,val2,...)
[b,dev] = glmfit(...)
[b,dev,stats] = glmfit(...)
```

Description

`b = glmfit(X,y,distr)` returns a $(p + 1)$ -by-1 vector **b** of coefficient estimates for a generalized linear regression of the responses in **y** on the predictors in **X**, using the distribution *distr*. **X** is an n -by- p matrix of p predictors at each of n observations. *distr* can be any of the following strings: 'binomial', 'gamma', 'inverse gaussian', 'normal' (the default), and 'poisson'.

In most cases, **y** is an n -by-1 vector of observed responses. For the binomial distribution, **y** can be a binary vector indicating success or failure at each observation, or a two column matrix with the first column indicating the number of successes for each observation and the second column indicating the number of trials for each observation.

This syntax uses the canonical link (see below) to relate the distribution to the predictors.

Note: By default, `glmfit` adds a first column of 1s to **X**, corresponding to a constant term in the model. Do not enter a column of 1s directly into **X**. You can change the default behavior of `glmfit` using the 'constant' parameter, below.

`glmfit` treats NaNs in either **X** or **y** as missing values, and ignores them.

`b = glmfit(X,y,distr,param1,val1,param2,val2,...)` additionally allows you to specify optional parameter name/value pairs to control the model fit. Acceptable parameters are as follows.

Parameter	Value	Description
'link'	'identity', default for the distribution 'normal'	$\mu = Xb$
	'log', default for the distribution 'poisson'	$\log(\mu) = Xb$
	'logit', default for the distribution 'binomial'	$\log(\mu/(1 - \mu)) = Xb$
	'probit'	$\text{norminv}(\mu) = Xb$
	'comploglog'	$\log(-\log(1 - \mu)) = Xb$
	'reciprocal', default for the distribution 'gamma'	$1/\mu = Xb$
	'loglog'	$\log(-\log(\mu)) = Xb$
	p (a number), default for the distribution 'inverse gaussian' (with $p = -2$)	$\mu^p = Xb$
	cell array of the form {FL FD FI}, containing three function handles, created using @, that define the link (FL), the derivative of the link (FD), and the inverse link (FI).	<p>Custom-defined link function. You must provide</p> <ul style="list-style-type: none"> • FL(mu) • FD = dFL(mu) / dmu • FI = FL^(-1)
'estdisp'	'on'	Estimates a dispersion parameter for the binomial or Poisson distribution.
	'off' (Default for binomial or Poisson distribution)	Uses the theoretical value of 1.0 for those distributions.
'offset'	Vector	Used as an additional predictor variable, but with a coefficient value fixed at 1.0.
'weights'	Vector of prior weights, such as the inverses of the relative variance of each observation	

Parameter	Value	Description
'constant'	'on' (default)	Includes a constant term in the model. The coefficient of the constant term is the first element of b .
	'off'	Omit the constant term.

`[b,dev] = glmfit(...)` returns `dev`, the deviance of the fit at the solution vector. The deviance is a generalization of the residual sum of squares. It is possible to perform an analysis of deviance to compare several models, each a subset of the other, and to test whether the model with more terms is significantly better than the model with fewer terms.

`[b,dev,stats] = glmfit(...)` returns `dev` and `stats`.

`stats` is a structure with the following fields:

- `beta` — Coefficient estimates `b`
- `dfe` — Degrees of freedom for error
- `sfit` — Estimated dispersion parameter
- `s` — Theoretical or estimated dispersion parameter
- `estdisp` — 0 when the `'estdisp'` name-value pair argument value is `'off'` and 1 when the `'estdisp'` name-value pair argument value is `'on'`.
- `covb` — Estimated covariance matrix for `B`
- `se` — Vector of standard errors of the coefficient estimates `b`
- `coeffcorr` — Correlation matrix for `b`
- `t` — t statistics for `b`
- `p` — p -values for `b`
- `resid` — Vector of residuals
- `residp` — Vector of Pearson residuals
- `residd` — Vector of deviance residuals
- `resida` — Vector of Anscombe residuals

If you estimate a dispersion parameter for the binomial or Poisson distribution, then `stats.s` is set equal to `stats.sfit`. Also, the elements of `stats.se` differ by the factor `stats.s` from their theoretical values.

Examples

Fit Generalized Linear Model with Probit Link

Enter sample data.

```
x = [2100 2300 2500 2700 2900 3100 ...  
     3300 3500 3700 3900 4100 4300]';  
n = [48 42 31 34 31 21 23 23 21 16 17 21]';  
y = [1 2 0 3 8 8 14 17 19 15 17 21]';
```

Each y value is the number of successes in corresponding number of trials in n , and x contains the predictor variable values.

Fit a probit regression model for y on x .

```
b = glmfit(x,[y n], 'binomial', 'link', 'probit');
```

Compute the estimated number of successes and plot the percent observed and estimated percent success versus the x values.

```
yfit = glmval(b,x, 'probit', 'size', n);  
plot(x, y./n, 'o', x, yfit./n, '-', 'LineWidth', 2)
```

Use Custom-defined Link Function

Load the sample data.

```
load fisheriris
```

The column vector, `species`, consists of iris flowers of three different species, `setosa`, `versicolor`, `virginica`. The double matrix `meas` consists of four types of measurements on the flowers, the length and width of sepals and petals in centimeters, respectively.

Define the response and predictor variables.

```
X = meas(51:end,:);
y = strcmp('versicolor',species(51:end));
```

Define three function handles, created using `@`, that define the link, the derivative of the link, and the inverse link for a logit link function, and store them in a cell array.

```
link = @(mu) log(mu ./ (1-mu));
```

```
derlink = @(mu) 1 ./ (mu .* (1-mu));  
invlink = @(resp) 1 ./ (1 + exp(-resp));  
F = {link, derlink, invlink};
```

Fit a logistic regression using `glmfit` with the link function you defined.

```
b = glmfit(X,y,'binomial','link',F)
```

```
b =  
  
    42.6378  
     2.4652  
     6.6809  
    -9.4294  
   -18.2861
```

Now, fit a generalized linear model using the `logit` link function and compare the results.

```
b = glmfit(X,y,'binomial','link','logit')
```

```
b =  
  
    42.6378  
     2.4652  
     6.6809  
    -9.4294  
   -18.2861
```

glmval

Generalized linear model values

Syntax

```
yhat = glmval(b,X,link)
[yhat,dylo,dyhi] = glmval(b,X,link,stats)
[...] = glmval(...,param1,val1,param2,val2,...)
```

Description

`yhat = glmval(b,X,link)` computes predicted values for the generalized linear model with link function `link` and predictors `X`. Distinct predictor variables should appear in different columns of `X`. `b` is a vector of coefficient estimates as returned by the `glmfit` function. `link` can be any of the strings or the custom-defined link functions used as values for the 'link' name-value pair argument in the `glmfit` function.

Note: By default, `glmval` adds a first column of 1s to `X`, corresponding to a constant term in the model. Do not enter a column of 1s directly into `X`. You can change the default behavior of `glmval` using the 'constant' parameter, below.

`[yhat,dylo,dyhi] = glmval(b,X,link,stats)` also computes 95% confidence bounds for the predicted values. When the `stats` structure output of the `glmfit` function is specified, `dylo` and `dyhi` are also returned. `dylo` and `dyhi` define a lower confidence bound of `yhat-dylo`, and an upper confidence bound of `yhat+dyhi`. Confidence bounds are nonsimultaneous, and apply to the fitted curve, not to a new observation.

`[...] = glmval(...,param1,val1,param2,val2,...)` specifies optional parameter name/value pairs to control the predicted values. Acceptable parameters are:

Parameter	Value
'confidence' — the confidence level for the confidence bounds	A scalar between 0 and 1

Parameter	Value
'size' — the size parameter (N) for a binomial model	A scalar, or a vector with one value for each row of X
'offset' — used as an additional predictor variable, but with a coefficient value fixed at 1.0	A vector
'constant'	<ul style="list-style-type: none"> 'on' — Includes a constant term in the model. The coefficient of the constant term is the first element of b. 'off' — Omit the constant term
'simultaneous' — Compute simultaneous confidence intervals (true), or compute non-simultaneous confidence intervals (default false)	true or false

Examples

Fit Generalized Linear Model with Probit Link

Enter sample data.

```
x = [2100 2300 2500 2700 2900 3100 ...
      3300 3500 3700 3900 4100 4300]';
n = [48 42 31 34 31 21 23 23 21 16 17 21]';
y = [1 2 0 3 8 8 14 17 19 15 17 21]';
```

Each **y** value is the number of successes in corresponding number of trials in **n**, and **x** contains the predictor variable values.

Fit a generalized linear model for **y** on **x** using a probit link function.

```
b = glmfit(x,[y n], 'binomial', 'link', 'probit');
```

Compute the estimated number of successes and plot the observed and estimated percent success versus the **x** values.

```
yfit = glmval(b,x,'probit','size',n);
plot(x, y./n, 'o', x, yfit./n, '-', 'LineWidth', 2)
```

Use Custom-defined Link Function

Enter sample data.

```
x = [2100 2300 2500 2700 2900 3100 ...
      3300 3500 3700 3900 4100 4300]';
n = [48 42 31 34 31 21 23 23 21 16 17 21]';
y = [1 2 0 3 8 8 14 17 19 15 17 21]';
```

Each y value is the number of successes in corresponding number of trials in n , and x contains the predictor variable values.

Now define three function handles, created using `@`, that define the link, the derivative of the link, and the inverse link for a probit link function, and store them in a cell array.

```
link = @(mu) norminv(mu);
derlink = @(mu) 1 ./ normpdf(norminv(mu));
invlink = @(resp) normcdf(resp);
```

```
F = {link, derlink, invlink};
```

Fit a generalized linear model for y on x using the link function you defined.

```
b = glmfit(x,[y n], 'binomial', 'link', F);
```

Compute the estimated number of successes and plot the observed and estimated percent success versus the x values.

```
yfit = glmval(b,x,F, 'size', n);  
plot(x, y./n, 'o', x, yfit./n, '-', 'LineWidth', 2)
```

glyphplot

Glyph plot

Syntax

```
glyphplot(X)
glyphplot(X, 'glyph', 'face')
glyphplot(X, 'glyph', 'face', 'features', f)
glyphplot(X, ..., 'grid', [rows, cols])
glyphplot(X, ..., 'grid', [rows, cols], 'page', p)
glyphplot(X, ..., 'centers', C)
glyphplot(X, ..., 'centers', C, 'radius', r)
glyphplot(X, ..., 'obslabels', labels)
glyphplot(X, ..., 'standardize', method)
glyphplot(X, ..., prop1, val1, ...)
h = glyphplot(X, ...)
```

Description

`glyphplot(X)` creates a star plot from the multivariate data in the n -by- p matrix X . Rows of X correspond to observations, columns to variables. A star plot represents each observation as a “star” whose i th spoke is proportional in length to the i th coordinate of that observation. `glyphplot` standardizes X by shifting and scaling each column separately onto the interval $[0, 1]$ before making the plot, and centers the glyphs on a rectangular grid that is as close to square as possible. `glyphplot` treats NaNs in X as missing values, and does not plot the corresponding rows of X . `glyphplot(X, 'glyph', 'star')` is a synonym for `glyphplot(X)`.

`glyphplot(X, 'glyph', 'face')` creates a face plot from X . A face plot represents each observation as a “face,” whose i th facial feature is drawn with a characteristic proportional to the i th coordinate of that observation. The features are described in “Face Features” on page 21-1837Face Features.

`glyphplot(X, 'glyph', 'face', 'features', f)` creates a face plot where the i th element of the index vector f defines which facial feature will represent the i th column of

X . f must contain integers from 0 to 17, where 0 indicate that the corresponding column of X should not be plotted. See “Face Features” on page 21-1837 for more information.

`glyphplot(X, ..., 'grid', [rows, cols])` organizes the glyphs into a rows-by-cols grid.

`glyphplot(X, ..., 'grid', [rows, cols], 'page', p)` organizes the glyph into one or more pages of a rows-by-cols grid, and displays the page p . If p is a vector, `glyphplot` displays multiple pages in succession. If p is 'all', `glyphplot` displays all pages. If p is 'scroll', `glyphplot` displays a single plot with a scrollbar.

`glyphplot(X, ..., 'centers', C)` creates a plot with each glyph centered at the locations in the n -by-2 matrix C .

`glyphplot(X, ..., 'centers', C, 'radius', r)` creates a plot with glyphs positioned using C , and scale the glyphs so the largest has radius r .

`glyphplot(X, ..., 'obslabels', labels)` labels each glyph with the text in the character array or cell array of strings `labels`. By default, the glyphs are labelled 1:N. Use '' for blank labels.

`glyphplot(X, ..., 'standardize', method)` standardizes X before making the plot. Choices for *method* are

- 'column' — Maps each column of X separately onto the interval [0,1]. This is the default.
- 'matrix' — Maps the entire matrix X onto the interval [0, 1].
- 'PCA' — Transforms X to its principal component scores, in order of decreasing eigenvalue, and maps each one onto the interval [0, 1].
- 'off' — No standardization. Negative values in X may make a star plot uninterpretable.

`glyphplot(X, ..., prop1, val1, ...)` sets properties to the specified property values for all line graphics objects created by `glyphplot`.

`h = glyphplot(X, ...)` returns a matrix of handles to the graphics objects created by `glyphplot`. For a star plot, `h(:, 1)` and `h(:, 2)` contain handles to the line objects for each star's perimeter and spokes, respectively. For a face plot, `h(:, 1)` and `h(:, 2)` contain object handles to the lines making up each face and to the pupils, respectively. `h(:, 3)` contains handles to the text objects for the labels, if present.

Face Features

The following table describes the correspondence between the columns of the vector f , the value of the 'Features' input parameter, and the facial features of the glyph plot. If X has fewer than 17 columns, unused features are displayed at their default value.

Column	Facial Feature
1	Size of face
2	Forehead/jaw relative arc length
3	Shape of forehead
4	Shape of jaw
5	Width between eyes
6	Vertical position of eyes
7	Height of eyes
8	Width of eyes (this also affects eyebrow width)
9	Angle of eyes (this also affects eyebrow angle)
10	Vertical position of eyebrows
11	Width of eyebrows (relative to eyes)
12	Angle of eyebrows (relative to eyes)
13	Direction of pupils
14	Length of nose
15	Vertical position of mouth
16	Shape of mouth
17	Mouth arc length

Examples

Star and Face Plots of Multivariate Data

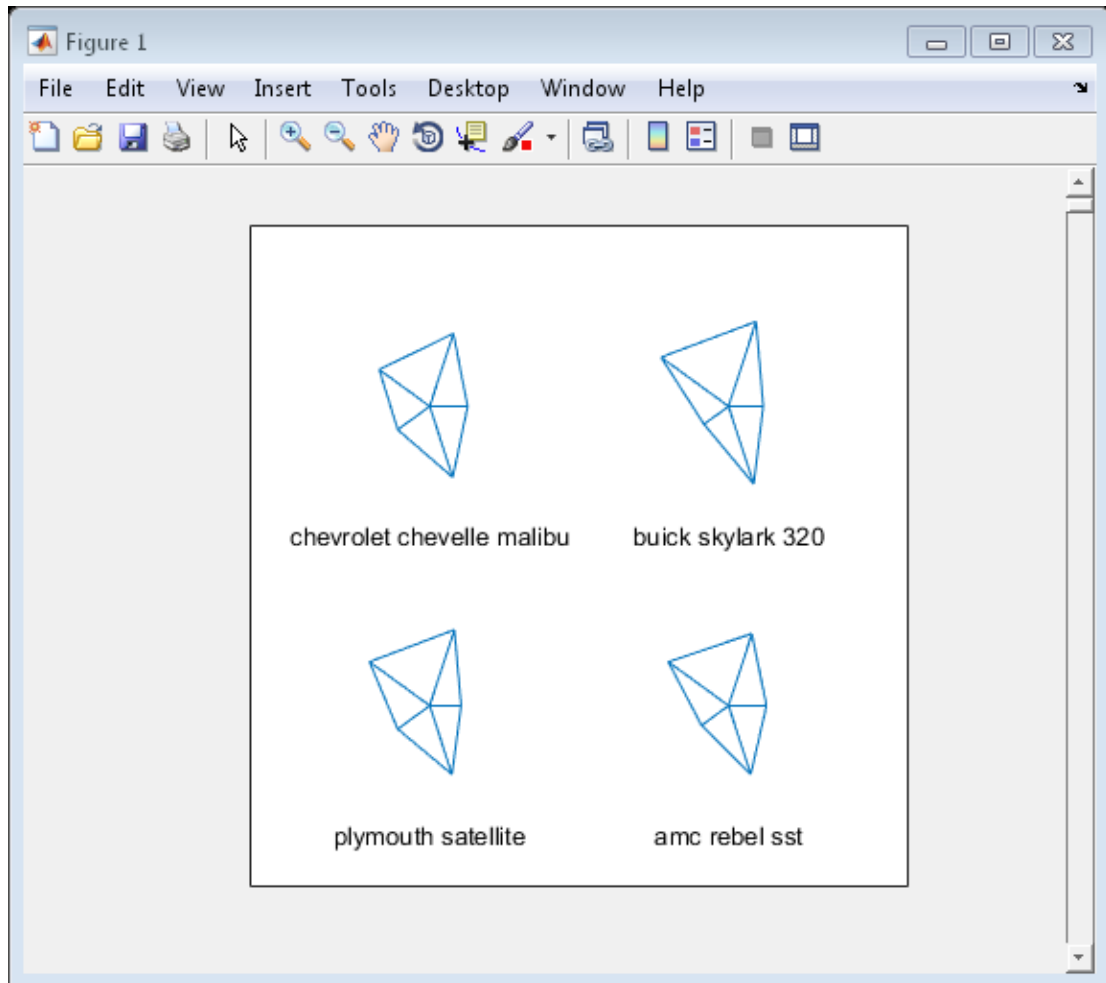

Load the sample data.

```
load carsmall
```

```
X = [Acceleration Displacement Horsepower MPG Weight];
```

Create a star plot of the data in X . Standardize the data before plotting.

```
glyphplot(X, 'standardize', 'column', 'obslabels', Model, 'grid', [2 2], ...
           'page', 'scroll');
```

Create a faceplot of the data in X .

```
glyphplot(X, 'glyph', 'face', 'obslabels', Model, 'grid', [2 3], 'page', 9);
```

gmdistribution class

Gaussian mixture models

Description

An object of the `gmdistribution` class defines a Gaussian mixture distribution, which is a multivariate distribution that consists of a mixture of one or more multivariate Gaussian distribution components. The number of components for a given `gmdistribution` object is fixed. Each multivariate Gaussian component is defined by its mean and covariance, and the mixture is defined by a vector of mixing proportions.

Construction

To create a Gaussian mixture distribution by specifying the distribution parameters, use the `gmdistribution` constructor. To fit a Gaussian mixture distribution model to data, use `fitgmdist`.

<code>fit</code>	Gaussian mixture parameter estimates
<code>.gmdistribution</code>	Construct Gaussian mixture distribution

Properties

All objects of the class have the properties listed in the following table.

<code>CovarianceType</code>	Type of covariance matrices
<code>DistributionName</code>	Type of distribution
<code>mu</code>	Input matrix of means μ
<code>NumComponents</code>	Number k of mixture components

NumVariables	Dimension d of multivariate Gaussian distributions
ComponentProportion	Input vector of mixing proportions
SharedCovariance	<code>true</code> if all covariance matrices are restricted to be the same
Sigma	Input array of covariances

Objects constructed with `fitgmdist` have the additional properties listed in the following table.

AIC	Akaike Information Criterion
BIC	Bayes Information Criterion
Converged	Determine if algorithm converged
NumIterations	Number of iterations
NegativeLogLikelihood	Negative of log-likelihood
RegularizationValue	Value of 'Regularize' parameter

Methods

<code>cdf</code>	Cumulative distribution function for Gaussian mixture distribution
<code>cluster</code>	Construct clusters from Gaussian mixture distribution

disp	Display Gaussian mixture distribution object
display	Display Gaussian mixture distribution object
fit	Gaussian mixture parameter estimates
mahal	Mahalanobis distance to component means
pdf	Probability density function for Gaussian mixture distribution
posterior	Posterior probabilities of components
random	Random numbers from Gaussian mixture distribution
subsasgn	Subscripted reference for Gaussian mixture distribution object
subsref	Subscripted reference for Gaussian mixture distribution object

Copy Semantics

Value. To learn how value classes affect copy operations, see “Copying Objects” in the MATLAB documentation.

Examples

Fit a Gaussian Mixture Model

Generate data from a mixture of two bivariate Gaussian distributions using the `mvnrnd` function. Fit the resulting data.

Generate the data using 1000 points from each distribution.

```
MU1 = [1 2];  
SIGMA1 = [2 0; 0 .5];  
MU2 = [-3 -5];  
SIGMA2 = [1 0; 0 1];  
X = [mvnrnd(MU1,SIGMA1,1000);mvnrnd(MU2,SIGMA2,1000)];  
  
scatter(X(:,1),X(:,2),10,'.')  
hold on
```

Fit a two-component Gaussian mixture model.

```
options = statset('Display','final');  
obj = fitgmdist(X,2,'Options',options);
```

```
18 iterations, log-likelihood = -7058.35
```

Plot the fit.

```
h = ezcontour(@(x,y)pdf(obj,[x y]),[-8 6],[-8 6]);
```

fitgmdist

gmdistribution

Class: gmdistribution

Construct Gaussian mixture distribution

Syntax

```
obj = gmdistribution(mu,sigma,p)
```

Description

`obj = gmdistribution(mu,sigma,p)` constructs an object `obj` of the `gmdistribution` class defining a Gaussian mixture distribution.

`mu` is a k -by- d matrix specifying the d -dimensional mean of each of the k components.

`sigma` specifies the covariance of each component. The size of `sigma` is:

- d -by- d -by- k if there are no restrictions on the form of the covariance. In this case, `sigma(:, :, I)` is the covariance of component `I`.
- 1-by- d -by- k if the covariance matrices are restricted to be diagonal, but not restricted to be same across components. In this case, `sigma(:, :, I)` contains the diagonal elements of the covariance of component `I`.
- d -by- d matrix if the covariance matrices are restricted to be the same across components, but not restricted to be diagonal. In this case, `sigma` is the pooled estimate of covariance.
- 1-by- d if the covariance matrices are restricted to be diagonal and the same across components. In this case, `sigma` contains the diagonal elements of the pooled estimate of covariance.

`p` is an optional 1-by- k vector specifying the mixing proportions of each component. If `p` does not sum to 1, `gmdistribution` normalizes it. The default is equal proportions.

Examples

Construct a Gaussian Mixture Distribution

Create a `gmdistribution` distribution defining a two-component mixture of bivariate Gaussian distributions.

```
mu = [1 2;-3 -5];  
sigma = cat(3,[2 0;0 .5],[1 0;0 1]);  
p = ones(1,2)/2;  
obj = gmdistribution(mu,sigma,p);  
  
ezsurf(@(x,y)pdf(obj,[x y]),[-10 10],[-10 10])
```

References

- [1] McLachlan, G., and D. Peel. *Finite Mixture Models*. Hoboken, NJ: John Wiley & Sons, Inc., 2000.

gname

Add case names to plot

Syntax

```
gname(cases)
gname
h = gname(cases,line_handle)
```

Description

`gname(cases)` displays a figure window and waits for you to press a mouse button or a keyboard key. The input argument `cases` is a character array or a cell array of strings, in which each row of the character array or each element of the cell array contains the case name of a point. Moving the mouse over the graph displays a pair of cross-hairs. If you position the cross-hairs near a point with the mouse and click once, the graph displays the label corresponding to that point. Alternatively, you can click and drag the mouse to create a rectangle around several points. When you release the mouse button, the graph displays the labels for all points in the rectangle. Right-click a point to remove its label. When you are done labelling points, press the **Enter** or **Escape** key to stop labeling.

`gname` with no arguments labels each case with its case number.

`cases` typically contains unique case names for each point, and is a cell array of strings or a character matrix with each row representing a name. `cases` can also be any grouping variable, which `gname` converts to labels.

`h = gname(cases,line_handle)` returns a vector of handles to the text objects on the plot. Use the scalar `line_handle` to identify the correct line if there is more than one line object on the plot.

You can use `gname` to label plots created by the `plot`, `scatter`, `gscatter`, `plotmatrix`, and `gplotmatrix` functions.

Examples

This example uses the city ratings data sets to find out which cities are the best and worst for education and the arts.

```
load cities
education = ratings(:,6);
arts = ratings(:,7);
plot(education,arts,'+')
gname(names)
```

Click the point at the top of the graph to display its label, “New York.”

gpcdf

Generalized Pareto cumulative distribution function

Syntax

```
p = gpcdf(x,x,sigma,theta)
p = gpcdf(x,k,sigma,theta,'upper')
```

Description

`p = gpcdf(x,x,sigma,theta)` returns the cdf of the generalized Pareto (GP) distribution with the tail index (shape) parameter `k`, scale parameter `sigma`, and threshold (location) parameter, `theta`, evaluated at the values in `x`. The size of `p` is the common size of the input arguments. A scalar input functions as a constant matrix of the same size as the other inputs.

`p = gpcdf(x,k,sigma,theta,'upper')` returns the complement of the cdf of the generalized Pareto (GP) distribution, using an algorithm that more accurately computes the extreme upper tail probabilities.

Default values for `k`, `sigma`, and `theta` are 0, 1, and 0, respectively.

When `k = 0` and `theta = 0`, the GP is equivalent to the exponential distribution. When `k > 0` and `theta = sigma/k`, the GP is equivalent to the Pareto distribution. The mean of the GP is not finite when $k \geq 1$, and the variance is not finite when $k \geq 1/2$. When $k \geq 0$, the GP has positive density for

$x > \text{theta}$, or, when

$$k < 0, 0 \leq \frac{x-\theta}{\sigma} \leq -\frac{1}{k}.$$

gpfit

Generalized Pareto parameter estimates

Syntax

```
parmhat = gpfit(X)
[parmhat,parmci] = gpfit(X)
[parmhat,parmci] = gpfit(X,alpha)
[...] = gpfit(X,alpha,options)
```

Description

`parmhat = gpfit(X)` returns maximum likelihood estimates of the parameters for the two-parameter generalized Pareto (GP) distribution given the data in `X`. `parmhat(1)` is the tail index (shape) parameter, `K` and `parmhat(2)` is the scale parameter, `sigma`. `gpfit` does not fit a threshold (location) parameter.

`[parmhat,parmci] = gpfit(X)` returns 95% confidence intervals for the parameter estimates.

`[parmhat,parmci] = gpfit(X,alpha)` returns $100(1-\alpha)\%$ confidence intervals for the parameter estimates.

`[...] = gpfit(X,alpha,options)` specifies control parameters for the iterative algorithm used to compute ML estimates. This argument can be created by a call to `statset`. See `statset('gpfit')` for parameter names and default values.

Other functions for the generalized Pareto, such as `gpcdf` allow a threshold parameter, `theta`. However, `gpfit` does not estimate `theta`. It is assumed to be known, and subtracted from `X` before calling `gpfit`.

When `K = 0` and `theta = 0`, the GP is equivalent to the exponential distribution. When `K > 0` and `theta = sigma/K`, the GP is equivalent to the Pareto distribution. The mean of the GP is not finite when $K \geq 1$, and the variance is not finite when $K \geq 1/2$. When $K \geq 0$, the GP has positive density for

$X > \text{theta}$, or, when $K < 0$, for

$$0 \leq \frac{x - \theta}{\sigma} \leq -\frac{1}{k}$$

gpinv

Generalized Pareto inverse cumulative distribution function

Syntax

`X = gpinv(P,K,sigma,theta)`

Description

`X = gpinv(P,K,sigma,theta)` returns the inverse cdf for a generalized Pareto (GP) distribution with tail index (shape) parameter `K`, scale parameter `sigma`, and threshold (location) parameter `theta`, evaluated at the values in `P`. The size of `X` is the common size of the input arguments. A scalar input functions as a constant matrix of the same size as the other inputs.

Default values for `K`, `sigma`, and `theta` are 0, 1, and 0, respectively.

When `K = 0` and `theta = 0`, the GP is equivalent to the exponential distribution. When `K > 0` and `theta = sigma/K`, the GP is equivalent to the Pareto distribution. The mean of the GP is not finite when $K \geq 1$, and the variance is not finite when $K \geq 1/2$. When $K \geq 0$, the GP has positive density for

$X > \text{theta}$, or, when

$$K < 0, 0 \leq \frac{x-\theta}{\sigma} \leq -\frac{1}{k}.$$

icdf | gpcdf | gppdf | gpstat | gpfit | gplike | gprnd

gplike

Generalized Pareto negative log-likelihood

Syntax

```
nlogL = gplike(params,data)
[nlogL,ACOV] = gplike(params,data)
```

Description

`nlogL = gplike(params,data)` returns the negative of the log-likelihood `nlogL` for the two-parameter generalized Pareto (GP) distribution, evaluated at parameters `params`. `params(1)` is the tail index (shape) parameter, `K`, `params(2)` is the scale parameter, `sigma`, and `params(3)` is the threshold (location) parameter, `mu`.

`[nlogL,ACOV] = gplike(params,data)` returns the inverse of Fisher's information matrix, `ACOV`. If the input parameter values in `params` are the maximum likelihood estimates, the diagonal elements of `ACOV` are their asymptotic variances. `ACOV` is based on the observed Fisher's information, not the expected information.

When `K = 0` and `theta = 0`, the GP is equivalent to the exponential distribution. When `K > 0` and `theta = sigma/K`, the GP is equivalent to the Pareto distribution. The mean of the GP is not finite when $K \geq 1$, and the variance is not finite when $K \geq 1/2$. When $K \geq 0$, the GP has positive density for

$X > \text{theta}$, or, when

$$K < 0, 0 \leq \frac{x - \theta}{\sigma} \leq -\frac{1}{k}.$$

gppdf

Generalized Pareto probability density function

Syntax

$P = \text{gppdf}(X, K, \text{sigma}, \text{theta})$

Description

$P = \text{gppdf}(X, K, \text{sigma}, \text{theta})$ returns the pdf of the generalized Pareto (GP) distribution with the tail index (shape) parameter K , scale parameter sigma , and threshold (location) parameter, theta , evaluated at the values in X . The size of P is the common size of the input arguments. A scalar input functions as a constant matrix of the same size as the other inputs.

Default values for K , sigma , and theta are 0, 1, and 0, respectively.

When $K = 0$ and $\text{theta} = 0$, the GP is equivalent to the exponential distribution. When $K > 0$ and $\text{theta} = \text{sigma}/K$, the GP is equivalent to the Pareto distribution. The mean of the GP is not finite when $K \geq 1$, and the variance is not finite when $K \geq 1/2$. When $K \geq 0$, the GP has positive density for

$X > \text{theta}$, or, when

$$K < 0, 0 \leq \frac{x - \theta}{\sigma} \leq -\frac{1}{k}.$$

gplotmatrix

Matrix of scatter plots by group

Syntax

```
gplotmatrix(x,y,group)
gplotmatrix(x,y,group,clr,sym,siz)
gplotmatrix(x,y,group,clr,sym,siz,doleg)
gplotmatrix(x,y,group,clr,sym,siz,doleg,dispopt)
gplotmatrix(x,y,group,clr,sym,siz,doleg,dispopt,xnam,ynam)
[h,ax,bigax] = gplotmatrix(...)
```

Description

`gplotmatrix(x,y,group)` creates a matrix of scatter plots. Each individual set of axes in the resulting figure contains a scatter plot of a column of `x` against a column of `y`. All plots are grouped by the grouping variable `group`.

`x` and `y` are matrices with the same number of rows. If `x` has p columns and `y` has q columns, the figure contains a p -by- q matrix of scatter plots. If you omit `y` or specify it as the empty matrix, `[]`, `gplotmatrix` creates a square matrix of scatter plots of columns of `x` against each other.

`group` is a grouping variable that can be a categorical variable, vector, string array, or cell array of strings. `group` must have the same number of rows as `x` and `y`. Points with the same value of `group` are placed in the same group, and appear on the graph with the same marker and color. Alternatively, `group` can be a cell array containing several grouping variables (such as `{g1 g2 g3}`); in that case, observations are in the same group if they have common values of all grouping variables.

`gplotmatrix(x,y,group,clr,sym,siz)` specifies the color, marker type, and size for each group. `clr` is a string array of colors recognized by the `plot` function. The default for `clr` is `'bgrcmk'`. `sym` is a string array of symbols recognized by the `plot` command, with the default value `'.'`. `siz` is a vector of sizes, with the default determined by the `DefaultLineMarkerSize` property. If you do not specify enough values for all groups, `gplotmatrix` cycles through the specified values as needed.

`gplotmatrix(x,y,group,clr,sym,siz,doleg)` controls whether a legend is displayed on the graph (*doleg* is 'on', the default) or not (*doleg* is 'off').

`gplotmatrix(x,y,group,clr,sym,siz,doleg,dispopt)` controls what appears along the diagonal of a plot matrix of *y* versus *x*. Allowable values are 'none', to leave the diagonals blank, 'hist', to plot histograms, or 'variable', to write the variable names. `gplotmatrix` displays histograms along the diagonal only when there is only one variable (i.e., `gplotmatrix(x,[],[],[],[],[],[],'hist')`).

`gplotmatrix(x,y,group,clr,sym,siz,doleg,dispopt,xnam,yname)` specifies the names of the columns in the *x* and *y* arrays. These names are used to label the *x*- and *y*-axes. *xnam* and *yname* must be character arrays or cell arrays of strings, with one name for each column of *x* and *y*, respectively.

`[h,ax,bigax] = gplotmatrix(...)` returns three arrays of handles. *h* is an array of handles to the lines on the graphs. The array's third dimension corresponds to groups in *G*. *ax* is a matrix of handles to the axes of the individual plots. If *dispopt* is 'hist', *ax* contains one extra row of handles to invisible axes in which the histograms are plotted. *bigax* is a handle to big (invisible) axes framing the entire plot matrix. *bigax* is fixed to point to the current axes, so a subsequent `title`, `xlabel`, or `ylabel` command will produce labels that are centered with respect to the entire plot matrix.

Examples

Create Grouped Data Scatter Plot Matrix

Load the sample data.

```
load discrim;
```

The `ratings` array contains rating values for 329 U.S. cities in the nine different categories listed in the `categories` array. The `group` array contains a city size code that is equal to 2 for the 26 largest cities, and 1 otherwise.

Create a matrix of scatter plots to compare the first two categories, `climate` and `housing`, with categories 4 (`crime`) and 7 (`arts`). Specify `group` as the grouping variable to visually distinguish the data for large and small cities.

```
figure;
gplotmatrix(ratings(:,1:2),ratings(:,[4 7]),group);
```

The figure displays a matrix of scatter plots for the specified comparisons, with each city size group represented by a different color.

For better clarity, you can adjust the appearance of the graphs by specifying colors and plotting symbols, and labeling the axes with the rating categories.

```
figure;
gplotmatrix(ratings(:,1:2),ratings(:,[4 7]),group,...
    'br','o',[],'on','',categories(1:2,:),...
    categories([4 7],:));
```

gprnd

Generalized Pareto random numbers

Syntax

```
R = gprnd(K,sigma,theta)
R = gprnd(K,sigma,theta,m,n,...)
R = gprnd(K,sigma,theta,[m,n,...])
```

Description

`R = gprnd(K,sigma,theta)` returns an array of random numbers chosen from the generalized Pareto (GP) distribution with tail index (shape) parameter `K`, scale parameter `sigma`, and threshold (location) parameter, `theta`. The size of `R` is the common size of the input arguments if all are arrays. If any parameter is a scalar, the size of `R` is the size of the other parameters.

`R = gprnd(K,sigma,theta,m,n,...)` or `R = gprnd(K,sigma,theta,[m,n,...])` generates an `m`-by-`n`-by-... array. The `K`, `sigma`, `theta` parameters can each be scalars or arrays of the same size as `R`.

When `K = 0` and `theta = 0`, the GP is equivalent to the exponential distribution. When `K > 0` and `theta = sigma/K`, the GP is equivalent to the Pareto distribution. The mean of the GP is not finite when $K \geq 1$, and the variance is not finite when $K \geq 1/2$. When $K \geq 0$, the GP has positive density for

$X > \text{theta}$, or, when

$$0 \leq \frac{x - \theta}{\sigma} \leq -\frac{1}{k}$$

random | gppdf | gpcdf | gpinv | gpstat | gpfit | gplike

gpstat

Generalized Pareto mean and variance

Syntax

```
[M,V] = gpstat(K,sigma,theta)
```

Description

`[M,V] = gpstat(K,sigma,theta)` returns the mean of and variance for the generalized Pareto (GP) distribution with the tail index (shape) parameter `K`, scale parameter `sigma`, and threshold (location) parameter, `theta`.

The default value for `theta` is 0.

When `K = 0` and `theta = 0`, the GP is equivalent to the exponential distribution. When `K > 0` and `theta = sigma/K`, the GP is equivalent to the Pareto distribution. The mean of the GP is not finite when $K \geq 1$, and the variance is not finite when $K \geq 1/2$. When $K \geq 0$, the GP has positive density for $X > \theta$, or when

$$K < 0, 0 \leq \frac{x-\theta}{\sigma} \leq -\frac{1}{k}.$$

growTrees

Class: TreeBagger

Train additional trees and add to ensemble

Syntax

```
B = growTrees(B,ntrees)
```

```
B = growTrees(B,ntrees, 'param1',val1, 'param2',val2, ...)
```

Description

`B = growTrees(B,ntrees)` grows `ntrees` new trees and appends them to those trees already stored in the ensemble `B`.

`B = growTrees(B,ntrees, 'param1',val1, 'param2',val2, ...)` specifies optional parameter name/value pairs:

'nprint'

Specifies that a diagnostic message showing training progress should display after every `value` training cycles (grown trees). Default is no diagnostic messages.

'options'

A `struct` that specifies options that govern computation when growing the ensemble of decision trees. One option requests that the computation of decision trees on multiple bootstrap replicates uses multiple processors, if the Parallel Computing Toolbox is available. Two options specify the random number streams to use in selecting bootstrap replicates. You can create this argument with a call to `statset`. You can retrieve values of the individual fields with a call to `statget`. Applicable `statset` parameters are:

- 'UseParallel' — If `true` and if a `parpool` of the Parallel Computing Toolbox is open, compute decision trees drawn on separate bootstrap replicates in parallel. If the Parallel Computing Toolbox is not installed, or a `parpool`

is not open, computation occurs in serial mode. Default is `false`, or serial computation.

- **UseSubstreams** — Set to `true` to compute in parallel in a reproducible fashion. Default is `false`. To compute reproducibly, set **Streams** to a type allowing substreams: `'mlfg6331_64'` or `'mrg32k3a'`.
- **Streams** — A `RandStream` object or cell array of such objects. If you do not specify **Streams**, `growTrees` uses the default stream or streams. If you choose to specify **Streams**, use a single object except in the case
 - You have an open Parallel pool
 - `UseParallel` is `true`
 - `UseSubstreams` is `false`

In that case, use a cell array the same size as the Parallel pool.

grp2idx

Create index vector from grouping variable

Syntax

```
[G,GN]=grp2idx(S)  
[G,GN,GL] = grp2idx(S)
```

Description

`[G,GN]=grp2idx(S)` creates an index vector `G` from the grouping variable `S`. `S` can be a categorical, numeric, or logical vector; a cell vector of strings; or a character matrix with each row representing a group label. The result `G` is a vector taking integer values from 1 up to the number `K` of distinct groups. `GN` is a cell array of strings representing group labels. `GN(G)` reproduces `S` (aside from any differences in type).

The order of `GN` depends on the grouping variable:

- For numeric and logical grouping variables, the order is the sorted order of `S`.
- For categorical grouping variables, the order is the order of `getlabels(S)`.
- For string grouping variables, the order is the order of first appearance in `S`.

`[G,GN,GL] = grp2idx(S)` returns a column vector `GL` representing the group levels. The set of groups and their order in `GL` and `GN` are the same, except that `GL` has the same type as `S`. If `S` is a character matrix, `GL(G, :)` reproduces `S`, otherwise `GL(G)` reproduces `S`.

`grp2idx` treats NaNs (numeric or logical), empty strings (char or cell array of strings), or `<undefined>` values (categorical) in `S` as missing values and returns NaNs in the corresponding rows of `G`. `GN` and `GL` don't include entries for missing values.

Examples

Load the data in `hospital.mat` and create a categorical grouping variable:

```
load hospital
edges = 0:10:100;
labels = strcat(num2str((0:10:90)', '%d'), {'s'});
AgeGroup = ordinal(hospital.Age, labels, [], edges);

ages = hospital.Age(1:5)
ages =
    38
    43
    38
    40
    49

group = AgeGroup(1:5)
group =
    30s
    40s
    30s
    40s
    40s

indices = grp2idx(group)
indices =
    4
    5
    4
    5
    5
```

`gscatter` | `grpstats` | `crosstab` | `getlabels`

grpstats

Summary statistics organized by group

Syntax

```
statarray = grpstats(tbl,groupvar)
statarray = grpstats(tbl,groupvar,whichstats)
statarray = grpstats(tbl,groupvar,whichstats,Name,Value)

means = grpstats(X,group)
[stats1,...,statsN] = grpstats(X,group,whichstats)
[stats1,...,statsN] = grpstats(X,group,whichstats,'Alpha',alpha)

grpstats(X,group,alpha)
```

Description

`statarray = grpstats(tbl,groupvar)` returns a table or dataset array with the means for the data groups specified in `tbl` determined by the values of the grouping variable or variables specified in `groupvar`.

- If there is a single grouping variable, then there is a row in `statarray` for each value of the grouping variable. `grpstats` sorts the groups by order of appearance (if the grouping variable is a character array), in ascending numeric order (if the grouping variable is numeric), or in order of the levels (if the grouping variable is categorical).
- If `groupvar` is a cell array of strings containing multiple grouping variable names, or a vector of column numbers, then there is a row in `statarray` for each observed unique combination of values of the grouping variables. `grpstats` sorts the groups by the values of the first grouping variable, then the second grouping variable, and so on.
- If any variables in `tbl` (other than those specified in `groupvar`) are not numeric or logical arrays, then you must specify the names or column numbers of the numeric and logical variables for which you want to calculate means using the name-value pair argument, `DataVars`.

`statarray = grpstats(tbl,groupvar,whichstats)` returns the group values for the summary statistics types specified in `whichstats`.

`statarray = grpstats(tbl,groupvar,whichstats,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments.

`means = grpstats(X,group)` returns a column vector or matrix with the means of the groups of the data in the matrix or vector `X` determined by the values of the grouping variable or variables, `group`. The rows of `means` correspond to the grouping variable values.

- If there is a single grouping variable, then there is a row in `means` for each value of the grouping variable. `grpstats` sorts the groups by order of appearance (if the grouping variable is a character array), in ascending numeric order (if the grouping variable is numeric), or in order of the levels (if the grouping variable is categorical).
- If `group` is a cell array of grouping variables, then there is a row in `means` for each observed unique combination of values of the grouping variables. `grpstats` sorts the groups by the values of the first grouping variable, then the second grouping variable, and so on.
- If `X` is a matrix, then `means` is a matrix with the same number of columns as `X`. Each column of `means` has the group means for the corresponding column of `X`.

`[stats1,...,statsN] = grpstats(X,group,whichstats)` returns column vectors or arrays with group values for the summary statistic types specified in `whichstats`.

`[stats1,...,statsN] = grpstats(X,group,whichstats,'Alpha',alpha)` specifies the significance level for confidence and prediction intervals.

`grpstats(X,group,alpha)` plots the means of the groups of data in the vector or matrix `X` determined by the values of the grouping variable, `group`. The grouping variable values are on the horizontal plot axis. Each group mean has $100 \times (1 - \alpha)\%$ confidence intervals.

- If `X` is a matrix, then `grpstats` plots the means and confidence intervals for each column of `X`.
- If `group` is a cell array of grouping variables, then `grpstats` plots the means and confidence intervals for the groups of data in `X` determined by the unique combinations of values of the grouping variables. For example, if there are two grouping variables, each with two values, there are four possible combinations of grouping variable values. The plot includes only the combinations of values that exist in the input grouping variables (not all possible combinations).

Examples

Dataset Array Summary Statistics Organized by Group

Load the sample data.

```
load('hospital')
```

The dataset array `hospital` has 100 observations and 7 variables.

Create a dataset array with only the variables `Sex`, `Age`, `Weight`, and `Smoker`.

```
ds = hospital(:, {'Sex', 'Age', 'Weight', 'Smoker'});
```

`Sex` is a nominal array, with levels `Male` and `Female`. The variables `Age` and `Weight` have numeric values, and `Smoker` has logical values.

Compute the mean for the numeric and logical arrays, `Age`, `Weight`, and `Smoker`, grouped by the levels in `Sex`.

```
statarray = grpstats(ds, 'Sex')
```

```
statarray =
```

	Sex	GroupCount	mean_Age	mean_Weight	mean_Smoker
Female	Female	53	37.717	130.47	0.24528
Male	Male	47	38.915	180.53	0.44681

`statarray` is a dataset array with two rows, corresponding to the levels in `Sex`.

`GroupCount` is the number of observations in each group. The means of `Age`, `Weight`, and `Smoker`, grouped by `Sex`, are given in `mean_Age`, `mean_Weight`, and `mean_Smoker`.

Compute the mean for `Age` and `Weight`, grouped by the values in `Smoker`.

```
statarray = grpstats(ds, 'Smoker', 'mean', 'DataVars', {'Age', 'Weight'})
```

```
statarray =
```

	Smoker	GroupCount	mean_Age	mean_Weight
0	false	66	37.97	149.91
1	true	34	38.882	161.94

In this case, not all variables in `ds` (excluding the grouping variable, `Smoker`) are numeric or logical arrays; the variable `Sex` is a nominal array. When not all variables in

the input dataset array are numeric or logical arrays, you must specify the variables for which you want to calculate summary statistics using `DataVars`.

Compute the minimum and maximum weight, grouped by the combinations of values in `Sex` and `Smoker`.

```
statarray = grpstats(ds, {'Sex', 'Smoker'}, {'min', 'max'}, ...
                    'DataVars', 'Weight')
```

```
statarray =
```

	Sex	Smoker	GroupCount	min_Weight	max_Weight
Female_0	Female	false	40	111	147
Female_1	Female	true	13	115	146
Male_0	Male	false	26	158	194
Male_1	Male	true	21	164	202

There are two unique values in `Smoker` and two levels in `Sex`, for a total of four possible combinations of values: Female Nonsmoker (`Female_0`), Female Smoker (`Female_1`), Male Nonsmoker (`Male_0`), and Male Smoker (`Male_1`).

Specify the names for the columns in the output.

```
statarray = grpstats(ds, {'Sex', 'Smoker'}, {'min', 'max'}, ...
                    'DataVars', 'Weight', 'VarNames', {'Gender', 'Smoker'}, ...
                    'GroupCount', 'LowestWeight', 'HighestWeight')
```

```
statarray =
```

	Gender	Smoker	GroupCount	LowestWeight	HighestWeight
Female_0	Female	false	40	111	147
Female_1	Female	true	13	115	146
Male_0	Male	false	26	158	194
Male_1	Male	true	21	164	202

Summary Statistics for a Dataset Array Without Grouping

Load the sample data.

```
load('hospital')
```

The dataset array `hospital` has 100 observations and 7 variables.

Create a dataset array with only the variables `Age`, `Weight`, and `Smoker`.

```
ds = hospital(:, {'Age', 'Weight', 'Smoker'});
```

The variables `Age` and `Weight` have numeric values, and `Smoker` has logical values.

Compute the mean, minimum, and maximum for the numeric and logical arrays, `Age`, `Weight`, and `Smoker`, with no grouping.

```
statarray = grpstats(ds, [], {'mean', 'min', 'max'})
```

```
statarray =
```

	GroupCount	mean_Age	min_Age	max_Age	mean_Weight
All	100	38.28	25	50	154

	min_Weight	max_Weight	mean_Smoker	min_Smoker	max_Smoker
All	111	202	0.34	false	true

The observation name `All` indicates that all observations in `ds` were used to compute the summary statistics.

Group Means for a Matrix Using One or More Grouping Variables

Load the sample data.

```
load('carsmall')
```

All variables are measured for 100 cars. `Origin` is the country of origin for each car (France, Germany, Italy, Japan, Sweden, or USA). `Cylinders` has three unique values, 4, 6, and 8, indicating the number of cylinders in each car.

Calculate the mean acceleration, grouped by country of origin.

```
means = grpstats(Acceleration, Origin)
```

```
means =
```

```
18.0500
16.3778
15.5000
15.8867
16.6000
14.4377
```

`means` is a 6-by-1 vector of mean accelerations, where each value corresponds to a country of origin.

Calculate the mean acceleration, grouped by both country of origin and number of cylinders.

```
means = grpstats(Acceleration,{Origin,Cylinders})
```

```
means =  
    18.0500  
    16.3375  
    16.7000  
    15.5000  
    15.9143  
    15.5000  
    16.6000  
    17.0818  
    16.5267  
    11.6406
```

There are 18 possible combinations of grouping variable values because `Origin` has 6 unique values and `Cylinders` has 3 unique values. Only 10 of the possible combinations appear in the data, so `means` is a 10-by-1 vector of group means corresponding to the observed combinations of values.

Return the group names along with the mean acceleration for each group.

```
[means,grps] = grpstats(Acceleration,{Origin,Cylinders},...  
                        {'mean','gname'})
```

```
means =  
    17.0818  
    16.5267  
    11.6406  
    18.0500  
    15.9143  
    15.5000  
    16.3375  
    16.7000  
    16.6000  
    15.5000
```

```
grps =  
    'USA'    '4'
```

```
'USA'      '6'
'USA'      '8'
'France'   '4'
'Japan'    '4'
'Japan'    '6'
'Germany'  '4'
'Germany'  '6'
'Sweden'   '4'
'Italy'    '4'
```

The output `grps` shows the 10 observed combinations of grouping variable values. For example, the mean acceleration of 4-cylinder cars made in France is 18.05.

Multiple Summary Statistics for a Matrix Organized by Group

Load the sample data.

```
load('carsmall')
```

The variable `Acceleration` was measured for 100 cars. The variable `Origin` is the country of origin for each car (France, Germany, Italy, Japan, Sweden, or USA).

Return the minimum, median, and maximum acceleration, grouped by country of origin.

```
[grpMin,grpMed,grpMax,grp] = grpstats(Acceleration,Origin,...
                                     {'min','median','max','gname'})
```

```
grpMin =
```

```
8.0000
15.3000
13.9000
12.2000
15.7000
15.5000
```

```
grpMed =
```

```
14.7000
17.5000
15.7000
15.3000
16.6000
```

```
15.5000

grpMax =

22.2000
21.9000
18.2000
24.6000
17.5000
15.5000

grp =

'USA'
'France'
'Japan'
'Germany'
'Sweden'
'Italy'
```

The sample car with the lowest acceleration is made in the USA, and the sample car with the highest acceleration is made in Germany.

Plot Prediction Intervals for a New Observation in Each Group

Load the sample data.

```
load('carsmall')
```

The variable `Weight` was measured for 100 cars. The variable `Model_Year` has three unique values, 70, 76, and 82, which correspond to model years 1970, 1976, and 1982.

Calculate the mean weight and 90% prediction intervals for each model year.

```
[means,pred,grp] = grpstats(Weight,Model_Year,...
    {'mean','predci','gname'},'Alpha',0.1);
```

Plot error bars showing the mean weight and 90% prediction intervals, grouped by model year. Label the horizontal axis with the group names.

```
ngrps = length(grp); % Number of groups
```

```
figure()
errorbar((1:ngrps)',means,pred(:,2)-means)
set(gca,'xtick',1:ngrps,'xticklabel',grp)
title('90% Prediction Intervals for Weight by Year')
```

Plot Group Means and Confidence Intervals

Load the sample data.

```
load('carsmall')
```

The variables `Acceleration` and `Weight` are the acceleration and weight values measured for 100 cars. The variable `Cylinders` is the number of cylinders in each car. The variable `Model_Year` has three unique values, 70, 76, and 82, which correspond to model years 1970, 1976, and 1982.

Plot mean acceleration, grouped by `Cylinders`, with 95% confidence intervals.

```
grpstats(Acceleration,Cylinders,0.05)
```

The mean acceleration for cars with 8 cylinders is significantly lower than for cars with 4 or 6 cylinders.

Plot mean acceleration and weight, grouped by `Cylinders`, and 95% confidence intervals. Scale the `Weight` values by 1000 so the means of `Weight` and `Acceleration` are the same order of magnitude.

```
grpstats([Acceleration,Weight/1000],Cylinders,0.05)
```

The average weight of cars increases with the number of cylinders, and the average acceleration decreases with the number of cylinders.

Plot mean acceleration, grouped by both `Cylinders` and `Model_Year`. Specify 95% confidence intervals.

```
grpstats(Acceleration, {Cylinders, Model_Year}, 0.05)
```

There are nine possible combinations of grouping variable values because there are three unique values in `Cylinders` and three unique values in `Model_Year`. The plot does not show 8-cylinder cars with model year 1982 because the data did not include this combination.

The mean acceleration of 8-cylinder cars made in 1976 is significantly larger than the mean acceleration of 8-cylinder cars made in 1970.

- “Summary Statistics Grouped by Category” on page 2-38
- “Test Differences Between Category Means” on page 2-29
- “Plot Data Grouped by Category” on page 2-25
- “Calculations on Dataset Arrays” on page 2-108

Input Arguments

tbl — Input data

table | dataset array

Input data, specified as a table or dataset array. `tbl` must include at least one variable that is a grouping variable.

Summary statistics can only be calculated for variables that have a numeric or logical data type. If any variables in `tbl` (other than the grouping variables) are not numeric or logical arrays, then use the name-value pair argument `DataVars` to specify the names or column numbers of the numeric and logical variables for which to calculate summary statistics.

groupvar — Identifiers for the grouping variables

cell array of strings | vector of positive integers | logical vector | []

Identifiers for the grouping variables in the input data, `tbl`, specified as one of the following:

String or cell array of strings	Names of the grouping variables
Positive integer or vector of positive integers	Variable numbers of the grouping variables
Vector of logical values with number of elements equal to the number of variables in <code>tbl</code>	Logical indicator with value <code>true</code> for grouping variables and <code>false</code> otherwise
[]	No groups (returns summary statistics for all data)

Any variable that is identified by `groupvar` as a grouping variable must have a valid grouping variable data type: categorical array, logical or numeric vector, or cell array of strings.

For example, consider an input table, `tbl`, with six variables. The fourth variable is named `Gender`. To be a valid grouping variable, the data type of `Gender` might be a cell array of strings or a nominal array, with the unique values `Male` and `Female`. To specify the variable `Gender` as the grouping variable, you can use any of these syntaxes:

- `statarray = grpstats(tbl, 'Gender')`
- `statarray = grpstats(tbl, 4)`
- `statarray = grpstats(tbl, logical([0 0 0 1 0 0]))`

Data Types: double | logical | cell | char

whichstats — Types of summary statistics

string | function handle

Types of summary statistics to compute, specified as a string or function handle, or a cell array of strings and function handles. Use a cell array to specify multiple types of summary statistics.

Possible string values are:

'mean'	Mean
'sem'	Standard error of the mean
'numel'	Count, or number, of non-NaN elements
'gname'	Group name
'std'	Standard deviation
'var'	Variance
'min'	Minimum
'max'	Maximum
'range'	Range
'meanci'	95% confidence interval for the mean
'predci'	95% prediction interval for a new observation

Example: `[stat1,stat2] = grpstats(X,group,{'mean','sem'})`

You can specify different significance levels for the 'meanci' and 'predci' options using the name-value pair argument, Alpha.

To specify other types of summary statistics, you can use function handles. You can use the handle to any function that accepts a column or matrix of data, and returns the same size output each time `grpstats` calls it (even if the output for some groups is empty).

If the function accepts a column of data, then the function can return either a scalar value, or an *nvals*-by-1 column vector for descriptive statistics of length *nvals* (for example, confidence intervals have length two). If the function accepts a matrix, it must either return a 1-by-*ncols* row vector, or an *nvals*-by-*ncols* matrix, where *ncols* is the number of columns in the input data matrix.

Example: `[stat1,stat2,stat3] = grpstats(X,group,{'mean','std',@skewness})`

For functions that do not compute column-wise statistics, specify the computation direction while specifying the function.

Example: `stat1 = grpstats(X,group,@(x)sum(x,1))`

Data Types: `char` | `function_handle`

alpha — Significance level

scalar value in the range (0,1)

Significance level, specified as a scalar value in the range (0,1).

- When you specify `'meanci'` or `'predci'` in `whichstats`, you can use `alpha` to specify the significance level for the confidence or prediction intervals. If you specify `alpha`, then `grpstats` returns $100 \times (1 - \text{alpha})\%$ confidence or prediction intervals. If you do not specify `alpha`, then `grpstats` returns 95% intervals (`alpha = 0.05`).
- Use `alpha` with the `grpstats(X,group,alpha)` syntax to plot group means and corresponding $100 \times (1 - \text{alpha})\%$ confidence intervals.

Data Types: `double`

X — Input data

vector | matrix

Input data, specified as a vector or a matrix. If `X` is a matrix, then `grpstats` returns summary statistics for each column of `X`.

Data Types: `double` | `single`

group — Grouping variable

categorical array | logical or numeric vector | cell array of strings | `[]`

Grouping variable, specified as a categorical array, logical or numeric vector, or cell array of strings. Each unique value in a grouping variable defines a group. `grpstats` groups data for summary statistics using the grouping variable values.

There must be a grouping variable value for each row of the input data `X`. Observations (rows) with the same value of the grouping variable are in the same group. Use `[]` to compute summary statistics for all data, without using groups.

For example, if `Gender` is a cell array of strings with values `'Male'` and `'Female'`, you can use `Gender` as a grouping variable to summarize your data by gender.

You can also use more than one grouping variable to group data for summary statistics. In this case, specify a cell array of grouping variables.

For example, if `Smoker` is a logical vector with values 0 for nonsmokers and 1 for smokers, then specifying the cell array `{Gender, Smoker}` divides observations into four groups: Male Smoker, Male Nonsmoker, Female Smoker, and Female Nonsmoker. `grpstats` returns summary statistics only for the combinations of values that exist in the input grouping variables (not all possible combinations).

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `'DataVars', [1,3,4], 'Alpha', 0.01` specifies that summary statistics be calculated for the 1st, 3rd, and 4th variables in a dataset array, with 99% confidence intervals.

'Alpha' — Significance level

0.05 (default) | scalar value in the range (0,1)

Significance level for confidence and prediction intervals, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the range (0,1).

When you include `'meanci'` or `'predci'` in `whichstats`, you can use `Alpha` to specify the significance level for confidence or prediction intervals. If you specify the value a , then `grpstats` returns $100 \times (1 - a)\%$ confidence or prediction intervals.

If you do not specify a value for `Alpha`, then `grpstats` returns 95% intervals ($a = 0.05$).

Example: `'Alpha', 0.1`

Data Types: `double`

'DataVars' — Variable names or columns

cell array of strings | vector of positive integers | logical vector

Variable names or columns indicating which variables in the input data `tbl` you want to compute summary statistics for, specified as the comma-separated pair consisting of `'DataVars'` and a cell array of strings, vector of positive integers, or a logical vector. Use a string to specify a variable name, a positive integer to specify a variable column number, or logical values to indicate which variables to include (`true` if you want to compute summary statistics, `false` otherwise).

You must specify `DataVars` if there are any variables in `tbl` (other than the grouping variables specified in `groupvar`) that are not numeric or logical arrays. Summary statistics can only be calculated for variables that have a numeric or logical data type.

Example: `'DataVars', {'Height', 'Weight'}`

Data Types: `double | cell | char`

'VarNames' — Variable names for output

cell array of strings

Variable names for the output `statarray`, specified as the comma-separated pair consisting of `'VarNames'` and a cell array of strings. By default, `grpstats` constructs output variable names by appending a prefix to the variable names from the input data `tbl`. This prefix corresponds to the summary statistic name.

Example: `'VarNames', {'Gender', 'GroupCount', 'MaleMean', 'FemaleMean'}`

Data Types: `cell`

Output Arguments

`statarray` — Group summary statistics

table | dataset array

Group summary statistics, returned as a table or a dataset array. If `tbl` is a table, `grpstats` returns `statarray` as a table. If `tbl` is a dataset array, `grpstats` returns `statarray` as a dataset array.

`statarray` contains summary statistic values for the groups of data in `tbl` determined by the levels of the grouping variables specified by `groupvar`. There is a row in `statarray` for each observed value or combination of values in the variables specified by `groupvar`. The output `statarray` contains:

- All grouping variables specified by `groupvar`.
- The variable `GroupCount`, containing the number of observations in each group.
- Group summary statistic values for all variables in `tbl` (other than those specified by `groupvar`), or for only the variables specified using `DataVars`.

The total number of variables in `statarray` is $n_{groupvars} + 1 + n_{datavars} \times n_{stats}$, where $n_{groupvars}$ is the number of variables in `groupvar`, $n_{datavars}$ is the number

of variables for which summary statistics are computed, and *nstats* is the number of summary statistic types specified in *whichstats*.

`grpstats` assigns default names to the variables in `statarray`, unless you specify variable names using the name-value pair argument `VarNames`.

means — Group means

column vector | array

Group means for the groups of data in the vector or matrix *X* determined by the levels of group, returned as an *ngroups-by-ncols* array. Here, *ngroups* is the number of unique values in the grouping variable, and *ncols* is the number of columns in *X*. If *X* is a vector, then `means` is a column vector.

stats1, ..., statsN — Group summary statistics

column vectors | arrays

Group summary statistics for the groups of data in the vector or matrix *X* determined by the levels of group, returned as *ngroups-by-ncols* arrays. Here, *ngroups* is the number of unique values in the grouping variable, and *ncols* is the number of columns in *X*. You must specify an output argument for each type of summary statistic specified in *whichstats*.

If a summary statistic type in *whichstats* returns a value of length *nvals* (for example, a confidence interval is a descriptive statistic of length two), then the corresponding output argument is an *ngroups-by-ncols-by-nvals* array.

More About

Algorithms

- `grpstats` treats NaNs as missing values, and removes them from the input data before calculating summary statistics.
- `grpstats` ignores empty group names.

dataset | table

grpstats

Class: RepeatedMeasuresModel

Compute descriptive statistics of repeated measures data by group

Syntax

```
statstbl = grpstats(rm,g)
statstbl = grpstats(rm,g,stats)
```

Description

`statstbl = grpstats(rm,g)` returns the count, mean, and variance for the data used to fit the repeated measures model `rm`, grouped by the factors, `g`.

`statstbl = grpstats(rm,g,stats)` returns the statistics specified by `stats` for the data used to fit the repeated measures model `rm`, grouped by the factors, `g`.

Tips

- `grpstats` computes results separately for each group. The results do not depend on the fitted repeated measures model. It computes the results on all available data, without omitting entire rows that contain NaNs.

Input Arguments

rm — Repeated measures model
RepeatedMeasuresModel object

Repeated measures model, returned as a `RepeatedMeasuresModel` object.

For properties and methods of this object, see `RepeatedMeasuresModel`.

g — Name of grouping factor or factors

string | cell array of strings

Name of grouping factor or factors, specified as a string or cell array of strings.

Example: 'Drug'

Example: {'Drug', 'Sex'}

Data Types: char

stats — Statistics to compute

string | function handle | cell array of multiple strings and function handles

Statistics to compute, specified as one of the following:

- String specifying the name of the statistics to compute. Names can be one of the following.

Name	Description
'mean'	Mean
'sem'	Standard error of the mean
'numel'	Count or number of elements
'gname'	Group name
'std'	Standard deviation
'var'	Variance
'min'	Minimum
'max'	Maximum
'range'	Maximum minus minimum
'meanci'	95% confidence interval for the mean
'predci'	95% prediction interval for a new observation

- Function handle — The function you specify must accept a vector of response values for a single group, and compute descriptive statistics for it. A function should typically return a value that has one row. A function must return the same size output each time `grpstats` calls it, even if the input for some groups is empty.
- A cell array of strings and function handles.

Example: @median

Example: @skewness

Example: 'gname'

Example: {'gname', 'range', 'predci'}

Data Types: char | function_handle | cell

Output Arguments

statstb1 — Statistics values for each group

table

Statistics values for each group, returned as a table.

Examples

Compute Group Statistics

Load the sample data.

```
load fisheriris
```

The column vector, `species` consists of iris flowers of three different species: `setosa`, `versicolor`, and `virginica`. The double matrix `meas` consists of four types of measurements on the flowers: the length and width of sepals and petals in centimeters, respectively.

Store the data in a table array.

```
t = table(species,meas(:,1),meas(:,2),meas(:,3),meas(:,4),...  
'VariableNames',{'species','meas1','meas2','meas3','meas4'});  
Meas = dataset([1 2 3 4]','VarNames',{'Measurements'});
```

Fit a repeated measures model, where the measurements are the responses and the `species` is the predictor variable.

```
rm = fitrm(t,'meas1-meas4~species','WithinDesign',Meas);
```

Compute group counts, mean, and standard deviation with respect to `species`.

```
grpstats(rm,'species')
```

```
ans =
```

species	GroupCount	mean	std
'setosa'	200	2.5355	1.8483
'versicolor'	200	3.573	1.7624
'virginica'	200	4.285	1.9154

Now, compute the range of data and 95% confidence intervals for the group means for the factor species. Also display the group name.

```
grpstats(rm, 'species', {'gname', 'range', 'predci'})
```

```
ans =
```

species	gname	GroupCount	range	predci	
'setosa'	'setosa'	200	5.7	-1.1185	6.1895
'versicolor'	'versicolor'	200	6	0.088976	7.057
'virginica'	'virginica'	200	6.5	0.4985	8.0715

Statistics for Data Grouped by Two Factors

Load the sample data.

```
load repeatedmeas
```

The table `between` includes the between-subject variables age, IQ, group, gender, and eight repeated measures `y1` through `y8` as responses. The table `within` includes the within-subject variables `w1` and `w2`. This is simulated data.

Fit a repeated measures model, where the repeated measures `y1` through `y8` are the responses, and age, IQ, group, gender, and the group-gender interaction are the predictor variables. Also specify the within-subject design matrix.

```
rm = fitrm(between, 'y1-y8 ~ Group*Gender + Age + IQ', 'WithinDesign', within);
```

Compute group counts, mean, standard deviation, skewness, and kurtosis of data grouped by the factors Group and Gender.

```
GS = grpstats(rm, {'Group', 'Gender'}, {'mean', 'std', @skewness, @kurtosis})
```

```
GS =
```

Group	Gender	GroupCount	mean	std	skewness	kurtosis
A	Female	40	16.554	21.498	0.35324	3.7807
A	Male	40	9.8335	20.602	-0.38722	2.7834
B	Female	40	11.261	25.779	-0.49177	4.1484
B	Male	40	3.6078	24.646	0.55447	2.7966
C	Female	40	-11.335	27.186	1.7499	6.1429
C	Male	40	-14.028	31.984	1.7362	5.141

See Also`fitrm | plot`

gscatter

Scatter plot by group

Syntax

```
gscatter(x,y,group)
gscatter(x,y,group,clr,sym,siz)
gscatter(x,y,group,clr,sym,siz,doleg)
gscatter(x,y,group,clr,sym,siz,doleg,xnam,ynam)
h = gscatter(...)
```

Description

`gscatter(x,y,group)` creates a scatter plot of `x` and `y`, grouped by `group`. `x` and `y` are vectors of the same size. `group` is a grouping variable in the form of a categorical variable, vector, string array, or cell array of strings. Alternatively, `group` can be a cell array containing several grouping variables (such as `{g1 g2 g3}`), in which case observations are in the same group if they have common values of all grouping variables. Points in the same group and appear on the graph with the same marker and color.

`gscatter(x,y,group,clr,sym,siz)` specifies the color, marker type, and size for each group. `clr` is a string array of colors recognized by the `plot` function. The default for `clr` is `'bgrcmk'`. `sym` is a string array of symbols recognized by the `plot` command, with the default value `'.'`. `siz` is a vector of sizes, with the default determined by the `'DefaultLineMarkerSize'` property. If you do not specify enough values for all groups, `gscatter` cycles through the specified values as needed.

`gscatter(x,y,group,clr,sym,siz,doleg)` controls whether a legend is displayed on the graph (`doleg` is `'on'`, the default) or not (`doleg` is `'off'`).

`gscatter(x,y,group,clr,sym,siz,doleg,xnam,ynam)` specifies the name to use for the `x`-axis and `y`-axis labels. If the `x` and `y` inputs are simple variable names and `xnam` and `yname` are omitted, `gscatter` labels the axes with the variable names.

`h = gscatter(...)` returns an array of handles to the lines on the graph.

Examples

Scatter Plot of Climate and Housing Ratings

Load the sample data.

```
load discrim
```

The sample data contains ratings of cities according to nine factors such as climate, housing, education, and health in the matrix `ratings`.

Plot the relationship between the ratings for climate (first column) and housing (second column) grouped by city size in the matrix `group`. Choose different colors and plotting symbols for each group.

```
figure;  
gscatter(ratings(:,1),ratings(:,2),group,'br','xo')  
xlabel('climate');  
ylabel('housing');
```

gplotmatrix | grpstats | scatter

gt

Class: grandstream

Greater than relation for handles

Syntax

`h1 > h2`

Description

`h1 > h2` performs element-wise comparisons between handle arrays `h1` and `h2`. `h1` and `h2` must be of the same dimensions unless one is a scalar. The result is a logical array of the same dimensions, where each element is an element-wise `>` result.

If one of `h1` or `h2` is scalar, scalar expansion is performed and the result will match the dimensions of the array that is not scalar.

`tf = gt(h1, h2)` stores the result in a logical array of the same dimensions.

`grandstream` | `ge` | `le` | `ne` | `eq` | `lt`

haltonset class

Superclasses: grandset

Halton quasi-random point sets

Description

haltonset is a quasi-random point set class that produces points from the Halton sequence.

Construction

.haltonset

Construct Halton quasi-random point set

Methods

Inherited Methods

Methods in the following table are inherited from grandset.

disp	Display grandset object
end	Last index in indexing expression for point set
length	Length of point set
ndims	Number of dimensions in matrix
net	Generate quasi-random point set
scramble	Scramble quasi-random point set

size	Number of dimensions in matrix
suboref	Subscripted reference for grandset

Properties

Inherited Properties

Properties in the following table are inherited from `grandset`.

Dimensions	Number of dimensions
Leap	Interval between points
ScrambleMethod	Settings that control scrambling
Skip	Number of initial points to omit from sequence
Type	Name of sequence on which point set P is based

Copy Semantics

`Handle`. To learn how this affects your use of the class, see “Comparing Handle and Value Classes” in the MATLAB Object-Oriented Programming documentation.

How To

- “Quasi-Random Point Sets” on page 6-16

haltonset

Class: haltonset

Construct Halton quasi-random point set

Syntax

```
p = haltonset(d)
p = haltonset(d,prop1,val1,prop2,val2,...)
```

Description

`p = haltonset(d)` constructs a d -dimensional point set `p` of the `haltonset` class, with default property settings.

`p = haltonset(d,prop1,val1,prop2,val2,...)` specifies property name/value pairs used to construct `p`.

The object `p` returned by `haltonset` encapsulates properties of a specified quasi-random sequence. The point set is finite, with a length determined by the `Skip` and `Leap` properties and by limits on the size of point set indices (maximum value of 2^{53}). Values of the point set are not generated and stored in memory until you access `p` using `net` or parenthesis indexing.

Examples

Generate a 3-D Halton point set, skip the first 1000 values, and then retain every 101st point:

```
p = haltonset(3,'Skip',1e3,'Leap',1e2)
p =
    Halton point set in 3 dimensions (8.918019e+013 points)
    Properties:
        Skip : 1000
        Leap : 100
        ScrambleMethod : none
```

Use `scramble` to apply reverse-radix scrambling:

```
p = scramble(p, 'RR2')
p =
  Halton point set in 3 dimensions (8.918019e+013 points)
  Properties:
      Skip : 1000
      Leap : 100
  ScrambleMethod : RR2
```

Use `net` to generate the first four points:

```
X0 = net(p,4)
X0 =
    0.0928    0.6950    0.0029
    0.6958    0.2958    0.8269
    0.3013    0.6497    0.4141
    0.9087    0.7883    0.2166
```

Use parenthesis indexing to generate every third point, up to the 11th point:

```
X = p(1:3:11,:)
X =
    0.0928    0.6950    0.0029
    0.9087    0.7883    0.2166
    0.3843    0.9840    0.9878
    0.6831    0.7357    0.7923
```

harmmean

Harmonic mean

Syntax

```
m = harmmean(X)
harmmean(X,dim)
```

Description

`m = harmmean(X)` calculates the harmonic mean of a sample. For vectors, `harmmean(x)` is the harmonic mean of the elements in `x`. For matrices, `harmmean(X)` is a row vector containing the harmonic means of each column. For N -dimensional arrays, `harmmean` operates along the first nonsingleton dimension of `X`.

`harmmean(X,dim)` takes the harmonic mean along dimension `dim` of `X`.

The harmonic mean is

$$m = \frac{n}{\sum_{i=1}^n \frac{1}{x_i}}$$

Examples

The arithmetic mean is greater than or equal to the harmonic mean.

```
x = exprnd(1,10,6);
```

```
harmonic = harmmean(x)
```

```
harmonic =
```

```
    0.3382    0.3200    0.3710    0.0540    0.4936    0.0907
```

```
average = mean(x)
```

```
average =
```

1.3509 1.1583 0.9741 0.5319 1.0088 0.8122

hist3

Bivariate histogram

Syntax

```
hist3(X)
hist3(X,nbins)
hist3(X,ctrs)
hist3(X,'Edges',edges)
N = hist3(X,...)
[N,C] = hist3(X,...)
hist3(...,param1,val1,param2,val2,...)
```

Description

`hist3(X)` bins the elements of the m -by-2 matrix X into a 10-by-10 grid of equally spaced containers, and plots a histogram. Each column of X corresponds to one dimension in the bin grid.

`hist3(X,nbins)` plots a histogram using an `nbins(1)`-by-`nbins(2)` grid of bins. `hist3(X,'Nbins',nbins)` is equivalent to `hist3(X,nbins)`.

`hist3(X,ctrs)`, where `ctrs` is a two-element cell array of numeric vectors with monotonically non-decreasing values, uses a 2-D grid of bins centered on `ctrs{1}` in the first dimension and on `ctrs{2}` in the second. `hist3` assigns rows of X falling outside the range of that grid to the bins along the outer edges of the grid, and ignores rows of X containing NaNs. `hist3(X,'Ctrs',ctrs)` is equivalent to `hist3(X,ctrs)`.

`hist3(X,'Edges',edges)`, where `edges` is a two-element cell array of numeric vectors with monotonically non-decreasing values, uses a 2-D grid of bins with edges at `edges{1}` in the first dimension and at `edges{2}` in the second. The (i,j) th bin includes the value $X(k,:)$ if

```
edges{1}(i) <= X(k,1) < edges{1}(i+1)
edges{2}(j) <= X(k,2) < edges{2}(j+1)
```

Rows of X that fall on the upper edges of the grid, `edges{1}(end)` or `edges{2}(end)`, are counted in the (I, j) th or (i, J) th bins, where I and J are the lengths of `edges{1}` and `edges{2}`. `hist3` does not count rows of X falling outside the range of the grid. Use `-Inf` and `Inf` in `edges` to include all non-NaN values.

`N = hist3(X, ...)` returns a matrix containing the number of elements of X that fall in each bin of the grid, and does not plot the histogram.

`[N,C] = hist3(X, ...)` returns the positions of the bin centers in a 1-by-2 cell array of numeric vectors, and does not plot the histogram. `hist3(ax,X, ...)` plots onto an `axes` with handle `ax` instead of the current `axes`. See the `axes` reference page for more information about handles to plots.

`hist3(...,param1,val1,param2,val2,...)` allows you to specify graphics parameter name/value pairs to fine-tune the plot.

Examples

Plot Density Histogram with Intensity Map

Load the sample data.

```
load seamount
```

Correct grid for negative y-values and draw histogram in 2D.

```
hold on  
dat = [-y,x];  
hist3(dat)
```

Extract histogram data.

```
n = hist3(dat); % default is to 10x10 bins
n1 = n';
n1(size(n,1) + 1, size(n,2) + 1) = 0;
```

Generate grid for 2-D projected view of intensities.

```
xb = linspace(min(dat(:,1)),max(dat(:,1)),size(n,1)+1);
yb = linspace(min(dat(:,2)),max(dat(:,2)),size(n,1)+1);
```

Make a pseudocolor plot.

```
h = pcolor(xb,yb,n1);
```

Set the z-level and colormap of the displayed grid, and display the default 3-D perspective view.

```
h.ZData = ones(size(n1)) * -max(max(n));
colormap(hot) % heat map
title('Seamount:Data Point Density Histogram and Intensity Map');
grid on
view(3);
```

Histogram with Semi-Transparent Bars

Load the sample data.

```
load carbig
```

Use the data to make histogram on a 7-by-7 grid of bins.

```
X = [MPG,Weight];  
hist3(X,[7 7]);  
xlabel('MPG'); ylabel('Weight');
```

Make a histogram with semi-transparent bars.

```
hist3(X,[7 7], 'FaceAlpha', .65);  
xlabel('MPG'); ylabel('Weight');  
set(gcf, 'renderer', 'opengl');
```

Specify bin centers, different in each direction; get back counts, but don't make the plot.

```
cnt = hist3(X, {0:10:50 2000:500:5000});
```

Histogram Bars Colored According to Height

Load the sample data.

```
load carbig
```

Make a histogram on a 7-by-7 grid of bins.

```
X = [MPG,Weight];
hist3(X,[7 7]);
```

```
xlabel('MPG'); ylabel('Weight');  
set(gcf, 'renderer', 'opengl');
```

Color the bars based on the frequency of the observations, i.e. according to the height of the bars.

```
set(get(gca, 'child'), 'FaceColor', 'interp', 'CDataMode', 'auto');
```

histfit

Histogram with a distribution fit

Syntax

```
histfit(data)  
histfit(data,nbins)  
histfit(data,nbins,dist)
```

```
h = histfit(____)
```

Description

`histfit(data)` plots a histogram of values in `data` using the number of bins equal to the square root of the number of elements in `data` and fits a normal density function.

`histfit(data,nbins)` plots a histogram using `nbins` bins and fits a normal density function.

`histfit(data,nbins,dist)` plots a histogram with `nbins` bins and fits a density function from the distribution specified by `dist`.

`h = histfit(____)` returns a vector of handles `h`, where `h(1)` is the handle to the histogram and `h(2)` is the handle to the density curve. It can include any of the input arguments in previous syntaxes.

Examples

Histogram with a Normal Distribution Fit

Generate a sample of size 100 from a normal distribution with mean 10 and variance 1.

```
rng default; % For reproducibility  
r = normrnd(10,1,100,1);
```

Construct a histogram with a normal distribution fit.

```
histfit(r)
```

Histogram for a Given Number of Bins

Generate a sample of size 100 from a normal distribution with mean 10 and variance 1.

```
rng default; % For reproducibility  
r = normrnd(10,1,100,1);
```

Construct a histogram using six bins with a normal distribution fit.

```
histfit(r,6)
```

Histogram with a Specified Distribution Fit

Generate a sample of size 100 from a beta distribution with parameters (3,10).

```
rng default; % For reproducibility  
b = betarnd(3,10,100,1);
```

Construct a histogram using 10 bins with a beta distribution fit.

```
histfit(b,10,'beta')
```

Histogram with a Kernel Smoothing Function Fit

Generate a sample of size 100 from a beta distribution with parameters (3,10).

```
rng default; % For reproducibility  
b = betarnd(3,10,[100,1]);
```

Construct a histogram using 10 bins with a smoothing function fit.

```
histfit(b,10,'kernel')
```

Handle for a Histogram with a Distribution Fit

Generate a sample of size 100 from a normal distribution with mean 10 and variance 1.

```
rng default % for reproducibility  
r = normrnd(10,1,100,1);
```

Construct a histogram with a normal distribution fit.

```
h = histfit(r,10,'normal')
```

```
h =
```

2x1 graphics array:

Patch
Line

Change the bar colors of the histogram.

```
h(1).FaceColor = [.8 .8 1];
```

Change the color of the density curve.

```
h(2).Color = [.2 .2 .2];
```

Input Arguments

data — Input data

vector

Input data, specified as a vector.

Example: `data = [1.5 2.5 4.6 1.2 3.4]`

Example: `data = [1.5 2.5 4.6 1.2 3.4]'`

Data Types: `double` | `single`

nbins — Number of bins

positive integer | []

Number of bins for the histogram, specified as a positive integer. Default value is the square root of the number of elements in `data`, rounded up. Use [] for the default number of bins when fitting a distribution.

Example: `y = histfit(x,8)`

Example: `y = histfit(x,10,'gamma')`

Example: `y = histfit(x,[],'weibull')`

Data Types: double | single

dist — Distribution to fit

'normal' (default) | string

Distribution to fit to the histogram, specified as a string. The following table shows the supported distributions.

dist	Description
'beta'	Beta
'birnbaumsaunders'	Birnbaum-Saunders
'burr'	Burr Type XII
'exponential'	Exponential
'extreme value' or 'ev'	Extreme value
'gamma'	Gamma
'generalized extreme value' or 'gev'	Generalized extreme value
'generalized pareto' or 'gp'	Generalized Pareto (threshold 0)
'inversegaussian'	Inverse Gaussian
'logistic'	Logistic
'loglogistic'	Loglogistic
'lognormal'	Lognormal
'nakagami'	Nakagami
'negative binomial' or 'nbin'	Negative binomial

dist	Description
'normal'	Normal
'poisson'	Poisson
'rayleigh'	Rayleigh
'rician'	Rician
'tlocation-scale'	t location-scale
'weibull' or 'wbl'	Weibull
'kernel'	Nonparametric kernel-smoothing distribution. The density is evaluated at 100 equally spaced points that cover the range of the data in <code>data</code> . It works best with continuously distributed samples.

Data Types: char

Output Arguments

h — Handles for the plot

plot handle

Handles for the plot, returned as a vector, where `h(1)` is the handle to the histogram, and `h(2)` is the handle to the density curve.

hmmdecode

Hidden Markov model posterior state probabilities

Syntax

```
PSTATES = hmmdecode(seq, TRANS, EMIS)
[PSTATES, logpseq] = hmmdecode(...)
[PSTATES, logpseq, FORWARD, BACKWARD, S] = hmmdecode(...)
hmmdecode(..., 'Symbols', SYMBOLS)
```

Description

`PSTATES = hmmdecode(seq, TRANS, EMIS)` calculates the posterior state probabilities, `PSTATES`, of the sequence `seq`, from a hidden Markov model. The posterior state probabilities are the conditional probabilities of being at state k at step i , given the observed sequence of symbols, `sym`. You specify the model by a transition probability matrix, `TRANS`, and an emissions probability matrix, `EMIS`. `TRANS(i, j)` is the probability of transition from state i to state j . `EMIS(k, seq)` is the probability that symbol `seq` is emitted from state k .

`PSTATES` is an array with the same length as `seq` and one row for each state in the model. The (i, j) th element of `PSTATES` gives the probability that the model is in state i at the j th step, given the sequence `seq`.

Note The function `hmmdecode` begins with the model in state 1 at step 0, prior to the first emission. `hmmdecode` computes the probabilities in `PSTATES` based on the fact that the model begins in state 1.

`[PSTATES, logpseq] = hmmdecode(...)` returns `logpseq`, the logarithm of the probability of sequence `seq`, given transition matrix `TRANS` and emission matrix `EMIS`.

`[PSTATES, logpseq, FORWARD, BACKWARD, S] = hmmdecode(...)` returns the forward and backward probabilities of the sequence scaled by `S`.

`hmmdecode(..., 'Symbols', SYMBOLS)` specifies the symbols that are emitted. `SYMBOLS` can be a numeric array or a cell array of the names of the symbols. The default symbols are integers 1 through `N`, where `N` is the number of possible emissions.

Examples

```
trans = [0.95,0.05;  
         0.10,0.90];  
emis = [1/6 1/6 1/6 1/6 1/6 1/6;  
        1/10 1/10 1/10 1/10 1/10 1/2];  
  
[seq,states] = hmmgenerate(100,trans,emis);  
pStates = hmmdecode(seq,trans,emis);  
[seq,states] = hmmgenerate(100,trans,emis,...  
    'Symbols',{'one','two','three','four','five','six'})  
pStates = hmmdecode(seq,trans,emis,...  
    'Symbols',{'one','two','three','four','five','six'});
```

See Also

`hmmgenerate` | `hmmestimate` | `hmmviterbi` | `hmmtrain`

hmmestimate

Hidden Markov model parameter estimates from emissions and states

Syntax

```
[TRANS,EMIS] = hmmestimate(seq,states)
hmmestimate(...,'Symbols',SYMBOLS)
hmmestimate(...,'Statenames',STATENAMES)
hmmestimate(...,'Pseudoemissions',PSEUDOE)
hmmestimate(...,'Pseudotransitions',PSEUDOTR)
```

Description

`[TRANS,EMIS] = hmmestimate(seq,states)` calculates the maximum likelihood estimate of the transition, `TRANS`, and emission, `EMIS`, probabilities of a hidden Markov model for sequence, `seq`, with known states, `states`.

`hmmestimate(...,'Symbols',SYMBOLS)` specifies the symbols that are emitted. `SYMBOLS` can be a numeric array or a cell array of the names of the symbols. The default symbols are integers 1 through `N`, where `N` is the number of possible emissions.

`hmmestimate(...,'Statenames',STATENAMES)` specifies the names of the states. `STATENAMES` can be a numeric array or a cell array of the names of the states. The default state names are 1 through `M`, where `M` is the number of states.

`hmmestimate(...,'Pseudoemissions',PSEUDOE)` specifies pseudocount emission values in the matrix `PSEUDO`. Use this argument to avoid zero probability estimates for emissions with very low probability that might not be represented in the sample sequence. `PSEUDOE` should be a matrix of size m -by- n , where m is the number of states in the hidden Markov model and n is the number of possible emissions. If the $i \rightarrow k$ emission does not occur in `seq`, you can set `PSEUDOE(i,k)` to be a positive number representing an estimate of the expected number of such emissions in the sequence `seq`.

`hmmestimate(...,'Pseudotransitions',PSEUDOTR)` specifies pseudocount transition values. You can use this argument to avoid zero probability estimates for transitions with very low probability that might not be represented in the sample sequence. `PSEUDOTR` should be a matrix of size m -by- m , where m is the number of states

in the hidden Markov model. If the $i \rightarrow j$ transition does not occur in `states`, you can set `PSEUDOTR(i, j)` to be a positive number representing an estimate of the expected number of such transitions in the sequence `states`.

Pseudotransitions and Pseudoemissions

If the probability of a specific transition or emission is very low, the transition might never occur in the sequence `states`, or the emission might never occur in the sequence `seq`. In either case, the algorithm returns a probability of 0 for the given transition or emission in `TRANS` or `EMIS`. You can compensate for the absence of transition with the 'Pseudotransitions' and 'Pseudoemissions' arguments. The simplest way to do this is to set the corresponding entry of `PSEUDO` or `PSEUDOTR` to 1. For example, if the transition $i \rightarrow j$ does not occur in `states`, set `PSEUDOTR(i, j) = 1`. This forces `TRANS(i, j)` to be positive. If you have an estimate for the expected number of transitions $i \rightarrow j$ in a sequence of the same length as `states`, and the actual number of transitions $i \rightarrow j$ that occur in `seq` is substantially less than what you expect, you can set `PSEUDOTR(i, j)` to the expected number. This increases the value of `TRANS(i, j)`. For transitions that do occur in `states` with the frequency you expect, set the corresponding entry of `PSEUDOTR` to 0, which does not increase the corresponding entry of `TRANS`.

If you do not know the sequence of states, use `hmmtrain` to estimate the model parameters.

Examples

```
trans = [0.95,0.05; 0.10,0.90];
emis = [1/6 1/6 1/6 1/6 1/6 1/6;
        1/10 1/10 1/10 1/10 1/10 1/2];

[seq,states] = hmmgenerate(1000,trans,emis);
[estimateTR,estimateE] = hmestimate(seq,states);
```

`hmmgenerate` | `hmmdecode` | `hmmviterbi` | `hmmtrain`

hmmgenerate

Hidden Markov model states and emissions

Syntax

```
[seq,states] = hmmgenerate(len,TRANS,EMIS)
hmmgenerate(...,'Symbols',SYMBOLS)
hmmgenerate(...,'Statenames',STATENAMES)
```

Description

[seq,states] = hmmgenerate(len,TRANS,EMIS) takes a known Markov model, specified by transition probability matrix TRANS and emission probability matrix EMIS, and uses it to generate

- A random sequence `seq` of emission symbols
- A random sequence `states` of states

The length of both `seq` and `states` is `len`. $\text{TRANS}(i, j)$ is the probability of transition from state `i` to state `j`. $\text{EMIS}(k, l)$ is the probability that symbol `l` is emitted from state `k`.

Note The function `hmmgenerate` begins with the model in state 1 at step 0, prior to the first emission. The model then makes a transition to state i_1 , with probability T_{1i_1} , and generates an emission a_{k_1} with probability $E_{i_1k_1}$. `hmmgenerate` returns i_1 as the first entry of `states`, and a_{k_1} as the first entry of `seq`.

`hmmgenerate(...,'Symbols',SYMBOLS)` specifies the symbols that are emitted. SYMBOLS can be a numeric array or a cell array of the names of the symbols. The default symbols are integers 1 through N, where N is the number of possible emissions.

`hmmgenerate(...,'Statenames',STATENAMES)` specifies the names of the states. STATENAMES can be a numeric array or a cell array of the names of the states. The default state names are 1 through M, where M is the number of states.

Since the model always begins at state 1, whose transition probabilities are in the first row of TRANS, in the following example, the first entry of the output states is be 1 with probability 0.95 and 2 with probability 0.05.

Examples

```
trans = [0.95,0.05;
         0.10,0.90];
emis = [1/6 1/6 1/6 1/6 1/6 1/6;
        1/10 1/10 1/10 1/10 1/10 1/2];

[seq,states] = hmmgenerate(100,trans,emis)
[seq,states] = hmmgenerate(100,trans,emis,...
    'Symbols',{'one','two','three','four','five','six'},...
    'Statenames',{'fair';'loaded'})
```

See Also

[hmmviterbi](#) | [hmmdecode](#) | [hmmestimate](#) | [hmmtrain](#)

hmmtrain

Hidden Markov model parameter estimates from emissions

Syntax

```
[ESTTR,ESTEMIT] = hmmtrain(seq,TRGUESS,EMITGUESS)
hmmtrain(...,'Algorithm',algorithm)
hmmtrain(...,'Symbols',SYMBOLS)
hmmtrain(...,'Tolerance',tol)
hmmtrain(...,'Maxiterations',maxiter)
hmmtrain(...,'Verbose',true)
hmmtrain(...,'Pseudoemissions',PSEUDOE)
hmmtrain(...,'Pseudotransitions',PSEUDOTR)
```

Description

[ESTTR,ESTEMIT] = `hmmtrain(seq,TRGUESS,EMITGUESS)` estimates the transition and emission probabilities for a hidden Markov model using the Baum-Welch algorithm. `seq` can be a row vector containing a single sequence, a matrix with one row per sequence, or a cell array with each cell containing a sequence. `TRGUESS` and `EMITGUESS` are initial estimates of the transition and emission probability matrices. `TRGUESS(i,j)` is the estimated probability of transition from state `i` to state `j`. `EMITGUESS(i,k)` is the estimated probability that symbol `k` is emitted from state `i`.

`hmmtrain(...,'Algorithm',algorithm)` specifies the training algorithm. *algorithm* can be either 'BaumWelch' or 'Viterbi'. The default algorithm is 'BaumWelch'.

`hmmtrain(...,'Symbols',SYMBOLS)` specifies the symbols that are emitted. `SYMBOLS` can be a numeric array or a cell array of the names of the symbols. The default symbols are integers 1 through `N`, where `N` is the number of possible emissions.

`hmmtrain(...,'Tolerance',tol)` specifies the tolerance used for testing convergence of the iterative estimation process. The default tolerance is `1e-4`.

`hmmtrain(...,'Maxiterations',maxiter)` specifies the maximum number of iterations for the estimation process. The default maximum is `100`.

`hmmtrain(..., 'Verbose', true)` returns the status of the algorithm at each iteration.

`hmmtrain(..., 'Pseudoemissions', PSEUDOE)` specifies pseudocount emission values for the Viterbi training algorithm. Use this argument to avoid zero probability estimates for emissions with very low probability that might not be represented in the sample sequence. `PSEUDOE` should be a matrix of size m -by- n , where m is the number of states in the hidden Markov model and n is the number of possible emissions. If the $i \rightarrow k$ emission does not occur in `seq`, you can set `PSEUDOE(i, k)` to be a positive number representing an estimate of the expected number of such emissions in the sequence `seq`.

`hmmtrain(..., 'Pseudotransitions', PSEUDOTR)` specifies pseudocount transition values for the Viterbi training algorithm. Use this argument to avoid zero probability estimates for transitions with very low probability that might not be represented in the sample sequence. `PSEUDOTR` should be a matrix of size m -by- m , where m is the number of states in the hidden Markov model. If the $i \rightarrow j$ transition does not occur in `states`, you can set `PSEUDOTR(i, j)` to be a positive number representing an estimate of the expected number of such transitions in the sequence `states`.

If you know the states corresponding to the sequences, use `hmmestimate` to estimate the model parameters.

Tolerance

The input argument `'tolerance'` controls how many steps the `hmmtrain` algorithm executes before the function returns an answer. The algorithm terminates when all of the following three quantities are less than the value that you specify for `tolerance`:

- The log likelihood that the input sequence `seq` is generated by the currently estimated values of the transition and emission matrices
- The change in the norm of the transition matrix, normalized by the size of the matrix
- The change in the norm of the emission matrix, normalized by the size of the matrix

The default value of `'tolerance'` is `.0001`. Increasing the tolerance decreases the number of steps the `hmmtrain` algorithm executes before it terminates.

maxiterations

The maximum number of iterations, `'maxiterations'`, controls the maximum number of steps the algorithm executes before it terminates. If the algorithm

executes `maxiter` iterations before reaching the specified tolerance, the algorithm terminates and the function returns a warning. If this occurs, you can increase the value of `'maxiterations'` to make the algorithm reach the desired tolerance before terminating.

Examples

```
trans = [0.95,0.05;
         0.10,0.90];
emis = [1/6, 1/6, 1/6, 1/6, 1/6, 1/6;
        1/10, 1/10, 1/10, 1/10, 1/10, 1/2];

seq1 = hmmgenerate(100,trans,emis);
seq2 = hmmgenerate(200,trans,emis);
seqs = {seq1,seq2};
[estTR,estE] = hmmtrain(seqs,trans,emis);
```

hmmviterbi

Hidden Markov model most probable state path

Syntax

```
STATES = hmmviterbi(seq,TRANS,EMIS)
hmmviterbi(...,'Symbols',SYMBOLS)
hmmviterbi(...,'Statenames',STATENAMES)
```

Description

`STATES = hmmviterbi(seq,TRANS,EMIS)` given a sequence, `seq`, calculates the most likely path through the hidden Markov model specified by transition probability matrix, `TRANS`, and emission probability matrix `EMIS`. `TRANS(i,j)` is the probability of transition from state `i` to state `j`. `EMIS(i,k)` is the probability that symbol `k` is emitted from state `i`.

Note The function `hmmviterbi` begins with the model in state 1 at step 0, prior to the first emission. `hmmviterbi` computes the most likely path based on the fact that the model begins in state 1.

`hmmviterbi(...,'Symbols',SYMBOLS)` specifies the symbols that are emitted. `SYMBOLS` can be a numeric array or a cell array of the names of the symbols. The default symbols are integers 1 through `N`, where `N` is the number of possible emissions.

`hmmviterbi(...,'Statenames',STATENAMES)` specifies the names of the states. `STATENAMES` can be a numeric array or a cell array of the names of the states. The default state names are 1 through `M`, where `M` is the number of states.

Examples

```
trans = [0.95,0.05;
         0.10,0.90];
```

```
emis = [1/6 1/6 1/6 1/6 1/6 1/6;  
        1/10 1/10 1/10 1/10 1/10 1/2];  
  
[seq,states] = hmmgenerate(100,trans,emis);  
estimatedStates = hmmviterbi(seq,trans,emis);  
  
[seq,states] = ...  
    hmmgenerate(100,trans,emis,...  
                'Statenames',{'fair';'loaded'});  
estimatedStates = ...  
    hmmviterbi(seq,trans,emis,...  
                'Statenames',{'fair';'loaded'});
```

horzcat

Class: dataset

Horizontal concatenation for dataset arrays

Compatibility

The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

Syntax

```
ds = horzcat(ds1, ds2, ...)
```

Description

`ds = horzcat(ds1, ds2, ...)` horizontally concatenates the dataset arrays `ds1`, `ds2`, You may concatenate dataset arrays that have duplicate variable names, however, the variables must contain identical data, and `horzcat` includes only one copy of the variable in the output dataset.

Observation names for all dataset arrays that have them must be identical except for order. `horzcat` concatenates by matching observation names when present, or by position for datasets that do not have observation names.

See Also

`cat` | `vertcat`

hougen

Hougen-Watson model

Syntax

```
yhat = hougen(beta, x)
```

Description

`yhat = hougen(beta, x)` returns the predicted values of the reaction rate, `yhat`, as a function of the vector of parameters, `beta`, and the matrix of data, `X`. `beta` must have 5 elements and `X` must have three columns.

`hougen` is a utility function for `rsmdemo`.

The model form is:

$$\hat{y} = \frac{\beta_1 x_2 - x_3 / \beta_5}{1 + \beta_2 x_1 + \beta_3 x_2 + \beta_4 x_3}$$

`rsmdemo`

hygecdf

Hypergeometric cumulative distribution function

Syntax

```
hygecdf(x,M,K,N)  
hygecdf(x,M,K,N,'upper')
```

Description

`hygecdf(x,M,K,N)` computes the hypergeometric cdf at each of the values in `x` using the corresponding size of the population, `M`, number of items with the desired characteristic in the population, `K`, and number of samples drawn, `N`. Vector or matrix inputs for `x`, `M`, `K`, and `N` must all have the same size. A scalar input is expanded to a constant matrix with the same dimensions as the other inputs.

`hygecdf(x,M,K,N,'upper')` returns the complement of the hypergeometric cdf at each value in `x`, using an algorithm that more accurately computes the extreme upper tail probabilities.

The hypergeometric cdf is

$$p = F(x | M, K, N) = \sum_{i=0}^x \frac{\binom{K}{i} \binom{M-K}{N-i}}{\binom{M}{N}}$$

The result, p , is the probability of drawing up to x of a possible K items in N drawings without replacement from a group of M objects.

Examples

Compute Hypergeometric Distribution CDF

Suppose you have a lot of 100 floppy disks and you know that 20 of them are defective. What is the probability of drawing zero to two defective floppies if you select 10 at random?

```
p = hygecdf(2,100,20,10)
```

```
p =  
    0.6812
```

See Also

hygeinv

Hypergeometric inverse cumulative distribution function

Syntax

```
hygeinv(P,M,K,N)
```

Description

`hygeinv(P,M,K,N)` returns the smallest integer X such that the hypergeometric cdf evaluated at X equals or exceeds P . You can think of P as the probability of observing X defective items in N drawings without replacement from a group of M items where K are defective.

Examples

Suppose you are the Quality Assurance manager for a floppy disk manufacturer. The production line turns out floppy disks in batches of 1,000. You want to sample 50 disks from each batch to see if they have defects. You want to accept 99% of the batches if there are no more than 10 defective disks in the batch. What is the maximum number of defective disks should you allow in your sample of 50?

```
x = hygeinv(0.99,1000,10,50)
x =
    3
```

What is the median number of defective floppy disks in samples of 50 disks from batches with 10 defective disks?

```
x = hygeinv(0.50,1000,10,50)
x =
    0
```

See Also

[icdf](#) | [hygecdf](#) | [hygepdf](#) | [hygestat](#) | [hygernd](#)

hygepdf

Hypergeometric probability density function

Syntax

$Y = \text{hygepdf}(X, M, K, N)$

Description

$Y = \text{hygepdf}(X, M, K, N)$ computes the hypergeometric pdf at each of the values in X using the corresponding size of the population, M , number of items with the desired characteristic in the population, K , and number of samples drawn, N . X , M , K , and N can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs.

The parameters in M , K , and N must all be positive integers, with $N \leq M$. The values in X must be less than or equal to all the parameter values.

The hypergeometric pdf is

$$y = f(x | M, K, N) = \frac{\binom{K}{x} \binom{M-K}{N-x}}{\binom{M}{N}}$$

The result, y , is the probability of drawing exactly x of a possible K items in n drawings without replacement from a group of M objects.

Examples

Suppose you have a lot of 100 floppy disks and you know that 20 of them are defective. What is the probability of drawing 0 through 5 defective floppy disks if you select 10 at random?

```
p = hygepdf(0:5,100,20,10)
p =
    0.0951    0.2679    0.3182    0.2092    0.0841    0.0215
```

See Also

pdf | hygecdf | hygeinv | hygestat | hygernd

hygernd

Hypergeometric random numbers

Syntax

```
R = hygernd(M,K,N)
R = hygernd(M,K,N,m,n,...)
R = hygernd(M,K,N,[m,n,...])
```

Description

`R = hygernd(M,K,N)` generates random numbers from the hypergeometric distribution with corresponding size of the population, `M`, number of items with the desired characteristic in the population, `K`, and number of samples drawn, `N`. `M`, `K`, and `N` can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of `R`. A scalar input for `M`, `K`, or `N` is expanded to a constant array with the same dimensions as the other inputs.

`R = hygernd(M,K,N,m,n,...)` or `R = hygernd(M,K,N,[m,n,...])` generates an `m-by-n-by-...` array. The `M`, `K`, `N` parameters can each be scalars or arrays of the same size as `R`.

Examples

```
numbers = hygernd(1000,40,50)
numbers =
    1
```

See Also

[random](#) | [hygepdf](#) | [hygecdf](#) | [hygeinv](#) | [hygestat](#)

hygestat

Hypergeometric mean and variance

Syntax

```
[MN,V] = hygestat(M,K,N)
```

Description

`[MN,V] = hygestat(M,K,N)` returns the mean of and variance for the hypergeometric distribution with corresponding size of the population, M , number of items with the desired characteristic in the population, K , and number of samples drawn, N . Vector or matrix inputs for M , K , and N must have the same size, which is also the size of MN and V . A scalar input for M , K , or N is expanded to a constant matrix with the same dimensions as the other inputs.

The mean of the hypergeometric distribution with parameters M , K , and N is NK/M , and the variance is $NK(M-K)(M-N) / [M^2(M-1)]$.

Examples

The hypergeometric distribution approaches the binomial distribution, where $p = K/M$, as M goes to infinity.

```
[m,v] = hygestat(10.^(1:4),10.^(0:3),9)
m =
    0.9000    0.9000    0.9000    0.9000
v =
    0.0900    0.7445    0.8035    0.8094
```

```
[m,v] = binostat(9,0.1)
m =
    0.9000
v =
    0.8100
```

icdf

Inverse cumulative distribution functions

Syntax

$Y = \text{icdf}(\text{name}, X, A)$

$Y = \text{icdf}(\text{name}, X, A, B)$

$Y = \text{icdf}(\text{name}, X, A, B, C)$

Description

$Y = \text{icdf}(\text{name}, X, A)$ computes the inverse cumulative distribution function for the one-parameter family of distributions specified by **name**. Parameter values for the distribution are given in **A**. The inverse cumulative distribution function is evaluated at the values in **X** and its values are returned in **Y**.

If **X** and **A** are arrays, they must be the same size. If **X** is a scalar, it is expanded to a constant matrix the same size as **A**. If **A** is a scalar, it is expanded to a constant matrix the same size as **X**.

Y is the common size of **X** and **A** after any necessary scalar expansion.

$Y = \text{icdf}(\text{name}, X, A, B)$ computes the inverse cumulative distribution function for two-parameter families of distributions, where parameter values are given in **A** and **B**.

If **X**, **A**, and **B** are arrays, they must be the same size. If **X** is a scalar, it is expanded to a constant matrix the same size as **A** and **B**. If either **A** or **B** are scalars, they are expanded to constant matrices the same size as **X**.

Y is the common size of **X**, **A**, and **B** after any necessary scalar expansion.

$Y = \text{icdf}(\text{name}, X, A, B, C)$ computes the inverse cumulative distribution function for three-parameter families of distributions, where parameter values are given in **A**, **B**, and **C**.

If **X**, **A**, **B**, and **C** are arrays, they must be the same size. If **X** is a scalar, it is expanded to a constant matrix the same size as **A**, **B**, and **C**. If any of **A**, **B** or **C** are scalars, they are expanded to constant matrices the same size as **X**.

Y is the common size of X, A, B and C after any necessary scalar expansion.

Examples

Compute the icdf of the normal distribution with mean 0 and standard deviation 1 at inputs 0.1, 0.3, ..., 0.9:

```
x1 = icdf('Normal',0.1:0.2:0.9,0,1)
x1 =
    -1.2816   -0.5244    0    0.5244    1.2816
```

The order of the parameters is the same as for `norminv`.

Compute the icdfs of Poisson distributions with rate parameters 0, 1, ..., 4 at inputs 0.1, 0.3, ..., 0.9, respectively:

```
x2 = icdf('Poisson',0.1:0.2:0.9,0:4)
x2 =
    NaN     0     2     4     7
```

The order of the parameters is the same as for `poissinv`.

icdf

Class: `piecwisedistribution`

Inverse cumulative distribution function for piecewise distribution

Syntax

```
X = icdf(obj,P)
```

Description

`X = icdf(obj,P)` returns an array `X` of values of the inverse cumulative distribution function for the piecewise distribution object `obj`, evaluated at the values in the array `P`.

Examples

Fit Pareto tails to a *t* distribution at cumulative probabilities 0.1 and 0.9:

```
t = trnd(3,100,1);
obj = paretotails(t,0.1,0.9);
[p,q] = boundary(obj)
p =
    0.1000
    0.9000
q =
   -1.7766
    1.8432

icdf(obj,p)
ans =
   -1.7766
    1.8432
```

See Also

icdf

Class: ProbDistUnivKernel

Return inverse cumulative distribution function (ICDF) for ProbDistUnivKernel object

Syntax

$Y = \text{icdf}(PD, P)$

Description

$Y = \text{icdf}(PD, P)$ returns Y , an array containing the inverse cumulative distribution function (ICDF) for the ProbDistUnivKernel object PD , evaluated at values in P .

Input Arguments

PD	An object of the class ProbDistUnivKernel.
P	A numeric array of values from 0 to 1 where you want to evaluate the ICDF.

Output Arguments

Y	An array containing the inverse cumulative distribution function (ICDF) for the ProbDistUnivKernel object PD .
-----	--

See Also

icdf

icdf

Class: ProbDistUnivParam

Return inverse cumulative distribution function (ICDF) for ProbDistUnivParam object

Syntax

$Y = \text{icdf}(PD, P)$

Description

$Y = \text{icdf}(PD, P)$ returns Y , an array containing the inverse cumulative distribution function (ICDF) for the ProbDistUnivParam object PD , evaluated at values in P .

Input Arguments

PD	An object of the class ProbDistUnivParam.
P	A numeric array of values from 0 to 1 where you want to evaluate the ICDF.

Output Arguments

Y	An array containing the inverse cumulative distribution function (ICDF) for the ProbDistUnivParam object PD .
-----	---

icdf

icdf

Class: prob.TruncatableDistribution

Package: prob

Inverse cumulative distribution function of probability distribution object

Syntax

```
y = icdf(pd,prob)
```

Description

`y = icdf(pd,prob)` returns the inverse cumulative distribution function (icdf) values of the probability distribution `pd` at the probabilities in `prob`.

Input Arguments

pd — Probability distribution

probability distribution object

Probability distribution, specified as a probability distribution object. Create a probability distribution object with specified parameter values using `makedist`. Alternatively, for fittable distributions, create a probability distribution object by fitting it to data using `fitdist` or the Distribution Fitting app.

prob — Probabilities

array of scalar values in the range [0,1]

Probabilities at which to compute the icdf, specified as an array of scalar values in the range [0,1]. For example, specifying `[.25 .5 .75]` returns a vector containing three icdf values corresponding to these probabilities.

Data Types: `single` | `double`

Output Arguments

y — Inverse cumulative distribution function

array

Inverse cumulative distribution function (icdf) values of the specified probability distribution, evaluated at the probabilities in `prob`, returned as an array. `y` has the same dimensions as `x`.

Examples

Compute Standard Normal Critical Values

Create a standard normal distribution object.

```
pd = makedist('Normal')
```

```
pd =
```

```
NormalDistribution
```

```
Normal distribution
```

```
mu = 0
```

```
sigma = 1
```

Determine the critical values at the 5% significance level for a test statistic with a standard normal distribution, by computing the upper and lower 2.5% values.

```
y = icdf(pd, [.025, .975])
```

```
y =
```

```
-1.9600    1.9600
```

Plot the cdf and shade the critical regions.

```
p = normspec(y,0,1,'outside')
```

inconsistent

Inconsistency coefficient

Syntax

```
Y = inconsistent(Z)
Y = inconsistent(Z,d)
```

Description

`Y = inconsistent(Z)` computes the inconsistency coefficient for each link of the hierarchical cluster tree `Z`, where `Z` is an $(m-1)$ -by-3 matrix generated by the `linkage` function. The inconsistency coefficient characterizes each link in a cluster tree by comparing its height with the average height of other links at the same level of the hierarchy. The higher the value of this coefficient, the less similar the objects connected by the link.

`Y = inconsistent(Z,d)` computes the inconsistency coefficient for each link in the hierarchical cluster tree `Z` to depth `d`, where `d` is an integer denoting the number of levels of the cluster tree that are included in the calculation. By default, `d=2`.

The output, `Y`, is an $(m-1)$ -by-4 matrix formatted as follows.

Column	Description
1	Mean of the heights of all the links included in the calculation.
2	Standard deviation of the heights of all the links included in the calculation.
3	Number of links included in the calculation.
4	Inconsistency coefficient.

For each link, k , the inconsistency coefficient is calculated as:

$$Y(k,4) = (z(k,3) - Y(k,1)) / Y(k,2)$$

For leaf nodes, nodes that have no further nodes under them, the inconsistency coefficient is set to 0.

Examples

Compute Inconsistency Coefficient

Create the sample data.

```
X = gallery('uniformdata',[10 2],12);  
Y = pdist(X);
```

Generate the hierarchical cluster tree.

```
Z = linkage(Y,'single');
```

Generate a dendrogram plot of the hierarchical cluster tree.

```
dendrogram(Z)
```

Compute the inconsistency coefficient for each link in the cluster tree Z to depth 3.

$W = \text{inconsistent}(Z, 3)$

$W =$

increaseB

Class: clustering.evaluation.GapEvaluation

Package: clustering.evaluation

Increase reference data sets

Syntax

```
eva_out = increaseB(eva,nref)
```

Description

`eva_out = increaseB(eva,nref)` returns a gap criterion clustering evaluation object `eva_out` that uses the same evaluation criteria as the input object `eva` and an additional number of reference data sets as specified by `nref`.

Input Arguments

eva — Clustering evaluation data

clustering evaluation object

Clustering evaluation data, specified as a clustering evaluation object. Create a clustering evaluation object using `evalclusters`.

nref — Number of additional reference data sets

positive integer value

Number of additional reference data sets, specified as a positive integer value.

Output Arguments

eva_out — Updated clustering evaluation data

clustering evaluation object

Updated clustering evaluation data, returned as a gap criterion clustering evaluation object. `eva_out` contains evaluation data obtained using the reference data sets from the input object `eva` plus a number of additional reference data sets as specified in `nref`.

`increaseB` updates the `B` property of the input object `eva` to reflect the increase in the number of reference data sets used to compute the gap criterion values. `increaseB` also updates the `CriterionValues` property with gap criterion values computed using the total number of reference data sets. `increaseB` might also update the `OptimalK` and `OptimalY` properties to reflect the optimal number of clusters and optimal clustering solution as determined using the total number of reference data sets. Additionally, `increaseB` might also update the `LogW`, `ExpectedLogW`, `StdLogW`, and `SE` properties.

Examples

Evaluate Clustering Solutions Using Additional Reference Data

Create a gap clustering evaluation object using `evalclusters`, then use `increaseB` to increase the number of reference data sets used to compute the gap criterion values.

Load the sample data.

```
load fisheriris;
```

The data contains length and width measurements from the sepals and petals of three species of iris flowers.

Cluster the flower measurement data using `kmeans`, and use the gap criterion to evaluate proposed solutions of one through five clusters. Use 50 reference data sets.

```
eva = evalclusters(meas, 'kmeans', 'gap', 'klist', 1:5, 'B', 50)
```

```
eva =
```

```
GapEvaluation with properties:
```

```
NumObservations: 150
  InspectedK: [1 2 3 4 5]
CriterionValues: [0.0848 0.5920 0.8750 1.0044 1.0462]
  OptimalK: 5
```

The clustering evaluation object `eva` contains data on each proposed clustering solution. The returned results indicate that the optimal number of clusters is five.

The value of the **B** property of `eva` shows 50 reference data sets.

```
eva.B
```

```
ans =
```

```
    50
```

Increase the number of reference data sets by 50, for a total of 100 sets.

```
eva = increaseB(eva,50)
```

```
eva =
```

```
GapEvaluation with properties:
```

```
  NumObservations: 150
```

```
  InspectedK: [1 2 3 4 5]
```

```
  CriterionValues: [0.0824 0.5899 0.8742 1.0044 1.0463]
```

```
  OptimalK: 4
```

The returned results now indicate that the optimal number of clusters is four.

The value of the **B** property of `eva` now shows 100 reference data sets.

```
eva.B
```

```
ans =
```

```
   100
```

`evalclusters`

InputData property

Class: ProbDist

Read-only structure containing information about input data to ProbDist object

Description

InputData is a read-only property of the ProbDist class. InputData is a structure containing information about input data to a ProbDist object. It includes the following fields:

- data
- cens
- freq

Values

Possible values for the three fields in the structure are any data supplied to the `fitdist` function:

- **data** — Data passed to the `fitdist` function when creating the ProbDist object. This field is empty if the ProbDist object was created without fitting to data, that is by using the `ProbDistUnivParam` constructor.
- **cens** — The vector supplied with the `'censoring'` parameter when creating the ProbDist object using the `fitdist` function. This field is empty if the ProbDist object was created without fitting to data, that is by using the `ProbDistUnivParam` constructor.
- **freq** — The vector supplied with the `'frequency'` parameter when creating the ProbDist object using the `fitdist` function. This field is empty if the ProbDist object was created without fitting to data, that is by using the `ProbDistUnivParam` constructor.

Use this information to view and compare the data supplied to create distributions.

interactionplot

Interaction plot for grouped data

Syntax

```
interactionplot(Y, GROUP)
interactionplot(Y, GROUP, 'varnames', VARNAMES)
[h, AX, bigax] = interactionplot(...)
```

Description

`interactionplot(Y, GROUP)` displays the two-factor interaction plot for the group means of matrix `Y` with groups defined by entries in the cell array `GROUP`. `Y` is a numeric matrix or vector. If `Y` is a matrix, the rows represent different observations and the columns represent replications of each observation. If `Y` is a vector, the rows give the means of each entry in the cell array `GROUP`. Each cell of `GROUP` must contain a grouping variable that can be a categorical variable, numeric vector, character matrix, or a single-column cell array of strings. `GROUP` can also be a matrix whose columns represent different grouping variables. Each grouping variable must have the same number of rows as `Y`. The number of grouping variables must be greater than 1.

The interaction plot is a matrix plot, with the number of rows and columns both equal to the number of grouping variables. The grouping variable names are printed on the diagonal of the plot matrix. The plot at off-diagonal position (i,j) is the interaction of the two variables whose names are given at row diagonal (i,i) and column diagonal (j,j) , respectively.

`interactionplot(Y, GROUP, 'varnames', VARNAMES)` displays the interaction plot with user-specified grouping variable names `VARNAMES`. `VARNAMES` is a character matrix or a cell array of strings, one per grouping variable. Default names are 'X1', 'X2',

`[h, AX, bigax] = interactionplot(...)` returns a handle `h` to the figure window, a matrix `AX` of handles to the subplot axes, and a handle `bigax` to the big (invisible) axes framing the subplots.

Examples

Display Interaction Plots

Randomly generate data for a response variable y .

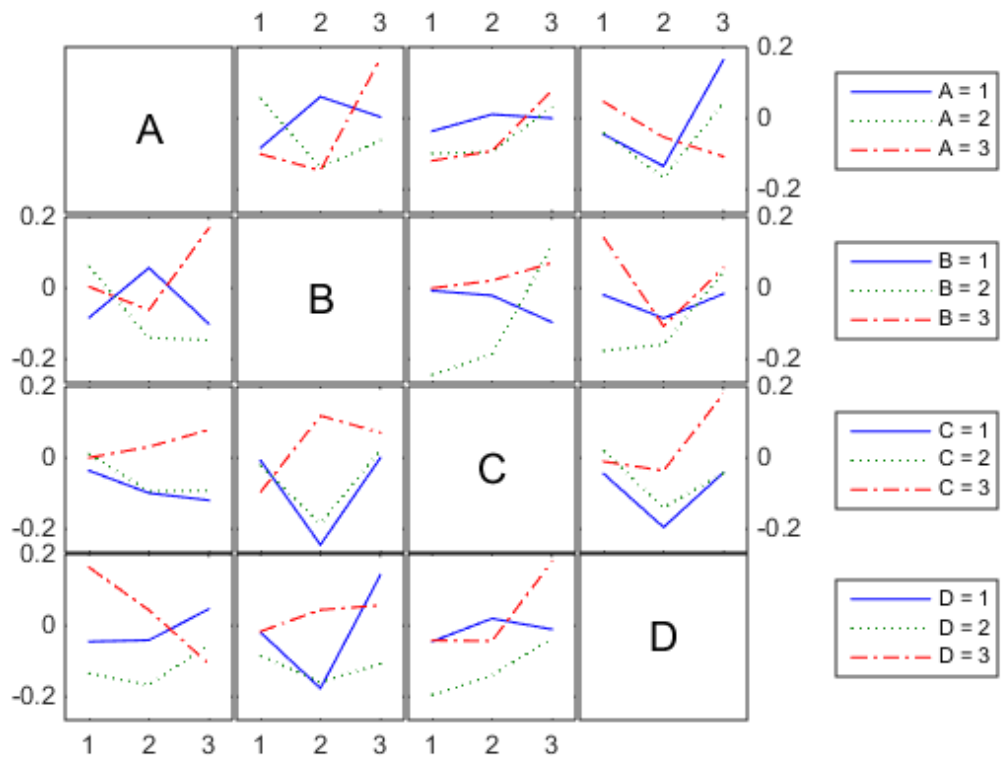

```
rng default; % For reproducibility  
y = randn(1000,1);
```

Randomly generate data for four three-level factors.

```
group = ceil(3*rand(1000,4));
```

Display the interaction plots for the factors and name the factors 'A', 'B', 'C', 'D'.

```
interactionplot(y,group, 'varnames', {'A', 'B', 'C', 'D'})
```

`maineffectsplot` | `multivarichart`

intersect

Class: dataset

Set intersection for dataset array observations

Compatibility

The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

Syntax

```
C = intersect(A,B)
C = intersect(A,B,vars)
C = intersect(A,B,vars,setOrder)
[C,iA,iB] = intersect( ___ )
```

Description

`C = intersect(A,B)` for dataset arrays `A` and `B` returns the common set of observations from the two arrays, with repetitions removed. The observations in the dataset array `C` are in sorted order.

`C = intersect(A,B,vars)` returns the set of common observations from the two arrays, considering only the variables specified in `vars`, with repetitions removed. The observations in the dataset array `C` are sorted by those variables.

The values for variables not specified in `vars` for each observation in `C` are taken from the corresponding observations in `A`. If there are multiple observations in `A` that correspond to an observation in `C`, then those values are taken from the first occurrence.

`C = intersect(A,B,vars,setOrder)` returns the observations in `C` in the order specified by `setOrder`.

`[C, iA, iB] = intersect(____)` also returns index vectors `iA` and `iB` such that `C = A(iA, :)` and `C = B(iB, :)`. If there are repeated observations in `A` or `B`, then `intersect` returns the index of the first occurrence. You can use any of the previous input arguments.

Input Arguments

A, B

Input dataset arrays.

vars

Cell array of strings containing variable names or a vector of integers containing variable column numbers, indicating the variables in `A` and `B` that `intersect` considers.

Specify `vars` as `[]` to use its default value of all variables.

setOrder

Flag indicating the sorting order for the observations in `C`. The possible values of `setOrder` are:

- | | |
|----------|---|
| 'sorted' | Observations in <code>C</code> are in sorted order (default). |
| 'stable' | Observations in <code>C</code> are in the same order that they appear in <code>A</code> . |

Output Arguments

C

Dataset array with the common set of observations in `A` and `B`, with repetitions removed. `C` is in sorted order (by default), or the order specified by `setOrder`.

iA

Index vector, indicating the observations in `A` that are common to `B`. The vector `iA` contains the index to the first occurrence of any repeated observations in `A`.

iB

Index vector, indicating the observations in **B** that are common to **A**. The vector **iB** contains the index to the first occurrence of any repeated observations in **B**.

Examples

Intersection of Two Dataset Arrays

Navigate to the folder containing sample data, and load sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

```
A = dataset('XLSFile','hospitalSmall.xlsx');
B = dataset('XLSFile','hospitalSmall.xlsx','Sheet',2);
```

Return the intersection and index vectors.

```
[C,iA,iB] = intersect(A,B);
```

C =

id	name	sex	age	wgt	smoke
'TRW-072'	'WHITE'	'm'	39	202	1

There is one observation in common between **A** and **B**.

Find the observation in the original dataset arrays.

```
A(iA,:)
```

ans =

id	name	sex	age	wgt	smoke
'TRW-072'	'WHITE'	'm'	39	202	1

```
B(iB,:)
```

ans =

id	name	sex	age	wgt	smoke
'TRW-072'	'WHITE'	'm'	39	202	1

prob.InverseGaussianDistribution class

Package: prob

Superclasses: prob.ToolboxFittableParametricDistribution

Inverse Gaussian probability distribution object

Description

`prob.InverseGaussianDistribution` is an object consisting of parameters, a model description, and sample data for an inverse Gaussian probability distribution.

Create a probability distribution object with specified parameter values using `makedist`. Alternatively, fit a distribution to data using `fitdist` or the Distribution Fitting app.

Construction

`pd = makedist('InverseGaussian')` creates an inverse Gaussian probability distribution object using the default parameter values.

`pd = makedist('InverseGaussian','mu',mu,'lambda',lambda)` creates an inverse Gaussian probability distribution object using the specified parameter values.

Input Arguments

mu — Scale parameter

1 (default) | positive scalar value

Scale parameter for the inverse Gaussian distribution, specified as a positive scalar value.

Data Types: `single` | `double`

lambda — Shape parameter

1 (default) | positive scalar value

Shape parameter for the inverse Gaussian distribution, specified as a positive scalar value.

Data Types: `single` | `double`

Properties

mu — Scale parameter

positive scalar value

Scale parameter for the inverse Gaussian distribution, stored as a positive scalar value.

Data Types: `single` | `double`

lambda — Shape parameter

positive scalar value

Shape parameter for the inverse Gaussian distribution, stored as a positive scalar value.

Data Types: `single` | `double`

DistributionName — Probability distribution name

probability distribution name string

Probability distribution name, stored as a valid probability distribution name string. This property is read-only.

Data Types: `char`

InputData — Data used for distribution fitting

structure

Data used for distribution fitting, stored as a structure containing the following:

- **data**: Data vector used for distribution fitting.
- **cens**: Censoring vector, or empty if none.
- **freq**: Frequency vector, or empty if none.

This property is read-only.

Data Types: `struct`

IsTruncated — Logical flag for truncated distribution

0 | 1

Logical flag for truncated distribution, stored as a logical value. If `IsTruncated` equals 0, the distribution is not truncated. If `IsTruncated` equals 1, the distribution is truncated. This property is read-only.

Data Types: `logical`

NumParameters — Number of parameters

positive integer value

Number of parameters for the probability distribution, stored as a positive integer value. This property is read-only.

Data Types: `single` | `double`

ParameterCovariance — Covariance matrix of the parameter estimates

matrix of scalar values

Covariance matrix of the parameter estimates, stored as a p -by- p matrix, where p is the number of parameters in the distribution. The (i, j) element is the covariance between the estimates of the i th parameter and the j th parameter. The (i, i) element is the estimated variance of the i th parameter. If parameter i is fixed rather than estimated by fitting the distribution to data, then the (i, i) elements of the covariance matrix are 0. This property is read-only.

Data Types: `single` | `double`

ParameterDescription — Distribution parameter descriptions

cell array of strings

Distribution parameter descriptions, stored as a cell array of strings. Each cell contains a short description of one distribution parameter. This property is read-only.

Data Types: `char`

ParameterIsFixed — Logical flag for fixed parameters

array of logical values

Logical flag for fixed parameters, stored as an array of logical values. If 0, the corresponding parameter in the `ParameterNames` array is not fixed. If 1, the corresponding parameter in the `ParameterNames` array is fixed. This property is read-only.

Data Types: `logical`

ParameterNames — Distribution parameter names

cell array of strings

Distribution parameter names, stored as a cell array of strings. This property is read-only.

Data Types: char

ParameterValues — Distribution parameter values

vector of scalar values

Distribution parameter values, stored as a vector. This property is read-only.

Data Types: single | double

Truncation — Truncation interval

vector of scalar values

Truncation interval for the probability distribution, stored as a vector containing the lower and upper truncation boundaries. This property is read-only.

Data Types: single | double

Methods

Inherited Methods

cdf

Cumulative distribution function of probability distribution object

icdf

Inverse cumulative distribution function of probability distribution object

iqr

Interquartile range of probability distribution object

median

Median of probability distribution object

pdf	Probability density function of probability distribution object
random	Generate random numbers from probability distribution object
truncate	Truncate probability distribution object
mean	Mean of probability distribution object
negloglik	Negative loglikelihood of probability distribution object
paramci	Confidence intervals for probability distribution parameters
proflik	Profile likelihood function for probability distribution object
std	Standard deviation of probability distribution object
var	Variance of probability distribution object

Definitions

Inverse Gaussian Distribution

Also known as the Wald distribution, the inverse Gaussian is used to model nonnegative positively skewed data. Inverse Gaussian distributions have many similarities to standard Gaussian (normal) distributions, which lead to applications in inferential statistics.

The inverse Gaussian distribution uses the following parameters.

Parameter	Description	Support
mu	Scale parameter	$\mu > 0$
lambda	Shape parameter	$\lambda > 0$

The probability density function (pdf) is

$$f(x | \mu, \lambda) = \sqrt{\frac{\lambda}{2\pi x^3}} \exp\left\{-\frac{\lambda}{2\mu^2 x}(x - \mu)^2\right\} ; x > 0.$$

Examples

Create an Inverse Gaussian Distribution Object Using Default Parameters

Create an inverse Gaussian distribution object using the default parameter values.

```
pd = makedist('InverseGaussian')
```

```
pd =
```

```
InverseGaussianDistribution
Inverse Gaussian distribution
    mu = 1
    lambda = 1
```

Create an Inverse Gaussian Distribution Object Using Specified Parameters

Create an inverse Gaussian distribution object by specifying parameter values.

```
pd = makedist('InverseGaussian', 'mu', 2, 'lambda', 4)
```

```
pd =
```

```
InverseGaussianDistribution
Inverse Gaussian distribution
    mu = 2
    lambda = 4
```

Compute the standard deviation of the distribution.

```
s = std(pd)
```

```
s =
```

```
1.4142
```

- [“Property Attributes”](#)

invpred

Inverse prediction

Syntax

```
X0 = invpred(X,Y,Y0)
[X0,DXLO,DXUP] = invpred(X,Y,Y0)
[X0,DXLO,DXUP] = invpred(X,Y,Y0,name1,val1,name2,val2,...)
```

Description

`X0 = invpred(X,Y,Y0)` accepts vectors `X` and `Y` of the same length, fits a simple regression, and returns the estimated value `X0` for which the height of the line is equal to `Y0`. The output, `X0`, has the same size as `Y0`, and `Y0` can be an array of any size.

`[X0,DXLO,DXUP] = invpred(X,Y,Y0)` also computes 95% inverse prediction intervals. `DXLO` and `DXUP` define intervals with lower bound `X0-DXLO` and upper bound `X0+DXUP`. Both `DXLO` and `DXUP` have the same size as `Y0`.

The intervals are not simultaneous and are not necessarily finite. Some intervals may extend from a finite value to `-Inf` or `+Inf`, and some may extend over the entire real line.

`[X0,DXLO,DXUP] = invpred(X,Y,Y0,name1,val1,name2,val2,...)` specifies optional argument name/value pairs chosen from the following list. Argument names are case insensitive and partial matches are allowed.

Name	Value
'alpha'	A value between 0 and 1 specifying a confidence level of $100 \cdot (1 - \text{alpha})\%$. Default is <code>alpha=0.05</code> for 95% confidence.
'predopt'	Either 'observation', the default value to compute the intervals for <code>X0</code> at which a new observation could equal <code>Y0</code> , or 'curve' to compute intervals for the <code>X0</code> value at which the curve is equal to <code>Y0</code> .

Examples

Inverse Prediction

Generate sample data.

```
x = 4*rand(25,1);  
y = 10 + 5*x + randn(size(x));
```

Make a scatterplot of the data.

```
scatter(x,y)
```

Predict the x value for a given y value of 20.

```
x0 = invpred(x,y,20)
```

```
x0 =
```

```
1.9967
```

See Also

`polyfit` | `polyconf` | `polytool` | `polyval`

iqr

Interquartile range

Syntax

```
y = iqr(X)
iqr(X,dim)
```

Description

`y = iqr(X)` returns the interquartile range of the values in `X`. For vector input, `y` is the difference between the 75th and the 25th percentiles of the sample in `X`. For matrix input, `y` is a row vector containing the interquartile range of each column of `X`. For `N`-dimensional arrays, `iqr` operates along the first nonsingleton dimension of `X`.

`iqr(X,dim)` calculates the interquartile range along the dimension `dim` of `X`.

Examples

This Monte Carlo simulation shows the relative efficiency of the IQR to the sample standard deviation for normal data.

```
x = normrnd(0,1,100,100);
s = std(x);
s_IQR = 0.7413*iqr(x);
efficiency = (norm(s-1)./norm(s_IQR-1)).^2
efficiency =
    0.3297
```

More About

Tips

The IQR is a robust estimate of the spread of the data, since changes in the upper and lower 25% of the data do not affect it. If there are outliers in the data, then the IQR is

more representative than the standard deviation as an estimate of the spread of the body of the data. The IQR is less efficient than the standard deviation as an estimate of the spread when the data is all from the normal distribution.

Multiply the IQR by 0.7413 to estimate σ (the second parameter of the normal distribution.)

std | mad | range

iqr

Class: ProbDistUnivKernel

Return interquartile range (IQR) for ProbDistUnivKernel object

Syntax

$Y = \text{iqr}(PD)$

Description

$Y = \text{iqr}(PD)$ returns Y , the interquartile range for the ProbDistUnivKernel object PD . The interquartile range is the distance between the 75th and 25th percentiles.

Input Arguments

PD An object of the class ProbDistUnivKernel.

Output Arguments

Y The value of the interquartile range for the ProbDistUnivKernel object PD .

See Also

`iqr` | `ProbDistUnivKernel.icdf`

iqr

Class: ProbDistUnivParam

Return interquartile range (IQR) for ProbDistUnivParam object

Syntax

$Y = \text{iqr}(PD)$

Description

$Y = \text{iqr}(PD)$ returns Y , the interquartile range for the ProbDistUnivParam object PD . The interquartile range is the distance between the 75th and 25th percentiles.

Input Arguments

PD An object of the class ProbDistUnivParam.

Output Arguments

Y The value of the interquartile range for the ProbDistUnivParam object PD .

See Also

`iqr` | `ProbDistUnivParam.icdf`

iqr

Class: prob.TruncatableDistribution

Package: prob

Interquartile range of probability distribution object

Syntax

```
r = iqr(pd)
```

Description

`r = iqr(pd)` returns the interquartile range `r` of the probability distribution `pd`.

Input Arguments

pd — **Probability distribution**

probability distribution object

Probability distribution, specified as a probability distribution object. Create a probability distribution object with specified parameter values using `makedist`. Alternatively, for fittable distributions, create a probability distribution object by fitting it to data using `fitdist` or the Distribution Fitting app.

Output Arguments

r — **Interquartile range**

scalar value

Interquartile range of the probability distribution, returned as a scalar value. The value of `r` is the difference between the values of the 75th and 25th percentile of the probability distribution.

Examples

Interquartile Range of a Fitted Distribution

Load the sample data. Create a vector containing the first column of students' exam grade data.

```
load examgrades;  
x = grades(:,1);
```

Create a normal distribution object by fitting it to the data.

```
pd = fitdist(x, 'Normal')  
  
pd =  
  
NormalDistribution  
  
Normal distribution  
    mu = 75.0083    [73.4321, 76.5846]  
    sigma = 8.7202    [7.7391, 9.98843]
```

Compute the interquartile range of the fitted distribution.

```
r = iqr(pd)  
  
r =  
  
    11.7634
```

The returned result indicates that the difference between the 75th and 25th percentile of the students' grades is 11.7634.

Use `icdf` to determine the 75th and 25th percentiles of the students' grades.

```
y = icdf(pd, [0.25, 0.75])  
  
y =  
    69.1266    80.8900
```

Calculate the difference between the 75th and 25th percentiles. This yields the same result as `iqr`.

```
y(2) - y(1)
```

```
ans =  
    11.7634
```

Use `boxplot` to visualize the interquartile range.

```
boxplot(x)
```

The top line of the box shows the 75th percentile, and the bottom line shows the 25th percentile. The center line shows the median, which is the 50th percentile.

isbranch

Class: classregtree

Test node for branch

Syntax

```
ib = isbranch(t)
ib = isbranch(t,nodes)
```

Description

`ib = isbranch(t)` returns an n -element logical vector `ib` that is `true` for each branch node and `false` for each leaf node.

`ib = isbranch(t,nodes)` takes a vector `nodes` of node numbers and returns a vector of logical values for the specified nodes.

Examples

Create a classification tree for Fisher's iris data:

```
load fisheriris;

t = classregtree(meas,species,...
                'names',{'SL' 'SW' 'PL' 'PW'})
t =
Decision tree for classification
1  if PL<2.45 then node 2 elseif PL>=2.45 then node 3 else setosa
2  class = setosa
3  if PW<1.75 then node 4 elseif PW>=1.75 then node 5 else versicolor
4  if PL<4.95 then node 6 elseif PL>=4.95 then node 7 else versicolor
5  class = virginica
6  if PW<1.65 then node 8 elseif PW>=1.65 then node 9 else versicolor
7  class = virginica
8  class = versicolor
9  class = virginica
```

isempty

Class: dataset

True for empty dataset array

Compatibility

The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

Syntax

```
tf = isempty(A)
```

Description

`tf = isempty(A)` returns true (1) if `A` is an empty dataset and false (0) otherwise. An empty array has no elements, that is `prod(size(A))==0`.

See Also

`size`

islevel

Determine if levels are in nominal or ordinal array

Compatibility

The `nominal` and `ordinal` array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the MATLAB categorical data type instead.

Syntax

```
tf = islevel(levels,A)
```

Description

`tf = islevel(levels,A)` returns a logical array indicating which of the levels in `levels` correspond to a level in the nominal or ordinal array `A`.

Input Arguments

A — Nominal or ordinal array

nominal array | ordinal array

Nominal or ordinal array, specified as a `nominal` or `ordinal` array object created using `nominal` or `ordinal`.

levels — Levels to test

string | cell array of strings | 2-D character matrix

Levels to test, specified as a string, cell array of strings, or 2-D character matrix.

Data Types: `char` | `cell`

Output Arguments

tf – Logical array

array the same size as levels

Logical array, returned as an array the same size as levels. tf has value 1 (true) where the corresponding element of levels is the label of a level in the nominal or ordinal array A, even if the level contains no elements. tf has value 0 (false) otherwise.

More About

- Using nominal Objects
- Using ordinal Objects

`isequal` | `ismember` | `nominal` | `ordinal`

ismember

Class: dataset

Dataset array elements that are members of set

Compatibility

The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

Syntax

```
LiA = ismember(A,B)  
LiA = ismember(A,B,vars)  
[LiA,LocB] = ismember( ___ )
```

Description

`LiA = ismember(A,B)` for `dataset` arrays `A` and `B` returns a vector of logical values the same length as `A`. The output vector, `LiA`, has value `1` (true) in the elements that correspond to observations in `A` that are also present in `B`, and `0` (false) otherwise.

`LiA = ismember(A,B,vars)` returns a vector of logical values the same length as `A`. The output vector, `LiA`, has value `1` (true) in the elements that correspond to observations in `A` that are also present in `B` for the variables specified in `vars` only, and `0` (false) otherwise.

`[LiA,LocB] = ismember(___)` also returns a vector the same length as `A` containing the index to the first observation in `B` that corresponds to each observation in `A`, or `0` if there is no such observation. You can use any of the previous input arguments.

Input Arguments

A

Query dataset array, containing the observations to be found in B.

B

Set dataset array. When an observation in A is found in B, for all variables or only those variables specified in vars, the corresponding element of LiA is 1.

vars

Cell array of strings containing variable names or a vector of integers containing variable column numbers, indicating which variables to match observations on in A and B.

Output Arguments

LiA

Vector of logical values the same length as A. LiA has value 1 (true) when the corresponding observation in A is present in B. Otherwise, LiA has value 0 (false).

If you specify vars, LiA has value 1 when the corresponding observation in A is present in B for the variables in vars only.

LocB

Vector the same length as A containing the index to the first observation in B that corresponds to each observation in A, for all variables or only those variables specified in vars.

Examples

Find Observations That Are Members of a Dataset Array

Load sample data.

```
load('hospital')
```

```
B = hospital(1:50,1:5);
```

This set dataset array, **B**, has 50 observations on 5 variables.

Specify a query dataset array.

```
rng('default')
rIx = randsample(100,10);
A = hospital(rIx,1:5)
```

```
A =
```

ismissing

Class: dataset

Find dataset array elements with missing values

Compatibility

The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

Syntax

```
I = ismissing(ds)
I = ismissing(ds,Name,Value)
```

Description

`I = ismissing(ds)` returns a logical array that indicates which elements in the dataset array, `ds`, contain a missing value. By default, `ismissing` recognizes NaN as a missing value in numeric variables, ' ' as a missing value in string variables, and <undefined> as a missing value in categorical arrays.

- `ds2 = ds(~any(I,2),:)` creates a new dataset array containing only the complete observations in `ds`.
- `ds2 = ds(:,~any(I,1))` creates a new dataset array containing only the variables from `ds` with no missing values.

`I = ismissing(ds,Name,Value)` returns missing value indices with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

ds

dataset array

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

'`NumericTreatAsMissing`'

Vector of numeric values to treat as missing value indicators in floating point ds variables. `ismissing` always treats a NaN value as a missing value.

Default:

'`StringTreatAsMissing`'

String or cell array of strings to treat as missing value indicators in string ds variables. `ismissing` always treats the empty string ' ' as a missing value.

Output Arguments

`I`

Logical array indicating which elements in ds contain a missing value. `I` is the same size as ds, with value 1 for elements that contain a missing value.

isvalid

Class: grandstream

Test handle validity

Syntax

```
tf = isvalid(h)
```

Description

`tf = isvalid(h)` performs an element-wise check for validity on the handle elements of `h`. The result is a logical array of the same dimensions as `h`, where each element is the element-wise validity result.

A handle is invalid if it has been deleted or if it is an element of a handle array and has not yet been initialized.

See Also

`delete` | `grandstream`

NumIterations property

Class: gmdistribution

Number of iterations

Description

The number of iterations of the algorithm.

Note: This property applies only to `gmdistribution` objects constructed with `fitgmdist`.

iwishrnd

Inverse Wishart random numbers

Syntax

```
W = wishrnd(Tau,df)
W = wishrnd(Tau,df,DI)
[W,DI] = wishrnd(Tau,df)
```

Description

`W = wishrnd(Tau,df)` generates a random matrix `W` from the inverse Wishart distribution with parameters `Tau` and `df`. The inverse of `W` has the Wishart distribution with covariance matrix `Sigma = inv(Tau)` and with `df` degrees of freedom. `Tau` is a symmetric and positive definite matrix.

`W = wishrnd(Tau,df,DI)` expects `DI` to be the transpose of the inverse of the Cholesky factor of `Tau`, so that `DI' * DI = inv(Tau)`, where `inv` is the MATLAB inverse function. `DI` is lower-triangular and the same size as `Tau`. If you call `wishrnd` multiple times using the same value of `Tau`, it is more efficient to supply `DI` instead of computing it each time.

`[W,DI] = wishrnd(Tau,df)` returns `DI` so you can use it as an input in future calls to `wishrnd`.

Note that different sources use different parametrizations for the inverse Wishart distribution. This function defines the parameter `tau` so that the mean of the output matrix is `Tau / (df - d - 1)` where `d` is the dimension of `Tau`.

`wishrnd`

jackknife

Jackknife sampling

Syntax

```
jackstat = jackknife(jackfun,X)
jackstat = jackknife(jackfun,X,Y,...)
jackstat = jackknife(jackfun,...,'Options',option)
```

Description

`jackstat = jackknife(jackfun,X)` draws jackknife data samples from the n -by- p data array `X`, computes statistics on each sample using the function `jackfun`, and returns the results in the matrix `jackstat`. `jackknife` regards each row of `X` as one data sample, so there are n data samples. Each of the n rows of `jackstat` contains the results of applying `jackfun` to one jackknife sample. `jackfun` is a function handle specified with `@`. Row i of `jackstat` contains the results for the sample consisting of `X` with the i th row omitted:

```
s = x;
s(i,:) = [];
jackstat(i,:) = jackfun(s);
```

If `jackfun` returns a matrix or array, then this output is converted to a row vector for storage in `jackstat`. If `X` is a row vector, it is converted to a column vector.

`jackstat = jackknife(jackfun,X,Y,...)` accepts additional arguments to be supplied as inputs to `jackfun`. They may be scalars, column vectors, or matrices. `jackknife` creates each jackknife sample by sampling with replacement from the rows of the non-scalar data arguments (these must have the same number of rows). Scalar data are passed to `jackfun` unchanged. Non-scalar arguments must have the same number of rows, and each jackknife sample omits the same row from these arguments.

`jackstat = jackknife(jackfun,...,'Options',option)` provides an option to perform jackknife iterations in parallel, if the Parallel Computing Toolbox is available. Set `'Options'` as a structure you create with `statset`. `jackknife` uses the following field in the structure:

`'UseParallel'` If `true` and if a `parpool` of the Parallel Computing Toolbox is open, use multiple processors to compute jackknife iterations. If the Parallel Computing Toolbox is not installed, or a `parpool` is not open, computation occurs in serial mode. Default is `false`, or serial computation.

Examples

Estimate the bias of the MLE variance estimator of random samples taken from the vector `y` using `jackknife`. The bias has a known formula in this problem, so you can compare the `jackknife` value to this formula.

```
sigma = 5;
y = normrnd(0,sigma,100,1);
m = jackknife(@var, y, 1);
n = length(y);
bias = -sigma^2 / n % known bias formula
jbias = (n - 1)*(mean(m)-var(y,1)) % jackknife bias estimate

bias =
    -0.2500

jbias =
    -0.3378
```

jbtest

Jarque-Bera test

Syntax

```
h = jbtest(x)
h = jbtest(x,alpha)
h = jbtest(x,alpha,mctol)
[h,p] = jbtest(____)
[h,p,jbstat,critval] = jbtest(____)
```

Description

`h = jbtest(x)` returns a test decision for the null hypothesis that the data in vector `x` comes from a normal distribution with an unknown mean and variance, using the Jarque-Bera test. The alternative hypothesis is that it does not come from such a distribution. The result `h` is 1 if the test rejects the null hypothesis at the 5% significance level, and 0 otherwise.

`h = jbtest(x,alpha)` returns a test decision for the null hypothesis at the significance level specified by `alpha`.

`h = jbtest(x,alpha,mctol)` returns a test decision based on a p -value computed using a Monte Carlo simulation with a maximum Monte Carlo standard error less than or equal to `mctol`.

`[h,p] = jbtest(____)` also returns the p -value `p` of the hypothesis test, using any of the input arguments from the previous syntaxes.

`[h,p,jbstat,critval] = jbtest(____)` also returns the test statistic `jbstat` and the critical value `critval` for the test.

Examples

Test for a Normal Distribution

Load the data set.

```
load carbig;
```

Test the null hypothesis that car mileage, in miles per gallon (MPG), follows a normal distribution across different makes of cars.

```
h = jbttest(MPG)
```

```
h =
```

```
1
```

The returned value of $h = 1$ indicates that `jbttest` rejects the null hypothesis at the default 5% significance level.

Test the Hypothesis at a Different Significance Level

Load the data set.

```
load carbig;
```

Test the null hypothesis that car mileage in miles per gallon (MPG) follows a normal distribution across different makes of cars at the 1% significance level.

```
[h,p] = jbttest(MPG,0.01)
```

```
h =
```

```
1
```

```
p =
```

```
0.0022
```

The returned value of $h = 1$, and the returned p -value less than $\alpha = 0.01$ indicate that `jbttest` rejects the null hypothesis.

Test for a Normal Distribution Using Monte Carlo Simulation

Load the data set.

```
load carbig;
```

Test the null hypothesis that car mileage, in miles per gallon (MPG), follows a normal distribution across different makes of cars. Use a Monte Carlo simulation to obtain an exact p -value.

```
[h,p,jbstat,critval] = jbtest(MPG,[],0.0001)
h =
    1

p =
    0.0022

jbstat =
    18.2275

critval =
    5.8461
```

The returned value of `h = 1` indicates that `jbtest` rejects the null hypothesis at the default 5% significance level. Additionally, the test statistic, `jbstat`, is larger than the critical value, `critval`, which indicates rejection of the null hypothesis.

Input Arguments

x — Sample data

vector

Sample data for the hypothesis test, specified as a vector. `jbtest` treats NaN values in `x` as missing values and ignores them.

Data Types: `single` | `double`

alpha — Significance level

0.05 (default) | scalar value in the range (0,1)

Significance level of the hypothesis test, specified as a scalar value in the range (0,1). If `alpha` is in the range [0.001,0.50], and if the sample size is less than or equal to 2000, `jbtest` looks up the critical value for the test in a table of precomputed values. To conduct the test at a significance level outside of these specifications, use `mctol`.

Example: 0.01

Data Types: `single` | `double`

mctol — Maximum Monte Carlo standard error

nonnegative scalar value

Maximum Monte Carlo standard error for the p -value, p , specified as a nonnegative scalar value. If you specify a value for `mctol`, `jbtest` computes a Monte Carlo approximation for p directly, rather than interpolating into a table of precomputed values. `jbtest` chooses the number of Monte Carlo replications large enough to make the Monte Carlo standard error for p less than `mctol`.

If you specify a value for `mctol`, you must also specify a value for `alpha`. You can specify `alpha` as `[]` to use the default value of 0.05.

Example: 0.0001

Data Types: `single` | `double`

Output Arguments

h — Hypothesis test result

1 | 0

Hypothesis test result, returned as a logical value.

- If $h = 1$, this indicates the rejection of the null hypothesis at the alpha significance level.
- If $h = 0$, this indicates a failure to reject the null hypothesis at the alpha significance level.

p — p -value

scalar value in the range (0,1)

p -value of the test, returned as a scalar value in the range (0,1). p is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. Small values of p cast doubt on the validity of the null hypothesis.

`jbtest` warns when p is not found within the tabulated range of [0.001,0.50], and returns either the smallest or largest tabulated value. In this case, you can use `mctol` to compute a more accurate p -value.

jbstat — Test statistic

nonnegative scalar value

Test statistic for the Jarque-Bera test, returned as a nonnegative scalar value.

critval — Critical value

nonnegative scalar value

Critical value for the Jarque-Bera test at the `alpha` significance level, returned as a nonnegative scalar value. If `alpha` is in the range `[0.001,0.50]`, and if the sample size is less than or equal to 2000, `jbstest` looks up the critical value for the test in a table of precomputed values. If you use `mctol`, `jbstest` determines the critical value of the test using a Monte Carlo simulation. The null hypothesis is rejected when `jbstat` > `critval`.

More About

Jarque-Bera Test

The Jarque-Bera test is a two-sided goodness-of-fit test suitable when a fully specified null distribution is unknown and its parameters must be estimated.

The test is specifically designed for alternatives in the Pearson system of distributions. The test statistic is

$$JB = \frac{n}{6} \left(s^2 + \frac{(k-3)^2}{4} \right),$$

where n is the sample size, s is the sample skewness, and k is the sample kurtosis. For large sample sizes, the test statistic has a chi-square distribution with two degrees of freedom.

Monte Carlo Standard Error

The Monte Carlo standard error is the error due to simulating the p -value.

The Monte Carlo standard error is calculated as

$$SE = \sqrt{\frac{(\hat{p})(1 - \hat{p})}{\text{mcreps}}},$$

where \hat{p} is the estimated p -value of the hypothesis test, and `mcreps` is the number of Monte Carlo replications performed. `jbtest` chooses the number of Monte Carlo replications, `mcreps`, large enough to make the Monte Carlo standard error for \hat{p} less than the value specified for `mctol`.

Algorithms

Jarque-Bera tests often use the chi-square distribution to estimate critical values for large samples, deferring to the Lilliefors test (see `lillietest`) for small samples. `jbtest`, by contrast, uses a table of critical values computed using Monte Carlo simulation for sample sizes less than 2000 and significance levels from 0.001 to 0.50. Critical values for a test are computed by interpolating into the table, using the analytic chi-square approximation only when extrapolating for larger sample sizes.

johnsrnd

Johnson system random numbers

Syntax

```
r = johnsrnd(quantiles,m,n)
r = johnsrnd(quantiles)
[r,type] = johnsrnd(...)
[r,type,coefs] = johnsrnd(...)
```

Description

`r = johnsrnd(quantiles,m,n)` returns an m -by- n matrix of random numbers drawn from the distribution in the Johnson system that satisfies the quantile specification given by `quantiles`. `quantiles` is a four-element vector of quantiles for the desired distribution that correspond to the standard normal quantiles $[-1.5 -0.5 0.5 1.5]$. In other words, you specify a distribution from which to draw random values by designating quantiles that correspond to the cumulative probabilities $[0.067 0.309 0.691 0.933]$. `quantiles` may also be a 2-by-4 matrix whose first row contains four standard normal quantiles, and whose second row contains the corresponding quantiles of the desired distribution. The standard normal quantiles must be spaced evenly.

Note: Because `r` is a random sample, its sample quantiles typically differ somewhat from the specified distribution quantiles.

`r = johnsrnd(quantiles)` returns a scalar value.

`r = johnsrnd(quantiles,m,n,...)` or `r = johnsrnd(quantiles,[m,n,...])` returns an m -by- n -by-... array.

`[r,type] = johnsrnd(...)` returns the type of the specified distribution within the Johnson system. `type` is 'SN', 'SL', 'SB', or 'SU'. Set `m` and `n` to zero to identify the distribution type without generating any random values.

The four distribution types in the Johnson system correspond to the following transformations of a normal random variate:

- 'SN' — Identity transformation (normal distribution)
- 'SL' — Exponential transformation (lognormal distribution)
- 'SB' — Logistic transformation (bounded)
- 'SU' — Hyperbolic sine transformation (unbounded)

`[r,type,coefs] = johnsrnd(...)` returns coefficients `coefs` of the transformation that defines the distribution. `coefs` is `[gamma, eta, epsilon, lambda]`. If `z` is a standard normal random variable and `h` is one of the transformations defined above, `r = lambda*h((z-gamma)/eta)+epsilon` is a random variate from the distribution type corresponding to `h`.

Examples

Generate Random Samples Using the Johnson System

This example shows several different approaches to using the Johnson system of flexible distribution families to generate random numbers and fit a distribution to sample data.

Generate random values with longer tails than a standard normal.

```
rng default; % For reproducibility
r = johnsrnd([-1.7 -.5 .5 1.7],1000,1);
figure;
qqplot(r);
```

Generate random values skewed to the right.

```
r = johnsrnd([-1.3 -.5 .5 1.7],1000,1);  
figure;  
qqplot(r);
```

Generate random values that match some sample data well in the right-hand tail.

```
load carbig;
qnorm = [.5 1 1.5 2];
q = quantile(Acceleration, normcdf(qnorm));
r = johnsrnd([qnorm;q],1000,1);
[q;quantile(r,normcdf(qnorm))]
```

ans =

```
16.7000    18.2086    19.5376    21.7263
16.6986    18.2220    19.9078    22.0918
```

Determine the distribution type and the coefficients.

```
[r,type,coefs] = johnsrnd([qnorm;q],0)
```

```
r =
```

```
    []
```

```
type =
```

```
SU
```

```
coefs =
```

```
    1.0920    0.5829   18.4382    1.4494
```

join

Class: dataset

Merge observations

Compatibility

The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

Syntax

```
C = join(A,B)
C = join(A,B,keys)
C = join(A,B,param1,va11,param2,va12,...)
[C,IB] = join(...)
C = join(A,B,'Type',TYPE,...)
C = join(A,B,'Type',TYPE,'MergeKeys',true,...)
[C,IA,IB] = join(A,B,'Type',TYPE,...)
```

Description

`C = join(A,B)` creates a dataset array `C` by merging observations from the two dataset arrays `A` and `B`. `join` performs the merge by first finding *key variables*, that is, pairs of dataset variables, one in `A` and one in `B`, that share the same name. Each observation in `B` must contain a unique combination of values in the key variables, and must contain all combinations of values that are present in the keys from `A`. `join` then uses these key variables to define a many-to-one correspondence between observations in `A` and those in `B`. `join` uses this correspondence to replicate the observations in `B` and combine them with the observations in `A` to create `C`.

`C = join(A,B,keys)` performs the merge using the variables specified by `keys` as the key variables in both `A` and `B`. `keys` is a positive integer, a vector of positive integers, a variable name, a cell array of variable names, or a logical vector.

C contains one observation for each observation in **A**. Variables in **C** include all of the variables from **A**, as well as one variable corresponding to each variable in **B** (except for the keys from **B**). If **A** and **B** contain variables with identical names, `join` adds the suffix `'_left'` and `'_right'` to the corresponding variables in **C**.

`C = join(A,B,param1,va11,param2,va12,...)` specifies optional parameter name/value pairs to control how the dataset variables in **A** and **B** are used in the merge. Parameters are:

- `'Keys'` — Specifies the variables to use as keys in both **A** and **B**.
- `'LeftKeys'` — Specifies the variables to use as keys in **A**.
- `'RightKeys'` — Specifies the variables to use as keys in **B**.

You may provide either the `'Keys'` parameter, or both the `'LeftKeys'` and `'RightKeys'` parameters. The value for these parameters is a positive integer, a vector of positive integers, a variable name, a cell array containing variable names, or a logical vector. `'LeftKeys'` or `'RightKeys'` must both specify the same number of key variables, and `join` pairs the left and right keys in the order specified.

- `'LeftVars'` — Specifies which variables from **A** to include in **C**. By default, `join` includes all variables from **A**.
- `'RightVars'` — Specifies which variables from **B** to include in **C**. By default, `join` includes all variables from **B** except the key variables.

You can use `'LeftVars'` or `'RightVars'` to include or exclude key variables as well as data variables. The value for these parameters is a positive integer, a vector of positive integers, a variable name, a cell array containing one or more variable names, or a logical vector.

`[C,IB] = join(...)` returns an index vector **IB**, where `join` constructs **C** by horizontally concatenating `A(:,LeftVars)` and `B(IB,RightVars)`. `join` can also perform more complicated inner and outer join operations that allow a many-to-many correspondence between **A** and **B**, and allow unmatched observations in either **A** or **B**.

`C = join(A,B,'Type',TYPE,...)` performs the join operation specified by **TYPE**. **TYPE** is one of `'inner'`, `'leftouter'`, `'rightouter'`, `'fullouter'`, or `'outer'` (which is a synonym for `'fullouter'`). For an inner join, **C** only contains observations corresponding to a combination of key values that occurred in both **A** and **B**. For a left (or right) outer join, **C** also contains observations corresponding to keys in **A** (or **B**) that did not match any in **B** (or **A**). Variables in **C** taken from **A** (or **B**) contain null values in those observations. A full outer join is equivalent to a left and right outer join. **C** contains

variables corresponding to the key variables from both A and B, and `join` sorts the observations in C by the key values.

For inner and outer joins, C contains variables corresponding to the key variables from both A and B by default, as well as all the remaining variables. `join` sorts the observations in the result C by the key values.

`C = join(A,B, 'Type', TYPE, 'MergeKeys', true, ...)` includes a single variable in C for each key variable pair from A and B, rather than including two separate variables. For outer joins, `join` creates the single variable by merging the key values from A and B, taking values from A where a corresponding observation exists in A, and from B otherwise. Setting the 'MergeKeys' parameter to `true` overrides inclusion or exclusion of any key variables specified via the 'LeftVars' or 'RightVars' parameter. Setting the 'MergeKeys' parameter to `false` is equivalent to not passing in the 'MergeKeys' parameter.

`[C, IA, IB] = join(A,B, 'Type', TYPE, ...)` returns index vectors IA and IB indicating the correspondence between observations in C and those in A and B. For an inner join, `join` constructs C by horizontally concatenating A(IA,LeftVars) and B(IB,RightVars). For an outer join, IA or IB may also contain zeros, indicating the observations in C that do not correspond to observations in A or B, respectively.

Examples

Create a dataset array from Fisher's iris data:

```
load fisheriris
NumObs = size(meas,1);
NameObs = strcat({'Obs'},num2str((1:NumObs)','%-d'));
iris = dataset({nominal(species),'species'},...
               {meas,'SL','SW','PL','PW'},...
               'ObsNames',NameObs);
```

Create a separate dataset array with the diploid chromosome counts for each species of iris:

```
snames = nominal({'setosa';'versicolor';'virginica'});
CC = dataset({snames,'species'},{[38;108;70],'cc'})
CC =
    species      cc
    setosa       38
    versicolor   108
```

```
virginica      70
```

Broadcast the data in `CC` to the rows of `iris` using the key variable `species` in each dataset:

```
iris2 = join(iris,CC);
iris2([1 2 51 52 101 102],:)
ans =
```

	species	SL	SW	PL	PW	cc
Obs1	setosa	5.1	3.5	1.4	0.2	38
Obs2	setosa	4.9	3	1.4	0.2	38
Obs51	versicolor	7	3.2	4.7	1.4	108
Obs52	versicolor	6.4	3.2	4.5	1.5	108
Obs101	virginica	6.3	3.3	6	2.5	70
Obs102	virginica	5.8	2.7	5.1	1.9	70

Create two datasets and join them using the `'MergeKeys'` flag:

```
% Create two data sets that both contain the key variable
% 'Key1'. The two arrays contain observations with common
% values of Key1, but each array also contains observations
% with values of Key1 not present in the other.
a = dataset({'a' 'b' 'c' 'e' 'h'},[1 2 3 11 17]','...
    'VarNames',{'Key1' 'Var1'})
b = dataset({'a' 'b' 'd' 'e'},[4 5 6 7]','...
    'VarNames',{'Key1' 'Var2'})

% Combine a and b with an outer join, which matches up
% observations with common key values, but also retains
% observations whose key values don't have a match.
% Keep the key values as separate variables in the result.
couter = join(a,b,'key','Key1','Type','outer')

% Join a and b, merging the key values as a single variable
% in the result.
coutermerge = join(a,b,'key','Key1','Type','outer',...
    'MergeKeys',true)

% Join a and b, retaining only observations whose key
% values match.
cinner = join(a,b,'key','Key1','Type','inner',...
    'MergeKeys',true)

a =
```

Key1	Var1
'a'	1
'b'	2
'c'	3
'e'	11
'h'	17

b =

Key1	Var2
'a'	4
'b'	5
'd'	6
'e'	7

couter =

Key1_left	Var1	Key1_right	Var2
'a'	1	'a'	4
'b'	2	'b'	5
'c'	3	''	NaN
''	NaN	'd'	6
'e'	11	'e'	7
'h'	17	''	NaN

coutermerge =

Key1	Var1	Var2
'a'	1	4
'b'	2	5
'c'	3	NaN
'd'	NaN	6

KDTreeSearcher class

Superclasses: NeighborSearcher

Nearest neighbors search using *kd*-tree

Description

A `KDTreeSearcher` object represents *k*NN (*k*-nearest neighbor) search using a *kd*-tree. Search objects store information about the data used, the distance metric and parameters, and the maximal number of data points in each leaf node. You cannot create this object for sparse input data. The search performance for this object, compared with the `ExhaustiveSearcher` object, tends to be better for smaller dimensions (10 or fewer) and worse for larger dimensions. For more details on search objects, see “What Are Search Objects?”.

Construction

`NS = KDTreeSearcher(X, 'Name', Value)` constructs a *kd*-tree based on *X* and saves the information in a `KDTreeSearcher` object, where rows of *X* correspond to observations and columns correspond to variables. You can use this tree to find neighbors in *X* nearest to the query points.

`NS = createns(X, 'NSMethod', 'kdtree', 'Name', Value)` creates a *kd*-tree based on *X* using `createns` and saves the information in a `KDTreeSearcher` object where rows of *X* correspond to observations and columns correspond to variables. You can use this tree to find neighbors in *X* nearest to the query points.

Name-Value Pair Arguments

`KDTreeSearcher` and `createns` accept one or more of the following optional name-value pairs as input.

'Distance'

A string specifying the default distance metric used when you call the `knnsearch` method.

- `'euclidean'` — Euclidean distance (default).

- 'cityblock' — City block distance.
- 'chebychev' — Chebychev distance (maximum coordinate difference).
- 'minkowski' — Minkowski distance.

For more details on these distance metrics, see “Distance Metrics”.

'P'

A positive scalar indicating the exponent of the Minkowski distance. This parameter is only valid when `Distance` is 'minkowski'. Default is 2.

'BucketSize'

A positive integer, indicating the maximum number of data points in each leaf node of the *kd*-tree. Default is 50.

Properties

X

A matrix used to create the object.

Distance

A string specifying a built-in distance metric that you provide when you create the object. This property is the default distance metric used when you call the `knnsearch` method to find nearest neighbors for future query points.

DistParameter

Specifies the additional parameter for the chosen distance metric. The value is:

- If 'Distance' is 'minkowski': A positive scalar indicating the exponent of the Minkowski distance.
- Otherwise: Empty.

Methods

`knnsearch`

Find *k*-nearest neighbors using
KDTreeSearcher object

rangesearch

Find all neighbors within specified distance using KDTreeSearcher object

Examples

Specify the Minkowski Distance for Nearest Neighbor Search

Load Fisher's iris data. Focus on the petal dimensions.

```
load fisheriris
X = meas(:, [3 4]); % Predictors
```

Grow a 2d-tree using `createns` and the training data. Specify the Minkowski distance metric.

```
Mdl = createns(X, 'NSMethod', 'kdtree', 'Distance', 'Minkowski')
```

```
Mdl =
```

```
    KDTreeSearcher with properties:
```

```
        BucketSize: 50
           Distance: 'minkowski'
    DistParameter: 2
                X: [150x2 double]
```

`Mdl` is a `KDTreeSearcher` model object. Access properties of `Mdl` using dot notation. For example, use `Mdl.DistParameter` to access the Minkowski distance exponent.

```
Mdl.DistParameter
```

```
ans =
```

```
    2
```

You can pass query data and `Mdl` to:

- “`knnsearch (KDTreeSearcher)`” to find indices and distances of nearest neighbors.

- “rangesearch (KDTreeSearcher)” to find indices of all nearest neighbors within a distance that you specify.

- “Distance Metrics”

Kernel property

Class: ProbDistKernel

Read-only string specifying name of kernel smoothing function for ProbDistKernel object

Description

`Kernel` is a read-only property of the `ProbDistKernel` class. `Kernel` is a string specifying the name of the kernel smoothing function used to create a `ProbDistKernel` object.

Values

'normal'
'box'
'triangle'
'epanechnikov'

Use this information to view and compare the kernel smoothing function used to create distributions.

See Also

`ksdensity`

prob.KernelDistribution class

Package: prob

Superclasses: prob.TruncatableDistribution

Kernel probability distribution object

Description

prob.KernelDistribution is an object consisting of parameters, a model description, and sample data for a nonparametric kernel-smoothing distribution. Create a prob.KernelDistribution object using `fitdist` or `dfittool`.

Construction

`pd = fitdist(x, 'Kernel')` creates a probability distribution object by fitting a kernel-smoothing distribution to the data in `x`.

`pd = fitdist(x, 'Kernel', Name, Value)` creates a probability distribution object with additional options specified by one or more name-value pair arguments. For example, you can change the kernel function or specify the kernel bandwidth.

Input Arguments

x — Input data

column vector

Input data to fit with a kernel-smoothing distribution, specified as a column vector of scalar values. `fitdist` ignores NaN values in `x`.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

'Kernel' — Kernel smoother type`'normal' (default) | 'box' | 'triangle' | 'epanechnikov'`

Kernel smoother type, specified as the comma-separated pair consisting of `'Kernel'` and one of the following kernel smoothing function types:

- `'normal'`
- `'box'`
- `'triangle'`
- `'epanechnikov'`

'Support' — Kernel density support`'unbounded' (default) | 'positive' | two-element vector`

Kernel density support, specified as the comma-separated pair consisting of `'Support'` and a string or two-element vector. The string must be one of the following.

<code>'unbounded'</code>	Density can extend over the whole real line.
<code>'positive'</code>	Density is restricted to positive values.

Alternatively, you can specify a two-element vector giving finite lower and upper limits for the support of the density.

Data Types: `single` | `double`

'Width' — Bandwidth of kernel smoothing window

scalar value

Bandwidth of the kernel smoothing window, specified as the comma-separated pair consisting of `'Width'` and a scalar value. The default value used by `fitdist` is optimal for estimating normal densities, but you might want to choose a smaller value to reveal features such as multiple modes.

Data Types: `single` | `double`

Properties

Kernel — Kernel smoother type`'normal' | 'box' | 'triangle' | 'epanechnikov'`

Kernel function type, stored as a valid kernel function type name.

BandWidth — Bandwidth of kernel smoothing window

positive scalar value

Bandwidth of the kernel smoothing window, stored as a positive scalar value.

Data Types: `single` | `double`

DistributionName — Probability distribution name

probability distribution name string

Probability distribution name, stored as a valid probability distribution name string. This property is read-only.

Data Types: `char`

InputData — Data used for distribution fitting

structure

Data used for distribution fitting, stored as a structure containing the following:

- `data`: Data vector used for distribution fitting.
- `cens`: Censoring vector, or empty if none.
- `freq`: Frequency vector, or empty if none.

This property is read-only.

Data Types: `struct`

IsTruncated — Logical flag for truncated distribution

0 | 1

Logical flag for truncated distribution, stored as a logical value. If `IsTruncated` equals 0, the distribution is not truncated. If `IsTruncated` equals 1, the distribution is truncated. This property is read-only.

Data Types: `logical`

Truncation — Truncation interval

vector of scalar values

Truncation interval for the probability distribution, stored as a vector containing the lower and upper truncation boundaries. This property is read-only.

Data Types: `single` | `double`

Methods

<code>mean</code>	Mean of probability distribution object
<code>negloglik</code>	Negative loglikelihood
<code>std</code>	Standard deviation of probability distribution object
<code>var</code>	Variance of probability distribution object

Inherited Methods

<code>cdf</code>	Cumulative distribution function of probability distribution object
<code>icdf</code>	Inverse cumulative distribution function of probability distribution object
<code>iqr</code>	Interquartile range of probability distribution object
<code>median</code>	Median of probability distribution object
<code>pdf</code>	Probability density function of probability distribution object
<code>random</code>	Generate random numbers from probability distribution object

truncate

Truncate probability distribution object

Definitions

Kernel Distribution

The kernel distribution is a nonparametric estimation of the probability density function (pdf) of a random variable.

The kernel distribution uses the following options.

Option	Description	Possible Values
Kernel	Kernel function type	normal, box, triangle, epanechnikov
BandWidth	Kernel smoothing parameter	BandWidth > 0

The kernel density estimator is

$$\hat{f}_h(x) = \frac{1}{nh} \sum_{i=1}^n K\left(\frac{x-x_i}{h}\right) ; \quad -\infty < x < \infty,$$

where n is the sample size, $K(\cdot)$ is the kernel function, and h is the bandwidth.

Examples

Fit a Kernel Distribution Object to Data

Load the sample data. Visualize the patient weight data using a histogram.

```
load hospital;
hist(hospital.Weight)
```

The histogram shows that the data has two modes, one for female patients and one for male patients.

Create a probability distribution object by fitting a kernel distribution to the patient weight data.

```
pd_kernel = fitdist(hospital.Weight, 'Kernel')
```

```
pd_kernel =
```

```
KernelDistribution
```

```
Kernel = normal
```

```
Bandwidth = 14.3792
```

Support = unbounded

For comparison, create another probability distribution object by fitting a normal distribution to the patient weight data.

```
pd_normal = fitdist(hospital.Weight, 'Normal')
```

```
pd_normal =
```

```
NormalDistribution
```

```
Normal distribution
```

```
mu = 154 [148.728, 159.272]  
sigma = 26.5714 [23.3299, 30.8674]
```

Define the x values and compute the pdf of each distribution.

```
x = 50:1:250;  
pdf_kernel = pdf(pd_kernel,x);  
pdf_normal = pdf(pd_normal,x);
```

Plot the pdf of each distribution.

```
plot(x,pdf_kernel, 'Color', 'b', 'LineWidth',2);  
hold on;  
plot(x,pdf_normal, 'Color', 'r', 'LineStyle', ':', 'LineWidth',2);  
legend('Kernel Distribution', 'Normal Distribution', 'Location', 'SouthEast');  
hold off;
```

Fitting a kernel distribution instead of a unimodal distribution such as the normal reveals the separate modes for the female and male patients.

kfoldEdge

Classification edge for observations not used for training

Syntax

```
edge = kfoldEdge(CVMdl)
edge = kfoldEdge(CVMdl,Name,Value)
```

Description

`edge = kfoldEdge(CVMdl)` returns the classification edge obtained by the cross-validated ECOC model (`ClassificationPartitionedECOC`) `CVMdl`. For every fold, `kfoldEdge` computes the classification edge for in-fold observations using an ECOC model trained on out-of-fold observations. `CVMdl.X` contains both sets of observations.

`edge = kfoldEdge(CVMdl,Name,Value)` returns the classification edge with additional options specified by one or more `Name,Value` pair arguments.

For example, specify the number of folds, decoding scheme, or verbosity level.

Input Arguments

CVMdl — Cross-validated ECOC model

`ClassificationPartitionedECOC` model

Cross-validated ECOC model, specified as a `ClassificationPartitionedECOC` model. You can create a `ClassificationPartitionedECOC` model by:

- Passing a trained ECOC model (`ClassificationECOC`) to `crossval`
- Training an ECOC model using `fitcecoc` and setting any one of these cross-validation name-value pair arguments: `'CrossVal'`, `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

'BinaryLoss' — Binary learner loss function

`CVMD1.BinaryLoss` (default) | function handle | 'hamming' | 'linear' | 'exponential' | 'binodeviance' | 'hinge' | 'quadratic'

Binary learner loss function, specified as the comma-separated pair consisting of 'BinaryLoss' and a function handle or string.

- If the value is a string, then it must correspond to a built-in function. This table summarizes the built-in functions, where y_j is a class label for a particular binary learner (in $\{-1, 1, 0\}$) and f_j is the score for observation j .

Value	Description	Score Domain	Formula
'binodeviance'	Binomial deviance	$(-\infty, \infty)$	$\frac{\log[1 + \exp(-2yf)]}{\log(2)}$
'exponential'	Exponential	$(-\infty, \infty)$	$\exp(-yf)$
'hamming'	Hamming	$(-\infty, \infty)$ or $[0, 1]$	$1 - \text{sign}(yf)$
'hinge'	Hinge	$(-\infty, \infty)$	$\max(0, 1 - yf)$
'linear'	Linear	$(-\infty, \infty)$	$1 - yf$
'quadratic'	Quadratic	$[0, 1]$	$[1 - y(2f - 1)]^2$

- For a custom binary loss function, e.g., `customFunction`, specify its function handle 'BinaryLoss', @`customFunction`.

`customFunction` should have this form

```
bLoss = customFunction(M, f)
where:
```

- `M` is the K -by- L coding matrix stored in `CVMD1.CodingMatrix`.
- `f` is the 1-by- L row vector of classification scores.
- `bLoss` is the classification loss.

- K is the number of classes.
- L is the number of binary learners.

Example: 'BinaryLoss', 'binodeviance'

Data Types: char | function_handle

'Decoding' — Decoding scheme

'lossweighted' (default) | 'lossbased'

Decoding scheme that aggregates the “binary losses”, specified as the comma-separated pair consisting of 'Decoding' and 'lossweighted' or 'lossbased'.

Example: 'Decoding', 'lossbased'

Data Types: char

'Folds' — Fold indices for prediction

1:Mdl.KFold (default) | numeric vector of positive integers

Fold indices for prediction, specified as the comma-separated pair consisting of 'Folds' and a numeric vector of positive integers. The elements of **Folds** must range from 1 through `Mdl.KFold`.

The software only uses the folds specified in **Folds** for prediction.

Example: 'Folds', [1 4 10]

Data Types: single | double

'Mode' — Edge meaning

'average' (default) | 'individual'

Edge meaning, specified as the comma-separated pair consisting of 'Mode' and 'average' or 'individual'.

This table describes the values.

Value	Description
'average'	edge is the scalar average over all folds.
'individual'	edge is a vector of length k containing one edge per fold. k is the number of folds.

Example: 'Mode', 'individual'

Data Types: char

'Options' — Estimation options

[] (default) | structure array returned by `statset`

Estimation options, specified as the comma-separated pair consisting of 'Options' and a structure array returned by `statset`.

To invoke parallel computing:

- You need a Parallel Computing Toolbox license.
- Specify 'Options', `statset('UseParallel',1)`.

'Verbose' — Verbosity level

0 (default) | 1

Verbosity level, specified as the comma-separated pair consisting of 'Verbose' and 0 or 1. `Verbose` controls the amount of diagnostic messages that the software displays in the Command Window.

If `Verbose` is 0, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: 'Verbose', 1

Data Types: single | double

Output Arguments

edge — Classification edge

numeric scalar | numeric row vector

Classification edge, returned as a numeric scalar or numeric row vector.

If `Mode` is 'average', then `edge` is the average classification edge among all binary learners. Otherwise, `edge` is a 1-by-L numeric row vector containing the classification edge for each, respective binary learner, where L is the number of binary learners (`size(CVMdl.CodingMatrix,2)`).

Data Types: single | double

Definitions

Classification Edge

The *classification edge* is the weighted mean of the *classification margins*.

One way to choose among multiple classifiers, e.g., to perform feature selection, is to choose the classifier that yields the highest edge.

Classification Margin

The *classification margins* are, for each observation, the difference between the negative loss for the positive class and maximal negative loss among the negative classes. If the margins are on the same scale, then they serve as a classification confidence measure, i.e., among multiple classifiers, those that yield larger margins are better “[4]”.

Binary Loss

A *binary loss* is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Let:

- m_{kj} be element (k,j) of the coding design matrix M (i.e., the code corresponding to class k of binary learner j)
- s_j be the score of binary learner j for an observation
- g be the binary loss function
- \hat{k} be the predicted class for the observation

In *loss-based decoding* [3], the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j).$$

In *loss-weighted decoding* [3], the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \frac{\sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j)}{\sum_{j=1}^L |m_{kj}|}.$$

Allwein et al. [1] suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where y_j is a class label for a particular binary learner (in the set $\{-1, 1, 0\}$), s_j is the score for observation j , and $g(y_j, s_j)$.

Value	Description	Score Domain	$g(y_j, s_j)$
'binodeviance'	Binomial deviance	$(-\infty, \infty)$	$\log[1 + \exp(-2y_j s_j)] / [2\log(2)]$
'exponential'	Exponential	$(-\infty, \infty)$	$\exp(-y_j s_j) / 2$
'hamming'	Hamming	$\{-1, 1\}$	$[1 - \operatorname{sign}(y_j s_j)] / 2$
'hinge'	Hinge	$(-\infty, \infty)$	$\max(0, 1 - y_j s_j) / 2$
'linear'	Linear	$(-\infty, \infty)$	$(1 - y_j s_j) / 2$
'quadratic'	Quadratic	$[0, 1]$	$[1 - y_j(2s_j - 1)]^2 / 2$

The software normalizes the binary losses such that the loss is 0.5 when $y_j = 0$, and aggregates using the average of the binary learners [1].

Do not confuse the binary loss with the overall classification loss (specified by the LossFun name-value pair argument of `predict` and `loss`), e.g., classification error, which measures how well an ECOC classifier performs as a whole.

Examples

Estimate k -Fold Cross-Validation Edge of ECOC Models

Load Fisher's iris data set.

```
load fisheriris
```

```
X = meas;
Y = categorical(species);
classOrder = unique(Y);
rng(1); % For reproducibility
```

Train an ECOC model using SVM binary classifiers and specify to cross validate. It is good practice to standardize the predictors and define the class order. Specify to standardize the predictors using an SVM template.

```
t = templateSVM('Standardize',1);
CVMdl = fitcecoc(X,Y,'CrossVal','on','Learners',t,'ClassNames',classOrder);
```

CVMdl is a `ClassificationPartitionedModel` model. By default, the software implements 10-fold cross validation. You can alter the number of folds using the 'KFold' name-value pair argument.

Estimate the average of the out-of-fold edges.

```
edge = kfoldEdge(CVMdl)
```

```
edge =
    0.4825
```

Alternatively, you can obtain the per-fold edges by specifying the name-value pair 'Mode', 'individual' in `kfoldEdge`.

Display Individual Edges for Each Cross-Validation Fold

The classification edge is a relative measure of classifier quality. You can determine ill-performing folds by displaying the edges for each fold.

Load Fisher's iris data set.

```
load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y);
rng(1); % For reproducibility
```

Train an ECOC model using SVM binary classifiers and specify to use 8-fold cross validation. It is good practice to standardize the predictors and define the class order. Specify to standardize the predictors using an SVM template.

```
t = templateSVM('Standardize',1);
CVMdl = fitcecoc(X,Y,'KFold',8,'Learners',t,'ClassNames',classOrder);
```

Estimate the classification edge for each fold.

```
edges = kfoldEdge(CVMdl,'Mode','individual')
```

```
edges =
    0.4791
    0.4872
    0.4260
    0.5302
    0.5064
    0.4575
    0.4860
    0.4687
```

The edges have similar magnitudes across folds. Ill-performing folds have low edges relative to the other folds.

You can return the classification edge for the entire model by specifying the well-performing folds using the 'Folds' name-value pair argument.

Select ECOC Model Features by Comparing Cross-Validation Edges

The classifier edge measures the average of the classifier margins. One way to perform feature selection is to compare cross-validation edges from multiple models. Based solely on this criterion, the classifier with the highest edge is the best classifier.

Load Fisher's iris data set.

```
load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y); % Class order
rng(1); % For reproducibility
```

Define these two data sets:

- `fullX` contains all predictors.
- `partX` contains the petal dimensions.

```
fullX = X;
partX = X(:,3:4);
```

Train an ECOC model using SVM binary classifiers for each predictor set, and specify to cross validate. It is good practice to standardize the predictors and define the class order. Specify to standardize the predictors using an SVM template.

```
t = templateSVM('Standardize',1);
CVMdl = fitcecoc(fullX,Y,'CrossVal','on','Learners',t,...
    'ClassNames',classOrder);
PCVMdl = fitcecoc(partX,Y,'CrossVal','on','Learners',t,...
    'ClassNames',classOrder);
```

CVMdl and PCVMdl are ClassificationPartitionedECOC models. By default, the software implements 10-fold cross validation.

Estimate the test-sample edge for each classifier.

```
fullEdge = kfoldEdge(CVMdl)
partEdge = kfoldEdge(PCVMdl)
```

```
fullEdge =
```

```
    0.4825
```

```
partEdge =
```

```
    0.4951
```

PCVMdl achieves an edge that is similar to the more complex model CVMdl.

kfoldEdge

Class: ClassificationPartitionedEnsemble

Classification edge for observations not used for training

Syntax

```
E = kfoldEdge(obj)
E = kfoldEdge(obj,Name,Value)
```

Description

`E = kfoldEdge(obj)` returns classification edge (average classification margin) obtained by cross-validated classification ensemble `obj`. For every fold, this method computes classification edge for in-fold observations using an ensemble trained on out-of-fold observations.

`E = kfoldEdge(obj,Name,Value)` calculates edge with additional options specified by one or more `Name,Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Input Arguments

ens

Object of class `ClassificationPartitionedEnsemble`. Create `ens` with `fitensemble` along with one of the cross-validation options: `'crossval'`, `'kfold'`, `'holdout'`, `'leaveout'`, or `'cvpartition'`. Alternatively, create `ens` from a classification ensemble with `crossval`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

'folds'

Indices of folds ranging from 1 to `ens.KFold`. Use only these folds for predictions.

Default: `1:ens.KFold`

'mode'

String representing the meaning of the output edge:

- `'average'` — edge is a scalar value, the average over all folds.
- `'individual'` — edge is a vector of length `ens.KFold` with one element per fold.
- `'cumulative'` — edge is a vector of length `min(ens.NTrainedPerFold)` in which element `J` is obtained by averaging values across all folds for weak learners `1:J` in each fold.

Default: `'average'`

Output Arguments

E

The average classification margin. `E` is a scalar or vector, depending on the setting of the mode name-value pair.

Definitions

Edge

The *edge* is the weighted mean value of the classification margin. The weights are the class probabilities in `obj.Prior`.

Margin

The classification *margin* is the difference between the classification *score* for the true class and maximal classification score for the false classes. Margin is a column vector with the same number of rows as in the matrix `obj.X`.

Score (ensemble)

For ensembles, a classification *score* represents the confidence of a classification into a class. The higher the score, the higher the confidence.

Different ensemble algorithms have different definitions for their scores. Furthermore, the range of scores depends on ensemble type. For example:

- AdaBoostM1 scores range from $-\infty$ to ∞ .
- Bag scores range from 0 to 1.

Examples

Compute the k-fold edge for an ensemble trained on the Fisher iris data:

```
load fisheriris
ens = fitensemble(meas,species,'AdaBoostM2',100,'Tree');
cvens = crossval(ens);
E = kfoldEdge(cvens)
```

```
E =
    3.2078
```

See Also

[kfoldLoss](#) | [kfoldMargin](#) | [crossval](#) | [kfoldPredict](#) | [kfoldfun](#)

kfoldEdge

Class: ClassificationPartitionedModel

Classification edge for observations not used for training

Syntax

```
E = kfoldEdge(obj)
E = kfoldEdge(obj, Name, Value)
```

Description

`E = kfoldEdge(obj)` returns classification edge (average classification margin) obtained by cross-validated classification model `obj`. For every fold, this method computes classification edge for in-fold observations using an ensemble trained on out-of-fold observations.

`E = kfoldEdge(obj, Name, Value)` calculates edge with additional options specified by one or more `Name, Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Input Arguments

obj

Object of class `ClassificationPartitionedModel`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

'folds'

Indices of folds ranging from 1 to `obj.KFold`. Use only these folds for predictions.

Default: 1:obj.KFold

'mode'

String representing the meaning of the output edge:

- 'average' — edge is a scalar value, the average over all folds.
- 'individual' — edge is a vector of length obj.KFold with one element per fold.

Default: 'average'

Output Arguments

E

The average classification margin. E is a scalar or vector, depending on the setting of the mode name-value pair.

Definitions

Edge

The *edge* is the weighted mean value of the classification *margin*. The weights are class prior probabilities. If you supply additional weights, those weights are normalized to sum to the prior probabilities in the respective classes, and are then used to compute the weighted average.

Margin

The classification *margin* is the difference between the classification *score* for the true class and maximal classification score for the false classes.

The classification margin is a column vector with the same number of rows as in the matrix X. A high value of margin indicates a more reliable prediction than a low value.

Score

For discriminant analysis, the *score* of a classification is the posterior probability of the classification. For the definition of posterior probability in discriminant analysis, see “Posterior Probability” on page 15-7.

For trees, the *score* of a classification of a leaf node is the posterior probability of the classification at that node. The posterior probability of the classification at a node is the number of training sequences that lead to that node with the classification, divided by the number of training sequences that lead to that node.

For example, consider classifying a predictor X as `true` when $X < 0.15$ or $X > 0.95$, and X is false otherwise.

Generate 100 random points and classify them:

```
rng(0,'twister') % for reproducibility
X = rand(100,1);
Y = (abs(X - .55) > .4);
tree = fitctree(X,Y);
view(tree,'Mode','Graph')
```

Prune the tree:

```
tree1 = prune(tree, 'Level', 1);  
view(tree1, 'Mode', 'Graph')
```

The pruned tree correctly classifies observations that are less than 0.15 as **true**. It also correctly classifies observations from .15 to .94 as **false**. However, it incorrectly classifies observations that are greater than .94 as **false**. Therefore, the score for observations that are greater than .15 should be about $.05/.85=.06$ for **true**, and about $.8/.85=.94$ for **false**.

Compute the prediction scores for the first 10 rows of X:

```
[~,score] = predict(tree1,X(1:10));
[score X(1:10,:)]
```

```
ans =
```

```
0.9059    0.0941    0.8147
```

0.9059	0.0941	0.9058
0	1.0000	0.1270
0.9059	0.0941	0.9134
0.9059	0.0941	0.6324
0	1.0000	0.0975
0.9059	0.0941	0.2785
0.9059	0.0941	0.5469
0.9059	0.0941	0.9575
0.9059	0.0941	0.9649

Indeed, every value of X (the right-most column) that is less than 0.15 has associated scores (the left and center columns) of 0 and 1, while the other values of X have associated scores of 0.91 and 0.09. The difference (score 0.09 instead of the expected .06) is due to a statistical fluctuation: there are 8 observations in X in the range (.95, 1) instead of the expected 5 observations.

Examples

Estimate the k -fold Edge of a Classifier

Compute the k -fold edge for a model trained on Fisher's iris data.

Load Fisher's iris data set.

```
load fisheriris
```

Train a classification tree classifier.

```
tree = fitctree(meas,species);
```

Cross validate the classifier using 10-fold cross validation.

```
cvtree = crossval(tree);
```

Compute the k -fold edge.

```
edge = kfoldEdge(cvtree)
```

```
edge =
```

```
0.8578
```

ClassificationPartitionedModel | kfoldPredict |
ClassificationPartitionedEnsemble

kfoldfun

Class: ClassificationPartitionedECOC

Cross validate function

Syntax

```
vals = kfoldfun(CVMdl, fun)
```

Description

`vals = kfoldfun(CVMdl, fun)` cross validates the function `fun` by applying `fun` to the data stored in the cross-validated model `CVMdl`. You must pass `fun` as a function handle.

Input Arguments

CVMdl — Cross-validated model

ClassificationPartitionedECOC model |
ClassificationPartitionedEnsemble model |
ClassificationPartitionedModel model

Cross-validated model, specified as a `ClassificationPartitionedECOC` model, `ClassificationPartitionedEnsemble` model, or a `ClassificationPartitionedModel` model.

fun — Cross-validated function

function handle

Cross-validated function, specified as a function handle. `fun` has the syntax

```
testvals = fun(CMP, Xtrain, Ytrain, Wtrain, Xtest, Ytest, Wtest)
```

- `CMP` is a compact model stored in one element of the `CVMdl.Trained` property.
- `Xtrain` is the training matrix of predictor values.
- `Ytrain` is the training array of response values.
- `Wtrain` are the training weights for observations.

- `Xtest` and `Ytest` are the test data, with associated weights `Wtest`.
- The returned value `testvals` needs the same size across all folds.

Data Types: `function_handle`

Output Arguments

vals — Cross-validation results

numeric matrix

Cross-validation results, returned as an numeric matrix. `vals` is the arrays of `testvals` output, concatenated vertically over all folds. For example, if `testvals` from every fold is a numeric vector of length `N`, `kfoldfun` returns a `KFold`-by-`N` numeric matrix with one row per fold.

Data Types: `double`

Examples

Estimate Classification Error Using a Custom Loss Function

Train an ECOC multiclass classifier, and then cross validate it using a custom k -fold loss function.

Load Fisher's iris data set.

```
load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y); % Class order
rng(1); % For reproducibility
```

Train an ECOC model using SVM binary classifiers for each predictor set, and specify to cross validate. It is good practice to standardize the predictors and define the class order. Specify to standardize the predictors using an SVM template.

```
t = templateSVM('Standardize',1);
CVMdl = fitcecoc(X,Y,'CrossVal','on','Learners',t,...
    'ClassNames',classOrder);
```

`CVMdl` is a `ClassificationPartitionedECOC` model. By default, the software implements 10-fold cross validation.

Compute the classification error (proportion of misclassified observations) for the out-of-fold observations.

```
L = kfoldLoss(CVMdl)

L =

    0.0400
```

Examine the result when the cost of misclassifying a flower as 'versicolor' is 10, and any other error is 1. Write a function called `noversicolor.m` that attributes a cost of 1 for misclassification, but 10 for misclassifying a flower as `versicolor`, and save it on your MATLAB path.

```
function averageCost = noversicolor(CMP,Xtrain,Ytrain,Wtrain,Xtest,Ytest,Wtest)
%noversicolor Example custom cross-validation function
%   Attributes a cost of 10 for misclassifying versicolor irises, and 1 for
%   the other irises. This example function requires the |fisheriris| data
%   set.
Ypredict = predict(CMP,Xtest);
misclassified = not(strcmp(Ypredict,Ytest)); % Different result
classifiedAsVersicolor = strcmp(Ypredict,'versicolor'); % Index of bad decisions
cost = sum(misclassified) + ...
    9*sum(misclassified & classifiedAsVersicolor); % Total differences
averageCost = cost/numel(Ytest); % Average error
end
```

Compute the mean misclassification error with the `noversicolor` cost.

```
foldLoss = kfoldfun(CVMdl,@noversicolor);
mean(foldLoss)

ans =

    0.0667
```

kfoldfun

Class: ClassificationPartitionedModel

Cross validate function

Syntax

```
vals = kfoldfun(CVMdl, fun)
```

Description

`vals = kfoldfun(CVMdl, fun)` cross validates the function `fun` by applying `fun` to the data stored in the cross-validated model `CVMdl`. You must pass `fun` as a function handle.

Input Arguments

CVMdl — Cross-validated model

ClassificationPartitionedECOC model |
ClassificationPartitionedEnsemble model |
ClassificationPartitionedModel model

Cross-validated model, specified as a `ClassificationPartitionedECOC` model, `ClassificationPartitionedEnsemble` model, or a `ClassificationPartitionedModel` model.

fun — Cross-validated function

function handle

Cross-validated function, specified as a function handle. `fun` has the syntax

```
testvals = fun(CMP, Xtrain, Ytrain, Wtrain, Xtest, Ytest, Wtest)
```

- `CMP` is a compact model stored in one element of the `CVMdl.Trained` property.
- `Xtrain` is the training matrix of predictor values.
- `Ytrain` is the training array of response values.

- `Wtrain` are the training weights for observations.
- `Xtest` and `Ytest` are the test data, with associated weights `Wtest`.
- The returned value `testvals` needs the same size across all folds.

Data Types: `function_handle`

Output Arguments

vals — Cross-validation results

numeric matrix

Cross-validation results, returned as an numeric matrix. `vals` is the arrays of `testvals` output, concatenated vertically over all folds. For example, if `testvals` from every fold is a numeric vector of length `N`, `kfoldfun` returns a `KFold`-by-`N` numeric matrix with one row per fold.

Data Types: `double`

Examples

Estimate Classification Error Using a Custom Loss Function

Train a classification tree classifier, and then cross validate it using a custom k -fold loss function.

Load Fisher's iris data set.

```
load fisheriris
```

Train a classification tree classifier.

```
Mdl = fitctree(meas,species);
```

`Mdl` is a `ClassificationTree` model.

Cross validate `Mdl` using the default 10-fold cross validation. Compute the classification error (proportion of misclassified observations) for the out-of-fold observations.

```
rng(1); % For reproducibility
CVMdl = crossval(Mdl);
```

```
L = kfoldLoss(CVMdl)
```

```
L =
```

```
0.0467
```

Examine the result when the cost of misclassifying a flower as 'versicolor' is 10, and any other error is 1. Write a function called `noversicolor.m` that attributes a cost of 1 for misclassification, but 10 for misclassifying a flower as `versicolor`, and save it on your MATLAB path.

```
function averageCost = noversicolor(CMP,Xtrain,Ytrain,Wtrain,Xtest,Ytest,Wtest)
%noversicolor Example custom cross-validation function
% Attributes a cost of 10 for misclassifying versicolor irises, and 1 for
% the other irises. This example function requires the |fisheriris| data
% set.
Ypredict = predict(CMP,Xtest);
misclassified = not(strcmp(Ypredict,Ytest)); % Different result
classifiedAsVersicolor = strcmp(Ypredict,'versicolor'); % Index of bad decisions
cost = sum(misclassified) + ...
    9*sum(misclassified & classifiedAsVersicolor); % Total differences
averageCost = cost/numel(Ytest); % Average error
end
```

Compute the mean misclassification error with the `noversicolor` cost.

```
mean(kfoldfun(CVMdl,@noversicolor))
```

```
ans =
```

```
0.2267
```

kfoldfun

Class: RegressionPartitionedModel

Cross validate function

Syntax

```
vals = kfoldfun(obj, fun)
```

Description

`vals = kfoldfun(obj, fun)` cross validates the function `fun` by applying `fun` to the data stored in the cross-validated model `obj`. You must pass `fun` as a function handle.

Input Arguments

obj

Object of class `RegressionPartitionedModel` or `RegressionPartitionedEnsemble`. Create `obj` with `fitrtree` or `fitensemble` along with one of the cross-validation options: `'CrossVal'`, `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'`. Alternatively, create `obj` from a regression tree or regression ensemble with `crossval`.

fun

A function handle for a cross-validation function. `fun` has the syntax

```
testvals = fun(CMP, Xtrain, Ytrain, Wtrain, Xtest, Ytest, Wtest)
```

- `CMP` is a compact model stored in one element of the `obj.Trained` property.
- `Xtrain` is the training matrix of predictor values.
- `Ytrain` is the training array of response values.
- `Wtrain` are the training weights for observations.
- `Xtest` and `Ytest` are the test data, with associated weights `Wtest`.

- The returned value `testvals` must have the same size across all folds.

Output Arguments

`vals`

The arrays of `testvals` output, concatenated vertically over all folds. For example, if `testvals` from every fold is a numeric vector of length `N`, `kfoldfun` returns a `KFold`-by-`N` numeric matrix with one row per fold.

Examples

Cross validate a regression tree, and obtain the mean squared error (see `kfoldLoss`):

```
load imports-85
t = fitrtree(X(:,[4 5]),X(:,16),...
    'predictorNames',{'length' 'width'},...
    'responseName','price');
cv = crossval(t);
L = kfoldLoss(cv)
```

```
L =
    1.5489e+007
```

Examine the result of simple averaging of responses instead of using predictions:

```
f = @(cmp,Xtrain,Ytrain,Wtrain,Xtest,Ytest,Wtest)...
    mean((Ytest-mean(Ytrain)).^2)
mean(kfoldfun(cv,f))
```

```
ans =
    6.3497e+007
```

See Also

`RegressionPartitionedEnsemble` | `kfoldLoss` | `crossval` | `fitrtree` | `kfoldPredict` | `RegressionPartitionedModel`

kfoldLoss

Classification loss for observations not used for training

Syntax

```
loss = kfoldLoss(CVMdl)
loss = kfoldLoss(CVMdl,Name,Value)
```

Description

`loss = kfoldLoss(CVMdl)` returns the classification loss obtained by the cross-validated ECOC model (`ClassificationPartitionedECOC`) `CVMdl`. For every fold, this function computes the classification loss for in-fold observations using a model trained on out-of-fold observations. `CVMdl.X` contains both sets of observations.

`loss = kfoldLoss(CVMdl,Name,Value)` returns the classification loss with additional options specified by one or more `Name,Value` pair arguments.

For example, specify the number of folds, decoding scheme, or verbosity level.

Input Arguments

CVMdl — Cross-validated ECOC model

`ClassificationPartitionedECOC` model

Cross-validated ECOC model, specified as a `ClassificationPartitionedECOC` model. You can create a `ClassificationPartitionedECOC` model by:

- Passing a trained ECOC model (`ClassificationECOC`) to `crossval`
- Training an ECOC model using `fitcecoc` and setting any one of these cross-validation name-value pair arguments: `'CrossVal'`, `'Kfold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

'BinaryLoss' — Binary learner loss function

`CVMD1.BinaryLoss` (default) | function handle | 'hamming' | 'linear' | 'exponential' | 'binodeviance' | 'hinge' | 'quadratic'

Binary learner loss function, specified as the comma-separated pair consisting of 'BinaryLoss' and a function handle or string.

- If the value is a string, then it must correspond to a built-in function. This table summarizes the built-in functions, where y_j is a class label for a particular binary learner (in $\{-1, 1, 0\}$) and f_j is the score for observation j .

Value	Description	Score Domain	Formula
'binodeviance'	Binomial deviance	$(-\infty, \infty)$	$\log[1 + \exp(-2yf)] / \log(2)$
'exponential'	Exponential	$(-\infty, \infty)$	$\exp(-yf)$
'hamming'	Hamming	$(-\infty, \infty)$ or $[0, 1]$	$1 - \text{sign}(yf)$
'hinge'	Hinge	$(-\infty, \infty)$	$\max(0, 1 - yf)$
'linear'	Linear	$(-\infty, \infty)$	$1 - yf$
'quadratic'	Quadratic	$[0, 1]$	$[1 - y(2f - 1)]^2$

- For a custom binary loss function, e.g., `customFunction`, specify its function handle 'BinaryLoss', @`customFunction`.

`customFunction` should have this form

```
bLoss = customFunction(M, f)
where:
```

- `M` is the K -by- L coding matrix stored in `CVMD1.CodingMatrix`.
- `f` is the 1-by- L row vector of classification scores.
- `bLoss` is the classification loss.

- K is the number of classes.
- L is the number of binary learners.

Example: 'BinaryLoss', 'binodeviance'

Data Types: char | function_handle

'Decoding' — Decoding scheme

'lossweighted' (default) | 'lossbased'

Decoding scheme that aggregates the “binary losses”, specified as the comma-separated pair consisting of 'Decoding' and 'lossweighted' or 'lossbased'.

Example: 'Decoding', 'lossbased'

Data Types: char

'Folds' — Fold indices for prediction

1:Mdl.KFold (default) | numeric vector of positive integers

Fold indices for prediction, specified as the comma-separated pair consisting of 'Folds' and a numeric vector of positive integers. The elements of **Folds** must range from 1 through `Mdl.KFold`.

The software only uses the folds specified in **Folds** for prediction.

Example: 'Folds', [1 4 10]

Data Types: single | double

'LossFun' — Loss function

'classiferror' (default) | function handle

Loss function, specified as the comma-separated pair consisting of 'LossFun' and a function handle or 'classiferror'.

You can:

- Specify the built-in function 'classiferror', then the loss function is the classification error, in other words, the proportion of misclassified observations.
- Specify your own function using function handle notation.

Suppose that $n = \text{size}(X, 1)$ is the sample size and k is the number of classes. Your function needs the signature `lossvalue = lossfun(C,S,W,Cost)`, where:

- The output argument `lossvalue` is a scalar.
- You choose the function name (*Lossfun*).
- `C` is an n -by- k logical matrix with rows indicating which class the corresponding observation belongs. The column order corresponds to the class order in `CVMdl.ClassNames`.

Construct `C` by setting $C(p, q) = 1$ if observation p is in class q , for each row. Set every element of row p to 0.

- `S` is an n -by- k numeric matrix of negated loss values for classes. Each row corresponds to an observation. The column order corresponds to the class order in `CVMdl.ClassNames`. `S` resembles the output argument `negLoss` of `kfoldPredict`.
- `W` is an n -by-1 numeric vector of observation weights. If you pass `W`, the software normalizes its elements to sum to 1.
- `Cost` is a k -by- k numeric matrix of misclassification costs. For example, `Cost = ones(K) - eye(K)` specifies a cost of 0 for correct classification, and 1 for misclassification.

Specify your function using `'LossFun', @lossfun`.

Data Types: `function_handle` | `char`

'Mode' — Edge meaning

`'average'` (default) | `'individual'`

Edge meaning, specified as the comma-separated pair consisting of `'Mode'` and `'average'` or `'individual'`.

This table describes the values.

Value	Description
<code>'average'</code>	<code>edge</code> is the scalar average over all folds.
<code>'individual'</code>	<code>edge</code> is a vector of length k containing one edge per fold. k is the number of folds.

Example: `'Mode', 'individual'`

Data Types: char

'Options' — Estimation options

[] (default) | structure array returned by `statset`

Estimation options, specified as the comma-separated pair consisting of 'Options' and a structure array returned by `statset`.

To invoke parallel computing:

- You need a Parallel Computing Toolbox license.
- Specify 'Options', `statset('UseParallel',1)`.

'Verbose' — Verbosity level

0 (default) | 1

Verbosity level, specified as the comma-separated pair consisting of 'Verbose' and 0 or 1. `Verbose` controls the amount of diagnostic messages that the software displays in the Command Window.

If `Verbose` is 0, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: 'Verbose', 1

Data Types: single | double

Output Arguments

loss — Classification loss

numeric scalar | numeric row vector

Classification loss, returned as a numeric scalar or numeric row vector.

If `Mode` is 'average', then `loss` is the average classification loss among all binary learners. Otherwise, `loss` is a 1-by-L numeric row vector containing the classification loss for each, respective binary learner, where L is the number of binary learners (`size(CVMdl.CodingMatrix,2)`).

Data Types: single | double

Definitions

Classification Error

The *classification error* is a binary classification error measure that has the form

$$L = \frac{\sum_{j=1}^n w_j e_j}{\sum_{j=1}^n w_j},$$

where:

- w_j is the weight for observation j . The software renormalizes the weights to sum to 1.
- $e_j = 1$ if the predicted class of observation j differs from its true class, and 0 otherwise.

In other words, it is the proportion of observations that the classifier misclassifies.

Binary Loss

A *binary loss* is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Let:

- m_{kj} be element (k,j) of the coding design matrix M (i.e., the code corresponding to class k of binary learner j)
- s_j be the score of binary learner j for an observation
- g be the binary loss function
- \hat{k} be the predicted class for the observation

In *loss-based decoding* [3], the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j).$$

In *loss-weighted decoding* [3], the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \frac{\sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j)}{\sum_{j=1}^L |m_{kj}|}.$$

Allwein et al. [1] suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where y_j is a class label for a particular binary learner (in the set $\{-1, 1, 0\}$), s_j is the score for observation j , and $g(y_j, s_j)$.

Value	Description	Score Domain	$g(y_j, s_j)$
'binodeviance'	Binomial deviance	$(-\infty, \infty)$	$\log[1 + \exp(-2y_j s_j)] / [2\log(2)]$
'exponential'	Exponential	$(-\infty, \infty)$	$\exp(-y_j s_j) / 2$
'hamming'	Hamming	$\{-1, 1\}$	$[1 - \operatorname{sign}(y_j s_j)] / 2$
'hinge'	Hinge	$(-\infty, \infty)$	$\max(0, 1 - y_j s_j) / 2$
'linear'	Linear	$(-\infty, \infty)$	$(1 - y_j s_j) / 2$
'quadratic'	Quadratic	$[0, 1]$	$[1 - y_j(2s_j - 1)]^2 / 2$

The software normalizes the binary losses such that the loss is 0.5 when $y_j = 0$, and aggregates using the average of the binary learners [1].

Do not confuse the binary loss with the overall classification loss (specified by the LossFun name-value pair argument of `predict` and `loss`), e.g., classification error, which measures how well an ECOC classifier performs as a whole.

Examples

Determine k -Fold Cross-Validation Loss of ECOC Models

Load Fisher's iris data set.

```
load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y); % Class order
rng(1); % For reproducibility
```

Train an ECOC model using SVM binary classifiers, and specify to cross validate. It is good practice to standardize the predictors and define the class order. Specify to standardize the predictors using an SVM template.

```
t = templateSVM('Standardize',1);
CVMdl = fitcecoc(X,Y,'CrossVal','on','Learners',t,'ClassNames',classOrder);
```

CVMdl is a ClassificationPartitionedECOC model. By default, the software implements 10-fold cross validation. You can alter the number of folds using the 'KFold' name-value pair argument.

Estimate the average out-of-fold classification error.

```
L = kfoldLoss(CVMdl)
```

```
L =
    0.0400
```

The average classification error for the folds is 4%.

Alternatively, you can obtain the per-fold losses by specifying the name-value pair 'Mode','individual' in kfoldLoss.

Display Individual Losses for Each Cross-Validation Fold

The classification loss is a measure of classifier quality. You can determine ill-performing folds by displaying the losses for each fold.

Load Fisher's iris data set.

```
load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y);
rng(1); % For reproducibility
```

Train an ECOC model using SVM binary classifiers and specify to use 8-fold cross validation. It is good practice to standardize the predictors and define the class order. Specify to standardize the predictors using an SVM template.

```
t = templateSVM('Standardize',1);
CVMdl = fitcecoc(X,Y,'KFold',8,'Learners',t,'ClassNames',classOrder);
```

Estimate the average classification loss across folds, and the losses for each fold.

```
loss = kfoldLoss(CVMdl)
losses = kfoldLoss(CVMdl,'Mode','individual')
```

```
loss =
    0.0333
```

```
losses =
    0.0556
    0.0526
    0.1579
         0
         0
         0
         0
         0
```

The third fold misclassifies a much higher portion of observations than any other fold.

Return the classification loss for the entire model by specifying the well-performing folds using the 'Folds' name-value pair argument.

```
loss = kfoldLoss(CVMdl,'Folds',[1:2 4:8])
```

```
loss =
    0.0153
```

The total classification loss decreased by approximately half its original size.

Consider adjusting parameters of the binary classifiers or the coding design to see if performance for all folds improves.

Determine ECOC Model Quality Using a Custom Cross-Validation Loss

Suppose that it is interesting to know how well a model classifies a particular class. This example shows how to pass such a custom loss function to `kfoldLoss`.

Load Fisher's iris data set.

```
load fisheriris
X = meas;
Y = categorical(species);
n = numel(Y); % Sample size
classOrder = unique(Y) % Class order
K = numel(classOrder); % Number of classes
rng(1) % For reproducibility
```

```
classOrder =

    setosa
    versicolor
    virginica
```

Train an ECOC model using SVM binary classifiers, and specify to cross validate. It is good practice to standardize the predictors and define the class order. Specify to standardize the predictors using an SVM template.

```
t = templateSVM('Standardize',1);
CVMdl = fitcecoc(X,Y,'CrossVal','on','Learners',t,'ClassNames',classOrder);
```

CVMdl is a `ClassificationPartitionedECOC` model. By default, the software implements 10-fold cross validation. You can alter the number of folds using the 'KFold' name-value pair argument.

Compute the negated losses for the out-of-fold observations.

```
[~,negLoss] = kfoldPredict(CVMdl);
```

Create a function that takes the minimal loss for each observation, and then averages the minimal losses across all observations.

```
lossfun = @(C,S,~,~)mean(min(-negLoss,[],2));
```

Compute the cross-validated custom loss.

```
kfoldLoss(CVMdl, 'LossFun', lossfun)
```

```
ans =
```

```
0.0101
```

The average, minimal, binary loss for the out-of-fold observations is 0.0101.

kfoldLoss

Class: ClassificationPartitionedEnsemble

Classification loss for observations not used for training

Syntax

```
L = kfoldLoss(ens)
L = kfoldLoss(ens,Name,Value)
```

Description

`L = kfoldLoss(ens)` returns loss obtained by cross-validated classification model `ens`. For every fold, this method computes classification loss for in-fold observations using a model trained on out-of-fold observations.

`L = kfoldLoss(ens,Name,Value)` calculates loss with additional options specified by one or more `Name,Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Input Arguments

ens

Object of class `ClassificationPartitionedEnsemble`. Create `ens` with `fitensemble` along with one of the cross-validation options: `'crossval'`, `'kfold'`, `'holdout'`, `'leaveout'`, or `'cvpartition'`. Alternatively, create `ens` from a classification ensemble with `crossval`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

'folds'

Indices of folds ranging from 1 to `ens.KFold`. Use only these folds for predictions.

Default: `1:ens.KFold`

'lossfun'

Function handle or string representing a loss function. Built-in loss functions:

- `'binodeviance'` — See “Loss Functions” on page 21-2080
- `'classiferror'` — Fraction of misclassified data
- `'exponential'` — See “Loss Functions” on page 21-2080
- `'hinge'` — See “Loss Functions” on page 21-2080.
- `'mincost'` — Smallest misclassification cost as given by the `obj.Cost` matrix. See “Loss Functions” on page 21-2080.

You can write your own loss function in the syntax described in “Loss Functions” on page 21-2080.

Default: `'classiferror'`

'mode'

A string for determining the output of `kfoldLoss`:

- `'average'` — `L` is a scalar, the loss averaged over all folds.
- `'individual'` — `L` is a vector of length `ens.KFold`, where each entry is the loss for a fold.
- `'cumulative'` — `L` is a vector in which element `J` is obtained by using learners `1:J` from the input list of learners.

Default: `'average'`

Output Arguments

L

Loss, by default the fraction of misclassified data. `L` can be a vector, and can mean different things, depending on the name-value pair settings.

Definitions

Loss Functions

The built-in loss functions are:

- 'binodeviance' — For binary classification, assume the classes y_n are -1 and 1. With weight vector w normalized to have sum 1, and predictions of row n of data X as $f(X_n)$, the binomial deviance is

$$\sum w_n \log(1 + \exp(-2y_n f(X_n))).$$

- 'classiferror' — Fraction of misclassified data, weighted by w .
- 'exponential' — With the same definitions as for 'binodeviance', the exponential loss is

$$\sum w_n \exp(-y_n f(X_n)).$$

- 'hinge' — Classification error measure that has the form

$$L = \frac{\sum_{j=1}^n w_j \max\{0, 1 - y_j' f(X_j)\}}{\sum_{j=1}^n w_j},$$

where:

- w_j is weight j .
- For binary classification, $y_j = 1$ for the positive class and -1 for the negative class. For problems where the number of classes $K > 3$, y_j is a vector of 0s, but with a 1 in the position corresponding to the true class, e.g., if the second observation is in the third class and $K = 4$, then $y_2 = [0 \ 0 \ 1 \ 0]'$.
- $f(X_j)$ is, for binary classification, the posterior probability or, for $K > 3$, a vector of posterior probabilities for each class given observation j .

- `'mincost'` — Predict the label with the smallest expected misclassification cost, with expectation taken over the posterior probability, and cost as given by the `COST` property of the classifier (a matrix). The loss is then the true misclassification cost averaged over the observations.

To write your own loss function, create a function file of the form

```
function loss = lossfun(C,S,W,COST)
```

- `N` is the number of rows of `ens.X`.
- `K` is the number of classes in `ens.ClassNames`.
- `C` is an `N`-by-`K` logical matrix, with one `true` per row for the true class. The index for each class is its position in `tree.ClassNames`.
- `S` is an `N`-by-`K` numeric matrix. `S` is a matrix of posterior probabilities for classes with one row per observation, similar to the `score` output from `predict`.
- `W` is a numeric vector with `N` elements, the observation weights.
- `COST` is a `K`-by-`K` numeric matrix of misclassification costs. The default `'classiferror'` gives a cost of `0` for correct classification, and `1` for misclassification.
- The output `loss` should be a scalar.

Pass the function handle `@lossfun` as the value of the `lossfun` name-value pair.

Examples

Find the average cross-validated classification error for an ensemble model of the ionosphere data:

```
load ionosphere
ens = fitensemble(X,Y,'AdaBoostM1',100,'Tree');
cvens = crossval(ens);
L = kfoldLoss(cvens)
```

```
L =
    0.0826
```

See Also

`kfoldEdge` | `kfoldMargin` | `crossval` | `kfoldPredict` | `kfoldfun`

kfoldLoss

Class: ClassificationPartitionedModel

Classification loss for observations not used for training

Syntax

```
L = kfoldLoss(obj)
L = kfoldLoss(obj,Name,Value)
```

Description

`L = kfoldLoss(obj)` returns loss obtained by cross-validated classification model `obj`. For every fold, this method computes classification loss for in-fold observations using a model trained on out-of-fold observations.

`L = kfoldLoss(obj,Name,Value)` calculates loss with additional options specified by one or more `Name,Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Input Arguments

obj

Object of class `ClassificationPartitionedModel`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

'folds'

Indices of folds ranging from 1 to `obj.KFold`. Use only these folds for predictions.

Default: 1:obj.KFold

'lossfun'

Function handle or string representing a loss function. Built-in loss functions:

- 'binodeviance' — See “Loss Functions” on page 21-2084.
- 'classiferror' — Fraction of misclassified observations. See “Loss Functions” on page 21-2084.
- 'exponential' — See “Loss Functions” on page 21-2084.
- 'hinge' — See “Loss Functions” on page 21-2084.
- 'mincost' — Smallest misclassification cost as given by the obj.Cost matrix. See “Loss Functions” on page 21-2084.

You can write your own loss function in the syntax described in “Loss Functions” on page 21-2084.

Default: 'mincost'

'mode'

A string for determining the output of kfoldLoss:

- 'average' — L is a scalar, the loss averaged over all folds.
- 'individual' — L is a vector of length obj.KFold, where each entry is the loss for a fold.

Default: 'average'

Output Arguments

L

Loss, by default the fraction of misclassified data. L can be a vector, and can mean different things, depending on the name-value pair settings.

Definitions

Classification Error

The default classification error is the fraction of the data X that obj misclassifies, where Y are the true classifications.

Weighted classification error is the sum of weight i times the Boolean value that is 1 when obj misclassifies the i th row of X , divided by the sum of the weights.

Loss Functions

The built-in loss functions are:

- 'binodeviance' — For binary classification, assume the classes y_n are -1 and 1. With weight vector w normalized to have sum 1, and predictions of row n of data X as $f(X_n)$, the binomial deviance is

$$\sum w_n \log(1 + \exp(-2y_n f(X_n))).$$

- 'exponential' — With the same definitions as for 'binodeviance', the exponential loss is

$$\sum w_n \exp(-y_n f(X_n)).$$

- 'classiferror' — Predict the label with the largest posterior probability. The loss is then the fraction of misclassified observations.
- 'hinge' — Classification error measure that has the form

$$L = \frac{\sum_{j=1}^n w_j \max\{0, 1 - y_j' f(X_j)\}}{\sum_{j=1}^n w_j},$$

where:

- w_j is weight j .

- For binary classification, $y_j = 1$ for the positive class and -1 for the negative class. For problems where the number of classes $K > 3$, y_j is a vector of 0s, but with a 1 in the position corresponding to the true class, e.g., if the second observation is in the third class and $K = 4$, then $y_2 = [0\ 0\ 1\ 0]'$.
- $f(X_j)$ is, for binary classification, the posterior probability or, for $K > 3$, a vector of posterior probabilities for each class given observation j .
- 'mincost' — Predict the label with the smallest expected misclassification cost, with expectation taken over the posterior probability, and cost as given by the **Cost** property of the classifier (a matrix). The loss is then the true misclassification cost averaged over the observations.

To write your own loss function, create a function file in this form:

```
function loss = lossfun(C,S,W,COST)
```

- **N** is the number of rows of **X**.
- **K** is the number of classes in the classifier, represented in the **ClassNames** property.
- **C** is an **N**-by-**K** logical matrix, with one **true** per row for the true class. The index for each class is its position in the **ClassNames** property.
- **S** is an **N**-by-**K** numeric matrix. **S** is a matrix of posterior probabilities for classes with one row per observation, similar to the **posterior** output from **predict**.
- **W** is a numeric vector with **N** elements, the observation weights. If you pass **W**, the elements are normalized to sum to the prior probabilities in the respective classes.
- **COST** is a **K**-by-**K** numeric matrix of misclassification costs. For example, you can use **COST = ones(K) - eye(K)**, which means a cost of 0 for correct classification, and 1 for misclassification.
- The output **loss** should be a scalar.

Pass the function handle `@lossfun` as the value of the **LossFun** name-value pair.

Examples

Find the average cross-validated classification error for a model of the **ionosphere** data:

```
load ionosphere
tree = fitctree(X,Y);
```

```
cvtree = crossval(tree);  
L = kfoldLoss(cvtree)
```

```
L =  
    0.1197
```

crossval | kfoldPredict

How To

- “Examine the Quality of a KNN Classifier” on page 16-29

kfoldLoss

Class: RegressionPartitionedEnsemble

Cross-validation loss of partitioned regression ensemble

Syntax

```
L = kfoldLoss(cvens)
L = kfoldLoss(cvens,Name,Value)
```

Description

`L = kfoldLoss(cvens)` returns the cross-validation loss of `cvens`.

`L = kfoldLoss(cvens,Name,Value)` returns cross-validation loss with additional options specified by one or more `Name,Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Input Arguments

`cvens`

Object of class `RegressionPartitionedEnsemble`. Create `obj` with `fitensemble` along with one of the cross-validation options: `'crossval'`, `'kfold'`, `'holdout'`, `'leaveout'`, or `'cvpartition'`. Alternatively, create `obj` from a regression ensemble with `crossval`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

'folds'

Indices of folds ranging from 1 to `cvens.KFold`. Use only these folds for predictions.

Default: `1:cvens.KFold`

'lossfun'

Function handle for loss function, or the string `'mse'`, meaning mean squared error. If you pass a function handle `fun`, `loss` calls it as

```
fun(Y,Yfit,W)
```

where `Y`, `Yfit`, and `W` are numeric vectors of the same length.

- `Y` is the observed response.
- `Yfit` is the predicted response.
- `W` is the observation weights.

The returned value `fun(Y,Yfit,W)` should be a scalar.

Default: `'mse'`

'mode'

String representing the meaning of the output `L`:

- `'ensemble'` — `L` is a scalar value, the loss for the entire ensemble.
- `'individual'` — `L` is a vector with one element per trained learner.
- `'cumulative'` — `L` is a vector in which element `J` is obtained by using learners `1:J` from the input list of learners.

Default: `'ensemble'`

Output Arguments

L

The loss (mean squared error) between the observations in a fold when compared against predictions made with an ensemble trained on the out-of-fold data. `L` can be a vector, and can mean different things, depending on the name-value pair settings.

Examples

Find the cross-validation loss for a regression ensemble of the `carsmall` data:

```
load carsmall
X = [Displacement Horsepower Weight];
rens = fitensemble(X,MPG,'LSboost',100,'Tree');
cvrens = crossval(rens);
L = kfoldLoss(cvrens)
```

```
L =
    25.6935
```

See Also

[RegressionPartitionedEnsemble](#) | [loss](#) | [kfoldPredict](#)

kfoldLoss

Class: RegressionPartitionedModel

Cross-validation loss of partitioned regression model

Syntax

```
L = kfoldLoss(cvmodel)
L = kfoldLoss(cvmodel,Name,Value)
```

Description

`L = kfoldLoss(cvmodel)` returns the cross-validation loss of `cvmodel`.

`L = kfoldLoss(cvmodel,Name,Value)` returns cross-validation loss with additional options specified by one or more `Name,Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Input Arguments

cvmodel

Object of class `RegressionPartitionedModel`. Create `obj` with `fitrtree` along with one of the cross-validation options: `'CrossVal'`, `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'`. Alternatively, create `obj` from a regression tree with `crossval`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

'folds'

Indices of folds ranging from 1 to `obj.KFold`. Use only these folds for predictions.

Default: 1:obj.KFold

'lossfun'

Function handle for loss function, or the string 'mse', meaning mean squared error. If you pass a function handle `fun`, `kfoldLoss` calls it as

```
fun(Y,Yfit,W)
```

where `Y`, `Yfit`, and `W` are numeric vectors of the same length.

- `Y` is the observed response.
- `Yfit` is the predicted response.
- `W` is the observation weights.

The returned value `fun(Y,Yfit,W)` should be a scalar.

Default: 'mse'

'mode'

One of the following strings:

- 'average' — `L` is the average loss over all folds.
- 'individual' — `L` is a vector of the individual losses of in-fold observations trained on out-of-fold data.

Default: 'average'

Output Arguments

L

The loss (mean squared error) between the observations in a fold when compared against predictions made with a tree trained on the out-of-fold data. If `mode` is 'individual', `L` is a vector of the losses. If `mode` is 'average', `L` is the average loss.

Examples

Construct a partitioned regression model, and examine the cross-validation losses for the folds:

```
load carsmall
XX = [Cylinders Displacement Horsepower Weight];
YY = MPG;
cvmodel = fitrtree(XX,YY,'crossval','on');
L = kfoldLoss(cvmodel,'mode','individual')
```

```
L =
    44.9635
    11.8525
    18.2046
     9.2965
    29.4329
    54.8659
    24.6446
     8.2085
    19.7593
    16.7394
```

Alternatives

You can avoid constructing a cross-validated tree model by calling `cvLoss` instead of `kfoldLoss`. The cross-validated tree can save time if you are going to examine it more than once.

See Also

`loss` | `kfoldPredict` | `fitrtree`

kfoldMargin

Classification margins for observations not used for training

Syntax

```
margin = kfoldMargin(CVMdl)
margin = kfoldMargin(CVMdl,Name,Value)
```

Description

`margin = kfoldMargin(CVMdl)` returns classification margins obtained by the cross-validated ECOC model (`ClassificationPartitionedECOC`) `CVMdl`. For every fold, this method computes classification margins for in-fold observations using a model trained on out-of-fold observations. `CVMdl.X` contains both sets of observations.

`margin = kfoldMargin(CVMdl,Name,Value)` returns classification margins with additional options specified by one or more `Name,Value` pair arguments.

For example, specify the binary learner loss function, decoding scheme, or verbosity level.

Input Arguments

CVMdl — Cross-validated ECOC model

`ClassificationPartitionedECOC` model

Cross-validated ECOC model, specified as a `ClassificationPartitionedECOC` model. You can create a `ClassificationPartitionedECOC` model by:

- Passing a trained ECOC model (`ClassificationECOC`) to `crossval`
- Training an ECOC model using `fitcecoc` and setting any one of these cross-validation name-value pair arguments: `'CrossVal'`, `'Kfold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

'BinaryLoss' — Binary learner loss function

`CVMD1.BinaryLoss` (default) | function handle | 'hamming' | 'linear' | 'exponential' | 'binodeviance' | 'hinge' | 'quadratic'

Binary learner loss function, specified as the comma-separated pair consisting of 'BinaryLoss' and a function handle or string.

- If the value is a string, then it must correspond to a built-in function. This table summarizes the built-in functions, where y_j is a class label for a particular binary learner (in $\{-1, 1, 0\}$) and f_j is the score for observation j .

Value	Description	Score Domain	Formula
'binodeviance'	Binomial deviance	$(-\infty, \infty)$	$\frac{\log[1 + \exp(-2yf)]}{\log(2)}$
'exponential'	Exponential	$(-\infty, \infty)$	$\exp(-yf)$
'hamming'	Hamming	$(-\infty, \infty)$ or $[0, 1]$	$1 - \text{sign}(yf)$
'hinge'	Hinge	$(-\infty, \infty)$	$\max(0, 1 - yf)$
'linear'	Linear	$(-\infty, \infty)$	$1 - yf$
'quadratic'	Quadratic	$[0, 1]$	$[1 - y(2f - 1)]^2$

- For a custom binary loss function, e.g., `customFunction`, specify its function handle 'BinaryLoss', @`customFunction`.

`customFunction` should have this form

```
bLoss = customFunction(M, f)
where:
```

- `M` is the K -by- L coding matrix stored in `CVMD1.CodingMatrix`.
- `f` is the 1-by- L row vector of classification scores.
- `bLoss` is the classification loss.

- K is the number of classes.
- L is the number of binary learners.

Example: 'BinaryLoss', 'binodeviance'

Data Types: char | function_handle

'Decoding' — Decoding scheme

'lossweighted' (default) | 'lossbased'

Decoding scheme that aggregates the “binary losses”, specified as the comma-separated pair consisting of 'Decoding' and 'lossweighted' or 'lossbased'.

Example: 'Decoding', 'lossbased'

Data Types: char

'Options' — Estimation options

[] (default) | structure array returned by `statset`

Estimation options, specified as the comma-separated pair consisting of 'Options' and a structure array returned by `statset`.

To invoke parallel computing:

- You need a Parallel Computing Toolbox license.
- Specify 'Options', `statset('UseParallel',1)`.

'Verbose' — Verbosity level

0 (default) | 1

Verbosity level, specified as the comma-separated pair consisting of 'Verbose' and 0 or 1. `Verbose` controls the amount of diagnostic messages that the software displays in the Command Window.

If `Verbose` is 0, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: 'Verbose', 1

Data Types: single | double

Output Arguments

margin — Classification margins

numeric vector

Classification margins, returned as a numeric vector. `margin` is an n -by-1 vector, where each row is the margin of the corresponding observation, and n is the number of observations (i.e., `size(CVMdl.X,1)`).

Data Types: `single` | `double`

Definitions

Classification Margin

The *classification margins* are, for each observation, the difference between the negative loss for the positive class and maximal negative loss among the negative classes. If the margins are on the same scale, then they serve as a classification confidence measure, i.e., among multiple classifiers, those that yield larger margins are better “[4]”.

Binary Loss

A *binary loss* is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Let:

- m_{kj} be element (k,j) of the coding design matrix M (i.e., the code corresponding to class k of binary learner j)
- s_j be the score of binary learner j for an observation
- g be the binary loss function
- \hat{k} be the predicted class for the observation

In *loss-based decoding* [3], the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j).$$

In *loss-weighted decoding* [3], the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \frac{\sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j)}{\sum_{j=1}^L |m_{kj}|}.$$

Allwein et al. [1] suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where y_j is a class label for a particular binary learner (in the set $\{-1, 1, 0\}$), s_j is the score for observation j , and $g(y_j, s_j)$.

Value	Description	Score Domain	$g(y_j, s_j)$
'binodeviance'	Binomial deviance	$(-\infty, \infty)$	$\log[1 + \exp(-2y_j s_j)] / [2\log(2)]$
'exponential'	Exponential	$(-\infty, \infty)$	$\exp(-y_j s_j) / 2$
'hamming'	Hamming	$\{-1, 1\}$	$[1 - \operatorname{sign}(y_j s_j)] / 2$
'hinge'	Hinge	$(-\infty, \infty)$	$\max(0, 1 - y_j s_j) / 2$
'linear'	Linear	$(-\infty, \infty)$	$(1 - y_j s_j) / 2$
'quadratic'	Quadratic	$[0, 1]$	$[1 - y_j(2s_j - 1)]^2 / 2$

The software normalizes the binary losses such that the loss is 0.5 when $y_j = 0$, and aggregates using the average of the binary learners [1].

Do not confuse the binary loss with the overall classification loss (specified by the LossFun name-value pair argument of `predict` and `loss`), e.g., classification error, which measures how well an ECOC classifier performs as a whole.

Examples

Estimate *k*-Fold Cross-Validated Margins of ECOC Models

Load Fisher's iris data set.

```
load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y);
rng(1); % For reproducibility
```

Train an ECOC model using SVM binary classifiers and specify to cross validate. It is good practice to standardize the predictors and define the class order. Specify to standardize the predictors using an SVM template.

```
t = templateSVM('Standardize',1);
CVMdl = fitcecoc(X,Y,'CrossVal','on','Learners',t,'ClassNames',classOrder);
```

CVMdl is a `ClassificationPartitionedModel` model. By default, the software implements 10-fold cross validation. You can alter the number of folds using the 'KFold' name-value pair argument.

Estimate the out-of-fold margins. Display the distribution of the `mnargins` using a boxplot.

```
margin = kfoldMargin(CVMdl);

figure;
boxplot(margin);
title('Cross-Validated Margins')
```

An observation margin is the positive-class, negated loss minus the maximum negative-class, negated loss. Classifiers that yield relatively large margins are desirable.

Select ECOC Model Features by Comparing Cross-Validation Margins

The classifier margin measures the average of the classifier margins. One way to perform feature selection is to compare cross-validation margins from multiple models. Based solely on this criterion, the classifier with the greater margins is the best classifier.

Load Fisher's iris data set.

```
load fisheriris
X = meas;
Y = categorical(species);
```

```
classOrder = unique(Y); % Class order
rng(1); % For reproducibility
```

Define these two data sets:

- `fullX` contains all predictors.
- `partX` contains the petal dimensions.

```
fullX = X;
partX = X(:,3:4);
```

Train an ECOC model using SVM binary classifiers for each predictor set, and specify to cross validate. It is good practice to standardize the predictors and define the class order. Specify to standardize the predictors using an SVM template.

```
t = templateSVM('Standardize',1);
CVMdl = fitcecoc(fullX,Y,'CrossVal','on','Learners',t,...
    'ClassNames',classOrder);
PCVMdl = fitcecoc(partX,Y,'CrossVal','on','Learners',t,...
    'ClassNames',classOrder);
```

`CVMdl` and `PCVMdl` are `ClassificationPartitionedECOC` models. By default, the software implements 10-fold cross validation.

Estimate the test sample margin for each classifier. Specify to use loss-based decoding for aggregating the binary learner results. For each model, display the distribution of the margins using a boxplot.

```
fullMargins = kfoldMargin(CVMdl,'Decoding','lossbased');
partMargins = kfoldMargin(PCVMdl,'Decoding','lossbased');

figure;
boxplot([fullMargins partMargins],'Labels',{'All Predictors','Two Predictors'});
title('Boxplots of Cross-Validated Margins')
```

The margin distributions are approximately the same, but PCVMD1 is a less complex model, which might make it more desirable.

kfoldMargin

Class: ClassificationPartitionedModel

Classification margins for observations not used for training

Syntax

```
M = kfoldMargin(obj)
```

Description

`M = kfoldMargin(obj)` returns classification margins obtained by cross-validated classification model `obj`. For every fold, this method computes classification margins for in-fold observations using a model trained on out-of-fold observations.

Input Arguments

obj

A partitioned classification model of type `ClassificationPartitionedModel` or `ClassificationPartitionedEnsemble`.

Output Arguments

M

The classification margin.

Definitions

Margin

The classification *margin* is the difference between the classification *score* for the true class and maximal classification score for the false classes.

The classification margin is a column vector with the same number of rows as in the matrix X . A high value of margin indicates a more reliable prediction than a low value.

Score

For discriminant analysis, the *score* of a classification is the posterior probability of the classification. For the definition of posterior probability in discriminant analysis, see “Posterior Probability” on page 15-7.

For ensembles, a classification *score* represents the confidence of a classification into a class. The higher the score, the higher the confidence.

Different ensemble algorithms have different definitions for their scores. Furthermore, the range of scores depends on ensemble type. For example:

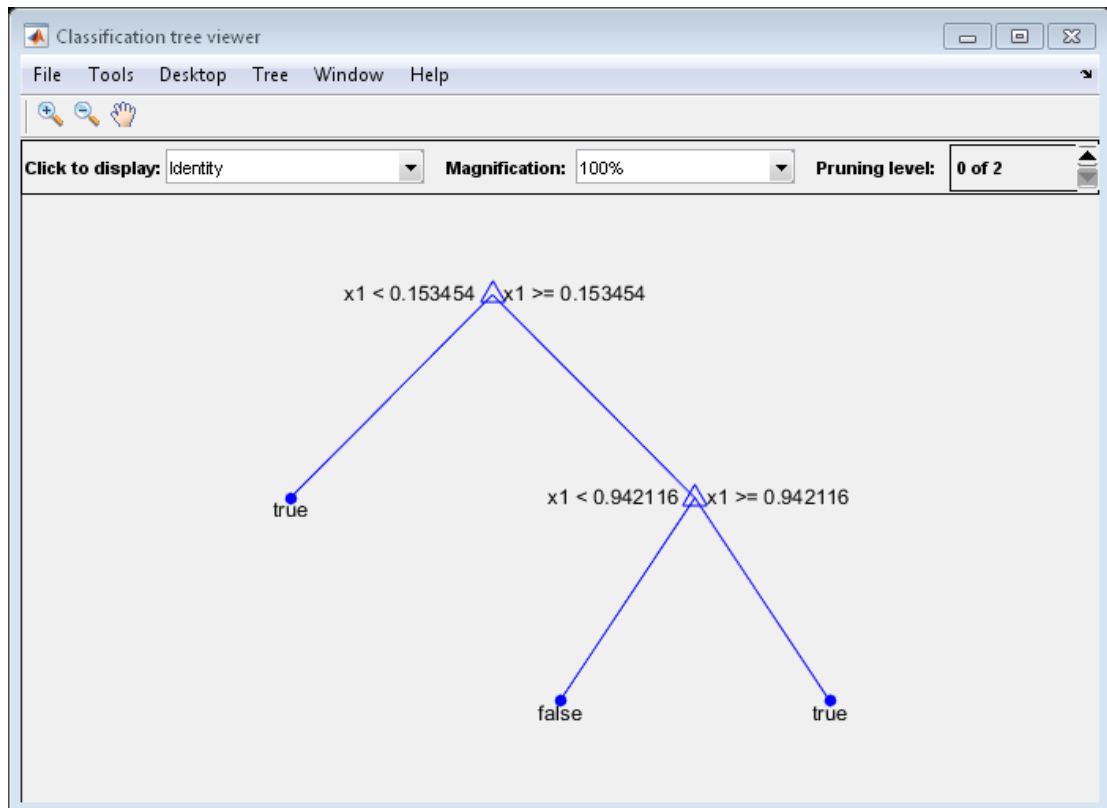

- AdaBoostM1 scores range from $-\infty$ to ∞ .
- Bag scores range from 0 to 1.

For trees, the *score* of a classification of a leaf node is the posterior probability of the classification at that node. The posterior probability of the classification at a node is the number of training sequences that lead to that node with the classification, divided by the number of training sequences that lead to that node.

For example, consider classifying a predictor X as true when $X < 0.15$ or $X > 0.95$, and X is false otherwise.

Generate 100 random points and classify them:

```
rng(0, 'twister') % for reproducibility
X = rand(100,1);
Y = (abs(X - .55) > .4);
tree = fitctree(X,Y);
view(tree, 'Mode', 'Graph')
```

Prune the tree:

```
tree1 = prune(tree, 'Level', 1);  
view(tree1, 'Mode', 'Graph')
```

The pruned tree correctly classifies observations that are less than 0.15 as **true**. It also correctly classifies observations from .15 to .94 as **false**. However, it incorrectly classifies observations that are greater than .94 as **false**. Therefore, the score for observations that are greater than .15 should be about $.05/.85=.06$ for **true**, and about $.8/.85=.94$ for **false**.

Compute the prediction scores for the first 10 rows of X:

```
[~,score] = predict(tree1,X(1:10));
[score X(1:10,:)]
```

```
ans =
```

```
0.9059    0.0941    0.8147
```

```

0.9059    0.0941    0.9058
         0    1.0000    0.1270
0.9059    0.0941    0.9134
0.9059    0.0941    0.6324
         0    1.0000    0.0975
0.9059    0.0941    0.2785
0.9059    0.0941    0.5469
0.9059    0.0941    0.9575
0.9059    0.0941    0.9649

```

Indeed, every value of X (the right-most column) that is less than 0.15 has associated scores (the left and center columns) of 0 and 1, while the other values of X have associated scores of 0.91 and 0.09. The difference (score 0.09 instead of the expected .06) is due to a statistical fluctuation: there are 8 observations in X in the range (.95, 1) instead of the expected 5 observations.

Examples

Estimate the k -fold Margins of a Classifier

Find the k -fold margins for an ensemble that classifies the ionosphere data.

Load the ionosphere data set.

```
load ionosphere
```

Train a classification ensemble of decision trees.

```
Mdl = fitensemble(X,Y,'AdaBoostM1',100,'Tree');
```

Cross validate the classifier using 10-fold cross validation.

```
cvens = crossval(Mdl);
```

Compute the `_k_fold` margins. Display summary statistics for the margins.

```
m = kfoldMargin(cvens);
marginStats = table(min(m),mean(m),max(m),...
    'VariableNames',{'Min','Mean','Max'})
```

```
marginStats =
```

Min	Mean	Max
-11.312	7.3236	23.517

See Also

`ClassificationPartitionedModel` | `kfoldEdge` | `kfoldLoss` | `kfoldfun` | `crossval` | `kfoldPredict`

kfoldPredict

Predict responses for observations not used for training

Syntax

```
label = kfoldPredict(CVMdl)
label = kfoldPredict(CVMdl,Name,Value)
[label,NegLoss,PBScore] = kfoldPredict(____)
[label,NegLoss,PBScore,Posterior] = kfoldPredict(____)
```

Description

`label = kfoldPredict(CVMdl)` returns class labels predicted by the cross-validated ECOC model (`ClassificationPartitionedECOC`) `CVMdl`. For every fold, `kfoldPredict` predicts class labels for in-fold observations using a model trained on out-of-fold observations. `CVMdl.X` contains both sets of observations.

The software predicts the classification of an observation by assigning the observation to the class yielding the largest negated average binary loss (or, equivalently, the smallest average binary loss).

`label = kfoldPredict(CVMdl,Name,Value)` returns predicted class labels with additional options specified by one or more `Name,Value` pair arguments.

For example, specify the posterior probability estimation method, decoding scheme, or verbosity level.

`[label,NegLoss,PBScore] = kfoldPredict(____)` additionally returns negated values of the average binary loss per class (`NegLoss`) for in-fold observations, and positive-class scores (`PBScore`) for in-fold observations classified by each binary learner.

If the coding matrix varies across folds (that is, if the coding scheme is `sparserandom` or `denserandom`), then `PBScore` is empty (`[]`).

`[label,NegLoss,PBScore,Posterior] = kfoldPredict(____)` additionally returns posterior class probability estimates for in-fold observations (`Posterior`).

To obtain posterior class probabilities, you must set `'FitPosterior',1` when training the ECOC model using `fitceoc`. Otherwise, `kfoldPredict` throws an error.

Input Arguments

CVMd1 — Cross-validated ECOC model

ClassificationPartitionedECOC model

Cross-validated ECOC model, specified as a ClassificationPartitionedECOC model. You can create a ClassificationPartitionedECOC model by:

- Passing a trained ECOC model (ClassificationECOC) to crossval
- Training an ECOC model using fitcecoc and setting any one of these cross-validation name-value pair arguments: 'CrossVal', 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1,Value1, ...,NameN,ValueN.

'BinaryLoss' — Binary learner loss function

CVMd1.BinaryLoss (default) | function handle | 'hamming' | 'linear' | 'exponential' | 'binodeviance' | 'hinge' | 'quadratic'

Binary learner loss function, specified as the comma-separated pair consisting of 'BinaryLoss' and a function handle or string.

- If the value is a string, then it must correspond to a built-in function. This table summarizes the built-in functions, where y_j is a class label for a particular binary learner (in $\{-1,1,0\}$) and f_j is the score for observation j .

Value	Description	Score Domain	Formula
'binodeviance'	Binomial deviance	$(-\infty, \infty)$	$\frac{\log[1 + \exp(-2yf)]}{\log(2)}$
'exponential'	Exponential	$(-\infty, \infty)$	$\exp(-yf)$
'hamming'	Hamming	$(-\infty, \infty)$ or $[0,1]$	$1 - \text{sign}(yf)$
'hinge'	Hinge	$(-\infty, \infty)$	$\max(0, 1 - yf)$
'linear'	Linear	$(-\infty, \infty)$	$1 - yf$

Value	Description	Score Domain	Formula
'quadratic'	Quadratic	[0,1]	$[1 - y(2f - 1)]^2$

- For a custom binary loss function, e.g., `customFunction`, specify its function handle `'BinaryLoss', @customFunction`.

`customFunction` should have this form

```
bLoss = customFunction(M,f)
where:
```

- `M` is the K -by- L coding matrix stored in `CVMD1.CodingMatrix`.
- `f` is the 1-by- L row vector of classification scores.
- `bLoss` is the classification loss.
- K is the number of classes.
- L is the number of binary learners.

Example: `'BinaryLoss', 'binodeviance'`

Data Types: char | function_handle

'Decoding' – Decoding scheme

`'lossweighted'` (default) | `'lossbased'`

Decoding scheme that aggregates the “binary losses”, specified as the comma-separated pair consisting of `'Decoding'` and `'lossweighted'` or `'lossbased'`.

Example: `'Decoding', 'lossbased'`

Data Types: char

'NumKLInitializations' – Number of random initial values

0 (default) | nonnegative integer

Number of random initial values for fitting posterior probabilities by Kullback-Leibler divergence minimization, specified as the comma-separated pair consisting of `'NumKLInitializations'` and a nonnegative integer.

If you do not request the fourth output argument (Posterior) and set `'PosteriorMethod', 'kl'` (the default), then the software ignores the value of `NumKLInitializations`.

For more details, see “Posterior Estimation Using Kullback-Leibler Divergence” on page 21-3340.

Example: `'NumKLInitializations',5`

Data Types: `single` | `double`

'Options' — Estimation options

`[]` (default) | structure array returned by `statset`

Estimation options, specified as the comma-separated pair consisting of `'Options'` and a structure array returned by `statset`.

To invoke parallel computing:

- You need a Parallel Computing Toolbox license.
- Specify `'Options',statset('UseParallel',1)`.

'PosteriorMethod' — Posterior probability estimation method

`'kl'` (default) | `'qp'`

Posterior probability estimation method, specified as the comma-separated pair consisting of `'PosteriorMethod'` and `'kl'` or `'qp'`.

- If `PosteriorMethod` is `'kl'`, then the software estimates multiclass posterior probabilities by minimizing the Kullback-Leibler divergence between the predicted and expected posterior probabilities returned by binary learners. For details, see “Posterior Estimation Using Kullback-Leibler Divergence”.
- If `PosteriorMethod` is `'qp'`, then the software estimates multiclass posterior probabilities by solving a least-squares problem using quadratic programming. You need an Optimization Toolbox license to use this option. For details, see “Posterior Estimation Using Quadratic Programming”.
- If you do not request the fourth output argument (`Posterior`), then the software ignores the value of `PosteriorMethod`.

Example: `'PosteriorMethod','qp'`

Data Types: `char`

'Verbose' — Verbosity level

`0` (default) | `1`

Verbosity level, specified as the comma-separated pair consisting of 'Verbose' and 0 or 1. **Verbose** controls the amount of diagnostic messages that the software displays in the Command Window.

If **Verbose** is 0, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: 'Verbose', 1

Data Types: single | double

Output Arguments

label — Predicted class labels

categorical array | character array | logical vector | vector of numeric values | cell array of strings

Predicted class labels, returned as a categorical or character array, logical or numeric vector, or cell array of strings.

label:

- Is the same data type as `CVMdl.Y`
- Has length equal to the number of rows of `CVMdl.X`

The software predicts the classification of an observation by assigning the observation to the class yielding the largest negated average binary loss (or, equivalently, the smallest average binary loss).

NegLoss — Negated average binary losses

numeric matrix

Negated average binary losses, returned as a numeric matrix. **NegLoss** is an n-by-K matrix, where n is the number of observations (`size(CVMdl.X, 1)`) and K is the number of unique classes (`size(CVMdl.ClassNames, 1)`).

PBScore — Positive-class scores

numeric matrix

Positive-class scores for each binary learner, returned as a numeric matrix. **PBScore** is an n-by-L matrix, where n is the number of observations (`size(CVMdl.X, 1)`) and L is the number of binary learners (`size(CVMdl.CodingMatrix, 2)`).

If the coding matrix varies across folds (that is, if the coding scheme is `sparserandom` or `denserandom`), then `PBScore` is empty (`[]`).

Posterior — Posterior class probabilities

numeric matrix

Posterior class probabilities, returned as a numeric matrix. `Posterior` is an n -by- K matrix, where n is the number of observations (`size(CVMdl.X,1)`) and K is the number of unique classes (`size(CVMdl.ClassNames,1)`).

You must set `'FitPosterior',1` when training the ECOC model using `fitcecoc` to request `Posterior`. Otherwise, the software throws an error.

Definitions

Binary Loss

A *binary loss* is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Let:

- m_{kj} be element (k,j) of the coding design matrix M (i.e., the code corresponding to class k of binary learner j)
- s_j be the score of binary learner j for an observation
- g be the binary loss function
- \hat{k} be the predicted class for the observation

In *loss-based decoding* [3], the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j).$$

In *loss-weighted decoding* [3], the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \frac{\sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j)}{\sum_{j=1}^L |m_{kj}|}.$$

Allwein et al. [1] suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where y_j is a class label for a particular binary learner (in the set $\{-1, 1, 0\}$), s_j is the score for observation j , and $g(y_j, s_j)$.

Value	Description	Score Domain	$g(y_j, s_j)$
'binodeviance'	Binomial deviance	$(-\infty, \infty)$	$\log[1 + \exp(-2y_j s_j)] / [2\log(2)]$
'exponential'	Exponential	$(-\infty, \infty)$	$\exp(-y_j s_j) / 2$
'hamming'	Hamming	$\{-1, 1\}$	$[1 - \operatorname{sign}(y_j s_j)] / 2$
'hinge'	Hinge	$(-\infty, \infty)$	$\max(0, 1 - y_j s_j) / 2$
'linear'	Linear	$(-\infty, \infty)$	$(1 - y_j s_j) / 2$
'quadratic'	Quadratic	$[0, 1]$	$[1 - y_j(2s_j - 1)]^2 / 2$

The software normalizes the binary losses such that the loss is 0.5 when $y_j = 0$, and aggregates using the average of the binary learners [1].

Do not confuse the binary loss with the overall classification loss (specified by the LossFun name-value pair argument of `predict` and `loss`), e.g., classification error, which measures how well an ECOC classifier performs as a whole.

Examples

Predict k -Fold Cross-Validation Labels of ECOC Models

Load Fisher's iris data set.

```
load fisheriris
X = meas;
Y = categorical(species);
```

```
classOrder = unique(Y);  
rng(1); % For reproducibility
```

Train an ECOC model using SVM binary classifiers and specify to cross validate. It is good practice to standardize the predictors and define the class order. Specify to standardize the predictors using an SVM template.

```
t = templateSVM('Standardize',1);  
CVMdl = fitcecoc(X,Y,'CrossVal','on','Learners',t,'ClassNames',classOrder);
```

CVMdl is a `ClassificationPartitionedModel` model. By default, the software implements 10-fold cross validation. You can alter the number of folds using the 'KFold' name-value pair argument.

Predict the out-of-fold labels. Print a random subset of true and predicted labels.

```
labels = kfoldPredict(CVMdl);  
idx = randsample(numel(labels),10);  
table(Y(idx),labels(idx),...  
      'VariableNames',{'TrueLabels','PredictedLabels'})
```

```
ans =
```

TrueLabels	PredictedLabels
setosa	setosa
versicolor	versicolor
setosa	setosa
virginica	virginica
versicolor	versicolor
setosa	setosa
virginica	virginica
virginica	virginica
setosa	setosa
setosa	setosa

CVMdl correctly labeled the out-of-fold observations with indices `idx`.

Predict Cross-Validation Labels of ECOC Models Using Custom Binary Loss Function

Load Fisher's iris data set.

```
load fisheriris
```

```

X = meas;
Y = categorical(species);
classOrder = unique(Y); % Class order
K = numel(classOrder); % Number of classes
rng(1); % For reproducibility

```

Train an ECOC model using SVM binary classifiers and specify to cross validate. It is good practice to standardize the predictors and define the class order. Specify to standardize the predictors using an SVM template.

```

t = templateSVM('Standardize',1);
CVMdl = fitcecoc(X,Y,'CrossVal','on','Learners',t,'ClassNames',classOrder);

```

CVMdl is a `ClassificationPartitionedModel` model. By default, the software implements 10-fold cross validation. You can alter the number of folds using the `'KFold'` name-value pair argument.

SVM scores are signed distances from the observation to the decision boundary.

Therefore, the domain is $(-\infty, \infty)$. Create a custom binary loss function that:

- Maps the coding design matrix (M) and positive-class classification scores (s) for each learner to the binary loss for each observation
- Uses linear loss
- Aggregates the binary learner loss using the median.

You can create a separate function for the binary loss function, and then save it on the MATLAB® path. Or, you can specify an anonymous binary loss function.

```

customBL = @(M,s)nanmedian(1 - bsxfun(@times,M,s),2)/2;

```

Predict cross-validation labels and estimate the median binary loss per class. Print the median negative binary losses per class for a random set of 10 out-of-fold observations.

```

[label,NegLoss] = kfoldPredict(CVMdl,'BinaryLoss',customBL);

```

```

idx = randsample(numel(label),10);
classOrder
table(Y(idx),label(idx),NegLoss(idx,:), 'VariableNames',...
      {'TrueLabel','PredictedLabel','NegLoss'})

```

```

classOrder =
    setosa

```

```

    versicolor
    virginica

ans =

    TrueLabel      PredictedLabel      NegLoss
    _____      _____      _____
    setosa         versicolor         0.37141      2.1292      -4.0006
    versicolor    versicolor         -1.2167      0.3669      -0.65017
    setosa         versicolor         0.23927      2.08        -3.8193
    virginica     virginica          -1.9154     -0.19947     0.6149
    versicolor    versicolor         -1.3746     0.45535     -0.58076
    setosa         versicolor         0.20061     2.2774      -3.9781
    virginica     versicolor         -1.4928     0.090689    -0.097935
    virginica     virginica          -1.7669     -0.13464     0.4015
    setosa         versicolor         0.19999     1.9113      -3.6113
    setosa         versicolor         0.16108     1.9684      -3.6295

```

The order of the columns corresponds to the elements of `classOrder`. The software predicts the label based on the maximum negated loss. The results seem to indicate that the median of the linear losses might not perform as well as other losses.

Estimate Cross-Validation Posterior Probabilities of ECOC Models

Load Fisher's iris data set. Train the classifier using the petal dimensions as predictors.

```

load fisheriris
X = meas(:,3:4);
Y = categorical(species);
classOrder = unique(Y);
rng(1); % For reproducibility

```

Create an SVM template, and specify the Gaussian kernel. It is good practice to standardize the predictors.

```
t = templateSVM('Standardize',1,'KernelFunction','gaussian');
```

`t` is an SVM template. Most of its properties are empty. When the software trains the ECOC classifier, it sets the applicable properties to their default values.

Train the ECOC classifier using the SVM template, and specify to cross validate. Transform classification scores to class posterior probabilities (returned by

kfoldPredict) using the 'FitPosterior' name-value pair argument. It is good practice to specify the class order.

```
CVMdl = fitcecoc(X,Y,'Learners',t,'CrossVal','on','FitPosterior',true,...
    'ClassNames',classOrder);
```

CVMdl is a ClassificationPartitionedECOC model. By default, the software uses 10-fold cross validation.

Predict the out-of-fold class posterior probabilities. Specify to use 10 random initial values for the Kullback-Leibler algorithm.

```
[label,~,~,Posterior] = kfoldPredict(CVMdl,'NumKLInitializations',10);
```

The software assigns an observation to the class that yields the smallest average binary loss. Since all binary learners are computing posterior probabilities, the binary loss function is quadratic.

Display a random set of results.

```
idx = randsample(size(X,1),10);
CVMdl.ClassNames
table(Y(idx),label(idx),Posterior(idx,:),...
    'VariableNames',{'TrueLabel','PredLabel','Posterior'})
```

ans =

```
setosa
versicolor
virginica
```

ans =

TrueLabel	PredLabel	Posterior		
versicolor	versicolor	0.0086394	0.98243	0.0089291
versicolor	virginica	2.2197e-14	0.12447	0.87553
setosa	setosa	0.999	0.00022837	0.00076884
versicolor	versicolor	2.2194e-14	0.98916	0.010839
virginica	virginica	0.012318	0.012925	0.97476
virginica	virginica	0.0015571	0.0015638	0.99688
virginica	virginica	0.0042895	0.0043556	0.99135

```
setosa      setosa      0.999      0.00028329  0.00071382
virginica   virginica   0.0094719  0.0098229   0.98071
setosa      setosa      0.999      0.00013562  0.00086192
```

The columns of `Posterior` correspond to the class order of `Mdl.ClassNames`.

Estimate Cross-Validation Posterior Probabilities Using Parallel Computing

Train an error-correcting output codes, multiclass model and estimate posterior probabilities using parallel computing.

Load the `arrhythmia` data set.

```
load arrhythmia
Y = categorical(Y);
tabulate(Y)
n = numel(Y);
K = numel(unique(Y));
```

Value	Count	Percent
1	245	54.20%
2	44	9.73%
3	15	3.32%
4	15	3.32%
5	13	2.88%
6	25	5.53%
7	3	0.66%
8	2	0.44%
9	9	1.99%
10	50	11.06%
14	4	0.88%
15	5	1.11%
16	22	4.87%

Several classes are not represented in the data, and many of the other classes have low relative frequencies.

Specify an ensemble learning template that uses the GentleBoost method, and 50 weak, classification tree learners.

```
t = templateEnsemble('GentleBoost',50,'Tree');
```

`t` is a template object. Most of the options are empty (`[]`). The software uses default values for all empty options during training.

Since there are many classes, specify a sparse random coding design.

```
rng(1); % For reproducibility
Coding = designecoc(K, 'sparserandom');
```

Train an ECOC model using parallel computing, and specify to cross validate and fit posterior probabilities (returned by `kfoldPredict`).

```
pool = parpool; % Invokes workers
options = statset('UseParallel',1);
CVMdl = fitcecoc(X,Y, 'Learner',t, 'Options',options, 'Coding',Coding, ...
    'FitPosterior',1, 'CrossVal', 'on');
```

Starting parallel pool (parpool) using the 'local' profile ... connected to 4 workers.
Warning: One or more folds do not contain points from all the groups.

`CVMdl` is a `ClassificationPartitionedECOC` model. By default, the software implements 10-fold cross validation. You can alter the number of folds using the `'KFold'` name-value pair argument.

The pool invokes four workers. The number of workers might vary among systems. Also, there is a good chance that one or more folds do not contain observations from all classes since some classes have low relative frequency.

Estimate posterior probabilities, and display the posterior probability of being classified as not having arrhythmia (class 1) given the data for a random set of out-of-fold observations.

```
[~,~,~,posterior] = kfoldPredict(CVMdl, 'Options',options);
idx = randsample(n,10);
table(idx,Y(idx),posterior(idx,1), ...
    'VariableNames', {'OOFSampleIndex', 'TrueLabel', 'PosteriorNoArrhythmia'})
```

ans =

OOFSampleIndex	TrueLabel	PosteriorNoArrhythmia
171	1	0.33654
221	1	0.85135
72	16	0.9174
3	10	0.025649
202	1	0.8438
243	1	0.94338
18	1	0.81789

49	6	0.090153
234	1	0.61626
315	1	0.97187

- “Quick Start Parallel Computing for Statistics Toolbox” on page 20-2

Algorithms

The software can estimate class posterior probabilities using quadratic programming or by minimizing the Kullback-Leibler divergence. For the following descriptions of the posterior estimation algorithms, let:

- m_{kj} be the element (k,j) of the coding design matrix M .
- I be the indicator function.
- \hat{p}_k be the class posterior probability estimate for class k of an observation, $k = 1, \dots, K$.
- r_j be the positive-class posterior probability for binary learner j . That is, r_j is the probability that binary learner j classifies an observation into the positive class, given the training data.

Posterior Estimation Using Kullback-Leibler Divergence

By default, the software minimizes the Kullback-Leibler divergence to estimate class posterior probabilities. The Kullback-Leibler divergence between the expected and observed positive-class posterior probabilities is

$$\Delta(r, \hat{r}) = \sum_{j=1}^L w_j \left[r_j \log \frac{r_j}{\hat{r}_j} + (1 - r_j) \log \frac{1 - r_j}{1 - \hat{r}_j} \right],$$

where $w_j = \sum_{S_j} w_i^*$ is the weight for binary learner j with S_j the set of observation

indices that binary learner j is trained on and w_i^* is the weight of observation i . The software minimizes the divergence iteratively. The first step is to choose initial values $\hat{p}_k^{(0)}$; $k = 1, \dots, K$ for the class posterior probabilities.

- If you do not specify `NumKLIterations`, then the software uses both sets of deterministic initial values described next, and uses the one that minimizes Δ .

- $\hat{p}_k^{(0)} = 1 / K; k = 1, \dots, K$.
- $\hat{p}_k^{(0)}; k = 1, \dots, K$ is the solution of the system

$$M_{01} \hat{p}^{(0)} = r,$$

where M_{01} is M with all $m_{kj} = -1$ replaced with 0, and r is a vector of positive-class posterior probabilities returned by the L binary learners [2]. The software uses `lsqnonneg` to solve the system.

- If you specify 'NumKLIterations', c , where c is a natural number, then the software does the following to choose $\hat{p}_k^{(0)}; k = 1, \dots, K$, and uses the one that minimizes Δ .
 - The software chooses both sets of deterministic initial values as described previously.
 - The software randomly generates c vectors of length K using `rand`, and then normalizes each vector to sum to 1.

At iteration t , the software:

1 Computes

$$\hat{r}_j^{(t)} = \frac{\sum_{k=1}^K \hat{p}_k^{(t)} I(m_{kj} = +1)}{\sum_{k=1}^K \hat{p}_k^{(t)} I(m_{kj} = +1 \cup m_{kj} = -1)}.$$

2 Estimates the next class posterior probability using

$$\hat{p}_k^{(t+1)} = \hat{p}_k^{(t)} \frac{\sum_{j=1}^L w_j [r_j I(m_{kj} = +1) + (1 - r_j) I(m_{kj} = -1)]}{\sum_{j=1}^L w_j [\hat{r}_j^{(t)} I(m_{kj} = +1) + (1 - \hat{r}_j^{(t)}) I(m_{kj} = -1)]}.$$

- 3 Normalizes $\hat{p}_k^{(t+1)}$; $k = 1, \dots, K$ so that they sum to 1.
- 4 Checks for convergence.

For more details, see [5] and [7].

Posterior Estimation Using Quadratic Programming

Posterior probability estimation using quadratic programming requires an Optimization Toolbox license. To estimate posterior probabilities for an observation using this method, the software:

- 1 Estimates the positive-class posterior probabilities, r_j , for binary learners $j = 1, \dots, L$.
- 2 Using the relationship between r_j and \hat{p}_k [6], minimizes

$$\sum_{j=1}^L \left[-r_j \sum_{k=1}^K \hat{p}_k I(m_{kj} = -1) + (1 - r_j) \sum_{k=1}^K \hat{p}_k I(m_{kj} = +1) \right]^2$$

with respect to \hat{p}_k and the restrictions

$$\begin{aligned} 0 &\leq \hat{p}_k \leq 1 \\ \sum_k \hat{p}_k &= 1. \end{aligned}$$

The software performs minimization using `quadprog`.

kfoldPredict

Class: ClassificationPartitionedModel

Predict response for observations not used for training

Syntax

```
label = kfoldPredict(obj)
[label, score] = kfoldPredict(obj)
[label, score, cost] = kfoldPredict(obj)
```

Description

`label = kfoldPredict(obj)` returns class labels predicted by `obj`, a cross-validated classification. For every fold, `kfoldPredict` predicts class labels for in-fold observations using a model trained on out-of-fold observations.

`[label, score] = kfoldPredict(obj)` returns the predicted classification scores for in-fold observations using a model trained on out-of-fold observations.

`[label, score, cost] = kfoldPredict(obj)` returns misclassification costs.

Input Arguments

obj

Object of class `ClassificationPartitionedModel` or `ClassificationPartitionedEnsemble`.

Output Arguments

label

Vector of class labels of the same type as the response data used in training `obj`. Each entry of `label` corresponds to a predicted class label for the corresponding row of `X`.

score

Numeric matrix of size N-by-K, where N is the number of observations (rows) in `obj.X`, and K is the number of classes (in `obj.ClassNames`). `score(i, j)` represents the confidence that row `i` of `obj.X` is of class `j`. For details, see “Definitions” on page 21-2127.

cost

Numeric matrix of misclassification costs of size N-by-K. `cost(i, j)` is the average misclassification cost of predicting that row `i` of `obj.X` is of class `j`.

Definitions

Cost (discriminant analysis)

The *average misclassification cost* is the mean misclassification cost for predictions made by the cross-validated classifiers trained on out-of-fold observations. The matrix of expected costs per observation is defined in “Cost” on page 15-8.

Score

For discriminant analysis, the *score* of a classification is the posterior probability of the classification. For the definition of posterior probability in discriminant analysis, see “Posterior Probability” on page 15-7.

For ensembles, a classification *score* represents the confidence of a classification into a class. The higher the score, the higher the confidence.

Different ensemble algorithms have different definitions for their scores. Furthermore, the range of scores depends on ensemble type. For example:

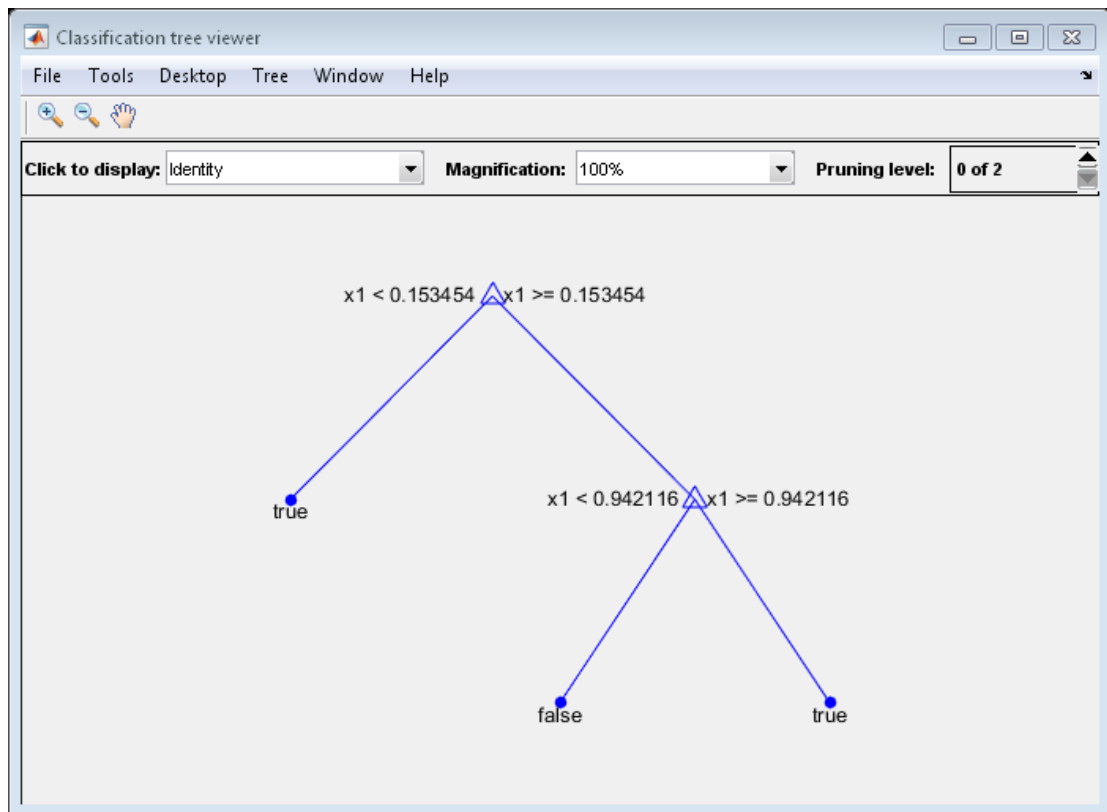

- `AdaBoostM1` scores range from $-\infty$ to ∞ .
- `Bag` scores range from 0 to 1.

For trees, the *score* of a classification of a leaf node is the posterior probability of the classification at that node. The posterior probability of the classification at a node is the number of training sequences that lead to that node with the classification, divided by the number of training sequences that lead to that node.

For example, consider classifying a predictor X as true when $X < 0.15$ or $X > 0.95$, and X is false otherwise.

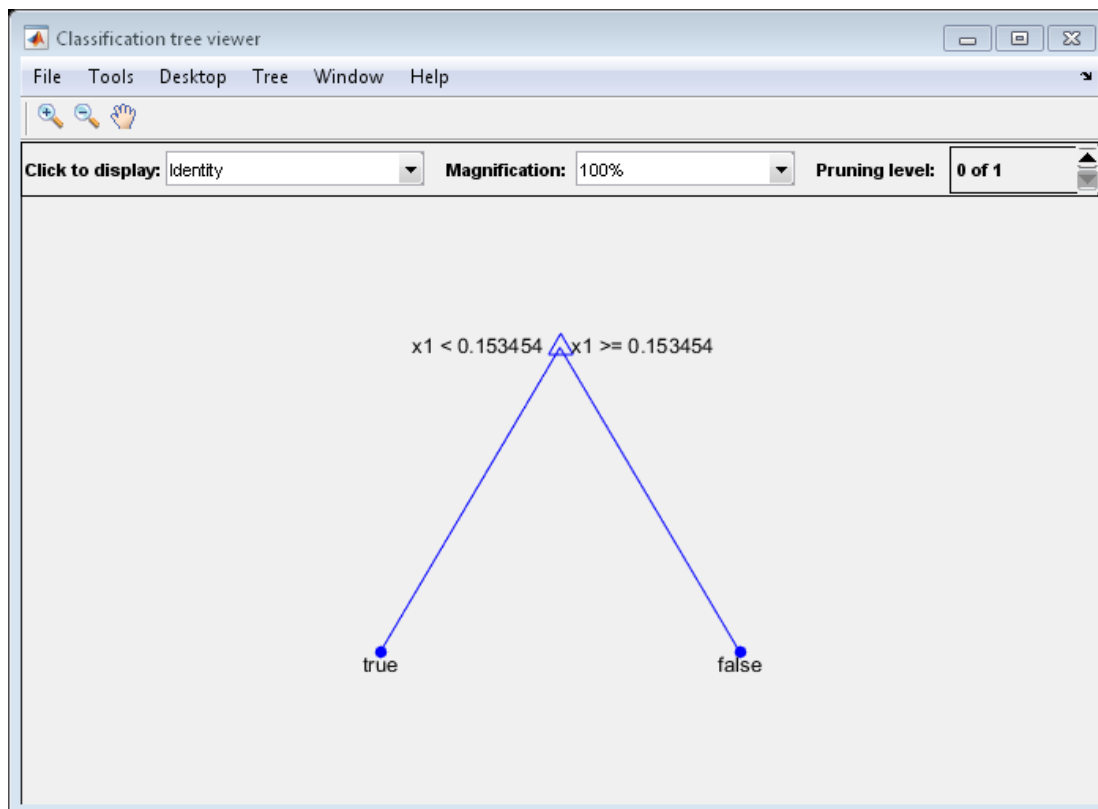

Generate 100 random points and classify them:

```
rng(0,'twister') % for reproducibility
X = rand(100,1);
Y = (abs(X - .55) > .4);
tree = fitctree(X,Y);
view(tree,'Mode','Graph')
```

Prune the tree:

```
tree1 = prune(tree,'Level',1);
view(tree1,'Mode','Graph')
```

The pruned tree correctly classifies observations that are less than 0.15 as **true**. It also correctly classifies observations from .15 to .94 as **false**. However, it incorrectly classifies observations that are greater than .94 as **false**. Therefore, the score for observations that are greater than .15 should be about $.05/.85=.06$ for **true**, and about $.8/.85=.94$ for **false**.

Compute the prediction scores for the first 10 rows of X:

```
[~,score] = predict(tree1,X(1:10));
[score X(1:10,:)]
```

ans =

```
0.9059    0.0941    0.8147
```

```
0.9059    0.0941    0.9058
         0    1.0000    0.1270
0.9059    0.0941    0.9134
0.9059    0.0941    0.6324
         0    1.0000    0.0975
0.9059    0.0941    0.2785
0.9059    0.0941    0.5469
0.9059    0.0941    0.9575
0.9059    0.0941    0.9649
```

Indeed, every value of X (the right-most column) that is less than 0.15 has associated scores (the left and center columns) of 0 and 1, while the other values of X have associated scores of 0.91 and 0.09. The difference (score 0.09 instead of the expected .06) is due to a statistical fluctuation: there are 8 observations in X in the range (.95, 1) instead of the expected 5 observations.

Examples

Estimate Cross-Validation Predictions from an Ensemble

Find the cross-validation predictions for a model based on Fisher's iris data.

Load Fisher's iris data set.

```
load fisheriris
```

Train an ensemble of classification trees.

```
rng(1); % For reproducibility
Mdl = fitensemble(meas,species,'AdaBoostM2',100,'Tree');
```

Cross validate the trained ensemble using 10-fold cross validation.

```
CVMdl = crossval(Mdl);
```

Estimate cross-validation predicted labels and scores.

```
[elabel score] = kfoldPredict(CVMdl);
```

Display the maximum and minimum scores of each class.

```
max(score)
```

```
min(escore)
```

```
ans =
```

```
  9.3862    8.9871   10.1866
```

```
ans =
```

```
  0.0017    3.8359    0.8981
```

kfoldPredict

Class: RegressionPartitionedModel

Predict response for observations not used for training.

Syntax

```
yfit = kfoldPredict(obj)
```

Description

`yfit = kfoldPredict(obj)` returns the predicted values for the responses of the training data based on `obj`, an object trained on out-of-fold observations.

Input Arguments

obj

Object of class `RegressionPartitionedModel`. Create `obj` with `fitrtree` or `fitensemb` along with one of the cross-validation options: `'crossval'`, `'kfold'`, `'holdout'`, `'leaveout'`, or `'cvpartition'`. Alternatively, create `obj` from a regression tree or regression ensemble with `crossval`.

Output Arguments

yfit

A vector of predicted values for the response data based on a model trained on out-of-fold observations.

Examples

Construct a partitioned regression model, and examine the cross-validation loss. The cross-validation loss is the mean squared error between `yfit` and the true response data:

```
load carsmall
XX = [Cylinders Displacement Horsepower Weight];
YY = MPG;
tree = fitrtree(XX,YY);
cvmodel = crossval(tree);
L = kfoldLoss(cvmodel)
```

```
L =
    26.5271
```

```
yfit = kfoldPredict(cvmodel);
mean( (yfit - tree.Y).^2 )
```

```
ans =
    26.5271
```

[kfoldLoss](#) | [fitrtree](#)

kmeans

k-means clustering

Syntax

```
idx = kmeans(X,k)
idx = kmeans(X,k,Name,Value)
[idx,C] = kmeans( ___ )
[idx,C,sumd] = kmeans( ___ )
[idx,C,sumd,D] = kmeans( ___ )
```

Description

`idx = kmeans(X,k)` performs *k*-means clustering to partition the observations of the *n*-by-*p* data matrix *X* into *k* clusters, and returns an *n*-by-1 vector (**idx**) containing cluster indices of each observation. Rows of *X* correspond to points and columns correspond to variables.

By default, `kmeans` uses the squared Euclidean distance measure and the *k*-means++ algorithm for cluster center initialization.

`idx = kmeans(X,k,Name,Value)` returns the cluster indices with additional options specified by one or more **Name,Value** pair arguments.

For example, specify the cosine distance, the number of times to repeat the clustering using new initial values, or to use parallel computing.

`[idx,C] = kmeans(___)` returns the *k* cluster centroid locations in the *k*-by-*p* matrix **C**.

`[idx,C,sumd] = kmeans(___)` returns the within-cluster sums of point-to-centroid distances in the *k*-by-1 vector **sumd**.

`[idx,C,sumd,D] = kmeans(___)` returns distances from each point to every centroid in the *n*-by-*k* matrix **D**.

Examples

Train a *k*-Means Clustering Algorithm

Cluster data using *k*-means clustering, then plot the cluster regions.

Load Fisher's iris data set. Use the petal lengths and widths as predictors.

```
load fisheriris
X = meas(:,3:4);

figure;
plot(X(:,1),X(:,2),'k*','MarkerSize',5);
title 'Fisher''s Iris Data';
xlabel 'Petal Lengths (cm)';
ylabel 'Petal Widths (cm)';
```

The larger cluster seems to be split into a lower variance region and a higher variance region. This might indicate that the larger cluster is two, overlapping clusters.

Cluster the data. Specify $k = 3$ clusters.

```
rng(1); % For reproducibility
[idx,C] = kmeans(X,3);
```

`kmeans` uses the k -means++ algorithm for centroid initialization and squared Euclidean distance by default. It is good practice to search for lower, local minima by setting the 'Replicates' name-value pair argument.

`idx` is a vector of predicted cluster indices corresponding to the observations in `X`. `C` is a 3-by-2 matrix containing the final centroid locations.

Use `kmeans` to compute the distance from each centroid to points on a grid. To do this, pass the centroids (`C`) and points on a grid to `kmeans`, and implement one iteration of the algorithm.

```
x1 = min(X(:,1)):0.01:max(X(:,1));
x2 = min(X(:,2)):0.01:max(X(:,2));
[x1G,x2G] = meshgrid(x1,x2);
XGrid = [x1G(:),x2G(:)]; % Defines a fine grid on the plot

idx2Region = kmeans(XGrid,3,'MaxIter',1,'Start',C);...
    % Assigns each node in the grid to the closest centroid
```

Warning: Failed to converge in 1 iterations.

`kmeans` displays a warning stating that the algorithm did not converge, which you should expect since the software only implemented one iteration.

Plot the cluster regions.

```
figure;
gscatter(XGrid(:,1),XGrid(:,2),idx2Region,...
    [0,0.75,0.75;0.75,0,0.75;0.75,0.75,0],'..');
hold on;
plot(X(:,1),X(:,2),'k*','MarkerSize',5);
title 'Fisher''s Iris Data';
xlabel 'Petal Lengths (cm)';
ylabel 'Petal Widths (cm)';
legend('Region 1','Region 2','Region 3','Data','Location','Best');
hold off;
```

Partition Data into Two Clusters

Randomly generate the sample data.

```
rng default; % For reproducibility
X = [randn(100,2)*0.75+ones(100,2);
     randn(100,2)*0.5-ones(100,2)];
```

```
figure;
plot(X(:,1),X(:,2),'*');
title 'Randomly Generated Data';
```

There appears to be two clusters in the data.

Partition the data into two clusters, and choose the best arrangement out of five initializations. Display the final output.

```
opts = statset('Display','final');  
[idx,C] = kmeans(X,2,'Distance','cityblock',...  
    'Replicates',5,'Options',opts);
```

```
Replicate 1, 4 iterations, total sum of distances = 201.533.  
Replicate 2, 6 iterations, total sum of distances = 201.533.  
Replicate 3, 4 iterations, total sum of distances = 201.533.  
Replicate 4, 4 iterations, total sum of distances = 201.533.  
Replicate 5, 3 iterations, total sum of distances = 201.533.  
Best total sum of distances = 201.533
```

By default, the software initializes the replicates separately using k -means++.

Plot the clusters and the cluster centroids.

```
figure;  
plot(X(idx==1,1),X(idx==1,2),'r.','MarkerSize',12)  
hold on  
plot(X(idx==2,1),X(idx==2,2),'b.','MarkerSize',12)  
plot(C(:,1),C(:,2),'kx',...  
      'MarkerSize',15,'LineWidth',3)  
legend('Cluster 1','Cluster 2','Centroids',...  
      'Location','NW')  
title 'Cluster Assignments and Centroids'  
hold off
```

You can determine how well separated the clusters are by passing `idx` to “silhouette”.

Cluster Data Using Parallel Computing

Clustering large data sets might take time, particularly if you use online updates (set by default). If you have a Parallel Computing Toolbox license and you invoke a pool of workers, then `kmeans` runs each clustering task (or replicate) in parallel. Therefore, if `Replicates > 1`, then the parallel computing decreases time to convergence.

Randomly generate a large data set from a Gaussian mixture model.

```
Mu = bsxfun(@times,ones(20,30),(1:20)'); % Gaussian mixture mean
rn30 = randn(30,30);
Sigma = rn30'*rn30; % Symmetric and positive-definite covariance
Mdl = gmdistribution(Mu,Sigma);

rng(1); % For reproducibility
X = random(Mdl,10000);
```

`Mdl` is a 30-dimensional `gmdistribution` model with 20 components. `X` is a 10000-by-30 matrix of data generated from `Mdl`.

Invoke a parallel pool of workers. Specify options for parallel computing.

```
pool = parpool; % Invokes workers
stream = RandStream('mlfg6331_64'); % Random number stream
options = statset('UseParallel',1,'UseSubstreams',1,...
    'Streams',stream);
```

Starting parallel pool (`parpool`) using the 'local' profile ... connected to 2 workers.

The input argument `'mlfg6331_64'` of `RandStream` specifies to use the multiplicative lagged Fibonacci generator algorithm. `options` is a structure array containing fields that specify options for controlling estimation.

The Command Window indicates that two workers are available. The number of workers might vary on your system.

Cluster the data using k -means clustering. Specify that there are $k = 20$ clusters in the data and increase the number of iterations. Typically, the objective function contains local minima. Specify 10 replicates to help find a lower, local minimum.

```
tic; % Start stopwatch timer
[idx,C,sumd,D] = kmeans(X,20,'Options',options,'MaxIter',10000,...
    'Display','final','Replicates',10);
```

```
toc % Terminate stopwatch timer
```

```
Replicate 4, 121 iterations, total sum of distances = 7.58059e+06.  
Replicate 7, 234 iterations, total sum of distances = 7.5904e+06.  
Replicate 3, 146 iterations, total sum of distances = 7.59086e+06.  
Replicate 2, 179 iterations, total sum of distances = 7.57758e+06.  
Replicate 6, 118 iterations, total sum of distances = 7.58614e+06.  
Replicate 5, 88 iterations, total sum of distances = 7.59462e+06.  
Replicate 1, 99 iterations, total sum of distances = 7.57765e+06.  
Replicate 9, 147 iterations, total sum of distances = 7.57639e+06.  
Replicate 10, 107 iterations, total sum of distances = 7.60079e+06.  
Replicate 8, 144 iterations, total sum of distances = 7.58117e+06.  
Best total sum of distances = 7.57639e+06  
Elapsed time is 123.857736 seconds.
```

The Command Window displays the number of iterations and the terminal objective function value for each replicate. The output arguments contain the results of replicate 9 because it has the lowest total sum of distances.

- “Create Clusters and Determine Separation” on page 14-22
- “Determine the Correct Number of Clusters” on page 14-24
- “Avoid Local Minima” on page 14-27

Input Arguments

X — Data

numeric matrix

Data, specified as a numeric matrix. The rows of *X* correspond to observations, and the columns correspond to variables.

If *X* is a numeric vector, then `kmeans` treats it as an *n*-by-1 data matrix, regardless of its orientation.

Data Types: `single` | `double`

k — Number of clusters

positive integer

Number of clusters in the data, specified as a positive integer.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example:

```
'Distance', 'cosine', 'Replicates', 10, 'Options', statset('UseParallel', 1)
```

specifies the cosine distance, 10 replicate clusters at different starting values, and to use parallel computing.

'Display' — Level of output to display

'off' (default) | 'final' | 'iter'

Level of output to display in the Command Window, specified as the comma-separated pair consisting of 'Display' and a string. Available options are:

- 'final' — Displays results of the final iteration
- 'iter' — Displays results of each iteration
- 'off' — Displays nothing

Example: 'Display', 'final'

Data Types: char

'Distance' — Distance measure

'sqeuclidean' (default) | 'cityblock' | 'cosine' | 'correlation' | 'hamming'

Distance measure, in p -dimensional space, used for minimization, specified as the comma-separated pair consisting of 'Distance' and a string.

kmeans computes centroid clusters differently for the different, supported distance measures. This table summarizes the available distance measures. In the formulae, x is an observation (that is, a row of X) and c is a centroid (a row vector).

Distance Measure	Description	Formula
'sqeuclidean'	Squared Euclidean distance (default). Each centroid is the mean of the points in that cluster.	$d(x, c) = (x - c)(x - c)'$

Distance Measure	Description	Formula
'cityblock'	Sum of absolute differences, i.e., the L_1 distance. Each centroid is the component-wise median of the points in that cluster.	$d(x, c) = \sum_{j=1}^p x_j - c_j $
'cosine'	One minus the cosine of the included angle between points (treated as vectors). Each centroid is the mean of the points in that cluster, after normalizing those points to unit Euclidean length.	$d(x, c) = 1 - \frac{xc'}{\sqrt{(xx')(cc')}}$
'correlation'	One minus the sample correlation between points (treated as sequences of values). Each centroid is the component-wise mean of the points in that cluster, after centering and normalizing those points to zero mean and unit standard deviation.	$d(x, c) = 1 - \frac{(x - \bar{x})(c - \bar{c})'}{\sqrt{(x - \bar{x})(x - \bar{x})'} \sqrt{(c - \bar{c})(c - \bar{c})'}}$ <p>where</p> <ul style="list-style-type: none"> • $\bar{x} = \frac{1}{p} \left(\sum_{j=1}^p x_j \right) \bar{1}_p$ • $\bar{c} = \frac{1}{p} \left(\sum_{j=1}^p c_j \right) \bar{1}_p$ • $\bar{1}_p$ is a row vector of p ones.
'hamming'	This measure is only suitable for binary data. It is the proportion of bits that differ. Each centroid is the component-wise median of points in that cluster.	$d(x, y) = \frac{1}{p} \sum_{j=1}^p I\{x_j \neq y_j\},$ <p>where I is the indicator function.</p>

Example: 'Distance', 'cityblock'

Data Types: char

'EmptyAction' — Action to take if cluster loses all member observations

'singleton' (default) | 'error' | 'drop'

Action to take if a cluster loses all its member observations, specified as the comma-separated pair consisting of 'EmptyAction' and a string. This table summarizes the available options.

Value	Description
'error'	Treat an empty cluster as an error.
'drop'	Remove any clusters that become empty. <code>kmeans</code> sets the corresponding return values in C and D to NaN.
'singleton'	Create a new cluster consisting of the one point furthest from its centroid (default).

Example: 'EmptyAction', 'error'

Data Types: char

'MaxIter' — Maximum number of iterations

100 (default) | positive integer

Maximum number of iterations, specified as the comma-separated pair consisting of 'MaxIter' and a positive integer.

Example: 'MaxIter', 1000

Data Types: double | single

'OnlinePhase' — Online update flag

'on' (default) | 'off'

Online update flag, specified as the comma-separated pair consisting of 'OnlinePhase' and 'on' or 'off'.

If `OnlinePhase` is on (the default), then `kmeans` performs an online update phase in addition to a batch update phase. The online phase can be time consuming for large data

sets, but guarantees a solution that is a local minimum of the distance criterion. In other words, the software finds a partition of the data in which moving any single point to a different cluster increases the total sum of distances.

Example: 'OnlinePhase', 'off'

Data Types: char

'Options' — Options for controlling iterative algorithm for minimizing fitting criteria

[] (default) | structure array returned by `statset`

Options for controlling the iterative algorithm for minimizing the fitting criteria, specified as the comma-separated pair consisting of 'Options' and a structure array returned by `statset`. These options require Parallel Computing Toolbox.

This table summarizes the available options.

Option	Description
'Streams'	<p>A <code>RandStream</code> object or cell array of such objects. If you do not specify <code>Streams</code>, <code>kmeans</code> uses the default stream or streams. If you specify <code>Streams</code>, use a single object except when:</p> <ul style="list-style-type: none"> • You have an open parallel pool • <code>UseParallel</code> is <code>true</code>. • <code>UseSubstreams</code> is <code>false</code>. <p>In that case, use a cell array the same size as the parallel pool. If a parallel pool is not open, then <code>Streams</code> must supply a single random number stream.</p>
'UseParallel'	<ul style="list-style-type: none"> • If <code>true</code>, <code>Replicates</code> > 1, and if a parallel pool of workers from the Parallel Computing Toolbox is open, then the software implements k-means on each replicate in parallel. • If the Parallel Computing Toolbox is not installed, or a parallel pool of workers is not open, computation occurs in serial

Option	Description
	mode. Default is <code>default</code> , meaning serial computation.
<code>'UseSubstreams'</code>	Set to <code>true</code> to compute in parallel in a reproducible fashion. Default is <code>false</code> . To compute reproducibly, set <code>Streams</code> to a type allowing substreams: <code>'mlfg6331_64'</code> or <code>'mrg32k3a'</code> .

To ensure more predictable results, use `parpool` and explicitly create a parallel pool before invoking `kmeans` and setting `'Options',statset('UseParallel',1)`.

Example: `'Options',statset('UseParallel',1)`

Data Types: `struct`

'Replicates' — Number of times to repeat clustering using new initial cluster centroid positions

1 (default) | positive integer

Number of times to repeat clustering using new initial cluster centroid positions, specified as the comma-separated pair consisting of `'Replicates'` and an integer. `kmeans` returns the solution with the lowest `sumd`.

You can set `'Replicates'` implicitly by supplying a 3-D array as the value for the `'Start'` name-value pair argument.

Example: `'Replicates',5`

Data Types: `double` | `single`

'Start' — Method for choosing initial cluster centroid positions

`'plus'` (default) | `'cluster'` | `'sample'` | `'uniform'` | numeric matrix | numeric array

Method for choosing initial cluster centroid positions (or *seeds*), specified as the comma-separated pair consisting of `'Start'` and a string, a numeric matrix, or a numeric array. This table summarizes the available options for choosing seeds.

Value	Description
<code>'cluster'</code>	Perform a preliminary clustering phase on a random 10% subsample of <code>X</code> . This

Value	Description
	preliminary phase is itself initialized using 'sample'.
'plus' (default)	Select k seeds by implementing the <i>k</i> -means++ algorithm for cluster center initialization.
'sample'	Select k observations from <i>X</i> at random.
'uniform'	Select k points uniformly at random from the range of <i>X</i> . Not valid with the Hamming distance.
numeric matrix	<i>k</i> -by- <i>p</i> matrix of centroid starting locations. The rows of <code>Start</code> correspond to seeds. The software infers <i>k</i> from the first dimension of <code>Start</code> , so you can pass in <code>[]</code> for <i>k</i> .
numeric array	<i>k</i> -by- <i>p</i> - <i>r</i> array of centroid starting locations. The rows of each page correspond to seeds. The third dimension invokes replication of the clustering routine. Page <i>j</i> contains the set of seeds for replicate <i>j</i> . The software infers the number of replicates (specified by the 'Replicates' name-value pair argument) from the size of the third dimension.

Example: 'Start', 'sample'

Data Types: char | double | single

Note: The software treats NaNs as missing data, and removes any row of *X* containing at least one NaN. Removing rows of *X* reduces the sample size.

Output Arguments

idx — Cluster indices

numeric column vector

Cluster indices, returned as a numeric column vector. `idx` has as many rows as `X`, and each row indicates the cluster assignment of the corresponding observation.

C — Cluster centroid locations

numeric matrix

Cluster centroid locations, returned as a numeric matrix. `C` is a k -by- p matrix, where row j is the centroid of cluster j .

sumd — Within-cluster sums of point-to-centroid distances

numeric column vector

Within-cluster sums of point-to-centroid distances, returned as a numeric column vector. `sumd` is a k -by-1 vector, where element j is the sum of point-to-centroid distances within cluster j .

D — Distances from each point to every centroid

numeric matrix

Distances from each point to every centroid, returned as a numeric matrix. `D` is an n -by- k matrix, where element (j,m) is the distance from observation j to centroid m .

More About

***k*-Means Clustering**

k-means clustering, or Lloyd's algorithm [2], is an iterative, data-partitioning algorithm that assigns n observations to exactly one of k clusters defined by centroids, where k is chosen before the algorithm starts.

The algorithm proceeds as follows:

- 1 Choose k initial cluster centers (*centroid*). For example, choose k observations at random (by using `'Start'`, `'sample'`) or use the *k*-means ++ algorithm for cluster center initialization (the default).
- 2 Compute point-to-cluster-centroid distances of all observations to each centroid.
- 3 There are two ways to proceed (specified by `OnlinePhase`):
 - Batch update — Assign each observation to the cluster with the closest centroid.

- Online update — Individually assign observations to a different centroid if the reassignment decreases the sum of the within-cluster, sum-of-squares point-to-cluster-centroid distances.

For more details, see “Algorithms” on page 21-2151.

- 4 Compute the average of the observations in each cluster to obtain k new centroid locations.
- 5 Repeat steps 2 through 4 until cluster assignments do not change, or the maximum number of iterations is reached.

***k*-means++ Algorithm**

The *k*-means++ algorithm uses an heuristic to find centroid seeds for *k*-means clustering. According to Arthur and Vassilvitskii [1], *k*-means++ improves the running time of Lloyd’s algorithm, and the quality of the final solution.

The *k*-means++ algorithm chooses seeds as follows, assuming the number of clusters is k .

- 1 Select an observation uniformly at random from the data set, X . The chosen observation is the first centroid, and is denoted c_1 .
- 2 Compute distances from each observation to c_1 . Denote the distance observation m is from c_j $d(x_m, c_j)$.
- 3 Select the next centroid, c_2 at random from X with probability

$$\frac{d^2(x_m, c_1)}{\sum_{j=1}^n d^2(x_j, c_1)}$$

- 4 To choose center j :
 - a Compute the distances from each observation to each centroid, and assign each observation to its closest centroid.
 - b For $m = 1, \dots, n$ and $p = 1, \dots, j - 1$, select centroid j at random from X with probability

$$\frac{d^2(x_m, c_p)}{\sum_{\{h; x_h \in C_p\}} d^2(x_h, c_p)},$$

where C_p is the set of all observations closest to centroid c_p and x_m belongs to C_p .

That is, select each subsequent center with a probability proportional to the distance from itself to the closest center that you already chose.

- 5 Repeat step 4 until k centroids are chosen.

Arthur and Vassilvitskii [1] demonstrate, using a simulation study for several cluster orientations, that k -means++ achieves faster convergence to a lower sum of within-cluster, sum-of-squares point-to-cluster-centroid distances than Lloyd's algorithm.

Algorithms

- `kmeans` uses a two-phase iterative algorithm to minimize the sum of point-to-centroid distances, summed over all k clusters.
 - 1 This first phase uses *batch updates*, where each iteration consists of reassigning points to their nearest cluster centroid, all at once, followed by recalculation of cluster centroids. This phase occasionally does not converge to solution that is a local minimum. That is, a partition of the data where moving any single point to a different cluster increases the total sum of distances. This is more likely for small data sets. The batch phase is fast, but potentially only approximates a solution as a starting point for the second phase.
 - 2 This second phase uses *online updates*, where points are individually reassigned if doing so reduces the sum of distances, and cluster centroids are recomputed after each reassignment. Each iteration during this phase consists of one pass through all the points. This phase converges to a local minimum, although there might be other local minima with lower total sum of distances. In general, finding the global minimum is solved by an exhaustive choice of starting points, but using several replicates with random starting points typically results in a solution that is a global minimum.
- If `Replicates = $r > 1$` and `Start` is `plus` (the default), then the software selects r possibly different sets of seeds according to the k -means++ algorithm.

- If you enable the `UseParallel` option in `Options` and `Replicates > 1`, then each worker selects seeds and clusters in parallel.
- “Introduction to *k*-Means Clustering” on page 14-21

kmedoids

k-medoids clustering

Syntax

```
[idx,C] = kmedoids( ___ )
[idx,C,sumd] = kmedoids( ___ )
[idx,C,sumd,D] = kmedoids( ___ )
[idx,C,sumd,D,midx] = kmedoids( ___ )
[idx,C,sumd,D,midx,info] = kmedoids( ___ )
```

Description

`idx = kmedoids(X,k)` performs “*k*-medoids Clustering” on page 21-2168 to partition the observations of the *n*-by-*p* matrix *X* into *k* clusters, and returns an *n*-by-1 vector *idx* containing cluster indices of each observation. Rows of *X* correspond to points and columns correspond to variables. By default, `kmedoids` uses squared Euclidean distance measure and the *k*-means++ algorithm for choosing initial cluster medoid positions.

`idx = kmedoids(X,k,Name,Value)` uses additional options specified by one or more *Name,Value* pair arguments.

`[idx,C] = kmedoids(___)` returns the *k* cluster medoid locations in the *k*-by-*p* matrix *C*.

`[idx,C,sumd] = kmedoids(___)` returns the within-cluster sums of point-to-medoid distances in the *k*-by-1 vector *sumd*.

`[idx,C,sumd,D] = kmedoids(___)` returns distances from each point to every medoid in the *n*-by-*k* matrix *D*.

`[idx,C,sumd,D,midx] = kmedoids(___)` returns the indices *midx* such that *C* = *X*(*midx*,:). *midx* is a *k*-by-1 vector.

`[idx,C,sumd,D,midx,info] = kmedoids(___)` returns a structure *info* with information about the options used by the algorithm when executed.

Examples

Group Data into Two Clusters

Randomly generate data.

```
rng('default'); % For reproducibility
X = [randn(100,2)*0.75+ones(100,2);
     randn(100,2)*0.55-ones(100,2)];
figure;
plot(X(:,1),X(:,2),'.');
title('Randomly Generated Data');
```

Group data into two clusters using `kmedoids`. Use the `cityblock` distance measure.

```
opts = statset('Display','iter');
[idx,C,sumd,d,midx,info] = kmedoids(X,2,'Distance','cityblock','Options',opts);
```

```
    rep    iter      sum
     1      1    209.856
     1      2    209.856
```

```
Best total sum of distances = 209.856
```

`info` is a struct that contains information about how the algorithm was executed. For example, `bestReplicate` field indicates the replicate that was used to produce the final solution. In this example, the replicate number 1 was used since the default number of replicates is 1 for the default algorithm, which is `pam` in this case.

```
info
```

```
info =
```

```
    algorithm: 'pam'
         start: 'plus'
         distance: 'cityblock'
    iterations: 2
    bestReplicate: 1
```

Plot the clusters and the cluster medoids.

```
figure;
plot(X(idx==1,1),X(idx==1,2),'r.','MarkerSize',7)
hold on
plot(X(idx==2,1),X(idx==2,2),'b.','MarkerSize',7)
plot(C(:,1),C(:,2),'co',...
     'MarkerSize',7,'LineWidth',1.5)
legend('Cluster 1','Cluster 2','Medoids',...
     'Location','NW');
title('Cluster Assignments and Medoids');
hold off
```

Cluster Categorical Data Using k -Medoids

This example uses "Mushroom" data set [3][4][5] [6][7] from the UCI machine learning archive [7], described in <http://archive.ics.uci.edu/ml/datasets/Mushroom>. The data set includes 22 predictors for 8,124 observations of various mushrooms. The predictors are categorical data types. For example, cap shape is categorized with features of 'b' for bell-shaped cap and 'c' for conical. Mushroom color is also categorized with features of 'n' for brown, and 'p' for pink. The data set also includes a classification for each mushroom of either edible or poisonous.

Since the features of the mushroom data set are categorical, it is not possible to define the mean of several data points, and therefore the widely-used k -means clustering algorithm cannot be meaningfully applied to this data set. k -medoids is a related

algorithm that partitions data into k distinct clusters, by finding medoids that minimize the sum of dissimilarities between points in the data and their nearest medoid.

The medoid of a set is a member of that set whose average dissimilarity with the other members of the set is the smallest. Similarity can be defined for many types of data that do not allow a mean to be calculated, allowing k -medoids to be used for a broader range of problems than k -means.

Using k -medoids, this example clusters the mushrooms into two groups, based on the predictors provided. It then explores the relationship between those clusters and the classifications of the mushrooms as either edible or poisonous.

This example assumes that you have downloaded the "Mushroom" data set [3][4][5][6][7] from the UCI database (<http://archive.ics.uci.edu/ml/machine-learning-databases/mushroom/>) and saved it in your current directory as a text file named `agaricus-lepiota.txt`. There is no column headers in the data, so `readtable` uses the default variable names.

```
clear all
data = readtable('agaricus-lepiota.txt', 'ReadVariableNames', false);
```

Display the first 5 mushrooms with their first few features.

```
data(1:5, 1:10)
```

```
ans =
```

Var1	Var2	Var3	Var4	Var5	Var6	Var7	Var8	Var9	Var10
'p'	'x'	's'	'n'	't'	'p'	'f'	'c'	'n'	'k'
'e'	'x'	's'	'y'	't'	'a'	'f'	'c'	'b'	'k'
'e'	'b'	's'	'w'	't'	'l'	'f'	'c'	'b'	'n'
'p'	'x'	'y'	'w'	't'	'p'	'f'	'c'	'n'	'n'
'e'	'x'	's'	'g'	'f'	'n'	'f'	'w'	'b'	'k'

Extract the first column, labeled data for edible and poisonous groups. Then delete the column.

```
labels = data(:, 1);
labels = categorical(labels{:, :});
data(:, 1) = [];
```

Store the names of predictors (features), which are described in <http://archive.ics.uci.edu/ml/machine-learning-databases/mushroom/agaricus-lepiota.names>.

```
VarNames = {'cap_shape' 'cap_surface' 'cap_color' 'bruises' 'odor' ...  
           'gill_attachment' 'gill_spacing' 'gill_size' 'gill_color' ...  
           'stalk_shape' 'stalk_root' 'stalk_surface_above_ring' ...  
           'stalk_surface_below_ring' 'stalk_color_above_ring' ...  
           'stalk_color_below_ring' 'veil_type' 'veil_color' 'ring_number' ....  
           'ring_type' 'spore_print_color' 'population' 'habitat'};
```

Set the variable names.

```
data.Properties.VariableNames = VarNames;
```

There are a total of 2480 missing values denoted as '?'.
sum(char(data{:, :}) == '?')

```
ans =
```

```
2480
```

Based on the inspection of the data set and its description, the missing values belong only to the 11th variable (`stalk_root`). Remove the column from the table.

```
data(:,11) = [];
```

`kmedoids` only accepts numeric data. You need to cast the categories you have into numeric type. The distance function you will use to define the dissimilarity of the data will be based on the double representation of the categorical data.

```
cats = categorical(data{:, :});  
data = double(cats);
```

`kmedoids` can use any distance metric supported by `pdist2` to cluster. For this example you will cluster the data using the Hamming distance because this is an appropriate distance metric for categorical data as illustrated below. The Hamming distance between two vectors is the percentage of the vector components that differ. For instance, consider these two vectors.

```
v1 = [1 0 2 1];
```

```
v2 = [1 1 2 1];
```

They are equal in the 1st, 3rd and 4th coordinate. Since 1 of the 4 coordinates differ, the Hamming distance between these two vectors is .25.

You can use the function `pdist2` to measure the Hamming distance between the first and second row of data, the numerical representation of the categorical mushroom data. The value `.2857` means that 6 of the 21 features of the mushroom differ.

```
pdist2(data(1,:),data(2:,:), 'hamming')
```

```
ans =
```

```
0.2857
```

In this example, you're clustering the mushroom data into two clusters based on features to see if the clustering corresponds to edibility. The `kmedoids` function is guaranteed to converge to a local minima of the clustering criterion; however, this may not be a global minimum for the problem. It is a good idea to cluster the problem a few times using the `'replicates'` parameter. When `'replicates'` is set to a value, n , greater than 1, the `k-medoids` algorithm is run n times, and the best result is returned.

To run `kmedoids` to cluster data into 2 clusters, based on the Hamming distance and to return the best result of 3 replicates, you run the following.

```
rng('default'); %For reproducibility
[IDX, C, SUMD, D, MIDX, INFO] = kmedoids(data,2,'distance','hamming','replicates',3);
```

Let's assume that mushrooms in the predicted group 1 are poisonous and group 2 are all edible. To determine the performance of clustering results, calculate how many mushrooms in group 1 are indeed poisonous and group 2 are edible based on the known labels. In other words, calculate the number of false positives, false negatives, as well as true positives and true negatives.

Construct a confusion matrix (or matching matrix), where the diagonal elements represent the number of true positives and true negatives, respectively. The off-diagonal elements represent false negatives and false positives, respectively. For convenience, use the `confusionmat` function, which calculates a confusion matrix given known labels and predicted labels. Get the predicted label information from the `IDX` variable. `IDX` contains values of 1 and 2 for each data point, representing poisonous and edible groups, respectively.

```
predLabels = labels; %Initialize a vector for predicted labels.
predLabels(IDX==1) = categorical({'p'}); %Assign group 1 to be poisonous.
predLabels(IDX==2) = categorical({'e'}); %Assign group 2 to be edible.
confMatrix = confusionmat(labels,predLabels)
```

```
confMatrix =
```

```
      4176      32
      816     3100
```

Out of 4208 edible mushrooms, 4176 were correctly predicted to be in group 2 (edible group), and 32 were incorrectly predicted to be in group 1 (poisonous group). Similarly, out of 3916 poisonous mushrooms, 3100 were correctly predicted to be in group 1 (poisonous group), and 816 were incorrectly predicted to be in group 2 (edible group).

Given this confusion matrix, calculate the accuracy, which is the proportion of true results (both true positives and true negatives) against the overall data, and precision, which is the proportion of the true positives against all the positive results (true positives and false positives).

```
accuracy = (confMatrix(1,1)+confMatrix(2,2))/(sum(sum(confMatrix)))
```

```
accuracy =
```

```
0.8956
```

```
precision = confMatrix(1,1) / (confMatrix(1,1)+confMatrix(2,1))
```

```
precision =
```

```
0.8365
```

The results indicated that applying the k-medoids algorithm to the categorical features of mushrooms resulted in clusters that were associated with edibility.

Input Arguments

X — Data

numeric matrix

Data, specified as a numeric matrix. The rows of X correspond to observations, and the columns correspond to variables.

k — Number of medoids

positive integer

Number of medoids in the data, specified as a positive integer.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Example:

```
'Distance','euclidean','Replicates',3,'Options',statset('UseParallel',1)
```

specifies Euclidean distance, three replicate medoids at different starting values, and to use parallel computing.

'Algorithm' — Algorithm to find medoids

```
'pam' | 'small' | 'clara' | 'large'
```

Algorithm to find medoids, specified as the comma-separated pair consisting of 'Algorithm' and a string. The default algorithm depends on the number of rows of X.

- If the number of rows of X is less than 3000, 'pam' is the default algorithm.
- If the number of rows is between 3000 and 10000, 'small' is the default algorithm.
- For all other cases, 'large' is the default algorithm.

You can override the default choice by explicitly stating the algorithm. This table summarizes the available algorithms.

Algorithm	Description
'pam'	<p>Partitioning Around Medoids (PAM) is the classical algorithm for solving the k-medoids problem described in [1]. After applying the initialization function to select initial medoid positions, the program performs the swap-step of the PAM algorithm, that is, it searches over all possible swaps between medoids and non-medoids to see if the sum of medoid to cluster member distances goes down. You can specify which initialization function to use via the 'Start' name-value pair argument.</p> <p>The algorithm proceeds as follows.</p> <ol style="list-style-type: none"> 1 Build-step: Each of k clusters is associated with a potential medoid. This assignment is performed using a technique specified by the 'Start' name-value pair argument.

Algorithm	Description
	<p>2 Swap-step: Within each cluster, each point is tested as a potential medoid by checking if the sum of within-cluster distances gets smaller using that point as the medoid. If so, the point is defined as a new medoid. Every point is then assigned to the cluster with the closest medoid.</p> <p>The algorithm iterates the build- and swap-steps until the medoids do not change, or other termination criteria are met.</p> <p>The algorithm can produce better solutions than the other algorithms in some situations, but it can be prohibitively long running.</p>
'small'	<p>Use an algorithm similar to the k-means algorithm to find k medoids. This option employs a variant of the Lloyd's iterations based on [2].</p> <p>The algorithm proceeds as follows.</p> <ol style="list-style-type: none"> 1 For each point in each cluster, calculate the sum of distances from the point to every other point in the cluster. Choose the point that minimizes the sum as the new medoid. 2 Update the cluster membership for each data point to reflect the new medoid. <p>The algorithm repeats these steps until no further updates occur or other termination criteria are met. The algorithm has an optional PAM-like online update phase (specified by the 'OnlinePhase' name-value pair argument) that improves cluster quality. It tends to return higher quality solutions than the clara or large algorithms, but it may not be the best choice for very large data.</p>

Algorithm	Description
'clara'	<p>Clustering LARge Applications (CLARA) [1] repeatedly performs the PAM algorithm on random subsets of the data. It aims to overcome scaling challenges posed by the PAM algorithm through sampling.</p> <p>The algorithm proceeds as follows.</p> <ol style="list-style-type: none"> 1 Select a subset of the data and apply the PAM algorithm to the subset. 2 Assign points of the full data set to clusters by picking the closest medoid. <p>The algorithm repeats these steps until the medoids do not change, or other termination criteria are met.</p> <p>For the best performance, it is recommended that you perform multiple replicates. By default, the program performs five replicates. Each replicate samples s rows from X (specified by 'NumSamples' name-value pair argument) to perform clustering on. By default, $40+2*k$ samples are selected.</p>
'large'	<p>This is similar to the <code>small</code> scale algorithm and repeatedly performs searches using a k-means like update. However, the algorithm examines only a random sample of cluster members during each iteration. The user-adjustable parameter, 'PercentNeighbors', controls the number of neighbors to examine. If there is no improvement after the neighbors are examined, the algorithm terminates the local search. The algorithm performs a total of r replicates (specified by 'Replicates' name-value pair argument) and returns the best clustering result. The algorithm has an optional PAM-like online phase (specified by the 'OnlinePhase' name-value pair argument) that improves cluster quality.</p>

Example: 'Algorithm', 'pam'

'OnlinePhase' — Flag to perform PAM-like online update phase

'on' (default) | 'off'

A flag to perform PAM-like online update phase, specified as a comma-separated pair consisting of 'OnlinePhase' and 'on' or 'off'.

If it is on, then `kmedoids` performs a PAM-like update to the medoids after the Lloyd iterations in the `small` and `large` algorithms. During this online update phase, the algorithm chooses a small subset of data points in each cluster that are the furthest from and nearest to medoid. For each chosen point, it reassigns the clustering of the entire data set and check if this creates a smaller sum of distances than the best known.

In other words, the swap considerations are limited to the points near the medoids and far from the medoids. The near points are considered in order to refine the clustering. The far points are considered in order to escape local minima. Turning on this feature tends to improve the quality of solutions generated by both algorithms. Total run time tends to increase as well, but the increase typically is less than one iteration of PAM.

Example: `OnlinePhase, 'off'`

'Distance' — Distance measure

'squeclidean' (default) | 'euclidean' | 'seuclidean' | 'cityblock' | 'minkowski' | 'chebychev' | 'mahalanobis' | 'cosine' | 'correlation' | 'spearman' | 'hamming' | 'jaccard' | custom distance function

Distance measure, in p-dimensional space, specified as the comma-separated pair consisting of 'Distance' and a string. `kmedoids` minimizes the sum of medoid to cluster member distances. See `pdist` for the definition of each distance measure. `kmedoids` supports all distance measures supported by `pdist`.

Example: `'Distance', 'hamming'`

'Options' — Options to control iterative algorithm to minimize fitting criteria

[] (default) | structure array returned by `statset`

Options to control the iterative algorithm to minimize fitting criteria, specified as the comma-separated pair consisting of 'Options' and a structure array returned by `statset`. This table summarizes these options.

Option	Description
Display	Level of display output. Choices are 'off' (default) and 'iter'.
MaxIter	Maximum number of iterations allowed. The default is 100.
UseParallel	If true and a <code>parpool</code> is open, compute in parallel. If Parallel Computing Toolbox is not available, or a <code>parpool</code> is not open,

Option	Description
	computation occurs in serial mode. The default is <code>false</code> , meaning serial computation.
<code>UseSubstreams</code>	Set to <code>true</code> to compute in parallel in a reproducible fashion. The default is <code>false</code> . To compute reproducibly, you must also set <code>Streams</code> to a type allowing substreams: <code>'mlfg6331_64'</code> or <code>'mrg32k3a'</code> .
<code>Streams</code>	A <code>RandStream</code> object or cell array of such objects. For details about these options and parallel computing in Statistics Toolbox, see “Speed Up Statistical Computations” or enter <code>help parallelstats</code> at the command line.

Example: `'Options',statset('Display','off')`

'Replicates' — Number of times to repeat clustering using new initial cluster medoid positions

positive integer

Number of times to repeat clustering using new initial cluster medoid positions, specified as a positive integer. The default value depends on the choice of algorithm. For `pam` and `small`, the default is 1. For `clara`, the default is 5. For `large`, the default is 3.

Example: `'Replicates',4`

'NumSamples' — Number of samples to take from data when executing clara algorithm

40+2*k (default) | positive integer

Number of samples to take from the data when executing the `clara` algorithm, specified as a positive integer. The default number of samples is calculated as $40+2*k$.

Example: `'NumSamples',160`

'PercentNeighbors' — Percent of data set to examine using large algorithm

0.001 (default) | scalar value between 0 and 1

Percent of the data set to examine using the `large` algorithm, specified as a positive number.

The program examines `percentneighbors*size(X,1)` number of neighbors for the medoids. If there is no improvement in the within-cluster sum of distances, then the algorithm terminates.

The value of this parameter between 0 and 1, where a value closer to 1 tends to give higher quality solutions, but the algorithm takes longer to run, and a value closer to 0 tends to give lower quality solutions, but finishes faster.

Example: `'PercentNeighbors', 0.01`

'Start' — Method for choosing initial cluster medoid positions

`'plus'` (default) | `'sample'` | `'cluster'` | `matrix`

Method for choosing initial cluster medoid positions, specified as the comma-separated pair consisting of `'Start'` and a string or a matrix. This table summarizes the available methods.

Method	Description
<code>'plus'</code> (default)	Select k observations from X according to the k -means++ algorithm for cluster center initialization.
<code>'sample'</code>	Select k observations from X at random.
<code>'cluster'</code>	Perform preliminary clustering phase on a random subsample (10%) of X . This preliminary phase is itself initialized using <code>sample</code> , that is, the observations are selected at random.
<code>matrix</code>	A custom k -by- p matrix of starting locations. In this case, you can pass in <code>[]</code> for the k input argument, and <code>kmedoids</code> infers k from the first dimension of the matrix. You can also supply a 3-D array, implying a value for <code>'Replicates'</code> from the array's third dimension.

Example: `'Start', 'sample'`

Output Arguments

`idx` — Medoid indices

numeric column vector

Medoid indices, returned as a numeric column vector. `idx` has as many rows as `X`, and each row indicates the medoid assignment of the corresponding observation.

C — Cluster medoid locations

numeric matrix

Cluster medoid locations, returned as a numeric matrix. `C` is a k -by- p matrix, where row j is the medoid of cluster j .

sumd — Within-cluster sums of point-to-medoid distances

numeric column vector

Within-cluster sums of point-to-medoid distances, returned as a numeric column vector. `sumd` is a k -by-1 vector, where element j is the sum of point-to-medoid distances within cluster j .

D — Distances from each point to every medoid

numeric matrix

Distances from each point to every medoid, returned as a numeric matrix. `D` is an n -by- k matrix, where element (j,m) is the distance from observation j to medoid m .

midx — Index to X

column vector

Index to `X`, returned as a column vector of indices. `midx` is a k -by-1 vector and the indices satisfy `C = X(midx, :)`.

info — Algorithm information

struct

Algorithm information, returned as a struct. `info` contains options used by the function when executed such as k -medoid clustering algorithm (`algorithm`), method used to choose initial cluster medoid positions (`start`), distance measure (`distance`), number of iterations taken in the best replicate (`iterations`) and the replicate number of the returned results (`bestReplicate`).

More About

***k*-medoids Clustering**

k-medoids clustering is a partitioning method commonly used in domains that require robustness to outlier data, arbitrary distance metrics, or ones for which the mean or median does not have a clear definition.

It is similar to *k*-means, and the goal of both methods is to divide a set of measurements or observations into *k* subsets or clusters so that the subsets minimize the sum of distances between a measurement and a center of the measurement's cluster. In the *k*-means algorithm, the center of the subset is the mean of measurements in the subset, often called a centroid. In the *k*-medoids algorithm, the center of the subset is a member of the subset, called a medoid.

The *k*-medoids algorithm returns medoids which are the actual data points in the data set. This allows you to use the algorithm in situations where the mean of the data does not exist within the data set. This is the main difference between *k*-medoids and *k*-means where the centroids returned by *k*-means may not be within the data set. Hence *k*-medoids is useful for clustering categorical data where a mean is impossible to define or interpret.

The function `kmedoids` provides several iterative algorithms that minimize the sum of distances from each object to its cluster medoid, over all clusters. One of the algorithms is called partitioning around medoids (PAM) [1] which proceeds in two steps.

- 1 **Build-step:** Each of *k* clusters is associated with a potential medoid. This assignment is performed using a technique specified by the '`Start`' name-value pair argument.
- 2 **Swap-step:** Within each cluster, each point is tested as a potential medoid by checking if the sum of within-cluster distances gets smaller using that point as the medoid. If so, the point is defined as a new medoid. Every point is then assigned to the cluster with the closest medoid.

The algorithm iterates the build- and swap-steps until the medoids do not change, or other termination criteria are met.

You can control the details of the minimization using several optional input parameters to `kmedoids`, including ones for the initial values of the cluster medoids, and for the maximum number of iterations. By default, `kmedoids` uses the *k*-means++ algorithm for cluster medoid initialization and the squared Euclidean metric to determine distances.

knnsearch

Class: ExhaustiveSearcher

Find k -nearest neighbors using `ExhaustiveSearcher` object

Syntax

```
IDX = knnsearch(NS,Y)
[IDX,D] = knnsearch(NS,Y)
[IDX,D] = knnsearch(NS,Y,'Name',Value)
```

Description

`IDX = knnsearch(NS,Y)` finds the nearest neighbor (closest point) in `NS.X` for each point in `Y`. Rows of `Y` correspond to observations and columns correspond to features. `Y` must have the same number of columns as `NS.X`. `IDX` is a column vector with n_y rows, where n_y is the number of rows in `Y`. Each row in `IDX` contains the index of observation in `NS.X` which has the smallest distance to the corresponding observation in `Y`.

`[IDX,D] = knnsearch(NS,Y)` returns a column vector `D` containing the distances between each observation in `Y` and the corresponding closest observation in `NS.X`. That is, `D(i)` is the distance between `NS.X(IDX(i),:)` and `Y(i,:)`.

`[IDX,D] = knnsearch(NS,Y,'Name',Value)` accepts one or more comma-separated argument name/value pairs. Specify *Name* inside single quotes.

Input Arguments

Name-Value Pair Arguments

'k'

A positive integer, k , specifying the number of nearest neighbors in `NS.X` for each point in `Y`. `IDX` and `D` are n_y -by- k matrices. `D` sorts the distances in each row in ascending order. Each row in `IDX` contains the indices of the k closest neighbors in `NS.X` corresponding to the k smallest distances in `D`.

Default: 1

'IncludeTies'

A logical value indicating whether `knnsearch` includes all the neighbors whose distance values are equal to the `K`th smallest distance. If `IncludeTies` is `true`, `knnsearch` includes all these neighbors. In this case, `IDX` and `D` are n -by-1 cell arrays. Each row in `IDX` and `D` contains a vector with at least `K` numeric numbers. `D` sorts the distances in each vector in ascending order. Each row in `IDX` contains the indices of the closest neighbors corresponding to these smallest distances in `D`.

Default: `false`

'Distance'

- 'euclidean' — Euclidean distance (default).
- 'seuclidean' — Standardized Euclidean distance. Each coordinate difference between `X` and each query point is scaled by dividing by a scale value `S`. The default value of `S` is `NS.DistanceParameter` if `NS.Distance` is 'seuclidean', otherwise the default is the standard deviation computed from `X`, `S=nanstd(X)`. To specify another value for `S`, use the 'Scale' argument.
- 'cityblock' — City block distance.
- 'chebychev' — Chebychev distance (maximum coordinate difference).
- 'minkowski' — Minkowski distance.
- 'mahalanobis' — Mahalanobis distance, which is computed using a positive definite covariance matrix `C`. The default value of `C` is `nancov(X)`. To change the value of `C`, use the `Cov` parameter.
- 'cosine' — One minus the cosine of the included angle between observations (treated as vectors).
- 'correlation' — One minus the sample linear correlation between observations (treated as sequences of values).
- 'spearman' — One minus the sample Spearman's rank correlation between observations (treated as sequences of values).
- 'hamming' — Hamming distance, which is the percentage of coordinates that differ.
- 'jaccard' — One minus the Jaccard coefficient, which is the percentage of nonzero coordinates that differ.
- custom distance function — A distance function specified using `@` (for example, `@distfun`). A distance function must be of the form `function D2 = distfun(ZI,`

ZJ), taking as arguments a 1-by- n vector ZI containing a single row of from X or from the query points Y, an $m2$ -by- n matrix ZJ containing multiple rows of X or Y, and returning an $m2$ -by-1 vector of distances D2, whose j th element is the distance between the observations ZI and ZJ ($j, :$).

For more information on these distance metrics, see “Distance Metrics”.

Default: NS.Distance

'P'

A positive scalar, p , indicating the exponent of the Minkowski distance. This parameter is only valid if `knnsearch` uses the 'minkowski' distance metric.

Default: NS.DistanceParameter if NS.Distance is 'minkowski' and 2 otherwise.

'Cov'

A positive definite matrix indicating the covariance matrix when computing the Mahalanobis distance. This parameter is only valid when `knnsearch` uses the 'mahalanobis' distance metric.

Default: NS.DistanceParameter if NS.Distance is 'mahalanobis', or `nancov(X)` otherwise.

'Scale'

A vector **S** with the length equal to the number of columns in X. Each coordinate of X and each query point is scaled by the corresponding element of **S** when computing the standardized Euclidean distance. This parameter is only valid when `Distance` is 'seuclidean'.

Default: `nanstd(X)`

Examples

Search for k -Nearest Neighbors

Find k -nearest neighbors of query data given training data using `knnsearch` on an `ExhaustiveSearcher` model.

Load Fisher's iris data. Focus on the petal dimensions.

```
load fisheriris
X = meas(:,3:4); % Predictors
Y = species;    % Response
```

Train a k -nearest neighbors searcher using the predictors. Specify to use the cosine distance.

```
ESMdl = ExhaustiveSearcher(X, 'Distance', 'cosine')
```

```
ESMdl =
```

```
ExhaustiveSearcher with properties:
```

```
    Distance: 'cosine'
  DistParameter: []
           X: [150x2 double]
```

ESMdl is an ExhaustiveSearcher model. You can access its properties using dot notation.

Find the 10 nearest neighbors from X to a query point (`newpoint`), first using the cosine, and then Mahalanobis distance metrics. The query point must have the same column dimension as the data used to train the model.

```
newpoint = [5 1.45];
[IdxCs,DCs] = knnsearch(ESMdl,newpoint,'k',10);
[IdxMs,DMs] = knnsearch(ESMdl,newpoint,'k',10,...
    'Distance','mahalanobis');
```

IdxCs and IdxMs are 1-by-10 matrices containing the row indices of X corresponding to the nearest neighbors to `newpoint` using cosine and Mahalanobis distances, respectively. Element (1,1) is the nearest, element (1,2) is the next nearest, and so on.

Plot the training data.

```
figure;
gscatter(X(:,1),X(:,2),Y);
title('Fisher's Iris Data -- Nearest Neighbors');
xlabel('Petal length (cm)');
```

```
ylabel('Petal width (cm)');  
hold on
```

Plot a cross for the query point.

```
plot(newpoint(1),newpoint(2),'kx','MarkerSize',10,...  
     'LineWidth',2);
```

Plot circles to identify the cosine nearest neighbors.

```
plot(X(IdxCs,1),X(IdxCs,2),'o','Color',[.5 .5 .5],'MarkerSize',10);
```

Plot pentagrams to identify the Mahalanobis nearest neighbors.

```
plot(X(IdxMs,1),X(IdxMs,2),'p','Color',[.5 .5 .5],'MarkerSize',10);
legend('setosa','versicolor','virginica','query point',...
       'cosine','mahalanobis','Location','Best');
hold off;
```

knnsearch

Class: KDTreeSearcher

Find k -nearest neighbors using KDTreeSearcher object

Syntax

```
IDX = knnsearch(NS,Y)
[IDX,D] = knnsearch(NS,Y)
[IDX,D] = knnsearch(NS,Y, 'Name', Value)
```

Description

`IDX = knnsearch(NS, Y)` finds the nearest neighbor (closest point) in `NS.X` for each point in `Y`. Rows of `Y` correspond to observations and columns correspond to features. `Y` must have the same number of columns as `NS.X`. `IDX` is a column vector with n_y rows, where n_y is the number of rows in `Y`. Each row in `IDX` contains the index of observation in `NS.X` which has the smallest distance to the corresponding observation in `Y`.

`[IDX, D] = knnsearch(NS, Y)` returns a column vector `D` containing the distances between each observation in `Y` and the corresponding closest observation in `NS.X`. That is, `D(i)` is the distance between `NS.X(IDX(i), :)` and `Y(i, :)`.

`[IDX, D] = knnsearch(NS, Y, 'Name', Value)` accepts one or more comma-separated name-value pair arguments. Specify *Name* inside single quotes.

Input Arguments

NS

KDTreeSearcher object, constructed using KDTreeSearcher or createns.

Y

m_y -by- n numeric matrix, where each row represents one n -dimensional point. The number of columns n must equal the number of columns in `NS.X`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

'K'

A positive integer, k , specifying the number of nearest neighbors in `NS.X` for each point in `Y`. Default is 1. `IDX` and `D` are ny -by- k matrices. `D` sorts the distances in each row in ascending order. Each row in `IDX` contains the indices of the k closest neighbors in `NS.X` corresponding to the k smallest distances in `D`.

'Distance'

Select one of the following distance algorithms.

- 'euclidean' — Euclidean distance (default).
- 'cityblock' — City block distance.
- 'chebychev' — Chebychev distance (maximum coordinate difference).
- 'minkowski' — Minkowski distance.

Default is `NS.Distance`. For details on these distance metrics, see “Distance Metrics”.

'IncludeTies'

A logical value indicating whether `knnsearch` includes all the neighbors whose distance values are equal to the K th smallest distance. If `IncludeTies` is true, `knnsearch` includes all these neighbors. In this case, `IDX` and `D` are ny -by-1 cell arrays. Each row in `IDX` and `D` contains a vector with at least K numeric numbers. `D` sorts the distances in each vector in ascending order. Each row in `IDX` contains the indices of the closest neighbors corresponding to these smallest distances in `D`.

Default: false

'P'

A positive scalar, p , indicating the exponent of the Minkowski distance. This parameter is only valid when the `Distance` is 'minkowski'. Default is `NS.DistanceParameter` if `NS.Distance` is 'minkowski' and 2 otherwise.

Examples

Search for k -Nearest Neighbors

Find k -nearest neighbors of query data given training data using `knnsearch` on a `KDTreeSearcher` model.

Load Fisher's iris data. Focus on the petal dimensions.

```
load fisheriris
X = meas(:,3:4); % Predictors
Y = species;    % Response
```

Train a k -nearest neighbors searcher using the predictors. Specify to use the Minkowski distance with exponent 5.

```
KDTreeMdl = KDTreeSearcher(X, 'Distance', 'minkowski', 'P', 5)
```

```
KDTreeMdl =
```

```
    KDTreeSearcher with properties:
```

```
        BucketSize: 50
           Distance: 'minkowski'
    DistParameter: 5
              X: [150x2 double]
```

`KDTreeMdl` is a `KDTreeSearcher` model. You can access its properties using dot notation.

Find the 10 nearest neighbors from `X` to a query point (`newpoint`), using first Minkowski then Chebychev distance metrics. The query point must have the same column dimension as the data used to train the model.

```
newpoint = [5 1.45];
[IdxMk, DMk] = knnsearch(KDTreeMdl, newpoint, 'k', 10);
[IdxCb, DCb] = knnsearch(KDTreeMdl, newpoint, 'k', 10, ...
    'Distance', 'chebychev');
```

`IdxMk` and `IdxCb` are 1-by-10 matrices containing the row indices of `X` corresponding to the nearest neighbors to `newpoint` using Minkowski and then Chebychev distances, respectively. Element (1,1) is the nearest, element (1,2) is the next nearest, and so on.

Plot the training data.

```
figure;  
gscatter(X(:,1),X(:,2),Y);  
title('Fisher''s Iris Data -- Nearest Neighbors');  
xlabel('Petal length (cm)');  
ylabel('Petal width (cm)');  
hold on
```

Zoom in on the points of interest.

```
h = gca; % Get current axis handle.  
h.XLim = [4.5 5.5];  
h.YLim = [1 2];
```

```
axis square;
```

Plot a cross for the query point.

```
plot(newpoint(1),newpoint(2),'kx','MarkerSize',10,...  
     'LineWidth',2);
```

Plot circles to identify the Minkowski nearest neighbors.

```
plot(X(IdXMk,1),X(IdXMk,2),'o','Color',[.5 .5 .5],'MarkerSize',10);
```

Plot pentagrams to identify the Chebychev nearest neighbors.

```
plot(X(IdxCb,1),X(IdxCb,2),'p','Color',[.5 .5 .5],'MarkerSize',10);
legend('setosa','versicolor','virginica','query point',...
      'minkowski','chebychev','Location','Best');
hold off;
```

Several observations are equal, which is why only eight nearest neighbors are identified in the plot.

Algorithms

For information on a specific search algorithm, see “Distance Metrics”.

How To

- “ k -Nearest Neighbor Search and Radius Search” on page 16-11
- “Distance Metrics”

knnsearch

Find k -nearest neighbors using data

Syntax

```
IDX = knnsearch(X,Y)
[IDX,D] = knnsearch(X,Y)
[IDX,D] = knnsearch(X,Y, 'Name', Value)
```

Description

`IDX = knnsearch(X,Y)` finds the nearest neighbor in X for each point in Y . IDX is a column vector with my rows. Each row in IDX contains the index of nearest neighbor in X for the corresponding row in Y .

`[IDX,D] = knnsearch(X,Y)` returns an my -by-1 vector D containing the distances between each observation in Y and the corresponding closest observation in X . That is, $D(i)$ is the distance between $X(Idx(i), :)$ and $Y(i, :)$.

`[IDX,D] = knnsearch(X,Y, 'Name', Value)` accepts one or more optional comma-separated name-value pair arguments. Specify *Name* inside single quotes.

`knnsearch` does not save a search object. To create a search object, use `createns`.

Input Arguments

X

An m -by- n numeric matrix. Rows of X correspond to observations and columns correspond to variables.

Y

An my -by- n numeric matrix of query points. Rows of Y correspond to observations and columns correspond to variables.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

'K'

Positive integer specifying the number of nearest neighbors in `X` for each point in `Y`. Default is 1. `IDX` and `D` are *m*-by-*K* matrices. `D` sorts the distances in each row in ascending order. Each row in `IDX` contains the indices of the *K* closest neighbors in `X` corresponding to the *K* smallest distances in `D`.

'IncludeTies'

A logical value indicating whether `knnsearch` includes all the neighbors whose distance values are equal to the *K*th smallest distance. If `IncludeTies` is `true`, `knnsearch` includes all these neighbors. In this case, `IDX` and `D` are *m*-by-1 cell arrays. Each row in `IDX` and `D` contains a vector with at least *K* numeric numbers. `D` sorts the distances in each vector in ascending order. Each row in `IDX` contains the indices of the closest neighbors corresponding to these smallest distances in `D`.

Default: `false`

'NSMethod'

Nearest neighbors search method. Value is either:

- `'kdtree'` — Creates and uses a Kd-tree to find nearest neighbors. This is the default value when the number of columns of `X` is less than 10, `X` is not sparse, and the distance measure is one of the following measures. `'kdtree'` is only valid when the distance measure is one of the following:
 - `'euclidean'`
 - `'cityblock'`
 - `'minkowski'`
 - `'chebychev'`
- `'exhaustive'` — Uses the exhaustive search algorithm by computing the distance values from all the points in `X` to each point in `Y` to find nearest neighbors.

'Distance'

A string or a function handle specifying the distance metric. The value can be one of the following:

- `'euclidean'` — Euclidean distance (default).
- `'seuclidean'` — Standardized Euclidean distance. Each coordinate difference between rows in `X` and the query matrix is scaled by dividing by the corresponding element of the standard deviation computed from `X`, `S=nanstd(X)`. To specify another value for `S`, use the `Scale` argument.
- `'cityblock'` — City block distance.
- `'chebychev'` — Chebychev distance (maximum coordinate difference).
- `'minkowski'` — Minkowski distance. The default exponent is 2. To specify a different exponent, use the `'P'` argument.
- `'mahalanobis'` — Mahalanobis distance, computed using a positive definite covariance matrix `C`. The default value of `C` is `nancov(X)`. To change the value of `C`, use the `Cov` parameter.
- `'cosine'` — 1 minus the cosine of the included angle between observations (treated as vectors).
- `'correlation'` — One minus the sample linear correlation between observations (treated as sequences of values).
- `'spearman'` — One minus the sample Spearman's rank correlation between observations (treated as sequences of values).
- `'hamming'` — Hamming distance, which is the percentage of coordinates that differ.
- `'jaccard'` — One minus the Jaccard coefficient, which is the percentage of nonzero coordinates that differ.
- custom distance function — A distance function specified using `@` (for example, `@distfun`). A custom distance function must
 - Have the form `function D2 = distfun(ZI, ZJ)`
 - Take as arguments:
 - A 1-by- n vector `ZI` containing a single row from `X` or from the query points `Y`
 - An $m2$ -by- n matrix `ZJ` containing multiple rows of `X` or `Y`
 - Return an $m2$ -by-1 vector of distances `D2`, whose j th element is the distance between the observations `ZI` and `ZJ(j, :)`

For more information on these distance metrics, see “Distance Metrics”.

'P'

A positive scalar, p , indicating the exponent of the Minkowski distance. This parameter is only valid if the `Distance` is `'minkowski'`. Default is 2.

'Cov'

A positive definite matrix indicating the covariance matrix when computing the Mahalanobis distance. This parameter is only valid when `Distance` is `'mahalanobis'`. Default is `nancov(X)`.

'Scale'

A vector `S` containing nonnegative values, with length equal to the number of columns in `X`. Each coordinate of `X` and each query point is scaled by the corresponding element of `S` when computing the standardized Euclidean distance. This argument is only valid when `Distance` is `'seuclidean'`. Default is `nanstd(X)`.

'BucketSize'

The maximum number of data points in the leaf node of the *kd*-tree. This argument is only meaningful when using the *kd*-tree search method. Default is 50.

Examples

Classify Using k-Nearest Neighbors

Find the 10 nearest neighbors in `x` to each point in `y` using first the `'minkowski'` distance metric with a p value of 5, and then using the `'chebychev'` distance metric.

Load Fisher's iris data set

```
load fisheriris
x = meas(:,3:4);
y = [5 1.45;6 2;2.75 .75];
```

Perform a `knnsearch` between `x` and the query points in `y`, using first Minkowski then Chebychev distance metrics.

```
[n,d]=knnsearch(x,y,'k',10,'distance','minkowski','p',5);
[ncb,dcb] = knnsearch(x,y,'k',10,...
    'distance','chebychev');
```

Visualize the results of the two different nearest neighbors searches. Plot the training data. Plot an X for the query points. Use circles to denote the Minkowski nearest neighbors. Use pentagrams to denote the Chebychev nearest neighbors.

```
gscatter(x(:,1),x(:,2),species)
line(y(:,1),y(:,2),'marker','x','color','k',...
    'markersize',10,'linewidth',2,'linestyle','none')
line(x(n,1),x(n,2),'color',[.5 .5 .5],'marker','o',...
    'linestyle','none','markersize',10)
line(x(ncb,1),x(ncb,2),'color',[.5 .5 .5],'marker','p',...
    'linestyle','none','markersize',10)
legend('setosa','versicolor','virginica','query point',...
    'minkowski','chebychev','Location','best')
```

More About

Tips

- For a fixed positive integer K , `knnsearch` finds the K points in X that are nearest each point in Y . In contrast, for a fixed positive real value r , `rangesearch` finds all the points in X that are within a distance r of each point in Y .

Algorithms

For information on a specific search algorithm, see “Distance Metrics”.

- “ k -Nearest Neighbor Search and Radius Search” on page 16-11

kruskalwallis

Kruskal-Wallis test

Syntax

```
p = kruskalwallis(x)
p = kruskalwallis(x,group)
p = kruskalwallis(x,group,displayopt)
[p,tbl,stats] = kruskalwallis( ___ )
```

Description

`p = kruskalwallis(x)` returns the p -value for the null hypothesis that the data in each column of the matrix `x` comes from the same distribution, using a Kruskal-Wallis test. The alternative hypothesis is that not all samples come from the same distribution. `kruskalwallis` also returns an ANOVA table and a box plot.

`p = kruskalwallis(x,group)` returns the p -value for a test of the null hypothesis that the data in each categorical group, as specified by the grouping variable `group` comes from the same distribution. The alternative hypothesis is that not all groups come from the same distribution.

`p = kruskalwallis(x,group,displayopt)` returns the p -value of the test and lets you display or suppress the ANOVA table and box plot.

`[p,tbl,stats] = kruskalwallis(___)` also returns the ANOVA table as the cell array `tbl` and the structure `stats` containing information about the test statistics.

Examples

Test Data Samples for the Same Distribution

Create two different normal probability distribution objects. The first distribution has $\mu = 0$ and $\sigma = 1$, and the second distribution has $\mu = 2$ and $\sigma = 1$.

```
pd1 = makedist('Normal');  
pd2 = makedist('Normal','mu',2,'sigma',1);
```

Create a matrix of sample data by generating random numbers from these two distributions.

```
rng('default'); % for reproducibility  
x = [random(pd1,20,2),random(pd2,20,1)];
```

The first two columns of `x` contain data generated from the first distribution, while the third column contains data generated from the second distribution.

Test the null hypothesis that the sample data from each column in `x` comes from the same distribution.

```
p = kruskalwallis(x)
```

```
p =
```

```
3.6896e-06
```

Kruskal-Wallis ANOVA Table					
Source	SS	df	MS	Chi-sq	Prob>Chi-sq
Columns	7631.1	2	3815.55	25.02	3.68957e-06
Error	10363.9	57	181.82		
Total	17995	59			

The returned value of `p` indicates that `kruskalwallis` rejects the null hypothesis that all three data samples come from the same distribution at a 1% significance level. The ANOVA table provides additional test results, and the box plot visually presents the summary statistics for each column in `x`.

Conduct Followup Tests for Unequal Medians

Create two different normal probability distribution objects. The first distribution has `mu = 0` and `sigma = 1`. The second distribution has `mu = 2` and `sigma = 1`.

```
pd1 = makedist('Normal');  
pd2 = makedist('Normal','mu',2,'sigma',1);
```

Create a matrix of sample data by generating random numbers from these two distributions.

```
rng('default'); % for reproducibility
x = [random(pd1,20,2),random(pd2,20,1)];
```

The first two columns of `x` contain data generated from the first distribution, while the third column contains data generated from the second distribution.

Test the null hypothesis that the sample data from each column in `x` comes from the same distribution. Suppress the output displays, and generate the structure `stats` to use in further testing.

```
[p,tbl,stats] = kruskalwallis(x,[],'off')
```

```
p =
```

```
3.6896e-06
```

```
tbl =
```

```
Columns 1 through 4
```

'Source'	'SS'	'df'	'MS'
'Columns'	[7.6311e+03]	[2]	[3.8155e+03]
'Error'	[1.0364e+04]	[57]	[181.8228]
'Total'	[17995]	[59]	[]

```
Columns 5 through 6
```

'Chi-sq'	'Prob>Chi-sq'
[25.0200]	[3.6896e-06]
[]	[]
[]	[]

```
stats =
```

```
gnames: [3x1 char]
n: [20 20 20]
source: 'kruskalwallis'
meanranks: [26.7500 18.9500 45.8000]
sumt: 0
```

The returned value of `p` indicates that the test rejects the null hypothesis at the 1% significance level. You can use the structure `stats` to perform additional followup testing. The cell array `tbl` contains the same data as the graphical ANOVA table, including column and row labels.

Conduct a followup test to identify which data sample comes from a different distribution.

```
c = multcompare(stats)
```

Note: Intervals can be used for testing but are not simultaneous confidence intervals.

```
c =
```

```
1.0000    2.0000   -5.1435    7.8000   20.7435
1.0000    3.0000  -31.9935  -19.0500   -6.1065
2.0000    3.0000  -39.7935  -26.8500  -13.9065
```

The results indicate that there is a significant difference between groups 1 and 3, so the test rejects the null hypothesis that the data in these two groups comes from the same distribution. The same is true for groups 2 and 3. However, there is not a significant difference between groups 1 and 2, so the test does not reject the null hypothesis that these two groups come from the same distribution. Therefore, these results suggest that the data in groups 1 and 2 come from the same distribution, and the data in group 3 comes from a different distribution.

Test for the Same Distribution Across Groups

Create a vector, `strength`, containing measurements of the strength of metal beams. Create a second vector, `alloy`, containing strings indicating the type of metal alloy from which the corresponding beam is made.

```

strength = [82 86 79 83 84 85 86 87 74 82 ...
            78 75 76 77 79 79 77 78 82 79];

alloy = {'st', 'st', 'st', 'st', 'st', 'st', 'st', 'st', ...
        'al1', 'al1', 'al1', 'al1', 'al1', 'al1', ...
        'al2', 'al2', 'al2', 'al2', 'al2', 'al2'};

```

Test the null hypothesis that the beam strength measurements have the same distribution across all three alloys.

```

p = kruskalwallis(strength, alloy, 'off')

p =

    0.0018

```

The returned value of `p` indicates that the test rejects the null hypothesis at the 1% significance level.

Input Arguments

x — Sample data

vector | matrix

Sample data for the hypothesis test, specified as a vector or an m -by- n matrix. If `x` is an m -by- n matrix, each of the n columns represents an independent sample containing m mutually independent observations.

Data Types: `single` | `double`

group — Grouping variable

categorical variable | vector | character array | cell array

Grouping variable, specified as a categorical variable, vector, character array, or cell array.

- If `x` is a vector, then each element in `group` identifies the group to which the corresponding element in `x` belongs, and `group` must be a vector of the same length as `x`. If a row of `group` contains an empty cell or empty string, that row and the corresponding observation in `x` are disregarded. NaN values in either `x` or `group` are similarly ignored.

- If `x` is a matrix, then each column in `x` represents a different group, and you can use `group` to specify labels for these columns. The number of elements in `group` and the number of columns in `x` must be equal.

The labels contained in `group` also annotate the box plot.

Example:

```
{'red', 'blue', 'green', 'blue', 'red', 'blue', 'green', 'green', 'red'}
```

Data Types: `single` | `double` | `char`

displayopt — Display option

'on' (default) | 'off'

Display option, specified as 'on' or 'off'. If `displayopt` is 'on', `kruskalwallis` displays the following figures:

- An ANOVA table containing the sums of squares, degrees of freedom, and other quantities calculated based on the ranks of the data in `x`.
- A box plot of the data in each column of the data matrix `x`. The box plots are based on the actual data values, rather than on the ranks.

If `displayopt` is 'off', `kruskalwallis` does not display these figures.

If you specify a value for `displayopt`, you must also specify a value for `group`. If you do not have a grouping variable, specify `group` as `[]`.

Example: 'off'

Output Arguments

p — p-value

scalar value in the range [0,1]

p-value of the test, returned as a scalar value in the range [0,1]. *p* is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. Small values of *p* cast doubt on the validity of the null hypothesis.

tb1 — ANOVA table

cell array

ANOVA table of test results, returned as a cell array. `tbl` includes the sums of squares, degrees of freedom, and other quantities calculated based on the ranks of the data in `x`, as well as column and row labels.

stats — Test data

structure

Test data, returned as a structure. You can perform followup multiple comparison tests on pairs of sample medians by using `multcompare`, with `stats` as the input value.

More About

Kruskal-Wallis Test

The Kruskal-Wallis test is a nonparametric version of classical one-way ANOVA, and an extension of the Wilcoxon rank sum test to more than two groups. It compares the medians of the groups of data in `x` to determine if the samples come from the same population (or, equivalently, from different populations with the same distribution).

The Kruskal-Wallis test uses ranks of the data, rather than numeric values, to compute the test statistics. It finds ranks by ordering the data from smallest to largest across all groups, and taking the numeric index of this ordering. The rank for a tied observation is equal to the average rank of all observations tied with it. The F -statistic used in classical one-way ANOVA is replaced by a chi-square statistic, and the p -value measures the significance of the chi-square statistic.

The Kruskal-Wallis test assumes that all samples come from populations having the same continuous distribution, apart from possibly different locations due to group effects, and that all observations are mutually independent. By contrast, classical one-way ANOVA replaces the first assumption with the stronger assumption that the populations have normal distributions.

ksdensity

Kernel smoothing function estimate

Syntax

```
[f,xi] = ksdensity(x)
[f,xi] = ksdensity(x,pts)
[f,xi] = ksdensity(x,pts,Name,Value)
[f,xi,bw] = ksdensity( ___ )
```

```
ksdensity( ___ )
ksdensity(ax, ___ )
```

Description

`[f,xi] = ksdensity(x)` returns a probability density estimate, `f`, for the sample in the vector `x`. The estimate is based on a normal kernel function, and is evaluated at 100 equally spaced points, `xi`, that cover the range of the data in `x`.

`ksdensity` works best with continuously distributed samples.

`[f,xi] = ksdensity(x,pts)` returns a probability density estimate, `f`, for the sample in the vector `x`, evaluated at the specified values in vector `pts`. Here, the `xi` and `pts` vectors contain identical values.

`[f,xi] = ksdensity(x,pts,Name,Value)` returns a probability density estimate, `f`, for the sample in the vector `x`, with additional options specified by one or more `Name,Value` pair arguments.

For example, you can define the function type `ksdensity` evaluates, such as probability density, cumulative probability, survivor function, and so on. Or you can specify the bandwidth of the smoothing window.

`[f,xi,bw] = ksdensity(___)` also returns the bandwidth of the kernel smoothing window, `bw`. The default bandwidth is the optimal for normal densities.

`ksdensity(___)` plots the kernel smoothing function estimate.

`ksdensity(ax, ___)` plots the results using axes with the handle, `ax`, instead of the current axes returned by `gca`.

Examples

Estimate Density

Generate a sample data set from a mixture of two normal distributions.

```
rng default % for reproducibility
x = [randn(30,1); 5+randn(30,1)];
```

Plot the estimated density.

```
[f,xi] = ksdensity(x);
figure
plot(xi,f);
```

The density estimate shows the bimodality of the sample.

Estimate Cumulative Distribution Function at Specified Values

Load the sample data.

```
load hospital
```

Compute and plot the estimated cdf evaluated at a specified set of values.

```
pts = (min(hospital.Weight):2:max(hospital.Weight));  
figure()  
ecdf(hospital.Weight)  
hold on
```

```
[f,xi,bw] = ksdensity(hospital.Weight,pts,'support','positive',...  
    'function','cdf');  
plot(xi,f,'-g','LineWidth',2)  
legend('empirical cdf','kernel-bw:default','Location','NorthWest')  
xlabel('Patient weights')  
ylabel('Estimated cdf')
```

`ksdensity` seems to smooth the cumulative distribution function estimate too much. An estimate with a smaller bandwidth might produce a closer estimate to the empirical cumulative distribution function.

Return the bandwidth of the smoothing window.

`bw`

```
bw =  
  
0.1070
```

Plot the cumulative distribution function estimate using a smaller bandwidth.

```
[f,xi] = ksdensity(hospital.Weight,pts,'support','positive',...  
    'function','cdf','bandwidth',0.05);  
plot(xi,f,'--r','LineWidth',2)  
legend('empirical cdf','kernel-bw:default','kernel-bw:0.05',...  
    'Location','NorthWest')  
hold off
```

The `ksdensity` estimate with a smaller bandwidth matches the empirical cumulative distribution function better.

Plot Estimated Cumulative Density Function for Given Number of Points

Load the sample data.

```
load hospital
```

Plot the estimated cdf evaluated at 50 equally spaced points.

```
figure()
ksdensity(hospital.Weight, 'support', 'positive', 'function', 'cdf', ...
'npoints', 50)
xlabel('Patient weights')
ylabel('Estimated cdf')
```

Estimate Survivor and Cumulative Hazard for Censored Failure Data

Generate sample data from an exponential distribution with mean 3.

```
rng default % for reproducibility
x = random('exp',3,100,1);
```

Create a logical vector that indicates censoring. Here, observations with lifetimes longer than 10 are censored.

```
T = 10;
cens = (x>10);
```

Compute and plot the estimated density function.

```
figure  
ksdensity(x, 'support', 'positive', 'censoring', cens);
```

Compute and plot the survivor function.

```
figure  
ksdensity(x, 'support', 'positive', 'censoring', cens, ...  
          'function', 'survivor');
```

Compute and plot the cumulative hazard function.

```
figure
ksdensity(x, 'support', 'positive', 'censoring', cens, ...
'function', 'cumhazard');
```

Estimate Inverse Cumulative Distribution Function for Specified Probability Values

Generate a mixture of two normal distributions, and plot the estimated inverse cumulative distribution function at a specified set of probability values.

```
rng default % for reproducibility
x = [randn(30,1); 5+randn(30,1)];
pi = linspace(.01,.99,99);
figure
ksdensity(x,pi,'function','icdf');
```

Return Bandwidth of Smoothing Window

Generate a mixture of two normal distributions.

```
rng default % For reproducibility
x = [randn(30,1); 5+randn(30,1)];
```

Return the bandwidth of the smoothing window for the probability density estimate.

```
[f,xi,bw] = ksdensity(x);
bw
```

```
bw =
```

1.5141

The default bandwidth is optimal for normal densities.

Plot the estimated density.

```
figure
plot(xi,f);
xlabel('xi')
ylabel('f')
hold on
```

Plot the density using an increased bandwidth value.

```
[f,xi] = ksdensity(x,'width',1.8);  
plot(xi,f,'--r','LineWidth',1.5)
```

A higher bandwidth further smooths the density estimate, which might mask some characteristics of the distribution.

Now, plot the density using a decreased bandwidth value.

```
[f,xi] = ksdensity(x,'width',0.8);  
plot(xi,f,'-.k','LineWidth',1.5)  
legend('bw = default','bw = 1.8','bw = 0.8')  
hold off
```

A smaller bandwidth smooths the density estimate less, which exaggerates some characteristics of the sample.

Input Arguments

x — Sample data

column vector

Sample data, for which `ksdensity` returns `f` values, specified as a column vector.

Example: `[f,xi] = ksdensity(x)`

Data Types: `single` | `double`

pts — Points to evaluate f

vector

Points to evaluate `f` at, specified as a vector. `pts` can be a row or column vector. `f` has the same dimensions as `pts`.

Example: `pts = (0:1:25); ksdensity(x,pts);`

Data Types: `single` | `double`

ax — Axes handle

handle

Axes handle for the figure `ksdensity` plots to, specified as a handle.

For example, if `h` is a handle for a figure, then `ksdensity` can plot to that figure as follows.

Example: `ksdensity(h,x)`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example:

`'censoring',cens,'kernel','triangle','npoints',20,'function','cdf'` specifies that `ksdensity` estimates the cdf by evaluating at 20 equally spaced points that covers the range of data, using the triangle kernel smoothing function and accounting for the censored data information in vector `cens`.

'censoring' — Logical vector

vector of 0s (default) | vector of 0s and 1s

Logical vector indicating which entries are censored, specified as a vector of binary values. A value of 0 indicates there is no censoring, 1 indicates that observation is censored. Default is there is no censoring.

Example: `'censoring',censdata`

Data Types: `logical`

'kernel' — Type of kernel smoother

'normal' (default) | 'box' | 'triangle' | 'epanechnikov' | function handle | string

Type of kernel smoother, specified as the comma-separated pair consisting of 'kernel' and one of the following.

- 'normal' (default)
- 'box'
- 'triangle'
- 'epanechnikov'
- You can also specify a custom kernel function, as a function handle or as a string, e.g., @normpdf or 'normpdf'. This calls the function with one argument that is an array of distances between data values and locations where the density is evaluated. The function must return an array of the same size containing corresponding values of the kernel function.

When 'function' is 'pdf', this kernel function returns density values. Otherwise, it returns cumulative probability values.

Specifying a custom kernel when 'function' is 'icdf' returns an error.

If 'support' is 'positive', then `ksdensity` transforms x using a log function, estimates the density of the transformed values, and transforms back to the original scale. If 'support' is a vector $[L \ U]$, then `ksdensity` uses the transformation $\log((X-L)/(U-X))$. The width parameter and bw outputs are on the scale of the transformed values.

Example: 'kernel', 'box'

Data Types: char | function_handle

'npoints' — Number of equally spaced points

100 (default) | scalar value

Number of equally spaced points in x_i , specified as the comma-separated pair consisting of 'npoints' and a scalar value.

For instance, for a kernel smooth estimate of a specified function at 80 equally spaced points within the range of sample data, input:

Example: 'npoints', 80

Data Types: `single` | `double`

'support' — Support for the density

'unbounded' (default) | 'positive' | two-element vector, [L U]

Support for the density, specified as the comma-separated pair consisting of 'support' and one of the following.

'unbounded'	Default. Allow the density to extend over the whole real line.
'positive'	Restrict the density to positive values.
Two-element vector, [L U]	Give the finite lower and upper bounds for the support of the density.

Example: 'support', 'positive'

Example: 'support', [0 10]

Data Types: `single` | `double` | `char`

'weights' — Weights for each x value

vector

Weights for each x value, specified as the comma-separated pair consisting of 'weights' and a vector of the same length as x.

For instance, if the weights for the data values are in vector `xw`, then you can specify the weights as follows.

Example: 'weights', `xw`

Data Types: `single` | `double`

'bandwidth' — Bandwidth of the kernel smoothing window

optimal value for normal densities (default) | scalar value

The bandwidth of the kernel-smoothing window, which is a function of the number of points in `x`, specified as the comma-separated pair consisting of 'width' and a scalar. The default is optimal for estimating normal densities, but you might want to choose a larger or smaller value to smooth more or less.

Example: 'bandwidth', 0.8

Data Types: `single` | `double`

'function' — Function to estimate

`'pdf'` (default) | `'cdf'` | `'icdf'` | `'survivor'` | `'cumhazard'`

Function to estimate, specified as the comma-separated pair consisting of `'function'` and one of the following.

<code>'pdf'</code>	Default. Probability density function.
<code>'cdf'</code>	Cumulative distribution function.
<code>'icdf'</code>	Inverse cumulative distribution function. For <code>'icdf'</code> , <code>f = ksdensity(x,pi,'function','icdf')</code> computes the estimated inverse cdf of the values in <code>x</code> , and evaluates it at the probability values specified in <code>pi</code> .
<code>'survivor'</code>	Survivor function.
<code>'cumhazard'</code>	Cumulative hazard function.

Example: `'function','icdf'`

Data Types: `char`

Output Arguments

f — Estimated function values

vector

Estimated function values, returned as a vector of the same dimension as `xi` or `pts`.

xi — Evaluation points

100 equally spaced points (default) | vector

Evaluation points at which `ksdensity` calculates `f`, returned as a vector. Default is 100 equally spaced points that cover the range of data in `x`.

bw — Bandwidth of smoothing window

scalar value

Bandwidth of smoothing window, returned as a scalar value.

kstest

One-sample Kolmogorov-Smirnov test

Syntax

```
h = kstest(x)
h = kstest(x,Name,Value)
[h,p] = kstest( ___ )
[h,p,ksstat,cv] = kstest( ___ )
```

Description

`h = kstest(x)` returns a test decision for the null hypothesis that the data in vector `x` comes from a standard normal distribution, against the alternative that it does not come from such a distribution, using the one-sample Kolmogorov-Smirnov test. The result `h` is 1 if the test rejects the null hypothesis at the 5% significance level, or 0 otherwise.

`h = kstest(x,Name,Value)` returns a test decision for the one-sample Kolmogorov-Smirnov test with additional options specified by one or more name-value pair arguments. For example, you can test for a distribution other than standard normal, change the significance level, or conduct a one-sided test.

`[h,p] = kstest(___)` also returns the p -value `p` of the hypothesis test, using any of the input arguments from the previous syntaxes.

`[h,p,ksstat,cv] = kstest(___)` also returns the value of the test statistic `ksstat` and the approximate critical value `cv` of the test.

Examples

Test for a Standard Normal Distribution

Load the sample data. Create a vector containing the first column of the students' exam grades data.

```
load examgrades;  
test1 = grades(:,1);
```

Test the null hypothesis that the data comes from a normal distribution with a mean of 75 and a standard deviation of 10. Use these parameters to center and scale each element of the data vector since, by default, `kstest` tests for a standard normal distribution.

```
x = (test1-75)/10;  
h = kstest(x)
```

```
h =  
0
```

The returned value of `h = 0` indicates that `kstest` fails to reject the null hypothesis at the default 5% significance level.

Plot the empirical cumulative distribution function (cdf) and the standard normal cdf for a visual comparison.

```
[f,x_values] = ecdf(x);  
F = plot(x_values,f);  
set(F,'LineWidth',2);  
hold on;  
G = plot(x_values,normcdf(x_values,0,1),'r-');  
set(G,'LineWidth',2);  
legend([F G],...  
       'Empirical CDF', 'Standard Normal CDF',...  
       'Location', 'SE');
```

The plot shows the similarity between the empirical cdf of the centered and scaled data vector and the cdf of the standard normal distribution.

Specify the Hypothesized Distribution Using a Two-Column Matrix

Load the sample data. Create a vector containing the first column of the students' exam grades data.

```
load examgrades;  
x = grades(:,1);
```

Specify the hypothesized distribution as a two-column matrix. Column 1 contains the data vector x . Column 2 contains cdf values evaluated at each value in x for a

hypothesized Student's t distribution with a location parameter of 75, a scale parameter of 10, and one degree of freedom.

```
test_cdf = [x,cdf('tlocation',x,75,10,1)];
```

Test if the data are from the hypothesized distribution.

```
h = kstest(x, 'CDF',test_cdf)
```

```
h =  
1
```

The returned value of $h = 1$ indicates that `kstest` rejects the null hypothesis at the default 5% significance level.

Specify the Hypothesized Distribution Using a Probability Distribution Object

Load the sample data. Create a vector containing the first column of the students' exam grades data.

```
load examgrades;  
x = grades(:,1);
```

Create a probability distribution object to test if the data comes from a Student's t distribution with a location parameter of 75, a scale parameter of 10, and one degree of freedom.

```
test_cdf = makedist('tlocation','mu',75,'sigma',10,'nu',1);
```

Test the null hypothesis that the data comes from the hypothesized distribution.

```
h = kstest(x, 'CDF',test_cdf)
```

```
h =  
1
```

The returned value of $h = 1$ indicates that `kstest` rejects the null hypothesis at the default 5% significance level.

Test the Hypothesis at Different Significance Levels

Load the sample data. Create a vector containing the first column of the students' exam grades.

```
load examgrades;  
test1 = grades(:,1);
```

Create a probability distribution object to test if the data comes from a Student's t distribution with a location parameter of 75, a scale parameter of 10, and one degree of freedom.

```
test_cdf = makedist('tlocation', 'mu', 75, 'sigma', 10, 'nu', 1);
```

Test the null hypothesis that data comes from the hypothesized distribution at the 1% significance level.

```
[h,p] = kstest(x, 'CDF', test_cdf, 'Alpha', 0.01)
```

```
h =  
    1  
  
p =  
    0.0021
```

The returned value of $h = 1$ indicates that `kstest` rejects the null hypothesis at the 1% significance level.

Conduct a One-Sided Hypothesis Test

Load the sample data. Create a vector containing the third column of the stock return data matrix.

```
load stockreturns;  
x = stocks(:,3);
```

Test the null hypothesis that the data comes from a standard normal distribution, against the alternative hypothesis that the population cdf of the data is larger than the standard normal cdf.

```
[h,p,k,c] = kstest(x, 'Tail', 'larger')
```

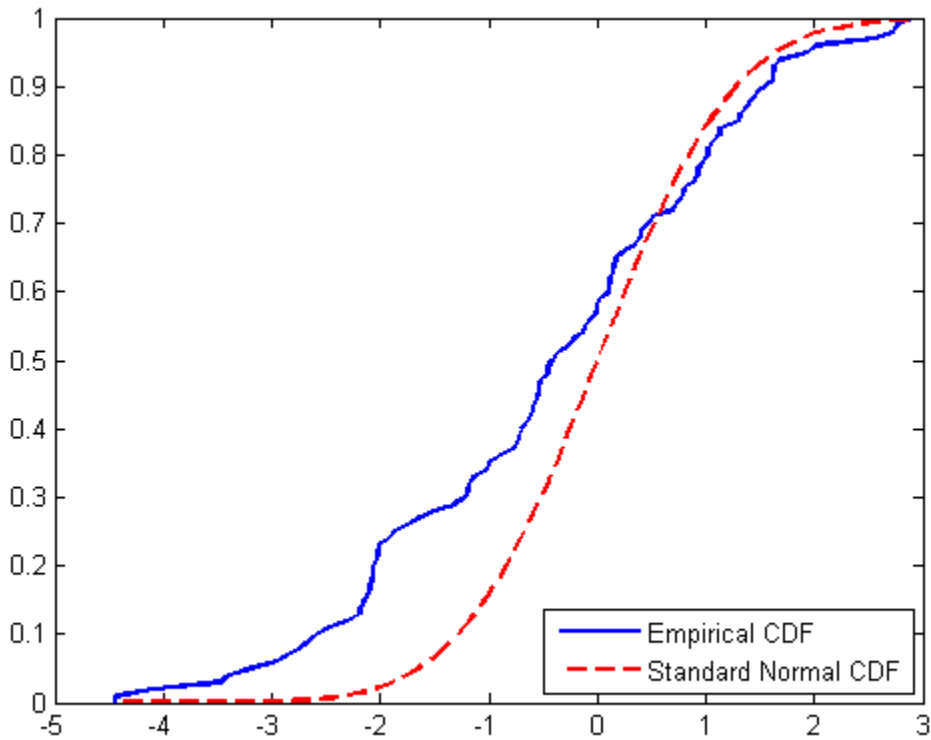

```
h =  
    1  
p =  
    5.0854e-05  
k =  
    0.2197  
c =
```

0.1207

The returned value of `h = 1` indicates that `kstest` rejects the null hypothesis in favor of the alternative hypothesis at the default 5% significance level.

Plot the empirical cdf and the standard normal cdf for a visual comparison.

```
[f,x_values] = ecdf(x);  
J = plot(x_values,f);  
hold on;  
K = plot(x_values,normcdf(x_values),'r--');  
set(J,'LineWidth',2);  
set(K,'LineWidth',2);  
legend([J K], 'Empirical CDF', 'Standard Normal CDF', 'Location', 'SE');
```

The plot shows the difference between the empirical cdf of the data vector x and the cdf of the standard normal distribution.

Input Arguments

x — Sample data

vector

Sample data, specified as a vector.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`,`Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1`,`Value1`, ..., `NameN`,`ValueN`.

Example: `'Tail', 'right', 'Alpha', 0.01` specifies a right-tailed hypothesis test at the 1% significance level.

'Alpha' — Significance level

0.05 (default) | scalar value in the range (0,1)

Significance level of the hypothesis test, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the range (0,1).

Example: `'Alpha', 0.01`

Data Types: `single` | `double`

'CDF' — cdf of hypothesized continuous distribution

matrix | probability distribution object

cdf of hypothesized continuous distribution, specified the comma-separated pair consisting of `'CDF'` and either a two-column matrix or a continuous probability distribution object. When `CDF` is a matrix, column 1 contains a set of possible x values, and column 2 contains the corresponding hypothesized cumulative distribution function values $G(x)$. The calculation is most efficient if `CDF` is specified such that column 1 contains the values in the data vector x . If there are values in x not found in column 1 of `CDF`, `kstest` approximates $G(x)$ by interpolation. All values in x must lie in the interval

between the smallest and largest values in the first column of CDF. By default, `kstest` tests for a standard normal distribution.

The one-sample Kolmogorov-Smirnov test is only valid for continuous cumulative distribution functions, and requires CDF to be predetermined. The result is not accurate if CDF is estimated from the data. To test `x` against the normal, lognormal, extreme value, Weibull, or exponential distribution without specifying distribution parameters, use `lillietest` instead.

Data Types: `single` | `double`

'Tail' — Type of alternative hypothesis

'unequal' (default) | 'larger' | 'smaller'

Type of alternative hypothesis to evaluate, specified as the comma-separated pair consisting of 'Tail' and one of the following.

'unequal'	Test the alternative hypothesis that the cdf of the population from which <code>x</code> is drawn is not equal to the cdf of the hypothesized distribution.
'larger'	Test the alternative hypothesis that the cdf of the population from which <code>x</code> is drawn is greater than the cdf of the hypothesized distribution.
'smaller'	Test the alternative hypothesis that the cdf of the population from which <code>x</code> is drawn is less than the cdf of the hypothesized distribution.

If the values in the data vector `x` tend to be larger than expected from the hypothesized distribution, the empirical distribution function of `x` tends to be smaller, and vice versa.

Example: 'Tail', 'larger'

Output Arguments

h — Hypothesis test result

1 | 0

Hypothesis test result, returned as a logical value.

- If `h = 1`, this indicates the rejection of the null hypothesis at the Alpha significance level.

- If $h = 0$, this indicates a failure to reject the null hypothesis at the Alpha significance level.

p – p-value

scalar value in the range [0,1]

p -value of the test, returned as a scalar value in the range [0,1]. p is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. Small values of p cast doubt on the validity of the null hypothesis.

ksstat – Test statistic

nonnegative scalar value

Test statistic of the hypothesis test, returned as a nonnegative scalar value.

cv – Critical value

nonnegative scalar value

Critical value, returned as a nonnegative scalar value.

More About

One-Sample Kolmogorov-Smirnov Test

The one-sample Kolmogorov-Smirnov test is a nonparametric test of the null hypothesis that the population cdf of the data is equal to the hypothesized cdf.

The two-sided test for “unequal” cdf functions tests the null hypothesis against the alternative that the population cdf of the data is not equal to the hypothesized cdf. The test statistic is the maximum absolute difference between the empirical cdf calculated from x and the hypothesized cdf:

$$D^* = \max_x \left(\left| \hat{F}(x) - G(x) \right| \right),$$

where $\hat{F}(x)$ is the empirical cdf and $G(x)$ is the cdf of the hypothesized distribution.

The one-sided test for a “larger” cdf function tests the null hypothesis against the alternative that the population cdf of the data is greater than the hypothesized cdf.

The test statistic is the maximum amount by which the empirical cdf calculated from x exceeds the hypothesized cdf:

$$D^* = \max_x \left(\hat{F}(x) - G(x) \right).$$

The one-sided test for a “smaller” cdf function tests the null hypothesis against the alternative that the population cdf of the data is less than the hypothesized cdf. The test statistic is the maximum amount by which the hypothesized cdf exceeds the empirical cdf calculated from x :

$$D^* = \max_x \left(G(x) - \hat{F}(x) \right).$$

`kstest` computes the critical value `cv` using an approximate formula or by interpolation in a table. The formula and table cover the range $0.01 \leq \text{alpha} \leq 0.2$ for two-sided tests and $0.005 \leq \text{alpha} \leq 0.1$ for one-sided tests. `cv` is returned as `NaN` if `alpha` is outside this range.

Algorithms

`kstest` decides to reject the null hypothesis by comparing the p -value `p` with the significance level `Alpha`, not by comparing the test statistic `ksstat` with the critical value `cv`. Since `cv` is approximate, comparing `ksstat` with `cv` occasionally leads to a different conclusion than comparing `p` with `Alpha`.

`adtest` | `kstest2` | `lillietest`

kstest2

Two-sample Kolmogorov-Smirnov test

Syntax

```
h = kstest2(x1,x2)
h = kstest2(x1,x2,Name,Value)
[h,p] = kstest2(____)
[h,p,ks2stat] = kstest2(____)
```

Description

`h = kstest2(x1,x2)` returns a test decision for the null hypothesis that the data in vectors `x1` and `x2` are from the same continuous distribution, using the two-sample Kolmogorov-Smirnov test. The alternative hypothesis is that `x1` and `x2` are from different continuous distributions. The result `h` is 1 if the test rejects the null hypothesis at the 5% significance level, and 0 otherwise.

`h = kstest2(x1,x2,Name,Value)` returns a test decision for a two-sample Kolmogorov-Smirnov test with additional options specified by one or more name-value pair arguments. For example, you can change the significance level or conduct a one-sided test.

`[h,p] = kstest2(____)` also returns the asymptotic p -value `p`, using any of the input arguments from the previous syntaxes.

`[h,p,ks2stat] = kstest2(____)` also returns the test statistic `ks2stat`.

Examples

Test Two Samples for the Same Distribution

Generate sample data from two different Weibull distributions.

```
rng(1); % For reproducibility
x1 = wblrnd(1,1,1,50);
x2 = wblrnd(1.2,2,1,50);
```

Test the null hypothesis that data in vectors `x1` and `x2` comes from populations with the same distribution.

```
h = kstest2(x1,x2)
```

```
h =  
1
```

The returned value of `h = 1` indicates that `kstest` rejects the null hypothesis at the default 5% significance level.

Test the Hypothesis at Different Significance Levels

Generate sample data from two different Weibull distributions.

```
rng(1); % For reproducibility  
x1 = wblrnd(1,1,1,50);  
x2 = wblrnd(1.2,2,1,50);
```

Test the null hypothesis that data vectors `x1` and `x2` are from populations with the same distribution at the 1% significance level.

```
[h,p] = kstest2(x1,x2,'Alpha',0.01)
```

```
h =  
0  
p =  
0.0317
```

The returned value of `h = 0` indicates that `kstest` does not reject the null hypothesis at the 1% significance level.

One-Sided Hypothesis Test

Generate sample data from two different Weibull distributions.

```
rng(1); % For reproducibility  
x1 = wblrnd(1,1,1,50);  
x2 = wblrnd(1.2,2,1,50);
```

Test the null hypothesis that data in vectors `x1` and `x2` comes from populations with the same distribution, against the alternative hypothesis that the cdf of the distribution of `x1` is larger than the cdf of the distribution of `x2`.

```
[h,p,k] = kstest2(x1,x2,'Tail','larger')
```

```
h =  
    1  
p =  
    0.0158  
k =  
    0.2800
```

The returned value of `h = 1` indicates that `kstest` rejects the null hypothesis, in favor of the alternative hypothesis that the cdf of the distribution of `x1` is larger than the cdf of the distribution of `x2`, at the default 5% significance level. The returned value of `k` is the test statistic for the two-sample Kolmogorov-Smirnov test.

Input Arguments

x1 — Sample data

vector

Sample data from the first sample, specified as a vector. Data vectors `x1` and `x2` do not need to be the same size.

Data Types: `single` | `double`

x2 — Sample data

vector

Sample data from the second sample, specified as a vector. Data vectors `x1` and `x2` do not need to be the same size.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1, ..., NameN,ValueN`.

Example:

'A1pha' — Significance level

`0.05` (default) | scalar value in the range (0,1)

Significance level of the hypothesis test, specified as the comma-separated pair consisting of 'Alpha' and a scalar value in the range (0,1).

Example: 'Alpha',0.01

Data Types: single | double

'Tail' — Type of alternative hypothesis

'unequal' (default) | 'larger' | 'smaller'

Type of alternative hypothesis to evaluate, specified as the comma-separated pair consisting of 'Tail' and one of the following.

- | | |
|-----------|---|
| 'unequal' | Test the alternative hypothesis that the empirical cdf of x1 is unequal to the empirical cdf of x2. |
| 'larger' | Test the alternative hypothesis that the empirical cdf of x1 is larger than the empirical cdf of x2. |
| 'smaller' | Test the alternative hypothesis that the empirical cdf of x1 is smaller than the empirical cdf of x2. |

If the data values in x1 tend to be larger than those in x2, the empirical distribution function of x1 tends to be smaller than that of x2, and vice versa.

Example: 'Tail','larger'

Output Arguments

h — Hypothesis test result

1 | 0

Hypothesis test result, returned as a logical value.

- If $h = 1$, this indicates the rejection of the null hypothesis at the Alpha significance level.
- If $h = 0$, this indicates a failure to reject the null hypothesis at the Alpha significance level.

p — Asymptotic p-value

scalar value in the range (0,1)

Asymptotic p -value of the test, returned as a scalar value in the range (0,1). p is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. The asymptotic p -value becomes very accurate for large sample sizes, and is believed to be reasonably accurate for sample sizes n_1 and n_2 , such that $(n_1 * n_2) / (n_1 + n_2) \geq 4$.

ks2stat — Test statistic

nonnegative scalar value

Test statistic, returned as a nonnegative scalar value.

More About

Two-Sample Kolmogorov-Smirnov Test

The two-sample Kolmogorov-Smirnov test is a nonparametric hypothesis test that evaluates the difference between the cdfs of the distributions of the two sample data vectors over the range of x in each data set.

The two-sided test uses the maximum absolute difference between the cdfs of the distributions of the two data vectors. The test statistic is

$$D^* = \max_x \left(\left| F_1(x) - F_2(x) \right| \right),$$

where $\hat{F}_1(x)$ is the proportion of x_1 values less than or equal to x and $\hat{F}_2(x)$ is the proportion of x_2 values less than or equal to x .

The one-sided test uses the actual value of the difference between the cdfs of the distributions of the two data vectors rather than the absolute value. The test statistic is

$$D^* = \max_x \left(F_1(x) - F_2(x) \right).$$

Algorithms

In `kstest2`, the decision to reject the null hypothesis is based on comparing the p -value p with the significance level Alpha , not by comparing the test statistic `ks2stat` with a critical value.

adtest | kstest | lillietest

kurtosis

Kurtosis

Syntax

```
k = kurtosis(X)
k = kurtosis(X,flag)
k = kurtosis(X,flag,dim)
```

Description

`k = kurtosis(X)` returns the sample kurtosis of `X`. For vectors, `kurtosis(x)` is the kurtosis of the elements in the vector `x`. For matrices `kurtosis(X)` returns the sample kurtosis for each column of `X`. For `N`-dimensional arrays, `kurtosis` operates along the first nonsingleton dimension of `X`.

`k = kurtosis(X,flag)` specifies whether to correct for bias (`flag` is 0) or not (`flag` is 1, the default). When `X` represents a sample from a population, the kurtosis of `X` is biased, that is, it will tend to differ from the population kurtosis by a systematic amount that depends on the size of the sample. You can set `flag` to 0 to correct for this systematic bias.

`k = kurtosis(X,flag,dim)` takes the kurtosis along dimension `dim` of `X`.

`kurtosis` treats NaNs as missing values and removes them.

Examples

```
X = randn([5 4])
X =
    1.1650    1.6961   -1.4462   -0.3600
    0.6268    0.0591   -0.7012   -0.1356
    0.0751    1.7971    1.2460   -1.3493
    0.3516    0.2641   -0.6390   -1.2704
   -0.6965    0.8717    0.5774    0.9846
```

```
k = kurtosis(X)
k =
    2.1658    1.2967    1.6378    1.9589
```

More About

Algorithms

Kurtosis is a measure of how outlier-prone a distribution is. The kurtosis of the normal distribution is 3. Distributions that are more outlier-prone than the normal distribution have kurtosis greater than 3; distributions that are less outlier-prone have kurtosis less than 3.

The kurtosis of a distribution is defined as

$$k = \frac{E(x - \mu)^4}{\sigma^4}$$

where μ is the mean of x , σ is the standard deviation of x , and $E(t)$ represents the expected value of the quantity t . `kurtosis` computes a sample version of this population value.

Note Some definitions of kurtosis subtract 3 from the computed value, so that the normal distribution has kurtosis of 0. The `kurtosis` function does not use this convention.

When you set `flag` to 1, the following equation applies:

$$k_1 = \frac{\frac{1}{n} \sum_{i=1}^n (x_i - \bar{x})^4}{\left(\frac{1}{n} \sum_{i=1}^n (x_i - \bar{x})^2 \right)^2}$$

When you set `flag` to 0, the following equation applies:

$$k_0 = \frac{n-1}{(n-2)(n-3)}((n+1)k_1 - 3(n-1)) + 3$$

This bias-corrected formula requires that X contain at least four elements.

lasso

Regularized least-squares regression using lasso or elastic net algorithms

Syntax

```
B = lasso(X,Y)
[B,FitInfo] = lasso(X,Y)
[B,FitInfo] = lasso(X,Y,Name,Value)
```

Description

`B = lasso(X,Y)` returns fitted least-squares regression coefficients for a set of regularization coefficients `Lambda`.

`[B,FitInfo] = lasso(X,Y)` returns a structure containing information about the fits.

`[B,FitInfo] = lasso(X,Y,Name,Value)` fits regularized regressions with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

X

Numeric matrix with `n` rows and `p` columns. Each row represents one observation, and each column represents one predictor (variable).

Y

Numeric vector of length `n`, where `n` is the number of rows of `X`. `Y(i)` is the response to row `i` of `X`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single

quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

'Alpha'

Scalar value from 0 to 1 (excluding 0) representing the weight of lasso (L^1) versus ridge (L^2) optimization. Alpha = 1 represents lasso regression, Alpha close to 0 approaches ridge regression, and other values represent elastic net optimization. See “Definitions” on page 21- .

Default: 1

'CV'

Method `lasso` uses to estimate mean squared error:

- K, a positive integer — `lasso` uses K-fold cross validation.
- `cvp`, a `cvpartition` object — `lasso` uses the cross-validation method expressed in `cvp`. You cannot use a 'leaveout' partition with `lasso`.
- 'resubstitution' — `lasso` uses X and Y to fit the model and to estimate the mean squared error, without cross validation.

Default: 'resubstitution'

'DFmax'

Maximum number of nonzero coefficients in the model. `lasso` returns results only for Lambda values that satisfy this criterion.

Default: Inf

'Lambda'

Vector of nonnegative Lambda values. See “Definitions” on page 21- .

- If you do not supply Lambda, `lasso` calculates the largest value of Lambda that gives a nonnull model. In this case, `LambdaRatio` gives the ratio of the smallest to the largest value of the sequence, and `NumLambda` gives the length of the vector.
- If you supply Lambda, `lasso` ignores `LambdaRatio` and `NumLambda`.

Default: Geometric sequence of `NumLambda` values, the largest just sufficient to produce $B = 0$

'LambdaRatio'

Positive scalar, the ratio of the smallest to the largest `Lambda` value when you do not set `Lambda`.

If you set `LambdaRatio = 0`, `lasso` generates a default sequence of `Lambda` values, and replaces the smallest one with 0.

Default: 1e-4

'MCReps'

Positive integer, the number of Monte Carlo repetitions for cross validation.

- If CV is 'resubstitution' or a `cvpartition` of type 'resubstitution', `MCReps` must be 1.
- If CV is a `cvpartition` of type 'holdout', `MCReps` must be greater than 1.

Default: 1

'NumLambda'

Positive integer, the number of `Lambda` values `lasso` uses when you do not set `Lambda`. `lasso` can return fewer than `NumLambda` fits if the residual error of the fits drops below a threshold fraction of the variance of `Y`.

Default: 100

'Options'

Structure that specifies whether to cross validate in parallel, and specifies the random stream or streams. Create the `Options` structure with `statset`. Option fields:

- `UseParallel` — Set to `true` to compute in parallel. Default is `false`.
- `UseSubstreams` — Set to `true` to compute in parallel in a reproducible fashion. To compute reproducibly, set `Streams` to a type allowing substreams: 'mlfg6331_64' or 'mrg32k3a'. Default is `false`.

- **Streams** — A `RandStream` object or cell array consisting of one such object. If you do not specify `Streams`, `lasso` uses the default stream.

'PredictorNames'

Cell array of strings representing names of the predictor variables, in the order in which they appear in `X`.

Default: {}

'RelTol'

Convergence threshold for the coordinate descent algorithm (see Friedman, Tibshirani, and Hastie [3]). The algorithm terminates when successive estimates of the coefficient vector differ in the L^2 norm by a relative amount less than `RelTol`.

Default: 1e-4

'Standardize'

Boolean value specifying whether `lasso` scales `X` before fitting the models.

Default: true

'Weights'

Observation weights, a nonnegative vector of length `n`, where `n` is the number of rows of `X`. `lasso` scales `Weights` to sum to 1.

Default: 1/n * ones(n,1)

Output Arguments

B

Fitted coefficients, a `p`-by-`L` matrix, where `p` is the number of predictors (columns) in `X`, and `L` is the number of `Lambda` values.

FitInfo

Structure containing information about the model fits.

Field in FitInfo	Description
Intercept	Intercept term β_0 for each linear model, a 1-by-L vector
Lambda	Lambda parameters in ascending order, a 1-by-L vector
Alpha	Value of Alpha parameter, a scalar
DF	Number of nonzero coefficients in B for each value of Lambda, a 1-by-L vector
MSE	Mean squared error (MSE), a 1-by-L vector

If you set the CV name-value pair to cross validate, the `FitInfo` structure contains additional fields.

Field in FitInfo	Description
SE	The standard error of MSE for each Lambda, as calculated during cross validation, a 1-by-L vector
LambdaMinMSE	The Lambda value with minimum MSE, a scalar
Lambda1SE	The largest Lambda such that MSE is within one standard error of the minimum, a scalar
IndexMinMSE	The index of Lambda with value LambdaMinMSE, a scalar
Index1SE	The index of Lambda with value Lambda1SE, a scalar

Examples

Remove Redundant Predictors

Construct a data set with redundant predictors, and identify those predictors using cross-validated lasso.

Create a matrix X of 100 five-dimensional normal variables and a response vector Y from just two components of X, with small added noise.

```
X = randn(100,5);
r = [0;2;0;-3;0]; % only two nonzero coefficients
Y = X*r + randn(100,1)*.1; % small added noise
```

Construct the default lasso fit.

```
B = lasso(X,Y);
```

Find the coefficient vector for the 25th value in B.

```
B(:,25)
```

```
ans =
```

```

         0
    1.6093
         0
   -2.5865
         0

```

lasso identifies and removes the redundant predictors.

Plot a Regularized Fit with Cross Validation

Visually examine the cross-validated error of various levels of regularization.

Load the acetylene data and prepare the data with interactions for fitting.

```
load acetylene
Xs = [x1 x2 x3];
X = x2fx(Xs, 'interaction');
X(:,1) = []; % No constant term
```

Construct the lasso fit using ten-fold cross validation. Include the FitInfo output so you can plot the result.

```
[B FitInfo] = lasso(X,y, 'CV', 10);
```

Plot the cross-validated fits.

```
lassoPlot(B,FitInfo, 'PlotType', 'CV');
```

More About

Lasso

For a given value of λ , a nonnegative parameter, **lasso** solves the problem

$$\min_{\beta_0, \beta} \left(\frac{1}{2N} \sum_{i=1}^N (y_i - \beta_0 - x_i^T \beta)^2 + \lambda \sum_{j=1}^p |\beta_j| \right),$$

where

- N is the number of observations.
- y_i is the response at observation i .

- x_i is data, a vector of p values at observation i .
- λ is a nonnegative regularization parameter corresponding to one value of Λ .
- The parameters β_0 and β are scalar and p -vector respectively.

As λ increases, the number of nonzero components of β decreases.

The lasso problem involves the L^1 norm of β , as contrasted with the elastic net algorithm.

Elastic Net

For an α strictly between 0 and 1, and a nonnegative λ , elastic net solves the problem

$$\min_{\beta_0, \beta} \left(\frac{1}{2N} \sum_{i=1}^N (y_i - \beta_0 - x_i^T \beta)^2 + \lambda P_\alpha(\beta) \right),$$

where

$$P_\alpha(\beta) = \frac{(1-\alpha)}{2} \|\beta\|_2^2 + \alpha \|\beta\|_1 = \sum_{j=1}^p \left(\frac{(1-\alpha)}{2} \beta_j^2 + \alpha |\beta_j| \right).$$

Elastic net is the same as lasso when $\alpha = 1$. As α shrinks toward 0, elastic net approaches ridge regression. For other values of α , the penalty term $P_\alpha(\beta)$ interpolates between the L^1 norm of β and the squared L^2 norm of β .

lassoPlot | ridge

lassoglm

Lasso or elastic net regularization for generalized linear model regression

Syntax

```
B = lassoglm(X,Y)
[B,FitInfo] = lassoglm(X,Y)
[B,FitInfo] = lassoglm(X,Y,distr)
[B,FitInfo] = lassoglm(X,Y,distr,Name,Value)
```

Description

`B = lassoglm(X,Y)` returns penalized maximum-likelihood fitted coefficients for a generalized linear model of the response `Y` to the data matrix `X`. `Y` are assumed to have a Gaussian probability distribution.

`[B,FitInfo] = lassoglm(X,Y)` returns a structure containing information about the fits.

`[B,FitInfo] = lassoglm(X,Y,distr)` fits the model using the probability distribution type for `Y` as specified in `distr`.

`[B,FitInfo] = lassoglm(X,Y,distr,Name,Value)` fits regularized generalized linear regressions with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

X

Numeric matrix with `n` rows and `p` columns. Each row represents one observation, and each column represents one predictor (variable).

Y

When `distr` is not `'binomial'`, `Y` is a numeric vector or categorical array of length `n`, where `n` is the number of rows of `X`. `Y(i)` is the response to row `i` of `X`.

When `distr` is 'binomial', Y is either a:

- Numeric vector of length n , where each entry represents success (1) or failure (0)
- Logical vector of length n , where each entry represents success or failure
- Categorical array of length n , where each entry represents success or failure
- Two column numeric matrix, where the first column contains the number of successes for each observation, and the second column contains the total number of trials

distr

Distributional family for the nonsystematic variation in the responses, a string. Choices:

- 'normal'
- 'binomial'
- 'poisson'
- 'gamma'
- 'inverse gaussian'

By default, `lassoglm` uses the canonical link function corresponding to `distr`. Specify another link function using the 'link' name-value pair.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

'Alpha'

Scalar value from 0 to 1 (excluding 0) representing the weight of lasso (L^1) versus ridge (L^2) optimization. Alpha = 1 represents lasso regression, and other values represent elastic net optimization. Alpha close to 0 approaches ridge regression. See “Definitions” on page 21- .

Default: 1

'CV'

Method `lassoglm` uses to estimate deviance:

- `K`, a positive integer — `lassoglm` uses `K`-fold cross validation.
- `cvp`, a `cvpartition` object — `lassoglm` uses the cross-validation method expressed in `cvp`. You cannot use a 'leaveout' partition with `lassoglm`.
- 'resubstitution' — `lassoglm` uses `X` and `Y` to fit the model and to estimate the deviance, without cross validation.

Default: 'resubstitution'

'DFmax'

Maximum number of nonzero coefficients in the model. `lassoglm` returns results for Lambda values that satisfy this criterion.

Default: Inf

'Lambda'

Vector of nonnegative Lambda values. See “Lasso” on page 21-2260.

- If you do not supply `Lambda`, `lassoglm` estimates the largest value of `Lambda` that gives a nonnull model. In this case, `LambdaRatio` gives the ratio of the smallest to the largest value of the sequence, and `NumLambda` gives the length of the vector.
- If you supply `Lambda`, `lassoglm` ignores `LambdaRatio` and `NumLambda`.

Default: Geometric sequence of `NumLambda` values, the largest just sufficient to produce `B = 0`

'LambdaRatio'

Positive scalar, the ratio of the smallest to the largest Lambda value when you do not explicitly set `Lambda`.

If you set `LambdaRatio = 0`, `lassoglm` generates a default sequence of `Lambda` values, and replaces the smallest one with 0.

Default: 1e-4

'Link'

Specify the mapping between the mean μ of the response and the linear predictor Xb .

Value	Description
'comploglog'	$\log(-\log((1-\mu))) = Xb$
'identity', default for the distribution 'normal'	$\mu = Xb$
'log', default for the distribution 'poisson'	$\log(\mu) = Xb$
'logit', default for the distribution 'binomial'	$\log(\mu/(1-\mu)) = Xb$
'loglog'	$\log(-\log(\mu)) = Xb$
'probit'	$\Phi^{-1}(\mu) = Xb$, where Φ is the normal (Gaussian) CDF function
'reciprocal', default for the distribution 'gamma'	$\mu^{-1} = Xb$
p (a number), default for the distribution 'inverse gaussian' (with $p = -2$)	$\mu^p = Xb$
Cell array of the form {FL FD FI}, containing three function handles, created using @, that define the link (FL), the derivative of the link (FD), and the inverse link (FI). Equivalently, can be a structure of function handles with field Link containing FL, field Derivative containing FD, and field Inverse containing FI.	User-specified link function (see “Custom Link Function” on page 10-16)

'MCReps'

Positive integer, the number of Monte Carlo repetitions for cross validation.

- If CV is 'resubstitution' or a cvpartition of type 'resubstitution', MCReps must be 1.
- If CV is a cvpartition of type 'holdout', MCReps must be greater than 1.

Default: 1

'NumLambda'

Positive integer, the number of Lambda values `lassoglm` uses when you do not set Lambda. `lassoglm` can return fewer than `NumLambda` fits if the deviance of the fits drops below a threshold fraction of the null deviance (deviance of the fit without any predictors X).

Default: 100

'Offset'

Numeric vector with the same number of rows as X. `lassoglm` uses `Offset` as an additional predictor variable, but keeps its coefficient value fixed at 1.0.

'Options'

Structure that specifies whether to cross validate in parallel, and specifies the random stream or streams. Create the `Options` structure with `statset`. Option fields:

- `UseParallel` — Set to `true` to compute in parallel. Default is `false`.
- `UseSubstreams` — Set to `true` to compute in parallel in a reproducible fashion. To compute reproducibly, set `Streams` to a type allowing substreams: `'mlfg6331_64'` or `'mrg32k3a'`. Default is `false`.
- `Streams` — `RandStream` object or cell array consisting of one such object. If you do not specify `Streams`, `lassoglm` uses the default stream.

'PredictorNames'

Cell array of strings representing names of the predictor variables, in the order in which they appear in X.

Default: {}

'RelTol'

Convergence threshold for the coordinate descent algorithm (see Friedman, Tibshirani, and Hastie [3]). The algorithm terminates when successive estimates of the coefficient vector differ in the L^2 norm by a relative amount less than `RelTol`.

Default: 1e-4

'Standardize'

Boolean value specifying whether `lassoglm` scales X before fitting the models.

Default: `true`

'Weights'

Observation weights, a nonnegative vector of length `n`, where `n` is the number of rows of X. At least two values must be positive.

Default: `1/n * ones(n,1)`

Output Arguments

B

Fitted coefficients, a `p`-by-`L` matrix, where `p` is the number of predictors (columns) in X, and `L` is the number of Lambda values.

FitInfo

Structure containing information about the model fits.

Field in FitInfo	Description
Alpha	Value of Alpha parameter, a scalar.
Deviance	Deviance of the fitted model for each value of Lambda, a 1-by-L vector. If cross validation was performed, the values for Deviance represent the estimated expected deviance of the model applied to new data, as calculated by cross validation. Otherwise, Deviance is the deviance of the fitted model applied to the data used to perform the fit.
DF	Number of nonzero coefficients in B for each Lambda value, a 1-by-L vector.
Intercept	Intercept term β_0 for each linear model, a 1-by-L vector.

Field in FitInfo	Description
Lambda	Lambda parameters in ascending order, a 1-by-L vector.

If you set the CV name-value pair to cross validate, the `FitInfo` structure contains additional fields.

Field in FitInfo	Description
IndexMinDeviance	Index of Lambda with value LambdaMinDeviance, a scalar.
Index1SE	Index of Lambda with value Lambda1SE, a scalar.
LambdaMinDeviance	Lambda value with minimum expected deviance, as calculated by cross validation, a scalar.
Lambda1SE	Largest Lambda such that Deviance is within one standard error of the minimum, a scalar.
SE	Standard error of Deviance for each Lambda, as calculated during cross validation, a 1-by-L vector.

Examples

Lasso Regularization of a Generalized Linear Model

Construct data from a Poisson model, and identify the important predictors using `lassoglm`.

Create data with 20 predictors, and Poisson responses using just three of the predictors, plus a constant.

```
rng('default') % for reproducibility
X = randn(100,20);
mu = exp(X(:,[5 10 15])*[.4;.2;.3] + 1);
y = poissrnd(mu);
```

Construct a cross-validated lasso regularization of a Poisson regression model of the data.

```
[B FitInfo] = lassoglm(X,y, 'poisson', 'CV', 10);
```

Examine the cross-validation plot to see the effect of the `Lambda` regularization parameter.

```
lassoPlot(B,FitInfo,'plottype','CV');
```

The green circle and dashed line locate the Lambda with minimal cross-validation error. The blue circle and dashed line locate the point with minimal cross-validation error plus one standard deviation.

Find the nonzero model coefficients corresponding to the two identified points.

```
minpts = find(B(:,FitInfo.IndexMinDeviance))
```

```
minpts =
```

```
3
5
```

```

6
10
11
15
16

min1pts = find(B(:,FitInfo.Index1SE))

min1pts =

5
10
15

```

The coefficients from the minimal plus one standard error point are exactly those coefficients used to create the data.

More About

Link Function

A link function $f(\mu)$ maps a distribution with mean μ to a linear model with data X and coefficient vector b using the formula

$$f(\mu) = Xb.$$

Find the formulas for the link functions in the `Link` name-value pair description. Here, “typical” means a link function that is typically used for the listed distribution.

Distributional Family	Link Function (typical, {default})
'normal'	{'identity'}
'binomial'	'comploglog', 'loglog', 'probit', {'logit'}
'poisson'	{'log'}
'gamma'	{'reciprocal'}
'inverse gaussian'	{-2}

Lasso

For a nonnegative value of λ , **lasso** solves the problem

$$\min_{\beta_0, \beta} \left(\frac{1}{N} \text{Deviance}(\beta_0, \beta) + \lambda \sum_{j=1}^p |\beta_j| \right),$$

where

- Deviance is the deviance of the model fit to the responses using intercept β_0 and predictor coefficients β . The formula for Deviance depends on the **distr** parameter you supply to **lasso**. Minimizing the λ -penalized deviance is equivalent to maximizing the λ -penalized log likelihood.
- N is the number of observations.
- λ is a nonnegative regularization parameter corresponding to one value of Lambda.
- Parameters β_0 and β are scalar and p -vector respectively.

As λ increases, the number of nonzero components of β decreases.

The lasso problem involves the L^1 norm of β , as contrasted with the elastic net algorithm.

Elastic Net

For an α strictly between 0 and 1, and a nonnegative λ , elastic net solves the problem

$$\min_{\beta_0, \beta} \left(\frac{1}{N} \text{Deviance}(\beta_0, \beta) + \lambda P_\alpha(\beta) \right),$$

where

$$P_\alpha(\beta) = \frac{(1-\alpha)}{2} \|\beta\|_2^2 + \alpha \|\beta\|_1 = \sum_{j=1}^p \left(\frac{(1-\alpha)}{2} \beta_j^2 + \alpha |\beta_j| \right).$$

Elastic net is the same as lasso when $\alpha = 1$. For other values of α , the penalty term $P_\alpha(\beta)$ interpolates between the L^1 norm of β and the squared L^2 norm of β . As α shrinks toward 0, elastic net approaches **ridge** regression.

lassoPlot

Trace plot of lasso fit

Syntax

```
ax = lassoPlot(B)
ax = lassoPlot(B,FitInfo)
ax = lassoPlot(B,FitInfo,Name,Value)
[ax,figh] = lassoPlot(B,...)
```

Description

`ax = lassoPlot(B)` creates a trace plot of the values in **B** against the L^1 norm of **B**. `ax` is a handle to the plot axis.

`ax = lassoPlot(B,FitInfo)` creates a plot with type depending on the data type of `FitInfo` and the value, if any, of the `PlotType` name-value pair.

`ax = lassoPlot(B,FitInfo,Name,Value)` creates a plot with additional options specified by one or more `Name,Value` pair arguments.

`[ax,figh] = lassoPlot(B,...)` returns a handle to the figure window.

Input Arguments

B

Coefficients of a sequence of regression fits, as returned from the `lasso` or `lassoglm` functions. **B** is a `p`-by-`NLambda` matrix, where `p` is the number of predictors, and each column of **B** is a set of coefficients `lasso` calculates using one `Lambda` penalty value.

FitInfo

Information controlling the plot:

- `FitInfo` is a structure, especially as returned from `lasso` or `lassoglm` — `lassoPlot` creates a plot based on the `PlotType` name-value pair.

- `FitInfo` is a vector — `lassoPlot` forms the x -axis of the plot from the values in `FitInfo`. The length of `FitInfo` must equal the number of columns of `B`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1, . . . ,NameN,ValueN`.

'Parent'

Axis in which to draw the plot.

Default: New plot

'PlotType'

Choose the plot type when you give a `FitInfo` vector or structure:

FitInfo Type	PlotType	Plot
Vector or Structure	'L1'	<code>plotLasso</code> creates the x -axis from the L^1 norm of the coefficients in <code>B</code> . The x -axis at the top of the plot contains the degrees of freedom (df), meaning the number of nonzero coefficients of <code>B</code> .
Structure	'Lambda'	<code>plotLasso</code> creates the x -axis from the <code>Lambda</code> field of <code>FitInfo</code> . The x -axis at the top of the plot contains the degrees of freedom (df), meaning the number of nonzero coefficients of <code>B</code> .
Cross-Validated Structure	'CV'	<ul style="list-style-type: none"> • For each <code>Lambda</code>, plots an estimate of the mean squared prediction error on new data for the model fitted by <code>lasso</code> with that value of <code>Lambda</code>. • Plots error bars for the estimates. • Plots the value of <code>Lambda</code> with minimum cross-validated MSE. • Plots the greatest <code>Lambda</code> that is within one standard error of minimum MSE (so makes the sparsest model within that region).

Default: 'L1'

'PredictorNames'

Cell array of strings to label each coefficient of **B**. If the length of **PredictorNames** is less than the number of rows of **B**, the remaining labels are padded with default values.

`lassoPlot` uses the predictor names in `FitInfo` only if:

- You created `FitInfo` with a call to `lasso` that included a `PredictorNames` name-value pair.
- You call `lassoPlot` *without* a `PredictorNames` name-value pair.
- You include `FitInfo` in your `lassoPlot` call.

Default: {'B1', 'B2', ...}

'XScale'

- 'linear' for linear x-axis
- 'log' for logarithmic scaled x-axis

Default: 'linear', except 'log' for the 'CV' plot type

Output Arguments

ax

Handle to the axis of the plot (see “Coordinate System”).

figh

Handle to the figure window (see “Special Object Identifiers”).

Examples

Lasso Plot with Default Plot Type

Load the sample data

```
load acetylene
```

Prepare the design matrix for lasso fit with interactions.

```
X = [x1 x2 x3];
D = x2fx(X, 'interaction');
D(:,1) = []; % No constant term
```

Fit a regularized model of the data using `lasso` .

```
B = lasso(D,y);
```

Plot the fits with the default plot type.

```
lassoPlot(B);
```

Lasso Plot with Lambda Plot Type

Load the sample data.

```
load acetylene
```

Prepare the data for lasso fit with interactions.

```
X = [x1 x2 x3];  
D = x2fx(X, 'interaction');  
D(:,1) = []; % No constant term
```

Fit a regularized model of the data with lasso .

```
[B FitInfo] = lasso(D,y);
```

Plot the fits with the Lambda plot type and logarithmic scaling.

```
lassoPlot(B,FitInfo, 'PlotType', 'Lambda', 'XScale', 'log');
```

Lasso Plot with Cross-Validated Fits

Load the sample data.

```
load acetylene
```

Prepare the design matrix for a lasso fit with interactions.

```
X = [x1 x2 x3];
D = x2fx(X, 'interaction');
D(:,1) = []; % No constant term
```

Fit a regularized model of the data with lasso and cross validation.

```
[B FitInfo] = lasso(D,y,'CV',10);
```

Plot the cross-validated fits.

```
lassoPlot(B,FitInfo, 'PlotType', 'CV');
```

le

Class: grandstream

Less than or equal relation for handles

Syntax

`h1 <= h2`

Description

Handles are equal if they are handles for the same object. All comparisons use a number associated with each handle object. Nothing can be assumed about the result of a handle comparison except that the repeated comparison of two handles in the same MATLAB session will yield the same result. The order of handle values is purely arbitrary and has no connection to the state of the handle objects being compared.

`h1 <= h2` performs element-wise comparisons between handle arrays `h1` and `h2`. `h1` and `h2` must be of the same dimensions unless one is a scalar. The result is a logical array of the same dimensions, where each element is an element-wise `<=` result.

If one of `h1` or `h2` is scalar, scalar expansion is performed and the result will match the dimensions of the array that is not scalar.

`tf = le(h1, h2)` stores the result in a logical array of the same dimensions.

See Also

`grandstream` | `ge` | `gt` | `ne` | `eq` | `lt`

Leap property

Class: grandset

Interval between points

Description

Number of points to leap over and omit for each point taken from the sequence. The **Leap** property of a point set contains a positive integer which specifies the number of points in the sequence to leap over and omit for every point taken. The default **Leap** value is 0, which corresponds to taking every point from the sequence.

Leaping is a technique used to improve the quality of a point set. However, you must choose the **Leap** values with care; many **Leap** values create sequences that fail to touch on large sub-hyper-rectangles of the unit hypercube, and so fail to be a uniform quasi-random point set.

Choosing Leap Values for Halton Sets

A known rule for choosing **Leap** values for Halton sets is to set it to $(P-1)$ where P is a prime number that has not been used to generate one of the dimensions, i.e. for a k -dimensional point set P would be the $(k+1)$ th or greater prime.

Examples

Experiment with different leap values:

```
% No leaping produces the standard Halton sequence.
```

```
P = haltonset(5);
```

```
P(1:5,:)
```

```
% Set a leap of 1. The point set now includes every other
```

```
% point from the sequence.
```

```
P.Lean = 1;
```

```
P(1:5,:)
```

See Also

net | grandset | subsref | haltonset | Skip

length

Class: dataset

Length of dataset array

Compatibility

The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

Syntax

`n = length(A)`

Description

`n = length(A)` returns the number of observations in the dataset A. `length` is equivalent to `size(A,1)`.

See Also

`size`

length

Class: grandset

Length of point set

Syntax

`length(p)`

Description

`length(p)` returns the number of points in the point set `p`. It is equivalent to `size(p, 1)`.

See Also

`grandset` | `size`

levelcounts

Element counts by level of a nominal or ordinal array

Compatibility

The `nominal` and `ordinal` array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the MATLAB categorical data type instead.

Syntax

```
C = levelcounts(A)
C = levelcounts(A,dim)
```

Description

`C = levelcounts(A)` returns counts of the number of elements in the nominal or ordinal array `A` equal to each of the possible levels in `A` into the vector `C`, which has as many elements as `A` has levels.

- If `A` is a matrix, then `C` is a matrix of column counts.
- If `A` is an N -dimensional array, `levelcounts` operates along the first nonsingleton dimension.

`C = levelcounts(A,dim)` operates along the dimension `dim`.

Examples

Count Observations in Each Level

Create a nominal array from string data in a cell array.

```
colors = nominal({'r','b','g'; 'g','r','b'; 'b','r','g'},...
                 {'blue','green','red'})
```

```
colors =  
  red     blue     green  
  green   red      blue  
  blue    red      green
```

Count the number of observations of each level in each column.

```
levelcounts(colors)
```

```
ans =  
  1     1     1  
  1     0     2  
  1     2     0
```

Count the number of observations of each level in each row.

```
levelcounts(colors,2)
```

```
ans =  
  1     1     1  
  1     1     1  
  1     1     1
```

Alternatively, you can use `summary` to display the counts with their labels. The default is to count elements in each column.

```
summary(colors)
```

```
blue     1     1     1  
green    1     0     2  
red      1     2     0
```

You can also count elements in each row.

```
summary(colors,2)
```

blue	green	red
1	1	1
1	1	1
1	1	1

Input Arguments

A — Nominal or ordinal array

nominal array | ordinal array

Nominal or ordinal array, specified as a `nominal` or `ordinal` array object created using `nominal` or `ordinal`.

dim — Dimension along which to count

positive integer value

Dimension along which to count the number of elements in each level, specified as a positive integer value. For example, if the dimension is `1`, then `levelcounts` counts along each column, while if the dimension is `2`, then `levelcounts` counts along each row.

Data Types: `double` | `single`

- Using nominal Objects
- Using ordinal Objects

See Also

`nominal` | `ordinal` | `summary`

leverage

Leverage

Syntax

```
h = leverage(data)
h = leverage(data, model)
```

Description

`h = leverage(data)` finds the leverage of each row (point) in the matrix `data` for a linear additive regression model.

`h = leverage(data, model)` finds the leverage on a regression, using a specified model type, where `model` can be one of these strings:

- 'linear' - includes constant and linear terms
- 'interaction' - includes constant, linear, and cross product terms
- 'quadratic' - includes interactions and squared terms
- 'purequadratic' - includes constant, linear, and squared terms

Leverage is a measure of the influence of a given observation on a regression due to its location in the space of the inputs.

Examples

One rule of thumb is to compare the leverage to $2p/n$ where n is the number of observations and p is the number of parameters in the model. For the Hald data set this value is 0.7692.

```
load hald
h = max(leverage(ingredients, 'linear'))
h =
    0.7004
```

Since $0.7004 < 0.7692$, there are no high leverage points using this rule.

More About

Algorithms

```
[Q,R] = qr(x2fx(data, 'model'));
```

```
leverage = (sum(Q' .* Q'))'
```

```
• regstats
```

lhsdesign

Latin hypercube sample

Syntax

```
X = lhsdesign(n,p)
X = lhsdesign(...,'smooth','off')
X = lhsdesign(...,'criterion',criterion)
X = lhsdesign(...,'iterations',k)
```

Description

`X = lhsdesign(n,p)` returns an n -by- p matrix, X , containing a latin hypercube sample of n values on each of p variables. For each column of X , the n values are randomly distributed with one from each interval $(0, 1/n)$, $(1/n, 2/n)$, ..., $(1-1/n, 1)$, and they are randomly permuted.

`X = lhsdesign(...,'smooth','off')` produces points at the midpoints of the above intervals: $0.5/n$, $1.5/n$, ..., $1-0.5/n$. The default is 'on'.

`X = lhsdesign(...,'criterion',criterion)` iteratively generates latin hypercube samples to find the best one according to the criterion *criterion*, which can be one of the following strings.

Criterion	Description
'none'	No iteration.
'maximin'	Maximize minimum distance between points. This is the default.
'correlation'	Reduce correlation.

`X = lhsdesign(...,'iterations',k)` iterates up to k times in an attempt to improve the design according to the specified criterion. The default is $k = 5$.

See Also

haltonset | sobolset | lhsnorm | unifrnd

lhsnorm

Latin hypercube sample from normal distribution

Syntax

```
X = lhsnorm(mu,sigma,n)
X = lhsnorm(mu,sigma,n,flag)
[X,Z] = lhsnorm(...)
```

Description

`X = lhsnorm(mu,sigma,n)` returns an n -by- p matrix, X , containing a latin hypercube sample of size n from a p -dimensional multivariate normal distribution with mean vector, μ , and covariance matrix, σ .

X is similar to a random sample from the multivariate normal distribution, but the marginal distribution of each column is adjusted so that its sample marginal distribution is close to its theoretical normal distribution.

`X = lhsnorm(mu,sigma,n,flag)` controls the amount of smoothing in the sample. If `flag` is 'off', each column has points equally spaced on the probability scale. In other words, each column is a permutation of the values $G(0.5/n)$, $G(1.5/n)$, ..., $G(1-0.5/n)$ where G is the inverse normal cumulative distribution for that column's marginal distribution. If `flag` is 'on' (the default), each column has points uniformly distributed on the probability scale. For example, in place of $0.5/n$ you use a value having a uniform distribution on the interval $(0/n, 1/n)$.

`[X,Z] = lhsnorm(...)` also returns Z , the original multivariate normal sample before the marginals are adjusted to obtain X .

References

- [1] Stein, M. "Large sample properties of simulations using latin hypercube sampling." *Technometrics*. Vol. 29, No. 2, 1987, pp. 143–151. Correction, Vol. 32, p. 367.

lhsdesign | mvnrnd

lillietest

Lilliefors test

Syntax

```
h = lillietest(x)
h = lillietest(x,Name,Value)
[h,p] = lillietest( ___ )
[h,p,kstat,critval] = lillietest( ___ )
```

Description

`h = lillietest(x)` returns a test decision for the null hypothesis that the data in vector `x` comes from a distribution in the normal family, against the alternative that it does not come from such a distribution, using a Lilliefors test. The result `h` is 1 if the test rejects the null hypothesis at the 5% significance level, and 0 otherwise.

`h = lillietest(x,Name,Value)` returns a test decision with additional options specified by one or more name-value pair arguments. For example, you can test the data against a different distribution family, change the significance level, or calculate the p -value using a Monte Carlo approximation.

`[h,p] = lillietest(___)` also returns the p -value `p`, using any of the input arguments from the previous syntaxes.

`[h,p,kstat,critval] = lillietest(___)` also returns the test statistic `kstat` and the critical value `critval` for the test.

Examples

Test for a Normal Distribution

Load the sample data. Test the null hypothesis that car mileage, in miles per gallon (MPG), follows a normal distribution across different makes of cars.

```
load carbig.mat;
```

```
[h,p,k,c] = lillietest(MPG)
```

```
Warning: P is less than the smallest tabulated value, returning 0.001.
```

```
h =  
  1  
p =  
  1.0000e-003  
k =  
  0.0789  
c =  
  0.0451
```

The test statistic k is greater than the critical value c , so `lillietest` returns a result of $h = 1$ to indicate rejection of the null hypothesis at the default 5% significance level. The warning indicates that the returned p -value is the smallest value in the table of precomputed values. To find a more accurate p -value, use `MCTol` to run a Monte Carlo approximation.

Test the Hypothesis at Different Significance Levels

Load the sample data. Create a vector containing the first column of the students' exam grades data.

```
load examgrades;  
x = grades(:,1);
```

Test the null hypothesis that the sample data comes from a normal distribution at the 1% significance level.

```
[h,p] = lillietest(x, 'Alpha', 0.01)  
  
h =  
  0  
p =  
  0.0348
```

The returned value of $h = 0$ indicates that `lillietest` does not reject the null hypothesis at the 1% significance level.

Test for an Exponential Distribution

Load the sample data. Test the null hypothesis that car mileage, in miles per gallon (MPG), follows an exponential distribution across different makes of cars.

```
load carbig.mat;
```

```
h = lillietest(MPG, 'Distr', 'exp')
```

```
h =  
    1
```

The returned value of $h = 1$ indicates that `lillietest` rejects the null hypothesis at the default 5% significance level.

Determine the p -value Using Monte Carlo Approximation

Load the sample data. Test the null hypothesis that car mileage, in miles per gallon (MPG), follows a normal distribution across different makes of cars. Determine the p -value using a Monte Carlo approximation with a maximum Monte Carlo standard error of $1e-4$.

```
load carbig.mat;  
[h,p] = lillietest(MPG, 'MCTol', 1e-4)
```

```
h =  
    1  
p =  
    0
```

The returned value of $h = 1$ indicates that `lillietest` rejects the null hypothesis that the data comes from a normal distribution at the 5% significance level.

Input Arguments

x — Sample data

vector

Sample data, specified as a vector.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'Distr', 'exp', 'Alpha', 0.01` tests the null hypothesis that the population distribution belongs to the exponential distribution family at the 1% significance level.

'Alpha' — Significance level

0.05 (default) | scalar value in the range (0,1)

Significance level of the hypothesis test, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the range (0,1).

- If `MCTol` is not used, Alpha must be in the range [0.001,0.50].
- If `MCTol` is used, Alpha must be in the range (0,1).

Example: `'Alpha', 0.01`

Data Types: `single` | `double`

'Distr' — Distribution family

`'norm'` (default) | `'exp'` | `'ev'`

Distribution family for the hypothesis test, specified as the comma-separated pair consisting of `'Distr'` and one of the following.

<code>'norm'</code>	Normal distribution
<code>'exp'</code>	Exponential distribution
<code>'ev'</code>	Extreme value distribution

Example: `'Distr', 'exp'`

'MCTol' — Maximum Monte Carlo standard error

scalar value in the range (0,1)

Maximum Monte Carlo standard error for p , the p -value of the test, specified as the comma-separated pair consisting of `'MCTol'` and a scalar value in the range (0,1).

Example: `'MCTol', 0.001`

Data Types: `single` | `double`

Output Arguments

h — Hypothesis test result

1 | 0

Hypothesis test result, returned as a logical value.

- If $h = 1$, this indicates the rejection of the null hypothesis at the Alpha significance level.
- If $h = 0$, this indicates a failure to reject the null hypothesis at the Alpha significance level.

p — *p*-value

scalar value in the range (0,1)

p-value of the test, returned as a scalar value in the range (0,1). *p* is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. Small values of *p* cast doubt on the validity of the null hypothesis.

- If `MCTol` is not used, *p* is computed using inverse interpolation into the table of critical values, and is returned as a scalar value in the range [0.001,0.50]. `lillietest` warns when *p* is not found within the tabulated range and returns either the smallest or largest tabulated value.
- If `MCTol` is used, `lillietest` conducts a Monte Carlo simulation to compute a more accurate *p*-value, and *p* is returned as a scalar value in the range (0,1).

kstat — Test statistic

nonnegative scalar value

Test statistic, returned as a nonnegative scalar value.

critval — Critical value

nonnegative scalar value

Critical value for the hypothesis test, returned as a nonnegative scalar value.

More About

Lilliefors Test

The Lilliefors test is a two-sided goodness-of-fit test suitable when the parameters of the null distribution are unknown and must be estimated. This is in contrast to the one-sample Kolmogorov-Smirnov test, which requires the null distribution to be completely specified.

The Lilliefors test statistic is:

$$D^* = \max_x |F(x) - G(x)|,$$

where $\hat{F}(x)$ is the empirical cdf of the sample data and $G(x)$ is the cdf of the hypothesized distribution with estimated parameters equal to the sample parameters.

`lillietest` can be used to test whether the data vector `x` has a lognormal or Weibull distribution by applying a transformation to the data vector and running the appropriate Lilliefors test:

- To test `x` for a lognormal distribution, test if `log(x)` has a normal distribution.
- To test `x` for a Weibull distribution, test if `log(x)` has an extreme value distribution.

The Lilliefors test cannot be used when the null hypothesis is not a location-scale family of distributions.

Monte Carlo Standard Error

The Monte Carlo standard error is the error due to simulating the p -value.

The Monte Carlo standard error is calculated as:

$$SE = \sqrt{\frac{(\hat{p})(1 - \hat{p})}{\text{mcreps}}},$$

where \hat{p} is the estimated p -value of the hypothesis test, and `mcreps` is the number of Monte Carlo replications performed.

The number of Monte Carlo replications, `mcreps`, is determined such that the Monte Carlo standard error for \hat{p} less than the value specified for `MCTol`.

Algorithms

To compute the critical value for the hypothesis test, `lillietest` interpolates into a table of critical values pre-computed using Monte Carlo simulation for sample sizes less than 1000 and significance levels between 0.001 and 0.50. The table used by `lillietest` is larger and more accurate than the table originally introduced by

Lilliefors. If a more accurate p -value is desired, or if the desired significance level is less than 0.001 or greater than 0.50, the `MCTol` input argument can be used to run a Monte Carlo simulation to calculate the p -value more exactly.

When the computed value of the test statistic is greater than the critical value, `lillietest` rejects the null hypothesis at significance level `Alpha`.

`lillietest` treats NaN values in `x` as missing values and ignores them.

LinearModel class

Linear regression model class

Description

An object comprising training data, model description, diagnostic information, and fitted coefficients for a linear regression. Predict model responses with the `predict` or `feval` methods.

Construction

`mdl = fitlm(tbl)` or `mdl = fitlm(X,y)` create a linear model of a table or dataset array `tbl`, or of the responses `y` to a data matrix `X`. For details, see `fitlm`.

`mdl = stepwiselm(tbl)` or `mdl = stepwiselm(X,y)` create a linear model of a table or dataset array `tbl`, or of the responses `y` to a data matrix `X`, with unimportant predictors excluded. For details, see `stepwiselm`.

Input Arguments

tbl — Input data

table | dataset array

Input data, specified as a table or dataset array. When `modelspec` is a `formula`, it specifies the variables to be used as the predictors and response. Otherwise, if you do not specify the predictor and response variables, the last variable is the response variable and the others are the predictor variables by default.

Predictor variables can be numeric, or any grouping variable type, such as logical or categorical (see “Grouping Variables” on page 2-52). The response must be numeric or logical.

To set a different column as the response variable, use the `ResponseVar` name-value pair argument. To use a subset of the columns as predictors, use the `PredictorVars` name-value pair argument.

Data Types: `single` | `double` | `logical`

X — Predictor variables

matrix

Predictor variables, specified as an n -by- p matrix, where n is the number of observations and p is the number of predictor variables. Each column of X represents one variable, and each row represents one observation.

By default, there is a constant term in the model, unless you explicitly remove it, so do not include a column of 1s in X .

Data Types: `single` | `double` | `logical`

y — Response variable

vector

Response variable, specified as an n -by-1 vector, where n is the number of observations. Each entry in y is the response for the corresponding row of X .

Data Types: `single` | `double`

Properties

CoefficientCovariance

Covariance matrix of coefficient estimates.

CoefficientNames

Cell array of strings containing a label for each coefficient.

Coefficients

Coefficient values stored as a table. `Coefficients` has one row for each coefficient and these columns:

- `Estimate` — Estimated coefficient value
- `SE` — Standard error of the estimate
- `tStat` — t statistic for a test that the coefficient is zero
- `pValue` — p -value for the t statistic

To obtain any of these columns as a vector, index into the property using dot notation. For example, in `mdl` the estimated coefficient vector is

```
beta = mdl.Coefficients.Estimate
```

Use `coefTest` to perform other tests on the coefficients.

DFE

Degrees of freedom for error (residuals), equal to the number of observations minus the number of estimated coefficients.

Diagnostics

Table with the same number of rows as the input data (`tbl` or `X`). **Diagnostics** contains diagnostics helpful in finding outliers and influential observations. Many diagnostics describe the effect on the fit of deleting single observations. **Diagnostics** contains the following fields.

Field	Meaning	Utility
Leverage	Diagonal elements of <code>HatMatrix</code>	Leverage indicates to what extent the predicted value for an observation is determined by the observed value for that observation. A value close to 1 indicates that the prediction is largely determined by that observation, with little contribution from the other observations. A value close to 0 indicates the fit is largely determined by the other observations. For a model with <code>P</code> coefficients and <code>N</code> observations, the average value of Leverage is P/N . An observation with Leverage larger than $2 * P/N$ can be regarded as having high leverage.
CooksDistance	Cook's measure of scaled change in fitted values	CooksDistance is a measure of scaled change in fitted values. An observation with CooksDistance larger than three times the mean Cook's distance can be an outlier.
Dffits	Delete-1 scaled differences in fitted values vs. observation number	Dffits is the scaled change in the fitted values for each observation that would result from excluding that observation from the fit. Values with an absolute value larger than $2 * \text{sqrt}(P/N)$ may be considered influential.
S2_i	Delete-1 variance vs. observation number	S2_i is a set of residual variance estimates obtained by deleting each observation in turn. These can be compared with the value of the MSE property.

Field	Meaning	Utility
CovRatio	Delete-1 ratio of determinant of covariance vs. observation number	CovRatio is the ratio of the determinant of the coefficient covariance matrix with each observation deleted in turn to the determinant of the covariance matrix for the full model. Values larger than $1 + 3 \cdot P / N$ or smaller than $1 - 3 \cdot P / N$ indicate influential points.
Dfbetas	Delete-1 scaled differences in covariance estimates vs. observation number	Dfbetas is an N-by-P matrix of the scaled change in the coefficient estimates that would result from excluding each observation in turn. Values larger than $3 / \sqrt{N}$ in absolute value indicate that the observation has a large influence on the corresponding coefficient.
HatMatrix	Projection matrix to compute fitted from observed responses	HatMatrix is an N-by-N matrix such that $\text{Fitted} = \text{HatMatrix} \cdot Y$, where Y is the response vector and Fitted is the vector of fitted response values.

Rows not used in the fit because of missing values (in `ObservationInfo.Missing`) contain NaN values.

Rows not used in the fit because of excluded values (in `ObservationInfo.Excluded`) contain NaN values, with the following exception: Delete-1 diagnostics refer to the statistic with and without that observation (row) included in the fit. These diagnostics help identify important observations.

Fitted

Predicted response to the input data by using the model. Use `predict` to compute predictions for other predictor values, or to compute confidence bounds on `Fitted`.

Formula

Object containing information about the model.

LogLikelihood

Log likelihood of the model distribution at the response values, with mean fitted from the model, and other parameters estimated as part of the model fit.

ModelCriterion

AIC and other information criteria for comparing models. A structure with fields:

- **AIC** — Akaike information criterion
- **AICc** — Akaike information criterion corrected for sample size
- **BIC** — Bayesian information criterion
- **CAIC** — Consistent Akaike information criterion

To obtain any of these values as a scalar, index into the property using dot notation. For example, in a model `mdl`, the AIC value `aic` is:

```
aic = mdl.ModelCriterion.AIC
```

MSE

Mean squared error (residuals), SSE/DFE.

NumCoefficients

Number of coefficients in the model, a positive integer. `NumCoefficients` includes coefficients that are set to zero when the model terms are rank deficient.

NumEstimatedCoefficients

Number of estimated coefficients in the model, a positive integer.

`NumEstimatedCoefficients` does not include coefficients that are set to zero when the model terms are rank deficient. `NumEstimatedCoefficients` is the degrees of freedom for regression.

NumObservations

Number of observations the fitting function used in fitting. This is the number of observations supplied in the original table, dataset, or matrix, minus any excluded rows (set with the `Excluded` name-value pair) or rows with missing values.

NumPredictors

Number of variables `fitlm` used as predictors for fitting.

NumVariables

Number of variables in the data. `NumVariables` is the number of variables in the original table or dataset, or the total number of columns in the predictor matrix and

response vector when the fit is based on those arrays. It includes variables, if any, that are not used as predictors or as the response.

ObservationInfo

Table with the same number of rows as the input data (`tbl` or `X`).

Field	Description
Weights	Observation weights. Default is all 1.
Excluded	Logical value, 1 indicates an observation that you excluded from the fit with the <code>Exclude</code> name-value pair.
Missing	Logical value, 1 indicates a missing value in the input. Missing values are not used in the fit.
Subset	Logical value, 1 indicates the observation is not excluded or missing, so is used in the fit.

ObservationNames

Cell array of strings containing the names of the observations used in the fit.

- If the fit is based on a table or dataset containing observation names, `ObservationNames` uses those names.
- Otherwise, `ObservationNames` is an empty cell array

PredictorNames

Cell array of strings, the names of the predictors used in fitting the model.

Residuals

Table of residuals, with one row for each observation and these variables.

Field	Description
Raw	Observed minus fitted values.
Pearson	Raw residuals divided by RMSE.
Standardized	Raw residuals divided by their estimated standard deviation.

Field	Description
Studentized	Residual divided by an independent estimate of the residual standard deviation. The residual for observation i is divided by an estimate of the error standard deviation based on all observations except for observation i .

To obtain any of these columns as a vector, index into the property using dot notation. For example, in a model `mdl`, the ordinary raw residual vector `r` is:

```
r = mdl.Residuals.Raw
```

Rows not used in the fit because of missing values (in `ObservationInfo.Missing`) contain NaN values.

Rows not used in the fit because of excluded values (in `ObservationInfo.Excluded`) contain NaN values, with the following exceptions:

- `raw` contains the difference between the observed and predicted values.
- `standardized` is the residual, standardized in the usual way.
- `studentized` matches the standardized values because this residual is not used in the estimate of the residual standard deviation.

ResponseName

String giving naming the response variable.

RMSE

Root mean squared error (residuals), `sqrt(MSE)`.

Robust

Structure that is empty unless `fitlm` constructed the model using robust regression.

Field	Description
WgtFun	Robust weighting function, such as 'bisquare' (see <code>robustfit</code>)
Tune	Value specified for tuning parameter (can be <code>[]</code>)

Field	Description
Weights	Vector of weights used in final iteration of robust fit

Rsquared

Proportion of total sum of squares explained by the model. The ordinary R-squared value relates to the SSR and SST properties:

$$\text{Rsquared} = \text{SSR}/\text{SST} = 1 - \text{SSE}/\text{SST}.$$

For a linear or nonlinear model, **Rsquared** is a structure with two fields:

- **Ordinary** — Ordinary (unadjusted) R-squared
- **Adjusted** — R-squared adjusted for the number of coefficients

For a generalized linear model, **Rsquared** is a structure with five fields:

- **Ordinary** — Ordinary (unadjusted) R-squared
- **Adjusted** — R-squared adjusted for the number of coefficients
- **LLR** — Log-likelihood ratio
- **Deviance** — Deviance
- **AdjGeneralized** — Adjusted generalized R-squared

To obtain any of these values as a scalar, index into the property using dot notation. For example, the adjusted R-squared value in `mdl` is

```
r2 = mdl.Rsquared.Adjusted
```

SSE

Sum of squared errors (residuals).

The Pythagorean theorem implies

$$\text{SST} = \text{SSE} + \text{SSR}.$$

SSR

Regression sum of squares, the sum of squared deviations of the fitted values from their mean.

The Pythagorean theorem implies

$$\text{SST} = \text{SSE} + \text{SSR}.$$

SST

Total sum of squares, the sum of squared deviations of y from $\text{mean}(y)$.

The Pythagorean theorem implies

$$\text{SST} = \text{SSE} + \text{SSR}.$$

Steps

Structure that is empty unless `stepwise1m` constructed the model.

Field	Description
Start	Formula representing the starting model
Lower	Formula representing the lower bound model, these terms that must remain in the model
Upper	Formula representing the upper bound model, model cannot contain more terms than Upper
Criterion	Criterion used for the stepwise algorithm, such as 'sse'
PEnter	Value of the parameter, such as 0.05
PRemove	Value of the parameter, such as 0.10
History	Table representing the steps taken in the fit

The **History** table has one row for each step including the initial fit, and the following variables (columns).

Field	Description
Action	Action taken during this step, one of: <ul style="list-style-type: none"> 'Start' — First step 'Add' — A term is added 'Remove' — A term is removed
TermName	<ul style="list-style-type: none"> 'Start' step: The starting model specification 'Add' or 'Remove' steps: The term moved in that step
Terms	Terms matrix (see <code>modelspec</code> of <code>fitlm</code>)
DF	Regression degrees of freedom after this step

Field	Description
delDF	Change in regression degrees of freedom from previous step (negative for steps that remove a term)
Deviance	Deviance (residual sum of squares) at that step
FStat	F statistic that led to this step
PValue	p -value of the F statistic

VariableInfo

Table containing metadata about `Variables`. There is one row for each term in the model, and the following columns.

Field	Description
Class	String giving variable class, such as 'double'
Range	Cell array giving variable range: <ul style="list-style-type: none"> • Continuous variable — Two-element vector $[min, max]$, the minimum and maximum values • Categorical variable — Cell array of distinct variable values
InModel	Logical vector, where <code>true</code> indicates the variable is in the model
IsCategorical	Logical vector, where <code>true</code> indicates a categorical variable

VariableNames

Cell array of strings containing names of the variables in the fit.

- If the fit is based on a table or dataset, this property provides the names of the variables in that table or dataset.
- If the fit is based on a predictor matrix and response vector, `VariableNames` is the values in the `VarNames` name-value pair of the fitting method.
- Otherwise the variables have the default fitting names.

Variables

Table containing the data, both observations and responses, that the fitting function used to construct the fit. If the fit is based on a table or dataset array, `Variables` contains

all of the data from that table or dataset array. Otherwise, `Variables` is a table created from the input data matrix `X` and response vector `y`.

Methods

<code>addTerms</code>	Add terms to linear regression model
<code>anova</code>	Analysis of variance for linear model
<code>coefCI</code>	Confidence intervals of coefficient estimates of linear model
<code>coefTest</code>	Linear hypothesis test on linear regression model coefficients
<code>disp</code>	Display linear regression model
<code>dwtest</code>	Durbin-Watson test of linear model
<code>feval</code>	Evaluate linear regression model prediction
<code>fit</code>	Create linear regression model
<code>plot</code>	Scatter plot or added variable plot of linear model
<code>plotAdded</code>	Added variable plot or leverage plot for linear model
<code>plotAdjustedResponse</code>	Adjusted response plot for linear regression model
<code>plotDiagnostics</code>	Plot diagnostics of linear regression model

<code>plotEffects</code>	Plot main effects of each predictor in linear regression model
<code>plotInteraction</code>	Plot interaction effects of two predictors in linear regression model
<code>plotResiduals</code>	Plot residuals of linear regression model
<code>plotSlice</code>	Plot of slices through fitted linear regression surface
<code>predict</code>	Predict response of linear regression model
<code>random</code>	Simulate responses for linear regression model
<code>removeTerms</code>	Remove terms from linear model
<code>step</code>	Improve linear regression model by adding or removing terms
<code>stepwise</code>	Create linear regression model by stepwise regression

Copy Semantics

Value. To learn how value classes affect copy operations, see “Copying Objects” in the MATLAB documentation.

Definitions

Hat Matrix

The *hat matrix* H is defined in terms of the data matrix X :

$$H = X(X^T X)^{-1} X^T.$$

The diagonal elements H_{ii} satisfy

$$0 \leq h_{ii} \leq 1$$
$$\sum_{i=1}^n h_{ii} = p,$$

where n is the number of observations (rows of X), and p is the number of coefficients in the regression model.

Leverage

The *leverage* of observation i is the value of the i th diagonal term, h_{ii} , of the hat matrix H . Because the sum of the leverage values is p (the number of coefficients in the regression model), an observation i can be considered to be an outlier if its leverage substantially exceeds p/n , where n is the number of observations.

Cook's Distance

Cook's distance is the scaled change in fitted values. Each element in `CooksDistance` is the normalized change in the vector of coefficients due to the deletion of an observation. The Cook's distance, D_i , of observation i is

$$D_i = \frac{\sum_{j=1}^n (\hat{y}_j - \hat{y}_{j(i)})^2}{p \text{MSE}},$$

where

- \hat{y}_j is the j th fitted response value.
- $\hat{y}_{j(i)}$ is the j th fitted response value, where the fit does not include observation i .
- MSE is the mean squared error.

- p is the number of coefficients in the regression model.

Cook's distance is algebraically equivalent to the following expression:

$$D_i = \frac{r_i^2}{p \text{MSE}} \left(\frac{h_{ii}}{(1-h_{ii})^2} \right),$$

where r_i is the i th residual, and h_{ii} is the i th leverage value.

`CooksDistance` is an n -by-1 column vector in the `Diagnostics` table of the `LinearModel` object.

Examples

Linear Regression Model of Matrix Data

Fit a linear model of the Hald data.

Load the data.

```
load hald
X = ingredients; % predictor variables
y = heat; % response
```

Fit a default linear model to the data.

```
mdl = fitlm(X,y)
```

```
mdl =
```

Linear regression model:

```
y ~ 1 + x1 + x2 + x3 + x4
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	62.405	70.071	0.8906	0.39913
x1	1.5511	0.74477	2.0827	0.070822
x2	0.51017	0.72379	0.70486	0.5009
x3	0.10191	0.75471	0.13503	0.89592
x4	-0.14406	0.70905	-0.20317	0.84407

```

Number of observations: 13, Error degrees of freedom: 8
Root Mean Squared Error: 2.45
R-squared: 0.982, Adjusted R-Squared 0.974
F-statistic vs. constant model: 111, p-value = 4.76e-07

```

Linear Regression with Categorical Predictor and Nonlinear Model

Fit a model of a table that contains a categorical predictor. Use a nonlinear response formula.

Load the `carsmall` data.

```
load carsmall
```

Construct a table containing continuous predictor variable `Weight`, nominal predictor variable `Year`, and response variable `MPG`.

```
tbl = table(MPG,Weight);
tbl.Year = nominal(Model_Year);
```

Create a fitted model of `MPG` as a function of `Year`, `Weight`, and `Weight2`. (You don't have to include `Weight` explicitly in your formula because it is a lower-order term of `Weight2`.)

```
mdl = fitlm(tbl, 'MPG ~ Year + Weight^2')
```

```
mdl =
```

```
Linear regression model:
MPG ~ 1 + Weight + Year + Weight^2
```

```
Estimated Coefficients:
```

	Estimate	SE	tStat	pValue
(Intercept)	54.206	4.7117	11.505	2.6648e-19
Weight	-0.016404	0.0031249	-5.2493	1.0283e-06
Year_76	2.0887	0.71491	2.9215	0.0044137
Year_82	8.1864	0.81531	10.041	2.6364e-16
Weight^2	1.5573e-06	4.9454e-07	3.149	0.0022303

```

Number of observations: 94, Error degrees of freedom: 89
Root Mean Squared Error: 2.78
R-squared: 0.885, Adjusted R-Squared 0.88
F-statistic vs. constant model: 172, p-value = 5.52e-41

```

`fitlm` creates two dummy (indicator) variables for the nominal variate, `Year`. The dummy variable `Year_76` takes the value 1 if model year is 1976 and takes the value 0 if it is not. The dummy variable `Year_82` takes the value 1 if model year is 1982 and takes the value 0 if it is not. And the year 1970 is the reference year. The corresponding model is

$$MPG = 54.206 - 0.0164(Weight) + 2.0887(Year_76) + 8.1864(Year_82) + (1.557e - 06)(Weight)^2$$

Robust Linear Regression Model

Fit a linear regression model of the Hald data using robust fitting.

Load the data.

```
load hald
X = ingredients; % predictor variables
y = heat; % response
```

Fit a robust linear model to the data.

```
mdl = fitlm(X,y,'linear','RobustOpts','on')
```

```
mdl =
```

Linear regression model (robust fit):

```
y ~ 1 + x1 + x2 + x3 + x4
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	60.09	75.818	0.79256	0.4509
x1	1.5753	0.80585	1.9548	0.086346
x2	0.5322	0.78315	0.67957	0.51596
x3	0.13346	0.8166	0.16343	0.87424
x4	-0.12052	0.7672	-0.15709	0.87906

Number of observations: 13, Error degrees of freedom: 8

Root Mean Squared Error: 2.65

R-squared: 0.979, Adjusted R-Squared 0.969

F-statistic vs. constant model: 94.6, p-value = 9.03e-07

- “Linear Regression Workflow” on page 9-41
- “Robust Regression versus Standard Least-Squares Fit” on page 9-118

Algorithms

The main fitting algorithm is QR decomposition. For robust fitting, the algorithm is `robustfit`.

Alternatives

To remove redundant predictors in linear regression using lasso or elastic net, use the `lasso` function.

To regularize a regression with correlated terms using ridge regression, use the `ridge` or `lasso` functions.

To regularize a regression with correlated terms using partial least squares, use the `plsregress` function.

`fitlm` | `stepwiselm`

How To

- “Linear Regression” on page 9-11

LinearMixedModel class

Linear mixed-effects model class

Description

A `LinearMixedModel` object represents a model of a response variable with fixed and random effects. It comprises data, a model description, fitted coefficients, covariance parameters, design matrices, residuals, residual plots, and other diagnostic information for a linear mixed-effects model. You can predict model responses with the `predict` function and generate random data at new design points using the `random` function.

Construction

You can fit a linear mixed-effects model using `fitlme(tbl, formula)` if your data is in a table or dataset array. Alternatively, if your model is not easily described using a formula, you can create matrices to define the fixed and random effects, and fit the model using `fitlmematrix(X, y, Z, G)`.

Input Arguments

tbl — Input data

table | dataset array

Input data, which includes the response variable, predictor variables, and grouping variables, specified as a table or dataset array. The predictor variables can be continuous or grouping variables (see “Grouping Variables” on page 2-52). You must specify the model for the variables using formula.

Data Types: single | double | char | cell

formula — Formula for model specification

string of the form 'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)'

Formula for model specification, specified as a string of the form 'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)'. For a full description, see “Formula” on page 21-2316.

Example: `'y ~ treatment +(1|block)'`

X — Fixed-effects design matrix

n-by-*p* matrix

Fixed-effects design matrix, specified as an *n*-by-*p* matrix, where *n* is the number of observations, and *p* is the number of fixed-effects predictor variables. Each row of **X** corresponds to one observation, and each column of **X** corresponds to one variable.

Data Types: `single` | `double`

y — Response values

n-by-1 vector

Response values, specified as an *n*-by-1 vector, where *n* is the number of observations.

Data Types: `single` | `double`

Z — Random-effects design

n-by-*q* matrix | cell array of *R* *n*-by-*q*(*r*) matrices, *r* = 1, 2, ..., *R*

Random-effects design, specified as either of the following.

- If there is one random-effects term in the model, then **Z** must be an *n*-by-*q* matrix, where *n* is the number of observations and *q* is the number of variables in the random-effects term.
- If there are *R* random-effects terms, then **Z** must be a cell array of length *R*. Each cell of **Z** contains an *n*-by-*q*(*r*) design matrix $Z\{r\}$, *r* = 1, 2, ..., *R*, corresponding to each random-effects term. Here, *q*(*r*) is the number of random effects term in the *r*th random effects design matrix, $Z\{r\}$.

Data Types: `single` | `double` | `cell`

G — Grouping variable or variables

n-by-1 vector | cell array of *R* *n*-by-1 vectors

Grouping variable or variables, specified as either of the following.

- If there is one random-effects term, then **G** must be an *n*-by-1 vector corresponding to a single grouping variable with *M* levels or groups.

G can be a categorical vector, numeric vector, character array, or cell array of strings.

- If there are multiple random-effects terms, then **G** must be a cell array of length *R*. Each cell of **G** contains a grouping variable $G\{r\}$, *r* = 1, 2, ..., *R*, with *M*(*r*) levels.

$G\{r\}$ can be a categorical vector, numeric vector, character array, or cell array of strings.

Data Types: `single` | `double` | `char` | `cell`

Properties

Coefficients — Fixed-effects coefficient estimates

dataset array

Fixed-effects coefficient estimates and related statistics, stored as a dataset array containing the following fields.

Name	Name of the term.
Estimate	Estimated value of the coefficient.
SE	Standard error of the coefficient.
tStat	<i>t</i> -statistics for testing the null hypothesis that the coefficient is equal to zero.
DF	Degrees of freedom for the <i>t</i> -test. Method to compute DF is specified by the 'DFMethod' name-value pair argument. Coefficients always uses the 'Residual' method for 'DFMethod'.
pValue	<i>p</i> -value for the <i>t</i> -test.
Lower	Lower limit of the confidence interval for coefficient. Coefficients always uses the 95% confidence level, i.e. 'alpha' is 0.05.
Upper	Upper limit of confidence interval for coefficient. Coefficients always uses the 95% confidence level, i.e. 'alpha' is 0.05.

You can change 'DFMethod' and 'alpha' while computing confidence intervals for or testing hypotheses involving fixed- and random-effects, using the `coefCI` and `coefTest` methods.

CoefficientCovariance — Covariance of the estimated fixed-effects coefficients

p-by-*p* matrix

Covariance of the estimated fixed-effects coefficients of the linear mixed-effects model, stored as a p -by- p matrix, where p is the number of fixed-effects coefficients.

You can display the covariance parameters associated with the random effects using the `covarianceParameters` method.

Data Types: `double`

CoefficientNames — Names of the fixed-effects coefficients

1-by- p cell array of strings

Names of the fixed-effects coefficients of a linear mixed-effects model, stored as a 1-by- p cell array of strings.

Data Types: `cell`

DFE — Residual degrees of freedom

positive integer value

Residual degrees of freedom, stored as a positive integer value. $DFE = n - p$, where n is the number of observations, and p is the number of fixed-effects coefficients.

This corresponds to the 'Residual' method of calculating degrees of freedom in the `fixedEffects` and `randomEffects` methods.

Data Types: `double`

FitMethod — Method used to fit the linear mixed-effects model

ML | REML

Method used to fit the linear mixed-effects model, stored as either of the following strings.

- ML, if the fitting method is maximum likelihood
- REML, if the fitting method is restricted maximum likelihood

Data Types: `char`

Formula — Specification of the fixed- and random-effects terms, and grouping variables

object

Specification of the fixed-effects terms, random-effects terms, and grouping variables that define the linear mixed-effects model, stored as an object.

For more information on how to specify the model to fit using a formula, see “Formula” on page 21-2316.

LogLikelihood — Maximized log or restricted log likelihood

scalar value

Maximized log likelihood or maximized restricted log likelihood of the fitted linear mixed-effects model depending on the fitting method you choose, stored as a scalar value.

Data Types: double

ModelCriterion — Model criterion

dataset array

Model criterion to compare fitted linear mixed-effects models, stored as a dataset array with the following columns.

AIC	Akaike Information Criterion
BIC	Bayesian Information Criterion
Loglikelihood	Log likelihood value of the model
Deviance	-2 times the log likelihood of the model

If n is the number of observations used in fitting the model, and p is the number of fixed-effects coefficients, then for calculating AIC and BIC,

- The total number of parameters is $nc + p + 1$, where nc is the total number of parameters in the random-effects covariance excluding the residual variance
- The effective number of observations is
 - n , when the fitting method is maximum likelihood (ML)
 - $n - p$, when the fitting method is restricted maximum likelihood (REML)

MSE — ML or REML estimate

positive scalar value

ML or REML estimate, based on the fitting method used for estimating σ^2 , stored as a positive scalar value. σ^2 is the residual variance or variance of the observation error term of the linear mixed-effects model.

Data Types: double

NumCoefficients — Number of fixed-effects coefficients

positive integer value

Number of fixed-effects coefficients in the fitted linear mixed-effects model, stored as a positive integer value.

Data Types: double

NumEstimatedCoefficients — Number of estimated fixed-effects coefficients

positive integer value

Number of estimated fixed-effects coefficients in the fitted linear mixed-effects model, stored as a positive integer value.

Data Types: double

NumObservations — Number of observations

positive integer value

Number of observations used in the fit, stored as a positive integer value. This is the number of rows in the table or dataset array, or the design matrices minus the excluded rows or rows with NaN values.

Data Types: double

NumPredictors — Number of predictors

positive integer value

Number of variables used as predictors in the linear mixed-effects model, stored as a positive integer value.

Data Types: double

NumVariables — Total number of variables

positive integer value

Total number of variables including the response and predictors, stored as a positive integer value.

- If the sample data is in a table or dataset array `tbl`, `NumVariables` is the total number of variables in `tbl` including the response variable.
- If the fit is based on matrix input, `NumVariables` is the total number of columns in the predictor matrix or matrices, and response vector.

`NumVariables` includes variables, if there are any, that are not used as predictors or as the response.

Data Types: `double`

ObservationInfo — Information about the observations

table

Information about the observations used in the fit, stored as a table.

`ObservationInfo` has one row for each observation and the following four columns.

<code>Weights</code>	The value of the weighted variable for that observation. Default value is 1.
<code>Excluded</code>	<code>true</code> , if the observation was excluded from the fit using the ' <code>Exclude</code> ' name-value pair argument, <code>false</code> , otherwise. 1 stands for <code>true</code> and 0 stands for <code>false</code> .
<code>Missing</code>	<code>true</code> , if the observation was excluded from the fit because any response or predictor value is missing, <code>false</code> , otherwise. Missing values include NaN for numeric variables, empty cells for cell arrays, blank rows for character arrays, and the <code><undefined></code> value for categorical arrays.
<code>Subset</code>	<code>true</code> , if the observation was used in the fit, <code>false</code> , if it was not used because it is missing or excluded.

Data Types: `table`

ObservationNames — Names of observations

cell array of strings

Names of observations used in the fit, stored as a cell array of strings.

- If the data is in a table or dataset array, `tbl`, containing observation names, `ObservationNames` has those names.
- If the data is provided in matrices, or a table or dataset array without observation names, then `ObservationNames` is an empty cell array.

Data Types: `cell`

PredictorNames — Names of predictors

cell array of strings

Names of the variables that you use as predictors in the fit, stored as a cell array of strings that has the same length as `NumPredictors`.

Data Types: `cell`

ResponseName — Names of response variable

character string

Name of the variable used as the response variable in the fit, stored as a character string.

Data Types: `char`

Rsquared — Proportion of variability in the response explained by the fitted model

structure

Proportion of variability in the response explained by the fitted model, stored as a structure. It is the multiple correlation coefficient or R-squared. `Rsquared` has two fields.

Ordinary

R-squared value, stored as a scalar value in a structure. `Rsquared.Ordinary = 1 - SSE./SST`

Adjusted

R-squared value adjusted for the number of fixed-effects coefficients, stored as a scalar value in a structure.

`Rsquared.Adjusted = 1 - (SSE./SST)*(DFT./DFE)`,

where $DFE = n - p$, $DFT = n - 1$, and n is the total number of observations, p is the number of fixed-effects coefficients.

Data Types: `struct`

SSE — Error sum of squares

positive scalar value

Error sum of squares, that is, sum of the squared conditional residuals, stored as a positive scalar value.

$SSE = \text{sum}((y - F).^2)$, where y is the response vector, and F is the fitted conditional response of the linear mixed-effects model. The conditional model has contributions from both fixed and random effects.

Data Types: double

SSR — Regression sum of squares

positive scalar value

Regression sum of squares, that is, the sum of squares explained by the linear mixed-effects regression, stored as a positive scalar value. It is the sum of squared deviations of the conditional fitted values from their mean.

$SSR = \text{sum}((F - \text{mean}(F)).^2)$, where F is the fitted conditional response of the linear mixed-effects model. The conditional model has contributions from both fixed and random effects.

Data Types: double

SST — Total sum of squares

positive scalar value

Total sum of squares, that is, the sum of the squared deviations of the observed response values from their mean, stored as a positive scalar value.

$SST = \text{sum}((y - \text{mean}(y)).^2) = SSR + SSE$, where y is the response vector.

Data Types: double

Variables — Variables

table

Variables, stored as a table.

- If the fit is based on a table or dataset array `tbl`, then `Variables` is identical to `tbl`.
- If the fit is based on matrix input, then `Variables` is a table containing all the variables in the predictor matrix or matrices, and response variable.

Data Types: table

VariableInfo — Information about the variables

table

Information about the variables used in the fit, stored as a table.

`VariableInfo` has one row for each variable and contains the following four columns.

<code>Class</code>	Class of the variable ('double', 'cell', 'nominal', and so on).
<code>Range</code>	Value range of the variable. <ul style="list-style-type: none">• For a numerical variable, it is a two-element vector of the form <code>[min,max]</code>.• For a cell or categorical variable, it is a cell or categorical array containing all unique values of the variable.
<code>InModel</code>	<code>true</code> , if the variable is a predictor in the fitted model. <code>false</code> , if the variable is not in the fitted model.
<code>IsCategorical</code>	<code>true</code> , if the variable has a type that is treated as a categorical predictor, such as cell, logical, or categorical, or if it is specified as categorical by the 'Categorical' name-value pair argument of the <code>fit</code> method. <code>false</code> , if it is a continuous predictor.

Data Types: table

VariableNames — Names of the variables

cell array of strings

Names of the variables used in the fit, stored as a cell array of strings.

- If sample data is in a table or dataset array `tbl`, `VariableNames` contains the names of the variables in `tbl`.
- If sample data is in matrix format, then `VariableInfo` includes variable names you supply while fitting the model. If you do not supply the variable names, then `VariableInfo` contains the default names.

Data Types: cell

Methods

anova	Analysis of variance for linear mixed-effects model
coefCI	Confidence intervals for coefficients of linear mixed-effects model
coefTest	Hypothesis test on fixed and random effects of linear mixed-effects model
compare	Compare linear mixed-effects models
covarianceParameters	Extract covariance parameters of linear mixed-effects model
designMatrix	Fixed- and random-effects design matrices
disp	Display linear mixed-effects model
fit	Fit linear mixed-effects model using tables
fitmatrix	Fit linear mixed-effects model using design matrices
fitted	Fitted responses from a linear mixed-effects model
fixedEffects	Estimates of fixed effects and related statistics
plotResiduals	Plot residuals of linear mixed-effects model

<code>predict</code>	Predict response of linear mixed-effects model
<code>random</code>	Generate random responses from fitted linear mixed-effects model
<code>randomEffects</code>	Estimates of random effects and related statistics
<code>residuals</code>	Residuals of fitted linear mixed-effects model
<code>response</code>	Response vector of the linear mixed-effects model

Definitions

Formula

In general, a formula for model specification is a string of the form `'y ~ terms'`. For the linear mixed-effects models, this formula is in the form `'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)'`, where `fixed` and `random` contain the fixed-effects and the random-effects terms.

Suppose a table `tbl` contains the following:

- A response variable, `y`
- Predictor variables, `Xj`, which can be continuous or grouping variables
- Grouping variables, `g1`, `g2`, ..., `gR`,

where the grouping variables in `Xj` and `gr` can be categorical, logical, character arrays, or cell arrays of strings.

Then, in a formula of the form, `'y ~ fixed + (random1|g1) + ... + (randomR|gR)'`, the term `fixed` corresponds to a specification of the fixed-effects design matrix

X , `random1` is a specification of the random-effects design matrix Z_1 corresponding to grouping variable g_1 , and similarly `randomR` is a specification of the random-effects design matrix Z_R corresponding to grouping variable g_R . You can express the `fixed` and `random` terms using Wilkinson notation.

Wilkinson notation describes the factors present in models. The notation relates to factors present in models, not to the multipliers (coefficients) of those factors.

Wilkinson Notation	Factors in Standard Notation
1	Constant (intercept) term
X^k , where k is a positive integer	X, X^2, \dots, X^k
$X1 + X2$	$X1, X2$
$X1 * X2$	$X1, X2, X1.*X2$ (elementwise multiplication of $X1$ and $X2$)
$X1 : X2$	$X1.*X2$ only
$- X2$	Do not include $X2$
$X1 * X2 + X3$	$X1, X2, X3, X1 * X2$
$X1 + X2 + X3 + X1 : X2$	$X1, X2, X3, X1 * X2$
$X1 * X2 * X3 - X1 : X2 : X3$	$X1, X2, X3, X1 * X2, X1 * X3, X2 * X3$
$X1 * (X2 + X3)$	$X1, X2, X3, X1 * X2, X1 * X3$

Statistics Toolbox notation always includes a constant term unless you explicitly remove the term using `-1`. Here are some examples for linear mixed-effects model specification.

Examples:

Formula	Description
' $y \sim X1 + X2$ '	Fixed effects for the intercept, $X1$ and $X2$. This is equivalent to ' $y \sim 1 + X1 + X2$ '.
' $y \sim -1 + X1 + X2$ '	No intercept and fixed effects for $X1$ and $X2$. The implicit intercept term is suppressed by including <code>-1</code> .
' $y \sim 1 + (1 g1)$ '	Fixed effects for the intercept plus random effect for the intercept for each level of the grouping variable $g1$.

Formula	Description
'y ~ X1 + (1 g1)'	Random intercept model with a fixed slope.
'y ~ X1 + (X1 g1)'	Random intercept and slope, with possible correlation between them. This is equivalent to 'y ~ 1 + X1 + (1 + X1 g1)'.
'y ~ X1 + (1 g1) + (-1 + X1 g1)'	Independent random effects terms for intercept and slope.
'y ~ 1 + (1 g1) + (1 g2) + (1 g1:g2)'	Random intercept model with independent main effects for g1 and g2, plus an independent interaction effect.

Copy Semantics

Value. To learn how value classes affect copy operations, see “Copying Objects” in the MATLAB documentation.

Examples

Random Intercept Model with Categorical Predictor

Load the sample data.

```
load flu
```

The `flu` dataset array has a `Date` variable, and 10 variables containing estimated influenza rates (in 9 different regions, estimated from Google searches, plus a nationwide estimate from the Center for Disease Control and Prevention, CDC).

To fit a linear-mixed effects model, your data must be in a properly formatted dataset array. To fit a linear mixed-effects model with the influenza rates as the responses and region as the predictor variable, combine the nine columns corresponding to the regions into a tall array. The new dataset array, `flu2`, must have the response variable, `FluRate`, the nominal variable, `Region`, that shows which region each estimate is from, and the grouping variable `Date`.

```
flu2 = stack(flu,2:10, 'NewDataVarName', 'FluRate', ...
```

```
'IndVarName', 'Region');
flu2.Date = nominal(flu2.Date);
```

Fit a linear mixed-effects model with fixed effects for region and a random intercept that varies by `Date`.

Because region is a nominal variable, `fitlme` takes the first region, NE, as the reference and creates eight dummy variables representing the other eight regions. For example, $I[\text{MidAtl}]$ is the dummy variable representing the region `MidAtl`. For details, see “Dummy Indicator Variables” on page 2-55.

The corresponding model is

$$y_{im} = \beta_0 + \beta_1 I[\text{MidAtl}]_i + \beta_2 I[\text{ENCentral}]_i + \beta_3 I[\text{WNCentral}]_i + \beta_4 I[\text{SAtl}]_i \\ + \beta_5 I[\text{ESCentral}]_i + \beta_6 I[\text{WSCentral}]_i + \beta_7 I[\text{Mtn}]_i + \beta_8 I[\text{Pac}]_i + b_{0m} + \varepsilon_{im}, \quad m = 1, 2, \dots, 52,$$

where y_{im} is the observation i for level m of grouping variable `Date`, β_j , $j = 0, 1, \dots, 8$, are the fixed-effects coefficients, b_{0m} is the random effect for level m of the grouping variable `Date`, and ε_{im} is the observation error for observation i . The random effect has the prior distribution, $b \sim N(0, \sigma_b^2)$ and the error term has the distribution, $\varepsilon \sim N(0, \sigma^2)$.

```
lme = fitlme(flu2, 'FluRate ~ 1 + Region + (1|Date)')
```

Linear mixed-effects model fit by ML

Model information:

Number of observations	468
Fixed effects coefficients	9
Random effects coefficients	52
Covariance parameters	2

Formula:

```
FluRate ~ 1 + Region + (1|Date)
```

Model fit statistics:

AIC	BIC	LogLikelihood	Deviance
318.71	364.35	-148.36	296.71

Fixed effects coefficients (95% CIs):

Name	Estimate	SE	tStat	DF	pValue
'(Intercept)'	1.2233	0.096678	12.654	459	1.085e-31
'Region_MidAtl'	0.010192	0.052221	0.19518	459	0.84534

'Region_ENCentral'	0.051923	0.052221	0.9943	459	0.3206
'Region_WNCentral'	0.23687	0.052221	4.5359	459	7.3324e-06
'Region_SAt1'	0.075481	0.052221	1.4454	459	0.14902
'Region_ESCentral'	0.33917	0.052221	6.495	459	2.1623e-10
'Region_WSCentral'	0.069	0.052221	1.3213	459	0.18705
'Region_Mtn'	0.046673	0.052221	0.89377	459	0.37191
'Region_Pac'	-0.16013	0.052221	-3.0665	459	0.0022936

Random effects covariance parameters (95% CIs):

Group: Date (52 Levels)

Name1	Name2	Type	Estimate	Lower	Upper
'(Intercept)'	'(Intercept)'	'std'	0.6443	0.5297	0.78368

Group: Error

Name	Estimate	Lower	Upper
'Res Std'	0.26627	0.24878	0.285

The p -values 7.3324e-06 and 2.1623e-10 respectively show that the fixed effects of the flu rates in regions `WNCentral` and `ESCentral` are significantly different relative to the flu rates in region `NE`.

The confidence limits for the standard deviation of the random-effects term, σ_b^2 , do not include 0 (0.5297, 0.78368), which indicates that the random-effects term is significant. You can also test the significance of the random-effects terms using the `compare` method.

The estimated value of an observation is the sum of the fixed effects and the random-effect value at the grouping variable level corresponding to that observation. For example, the estimated best linear unbiased predictor (BLUP) of the flu rate for region `WNCentral` in week `10/9/2005` is

$$\begin{aligned}\hat{y}_{WNCentral,10/9/2005} &= \hat{\beta}_0 + \hat{\beta}_3 I[WNCentral] + \hat{b}_{10/9/2005} \\ &= 1.2233 + 0.23687 - 0.1718 \\ &= 1.28837.\end{aligned}$$

This is the fitted conditional response, since it includes contribution to the estimate from both the fixed and random effects. You can compute this value as follows.

```
beta = fixedEffects(lme);
[~,~,STATS] = randomEffects(lme); % Compute the random-effects statistics (STATS)
STATS.Level = nominal(STATS.Level);
y_hat = beta(1) + beta(4) + STATS.Estimate(STATS.Level=='10/9/2005')
```

```
y_hat =
    1.2884
```

You can simply display the fitted value using the `fitted` method.

```
F = fitted(lme);
F(flu2.Date == '10/9/2005' & flu2.Region == 'WNCentral')
ans =
    1.2884
```

Compute the fitted marginal response for region `WNCentral` in week 10/9/2005.

```
F = fitted(lme, 'Conditional', false);
F(flu2.Date == '10/9/2005' & flu2.Region == 'WNCentral')
ans =
    1.4602
```

Linear Mixed-Effects Model with a Random Slope

Load the sample data.

```
load carbig
```

Fit a linear mixed-effects model for miles per gallon (MPG), with fixed effects for acceleration, horsepower and cylinders, and potentially correlated random effect for intercept and acceleration grouped by model year. This model corresponds to

$$MPG_{im} = \beta_0 + \beta_1 Acc_i + \beta_2 HP + b_{0m} + b_{1m} Acc_{im} + \varepsilon_{im}, \quad m = 1, 2, 3,$$

with the random-effects terms having the following prior distribution

$$b_m = \begin{pmatrix} b_{0m} \\ b_{1m} \end{pmatrix} \sim N \left(0, \begin{pmatrix} \sigma_0^2 & \sigma_{0,1} \\ \sigma_{0,1} & \sigma_1^2 \end{pmatrix} \right),$$

where $D(\theta)$ is the covariance matrix.

First, prepare the design matrices for fitting the linear mixed-effects model.

```
X = [ones(406,1) Acceleration Horsepower];
```

```
Z = [ones(406,1) Acceleration];
Model_Year = nominal(Model_Year);
G = Model_Year;
```

Now, fit the model using `fitlmematrix` with the defined design matrices and grouping variables. Use the 'fminunc' optimization algorithm.

```
lme = fitlmematrix(X,MPG,Z,G,'FixedEffectPredictors',...
{'Intercept','Acceleration','Horsepower'},'RandomEffectPredictors',...
{{'Intercept','Acceleration'}},'RandomEffectGroups',{'Model_Year'},...
'FitMethod','REML')
```

```
lme =
```

Linear mixed-effects model fit by REML

Model information:

Number of observations	392
Fixed effects coefficients	3
Random effects coefficients	26
Covariance parameters	4

Formula:

```
y ~ Intercept + Acceleration + Horsepower + (Intercept + Acceleration | Model_Year)
```

Model fit statistics:

AIC	BIC	LogLikelihood	Deviance
2202.9	2230.7	-1094.5	2188.9

Fixed effects coefficients (95% CIs):

Name	Estimate	SE	tStat	DF	pValue	Lower
'Intercept'	50.064	2.3176	21.602	389	1.4185e-68	44.429
'Acceleration'	-0.57897	0.13843	-4.1825	389	3.5654e-05	-0.8562
'Horsepower'	-0.16958	0.0073242	-23.153	389	3.5289e-75	-0.1847

Random effects covariance parameters (95% CIs):

Group: Model_Year (13 Levels)

Name1	Name2	Type	Estimate	Lower	Upper
'Intercept'	'Intercept'	'std'	3.72	1.5215	5.9185
'Acceleration'	'Intercept'	'corr'	-0.8769	-0.98275	-0.77105
'Acceleration'	'Acceleration'	'std'	0.3593	0.19418	0.52442

Group: Error

Name	Estimate	Lower	Upper
------	----------	-------	-------

```
'Res Std'          3.6913      3.4331      3.9688
```

The fixed effects coefficients display includes the estimate, standard errors (SE), and the 95% confidence interval limits (**Lower** and **Upper**). The *p*-values for (**pValue**) indicate that all three fixed-effects coefficients are significant.

The confidence intervals for the standard deviations and the correlation between the random effects for intercept and acceleration do not include zeros, hence they seem significant. Use the **compare** method to test for the random effects.

Display the covariance matrix of the estimated fixed-effects coefficients.

```
lme.CoefficientCovariance
```

```
ans =
      5.3711   -0.2809   -0.0126
     -0.2809    0.0192    0.0005
     -0.0126    0.0005    0.0001
```

The diagonal elements show the variances of the fixed-effects coefficient estimates. For example, the variance of the estimate of the intercept is 5.3711. Note that the standard errors of the estimates are the square roots of the variances. For example, the standard error of the intercept is 2.3176, which is `sqrt(5.3711)`.

The off-diagonal elements show the correlation between the fixed-effects coefficient estimates. For example, the correlation between the intercept and acceleration is `-0.2809` and the correlation between acceleration and horsepower is `0.0005`.

Display the coefficient of determination for the model.

```
lme.Rsquared
```

```
ans =
      Ordinary: 0.7826
      Adjusted: 0.7815
```

The adjusted value is the R-squared value adjusted for the number of predictors in the model.

linhpytest

Linear hypothesis test

Syntax

```
p = linhpytest(beta,COVB,c,H,dfe)
[p,t,r] = linhpytest(...)
```

Description

`p = linhpytest(beta,COVB,c,H,dfe)` returns the p value `p` of a hypothesis test on a vector of parameters. `beta` is a vector of k parameter estimates. `COVB` is the k -by- k estimated covariance matrix of the parameter estimates. `c` and `H` specify the null hypothesis in the form $H*\mathbf{b} = \mathbf{c}$, where `b` is the vector of unknown parameters estimated by `beta`. `dfe` is the degrees of freedom for the `COVB` estimate, or `Inf` if `COVB` is known rather than estimated.

`beta` is required. The remaining arguments have default values:

- `COVB = eye(k)`
- `c = zeros(k,1)`
- `H = eye(K)`
- `dfe = Inf`

If `H` is omitted, `c` must have k elements and it specifies the null hypothesis values for the entire parameter vector.

Note: The following functions return outputs suitable for use as the `COVB` input argument to `linhpytest`: `nlinfit`, `coxphfit`, `glmfit`, `mnrfit`, `regstats`, `robustfit`. `nlinfit` returns `COVB` directly; the other functions return `COVB` in `stats.covb`.

`[p,t,r] = linhpytest(...)` also returns the test statistic `t` and the rank `r` of the hypothesis matrix `H`. If `dfe` is `Inf` or is not given, `t*r` is a chi-square statistic with `r`

degrees of freedom . If `dfe` is specified as a finite value, `t` is an F statistic with `r` and `dfe` degrees of freedom.

`linhpytest` performs a test based on an asymptotic normal distribution for the parameter estimates. It can be used after any estimation procedure for which the parameter covariances are available, such as `regstats` or `glmfit`. For linear regression, the p -values are exact. For other procedures, the p -values are approximate, and may be less accurate than other procedures such as those based on a likelihood ratio.

Examples

Fit a multiple linear model to the data in `hald.mat`:

```
load hald
stats = regstats(heat,ingredients,'linear');
beta = stats.beta
beta =
    62.4054
     1.5511
     0.5102
     0.1019
    -0.1441
```

Perform an F -test that the last two coefficients are both 0:

```
SIGMA = stats.covb;
dfe = stats.fstat.dfe;
H = [0 0 0 1 0;0 0 0 0 1];
c = [0;0];
[p,F] = linhpytest(beta,SIGMA,c,H,dfe)
p =
    0.4668
F =
    0.8391
```

linkage

Agglomerative hierarchical cluster tree

Syntax

```
Z = linkage(X)
Z = linkage(X,method)
Z = linkage(X,method,metric)
Z = linkage(X,method,pdist_inputs)
Z = linkage(X,method,metric,'savememory',value)
Z = linkage(Y)
Z = linkage(Y,method)
```

Description

`Z = linkage(X)` returns a matrix `Z` that encodes a tree of hierarchical clusters of the rows of the real matrix `X`.

`Z = linkage(X,method)` creates the tree using the specified *method*, where *method* describes how to measure the distance between clusters.

`Z = linkage(X,method,metric)` performs clustering using the distance measure *metric* to compute distances between the rows of `X`.

`Z = linkage(X,method,pdist_inputs)` passes parameters to the `pdist` function, which is the function that computes the distance between rows of `X`.

`Z = linkage(X,method,metric,'savememory',value)` uses a memory-saving algorithm when *value* is 'true', and uses the standard algorithm when *value* is 'false'.

`Z = linkage(Y)` uses a vector representation `Y` of a distance matrix. `Y` can be a distance matrix as computed by `pdist`, or a more general dissimilarity matrix conforming to the output format of `pdist`.

`Z = linkage(Y,method)` creates the tree using the specified *method*, where *method* describes how to measure the distance between clusters.

Input Arguments

X

Matrix with two or more rows. The rows represent observations, the columns represent categories or dimensions.

method

Algorithm for computing distance between clusters.

Method	Description
'average'	Unweighted average distance (UPGMA)
'centroid'	Centroid distance (UPGMC), appropriate for Euclidean distances only
'complete'	Furthest distance
'median'	Weighted center of mass distance (WPGMC), appropriate for Euclidean distances only
'single'	Shortest distance
'ward'	Inner squared distance (minimum variance algorithm), appropriate for Euclidean distances only
'weighted'	Weighted average distance (WPGMA)

Default: 'single'

metric

Any distance metric that the `pdist` function accepts.

Metric	Description
'euclidean'	Euclidean distance (default).
'seuclidean'	Standardized Euclidean distance. Each coordinate difference between rows in <code>X</code> is scaled by dividing by the corresponding element of the standard deviation <code>S=nanstd(X)</code> . To specify another value for <code>S</code> , use <code>D=pdist(X, 'seuclidean', S)</code> .
'cityblock'	City block metric.

Metric	Description
'minkowski'	Minkowski distance. The default exponent is 2. To specify a different exponent, use <code>D = pdist(X, 'minkowski', P)</code> , where <code>P</code> is a scalar positive value of the exponent.
'chebychev'	Chebychev distance (maximum coordinate difference).
'mahalanobis'	Mahalanobis distance, using the sample covariance of <code>X</code> as computed by <code>nancov</code> . To compute the distance with a different covariance, use <code>D = pdist(X, 'mahalanobis', C)</code> , where the matrix <code>C</code> is symmetric and positive definite.
'cosine'	One minus the cosine of the included angle between points (treated as vectors).
'correlation'	One minus the sample correlation between points (treated as sequences of values).
'spearman'	One minus the sample Spearman's rank correlation between observations (treated as sequences of values).
'hamming'	Hamming distance, which is the percentage of coordinates that differ.
'jaccard'	One minus the Jaccard coefficient, which is the percentage of nonzero coordinates that differ.
custom distance function	<p>A distance function specified using <code>@</code>:</p> <pre>D = pdist(X, @distfun)</pre> <p>A distance function must be of form</p> <pre>d2 = distfun(XI, XJ)</pre> <p>taking as arguments a 1-by-n vector <code>XI</code>, corresponding to a single row of <code>X</code>, and an $m2$-by-n matrix <code>XJ</code>, corresponding to multiple rows of <code>X</code>. <code>distfun</code> must accept a matrix <code>XJ</code> with an arbitrary number of rows. <code>distfun</code> must return an $m2$-by-1 vector of distances <code>d2</code>, whose kth element is the distance between <code>XI</code> and <code>XJ(k, :)</code>.</p>

Default: 'euclidean'

pdist_inputs

A cell array of parameters accepted by the `pdist` function. For example, to set the *metric* to `minkowski` and use an exponent of 5, set `pdist_inputs` to `{'minkowski',5}`.

savememory

A string, either `'on'` or `'off'`. When applicable, the `'on'` setting causes `linkage` to construct clusters without computing the distance matrix. `savememory` is applicable when:

- `linkage` is `'centroid'`, `'median'`, or `'ward'`
- `distance` is `'euclidean'` (default)

When `savememory` is `'on'`, `linkage` run time is proportional to the number of dimensions (number of columns of X). When `savememory` is `'off'`, `linkage` memory requirement is proportional to N^2 , where N is the number of observations. So choosing the best (least-time) setting for `savememory` depends on the problem dimensions, number of observations, and available memory. The default `savememory` setting is a rough approximation of an optimal setting.

Default: `'on'` when X has 20 columns or fewer, or the computer does not have enough memory to store the distance matrix; otherwise `'off'`

Y

A vector of distances with the same format as the output of the `pdist` function:

- A row vector of length $m(m-1)/2$, corresponding to pairs of observations in a matrix X with m rows
- Distances arranged in the order $(2,1)$, $(3,1)$, ..., $(m,1)$, $(3,2)$, ..., $(m,2)$, ..., $(m,m-1)$

Y can be a more general dissimilarity matrix conforming to the output format of `pdist`.

Output Arguments**Z**

Z is a $(m-1)$ -by-3 matrix, where m is the number of observations in the original data. Columns 1 and 2 of Z contain cluster indices linked in pairs to form a binary tree. The

leaf nodes are numbered from 1 to m . Leaf nodes are the singleton clusters from which all higher clusters are built. Each newly-formed cluster, corresponding to row $Z(I, :)$, is assigned the index $m+I$. $Z(I, 1:2)$ contains the indices of the two component clusters that form cluster $m+I$. There are $m-1$ higher clusters which correspond to the interior nodes of the clustering tree. $Z(I, 3)$ contains the linkage distances between the two clusters merged in row $Z(I, :)$.

For example, suppose there are 30 initial nodes and at step 12 cluster 5 and cluster 7 are combined. Suppose their distance at that time is 1.5. Then $Z(12, :)$ will be $[5, 7, 1.5]$. The newly formed cluster will have index $12 + 30 = 42$. If cluster 42 appears in a later row, it means the cluster created at step 12 is being combined into some larger cluster.

Examples

Compare Cluster Assignments to Clusters

Load the sample data.

```
load fisheriris
```

Compute four clusters of the Fisher iris data using Ward linkage and ignoring species information.

```
Z = linkage(meas, 'ward', 'euclidean');  
c = cluster(Z, 'maxclust', 4);
```

See how the cluster assignments correspond to the three species.

```
crosstab(c, species)
```

```
ans =
```

```
    0    25     1  
    0    24    14  
    0     1    35  
   50     0     0
```

Display the first five rows of Z .

```
firstfive = Z(1:5,:)
```

```
firstfive =
```

```
102.0000 143.0000      0
   8.0000  40.0000  0.1000
   1.0000  18.0000  0.1000
  10.0000  35.0000  0.1000
 129.0000 133.0000  0.1000
```

Create a dendrogram plot of Z .

```
dendrogram(Z)
```

Cluster Data and Plot the Result

Randomly generate the sample data with 20000 observations.

```
rng default; % For reproducibility
X = rand(20000,3);
```

Create a hierarchical cluster tree using Ward's linkage.

```
Z = linkage(X,'ward','euclidean','savememory','on');
```

If you set `savememory` to `'off'`, you can get an out-of-memory error if your machine doesn't have enough memory to hold the distance matrix.

Cluster data into four groups and plot the result.

```
c = cluster(Z, 'maxclust', 4);  
scatter3(X(:,1), X(:,2), X(:,3), 10, c)
```

More About

Linkages

The following notation is used to describe the linkages used by the various methods:

- Cluster r is formed from clusters p and q .
- n_r is the number of objects in cluster r .
- x_{ri} is the i th object in cluster r .

- *Single linkage*, also called *nearest neighbor*, uses the smallest distance between objects in the two clusters:

$$d(r, s) = \min(\text{dist}(x_{ri}, x_{sj}), i \in (1, \dots, n_r), j \in (1, \dots, n_s))$$

- *Complete linkage*, also called *furthest neighbor*, uses the largest distance between objects in the two clusters:

$$d(r, s) = \max(\text{dist}(x_{ri}, x_{sj}), i \in (1, \dots, n_r), j \in (1, \dots, n_s))$$

- *Average linkage* uses the average distance between all pairs of objects in any two clusters:

$$d(r, s) = \frac{1}{n_r n_s} \sum_{i=1}^{n_r} \sum_{j=1}^{n_s} \text{dist}(x_{ri}, x_{sj})$$

- *Centroid linkage* uses the Euclidean distance between the centroids of the two clusters:

$$d(r, s) = \|\bar{x}_r - \bar{x}_s\|_2$$

where

$$\bar{x}_r = \frac{1}{n_r} \sum_{i=1}^{n_r} x_{ri}$$

- *Median linkage* uses the Euclidean distance between weighted centroids of the two clusters,

$$d(r, s) = \|\tilde{x}_r - \tilde{x}_s\|_2$$

where \tilde{x}_r and \tilde{x}_s are weighted centroids for the clusters r and s . If cluster r was created by combining clusters p and q , \tilde{x}_r is defined recursively as

$$\tilde{x}_r = \frac{1}{2}(\tilde{x}_p + \tilde{x}_q)$$

- *Ward's linkage* uses the incremental sum of squares; that is, the increase in the total within-cluster sum of squares as a result of joining two clusters. The within-cluster sum of squares is defined as the sum of the squares of the distances between all objects in the cluster and the centroid of the cluster. The sum of squares measure is equivalent to the following distance measure $d(r,s)$, which is the formula linkage uses:

$$d(r,s) = \sqrt{\frac{2n_r n_s}{n_r + n_s}} \|\bar{x}_r - \bar{x}_s\|_2,$$

where

- $\|\cdot\|_2$ is Euclidean distance
- \bar{x}_r and \bar{x}_s are the centroids of clusters r and s
- n_r and n_s are the number of elements in clusters r and s

In some references the Ward linkage does not use the factor of 2 multiplying $n_r n_s$. The `linkage` function uses this factor so the distance between two singleton clusters is the same as the Euclidean distance.

- *Weighted average linkage* uses a recursive definition for the distance between two clusters. If cluster r was created by combining clusters p and q , the distance between r and another cluster s is defined as the average of the distance between p and s and the distance between q and s :

$$d(r,s) = \frac{(d(p,s) + d(q,s))}{2}$$

Tips

- Computing `linkage(Y)` can be slow when Y is a vector representation of the distance matrix. For the 'centroid', 'median', and 'ward' methods, `linkage` checks whether Y is a Euclidean distance. Avoid this time-consuming check by passing in X instead of Y .
- The `centroid` and `median` methods can produce a cluster tree that is not monotonic. This occurs when the distance from the union of two clusters, r and s , to a third cluster is less than the distance between r and s . In this case, in a dendrogram drawn with the default orientation, the path from a leaf to the root node takes some

downward steps. To avoid this, use another method. The following image shows a nonmonotonic cluster tree.

In this case, cluster 1 and cluster 3 are joined into a new cluster, while the distance between this new cluster and cluster 2 is less than the distance between cluster 1 and cluster 3. This leads to a nonmonotonic tree.

- You can provide the output `Z` to other functions including `dendrogram` to display the tree, `cluster` to assign points to clusters, `inconsistent` to compute inconsistent measures, and `cophenet` to compute the cophenetic correlation coefficient.

prob.LogisticDistribution class

Package: prob

Superclasses: prob.ToolboxFittableParametricDistribution

Logistic probability distribution object

Description

`prob.LogisticDistribution` is an object consisting of parameters, a model description, and sample data for a logistic probability distribution.

Create a probability distribution object with specified parameter values using `makedist`. Alternatively, fit a distribution to data using `fitdist` or the Distribution Fitting app.

Construction

`pd = makedist('Logistic')` creates a logistic probability distribution object using the default parameter values.

`pd = makedist('Logistic', 'mu', mu, 'sigma', sigma)` creates a logistic probability distribution object using the specified parameter values.

Input Arguments

mu — Mean

0 (default) | scalar value

Mean of the logistic distribution, specified as a scalar value.

Data Types: `single` | `double`

sigma — Scale parameter

1 (default) | nonnegative scalar value

Scale parameter of the logistic distribution, specified as a nonnegative scalar value.

Data Types: `single` | `double`

Properties

mu — Mean

scalar value

Mean of the logistic distribution, stored as a scalar value.

Data Types: `single` | `double`

sigma — Scale parameter

nonnegative scalar value

Scale parameter of the logistic distribution, stored as a nonnegative scalar value.

Data Types: `single` | `double`

DistributionName — Probability distribution name

probability distribution name string

Probability distribution name, stored as a valid probability distribution name string. This property is read-only.

Data Types: `char`

InputData — Data used for distribution fitting

structure

Data used for distribution fitting, stored as a structure containing the following:

- **data**: Data vector used for distribution fitting.
- **cens**: Censoring vector, or empty if none.
- **freq**: Frequency vector, or empty if none.

This property is read-only.

Data Types: `struct`

IsTruncated — Logical flag for truncated distribution

0 | 1

Logical flag for truncated distribution, stored as a logical value. If `IsTruncated` equals 0, the distribution is not truncated. If `IsTruncated` equals 1, the distribution is truncated. This property is read-only.

Data Types: `logical`

NumParameters — Number of parameters

positive integer value

Number of parameters for the probability distribution, stored as a positive integer value. This property is read-only.

Data Types: `single` | `double`

ParameterCovariance — Covariance matrix of the parameter estimates

matrix of scalar values

Covariance matrix of the parameter estimates, stored as a p -by- p matrix, where p is the number of parameters in the distribution. The (i,j) element is the covariance between the estimates of the i th parameter and the j th parameter. The (i,i) element is the estimated variance of the i th parameter. If parameter i is fixed rather than estimated by fitting the distribution to data, then the (i,i) elements of the covariance matrix are 0. This property is read-only.

Data Types: `single` | `double`

ParameterDescription — Distribution parameter descriptions

cell array of strings

Distribution parameter descriptions, stored as a cell array of strings. Each cell contains a short description of one distribution parameter. This property is read-only.

Data Types: `char`

ParameterIsFixed — Logical flag for fixed parameters

array of logical values

Logical flag for fixed parameters, stored as an array of logical values. If 0, the corresponding parameter in the `ParameterNames` array is not fixed. If 1, the corresponding parameter in the `ParameterNames` array is fixed. This property is read-only.

Data Types: `logical`

ParameterNames — Distribution parameter names

cell array of strings

Distribution parameter names, stored as a cell array of strings. This property is read-only.

Data Types: char

ParameterValues — Distribution parameter values

vector of scalar values

Distribution parameter values, stored as a vector. This property is read-only.

Data Types: single | double

Truncation — Truncation interval

vector of scalar values

Truncation interval for the probability distribution, stored as a vector containing the lower and upper truncation boundaries. This property is read-only.

Data Types: single | double

Methods

Inherited Methods

cdf	Cumulative distribution function of probability distribution object
icdf	Inverse cumulative distribution function of probability distribution object
iqr	Interquartile range of probability distribution object
median	Median of probability distribution object
pdf	Probability density function of probability distribution object
random	Generate random numbers from probability distribution object

truncate	Truncate probability distribution object
mean	Mean of probability distribution object
negloglik	Negative loglikelihood of probability distribution object
paramci	Confidence intervals for probability distribution parameters
proflik	Profile likelihood function for probability distribution object
std	Standard deviation of probability distribution object
var	Variance of probability distribution object

Definitions

Logistic Distribution

The logistic distribution is used for growth models and in logistic regression. It has longer tails and a higher kurtosis than the normal distribution.

The logistic distribution uses the following parameters.

Parameter	Description	Support
mu	Mean	$-\infty < \mu < \infty$
sigma	Scale parameter	$\sigma \geq 0$

The probability density function (pdf) is

$$f(x | \mu, \sigma) = \frac{\exp\left\{\frac{x - \mu}{\sigma}\right\}}{\sigma\left(1 + \exp\left\{\frac{x - \mu}{\sigma}\right\}\right)^2} ; \quad -\infty < x < \infty.$$

Examples

Create a Logistic Distribution Object Using Default Parameters

Create a logistic distribution object using the default parameter values.

```
pd = makedist('Logistic')
```

```
pd =
```

```
LogisticDistribution
```

```
Logistic distribution
```

```
mu = 0
```

```
sigma = 1
```

Create a Logistic Distribution Object Using Specified Parameters

Create a logistic distribution object by specifying parameter values.

```
pd = makedist('Logistic', 'mu',2,'sigma',4)
```

```
pd =
```

```
LogisticDistribution
```

```
Logistic distribution
```

```
mu = 2
```

```
sigma = 4
```

Compute the standard deviation of the distribution.

```
s = std(pd)
```

```
s =
```

Loglogistic probability distribution object

Description

`prob.LoglogisticDistribution` is an object consisting of parameters, a model description, and sample data for a loglogistic probability distribution.

Create a probability distribution object with specified parameter values using `makedist`. Alternatively, fit a distribution to data using `fitdist` or the Distribution Fitting app.

Construction

`pd = makedist('Loglogistic')` creates a loglogistic probability distribution object using the default parameter values.

`pd = makedist('Loglogistic', 'mu', mu, 'sigma', sigma)` creates a loglogistic probability distribution object using the specified parameter values .

Input Arguments

mu — Log mean

0 (default) | positive scalar value

Log mean for the loglogistic distribution, specified as a positive scalar value.

Data Types: `single` | `double`

sigma — Log scale parameter

1 (default) | positive scalar value

Log scale parameter for the loglogistic distribution, specified as a positive scalar value.

Data Types: `single` | `double`

Properties

mu — Log mean

positive scalar value

Log mean for the loglogistic distribution, stored as a positive scalar value.

Data Types: `single` | `double`

sigma — Log scale parameter

positive scalar value

Log scale parameter for the loglogistic distribution, stored as a positive scalar value.

Data Types: `single` | `double`

DistributionName — Probability distribution name

probability distribution name string

Probability distribution name, stored as a valid probability distribution name string. This property is read-only.

Data Types: `char`

InputData — Data used for distribution fitting

structure

Data used for distribution fitting, stored as a structure containing the following:
