- **data**: Data vector used for distribution fitting.
- **cens**: Censoring vector, or empty if none.
- **freq**: Frequency vector, or empty if none.

This property is read-only.

Data Types: `struct`

IsTruncated — Logical flag for truncated distribution

0 | 1

Logical flag for truncated distribution, stored as a logical value. If **IsTruncated** equals 0, the distribution is not truncated. If **IsTruncated** equals 1, the distribution is truncated. This property is read-only.

Data Types: `logical`

NumParameters — Number of parameters

positive integer value

Number of parameters for the probability distribution, stored as a positive integer value. This property is read-only.

Data Types: `single` | `double`

ParameterCovariance — Covariance matrix of the parameter estimates

matrix of scalar values

Covariance matrix of the parameter estimates, stored as a p -by- p matrix, where p is the number of parameters in the distribution. The (i,j) element is the covariance between the estimates of the i th parameter and the j th parameter. The (i,i) element is the estimated variance of the i th parameter. If parameter i is fixed rather than estimated by fitting the distribution to data, then the (i,i) elements of the covariance matrix are 0. This property is read-only.

Data Types: `single` | `double`

ParameterDescription — Distribution parameter descriptions

cell array of strings

Distribution parameter descriptions, stored as a cell array of strings. Each cell contains a short description of one distribution parameter. This property is read-only.

Data Types: `char`

ParameterIsFixed — Logical flag for fixed parameters

array of logical values

Logical flag for fixed parameters, stored as an array of logical values. If 0, the corresponding parameter in the `ParameterNames` array is not fixed. If 1, the corresponding parameter in the `ParameterNames` array is fixed. This property is read-only.

Data Types: `logical`

ParameterNames — Distribution parameter names

cell array of strings

Distribution parameter names, stored as a cell array of strings. This property is read-only.

Data Types: char

ParameterValues — Distribution parameter values

vector of scalar values

Distribution parameter values, stored as a vector. This property is read-only.

Data Types: single | double

Truncation — Truncation interval

vector of scalar values

Truncation interval for the probability distribution, stored as a vector containing the lower and upper truncation boundaries. This property is read-only.

Data Types: single | double

Definitions

Loglogistic Distribution

The loglogistic distribution is closely related to the logistic distribution. If x is distributed loglogistically with parameters μ and σ , then $\log(x)$ is distributed logistically with mean and standard deviation. This distribution is often used in survival analysis to model events that experience an initial rate increase, followed by a rate decrease.

The loglogistic distribution uses the following parameters.

Parameter	Description	Support
mu	Log mean	$\mu > 0$
sigma	Log scale parameter	$\sigma > 0$

The probability density function (pdf) is

$$f(x | \mu, \sigma) = \frac{1}{\sigma} \frac{1}{x} \frac{e^z}{(1+e^z)^2} ; \quad x \geq 0,$$

where $z = \frac{\log(x) - \mu}{\sigma}$.

Examples

Create a Loglogistic Distribution Object Using Default Parameters

Create a loglogistic distribution object using the default parameter values.

```
pd = makedist('Loglogistic')
```

```
pd =
```

```
LoglogisticDistribution
```

```
Log-Logistic distribution
```

```
mu = 0
```

```
sigma = 1
```

Create a Loglogistic Distribution Object Using Specified Parameters

Create a loglogistic distribution object by specifying the parameter values.

```
pd = makedist('Loglogistic', 'mu', 5, 'sigma', 2)
```

```
pd =
```

```
LoglogisticDistribution
```

```
Log-Logistic distribution
```

```
mu = 5
```

```
sigma = 2
```

Generate random numbers from the loglogistic distribution and compute their log values.

```
rng(19) % for reproducibility
```

```
x = random(pd, 10000, 1);
```

```
logx = log(x);
```

Compute the mean of the log values.

```
m = mean(logx)
```

```
m =
```

```
4.9828
```

The mean of the log of x is equal to the μ parameter of x , since x has a loglogistic distribution.

Plot $\log x$.

```
hist(logx,50)
```

The plot shows that the log values of x have a logistic distribution.

logncdf

Lognormal cumulative distribution function

Syntax

```
p = logncdf(x,mu,sigma)
[p,plo,pup] = logncdf(x,mu,sigma,pcov,alpha)
[p,plo,pup] = logncdf( __ , 'upper' )
```

Description

`p = logncdf(x,mu,sigma)` returns values at `x` of the lognormal cdf with distribution parameters `mu` and `sigma`. `mu` and `sigma` are the mean and standard deviation, respectively, of the associated normal distribution. `x`, `mu`, and `sigma` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input for `x`, `mu`, or `sigma` is expanded to a constant array with the same dimensions as the other inputs.

`[p,plo,pup] = logncdf(x,mu,sigma,pcov,alpha)` returns confidence bounds for `p` when the input parameters `mu` and `sigma` are estimates. `pcov` is the covariance matrix of the estimated parameters. `alpha` specifies $100(1 - \alpha)\%$ confidence bounds. The default value of `alpha` is 0.05. `plo` and `pup` are arrays of the same size as `p` containing the lower and upper confidence bounds.

`[p,plo,pup] = logncdf(__ , 'upper')` returns the complement of the lognormal cdf at each value in `x`, using an algorithm that more accurately computes the extreme upper tail probabilities. You can use `'upper'` with any of the previous syntaxes.

`logncdf` computes confidence bounds for `p` using a normal approximation to the distribution of the estimate

$$\frac{x - \hat{\mu}}{\hat{\sigma}}$$

and then transforming those bounds to the scale of the output `p`. The computed bounds give approximately the desired confidence level when you estimate `mu`, `sigma`, and `pcov`

from large samples, but in smaller samples other methods of computing the confidence bounds might be more accurate.

The lognormal cdf is

$$p = F(x | \mu, \sigma) = \frac{1}{\sigma\sqrt{2\pi}} \int_0^x \frac{e^{-\frac{(\ln(t)-\mu)^2}{2\sigma^2}}}{t} dt$$

Examples

Compute the Lognormal Distribution cdf

Compute the cdf of a lognormal distribution with `mu = 0` and `sigma = 1`.

```
x = (0:0.2:10);  
y = logncdf(x,0,1);
```

Plot the cdf.

```
plot(x,y);  
grid;  
xlabel('x');  
ylabel('p');
```

lognfit

Lognormal parameter estimates

Syntax

```
parmhat = lognfit(data)
[parmhat,parmci] = lognfit(data)
[parmhat,parmci] = lognfit(data,alpha)
[...] = lognfit(data,alpha,censoring)
[...] = lognfit(data,alpha,censoring,freq)
[...] = lognfit(data,alpha,censoring,freq,options)
```

Description

`parmhat = lognfit(data)` returns a vector of maximum likelihood estimates `parmhat(1) = mu` and `parmhat(2) = sigma` of parameters for a lognormal distribution fitting `data`. `mu` and `sigma` are the mean and standard deviation, respectively, of the associated normal distribution.

`[parmhat,parmci] = lognfit(data)` returns 95% confidence intervals for the parameter estimates `mu` and `sigma` in the 2-by-2 matrix `parmci`. The first column of the matrix contains the lower and upper confidence bounds for parameter `mu`, and the second column contains the confidence bounds for parameter `sigma`.

`[parmhat,parmci] = lognfit(data,alpha)` returns $100(1 - \text{alpha})\%$ confidence intervals for the parameter estimates, where `alpha` is a value in the range (0 1) specifying the width of the confidence intervals. By default, `alpha` is 0.05, which corresponds to 95% confidence intervals.

`[...] = lognfit(data,alpha,censoring)` accepts a Boolean vector `censoring`, of the same size as `data`, which is 1 for observations that are right-censored and 0 for observations that are observed exactly.

`[...] = lognfit(data,alpha,censoring,freq)` accepts a frequency vector, `freq`, of the same size as `data`. Typically, `freq` contains integer frequencies for the corresponding elements in `data`, but can contain any nonnegative values. Pass in `[]` for `alpha`, `censoring`, or `freq` to use their default values.

[...] = `lognfit(data,alpha,censoring,freq,options)` accepts a structure, `options`, that specifies control parameters for the iterative algorithm the function uses to compute maximum likelihood estimates when there is censoring. The lognormal fit function accepts an `options` structure which can be created using the function `statset`. Enter `statset('lognfit')` to see the names and default values of the parameters that `lognfit` accepts in the `options` structure. See the reference page for `statset` for more information about these options.

Note: With no censoring, `lognfit` computes `sigma` using the square root of the unbiased estimator of the variance. With censoring, `sigma` is the maximum likelihood estimate.

Examples

This example generates 100 independent samples of lognormally distributed data with $\mu = 0$ and $\sigma = 3$. `parmhat` estimates μ and σ and `parmci` gives 99% confidence intervals around `parmhat`. Notice that `parmci` contains the true values of μ and σ .

```
data = lognrnd(0,3,100,1);
[parmhat,parmci] = lognfit(data,0.01)
parmhat =
    -0.2480    2.8902
parmci =
    -1.0071    2.4393
     0.5111    3.5262
```

More About

- “Lognormal Distribution” on page B-86

See Also

`mle` | `lognlike` | `lognpdf` | `logncdf` | `logninv` | `lognstat` | `lognrnd`

logninv

Lognormal inverse cumulative distribution function

Syntax

```
X = logninv(P,mu,sigma)  
[X,XLO,XUP] = logninv(P,mu,sigma,pcov,alpha)
```

Description

`X = logninv(P,mu,sigma)` returns values at **P** of the inverse lognormal cdf with distribution parameters **mu** and **sigma**. **mu** and **sigma** are the mean and standard deviation, respectively, of the associated normal distribution. **mu** and **sigma** can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of **X**. A scalar input for **P**, **mu**, or **sigma** is expanded to a constant array with the same dimensions as the other inputs.

`[X,XLO,XUP] = logninv(P,mu,sigma,pcov,alpha)` returns confidence bounds for **X** when the input parameters **mu** and **sigma** are estimates. **pcov** is the covariance matrix of the estimated parameters. **alpha** specifies 100(1 - **alpha**)% confidence bounds. The default value of **alpha** is 0.05. **XLO** and **XUP** are arrays of the same size as **X** containing the lower and upper confidence bounds.

`logninv` computes confidence bounds for **P** using a normal approximation to the distribution of the estimate

$$\hat{\mu} + \hat{\sigma}q$$

where *q* is the *P*th quantile from a normal distribution with mean 0 and standard deviation 1. The computed bounds give approximately the desired confidence level when you estimate **mu**, **sigma**, and **pcov** from large samples, but in smaller samples other methods of computing the confidence bounds might be more accurate.

The lognormal inverse function is defined in terms of the lognormal cdf as

$$x = F^{-1}(p | \mu, \sigma) = \{x : F(x | \mu, \sigma) = p\}$$

where

$$p = F(x | \mu, \sigma) = \frac{1}{\sigma\sqrt{2\pi}} \int_0^x \frac{e^{-\frac{(\ln(t)-\mu)^2}{2\sigma^2}}}{t} dt$$

Examples

Compute the Lognormal Distribution Inverse cdf

Compute the inverse cdf of a lognormal distribution with $\mu = 0$ and $\sigma = 0.5$.

```
p = (0.005:0.01:0.995);  
crit = logninv(p,1,0.5);
```

Plot the inverse cdf.

```
figure;  
plot(p,crit)  
xlabel('Probability');  
ylabel('Critical Value');  
grid
```

More About

- “Lognormal Distribution” on page B-86

References

See Also

`icdf` | `logncdf` | `lognpdf` | `lognstat` | `lognfit` | `lognlike` | `lognrnd`

lognlike

Lognormal negative log-likelihood

Syntax

```
nlogL = lognlike(params,data)
[nlogL,avar] = lognlike(params,data)
[...] = lognlike(params,data,censoring)
[...] = lognlike(params,data,censoring,freq)
```

Description

`nlogL = lognlike(params,data)` returns the negative log-likelihood of `data` for the lognormal distribution with parameters `params`. `params(1)` is the mean of the associated normal distribution, `mu`, and `params(2)` is the standard deviation of the associated normal distribution, `sigma`. The values of `mu` and `sigma` are scalars, and the output `nlogL` is a scalar.

`[nlogL,avar] = lognlike(params,data)` returns the inverse of Fisher's information matrix. If the input parameter value in `params` is the maximum likelihood estimate, `avar` is its asymptotic variance. `avar` is based on the observed Fisher's information, not the expected information.

`[...] = lognlike(params,data,censoring)` accepts a Boolean vector, `censoring`, of the same size as `data`, which is 1 for observations that are right-censored and 0 for observations that are observed exactly.

`[...] = lognlike(params,data,censoring,freq)` accepts a frequency vector, `freq`, of the same size as `data`. The vector `freq` typically contains integer frequencies for the corresponding elements in `data`, but can contain any nonnegative values. Pass in `[]` for `censoring` to use its default value.

prob.LognormalDistribution class

Package: prob

Superclasses: prob.ToolboxFittableParametricDistribution

Lognormal probability distribution object

Description

`prob.LognormalDistribution` is an object consisting of parameters, a model description, and sample data for a lognormal probability distribution.

Create a probability distribution object with specified parameter values using `makedist`. Alternatively, fit a distribution to data using `fitdist` or the Distribution Fitting app.

Construction

`pd = makedist('Lognormal')` creates a lognormal probability distribution object using the default parameter values.

`pd = makedist('Lognormal', 'mu', mu, 'sigma', sigma)` creates a lognormal probability distribution object using the specified parameter values.

Input Arguments

mu — Log mean

0 (default) | scalar value

Log mean for the lognormal distribution, specified as a scalar value. `mu` is the mean of the log of x , when x has a lognormal distribution.

Data Types: `single` | `double`

sigma — Log standard deviation

1 (default) | nonnegative scalar value

Log standard deviation for the lognormal distribution, specified as a nonnegative scalar value. `sigma` is the standard deviation of the log of x , when x has a lognormal distribution.

Data Types: `single` | `double`

Properties

mu — Log mean

scalar value

Log mean for the lognormal distribution, stored as a scalar value.

Data Types: `single` | `double`

sigma — Log standard deviation

nonnegative scalar value

Log standard deviation for the lognormal distribution, stored as a nonnegative scalar value.

Data Types: `single` | `double`

DistributionName — Probability distribution name

probability distribution name string

Probability distribution name, stored as a valid probability distribution name string. This property is read-only.

Data Types: `char`

InputData — Data used for distribution fitting

structure

Data used for distribution fitting, stored as a structure containing the following:

- **data**: Data vector used for distribution fitting.
- **cens**: Censoring vector, or empty if none.
- **freq**: Frequency vector, or empty if none.

This property is read-only.

Data Types: `struct`

IsTruncated — Logical flag for truncated distribution

0 | 1

Logical flag for truncated distribution, stored as a logical value. If `IsTruncated` equals 0, the distribution is not truncated. If `IsTruncated` equals 1, the distribution is truncated. This property is read-only.

Data Types: `logical`

NumParameters — Number of parameters

positive integer value

Number of parameters for the probability distribution, stored as a positive integer value. This property is read-only.

Data Types: `single` | `double`

ParameterCovariance — Covariance matrix of the parameter estimates

matrix of scalar values

Covariance matrix of the parameter estimates, stored as a p -by- p matrix, where p is the number of parameters in the distribution. The (i, j) element is the covariance between the estimates of the i th parameter and the j th parameter. The (i, i) element is the estimated variance of the i th parameter. If parameter i is fixed rather than estimated by fitting the distribution to data, then the (i, i) elements of the covariance matrix are 0. This property is read-only.

Data Types: `single` | `double`

ParameterDescription — Distribution parameter descriptions

cell array of strings

Distribution parameter descriptions, stored as a cell array of strings. Each cell contains a short description of one distribution parameter. This property is read-only.

Data Types: `char`

ParameterIsFixed — Logical flag for fixed parameters

array of logical values

Logical flag for fixed parameters, stored as an array of logical values. If 0, the corresponding parameter in the `ParameterNames` array is not fixed. If 1, the corresponding parameter in the `ParameterNames` array is fixed. This property is read-only.

Data Types: `logical`

ParameterNames — Distribution parameter names

cell array of strings

Distribution parameter names, stored as a cell array of strings. This property is read-only.

Data Types: char

ParameterValues — Distribution parameter values

vector of scalar values

Distribution parameter values, stored as a vector. This property is read-only.

Data Types: single | double

Truncation — Truncation interval

vector of scalar values

Truncation interval for the probability distribution, stored as a vector containing the lower and upper truncation boundaries. This property is read-only.

Data Types: single | double

Definitions

Lognormal Distribution

The lognormal distribution is closely related to the normal distribution. If x is distributed lognormally with parameters μ and σ , then $\log(x)$ is distributed normally with mean μ and standard deviation σ . The lognormal distribution is applicable when the quantity of interest must be positive, since $\log(x)$ exists only when x is positive.

The lognormal distribution uses the following parameters.

Parameter	Description	Support
mu	Log mean	$-\infty < \mu < \infty$
sigma	Log standard deviation	$\sigma \geq 0$

The probability density function (pdf) of the lognormal distribution is

$$f(x | \mu, \sigma) = \frac{1}{x\sigma\sqrt{2\pi}} \exp\left\{-\frac{(\ln x - \mu)^2}{2\sigma^2}\right\} ; \quad x > 0.$$

Examples

Create a Lognormal Distribution Object Using Default Parameters

Create a lognormal distribution object using the default parameter values.

```
pd = makedist('Lognormal')
```

```
pd =
```

```
LognormalDistribution
```

```
Lognormal distribution
```

```
mu = 0
```

```
sigma = 1
```

Create a Lognormal Distribution Object Using Specified Parameters

Create a lognormal distribution object by specifying the parameter values.

```
pd = makedist('Lognormal', 'mu', 5, 'sigma', 2)
```

```
pd =
```

```
LognormalDistribution
```

```
Lognormal distribution
    mu = 5
    sigma = 2
```

Compute the mean of the lognormal distribution.

```
mean(pd)
```

```
ans =
```

```
1.0966e+03
```

The mean of the lognormal distribution is not equal to the μ parameter.

Generate random numbers from the lognormal distribution and compute their log values.

```
rng(47); % for reproducibility
x = random(pd,10000,1);
logx = log(x);
```

Compute the mean of the log values.

```
m = mean(logx)
```

```
m =
```

```
4.9999
```

The mean of the log of x is equal to the μ parameter of x , since x has a lognormal distribution.

Plot $\log x$.

```
hist(logx,50)
```

The plot shows that the log values of x are normally distributed with a mean equal to 5 and a standard deviation equal to 2.

lognpdf

Lognormal probability density function

Syntax

`Y = lognpdf(X,mu,sigma)`

Description

`Y = lognpdf(X,mu,sigma)` returns values at `X` of the lognormal pdf with distribution parameters `mu` and `sigma`. `mu` and `sigma` are the mean and standard deviation, respectively, of the associated normal distribution. `X`, `mu`, and `sigma` can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of `Y`. A scalar input for `X`, `mu`, or `sigma` is expanded to a constant array with the same dimensions as the other inputs.

The lognormal pdf is

$$y = f(x | \mu, \sigma) = \frac{1}{x\sigma\sqrt{2\pi}} e^{-\frac{(\ln x - \mu)^2}{2\sigma^2}}$$

The normal and lognormal distributions are closely related. If X is distributed lognormally with parameters μ and σ , then $\log(X)$ is distributed normally with mean μ and standard deviation σ .

The mean m and variance v of a lognormal random variable are functions of μ and σ that can be calculated with the `lognstat` function. They are:

$$m = \exp\left(\mu + \frac{\sigma^2}{2}\right)$$
$$v = \exp\left(2\mu + \sigma^2\right)\left(\exp\left(\sigma^2\right) - 1\right)$$

So, a lognormal distribution with mean m and variance v has parameters

$$\mu = \log\left(m^2 / \sqrt{v + m^2}\right)$$
$$\sigma = \sqrt{\log(v / m^2 + 1)}$$

If you do not know the population mean and variance, m and v , for the lognormal distribution, you can estimate μ and σ in the following way:

```
mu = mean(log(X))  
sigma = std(log(X))
```

The lognormal distribution is applicable when the quantity of interest must be positive, since $\log(X)$ exists only when X is positive.

Examples

Compute the Lognormal Distribution pdf

Compute the pdf of a lognormal distribution with `mu = 0` and `sigma = 1`.

```
x = (0:0.02:10);  
y = lognpdf(x,0,1);
```

Plot the pdf.

```
plot(x,y); grid;  
xlabel('x'); ylabel('p')
```

lognrnd

Lognormal random numbers

Syntax

```
R = lognrnd(mu, sigma)
R = lognrnd(mu, sigma, m, n, ...)
R = lognrnd(mu, sigma, [m, n, ...])
```

Description

`R = lognrnd(mu, sigma)` returns an array of random numbers generated from the lognormal distribution with parameters `mu` and `sigma`. `mu` and `sigma` are the mean and standard deviation, respectively, of the associated normal distribution. `mu` and `sigma` can be vectors, matrices, or multidimensional arrays that have the same size, which is also the size of `R`. A scalar input for `mu` or `sigma` is expanded to a constant array with the same dimensions as the other input.

`R = lognrnd(mu, sigma, m, n, ...)` or `R = lognrnd(mu, sigma, [m, n, ...])` generates an `m`-by-`n`-by-... array. The `mu`, `sigma` parameters can each be scalars or arrays of the same size as `R`.

The normal and lognormal distributions are closely related. If X is distributed lognormally with parameters μ and σ , then $\log(X)$ is distributed normally with mean μ and standard deviation σ .

The mean m and variance v of a lognormal random variable are functions of μ and σ that can be calculated with the `lognstat` function. They are:

$$m = \exp\left(\mu + \sigma^2 / 2\right)$$

$$v = \exp\left(2\mu + \sigma^2\right)\left(\exp\left(\sigma^2\right) - 1\right)$$

A lognormal distribution with mean m and variance v has parameters

$$\mu = \log\left(m^2 / \sqrt{v + m^2}\right)$$
$$\sigma = \sqrt{\log(v / m^2 + 1)}$$

Examples

Generate one million lognormally distributed random numbers with mean 1 and variance 2:

```
m = 1;
v = 2;
mu = log((m^2)/sqrt(v+m^2));
sigma = sqrt(log(v/(m^2)+1));

[M,V]= lognstat(mu,sigma)
M =
    1
V =
    2.0000

X = lognrnd(mu,sigma,1,1e6);

MX = mean(X)
MX =
    0.9974
VX = var(X)
VX =
    1.9776
```

lognstat

Lognormal mean and variance

Syntax

```
[M,V] = lognstat(mu,sigma)
```

Description

`[M,V] = lognstat(mu,sigma)` returns the mean of and variance of the lognormal distribution with parameters `mu` and `sigma`. `mu` and `sigma` are the mean and standard deviation, respectively, of the associated normal distribution. `mu` and `sigma` can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of `M` and `V`. A scalar input for `mu` or `sigma` is expanded to a constant array with the same dimensions as the other input.

The normal and lognormal distributions are closely related. If X is distributed lognormally with parameters μ and σ , then $\log(X)$ is distributed normally with mean μ and standard deviation σ .

The mean m and variance v of a lognormal random variable are functions of μ and σ that can be calculated with the `lognstat` function. They are:

$$m = \exp(\mu + \sigma^2 / 2)$$
$$v = \exp(2\mu + \sigma^2)(\exp(\sigma^2) - 1)$$

A lognormal distribution with mean m and variance v has parameters

$$\mu = \log\left(m^2 / \sqrt{v + m^2}\right)$$
$$\sigma = \sqrt{\log(v / m^2 + 1)}$$

Examples

Generate one million lognormally distributed random numbers with mean 1 and variance 2:

```
m = 1;
v = 2;
mu = log((m^2)/sqrt(v+m^2));
sigma = sqrt(log(v/(m^2)+1));

[M,V]= lognstat(mu,sigma)
M =
    1
V =
    2.0000

X = lognrnd(mu,sigma,1,1e6);

MX = mean(X)
MX =
    0.9974
VX = var(X)
VX =
    1.9776
```

logP

Class: CompactClassificationDiscriminant

Log unconditional probability density for discriminant analysis classifier

Syntax

`lp = logP(obj, Xnew)`

Description

`lp = logP(obj, Xnew)` returns the log of the unconditional probability density of each row of `Xnew`, computed using the discriminant analysis model `obj`.

Input Arguments

obj

Discriminant analysis classifier, produced using `fitcdiscr`.

Xnew

Matrix where each row represents an observation, and each column represents a predictor. The number of columns in `Xnew` must equal the number of predictors in `obj`.

Output Arguments

lp

Column vector with the same number of rows as `Xnew`. Each entry is the logarithm of the unconditional probability density of the corresponding row of `Xnew`.

Definitions

Unconditional Probability Density

The unconditional probability density of a point x of a discriminant analysis model is

$$P(x) = \sum_{k=1}^K P(x, k),$$

where $P(x, k)$ is the conditional density of the model at x for class k , when the total number of classes is K .

The conditional density $P(x, k)$ is

$$P(x, k) = P(k)P(x | k),$$

where $P(k)$ is the prior probability of class k , and $P(x | k)$ is the conditional density of x given class k . The conditional density function of the multivariate normal with mean μ_k and covariance Σ_k at a point x is

$$P(x | k) = \frac{1}{(2\pi|\Sigma_k|)^{1/2}} \exp\left(-\frac{1}{2}(x - \mu_k)^T \Sigma_k^{-1} (x - \mu_k)\right),$$

where $|\Sigma_k|$ is the determinant of Σ_k , and Σ_k^{-1} is the inverse matrix.

Examples

Compute the Log Unconditional Probability Density of an Observation

Construct a discriminant analysis classifier for Fisher's iris data, and examine its prediction for an average measurement.

Load Fisher's iris data and construct a default discriminant analysis classifier.

```
load fisheriris
Mdl = fitcdiscr(meas, species);
```

Find the log probability of the discriminant model applied to an average iris.

```
logPAverage = logP(Mdl,mean(meas))
```

```
logPAverage =  
-1.7254
```

More About

- “Discriminant Analysis” on page 15-3

logP

Class: CompactClassificationNaiveBayes

Log unconditional probability density for naive Bayes classifier

Syntax

`lp = logP(Mdl,X)`

Description

`lp = logP(Mdl,X)` returns the log unconditional probability density of the observations (rows) in `X` using the naive Bayes model `Mdl`.

You can use `lp` to identify outliers in the training data.

Input Arguments

Mdl — Naive Bayes classifier

`ClassificationNaiveBayes` model | `CompactClassificationNaiveBayes` model

Naive Bayes classifier, specified as a `ClassificationNaiveBayes` model or `CompactClassificationNaiveBayes` model returned by `fitcnb` or `compact`, respectively.

X — Predictor data

numeric matrix

Predictor data, specified as a numeric matrix.

Each row of `X` corresponds to one observation (also known as an instance or example), and each column corresponds to one variable (also known as a feature). The variables making up the columns of `X` should be the same as the variables that trained `Mdl`.

Data Types: `double` | `single`

Output Arguments

lp — Log of unconditional probability density

numeric column vector

Log of the unconditional probability density of the predictors, returned as a numeric column vector. `lp` has as many elements as rows in `X`, and each element is the log probability density of the corresponding row in `X`.

If any rows in `X` contain at least one NaN, then the corresponding element of `lp` is NaN.

Definitions

Unconditional Probability Density

The *unconditional probability density* of the predictors is its distribution marginalized over the classes.

In other words, the unconditional probability density is

$$P(X_1, \dots, X_P) = \sum_{k=1}^K P(X_1, \dots, X_P, Y = k) = \sum_{k=1}^K P(X_1, \dots, X_P | y = k) \pi(Y = k),$$

where $\pi(Y = k)$ is the class prior probability. The conditional distribution of the data given the class ($P(X_1, \dots, X_P | y = k)$) and the class prior probability distributions are training options (i.e., are specified when training the classifier).

Prior Probability

The *prior probability* is the believed relative frequency that observations from a class occur in the population for each class.

Examples

Compute Unconditional Probability Densities of Observations

Load Fisher's iris data set.

```
load fisheriris
X = meas; % Predictors
Y = species; % Response
```

Train a naive Bayes classifier. It is good practice to specify the class order. Assume that each predictor is conditionally normally distributed given its label.

```
Mdl = fitcnb(X,Y,'ClassNames',{'setosa','versicolor','virginica'});
```

Mdl is a trained `ClassificationNaiveBayes` classifier.

Compute the unconditional probability densities of the in-sample observations.

```
lp = logP(Mdl,X);
hist(lp)
xlabel 'Log-unconditional probability'
ylabel 'Frequency'
title 'Histogram: Log-Unconditional Probability'
```

Identify indices of observations having log-unconditional probability less than -7.

```
idx = find(lp < -7)
```

```
idx =
```

```
61  
118  
132
```

loss

Class: ClassificationKNN

Loss of k -nearest neighbor classifier

Syntax

```
L = loss mdl, X, Y
```

```
L = loss mdl, X, Y, Name, Value
```

Description

`L = loss(mdl, X, Y)` returns a scalar representing how well `mdl` classifies the data in `X`, when `Y` contains the true classifications.

When computing the loss, **loss** normalizes the class probabilities in `Y` to the class probabilities used for training, stored in the `Prior` property of `mdl`.

`L = loss(mdl, X, Y, Name, Value)` returns the loss with additional options specified by one or more `Name, Value` pair arguments.

Input Arguments

mdl — Classifier model

classifier model object

k -nearest neighbor classifier model, returned as a classifier model object.

Note that using the `'CrossVal'`, `'Kfold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'` options results in a model of class `ClassificationPartitionedModel`. You cannot use a partitioned tree for prediction, so this kind of tree does not have a `predict` method.

Otherwise, `mdl` is of class `ClassificationKNN`, and you can use the `predict` method to make predictions.

X — Matrix of predictor values

matrix

Matrix of predictor values. Each column of *X* represents one variable, and each row represents one observation.

Y — Categorical variables

categorical array | cell array of strings | character array | logical vector | numeric vector

A categorical array, cell array of strings, character array, logical vector, or a numeric vector with the same number of rows as *X*. Each row of *Y* represents the classification of the corresponding row of *X*.

Name-Value Pair Arguments

Specify optional comma-separated pairs of *Name*,*Value* arguments. *Name* is the argument name and *Value* is the corresponding value. *Name* must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as *Name*₁,*Value*₁, . . . ,*Name*_N,*Value*_N.

'lossfun'

Function handle or string representing a loss function. The built-in loss functions are:

- 'binodeviance' — See “Loss Functions” on page 21-2388.
- 'classiferror' — Fraction of misclassified observations. See “Loss Functions” on page 21-2388.
- 'exponential' — See “Loss Functions” on page 21-2388.
- 'hinge' — See “Loss Functions” on page 21-2388.
- 'mincost' — Smallest misclassification cost as given by the mdl.*Cost* matrix. See “Loss Functions” on page 21-2388.

You can write your own loss function using the syntax described in “Loss Functions” on page 21-2388.

Default: 'mincost'

'weights'

Numeric vector of length *N*, where *N* is the number of rows of *X*. *weights* are nonnegative. *loss* normalizes the weights so that observation weights in each class sum to the prior probability of that class. When you supply *weights*, *loss* computes weighted classification loss.

Default: ones(N, 1)

Output Arguments

L

Classification error, a scalar. The meaning of the error depends on the values in **weights** and **lossfun**. See “Classification Error” on page 21-2394.

Definitions

Classification Error

The default classification error is the fraction of data **X** that mdl misclassifies, where **Y** represents the true classifications.

The weighted classification error is the sum of weight *i* times the Boolean value that is 1 when mdl misclassifies the *i*th row of **X**, divided by the sum of the weights.

Loss Functions

The built-in loss functions are:

- **'binodeviance'** — For binary classification, assume the classes y_n are -1 and 1. With weight vector w normalized to have sum 1, and predictions of row n of data X as $f(X_n)$, the binomial deviance is

$$\sum w_n \log(1 + \exp(-2y_n f(X_n))).$$

- **'exponential'** — With the same definitions as for **'binodeviance'**, the exponential loss is

$$\sum w_n \exp(-y_n f(X_n)).$$

- **'classiferror'** — Predict the label with the largest posterior probability. The loss is then the fraction of misclassified observations.

- 'hinge' — Classification error measure that has the form

$$L = \frac{\sum_{j=1}^n w_j \max\{0, 1 - y_j' f(X_j)\}}{\sum_{j=1}^n w_j},$$

where:

- w_j is weight j .
- For binary classification, $y_j = 1$ for the positive class and -1 for the negative class. For problems where the number of classes $K > 3$, y_j is a vector of 0s, but with a 1 in the position corresponding to the true class, e.g., if the second observation is in the third class and $K = 4$, then $y_2 = [0 \ 0 \ 1 \ 0]'$.
- $f(X_j)$ is, for binary classification, the posterior probability or, for $K > 3$, a vector of posterior probabilities for each class given observation j .
- 'mincost' — Predict the label with the smallest expected misclassification cost, with expectation taken over the posterior probability, and cost as given by the **COST** property of the classifier (a matrix). The loss is then the true misclassification cost averaged over the observations.

To write your own loss function, create a function file in this form:

```
function loss = lossfun(C,S,W,COST)
```

- N is the number of rows of X .
- K is the number of classes in the classifier, represented in the **ClassNames** property.
- C is an N -by- K logical matrix, with one **true** per row for the true class. The index for each class is its position in the **ClassNames** property.
- S is an N -by- K numeric matrix. S is a matrix of posterior probabilities for classes with one row per observation, similar to the **posterior** output from **predict**.
- W is a numeric vector with N elements, the observation weights. If you pass W , the elements are normalized to sum to the prior probabilities in the respective classes.
- **COST** is a K -by- K numeric matrix of misclassification costs. For example, you can use **COST = ones(K) - eye(K)**, which means a cost of 0 for correct classification, and 1 for misclassification.

- The output `loss` should be a scalar.

Pass the function handle `@lossfun` as the value of the `LossFun` name-value pair.

True Misclassification Cost

There are two costs associated with KNN classification: the true misclassification cost per class, and the expected misclassification cost per observation.

You can set the true misclassification cost per class in the `Cost` name-value pair when you run `fitcknn`. `Cost(i, j)` is the cost of classifying an observation into class `j` if its true class is `i`. By default, `Cost(i, j)=1` if `i~j`, and `Cost(i, j)=0` if `i=j`. In other words, the cost is 0 for correct classification, and 1 for incorrect classification.

Expected Cost

There are two costs associated with KNN classification: the true misclassification cost per class, and the expected misclassification cost per observation. The third output of `predict` is the expected misclassification cost per observation.

Suppose you have `Nobs` observations that you want to classify with a trained classifier `mdl`. Suppose you have `K` classes. You place the observations into a matrix `Xnew` with one observation per row. The command

```
[label,score,cost] = predict(mdl,Xnew)
```

returns, among other outputs, a `cost` matrix of size `Nobs`-by-`K`. Each row of the `cost` matrix contains the expected (average) cost of classifying the observation into each of the `K` classes. `cost(n, k)` is

$$\sum_{i=1}^K \hat{P}(i | X_{new(n)})C(k | i),$$

where

- `K` is the number of classes.
- $\hat{P}(i | X_{new(n)})$ is the posterior probability of class `i` for observation `Xnew(n)`.

- $C(k | i)$ is the true misclassification cost of classifying an observation as k when its true class is i .

Examples

Loss Calculation

Construct a k -nearest neighbor classifier for the Fisher iris data, where $k = 5$.

Load the data.

```
load fisheriris
```

Construct a classifier for 5-nearest neighbors.

```
mdl = fitcknn(meas,species,'NumNeighbors',5);
```

Examine the loss of the classifier for a mean observation classified 'versicolor'.

```
X = mean(meas);  
Y = {'versicolor'};  
L = loss(mdl,X,Y)
```

```
L =
```

```
0
```

The classifier has no doubt that 'versicolor' is the correct classification (all five nearest neighbors classify as 'versicolor').

loss

Class: CompactClassificationDiscriminant

Classification error

Syntax

`L = loss(obj,X,Y)`

`L = loss(obj,X,Y,Name,Value)`

Description

`L = loss(obj,X,Y)` returns a scalar representing how well `obj` classifies the data in `X`, when `Y` contains the true classifications.

When computing the loss, `loss` normalizes the class probabilities in `Y` to the class probabilities used for training, stored in the `Prior` property of `obj`.

`L = loss(obj,X,Y,Name,Value)` returns the loss with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

obj

Discriminant analysis classifier of class `ClassificationDiscriminant` or `CompactClassificationDiscriminant`, typically constructed with `fitcdiscr`.

X

Matrix where each row represents an observation, and each column represents a predictor. The number of columns in `X` must equal the number of predictors in `obj`.

Y

Class labels, with the same data type as exists in `obj`. The number of elements of `Y` must equal the number of rows of `X`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

'lossfun'

Function handle or string representing a loss function. Built-in loss functions:

- `'binodeviance'` — See “Loss Functions” on page 21-2394.
- `'classiferror'` — Fraction of misclassified observations. See “Loss Functions” on page 21-2394.
- `'exponential'` — See “Loss Functions” on page 21-2394.
- `'hinge'` — See “Loss Functions” on page 21-2394.
- `'mincost'` — Smallest misclassification cost as given by the `obj.Cost` matrix. See “Loss Functions” on page 21-2394.

You can write your own loss function using the syntax described in “Loss Functions” on page 21-2394.

Default: `'mincost'`

'weights'

Numeric vector of length `N`, where `N` is the number of rows of `X`. `weights` are nonnegative. `loss` normalizes the weights so that observation weights in each class sum to the prior probability of that class. When you supply `weights`, `loss` computes weighted classification loss.

Default: `ones(N,1)`

Output Arguments

L

Classification error, a scalar. The meaning of the error depends on the values in `weights` and `lossfun`. See “Classification Error” on page 21-2394.

Definitions

Classification Error

The default classification error is the fraction of data X that obj misclassifies, where Y represents the true classifications.

Weighted classification error is the sum of weight i times the Boolean value that is 1 when obj misclassifies the i th row of X , divided by the sum of the weights.

Loss Functions

The built-in loss functions are:

- 'binodeviance' — For binary classification, assume the classes y_n are -1 and 1. With weight vector w normalized to have sum 1, and predictions of row n of data X as $f(X_n)$, the binomial deviance is

$$\sum w_n \log(1 + \exp(-2y_n f(X_n))).$$

- 'exponential' — With the same definitions as for 'binodeviance', the exponential loss is

$$\sum w_n \exp(-y_n f(X_n)).$$

- 'classiferror' — Predict the label with the largest posterior probability. The loss is then the fraction of misclassified observations.
- 'hinge' — Classification error measure that has the form

$$L = \frac{\sum_{j=1}^n w_j \max\{0, 1 - y_j' f(X_j)\}}{\sum_{j=1}^n w_j},$$

- w_j is weight j .
- For binary classification, $y_j = 1$ for the positive class and -1 for the negative class. For problems where the number of classes $K > 3$, y_j is a vector of 0s, but with a 1 in the position corresponding to the true class, e.g., if the second observation is in the third class and $K = 4$, then $y_2 = [0\ 0\ 1\ 0]'$.
- $f(X_j)$ is, for binary classification, the posterior probability or, for $K > 3$, a vector of posterior probabilities for each class given observation j .
- 'mincost' — Predict the label with the smallest expected misclassification cost, with expectation taken over the posterior probability, and cost as given by the **COST** property of the classifier (a matrix). The loss is then the true misclassification cost averaged over the observations.

To write your own loss function, create a function file in this form:

```
function loss = lossfun(C,S,W,COST)
```

- **N** is the number of rows of **X**.
- **K** is the number of classes in the classifier, represented in the **ClassNames** property.
- **C** is an **N**-by-**K** logical matrix, with one **true** per row for the true class. The index for each class is its position in the **ClassNames** property.
- **S** is an **N**-by-**K** numeric matrix. **S** is a matrix of posterior probabilities for classes with one row per observation, similar to the **posterior** output from **predict**.
- **W** is a numeric vector with **N** elements, the observation weights. If you pass **W**, the elements are normalized to sum to the prior probabilities in the respective classes.
- **COST** is a **K**-by-**K** numeric matrix of misclassification costs. For example, you can use **COST = ones(K) - eye(K)**, which means a cost of **0** for correct classification, and **1** for misclassification.
- The output **loss** should be a scalar.

Pass the function handle `@lossfun` as the value of the **LossFun** name-value pair.

Posterior Probability

The posterior probability that a point z belongs to class j is the product of the prior probability and the multivariate normal density. The density function of the multivariate normal with mean μ_j and covariance Σ_j at a point z is

$$P(x | k) = \frac{1}{(2\pi|\Sigma_k|)^{1/2}} \exp\left(-\frac{1}{2}(x - \mu_k)^T \Sigma_k^{-1} (x - \mu_k)\right),$$

where $|\Sigma_k|$ is the determinant of Σ_k , and Σ_k^{-1} is the inverse matrix.

Let $P(k)$ represent the prior probability of class k . Then the posterior probability that an observation x is of class k is

$$\hat{P}(k | x) = \frac{P(x | k)P(k)}{P(x)},$$

where $P(x)$ is a normalization constant, the sum over k of $P(x | k)P(k)$.

Prior Probability

The prior probability is one of three choices:

- 'uniform' — The prior probability of class k is one over the total number of classes.
- 'empirical' — The prior probability of class k is the number of training samples of class k divided by the total number of training samples.
- Custom — The prior probability of class k is the k th element of the `prior` vector. See `fitcdiscr`.

After creating a classifier `obj`, you can set the prior using dot notation:

```
obj.Prior = v;
```

where `v` is a vector of positive elements representing the frequency with which each element occurs. You do not need to retrain the classifier when you set a new prior.

Cost

The matrix of expected costs per observation is defined in “Cost” on page 15-8.

Examples

Compute the resubstituted classification error for the Fisher iris data:

```
load fisheriris
obj = fitcdiscr(meas,species);
L = loss(obj,meas,species)
```

```
L =
    0.0200
```

How To

- “Discriminant Analysis” on page 15-3

loss

Class: CompactClassificationECOC

Classification loss for error-correcting output code multiclass classifiers

Syntax

`L = loss(Mdl,X,Y)`

`L = loss(Mdl,X,Y,Name,Value)`

Description

`L = loss(Mdl,X,Y)` returns the classification loss (L), a scalar representing how well the trained error-correcting output code (ECOC) multiclass classifier Mdl classifies the predictor data (X) as compared to the true class labels (Y). Each row of X and Y is an observation.

`L = loss(Mdl,X,Y,Name,Value)` returns the classification loss with additional options specified by one or more Name,Value pair arguments.

For example, specify a decoding scheme, classification loss function, or verbosity level.

Input Arguments

Mdl — ECOC multiclass classifier

ClassificationECOC model | CompactClassificationECOC model

ECOC multiclass classifier, specified as a ClassificationECOC or CompactClassificationECOC model. You can create a:

- ClassificationECOC model by training the ECOC classifier using `fitcecoc`
- CompactClassificationECOC model by passing a ClassificationECOC classifier to `compact`

X — Predictor data

numeric matrix

Predictor data, specified as a numeric matrix.

Each row of X corresponds to one observation (also called an instance or example), and each column corresponds to one variable (also known as a feature). The variables composing the columns of X should be the same as the variables that trained the `Mdl` classifier.

The length of Y and the number of rows of X must be equal.

If you trained `Mdl` specifying to standardize the predictor data, then the software standardizes the columns of X using the corresponding means and standard deviations that the software stored in `Mdl.BinaryLearner{j}.Mu` and `Mdl.BinaryLearner{j}.Sigma` for learner j .

Data Types: `double` | `single`

Y — Class labels

categorical array | character array | logical vector | vector of numeric values | cell array of strings

Class labels, specified as a categorical or character array, logical or numeric vector, or cell array of strings. Y must be the same as the data type of `Mdl.ClassNames`.

The length of Y and the number of rows of X must be equal.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

'BinaryLoss' — Binary learner loss function

function handle | 'hamming' | 'linear' | 'exponential' | 'binodeviance' | 'hinge' | 'quadratic'

Binary learner loss function, specified as the comma-separated pair consisting of `'BinaryLoss'` and a function handle or string.

- If the value is a string, then it must correspond to a built-in function. This table summarizes the built-in functions, where y_j is a class label for a particular binary learner (in the set $\{-1, 1, 0\}$), s_j is the score for observation j , and $g(y_j, s_j)$ is the binary loss formula.

Value	Description	Score Domain	$g(y_i, s_i)$
'binodeviance'	Binomial deviance	$(-\infty, \infty)$	$\log[1 + \exp(-2y_i s_i)] / [2\log(2)]$
'exponential'	Exponential	$(-\infty, \infty)$	$\exp(-y_i s_i) / 2$
'hamming'	Hamming	$\{-1, 1\}$	$[1 - \text{sign}(y_i s_i)] / 2$
'hinge'	Hinge	$(-\infty, \infty)$	$\max(0, 1 - y_i s_i) / 2$
'linear'	Linear	$(-\infty, \infty)$	$(1 - y_i s_i) / 2$
'quadratic'	Quadratic	$[0, 1]$	$[1 - y_i(2s_i - 1)]^2 / 2$

The software normalizes the binary losses such that the loss is 0.5 when $y_j = 0$. Also, the software calculates the mean binary loss for each class.

- For a custom binary loss function, e.g., `customFunction`, specify its function handle `'BinaryLoss', @customFunction`.

`customFunction` should have this form

```
bLoss = customFunction(M,s)
```

where:

- M is the K -by- L coding matrix stored in `Mdl.CodingMatrix`.
- s is the 1-by- L row vector of classification scores.
- `bLoss` is the classification loss. This scalar aggregates the binary losses for every learner in a particular class. For example, you can use the mean binary loss to aggregate the loss over the learners for each class.
- K is the number of classes.
- L is the number of binary learners.

For an example on passing a custom binary loss function, see “Predict Test-Sample Labels of ECOC Models Using Custom Binary Loss Function”.

This list describes the default values of `BinaryLoss`. If all binary learners are:

- SVMs, then `BinaryLoss` is `'hinge'`
- Ensembles trained by `AdaboostM1` or `GentleBoost`, then `BinaryLoss` is `'exponential'`

- Ensembles trained by `LogitBoost`, then `BinaryLoss` is `'binodeviance'`
- Predicting class posterior probabilities (i.e., set `'FitPosterior',1` in `fitcecoc`), then `BinaryLoss` is `'quadratic'`

Otherwise, the default `BinaryLoss` is `'hamming'`.

Example: `'BinaryLoss','binodeviance'`

Data Types: char | function_handle

'Decoding' — Decoding scheme

`'lossweighted'` (default) | `'lossbased'`

Decoding scheme that aggregates the “binary losses”, specified as the comma-separated pair consisting of `'Decoding'` and `'lossweighted'` or `'lossbased'`.

Example: `'Decoding','lossbased'`

Data Types: char

'Options' — Estimation options

`[]` (default) | structure array returned by `statset`

Estimation options, specified as the comma-separated pair consisting of `'Options'` and a structure array returned by `statset`.

To invoke parallel computing:

- You need a Parallel Computing Toolbox license.
- Specify `'Options',statset('UseParallel',1)`.

'LossFun' — Loss function

`'classiferror'` (default) | function handle

Loss function, specified as the comma-separated pair consisting of `'LossFun'` and a function handle or `'classiferror'`.

You can:

- Specify the built-in function `'classiferror'`. Subsequently, the loss function is classification error, i.e., the proportion of misclassified observations.
- Specify your own function using function handle notation.

Suppose that $n = \text{size}(X, 1)$ is the sample size and k is the number of classes. Your function must have the signature `lossvalue = lossfun(C,S,W,Cost)`, where:

- The output argument `lossvalue` is a scalar.
- You choose the function name (*lossfun*).
- `C` is an n -by- k logical matrix with rows indicating which class the corresponding observation belongs. The column order corresponds to the class order in `Mdl.ClassNames`.

Construct `C` by setting $C(p, q) = 1$ if observation p is in class q , for each row. Set all other elements of row p to 0.

- `S` is an n -by- k numeric matrix of negated loss values for classes. Each row corresponds to an observation. The column order corresponds to the class order in `Mdl.ClassNames`. `S` resembles the output argument `negLoss` of `predict`.
- `W` is an n -by-1 numeric vector of observation weights. If you pass `W`, the software normalizes its elements to sum to 1.
- `Cost` is a k -by- k numeric matrix of misclassification costs. For example, `Cost = ones(K) - eye(K)` specifies a cost of 0 for correct classification, and 1 for misclassification.

Specify your function using `'LossFun', @lossfun`.

Data Types: `function_handle` | `char`

'Verbose' — Verbosity level

0 (default) | 1

Verbosity level, specified as the comma-separated pair consisting of `'Verbose'` and 0 or 1. `Verbose` controls the amount of diagnostic messages that the software displays in the Command Window.

If `Verbose` is 0, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: `'Verbose', 1`

Data Types: `single` | `double`

'Weights' — Observation weights

`ones(size(X,1))` (default) | numeric vector

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a numeric vector. `Weights` requires the same length as the number of rows of `X`, i.e., `size(X,1)`. The software normalizes `Weights` to sum up to the value of the prior probability in the respective class.

If you do not specify your own loss function (using `LossFun`), then the software normalizes `Weights` to sum up to the value of the prior probability in the respective class.

Output Arguments

L — Classification loss

scalar

Classification loss, returned as a scalar. `L` is a generalization or resubstitution quality measure. Its interpretation depends on the loss function and weighting scheme, but, in general, better classifiers yield smaller loss values.

Definitions

Classification Error

The *classification error* is a binary classification error measure that has the form

$$L = \frac{\sum_{j=1}^n w_j e_j}{\sum_{j=1}^n w_j},$$

where:

- w_j is the weight for observation j . The software renormalizes the weights to sum to 1.
- $e_j = 1$ if the predicted class of observation j differs from its true class, and 0 otherwise.

In other words, it is the proportion of observations that the classifier misclassifies.

Binary Loss

A *binary loss* is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Let:

- m_{kj} be element (k,j) of the coding design matrix M (i.e., the code corresponding to class k of binary learner j)
- s_j be the score of binary learner j for an observation
- g be the binary loss function
- \hat{k} be the predicted class for the observation

In *loss-based decoding* [3], the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j).$$

In *loss-weighted decoding* [3], the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \frac{\sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j)}{\sum_{j=1}^L |m_{kj}|}.$$

Allwein et al. [1] suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where y_j is a class label for a particular binary learner (in the set $\{-1, 1, 0\}$), s_j is the score for observation j , and $g(y_j, s_j)$.

Value	Description	Score Domain	$g(y_j, s_j)$
'binodeviance'	Binomial deviance	$(-\infty, \infty)$	$\log[1 + \exp(-2y_j s_j)] / [2\log(2)]$
'exponential'	Exponential	$(-\infty, \infty)$	$\exp(-y_j s_j) / 2$
'hamming'	Hamming	$\{-1, 1\}$	$[1 - \text{sign}(y_j s_j)] / 2$
'hinge'	Hinge	$(-\infty, \infty)$	$\max(0, 1 - y_j s_j) / 2$
'linear'	Linear	$(-\infty, \infty)$	$(1 - y_j s_j) / 2$
'quadratic'	Quadratic	$[0, 1]$	$[1 - y_j(2s_j - 1)]^2 / 2$

The software normalizes the binary losses such that the loss is 0.5 when $y_j = 0$, and aggregates using the average of the binary learners [1].

Do not confuse the binary loss with the overall classification loss (specified by the LossFun name-value pair argument of `predict` and `loss`), e.g., classification error, which measures how well an ECOC classifier performs as a whole.

Examples

Determine the Test Sample Loss of ECOC Models

Load Fisher's iris data set.

```
load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y); % Class order
rng(1); % For reproducibility
```

Train an ECOC model using SVM binary classifiers, and specify a 15% holdout sample. It is good practice to standardize the predictors and define the class order. Specify to standardize the predictors using an SVM template.

```
t = templateSVM('Standardize',1);
CVMdl = fitcecoc(X,Y,'Holdout',0.15,'Learners',t,'ClassNames',classOrder);
CMdl = CVMdl.Trained{1}; % Extract trained, compact classifier
testInds = test(CVMdl.Partition); % Extract the test indices
XTest = X(testInds,:);
YTest = Y(testInds,:);
```

`CVMD1` is a `ClassificationPartitionedECOC` model. It contains the property `Trained`, which is a 1-by-1 cell array holding a `CompactClassificationECOC` model that the software trained using the training set.

Estimate the test-sample loss.

```
L = loss(CMD1,XTest,YTest)
```

```
L =  
  
    0
```

The ECOC model correctly classifies all out-of-sample irises.

Determine ECOC Model Quality Using a Custom Loss

Suppose that it is interesting to know how well a model classifies a particular class. This example shows how to pass such a custom loss function to `LOSS`.

Load Fisher's iris data set.

```
load fisheriris  
X = meas;  
Y = categorical(species);  
n = numel(Y);           % Sample size  
classOrder = unique(Y) % Class order  
K = numel(classOrder); % Number of classes  
rng(1) % For reproducibility
```

```
classOrder =  
  
    setosa  
    versicolor  
    virginica
```

Train an ECOC model using SVM binary classifiers and specifying a 15% holdout sample. It is good practice to standardize the predictors and define the class order. Specify to standardize the predictors using an SVM template.

```
t = templateSVM('Standardize',1);
```

```

CVMdl = fitcecoc(X,Y,'Holdout',0.15,'Learners',t,'ClassNames',classOrder);
CMdl = CVMdl.Trained{1}; % Extract trained, compact classifier
testInds = test(CVMdl.Partition); % Extract the test indices
XTest = X(testInds,:);
YTest = Y(testInds,:);

```

CVMdl is a `ClassificationPartitionedECOC` model. It contains the property `Trained`, which is a 1-by-1 cell array holding a `CompactClassificationECOC` model that the software trained using the training set.

Compute the negated losses for the test-sample observations.

```

[~,negLoss] = predict(CMdl,XTest);

```

Create a function that takes the minimal loss for each observation, and then averages the minimal losses across all observations.

```

lossfun = @(C,S,~,~)mean(min(-negLoss,[],2));

```

Compute the test-sample custom loss.

```

loss(CMdl,XTest,YTest,'LossFun',lossfun)

```

```

ans =

```

```

    0.0033

```

The average, minimal, binary loss in the test sample is 0.0033.

loss

Class: CompactClassificationEnsemble

Classification error

Syntax

`L = loss(ens,X,Y)`

`L = loss(ens,X,Y,Name,Value)`

Description

`L = loss(ens,X,Y)` returns the classification error for ensemble `ens` computed using matrix of predictors `X` and true class labels `Y`.

When computing the loss, `loss` normalizes the class probabilities in `Y` to the class probabilities used for training, stored in the `Prior` property of `ens`.

`L = loss(ens,X,Y,Name,Value)` computes classification error with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

ens

Classification ensemble created with `fitensemble`, or a compact classification ensemble created with `compact`.

X

Matrix of data to classify. Each row of `X` represents one observation, and each column represents one predictor. `X` must have the same number of columns as the data used to train `ens`. `X` should have the same number of rows as the number of elements in `Y`.

Y

Classification of `X`. `Y` should be of the same type as the classification used to train `ens`, and its number of elements should equal the number of rows of `X`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

'learners'

Indices of weak learners in the ensemble ranging from 1 to `ens.NumTrained`. `loss` uses only these learners for calculating loss.

Default: `1:NumTrained`

'lossfun'

Function handle or string representing a loss function. Built-in loss functions:

- 'binodeviance' — See “Loss Functions” on page 21-2411
- 'classiferror' — Fraction of misclassified data
- 'exponential' — See “Loss Functions” on page 21-2411
- 'hinge' — See “Loss Functions” on page 21-2411.
- 'mincost' — Smallest misclassification cost as given by the `obj.Cost` matrix. See “Loss Functions” on page 21-2411.

You can write your own loss function in the syntax described in “Loss Functions” on page 21-2411.

Default: 'classiferror'

'mode'

String representing the meaning of the output `L`:

- 'ensemble' — `L` is a scalar value, the loss for the entire ensemble.
- 'individual' — `L` is a vector with one element per trained learner.
- 'cumulative' — `L` is a vector in which element `J` is obtained by using learners `1:J` from the input list of learners.

Default: 'ensemble'

'UseObsForLearner'

A logical matrix of size N-by-T, where:

- N is the number of rows of X.
- T is the number of weak learners in ens.

When `UseObsForLearner(i, j)` is true, learner j is used in predicting the class of row i of X.

Default: `true(N, T)`

'weights'

Vector of observation weights, with nonnegative entries. The length of `weights` must equal the number of rows in X. When you specify `weights`, `loss` normalizes the weights so that observation weights in each class sum to the prior probability of that class.

Default: `ones(size(X, 1), 1)`

Output Arguments

L

Loss, by default the fraction of misclassified data. L can be a vector, and can mean different things, depending on the name-value pair settings.

Definitions

Classification Error

The default classification error is the fraction of the data X that ens misclassifies, where Y are the true classifications.

Weighted classification error is the sum of weight *i* times the Boolean value that is 1 when tree misclassifies the *i*th row of X, divided by the sum of the weights.

Loss Functions

The built-in loss functions are:

- 'binodeviance' — For binary classification, assume the classes y_n are -1 and 1. With weight vector w normalized to have sum 1, and predictions of row n of data X as $f(X_n)$, the binomial deviance is

$$\sum w_n \log(1 + \exp(-2y_n f(X_n))).$$

- 'classiferror' — Fraction of misclassified data, weighted by w .
- 'exponential' — With the same definitions as for 'binodeviance', the exponential loss is

$$\sum w_n \exp(-y_n f(X_n)).$$

- 'hinge' — Classification error measure that has the form

$$L = \frac{\sum_{j=1}^n w_j \max\{0, 1 - y_j' f(X_j)\}}{\sum_{j=1}^n w_j},$$

where:

- w_j is weight j .
- For binary classification, $y_j = 1$ for the positive class and -1 for the negative class. For problems where the number of classes $K > 3$, y_j is a vector of 0s, but with a 1 in the position corresponding to the true class, e.g., if the second observation is in the third class and $K = 4$, then $y_2 = [0 \ 0 \ 1 \ 0]'$.
- $f(X_j)$ is, for binary classification, the posterior probability or, for $K > 3$, a vector of posterior probabilities for each class given observation j .
- 'mincost' — Predict the label with the smallest expected misclassification cost, with expectation taken over the posterior probability, and cost as given by the **COST** property of the classifier (a matrix). The loss is then the true misclassification cost averaged over the observations.

To write your own loss function, create a function file of the form

```
function loss = lossfun(C,S,W,COST)
```

- `N` is the number of rows of `ens.X`.
- `K` is the number of classes in `ens`, represented in `ens.ClassNames`.
- `C` is an `N`-by-`K` logical matrix, with one `true` per row for the true class. The index for each class is its position in `tree.ClassNames`.
- `S` is an `N`-by-`K` numeric matrix. `S` is a matrix of posterior probabilities for classes with one row per observation, similar to the `score` output from `predict`.
- `W` is a numeric vector with `N` elements, the observation weights.
- `COST` is a `K`-by-`K` numeric matrix of misclassification costs. The default `'classiferror'` gives a cost of `0` for correct classification, and `1` for misclassification.
- The output `loss` should be a scalar.

Pass the function handle `@lossfun` as the value of the `lossfun` name-value pair.

Examples

Create a compact classification ensemble for the ionosphere data, and find the fraction of training data that the ensemble misclassifies:

```
load ionosphere
ada = fitensemble(X,Y,'AdaBoostM1',100,'tree');
adb = compact(ada);
L = loss(adb,X,Y)
```

```
L =
    0.0085
```

`loss` | `margin` | `predict` | `edge`

loss

Class: CompactClassificationNaiveBayes

Classification error for naive Bayes classifier

Syntax

```
L = loss(Mdl,X,Y)
L = loss(Mdl,X,Y,Name,Value)
```

Description

`L = loss(Mdl,X,Y)` returns the minimum misclassification cost loss (L), a scalar representing how well the trained naive Bayes classifier Mdl classifies the predictor data (X) as compared to the true class labels (Y).

`loss` normalizes the class probabilities in Y to the prior class probabilities `fitcnb` used for training, stored in the `Prior` property of Mdl.

`L = loss(Mdl,X,Y,Name,Value)` returns the classification loss with additional options specified by one or more Name,Value pair arguments.

Input Arguments

Mdl — Naive Bayes classifier

ClassificationNaiveBayes model | CompactClassificationNaiveBayes model

Naive Bayes classifier, specified as a `ClassificationNaiveBayes` model or `CompactClassificationNaiveBayes` model returned by `fitcnb` or `compact`, respectively.

X — Predictor data

numeric matrix

Predictor data, specified as a numeric matrix.

Each row of X corresponds to one observation (also known as an instance or example), and each column corresponds to one variable (also known as a feature). The variables making up the columns of X should be the same as the variables that trained Mdl .

The length of Y and the number of rows of X must be equal.

Data Types: `double` | `single`

Y – Class labels

categorical array | character array | logical vector | vector of numeric values | cell array of strings

Class labels, specified as a categorical or character array, logical or numeric vector, or cell array of strings. Y must be the same as the data type of $Mdl.ClassNames$.

The length of Y and the number of rows of X must be equal.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

'LossFun' – Loss function

`'classiferror'` (default) | `'binodeviance'` | `'exponential'` | `'hinge'` | function handle

Loss function, specified as the comma-separated pair consisting of `'LossFun'` and a function handle or string.

- This table describes the built-in loss functions. Specify one using its corresponding string.

String	Loss Function
<code>'binodeviance'</code>	“Binomial deviance”
<code>'classiferror'</code>	“Classification error”
<code>'exponential'</code>	“Exponential loss”
<code>'hinge'</code>	“Hinge loss”
<code>'mincost'</code>	“Minimum misclassification cost loss”

- Specify your own function using function handle notation.

Suppose that $n = \text{size}(X, 1)$ is the sample size and $k = \text{size}(\text{Mdl.ClassNames}, 1)$ is the number of classes. Your function must have the signature `lossvalue = lossfun(C,S,W,Cost)`, where:

- The output argument `lossvalue` is a scalar.
- You choose the function name (*lossfun*).
- `C` is an n -by- k logical matrix with rows indicating to which class the corresponding observation belongs. The column order corresponds to the class order in `Mdl.ClassNames`.

Construct `C` by setting $C(p, q) = 1$ if observation p is in class q , for each row. Set all other elements of row p to 0.

- `S` is an n -by- k numeric matrix of classification scores. The column order corresponds to the class order in `Mdl.ClassNames`. `S` is a matrix of posterior probabilities, similar to the output of `predict`.
- `W` is an n -by-1 numeric vector of observation weights. If you pass `W`, the software normalizes the weights to sum to the prior probability of their respective class. If `Mdl` is a compact model, then you must also supply the weights using the `'Weights'` name-value pair argument.
- `Cost` is a k -by- k numeric matrix of misclassification costs. For example, `Cost = ones(K) - eye(K)` specifies a cost of 0 for correct classification, and 1 for misclassification.

Specify your function using `'LossFun', @lossfun`.

'Weights' — Observation weights

`ones(size(X,1),1)` (default) | numeric vector

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and a numeric vector.

The size of `Weights` must be equal to the number of rows of `X`. The software weighs the observations in each row of `X` with the corresponding weight in `Weights`.

If you do not specify your own loss function, then the software normalizes `Weights` to add up to 1.

Data Types: `double`

Output Arguments

L — Classification loss

scalar

Classification loss, returned as a scalar. L is a generalization or resubstitution quality measure. Its interpretation depends on the loss function and weighting scheme, but, in general, better classifiers yield smaller loss values.

Definitions

Binomial Deviance

The *binomial deviance* (or *multinomial deviance* for number of classes $K > 3$) is a classification error measure that has the form

$$L = \frac{\sum_{j=1}^n w_j \log(1 + \exp(-2y_j'f(X_j)))}{\sum_{j=1}^n w_j},$$

where:

- w_j is weight j .
- For binary classification, $y_j = 1$ for the positive class and -1 for the negative class. For problems where the number of classes $K > 3$, y_j is a vector of 0s, but with a 1 in the position corresponding to the true class, e.g., if the second observation is in the third class and $K = 4$, then $y_2 = [0 \ 0 \ 1 \ 0]'$.
- $f(X_j)$ is, for binary classification, the posterior probability or, for $K > 3$, a vector of posterior probabilities for each class given observation j .

The binomial deviance has connections to the maximization of the binomial likelihood function. For details on binomial deviance, see “[1]”.

Classification Error

The *classification error* is a binary classification error measure that has the form

$$L = \frac{\sum_{j=1}^n w_j e_j}{\sum_{j=1}^n w_j},$$

where:

- w_j is the weight for observation j . The software renormalizes the weights to sum to 1.
- $e_j = 1$ if the predicted class of observation j differs from its true class, and 0 otherwise.

In other words, it is the proportion of observations that the classifier misclassifies.

Exponential Loss

Exponential loss is a classification error measure that is similar to binomial deviance, and has the form

$$L = \frac{\sum_{j=1}^n w_j \exp(-y_j' f(X_j))}{\sum_{j=1}^n w_j},$$

where:

- w_j is weight j .
- For binary classification, $y_j = 1$ for the positive class and -1 for the negative class. For problems where the number of classes $K > 3$, y_j is a vector of 0s, but with a 1 in the position corresponding to the true class, e.g., if the second observation is in the third class and $K = 4$, then $y_2 = [0 \ 0 \ 1 \ 0]'$.
- $f(X_j)$ is, for binary classification, the posterior probability or, for $K > 3$, a vector of posterior probabilities for each class given observation j .

Hinge Loss

Hinge loss is a binary classification error measure that has the form

$$L = \frac{\sum_{j=1}^n w_j \max\{0, 1 - y_j' f(X_j)\}}{\sum_{j=1}^n w_j},$$

where:

- w_j is weight j .
- For binary classification, $y_j = 1$ for the positive class and -1 for the negative class. For problems where the number of classes $K > 3$, y_j is a vector of 0s, but with a 1 in the position corresponding to the true class, e.g., if the second observation is in the third class and $K = 4$, then $y_2 = [0 \ 0 \ 1 \ 0]'$.
- $f(X_j)$ is, for binary classification, the posterior probability or, for $K > 3$, a vector of posterior probabilities for each class given observation j .

Hinge loss linearly penalizes for misclassified observations, and is related to the support vector machine (SVM) objective function used for optimization. For more details on hinge loss, see “[1]”.

Minimum Misclassification Cost Loss

The *minimum misclassification cost loss* is the weighted average of the minimum expected “misclassification costs” for each observation.

In other words, the minimum misclassification cost is

$$L = \frac{\sum_{j=1}^n w_j c_j}{\sum_j w_j},$$

where:

- w_j is the weight of observation j .
- c_j is the minimum of the expected misclassification costs for observation j .

Misclassification Cost

A *misclassification cost* is the relative severity of a classifier labeling an observation into the wrong class.

There are two types of misclassification costs: true and expected. Let K be the number of classes.

- *True misclassification cost* — A K -by- K matrix, where element (i,j) indicates the misclassification cost of predicting an observation into class j if its true class is i . The software stores the misclassification cost in the property `Mdl.Cost`, and used in computations. By default, `Mdl.Cost(i, j) = 1` if $i \neq j$, and `Mdl.Cost(i, j) = 0` if $i = j$. In other words, the cost is 0 for correct classification, and 1 for any incorrect classification.
- *Expected misclassification cost* — A K -dimensional vector, where element k is the weighted average misclassification cost of classifying an observation into class k , weighted by the class posterior probabilities. In other words,

$$c_k = \sum_{j=1}^K \hat{P}(Y = j | x_1, \dots, x_P) \text{Cost}_{jk}.$$

the software classifies observations to the class corresponding with the lowest expected misclassification cost.

Posterior Probability

The *posterior probability* is the probability that an observation belongs in a particular class, given the data.

For naive Bayes, the posterior probability that a classification is k for a given observation (x_1, \dots, x_P) is

$$\hat{P}(Y = k | x_1, \dots, x_P) = \frac{P(X_1, \dots, X_P | y = k) \pi(Y = k)}{P(X_1, \dots, X_P)},$$

where:

- $P(X_1, \dots, X_P | y = k)$ is the conditional joint density of the predictors given they are in class k . `Mdl.DistributionNames` stores the distribution names of the predictors.
- $\pi(Y = k)$ is the class prior probability distribution. `Mdl.Prior` stores the prior distribution.
- $P(X_1, \dots, X_P)$ is the joint density of the predictors. The classes are discrete, so

$$P(X_1, \dots, X_P) = \sum_{k=1}^K P(X_1, \dots, X_P | y = k) \pi(Y = k).$$

Prior Probability

The *prior probability* is the believed relative frequency that observations from a class occur in the population for each class.

Examples

Determine Test Sample Minimum Cost Loss of Naive Bayes Classifiers

Load Fisher's iris data set.

```
load fisheriris
X = meas;      % Predictors
Y = species;   % Response
rng(1);        % For reproducibility
```

Train a naive Bayes classifier. Specify a 15% holdout sample for testing. It is good practice to specify the class order. Assume that each predictor is conditionally normally distributed given its label.

```
CVMD1 = fitcnb(X,Y,'ClassNames',{'setosa','versicolor','virginica'},...
    'Holdout',0.15);
CMD1 = CVMD1.Trained{1}; % Extract the trained, compact classifier
testInds = test(CVMD1.Partition); % Extract the test indices
XTest = X(testInds,:);
YTest = Y(testInds);
```

`CVMD1` is a `ClassificationPartitionedModel` classifier. It contains the property `Trained`, which is a 1-by-1 cell array holding a `CompactClassificationNaiveBayes` classifier that the software trained using the training set.

Determine how well the algorithm generalizes by estimating the test sample minimum cost loss.

```
L = loss(CMdl,XTest,YTest)
```

```
L =
```

```
0.0476
```

The test sample average classification cost is approximately 0.05.

You might improve the classification error by specifying better predictor distributions when you train the classifier.

Determine the Test Sample Classification Error of Naive Bayes Classifiers

Load Fisher's iris data set.

```
load fisheriris
X = meas; % Predictors
Y = species; % Response
rng(1); % For reproducibility
```

Train a naive Bayes classifier. Specify a 15% holdout sample for testing. It is good practice to specify the class order. Assume that each predictor is conditionally normally distributed given its label.

```
CVMD1 = fitcnb(X,Y,'ClassNames',{'setosa','versicolor','virginica'},...
    'Holdout',0.15);
CMdl = CVMD1.Trained{1}; % Extract the trained, compact classifier
testInds = test(CVMD1.Partition); % Extract the test indices
XTest = X(testInds,:);
YTest = Y(testInds);
```

CVMD1 is a `ClassificationPartitionedModel` classifier. It contains the property `Trained`, which is a 1-by-1 cell array holding a `CompactClassificationNaiveBayes` classifier that the software trained using the training set.

Determine how well the algorithm generalizes by estimating the test sample classification error.

```
L = loss(CMdl,XTest,YTest,'LossFun','classiferror')
```

L =

0.0476

The classifier misclassified approximately 5% of the test sample observations.

loss

Class: CompactClassificationSVM

Classification error for support vector machine classifiers

Syntax

```
L = loss(SVMModel,X,Y)
L = loss(SVMModel,X,Y,Name,Value)
```

Description

`L = loss(SVMModel,X,Y)` returns the classification error (L), a scalar representing how well the trained support vector machine (SVM) classifier `SVMModel` classifies the predictor data (X) as compared to the true class labels (Y).

`loss` normalizes the class probabilities in Y to the prior class probabilities `fitcsvm` used for training, stored in the `Prior` property of `SVMModel`.

`L = loss(SVMModel,X,Y,Name,Value)` returns the classification error with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

SVMModel — SVM classifier

ClassificationSVM classifier | CompactClassificationSVM classifier

SVM classifier, specified as a `ClassificationSVM` classifier or `CompactClassificationSVM` classifier returned by `fitcsvm` or `compact`, respectively.

X — Predictor data

numeric matrix

Predictor data, specified as a numeric matrix.

Each row of X corresponds to one observation (also known as an instance or example), and each column corresponds to one variable (also known as a feature). The variables

making up the columns of X should be the same as the variables that trained the `SVMMODEL` classifier.

The length of Y and the number of rows of X must be equal.

If you set `'Standardize', true` in `fitcsvm` to train `SVMMODEL`, then the software standardizes the columns of X using the corresponding means in `SVMMODEL.Mu` and standard deviations in `SVMMODEL.Sigma`.

Data Types: `double` | `single`

Y — Class labels

categorical array | character array | logical vector | vector of numeric values | cell array of strings

Class labels, specified as a categorical or character array, logical or numeric vector, or cell array of strings. Y must be the same as the data type of `SVMMODEL.ClassNames`.

The length of Y and the number of rows of X must be equal.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

'LossFun' — Loss function

`'ClassifError'` (default) | `'binodeviance'` | `'exponential'` | `'hinge'` | function handle

Loss function, specified as the comma-separated pair consisting of `'LossFun'` and a function handle or string.

- The following lists available loss functions. Specify one using its corresponding string.

Value	Loss Function
<code>'binodeviance'</code>	“Binomial deviance”
<code>'classiferror'</code>	“Classification error”
<code>'exponential'</code>	“Exponential loss”

Value	Loss Function
'hinge'	“Hinge loss”

- Specify your own function using function handle notation.

Suppose that $n = \text{size}(X,1)$ is the sample size and $k = \text{size}(\text{SVMModel.ClassNames},1)$ is the number of classes. Your function must have the signature `lossvalue = lossfun(C,S,W,Cost)`, where:

- The output argument `lossvalue` is a scalar.
- You choose the function name (*lossfun*).
- `C` is an n -by- k logical matrix with rows indicating which class the corresponding observation belongs. The column order corresponds to the class order in `SVMModel.ClassNames`.

Construct `C` by setting $C(p,q) = 1$ if observation p is in class q , for each row. Set all other elements of row p to 0.

- `S` is an n -by- k numeric matrix of classification scores. The column order corresponds to the class order in `SVMModel.ClassNames`. `S` is a matrix of classification scores, similar to the output of `predict`.
- `W` is an n -by-1 numeric vector of observation weights. If you pass `W`, the software normalizes them to sum to 1.
- `Cost` is a k -by- k numeric matrix of misclassification costs. For example, `Cost = ones(K) - eye(K)` specifies a cost of 0 for correct classification, and 1 for misclassification.

Specify your function using `'LossFun',@lossfun`.

'Weights' — Observation weights

`ones(size(X,1),1)` (default) | numeric vector

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and a numeric vector.

The size of `Weights` must be equal to the number of rows of `X`. The software weighs the observations in each row of `X` with the corresponding weight in `Weights`.

If you do not specify your own loss function, then the software normalizes `Weights` to sum up to the value of the prior probability in the respective class.

Data Types: double

Output Arguments

L — Classification loss

scalar

Classification loss, returned as a scalar. L is a generalization or resubstitution quality measure. Its interpretation depends on the loss function and weighting scheme, but, in general, better classifiers yield smaller loss values.

Definitions

Binomial Deviance

The binomial deviance is a binary classification error measure that has the form

$$L = \frac{\sum_{j=1}^n w_j \log(1 + \exp(-2y_j f(X_j)))}{\sum_{j=1}^n w_j},$$

where:

- w_j is weight j . The software renormalizes the weights to sum to 1.
- $y_j = \{-1, 1\}$.
- $f(X_j)$ is the score for observation j .

The binomial deviance has connections to the maximization of the binomial likelihood function. For details on binomial deviance, see “[1]”.

Classification Error

The *classification error* is a binary classification error measure that has the form

$$L = \frac{\sum_{j=1}^n w_j e_j}{\sum_{j=1}^n w_j},$$

where:

- w_j is the weight for observation j . The software renormalizes the weights to sum to 1.
- $e_j = 1$ if the predicted class of observation j differs from its true class, and 0 otherwise.

In other words, it is the proportion of observations that the classifier misclassifies.

Exponential Loss

A binary classification error measure that is similar to binomial deviance, and has the form

$$L = \frac{\sum_{j=1}^n w_j \exp(-y_j f(X_j))}{\sum_{j=1}^n w_j},$$

where:

- w_j is weight j . The software renormalizes the weights to sum to 1.
- $y_j = \{-1, 1\}$.
- $f(X_j)$ is the score for observation j .

Hinge Loss

Hinge loss is a binary classification error measure that has the form

$$L = \frac{\sum_{j=1}^n w_j \max\{0, 1 - y_j' f(X_j)\}}{\sum_{j=1}^n w_j},$$

where:

- w_j is weight j . The software renormalizes the weights to sum to 1.
- $y_j = \{-1, 1\}$.
- $f(X_j)$ is the score for observation j .

Hinge loss linearly penalizes for misclassified observations, and is related to the SVM objective function used for optimization. For more details on hinge loss, see “[1]”.

Score

The SVM *score* for classifying observation x is the signed distance from x to the decision boundary ranging from $-\infty$ to $+\infty$. A positive score for a class indicates that x is predicted to be in that class, a negative score indicates otherwise.

The score is also the numerical, predicted response for x , $f(x)$, computed by the trained SVM classification function

$$f(x) = \sum_{j=1}^n \alpha_j y_j G(x_j, x) + b,$$

where $(\alpha_1, \dots, \alpha_n, b)$ are the estimated SVM parameters, $G(x_j, x)$ is the dot product in the predictor space between x and the support vectors, and the sum includes the training set observations.

Examples

Determine the Test Sample Classification Error of SVM Classifiers

Load the ionosphere data set.

```
load ionosphere
rng(1); % For reproducibility
```

Train an SVM classifier. Specify a 15% holdout sample for testing. It is good practice to specify the class order and standardize the data.

```
CVSVMModel = fitcsvm(X,Y,'Holdout',0.15,'ClassNames',{'b','g'},...
    'Standardize',true);
CompactSVMModel = CVSVMModel.Trained{1}; % Extract the trained, compact classifier
testInds = test(CVSVMModel.Partition); % Extract the test indices
XTest = X(testInds,:);
YTest = Y(testInds,:);
```

CVSVMModel is a `ClassificationPartitionedModel` classifier. It contains the property `Trained`, which is a 1-by-1 cell array holding a `CompactClassificationSVM` classifier that the software trained using the training set.

Determine how well the algorithm generalizes by estimating the test sample classification error.

```
L = loss(CompactSVMModel,XTest,YTest)
```

```
L =
    0.0787
```

The SVM classifier misclassifies approximately 8% of the test sample radar returns.

Determine the Test Sample Hinge Loss of SVM Classifiers

Load the ionosphere data set.

```
load ionosphere
rng(1); % For reproducibility
```

Train an SVM classifier. Specify a 15% holdout sample for testing. It is good practice to specify the class order and standardize the data.

```
CVSVMModel = fitcsvm(X,Y,'Holdout',0.15,'ClassNames',{'b','g'},...
    'Standardize',true);
CompactSVMModel = CVSVMModel.Trained{1}; % Extract the trained, compact classifier
testInds = test(CVSVMModel.Partition); % Extract the test indices
XTest = X(testInds,:);
```

```
YTest = Y(testInds,:);
```

`CVSVMModel` is a `ClassificationPartitionedModel` classifier. It contains the property `Trained`, which is a 1-by-1 cell array holding a `CompactClassificationSVM` classifier that the software trained using the training set.

Determine how well the algorithm generalizes by estimating the test sample hinge loss.

```
L = loss(CompactSVMModel,XTest,YTest,'LossFun','Hinge')
```

```
L =
```

```
    0.2998
```

The hinge loss is approximately 0.3. Classifiers with hinge losses close to 0 are desirable.

loss

Class: CompactClassificationTree

Classification error

Syntax

```
L = loss(tree,X,Y)
L = loss(tree,X,Y,Name,Value)
L = loss(tree,X,Y,'Subtrees',subtreevector)
[L,se] = loss(tree,X,Y,'Subtrees',subtreevector)
[L,se,NLeaf] = loss(tree,X,Y,'Subtrees',subtreevector)
[L,se,NLeaf,bestlevel] = loss(tree,X,Y,'Subtrees',subtreevector)
[L,...] = loss(tree,X,Y,'Subtrees',subtreevector,Name,Value)
```

Description

`L = loss(tree,X,Y)` returns a scalar representing how well `tree` classifies the data in `X`, when `Y` contains the true classifications.

When computing the loss, `loss` normalizes the class probabilities in `Y` to the class probabilities used for training, stored in the `Prior` property of `tree`.

`L = loss(tree,X,Y,Name,Value)` returns the loss with additional options specified by one or more `Name,Value` pair arguments.

`L = loss(tree,X,Y,'Subtrees',subtreevector)` returns a vector of classification errors for the trees in the pruning sequence `subtreevector`.

`[L,se] = loss(tree,X,Y,'Subtrees',subtreevector)` returns the vector of standard errors of the classification errors.

Note: `loss` returns `se` and further outputs only when the `LossFun` name-value pair is the default `'classiferror'`.

`[L,se,NLeaf] = loss(tree,X,Y,'Subtrees',subtreevector)` returns the vector of numbers of leaf nodes in the trees of the pruning sequence.

`[L,se,NLeaf,bestlevel] = loss(tree,X,Y,'Subtrees',subtreevector)` returns the best pruning level as defined in the `TreeSize` name-value pair. By default, `bestlevel` is the pruning level that gives loss within one standard deviation of minimal loss.

`[L,...] = loss(tree,X,Y,'Subtrees',subtreevector,Name,Value)` returns loss statistics with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

tree

A classification tree or compact classification tree constructed by `fitctree` or `compact`.

X

Matrix of data to classify. Each row of `X` represents one observation, and each column represents one predictor. `X` must have the same number of columns as the data used to train `tree`. `X` should have the same number of rows as the number of elements in `Y`.

Y

Classification of `X`. `Y` should be of the same type as the classification used to train `tree`, and its number of elements should equal the number of rows of `X`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

'LossFun'

Function handle or string representing a loss function. Built-in loss functions:

- `'binodeviance'` — See “Loss Functions” on page 21-2436
- `'classiferror'` — Fraction of misclassified observations. See “Loss Functions” on page 21-2436.
- `'exponential'` — See “Loss Functions” on page 21-2436
- `'hinge'` — See “Loss Functions” on page 21-2436.
- `'mincost'` — Smallest misclassification cost as given by the tree. Cost matrix. See “Loss Functions” on page 21-2436.

You can write your own loss function in the syntax described in “Loss Functions” on page 21-2436.

Default: `'mincost'`

'Weights'

A numeric vector of length `N`, where `N` is the number of rows of `X`. `Weights` are nonnegative. `loss` normalizes the weights so that observation weights in each class sum to the prior probability of that class. When you supply `Weights`, `loss` computes weighted classification loss.

Default: `ones(N,1)`

Name, Value arguments associated with pruning subtrees:

'Subtrees'

A vector with integer values from 0 (full unpruned tree) to the maximal pruning level `max(tree.PruneList)`. You can set `Subtrees` to `'all'`, meaning the entire pruning sequence.

Default: 0

'TreeSize'

One of the following strings:

- `'se'` — `loss` returns the highest pruning level with loss within one standard deviation of the minimum (`L+se`, where `L` and `se` relate to the smallest value in `Subtrees`).

- 'min' — `loss` returns the element of `Subtrees` with smallest loss, usually the smallest element of `Subtrees`.

Output Arguments

L

Classification error, a vector the length of `Subtrees`. The meaning of the error depends on the values in `Weights` and `LossFun`; see “Classification Error” on page 21-2435.

se

Standard error of loss, a vector the length of `Subtrees`.

NLeaf

Number of leaves (terminal nodes) in the pruned subtrees, a vector the length of `Subtrees`.

bestlevel

A scalar whose value depends on `TreeSize`:

- `TreeSize = 'se'` — `loss` returns the highest pruning level with loss within one standard deviation of the minimum ($L+se$, where L and se relate to the smallest value in `Subtrees`).
- `TreeSize = 'min'` — `loss` returns the element of `Subtrees` with smallest loss, usually the smallest element of `Subtrees`.

Definitions

Classification Error

The default classification error is the fraction of data X that tree misclassifies, where Y represents the true classifications.

Weighted classification error is the sum of weight i times the Boolean value that is 1 when tree misclassifies the i th row of X , divided by the sum of the weights.

Loss Functions

The built-in loss functions are:

- 'binodeviance' — For binary classification, assume the classes y_n are -1 and 1. With weight vector w normalized to have sum 1, and predictions of row n of data X as $f(X_n)$, the binomial deviance is

$$\sum w_n \log(1 + \exp(-2y_n f(X_n))).$$

- 'exponential' — With the same definitions as for 'binodeviance', the exponential loss is

$$\sum w_n \exp(-y_n f(X_n)).$$

- 'classiferror' — Predict the label with the largest posterior probability. The loss is then the fraction of misclassified observations.
- 'hinge' — Classification error measure that has the form

$$L = \frac{\sum_{j=1}^n w_j \max\{0, 1 - y_j' f(X_j)\}}{\sum_{j=1}^n w_j},$$

where:

- w_j is weight j .
- For binary classification, $y_j = 1$ for the positive class and -1 for the negative class. For problems where the number of classes $K > 3$, y_j is a vector of 0s, but with a 1 in the position corresponding to the true class, e.g., if the second observation is in the third class and $K = 4$, then $y_2 = [0 \ 0 \ 1 \ 0]'$.
- $f(X_j)$ is, for binary classification, the posterior probability or, for $K > 3$, a vector of posterior probabilities for each class given observation j .
- 'mincost' — Predict the label with the smallest expected misclassification cost, with expectation taken over the posterior probability, and cost as given by the **Cost**

property of the classifier (a matrix). The loss is then the true misclassification cost averaged over the observations.

To write your own loss function, create a function file in this form:

```
function loss = lossfun(C,S,W,COST)
```

- N is the number of rows of X.
- K is the number of classes in the classifier, represented in the `ClassNames` property.
- C is an N-by-K logical matrix, with one `true` per row for the true class. The index for each class is its position in the `ClassNames` property.
- S is an N-by-K numeric matrix. S is a matrix of posterior probabilities for classes with one row per observation, similar to the `posterior` output from `predict`.
- W is a numeric vector with N elements, the observation weights. If you pass W, the elements are normalized to sum to the prior probabilities in the respective classes.
- COST is a K-by-K numeric matrix of misclassification costs. For example, you can use `COST = ones(K) - eye(K)`, which means a cost of 0 for correct classification, and 1 for misclassification.
- The output `loss` should be a scalar.

Pass the function handle `@lossfun` as the value of the `LossFun` name-value pair.

True Misclassification Cost

There are two costs associated with classification: the true misclassification cost per class, and the expected misclassification cost per observation.

You can set the true misclassification cost per class in the `Cost` name-value pair when you create the classifier using the `fitctree` method. `Cost(i,j)` is the cost of classifying an observation into class `j` if its true class is `i`. By default, `Cost(i,j)=1` if `i~j`, and `Cost(i,j)=0` if `i=j`. In other words, the cost is 0 for correct classification, and 1 for incorrect classification.

Expected Misclassification Cost

There are two costs associated with classification: the true misclassification cost per class, and the expected misclassification cost per observation.

Suppose you have `Nobs` observations that you want to classify with a trained classifier. Suppose you have `K` classes. You place the observations into a matrix `Xnew` with one observation per row.

The expected cost matrix `CE` has size `Nobs`-by-`K`. Each row of `CE` contains the expected (average) cost of classifying the observation into each of the `K` classes. `CE(n,k)` is

$$\sum_{i=1}^K \hat{P}(i | X_{new}(n)) C(k | i),$$

where

- `K` is the number of classes.
- $\hat{P}(i | X_{new}(n))$ is the posterior probability of class `i` for observation `Xnew(n)`.
- `C(k | i)` is the true misclassification cost of classifying an observation as `k` when its true class is `i`.

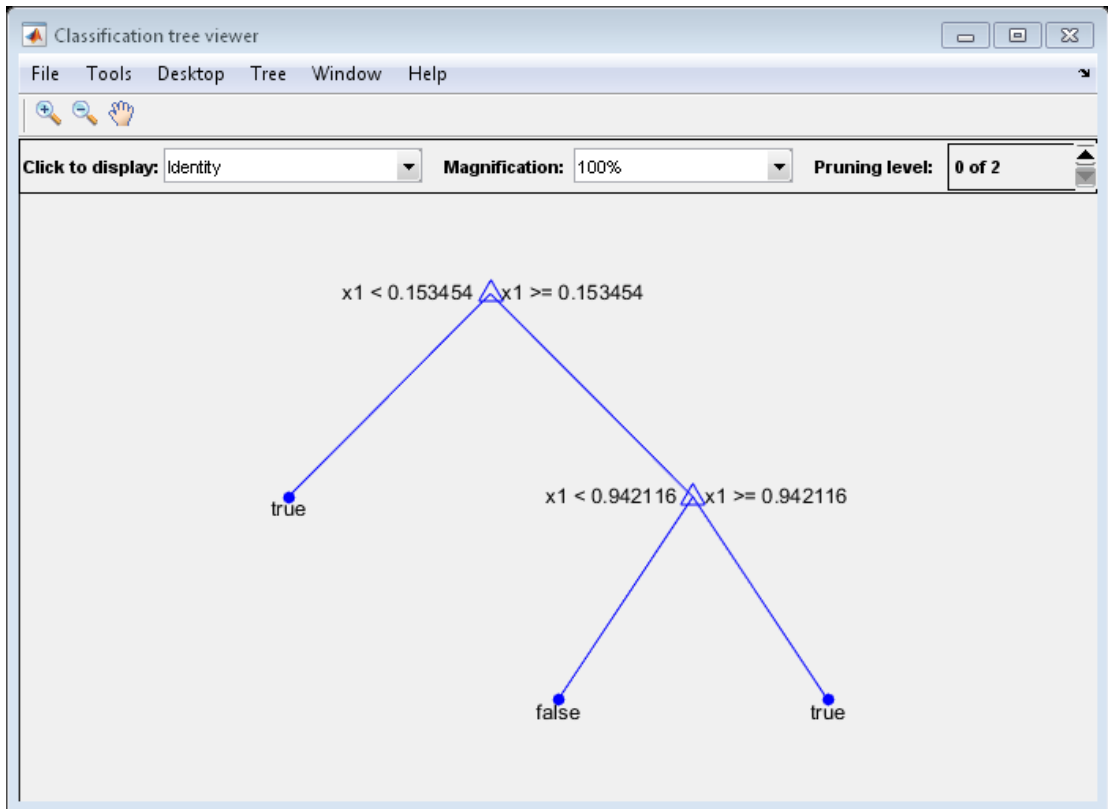

Score (tree)

For trees, the *score* of a classification of a leaf node is the posterior probability of the classification at that node. The posterior probability of the classification at a node is the number of training sequences that lead to that node with the classification, divided by the number of training sequences that lead to that node.

For example, consider classifying a predictor `X` as `true` when `X < 0.15` or `X > 0.95`, and `X` is `false` otherwise.

Generate 100 random points and classify them:

```
rng(0,'twister') % for reproducibility
X = rand(100,1);
Y = (abs(X - .55) > .4);
tree = fitctree(X,Y);
view(tree,'Mode','Graph')
```

Prune the tree:

```
tree1 = prune(tree, 'Level', 1);  
view(tree1, 'Mode', 'Graph')
```

The pruned tree correctly classifies observations that are less than 0.15 as **true**. It also correctly classifies observations from .15 to .94 as **false**. However, it incorrectly classifies observations that are greater than .94 as **false**. Therefore, the score for observations that are greater than .15 should be about $.05/.85=.06$ for **true**, and about $.8/.85=.94$ for **false**.

Compute the prediction scores for the first 10 rows of X:

```
[~,score] = predict(tree1,X(1:10));
[score X(1:10,:)]
```

```
ans =
```

```
0.9059    0.0941    0.8147
```

0.9059	0.0941	0.9058
0	1.0000	0.1270
0.9059	0.0941	0.9134
0.9059	0.0941	0.6324
0	1.0000	0.0975
0.9059	0.0941	0.2785
0.9059	0.0941	0.5469
0.9059	0.0941	0.9575
0.9059	0.0941	0.9649

Indeed, every value of X (the right-most column) that is less than 0.15 has associated scores (the left and center columns) of 0 and 1, while the other values of X have associated scores of 0.91 and 0.09. The difference (score 0.09 instead of the expected .06) is due to a statistical fluctuation: there are 8 observations in X in the range (.95, 1) instead of the expected 5 observations.

Examples

Compute the resubstituted classification error for the `ionosphere` data:

```
load ionosphere
tree = fitctree(X,Y);
L = loss(tree,X,Y)
```

```
L =
    0.0114
```

`margin` | `predict` | `fitctree` | `edge`

loss

Class: CompactRegressionEnsemble

Regression error

Syntax

`L = loss(ens, X, Y)`

`L = loss(ens, X, Y, Name, Value)`

Description

`L = loss(ens, X, Y)` returns the mean squared error between the predictions of `ens` to the data in `X`, compared to the true responses `Y`.

`L = loss(ens, X, Y, Name, Value)` computes the error in prediction with additional options specified by one or more `Name, Value` pair arguments.

Input Arguments

ens

A regression ensemble created with `fitensemble`, or the `compact` method.

X

A matrix of predictor values. Each column of `X` represents one variable, and each row represents one observation.

NaN values in `X` are taken to be missing values. Observations with all missing values for `X` are not used in the calculation of `loss`.

Y

A numeric column vector with the same number of rows as `X`. Each entry in `Y` is the response to the data in the corresponding row of `X`.

NaN values in Y are taken to be missing values. Observations with missing values for Y are not used in the calculation of loss.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

'learners'

Indices of weak learners in the ensemble ranging from 1 to `ens.NumTrained`. `oobEdge` uses only these learners for calculating loss.

Default: `1:NumTrained`

'lossfun'

Function handle for loss function, or the string 'mse', meaning mean squared error. If you pass a function handle `fun`, `loss` calls it as

```
fun(Y,Yfit,W)
```

where Y , $Yfit$, and W are numeric vectors of the same length.

- Y is the observed response.
- $Yfit$ is the predicted response.
- W is the observation weights.

The returned value `fun(Y,Yfit,W)` should be a scalar.

Default: 'mse'

'mode'

String representing the meaning of the output L :

- 'ensemble' — L is a scalar value, the loss for the entire ensemble.
- 'individual' — L is a vector with one element per trained learner.
- 'cumulative' — L is a vector in which element J is obtained by using learners `1:J` from the input list of learners.

Default: 'ensemble'

'UseObsForLearner'

A logical matrix of size N-by-NumTrained, where N is the number of observations in ens.X, and NumTrained is the number of weak learners. When UseObsForLearner(I,J) is true, predict uses learner J in predicting observation I.

Default: true(N,NumTrained)

'weights'

Numeric vector of observation weights with the same number of elements as Y. The formula for loss with weights is in “Weighted Mean Squared Error” on page 21-2444.

Default: ones(size(Y))

Output Arguments

L

Weighted mean squared error of predictions. The formula for loss is in “Weighted Mean Squared Error” on page 21-2444.

Definitions

Weighted Mean Squared Error

Let n be the number of rows of data, x_j be the j th row of data, y_j be the true response to x_j , and let $f(x_j)$ be the response prediction of ens to x_j . Let w be the vector of weights (all one by default).

First the weights are divided by their sum so they add to one: $w \rightarrow w/\sum w$. The mean squared error L is

$$L = \sum_{j=1}^n w_j (f(x_j) - y_j)^2.$$

Examples

Find the loss of an ensemble predictor of the `carsmall` data to find MPG as a function of engine displacement, horsepower, and vehicle weight:

```
load carsmall
X = [Displacement Horsepower Weight];
ens = fitensemble(X,MPG,'LSBoost',100,'Tree');
L = loss(ens,X,MPG)
```

```
L =
    4.3904
```

See Also

[predict](#) | [fitensemble](#)

loss

Class: CompactRegressionTree

Regression error

Syntax

```
L = loss(tree,X,Y)
[L,se] = loss(tree,X,Y)
[L,se,NLeaf] = loss(tree,X,Y)
[L,se,NLeaf,bestlevel] = loss(tree,X,Y)
L = loss(tree,X,Y,Name,Value)
```

Description

`L = loss(tree,X,Y)` returns the mean squared error between the predictions of `tree` to the data in `X`, compared to the true responses `Y`.

`[L,se] = loss(tree,X,Y)` returns the standard error of the loss.

`[L,se,NLeaf] = loss(tree,X,Y)` returns the number of leaves (terminal nodes) in the tree.

`[L,se,NLeaf,bestlevel] = loss(tree,X,Y)` returns the optimal pruning level for tree.

`L = loss(tree,X,Y,Name,Value)` computes the error in prediction with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

tree

Regression tree created with `fitrtree`, or the `compact` method.

X

A matrix of predictor values. Each column of X represents one variable, and each row represents one observation.

Y

A numeric column vector with the same number of rows as X. Each entry in Y is the response to the data in the corresponding row of X.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

'LossFun'

Function handle for loss, or the string 'mse' representing mean-squared error. If you pass a function handle **fun**, **loss** calls **fun** as:

```
fun(Y,Yfit,W)
```

- Y is the vector of true responses.
- Yfit is the vector of predicted responses.
- W is the observation weights. If you pass W, the elements are normalized to sum to 1.

All the vectors have the same number of rows as Y.

Default: 'mse'

'Subtrees'

A vector with integer values from 0 (full unpruned tree) to the maximal pruning level `max(tree.PruneList)`. You can set **Subtrees** to 'all', meaning the entire pruning sequence.

Default: 0

'TreeSize'

A string, either:

- `'se'` — `loss` returns `bestlevel` that corresponds to the smallest tree whose mean squared error (MSE) is within one standard error of the minimum MSE.
- `'min'` — `loss` returns `bestlevel` that corresponds to the minimal MSE tree.

'Weights'

Numeric vector of observation weights with the same number of elements as `Y`.

Default: `ones(size(Y))`

Output Arguments

L

Classification error, a vector the length of `Subtrees`. The error for each tree is the mean squared error, weighted with `Weights`. If you include `LossFun`, `L` reflects the loss calculated with `LossFun`.

se

Standard error of loss, a vector the length of `Subtrees`.

NLeaf

Number of leaves (terminal nodes) in the pruned subtrees, a vector the length of `Subtrees`.

bestlevel

A scalar whose value depends on `TreeSize`:

- `TreeSize = 'se'` — `loss` returns the highest pruning level with loss within one standard deviation of the minimum (`L+se`, where `L` and `se` relate to the smallest value in `Subtrees`).
- `TreeSize = 'min'` — `loss` returns the element of `Subtrees` with smallest loss, usually the smallest element of `Subtrees`.

Definitions

Mean Squared Error

The mean squared error m of the predictions $f(X_n)$ with weight vector w is

$$m = \frac{\sum w_n (f(X_n) - Y_n)^2}{\sum w_n}.$$

Examples

Find the loss of a regression tree predictor of the `carsmall` data to find MPG as a function of engine displacement, horsepower, and vehicle weight:

```
load carsmall
X = [Displacement Horsepower Weight];
tree = fitrtree(X,MPG);
L = loss(tree,X,MPG)
```

```
L =
    4.8952
```

Find the pruning level that gives the optimal level of loss for the `carsmall` data:

```
load carsmall
X = [Displacement Horsepower Weight];
tree = fitrtree(X,MPG);
[L,se,NLeaf,bestlevel] = loss(tree,X,MPG,'Subtrees','all');
bestlevel
```

```
bestlevel =
    4
```

See Also

`predict` | `fitrtree`

lowerparams

Class: paretotails

Lower Pareto tails parameters

Syntax

```
params = lowerparams(obj)
```

Description

`params = lowerparams(obj)` returns the 2-element vector `params` of shape and scale parameters, respectively, of the lower tail of the Pareto tails object `obj`. `lowerparams` does not return a location parameter.

Examples

Fit Pareto tails to a t distribution at cumulative probabilities 0.1 and 0.9:

```
t = trnd(3,100,1);  
obj = paretotails(t,0.1,0.9);
```

```
lowerparams(obj)  
ans =  
    -0.1901    1.1898  
upperparams(obj)  
ans =  
    0.3646    0.5103
```

See Also

`paretotails` | `upperparams`

lt

Class: grandstream

Less than relation for handles

Syntax

`h1 < h2`

Description

`h1 < h2` performs element-wise comparisons between handle arrays `h1` and `h2`. `h1` and `h2` must be of the same dimensions unless one is a scalar. The result is a logical array of the same dimensions, where each element is an element-wise `<` result.

If one of `h1` or `h2` is scalar, scalar expansion is performed and the result will match the dimensions of the array that is not scalar.

`tf = lt(h1, h2)` stores the result in a logical array of the same dimensions.

See Also

`grandstream` | `ge` | `gt` | `ne` | `eq` | `le`

lsline

Add least-squares line to scatter plot

Syntax

```
lsline  
lsline(ax)  
h = lsline( ___ )
```

Description

`lsline` superimposes a least-squares line on each scatter plot in the current axes. Scatter plots are produced by the MATLAB `scatter` and `plot` functions. Data points connected with solid, dashed, or dash-dot lines (' - ', ' - - ', or ' . - ') are not considered to be scatter plots by `lsline`, and are ignored.

`lsline(ax)` superimposes a least-squares line on the scatter plot in axis `ax`.

`h = lsline(___)` returns a column vector of handles `h` to the least-squares lines, using any of the previous syntaxes.

Examples

Plot a Least-Squares Line

Generate three sets of sample data and plot on the same figure.

```
x = 1:10;  
rng default; % For reproducibility  
figure;  
  
y1 = x + randn(1,10);  
scatter(x,y1,25,'b','*')  
hold on
```

```
y2 = 2*x + randn(1,10);  
plot(x,y2, 'mo')
```

```
y3 = 3*x + randn(1,10);  
plot(x,y3, 'rx:')
```

Add a least-squares line for each set of sample data.

```
lsline
```

Specify Axes for Least-Squares and Reference Lines

Define the x-variable and two different y-variables to use for the plots.

```
rng default % For reproducibility
x = 1:10;
y1 = x + randn(1,10);
y2 = 2*x + randn(1,10);
```

Define `ax1` as the top half of the figure, and `ax2` as the bottom half of the figure. Create the first scatter plot on the top axis using `y1`, and the second scatter plot on the bottom axis using `y2`.

```
figure
```

```
ax1 = subplot(2,1,1);  
ax2 = subplot(2,1,2);  
  
scatter(ax1,x,y1)  
scatter(ax2,x,y2)
```

Superimpose a least-squares line on the top plot, and a reference line at the mean of the y_2 values in the bottom plot.

```
lsline(ax1)  
  
mu = mean(y2);  
refline(ax2,[0 mu])
```

**See Also**

scatter | plot | refline | refcurve | gline

mad

Mean or median absolute deviation

Syntax

```
y = mad(X)
Y = mad(X,1)
Y = mad(X,0)
```

Description

`y = mad(X)` returns the mean absolute deviation of the values in `X`. For vector input, `y` is `mean(abs(X-mean(X)))`. For a matrix input, `y` is a row vector containing the mean absolute deviation of each column of `X`. For N -dimensional arrays, `mad` operates along the first nonsingleton dimension of `X`.

`Y = mad(X,1)` returns the median absolute deviation of the values in `X`. For vector input, `y` is `median(abs(X-median(X)))`. For a matrix input, `y` is a row vector containing the median absolute deviation of each column of `X`. For N -dimensional arrays, `mad` operates along the first nonsingleton dimension of `X`.

`Y = mad(X,0)` is the same as `mad(X)`, and returns the mean absolute deviation of the values in `X`.

`mad(X,flag,dim)` computes absolute deviations along the dimension `dim` of `X`. `flag` is 0 or 1 to indicate mean or median absolute deviation, respectively.

`mad` treats NaNs as missing values and removes them.

For normally distributed data, multiply `mad` by one of the following factors to obtain an estimate of the normal scale parameter σ :

- `sigma = 1.253*mad(X,0)` — For mean absolute deviation
- `sigma = 1.4826*mad(X,1)` — For median absolute deviation

Examples

The following compares the robustness of different scale estimates for normally distributed data in the presence of outliers:

```
x = normrnd(0,1,1,50);  
xo = [x 10]; % Add outlier
```

```
r1 = std(xo)/std(x)  
r1 =  
    1.7385
```

```
r2 = mad(xo,0)/mad(x,0)  
r2 =  
    1.2306
```

```
r3 = mad(xo,1)/mad(x,1)  
r3 =  
    1.0602
```

std | range | iqr

mahal

Mahalanobis distance

Syntax

```
d = mahal(Y,X)
```

Description

`d = mahal(Y,X)` computes the Mahalanobis distance (in squared units) of each observation in `Y` from the reference sample in matrix `X`. If `Y` is n -by- m , where n is the number of observations and m is the dimension of the data, `d` is n -by-1. `X` and `Y` must have the same number of columns, but can have different numbers of rows. `X` must have more rows than columns.

For observation `I`, the Mahalanobis distance is defined by $d(I) = (Y(I,:) - \mu) * \text{inv}(\text{SIGMA}) * (Y(I,:) - \mu)'$, where `mu` and `SIGMA` are the sample mean and covariance of the data in `X`. `mahal` performs an equivalent, but more efficient, computation.

Examples

Compare Mahalanobis and Squared Euclidean Distances

Generate correlated bivariate data.

```
X = mvnrnd([0;0],[1 .9;.9 1],100);
```

Input observations.

```
Y = [1 1;1 -1;-1 1;-1 -1];
```

Compute the Mahalanobis distance of observations in `Y` from the reference sample in `X`.

```
d1 = mahal(Y,X)
```

```
d1 =  
  
    0.6288  
    19.3520  
    21.1384  
    0.9404
```

Compute their squared Euclidean distances from the mean of X .

```
d2 = sum((Y-repmat(mean(X),4,1)).^2, 2)
```

```
d2 =  
  
    1.6170  
    1.9334  
    2.1094  
    2.4258
```

Plot the observations with Y values colored according to the Mahalanobis distance.

```
scatter(X(:,1),X(:,2))  
hold on  
scatter(Y(:,1),Y(:,2),100,d1,'*', 'LineWidth',2)  
hb = colorbar;  
ylabel(hb,'Mahalanobis Distance')  
legend('X', 'Y', 'Location', 'NW')
```

The observations in Y with equal coordinate values are much closer to X in Mahalanobis distance than observations with opposite coordinate values, even though all observations are approximately equidistant from the mean of X in Euclidean distance. The Mahalanobis distance, by considering the covariance of the data and the scales of the different variables, is useful for detecting outliers in such cases.

See Also

`pdist` | `mahal`

mahal

Class: CompactClassificationDiscriminant

Mahalanobis distance to class means

Syntax

`M = mahal(obj,X)`

`M = mahal(obj,X,Name,Value)`

Description

`M = mahal(obj,X)` returns the squared Mahalanobis distances from observations in `X` to the class means in `obj`.

`M = mahal(obj,X,Name,Value)` computes the squared Mahalanobis distance with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

obj

Discriminant analysis classifier of class `ClassificationDiscriminant` or `CompactClassificationDiscriminant`, typically constructed with `fitcdiscr`.

X

Numeric matrix of size `n`-by-`p`, where `p` is the number of predictors in `obj`, and `n` is any positive integer. `mahal` computes the Mahalanobis distances from the rows of `X` to each of the `K` means of the classes in `obj`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single

quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

'ClassLabels'

Class labels consisting of n elements of `obj.Y`, where n is the number of rows of `X`.

Output Arguments

M

Size and meaning of output `M` depends on whether the `ClassLabels` name-value pair is present:

- No `ClassLabels` — `M` is a numeric matrix of size n -by- K , where K is the number of classes in `obj`, and n is the number of rows in `X`. $M(i, j)$ is the squared Mahalanobis distance from the i th row of `X` to the mean of class j .
- `ClassLabels` exists — `M` is a column vector with n elements. $M(i)$ is the squared Mahalanobis distance from the i th row of `X` to the mean for the class of the i th element of `ClassLabels`.

Definitions

Mahalanobis Distance

The Mahalanobis distance $d(x,y)$ between n -dimensional points x and y , with respect to a given n -by- n covariance matrix S , is

$$d(x, y) = \sqrt{(x - y)^T S^{-1} (x - y)}.$$

Examples

Find the Mahalanobis distances from the mean of the Fisher iris data to the class means, using distinct covariance matrices for each class:

```
load fisheriris
obj = fitcdiscr(meas,species,...
  'DiscrimType','quadratic');
mahadist = mahal(obj,mean(meas))

mahadist =
    220.0667    5.0254    30.5804
```

How To

- “Discriminant Analysis” on page 15-3

mahal

Class: gmdistribution

Mahalanobis distance to component means

Syntax

```
D = mahal(obj,X)
```

Description

`D = mahal(obj,X)` computes the Mahalanobis distance (in squared units) of each observation in `X` to the mean of each of the k components of the Gaussian mixture distribution defined by `obj`. `obj` is an object created by `gmdistribution` or `fitgmdist`. `X` is an n -by- d matrix, where n is the number of observations and d is the dimension of the data. `D` is n -by- k , with `D(I,J)` the distance of observation `I` from the mean of component `J`.

Examples

Measure Mahalanobis Distances in Gaussian Mixture Data

Generate data from a mixture of two bivariate Gaussian distributions using the `mvnrnd` function.

```
MU1 = [1 2];  
SIGMA1 = [2 0; 0 .5];  
MU2 = [-3 -5];  
SIGMA2 = [1 0; 0 1];  
rng(1); % For reproducibility  
X = [mvnrnd(MU1,SIGMA1,1000);mvnrnd(MU2,SIGMA2,1000)];  
  
scatter(X(:,1),X(:,2),10,'.')
```

hold on

Fit a two-component Gaussian mixture model.

```
obj = fitgmdist(X,2);  
h = ezcontour(@(x,y)pdf(obj,[x y]),[-8 6],[-8 6]);
```

Compute the Mahalanobis distance of each point in X to the mean of each component of obj .

```
D = mahal(obj,X);
```

```
delete(h)  
scatter(X(:,1),X(:,2),10,D(:,1),'.')  
hb = colorbar;  
ylabel(hb,'Mahalanobis Distance to Component 1')
```

maineffectsplot

Main effects plot for grouped data

Syntax

```
maineffectsplot(Y, GROUP)
maineffectsplot(Y, GROUP, param1, val1, param2, val2, ...)
[figh, AXESH] = maineffectsplot(...)
```

Description

`maineffectsplot(Y, GROUP)` displays main effects plots for the group means of matrix `Y` with groups defined by entries in the cell array `GROUP`. `Y` is a numeric matrix or vector. If `Y` is a matrix, the rows represent different observations and the columns represent replications of each observation. Each cell of `GROUP` must contain a grouping variable that can be a categorical variable, numeric vector, character matrix, or single-column cell array of strings. `GROUP` can also be a matrix whose columns represent different grouping variables. Each grouping variable must have the same number of rows as `Y`. The number of grouping variables must be greater than 1.

The display has one subplot per grouping variable, with each subplot showing the group means of `Y` as a function of one grouping variable.

`maineffectsplot(Y, GROUP, param1, val1, param2, val2, ...)` specifies one or more of the following name/value pairs:

- `'varnames'` — Grouping variable names in a character matrix or a cell array of strings, one per grouping variable. Default names are `'X1'`, `'X2'`, ...
- `'statistic'` — String values that indicate whether the group mean or the group standard deviation should be plotted. Use `'mean'` or `'std'`. The default is `'mean'`. If the value is `'std'`, `Y` is required to have multiple columns.
- `'parent'` — A handle to the figure window for the plots. The default is the current figure window.

`[figh, AXESH] = maineffectsplot(...)` returns the handle `figh` to the figure window and an array of handles `AXESH` to the subplot axes.

Examples

Main Effects Plot

Load the sample data.

```
load carsmall;
```

Display main effects plots for car weight with two grouping variables, model year and number of cylinders.

```
maineffectsplot(Weight,{Model_Year,Cylinders}, ...  
                'varnames',{'Model Year',' # of Cylinders'})
```

ClassificationDiscriminant.make

Class: ClassificationDiscriminant

Construct discriminant analysis classifier from parameters (to be removed)

Compatibility

ClassificationDiscriminant.make will be removed in a future release. Use `makecdiscr` instead.

Syntax

```
cobj = ClassificationDiscriminant.make(Mu, Sigma)
cobj = ClassificationDiscriminant.make(Mu, Sigma, Name, Value)
```

Description

`cobj = ClassificationDiscriminant.make(Mu, Sigma)` constructs a compact discriminant analysis classifier from the class means `MU` and covariance matrix `Sigma`.

`cobj = ClassificationDiscriminant.make(Mu, Sigma, Name, Value)` constructs a compact classifier with additional options specified by one or more `Name, Value` pair arguments.

Input Arguments

Mu — Class means

matrix of scalar values

Class means, specified as a K -by- p matrix of scalar values class means of size. K is the number of classes, and p is the number of predictors. Each row of `MU` represents the mean of the multivariate normal distribution of the corresponding class. The class indices are in the `ClassNames` attribute.

Sigma — Within-class covariance

matrix of scalar values

Within-class covariance, specified as a matrix of scalar values.

- For a linear discriminant, **Sigma** is a symmetric, positive semidefinite matrix of size p -by- p , where p is the number of predictors.
- For a quadratic discriminant, **Sigma** is an array of size p -by- p -by- K , where K is the number of classes. For each i , **Sigma**($:$, $:$, i) is a symmetric, positive semidefinite matrix.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of **Name**,**Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as **Name1**,**Value1**, ..., **NameN**,**ValueN**.

'ClassNames' — Class names

numeric vector | categorical vector | logical vector | character array | cell array of strings

Class names as ordered in **Mu**, specified as the comma-separated pair consisting of **'ClassNames'** and an array containing grouping variables. Use any data type for a grouping variable, including numeric vector, categorical vector, logical vector, character array, or cell array of strings.

ClassNames names the classes, as ordered in **Mu**.

Default is $1:K$, where K is the number of classes (the number of rows of **Mu**).

Data Types: `single` | `double` | `logical` | `char` | `cell`

'Cost' — Cost of misclassification

square matrix | structure

Cost of misclassification, specified as the comma-separated pair consisting of **'Cost'** and a square matrix, where **Cost**(i , j) is the cost of classifying a point into class

j if its true class is i . Alternatively, `Cost` can be a structure `S` having two fields: `S.ClassNames` containing the group names as a variable of the same type as y , and `S.ClassificationCosts` containing the cost matrix.

The default is `Cost(i, j)=1` if $i \neq j$, and `Cost(i, j)=0` if $i=j$.

Data Types: `single` | `double` | `struct`

'PredictorNames' — Predictor variable names

`{ 'x1', 'x2', ... }` (default) | cell array of strings

Predictor variable names, specified as the comma-separated pair consisting of `'PredictorNames'` and a cell array of strings containing the names for the predictor variables, in the order in which they appear in x .

Data Types: `cell`

'Prior' — Prior probabilities

`'uniform'` (default) | vector of scalar values | structure

Prior probabilities for each class, specified as the comma-separated pair consisting of `'Prior'` and one of the following.

- `'uniform'`, a string meaning all class prior probabilities are equal.
- A vector containing one scalar value for each class.
- A structure `S` with two fields:
 - `S.ClassNames` containing the class names as a variable of the same type as `ClassNames`.
 - `S.ClassProbs` containing a vector of corresponding probabilities.

Data Types: `single` | `double` | `struct`

'ResponseName' — Response variable name

`'Y'` (default) | string

Response variable name, specified as the comma-separated pair consisting of `'ResponseName'` and a string containing the name of the response variable y .

Example: `'ResponseName', 'Response'`

Data Types: `char`

Output Arguments

cobj — Discriminant analysis classifier
discriminant analysis classifier object

Discriminant analysis classifier, returned as a discriminant analysis classifier object of class `CompactClassificationDiscriminant`. You can use the `predict` method to predict classification labels for new data.

Examples

Construct a Compact Linear Discriminant Analysis Classifier

Construct a compact linear discriminant analysis classifier from the means and covariances of the Fisher iris data.

```
load fisheriris
mu(1,:) = mean(meas(1:50,:));
mu(2,:) = mean(meas(51:100,:));
mu(3,:) = mean(meas(101:150,:));

mm1 = repmat(mu(1,:),50,1);
mm2 = repmat(mu(2,:),50,1);
mm3 = repmat(mu(3,:),50,1);
cc = meas;
cc(1:50,:) = cc(1:50,:) - mm1;
cc(51:100,:) = cc(51:100,:) - mm2;
cc(101:150,:) = cc(101:150,:) - mm3;
sigstar = cc' * cc / 147; % unbiased estimator of sigma
cpct = ClassificationDiscriminant.make(mu,sigstar,...
    'ClassNames',{ 'setosa', 'versicolor', 'virginica' });

cpct =
classreg.learning.classif.CompactClassificationDiscriminant:
    PredictorNames: {'x1' 'x2' 'x3' 'x4'}
    ResponseName: 'Y'
    ClassNames: {'setosa' 'versicolor' 'virginica'}
    ScoreTransform: 'none'
    DiscrimType: 'linear'
    Mu: [3x4 double]
```

Coeffs: [3x3 struct]

See Also

`compact` | `CompactClassificationDiscriminant` | `fitcdiscr` | `makecdiscr`

How To

- “Discriminant Analysis” on page 15-3

makecdiscr

Construct discriminant analysis classifier from parameters

Syntax

```
cobj = makecdiscr(Mu,Sigma)
cobj = makecdiscr(Mu,Sigma,Name,Value)
```

Description

`cobj = makecdiscr(Mu,Sigma)` constructs a compact discriminant analysis classifier from the class means `Mu` and covariance matrix `Sigma`.

`cobj = makecdiscr(Mu,Sigma,Name,Value)` constructs a compact classifier with additional options specified by one or more name-value pair arguments. For example, you can specify the cost of misclassification or the prior probabilities for each class.

Examples

Construct a Compact Linear Discriminant Analysis Classifier

Construct a compact linear discriminant analysis classifier from the means and covariances of the Fisher iris data.

```
load fisheriris
mu(1,:) = mean(meas(1:50,:));
mu(2,:) = mean(meas(51:100,:));
mu(3,:) = mean(meas(101:150,:));

mm1 = repmat(mu(1,:),50,1);
mm2 = repmat(mu(2,:),50,1);
mm3 = repmat(mu(3,:),50,1);
cc = meas;
cc(1:50,:) = cc(1:50,:) - mm1;
cc(51:100,:) = cc(51:100,:) - mm2;
cc(101:150,:) = cc(101:150,:) - mm3;
sigstar = cc' * cc / 147; % unbiased estimator of sigma
```

```
cpct = makecdiscr(mu,sigstar,...
    'ClassNames',{ 'setosa', 'versicolor', 'virginica' })

cpct =
classreg.learning.classif.CompactClassificationDiscriminant:
  PredictorNames: {'x1' 'x2' 'x3' 'x4'}
  ResponseName: 'Y'
  ClassNames: {'setosa' 'versicolor' 'virginica'}
  ScoreTransform: 'none'
  DiscrimType: 'linear'
  Mu: [3x4 double]
  Coeffs: [3x3 struct]
```

Input Arguments

Mu — Class means

matrix of scalar values

Class means, specified as a K -by- p matrix of scalar values class means of size. K is the number of classes, and p is the number of predictors. Each row of **Mu** represents the mean of the multivariate normal distribution of the corresponding class. The class indices are in the **ClassNames** attribute.

Data Types: `single` | `double`

Sigma — Within-class covariance

matrix of scalar values

Within-class covariance, specified as a matrix of scalar values.

- For a linear discriminant, **Sigma** is a symmetric, positive semidefinite matrix of size p -by- p , where p is the number of predictors.
- For a quadratic discriminant, **Sigma** is an array of size p -by- p -by- K , where K is the number of classes. For each i , **Sigma**($:$, $:$, i) is a symmetric, positive semidefinite matrix.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of **Name**,**Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single

quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'ClassNames', {'setosa' 'versicolor' 'virginica'}` specifies a discriminant analysis classifier that uses 'setosa', 'versicolor', and 'virginica' as the grouping variables.

'ClassNames' — Class names

numeric vector | categorical vector | logical vector | character array | cell array of strings

Class names as ordered in `Mu`, specified as the comma-separated pair consisting of 'ClassNames' and an array containing grouping variables. Use any data type for a grouping variable, including numeric vector, categorical vector, logical vector, character array, or cell array of strings.

The default is `1:K`, where `K` is the number of classes (the number of rows of `Mu`).

Example: `'ClassNames', {'setosa' 'versicolor' 'virginica'}`

Data Types: `single` | `double` | `logical` | `char` | `cell`

'Cost' — Cost of misclassification

square matrix | structure

Cost of misclassification, specified as the comma-separated pair consisting of 'Cost' and a square matrix, where `Cost(i, j)` is the cost of classifying a point into class `j` if its true class is `i`. Alternatively, `Cost` can be a structure `S` having two fields: `S.ClassNames` containing the group names as a variable of the same type as `y`, and `S.ClassificationCosts` containing the cost matrix.

The default is `Cost(i, j)=1` if `i~=j`, and `Cost(i, j)=0` if `i=j`.

Data Types: `single` | `double` | `struct`

'PredictorNames' — Predictor variable names

`{'x1', 'x2', ...}` (default) | cell array of strings

Predictor variable names, specified as the comma-separated pair consisting of 'PredictorNames' and a cell array of strings containing the names for the predictor variables, in the order in which they appear in `x`.

Data Types: `cell`

'Prior' — Prior probabilities

'uniform' (default) | vector of scalar values | structure

Prior probabilities for each class, specified as the comma-separated pair consisting of 'Prior' and one of the following:

- 'uniform', a string meaning all class prior probabilities are equal
- A vector containing one scalar value for each class
- A structure **S** with two fields:
 - **S.ClassNames** containing the class names as a variable of the same type as **ClassNames**
 - **S.ClassProbs** containing a vector of corresponding probabilities

Data Types: single | double | struct

'ResponseName' — Response variable name

'Y' (default) | string

Response variable name, specified as the comma-separated pair consisting of 'ResponseName' and a string containing the name of the response variable *y*.

Example: 'ResponseName', 'Response'

Data Types: char

Output Arguments

cobj — Discriminant analysis classifier

discriminant analysis classifier object

Discriminant analysis classifier, returned as a discriminant analysis classifier object of class `CompactClassificationDiscriminant`. You can use the `predict` method to predict classification labels for new data.

More About

Tips

- You can change the discriminant type using dot notation after constructing `cobj`:

```
cobj.DiscrimType = 'discrimType'
```

where *discrimType* is one of 'linear', 'quadratic', 'diagLinear', 'diagQuadratic', 'pseudoLinear', or 'pseudoQuadratic'. You can change between linear types or between quadratic types, but cannot change between a linear and a quadratic type.

- `cobj` is a linear classifier when `Sigma` is a matrix. `cobj` is a quadratic classifier when `Sigma` is a three-dimensional array.
- “Discriminant Analysis” on page 15-3

makedist

Create probability distribution object

Syntax

```
pd = makedist(distname)
pd = makedist(distname,Name,Value)
```

Description

`pd = makedist(distname)` creates a probability distribution object for the distribution `distname`, using the default parameter values.

`pd = makedist(distname,Name,Value)` creates a probability distribution object with one or more distribution parameter values specified by name-value pair arguments.

Examples

Create a Normal Distribution Object

Create a normal distribution object using the default parameter values.

```
pd = makedist('Normal')
```

```
pd =
```

```
NormalDistribution
```

```
Normal distribution
```

```
mu = 0
```

```
sigma = 1
```

Compute the interquartile range of the distribution.

```
r = iqr(pd)
```

```
r =
```

```
1.3490
```

Create a Gamma Distribution Object

Create a gamma distribution object using the default parameter values.

```
pd = makedist('Gamma')
```

```
pd =
```

```
GammaDistribution
```

```
Gamma distribution
```

```
  a = 1
```

```
  b = 1
```

Compute the mean of the gamma distribution.

```
mean = mean(pd)
```

```
mean =
```

```
  1
```

Specify Parameters for a Normal Distribution Object

Create a normal distribution object with parameter values $\mu = 75$ and $\sigma = 10$.

```
pd = makedist('Normal','mu',75,'sigma',10)
```

```
pd =
```

```
NormalDistribution
```

```
Normal distribution
```

```
  mu = 75
```

```
  sigma = 10
```

Specify Parameters for a Gamma Distribution Object

Create a gamma distribution object with the parameter value $a = 3$ and the default value $b = 1$.

```
pd = makedist('Gamma','a',3)
```

```
pd =
    GammaDistribution
    Gamma distribution
    a = 3
    b = 1
```

Input Arguments

distname — Distribution name

string

Distribution name, specified as one of the following strings. The distribution specified by **distname** determines the class type of the returned probability distribution object.

Distribution Name	Description	Distribution Class
'Beta'	Beta distribution	prob.BetaDistribution
'Binomial'	Binomial distribution	prob.BinomialDistribution
'BirnbbaumSaunders'	Birnbbaum-Saunders distribution	prob.BirnbbaumSaundersDistribution
'Burr'	Burr distribution	prob.BurrDistribution
'Exponential'	Exponential distribution	prob.ExponentialDistribution
'ExtremeValue'	Extreme Value distribution	prob.ExtremeValueDistribution
'Gamma'	Gamma distribution	prob.GammaDistribution
'GeneralizedExtremeValue'	Generalized Extreme Value distribution	prob.GeneralizedExtremeValueDistribution
'GeneralizedPareto'	Generalized Pareto distribution	prob.GeneralizedParetoDistribution
'InverseGaussian'	Inverse Gaussian distribution	prob.InverseGaussianDistribution
'Logistic'	Logistic distribution	prob.LogisticDistribution
'Loglogistic'	Loglogistic distribution	prob.LoglogisticDistribution
'Lognormal'	Lognormal distribution	prob.LognormalDistribution

Distribution Name	Description	Distribution Class
'Multinomial'	Multinomial distribution	prob.MultinomialDistribution
'Nakagami'	Nakagami distribution	prob.NakagamiDistribution
'NegativeBinomial'	Negative Binomial distribution	prob.NegativeBinomialDistribution
'Normal'	Normal distribution	prob.NormalDistribution
'PiecewiseLinear'	Piecewise Linear distribution	prob.PiecewiseLinearDistribution
'Poisson'	Poisson distribution	prob.PoissonDistribution
'Rayleigh'	Rayleigh distribution	prob.RayleighDistribution
'Rician'	Rician distribution	prob.RicianDistribution
'tLocationScale'	<i>t</i> Location-Scale distribution	prob.tLocationScaleDistribution
'Triangular'	Triangular distribution	prob.TriangularDistribution
'Uniform'	Uniform distribution	prob.UniformDistribution
'Weibull'	Weibull distribution	prob.WeibullDistribution

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `makedist('Normal', 'mu', 10)` specifies a normal distribution with parameter `mu` equal to 10, and parameter `sigma` equal to the default value of 1.

Beta Distribution

'a' — First shape parameter

1 (default) | nonnegative scalar value

Example: 'a', 3

Data Types: single | double

'b' — Second shape parameter

1 (default) | nonnegative scalar value

Example: 'b',5

Data Types: single | double

Binomial Distribution

'N' — Number of trials

1 (default) | positive integer value

Example: 'N',25

Data Types: single | double

'p' — Probability of success

0.5 (default) | scalar value in the range [0,1]

Example: 'p',0.25

Data Types: single | double

Birnbaum-Saunders Distribution

'beta' — Scale parameter

1 (default) | positive scalar value

Example: 'beta',2

Data Types: single | double

'gamma' — Shape parameter

1 (default) | nonnegative scalar value

Example: 'gamma',0

Data Types: single | double

Burr Distribution

'alpha' — Scale parameter

1 (default) | positive scalar value

Example: 'alpha',2

Data Types: single | double

'c' — First shape parameter

1 (default) | positive scalar value

Example: 'c',2

Data Types: single | double

'k' — Second shape parameter

1 (default) | positive scalar value

Example: 'k',5

Data Types: single | double

Exponential Distribution

'mu' — Mean parameter

1 (default) | positive scalar value

Example: 'mu',5

Data Types: single | double

Extreme Value Distribution

'mu' — Location parameter

0 (default) | scalar value

Example: 'mu',-2

Data Types: single | double

'sigma' — Scale parameter

1 (default) | nonnegative scalar value

Example: 'sigma',2

Data Types: single | double

Gamma Distribution

'a' — Shape parameter

1 (default) | positive scalar value

Example: 'a',2

Data Types: single | double

'b' — Scale parameter

1 (default) | nonnegative scalar value

Example: 'b',0

Data Types: single | double

Generalized Extreme Value Distribution

'k' — Shape parameter

0 (default) | scalar value

Example: 'k',0

Data Types: single | double

'sigma' — Scale parameter

1 (default) | nonnegative scalar value

Example: 'sigma',2

Data Types: single | double

'mu' — Location parameter

0 (default) | scalar value

Example: 'mu',1

Data Types: single | double

Generalized Pareto Distribution

'k' — Shape parameter

1 (default) | scalar value

Example: 'k',0

Data Types: single | double

'sigma' — Scale parameter

1 (default) | nonnegative scalar value

Example: 'sigma',2

Data Types: single | double

'theta' — Location parameter

1 (default) | scalar value

Example: 'theta',2

Data Types: single | double

Inverse Gaussian Distribution

'mu' — Scale parameter

1 (default) | positive scalar value

Example: 'mu', 2

Data Types: single | double

'lambda' — Shape parameter

1 (default) | positive scalar value

Example: 'lambda', 4

Data Types: single | double

Logistic Distribution

'mu' — Mean

0 (default) | scalar value

Example: 'mu', 2

Data Types: single | double

'sigma' — Scale parameter

1 (default) | nonnegative scalar value

Example: 'sigma', 4

Data Types: single | double

Loglogistic Distribution

'mu' — Log mean

0 (default) | scalar value

Example: 'mu', 2

Data Types: single | double

'sigma' — Log scale parameter

1 (default) | nonnegative scalar value

Example: 'sigma', 4

Data Types: `single` | `double`

Lognormal Distribution

'mu' — Log mean

0 (default) | scalar value

Example: `'mu', 2`

Data Types: `single` | `double`

'sigma' — Log standard deviation

1 (default) | nonnegative scalar value

Example: `'sigma', 2`

Data Types: `single` | `double`

Multinomial Distribution

'probabilities' — Outcome probabilities

[0.500 0.500] (default) | vector of scalar values in the range [0,1]

Example: `'probabilities', [0.1 0.2 0.5 0.2]`

Data Types: `single` | `double`

Nakagami Distribution

'mu' — Shape parameter

1 (default) | positive scalar value

Example: `'mu', 5`

Data Types: `single` | `double`

'omega' — Scale parameter

1 (default) | positive scalar value

Example: `'omega', 5`

Data Types: `single` | `double`

Negative Binomial Distribution

'R' — Number of successes

1 (default) | positive scalar value

Example: 'R',5

Data Types: single | double

'p' — Probability of success

0.5 (default) | scalar value in the range (0,1]

Example: 'p',0.1

Data Types: single | double

Normal Distribution

'mu' — Mean

0 (default) | scalar value

Example: 'mu',2

Data Types: single | double

'sigma' — Standard deviation

1 (default) | nonnegative scalar value

Example: 'sigma',2

Data Types: single | double

Piecewise Linear Distribution

'x' — Data values

1 (default) | vector of scalar values

Example: 'x',[1 2 3]

Data Types: single | double

'Fx' — cdf values

1 (default) | vector of scalar values

Example: 'Fx',[.2 .5 1]

Data Types: single | double

Poisson Distribution

'lambda' — Mean

1 (default) | nonnegative scalar value

Example: 'lambda',5

Data Types: single | double

Rayleigh Distribution

'b' — Defining parameter

1 (default) | positive scalar value

Example: 'b',3

Data Types: single | double

Rician Distribution

's' — Noncentrality parameter

1 (default) | nonnegative scalar value

Example: 's',0

Data Types: single | double

'sigma' — Scale parameter

1 (default) | positive scalar value

Example: 'sigma',2

Data Types: single | double

***t* Location-Scale Distribution**

'mu' — Location parameter

0 (default) | scalar value

Example: 'mu',-2

Data Types: single | double

'sigma' — Scale parameter

1 (default) | positive scalar value

Example: 'sigma',2

Data Types: single | double

'nu' — Degrees of freedom

5 (default) | positive scalar value

Example: 'nu', 20

Data Types: single | double

Triangular Distribution

'a' — Lower limit

0 (default) | scalar value

Example: 'a', -2

Data Types: single | double

'b' — Peak location

0.5 (default) | scalar value greater than or equal to a

Example: 'b', 1

Data Types: single | double

'c' — Upper limit

1 (default) | scalar value greater than or equal to b

Example: 'c', 5

Data Types: single | double

Uniform Distribution

'lower' — Lower parameter

0 (default) | scalar value

Example: 'lower', -4

Data Types: single | double

'upper' — Upper parameter

1 (default) | scalar value greater than lower

Example: 'upper', 2

Data Types: single | double

Weibull Distribution

'a' — Scale parameter

1 (default) | positive scalar value

Example: 'a',2

Data Types: single | double

'b' — Shape parameter

1 (default) | positive scalar value

Example: 'b',5

Data Types: single | double

Output Arguments

pd — Probability distribution

probability distribution object

Probability distribution, returned as a probability distribution object of the type specified by `distname`.

Alternative Functionality

App

The Distribution Fitting app opens a graphical user interface for you to import data from the workspace and interactively fit a probability distribution to that data. You can then save the distribution to the workspace as a probability distribution object. Open the Distribution Fitting app using `dfittool`, or click Distribution Fitting on the Apps tab.

manova

Class: RepeatedMeasuresModel

Multivariate analysis of variance

Syntax

```
manovatbl = manova(rm)
manovatbl = manova(rm,Name,Value)
[manovatbl,A,C,D] = manova( ___ )
```

Description

`manovatbl = manova(rm)` returns the results of multivariate analysis of variance (`manova`) for the repeated measures model `rm`.

`manovatbl = manova(rm,Name,Value)` also returns `manova` results with additional options, specified by one or more `Name,Value` pair arguments.

`[manovatbl,A,C,D] = manova(___)` also returns arrays `A`, `C`, and `D` for the hypotheses tests of the form $A*B*C = D$, where `D` is zero.

Tips

- The multivariate response for each observation (subject) is the vector of repeated measures.
- To test a more general hypothesis $A*B*C = D$, use `coefstest`.

Input Arguments

rm — Repeated measures model

RepeatedMeasuresModel object

Repeated measures model, returned as a `RepeatedMeasuresModel` object.

For properties and methods of this object, see `RepeatedMeasuresModel`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

'WithinModel' — Model specifying within-subjects hypothesis test

'separatemeans' (default) | model specification using formula

Model specifying the within-subjects hypothesis test, specified as one of the following:

- `'separatemeans'` — Compute a separate mean for each group, and test for equality among the means.
- Model specification — This is a model specification in the within-subject factors. Test each term in the model. In this case, `tbl` contains a separate manova for each term in the formula, with the multivariate response equal to the vector of coefficients of that term.
- An r -by- nc matrix, C , specifying nc contrasts among the r repeated measures. If Y represents the matrix of repeated measures you use in the repeated measures model `rm`, then the output `tbl` contains a separate manova for each column of $Y*C$.

Example: `'WithinModel', 'separatemeans'`

'By' — Single between-subjects factor

string

Single between-subjects factor, specified as the comma-separated pair consisting of `'By'` and a string. `manova` performs a separate test of the within-subjects model for each value of this factor.

For example, if you have a between-subjects factor, `Drug`, then you can specify that factor to perform manova as follows.

Example: `'By', 'Drug'`

Output Arguments

`manova` `tbl` — Results of multivariate analysis of variance

table

Results of multivariate analysis of variance for the repeated measures model `rm`, returned as a `table`.

`manova` uses these methods to measure the contributions of the model terms to the overall covariance:

- Wilks' Lambda
- Pillai's trace
- Hotelling-Lawley trace
- Roy's maximum root statistic

For details, see "Multivariate Analysis of Variance for Repeated Measures" on page 8-56.

`manova` returns the results for these tests for each group. `manovatbl` contains the following columns.

Column Name	Definition
Within	Within-subject terms
Between	Between-subject terms
Statistic	Name of the statistic computed
Value	Value of the corresponding statistic
F	<i>F</i> -statistic value
RSquare	Measure for variance explained
df1	Numerator degrees of freedom
df2	Denominator degrees of freedom
pValue	<i>p</i> -value for the corresponding <i>F</i> -statistic value

Data Types: `table`

A — Specification based on between-subjects model

`matrix` | `cell array`

Specification based on the between-subjects model, returned as a matrix or a cell array. It permits the hypothesis on the elements within given columns of **B** (within time hypothesis). If `manovatbl` contains multiple hypothesis tests, **A** might be a cell array.

Data Types: `single` | `double` | `cell`

C — Specification based on within-subjects model

`matrix` | `cell array`

Specification based on the within-subjects model, returned as a matrix or a cell array. It permits the hypotheses on the elements within given rows of **B** (between time hypotheses). If `manovatbl` contains multiple hypothesis tests, **C** might be a cell array.

Data Types: `single` | `double` | `cell`

D — Hypothesis value

0

Hypothesis value, returned as 0.

Examples

Perform Multivariate Analysis of Variance

Load the sample data.

```
load fisheriris
```

The column vector `species` consists of iris flowers of three different species: `setosa`, `versicolor`, `virginica`. The double matrix `meas` consists of four types of measurements on the flowers: the length and width of sepals and petals in centimeters, respectively.

Store the data in a table array.

```
t = table(species,meas(:,1),meas(:,2),meas(:,3),meas(:,4),...  
'VariableNames',{'species','meas1','meas2','meas3','meas4'});  
Meas = table([1 2 3 4]','VariableNames',{'Measurements'});
```

Fit a repeated measures model where the measurements are the responses and the species is the predictor variable.

```
rm = fitrm(t,'meas1-meas4~species','WithinDesign',Meas);
```

Perform multivariate analysis of variance.

```
manova(rm)
```

```
ans =
```

More About

- “Model Specification for Repeated Measures Models” on page 8-50
- “Multivariate Analysis of Variance for Repeated Measures” on page 8-56

manova1

One-way multivariate analysis of variance

Syntax

```
d = manova1(X,group)
d = manova1(X,group,alpha)
[d,p] = manova1(...)
[d,p,stats] = manova1(...)
```

Description

`d = manova1(X,group)` performs a one-way Multivariate Analysis of Variance (MANOVA) for comparing the multivariate means of the columns of `X`, grouped by `group`. `X` is an m -by- n matrix of data values, and each row is a vector of measurements on n variables for a single observation. `group` is a grouping variable defined as a categorical variable, vector, string array, or cell array of strings. Two observations are in the same group if they have the same value in the `group` array. The observations in each group represent a sample from a population.

The function returns `d`, an estimate of the dimension of the space containing the group means. `manova1` tests the null hypothesis that the means of each group are the same n -dimensional multivariate vector, and that any difference observed in the sample `X` is due to random chance. If `d = 0`, there is no evidence to reject that hypothesis. If `d = 1`, then you can reject the null hypothesis at the 5% level, but you cannot reject the hypothesis that the multivariate means lie on the same line. Similarly, if `d = 2` the multivariate means may lie on the same plane in n -dimensional space, but not on the same line.

`d = manova1(X,group,alpha)` gives control of the significance level, `alpha`. The return value `d` will be the smallest dimension having `p > alpha`, where `p` is a p -value for testing whether the means lie in a space of that dimension.

`[d,p] = manova1(...)` also returns a `p`, a vector of p -values for testing whether the means lie in a space of dimension 0, 1, and so on. The largest possible dimension is either the dimension of the space, or one less than the number of groups. There is one element of `p` for each dimension up to, but not including, the largest.

If the i th p -value is near zero, this casts doubt on the hypothesis that the group means lie on a space of $i-1$ dimensions. The choice of a critical p -value to determine whether the result is judged statistically significant is left to the researcher and is specified by the value of the input argument `alpha`. It is common to declare a result significant if the p -value is less than 0.05 or 0.01.

`[d,p,stats] = manova1(...)` also returns `stats`, a structure containing additional MANOVA results. The structure contains the following fields.

Field	Contents
<code>W</code>	Within-groups sum of squares and cross-products matrix
<code>B</code>	Between-groups sum of squares and cross-products matrix
<code>T</code>	Total sum of squares and cross-products matrix
<code>dfW</code>	Degrees of freedom for <code>W</code>
<code>dfB</code>	Degrees of freedom for <code>B</code>
<code>dfT</code>	Degrees of freedom for <code>T</code>
<code>lambda</code>	Vector of values of Wilk's lambda test statistic for testing whether the means have dimension 0, 1, etc.
<code>chisq</code>	Transformation of <code>lambda</code> to an approximate chi-square distribution
<code>chisqdf</code>	Degrees of freedom for <code>chisq</code>
<code>eigenval</code>	Eigenvalues of W^1B
<code>eigenvec</code>	Eigenvectors of W^1B ; these are the coefficients for the canonical variables <code>C</code> , and they are scaled so the within-group variance of the canonical variables is 1
<code>canon</code>	Canonical variables <code>C</code> , equal to $XC * \text{eigenvec}$, where XC is X with columns centered by subtracting their means
<code>mdist</code>	A vector of Mahalanobis distances from each point to the mean of its group
<code>gmdist</code>	A matrix of Mahalanobis distances between each pair of group means

The canonical variables `C` are linear combinations of the original variables, chosen to maximize the separation between groups. Specifically, `C(:, 1)` is the linear combination of the X columns that has the maximum separation between groups. This means that among all possible linear combinations, it is the one with the most significant F statistic

in a one-way analysis of variance. $C(:, 2)$ has the maximum separation subject to it being orthogonal to $C(:, 1)$, and so on.

You may find it useful to use the outputs from `manova1` along with other functions to supplement your analysis. For example, you may want to start with a grouped scatter plot matrix of the original variables using `gplotmatrix`. You can use `gscatter` to visualize the group separation using the first two canonical variables. You can use `manovacluster` to graph a dendrogram showing the clusters among the group means.

Assumptions

The MANOVA test makes the following assumptions about the data in X :

- The populations for each group are normally distributed.
- The variance-covariance matrix is the same for each population.
- All observations are mutually independent.

Examples

you can use `manova1` to determine whether there are differences in the averages of four car characteristics, among groups defined by the country where the cars were made.

```
load carbig
[d,p] = manova1([MPG Acceleration Weight Displacement],...
                Origin)
d =
     3
p =
     0
    0.0000
    0.0075
    0.1934
```

There are four dimensions in the input matrix, so the group means must lie in a four-dimensional space. `manova1` shows that you cannot reject the hypothesis that the means lie in a 3-D subspace.

manovacluster

Dendrogram of group mean clusters following MANOVA

Syntax

```
manovacluster(stats)  
manovacluster(stats,method)  
H = manovacluster(stats,method)
```

Description

`manovacluster(stats)` generates a dendrogram plot of the group means after a multivariate analysis of variance (MANOVA). `stats` is the output `stats` structure from `manova1`. The clusters are computed by applying the single linkage method to the matrix of Mahalanobis distances between group means.

See `dendrogram` for more information on the graphical output from this function. The dendrogram is most useful when the number of groups is large.

`manovacluster(stats,method)` uses the specified method in place of single linkage. `method` can be any of the following character strings that identify ways to create the cluster hierarchy. (See `linkage` for additional information.)

Method	Description
'single'	Shortest distance (default)
'complete'	Largest distance
'average'	Average distance
'centroid'	Centroid distance
'ward'	Incremental sum of squares

`H = manovacluster(stats,method)` returns a vector of handles to the lines in the figure.

Examples

Dendrogram of Group Means After MANOVA

Load the sample data.

```
load carbig
```

Define the variable matrix.

```
X = [MPG Acceleration Weight Displacement];
```

Perform one-way MANOVA to compare the means of MPG, Acceleration, Weight, and Displacement grouped by Origin.

```
[d,p,stats] = manova1(X,Origin);
```

Create a dendrogram plot of the group means.

```
manovacluster(stats)
```

See Also

`cluster` | `dendrogram` | `linkage` | `manova1`

margin

Class: ClassificationKNN

Margin of k -nearest neighbor classifier

Syntax

```
m = margin mdl, X, Y
```

Description

`m = margin(mdl, X, Y)` returns the classification margins for the matrix of predictors X and class labels Y . For the definition, see “Margin” on page 21-2510.

Input Arguments

mdl — Classifier model

classifier model object

k -nearest neighbor classifier model, returned as a classifier model object.

Note that using the 'CrossVal', 'KFold', 'Holdout', 'Leaveout', or 'CVPartition' options results in a model of class `ClassificationPartitionedModel`. You cannot use a partitioned tree for prediction, so this kind of tree does not have a `predict` method.

Otherwise, `mdl` is of class `ClassificationKNN`, and you can use the `predict` method to make predictions.

X — Matrix of predictor values

matrix

Matrix of predictor values. Each column of X represents one variable, and each row represents one observation.

Y — Categorical variables

categorical array | cell array of strings | character array | logical vector | numeric vector

A categorical array, cell array of strings, character array, logical vector, or a numeric vector with the same number of rows as X. Each row of Y represents the classification of the corresponding row of X.

Output Arguments

m

Numeric column vector of length `size(X,1)`. Each entry in **m** represents the margin for the corresponding rows of X and (true class) Y, computed using `mdl`.

Definitions

Margin

The classification *margin* is the difference between the classification *score* for the true class and maximal classification score for the false classes.

Score

The *score* of a classification is the posterior probability of the classification. The posterior probability is the number of neighbors that have that classification, divided by the number of neighbors. For a more detailed definition that includes weights and prior probabilities, see “Posterior Probability” on page 21-3315.

Examples

Margin Calculation

Construct a *k*-nearest neighbor classifier for the Fisher iris data, where *k* = 5.

Load the data.

```
load fisheriris
```

Construct a classifier for 5-nearest neighbors.

```
mdl = fitcknn(meas,species,'NumNeighbors',5);
```

Examine the margin of the classifier for a mean observation classified 'versicolor'.

```
X = mean(meas);  
Y = {'versicolor'};  
m = margin(mdl,X,Y)
```

```
m =
```

```
1
```

The classifier has no doubt that 'versicolor' is the correct classification (all five nearest neighbors classify as 'versicolor').

[ClassificationKNN](#) | [edge](#) | [fitcknn](#) | [loss](#)

More About

- “Classification Using Nearest Neighbors” on page 16-8

margin

Class: CompactClassificationDiscriminant

Classification margins

Syntax

```
m = margin(obj,X,Y)
```

Description

`m = margin(obj,X,Y)` returns the classification margins for the matrix of predictors `X` and class labels `Y`. For the definition, see “Definitions” on page 21-2513.

Input Arguments

obj

Discriminant analysis classifier of class `ClassificationDiscriminant` or `CompactClassificationDiscriminant`, typically constructed with `fitcdiscr`.

X

Matrix where each row represents an observation, and each column represents a predictor. The number of columns in `X` must equal the number of predictors in `obj`.

Y

Class labels, with the same data type as exists in `obj`. The number of elements of `Y` must equal the number of rows of `X`.

Output Arguments

m

Numeric column vector of length `size(X,1)`. Each entry in `m` represents the margin for the corresponding rows of `X` and (true class) `Y`, computed using `obj`.

Definitions

Margin

The classification *margin* is the difference between the classification *score* for the true class and maximal classification score for the false classes.

The classification margin is a column vector with the same number of rows as in the matrix X. A high value of margin indicates a more reliable prediction than a low value.

Score (discriminant analysis)

For discriminant analysis, the *score* of a classification is the posterior probability of the classification. For the definition of posterior probability in discriminant analysis, see “Posterior Probability” on page 15-7.

Examples

Compute the classification margin for the Fisher iris data, trained on its first two columns of data, and view the last 10 entries:

```
load fisheriris
X = meas(:,1:2);
obj = fitcdiscr(X,species);
M = margin(obj,X,species);
M(end-10:end)
```

```
ans =
    0.6551
    0.4838
    0.6551
   -0.5127
    0.5659
    0.4611
    0.4949
    0.1024
    0.2787
   -0.1439
   -0.4444
```

The classifier trained on all the data is better:

```
obj = fitcdiscr(meas,species);  
M = margin(obj,meas,species);  
M(end-10:end)
```

```
ans =  
    0.9983  
    1.0000  
    0.9991  
    0.9978  
    1.0000  
    1.0000  
    0.9999  
    0.9882  
    0.9937  
    1.0000  
    0.9649
```

How To

- “Discriminant Analysis” on page 15-3

margin

Class: CompactClassificationECOC

Classification margins for error-correcting output code multiclass classifiers

Syntax

```
m = margin(Mdl,X,Y)
m = margin(Mdl,X,Y,Name,Value)
```

Description

`m = margin(Mdl,X,Y)` returns the classification margins (m) for the trained error-correcting output code (ECOC) multiclass classifier `Mdl` using the predictor data `X` and class labels `Y`. Each row of `X` and `Y` is an observation.

`m = margin(Mdl,X,Y,Name,Value)` returns the classification margins with additional options specified by one or more `Name,Value` pair arguments.

For example, specify a decoding scheme, binary learner loss function, or verbosity level.

Input Arguments

Mdl — ECOC multiclass classifier

ClassificationECOC model | CompactClassificationECOC model

ECOC multiclass classifier, specified as a `ClassificationECOC` or `CompactClassificationECOC` model. You can create a:

- `ClassificationECOC` model by training the ECOC classifier using `fitcecoc`
- `CompactClassificationECOC` model by passing a `ClassificationECOC` classifier to `compact`

X — Predictor data

numeric matrix

Predictor data, specified as a numeric matrix.

Each row of `X` corresponds to one observation (also called an instance or example), and each column corresponds to one variable (also known as a feature). The variables composing the columns of `X` should be the same as the variables that trained the `Mdl` classifier.

The length of `Y` and the number of rows of `X` must be equal.

If you trained `Mdl` specifying to standardize the predictor data, then the software standardizes the columns of `X` using the corresponding means and standard deviations that the software stored in `Mdl.BinaryLearner{j}.Mu` and `Mdl.BinaryLearner{j}.Sigma` for learner `j`.

Data Types: `double` | `single`

Y — Class labels

categorical array | character array | logical vector | vector of numeric values | cell array of strings

Class labels, specified as a categorical or character array, logical or numeric vector, or cell array of strings. `Y` must be the same as the data type of `Mdl.ClassNames`.

The length of `Y` and the number of rows of `X` must be equal.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

'BinaryLoss' — Binary learner loss function

function handle | 'hamming' | 'linear' | 'exponential' | 'binodeviance' | 'hinge' | 'quadratic'

Binary learner loss function, specified as the comma-separated pair consisting of 'BinaryLoss' and a function handle or string.

- If the value is a string, then it must correspond to a built-in function. This table summarizes the built-in functions, where y_j is a class label for a particular binary learner (in the set $\{-1, 1, 0\}$), s_j is the score for observation j , and $g(y_j, s_j)$ is the binary loss formula.

Value	Description	Score Domain	$g(y_i, s_i)$
'binodeviance'	Binomial deviance	$(-\infty, \infty)$	$\log[1 + \exp(-2y_i s_i)] / [2\log(2)]$
'exponential'	Exponential	$(-\infty, \infty)$	$\exp(-y_i s_i) / 2$
'hamming'	Hamming	$\{-1, 1\}$	$[1 - \text{sign}(y_i s_i)] / 2$
'hinge'	Hinge	$(-\infty, \infty)$	$\max(0, 1 - y_i s_i) / 2$
'linear'	Linear	$(-\infty, \infty)$	$(1 - y_i s_i) / 2$
'quadratic'	Quadratic	$[0, 1]$	$[1 - y_i(2s_i - 1)]^2 / 2$

The software normalizes the binary losses such that the loss is 0.5 when $y_j = 0$. Also, the software calculates the mean binary loss for each class.

- For a custom binary loss function, e.g., `customFunction`, specify its function handle `'BinaryLoss', @customFunction`.

`customFunction` should have this form

```
bLoss = customFunction(M,s)
```

where:

- M is the K -by- L coding matrix stored in `Mdl.CodingMatrix`.
- s is the 1-by- L row vector of classification scores.
- `bLoss` is the classification loss. This scalar aggregates the binary losses for every learner in a particular class. For example, you can use the mean binary loss to aggregate the loss over the learners for each class.
- K is the number of classes.
- L is the number of binary learners.

For an example on passing a custom binary loss function, see “Predict Test-Sample Labels of ECOC Models Using Custom Binary Loss Function”.

This list describes the default values of `BinaryLoss`. If all binary learners are:

- SVMs, then `BinaryLoss` is `'hinge'`
- Ensembles trained by `AdaboostM1` or `GentleBoost`, then `BinaryLoss` is `'exponential'`

- Ensembles trained by `LogitBoost`, then `BinaryLoss` is `'binodeviance'`
- Predicting class posterior probabilities (i.e., set `'FitPosterior',1` in `fitcecoc`), then `BinaryLoss` is `'quadratic'`

Otherwise, the default `BinaryLoss` is `'hamming'`.

Example: `'BinaryLoss','binodeviance'`

Data Types: `char` | `function_handle`

'Decoding' — Decoding scheme

`'lossweighted'` (default) | `'lossbased'`

Decoding scheme that aggregates the “binary losses”, specified as the comma-separated pair consisting of `'Decoding'` and `'lossweighted'` or `'lossbased'`.

Example: `'Decoding','lossbased'`

Data Types: `char`

'Options' — Estimation options

`[]` (default) | structure array returned by `statset`

Estimation options, specified as the comma-separated pair consisting of `'Options'` and a structure array returned by `statset`.

To invoke parallel computing:

- You need a Parallel Computing Toolbox license.
- Specify `'Options',statset('UseParallel',1)`.

'Verbose' — Verbosity level

`0` (default) | `1`

Verbosity level, specified as the comma-separated pair consisting of `'Verbose'` and `0` or `1`. `Verbose` controls the amount of diagnostic messages that the software displays in the Command Window.

If `Verbose` is `0`, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: `'Verbose',1`

Data Types: `single` | `double`

Output Arguments

m — Classification margins
numeric column vector

Classification margins, returned as a numeric column vector.

m has the same length as **Y**. The software estimates each entry of **m** using the trained ECOC model **Mdl**, the corresponding row of **X**, and the true class label **Y**.

Definitions

Classification Margin

The *classification margins* are, for each observation, the difference between the negative loss for the positive class and maximal negative loss among the negative classes. If the margins are on the same scale, then they serve as a classification confidence measure, i.e., among multiple classifiers, those that yield larger margins are better “[4]”.

Binary Loss

A *binary loss* is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Let:

- m_{kj} be element (k,j) of the coding design matrix M (i.e., the code corresponding to class k of binary learner j)
- s_j be the score of binary learner j for an observation
- g be the binary loss function
- \hat{k} be the predicted class for the observation

In *loss-based decoding* [3], the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j).$$

In *loss-weighted decoding* [3], the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \frac{\sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j)}{\sum_{j=1}^L |m_{kj}|}.$$

Allwein et al. [1] suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where y_j is a class label for a particular binary learner (in the set $\{-1, 1, 0\}$), s_j is the score for observation j , and $g(y_j, s_j)$.

Value	Description	Score Domain	$g(y_j, s_j)$
'binodeviance'	Binomial deviance	$(-\infty, \infty)$	$\log[1 + \exp(-2y_j s_j)] / [2\log(2)]$
'exponential'	Exponential	$(-\infty, \infty)$	$\exp(-y_j s_j) / 2$
'hamming'	Hamming	$\{-1, 1\}$	$[1 - \operatorname{sign}(y_j s_j)] / 2$
'hinge'	Hinge	$(-\infty, \infty)$	$\max(0, 1 - y_j s_j) / 2$
'linear'	Linear	$(-\infty, \infty)$	$(1 - y_j s_j) / 2$
'quadratic'	Quadratic	$[0, 1]$	$[1 - y_j(2s_j - 1)]^2 / 2$

The software normalizes the binary losses such that the loss is 0.5 when $y_j = 0$, and aggregates using the average of the binary learners [1].

Do not confuse the binary loss with the overall classification loss (specified by the LossFun name-value pair argument of `predict` and `loss`), e.g., classification error, which measures how well an ECOC classifier performs as a whole.

Examples

Estimate Test-Sample Classification Margins of ECOC Models

Load Fisher's iris data set.

```
load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y); % Class order
rng(1); % For reproducibility
```

Train an ECOC model using SVM binary classifiers, and specify a 30% holdout sample. It is good practice to standardize the predictors and define the class order. Specify to standardize the predictors using an SVM template.

```
t = templateSVM('Standardize',1);
CVMdl = fitcecoc(X,Y,'Holdout',0.30,'Learners',t,'ClassNames',classOrder);
CMdl = CVMdl.Trained{1}; % Extract trained, compact classifier
testInds = test(CVMdl.Partition); % Extract the test indices
XTest = X(testInds,:);
YTest = Y(testInds,:);
```

CVMdl is a `ClassificationPartitionedECOC` model. It contains the property `Trained`, which is a 1-by-1 cell array holding a `CompactClassificationECOC` model that the software trained using the training set.

Estimate the test-sample classification margins. Display the distribution of the margins using a boxplot.

```
m = margin(CMdl,XTest,YTest);

figure;
boxplot(m);
title 'Test-Sample Margins'
```

An observation margin is the positive-class, negated loss minus the maximum negative-class, negated loss. Classifiers that yield relatively large margins are desirable.

Select ECOC Model Features by Examining Test-Sample Margins

The classifier margins measure, for each observation, the difference between the positive-class, negated loss score and the maximal negative-class, negated loss. One way to perform feature selection is to compare test-sample margins from multiple models. Based solely on this criterion, the model with the highest margins is the best model.

Load Fisher's iris data set.

```
load fisheriris
X = meas;
```

```
Y = categorical(species);
classOrder = unique(Y); % Class order
rng(1); % For reproducibility
```

Partition the data set into training and test sets. Specify a 30% holdout sample for testing.

```
Partition = cvpartition(Y, 'Holdout', 0.30);
testInds = test(Partition); % Indices for the test set
XTest = X(testInds,:);
YTest = Y(testInds,:);
```

Define these two data sets:

- `fullX` contains all four predictors.
- `partX` contains the sepal measurements.

```
fullX = X;
partX = X(:,1:2);
```

Train an ECOC model using SVM binary classifiers for each predictor set, and specify the partition definition. It is good practice to standardize the predictors and define the class order. Specify to standardize the predictors using an SVM template.

```
t = templateSVM('Standardize',1);
CVMdl = fitcecoc(fullX,Y, 'CVPartition', Partition, 'Learners', t, ...
    'ClassNames', classOrder);
PCVMdl = fitcecoc(partX,Y, 'CVPartition', Partition, 'Learners', t, ...
    'ClassNames', classOrder);
CMdl = CVMdl.Trained{1};
PCMdl = PCVMdl.Trained{1};
```

Estimate the test-sample margins for each classifier. For each model, display the distribution of the margins using a boxplot.

```
fullMargins = margin(CMdl,XTest,YTest);
partMargins = margin(PCMdl,XTest(:,3:4),YTest);

figure;
boxplot([fullMargins partMargins], 'Labels', {'All Predictors', 'Two Predictors'});
title('Boxplots of Test-Sample Margins')
```

The margin distribution of `CMd1` is situated higher, and with less variability than the margin distribution of `PCMd1`.

- “Quick Start Parallel Computing for Statistics Toolbox” on page 20-2

Tip

To compare margins or edges of several classifiers, use template objects to specify a common score transform function among the classifiers when you train them using `fitcecoc`.

margin

Class: CompactClassificationEnsemble

Classification margins

Syntax

```
M = margin(ens,X,Y)
M = margin(ens,X,Y,Name,Value)
```

Description

`M = margin(ens,X,Y)` returns the classification margin for the predictions of `ens` on data `X`, when the true classifications are `Y`.

`M = margin(ens,X,Y,Name,Value)` calculates margin with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

ens

Classification ensemble created with `fitensemble`, or a compact classification ensemble created with `compact`.

X

Matrix of data to classify. Each row of `X` represents one observation, and each column represents one predictor. `X` must have the same number of columns as the data used to train `ens`. `X` should have the same number of rows as the number of elements in `Y`.

Y

Classification of `X`. `Y` should be of the same type as the classification used to train `ens`, and its number of elements should equal the number of rows of `X`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

'learners'

Indices of weak learners in the ensemble ranging from 1 to `ens.NumTrained`. `oobEdge` uses only these learners for calculating loss.

Default: `1:NumTrained`

'UseObsForLearner'

A logical matrix of size N-by-T, where:

- N is the number of rows of X.
- T is the number of weak learners in `ens`.

When `UseObsForLearner(i, j)` is true, learner j is used in predicting the class of row i of X.

Default: `true(N, T)`

Output Arguments

M

A numeric column vector with the same number of rows as X. Each row of M gives the classification margin for that row of X.

Definitions

Margin

The classification *margin* is the difference between the classification *score* for the true class and maximal classification score for the false classes. Margin is a column vector with the same number of rows as in the matrix X.

Score (ensemble)

For ensembles, a classification *score* represents the confidence of a classification into a class. The higher the score, the higher the confidence.

Different ensemble algorithms have different definitions for their scores. Furthermore, the range of scores depends on ensemble type. For example:

- AdaBoostM1 scores range from $-\infty$ to ∞ .
- Bag scores range from 0 to 1.

Examples

Find the margin for classifying an average flower from the Fisheriris data as 'versicolor':

```
load fisheriris % X = meas, Y = species
ens = fitensemble(meas,species,'AdaBoostM2',100,'Tree');
flower = mean(meas);
predict(ens,flower)

ans =
    'versicolor'

margin(ens,mean(meas),'versicolor')

ans =
    3.2140
```

See Also

`predict` | `edge` | `loss`

margin

Class: CompactClassificationNaiveBayes

Classification margins for naive Bayes classifiers

Syntax

```
m = margin(Mdl,X,Y)
```

Description

`m = margin(Mdl,X,Y)` returns the classification margins (`m`) for the trained naive Bayes classifier `Mdl` using the predictor data `X` and class labels `Y`.

Input Arguments

Mdl — Naive Bayes classifier

ClassificationNaiveBayes model | CompactClassificationNaiveBayes model

Naive Bayes classifier, specified as a `ClassificationNaiveBayes` model or `CompactClassificationNaiveBayes` model returned by `fitcnb` or `compact`, respectively.

X — Predictor data

numeric matrix

Predictor data, specified as a numeric matrix.

Each row of `X` corresponds to one observation (also known as an instance or example), and each column corresponds to one variable (also known as a feature). The variables making up the columns of `X` should be the same as the variables that trained `Mdl`.

The length of `Y` and the number of rows of `X` must be equal.

Data Types: `double` | `single`

Y — Class labels

categorical array | character array | logical vector | vector of numeric values | cell array of strings

Class labels, specified as a categorical or character array, logical or numeric vector, or cell array of strings. Y must be the same as the data type of `Mdl.ClassNames`.

The length of Y and the number of rows of X must be equal.

Output Arguments

m — Classification margins

numeric vector

Classification margins, returned as a numeric vector.

m has the same length equal to `size(X,1)`. Each entry of m is the classification margin of the corresponding observation (row) of X and element of Y.

Definitions

Classification Edge

The *classification edge* is the weighted mean of the classification margins.

If you supply weights, then the software normalizes them to sum to the prior probability of their respective class. The software uses the normalized weights to compute the weighted mean.

One way to choose among multiple classifiers, e.g., to perform feature selection, is to choose the classifier that yields the highest edge.

Classification Margin

The *classification margins* are, for each observation, the difference between the score for the true class and maximal score for the false classes. Provided that they are on the same scale, margins serve as a classification confidence measure, i.e., among multiple classifiers, those that yield larger margins are better “[2]”.

Posterior Probability

The *posterior probability* is the probability that an observation belongs in a particular class, given the data.

For naive Bayes, the posterior probability that a classification is k for a given observation (x_1, \dots, x_p) is

$$\hat{P}(Y = k | x_1, \dots, x_p) = \frac{P(X_1, \dots, X_p | y = k)\pi(Y = k)}{P(X_1, \dots, X_p)},$$

where:

- $P(X_1, \dots, X_p | y = k)$ is the conditional joint density of the predictors given they are in class k . `Mdl.DistributionNames` stores the distribution names of the predictors.
- $\pi(Y = k)$ is the class prior probability distribution. `Mdl.Prior` stores the prior distribution.
- $P(X_1, \dots, X_p)$ is the joint density of the predictors. The classes are discrete, so

$$P(X_1, \dots, X_p) = \sum_{k=1}^K P(X_1, \dots, X_p | y = k)\pi(Y = k).$$

Prior Probability

The *prior probability* is the believed relative frequency that observations from a class occur in the population for each class.

Score

The naive Bayes *score* is the class posterior probability given the observation.

Examples

Estimate Test-Sample Classification Margins of Naive Bayes Classifiers

Load Fisher's iris data set.

```
load fisheriris
X = meas;    % Predictors
Y = species; % Response
rng(1);
```

Train a naive Bayes classifier. Specify a 30% holdout sample for testing. It is good practice to specify the class order. Assume that each predictor is conditionally normally distributed given its label.

```
CVMD1 = fitcnb(X,Y,'Holdout',0.30,...
    'ClassNames',{'setosa','versicolor','virginica'});
CMD1 = CVMD1.Trained{1}; ...
    % Extract the trained, compact classifier
testInds = test(CVMD1.Partition); % Extract the test indices
XTest = X(testInds,:);
YTest = Y(testInds);
```

CVMD1 is a `ClassificationPartitionedModel` classifier. It contains the property `Trained`, which is a 1-by-1 cell array holding a `CompactClassificationNaiveBayes` classifier that the software trained using the training set.

Estimate the test sample classification margins. Display the distribution of the margins using a boxplot.

```
m = margin(CMD1,XTest,YTest);

figure;
boxplot(m);
title 'Distribution of the Test-Sample Margins';
```

An observation margin is the observed true class score minus the maximum false class score among all scores in the respective class. Classifiers that yield relatively large margins are desirable.

Select Naive Bayes Classifier Features by Examining Test Sample Margins

The classifier margins measure, for each observation, the difference between the true class observed score and the maximal false class score for a particular class. One way to perform feature selection is to compare test sample margins from multiple models. Based solely on this criterion, the model with the highest margins is the best model.

Load Fisher's iris data set.

```
load fisheriris
```

```
X = meas;    % Predictors
Y = species; % Response
rng(1);
```

Partition the data set into training and test sets. Specify a 30% holdout sample for testing.

```
Partition = cvpartition(Y, 'Holdout', 0.30);
testInds = test(Partition); % Indices for the test set
XTest = X(testInds,:);
YTest = Y(testInds);
```

Partition defines the data set partition.

Define these two data sets:

- `fullX` contains all predictors.
- `partX` contains the last 2 predictors.

```
fullX = X;
partX = X(:,3:4);
```

Train naive Bayes classifiers for each predictor set. Specify the partition definition.

```
FCVMdl = fitcnb(fullX,Y, 'CVPartition', Partition);
PCVMdl = fitcnb(partX,Y, 'CVPartition', Partition);
FCMdl = FCVMdl.Trained{1};
PCMdl = PCVMdl.Trained{1};
```

`FullCVMdl` and `PartCVMdl` are `ClassificationPartitionedModel` classifiers. They contain the property `Trained`, which is a 1-by-1 cell array holding a `CompactClassificationNaiveBayes` classifier that the software trained using the training set.

Estimate the test sample margins for each classifier. Display the distributions of the margins for each model using boxplots.

```
fullM = margin(FCMdl,XTest,YTest);
partM = margin(PCMdl,XTest(:,3:4),YTest);

figure;
boxplot([fullM partM], 'Labels', {'All Predictors', 'Two Predictors'})
h = gca;
h.YLim = [0.98 1.01]; % Modify axis to see boxes.
```

```
title 'Boxplots of Test-Sample Margins';
```

The margins have a similar distribution, but PCMD1 is less complex.

margin

Class: CompactClassificationSVM

Classification margins for support vector machine classifiers

Syntax

```
m = margin(SVMModel,X,Y)
```

Description

`m = margin(SVMModel,X,Y)` returns the classification margins (`m`) for the trained support vector machine (SVM) classifier `SVMModel` using the predictor data `X` and class labels `Y`.

Input Arguments

SVMModel — SVM classifier

ClassificationSVM classifier | CompactClassificationSVM classifier

SVM classifier, specified as a `ClassificationSVM` classifier or `CompactClassificationSVM` classifier returned by `fitcsvm` or `compact`, respectively.

X — Predictor data

numeric matrix

Predictor data, specified as a numeric matrix.

Each row of `X` corresponds to one observation (also known as an instance or example), and each column corresponds to one variable (also known as a feature). The variables making up the columns of `X` should be the same as the variables that trained the `SVMModel` classifier.

The length of `Y` and the number of rows of `X` must be equal.

If you set `'Standardize', true` in `fitcsvm` to train `SVMModel`, then the software standardizes the columns of `X` using the corresponding means in `SVMModel.Mu` and standard deviations in `SVMModel.Sigma`.

Data Types: `double` | `single`

Y — Class labels

categorical array | character array | logical vector | vector of numeric values | cell array of strings

Class labels, specified as a categorical or character array, logical or numeric vector, or cell array of strings. `Y` must be the same as the data type of `SVMModel.ClassNames`.

The length of `Y` and the number of rows of `X` must be equal.

Output Arguments

m — Classification margins

numeric vector

Classification margins, returned as a numeric vector.

`m` has the same length as `Y`. The software estimates each entry of `m` using the trained SVM classifier `SVMModel`, the corresponding row of `X`, and the true class label `Y`.

Definitions

Classification Margin

The *classification margins* are, for each observation, the difference between the score for the true class and maximal score for the false classes. Provided that they are on the same scale, margins serve as a classification confidence measure, i.e., among multiple classifiers, those that yield larger margins are better “[2]”.

Classification Edge

The *edge* is the weighted mean of the *classification margins*.

The weights are the prior class probabilities. If you supply weights, then the software normalizes them to sum to the prior probabilities in the respective classes. The software uses the renormalized weights to compute the weighted mean.

One way to choose among multiple classifiers, e.g., to perform feature selection, is to choose the classifier that yields the highest edge.

Score

The SVM *score* for classifying observation x is the signed distance from x to the decision boundary ranging from $-\infty$ to $+\infty$. A positive score for a class indicates that x is predicted to be in that class, a negative score indicates otherwise.

The score is also the numerical, predicted response for x , $f(x)$, computed by the trained SVM classification function

$$f(x) = \sum_{j=1}^n \alpha_j y_j G(x_j, x) + b,$$

where $(\alpha_1, \dots, \alpha_n, b)$ are the estimated SVM parameters, $G(x_j, x)$ is the dot product in the predictor space between x and the support vectors, and the sum includes the training set observations.

Examples

Estimate Test Sample Classification Margins of SVM Classifiers

Load the `ionosphere` data set.

```
load ionosphere
rng(1); % For reproducibility
```

Train an SVM classifier. Specify a 15% holdout sample for testing. It is good practice to specify the class order and standardize the data.

```
CVSVMModel = fitcsvm(X,Y,'Holdout',0.15,'ClassNames',{'b','g'},...
```

```
'Standardize',true);
CompactSVMModel = CVSSVMModel.Trained{1}; ...
% Extract the trained, compact classifier
testInds = test(CVSSVMModel.Partition); % Extract the test indices
XTest = X(testInds,:);
YTest = Y(testInds,:);
```

CVSSVMModel is a `ClassificationPartitionedModel` classifier. It contains the property `Trained`, which is a 1-by-1 cell array holding a `CompactClassificationSVM` classifier that the software trained using the training set.

Estimate the test sample classification margins.

```
m = margin(CompactSVMModel,XTest,YTest);
m(10:20)
```

```
ans =
```

```
3.5461
5.5939
4.9948
4.5611
-4.7963
5.5127
-2.8776
1.8673
9.4986
9.5018
20.9954
```

An observation margin is the observed true class score minus the maximum false class score among all scores in the respective class. Classifiers that yield relatively large margins are desirable.

Select SVM Classifier Features by Examining Test Sample Margins

The classifier margins measure, for each observation, the difference between the true class observed score and the maximal false class score for a particular class. One way to perform feature selection is to compare test sample margins from multiple models. Based solely on this criterion, the model with the highest margins is the best model.

Load the `ionosphere` data set.

```
load ionosphere
rng(1); % For reproducibility
```

Partition the data set into training and test sets. Specify a 15% holdout sample for testing.

```
Partition = cvpartition(Y, 'Holdout', 0.15);
testInds = test(Partition); % Indices for the test set
XTest = X(testInds,:);
YTest = Y(testInds,:);
```

Partition defines the data set partition.

Define these two data sets:

- `fullX` contains all predictors (except the removed column of 0s).
- `partX` contains the last 20 predictors.

```
fullX = X;
partX = X(:,end-20:end);
```

Train SVM classifiers for each predictor set. Specify the partition definition.

```
FullCVSVMModel = fitcsvm(fullX,Y, 'CVPartition', Partition);
PartCVSVMModel = fitcsvm(partX,Y, 'CVPartition', Partition);
FCSVMModel = FullCVSVMModel.Trained{1};
PCSVModel = PartCVSVMModel.Trained{1};
```

`FullCVSVMModel` and `PartCVSVMModel` are `ClassificationPartitionedModel` classifiers. They contain the property `Trained`, which is a 1-by-1 cell array holding a `CompactClassificationSVM` classifier that the software trained using the training set.

Estimate the test sample margins for each classifier.

```
fullM = margin(FCSVMModel, XTest, YTest);
partM = margin(PCSVModel, XTest(:,end-20:end), YTest);
n = size(XTest, 1);
p = sum(fullM < partM) / n
```

p =

```
0.2500
```

Approximately 25% of the margins from the full model are less than those from the model with fewer predictors. This suggests that the model trained using all of the predictors is better.

Algorithms

For binary classification, the software defines the margin for observation j , m_j , as

$$m_j = 2y_j f(x_j),$$

where $y_j \in \{-1, 1\}$, and $f(x_j)$ is the predicted score of observation j for the positive class. However, the literature commonly uses $m_j = y_j f(x_j)$ to define the margin.

margin

Class: CompactClassificationTree

Classification margins

Syntax

```
m = margin(tree,X,Y)
```

Description

`m = margin(tree,X,Y)` returns the classification margins for the matrix of predictors `X` and class labels `Y`. For the definition, see “Margin” on page 21-2544.

Input Arguments

tree

A classification tree created by `fitctree`, or a compact classification tree created by `compact`.

X

A matrix where each row represents an observation, and each column represents a predictor. The number of columns in `X` must equal the number of predictors in `tree`.

Y

Class labels, with the same data type as exists in `tree`.

Output Arguments

m

A numeric column vector of length `size(X,1)`. Each entry in `m` represents the margin for the corresponding rows of `X` and (true class) `Y`, computed using `tree`.

Definitions

Margin

The classification *margin* is the difference between the classification *score* for the true class and maximal classification score for the false classes. Margin is a column vector with the same number of rows as in the matrix X .

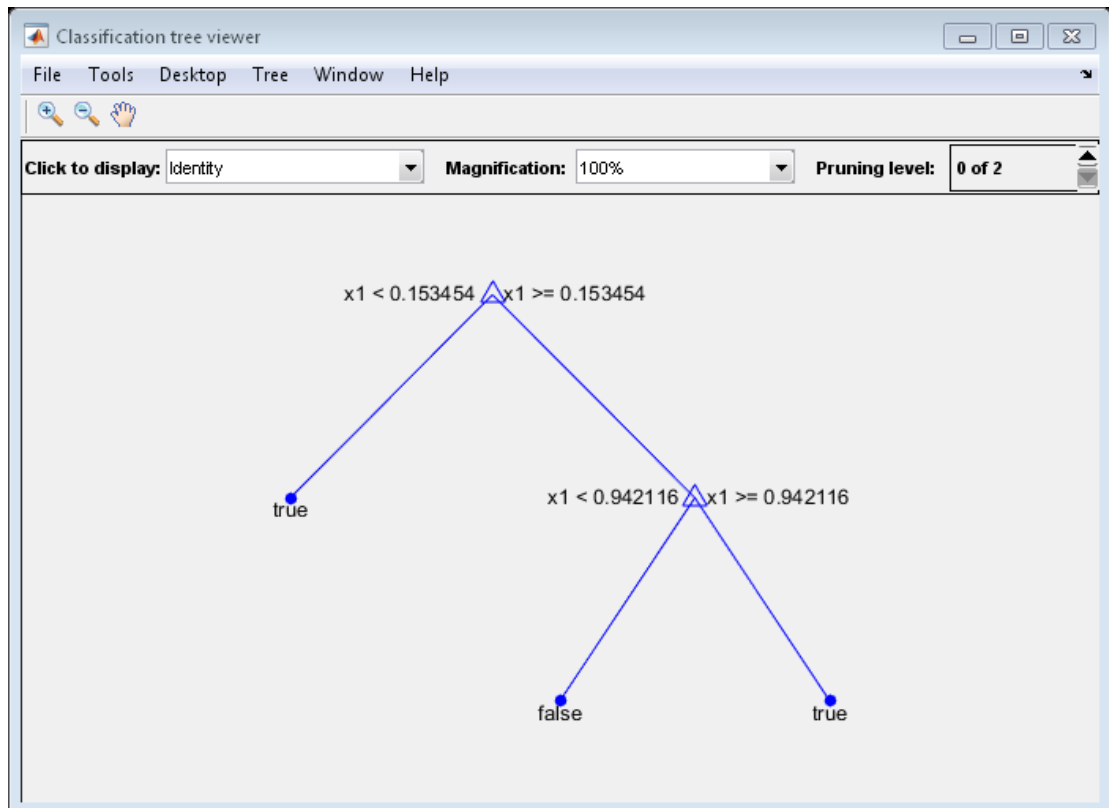

Score (tree)

For trees, the *score* of a classification of a leaf node is the posterior probability of the classification at that node. The posterior probability of the classification at a node is the number of training sequences that lead to that node with the classification, divided by the number of training sequences that lead to that node.

For example, consider classifying a predictor X as `true` when $X < 0.15$ or $X > 0.95$, and X is false otherwise.

Generate 100 random points and classify them:

```
rng(0, 'twister') % for reproducibility
X = rand(100,1);
Y = (abs(X - .55) > .4);
tree = fitctree(X,Y);
view(tree, 'Mode', 'Graph')
```

Prune the tree:

```
tree1 = prune(tree, 'Level', 1);  
view(tree1, 'Mode', 'Graph')
```

The pruned tree correctly classifies observations that are less than 0.15 as **true**. It also correctly classifies observations from .15 to .94 as **false**. However, it incorrectly classifies observations that are greater than .94 as **false**. Therefore, the score for observations that are greater than .15 should be about $.05/.85=.06$ for **true**, and about $.8/.85=.94$ for **false**.

Compute the prediction scores for the first 10 rows of X:

```
[~,score] = predict(tree1,X(1:10));
[score X(1:10,:)]
```

```
ans =
```

```
0.9059    0.0941    0.8147
```

```

0.9059    0.0941    0.9058
         0    1.0000    0.1270
0.9059    0.0941    0.9134
0.9059    0.0941    0.6324
         0    1.0000    0.0975
0.9059    0.0941    0.2785
0.9059    0.0941    0.5469
0.9059    0.0941    0.9575
0.9059    0.0941    0.9649

```

Indeed, every value of X (the right-most column) that is less than 0.15 has associated scores (the left and center columns) of 0 and 1, while the other values of X have associated scores of 0.91 and 0.09. The difference (score 0.09 instead of the expected .06) is due to a statistical fluctuation: there are 8 observations in X in the range (.95, 1) instead of the expected 5 observations.

Examples

Compute the classification margin for the Fisher iris data, trained on its first two columns of data, and view the last 10 entries.

```

load fisheriris
X = meas(:,1:2);
tree = fitctree(X,species);
M = margin(tree,X,species);
M(end-10:end)

```

```

ans =
    0.1111
    0.1111
    0.1111
   -0.2857
    0.6364
    0.6364
    0.1111
    0.7500
    1.0000
    0.6364
    0.2000

```

The classification tree trained on all the data is better.

```
tree = fitctree(meas,species);  
M = margin(tree,meas,species);  
M(end-10:end)
```

```
ans =  
    0.9565  
    0.9565  
    0.9565  
    0.9565  
    0.9565  
    0.9565  
    0.9565  
    0.9565  
    0.9565  
    0.9565
```

margin

Class: CompactTreeBagger

Classification margin

Syntax

```
mar = margin(B,X,Y)
mar = margin(B,X,Y, 'param1',val1, 'param2',val2, ...)
```

Description

`mar = margin(B,X,Y)` computes the classification margins for predictors `X` given true response `Y`. The `Y` can be either a numeric vector, character matrix, cell array of strings, categorical vector or logical vector. `mar` is a numeric array of size `Nobs-by-NTrees`, where `Nobs` is the number of rows of `X` and `Y`, and `NTrees` is the number of trees in the ensemble `B`. For observation `I` and tree `J`, `mar(I,J)` is the difference between the score for the true class and the largest score for other classes. This method is available for classification ensembles only.

`mar = margin(B,X,Y, 'param1',val1, 'param2',val2, ...)` specifies optional parameter name/value pairs:

<code>'mode'</code>	String indicating how the method computes errors. If set to <code>'cumulative'</code> (default), <code>margin</code> computes cumulative errors and <code>mar</code> is an <code>Nobs-by-NTrees</code> matrix, where the first column gives error from <code>trees(1)</code> , second column gives error from <code>trees(1:2)</code> etc, up to <code>trees(1:NTrees)</code> . If set to <code>'individual'</code> , <code>mar</code> is a <code>Nobs-by-NTrees</code> matrix, where each element is an error from each tree in the ensemble. If set to <code>'ensemble'</code> , <code>mar</code> a single column of length <code>Nobs</code> showing the cumulative margins for the entire ensemble.
<code>'trees'</code>	Vector of indices indicating what trees to include in this calculation. By default, this argument is set to <code>'all'</code> and the method uses all trees. If <code>'trees'</code> is a numeric vector, the method returns a vector of length <code>NTrees</code> for <code>'cumulative'</code> and <code>'individual'</code> modes,

where `NTrees` is the number of elements in the input vector, and a scalar for `'ensemble'` mode. For example, in the `'cumulative'` mode, the first element gives error from `trees(1)`, the second element gives error from `trees(1:2)` etc.

- `'treeweights'` Vector of tree weights. This vector must have the same length as the `'trees'` vector. The method uses these weights to combine output from the specified trees by taking a weighted average instead of the simple non-weighted majority vote. You cannot use this argument in the `'individual'` mode.
- `'useifort'` Logical matrix of size `Nobs`-by-`NTrees` indicating which trees should be used to make predictions for each observation. By default the method uses all trees for all observations.

See Also

`TreeBagger.margin`

margin

Class: TreeBagger

Classification margin

Syntax

```
mar = margin(B,X,Y)
mar = margin(B,X,Y, 'param1',val1, 'param2',val2, ...)
```

Description

`mar = margin(B,X,Y)` computes the classification margins for predictors `X` given true response `Y`. The `Y` can be either a numeric vector, character matrix, cell array of strings, categorical vector or logical vector. `mar` is a numeric array of size `Nobs-by-NTrees`, where `Nobs` is the number of rows of `X` and `Y`, and `NTrees` is the number of trees in the ensemble `B`. For observation `I` and tree `J`, `mar(I,J)` is the difference between the score for the true class and the largest score for other classes. This method is available for classification ensembles only.

`mar = margin(B,X,Y, 'param1',val1, 'param2',val2, ...)` specifies optional parameter name/value pairs:

<code>'mode'</code>	String indicating how the method computes errors. If set to <code>'cumulative'</code> (default), <code>margin</code> computes cumulative errors and <code>mar</code> is an <code>Nobs-by-NTrees</code> matrix, where the first column gives error from <code>trees(1)</code> , second column gives error from <code>trees(1:2)</code> etc, up to <code>trees(1:NTrees)</code> . If set to <code>'individual'</code> , <code>mar</code> is a <code>Nobs-by-NTrees</code> matrix, where each element is an error from each tree in the ensemble. If set to <code>'ensemble'</code> , <code>mar</code> a single column of length <code>Nobs</code> showing the cumulative margins for the entire ensemble.
<code>'trees'</code>	Vector of indices indicating what trees to include in this calculation. By default, this argument is set to <code>'all'</code> and the method uses all trees. If <code>'trees'</code> is a numeric vector, the method returns a vector of length <code>NTrees</code> for <code>'cumulative'</code> and <code>'individual'</code> modes,

where `NTrees` is the number of elements in the input vector, and a scalar for `'ensemble'` mode. For example, in the `'cumulative'` mode, the first element gives error from `trees(1)`, the second element gives error from `trees(1:2)` etc.

- `'treeweights'` Vector of tree weights. This vector must have the same length as the `'trees'` vector. The method uses these weights to combine output from the specified trees by taking a weighted average instead of the simple non-weighted majority vote. You cannot use this argument in the `'individual'` mode.
- `'useifort'` Logical matrix of size `Nobs`-by-`NTrees` indicating which trees should be used to make predictions for each observation. By default the method uses all trees for all observations.

`CompactTreeBagger.margin`

margmean

Class: RepeatedMeasuresModel

Estimate marginal means

Syntax

```
tbl = margmean(rm, vars)
tbl = margmean(rm, vars, 'alpha', alpha)
```

Description

`tbl = margmean(rm, vars)` returns the estimated marginal means for the variables `vars`, in the table `tbl`.

`tbl = margmean(rm, vars, 'alpha', alpha)` returns the $100 \times (1 - \alpha)\%$ confidence intervals for the marginal means.

Input Arguments

rm — Repeated measures model

RepeatedMeasuresModel object

Repeated measures model, returned as a RepeatedMeasuresModel object.

For properties and methods of this object, see RepeatedMeasuresModel.

vars — Variables for which to compute the marginal means

string | cell array of strings

Variables for which to compute the marginal means, specified as a string representing the name of a between or within-subjects factor in `rm`, or a cell array of strings representing the names of multiple variables. Each between-subjects factor must be categorical.

For example, if you want to compute the marginal means for the variables `Drug` and `Gender`, then you can specify as follows.

Example: { 'Drug' , 'Gender' }

Data Types: char | cell

alpha — Confidence level

0.05 (default) | scalar value in the range of 0 to 1

Confidence level of the confidence intervals for population marginal means, specified as a scalar value in the range of 0 to 1. The confidence level is $100*(1-\alpha)\%$.

For example, you can specify a 99% confidence level as follows.

Example: 'alpha', 0.01

Data Types: double | single

Output Arguments

tbl — Estimated marginal means

table

Estimated marginal means, returned as a table. tbl contains one row for each combination of the groups of the variables you specify in vars, one column for each variable, and the following columns.

Column name	Description
Mean	Estimated marginal means
StdErr	Standard errors of the estimates
Lower	Lower limit of a 95% confidence interval for the true population mean
Upper	Upper limit of a 95% confidence interval for the true population mean

Examples

Compute Marginal Means Grouped by Two Factors

Load the sample data.

```
load repeatedmeas
```

The table `between` includes the between-subject variables `age`, `IQ`, `group`, `gender`, and eight repeated measures `y1` to `y8` as responses. The table `within` includes the within-subject variables `w1` and `w2`. This is simulated data.

Fit a repeated measures model, where the repeated measures `y1` to `y8` are the responses, and `age`, `IQ`, `group`, `gender`, and the `group-gender` interaction are the predictor variables. Also specify the within-subject design matrix.

```
rm = fitrm(between, 'y1-y8 ~ Group*Gender + Age + IQ', 'WithinDesign', within);
```

Compute the marginal means grouped by the between-subjects factor `Group` and the within-subject factor `Time`.

```
M = margmean(rm, {'Group' 'Time'})
```

M =

Group	Time	Mean	StdErr	Lower	Upper
A	1	20.03	11.966	-4.7859	44.846
A	2	5.8101	8.0942	-10.976	22.597
A	3	20.694	5.1928	9.9247	31.463
A	4	16.802	5.1693	6.0813	27.522
A	5	13.157	6.2678	0.15862	26.156
A	6	0.38527	5.8028	-11.649	12.42
A	7	8.1398	6.4472	-5.2309	21.51

C	1	19.951	12.236	-5.4261	45.327
C	2	23.63	8.2771	6.4646	40.796
C	3	-22.121	5.3101	-33.133	-11.109
C	4	-14.307	5.2861	-25.27	-3.3443
C	5	-20.138	6.4094	-33.43	-6.8456
C	6	-28.583	5.9339	-40.889	-16.277
C	7	-25.273	6.5928	-38.946	-11.6
C	8	-21.836	7.7801	-37.971	-5.7009

Display the description for table M.

```
M.Properties.Description
```

```
ans =
```

```
Estimated marginal means  
Means computed with Age=13.7, IQ=98.2667
```

Compute Estimated Marginal Means and Confidence Intervals

Load the sample data.

```
load fisheriris
```

The column vector, `species`, consists of iris flowers of three different species, `setosa`, `versicolor`, `virginica`. The double matrix `meas` consists of four types of measurements on the flowers, the length and width of sepals and petals in centimeters, respectively.

Store the data in a table array.

```
t = table(species,meas(:,1),meas(:,2),meas(:,3),meas(:,4),...  
'VariableNames',{'species','meas1','meas2','meas3','meas4'});  
Meas = dataset([1 2 3 4]','VarNames',{'Measurements'});
```

Fit a repeated measures model, where the measurements are the responses and the species is the predictor variable.

```
rm = fitrm(t,'meas1-meas4~species','WithinDesign',Meas);
```

Compute the marginal means grouped by the factor species.

```
margmean(rm,'species')
```

```
ans =
```

species	Mean	StdErr	Lower	Upper
'setosa'	2.5355	0.042807	2.4509	2.6201
'versicolor'	3.573	0.042807	3.4884	3.6576
'virginica'	4.285	0.042807	4.2004	4.3696

`StdError` field shows the standard errors of the estimated marginal means. The `Lower` and `Upper` fields show the lower and upper bounds for the 95% confidence intervals

of the group marginal means, respectively. None of the confidence intervals overlap, which indicates that marginal means differ with species. You can also plot the estimated marginal means using the `plotprofile` method.

Compute the 99% confidence intervals for the marginal means.

```
margmean(rm, 'species', 'alpha', 0.01)
```

```
ans =
```

species	Mean	StdErr	Lower	Upper
'setosa'	2.5355	0.042807	2.4238	2.6472
'versicolor'	3.573	0.042807	3.4613	3.6847
'virginica'	4.285	0.042807	4.1733	4.3967

mauchly

Class: RepeatedMeasuresModel

Mauchly's test for sphericity

Syntax

```
tbl = mauchly(rm)
tbl = mauchly(rm, C)
```

Description

`tbl = mauchly(rm)` returns the result of the Mauchly's test for sphericity for the repeated measures model `rm`.

It tests the null hypothesis that the sphericity assumption is true for the response variables in `rm`.

For more information, see “Mauchly's Test of Sphericity” on page 8-54.

`tbl = mauchly(rm, C)` returns the result of the Mauchly's test based on the contrast matrix `C`.

Input Arguments

rm — Repeated measures model

RepeatedMeasuresModel object

Repeated measures model, returned as a RepeatedMeasuresModel object.

For properties and methods of this object, see RepeatedMeasuresModel.

C — Contrasts

matrix

Contrasts, specified as a matrix. The default value of `C` is the `Q` factor in a QR decomposition of the matrix `M`, where `M` is defined so that `Y*M` is the difference between all successive pairs of columns of the repeated measures matrix `Y`.

Data Types: `single` | `double`

Output Arguments

tbl — Results of Mauchly's test of sphericity

table

Results of Mauchly's test for sphericity for the repeated measures model `rm`, returned as a table.

`tbl` contains the following columns.

Column Name	Definition
<code>W</code>	Value of Mauchly's <i>W</i> statistic
<code>ChiStat</code>	Chi-square statistic value
<code>DF</code>	Degrees of freedom of the Chi-square statistic
<code>pValue</code>	<i>p</i> -value corresponding to the Chi-square statistic

Data Types: `table`

Examples

Perform Mauchly's Test

Load the sample data.

```
load fisheriris
```

The column vector `species` consists of iris flowers of three different species: `setosa`, `versicolor`, and `virginica`. The double matrix `meas` consists of four types of measurements on the flowers: the length and width of sepals and petals in centimeters, respectively.

Store the data in a table array.

```
t = table(species,meas(:,1),meas(:,2),meas(:,3),meas(:,4),...  
'VariableNames',{'species','meas1','meas2','meas3','meas4'});  
Meas = dataset([1 2 3 4]','VarNames',{'Measurements'});
```

Fit a repeated measures model, where the measurements are the responses and the species is the predictor variable.

```
rm = fitrm(t,'meas1-meas4~species','WithinDesign',Meas);
```

Perform Mauchly's test to assess the sphericity assumption.

```
mauchly(rm)
```

```
ans =
```

W	ChiStat	DF	pValue
0.55814	84.976	5	1.1102e-16

The small p -value (in the `pValue` field) indicates that the sphericity, hence the compound symmetry assumption, does not hold. You should use epsilon corrections to compute the p -values for a repeated measures anova. You can compute the epsilon corrections using the `epsilon` method and perform the repeated measures anova with the corrected p -values using the `ranova` method.

mat2dataset

Convert matrix to dataset array

Compatibility

The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

Syntax

```
ds = mat2dataset(X)
ds = mat2dataset(X,Name,Value)
```

Description

`ds = mat2dataset(X)` converts a matrix to a `dataset` array.

`ds = mat2dataset(X,Name,Value)` performs the conversion using additional options specified by one or more `Name,Value` pair arguments.

Examples

Convert Matrix to Dataset Array

Convert a matrix to a dataset array using the default options.

Load sample data.

```
load('fisheriris')
X = meas;
size(X)
```

```
ans =
```

```
150      4
```

Convert the matrix to a dataset array.

```
ds = mat2dataset(X);  
size(ds)
```

```
ans =
```

```
150      4
```

```
ds(1:5,:) 
```

```
ans =
```

```
    X1    X2    X3    X4  
    5.1    3.5    1.4    0.2  
    4.9     3    1.4    0.2  
    4.7    3.2    1.3    0.2  
    4.6    3.1    1.5    0.2  
     5    3.6    1.4    0.2
```

When you do not specify variable names, `mat2dataset` uses the matrix name and column numbers to create default variable names.

Convert Matrix to Dataset Array with Variable Names

Load sample data.

```
load('fisheriris')  
X = meas;  
size(X)
```

```
ans =
```

```
150      4
```

Convert the matrix to a dataset array, providing a variable name for each of the four column of X.

```
ds = mat2dataset(X, 'VarNames', {'SLength', ...  
    'SWidth', 'PLength', 'PWidth'});  
size(ds)
```

```
ans =
```

```

150      4
ds(1:5,:)
ans =
    SWidth    SLength    PWidth    PLength
    5.1        3.5        1.4        0.2
    4.9         3        1.4        0.2
    4.7        3.2        1.3        0.2
    4.6        3.1        1.5        0.2
    5          3.6        1.4        0.2

```

Create a Dataset Array with Multicolumn Variables

Convert a matrix to a dataset array containing multicolumn variables.

Load sample data.

```

load('fisheriris')
X = meas;
size(X)

```

```
ans =
```

```
150      4
```

Convert the matrix to a dataset array, combining the sepal measurements (the first two columns) into one variable named `SepalMeas`, and the petal measurements (third and fourth columns) into one variable names `PetalMeas`.

```

ds = mat2dataset(X,'NumCols',[2,2],...
'VarNames',{'SepalMeas','PetalMeas'});
ds(1:5,:)

```

```
ans =
```

```

SepalMeas      PetalMeas
    5.1        3.5        1.4        0.2
    4.9         3        1.4        0.2
    4.7        3.2        1.3        0.2
    4.6        3.1        1.5        0.2
    5          3.6        1.4        0.2

```

The output dataset array has 150 observations and 2 variables.

```
size(ds)
```

```
ans =
```

```
    150     2
```

- “Create a Dataset Array from a File” on page 2-69

Input Arguments

X — Input matrix

matrix

Input matrix to convert to a dataset array, specified as an M -by- N numeric matrix. Each column of X becomes a variable in the output M -by- N dataset array.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'NumCols',[1,1,2,1]` specifies that the 3rd and 4th columns of the input matrix should be combined into a single variable.

'VarNames' — Variable names for output dataset array

cell array of strings

Variable names for the output dataset array, specified as the comma-separated pair consisting of `'VarNames'` and a cell array of strings. You must provide a variable name for each variable in `ds`. The names must be valid MATLAB identifiers, and must be unique.

Example: `'VarNames',{'myVar1','myVar2','myVar3'}`

'ObsNames' — Observation names for output dataset array

cell array of strings

Observation names for the output dataset array, specified as the comma-separated pair consisting of 'ObsNames' and a cell array of strings. The names do not need to be valid MATLAB identifiers, but they must be unique.

'NumCols' — Number of columns for each variable

vector of nonnegative integers

Number of columns for each variable in `ds`, specified as the comma-separated pair consisting of 'NumCols' and a vector of nonnegative integers. When the number of columns for a variable is greater than one, `mat2dataset` combines multiple columns in `X` into a single variable in `ds`. The vector you assign to `NumCols` must sum to `size(X,2)`.

For example, to convert a matrix with eight columns into a dataset array with five variables, specify a vector with five elements that sum to eight, such as 'NumCols', `[1,1,3,1,2]`.

Output Arguments

`ds` — Output dataset array

dataset array

Output dataset array, returned by default with a variable for each column of `X`, and an observation for each row of `X`. If you specify `NumCols`, then the number of variables in `ds` is equal to the length of the specified vector of column numbers.

mdscale

Nonclassical multidimensional scaling

Syntax

```
Y = mdscale(D,p)
[Y, stress] = mdscale(D,p)
[Y, stress, disparities] = mdscale(D,p)
[...] = mdscale(D,p, 'Name', value)
```

Description

`Y = mdscale(D,p)` performs nonmetric multidimensional scaling on the n -by- n dissimilarity matrix `D`, and returns `Y`, a configuration of n points (rows) in p dimensions (columns). The Euclidean distances between points in `Y` approximate a monotonic transformation of the corresponding dissimilarities in `D`. By default, `mdscale` uses Kruskal's normalized stress1 criterion.

You can specify `D` as either a full n -by- n matrix, or in upper triangle form such as is output by `pdist`. A full dissimilarity matrix must be real and symmetric, and have zeros along the diagonal and non-negative elements everywhere else. A dissimilarity matrix in upper triangle form must have real, non-negative entries. `mdscale` treats NaNs in `D` as missing values, and ignores those elements. `Inf` is not accepted.

You can also specify `D` as a full similarity matrix, with ones along the diagonal and all other elements less than one. `mdscale` transforms a similarity matrix to a dissimilarity matrix in such a way that distances between the points returned in `Y` approximate $\sqrt{1-D}$. To use a different transformation, transform the similarities prior to calling `mdscale`.

`[Y, stress] = mdscale(D,p)` returns the minimized stress, i.e., the stress evaluated at `Y`.

`[Y, stress, disparities] = mdscale(D,p)` returns the disparities, that is, the monotonic transformation of the dissimilarities `D`.

[...] = `mdscale(D,p,'Name',value)` specifies one or more optional parameter name/value pairs that control further details of `mdscale`. Specify *Name* in single quotes. Available parameters are

- **Criterion**— The goodness-of-fit criterion to minimize. This also determines the type of scaling, either non-metric or metric, that `mdscale` performs. Choices for non-metric scaling are:
 - `'stress'` — Stress normalized by the sum of squares of the inter-point distances, also known as `stress1`. This is the default.
 - `'sstress'` — Squared stress, normalized with the sum of 4th powers of the inter-point distances.

Choices for metric scaling are:

- `'metricstress'` — Stress, normalized with the sum of squares of the dissimilarities.
- `'metricsstress'` — Squared stress, normalized with the sum of 4th powers of the dissimilarities.
- `'sammon'` — Sammon's nonlinear mapping criterion. Off-diagonal dissimilarities must be strictly positive with this criterion.
- `'strain'` — A criterion equivalent to that used in classical multidimensional scaling.
- **Weights** — A matrix or vector the same size as `D`, containing nonnegative dissimilarity weights. You can use these to weight the contribution of the corresponding elements of `D` in computing and minimizing stress. Elements of `D` corresponding to zero weights are effectively ignored.

Note: When you specify weights as a full matrix, its diagonal elements are ignored and have no effect, since the corresponding diagonal elements of `D` do not enter into the stress calculation.

- **Start** — Method used to choose the initial configuration of points for `Y`. The choices are
 - `'cmdscale'` — Use the classical multidimensional scaling solution. This is the default. `'cmdscale'` is not valid when there are zero weights.
 - `'random'` — Choose locations randomly from an appropriately scaled `p`-dimensional normal distribution with uncorrelated coordinates.

- An n -by- p matrix of initial locations, where n is the size of the matrix D and p is the number of columns of the output matrix Y . In this case, you can pass in `[]` for p and `mdscale` infers p from the second dimension of the matrix. You can also supply a 3-D array, implying a value for 'Replicates' from the array's third dimension.
- **Replicates** — Number of times to repeat the scaling, each with a new initial configuration. The default is 1.
- **Options** — Options for the iterative algorithm used to minimize the fitting criterion. Pass in an options structure created by `statset`. For example,

```
opts = statset(param1,val1,param2,val2, ...);  
[...] = mdscale(...,'Options',opts)
```

The choices of `statset` parameters are

- 'Display' — Level of display output. The choices are 'off' (the default), 'iter', and 'final'.
- 'MaxIter' — Maximum number of iterations allowed. The default is 200.
- 'TolFun' — Termination tolerance for the stress criterion and its gradient. The default is $1e-4$.
- 'TolX' — Termination tolerance for the configuration location step size. The default is $1e-4$.

Examples

```
load cereal.mat  
X = [Calories Protein Fat Sodium Fiber ...  
     Carbo Sugars Shelf Potass Vitamins];  
  
% Take a subset from a single manufacturer.  
X = X(strcmp('K',cellstr(Mfg)),:);  
  
% Create a dissimilarity matrix.  
dissimilarities = pdist(X);  
  
% Use non-metric scaling to recreate the data in 2D,  
% and make a Shepard plot of the results.  
[Y,stress,disparities] = mdscale(dissimilarities,2);  
distances = pdist(Y);
```

```

[dum,ord] = sortrows([disparities(:) dissimilarities(:)]);
plot(dissimilarities(distances,'bo', ...
dissimilarities(ord),disparities(ord),'r.-');
xlabel('Dissimilarities'); ylabel('Distances/Disparities')
legend({'Distances' 'Disparities'},'Location','NW');

```

```

% Do metric scaling on the same dissimilarities.
figure
[Y,stress] = ...
mdscale(dissimilarities,2,'criterion','metricsstress');
distances = pdist(Y);
plot(dissimilarities,distances,'bo', ...
[0 max(dissimilarities)],[0 max(dissimilarities)],'r.-');
xlabel('Dissimilarities'); ylabel('Distances')

```

mdsProx

Class: CompactTreeBagger

Multidimensional scaling of proximity matrix

Syntax

```
[SC,EIGEN] = mdsProx(B,X)
[SC,EIGEN] = mdsProx(B,X, 'param1',val1, 'param2',val2,...)
```

Description

[SC,EIGEN] = mdsProx(B,X) applies classical multidimensional scaling to the proximity matrix computed for the data in the matrix X, and returns scaled coordinates **SC** and eigenvalues **EIGEN** of the scaling transformation. The method applies multidimensional scaling to the matrix of distances defined as $1 - \text{prox}$, where **prox** is the proximity matrix returned by the **proximity** method.

You can supply the proximity matrix directly by using the 'data' parameter.

[SC,EIGEN] = mdsProx(B,X, 'param1',val1, 'param2',val2,...) specifies optional parameter name/value pairs:

- | | |
|----------|--|
| 'data' | Flag indicating how the method treats the X input argument. If set to 'predictors' (default), mdsProx assumes X to be a matrix of predictors and used for computation of the proximity matrix. If set to 'proximity', the method treats X as a proximity matrix returned by the proximity method. |
| 'colors' | If you supply this argument, mdsProx makes overlaid scatter plots of two scaled coordinates using specified colors for different classes. You must supply the colors as a string with one character for each color. If there are more classes in the data than characters in the supplied string, mdsProx only plots the first C classes, where C is the length of the string. For regression or if you do not provide the vector of true class labels, the method uses the first color for all observations in X. |

- 'labels' Vector of true class labels for a classification ensemble. True class labels can be either a numeric vector, character matrix, or cell array of strings. If supplied, this vector must have as many elements as there are observations (rows) in X . This argument has no effect unless you also supply the 'colors' argument.
- 'mdscoords' Indices of the two scaled coordinates to plot. By default, `mdsProx` makes a scatter plot of the first and second scaled coordinates which correspond to the two largest eigenvalues. You can specify any other two or three indices not exceeding the dimensionality of the scaled data. This argument has no effect unless you also supply the 'colors' argument.

mdsProx

Class: TreeBagger

Multidimensional scaling of proximity matrix

Syntax

```
[S,E] = mdsProx(B)
[S,E] = mdsProx(B, 'param1',val1, 'param2',val2, ...)
```

Description

[S,E] = mdsProx(B) returns scaled coordinates, S, and eigenvalues, E, for the proximity matrix in the ensemble B. An earlier call to `fillProximities(B)` must create the proximity matrix.

[S,E] = mdsProx(B, 'param1',val1, 'param2',val2, ...) specifies optional parameter name/value pairs:

- | | |
|-------------|--|
| 'keep' | Array of indices of observations in the training data to use for multidimensional scaling. By default, this argument is set to 'all'. If you provide numeric or logical indices, the method uses only the subset of the training data specified by these indices to compute the scaled coordinates and eigenvalues. |
| 'colors' | If you supply this argument, <code>mdsProx</code> makes overlaid scatter plots of two scaled coordinates using specified colors for different classes. You must supply the colors as a string with one character for each color. If there are more classes in the data than characters in the supplied string, <code>mdsProx</code> only plots the first C classes, where C is the length of the string. For regression or if you do not provide the vector of true class labels, the method uses the first color for all observations in X. |
| 'mdscoords' | Indices of the two scaled coordinates to plot. By default, <code>mdsProx</code> makes a scatter plot of the first and second scaled coordinates which correspond to the two largest eigenvalues. You can specify any |

other two or three indices not exceeding the dimensionality of the scaled data. This argument has no effect unless you also supply the 'colors' argument.

mean

Class: prob.KernelDistribution

Package: prob

Mean of probability distribution object

Syntax

`m = mean(pd)`

Description

`m = mean(pd)` returns the mean `m` of the probability distribution `pd`.

Input Arguments

pd — **Probability distribution**

probability distribution object

Probability distribution, specified as a probability distribution object. Fit a probability distribution object to data using `fitdist` or the Distribution Fitting app.

Output Arguments

m — **Mean**

scalar value

Mean of the probability distribution, returned as a scalar value.

Examples

Mean of a Kernel Distribution

Load the sample data. Create a probability distribution object by fitting a kernel distribution to the miles per gallon (MPG) data.

```
load carsmall;  
pd = fitdist(MPG, 'Kernel')
```

```
pd =
```

```
KernelDistribution
```

```
Kernel = normal  
Bandwidth = 4.11428  
Support = unbounded
```

Compute the mean of the distribution.

```
mean(pd)
```

```
ans =
```

```
23.7181
```

See Also

[dfittool](#) | [fitdist](#)

mean

Class: ProbDistUnivParam

Return mean of ProbDistUnivParam object

Syntax

$M = \text{mean}(PD)$

Description

$M = \text{mean}(PD)$ returns M , the mean of the ProbDistUnivParam object PD .

Input Arguments

PD An object of the class ProbDistUnivParam.

Output Arguments

M The mean of the ProbDistUnivParam object PD .

See Also

mean

mean

Class: prob.ParametricTruncatableDistribution

Package: prob

Mean of probability distribution object

Syntax

`m = mean(pd)`

Description

`m = mean(pd)` returns the mean `m` of the probability distribution `pd`.

Input Arguments

pd — Probability distribution

probability distribution object

Probability distribution, specified as a probability distribution object. Create a probability distribution object with specified parameter values using `makedist`.

Output Arguments

m — Mean

scalar value

Mean of the probability distribution, returned as a scalar value.

Examples

Mean of a Uniform Distribution

Create a uniform distribution object

```
pd = makedist('Uniform', 'lower', -3, 'upper', 5)
```

```
pd =
```

```
UniformDistribution
```

```
Uniform distribution
```

```
Lower = -3
```

```
Upper = 5
```

Compute the mean of the distribution.

```
m = mean(pd)
```

```
m =
```

```
1
```

makedist

mean

Class: prob.ToolboxFittableParametricDistribution

Package: prob

Mean of probability distribution object

Syntax

```
m = mean(pd)
```

Description

`m = mean(pd)` returns the mean `m` of the probability distribution `pd`.

Input Arguments

pd — Probability distribution

probability distribution object

Probability distribution, specified as a probability distribution object. Create a probability distribution object with specified parameter values using `makedist`. Alternatively, create a probability distribution object by fitting it to data using `fitdist` or the Distribution Fitting app.

Output Arguments

m — Mean

scalar value

Mean of the probability distribution, returned as a scalar value.

Examples

Mean of a Fitted Distribution

Load the sample data. Create a vector containing the first column of students' exam grade data.

```
load examgrades;  
x = grades(:,1);
```

Create a normal distribution object by fitting it to the data.

```
pd = fitdist(x,'Normal')  
  
pd =  
  
NormalDistribution  
  
Normal distribution  
    mu = 75.0083    [73.4321, 76.5846]  
    sigma = 8.7202    [7.7391, 9.98843]
```

Compute the mean of the fitted distribution.

```
m = mean(pd)  
  
m =  
  
75.0083
```

The mean of the normal distribution is equal to the parameter μ .

Mean of a Skewed Distribution

Create a Weibull probability distribution object.

```
pd = makedist('Weibull','a',5,'b',2)  
  
pd =  
  
WeibullDistribution  
  
Weibull distribution  
    A = 5  
    B = 2
```

Compute the mean of the distribution.

```
mean = mean(pd)
```

```
mean =  
    4.4311
```

`dfittool` | `fitdist` | `makedist`

meanMargin

Class: CompactTreeBagger

Mean classification margin

Syntax

```
mar = meanMargin(B,X,Y)
mar = meanMargin(B,X,Y, 'param1',val1, 'param2',val2,...)
```

Description

`mar = meanMargin(B,X,Y)` computes average classification margins for predictors `X` given true response `Y`. The `Y` can be either a numeric vector, character matrix, cell array of strings, categorical vector or logical vector. `meanMargin` averages the margins over all observations (rows) in `X` for each tree. `mar` is a matrix of size 1-by-`NTrees`, where `NTrees` is the number of trees in the ensemble `B`. This method is available for classification ensembles only.

`mar = meanMargin(B,X,Y, 'param1',val1, 'param2',val2,...)` specifies optional parameter name/value pairs:

'mode'	String indicating how <code>meanMargin</code> computes errors. If set to 'cumulative' (default), is a vector of length <code>NTrees</code> where the first element gives mean margin from <code>trees(1)</code> , second column gives mean margins from <code>trees(1:2)</code> etc, up to <code>trees(1:NTrees)</code> . If set to 'individual', <code>mar</code> is a vector of length <code>NTrees</code> , where each element is a mean margin from each tree in the ensemble. If set to 'ensemble', <code>mar</code> is a scalar showing the cumulative mean margin for the entire ensemble.
'trees'	Vector of indices indicating what trees to include in this calculation. By default, this argument is set to 'all' and the method uses all trees. If 'trees' is a numeric vector, the method returns a vector of length <code>NTrees</code> for 'cumulative' and 'individual' modes, where <code>NTrees</code> is the number of elements in the input vector, and a scalar for 'ensemble' mode. For example, in the 'cumulative'

mode, the first element gives mean margin from `trees(1)`, the second element gives mean margin from `trees(1:2)` etc.

'`treeweights`' Vector of tree weights. This vector must have the same length as the '`trees`' vector. `meanMargin` uses these weights to combine output from the specified trees by taking a weighted average instead of the simple nonweighted majority vote. You cannot use this argument in the '`individual`' mode.

`CompactTreeBagger.meanMargin`

meansurrvarassoc

Class: `classregtree`

Mean predictive measure of association for surrogate splits in decision tree

Syntax

`MA = meansurrvarassoc(T)`

`MA = meansurrvarassoc(T,N)`

Description

`MA = meansurrvarassoc(T)` returns a p -by- p matrix, `MA`, with predictive measures of association for p predictors. Element `MA(i,j)` is the predictive measure of association averaged over surrogate splits on predictor j for which predictor i is the optimal split predictor. This average is computed by summing positive values of the predictive measure of association over optimal splits on predictor i and surrogate splits on predictor j and dividing by the total number of optimal splits on predictor i , including splits for which the predictive measure of association between predictors i and j is negative.

`MA = meansurrvarassoc(T,N)` takes an array `N` of node numbers and returns the predictive measure of association averaged over the specified nodes.

surrogateAssociation

Class: CompactClassificationTree

Mean predictive measure of association for surrogate splits in decision tree

Syntax

```
ma = surrogateAssociation(tree)
ma = surrogateAssociation(tree,N)
```

Description

`ma = surrogateAssociation(tree)` returns a matrix of predictive measures of association for the predictors in `tree`.

`ma = surrogateAssociation(tree,N)` returns a matrix of predictive measures of association averaged over the nodes in vector `N`.

Input Arguments

tree

A classification tree constructed with `fitctree`, or a compact regression tree constructed with `compact`.

N

Vector of node numbers in `tree`.

Output Arguments

ma

- `ma = surrogateAssociation(tree)` returns a P-by-P matrix, where P is the number of predictors in `tree`. `ma(i,j)` is the predictive measure of association

between the optimal split on variable i and a surrogate split on variable j . See “Predictive Measure of Association” on page 21-2589.

- `ma = surrogateAssociation(tree,N)` returns a P-by-P representing the predictive measure of association between variables averaged over nodes in the vector N . N contains node numbers from 1 to `max(tree.NumNodes)`.

Definitions

Predictive Measure of Association

The predictive measure of association between the optimal split on variable i and a surrogate split on variable j is:

$$\lambda_{i,j} = \frac{\min(P_L, P_R) - (1 - P_{L_i L_j} - P_{R_i R_j})}{\min(P_L, P_R)}.$$

Here

- P_L and P_R are the node probabilities for the optimal split of node i into Left and Right nodes respectively.
- $P_{L_i L_j}$ is the probability that both (optimal) node i and (surrogate) node j send an observation to the Left.
- $P_{R_i R_j}$ is the probability that both (optimal) node i and (surrogate) node j send an observation to the Right.

Clearly, $\lambda_{i,j}$ lies from $-\infty$ to 1. Variable j is a worthwhile surrogate split for variable i if $\lambda_{i,j} > 0$.

Element `ma(i,j)` is the predictive measure of association averaged over surrogate splits on predictor j for which predictor i is the optimal split predictor. This average is computed by summing positive values of the predictive measure of association over optimal splits on predictor i and surrogate splits on predictor j and dividing by the total number of optimal splits on predictor i , including splits for which the predictive measure of association between predictors i and j is negative.

Examples

Find the mean predictive measure of association between the variables in the Fisher iris data:

```
load fisheriris
obj = fitctree(meas,species,'surrogate','on');
msva = surrogateAssociation(obj)
```

```
msva =
    1.0000         0         0         0
         0    1.0000         0         0
    0.4633    0.2500    1.0000    0.5000
    0.2065    0.1413    0.4022    1.0000
```

Find the mean predictive measure of association averaged over the odd-numbered nodes in obj:

```
N = 1:2:obj.NumNodes;
msva = surrogateAssociation(obj,N)
```

```
msva =
    1.0000         0         0         0
         0    1.0000         0         0
    0.7600    0.5000    1.0000    1.0000
    0.4130    0.2826    0.8043    1.0000
```

ClassificationTree | fitctree

surrogateAssociation

Class: CompactRegressionTree

Mean predictive measure of association for surrogate splits in decision tree

Syntax

```
ma = surrogateAssociation(tree)
ma = surrogateAssociation(tree,N)
```

Description

`ma = surrogateAssociation(tree)` returns a matrix of predictive measures of association for the predictors in `tree`.

`ma = surrogateAssociation(tree,N)` returns a matrix of predictive measures of association averaged over the nodes in vector `N`.

Input Arguments

tree

A regression tree constructed with `fitrtree`, or a compact regression tree constructed with `compact`.

N

Vector of node numbers in `tree`.

Output Arguments

ma

- `ma = surrogateAssociation(tree)` returns a P-by-P matrix, where P is the number of predictors in `tree`. `ma(i,j)` is the predictive measure of association

between the optimal split on variable i and a surrogate split on variable j . See “Predictive Measure of Association” on page 21-2592.

- `ma = surrogateAssociation(tree,N)` returns a P-by-P representing the predictive measure of association between variables averaged over nodes in the vector N . N contains node numbers from 1 to `max(tree.NumNodes)`.

Definitions

Predictive Measure of Association

The predictive measure of association between the optimal split on variable i and a surrogate split on variable j is:

$$\lambda_{i,j} = \frac{\min(P_L, P_R) - (1 - P_{L_i L_j} - P_{R_i R_j})}{\min(P_L, P_R)}.$$

Here

- P_L and P_R are the node probabilities for the optimal split of node i into Left and Right nodes respectively.
- $P_{L_i L_j}$ is the probability that both (optimal) node i and (surrogate) node j send an observation to the Left.
- $P_{R_i R_j}$ is the probability that both (optimal) node i and (surrogate) node j send an observation to the Right.

Clearly, $\lambda_{i,j}$ lies from $-\infty$ to 1. Variable j is a worthwhile surrogate split for variable i if $\lambda_{i,j} > 0$.

Element `ma(i,j)` is the predictive measure of association averaged over surrogate splits on predictor j for which predictor i is the optimal split predictor. This average is computed by summing positive values of the predictive measure of association over optimal splits on predictor i and surrogate splits on predictor j and dividing by the total number of optimal splits on predictor i , including splits for which the predictive measure of association between predictors i and j is negative.

Examples

Find the mean predictive measure of association between the Displacement, Horsepower, and Weight variables in the carsmall data:

```
load carsmall
X = [Displacement Horsepower Weight];
tree = fitrtree(X,MPG,'surrogate','on');
ma = surrogateAssociation(tree)
```

```
ma =
    1.0000    0.2708    0.3854
    0.4764    1.0000    0.4568
    0.3472    0.2326    1.0000
```

Find the mean predictive measure of association averaged over the odd-numbered nodes in tree:

```
N = 1:2:tree.NumNodes;
ma = surrogateAssociation(tree,N)
```

```
ma =
    1.0000    0.2500    0.3750
    0.5910    1.0000    0.5861
    0.5000    0.2361    1.0000
```

median

Class: ProbDistUnivKernel

Return median of ProbDistUnivKernel object

Syntax

$M = \text{median}(PD)$

Description

$M = \text{median}(PD)$ returns M , the median of the ProbDistUnivKernel object PD .

Input Arguments

PD An object of the class ProbDistUnivKernel.

Output Arguments

M The median of the ProbDistUnivKernel object PD .

See Also

median

median

Class: ProbDistUnivParam

Return median of ProbDistUnivParam object

Syntax

$M = \text{median}(PD)$

Description

$M = \text{median}(PD)$ returns M , the median of the ProbDistUnivParam object PD .

Input Arguments

PD An object of the class ProbDistUnivParam.

Output Arguments

M The median of the ProbDistUnivParam object PD .

See Also

median

median

Class: prob.TruncatableDistribution

Package: prob

Median of probability distribution object

Syntax

```
m = median(pd)
```

Description

`m = median(pd)` returns the median `m` for the probability distribution `pd`.

Input Arguments

pd — Probability distribution

probability distribution object

Probability distribution, specified as a probability distribution object. Create a probability distribution object with specified parameter values using `makedist`. Alternatively, for fittable distributions, create a probability distribution object by fitting it to data using `fitdist` or the Distribution Fitting app.

Output Arguments

m — Median

scalar value

Median of the probability distribution, returned as a scalar value. The value of `m` is the 50th percentile of the probability distribution.

Examples

Median of a Fitted Distribution

Load the sample data. Create a vector containing the first column of students' exam grade data.

```
load examgrades;  
x = grades(:,1);
```

Create a normal distribution object by fitting it to the data.

```
pd = fitdist(x, 'Normal')  
  
pd =  
  
NormalDistribution  
  
Normal distribution  
mu = 75.0083 [73.4321, 76.5846]  
sigma = 8.7202 [7.7391, 9.98843]
```

Compute the median of the fitted distribution.

```
m = median(pd)  
  
m =  
  
75.0083
```

For a symmetrical distribution such as the normal distribution, the median will be equal to the mean, μ .

Median of a Skewed Distribution

Create a Weibull probability distribution object.

```
pd = makedist('Weibull', 'a', 5, 'b', 2)  
  
pd =  
  
WeibullDistribution
```

```
Weibull distribution
A = 5
B = 2
```

Compute the median of the distribution.

```
m = median(pd)
```

```
m =
    4.1628
```

For a skewed distribution such as the Weibull distribution, the median and the mean may not be equal.

Calculate the mean of the Weibull distribution and compare it to the median.

```
mean = mean(pd)
```

```
mean =
    4.4311
```

The mean of the distribution is greater than the median.

Plot the pdf to visualize the distribution.

```
x = [0:.1:15];
pdf = pdf(pd,x);
plot(x,pdf)
```

MergeLeaves property

Class: TreeBagger

Flag to merge leaves that do not improve risk

Description

The `MergeLeaves` property is true if decision trees have their leaves with the same parent merged for splits that do not decrease the total risk, and false otherwise. The default value is false.

See Also

`ClassificationTree` | `RegressionTree` | `TreeBagger` | `fitctree` | `fitrtree`

mergelevels

Merge levels of nominal or ordinal arrays

Compatibility

The `nominal` and `ordinal` array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the MATLAB categorical data type instead.

Syntax

```
B = mergelevels(A,oldlevels)
B = mergelevels(A,oldlevels,newlevel)
```

Description

`B = mergelevels(A,oldlevels)` merges two or more levels of `A`.

- If `A` is a nominal array, `mergelevels` uses the first label in `oldlevels` as the new level.
- If `A` is an ordinal array, the levels specified by `oldlevels` must be consecutive, and `mergelevels` uses the label corresponding to the lowest level in `oldlevels` as the label for the new level.

`B = mergelevels(A,oldlevels,newlevel)` merges two or more levels into the new level with label `newlevel`.

Examples

Create New Category From Merged Levels

Create a nominal array from string data in a cell array.

```
colors = nominal({'r','b','g'; 'g','r','b'; 'b','r','g'},...
```

```
{'blue', 'green', 'red'})
```

```
colors =
```

```
    red      blue      green
    green    red       blue
    blue     red       green
```

Merge the elements of the 'red' and 'blue' levels into a new level labeled 'purple'.

```
colors = mergelevels(colors, {'red', 'blue'}, 'purple')
```

```
colors =
```

```
    purple    purple    green
    green     purple    purple
    purple    purple    green
```

Display the levels of `colors`.

```
getlevels(colors)
```

```
ans =
```

```
    purple    green
```

- “Merge Category Levels” on page 2-19

Input Arguments

A — Nominal or ordinal array

nominal array | ordinal array

Nominal or ordinal array, specified as a `nominal` or `ordinal` array object created using `nominal` or `ordinal`.

oldlevels — Levels to merge

cell array of strings | 2-D character matrix

Levels to merge, specified as a cell array of strings or 2-D character matrix. For ordinal arrays, the levels in `oldlevels` must be consecutive.

Data Types: `char` | `cell`

newlevel — Level to create

string

Level to create from the merged levels, specified as a string that gives the label for the new level.

Data Types: `char`

Output Arguments

B — Nominal or ordinal array

nominal array | ordinal array

Nominal or ordinal array, returned as a `nominal` or `ordinal` array object.

More About

- Using nominal Objects
- Using ordinal Objects

See Also

`addlevels` | `droplevels` | `nominal` | `ordinal` | `reorderlevels`

Method property

Class: TreeBagger

Method used by trees (classification or regression)

Description

The Method property is 'classification' for classification ensembles and 'regression' for regression ensembles.

mhsample

Metropolis-Hastings sample

Syntax

```
smp1 = mhsample(start,nsamples,'pdf',pdf,'proppdf',proppdf,  
'proprnd',proprnd)  
smp1 = mhsample(...,'symmetric',sym)  
smp1 = mhsample(...,'burnin',K)  
smp1 = mhsample(...,'thin',m)  
smp1 = mhsample(...,'nchain',n)  
[smp1,accept] = mhsample(...)
```

Description

`smp1 = mhsample(start,nsamples,'pdf',pdf,'proppdf',proppdf,'proprnd',proprnd)` draws `nsamples` random samples from a target stationary distribution `pdf` using the Metropolis-Hastings algorithm.

`start` is a row vector containing the start value of the Markov Chain, `nsamples` is an integer specifying the number of samples to be generated, and `pdf`, `proppdf`, and `proprnd` are function handles created using `@`. `proppdf` defines the proposal distribution density, and `proprnd` defines the random number generator for the proposal distribution. `pdf` and `proprnd` take one argument as an input with the same type and size as `start`. `proppdf` takes two arguments as inputs with the same type and size as `start`.

`smp1` is a column vector or matrix containing the samples. If the log density function is preferred, `'pdf'` and `'proppdf'` can be replaced with `'logpdf'` and `'logproppdf'`. The density functions used in Metropolis-Hastings algorithm are not necessarily normalized.

The proposal distribution $q(x,y)$ gives the probability density for choosing x as the next point when y is the current point. It is sometimes written as $q(x|y)$.

If the `proppdf` or `logproppdf` satisfies $q(x,y) = q(y,x)$, that is, the proposal distribution is symmetric, `mhsample` implements Random Walk Metropolis-Hastings sampling. If

the `proppdf` or `logproppdf` satisfies $q(x,y) = q(x)$, that is, the proposal distribution is independent of current values, `mhsample` implements Independent Metropolis-Hastings sampling.

`smpl = mhsample(..., 'symmetric', sym)` draws `nsamples` random samples from a target stationary distribution `pdf` using the Metropolis-Hastings algorithm. `sym` is a logical value that indicates whether the proposal distribution is symmetric. The default value is `false`, which corresponds to the asymmetric proposal distribution. If `sym` is `true`, for example, the proposal distribution is symmetric, `proppdf` and `logproppdf` are optional.

`smpl = mhsample(..., 'burnin', K)` generates a Markov chain with values between the starting point and the k^{th} point omitted in the generated sequence. Values beyond the k^{th} point are kept. `k` is a nonnegative integer with default value of 0.

`smpl = mhsample(..., 'thin', m)` generates a Markov chain with `m-1` out of `m` values omitted in the generated sequence. `m` is a positive integer with default value of 1.

`smpl = mhsample(..., 'nchain', n)` generates `n` Markov chains using the Metropolis-Hastings algorithm. `n` is a positive integer with a default value of 1. `smpl` is a matrix containing the samples. The last dimension contains the indices for individual chains.

`[smpl, accept] = mhsample(...)` also returns `accept`, the acceptance rate of the proposed distribution. `accept` is a scalar if a single chain is generated and is a vector if multiple chains are generated.

Examples

Estimate Moments Using Independent Metropolis-Hastings Sampling

Use Independent Metropolis-Hastings sampling to estimate the second order moment of a Gamma distribution.

```
rng default; % For reproducibility
alpha = 2.43;
beta = 1;
pdf = @(x)gampdf(x,alpha,beta); % Target distribution
proppdf = @(x,y)gampdf(x,floor(alpha),floor(alpha)/alpha);
proprnd = @(x)sum(...
```

```
        exprnd(floor(alpha)/alpha,floor(alpha),1));
nsamples = 5000;
smp1 = mhsample(1,nsamples,'pdf',pdf,'proprnd',proprnd,...
               'proppdf',proppdf);
```

Plot the results.

```
xxhat = cumsum(smp1.^2)./(1:nsamples)';
figure;
plot(1:nsamples,xxhat)
```

Random Walk Metropolis-Hastings Sampling

Use Random Walk Metropolis-Hastings sampling to generate sample data from a standard normal distribution.

```
rng default % For reproducibility
delta = .5;
pdf = @(x) normpdf(x);
proppdf = @(x,y) unifpdf(y-x,-delta,delta);
proprnd = @(x) x + rand*2*delta - delta;
nsamples = 15000;
x = mhsample(1,nsamples,'pdf',pdf,'proprnd',proprnd,'symmetric',1);
```

Plot the sample data.

```
figure;
h = histfit(x,50);
h(1).FaceColor = [.8 .8 1];
```

- “Using the Metropolis-Hastings Algorithm” on page 6-13

MinLeaf property

Class: TreeBagger

Minimum number of observations per tree leaf

Description

The `MinLeaf` property specifies the minimum number of observations per tree leaf. The default values are 1 for classification and 5 for regression. For `fitctree` or `fitrtree` training, the `'minparent'` value is set to $2 * \text{MinLeaf}$.

mle

Maximum likelihood estimates

Syntax

```
phat = mle(data)
phat = mle(data, 'distribution', dist)

phat = mle(data, 'pdf', pdf, 'start', start)
phat = mle(data, 'pdf', pdf, 'start', start, 'cdf', cdf)

phat = mle(data, 'logpdf', logpdf, 'start', start)
phat = mle(data, 'logpdf', logpdf, 'start', start, 'logsf', logsf)

phat = mle(data, 'nloglf', nloglf, 'start', start)

phat = mle( ____, Name, Value)
[phat, pci] = mle( ____, Name, Value)
```

Description

`phat = mle(data)` returns maximum likelihood estimates (MLEs) for the parameters of a normal distribution, using the sample data in the vector `data`.

`phat = mle(data, 'distribution', dist)` returns parameter estimates for a distribution specified by `dist`.

`phat = mle(data, 'pdf', pdf, 'start', start)` returns parameter estimates for a custom distribution specified by the probability density function `pdf`. You must also specify the initial parameter values, `start`.

`phat = mle(data, 'pdf', pdf, 'start', start, 'cdf', cdf)` returns parameter estimates for a custom distribution specified by the probability density function `pdf` and custom cumulative distribution function `cdf`.

`phat = mle(data, 'logpdf', logpdf, 'start', start)` returns parameter estimates for a custom distribution specified by the log probability density function `logpdf`. You must also specify the initial parameter values, `start`.

`phat = mle(data, 'logpdf', logpdf, 'start', start, 'logsf', logsf)` returns parameter estimates for a custom distribution specified by the log probability density function `logpdf` and custom log survival function `logsf`.

`phat = mle(data, 'nloglf', nloglf, 'start', start)` returns parameter estimates for the custom distribution specified by the negative loglikelihood function `nloglf`. You must also specify the initial parameter values, `start`.

`phat = mle(____, Name, Value)` also returns the parameter estimates with additional options specified by one or more name-value pair arguments. You can use any of the input arguments in the previous syntaxes.

`[phat, pci] = mle(____)` also returns the 95% confidence intervals for the parameters.

Examples

Estimate Parameters of Burr Distribution

Load the sample data.

```
load carbig
```

The variable `MPG` has the miles per gallon for different models of cars.

Draw a histogram of `MPG` data.

```
hist(MPG)
```

The distribution is somewhat right skewed. A symmetric distribution, such as normal distribution, might not be a good fit.

Estimate the parameters of the Burr Type XII distribution for the MPG data.

```
phat = mle(MPG, 'distribution', 'burr')
```

```
phat =
```

```
34.6447    3.7898    3.5722
```

The maximum likelihood estimates for the scale parameter α is 34.6447. The estimates for the two shape parameters c and k of the Burr Type XII distribution are 3.7898 and 3.5722, respectively.

Fit Custom Distribution to Censored Data

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load readmissiontimes
```

The data includes `ReadmissionTime`, which has readmission times for 100 patients. The column vector `Censored` has the censorship information for each patient, where 1 indicates a censored observation, and 0 indicates the exact readmission time is observed. This is simulated data.

Define a custom probability density and cumulative distribution function.

```
custpdf = @(data,lambda) lambda*exp(-lambda*data);
custcdf = @(data,lambda) 1-exp(-lambda*data);
```

Estimate the parameter, `lambda`, of the custom distribution for the censored sample data.

```
phat = mle(ReadmissionTime,'pdf',custpdf,...
'cdf',custcdf,'start',0.05,'Censoring',Censored)
phat
```

```
phat =
```

```
0.1096
```

Fit Custom Log pdf and Survival Function

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load readmissiontimes
```

The data includes `ReadmissionTime`, which has readmission times for 100 patients. The column vector `Censored` has the censorship information for each patient, where 1 indicates a censored observation, and 0 indicates the exact readmission time is observed. This is simulated data.

Define a custom log probability density and survival function.

```
custlogpdf = @(data,lambda,k) log(k) - k*log(lambda) ...
             + (k-1)*log(data) - (data/lambda).^k;
custlogsf = @(data,lambda,k) -(data/lambda).^k;
```

Estimate the parameters, `lambda` and `k`, of the custom distribution for the censored sample data.

```
phat = mle(ReadmissionTime, 'logpdf', custlogpdf, ...
           'logsf', custlogsf, 'start', [1,0.75], 'Censoring', Censored)
```

```
phat =
```

```
    9.2090    1.4223
```

The scale and shape parameters of the custom-defined distribution are 9.2090 and 1.4223, respectively.

Fit Custom Log Negative Likelihood Function

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load readmissiontimes
```

The data includes `ReadmissionTime`, which has readmission times for 100 patients. This is simulated data.

Define a negative log likelihood function.

```
custnloglf=@(lambda,data,cens,freq) -length(data)*log(lambda) ...
+ nansum(lambda*data);
```

Estimate the parameters of the defined distribution.

```
phat = mle(ReadmissionTime, 'nloglf', custnloglf, 'start', 0.05)
phat =
    0.1462
```

Estimate Probability of Success

Generate 100 random observations from a binomial distribution with the number of trials, $n = 20$, and the probability of success, $p = 0.75$.

```
data = binornd(20, 0.75, 100, 1);
```

Estimate the probability of success and 95% confidence limits using the simulated sample data.

```
[phat, pci] = mle(data, 'distribution', 'binomial', ...
                 'alpha', .05, 'ntrials', 20)
phat =
    0.7370
pci =
    0.7171
    0.7562
```

The estimate of probability of success is 0.737 and the lower and upper limits of the 95% confidence interval are 0.7171 and 0.7562. This interval covers the true value used to simulate the data.

Input Arguments

data — Sample data

vector

Sample data `mle` uses to estimate the distribution parameters, specified as a vector.

Data Types: `single` | `double`

dist — Distribution type

'normal' (default) | string

Distribution type to estimate parameters for, specified as one of the following.

Example: 'rician'

pdf — Custom probability density function

function handle

Custom probability distribution function, specified as a function handle created using @.

This custom function accepts the vector `data` and one or more individual distribution parameters as input parameters, and returns a vector of probability density values.

For example, if the name of the custom probability density function is `newpdf`, then you can specify the function handle in `mle` as follows.

Example: `@newpdf`

Data Types: `function_handle`

cdf — Custom cumulative distribution function

function handle

Custom cumulative distribution function, specified as a function handle created using @.

This custom function accepts the vector `data` and one or more individual distribution parameters as input parameters, and returns a vector of cumulative probability values.

You must define `cdf` with `pdf` if data is censored and you use the `'censoring'` name-value pair argument. If `'censoring'` is not present, you do not have to specify `cdf` while using `pdf`.

For example, if the name of the custom cumulative distribution function is `newcdf`, then you can specify the function handle in `mle` as follows.

Example: `@newcdf`

Data Types: `function_handle`

logpdf — Custom log probability density function

function handle

Custom log probability density function, specified as a function handle created using @.

This custom function accepts the vector `data` and one or more individual distribution parameters as input parameters, and returns a vector of log probability values.

For example, if the name of the custom log probability density function is `customlogpdf`, then you can specify the function handle in `mle` as follows.

Example: `@customlogpdf`

Data Types: `function_handle`

logsf — Custom log survival function

`function handle`

Custom log survival function, specified as a function handle created using `@`.

This custom function accepts the vector `data` and one or more individual distribution parameters as input parameters, and returns a vector of log survival probability values.

You must define `logsf` with `logpdf` if data is censored and you use the `'censoring'` name-value pair argument. If `'censoring'` is not present, you do not have to specify `logsf` while using `logpdf`.

For example, if the name of the custom log survival function is `logsurvival`, then you can specify the function handle in `mle` as follows.

Example: `@logsurvival`

Data Types: `function_handle`

nloglf — Custom negative loglikelihood function

`function handle`

Custom negative loglikelihood function, specified as a function handle created using `@`.

This custom function accepts the following input arguments.

<code>params</code>	Vector of distribution parameter values. <code>mle</code> detects the number of parameters from the number of elements in <code>start</code> .
<code>data</code>	Vector of data.
<code>cens</code>	Boolean vector of censored values.
<code>freq</code>	Vector of integer data frequencies.

`nloglf` must accept all four arguments even if you do not use the `'censoring'` or `'frequency'` name-value pair arguments. You can write `'nloglf'` to ignore `cens` and `freq` arguments in that case.

`nloglf` returns a scalar negative loglikelihood value and optionally, a negative loglikelihood gradient vector (see the `'GradObj'` field in `'options'`).

If the name of the custom negative log likelihood function is `negloglik`, then you can specify the function handle in `mle` as follows.

Example: @negloglik

Data Types: function_handle

start — Initial parameter values

scalar | vector

Initial parameter values for the custom functions, specified as a scalar value or a vector of scalar values.

Use **start** when you fit custom distributions, that is, when you use pdf and cdf, logpdf and logsf, or nloglf input arguments.

Example: 0.05

Example: [100,2]

Data Types: single | double

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Example: 'censoring',Cens,'alpha',0.01,'options',Opt specifies that mle estimates the parameters for the distribution of censored data specified by array Cens, computes the 99% confidence limits for the parameter estimates, and uses the algorithm control parameters specified by the structure Opt.

'censoring' — Indicator for censoring

array of 0s (default) | array of 0s and 1s

Indicator for censoring, specified as the comma-separated pair consisting of 'censoring' and a Boolean array of the same size as data. Use 1 for observations that are right censored and 0 for observations that are fully observed. The default is all observations are fully observed.

Censoring is not supported for all distributions.

For example, if the censored data information is in the binary array called Censored, then you can specify the censored data as follows.

Example: 'censoring',Censored

Data Types: `logical`

'frequency' — Frequency of observations

array of 1s (default) | vector of nonnegative integer counts

Frequency of observations, specified as the comma-separated pair consisting of 'frequency' and an array containing nonnegative integer counts, which is the same size as `data`. The default is one observation per element of `data`.

For example, if the observation frequencies are stored in an array named `Freq`, you can specify the frequencies as follows.

Example: `'frequency', Freq`

Data Types: `single` | `double`

'alpha' — Confidence level

0.05 (default) | scalar value in the range (0,1)

Confidence level for the confidence interval of parameter estimates, `pCi`, specified as the comma-separated pair consisting of 'alpha' and a scalar value in the range (0,1). The confidence level of `pCi` is $100(1 - \alpha)\%$. The default is 0.05 for 95% confidence.

For example, for 99% confidence limits, you can specify the confidence level as follows.

Example: `'alpha', 0.01`

Data Types: `single` | `double`

'ntrials' — Number of trials

scalar value | vector

Number of trials for the corresponding element of `data`, specified as the comma-separated pair consisting of 'ntrials' and a scalar or a vector of the same size as `data`.

Applies only to binomial distribution.

Example: `'ntrials', total`

Data Types: `single` | `double`

'options' — Fitting algorithm control parameters

structure

Fitting algorithm control parameters, specified as the comma-separated pair consisting of 'options' and a structure returned by `statset`.

Not applicable to all distributions.

Use the 'options' name-value pair argument to control details of the maximum likelihood optimization when fitting a custom distribution. For parameter names and default values, type `statset('mlecustom')`. You can set the options under a new name and use that in the name-value pair argument. `mle` interprets the following `statset` parameters for custom distribution fitting.

Parameter	Value
'GradObj'	<p>Default is 'off'.</p> <p>'on' or 'off', indicating whether or not <code>fmincon</code> can expect the custom function provided with the <code>nloglf</code> input argument to return the gradient vector of the negative log-likelihood as a second output.</p> <p><code>mle</code> ignores 'GradObj' when using <code>fminsearch</code>.</p>
'DerivStep'	<p>Default is $\text{eps}^{(1/3)}$.</p> <p>The relative difference, specified as a scalar or a vector the same size as <code>start</code>, used in finite difference derivative approximations when using <code>fmincon</code>, and 'GradObj' is 'off'.</p> <p><code>mle</code> ignores 'DerivStep' when using <code>fminsearch</code>.</p>
'FunValCheck'	<p>Default is 'on'.</p> <p>'on' or 'off', indicating whether or not <code>mle</code> should check the values returned by the custom distribution functions for validity.</p> <p>A poor choice of starting point can sometimes cause these functions to return NaNs, infinite values, or out-of-range values if they are written without suitable error checking.</p>
'TolBnd'	<p>Default is $1e-6$.</p> <p>An offset for upper and lower bounds when using <code>fmincon</code>.</p> <p><code>mle</code> treats upper and lower bounds as strict inequalities, that is, open bounds. With <code>fmincon</code>, this is approximated by creating closed bounds inset from the specified upper and lower bounds by <code>TolBnd</code>.</p>

Example: `'options',statset('mlecustom')`

Data Types: `struct`

'lowerbound' — Lower bounds for distribution parameters

$-\infty$ (default) | vector

Lower bounds for distribution parameters, specified as the comma-separated pair consisting of `'lowerbound'` and a vector the same size as `start`.

This name-value pair argument is valid only when you use the `pdf` and `cdf`, `logpdf` and `logcdf`, or `nloglf` input arguments.

Example: `'lowerbound',0`

Data Types: `single` | `double`

'upperbound' — Upper bounds for distribution parameters

∞ (default) | vector

Upper bounds for distribution parameters, specified as the comma-separated pair consisting of `'upperbound'` and a vector the same size as `start`.

This name-value pair argument is valid only when you use the `pdf` and `cdf`, `logpdf` and `logsf`, or `nloglf` input arguments.

Example: `'upperbound',1`

Data Types: `single` | `double`

'optimfun' — Optimization function

`'fminsearch'` (default) | `'fmincon'`

Optimization function `mle` uses in maximizing the likelihood, specified as the comma-separated pair consisting of `'optimfun'` and either `'fminsearch'` or `'fmincon'`.

Default is `'fminsearch'`.

You can only specify `'fmincon'` if Optimization Toolbox is available.

The `'optimfun'` name-value pair argument is valid only when you fit custom distributions, that is, when you use the `pdf` and `cdf`, `logpdf` and `logsf`, or `nloglf` input arguments.

Example: `'optimfun','fmincon'`

Output Arguments

phat — Parameter estimates

scalar value | row vector

Parameter estimates, returned as a scalar value or a row vector.

pci — Confidence intervals for parameter estimates

2-by- k matrix

Confidence intervals for parameter estimates, returned as a column vector or a matrix depending on the number of parameters, hence the size of `phat`.

`pci` is a 2-by- k matrix, where k is the number of parameters `mle` estimates. The first and second rows of the `pci` show the upper and lower confidence limits, respectively.

More About

Survival Function

The survival function is the probability of survival as a function of time. It is also called the survivor function. It gives the probability that the survival time of an individual exceeds a certain value. Since the cumulative distribution function, $F(t)$, is the probability that the survival time is less than or equal to a given point in time, the survival function for a continuous distribution, $S(t)$, is the complement of the cumulative distribution function: $S(t) = 1 - F(t)$.

Tips

When you supply distribution functions, `mle` computes the parameter estimates using an iterative maximization algorithm. With some models and data, a poor choice of starting point can cause `mle` to converge to a local optimum that is not the global maximizer, or to fail to converge entirely. Even in cases for which the log-likelihood is well-behaved near the global maximum, the choice of starting point is often crucial to convergence of the algorithm. In particular, if the initial parameter values are far from the MLEs, underflow in the distribution functions can lead to infinite log-likelihoods.

`fitdist` | `mlecov` | `statset`

mlecov

Asymptotic covariance of maximum likelihood estimators

Syntax

```
acov = mlecov(params,data,'pdf',pdf)
acov = mlecov(params,data,'pdf',pdf,'cdf',cdf)

acov = mlecov(params,data,'logpdf',logpdf)
acov = mlecov(params,data,'logpdf',logpdf,'logsf',logsf)

acov = mlecov(params,data,'nloglf',nloglf)

acov = mlecov( ____,Name,Value)
```

Description

`acov = mlecov(params,data,'pdf',pdf)` returns an approximation to the asymptotic covariance matrix of the maximum likelihood estimators of the parameters for a distribution specified by the custom probability density function `pdf`.

`mlecov` computes a finite difference approximation to the Hessian of the log-likelihood at the maximum likelihood estimates `params`, given the observed `data`, and returns the negative inverse of that Hessian.

`acov = mlecov(params,data,'pdf',pdf,'cdf',cdf)` returns an approximation to the asymptotic covariance matrix of the maximum likelihood estimators of the parameters for a distribution specified by the custom probability density function `pdf` and cumulative distribution function `cdf`.

`acov = mlecov(params,data,'logpdf',logpdf)` returns an approximation to the asymptotic covariance matrix of the maximum likelihood estimators of the parameters for a distribution specified by the custom log probability density function `logpdf`.

`acov = mlecov(params,data,'logpdf',logpdf,'logsf',logsf)` returns an approximation to the asymptotic covariance matrix of the maximum likelihood estimators of the parameters for a distribution specified by the custom log probability density function `logpdf` and custom log survival function `logsf`.

`acov = mlecov(params,data,'nloglf',nloglf)` returns an approximation to the asymptotic covariance matrix of the maximum likelihood estimators of the parameters for a distribution specified by the custom negative loglikelihood function `nloglf`.

`acov = mlecov(____,Name,Value)` also returns an approximation to the asymptotic covariance matrix of the maximum likelihood estimators of the parameters with additional options specified by one or more name-value pair arguments. You can use any of the input arguments in the previous syntaxes.

Examples

Custom Probability Density Function

Load the sample data.

```
load carbig
```

The vector `Weight` shows the weights of 406 cars.

In the MATLAB Editor, create a function that returns the probability density function (pdf) of a lognormal distribution. Save the file in your current working folder as `lognormpdf.m`.

```
function newpdf = lognormpdf(data,mu,sigma)
newpdf = exp((- (log(data)-mu).^2)/(2*sigma^2))./(data*sigma*sqrt(2*pi));
```

Estimate the parameters, `mu` and `sigma`, of the custom-defined distribution.

```
phat = mle(Weight,'pdf',@lognormpdf,'start',[4.5 0.3])
```

```
phat =
```

```
    7.9600    0.2804
```

Compute the approximate covariance matrix of the parameter estimates.

```
acov = mlecov(phat,Weight,'pdf',@lognormpdf)
```

```
acov =
```

```
    1.0e-03 *
```

```
    0.1937    -0.0000
```

```
-0.0000    0.0968
```

Estimate the standard errors of estimates.

```
se = sqrt(diag(acov))
```

```
se =
```

```
0.0139  
0.0098
```

The standard error of the estimates of mu and sigma are 0.0139 and 0.0098, respectively.

Custom Log Probability Density Function

In the MATLAB Editor, create a function that returns the log probability density function of a beta distribution. Save the file in your current working folder as `betalogpdf.m`.

```
function logpdf = betalogpdf(x,a,b)  
logpdf = (a-1)*log(x)+(b-1)*log(1-x)-betaIn(a,b);
```

Generate sample data from a beta distribution with parameters 1.23 and 3.45 and estimate the parameters using the simulated data.

```
rng('default')  
x = betarnd(1.23,3.45,25,1);  
phat = mle(x,'dist','beta')
```

```
phat =
```

```
1.1213    2.7182
```

Compute the approximate covariance matrix of the parameter estimates.

```
acov = mlecov(phat,x,'logpdf',@betalogpdf)
```

```
acov =
```

```
0.0810    0.1646  
0.1646    0.6074
```

Custom Log pdf and Survival Function

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load readmissiontimes
```

The sample data includes `ReadmissionTime`, which has readmission times for 100 patients. The column vector `Censored` has the censorship information for each patient, where 1 indicates a censored observation, and 0 indicates the exact readmission time is observed. This is simulated data.

Define a custom log probability density and survival function.

```
custlogpdf = @(data,lambda,k) log(k) - k*log(lambda) ...
             + (k-1)*log(data) - (data/lambda).^k;
custlogsf = @(data,lambda,k) -(data/lambda).^k;
```

Estimate the parameters, `lambda` and `k`, of the custom distribution for the censored sample data.

```
phat = mle(ReadmissionTime, 'logpdf', custlogpdf, ...
           'logsf', custlogsf, 'start', [1, 0.75], 'Censoring', Censored)
```

```
phat =
```

```
    9.2090    1.4223
```

The scale and shape parameters of the custom-defined distribution are 9.2090 and 1.4223, respectively.

Compute the approximate covariance matrix of the parameter estimates.

```
acov = mlecov(phat, ReadmissionTime, ...
              'logpdf', custlogpdf, 'logsf', custlogsf, 'Censoring', Censored)
```

```
acov =
```

```
    0.5653    0.0102
    0.0102    0.0163
```

Custom Log Negative Likelihood Function

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load readmissiontimes
```

The sample data includes `ReadmissionTime`, which has readmission times for 100 patients. This is simulated data.

Define a negative log likelihood function.

```
custnloglf = @(lambda,data,cens,freq) -length(data)*log(lambda)...
+ nansum(lambda*data);
```

Estimate the parameters of the defined distribution.

```
phat = mle(ReadmissionTime,'nloglf',custnloglf,'start',0.05)
```

```
phat =
```

```
0.1462
```

Compute the variance of the parameter estimate.

```
acov = mlecov(phat,ReadmissionTime,'nloglf',custnloglf)
```

```
acov =
```

```
2.1374e-04
```

Compute the standard error.

```
sqrt(acov)
```

```
ans =
```

```
0.0146
```

Input Arguments

params — Parameter estimates

scalar value | vector

Parameter estimates, specified as a scalar value or vector of scalar values. These parameter estimates must be maximum likelihood estimates. For example, you can specify parameter estimates returned by `mle`.

Data Types: `single` | `double`

data — Sample data

vector

Sample data `mle` uses to estimate the distribution parameters, specified as a vector.

Data Types: `single` | `double`

pdf — Custom probability density function

function handle

Custom probability distribution function, specified as a function handle created using `@`.

This custom function accepts the vector `data` and one or more individual distribution parameters as input parameters, and returns a vector of probability density values.

For example, if the name of the custom probability density function is `newpdf`, then you can specify the function handle in `mlecov` as follows.

Example: `@newpdf`

Data Types: `function_handle`

cdf — Custom cumulative distribution function

function handle

Custom cumulative distribution function, specified as a function handle created using `@`.

This custom function accepts the vector `data` and one or more individual distribution parameters as input parameters, and returns a vector of cumulative probability values.

You must define `cdf` with `pdf` if data is censored and you use the `'censoring'` name-value pair argument. If `'censoring'` is not present, you do not have to specify `cdf` while using `pdf`.

For example, if the name of the custom cumulative distribution function is `newcdf`, then you can specify the function handle in `mlecov` as follows.

Example: `@newcdf`

Data Types: `function_handle`

logpdf — Custom log probability density function

function handle

Custom log probability density function, specified as a function handle created using `@`.

This custom function accepts the vector `data` and one or more individual distribution parameters as input parameters, and returns a vector of log probability values.

For example, if the name of the custom log probability density function is `customlogpdf`, then you can specify the function handle in `mlecov` as follows.

Example: `@customlogpdf`

Data Types: `function_handle`

logsf — Custom log survival function

function handle

Custom log survival function, specified as a function handle created using `@`.

This custom function accepts the vector `data` and one or more individual distribution parameters as input parameters, and returns a vector of log survival probability values.

You must define `logsf` with `logpdf` if data is censored and you use the `'censoring'` name-value pair argument. If `'censoring'` is not present, you do not have to specify `logsf` while using `logpdf`.

For example, if the name of the custom log survival function is `logsurvival`, then you can specify the function handle in `mlecov` as follows.

Example: `@logsurvival`

Data Types: `function_handle`

nloglf — Custom negative loglikelihood function

function handle

Custom negative loglikelihood function, specified as a function handle created using `@`.

This custom function accepts the following input arguments.

<code>params</code>	Vector of distribution parameter values
---------------------	---

<code>data</code>	Vector of data
<code>cens</code>	Boolean vector of censored values
<code>freq</code>	Vector of integer data frequencies

`nloglf` must accept all four arguments even if you do not use the `'censoring'` or `'frequency'` name-value pair arguments. You can write `'nloglf'` to ignore `cens` and `freq` arguments in that case.

`nloglf` returns a scalar negative loglikelihood value and optionally, a negative loglikelihood gradient vector (see the `'GradObj'` field in `'options'`).

If the name of the custom negative log likelihood function is `negloglik`, then you can specify the function handle in `mlecov` as follows.

Example: `@negloglik`

Data Types: `function_handle`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'censoring',cens,'options',opt` specifies that `mlecov` reads the censored data information from the vector `cens` and performs according to the new `options` structure `opt`.

'censoring' — Indicator for censoring

array of 0s (default) | array of 0s and 1s

Indicator for censoring, specified as the comma-separated pair consisting of `'censoring'` and a Boolean array of the same size as `data`. Use 1 for observations that are right censored and 0 for observations that are fully observed. The default is all observations are fully observed.

For censored data, you must use `cdf` with `pdf`, or `logsf` with `logpdf`, or `nloglf` must be defined to account for censoring.

For example, if the censored data information is in the binary array called `Censored`, then you can specify the censored data as follows.

Example: `'censoring', Censored`

Data Types: `logical`

'frequency' — Frequency of observations

array of 1s (default) | vector of nonnegative integer counts

Frequency of observations, specified as the comma-separated pair consisting of `'frequency'` and an array containing nonnegative integer counts, which is the same size as `data`. The default is one observation per element of `data`.

For example, if the observation frequencies are stored in an array named `Freq`, you can specify the frequencies as follows.

Example: `'frequency', Freq`

Data Types: `single` | `double`

'options' — Numerical options

structure

Numerical options for the finite difference Hessian calculation, specified as the comma-separated pair consisting of `'options'` and a structure returned by `statset`.

You can set the options under a new name and use it in the name-value pair argument. The applicable `statset` parameters are as follows.

Parameter	Value
<code>'GradObj'</code>	Default is <code>'off'</code> . <code>'on'</code> or <code>'off'</code> , indicating whether or not the function provided with the <code>nloglf</code> input argument can return the gradient vector of the negative log-likelihood as a second output.
<code>'DerivStep'</code>	Default is <code>eps^(1/4)</code> . Relative step size used in finite difference for Hessian calculations. It can be a scalar, or the same size as <code>params</code> . A smaller value than the default might be appropriate if <code>'GradObj'</code> is <code>'on'</code> .

Example: `'options', statset('mlecov')`

Data Types: `struct`

Output Arguments

acov — Approximation to asymptotic covariance matrix

p-by-*p* matrix

Approximation to asymptotic covariance matrix, returned as a *p*-by-*p* matrix, where *p* is the number of parameters in `params`.

More About

Survival Function

The survival function is the probability of survival as a function of time. It is also called the survivor function. It gives the probability that the survival time of an individual exceeds a certain value. Since the cumulative distribution function, $F(t)$, is the probability that the survival time is less than or equal to a given point in time, the survival function for a continuous distribution, $S(t)$, is the complement of the cumulative distribution function: $S(t) = 1 - F(t)$.

`mle`

mnpdf

Multinomial probability density function

Syntax

```
Y = mnpdf(X,PROB)
```

Description

`Y = mnpdf(X,PROB)` returns the pdf for the multinomial distribution with probabilities `PROB`, evaluated at each row of `X`. `X` and `PROB` are m -by- k matrices or 1-by- k vectors, where k is the number of multinomial bins or categories. Each row of `PROB` must sum to one, and the sample sizes for each observation (rows of `X`) are given by the row sums `sum(X,2)`. `Y` is an m -by- k matrix, and `mnpdf` computes each row of `Y` using the corresponding rows of the inputs, or replicates them if needed.

Examples

Compute the Multinomial Distribution pdf

Compute the pdf of a multinomial distribution with a sample size of $n = 10$. The probabilities are $p = 1/2$ for outcome 1, $p = 1/3$ for outcome 2, and $p = 1/6$ for outcome 3.

```
p = [1/2 1/3 1/6];  
n = 10;  
x1 = 0:n;  
x2 = 0:n;  
[X1,X2] = meshgrid(x1,x2);  
X3 = n-(X1+X2);
```

Compute the pdf of the distribution.

```
Y = mnpdf([X1(:),X2(:),X3(:)],repmat(p,(n+1)^2,1));
```

Plot the pdf on a 3-dimensional figure.

```
Y = reshape(Y,n+1,n+1);  
bar3(Y)
```

```
h = gca;  
h.XTickLabel = [0:n];  
h.YTickLabel = [0:n];  
xlabel('x_1')  
ylabel('x_2')  
zlabel('Probability Mass')  
title('Trinomial Distribution')
```

Note that the visualization does not show x_3 , which is determined by the constraint $x_1 + x_2 + x_3 = n$.

mnrnd

mnrfit

Multinomial logistic regression

Syntax

```
B = mnrfi(X,Y)
B = mnrfi(X,Y,Name,Value)
[B,dev,stats] = mnrfi(____)
```

Description

`B = mnrfi(X,Y)` returns a matrix, `B`, of coefficient estimates for a multinomial logistic regression of the nominal responses in `Y` on the predictors in `X`.

`B = mnrfi(X,Y,Name,Value)` returns a matrix, `B`, of coefficient estimates for a multinomial model fit with additional options specified by one or more `Name,Value` pair arguments.

For example, you can fit a nominal, an ordinal, or a hierarchical model, or change the link function.

`[B,dev,stats] = mnrfi(____)` also returns the deviance of the fit, `dev`, and the structure `stats` for any of the previous input arguments. `stats` contains model statistics such as degrees of freedom, standard errors for coefficient estimates, and residuals.

Examples

Multinomial Regression for Nominal Responses

Fit a multinomial regression for nominal outcomes and interpret the results.

Load the sample data.

```
load fisheriris
```

The column vector, `species`, consists of iris flowers of three different species, `setosa`, `versicolor`, `virginica`. The double matrix `meas` consists of four types of measurements on the flowers, the length and width of sepals and petals in centimeters, respectively.

Define the nominal response variable using a categorical array.

```
sp = categorical(species);
```

Fit a multinomial regression model to predict the species using the measurements.

```
[B,dev,stats] = mnrfit(meas,sp);
```

```
B
```

```
B =
```

```
13.3860    15.4492
 2.4623     1.8196
 5.2948     2.5700
-7.4916    -4.3714
-8.9322    -7.6467
```

This is a nominal model for the response category relative risks, with separate slopes on all four predictors, that is, each category of `meas`. The first row of `B` contains the intercept terms for the relative risk of the first two response categories, `setosa` and `versicolor` versus the reference category, `virginica`. The last four rows contain the slopes for the models for the first two categories. `mnrfit` accepts the third category as the reference category.

The models for the relative risk of an iris flower being a `setosa` versus a `virginica`, and the relative risk of an iris flower being a `versicolor` species versus a `virginica` species are respectively

$$\ln\left(\frac{\pi_{setosa}}{\pi_{virginica}}\right) = 13.38 + 2.46X_1 + 5.29X_2 - 7.49X_3 - 8.93X_4$$

and

$$\ln\left(\frac{\pi_{versicolor}}{\pi_{virginica}}\right) = 15.45 + 1.82X_1 + 2.57X_2 - 4.37X_3 - 7.65X_4$$

The coefficients express the effects of the predictor variables on the relative risk or the log odds of being in one category versus the reference category.

For example, the estimated coefficient 2.46 indicates that the probability of being species 1 (setosa) compared to the probability of being species 3 (virginica) (the relative risk of being a setosa versus a virginica) increases $\exp(2.46)$ times for each unit increase in X_1 , the first measurement, given all else equal.

In terms of log odds, you can say that the relative log odds of being a setosa versus a virginica increases 2.46 times with a one-unit increase in X_1 given all else is equal.

Check the statistical significance of the model coefficients.

```
stats.p
```

```
ans =
```

```

0.2457    0.0031
0.4543    0.1048
0.0773    0.0815
0.0258    0.0007
0.1856    0.0002
```

The P -value of 0.0258 indicates that the third measure is significant on the relative risk of being a setosa versus a virginica (species 1 compared to species 3). The P -values of 0.0007 and 0.0002 indicate that the third and fourth measures are significant on the relative risk of being a versicolor versus a virginica (species 2 compared to species 3).

Request the standard errors of coefficient estimates.

```

Multinomial Regression for Ordinal Responses

Fit a multinomial regression model for categorical responses with natural ordering among categories.

Load the sample data and define the predictor variables.

```
load carbig  
X = [Acceleration Displacement Horsepower Weight];
```

The predictor variables are the acceleration, engine displacement, horsepower, and weight of the cars. The response variable is miles per gallon (mpg).

Create an ordinal response variable categorizing MPG into four levels from 9 to 48 mpg by labeling the response values in the range 9-19 as 1, 20-29 as 2, 30-39 as 3, and 40-48 as 4.

```
miles = ordinal(MPG,{'1','2','3','4'},[],[9,19,29,39,48]);
```

Fit an ordinal response model for the response variable miles.

```
[B,dev,stats] = mnrfits(X,miles,'model','ordinal');
B
```

```
B =
```

```
-16.6895
-11.7208
-8.0606
 0.1048
 0.0103
 0.0645
 0.0017
```

The first three elements of **B** are the intercept terms for the models, and the last four elements of **B** are the coefficients of the covariates, assumed common across all categories. This model corresponds to *parallel regression*, which is also called the *proportional odds* model, where there is a different intercept but common slopes among categories. You can specify this using the 'interactions', 'off' name-value pair argument, which is the default for ordinal models.

```
[B(1:3)'; repmat(B(4:end),1,3)]
```

```
ans =
```

```
-16.6895  -11.7208  -8.0606
  0.1048   0.1048   0.1048
  0.0103   0.0103   0.0103
  0.0645   0.0645   0.0645
  0.0017   0.0017   0.0017
```

The link function in the model is logit ('link', 'logit'), which is the default for an ordinal model. The coefficients express the relative risk or log odds of the mpg of a car being less than or equal to one value versus greater than that value.

The proportional odds model in this example is

$$\ln \left(\frac{P(\text{mpg} \leq 19)}{P(\text{mpg} > 19)} \right) = -16.6895 + 0.1048X_A + 0.0103X_D + 0.0645X_H + 0.0017X_W$$

$$\ln \left(\frac{P(\text{mpg} \leq 29)}{P(\text{mpg} > 29)} \right) = -11.7208 + 0.1048X_A + 0.0103X_D + 0.0645X_H + 0.0017X_W$$

$$\ln \left(\frac{P(\text{mpg} \leq 39)}{P(\text{mpg} > 39)} \right) = -8.0606 + 0.1048X_A + 0.0103X_D + 0.0645X_H + 0.0017X_W$$

For example, the coefficient estimate of 0.1048 indicates that a unit change in acceleration would impact the odds of the mpg of a car being less than or equal to 19 versus more than 19, or being less than or equal to 29 versus greater than 29, or being less than or equal to 39 versus greater than 39, by a factor of $\exp(0.1048)$ given all else is equal.

Assess the significance of the coefficients.

```
stats.p
```

```
ans =
```

```
0.0000  
0.0000  
0.0000  
0.1899  
0.0350  
0.0000  
0.0118
```

The P -values of 0.035, 0.0000, and 0.0118 for engine displacement, horsepower, and weight of a car, respectively, indicate that these factors are significant on the odds of mpg of a car being less than or equal to a certain value versus being greater than that value.

Hierarchical Multinomial Regression Model

Fit a hierarchical multinomial regression model.

Navigate to the folder containing sample data.

```
cd(matlabroot)
```

```
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load smoking
```

The data set `smoking` contains five variables: sex, age, weight, and systolic and diastolic blood pressure. Sex is a binary variable where 1 indicates female patients, and 0 indicates male patients.

Define the response variable.

```
Y = categorical(smoking.Smoker);
```

The data in `Smoker` has four categories:

- 0: Nonsmoker, 0 cigarettes a day
- 1: Smoker, 1–5 cigarettes a day
- 2: Smoker, 6–10 cigarettes a day
- 3: Smoker, 11 or more cigarettes a day

Define the predictor variables.

```
X = [smoking.Sex smoking.Age smoking.Weight...
     smoking.SystolicBP smoking.DiastolicBP];
```

Fit a hierarchical multinomial model.

```
[B,dev,stats] = mnrfits(X,Y,'model','hierarchical');
B
```

```
B =
```

```
43.8148    5.9571   44.0712
 1.8709   -0.0230    0.0662
 0.0188    0.0625    0.1335
 0.0046   -0.0072   -0.0130
-0.2170    0.0416   -0.0324
-0.2273   -0.1449   -0.4824
```

The first column of `B` includes the intercept and the coefficient estimates for the model of the relative risk of being a nonsmoker versus a smoker. The second column includes the parameter estimates for modeling the log odds of smoking 1–5 cigarettes a day versus

more than five cigarettes a day given that a person is a smoker. Finally, the third column includes the parameter estimates for modeling the log odds of a person smoking 6–10 cigarettes a day versus more than 10 cigarettes a day given he/she smokes more than 5 cigarettes a day.

The coefficients differ across categories. You can specify this using the 'interactions', 'on' name-value pair argument, which is the default for hierarchical models. So, the model in this example is

$$\ln\left(\frac{P(y=0)}{P(y>0)}\right) = 43.8148 + 1.8709X_S + 0.0188X_A + 0.0046X_W - 0.2170X_{SBP} - 0.2273X_{DBP}$$

$$\ln\left(\frac{P(1 \leq y \leq 5)}{P(y > 5)}\right) = 5.9571 - 0.0230X_S + 0.0625X_A + 0.0072X_W + 0.0416X_{SBP} - 0.1449X_{DBP}$$

$$\ln\left(\frac{P(6 \leq y \leq 10)}{P(y > 10)}\right) = 44.0712 + 0.0662X_S + 0.1335X_A - 0.0130X_W - 0.0324X_{SBP} - 0.4824X_{DBP}$$

For example, the coefficient estimate of 1.8709 indicates that the likelihood of being a smoker versus a nonsmoker increases by $\exp(1.8709) = 6.49$ times as the gender changes from female to male given everything else held constant.

Assess the statistical significance of the terms.

```
stats.p
```

```
ans =
```

0.0000	0.5363	0.2149
0.3549	0.9912	0.9835
0.6850	0.2676	0.2313
0.9032	0.8523	0.8514
0.0009	0.5187	0.8165
0.0004	0.0483	0.0545

Sex, age, or weight don't appear significant on any level. The p -values of 0.0009 and 0.0004 indicate that both types of blood pressure are significant on the relative risk of a person being a smoker versus a nonsmoker. The p -value of 0.0483 shows that only

diastolic blood pressure is significant on the odds of a person smoking 0–5 cigarettes a day versus more than 5 cigarettes a day. Similarly, the p -value of 0.0545 indicates that diastolic blood pressure is significant on the odds of a person smoking 6–10 cigarettes a day versus more than 10 cigarettes a day.

Check if any nonsignificant factors are correlated to each other. Draw a scatterplot of age versus weight grouped by sex.

```
figure()
gscatter(smoking.Age,smoking.Weight,smoking.Sex)
legend('Male','Female')
xlabel('Age')
ylabel('Weight')
```

The range of weight of an individual seems to differ according to gender. Age does not seem to have any obvious correlation with sex or weight. Age is insignificant and weight seems to be correlated with sex, so you can eliminate both and reconstruct the model.

Eliminate age and weight from the model and fit a hierarchical model with sex, systolic blood pressure, and diastolic blood pressure as the predictor variables.

```
X = double([smoking.Sex smoking.SystolicBP...
smoking.DiastolicBP]);
[B,dev,stats] = mnrfit(X,Y,'model','hierarchical');
B
```

```
B =
```

```
    44.8456    5.3230    25.0248
     1.6045    0.2330    0.4982
    -0.2161    0.0497    0.0179
    -0.2222   -0.1358   -0.3092
```

Here, a coefficient estimate of 1.6045 indicates that the likelihood of being a nonsmoker versus a smoker increases by $\exp(1.6045) = 4.97$ times as sex changes from male to female. A unit increase in the systolic blood pressure indicates an $\exp(-.2161) = 0.8056$ decrease in the likelihood of being a nonsmoker versus a smoker. Similarly, a unit increase in the diastolic blood pressure indicates an $\exp(-.2222) = 0.8007$ decrease in the relative rate of being a nonsmoker versus being a smoker.

Assess the statistical significance of the terms.

```
stats.p
```

```
ans =
```

```
    0.0000    0.4715    0.2325
    0.0210    0.7488    0.6362
    0.0010    0.4107    0.8899
    0.0003    0.0483    0.0718
```

The p -values of 0.0210, 0.0010, and 0.0003 indicate that the terms sex and both types of blood pressure are significant on the relative risk of a person being a nonsmoker versus a smoker, given the other terms in the model. Based on the p -value of 0.0483, diastolic blood pressure appears significant on the relative risk of a person smoking 1–5 cigarettes versus more than 5 cigarettes a day, given that this person is a smoker. Because none of the p -values on the third column are less than 0.05, you can say that none of the

variables are statistically significant on the relative risk of a person smoking from 6–10 cigarettes versus more than 10 cigarettes, given that this person smokes more than 5 cigarettes a day.

Input Arguments

X — Observations on predictor variables

n-by-*p* matrix

Observations on predictor variables, specified as an *n*-by-*p* matrix. *X* contains *n* observations for *p* predictors.

Note: `mnrfit` automatically includes a constant term (intercept) in all models. Do not include a column of 1s in *X*.

Data Types: `single` | `double`

Y — Response values

n-by-*k* matrix | *n*-by-1 column vector

Response values, specified as a column vector or a matrix. *Y* can be one of the following:

- An *n*-by-*k* matrix, where $Y(i,j)$ is the number of outcomes of the multinomial category *j* for the predictor combinations given by $X(i,:)$. In this case, the number of observations are made at each predictor combination.
- An *n*-by-1 column vector of scalar integers from 1 to *k* indicating the value of the response for each observation. In this case, all sample sizes are 1.
- An *n*-by-1 categorical array indicating the nominal or ordinal value of the response for each observation. In this case, all sample sizes are 1.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: 'Model', 'ordinal', 'Link', 'probit' specifies an ordinal model with a probit link function.

'Model' — Type of model to fit

'nominal' (default) | 'ordinal' | 'hierarchical'

Type of model to fit, specified as the comma-separated pair consisting of 'Model' and one of the following.

'nominal'	Default. There is no ordering among the response categories.
'ordinal'	There is a natural ordering among the response categories.
'hierarchical'	The choice of response category is sequential/nested.

Example: 'Model', 'ordinal'

'Interactions' — Indicator for interaction between multinomial categories and coefficients

'on' | 'off'

Indicator for an interaction between the multinomial categories and coefficients, specified as the comma-separated pair consisting of 'Interactions' and one of the following.

'on'	Default for nominal and hierarchical models. Fit a model with different coefficients across categories.
'off'	Default for ordinal models. Fit a model with a common set of coefficients for the predictor variables, across all multinomial categories. This is often described as <i>parallel regression</i> or the <i>proportional odds model</i> .

In all cases, the model has different intercepts across categories. The choice of 'Interactions' determines the dimensions of the output array B.

Example: 'Interactions', 'off'

Data Types: logical

'Link' — Link function

'logit' (default) | 'probit' | 'comloglog' | 'loglog'

Link function to use for ordinal and hierarchical models, specified as the comma-separated pair consisting of 'Link' and one of the following.

'logit'	Default. $f(\gamma) = \ln(\gamma/(1-\gamma))$
'probit'	$f(\gamma) = \Phi^{-1}(\gamma)$ — error term is normally distributed with variance 1
'comploglog'	Complementary log-log $f(\gamma) = \ln(-\ln(1-\gamma))$
'loglog'	$f(\gamma) = \ln(-\ln(\gamma))$

The link function defines the relationship between response probabilities and the linear combination of predictors, $X\beta$. The link functions might be functions of cumulative or conditional probabilities based on whether the model is for an ordinal or a sequential/nested response. For example, for an ordinal model, γ represents the cumulative probability of being in categories 1 to j and the model with a logit link function as follows:

$$\ln\left(\frac{\gamma}{1-\gamma}\right) = \ln\left(\frac{\pi_1 + \pi_2 + \dots + \pi_j}{\pi_{j+1} + \dots + \pi_k}\right) = \beta_{0j} + \beta_1 X_1 + \beta_2 X_2 + \dots + \beta_p X_p,$$

where k represents the last category.

You cannot specify the 'Link' parameter for nominal models; these always use a multinomial logit link,

$$\ln\left(\frac{\pi_j}{\pi_r}\right) = \beta_{j0} + \beta_{j1} X_{j1} + \beta_{j2} X_{j2} + \dots + \beta_{jp} X_{jp}, \quad j = 1, \dots, k-1,$$

where π stands for a categorical probability, and r corresponds to the reference category. `mnrfit` uses the last category as the reference category for nominal models.

Example: 'Link', 'loglog'

'EstDisp' — Indicator for estimating dispersion parameter

'off' (default) | 'on'

Indicator for estimating a dispersion parameter, specified as the comma-separated pair consisting of 'EstDisp' and one of the following.

'off'	Default. Use the theoretical dispersion value of 1.
'on'	Estimate a dispersion parameter for the multinomial distribution in computing standard errors.

Example: 'EstDisp', 'on'

Output Arguments

B — Coefficient estimates

vector | matrix

Coefficient estimates for a multinomial logistic regression of the responses in *Y*, returned as a vector or a matrix.

- If 'Interaction' is 'off', then **B** is a $k - 1 + p$ vector. The first $k - 1$ rows of **B** correspond to the intercept terms, one for each $k - 1$ multinomial categories, and the remaining p rows correspond to the predictor coefficients, which are common for all of the first $k - 1$ categories.
- If 'Interaction' is 'on', then **B** is a $(p + 1)$ -by- $(k - 1)$ matrix. Each column of **B** corresponds to the estimated intercept term and predictor coefficients, one for each of the first $k - 1$ multinomial categories.

The estimates for the k th category are taken to be zero as `mnrfit` takes the last category as the reference category.

dev — Deviance of the fit

scalar value

Deviance of the fit, returned as a scalar value. It is twice the difference between the maximum achievable log likelihood and that attained under the fitted model. This corresponds to the sum of deviance residuals,

$$dev = 2 * \sum_i^n \sum_j^k y_{ij} * \log \left(\frac{y_{ij}}{\pi_{ij} * m_i} \right) = \sum_i^n rd_i,$$

where rd_i are the deviance residuals. For deviance residuals see `stats`.

stats — Model statistics

structure

Model statistics, returned as a structure that contains the following fields.

beta	The coefficient estimates. These are the same as B .
dfe	Degrees of freedom for error <ul style="list-style-type: none"> • If 'Interactions' is 'off', then degrees of freedom is $n*(k - 1) - (k - 1 + p)$. • If 'Interactions' is 'on', then degrees of freedom is $(n - p + 1)*(k - 1)$.
sfit	Estimated dispersion parameter.
s	Theoretical or estimated dispersion parameter. <ul style="list-style-type: none"> • If 'Estdisp' is 'off', then s is the theoretical dispersion parameter, 1. • If 'Estdisp' is 'on', then s is equal to the estimated dispersion parameter, sfit.
estdisp	Indicator for a theoretical or estimated dispersion parameter.
se	Standard errors of coefficient estimates, B .
coeffcorr	Estimated correlation matrix for B .
covb	Estimated covariance matrix for B .
t	<i>t</i> statistics for B .
p	<i>p</i> -values for B .
resid	Raw residuals. Observed minus fitted values, $r_{ij} = y_{ij} - \hat{\pi}_{ij} * m_i, \quad \begin{cases} i = 1, \dots, n \\ j = 1, \dots, k \end{cases}$ <p>where π_{ij} is the categorical, cumulative or conditional probability, and m_i is the corresponding sample size.</p>
residp	Pearson residuals, which are the raw residuals scaled by the estimated standard deviation:

	$rp_{ij} = \frac{r_{ij}}{\hat{\sigma}_{ij}} = \frac{y_{ij} - \hat{\pi}_{ij} * m_i}{\sqrt{\hat{\pi}_{ij} * (1 - \hat{\pi}_{ij}) * m_i}}, \quad \begin{cases} i = 1, \dots, n \\ j = 1, \dots, k \end{cases}$ <p>where π_{ij} is the categorical, cumulative, or conditional probability, and m_i is the corresponding sample size.</p>
residd	<p>Deviance residuals:</p> $rd_i = 2 * \sum_j^k y_{ij} * \log \left(\frac{y_{ij}}{\pi_{ij} * m_i} \right), \quad i = 1, \dots, n.$ <p>where π_{ij} is the categorical, cumulative, or conditional probability, and m_i is the corresponding sample size.</p>

mnrnd

Multinomial random numbers

Syntax

```
r = mnrnd(n,p)
R = mnrnd(n,p,m)
R = mnrnd(N,P)
```

Description

`r = mnrnd(n,p)` returns random values `r` from the multinomial distribution with parameters `n` and `p`. `n` is a positive integer specifying the number of trials (sample size) for each multinomial outcome. `p` is a 1-by- k vector of multinomial probabilities, where k is the number of multinomial bins or categories. `p` must sum to one. (If `p` does not sum to one, `r` consists entirely of NaN values.) `r` is a 1-by- k vector, containing counts for each of the k multinomial bins.

`R = mnrnd(n,p,m)` returns `m` random vectors from the multinomial distribution with parameters `n` and `p`. `R` is a m -by- k matrix, where k is the number of multinomial bins or categories. Each row of `R` corresponds to one multinomial outcome.

`R = mnrnd(N,P)` generates outcomes from different multinomial distributions. `P` is a m -by- k matrix, where k is the number of multinomial bins or categories and each of the m rows contains a different set of multinomial probabilities. Each row of `P` must sum to one. (If any row of `P` does not sum to one, the corresponding row of `R` consists entirely of NaN values.) `N` is a m -by-1 vector of positive integers or a single positive integer (replicated by `mnrnd` to a m -by-1 vector). `R` is a m -by- k matrix. Each row of `R` is generated using the corresponding rows of `N` and `P`.

Examples

Generate 2 random vectors with the same probabilities:

```
n = 1e3;
```

```
p = [0.2,0.3,0.5];
R = mnrnd(n,p,2)
R =
    215    282    503
    194    303    503
```

Generate 2 random vectors with different probabilities:

```
n = 1e3;
P = [0.2, 0.3, 0.5; ...
     0.3, 0.4, 0.3];
R = mnrnd(n,P)
R =
    186    290    524
    290    389    321
```

yhat = mnrvl(B,X,ssize)
[yhat,dlow,dhi] = mnrvl(B,X,ssize,stats)
[yhat,dlow,dhi] = mnrvl(B,X,ssize,stats,Name,Value)
```

Description

`pihat = mnrvl(B,X)` returns the predicted probabilities for the multinomial logistic regression model with predictors, `X`, and the coefficient estimates, `B`.

`pihat` is an n -by- k matrix of predicted probabilities for each multinomial category. `B` is the vector or matrix that contains the coefficient estimates returned by `mnrfit`. And `X` is an n -by- p matrix which contains n observations for p predictors.

Note: `mnrval` automatically includes a constant term in all models. Do not enter a column of 1s in `X`.

`[pihat,dlow,dhi] = mnrvl(B,X,stats)` also returns 95% error bounds on the predicted probabilities, `pihat`, using the statistics in the structure, `stats`, returned by `mnrfit`.

The lower and upper confidence bounds for `pihat` are `pihat` minus `dlow` and `pihat` plus `dhi`, respectively. Confidence bounds are nonsimultaneous and only apply to the fitted curve, not to new observations.

`[pihat,dlow,dhi] = mnrvl(B,X,stats,Name,Value)` returns the predicted probabilities and 95% error bounds on the predicted probabilities `pihat`, with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify the model type, link function, and the type of probabilities to return.

`yhat = mnrval(B,X,ssize)` returns the predicted category counts for sample sizes, `ssize`.

`[yhat,dlow,dhi] = mnrval(B,X,ssize,stats)` also computes 95% error bounds on the predicted counts `yhat`, using the statistics in the structure, `stats`, returned by `mnrfit`.

The lower and upper confidence bounds for `yhat` are `yhat` minus `dlo` and `yhat` plus `dhi`, respectively. Confidence bounds are nonsimultaneous and they apply to the fitted curve, not to new observations.

`[yhat,dlow,dhi] = mnrval(B,X,ssize,stats,Name,Value)` returns the predicted category counts and 95% error bounds on the predicted counts `yhat`, with additional options specified by one or more `Name, Value` pair arguments.

For example, you can specify the model type, link function, and the type of predicted counts to return.

Examples

Estimate Category Probabilities for Nominal Responses

Fit a multinomial regression for nominal outcomes and estimate the category probabilities.

Load the sample data.

```
load('fisheriris.mat')
```

The column vector, `species`, consists of iris flowers of three different species, `setosa`, `versicolor`, `virginica`. The double matrix `meas` consists of four types of measurements on the flowers, the length and width of sepals and petals in centimeters, respectively.

Define the nominal response variable.

```
sp = nominal(species);
sp = double(sp);
```

Now in `sp`, 1, 2, and 3 indicate the species `setosa`, `versicolor`, and `virginica`, respectively.

Fit a nominal model to estimate the species using the flower measurements as the predictor variables.

```
[B,dev,stats] = mnrfits(meas,sp);
```

Estimate the probability of being a certain kind of species for an iris flower having the measurements (6.2, 3.7, 5.8, 0.2).

```
x = [6.2, 3.7, 5.8, 0.2];  
pihat = mnrvfit(B,x);  
pihat
```

```
pihat =  
  
    0.0017    0.9982    0.0001
```

The probability of an iris flower having the measurements (6.2, 3.7, 5.8, 0.2) being a setosa is 0.0017, a versicolor is 0.9982, and a virginica is 0.0001.

Estimate Upper and Lower Error Bounds for Probability Estimates of Ordinal Responses

Fit a multinomial regression model for categorical responses with natural ordering among categories. Then estimate the upper and lower confidence bounds for the category probability estimates.

Load the sample data and define the predictor variables.

```
load('carbig.mat')  
X = [Acceleration Displacement Horsepower Weight];
```

The predictor variables are the acceleration, engine displacement, horsepower, and the weight of the cars. The response variable is miles per gallon (MPG).

Create an ordinal response variable categorizing MPG into four levels from 9 to 48 mpg.

```
miles = ordinal(MPG,{'1','2','3','4'},[],[9,19,29,39,48]);  
miles = double(miles);
```

Now in miles, 1 indicates the cars with miles per gallon from 9 to 19, and 2 indicates the cars with miles per gallon from 20 to 29. Similarly, 3 and 4 indicate the cars with miles per gallon from 30 to 39 and 40 to 48, respectively.

Fit a multinomial regression model for the response variable `miles`. For an ordinal model, the default `'link'` is `logit` and the default `'interactions'` is `'off'`.

```
[B,dev,stats] = mnrfit(X,miles,'model','ordinal');
```

Compute the probability estimates and 95% error bounds for probability confidence intervals for miles per gallon of a car with $x = (12, 113, 110, 2670)$.

```
x = [12,113,110,2670];
[pihat,dlow,hi] = mnrval(B,x,stats,'model','ordinal');
pihat
```

```
pihat =
```

```
    0.0615    0.8426    0.0932    0.0027
```

Calculate the confidence bounds for the category probability estimates.

```
LL = pihat - dlow;
UL = pihat + hi;
[LL;UL]
```

```
ans =
```

```
    0.0073    0.7829    0.0283   -0.0003
    0.1157    0.9022    0.1580    0.0057
```

Estimate Category Counts and Error Bounds for Nominal Responses

Fit a multinomial regression for nominal outcomes and estimate the category counts.

Load the sample data.

```
load('fisheriris.mat')
```

The column vector, `species`, consists of iris flowers of three different species, `setosa`, `versicolor`, and `virginica`. The double matrix `meas` consists of four types of measurements on the flowers, the length and width of sepals and petals in centimeters, respectively.

Define the nominal response variable.

```
sp = nominal(species);
sp = double(sp);
```

Now in `sp`, 1, 2, and 3 indicate the species `setosa`, `versicolor`, and `virginica`, respectively.

Fit a nominal model to estimate the species based on the flower measurements.

```
[B,dev,stats] = mnrfits(meas,sp);
```

Estimate the number in each species category for a sample of 100 iris flowers all with the measurements (6.2, 3.7, 5.8, 0.2).

```
x = [6.2,3.7,5.8,0.2];  
yhat = mnrvl(B,x,18)
```

```
yhat =
```

```
0.0314    17.9671    0.0016
```

Estimate the error bounds for the counts.

```
[yhat,dlow,hi] = mnrvl(B,x,18,stats,'model','nominal');
```

Calculate the confidence bounds for the category probability estimates.

```
LL = yhat - dlow;  
UL = yhat + hi;  
[LL;UL]
```

```
ans =
```

```
-0.7084    17.2272   -0.0115  
0.7711    18.7069    0.0146
```

Plot the Count Estimates

Create sample data with one predictor variable and a categorical response variable with three categories.

```
x = [-3 -2 -1 0 1 2 3]';  
Y = [1 11 13; 2 9 14; 6 14 5; 5 10 10; ...  
     5 14 6; 7 13 5; 8 11 6];  
[Y x]
```

```
ans =
```

```
1    11    13    -3  
2     9    14    -2  
6    14     5    -1  
5    10    10     0  
5    14     6     1  
7    13     5     2
```

8 11 6 3

There are observations on seven different values of the predictor variable x . The response variable Y has three categories and the data shows how many of the 25 individuals are in each category of Y for each observation of x . For example, when x is -3, 1 of 25 individuals is observed in category 1, 11 observed in category 2, and 13 observed in category 3. Similarly, when x is 1, 5 of the individuals are observed in category 1, 14 are observed in category 2, and 6 are observed in category 3.

Plot the number in each category versus the x values, on a stacked bar graph.

```
bar(x,Y, 'stacked');  
ylim([0 25]);
```

Fit a nominal model for the individual response category probabilities, with separate slopes on the single predictor variable, x , for each category.

```
betaHatNom = mnrfi(x,Y,'model','nominal',...  
    'interactions','on')
```

```
betaHatNom =
```

```
-0.6028    0.3832  
 0.4068    0.1948
```

The first row of `betaHatOrd` contains the intercept terms for the first two response categories. The second row contains the slopes. `mnrfi` accepts the third category as the reference category and hence assumes the coefficients for the third category are zero.

Compute the predicted probabilities for the three response categories.

```
xx = linspace(-4,4)';  
piHatNom = mnrv(betaHatNom,xx,'model','nominal',...  
    'interactions','on');
```

The probability of being in the third category is simply $1 - P(Y = 1) - P(Y = 2)$.

Plot the estimated cumulative number in each category on the bar graph.

```
line(xx,cumsum(25*piHatNom,2),'LineWidth',2);
```

The cumulative probability for the third category is always 1.

Now, fit a "parallel" ordinal model for the cumulative response category probabilities, with a common slope on the single predictor variable, x , across all categories:

```
betaHatOrd = mnrfits(x,Y,'model','ordinal',...
    'interactions','off')
```

```
betaHatOrd =
```

```
-1.5001
 0.7266
 0.2642
```

The first two elements of `betaHatOrd` are the intercept terms for the first two response categories. The last element of `betaHatOrd` is the common slope.

Compute the predicted cumulative probabilities for the first two response categories. The cumulative probability for the third category is always 1.

```
piHatOrd = mnrvl(betaHatOrd,xx,'type','cumulative',...  
                'model','ordinal','interactions','off');
```

Plot the estimated cumulative number on the bar graph of the observed cumulative number.

```
figure()  
bar(x,cumsum(Y,2),'grouped');  
ylim([0 25]);  
line(xx,25*piHatOrd,'LineWidth',2);
```

Input Arguments

B — Coefficient estimates

vector or matrix returned by `mnrfit`

Coefficient estimates for the multinomial logistic regression model, specified as a vector or matrix returned by `mnrfit`. It is a vector or matrix depending on the model and interactions.

Example: `B = mnrfit(X,y); pihat = mnrval(B,X)`

Data Types: `single` | `double`

X — Sample data

matrix

Sample data on predictors, specified as an n -by- p . X contains n observations for p predictors.

Note: `mnrval` automatically includes a constant term in all models. Do not enter a column of 1s in X .

Example: `pihat = mnrval(B,X)`

Data Types: `single` | `double`

stats — Model statisticsstructure returned by `mnrfit`

Model statistics, specified as a structure returned by `mnrfit`. You must use the `stats` input argument in `mnrval` to compute the lower and upper error bounds on the category probabilities and counts.

Example: `[B,dev,stats] = mnrfit(X,y);[pihat,dlo,dhi] = mnrval(B,X,stats)`

ssize — Sample sizes

column vector of positive integers

Sample sizes to return the number of items in response categories for each combination of the predictor variables, specified as an n -by-1 column vector of positive integers.

For example, for a response variable having three categories, if an observation of the number of individuals in each category is y_1 , y_2 , and y_3 , respectively, then the sample size, m , for that observation is $m = y_1 + y_2 + y_3$.

If the sample sizes for n observations are in vector `sample`, then you can enter the sample sizes as follows.

Example: `yhat = mnrval(B,X,sample)`

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'model', 'ordinal', 'link', 'probit', 'type', 'cumulative'` specifies that `mnrval` returns the estimates for cumulative probabilities for an ordinal model with a probit link function.

'model' — Type of multinomial model

`'nominal'` (default) | `'ordinal'` | `'hierarchical'`

Type of multinomial model fit by `mnrfit`, specified as the comma-separated pair consisting of `'model'` and one of the following.

<code>'nominal'</code>	Default. Specify when there is no ordering among the response categories.
<code>'ordinal'</code>	Specify when there is a natural ordering among the response categories.
<code>'hierarchical'</code>	Specify when the choice of response category is sequential.

Example: `'model', 'ordinal'`

'interactions' — Indicator for interaction between multinomial categories and coefficients

`'on'` | `'off'`

Indicator for an interaction between the multinomial categories and coefficients in the model fit by `mnrfit`, specified as the comma-separated pair consisting of `'interactions'` and one of the following.

<code>'on'</code>	Default for nominal and hierarchical models. Specify to fit a model with different intercepts and coefficients across categories.
<code>'off'</code>	Default for ordinal models. Specify to fit a model with different intercepts, but a common set of coefficients for the predictor variables, across all multinomial categories. This is often described as <i>parallel regression</i> or <i>proportional odds model</i> .

Example: `'interactions', 'off'`

Data Types: logical

'link' — Link function

'logit' (default) | 'probit' | 'comploglog' | 'loglog'

Link function `mnrfit` uses for ordinal and hierarchical models, specified as the comma-separated pair consisting of `'link'` and one of the following.

'logit'	Default. $f(\gamma) = \ln(\gamma/(1 - \gamma))$
'probit'	$f(\gamma) = \Phi^{-1}(\gamma)$ — error term is normally distributed with variance 1
'comploglog'	Complementary log-log $f(\gamma) = \ln(-\ln(1 - \gamma))$
'loglog'	$f(\gamma) = \ln(-\ln(\gamma))$

The link function defines the relationship between response probabilities and the linear combination of predictors, $X\beta$.

γ might be cumulative or conditional probabilities based on whether the model is for an ordinal or a sequential/nested response.

You cannot specify the `'link'` parameter for nominal models; these always use a multinomial logit link,

$$\ln\left(\frac{\pi_j}{\pi_r}\right) = \beta_{j0} + \beta_{j1}X_{j1} + \beta_{j2}X_{j2} + \cdots + \beta_{jp}X_{jp}, \quad j = 1, \dots, k-1,$$

where π stands for a categorical probability, and r corresponds to the reference category, k is the total number of response categories, p is the number of predictor variables. `mnrfit` uses the last category as the reference category for nominal models.

Example: `'link', 'loglog'`

'type' — Type of probabilities or counts to estimate

'category' (default) | 'cumulative' | 'conditional'

Type of probabilities or counts to estimate, specified as the comma-separated pair including `'type'` and one of the following.

'category'	Default. Specify to return predictions and error bounds for the probabilities (or counts) of the k multinomial categories.
'cumulative'	Specify to return predictions and confidence bounds for the cumulative probabilities (or counts) of the first $k - 1$ multinomial categories, as an n -by- $(k - 1)$ matrix. The predicted cumulative probability for the k th category is always 1.
'conditional'	Specify to return predictions and error bounds in terms of the first $k - 1$ conditional category probabilities (counts), i.e., the probability (count) for category j , given an outcome in category j or higher. When 'type' is 'conditional', and you supply the sample size argument <code>ssize</code> , the predicted counts at each row of X are conditioned on the corresponding element of <code>ssize</code> , across all categories.

Example: 'type','cumulative'

'confidence' — Confidence level

0.95 (default) | Scalar value in the range (0,1)

Confidence level for the error bounds, specified as the comma-separated pair consisting of 'confidence' and a scalar value in the range (0,1).

For example, for 99% error bounds, you can specify the confidence as follows:

Example: 'confidence',0.99

Data Types: single | double

Output Arguments

pihat — Probability estimates

n -by- $(k - 1)$ matrix

Probability estimates for each multinomial category, returned as an n -by- $(k - 1)$ matrix, where n is the number of observations, and k is the number of response categories.

yhat — Count estimates

n -by- $k-1$ matrix

Count estimates for the number in each response category, returned as an n -by- k - 1 matrix, where n is the number of observations, and k is the number of response categories.

dlow — Lower error bound

column vector

Lower error bound to compute the lower confidence bound for `pihat` or `yhat`, returned as a column vector.

The lower confidence bound for `pihat` is `pihat` minus `dlow`. Similarly, the lower confidence bound for `yhat` is `yhat` minus `dlow`. Confidence bounds are nonsimultaneous and only apply to the fitted curve, not to new observations.

dhi — Upper error bound

column vector

Upper error bound to compute the upper confidence bound for `pihat` or `yhat`, returned as a column vector.

The upper confidence bound for `pihat` is `pihat` plus `dhi`. Similarly, the upper confidence bound for `yhat` is `yhat` plus `dhi`. Confidence bounds are nonsimultaneous and only apply to the fitted curve, not to new observations.

moment

Central moments

Syntax

```
m = moment(X,order)
moment(X,order,dim)
```

Description

`m = moment(X,order)` returns the central sample moment of `X` specified by the positive integer `order`. For vectors, `moment(x,order)` returns the central moment of the specified order for the elements of `x`. For matrices, `moment(X,order)` returns central moment of the specified order for each column. For N-dimensional arrays, `moment` operates along the first nonsingleton dimension of `X`.

`moment(X,order,dim)` takes the moment along dimension `dim` of `X`.

Examples

```
X = randn([6 5])
X =
    1.1650    0.0591    1.2460   -1.2704   -0.0562
    0.6268    1.7971   -0.6390    0.9846    0.5135
    0.0751    0.2641    0.5774   -0.0449    0.3967
    0.3516    0.8717   -0.3600   -0.7989    0.7562
   -0.6965   -1.4462   -0.1356   -0.7652    0.4005
    1.6961   -0.7012   -1.3493    0.8617   -1.3414

m = moment(X,3)
m =
   -0.0282    0.0571    0.1253    0.1460   -0.4486
```

More About

Tips

Note that the central first moment is zero, and the second central moment is the variance computed using a divisor of n rather than $n - 1$, where n is the length of the vector x or the number of rows in the matrix X .

The central moment of order k of a distribution is defined as

$$m_k = E(x - \mu)^k$$

where $E(x)$ is the expected value of x .

kurtosis | mean | skewness | std | var

mu property

Class: gmdistribution

Input matrix of means μ

Description

Input matrix of means μ .

multcompare

Multiple comparison test

Syntax

```
c = multcompare(stats)
c = multcompare (stats,Name,Value)
[c,m] = multcompare( ___ )
[c,m,h] = multcompare( ___ )
[c,m,h,gnames] = multcompare( ___ )
```

Description

`c = multcompare(stats)` returns a matrix `c` of the pairwise comparison results from a multiple comparison test using the information contained in the `stats` structure. `multcompare` also displays an interactive graph of the estimates and comparison intervals. Each group mean is represented by a symbol, and the interval is represented by a line extending out from the symbol. Two group means are significantly different if their intervals are disjoint; they are not significantly different if their intervals overlap. If you use your mouse to select any group, then the graph will highlight all other groups that are significantly different, if any.

`c = multcompare (stats,Name,Value)` returns a matrix of pairwise comparison results, `c`, using additional options specified by one or more `Name,Value` pair arguments. For example, you can specify the confidence interval, or the type of critical value to use in the multiple comparison.

`[c,m] = multcompare(___)` also returns a matrix, `m`, which contains estimated values of the means (or whatever statistics are being compared) for each group and the corresponding standard errors. You can use any of the previous syntaxes.

`[c,m,h] = multcompare(___)` also returns a handle, `h`, to the comparison graph.

`[c,m,h,gnames] = multcompare(___)` also returns a cell array, `gnames`, which contains the names of the groups.

Examples

Multiple Comparison of Group Means

Load the sample data.

```
load carsmall
```

Perform a one-way analysis of variance (ANOVA) to see if there is any difference between the mileage of the cars by origin.

```
[p,t,stats] = anova1(MPG,Origin,'off');
```

Perform a multiple comparison of the group means.

```
[c,m,h,nms] = multcompare(stats);
```

`multcompare` displays the estimates with comparison intervals around them. You can click the graphs of each country to compare its mean to those of other countries.

Now display the mean estimates and the standard errors with the corresponding group names.

```
[nms num2cell(m)]
```

```
ans =
```

```
'USA'      [21.1328]    [0.8814]
'Japan'    [31.8000]    [1.8206]
'Germany'  [28.4444]    [2.3504]
```

```
'France'      [23.6667]    [4.0711]
'Sweden'     [22.5000]    [4.9860]
'Italy'      [      28]    [7.0513]
```

Multiple Comparison of Material Strength

Input the data.

```
strength = [82 86 79 83 84 85 86 87 74 82 ...
            78 75 76 77 79 79 77 78 82 79];
alloy = {'st', 'st', 'st', 'st', 'st', 'st', 'st', 'st', ...
        'al1', 'al1', 'al1', 'al1', 'al1', 'al1', ...
        'al2', 'al2', 'al2', 'al2', 'al2', 'al2'};
```

The data are from a study of the strength of structural beams in Hogg (1987). The vector strength measures deflections of beams in thousandths of an inch under 3,000 pounds of force. The vector alloy identifies each beam as steel ('st'), alloy 1 ('al1'), or alloy 2 ('al2'). Although alloy is sorted in this example, grouping variables do not need to be sorted.

First perform one-way ANOVA.

```
[p,a,s] = anova1(strength,alloy);
```

ANOVA Table					
Source	SS	df	MS	F	Prob>F
Groups	184.8	2	92.4	15.4	0.0002
Error	102	17	6		
Total	286.8	19			

The small p -value suggests that the strength of the beams is not the same.

Now, perform a multiple comparison of the mean strength of the beams.

```
[c,m,h,nms] = multcompare(s);
```

Display the comparison results with the corresponding group names.

```
[nms(c(:,1)), nms(c(:,2)), num2cell(c(:,3:6))]
```

```
ans =
```

```
'st'      'al1'      [ 3.6064]      [ 7]      [10.3936]      [1.6831e-04]
'st'      'al2'      [ 1.6064]      [ 5]      [ 8.3936]      [ 0.0040]
'al1'     'al2'      [-5.6280]     [-2]      [ 1.6280]      [ 0.3560]
```

The third row of the output matrix shows that the differences in strength between the two alloys is not significant. A 95% confidence interval for the difference is [-5.6, 1.6], so

you cannot reject the hypothesis that the true difference is zero. This is also confirmed by the corresponding p -value of 0.3560 in the sixth column.

The first two rows show that both comparisons involving the first group (steel) have confidence intervals that do not include zero. And the corresponding p -values (1.6831e-04 and 0.0040, respectively) are small. In other words, those differences are significant. The graph shows the same information.

Input Arguments

stats — Test data

structure

Test data, specified as a structure. You can create a structure using one of the following functions:

- `anova1` — One-way analysis of variance.
- `anova2` — Two-way analysis of variance.
- `anovan` — N -way analysis of variance.
- `aoctool` — Interactive analysis of covariance tool.
- `friedman` — Friedman's test.
- `kruskalwallis` — Kruskal-Wallis test.

`multcompare` does not support multiple comparisons using `anovan` output for a model that includes random or nested effects. The calculations for a random effects model produce a warning that all effects are treated as fixed. Nested models are not accepted.

Data Types: `struct`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`,`Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1`,`Value1`,`...`,`NameN`,`ValueN`.

Example: `'Alpha',0.01,'CType','bonferroni','Display','off'` computes the Bonferroni critical values, conducts the hypothesis tests at the 1% significance level, and omits the interactive display.

'Alpha' — Significance level

0.05 (default) | scalar value in the range (0,1)

Significance level of the multiple comparison test, specified as the comma-separated pair consisting of 'Alpha' and a scalar value in the range (0,1). The value specified for 'Alpha' determines the $100 \times (1 - \alpha)$ confidence levels of the intervals returned in the matrix *c* and in the figure.

Example: 'Alpha',0.01

Data Types: single | double

'CType' — Type of critical value

'tukey-kramer' (default) | 'hsd' | 'lsd' | 'bonferroni' | 'dunn-sidak' | 'scheffe'

Type of critical value to use for the multiple comparison, specified as the comma-separated pair consisting of 'CType' and one of the following.

Value	Description
'tukey-kramer' or 'hsd'	Tukey's honestly significant difference criterion. This is based on the Studentized range distribution. It is optimal for balanced one-way ANOVA and similar procedures with equal sample sizes. It has been proven to be conservative for one-way ANOVA with different sample sizes. According to the unproven Tukey-Kramer conjecture, it is also accurate for problems where the quantities being compared are correlated, as in analysis of covariance with unbalanced covariate values.
'bonferroni'	Critical values from the <i>t</i> distribution, after a Bonferroni adjustment to compensate for multiple comparisons. This procedure is conservative, but usually less so than the Scheffé procedure.
'dunn-sidak'	Critical values from the <i>t</i> distribution, after an adjustment for multiple comparisons that was proposed by Dunn and proved accurate by Sidák. This procedure is similar to, but less conservative than, the Bonferroni procedure.
'lsd'	Tukey's least significant difference procedure. This procedure is a simple <i>t</i> -test. It is reasonable if the preliminary test (say, the one-way ANOVA <i>F</i> statistic) shows a significant difference.

Value	Description
	If it is used unconditionally, it provides no protection against multiple comparisons.
'scheffe'	Critical values from Scheffé's S procedure, derived from the F distribution. This procedure provides a simultaneous confidence level for comparisons of all linear combinations of the means. It is conservative for comparisons of simple differences of pairs.

Example: 'CType', 'bonferroni'

'Display' — Display toggle

'on' (default) | 'off'

Display toggle, specified as the comma-separated pair consisting of 'Display' and either 'on' or 'off'. If you specify 'on', then `multcompare` displays a graph of the estimates and their comparison intervals. If you specify 'off', then `multcompare` omits the graph.

Example: 'Display', 'off'

'Dimension' — Dimension over which to calculate marginal means

1 (default) | positive integer value | vector of positive integer values

A vector specifying the dimension or dimensions over which to calculate the population marginal means, specified as a positive integer value, or a vector of such values. Use the 'Dimension' name-value pair only if you create the input structure `stats` using the function `anovan`.

For example, if you specify 'Dimension' as 1, then `multcompare` compares the means for each value of the first grouping variable, adjusted by removing effects of the other grouping variables as if the design were balanced. If you specify 'Dimension' as [1, 3], then `multcompare` computes the population marginal means for each combination of the first and third grouping variables, removing effects of the second grouping variable. If you fit a singular model, some cell means may not be estimable and any population marginal means that depend on those cell means will have the value NaN.

Population marginal means are described by Milliken and Johnson (1992) and by Searle, Speed, and Milliken (1980). The idea behind population marginal means is to remove any effect of an unbalanced design by fixing the values of the factors specified by 'Dimension', and averaging out the effects of other factors as if each factor combination

occurred the same number of times. The definition of population marginal means does not depend on the number of observations at each factor combination. For designed experiments where the number of observations at each factor combination has no meaning, population marginal means can be easier to interpret than simple means ignoring other factors. For surveys and other studies where the number of observations at each combination does have meaning, population marginal means may be harder to interpret.

Example: `'Dimension', [1,3]`

Data Types: `single` | `double`

'Estimate' — Estimates to be compared

`'column'` (default) | `'row'` | `'slope'` | `'intercept'` | `'pmm'`

Estimates to be compared, specified as the comma-separated pair consisting of 'Estimate' and an allowable value. The allowable values for 'Estimate' depend on the function used to generate the input structure stats, according to the following table.

Source	Values
<code>anova1</code>	None. This name-value pair is ignored, and <code>multcompare</code> always compares the group means.
<code>anova2</code>	Either <code>'column'</code> to compare column means, or <code>'row'</code> to compare row means.
<code>anovan</code>	None. This name-value pair is ignored, and <code>multcompare</code> always compares the population marginal means as specified by the <code>'Dimension'</code> name-value pair argument.
<code>aoctool</code>	Either <code>'slope'</code> , <code>'intercept'</code> , or <code>'pmm'</code> to compare slopes, intercepts, or population marginal means, respectively. If the analysis of covariance model did not include separate slopes, then <code>'slope'</code> is not allowed. If it did not include separate intercepts, then no comparisons are possible.
<code>friedman</code>	None. This name-value pair is ignored, and <code>multcompare</code> always compares the average column ranks.
<code>kruskalwallis</code>	None. This name-value pair is ignored, and <code>multcompare</code> always compares the average group ranks.

Example: `'Estimate', 'row'`

Output Arguments

c — Matrix of multiple comparison results

matrix of scalar values

Matrix of multiple comparison results, returned as a p -by-6 matrix of scalar values, where p is the number of pairs of groups. Each row of the matrix contains the result of one paired comparison test. Columns 1 and 2 contain the indices of the two samples being compared. Column 3 contains the lower confidence interval, column 4 contains the estimate, and column 5 contains the upper confidence interval. Column 6 contains the p -value for the hypothesis test that the corresponding mean difference is not equal to 0.

For example, suppose one row contains the following entries.

```
2.0000  5.0000  1.9442  8.2206  14.4971  0.0432
```

These numbers indicate that the mean of group 2 minus the mean of group 5 is estimated to be 8.2206, and a 95% confidence interval for the true difference of the means is [1.9442, 14.4971]. The p -value for the corresponding hypothesis test that the difference of the means of groups 2 and 5 is significantly different from zero is 0.0432.

In this example the confidence interval does not contain 0, so the difference is significant at the 5% significance level. If the confidence interval did contain 0, the difference would not be significant. The p -value of 0.0432 also indicates that the difference of the means of groups 2 and 5 is significantly different from 0.

m — Matrix of estimates

matrix of scalar values

Matrix of the estimates, returned as a matrix of scalar values. The first column of m contains the estimated values of the means (or whatever statistics are being compared) for each group, and the second column contains their standard errors.

h — Handle to the figure

handle

Handle to the figure containing the interactive graph, returned as a handle. The title of this graph contains instructions for interacting with the graph, and the x -axis label contains information about which means are significantly different from the selected mean. If you plan to use this graph for presentation, you may want to omit the title and the x -axis label. You can remove them using interactive features of the graph window, or you can use the following commands.

```
title('')  
xlabel('')
```

gnames — Group names

cell array of strings

Group names, returned as a cell array of strings. Each row of `gnames` contains the name of a group.

More About

Multiple Comparison Tests

A one-way analysis of variance compares the means of several groups to test the hypothesis that they are all equal, against the general alternative that they are not all equal. Sometimes this alternative may be too general. You may need information about which pairs of means are significantly different, and which are not. A *multiple comparison test* can provide this information.

When you perform a simple *t*-test of one group mean against another, you specify a significance level that determines the cutoff value of the *t*-statistic. For example, you can specify the value `alpha = 0.05` to insure that when there is no real difference, you will incorrectly find a significant difference no more than 5% of the time. When there are many group means, there are also many pairs to compare. If you applied an ordinary *t*-test in this situation, the `alpha` value would apply to each comparison, so the chance of incorrectly finding a significant difference would increase with the number of comparisons. Multiple comparison procedures are designed to provide an upper bound on the probability that *any* comparison will be incorrectly found significant.

multcompare

Class: RepeatedMeasuresModel

Multiple comparison of estimated marginal means

Syntax

```
tbl = multcompare(rm, var)
tbl = multcompare(rm, var, Name, Value)
```

Description

`tbl = multcompare(rm, var)` returns multiple comparisons of the estimated marginal means based on the variable `var` in the repeated measures model `rm`.

`tbl = multcompare(rm, var, Name, Value)` returns multiple comparisons of the estimated marginal means with additional options specified by one or more `Name, Value` pair arguments.

For example, you can specify the comparison type or which variable to group by.

Input Arguments

rm — Repeated measures model

RepeatedMeasuresModel object

Repeated measures model, returned as a RepeatedMeasuresModel object.

For properties and methods of this object, see RepeatedMeasuresModel.

var — Variables for which to compute marginal means

string

Variables for which to compute the marginal means, specified as a string representing the name of a between- or within-subjects factor in `rm`. If `var` is a between-subjects factor, it must be categorical.

Data Types: char | cell

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

'Alpha' — Confidence level

0.05 (default) | scalar value in the range of 0 through 1

Confidence level of the confidence intervals for population marginal means, specified as the comma-separated pair consisting of 'alpha' and a scalar value in the range of 0 through 1. The confidence level is $100*(1-\alpha)\%$.

Example: 'alpha', 0.01

Data Types: double | single

'By' — Factor to perform comparisons by

string

Factor to do the comparisons by, specified as the comma-separated pair consisting of 'By' and a string. The comparison between levels of var occurs separately for each value of the factor you specify.

If you have more than one between-subjects factors, *A*, *B*, and *C*, and if you want to do the comparisons of *A* levels separately for each level of *C*, then specify *A* as the `var` argument and specify *C* using the 'By' argument as follows.

Example: 'By', C

Data Types: char

'ComparisonType' — Type of critical value to use

'tukey-kramer' (default) | 'dunn-sidak' | 'bonferroni' | 'scheffe' | 'lsd'

Type of critical value to use, specified as the comma-separated pair consisting of 'ComparisonType' and one of the following.

Comparison Type	Definition
'tukey-kramer'	Default. Also called Tukey's Honest Significant Difference procedure. It is based on the Studentized range

Comparison Type	Definition
	<p>distribution. According to the unproven Tukey-Kramer conjecture, it is also accurate for problems where the quantities being compared are correlated, as in analysis of covariance with unbalanced covariate values.</p>
'dunn-sidak'	<p>Use critical values from the t distribution, after an adjustment for multiple comparisons that was proposed by Dunn and proved accurate by Sidák. The critical value is</p> $t_{1-\eta/2, v}$ <p>where</p> $\eta = 1 - (1 - \alpha)^{1/\binom{ng}{2}}$ <p>and ng is the number of groups (marginal means). This procedure is similar to, but less conservative than, the Bonferroni procedure.</p>
'bonferroni'	<p>Use critical values from the t distribution, after a Bonferroni adjustment to compensate for multiple comparisons. The critical value is</p> $t_{\alpha/2\binom{ng}{2}, v}$ <p>where ng is the number of groups (marginal means), and v is the error degrees of freedom. This procedure is conservative, but usually less so than the Scheffé procedure.</p>

Comparison Type	Definition
'scheffe'	<p>Use critical values from Scheffé's S procedure, derived from the F distribution. The critical value is</p> $\sqrt{(ng-1)F_{\alpha,ng-1,v}}$ <p>where ng is the number of groups (marginal means), and v is the error degrees of freedom. This procedure provides a simultaneous confidence level for comparisons of all linear combinations of the means, and it is conservative for comparisons of simple differences of pairs.</p>
'lsd'	<p>Least significant difference. This option uses plain t-tests. The critical value is</p> $t_{\alpha/2,v}$ <p>where v is the error degrees of freedom. It provides no protection against the multiple comparison problem.</p>

Example: 'ComparisonType', 'dunn-sidak'

Output Arguments

tbl — Results of multiple comparison

table

Results of multiple comparisons of estimated marginal means, returned as a table. tbl has the following columns.

Column Name	Description
Difference	Estimated difference between the corresponding two marginal means

Column Name	Description
StdErr	Standard error of the estimated difference between the corresponding two marginal means
pValue	p -value for a test that the difference between the corresponding two marginal means is 0
Lower	Lower limit of simultaneous 95% confidence intervals for the true difference
Upper	Upper limit of simultaneous 95% confidence intervals for the true difference

Examples

Multiple Comparison of Estimated Marginal Means

Load the sample data.

```
load fisheriris
```

The column vector `species` consists of iris flowers of three different species: `setosa`, `versicolor`, and `virginica`. The double matrix `meas` consists of four types of measurements on the flowers: the length and width of sepals and petals in centimeters, respectively.

Store the data in a table array.

```
t = table(species,meas(:,1),meas(:,2),meas(:,3),meas(:,4),...
'VariableNames',{'species','meas1','meas2','meas3','meas4'});
Meas = dataset([1 2 3 4]','VarNames',{'Measurements'});
```

Fit a repeated measures model, where the measurements are the responses and the species is the predictor variable.

```
rm = fitrm(t,'meas1-meas4~species','WithinDesign',Meas);
```

Perform a multiple comparison of the estimated marginal means of species.

```
tbl = multcompare(rm,'species')
```

```
tbl =
```

```
species_1    species_2    Difference    StdErr    pValue    Lower
```

'setosa'	'versicolor'	-1.0375	0.060539	9.5606e-10	-1.1794
'setosa'	'virginica'	-1.7495	0.060539	9.5606e-10	-1.8914
'versicolor'	'setosa'	1.0375	0.060539	9.5606e-10	0.89562
'versicolor'	'virginica'	-0.712	0.060539	9.5606e-10	-0.85388
'virginica'	'setosa'	1.7495	0.060539	9.5606e-10	1.6076
'virginica'	'versicolor'	0.712	0.060539	9.5606e-10	0.57012

The small p -values (in the `pValue` field) indicate that the estimated marginal means for the three species significantly differ from each other.

Perform Multiple Comparisons with Specified Options

Load the sample data.

```
load repeatedmeas
```

The table `between` includes the between-subject variables `age`, `IQ`, `group`, `gender`, and eight repeated measures `y1` through `y8` as responses. The table `within` includes the within-subject variables `w1` and `w2`. This is simulated data.

Fit a repeated measures model, where the repeated measures `y1` through `y8` are the responses, and `age`, `IQ`, `group`, `gender`, and the `group-gender` interaction are the predictor variables. Also specify the within-subject design matrix.

```
R = fitrm(between, 'y1-y8 ~ Group*Gender + Age + IQ', 'WithinDesign', within);
```

Perform a multiple comparison of the estimated marginal means based on the variable `Group`.

```
T = multcompare(R, 'Group')
```

```
T =
```

Group_1	Group_2	Difference	StdErr	pValue	Lower	Upper
A	B	4.9875	5.6271	0.65436	-9.1482	19.123
A	C	23.094	5.9261	0.0021493	8.2074	37.981
B	A	-4.9875	5.6271	0.65436	-19.123	9.1482
B	C	18.107	5.8223	0.013588	3.4805	32.732
C	A	-23.094	5.9261	0.0021493	-37.981	-8.2074
C	B	-18.107	5.8223	0.013588	-32.732	-3.4805

The small p -value of 0.0021493 indicates that there is significant difference between the marginal means of groups A and C. The p -values of 0.65436 indicates that the difference between the marginal means for groups A and B is not significantly different from 0.

`multcompare` uses the Tukey-Kramer test statistic by default. Change the comparison type to the Scheffe procedure.

```
T = multcompare(R, 'Group', 'ComparisonType', 'Scheffe')
```

```
T =
```

Group_1	Group_2	Difference	StdErr	pValue	Lower	Upper
A	B	4.9875	5.6271	0.67981	-9.7795	19.755
A	C	23.094	5.9261	0.0031072	7.5426	38.646
B	A	-4.9875	5.6271	0.67981	-19.755	9.7795
B	C	18.107	5.8223	0.018169	2.8273	33.386
C	A	-23.094	5.9261	0.0031072	-38.646	-7.5426
C	B	-18.107	5.8223	0.018169	-33.386	-2.8273

The Scheffe test produces larger p -values, but similar conclusions.

Perform multiple comparisons of estimated marginal means based on the variable `Group` for each gender separately.

```
T = multcompare(R, 'Group', 'By', 'Gender')
```

```
T =
```

Gender	Group_1	Group_2	Difference	StdErr	pValue	Lower
Female	A	B	4.1883	8.0177	0.86128	-15.953
Female	A	C	24.565	8.2083	0.017697	3.9449
Female	B	A	-4.1883	8.0177	0.86128	-24.329
Female	B	C	20.376	8.1101	0.049957	0.0033459
Female	C	A	-24.565	8.2083	0.017697	-45.184
Female	C	B	-20.376	8.1101	0.049957	-40.749
Male	A	B	5.7868	7.9498	0.74977	-14.183
Male	A	C	21.624	8.1829	0.038022	1.0676
Male	B	A	-5.7868	7.9498	0.74977	-25.757
Male	B	C	15.837	8.0511	0.14414	-4.3881
Male	C	A	-21.624	8.1829	0.038022	-42.179
Male	C	B	-15.837	8.0511	0.14414	-36.062

The results indicate that the difference between marginal means for groups A and B is not significant from 0 for either gender (corresponding p -values are 0.86128 for females and 0.74977 for males). The difference between marginal means for groups A and C is significant for both genders (corresponding p -values are 0.017697 for females and 0.038022 for males). While the difference between marginal means for groups B and C is significantly different from 0 for females (p -value is 0.049957), it is not significantly different from 0 for males (p -value is 0.14414).

prob.MultinomialDistribution class

Package: prob

Superclasses: prob.ParametricTruncatableDistribution

Multinomial probability distribution object

Description

`prob.MultinomialDistribution` is an object consisting of parameters and a model description for a multinomial probability distribution. Create a probability distribution object with specified parameters using `makedist`.

Construction

`pd = makedist('Multinomial')` creates a multinomial probability distribution object using the default parameter values.

`pd = makedist('Multinomial', 'Probabilities', probabilities)` creates a multinomial distribution object using the specified parameter value.

Input Arguments

probabilities — outcome probabilities

`[0.500 0.500]` (default) | vector of scalar values in the range `[0, 1]`

Outcome probabilities, specified as a vector of scalar values in the range `[0, 1]`. Each vector element is the probability that a multinomial trial has a particular corresponding outcome. The values in `probabilities` must sum to 1.

Data Types: `single` | `double`

Properties

probabilities — outcome probabilities

vector of scalar values in the range `[0, 1]`

Outcome probabilities for the multinomial distribution, stored as a vector of scalar values in the range $[0, 1]$. The values in `probabilities` must sum to 1.

Data Types: `single` | `double`

DistributionName — Probability distribution name

probability distribution name string

Probability distribution name, stored as a valid probability distribution name string. This property is read-only.

Data Types: `char`

IsTruncated — Logical flag for truncated distribution

0 | 1

Logical flag for truncated distribution, stored as a logical value. If `IsTruncated` equals 0, the distribution is not truncated. If `IsTruncated` equals 1, the distribution is truncated. This property is read-only.

Data Types: `logical`

NumParameters — Number of parameters

positive integer value

Number of parameters for the probability distribution, stored as a positive integer value. This property is read-only.

Data Types: `single` | `double`

ParameterDescription — Distribution parameter descriptions

cell array of strings

Distribution parameter descriptions, stored as a cell array of strings. Each cell contains a short description of one distribution parameter. This property is read-only.

Data Types: `char`

ParameterNames — Distribution parameter names

cell array of strings

Distribution parameter names, stored as a cell array of strings. This property is read-only.

Data Types: char

ParameterValues — Distribution parameter values

vector of scalar values

Distribution parameter values, stored as a vector. This property is read-only.

Data Types: single | double

Truncation — Truncation interval

vector of scalar values

Truncation interval for the probability distribution, stored as a vector containing the lower and upper truncation boundaries. This property is read-only.

Data Types: single | double

Methods

Inherited Methods

cdf	Cumulative distribution function of probability distribution object
icdf	Inverse cumulative distribution function of probability distribution object
iqr	Interquartile range of probability distribution object
median	Median of probability distribution object
pdf	Probability density function of probability distribution object
random	Generate random numbers from probability distribution object

truncate	Truncate probability distribution object
mean	Mean of probability distribution object
std	Standard deviation of probability distribution object
var	Variance of probability distribution object

Definitions

Multinomial Distribution

The multinomial distribution is a generalization of the binomial distribution. While the binomial distribution gives the probability of the number of “successes” in n independent trials of a two-outcome process, the multinomial distribution gives the probability of each combination of outcomes in n independent trials of a k -outcome process. The probability of each outcome in any one trial is given by the fixed probabilities p_1, \dots, p_k .

The multinomial distribution uses the following parameters.

Parameter	Description	Support
probabilities	Outcome probabilities	$0 \leq \text{probabilities}(i) \leq 1 ; \sum_{\text{all}(i)} \text{probabilities}(i) = 1$

The probability density function (pdf) is

$$f(x | n, p) = \frac{n!}{x_1! \dots x_k!} p_1^{x_1} \dots p_k^{x_k} ; \sum_1^k x_i = n, \sum_1^k p_i = 1,$$

where $x = (x_1, \dots, x_k)$ gives the number of each k outcome in n trials of a process with fixed probabilities $p = (p_1, \dots, p_k)$ of individual outcomes in any one trial.

Examples

Create a Multinomial Distribution Object Using Default Parameters

Create a multinomial distribution object using the default parameter values.

```
pd = makedist('Multinomial')
```

```
pd =
```

```
    MultinomialDistribution
```

```
    Probabilities:
    0.5000    0.5000
```

Create a Multinomial Distribution Object Using Specified Parameters

Create a multinomial distribution object for a distribution with three possible outcomes. Outcome 1 has a probability of 1/2, outcome 2 has a probability of 1/3, and outcome 3 has a probability of 1/6.

```
pd = makedist('Multinomial','probabilities',[1/2 1/3 1/6])
```

```
pd =
```

```
    MultinomialDistribution
```

```
    Probabilities:
    0.5000    0.3333    0.1667
```

Generate a random outcome from the distribution.

```
rng('default'); % for reproducibility
```

```
r = random(pd)
```

```
r =
```

```
    2
```

The result of this trial is outcome 2. By default, the number of trials in each experiment, n , equals 1.

Generate random outcomes from the distribution when the number of trials in each experiment, n , equals 1, and the experiment is repeated ten times.

```
rng('default'); % for reproducibility
```

```
r = random(pd,10,1)
```

```
r =
     2
     3
     1
     3
     2
     1
     1
     2
     3
     3
```

Each element in the array is the outcome of an individual experiment that contains one trial.

Generate random outcomes from the distribution when the number of trials in each experiment, n , equals 5, and the experiment is repeated ten times.

```
rng('default'); % for reproducibility
r = random(pd,10,5)
```

```
r =
     2     1     2     2     1
     3     3     1     1     1
     1     3     3     1     2
     3     1     3     1     2
     2     2     2     1     1
     1     1     2     2     1
     1     1     2     2     1
     2     3     1     1     2
     3     2     2     3     2
     3     3     1     1     2
```

Each element in the resulting matrix is the outcome of one trial. The columns correspond to the five trials in each experiment, and the rows correspond to the ten experiments. For example, in the first experiment (corresponding to the first row), 2 of the 5 trials resulted in outcome 1, and 3 of the 5 trials resulted in outcome 2.

multivarichart

Multivari chart for grouped data

Syntax

```
multivarichart(y, GROUP)
multivarichart(Y)
multivarichart(..., param1, val1, param2, val2, ...)
[charthandle, AXESH] = multivarichart(...)
```

Description

`multivarichart(y, GROUP)` displays the multivari chart for the vector `y` grouped by entries in the cell array `GROUP`. Each cell of `GROUP` must contain a grouping variable that can be a categorical variable, numeric vector, character matrix, or single-column cell array of strings. `GROUP` can also be a matrix whose columns represent different grouping variables. Each grouping variable must have the same number of elements as `y`. The number of grouping variables must be 2, 3, or 4.

Each subplot of the plot matrix contains a multivari chart for the first and second grouping variables. The x -axis in each subplot indicates values of the first grouping variable. The legend at the bottom of the figure window indicates values of the second grouping variable. The subplot at position (i,j) is the multivari chart for the subset of `y` at the i th level of the third grouping variable and the j th level of the fourth grouping variable. If the third or fourth grouping variable is absent, it is considered to have only one level.

`multivarichart(Y)` displays the multivari chart for a matrix `Y`. The data in different columns represent changes in one factor. The data in different rows represent changes in another factor.

`multivarichart(..., param1, val1, param2, val2, ...)` specifies one or more of the following name/value pairs:

- `'varnames'` — Grouping variable names in a character matrix or a cell array of strings, one per grouping variable. Default names are `'X1'`, `'X2'`,

- 'plotorder' — A string with the value 'sorted' or a vector containing a permutation of the integers from 1 to the number of grouping variables.

If 'plotorder' is a string with value 'sorted', the grouping variables are rearranged in descending order according to the number of levels in each variable.

If 'plotorder' is a vector, it indicates the order in which each grouping variable should be plotted. For example, [2,3,1,4] indicates that the second grouping variable should be used as the *x*-axis of each subplot, the third grouping variable should be used as the legend, the first grouping variable should be used as the columns of the plot, and the fourth grouping variable should be used as the rows of the plot.

[charthandle,AXESH] = multivarichart(...) returns a handle charthandle to the figure window and a matrix AXESH of handles to the subplot axes.

Examples

Multivari Chart for Grouped Data

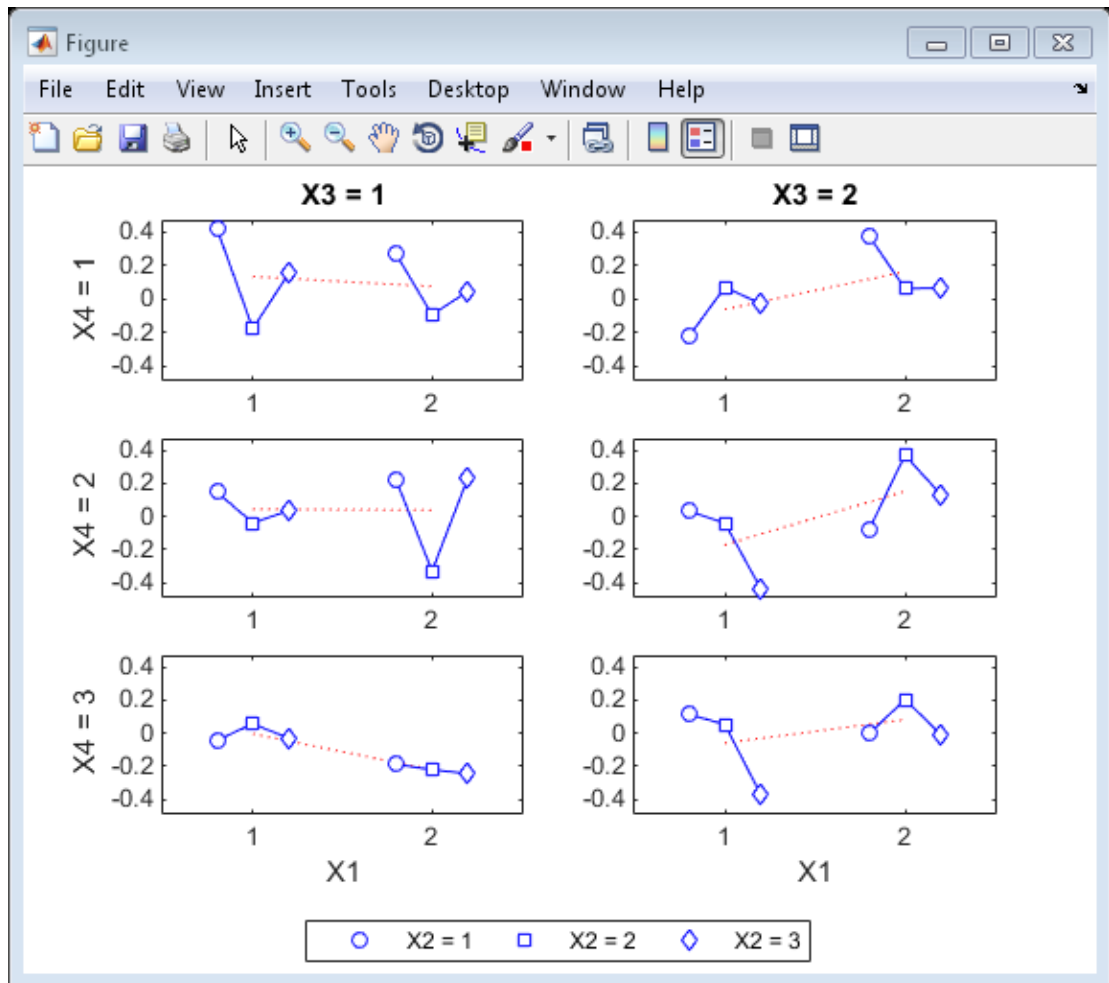

Display a multivari chart for data with two grouping variables.

```
rng default; % For reproducibility
y = randn(100,1); % Randomly generate response
group = [ceil(3*rand(100,1)) ceil(2*rand(100,1))];
multivarichart(y,group)
```

Display a multivari chart for data with four grouping variables.

```
y = randn(1000,1); % Randomly generate response
group = {ceil(2*rand(1000,1)),ceil(3*rand(1000,1)), ...
         ceil(2*rand(1000,1)),ceil(3*rand(1000,1))};
multivarichart(y,group)
```

mvncdf

Multivariate normal cumulative distribution function

Syntax

```
y = mvncdf(X)
y = mvncdf(X,mu,SIGMA)
y = mvncdf(xl,xu,mu,SIGMA)
[y,err] = mvncdf(...)
[...] = mvncdf(...,options)
```

Description

`y = mvncdf(X)` returns the cumulative probability of the multivariate normal distribution with zero mean and identity covariance matrix, evaluated at each row of `X`. Rows of the n -by- d matrix `X` correspond to observations or points, and columns correspond to variables or coordinates. `y` is an n -by-1 vector.

`y = mvncdf(X,mu,SIGMA)` returns the cumulative probability of the multivariate normal distribution with mean `mu` and covariance `SIGMA`, evaluated at each row of `X`. `mu` is a 1-by- d vector, and `SIGMA` is a d -by- d symmetric, positive definite matrix. `mu` can also be a scalar value, which `mvncdf` replicates to match the size of `X`. If the covariance matrix is diagonal, containing variances along the diagonal and zero covariances off the diagonal, `SIGMA` may also be specified as a 1-by- d vector containing just the diagonal. Pass in the empty matrix `[]` for `mu` to use as its default value when you want to only specify `SIGMA`.

The multivariate normal cumulative probability at `X` is defined as the probability that a random vector `V`, distributed as multivariate normal, will fall within the semi-infinite rectangle with upper limits defined by `X`, for example, $\Pr\{V(1) \leq X(1), V(2) \leq X(2), \dots, V(d) \leq X(d)\}$.

`y = mvncdf(xl,xu,mu,SIGMA)` returns the multivariate normal cumulative probability evaluated over the rectangle with lower and upper limits defined by `xl` and `xu`, respectively.

`[y,err] = mvncdf(...)` returns an estimate of the error in `y`. For bivariate and trivariate distributions, `mvncdf` uses adaptive quadrature on a transformation of the t density, based on methods developed by Drezner and Wesolowsky and by Genz, as described in the references. The default absolute error tolerance for these cases is $1e-8$. For four or more dimensions, `mvncdf` uses a quasi-Monte Carlo integration algorithm based on methods developed by Genz and Bretz, as described in the references. The default absolute error tolerance for these cases is $1e-4$.

`[...] = mvncdf(...,options)` specifies control parameters for the numerical integration used to compute `y`. This argument can be created by a call to `statset`. Choices of `statset` parameters:

- `'TolFun'` — Maximum absolute error tolerance. Default is $1e-8$ when $d < 4$, or $1e-4$ when $d \geq 4$.
- `'MaxFunEvals'` — Maximum number of integrand evaluations allowed when $d \geq 4$. Default is $1e7$. `'MaxFunEvals'` is ignored when $d < 4$.
- `'Display'` — Level of display output. Choices are `'off'` (the default), `'iter'`, and `'final'`. `'Display'` is ignored when $d < 4$.

Examples

Compute the Multivariate Normal cdf

Compute and plot the cdf of a multivariate normal distribution with parameters `MU = [1 -1]` and `SIGMA = [.9 .4; .4 .3]`.

```
mu = [1 -1];
SIGMA = [.9 .4; .4 .3];
figure;
[X1,X2] = meshgrid(linspace(-1,3,25)',linspace(-3,1,25)');
X = [X1(:) X2(:)];
p = mvncdf(X,mu,SIGMA);
surf(X1,X2,reshape(p,25,25));
```

mvnpdf | mvnrnd

mvnpdf

Multivariate normal probability density function

Syntax

```
y = mvnpdf(X)
y = mvnpdf(X,MU)
y = mvnpdf(X,MU,SIGMA)
```

Description

`y = mvnpdf(X)` returns the n -by-1 vector **y**, containing the probability density of the multivariate normal distribution with zero mean and identity covariance matrix, evaluated at each row of the n -by- d matrix **X**. Rows of **X** correspond to observations and columns correspond to variables or coordinates.

`y = mvnpdf(X,MU)` returns the density of the multivariate normal distribution with mean **MU** and identity covariance matrix, evaluated at each row of **X**. **MU** is a 1-by- d vector, or an n -by- d matrix. If **MU** is a matrix, the density is evaluated for each row of **X** with the corresponding row of **MU**. **MU** can also be a scalar value, which `mvnpdf` replicates to match the size of **X**.

`y = mvnpdf(X,MU,SIGMA)` returns the density of the multivariate normal distribution with mean **MU** and covariance **SIGMA**, evaluated at each row of **X**. **SIGMA** is a d -by- d matrix, or a d -by- d -by- n array, in which case the density is evaluated for each row of **X** with the corresponding page of **SIGMA**, i.e., `mvnpdf` computes $y(i)$ using $X(i,:)$ and $SIGMA(:, :, i)$. If the covariance matrix is diagonal, containing variances along the diagonal and zero covariances off the diagonal, **SIGMA** may also be specified as a 1-by- d vector or a 1-by- d -by- n array, containing just the diagonal. Specify `[]` for **MU** to use its default value when you want to specify only **SIGMA**.

If **X** is a 1-by- d vector, `mvnpdf` replicates it to match the leading dimension of **MU** or the trailing dimension of **SIGMA**.

Examples

```
mu = [1 -1];
```

```
SIGMA = [.9 .4; .4 .3];  
X = mvnrnd(mu,SIGMA,10);  
p = mvnpdf(X,mu,SIGMA);
```

mvregress

Multivariate linear regression

Syntax

```
beta = mvregress(X,Y)
beta = mvregress(X,Y,Name,Value)
[beta,Sigma] = mvregress( ___ )
[beta,Sigma,E,CovB,logL] = mvregress( ___ )
```

Description

`beta = mvregress(X,Y)` returns the estimated coefficients for a multivariate normal regression of the d -dimensional responses in Y on the design matrices in X .

`beta = mvregress(X,Y,Name,Value)` returns the estimated coefficients using additional options specified by one or more name-value pair arguments. For example, you can specify the estimation algorithm, initial estimate values, or maximum number of iterations for the regression.

`[beta,Sigma] = mvregress(___)` also returns the estimated d -by- d variance-covariance matrix of Y , using any of the input arguments from the previous syntaxes.

`[beta,Sigma,E,CovB,logL] = mvregress(___)` also returns a matrix of residuals E , estimated variance-covariance matrix of the regression coefficients $CovB$, and the value of the log likelihood objective function after the last iteration $logL$.

Examples

Multivariate Regression Model for Panel Data with Different Intercepts

Fit a multivariate regression model to panel data, assuming different intercepts and common slopes.

Load the sample data.

```
load('flu')
```

The dataset array `flu` contains national CDC flu estimates, and nine separate regional estimates based on Google query data.

Extract the response and predictor data.

```
Y = double(flu(:,2:end-1));  
[n,d] = size(Y);  
x = flu.WtdILI;
```

The responses in `Y` are the nine regional flu estimates. Observations exist for every week over a one-year period, so $n = 52$. The dimension of the responses corresponds to the regions, so $d = 9$. The predictors in `x` are the weekly national flu estimates.

Plot the flu data, grouped by region.

```
figure;  
regions = flu.Properties.VarNames(2:end-1);  
plot(x,Y,'x')  
legend(regions,'Location','NorthWest')
```

Fit the multivariate regression model

$$y_{ij} = \alpha_j + \beta x_{ij} + \varepsilon_{ij}, \quad i = 1, \dots, n; \quad j = 1, \dots, d,$$

with between-region concurrent correlation

$$COV(\varepsilon_{ij}, \varepsilon_{ij'}) = \sigma_{jj'}, \quad j = 1, \dots, d.$$

There are $K = 10$ regression coefficients to estimate: nine intercept terms and a common slope. The input argument X should be an n -element cell array of d -by- K design matrices.

```
X = cell(n,1);
for i=1:n
    X{i} = [eye(d) repmat(x(i),d,1)];
end
[beta,Sigma] = mvregress(X,Y);
```

beta contains estimates of the K -dimensional coefficient vector

$$(\alpha_1, \alpha_2, \dots, \alpha_9, \beta)'$$

Sigma contains estimates of the d -by- d variance-covariance matrix for the between-region concurrent correlations

$$\begin{pmatrix} \sigma_{11} & \cdots & \sigma_{1,9} \\ \vdots & \ddots & \vdots \\ \sigma_{9,1} & \cdots & \sigma_{9,9} \end{pmatrix}.$$

Plot the fitted regression model.

```
B = [beta(1:d)'; repmat(beta(end),1,d)];
xx = linspace(.5,3.5)';
fits = [ones(size(xx)),xx]*B;

figure;
h = plot(x,Y,'x',xx,fits,'-');
```

```

for i = 1:d
    set(h(d+i), 'color', get(h(i), 'color'));
end
legend(regions, 'Location', 'NorthWest');

```

The plot shows that each regression line has a different intercept but the same slope. Upon visual inspection, some regression lines appear to fit the data better than others.

Multivariate Regression for Panel Data with Different Slopes

Fit a multivariate regression model to panel data using least squares, assuming different intercepts and slopes.

Load the sample data.

```
load('flu');
```

The dataset array `flu` contains national CDC flu estimates, and nine separate regional estimates based on Google queries.

Extract the response and predictor data.

```
Y = double(flu(:,2:end-1));
[n,d] = size(Y);
x = flu.WtdILI;
```

The responses in Y are the nine regional flu estimates. Observations exist for every week over a one-year period, so $n = 52$. The dimension of the responses corresponds to the regions, so $d = 9$. The predictors in x are the weekly national flu estimates.

Fit the multivariate regression model

$$y_{ij} = \alpha_j + \beta_j x_{ij} + \varepsilon_{ij}, \quad i = 1, \dots, n; \quad j = 1, \dots, d,$$

with between-region concurrent correlation

$$COV(\varepsilon_{ij}, \varepsilon_{i'j'}) = \sigma_{jj'}, \quad j = 1, \dots, d.$$

There are $K = 18$ regression coefficients to estimate: nine intercept terms, and nine slope terms. X is an n -element cell array of d -by- K design matrices.

```
X = cell(n,1);
for i=1:n
    X{i} = [eye(d) x(i)*eye(d)];
end
[beta,Sigma] = mvregress(X,Y, 'algorithm', 'cwlsl');
```

`beta` contains estimates of the K -dimensional coefficient vector,

$$(\alpha_1, \alpha_2, \dots, \alpha_9, \beta_1, \beta_2, \dots, \beta_9)'$$

Plot the fitted regression model.

```
B = [beta(1:d)';beta(d+1:end)'];
xx = linspace(.5,3.5)';
fits = [ones(size(xx)),xx]*B;

figure;
h = plot(x,Y, 'x',xx,fits, '-');
for i = 1:d
```

```

    set(h(d+i), 'color', get(h(i), 'color'));
end

regions = flu.Properties.VarNames(2:end-1);
legend(regions, 'Location', 'NorthWest');

```

The plot shows that each regression line has a different intercept and slope.

Multivariate Regression With a Single Design Matrix

Fit a multivariate regression model using a single n -by- P design matrix for all response dimensions.

Load the sample data.

```
load('flu');
```

The dataset array `flu` contains national CDC flu estimates, and nine separate regional estimates based on Google queries.

Extract the response and predictor data.

```
Y = double(flu(:,2:end-1));
[n,d] = size(Y);
x = flu.WtdILI;
```

The responses in Y are the nine regional flu estimates. Observations exist for every week over a one-year period, so $n = 52$. The dimension of the responses corresponds to the regions, so $d = 9$. The predictors in x are the weekly national flu estimates.

Create an n -by- P design matrix X . Add a column of ones to include a constant term in the regression.

```
X = [ones(size(x)),x];
```

Fit the multivariate regression model

$$y_{ij} = \alpha_j + \beta_j x_{ij} + \varepsilon_{ij}, \quad i = 1, \dots, n; \quad j = 1, \dots, d,$$

with between-region concurrent correlation

$$COV(\varepsilon_{ij}, \varepsilon_{i'j'}) = \sigma_{jj'}, \quad j = 1, \dots, d.$$

There are 18 regression coefficients to estimate: nine intercept terms, and nine slope terms.

```
[beta,Sigma,E,CovB,logL] = mvregress(X,Y);
```

beta contains estimates of the P -by- d coefficient matrix. **Sigma** contains estimates of the d -by- d variance-covariance matrix for the between-region concurrent correlations. **E** is a matrix of the residuals. **CovB** is the estimated variance-covariance matrix of the regression coefficients. **logL** is the value of the log likelihood objective function after the last iteration.

Plot the fitted regression model.

```
B = beta;
xx = linspace(.5,3.5)';
fits = [ones(size(xx)),xx]*B;
```

```

figure;
h = plot(x,Y,'x', xx,fits,'-');
for i = 1:d
    set(h(d+i),'color',get(h(i),'color'));
end

regions = flu.Properties.VarNames(2:end-1);
legend(regions,'Location','NorthWest');

```

The plot shows that each regression line has a different intercept and slope.

Input Arguments

X — Design matrices

matrix | cell array of matrices

Design matrices for the multivariate regression, specified as a matrix or cell array of matrices. n is the number of observations in the data, K is the number of regression coefficients to estimate, p is the number of predictor variables, and d is the number of dimensions in the response variable matrix Y .

- If $d = 1$, then specify X as a single n -by- K design matrix.
- If $d > 1$ and all d dimensions have the same design matrix, then you can specify X as a single n -by- p design matrix (not in a cell array).
- If $d > 1$ and all n observations have the same design matrix, then you can specify X as a cell array containing a single d -by- K design matrix.
- If $d > 1$ and all n observations do not have the same design matrix, then specify X as a cell array of length n containing d -by- K design matrices.

To include a constant term in the regression model, each design matrix should contain a column of ones.

`mvregress` treats NaN values in X as missing values, and ignores rows in X with missing values.

Data Types: single | double | cell

Y — Response variables

matrix

Response variables, specified as an n -by- d matrix. n is the number of observations in the data, and d is the number of dimensions in the response. When $d = 1$, `mvregress` treats the values in Y like n independent response values.

`mvregress` treats NaN values in Y as missing values, and handles them according to the estimation algorithm specified using the name-value pair argument `algorithm`.

Data Types: single | double

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'algorithm', 'cwlsl', 'covar0', C` specifies covariance-weighted least squares estimation using the covariance matrix `C`.

'algorithm' — Estimation algorithm

`'mvn' | 'ecm' | 'cwlsl'`

Estimation algorithm, specified as the comma-separated pair consisting of `'algorithm'` and one of the following.

<code>'mvn'</code>	Ordinary multivariate normal maximum likelihood estimation.
<code>'ecm'</code>	Maximum likelihood estimation via the ECM algorithm.
<code>'cwlsl'</code>	Covariance-weighted least squares estimation.

The default algorithm depends on the presence of missing data.

- For complete data, the default is `'mvn'`.
- If there are any missing responses (indicated by `NaN`), the default is `'ecm'`, provided the sample size is sufficient to estimate all parameters. Otherwise, the default algorithm is `'cwlsl'`.

Note: If `algorithm` has the value `'mvn'`, then `mvregress` removes observations with missing response values before estimation.

Example: `'algorithm', 'ecm'`

'beta0' — Initial estimates for regression coefficients

vector

Initial estimates for the regression coefficients, specified as the comma-separated pair consisting of `'beta0'` and a vector with K elements. The default value is a vector of 0s.

The `beta0` argument is not used if the estimation algorithm is `'mvn'`.

'covar0' — Initial estimate for variance-covariance matrix

matrix

Initial estimate for the variance-covariance matrix, Σ , specified as the comma-separated pair consisting of `'covar0'` and a symmetric, positive definite, d -by- d matrix. The default value is the identity matrix.

If the estimation algorithm is `'cwlsl'`, then `mvregress` uses `covar0` as the weighting matrix at each iteration, without changing it.

'covtype' — Type of variance-covariance matrix

'full' (default) | 'diagonal'

Type of variance-covariance matrix to estimate for Y , specified as the comma-separated pair consisting of `'covtype'` and one of the following.

<code>'full'</code>	Estimate all $d(d + 1)/2$ variance-covariance elements.
<code>'diagonal'</code>	Estimate only the d diagonal elements of the variance-covariance matrix.

Example: `'covtype', 'diagonal'`

'maxiter' — Maximum number of iterations

100 (default) | positive integer

Maximum number of iterations for the estimation algorithm, specified as the comma-separated pair consisting of `'maxiter'` and a positive integer.

Iterations continue until estimates are within the convergence tolerances `tolbeta` and `tolobj`, or the maximum number of iterations specified by `maxiter` is reached. If both `tolbeta` and `tolobj` are 0, then `mvregress` performs `maxiter` iterations with no convergence tests.

Example: `'maxiter', 50`

'outputfcn' — Function to evaluate each iteration

function handle

Function to evaluate at each iteration, specified as the comma-separated pair consisting of 'outputfcn' and a function handle. The function must return a logical `true` or `false`. At each iteration, `mvregress` evaluates the function. If the result is `true`, iterations stop. Otherwise, iterations continue. For example, you could specify a function that plots or displays current iteration results, and returns `true` if you close the figure.

The function must accept three input arguments, in this order:

- Vector of current coefficient estimates
- Structure containing these three fields:

<code>Covar</code>	Current value of the variance-covariance matrix
<code>iteration</code>	Current iteration number
<code>fval</code>	Current value of the loglikelihood objective function

- Text string that takes these three values:

<code>'init'</code>	When the function is called during initialization
<code>'iter'</code>	When the function is called after an iteration
<code>'done'</code>	When the function is called after completion

'tolbeta' — Convergence tolerance for regression coefficients

`sqrt(eps)` (default) | positive scalar value

Convergence tolerance for regression coefficients, specified as the comma-separated pair consisting of 'tolbeta' and a positive scalar value.

Let \mathbf{b}^t denote the estimate of the coefficient vector at iteration t , and τ_β be the tolerance specified by `tolbeta`. The convergence criterion for regression coefficient estimation is

$$\|\mathbf{b}^t - \mathbf{b}^{t-1}\| < \tau_\beta \sqrt{K} (1 + \|\mathbf{b}^t\|),$$

where K is the length of \mathbf{b}^t and $\|\mathbf{v}\|$ is the norm of a vector \mathbf{v} .

Iterations continue until estimates are within the convergence tolerances `tolbeta` and `tolobj`, or the maximum number of iterations specified by `maxiter` is reached. If

both `tolbeta` and `tolobj` are 0, then `mvregress` performs `maxiter` iterations with no convergence tests.

Example: `'tolbeta', 1e-5`

'tolobj' — Convergence tolerance for loglikelihood objective function

`eps^(3/4)` (default) | positive scalar value

Convergence tolerance for the loglikelihood objective function, specified as the comma-separated pair consisting of `'tolobj'` and a positive scalar value.

Let L^t denote the value of the loglikelihood objective function at iteration t , and τ_ℓ be the tolerance specified by `tolobj`. The convergence criterion for the objective function is

$$\left|L^t - L^{t-1}\right| < \tau_\ell \left(1 + \left|L^t\right|\right).$$

Iterations continue until estimates are within the convergence tolerances `tolbeta` and `tolobj`, or the maximum number of iterations specified by `maxiter` is reached. If both `tolbeta` and `tolobj` are 0, then `mvregress` performs `maxiter` iterations with no convergence tests.

Example: `'tolobj', 1e-5`

'varformat' — Format for parameter estimate variance-covariance matrix

`'beta'` (default) | `'full'`

Format for the parameter estimate variance-covariance matrix, `CovB`, specified as the comma-separated pair consisting of `'varformat'` and one of the following.

<code>'beta'</code>	Return the variance-covariance matrix for only the regression coefficient estimates, <code>beta</code> .
<code>'full'</code>	Return the variance-covariance matrix for both the regression coefficient estimates, <code>beta</code> , and the variance-covariance matrix estimate, <code>Sigma</code> .

Example: `'varformat', 'full'`

'vartype' — Type of variance-covariance matrix for parameter estimates

`'hessian'` (default) | `'fisher'`

Type of variance-covariance matrix for parameter estimates, specified as the comma-separated pair consisting of 'vartype' and either 'hessian' or 'fisher'.

- If the value is 'hessian', then `mvregress` uses the Hessian, or observed information, matrix to compute CovB.
- If the value is 'fisher', then `mvregress` uses the complete-data Fisher, or expected information, matrix to compute CovB.

The 'hessian' method takes into account the increase uncertainties due to missing data, while the 'fisher' method does not.

Example: 'vartype', 'fisher'

Output Arguments

beta — Estimated regression coefficients

column vector | matrix

Estimated regression coefficients, returned as a column vector or matrix.

- If you specify X as a single n -by- K design matrix, then `mvregress` returns beta as a column vector of length K . For example, if X is a 20-by-5 design matrix, then beta is a 5-by-1 column vector.
- If you specify X as a cell array containing one or more d -by- K design matrices, then `mvregress` returns beta as a column vector of length K . For example, if X is a cell array containing 2-by-10 design matrices, then beta is a 10-by-1 column vector.
- If you specify X as a single n -by- p design matrix (not in a cell array), and Y has dimension $d > 1$, then `mvregress` returns beta as a p -by- d matrix. For example, if X is a 20-by-5 design matrix, and Y has two dimensions such that $d = 2$, then beta is a 5-by-2 matrix, and the fitted Y values are $X \times \text{beta}$.

Sigma — Estimated variance-covariance matrix

square matrix

Estimated variance-covariance matrix for the responses in Y, returned as a d -by- d square matrix.

Note: The estimated variance-covariance matrix, **Sigma**, is not the sample covariance matrix of the residual matrix, **E**.

E — Residuals

matrix

Residuals for the fitted regression model, returned as an n -by- d matrix.

If algorithm has the value 'ecm' or 'cwlsl', then `mvregress` computes the residual values corresponding to missing values in Y as the difference between the conditionally imputed values and the fitted values.

Note: If algorithm has the value 'mvn', then `mvregress` removes observations with missing response values before estimation.

CovB — Parameter estimate variance-covariance matrix

square matrix

Parameter estimate variance-covariance matrix, returned as a square matrix.

- If `varformat` has the value 'beta' (default), then `CovB` is the estimated variance-covariance matrix of the coefficient estimates in `beta`.
- If `varformat` has the value 'full', then `CovB` is the estimated variance-covariance matrix of the combined estimates in `beta` and `Sigma`.

logL — Loglikelihood objective function value

scalar value

Loglikelihood objective function value after the last iteration, returned as a scalar value.

More About

Multivariate Normal Regression

Multivariate normal regression is the regression of a d -dimensional response on a design matrix of predictor variables, with normally distributed errors. The errors can be heteroscedastic and correlated.

The model is

$$\mathbf{y}_i = \mathbf{X}_i\boldsymbol{\beta} + \mathbf{e}_i, \quad i = 1, \dots, n,$$

where

- \mathbf{y}_i is a d -dimensional vector of responses.
- \mathbf{X}_i is a design matrix of predictor variables.
- β is vector or matrix of regression coefficients.
- \mathbf{e}_i is a d -dimensional vector of error terms, with multivariate normal distribution

$$\mathbf{e}_i \sim MVN_d(\mathbf{0}, \Sigma).$$

Conditionally Imputed Values

The expectation/conditional maximization ('ecm') and covariance-weighted least squares ('cwlsl') estimation algorithms include imputation of missing response values.

Let $\tilde{\mathbf{y}}$ denote missing observations. The conditionally imputed values are the expected value of the missing observation given the observed data, $E(\tilde{\mathbf{y}} | \mathbf{y})$.

The joint distribution of the missing and observed responses is a multivariate normal distribution,

$$\begin{pmatrix} \tilde{\mathbf{y}} \\ \mathbf{y} \end{pmatrix} \sim MVN \left\{ \begin{pmatrix} \tilde{\mathbf{X}}\beta \\ \mathbf{X}\beta \end{pmatrix}, \begin{pmatrix} \Sigma_{\tilde{\mathbf{y}}} & \Sigma_{\tilde{\mathbf{y}}\mathbf{y}} \\ \Sigma_{\mathbf{y}\tilde{\mathbf{y}}} & \Sigma_{\mathbf{y}} \end{pmatrix} \right\}.$$

Using properties of the multivariate normal distribution, the imputed conditional expectation is given by

$$E(\tilde{\mathbf{y}} | \mathbf{y}) = \tilde{\mathbf{X}}\beta + \Sigma_{\tilde{\mathbf{y}}\mathbf{y}}\Sigma_{\mathbf{y}}^{-1}(\mathbf{y} - \mathbf{X}\beta).$$

Note: `mvregress` only imputes missing response values. Observations with missing values in the design matrix are removed.

manova1 | mvregresslike

mvregresslike

Negative log-likelihood for multivariate regression

Syntax

```
nlogL = mvregresslike(X,Y,b,SIGMA,alg)
[nlogL,COVB] = mvregresslike(...)
[nlogL,COVB] = mvregresslike(...,type,format)
```

Description

`nlogL = mvregresslike(X,Y,b,SIGMA,alg)` computes the negative log-likelihood `nlogL` for a multivariate regression of the d -dimensional multivariate observations in the n -by- d matrix `Y` on the predictor variables in the matrix or cell array `X`, evaluated for the p -by-1 column vector `b` of coefficient estimates and the d -by- d matrix `SIGMA` specifying the covariance of a row of `Y`. If $d = 1$, `X` can be an n -by- p design matrix of predictor variables. For any value of d , `X` can also be a cell array of length n , with each cell containing a d -by- p design matrix for one multivariate observation. If all observations have the same d -by- p design matrix, `X` can be a single cell.

NaN values in `X` or `Y` are taken as missing. Observations with missing values in `X` are ignored. Treatment of missing values in `Y` depends on the algorithm specified by `alg`.

`alg` should match the algorithm used by `mvregress` to obtain the coefficient estimates `b`, and must be one of the following:

- 'ecm' — ECM algorithm
- 'cwls' — Least squares conditionally weighted by `SIGMA`
- 'mvm' — Multivariate normal estimates computed after omitting rows with any missing values in `Y`

`[nlogL,COVB] = mvregresslike(...)` also returns an estimated covariance matrix `COVB` of the parameter estimates `b`.

`[nlogL,COVB] = mvregresslike(...,type,format)` specifies the type and format of `COVB`.

type is either:

- 'hessian' — To use the Hessian or observed information. This method takes into account the increased uncertainties due to missing data. This is the default.
- 'fisher' — To use the Fisher or expected information. This method uses the complete data expected information, and does not include uncertainty due to missing data.

format is either:

- 'beta' — To compute COVB for **b** only. This is the default.
- 'full' — To compute COVB for both **b** and **SIGMA**.

mvnrnd

Multivariate normal random numbers

Syntax

```
R = mvnrnd(MU, SIGMA)
r = mvnrnd(MU, SIGMA, cases)
```

Description

`R = mvnrnd(MU, SIGMA)` returns an n -by- d matrix `R` of random vectors chosen from the multivariate normal distribution with mean `MU`, and covariance `SIGMA`. `MU` is a vector or n -by- d matrix, and `mvnrnd` generates each row of `R` using the corresponding row of `mu`. `SIGMA` is a d -by- d symmetric positive semi-definite matrix, or a d -by- d -by- n array. If `SIGMA` is an array, `mvnrnd` generates each row of `R` using the corresponding page of `SIGMA`, i.e., `mvnrnd` computes `R(i, :)` using `MU(i, :)` and `SIGMA(:, :, i)`. If the covariance matrix is diagonal, containing variances along the diagonal and zero covariances off the diagonal, `SIGMA` may also be specified as a 1-by- d vector or a 1-by- d -by- n array, containing just the diagonal. If `MU` is a 1-by- d vector, `mvnrnd` replicates it to match the trailing dimension of `SIGMA`.

`r = mvnrnd(MU, SIGMA, cases)` returns a `cases`-by- d matrix `R` of random vectors chosen from the multivariate normal distribution with a common 1-by- d mean vector `MU`, and a common d -by- d covariance matrix `SIGMA`.

Examples

Generate Multivariate Normal Random Numbers

Generate random numbers from a multivariate normal distribution with parameters `mu = [2 3]` and `SIGMA = [1 1.5; 1.5 3]`.

```
mu = [2 3];
SIGMA = [1 1.5; 1.5 3];
rng default; % For reproducibility
r = mvnrnd(mu, SIGMA, 100);
```

Plot the random numbers.

```
figure;  
plot(r(:,1),r(:,2),'+')
```

mvnpdf | mvncdf | normrnd

mvtcdf

Multivariate t cumulative distribution function

Syntax

```
y = mvtcdf(X,C,DF)
y = mvtcdf(xl,xu,C,DF)
[y,err] = mvtcdf(...)
[...] = mvntdf(...,options)
```

Description

`y = mvtcdf(X,C,DF)` returns the cumulative probability of the multivariate t distribution with correlation parameters **C** and degrees of freedom **DF**, evaluated at each row of **X**. Rows of the n -by- d matrix **X** correspond to observations or points, and columns correspond to variables or coordinates. **y** is an n -by-1 vector.

C is a symmetric, positive definite, d -by- d matrix, typically a correlation matrix. If its diagonal elements are not 1, `mvtcdf` scales **C** to correlation form. `mvtcdf` does not rescale **X**. **DF** is a scalar, or a vector with n elements.

The multivariate t cumulative probability at **X** is defined as the probability that a random vector **T**, distributed as multivariate t , will fall within the semi-infinite rectangle with upper limits defined by **X**, i.e., $\Pr\{T(1)\leq X(1), T(2)\leq X(2), \dots, T(d)\leq X(d)\}$.

`y = mvtcdf(xl,xu,C,DF)` returns the multivariate t cumulative probability evaluated over the rectangle with lower and upper limits defined by **xl** and **xu**, respectively.

`[y,err] = mvtcdf(...)` returns an estimate of the error in **y**. For bivariate and trivariate distributions, `mvtcdf` uses adaptive quadrature on a transformation of the t density, based on methods developed by Genz, as described in the references. The default absolute error tolerance for these cases is $1e-8$. For four or more dimensions, `mvtcdf` uses a quasi-Monte Carlo integration algorithm based on methods developed by Genz and Bretz, as described in the references. The default absolute error tolerance for these cases is $1e-4$.

`[...] = mvtcdf(...,options)` specifies control parameters for the numerical integration used to compute y . This argument can be created by a call to `statset`.

Choices of `statset` parameters are:

- `'TolFun'` — Maximum absolute error tolerance. Default is $1e-8$ when $d < 4$, or $1e-4$ when $d \geq 4$.
- `'MaxFunEvals'` — Maximum number of integrand evaluations allowed when $d \geq 4$. Default is $1e7$. `'MaxFunEvals'` is ignored when $d < 4$.
- `'Display'` — Level of display output. Choices are `'off'` (the default), `'iter'`, and `'final'`. `'Display'` is ignored when $d < 4$.

Examples

Compute the Multivariate t Distribution cdf

Compute the cdf of a multivariate t distribution with correlation parameters $C = [1 \ .4; \ .4 \ 1]$ and 2 degrees of freedom.

```
C = [1 .4; .4 1];
df = 2;
[X1,X2] = meshgrid(linspace(-2,2,25)',linspace(-2,2,25)');
X = [X1(:) X2(:)];
p = mvtcdf(X,C,df);
```

Plot the cdf.

```
figure;
surf(X1,X2,reshape(p,25,25));
```

mvtpdf | mvtrnd

mvtpdf

Multivariate t probability density function

Syntax

```
y = mvtpdf(X,C,df)
```

Description

`y = mvtpdf(X,C,df)` returns the probability density of the multivariate t distribution with correlation parameters `C` and degrees of freedom `df`, evaluated at each row of `X`. Rows of the n -by- d matrix `X` correspond to observations or points, and columns correspond to variables or coordinates. `C` is a symmetric, positive definite, d -by- d matrix, typically a correlation matrix. If its diagonal elements are not 1, `mvtpdf` scales `C` to correlation form. `mvtcdf` does not rescale `X`. `df` is a scalar, or a vector with n elements. `y` is an n -by-1 vector.

Examples

Compute the Multivariate t Distribution pdf

Compute the pdf of a multivariate t distribution with correlation parameters `C = [1 .4; .4 1]` and 2 degrees of freedom.

```
[X1,X2] = meshgrid(linspace(-2,2,25)',linspace(-2,2,25)');  
X = [X1(:) X2(:)];  
C = [1 .4; .4 1];  
df = 2;  
p = mvtpdf(X,C,df);
```

Plot the pdf.

```
figure;  
surf(X1,X2,reshape(p,25,25))
```

mvtcdf | mvtrnd

mvtrnd

Multivariate t random numbers

Syntax

```
R = mvtrnd(C,df,cases)
R = mvtrnd(C,df)
```

Description

`R = mvtrnd(C,df,cases)` returns a matrix of random numbers chosen from the multivariate t distribution, where **C** is a correlation matrix. **df** is the degrees of freedom and is either a scalar or is a vector with **cases** elements. If **p** is the number of columns in **C**, then the output **R** has **cases** rows and **p** columns.

Let **t** represent a row of **R**. Then the distribution of **t** is that of a vector having a multivariate normal distribution with mean 0, variance 1, and covariance matrix **C**, divided by an independent chi-square random value having **df** degrees of freedom. The rows of **R** are independent.

C must be a square, symmetric and positive definite matrix. If its diagonal elements are not all 1 (that is, if **C** is a covariance matrix rather than a correlation matrix), `mvtrnd` rescales **C** to transform it to a correlation matrix before generating the random numbers.

`R = mvtrnd(C,df)` returns a single random number from the multivariate t distribution.

Examples

Generate Multivariate t Distribution Random Numbers

Generate random numbers from a multivariate t distribution with correlation parameters `SIGMA = [1 0.8;0.8 1]` and 3 degrees of freedom.

```
rng default; % For reproducibility
SIGMA = [1 0.8;0.8 1];
```

```
R = mvtrnd(SIGMA,3,100);
```

Plot the random numbers.

```
figure;  
plot(R(:,1),R(:,2),'+')
```

NumObservations property

Class: cvpartition

Number of observations (including observations with missing group values)

Description

Number of observations (including observations with missing group values).

NaiveBayes class

Naive Bayes classifier

Description

A `NaiveBayes` object defines a Naive Bayes classifier. A Naive Bayes classifier assigns a new observation to the most probable class, assuming the features are conditionally independent given the class value.

Construction

`.NaiveBayes`

Create `NaiveBayes` object

Methods

`disp`

Display `NaiveBayes` classifier object

`display`

Display `NaiveBayes` classifier object

`fit`

Create Naive Bayes classifier object by fitting training data

`posterior`

Compute posterior probability of each class for test data

`predict`

Predict class label for test data

`subsasgn`

Subscripted reference for `NaiveBayes` object

suboref

Subscribed reference for NaiveBayes object

Properties

CIIsNonEmpty

Flag for non-empty classes

ClassLevels

Class levels

Prior

Class priors

Dist

Distribution names

NClasses

Number of classes

NDims

Number of dimensions

Params

Parameter estimates

Copy Semantics

Value. To learn how this affects your use of the class, see “Comparing Handle and Value Classes” in the MATLAB Object-Oriented Programming documentation.

Examples

Predict the class label using the Naive Bayes classifier:

```
load fisheriris
```

Use the default Gaussian distribution and a confusion matrix:

```
O1 = fitNaiveBayes(meas,species);
```

```
C1 = O1.predict(meas);
cMat1 = confusionmat(species,C1)
This returns:
```

```
cMat1 =

    50     0     0
     0    47     3
     0     3    47
```

Use the Gaussian distribution for features 1 and 3 and use the kernel density estimation for features 2 and 4:

```
O2 = fitNaiveBayes(meas,species,'dist',...
{'normal','kernel','normal','kernel'});
C2 = O2.predict(meas);
cMat2 = confusionmat(species,C2)
This returns:
```

```
cMat2 =

    50     0     0
     0    47     3
     0     3    47
```

NaiveBayes

Class: NaiveBayes

Create NaiveBayes object

Description

You cannot create a `NaiveBayes` classifier by calling the constructor. Use `fitNaiveBayes` to create a `NaiveBayes` classifier by fitting the object to training data.

See Also

`fitNaiveBayes`

prob.NakagamiDistribution class

Package: prob

Superclasses: prob.ToolboxFittableParametricDistribution

Nakagami probability distribution object

Description

`prob.NakagamiDistribution` is an object consisting of parameters, a model description, and sample data for a Nakagami probability distribution.

Create a probability distribution object with specified parameter values using `makedist`. Alternatively, fit a distribution to data using `fitdist` or the Distribution Fitting app.

Construction

`pd = makedist('Nakagami')` creates a Nakagami probability distribution object using the default parameter values.

`pd = makedist('Nakagami', 'mu', mu, 'omega', omega)` creates a Nakagami probability distribution object using the specified parameter values.

Input Arguments

mu — Shape parameter

1 (default) | positive scalar value

Shape parameter for the Nakagami distribution, specified as a positive scalar value.

Data Types: `single` | `double`

omega — Scale parameter

1 (default) | positive scalar value

Scale parameter for the Nakagami distribution, specified as a positive scalar value.

Data Types: `single` | `double`

Properties

mu — Shape parameter

positive scalar value

Shape parameter for the Nakagami distribution, stored as a positive scalar value.

Data Types: `single` | `double`

omega — Scale parameter

positive scalar value

Scale parameter for the Nakagami distribution, stored as a positive scalar value.

Data Types: `single` | `double`

DistributionName — Probability distribution name

probability distribution name string

Probability distribution name, stored as a valid probability distribution name string. This property is read-only.

Data Types: `char`

InputData — Data used for distribution fitting

structure

Data used for distribution fitting, stored as a structure containing the following:

- **data**: Data vector used for distribution fitting.
- **cens**: Censoring vector, or empty if none.
- **freq**: Frequency vector, or empty if none.

This property is read-only.

Data Types: `struct`

IsTruncated — Logical flag for truncated distribution

0 | 1

Logical flag for truncated distribution, stored as a logical value. If `IsTruncated` equals 0, the distribution is not truncated. If `IsTruncated` equals 1, the distribution is truncated. This property is read-only.

Data Types: `logical`

NumParameters — Number of parameters

positive integer value

Number of parameters for the probability distribution, stored as a positive integer value. This property is read-only.

Data Types: `single` | `double`

ParameterCovariance — Covariance matrix of the parameter estimates

matrix of scalar values

Covariance matrix of the parameter estimates, stored as a p -by- p matrix, where p is the number of parameters in the distribution. The (i,j) element is the covariance between the estimates of the i th parameter and the j th parameter. The (i,i) element is the estimated variance of the i th parameter. If parameter i is fixed rather than estimated by fitting the distribution to data, then the (i,i) elements of the covariance matrix are 0. This property is read-only.

Data Types: `single` | `double`

ParameterDescription — Distribution parameter descriptions

cell array of strings

Distribution parameter descriptions, stored as a cell array of strings. Each cell contains a short description of one distribution parameter. This property is read-only.

Data Types: `char`

ParameterIsFixed — Logical flag for fixed parameters

array of logical values

Logical flag for fixed parameters, stored as an array of logical values. If 0, the corresponding parameter in the `ParameterNames` array is not fixed. If 1, the corresponding parameter in the `ParameterNames` array is fixed. This property is read-only.

Data Types: `logical`

ParameterNames — Distribution parameter names

cell array of strings

Distribution parameter names, stored as a cell array of strings. This property is read-only.

Data Types: char

ParameterValues — Distribution parameter values

vector of scalar values

Distribution parameter values, stored as a vector. This property is read-only.

Data Types: single | double

Truncation — Truncation interval

vector of scalar values

Truncation interval for the probability distribution, stored as a vector containing the lower and upper truncation boundaries. This property is read-only.

Data Types: single | double

Methods

Inherited Methods

cdf	Cumulative distribution function of probability distribution object
icdf	Inverse cumulative distribution function of probability distribution object

Definitions

Nakagami Distribution

The Nakagami distribution is commonly used in communication theory to model scattered signals that reach a receiver using multiple paths.

The Nakagami distribution uses the following parameters.

Parameter	Description	Support
mu	Shape parameter	$\mu > 0$
omega	Scale parameter	$\omega > 0$

The probability density function (pdf) is

$$f(x | \mu, \omega) = 2 \left(\frac{\mu^\mu}{\omega} \right) \frac{1}{\Gamma(\mu)} x^{(2\mu-1)} \exp\left\{ -\frac{\mu}{\omega} x^2 \right\} ; \quad x > 0,$$

where $\Gamma(\cdot)$ is the Gamma function.

Examples

Create a Nakagami Distribution Object Using Default Parameters

Create a Nakagami distribution object using the default parameter values.

```
pd = makedist('Nakagami')
```

```
pd =
```

```
NakagamiDistribution
```

```
Nakagami distribution
```

```
mu = 1
```

```
omega = 1
```

Create a Nakagami Distribution Object Using Specified Parameters

Create a Nakagami distribution object by specifying parameter values.

```
pd = makedist('Nakagami', 'mu', 5, 'omega', 2)
```

```
pd =
```

```
NakagamiDistribution
```

```
Nakagami distribution
```

```
mu = 5
```

```
omega = 2
```

Compute the mean of the distribution.

```
m = mean(pd)
```

```
m =
```

nancov

Covariance ignoring NaN values

Syntax

```
Y = nancov(X)
Y = nancov(X1,X2)
Y = nancov(...,1)
Y = nancov(...,'pairwise')
```

Description

$Y = \text{nancov}(X)$ is the covariance `cov` of X , computed after removing observations with NaN values.

For vectors x , $\text{nancov}(x)$ is the sample variance of the remaining elements, once NaN values are removed. For matrices X , $\text{nancov}(X)$ is the sample covariance of the remaining observations, once observations (rows) containing any NaN values are removed.

$Y = \text{nancov}(X1, X2)$, where $X1$ and $X2$ are matrices with the same number of elements, is equivalent to $\text{nancov}(X)$, where $X = [X1(:) \ X2(:)]$.

`nancov` removes the mean from each variable (column for matrix X) before calculating Y . If n is the number of remaining observations after removing observations with NaN values, `nancov` normalizes Y by either $n - 1$ or n , depending on whether $n > 1$ or $n = 1$, respectively. To specify normalization by n , use $Y = \text{nancov}(\dots, 1)$.

$Y = \text{nancov}(\dots, 'pairwise')$ computes $Y(i, j)$ using rows with no NaN values in columns i or j . The result Y may not be a positive definite matrix.

Examples

Generate random data for two variables (columns) with random missing values:

```
X = rand(10,2);
```

```

p = randperm(numel(X));
X(p(1:5)) = NaN
X =
    0.8147    0.1576
      NaN      NaN
    0.1270    0.9572
    0.9134      NaN
    0.6324      NaN
    0.0975    0.1419
    0.2785    0.4218
    0.5469    0.9157
    0.9575    0.7922
    0.9649      NaN

```

Establish a correlation between a third variable and the other two variables:

```

X(:,3) = sum(X,2)
X =
    0.8147    0.1576    0.9723
      NaN      NaN      NaN
    0.1270    0.9572    1.0842
    0.9134      NaN      NaN
    0.6324      NaN      NaN
    0.0975    0.1419    0.2394
    0.2785    0.4218    0.7003
    0.5469    0.9157    1.4626
    0.9575    0.7922    1.7497
    0.9649      NaN      NaN

```

Compute the covariance matrix for the three variables after removing observations (rows) with NaN values:

```

Y = nancov(X)
Y =
    0.1311    0.0096    0.1407
    0.0096    0.1388    0.1483
    0.1407    0.1483    0.2890

```

See Also

NaN | cov | var | nanvar

nanmax

Maximum ignoring NaN values

Syntax

```
y = nanmax(X)
Y = nanmax(X1,X2)
y = nanmax(X,[],dim)
[y,indices] = nanmax(...)
```

Description

`y = nanmax(X)` is the maximum `max` of `X`, computed after removing NaN values.

For vectors `x`, `nanmax(x)` is the maximum of the remaining elements, once NaN values are removed. For matrices `X`, `nanmax(X)` is a row vector of column maxima, once NaN values are removed. For multidimensional arrays `X`, `nanmax` operates along the first nonsingleton dimension.

`Y = nanmax(X1,X2)` returns an array `Y` the same size as `X1` and `X2` with `Y(i,j) = nanmax(X1(i,j),X2(i,j))`. Scalar inputs are expanded to an array of the same size as the other input.

`y = nanmax(X,[],dim)` operates along the dimension `dim` of `X`.

`[y,indices] = nanmax(...)` also returns the row indices of the maximum values for each column in the vector `indices`.

Examples

Find column maxima and their indices for data with missing values:

```
X = magic(3);
X([1 6:9]) = repmat(NaN,1,5)
X =
    NaN     1    NaN
```

```
      3      5      NaN
      4      NaN      NaN
[y,indices] = nanmax(X)
y =
      4      5      NaN
indices =
      3      2      1
```

See Also

NaN | max | nanmin

nanmean

Mean ignoring NaN values

Syntax

```
y = nanmean(X)
y = nanmean(X,dim)
```

Description

`y = nanmean(X)` is the mean of `X`, computed after removing NaN values.

For vectors `x`, `nanmean(x)` is the mean of the remaining elements, once NaN values are removed. For matrices `X`, `nanmean(X)` is a row vector of column means, once NaN values are removed. For multidimensional arrays `X`, `nanmean` operates along the first nonsingleton dimension.

`y = nanmean(X,dim)` takes the mean along dimension `dim` of `X`.

Note: If `X` contains a vector of all NaN values along some dimension, the vector is empty once the NaN values are removed, so the sum of the remaining elements is 0. Since the mean involves division by 0, its value is NaN. The output NaN is not a mean of NaN values.

Examples

Find column means for data with missing values:

```
X = magic(3);
X([1 6:9]) = repmat(NaN,1,5)
X =
    NaN     1    NaN
     3     5    NaN
     4    NaN    NaN
y = nanmean(X)
y =
```

3.5000 3.0000 NaN

See Also

NaN | mean | nanmedian

nanmedian

Median ignoring NaN values

Syntax

```
y = nanmedian(X)
y = nanmedian(X,dim)
```

Description

`y = nanmedian(X)` is the median of `X`, computed after removing NaN values.

For vectors `x`, `nanmedian(x)` is the median of the remaining elements, once NaN values are removed. For matrices `X`, `nanmedian(X)` is a row vector of column medians, once NaN values are removed. For multidimensional arrays `X`, `nanmedian` operates along the first nonsingleton dimension.

`y = nanmedian(X,dim)` takes the mean along dimension `dim` of `X`.

Examples

Find column medians for data with missing values:

```
X = magic(3);
X([1 6:9]) = repmat(NaN,1,5)
X =
    NaN     1    NaN
     3     5    NaN
     4    NaN    NaN
y = nanmedian(X)
y =
    3.5000    3.0000    NaN
```

See Also

NaN | median | nanmean

nanmin

Minimum ignoring NaN values

Syntax

```
y = nanmin(X)
Y = nanmin(X1,X2)
y = nanmin(X,[],dim)
[y,indices] = nanmin(...)
```

Description

`y = nanmin(X)` is the minimum `min` of `X`, computed after removing NaN values.

For vectors `x`, `nanmin(x)` is the minimum of the remaining elements, once NaN values are removed. For matrices `X`, `nanmin(X)` is a row vector of column minima, once NaN values are removed. For multidimensional arrays `X`, `nanmin` operates along the first nonsingleton dimension.

`Y = nanmin(X1,X2)` returns an array `Y` the same size as `X1` and `X2` with `Y(i,j) = nanmin(X1(i,j),X2(i,j))`. Scalar inputs are expanded to an array of the same size as the other input.

`y = nanmin(X,[],dim)` operates along the dimension `dim` of `X`.

`[y,indices] = nanmin(...)` also returns the row indices of the minimum values for each column in the vector `indices`.

Examples

Find column minima and their indices for data with missing values:

```
X = magic(3);
X([1 6:9]) = repmat(NaN,1,5)
X =
    NaN     1    NaN
```

```
      3      5      NaN
      4      NaN      NaN
[y,indices] = nanmin(X)
y =
      3      1      NaN
indices =
      2      1      1
```

See Also

NaN | min | nanmax

nanstd

Standard deviation ignoring NaN values

Syntax

```
y = nanstd(X)
y = nanstd(X,1)
y = nanstd(X,flag,dim)
```

Description

`y = nanstd(X)` is the standard deviation `std` of `X`, computed after removing NaN values.

For vectors `x`, `nanstd(x)` is the sample standard deviation of the remaining elements, once NaN values are removed. For matrices `X`, `nanstd(X)` is a row vector of column sample standard deviations, once NaN values are removed. For multidimensional arrays `X`, `nanstd` operates along the first nonsingleton dimension.

If n is the number of remaining observations after removing observations with NaN values, `nanstd` normalizes `y` by $n-1$. To specify normalization by n , use `y = nanstd(X,1)`.

`y = nanstd(X,flag,dim)` takes the standard deviation along the dimension `dim` of `X`. The `flag` is 0 or 1 to specify normalization by $n-1$ or n , respectively, where n is the number of remaining observations after removing observations with NaN values.

Examples

Find column standard deviations for data with missing values:

```
X = magic(3);
X([1 6:9]) = repmat(NaN,1,5)
X =
    NaN     1    NaN
     3     5    NaN
```

```
      4   NaN   NaN
y = nanstd(X)
y =
    0.7071   2.8284   NaN
```

See Also

[NaN](#) | [std](#) | [nanvar](#) | [nanmean](#)

nansum

Sum ignoring NaN values

Syntax

```
y = nansum(X)
y = nansum(X,dim)
```

Description

`y = nansum(X)` is the sum of `X`, computed after removing NaN values.

For vectors `x`, `nansum(x)` is the sum of the remaining elements, once NaN values are removed. For matrices `X`, `nansum(X)` is a row vector of column sums, once NaN values are removed. For multidimensional arrays `X`, `nansum` operates along the first nonsingleton dimension.

`y = nansum(X,dim)` takes the sum along dimension `dim` of `X`.

Note: If `X` contains a vector of all NaN values along some dimension, the vector is empty once the NaN values are removed, so the sum of the remaining elements is 0. The output 0 is not a sum of NaN values.

Examples

Find column sums for data with missing values:

```
X = magic(3);
X([1 6:9]) = repmat(NaN,1,5)
X =
    NaN     1    NaN
     3     5    NaN
     4    NaN    NaN
y = nansum(X)
y =
```

NaN | sum

nanvar

Variance, ignoring NaN values

Syntax

```
y = nanvar(X)
y = nanvar(X,1)
y = nanvar(X,w)
y = nanvar(X,w,dim)
```

Description

`y = nanvar(X)` is the variance `var` of `X`, computed after removing NaN values.

For vectors `x`, `nanvar(x)` is the sample variance of the remaining elements, once NaN values are removed. For matrices `X`, `nanvar(X)` is a row vector of column sample variances, once NaN values are removed. For multidimensional arrays `X`, `nanvar` operates along the first nonsingleton dimension.

`nanvar` removes the mean from each variable (column for matrix `X`) before calculating `Y`. If n is the number of remaining observations after removing observations with NaN values, `nanvar` normalizes `y` by either $n - 1$ or n , depending on whether $n > 1$ or $n = 1$, respectively. To specify normalization by n , use `y = nanvar(X,1)`.

`y = nanvar(X,w)` computes the variance using the weight vector `w`. The length of `w` must equal the length of the dimension over which `nanvar` operates, and its elements must be nonnegative. Elements of `X` corresponding to NaN values of `w` are ignored.

`y = nanvar(X,w,dim)` takes the variance along the dimension `dim` of `X`. Set `w` to `[]` to use the default normalization by $n - 1$.

Examples

Find column standard deviations for data with missing values:

```
X = magic(3);
```

```
X([1 6:9]) = repmat(NaN,1,5)
X =
    NaN     1    NaN
     3     5    NaN
     4    NaN    NaN
y = nanvar(X)
y =
    0.5000    8.0000    NaN
```

nbincdf

Negative binomial cumulative distribution function

Syntax

```
y = nbincdf(x,R,p)
y = nbincdf(x,R,p, 'upper')
```

Description

`y = nbincdf(x,R,p)` computes the negative binomial cdf at each of the values in `x` using the corresponding number of successes, `R` and probability of success in a single trial, `p`. `x`, `R`, and `p` can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of `y`. A scalar input for `x`, `R`, or `p` is expanded to a constant array with the same dimensions as the other inputs.

`y = nbincdf(x,R,p, 'upper')` returns the complement of the negative binomial cdf at each value in `x`, using an algorithm that more accurately computes the extreme upper tail probabilities.

The negative binomial cdf is

$$y = F(x | r, p) = \sum_{i=0}^x \binom{r+i-1}{i} p^r q^i I_{(0,1,\dots)}(i)$$

The simplest motivation for the negative binomial is the case of successive random trials, each having a constant probability `p` of success. The number of *extra* trials you must perform in order to observe a given number `R` of successes has a negative binomial distribution. However, consistent with a more general interpretation of the negative binomial, `nbincdf` allows `R` to be any positive value, including nonintegers. When `R` is noninteger, the binomial coefficient in the definition of the cdf is replaced by the equivalent expression

$$\frac{\Gamma(r+i)}{\Gamma(r)\Gamma(i+1)}$$

Examples

Compute Negative Binomial Distribution CDF

```
x = (0:15);  
p = nbincdf(x,3,0.5);  
stairs(x,p)
```

More About

- “Negative Binomial Distribution” on page B-105

`cdf` | `nbinpdf` | `nbininv` | `nbinstat` | `nbinfit` | `nbinrnd`

nbinfit

Negative binomial parameter estimates

Syntax

```
parmhat = nbinfit(data)
[parmhat,parmci] = nbinfit(data,alpha)
[...] = nbinfit(data,alpha,options)
```

Description

`parmhat = nbinfit(data)` returns the maximum likelihood estimates (MLEs) of the parameters of the negative binomial distribution given the data in the vector `data`.

`[parmhat,parmci] = nbinfit(data,alpha)` returns MLEs and $100(1-\alpha)$ percent confidence intervals. By default, `alpha = 0.05`, which corresponds to 95% confidence intervals.

`[...] = nbinfit(data,alpha,options)` accepts a structure, `options`, that specifies control parameters for the iterative algorithm the function uses to compute maximum likelihood estimates. The negative binomial fit function accepts an `options` structure which you can create using the function `statset`. Enter `statset('nbinfit')` to see the names and default values of the parameters that `nbinfit` accepts in the `options` structure. See the reference page for `statset` for more information about these options.

Note The variance of a negative binomial distribution is greater than its mean. If the sample variance of the data in `data` is less than its sample mean, `nbinfit` cannot compute MLEs. You should use the `poissfit` function instead.

`nbincdf` | `nbininv` | `nbinpdf` | `nbinrnd` | `nbinstat` | `mle` | `statset`

nbiniinv

Negative binomial inverse cumulative distribution function

Syntax

```
X = nbiniinv(Y,R,P)
```

Description

`X = nbiniinv(Y,R,P)` returns the inverse of the negative binomial cdf with corresponding number of successes, `R` and probability of success in a single trial, `P`. Since the binomial distribution is discrete, `nbiniinv` returns the least integer `X` such that the negative binomial cdf evaluated at `X` equals or exceeds `Y`. `Y`, `R`, and `P` can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of `X`. A scalar input for `Y`, `R`, or `P` is expanded to a constant array with the same dimensions as the other inputs.

The simplest motivation for the negative binomial is the case of successive random trials, each having a constant probability `P` of success. The number of *extra* trials you must perform in order to observe a given number `R` of successes has a negative binomial distribution. However, consistent with a more general interpretation of the negative binomial, `nbiniinv` allows `R` to be any positive value, including nonintegers.

Examples

How many times would you need to flip a fair coin to have a 99% probability of having observed 10 heads?

```
flips = nbiniinv(0.99,10,0.5) + 10  
flips =  
    33
```

Note that you have to flip at least 10 times to get 10 heads. That is why the second term on the right side of the equals sign is a 10.

`icdf` | `nbincdf` | `nbinpdf` | `nbinstat` | `nbinfit` | `nbinrnd`

nbincpdf

Negative binomial probability density function

Syntax

`Y = nbincpdf(X,R,P)`

Description

`Y = nbincpdf(X,R,P)` returns the negative binomial pdf at each of the values in `X` using the corresponding number of successes, `R` and probability of success in a single trial, `P`. `X`, `R`, and `P` can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of `Y`. A scalar input for `X`, `R`, or `P` is expanded to a constant array with the same dimensions as the other inputs. Note that the density function is zero unless the values in `X` are integers.

The negative binomial pdf is

$$y = f(x | r, p) = \binom{r+x-1}{x} p^r q^x I_{(0,1,\dots)}(x)$$

The simplest motivation for the negative binomial is the case of successive random trials, each having a constant probability `P` of success. The number of *extra* trials you must perform in order to observe a given number `R` of successes has a negative binomial distribution. However, consistent with a more general interpretation of the negative binomial, `nbincpdf` allows `R` to be any positive value, including nonintegers. When `R` is noninteger, the binomial coefficient in the definition of the pdf is replaced by the equivalent expression

$$\frac{\Gamma(r+x)}{\Gamma(r)\Gamma(x+1)}$$

Examples

Compute the Negative Binomial Distribution pdf

Compute the pdf of a negative binomial distribution with parameters $R = 3$ and $p = 0.5$.

```
x = (0:10);  
y = nbinpdf(x,3,0.5);
```

Plot the pdf.

```
figure;  
plot(x,y, '+')  
xlim([-0.5,10.5])
```

nbinrnd

Negative binomial random numbers

Syntax

```
RND = nbinrnd(R,P)
RND = nbinrnd(R,P,m,n,...)
RND = nbinrnd(R,P,[m,n,...])
```

Description

`RND = nbinrnd(R,P)` is a matrix of random numbers chosen from a negative binomial distribution with corresponding number of successes, `R` and probability of success in a single trial, `P`. `R` and `P` can be vectors, matrices, or multidimensional arrays that have the same size, which is also the size of `RND`. A scalar input for `R` or `P` is expanded to a constant array with the same dimensions as the other input.

`RND = nbinrnd(R,P,m,n,...)` or `RND = nbinrnd(R,P,[m,n,...])` generates an `m`-by-`n`-by-... array. The `R`, `P` parameters can each be scalars or arrays of the same size as `R`.

The simplest motivation for the negative binomial is the case of successive random trials, each having a constant probability `P` of success. The number of *extra* trials you must perform in order to observe a given number `R` of successes has a negative binomial distribution. However, consistent with a more general interpretation of the negative binomial, `nbinrnd` allows `R` to be any positive value, including nonintegers.

Examples

Suppose you want to simulate a process that has a defect probability of 0.01. How many units might Quality Assurance inspect before finding three defective items?

```
r = nbinrnd(3,0.01,1,6)+3
r =
    496    142    420    396    851    178
```

random | nbinpdf | nbincdf | nbininv | nbinstat | nbinfit

nbinstat

Negative binomial mean and variance

Syntax

```
[M,V] = nbinstat(R,P)
```

Description

`[M,V] = nbinstat(R,P)` returns the mean of and variance for the negative binomial distribution with corresponding number of successes, `R` and probability of success in a single trial, `P`. `R` and `P` can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of `M` and `V`. A scalar input for `R` or `P` is expanded to a constant array with the same dimensions as the other input.

The mean of the negative binomial distribution with parameters r and p is rq / p , where $q = 1 - p$. The variance is rq / p^2 .

The simplest motivation for the negative binomial is the case of successive random trials, each having a constant probability `P` of success. The number of *extra* trials you must perform in order to observe a given number `R` of successes has a negative binomial distribution. However, consistent with a more general interpretation of the negative binomial, `nbinstat` allows `R` to be any positive value, including nonintegers.

Examples

```
p = 0.1:0.2:0.9;
r = 1:5;
[R,P] = meshgrid(r,p);
[M,V] = nbinstat(R,P)
M =

ncfcdf

Noncentral F cumulative distribution function

Syntax

```
p = ncfcdf(x, nu1, nu2, delta)
p = ncfcdf(x, nu1, nu2, delta, 'upper')
```

Description

`p = ncfcdf(x, nu1, nu2, delta)` computes the noncentral F cdf at each value in `x` using the corresponding numerator degrees of freedom in `nu1`, denominator degrees of freedom in `nu2`, and positive noncentrality parameters in `delta`. `nu1`, `nu2`, and `delta` can be vectors, matrices, or multidimensional arrays that have the same size, which is also the size of `p`. A scalar input for `x`, `nu1`, `nu2`, or `delta` is expanded to a constant array with the same dimensions as the other inputs.

`p = ncfcdf(x, nu1, nu2, delta, 'upper')` returns the complement of the noncentral F cdf at each value in `x`, using an algorithm that more accurately computes the extreme upper tail probabilities.

The noncentral F cdf is

$$F(x | v_1, v_2, \delta) = \sum_{j=0}^{\infty} \left(\frac{\left(\frac{1}{2}\delta\right)^j}{j!} e^{-\frac{\delta}{2}} \right) I\left(\frac{v_1 \cdot x}{v_2 + v_1 \cdot x} \middle| \frac{v_1}{2} + j, \frac{v_2}{2}\right)$$

where $I(x | a, b)$ is the incomplete beta function with parameters a and b .

Examples

Compute Noncentral F Distribution cdf

Compare the noncentral F cdf with $\delta = 10$ to the F cdf with the same number of numerator and denominator degrees of freedom (5 and 20 respectively).

```
x = (0.01:0.1:10.01)';  
p1 = ncfcdf(x,5,20,10);  
p = fcdf(x,5,20);  
plot(x,p,'- ',x,p1,'- ')
```

ncfinv

Noncentral F inverse cumulative distribution function

Syntax

```
X = ncfinv(P,NU1,NU2,DELTA)
```

Description

`X = ncfinv(P,NU1,NU2,DELTA)` returns the inverse of the noncentral F cdf with numerator degrees of freedom `NU1`, denominator degrees of freedom `NU2`, and positive noncentrality parameter `DELTA` for the corresponding probabilities in `P`. `P`, `NU1`, `NU2`, and `DELTA` can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of `X`. A scalar input for `P`, `NU1`, `NU2`, or `DELTA` is expanded to a constant array with the same dimensions as the other inputs.

Examples

One hypothesis test for comparing two sample variances is to take their ratio and compare it to an F distribution. If the numerator and denominator degrees of freedom are 5 and 20 respectively, then you reject the hypothesis that the first variance is equal to the second variance if their ratio is less than that computed below.

```
critical = finv(0.95,5,20)
critical =
    2.7109
```

Suppose the truth is that the first variance is twice as big as the second variance. How likely is it that you would detect this difference?

```
prob = 1 - nfcdf(critical,5,20,2)
prob =
    0.1297
```

If the true ratio of variances is 2, what is the typical (median) value you would expect for the F statistic?

```
ncfinv(0.5,5,20,2)
ans =
    1.2786
```

icdf | nfcdf | ncfpdf | ncfstat | ncfrnd

ncfpdf

Noncentral F probability density function

Syntax

```
Y = ncfpdf(X, NU1, NU2, DELTA)
```

Description

`Y = ncfpdf(X, NU1, NU2, DELTA)` computes the noncentral F pdf at each of the values in X using the corresponding numerator degrees of freedom in $NU1$, denominator degrees of freedom in $NU2$, and positive noncentrality parameters in $DELTA$. X , $NU1$, $NU2$, and $DELTA$ can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of Y . A scalar input for $NU1$, $NU2$, or $DELTA$ is expanded to a constant array with the same dimensions as the other inputs.

The F distribution is a special case of the noncentral F where $\delta = 0$. As δ increases, the distribution flattens like the plot in the example.

Examples

Compute Noncentral F Distribution pdf

Compute the pdf of a noncentral F distribution with degrees of freedom $NU1 = 5$ and $NU2 = 20$, and noncentrality parameter $DELTA = 10$. For comparison, also compute the pdf of an F distribution with the same degrees of freedom.

```
x = (0.01:0.1:10.01)';  
p1 = ncfpdf(x,5,20,10);  
p = fpdf(x,5,20);
```

Plot the pdf of the noncentral F distribution and the pdf of the F distribution on the same figure.

```
figure;  
plot(x,p1,'b-','LineWidth',2)  
hold on
```

```
plot(x,p,'g--','LineWidth',2)  
legend('Noncentral F','F distribution')
```

pdf | ncfcdf | ncfinv | ncfstat | ncfrnd

ncfrnd

Noncentral F random numbers

Syntax

```
R = ncfrnd(NU1, NU2, DELTA)
R = ncfrnd(NU1, NU2, DELTA, m, n, ... )
R = ncfrnd(NU1, NU2, DELTA, [m, n, ... ])
```

Description

`R = ncfrnd(NU1, NU2, DELTA)` returns a matrix of random numbers chosen from the noncentral F distribution with corresponding numerator degrees of freedom in `NU1`, denominator degrees of freedom in `NU2`, and positive noncentrality parameters in `DELTA`. `NU1`, `NU2`, and `DELTA` can be vectors, matrices, or multidimensional arrays that have the same size, which is also the size of `R`. A scalar input for `NU1`, `NU2`, or `DELTA` is expanded to a constant matrix with the same dimensions as the other inputs.

`R = ncfrnd(NU1, NU2, DELTA, m, n, ...)` or `R = ncfrnd(NU1, NU2, DELTA, [m, n, ...])` generates an `m`-by-`n`-by-... array. The `NU1`, `NU2`, `DELTA` parameters can each be scalars or arrays of the same size as `R`.

Examples

Compute six random numbers from a noncentral F distribution with 10 numerator degrees of freedom, 100 denominator degrees of freedom and a noncentrality parameter, δ , of 4.0. Compare this to the F distribution with the same degrees of freedom.

```
r = ncfrnd(10,100,4,1,6)
r =
    2.5995    0.8824    0.8220    1.4485    1.4415    1.4864

r1 = frnd(10,100,1,6)
r1 =
    0.9826    0.5911    1.0967    0.9681    2.0096    0.6598
```

random | ncfpdf | ncfcdf | ncfinv | ncfstat

ncfstat

Noncentral F mean and variance

Syntax

`[M,V] = ncfstat(NU1,NU2,DELTA)`

Description

`[M,V] = ncfstat(NU1,NU2,DELTA)` returns the mean of and variance for the noncentral F pdf with corresponding numerator degrees of freedom in `NU1`, denominator degrees of freedom in `NU2`, and positive noncentrality parameters in `DELTA`. `NU1`, `NU2`, and `DELTA` can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of `M` and `V`. A scalar input for `NU1`, `NU2`, or `DELTA` is expanded to a constant array with the same dimensions as the other input.

The mean of the noncentral F distribution with parameters ν_1 , ν_2 , and δ is

$$\frac{\nu_2(\delta + \nu_1)}{\nu_1(\nu_2 - 2)}$$

where $\nu_2 > 2$.

The variance is

$$2 \left(\frac{\nu_2}{\nu_1} \right)^2 \left[\frac{(\delta + \nu_1)^2 + (2\delta + \nu_1)(\nu_2 - 2)}{(\nu_2 - 2)^2(\nu_2 - 4)} \right]$$

where $\nu_2 > 4$.

Examples

`[m,v]= ncfstat(10,100,4)`

m =
1.4286
v =
0.4252

NClasses property

Class: NaiveBayes

Number of classes

Description

The `NClasses` property specifies the number of classes in the grouping variable used to create the Naive Bayes classifier.

NumComponents property

Class: `gmdistribution`

Number k of mixture components

Description

The number k of mixture components.

nctcdf

Noncentral t cumulative distribution function

Syntax

```
p = nctcdf(x,nu,delta)
p = nctcdf(x,nu,delta,'upper')
```

Description

`p = nctcdf(x,nu,delta)` computes the noncentral t cdf at each value in `x` using the corresponding degrees of freedom in `nu` and noncentrality parameters in `delta`. `x`, `nu`, and `delta` can be vectors, matrices, or multidimensional arrays that have the same size, which is also the size of `p`. A scalar input for `x`, `nu`, or `delta` is expanded to a constant array with the same dimensions as the other inputs.

`p = nctcdf(x,nu,delta,'upper')` returns the complement of the noncentral t cdf at each value in `x`, using an algorithm that more accurately computes the extreme upper tail probabilities.

Examples

Compute Noncentral t Distribution cdf

Compare the noncentral t cdf with `DELTA = 1` to the t cdf with the same number of degrees of freedom (10).

```
x = (-5:0.1:5)';
p1 = nctcdf(x,10,1);
p = tcdf(x,10);
plot(x,p,'-',x,p1,':')
```

nctinv

Noncentral t inverse cumulative distribution function

Syntax

```
X = nctinv(P,NU,DELTA)
```

Description

`X = nctinv(P,NU,DELTA)` returns the inverse of the noncentral t cdf with `NU` degrees of freedom and noncentrality parameter `DELTA` for the corresponding probabilities in `P`. `P`, `NU`, and `DELTA` can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of `X`. A scalar input for `P`, `NU`, or `DELTA` is expanded to a constant array with the same dimensions as the other inputs.

Examples

```
x = nctinv([0.1 0.2],10,1)
x =
    -0.2914    0.1618
```

nctpdf

Noncentral t probability density function

Syntax

```
Y = nctpdf(X,V,DELTA)
```

Description

`Y = nctpdf(X,V,DELTA)` computes the noncentral t pdf at each of the values in `X` using the corresponding degrees of freedom in `V` and noncentrality parameters in `DELTA`. Vector or matrix inputs for `X`, `V`, and `DELTA` must have the same size, which is also the size of `Y`. A scalar input for `X`, `V`, or `DELTA` is expanded to a constant matrix with the same dimensions as the other inputs.

Examples

Compute Noncentral t Distribution pdf

Compute the pdf of a noncentral t distribution with degrees of freedom `V = 10` and noncentrality parameter `DELTA = 1`. For comparison, also compute the pdf of a t distribution with the same degrees of freedom.

```
x = (-5:0.1:5)';  
nct = nctpdf(x,10,1);  
t = tpdf(x,10);
```

Plot the pdf of the noncentral t distribution and the pdf of the t distribution on the same figure.

```
plot(x,nct,'b-','LineWidth',2)  
hold on  
plot(x,t,'g--','LineWidth',2)  
legend('nct','t')
```

nctrnd

Noncentral t random numbers

Syntax

```
R = nctrnd(V, DELTA)
R = nctrnd(V, DELTA, m, n, ...)
R = nctrnd(V, DELTA, [m, n, ...])
```

Description

`R = nctrnd(V, DELTA)` returns a matrix of random numbers chosen from the noncentral T distribution using the corresponding degrees of freedom in `V` and noncentrality parameters in `DELTA`. `V` and `DELTA` can be vectors, matrices, or multidimensional arrays. A scalar input for `V` or `DELTA` is expanded to a constant array with the same dimensions as the other input.

`R = nctrnd(V, DELTA, m, n, ...)` or `R = nctrnd(V, DELTA, [m, n, ...])` generates an m -by- n -by-... array. The `V`, `DELTA` parameters can each be scalars or arrays of the same size as `R`.

Examples

```
nctrnd(10,1,5,1)
ans =
    1.6576
    1.0617
    1.4491
    0.2930
    3.6297
```

random | nctpdf | nctcdf | nctinv | nctstat

nctstat

Noncentral t mean and variance

Syntax

`[M,V] = nctstat(NU,DELTA)`

Description

`[M,V] = nctstat(NU,DELTA)` returns the mean of and variance for the noncentral t pdf with NU degrees of freedom and noncentrality parameter $DELTA$. NU and $DELTA$ can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of M and V . A scalar input for NU or $DELTA$ is expanded to a constant array with the same dimensions as the other input.

The mean of the noncentral t distribution with parameters ν and δ is

$$\frac{\delta(\nu/2)^{1/2}\Gamma((\nu-1)/2)}{\Gamma(\nu/2)}$$

where $\nu > 1$.

The variance is

$$\frac{\nu}{(\nu-2)}(1+\delta^2) - \frac{\nu}{2}\delta^2 \left[\frac{\Gamma((\nu-1)/2)}{\Gamma(\nu/2)} \right]^2$$

where $\nu > 2$.

Examples

`[m,v] = nctstat(10,1)`

`m =`

1.0837

v =
1.3255

ncx2cdf

Noncentral chi-square cumulative distribution function

Syntax

```
p = ncx2cdf(x,v,delta)
p = ncx2cdf(x,v,delta,'upper')
```

Description

`p = ncx2cdf(x,v,delta)` computes the noncentral chi-square cdf at each value in `x` using the corresponding degrees of freedom in `v` and positive noncentrality parameters in `delta`. `x`, `v`, and `delta` can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of `p`. A scalar input for `x`, `v`, or `delta` is expanded to a constant array with the same dimensions as the other inputs.

`p = ncx2cdf(x,v,delta,'upper')` returns the complement of the noncentral chi-square cdf at each value in `x`, using an algorithm that more accurately computes the extreme upper tail probabilities.

Some texts refer to this distribution as the generalized Rayleigh, Rayleigh-Rice, or Rice distribution.

The noncentral chi-square cdf is

$$F(x | v, \delta) = \sum_{j=0}^{\infty} \left(\frac{\left(\frac{1}{2}\delta\right)^j}{j!} e^{-\frac{\delta}{2}} \right) \Pr\left[\chi_{v+2j}^2 \leq x\right]$$

Examples

Compute Noncentral Chi-Square cdf

Compare the noncentral chi-square cdf with `DELTA = 2` to the chi-square cdf with the same number of degrees of freedom (4):

```
x = (0:0.1:10)';  
ncx2 = ncx2cdf(x,4,2);  
chi2 = chi2cdf(x,4);  
  
plot(x,ncx2,'b-','LineWidth',2)  
hold on  
plot(x,chi2,'g--','LineWidth',2)  
legend('ncx2','chi2','Location','NW')
```

icdf | ncx2cdf | ncx2pdf | ncx2stat | ncx2rnd

ncx2pdf

Noncentral chi-square probability density function

Syntax

```
Y = ncx2pdf(X,V,DELTA)
```

Description

`Y = ncx2pdf(X,V,DELTA)` computes the noncentral chi-square pdf at each of the values in `X` using the corresponding degrees of freedom in `V` and positive noncentrality parameters in `DELTA`. Vector or matrix inputs for `X`, `V`, and `DELTA` must have the same size, which is also the size of `Y`. A scalar input for `X`, `V`, or `DELTA` is expanded to a constant array with the same dimensions as the other inputs.

Some texts refer to this distribution as the generalized Rayleigh, Rayleigh-Rice, or Rice distribution.

Examples

Compute Noncentral Chi-Square Distribution pdf

Compute the pdf of a noncentral chi-square distribution with degrees of freedom $V = 4$ and noncentrality parameter $DELTA = 2$. For comparison, also compute the pdf of a chi-square distribution with the same degrees of freedom.

```
x = (0:0.1:10)';  
ncx2 = ncx2pdf(x,4,2);  
chi2 = chi2pdf(x,4);
```

Plot the pdf of the noncentral chi-square distribution on the same figure as the pdf of the chi-square distribution.

```
figure;  
plot(x,ncx2,'b-', 'LineWidth',2)  
hold on
```

```
plot(x,chi2,'g--','LineWidth',2)  
legend('ncx2','chi2')
```

ncx2rnd

Noncentral chi-square random numbers

Syntax

```
R = ncx2rnd(V,DELTA)
R = ncx2rnd(V,DELTA,m,n,...)
R = ncx2rnd(V,DELTA,[m,n,...])
```

Description

`R = ncx2rnd(V,DELTA)` returns a matrix of random numbers chosen from the noncentral chi-square distribution using the corresponding degrees of freedom in `V` and positive noncentrality parameters in `DELTA`. `V` and `DELTA` can be vectors, matrices, or multidimensional arrays that have the same size, which is also the size of `R`. A scalar input for `V` or `DELTA` is expanded to a constant array with the same dimensions as the other input.

`R = ncx2rnd(V,DELTA,m,n,...)` or `R = ncx2rnd(V,DELTA,[m,n,...])` generates an `m`-by-`n`-by-... array. The `V`, `DELTA` parameters can each be scalars or arrays of the same size as `R`.

Examples

```
ncx2rnd(4,2,6,3)
ans =
    6.8552    5.9650   11.2961
    5.2631    4.2640    5.9495

random | ncx2pdf | ncx2cdf | ncx2inv | ncx2stat

ncx2stat

Noncentral chi-square mean and variance

Syntax

```
[M,V] = ncx2stat(NU,DELTA)
```

Description

`[M,V] = ncx2stat(NU,DELTA)` returns the mean of and variance for the noncentral chi-square pdf with `NU` degrees of freedom and noncentrality parameter `DELTA`. `NU` and `DELTA` can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of `M` and `V`. A scalar input for `NU` or `DELTA` is expanded to a constant array with the same dimensions as the other input.

The mean of the noncentral chi-square distribution with parameters v and δ is $v+\delta$, and the variance is $2(v+2\delta)$.

Examples

```
[m,v] = ncx2stat(4,2)
m =
     6
v =
    16
```

See Also

`ncx2pdf` | `ncx2cdf` | `ncx2inv` | `ncx2rnd`

NumVariables property

Class: gmdistribution

Dimension d of multivariate Gaussian distributions

Description

The dimension d of the multivariate Gaussian distributions.

ndims

Class: dataset

Number of dimensions of dataset array

Compatibility

The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

Syntax

```
n = ndims(A)
```

Description

`n = ndims(A)` returns the number of dimensions in the dataset A. The number of dimensions in an array is always 2.

See Also

`size`

ndims

Class: grandset

Number of dimensions in matrix

Syntax

```
n = ndims(p)
```

Description

`n = ndims(p)` returns the number of dimensions in the matrix that is created by the syntax `p(:, :)`. Since this is always a 2-D matrix, `n` is always equal to 2.

See Also

`grandset` | `size`

NDims property

Class: NaiveBayes

Number of dimensions

Description

The `NDims` property specifies the number of dimensions, which is equal to the number of features in the training data used to create the Naive Bayes classifier.

ne

Class: grandstream

Not equal relation for handles

Syntax

`h1 ~= h2`

Description

Handles are equal if they are handles for the same object and are unequal otherwise.

`h1 ~= h2` performs element-wise comparisons between handle arrays `h1` and `h2`. `h1` and `h2` must be of the same dimensions unless one is a scalar. The result is a logical array of the same dimensions, where each element is an element-wise `~=` result.

If one of `h1` or `h2` is scalar, scalar expansion is performed and the result will match the dimensions of the array that is not scalar.

`tf = ne(h1, h2)` stores the result in a logical array of the same dimensions.

`grandstream` | `ge` | `gt` | `lt` | `eq` | `le`

prob.NegativeBinomialDistribution class

Package: prob

Superclasses: prob.ToolboxFittableParametricDistribution

Negative binomial distribution object

Description

`prob.NegativeBinomialDistribution` is an object consisting of parameters, a model description, and sample data for a negative binomial probability distribution.

Create a probability distribution object with specified parameter values using `makedist`. Alternatively, fit a distribution to data using `fitdist` or the Distribution Fitting app.

Construction

`pd = makedist('NegativeBinomial')` creates a negative binomial probability distribution object using the default parameter values.

`pd = makedist('NegativeBinomial', 'R', r, 'p', p)` creates a negative binomial probability distribution object using the specified parameter values.

Input Arguments

r — Number of successes

1 (default) | positive scalar value

Number of successes for the negative binomial distribution, specified as a positive scalar value.

Data Types: `single` | `double`

p — Probability of success

0.5 (default) | positive scalar value in the range (0, 1]

Probability of success of any individual trial for the negative binomial distribution, specified as a positive scalar value in the range (0, 1].

Data Types: `single` | `double`

Properties

r — Number of successes

positive scalar value

Number of successes for the negative binomial distribution, stored as a positive scalar value.

Data Types: `single` | `double`

p — Probability of success

positive scalar value in the range $(0, 1]$

Probability of success of any individual trial for the negative binomial distribution, specified as a positive scalar value in the range $(0, 1]$.

Data Types: `single` | `double`

DistributionName — Probability distribution name

probability distribution name string

Probability distribution name, stored as a valid probability distribution name string. This property is read-only.

Data Types: `char`

InputData — Data used for distribution fitting

structure

Data used for distribution fitting, stored as a structure containing the following:

- **data**: Data vector used for distribution fitting.
- **cens**: Censoring vector, or empty if none.
- **freq**: Frequency vector, or empty if none.

This property is read-only.

Data Types: `struct`

IsTruncated — Logical flag for truncated distribution

0 | 1

Logical flag for truncated distribution, stored as a logical value. If `IsTruncated` equals 0, the distribution is not truncated. If `IsTruncated` equals 1, the distribution is truncated. This property is read-only.

Data Types: `logical`

NumParameters — Number of parameters

positive integer value

Number of parameters for the probability distribution, stored as a positive integer value. This property is read-only.

Data Types: `single` | `double`

ParameterCovariance — Covariance matrix of the parameter estimates

matrix of scalar values

Covariance matrix of the parameter estimates, stored as a p -by- p matrix, where p is the number of parameters in the distribution. The (i, j) element is the covariance between the estimates of the i th parameter and the j th parameter. The (i, i) element is the estimated variance of the i th parameter. If parameter i is fixed rather than estimated by fitting the distribution to data, then the (i, i) elements of the covariance matrix are 0. This property is read-only.

Data Types: `single` | `double`

ParameterDescription — Distribution parameter descriptions

cell array of strings

Distribution parameter descriptions, stored as a cell array of strings. Each cell contains a short description of one distribution parameter. This property is read-only.

Data Types: `char`

ParameterIsFixed — Logical flag for fixed parameters

array of logical values

Logical flag for fixed parameters, stored as an array of logical values. If 0, the corresponding parameter in the `ParameterNames` array is not fixed. If 1, the corresponding parameter in the `ParameterNames` array is fixed. This property is read-only.

Data Types: `logical`

ParameterNames — Distribution parameter names

cell array of strings

Distribution parameter names, stored as a cell array of strings. This property is read-only.

Data Types: char

ParameterValues — Distribution parameter values

vector of scalar values

Distribution parameter values, stored as a vector. This property is read-only.

Data Types: single | double

Truncation — Truncation interval

vector of scalar values

Truncation interval for the probability distribution, stored as a vector containing the lower and upper truncation boundaries. This property is read-only.

Data Types: single | double

var	Variance of probability distribution object

Definitions

Negative Binomial Distribution

The negative binomial distribution models the number of failures x before a specified number of successes is reached in a series of independent, identical trials. This distribution can also model count data, in which case r does not need to be an integer value.

The negative binomial distribution uses the following parameters.

Parameter	Description	Support
R	Number of successes	$r > 0$
p	Probability of success	$0 < p \leq 1$

The probability density function (pdf) when r is an integer is

$$f(x | r, p) = \binom{r+x-1}{x} p^r q^x \quad ; \quad x = 1, 2, \dots, \infty,$$

where $q = 1 - p$ and $\binom{r+x-1}{x}$ is the binomial coefficient.

When r is not an integer, the binomial coefficient in the definition of the pdf is replaced by the equivalent expression

$$\frac{\Gamma(r+x)}{\Gamma(r)\Gamma(x+1)},$$

where $\Gamma(\cdot)$ is the Gamma function.

Examples

Create a Negative Binomial Distribution Object Using Default Parameters

Create a negative binomial distribution object using the default parameter values.

```
pd = makedist('NegativeBinomial')
```

```
pd =
```

```
NegativeBinomialDistribution
```

```
Negative Binomial distribution
```

```
R = 1
```

```
P = 0.5
```

Create a Negative Binomial Distribution Object Using Specified Parameters

Create a negative binomial distribution object by specifying the parameter values.

```
pd = makedist('NegativeBinomial','r',5,'p',.1)
```

```
pd =
```

```
NegativeBinomialDistribution
```

```
Negative Binomial distribution
```

```
R = 5
```

```
P = 0.1
```

Compute the mean of the distribution.

```
m = mean(pd)
```

```
m =
```

```
45
```

negloglik

Class: prob.KernelDistribution

Package: prob

Negative loglikelihood

Syntax

```
nll = negloglik(pd)
```

Description

`nll = negloglik(pd)` returns the value of the negative log likelihood function for the data used to fit the probability distribution `pd`.

Input Arguments

pd — **Probability distribution**

probability distribution object

Probability distribution, specified as a probability distribution object. Fit a probability distribution object to data using `fitdist` or the Distribution Fitting app.

Output Arguments

nll — **Negative log likelihood**

scalar value

Negative log likelihood value for the data used to fit the distribution, returned as a scalar value.

Examples

Negative Loglikelihood for a Kernel Distribution

Load the sample data. Fit a kernel distribution to the miles per gallon (MPG) data.

```
load carsmall;  
pd = fitdist(MPG, 'Kernel')
```

```
pd =  
  
KernelDistribution  
  
Kernel = normal  
Bandwidth = 4.11428  
Support = unbounded
```

Compute the negative loglikelihood.

```
nll = negloglik(pd)  
  
nll =  
  
327.3139
```

NeighborSearcher class

Nearest neighbor search object

Description

NeighborSearcher is an abstract class used for nearest neighbor search. You cannot create instances of this class directly. Instead, create an instance of a derived class such as ExhaustiveSearcher or KDTreeSearcher either by calling the derived class constructor or by calling the function `createns`.

Construction

NeighborSearcher is an abstract class. You cannot create instances of this class directly. You can construct an object in a subclass, such as KDTreeSearcher or ExhaustiveSearcher, either by calling the subclass constructors or by using the `createns` function.

Properties

x

A matrix used to create the object.

Distance

A string specifying a built-in distance metric (applies to both ExhaustiveSearcher and KDTreeSearcher) or a function handle (only applies to ExhaustiveSearcher) that you provide when you create the object. This property is the default distance metric used when you call the `knnsearch` method to find nearest neighbors for future query points.

DistParameter

Specifies the additional parameter for the chosen distance metric. The value is:

- If 'Distance' is 'minkowski': A positive scalar indicating the exponent of the Minkowski distance. (Applies for both ExhaustiveSearcher and KDTreeSearcher.)
- If 'Distance' is 'mahalanobis': A positive definite matrix representing the covariance matrix used for computing the Mahalanobis distance. (Only applies for ExhaustiveSearcher.)
- If 'Distance' is 'seuclidean': A vector representing the scale value of the data when computing the 'seuclidean' distance. (Only applies for ExhaustiveSearcher.)
- Otherwise: Empty.

createns | ExhaustiveSearcher | KDTreeSearcher

net

Class: grandset

Generate quasi-random point set

Syntax

```
X = net(p,n)
```

Description

`X = net(p,n)` returns the first n points X from the point set p of the `grandset` class. X is n -by- d , where d is the dimension of the point set.

Objects p of the `@grandset` class encapsulate properties of a specified quasi-random sequence. Values of the point set are not generated and stored in memory until p is accessed using `net` or parenthesis indexing.

Examples

Use `haltonset` to generate a 3-D Halton point set, skip the first 1000 values, and then retain every 101st point:

```
p = haltonset(3,'Skip',1e3,'Leap',1e2)
p =
    Halton point set in 3 dimensions (8.918019e+013 points)
    Properties:
        Skip : 1000
        Leap : 100
    ScrambleMethod : none
```

Use `scramble` to apply reverse-radix scrambling:

```
p = scramble(p,'RR2')
p =
    Halton point set in 3 dimensions (8.918019e+013 points)
    Properties:
```

```
Skip : 1000  
Leap : 100  
ScrambleMethod : RR2
```

Use `net` to generate the first four points:

```
X0 = net(p,4)  
X0 =  
    0.0928    0.6950    0.0029  
    0.6958    0.2958    0.8269  
    0.3013    0.6497    0.4141  
    0.9087    0.7883    0.2166
```

Use parenthesis indexing to generate every third point, up to the 11th point:

```
X = p(1:3:11,:)   
X =  
    0.0928    0.6950    0.0029  
    0.9087    0.7883    0.2166  
    0.3843    0.9840    0.9878  
    0.6831    0.7357    0.7923
```

nLinearCoeffs

Class: CompactClassificationDiscriminant

Number of nonzero linear coefficients

Syntax

ncoeffs = nLinearCoeffs(obj)

ncoeffs = nLinearCoeffs(obj,delta)

Description

ncoeffs = nLinearCoeffs(obj) returns the number of nonzero linear coefficients in the linear discriminant model obj.

ncoeffs = nLinearCoeffs(obj,delta) returns the number of nonzero linear coefficients for threshold parameter delta.

Input Arguments

obj

Discriminant analysis classifier, produced using fitcdiscr.

delta

Scalar or vector value of the Delta parameter. See “Gamma and Delta” on page 21-2844.

Output Arguments

ncoeffs

Nonnegative integer, the number of nonzero coefficients in the discriminant analysis model obj.

If you call `nLinearCoeffs` with a `delta` argument, `ncoeffs` is the number of nonzero linear coefficients for threshold parameter `delta`. If `delta` is a vector, `ncoeffs` is a vector with the same number of elements.

If `obj` is a quadratic discriminant model, `ncoeffs` is the number of predictors in `obj`.

Definitions

Gamma and Delta

Regularization is the process of finding a small set of predictors that yield an effective predictive model. For linear discriminant analysis, there are two parameters, γ and δ , that control regularization as follows. `cvshrink` helps you select appropriate values of the parameters.

Let Σ represent the covariance matrix of the data X , and let \hat{X} be the centered data (the data X minus the mean by class). Define

$$D = \text{diag}(\hat{X}^T * \hat{X}).$$

The regularized covariance matrix $\tilde{\Sigma}$ is

$$\tilde{\Sigma} = (1 - \gamma)\Sigma + \gamma D.$$

Whenever $\gamma \geq \text{MinGamma}$, $\tilde{\Sigma}$ is nonsingular.

Let μ_k be the mean vector for those elements of X in class k , and let μ_0 be the global mean vector (the mean of the rows of X). Let C be the correlation matrix of the data X , and let \tilde{C} be the regularized correlation matrix:

$$\tilde{C} = (1 - \gamma)C + \gamma I,$$

where I is the identity matrix.

The linear term in the regularized discriminant analysis classifier for a data point x is

$$(x - \mu_0)^T \tilde{\Sigma}^{-1} (\mu_k - \mu_0) = \left[(x - \mu_0)^T D^{-1/2} \right] \left[\tilde{C}^{-1} D^{-1/2} (\mu_k - \mu_0) \right].$$

The parameter δ enters into this equation as a threshold on the final term in square brackets. Each component of the vector $\left[\tilde{C}^{-1} D^{-1/2} (\mu_k - \mu_0) \right]$ is set to zero if it is smaller in magnitude than the threshold δ . Therefore, for class k , if component j is thresholded to zero, component j of x does not enter into the evaluation of the posterior probability.

The `DeltaPredictor` property is a vector related to this threshold. When $\delta \geq \text{DeltaPredictor}(\mathbf{i})$, all classes k have

$$\left| \tilde{C}^{-1} D^{-1/2} (\mu_k - \mu_0) \right| \leq \delta.$$

Therefore, when $\delta \geq \text{DeltaPredictor}(\mathbf{i})$, the regularized classifier does not use predictor \mathbf{i} .

Examples

Find the Number of Nonzero Coefficients in a Discriminant Analysis Classifier

Find the number of nonzero coefficients in a discriminant analysis classifier for various Delta values.

Create a discriminant analysis classifier from the `fishseriris` data.

```
load fisheriris
obj = fitcdiscr(meas,species);
```

Find the number of nonzero coefficients in `obj`.

```
ncoeffs = nLinearCoeffs(obj)
```

```
ncoeffs =
```

```
4
```

Find the number of nonzero coefficients for `delta = 1, 2, 4, and 8`.

```
delta = [1 2 4 8];
ncoeffs = nLinearCoeffs(obj,delta)
```

```
ncoeffs =  
    4  
    4  
    3  
    0
```

The `DeltaPredictor` property gives the values of `delta` where the number of nonzero coefficients changes.

```
ncoeffs2 = nLinearCoeffs(obj,obj.DeltaPredictor)
```

```
ncoeffs2 =  
    4  
    3  
    1  
    2
```

nlinfit

Nonlinear regression

Syntax

```
beta = nlinfit(X,Y,modelfun,beta0)
beta = nlinfit(X,Y,modelfun,beta0,options)
beta = nlinfit( ___,Name,Value)
[beta,R,J,CovB,MSE,ErrorModelInfo] = nlinfit( ___ )
```

Description

`beta = nlinfit(X,Y,modelfun,beta0)` returns a vector of estimated coefficients for the nonlinear regression of the responses in `Y` on the predictors in `X` using the model specified by `modelfun`. The coefficients are estimated using iterative least squares estimation, with initial values specified by `beta0`.

`beta = nlinfit(X,Y,modelfun,beta0,options)` fits the nonlinear regression using the algorithm control parameters in the structure options. You can return any of the output arguments in the previous syntaxes.

`beta = nlinfit(___,Name,Value)` uses additional options specified by one or more name-value pair arguments. For example, you can specify observation weights or a nonconstant error model. You can use any of the input arguments in the previous syntaxes.

`[beta,R,J,CovB,MSE,ErrorModelInfo] = nlinfit(___)` additionally returns the residuals, `R`, the Jacobian of `modelfun`, `J`, the estimated variance-covariance matrix for the estimated coefficients, `CovB`, an estimate of the variance of the error term, `MSE`, and a structure containing details about the error model, `ErrorModelInfo`.

Examples

Nonlinear Regression Model Using Default Options

Load sample data.

```
S = load('reaction');
X = S.reactants;
y = S.rate;
beta0 = S.beta;
```

Fit the Hougen-Watson model to the rate data using the initial values in `beta0`.

```
beta = nlinfit(X,y,@hougen,beta0)
```

```
beta =
    1.2526
    0.0628
    0.0400
    0.1124
    1.1914
```

Nonlinear Regression Using Robust Options

Generate sample data from the nonlinear regression model

$$y = b_1 + b_2 \exp\{-b_3 x\} + \varepsilon,$$

where b_1 , b_2 , and b_3 are coefficients, and the error term is normally distributed with mean 0 and standard deviation 0.1.

```
modelfun = @(b,x)(b(1)+b(2)*exp(-b(3)*x));
rng('default') % for reproducibility
b = [1;3;2];
x = exprnd(2,100,1);
y = modelfun(b,x) + normrnd(0,0.1,100,1);
```

Set robust fitting options.

```
opts = statset('nlinfit');
opts.RobustWgtFun = 'bisquare';
```

Fit the nonlinear model using the robust fitting options.

```
beta0 = [2;2;2];
beta = nlinfit(x,y,modelfun,beta0,opts)
beta =
```

```
1.0041
3.0997
2.1483
```

Nonlinear Regression Using Observation Weights

Load sample data.

```
S = load('reaction');
X = S.reactants;
y = S.rate;
beta0 = S.beta;
```

Specify a vector of known observation weights.

```
W = [8 2 1 6 12 9 12 10 10 12 2 10 8]';
```

Fit the Hougen-Watson model to the rate data using the specified observation weights.

```
[beta,R,J,CovB] = nlinfit(X,y,@hougen,beta0,'Weights',W);
beta
```

```
beta =
    2.2068
    0.1077
    0.0766
    0.1818
    0.6516
```

Display the coefficient standard errors.

```
sqrt(diag(CovB))
```

```
ans =
    2.5721
    0.1251
    0.0950
    0.2043
    0.7735
```

Nonlinear Regression Using Weights Function Handle

Load sample data.

```
S = load('reaction');
```

```
X = S.reactants;  
y = S.rate;  
beta0 = S.beta;
```

Specify a function handle for observation weights. The function accepts the model fitted values as input, and returns a vector of weights.

```
a = 1; b = 1;  
weights = @(yhat) 1./((a + b*abs(yhat)).^2);
```

Fit the Hougen-Watson model to the rate data using the specified observation weights function.

```
[beta,R,J,CovB] = nlinfit(X,y,@hougen,beta0,'Weights',weights);  
beta
```

```
beta =
```

```
    0.8308  
    0.0409  
    0.0251  
    0.0801  
    1.8261
```

Display the coefficient standard errors.

```
sqrt(diag(CovB))
```

```
ans =
```

```
    0.5822  
    0.0297  
    0.0197  
    0.0578  
    1.2810
```

Nonlinear Regression Using Nonconstant Error Model

Load sample data.

```
S = load('reaction');  
X = S.reactants;  
y = S.rate;  
beta0 = S.beta;
```

Fit the Hougen-Watson model to the rate data using the combined error model.

```
[beta,R,J,CovB,MSE,ErrorModelInfo] = nlinfit(X,y,@hougen,beta0,'ErrorModel','combined',
beta
```

```
beta =
```

```
    1.2526
    0.0628
    0.0400
    0.1124
    1.1914
```

Display the error model information.

```
ErrorModelInfo
```

```
ErrorModelInfo =
```

```
    ErrorModel: 'combined'
  ErrorParameters: [0.1517 5.6783e-08]
    ErrorVariance: @(x)mse*(errorparam(1)+errorparam(2)*abs(model(beta,x))).^2
              MSE: 1.6245
    ScheffeSimPred: 6
    WeightFunction: 0
      FixedWeights: 0
    RobustWeightFunction: 0
```

Input Arguments

X — Predictor variables

matrix

Predictor variables for the nonlinear regression function, specified as a matrix. Typically, X is a design matrix of predictor (independent variable) values, with one row for each value in Y, and one column for each coefficient. However, X can be any array that modelfun can accept.

Data Types: `single` | `double`

Y — Response values

vector

Response values (dependent variable) for fitting the nonlinear regression function, specified as a vector with the same number of rows as X.

Data Types: `single` | `double`

modelfun — Nonlinear regression model function

function handle

Nonlinear regression model function, specified as a function handle. `modelfun` must accept two input arguments, a coefficient vector and an array X —in that order—and return a vector of fitted response values.

For example, to specify the `hougen` nonlinear regression function, use the function handle `@hougen`.

Data Types: `function_handle`

beta0 — Initial coefficient values

vector

Initial coefficient values for the least squares estimation algorithm, specified as a vector.

Note: Poor starting values can lead to a solution with large residual error.

Data Types: `single` | `double`

options — Estimation algorithm options

structure created using `statset`

Estimation algorithm options, specified as a structure you create using `statset`. The following `statset` parameters are applicable to `nlinfit`.

DerivStep — Relative difference for finite difference gradient

$\text{eps}^{(1/3)}$ (default) | positive scalar value | vector

Relative difference for the finite difference gradient calculation, specified as a positive scalar value, or a vector the same size as `beta`. Use a vector to specify a different relative difference for each coefficient.

Display — Level of output display

'off' (default) | 'iter' | 'final'

Level of output display during estimation, specified as one of 'off', 'iter', or 'final'. If you specify 'iter', output is displayed at each iteration. If you specify 'final', output is displayed after the final iteration.

FunValCheck — Indicator for whether to check for invalid values

'on' (default) | 'off'

Indicator for whether to check for invalid values such as NaN or Inf from the objective function, specified as 'on' or 'off'.

MaxIter — Maximum number of iterations

100 (default) | positive integer

Maximum number of iterations for the estimation algorithm, specified as a positive integer. Iterations continue until estimates are within the convergence tolerance, or the maximum number of iterations specified by MaxIter is reached.

RobustWgtFun — Weight function

string | function handle | []

Weight function for robust fitting, specified as a valid string or function handle.

Note: RobustWgtFun must have value [] when you use observation weights, W.

The following table describes the possible string values. Let r denote normalized residuals and w denote robust weights. The indicator function $I[x]$ is equal to 1 if the expression x is true, and 0 otherwise.

Weight Function	Equation	Default Tuning Constant
' ' (default)	No robust fitting	—
'andrews'	$w = I[r < \pi] \times \sin(r) / r$	1.339
'bisquare'	$w = I[r < 1] \times (1 - r^2)^2$	4.685
'cauchy'	$w = \frac{1}{1 + r^2}$	2.385
'fair'	$w = \frac{1}{1 + r }$	1.400

Weight Function	Equation	Default Tuning Constant
'huber'	$w = \frac{1}{\max(1, r)}$	1.345
'logistic'	$w = \frac{\tanh(r)}{r}$	1.205
'talwar'	$w = I[r < 1]$	2.795
'welsch'	$w = \exp\{-r^2\}$	2.985

You can alternatively specify a function handle that accepts a vector of normalized residuals as input, and returns a vector of robust weights as output. If you use a function handle, you must provide a Tune constant.

Tune — Tuning constant

positive scalar value

Tuning constant for robust fitting, specified as a positive scalar value. The tuning constant is used to normalize residuals before applying a robust weight function. The default tuning constant depends on the function specified by `RobustWgtFun`.

If you use a function handle to specify `RobustWgtFun`, then you must specify a value for `Tune`.

ToIFun — Termination tolerance on residual sum of squares

1e-8 (default) | positive scalar value

Termination tolerance for the residual sum of squares, specified as a positive scalar value. Iterations continue until estimates are within the convergence tolerance, or the maximum number of iterations specified by `MaxIter` is reached.

ToIX — Termination tolerance on estimated coefficients

1e-8 (default) | positive scalar value

Termination tolerance on the estimated coefficients, beta, specified as a positive scalar value. Iterations continue until estimates are within the convergence tolerance, or the maximum number of iterations specified by `MaxIter` is reached.

Robust — Indicator for robust fitting

'off' (default) | 'on'

Indicator for robust fitting, specified as 'off' or 'on'.

Note: Robust will be removed in a future software release. Use RobustWgtFun for robust fitting.

WgtFun — Weight function for robust fitting

string | function handle

Weight function for robust fitting, specified as a string indicating a weight function, or a function handle. WgtFun is valid only when Robust has value 'on'.

Note: WgtFun will be removed in a future software release. Use RobustWgtFun instead.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Example: 'ErrorModel','proportional','ErrorParameters',0.5 specifies a proportional error model, with initial value 0.5 for the error parameter estimation

'ErrorModel' — Form of error term

'constant' (default) | 'proportional' | 'combined'

Form of the error term, specified as the comma-separated pair consisting of 'ErrorModel' and one of the following strings indicating the error model. Each model defines the error using a standard mean-zero and unit-variance variable e in combination with independent components: the function value f , and one or two parameters a and b .

'constant' (default)

$$y = f + ae$$

'proportional'

$$y = f + bfe$$

'combined'

$$y = f + (a + b|f|)e$$

The only allowed error model when using Weights is 'constant'.

Note: `options.RobustWgtFun` must have value `[]` when using an error model other than `'constant'`.

'ErrorParameters' — Initial estimates for error model parameters

1 or `[1,1]` (default) | scalar value | two-element vector

Initial estimates for the error model parameters in the chosen `ErrorModel`, specified as the comma-separated pair consisting of `'ErrorParameters'` and a scalar value or two-element vector.

Error Model	Parameters	Default Values
'constant'	a	1
'proportional'	b	1
'combined'	a, b	<code>[1,1]</code>

For example, if `'ErrorModel'` has the value `'combined'`, you can specify the starting value 1 for a and the starting value 2 for b as follows.

Example: `'ErrorParameters',[1,2]`

You can only use the `'constant'` error model when using `Weights`.

Note: `options.RobustWgtFun` must have value `[]` when using an error model other than `'constant'`.

Data Types: `double` | `single`

'Weights' — Observation weights

vector | function handle

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and a vector of real positive weights or a function handle. You can use observation weights to down-weight the observations that you want to have less influence on the fitted model.

- If W is a vector, then it must be the same size as Y .
- If W is a function handle, then it must accept a vector of predicted response values as input, and return a vector of real positive weights as output.

Note: `options.RobustWgtFun` must have value [] when you use observation weights.

Data Types: `double` | `single` | `function_handle`

Output Arguments

beta — Estimated regression coefficients

vector

Estimated regression coefficients, returned as a vector. The number of elements in **beta** equals the number of elements in `beta0`.

Let $f(\mathbf{X}_i, \mathbf{b})$ denote the nonlinear function specified by `modelfun`, where \mathbf{x}_i are the predictors for observation i , $i = 1, \dots, N$, and \mathbf{b} are the regression coefficients. The vector of coefficients returned in **beta** minimizes the weighted least squares equation,

$$\sum_{i=1}^N w_i [y_i - f(\mathbf{x}_i, \mathbf{b})]^2.$$

For unweighted nonlinear regression, all of the weight terms are equal to 1.

R — Residuals

vector

Residuals for the fitted model, returned as a vector.

- If you specify observation weights using the name-value pair argument `Weights`, then **R** contains weighted residuals.
- If you specify an error model other than `'constant'` using the name-value pair argument `ErrorModel`, then you can no longer interpret **R** as model fit residuals.

J — Jacobian

matrix

Jacobian of the nonlinear regression model, `modelfun`, returned as an N -by- p matrix, where N is the number of observations and p is the number of estimated coefficients.

- If you specify observation weights using the name-value pair argument `Weights`, then **J** is the weighted model function Jacobian.

- If you specify an error model other than 'constant' using the name-value pair argument `ErrorModel`, then you can no longer interpret `J` as the model function Jacobian.

CovB — Estimated variance-covariance matrix

matrix

Estimated variance-covariance matrix for the fitted coefficients, `beta`, returned as a p -by- p matrix, where p is the number of estimated coefficients. If the model Jacobian, `J`, has full column rank, then $\text{CovB} = \text{inv}(J' * J) * \text{MSE}$, where `MSE` is the mean squared error.

MSE — Mean squared error

scalar value

Mean squared error (MSE) of the fitted model, returned as a scalar value. `MSE` is an estimate of the variance of the error term. If the model Jacobian, `J`, has full column rank, then $\text{MSE} = (R' * R) / (N - p)$, where `N` is the number of observations, and `p` is the number of estimated coefficients.

ErrorModelInfo — Information about error model fit

structure

Information about the error model fit, returned as a structure with the following fields:

<code>ErrorModel</code>	Chosen error model
<code>ErrorParameters</code>	Estimated error parameters
<code>ErrorVariance</code>	Function handle that accepts an N -by- p matrix, <code>X</code> , and returns an N -by-1 vector of error variances using the estimated error model
<code>MSE</code>	Mean squared error
<code>ScheffeSimPred</code>	Scheffé parameter for simultaneous prediction intervals when using the estimated error model
<code>WeightFunction</code>	Logical with value <code>true</code> if you used a custom weight function previously in <code>nlinfit</code>
<code>FixedWeights</code>	Logical with value <code>true</code> if you used fixed weights previously in <code>nlinfit</code>
<code>RobustWeightFunction</code>	Logical with value <code>true</code> if you used robust fitting previously in

More About

Weighted Residuals

A *weighted residual* is a residual multiplied by the square root of the corresponding observation weight.

Given estimated regression coefficients, \mathbf{b} , the residual for observation i is

$$r_i = y_i - f(\mathbf{x}_i, \mathbf{b}),$$

where y_i is the observed response and $f(\mathbf{x}_i, \mathbf{b})$ is the fitted response at predictors \mathbf{x}_i .

When you fit a weighted nonlinear regression with weights w_i , $i = 1, \dots, N$, `nlinfit` returns the weighted residuals,

$$r_i^* = \sqrt{w_i} (y_i - f(\mathbf{x}_i, \mathbf{b})).$$

Weighted Model Function Jacobian

The *weighted model function Jacobian* is the nonlinear model Jacobian multiplied by the square root of the observation weight matrix.

Given estimated regression coefficients, \mathbf{b} , the estimated model Jacobian, \mathbf{J} , for the nonlinear function $f(\mathbf{x}_i, \mathbf{b})$ has elements

$$\mathbf{J}_{ij} = \frac{\partial f(\mathbf{x}_i, \mathbf{b})}{\partial b_j},$$

where b_j is the j th element of \mathbf{b} .

When you fit a weighted nonlinear regression with diagonal weights matrix \mathbf{W} , `nlinfit` returns the weighted Jacobian matrix,

$$\mathbf{J}^* = \mathbf{W}^{1/2} \mathbf{J}.$$

Tips

- To produce error estimates on predictions, use the optional output arguments `R`, `J`, `CovB`, or `MSE` as inputs to `nlpredci`.
- To produce error estimates on the estimated coefficients, `beta`, use the optional output arguments `R`, `J`, `CovB`, or `MSE` as inputs to `nlparci`.
- If you use the robust fitting option, `RobustWgtFun`, you must use `CovB`—and might need `MSE`—as inputs to `nlpredci` or `nlparci` to ensure that the confidence intervals take the robust fit properly into account.

Algorithms

- `nlinfit` treats NaN values in `Y` or `modelfun(beta0,X)` as missing data, and ignores the corresponding observations.
- For nonrobust estimation, `nlinfit` uses the Levenberg-Marquardt nonlinear least squares algorithm [1].
- For robust estimation, `nlinfit` uses an iterative reweighted least squares algorithm ([2], [3]). At each iteration, the robust weights are recalculated based on each observation's residual from the previous iteration. These weights downweight outliers, so that their influence on the fit is decreased. Iterations continue until the weights converge.
- When you specify a function handle for observation weights, the weights depend on the fitted model. In this case, `nlinfit` uses an iterative generalized least squares algorithm to fit the nonlinear regression model.
- “Nonlinear Regression” on page 11-2

nlintool

Interactive nonlinear regression

Syntax

```
nlintool(X,y,fun,beta0)
nlintool(X,y,fun,beta0,alpha)
nlintool(X,y,fun,beta0,alpha,'xname','yname')
```

Description

`nlintool(X,y,fun,beta0)` is a graphical user interface to the `nlinfit` function, and uses the same input arguments. The interface displays plots of the fitted response against each predictor, with the other predictors held fixed. The fixed values are in the text boxes below each predictor axis. Change the fixed values by typing in a new value or by dragging the vertical lines in the plots to new positions. When you change the value of a predictor, all plots update to display the model at the new point in predictor space. Dashed red curves show 95% simultaneous confidence bands for the function.

`nlintool(X,y,fun,beta0,alpha)` shows $100(1-\alpha)\%$ confidence bands. These are simultaneous confidence bounds for the function value. Using the **Bounds** menu you can switch between simultaneous and non-simultaneous bounds, and between bounds on the function and bounds for predicting a new observation.

`nlintool(X,y,fun,beta0,alpha,'xname','yname')` labels the plots using the string matrix `'xname'` for the predictors and the string `'yname'` for the response.

Examples

The data in `reaction.mat` are partial pressures of three chemical reactants and the corresponding reaction rates. The function `hougen` implements the nonlinear Hougen-Watson model for reaction rates. The following fits the model to the data:

```
load reaction
nlintool(reactants,rate,@hougen,beta,0.01,xn,yn)
```

nlmefit

Nonlinear mixed-effects estimation

Syntax

```
beta = nlmefit(X,y,group,V,fun,beta0)
[beta,PSI] = nlmefit(X,y,group,V,fun,beta0)
[beta,PSI,stats] = nlmefit(X,y,group,V,fun,beta0)
[beta,PSI,stats,B] = nlmefit(X,y,group,V,fun,beta0)
[beta,PSI,stats,B] = nlmefit(X,y,group,V,fun,beta0,'Name',value)
```

Description

`beta = nlmefit(X,y,group,V,fun,beta0)` fits a nonlinear mixed-effects regression model and returns estimates of the fixed effects in `beta`. By default, `nlmefit` fits a model in which each parameter is the sum of a fixed and a random effect, and the random effects are uncorrelated (their covariance matrix is diagonal).

`X` is an n -by- h matrix of n observations on h predictors.

`y` is an n -by-1 vector of responses.

`group` is a grouping variable indicating m groups in the observations. `group` is a categorical variable, a numeric vector, a character matrix with rows for group names, or a cell array of strings. For more information on grouping variables, see “Grouping Variables” on page 2-52.

`V` is an m -by- g matrix or cell array of g group-specific predictors. These are predictors that take the same value for all observations in a group. The rows of `V` are assigned to groups using `grp2idx`, according to the order specified by `grp2idx(group)`. Use a cell array for `V` if group predictors vary in size across groups. Use `[]` for `V` if there are no group-specific predictors.

`fun` is a handle to a function that accepts predictor values and model parameters and returns fitted values. `fun` has the form

```
yfit = modelfun(PHI,XFUN,VFUN)
```

The arguments are:

- PHI — A 1-by- p vector of model parameters.
 - XFUN — A k -by- h array of predictors, where:
 - $k = 1$ if XFUN is a single row of X.
 - $k = n_i$ if XFUN contains the rows of X for a single group of size n_i .
 - $k = n$ if XFUN contains all rows of X.
 - VFUN — Group-specific predictors given by one of:
 - A 1-by- g vector corresponding to a single group and a single row of V.
 - An n -by- g array, where the j th row is $V(I,j)$ if the j th observation is in group I.
- If V is empty, nlmefit calls modelfun with only two inputs.
- yfit — A k -by-1 vector of fitted values

When either PHI or VFUN contains a single row, it corresponds to all rows in the other two input arguments.

Note: If modelfun can compute yfit for more than one vector of model parameters per call, use the 'Vectorization' parameter (described later) for improved performance.

beta0 is a q -by-1 vector with initial estimates for q fixed effects. By default, q is the number of model parameters p .

nlmefit fits the model by maximizing an approximation to the marginal likelihood with random effects integrated out, assuming that:

- Random effects are multivariate normally distributed and independent between groups.
- Observation errors are independent, identically normally distributed, and independent of the random effects.

[beta,PSI] = nlmefit(X,y,group,V,fun,beta0) also returns PSI, an r -by- r estimated covariance matrix for the random effects. By default, r is equal to the number of model parameters p .

[beta,PSI,stats] = nlmefit(X,y,group,V,fun,beta0) also returns stats, a structure with fields:

- dfe — The error degrees of freedom for the model

- `logl` — The maximized loglikelihood for the fitted model
- `rmse` — The square root of the estimated error variance (computed on the log scale for the `exponential` error model)
- `errorparam` — The estimated parameters of the error variance model
- `aic` — The Akaike information criterion, calculated as $\text{aic} = -2 * \text{logl} + 2 * \text{numParam}$, where `numParam` is the number of fitting parameters, including the degree of freedom for covariance matrix of the random effects, the number of fixed effects and the number of parameters of the error model, and `logl` is a field in the `stats` structure
- `bic` — The Bayesian information criterion, calculated as $\text{bic} = -2 * \text{logl} + \log(M) * \text{numParam}$
 - `M` is the number of groups.
 - `numParam` and `logl` are defined as in `aic`.

Note that some literature suggests that the computation of `bic` should be , $\text{bic} = -2 * \text{logl} + \log(N) * \text{numParam}$, where `N` is the number of observations.

- `covb` — The estimated covariance matrix of the parameter estimates
- `sebeta` — The standard errors for `beta`
- `ires` — The population residuals (`y-y_population`), where `y_population` is the individual predicted values
- `pres` — The population residuals (`y-y_population`), where `y_population` is the population predicted values
- `iwres` — The individual weighted residuals
- `pwres` — The population weighted residuals
- `cwres` — The conditional weighted residuals

`[beta,PSI,stats,B] = nlmefit(X,y,group,V,fun,beta0)` also returns `B`, an r -by- m matrix of estimated random effects for the m groups. By default, r is equal to the number of model parameters p .

`[beta,PSI,stats,B] = nlmefit(X,y,group,V,fun,beta0,'Name',value)` specifies one or more optional parameter name/value pairs. Specify *Name* inside single quotes.

Use the following parameters to fit a model different from the default. (The default model is obtained by setting both `FEConstDesign` and `REConstDesign` to `eye(p)`, or by setting both `FEParamsSelect` and `REParamsSelect` to `1:p`.) Use at most one

parameter with an 'FE' prefix and one parameter with an 'RE' prefix. The `nlmefit` function requires you to specify at least one fixed effect and one random effect.

Parameter	Value
FEParamsSelect	A vector specifying which elements of the parameter vector <code>PHI</code> include a fixed effect, given as a numeric vector of indices from 1 to <code>p</code> or as a 1-by- <code>p</code> logical vector. If <code>q</code> is the specified number of elements, then the model includes <code>q</code> fixed effects.
FEConstDesign	A p -by- q design matrix <code>ADESIGN</code> , where <code>ADESIGN*beta</code> are the fixed components of the p elements of <code>PHI</code> .
FEGroupDesign	A p -by- q -by- m array specifying a different p -by- q fixed-effects design matrix for each of the m groups.
FEobsDesign	A p -by- q -by- n array specifying a different p -by- q fixed-effects design matrix for each of the n observations.
REParamsSelect	A vector specifying which elements of the parameter vector <code>PHI</code> include a random effect, given as a numeric vector of indices from 1 to <code>p</code> or as a 1-by- <code>p</code> logical vector. The model includes <code>r</code> random effects, where <code>r</code> is the specified number of elements.
REConstDesign	A p -by- r design matrix <code>BDESIGN</code> , where <code>BDESIGN*B</code> are the random components of the p elements of <code>PHI</code> .
REGroupDesign	A p -by- r -by- m array specifying a different p -by- r random-effects design matrix for each of m groups.
REobsDesign	A p -by- r -by- n array specifying a different p -by- r random-effects design matrix for each of n observations.

Use the following parameters to control the iterative algorithm for maximizing the likelihood:

Parameter	Value
RefineBeta0	Determines whether <code>nlmefit</code> makes an initial refinement of <code>beta0</code> by first fitting <code>modelfun</code> without random effects and replacing <code>beta0</code> with <code>beta</code> .

Parameter	Value
	Choices are 'on' and 'off'. The default value is 'on'.
ErrorModel	<p>A string specifying the form of the error term. Default is 'constant'. Each model defines the error using a standard normal (Gaussian) variable e, the function value f, and one or two parameters a and b. Choices are:</p> <ul style="list-style-type: none"> • 'constant': $y = f + a*e$ • 'proportional': $y = f + b*f*e$ • 'combined': $y = f + (a+b*f)*e$ • 'exponential': $y = f*\exp(a*e)$, or equivalently $\log(y) = \log(f) + a*e$ <p>If this parameter is given, the output <code>stats.errorparam</code> field has the value</p> <ul style="list-style-type: none"> • a for 'constant' and 'exponential' • b for 'proportional' • $[a\ b]$ for 'combined'
ApproximationType	<p>The method used to approximate the likelihood of the model. Choices are:</p> <ul style="list-style-type: none"> • 'LME' — Use the likelihood for the linear mixed-effects model at the current conditional estimates of <code>beta</code> and <code>B</code>. This is the default. • 'RELME' — Use the restricted likelihood for the linear mixed-effects model at the current conditional estimates of <code>beta</code> and <code>B</code>. • 'FO' — First-order Laplacian approximation without random effects. • 'FOCE' — First-order Laplacian approximation at the conditional estimates of <code>B</code>.

Parameter	Value
Vectorization	<p data-bbox="649 298 1325 361">Indicates acceptable sizes for the PHI, XFUN, and VFUN input arguments to <code>modelfun</code>. Choices are:</p> <ul data-bbox="655 388 1325 1187" style="list-style-type: none"> <li data-bbox="655 388 1325 680">• <code>'SinglePhi'</code> — <code>modelfun</code> can only accept a single set of model parameters at a time, so PHI must be a single row vector in each call. <code>nlmefit</code> calls <code>modelfun</code> in a loop, if necessary, with a single PHI vector and with XFUN containing rows for a single observation or group at a time. VFUN may be a single row that applies to all rows of XFUN, or a matrix with rows corresponding to rows in XFUN. This is the default. <li data-bbox="655 694 1325 916">• <code>'SingleGroup'</code> — <code>modelfun</code> can only accept inputs corresponding to a single group in the data, so XFUN must contain rows of X from a single group in each call. Depending on the model, PHI is a single row that applies to the entire group or a matrix with one row for each observation. VFUN is a single row. <li data-bbox="655 930 1325 1187">• <code>'Full'</code> — <code>modelfun</code> can accept inputs for multiple parameter vectors and multiple groups in the data. Either PHI or VFUN may be a single row that applies to all rows of XFUN or a matrix with rows corresponding to rows in XFUN. This option can improve performance by reducing the number of calls to <code>modelfun</code>, but may require <code>modelfun</code> to perform singleton expansion on PHI or V.
CovParameterization	<p data-bbox="649 1201 1325 1326">Specifies the parameterization used internally for the scaled covariance matrix. Choices are <code>'chol'</code> for the Cholesky factorization or <code>'logm'</code> the matrix logarithm. The default is <code>'logm'</code>.</p>

Parameter	Value
CovPattern	<p>Specifies an r-by-r logical or numeric matrix P that defines the pattern of the random-effects covariance matrix PSI. <code>nlmeFit</code> estimates the variances along the diagonal of PSI and the covariances specified by nonzeros in the off-diagonal elements of P. Covariances corresponding to zero off-diagonal elements in P are constrained to be zero. If P does not specify a row-column permutation of a block diagonal matrix, <code>nlmeFit</code> adds nonzero elements to P as needed. The default value of P is <code>eye(r)</code>, corresponding to uncorrelated random effects.</p> <p>Alternatively, P may be a 1-by-r vector containing values in $1:r$, with equal values specifying groups of random effects. In this case, <code>nlmeFit</code> estimates covariances only within groups, and constrains covariances across groups to be zero.</p>
ParamTransform	<p>A vector of p-values specifying a transformation function $f()$ for each of the P parameters: $XB = ADESIGN*BETA + BDESIGN*B$ $PHI = f(XB)$. Each element of the vector must be one of the following integer codes specifying the transformation for the corresponding value of PHI:</p> <ul style="list-style-type: none"> • 0: $PHI = XB$ (default for all parameters) • 1: $\log(PHI) = XB$ • 2: $\text{probit}(PHI) = XB$ • 3: $\text{logit}(PHI) = XB$

Parameter	Value
Options	<p>A structure of the form returned by <code>statset.nlmefit</code> uses the following <code>statset</code> parameters:</p> <ul style="list-style-type: none"> • <code>'DerivStep'</code> — Relative difference used in finite difference gradient calculation. May be a scalar, or a vector whose length is the number of model parameters p. The default is $\text{eps}^{(1/3)}$. • <code>'Display'</code> — Level of iterative display during estimation. Choices are: <ul style="list-style-type: none"> • <code>'off'</code> (default) — Displays no information • <code>'final'</code> — Displays information after the final iteration • <code>'iter'</code> — Displays information at each iteration • <code>'FunValCheck'</code> — Check for invalid values, such as NaN or Inf, from <code>modelfun</code>. Choices are <code>'on'</code> and <code>'off'</code>. The default is <code>'on'</code>. • <code>'MaxIter'</code> — Maximum number of iterations allowed. The default is 200. • <code>'OutputFcn'</code> — Function handle specified using <code>@</code>, a cell array with function handles or an empty array (default). The solver calls all output functions after each iteration. • <code>'TolFun'</code> — Termination tolerance on the loglikelihood function. The default is $1\text{e-}4$. • <code>'TolX'</code> — Termination tolerance on the estimated fixed and random effects. The default is $1\text{e-}4$.
OptimFun	<p>Specifies the optimization function used in maximizing the likelihood. Choices are <code>'fminsearch'</code> to use <code>fminsearch</code> or <code>'fminunc'</code> to use <code>fminunc</code>. The default is <code>'fminsearch'</code>. You can specify <code>'fminunc'</code> only if Optimization Toolbox software is installed.</p>

Examples

Nonlinear Mixed-Effects Model

Enter and display data on the growth of five orange trees.

```
CIRC = [30 58 87 115 120 142 145;  
        33 69 111 156 172 203 203;  
        30 51 75 108 115 139 140;  
        32 62 112 167 179 209 214;  
        30 49 81 125 142 174 177];  
time = [118 484 664 1004 1231 1372 1582];  
  
h = plot(time,CIRC','o','LineWidth',2);  
xlabel('Time (days)')  
ylabel('Circumference (mm)')  
title('{\bf Orange Tree Growth}')  
legend([repmat('Tree ',5,1),num2str((1:5)')],...  
        'Location','NW')  
grid on  
hold on
```

Use an anonymous function to specify a logistic growth model.

```
model = @(PHI,t)(PHI(:,1))./(1+exp(-(t-PHI(:,2))./PHI(:,3))));
```

Fit the model using `nlmefit` with default settings (that is, assuming each parameter is the sum of a fixed and a random effect, with no correlation among the random effects):

```
TIME = repmat(time,5,1);
NUMS = repmat((1:5)',size(time));

beta0 = [100 100 100];
[beta1,PSI1,stats1] = nlmefit(TIME(:),CIRC(:),NUMS(:),...
    [],model,beta0)
```

```
beta1 =  
  
    191.3189  
    723.7608  
    346.2517  
  
PSI1 =  
  
    962.1533      0      0  
      0    0.0000      0  
      0      0    297.9880  
  
stats1 =  
  
      dfe: 28  
      logl: -131.5457  
      mse: 59.7882  
      rmse: 7.9016  
      errorparam: 7.7323  
      aic: 277.0913  
      bic: 274.3574  
      covb: [3x3 double]  
      sebeta: [15.2249 33.1579 26.8235]  
      ires: [35x1 double]  
      pres: [35x1 double]  
      iwres: [35x1 double]  
      pwres: [35x1 double]  
      cwres: [35x1 double]
```

The negligible variance of the second random effect, $\text{PSI1}(2,2)$, suggests that it can be removed to simplify the model.

```
[beta2,PSI2,stats2,b2] = nlmeFit(TIME(:),CIRC(:),...  
    NUMS(:),[],model,beta0,'REParamsSelect',[1 3])
```

```
beta2 =  
  
    191.3189  
    723.7613  
    346.2502
```

```
PSI2 =
```

```
    962.5602      0
      0  297.4975
```

```
stats2 =
```

```
    dfe: 29
    logl: -131.5457
    mse: 59.7869
    rmse: 7.7645
    errorparam: 7.7322
    aic: 275.0913
    bic: 272.7479
    covb: [3x3 double]
    sebeta: [15.2275 33.1579 26.8214]
    ires: [35x1 double]
    pres: [35x1 double]
    iwres: [35x1 double]
    pwres: [35x1 double]
    cwres: [35x1 double]
```

```
b2 =
```

```
   -28.5275    31.6066   -36.5086    39.0762    -5.6467
     9.9837    -0.7608     5.9959    -9.4449    -5.7738
```

The loglikelihood `logl` is unaffected, and both the Akaike and Bayesian information criteria (`aic` and `bic`) are reduced, supporting the decision to drop the second random effect from the model.

Use the estimated fixed effects in `beta2` and the estimated random effects for each tree in `b2` to plot the model through the data.

```
PHI = repmat(beta2,1,5) + ...           % Fixed effects
      [b2(1,:);zeros(1,5);b2(2,:)];    % Random effects

tplot = 0:0.1:1600;
for I = 1:5
    fitted_model=@(t)(PHI(1,I))./(1+exp(-(t-PHI(2,I)))./ ...
```

```

    PHI(3,I));
    plot(tplot,fitted_model(tplot),'Color',h(I).Color, ...
        'LineWidth',2)
end

```

nlmefitsa

Fit nonlinear mixed-effects model with stochastic EM algorithm

Syntax

```
[BETA,PSI,STATS,B] = nlmefitsa(X,Y,GROUP,V,MODELFUN,BETA0)
[BETA,PSI,STATS,B] =
nlmefitsa(X,Y,GROUP,V,MODELFUN,BETA0, 'Name', Value)
```

Description

`[BETA,PSI,STATS,B] = nlmefitsa(X,Y,GROUP,V,MODELFUN,BETA0)` fits a nonlinear mixed-effects regression model and returns estimates of the fixed effects in BETA. By default, `nlmefitsa` fits a model where each model parameter is the sum of a corresponding fixed and random effect, and the covariance matrix of the random effects is diagonal, i.e., uncorrelated random effects.

The BETA, PSI, and other values this function returns are the result of a random (Monte Carlo) simulation designed to converge to the maximum likelihood estimates of the parameters. Because the results are random, it is advisable to examine the plot of simulation to results to be sure that the simulation has converged. It may also be helpful to run the function multiple times, using multiple starting values, or use the 'Replicates' parameter to perform multiple simulations.

`[BETA,PSI,STATS,B] = nlmefitsa(X,Y,GROUP,V,MODELFUN,BETA0, 'Name', Value)` accepts one or more comma-separated parameter name/value pairs. Specify *Name* inside single quotes.

Input Arguments

Definitions:

In the following list of arguments, the following variable definitions apply:

- *n* — number of observations

- h — number of predictor variables
- m — number of groups
- g — number of group-specific predictor variables
- p — number of parameters
- f — number of fixed effects

X

An n -by- h matrix of n observations on h predictor variables.

Y

An n -by-1 vector of responses.

GROUP

A grouping variable indicating to which of m groups each observation belongs. **GROUP** can be a categorical variable, a numeric vector, a character matrix with rows for group names, or a cell array of strings.

V

An m -by- g matrix of g group-specific predictor variables for each of the m groups in the data. These are predictor values that take on the same value for all observations in a group. Rows of **V** are ordered according to `GRP2IDX(GROUP)`. Use an m -by- g cell array for **V** if any of the group-specific predictor values vary in size across groups. Specify `[]` for **V** if there are no group predictors.

MODELFUN

A handle to a function that accepts predictor values and model parameters, and returns fitted values. **MODELFUN** has the form `YFIT = MODELFUN(PHI, XFUN, VFUN)` with input arguments

- **PHI** — A 1-by- p vector of model parameters.
- **XFUN** — An l -by- h array of predictor variables where
 - l is 1 if **XFUN** is a single row of **X**
 - l is n_i if **XFUN** contains the rows of **X** for a single group of size n_i
 - l is n if **XFUN** contains all rows of **X**.

- **VFUN** — Either
 - A 1-by- g vector of group-specific predictors for a single group, corresponding to a single row of V
 - An n -by- g matrix, where the k -th row of **VFUN** is $V(i,:)$ if the k -th observation is in group i .

If V is empty, `nlmefitsa` calls **MODELFUN** with only two inputs.

MODELFUN returns an l -by-1 vector of fitted values **YFIT**. When either **PHI** or **VFUN** contains a single row, that one row corresponds to all rows in the other two input arguments. For improved performance, use the '**Vectorization**' parameter name/value pair (described below) if **MODELFUN** can compute **YFIT** for more than one vector of model parameters in one call.

BETA0

An f -by-1 vector with initial estimates for the f fixed effects. By default, f is equal to the number of model parameters p . **BETA0** can also be an f -by-**REPS** matrix, and the estimation is repeated **REPS** times using each column of **BETA0** as a set of starting values.

Name-Value Pair Arguments

By default, `nlmefitsa` fits a model where each model parameter is the sum of a corresponding fixed and random effect. Use the following parameter name/value pairs to fit a model with a different number of or dependence on fixed or random effects. Use at most one parameter name with an '**FE**' prefix and one parameter name with an '**RE**' prefix. Note that some choices change the way `nlmefitsa` calls **MODELFUN**, as described further below.

'FEParamsSelect'

A vector specifying which elements of the model parameter vector **PHI** include a fixed effect, as a numeric vector with elements in $1:p$, or as a 1-by- p logical vector. The model will include f fixed effects, where f is the specified number of elements.

'FEConstDesign'

A p -by- f design matrix **ADESIGN**, where **ADESIGN*****BETA** are the fixed components of the p elements of **PHI**.

'FEGroupDesign'

A p -by- f -by- m array specifying a different p -by- f fixed effects design matrix for each of the m groups.

'REParamsSelect'

A vector specifying which elements of the model parameter vector PHI include a random effect, as a numeric vector with elements in $1:p$, or as a 1-by- p logical vector. The model will include r random effects, where r is the specified number of elements.

'REConstDesign'

A p -by- r design matrix BDESIGN, where BDESIGN*B are the random components of the p elements of PHI. This matrix must consist of 0s and 1s, with at most one 1 per row.

The default model is equivalent to setting both FEConstDesign and REConstDesign to $\text{eye}(p)$, or to setting both FEParamsSelect and REParamsSelect to $1:p$.

Additional optional parameter name/value pairs control the iterative algorithm used to maximize the likelihood:

'CovPattern'

Specifies an r -by- r logical or numeric matrix PAT that defines the pattern of the random effects covariance matrix PSI. nlmefitsa computes estimates for the variances along the diagonal of PSI as well as covariances that correspond to non-zeroes in the off-diagonal of PAT. nlmefitsa constrains the remaining covariances, i.e., those corresponding to off-diagonal zeroes in PAT, to be zero. PAT must be a row-column permutation of a block diagonal matrix, and nlmefitsa adds non-zero elements to PAT as needed to produce such a pattern. The default value of PAT is $\text{eye}(r)$, corresponding to uncorrelated random effects.

Alternatively, specify PAT as a 1-by- r vector containing values in $1:r$. In this case, elements of PAT with equal values define groups of random effects, nlmefitsa estimates covariances only within groups, and constrains covariances across groups to be zero.

'Cov0'

Initial value for the covariance matrix PSI. Must be an r -by- r positive definite matrix. If empty, the default value depends on the values of BETA0.

'ComputeStdErrors'

`true` to compute standard errors for the coefficient estimates and store them in the output `STATS` structure, or `false` (default) to omit this computation.

'ErrorModel'

A string specifying the form of the error term. Default is `'constant'`. Each model defines the error using a standard normal (Gaussian) variable e , the function value f , and one or two parameters a and b . Choices are

- `'constant'` — $y = f + a * e$
- `'proportional'` — $y = f + b * f * e$
- `'combined'` — $y = f + (a + b * f) * e$
- `'exponential'` — $y = f * \exp(a * e)$, or equivalently $\log(y) = \log(f) + a * e$

If this parameter is given, the output `STATS.errorparam` field has the value

- a for `'constant'` and `'exponential'`
- b for `'proportional'`
- $[a \ b]$ for `'combined'`

'ErrorParameters'

A scalar or two-element vector specifying starting values for parameters of the error model. This specifies the a , b , or $[a \ b]$ values depending on the `ErrorModel` parameter.

'LogLikMethod'

Specifies the method for approximating the loglikelihood. Choices are:

- `'is'` — Importance sampling
- `'gq'` — Gaussian quadrature
- `'lin'` — Linearization
- `'none'` — Omit the loglikelihood approximation (default)

'NBurnIn'

Number of initial burn-in iterations during which the parameter estimates are not recomputed. Default is 5.

'NChains'

Number c of "chains" simulated. Default is 1. Setting $c > 1$ causes c simulated coefficient vectors to be computed for each group during each iteration. Default depends on the data, and is chosen to provide about 100 groups across all chains.

'NIterations'

Number of iterations. This can be a scalar or a three-element vector. Controls how many iterations are performed for each of three phases of the algorithm:

- 1 simulated annealing
- 2 full step size
- 3 reduced step size

Default is [150 150 100]. A scalar is distributed across the three phases in the same proportions as the default.

'NMCMCIterations'

Number of Markov Chain Monte Carlo (MCMC) iterations. This can be a scalar or a three-element vector. Controls how many of three different types of MCMC updates are performed during each phase of the main iteration:

- 1 full multivariate update
- 2 single coordinate update
- 3 multiple coordinate update

Default is [2 2 2]. A scalar value is treated as a three-element vector with all elements equal to the scalar.

'OptimFun'

Either 'fminsearch' or 'fminunc', specifying the optimization function to be used during the estimation process. Default is 'fminsearch'. Use of 'fminunc' requires Optimization Toolbox.

'Options'

A structure created by a call to `statset`. `nlmefitsa` uses the following `statset` parameters:

- `'DerivStep'` — Relative difference used in finite difference gradient calculation. May be a scalar, or a vector whose length is the number of model parameters p . The default is $\text{eps}^{(1/3)}$.
- `Display` — Level of display during estimation.
 - `'off'` (default) — Displays no information
 - `'final'` — Displays information after the final iteration of the estimation algorithm
 - `'iter'` — Displays information at each iteration
- `FunValCheck`
 - `'on'` (sdefault) — Check for invalid values (such as NaN or Inf) from `MODELFUN`
 - `'off'` — Skip this check
- `OutputFcn` — Function handle specified using `@`, a cell array with function handles or an empty array. `nlmefitsa` calls all output functions after each iteration. See `nlmefitoutputfcn.m` (the default output function for `nlmefitsa`) for an example of an output function.

'ParamTransform'

A vector of p -values specifying a transformation function $f()$ for each of the p parameters:

```
XB = ADESIGN*BETA + BDESIGN*B
PHI = f(XB)
```

Each element of the vector must be one of the following integer codes specifying the transformation for the corresponding value of `PHI`:

- 0: $\text{PHI} = \text{XB}$ (default for all parameters)
- 1: $\log(\text{PHI}) = \text{XB}$
- 2: $\text{probit}(\text{PHI}) = \text{XB}$
- 3: $\text{logit}(\text{PHI}) = \text{XB}$

'Replicates'

Number `REPS` of estimations to perform starting from the starting values in the vector `BETA0`. If `BETA0` is a matrix, `REPS` must match the number of columns in `BETA0`. Default is the number of columns in `BETA0`.

'Vectorization'

Determines the possible sizes of the PHI, XFUN, and VFUN input arguments to MODELFUN. Possible values are:

- 'SinglePhi' — MODELFUN is a function (such as an ODE solver) that can only compute YFIT for a single set of model parameters at a time, i.e., PHI must be a single row vector in each call. nlmefitsa calls MODELFUN in a loop if necessary using a single PHI vector and with XFUN containing rows for a single observation or group at a time. VFUN may be a single row that applies to all rows of XFUN, or a matrix with rows corresponding to rows in XFUN.
- 'SingleGroup' — MODELFUN can only accept inputs corresponding to a single group in the data, i.e., XFUN must contain rows of X from a single group in each call. Depending on the model, PHI is a single row that applies to the entire group, or a matrix with one row for each observation. VFUN is a single row.
- 'Full' — MODELFUN can accept inputs for multiple parameter vectors and multiple groups in the data. Either PHI or VFUN may be a single row that applies to all rows of XFUN, or a matrix with rows corresponding to rows in XFUN. Using this option can improve performance by reducing the number of calls to MODELFUN, but may require MODELFUN to perform singleton expansion on PHI or V.

The default for 'Vectorization' is 'SinglePhi'. In all cases, if V is empty, nlmefitsa calls MODELFUN with only two inputs.

Output Arguments

BETA

Estimates of the fixed effects

PSI

An r -by- r estimated covariance matrix for the random effects. By default, r is equal to the number of model parameters p .

STATS

A structure with the following fields:

- `logl` — The maximized loglikelihood for the fitted model; empty if the `LogLikMethod` parameter has its default value of 'none'
- `rmse` — The square root of the estimated error variance (computed on the log scale for the `exponential` error model)
- `errorparam` — The estimated parameters of the error variance model
- `aic` — The Akaike information criterion (empty if `logl` is empty), calculated as $\text{aic} = -2 * \text{logl} + 2 * \text{numParam}$, where
 - `logl` is the maximized loglikelihood.
 - `numParam` is the number of fitting parameters, including the degree of freedom for covariance matrix of the random effects, the number of fixed effects and the number of parameters of the error model.
- `bic` — The Bayesian information criterion (empty if `logl` is empty), calculated as $\text{bic} = -2 * \text{logl} + \log(M) * \text{numParam}$
 - `M` is the number of groups.
 - `logl` and `numParam` are defined as in `aic`.

Note that some literature suggests that the computation of `bic` should be , $\text{bic} = -2 * \text{logl} + \log(N) * \text{numParam}$, where `N` is the number of observations. To adjust the value of the output you can redefine `bic` as follows: $\text{bic} = \text{bic} - \text{numel}(\text{unique}(\text{group})) + \text{numel}(Y)$

- `sebeta` — The standard errors for BETA (empty if the `ComputeStdErrors` parameter has its default value of false)
- `covb` — The estimated covariance of the parameter estimates (empty if `ComputeStdErrors` is false)
- `dfe` — The error degrees of freedom
- `pres` — The population residuals (`y-y_population`), where `y_population` is the population predicted values
- `ires` — The population residuals (`y-y_population`), where `y_population` is the individual predicted values
- `pwres` — The population weighted residuals
- `cwres` — The conditional weighted residuals
- `iwres` — The individual weighted residuals

Examples

Nonlinear Mixed-Effects Model with Stochastic EM Algorithm

Load the sample data.

```
load indomethacin
```

Fit a model to data on concentrations of the drug indomethacin in the bloodstream of six subjects over eight hours.

```
model = @(phi,t)(phi(:,1).*exp(-phi(:,2).*t)+phi(:,3).*exp(-phi(:,4).*t));
phi0 = [1 1 1 1];
xform = [0 1 0 1]; % log transform for 2nd and 4th parameters
[beta,PSI,stats,br] = nlmefitsa(time,concentration,...
    subject,[],model,phi0,'ParamTransform',xform)
```

```
beta =
```

```
    0.8563
   -0.7950
    2.7744
    1.0772
```

```
PSI =
```

```
    0.0529         0         0         0
         0    0.0220         0         0
         0         0    0.4762         0
         0         0         0    0.0120
```

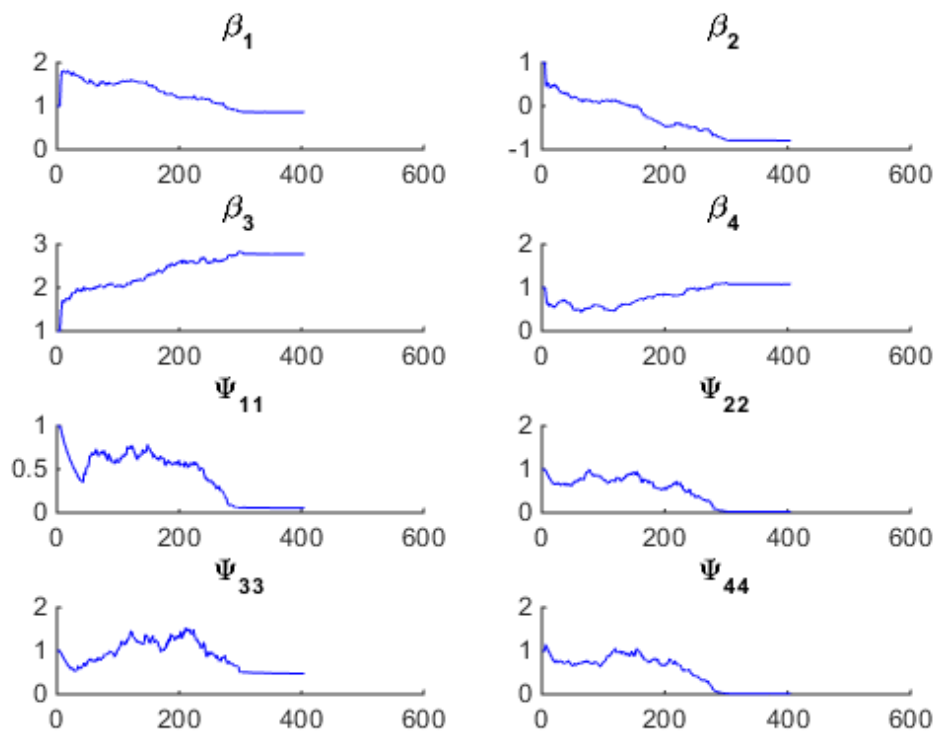

```
stats =
```

```
    logl: []
     aic: []
     bic: []
  sebeta: []
     dfe: 57
    covb: []
errorparam: 0.0809
     rmse: 0.0775
```

```
ires: [66x1 double]
pres: [66x1 double]

-0.7557   -0.0550    0.8736   -0.7875    0.5304    0.1727
-0.0010   -0.0198    0.0137   -0.0757    0.0478   -0.0076
```

Plot the data along with an overall population fit

```
clf
phi = [beta(1), exp(beta(2)), beta(3), exp(beta(4))];
h = gscatter(time,concentration,subject);
xlabel('Time (hours)')
ylabel('Concentration (mcg/ml)')
title('{\bf Indomethacin Elimination}')
xx = linspace(0,8);
line(xx,model(phi,xx), 'linewidth',2, 'color','k')
```

Plot individual curves based on random-effect estimates.

```
for j=1:6
```

```
phir = [beta(1)+br(1,j), exp(beta(2)+br(2,j)), ...  
        beta(3)+br(3,j), exp(beta(4)+br(4,j))];  
line(xx,model(phir,xx), 'color',get(h(j), 'color'))  
end
```

More About

Algorithms

In order to estimate the parameters of a nonlinear mixed effects model, we would like to choose the parameter values that maximize a likelihood function. These values are called the maximum likelihood estimates. The likelihood function can be written in the form

$$p(y | \beta, \sigma^2, \Sigma) = \int p(y | \beta, b, \sigma^2) p(b | \Sigma) db$$

where

- y is the response data
- β is the vector of population coefficients
- σ^2 is the residual variance
- Σ is the covariance matrix for the random effects
- b is the set of unobserved random effects

Each $p()$ function on the right-hand-side is a normal (Gaussian) likelihood function that may depend on covariates.

Since the integral does not have a closed form, it is difficult to find parameters that maximize it. Delyon, Lavielle, and Moulines [1] proposed to find the maximum likelihood estimates using an Expectation-Maximization (EM) algorithm in which the E step is replaced by a stochastic procedure. They called their algorithm SAEM, for Stochastic Approximation EM. They demonstrated that this algorithm has desirable theoretical properties, including convergence under practical conditions and convergence to a local maximum of the likelihood function. Their proposal involves three steps:

- 1** Simulation: Generate simulated values of the random effects b from the posterior density $p(b | \Sigma)$ given the current parameter estimates.
 - 2** Stochastic approximation: Update the expected value of the loglikelihood function by taking its value from the previous step, and moving part way toward the average value of the loglikelihood calculated from the simulated random effects.
 - 3** Maximization step: Choose new parameter estimates to maximize the loglikelihood function given the simulated values of the random effects.
- “Mixed-Effects Models” on page 11-20
 - “Grouping Variables” on page 2-52

NegativeLogLikelihood property

Class: gmdistribution

Negative of log-likelihood

Description

The negative of the log-likelihood of the data.

Note: This property applies only to `gmdistribution` objects constructed with `fitgmdist`.

NLogL property

Class: ProbDistParametric

Read-only value specifying negative log likelihood for input data to ProbDistParametric object

Description

NLogL is a read-only property of the ProbDistParametric class. NLogL is a value specifying the negative log likelihood for input data used to fit a distribution represented by a ProbDistParametric object.

Values

The value is a numeric scalar for a distribution fit to input data, that is, a distribution created using the `fitdist` function. This property is empty for distributions created without fitting to data, that is, by using the ProbDistUnivParam constructor. Use this information to view and compare the negative log likelihood for input data supplied to create distributions.

NLogL property

Class: ProbDistUnivKernel

Read-only value specifying negative log likelihood for input data to ProbDistUnivKernel object

Description

NLogL is a read-only property of the ProbDistUnivKernel class. NLogL is a value specifying the negative log likelihood for input data used to fit a distribution represented by a ProbDistUnivKernel object.

Values

The value is a numeric scalar for a distribution fit to input data, that is, a distribution created using the `fitdist` function. Use this information to view and compare the negative log likelihood for input data used to create distributions.

nlparci

Nonlinear regression parameter confidence intervals

Syntax

```
ci = nlparci(beta,resid,'covar',sigma)
ci = nlparci(beta,resid,'jacobian',J)
ci = nlparci(...,'alpha',alpha)
```

Description

`ci = nlparci(beta,resid,'covar',sigma)` returns the 95% confidence intervals `ci` for the nonlinear least squares parameter estimates `beta`. Before calling `nlparci`, use `nlinfit` to fit a nonlinear regression model and get the coefficient estimates `beta`, residuals `resid`, and estimated coefficient covariance matrix `sigma`.

`ci = nlparci(beta,resid,'jacobian',J)` is an alternative syntax that also computes 95% confidence intervals. `J` is the Jacobian computed by `nlinfit`. If the 'robust' option is used with `nlinfit`, use the 'covar' input rather than the 'jacobian' input so that the required `sigma` parameter takes the robust fitting into account.

`ci = nlparci(...,'alpha',alpha)` returns $100(1-\alpha)\%$ confidence intervals.

`nlparci` treats NaNs in `resid` or `J` as missing values, and ignores the corresponding observations.

The confidence interval calculation is valid for systems where the length of `resid` exceeds the length of `beta` and `J` has full column rank. When `J` is ill-conditioned, confidence intervals may be inaccurate.

Examples

Fit to exponential decay

Suppose you have data, and want to fit a model of the form

$$y_i = a_1 + a_2 \exp(-a_3 x_i) + \varepsilon_i.$$

Here the a_i are the parameters you want to estimate, x_i are the data points, the y_i are the responses, and the ε_i are noise terms.

- 1 Write a function handle that represents the model:

```
mdl = @(a,x)(a(1) + a(2)*exp(-a(3)*x));
```

- 2 Generate synthetic data with parameters $\mathbf{a} = [1;3;2]$, with the x data points distributed exponentially with parameter 2, and normally distributed noise with standard deviation 0.1:

```
rng(9845,'twister') % for reproducibility
a = [1;3;2];
x = exprnd(2,100,1);
epsn = normrnd(0,0.1,100,1);
y = mdl(a,x) + epsn;
```

- 3 Fit the model to data starting from the arbitrary guess $\mathbf{a0} = [2;2;2]$:

```
a0 = [2;2;2];
[ahat,r,J,cov,mse] = nlinfit(x,y,mdl,a0);
ahat
```

```
ahat =
    1.0153
    3.0229
    2.1070
```

- 4 Check whether $[1;3;2]$ is in a 95% confidence interval using the Jacobian argument in `nlparci`:

```
ci = nlparci(ahat,r,'Jacobian',J)
```

```
ci =
    0.9869    1.0438
    2.9401    3.1058
    1.9963    2.2177
```

- 5 You can obtain the same result using the covariance argument:

```
ci = nlparci(ahat,r,'covar',cov)
```

```
ci =
    0.9869    1.0438
    2.9401    3.1058
```

1.9963 2.2177

`nlinfit` | `nlpredci`

nlpredci

Nonlinear regression prediction confidence intervals

Syntax

```
[Ypred,delta] = nlpredci(modelfun,X,beta,R,'Covar',CovB)
[Ypred,delta] = nlpredci(modelfun,X,beta,R,'Covar',CovB,Name,Value)
```

```
[Ypred,delta] = nlpredci(modelfun,X,beta,R,'Jacobian',J)
[Ypred,delta] = nlpredci(modelfun,X,beta,R,'Jacobian',J,Name,Value)
```

Description

`[Ypred,delta] = nlpredci(modelfun,X,beta,R,'Covar',CovB)` returns predictions, `Ypred`, and 95% confidence interval half-widths, `delta`, for the nonlinear regression model `modelfun` at input values `X`. Before calling `nlpredci`, use `nlinfit` to fit `modelfun` and get the estimated coefficients, `beta`, residuals, `R`, and variance-covariance matrix, `CovB`.

`[Ypred,delta] = nlpredci(modelfun,X,beta,R,'Covar',CovB,Name,Value)` uses additional options specified by one or more name-value pair arguments.

`[Ypred,delta] = nlpredci(modelfun,X,beta,R,'Jacobian',J)` returns predictions, `Ypred`, and 95% confidence interval half-widths, `delta`, for the nonlinear regression model `modelfun` at input values `X`. Before calling `nlpredci`, use `nlinfit` to fit `modelfun` and get the estimated coefficients, `beta`, residuals, `R`, and Jacobian, `J`.

If you use a robust option with `nlinfit`, then you should use the `Covar` syntax rather than the `Jacobian` syntax. The variance-covariance matrix, `CovB`, is required to properly take the robust fitting into account.

`[Ypred,delta] = nlpredci(modelfun,X,beta,R,'Jacobian',J,Name,Value)` uses additional options specified by one or more name-value pair arguments.

Examples

Confidence Interval for Nonlinear Regression Curve

Load sample data.

```
S = load('reaction');  
X = S.reactants;  
y = S.rate;  
beta0 = S.beta;
```

Fit the Hougen-Watson model to the rate data using the initial values in `beta0`.

```
[beta,R,J] = nlinfit(X,y,@hougen,beta0);
```

Obtain the predicted response and 95% confidence interval half-width for the value of the curve at average reactant levels.

```
[ypred,delta] = nlpredci(@hougen,mean(X),beta,R,'Jacobian',J)
```

```
ypred =  
    5.4622
```

```
delta =  
    0.1921
```

Compute the 95% confidence interval for the value of the curve.

```
[ypred-delta,ypred+delta]
```

```
ans =  
    5.2702    5.6543
```

Prediction Interval for New Observation

Load sample data.

```
S = load('reaction');  
X = S.reactants;  
y = S.rate;  
beta0 = S.beta;
```

Fit the Hougen-Watson model to the rate data using the initial values in beta0.

```
[beta,R,J] = nlinfit(X,y,@hougen,beta0);
```

Obtain the predicted response and 95% prediction interval half-width for a new observation with reactant levels [100,100,100].

```
[ypred,delta] = nlpredci(@hougen,[100,100,100],beta,R,'Jacobian',J,...
    'PredOpt','observation')
```

```
ypred =
    1.8346
```

```
delta =
    0.5101
```

Compute the 95% prediction interval for the new observation.

```
[ypred-delta,ypred+delta]
ans =
    1.3245    2.3447
```

Simultaneous Confidence Intervals for Robust Fit Curve

Generate sample data from the nonlinear regression model

$$y = b_1 + b_2 \exp\{-b_3 x\} + \varepsilon,$$

where b_1 , b_2 , and b_3 are coefficients, and the error term is normally distributed with mean 0 and standard deviation 0.5.

```
modelfun = @(b,x)(b(1)+b(2)*exp(-b(3)*x));
rng('default') % for reproducibility
b = [1;3;2];
x = exprnd(2,100,1);
y = modelfun(b,x) + normrnd(0,0.5,100,1);
```

Fit the nonlinear model using robust fitting options.

```
opts = statset('nlinfit');
```

```

opts.RobustWgtFun = 'bisquare';
beta0 = [2;2;2];
[beta,R,J,CovB,MSE] = nlinfit(x,y,modelfun,beta0,opts);

Plot the fitted regression model and simultaneous 95% confidence bounds.

xrange = min(x):.01:max(x);
[ypred,delta] = nlpredci(modelfun,xrange,beta,R,'Covar',CovB,...
    'MSE',MSE,'SimOpt','on');

lower = ypred - delta;
upper = ypred + delta;

figure()
plot(x,y,'ko') % observed data
hold on
plot(xrange,ypred,'k','LineWidth',2)
plot(xrange,[lower;upper],'r--','LineWidth',1.5)

```

Confidence Interval Using Observation Weights

Load sample data.

```
S = load('reaction');
X = S.reactants;
y = S.rate;
beta0 = S.beta;
```

Specify a function handle for observation weights, then fit the Hougen-Watson model to the rate data using the specified observation weights function.

```
a = 1; b = 1;
weights = @(yhat) 1./((a + b*abs(yhat)).^2);
[beta,R,J,CovB] = nlinfit(X,y,@hougen,beta0,'Weights',weights);
```

Compute the 95% prediction interval for a new observation with reactant levels [100, 100, 100] using the observation weight function.

```
[ypred,delta] = nlpredci(@hougen,[100,100,100],beta,R,'Jacobian',J,...
    'PredOpt','observation','Weights',weights);
[ypred-delta,ypred+delta]
```

```
ans =
```

```
1.5264    2.1033
```

Confidence Interval Using Nonconstant Error Model

Load sample data.

```
S = load('reaction');
X = S.reactants;
y = S.rate;
beta0 = S.beta;
```

Fit the Hougen-Watson model to the rate data using the combined error variance model.

```
[beta,R,J,CovB,MSE,S] = nlinfit(X,y,@hougen,beta0,'ErrorModel','combined');
```

Compute the 95% prediction interval for a new observation with reactant levels [100, 100, 100] using the fitted error variance model.

```
[ypred,delta] = nlpredci(@hougen,[100,100,100],beta,R,'Jacobian',J,...
    'PredOpt','observation','ErrorModelInfo',S);
[ypred-delta,ypred+delta]
```

```
ans =
```

1.3245 2.3447

Input Arguments

modelfun — Nonlinear regression model function

function handle

Nonlinear regression model function, specified as a function handle. `modelfun` must accept two input arguments, a coefficient vector and an array X —in that order—and return a vector of fitted response values.

For example, to specify the `hougen` nonlinear regression function, use the function handle `@hougen`.

Data Types: `function_handle`

X — Input values for predictions

matrix

Input values for predictions, specified as a matrix. `nlpredci` makes a prediction for the covariates in each row of X . There should be a column in X for each coefficient in the model.

Data Types: `single` | `double`

beta — Estimated regression coefficients

vector returned by `nlinfit`

Estimated regression coefficients, specified as the vector of fitted coefficients returned by a previous call to `nlinfit`.

Data Types: `single` | `double`

R — Residuals

vector returned by `nlinfit`

Residuals for the fitted `modelfun`, specified as the vector of residuals returned by a previous call to `nlinfit`.

CovB — Estimated variance-covariance matrix

matrix returned by `nlinfit`

Estimated variance-covariance matrix for the fitted coefficients, `beta`, specified as the variance-covariance matrix returned by a previous call to `nlinf`.

J — Estimated Jacobian

matrix returned by `nlinf`

Estimated Jacobian of the nonlinear regression model, `modelfun`, specified as the Jacobian matrix returned by a previous call to `nlinf`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1`, `Value1`, ..., `NameN`, `ValueN`.

Example: `'Alpha',0.1,'PredOpt','observation'` specifies 90% prediction intervals for new observations.

'Alpha' — Significance level

0.05 (default) | scalar value in the range (0,1)

Significance level for the confidence interval, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the range (0,1). If `Alpha` has value α , then `nlpredci` returns intervals with $100 \times (1 - \alpha)\%$ confidence level.

The default confidence level is 95% ($\alpha = 0.05$).

Example: `'Alpha',0.1`

Data Types: `single` | `double`

'ErrorModelInfo' — Information about error model fit

structure returned by `nlinf`

Information about the error model fit, specified as the comma-separated pair consisting of `'ErrorModelInfo'` and a structure returned by a previous call to `nlinf`.

`ErrorModelInfo` only has an effect on the returned prediction interval when `PredOpt` has the value `'observation'`. If you do not use `ErrorModelInfo`, then `nlpredci` assumes the error variance model is `'constant'`.

The error model structure returned by `nlinfit` has the following fields:

<code>ErrorModel</code>	Chosen error model
<code>ErrorParameters</code>	Estimated error parameters
<code>ErrorVariance</code>	Function handle that accepts an N -by- p matrix, X , and returns an N -by-1 vector of error variances using the estimated error model
<code>MSE</code>	Mean squared error
<code>ScheffeSimPred</code>	Scheffé parameter for simultaneous prediction intervals when using the estimated error model
<code>WeightFunction</code>	Logical with value <code>true</code> if you used a custom weight function previously in <code>nlinfit</code>
<code>FixedWeights</code>	Logical with value <code>true</code> if you used fixed weights previously in <code>nlinfit</code>
<code>RobustWeightFunction</code>	Logical with value <code>true</code> if you used robust fitting previously in

'MSE' — Mean squared error

MSE returned by `nlinfit`

Mean squared error (MSE) for the fitted nonlinear regression model, specified as the comma-separated pair consisting of 'MSE' and the MSE value returned by a previous call to `nlinfit`.

If you use a robust option with `nlinfit`, then you must specify the MSE when predicting new observations to properly take the robust fitting into account. If you do not specify the MSE, then `nlpredci` computes the MSE from the residuals, R , and does not take the robust fitting into account.

For example, if `mse` is the MSE value returned by `nlinfit`, then you can specify 'MSE',`mse`.

Data Types: `single` | `double`

'PredOpt' — Prediction interval to compute

'`curve`' (default) | '`observation`'

Prediction interval to compute, specified as the comma-separated pair consisting of 'PredOpt' and either '`curve`' or '`observation`'.

- If you specify the value `'curve'`, then `nlpredci` returns confidence intervals for the estimated curve (function value) at the observations `X`.
- If you specify the value `'observation'`, then `nlpredci` returns prediction intervals for new observations at `X`.

If you specify `'observation'` after using a robust option with `nlfit`, then you must also specify a value for `MSE` to provide the robust estimate of the mean squared error.

Example: `'PredOpt', 'observation'`

Data Types: char

'SimOpt' — Indicator for specifying simultaneous bounds

`'off'` (default) | `'on'`

Indicator for specifying simultaneous bounds, specified as the comma-separated pair consisting of `'SimOpt'` and either `'off'` or `'on'`. Use the value `'off'` to compute nonsimultaneous bounds, and `'on'` for simultaneous bounds.

'Weights' — Observation weights

vector | function handle

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and a vector of positive scalar values or a function handle. The default is no weights.

- If you specify a vector of weights, then it must have the same number of elements as the number of observations (rows) in `X`.
- If you specify a function handle for the weights, then it must accept a vector of predicted response values as input, and return a vector of real positive weights as output.

Given weights, `W`, `nlpredci` estimates the error variance at observation `i` by $mse \cdot (1/W(i))$, where `mse` is the mean squared error value specified using `MSE`.

Example: `'Weights', @WFun`

Data Types: double | single | function_handle

Output Arguments

Ypred — Predicted responses

vector

Predicted responses, returned as a vector with the same number of rows as **X**.

delta — Confidence interval half-widths

vector

Confidence interval half-widths, returned as a vector with the same number of rows as **X**. By default, **delta** contains the half-widths for nonsimultaneous 95% confidence intervals for **modelfun** at the observations in **X**. You can compute the lower and upper bounds of the confidence intervals as **Ypred-delta** and **Ypred+delta**, respectively.

If 'PredOpt' has value 'observation', then **delta** contains the half-widths for prediction intervals of new observations at the values in **X**.

More About

Confidence Intervals for Estimable Predictions

When the estimated model Jacobian is not of full rank, then it might not be possible to construct sensible confidence intervals at all prediction points. In this case, **nlpredci** still tries to construct confidence intervals for any *estimable* prediction points.

For example, suppose you fit the linear function $f(\mathbf{x}_i, \beta) = \beta_1 x_{i1} + \beta_2 x_{i2} + \beta_3 x_{i3}$ at the points in the design matrix

$$\mathbf{X} = \begin{pmatrix} 1 & 1 & 0 \\ 1 & 1 & 0 \\ 1 & 1 & 0 \\ 1 & 0 & 1 \\ 1 & 0 & 1 \\ 1 & 0 & 1 \end{pmatrix}.$$

The estimated Jacobian at the values in **X** is the design matrix itself, $\mathbf{J} = \mathbf{X}$. Thus, the Jacobian is not of full rank:

```
rng('default') % For reproducibility
y = randn(6,1);

linfun = @(b,x) x*b;
```

```
beta0 = [1;1;1];
X = [repmat([1 1 0],3,1); repmat([1 0 1],3,1)];

[beta,R,J] = nlinfit(X,y,linfun,beta0);
```

Warning: The Jacobian at the solution is ill-conditioned, and some model parameters may not be estimated well (they are not identifiable). Use caution in making predictions.

> In nlinfit at 283

In this example, `nlpredci` can only compute prediction intervals at points that satisfy the linear relationship

$$x_{i1} = x_{i2} + x_{i3}.$$

If you try to compute confidence intervals for predictions at nonidentifiable points, `nlpredci` returns NaN for the corresponding interval half-widths:

```
xpred = [1 1 1;0 1 -1;2 1 1];
[ypred,delta] = nlpredci(linfun,xpred,beta,R,'Jacobian',J)

ypred =

    -0.0035
     0.0798
    -0.0047
```

```
delta =

     NaN
     3.8102
     3.8102
```

Here, the first element of `delta` is NaN because the first row in `xpred` does not satisfy the required linear dependence, and is therefore not an estimable contrast.

Tips

- To compute confidence intervals for complex parameters or data, you need to split the problem into its real and imaginary parts. When calling `nlinfit`:
 - 1 Define your parameter vector `beta` as the concatenation of the real and imaginary parts of the original parameter vector.

- 2** Concatenate the real and imaginary parts of the response vector Y as a single vector.
- 3** Modify your model function `modelfun` to accept X and the purely real parameter vector, and return a concatenation of the real and imaginary parts of the fitted values.

With the problem formulated this way, `nlinfit` computes real estimates, and confidence intervals are feasible.

Algorithms

- `nlpredci` treats NaN values in the residuals, R , or the Jacobian, J , as missing values, and ignores the corresponding observations.
- If the Jacobian, J , does not have full column rank, then some of the model parameters might be nonidentifiable. In this case, `nlpredci` tries to construct confidence intervals for estimable predictions, and returns NaN for those that are not.

`nlinfit` | `nlparci` | `NonLinearModel`

nnmf

Nonnegative matrix factorization

Syntax

```
[W,H] = nnmf(A,k)
[W,H] = nnmf(A,k,param1,val1,param2,val2,...)
[W,H,D] = nnmf(...)
```

Description

`[W,H] = nnmf(A,k)` factors the nonnegative n -by- m matrix A into nonnegative factors W (n -by- k) and H (k -by- m). The factorization is not exact; $W*H$ is a lower-rank approximation to A . The factors W and H are chosen to minimize the root-mean-squared residual D between A and $W*H$:

$$D = \text{norm}(A-W*H, 'fro') / \text{sqrt}(N*M)$$

The factorization uses an iterative method starting with random initial values for W and H . Because the root-mean-squared residual D may have local minima, repeated factorizations may yield different W and H . Sometimes the algorithm converges to a solution of lower rank than k , which may indicate that the result is not optimal.

W and H are normalized so that the rows of H have unit length. The columns of W are ordered by decreasing length.

`[W,H] = nnmf(A,k,param1,val1,param2,val2,...)` specifies optional parameter name/value pairs from the following table.

Parameter	Value
'algorithm'	<p>Either 'als' (the default) to use an alternating least-squares algorithm, or 'mult' to use a multiplicative update algorithm.</p> <p>In general, the 'als' algorithm converges faster and more consistently. The 'mult' algorithm is more sensitive to initial values, which makes it a good choice when using 'replicates' to find W and H from multiple random starting values.</p>

Parameter	Value
'w0'	An n -by- k matrix to be used as the initial value for W .
'h0'	A k -by- m matrix to be used as the initial value for H .
'options'	<p>An options structure as created by the <code>statset</code> function. <code>nnmf</code> uses the following fields of the options structure:</p> <ul style="list-style-type: none"> • Display — Level of display. Choices: <ul style="list-style-type: none"> • 'off' (default) — No display • 'final' — Display final result • 'iter' — Iterative display of intermediate results • MaxIter — Maximum number of iterations. Default is 100. Unlike in optimization settings, reaching MaxIter iterations is treated as convergence. • TolFun — Termination tolerance on change in size of the residual. Default is $1e-4$. • TolX — Termination tolerance on relative change in the elements of W and H. Default is $1e-4$. • UseParallel — Set to <code>true</code> to compute in parallel. Default is <code>false</code>. • UseSubstreams — Set to <code>true</code> to compute in parallel in a reproducible fashion. Default is <code>false</code>. To compute reproducibly, set Streams to a type allowing substreams: 'mlfg6331_64' or 'mrg32k3a'. • Streams — A <code>RandStream</code> object or cell array of such objects. If you do not specify Streams, <code>nnmf</code> uses the default stream or streams. If you choose to specify Streams, use a single object except in the case <ul style="list-style-type: none"> • You have an open Parallel pool • UseParallel is <code>true</code> • UseSubstreams is <code>false</code> <p>In that case, use a cell array the same size as the Parallel pool.</p>

Parameter	Value
'replicates'	The number of times to repeat the factorization, using new random starting values for W and H, except at the first replication if 'w0' and 'h0' are given. This is most beneficial with the 'mult' algorithm. The default is 1.

[W,H,D] = nnmf(...) also returns D, the root mean square residual.

Examples

Nonnegative Rank-Two Approximation and Biplot

Load the sample data.

```
load fisheriris
```

Compute a nonnegative rank-two approximation of the measurements of the four variables in Fisher's iris data.

```
[W,H] = nnmf(meas,2);
H
```

H =

```
    0.6943    0.2853    0.6223    0.2220
    0.8020    0.5685    0.1830    0.0147
```

The first and third variables in `meas` (sepal length and petal length, with coefficients 0.6852 and 0.6357, respectively) provide relatively strong weights to the first column of W. The first and second variables in `meas` (sepal length and sepal width, with coefficients 0.8011 and 0.5740) provide relatively strong weights to the second column of W.

Create a biplot of the data and the variables in `meas` in the column space of W.

```
biplot(H', 'scores', W, 'varlabels', {'sl', 'sw', 'pl', 'pw'});
axis([0 1.1 0 1.1])
xlabel('Column 1')
ylabel('Column 2')
```

Change Algorithm

Starting from a random array X with rank 20, try a few iterations at several replicates using the multiplicative algorithm:

```
X = rand(100,20)*rand(20,50);
opt = statset('MaxIter',5,'Display','final');
[WO,H0] = nnmf(X,5,'replicates',10,...
               'options',opt,...
               'algorithm','mult');
```

rep	iteration	rms resid	delta x
1	5	0.560887	0.0245182
2	5	0.66418	0.0364471
3	5	0.609125	0.0358355

```

4      5      0.608894      0.0415491
5      5      0.619291      0.0455135
6      5      0.621549      0.0299965
7      5      0.640549      0.0438758
8      5      0.673015      0.0366856
9      5      0.606835      0.0318931
10     5      0.633526      0.0319591
Final root mean square residual = 0.560887

```

Continue with more iterations from the best of these results using alternating least squares:

```

opt = statset('Maxiter',1000,'Display','final');
[W,H] = nnmf(X,5,'w0',W0,'h0',H0,...
             'options',opt,...
             'algorithm','als');

    rep    iteration    rms resid    |delta x|
    1         24      0.257336    0.00271859
Final root mean square residual = 0.257336

```

nodeclass

Class: classregtree

Class values of nodes of classification tree

Syntax

```
NAME=nodeclass(T)  
NAME=nodeclass(T,J)  
[NAME,ID]=nodeclass(...)
```

Description

`NAME=nodeclass(T)` returns an n -element cell array with the names of the most probable classes in each node of the tree `T`, where n is the number of nodes in the tree. Every element of this array is a string equal to one of the class names returned by `classname(T)`. For regression trees, `nodeclass` returns an empty cell array.

`NAME=nodeclass(T,J)` takes an array `J` of node numbers and returns the class names for the specified nodes.

`[NAME,ID]=nodeclass(...)` also returns a numeric array with the class index for each node. The class index is determined by the order of classes `classname` returns.

See Also

`classregtree` | `numnodes` | `classname`

nodeerr

Class: classregtree

Return vector of node errors

Syntax

```
e = nodeerr(t)
e = nodeerr(t,nodes)
```

Description

`e = nodeerr(t)` returns an n -element vector \mathbf{e} of the errors of the nodes in the tree t , where n is the number of nodes. For a regression tree, the error $\mathbf{e}(i)$ for node i is the variance of the observations assigned to node i . For a classification tree, $\mathbf{e}(i)$ is the misclassification probability for node i .

`e = nodeerr(t,nodes)` takes a vector `nodes` of node numbers and returns the errors for the specified nodes.

The error \mathbf{e} is the so-called *resubstitution error* computed by applying the tree to the same data used to create the tree. This error is likely to under estimate the error you would find if you applied the tree to new data. The `test` function provides options to compute the error (or cost) using cross-validation or a test sample.

Examples

Create a classification tree for Fisher's iris data:

```
load fisheriris;

t = classregtree(meas,species,...
                'names',{'SL' 'SW' 'PL' 'PW'})
t =
Decision tree for classification
1  if PL<2.45 then node 2 elseif PL>=2.45 then node 3 else setosa
2  class = setosa
3  if PW<1.75 then node 4 elseif PW>=1.75 then node 5 else versicolor
```

```

4 if PL<4.95 then node 6 elseif PL>=4.95 then node 7 else versicolor
5 class = virginica
6 if PW<1.65 then node 8 elseif PW>=1.65 then node 9 else versicolor
7 class = virginica
8 class = versicolor
9 class = virginica

```

```
view(t)

classregtree | test | numnodes

nodemean

Class: classregtree

Mean values of nodes of regression tree

Syntax

NM = nodemean(T)

NM = nodemean(T,J)

Description

NM = nodemean(T) returns an n -element numeric array with mean values in each node of the tree T, where n is the number of nodes in the tree. Every element of this array is computed by averaging true Y values over all observations in the node. For classification trees, nodemean returns an empty numeric array.

NM = nodemean(T,J) takes an array J of node numbers and returns the mean values for the specified nodes.

See Also

classregtree | numnodes

nodeprob

Class: classregtree

Node probabilities

Syntax

```
p = nodeprob(t)
p = nodeprob(t,nodes)
```

Description

`p = nodeprob(t)` returns an n -element vector **p** of the probabilities of the nodes in the tree **t**, where n is the number of nodes. The probability of a node is computed as the proportion of observations from the original data that satisfy the conditions for the node. For a classification tree, this proportion is adjusted for any prior probabilities assigned to each class.

`p = nodeprob(t,nodes)` takes a vector **nodes** of node numbers and returns the probabilities for the specified nodes.

Examples

Create a classification tree for Fisher's iris data:

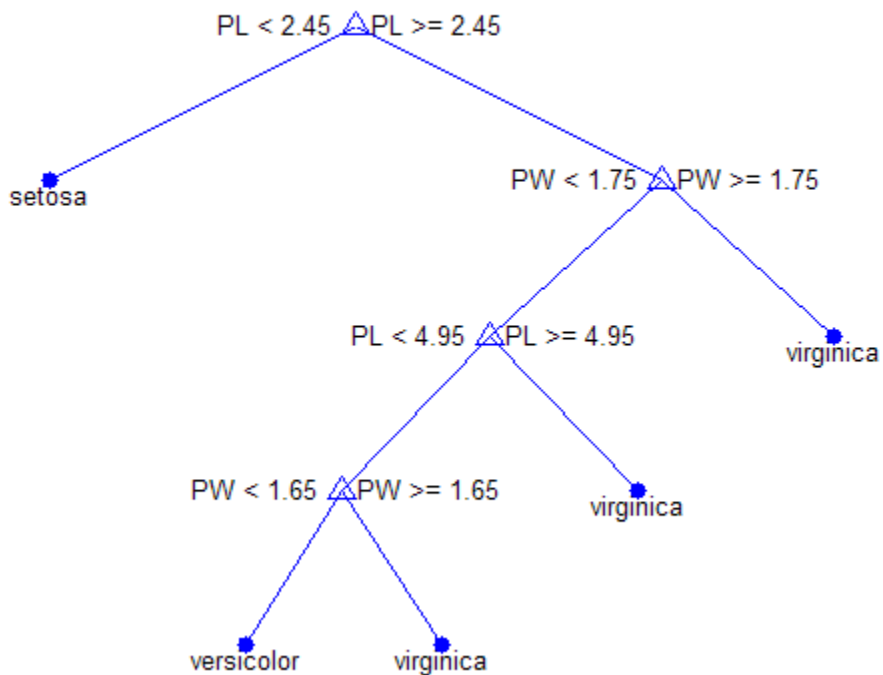

```
load fisheriris;

t = classregtree(meas,species,...
                'names',{'SL' 'SW' 'PL' 'PW'})
t =
Decision tree for classification
1  if PL<2.45 then node 2 elseif PL>=2.45 then node 3 else setosa
2  class = setosa
3  if PW<1.75 then node 4 elseif PW>=1.75 then node 5 else versicolor
4  if PL<4.95 then node 6 elseif PL>=4.95 then node 7 else versicolor

`classregtree` | `numnodes` | `nodesize`

nodesize

Class: classregtree

Return node size

Syntax

```
sizes = nodesize(t)
sizes = nodesize(t,nodes)
```

Description

`sizes = nodesize(t)` returns an n -element vector `sizes` of the sizes of the nodes in the tree `t`, where n is the number of nodes. The size of a node is defined as the number of observations from the data used to create the tree that satisfy the conditions for the node.

`sizes = nodesize(t,nodes)` takes a vector `nodes` of node numbers and returns the sizes for the specified nodes.

Examples

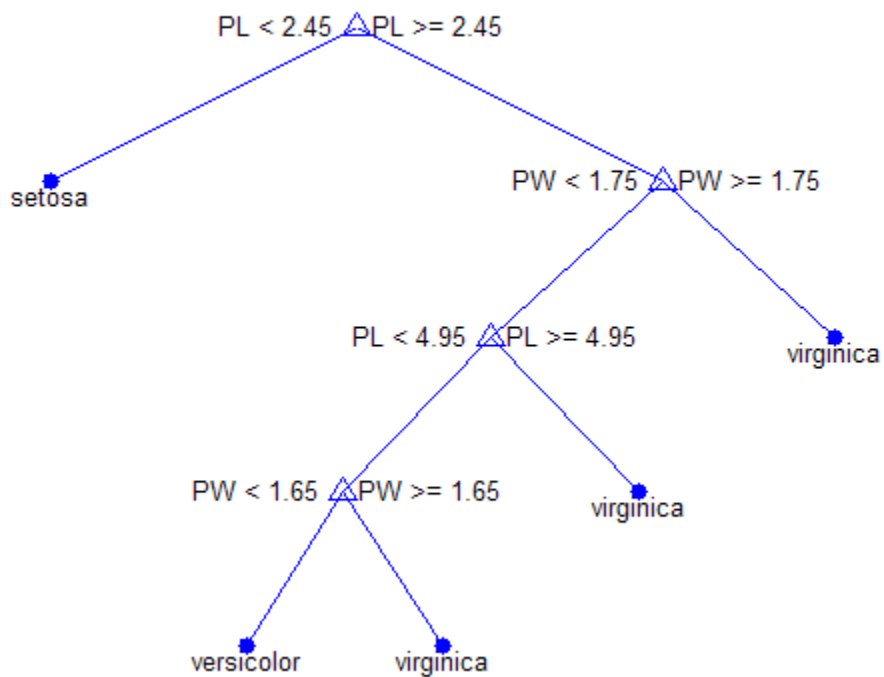

Create a classification tree for Fisher's iris data:

```
load fisheriris;

t = classregtree(meas,species,...
                'names',{'SL' 'SW' 'PL' 'PW'})
t =

classregtree | numnodes

nominal

Create nominal array

After creating a `nominal` array, you can use related functions to add, drop, or merge categories, and more.

For more information, see [Using nominal Objects](#).

Compatibility

The `nominal` and `ordinal` array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the MATLAB categorical data type instead.

Syntax

```
B = nominal(X)
B = nominal(X,labels)
B = nominal(X,labels,levels)

B = nominal(X,labels,[],edges)
```

Description

`B = nominal(X)` creates a nominal array `B` from the array `X`. `nominal` creates the levels of `B` from the sorted unique values in `X`, and creates default labels for them.

`B = nominal(X,labels)` labels the levels in `B` according to `labels`.

`B = nominal(X,labels,levels)` creates a nominal array with possible levels defined by `levels`.

`B = nominal(X,labels,[],edges)` creates a nominal array by binning a numeric array `X` with bin edges given by the numeric vector `edges`.

Examples

Create and Label Nominal Arrays

Create nominal arrays from a cell array of strings and from integer data, and provide explicit labels.

Create a nominal array from a cell array of strings with values 'r', 'g', and 'b'. Label these levels 'red', 'green', and 'blue', respectively. Note that the labels are specified according to the sorted (alphabetical) order of the elements in X.

```
X = {'r' 'b' 'g'; 'g' 'r' 'b'; 'b' 'r' 'g'}  
B = nominal(X,{'blue','green','red'})
```

X =

```
'r'    'b'    'g'  
'g'    'r'    'b'  
'b'    'r'    'g'
```

B =

```
red      blue     green  
green    red      blue  
blue     red      green
```

Create a nominal array from integer data with values 1 to 4, merging odd and even values into two nominal levels with labels 'odd' and 'even'. Achieve the merging by duplicating the labels.

```
X = randi([1 4],5,2)  
B = nominal(X,{'odd','even','odd','even'})
```

X =

```
4     1  
4     2  
1     3  
4     4  
3     4
```

B =

even	odd
even	even
odd	odd
even	even
odd	even

- “Create Nominal and Ordinal Arrays” on page 2-4
- “Plot Data Grouped by Category” on page 2-25

Input Arguments

X — Input array

numeric | logical | character | categorical | cell array of strings

Input array to convert to **nominal**, specified as a numeric, logical, character, or categorical array, or a cell array of strings. The levels of the resulting **nominal** array correspond to the sorted unique values in X.

labels — Labels for the discrete levels

character array | cell array of strings

Labels for the discrete levels, specified as a character array or cell array of strings. By default, **nominal** assigns the labels to the levels in B in order according to the sorted unique values in X.

You can include duplicate labels in labels in order to merge multiple values in X into a single level in B.

Data Types: char | cell

levels — Possible nominal levels

vector

Possible nominal levels for the output **nominal** array, specified as a vector whose values can be compared to those in X using the equality operator. **nominal** assigns labels to each level from the corresponding elements of labels. If X contains any values not present in levels, the levels of the corresponding elements of B are undefined.

edges — Bin edges

numeric vector

Bin edges to create a nominal array by binning a numeric array, specified as a numeric vector. The uppermost bin includes values equal to the right-most edge. `nominal` assigns labels to each level in the resulting nominal array from the corresponding elements of labels. When you specify edges, it must have one more element than labels.

Output Arguments

B — Nominal array

nominal array object

Nominal array, returned as a `nominal` array object.

By default, an element of B is undefined if the corresponding element of X is NaN (when X is numeric), an empty string (when X is a character), or undefined (when X is categorical). `nominal` treats such elements as “undefined” or “missing” and does not include entries for them among the possible levels. To create an explicit level for such elements instead of treating them as undefined, you must use the `levels` input argument, and include NaN, the empty string, or an undefined element.

More About

- Using nominal Objects

See Also

ordinal

Using nominal Objects

Arrays for nominal data

Nominal data are discrete, nonnumeric values that do not have a natural ordering. `nominal` array objects provide efficient storage and convenient manipulation of such data, while also maintaining meaningful labels for the values.

You can manipulate `nominal` arrays much like ordinary numeric arrays, including subscripting, concatenating, and reshaping. It can be useful to use `nominal` arrays as grouping variables when the elements indicate the group an observation belongs to.

Note: The `nominal` and `ordinal` array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the MATLAB `categorical` data type instead.

Examples

Create and Manipulate Nominal Arrays

Create a nominal array from string data in a cell array.

```
colors = nominal({'r','b','g';'g','r','b';'b','r','g'},...
                {'blue','green','red'})
```

```
colors =
```

```
    red    blue    green
    green  red     blue
    blue   red     green
```

Identify the elements in `colors` that are members of the level `'red'`. A value of 1 in the resulting array indicates that the corresponding element of `colors` is a member of `'red'`.

```
colors == 'red'
```

```
ans =
```

```
    1    0    0
    0    1    0
    0    1    0
```

Identify the elements of `colors` that are members of either 'red' or 'blue'.

```
ismember(colors,{'red' 'blue'})
```

```
ans =
```

```
    1    1    0
    0    1    1
    1    1    0
```

Merge the elements of the 'red' and 'blue' levels into a new level labeled 'purple'.

```
colors = mergelevels(colors,{'red','blue'},'purple')
```

```
colors =
```

```
    purple    purple    green
    green    purple    purple
    purple    purple    green
```

Display the levels of `colors`.

```
getlevels(colors)
```

```
ans =
```

```
    purple    green
```

Summarize the number of elements in each level. By default, `summary` returns counts for each column of the input array.

```
summary(colors)
```

purple	2	3	1
green	1	0	2

Create a pie chart for the data in colors.

```
pie(colors)
```

- “Add and Drop Category Levels” on page 2-21
- “Plot Data Grouped by Category” on page 2-25
- “Summary Statistics Grouped by Category” on page 2-38

Properties

labels — Level labels

cell array of strings

Level labels, specified as a cell array of string. Access labels using `getlabels`.

Data Types: `cell`

undefined — Label for undefined levels

'<undefined>' (default)

Label for undefined levels, specified as '<undefined>'. You can find undefined elements in categorical arrays using `isundefined`.

Object Functions

`addlevels` `droplevels` `getlabels` `getlevels` `islevel` `levelcounts` `mergelevels`
`reorderlevels` `setlabels`

You can also use many other MATLAB array functions with categorical arrays. The following is a partial list. For a complete list, see “Other MATLAB Functions Supporting Nominal and Ordinal Arrays” on page 2-3.

`double` `hist` `isequal` `isundefined` `pie` `summary` `times`

Create Object

Create nominal arrays using the `nominal` function.

See Also

`ordinal`

- “Grouping Variables” on page 2-52

notify

Class: grandstream

Notify listeners of event

Syntax

```
notify(h, 'eventname')  
notify(h, 'eventname', data)
```

Description

`notify(h, 'eventname')` notifies listeners added to the event named `eventname` on handle object array `h` that the event is taking place. `h` is the array of handles to objects triggering the event, and `eventname` must be a string.

`notify(h, 'eventname', data)` provides a way of encapsulating information about an event which can then be accessed by each registered listener. `data` must belong to the `event.EventData` class.

See Also

`addlistener` | `event.EventData` | `events` | `grandstream`

NonLinearModel class

Nonlinear regression model class

Description

An object comprising training data, model description, diagnostic information, and fitted coefficients for a nonlinear regression. Predict model responses with the `predict` or `feval` methods.

Construction

`nlm = fitnlm(tbl,modelfun,beta0)` or `nlm = fitnlm(X,y,modelfun,beta0)`
create a nonlinear model of a table or dataset array `tbl`, or of the responses `y` to a data matrix `X`. For details, see `fitnlm`.

Input Arguments

tbl — Input data

table | dataset array

Input data, specified as a table or dataset array. When `modelspec` is a `formula`, it specifies the variables to be used as the predictors and response. Otherwise, if you do not specify the predictor and response variables, the last variable is the response variable and the others are the predictor variables by default.

Predictor variables can be numeric, or any grouping variable type, such as logical or categorical (see “Grouping Variables” on page 2-52). The response must be numeric or logical.

To set a different column as the response variable, use the `ResponseVar` name-value pair argument. To use a subset of the columns as predictors, use the `PredictorVars` name-value pair argument.

Data Types: `single` | `double` | `logical`

X — Predictor variables

matrix

Predictor variables, specified as an n -by- p matrix, where n is the number of observations and p is the number of predictor variables. Each column of X represents one variable, and each row represents one observation.

By default, there is a constant term in the model, unless you explicitly remove it, so do not include a column of 1s in X .

Data Types: `single` | `double` | `logical`

y — Response variable

vector

Response variable, specified as an n -by-1 vector, where n is the number of observations. Each entry in y is the response for the corresponding row of X .

Data Types: `single` | `double`

modelfun — Functional form of the model

function handle | string of the form ' $y \sim f(b_1, b_2, \dots, b_j, x_1, x_2, \dots, x_k)$ '

Functional form of the model, specified as either of the following.

- Function handle `@modelfun` or `@(b,x)modelfun`, where
 - b is a coefficient vector with the same number of elements as `beta0`.
 - x is a matrix with the same number of columns as X or the number of predictor variable columns of `tbl`.

`modelfun(b,x)` returns a column vector that contains the same number of rows as x . Each row of the vector is the result of evaluating `modelfun` on the corresponding row of x . In other words, `modelfun` is a vectorized function, one that operates on all data rows and returns all evaluations in one function call. `modelfun` should return real numbers to obtain meaningful coefficients.

- String of the form ' $y \sim f(b_1, b_2, \dots, b_j, x_1, x_2, \dots, x_k)$ ', where f represents a scalar function of the scalar coefficient variables b_1, \dots, b_j and the scalar data variables x_1, \dots, x_k .

beta0 — Coefficients

numeric vector

Coefficients for the nonlinear model, specified as a numeric vector. `NonLinearModel` starts its search for optimal coefficients from `beta0`.

Data Types: `single` | `double`

Properties

CoefficientCovariance

Covariance matrix of coefficient estimates.

CoefficientNames

Cell array of strings containing a label for each coefficient.

Coefficients

Coefficient values stored as a table. **Coefficients** has one row for each coefficient and these columns:

- **Estimate** — Estimated coefficient value
- **SE** — Standard error of the estimate
- **tStat** — t statistic for a test that the coefficient is zero
- **pValue** — p -value for the t statistic

To obtain any of these columns as a vector, index into the property using dot notation. For example, in `mdl` the estimated coefficient vector is

```
beta = mdl.Coefficients.Estimate
```

Use `coefTest` to perform other tests on the coefficients.

Diagnostics

Table with diagnostics helpful in finding outliers and influential observations. The table contains the following fields.

Field	Meaning	Utility
Leverage	Diagonal elements of <code>HatMatrix</code>	Leverage indicates to what extent the predicted value for an observation is determined by the observed value for that observation. A value close to 1 indicates that the prediction is largely determined by that observation, with little contribution from the

Field	Meaning	Utility
		other observations. A value close to 0 indicates the fit is largely determined by the other observations. For a model with P coefficients and N observations, the average value of Leverage is P/N . An observation with Leverage larger than $2 \cdot P/N$ can be regarded as having high leverage.
CooksDistance	Cook's measure of scaled change in fitted values	CooksDistance is a measure of scaled change in fitted values. An observation with CooksDistance larger than three times the mean Cook's distance can be an outlier.
HatMatrix	Projection matrix to compute fitted from observed responses	HatMatrix is an N -by- N matrix such that $\text{Fitted} = \text{HatMatrix} \cdot Y$, where Y is the response vector and Fitted is the vector of fitted response values.

DFE

Degrees of freedom for error (residuals), equal to the number of observations minus the number of estimated coefficients.

Fitted

Vector of predicted values based on the training data. `fitnlm` attempts to make **Fitted** as close as possible to the response data.

Formula

Object that represents the mathematical form of the model.

Iterative

Structure with information about the fitting process. Fields:

- **InitialCoefs** — Initial coefficient values (the **beta0** vector)
- **IterOpts** — Options included in the **Options** name-value pair argument for `fitnlm`.

LogLikelihood

Log likelihood of the model distribution at the response values, with mean fitted from the model, and other parameters estimated as part of the model fit.

ModelCriterion

AIC and other information criteria for comparing models. A structure with fields:

- **AIC** — Akaike information criterion
- **AICc** — Akaike information criterion corrected for sample size
- **BIC** — Bayesian information criterion
- **CAIC** — Consistent Akaike information criterion

To obtain any of these values as a scalar, index into the property using dot notation. For example, in a model `mdl`, the AIC value `aic` is:

```
aic = mdl.ModelCriterion.AIC
```

MSE

Mean squared error, a scalar that is an estimate of the variance of the error term in the model.

NumCoefficients

Number of coefficients in the fitted model, a scalar. `NumCoefficients` is the same as `NumEstimatedCoefficients` for `NonLinearModel` objects. `NumEstimatedCoefficients` is equal to the degrees of freedom for regression.

NumEstimatedCoefficients

Number of estimated coefficients in the fitted model, a scalar. `NumEstimatedCoefficients` is the same as `NumCoefficients` for `NonLinearModel` objects. `NumEstimatedCoefficients` is equal to the degrees of freedom for regression.

NumPredictors

Number of variables `fitnlm` used as predictors for fitting.

NumVariables

Number of variables in the data. `NumVariables` is the number of variables in the original table or dataset, or the total number of columns in the predictor matrix and response vector when the fit is based on those arrays. It includes variables, if any, that are not used as predictors or as the response.

ObservationInfo

Table with the same number of rows as the input data (`tbl` or `X`).

Field	Description
Weights	Observation weights. Default is all 1.
Excluded	Logical value, 1 indicates an observation that you excluded from the fit with the <code>Exclude</code> name-value pair.
Missing	Logical value, 1 indicates a missing value in the input. Missing values are not used in the fit.
Subset	Logical value, 1 indicates the observation is not excluded or missing, so is used in the fit.

ObservationNames

Cell array of strings containing the names of the observations used in the fit.

- If the fit is based on a table or dataset containing observation names, `ObservationNames` uses those names.
- Otherwise, `ObservationNames` is an empty cell array

PredictorNames

Cell array of strings, the names of the predictors used in fitting the model.

Residuals

Table of residuals, with one row for each observation and these variables.

Field	Description
Raw	Observed minus fitted values.
Pearson	Raw residuals divided by RMSE.
Standardized	Raw residuals divided by their estimated standard deviation.
Studentized	Residual divided by an independent estimate of the residual standard deviation. The residual for observation i is divided by an estimate of the error standard deviation based on all observations except for observation i .

To obtain any of these columns as a vector, index into the property using dot notation. For example, in a model `mdl`, the ordinary raw residual vector `r` is:

```
r = mdl.Residuals.Raw
```

Rows not used in the fit because of missing values (in `ObservationInfo.Missing`) contain NaN values.

Rows not used in the fit because of excluded values (in `ObservationInfo.Excluded`) contain NaN values, with the following exceptions:

- `raw` contains the difference between the observed and predicted values.
- `standardized` is the residual, standardized in the usual way.
- `studentized` matches the standardized values because this residual is not used in the estimate of the residual standard deviation.

ResponseName

String giving naming the response variable.

RMSE

Root mean squared error, a scalar that is an estimate of the standard deviation of the error term in the model.

Robust

Structure that is empty unless `fitnlm` constructed the model using robust regression.

Field	Description
<code>WgtFun</code>	Robust weighting function, such as 'bisquare' (see <code>robustfit</code>)
<code>Tune</code>	Value specified for tuning parameter (can be <code>[]</code>)
<code>Weights</code>	Vector of weights used in final iteration of robust fit

Rsquared

Proportion of total sum of squares explained by the model. The ordinary R-squared value relates to the `SSR` and `SST` properties:

$$\text{Rsquared} = \text{SSR}/\text{SST} = 1 - \text{SSE}/\text{SST}.$$

For a linear or nonlinear model, `Rsquared` is a structure with two fields:

- `Ordinary` — Ordinary (unadjusted) R-squared
- `Adjusted` — R-squared adjusted for the number of coefficients

For a generalized linear model, `Rsquared` is a structure with five fields:

- `Ordinary` — Ordinary (unadjusted) R-squared
- `Adjusted` — R-squared adjusted for the number of coefficients
- `LLR` — Log-likelihood ratio
- `Deviance` — Deviance
- `AdjGeneralized` — Adjusted generalized R-squared

To obtain any of these values as a scalar, index into the property using dot notation. For example, the adjusted R-squared value in `mdl` is

```
r2 = mdl.Rsquared.Adjusted
```

SSE

Sum of squared errors (residuals).

The Pythagorean theorem implies
 $\text{SST} = \text{SSE} + \text{SSR}.$

SSR

Regression sum of squares, the sum of squared deviations of the fitted values from their mean.

The Pythagorean theorem implies
 $\text{SST} = \text{SSE} + \text{SSR}.$

SST

Total sum of squares, the sum of squared deviations of y from $\text{mean}(y)$.

The Pythagorean theorem implies
 $\text{SST} = \text{SSE} + \text{SSR}.$

VariableInfo

Table containing metadata about `Variables`. There is one row for each term in the model, and the following columns.

Field	Description
Class	String giving variable class, such as 'double'
Range	Cell array giving variable range: <ul style="list-style-type: none">• Continuous variable — Two-element vector $[min, max]$, the minimum and maximum values• Categorical variable — Cell array of distinct variable values
InModel	Logical vector, where <code>true</code> indicates the variable is in the model
IsCategorical	Logical vector, where <code>true</code> indicates a categorical variable

VariableNames

Cell array of strings containing names of the variables in the fit.

- If the fit is based on a table or dataset, this property provides the names of the variables in that table or dataset.
- If the fit is based on a predictor matrix and response vector, `VariableNames` is the values in the `VarNames` name-value pair of the fitting method.
- Otherwise the variables have the default fitting names.

Variables

Table containing the data, both observations and responses, that the fitting function used to construct the fit. If the fit is based on a table or dataset array, `Variables` contains all of the data from that table or dataset array. Otherwise, `Variables` is a table created from the input data matrix `X` and response vector `y`.

Methods

`coefCI`

Confidence intervals of coefficient estimates of nonlinear regression model

coefTest	Linear hypothesis test on nonlinear regression model coefficients
disp	Display nonlinear regression model
feval	Evaluate nonlinear regression model prediction
fit	Fit nonlinear regression model
plotDiagnostics	Plot diagnostics of nonlinear regression model
plotResiduals	Plot residuals of nonlinear regression model
plotSlice	Plot of slices through fitted nonlinear regression surface
predict	Predict response of nonlinear regression model
random	Simulate responses for nonlinear regression model

Definitions

Hat Matrix

The *hat matrix* H is defined in terms of the data matrix X and the Jacobian matrix J :

$$J_{i,j} = \left. \frac{\partial f}{\partial \beta_j} \right|_{x_i, \beta}$$

Here f is the nonlinear model function, and β is the vector of model coefficients.

The Hat Matrix H is

$$H = J(J^T J)^{-1} J^T.$$

The diagonal elements H_{ii} satisfy

$$0 \leq h_{ii} \leq 1$$

$$\sum_{i=1}^n h_{ii} = p,$$

where n is the number of observations (rows of X), and p is the number of coefficients in the regression model.

Leverage

The *leverage* of observation i is the value of the i th diagonal term, h_{ii} , of the hat matrix H . Because the sum of the leverage values is p (the number of coefficients in the regression model), an observation i can be considered to be an outlier if its leverage substantially exceeds p/n , where n is the number of observations.

Cook's Distance

The Cook's distance D_i of observation i is

$$D_i = \frac{\sum_{j=1}^n (\hat{y}_j - \hat{y}_{j(i)})^2}{p MSE},$$

where

- \hat{y}_j is the j th fitted response value.
- $\hat{y}_{j(i)}$ is the j th fitted response value, where the fit does not include observation i .
- MSE is the mean squared error.
- p is the number of coefficients in the regression model.

Cook's distance is algebraically equivalent to the following expression:

$$D_i = \frac{r_i^2}{p \text{MSE}} \left(\frac{h_{ii}}{(1-h_{ii})^2} \right),$$

where e_i is the i th residual.

Copy Semantics

Value. To learn how value classes affect copy operations, see “Copying Objects” in the MATLAB documentation.

Examples

Nonlinear Model

Create a nonlinear model for auto mileage based on the `carbig` data. Predict the mileage of an average car.

Load the data and create a nonlinear model.

```
load carbig
X = [Horsepower,Weight];
y = MPG;
modelfun = @(b,x)b(1) + b(2)*x(:,1).^b(3) + ...
    b(4)*x(:,2).^b(5);
beta0 = [-50 500 -1 500 -1];
mdl = fitnlm(X,y,modelfun,beta0)
```

mdl =

```
Nonlinear regression model:
    y ~ b1 + b2*x1^b3 + b4*x2^b5
```

Estimated Coefficients:

Estimate	SE	tStat	pValue
_____	_____	_____	_____

b1	-49.383	119.97	-0.41164	0.68083
b2	376.43	567.05	0.66384	0.50719
b3	-0.78193	0.47168	-1.6578	0.098177
b4	422.37	776.02	0.54428	0.58656
b5	-0.24127	0.48325	-0.49926	0.61788

Number of observations: 392, Error degrees of freedom: 387
Root Mean Squared Error: 3.96
R-Squared: 0.745, Adjusted R-Squared 0.743
F-statistic vs. constant model: 283, p-value = 1.79e-113

Find the predicted mileage of an average auto. The data contain some observations with NaN, so compute the mean using `nanmean`.

```
Xnew = nanmean(X)
```

```
Xnew =  
 1.0e+03 *  
 0.1051  2.9794
```

```
MPGnew = predict mdl, Xnew)
```

```
MPGnew =  
  
 21.8073
```

prob.NormalDistribution class

Package: prob

Superclasses: prob.ToolboxFittableParametricDistribution

Normal probability distribution object

Description

`prob.NormalDistribution` is an object consisting of parameters, a model description, and sample data for a normal probability distribution.

Create a probability distribution object with specified parameter values using `makedist`. Alternatively, fit a distribution to data using `fitdist` or the Distribution Fitting app.

Construction

`pd = makedist('Normal')` creates a normal probability distribution object using the default parameter values.

`pd = makedist('Normal', 'mu', mu, 'sigma', sigma)` creates a normal distribution object using the specified parameter values.

Input Arguments

mu — Mean

0 (default) | scalar value

Mean of the normal distribution, specified as a scalar value.

Data Types: `single` | `double`

sigma — Standard deviation

1 (default) | nonnegative scalar value

Standard deviation of the normal distribution, specified as a nonnegative scalar value.

Data Types: `single` | `double`

Properties

mu — Mean

scalar value

Mean of the normal distribution, stored as a scalar value.

Data Types: `single` | `double`

sigma — Standard deviation

nonnegative scalar value

Standard deviation of the normal distribution, stored as a nonnegative scalar value.

Data Types: `single` | `double`

DistributionName — Probability distribution name

probability distribution name string

Probability distribution name, stored as a valid probability distribution name string. This property is read-only.

Data Types: `char`

InputData — Data used for distribution fitting

structure

Data used for distribution fitting, stored as a structure containing the following:

- **data**: Data vector used for distribution fitting.
- **cens**: Censoring vector, or empty if none.
- **freq**: Frequency vector, or empty if none.

This property is read-only.

Data Types: `struct`

IsTruncated — Logical flag for truncated distribution

0 | 1

Logical flag for truncated distribution, stored as a logical value. If `IsTruncated` equals 0, the distribution is not truncated. If `IsTruncated` equals 1, the distribution is truncated. This property is read-only.

Data Types: `logical`

NumParameters — Number of parameters

positive integer value

Number of parameters for the probability distribution, stored as a positive integer value. This property is read-only.

Data Types: `single` | `double`

ParameterCovariance — Covariance matrix of the parameter estimates

matrix of scalar values

Covariance matrix of the parameter estimates, stored as a p -by- p matrix, where p is the number of parameters in the distribution. The (i,j) element is the covariance between the estimates of the i th parameter and the j th parameter. The (i,i) element is the estimated variance of the i th parameter. If parameter i is fixed rather than estimated by fitting the distribution to data, then the (i,i) elements of the covariance matrix are 0. This property is read-only.

Data Types: `single` | `double`

ParameterDescription — Distribution parameter descriptions

cell array of strings

Distribution parameter descriptions, stored as a cell array of strings. Each cell contains a short description of one distribution parameter. This property is read-only.

Data Types: `char`

ParameterIsFixed — Logical flag for fixed parameters

array of logical values

Logical flag for fixed parameters, stored as an array of logical values. If 0, the corresponding parameter in the `ParameterNames` array is not fixed. If 1, the corresponding parameter in the `ParameterNames` array is fixed. This property is read-only.

Data Types: `logical`

ParameterNames — Distribution parameter names

cell array of strings

Distribution parameter names, stored as a cell array of strings. This property is read-only.

Data Types: char

ParameterValues — Distribution parameter values

vector of scalar values

Distribution parameter values, stored as a vector. This property is read-only.

Data Types: single | double

Truncation — Truncation interval

vector of scalar values

Truncation interval for the probability distribution, stored as a vector containing the lower and upper truncation boundaries. This property is read-only.

Data Types: single | double

Methods

Inherited Methods

cdf	Cumulative distribution function of probability distribution object
icdf	Inverse cumulative distribution function of probability distribution object
iqr	Interquartile range of probability distribution object

var	Variance of probability distribution object

Definitions

Normal Distribution

The normal distribution, sometimes called the Gaussian distribution, is a two-parameter family of curves. The usual justification for using the normal distribution for modeling is the Central Limit theorem, which states (roughly) that the sum of independent samples from any distribution with finite mean and variance converges to the normal distribution as the sample size goes to infinity.

The normal distribution uses the following parameters.

Parameter	Description	Support
mu	Mean	$-\infty < \mu < \infty$
sigma	Standard deviation	$\sigma \geq 0$

The probability density function (pdf) is

$$f(x | \mu, \sigma) = \frac{1}{\sigma\sqrt{2\pi}} e^{-\frac{(x-\mu)^2}{2\sigma^2}}, \quad -\infty < x < \infty.$$

Examples

Create a Normal Distribution Object Using Default Parameters

Create a normal distribution object using the default parameter values.

```
pd = makedist('Normal')
```

```
pd =
```

```
NormalDistribution
```

```
Normal distribution
```

```
mu = 0
```

```
sigma = 1
```

Create a Normal Distribution Object Using Specified Parameters

Create a normal distribution object by specifying the parameter values.

```
pd = makedist('Normal', 'mu', 75, 'sigma', 10)
```

```
pd =
```

```
NormalDistribution
```

```
Normal distribution
```

```
mu = 75
```

```
sigma = 10
```

Compute the interquartile range of the distribution.

```
r = iqr(pd)
```

```
r =
```

13.4898

Fit a Normal Distribution Object

Load the sample data. Create a vector containing the first column of students' exam grades data.

```
load examgrades;  
x = grades(:,1);
```

Create a normal distribution object by fitting it to the data.

```
pd = fitdist(x,'Normal')  
  
pd =  
  
NormalDistribution  
  
Normal distribution  
    mu = 75.0083    [73.4321, 76.5846]  
    sigma = 8.7202    [7.7391, 9.98843]
```

normcdf

Normal cumulative distribution function

Syntax

```
p = normcdf(x)
p = normcdf(x,mu,sigma)
[p,plo,pup] = normcdf(x,mu,sigma,pcov,alpha)
[p,plo,pup] = normcdf( ____, 'upper' )
```

Description

`p = normcdf(x)` returns the standard normal cdf at each value in `x`. The standard normal distribution has parameters `mu = 0` and `sigma = 1`. `x` can be a vector, matrix, or multidimensional array.

`p = normcdf(x,mu,sigma)` returns the normal cdf at each value in `x` using the specified values for the mean `mu` and standard deviation `sigma`. `x`, `mu`, and `sigma` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs. The parameters in `sigma` must be positive.

`[p,plo,pup] = normcdf(x,mu,sigma,pcov,alpha)` returns confidence bounds for `p` when the input parameters `mu` and `sigma` are estimates. `pcov` is the covariance matrix of the estimated parameters. `alpha` specifies `100(1 - alpha)%` confidence bounds. The default value of `alpha` is 0.05. `plo` and `pup` are arrays of the same size as `p` containing the lower and upper confidence bounds.

`[p,plo,pup] = normcdf(____, 'upper')` returns the complement of the normal cdf at each value in `x`, using an algorithm that more accurately computes the extreme upper tail probabilities. You can use `'upper'` with any of the previous syntaxes.

The function `normcdf` computes confidence bounds for `p` using a normal approximation to the distribution of the estimate

$$\frac{X - \hat{\mu}}{\hat{\sigma}}$$

and then transforming those bounds to the scale of the output `p`. The computed bounds give approximately the desired confidence level when you estimate `mu`, `sigma`, and `pcov` from large samples, but in smaller samples other methods of computing the confidence bounds might be more accurate.

The normal cdf is

$$p = F(x | \mu, \sigma) = \frac{1}{\sigma\sqrt{2\pi}} \int_{-\infty}^x e^{-\frac{(t-\mu)^2}{2\sigma^2}} dt$$

The result, p , is the probability that a single observation from a normal distribution with parameters μ and σ will fall in the interval $(-\infty, x]$.

The *standard normal* distribution has $\mu = 0$ and $\sigma = 1$.

Examples

Compute Normal Distribution cdf

What is the probability that an observation from a standard normal distribution will fall on the interval `[-1 1]`?

```
p = normcdf([-1 1]);
p(2) - p(1)
```

```
ans =
    0.6827
```

More generally, about 68% of the observations from a normal distribution fall within one standard deviation, σ , of the mean, μ .

More About

- “Normal Distribution” on page B-119

See Also

`cdf` | `normpdf` | `norminv` | `normstat` | `normfit` | `normlike` | `normrnd`

normfit

Normal parameter estimates

Syntax

```
[muhat,sigmahat] = normfit(data)
[muhat,sigmahat,muci,sigmaci] = normfit(data)
[muhat,sigmahat,muci,sigmaci] = normfit(data,alpha)
[...] = normfit(data,alpha,censoring)
[...] = normfit(data,alpha,censoring,freq)
[...] = normfit(data,alpha,censoring,freq,options)
```

Description

`[muhat,sigmahat] = normfit(data)` returns an estimate of the mean μ in `muhat`, and an estimate of the standard deviation σ in `sigmahat`, of the normal distribution given the data in `data`.

`[muhat,sigmahat,muci,sigmaci] = normfit(data)` returns 95% confidence intervals for the parameter estimates on the mean and standard deviation in the arrays `muci` and `sigmaci`, respectively. The first row of `muci` contains the lower bounds of the confidence intervals for μ the second row contains the upper bounds. The first row of `sigmaci` contains the lower bounds of the confidence intervals for σ , and the second row contains the upper bounds.

`[muhat,sigmahat,muci,sigmaci] = normfit(data,alpha)` returns 100(1 - `alpha`) % confidence intervals for the parameter estimates, where `alpha` is a value in the range [0 1] specifying the width of the confidence intervals. By default, `alpha` is 0.05, which corresponds to 95% confidence intervals.

`[...] = normfit(data,alpha,censoring)` accepts a Boolean vector, `censoring`, of the same size as `data`, which is 1 for observations that are right-censored and 0 for observations that are observed exactly. `data` must be a vector in order to pass in the argument `censoring`.

`[...] = normfit(data,alpha,censoring,freq)` accepts a frequency vector, `freq`, of the same size as `data`. Typically, `freq` contains integer frequencies for the

corresponding elements in `data`, but can contain any nonnegative values. Pass in `[]` for `alpha`, `censoring`, or `freq` to use their default values.

`[...] = normfit(data,alpha,censoring,freq,options)` accepts a structure, `options`, that specifies control parameters for the iterative algorithm the function uses to compute maximum likelihood estimates when there is censoring. The normal fit function accepts an `options` structure which you can create using the function `statset`. Enter `statset('normfit')` to see the names and default values of the parameters that `normfit` accepts in the `options` structure. See the reference page for `statset` for more information about these options.

Note: With no censoring, `normfit` computes `muhat` using the sample mean and `sigmahat` using the square root of the unbiased estimator of the variance. With censoring, both `muhat` and `sigmahat` are the maximum likelihood estimates.

Examples

In this example the data is a two-column random normal matrix. Both columns have $\mu = 10$ and $\sigma = 2$. Note that the confidence intervals below contain the "true values."

```
data = normrnd(10,2,100,2);
[mu,sigma,muci,sigmaci] = normfit(data)
mu =
    10.1455    10.0527
sigma =
    1.9072    2.1256
muci =
    9.7652    9.6288
    10.5258    10.4766
sigmaci =
    1.6745    1.8663
    2.2155    2.4693
```

norminv

Normal inverse cumulative distribution function

Syntax

```
X = norminv(P,mu,sigma)
[X,XLO,XUP] = norminv(P,mu,sigma,pcov,alpha)
```

Description

`X = norminv(P,mu,sigma)` computes the inverse of the normal cdf using the corresponding mean `mu` and standard deviation `sigma` at the corresponding probabilities in `P`. `P`, `mu`, and `sigma` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs. The parameters in `sigma` must be positive, and the values in `P` must lie in the interval [0 1].

`[X,XLO,XUP] = norminv(P,mu,sigma,pcov,alpha)` produces confidence bounds for `X` when the input parameters `mu` and `sigma` are estimates. `pcov` is the covariance matrix of the estimated parameters. `alpha` specifies 100(1 - `alpha`)% confidence bounds. The default value of `alpha` is 0.05. `XLO` and `XUP` are arrays of the same size as `X` containing the lower and upper confidence bounds.

The function `norminv` computes confidence bounds for `P` using a normal approximation to the distribution of the estimate

$$\hat{\mu} + \hat{\sigma} q$$

where q is the P th quantile from a normal distribution with mean 0 and standard deviation 1. The computed bounds give approximately the desired confidence level when you estimate `mu`, `sigma`, and `pcov` from large samples, but in smaller samples other methods of computing the confidence bounds may be more accurate.

The normal inverse function is defined in terms of the normal cdf as

$$x = F^{-1}(p | \mu, \sigma) = \{x : F(x | \mu, \sigma) = p\}$$

where

$$p = F(x | \mu, \sigma) = \frac{1}{\sigma\sqrt{2\pi}} \int_{-\infty}^x e^{-\frac{(t-\mu)^2}{2\sigma^2}} dt$$

The result, x , is the solution of the integral equation above where you supply the desired probability, p .

Examples

Find an interval that contains 95% of the values from a standard normal distribution.

```
x = norminv([0.025 0.975],0,1)
x =
   -1.9600    1.9600
```

Note that the interval x is not the only such interval, but it is the shortest.

```
x1 = norminv([0.01 0.96],0,1)
x1 =
   -2.3263    1.7507
```

The interval $x1$ also contains 95% of the probability, but it is longer than x .

normlike

Normal negative log-likelihood

Syntax

```
nlogL = normlike(params,data)
[nlogL,AVAR] = normlike(params,data)
[...] = normlike(param,data,censoring)
[...] = normlike(param,data,censoring,freq)
```

Description

`nlogL = normlike(params,data)` returns the negative of the normal log-likelihood function. `params(1)` is the mean, `mu`, and `params(2)` is the standard deviation, `sigma`.

`[nlogL,AVAR] = normlike(params,data)` also returns the inverse of Fisher's information matrix, `AVAR`. If the input parameter values in `params` are the maximum likelihood estimates, the diagonal elements of `AVAR` are their asymptotic variances. `AVAR` is based on the observed Fisher's information, not the expected information.

`[...] = normlike(param,data,censoring)` accepts a Boolean vector, `censoring`, of the same size as `data`, which is 1 for observations that are right-censored and 0 for observations that are observed exactly.

`[...] = normlike(param,data,censoring,freq)` accepts a frequency vector, `freq`, of the same size as `data`. The vector `freq` typically contains integer frequencies for the corresponding elements in `data`, but can contain any nonnegative values. Pass in `[]` for `censoring` to use its default value.

`normlike` is a utility function for maximum likelihood estimation.

normpdf

Normal probability density function

Syntax

`Y = normpdf(X, mu, sigma)`

`Y = normpdf(X)`

`Y = normpdf(X, mu)`

Description

`Y = normpdf(X, mu, sigma)` computes the pdf at each of the values in `X` using the normal distribution with mean `mu` and standard deviation `sigma`. `X`, `mu`, and `sigma` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs. The parameters in `sigma` must be positive.

The normal pdf is

$$y = f(x | \mu, \sigma) = \frac{1}{\sigma \sqrt{2\pi}} e^{-\frac{(x-\mu)^2}{2\sigma^2}}$$

The *likelihood function* is the pdf viewed as a function of the parameters. Maximum likelihood estimators (MLEs) are the values of the parameters that maximize the likelihood function for a fixed value of `x`.

The *standard normal* distribution has $\mu = 0$ and $\sigma = 1$.

If `x` is standard normal, then `xo + mu` is also normal with mean μ and standard deviation σ . Conversely, if `y` is normal with mean μ and standard deviation σ , then `x = (y - mu) / sigma` is standard normal.

`Y = normpdf(X)` uses the standard normal distribution (`mu = 0`, `sigma = 1`).

`Y = normpdf(X, mu)` uses the normal distribution with unit standard deviation (`sigma = 1`).

Examples

```
mu = [0:0.1:2];  
[y i] = max(normpdf(1.5,mu,1));  
MLE = mu(i)  
MLE =  
    1.5000
```

pdf | normcdf | norminv | normstat | normfit | normlike | normrnd | mvnpdf

normplot

Normal probability plot

Syntax

```
h = normplot(X)
```

Description

`h = normplot(X)` displays a normal probability plot of the data in `X`. For matrix `X`, `normplot` displays a line for each column of `X`. `h` is a handle to the plotted lines.

The plot has the sample data displayed with the plot symbol '+' . Superimposed on the plot is a line joining the first and third quartiles of each column of `X` (a robust linear fit of the sample order statistics.) This line is extrapolated out to the ends of the sample to help evaluate the linearity of the data.

The purpose of a normal probability plot is to graphically assess whether the data in `X` could come from a normal distribution. If the data are normal the plot will be linear. Other distribution types will introduce curvature in the plot. `normplot` uses midpoint probability plotting positions. Use `probplot` when the data included censored observations.

Examples

Generate a Normal Probability Plot

Generate random sample data from a normal distribution with `mu = 10` and `sigma = 1`.

```
rng default; % For reproducibility
x = normrnd(10,1,25,1);
```

Create a normal probability plot of the sample data.

```
figure;
```

```
normplot(x)
```

The plot indicates that the data follows a normal distribution.

normrnd

Normal random numbers

Syntax

```
R = normrnd(mu, sigma)
R = normrnd(mu, sigma, m, n, ...)
R = normrnd(mu, sigma, [m, n, ...])
```

Description

`R = normrnd(mu, sigma)` generates random numbers from the normal distribution with mean parameter `mu` and standard deviation parameter `sigma`. `mu` and `sigma` can be vectors, matrices, or multidimensional arrays that have the same size, which is also the size of `R`. A scalar input for `mu` or `sigma` is expanded to a constant array with the same dimensions as the other input.

`R = normrnd(mu, sigma, m, n, ...)` or `R = normrnd(mu, sigma, [m, n, ...])` generates an `m`-by-`n`-by-... array. The `mu`, `sigma` parameters can each be scalars or arrays of the same size as `R`.

Examples

```
n1 = normrnd(1:6, 1./(1:6))
n1 =
    2.1650    2.3134    3.0250    4.0879    4.8607    6.2827
```

```
n2 = normrnd(0, 1, [1 5])
n2 =
    0.0591    1.7971    0.2641    0.8717   -1.4462
```

```
n3 = normrnd([1 2 3; 4 5 6], 0.1, 2, 3)
n3 =
    0.9299    1.9361    2.9640
    4.1246    5.0577    5.9864
```

normspec

Normal density plot between specifications

Syntax

```
normspec(specs)
normspec(specs,mu,sigma)
normspec(specs,mu,sigma,region)
p = normspec(...)
[p,h] = normspec(...)
```

Description

`normspec(specs)` plots the standard normal density, shading the portion inside the specification limits given by the two-element vector `specs`. Set `specs(1)` to `-Inf` if there is no lower limit; set `specs(2)` to `Inf` if there is no upper limit.

`normspec(specs,mu,sigma)` shades the portion inside the specification limits of a normal density with parameters `mu` and `sigma`. The defaults are `mu = 0` and `sigma = 1`.

`normspec(specs,mu,sigma,region)` shades the *region* either `'inside'` or `'outside'` the specification limits. The default is `'inside'`.

`p = normspec(...)` also returns the probability, `p`, of the shaded area.

`[p,h] = normspec(...)` also returns a handle `h` to the line objects.

Examples

Create a Normal Density Plot

This example shows how to create a normal density plot.

A production process fills cans of paint. The average amount of paint in any can is 1 gallon, but variability in the process produces a standard deviation of 2 ounces (2/128

gallons). What is the probability that the cans will be filled under specification by 3 or more ounces?

```
p = normspec([1-3/128,Inf],1,2/128,'outside')
```

p =

0.0668

capaplot | histfit

normstat

Normal mean and variance

Syntax

```
[M,V] = normstat(mu,sigma)
```

Description

`[M,V] = normstat(mu,sigma)` returns the mean of and variance for the normal distribution using the corresponding mean `mu` and standard deviation `sigma`. `mu` and `sigma` can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of `M` and `V`. A scalar input for `mu` or `sigma` is expanded to a constant array with the same dimensions as the other input.

The mean of the normal distribution with parameters μ and σ is μ , and the variance is σ^2 .

Examples

```
n = 1:5;  
[m,v] = normstat(n'*n,n'*n)  
m =
```

```
 1  2  3  4  5  
 2  4  6  8 10  
 3  6  9 12 15  
 4  8 12 16 20  
 5 10 15 20 25
```

```
v =  
 1  4  9 16 25  
 4 16 36 64 100  
 9 36 81 144 225  
16 64 144 256 400  
25 100 225 400 625
```

nsegments

Class: `piecewisedistribution`

Number of segments

Syntax

```
n = nsegments(obj)
```

Description

`n = nsegments(obj)` returns the number of segments `n` in the piecewise distribution object `obj`.

Examples

Fit Pareto tails to a t distribution at cumulative probabilities 0.1 and 0.9:

```
t = trnd(3,100,1);  
obj = paretotails(t,0.1,0.9);
```

```
n = nsegments(obj)  
n =  
    3
```

See Also

`paretotails` | `boundary` | `segment`

NTrees property

Class: TreeBagger

Number of decision trees in ensemble

Description

The `NTrees` property is a scalar equal to the number of decision trees in the ensemble.

See Also

Trees

NumParams property

Class: ProbDistParametric

Read-only value specifying number of parameters of ProbDistParametric object

Description

NumParams is a read-only property of the ProbDistParametric class. NumParams is a value specifying the number of parameters of a distribution represented by a ProbDistParametric object.

Values

This value is an integer that counts both the specified parameters and parameters that are fit to the data. Use this information to view and compare the number of parameters supplied to create distributions.

numel

Class: dataset

Number of elements in dataset array

Compatibility

The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

Syntax

```
n = numel(A)
n = numel(A, varargin)
```

Description

`n = numel(A)` returns 1. To find the number of elements, `n`, in the dataset array `A`, use `prod(size(A))` or `numel(A, ':', ':')`.

`n = numel(A, varargin)` returns the number of subscripted elements, `n`, in `A(index1, index2, ..., indexn)`, where `varargin` is a cell array whose elements are `index1`, `index2`, ... `indexn`.

See Also

`length` | `size`

numnodes

Class: classregtree

Number of nodes

Syntax

```
n = numnodes(t)
```

Description

`n = numnodes(t)` returns the number of nodes `n` in the tree `t`.

Examples

Create a classification tree for Fisher's iris data:

```
load fisheriris;
t = classregtree(meas,species,...
                'names',{'SL' 'SW' 'PL' 'PW'})
t=
Decision tree for classification
1  if PL<2.45 then node 2 elseif PL>=2.45 then node 3 else setosa
2  class = setosa
3  if PW<1.75 then node 4 elseif PW>=1.75 then node 5 else versicolor
4  if PL<4.95 then node 6 elseif PL>=4.95 then node 7 else versicolor
5  class = virginica
6  if PW<1.65 then node 8 elseif PW>=1.65 then node 9 else versicolor
7  class = virginica
8  class = versicolor
9  class = virginica
view(t)
```

Click to display: Magnification: Pruning level:

`n = numnodes(t)`

`n =`

`classregtree`

NumTestSets property

Class: cvpartition

Number of test sets

Description

Value is the number of folds in partitions of type 'kfold' and 'leaveout'.

Value is 1 in partitions of type 'holdout' and 'resubstitution'.

NVarToSample property

Class: TreeBagger

Number of variables for random feature selection

Description

The `NVarToSample` property specifies the number of predictor or feature variables to select at random for each decision split. By default, it is set to the square root of the total number of variables for classification and one third of the total number of variables for regression. Setting this argument to any valid value except 'all' invokes Breiman's "random forest" algorithm.

See Also

`ClassificationTree` | `RegressionTree` | `TreeBagger` | `fitctree` | `fitrtree`

ObsNames property

Class: dataset

Cell array of nonempty, distinct strings giving names of observations in data set

Compatibility

The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

Description

A cell array of nonempty, distinct strings giving the names of the observations in the data set. This property may be empty, but if not empty, the number of strings must equal the number of observations.

optimalleaforder

Optimal leaf ordering for hierarchical clustering

Syntax

```
leafOrder = optimalleaforder(tree,D)  
leafOrder = optimalleaforder(tree,D,Name,Value)
```

Description

`leafOrder = optimalleaforder(tree,D)` returns an optimal leaf ordering for the hierarchical binary cluster tree, `tree`, using the distances, `D`. An optimal leaf ordering of a binary tree maximizes the sum of the similarities between adjacent leaves by flipping tree branches without dividing the clusters.

`leafOrder = optimalleaforder(tree,D,Name,Value)` returns the optimal leaf ordering using one or more name-value pair arguments.

Examples

Plot Dendrogram With Optimal Leaf Order

Create a hierarchical binary cluster tree using `linkage`. Then, compare the dendrogram plot with the default ordering to a dendrogram with an optimal leaf ordering.

Generate sample data.

```
rng('default') % For reproducibility  
X = rand(10,2);
```

Create a distance vector and a hierarchical binary clustering tree. Use the distances and clustering tree to determine an optimal leaf order.

```
D = pdist(X);  
tree = linkage(D,'average');  
leafOrder = optimalleaforder(tree,D);
```

Plot the dendrogram with the default ordering and the dendrogram with the optimal leaf ordering.

```
figure()
subplot(2,1,1)
dendrogram(tree)
title('Default Leaf Order')

subplot(2,1,2)
dendrogram(tree,'reorder',leafOrder)
title('Optimal Leaf Order')
```

The order of the leaves in the bottom figure corresponds to the elements in leafOrder .

leafOrder

```
leafOrder =  
    1     4     9    10     2     5     8     3     7     6
```

Optimal Leaf Order Using Inverse Distance Similarity

Generate sample data.

```
rng('default') % For reproducibility  
X = rand(10,2);
```

Create a distance vector and a hierarchical binary clustering tree.

```
D = pdist(X);  
tree = linkage(D, 'average');
```

Use the inverse distance similarity transformation to determine an optimal leaf order.

```
leafOrder = optimalleaforder(tree,D, 'Transformation', 'inverse')
```

```
leafOrder =  
    1     4     9    10     2     5     8     3     7     6
```

Input Arguments

tree — Hierarchical binary cluster tree

matrix returned by `linkage`

Hierarchical binary cluster tree, specified as an $(M - 1)$ -by-3 matrix that you generate using `linkage`, where M is the number of leaves.

D — Distances

matrix | vector

Distances for determining similarities between leaves, specified as a matrix or vector of distances. For example, you can generate distances using `pdist`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single

quotes (' '). You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Example: 'Criteria', 'group', 'Transformation', 'inverse' specifies that the sum of similarities be maximized between every leaf and all other leaves in adjacent clusters, using an inverse similarity transformation.

'Criteria' – Optimization criterion

'adjacent' (default) | 'group'

Optimization criterion for determining an optimal leaf ordering, specified as the comma-separated pair consisting of 'criteria' and one of these strings:

- 'adjacent' Maximize the sum of similarities between adjacent leaves.
- 'group' Maximize the sum of similarities between every leaf and all other leaves in the adjacent clusters at the same level of the dendrogram.

Example: 'Criteria', 'group'

Data Types: char

'Transformation' – Method for transforming distances to similarities

'linear' (default) | 'inverse' | function handle

Method for transforming distances to similarities, specified as the comma-separated pair consisting of 'Transformation' and one of 'linear', 'inverse', or a function handle.

Let $d_{i,j}$ and $Sim_{i,j}$ denote the distance and similarity between leaves i and j , respectively. The included similarity transformations are:

- 'linear' $Sim_{i,j} = \max_{i,j} (d_{i,j}) - d_{i,j}$
- 'inverse' $Sim_{i,j} = 1/d_{i,j}$

To use a custom transformation function, specify a handle to a function that accepts a matrix of distances, **D**, and returns a matrix of similarities, **S**. The function should be monotonic decreasing in the range of distance values. **S** must have the same size as **D**, with $S(i, j)$ being the similarity computed based on $D(i, j)$.

Example: 'Transformation', @myTransform

Data Types: char | function_handle

Output Arguments

leafOrder — Optimal leaf order

vector

Optimal leaf order, returned as a length- M vector, where M is the number of leaves. `leafOrder` is a permutation of the vector `1:M`, giving an optimal leaf ordering based on the specified distances and similarity transformation.

References

- [1] Bar-Joseph, Z., Gifford, D.K., and Jaakkola, T.S. (2001). Fast optimal leaf ordering for hierarchical clustering. *Bioinformatics* *17*, Suppl 1:S22–9. PMID: 11472989.

`dendrogram` | `linkage` | `pdist`

oobEdge

Class: ClassificationBaggedEnsemble

Out-of-bag classification edge

Syntax

```
edge = oobEdge(ens)
edge = oobEdge(ens, Name, Value)
```

Description

`edge = oobEdge(ens)` returns out-of-bag classification edge for `ens`.

`edge = oobEdge(ens, Name, Value)` computes classification edge with additional options specified by one or more `Name, Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Input Arguments

ens

A classification bagged ensemble, constructed with `fitensemble`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

'learners'

Indices of weak learners in the ensemble ranging from 1 to `ens.NumTrained`. `oobEdge` uses only these learners for calculating loss.

Default: 1:NumTrained

'mode'

String representing the meaning of the output L:

- 'ensemble' — L is a scalar value, the loss for the entire ensemble.
- 'individual' — L is a vector with one element per trained learner.
- 'cumulative' — L is a vector in which element J is obtained by using learners 1:J from the input list of learners.

Default: 'ensemble'

Output Arguments

edge

Classification edge, a weighted average of the classification margin.

Definitions

Edge

The *edge* is the weighted mean value of the classification margin. The weights are the class probabilities in `ens.Prior`.

Margin

The classification *margin* is the difference between the classification *score* for the true class and maximal classification score for the false classes. Margin is a column vector with the same number of rows as in the matrix `ens.X`.

Out of Bag

Bagging, which stands for “bootstrap aggregation”, is a type of ensemble learning. To bag a weak learner such as a decision tree on a dataset, `fitensemble` generates

many bootstrap replicas of the dataset and grows decision trees on these replicas. `fitensemble` obtains each bootstrap replica by randomly selecting N observations out of N with replacement, where N is the dataset size. To find the predicted response of a trained ensemble, `predict` take an average over predictions from individual trees.

Drawing N out of N observations with replacement omits on average 37% ($1/e$) of observations for each decision tree. These are "out-of-bag" observations. For each observation, `oobLoss` estimates the out-of-bag prediction by averaging over predictions from all trees in the ensemble for which this observation is out of bag. It then compares the computed prediction against the true response for this observation. It calculates the out-of-bag error by comparing the out-of-bag predicted responses against the true responses for all observations used for training. This out-of-bag average is an unbiased estimator of the true ensemble error.

Examples

Find the out-of-bag edge for a bagged ensemble from the Fisher iris data:

```
load fisheriris
ens = fitensemble(meas,species,'Bag',100,...
    'Tree','type','classification');
edge = oobEdge(ens)

edge =
    0.8730
```

See Also

`oobMargin` | `oobPredict` | `oobLoss`

oobError

Class: TreeBagger

Out-of-bag error

Syntax

```
err = oobError(B)
err = oobError(B, 'param1', val1, 'param2', val2, ...)
```

Description

`err = oobError(B)` computes the misclassification probability (for classification trees) or mean squared error (for regression trees) for out-of-bag observations in the training data, using the trained bagger `B`. `err` is a vector of length `NTrees`, where `NTrees` is the number of trees in the ensemble.

`err = oobError(B, 'param1', val1, 'param2', val2, ...)` specifies optional parameter name/value pairs:

<code>'mode'</code>	String indicating how <code>oobError</code> computes errors. If set to <code>'cumulative'</code> (default), the method computes cumulative errors and <code>err</code> is a vector of length <code>NTrees</code> , where the first element gives error from <code>trees(1)</code> , second element gives error from <code>trees(1:2)</code> etc, up to <code>trees(1:NTrees)</code> . If set to <code>'individual'</code> , <code>err</code> is a vector of length <code>NTrees</code> , where each element is an error from each tree in the ensemble. If set to <code>'ensemble'</code> , <code>err</code> is a scalar showing the cumulative error for the entire ensemble.
<code>'trees'</code>	Vector of indices indicating what trees to include in this calculation. By default, this argument is set to <code>'all'</code> and the method uses all trees. If <code>'trees'</code> is a numeric vector, the method returns a vector of length <code>NTrees</code> for <code>'cumulative'</code> and <code>'individual'</code> modes, where <code>NTrees</code> is the number of elements in the input vector, and a scalar for <code>'ensemble'</code> mode. For example, in the <code>'cumulative'</code> mode, the first element

gives error from `trees(1)`, the second element gives error from `trees(1:2)` etc.

'treeweights' Vector of tree weights. This vector must have the same length as the 'trees' vector. `oobError` uses these weights to combine output from the specified trees by taking a weighted average instead of the simple nonweighted majority vote. You cannot use this argument in the 'individual' mode.

`CompactTreeBagger.error`

OOBIndices property

Class: TreeBagger

Indicator matrix for out-of-bag observations

Description

The `OOBIndices` property is a logical array of size `Nobs-by-NTrees` where `Nobs` is the number of observations in the training data and `NTrees` is the number of trees in the ensemble. The (I, J) element is true if observation `I` is out-of-bag for tree `J` and false otherwise. In other words, a true value means observation `I` was not selected for the training data used to grow tree `J`.

See Also

`ClassificationTree` | `RegressionTree` | `TreeBagger` | `fitctree` | `fitrtree`

OOBInstanceWeight property

Class: TreeBagger

Count of out-of-bag trees for each observation

Description

The `OOBInstanceWeight` property is a numeric array of size `Nobs`-by-1 containing the number of trees used for computing out-of-bag response for each observation. `Nobs` is the number of observations in the training data used to create the ensemble.

oobLoss

Class: ClassificationBaggedEnsemble

Out-of-bag classification error

Syntax

`L = oobloss(ens)`

`L = oobloss(ens,Name,Value)`

Description

`L = oobloss(ens)` returns the classification error for `ens` computed for out-of-bag data.

`L = oobloss(ens,Name,Value)` computes error with additional options specified by one or more `Name,Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Input Arguments

ens

A classification bagged ensemble, constructed with `fitensemble`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

'learners'

Indices of weak learners in the ensemble ranging from 1 to `NumTrained`. `oobLoss` uses only these learners for calculating loss.

Default: 1:NumTrained

'lossfun'

Function handle or string representing a loss function. Built-in loss functions:

- 'binodeviance' — See “Loss Functions” on page 21-2998
- 'classiferror' — Fraction of misclassified data
- 'exponential' — See “Loss Functions” on page 21-2998
- 'hinge' — See “Loss Functions” on page 21-2998.
- 'mincost' — Smallest misclassification cost as given by the obj.Cost matrix. See “Loss Functions” on page 21-2998.

You can write your own loss function in the syntax described in “Loss Functions” on page 21-2998.

Default: 'classiferror'

'mode'

String representing the meaning of the output L:

- 'ensemble' — L is a scalar value, the loss for the entire ensemble.
- 'individual' — L is a vector with one element per trained learner.
- 'cumulative' — L is a vector in which element J is obtained by using learners 1:J from the input list of learners.

Default: 'ensemble'

Output Arguments

L

Classification error of the out-of-bag observations, a scalar. L can be a vector, or can represent a different quantity, depending on the name-value settings.

Definitions

Out of Bag

Bagging, which stands for “bootstrap aggregation”, is a type of ensemble learning. To bag a weak learner such as a decision tree on a dataset, `fitensemble` generates many bootstrap replicas of the dataset and grows decision trees on these replicas. `fitensemble` obtains each bootstrap replica by randomly selecting N observations out of N with replacement, where N is the dataset size. To find the predicted response of a trained ensemble, `predict` take an average over predictions from individual trees.

Drawing N out of N observations with replacement omits on average 37% ($1/e$) of observations for each decision tree. These are "out-of-bag" observations. For each observation, `oobLoss` estimates the out-of-bag prediction by averaging over predictions from all trees in the ensemble for which this observation is out of bag. It then compares the computed prediction against the true response for this observation. It calculates the out-of-bag error by comparing the out-of-bag predicted responses against the true responses for all observations used for training. This out-of-bag average is an unbiased estimator of the true ensemble error.

Loss Functions

The built-in loss functions are:

- `'binodeviance'` — For binary classification, assume the classes y_n are -1 and 1 . With weight vector w normalized to have sum 1, and predictions of row n of data X as $f(X_n)$, the binomial deviance is

$$\sum w_n \log(1 + \exp(-2y_n f(X_n))).$$

- `'classiferror'` — Fraction of misclassified data, weighted by w .
- `'exponential'` — With the same definitions as for `'binodeviance'`, the exponential loss is

$$\sum w_n \exp(-y_n f(X_n)).$$

- `'hinge'` — Classification error measure that has the form

$$L = \frac{\sum_{j=1}^n w_j \max\{0, 1 - y_j' f(X_j)\}}{\sum_{j=1}^n w_j},$$

where:

- w_j is weight j .
- For binary classification, $y_j = 1$ for the positive class and -1 for the negative class. For problems where the number of classes $K > 3$, y_j is a vector of 0s, but with a 1 in the position corresponding to the true class, e.g., if the second observation is in the third class and $K = 4$, then $y_2 = [0 \ 0 \ 1 \ 0]'$.
- $f(X_j)$ is, for binary classification, the posterior probability or, for $K > 3$, a vector of posterior probabilities for each class given observation j .
- 'mincost' — Predict the label with the smallest expected misclassification cost, with expectation taken over the posterior probability, and cost as given by the **COST** property of the classifier (a matrix). The loss is then the true misclassification cost averaged over the observations.

To write your own loss function, create a function file of the form

```
function loss = lossfun(C,S,W,COST)
```

- **N** is the number of rows of **X**.
- **K** is the number of classes in tree, represented in **tree.ClassNames**.
- **C** is an **N**-by-**K** logical matrix, with one **true** per row for the true class. The index for each class is its position in **tree.ClassNames**.
- **S** is an **N**-by-**K** numeric matrix. **S** is a matrix of posterior probabilities for classes with one row per observation, similar to the **posterior** output from **predict**.
- **W** is a numeric vector with **N** elements, the observation weights.
- **COST** is a **K**-by-**K** numeric matrix of misclassification costs. The default 'classiferror' cost function uses a cost of 0 for correct classification, and 1 for misclassification. In other words, 'classiferror' uses **COST=ones(K)-eye(K)**.
- The output **loss** should be a scalar.

Pass the function handle `@lossfun` as the value of the `lossfun` name-value pair.

Examples

Find the out-of-bag error for a bagged ensemble from the Fisher iris data:

```
load fisheriris
ens = fitensemble(meas,species,'Bag',100,...
    'Tree','type','classification');
L = oobLoss(ens)

L =
    0.0467
```

See Also

`loss` | `oobMargin` | `oobPredict` | `oobEdge`

oobLoss

Class: RegressionBaggedEnsemble

Out-of-bag regression error

Syntax

`L = oobLoss(ens)`

`L = oobLoss(ens,Name,Value)`

Description

`L = oobLoss(ens)` returns the mean squared error for `ens` computed for out-of-bag data.

`L = oobLoss(ens,Name,Value)` computes error with additional options specified by one or more `Name,Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Input Arguments

ens

A regression bagged ensemble, constructed with `fitensemble`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

'learners'

Indices of weak learners in the ensemble ranging from 1 to `NumTrained`. `oobLoss` uses only these learners for calculating loss.

Default: `1:NumTrained`

'lossfun'

Function handle for loss function, or the string `'mse'`, meaning mean squared error. If you pass a function handle `fun`, `oobLoss` calls it as

```
FUN(Y,Yfit,W)
```

where `Y`, `Yfit`, and `W` are numeric vectors of the same length. `Y` is the observed response, `Yfit` is the predicted response, and `W` is the observation weights.

Default: `'mse'`

'mode'

String representing the meaning of the output `L`:

- `'ensemble'` — `L` is a scalar value, the loss for the entire ensemble.
- `'individual'` — `L` is a vector with one element per trained learner.
- `'cumulative'` — `L` is a vector in which element `J` is obtained by using learners `1:J` from the input list of learners.

Default: `'ensemble'`

Output Arguments

L

Mean squared error of the out-of-bag observations, a scalar. `L` can be a vector, or can represent a different quantity, depending on the name-value settings.

Definitions

Out of Bag

Bagging, which stands for “bootstrap aggregation”, is a type of ensemble learning. To bag a weak learner such as a decision tree on a dataset, `fitensemble` generates

many bootstrap replicas of the dataset and grows decision trees on these replicas. `fitensemble` obtains each bootstrap replica by randomly selecting N observations out of N with replacement, where N is the dataset size. To find the predicted response of a trained ensemble, `predict` take an average over predictions from individual trees.

Drawing N out of N observations with replacement omits on average 37% ($1/e$) of observations for each decision tree. These are "out-of-bag" observations. For each observation, `oobLoss` estimates the out-of-bag prediction by averaging over predictions from all trees in the ensemble for which this observation is out of bag. It then compares the computed prediction against the true response for this observation. It calculates the out-of-bag error by comparing the out-of-bag predicted responses against the true responses for all observations used for training. This out-of-bag average is an unbiased estimator of the true ensemble error.

Examples

Compute the out-of-bag error for the `carsmall` data:

```
load carsmall
X = [Displacement Horsepower Weight];
ens = fitensemble(X,MPG,'bag',100,'Tree',...
    'type','regression');
L = oobLoss(ens)

L =
    17.0665
```

`oobPredict` | `loss`

oobMargin

Class: ClassificationBaggedEnsemble

Out-of-bag classification margins

Syntax

```
margin = oobMargin(ens)
margin = oobMargin(ens,Name,Value)
```

Description

`margin = oobMargin(ens)` returns out-of-bag classification margins.

`margin = oobMargin(ens,Name,Value)` calculates margins with additional options specified by one or more Name,Value pair arguments.

Input Arguments

ens

A classification bagged ensemble, constructed with `fitensemble`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1,Value1, ...,NameN,ValueN.

'learners'

Indices of weak learners in the ensemble ranging from 1 to `ens.NumTrained`. `oobEdge` uses only these learners for calculating loss.

Default: 1:NumTrained

Output Arguments

margin

A numeric column vector of length `size(ens.X,1)`.

Definitions

Out of Bag

Bagging, which stands for “bootstrap aggregation”, is a type of ensemble learning. To bag a weak learner such as a decision tree on a dataset, `fitensemble` generates many bootstrap replicas of the dataset and grows decision trees on these replicas. `fitensemble` obtains each bootstrap replica by randomly selecting N observations out of N with replacement, where N is the dataset size. To find the predicted response of a trained ensemble, `predict` take an average over predictions from individual trees.

Drawing N out of N observations with replacement omits on average 37% ($1/e$) of observations for each decision tree. These are "out-of-bag" observations. For each observation, `oobLoss` estimates the out-of-bag prediction by averaging over predictions from all trees in the ensemble for which this observation is out of bag. It calculates the out-of-bag error by comparing the out-of-bag predicted responses against the true responses for all observations used for training. This out-of-bag average is an unbiased estimator of the true ensemble error.

Margin

The classification *margin* is the difference between the classification *score* for the true class and maximal classification score for the false classes. Margin is a column vector with the same number of rows as in the matrix `ens.X`.

Examples

Find the out-of-bag margin for a bagged ensemble from the Fisher iris data: Find how many elements of margin are equal to 1.

```
load fisheriris
ens = fitensemble(meas,species,'Bag',100,...
  'Tree','type','classification');
margin = oobMargin(ens);
sum(margin == 1)

ans =
    108
```

oobMargin

Class: TreeBagger

Out-of-bag margins

Syntax

```
mar = oobMargin(B)
```

```
mar = oobMargin(B, 'param1', val1, 'param2', val2, ...)
```

Description

`mar = oobMargin(B)` computes an `Nobs`-by-`NTrees` matrix of classification margins for out-of-bag observations in the training data, using the trained bagger `B`.

`mar = oobMargin(B, 'param1', val1, 'param2', val2, ...)` specifies optional parameter name/value pairs:

'mode'	String indicating how <code>oobMargin</code> computes errors. If set to 'cumulative' (default), the method computes cumulative margins and <code>mar</code> is an <code>Nobs</code> -by- <code>NTrees</code> matrix, where the first column gives margins from <code>trees(1)</code> , second column gives margins from <code>trees(1:2)</code> etc, up to <code>trees(1:NTrees)</code> . If set to 'individual', <code>mar</code> is an <code>Nobs</code> -by- <code>NTrees</code> matrix, where each column gives margins from each tree in the ensemble. If set to 'ensemble', <code>mar</code> is a single column of length <code>Nobs</code> showing the cumulative margins for the entire ensemble.
'trees'	Vector of indices indicating what trees to include in this calculation. By default, this argument is set to 'all' and the method uses all trees. If 'trees' is a numeric vector, the method returns an <code>Nobs</code> -by- <code>NTrees</code> matrix for 'cumulative' and 'individual' modes, where <code>NTrees</code> is the number of elements in the input vector, and a single column for 'ensemble' mode. For example, in the 'cumulative' mode, the first column gives margins from <code>trees(1)</code> , the second column gives margins from <code>trees(1:2)</code> etc.

'treeweights' Vector of tree weights. This vector must have the same length as the 'trees' vector. `oobMargin` uses these weights to combine output from the specified trees by taking a weighted average instead of the simple nonweighted majority vote. You cannot use this argument in the 'individual' mode.

`CompactTreeBagger.margin`

oobMeanMargin

Class: TreeBagger

Out-of-bag mean margins

Syntax

```
mar = oobMeanMargin(B)
mar = oobMeanMargin(B, 'param1', val1, 'param2', val2, ...)
```

Description

`mar = oobMeanMargin(B)` computes average classification margins for out-of-bag observations in the training data, using the trained bagger `B`. `oobMeanMargin` averages the margins over all out-of-bag observations. `mar` is a row-vector of length `NTrees`, where `NTrees` is the number of trees in the ensemble.

`mar = oobMeanMargin(B, 'param1', val1, 'param2', val2, ...)` specifies optional parameter name/value pairs:

<code>'mode'</code>	String indicating how <code>oobMargin</code> computes errors. If set to <code>'cumulative'</code> (default), is a vector of length <code>NTrees</code> where the first element gives mean margin from <code>trees(1)</code> , second column gives mean margins from <code>trees(1:2)</code> etc, up to <code>trees(1:NTrees)</code> . If set to <code>'individual'</code> , <code>mar</code> is a vector of length <code>NTrees</code> , where each element is a mean margin from each tree in the ensemble. If set to <code>'ensemble'</code> , <code>mar</code> is a scalar showing the cumulative mean margin for the entire ensemble.
<code>'trees'</code>	Vector of indices indicating what trees to include in this calculation. By default, this argument is set to <code>'all'</code> and the method uses all trees. If <code>'trees'</code> is a numeric vector, the method returns a vector of length <code>NTrees</code> for <code>'cumulative'</code> and <code>'individual'</code> modes, where <code>NTrees</code> is the number of elements in the input vector, and a scalar for <code>'ensemble'</code> mode. For example, in the <code>'cumulative'</code> mode, the first element gives mean margin from <code>trees(1)</code> , the second element gives mean margin from <code>trees(1:2)</code> etc.

'treeweights' Vector of tree weights. This vector must have the same length as the 'trees' vector. `oobMeanMargin` uses these weights to combine output from the specified trees by taking a weighted average instead of the simple nonweighted majority vote. You cannot use this argument in the 'individual' mode.

See Also

`CompactTreeBagger.meanMargin`

OOBPermutedVarCountRaiseMargin property

Class: TreeBagger

Variable importance for raising margin

Description

The `OOBPermutedVarCountRaiseMargin` property is a numeric array of size 1-by-`Nvars` containing a measure of variable importance for each predictor. For any variable, the measure is the difference between the number of raised margins and the number of lowered margins if the values of that variable are permuted across the out-of-bag observations. This measure is computed for every tree, then averaged over the entire ensemble and divided by the standard deviation over the entire ensemble. This property is empty for regression trees.

OOBPermutedVarDeltaError property

Class: TreeBagger

Variable importance for prediction error

Description

The `OOBPermutedVarDeltaError` property is a numeric array of size 1-by-*Nvars* containing a measure of importance for each predictor variable (feature). For any variable, the measure is the increase in prediction error if the values of that variable are permuted across the out-of-bag observations. This measure is computed for every tree, then averaged over the entire ensemble and divided by the standard deviation over the entire ensemble.

OOBPermutedVarDeltaMeanMargin property

Class: TreeBagger

Variable importance for classification margin

Description

The OOBPermutedVarDeltaMeanMargin property is a numeric array of size 1-by-Nvars containing a measure of importance for each predictor variable (feature). For any variable, the measure is the decrease in the classification margin if the values of that variable are permuted across the out-of-bag observations. This measure is computed for every tree, then averaged over the entire ensemble and divided by the standard deviation over the entire ensemble. This property is empty for regression trees.

oobPredict

Class: ClassificationBaggedEnsemble

Predict out-of-bag response of ensemble

Syntax

```
[label, score] = oobPredict(ens)
[label, score] = oobPredict(ens, Name, Value)
```

Description

[label, score] = oobPredict(ens) returns class labels and scores for `ens` for out-of-bag data.

[label, score] = oobPredict(ens, Name, Value) computes labels and scores with additional options specified by one or more Name, Value pair arguments.

Input Arguments

ens

A classification bagged ensemble, constructed with `fitensemble`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

'learners'

Indices of weak learners in the ensemble ranging from 1 to `ens.NumTrained`. `oobEdge` uses only these learners for calculating loss.

Default: 1:NumTrained

Output Arguments

label1

Classification labels of the same data type as the training data `Y`. There are `N` elements or rows, where `N` is the number of training observations. The label is the class with the highest score. In case of a tie, the label is earliest in `ens.ClassNames`.

score

An `N`-by-`K` numeric matrix for `N` observations and `K` classes. A high score indicates that an observation is likely to come from this class. Scores are in the range 0 to 1.

Definitions

Out of Bag

Bagging, which stands for “bootstrap aggregation”, is a type of ensemble learning. To bag a weak learner such as a decision tree on a dataset, `fitensemble` generates many bootstrap replicas of the dataset and grows decision trees on these replicas. `fitensemble` obtains each bootstrap replica by randomly selecting `N` observations out of `N` with replacement, where `N` is the dataset size. To find the predicted response of a trained ensemble, `predict` take an average over predictions from individual trees.

Drawing `N` out of `N` observations with replacement omits on average 37% ($1/e$) of observations for each decision tree. These are "out-of-bag" observations. For each observation, `oobLoss` estimates the out-of-bag prediction by averaging over predictions from all trees in the ensemble for which this observation is out of bag. It then compares the computed prediction against the true response for this observation. It calculates the out-of-bag error by comparing the out-of-bag predicted responses against the true responses for all observations used for training. This out-of-bag average is an unbiased estimator of the true ensemble error.

Score (ensemble)

For ensembles, a classification *score* represents the confidence of a classification into a class. The higher the score, the higher the confidence.

Different ensemble algorithms have different definitions for their scores. Furthermore, the range of scores depends on ensemble type. For example:

- AdaBoostM1 scores range from $-\infty$ to ∞ .
- Bag scores range from 0 to 1.

Examples

Find the out-of-bag predictions and scores for the Fisher iris data. Find the scores in the range (0.2,0.8); these are the scores where there is notable uncertainty in the resulting classifications.

```
load fisheriris
ens = fitensemble(meas,species,'Bag',100,...
    'Tree','type','classification');
[label score] = oobPredict(ens);
unsure = ( (score > .2) & (score < .8));
sum(sum(unsure)) % How many uncertain predictions?

ans =
    16
```

oobPredict

Class: RegressionBaggedEnsemble

Predict out-of-bag response of ensemble

Syntax

```
Yfit = oobPredict(ens)
Yfit = oobPredict(ens,Name,Value)
```

Description

`Yfit = oobPredict(ens)` returns the predicted responses for the out-of-bag data in `ens`.

`Yfit = oobPredict(ens,Name,Value)` predicts responses with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

ens

A regression bagged ensemble, constructed with `fitensemble`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

'learners'

Indices of weak learners in the ensemble ranging from 1 to `NumTrained`. `oobLoss` uses only these learners for calculating loss.

Default: 1:NumTrained

Output Arguments

Yfit

A vector of predicted responses for out-of-bag data. `Yfit` has `size(ens.X,1)` elements.

You can find the indices of out-of-bag observations for weak learner `L` with the command `~ens.UseObsForLearner(:,L)`

Definitions

Out of Bag

Bagging, which stands for “bootstrap aggregation”, is a type of ensemble learning. To bag a weak learner such as a decision tree on a dataset, `fitensemble` generates many bootstrap replicas of the dataset and grows decision trees on these replicas. `fitensemble` obtains each bootstrap replica by randomly selecting `N` observations out of `N` with replacement, where `N` is the dataset size. To find the predicted response of a trained ensemble, `predict` take an average over predictions from individual trees.

Drawing `N` out of `N` observations with replacement omits on average 37% ($1/e$) of observations for each decision tree. These are "out-of-bag" observations. For each observation, `oobLoss` estimates the out-of-bag prediction by averaging over predictions from all trees in the ensemble for which this observation is out of bag. It then compares the computed prediction against the true response for this observation. This out-of-bag average is an unbiased estimator of the true ensemble error.

Examples

Compute out-of-bag predictions for the `carsmall` data. Look at the first three terms of the fit:

```
load carsmall
X = [Displacement Horsepower Weight];
ens = fitensemble(X,MPG,'bag',100,'Tree',...
    'type','regression');
Yfit = oobPredict(ens);
Yfit(1:3) % first three terms
```

```
ans =
    15.7964
    14.7162
    14.8062
```

See Also

[oobLoss](#) | [predict](#)

oobPredict

Class: TreeBagger

Ensemble predictions for out-of-bag observations

Syntax

```
Y = oobPredict(B)
Y = oobPredict(B, 'param1', val1, 'param2', val2, ...)
```

Description

`Y = oobPredict(B)` computes predicted responses using the trained bagger `B` for out-of-bag observations in the training data. The output has one prediction for each observation in the training data. The returned `Y` is a cell array of strings for classification and a numeric array for regression.

`Y = oobPredict(B, 'param1', val1, 'param2', val2, ...)` specifies optional parameter name/value pairs:

<code>'trees'</code>	Array of tree indices to use for computation of responses. Default is <code>'all'</code> .
<code>'treeweights'</code>	Array of <code>NTrees</code> weights for weighting votes from the specified trees.

ordinal

Create ordinal array

After creating an `ordinal` array, you can use related functions to add, drop, or merge categories, and more.

For more information, see [Using ordinal Objects](#).

Compatibility

The `nominal` and `ordinal` array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the MATLAB categorical data type instead.

Syntax

```
B = ordinal(X)
B = ordinal(X,labels)
B = ordinal(X,labels,levels)

B = ordinal(X,labels,[],edges)
```

Description

`B = ordinal(X)` creates an `ordinal` array object `B` from the array `X`. `ordinal` creates the levels of `B` from the sorted unique values in `X`, and creates default labels for them.

`B = ordinal(X,labels)` labels the levels in `B` according to `labels`.

`B = ordinal(X,labels,levels)` creates an `ordinal` array with possible levels defined by `levels`.

`B = ordinal(X,labels,[],edges)` creates an `ordinal` array by binning a numeric array `X` with bin edges given by the numeric vector `edges`.

Examples

Create and Label Ordinal Arrays

Create an ordinal array from integer data, providing explicit labels.

```
quality = ordinal([1 2 3 3 2 1 2 1 3],...  
                 {'low' 'medium' 'high'})
```

```
quality =
```

```
Columns 1 through 7
```

```
low      medium    high      high      medium    low      medium
```

```
Columns 8 through 9
```

```
low      high
```

Show that the first element is less than the second element (low is less than medium).

```
quality(1) < quality(2)
```

```
ans =
```

```
1
```

Create an ordinal array by binning values between 0 and 1 into thirds with labels 'small', 'medium', and 'large'.

```
X = rand(5,2)
```

```
A = ordinal(X,{'small' 'medium' 'large'},[],[0 1/3 2/3 1])
```

```
X =
```

```
0.8147    0.0975  
0.9058    0.2785  
0.1270    0.5469  
0.9134    0.9575
```

```
0.6324    0.9649
```

```
A =
```

```
large      small
large      small
small      medium
large      large
medium     large
```

- “Create Nominal and Ordinal Arrays” on page 2-4

Input Arguments

X — Input array

numeric | logical | character | categorical | cell array of strings

Input array to convert to `ordinal`, specified as a numeric, logical, character, or categorical array, or a cell array of strings. The levels of the resulting `ordinal` array correspond to the sorted unique values in `X`.

labels — Labels for the discrete levels

character array | cell array of strings

Labels for the discrete levels, specified as a character array or cell array of strings. By default, `ordinal` assigns the labels to the levels in `B` in order according to the sorted unique values in `X`.

You can include duplicate labels in `labels` in order to merge multiple values in `X` into a single level in `B`.

Data Types: `char` | `cell`

levels — Possible ordinal levels

vector

Possible ordinal levels for the output `ordinal` array, specified as a vector whose values can be compared to those in `X` using the equality operator. `ordinal` assigns labels to each level from the corresponding elements of `labels`. If `X` contains any values not present in `levels`, the levels of the corresponding elements of `B` are undefined.

edges — Bin edges

numeric vector

Bin edges to create a ordinal array by binning a numeric array, specified as a numeric vector. The uppermost bin includes values equal to the right-most edge. `ordinal` assigns labels to each level in the resulting nominal array from the corresponding elements of labels. When you specify edges, it must have one more element than labels.

Output Arguments

B — Ordinal array

ordinal array object

Nominal array, returned as an `ordinal` array object.

By default, an element of B is undefined if the corresponding element of X is NaN (when X is numeric), an empty string (when X is a character), or undefined (when X is categorical). `nominal` treats such elements as “undefined” or “missing” and does not include entries for them among the possible levels. To create an explicit level for such elements instead of treating them as undefined, you must use the `levels` input argument, and include NaN, the empty string, or an undefined element.

More About

- Using ordinal Objects

nominal

Using ordinal Objects

Arrays for ordinal data

Ordinal data are discrete, nonnumeric values that have a natural ordering. `ordinal` array objects provide efficient storage and convenient manipulation of such data, while also maintaining meaningful labels for the values.

You can manipulate `ordinal` arrays much like ordinary numeric arrays, including subscripting, concatenating, and reshaping. It can be useful to use `ordinal` arrays as grouping variables when the elements indicate the group an observation belongs to.

Note: The `nominal` and `ordinal` array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the MATLAB categorical data type instead.

Examples

Create and Manipulate Ordinal Arrays

Create an ordinal array from integer data.

```
quality = ordinal([1 2 3; 3 2 1; 2 1 3], {'low' 'medium' 'high'})
```

```
quality =
```

```
    low    medium    high
    high    medium    low
    medium    low    high
```

Identify the elements in `quality` that are members of a level that is greater than or equal to `'medium'`. A value of 1 in the resulting array indicates that the corresponding element of `quality` is in this category.

```
quality >= 'medium'
```

```
ans =
```

```
0    1    1
1    1    0
1    0    1
```

Identify the elements of `quality` that are members of either `'low'` or `'high'`.

```
ismember(quality,{'low' 'high'})
```

```
ans =
```

```
1    0    1
1    0    1
0    1    1
```

Merge the elements of the `'medium'` and `'high'` levels into a new level labeled `'ok'`.

```
quality = mergelevels(quality,{'medium','high'},'ok')
```

```
quality =
```

```
low    ok    ok
ok     ok    low
ok     low   ok
```

Display the levels of `quality`.

```
getlevels(quality)
```

```
ans =
```

```
low    ok
```

Summarize the number of elements in each level. By default, `summary` returns counts for each column of the input array.

```
summary(quality)
```

```
low    1    1    1
```

ok 2 2 2

- “Reorder Category Levels” on page 2-11
- “Categorize Numeric Data” on page 2-16
- “Merge Category Levels” on page 2-19
- “Sort Ordinal Arrays” on page 2-40

Properties

labels — Level labels

cell array of strings

Level labels, specified as a cell array of string. Access labels using `getlabels`.

Data Types: `cell`

undefined — Label for undefined levels

'<undefined>' (default)

Label for undefined levels, specified as '<undefined>'. You can find undefined elements in categorical arrays using `isundefined`.

Object Functions

`addlevels` `droplevels` `getlabels` `getlevels` `islevel` `levelcounts` `mergelevels`
`reorderlevels` `setlabels`

You can also use many other MATLAB array functions with categorical arrays. The following is a partial list. For a complete list, see “Other MATLAB Functions Supporting Nominal and Ordinal Arrays” on page 2-3.

`double` `hist` `isequal` `isundefined` `pie` `summary` `times`

Create Object

Create ordinal arrays using the `ordinal` function.

outlierMeasure

Class: CompactTreeBagger

Outlier measure for data

Syntax

```
out = outlierMeasure(B,X)
out = outlierMeasure(B,X, 'param1',val1, 'param2',val2, ...)
```

Description

`out = outlierMeasure(B,X)` computes outlier measures for predictors `X` using trees in the ensemble `B`. The method computes the outlier measure for a given observation by taking an inverse of the average squared proximity between this observation and other observations. `outlierMeasure` then normalizes these outlier measures by subtracting the median of their distribution, taking the absolute value of this difference, and dividing by the median absolute deviation. A high value of the outlier measure indicates that this observation is an outlier.

You can supply the proximity matrix directly by using the `'data'` parameter.

`out = outlierMeasure(B,X, 'param1',val1, 'param2',val2, ...)` specifies optional parameter name/value pairs:

<code>'data'</code>	Flag indicating how to treat the <code>X</code> input argument. If set to <code>'predictors'</code> (default), the method assumes <code>X</code> is a matrix of predictors and uses it for computation of the proximity matrix. If set to <code>'proximity'</code> , the method treats <code>X</code> as a proximity matrix returned by the <code>proximity</code> method. If you do not supply the proximity matrix, <code>outlierMeasure</code> computes it internally. If you use the <code>proximity</code> method to compute a proximity matrix, supplying it as input to <code>outlierMeasure</code> reduces computing time.
<code>'labels'</code>	Vector of true class labels. True class labels can be either a numeric vector, character matrix, or cell array of strings. When you supply this parameter, the method performs the outlier calculation for any

observations using only other observations from the same class. This parameter must specify one label for each observation (row) in X .

See Also

proximity

OutlierMeasure property

Class: TreeBagger

Measure for determining outliers

Description

The `OutlierMeasure` property is a numeric array of size `Nobs-by-1`, where `Nobs` is the number of observations in the training data, containing outlier measures for each observation.

See Also

`CompactTreeBagger.outlierMeasure`

parallelcoords

Parallel coordinates plot

Syntax

```
parallelcoords(X)
parallelcoords(X,...,'Standardize','on')
parallelcoords(X,...,'Standardize','PCA')
parallelcoords(X,...,'Standardize','PCAStd')
parallelcoords(X,...,'Quantile',alpha)
parallelcoords(X,...,'Group',group)
parallelcoords(X,...,'Labels',labels)
parallelcoords(X,...,PropertyName,PropertyValue,...)
h = parallelcoords(X,...)
parallelcoords(axes,...)
```

Description

`parallelcoords(X)` creates a parallel coordinates plot of the multivariate data in the n -by- p matrix X . Rows of X correspond to observations, columns to variables. A parallel coordinates plot is a tool for visualizing high dimensional data, where each observation is represented by the sequence of its coordinate values plotted against their coordinate indices. `parallelcoords` treats NaNs in X as missing values and does not plot those coordinate values.

`parallelcoords(X,...,'Standardize','on')` scales each column of X to have mean 0 and standard deviation 1 before making the plot.

`parallelcoords(X,...,'Standardize','PCA')` creates a parallel coordinates plot from the principal component scores of X , in order of decreasing eigenvalues. `parallelcoords` removes rows of X containing missing values (NaNs) for principal components analysis (PCA) standardization.

`parallelcoords(X,...,'Standardize','PCAStd')` creates a parallel coordinates plot using the standardized principal component scores.

`parallelcoords(X, ..., 'Quantile', alpha)` plots only the median and the α and $1 - \alpha$ quantiles of $f(t)$ at each value of t . This is useful if X contains many observations.

`parallelcoords(X, ..., 'Group', group)` plots the data in different groups with different colors. Groups are defined by `group`, a numeric array containing a group index for each observation. `group` can also be a categorical variable, character matrix, or cell array of strings, containing a group name for each observation.

`parallelcoords(X, ..., 'Labels', labels)` labels the coordinate tick marks along the horizontal axis using `labels`, a character array or cell array of strings.

`parallelcoords(X, ..., PropertyName, PropertyValue, ...)` sets properties to the specified property values for all line graphics objects created by `parallelcoords`.

`h = parallelcoords(X, ...)` returns a column vector of handles to the line objects created by `parallelcoords`, one handle per row of X . If you use the 'Quantile' input argument, `h` contains one handle for each of the three lines objects created. If you use both the 'Quantile' and the 'Group' input arguments, `h` contains three handles for each group.

`parallelcoords(axes, ...)` plots into the axes with handle `axes`.

Examples

```
% Make a grouped plot of the raw data
load fisheriris
labels = {'Sepal Length', 'Sepal Width', ...
         'Petal Length', 'Petal Width'};
parallelcoords(meas, 'group', species, 'labels', labels);

% Plot only the median and quartiles of each group
parallelcoords(meas, 'group', species, 'labels', labels, ...
              'quantile', .25);
```

paramci

Class: ProbDistUnivParam

Return parameter confidence intervals of ProbDistUnivParam object

Syntax

```
CI = paramci(PD)
CI = paramci(PD, Alpha)
```

Description

`CI = paramci(PD)` returns `CI`, a 2-by-`N` array containing 95% confidence intervals for the parameters of the ProbDistUnivParam object `PD`. `N` is the number of parameters in the distribution. When you create `PD` by specifying parameters (such as using the ProbDistUnivParam constructor or using the `fitdist` function and specifying a 'binomial' or 'generalized pareto' distribution) rather than by fitting to data, the confidence intervals have a width of 0 because the parameters are viewed as estimates of an unknown parameter.

`CI = paramci(PD, Alpha)` returns $100 \cdot (1 - \text{Alpha})\%$ confidence intervals. Default Alpha is 0.05, which specifies 95% confidence intervals.

Note: If you create `PD` with a distribution that does not support confidence intervals, then `CI` contains NaN values.

Input Arguments

PD	An object of the class ProbDistUnivParam.
Alpha	A value between 0 and 1 that specifies a confidence interval. Default is 0.05, which specifies 95% confidence intervals.

Output Arguments

CI A 2-by-N array containing $100 \cdot (1 - \text{Alpha})\%$ confidence intervals for the parameters of the `ProbDistUnivParam` object PD. N is the number of parameters in the distribution.

See Also

`fitdist`

paramci

Class: prob.ToolboxFittableParametricDistribution

Package: prob

Confidence intervals for probability distribution parameters

Syntax

```
ci = paramci(pd)
ci = paramci(pd,Name,Value)
```

Description

`ci = paramci(pd)` returns the array `ci` containing the lower and upper boundaries of the 95% confidence interval for each parameter in probability distribution `pd`.

`ci = paramci(pd,Name,Value)` returns confidence intervals with additional options specified by one or more name-value pair arguments. For example, you can specify a different percentage for the confidence interval, or compute confidence intervals only for selected parameters.

Input Arguments

pd — Probability distribution

probability distribution object

Probability distribution, specified as a probability distribution object. Create a probability distribution object with specified parameter values using `makedist`. Alternatively, create a probability distribution object by fitting it to data using `fitdist` or the Distribution Fitting app.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single

quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `'Alpha', 0.01` specifies a 99% confidence interval.

'Alpha' — Alpha level

`0.05` (default) | scalar value in the range (0,1)

Alpha level for the confidence interval, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the range (0,1). The default value `0.05` corresponds to a 95% confidence interval.

Example: `'Alpha', 0.01`

Data Types: `single` | `double`

'Parameter' — Parameter list

`vector` | `cell array of strings`

Parameter list for which to compute confidence intervals, specified as the comma-separated pair consisting of `'Parameter'` and a vector or a cell array of strings containing the parameter names. By default, `paramci` computes confidence intervals for all distribution parameters.

Example: `'Parameter', 'mu'`

Data Types: `char`

'Type' — Computation method

`'exact'` | `'Wald'` | `'lr'`

Computation method for the confidence intervals, specified as the comma-separated pair consisting of `'Type'` and `'exact'`, `'Wald'`, or `'lr'`.

`'exact'` computes the confidence intervals using an exact method, and is available for the following distributions.

Binomial	Compute using the Clopper-Pearson method based on exact probability calculations. This method does not provide exact coverage probabilities.
Exponential	Compute using a method based on a chi-square distribution. This method provides exact coverage for complete and Type 2 censored samples.

Normal	Computation method based on t and chi-square distributions for uncensored samples provides exact coverage for uncensored samples. For censored samples, <code>paramci</code> uses the Wald method if <code>Type</code> is <code>exact</code> .
Lognormal	Computation method based on t and chi-square distributions for uncensored samples provides exact coverage. For censored samples, <code>paramci</code> uses the Wald method if <code>Type</code> is <code>exact</code> .
Poisson	Computation method based on a chi-square distribution provides exact coverage. For large degrees of freedom, the chi-square is approximated by a normal distribution for numerical efficiency.
Rayleigh	Computation method based on a chi-square distribution provides exact coverage probabilities.

'`exact`' is the default when it is available. Alternatively, you can specify '`Wald`' to compute the confidence intervals using the Wald method, or '`lr`' to compute the confidence intervals using the likelihood ratio method.

Example: '`Type`', '`Wald`'

'`LogFlag`' — Boolean flag for log scale

vector

Boolean flag for the log scale, specified as the comma-separated pair consisting of '`LogFlag`' and a vector containing Boolean values corresponding to each distribution parameter. The flag specifies which Wald intervals to compute on a log scale. The default values depend on the distribution.

Example: '`LogFlag`', `[0,1]`

Data Types: `logical`

Output Arguments

`ci` — Confidence interval

array

Confidence interval, returned as a p -by-2 array containing the lower and upper bounds of the $(1 - \text{Alpha})\%$ confidence interval for each distribution parameter. p is the number of distribution parameters.

Examples

Parameter Confidence Intervals

Load the sample data. Create a vector containing the first column of students' exam grade data.

```
load examgrades;  
x = grades(:,1);
```

Fit a normal distribution object to the data.

```
pd = fitdist(x, 'Normal')  
  
pd =  
  
NormalDistribution  
  
Normal distribution  
mu = 75.0083 [73.4321, 76.5846]  
sigma = 8.7202 [7.7391, 9.98843]
```

Compute the 95% confidence interval for the distribution parameters.

```
ci = paramci(pd)  
  
ci =  
  
73.4321 7.7391  
76.5846 9.9884
```

Column 1 of `ci` contains the lower and upper 95% confidence interval boundaries for the μ parameter, and column 2 contains the boundaries for the σ parameter.

Change Parameter Confidence Intervals

Load the sample data. Create a vector containing the first column of students' exam grade data.

```
load examgrades;  
x = grades(:,1);
```

Fit a normal distribution object to the data.

```
pd = fitdist(x, 'Normal')
```

```
pd =  
  
NormalDistribution  
  
Normal distribution  
    mu = 75.0083    [73.4321, 76.5846]  
    sigma = 8.7202    [7.7391, 9.98843]
```

Compute the 99% confidence interval for the distribution parameters.

```
ci = paramci(pd, 'Alpha', .01)
```

```
ci =  
  
    72.9245    7.4627  
    77.0922    10.4403
```

Column 1 of `ci` contains the lower and upper 99% confidence interval boundaries for the mu parameter, and column 2 contains the boundaries for the sigma parameter.

ParamCov property

Class: ProbDistParametric

Read-only covariance matrix of parameter estimates of ProbDistParametric object

Description

ParamCov is a read-only property of the ProbDistParametric class. ParamCov is a covariance matrix containing the parameter estimates of a distribution represented by a ProbDistParametric object. ParamCov has a size of NumParams-by-NumParams.

Values

This covariance matrix includes estimates for both the specified parameters and parameters that are fit to the data. For specified parameters, the covariance is 0, indicating the parameter is known exactly. Use this information to view and compare the descriptions of parameters supplied to create distributions.

ParamDescription property

Class: ProbDistParametric

Read-only cell array specifying descriptions of parameters of ProbDistParametric object

Description

ParamDescription is a read-only property of the ProbDistParametric class. ParamDescription is a cell array of strings specifying the descriptions or meanings of the parameters of a distribution represented by a ProbDistParametric object. ParamDescription has a length of NumParams.

Values

This cell array includes a brief description of the meaning of both the specified parameters and parameters that are fit to the data. The description is the same as the parameter name when no further description information is available. Use this information to view and compare the descriptions of parameters used to create distributions.

ParamIsFixed property

Class: ProbDistParametric

Read-only logical array specifying fixed parameters of ProbDistParametric object

Description

ParamIsFixed is a read-only property of the ProbDistParametric class.

ParamIsFixed is a logical array specifying the fixed parameters of a distribution represented by a ProbDistParametric object. ParamIsFixed has a length of NumParams.

Values

This array specifies a 1 (**true**) for fixed parameters, and a 0 (**false**) for parameters that are estimated from the input data. Use this information to view and compare the fixed parameters used to create distributions.

ParamNames property

Class: ProbDistParametric

Read-only cell array specifying names of parameters of ProbDistParametric object

Description

ParamNames is a read-only property of the ProbDistParametric class. ParamNames is a cell array of strings specifying the names of the parameters of a distribution represented by a ProbDistParametric object. ParamNames has a length of NumParams.

Values

This cell array includes the names of both the specified parameters and parameters that are fit to the data. Use this information to view and compare the names of parameters used to create distributions.

Params property

Class: NaiveBayes

Parameter estimates

Description

The `Params` property is an `NClasses`-by-`NDims` cell array containing the parameter estimates, excluding the class priors. `Params(i, j)` contains the parameter estimates for the `j`th feature in the `i`th class. `Params(i, j)` is an empty cell if the `i`th class is empty.

The entry in `Params(i, j)` depends on the distribution type used for the `j`th feature, as follows:

'normal'	A vector of length two. The first element is the mean, and the second element is standard deviation.
'kernel'	A <code>ProbDistUnivKernel</code> object
'mvmn'	A vector containing the probability for each possible value of the <code>j</code> th feature in the <code>i</code> th class. The order of the probabilities is decided by the sorted order of all the unique values of the <code>j</code> th feature.
'mn'	A scalar representing the probability the <code>j</code> th token appearing in the <code>i</code> th class, <code>Prob(token j class i)</code> . It is estimated as $(1 + \text{the number of occurrence of token } J \text{ in class } I) / (\text{NDims} + \text{the total number of token occurrence in class } I)$.

Params property

Class: ProbDistParametric

Read-only array specifying values of parameters of ProbDistParametric object

Description

Params is a read-only property of the ProbDistParametric class. Params is an array of values specifying the values of the parameters of a distribution represented by a ProbDistParametric object. Params has a length of NumParams.

Values

This array includes the values of both the specified parameters and parameters that are fit to the data. Use this information to view and compare the values of parameters used to create distributions.

prob.ParametricTruncatableDistribution class

Package: prob

Superclasses: prob.TruncatableDistribution

Parametric truncatable probability distribution object

Description

Create a probability distribution object with specified parameter values using `makedist`.

Methods

<code>mean</code>	Mean of probability distribution object
<code>std</code>	Standard deviation of probability distribution object
<code>var</code>	Variance of probability distribution object

Inherited Methods

<code>cdf</code>	Cumulative distribution function of probability distribution object
<code>icdf</code>	Inverse cumulative distribution function of probability distribution object
<code>iqr</code>	Interquartile range of probability distribution object
<code>median</code>	Median of probability distribution object

pdf

Probability density function of probability distribution object

random

Generate random numbers from probability distribution object

truncate

Truncate probability distribution object

parent

Class: classregtree

Parent node

Syntax

```
p = parent(t)
p = parent(t,nodes)
```

Description

`p = parent(t)` returns an n -element vector **p** containing the number of the parent node for each node in the tree **t**, where n is the number of nodes. The parent of the root node is 0.

`p = parent(t,nodes)` takes a vector **nodes** of node numbers and returns the parent nodes for the specified nodes.

Examples

Create a classification tree for Fisher's iris data:

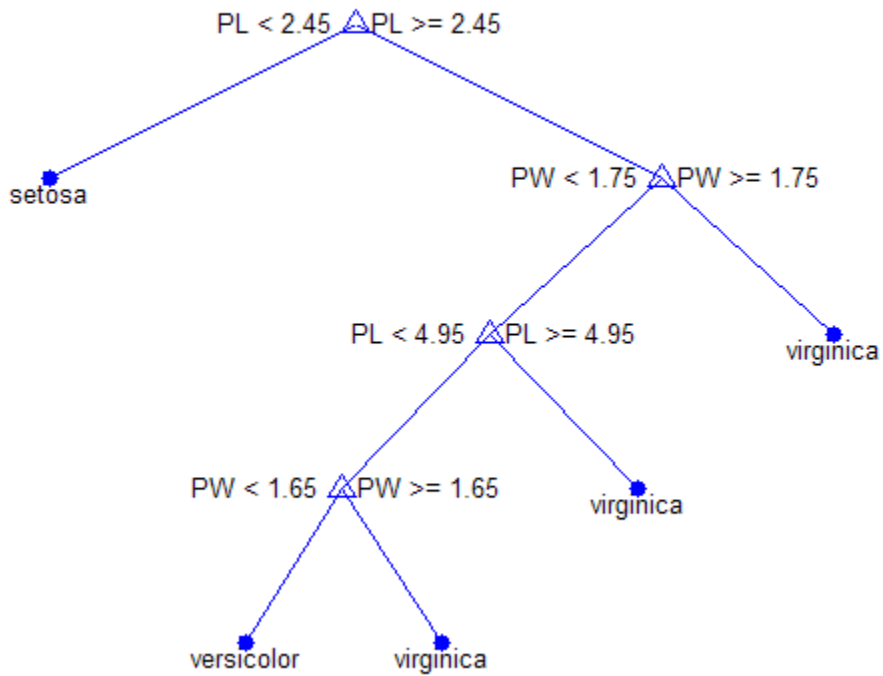

```
load fisheriris;

t = classregtree(meas,species,...
                'names',{'SL' 'SW' 'PL' 'PW'})
t =
Decision tree for classification
1  if PL<2.45 then node 2 else node 3
2  class = setosa
3  if PW<1.75 then node 4 else node 5
4  if PL<4.95 then node 6 else node 7
5  class = virginica
6  if PW<1.65 then node 8 else node 9
7  class = virginica
8  class = versicolor
```

```
9 class = virginica
```

```
view(t)
```

paretotails class

Superclasses: `piecewisedistribution`

Empirical distributions with Pareto tails

Construction

<code>.paretotails</code>	Construct Pareto tails object
---------------------------	-------------------------------

Methods

<code>lowerparams</code>	Lower Pareto tails parameters
<code>upperparams</code>	Upper Pareto tails parameters

Inherited Methods

Methods in the following table are inherited from `piecewisedistribution`.

<code>boundary</code>	Piecewise distribution boundaries
<code>cdf</code>	Cumulative distribution function for piecewise distribution
<code>disp</code>	Display <code>piecewisedistribution</code> object
<code>display</code>	Display <code>piecewisedistribution</code> object
<code>icdf</code>	Inverse cumulative distribution function for piecewise distribution

nsegments	Number of segments
pdf	Probability density function for piecewise distribution
random	Random numbers from piecewise distribution
segment	Segments containing values

Properties

Objects of the `paretotails` class have no properties accessible by dot indexing, `get` methods, or `set` methods. To obtain information about a `paretotails` object, use the appropriate method.

Copy Semantics

Value. To learn how this affects your use of the class, see “Comparing Handle and Value Classes” in the MATLAB Object-Oriented Programming documentation.

How To

- “Generalized Pareto Distribution”

paretotails

Class: paretotails

Construct Pareto tails object

Syntax

```
obj = paretotails(x,pl,pu)
obj = paretotails(x,pl,pu,cdffun)
```

Description

`obj = paretotails(x,pl,pu)` creates an object `obj` defining a distribution consisting of the empirical distribution of `x` in the center and Pareto distributions in the tails. `x` is a real-valued vector of data values whose extreme observations are fit to generalized Pareto distributions (GPDs). `pl` and `pu` identify the lower- and upper-tail cumulative probabilities such that $100 \cdot pl$ and $100 \cdot (1 - pu)$ percent of the observations in `x` are, respectively, fit to a GPD by maximum likelihood. If `pl` is 0, or if there are not at least two distinct observations in the lower tail, then no lower Pareto tail is fit. If `pu` is 1, or if there are not at least two distinct observations in the upper tail, then no upper Pareto tail is fit.

`obj = paretotails(x,pl,pu,cdffun)` uses `cdffun` to estimate the cdf of `x` between the lower and upper tail probabilities. `cdffun` may be any of the following:

- `'ecdf'` — Uses an interpolated empirical cdf, with data values as the midpoints in the vertical steps in the empirical cdf, and computed by linear interpolation between data values. This is the default.
- `'kernel'` — Uses a kernel-smoothing estimate of the cdf.
- `@fun` — Uses a handle to a function of the form `[p,xi] = fun(x)` that accepts the input data vector `x` and returns a vector `p` of cdf values and a vector `xi` of evaluation points. Values in `xi` must be sorted and distinct but need not equal the values in `x`.

`cdffun` is used to compute the quantiles corresponding to `pl` and `pu` by inverse interpolation, and to define the fitted distribution between these quantiles.

The output object `obj` is a Pareto tails object with methods to evaluate the cdf, inverse cdf, and other functions of the fitted distribution. These methods are well-suited to copula and other Monte Carlo simulations. The pdf method in the tails is the GPD density, but in the center it is computed as the slope of the interpolated cdf.

The `paretotails` class is a subclass of the `piecewisedistribution` class, and many of its methods are derived from that class.

Examples

Fit Pareto Tails to a Probability Distribution

Generate sample data containing 100 random numbers from a t distribution with 3 degrees of freedom.

```
rng default; % For reproducibility
t = trnd(3,100,1);
```

Fit pareto tails to the distribution at cumulative probabilities 0.1 and 0.9.

```
obj = paretotails(t,0.1,0.9);
[p,q] = boundary(obj);
```

Plot the cdf of the Pareto tails and the cdf of the fitted t distribution on the same figure.

```
x = linspace(-5,5);
plot(x,cdf(obj,x),'b-','LineWidth',2)
hold on;
plot(x,tcdf(x,3),'r:','LineWidth',2)
plot(q,p,'bo','LineWidth',2,'MarkerSize',5)
legend('Pareto Tails Object','t Distribution',...
       'Location','NW')
hold off;
```

Syntax

```
rho = partialcorr(x)
rho = partialcorr(x,z)
rho = partialcorr(x,y,z)
rho = partialcorr( ____,Name,Value)
[rho,pval] = partialcorr( ____ )
```

Description

`rho = partialcorr(x)` returns the sample linear partial correlation coefficients between pairs of variables in `x`, controlling for the remaining variables in `x`.

`rho = partialcorr(x,z)` returns the sample linear partial correlation coefficients between pairs of variables in `x`, controlling for the variables in `z`.

`rho = partialcorr(x,y,z)` returns the sample linear partial correlation coefficients between pairs of variables in `x` and `y`, controlling for the variables in `z`.

`rho = partialcorr(____,Name,Value)` returns the sample linear partial correlation coefficients with additional options specified by one or more name-value pair arguments, using input arguments from any of the previous syntaxes. For example, you can specify whether to use Pearson or Spearman partial correlations, or specify how to treat missing values.

`[rho,pval] = partialcorr(____)` also returns a matrix `pval` of p -values for testing the hypothesis of no partial correlation against the one- or two-sided alternative that there is a nonzero partial correlation.

Examples

Compute Partial Correlation Coefficients

Compute partial correlation coefficients between pairs of variables in the input matrix.

Load the sample data. Convert the strings in `hospital.Sex` to numeric group identifiers.

```
load hospital;
hospital.SexID = grp2idx(hospital.Sex);
```

Create an input matrix containing the sample data.

```
x = [hospital.SexID hospital.Age hospital.Smoker hospital.Weight];
```

Each row in `x` contains a patient's gender, age, smoking status, and weight.

Compute partial correlation coefficients between pairs of variables in `x`, while controlling for the effects of the remaining variables in `x`.

```
rho = partialcorr(x)
```

```
rho =
```

```
    1.0000   -0.0105    0.0273    0.9421
   -0.0105    1.0000    0.0419    0.0369
    0.0273    0.0419    1.0000    0.0451
    0.9421    0.0369    0.0451    1.0000
```

The matrix `rho` indicates, for example, a correlation of 0.9421 between gender and weight after controlling for all other variables in `x`. You can return the p -values as a second output, and examine them to confirm whether these correlations are statistically significant.

For a clearer display, create a table with appropriate variable and row labels.

```
rho = array2table(rho, ...
    'VariableNames', {'SexID', 'Age', 'Smoker', 'Weight'}, ...
    'RowNames', {'SexID', 'Age', 'Smoker', 'Weight'});
```

```
disp('Partial Correlation Coefficients')
disp(rho)
```

```
Partial Correlation Coefficients
```

	SexID	Age	Smoker	Weight
SexID	1	-0.01052	0.027324	0.9421
Age	-0.01052	1	0.041945	0.036873
Smoker	0.027324	0.041945	1	0.045106

```
Weight      0.9421    0.036873    0.045106      1
```

Test for Partial Correlations with Controlled Variables

Test for partial correlation between pairs of variables in the input matrix, while controlling for the effects of a second set of variables.

Load the sample data. Convert the strings in `hospital.Sex` to numeric group identifiers.

```
load hospital;
hospital.SexID = grp2idx(hospital.Sex);
```

Create two matrices containing the sample data.

```
x = [hospital.Age hospital.BloodPressure];
z = [hospital.SexID hospital.Smoker hospital.Weight];
```

The `x` matrix contains the variables to test for partial correlation. The `z` matrix contains the variables to control for. The measurements for `BloodPressure` are contained in two columns: The first column contains the upper (systolic) number, and the second column contains the lower (diastolic) number. `partialcorr` treats each column as a separate variable.

Test for partial correlation between pairs of variables in `x`, while controlling for the effects of the variables in `z`. Compute the correlation coefficients.

```
[rho,pval] = partialcorr(x,z)
```

```
rho =
```

```
    1.0000    0.1300    0.0462
    0.1300    1.0000    0.0012
    0.0462    0.0012    1.0000
```

```
pval =
```

```
         0    0.2044    0.6532
    0.2044         0    0.9903
    0.6532    0.9903         0
```

The large values in `pval` indicate that there is no significant correlation between age and either blood pressure measurement after controlling for gender, smoking status, and weight.

For a clearer display, create tables with appropriate variable and row labels.

```
rho = array2table(rho, ...
    'VariableNames', {'Age', 'BPTop', 'BPBottom'}, ...
    'RowNames', {'SexID', 'Smoker', 'Weight'});

pval = array2table(pval, ...
    'VariableNames', {'Age', 'BPTop', 'BPBottom'}, ...
    'RowNames', {'SexID', 'Smoker', 'Weight'});

disp('Partial Correlation Coefficients')
disp(rho)
disp('p-values')
disp(pval)
```

```
Partial Correlation Coefficients
```

	Age	BPTop	BPBottom
SexID	1	0.13	0.046202
Smoker	0.13	1	0.0012475
Weight	0.046202	0.0012475	1

```
p-values
```

	Age	BPTop	BPBottom
SexID	0	0.20438	0.65316
Smoker	0.20438	0	0.99032
Weight	0.65316	0.99032	0

Test for Paired Partial Correlation Coefficients

Test for partial correlation between pairs of variables in the *x* and *y* input matrices, while controlling for the effects of a third set of variables.

Load the sample data. Convert the strings in `hospital.Sex` to numeric group identifiers.

```
load hospital;
hospital.SexID = grp2idx(hospital.Sex);
```

Create three matrices containing the sample data.

```
x = [hospital.BloodPressure];
y = [hospital.Weight hospital.Age];
z = [hospital.SexID hospital.Smoker];
```

`partialcorr` can test for partial correlation between the pairs of variables in `x` (the systolic and diastolic blood pressure measurements) and `y` (weight and age), while controlling for the variables in `z` (gender and smoking status). The measurements for `BloodPressure` are contained in two columns: The first column contains the upper (systolic) number, and the second column contains the lower (diastolic) number. `partialcorr` treats each column as a separate variable.

Test for partial correlation between pairs of variables in `x` and `y`, while controlling for the effects of the variables in `z`. Compute the correlation coefficients.

```
[rho,pval] = partialcorr(x,y,z)
```

```
rho =
```

```
   -0.0257    0.1289  
    0.0292    0.0472
```

```
pval =
```

```
   0.8018    0.2058  
   0.7756    0.6442
```

The results in `pval` indicate that, after controlling for gender and smoking status, there is no significant correlation between either of a patient's blood pressure measurements and that patient's weight or age.

For a clearer display, create tables with appropriate variable and row labels.

```
rho = array2table(rho, ...  
    'VariableNames', {'BPTop', 'BPBottom'}, ...  
    'RowNames', {'Weight', 'Age'});
```

```
pval = array2table(pval, ...  
    'VariableNames', {'BPTop', 'BPBottom'}, ...  
    'RowNames', {'Weight', 'Age'});
```

```
disp('Partial Correlation Coefficients')  
disp(rho)  
disp('p-values')  
disp(pval)
```

```
Partial Correlation Coefficients  
                BPTop    BPBottom
```

```

          -----
Weight    -0.02568    0.12893
Age       0.029168    0.047226

p-values
          BPTop    BPBottom
          -----
Weight    0.80182    0.2058
Age       0.77556    0.64424

```

One-Tailed Partial Correlation Test

Test the hypothesis that pairs of variables have no correlation, against the alternative hypothesis that the correlation is greater than 0.

Load the sample data. Convert the strings in `hospital.Sex` to numeric group identifiers.

```
load hospital;
hospital.SexID = grp2idx(hospital.Sex);
```

Create three matrices containing the sample data.

```
x = [hospital.BloodPressure];
y = [hospital.Weight hospital.Age];
z = [hospital.SexID hospital.Smoker];
```

`partialcorr` can test for partial correlation between the pairs of variables in `x` (the systolic and diastolic blood pressure measurements) and `y` (weight and age), while controlling for the variables in `z` (gender and smoking status). The measurements for `BloodPressure` are contained in two columns: The first column contains the upper (systolic) number, and the second column contains the lower (diastolic) number. `partialcorr` treats each column as a separate variable.

Compute the correlation coefficients using a right-tailed test.

```
[rho,pval] = partialcorr(x,y,z, 'Tail', 'right')
```

```
rho =
```

```

-0.0257    0.1289
 0.0292    0.0472

```

```
pval =  
  
    0.5991    0.1029  
    0.3878    0.3221
```

The results in `pval` indicate that `partialcorr` does not reject the null hypothesis of nonzero correlations between the variables in `x` and `y`, after controlling for the variables in `z`, when the alternative hypothesis is that the correlations are greater than 0.

For a clearer display, create tables with appropriate variable and row labels.

```
rho = array2table(rho, ...  
    'VariableNames', {'BPTop', 'BPBottom'}, ...  
    'RowNames', {'Weight', 'Age'});  
  
pval = array2table(pval, ...  
    'VariableNames', {'BPTop', 'BPBottom'}, ...  
    'RowNames', {'Weight', 'Age'});  
  
disp('Partial Correlation Coefficients')  
disp(rho)  
disp('p-values')  
disp(pval)
```

```
Partial Correlation Coefficients  
  
      BPSys      BPDia  
Weight -0.02568    0.12893  
Age     0.029168   0.047226
```

```
p-values  
  
      BPSys      BPDia  
Weight 0.59909    0.1029  
Age     0.38778   0.32212
```

Input Arguments

x — Data matrix

matrix

Data matrix, specified as an n -by- p_x matrix. The rows of `x` correspond to observations, and the columns correspond to variables.

Data Types: `single` | `double`

y — Data matrix

matrix

Data matrix, specified as an n -by- p_y matrix. The rows of **y** correspond to observations, and the columns correspond to variables.

Data Types: single | double

z — Data matrix

matrix

Data matrix, specified as an n -by- p_z matrix. The rows of **z** correspond to observations, and columns correspond to variables.

Data Types: single | double

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example: 'Type', 'Spearman', 'Rows', 'complete' computes Spearman partial correlations using only the data in rows that contain no missing values.

'Type' — Type of partial correlations

'Pearson' (default) | 'Spearman'

Type of partial correlations to compute, specified as the comma-separated pair consisting of 'Type' and one of the following.

'Pearson'	Compute Pearson (linear) partial correlations.
'Spearman'	Compute Spearman (rank) partial correlations.

Example: 'Type', 'Spearman'

'Rows' — Rows to use in computation

'all' (default) | 'complete' | 'pairwise'

Rows to use in computation, specified as the comma-separated pair consisting of 'Rows' and one of the following.

'all'	Use all rows regardless of missing (NaN) values.
'complete'	Use only rows with no missing values.
'pairwise'	Compute $\text{rho}(i, j)$ using rows with no missing values in column i or j .

Using 'pairwise' can produce a rho that is not positive definite. 'complete' always produces a positive definite rho, but when data is missing, the estimates are generally based on fewer observations.

Example: 'Rows', 'complete'

'Tail' — Alternative hypothesis

'both' (default) | 'right' | 'left'

Alternative hypothesis to test against, specified as the comma-separated pair consisting of 'Tail' and one of the following.

'both'	Test the alternative hypothesis that the correlation is not 0.
'right'	Test the alternative hypothesis that the correlation is greater than 0.
'left'	Test the alternative hypothesis that the correlation is less than 0.

Example: 'Tail', 'right'

Output Arguments

rho — Sample linear partial correlation coefficients

matrix

Sample linear partial correlation coefficients, returned as a matrix.

- If you input only an x matrix, rho is a symmetric p_x -by- p_x matrix. The (i,j) th entry is the sample linear partial correlation between the i -th and j -th columns in x .

- If you input x and z matrices, `rho` is a symmetric p_x -by- p_x matrix. The (i,j) th entry is the sample linear partial correlation between the i th and j th columns in x , controlled for the variables in z .
- If you input x , y , and z matrices, `rho` is a p_x -by- p_y matrix, where the (i,j) th entry is the sample linear partial correlation between the i th column in x and the j th column in y , controlled for the variables in z .

If the covariance matrix of $[x, z]$ is

$$S = \begin{pmatrix} S_{xx} & S_{xz} \\ S_{xz}^T & S_{zz} \end{pmatrix},$$

then the partial correlation matrix of x , controlling for z , can be defined formally as a normalized version of the covariance matrix $S_{xy} = S_{xx} - (S_{xz}S_{zz}^{-1}S_{xz}^T)$

pval — **p-values**

matrix

p -values, returned as a matrix. Each element of `pval` is the p -value for the corresponding element of `rho`.

If `pval(i, j)` is small, then the corresponding partial correlation `rho(i, j)` is statistically significantly different from 0.

`partialcorr` computes p -values for linear and rank partial correlations using a Student's t distribution for a transformation of the correlation. This is exact for linear partial correlation when x and z are normal, but is a large-sample approximation otherwise.

See Also

`corr` | `corrcoef` | `partialcorri` | `tiedrank`

partialcorri

Partial correlation coefficients adjusted for internal variables

Syntax

```
rho = partialcorri(y,x)
rho = partialcorri(y,x,z)
rho = partialcorri( ____,Name,Value)
[rho,pval] = partialcorri( ____,Name,Value)
```

Description

`rho = partialcorri(y,x)` returns the sample linear partial correlation coefficients between pairs of variables in `y` and `x`, adjusting for the remaining variables in `x`.

`rho = partialcorri(y,x,z)` returns the sample linear partial correlation coefficients between pairs of variables in `y` and `x`, adjusting for the remaining variables in `x`, after first controlling both `x` and `y` for the variables in `z`.

`rho = partialcorri(____,Name,Value)` returns the sample linear partial correlation coefficients with additional options specified by one or more name-value pair arguments, using input arguments from any of the previous syntaxes. For example, you can specify whether to use Pearson or Spearman partial correlations, or specify how to treat missing values.

`[rho,pval] = partialcorri(____,Name,Value)` also returns a matrix `pval` of p -values for testing the hypothesis of no partial correlation against the one- or two-sided alternative that there is a nonzero partial correlation.

Examples

Compute Partial Correlation Coefficients

Compute partial correlation coefficients for each pair of variables in the `x` and `y` input matrices, while controlling for the effects of the remaining variables in `x`.

Load the sample data.

```
load carsmall;
```

The data contains measurements from cars manufactured in 1970, 1976, and 1982. It includes `MPG` and `Acceleration` as performance measures, and `Displacement`, `Horsepower`, and `Weight` as design variables. `Acceleration` is the time required to accelerate from 0 to 60 miles per hour, so a high value for `Acceleration` corresponds to a vehicle with low acceleration.

Define the input matrices. The `y` matrix includes the performance measures, and the `x` matrix includes the design variables.

```
y = [MPG,Acceleration];
x = [Displacement,Horsepower,Weight];
```

Compute the correlation coefficients. Include only rows with no missing values in the computation.

```
rho = partialcorri(y,x,'Rows','complete')
```

```
rho =
    -0.0537    -0.1520    -0.4856
    -0.3994    -0.4008     0.4912
```

The results suggest, for example, a 0.4912 correlation between weight and acceleration after controlling for the effects of displacement and horsepower. You can return the p -values as a second output, and examine them to confirm whether these correlations are statistically significant.

For a clearer display, create a table with appropriate variable and row labels.

```
rho = array2table(rho, ...
    'VariableNames',{'Displacement','Horsepower','Weight'}, ...
    'RowNames',{'MPG','Acceleration'});
```

```
disp('Partial Correlation Coefficients')
disp(rho)
```

```
Partial Correlation Coefficients
                Displacement    Horsepower    Weight
-----
MPG                -0.053684    -0.15199    -0.48563
```

```
Acceleration    -0.39941    -0.40075    0.49123
```

Test Partial Correlations While Controlling for Additional Variables

Test for partial correlation between pairs of variables in the x and y input matrices, while controlling for the effects of the remaining variables in x plus additional variables in matrix z .

Load the sample data.

```
load carsmall;
```

The data contains measurements from cars manufactured in 1970, 1976, and 1982. It includes `MPG` and `Acceleration` as performance measures, and `Displacement`, `Horsepower`, and `Weight` as design variables. `Acceleration` is the time required to accelerate from 0 to 60 miles per hour, so a high value for `Acceleration` corresponds to a vehicle with low acceleration.

Create a new variable `Headwind`, and randomly generate data to represent the notion of an average headwind along the performance measurement route.

```
rng('default'); % For reproducibility
Headwind = (10:-0.2:-9.8)' + 5*randn(100,1);
```

Since headwind can affect the performance measures, control for its effects when testing for partial correlation between the remaining variables.

Define the input matrices. The y matrix includes the performance measures, and the x matrix includes the design variables. The z matrix contains additional variables to control for when computing the partial correlations, such as headwind.

```
y = [MPG,Acceleration];
x = [Displacement,Horsepower,Weight];
z = Headwind;
```

Compute the partial correlation coefficients. Include only rows with no missing values in the computation.

```
[rho,pval] = partialcorri(y,x,z, 'Rows', 'complete')

rho =

    0.0572    -0.1055   -0.5736
   -0.3845   -0.3966    0.4674
```

```
pval =
    0.5923    0.3221    0.0000
    0.0002    0.0001    0.0000
```

The small returned p -value of 0.001 in `pval` indicates, for example, a significant negative correlation between horsepower and acceleration, after controlling for displacement, weight, and headwind.

For a clearer display, create tables with appropriate variable and row labels.

```
rho = array2table(rho, ...
    'VariableNames', {'Displacement', 'Horsepower', 'Weight'}, ...
    'RowNames', {'MPG', 'Acceleration'});

pval = array2table(pval, ...
    'VariableNames', {'Displacement', 'Horsepower', 'Weight'}, ...
    'RowNames', {'MPG', 'Acceleration'});

disp('Partial Correlation Coefficients, Accounting for Headwind')
disp(rho)
disp('p-values, Accounting for Headwind')
disp(pval)
```

```
Partial Correlation Coefficients, Accounting for Headwind
                Displacement    Horsepower    Weight
-----
MPG              0.057197        -0.10555    -0.57358
Acceleration     -0.38452         -0.39658     0.4674

P-values, Accounting for Headwind
                Displacement    Horsepower    Weight
-----
MPG              0.59233         0.32212    3.4401e-09
Acceleration     0.00018272         0.00010902  3.4091e-06
```

Input Arguments

x — Data matrix

matrix

Data matrix, specified as an n -by- p_x matrix. The rows of `x` correspond to observations, and the columns correspond to variables.

Data Types: `single` | `double`

y — **Data matrix**
matrix

Data matrix, specified as an n -by- p_y matrix. The rows of **y** correspond to observations, and the columns correspond to variables.

Data Types: `single` | `double`

z — **Data matrix**
matrix

Data matrix, specified as an n -by- p_z matrix. The rows of **z** correspond to observations, and the columns correspond to variables.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as **Name1**, **Value1**, . . . , **NameN**, **ValueN**.

Example: `'Type', 'Spearman', 'Rows', 'complete'` computes Spearman partial correlations using only the data in rows that contain no missing values.

'Type' — **Type of partial correlations**
'Pearson' (default) | 'Spearman'

Type of partial correlations to compute, specified as the comma-separated pair consisting of **'Type'** and either **'Pearson'** or **'Spearman'**. **Pearson** computes the Pearson (linear) partial correlations. **Spearman** computes the Spearman (rank) partial correlations.

Example: `'Type', 'Spearman'`

'Rows' — **Rows to use in computation**
'all' (default) | 'complete' | 'pairwise'

Rows to use in computation, specified as the comma-separated pair consisting of **'Rows'** and one of the following.

'all'	Use all rows regardless of missing (NaN) values.
'complete'	Use only rows with no missing values.
'pairwise'	Use all available values in each column of y when computing the partial correlation coefficients and p -values corresponding to that column. For each column of y, rows will be dropped corresponding to missing values in x (and/or z, if supplied). However, remaining rows with valid values in that column of y are used, even if there are missing values in other columns of y.

Example: 'Rows', 'complete'

'Tail' — Alternative hypothesis

'both' (default) | 'right' | 'left'

Alternative hypothesis to test against, specified as the comma-separated pair consisting of 'Tail' and one of the following.

'both'	Test the alternative hypothesis that the correlation is not zero.
'right'	Test the alternative hypothesis that the correlation is greater than 0.
'left'	Test the alternative hypothesis that the correlation is less than 0.

Example: 'Tail', 'right'

Output Arguments

rho — Sample linear partial correlation coefficients

matrix

Sample linear partial correlation coefficients, returned as a p_y -by- p_x matrix.

- If you input x and y matrices, the (i,j) th entry is the sample linear partial correlation between the i th column in y and the j th column in x, controlled for all the columns of x except column j .

- If you input x , y , and z matrices, the (i,j) th entry is the sample linear partial correlation between the i th column in y and the j th column in x , adjusted for all the columns of x except column j , after first controlling both x and y for the variables in z .

pval — *p*-values*matrix*

p-values, returned as a matrix. Each element of `pval` is the *p*-value for the corresponding element of `rho`. If `pval(i, j)` is small, then the corresponding partial correlation `rho(i, j)` is statistically significantly different from zero.

`partialcorri` computes *p*-values for linear and rank partial correlations using a Student's *t* distribution for a transformation of the correlation. This is exact for linear partial correlation when x and z are normal, but is a large-sample approximation otherwise.

See Also`corr` | `partialcorr`

pca

Principal component analysis of raw data

Syntax

```
coeff = pca(X)
coeff = pca(X,Name,Value)
[coeff,score,latent] = pca( ___ )
[coeff,score,latent,tsquared] = pca( ___ )
[coeff,score,latent,tsquared,explained,mu] = pca( ___ )
```

Description

`coeff = pca(X)` returns the principal component coefficients for the n -by- p data matrix X . Rows of X correspond to observations and columns correspond to variables. The coefficient matrix is p -by- p . Each column of `coeff` contains coefficients for one principal component, and the columns are in descending order of component variance. By default, `pca` centers the data and uses the singular value decomposition (SVD) algorithm.

`coeff = pca(X,Name,Value)` returns any of the output arguments in the previous syntaxes using additional options for computation and handling of special data types, specified by one or more `Name,Value` pair arguments.

For example, you can specify the number of principal components `pca` returns or an algorithm other than SVD to use.

`[coeff,score,latent] = pca(___)` also returns the principal component scores in `score` and the principal component variances in `latent`. You can use any of the input arguments in the previous syntaxes.

Principal component scores are the representations of X in the principal component space. Rows of `score` correspond to observations, and columns correspond to components.

The principal component variances are the eigenvalues of the covariance matrix of X .

`[coeff,score,latent,tsquared] = pca(___)` also returns the Hotelling's T-squared statistic for each observation in X .

`[coeff, score, latent, tsquared, explained, mu] = pca(___)` also returns `explained`, the percentage of the total variance explained by each principal component and `mu`, the estimated mean of each variable in X .

Examples

Principal Components of a Data Set

Load the sample data set.

```
load hald
```

The ingredients data has 13 observations for 4 variables.

Find the principal components for the ingredients data.

```
coeff = pca(ingredients)
coeff =
    -0.0678    -0.6460     0.5673     0.5062
    -0.6785    -0.0200    -0.5440     0.4933
     0.0290     0.7553     0.4036     0.5156
     0.7309    -0.1085    -0.4684     0.4844
```

The rows of `coeff` contain the coefficients for the four ingredient variables, and its columns correspond to four principal components.

PCA in the Presence of Missing Data

Find the principal component coefficients when there are missing values in a data set.

Load the sample data set.

```
load imports-85
```

Data matrix X has 13 continuous variables in columns 3 to 15: wheel-base, length, width, height, curb-weight, engine-size, bore, stroke, compression-ratio, horsepower, peak-rpm, city-mpg, and highway-mpg. The variables bore and stroke are missing four values in rows 56 to 59, and the variables horsepower and peak-rpm are missing two values in rows 131 and 132.

Perform principal component analysis.

```
coeff = pca(X(:,3:15));
```

By default, `pca` performs the action specified by the `'Rows'`, `'complete'` name-value pair argument. This option removes the observations with NaN values before calculation. Rows of NaNs are reinserted into `score` and `tsquared` at the corresponding locations, namely rows 56 to 59, 131, and 132.

Use `'pairwise'` to perform the principal component analysis.

```
coeff = pca(X(:,3:15), 'Rows', 'pairwise');
```

In this case, `pca` computes the (i,j) element of the covariance matrix using the rows with no NaN values in the columns i or j of X . Note that the resulting covariance matrix might not be positive definite. This option applies when the algorithm `pca` uses is eigenvalue decomposition. When you don't specify the algorithm, as in this example, `pca` sets it to `'eig'`. If you require `'svd'` as the algorithm, with the `'pairwise'` option, then `pca` returns a warning message, sets the algorithm to `'eig'` and continues.

If you use the `'Rows'`, `'all'` name-value pair argument, `pca` terminates because this option assumes there are no missing values in the data set.

```
coeff = pca(X(:,3:15), 'Rows', 'all');
```

```
Error using pca (line 180)
```

```
Raw data contains NaN missing value while 'Rows' option is set to 'all'. Consider using
```

Weighted PCA

Use the inverse variable variances as weights while performing the principal components analysis.

Load the sample data set.

```
load hald
```

Perform the principal component analysis using the inverse of variances of the ingredients as variable weights.

```
[wcoeff,~,latent,~,explained] = pca(ingredients,...
'VariableWeights','variance')
```

```
wcoeff =
```

```

-2.7998    2.9940   -3.9736    1.4180
-8.7743   -6.4411    4.8927    9.9863
```

```
2.5240 -3.8749 -4.0845 1.7196
9.1714 7.5529 3.2710 11.3273
```

```
latent =
```

```

0.0016
```

```
explained =
```

```
55.8926
39.4017
4.6652
0.0406
```

Note that the coefficient matrix, `wcoeff`, is not orthonormal.

Calculate the orthonormal coefficient matrix.

```
coefforth = inv(diag(std(ingredients)))* wcoeff
```

```
coefforth =
```

```
-0.4760 0.5090 -0.6755 0.2411
-0.5639 -0.4139 0.3144 0.6418
0.3941 -0.6050 -0.6377 0.2685
0.5479 0.4512 0.1954 0.6767
```

Check orthonormality of the new coefficient matrix, `coefforth`.

```
coefforth*coefforth'
```

```
ans =
```

```

0.0000 1.0000 -0.0000 -0.0000
-0.0000 -0.0000 1.0000 0
-0.0000 -0.0000 0 1.0000
```

PCA Using ALS for Missing Data

Find the principal components using the alternating least squares (ALS) algorithm when there are missing values in the data.

Load the sample data.

```
load hald
```

The ingredients data has 13 observations for 4 variables.

Perform principal component analysis using the ALS algorithm and display the component coefficients.

```
[coeff,score,latent,tsquared,explained] = pca(ingredients);
coeff
```

```
coeff =
```

```

-0.0678  -0.6460   0.5673   0.5062
-0.6785  -0.0200  -0.5440   0.4933
 0.0290   0.7553   0.4036   0.5156
 0.7309  -0.1085  -0.4684   0.4844
```

Introduce missing values randomly.

```
y = ingredients;
rng('default'); % for reproducibility
ix = random('unif',0,1,size(y))<0.30;
y(ix) = NaN
```

```
y =
```

```

    7    26     6   NaN
    1    29    15    52
   NaN   NaN     8    20
   11    31   NaN   47
    7    52     6    33
   NaN   55   NaN   NaN
   NaN   71   NaN    6
    1    31   NaN   44
    2   NaN   NaN   22
   21    47     4    26
   NaN   40    23    34
   11    66     9   NaN
   10    68     8    12
```

Approximately 30% of the data has missing values now, indicated by NaN.

Perform principal component analysis using the ALS algorithm and display the component coefficients.

```
[coeff1,score1,latent,tsquared,explained,mu1] = pca(y,...  
'algorithm','als');  
coeff1
```

```
coeff1 =  
  
    -0.0362    0.8215   -0.5252    0.2190  
   -0.6831   -0.0998    0.1828    0.6999  
    0.0169    0.5575    0.8215   -0.1185  
    0.7292   -0.0657    0.1261    0.6694
```

Display the estimated mean.

```
mu1  
  
mu1 =  
  
    8.9956    47.9088    9.0451    28.5515
```

Reconstruct the observed data.

```
t = score1*coeff1' + repmat(mu1,13,1)  
  
t =  
  
    7.0000    26.0000    6.0000    51.5250  
    1.0000    29.0000    15.0000    52.0000  
   10.7819    53.0230    8.0000    20.0000  
   11.0000    31.0000    13.5500    47.0000  
    7.0000    52.0000    6.0000    33.0000  
   10.4818    55.0000    7.8328    17.9362  
    3.0982    71.0000    11.9491    6.0000  
    1.0000    31.0000   -0.5161    44.0000  
    2.0000    53.7914    5.7710    22.0000  
   21.0000    47.0000    4.0000    26.0000  
   21.5809    40.0000    23.0000    34.0000  
   11.0000    66.0000    9.0000    5.7078  
   10.0000    68.0000    8.0000    12.0000
```

The ALS algorithm estimates the missing values in the data.

Another way to compare the results is to find the angle between the two spaces spanned by the coefficient vectors. Find the angle between the coefficients found for complete data and data with missing values using ALS.

```
subspace(coeff,coeff1)
```

```
ans =
```

```
2.2925e-16
```

This is a small value. It indicates that the results if you use `pca` with `'Rows', 'complete'` name-value pair argument when there is no missing data and if you use `pca` with `'algorithm', 'als'` name-value pair argument when there is missing data are close to each other.

Perform the principal component analysis using `'Rows', 'complete'` name-value pair argument and display the component coefficients.

```
[coeff2,score2,latent,tsquared,explained,mu2] = pca(y,...
'Rows','complete');
coeff2
```

```
coeff2 =
```

```
-0.2054    0.8587    0.0492
-0.6694   -0.3720    0.5510
 0.1474   -0.3513   -0.5187
 0.6986   -0.0298    0.6518
```

In this case, `pca` removes the rows with missing values, and `y` has only four rows with no missing values. `pca` returns only three principal components. You cannot use the `'Rows', 'pairwise'` option because the covariance matrix is not positive semidefinite and `pca` returns an error message.

Find the angle between the coefficients found for complete data and data with missing values using listwise deletion (when `'Rows', 'complete'`).

```
subspace(coeff(:,1:3),coeff2)
```

```
ans =
```

```
0.3576
```

The angle between the two spaces is substantially larger. This indicates that these two results are different.

Display the estimated mean.

```
mu2
```

```
mu2 =
```

```
7.8889 46.9091 9.8750 29.6000
```

In this case, the mean is just the sample mean of y .

Reconstruct the observed data.

```
score2*coeff2'
```

```
ans =
```

```
      NaN      NaN      NaN      NaN
-7.5162 -18.3545  4.0968 22.0056
      NaN      NaN      NaN      NaN
      NaN      NaN      NaN      NaN
-0.5644  5.3213 -3.3432  3.6040
      NaN      NaN      NaN      NaN
      NaN      NaN      NaN      NaN
      NaN      NaN      NaN      NaN
      NaN      NaN      NaN      NaN
12.8315 -0.1076 -6.3333 -3.7758
      NaN      NaN      NaN      NaN
      NaN      NaN      NaN      NaN
 1.4680 20.6342 -2.9292 -18.0043
```

This shows that deleting rows containing NaN values does not work as well as the ALS algorithm. Using ALS is better when the data has too many missing values.

Principal Component Coefficients, Scores, and Variances

Find the coefficients, scores, and variances of the principal components.

Load the sample data set.

```
load hald
```

The ingredients data has 13 observations for 4 variables.

Find the principal component coefficients, scores, and variances of the components for the ingredients data.

```
[coeff,score,latent] = pca(ingredients)
```

```
coeff =
```

-0.0678	-0.6460	0.5673	0.5062

latent =

517.7969
67.4964
12.4054
0.2372

Each column of **score** corresponds to one principal component. The vector, **latent**, stores the variances of the four principal components.

Reconstruct the centered ingredients data.

Xcentered = score*coeff'

Xcentered =

-0.4615	-22.1538	-5.7692	30.0000
-6.4615	-19.1538	3.2308	22.0000
3.5385	7.8462	-3.7692	-10.0000
3.5385	-17.1538	-3.7692	17.0000
-0.4615	3.8462	-5.7692	3.0000
3.5385	6.8462	-2.7692	-8.0000

```
-4.4615  22.8462   5.2308 -24.0000
-6.4615 -17.1538  10.2308  14.0000
-5.4615   5.8462   6.2308  -8.0000
13.5385  -1.1538  -7.7692  -4.0000
-6.4615  -8.1538  11.2308   4.0000
 3.5385  17.8462  -2.7692 -18.0000
 2.5385  19.8462  -3.7692 -18.0000
```

The new data in `Xcentered` is the original ingredients data centered by subtracting the column means from corresponding columns.

T-Squared Statistic

Find the Hotelling's T-squared statistic values.

Load the sample data set.

```
load hald
```

The ingredients data has 13 observations for 4 variables.

Perform the principal component analysis and request the T-squared values.

```
[coeff,score,latent,tsquared] = pca(ingredients);
tsquared
```

```
tsquared =
    5.6803
    3.0758
    6.0002
    2.6198
    3.3681
    0.5668
    3.4818
    3.9794
    2.6086
    7.4818
    4.1830
    2.2327
    2.7216
```

Request only the first two principal components and compute the T-squared values in the reduced space of requested principal components.

```
[coeff,score,latent,tsquared] = pca(ingredients,'NumComponents',2);
tsquared

tsquared =

    5.6803
    3.0758
    6.0002
    2.6198
    3.3681
    0.5668
    3.4818
    3.9794
    2.6086
    7.4818
    4.1830
    2.2327
    2.7216
```

Note that even when you specify a reduced component space, `pca` computes the T-squared values in the full space, using all four components.

The T-squared value in the reduced space corresponds to the Mahalanobis distance in the reduced space.

```
tsqreduced = mahal(score,score)

tsqreduced =

    3.3179
    2.0079
    0.5874
    1.7382
    0.2955
    0.4228
    3.2457
    2.6914
    1.3619
    2.9903
    2.4371
    1.3788
    1.5251
```

Calculate the T-squared values in the discarded space by taking the difference of the T-squared values in the full space and Mahalanobis distance in the reduced space.

```
tsqdiscarded = tsquared - tsqreduced
```

```
tsqdiscarded =
```

```

1.2880
1.2467
4.4915
1.7459
0.8539
1.1965
```

Percent Variability Explained by Principal Components

Find the percent variability explained by the principal components.

Load the sample data set.

```
load imports-85
```

Data matrix X has 13 continuous variables in columns 3 to 15: wheel-base, length, width, height, curb-weight, engine-size, bore, stroke, compression-ratio, horsepower, peak-rpm, city-mpg, and highway-mpg.

Find the percent variability explained by principal components of these variables.

```
[coeff,score,latent,tsquared,explained] = pca(X(:,3:15));
```

```
explained
```

```
explained =
```

```
64.3429
35.4484
0.1550
0.0379
0.0078
0.0048
```

```

0.0013
0.0011
0.0005
0.0002
0.0002
0.0000
0.0000

```

The first two components explain 99.79% of all variability.

To skip any of the outputs, you can use `~` instead in the corresponding element. For example, if you don't want to get the T-squared values, specify

```
[coeff,score,latent,~,explained] = pca(X(:,3:15));
```

- “Quality of Life in U.S. Cities” on page 13-76

Input Arguments

X — Input data

matrix

Input data for which to compute the principal components, specified as an n -by- p matrix. Rows of X correspond to observations and columns to variables.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of **Name**,**Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example:

```
'Algorithm','eig','Centered',false,'Rows','all','NumComponents',3
```

specifies that `pca` uses eigenvalue decomposition algorithm, not center the data, use all of the observations, and return only the first three principal components.

'Algorithm' — Principal component algorithm

`'svd'` (default) | `'eig'` | `'als'`

Principal component algorithm that `pca` uses to perform the principal component analysis, specified as the comma-separated pair consisting of `'Algorithm'` and one of the following.

<code>'svd'</code>	Default. Singular value decomposition (SVD) of X .
<code>'eig'</code>	Eigenvalue decomposition (EIG) of the covariance matrix. The EIG algorithm is faster than SVD when the number of observations, n , exceeds the number of variables, p , but is less accurate because the condition number of the covariance is the square of the condition number of X .
<code>'als'</code>	<p>Alternating least squares (ALS) algorithm. This algorithm finds the best rank-k approximation by factoring X into a n-by-k left factor matrix, L, and a p-by-k right factor matrix, R, where k is the number of principal components. The factorization uses an iterative method starting with random initial values.</p> <p>ALS is designed to better handle missing values. It is preferable to pairwise deletion (<code>'Rows', 'pairwise'</code>) and deals with missing values without listwise deletion (<code>'Rows', 'complete'</code>). It can work well for data sets with a small percentage of missing data at random, but might not perform well on sparse data sets.</p>

Example: `'Algorithm', 'eig'`

Data Types: `char`

'Centered' — Indicator for centering columns

`true` (default) | `false`

Indicator for centering the columns, specified as the comma-separated pair consisting of `'Centered'` and one of these logical expressions.

<code>true</code>	Default. <code>pca</code> centers X by subtracting column means before computing singular value decomposition or eigenvalue decomposition. If X contains NaN missing values, <code>nanmean</code> is used to find the mean with any available data. You can reconstruct the centered data using <code>score*coeff'</code> .
<code>false</code>	In this case <code>pca</code> does not center the data. You can reconstruct the original data using <code>score*coeff'</code> .

Example: `'Centered', false`

Data Types: `logical`

'Economy' — Indicator for economy size output

true (default) | false

Indicator for the economy size output when the degrees of freedom, d , is smaller than the number of variables, p , specified as the comma-separated pair consisting of 'Economy' and one of these logical expressions.

true	Default. <code>pca</code> returns only the first d elements of <code>latent</code> and the corresponding columns of <code>coeff</code> and <code>score</code> . This option can be significantly faster when the number of variables p is much larger than d .
false	<code>pca</code> returns all elements of <code>latent</code> . The columns of <code>coeff</code> and <code>score</code> corresponding to zero elements in <code>latent</code> are zeros.

Note that when $d < p$, `score(:, d+1:p)` and `latent(d+1:p)` are necessarily zero, and the columns of `coeff(:, d+1:p)` define directions that are orthogonal to X .

Example: 'Economy', false

Data Types: logical

'NumComponents' — Number of components requested

number of variables (default) | scalar integer

Number of components requested, specified as the comma-separated pair consisting of 'NumComponents' and a scalar integer k satisfying $0 < k \leq p$, where p is the number of original variables in X . When specified, `pca` returns the first k columns of `coeff` and `score`.

Example: 'NumComponents', 3

Data Types: single | double

'Rows' — Action to take for NaN values

'complete' (default) | 'pairwise' | 'all'

Action to take for NaN values in the data matrix X , specified as the comma-separated pair consisting of 'ROWS' and one of the following.

'complete'	Default. Observations with NaN values are removed before calculation. Rows of NaNs are reinserted into <code>score</code> and <code>tsquared</code> at the corresponding locations.
------------	---

'pairwise'	<p>This option only applies when the algorithm is 'eig'. If you don't specify the algorithm along with 'pairwise', then <code>pca</code> sets it to 'eig'. If you specify 'svd' as the algorithm, along with the option 'Rows', 'pairwise', then <code>pca</code> returns a warning message, sets the algorithm to 'eig' and continues.</p> <p>When you specify the 'Rows', 'pairwise' option, <code>pca</code> computes the (i,j) element of the covariance matrix using the rows with no NaN values in the columns i or j of X.</p> <p>Note that the resulting covariance matrix might not be positive definite. In that case, <code>pca</code> terminates with an error message.</p>
'all'	<p>X is expected to have no missing values. <code>pca</code> uses all of the data and terminates if any NaN value is found.</p>

Example: 'Rows', 'pairwise'

Data Types: char

'Weights' — Observation weights

ones (default) | row vector

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a vector of length n containing all positive elements.

Data Types: single | double

'VariableWeights' — Variable weights

row vector | 'variance'

Variable weights, specified as the comma-separated pair consisting of 'VariableWeights' and one of the following.

Vector of length p containing all positive elements.

The string 'variance'. The variable weights are the inverse of sample variance. If you also assign weights to observations using 'Weights', then the variable weights become the inverse of weighted sample variance.

If 'Centered' is set to `true` at the same time, the data matrix X is centered and standardized. In this case, `pca` returns the principal components based on the correlation matrix.

Example: 'VariableWeights', 'variance'

Data Types: single | double | char

'Coeff0' – Initial value for coefficients

matrix of random values (default) | p -by- k matrix

Initial value for the coefficient matrix `coeff`, specified as the comma-separated pair consisting of 'Coeff0' and a p -by- k matrix, where p is the number of variables, and k is the number of principal components requested.

Note: You can use this name-value pair only when 'algorithm' is 'als'.

Data Types: single | double

'Score0' – Initial value for scores

matrix of random values (default) | k -by- m matrix

Initial value for scores matrix `score`, specified as a comma-separated pair consisting of 'Score0' and an n -by- k matrix, where n is the number of observations and k is the number of principal components requested.

Note: You can use this name-value pair only when 'algorithm' is 'als'.

Data Types: single | double

'Options' – Options for iterations

structure

Options for the iterations, specified as a comma-separated pair consisting of 'Options' and a structure created by the `statset` function. `pca` uses the following fields in the options structure.

'Display'	Level of display output. Choices are 'off', 'final', and 'iter'.
'MaxIter'	Maximum number steps allowed. The default is 100. Unlike in optimization settings, reaching the <code>MaxIter</code> value is regarded as convergence.

'TolFun'	Positive number giving the termination tolerance for the cost function. The default is 1e-6.
'TolX'	Positive number giving the convergence threshold for the relative change in the elements of the left and right factor matrices, L and R, in the ALS algorithm. The default is 1e-6.

Note: You can use this name-value pair only when 'algorithm' is 'als'.

You can change the values of these fields and specify the new structure in `pca` using the 'Options' name-value pair argument.

```
Example: opt = statset('pca'); opt.MaxIter = 2000; coeff =  
pca(X, 'Options', opt);
```

Data Types: struct

Output Arguments

coeff — Principal component coefficients

matrix

Principal component coefficients, returned as a p -by- p matrix. Each column of `coeff` contains coefficients for one principal component. The columns are in the order of descending component variance, latent.

score — Principal component scores

matrix

Principal component scores, returned as a matrix. Rows of `score` correspond to observations, and columns to components.

latent — Principal component variances

column vector

Principal component variances, that is the eigenvalues of the covariance matrix of `X`, returned as a column vector.

tsquared — Hotelling's T-squared statistic

column vector

“Hotelling’s T-Squared Statistic” on page 21-3093, which is the sum of squares of the standardized scores for each observation, returned as a column vector.

explained — Percentage of total variance explained

column vector

Percentage of the total variance explained by each principal component, returned as a column vector.

mu — Estimated means

row vector

Estimated means of the variables in X , returned as a row vector. When 'algorithm' is 'als', this is estimated by ALS algorithm. When 'algorithm' is not 'als', mu is equal to the sample mean of X .

More About

Hotelling’s T-Squared Statistic

Hotelling’s T-squared statistic is a statistical measure of the multivariate distance of each observation from the center of the data set.

Even when you request fewer components than the number of variables, `pca` uses all principal components to compute the T-squared statistic (computes it in the full space). If you want the T-squared statistic in the reduced or the discarded space, do one of the following:

- For the T-squared statistic in the reduced space, use `mahal(score, score)`.
- For the T-squared statistic in the discarded space, first compute the T-squared statistic using `[coeff, score, latent, tsquared] = pca(X, 'NumComponents', k, ...)`, compute the T-squared statistic in the reduced space using `tsqreduced = mahal(score, score)`, and then take the difference: `tsquared - tsqreduced`.

Degrees of Freedom

The degrees of freedom, d , is equal to $n - 1$, if data is centered and n otherwise, where:

- n is the number of rows without any NaNs if you use 'Rows', 'complete'.

- n is the number of rows without any NaNs in the column pair that has the maximum number of rows without NaNs if you use 'Rows', 'pairwise'.

Variable Weights

Note that when variable weights are used, the coefficient matrix is not orthonormal. Suppose the variable weights vector you used is called `varwei`, and the principal component coefficients vector `pca` returned is `wcoeff`. You can then calculate the orthonormal coefficients using the transformation `diag(sqrt(varwei))*wcoeff`.

pcacov

Principal component analysis on covariance matrix

Syntax

```
COEFF = pcacov(V)
[COEFF,latent] = pcacov(V)
[COEFF,latent,explained] = pcacov(V)
```

Description

`COEFF = pcacov(V)` performs principal components analysis on the p-by-p covariance matrix `V` and returns the principal component coefficients, also known as loadings. `COEFF` is a p-by-p matrix, with each column containing coefficients for one principal component. The columns are in order of decreasing component variance.

`pcacov` does not standardize `V` to have unit variances. To perform principal components analysis on standardized variables, use the correlation matrix $R = V ./ (SD * SD')$, where $SD = \text{sqrt}(\text{diag}(V))$, in place of `V`. To perform principal components analysis directly on the data matrix, use `pca`.

`[COEFF,latent] = pcacov(V)` returns `latent`, a vector containing the principal component variances, that is, the eigenvalues of `V`.

`[COEFF,latent,explained] = pcacov(V)` returns `explained`, a vector containing the percentage of the total variance explained by each principal component.

Examples

```
load hald
covx = cov(ingredients);
[COEFF,latent,explained] = pcacov(covx)
COEFF =
    0.0678 -0.6460  0.5673 -0.5062
    0.6785 -0.0200 -0.5440 -0.4933
   -0.0290  0.7553  0.4036 -0.5156
```

-0.7309 -0.1085 -0.4684 -0.4844

latent =
517.7969
67.4964
12.4054
0.2372

barttest | biplot | factoran | pcares | pca | rotatefactors

pcares

Residuals from principal component analysis

Syntax

```
residuals = pcares(X,ndim)
[residuals,reconstructed] = pcares(X,ndim)
```

Description

`residuals = pcares(X,ndim)` returns the `residuals` obtained by retaining `ndim` principal components of the `n`-by-`p` matrix `X`. Rows of `X` correspond to observations, columns to variables. `ndim` is a scalar and must be less than or equal to `p`. `residuals` is a matrix of the same size as `X`. Use the data matrix, *not* the covariance matrix, with this function.

`pcares` does not normalize the columns of `X`. To perform the principal components analysis based on standardized variables, that is, based on correlations, use `pcares(zscore(X), ndim)`. You can perform principal components analysis directly on a covariance or correlation matrix, but without constructing residuals, by using `pcacov`.

`[residuals,reconstructed] = pcares(X,ndim)` returns the reconstructed observations; that is, the approximation to `X` obtained by retaining its first `ndim` principal components.

Examples

This example shows the drop in the residuals from the first row of the Hald data as the number of component dimensions increases from one to three.

```
load hald
r1 = pcares(ingredients,1);
r2 = pcares(ingredients,2);
r3 = pcares(ingredients,3);
```

```
r11 = r1(1,:)
r11 =
    2.0350    2.8304   -6.8378    3.0879

r21 = r2(1,:)
r21 =

factoran | pcacov | pca

ppca

Probabilistic principal component analysis

Syntax

```
[coeff, score, pcvar] = ppca(Y, K)
[coeff, score, pcvar] = ppca(Y, K, Name, Value)
[coeff, score, pcvar, mu] = ppca( ___ )
[coeff, score, pcvar, mu, v, S] = ppca( ___ )
```

Description

`[coeff, score, pcvar] = ppca(Y, K)` returns the principal component coefficients for the n -by- p data matrix Y based on a probabilistic principal component analysis (PPCA). It also returns the principal component scores, which are the representations of Y in the principal component space, and the principal component variances, which are the eigenvalues of the covariance matrix of Y , in `pcvar`.

Each column of `coeff` contains coefficients for one principal component, and the columns are in descending order of component variance. Rows of `score` correspond to observations, and columns correspond to components. Rows of Y correspond to observations and columns correspond to variables.

Probabilistic principal component analysis might be preferable to other algorithms that handle missing data, such as the alternating least squares algorithm when any data vector has one or more missing values. It assumes that the values are missing at random through the data set. An expectation-maximization algorithm is used for both complete and missing data.

`[coeff, score, pcvar] = ppca(Y, K, Name, Value)` returns the principal component coefficients, scores, and variances using additional options for computation and handling of special data types, specified by one or more `Name, Value` pair arguments.

For example, you can introduce initial values for the residual variance, `v`, or change the termination criteria.

`[coeff, score, pcvar, mu] = ppca(___)` also returns the estimated mean of each variable in Y . You can use any of the input arguments in the previous syntaxes.

`[coeff,score,pcvar,mu,v,S] = ppca(___)` also returns the isotropic residual variance in `v` and the final results at convergence in structure `S`.

Examples

Perform Probabilistic Principal Component Analysis

Load the sample data.

```
load fisheriris
```

The double matrix `meas` consists of four types of measurements on the flowers, which, respectively, are the length and width of sepals and petals.

Introduce missing values randomly.

```
y = meas;  
rng('default'); % for reproducibility  
ix = random('unif',0,1,size(y))<0.20;  
y(ix) = NaN;
```

Now, approximately 20% of the data is missing, indicated by NaN.

Perform probabilistic principal component analysis and request the component coefficients and variances.

```
[coeff,score,pcvar,mu] = ppca(y,3);  
coeff
```

```
coeff =
```

```
    0.3562    0.6709   -0.5518  
   -0.0765    0.7121    0.6332  
    0.8592   -0.1596    0.0596  
    0.3592   -0.1318    0.5395
```

```
pcvar
```

```
pcvar =
```

```
    4.0912  
    0.2126  
    0.0617
```

Perform principal component analysis using the alternating least squares algorithm and request the component coefficients and variances.

```
[coeff2,score2,pcvar2,mu2] = pca(y,'algorithm','als',...
'NumComponents',3);
```

```
coeff2
```

```
coeff2 =
```

```
    0.3376    0.4955    0.7404
   -0.0731    0.8607   -0.4479
    0.8657   -0.1169   -0.1231
    0.3623   -0.0087   -0.4859
```

```
pcvar2
```

```
pcvar2 =
```

```
    4.0734
    0.2651
    0.1221
```

The coefficients and the variances of the first two principal components are similar.

Another way to compare the results is to find the angle between the two spaces spanned by the coefficient vectors.

```
subspace(coeff,coeff2)
```

```
ans =
```

```
    0.0881
```

The angle between the two spaces is pretty small. This indicates that these two results are close to each other.

Change the Termination Criteria for Probabilistic Principal Component Analysis

Load the sample data set.

```
load imports-85
```

Data matrix X has 13 continuous variables in columns 3 to 15: wheel-base, length, width, height, curb-weight, engine-size, bore, stroke, compression-ratio, horsepower, peak-rpm, city-mpg, and highway-mpg. The variables bore and stroke are missing four values in

rows 56 to 59, and the variables horsepower and peak-rpm are missing two values in rows 131 and 132.

Perform probabilistic principal component analysis and display the first three principal components.

```
[coeff,score,pcvar] = ppca(X(:,3:15),3);
```

```
Warning: Maximum number of iterations 1000 reached'.  
> In ppca at 249
```

Change the termination tolerance for the cost function to 0.01.

```
opt = statset('ppca');  
opt.TolFun = 0.01;
```

Perform probabilistic principal component analysis.

```
[coeff,score,pcvar] = ppca(X(:,3:15),3,'Options',opt);
```

`ppca` now terminates before the maximum number of iterations is reached because it meets the tolerance for the cost function.

Reconstruct Observations

Load the sample data.

```
load hald  
y = ingredients;
```

The ingredients data has 13 observations for 4 variables.

Introduce missing values to the data.

```
y(2:16:end) = NaN;
```

Every 16th value is NaN. This corresponds to 7.69% of the data.

Find the first three principal components of data using PPCA and display the reconstructed observations.

```
[coeff,score,pcvar,mu,v,S] = ppca(y,3);  
S.Recon
```

```
ans =
```

```

6.8533    25.8675    5.8388    59.8755
1.0431    28.9690    14.9652   51.9758
11.5770   56.5080    8.6352   20.5062

9.9174    67.9309    7.9087   11.9230

```

You can also reconstruct the observations using the principal components and the estimated mean.

```
t = score*coeff' + repmat(mu,13,1);
```

Results at Convergence

Load the sample data.

```
load hald
```

Here, `ingredients` is a real-valued matrix of predictor variables.

Perform the probabilistic principal components analysis and display coefficients.

```
[coeff,score,pcvariance,mu,v,S] = ppca(ingredients,3);
coeff
```

```
coeff =
```

```

-0.0693    -0.6459    0.5673
-0.6786    -0.0184   -0.5440
 0.0308    0.7552    0.4036
 0.7306   -0.1102   -0.4684

```

Display the algorithm results at convergence of the PPCA.

```
S
```

```
S =
```

```
W: [4x3 double]
```

```
Xexp: [13x3 double]
Recon: [13x4 double]
v: 0.2372
NumIter: 1000
RMSResid: 0.2340
nloglk: 149.3388
```

Display the matrix W .

`S.W`

`ans =`

```
0.5624    2.0279    5.4075
4.8320   -10.3894    5.9202
-3.7521   -3.0555   -4.1552
-1.5144   11.7122   -7.2564
```

Orthogonalizing W recovers the coefficients.

0.7306    0.1102   -0.4684
```

Input Arguments

Y — Input data

n-by-*p* matrix

Input data for which to compute the principal components, specified as an *n*-by-*p* matrix. Rows of Y correspond to observations and columns correspond to variables.

Data Types: `single` | `double`

K — Number of principal components

positive integer value less than rank

Number of principal components to return, specified as an integer value less than the rank of data. The maximum possible rank is $\min(n,p)$, where n is the number of

observations and p is the number of variables. However, if the data is correlated, the rank might be smaller than $\min(n,p)$.

ppca orders the components based on their variance.

If K is $\min(n,p)$, ppca sets K equal to $\min(n,p) - 1$, and 'WO' is truncated to $\min(p,n) - 1$ columns if you specify a p -by- p WO matrix.

For example, you can request only the first three components, based on the component variance as follows.

```
Example: coeff = ppca(Y,3)
```

```
Data Types: single | double
```

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Example: 'WO',init,'Options',opt specifies that the initial values for 'WO' are in matrix init and ppca uses the options defined by opt.

'WO' — Initial value of W

matrix of random values (default) | p -by- k matrix

Initial value of W in the probabilistic principal component analysis algorithm, specified as a comma-separated pair consisting of 'WO' and a p -by- k matrix.

```
Data Types: single | double
```

'v0' — Initial value of residual variance

random number (default) | positive scalar value

Initial value of residual variance, specified as the comma-separated pair consisting of 'v0' and a positive scalar value.

```
Data Types: single | double
```

'Options' — Options for iterations

structure

Options for the iterations, specified as a comma-separated pair 'Options' and a structure created by the `statset` function. `ppca` uses the following fields in the options structure.

'Display'	Level of display output. Choices are 'off', 'final', and 'iter'.
'MaxIter'	Maximum number of steps allowed. The default is 1000. Unlike in optimization settings, reaching the <code>MaxIter</code> value is regarded as convergence.
'TolFun'	Positive integer stating the termination tolerance for the cost function. The default is 1e-6.
'TolX'	Positive integer stating the convergence threshold for the relative change in the elements of W . The default is 1e-6.

You can change the values of these fields and specify the new structure in `ppca` using the 'Options' name-value pair argument.

```
Example: opt = statset('ppca'); opt.MaxIter = 2000; coeff =  
ppca(Y,3,'Options',opt);
```

Data Types: struct

Output Arguments

coeff — Principal component coefficients

p-by-*k* matrix

Principal component coefficients, returned as a *p*-by-*k* matrix. Each column of `coeff` contains coefficients for one principal component. The columns are in the order of descending component variance, `pcvar`.

score — Principal component scores

n-by-*k* matrix

Principal component scores, returned as an *n*-by-*k* matrix. Rows of `score` correspond to observations, and columns correspond to components.

pcvar — Principal component variances

column vector

Principal component variances, which are the eigenvalues of the covariance matrix of Y , returned as a column vector.

μ — Estimated mean

row vector

Estimated mean of each variable in Y , returned as a row vector.

v — Isotropic residual variance

scalar value

Isotropic residual variance, returned as a scalar value.

S — Final results at convergence

structure

Final results at convergence, returned as a structure containing the following fields.

W	W at convergence.
Xexp	Conditional expectation of the estimated latent variable x .
Recon	Reconstructed observations using k principal components. This is a low dimension approximation of the input data Y , and is equal to $\mu + \text{score} * \text{coeff}$.
v	Residual variance.
RMSResid	Root mean square of residuals.
NumIter	Number of iteration counts.
nloglk	Negative loglikelihood function value.

More About

Probabilistic Principal Component Analysis

Probabilistic principal component analysis (PPCA) is a method to estimate the principal axes when any data vector has one or more missing values.

PPCA is based on an isotropic error model. It seeks to relate a p -dimensional observation vector y to a corresponding k -dimensional vector of latent (or unobserved) variable x , which is normal with mean zero and covariance $I(k)$. The relationship is

$$y^T = W * x^T + \mu + \varepsilon,$$

where y is the row vector of observed variable, x is the row vector of latent variables, and ε is the isotropic error term. ε is Gaussian with mean zero and covariance of $v * I(k)$, where v is the residual variance. Here, k needs to be smaller than the rank for the residual variance to be greater than 0 ($v > 0$). Standard principal component analysis, where the residual variance is zero, is the limiting case of PPCA. The observed variables, y , are conditionally independent given the values of the latent variables, x . So, the latent variables explain the correlations between the observation variables and the error explains the variability unique to a particular y_i . The p -by- k matrix W relates the latent and observation variables, and the vector μ permits the model to have a nonzero mean. PPCA assumes that the values are missing at random through the data set. This means that whether a data value is missing or not does not depend on the latent variable given the observed data values.

Under this model,

$$y \sim N(\mu, W * W^T + v * I(k)).$$

There is no closed-form analytical solution for W and v , so their estimates are determined by iterative maximization of the corresponding loglikelihood using an expectation-maximization (EM) algorithm. This EM algorithm handles missing values by treating them as additional latent variables. At convergence, the columns of W spans the subspace, but they are not orthonormal. `ppca` obtains the orthonormal coefficients, `coeff`, for the components by orthogonalization of W .

ComponentProportion property

Class: gmdistribution

Input vector of mixing proportions

Description

Optional input vector of mixing proportions ρ , or its default value.

pdf

Probability density functions

Syntax

```
Y = pdf(name, X, A)
Y = pdf(name, X, A, B)
Y = pdf(name, X, A, B, C)
```

Description

`Y = pdf(name, X, A)` computes the probability density function for the one-parameter family of distributions specified by `name`. Parameter values for the distribution are given in `A`. Densities are evaluated at the values in `X` and returned in `Y`.

If `X` and `A` are arrays, they must be the same size. If `X` is a scalar, it is expanded to a constant matrix the same size as `A`. If `A` is a scalar, it is expanded to a constant matrix the same size as `X`.

`Y` is the common size of `X` and `A` after any necessary scalar expansion.

`Y = pdf(name, X, A, B)` computes the probability density function for two-parameter families of distributions, where parameter values are given in `A` and `B`.

If `X`, `A`, and `B` are arrays, they must be the same size. If `X` is a scalar, it is expanded to a constant matrix the same size as `A` and `B`. If either `A` or `B` are scalars, they are expanded to constant matrices the same size as `X`.

`Y` is the common size of `X`, `A`, and `B` after any necessary scalar expansion.

`Y = pdf(name, X, A, B, C)` computes the probability density function for three-parameter families of distributions, where parameter values are given in `A`, `B`, and `C`.

If `X`, `A`, `B`, and `C` are arrays, they must be the same size. If `X` is a scalar, it is expanded to a constant matrix the same size as `A`, `B`, and `C`. If any of `A`, `B` or `C` are scalars, they are expanded to constant matrices the same size as `X`.

Y is the common size of X, A, B and C after any necessary scalar expansion.

Examples

Compute the pdf of the normal distribution with mean 0 and standard deviation 1 at inputs $-2, -1, 0, 1, 2$:

```
p1 = pdf('Normal', -2:2, 0, 1)
p1 =
    0.0540    0.2420    0.3989    0.2420    0.0540
```

The order of the parameters is the same as for `normpdf`.

Compute the pdfs of Poisson distributions with rate parameters 0, 1, ..., 4 at inputs 1, 2, ..., 5, respectively:

```
p2 = pdf('Poisson', 0:4, 1:5)
p2 =
    0.3679    0.2707    0.2240    0.1954    0.1755
```

The order of the parameters is the same as for `poisspdf`.

pdf

Class: `gmdistribution`

Probability density function for Gaussian mixture distribution

Syntax

`y = pdf(obj,X)`

Description

`y = pdf(obj,X)` returns a vector `y` of length n containing the values of the probability density function (pdf) for the `gmdistribution` object `obj`, evaluated at the n -by- d data matrix `X`, where n is the number of observations and d is the dimension of the data. `obj` is an object created by `gmdistribution` or `fitgmdist`. `y(I)` is the pdf of observation `I`.

Examples

Construct a Gaussian Mixture Distribution

Create a `gmdistribution` distribution defining a two-component mixture of bivariate Gaussian distributions.

```
mu = [1 2;-3 -5];
sigma = cat(3,[2 0;0 .5],[1 0;0 1]);
p = ones(1,2)/2;
obj = gmdistribution(mu,sigma,p);

ezsurf(@(x,y)pdf(obj,[x y]),[-10 10],[-10 10])
```

See Also

gmdistribution | fitgmdist | cdf | mvnpdf

pdf

Class: `piecwisedistribution`

Probability density function for piecewise distribution

Syntax

```
P = pdf(obj,X)
```

Description

`P = pdf(obj,X)` returns an array `P` of values of the probability density function for the piecewise distribution object `obj`, evaluated at the values in the array `X`.

Note: For a Pareto tails object, the pdf is computed using the generalized Pareto distribution in the tails. In the center, the pdf is computed using the slopes of the cdf, which are interpolated between a set of discrete values. Therefore the pdf in the center is piecewise constant. It is noisy for a `cdfun` specified in `paretotails` via the `'ecdf'` option, and somewhat smoother for the `'kernel'` option, but generally not a good estimate of the underlying density of the original data.

Examples

Fit Pareto tails to a t distribution at cumulative probabilities 0.1 and 0.9:

```
t = trnd(3,100,1);
obj = paretotails(t,0.1,0.9);
[p,q] = boundary(obj)
p =
    0.1000
    0.9000
q =
   -1.7766
    1.8432
```

```
pdf(obj,q)
ans =
    0.2367
    0.1960
```

pdf

Class: ProbDist

Return probability density function (PDF) for ProbDist object

Syntax

$Y = \text{pdf}(PD, X)$

Description

$Y = \text{pdf}(PD, X)$ returns Y , an array containing the probability density function (PDF) for the ProbDist object PD , evaluated at values in X .

Input Arguments

PD	An object of the class <code>ProbDistUnivParam</code> or <code>ProbDistUnivKernel</code> .
X	A numeric array of values where you want to evaluate the PDF.

Output Arguments

Y	An array containing the probability density function (PDF) for the ProbDist object PD .

pdf

pdf

Class: prob.TruncatableDistribution

Package: prob

Probability density function of probability distribution object

Syntax

```
y = pdf(pd, x)
```

Description

`y = pdf(pd, x)` returns the probability density function (pdf) of the continuous probability distribution `pd` at the values in `x`. For discrete distributions, `pdf` returns the probability mass function.

Input Arguments

pd — Probability distribution

probability distribution object

Probability distribution, specified as a probability distribution object. Create a probability distribution object with specified parameter values using `makedist`. Alternatively, for fittable distributions, create a probability distribution object by fitting it to data using `fitdist` or the Distribution Fitting app.

x — Values at which to calculate pdf

array

Values at which to calculate pdf, specified as an array.

Data Types: `single` | `double`

Output Arguments

y — Probability density function

array

Probability density function of `pd`, evaluated at the values in data vector `x`, returned as a array. `y` has the same dimensions as input `x`.

Examples

Plot the pdf of a Standard Normal Distribution

Create a standard normal distribution object.

```
pd = makedist('Normal')
```

```
pd =
```

```
NormalDistribution
```

```
Normal distribution
```

```
mu = 0
```

```
sigma = 1
```

Specify the `x` values and compute the pdf.

```
x = -3:.1:3;
```

```
pdf_normal = pdf(pd,x);
```

Plot the pdf.

```
plot(x,pdf_normal,'LineWidth',2)
```

Plot the pdf of a Weibull Distribution

Create a Weibull probability distribution object.

```
pd = makedist('Weibull','a',5,'b',2)
```

```
pd =
```

```
WeibullDistribution
```

```
Weibull distribution
```

```
A = 5
```

```
B = 2
```

Specify the x values and compute the pdf.

```
x = 0:.1:15;  
pdf = pdf(pd,x);
```

Plot the pdf.

```
plot(x,pdf, 'LineWidth',2)
```

pdist

Pairwise distance between pairs of objects

Syntax

```
D = pdist(X)
D = pdist(X,distance)
```

Description

`D = pdist(X)` computes the Euclidean distance between pairs of objects in m -by- n data matrix X . Rows of X correspond to observations, and columns correspond to variables. D is a row vector of length $m(m-1)/2$, corresponding to pairs of observations in X . The distances are arranged in the order (2,1), (3,1), ..., (m,1), (3,2), ..., (m,2), ..., (m,m-1)). D is commonly used as a dissimilarity matrix in clustering or multidimensional scaling.

To save space and computation time, D is formatted as a vector. However, you can convert this vector into a square matrix using the `squareform` function so that element i, j in the matrix, where $i < j$, corresponds to the distance between objects i and j in the original data set.

`D = pdist(X,distance)` computes the distance between objects in the data matrix, X , using the method specified by `distance`, which can be any of the following character strings.

Metric	Description
'euclidean'	Euclidean distance (default).
'seuclidean'	Standardized Euclidean distance. Each coordinate difference between rows in X is scaled by dividing by the corresponding element of the standard deviation $S = \text{nanstd}(X)$. To specify another value for S , use <code>D=pdist(X, 'seuclidean', S)</code> .
'cityblock'	City block metric.
'minkowski'	Minkowski distance. The default exponent is 2. To specify a different exponent, use <code>D = pdist(X, 'minkowski', P)</code> , where P is a scalar positive value of the exponent.

Metric	Description
'chebychev'	Chebychev distance (maximum coordinate difference).
'mahalanobis'	Mahalanobis distance, using the sample covariance of X as computed by <code>nancov</code> . To compute the distance with a different covariance, use <code>D = pdist(X, 'mahalanobis', C)</code> , where the matrix C is symmetric and positive definite.
'cosine'	One minus the cosine of the included angle between points (treated as vectors).
'correlation'	One minus the sample correlation between points (treated as sequences of values).
'spearman'	One minus the sample Spearman's rank correlation between observations (treated as sequences of values).
'hamming'	Hamming distance, which is the percentage of coordinates that differ.
'jaccard'	One minus the Jaccard coefficient, which is the percentage of nonzero coordinates that differ.
custom distance function	<p>A distance function specified using @:</p> <pre>D = pdist(X,@distfun)</pre> <p>A distance function must be of form</p> <pre>d2 = distfun(XI,XJ)</pre> <p>taking as arguments a 1-by-n vector XI, corresponding to a single row of X, and an $m2$-by-n matrix XJ, corresponding to multiple rows of X. <code>distfun</code> must accept a matrix XJ with an arbitrary number of rows. <code>distfun</code> must return an $m2$-by-1 vector of distances $d2$, whose kth element is the distance between XI and $XJ(k, :)$.</p>

The output D is arranged in the order of $((2,1),(3,1),\dots, (m,1),(3,2),\dots,(m,2),\dots,(m,m-1))$, i.e. the lower left triangle of the full m -by- m distance matrix in column order. To get the distance between the i th and j th observations ($i < j$), either use the formula $D((i-1)*(m-i/2)+j-i)$, or use the helper function `Z = squareform(D)`, which returns an m -by- m square symmetric matrix, with the (i,j) entry equal to distance between observation i and observation j .

Metrics

Given an m -by- n data matrix X , which is treated as m (1-by- n) row vectors x_1, x_2, \dots, x_m , the various distances between the vector x_s and x_t are defined as follows:

- Euclidean distance

$$d_{st}^2 = (x_s - x_t)(x_s - x_t)'$$

Notice that the Euclidean distance is a special case of the Minkowski metric, where $p = 2$.

- Standardized Euclidean distance

$$d_{st}^2 = (x_s - x_t)V^{-1}(x_s - x_t)'$$

where V is the n -by- n diagonal matrix whose j th diagonal element is $S(j)^2$, where S is the vector of standard deviations.

- Mahalanobis distance

$$d_{st}^2 = (x_s - x_t)C^{-1}(x_s - x_t)'$$

where C is the covariance matrix.

- City block metric

$$d_{st} = \sum_{j=1}^n |x_{sj} - x_{tj}|$$

Notice that the city block distance is a special case of the Minkowski metric, where $p=1$.

- Minkowski metric

$$d_{st} = p \sqrt[p]{\sum_{j=1}^n |x_{sj} - x_{tj}|^p}$$

Notice that for the special case of $p = 1$, the Minkowski metric gives the city block metric, for the special case of $p = 2$, the Minkowski metric gives the Euclidean distance, and for the special case of $p = \infty$, the Minkowski metric gives the Chebychev distance.

- Chebychev distance

$$d_{st} = \max_j \{|x_{sj} - x_{tj}|\}$$

Notice that the Chebychev distance is a special case of the Minkowski metric, where $p = \infty$.

- Cosine distance

$$d_{st} = 1 - \frac{x_s x_t'}{\sqrt{(x_s x_s')(x_t x_t')}}}$$

- Correlation distance

$$d_{st} = 1 - \frac{(x_s - \bar{x}_s)(x_t - \bar{x}_t)'}{\sqrt{(x_s - \bar{x}_s)(x_s - \bar{x}_s)'} \sqrt{(x_t - \bar{x}_t)(x_t - \bar{x}_t)'}}$$

where

$$\bar{x}_s = \frac{1}{n} \sum_j x_{sj} \quad \text{and} \quad \bar{x}_t = \frac{1}{n} \sum_j x_{tj}$$

- Hamming distance

$$d_{st} = (\#(x_{sj} \neq x_{tj}) / n)$$

- Jaccard distance

$$d_{st} = \frac{\#[(x_{sj} \neq x_{tj}) \cap ((x_{sj} \neq 0) \cup (x_{tj} \neq 0))]}{\#[(x_{sj} \neq 0) \cup (x_{tj} \neq 0)]}$$

- Spearman distance

$$d_{st} = 1 - \frac{(r_s - \bar{r}_s)(r_t - \bar{r}_t)'}{\sqrt{(r_s - \bar{r}_s)(r_s - \bar{r}_s)'} \sqrt{(r_t - \bar{r}_t)(r_t - \bar{r}_t)'}}$$

where

- r_{sj} is the rank of x_{sj} taken over $x_{1j}, x_{2j}, \dots, x_{mj}$, as computed by `tiedrank`
- r_s and r_t are the coordinate-wise rank vectors of x_s and x_t , i.e., $r_s = (r_{s1}, r_{s2}, \dots, r_{sn})$
- $\bar{r}_s = \frac{1}{n} \sum_j r_{sj} = \frac{(n+1)}{2}$
- $\bar{r}_t = \frac{1}{n} \sum_j r_{tj} = \frac{(n+1)}{2}$

Examples

Generate random data and find the unweighted Euclidean distance and then find the weighted distance using two different methods:

```
% Compute the ordinary Euclidean distance.
X = randn(100, 5);
D = pdist(X, 'euclidean'); % euclidean distance

% Compute the Euclidean distance with each coordinate
% difference scaled by the standard deviation.
Dstd = pdist(X, 'seuclidean');

% Use a function handle to compute a distance that weights
% each coordinate contribution differently.
Wgts = [.1 .3 .3 .2 .1]; % coordinate weights
weuc = @(XI,XJ,W)(sqrt(bsxfun(@minus,XI,XJ).^2 * W'));
Dwgt = pdist(X, @(Xi,Xj) weuc(Xi,Xj,Wgts));
```

pdist2

Pairwise distance between two sets of observations

Syntax

```
D = pdist2(X,Y)
D = pdist2(X,Y,distance)
D = pdist2(X,Y,'minkowski',P)
D = pdist2(X,Y,'mahalanobis',C)
D = pdist2(X,Y,distance,'Smallest',K)
D = pdist2(X,Y,distance,'Largest',K)
[D,I] = pdist2(X,Y,distance,'Smallest',K)
[D,I] = pdist2(X,Y,distance,'Largest',K)
```

Description

`D = pdist2(X,Y)` returns a matrix `D` containing the Euclidean distances between each pair of observations in the mx -by- n data matrix `X` and my -by- n data matrix `Y`. Rows of `X` and `Y` correspond to observations, columns correspond to variables. `D` is an mx -by- my matrix, with the (i,j) entry equal to distance between observation i in `X` and observation j in `Y`. The (i,j) entry will be NaN if observation i in `X` or observation j in `Y` contain NaNs.

`D = pdist2(X,Y,distance)` computes `D` using `distance`. Choices are:

Metric	Description
'euclidean'	Euclidean distance (default).
'seuclidean'	Standardized Euclidean distance. Each coordinate difference between rows in <code>X</code> and <code>Y</code> is scaled by dividing by the corresponding element of the standard deviation computed from <code>X</code> , <code>S=nanstd(X)</code> . To specify another value for <code>S</code> , use <code>D = PDIST2(X,Y,'seuclidean',S)</code> .
'cityblock'	City block metric.
'minkowski'	Minkowski distance. The default exponent is 2. To compute the distance with a different exponent, use <code>D =</code>

Metric	Description
	<code>pdist2(X,Y,'minkowski',P)</code> , where the exponent <code>P</code> is a scalar positive value.
'chebychev'	Chebychev distance (maximum coordinate difference).
'mahalanobis'	Mahalanobis distance, using the sample covariance of <code>X</code> as computed by <code>nancov</code> . To compute the distance with a different covariance, use <code>D = pdist2(X,Y,'mahalanobis',C)</code> where the matrix <code>C</code> is symmetric and positive definite.
'cosine'	One minus the cosine of the included angle between points (treated as vectors).
'correlation'	One minus the sample correlation between points (treated as sequences of values).
'spearman'	One minus the sample Spearman's rank correlation between observations, treated as sequences of values.
'hamming'	Hamming distance, the percentage of coordinates that differ.
'jaccard'	One minus the Jaccard coefficient, the percentage of nonzero coordinates that differ.
function	<p>A distance function specified using <code>@</code>:</p> $D = \text{pdist2}(X,Y,@\text{distfun}).$ <p>A distance function must be of the form</p> <pre>function D2 = distfun(ZI, ZJ) taking as arguments a 1-by-<i>n</i> vector <i>ZI</i> containing a single observation from <i>X</i> or <i>Y</i>, an <i>m2</i>-by-<i>n</i> matrix <i>ZJ</i> containing multiple observations from <i>X</i> or <i>Y</i>, and returning an <i>m2</i>-by-1 vector of distances <i>D2</i>, whose <i>J</i>th element is the distance between the observations <i>ZI</i> and <i>ZJ</i> (<i>J</i>, :).</pre> <p>If your data is not sparse, generally it is faster to use a built-in distance than to use a function handle.</p>

`D = pdist2(X,Y,distance,'Smallest',K)` returns a `K`-by-`my` matrix `D` containing the `K` smallest pairwise distances to observations in `X` for each observation in `Y`. `pdist2` sorts the distances in each column of `D` in ascending order. `D = pdist2(X,Y,distance,'Largest',K)` returns the `K` largest pairwise distances sorted in descending order. If `K` is greater than `mx`, `pdist2` returns an `mx`-by-`my` distance

matrix. For each observation in Y , `pdist2` finds the K smallest or largest distances by computing and comparing the distance values to all the observations in X .

`[D,I] = pdist2(X,Y,distance,'Smallest',K)` returns a K -by- m_y matrix I containing indices of the observations in X corresponding to the K smallest pairwise distances in D . `[D,I] = pdist2(X,Y,distance,'Largest',K)` returns indices corresponding to the K largest pairwise distances.

Metrics

Given an m_x -by- n data matrix X , which is treated as m_x (1-by- n) row vectors x_1, x_2, \dots, x_{m_x} , and m_y -by- n data matrix Y , which is treated as m_y (1-by- n) row vectors y_1, y_2, \dots, y_{m_y} , the various distances between the vector x_s and y_t are defined as follows:

- Euclidean distance

$$d_{st}^2 = (x_s - y_t)(x_s - y_t)'$$

Notice that the Euclidean distance is a special case of the Minkowski metric, where $p=2$.

- Standardized Euclidean distance

$$d_{st}^2 = (x_s - y_t)V^{-1}(x_s - y_t)'$$

where V is the n -by- n diagonal matrix whose j th diagonal element is $S(j)^2$, where S is the vector of standard deviations.

- Mahalanobis distance

$$d_{st}^2 = (x_s - y_t)C^{-1}(x_s - y_t)'$$

where C is the covariance matrix.

- City block metric

$$d_{st} = \sum_{j=1}^n |x_{sj} - y_{tj}|$$

Notice that the city block distance is a special case of the Minkowski metric, where $p=1$.

- Minkowski metric

$$d_{st} = p \sqrt[p]{\sum_{j=1}^n |x_{sj} - y_{tj}|^p}$$

Notice that for the special case of $p = 1$, the Minkowski metric gives the City Block metric, for the special case of $p = 2$, the Minkowski metric gives the Euclidean distance, and for the special case of $p=\infty$, the Minkowski metric gives the Chebychev distance.

- Chebychev distance

$$d_{st} = \max_j \{|x_{sj} - y_{tj}|\}$$

Notice that the Chebychev distance is a special case of the Minkowski metric, where $p=\infty$.

- Cosine distance

$$d_{st} = \left(1 - \frac{x_s y_t'}{\sqrt{(x_s x_s')(y_t y_t')}} \right)$$

- Correlation distance

$$d_{st} = 1 - \frac{(x_s - \bar{x}_s)(y_t - \bar{y}_t)'}{\sqrt{(x_s - \bar{x}_s)(x_s - \bar{x}_s)'} \sqrt{(y_t - \bar{y}_t)(y_t - \bar{y}_t)'}}$$

where

$$\bar{x}_s = \frac{1}{n} \sum_j x_{sj} \quad \text{and}$$

$$\bar{y}_t = \frac{1}{n} \sum_j y_{tj}$$

- Hamming distance

$$d_{st} = (\#(x_{sj} \neq y_{tj}) / n)$$

- Jaccard distance

$$d_{st} = \frac{\#[(x_{sj} \neq y_{tj}) \cap ((x_{sj} \neq 0) \cup (y_{tj} \neq 0))]}{\#[(x_{sj} \neq 0) \cup (y_{tj} \neq 0)]}$$

- Spearman distance

$$d_{st} = 1 - \frac{(r_s - \bar{r}_s)(r_t - \bar{r}_t)'}{\sqrt{(r_s - \bar{r}_s)(r_s - \bar{r}_s)' \sqrt{(r_t - \bar{r}_t)(r_t - \bar{r}_t)'}}$$

where

- r_{sj} is the rank of x_{sj} taken over $x_{1j}, x_{2j}, \dots, x_{mj}$, as computed by `tiedrank`
- r_{tj} is the rank of y_{tj} taken over $y_{1j}, y_{2j}, \dots, y_{mj}$, as computed by `tiedrank`
- r_s and r_t are the coordinate-wise rank vectors of x_s and y_t , i.e. $r_s = (r_{s1}, r_{s2}, \dots, r_{sn})$ and $r_t = (r_{t1}, r_{t2}, \dots, r_{tn})$
- $\bar{r}_s = \frac{1}{n} \sum_j r_{sj} = \frac{(n+1)}{2}$
- $\bar{r}_t = \frac{1}{n} \sum_j r_{tj} = \frac{(n+1)}{2}$

Examples

Generate random data and find the unweighted Euclidean distance, then find the weighted distance using two different methods:

```
% Compute the ordinary Euclidean distance
X = randn(100, 5);
Y = randn(25, 5);
D = pdist2(X,Y,'euclidean'); % euclidean distance

% Compute the Euclidean distance with each coordinate
% difference scaled by the standard deviation
Dstd = pdist2(X,Y,'seuclidean');

% Use a function handle to compute a distance that weights
% each coordinate contribution differently.
Wgts = [.1 .3 .3 .2 .1];
weuc = @(XI,XJ,W)(sqrt(bsxfun(@minus,XI,XJ).^2 * W'));
Dwgt = pdist2(X,Y, @(Xi,Xj) weuc(Xi,Xj,Wgts));
```

See Also

pearsrnd

Pearson system random numbers

Syntax

```
r = pearsrnd(mu, sigma, skew, kurt, m, n)
r = pearsrnd(mu, sigma, skew, kurt)
r = pearsrnd(mu, sigma, skew, kurt, m, n, ...)
r = pearsrnd(mu, sigma, skew, kurt, [m, n, ...])
[r, type] = pearsrnd(...)
[r, type, coefs] = pearsrnd(...)
```

Description

`r = pearsrnd(mu, sigma, skew, kurt, m, n)` returns an m -by- n matrix of random numbers drawn from the distribution in the Pearson system with mean `mu`, standard deviation `sigma`, skewness `skew`, and kurtosis `kurt`. The parameters `mu`, `sigma`, `skew`, and `kurt` must be scalars.

Note: Because `r` is a random sample, its sample moments, especially the skewness and kurtosis, typically differ somewhat from the specified distribution moments.

`pearsrnd` uses the definition of kurtosis for which a normal distribution has a kurtosis of 3. Some definitions of kurtosis subtract 3, so that a normal distribution has a kurtosis of 0. The `pearsrnd` function does not use this convention.

Some combinations of moments are not valid; in particular, the kurtosis must be greater than the square of the skewness plus 1. The kurtosis of the normal distribution is defined to be 3.

`r = pearsrnd(mu, sigma, skew, kurt)` returns a scalar value.

`r = pearsrnd(mu, sigma, skew, kurt, m, n, ...)` or `r = pearsrnd(mu, sigma, skew, kurt, [m, n, ...])` returns an m -by- n -by-... array.

`[r,type] = pearsrnd(...)` returns the type of the specified distribution within the Pearson system. `type` is a scalar integer from 0 to 7. Set `m` and `n` to 0 to identify the distribution type without generating any random values.

The seven distribution types in the Pearson system correspond to the following distributions:

- 0 — Normal distribution
- 1 — Four-parameter beta distribution
- 2 — Symmetric four-parameter beta distribution
- 3 — Three-parameter gamma distribution
- 4 — Not related to any standard distribution. The density is proportional to:
 $(1 + ((x - a)/b)^2)^{-c} \exp(-d \arctan((x - a)/b))$.
- 5 — Inverse gamma location-scale distribution
- 6 — F location-scale distribution
- 7 — Student's t location-scale distribution

`[r,type,coefs] = pearsrnd(...)` returns the coefficients `coefs` of the quadratic polynomial that defines the distribution via the differential equation

$$\frac{d}{dx} \log(p(x)) = \frac{-(a+x)}{c(0) + c(1)x + c(2)x^2}.$$

Examples

Generate random values from the standard normal distribution:

```
r = pearsrnd(0,1,0,3,100,1); % Equivalent to randn(100,1)
Determine the distribution type:
```

```
[r,type] = pearsrnd(0,1,1,4,0,0);
r =
type =
1
```

perfcurve

Compute Receiver Operating Characteristic (ROC) curve or other performance curve for classifier output

Syntax

```
[X,Y] = perfcurve(labels,scores,posclass)
[X,Y] = perfcurve(labels,scores,posclass,'Name',value)
[X,Y,T,AUC,OPTROCPT,SUBY,SUBYNAMES] =
perfcurve(labels,scores,posclass)
[X,Y,T,AUC] = perfcurve(labels,scores,posclass)
```

Description

`[X,Y] = perfcurve(labels,scores,posclass)` computes a ROC curve for a vector of classifier predictions `scores` given true class labels, `labels`. `labels` can be a numeric vector, logical vector, character matrix, cell array of strings or categorical vector. `scores` is a numeric vector of scores returned by a classifier for some data. `posclass` is the positive class label (scalar), either numeric (for numeric `labels`), logical (for logical `labels`), or char. The returned values `X` and `Y` are coordinates for the performance curve and can be visualized with `plot(X,Y)`. For more information on `labels`, `scores`, and `posclass`, see “Input Arguments” on page 21-3141 . For more information on `X` and `Y`, see “Output Arguments” on page 21-3145.

`[X,Y] = perfcurve(labels,scores,posclass,'Name',value)` specifies one or more optional parameter name/value pairs, with `Name` in single quotes. See “Input Arguments” on page 21-3141 for a list of inputs, parameter name/value pairs, and respective explanations.

See “Grouping Variables” on page 2-52 for more information on grouping variables.

`[X,Y,T,AUC,OPTROCPT,SUBY,SUBYNAMES] = perfcurve(labels,scores,posclass)` returns:

- An array of thresholds on classifier scores for the computed values of `X` and `Y` (`T`).
- The area under curve (AUC) for the computed values of `X` and `Y`.
- The optimal operating point of the ROC curve (`OPTROCPT`).

- An array of Y values for negative subclasses (SUBY).
- A cell array of negative class names (SUBYNAMES).

For more information on each output, see “Output Arguments” on page 21-3145.

`[X,Y,T,AUC] = perfcurve(labels,scores,posclass)` also returns pointwise confidence bounds for the computed values X, Y, T, and AUC if you supply cell arrays for `labels` and `scores` or set `NBoot` (see “Input Arguments” on page 21-3141) to a positive integer. To compute the confidence bounds, `perfcurve` uses either vertical averaging (VA) or threshold averaging (TA). The returned values Y are an *m*-by-3 array in which the 1st element in every row gives the mean value, the 2nd element gives the lower bound and the 3rd element gives the upper bound. The returned AUC is a row-vector with 3 elements following the same convention. For VA, the returned values T are an *m*-by-3 array and X is a column-vector. For TA, the returned values X are an *m*-by-3 matrix and T is a column-vector.

`perfcurve` computes confidence bounds using either cross validation or bootstrap. If you supply cell arrays for `labels` and `scores`, `perfcurve` uses cross validation and treats elements in the cell arrays as cross validation folds. `labels` can be a cell array of numeric vectors, logical vectors, character matrices, cell arrays of strings or categorical vectors. All elements in `labels` must have the same type. `scores` is a cell array of numeric vectors. The cell arrays for `labels` and `scores` must have the same number of elements, and the number of labels in cell *k* must be equal to the number of scores in cell *k* for any *k* in the range from 1 to the number of elements in `scores`.

If you set `NBoot` to a positive integer, `perfcurve` generates `nboot` bootstrap replicas to compute pointwise confidence bounds. You cannot supply cell arrays for `labels` and `scores` and set `NBoot` to a positive integer at the same time.

`perfcurve` returns pointwise confidence bounds. It does not return a simultaneous confidence band for the entire curve.

If you use 'XCrit' or 'YCrit' options described below to set the criterion for X or Y to an anonymous function, `perfcurve` can only compute confidence bounds by bootstrap.

Input Arguments

`labels`

`labels` can be a numeric vector, logical vector, character matrix, cell array of strings or categorical vector.

<code>scores</code>	<code>scores</code> is a numeric vector of scores returned by a classifier for some data. This vector must have as many elements as <code>labels</code> does.
<code>posclass</code>	<p><code>posclass</code> is the positive class label. If <code>labels</code> is a:</p> <ul style="list-style-type: none"> • Numeric vector, then <code>posclass</code> is a numeric scalar • Logical vector, then <code>posclass</code> is a logical scalar • Character matrix, then <code>posclass</code> is a character string • Cell array of strings, then <code>posclass</code> is a character string or cell containing a character string • Categorical vector, then <code>posclass</code> is a categorical scalar <p><code>posclass</code> must be a member of <code>labels</code>.</p>

Name-Value Pair Arguments

Name	Value and Description
<code>negClass</code>	List of negative classes. Can be either a numeric array or an array of chars or a cell array of strings. By default, <code>negClass</code> is set to 'all' and all classes found in the input array of labels that are not the positive class are considered negative. If <code>negClass</code> is a subset of the classes found in the input array of labels, instances with labels that do not belong to either positive or negative classes are discarded.
<code>xCrit</code>	<p>Criterion to compute for X. This criterion must be a monotone function of the positive class score. <code>perfcurve</code> supports the following criteria:</p> <ul style="list-style-type: none"> • TP — Number of true positive instances. • FN — Number of false negative instances. • FP — Number of false positive instances. • TN — Number of true negative instances. • TP+FP — Sum of TP and FP. • RPP — Rate of positive predictions. $RPP = (TP+FP) / (TP+FN+FP+TN)$ • RNP — Rate of negative predictions. $RNP = (TN+FN) / (TP+FN+FP+TN)$

Name	Value and Description
	<ul style="list-style-type: none"> • <code>accu</code> — Accuracy. $\text{accu} = (\text{TP} + \text{TN}) / (\text{TP} + \text{FN} + \text{FP} + \text{TN})$ • <code>TPR</code>, <code>sens</code>, <code>reca</code> — True positive rate, sensitivity, recall. $\text{TPR}, \text{sens}, \text{reca} = \text{TP} / (\text{TP} + \text{FN})$ • <code>FNR</code>, <code>miss</code> — False negative rate, miss. $\text{FNR}, \text{miss} = \text{FN} / (\text{TP} + \text{FN})$ • <code>FPR</code>, <code>fall</code> — False positive rate, fallout. $\text{FPR}, \text{fall} = \text{FP} / (\text{TN} + \text{FP})$ • <code>TNR</code>, <code>spec</code> — True negative rate, specificity. $\text{TNR}, \text{spec} = \text{TN} / (\text{TN} + \text{FP})$ • <code>PPV</code>, <code>prec</code> — Positive predictive value, precision. $\text{PPV}, \text{prec} = \text{TP} / (\text{TP} + \text{FP})$ • <code>NPV</code> — Negative predictive value. $\text{NPV} = \text{TN} / (\text{TN} + \text{FN})$ • <code>ecost</code> — Expected cost. $\text{ecost} = (\text{TP} * \text{COST}(P P) + \text{FN} * \text{COST}(N P) + \text{FP} * \text{COST}(P N) + \text{TN} * \text{COST}(N N)) / (\text{TP} + \text{FN} + \text{FP} + \text{TN})$ <p>In addition, you can define an arbitrary criterion by supplying an anonymous function of three arguments, (<code>C</code>, <code>scale</code>, <code>cost</code>), where <code>C</code> is a 2-by-2 confusion matrix, <code>scale</code> is a 2-by-1 array of class scales, and <code>cost</code> is a 2-by-2 misclassification cost matrix.</p>
	<hr/> <p>Caution Some of these criteria return NaN values at one of the two special thresholds, 'reject all' and 'accept all'.</p> <hr/>
yCrit	<p>Criterion to compute for Y. <code>perfcurve</code> supports the same criteria as for X. This criterion does not have to be a monotone function of the positive class score.</p>
xVals	<p>Values for the X criterion. The default value for <code>xVals</code> is 'all' and <code>perfcurve</code> computes X and Y values for all scores. If the value for <code>xVals</code> is not 'all', it must be a numeric array. In this case, <code>perfcurve</code> computes X and Y only for the specified <code>xVals</code>.</p>

Name	Value and Description
TVals	Thresholds for the positive class score. By default, TVals is unset and <code>perfcurve</code> computes X, Y, and T values for all scores. You can set TVals to either 'all' or a numeric array. If TVals is set to 'all' or unset and XVals is unset, <code>perfcurve</code> returns X, Y, and T values for all scores and computes pointwise confidence bounds for Y and X using threshold averaging. If TVals is set to a numeric array, <code>perfcurve</code> returns X, Y, and T values for the specified thresholds and computes pointwise confidence bounds for Y and X at these thresholds using threshold averaging. You cannot set XVals and TVals at the same time.
UseNearest	'on' to use nearest values found in the data instead of the specified numeric XVals or TVals and 'off' otherwise. If you specify numeric XVals and set UseNearest to 'on', <code>perfcurve</code> returns nearest unique values X found in the data, as well as corresponding values of Y and T. If you specify numeric XVals and set UseNearest to 'off', <code>perfcurve</code> returns these XVals sorted. By default this parameter is set to 'on'. If you compute confidence bounds by cross validation or bootstrap, this parameter is always 'off'.
ProcessNaN	Specifies how <code>perfcurve</code> processes NaN scores. The default value is 'ignore' and <code>perfcurve</code> removes observations with NaN scores from the data. If you set the parameter to 'addtofalse', <code>perfcurve</code> adds instances with NaN scores to false classification counts in the respective class. That is, <code>perfcurve</code> always counts instances from the positive class as false negative (FN), and always counts instances from the negative class as false positive (FP).
Prior	Either string or array with two elements. It represents prior probabilities for the positive and negative class, respectively. Default is 'empirical', that is, <code>perfcurve</code> derives prior probabilities from class frequencies. If set to 'uniform', <code>perfcurve</code> sets all prior probabilities equal.
Cost	A 2-by-2 matrix of misclassification costs $[C(P P) \ C(N P); \ C(P N) \ C(N N)]$ where $C(I J)$ is the cost of misclassifying class J as class I. By default set to $[0 \ 0.5; \ 0.5 \ 0]$.
Alpha	A numeric value between 0 and 1. <code>perfcurve</code> returns $100*(1-Alpha)$ percent pointwise confidence bounds for X, Y, T and AUC. By default set to 0.05 for 95% confidence interval.

Name	Value and Description
Weights	A numeric vector of nonnegative observation weights. This vector must have as many elements as <code>scores</code> or <code>labels</code> do. If you supply cell arrays for <code>scores</code> and <code>labels</code> and you need to supply <code>weights</code> , you must supply them as a cell array too. In this case, every element in <code>weights</code> must be a numeric vector with as many elements as the corresponding element in <code>scores</code> : <code>numel(weights{1})==numel(scores{1})</code> etc. To compute X, Y and T or to compute confidence bounds by cross validation, <code>perfcurve</code> uses these observation weights instead of observation counts. To compute confidence bounds by bootstrap, <code>perfcurve</code> samples N out of N with replacement using these weights as multinomial sampling probabilities.
NBoot	Number of bootstrap replicas for computation of confidence bounds. Must be a positive integer. By default this parameter is set to zero, and bootstrap confidence bounds are not computed. If you supply cell arrays for <code>labels</code> and <code>scores</code> , this parameter must be set to zero because <code>perfcurve</code> cannot use both cross validation and bootstrap to compute confidence bounds.
BootType	Confidence interval type <code>bootci</code> uses to compute confidence bounds. You can specify any type supported by <code>bootci</code> . By default set to <code>'bca'</code> .
BootArg	Optional input arguments for <code>bootci</code> used to compute confidence bounds. You can specify all arguments <code>bootci</code> supports. Empty by default.

Output Arguments

- X *x*-coordinates for the performance curve. By default, X is false positive rate, FPR, (equivalently, fallout, or 1-specificity). To change this output, use the `'xCrit'` name/value input. For accepted criterion, see `'xCrit'` in “Input Arguments” on page 21-3141 for more information.
- Y *y*-coordinates for the performance curve. By default, Y is true positive rate, TPR, (equivalently, recall, or sensitivity). To change this output, use the `'yCrit'` input. For accepted criterion, see `'xCrit'` in “Input Arguments” on page 21-3141 for more information.

- T** An array of thresholds on classifier scores for the computed values of X and Y. It has the same number of rows as X and Y. For each threshold, TP is the count of true positive observations with scores greater or equal to this threshold, and FP is the count of false positive observations with scores greater or equal to this threshold. `perfcurve` defines negative counts, TN and FN, in a similar way then sorts the thresholds in the descending order which corresponds to the ascending order of positive counts.
- For the M distinct thresholds found in the array of scores, `perfcurve` returns the X, Y and T arrays with M+1 rows. `perfcurve` sets elements T(2:M+1) to the distinct thresholds, and T(1) replicates T(2). By convention, T(1) represents the highest 'reject all' threshold and `perfcurve` computes the corresponding values of X and Y for TP=0 and FP=0. T(end) is the lowest 'accept all' threshold for which TN=0 and FN=0.
- AUC** The area under curve (AUC) for the computed values of X and Y. If you set `xVals` to 'all' (the default), `perfcurve` computes AUC using the returned X and Y values. If `xVals` is a numeric array, `perfcurve` computes AUC using X and Y values found from all distinct scores in the interval specified by the smallest and largest elements of `xVals`. More precisely, `perfcurve` finds X values for all distinct thresholds as if `xVals` were set to 'all', then uses a subset of these (with corresponding Y values) between `min(xVals)` and `max(xVals)` to compute AUC. The function uses trapezoidal approximation to estimate the area. If the first or last value of X or Y are NaNs, `perfcurve` removes them to allow calculation of AUC. This takes care of criteria that produce NaNs for the special 'reject all' or 'accept all' thresholds, for example, positive predictive value (PPV) or negative predictive value (NPV).

OPTROOPT The optimal operating point of the ROC curve as an array of size 1-by-2 with FPR and TPR values for the optimal ROC operating point. `perfcurve` computes `optroopt` only for the standard ROC curve and sets to NaNs otherwise. To obtain the optimal operating point for the ROC curve, `perfcurve` first finds the slope, S , using

$$S = \frac{\text{cost}(P | N) - \text{cost}(N | N) * N}{\text{cost}(N | P) - \text{cost}(P | P) * P}$$

where $\text{cost}(I | J)$ is the cost of assigning an instance of class J to class I , and $P=TP+FN$ and $N=TN+FP$ are the total instance counts in the positive and negative class, respectively. `perfcurve` then finds the optimal operating point by moving the straight line with slope S from the upper left corner of the ROC plot ($FPR=0$, $TPR=1$) down and to the right until it intersects the ROC curve.

SUBY An array of Y values for negative subclasses. If you only specify one negative class, **SUBY** is identical to Y . Otherwise **SUBY** is a matrix of size M -by- K , where M is the number of returned values for X and Y , and K is the number of negative classes. `perfcurve` computes Y values by summing counts over all negative classes. **SUBY** gives values of the Y criterion for each negative class separately. For each negative class, `perfcurve` places a new column in **SUBY** and fills it with Y values for TN and FP counted just for this class.

SUBYNAMES A cell array of negative class names. If you provide an input array, `negClass`, of negative class names, `perfcurve` copies it into **SUBYNAMES**. If you do not provide `negClass`, `perfcurve` extracts **SUBYNAMES** from input labels. The order of **SUBYNAMES** is the same as the order of columns in **SUBY**, that is, `SUBY(:,1)` is for negative class `SUBYNAMES{1}` etc.

Examples

Plot a ROC Curve for Classification Algorithms

Plot the ROC curve for classification by logistic regression.

```
load fisheriris
x = meas(51:end,1:2);
```

```

% Iris data, 2 classes and 2 features
y = (1:100) '>50';
% Versicolor = 0, virginica = 1
b = glmfit(x,y,'binomial');
% Logistic regression
p = glmval(b,x,'logit');
% Fit probabilities for scores
[X,Y,T,AUC] = perfcurve(species(51:end,:),p,'virginica');
plot(X,Y)
xlabel('False positive rate'); ylabel('True positive rate')
title('ROC for classification by logistic regression')

```

Obtain errors on TPR by vertical averaging.

```
[X,Y] = perfcurve(species(51:end,:),p,'virginica',...
```

```
'NBoot',1000,'XVals','All');  
% Plot errors  
errorbar(X,Y(:,1),Y(:,1)-Y(:,2),Y(:,3)-Y(:,1));
```

perms

Enumeration of permutations

Syntax

`P = perms(v)`

Description

`P = perms(v)`, where `v` is a row vector of length `n`, creates a matrix whose rows consist of all possible permutations of the `n` elements of `v`. The matrix `P` contains `n!` rows and `n` columns.

`perms` is only practical when `n` is less than about 11 (for `n = 11`, the output takes over 3 gigabytes).

Examples

```
perms([2 4 6])
```

```
ans =
```

```
6 4 2
6 2 4
4 6 2
4 2 6
2 4 6
2 6 4
```

piecwisedistribution class

Piecewise-defined distributions

Construction

`piecwisedistribution` is an abstract class. To construct a `piecwisedistribution` object, use the subclass constructor, `paretotails`.

Methods

<code>boundary</code>	Piecewise distribution boundaries
<code>cdf</code>	Cumulative distribution function for piecewise distribution
<code>disp</code>	Display <code>piecwisedistribution</code> object
<code>display</code>	Display <code>piecwisedistribution</code> object
<code>icdf</code>	Inverse cumulative distribution function for piecewise distribution
<code>nsegments</code>	Number of segments
<code>pdf</code>	Probability density function for piecewise distribution
<code>random</code>	Random numbers from piecewise distribution
<code>segment</code>	Segments containing values

Properties

Objects of the `piecewisedistribution` class have no properties accessible by dot indexing, `get` methods, or `set` methods. To obtain information about a `piecewisedistribution` object, use the appropriate method.

Copy Semantics

Value. To learn how this affects your use of the class, see “Comparing Handle and Value Classes” in the MATLAB Object-Oriented Programming documentation.

piecewisedistribution

Class: piecewisedistribution

Create piecewise distribution object

Description

piecewisedistribution is an abstract class, and you cannot create instances of it directly. You can create `paretotails` objects that are derived from this class.

See Also

`paretotails`

prob.PiecewiseLinearDistribution class

Package: prob

Superclasses: prob.ParametricTruncatableDistribution

Piecewise linear probability distribution object

Description

`prob.PiecewiseLinearDistribution` is an object consisting of a model description for a piecewise linear probability distribution. Create a probability distribution object with specified parameters using `makedist`.

Construction

`pd = makedist('PiecewiseLinear')` creates a piecewise linear probability distribution object using the default parameter values.

`pd = makedist('PiecewiseLinear', 'x', x, 'Fx', Fx)` creates a piecewise linear probability distribution object using the specified values.

Input Arguments

x — Data values

1 (default) | vector of scalar values

Data values at which the cumulative distribution function (cdf) changes slope, specified as a vector of scalar values.

Data Types: `single` | `double`

Fx — cdf value

1 (default) | vector of scalar values

cdf value at each value in `x`, specified as a vector of scalar values. `x` and `Fx` must be the same size. The first value in the vector `Fx` must be 0, and the last element must be 1. `Fx` increases linearly between `x(j)` and `x(j+1)`, for all `j`.

Data Types: `single` | `double`

Properties

x — Data values

vector of scalar values

Data values at which the cumulative distribution function (cdf) changes slope, stored as a vector of scalar values.

Data Types: `single` | `double`

Fx — cdf value

vector of scalar values

cdf value at each value in `x`, stored as a vector of scalar values.

Data Types: `single` | `double`

DistributionName — Probability distribution name

probability distribution name string

Probability distribution name, stored as a valid probability distribution name string. This property is read-only.

Data Types: `char`

IsTruncated — Logical flag for truncated distribution

0 | 1

Logical flag for truncated distribution, stored as a logical value. If `IsTruncated` equals 0, the distribution is not truncated. If `IsTruncated` equals 1, the distribution is truncated. This property is read-only.

Data Types: `logical`

NumParameters — Number of parameters

positive integer value

Number of parameters for the probability distribution, stored as a positive integer value. This property is read-only.

Data Types: `single` | `double`

ParameterDescription — Distribution parameter descriptions

cell array of strings

Distribution parameter descriptions, stored as a cell array of strings. Each cell contains a short description of one distribution parameter. This property is read-only.

Data Types: char

ParameterNames — Distribution parameter names

cell array of strings

Distribution parameter names, stored as a cell array of strings. This property is read-only.

Data Types: char

ParameterValues — Distribution parameter values

vector of scalar values

Distribution parameter values, stored as a vector. This property is read-only.

Data Types: single | double

Truncation — Truncation interval

vector of scalar values

Truncation interval for the probability distribution, stored as a vector containing the lower and upper truncation boundaries. This property is read-only.

Data Types: single | double

Methods

Inherited Methods

cdf

Cumulative distribution function of probability distribution object

icdf

Inverse cumulative distribution function of probability distribution object

iqr

Interquartile range of probability distribution object

median	Median of probability distribution object
pdf	Probability density function of probability distribution object
random	Generate random numbers from probability distribution object
truncate	Truncate probability distribution object
mean	Mean of probability distribution object
std	Standard deviation of probability distribution object
var	Variance of probability distribution object

Definitions

Piecewise Linear Distribution

The piecewise linear distribution is a nonparametric probability distribution created using a piecewise linear representation of the cumulative distribution function (cdf). The options specified for the piecewise linear distribution specify the form of the cdf. The probability density function (pdf) is a step function.

Examples

Create a Piecewise Linear Distribution Object Using Default Parameters

Create a piecewise linear distribution object using the default parameter values.

```
pd = makedist('PiecewiseLinear')
```

```
pd =
```

```
PiecewiseLinearDistribution
```

```
F(0) = 0
```

```
F(1) = 1
```

Create a Piecewise Linear Distribution Object Using Specified Parameters

Load the sample data. Visualize the patient weight data using a histogram.

```
load hospital;  
hist(hospital.Weight)
```

The histogram shows that the data has two modes, one for female patients and one for male patients.

Compute the empirical cumulative distribution function (ecdf) for the data.

```
[f,x] = ecdf(hospital.Weight);
```

Construct a piecewise linear approximation to the ecdf and plot both functions.

```
f = f(1:5:end); % keep a less dense grid of points  
x = x(1:5:end);
```

```
figure;  
ecdf(hospital.Weight)  
hold on  
plot(x,f,'ro','MarkerFace','r') % overlay grid  
plot(x,f,'k') % show interpolation
```

Create a piecewise linear probability distribution object using the piecewise approximation of the ecdf.

```
pd = makedist('PiecewiseLinear', 'x', x, 'Fx', f)
```

```
pd =
```

```
    PiecewiseLinearDistribution
```

```
F(111) = 0
```

```
F(118) = 0.05
```

```
F(124) = 0.13
```

```
F(130) = 0.25
```

```
F(135) = 0.37
```

```
F(142) = 0.5
```

```
F(163) = 0.55
```

```
F(171) = 0.61
```

```
F(178) = 0.7
```

```
F(183) = 0.82
```

```
F(189) = 0.94
```

```
F(202) = 1
```

Generate 100 random numbers from the distribution.

```
rw = random(pd, 100, 1);
```

Plot the random numbers to visually compare their distribution to the original data.

```
figure;  
hist(rw)
```

The random numbers generated from the piecewise linear distribution have the same bimodal distribution as the original data.

plot

Class: clustering.evaluation.ClusterCriterion

Package: clustering.evaluation

Plot clustering evaluation object criterion values

Syntax

```
plot(eva)  
h = plot(eva)
```

Description

`plot(eva)` displays a plot of the criterion values versus the number of clusters, based on the values stored in the clustering evaluation object `eva`.

`h = plot(eva)` returns a handle to the plot line.

Input Arguments

eva — Clustering evaluation data

clustering evaluation object

Clustering evaluation data, specified as a clustering evaluation object. Create a clustering evaluation object using `evalclusters`.

Output Arguments

h — Handle to plot line

scalar value

Handle to the plot line, returned as a scalar value.

Examples

Plot the Clustering Evaluation Criterion Values

Plot the criterion values versus the number of clusters for each clustering solution stored in a clustering evaluation object.

Load the sample data.

```
load fisheriris;
```

The data contains length and width measurements from the sepals and petals of three species of iris flowers.

Create a clustering evaluation object. Cluster the data using `kmeans`, and evaluate the optimal number of clusters using the Calinski-Harabasz criterion.

```
rng('default'); % For reproducibility  
eva = evalclusters(meas,'kmeans','CalinskiHarabasz','KList',[1:6]);
```

Plot the Calinski-Harabasz criterion values for each number of clusters tested.

```
figure;  
plot(eva);
```

The plot shows that the highest Calinski-Harabasz value occurs at three clusters, suggesting that the optimal number of clusters is three.

See Also
evalclusters

plot

Class: LinearModel

Scatter plot or added variable plot of linear model

Syntax

```
plot mdl  
h = plot(mdl)
```

Description

`plot(mdl)` creates a plot of the fitted linear model. The plot type depends on the number of predictor variables.

- If there is just one predictor variable, `plot` creates a scatter plot of the data along with a fitted curve and confidence bounds.
- If there are multiple predictor variables, `plot` creates an added variable plot.
- If there are no predictors, `plot` creates a histogram of the residuals.

`h = plot(mdl)` returns handles to the lines in the plot.

Input Arguments

mdl

Linear model, as constructed by `fitlm` or `stepwiselm`.

Output Arguments

h

Vector of handles to lines or patches in the plot.

Definitions

Added Variable Plot, Adjusted Response

An added variable plot illustrates the incremental effect on the response of specified terms by removing the effects of all other terms. The slope of the fitted line is the coefficient of the linear combination of the specified terms projected onto the best-fitting direction. The adjusted response includes the constant (intercept) terms, and averages out all other terms.

Examples

Create an Added Variable Plot

Create a model of car mileage as a function of weight and model year. Then create a plot to see the significance of the model.

Create a linear model of mileage from the `carsmall` data.

```
load carsmall
tbl = table(MPG,Weight);
tbl.Year = ordinal(Model_Year);
mdl = fitlm(tbl,'MPG ~ Year + Weight^2');
```

Create an added variable plot.

```
plot(mdl)
```

The plot illustrates that the model is significant—a horizontal line does not fit between the confidence bounds.

Alternatives

Use `plotAdded` to select particular predictors for an added variable plot.

plot

Class: RepeatedMeasuresModel

Plot data with optional grouping

Syntax

```
plot(rm)
plot(rm, Name, Value)
H = plot( ___ )
```

Description

`plot(rm)` plots the measurements in the repeated measures model `rm` for each subject as a function of time. If there is a single numeric within-subjects factor, `plot` uses the values of that factor as the time values. Otherwise, `plot` uses the discrete values 1 through r as the time values, where r is the number of repeated measurements.

`plot(rm, Name, Value)` also plots the measurements in the repeated measures model `rm`, with additional options specified by one or more `Name, Value` pair arguments.

For example, you can specify the factors to group by or change the line colors.

`H = plot(___)` returns handles, `H`, to the plotted lines.

Input Arguments

rm — Repeated measures model
RepeatedMeasuresModel object

Repeated measures model, returned as a `RepeatedMeasuresModel` object.

For properties and methods of this object, see `RepeatedMeasuresModel`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1`, `Value1`, . . . , `NameN`, `ValueN`.

'Group' — Name of between-subject factor or factors

string | cell array of strings

Name of between-subject factor or factors, specified as the comma-separated pair consisting of `'Group'` and a string or cell array of strings. This name-value pair argument groups the lines according to the factor values.

For example, if you have two between-subject factors, `drug` and `sex`, and you want to group the lines in the plot according to them, you can specify these factors as follows.

Example: `'Group', {'Drug', 'Sex'}`

Data Types: char | cell

'Marker' — Marker to use for each group

cell array of strings

Marker to use for each group, specified as the comma-separated pair consisting of `'Marker'` and a cell array of strings.

For example, if you have two between-subject factors, `drug` and `sex`, with each having two groups, you can specify `o` as the marker for the groups of `drug` and `x` as the marker for the groups of `sex` as follows.

Example: `'Marker', {'o', 'o', 'x', 'x'}`

Data Types: cell

'Color' — Color for each group

string | cell array of strings | rows of a three-column RGB matrix

Color for each group, specified as the comma-separated pair consisting of `'Color'` and a string, cell array of strings, or rows of a three-column RGB matrix.

For example, if you have two between-subject factors, `drug` and `sex`, with each having two groups, you can specify `red` as the color for the groups of `drug` and `blue` as the color for the groups of `sex` as follows.

Example: `'Color', 'rbb'`

Data Types: `single | double | cell`

'LineStyle' — Line style for each group

cell array of strings

Line style for each group, specified as the comma-separated pair consisting of 'LineStyle' and a cell array of strings.

For example, if you have two between-subject factors, drug and sex, with each having two groups, you can specify - as the line style of one group and : as the line style for the other group as follows.

Example: `'LineStyle', {'-' ':' '-' ':'}`

Data Types: `cell`

Output Arguments

H — Handle to plotted lines

handle

Handle to plotted lines, returned as a handle.

Examples

Plot Data by Group

Load the sample data.

```
load fisheriris
```

The column vector `species` consists of iris flowers of three different species: `setosa`, `versicolor`, and `virginica`. The double matrix `meas` consists of four types of measurements on the flowers: the length and width of sepals and petals in centimeters, respectively.

Store the data in a table array.

```
t = table(species,meas(:,1),meas(:,2),meas(:,3),meas(:,4),...
'VariableNames',{'species','meas1','meas2','meas3','meas4'});
```

```
Meas = dataset([1 2 3 4]', 'VarNames', {'Measurements'});
```

Fit a repeated measures model, where the measurements are the responses and the species is the predictor variable.

```
rm = fitrm(t, 'meas1-meas4~species', 'WithinDesign', Meas);
```

Plot data grouped by the factor species.

```
plot(rm, 'group', 'species')
```

Change the line style for each group.

```
plot(rm, 'group', 'species', 'LineStyle', {'-', '--', ':'})
```

Plot Data Grouped by Two Factors

Load the sample data.

load `repeatedmeas`

The table `between` includes the between-subject variables `age`, `IQ`, `group`, `gender`, and eight repeated measures `y1` through `y8` as responses. The table `within` includes the within-subject variables `w1` and `w2`. This is simulated data.

Fit a repeated measures model, where the repeated measures `y1` through `y8` are the responses, and `age`, `IQ`, `group`, `gender`, and the `group-gender` interaction are the predictor variables. Also specify the within-subject design matrix.

```
rm = fitrm(between,'y1-y8 ~ Group*Gender + Age + IQ','WithinDesign',within);
```

Plot data with Group coded by color and Gender coded by line type.

```
plot(R,'group',{ 'Group' 'Gender' },'Color',{'r' 'rb' 'bg' },...  
      'LineStyle',{'-' ':' '-.' ':' '-.-' ':' '-.-.' ':' '-.-.-' ':' },'Marker',{'.'})
```

plotAdded

Class: LinearModel

Added variable plot or leverage plot for linear model

Syntax

```
plotAdded(md1)
plotAdded(md1,coef)
h = plotAdded(md1,...)
h = plotAdded(md1,coef,Name,Value)
```

Description

`plotAdded(md1)` produces a generalized added variable plot for all terms in `md1` except the constant term.

`plotAdded(md1,coef)` produces an added variable plot for the `coef` terms in `md1`, after adjusting for all other terms.

`h = plotAdded(md1,...)` returns handles to the lines in the plot.

`h = plotAdded(md1,coef,Name,Value)` plots with additional options specified by one or more `Name,Value` pair arguments.

Tips

- For many plots, the Data Cursor tool in the figure window displays the x and y values for any data point, along with the observation name or number.

Input Arguments

md1

Linear model, as constructed by `fitlm` or `stepwiselm`.

coef

Coefficients in `mdl`. Represent as:

- String giving a single coefficient name
- Vector of coefficient numbers in the `mdl.CoefficientNames` property

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Note: The plot property name-value pairs apply to the first returned handle `h(1)`.

'Color'

Color of the line or marker, a string or `ColorSpec` specification. For details, see `linespec`.

'LineStyle'

Type of line, a string or Chart Line Properties specification. For details, see `linespec`.

'LineWidth'

Width of the line or edges of filled area, in points, a positive scalar. One point is 1/72 inch.

Default: 0.5

'MarkerEdgeColor'

Color of the marker or edge color for filled markers, a string or `ColorSpec` specification. For details, see `linespec`.

'MarkerFaceColor'

Color of the marker face for filled markers, a string or `ColorSpec` specification. For details, see `linespec`.

'MarkerSize'

Size of the marker in points, a strictly positive scalar. One point is 1/72 inch.

Output Arguments

h

Vector of handles to lines or patches in the plot.

Definitions

Added Variable Plot, Adjusted Response

An added variable plot illustrates the incremental effect on the response of specified terms by removing the effects of all other terms. The slope of the fitted line is the coefficient of the linear combination of the specified terms projected onto the best-fitting direction. The adjusted response includes the constant (intercept) terms, and averages out all other terms.

Examples

Create an Added Variable Plot

Create a model of car mileage as a function of weight and model year. Then create a plot to see the significance of the model.

Create a linear model of mileage from the `carsmall` data.

```
load carsmall
ds = dataset(MPG,Weight);
ds.Year = ordinal(Model_Year);
mdl = fitlm(ds,'MPG ~ Year + Weight^2');
```

Create an added variable plot.

```
plotAdded(mdl)
```

The plot illustrates that the model is significant—a horizontal line does not fit between the confidence bounds.

Create an Added Variable Plot for Particular Variables

Create a model of car mileage as a function of weight and model year. Then create a plot to see the effect of the weight terms (`Weight` and `Weight^2`).

Create a linear model of mileage from the `carsmall` data.

```
load carsmall
ds = dataset(MPG,Weight);
ds.Year = ordinal(Model_Year);
mdl = fitlm(ds,'MPG ~ Year + Weight^2');
```

Find the terms in the model corresponding to the `Weight` and `Weight^2`.

```
mdl.CoefficientNames
```

```
ans =
```

```
'(Intercept)' 'Weight' 'Year_76' 'Year_82' 'Weight^2'
```

The weight terms are 2 and 5.

Create an added variable plot with the weight terms.

```
coef = [2 5];
plotAdded(md1,coef)
```

The plot illustrates that the weight terms are significant—a horizontal line does not fit between the confidence bounds.

plotAdjustedResponse

Class: LinearModel

Adjusted response plot for linear regression model

Syntax

```
plotAdjustedResponse mdl, var
h = plotAdjustedResponse mdl, var
h = plotAdjustedResponse mdl, var, Name, Value
```

Description

`plotAdjustedResponse(mdl, var)` gives an adjusted response plot for the variable `var` in the `mdl` regression model.

`h = plotAdjustedResponse(mdl, var)` returns handles to the lines in the plot.

`h = plotAdjustedResponse(mdl, var, Name, Value)` plots with additional options specified by one or more `Name, Value` pair arguments.

Tips

- For many plots, the Data Cursor tool in the figure window displays the x and y values for any data point, along with the observation name or number.

Input Arguments

mdl

Linear model, as constructed by `fitlm` or `stepwiselm`.

var

Variable name, or scalar index of variable in `mdl.CoefficientNames`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1`, `Value1`, . . . , `NameN`, `ValueN`.

Note: The plot property name-value pairs apply to the first returned handle `h(1)`.

'Color'

Color of the line or marker, a string or `ColorSpec` specification. For details, see `linespec`.

'LineStyle'

Type of line, a string or `Chart Line Properties` specification. For details, see `linespec`.

'LineWidth'

Width of the line or edges of filled area, in points, a positive scalar. One point is 1/72 inch.

Default: 0.5

'MarkerEdgeColor'

Color of the marker or edge color for filled markers, a string or `ColorSpec` specification. For details, see `linespec`.

'MarkerFaceColor'

Color of the marker face for filled markers, a string or `ColorSpec` specification. For details, see `linespec`.

'MarkerSize'

Size of the marker in points, a strictly positive scalar. One point is 1/72 inch.

Output Arguments

h

Vector of handles to lines or patches in the plot.

Definitions

Adjusted Response Plot

The adjusted response plot shows the fitted response as a function of `var`, with the other predictors averaged out by averaging the fitted values over the data used in the fit. Adjusted data points are computed by adding the residual to the adjusted fitted value for each observation.

Examples

Plot Adjusted Responses

Plot the adjusted responses of a fitted linear model.

Load the `carsmall` data and fit a linear model of the mileage as a function of model year, weight, and weight squared.

```
load carsmall
ds = dataset(MPG,Weight);
ds.Year = ordinal(Model_Year);
mdl = fitlm(ds,'MPG ~ Year + Weight^2');
```

Plot the effect of 'Weight' averaged over Year values.

```
plotAdjustedResponse(mdl,'Weight')
```

Plot the effect of Year averaged over 'Weight' values. Include the h output.

```
h = plotAdjustedResponse(md1, 'Year');
```

Change the adjusted data to black x instead of red o.

```
set(h(1), 'Marker', 'x', 'Color', 'k')
```

How To

- “Linear Regression” on page 9-11

plotDiagnostics

Class: GeneralizedLinearModel

Plot diagnostics of generalized linear regression model

Syntax

```
plotDiagnostics mdl  
plotDiagnostics mdl, plottype  
h = plotDiagnostics(...)  
h = plotDiagnostics mdl, plottype, Name, Value
```

Description

`plotDiagnostics(mdl)` plots diagnostics from the `mdl` linear model using leverage as the plot type.

`plotDiagnostics(mdl, plottype)` plots diagnostics from the `mdl` generalized linear model in a plot of type `plottype`.

`h = plotDiagnostics(...)` returns handles to the lines in the plot.

`h = plotDiagnostics(mdl, plottype, Name, Value)` plots with additional options specified by one or more `Name, Value` pair arguments.

Tips

- For many plots, the Data Cursor tool in the figure window displays the x and y values for any data point, along with the observation name or number.

Input Arguments

mdl

Generalized linear model, as constructed by `fitglm` or `stepwiseglm`.

plottype

String specifying the type of plot:

'contour'	Residual vs. leverage with overlaid Cook's contours
'cookd'	Cook's distance
'leverage'	Leverage (diagonal of Hat matrix)

Default: 'leverage'

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Note: The plot property name-value pairs apply to the first returned handle `h(1)`.

'Color'

Color of the line or marker, a string or ColorSpec specification. For details, see `linespec`.

'LineStyle'

Type of line, a string or Chart Line Properties specification. For details, see `linespec`.

'LineWidth'

Width of the line or edges of filled area, in points, a positive scalar. One point is 1/72 inch.

Default: 0.5

'MarkerEdgeColor'

Color of the marker or edge color for filled markers, a string or ColorSpec specification. For details, see `linespec`.

'MarkerFaceColor'

Color of the marker face for filled markers, a string or `ColorSpec` specification. For details, see `linespec`.

'MarkerSize'

Size of the marker in points, a strictly positive scalar. One point is 1/72 inch.

Output Arguments

h

Vector of handles to lines or patches in the plot.

Definitions

Hat Matrix

The *hat matrix* H is defined in terms of the data matrix X and a diagonal weight matrix W :

$$H = X(X^T W X)^{-1} X^T W^T.$$

W has diagonal elements w_i :

$$w_i = \frac{g'(\mu_i)}{\sqrt{V(\mu_i)}},$$

where

- g is the link function mapping y_i to $x_i b$.
- g' is the derivative of the link function g .
- V is the variance function.

- μ_i is the i th mean.

The diagonal elements H_{ii} satisfy

$$0 \leq h_{ii} \leq 1$$
$$\sum_{i=1}^n h_{ii} = p,$$

where n is the number of observations (rows of X), and p is the number of coefficients in the regression model.

Leverage

The *leverage* of observation i is the value of the i th diagonal term, h_{ii} , of the hat matrix H . Because the sum of the leverage values is p (the number of coefficients in the regression model), an observation i can be considered to be an outlier if its leverage substantially exceeds p/n , where n is the number of observations.

Cook's Distance

The Cook's distance D_i of observation i is

$$D_i = w_i \frac{e_i^2}{p\hat{\phi}(1-h_{ii})^2},$$

where

- $\hat{\phi}$ is the dispersion parameter (estimated or theoretical).
- e_i is the linear predictor residual, $g(y_i) - x_i\hat{\beta}$, where
 - g is the link function.
 - y_i is the observed response.
 - x_i is the observation.

- $\hat{\beta}$ is the estimated coefficient vector.
- p is the number of coefficients in the regression model.
- h_{ii} is the i th diagonal element of the Hat Matrix H .

Examples

Diagnostic Plots for Generalized Linear Models

Create leverage and Cook's distance plots of a fitted generalized linear model.

Generate artificial data for the model, Poisson random numbers with two underlying predictors $X(1)$ and $X(2)$.

```
rng('default') % for reproducibility
rndvars = randn(100,2);
X = [2+rndvars(:,1),rndvars(:,2)];
mu = exp(1 + X*[1;2]);
y = poissrnd(mu);
```

Create a generalized linear regression model of Poisson data.

```
mdl = fitglm(X,y,...
    'y ~ x1 + x2', 'distr', 'poisson');
```

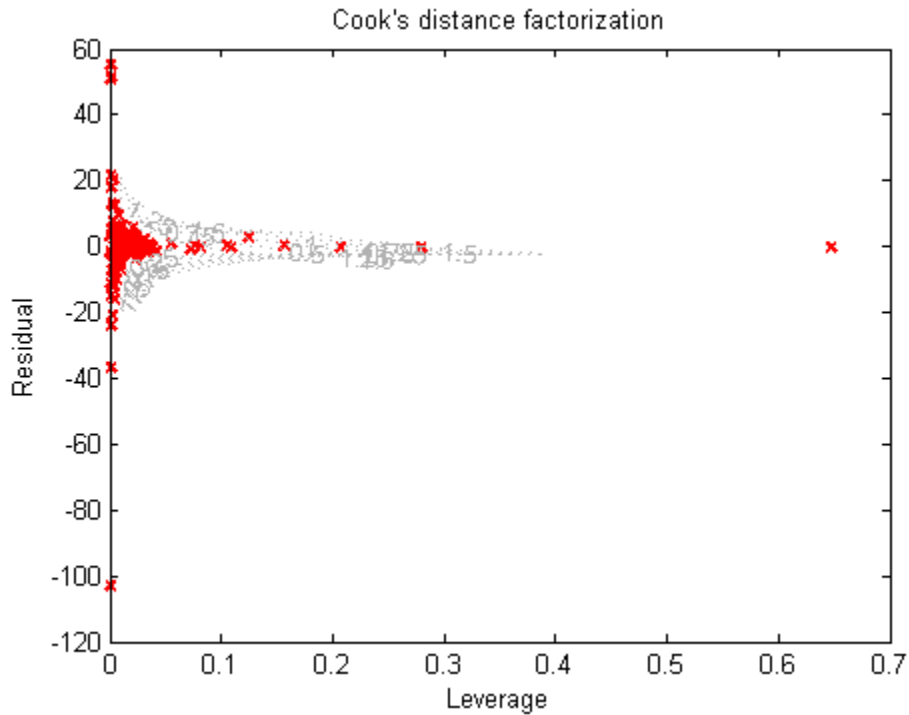

Create a leverage plot.

```
plotDiagnostics(mdl)
```

Create a contour plot with Cook's distance.

```
plotDiagnostics(md1, 'contour')
```

plotDiagnostics

Class: LinearModel

Plot diagnostics of linear regression model

Syntax

```
plotDiagnostics mdl
plotDiagnostics mdl, plottype
h = plotDiagnostics(...)
h = plotDiagnostics(mdl, plottype, Name, Value)
```

Description

`plotDiagnostics(mdl)` plots diagnostics from the `mdl` linear model using scaled delete-1 fitted values.

`plotDiagnostics(mdl, plottype)` plots diagnostics in a plot of type `plottype`.

`h = plotDiagnostics(...)` returns handles to the lines in the plot.

`h = plotDiagnostics(mdl, plottype, Name, Value)` plots with additional options specified by one or more `Name, Value` pair arguments.

Tips

- For many plots, the Data Cursor tool in the figure window displays the x and y values for any data point, along with the observation name or number.

Input Arguments

mdl

Linear model, as constructed by `fitlm` or `stepwiselm`.

plottype

String specifying the type of plot:

'contour'	Residual vs. leverage with overlaid Cook's contours
'cookd'	Cook's distance
'covratio'	Delete-1 ratio of determinant of covariance
'dfbetas'	Scaled delete-1 coefficient estimates
'dffits'	Scaled delete-1 fitted values
'leverage'	Leverage
's2_i'	Delete-1 variance estimate

Delete-1 means compute a new model without the current observation. If the delete-1 calculation differs significantly from the model using all observations, then the observation is influential.

Default: 'leverage'

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1,Value1, . . . ,NameN,ValueN.

Note: The plot property name-value pairs apply to the first returned handle `h(1)`.

'Color'

Color of the line or marker, a string or `ColorSpec` specification. For details, see `linespec`.

'LineStyle'

Type of line, a string or `Chart Line Properties` specification. For details, see `linespec`.

'LineWidth'

Width of the line or edges of filled area, in points, a positive scalar. One point is 1/72 inch.

Default: 0.5

'MarkerEdgeColor'

Color of the marker or edge color for filled markers, a string or `ColorSpec` specification. For details, see `linespec`.

'MarkerFaceColor'

Color of the marker face for filled markers, a string or `ColorSpec` specification. For details, see `linespec`.

'MarkerSize'

Size of the marker in points, a strictly positive scalar. One point is 1/72 inch.

Output Arguments

h

Vector of handles to lines or patches in the plot.

Definitions

Hat Matrix

The *hat matrix* H is defined in terms of the data matrix X :

$$H = X(X^T X)^{-1} X^T.$$

The diagonal elements H_{ii} satisfy

$$0 \leq h_{ii} \leq 1$$

$$\sum_{i=1}^n h_{ii} = p,$$

where n is the number of observations (rows of X), and p is the number of coefficients in the regression model.

Leverage

The *leverage* of observation i is the value of the i th diagonal term, h_{ii} , of the hat matrix H . Because the sum of the leverage values is p (the number of coefficients in the regression model), an observation i can be considered to be an outlier if its leverage substantially exceeds p/n , where n is the number of observations.

Cook's Distance

Cook's distance is the scaled change in fitted values. Each element in `CooksDistance` is the normalized change in the vector of coefficients due to the deletion of an observation. The Cook's distance, D_i , of observation i is

$$D_i = \frac{\sum_{j=1}^n (\hat{y}_j - \hat{y}_{j(i)})^2}{p \text{MSE}},$$

where

- \hat{y}_j is the j th fitted response value.
- $\hat{y}_{j(i)}$ is the j th fitted response value, where the fit does not include observation i .
- MSE is the mean squared error.
- p is the number of coefficients in the regression model.

Cook's distance is algebraically equivalent to the following expression:

$$D_i = \frac{r_i^2}{p \text{MSE}} \left(\frac{h_{ii}}{(1-h_{ii})^2} \right),$$

where r_i is the i th residual, and h_{ii} is the i th leverage value.

`CooksDistance` is an n -by-1 column vector in the `Diagnostics` table of the `LinearModel` object.

Examples

Leverage Plot of Linear Model

Plot the leverage values of observations in a fitted model.

Load the `carsmall` data and fit a linear model of the mileage as a function of model year, weight, and weight squared.

```
load carsmall
ds = dataset(MPG,Weight);
ds.Year = ordinal(Model_Year);
mdl = fitlm(ds,'MPG ~ Year + Weight^2');
```

Plot the leverage values.

```
plotDiagnostics(mdl)
```

Plot the Cook's distance.

```
plotDiagnostics(md1, 'cookd')
```

The two diagnostic plots give different results.

plotDiagnostics

Class: NonLinearModel

Plot diagnostics of nonlinear regression model

Syntax

```
plotDiagnostics mdl
plotDiagnostics mdl, plottype
h = plotDiagnostics(...)
h = plotDiagnostics(mdl, plottype, Name, Value)
```

Description

`plotDiagnostics(mdl)` plots diagnostics from the `mdl` linear model using leverage as the plot type.

`plotDiagnostics(mdl, plottype)` plots diagnostics in a plot of type `plottype`.

`h = plotDiagnostics(...)` returns handles to the lines in the plot.

`h = plotDiagnostics(mdl, plottype, Name, Value)` plots with additional options specified by one or more `Name, Value` pair arguments.

Tips

- For many plots, the Data Cursor tool in the figure window displays the x and y values for any data point, along with the observation name or number.

Input Arguments

mdl

Nonlinear regression model, constructed by `fitnlm`.

plottype

String specifying the type of plot:

'contour'	Residual vs. leverage with overlaid Cook's contours
'cookd'	Cook's distance
'leverage'	Leverage (diagonal of Hat matrix)

Default: 'leverage'

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Note: The plot property name-value pairs apply to the first returned handle `h(1)`.

'Color'

Color of the line or marker, a string or ColorSpec specification. For details, see `linespec`.

'LineStyle'

Type of line, a string or Chart Line Properties specification. For details, see `linespec`.

'LineWidth'

Width of the line or edges of filled area, in points, a positive scalar. One point is 1/72 inch.

Default: 0.5

'MarkerEdgeColor'

Color of the marker or edge color for filled markers, a string or ColorSpec specification. For details, see `linespec`.

'MarkerFaceColor'

Color of the marker face for filled markers, a string or `ColorSpec` specification. For details, see `linespec`.

'MarkerSize'

Size of the marker in points, a strictly positive scalar. One point is 1/72 inch.

Output Arguments

h

Vector of handles to lines or patches in the plot.

Definitions

Hat Matrix

The *hat matrix* H is defined in terms of the data matrix X and the Jacobian matrix J :

$$J_{i,j} = \left. \frac{\partial f}{\partial \beta_j} \right|_{x_i, \beta}$$

Here f is the nonlinear model function, and β is the vector of model coefficients.

The Hat Matrix H is

$$H = J(J^T J)^{-1} J^T.$$

The diagonal elements H_{ii} satisfy

$$0 \leq h_{ii} \leq 1$$

$$\sum_{i=1}^n h_{ii} = p,$$

where n is the number of observations (rows of X), and p is the number of coefficients in the regression model.

Leverage

The *leverage* of observation i is the value of the i th diagonal term, h_{ii} , of the hat matrix H . Because the sum of the leverage values is p (the number of coefficients in the regression model), an observation i can be considered to be an outlier if its leverage substantially exceeds p/n , where n is the number of observations.

Cook's Distance

The Cook's distance D_i of observation i is

$$D_i = \frac{\sum_{j=1}^n (\hat{y}_j - \hat{y}_{j(i)})^2}{p \text{MSE}},$$

where

- \hat{y}_j is the j th fitted response value.
- $\hat{y}_{j(i)}$ is the j th fitted response value, where the fit does not include observation i .
- MSE is the mean squared error.
- p is the number of coefficients in the regression model.

Cook's distance is algebraically equivalent to the following expression:

$$D_i = \frac{r_i^2}{p \text{MSE}} \left(\frac{h_{ii}}{(1 - h_{ii})^2} \right),$$

where e_i is the i th residual.

Examples

Nonlinear Model Leverage Plot

Create a leverage plot of a fitted nonlinear model, and find the points with high leverage.

Load the reaction data and fit a model of the reaction rate as a function of reactants.

```
load reaction
mdl = fitnlm(reactants,rate,@hougen,[1 .05 .02 .1 2]);
```

Create a leverage plot of the fitted model.

```
plotDiagnostics(mdl)
```

To examine the observation with high leverage, activate the Data Cursor and click the observation.

Alternatively, find the high-leverage observation at the command line.

```
find(md1.Diagnostics.Leverage > 0.8)
```

```
ans =
```

```
6
```

More About

- “Nonlinear Regression” on page 11-2

plotEffects

Class: LinearModel

Plot main effects of each predictor in linear regression model

Syntax

```
plotEffects mdl  
h = plotEffects(mdl)
```

Description

`plotEffects(mdl)` produces an effects plot for the predictors in the `mdl` regression model. The plot shows the estimated effect on the response from changing each predictor value, averaging out the effects of the other predictors. `plotEffects` chooses values to produce a relatively large effect on the response.

`h = plotEffects(mdl)` returns handles to the lines in the plot.

Tips

- For many plots, the Data Cursor tool in the figure window displays the x and y values for any data point, along with the observation name or number.

Input Arguments

mdl

Linear model, as constructed by `fitlm` or `stepwiselm`.

Output Arguments

h

Vector of handles to lines or patches in plot. $h(1)$ is a handle to the circles that represent the main effect estimates. $h(j+1)$ is a handle to the line that defines the confidence interval for the effect of predictor j .

Examples

Effects Plot

Plot the effects of two predictors in a fitted linear model.

Load the `carsmall` data and fit a linear model of the mileage as a function of model year, weight, and weight squared.

```
load carsmall
ds = dataset(MPG,Weight);
ds.Year = ordinal(Model_Year);
mdl = fitlm(ds,'MPG ~ Year + Weight^2');
```

Create an effects plot.

```
plotEffects(mdl)
```

The width of each horizontal line in the figure shows a confidence interval for the effect on the response of the listed change in each predictor. The estimated effect of changing Year from 70 to 82 is an increase of about 8, and is between 6 and 10 with 95% confidence.

- “Plots to Understand Predictor Effects” on page 9-28

Alternatives

Use `plotInteraction` for an effects plot of the interactions of two specified variables.

See Also

`LinearModel` | `plotAdjustedResponse` | `plotInteraction`

How To

- “Linear Regression” on page 9-11

plotInteraction

Class: LinearModel

Plot interaction effects of two predictors in linear regression model

Syntax

```
plotInteraction mdl, var1, var2)
plotInteraction mdl, var1, var2, ptype)
h = plotInteraction(...)
```

Description

`plotInteraction(mdl, var1, var2)` creates a plot of the interaction effects of the predictors `var1` and `var2` in `mdl`. The plot shows the estimated effect on the response from changing each predictor value, averaging out the effects of the other predictors. The plot also shows the estimated effect with the other predictor fixed at certain values. `plotInteraction` chooses values to produce a relatively large effect on the response. The plot lets you examine whether the effect of one predictor depends on the value of the other predictor.

`plotInteraction(mdl, var1, var2, ptype)` returns a plot of the type specified in `ptype`.

`h = plotInteraction(...)` returns handles to the lines in the plot.

Tips

- For many plots, the Data Cursor tool in the figure window displays the x and y values for any data point, along with the observation name or number.

Input Arguments

mdl

Linear model, as constructed by `fitlm` or `stepwiselm`.

var1

String naming the variable for plot. `plotInteraction` chooses values of `var1` to create relatively large changes in the response. When you set `ptype = 'predictions'`, the plot shows curves as a function of `var2` with various fixed values of `var1`.

var2

String naming the variable for plot. `plotInteraction` chooses values of `var2` to create relatively large changes in the response. When you set `ptype = 'predictions'`, the plot shows curves as a function of `var2` various fixed values of `var1`.

ptype

String naming the plot type.

- `'effects'` — The plot shows each effect as a circle, with a horizontal bar showing the confidence interval for the estimated effect. `plotInteraction` computes the effect values from the adjusted response curve, as shown by the `plotAdjustedResponse` function.
- `'predictions'` — The plot shows the adjusted response curve as a function of `var2`, with `var1` fixed at certain values.

Default: `'effects'`

Output Arguments

h

Vector of handles to lines or patches in the plot.

Examples

Interaction Plot

Create a model of car mileage as a function of weight and model year. Then create a plot to see if the predictors have interactions.

Create a linear model of mileage from the `carsmall` data.

```
load carsmall
```

```

ds = dataset(MPG,Weight);
ds.Year = ordinal(Model_Year);
var1 = 'Year';
var2 = 'Weight';
mdl = fitlm(ds,'MPG ~ Year * Weight^2');

```

Create an interaction plot.

```
plotInteraction(mdl,var1,var2)
```

The plot might show an interaction, because the groups of points are not perfectly vertical. But the error bars seem large enough that a vertical line could pass within all of the confidence intervals for each group, possibly indicating no interaction.

Prediction Curve Interaction Plot

Create a model of car mileage as a function of weight and model year. Then create an interaction curve plot to see if the predictors have interactions.

Create a linear model of mileage from the carsmall data.

```
load carsmall
ds = dataset(MPG,Weight);
ds.Year = ordinal(Model_Year);
var1 = 'Year';
var2 = 'Weight';
mdl = fitlm(ds,'MPG ~ Year * Weight^2');
```

Create an interaction plot with type 'predictions'.

```
plotInteraction(mdl,var1,var2,'predictions')
```

The curves are not parallel. This indicates interactions between the predictors. The effect is subtle enough not to definitively indicate a interaction.

- “Plots to Understand Predictor Effects” on page 9-28

Alternatives

Use `plotEffects` for an effects plot showing separate effects for all predictors.

- “Linear Regression” on page 9-11

plotprofile

Class: RepeatedMeasuresModel

Plot expected marginal means with optional grouping

Syntax

```
plotprofile(rm,X)
plotprofile(rm,Name,Value)
H = plotprofile( ___ )
```

Description

`plotprofile(rm,X)` plots the expected marginal means computed from the repeated measures model `rm` as a function of the variable `X`.

`plotprofile(rm,Name,Value)` plots the expected marginal means computed from the repeated measures model `rm` with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify the factors to group by or change the line colors.

`H = plotprofile(___)` returns handles, `H`, to the plotted lines.

Input Arguments

rm — Repeated measures model

RepeatedMeasuresModel object

Repeated measures model, returned as a `RepeatedMeasuresModel` object.

For properties and methods of this object, see `RepeatedMeasuresModel`.

X — Name of between-subjects or within-subjects factor

string

Name of a between-subjects or within-subjects factor, specified as a string.

For example, if you want to plot the marginal means as a function of the groups of a between-subjects variable `drug`, you can specify it as follows.

Example: `'Drug'`

Data Types: `char`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

'Group' — Name of between-subject factor or factors

`string` | cell array of strings

Name of between-subject factor or factors, specified as the comma-separated pair consisting of `'Group'` and a string or cell array of strings. This name-value pair argument groups the lines according to the factor values.

For example, if you have two between-subject factors, `drug` and `sex`, and you want to group the lines in the plot according to them, you can specify these factors as follows.

Example: `'Group', {'Drug', 'Sex'}`

Data Types: `char` | `cell`

'Marker' — Marker to use for each group

cell array of strings

Marker to use for each group, specified as the comma-separated pair consisting of `'Marker'` and a cell array of strings.

For example, if you have two between-subject factors, `drug` and `sex`, with each having two groups, you can specify `o` as the marker for the groups of `drug` and `x` as the marker for the groups of `sex` as follows.

Example: `'Marker', {'o', 'o', 'x', 'x'}`

Data Types: `cell`

'Color' — Color for each group

`string` | cell array of strings | rows of a three-column RGB matrix

Color for each group, specified as the comma-separated pair consisting of 'Color' and a string, cell array of strings, or rows of a three-column RGB matrix.

For example, if you have two between-subject factors, drug and sex, with each having two groups, you can specify red as the color for the groups of drug and blue as the color for the groups of sex as follows.

Example: 'Color', 'rbbb'

Data Types: single | double | cell

'LineStyle' — Line style for each group

cell array of strings

Line style for each group, specified as the comma-separated pair consisting of 'LineStyle' and a cell array of strings.

For example, if you have two between-subject factors, drug and sex, with each having two groups, you can specify - as the line style of one group and : as the line style for the other group as follows.

Example: 'LineStyle', {'-' ':' '-' ':' }

Data Types: cell

Output Arguments

H — Handle to plotted lines

handle

Handle to plotted lines, returned as a handle.

Examples

Plot Expected Marginal Means

Load the sample data.

```
load fisheriris
```

The column vector `species` consists of iris flowers of three different species: `setosa`, `versicolor`, and `virginica`. The double matrix `meas` consists of four types of measurements on the flowers: the length and width of sepals and petals in centimeters, respectively.

Store the data in a table array.

```
t = table(species,meas(:,1),meas(:,2),meas(:,3),meas(:,4),...  
'VariableNames',{'species','meas1','meas2','meas3','meas4'});  
Meas = dataset([1 2 3 4'],'VarNames',{'Measurements'});
```

Fit a repeated measures model, where the measurements are the responses and the species is the predictor variable.

```
rm = fitrm(t,'meas1-meas4~species','WithinDesign',Meas);
```

Perform data grouped by the factor species.

```
plotprofile(rm,'species')
```

The estimated marginal means seem to differ with group. You can compute the standard error and the 95% confidence intervals for the marginal means using the `margmean` method.

Plot Marginal Means for Two Groups

Load the sample data.

```
load repeatedmeas
```

The table `between` includes the between-subject variables `age`, `IQ`, `group`, `gender`, and eight repeated measures `y1` through `y8` as responses. The table `within` includes the within-subject variables `w1` and `w2`. This is simulated data.

Fit a repeated measures model, where the repeated measures `y1` through `y8` are the responses, and `age`, `IQ`, `group`, `gender`, and the group-gender interaction are the predictor variables. Also specify the within-subject design matrix.

```
rm = fitrm(between, 'y1-y8 ~ Group*Gender + Age + IQ', 'WithinDesign', within);
```

Plot the estimated marginal means based on the factors `Group` and `Gender`.

```
ax1 = subplot(1,2,1);  
plotprofile(R, 'Group')  
ax2 = subplot(1,2,2);  
plotprofile(R, 'Gender')  
linkaxes([ax1 ax2], 'y')
```

Plot the estimated marginal means based on the factor `Group` and grouped by `Gender`.

```
figure()  
plotprofile(R, 'Group', 'Group', 'Gender')
```

See Also

`fitrm` | `margmean` | `plot`

plotResiduals

Class: GeneralizedLinearModel

Plot residuals of generalized linear regression model

Syntax

```
plotResiduals mdl
plotResiduals mdl, plottype
h = plotResiduals(...)
h = plotResiduals(mdl, plottype, Name, Value)
```

Description

`plotResiduals(mdl)` gives a histogram plot of the residuals of the `mdl` nonlinear model.

`plotResiduals(mdl, plottype)` plots residuals in a plot of type `plottype`.

`h = plotResiduals(...)` returns handles to the lines in the plot.

`h = plotResiduals(mdl, plottype, Name, Value)` plots with additional options specified by one or more `Name, Value` pair arguments.

Tips

- For many plots, the Data Cursor tool in the figure window displays the x and y values for any data point, along with the observation name or number.

Input Arguments

mdl

Generalized linear model, as constructed by `fitglm` or `stepwiseglm`.

plottype

String specifying the type of plot:

'caseorder'	Residuals vs. case (row) order
'fitted'	Residuals vs. fitted values
'histogram'	Histogram
'lagged'	Residuals vs. lagged residual ($r(t)$ vs. $r(t-1)$)
'probability'	Normal probability plot
'symmetry'	Symmetry plot

Default: 'histogram'

Name-Value Pair Arguments

Specify optional comma-separated pairs of **Name**,**Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as **Name1**,**Value1**, . . . ,**NameN**,**ValueN**.

Note: The plot property name-value pairs apply to the first returned handle **h(1)**.

'Color'

Color of the line or marker, a string or **ColorSpec** specification. For details, see **linespec**.

'LineStyle'

Type of line, a string or **Chart Line Properties** specification. For details, see **linespec**.

'LineWidth'

Width of the line or edges of filled area, in points, a positive scalar. One point is 1/72 inch.

Default: 0.5

'MarkerEdgeColor'

Color of the marker or edge color for filled markers, a string or `ColorSpec` specification. For details, see `linespec`.

'MarkerFaceColor'

Color of the marker face for filled markers, a string or `ColorSpec` specification. For details, see `linespec`.

'MarkerSize'

Size of the marker in points, a strictly positive scalar. One point is 1/72 inch.

'ResidualType'

String giving type of residual used in the plot.

'Raw'	Observed minus fitted values
'LinearPredictor'	Residuals on the linear predictor scale, equal to the adjusted response value minus the fitted linear combination of the predictors
'Pearson'	Raw residuals divided by RMSE
'Anscombe'	Residuals defined on transformed data with the transformation chosen to remove skewness
'Deviance'	Residuals based on the contribution of each observation to the deviance

Default: 'Raw'

Output Arguments

h

Vector of handles to lines or patches in the plot.

Definitions

Deviance

Deviance is twice the log likelihood of the model. Because this overall log likelihood is a sum of log likelihoods for each observation, the residual plot of deviance type shows the log likelihood per observation.

Examples

Residual Plots for Generalized Linear Models

Create residual plots of a fitted generalized linear model.

Generate artificial data for the model, Poisson random numbers with two underlying predictors $X(1)$ and $X(2)$.

```
rng('default') % for reproducibility
rndvars = randn(100,2);
X = [2+rndvars(:,1),rndvars(:,2)];
mu = exp(1 + X*[1;2]);
y = poissrnd(mu);
```

Create a generalized linear regression model of Poisson data.

```
mdl = fitglm(X,y,'y ~ x1 + x2','distr','poisson');
```

Create a default residuals plot.

```
plotResiduals(mdl)
```

Create a probability plot.

```
plotResiduals(md1, 'probability')
```

The residuals do not match a normal distribution in the tails—they are more spread out.

Create a plot of the fitted residuals of Anscombe type.

- “Residuals — Model Quality for Training Data” on page 10-27

`GeneralizedLinearModel`

More About

- “Generalized Linear Models” on page 10-12

plotResiduals

Class: GeneralizedLinearMixedModel

Plot residuals of generalized linear mixed-effects model

Syntax

```
plotResiduals(glme,plottype)
plotResiduals(glme,plottype,Name,Value)
```

```
h = plotResiduals( ___ )
```

Description

`plotResiduals(glme,plottype)` plots the raw conditional residuals of the generalized linear mixed-effects model `glme` in a plot of the type specified by `plottype`.

`plotResiduals(glme,plottype,Name,Value)` plots the conditional residuals of `glme` using additional options specified by one or more `Name,Value` pair arguments. For example, you can specify to plot the Pearson residuals.

`h = plotResiduals(___)` returns a handle, `h`, to the lines or patches in the plot of residuals.

Input Arguments

glme — Generalized linear mixed-effects model

GeneralizedLinearMixedModel object

Generalized linear mixed-effects model, specified as a `GeneralizedLinearMixedModel` object. For properties and methods of this object, see `GeneralizedLinearMixedModel`.

plottype — Type of residual plot

'histogram' (default) | 'caseorder' | 'fitted' | 'lagged' | 'probability' | 'symmetry'

Type of residual plot, specified as one of the following strings.

'histogram'	Histogram of residuals
'caseorder'	Residuals versus case order. Case order is the same as the row order used in the input data <code>tbl</code> when fitting the model using <code>fitglm</code> .
'fitted'	Residuals versus fitted values
'lagged'	Residuals versus lagged residual ($r(t)$ versus $r(t - 1)$)
'probability'	Normal probability plot
'symmetry'	Symmetry plot

Example: `plotResiduals(glm, 'lagged')`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1`, `Value1`, ..., `NameN`, `ValueN`.

'ResidualType' — Residual type

'raw' (default) | 'Pearson'

Residual type, specified by the comma-separated pair consisting of `ResidualType` and one of the following.

Residual Type	Formula
'raw'	$r_{ci} = y_i - g^{-1}(x_i^T \hat{\beta} + z_i^T \hat{b} + \delta_i)$
'Pearson'	$r_{ci}^{pearson} = \frac{r_{ci}}{\sqrt{\frac{\hat{\sigma}^2}{w_i} v_i(\mu_i(\hat{\beta}, \hat{b}))}}$

In each of these equations:

- y_i is the i th element of the n -by-1 response vector, y , where $i = 1, \dots, n$.
- g^{-1} is the inverse link function for the model.
- x_i^T is the i th row of the fixed-effects design matrix X .
- z_i^T is the i th row of the random-effects design matrix Z .
- δ_i is the i th offset value.
- σ^2 is the dispersion parameter.
- w_i is the i th observation weight.
- v_i is the variance term for the i th observation.
- μ_i is the mean of the response for the i th observation.
- $\hat{\beta}$ and \hat{b} are estimated values of β and b .

Raw residuals from a generalized linear mixed-effects model have nonconstant variance. Pearson residuals are expected to have an approximately constant variance, and are generally used for analysis.

Example: 'ResidualType', 'Pearson'

Output Arguments

h — Handle to residual plot

graphics object

Handle to the residual plot, returned as a graphics object. You can use dot notation to change certain property values of the object, including face color for a histogram, and marker style and color for a scatterplot. For more information, see “Access Property Values”.

Examples

Create Plots of Residuals

Navigate to the folder containing the sample data. Load the sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')

load mfr
```

This simulated data is from a manufacturing company that operates 50 factories across the world, with each factory running a batch process to create a finished product. The company wants to decrease the number of defects in each batch, so it developed a new manufacturing process. To test the effectiveness of the new process, the company selected 20 of its factories at random to participate in an experiment: Ten factories implemented the new process, while the other ten continued to run the old process. In each of the 20 factories, the company ran five batches (for a total of 100 batches) and recorded the following data:

- Flag to indicate whether the batch used the new process (**newprocess**)
- Processing time for each batch, in hours (**time**)
- Temperature of the batch, in degrees Celsius (**temp**)
- Categorical variable indicating the supplier (A, B, or C) of the chemical used in the batch (**supplier**)
- Number of defects in the batch (**defects**)

The data also includes **time_dev** and **temp_dev**, which represent the absolute deviation of time and temperature, respectively, from the process standard of 3 hours at 20 degrees Celsius.

Fit a generalized linear mixed-effects model using **newprocess**, **time_dev**, **temp_dev**, and **supplier** as fixed-effects predictors. Include a random-effects term for intercept grouped by **factory**, to account for quality differences that might exist due to factory-specific variations. The response variable **defects** has a Poisson distribution, and the appropriate link function for this model is log. Use the Laplace fit method to estimate the coefficients. Specify the dummy variable encoding as **'effects'**, so the dummy variable coefficients sum to 0.

The number of defects can be modeled using a Poisson distribution

$$defects_{ij} \sim \text{Poisson}(\mu_{ij})$$

This corresponds to the generalized linear mixed-effects model

$$\log(\mu_{ij}) = \beta_0 + \beta_1 \text{newprocess}_{ij} + \beta_2 \text{time_dev}_{ij} + \beta_3 \text{temp_dev}_{ij} + \beta_4 \text{supplier_C}_{ij} + \beta_5 \text{supplier_B}_{ij} + b_i$$

where

- defects_{ij} is the number of defects observed in the batch produced by factory i during batch j .
- μ_{ij} is the mean number of defects corresponding to factory i (where $i = 1, 2, \dots, 20$) during batch j (where $j = 1, 2, \dots, 5$).
- newprocess_{ij} , time_dev_{ij} , and temp_dev_{ij} are the measurements for each variable that correspond to factory i during batch j . For example, newprocess_{ij} indicates whether the batch produced by factory i during batch j used the new process.
- supplier_C_{ij} and supplier_B_{ij} are dummy variables that use effects (sum-to-zero) coding to indicate whether company **C** or **B**, respectively, supplied the process chemicals for the batch produced by factory i during batch j .
- $b_i \sim N(0, \sigma_b^2)$ is a random-effects intercept for each factory i that accounts for factory-specific variation in quality.

```
glme = fitglme(mfr, 'defects ~ 1 + newprocess + time_dev + temp_dev + supplier + (1|factory)
```

Create diagnostic plots using Pearson residuals to test the model assumptions.

Plot a histogram to visually confirm that the mean of the Pearson residuals is equal to 0. If the model is correct, we expect the Pearson residuals to be centered at 0.

```
plotResiduals(glme, 'histogram', 'ResidualType', 'Pearson')
```

The histogram shows that the Pearson residuals are centered at 0.

Plot the Pearson residuals versus the fitted values, to check for signs of nonconstant variance among the residuals (heteroscedasticity). We expect the conditional Pearson residuals to have a constant variance. Therefore, a plot of conditional Pearson residuals versus conditional fitted values should not reveal any systematic dependence on the conditional fitted values.

```
plotResiduals(glme, 'fitted', 'ResidualType', 'Pearson')
```

The plot does not show a systematic dependence on the fitted values, so there are no signs of nonconstant variance among the residuals.

Plot the Pearson residuals versus lagged residuals, to check for correlation among the residuals. The conditional independence assumption in GLME implies that the conditional Pearson residuals are approximately uncorrelated.

```
plotResiduals(glme, 'lagged', 'ResidualType', 'Pearson')
```

There is no pattern to the plot, so there are no signs of correlation among the residuals.

`GeneralizedLinearMixedModel` | `fitglm` | `fitted` | `plot` | `residuals`

plotResiduals

Class: LinearModel

Plot residuals of linear regression model

Syntax

```
plotResiduals mdl
plotResiduals mdl, plottype
h = plotResiduals(...)
h = plotResiduals(mdl, plottype, Name, Value)
```

Description

`plotResiduals(mdl)` gives a histogram plot of the residuals of the `mdl` linear model.

`plotResiduals(mdl, plottype)` plots residuals in a plot of type `plottype`.

`h = plotResiduals(...)` returns handles to the lines in the plot.

`h = plotResiduals(mdl, plottype, Name, Value)` plots with additional options specified by one or more `Name, Value` pair arguments.

Tips

- For many plots, the Data Cursor tool in the figure window displays the x and y values for any data point, along with the observation name or number.

Input Arguments

mdl

Linear model, as constructed by `fitlm` or `stepwiselm`.

plottype

String specifying the type of plot:

'caseorder'	Residuals vs. case (row) order
'fitted'	Residuals vs. fitted values
'histogram'	Histogram
'lagged'	Residuals vs. lagged residual ($r(t)$ vs. $r(t-1)$)
'probability'	Normal probability plot
'symmetry'	Symmetry plot

Default: 'histogram'

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Note: The plot property name-value pairs apply to the first returned handle `h(1)`.

'Color'

Color of the line or marker, a string or ColorSpec specification. For details, see `linespec`.

'LineStyle'

Type of line, a string or Chart Line Properties specification. For details, see `linespec`.

'LineWidth'

Width of the line or edges of filled area, in points, a positive scalar. One point is 1/72 inch.

Default: 0.5

'MarkerEdgeColor'

Color of the marker or edge color for filled markers, a string or ColorSpec specification. For details, see `linespec`.

'MarkerFaceColor'

Color of the marker face for filled markers, a string or `ColorSpec` specification. For details, see `linespec`.

'MarkerSize'

Size of the marker in points, a strictly positive scalar. One point is 1/72 inch.

'ResidualType'

Type of residual used in the plot:

'Raw'	Observed minus fitted values
'Pearson'	Raw residuals divided by RMSE
'Standardized'	Raw residuals divided by their estimated standard deviation
'Studentized'	Raw residuals divided by an independent (delete-1) estimate of their standard deviation

Default: 'Raw'

Output Arguments

h

Vector of handles to lines or patches in the plot.

Examples

Linear Residuals Plot

Plot the residuals of a fitted linear model.

Load the `carsmall` data and fit a linear model of the mileage as a function of model year, weight, and weight squared.

```
load carsmall
```

```
tbl = table(MPG,Weight);
tbl.Year = ordinal(Model_Year);
mdl = fitlm(tbl,'MPG ~ Year + Weight^2');
```

Plot the raw residuals.

```
plotResiduals(mdl)
```

Residual Probability Plot

Create a normal probability plot of the residuals of a fitted linear model.

Load the `carsmall` data and fit a linear model of the mileage as a function of model year, weight, and weight squared.

```
load carsmall
X = [Weight,Model_Year];
mdl = fitlm(X,MPG,...
    'y ~ x2 + x1^2','Categorical',2);
```

Create a normal probability plot of the residuals of the fitted model.

```
plotResiduals mdl, 'probability')
```

plotResiduals

Class: LinearMixedModel

Plot residuals of linear mixed-effects model

Syntax

```
plotResiduals(lme,plottype)
plotResiduals(lme,plottype,Name,Value)
```

```
h = plotResiduals( ___ )
```

Description

`plotResiduals(lme,plottype)` plots the raw conditional residuals of the linear mixed-effects model `lme` in a plot of the type specified by `plottype`.

`plotResiduals(lme,plottype,Name,Value)` also plots the residuals of the linear mixed-effects model `lme` with additional options specified by one or more name-value pair arguments. For example, you can specify the residual type to plot.

`plotResiduals` also accepts some other name-value pair arguments that specify the properties of the primary line in the plot. For those name-value pairs, see `plot`.

`h = plotResiduals(___)` returns a handle, `h`, to the lines or patches in the plot of residuals.

Input Arguments

lme — Linear mixed-effects model

LinearMixedModel object

Linear mixed-effects model, returned as a LinearMixedModel object.

For properties and methods of this object, see LinearMixedModel.

plottype — Type of residual plot

'histogram' (default) | 'caseorder' | 'fitted' | 'lagged' | 'probability' | 'symmetry'

Type of residual plot, specified as one of the following strings.

'histogram'	Default. Histogram of residuals
'caseorder'	Residuals versus case (row) order
'fitted'	Residuals versus fitted values
'lagged'	Residuals versus lagged residual ($r(t)$ versus $r(t - 1)$)
'probability'	Normal probability plot
'symmetry'	Symmetry plot

Example: `plotResiduals(lme, 'lagged')`

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

'ResidualType' — Residual type

'Raw' (default) | 'Pearson' | 'Standardized'

Residual type, specified by the comma-separated pair consisting of **ResidualType** and one of the following.

Residual Type	Conditional	Marginal
'Raw'	$r_i^C = [y - X\hat{\beta} - Z\hat{b}]_i$	$r_i^M = [y - X\hat{\beta}]_i$
'Pearson'	$pr_i^C = \frac{r_i^C}{\sqrt{[\widehat{Var}_{y,b}(y - X\beta)]_i}}$	$pr_i^M = \frac{r_i^M}{\sqrt{[\widehat{Var}_y(y - X\beta)]_i}}$

Residual Type	Conditional	Marginal
'Standardized'	$st_i^C = \frac{r_i^C}{\sqrt{[\widehat{Var}_y(r^C)]_{ii}}}$	$st_i^M = \frac{r_i^M}{\sqrt{[\widehat{Var}_y(r^M)]_{ii}}}$

For more information on the conditional and marginal residuals and residual variances, see [Definitions](#) at the end of this page.

Example: 'ResidualType', 'Standardized'

Output Arguments

h — Handle to residual plot

handle

Handle to the residual plot, returned as a handle.

Examples

Examine Residuals

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load weight
```

`weight` contains data from a longitudinal study, where 20 subjects are randomly assigned to 4 exercise programs, and their weight loss is recorded over six 2-week time periods. This is simulated data.

Store the data in a table. Define `Subject` and `Program` as categorical variables.

```
tbl = table(InitialWeight,Program,Subject,Week,y);
tbl.Subject = nominal(tbl.Subject);
tbl.Program = nominal(tbl.Program);
```

Fit a linear mixed-effects model where the initial weight, type of program, week, and the interaction between the week and type of program are the fixed effects. The intercept and week vary by subject.

```
lme = fitlme(tbl, 'y ~ InitialWeight + Program*Week + (Week|Subject)');
```

Plot the histogram of the raw residuals.

```
plotResiduals(lme)
```

Plot the residuals versus the fitted values.

```
figure();  
plotResiduals(lme, 'fitted')
```

There is no obvious pattern, so there are no immediate signs of heteroscedasticity.

Create the normal probability plot of residuals.

```
figure();  
plotResiduals(lme, 'probability')
```

Data appears to be normal.

Find the observation number for the data that appears to be an outlier to the right of the plot.

```
find(residuals(lme)>0.25)
```

```
ans =
```

```
101
```

Create a box plot of the raw, Pearson, and standardized residuals.

```
r = residuals(lme);
```

```
pr = residuals(lme, 'ResidualType', 'Pearson');
st = residuals(lme, 'ResidualType', 'Standardized');
X = [r pr st];
boxplot(X, 'labels', {'Raw', 'Pearson', 'Standardized'});
```

All three box plots point out the outlier on the right tail of the distribution. The box plots of raw and Pearson residuals also point out a second possible outlier on the left tail. Find the corresponding observation number.

```
find(pr < -2)
```

```
ans =
```

```
10
```

Plot the raw residuals versus lagged residuals.

```
plotResiduals(lme, 'lagged')
```

There is no obvious pattern in the graph. The residuals do not appear to be correlated.

plotResiduals

Class: NonLinearModel

Plot residuals of nonlinear regression model

Syntax

```
plotResiduals mdl
plotResiduals mdl, plottype
h = plotResiduals(...)
h = plotResiduals(mdl, plottype, Name, Value)
```

Description

`plotResiduals(mdl)` gives a histogram plot of the residuals of the `mdl` nonlinear model.

`plotResiduals(mdl, plottype)` plots residuals in a plot of type `plottype`.

`h = plotResiduals(...)` returns handles to the lines in the plot.

`h = plotResiduals(mdl, plottype, Name, Value)` plots with additional options specified by one or more `Name, Value` pair arguments.

Tips

- For many plots, the Data Cursor tool in the figure window displays the x and y values for any data point, along with the observation name or number.

Input Arguments

mdl

Nonlinear regression model, constructed by `fitnlm`.

plottype

String specifying the type of plot:

'caseorder'	Residuals vs. case (row) order
'fitted'	Residuals vs. fitted values
'histogram'	Histogram
'lagged'	Residuals vs. lagged residual ($r(t)$ vs. $r(t-1)$)
'probability'	Normal probability plot
'symmetry'	Symmetry plot

Default: 'histogram'

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

Note: The plot property name-value pairs apply to the first returned handle `h(1)`.

'Color'

Color of the line or marker, a string or ColorSpec specification. For details, see `linespec`.

'LineStyle'

Type of line, a string or Chart Line Properties specification. For details, see `linespec`.

'LineWidth'

Width of the line or edges of filled area, in points, a positive scalar. One point is 1/72 inch.

Default: 0.5

'MarkerEdgeColor'

Color of the marker or edge color for filled markers, a string or `ColorSpec` specification. For details, see `linespec`.

'MarkerFaceColor'

Color of the marker face for filled markers, a string or `ColorSpec` specification. For details, see `linespec`.

'MarkerSize'

Size of the marker in points, a strictly positive scalar. One point is 1/72 inch.

'ResidualType'

Type of residual used in the plot:

'Raw'	Observed minus fitted values
'Pearson'	Raw residuals divided by RMSE
'Standardized'	Raw residuals divided by their estimated standard deviation
'Studentized'	Raw residuals divided by an independent (delete-1) estimate of their standard deviation

Default: 'Raw'

Output Arguments

h

Vector of handles to lines or patches in the plot.

Examples

Residual Plot

Plot the residuals of a fitted nonlinear model.

Load the reaction data and fit a model of the reaction rate as a function of reactants.

```
load reaction
mdl = fitnlm(reactants,rate,@hougen,[1 .05 .02 .1 2]);
```

Plot the residuals of the fitted model.

```
plotResiduals(mdl)
```

Residual Probability Plot

Create a normal probability plot of the residuals of a fitted nonlinear model.

Load the reaction data and fit a model of the reaction rate as a function of reactants.

```
load reaction
mdl = fitnlm(reactants,rate,@hougen,[1 .05 .02 .1 2]);
```

Create a normal probability plot of the residuals of the fitted model.

```
plotResiduals(mdl, 'probability')
```

More About

- “Nonlinear Regression” on page 11-2

plotSlice

Class: GeneralizedLinearModel

Plot of slices through fitted generalized linear regression surface

Syntax

```
plotSlice mdl  
h = plotSlice(mdl)
```

Description

`plotSlice(mdl)` creates a new figure containing a series of plots, each representing a slice through the regression surface predicted by `mdl`. For each plot, the surface slice is shown as a function of a single predictor variable, with the other predictor variables held constant.

`h = plotSlice(mdl)` returns handles to the lines in the plot.

Tips

- If there are more than eight predictors, `plotSlice` selects the first five for plotting. Use the **Predictors** menu to control which predictors are plotted.
- The **Bounds** menu lets you choose between simultaneous or non-simultaneous bounds, and between bounds on the function or bounds on a new observation.

Input Arguments

mdl

Generalized linear model, as constructed by `fitglm` or `stepwiseglm`.

Output Arguments

h

Vector of handles to lines or patches in the plot.

Examples

Slice Plot of Generalized Linear Regression Model

Create a slice plot of a Poisson generalized linear model.

Generate artificial data for the model using Poisson random numbers with two underlying predictors $X(1)$ and $X(2)$.

```
rng('default') % for reproducibility
rndvars = randn(100,2);
X = [2+rndvars(:,1),rndvars(:,2)];
mu = exp(1 + X*[1;2]);
y = poissrnd(mu);
```

Create a generalized linear regression model of Poisson data.

```
mdl = fitglm(X,y,'y ~ x1 + x2','distr','poisson');
```

Create the slice plot.

```
plotSlice(mdl)
```

Drag the x1 prediction line to the right and view the changes in the prediction and the response curve for the x2 predictor.

plotSlice

Class: LinearModel

Plot of slices through fitted linear regression surface

Syntax

```
plotSlice mdl  
h = plotSlice mdl
```

Description

`plotSlice(mdl)` creates a new figure containing a series of plots, each representing a slice through the regression surface predicted by `mdl`. For each plot, the surface slice is shown as a function of a single predictor variable, with the other predictor variables held constant.

`h = plotSlice(mdl)` returns handles to the lines in the plot.

Tips

- If there are more than eight predictors, `plotSlice` selects the first five for plotting. Use the **Predictors** menu to control which predictors are plotted.
- The **Bounds** menu lets you choose between simultaneous or non-simultaneous bounds, and between bounds on the function or bounds on a new observation.

Input Arguments

mdl

Linear model, as constructed by `fitlm` or `stepwiselm`.

Output Arguments

h

Vector of handles to lines or patches in the plot.

Examples

Slice Plot

Plot the slices through a fitted linear model.

Load the `carsmall` data and fit a linear model of the mileage as a function of model year, weight, and weight squared.

```
load carsmall
tbl = table(MPG,Weight);
tbl.Year = ordinal(Model_Year);
mdl = fitlm(tbl,'MPG ~ Year + Weight^2');
```

Create a slice plot.

```
plotSlice(mdl)
```

Drag the **Weight** prediction line to the right and observe the change in the predicted MPG and the response curve for **Year**.

plotSlice

Class: NonLinearModel

Plot of slices through fitted nonlinear regression surface

Syntax

```
plotSlice mdl  
h = plotSlice(mdl)
```

Description

`plotSlice(mdl)` creates a new figure containing a series of plots, each representing a slice through the regression surface predicted by `mdl`. For each plot, the surface slice is shown as a function of a single predictor variable, with the other predictor variables held constant.

`h = plotSlice(mdl)` returns handles to the lines in the plot.

Tips

- If there are more than eight predictors, `plotSlice` selects the first five for plotting. Use the **Predictors** menu to control which predictors are plotted.
- The **Bounds** menu lets you choose between simultaneous or non-simultaneous bounds, and between bounds on the function or bounds on a new observation.

Input Arguments

mdl

Nonlinear regression model, constructed by `fitnlm`.

Output Arguments

h

Vector of handles to lines or patches in the plot.

Examples

Slice Plot

Plot slices of a fitted nonlinear model.

Load the `reaction` data and fit a model of the reaction rate as a function of reactants.

```
load reaction
mdl = fitnlm(reactants,...
    rate,@hougen,[1 .05 .02 .1 2]);
```

Create a slice plot

```
plotSlice(mdl)
```

Drag the X1 prediction line to the right, and observe the change in the predicted response y and in the predicted response curves to X2 and X3.

plsregress

Partial least-squares regression

Syntax

```
[XL,YL] = plsregress(X,Y,ncomp)
[XL,YL,XS] = plsregress(X,Y,ncomp)
[XL,YL,XS,YS] = plsregress(X,Y,ncomp)
[XL,YL,XS,YS,BETA] = PLSREGRESS(X,Y,ncomp,...)
[XL,YL,XS,YS,BETA,PCTVAR] = plsregress(X,Y,ncomp)
[XL,YL,XS,YS,BETA,PCTVAR,MSE] = plsregress(X,Y,ncomp)
[XL,YL,XS,YS,BETA,PCTVAR,MSE] =
plsregress(...,param1,val1,param2,val2,...)
[XL,YL,XS,YS,BETA,PCTVAR,MSE,stats] = PLSREGRESS(X,Y,ncomp,...)
```

Description

`[XL,YL] = plsregress(X,Y,ncomp)` computes a partial least-squares (PLS) regression of Y on X , using `ncomp` PLS components, and returns the predictor and response loadings in `XL` and `YL`, respectively. X is an n -by- p matrix of predictor variables, with rows corresponding to observations and columns to variables. Y is an n -by- m response matrix. `XL` is a p -by-`ncomp` matrix of predictor loadings, where each row contains coefficients that define a linear combination of PLS components that approximate the original predictor variables. `YL` is an m -by-`ncomp` matrix of response loadings, where each row contains coefficients that define a linear combination of PLS components that approximate the original response variables.

`[XL,YL,XS] = plsregress(X,Y,ncomp)` returns the predictor scores `XS`, that is, the PLS components that are linear combinations of the variables in X . `XS` is an n -by-`ncomp` orthonormal matrix with rows corresponding to observations and columns to components.

`[XL,YL,XS,YS] = plsregress(X,Y,ncomp)` returns the response scores `YS`, that is, the linear combinations of the responses with which the PLS components `XS` have maximum covariance. `YS` is an n -by-`ncomp` matrix with rows corresponding to observations and columns to components. `YS` is neither orthogonal nor normalized.

`plsregress` uses the SIMPLS algorithm, first centering X and Y by subtracting off column means to get centered variables X_0 and Y_0 . However, it does not rescale the columns. To perform PLS with standardized variables, use `zscore` to normalize X and Y .

If `ncomp` is omitted, its default value is $\min(\text{size}(X,1) - 1, \text{size}(X,2))$.

The relationships between the scores, loadings, and centered variables X_0 and Y_0 are:

$$XL = (XS \backslash X_0)' = X_0' * XS,$$

$$YL = (XS \backslash Y_0)' = Y_0' * XS,$$

XL and YL are the coefficients from regressing X_0 and Y_0 on XS , and $XS * XL'$ and $XS * YL'$ are the PLS approximations to X_0 and Y_0 .

`plsregress` initially computes YS as:

$$YS = Y_0 * YL = Y_0 * Y_0' * XS,$$

By convention, however, `plsregress` then orthogonalizes each column of YS with respect to preceding columns of XS , so that $XS' * YS$ is lower triangular.

`[XL, YL, XS, YS, BETA] = PLSREGRESS(X, Y, ncomp, ...)` returns the PLS regression coefficients $BETA$. $BETA$ is a $(p+1)$ -by- m matrix, containing intercept terms in the first row:

$$Y = [\text{ones}(n,1), X] * BETA + Y_{\text{residuals}},$$

$Y_0 = X_0 * BETA(2:\text{end}, :) + Y_{\text{residuals}}$. Here $Y_{\text{residuals}}$ is the vector of response residuals.

`[XL, YL, XS, YS, BETA, PCTVAR] = plsregress(X, Y, ncomp)` returns a 2-by-`ncomp` matrix $PCTVAR$ containing the percentage of variance explained by the model. The first row of $PCTVAR$ contains the percentage of variance explained in X by each PLS component, and the second row contains the percentage of variance explained in Y .

`[XL, YL, XS, YS, BETA, PCTVAR, MSE] = plsregress(X, Y, ncomp)` returns a 2-by- $(ncomp+1)$ matrix MSE containing estimated mean-squared errors for PLS models with $0:ncomp$ components. The first row of MSE contains mean-squared errors for the predictor variables in X , and the second row contains mean-squared errors for the response variable(s) in Y .

[XL, YL, XS, YS, BETA, PCTVAR, MSE] =
 plsregress(..., param1, val1, param2, val2, ...) specifies optional parameter name/value pairs from the following table to control the calculation of MSE.

Parameter	Value
'cv'	<p>The method used to compute MSE.</p> <ul style="list-style-type: none"> • When the value is a positive integer k, <code>plsregress</code> uses k-fold cross-validation. • When the value is an object of the <code>cvpartition</code> class, other forms of cross-validation can be specified. • When the value is <code>'resubstitution'</code>, <code>plsregress</code> uses X and Y both to fit the model and to estimate the mean-squared errors, without cross-validation. <p>The default is <code>'resubstitution'</code>.</p>
'mcreps'	<p>A positive integer indicating the number of Monte-Carlo repetitions for cross-validation. The default value is 1. The value must be 1 if the value of <code>'cv'</code> is <code>'resubstitution'</code>.</p>
options	<p>A structure that specifies whether to run in parallel, and specifies the random stream or streams. Create the <code>options</code> structure with <code>statset</code>. Option fields:</p> <ul style="list-style-type: none"> • <code>UseParallel</code> — Set to <code>true</code> to compute in parallel. Default is <code>false</code>. • <code>UseSubstreams</code> — Set to <code>true</code> to compute in parallel in a reproducible fashion. Default is <code>false</code>. To compute reproducibly, set <code>Streams</code> to a type allowing substreams: <code>'mlfg6331_64'</code> or <code>'mrg32k3a'</code>. • <code>Streams</code> — A <code>RandStream</code> object or cell array consisting of one such object. If you do not specify <code>Streams</code>, <code>plsregress</code> uses the default stream.

[XL, YL, XS, YS, BETA, PCTVAR, MSE, stats] = PLSREGRESS(X, Y, ncomp, ...)
 returns a structure `stats` with the following fields:

- `W` — A p -by- n comp matrix of PLS weights so that $XS = X0*W$.
- `T2` — The T^2 statistic for each point in XS .
- `Xresiduals` — The predictor residuals, that is, $X0 - XS*XL'$.
- `Yresiduals` — The response residuals, that is, $Y0 - XS*YL'$.

Examples

Perform Partial Least-Squares Regression

Load data on near infrared (NIR) spectral intensities of 60 samples of gasoline at 401 wavelengths, and their octane ratings.

```
load spectra
X = NIR;
y = octane;
```

Perform PLS regression with ten components.

```
[XL,y1,XS,YS,beta,PCTVAR] = plsregress(X,y,10);
```

Plot the percent of variance explained in the response variable as a function of the number of components.

```
plot(1:10,cumsum(100*PCTVAR(2,:)),'-bo');
xlabel('Number of PLS components');
ylabel('Percent Variance Explained in y');
```

Compute the fitted response and display the residuals.

```
yfit = [ones(size(X,1),1) X]*beta;  
residuals = y - yfit;  
stem(residuals)  
xlabel('Observation');  
ylabel('Residual');
```

regress | sequentialfs

PointOrder property

Class: sobolset

Point generation method

Description

The `PointOrder` property contains a string that specifies the order in which the Sobol sequence points are produced. The property value must be one of `'standard'` or `'graycode'`. When set to `'standard'` the points produced match the original Sobol sequence implementation. When set to `'graycode'`, the sequence is generated using an implementation that uses the Gray code of the index instead of the index itself.

PointSet property

Class: grandstream

Point set from which stream is drawn

Description

The `PointSet` property contains a copy of the point set from which the stream is providing points. The point set is specified during construction of a quasi-random stream and cannot subsequently be altered.

Examples

```
Q = grandstream('sobol', 5, 'Skip', 8);  
% Create a new stream based on the same sequence as that in Q  
Q2 = grandstream(Q.PointSet);  
u1 = grand(Q, 10)  
u2 = grand(Q2, 10) % contains exactly the same values as u1
```

poisscdf

Poisson cumulative distribution function

Syntax

```
p = poisscdf(x,lambda)
p = poisscdf(x,lambda, 'upper')
```

Description

`p = poisscdf(x,lambda)` returns the Poisson cdf at each value in `x` using the corresponding mean parameters in `lambda`. `x` and `lambda` can be vectors, matrices, or multidimensional arrays that have the same size. A scalar input is expanded to a constant array with the same dimensions as the other input. The parameters in `lambda` must be positive.

`p = poisscdf(x,lambda, 'upper')` returns the complement of the Poisson cdf at each value in `x`, using an algorithm that more accurately computes the extreme upper tail probabilities.

The Poisson cdf is

$$p = F(x | \lambda) = e^{-\lambda} \sum_{i=0}^{\text{floor}(x)} \frac{\lambda^i}{i!}$$

Examples

Compute Poisson Distribution cdf

For example, consider a Quality Assurance department that performs random tests of individual hard disks. Their policy is to shut down the manufacturing process if an inspector finds more than four bad sectors on a disk. What is the probability of shutting down the process if the mean number of bad sectors (λ) is two?

```
probability = 1-poisscdf(4,2)
```

```
probability =  
0.0527
```

About 5% of the time, a normally functioning manufacturing process produces more than four flaws on a hard disk.

Suppose the average number of flaws (λ) increases to four. What is the probability of finding fewer than five flaws on a hard drive?

```
probability = poisscdf(4,4)
```

```
probability =  
0.6288
```

This means that this faulty manufacturing process continues to operate after this first inspection almost 63% of the time.

[cdf](#) | [poisspdf](#) | [poissinv](#) | [poisstat](#) | [poissfit](#) | [poissrnd](#)

poissfit

Poisson parameter estimates

Syntax

```
lambdahat = poissfit(data)
[lambdahat,lamdaci] = poissfit(data)
[lambdahat,lamdaci] = poissfit(data,alpha)
```

Description

`lambdahat = poissfit(data)` returns the maximum likelihood estimate (MLE) of the parameter of the Poisson distribution, λ , given the data `data`.

`[lambdahat,lamdaci] = poissfit(data)` also gives 95% confidence intervals in `lamdaci`.

`[lambdahat,lamdaci] = poissfit(data,alpha)` gives $100(1 - \text{alpha})\%$ confidence intervals. For example `alpha = 0.001` yields 99.9% confidence intervals.

The sample mean is the MLE of λ .

$$\hat{\lambda} = \frac{1}{n} \sum_{i=1}^n x_i$$

Examples

```
r = poissrnd(5,10,2);
[l,lci] = poissfit(r)
l =
    7.4000    6.3000
lci =
    5.8000    4.8000
    9.1000    7.9000
```

More About

- “Poisson Distribution” on page B-126

See Also

mle | poisspdf | poisscdf | poissinv | poisstat | poissrnd

poissinv

Poisson inverse cumulative distribution function

Syntax

```
X = poissinv(P,lambda)
```

Description

`X = poissinv(P,lambda)` returns the smallest value X such that the Poisson cdf evaluated at X equals or exceeds P , using mean parameters in `lambda`. `P` and `lambda` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other input.

Examples

If the average number of defects (λ) is two, what is the 95th percentile of the number of defects?

```
poissinv(0.95,2)
ans =
    5
```

What is the median number of defects?

```
median_defects = poissinv(0.50,2)
median_defects =
    2
```

prob.PoissonDistribution class

Package: prob

Superclasses: prob.ToolboxFittableParametricDistribution

Poisson probability distribution object

Description

`prob.PoissonDistribution` is an object consisting of parameters, a model description, and sample data for a Poisson probability distribution.

Create a probability distribution object with specified parameter values using `makedist`. Alternatively, fit a distribution to data using `fitdist` or the Distribution Fitting app.

Construction

`pd = makedist('Poisson')` creates a Poisson probability distribution object using the default parameter values.

`pd = makedist('Poisson', 'lambda', lambda)` creates a Poisson distribution object using the specified parameter value.

Input Arguments

lambda — Mean

1 (default) | nonnegative scalar value

Mean of the Poisson distribution, specified as a nonnegative scalar value.

Data Types: `single` | `double`

Properties

lambda — Mean

nonnegative scalar value

Mean of the Poisson distribution, stored as a nonnegative scalar value.

Data Types: `single` | `double`

DistributionName — Probability distribution name

probability distribution name string

Probability distribution name, stored as a valid probability distribution name string. This property is read-only.

Data Types: `char`

InputData — Data used for distribution fitting

structure

Data used for distribution fitting, stored as a structure containing the following:

- **data**: Data vector used for distribution fitting.
- **cens**: Censoring vector, or empty if none.
- **freq**: Frequency vector, or empty if none.

This property is read-only.

Data Types: `struct`

IsTruncated — Logical flag for truncated distribution

0 | 1

Logical flag for truncated distribution, stored as a logical value. If `IsTruncated` equals 0, the distribution is not truncated. If `IsTruncated` equals 1, the distribution is truncated. This property is read-only.

Data Types: `logical`

NumParameters — Number of parameters

positive integer value

Number of parameters for the probability distribution, stored as a positive integer value. This property is read-only.

Data Types: `single` | `double`

ParameterCovariance — Covariance matrix of the parameter estimates

matrix of scalar values

Covariance matrix of the parameter estimates, stored as a p -by- p matrix, where p is the number of parameters in the distribution. The (i,j) element is the covariance between

the estimates of the i th parameter and the j th parameter. The (i,i) element is the estimated variance of the i th parameter. If parameter i is fixed rather than estimated by fitting the distribution to data, then the (i,i) elements of the covariance matrix are 0. This property is read-only.

Data Types: `single` | `double`

ParameterDescription — Distribution parameter descriptions

cell array of strings

Distribution parameter descriptions, stored as a cell array of strings. Each cell contains a short description of one distribution parameter. This property is read-only.

Data Types: `char`

ParameterIsFixed — Logical flag for fixed parameters

array of logical values

Logical flag for fixed parameters, stored as an array of logical values. If 0, the corresponding parameter in the `ParameterNames` array is not fixed. If 1, the corresponding parameter in the `ParameterNames` array is fixed. This property is read-only.

Data Types: `logical`

ParameterNames — Distribution parameter names

cell array of strings

Distribution parameter names, stored as a cell array of strings. This property is read-only.

Data Types: `char`

ParameterValues — Distribution parameter values

vector of scalar values

Distribution parameter values, stored as a vector. This property is read-only.

Data Types: `single` | `double`

Truncation — Truncation interval

vector of scalar values

Truncation interval for the probability distribution, stored as a vector containing the lower and upper truncation boundaries. This property is read-only.

Data Types: `single` | `double`

Definitions

Poisson Distribution

The Poisson distribution is appropriate for applications that involve counting the number of times a random event occurs in a given amount of time, distance, area, etc. If the number of counts follows the Poisson distribution, then the interval between individual counts follows the exponential distribution.

The Poisson distribution uses the following parameters.

Parameter	Description	Support
lambda	Mean	$\lambda \geq 0$

The probability density function of the Poisson distribution is

$$f(x | \lambda) = \frac{\lambda^x}{x!} e^{-\lambda} \quad ; \quad x = 0, 1, 2, \dots, \infty .$$

Examples

Create a Poisson Distribution Object Using Default Parameters

Create a Poisson distribution object using the default parameter values.

```
pd = makedist('Poisson')
```

```
pd =  
  
    PoissonDistribution  
  
    Poisson distribution  
    lambda = 1
```

Create a Poisson Distribution Object Using Specified Parameters

Create a Poisson distribution object by specifying the parameter values.

```
pd = makedist('Poisson', 'lambda', 5)  
  
pd =  
  
    PoissonDistribution  
  
    Poisson distribution  
    lambda = 5
```

Compute the variance of the distribution.

```
v = var(pd)  
  
v =  
  
    5
```

For the Poisson distribution, both the mean and variance are equal to the parameter `lambda`.

poisspdf

Poisson probability density function

Syntax

`Y = poisspdf(X,lambda)`

Description

`Y = poisspdf(X,lambda)` computes the Poisson pdf at each of the values in `X` using mean parameters in `lambda`. `X` and `lambda` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other input. The parameters in `lambda` must all be positive.

The Poisson pdf is

$$f(x|\lambda) = \frac{\lambda^x}{x!} e^{-\lambda}; x = 0, 1, 2, \dots, \infty.$$

The density function is zero unless x is an integer.

Examples

A computer hard disk manufacturer has observed that flaws occur randomly in the manufacturing process at the average rate of two flaws in a 4 GB hard disk and has found this rate to be acceptable. What is the probability that a disk will be manufactured with no defects?

In this problem, $\lambda = 2$ and $x = 0$.

```
p = poisspdf(0,2)
p =
    0.1353
```

pdf | poisscdf | poissinv | poisstat | poissfit | poissrnd

poissrnd

Poisson random numbers

Syntax

```
R = poissrnd(lambda)
R = poissrnd(lambda,m,n,...)
R = poissrnd(lambda,[m,n,...])
```

Description

`R = poissrnd(lambda)` generates random numbers from the Poisson distribution with mean parameter `lambda`. `lambda` can be a vector, a matrix, or a multidimensional array. The size of `R` is the size of `lambda`.

`R = poissrnd(lambda,m,n,...)` or `R = poissrnd(lambda,[m,n,...])` generates an `m`-by-`n`-by-... array. The `lambda` parameter can be a scalar or an array of the same size as `R`.

Examples

Generate a random sample of 10 pseudo-observations from a Poisson distribution with $\lambda = 2$.

```
lambda = 2;

random_sample1 = poissrnd(lambda,1,10)
random_sample1 =
    1    0    1    2    1    3    4    2    0    0

random_sample2 = poissrnd(lambda,[1 10])
random_sample2 =
    1    1    1    5    0    3    2    2    3    4

random_sample3 = poissrnd(lambda(ones(1,10)))
random_sample3 =
```

3 2 1 1 0 0 4 0 2 0

random | poisspdf | poisscdf | poissinv | poisstat | poissfit

poisstat

Poisson mean and variance

Syntax

```
M = poisstat(lambda)
[M,V] = poisstat(lambda)
```

Description

`M = poisstat(lambda)` returns the mean of the Poisson distribution using mean parameters in `lambda`. The size of `M` is the size of `lambda`.

`[M,V] = poisstat(lambda)` also returns the variance `V` of the Poisson distribution.

For the Poisson distribution with parameter λ , both the mean and variance are equal to λ .

Examples

Find the mean and variance for the Poisson distribution with $\lambda = 2$.

```
[m,v] = poisstat([1 2; 3 4])
m =
     1     2
     3     4
v =
     1     2
     3     4
```

polyconf

Polynomial confidence intervals

Syntax

```
Y = polyconf(p,X)
[Y,DELTA] = polyconf(p,X,S)
[Y,DELTA] = polyconf(p,X,S,param1,val1,param2,val2,...)
```

Description

`Y = polyconf(p,X)` evaluates the polynomial `p` at the values in `X`. `p` is a vector of coefficients in descending powers.

`[Y,DELTA] = polyconf(p,X,S)` takes outputs `p` and `S` from `polyfit` and generates 95% prediction intervals $Y \pm \text{DELTA}$ for new observations at the values in `X`.

`[Y,DELTA] = polyconf(p,X,S,param1,val1,param2,val2,...)` specifies optional parameter name/value pairs chosen from the following list.

Parameter	Value
'alpha'	A value between 0 and 1 specifying a confidence level of $100 \cdot (1 - \text{alpha})\%$. The default is 0.05.
'mu'	A two-element vector containing centering and scaling parameters. With this option, <code>polyconf</code> uses $(X - \text{mu}(1)) / \text{mu}(2)$ in place of <code>X</code> .
'predopt'	Either 'observation' (the default) to compute prediction intervals for new observations at the values in <code>X</code> , or 'curve' to compute confidence intervals for the fit evaluated at the values in <code>X</code> . See below.
'simopt'	Either 'off' (the default) for nonsimultaneous bounds, or 'on' for simultaneous bounds. See below.

The 'predopt' and 'simopt' parameters can be understood in terms of the following functions:

- $p(x)$ — the unknown mean function estimated by the fit
- $l(x)$ — the lower confidence bound
- $u(x)$ — the upper confidence bound

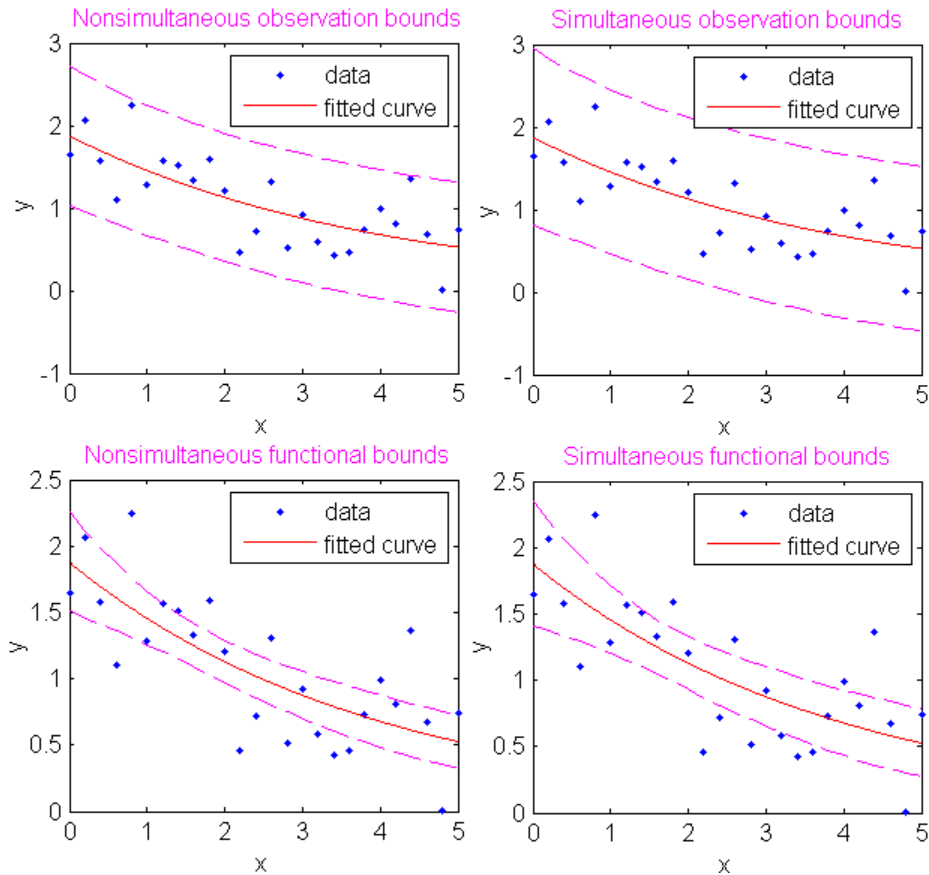

Suppose you make a new observation y_{n+1} at x_{n+1} , so that $y_{n+1}(x_{n+1}) = p(x_{n+1}) + \varepsilon_{n+1}$

By default, the interval $[l_{n+1}(x_{n+1}), u_{n+1}(x_{n+1})]$ is a 95% confidence bound on $y_{n+1}(x_{n+1})$.

The following combinations of the 'predopt' and 'simopt' parameters allow you to specify other bounds.

'simopt'	'predopt'	Bounded Quantity
'off'	'observation'	$y_{n+1}(x_{n+1})$ (default)
'off'	'curve'	$p(x_{n+1})$
'on'	'observation'	$y_{n+1}(x)$, for all x
'on'	'curve'	$p(x)$, for all x

In general, 'observation' intervals are wider than 'curve' intervals, because of the additional uncertainty of predicting a new response value (the curve plus random errors). Likewise, simultaneous intervals are wider than nonsimultaneous intervals, because of the additional uncertainty of bounding values for all predictors x .

Examples

This example uses code from the documentation example function `polydemo`, and calls the documentation example function `polystr` to convert the coefficient vector `p` into a string for the polynomial expression displayed in the figure title. It combines the functions `polyfit`, `polyval`, `roots`, and `polyconf` to produce a formatted display of data with a polynomial fit.

Note: Statistics Toolbox documentation example files are located in the `\help\toolbox\stats\examples` subdirectory of your MATLAB root folder (`matlabroot`). This subdirectory is not on the MATLAB path at installation. To use the files in this subdirectory, either add the subdirectory to the MATLAB path (`addpath`) or make the subdirectory your current working folder (`cd`).

Display simulated data with a quadratic trend, a fitted quadratic polynomial, and 95% prediction intervals for new observations:

```
xdata = -5:5;
ydata = xdata.^2 - 5*xdata - 3 + 5*randn(size(xdata));

degree = 2; % Degree of the fit
alpha = 0.05; % Significance level

% Compute the fit and return the structure used by
% POLYCONF.
[p,S] = polyfit(xdata,ydata,degree);

% Compute the real roots and determine the extent of the
% data.
r = roots(p)'; % Roots as a row vector.
real_r = r(imag(r) == 0); % Real roots.

% Assure that the data are row vectors.
xdata = reshape(xdata,1,length(xdata));
ydata = reshape(ydata,1,length(ydata));

% Extent of the data.
mx = min([real_r,xdata]);
Mx = max([real_r,xdata]);
my = min([ydata,0]);
My = max([ydata,0]);

% Scale factors for plotting.
sx = 0.05*(Mx-mx);
sy = 0.05*(My-my);

% Plot the data, the fit, and the roots.
hdata = plot(xdata,ydata,'md','MarkerSize',5,...
    'LineWidth',2);
hold on
xfit = mx-sx:0.01:Mx+sx;
```

```
yfit = polyval(p,xfit);
hfit = plot(xfit,yfit,'b-','LineWidth',2);
hroots = plot(real_r,zeros(size(real_r)),...
             'bo','MarkerSize',5,...
             'LineWidth',2,...
             'MarkerFaceColor','b');
grid on
plot(xfit,zeros(size(xfit)),'k-','LineWidth',2)
axis([mx-sx Mx+sx my-sy My+sy])

% Add prediction intervals to the plot.
[Y,DELTA] = polyconf(p,xfit,S,'alpha',alpha);
hconf = plot(xfit,Y+DELTA,'b--');
plot(xfit,Y-DELTA,'b--')

% Display the polynomial fit and the real roots.
approx_p = round(100*p)/100; % Round for display.
htitle = title(['{\bf Fit:   }',...
               texlabel(polystr(approx_p))]);
set(htitle,'Color','b')
approx_real_r = round(100*real_r)/100; % Round for display.
hxlabel = xlabel(['{\bf Real Roots:   }',...
                 num2str(approx_real_r)]);
set(hxlabel,'Color','b')

% Add a legend.
legend([hdata,hfit,hroots,hconf],...
      'Data','Fit','Real Roots of Fit',...
      '95% Prediction Intervals')
```

`polyfit` | `polytool` | `polyval`

polytool

Interactive polynomial fitting

Syntax

```
polytool(x,y)
polytool(x,y,n)
polytool(x,y,n,alpha)
polytool(x,y,n,alpha,xname,yname)
h = polytool(...)
```

Description

`polytool(x,y)` fits a line to the vectors `x` and `y` and displays an interactive plot of the result in a graphical interface. You can use the interface to explore the effects of changing the parameters of the fit and to export fit results to the workspace.

`polytool(x,y,n)` initially fits a polynomial of degree `n`. The default is 1, which produces a linear fit.

`polytool(x,y,n,alpha)` initially plots `100(1 - alpha)%` confidence intervals on the predicted values. The default is 0.05 which results in 95% confidence intervals.

`polytool(x,y,n,alpha,xname,yname)` labels the `x` and `y` values on the graphical interface using the strings `xname` and `yname`. Specify `n` and `alpha` as `[]` to use their default values.

`h = polytool(...)` outputs a vector of handles, `h`, to the line objects in the plot. The handles are returned in the degree: data, fit, lower bounds, upper bounds.

Examples

Interactive polynomial fitting

This example shows how to start an interactive fitting session with `polytool`.

Generate data from a quadratic curve with added noise.

```
rng('default') % for reproducibility
x = -5:5;
y = x.^2 - 5*x - 3 + 5*randn(size(x));
```

Fit a quadratic (degree-2) model with 0.90 confidence intervals.

```
n = 2;
alpha = 0.1;
polytool(x,y,n,alpha)
```

polyfit | polyconf | invpred | polyval

posterior

Class: `gmdistribution`

Posterior probabilities of components

Syntax

```
P = posterior(obj,X)
[P,nlogl] = posterior(obj,X)
```

Description

`P = posterior(obj,X)` returns the posterior probabilities of each of the k components in the Gaussian mixture distribution defined by `obj` for each observation in the data matrix X . X is n -by- d , where n is the number of observations and d is the dimension of the data. `obj` is an object created by `gmdistribution` or `fitgmdist`. P is n -by- k , with $P(I,J)$ the probability of component J given observation I .

`posterior` treats NaN values as missing data. Rows of X with NaN values are excluded from the computation.

`[P,nlogl] = posterior(obj,X)` also returns `nlogl`, the negative log-likelihood of the data.

Examples

Compute Posterior Probabilities for Gaussian Mixture Variates

Generate data from a mixture of two bivariate Gaussian distributions using the `mvnrnd` function.

```
MU1 = [2 2];
SIGMA1 = [2 0; 0 1];
MU2 = [-2 -1];
```

```
SIGMA2 = [1 0; 0 1];  
rng(1); % For reproducibility  
X = [mvnrnd(MU1,SIGMA1,1000);mvnrnd(MU2,SIGMA2,1000)];  
  
scatter(X(:,1),X(:,2),10,'.')  
hold on
```

Fit a two-component Gaussian mixture model.

```
obj = fitgmdist(X,2);  
h = ezcontour(@(x,y)pdf(obj,[x y]),[-8 6],[-8 6]);
```

Compute posterior probabilities of the components.

```
P = posterior(obj,X);  
  
delete(h)  
scatter(X(:,1),X(:,2),10,P(:,1))  
hb = colorbar;  
ylabel(hb,'Component 1 Probability')
```

**See Also**

`gmdistribution` | `mahal` | `fitgmdist` | `cluster`

posterior

Class: NaiveBayes

Compute posterior probability of each class for test data

Syntax

```
post = posterior(nb,test)
[post,cpre] = posterior(nb,test)
[post,cpre,logp] = posterior(nb,test)
[...] = posterior(..., 'HandleMissing',val)
```

Description

`post = posterior(nb,test)` returns the posterior probability of the observations in `test` according to the `NaiveBayes` object `nb`. `test` is a `N-by-nb.ndims` matrix, where `N` is the number of observations in the test data. Rows of `test` correspond to points, columns of `test` correspond to features. `post` is a `N-by-nb.nclasses` matrix containing the posterior probability of each observation for each class. `post(i,j)` is the posterior probability of point `i` belonging to class `j`. Classes are ordered the same as `nb.clevels`, i.e., column `j` of `post` corresponds to the `j`th class in `nb.clevels`. The posterior probabilities corresponding to any empty classes are `NaN`.

`[post,cpre] = posterior(nb,test)` returns `cpre`, an `N-by-1` vector, containing the class to which each row of `test` has been assigned. `cpre` has the same type as `nb.Clevels`.

`[post,cpre,logp] = posterior(nb,test)` returns `logp`, an `N-by-1` vector containing estimates of the log of the probability density function (PDF). `logp(i)` is the log of the PDF of point `i`. The PDF value of point `i` is the sum of `Prob(point I | class J) * Pr{class J}` taken over all classes.

`[...] = posterior(..., 'HandleMissing',val)` specifies how `posterior` treats `NaN` (missing values). `val` can be one of the following:

'off' (default) Observations with `NaN` in any of the columns are not classified into any class. The corresponding rows in `post` and `logp` are `NaN`. The

corresponding rows in `cpre` are `NaN` (if `obj.clevels` is numeric or logical), empty strings (if `obj.clevels` is char or cell array of strings) or `<undefined>` (if `obj.clevels` is categorical).

'on'

For observations having `NaN` in some (but not all) columns, `post` and `cpre` are computed using the columns with non-`NaN` values. Corresponding `logp` values are `NaN`.

See Also

`NaiveBayes` | `fitNaiveBayes` | `predict`

prctile

Percentiles of a data set

Syntax

```
Y = prctile(X,p)
Y = prctile(X,p,dim)
```

Description

`Y = prctile(X,p)` returns percentiles of the values in a data vector or matrix `X` for the percentages `p` in the interval `[0,100]`.

- If `X` is a vector, then `Y` is a scalar or a vector with the same length as the number of percentiles required (`length(p)`). `Y(i)` contains the `p(i)` percentile.
- If `X` is a matrix, then `Y` is a row vector or a matrix, where the number of rows of `Y` is equal to the number of percentiles required (`length(p)`). The `i`th row of `Y` contains the `p(i)` percentiles of each column of `X`.
- For multidimensional arrays, `prctile` operates along the first nonsingleton dimension of `X`.

`Y = prctile(X,p,dim)` returns percentiles along dimension `dim`.

Examples

Percentiles of a Data Vector

Generate a data set of size 10.

```
rng('default'); % for reproducibility
x = normrnd(5,2,1,10)
```

```
x =
    6.0753    8.6678    0.4823    6.7243    5.6375    2.3846    4.1328    5.6852    12....
```

Calculate the 42nd percentile.

```
Y = prctile(X,42)
```

```
Y =
    5.6709
```

Percentiles of a Data Matrix

Calculate the percentiles along the columns and rows of a data matrix for specified percentages.

Generate a 5-by-5 data matrix.

```
X = (1:5)'*(2:6)
```

```
X =
     2     3     4     5     6
     4     6     8    10    12
     6     9    12    15    18
     8    12    16    20    24
    10    15    20    25    30
```

Calculate the 25th, 50th, and 75th percentiles along the columns of X.

```
Y = prctile(X,[25 50 75],1)
```

```
Y =
    3.5000    5.2500    7.0000    8.7500   10.5000
    6.0000    9.0000   12.0000   15.0000   18.0000
    8.5000   12.7500   17.0000   21.2500   25.5000
```

The rows of Y correspond to the percentiles of columns of X. For example, the 25th, 50th, and 75th percentiles of the third column of X with elements (4, 8, 12, 16, 20) are 7, 12, and 17, respectively. `Y = prctile(X,[25 50 75])` returns the same percentile matrix.

Calculate the 25th, 50th, and 75th percentiles along the rows of X.

```
Y = prctile(X,[25 50 75],2)
```

```
Y =
    2.7500    4.0000    5.2500
    5.5000    8.0000   10.5000
    8.2500   12.0000   15.7500
   11.0000   16.0000   21.0000
```

13.7500 20.0000 26.2500

The rows of Y correspond to the percentiles of rows of X . For example, the 25th, 50th, and 75th percentiles of the first row of X with elements (2, 3, 4, 5, 6) are 2.75, 4, and 5.25, respectively.

Input Arguments

X — Input data

vector | array

Input data, specified as a vector or array.

Data Types: double | single

p — Percentages

scalar | vector

Percentages for which to compute percentiles, returned as a scalar or vector of scalars from 0 to 100.

Example: 25

Example: [25, 50, 75]

Data Types: double | single

dim — Dimension

1 (default) | positive integer

Dimension along which the percentiles of X are required, specified as a positive integer. For example, for a matrix X , when $\text{dim} = 1$, `prctile` returns the quantile(s) of the columns of X and when $\text{dim} = 2$, `prctile` returns the quantile(s) of the rows of X . For a multidimensional array X , the length of the dim th dimension of Y is equal to the length of p .

Data Types: double

Output Arguments

Y — Percentiles

scalar | array

Percentiles of a data vector or array, specified as a scalar or array for one or more percentage values.

- If X is a vector, then Y is a scalar or a vector with the same length as the number of percentiles required (`length(p)`). $Y(i)$ contains the $p(i)$ th percentile.
- If X is a matrix, then Y is a vector or a matrix with the length of the `dim`th dimension equal to the number percentiles required (`length(p)`). When `dim = 1`, for example, the i th row of Y contains the $p(i)$ th percentiles of columns of X .
- If X is an array of dimension d , then Y is an array with the length of the `dim`th dimension equal to the number of percentiles required (`length(p)`).

More About

Multidimensional Array

A *multidimensional array* is an array with more than two dimensions. For example, if X is a 1-by-3-by-4 array, then X is a 3-D array.

Nonsingleton Dimension

A *first nonsingleton dimension* is the first dimension of an array whose size is not equal to 1. For example, if X is a 1-by-2-by-3-by-4 array, then the second dimension is the first nonsingleton dimension of X .

Linear Interpolation

Linear interpolation uses linear polynomials to find $y_i = f(x_i)$, the values of the underlying function $Y = f(X)$ at the points in the vector or array x . Given the data points (x_1, y_1) and (x_2, y_2) , where $y_1 = f(x_1)$ and $y_2 = f(x_2)$, linear interpolation finds $y = f(x)$ for a given x between x_1 and x_2 as follows:

$$y = f(x) = y_1 + \frac{(x - x_1)}{(x_2 - x_1)}(y_2 - y_1).$$

Similarly, if the 100(1.5/ n)th percentile is $y_{1.5/n}$ and the 100(2.5/ n)th percentile is $y_{2.5/n}$, then linear interpolation finds the 100(2.3/ n)th percentile, $y_{2.3/n}$ as:

$$y_{\frac{2.3}{n}} = y_{\frac{1.5}{n}} + \left(\frac{\frac{2.3}{n} - \frac{1.5}{n}}{\frac{2.5}{n} - \frac{1.5}{n}} \right) \left(y_{\frac{2.5}{n}} - y_{\frac{1.5}{n}} \right).$$

Algorithms

For an n -element vector X , `prctile` returns percentiles as follows:

- 1 The sorted values in X are taken as the $100(0.5/n)$ th, $100(1.5/n)$ th, ..., $100([n - 0.5]/n)$ th percentiles. For example:
 - For a data vector of five elements such as $\{6, 3, 2, 10, 1\}$, the sorted elements $\{1, 2, 3, 6, 10\}$ respectively correspond to the 10th, 30th, 50th, 70th, and 90th percentiles.
 - For a data vector of six elements such as $\{6, 3, 2, 10, 8, 1\}$, the sorted elements $\{1, 2, 3, 6, 8, 10\}$ respectively correspond to the $(50/6)$ th, $(150/6)$ th, $(250/6)$ th, $(350/6)$ th, $(450/6)$ th, and $(550/6)$ th percentiles.
- 2 `prctile` uses linear interpolation to compute percentiles for percentages between $100(0.5/n)$ and $100([n - 0.5]/n)$.
- 3 `prctile` assigns the minimum or maximum values in X to the percentiles corresponding to the percentages outside that range.

`prctile` treats NaNs as missing values and removes them.

- “Quantiles and Percentiles” on page 3-7

predict

Class: ClassificationKNN

Predict k -nearest neighbor classification

Syntax

```
label = predict mdl, Xnew
[label, score] = predict mdl, Xnew
[label, score, cost] = predict mdl, Xnew
```

Description

`label = predict(mdl, Xnew)` returns a vector of predicted class labels for a matrix `Xnew`, based on `mdl`, a `ClassificationKNN` model.

`[label, score] = predict(mdl, Xnew)` returns a matrix of scores, indicating the likelihood that a label comes from a particular class.

`[label, score, cost] = predict(mdl, Xnew)` returns a matrix of costs; `label` is the vector of minimal costs for each row of `cost`

Input Arguments

mdl — Classifier model

classifier model object

k -nearest neighbor classifier model, returned as a classifier model object.

Note that using the `'CrossVal'`, `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'` options results in a model of class `ClassificationPartitionedModel`. You cannot use a partitioned tree for prediction, so this kind of tree does not have a `predict` method.

Otherwise, `mdl` is of class `ClassificationKNN`, and you can use the `predict` method to make predictions.

Xnew — Prediction points

matrix

Points at which `mdl` predicts classifications. Each row of `Xnew` is one point. The number of columns in `Xnew` must equal the number of predictors in `mdl`.

If you specified to standardize the predictor data, that is, `mdl.Mu` and `mdl.Sigma` are not empty (`[]`), then `predict` standardizes `Xnew` before predicting labels.

Output Arguments

label1

Predicted class labels for the points in `Xnew`, a vector with length equal to the number of rows of `Xnew`. The label is the class with minimal expected cost. See “Predicted Class Label” on page 21-3314.

score

Numeric matrix of size N-by-K, where N is the number of observations (rows) in `Xnew`, and K is the number of classes (in `mdl.ClassNames`). `score(i, j)` is the posterior probability that row `i` of `Xnew` is of class `j`. See “Posterior Probability” on page 21-3315.

cost

Matrix of expected costs of size N-by-K, where N is the number of observations (rows) in `Xnew`, and K is the number of classes (in `mdl.ClassNames`). `cost(i, j)` is the cost of classifying row `i` of `X` as class `j`. See “Expected Cost” on page 21-3316.

Definitions

Predicted Class Label

`predict` classifies so as to minimize the expected classification cost:

$$\hat{y} = \arg \min_{y=1, \dots, K} \sum_{k=1}^K \hat{P}(k | x) C(y | k),$$

where

- \hat{y} is the predicted classification.
- K is the number of classes.
- $\hat{P}(k | x)$ is the posterior probability of class k for observation x .
- $C(y | k)$ is the cost of classifying an observation as y when its true class is k .

Posterior Probability

For a vector (single query point) X_{new} and model `mdl`, let:

- K be the number of nearest neighbors used in prediction, `mdl.NumNeighbors`
- `nbd(mdl, Xnew)` be the K nearest neighbors to X_{new} in `mdl.X`
- `Y(nbd)` be the classifications of the points in `nbd(mdl, Xnew)`, namely `mdl.Y(nbd)`
- `W(nbd)` be the weights of the points in `nbd(mdl, Xnew)`
- `prior` be the priors of the classes in `mdl.Y`

If there is a vector of prior probabilities, then the observation weights W are normalized by class to sum to the priors. This might involve a calculation for the point X_{new} , because weights can depend on the distance from X_{new} to the points in `mdl.X`.

The posterior probability $p(j | X_{\text{new}})$ is

$$p(j | X_{\text{new}}) = \frac{\sum_{i \in \text{nbd}} W(i) 1_{Y(X(i)=j)}}{\sum_{i \in \text{nbd}} W(i)}.$$

Here, $1_{Y(X(i)=j)}$ means 1 when `mdl.Y(i) = j`, and 0 otherwise.

True Misclassification Cost

There are two costs associated with KNN classification: the true misclassification cost per class, and the expected misclassification cost per observation.

You can set the true misclassification cost per class in the `Cost` name-value pair when you run `fitcknn`. `Cost(i, j)` is the cost of classifying an observation into class j if its

true class is i . By default, $\text{Cost}(i, j) = 1$ if $i \neq j$, and $\text{Cost}(i, j) = 0$ if $i = j$. In other words, the cost is 0 for correct classification, and 1 for incorrect classification.

Expected Cost

There are two costs associated with KNN classification: the true misclassification cost per class, and the expected misclassification cost per observation. The third output of `predict` is the expected misclassification cost per observation.

Suppose you have `NOBS` observations that you want to classify with a trained classifier `mdl`. Suppose you have K classes. You place the observations into a matrix `Xnew` with one observation per row. The command

```
[label,score,cost] = predict(mdl,Xnew)
```

returns, among other outputs, a `COST` matrix of size `NOBS`-by- K . Each row of the `COST` matrix contains the expected (average) cost of classifying the observation into each of the K classes. `cost(n,k)` is

$$\sum_{i=1}^K \hat{P}(i | Xnew(n)) C(k | i),$$

where

- K is the number of classes.
- $\hat{P}(i | Xnew(n))$ is the posterior probability of class i for observation $Xnew(n)$.
- $C(k | i)$ is the true misclassification cost of classifying an observation as k when its true class is i .

Examples

***k*-Nearest Neighbor Classification Predictions**

Construct a k -nearest neighbor classifier for Fisher's iris data, where $k = 5$. Evaluate some model predictions on new data.

Load the data.

```
load fisheriris
X = meas;
Y = species;
```

Construct a classifier for 5-nearest neighbors. It is good practice to standardize non-categorical predictor data.

```
mdl = fitcknn(X,Y,'NumNeighbors',5,'Standardize',1);
```

Predict the classifications for flowers with minimum, mean, and maximum characteristics.

```
Xnew = [min(X);mean(X);max(X)];
[label,score,cost] = predict(mdl,Xnew)
```

```
label =
```

```
    'versicolor'
    'versicolor'
    'virginica'
```

```
score =
```

```
    0.4000    0.6000         0
         0    1.0000         0
         0         0    1.0000
```

```
cost =
```

```
    0.6000    0.4000    1.0000
    1.0000         0    1.0000
    1.0000    1.0000         0
```

The classifications have binary values for the score and cost matrices, meaning all five nearest neighbors of each of the three points have identical classifications.

predict

Class: CompactClassificationDiscriminant

Predict classification

Syntax

```
label = predict(obj,X)
[label,score] = predict(obj,X)
[label,score,cost] = predict(obj,X)
```

Description

`label = predict(obj,X)` returns a vector of predicted class labels for a matrix `X`, based on `obj`, a trained full or compact classifier.

`[label,score] = predict(obj,X)` returns a matrix of scores (posterior probabilities).

`[label,score,cost] = predict(obj,X)` returns a matrix of costs; `label` is the vector of minimal costs for each row of `cost`.

Input Arguments

obj

Discriminant analysis classifier of class `ClassificationDiscriminant` or `CompactClassificationDiscriminant`, typically constructed with `fitcdiscr`.

X

Matrix where each row represents an observation, and each column represents a predictor. The number of columns in `X` must equal the number of predictors in `obj`.

Output Arguments

label

Vector of class labels of the same type as the response data used in training obj. Each entry of `labels` corresponds to a predicted class label for the corresponding row of `X`; see “Predicted Class Label” on page 21-3321.

score

Numeric matrix of size N-by-K, where N is the number of observations (rows) in `X`, and K is the number of classes (in `obj.ClassNames`). `score(i, j)` is the posterior probability that row `i` of `X` is of class `j`; see “Posterior Probability” on page 21-3320.

cost

Matrix of expected costs of size N-by-K. `cost(i, j)` is the cost of classifying row `i` of `X` as class `j`. See “Cost” on page 21-3321.

Definitions

Posterior Probability

The posterior probability that a point z belongs to class j is the product of the prior probability and the multivariate normal density. The density function of the multivariate normal with mean μ_j and covariance Σ_j at a point z is

$$P(x | k) = \frac{1}{(2\pi|\Sigma_k|)^{1/2}} \exp\left(-\frac{1}{2}(x - \mu_k)^T \Sigma_k^{-1} (x - \mu_k)\right),$$

where $|\Sigma_k|$ is the determinant of Σ_k , and Σ_k^{-1} is the inverse matrix.

Let $P(k)$ represent the prior probability of class k . Then the posterior probability that an observation x is of class k is

$$\hat{P}(k | x) = \frac{P(x | k)P(k)}{P(x)},$$

where $P(x)$ is a normalization constant, the sum over k of $P(x|k)P(k)$.

Prior Probability

The prior probability is one of three choices:

- 'uniform' — The prior probability of class k is one over the total number of classes.
- 'empirical' — The prior probability of class k is the number of training samples of class k divided by the total number of training samples.
- Custom — The prior probability of class k is the k th element of the `prior` vector. See `fitcdiscr`.

After creating a classifier `obj`, you can set the prior using dot notation:

```
obj.Prior = v;
```

where `v` is a vector of positive elements representing the frequency with which each element occurs. You do not need to retrain the classifier when you set a new prior.

Cost

The matrix of expected costs per observation is defined in “Cost” on page 15-8.

Predicted Class Label

`predict` classifies so as to minimize the expected classification cost:

$$\hat{y} = \arg \min_{y=1,\dots,K} \sum_{k=1}^K \hat{P}(k|x)C(y|k),$$

where

- \hat{y} is the predicted classification.
- K is the number of classes.
- $\hat{P}(k|x)$ is the posterior probability of class k for observation x .
- $C(y|k)$ is the cost of classifying an observation as y when its true class is k .

Examples

Examine predictions for a few rows in the Fisher iris data:

```
load fisheriris
obj = fitcdiscr(meas,species);
X = meas(99:102,:); % take four rows
[label score cost] = predict(obj,X)
```

```
label =
    'versicolor'
    'versicolor'
    'virginica'
    'virginica'
```

```
score =
    0.0000    1.0000    0.0000
    0.0000    0.9999    0.0001
    0.0000    0.0000    1.0000
    0.0000    0.0011    0.9989
```

```
cost =
    1.0000    0.0000    1.0000
    1.0000    0.0001    0.9999
    1.0000    1.0000    0.0000
    1.0000    0.9989    0.0011
```

How To

- “Discriminant Analysis” on page 15-3

predict

Class: CompactClassificationECOC

Predict labels for error-correcting output code multiclass classifiers

Syntax

```
label = predict(Mdl,X)
label = predict(Mdl,X,Name,Value)
[label,NegLoss,PBScore] = predict( ___ )
[label,NegLoss,PBScore,Posterior] = predict( ___ )
```

Description

`label = predict(Mdl,X)` returns a vector of predicted class labels for the predictor data, based on the full or compact, trained error-correcting output code multiclass classifier `Mdl`. Each row of `X` is an observation.

The software predicts the classification of an observation by assigning the observation to the class yielding the largest negated average binary loss (or, equivalently, the smallest average binary loss).

`label = predict(Mdl,X,Name,Value)` returns predicted class labels with additional options specified by one or more `Name,Value` pair arguments.

For example, specify the posterior probability estimation method, decoding scheme, or verbosity level.

`[label,NegLoss,PBScore] = predict(___)` additionally returns negated average binary loss per class (`NegLoss`) for observations, and positive-class scores (`PBScore`) for the observations classified by each binary learner.

`[label,NegLoss,PBScore,Posterior] = predict(___)` additionally returns posterior class probability estimates for observations (`Posterior`).

To obtain posterior class probabilities, you must set `'FitPosterior',1` when training the ECOC model using `fitcecoc`. Otherwise, `predict` throws an error.

Input Arguments

Mdl — ECOC multiclass classifier

`ClassificationECOC` model | `CompactClassificationECOC` model

ECOC multiclass classifier, specified as a `ClassificationECOC` or `CompactClassificationECOC` model. You can create a:

- `ClassificationECOC` model by training the ECOC classifier using `fitcecoc`
- `CompactClassificationECOC` model by passing a `ClassificationECOC` classifier to `compact`

X — Predictor data

numeric matrix

Predictor data, specified as a numeric matrix.

Each row of `X` corresponds to one observation (also called an instance or example), and each column corresponds to one variable (also known as a feature). The variables composing the columns of `X` should be the same as the variables that trained the `Mdl` classifier.

If you trained `Mdl` specifying to standardize the predictor data, then the software standardizes the columns of `X` using the corresponding means and standard deviations that the software stored in `Mdl.BinaryLearner{j}.Mu` and `Mdl.BinaryLearner{j}.Sigma` for learner `j`.

Data Types: `double` | `single`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

'BinaryLoss' — Binary learner loss function

function handle | `'hamming'` | `'linear'` | `'exponential'` | `'binodeviance'` | `'hinge'` | `'quadratic'`

Binary learner loss function, specified as the comma-separated pair consisting of `'BinaryLoss'` and a function handle or string.

- If the value is a string, then it must correspond to a built-in function. This table summarizes the built-in functions, where y_j is a class label for a particular binary learner (in the set $\{-1, 1, 0\}$), s_j is the score for observation j , and $g(y_j, s_j)$ is the binary loss formula.

Value	Description	Score Domain	$g(y_j, s_j)$
'binodeviance'	Binomial deviance	$(-\infty, \infty)$	$\log[1 + \exp(-2y_j s_j)] / [2\log(2)]$
'exponential'	Exponential	$(-\infty, \infty)$	$\exp(-y_j s_j) / 2$
'hamming'	Hamming	$\{-1, 1\}$	$[1 - \text{sign}(y_j s_j)] / 2$
'hinge'	Hinge	$(-\infty, \infty)$	$\max(0, 1 - y_j s_j) / 2$
'linear'	Linear	$(-\infty, \infty)$	$(1 - y_j s_j) / 2$
'quadratic'	Quadratic	$[0, 1]$	$[1 - y_j(2s_j - 1)]^2 / 2$

The software normalizes the binary losses such that the loss is 0.5 when $y_j = 0$. Also, the software calculates the mean binary loss for each class.

- For a custom binary loss function, e.g., `customFunction`, specify its function handle `'BinaryLoss', @customFunction`.

`customFunction` should have this form

```
bLoss = customFunction(M,s)
```

where:

- M is the K -by- L coding matrix stored in `Mdl.CodingMatrix`.
- s is the 1-by- L row vector of classification scores.
- `bLoss` is the classification loss. This scalar aggregates the binary losses for every learner in a particular class. For example, you can use the mean binary loss to aggregate the loss over the learners for each class.
- K is the number of classes.
- L is the number of binary learners.

For an example on passing a custom binary loss function, see “Predict Test-Sample Labels of ECOC Models Using Custom Binary Loss Function”.

This list describes the default values of `BinaryLoss`. If all binary learners are:

- SVMs, then `BinaryLoss` is 'hinge'
- Ensembles trained by `AdaboostM1` or `GentleBoost`, then `BinaryLoss` is 'exponential'
- Ensembles trained by `LogitBoost`, then `BinaryLoss` is 'binodeviance'
- Predicting class posterior probabilities (i.e., set 'FitPosterior', 1 in `fitcecoc`), then `BinaryLoss` is 'quadratic'

Otherwise, the default `BinaryLoss` is 'hamming'.

Example: 'BinaryLoss', 'binodeviance'

Data Types: char | function_handle

'Decoding' — Decoding scheme

'lossweighted' (default) | 'lossbased'

Decoding scheme that aggregates the “binary losses”, specified as the comma-separated pair consisting of 'Decoding' and 'lossweighted' or 'lossbased'.

Example: 'Decoding', 'lossbased'

Data Types: char

'NumKLInitializations' — Number of random initial values

0 (default) | nonnegative integer

Number of random initial values for fitting posterior probabilities by Kullback-Leibler divergence minimization, specified as the comma-separated pair consisting of 'NumKLInitializations' and a nonnegative integer.

If you do not request the fourth output argument (Posterior) and set 'PosteriorMethod', 'kl' (the default), then the software ignores the value of `NumKLInitializations`.

For more details, see “Posterior Estimation Using Kullback-Leibler Divergence” on page 21-3340.

Example: 'NumKLInitializations', 5

Data Types: single | double

'Options' — Estimation options

[] (default) | structure array returned by `statset`

Estimation options, specified as the comma-separated pair consisting of `'Options'` and a structure array returned by `statset`.

To invoke parallel computing:

- You need a Parallel Computing Toolbox license.
- Specify `'Options',statset('UseParallel',1)`.

'PosteriorMethod' — Posterior probability estimation method

`'k1'` (default) | `'qp'`

Posterior probability estimation method, specified as the comma-separated pair consisting of `'PosteriorMethod'` and `'k1'` or `'qp'`.

- If `PosteriorMethod` is `'k1'`, then the software estimates multiclass posterior probabilities by minimizing the Kullback-Leibler divergence between the predicted and expected posterior probabilities returned by binary learners. For details, see “Posterior Estimation Using Kullback-Leibler Divergence”.
- If `PosteriorMethod` is `'qp'`, then the software estimates multiclass posterior probabilities by solving a least-squares problem using quadratic programming. You need an Optimization Toolbox license to use this option. For details, see “Posterior Estimation Using Quadratic Programming”.
- If you do not request the fourth output argument (`Posterior`), then the software ignores the value of `PosteriorMethod`.

Example: `'PosteriorMethod','qp'`

Data Types: `char`

'Verbose' — Verbosity level

`0` (default) | `1`

Verbosity level, specified as the comma-separated pair consisting of `'Verbose'` and `0` or `1`. `Verbose` controls the amount of diagnostic messages that the software displays in the Command Window.

If `Verbose` is `0`, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: `'Verbose',1`

Data Types: `single` | `double`

Output Arguments

label — Predicted class labels

categorical array | character array | logical vector | vector of numeric values | cell array of strings

Predicted class labels, returned as a categorical or character array, logical or numeric vector, or cell array of strings.

label:

- Is the same data type as the `Mdl.ClassNames`
- Has length equal to the number of rows of `X`

The software predicts the classification of an observation by assigning the observation to the class yielding the largest negated average binary loss (or, equivalently, the smallest average binary loss).

NegLoss — Negated average binary losses

numeric matrix

Negated, average binary losses, returned as a numeric matrix. `NegLoss` is an `n`-by-`K` matrix, where `n` is the number of observations (`size(X,1)`) and `K` is the number of unique classes (`size(Mdl.ClassNames,1)`).

PBScore — Positive-class scores

numeric matrix

Positive-class scores for each binary learner, returned as a numeric matrix. `PBScore` is an `n`-by-`L` matrix, where `n` is the number of observations (`size(X,1)`) and `L` is the number of binary learners (`size(Mdl.CodingMatrix,2)`).

Posterior — Posterior class probabilities

numeric matrix

Posterior class probabilities, returned as a numeric matrix. `Posterior` is an `n`-by-`K` matrix, where `n` is the number of observations (`size(X,1)`) and `K` is the number of unique classes (`size(Mdl.ClassNames,1)`).

You must set `'FitPosterior',1` when training the ECOC model using `fitcecoc` to request `Posterior`. Otherwise, the software throws an error.

Definitions

Binary Loss

A *binary loss* is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Let:

- m_{kj} be element (k,j) of the coding design matrix M (i.e., the code corresponding to class k of binary learner j)
- s_j be the score of binary learner j for an observation
- g be the binary loss function
- \hat{k} be the predicted class for the observation

In *loss-based decoding* [3], the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j).$$

In *loss-weighted decoding* [3], the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \frac{\sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j)}{\sum_{j=1}^L |m_{kj}|}.$$

Allwein et al. [1] suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where y_j is a class label for a particular binary learner (in the set $\{-1, 1, 0\}$), s_j is the score for observation j , and $g(y_j, s_j)$.

Value	Description	Score Domain	$g(y_j, s_j)$
'binodeviance'	Binomial deviance	$(-\infty, \infty)$	$\log[1 + \exp(-2y_j s_j)] / [2\log(2)]$
'exponential'	Exponential	$(-\infty, \infty)$	$\exp(-y_j s_j) / 2$
'hamming'	Hamming	$\{-1, 1\}$	$[1 - \text{sign}(y_j s_j)] / 2$
'hinge'	Hinge	$(-\infty, \infty)$	$\max(0, 1 - y_j s_j) / 2$
'linear'	Linear	$(-\infty, \infty)$	$(1 - y_j s_j) / 2$
'quadratic'	Quadratic	$[0, 1]$	$[1 - y_j(2s_j - 1)]^2 / 2$

The software normalizes the binary losses such that the loss is 0.5 when $y_j = 0$, and aggregates using the average of the binary learners [1].

Do not confuse the binary loss with the overall classification loss (specified by the LossFun name-value pair argument of `predict` and `loss`), e.g., classification error, which measures how well an ECOC classifier performs as a whole.

Examples

Predict Test-Sample Labels of Training Data Using ECOC Models

Load Fisher's iris data set.

```
load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y);
rng(1); % For reproducibility
```

Train an ECOC model using SVM binary classifiers and specify a 30% holdout sample. It is good practice to standardize the predictors and define the class order. Specify to standardize the predictors using an SVM template.

```
t = templateSVM('Standardize', 1);
```

```

CVMdl = fitcecoc(X,Y,'Holdout',0.30,'Learners',t,'ClassNames',classOrder);
CMdl = CVMdl.Trained{1}; % Extract trained, compact classifier
testInds = test(CVMdl.Partition); % Extract the test indices
XTest = X(testInds,:);
YTest = Y(testInds,:);

```

CVMdl is a `ClassificationPartitionedECOC` model. It contains the property `Trained`, which is a 1-by-1 cell array holding a `CompactClassificationECOC` model that the software trained using the training set.

Predict the test-sample labels. Print a random subset of true and predicted labels.

```

labels = predict(CMdl,XTest);
idx = randsample(sum(testInds),10);
table(YTest(idx),labels(idx),...
      'VariableNames',{'TrueLabels','PredictedLabels'})

```

ans =

TrueLabels	PredictedLabels
setosa	setosa
versicolor	virginica
setosa	setosa
virginica	virginica
versicolor	versicolor
setosa	setosa
virginica	virginica
virginica	virginica
setosa	setosa
setosa	setosa

Mdl correctly labeled all except one of the test-sample observations with indices `idx`.

Predict Test-Sample Labels of ECOC Models Using Custom Binary Loss Function

Load Fisher's iris data set.

```

load fisheriris
X = meas;
Y = categorical(species);

```

```
classOrder = unique(Y); % Class order
K = numel(classOrder); % Number of classes
rng(1); % For reproducibility
```

Train an ECOC model using SVM binary classifiers and specify a 30% holdout sample. It is good practice to standardize the predictors and define the class order. Specify to standardize the predictors using an SVM template.

```
t = templateSVM('Standardize',1);
CVMdl = fitcecoc(X,Y,'Holdout',0.30,'Learners',t,'ClassNames',classOrder);
CMdl = CVMdl.Trained{1}; % Extract trained, compact classifier
testInds = test(CVMdl.Partition); % Extract the test indices
XTest = X(testInds,:);
YTest = Y(testInds,:);
```

CVMdl is a `ClassificationPartitionedECOC` model. It contains the property `Trained`, which is a 1-by-1 cell array holding a `CompactClassificationECOC` model that the software trained using the training set.

SVM scores are signed distances from the observation to the decision boundary.

Therefore, the domain is $(-\infty, \infty)$. Create a custom binary loss function that:

- Maps the coding design matrix (M) and positive-class classification scores (s) for each learner to the binary loss for each observation
- Uses linear loss
- Aggregates the binary learner loss using the median.

You can create a separate function for the binary loss function, and then save it on the MATLAB® path. Or, you can specify an anonymous binary loss function.

```
customBL = @(M,s)nanmedian(1 - bsxfun(@times,M,s),2)/2;
```

Predict test-sample labels and estimate the median binary loss per class. Print the median negative binary losses per class for a random set of 10 test-sample observations.

```
[label,NegLoss] = predict(CMdl,XTest,'BinaryLoss',customBL);

idx = randsample(sum(testInds),10);
classOrder
table(YTest(idx),label(idx),NegLoss(idx,:), 'VariableNames',...
      {'TrueLabel','PredictedLabel','NegLoss'})
```

```
classOrder =
```

```
    setosa
    versicolor
    virginica
```

```
ans =
```

TrueLabel	PredictedLabel	NegLoss		
setosa	versicolor	0.1857	1.9878	-3.6735
versicolor	virginica	-1.3316	-0.12333	-0.045053
setosa	versicolor	0.13898	1.9261	-3.5651
virginica	virginica	-1.5133	-0.38263	0.39592
versicolor	versicolor	-0.87209	0.74777	-1.3757
setosa	versicolor	0.48381	1.9972	-3.981
virginica	virginica	-1.9364	-0.67508	1.1114
virginica	virginica	-1.579	-0.83339	0.91235
setosa	versicolor	0.51001	2.1208	-4.1308
setosa	versicolor	0.36119	2.0594	-3.9206

The order of the columns corresponds to the elements of `classOrder`. The software predicts the label based on the maximum negated loss. The results seem to indicate that the median of the linear losses might not perform as well as other losses.

Estimate Posterior Probabilities Using ECOC Classifiers

Load Fisher's iris data set. Train the classifier using the petal dimensions as predictors.

```
load fisheriris
X = meas(:,3:4);
Y = species;
rng(1); % For reproducibility
```

Create an SVM template, and specify the Gaussian kernel. It is good practice to standardize the predictors.

```
t = templateSVM('Standardize',1,'KernelFunction','gaussian');
```

`t` is an SVM template. Most of its properties are empty. When the software trains the ECOC classifier, it sets the applicable properties to their default values.

Train the ECOC classifier using the SVM template. Transform classification scores to class posterior probabilities (which are returned by `predict` or `resubPredict`) using the `'FitPosterior'` name-value pair argument. Display diagnostic messages during the training using the `'Verbose'` name-value pair argument. It is good practice to specify the class order.

```
Mdl = fitcecoc(X,Y,'Learners',t,'FitPosterior',1,...  
    'ClassNames',{'setosa','versicolor','virginica'},...  
    'Verbose',2);
```

```
Training binary learner 1 (SVM) out of 3 with 50 negative and 50 positive observations  
Negative class indices: 2  
Positive class indices: 1
```

```
Fitting posterior probabilities for learner 1 (SVM).  
Training binary learner 2 (SVM) out of 3 with 50 negative and 50 positive observations  
Negative class indices: 3  
Positive class indices: 1
```

```
Fitting posterior probabilities for learner 2 (SVM).  
Training binary learner 3 (SVM) out of 3 with 50 negative and 50 positive observations  
Negative class indices: 3  
Positive class indices: 2
```

```
Fitting posterior probabilities for learner 3 (SVM).
```

`Mdl` is a `ClassificationECOC` model. The same SVM template applies to each binary learner, but you can adjust options for each binary learner by passing in a cell vector of templates.

Predict the in-sample labels and class posterior probabilities. Display diagnostic messages during the computation of labels and class posterior probabilities using the `'Verbose'` name-value pair argument.

```
[label,~,~,Posterior] = resubPredict(Mdl,'Verbose',1);  
Mdl.BinaryLoss
```

```
Predictions from all learners have been computed.  
Loss for all observations has been computed.  
Computing posterior probabilities...
```

```
ans =
```

```
quadratic
```

The software assigns an observation to the class that yields the smallest average binary loss. Since all binary learners are computing posterior probabilities, the binary loss function is quadratic.

Display a random set of results.

```
idx = randsample(size(X,1),10,1);
Mdl.ClassNames
table(Y(idx),label(idx),Posterior(idx,:),...
      'VariableNames',{ 'TrueLabel', 'PredLabel', 'Posterior'})
```

```
ans =
```

```
'setosa'
'versicolor'
'virginica'
```

```
ans =
```

TrueLabel	PredLabel	Posterior		
'virginica'	'virginica'	0.0039321	0.0039869	0.99208
'virginica'	'virginica'	0.017067	0.018263	0.96467
'virginica'	'virginica'	0.014948	0.015856	0.9692
'versicolor'	'versicolor'	2.2197e-14	0.87317	0.12683

'versicolor'	'virginica'	2.2195e-14	0.059429	0.94057
'versicolor'	'versicolor'	2.2194e-14	0.97001	0.029986
'setosa'	'setosa'	0.999	0.0002499	0.00074741
'versicolor'	'versicolor'	0.0085646	0.98259	0.008849
'setosa'	'setosa'	0.999	0.00025013	0.00074718

The columns of `Posterior` correspond to the class order of `Mdl.ClassNames`.

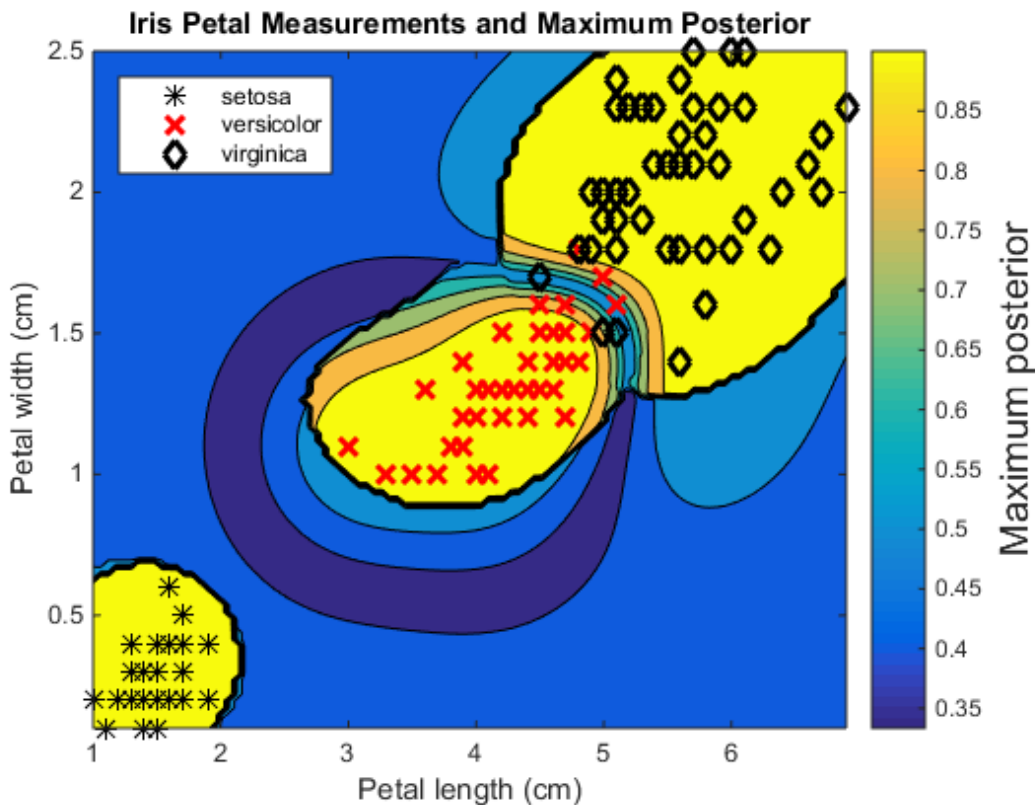

Define a grid of values in the observed predictor space. Predict the posterior probabilities for each instance in the grid.

```
xMax = max(X);
```

```
xMin = min(X);  
  
x1Pts = linspace(xMin(1),xMax(1));  
x2Pts = linspace(xMin(2),xMax(2));  
[x1Grid,x2Grid] = meshgrid(x1Pts,x2Pts);  
  
[~,~,~,PosteriorRegion] = predict(Mdl,[x1Grid(:),x2Grid(:)]);
```

For each coordinate on the grid, plot the maximum class posterior probability among all classes.

```
figure;  
contourf(x1Grid,x2Grid,...  
         reshape(max(PosteriorRegion,[],2),size(x1Grid,1),size(x1Grid,2)));  
h = colorbar;  
h.YLabel.String = 'Maximum posterior';  
h.YLabel.FontSize = 15;  
hold on  
gh = gscatter(X(:,1),X(:,2),Y,'krk','*xd',8);  
gh(2).LineWidth = 2;  
gh(3).LineWidth = 2;  
  
title 'Iris Petal Measurements and Maximum Posterior';  
xlabel 'Petal length (cm)';  
ylabel 'Petal width (cm)';  
axis tight  
legend(gh,'Location','NorthWest')  
hold off
```

Estimate Test-Sample Posterior Probabilities Using Parallel Computing

Train an error-correcting output codes, multiclass model and estimate posterior probabilities using parallel computing.

Load the arrhythmia data set.

```
load arrhythmia
Y = categorical(Y);
tabulate(Y)
n = numel(Y);
K = numel(unique(Y));
```

Value	Count	Percent
-------	-------	---------

1	245	54.20%
2	44	9.73%
3	15	3.32%
4	15	3.32%
5	13	2.88%
6	25	5.53%
7	3	0.66%
8	2	0.44%
9	9	1.99%
10	50	11.06%
14	4	0.88%
15	5	1.11%
16	22	4.87%

Several classes are not represented in the data, and many of the other classes have low relative frequencies.

Specify an ensemble learning template that uses the GentleBoost method and 50 weak, classification tree learners.

```
t = templateEnsemble('GentleBoost',50,'Tree');
```

`t` is a template object. Most of the options are empty (`[]`). The software uses default values for all empty options during training.

Since there are many classes, specify a sparse random coding design.

```
rng(1); % For reproducibility
Coding = designecoc(K,'sparserandom');
```

Train an ECOC model using parallel computing. Specify to hold out 15% of the data and fit posterior probabilities.

```
pool = parpool; % Invokes workers
options = statset('UseParallel',1);
CVMdl = fitcecoc(X,Y,'Learner',t,'Options',options,'Coding',Coding,...
    'FitPosterior',1,'Holdout',0.15);

CMDl = CVMdl.Trained{1}; % Extract trained, compact classifier
testInds = test(CVMdl.Partition); % Extract the test indices
XTest = X(testInds,:);
YTest = Y(testInds,:);
```

Starting parallel pool (parpool) using the 'local' profile ... connected to 4 workers.

CVMD1 is a `ClassificationPartitionedECOC` model. It contains the property `Trained`, which is a 1-by-1 cell array holding a `CompactClassificationECOC` model that the software trained using the training set.

The pool invokes four workers. The number of workers might vary among systems.

Estimate posterior probabilities, and display the posterior probability of being classified as not having arrhythmia (class 1) given the data for a random set of test-sample observations.

```
[~,~,~,posterior] = predict(CMD1,XTest,'Options',options);
idx = randsample(sum(testInds),10);
table(idx,YTest(idx),posterior(idx,1),...
      'VariableNames',{'TestSampleIndex','TrueLabel','PosteriorNoArrhythmia'})
```

ans =

TestSampleIndex	TrueLabel	PosteriorNoArrhythmia
11	6	0.60631
41	4	0.23674
51	2	0.13802
33	10	0.43831
12	1	0.94332
8	1	0.97278
37	1	0.62807

56	16	0.29375
30	1	0.64512

- “Quick Start Parallel Computing for Statistics Toolbox” on page 20-2

Algorithms

The software can estimate class posterior probabilities using quadratic programming or by minimizing the Kullback-Leibler divergence. For the following descriptions of the posterior estimation algorithms, let:

- m_{kj} be the element (k,j) of the coding design matrix M .
- I be the indicator function.
- \hat{p}_k be the class posterior probability estimate for class k of an observation, $k = 1, \dots, K$.

- r_j be the positive-class posterior probability for binary learner j . That is, r_j is the probability that binary learner j classifies an observation into the positive class, given the training data.

Posterior Estimation Using Kullback-Leibler Divergence

By default, the software minimizes the Kullback-Leibler divergence to estimate class posterior probabilities. The Kullback-Leibler divergence between the expected and observed positive-class posterior probabilities is

$$\Delta(r, r) = \sum_{j=1}^L w_j \left[r_j \log \frac{r_j}{r_j} + (1 - r_j) \log \frac{1 - r_j}{1 - r_j} \right],$$

where $w_j = \sum_{S_j} w_i^*$ is the weight for binary learner j with S_j the set of observation

indices that binary learner j is trained on and w_i^* is the weight of observation i . The software minimizes the divergence iteratively. The first step is to choose initial values $\hat{p}_k^{(0)}$; $k = 1, \dots, K$ for the class posterior probabilities.

- If you do not specify `NumKLIterations`, then the software uses both sets of deterministic initial values described next, and uses the one that minimizes Δ .
 - $\hat{p}_k^{(0)} = 1 / K$; $k = 1, \dots, K$.
 - $\hat{p}_k^{(0)}$; $k = 1, \dots, K$ is the solution of the system

$$M_{01} \hat{p}^{(0)} = r,$$

where M_{01} is M with all $m_{kj} = -1$ replaced with 0, and r is a vector of positive-class posterior probabilities returned by the L binary learners [2]. The software uses `lsqnonneg` to solve the system.

- If you specify `'NumKLIterations', c`, where c is a natural number, then the software does the following to choose $\hat{p}_k^{(0)}$; $k = 1, \dots, K$, and uses the one that minimizes Δ .

- The software chooses both sets of deterministic initial values as described previously.
- The software randomly generates \mathbf{c} vectors of length K using `rand`, and then normalizes each vector to sum to 1.

At iteration t , the software:

- 1 Computes

$$\hat{r}_j^{(t)} = \frac{\sum_{k=1}^K \hat{p}_k^{(t)} I(m_{kj} = +1)}{\sum_{k=1}^K \hat{p}_k^{(t)} I(m_{kj} = +1 \cup m_{kj} = -1)}.$$

- 2 Estimates the next class posterior probability using

$$\hat{p}_k^{(t+1)} = \hat{p}_k^{(t)} \frac{\sum_{j=1}^L w_j [r_j I(m_{kj} = +1) + (1 - r_j) I(m_{kj} = -1)]}{\sum_{j=1}^L w_j [\hat{r}_j^{(t)} I(m_{kj} = +1) + (1 - \hat{r}_j^{(t)}) I(m_{kj} = -1)]}.$$

- 3 Normalizes $\hat{p}_k^{(t+1)}$; $k = 1, \dots, K$ so that they sum to 1.
- 4 Checks for convergence.

For more details, see [5] and [7].

Posterior Estimation Using Quadratic Programming

Posterior probability estimation using quadratic programming requires an Optimization Toolbox license. To estimate posterior probabilities for an observation using this method, the software:

- 1 Estimates the positive-class posterior probabilities, r_j , for binary learners $j = 1, \dots, L$.
- 2 Using the relationship between r_j and \hat{p}_k [6], minimizes

$$\sum_{j=1}^L \left[-r_j \sum_{k=1}^K \hat{p}_k I(m_{kj} = -1) + (1 - r_j) \sum_{k=1}^K \hat{p}_k I(m_{kj} = +1) \right]^2$$

with respect to \hat{p}_k and the restrictions

$$\begin{aligned} 0 &\leq \hat{p}_k \leq 1 \\ \sum_k \hat{p}_k &= 1. \end{aligned}$$

The software performs minimization using `quadprog`.

predict

Class: CompactClassificationEnsemble

Predict classification

Syntax

```
labels = predict(ens,X)
[labels,score] = predict(ens,X)
[labels,...] = predict(ens,X,Name,Value)
```

Description

`labels = predict(ens,X)` returns a vector of predicted class labels for a matrix `X`, based on `ens`, a trained full or compact classification ensemble.

`[labels,score] = predict(ens,X)` also returns scores for all classes.

`[labels,...] = predict(ens,X,Name,Value)` predicts classifications with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

ens

A classification ensemble created by `fitensemble`, or a compact classification ensemble created by `compact`.

X

A matrix where each row represents an observation, and each column represents a predictor. The number of columns in `X` must equal the number of predictors in `ens`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single

quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

'learners'

Indices of weak learners `predict` uses for computation of responses, a numeric vector.

Default: `1:T`, where `T` is the number of weak learners in `ens`

'UseObsForLearner'

A logical matrix of size `N`-by-`T`, where:

- `N` is the number of rows of `X`.
- `T` is the number of weak learners in `ens`.

When `UseObsForLearner(i, j)` is `true`, learner `j` is used in predicting the class of row `i` of `X`.

Default: `true(N, T)`

Output Arguments

labels

Vector of classification labels. `labels` has the same data type as the labels used in training `ens`.

score

A matrix with one row per observation and one column per class. For each observation and each class, the score generated by each tree is the probability of this observation originating from this class computed as the fraction of observations of this class in a tree leaf. `predict` averages these scores over all trees in the ensemble.

Definitions

Score (ensemble)

For ensembles, a classification *score* represents the confidence of a classification into a class. The higher the score, the higher the confidence.

Different ensemble algorithms have different definitions for their scores. Furthermore, the range of scores depends on ensemble type. For example:

- `AdaBoostM1` scores range from $-\infty$ to ∞ .
- `Bag` scores range from 0 to 1.

Examples

Train a boosting ensemble for the `ionosphere` data, and predict the classification of the mean of the data:

```
load ionosphere;
ada = fitensemble(X,Y,'AdaBoostM1',100,'tree');
Xbar = mean(X);
[ypredict score] = predict(ada,Xbar)

ypredict =
    'g'

score =
    -2.9460    2.9460
```

See Also

`margin` | `edge` | `loss`

predict

Class: CompactClassificationNaiveBayes

Predict classification for naive Bayes models

Syntax

```
label = predict(Mdl,X)
[label,Posterior,Cost] = predict(Mdl,X)
```

Description

`label = predict(Mdl,X)` returns a vector of predicted class labels for predictor data (`X`), based on the trained, full or compact naive Bayes classifier `Mdl`.

`[label,Posterior,Cost] = predict(Mdl,X)` additionally returns posterior probabilities (`Posterior`) and predicted (expected) misclassification costs (`Cost`) corresponding to the observations (rows) in `X`.

Input Arguments

Mdl — Naive Bayes classifier

ClassificationNaiveBayes model | CompactClassificationNaiveBayes model

Naive Bayes classifier, specified as a `ClassificationNaiveBayes` model or `CompactClassificationNaiveBayes` model returned by `fitcnb` or `compact`, respectively.

X — Predictor data

numeric matrix

Predictor data, specified as a numeric matrix.

Each row of `X` corresponds to one observation (also known as an instance or example), and each column corresponds to one variable (also known as a feature). The variables making up the columns of `X` should be the same as the variables that trained `Mdl`.

The length of `Y` and the number of rows of `X` must be equal.

Data Types: `double` | `single`

Notes:

- If `Mdl.DistributionNames` is `'mn'`, then the software returns NaNs corresponding to rows of `X` containing at least one NaN.
 - If `Mdl.DistributionNames` is not `'mn'`, then the software ignores NaN values when estimating misclassification costs and posterior probabilities. Specifically, the software computes the conditional density of the predictors given the class by leaving out the factors corresponding to missing predictor values.
 - For predictor distribution specified as `'mvmn'`, if `X` contains levels that are not represented in the training data (i.e., not in `Mdl.CategoricalLevels` for that predictor), then the conditional density of the predictors given the class is 0. For those observations, the software returns the corresponding value of `Posterior` as a NaN. The software determines the class label for such observations using the class prior probability, stored in `Mdl.Prior`.
-

Output Arguments

label — Predicted class labels

categorical vector | character array | logical vector | numeric vector | cell vector of strings

Predicted class labels, returned as a categorical vector, character array, logical or numeric vector, or cell vector of strings.

`label`:

- Is the same data type as the observed class labels (`Mdl.Y`) that trained `Mdl`
- Has length equal to the number of rows of `Mdl.X`
- Is the class yielding the lowest expected misclassification cost (`Cost`)

Posterior — Class posterior probabilities

numeric matrix

Class posterior probabilities, returned as a numeric matrix. `Posterior` has rows equal to the number of rows of `X` and columns equal to the number of distinct classes in the training data (`size(Mdl.ClassNames, 1)`).

$\text{Posterior}(j, k)$ is the predicted posterior probability of class k (i.e., in class $\text{Mdl.ClassNames}(k)$) given the observation in row j of X .

Data Types: `double`

Cost — Expected misclassification costs

numeric matrix

Expected misclassification costs, returned as a numeric matrix. `Cost` has rows equal to the number of rows of X and columns equal to the number of distinct classes in the training data ($\text{size}(\text{Mdl.ClassNames}, 1)$).

$\text{Cost}(j, k)$ is the expected misclassification cost of the observation in row j of X being predicted into class k (i.e., in class $\text{Mdl.ClassNames}(k)$).

Definitions

Misclassification Cost

A *misclassification cost* is the relative severity of a classifier labeling an observation into the wrong class.

There are two types of misclassification costs: true and expected. Let K be the number of classes.

- *True misclassification cost* — A K -by- K matrix, where element (i, j) indicates the misclassification cost of predicting an observation into class j if its true class is i . The software stores the misclassification cost in the property `Mdl.Cost`, and used in computations. By default, $\text{Mdl.Cost}(i, j) = 1$ if $i \neq j$, and $\text{Mdl.Cost}(i, j) = 0$ if $i = j$. In other words, the cost is 0 for correct classification, and 1 for any incorrect classification.
- *Expected misclassification cost* — A K -dimensional vector, where element k is the weighted average misclassification cost of classifying an observation into class k , weighted by the class posterior probabilities. In other words,

$$c_k = \sum_{j=1}^K \hat{P}(Y = j | x_1, \dots, x_P) \text{Cost}_{jk}.$$

the software classifies observations to the class corresponding with the lowest expected misclassification cost.

Posterior Probability

The *posterior probability* is the probability that an observation belongs in a particular class, given the data.

For naive Bayes, the posterior probability that a classification is k for a given observation (x_1, \dots, x_p) is

$$\hat{P}(Y = k | x_1, \dots, x_p) = \frac{P(X_1, \dots, X_p | y = k)\pi(Y = k)}{P(X_1, \dots, X_p)},$$

where:

- $P(X_1, \dots, X_p | y = k)$ is the conditional joint density of the predictors given they are in class k . `Mdl.DistributionNames` stores the distribution names of the predictors.
- $\pi(Y = k)$ is the class prior probability distribution. `Mdl.Prior` stores the prior distribution.
- $P(X_1, \dots, X_p)$ is the joint density of the predictors. The classes are discrete, so

$$P(X_1, \dots, X_p) = \sum_{k=1}^K P(X_1, \dots, X_p | y = k)\pi(Y = k).$$

Prior Probability

The *prior probability* is the believed relative frequency that observations from a class occur in the population for each class.

Examples

Label Test Sample Observations of Naive Bayes Classifiers

Load Fisher's iris data set.

```
load fisheriris
X = meas; % Predictors
Y = species; % Response
rng(1);
```

Train a naive Bayes classifier and specify to holdout 30% of the data for a test sample. It is good practice to specify the class order. Assume that each predictor is conditionally, normally distributed given its label.

```
CVMD1 = fitcnb(X,Y,'Holdout',0.30,...
    'ClassNames',{'setosa','versicolor','virginica'});
CMD1 = CVMD1.Trained{1}; % Extract trained, compact classifier
testIdx = test(CVMD1.Partition); % Extract the test indices
XTest = X(testIdx,:);
YTest = Y(testIdx);
```

CVMD1 is a `ClassificationPartitionedModel` classifier. It contains the property `Trained`, which is a 1-by-1 cell array holding a `CompactClassificationNaiveBayes` classifier that the software trained using the training set.

Label the test sample observations. Display the results for a random set of 10 observations in the test sample.

```
idx = randsample(sum(testIdx),10);
label = predict(CMD1,XTest);
table(YTest(idx),label(idx),'VariableNames',...
    {'TrueLabel','PredictedLabel'})
```

ans =

TrueLabel	PredictedLabel
'setosa'	'setosa'
'versicolor'	'versicolor'
'setosa'	'setosa'
'virginica'	'virginica'
'versicolor'	'versicolor'
'setosa'	'setosa'
'virginica'	'virginica'
'virginica'	'virginica'
'setosa'	'setosa'
'setosa'	'setosa'

Estimate Posterior Probabilities and Misclassification Costs

A goal of classification is to estimate posterior probabilities of new observations using a trained algorithm. Many applications train algorithms on large data sets, which can use resources that are better used elsewhere. This example shows how to efficiently estimate posterior probabilities of new observations using a Naive Bayes classifier.

Load Fisher's iris data set.

```
load fisheriris
X = meas;    % Predictors
Y = species; % Response
rng(1);
```

Partition the data set into two sets: one in the training set, and the other is new unobserved data. Reserve 10 observations for the new data set.

```
n = size(X,1);
newInds = randsample(n,10);
inds = ~ismember(1:n,newInds);
XNew = X(newInds,:);
YNew = Y(newInds);
```

Train a naive Bayes classifier. It is good practice to specify the class order. Assume that each predictor is conditionally, normally distributed given its label. Conserve memory by reducing the size of the trained SVM classifier.

```
Mdl = fitcnb(X(inds,:),Y(inds),...
    'ClassNames',{'setosa','versicolor','virginica'});
CMdl = compact(Mdl);
whos('Mdl','CMdl')
```

Name	Size	Bytes	Class
CMdl	1x1	4772	classreg.learning.classif.CompactClassificationNaiveBayes
Mdl	1x1	12541	ClassificationNaiveBayes

The `CompactClassificationNaiveBayes` classifier (`CMdl`) uses less space than the `ClassificationNaiveBayes` classifier (`Mdl`) because the latter stores the data.

Predict the labels, posterior probabilities, and expected class misclassification costs. Since true labels are available, compare them with the predicted labels.

```

CMdl.ClassNames
[labels,PostProbs,MisClassCost] = predict(CMdl,XNew);
table(YNew,labels,PostProbs,'VariableNames',...
      {'TrueLabels','PredictedLabels',...
       'PosteriorProbabilities'})
MisClassCost

```

```
ans =
```

```

'setosa'
'versicolor'
'virginica'

```

```
ans =
```

TrueLabels	PredictedLabels	PosteriorProbabilities		
'setosa'	'setosa'	1	4.1259e-16	1.1846e-23
'versicolor'	'versicolor'	1.0373e-60	0.99999	5.8053e-06

```
MisClassCost =
```

0.0000	1.0000	1.0000
1.0000	0.0000	1.0000
1.0000	0.9991	0.0009
0.0000	1.0000	1.0000
1.0000	0.0001	0.9999
0.0000	1.0000	1.0000
1.0000	0.0000	1.0000
1.0000	0.0576	0.9424
0.0000	1.0000	1.0000
0.0000	1.0000	1.0000

`PostProbs` and `MisClassCost` are 15-by-3 numeric matrices, where each row corresponds to a new observation and each column corresponds to a class. The order of the columns corresponds to the order of `CMdl.ClassNames`.

Plot Posterior Probability Regions for Naive Bayes Classifiers

Load Fisher's iris data set. Train the classifier using the petal lengths and widths.

```
load fisheriris
X = meas(:,3:4);
Y = species;
```

Train a naive Bayes classifier. It is good practice to specify the class order. Assume that each predictor is conditionally, normally distributed given its label.

```
Mdl = fitcnb(X,Y,...
    'ClassNames',{ 'setosa', 'versicolor', 'virginica' });
```

`Mdl` is a `ClassificationNaiveBayes` model. You can access its properties using dot notation.

Define a grid of values in the observed predictor space. Predict the posterior probabilities for each instance in the grid.

```
xMax = max(X);
xMin = min(X);
h = 0.01;
[x1Grid,x2Grid] = meshgrid(xMin(1):h:xMax(1),xMin(2):h:xMax(2));

[~,PosteriorRegion] = predict(Mdl,[x1Grid(:),x2Grid(:)]);
```

Plot the posterior probability regions and the training data.

```
figure;
% Plot posterior regions
scatter(x1Grid(:),x2Grid(:),1,PosteriorRegion);
% Adjust color bar options
h = colorbar;
h.Ticks = [0 0.5 1];
h.TickLabels = { 'setosa', 'versicolor', 'virginica' };
h.YLabel.String = 'Posterior';
h.YLabel.Position = [-0.5 0.5 0];
% Adjust color map options
d = 1e-2;
cmap = zeros(201,3);
cmap(1:101,1) = 1:-d:0;
```

```
cmap(1:201,2) = [0:d:1 1-d:-d:0];
cmap(101:201,3) = 0:d:1;
colormap(cmap);
% Plot data
hold on
gh = gscatter(X(:,1),X(:,2),Y, 'k', 'dx*');
title 'Iris Petal Measurements and Posterior Probabilities';
xlabel 'Petal length (cm)';
ylabel 'Petal width (cm)';
axis tight
legend(gh, 'Location', 'Best')
hold off
```

predict

Class: CompactClassificationSVM

Predict labels for support vector machine classifiers

Syntax

```
label = predict(SVMModel,X)
[label,Score] = predict(SVMModel,X)
```

Description

`label = predict(SVMModel,X)` returns a vector of predicted class labels for predictor data `X`, based on the full or compact, trained SVM classifier `SVMModel`.

`[label,Score] = predict(SVMModel,X)` additionally returns class likelihood measures, i.e., either scores or posterior probabilities.

Input Arguments

SVMModel — SVM classifier

ClassificationSVM classifier | CompactClassificationSVM classifier

SVM classifier, specified as a `ClassificationSVM` classifier or `CompactClassificationSVM` classifier returned by `fitcsvm` or `compact`, respectively.

X — Predictor data

numeric matrix

Predictor data, specified as a numeric matrix.

Each row of `X` corresponds to one observation (also known as an instance or example), and each column corresponds to one variable (also known as a feature). The variables making up the columns of `X` should be the same as the variables that trained the `SVMModel` classifier.

The length of `Y` and the number of rows of `X` must be equal.

If you set `'Standardize', true` in `fitsvm` to train `SVModel`, then the software standardizes the columns of `X` using the corresponding means in `SVModel.Mu` and standard deviations in `SVModel.Sigma`.

Data Types: `double` | `single`

Output Arguments

label — Predicted class labels

categorical array | character array | logical vector | vector of numeric values | cell array of strings

Predicted class labels, returned as a categorical or character array, logical or numeric vector, or cell array of strings.

`label`:

- Is the same data type as the observed class labels (`Y`) that trained `SVModel`
- Has length equal to the number of rows of `X`

For one-class learning, the elements of `label` are the one class represented in the observed class labels.

Score — Predicted class scores or posterior probabilities

numeric column vector | numeric matrix

Predicted class “scores” or “posterior probabilities”, returned as a numeric column vector or numeric matrix.

- For one-class learning, `Score` is a column vector with the same number of rows as the training observations (`X`). The elements are the positive class scores for the corresponding observations. You cannot obtain posterior probabilities for one-class learning.
- For two-class learning, `Score` is a two column matrix with the same number of rows as `X`.
 - If you fit the optimal score-to-posterior probability transformation function using `fitPosterior` or `fitSVMPosterior`, then `Score` contains class posterior

probabilities. That is, if the value of `SVMModel.ScoreTransform` is not `none`, then the elements of the first and second columns of `Score` are the negative class (`SVMModel.ClassNames{1}`) and positive class (`SVMModel.ClassNames{2}`) posterior probabilities for the corresponding observations, respectively.

- Otherwise, the elements of the first column are the negative class scores and the elements of the second column are the positive class scores for the corresponding observations.

Data Types: `double` | `single`

Definitions

Score

The SVM *score* for classifying observation x is the signed distance from x to the decision boundary ranging from $-\infty$ to $+\infty$. A positive score for a class indicates that x is predicted to be in that class, a negative score indicates otherwise.

The score is also the numerical, predicted response for x , $f(x)$, computed by the trained SVM classification function

$$f(x) = \sum_{j=1}^n \alpha_j y_j G(x_j, x) + b,$$

where $(\alpha_1, \dots, \alpha_n, b)$ are the estimated SVM parameters, $G(x_j, x)$ is the dot product in the predictor space between x and the support vectors, and the sum includes the training set observations.

Posterior Probability

The probability that an observation belongs in a particular class, given the data.

For SVM, the posterior probability is a function of the score, $P(s)$, that observation j is in class $k = \{-1, 1\}$.

- For separable classes, the posterior probability is the step function

$$P(s_j) = \begin{cases} 0; & s < \max_{y_k=-1} s_k \\ \pi; & \max_{y_k=-1} s_k \leq s_j \leq \min_{y_k=+1} s_k, \\ 1; & s_j > \min_{y_k=+1} s_k \end{cases}$$

where:

- s_j is the score of observation j .
- $+1$ and -1 denote the positive and negative classes, respectively.
- π is the prior probability that an observation is in the positive class.
- For inseparable classes, the posterior probability is the sigmoid function

$$P(s_j) = \frac{1}{1 + \exp(As_j + B)},$$

where the parameters A and B are the slope and intercept parameters.

Prior Probability

The *prior probability* is the believed relative frequency that observations from a class occur in the population for each class.

Examples

Label Test Sample Observations of SVM Classifiers

Load the ionosphere data set.

```
load ionosphere
rng(1); % For reproducibility
```

Train an SVM classifier. Specify a 15% holdout sample for testing. It is good practice to specify the class order and standardize the data.

```
CVSVMModel = fitcsvm(X,Y,'Holdout',0.15,'ClassNames',{'b','g'},...
```

```

    'Standardize',true);
CompactSVMModel = CVSSVMModel.Trained{1}; % Extract trained, compact classifier
testInds = test(CVSSVMModel.Partition); % Extract the test indices
XTest = X(testInds,:);
YTest = Y(testInds,:);

```

CVSSVMModel is a `ClassificationPartitionedModel` classifier. It contains the property `Trained`, which is a 1-by-1 cell array holding a `CompactClassificationSVM` classifier that the software trained using the training set.

Label the test sample observations. Display the results for the first 10 observations in the test sample.

```

[label,score] = predict(CompactSVMModel,XTest);
table(YTest(1:10),label(1:10),score(1:10,2),'VariableNames',...
      {'TrueLabel','PredictedLabel','Score'})

```

ans =

TrueLabel	PredictedLabel	Score
'b'	'b'	-1.7177
'g'	'g'	2.0003
'b'	'b'	-9.6841
'g'	'g'	2.5618
'b'	'b'	-1.548
'g'	'g'	2.0984
'b'	'b'	-2.7018
'b'	'b'	-0.66291
'g'	'g'	1.6046
'g'	'g'	1.7731

Predict Labels and Posterior Probabilities of SVM Classifiers

A goal of classification is to predict labels of new observations using a trained algorithm. Many applications train algorithms on large data sets, which can use resources that are better used elsewhere. This example shows how to efficiently label new observations using an SVM classifier.

Load the ionosphere data set. Suppose that the last 10 observations become available after training the SVM classifier.

```
load ionosphere
```

```
n = size(X,1);           % Training sample size
isInds = 1:(n-10);      % In-sample indices
oosInds = (n-9):n;     % Out-of-sample indices
```

Train an SVM classifier. It is good practice to standardize the predictors and specify the order of the classes. Conserve memory by reducing the size of the trained SVM classifier.

```
SVMModel = fitcsvm(X(isInds,:),Y(isInds),'Standardize',true,...
    'ClassNames',{'b','g'});
CompactSVMModel = compact(SVMModel);
whos('SVMModel','CompactSVMModel')
```

Name	Size	Bytes	Class
CompactSVMModel	1x1	29576	classreg.learning.classif.CompactClassifi
SVMModel	1x1	137545	ClassificationSVM

The positive class is 'g'. The `CompactClassificationSVM` classifier (`CompactSVMModel`) uses less space than the `ClassificationSVM` classifier (`SVMModel`) because the latter stores the data.

Estimate the optimal score-to-posterior-probability-transformation function.

```
CompactSVMModel = fitPosterior(CompactSVMModel,...
    X(isInds,:),Y(isInds))
```

```
CompactSVMModel =
```

```
classreg.learning.classif.CompactClassificationSVM
    PredictorNames: {1x34 cell}
    ResponseName: 'Y'
    ClassNames: {'b' 'g'}
    ScoreTransform: '@(S)sigmoid(S,-1.968452e+00,3.121267e-01)'
    Alpha: [88x1 double]
    Bias: -0.2143
    KernelParameters: [1x1 struct]
        Mu: [1x34 double]
        Sigma: [1x34 double]
    SupportVectors: [88x34 double]
    SupportVectorLabels: [88x1 double]
```

The optimal score transformation function (`CompactSVMModel.ScoreTransform`) is the sigmoid function because the classes are inseparable.

Predict the out-of-sample labels and positive class posterior probabilities. Since true labels are available, compare them with the predicted labels.

```
[labels,PostProbs] = predict(CompactSVMModel,X(oosInds,:));  
table(Y(oosInds),labels,PostProbs(:,2), 'VariableNames',...  
      {'TrueLabels','PredictedLabels','PosClassPosterior'})
```

ans =

TrueLabels	PredictedLabels	PosClassPosterior
'g'	'g'	0.98419
'g'	'g'	0.95545
'g'	'g'	0.67792
'g'	'g'	0.94448
'g'	'g'	0.98744
'g'	'g'	0.92482
'g'	'g'	0.97111
'g'	'g'	0.96986
'g'	'g'	0.97803
'g'	'g'	0.94361

`PostProbs` is a 10-by-2 matrix; its first column is the negative class posterior probabilities, and second column is the positive class posterior probabilities corresponding to the new observations.

Plot Posterior Probability Regions for SVM Classifiers

Load Fisher's iris data set. Train the classifier using the petal lengths and widths, and remove the virginica species from the data.

```
load fisheriris  
classKeep = ~strcmp(species,'virginica');  
X = meas(classKeep,3:4);  
y = species(classKeep);
```

Train an SVM classifier using the data. It is good practice to specify the order of the classes.

```
SVMModel = fitcsvm(X,y,'ClassNames',{ 'setosa','versicolor' });
```

Estimate the optimal score transformation function.

```
rng(1); % For reproducibility
[SVMModel,ScoreParameters] = fitPosterior(SVMModel);
ScoreParameters
```

Warning: Classes are perfectly separated. The optimal score-to-posterior transformation is a step function.

```
ScoreParameters =
    Type: 'step'
    LowerBound: -0.8431
    UpperBound: 0.6897
    PositiveClassProbability: 0.5000
```

The optimal score transformation function is the step function because the classes are separable. The fields `LowerBound` and `UpperBound` of `ScoreParameters` indicate the lower and upper end points of the interval of scores corresponding to observations within the class-separating hyperplanes (the margin). No training observation falls within the margin. If a new score is in the interval, then the software assigns the corresponding observation a positive class posterior probability, i.e., the value in the `PositiveClassProbability` field of `ScoreParameters`.

Define a grid of values in the observed predictor space. Predict the posterior probabilities for each instance in the grid.

```
xMax = max(X);
xMin = min(X);
d = 0.01;
[x1Grid,x2Grid] = meshgrid(xMin(1):d:xMax(1),xMin(2):d:xMax(2));

[~,PosteriorRegion] = predict(SVMModel,[x1Grid(:),x2Grid(:)]);
```

Plot the positive class posterior probability region and the training data.

```
figure;
```

```

contourf(x1Grid,x2Grid,...
         reshape(PosteriorRegion(:,2),size(x1Grid,1),size(x1Grid,2)));
h = colorbar;
h.Label.String = 'P({\it{versicolor}})';
h.YLabel.FontSize = 16;
caxis([0 1]);
colormap jet;

hold on
gscatter(X(:,1),X(:,2),y,'mc','x',[15,10]);
sv = X(SVMModel.IsSupportVector,:);
plot(sv(:,1),sv(:,2),'yo','MarkerSize',15,'LineWidth',2);
axis tight
hold off

```

In two-class learning, if the classes are separable, then there are three regions: one where observations have positive class posterior probability 0, one where it is 1, and the other where it is the positive class prior probability.

Algorithms

- By default, the software computes optimal posterior probabilities using Platt's method "[1]":
 - 1 Performing 10-fold cross validation
 - 2 Fitting the sigmoid function parameters to the scores returned from the cross validation
 - 3 Estimating the posterior probabilities by entering the cross-validation scores into the fitted sigmoid function
- The software incorporates prior probabilities in the SVM objective function during training.
- For SVM, `predict` classifies observations into the class yielding the largest score (i.e., the largest posterior probability). The software accounts for misclassification costs by applying the average-cost correction before training the classifier. That is, given the class prior vector P , misclassification cost matrix C , and observation weight vector w , the software defines a new vector of observation weights (W) such that

$$W_j = w_j P_j \sum_{k=1}^K C_{jk}.$$

predict

Class: CompactClassificationTree

Predict classification

Syntax

```
label = predict(tree,X)
[label,score] = predict(tree,X)
[label,score,node] = predict(tree,X)
[label,score,node,cnum] = predict(tree,X)
[label,...] = predict(tree,X,Name,Value)
```

Description

`label = predict(tree,X)` returns a vector of predicted class labels for a matrix `X`, based on `tree`, a trained full or compact classification tree.

`[label,score] = predict(tree,X)` returns a matrix of scores, indicating the likelihood that a label comes from a particular class.

`[label,score,node] = predict(tree,X)` returns a vector of predicted node numbers for the classification, based on `tree`.

`[label,score,node,cnum] = predict(tree,X)` returns a vector of predicted class number for the classification, based on `tree`.

`[label,...] = predict(tree,X,Name,Value)` returns labels with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

tree

A classification tree created by `fitctree`, or a compact classification tree created by `compact`.

X

A matrix where each row represents an observation, and each column represents a predictor. The number of columns in **X** must equal the number of predictors in **tree**.

Name-Value Pair Arguments

Specify optional comma-separated pairs of **Name**,**Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as **Name1**,**Value1**, . . . ,**NameN**,**ValueN**.

'Subtrees'

Numeric vector of pruning levels, with 0 representing the full, unpruned tree. To use the **Subtrees** name-value pair, **tree** must include a pruning sequence as created by the **fitctree** or **prune** methods. If **Subtrees** has **T** elements, and **X** has **N** rows, then **labels** is an **N**-by-**T** matrix. The *i*th column of **labels** contains the fitted values produced by the **Subtrees(I)** subtree. Similarly, **score** is an **N**-by-**K**-by-**T** array, and **node** and **cnum** are **N**-by-**T** matrices. **Subtrees** must be sorted in ascending order. (To compute fitted values for a tree that is not part of the optimal pruning sequence, first use **prune** to prune the tree.)

Default: 0

Output Arguments

label1

Vector of class labels of the same type as the response data used in training **tree**. Each entry of **label1** corresponds to the class with minimal expected cost for the corresponding row of **X**. See “Predicted Class Label” on page 21-3370.

score

Numeric matrix of size **N**-by-**K**, where **N** is the number of observations (rows) in **X**, and **K** is the number of classes (in **tree.ClassNames**). **score(i,j)** is the posterior probability that row *i* of **X** is of class *j*.

node

Numeric vector of node numbers for the predicted classes. Each entry corresponds to the predicted node in tree for the corresponding row of X .

cnum

Numeric vector of class numbers corresponding to the predicted labels. Each entry of `cnum` corresponds to a predicted class number for the corresponding row of X .

Definitions

Predicted Class Label

`predict` classifies so as to minimize the expected classification cost:

$$\hat{y} = \arg \min_{y=1, \dots, K} \sum_{k=1}^K \hat{P}(k | x) C(y | k),$$

where

- \hat{y} is the predicted classification.
- K is the number of classes.
- $\hat{P}(k | x)$ is the posterior probability of class k for observation x .
- $C(y | k)$ is the cost of classifying an observation as y when its true class is k .

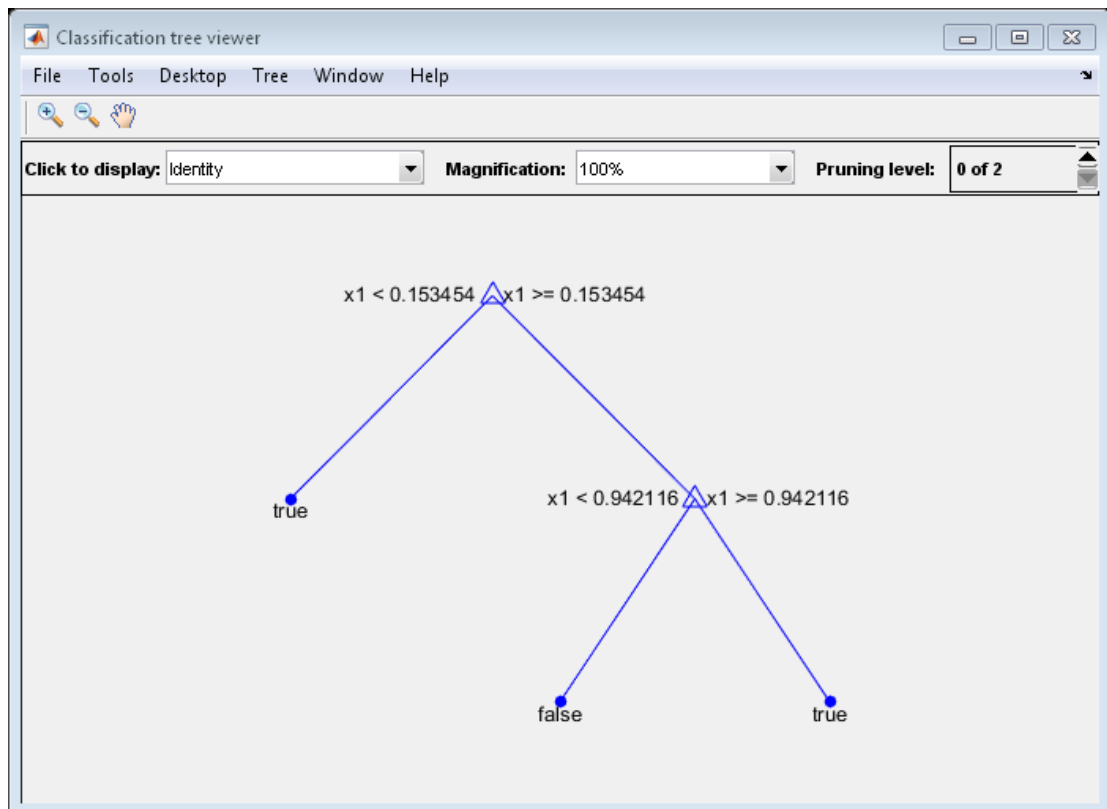

Score (tree)

For trees, the *score* of a classification of a leaf node is the posterior probability of the classification at that node. The posterior probability of the classification at a node is the number of training sequences that lead to that node with the classification, divided by the number of training sequences that lead to that node.

For example, consider classifying a predictor X as true when $X < 0.15$ or $X > 0.95$, and X is false otherwise.

Generate 100 random points and classify them:

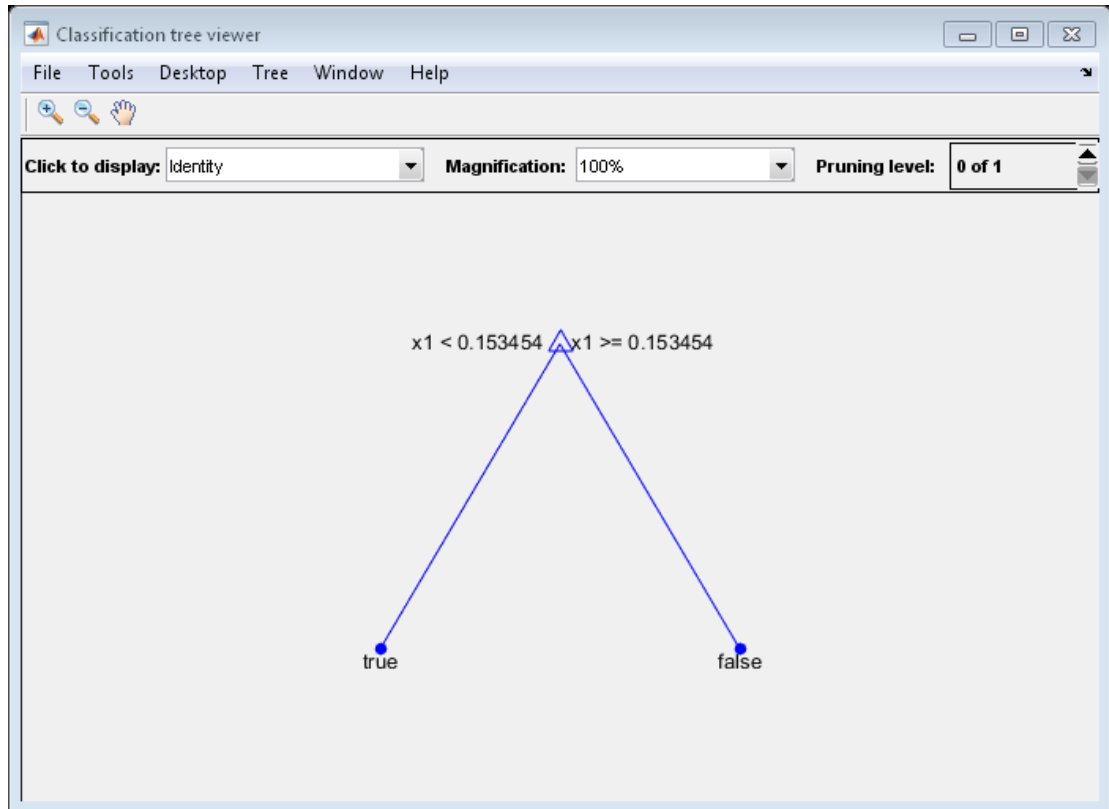

```
rng(0,'twister') % for reproducibility
X = rand(100,1);
Y = (abs(X - .55) > .4);
tree = fitctree(X,Y);
view(tree,'Mode','Graph')
```

Prune the tree:

```
tree1 = prune(tree,'Level',1);
```

```
view(tree1, 'Mode', 'Graph')
```

The pruned tree correctly classifies observations that are less than 0.15 as **true**. It also correctly classifies observations from .15 to .94 as **false**. However, it incorrectly classifies observations that are greater than .94 as **false**. Therefore, the score for observations that are greater than .15 should be about $.05/.85=.06$ for **true**, and about $.8/.85=.94$ for **false**.

Compute the prediction scores for the first 10 rows of X:

```
[~,score] = predict(tree1,X(1:10));
[score X(1:10,:)]
```

```
ans =
```

0.9059	0.0941	0.8147
0.9059	0.0941	0.9058
0	1.0000	0.1270
0.9059	0.0941	0.9134
0.9059	0.0941	0.6324
0	1.0000	0.0975
0.9059	0.0941	0.2785
0.9059	0.0941	0.5469
0.9059	0.0941	0.9575
0.9059	0.0941	0.9649

Indeed, every value of X (the right-most column) that is less than 0.15 has associated scores (the left and center columns) of 0 and 1, while the other values of X have associated scores of 0.91 and 0.09. The difference (score 0.09 instead of the expected .06) is due to a statistical fluctuation: there are 8 observations in X in the range (.95, 1) instead of the expected 5 observations.

True Misclassification Cost

There are two costs associated with classification: the true misclassification cost per class, and the expected misclassification cost per observation.

You can set the true misclassification cost per class in the `Cost` name-value pair when you create the classifier using the `fitctree` method. `Cost(i, j)` is the cost of classifying an observation into class j if its true class is i . By default, `Cost(i, j) = 1` if $i \neq j$, and `Cost(i, j) = 0` if $i = j$. In other words, the cost is 0 for correct classification, and 1 for incorrect classification.

Expected Cost

There are two costs associated with classification: the true misclassification cost per class, and the expected misclassification cost per observation.

Suppose you have `Nobs` observations that you want to classify with a trained classifier. Suppose you have `K` classes. You place the observations into a matrix `Xnew` with one observation per row.

The expected cost matrix `CE` has size `Nobs`-by-`K`. Each row of `CE` contains the expected (average) cost of classifying the observation into each of the `K` classes. `CE(n, k)` is

$$\sum_{i=1}^K \hat{P}(i | X_{new(n)})C(k | i),$$

where

- K is the number of classes.
- $\hat{P}(i | X_{new(n)})$ is the posterior probability of class i for observation $X_{new(n)}$.
- $C(k | i)$ is the true misclassification cost of classifying an observation as k when its true class is i .

Predictive Measure of Association

The predictive measure of association between the optimal split on variable i and a surrogate split on variable j is:

$$\lambda_{i,j} = \frac{\min(P_L, P_R) - (1 - P_{L_i L_j} - P_{R_i R_j})}{\min(P_L, P_R)}.$$

Here

- P_L and P_R are the node probabilities for the optimal split of node i into Left and Right nodes respectively.
- $P_{L_i L_j}$ is the probability that both (optimal) node i and (surrogate) node j send an observation to the Left.
- $P_{R_i R_j}$ is the probability that both (optimal) node i and (surrogate) node j send an observation to the Right.

Clearly, $\lambda_{i,j}$ lies from $-\infty$ to 1. Variable j is a worthwhile surrogate split for variable i if $\lambda_{i,j} > 0$.

Examples

Examine predictions for a few rows in the Fisher iris data.

```
load fisheriris
tree = fitctree(meas,species);
X = meas(99:102,:); % take four rows
[label score node cnum] = predict(tree,X)
```

```
label =
    'versicolor'
    'versicolor'
    'virginica'
    'virginica'

score =
     0     1.0000         0
     0     1.0000         0
     0     0.0217     0.9783
     0     0.0217     0.9783
```

```
node =
     8
     8
     5
     5
```

```
cnum =
     2
     2
     3
     3
```

Examine predictions from pruned trees for the Fisher iris model.

```
load fisheriris
tree = fitctree(meas,species);
X = meas(99:102,:); % taking four rows
[label score node cnum] = predict(tree,X,'Subtrees',[2 3 4])
```

```
label =
    'versicolor'    'versicolor'    'setosa'
    'versicolor'    'versicolor'    'setosa'
    'virginica'     'versicolor'    'setosa'
    'virginica'     'versicolor'    'setosa'

score(:, :, 1) =
     0     0.9074     0.0926
     0     0.9074     0.0926
```

```

Algorithms

`predict` generates predictions by following the branches of `tree` until it reaches a leaf node or a missing value. If `predict` reaches a leaf node, it returns the classification of that node.

If `predict` reaches a node with a missing value for a predictor, its behavior depends on the setting of the `Surrogate` name-value pair when `fitctree` constructs `tree`.

- **Surrogate = 'off'** (default) — `predict` returns the label with the largest number of training samples that reach the node.
- **Surrogate = 'on'** — `predict` uses the best surrogate split at the node. If all surrogate split variables with positive *predictive measure of association* are missing, `predict` returns the label with the largest number of training samples that reach the node. For a definition, see “Predictive Measure of Association” on page 21-3374.

predict

Class: CompactRegressionEnsemble

Predict response of ensemble

Syntax

```
Yfit = predict(ens,Xdata)
Yfit = predict(ens,Xdata,Name,Value)
```

Description

`Yfit = predict(ens,Xdata)` returns predicted responses to the data in `Xdata`, based on the `ens` regression ensemble model.

`Yfit = predict(ens,Xdata,Name,Value)` predicts with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

ens

Regression ensemble created by `fitensemble`, or by the `compact` method.

Xdata

Numeric array with the same number of columns as the array used for creating `ens`. Each row of `Xdata` corresponds to one data point, and each column corresponds to one predictor.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

'learners'

Indices of weak learners in the ensemble ranging from 1 to `ens.NumTrained`. `oobEdge` uses only these learners for calculating loss.

Default: `1:NumTrained`

'UseObsForLearner'

A logical matrix of size N-by-NumTrained, where N is the number of observations in `ens.X`, and NumTrained is the number of weak learners. When `UseObsForLearner(I,J)` is true, `predict` uses learner J in predicting observation I.

Default: `true(N,NumTrained)`

Output Arguments

Yfit

A numeric column vector with the same number of rows as `Xdata`. Each row of `Yfit` gives the predicted response to the corresponding row of `Xdata`, based on the `ens` regression model.

Examples

Find the predicted mileage for a four-cylinder car, with 200 cubic inch engine displacement, 150 horsepower, weighing 3000 lbs, based on the `carsmall` data:

```
load carsmall
X = [Cylinders Displacement Horsepower Weight];
rens = fitensemble(X,MPG,'LSBoost',100,'Tree');
Mileage = predict(rens,[4 200 150 3000])
```

```
Mileage =
    20.4982
```

`loss` | `fitensemble`

predict

Class: CompactRegressionTree

Predict response of regression tree

Syntax

```
Yfit = predict(tree,Xdata)
[Yfit,node] = predict(tree,Xdata)
[Yfit,node] = predict(tree,Xdata,Name,Value)
```

Description

`Yfit = predict(tree,Xdata)` returns predicted responses to the data in `Xdata`, based on the `tree` regression tree.

`[Yfit,node] = predict(tree,Xdata)` returns the predicted node numbers of `tree` in response to `Xdata`.

`[Yfit,node] = predict(tree,Xdata,Name,Value)` predicts response with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

tree

Regression tree created by `fitrtree`, or by the `compact` method.

Xdata

Numeric array with the same number of columns as the array used for creating `tree`. Each row of `Xdata` corresponds to one data point, and each column corresponds to one predictor.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

'Subtrees'

Numeric vector of pruning levels, with 0 representing the full, unpruned tree. To use the `Subtrees` name-value pair, tree must include a pruning sequence as created by the `fitree` or `prune` methods. If `Subtrees` has `T` elements, and `X` has `N` rows, then `Yfit` is an `N-by-T` matrix. The `i`th column of `Yfit` contains the fitted values produced by the `Subtrees(I)` subtree. Similarly, `node` is an `N-by-T` matrix. `Subtrees` must be sorted in ascending order. (To compute fitted values for a tree that is not part of the optimal pruning sequence, first use `prune` to prune the tree.)

Default: 0

Output Arguments

`Yfit`

A numeric column vector with the same number of rows as `Xdata`. Each row of `Yfit` gives the predicted response to the corresponding row of `Xdata`, based on the tree regression model.

`node`

Numeric vector of node numbers for the predictions. Each entry corresponds to the predicted leaf node in tree for the corresponding row of `Xdata`.

Examples

Find the predicted mileage for a car with 200 cubic inch engine displacement, 150 horsepower, weighing 3000 lbs, based on the `carsmall` data:

```
load carsmall
X = [Displacement Horsepower Weight];
```

```
tree = fitrtree(X,MPG);  
Mileage = predict(tree,[200 150 3000])
```

```
Mileage =  
    21.9375
```

See Also

`fitrtree` | `compact` | `loss`

predict

Class: CompactTreeBagger

Predict response

Syntax

```
YFIT = predict(B,X)
[YFIT,stdevs] = predict(B,X)
[YFIT,scores] = predict(B,X)
[YFIT,scores,stdevs] = predict(B,X)
Y = predict(B,X, 'param1',val1, 'param2',val2, ...)
```

Description

`YFIT = predict(B,X)` computes the predicted response of the trained ensemble `B` for predictors `X`. By default, `predict` takes a democratic (nonweighted) average vote from all trees in the ensemble. In `X`, rows represent observations and columns represent variables. `YFIT` is a cell array of strings for classification and a numeric array for regression.

For regression, `[YFIT,stdevs] = predict(B,X)` also returns standard deviations of the computed responses over the ensemble of the grown trees.

For classification, `[YFIT,scores] = predict(B,X)` returns scores for all classes. `scores` is a matrix with one row per observation and one column per class. For each observation and each class, the score generated by each tree is the probability of this observation originating from this class computed as the fraction of observations of this class in a tree leaf. `predict` averages these scores over all trees in the ensemble.

`[YFIT,scores,stdevs] = predict(B,X)` also returns standard deviations of the computed scores for classification. `stdevs` is a matrix with one row per observation and one column per class, with standard deviations taken over the ensemble of the grown trees.

`Y = predict(B,X, 'param1',val1, 'param2',val2, ...)` specifies optional parameter name/value pairs:

'trees'	Array of tree indices to use for computation of responses. Default is 'all'.
'treeweights'	Array of <code>Ntrees</code> weights for weighting votes from the specified trees.
'useifort'	Logical matrix of size <code>Nobs</code> -by- <code>Ntrees</code> indicating which trees to use to make predictions for each observation. By default all trees are used for all observations.

`RegressionTree.predict` | `ClassificationTree.predict` | `TreeBagger.predict`

predict

Class: GeneralizedLinearModel

Predict response of generalized linear regression model

Syntax

```
ypred = predict mdl, Xnew
[ypred, yci] = predict mdl, Xnew
[ypred, yci] = predict mdl, Xnew, Name, Value
```

Description

`ypred = predict(mdl, Xnew)` returns the predicted response of the `mdl` generalized linear regression model to the points in `Xnew`.

`[ypred, yci] = predict(mdl, Xnew)` returns confidence intervals for the true mean responses.

`[ypred, yci] = predict(mdl, Xnew, Name, Value)` predicts responses with additional options specified by one or more `Name, Value` pair arguments.

Tips

- For predictions with added noise, use `random`.
- For a syntax that can be easier to use with models created from dataset arrays, try `feval`.

Input Arguments

mdl

Generalized linear model, as constructed by `fitglm` or `stepwiseglm`.

Xnew

Points at which `mdl` predicts responses.

- If `Xnew` is a table or dataset array, it must contain the predictor names in `mdl`.
- If `Xnew` is a numeric matrix, it must have the same number of variables (columns) as was used to create `mdl`. Furthermore, all variables used in creating `mdl` must be numeric.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

'alpha'

Positive scalar from 0 to 1. Confidence level of `yci` is $100(1 - \text{alpha})\%$.

Default: 0.05, meaning a 95% confidence interval.

'BinomialSize'

Value of the binomial n parameter for each row in the training data. `BinomialSize` can be a vector the same length as `Xnew`, or a scalar that applies to each row. The default value 1 produces `ypred` values that are predicted proportions. Use `BinomialSize` only if `mdl` is fit to a binomial distribution.

Default: 1

'Offset'

Value of the offset for each row in `Xnew`. `Offset` can be a vector the same length as `Xnew`, or a scalar that applies to each row. The offset is used as an additional predictor with a coefficient value fixed at 1. In other words, if `b` is the fitted coefficient vector, and `link` is the link function,
 $\text{link}(\text{ypred}) = \text{Offset} + \text{Xnew} * \text{b}$.

Default: `zeros(size(Xnew,1))`

'Simultaneous'

Logical value specifying whether the confidence bounds are for all predictor values simultaneously (`true`), or hold for each individual predictor value (`false`). Simultaneous bounds are wider than separate bounds, because it is more stringent to require that the entire curve be within the bounds than to require that the curve at a single predictor value be within the bounds.

For details, see `polyconf`.

Default: `false`

Output Arguments

`ypred`

Vector of predicted mean values at `Xnew`.

`yci`

Confidence intervals, a two-column matrix with each row providing one interval. The meaning of the confidence interval depends on the settings of the name-value pairs.

Examples

Generalized Linear Model Predictions

Create a generalized linear model, and predict its response to new data.

Generate artificial data for the model using Poisson random numbers with two underlying predictors `X(1)` and `X(2)`.

```
rng('default') % for reproducibility
rndvars = randn(100,2);
X = [2+rndvars(:,1),rndvars(:,2)];
mu = exp(1 + X*[1;2]);
y = poissrnd(mu);
```

Create a generalized linear regression model of Poisson data.

```
mdl = fitglm(X,y,'y ~ x1 + x2','distr','poisson');
```

Create points for prediction.

```
[Xtest1 Xtest2] = meshgrid(-1:.5:3,-2:.5:2);  
Xnew = [Xtest1(:),Xtest2(:)];
```

Predict responses at the new points.

```
ypred = predict(md1,Xnew);
```

Plot the predictions.

```
surf(Xtest1,Xtest2,reshape(ypred,9,9))
```

Create confidence intervals on the predictions.

```
[ypred yci] = predict(md1,Xnew);
```

- “predict” on page 10-34

- “Generalized Linear Model Workflow” on page 10-39

Alternatives

`feval` gives the same predictions, but uses separate input arrays for each predictor, instead of one input array containing all predictors.

`random` predicts with added noise.

`GeneralizedLinearModel` | `random`

More About

- “Generalized Linear Models” on page 10-12

predict

Class: GeneralizedLinearMixedModel

Predict response of generalized linear mixed-effects model

Syntax

```
yPred = predict(glme)
yPred = predict(glme, tblnew)
yPred = predict( ____, Name, Value)
[yPred, yPredCI] = predict( ____)
[yPred, yPredCI, DF] = predict( ____)
```

Description

`yPred = predict(glme)` returns the predicted conditional means of the response, `yPred`, using the original predictor values used to fit the generalized linear mixed-effects model `glme`.

`yPred = predict(glme, tblnew)` returns the predicted conditional means using the new predictor values specified in `tblnew`.

If a grouping variable in `tblnew` has levels that are not in the original data, then the random effects for that grouping variable do not contribute to the 'Conditional' prediction at observations where the grouping variable has new levels.

`yPred = predict(____, Name, Value)` returns the predicted conditional means of the response using additional options specified by one or more `Name, Value` pair arguments. For example, you can specify the confidence level, simultaneous confidence bounds, or contributions from only fixed effects. You can use any of the input arguments in the previous syntaxes.

`[yPred, yPredCI] = predict(____)` also returns 95% point-wise confidence intervals, `yPredCI`, for each predicted value.

`[yPred, yPredCI, DF] = predict(____)` also returns the degrees of freedom, `DF`, used to compute the confidence intervals.

Input Arguments

glme — Generalized linear mixed-effects model

GeneralizedLinearMixedModel object

Generalized linear mixed-effects model, specified as a `GeneralizedLinearMixedModel` object. For properties and methods of this object, see `GeneralizedLinearMixedModel`.

tblnew — New input data

table | dataset array

New input data, which includes the response variable, predictor variables, and grouping variables, specified as a table or dataset array. The predictor variables can be continuous or grouping variables. `tblnew` must have the same variables as the original table or dataset array used in `fitglme` to fit the generalized linear mixed-effects model `glme`.

Data Types: `single` | `double` | `logical` | `char`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`,`Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1`,`Value1`, ..., `NameN`,`ValueN`.

'Alpha' — Confidence level

0.05 (default) | scalar value in the range [0,1]

Confidence level, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the range [0,1]. For a value α , the confidence level is $100 \times (1 - \alpha)\%$.

For example, for 99% confidence intervals, you can specify the confidence level as follows.

Example: `'Alpha',0.01`

Data Types: `single` | `double`

'Conditional' — Indicator for conditional predictions

true (default) | false

Indicator for conditional predictions, specified as the comma-separated pair consisting of `'Conditional'` and one of the following.

<code>true</code>	Contributions from both fixed effects and random effects (conditional)
<code>false</code>	Contribution from only fixed effects (marginal)

Example: `'Conditional', false`

'DFMethod' — Method for computing approximate degrees of freedom

`'residual'` (default) | `'none'`

Method for computing approximate degrees of freedom, specified as the comma-separated pair consisting of `'DFMethod'` and one of the following.

<code>'residual'</code>	The degrees of freedom are assumed to be constant and equal to $n - p$, where n is the number of observations and p is the number of fixed effects.
<code>'none'</code>	All degrees of freedom are set to infinity.

Example: `'DFMethod', 'none'`

'Offset' — Model offset

`zeros(m, 1)` (default) | m -by-1 vector of scalar values

Model offset, specified as a vector of scalar values of length m , where m is the number of rows in `tblnew`. The offset is used as an additional predictor and has a coefficient value fixed at 1.

'Simultaneous' — Type of confidence bounds

`false` (default) | `true`

Type of confidence bounds, specified as the comma-separated pair consisting of `'Simultaneous'` and either `false` or `true`.

- If `'Simultaneous'` is `false`, then `predict` computes nonsimultaneous confidence bounds.
- If `'Simultaneous'` is `true`, `predict` returns simultaneous confidence bounds.

Example: `'Simultaneous', true`

Output Arguments

ypred — Predicted responses

vector

Predicted responses, returned as a vector. If the 'Conditional' name-value pair argument is specified as `true`, `ypred` contains predictions for the conditional means of the responses given the random effects. Conditional predictions include contributions from both fixed and random effects. Marginal predictions include only contributions from fixed effects.

To compute marginal predictions, `predict` computes conditional predictions, but substitutes a vector of zeros in place of the empirical Bayes predictors (EBPs) of the random effects.

ypredCI — Point-wise confidence intervals

two-column matrix

Point-wise confidence intervals for the predicted values, returned as a two-column matrix. The first column of `ypredCI` contains the lower bound, and the second column contains the upper bound. By default, `ypredCI` contains the 95% nonsimultaneous confidence intervals for the predictions. You can change the confidence level using the `Alpha` name-value pair argument, and make them simultaneous using the `Simultaneous` name-value pair argument.

When fitting a GLME model using `fitglm` and one of the maximum likelihood fit methods ('`Laplace`' or '`ApproximateLaplace`'), `predict` computes the confidence intervals using the conditional mean squared error of prediction (CMSEP) approach conditional on the estimated covariance parameters and the observed response. Alternatively, you can interpret the confidence intervals as approximate Bayesian credible intervals conditional on the estimated covariance parameters and the observed response.

When fitting a GLME model using `fitglm` and one of the pseudo likelihood fit methods ('`MPL`' or '`REML`'), `predict` bases the computations on the fitted linear mixed-effects model from the final pseudo likelihood iteration.

DF — Degrees of freedom

vector | scalar value

Degrees of freedom used in computing the confidence intervals, returned as a vector or a scalar value.

- If 'Simultaneous' is `false`, then `DF` is a vector.
- If 'Simultaneous' is `true`, then `DF` is a scalar value.

Examples

Predict Responses at Original Design Values

Navigate to the folder containing the sample data. Load the sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')

load mfr
```

This simulated data is from a manufacturing company that operates 50 factories across the world, with each factory running a batch process to create a finished product. The company wants to decrease the number of defects in each batch, so it developed a new manufacturing process. To test the effectiveness of the new process, the company selected 20 of its factories at random to participate in an experiment: Ten factories implemented the new process, while the other ten continued to run the old process. In each of the 20 factories, the company ran five batches (for a total of 100 batches) and recorded the following data:

- Flag to indicate whether the batch used the new process (`newprocess`)
- Processing time for each batch, in hours (`time`)
- Temperature of the batch, in degrees Celsius (`temp`)
- Categorical variable indicating the supplier (A, B, or C) of the chemical used in the batch (`supplier`)
- Number of defects in the batch (`defects`)

The data also includes `time_dev` and `temp_dev`, which represent the absolute deviation of time and temperature, respectively, from the process standard of 3 hours at 20 degrees Celsius.

Fit a generalized linear mixed-effects model using `newprocess`, `time_dev`, `temp_dev`, and `supplier` as fixed-effects predictors. Include a random-effects term for intercept grouped by `factory`, to account for quality differences that might exist due to factory-specific variations. The response variable `defects` has a Poisson distribution, and the

appropriate link function for this model is log. Use the Laplace fit method to estimate the coefficients. Specify the dummy variable encoding as 'effects', so the dummy variable coefficients sum to 0.

The number of defects can be modeled using a Poisson distribution

$$defects_{ij} \sim \text{Poisson}(\mu_{ij})$$

This corresponds to the generalized linear mixed-effects model

$$\log(\mu_{ij}) = \beta_0 + \beta_1 newprocess_{ij} + \beta_2 time_dev_{ij} + \beta_3 temp_dev_{ij} + \beta_4 supplier_C_{ij} + \beta_5 supplier_B_{ij} +$$

where

- $defects_{ij}$ is the number of defects observed in the batch produced by factory i during batch j .
- μ_{ij} is the mean number of defects corresponding to factory i (where $i = 1, 2, \dots, 20$) during batch j (where $j = 1, 2, \dots, 5$).
- $newprocess_{ij}$, $time_dev_{ij}$, and $temp_dev_{ij}$ are the measurements for each variable that correspond to factory i during batch j . For example, $newprocess_{ij}$ indicates whether the batch produced by factory i during batch j used the new process.
- $supplier_C_{ij}$ and $supplier_B_{ij}$ are dummy variables that use effects (sum-to-zero) coding to indicate whether company C or B, respectively, supplied the process chemicals for the batch produced by factory i during batch j .
- $b_i \sim N(0, \sigma_b^2)$ is a random-effects intercept for each factory i that accounts for factory-specific variation in quality.

```
glme = fitglme(mfr, 'defects ~ 1 + newprocess + time_dev + temp_dev + supplier + (1|factory)
```

Predict the response values at the original design values. Display the first ten predictions along with the observed response values.

```
ypred = predict(glme);
[ypred(1:10),mfr.defects(1:10)]
```

```
ans =
```

```
4.9883    6.0000
```

5.9423	7.0000
5.1318	6.0000
5.6295	5.0000
5.3499	6.0000
5.2134	5.0000
4.6430	4.0000
4.5342	4.0000
5.3903	9.0000
4.6529	4.0000

Column 1 contains the predicted response values at the original design values. Column 2 contains the observed response values.

Predict Responses at Values in New Table

Navigate to the folder containing the sample data. Load the sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')

load mfr
```

This simulated data is from a manufacturing company that operates 50 factories across the world, with each factory running a batch process to create a finished product. The company wants to decrease the number of defects in each batch, so it developed a new manufacturing process. To test the effectiveness of the new process, the company selected 20 of its factories at random to participate in an experiment: Ten factories implemented the new process, while the other ten continued to run the old process. In each of the 20 factories, the company ran five batches (for a total of 100 batches) and recorded the following data:

- Flag to indicate whether the batch used the new process (`newprocess`)
- Processing time for each batch, in hours (`time`)
- Temperature of the batch, in degrees Celsius (`temp`)
- Categorical variable indicating the supplier (A, B, or C) of the chemical used in the batch (`supplier`)
- Number of defects in the batch (`defects`)

The data also includes `time_dev` and `temp_dev`, which represent the absolute deviation of time and temperature, respectively, from the process standard of 3 hours at 20 degrees Celsius.

Fit a generalized linear mixed-effects model using `newprocess`, `time_dev`, `temp_dev`, and `supplier` as fixed-effects predictors. Include a random-effects term for intercept grouped by `factory`, to account for quality differences that might exist due to factory-specific variations. The response variable `defects` has a Poisson distribution, and the appropriate link function for this model is log. Use the Laplace fit method to estimate the coefficients. Specify the dummy variable encoding as `'effects'`, so the dummy variable coefficients sum to 0.

The number of defects can be modeled using a Poisson distribution

$$defects_{ij} \sim \text{Poisson}(\mu_{ij})$$

This corresponds to the generalized linear mixed-effects model

$$\log(\mu_{ij}) = \beta_0 + \beta_1 newprocess_{ij} + \beta_2 time_dev_{ij} + \beta_3 temp_dev_{ij} + \beta_4 supplier_C_{ij} + \beta_5 supplier_B_{ij} + b_i$$

where

- $defects_{ij}$ is the number of defects observed in the batch produced by factory i during batch j .
- μ_{ij} is the mean number of defects corresponding to factory i (where $i = 1, 2, \dots, 20$) during batch j (where $j = 1, 2, \dots, 5$).
- $newprocess_{ij}$, $time_dev_{ij}$, and $temp_dev_{ij}$ are the measurements for each variable that correspond to factory i during batch j . For example, $newprocess_{ij}$ indicates whether the batch produced by factory i during batch j used the new process.
- $supplier_C_{ij}$ and $supplier_B_{ij}$ are dummy variables that use effects (sum-to-zero) coding to indicate whether company C or B, respectively, supplied the process chemicals for the batch produced by factory i during batch j .
- $b_i \sim N(0, \sigma_b^2)$ is a random-effects intercept for each factory i that accounts for factory-specific variation in quality.

```
glme = fitglme(mfr, 'defects ~ 1 + newprocess + time_dev + temp_dev + supplier + (1|factory)')
```

Predict the response values at the original design values.

```
ypred = predict(glme);
```

Create a new table by copying the first 10 rows of `mfr` into `tblnew`.

```
tblnew = mfr(1:10,:);
```

The first 10 rows of `mfr` include data collected from trials 1 through 5 for factories 1 and 2. Both factories used the old process for all of their trials during the experiment, so `newprocess = 0` for all 10 observations.

Change the value of `newprocess` to 1 for the observations in `tblnew`.

```
tblnew.newprocess = ones(height(tblnew),1);
```

Compute predicted response values and nonsimultaneous 99% confidence intervals using `tblnew`. Display the first 10 rows of the predicted values based on `tblnew`, the predicted values based on `mfr`, and the observed response values.

```
[ypred_new,ypredCI] = predict(glme,tblnew,'Alpha',0.01);  
[ypred_new,ypred(1:10),mfr.defects(1:10)]
```

```
ans =
```

3.4536	4.9883	6.0000

`GeneralizedLinearMixedModel` | `fitglm` | `fitted` | `random`

predict

Class: LinearModel

Predict response of linear regression model

Syntax

```
ypred = predict mdl, Xnew)
[ypred, yci] = predict mdl, Xnew)
[ypred, yci] = predict mdl, Xnew, Name, Value)
```

Description

`ypred = predict mdl, Xnew)` returns the predicted response of the `mdl` linear regression model to the points in `Xnew`.

`[ypred, yci] = predict mdl, Xnew)` returns confidence intervals for the true mean responses.

`[ypred, yci] = predict mdl, Xnew, Name, Value)` predicts responses with additional options specified by one or more `Name, Value` pair arguments.

Tips

- For predictions with added noise, use `random`.

Input Arguments

mdl

Linear model, as constructed by `fitlm` or `stepwiselm`.

Xnew

Points at which `mdl` predicts responses.

- If `Xnew` is a table or dataset array, it must contain the predictor names in `mdl`.
- If `Xnew` is a numeric matrix, it must have the same number of variables (columns) as was used to create `mdl`. Furthermore, all variables used in creating `mdl` must be numeric.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

'alpha'

Positive scalar from 0 to 1. Confidence level of `yci` is $100(1 - \text{alpha})\%$.

Default: 0.05, meaning a 95% confidence interval.

'Prediction'

String specifying the type of prediction:

- 'curve' — `predict` predicts confidence bounds for the fitted mean values.
- 'observation' — `predict` predicts confidence bounds for the new observations. This results in wider bounds because the error in a new observation is equal to the error in the estimated mean value, plus the variability in the observation from the true mean.

For details, see `polyconf`.

Default: 'curve'

'Simultaneous'

Logical value specifying whether the confidence bounds are for all predictor values simultaneously (`true`), or hold for each individual predictor value (`false`). Simultaneous bounds are wider than separate bounds, because it is more stringent to require that the entire curve be within the bounds than to require that the curve at a single predictor value be within the bounds.

For details, see `polyconf`.

Default: `false`

Output Arguments

`ypred`

Vector of predicted mean values at `Xnew`.

`yci`

Confidence intervals, a two-column matrix with each row providing one interval. The meaning of the confidence interval depends on the settings of the name-value pairs.

Examples

Predict Response to Data

Create a model of car mileage as a function of weight, and predict the response.

Create a quadratic model of car mileage as a function of weight from the `carsmall` data.

```
load carsmall
X = Weight;
y = MPG;
mdl = fitlm(X,y,'quadratic');
```

Create predicted responses to the data.

```
Xnew = X;
ypred = predict(mdl,Xnew);
```

Plot the original responses and the predicted responses to see how they differ.

```
plot(X,y,'o',Xnew,ypred,'x')
legend('Data','Predictions')
```

- “predict” on page 9-37
- “Linear Regression Workflow” on page 9-41

Alternatives

`feval` gives the same predictions, but uses multiple input arrays with one component in each input argument. `feval` can be simpler to use with a model created from a table or dataset array `tbl`. `feval` does not give confidence intervals on its predictions.

`random` predicts with added noise.

`random` | `stepwiselm` | `feval` | `LinearModel` | `fitlm`

How To

- “Linear Regression” on page 9-11

predict

Class: LinearMixedModel

Predict response of linear mixed-effects model

Syntax

```
ypréd = predict(lme)
ypréd = predict(lme,tblnew)
ypréd = predict(lme,Xnew,Znew)
ypréd = predict(lme,Xnew,Znew,Gnew)
ypréd = predict( ____,Name,Value)
[ypréd,yprédCI] = predict( ____)
[ypréd,yprédCI,DF] = predict( ____)
```

Description

`ypréd = predict(lme)` returns a vector of conditional predicted responses `ypréd` at the original predictors used to fit the linear mixed-effects model `lme`.

`ypréd = predict(lme,tblnew)` returns a vector of conditional predicted responses `ypréd` from the fitted linear mixed-effects model `lme` at the values in the new table or dataset array `tblnew`. Use a table or dataset array for `predict` if you use a table or dataset array for fitting the model `lme`.

If a particular grouping variable in `tblnew` has levels that are not in the original data, then the random effects for that grouping variable do not contribute to the 'Conditional' prediction at observations where the grouping variable has new levels.

`ypréd = predict(lme,Xnew,Znew)` returns a vector of conditional predicted responses `ypréd` from the fitted linear mixed-effects model `lme` at the values in the new fixed- and random-effects design matrices, `Xnew` and `Znew`, respectively. `Znew` can also be a cell array of matrices. In this case, the grouping variable `G` is `ones(n,1)`, where `n` is the number of observations used in the fit.

Use the matrix format for `predict` if using design matrices for fitting the model `lme`.

`ypred = predict(lme, Xnew, Znew, Gnew)` returns a vector of conditional predicted responses `ypred` from the fitted linear mixed-effects model `lme` at the values in the new fixed- and random-effects design matrices, `Xnew` and `Znew`, respectively, and the grouping variable `Gnew`.

`Znew` and `Gnew` can also be cell arrays of matrices and grouping variables, respectively.

`ypred = predict(___, Name, Value)` returns a vector of predicted responses `ypred` from the fitted linear mixed-effects model `lme` with additional options specified by one or more `Name, Value` pair arguments.

For example, you can specify the confidence level, simultaneous confidence bounds, or contributions from only fixed effects.

`[ypred, ypredCI] = predict(___)` also returns confidence intervals `ypredCI` for the predictions `ypred` for any of the input arguments in the previous syntaxes.

`[ypred, ypredCI, DF] = predict(___)` also returns the degrees of freedom `DF` used in computing the confidence intervals for any of the input arguments in the previous syntaxes.

Input Arguments

lme — Linear mixed-effects model

`LinearMixedModel` object

Linear mixed-effects model, returned as a `LinearMixedModel` object.

For properties and methods of this object, see `LinearMixedModel`.

tblnew — New input data

table | dataset array

New input data, which includes the response variable, predictor variables, and grouping variables, specified as a table or dataset array. The predictor variables can be continuous or grouping variables. `tblnew` must have the same variables as in the original table or dataset array used to fit the linear mixed-effects model `lme`.

Data Types: `single` | `double` | `logical` | `char`

Xnew — New fixed-effects design matrix

n-by-*p* matrix

New fixed-effects design matrix, specified as an n -by- p matrix, where n is the number of observations and p is the number of fixed predictor variables. Each row of X corresponds to one observation and each column of X corresponds to one variable.

Data Types: `single` | `double`

Znew — New random-effects design

n -by- q matrix | cell array of length R

New random-effects design, specified as an n -by- q matrix or a cell array of R design matrices $Z\{r\}$, where $r = 1, 2, \dots, R$. If **Znew** is a cell array, then each $Z\{r\}$ is an n -by- $q(r)$ matrix, where n is the number of observations, and $q(r)$ is the number of random predictor variables.

Data Types: `single` | `double` | `logical` | `char` | `cell`

Gnew — New grouping variable or variables

vector | cell array of grouping variables of length R

New grouping variable or variables, specified as a vector or a cell array, of length R , of grouping variables with the same levels or groups as the original grouping variables used to fit the linear mixed-effects model `lme`.

Data Types: `single` | `double` | `logical` | `char` | `cell`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1, ..., NameN,ValueN`.

'Alpha' — Confidence level

0.05 (default) | scalar value in the range 0 to 1

Confidence level, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the range 0 to 1. For a value α , the confidence level is $100*(1-\alpha)\%$.

For example, for 99% confidence intervals, you can specify the confidence level as follows.

Example: `'Alpha',0.01`

Data Types: `single` | `double`

'Conditional' — Indicator for conditional predictions

True (default) | False

Indicator for conditional predictions, specified as the comma-separated pair consisting of 'Conditional' and one of the following.

True	Contributions from both fixed effects and random effects (conditional)
False	Contribution from only fixed effects (marginal)

Example: 'Conditional, 'False'

'DFMethod' — Method for computing approximate degrees of freedom

'Residual' (default) | 'Satterthwaite' | 'None'

Method for computing approximate degrees of freedom to use in the confidence interval computation, specified as the comma-separated pair consisting of 'DFMethod' and one of the following.

'Residual'	Default. The degrees of freedom are assumed to be constant and equal to $n - p$, where n is the number of observations and p is the number of fixed effects.
'Satterthwaite'	Satterthwaite approximation.
'None'	All degrees of freedom are set to infinity.

For example, you can specify the Satterthwaite approximation as follows.

Example: 'DFMethod', 'Satterthwaite'

'Simultaneous' — Type of confidence bounds

false (default) | true

Type of confidence bounds, specified as the comma-separated pair consisting of 'Simultaneous' and one of the following.

false	Default. Nonsimultaneous bounds.
-------	----------------------------------

`true` Simultaneous bounds.

Example: `'Simultaneous', true`

'Prediction' — Type of prediction

`'curve'` (default) | `'observation'`

Type of prediction, specified as the comma-separated pair consisting of `'Prediction'` and one of the following.

`'curve'`

Default. Confidence bounds apply to the fitted function and do not include any variability associated with a new observation.

`'observation'`

Variability due to observation error for the new observations is included in the confidence bound calculations.

Example: `'Prediction', 'observation'`

Output Arguments

ypred — Predicted responses

vector

Predicted responses, returned as a vector. `ypred` can contain the conditional or marginal responses, depending on the value choice of the `'Conditional'` name-value pair argument. Conditional predictions include contributions from both fixed and random effects.

ypredCI — Point-wise confidence intervals

two-column matrix

Point-wise confidence intervals for the predicted values, returned as a two-column matrix. The first column of `yCI` contains the lower bounds, and the second column contains the upper bound. By default, `yCI` contains the 95% confidence intervals for the predictions. You can change the confidence level using the `Alpha` name-value pair

argument, make them simultaneous using the `Simultaneous` name-value pair argument, and also make them for a new observation rather than for the curve using the `Prediction` name-value pair argument.

DF — Degrees of freedom

vector | scalar value

Degrees of freedom used in computing the confidence intervals, returned as a vector or a scalar value.

- If the `'Simultaneous'` name-value pair argument is `false`, then `DF` is a vector.
- If the `'Simultaneous'` name-value pair argument is `true`, then `DF` is a scalar value.

Examples

Predict Responses at the Original Design Values

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load fertilizer
```

The dataset array includes data from a split-plot experiment, where soil is divided into three blocks based on the soil type: sandy, silty, and loamy. Each block is divided into five plots, where five different types of tomato plants (cherry, heirloom, grape, vine, and plum) are randomly assigned to these plots. The tomato plants in the plots are then divided into subplots, where each subplot is treated by one of four fertilizers. This is simulated data.

Store the data in a dataset array called `ds`, for practical purposes, and define `Tomato`, `Soil`, and `Fertilizer` as categorical variables.

```
ds = fertilizer;
ds.Tomato = nominal(ds.Tomato);
ds.Soil = nominal(ds.Soil);
ds.Fertilizer = nominal(ds.Fertilizer);
```

Fit a linear mixed-effects model, where `Fertilizer` and `Tomato` are the fixed-effects variables, and the mean yield varies by the block (soil type), and the plots within blocks (tomato types within soil types) independently.

```
lme = fitlme(ds, 'Yield ~ Fertilizer * Tomato + (1|Soil) + (1|Soil:Tomato)');
```

Predict the response values at the original design values. Display the first five predictions with the observed response values.

```
yhat = predict(lme);
[yhat(1:5) ds.Yield(1:5)]
```

```
ans =
```

```
115.4788 104.0000
135.1455 136.0000
152.8121 158.0000
160.4788 174.0000
58.0839 57.0000
```

Plot Predictions vs. Observed Responses

Load the sample data.

```
load carsmall
```

Fit a linear mixed-effects model, with a fixed effect for `Weight`, and a random intercept grouped by `Model_Year`. First, store the data in a table.

```
tbl = table(MPG,Weight,Model_Year);
lme = fitlme(tbl, 'MPG ~ Weight + (1|Model_Year)');
```

Create predicted responses to the data.

```
yhat = predict(lme,tbl);
```

Plot the original responses and the predicted responses to see how they differ. Group them by model year.

```
figure()
gscatter(Weight,MPG,Model_Year)
hold on
gscatter(Weight,yhat,Model_Year,[], 'o+x')
legend('70-data', '76-data', '82-data', '70-pred', '76-pred', '82-pred')
hold off
```

Predict Responses at Values in a New Dataset Array

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load fertilizer
```

The dataset array includes data from a split-plot experiment, where soil is divided into three blocks based on the soil type: sandy, silty, and loamy. Each block is divided into five plots, where five different types of tomato plants (cherry, heirloom, grape, vine, and

plum) are randomly assigned to these plots. The tomato plants in the plots are then divided into subplots, where each subplot is treated by one of four fertilizers. This is simulated data.

Store the data in a dataset array called `ds`, for practical purposes, and define `Tomato`, `Soil`, and `Fertilizer` as categorical variables.

```
ds = fertilizer;
ds.Tomato = nominal(ds.Tomato);
ds.Soil = nominal(ds.Soil);
ds.Fertilizer = nominal(ds.Fertilizer);
```

Fit a linear mixed-effects model, where `Fertilizer` and `Tomato` are the fixed-effects variables, and the mean yield varies by the block (soil type), and the plots within blocks (tomato types within soil types) independently.

```
lme = fitlme(ds, 'Yield ~ Fertilizer * Tomato + (1|Soil) + (1|Soil:Tomato)');
```

Create a new dataset array with design values. The new dataset array must have the same variables as the original dataset array you use for fitting the model `lme`.

```
dsnew = dataset();
dsnew.Soil = nominal({'Sandy'; 'Silty'});
dsnew.Tomato = nominal({'Cherry'; 'Vine'});
dsnew.Fertilizer = nominal([2;2]);
```

Predict the conditional and marginal responses at the original design points.

```
yhatC = predict(lme, dsnew);
yhatM = predict(lme, dsnew, 'Conditional', false);
[yhatC yhatM]
```

```
ans =
```

```
    92.7505    111.6667
    87.5891     82.6667
```

Predict Responses at the Values in New Design Matrices

Load the sample data.

```
load carbig
```

Fit a linear mixed-effects model for miles per gallon (MPG), with fixed effects for acceleration, horsepower, and cylinders, and potentially correlated random effects for intercept and acceleration grouped by model year.

First, prepare the design matrices for fitting the linear mixed-effects model.

```
X = [ones(406,1) Acceleration Horsepower];
Z = [ones(406,1) Acceleration];
Model_Year = nominal(Model_Year);
G = Model_Year;
```

Now, fit the model using `fitlmematrix` with the defined design matrices and grouping variables.

```
lme = fitlmematrix(X,MPG,Z,G,'FixedEffectPredictors',...
{'Intercept','Acceleration','Horsepower'},'RandomEffectPredictors',...
{{'Intercept','Acceleration'}},'RandomEffectGroups',{'Model_Year'});
```

Create the design matrices that contain the data at which to predict the response values. `Xnew` must have three columns as in `X`. The first column must be a column of 1s. And the values in the last two columns must correspond to `Acceleration` and `Horsepower`, respectively. The first column of `Znew` must be a column of 1s, and the second column must contain the same `Acceleration` values as in `Xnew`. The original grouping variable in `G` is the model year. So, `Gnew` must contain values for the model year. Note that `Gnew` must contain nominal values.

```
Xnew = [1,13.5,185; 1,17,205; 1,21.2,193];
Znew = [1,13.5; 1,17; 1,21.2];
Gnew = nominal([73 77 82]);
```

Predict the responses for the data in the new design matrices.

```
yhat = predict(lme,Xnew,Znew,Gnew)
```

```
yhat =
```

```
    8.7063
    5.4423
   12.5384
```

Now, repeat the same for a linear mixed-effects model with uncorrelated random-effects terms for intercept and acceleration. First, change the original random effects design and the random effects grouping variables. Then, refit the model.

```
Z = {ones(406,1),Acceleration};
G = {Model_Year,Model_Year};
```

```
lme = fitlmematrix(X,MPG,Z,G,'FixedEffectPredictors',...
{'Intercept','Acceleration','Horsepower'},'RandomEffectPredictors',...
```

```
{{ 'Intercept' }, { 'Acceleration' }}, 'RandomEffectGroups', {'Model_Year', 'Model_Year'})
```

Now, recreate the new random effects design, `Znew`, and the grouping variable design, `Gnew`, using which to predict the response values.

```
Znew = {[1;1;1],[13.5;17;21.2]};
MY = nominal([73 77 82]);
Gnew = {MY,MY};
```

Predict the responses using the new design matrices.

```
yhat = predict(lme,Xnew,Znew,Gnew)
```

```
yhat =
```

```
    8.6365
    5.9199
   12.1247
```

Compute Confidence Intervals for Predictions

Load the sample data.

```
load carbig
```

Fit a linear mixed-effects model for miles per gallon (MPG), with fixed effects for acceleration, horsepower, and cylinders, and potentially correlated random effects for intercept and acceleration grouped by model year. First, store the variables in a table.

```
tbl = table(MPG,Acceleration,Horsepower,Model_Year);
```

Now, fit the model using `fitlme` with the defined design matrices and grouping variables.

```
lme = fitlme(tbl,'MPG ~ Acceleration + Horsepower + (Acceleration|Model_Year)');
```

Create the new data and store it in a new table.

```
tblnew = table();
tblnew.Acceleration = linspace(8,25)';
tblnew.Horsepower = linspace(nanmin(Horsepower),nanmax(Horsepower))';
tblnew.Model_Year = repmat(70,100,1);
```

`linspace` creates 100 equally distanced values between the lower and the upper input limits. `Model_Year` is fixed at 70. You can repeat this for any model year.

Compute and plot the predicted values and 95% confidence limits (nonsimultaneous).

```
[ypred,yCI,DF] = predict(lme,tblnew);  
figure();  
h1 = line(tblnew.Acceleration,ypred);  
hold on;  
h2 = plot(tblnew.Acceleration,yCI,'g-.');
```

Display the degrees of freedom.

```
DF(1)
```

```
ans =
```

```
389
```

Compute and plot the simultaneous confidence bounds.

```
[ypred,yCI,DF] = predict(lme,tblnew,'Simultaneous',true);  
h3 = plot(tblnew.Acceleration,yCI,'r--');
```

Display the degrees of freedom.

```
DF
```

```
DF =
```

```
389
```

Compute the simultaneous confidence bounds using the Satterthwaite method to compute the degrees of freedom.

```
[ypred,yCI,DF] = predict(lme,tblnew,'Simultaneous',true,'DFMethod','Satterthwaite');  
h4 = plot(tblnew.Acceleration,yCI,'k:');  
hold off  
xlabel('Acceleration')  
ylabel('Response')  
ylim([-50,60])  
xlim([8,25])  
legend([h1,h2(1),h3(1),h4(1)], 'Predicted response', '95%', '95% Sim', ...  
    '95% Sim-Satt', 'Location', 'Best')
```

Display the degrees of freedom.

DF

DF =

3.6001

Definitions

Conditional and Marginal Predictions

A conditional prediction includes contributions from both fixed and random effects, whereas a marginal model includes contribution from only fixed effects.

Suppose the linear mixed-effects model `lme` has an n -by- p fixed-effects design matrix X and an n -by- q random-effects design matrix Z . Also, suppose the estimated p -by-1 fixed-effects vector is $\hat{\beta}$, and the q -by-1 estimated best linear unbiased predictor (BLUP) vector of random effects is \hat{b} . The predicted conditional response is

$$\hat{y}_{Cond} = X\hat{\beta} + Z\hat{b},$$

which corresponds to the 'Conditional', 'true' and 'Prediction', 'curve' name-value pair arguments. The predicted conditional response that also includes observation error is

$$\hat{y}_{Cond} = X\hat{\beta} + Z\hat{b} + \varepsilon,$$

which corresponds to the 'Conditional', 'true' and 'Prediction', 'observation' name-value pair arguments.

The predicted marginal response is

$$\hat{y}_{Mar} = X\hat{\beta}.$$

This corresponds to the 'Conditional', 'false' and 'Prediction', 'curve' name-value pair arguments. The marginal conditional response that also includes observation error is

$$\hat{y}_{Mar} = X\hat{\beta} + \varepsilon,$$

which corresponds to the 'Conditional', 'false' and 'Prediction', 'observation' name-value pair arguments.

When making predictions, if a particular grouping variable has new levels (1s that were not in the original data), then the random effects for the grouping variable do not contribute to the 'Conditional' prediction at observations where the grouping variable has new levels.

fitted | LinearMixedModel | random

predict

Class: NaiveBayes

Predict class label for test data

Syntax

```
cpre = predict(nb, test)
cpre = predict(..., 'HandleMissing', val)
```

Description

`cpre = predict(nb, test)` classifies each row of data in `test` into one of the classes according to the `NaiveBayes` classifier `nb`, and returns the predicted class level `cpre`. `test` is an `N`-by-`nb.ndim` matrix, where `N` is the number of observations in the test data. Rows of `test` correspond to points, columns of `test` correspond to features. `cpre` is an `N`-by-1 vector of the same type as `nb.CLevels`, and it indicates the class to which each row of `test` has been assigned.

`cpre = predict(..., 'HandleMissing', val)` specifies how `predict` treats NaN (missing values). `val` can be one of the following:

- | | |
|-----------------|--|
| 'off' (default) | Observations with NaN in any of the columns are not classified into any class. The corresponding rows in <code>cpre</code> are NaN (if <code>obj.clevels</code> is numeric or logical), empty strings (if <code>obj.clevels</code> is char or cell array of strings) or <code><undefined></code> (if <code>obj.clevels</code> is categorical). |
| 'on' | For observations having NaN in some (but not all) columns, <code>predict</code> computes <code>cpre</code> using the columns with non-NaN values. Corresponding <code>cpre</code> values are NaN. |

`NaiveBayes` | `fitNaiveBayes` | `posterior`

predict

Class: NonLinearModel

Predict response of nonlinear regression model

Syntax

```
ypred = predict mdl, Xnew  
[ypred, yci] = predict mdl, Xnew  
[ypred, yci] = predict mdl, Xnew, Name, Value
```

Description

`ypred = predict(mdl, Xnew)` returns the predicted response of the `mdl` nonlinear regression model to the points in `Xnew`.

`[ypred, yci] = predict(mdl, Xnew)` returns confidence intervals for the true mean responses.

`[ypred, yci] = predict(mdl, Xnew, Name, Value)` predicts responses with additional options specified by one or more `Name, Value` pair arguments.

Tips

- For predictions with added noise, use `random`.
- For a syntax that can be easier to use with models created from tables or dataset arrays, try `feval`.

Input Arguments

mdl

Nonlinear regression model, constructed by `fitnlm`.

Xnew

Points at which `mdl` predicts responses.

- If `Xnew` is a table or dataset array, it must contain the predictor names in `mdl`.
- If `Xnew` is a numeric matrix, it must have the same number of variables (columns) as was used to create `mdl`. Furthermore, all variables used in creating `mdl` must be numeric.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1`, `Value1`, . . . , `NameN`, `ValueN`.

'alpha'

Positive scalar from 0 to 1. Confidence level of `yci` is $100(1 - \text{alpha})\%$.

Default: 0.05, meaning a 95% confidence interval.

'Prediction'

String specifying the type of prediction:

- 'curve' — `predict` predicts confidence bounds for the fitted mean values.
- 'observation' — `predict` predicts confidence bounds for the new observations. This results in wider bounds because the error in a new observation is equal to the error in the estimated mean value, plus the variability in the observation from the true mean.

For details, see `polyconf`.

Default: 'curve'

'Simultaneous'

Logical value specifying whether the confidence bounds are for all predictor values simultaneously (`true`), or hold for each individual predictor value (`false`). Simultaneous bounds are wider than separate bounds, because it is more stringent to require that the entire curve be within the bounds than to require that the curve at a single predictor value be within the bounds.

For details, see `polyconf`.

Default: `false`

'Weights'

Vector of real, positive value weights or a function handle.

- If you specify a vector, then it must have the same number of elements as the number of observations (or rows) in `Xnew`.
- If you specify a function handle, then the function must accept a vector of predicted response values as input, and return a vector of real positive weights as output.

Given weights, `W`, `predict` estimates the error variance at observation `i` by $MSE * (1 / W(i))$, where `MSE` is the mean squared error.

Default: No weights

Output Arguments

`ypred`

Vector of predicted mean values at `Xnew`.

`yci`

Confidence intervals, a two-column matrix with each row providing one interval. The meaning of the confidence interval depends on the settings of the name-value pairs.

Examples

Predict Responses

Create a nonlinear model of car mileage as a function of weight, and predict the response.

Create an exponential model of car mileage as a function of weight from the `carsmall` data. Scale the weight by a factor of 1000 so all the variables are roughly equal in size.

```
load carsmall
X = Weight;
```

```
y = MPG;
modelfun = 'y ~ b1 + b2*exp(-b3*x/1000)';
beta0 = [1 1 1];
mdl = fitnlm(X,y,modelfun,beta0);
```

Create predicted responses to the data.

```
Xnew = X;
ypred = predict(mdl,Xnew);
```

Plot the original responses and the predicted responses to see how they differ.

```
plot(X,y,'o',X,ypred,'x')
legend('Data','Predicted')
```

Confidence Intervals for Predictions

Create a nonlinear model of car mileage as a function of weight, and examine confidence intervals of some responses.

Create an exponential model of car mileage as a function of weight from the `carsmall` data. Scale the weight by a factor of 1000 so all the variables are roughly equal in size.

```
load carsmall
X = Weight;
y = MPG;
modelfun = 'y ~ b1 + b2*exp(-b3*x/1000)';
beta0 = [1 1 1];
mdl = fitnlm(X,y,modelfun,beta0);
```

Create predicted responses to the smallest, mean, and largest data points.

```
Xnew = [min(X);mean(X);max(X)];
[ypred,yci] = predict(mdl,Xnew)
```

```
ypred =
    34.9469
    22.6868
    10.0617
```

```
yci =
    32.5212    37.3726
    21.4061    23.9674
     7.0148    13.1086
```

Simultaneous Confidence Intervals for Robust Fit Curve

Generate sample data from the nonlinear regression model

$$y = b_1 + b_2 \exp\{-b_3 x\} + \varepsilon,$$

where b_1 , b_2 , and b_3 are coefficients, and the error term is normally distributed with mean 0 and standard deviation 0.5.

```
modelfun = @(b,x)(b(1)+b(2)*exp(-b(3)*x));
rng('default') % for reproducibility
b = [1;3;2];
x = exprnd(2,100,1);
y = modelfun(b,x) + normrnd(0,0.5,100,1);
```

Fit the nonlinear model using robust fitting options.

```
opts = statset('nlinfit');
opts.RobustWgtFun = 'bisquare';
```

```
b0 = [2;2;2];
mdl = fitnlm(x,y,modelfun,b0,'Options',opts);
```

Plot the fitted regression model and simultaneous 95% confidence bounds.

```
xrange = [min(x):.01:max(x)]';
[ypred,yci] = predict(mdl,xrange,'Simultaneous',true);
```

```
figure()
plot(x,y,'ko') % observed data
hold on
plot(xrange,ypred,'k','LineWidth',2)
plot(xrange,yci,'r--','LineWidth',1.5)
```

Confidence Interval Using Observation Weights

Load sample data.

```
S = load('reaction');
X = S.reactants;
```

```
y = S.rate;
beta0 = S.beta;
```

Specify a function handle for observation weights, then fit the Hougen-Watson model to the rate data using the specified observation weights function.

```
a = 1; b = 1;
weights = @(yhat) 1./((a + b*abs(yhat)).^2);
mdl = fitnlm(X,y,@hougen,beta0,'Weights',weights);
```

Compute the 95% prediction interval for a new observation with reactant levels [100,100,100] using the observation weight function.

```
[ypred,yci] = predict(mdl,[100,100,100],'Prediction','observation',...
    'Weights',weights)
```

```
ypred =
    1.8149
```

```
yci =
    1.5264    2.1033
```

More About

- “Nonlinear Regression” on page 11-2

predict

Class: RepeatedMeasuresModel

Compute predicted values given predictor values

Syntax

```
ypred = predict(rm,tnew)
ypred = predict(rm,tnew,Name,Value)
[ypred,yci] = predict( ___ )
```

Description

`ypred = predict(rm,tnew)` returns the predicted values from the repeated measures model `rm` using the predictor values from the table `t`.

`ypred = predict(rm,tnew,Name,Value)` returns the predicted values from the repeated measures model `rm` with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify the within-subjects design matrix.

`[ypred,yci] = predict(___)` also returns the 95% confidence interval for the predicted values.

Input Arguments

rm — Repeated measures model

RepeatedMeasuresModel object

Repeated measures model, returned as a RepeatedMeasuresModel object.

For properties and methods of this object, see RepeatedMeasuresModel.

tnew — New data

table used to create `rm` (default) | table

New data including the values of the response variables and the between-subject factors used as predictors in the repeated measures model, `rm`, specified as a table. `tnew` must contain all of the between-subject factors used to create `rm`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

'Alpha' — Confidence level

0.05 (default) | scalar value in the range of 0 through 1

Confidence level of the confidence intervals for the predicted values, specified as the comma-separated pair consisting of 'alpha' and a scalar value in the range of 0 to 1. The confidence level is $100 \cdot (1 - \alpha)\%$.

Example: 'alpha', 0.01

Data Types: double | single

'WithinModel' — Model for within-subject factors

'separatemeans' | 'orthogonalcontrasts' | text string

Model for the within-subject factors, specified as the comma-separated pair consisting of 'WithinModel' and one of the following:

- 'separatemeans' — Compute a separate mean for each group.
- 'orthogonalcontrasts' — Valid when the within-subject design consists of a single numeric factor T . This specifies a model consisting of orthogonal polynomials up to order $T^{(r-1)}$, where r is the number of repeated measures.
- A string that defines a model specification in the within-subject factors.

Example: 'WithinModel', 'orthogonalcontrasts'

'WithinDesign' — Design for within-subject factors

vector | matrix | table

Design for within-subject factors, specified as the comma-separated pair consisting of 'WithinDesign' and a vector, matrix, or a table. It provides the values of the within-subject factors in the same form as the `RM.WithinDesign` property.

Example: 'WithinDesign', 'Time'

Data Types: single | double | table

Output Arguments

ypred — Predicted values

n-by-*r* matrix

Predicted values from the repeated measures model `rm`, returned as an *n*-by-*r* matrix, where *n* is the number of rows in `tnew` and *r* is the number of repeated measures in `rm`.

yci — Confidence intervals for predicted values

n-by-*r*-by-2 matrix

Confidence intervals for predicted values from the repeated measures model `rm`, returned as an *n*-by-*r*-by-2 matrix.

These are nonsimultaneous intervals for predicting the mean response at the specified predictor values. For predicted value `ypred(i, j)`, the lower limit of the interval is `yci(i, j, 1)` and the upper limit is `yci(i, j, 2)`.

Examples

Predict Response Values

Load the sample data.

```
load fisheriris
```

The column vector, `species` consists of iris flowers of three different species: `setosa`, `versicolor`, and `virginica`. The double matrix `meas` consists of four types of measurements on the flowers: the length and width of sepals and petals in centimeters, respectively.

Store the data in a table array.

```
t = table(species, meas(:,1), meas(:,2), meas(:,3), meas(:,4), ...  
'VariableNames', {'species', 'meas1', 'meas2', 'meas3', 'meas4'});  
Meas = dataset([1 2 3 4]', 'VarNames', {'Measurements'});
```

Fit a repeated measures model, where the measurements are the responses and the `species` is the predictor variable.

```
rm = fitrm(t,'meas1-meas4~species','WithinDesign',Meas);
```

Predict responses for the three species.

```
Y = predict(rm,t([1 51 101],:))
```

Y =

```
    5.0060    3.4280    1.4620    0.2460
    5.9360    2.7700    4.2600    1.3260
    6.5880    2.9740    5.5520    2.0260
```

Predict Response Values and Plot Predictions

Navigate to the folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load('longitudinalData')
```

The matrix Y contains response data for 16 individuals. The response is the blood level of a drug measured at five time points (time = 0, 2, 4, 6, and 8). Each row of Y corresponds to an individual, and each column corresponds to a time point. The first eight subjects are female, and the second eight subjects are male. This is simulated data.

Define a variable that stores gender information.

```
Gender = ['F' 'F' 'F' 'F' 'F' 'F' 'F' 'F' 'M' 'M' 'M' 'M' 'M' 'M' 'M'];
```

Store the data in a proper table array format to perform repeated measures analysis.

```
t = table(Gender,Y(:,1),Y(:,2),Y(:,3),Y(:,4),Y(:,5),...
'VariableNames',{'Gender','t0','t2','t4','t6','t8'});
```

Define the within-subjects variable.

```
Time = [0 2 4 6 8]';
```

Fit a repeated measures model, where the blood levels are the responses and gender is the predictor variable.

```
rm = fitrm(t,'t0-t8 ~ Gender','WithinDesign',Time);
```

Predict the responses at intermediate times.

```
time = linspace(0,8)';  
Y = predict(rm,t([1 5 8 12],:), ...  
    'WithinModel','orthogonalcontrasts','WithinDesign',time);
```

Plot the predictions along with the estimated marginal means.

```
plotprofile(rm,'Time','Group',{'Gender'})  
hold on;  
plot(time,Y,'Color','r','LineStyle',':');  
hold off
```

Compute and Plot Confidence Intervals

Navigate to the folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load('longitudinalData')
```

The matrix Y contains response data for 16 individuals. The response is the blood level of a drug measured at five time points (time = 0, 2, 4, 6, and 8). Each row of Y corresponds to an individual, and each column corresponds to a time point. The first eight subjects are female, and the second eight subjects are male. This is simulated data.

Define a variable that stores gender information.

predict

Class: TreeBagger

Predict response

Syntax

```
Y = predict(B,X)
[Y,stdevs] = predict(B,X)
[Y,scores] = predict(B,X)
[Y,scores,stdevs] = predict(B,X)
Y = predict(B,X,'param1',val1,'param2',val2,...)
```

Description

`Y = predict(B,X)` computes predicted response of the trained ensemble **B** for data **X**. The output has one prediction for each row of **X**. The returned **Y** is a cell array of strings for classification and a numeric array for regression.

For regression, `[Y,stdevs] = predict(B,X)` also returns standard deviations of the computed responses over the ensemble of the grown trees.

For classification, `[Y,scores] = predict(B,X)` returns scores for all classes. **scores** is a matrix with one row per observation and one column per class. For each observation and each class, the score generated by each tree is the probability of this observation originating from this class computed as the fraction of observations of this class in a tree leaf. **predict** averages these scores over all trees in the ensemble.

`[Y,scores,stdevs] = predict(B,X)` also returns standard deviations of the computed scores for classification. **stdevs** is a matrix with one row per observation and one column per class, with standard deviations taken over the ensemble of the grown trees.

`Y = predict(B,X,'param1',val1,'param2',val2,...)` specifies optional parameter name/value pairs:

<code>'trees'</code>	Array of tree indices to use for computation of responses. Default is <code>'all'</code> .
----------------------	--

- 'treeweights' Array of `Ntrees` weights for weighting votes from the specified trees.
- 'useifort' Logical matrix of size `Nobs`-by-`Ntrees` indicating which trees to use to make predictions for each observation. By default all trees are used for all observations.

`CompactTreeBagger.predict`

predictorImportance

Class: CompactClassificationEnsemble

Estimates of predictor importance

Syntax

```
imp = predictorImportance(ens)
[imp,ma] = predictorImportance(ens)
```

Description

`imp = predictorImportance(ens)` computes estimates of predictor importance for `ens` by summing these estimates over all weak learners in the ensemble. `imp` has one element for each input predictor in the data used to train this ensemble. A high value indicates that this predictor is important for `ens`.

`[imp,ma] = predictorImportance(ens)` returns a P-by-P matrix with predictive measures of association for P predictors, when the learners in `ens` contain surrogate splits. See “Definitions” on page 21-3438.

Input Arguments

ens

A classification ensemble created by `fitensemble`, or by the `compact` method.

Output Arguments

imp

A row vector with the same number of elements as the number of predictors (columns) in `ens.X`. The entries are the estimates of predictor importance, with 0 representing the smallest possible importance.

ma

A P-by-P matrix of predictive measures of association for P predictors. Element `ma(I, J)` is the predictive measure of association averaged over surrogate splits on predictor J for which predictor I is the optimal split predictor. `predictorImportance` averages this predictive measure of association over all trees in the ensemble.

Definitions

Predictor Importance

`predictorImportance` computes estimates of predictor importance for `ens` by summing changes in the *risk* due to splits on every predictor and dividing the sum by the number of branch nodes. If `ens` is grown without surrogate splits, this sum is taken over best splits found at each branch node. If `ens` is grown with surrogate splits, this sum is taken over all splits at each branch node including surrogate splits. `imp` has one element for each input predictor in the data used to train `ens`. Predictor importance associated with this split is computed as the difference between the risk for the parent node and the total risk for the two children.

Impurity and Node Error

`ClassificationTree` splits nodes based on either *impurity* or *node error*.

Impurity means one of several things, depending on your choice of the `SplitCriterion` name-value pair argument:

- Gini's Diversity Index (`gdi`) — The Gini index of a node is

$$1 - \sum_i p^2(i),$$

where the sum is over the classes i at the node, and $p(i)$ is the observed fraction of classes with class i that reach the node. A node with just one class (a *pure* node) has Gini index 0; otherwise the Gini index is positive. So the Gini index is a measure of node impurity.

- Deviance (`'deviance'`) — With $p(i)$ defined the same as for the Gini index, the deviance of a node is

$$-\sum_i p(i) \log p(i).$$

A pure node has deviance 0; otherwise, the deviance is positive.

- Twoing rule ('twoing') — Twoing is not a purity measure of a node, but is a different measure for deciding how to split a node. Let $L(i)$ denote the fraction of members of class i in the left child node after a split, and $R(i)$ denote the fraction of members of class i in the right child node after a split. Choose the split criterion to maximize

$$P(L)P(R) \left(\sum_i |L(i) - R(i)| \right)^2,$$

where $P(L)$ and $P(R)$ are the fractions of observations that split to the left and right respectively. If the expression is large, the split made each child node purer. Similarly, if the expression is small, the split made each child node similar to each other, and hence similar to the parent node, and so the split did not increase node purity.

- Node error — The node error is the fraction of misclassified classes at a node. If j is the class with the largest number of training samples at a node, the node error is $1 - p(j)$.

Predictive Measure of Association

The predictive measure of association between the optimal split on variable i and a surrogate split on variable j is:

$$\lambda_{i,j} = \frac{\min(P_L, P_R) - (1 - P_{L_i L_j} - P_{R_i R_j})}{\min(P_L, P_R)}.$$

Here

- P_L and P_R are the node probabilities for the optimal split of node i into Left and Right nodes respectively.

- $P_{L_i L_j}$ is the probability that both (optimal) node i and (surrogate) node j send an observation to the Left.
- $P_{R_i R_j}$ is the probability that both (optimal) node i and (surrogate) node j send an observation to the Right.

Clearly, $\lambda_{i,j}$ lies from $-\infty$ to 1. Variable j is a worthwhile surrogate split for variable i if $\lambda_{i,j} > 0$.

Element $\text{ma}(i, j)$ is the predictive measure of association averaged over surrogate splits on predictor j for which predictor i is the optimal split predictor. This average is computed by summing positive values of the predictive measure of association over optimal splits on predictor i and surrogate splits on predictor j and dividing by the total number of optimal splits on predictor i , including splits for which the predictive measure of association between predictors i and j is negative.

Examples

Estimate the predictor importance for all variables in the Fisher iris data:

```
load fisheriris
ens = fitensemble(meas,species,'AdaBoostM2',100,'Tree');
imp = predictorImportance(ens)
```

```
imp =
    0.0001    0.0005    0.0384    0.0146
```

The first two predictors are not very important in `ens`.

Estimate the predictor importance for all variables in the Fisher iris data for an ensemble where the trees contain surrogate splits:

```
load fisheriris
surrtree = templateTree('Surrogate','on');
ens2 = fitensemble(meas,species,'AdaBoostM2',100,surrtree);
[imp2,ma] = predictorImportance(ens2)
```

```
imp2 =
    0.0224    0.0142    0.0525    0.0508
```

```
ma =
```

1.0000	0	0.0001	0.0001
0.0115	1.0000	0.0023	0.0054
0.2810	0.1747	1.0000	0.5372
0.0789	0.0463	0.2339	1.0000

The first two predictors show much more importance than in the previous example.

See Also

`predictorImportance` | `templateTree`

predictorImportance

Class: CompactClassificationTree

Estimates of predictor importance

Syntax

```
imp = predictorImportance(tree)
```

Description

`imp = predictorImportance(tree)` computes estimates of predictor importance for `tree` by summing changes in the risk due to splits on every predictor and dividing the sum by the number of branch nodes.

Input Arguments

tree

A classification tree created by `fitctree`, or by the `compact` method.

Output Arguments

imp

A row vector with the same number of elements as the number of predictors (columns) in `tree.X`. The entries are the estimates of predictor importance, with 0 representing the smallest possible importance.

Definitions

Predictor Importance

`predictorImportance` computes estimates of predictor importance for tree by summing changes in the *risk* due to splits on every predictor and dividing the sum by the number of branch nodes. If `tree` is grown without surrogate splits, this sum is taken over best splits found at each branch node. If `tree` is grown with surrogate splits, this sum is taken over all splits at each branch node including surrogate splits. `imp` has one element for each input predictor in the data used to train `tree`. Predictor importance associated with this split is computed as the difference between the risk for the parent node and the total risk for the two children.

Estimates of predictor importance do not depend on the order of predictors if you use surrogate splits, but do depend on the order if you do not use surrogate splits.

If you use surrogate splits, `predictorImportance` computes estimates before the tree is reduced by pruning or merging leaves. If you do not use surrogate splits, `predictorImportance` computes estimates after the tree is reduced by pruning or merging leaves. Therefore, reducing the tree by pruning affects the predictor importance for a tree grown without surrogate splits, and does not affect the predictor importance for a tree grown with surrogate splits.

Impurity and Node Error

`ClassificationTree` splits nodes based on either *impurity* or *node error*.

Impurity means one of several things, depending on your choice of the `SplitCriterion` name-value pair argument:

- Gini's Diversity Index (`gdi`) — The Gini index of a node is

$$1 - \sum_i p^2(i),$$

where the sum is over the classes i at the node, and $p(i)$ is the observed fraction of classes with class i that reach the node. A node with just one class (a *pure* node) has Gini index 0; otherwise the Gini index is positive. So the Gini index is a measure of node impurity.

- Deviance ('deviance') — With $p(i)$ defined the same as for the Gini index, the deviance of a node is

$$-\sum_i p(i) \log p(i).$$

A pure node has deviance 0; otherwise, the deviance is positive.

- Twoing rule ('twoing') — Twoing is not a purity measure of a node, but is a different measure for deciding how to split a node. Let $L(i)$ denote the fraction of members of class i in the left child node after a split, and $R(i)$ denote the fraction of members of class i in the right child node after a split. Choose the split criterion to maximize

$$P(L)P(R) \left(\sum_i |L(i) - R(i)| \right)^2,$$

where $P(L)$ and $P(R)$ are the fractions of observations that split to the left and right respectively. If the expression is large, the split made each child node purer. Similarly, if the expression is small, the split made each child node similar to each other, and hence similar to the parent node, and so the split did not increase node purity.

- Node error — The node error is the fraction of misclassified classes at a node. If j is the class with the largest number of training samples at a node, the node error is $1 - p(j)$.

Examples

Estimate the predictor importance for all variables in the Fisher iris data:

```
load fisheriris
tree = fitctree(meas,species);
imp = predictorImportance(tree)

imp =
    0         0    0.0403    0.0303
```

The first two elements of `imp` are zero. Therefore, the first two predictors do not enter into `tree` calculations for classifying irises.

Estimate the predictor importance for all variables in the Fisher iris data for a tree grown with surrogate splits:

```
tree2 = fitctree(meas,species,...
    'Surrogate','on');
imp2 = predictorImportance(tree2)

imp2 =
    0.0287    0.0136    0.0560    0.0556
```

In this case, all predictors have some importance. As you expect by comparing to the first example, the first two predictors are less important than the final two.

Estimates of predictor importance do not depend on the order of predictors if you use surrogate splits, but do depend on the order if you do not use surrogate splits. For example, permute the order of the data columns in the previous example:

```
load fisheriris
meas3 = meas(:,[4 1 3 2]);
tree3 = fitctree(meas3,species);
imp3 = predictorImportance(tree2)

imp3 =
    0.0674         0    0.0033         0
```

The estimates of predictor importance are not a permutation of `imp` from the first example.

Estimate the predictor importance using surrogate splits.

```
tree4 = fitctree(meas3,species,...
    'Surrogate','on');
imp4 = predictorImportance(tree4)

imp4 =
    0.0556    0.0287    0.0560    0.0136
```

`imp4` is a permutation of `imp2`, demonstrating that estimates of predictor importance do not depend on the order of predictors with surrogate splits.

`predictorImportance` | `fitctree`

predictorImportance

Class: CompactRegressionEnsemble

Estimates of predictor importance

Syntax

```
imp = predictorImportance(ens)
[imp,ma] = predictorImportance(ens)
```

Description

`imp = predictorImportance(ens)` computes estimates of predictor importance for `ens` by summing these estimates over all weak learners in the ensemble. `imp` has one element for each input predictor in the data used to train this ensemble. A high value indicates that this predictor is important for `ens`.

`[imp,ma] = predictorImportance(ens)` returns a P-by-P matrix with predictive measures of association for P predictors.

Input Arguments

ens

A regression ensemble created by `fitensemble`, or by the `compact` method.

Output Arguments

imp

A row vector with the same number of elements as the number of predictors (columns) in `ens.X`. The entries are the estimates of predictor importance, with 0 representing the smallest possible importance.

ma

A P-by-P matrix of predictive measures of association for P predictors. Element $\text{ma}(I, J)$ is the predictive measure of association averaged over surrogate splits on predictor J for which predictor I is the optimal split predictor. `predictorImportance` averages this predictive measure of association over all trees in the ensemble.

Definitions

Predictor Importance

`predictorImportance` computes estimates of predictor importance for tree by summing changes in the mean squared error (MSE) due to splits on every predictor and dividing the sum by the number of branch nodes. If the tree is grown without surrogate splits, this sum is taken over best splits found at each branch node. If the tree is grown with surrogate splits, this sum is taken over all splits at each branch node including surrogate splits. `imp` has one element for each input predictor in the data used to train this tree. At each node, MSE is estimated as node error weighted by the node probability. Variable importance associated with this split is computed as the difference between MSE for the parent node and the total MSE for the two children.

Predictive Measure of Association

The predictive measure of association between the optimal split on variable i and a surrogate split on variable j is:

$$\lambda_{i,j} = \frac{\min(P_L, P_R) - (1 - P_{L_i L_j} - P_{R_i R_j})}{\min(P_L, P_R)}.$$

Here

- P_L and P_R are the node probabilities for the optimal split of node i into Left and Right nodes respectively.
- $P_{L_i L_j}$ is the probability that both (optimal) node i and (surrogate) node j send an observation to the Left.

- $P_{R_i R_j}$ is the probability that both (optimal) node i and (surrogate) node j send an observation to the Right.

Clearly, $\lambda_{i,j}$ lies from $-\infty$ to 1. Variable j is a worthwhile surrogate split for variable i if $\lambda_{i,j} > 0$.

Element $\text{ma}(i, j)$ is the predictive measure of association averaged over surrogate splits on predictor j for which predictor i is the optimal split predictor. This average is computed by summing positive values of the predictive measure of association over optimal splits on predictor i and surrogate splits on predictor j and dividing by the total number of optimal splits on predictor i , including splits for which the predictive measure of association between predictors i and j is negative.

Examples

Estimate the predictor importance for all numeric variables in the `carsmall` data:

```
load carsmall
X = [Acceleration Cylinders Displacement ...
     Horsepower Model_Year Weight];
ens = fitensemble(X,MPG,'LSBoost',100,'Tree');
imp = predictorImportance(ens)

imp =
    0.0082         0    0.0049    0.0133    0.0142    0.1737
```

The weight (last predictor) has the most impact on mileage (MPG). The second predictor has importance 0; this means the number of cylinders has no impact on predictions made with `ens`.

Estimate the predictor importance for all variables in the `carsmall` data for an ensemble where the trees contain surrogate splits:

```
load carsmall
surrtree = templateTree('Surrogate','on');
X = [Acceleration Cylinders Displacement ...
     Horsepower Model_Year Weight];
ens2 = fitensemble(X,MPG,'LSBoost',100,surrtree);
[imp2,ma] = predictorImportance(ens2)

imp2 =
```

```
      0.0725    0.1342    0.1425    0.1397    0.1380    0.1855
ma =
  1.0000    0.0414    0.0607    0.0782    0.0102    0.0322
     0      1.0000         0         0         0         0
  0.0441    0.0704    1.0000    0.0883    0.0175    0.0913
  0.0944    0.1166    0.1400    1.0000    0.0390    0.1308
  0.0121    0.0139    0.0127    0.0127    1.0000    0.0113
  0.0818    0.1317    0.2072    0.1878    0.0340    1.0000
```

While weight (last predictor) still has the most impact on mileage (MPG), this estimate has the second predictor (number of cylinders) is essentially tied for third most important predictor.

See Also

`predictorImportance` | `templateTree`

predictorImportance

Class: CompactRegressionTree

Estimates of predictor importance

Syntax

```
imp = predictorImportance(tree)
```

Description

`imp = predictorImportance(tree)` computes estimates of predictor importance for `tree` by summing changes in the mean squared error due to splits on every predictor and dividing the sum by the number of branch nodes.

Input Arguments

tree

A regression tree created by `fitrtree`, or by the `compact` method.

Output Arguments

imp

A row vector with the same number of elements as the number of predictors (columns) in `tree.X`. The entries are the estimates of predictor importance, with 0 representing the smallest possible importance.

Definitions

Predictor Importance

`predictorImportance` computes estimates of predictor importance for tree by summing changes in the mean squared error (MSE) due to splits on every predictor and dividing the sum by the number of branch nodes. If the tree is grown without surrogate splits, this sum is taken over best splits found at each branch node. If the tree is grown with surrogate splits, this sum is taken over all splits at each branch node including surrogate splits. `imp` has one element for each input predictor in the data used to train this tree. At each node, MSE is estimated as node error weighted by the node probability. Variable importance associated with this split is computed as the difference between MSE for the parent node and the total MSE for the two children.

Estimates of predictor importance do not depend on the order of predictors if you use surrogate splits, but do depend on the order if you do not use surrogate splits.

If you use surrogate splits, `predictorImportance` computes estimates before the tree is reduced by pruning or merging leaves. If you do not use surrogate splits, `predictorImportance` computes estimates after the tree is reduced by pruning or merging leaves. Therefore, reducing the tree by pruning affects the predictor importance for a tree grown without surrogate splits, and does not affect the predictor importance for a tree grown with surrogate splits.

Examples

Find predictor importance for the `carsmall` data. Use just the numeric predictors:

```
load carsmall
X = [Acceleration Cylinders Displacement ...
     Horsepower Model_Year Weight];
tree = fitrtree(X,MPG);
imp = predictorImportance(tree)

imp =
    0.0315         0    0.1082    0.0686    0.1629    1.2924
```

The weight (last predictor) has the most impact on mileage (MPG). The second predictor has importance 0; this means the number of cylinders has no impact on predictions made with tree.

Estimate the predictor importance for all variables in the `carsmall` data for a tree grown with surrogate splits:

```
load carsmall
X = [Acceleration Cylinders Displacement ...
     Horsepower Model_Year Weight];
tree2 = fitrtree(X,MPG,...
    'Surrogate','on');
imp2 = predictorImportance(tree2)

imp2 =
    0.5287    1.1977    1.2400    0.7059    1.0677    1.4106
```

While weight (last predictor) still has the most impact on mileage (MPG), this estimate has the second predictor (number of cylinders) as the third most important predictor.

`predictorImportance` | `fitrtree`

princomp

Principal component analysis (PCA) on data

Syntax

```
[COEFF,SCORE] = princomp(X)
[COEFF,SCORE,latent] = princomp(X)
[COEFF,SCORE,latent,tsquare] = princomp(X)
[...] = princomp(X,'econ')
```

Description

`COEFF = princomp(X)` performs principal components analysis (PCA) on the n -by- p data matrix X , and returns the principal component coefficients, also known as loadings. Rows of X correspond to observations, columns to variables. `COEFF` is a p -by- p matrix, each column containing coefficients for one principal component. The columns are in order of decreasing component variance.

`princomp` centers X by subtracting off column means, but does not rescale the columns of X . To perform principal components analysis with standardized variables, that is, based on correlations, use `princomp(zscore(X))`. To perform principal components analysis directly on a covariance or correlation matrix, use `pcacov`.

`[COEFF,SCORE] = princomp(X)` returns `SCORE`, the principal component scores; that is, the representation of X in the principal component space. Rows of `SCORE` correspond to observations, columns to components.

`[COEFF,SCORE,latent] = princomp(X)` returns `latent`, a vector containing the eigenvalues of the covariance matrix of X .

`[COEFF,SCORE,latent,tsquare] = princomp(X)` returns `tsquare`, which contains Hotelling's T^2 statistic for each data point.

The scores are the data formed by transforming the original data into the space of the principal components. The values of the vector `latent` are the variance of the columns of `SCORE`. Hotelling's T^2 is a measure of the multivariate distance of each observation from the center of the data set.

When $n \leq p$, `SCORE(:,n:p)` and `latent(n:p)` are necessarily zero, and the columns of `COEFF(:,n:p)` define directions that are orthogonal to X .

`[...] = princomp(X, 'econ')` returns only the elements of `latent` that are not necessarily zero, and the corresponding columns of `COEFF` and `SCORE`, that is, when $n \leq p$, only the first $n-1$. This can be significantly faster when p is much larger than n .

Examples

Compute principal components for the `ingredients` data in the Hald data set, and the variance accounted for by each component.

```
load hald;
[pc,score,latent,tsquare] = princomp(ingredients);
pc,latent
```

```
pc =
    -0.0678    -0.6460     0.5673     0.5062
    -0.6785    -0.0200    -0.5440     0.4933
     0.0290     0.7553     0.4036     0.5156
     0.7309    -0.1085    -0.4684     0.4844
```

```
latent =
    517.7969
     67.4964
     12.4054
      0.2372
```

The following command and plot show that two components account for 98% of the variance:

```
cumsum(latent)./sum(latent)
ans =
    0.86597
    0.97886
    0.9996
      1
biplot(pc(:,1:2), 'Scores', score(:,1:2), 'VarLabels', ...
        {'X1' 'X2' 'X3' 'X4'})
```

For a more detailed example and explanation of this analysis method, see “Principal Component Analysis (PCA)” on page 13-75.

ProbDist class

Object representing probability distribution

Description

ProbDist is an abstract class representing a probability distribution.

Construction

ProbDist is an abstract class. You cannot create instances of this class directly. You can construct an object in a subclass, such as `ProbDistUnivParam` or `ProbDistUnivKernel`, either by calling the subclass constructors (`ProbDistUnivParam` or `ProbDistUnivKernel`) or by using the `fitdist` function.

Methods

<code>cdf</code>	Return cumulative distribution function (CDF) for ProbDist object
<code>pdf</code>	Return probability density function (PDF) for ProbDist object
<code>random</code>	Generate random number drawn from ProbDist object

Properties

<code>DistName</code>	Read-only string containing probability distribution name of ProbDist object
-----------------------	--

InputData

Read-only structure containing information about input data to ProbDist object

Support

Read-only structure containing information about support of ProbDist object

Copy Semantics

Value. To learn how this affects your use of the class, see “Copying Objects” in the MATLAB Programming Fundamentals documentation.

See Also

ProbDistKernel class

Superclasses: ProbDist

Object representing nonparametric probability distribution defined by kernel smoothing

Description

ProbDistKernel is an abstract class defining the properties and methods of a nonparametric distribution defined by a kernel smoothing function.

Construction

ProbDistKernel is an abstract class. You cannot create instances of this class directly. You can construct an object in a subclass, `ProbDistUnivKernel`, either by calling the subclass constructor, `ProbDistUnivKernel`, or by using the `fitdist` function.

Methods

<code>cdf</code>	Return cumulative distribution function (CDF) for ProbDist object
<code>pdf</code>	Return probability density function (PDF) for ProbDist object
<code>random</code>	Generate random number drawn from ProbDist object

Note: The above methods are inherited from the `ProbDist` class.

Properties

BandWidth	Read-only value specifying bandwidth of kernel smoothing function for ProbDistKernel object
DistName	Read-only string containing probability distribution name of ProbDist object
InputData	Read-only structure containing information about input data to ProbDist object
Kernel	Read-only string specifying name of kernel smoothing function for ProbDistKernel object
Support	Read-only structure containing information about support of ProbDist object

Note: Some of the above properties are inherited from the `ProbDist` class.

Copy Semantics

Value. To learn how this affects your use of the class, see “Copying Objects” in the MATLAB Programming Fundamentals documentation.

ProbDistParametric class

Superclasses: ProbDist

Object representing parametric probability distribution

Description

ProbDistParametric is an abstract class defining the properties and methods of a parametric probability distribution.

Construction

ProbDistParametric is an abstract class. You cannot create instances of this class directly. You can construct an object in its subclass, `ProbDistUnivParam`, either by calling the subclass constructor, `ProbDistUnivParam`, or by using the `fitdist` function.

Methods

<code>cdf</code>	Return cumulative distribution function (CDF) for ProbDist object
<code>pdf</code>	Return probability density function (PDF) for ProbDist object
<code>random</code>	Generate random number drawn from ProbDist object

Note: The above methods are inherited from the `ProbDist` class.

Properties

DistName	Read-only string containing probability distribution name of ProbDist object
InputData	Read-only structure containing information about input data to ProbDist object
NLogL	Read-only value specifying negative log likelihood for input data to ProbDistParametric object
NumParams	Read-only value specifying number of parameters of ProbDistParametric object
ParamCov	Read-only covariance matrix of parameter estimates of ProbDistParametric object
ParamDescription	Read-only cell array specifying descriptions of parameters of ProbDistParametric object
ParamIsFixed	Read-only logical array specifying fixed parameters of ProbDistParametric object
ParamNames	Read-only cell array specifying names of parameters of ProbDistParametric object
Params	Read-only array specifying values of parameters of ProbDistParametric object
Support	Read-only structure containing information about support of ProbDist object

Note: Some of the above properties are inherited from the `ProbDist` class.

Copy Semantics

Value. To learn how this affects your use of the class, see “Copying Objects” in the MATLAB Programming Fundamentals documentation.

ProbDistUnivKernel class

Superclasses: ProbDistKernel

Object representing univariate kernel probability distribution

Description

A ProbDistUnivKernel object represents a univariate nonparametric probability distribution defined by kernel smoothing. You create this object using the `fitdist` function to fit the distribution to data.

Construction

Methods

<code>cdf</code>	Return cumulative distribution function (CDF) for ProbDist object
<code>icdf</code>	Return inverse cumulative distribution function (ICDF) for ProbDistUnivKernel object
<code>iqr</code>	Return interquartile range (IQR) for ProbDistUnivKernel object
<code>median</code>	Return median of ProbDistUnivKernel object
<code>pdf</code>	Return probability density function (PDF) for ProbDist object
<code>random</code>	Generate random number drawn from ProbDist object

Note: Some of the above methods are inherited from the `ProbDistKernel` class.

Properties

BandWidth	Read-only value specifying bandwidth of kernel smoothing function for <code>ProbDistKernel</code> object
DistName	Read-only string containing probability distribution name of <code>ProbDist</code> object
InputData	Read-only structure containing information about input data to <code>ProbDist</code> object
Kernel	Read-only string specifying name of kernel smoothing function for <code>ProbDistKernel</code> object
NLogL	Read-only value specifying negative log likelihood for input data to <code>ProbDistUnivKernel</code> object
Support	Read-only structure containing information about support of <code>ProbDist</code> object

Note: Some of the above properties are inherited from the `ProbDistKernel` class.

Copy Semantics

Value. To learn how this affects your use of the class, see “Copying Objects” in the MATLAB Programming Fundamentals documentation.

`fitdist` | `ksdensity` | `ProbDist` | `ProbDistUnivKernel` | `ProbDistKernel`

ProbDistUnivKernel

Class: ProbDistUnivKernel

Construct ProbDistUnivKernel object

Syntax

$PD = \text{ProbDistUnivKernel}(X)$

$PD = \text{ProbDistUnivKernel}(X, \text{param1}, \text{val1}, \text{param2}, \text{val2}, \dots)$

Description

Tip Although you can use this constructor function to create a ProbDistUnivKernel object, using the `fitdist` function is an easier way to create the ProbDistUnivKernel object.

$PD = \text{ProbDistUnivKernel}(X)$ creates PD , a ProbDistUnivKernel object, which represents a nonparametric probability distribution, based on a normal kernel smoothing function.

$PD = \text{ProbDistUnivKernel}(X, \text{param1}, \text{val1}, \text{param2}, \text{val2}, \dots)$ specifies optional parameter name/value pairs, as described in the Parameter/Values table. Parameter and value names are case insensitive.

Input Arguments

X A column vector of data.

Note: Any NaN values in X are ignored by the fitting calculations.

Parameter	Values
'censoring'	A Boolean vector the same size as X , containing 1s when the corresponding elements in X are right-censored observations and 0s

Parameter	Values
	<p>when the corresponding elements are exact observations. Default is a vector of 0s.</p> <hr/> <p>Note: Any NaN values in this censoring vector are ignored by the fitting calculations.</p>
'frequency'	<p>A vector the same size as X, containing nonnegative integers specifying the frequencies for the corresponding elements in X. Default is a vector of 1s.</p> <hr/> <p>Note: Any NaN values in this frequency vector are ignored by the fitting calculations.</p>
'kernel'	<p>A string specifying the type of kernel smoother to use. Choices are:</p> <ul style="list-style-type: none"> • 'normal' (default) • 'box' • 'triangle' • 'epanechnikov'
'support'	<p>Any of the following to specify the support:</p> <ul style="list-style-type: none"> • 'unbounded' — Default. If the density can extend over the whole real line. • 'positive' — To restrict it to positive values. • A two-element vector giving finite lower and upper limits for the support of the density.
'width'	<p>A value specifying the bandwidth of the kernel smoothing window. The default is optimal for estimating normal densities, but you may want to choose a smaller value to reveal features such as multiple modes.</p>

Output Arguments

PD

An object in the `ProbDistUnivKernel` class, which is derived from the `ProbDist` class. It represents a nonparametric probability distribution.

References

- [1] Bowman, A. W., and A. Azzalini. *Applied Smoothing Techniques for Data Analysis*. New York: Oxford University Press, 1997.

`fitdist` | `ksdensity`

ProbDistUnivParam class

Superclasses: ProbDistParametric

Object representing univariate parametric probability distribution

Description

A ProbDistUnivParam object represents a univariate parametric probability distribution. You create this object by using the constructor (`ProbDistUnivParam`) and supplying parameter values, or by using the `fitdist` function to fit the distribution to data.

Construction

<code>.ProbDistUnivParam</code>	Construct ProbDistUnivParam object
---------------------------------	------------------------------------

Methods

<code>cdf</code>	Return cumulative distribution function (CDF) for ProbDist object
<code>icdf</code>	Return inverse cumulative distribution function (ICDF) for ProbDistUnivParam object
<code>iqr</code>	Return interquartile range (IQR) for ProbDistUnivParam object
<code>mean</code>	Return mean of ProbDistUnivParam object
<code>median</code>	Return median of ProbDistUnivParam object

paramci	Return parameter confidence intervals of ProbDistUnivParam object
pdf	Return probability density function (PDF) for ProbDist object
random	Generate random number drawn from ProbDist object
std	Return standard deviation of ProbDistUnivParam object
var	Return variance of ProbDistUnivParam object

Note: Some of the above methods are inherited from the `ProbDistParametric` class.

Properties

DistName	Read-only string containing probability distribution name of ProbDist object
InputData	Read-only structure containing information about input data to ProbDist object
NLogL	Read-only value specifying negative log likelihood for input data to ProbDistParametric object
NumParams	Read-only value specifying number of parameters of ProbDistParametric object

ParamCov	Read-only covariance matrix of parameter estimates of ProbDistParametric object
ParamDescription	Read-only cell array specifying descriptions of parameters of ProbDistParametric object
ParamIsFixed	Read-only logical array specifying fixed parameters of ProbDistParametric object
ParamNames	Read-only cell array specifying names of parameters of ProbDistParametric object
Params	Read-only array specifying values of parameters of ProbDistParametric object
Support	Read-only structure containing information about support of ProbDist object

Note: The above properties are inherited from the `ProbDistParametric` class.

Note: Parameter values are also properties. For example, if you create `PD`, a univariate parametric probability distribution object that represents a normal distribution, then `PD.mu` and `PD.sigma` are properties that give the values of the μ and σ parameters.

Copy Semantics

Value. To learn how this affects your use of the class, see “Copying Objects” in the MATLAB Programming Fundamentals documentation.

ProbDistUnivParam

Class: ProbDistUnivParam

Construct ProbDistUnivParam object

Syntax

```
PD = ProbDistUnivParam(DistName, Params)
```

Description

PD = ProbDistUnivParam(*DistName*, *Params*) creates *PD*, a ProbDistUnivParam object, which represents a probability distribution. This distribution is defined by the parametric distribution specified by *DistName*, with parameters specified by the numeric vector *Params*.

Input Arguments

<i>DistName</i>	A string specifying a distribution. Choices are: <ul style="list-style-type: none">• 'beta'• 'binomial'• 'birnbaumsaunders'• 'exponential'• 'extreme value' or 'ev'• 'gamma'• 'generalized extreme value' or 'gev'• 'generalized pareto' or 'gp'• 'inversegaussian'• 'logistic'• 'loglogistic'
-----------------	--

- 'lognormal'
- 'nakagami'
- 'negative binomial' or 'nbin'
- 'normal'
- 'poisson'
- 'rayleigh'
- 'rician'
- 'tlocationscale'
- 'weibull' or 'wbl'

For more information on these parametric distributions, see Appendix B.

Params

Numeric vector of distribution parameters. The number and type of parameters depends on the distribution you specify with *DistName*. For information on parameters for each distribution type, see Appendix B.

Output Arguments

PD

An object in the `ProbDistUnivParam` class, which is derived from the `ProbDist` class. It represents a parametric probability distribution.

Examples

- 1 Create an object representing a normal distribution with a mean of 100 and a standard deviation of 10.

```
pd = ProbDistUnivParam('normal',[100 10])
```

```
pd =
```

```
normal distribution
```

```
mu = 100
```

- ```
sigma = 10
```
- 2 Generate a 4-by-5 matrix of random values from this distribution.

```
random(pd,4,5)
```

```
ans =
```

```

## How To

- Appendix B

# probplot

Probability plots

## Syntax

```
probplot(Y)
probplot(distribution,Y)
probplot(Y,cens,freq)
probplot(ax,Y)
probplot(...,'noref')
probplot(ax,PD)
probplot(ax,fun,params)
h = probplot(...)
```

## Description

`probplot(Y)` produces a normal probability plot comparing the distribution of the data `Y` to the normal distribution. `Y` can be a single vector, or a matrix with a separate sample in each column. The plot includes a reference line useful for judging whether the data follow a normal distribution.

`probplot` uses midpoint probability plotting positions. The  $i^{\text{th}}$  sorted value from a sample of size  $N$  is plotted against the midpoint in the jump of the empirical CDF on the  $y$  axis. With uncensored data, that midpoint is  $(i-0.5)/N$ . With censored data (see below), the  $y$  value is more complicated to compute.

`probplot(distribution,Y)` creates a probability plot for the distribution specified by *distribution*. Acceptable strings for *distribution* are:

- 'exponential' — Exponential probability plot (nonnegative values)
- 'extreme value' — Extreme value probability plot (all values)
- 'lognormal' — Lognormal probability plot (positive values)
- 'normal' — Normal probability plot (all values)
- 'rayleigh' — Rayleigh probability plot (positive values)
- 'weibull' — Weibull probability plot (positive values)

The  $y$  axis scale is based on the selected distribution. The  $x$  axis has a log scale for the Weibull and lognormal distributions, and a linear scale for the others.

Not all distributions are appropriate for all data sets, and `probplot` will error when asked to create a plot with a data set that is inappropriate for a specified distribution. Appropriate data ranges for each distribution are given parenthetically in the list above.

`probplot(Y,cens,freq)` or `probplot(distname,Y,cens,freq)` requires a vector  $Y$ . `cens` is a vector of the same size as  $Y$  and contains 1 for observations that are right-censored and 0 for observations that are observed exactly. `freq` is a vector of the same size as  $Y$ , containing integer frequencies for the corresponding elements in  $Y$ .

`probplot(ax,Y)` takes a handle `ax` to an existing probability plot, and adds additional lines for the samples in  $Y$ . `ax` is a handle for a set of axes.

`probplot(..., 'noref')` omits the reference line.

`probplot(ax,PD)` takes a probability distribution object, `PD`, and adds a fitted line to the axes specified by `ax` to represent the probability distribution specified by `PD`. `PD` is a `ProbDist` object of the `ProbDistUnivParam` class or `ProbDistUnivKernel` class.

`probplot(ax,fun,params)` takes a function `fun` and a set of parameters, `params`, and adds fitted lines to the axes of an existing probability plot specified by `ax`. `fun` is a function handle to a cdf function, specified with `@` (for example, `@wblcdf`). `params` is the set of parameters required to evaluate `fun`, and is specified as a cell array or vector. The function must accept a vector of  $X$  values as its first argument, then the optional parameters, and must return a vector of cdf values evaluated at  $X$ .

`h = probplot(...)` returns handles to the plotted lines.

## Examples

### Test Data for Weibull Distribution Using `probplot`

Generate sample data. The sample `x1` contains 100 random numbers from a Weibull distribution with scale parameter  $A = 3$  and shape parameter  $B = 3$ . The sample `x2` contains 100 random numbers from a Rayleigh distribution with scale parameter  $B = 3$ .

```
rng('default'); % For reproducibility
x1 = wblrnd(3,3,100,1);
x2 = raylrnd(3,100,1);
```

Create a probability plot to assess whether the data in `x1` and `x2` comes from a Weibull distribution.

```
figure;
probplot('weibull',[x1 x2])
legend('Weibull Sample','Rayleigh Sample','Location','NW')
```

The probability plot shows that the data in `x1` comes from a Weibull distribution, while the data in `x2` does not.

### Test Data for Normal Distribution Using `probplot`

Generate sample data containing about 20% outliers in the tails. The left tail of the sample data contains 10 values randomly generated from an exponential distribution

with parameter  $\mu = 1$ . The right tail contains 10 values randomly generated from an exponential distribution with parameter  $\mu = 5$ . The center of the sample data contains 80 values randomly generated from a standard normal distribution.

```
rng default % For reproducibility
left_tail = -exprnd(1,10,1);
right_tail = exprnd(5,10,1);
center = randn(80,1);
data = [left_tail;center;right_tail];
```

Create a probability plot to assess whether the data in `data` comes from a normal distribution. Plot a  $t$  location-scale curve on the same figure to compare with `data`.

```
figure;
probplot(data);
p = mle(data, 'dist', 'tlo');
t = @(data,mu,sig,df)cdf('tlocationscale',data,mu,sig,df);
h = probplot(gca,t,p);
h.Color = 'r';
h.LineStyle = '-';
title('\bf Probability Plot')
legend('Data', 'Normal', 't', 'Location', 'NW')
```

The plot shows that neither the normal line nor the  $t$  location-scale curve fit the tails very well because of the outliers.

# procrustes

Procrustes analysis

## Syntax

```
d = procrustes(X,Y)
[d,Z] = procrustes(X,Y)
[d,Z,transform] = procrustes(X,Y)
[...] = procrustes(...,'scaling',flag)
[...] = procrustes(...,'reflection',flag)
```

## Description

`d = procrustes(X,Y)` determines a linear transformation (translation, reflection, orthogonal rotation, and scaling) of the points in matrix `Y` to best conform them to the points in matrix `X`. The goodness-of-fit criterion is the sum of squared errors. `procrustes` returns the minimized value of this dissimilarity measure in `d`. `d` is standardized by a measure of the scale of `X`, given by:

$$\text{sum}(\text{sum}((X - \text{repmat}(\text{mean}(X,1), \text{size}(X,1), 1)) .^2, 1))$$

That is, the sum of squared elements of a centered version of `X`. However, if `X` comprises repetitions of the same point, the sum of squared errors is not standardized.

`X` and `Y` must have the same number of points (rows), and `procrustes` matches `Y(i)` to `X(i)`. Points in `Y` can have smaller dimension (number of columns) than those in `X`. In this case, `procrustes` adds columns of zeros to `Y` as necessary.

`[d,Z] = procrustes(X,Y)` also returns the transformed `Y` values.

`[d,Z,transform] = procrustes(X,Y)` also returns the transformation that maps `Y` to `Z`. `transform` is a structure array with fields:

- `c` — Translation component
- `T` — Orthogonal rotation and reflection component

- **b** — Scale component

That is:

```
c = transform.c;
T = transform.T;
b = transform.b;
```

```
Z = b*Y*T + c;
```

`[...] = procrustes(..., 'scaling', flag)`, when *flag* is `false`, allows you to compute the transformation without a scale component (that is, with **b** equal to 1). The default *flag* is `true`.

`[...] = procrustes(..., 'reflection', flag)`, when *flag* is `false`, allows you to compute the transformation without a reflection component (that is, with `det(T)` equal to 1). The default *flag* is `'best'`, which computes the best-fitting transformation, whether or not it includes a reflection component. A *flag* of `true` forces the transformation to be computed with a reflection component (that is, with `det(T)` equal to -1)

## Examples

### Procrustes Analysis

Generate the sample data in two dimensions.

```
rng('default')
n = 10;
X = normrnd(0,1,[n 2]);
```

Rotate, scale, translate, and add some noise to sample points.

```
S = [0.5 -sqrt(3)/2; sqrt(3)/2 0.5];
Y = normrnd(0.5*X*S+2,0.05,n,2);
```

Conform **Y** to **X** using procrustes analysis.

```
[d,Z,tr] = procrustes(X,Y);
```

Plot the original **X** and **Y** with the transformed **Y**.

```
plot(X(:,1),X(:,2), 'rx',Y(:,1),Y(:,2), 'b.',Z(:,1),Z(:,2), 'bx');
```

# proflik

**Class:** prob.ToolboxFittableParametricDistribution

**Package:** prob

Profile likelihood function for probability distribution object

## Syntax

```
[ll,param] = proflik(pd,pnum)
[ll,param] = proflik(pd,pnum, 'Display',display)
[ll,param] = proflik(pd,pnum,setparam)
[ll,param] = proflik(pd,pnum,setparam, 'Display',display)
[ll,param,other] = proflik(___)
```

## Description

[ll,param] = proflik(pd,pnum) returns a vector ll of loglikelihood values and a vector param of corresponding parameter values for the parameter in the position indicated by pnum.

[ll,param] = proflik(pd,pnum, 'Display',display) returns the loglikelihood values and corresponding parameter values, and plots the profile likelihood overlaid on an approximation of the loglikelihood.

[ll,param] = proflik(pd,pnum,setparam) returns the loglikelihood values and corresponding parameter values as specified by setparam.

[ll,param] = proflik(pd,pnum,setparam, 'Display',display) returns the loglikelihood values and corresponding parameter values as specified by setparam, and plots the profile likelihood overlaid on an approximation of the loglikelihood.

[ll,param,other] = proflik( \_\_\_ ) also returns a matrix other containing the values of the other parameters that maximize the likelihood, using any of the input arguments from the previous syntaxes.

## Input Arguments

### **pd** — Probability distribution

probability distribution object

Probability distribution, specified as a probability distribution object. Create a probability distribution object with specified parameter values using `makedist`. Alternatively, create a probability distribution object by fitting it to data using `fitdist` or the Distribution Fitting app.

### **pnum** — Parameter number

positive integer value

Parameter number for which to compute the profile likelihood, specified as a positive integer value corresponding to the position of the desired parameter in the parameter name vector. For example, a Weibull distribution has a parameter name vector `{ 'A', 'B' }`, so specify `pnum` as 2 to compute the profile likelihood for B.

Data Types: `single` | `double`

### **setparam** — Parameter value restriction

scalar value | vector of scalar values

Parameter value restriction, specified as a scalar value or a vector of such values. If you do not specify `setparam`, `proflik` chooses the values for output vector `param` based on the default confidence interval method for the probability distribution `pd`. If the parameter can take only restricted values, and if the confidence interval violates that restriction, you can use `setparam` to specify valid values.

Example: `[3,3.5,4]`

### **display** — Display toggle

'off' (default) | 'on'

Display toggle, specified as either 'on' or 'off'. Specify 'on' to display a plot of the profile loglikelihood overlaid on an approximation of the loglikelihood. Specify 'off' to omit the display. The approximation is based on a Taylor series expansion around the estimated parameter value, as a function of the parameter in position `pnum` or its logarithm. The intersection of the curves with the horizontal dotted line marks the endpoints of 95% confidence intervals.

## Output Arguments

### ll — Loglikelihood values

vector

Loglikelihood values, returned as a vector. The loglikelihood is the value of the likelihood with the parameter in position `pnum` set to the values in `param`, maximized over the remaining parameters.

### param — Parameter values

vector

Parameter values corresponding to the loglikelihood values in `ll`, returned as a vector. If you specify parameter values using `setparam`, then `param` is equal to `setparam`.

### other — Other parameter values

matrix

Other parameter values that maximize the likelihood, returned as a matrix. Each row of `other` contains the values for all parameters except the parameter in position `pnum`.

## Examples

### Profile Likelihood of a Distribution Parameter

Load the sample data. Create a probability distribution object by fitting a Weibull distribution to the miles per gallon (MPG) data.

```
load carsmall;
pd = fitdist(MPG,'Weibull')

pd =

 WeibullDistribution

 Weibull distribution
 A = 26.5079 [24.8333, 28.2954]
 B = 3.27193 [2.79441, 3.83104]
```

View the parameter names for the distribution.

```
pd.ParameterNames

ans =
```

```
'A' 'B'
```

For the Weibull distribution, **A** is in position 1, and **B** is in position 2.

Compute the profile likelihood for **B**, which is in position `pnum = 2`.

```
[ll,param] = proflik(pd,2);
```

Display the loglikelihood values for the estimated values of **B**.

```
[ll',param']
```

```
ans =
```

```
-329.9688 2.7132
-329.4312 2.7748
-328.9645 2.8365
-328.5661 2.8981
-328.2340 2.9597
-327.9658 3.0213
-327.7596 3.0830
-327.6135 3.1446
-327.5256 3.2062
-327.4943 3.2678
-327.5178 3.3295
-327.5946 3.3911
-327.7233 3.4527
-327.9023 3.5143
-328.1303 3.5760
-328.4060 3.6376
-328.7281 3.6992
-329.0956 3.7608
-329.5071 3.8224
-329.9617 3.8841
-330.4583 3.9457
```

These results show that the profile loglikelihood is maximized between the estimated **B** values of 3.2678 and 3.3295, which correspond to loglikelihood values -327.4943 and -327.5178. From the earlier fit, the MLE of **B** is 3.27193, which is in this interval as expected.

### Profile Likelihood With Restricted Parameter Values

Load the sample data. Create a probability distribution object by fitting a generalized extreme value distribution to the miles per gallon (MPG) data.

```
load carsmall;
pd = fitdist(MPG, 'GeneralizedExtremeValue')

pd =

GeneralizedExtremeValueDistribution

Generalized Extreme Value distribution
 k = -0.207765 [-0.381674, -0.0338564]
 sigma = 7.49674 [6.31755, 8.89603]
 mu = 20.6233 [18.8859, 22.3606]
```

View the parameter names for the distribution.

```
pd.ParameterNames

ans =

 'k' 'sigma' 'mu'
```

For the generalized extreme value distribution, **k** is in position 1, **sigma** is in position 2, and **mu** is in position 3.

Compute the profile likelihood for **mu**, which is in position **pnum = 3**. Restrict the computation to parameter values from 20 to 22, and display the plot.

```
[ll,param,other] = proflik(pd,3,20:.1:22, 'display', 'on');
```

The plot shows the estimated value for the parameter  $\mu$  that maximizes the loglikelihood.

Display the loglikelihood values for the estimated values of  $\mu$ , and the values of the other distribution parameters that maximize the corresponding loglikelihood.

```
[ll',param',other]
```

```
ans =
```

|           |         |         |        |
|-----------|---------|---------|--------|
| -327.5706 | 20.0000 | -0.1803 | 7.4087 |
| -327.4971 | 20.1000 | -0.1846 | 7.4218 |

| -327.4119 | 21.0000 | -0.2245 | 7.5560 |
| -327.4659 | 21.1000 | -0.2289 | 7.5723 |
| -327.5324 | 21.2000 | -0.2333 | 7.5889 |
| -327.6113 | 21.3000 | -0.2378 | 7.6057 |
| -327.7027 | 21.4000 | -0.2422 | 7.6228 |
| -327.8065 | 21.5000 | -0.2465 | 7.6400 |
| -327.9227 | 21.6000 | -0.2509 | 7.6575 |
| -328.0511 | 21.7000 | -0.2553 | 7.6751 |
| -328.1917 | 21.8000 | -0.2596 | 7.6930 |
| -328.3446 | 21.9000 | -0.2639 | 7.7111 |
| -328.5095 | 22.0000 | -0.2682 | 7.7293 |

The first column contains the loglikelihood value that corresponds to the estimate of  $\mu$  in the second column. The loglikelihood is maximized between the parameter values 20.6000 and 20.7000, corresponding to loglikelihood values -327.3223 and -327.3257. The third column contains the value of  $k$  that maximizes the corresponding loglikelihood for  $\mu$ . The fourth column contains the value of  $\sigma$  that maximizes the corresponding loglikelihood for  $\mu$ .

## proximity

**Class:** CompactTreeBagger

Proximity matrix for data

### Syntax

```
prox = proximity(B,X)
```

### Description

`prox = proximity(B,X)` computes a numeric matrix of size **Nobs**-by-**Nobs** of proximities for data **X**, where **Nobs** is the number of observations (rows) in **X**. Proximity between any two observations in the input data is defined as a fraction of trees in the ensemble **B** for which these two observations land on the same leaf. This is a symmetric matrix with ones on the diagonal and off-diagonal elements ranging from 0 to 1.

# Proximity property

**Class:** TreeBagger

Proximity matrix for observations

## Description

The `Proximity` property is a numeric matrix of size `Nobs`-by-`Nobs`, where `Nobs` is the number of observations in the training data, containing measures of the proximity between observations. For any two observations, their proximity is defined as the fraction of trees for which these observations land on the same leaf. This is a symmetric matrix with 1s on the diagonal and off-diagonal elements ranging from 0 to 1.

## See Also

`ClassificationTree` | `proximity` | `fitctree` | `fitrtree` | `RegressionTree` | `TreeBagger`

## prune

**Class:** ClassificationTree

Produce sequence of subtrees by pruning

## Syntax

```
tree1 = prune(tree)
tree1 = prune(tree,Name,Value)
```

## Description

`tree1 = prune(tree)` creates a copy of the classification tree `tree` with its optimal pruning sequence filled in.

`tree1 = prune(tree,Name,Value)` creates a pruned tree with additional options specified by one `Name,Value` pair argument. You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

## Tips

- `tree1 = prune(tree)` returns the decision tree `tree1` that is the full, unpruned `tree`, but with optimal pruning information added. This is useful only if you created `tree` by pruning another tree, or by using the `fitctree` function with pruning set 'off'. If you plan to prune a tree multiple times along the optimal pruning sequence, it is more efficient to create the optimal pruning sequence first.

## Input Arguments

**tree**

A classification tree created with `fitctree`.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

### 'Alpha'

A numeric scalar. `prune` prunes `tree` to the specified value of the pruning cost.

### 'Level'

A numeric scalar from 0 (no pruning) to the largest pruning level of this tree `max(tree.PruneList)`. `prune` returns the tree pruned to this level.

### 'Nodes'

A numeric vector with elements from 1 to `tree.NumNodes`. Any tree branch nodes listed in `nodes` become leaf nodes in `tree1`, unless their parent nodes are also pruned.

## Output Arguments

### `tree1`

A classification tree.

## Examples

### Prune and Display a Classification Tree

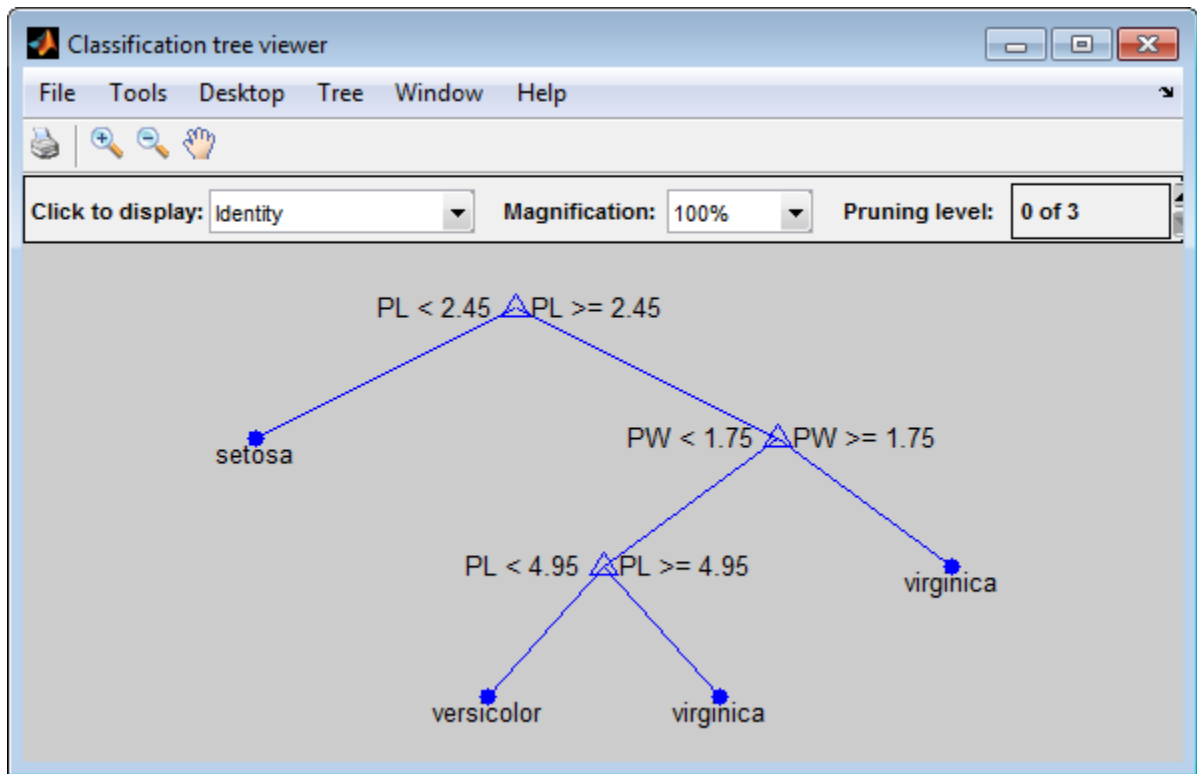

Construct and display a full classification tree for Fisher's iris data.

```
load fisheriris;
varnames = {'SL' 'SW' 'PL' 'PW'};
t1 = fitctree(meas, species, ...
 'minparent', 5, 'predictorNames', varnames);
view(t1, 'mode', 'graph');
```

Construct and display the next largest tree from the optimal pruning sequence.

```
t2 = prune(t1,'level',1);
view(t2,'mode','graph');
```

**See Also**  
fitctree

## prune

**Class:** `classregtree`

Prune tree

## Syntax

```
t2 = prune(t1, 'level', level)
t2 = prune(t1, 'nodes', nodes)
t2 = prune(t1)
```

## Description

`t2 = prune(t1, 'level', level)` takes a decision tree `t1` and a pruning level `level`, and returns the decision tree `t2` pruned to that level. If `level` is 0, there is no pruning. Trees are pruned based on an optimal pruning scheme that first prunes branches giving less improvement in error cost.

`t2 = prune(t1, 'nodes', nodes)` prunes the nodes listed in the `nodes` vector from the tree. Any `t1` branch nodes listed in `nodes` become leaf nodes in `t2`, unless their parent nodes are also pruned. Use `view` to display the node numbers for any node you select.

`t2 = prune(t1)` returns the decision tree `t2` that is the full, unpruned `t1`, but with optimal pruning information added. This is useful only if `t1` is created by pruning another tree, or by using the `classregtree` function with the `'prune'` parameter set to `'off'`. If you plan to prune a tree multiple times along the optimal pruning sequence, it is more efficient to create the optimal pruning sequence first.

Pruning is the process of reducing a tree by turning some branch nodes into leaf nodes and removing the leaf nodes under the original branch.

## Examples

### Prune a Decision Tree

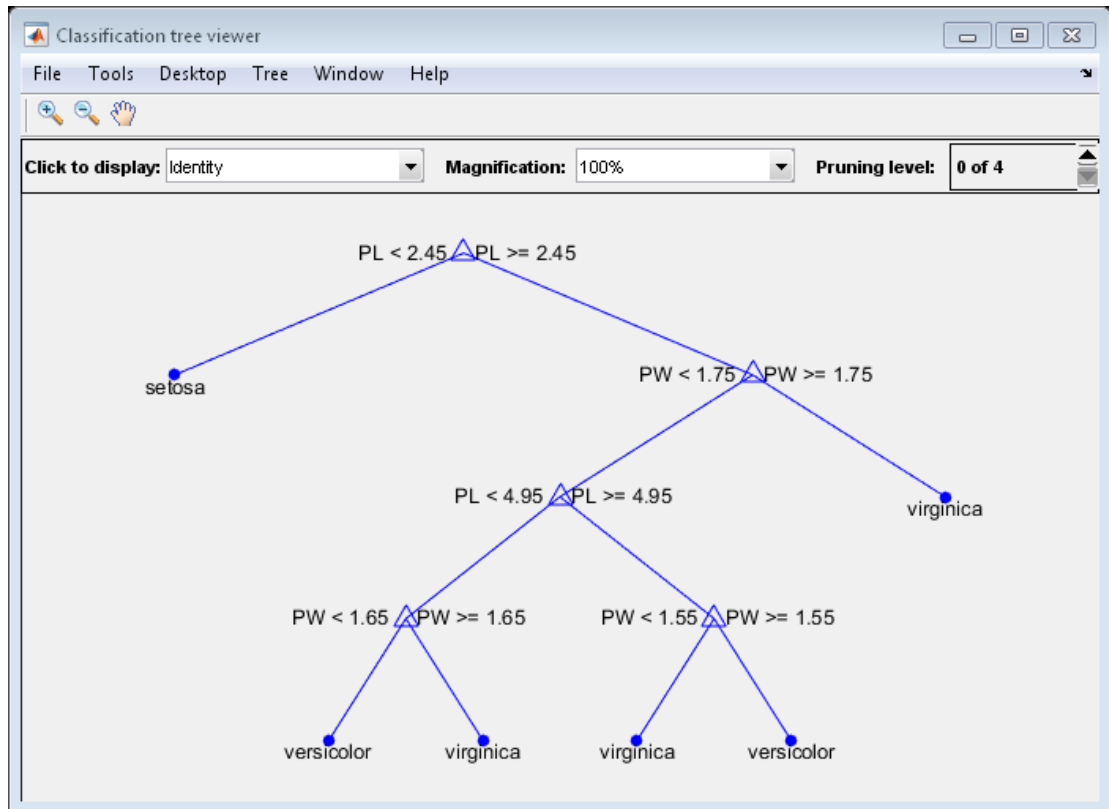

Display the full tree for Fisher's iris data:

```
load fisheriris;
t1 = classregtree(meas,species,...
 'names',{'SL' 'SW' 'PL' 'PW'},...
 'minparent',5)
view(t1)

t1 =

Decision tree for classification
1 if PL<2.45 then node 2 elseif PL>=2.45 then node 3 else setosa
2 class = setosa
3 if PW<1.75 then node 4 elseif PW>=1.75 then node 5 else versicolor
4 if PL<4.95 then node 6 elseif PL>=4.95 then node 7 else versicolor
5 class = virginica
6 if PW<1.65 then node 8 elseif PW>=1.65 then node 9 else versicolor
7 if PW<1.55 then node 10 elseif PW>=1.55 then node 11 else virginica
8 class = versicolor
9 class = virginica
10 class = virginica
11 class = versicolor
```

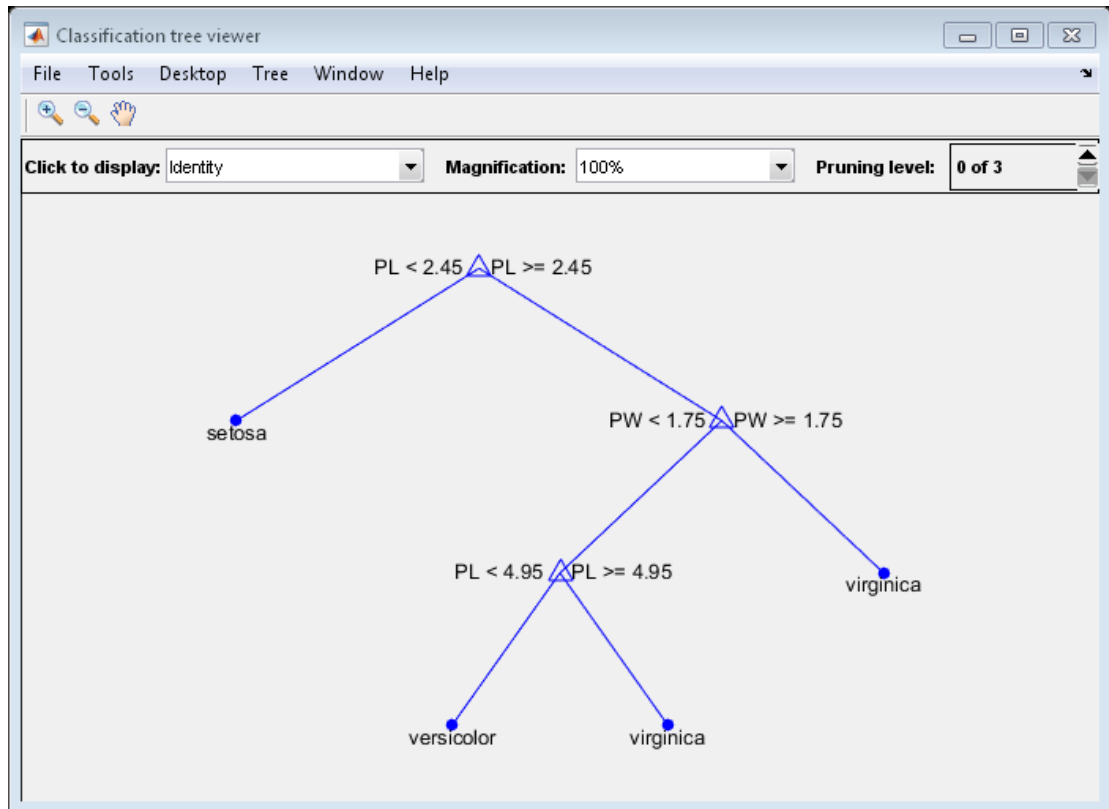

Display the next largest tree from the optimal pruning sequence:

```
t2 = prune(t1, 'level', 1)
view(t2)
```

```
t2 =
```

```
Decision tree for classification
1 if PL<2.45 then node 2 elseif PL>=2.45 then node 3 else setosa
2 class = setosa
3 if PW<1.75 then node 4 elseif PW>=1.75 then node 5 else versicolor
4 if PL<4.95 then node 6 elseif PL>=4.95 then node 7 else versicolor
5 class = virginica
6 class = versicolor
```

```
7 class = virginica
```

## prune

**Class:** RegressionTree

Produce sequence of subtrees by pruning

## Syntax

```
tree1 = prune(tree)
tree1 = prune(tree,Name,Value)
```

## Description

`tree1 = prune(tree)` creates a copy of the regression tree `tree` with its optimal pruning sequence filled in.

`tree1 = prune(tree,Name,Value)` creates a pruned tree with additional options specified by one `Name,Value` pair argument. You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

## Tips

- `tree1 = prune(tree)` returns the decision tree `tree1` that is the full, unpruned `tree`, but with optimal pruning information added. This is useful only if you created `tree` by pruning another tree, or by using `fitrtree` with pruning set 'off'. If you plan to prune a tree multiple times along the optimal pruning sequence, it is more efficient to create the optimal pruning sequence first.

## Input Arguments

**tree**

A regression tree created with `fitrtree`.

## Name-Value Pair Arguments

Optional comma-separated pair of Name,Value arguments, where **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes ( ' '). You can specify only one name-value pair argument.

### 'Alpha'

A numeric scalar from 0 (no pruning) to 1 (prune to one node). Prunes to minimize the sum of (Alpha times the number of leaf nodes) and a cost (mean squared error).

### 'Level'

A numeric scalar from 0 (no pruning) to the largest pruning level of this tree `max(tree.PruneList)`. `prune` returns the tree pruned to this level.

### 'Nodes'

A numeric vector with elements from 1 to `tree.NumNodes`. Any tree branch nodes listed in **Nodes** become leaf nodes in `tree1`, unless their parent nodes are also pruned.

## Output Arguments

### **tree1**

A regression tree.

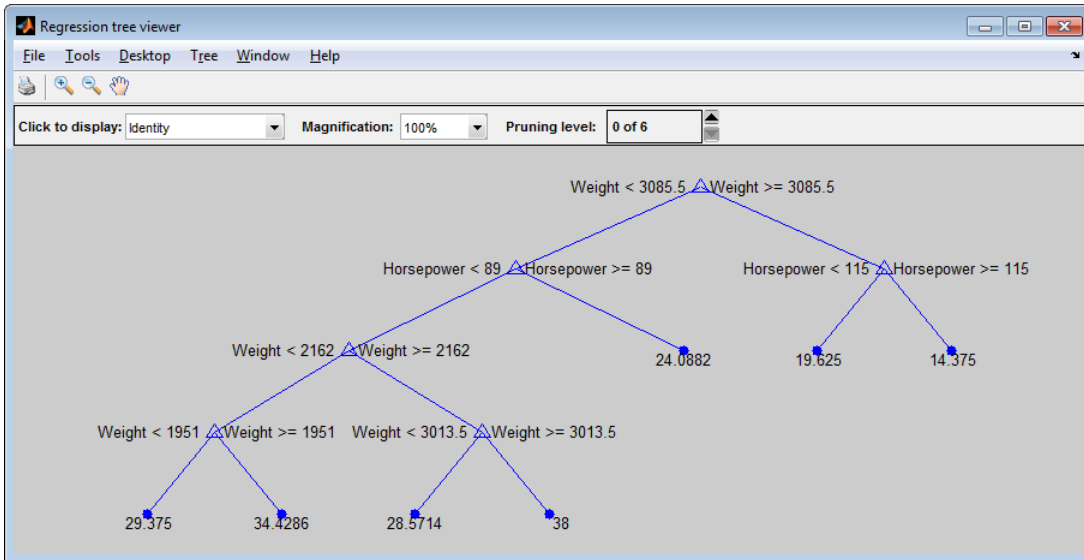

## Examples

Display a full tree for the `carsmall` data, as well as the tree pruned to level 10:

```
load carsmall;
varnames = {'Weight' 'Horsepower'};
t1 = fitrtree([Weight Horsepower],MPG,...
 'predictorNames',varnames)
view(t1,'Mode','graph');
```

```
t2 = prune(t1, 'Level', 10);
view(t2, 'Mode', 'graph');
```

**See Also**  
fitrtree

# Prune property

**Class:** TreeBagger

Flag to prune trees

## Description

The Prune property is true if decision trees are pruned and false if they are not. Pruning decision trees is not recommended for ensembles. The default value is false.

## See Also

ClassificationTree | RegressionTree | TreeBagger | fitctree | fitrtree

## prunelist

**Class:** classregtree

Pruning levels for decision tree nodes

### Syntax

`P = prunelist(T)`  
`P = prunelist(T,J)`

### Description

`P = prunelist(T)` returns an  $n$ -element numeric vector with the pruning levels in each node of the tree `T`, where  $n$  is the number of nodes. When you call `prune(T, 'level', level)`, nodes with the pruning levels below `level` are pruned, and nodes with the pruning levels greater or equal to `level` are not pruned.

`P = prunelist(T,J)` takes an array `J` of node numbers and returns the pruning levels for the specified nodes.

### See Also

`classregtree` | `numnodes`

# grand

**Class:** grandstream

Generate quasi-random points from stream

## Syntax

```
x = grand(q)
X = grand(q,n)
```

## Description

`x = grand(q)` returns the next value  $x$  in the quasi-random number stream  $q$  of the `grandstream` class.  $x$  is a 1-by- $d$  vector, where  $d$  is the dimension of the stream. The command sets `q.State` to the index in the underlying point set of the next value to be returned.

`X = grand(q,n)` returns the next  $n$  values  $X$  in an  $n$ -by- $d$  matrix.

Objects  $q$  of the `grandstream` class encapsulate properties of a specified quasi-random number stream. Values of the stream are not generated and stored in memory until  $q$  is accessed using `grand`.

## Examples

Use `grandstream` to construct a 3-D Halton stream, based on a point set that skips the first 1000 values and then retains every 101st point:

```
q = grandstream('halton',3,'Skip',1e3,'Leap',1e2)
q =
 Halton quasi-random stream in 3 dimensions
 Point set properties:
 Skip : 1000
 Leap : 100
 ScrambleMethod : none
```

```
nextIdx = q.State
nextIdx =
 1
```

Use `grand` to generate two samples of size four:

```
X1 = grand(q,4)
X1 =
 0.0928 0.3475 0.0051
 0.6958 0.2035 0.2371
 0.3013 0.8496 0.4307
 0.9087 0.5629 0.6166
nextIdx = q.State
nextIdx =
 5
```

```
X2 = grand(q,4)
X2 =
 0.2446 0.0238 0.8102
 0.5298 0.7540 0.0438
 0.3843 0.5112 0.2758
 0.8335 0.2245 0.4694
nextIdx = q.State
nextIdx =
 9
```

Use `reset` to reset the stream, then generate another sample:

```
reset(q)
nextIdx = q.State
nextIdx =
 1

X = grand(q,4)
X =
 0.0928 0.3475 0.0051
 0.6958 0.2035 0.2371
 0.3013 0.8496 0.4307
 0.9087 0.5629 0.6166
```

## See Also

`grandstream` | `reset`

# grandset class

Quasi-random point sets

## Description

`grandset` is a base class that encapsulates a sequence of multi-dimensional quasi-random numbers. This base class is abstract and cannot be instantiated directly. Concrete subclasses include `sobolset` and `haltonset`.

## Construction

`.grandset`

Abstract quasi-random point set class

## Methods

`disp`

Display grandset object

`end`

Last index in indexing expression for point set

`length`

Length of point set

`ndims`

Number of dimensions in matrix

`net`

Generate quasi-random point set

`scramble`

Scramble quasi-random point set

`size`

Number of dimensions in matrix

suboref

Subscripted reference for grandset

## Properties

Dimensions

Number of dimensions

Leap

Interval between points

ScrambleMethod

Settings that control scrambling

Skip

Number of initial points to omit from sequence

Type

Name of sequence on which point set **P** is based

## Copy Semantics

# grandset

**Class:** grandset

Abstract quasi-random point set class

## Description

grandset is an abstract class, and you cannot create instances of it directly. You must use `haltonset` or `sobolset` to create a `grandset` object.

## See Also

`haltonset` | `sobolset`

## grandstream class

Quasi-random number streams

### Construction

.grandstream

Construct quasi-random number stream

### Methods

addlistener

Add listener for event

delete

Delete handle object

disp

Display `grandstream` object

eq

Test handle equality

findobj

Find objects matching specified conditions

findprop

Find property of MATLAB handle object

ge

Greater than or equal relation for handles

gt

Greater than relation for handles

isvalid

Test handle validity

le

Less than or equal relation for handles

lt

Less than relation for handles

|        |                                          |
|--------|------------------------------------------|
| ne     | Not equal relation for handles           |
| notify | Notify listeners of event                |
| qrand  | Generate quasi-random points from stream |
| rand   | Generate quasi-random points from stream |
| reset  | Reset state                              |

## Properties

|          |                                      |
|----------|--------------------------------------|
| PointSet | Point set from which stream is drawn |
| State    | Current state of the stream          |

## Copy Semantics

Handle. To learn how this affects your use of the class, see “Comparing Handle and Value Classes” in the MATLAB Object-Oriented Programming documentation.

## grandstream

**Class:** grandstream

Construct quasi-random number stream

### Syntax

```
q = grandstream(type,d)
q = grandstream(type,d,prop1,val1,prop2,val2,...)
q = grandstream(p)
```

### Description

`q = grandstream(type,d)` constructs a *d*-dimensional quasi-random number stream *q* of the `grandstream` class, of type specified by the string *type*. *type* is either 'halton' or 'sobol', and *q* is based on a point set from either the `haltonset` class or `sobolset` class, respectively, with default property settings.

`q = grandstream(type,d,prop1,val1,prop2,val2,...)` specifies property name/value pairs for the point set on which the stream is based. Applicable properties depend on *type*.

`q = grandstream(p)` constructs a stream based on the specified point set *p*. *p* must be a point set from either the `haltonset` class or `sobolset` class.

### Examples

Construct a 3-D Halton stream, based on a point set that skips the first 1000 values and then retains every 101st point:

```
q = grandstream('halton',3,'Skip',1e3,'Leap',1e2)
q =
 Halton quasi-random stream in 3 dimensions
 Point set properties:
 Skip : 1000
 Leap : 100
```

```
ScrambleMethod : none
```

```
nextIdx = q.State
nextIdx =
 1
```

Use `qrand` to generate two samples of size four:

```
X1 = qrand(q,4)
X1 =
 0.0928 0.3475 0.0051
 0.6958 0.2035 0.2371
 0.3013 0.8496 0.4307
 0.9087 0.5629 0.6166
nextIdx = q.State
nextIdx =
 5
```

```
X2 = qrand(q,4)
X2 =
 0.2446 0.0238 0.8102
 0.5298 0.7540 0.0438
 0.3843 0.5112 0.2758
 0.8335 0.2245 0.4694
nextIdx = q.State
nextIdx =
 9
```

Use `reset` to reset the stream, and then generate another sample:

```
reset(q)
nextIdx = q.State
nextIdx =
 1
```

```
X = qrand(q,4)
X =
 0.0928 0.3475 0.0051
 0.6958 0.2035 0.2371
 0.3013 0.8496 0.4307
 0.9087 0.5629 0.6166
```

## See Also

`haltonset` | `reset` | `sobolset` | `qrand`

## qqplot

Quantile-quantile plot

### Syntax

```
qqplot(X)
qqplot(X,Y)
qqplot(X,PD)
qqplot(X,Y,pvec)
h = qqplot(X,Y,pvec)
```

### Description

`qqplot(X)` displays a quantile-quantile plot of the sample quantiles of  $X$  versus theoretical quantiles from a normal distribution. If the distribution of  $X$  is normal, the plot will be close to linear.

`qqplot(X,Y)` displays a quantile-quantile plot of two samples. If the samples do come from the same distribution, the plot will be linear.

`qqplot(X,PD)` makes an empirical quantile-quantile plot of the quantiles of the data in the vector  $X$  versus the quantiles of the distribution specified by  $PD$ , a `ProbDist` object of the `ProbDistUnivParam` class or `ProbDistUnivKernel` class.

For matrix  $X$  and  $Y$ , `qqplot` displays a separate line for each pair of columns. The plotted quantiles are the quantiles of the smaller data set.

The plot has the sample data displayed with the plot symbol '+' . Superimposed on the plot is a line joining the first and third quartiles of each distribution (this is a robust linear fit of the order statistics of the two samples). This line is extrapolated out to the ends of the sample to help evaluate the linearity of the data.

Use `qqplot(X,Y,pvec)` to specify the quantiles in the vector `pvec`.

`h = qqplot(X,Y,pvec)` returns handles to the lines in `h`.

## Examples

### Quantile-Quantile Plot With Two Samples

This example shows how to create a quantile-quantile plot using two sets of sample data.

Generate random numbers from two Poisson distributions. The vector `x` contains 50 random numbers from a Poisson distribution with `lambda = 10`. The vector `y` contains 100 random numbers from a Poisson distribution with `lambda = 5`.

```
rng default; % For reproducibility
x = poissrnd(10,50,1);
y = poissrnd(5,100,1);
```

Create a quantile-quantile plot using the two sets of sample data.

```
qqplot(x,y);
```

The solid line in the plot joins the first and third quartiles. The dashed line extrapolates the solid line.

## More About

- `normplot`

# quantile

Quantiles of a data set

## Syntax

```
Y = quantile(X,p)
Y = quantile(X,p,dim)
```

```
Y = quantile(X,N)
Y = quantile(X,N,dim)
```

## Description

`Y = quantile(X,p)` returns quantiles of the values in data vector or matrix `X` for the cumulative probability or probabilities `p` in the interval `[0,1]`.

- If `X` is a vector, then `Y` is a scalar or a vector having the same length as `p`.
- If `X` is a matrix, then `Y` is a row vector or a matrix where the number of rows of `Y` is equal to the length of `p`.
- For multidimensional arrays, `quantile` operates along the first nonsingleton dimension of `X`.

`Y = quantile(X,p,dim)` returns quantiles along dimension `dim`.

`Y = quantile(X,N)` returns quantiles for `N` evenly spaced cumulative probabilities ( $1/(N+1)$ ,  $2/(N+1)$ , ...,  $N/(N+1)$ ) for integer  $N > 1$ .

- If `X` is a vector, then `Y` is a scalar or a vector with length `N`.
- If `X` is a matrix, then `Y` is a matrix where the number of rows of `Y` is equal to `N`.
- For multidimensional arrays, `quantile` operates along the first nonsingleton dimension of `X`.

`Y = quantile(X,N,dim)` returns quantiles at the `N` evenly-spaced cumulative probabilities ( $1/(N+1)$ ,  $2/(N+1)$ , ...,  $N/(N+1)$ ) for integer  $N > 1$  along dimension `dim`.

## Examples

### Quantiles for Given Probabilities

Calculate the quantiles of a data set for specified probabilities.

Generate a data set of size 10.

```
rng('default'); % for reproducibility
x = normrnd(0,1,1,10)
```

```
x =
 0.5377 1.8339 -2.2588 0.8622 0.3188 -1.3077 -0.4336 0.3426 3.5784
```

Calculate the 0.3 quantile.

```
y = quantile(x,0.30)
```

```
y =
 -0.0574
```

Calculate the quantiles for the cumulative probabilities 0.025, 0.25, 0.5, 0.75, and 0.975.

```
y = quantile(x,[0.025 0.25 0.50 0.75 0.975])
```

```
y =
 -2.2588 -0.4336 0.4401 1.8339 3.5784
```

### Quantiles of a Matrix for Given Probabilities

Calculate the quantiles along the columns and rows of a data matrix for specified probabilities.

Generate a 4-by-6 data matrix.

```
rng('default'); % for reproducibility
X = normrnd(0,1,4,6)
```

```
X =
 0.5377 0.3188 3.5784 0.7254 -0.1241 0.6715
 1.8339 -1.3077 2.7694 -0.0631 1.4897 -1.2075
 -2.2588 -0.4336 -1.3499 0.7147 1.4090 0.7172
 0.8622 0.3426 3.0349 -0.2050 1.4172 1.6302
```

Calculate the 0.3 quantile for each column of  $X$  ( $\text{dim} = 1$ ).

```
y = quantile(x,0.3,1)
```

```
y =
 -0.3013 -0.6958 1.5336 -0.1056 0.9491 0.1078
```

`quantile` returns a row vector  $y$  when calculating one quantile for each column of a matrix. For example,  $-0.3013$  is the 0.3 quantile of the first column of  $X$  with elements  $(0.5377, 1.8339, -2.2588, 0.8622)$ . `y = quantile(X,0.3)` returns the same answer because the default value of `dim` is 1.

Calculate the 0.3 quantile for each row of  $X$  ( $\text{dim} = 2$ ).

```
y = quantile(x,0.3,2)
```

```
y =
 0.3844
 -0.8642
 -1.0750
 0.4985
```

`quantile` returns a column vector  $y$  when calculating one quantile for each row of a matrix. For example  $0.3844$  is the 0.3 quantile of the first row of  $X$  with elements  $(0.5377, 0.3188, 3.5784, 0.7254, -0.1241, 0.6715)$ .

### Quantiles for $N$ Evenly Spaced Cumulative Probabilities

Calculate the quantiles of a data set for a given number of quantiles.

Generate a data set of size 10.

```
rng('default'); % for reproducibility
x = normrnd(0,1,1,10)
```

```
x =
 0.5377 1.8339 -2.2588 0.8622 0.3188 -1.3077 -0.4336 0.3426 3.5784
```

Calculate four evenly spaced quantiles.

```
y = quantile(x,4)
```

```
y =
 -0.8706 0.3307 0.6999 2.3017
```

Using `y = quantile(x,[0.2,0.4,0.6,0.8])` is another way to return the four evenly spaced quantiles.

### Quantiles of a Matrix for Given Number of Quantiles

Calculate the  $N$  evenly spaced quantiles along the columns and rows of a data matrix.

Generate a 6-by-10 data matrix.

```
rng('default'); % for reproducibility
X = unidrnd(10,6,7)
```

X =

|    |    |    |    |   |   |    |
|----|----|----|----|---|---|----|
| 9  | 3  | 10 | 8  | 7 | 8 | 7  |
| 10 | 6  | 5  | 10 | 8 | 1 | 4  |
| 2  | 10 | 9  | 7  | 8 | 3 | 10 |
| 10 | 10 | 2  | 1  | 4 | 1 | 1  |
| 7  | 2  | 5  | 9  | 7 | 1 | 5  |
| 1  | 10 | 10 | 10 | 2 | 9 | 4  |

Calculate three evenly spaced quantiles for each column of X (`dim = 1`).

```
y = quantile(X,3,1)
```

y =

|         |         |         |         |        |        |        |
|---------|---------|---------|---------|--------|--------|--------|
| 2.0000  | 3.0000  | 5.0000  | 7.0000  | 4.0000 | 1.0000 | 4.0000 |
| 8.0000  | 8.0000  | 7.0000  | 8.5000  | 7.0000 | 2.0000 | 4.5000 |
| 10.0000 | 10.0000 | 10.0000 | 10.0000 | 8.0000 | 8.0000 | 7.0000 |

Each column of matrix `y` corresponds to the three evenly spaced quantiles of each column of matrix `X`. For example, the first column of `y` with elements (2, 8, 10) has the quantiles for the first column of `X` with elements (9, 10, 2, 10, 7, 1). `y = quantile(X,3)` returns the same answer because the default value of `dim` is 1.

Calculate three evenly spaced quantiles for each row of X (`dim = 2`).

```
y = quantile(X,3,2)
```

y =

|        |        |        |
|--------|--------|--------|
| 7.0000 | 8.0000 | 8.7500 |
| 4.2500 | 6.0000 | 9.5000 |
| 4.0000 | 8.0000 | 9.7500 |

```

1.0000 2.0000 8.5000
2.7500 5.0000 7.0000
2.5000 9.0000 10.0000

```

Each row of matrix `y` corresponds to the three evenly spaced quantiles of each row of matrix `X`. For example, the first row of `y` with elements (7, 8, 8.75) has the quantiles for the first column of `X` with elements (9, 3, 10, 8, 7, 8, 7).

### Median and Quartiles for Even Number of Data Elements

Find median and quartiles of a vector, `x`, with even number of elements.

Enter the data.

```
x = [2 5 6 10 11 13]
```

```
x =
 2 5 6 10 11 13
```

Calculate the median of `x`.

```
y = quantile(x,0.50)
```

```
y =
 8
```

Calculate the quartiles of `x`.

```
y = quantile(x,[0.25, 0.5, 0.75])
```

```
y =
 5 8 11
```

Using `y = quantile(x,3)` is another way to compute the quartiles of `x`.

These results might be different than the textbook definitions because `quantile` uses linear interpolation to find the median and quartiles.

### Median and Quartiles for Odd Number of Data Elements

Find median and quartiles of a vector, `x`, with odd number of elements.

Enter the data.

```
x = [2 4 6 8 10 12 14]
```

```
x =
 2 4 6 8 10 12 14
```

Find the median of  $x$ .

```
y = quantile(x,0.50)
```

```
y =
 8
```

Find the quartiles of  $x$ .

```
y = quantile(x,[0.25, 0.5, 0.75])
```

```
y =
 4.5000 8.0000 11.5000
```

Using `y = quantile(x,3)` is another way to compute the quartiles of  $x$ .

These results might be different than the textbook definitions because `quantile` uses linear interpolation to find the median and quartiles.

## Input Arguments

### **X** — Input data

vector | array

Input data, specified as a vector or array.

Data Types: `double` | `single`

### **p** — Cumulative probabilities

scalar | vector

Cumulative probabilities, for which to compute the quantiles, specified as a scalar or vector of scalars from 0 to 1.

Example: 0.3

Example: [0.25, 0.5, 0.75]

Example: (0:0.25:1)

Data Types: `double` | `single`

**N — Number of quantiles**

positive integer

Number of quantiles to compute, specified as a positive integer. `quantile` returns `N` quantiles that divide the data set into evenly distributed `N+1` segments.

Data Types: `double` | `single`**dim — Dimension**

1 (default) | positive integer

Dimension along which the quantiles of a matrix `X` are required, specified as a positive integer. For example, for a matrix `X`, when `dim = 1`, `quantile` returns the quantile(s) of the columns of `X` and when `dim = 2`, `quantile` returns the quantile(s) of the rows of `X`. For a multidimensional array `X`, the length of the `dim`th dimension of `Y` is same as length of `p`.

## Output Arguments

**Y — Quantiles**

scalar | array

Quantiles of a data vector or matrix, returned as a scalar or array for one or multiple values of cumulative probabilities.

- If `X` is a vector, then `Y` is a scalar or a vector with the same length as the number of quantiles required (`N` or `length(p)`). `Y(i)` contains the `p(i)` quantile.
- If `X` is a matrix, then `Y` is a vector or a matrix with the length of `dim`th dimension equal to the number of quantiles required (`N` or `length(p)`). When `dim = 1`, for example, the `i`th row of `Y` contains the `p(i)` quantiles of columns of `X`.
- If `X` is an array of dimension `d`, then `Y` is an array with the length of `dim`th dimension equal to the number of quantiles required (`N` or `length(p)`).

## More About

**Multidimensional Array**

A *multidimensional array* is an array with more than two dimensions. For example, if `X` is a 1-by-3-by-4 array, then `X` is a 3-D array.

### First Nonsingleton Dimension

A *first nonsingleton dimension* is the first dimension of an array whose size is not equal to 1. For example, if  $X$  is a 1-by-2-by-3-by-4 array, then the second dimension is the first nonsingleton dimension of  $X$ .

### Linear Interpolation

Linear interpolation uses linear polynomials to find  $y_i = f(x_i)$ , the values of the underlying function  $Y = f(X)$  at the points in the vector or array  $x$ . Given the data points  $(x_1, y_1)$  and  $(x_2, y_2)$ , where  $y_1 = f(x_1)$  and  $y_2 = f(x_2)$ , linear interpolation finds  $y = f(x)$  for a given  $x$  between  $x_1$  and  $x_2$  as follows:

$$y = f(x) = y_1 + \frac{(x - x_1)}{(x_2 - x_1)}(y_2 - y_1).$$

Similarly, if the  $1.5/n$  quantile is  $y_{1.5/n}$  and the  $2.5/n$  quantile is  $y_{2.5/n}$ , then linear interpolation finds the  $2.3/n$  quantile  $y_{2.3/n}$  as

$$y_{\frac{2.3}{n}} = y_{\frac{1.5}{n}} + \frac{\left(\frac{2.3}{n} - \frac{1.5}{n}\right)}{\left(\frac{2.5}{n} - \frac{1.5}{n}\right)} \left( y_{\frac{2.5}{n}} - y_{\frac{1.5}{n}} \right).$$

### Algorithms

For an  $n$ -element vector  $X$ , `quantile` computes quantiles as follows:

- 1 The sorted values in  $X$  are taken as the  $(0.5/n)$ ,  $(1.5/n)$ , ...,  $([n - 0.5]/n)$  quantiles. For example:
  - For a data vector of five elements such as  $\{6, 3, 2, 10, 1\}$ , the sorted elements  $\{1, 2, 3, 6, 10\}$  respectively correspond to the 0.1, 0.3, 0.5, 0.7, 0.9 quantiles.
  - For a data vector of six elements such as  $\{6, 3, 2, 10, 8, 1\}$ , the sorted elements  $\{1, 2, 3, 6, 8, 10\}$  respectively correspond to the  $(0.5/6)$ ,  $(1.5/6)$ ,  $(2.5/6)$ ,  $(3.5/6)$ ,  $(4.5/6)$ ,  $(5.5/6)$  quantiles.
- 2 `quantile` uses Linear interpolation to compute quantiles for probabilities between  $(0.5/n)$  and  $([n - 0.5]/n)$ .

- 3** For the quantiles corresponding to the probabilities outside that range, `quantile` assigns the minimum or maximum values in `X`.

`quantile` treats NaNs as missing values and removes them.

- “Quantiles and Percentiles” on page 3-7

`iqr` | `median` | `prctile`

## rand

**Class:** grandstream

Generate quasi-random points from stream

### Syntax

```
rand
rand(q, n)
rand(q)
rand(q, m, n)
rand(q, [m, n])
rand(q, m, n, p, ...)
rand(q, [m, n, p, ...])
```

### Description

`rand` returns a matrix of quasi-random values and is intended to allow objects of the `grandstream` class to be used in code that contains calls to the `rand` method of the MATLAB pseudo-random `randstream` class. Due to the multidimensional nature of quasi-random numbers, only some syntaxes of `rand` are supported by the `grandstream` class.

`rand(q, n)` returns an  $n$ -by- $n$  matrix only when  $n$  is equal to the number of dimensions. Any other value of  $n$  produces an error.

`rand(q)` returns a scalar only when the stream is in one dimension. Having more than one dimension in  $q$  produces an error.

`rand(q, m, n)` or `rand(q, [m, n])` returns an  $m$ -by- $n$  matrix only when  $n$  is equal to the number of dimensions in the stream. Any other value of  $n$  produces an error.

`rand(q, m, n, p, ... )` or `rand(q, [m, n, p, ... ])` produces an error unless  $p$  and all following dimensions sizes are equal to one.

## Examples

Generate the first 256 points from a 5-D Sobol sequence:

```
q = grandstream('sobol',5);
X = rand(q,256,5);
```

### See Also

[grandstream](#) | [grand](#) | [rand](#)

## randg

Gamma random numbers with unit scale

### Syntax

```
Y = randg
Y = randg(A)
Y = randg(A,m)
Y = randg(A,m,n,p,...)
Y = randg(A,[m,n,p,...])
```

### Description

`Y = randg` returns a scalar random value chosen from a gamma distribution with unit scale and shape.

`Y = randg(A)` returns a matrix of random values chosen from gamma distributions with unit scale. `Y` is the same size as `A`, and `randg` generates each element of `Y` using a shape parameter equal to the corresponding element of `A`.

`Y = randg(A,m)` returns an  $m$ -by- $m$  matrix of random values chosen from gamma distributions with shape parameters `A`. `A` is either an  $m$ -by- $m$  matrix or a scalar. If `A` is a scalar, `randg` uses that single shape parameter value to generate all elements of `Y`.

`Y = randg(A,m,n,p,...)` or `Y = randg(A,[m,n,p,...])` returns an  $m$ -by- $n$ -by- $p$ -by- $\dots$  array of random values chosen from gamma distributions with shape parameters `A`. `A` is either an  $m$ -by- $n$ -by- $p$ -by- $\dots$  array or a scalar.

`randg` produces pseudo-random numbers using the MATLAB functions `rand` and `randn`. The sequence of numbers generated is determined by the settings of the uniform random number generator that underlies `rand` and `randn`. Control that shared random number generator using `rng`. See the `rng` documentation for more information.

---

**Note:** To generate gamma random numbers and specify both the scale and shape parameters, you should call `gamrnd`.

---

## Examples

### Example 1

Generate a 100-by-1 array of values drawn from a gamma distribution with shape parameter 3.

```
r = randg(3,100,1);
```

### Example 2

Generate a 100-by-2 array of values drawn from gamma distributions with shape parameters 3 and 2.

```
A = [ones(100,1)*3,ones(100,1)*2];
r = randg(A,[100,2]);
```

### Example 3

To create reproducible output from `randg`, reset the random number generator used by `rand` and `randn` to its default startup settings. This way `randg` produces the same random numbers as if you restarted MATLAB.

```
rng('default')
randg(3,1,5)
```

```
ans =
```

```
 6.9223 4.3369 1.0505 3.2662 11.3269
```

### Example 4

Save the settings for the random number generator used by `rand` and `randn`, generate 5 values from `randg`, restore the settings, and repeat those values.

```
s = rng; % Obtain the current state of the random stream
r1 = randg(10,1,5)
```

```
r1 =
```

```
 9.4719 9.0433 15.0774 14.7763 6.3775
rng(s); % Reset the stream to the previous state
r2 = randg(10,1,5)

r2 =
 9.4719 9.0433 15.0774 14.7763 6.3775
```

r2 contains exactly the same values as r1.

## Example 5

Reinitialize the random number generator used by `rand` and `randn` with a seed based on the current time. `randg` returns different values each time you do this. Note that it is usually not necessary to do this more than once per MATLAB session.

```
rng('shuffle');
randg(2,1,5);
```

# random

Random numbers

## Syntax

```
Y = random(name,A)
Y = random(name,A,B)
Y = random(name,A,B,C)
Y = random(name,A,m,n,...)
Y = random(name,A,[m,n,...])
Y = random(name,A,B,m,n,...)
Y = random(name,A,B,[m,n,...])
Y = random(name,A,B,C,m,n,...)
Y = random(name,A,B,C,[m,n,...])
```

## Description

`Y = random(name,A)` where `name` is the name of a distribution that takes a single parameter, returns random numbers `Y` from the one-parameter family of distributions specified by `name`. Parameter values for the distribution are given in `A`.

`Y` is the same size as `A`.

`Y = random(name,A,B)` returns random numbers `Y` from a two-parameter family of distributions. Parameter values for the distribution are given in `A` and `B`.

If `A` and `B` are arrays, they must be the same size. If either `A` or `B` are scalars, they are expanded to constant matrices of the same size.

`Y = random(name,A,B,C)` returns random numbers `Y` from a three-parameter family of distributions. Parameter values for the distribution are given in `A`, `B`, and `C`.

If `A`, `B`, and `C` are arrays, they must be the same size. If any of `A`, `B`, or `C` are scalars, they are expanded to constant matrices of the same size.

`Y = random(name,A,m,n,...)` or `Y = random(name,A,[m,n,...])` returns an `m`-by-`n`-by... matrix of random numbers.

Similarly, `Y = random(name, A, B, m, n, ...)` or `Y = random(name, A, B, [m, n, ...])` returns an `m`-by-`n`-by... matrix of random numbers for distributions that require two parameters. `Y = random(name, A, B, C, m, n, ...)` or `Y = random(name, A, B, C, [m, n, ...])` returns an `m`-by-`n`-by... matrix of random numbers for distributions that require three parameters.

If any of `A`, `B`, or `C` are arrays, then the specified dimensions must match the common dimensions of `A`, `B`, and `C` after any necessary scalar expansion.

The following table denotes the acceptable strings for `name`, as well as the parameters for that distribution:

| name                    | Distribution                                  | Input Parameter A                      | Input Parameter B                        | Input Parameter C     |

## Examples

Generate a 2-by-4 array of random values from the normal distribution with mean 0 and standard deviation 1:

```
x1 = random('Normal',0,1,2,4)
x1 =
 1.1650 0.0751 -0.6965 0.0591
 0.6268 0.3516 1.6961 1.7971
```

The order of the parameters is the same as for `normrnd`.

Generate a single random value from Poisson distributions with rate parameters 1, 2, ..., 6, respectively:

```
x2 = random('Poisson',1:6,1,6)
x2 =
 0 0 1 2 5 7
```

## random

**Class:** GeneralizedLinearModel

Simulate responses for generalized linear regression model

### Syntax

```
ysim = random mdl, Xnew
ysim = random mdl, Xnew, Name, Value
```

### Description

`ysim = random(mdl, Xnew)` simulates responses from the `mdl` generalized linear model to the data in `Xnew`.

`ysim = random(mdl, Xnew, Name, Value)` simulates responses with additional options specified by one or more `Name, Value` pair arguments.

### Input Arguments

#### **mdl**

Generalized linear model, as constructed by `fitglm` or `stepwiseglm`.

#### **Xnew**

Points at which `mdl` predicts responses.

- If `Xnew` is a table or dataset array, it must contain the predictor names in `mdl`.
- If `Xnew` is a numeric matrix, it must have the same number of variables (columns) as was used to create `mdl`. Furthermore, all variables used in creating `mdl` must be numeric.

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single

quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### 'BinomialSize'

The value of the binomial  $n$  parameter for each row in the training data. `BinomialSize` can be a vector the same length as `Xnew`, or a scalar that applies to each row. The default value `1` produces `ysim` values that are predicted proportions. Use `BinomialSize` only if `mdl` is fit to a binomial distribution.

**Default:** `1`

### 'Offset'

Value of the offset for each row in `Xnew`. `Offset` can be a vector the same length as `Xnew`, or a scalar that applies to each row. The offset is used as an additional predictor with a coefficient value fixed at `1`. In other words, if `b` is the fitted coefficient vector, and `link` is the link function,

$$\text{link}(\text{ysim}) = \text{Offset} + \text{Xnew} * \mathbf{b}.$$

**Default:** `zeros(size(Xnew,1))`

## Output Arguments

### `ysim`

Vector of simulated values at `Xnew`.

`random` generates `ysim` using random values with mean given by the fitted model, and with the distribution used in `mdl`. The values in `ysim` are independent conditional on the predictors. For binomial and Poisson fits, `random` generates `ysim` with the specified distribution with no adjustment for any estimated dispersion.

## Examples

### Generalized Linear Model Simulation

Create a generalized linear model, and simulate its response to new data.

Generate artificial data for the model, Poisson random numbers with one underlying predictors X.

```
rng('default') % reproducible
X = rand(20,1);
mu = exp(1 + 2*X);
y = poissrnd(mu);
```

Create a generalized linear regression model of Poisson data.

```
mdl = fitglm(X,y,'y ~ x1','distr','poisson');
```

Create points for prediction.

```
Xnew = (0:.05:1)';
```

Simulate responses at the new points.

```
ysim = random(mdl,Xnew);
```

Plot the simulated values along with the original values.

```
plot(X,y,'rx',Xnew,ysim,'bo',...
 Xnew,feval(mdl,Xnew),'g-')
legend('Data','Simulated','Fitted Mean',...
 'Location','best')
```

- “random” on page 10-37

## Alternatives

For predictions without random noise, use `predict` or `feval`.

## random

**Class:** `GeneralizedLinearMixedModel`

Generate random responses from fitted generalized linear mixed-effects model

### Syntax

```
ysim = random(glme)
ysim = random(glme, tblnew)
ysim = random(____, Name, Value)
```

### Description

`ysim = random(glme)` returns simulated responses, `ysim`, from the fitted generalized linear mixed-effects model `glme`, at the original design points.

`ysim = random(glme, tblnew)` returns simulated responses using new input values specified in the table or dataset array, `tblnew`.

`ysim = random( ____, Name, Value)` returns simulated responses using additional options specified by one or more `Name, Value` pair arguments, using any of the previous syntaxes. For example, you can specify observation weights, binomial sizes, or offsets for the model.

### Input Arguments

**glme** — Generalized linear mixed-effects model

`GeneralizedLinearMixedModel` object

Generalized linear mixed-effects model, specified as a `GeneralizedLinearMixedModel` object. For properties and methods of this object, see `GeneralizedLinearMixedModel`.

**tblnew** — New input data

table | dataset array

New input data, which includes the response variable, predictor variables, and grouping variables, specified as a table or dataset array. The predictor variables can be continuous or grouping variables. `tblnew` must contain the same variables as the original table or dataset array, `tbl`, used to fit the generalized linear mixed-effects model `glme`.

Data Types: `single` | `double` | `logical` | `char`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

### 'BinomialSize' — Number of trials for binomial distribution

`ones(m, 1)` (default) |  $m$ -by-1 vector of positive integer values

Number of trials for binomial distribution, specified as the comma-separated pair consisting of 'BinomialSize' and an  $m$ -by-1 vector of positive integer values, where  $m$  is the number of rows in `tblnew`. The 'BinomialSize' name-value pair applies only to the binomial distribution. The value specifies the number of binomial trials when generating the random response values.

Data Types: `single` | `double`

### 'Offset' — Model offset

`zeros(m, 1)` (default) | vector of scalar values

Model offset, specified as a vector of scalar values of length  $m$ , where  $m$  is the number of rows in `tblnew`. The offset is used as an additional predictor and has a coefficient value fixed at 1.

### 'Weights' — Observation weights

$m$ -by-1 vector of nonnegative scalar values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and an  $m$ -by-1 vector of nonnegative scalar values, where  $m$  is the number of rows in `tblnew`. If the response distribution is binomial or Poisson, then 'Weights' must be a vector of positive integers.

Data Types: `single` | `double`

## Output Arguments

### **ysim** — Simulated response values

*m*-by-1 vector

Simulated response values, returned as an *m*-by-1 vector, where *m* is the number of rows in `tblnew`. `random` creates `ysim` by first generating the random-effects vector based on its fitted prior distribution. `random` then generates `ysim` from its fitted conditional distribution given the random effects. `random` takes into account the effect of observation weights specified when fitting the model using `fitglme`, if any.

## Definitions

### Conditional Distribution Method

`random` generates random data from the fitted generalized linear mixed-effects model as follows:

- Sample  $b_{sim} \sim P(b | \theta, \sigma^2)$ , where  $P(b | \theta, \sigma^2)$  is the estimated prior distribution of random effects, and  $\hat{\theta}$  is a vector of estimated covariance parameters, and  $\hat{\sigma}^2$  is the estimated dispersion parameter.
- Given  $b_{sim}$ , for  $i = 1$  to  $m$ , sample  $y_{sim\_i} \sim P(y_{new\_i} | b_{sim}, \beta, \theta, \sigma^2)$ , where  $P(y_{new\_i} | b_{sim}, \beta, \theta, \sigma^2)$  is the conditional distribution of the *i*th new response  $y_{new\_i}$  given  $b_{sim}$  and the model parameters.

## Examples

### Simulate Random Responses From a GLME Model

Navigate to the folder containing the sample data. Load the sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

load mfr

This simulated data is from a manufacturing company that operates 50 factories across the world, with each factory running a batch process to create a finished product. The company wants to decrease the number of defects in each batch, so it developed a new manufacturing process. To test the effectiveness of the new process, the company selected 20 of its factories at random to participate in an experiment: Ten factories implemented the new process, while the other ten continued to run the old process. In each of the 20 factories, the company ran five batches (for a total of 100 batches) and recorded the following data:

- Flag to indicate whether the batch used the new process (**newprocess**)
- Processing time for each batch, in hours (**time**)
- Temperature of the batch, in degrees Celsius (**temp**)
- Categorical variable indicating the supplier (A, B, or C) of the chemical used in the batch (**supplier**)
- Number of defects in the batch (**defects**)

The data also includes **time\_dev** and **temp\_dev**, which represent the absolute deviation of time and temperature, respectively, from the process standard of 3 hours at 20 degrees Celsius.

Fit a generalized linear mixed-effects model using **newprocess**, **time\_dev**, **temp\_dev**, and **supplier** as fixed-effects predictors. Include a random-effects term for intercept grouped by **factory**, to account for quality differences that might exist due to factory-specific variations. The response variable **defects** has a Poisson distribution, and the appropriate link function for this model is log. Use the Laplace fit method to estimate the coefficients. Specify the dummy variable encoding as 'effects', so the dummy variable coefficients sum to 0.

The number of defects can be modeled using a Poisson distribution

$$defects_{ij} \sim \text{Poisson}(\mu_{ij})$$

This corresponds to the generalized linear mixed-effects model

$$\log(\mu_{ij}) = \beta_0 + \beta_1 \text{newprocess}_{ij} + \beta_2 \text{time\_dev}_{ij} + \beta_3 \text{temp\_dev}_{ij} + \beta_4 \text{supplier\_C}_{ij} + \beta_5 \text{supplier\_B}_{ij} +$$

where

- $defects_{ij}$  is the number of defects observed in the batch produced by factory  $i$  during batch  $j$ .
- $\mu_{ij}$  is the mean number of defects corresponding to factory  $i$  (where  $i = 1, 2, \dots, 20$ ) during batch  $j$  (where  $j = 1, 2, \dots, 5$ ).
- $newprocess_{ij}$ ,  $time\_dev_{ij}$ , and  $temp\_dev_{ij}$  are the measurements for each variable that correspond to factory  $i$  during batch  $j$ . For example,  $newprocess_{ij}$  indicates whether the batch produced by factory  $i$  during batch  $j$  used the new process.
- $supplier\_C_{ij}$  and  $supplier\_B_{ij}$  are dummy variables that use effects (sum-to-zero) coding to indicate whether company C or B, respectively, supplied the process chemicals for the batch produced by factory  $i$  during batch  $j$ .
- $b_i \sim N(0, \sigma_b^2)$  is a random-effects intercept for each factory  $i$  that accounts for factory-specific variation in quality.

```
glme = fitglme(mfr, 'defects ~ 1 + newprocess + time_dev + temp_dev + supplier + (1|fact
```

Use `random` to simulate a new response vector from the fitted model.

```
rng(0, 'twister'); % For reproducibility
ynew = random(glme);
```

Display the first 10 rows of the simulated response vector.

```
ynew(1:10)
```

```
ans =
```

```
3
3
1
7
5
8
7
9
5
9
```

Simulate a new response vector using new input values. Create a new table by copying the first 10 rows of `mfr` into `tblnew`.

```
tblnew = mfr(1:10,:);
```

The first 10 rows of `mfr` include data collected from trials 1 through 5 for factories 1 and 2. Both factories used the old process for all of their trials during the experiment, so `newprocess = 0` for all 10 observations.

Change the value of `newprocess` to 1 for the observations in `tblnew`.

```
tblnew.newprocess = ones(height(tblnew),1);
```

Simulate new responses using the new input values in `tblnew`.

```
ynew2 = random(glme,tblnew)
```

```
ynew2 =
```

```
2

**Class:** `gmdistribution`

Random numbers from Gaussian mixture distribution

### Syntax

```
y = random(obj)
Y = random(obj,n)
[Y,idx] = random(obj,n)
```

### Description

`y = random(obj)` generates a 1-by- $d$  vector  $y$  drawn at random from the  $d$ -dimensional Gaussian mixture distribution defined by `obj`. `obj` is an object created by `gmdistribution` or `fitgmdist`.

`Y = random(obj,n)` generates an  $n$ -by- $d$  matrix  $Y$  of  $n$   $d$ -dimensional random samples.

`[Y,idx] = random(obj,n)` also returns an  $n$ -by-1 vector `idx`, where `idx(I)` is the index of the component used to generate  $Y(I, :)$ .

### Examples

#### Generate Gaussian Mixture Variates

Create a `gmdistribution` object defining a two-component mixture of bivariate Gaussian distributions.

```
MU = [1 2; -3 -5];
SIGMA = cat(3,[2 0;0 .5],[1 0;0 1]);
p = ones(1,2)/2;
obj = gmdistribution(MU,SIGMA,p);

ezcontour(@(x,y)pdf(obj,[x y]),[-10 10],[-10 10])
hold on
```

Generate 1000 random values.

```
rng(1); % For reproducibility
Y = random(obj,1000);

scatter(Y(:,1),Y(:,2),10,'.')
```

# random

**Class:** LinearModel

Simulate responses for linear regression model

## Syntax

```
ysim = random mdl
ysim = random mdl, Xnew
```

## Description

`ysim = random(mdl)` simulates responses from the fitted linear model `mdl` at the original design points.

`ysim = random(mdl, Xnew)` simulates responses from the `mdl` linear model to the data in `Xnew`, adding random noise.

## Input Arguments

### **mdl**

Linear model, as constructed by `fitlm` or `stepwiselm`.

### **Xnew**

Points at which `mdl` predicts responses.

- If `Xnew` is a table or dataset array, it must contain the predictor names in `mdl`.
- If `Xnew` is a numeric matrix, it must have the same number of variables (columns) as was used to create `mdl`. Furthermore, all variables used in creating `mdl` must be numeric.

## Output Arguments

### **ysim**

Vector of predicted mean values at *Xnew*, perturbed by random noise. The noise is independent, normally distributed, with mean zero, and variance equal to the estimated error variance of the model.

## Examples

### **Simulate Response Data**

Create a model of car mileage as a function of weight, and simulate the response.

Create a quadratic model of car mileage as a function of weight from the `carsmall` data.

```
load carsmall
X = Weight;
y = MPG;
mdl = fitlm(X,y,'quadratic');
```

Create simulated responses to the data.

```
Xnew = X;
ysim = random(mdl,Xnew);
```

Plot the original responses and the simulated responses to see how they differ.

```
plot(X,y,'o',X,ysim,'x')
legend('Data','Simulated')
```

- “random” on page 9-39

## Alternatives

For predictions without random noise, use `predict` or `feval`.

## random

**Class:** LinearMixedModel

Generate random responses from fitted linear mixed-effects model

### Syntax

```
ysim = random(lme)
ysim = random(lme, tblnew)
ysim = random(lme, Xnew, Znew)
ysim = random(lme, Xnew, Znew, Gnew)
```

### Description

`ysim = random(lme)` returns a vector of simulated responses `ysim` from the fitted linear mixed-effects model `lme` at the original fixed- and random-effects design points, used to fit `lme`.

`random` simulates new random-effects vector and new observation errors. So, the simulated response is

$$y_{sim} = X\hat{\beta} + Z\hat{b} + \varepsilon,$$

where  $\hat{\beta}$  is the estimated fixed-effects coefficients,  $\hat{b}$  is the new random effects, and  $\varepsilon$  is the new observation error.

`random` also accounts for the effect of observation weights, if you use any when fitting the model.

`ysim = random(lme, tblnew)` returns a vector of simulated responses `ysim` from the fitted linear mixed-effects model `lme` at the values in the new table or dataset array `tblnew`. Use a table or dataset array for `random` if you use a table or dataset array for fitting the model `lme`.

`ysim = random(lme, Xnew, Znew)` returns a vector of simulated responses `ysim` from the fitted linear mixed-effects model `lme` at the values in the new fixed- and random-

effects design matrices, `Xnew` and `Znew`, respectively. `Znew` can also be a cell array of matrices. Use the matrix format for `random` if you use design matrices for fitting the model `lme`.

`ysim = random(lme, Xnew, Znew, Gnew)` returns a vector of simulated responses `ysim` from the fitted linear mixed-effects model `lme` at the values in the new fixed- and random-effects design matrices, `Xnew` and `Znew`, respectively, and the grouping variable `Gnew`.

`Znew` and `Gnew` can also be cell arrays of matrices and grouping variables, respectively.

## Input Arguments

### **lme** — Linear mixed-effects model

LinearMixedModel object

Linear mixed-effects model, returned as a `LinearMixedModel` object.

For properties and methods of this object, see `LinearMixedModel`.

### **tblnew** — New input data

table | dataset array

New input data, which includes the response variable, predictor variables, and grouping variables, specified as a table or dataset array. The predictor variables can be continuous or grouping variables. `tblnew` must have the same variables as in the original table or dataset array used to fit the linear mixed-effects model `lme`.

Data Types: `single` | `double` | `logical` | `char`

### **Xnew** — New fixed-effects design matrix

$n$ -by- $p$  matrix

New fixed-effects design matrix, specified as an  $n$ -by- $p$  matrix, where  $n$  is the number of observations and  $p$  is the number of fixed predictor variables. Each row of `X` corresponds to one observation and each column of `X` corresponds to one variable.

Data Types: `single` | `double`

### **Znew** — New random-effects design

$n$ -by- $q$  matrix | cell array of length  $R$

New random-effects design, specified as an  $n$ -by- $q$  matrix or a cell array of  $R$  design matrices  $Z\{r\}$ , where  $r = 1, 2, \dots, R$ . If `Znew` is a cell array, then each  $Z\{r\}$  is an  $n$ -by- $q(r)$  matrix, where  $n$  is the number of observations, and  $q(r)$  is the number of random predictor variables.

Data Types: `single` | `double` | `logical` | `char` | `cell`

### **`gnew` — New grouping variable or variables**

vector | cell array of grouping variables of length  $R$

New grouping variable or variables, specified as a vector or a cell array, of length  $R$ , of grouping variables used to fit the linear mixed-effects model, `lme`.

`random` treats all levels of each grouping variable as new levels. It draws an independent random effects vector for each level of each grouping variable.

Data Types: `single` | `double` | `logical` | `char` | `cell`

## Output Arguments

### **`ysim` — Simulated response values**

$n$ -by-1 vector

Simulated response values, returned as an  $n$ -by-1 vector, where  $n$  is the number of observations.

## Examples

### **Generate Random Responses at the Original Design Values**

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load fertilizer
```

The dataset array includes data from a split-plot experiment, where soil is divided into three blocks based on the soil type: sandy, silty, and loamy. Each block is divided into

five plots, where five different types of tomato plants (cherry, heirloom, grape, vine, and plum) are randomly assigned to these plots. The tomato plants in the plots are then divided into subplots, where each subplot is treated by one of four fertilizers. This is simulated data.

Store the data in a dataset array called `ds`, for practical purposes, and define `Tomato`, `Soil`, and `Fertilizer` as categorical variables.

```
ds = fertilizer;
ds.Tomato = nominal(ds.Tomato);
ds.Soil = nominal(ds.Soil);
ds.Fertilizer = nominal(ds.Fertilizer);
```

Fit a linear mixed-effects model, where `Fertilizer` and `Tomato` are the fixed-effects variables, and the mean yield varies by the block (soil type), and the plots within blocks (tomato types within soil types) independently.

```
lme = fitlme(ds, 'Yield ~ Fertilizer * Tomato + (1|Soil) + (1|Soil:Tomato)');
```

Generate random response values at the original design points. Display the first five values.

```
rng(123, 'twister') % For reproducibility
ysim = random(lme);
ysim(1:5)
```

```
ans =
```

```
114.8785
134.2018
154.2818
169.7554
84.6089
```

### Plot Randomly Generated vs. Observed Response Values

Load the sample data.

```
load carsmall
```

Fit a linear mixed-effects model, with a fixed-effects for `Weight`, and a random intercept grouped by `Model_Year`. First, store the data in a table.

```
tbl = table(MPG, Weight, Model_Year);
lme = fitlme(tbl, 'MPG ~ Weight + (1|Model_Year)');
```

Randomly generate responses using the original data.

```
rng(123,'twister') % For reproducibility
ysim = random(lme,tbl);
```

Plot the original and the randomly generated responses to see how they differ. Group them by model year.

```
figure()
gscatter(Weight,MPG,Model_Year)
hold on
gscatter(Weight,ysim,Model_Year,[],'o+x')
legend('70-data','76-data','82-data','70-sim','76-sim','82-sim')
hold off
```

Note that the simulated random response values for year 82 are lower than the original data for that year. This might be due to a lower simulated random effect for year 82 than the estimated random effect in the original data.

### Generate Responses Using a New Dataset Array

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load fertilizer
```

The dataset array includes data from a split-plot experiment, where soil is divided into three blocks based on the soil type: sandy, silty, and loamy. Each block is divided into five plots, where five different types of tomato plants (cherry, heirloom, grape, vine, and plum) are randomly assigned to these plots. The tomato plants in the plots are then divided into subplots, where each subplot is treated by one of four fertilizers. This is simulated data.

Store the data in a dataset array called `ds`, for practical purposes, and define `Tomato`, `Soil`, and `Fertilizer` as categorical variables.

```
ds = fertilizer;
ds.Tomato = nominal(ds.Tomato);
ds.Soil = nominal(ds.Soil);
ds.Fertilizer = nominal(ds.Fertilizer);
```

Fit a linear mixed-effects model, where `Fertilizer` and `Tomato` are the fixed-effects variables, and the mean yield varies by the block (soil type), and the plots within blocks (tomato types within soil types) independently.

```
lme = fitlme(ds, 'Yield ~ Fertilizer * Tomato + (1|Soil) + (1|Soil:Tomato)');
```

Create a new dataset array with design values. The new dataset array must have the same variables as the original dataset array you use for fitting the model `lme`.

```
dsnew = dataset();
dsnew.Soil = nominal({'Sandy'; 'Silty'; 'Silty'});
dsnew.Tomato = nominal({'Cherry'; 'Vine'; 'Plum'});
dsnew.Fertilizer = nominal([2;2;4]);
```

Generate random responses at the new points.

```
rng(123,'twister') % For reproducibility
ysim = random(lme,dsnew)
```

```
ysim =

 99.6006
 101.9911
 161.4026
```

### Generate Random Responses Using New Design Matrices

Load the sample data.

```
load carbig
```

Fit a linear mixed-effects model for miles per gallon (MPG), with fixed effects for acceleration, horsepower, and cylinders, and potentially correlated random effect for intercept and acceleration grouped by model year.

First, prepare the design matrices for fitting the linear mixed-effects model.

```
X = [ones(406,1) Acceleration Horsepower];
Z = [ones(406,1) Acceleration];
Model_Year = nominal(Model_Year);
G = Model_Year;
```

Now, fit the model using `fitlmematrix` with the defined design matrices and grouping variables.

```
lme = fitlmematrix(X,MPG,Z,G,'FixedEffectPredictors',...
{'Intercept','Acceleration','Horsepower'},'RandomEffectPredictors',...
{{'Intercept','Acceleration'}},'RandomEffectGroups',{'Model_Year'});
```

Create the design matrices that contain the data at which to predict the response values. `Xnew` must have three columns as in `X`. The first column must be a column of 1s. And the values in the last two columns must correspond to `Acceleration` and `Horsepower`, respectively. The first column of `Znew` must be a column of 1s, and the second column must contain the same `Acceleration` values as in `Xnew`. The original grouping variable in `G` is the model year. So, `Gnew` must contain values for the model year. Note that `Gnew` must contain nominal values.

```
Xnew = [1,13.5,185; 1,17,205; 1,21.2,193];
Znew = [1,13.5; 1,17; 1,21.2];
```

```
Gnew = nominal([73 77 82]);
```

Generate random responses for the data in the new design matrices.

```
rng(123, 'twister') % For reproducibility
ysim = random(lme, Xnew, Znew, Gnew)
```

```
ysim =
```

```
15.7416
10.6085
 6.8796
```

Now, repeat the same for a linear mixed-effects model with uncorrelated random-effects terms for intercept and acceleration. First, change the original random effects design and the random effects grouping variables. Then, fit the model.

```
Z = {ones(406,1), Acceleration};
G = {Model_Year, Model_Year};
```

```
lme = fitlmematrix(X, MPG, Z, G, 'FixedEffectPredictors', ...
{'Intercept', 'Acceleration', 'Horsepower'}, 'RandomEffectPredictors', ...
{{'Intercept'}, {'Acceleration'}}, 'RandomEffectGroups', {'Model_Year', 'Model_Year'});
```

Now, recreate the new random effects design, `Znew`, and the grouping variable design, `Gnew`, using which to predict the response values.

```
Znew = {[1;1;1], [13.5;17;21.2]};
MY = nominal([73 77 82]);
Gnew = {MY, MY};
```

Generate random responses using the new design matrices.

```
rng(123, 'twister') % For reproducibility
ysim = random(lme, Xnew, Znew, Gnew)
```

```
ysim =
```

```
16.8280
10.4375
 4.1027
```

## random

**Class:** NonLinearModel

Simulate responses for nonlinear regression model

### Syntax

```
ysim = random mdl
ysim = random mdl, Xnew
ysim = random mdl, Xnew, 'Weights', W
```

### Description

`ysim = random(mdl)` simulates responses from the fitted nonlinear model `mdl` at the original design points.

`ysim = random(mdl, Xnew)` simulates responses from the fitted nonlinear model `mdl` to the data in `Xnew`, adding random noise.

`ysim = random(mdl, Xnew, 'Weights', W)` simulates responses using the observation weights, `W`.

### Input Arguments

#### **mdl**

Nonlinear regression model, constructed by `fitnlm`.

#### **Xnew**

Points at which `mdl` predicts responses.

- If `Xnew` is a table or dataset array, it must contain the predictor names in `mdl`.
- If `Xnew` is a numeric matrix, it must have the same number of variables (columns) as was used to create `mdl`. Furthermore, all variables used in creating `mdl` must be numeric.

**W**

Vector of real, positive value weights or a function handle.

- If you specify a vector, then it must have the same number of elements as the number of observations (or rows) in `Xnew`.
- If you specify a function handle, the function must accept a vector of predicted response values as input, and returns a vector of real positive weights as output.

Given weights, `W`, `random` estimates the error variance at observation `i` by  $\text{MSE} * (1 / W(i))$ , where `MSE` is the mean squared error.

**Default:** No weights

## Output Arguments

### `ysim`

Vector of predicted mean values at `Xnew`, perturbed by random noise. The noise is independent, normally distributed, with mean zero, and variance equal to the estimated error variance of the model.

## Examples

### Simulate Responses

Create a nonlinear model of car mileage as a function of weight, and simulate the response.

Create an exponential model of car mileage as a function of weight from the `carsmall` data. Scale the weight by a factor of 1000 so all the variables are roughly equal in size.

```
load carsmall
X = Weight;
y = MPG;
modelfun = 'y ~ b1 + b2*exp(-b3*x/1000)';
beta0 = [1 1 1];
mdl = fitnlm(X,y,modelfun,beta0);
```

Create simulated responses to the data.

```
Xnew = X;
ysim = random mdl, Xnew);
```

Plot the original responses and the simulated responses to see how they differ.

```
plot(X,y, 'o', X, ysim, 'x')
legend('Data', 'Simulated')
```

- “Predict or Simulate Responses Using a Nonlinear Model” on page 11-10

## Alternatives

For predictions without added noise, use `predict`.

## **More About**

- “Nonlinear Regression” on page 11-2

## random

**Class:** `piecewisedistribution`

Random numbers from piecewise distribution

### Syntax

```
r = random(obj)
R = random(obj,n)
R = random(obj,m,n)
R = random(obj,[m,n])
R = random(obj,m,n,p,...)
R = random(obj,[m,n,p,...])
```

### Description

`r = random(obj)` generates a pseudo-random number `r` drawn from the piecewise distribution object `obj`.

`R = random(obj,n)` generates an  $n$ -by- $n$  matrix of pseudo-random numbers `R`.

`R = random(obj,m,n)` or `R = random(obj,[m,n])` generates an  $m$ -by- $n$  matrix of pseudo-random numbers `R`.

`R = random(obj,m,n,p,...)` or `R = random(obj,[m,n,p,...])` generates an  $m$ -by- $n$ -by- $p$ -by-... array of pseudo-random numbers `R`.

### Examples

Fit Pareto tails to a  $t$  distribution at cumulative probabilities 0.1 and 0.9:

```
t = trnd(3,100,1);
obj = paretotails(t,0.1,0.9);

r = random(obj)
r =
```

## random

**Class:** RepeatedMeasuresModel

Generate new random response values given predictor values

## Syntax

```
ysim = random(rm, tnew)
```

## Description

`ysim = random(rm, tnew)` generates random response values from the repeated measures model `rm` using the predictor variables from table `tnew`.

## Input Arguments

**rm** — Repeated measures model

RepeatedMeasuresModel object

Repeated measures model, returned as a RepeatedMeasuresModel object.

For properties and methods of this object, see RepeatedMeasuresModel.

**tnew** — New data

table used to create `rm` (default) | table

New data including the values of the response variables and the between-subject factors used as predictors in the repeated measures model, `rm`, specified as a table. `tnew` must contain all of the between-subject factors used to create `rm`.

## Output Arguments

**ysim** — Random response values

*n*-by-*r* matrix

Random response values `random` generates, returned as an  $n$ -by- $r$  matrix, where  $n$  is the number of rows in `tnew`, and  $r$  is the number of repeated measures in `rm`.

## Examples

### Randomly Generate New Response Values

Load the sample data.

```
load fisheriris
```

The column vector `species` consists of iris flowers of three different species: `setosa`, `versicolor`, and `virginica`. The double matrix `meas` consists of four types of measurements on the flowers: the length and width of sepals and petals in centimeters, respectively.

Store the data in a table array.

```
t = table(species,meas(:,1),meas(:,2),meas(:,3),meas(:,4),...
'VariableNames',{'species','meas1','meas2','meas3','meas4'});
Meas = dataset([1 2 3 4'],'VarNames',{'Measurements'});
```

Fit a repeated measures model, where the measurements are the responses and the `species` is the predictor variable.

```
rm = fitrm(t,'meas1-meas4~species','WithinDesign',Meas);
```

Randomly generate new response values.

```
ysim = random(rm);
```

`random` uses the predictor values in the original sample data you use to fit the repeated measures model `rm` in table `t`.

### Randomly Generate Response Values Using New Data

Load the sample data.

```
load repeatedmeas
```

The table `between` includes the between-subject variables `age`, `IQ`, `group`, `gender`, and eight repeated measures `y1` through `y8` as responses. The table `within` includes the within-subject variables `w1` and `w2`. This is simulated data.

Fit a repeated measures model, where the repeated measures `y1` through `y8` are the responses, and `age`, `IQ`, `group`, `gender`, and the group-gender interaction are the predictor variables. Also specify the within-subject design matrix.

```
rm = fitrm(between, 'y1-y8 ~ Group*Gender + Age + IQ', 'WithinDesign', within);
```

Define a table with new values for the predictor variables.

```
tnew = table(16,93,{'B'},{'Male'},'VariableNames',{'Age','IQ','Group','Gender'})
```

```
tnew =
```

| Age | IQ | Group | Gender |
|-----|----|-------|--------|
| 16  | 93 | 'B'   | 'Male' |

Randomly generate new response values using the values in the new table `tnew`.

```
ysim = random(rm,tnew)
```

```
ysim =
```

```
159.0920 114.8927 -6.5618 46.9944 38.6707 -5.6725 70.8690 11.7813
```

## Algorithms

`random` computes `ysim` by creating predicted values and adding random noise values. For each row, the noise has a multivariate normal distribution with covariance the same as `rm.Covariance`.

# random

**Class:** prob.TruncatableDistribution

**Package:** prob

Generate random numbers from probability distribution object

## Syntax

```
r = random(pd)
```

```
r = random(pd, sz1, ..., szN)
```

```
r = random(pd, [sz1, ..., szN])
```

## Description

`r = random(pd)` generates a random number `r` from the probability distribution `pd`.

`r = random(pd, sz1, ..., szN)` generates a `sz1`-by-...-by-`szN` array of random numbers from the probability distribution `pd`.

`r = random(pd, [sz1, ..., szN])` generates a `sz1`-by-...-by-`szN` array of random numbers from the probability distribution `pd`.

## Input Arguments

### **pd** — Probability distribution

probability distribution object

Probability distribution, specified as a probability distribution object. Create a probability distribution object with specified parameter values using `makedist`. Alternatively, for fittable distributions, create a probability distribution object by fitting it to data using `fitdist` or the Distribution Fitting app.

### **sz1, ..., szN** — Size of each dimension

two or more integer values | vector of integer values

Size of each dimension, specified as two or more integer values, or a vector of such values. For example, specifying `5,3,2` or `[5,3,2]` generates a 5-by-3-by-2 array of random numbers from the probability distribution `pd`.

Data Types: `single` | `double`

## Output Arguments

### **r** — Random number

scalar value | array of values

Random number generated from the probability distribution, returned as a scalar value or an array of scalar values with the dimensions specified by `sz1,...,szN`.

## Examples

### Generate One Random Number

Create a standard normal probability distribution object.

```
pd = makedist('Normal')
```

```
pd =
```

```
NormalDistribution
```

```
Normal distribution
```

```
mu = 0
```

```
sigma = 1
```

Generate one random number from the distribution.

```
r = random(pd)
```

```
r =
```

```
0.5377
```

### Generate Multiple Random Numbers

Create a Weibull probability distribution object using the default parameter values.

```
pd = makedist('Weibull')
```

```
pd =
```

```
WeibullDistribution

Weibull distribution
A = 1
B = 1
```

Generate random numbers from distribution and visualize with a histogram.

```
r = random(pd,10000,1);
hist(r,100)
```

### Generate a Multidimensional Array of Random Numbers

Create a standard normal probability distribution object.

```
pd = makedist('Normal')
```

```
pd =
```

```
NormalDistribution
```

```
Normal distribution
```

```
mu = 0
```

```
sigma = 1
```

Generate a 2-by-3-by-2 array of random numbers from the distribution.

```
r = random(pd,[2,3,2])
```

```
random_make_array(:,:,1) =
```

```
-1.0689 -2.9443 0.3252
-0.8095 1.4384 -0.7549
```

```
random_make_array(:,:,2) =
```

```
1.3703 -0.1022 0.3192
-1.7115 -0.2414 0.3129
```

# randomEffects

**Class:** GeneralizedLinearMixedModel

Estimates of random effects and related statistics

## Syntax

```
B = randomEffects(glme)
[B,BNames] = randomEffects(glme)
[B,BNames,stats] = randomEffects(glme)
[B,BNames,stats] = randomEffects(glme,Name,Value)
```

## Description

`B = randomEffects(glme)` returns the estimates of the empirical Bayes predictors (EPBs) of random effects in the generalized linear mixed-effects model `glme` conditional on the estimated covariance parameters and the observed response.

`[B,BNames] = randomEffects(glme)` also returns the names of the coefficients, `BNames`. Each name corresponds to a coefficient in `B`.

`[B,BNames,stats] = randomEffects(glme)` also returns related statistics, `stats`, for the estimated EBP of random effects in `glme`.

`[B,BNames,stats] = randomEffects(glme,Name,Value)` returns any of the above output arguments using additional options specified by one or more `Name,Value` pair arguments. For example, you can specify the confidence interval level, or the method for computing the approximate degrees of freedom.

## Input Arguments

### **glme** — Generalized linear mixed-effects model

GeneralizedLinearMixedModel object

Generalized linear mixed-effects model, specified as a `GeneralizedLinearMixedModel` object. For properties and methods of this object, see `GeneralizedLinearMixedModel`.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( `' '` ). You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

### 'Alpha' — Confidence level

0.05 (default) | scalar value in the range [0,1]

Confidence level, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the range [0,1]. For a value  $\alpha$ , the confidence level is  $100 \times (1 - \alpha)\%$ .

For example, for 99% confidence intervals, you can specify the confidence level as follows.

Example: `'Alpha', 0.01`

Data Types: `single` | `double`

### 'DFMethod' — Method for computing approximate degrees of freedom

`'residual'` (default) | `'none'`

Method for computing approximate degrees of freedom, specified as the comma-separated pair consisting of `'DFMethod'` and one of the following.

`'residual'`

The degrees of freedom are assumed to be constant and equal to  $n - p$ , where  $n$  is the number of observations and  $p$  is the number of fixed effects.

`'none'`

All degrees of freedom are set to infinity.

Example: `'DFMethod', 'none'`

## Output Arguments

### **B** — Estimated empirical Bayes predictors for the random effects

column vector

Estimated empirical Bayes predictors (EBPs) for the random effects in the generalized linear mixed-effects model `glme`, returned as a column vector. The EBPs in `B` are

approximated by the mode of the empirical posterior distribution of the random effects given the estimated covariance parameters and the observed response.

Suppose `glme` has  $R$  grouping variables  $g_1, g_2, \dots, g_R$ , with levels  $m_1, m_2, \dots, m_R$ , respectively. Also suppose  $q_1, q_2, \dots, q_R$  are the lengths of the random-effects vectors that are associated with  $g_1, g_2, \dots, g_R$ , respectively. Then, **B** is a column vector of length  $q_1 * m_1 + q_2 * m_2 + \dots + q_R * m_R$ .

`randomEffects` creates **B** by concatenating the empirical Bayes predictors of random-effects vectors corresponding to each level of each grouping variable as `[g1level1; g1level2; ...; g1levelm1; g2level1; g2level2; ...; g2levelm2; ...; gRlevel1; gRlevel2; ...; gRlevelmR]`'.

### **BNames** — Names of random-effects coefficients

table

Names of random-effects coefficients in **B**, returned as a table.

### **stats** — Estimated empirical Bayes predictors and related statistics

table

Estimated empirical Bayes predictors (EBPs) and related statistics for the random effects in the generalized linear mixed-effects model `glme`, returned as a table. `stats` has one row for each of the random effects, and one column for each of the following statistics.

|          |                                                                                                                  |
|----------|------------------------------------------------------------------------------------------------------------------|
| Group    | Grouping variable associated with the random effect                                                              |
| Level    | Level within the grouping variable corresponding to the random effect                                            |
| Name     | Name of the random-effect coefficient                                                                            |
| Estimate | Empirical Bayes predictor (EBP) of random effect                                                                 |
| SEPred   | Square root of the conditional mean squared error of prediction (CMSEP) given covariance parameters and response |
| tStat    | $t$ -statistic for a test that the random-effects coefficient is equal to 0                                      |
| DF       | Estimated degrees of freedom for the $t$ -statistic                                                              |

|                     |                                                                             |
|---------------------|-----------------------------------------------------------------------------|
| <code>pValue</code> | $p$ -value for the $t$ -statistic                                           |
| <code>Lower</code>  | Lower limit of a 95% confidence interval for the random-effects coefficient |
| <code>Upper</code>  | Upper limit of a 95% confidence interval for the random-effects coefficient |

`randomEffects` computes the confidence intervals using the conditional mean squared error of prediction (CMSEP) approach conditional on the estimated covariance parameters and the observed response. An alternative interpretation of the confidence intervals is that they are approximate Bayesian credible intervals conditional on the estimated covariance parameters and the observed response.

When fitting a GLME model using `fitglme` and one of the pseudo likelihood fit methods ('MPL' or 'REMP'), `randomEffects` computes confidence intervals and related statistics based on the fitted linear mixed-effects model from the final pseudo likelihood iteration.

## Examples

### Compute and Plot Estimated Random Effects

Navigate to the folder containing the sample data. Load the sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')

load mfr
```

This simulated data is from a manufacturing company that operates 50 factories across the world, with each factory running a batch process to create a finished product. The company wants to decrease the number of defects in each batch, so it developed a new manufacturing process. To test the effectiveness of the new process, the company selected 20 of its factories at random to participate in an experiment: Ten factories implemented the new process, while the other ten continued to run the old process. In each of the 20 factories, the company ran five batches (for a total of 100 batches) and recorded the following data:

- Flag to indicate whether the batch used the new process (`newprocess`)
- Processing time for each batch, in hours (`time`)

- Temperature of the batch, in degrees Celsius (**temp**)
- Categorical variable indicating the supplier (A, B, or C) of the chemical used in the batch (**supplier**)
- Number of defects in the batch (**defects**)

The data also includes **time\_dev** and **temp\_dev**, which represent the absolute deviation of time and temperature, respectively, from the process standard of 3 hours at 20 degrees Celsius.

Fit a generalized linear mixed-effects model using **newprocess**, **time\_dev**, **temp\_dev**, and **supplier** as fixed-effects predictors. Include a random-effects term for intercept grouped by **factory**, to account for quality differences that might exist due to factory-specific variations. The response variable **defects** has a Poisson distribution, and the appropriate link function for this model is log. Use the Laplace fit method to estimate the coefficients. Specify the dummy variable encoding as 'effects', so the dummy variable coefficients sum to 0.

The number of defects can be modeled using a Poisson distribution

$$defects_{ij} \sim \text{Poisson}(\mu_{ij})$$

This corresponds to the generalized linear mixed-effects model

$$\log(\mu_{ij}) = \beta_0 + \beta_1 newprocess_{ij} + \beta_2 time\_dev_{ij} + \beta_3 temp\_dev_{ij} + \beta_4 supplier\_C_{ij} + \beta_5 supplier\_B_{ij} +$$

where

- $defects_{ij}$  is the number of defects observed in the batch produced by factory  $i$  during batch  $j$ .
- $\mu_{ij}$  is the mean number of defects corresponding to factory  $i$  (where  $i = 1, 2, \dots, 20$ ) during batch  $j$  (where  $j = 1, 2, \dots, 5$ ).
- $newprocess_{ij}$ ,  $time\_dev_{ij}$ , and  $temp\_dev_{ij}$  are the measurements for each variable that correspond to factory  $i$  during batch  $j$ . For example,  $newprocess_{ij}$  indicates whether the batch produced by factory  $i$  during batch  $j$  used the new process.
- $supplier\_C_{ij}$  and  $supplier\_B_{ij}$  are dummy variables that use effects (sum-to-zero) coding to indicate whether company C or B, respectively, supplied the process chemicals for the batch produced by factory  $i$  during batch  $j$ .

- $b_i \sim N(0, \sigma_b^2)$  is a random-effects intercept for each factory  $i$  that accounts for factory-specific variation in quality.

```
glme = fitglme(mfr, 'defects ~ 1 + newprocess + time_dev + temp_dev + supplier + (1|factory)')
```

Compute and display the names and estimated values of the empirical Bayes predictors (EBPs) for the random effects.

```
[B, BNames] = randomEffects(glme)
```

```
B =
```

```

Each row of **B** contains the estimated EPB for the random-effects coefficient named in the corresponding row of **Bnames**. For example, the value  $-0.2633$  in row 3 of **B** is the estimated EPB for '(Intercept)' for level '3' of factory.

### Compute 99% Confidence Intervals for Random Effects

Navigate to the folder containing the sample data. Load the sample data.

```

cd(matlabroot)
cd('help/toolbox/stats/examples')

load mfr

```

This simulated data is from a manufacturing company that operates 50 factories across the world, with each factory running a batch process to create a finished product. The company wants to decrease the number of defects in each batch, so it developed a new manufacturing process. To test the effectiveness of the new process, the company selected 20 of its factories at random to participate in an experiment: Ten factories implemented the new process, while the other ten continued to run the old process. In each of the 20 factories, the company ran five batches (for a total of 100 batches) and recorded the following data:

- Flag to indicate whether the batch used the new process (**newprocess**)
- Processing time for each batch, in hours (**time**)
- Temperature of the batch, in degrees Celsius (**temp**)
- Categorical variable indicating the supplier (A, B, or C) of the chemical used in the batch (**supplier**)

- Number of defects in the batch (**defects**)

The data also includes `time_dev` and `temp_dev`, which represent the absolute deviation of time and temperature, respectively, from the process standard of 3 hours at 20 degrees Celsius.

Fit a generalized linear mixed-effects model using `newprocess`, `time_dev`, `temp_dev`, and `supplier` as fixed-effects predictors. Include a random-effects term for intercept grouped by `factory`, to account for quality differences that might exist due to factory-specific variations. The response variable `defects` has a Poisson distribution, and the appropriate link function for this model is log. Use the Laplace fit method to estimate the coefficients. Specify the dummy variable encoding as `'effects'`, so the dummy variable coefficients sum to 0.

The number of defects can be modeled using a Poisson distribution

$$defects_{ij} \sim \text{Poisson}(\mu_{ij})$$

This corresponds to the generalized linear mixed-effects model

$$\log(\mu_{ij}) = \beta_0 + \beta_1 newprocess_{ij} + \beta_2 time\_dev_{ij} + \beta_3 temp\_dev_{ij} + \beta_4 supplier\_C_{ij} + \beta_5 supplier\_B_{ij} +$$

where

- $defects_{ij}$  is the number of defects observed in the batch produced by factory  $i$  during batch  $j$ .
- $\mu_{ij}$  is the mean number of defects corresponding to factory  $i$  (where  $i = 1, 2, \dots, 20$ ) during batch  $j$  (where  $j = 1, 2, \dots, 5$ ).
- $newprocess_{ij}$ ,  $time\_dev_{ij}$ , and  $temp\_dev_{ij}$  are the measurements for each variable that correspond to factory  $i$  during batch  $j$ . For example,  $newprocess_{ij}$  indicates whether the batch produced by factory  $i$  during batch  $j$  used the new process.
- $supplier\_C_{ij}$  and  $supplier\_B_{ij}$  are dummy variables that use effects (sum-to-zero) coding to indicate whether company C or B, respectively, supplied the process chemicals for the batch produced by factory  $i$  during batch  $j$ .
- $b_i \sim N(0, \sigma_b^2)$  is a random-effects intercept for each factory  $i$  that accounts for factory-specific variation in quality.

```
glme = fitglme(mfr, 'defects ~ 1 + newprocess + time_dev + temp_dev + supplier + (1|facto
```

Compute and display the 99% confidence intervals for the random-effects coefficients.

```
[B,BNames,stats] = randomEffects(glme, 'Alpha',0.01);
stats
```

```
stats =
```

```
Random effect coefficients: DFMethod = 'residual', Alpha = 0.01

| 0.21481 | 0.27195  | 94 | 0.78626 | -0.50635 | 0.62319 |

The first three columns of `stats` contain the group name, level, and random-effects coefficient name. Column 4 contains the estimated EBP of the random-effects coefficient. The last two columns of `stats`, `Lower` and `Upper`, contain the lower and upper bounds of the 99% confidence interval, respectively. For example, for the coefficient for ' (Intercept) ' for level 3 of `factory`, the estimated EBP is `-0.26325`, and the 99% confidence interval is `[-0.82191,0.29541]`.

# randomEffects

**Class:** LinearMixedModel

Estimates of random effects and related statistics

## Syntax

```
B = randomEffects(lme)
[B,Bnames] = randomEffects(lme)
[B,Bnames,stats] = randomEffects(lme)
[B,Bnames,stats] = randomEffects(lme,Name,Value)
```

## Description

`B = randomEffects(lme)` returns the estimates of the best linear unbiased predictors (BLUPs) of random effects in the linear mixed-effects model `lme`.

`[B,Bnames] = randomEffects(lme)` also returns the names of the coefficients in `Bnames`. Each name corresponds to a coefficient in `B`.

`[B,Bnames,stats] = randomEffects(lme)` also returns the estimated BLUPs of random effects in the linear mixed-effects model `lme` and related statistics.

`[B,Bnames,stats] = randomEffects(lme,Name,Value)` also returns the BLUPs of random effects in the linear mixed-effects model `lme` and related statistics with additional options specified by one or more `Name,Value` pair arguments.

## Input Arguments

**lme** — Linear mixed-effects model

LinearMixedModel object

Linear mixed-effects model, returned as a LinearMixedModel object.

For properties and methods of this object, see LinearMixedModel.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( `' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

### 'Alpha' — Confidence level

0.05 (default) | scalar value in the range 0 to 1

Confidence level, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the range 0 to 1. For a value  $\alpha$ , the confidence level is  $100*(1-\alpha)\%$ .

For example, for 99% confidence intervals, you can specify the confidence level as follows.

Example: `'Alpha', 0.01`

Data Types: `single` | `double`

### 'DFMethod' — Method for computing approximate degrees of freedom

'Residual' (default) | 'Satterthwaite' | 'None'

Method for computing approximate degrees of freedom for the  $t$ -statistics that test the random-effects coefficients against 0, specified as the comma-separated pair consisting of `'DFMethod'` and one of the following.

`'Residual'`

Default. The degrees of freedom are assumed to be constant and equal to  $n - p$ , where  $n$  is the number of observations and  $p$  is the number of fixed effects.

`'Satterthwaite'`

Satterthwaite approximation.

`'None'`

All degrees of freedom are set to infinity.

For example, you can specify the Satterthwaite approximation as follows.

Example: `'DFMethod', 'Satterthwaite'`

## Output Arguments

### **B** — Estimated best linear unbiased predictors of random effects

column vector

Estimated best linear unbiased predictors of random effects of linear mixed-effects model `lme`, returned as a column vector.

Suppose `lme` has  $R$  grouping variables  $g_1, g_2, \dots, g_R$ , with levels  $m_1, m_2, \dots, m_R$ , respectively. Also suppose  $q_1, q_2, \dots, q_R$  are the lengths of the random-effects vectors that are associated with  $g_1, g_2, \dots, g_R$ , respectively. Then, `B` is a column vector of length  $q_1 * m_1 + q_2 * m_2 + \dots + q_R * m_R$ .

`randomEffects` creates `B` by concatenating the best linear unbiased predictors of random-effects vectors corresponding to each level of each grouping variable as `[g1level1; g1level2; ...; g1levelm1; g2level1; g2level2; ...; g2levelm2; ...; gRlevel1; gRlevel2; ...; gRlevelmR]`'.

### **Bnames** — Names of random-effects coefficients

table

Names of random-effects coefficients in `B`, returned as a table.

### **stats** — Estimates of random effects BLUPs and related statistics

dataset array

Estimates of random effects BLUPs and related statistics, returned as a dataset array that has one row for each of the fixed effects and one column for each of the following statistics.

|          |                                                                       |
|----------|-----------------------------------------------------------------------|
| Group    | Grouping variable associated with the random effect                   |
| Level    | Level within the grouping variable corresponding to the random effect |
| Name     | Name of the random-effect coefficient                                 |
| Estimate | Best linear unbiased predictor (BLUP) of random effect                |
| SEPred   | Standard error of the estimate (BLUP minus random effect)             |
| tStat    | $t$ -statistic for a test that the random effect is zero              |
| DF       | Estimated degrees of freedom for the $t$ -statistic                   |

|        |                                                                |
|--------|----------------------------------------------------------------|
| pValue | <i>p</i> -value for the <i>t</i> -statistic                    |
| Lower  | Lower limit of a 95% confidence interval for the random effect |
| Upper  | Upper limit of a 95% confidence interval for the random effect |

## Examples

### Display Random-Effects Estimates and Coefficient Names

Load the sample data.

```
load carbig
```

Fit a linear mixed-effects model for miles per gallon (MPG), with fixed effects for acceleration and horsepower, and potentially correlated random effects for intercept and acceleration, grouped by the model year. First, store the data in a table.

```
tbl = table(Acceleration,Horsepower,Model_Year,MPG);
```

Fit the model.

```
lme = fitlme(tbl, 'MPG ~ Acceleration + Horsepower + (Acceleration|Model_Year)');
```

Compute the BLUPs of the random-effects coefficients and display the names of the corresponding random effects.

```
[B,Bnames] = randomEffects(lme)
```

```
B =
```

```

Bnames =

| Group        | Level | Name           |
|--------------|-------|----------------|
| 'Model_Year' | '70'  | '(Intercept)'  |
| 'Model_Year' | '70'  | 'Acceleration' |
| 'Model_Year' | '71'  | '(Intercept)'  |
| 'Model_Year' | '71'  | 'Acceleration' |
| 'Model_Year' | '72'  | '(Intercept)'  |
| 'Model_Year' | '72'  | 'Acceleration' |
| 'Model_Year' | '73'  | '(Intercept)'  |
| 'Model_Year' | '73'  | 'Acceleration' |
| 'Model_Year' | '74'  | '(Intercept)'  |
| 'Model_Year' | '74'  | 'Acceleration' |
| 'Model_Year' | '75'  | '(Intercept)'  |
| 'Model_Year' | '75'  | 'Acceleration' |
| 'Model_Year' | '76'  | '(Intercept)'  |
| 'Model_Year' | '76'  | 'Acceleration' |
| 'Model_Year' | '77'  | '(Intercept)'  |
| 'Model_Year' | '77'  | 'Acceleration' |
| 'Model_Year' | '78'  | '(Intercept)'  |
| 'Model_Year' | '78'  | 'Acceleration' |
| 'Model_Year' | '79'  | '(Intercept)'  |
| 'Model_Year' | '79'  | 'Acceleration' |
| 'Model_Year' | '80'  | '(Intercept)'  |
| 'Model_Year' | '80'  | 'Acceleration' |
| 'Model_Year' | '81'  | '(Intercept)'  |
| 'Model_Year' | '81'  | 'Acceleration' |
| 'Model_Year' | '82'  | '(Intercept)'  |

```
'Model_Year' '82' 'Acceleration'
```

Since intercept and acceleration have potentially correlated random effects, grouped by model year of the cars, `randomEffects` creates a separate row for intercept and acceleration at each level of the grouping variable.

Compute the covariance parameters of the random effects.

```
[~,~,stats] = covarianceParameters(lme)
stats{1}
```

```
ans =
```

```
Covariance Type: FullCholesky
```

| Group      | Name1         | Name2         | Type   | Estimate  |
|------------|---------------|---------------|--------|-----------|
| Model_Year | '(Intercept)' | '(Intercept)' | 'std'  | 6.6672    |
| Model_Year | 'Weight'      | '(Intercept)' | 'corr' | -1        |
| Model_Year | 'Weight'      | 'Weight'      | 'std'  | 0.0014668 |

The correlation value suggests that random effects seem negatively correlated. Plot the random effects for intercept versus acceleration to confirm this.

```
plot(B(1:2:end),B(2:2:end), 'r*')
```

### Compute Random-Effects Estimates and Related Statistics

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load fertilizer
```

The dataset array includes data from a split-plot experiment, where soil is divided into three blocks based on the soil type: sandy, silty, and loamy. Each block is divided into five plots, where five different types of tomato plants (cherry, heirloom, grape, vine, and

plum) are randomly assigned to these plots. The tomato plants in the plots are then divided into subplots, where each subplot is treated by one of four fertilizers. This is simulated data.

Store the data in a dataset array called `ds`, for practical purposes, and define `Tomato`, `Soil`, and `Fertilizer` as categorical variables.

```
ds = fertilizer;
ds.Tomato = nominal(ds.Tomato);
ds.Soil = nominal(ds.Soil);
ds.Fertilizer = nominal(ds.Fertilizer);
```

Fit a linear mixed-effects model, where `Fertilizer` and `Tomato` are the fixed-effects variables, and the mean yield varies by the block (soil type), and the plots within blocks (tomato types within soil types) independently.

```
lme = fitlme(ds, 'Yield ~ Fertilizer * Tomato + (1|Soil) + (1|Soil:Tomato)');
```

Compute the BLUPs and related statistics for random effects.

```
[~,~,stats] = randomEffects(lme)
```

```
stats =
```

```
Random effect coefficients: DFMethod = 'Residual', Alpha = 0.05
```

| Group         | Level            | Name          | Estimate | SEPr  |
|---------------|------------------|---------------|----------|-------|
| 'Soil'        | 'Loamy'          | '(Intercept)' | 1.0061   | 2.33  |
| 'Soil'        | 'Sandy'          | '(Intercept)' | -1.5236  | 2.33  |
| 'Soil'        | 'Silty'          | '(Intercept)' | 0.51744  | 2.33  |
| 'Soil:Tomato' | 'Loamy Cherry'   | '(Intercept)' | 12.46    | 7.176 |
| 'Soil:Tomato' | 'Loamy Grape'    | '(Intercept)' | -2.6429  | 7.176 |
| 'Soil:Tomato' | 'Loamy Heirloom' | '(Intercept)' | 16.681   | 7.176 |
| 'Soil:Tomato' | 'Loamy Plum'     | '(Intercept)' | -5.0172  | 7.176 |
| 'Soil:Tomato' | 'Loamy Vine'     | '(Intercept)' | -4.6874  | 7.176 |
| 'Soil:Tomato' | 'Sandy Cherry'   | '(Intercept)' | -17.393  | 7.176 |
| 'Soil:Tomato' | 'Sandy Grape'    | '(Intercept)' | -7.3679  | 7.176 |
| 'Soil:Tomato' | 'Sandy Heirloom' | '(Intercept)' | -8.621   | 7.176 |
| 'Soil:Tomato' | 'Sandy Plum'     | '(Intercept)' | 7.669    | 7.176 |
| 'Soil:Tomato' | 'Sandy Vine'     | '(Intercept)' | 0.28246  | 7.176 |
| 'Soil:Tomato' | 'Silty Cherry'   | '(Intercept)' | 4.9326   | 7.176 |
| 'Soil:Tomato' | 'Silty Grape'    | '(Intercept)' | 10.011   | 7.176 |
| 'Soil:Tomato' | 'Silty Heirloom' | '(Intercept)' | -8.0599  | 7.176 |

|               |              |               |         |       |
|---------------|--------------|---------------|---------|-------|
| 'Soil:Tomato' | 'Silty Plum' | '(Intercept)' | -2.6519 | 7.170 |
| 'Soil:Tomato' | 'Silty Vine' | '(Intercept)' | 4.405   | 7.170 |

The first three rows contain the random-effects estimates and the statistics for the three levels, **Loamy**, **Sandy**, and **Silty** of the grouping variable **Soil**. The corresponding *p*-values 0.66918, 0.51825, and 0.82593 indicate that these random-effects are not significantly different from 0. The following 15 rows include the BLUPS of random-effects estimates for the intercept, grouped by the variable **Tomato** nested in **Soil**, i.e. interaction of **Tomato** and **Soil**.

### Compute Confidence Intervals with Specified Options

Load the sample data.

```
load carsmall
```

**Shift** and **Operator** are nominal variables.

```
shift.Shift = nominal(shift.Shift);
shift.Operator = nominal(shift.Operator);
```

Fit a linear mixed-effects model with a random intercept grouped by operator, to assess if there is a significant difference in the performance according to the time of the shift. Use the restricted maximum likelihood method.

```
lme = fitlme(shift, 'QCDev ~ Shift + (1|Operator)');
```

Compute the 99% confidence intervals for random effects using the residuals option to compute the degrees of freedom. This is the default method.

```
[~,~,stats] = randomEffects(lme, 'alpha', 0.01)
```

```
stats =
```

```
Random effect coefficients: DFMethod = 'Residual', Alpha = 0.01
```

| Group      | Level | Name          | Estimate | SEPred  | tStat   |
|------------|-------|---------------|----------|---------|---------|
| 'Operator' | '1'   | '(Intercept)' | 0.57753  | 0.90378 | 0.63902 |
| 'Operator' | '2'   | '(Intercept)' | 1.1757   | 0.90378 | 1.3009  |
| 'Operator' | '3'   | '(Intercept)' | -2.1715  | 0.90378 | -2.4027 |
| 'Operator' | '4'   | '(Intercept)' | 2.3655   | 0.90378 | 2.6174  |
| 'Operator' | '5'   | '(Intercept)' | -1.9472  | 0.90378 | -2.1546 |

Compute the 99% confidence intervals for random effects using the Satterthwaite approximation to compute the degrees of freedom.

```
[~,~,stats] = randomEffects(lme, 'DFMethod', 'Satterthwaite', 'alpha', 0.01)
stats =
```

```
Random effect coefficients: DFMethod = 'Satterthwaite', Alpha = 0.01
```

| Group      | Level | Name          | Estimate | SEPred  | tStat   |
|------------|-------|---------------|----------|---------|---------|
| 'Operator' | '1'   | '(Intercept)' | 0.57753  | 0.90378 | 0.63902 |
| 'Operator' | '2'   | '(Intercept)' | 1.1757   | 0.90378 | 1.3009  |
| 'Operator' | '3'   | '(Intercept)' | -2.1715  | 0.90378 | -2.4027 |
| 'Operator' | '4'   | '(Intercept)' | 2.3655   | 0.90378 | 2.6174  |
| 'Operator' | '5'   | '(Intercept)' | -1.9472  | 0.90378 | -2.1546 |

The Satterthwaite method usually produces smaller values for the degrees of freedom (DF), which results in larger  $p$ -values (`pValue`) and larger confidence intervals (`Lower` and `Upper`) for the random-effects estimates.

# randsample

Random sample

## Syntax

```
y = randsample(n,k)
y = randsample(population,k)
y = randsample(n,k,replacement)
y = randsample(population,k,replacement)
y = randsample(n,k,true,w)
y = randsample(population,k,true,w)
y = randsample(s,...)
```

## Description

`y = randsample(n,k)` returns a  $k$ -by-1 vector `y` of values sampled uniformly at random, without replacement, from the integers 1 to  $n$ .

`y = randsample(population,k)` returns a vector of  $k$  values sampled uniformly at random, without replacement, from the values in the vector `population`. The orientation of `y` (row or column) is the same as `population`.

`y = randsample(n,k,replacement)` or `y = randsample(population,k,replacement)` returns a sample taken with replacement if `replacement` is `true`, or without replacement if `replacement` is `false`. The default is `false`.

`y = randsample(n,k,true,w)` or `y = randsample(population,k,true,w)` returns a weighted sample taken with replacement, using a vector of positive weights `w`, whose length is  $n$ . The probability that the integer  $i$  is selected for an entry of `y` is  $w(i) / \text{sum}(w)$ . Usually, `w` is a vector of probabilities. `randsample` does not support weighted sampling without replacement.

`y = randsample(s,...)` uses the stream `s` for random number generation. `s` is a member of the `RandStream` class. Default is the MATLAB default random number stream.

## Examples

Draw a single value from the integers 1 through 10:

```
n = 10;
x = randsample(n,1);
```

Draw a single value from the population 1 through n, where  $n > 1$ :

```
y = randsample(1:n,1);
```

---

**Note:** If `population` is a numeric vector containing only nonnegative integer values, and `population` can have length 1, use

```
y = population(randsample(length(population),k))
```

instead of `y = randsample(population,k)`.

---

Generate a random sequence of the characters A, C, G, and T, with replacement, according to the specified probabilities.

```
R = randsample('ACGT',48,true,[0.15 0.35 0.35 0.15])
```

## More About

### Tips

- To randomly sample data, with or without replacement, use `datasample`.

### See Also

`rand` | `randperm` | `datasample` | `RandStream`

# randtool

Interactive random number generation

## Syntax

```
randtool
```

## Description

randtool opens the Random Number Generation Tool.

The Random Number Generation Tool is a graphical user interface that generates random samples from specified probability distributions and displays the samples as histograms. Use the tool to explore the effects of changing parameters and sample size on the distributions.

Start by selecting a distribution, then enter the desired sample size.

You can also

- Use the controls at the bottom of the window to set parameter values for the distribution and to change their upper and lower bounds.
- Draw another sample from the same distribution, with the same size and parameters.
- Export the current sample to your workspace. A dialog box enables you to provide a name for the sample.

### **See Also**

`disttool` | `dfittool`

## range

Range of values

### Syntax

```
range(X)
y = range(X,dim)
```

### Description

`range(X)` returns the difference between the maximum and the minimum of a sample. For vectors, `range(x)` is the range of the elements. For matrices, `range(X)` is a row vector containing the range of each column of `X`. For N-dimensional arrays, `range` operates along the first nonsingleton dimension of `X`.

`y = range(X,dim)` operates along the dimension `dim` of `X`.

`range` treats NaNs as missing values and ignores them.

The range is an easily-calculated estimate of the spread of a sample. Outliers have an undue influence on this statistic, which makes it an unreliable estimator.

### Examples

The range of a large sample of standard normal random numbers is approximately six. This is the motivation for the process capability indices  $C_p$  and  $C_{pk}$  in statistical quality control applications.

```
rv = normrnd(0,1,1000,5);
near6 = range(rv)
near6 =
 6.1451 6.4986 6.2909 5.8894 7.0002
```

# rangesearch

Find all neighbors within specified distance

## Syntax

```
idx = rangesearch(X,Y,r)
[idx,D]= rangesearch(X,Y,r)
[idx,D]= rangesearch(X,Y,r,Name,Value)
```

## Description

`idx = rangesearch(X,Y,r)` finds all the *X* points that are within distance *r* of the *Y* points. Rows of *X* and *Y* correspond to observations, and columns correspond to variables.

`[idx,D]= rangesearch(X,Y,r)` returns the distances between each row of *Y* and the rows of *X* that are *r* or less distant.

`[idx,D]= rangesearch(X,Y,r,Name,Value)` finds nearby points with additional options specified by one or more *Name,Value* pair arguments.

## Input Arguments

### **X**

*m*x-by-*n* numeric matrix, where each row represents one *n*-dimensional point. The number of columns *n* must equal as the number of columns in *Y*.

### **Y**

*m*y-by-*n* numeric matrix, where each row represents one *n*-dimensional point. The number of columns *n* must equal as the number of columns in *X*.

### **r**

Search radius, a scalar. `rangesearch` finds all *X* points (rows) that are within distance *r* of each *Y* point. The meaning of distance depends on the **Distance** name-value pair.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

### 'BucketSize'

Maximum number of data points in the leaf node of the *kd*-tree. This argument is only meaningful when *kd*-tree is used for finding nearest neighbors.

**Default:** 50

### 'Cov'

Positive definite matrix indicating the covariance matrix when computing the Mahalanobis distance. This argument is only valid when the `Distance` name-value pair argument is 'mahalanobis'.

**Default:** `nancov(X)`

### 'Distance'

String or function handle specifying the distance metric.

| Value         | Description                                                                                                                                                                                                                                                                                                                                                                                    |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'euclidean'   | Euclidean distance.                                                                                                                                                                                                                                                                                                                                                                            |
| 'seuclidean'  | Standardized Euclidean distance. Each coordinate difference between <code>X</code> and a query point is scaled, meaning divided by a scale value <code>S</code> . The default value of <code>S</code> is the standard deviation computed from <code>X</code> , <code>S = nanstd(X)</code> . To specify another value for <code>S</code> , use the <code>Scale</code> name-value pair argument. |
| 'mahalanobis' | Mahalanobis distance, computed using a positive definite covariance matrix <code>C</code> . The default value of <code>C</code> is the sample covariance matrix of <code>X</code> , as computed by <code>nancov(X)</code> . To specify a different value for <code>C</code> , use the 'COV' name-value pair argument.                                                                          |
| 'cityblock'   | City block distance.                                                                                                                                                                                                                                                                                                                                                                           |

| Value            | Description                                                                                                                                                                                                                                                                                                                                                                                                      |
|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'minkowski'      | Minkowski distance. The default exponent is 2. To specify a different exponent, use the 'P' name-value pair argument.                                                                                                                                                                                                                                                                                            |
| 'chebychev'      | Chebychev distance (maximum coordinate difference).                                                                                                                                                                                                                                                                                                                                                              |
| 'cosine'         | One minus the cosine of the included angle between observations (treated as vectors).                                                                                                                                                                                                                                                                                                                            |
| 'correlation'    | One minus the sample linear correlation between observations (treated as sequences of values).                                                                                                                                                                                                                                                                                                                   |
| 'hamming'        | Hamming distance, the percentage of coordinates that differ.                                                                                                                                                                                                                                                                                                                                                     |
| 'jaccard'        | One minus the Jaccard coefficient, the percentage of nonzero coordinates that differ.                                                                                                                                                                                                                                                                                                                            |
| 'spearman'       | One minus the sample Spearman's rank correlation between observations (treated as sequences of values).                                                                                                                                                                                                                                                                                                          |
| @ <i>distfun</i> | Distance function handle. <i>distfun</i> has the form<br><pre>function D2 = DISTFUN(ZI,ZJ)</pre> ...<br>where <ul style="list-style-type: none"> <li>• ZI is a 1-by-N vector containing one row of X or Y.</li> <li>• ZJ is an M2-by-N matrix containing multiple rows of X or Y.</li> <li>• D2 is an M2-by-1 vector of distances, and D2(k) is the distance between the observations ZI and ZJ(J,:).</li> </ul> |

For definitions, see “Distance Metrics”.

**Default:** NS.Distance

**'NSMethod'**

Nearest neighbors search method.

| Value    | Meaning                                                                                                                     |
|----------|-----------------------------------------------------------------------------------------------------------------------------|
| 'kdtree' | Creates and uses a <i>kd</i> -tree to find nearest neighbors.<br>'kdtree' is only valid when the distance metric is one of: |

| Value        | Meaning                                                                                                                              |
|--------------|--------------------------------------------------------------------------------------------------------------------------------------|
|              | <ul style="list-style-type: none"> <li>• 'chebyshev'</li> <li>• 'cityblock'</li> <li>• 'euclidean'</li> <li>• 'minkowski'</li> </ul> |
| 'exhaustive' | Uses the exhaustive search algorithm. The distances from all X points to each Y point are computed to find nearest neighbors.        |

**Default:** 'kdtree' when the number of columns of X is not greater than 10, X is not sparse, and the distance metric is one of the valid 'kdtree' metrics. Otherwise, the default is 'exhaustive'.

**'p'**

Positive scalar indicating the exponent of Minkowski distance. This argument is only valid when the **Distance** name-value pair argument is 'minkowski'.

**Default:** 2

**'Scale'**

Vector **S** containing nonnegative values, with length equal to the number of columns in X. Each coordinate difference between X and a query point is scaled by the corresponding element of **S**. This argument is only valid when the **Distance** name-value pair argument is 'seuclidean'.

**Default:** nanstd(X)

## Output Arguments

**idx**

*m<sub>y</sub>*-by-1 cell array, where *m<sub>y</sub>* is the number of rows in Y. **idx{I}** contains the indices of points (rows) in X whose distances to Y(I,:) are not greater than *r*. The entries in **idx{I}** are in ascending order of distance.

**D**

$m_y$ -by-1 cell array, where  $m_y$  is the number of rows in  $Y$ .  $D\{I\}$  contains the distance values between  $Y(I, :)$  and the corresponding points in  $idx\{I\}$ .

## Examples

Find the  $X$  points that are within a Euclidean distance 1.5 of each  $Y$  point. Both  $X$  and  $Y$  are samples of 5-D normally distributed variables.

```
rng('default') % for reproducibility
X = randn(100,5);
Y = randn(10,5);
[idx, dist] = rangesearch(X,Y,1.5)
```

```
idx =
 [1x7 double]
 [1x2 double]
 [1x11 double]
 [1x2 double]
 [1x12 double]
 [1x9 double]
 [89]
 [1x0 double]
 [1x0 double]
 [1x0 double]
```

```
dist =
 [1x7 double]
 [1x2 double]
 [1x11 double]
 [1x2 double]
 [1x12 double]
 [1x9 double]
 [1.1739]
 [1x0 double]
 [1x0 double]
 [1x0 double]
```

In this case, the last three  $Y$  points are more than 1.5 distant from any  $X$  point.  $X(89, :)$  is 1.1739 distant from  $Y(7, :)$ , and there is no other  $X$  point that is within distance 1.5 of  $Y(7, :)$ . There are 12 points in  $X$  within distance 1.5 of  $Y(5, :)$ .

## Alternatives

`rangesearch` is the `ExhaustiveSearcher` method for distance search. It is equivalent to the `rangesearch` function with the `NSMethod` name-value pair set to `'exhaustive'`.

`rangesearch` is the `KDTreeSearcher` method for distance search. It is equivalent to the `rangesearch` function with the `NSMethod` name-value pair set to `'kdtree'`.

## More About

### Distance Metrics

For definitions, see “Distance Metrics”.

### Tips

- For a fixed positive integer  $K$ , `knnsearch` finds  $K$  points in  $X$  that are nearest each  $Y$  point. In contrast, for a fixed positive real value  $r$ , `rangesearch` finds all the  $X$  points that are within a distance  $r$  of each  $Y$  point.

### Algorithms

For an overview of the *kd*-tree algorithm, see “*k*-Nearest Neighbor Search Using a *kd*-Tree” on page 16-13.

The exhaustive search algorithm finds the distance of each point in  $X$  to each point in  $Y$ .

- “*k*-Nearest Neighbor Search and Radius Search” on page 16-11

# rangesearch

**Class:** ExhaustiveSearcher

Find all neighbors within specified distance using `ExhaustiveSearcher` object

## Syntax

```
idx = rangesearch(NS,Y,r)
[idx,D] = rangesearch(NS,Y,r)
[idx,D] = rangesearch(NS,Y,r,Name,Value)
```

## Description

`idx = rangesearch(NS,Y,r)` finds all points in `NS.X` that are within distance `r` of the `Y` points. Rows of `NS.X` and `Y` correspond to observations, and columns correspond to variables.

`[idx,D] = rangesearch(NS,Y,r)` returns the distances between each row of `Y` and the rows of `NS.X` that are `r` or less distant.

`[idx,D] = rangesearch(NS,Y,r,Name,Value)` finds nearby points with additional options specified by one or more `Name,Value` pair arguments.

## Tips

- For a fixed positive integer `K`, `knnsearch` finds the `K` points in `NS.X` that are nearest each `Y` point. In contrast, for a fixed positive real value `r`, `rangesearch` finds all the points in `NS.X` that are within a distance `r` of each `Y` point.

## Input Arguments

**NS**

`ExhaustiveSearcher` object, constructed using `ExhaustiveSearcher` or `createns`.

**Y**

*my-by-n* numeric matrix, where each row represents one *n*-dimensional point. The number of columns *n* must equal the number of columns in `NS.X`.

**r**

Search radius, a scalar. `rangesearch` finds all `NS.X` points (rows) that are within distance `r` of each `Y` point. The meaning of distance depends on the `Distance` name-value pair argument.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**'Cov'**

Positive definite matrix indicating the covariance matrix when computing the Mahalanobis distance. This argument is only valid when the `Distance` name-value pair argument is `'mahalanobis'`.

**Default:** `nancov(X)`

**'Distance'**

String or function handle specifying the distance metric.

| Value                      | Description                                                                                                                                                                                                                                                                                                                                                                                    |
|----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>'euclidean'</code>   | Euclidean distance.                                                                                                                                                                                                                                                                                                                                                                            |
| <code>'seuclidean'</code>  | Standardized Euclidean distance. Each coordinate difference between <code>X</code> and a query point is scaled, meaning divided by a scale value <code>S</code> . The default value of <code>S</code> is the standard deviation computed from <code>X</code> , <code>S = nanstd(X)</code> . To specify another value for <code>S</code> , use the <code>Scale</code> name-value pair argument. |
| <code>'mahalanobis'</code> | Mahalanobis distance, computed using a positive definite covariance matrix <code>C</code> . The default value of <code>C</code> is the sample covariance matrix of <code>X</code> , as computed by <code>nancov(X)</code> . To                                                                                                                                                                 |

| Value            | Description                                                                                                                                                                                                                                                                                                                                                                                                              |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                  | specify a different value for <i>C</i> , use the 'Cov' name-value pair argument.                                                                                                                                                                                                                                                                                                                                         |
| 'cityblock'      | City block distance.                                                                                                                                                                                                                                                                                                                                                                                                     |
| 'minkowski'      | Minkowski distance. The default exponent is 2. To specify a different exponent, use the 'P' name-value pair argument.                                                                                                                                                                                                                                                                                                    |
| 'chebychev'      | Chebychev distance (maximum coordinate difference).                                                                                                                                                                                                                                                                                                                                                                      |
| 'cosine'         | One minus the cosine of the included angle between observations (treated as vectors).                                                                                                                                                                                                                                                                                                                                    |
| 'correlation'    | One minus the sample linear correlation between observations (treated as sequences of values).                                                                                                                                                                                                                                                                                                                           |
| 'hamming'        | Hamming distance, the percentage of coordinates that differ.                                                                                                                                                                                                                                                                                                                                                             |
| 'jaccard'        | One minus the Jaccard coefficient, the percentage of nonzero coordinates that differ.                                                                                                                                                                                                                                                                                                                                    |
| 'spearman'       | One minus the sample Spearman's rank correlation between observations (treated as sequences of values).                                                                                                                                                                                                                                                                                                                  |
| @ <i>distfun</i> | Distance function handle. <i>distfun</i> has the form<br><pre>function D2 = DISTFUN(ZI,ZJ)</pre> <pre>...</pre> where <ul style="list-style-type: none"> <li>• ZI is a 1-by-N vector containing one row of X or Y.</li> <li>• ZJ is an M2-by-N matrix containing multiple rows of X or Y.</li> <li>• D2 is an M2-by-1 vector of distances, and D2(k) is the distance between the observations ZI and ZJ(J,:).</li> </ul> |

For definitions, see “Distance Metrics”.

**Default:** NS.Distance

**'P'**

Positive scalar indicating the exponent of Minkowski distance. This argument is only valid when the Distance name-value pair argument is 'minkowski'.

**Default:** 2

**'Scale'**

Vector **S** containing nonnegative values, with length equal to the number of columns in **X**. Each coordinate difference between **X** and a query point is scaled by the corresponding element of **S**. This argument is only valid when the **Distance** name-value pair argument is `'seuclidean'`.

**Default:** `nanstd(X)`

## Output Arguments

**idx**

*m<sub>y</sub>*-by-1 cell array, where *m<sub>y</sub>* is the number of rows in **Y**. `idx{I}` contains the indices of points (rows) in **NS.X** whose distances to **Y(I, :)** are not greater than *r*. The entries in `idx{I}` are in ascending order of distance.

**D**

*m<sub>y</sub>*-by-1 cell array, where *m<sub>y</sub>* is the number of rows in **Y**. `D{I}` contains the distance values between **Y(I, :)** and the corresponding points in `idx{I}`.

## Definitions

### Distance Metrics

For definitions, see “Distance Metrics”.

## Examples

### Identify Nearest Neighbors Within a Specified Distance

Search for all nearest neighbors within a specified distance of a query point using `rangesearch` on an `ExhaustiveSearcher` model.

Specify  $X$  and  $Y$  as samples of 5-dimensional, normally distributed variables.

```
rng(1); % For reproducibility
X = randn(100,5); % Training data
Y = randn(10,5); % Query data
```

Create a  $k$ -nearest neighbors searcher using  $X$ .

```
ESMd1 = ExhaustiveSearcher(X);
```

ESMd1 is an “ExhaustiveSearcher class” model. By default, the software sets the distance metric to the Euclidean distance. You can change the default distance using the 'Distance' name-value pair argument or using dot notation.

Find the points in the training data (specifically, the property `ESMd1.X`) that are within a Euclidean distance 1.5 of each point in the query data ( $Y$ ).

```
[Idx,D] = rangesearch(ESMd1,Y,1.5)
```

Idx =

```
[1x4 double]
[1x12 double]
[1x6 double]
[1x0 double]
[1x9 double]
[10]
[1x2 double]
[1x4 double]
[1x0 double]
[1x5 double]
```

D =

```
[1x4 double]
[1x12 double]
[1x6 double]
[1x0 double]
[1x9 double]
[1.2398]
[1x2 double]
[1x4 double]
[1x0 double]
```

```
[1x5 double]
```

`Idx` and `D` are cell vectors of numeric row vectors with length equal to the number of rows of `Y` (10 in this case). `Idx{j}` is a row vector containing the row indices of `X` corresponding to all observations within 1.5 units of observation `Y(j, :)`. `D{j}` contain their distances. The software orders the indices in `Idx{j}` and distances in `D{j}` by closest to furthest.

To illustrate the meanings `Idx` and `D`, print row indices of `ESMdl.X` corresponding to those that are within 1.5 units of observation 7 in `Y`. Also, print their distances.

```
Idx{7}
D{7}
```

```
ans =
```

```
60 30
```

```
ans =
```

```
1.2620 1.2638
```

`ESMdl.X(60, :)` is the closest observation in `X` to `Y(7, :)`, and `ESMdl.X(30, :)` is the next closest. `ESMdl.X(60, :)` is 1.2620 units away from `Y(7, :)`, and `ESMdl.X(30, :)` is 1.2638 units away. `ESMdl.X(60, :)` and `ESMdl.X(30, :)` are the only two observations in `ESMdl.X` that are within 1.5 units of `Y(7, :)`.

## Algorithms

The exhaustive search algorithm finds the distance of each point in `X` to each point in `Y`.

## Alternatives

`rangesearch` is the `ExhaustiveSearcher` method for distance search. It is equivalent to the `rangesearch` function with the `NSMethod` name-value pair argument set to `'exhaustive'`.

`rangesearch` is the `KDTreeSearcher` method for distance search. It is equivalent to the `rangesearch` function with the `NSMethod` name-value pair argument set to `'kdtree'`.

`rangesearch` | `fitcknn`

## rangesearch

**Class:** KDTreeSearcher

Find all neighbors within specified distance using KDTreeSearcher object

### Syntax

```
idx = rangesearch(NS,Y,r)
[idx,D] = rangesearch(NS,Y,r)
[idx,D] = rangesearch(NS,Y,r,Name,Value)
```

### Description

`idx = rangesearch(NS,Y,r)` finds all points in `NS.X` that are within distance `r` of the `Y` points. Rows of `NS.X` and `Y` correspond to observations, and columns correspond to variables.

`[idx,D] = rangesearch(NS,Y,r)` returns the distances between each row of `Y` and the rows of `NS.X` that are `r` or less distant.

`[idx,D] = rangesearch(NS,Y,r,Name,Value)` finds nearby points with additional options specified by one or more `Name,Value` pair arguments.

### Tips

- For a fixed positive integer `K`, `knnsearch` finds the `K` points in `NS.X` that are nearest each `Y` point. In contrast, for a fixed positive real value `r`, `rangesearch` finds all the points in `NS.X` that are within a distance `r` of each `Y` point.

### Input Arguments

**NS**

KDTreeSearcher object, constructed using KDTreeSearcher or createns.

**Y**

*m*-by-*n* numeric matrix, where each row represents one *n*-dimensional point. The number of columns *n* must equal the number of columns in `NS.X`.

**r**

Search radius, a scalar. `rangesearch` finds all `NS.X` points (rows) that are within distance `r` of each `Y` point. The meaning of distance depends on the `Distance` name-value pair argument.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**'Distance'**

String or function handle specifying the distance metric.

| Value       | Description                                                                                                           |
|-------------|-----------------------------------------------------------------------------------------------------------------------|
| 'euclidean' | Euclidean distance.                                                                                                   |
| 'cityblock' | City block distance.                                                                                                  |
| 'minkowski' | Minkowski distance. The default exponent is 2. To specify a different exponent, use the 'P' name-value pair argument. |
| 'chebychev' | Chebychev distance (maximum coordinate difference).                                                                   |

For definitions, see “Distance Metrics”.

**Default:** `NS.Distance`

**'P'**

Positive scalar indicating the exponent of Minkowski distance. This argument is only valid when the `Distance` name-value pair argument is `'minkowski'`.

**Default:** 2

## Output Arguments

### **idx**

*my*-by-1 cell array, where *my* is the number of rows in *Y*. `idx{I}` contains the indices of points (rows) in *NS.X* whose distances to *Y(I, :)* are not greater than *r*. The entries in `idx{I}` are in ascending order of distance.

### **D**

*my*-by-1 cell array, where *my* is the number of rows in *Y*. `D{I}` contains the distance values between *Y(I, :)* and the corresponding points in `idx{I}`.

## Definitions

### Distance Metrics

For definitions, see “Distance Metrics”.

## Examples

### Search for All Nearest Neighbors Within a Specified Distance

Search for all nearest neighbors within a specified distance of a query point using `rangesearch` on a `KDTreeSearcher` model.

Specify *X* and *Y* as samples of 5-dimensional, normally distributed variables.

```
rng(1); % For reproducibility
X = randn(100,5); % Training data
Y = randn(10,5); % Query data
```

Grow a *K* d-tree using *X*.

```
Mdl = KDTreeSearcher(X);
```

`Mdl` is a “`KDTreeSearcher` class” model. By default, the software sets the distance metric to the Euclidean distance. You can change the default distance using the `'Distance'` name-value pair argument or using dot notation.

Find the points in the training data (specifically, the property `Mdl.X`) that are within a Euclidean distance 1.5 of each point in the query data (`Y`).

```
[Idx,D] = rangesearch(Mdl,Y,1.5)
```

```
Idx =
```

```

[1x4 double]
[1x12 double]
[1x6 double]
[1x0 double]
[1x9 double]
[10]
[1x2 double]
[1x4 double]
[1x0 double]
[1x5 double]

```

```
D =
```

```

[1x4 double]
[1x12 double]
[1x6 double]
[1x0 double]
[1x9 double]
[1.2398]
[1x2 double]
[1x4 double]
[1x0 double]
[1x5 double]

```

`Idx` and `D` are cell vectors of numeric row vectors with length equal to the number of rows of `Y` (10 in this case). `Idx{j}` is a row vector containing the row indices of `X` corresponding to all observations within 1.5 units of observation `Y(j,:)`. `D{j}` contain their distances. The software orders the indices in `Idx{j}` and distances in `D{j}` by closest to furthest.

To illustrate the meanings `Idx` and `D`, print all row indices of `Mdl.X` corresponding to those that are within 1.5 units of observation 7 in `Y`. Also, print their distances.

```
Idx{7}
```

```
D{7}
```

```
ans =
```

```
 60 30
```

```
ans =
```

```
 1.2620 1.2638
```

`Mdl.X(60, :)` is the closest observation in `X` to `Y(7, :)`, and `Mdl.X(30, :)` is the next closest. `Mdl.X(60, :)` is 1.2620 units away from `Y(7, :)`, and `Mdl.X(30, :)` is 1.2638 units away. `Mdl.X(60, :)` and `Mdl.X(30, :)` are the only two observations in `Mdl.X` that are within 1.5 units of `Y(7, :)`.

## Algorithms

For an overview of the *kd*-tree algorithm, see “*k*-Nearest Neighbor Search Using a *kd*-Tree” on page 16-13.

## Alternatives

`rangesearch` is the `KDTreeSearcher` method for distance search. It is equivalent to the `rangesearch` function with the `NSMethod` name-value pair argument set to `'kdtree'`.

`rangesearch` is the `ExhaustiveSearcher` method for distance search. It is equivalent to the `rangesearch` function with the `NSMethod` name-value pair argument set to `'exhaustive'`.

## See Also

`createns` | `knnsearch` | `pdist2` | `ClassificationKNN` | `KDTreeSearcher` | `rangesearch` | `fitcknn`

# ranksum

Wilcoxon rank sum test

## Syntax

```
p = ranksum(x,y)
[p,h] = ranksum(x,y)
[p,h,stats] = ranksum(x,y)
[___] = ranksum(x,y,Name,Value)
```

## Description

`p = ranksum(x,y)` returns the  $p$ -value of a two-sided Wilcoxon rank sum test. `ranksum` tests the null hypothesis that data in `x` and `y` are samples from continuous distributions with equal medians, against the alternative that they are not. The test assumes that the two samples are independent. `x` and `y` can have different lengths.

This test is equivalent to a Mann-Whitney U-test.

`[p,h] = ranksum(x,y)` also returns a logical value indicating the test decision. The result `h = 1` indicates a rejection of the null hypothesis, and `h = 0` indicates a failure to reject the null hypothesis at the 5% significance level.

`[p,h,stats] = ranksum(x,y)` also returns the structure `stats` with information about the test statistic.

`[ ___ ] = ranksum(x,y,Name,Value)` returns any of the output arguments in the previous syntaxes, for a rank sum test with additional options specified by one or more `Name,Value` pair arguments.

## Examples

### Test for Equal Median of Two Populations

Test the hypothesis of equal medians for two independent unequal-sized samples.

Generate sample data.

```
rng('default') % for reproducibility
x = unifrnd(0,1,10,1);
y = unifrnd(0.25,1.25,15,1);
```

These samples come from populations with identical distributions except for a shift of 0.25 in the location.

Test the equality of medians of  $x$  and  $y$ .

```
p = ranksum(x,y)
```

```
p =
 0.0375
```

The  $p$ -value of 0.0375 indicates that `ranksum` rejects the null hypothesis of equal medians at the default 5% significance level.

### Statistics of the Test for Two Population Medians

Obtain the statistics of the test for the equality of two population medians.

Load the sample data.

```
load mileage
```

Test if the mileage per gallon is the same for the first and second type of cars.

```
[p,h,stats] = ranksum(mileage(:,1),mileage(:,2))
```

```
p =
 0.0043
```

```
h =
 1
```

```
stats =
 ranksum: 21.5000
```

Both the  $p$ -value, 0.043, and  $h = 1$  indicate the rejection of the null hypothesis of equal medians at the default 5% significance level. Because the sample sizes are small (six each), `ranksum` calculates the  $p$ -value using the exact method. The structure `stats` includes only the value of the rank sum test statistic.

### Increase in the Median

Test the hypothesis of an increase in the population median.

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load weather
```

The weather data shows the daily high temperatures taken in the same month in two consecutive years.

Perform a left-sided test to assess the increase in the median at the 1% significance level.

```
[p,h,stats] = ranksum(year1,year2,'alpha',0.01,...
'tail','left')
```

```
p =
```

```
 0.1271
```

```
h =
```

```
 0
```

```
stats =
```

```
 zval: -1.1403
 ranksum: 837.5000
```

Both the  $p$ -value of 0.1271 and  $h = 0$  indicate that there is not enough evidence to reject the null hypothesis and conclude that there is a positive shift in the median of observed high temperatures in the same month from year 1 to year 2 at the 1% significance level. Notice that `ranksum` uses the approximate method to calculate the  $p$ -value due to the large sample sizes.

Use the exact method to calculate the  $p$ -value.

```
[p,h,stats] = ranksum(year1,year2,'alpha',0.01,...
'tail','left','method','exact')
```

```
p =
```

```
0.1273

h =

0

stats =

 ranksum: 837.5000
```

The results of the approximate and exact methods are consistent with each other.

## Input Arguments

### **x** — Sample data

vector

Sample data, specified as a vector.

Data Types: `single` | `double`

### **y** — Sample data

vector

Sample data, specified as a vector. The length of **y** does not have to be the same as the length of **x**.

Data Types: `single` | `double`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of **Name**,**Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as **Name1**,**Value1**, ..., **NameN**,**ValueN**.

Example: `'alpha',0.01,'method','approximate','tail','right'` specifies a right-tailed rank sum test with 1% significance level, which returns the approximate p-value.

**'alpha' — Significance level**

0.05 (default) | scalar value in the range 0 to 1

Significance level of the decision of a hypothesis test, specified as the comma-separated pair consisting of 'alpha' and a scalar value in the range 0 to 1. The significance level of  $h$  is  $100 * \alpha\%$ .

Example: 'alpha', 0.01

Data Types: double | single

**'method' — Computation method of the  $p$ -value**

'exact' | 'approximate'

Computation method of the  $p$ -value,  $p$ , specified as the comma-separated pair consisting of 'method' and one of the following:

|               |                                                            |
|---------------|------------------------------------------------------------|
| 'exact'       | Exact computation of the $p$ -value, $p$ .                 |
| 'approximate' | Normal approximation while computing the $p$ -value, $p$ . |

When 'method' is unspecified, the default is:

- 'exact' if  $\min(n_x, n_y) < 10$  and  $n_x + n_y < 20$
- 'approximate' otherwise

$n_x$  and  $n_y$  are the sizes of the samples in  $x$  and  $y$ , respectively.

Example: 'method', 'exact'

Data Types: char

**'tail' — Type of test**

'both' (default) | 'right' | 'left'

Type of test, specified as the comma-separated pair consisting of 'tail' and one of the following:

|         |                                                                                                                                                           |
|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'both'  | Two-sided hypothesis test, where the alternative hypothesis states that $x$ and $y$ have different medians. Default test type if 'tail' is not specified. |
| 'right' | Right-tailed hypothesis test, where the alternative hypothesis states that the median of $x$ is greater than the median of $y$ .                          |
| 'left'  | Left-tailed hypothesis test, where the alternative hypothesis states that the median of $x$ is less than the median of $y$ .                              |

Example: 'tail','left'

Data Types: char

## Output Arguments

### **p** — *p*-value of the test

nonnegative scalar

*p*-value of the test, returned as a positive scalar from 0 to 1. **p** is the probability of observing a test statistic as or more extreme than the observed value under the null hypothesis. `ranksum` computes the two-sided *p*-value by doubling the most significant one-sided value.

### **h** — Result of the hypothesis test

1 | 0

Result of the hypothesis test, returned as a logical value.

- If **h** = 1, this indicates rejection of the null hypothesis at the 100 \* **alpha**% significance level.
- If **h** = 0, this indicates a failure to reject the null hypothesis at the 100 \* **alpha**% significance level.

### **stats** — Test statistics

structure

Test statistics, returned as a structure. The test statistics stored in **stats** are:

- **ranksum**: Value of the rank sum test statistic
- **zval**: Value of the z-statistic (computed when 'method' is 'approximate')

## More About

### Wilcoxon Rank Sum Test

The Wilcoxon rank sum test is a nonparametric test for two populations when samples are independent. If *X* and *Y* are independent samples with different sample sizes, the test statistic which `ranksum` returns is the rank sum of the first sample.

The Wilcoxon rank sum test is equivalent to the Mann-Whitney U-test. The Mann-Whitney U-test is a nonparametric test for equality of population medians of two independent samples X and Y.

The Mann-Whitney U-test statistic,  $U$ , is the number of times a  $y$  precedes an  $x$  in an ordered arrangement of the elements in the two independent samples X and Y. It is related to the Wilcoxon rank sum statistic in the following way: If X is a sample of size  $n_X$ , then

$$U = W - \frac{n_X(n_X + 1)}{2}.$$

### **z-Statistic**

For large samples, ranksum uses a z-statistic to compute the approximate  $p$ -value of the test.

If X and Y are two independent samples of size  $n_X$  and  $n_Y$ , where  $n_X < n_Y$  the z-statistic is

$$z = \frac{W - E(W)}{\sqrt{V(W)}} = \frac{W - \left[ \frac{n_X n_Y + n_X(n_X + 1)}{2} \right] - 0.5 * \text{sign}(W - E(W))}{\sqrt{\frac{n_X n_Y (n_X + n_Y + 1) - \text{tiescor}}{12}}},$$

with continuity correction and tie adjustment. Here *tiescor* is given by

$$\text{tiescor} = \frac{2 * \text{tieadj}}{(n_X + n_Y)(n_X + n_Y - 1)},$$

where ranksum uses `[ranks,tieadj] = tiedrank(x,y)` to obtain tie adjustments. The standard normal distribution gives the  $p$ -value for this z-statistic.

### **Algorithms**

ranksum treats NaNs in  $x$  and  $y$  as missing values and ignores them.

For a two-sided test of medians with unequal sample sizes, the test statistic that ranksum returns is the rank sum of the first sample.

## ranova

**Class:** RepeatedMeasuresModel

Repeated measures analysis of variance

### Syntax

```
ranovatbl = ranova(rm)
ranovatbl = ranova(rm, 'WithinModel', WM)
[ranovatbl, A, C, D] = ranova(___)
```

### Description

`ranovatbl = ranova(rm)` returns the results of repeated measures analysis of variance for a repeated measures model `rm` in table `ranovatbl`.

`ranovatbl = ranova(rm, 'WithinModel', WM)` returns the results of repeated measures analysis of variance using the responses specified by the within-subject model `WM`.

`[ranovatbl, A, C, D] = ranova( ___ )` also returns arrays `A`, `C`, and `D` for the hypotheses tests of the form  $A*B*C = D$ , where `D` is zero.

### Input Arguments

**rm** — Repeated measures model

RepeatedMeasuresModel object

Repeated measures model, returned as a RepeatedMeasuresModel object.

For properties and methods of this object, see RepeatedMeasuresModel.

**WM** — Model specifying responses

'separatemeans' (default) | *r*-by-*nc* contrast matrix | string that defines a model specification

Model specifying the responses, specified as one of the following:

- `'separatemeans'` — Compute a separate mean for each group.
- `C` —  $r$ -by- $nc$  contrast matrix specifying the  $nc$  contrasts among the  $r$  repeated measures. If  $Y$  represents a matrix of repeated measures, `ranova` tests the hypothesis that the means of  $Y*C$  are zero.
- A string that defines a model specification in the within-subject factors. You can define the model based on the rules for the `terms` in the `modelspec` argument of `fitrm`. Also see “Model Specification for Repeated Measures Models” on page 8-50.

For example, if there are three within-subject factors `w1`, `w2`, and `w3`, then you can specify a model for the within-subject factors as follows.

Example: `'WithinModel', 'w1+w2+w2*w3'`

Data Types: `single` | `double`

## Output Arguments

### `ranovatbl` — Results of repeated measures anova

table

Results of repeated measures anova, returned as a `table`.

`ranovatbl` includes a term represents all differences across the within-subjects factors. This term has either the name of the within-subjects factor if specified while fitting the model, or the name `Time` if the name of the within-subjects factor is not specified while fitting the model or there are more than one within-subjects factors. `ranovatbl` also includes all interactions between the terms in the within-subject model and all between-subject model terms. It contains the following columns.

| Column Name | Definition                                                                                             |
|-------------|--------------------------------------------------------------------------------------------------------|
| SumSq       | Sum of squares.                                                                                        |
| DF          | Degrees of freedom.                                                                                    |
| MeanSq      | Mean squared error.                                                                                    |
| F           | $F$ -statistic.                                                                                        |
| pValue      | $p$ -value for the corresponding $F$ -statistic. A small $p$ -value indicates significant term effect. |

| Column Name | Definition                                     |
|-------------|------------------------------------------------|
| pValueGG    | $p$ -value with Greenhouse-Geisser adjustment. |
| pValueHF    | $p$ -value with Huynh-Feldt adjustment.        |
| pValueLB    | $p$ -value with Lower bound adjustment.        |

The last three  $p$ -values are the adjusted  $p$ -values for use when the compound symmetry assumption is not satisfied. For details, see “Compound Symmetry Assumption and Epsilon Corrections” on page 8-52. The `mauchy` method tests for sphericity (hence, compound symmetry) and `epsilon` method returns the epsilon adjustment values.

### A — Specification based on between-subjects model

`matrix` | `cell array`

Specification based on the between-subjects model, returned as a matrix or a cell array. It permits the hypothesis on the elements within given columns of **B** (within time hypothesis). If `ranovatbl` contains multiple hypothesis tests, **A** might be a cell array.

Data Types: `single` | `double` | `cell`

### C — Specification based on within-subjects model

`matrix` | `cell array`

Specification based on the within-subjects model, returned as a matrix or a cell array. It permits the hypotheses on the elements within given rows of **B** (between time hypotheses). If `ranovatbl` contains multiple hypothesis tests, **C** might be a cell array.

Data Types: `single` | `double` | `cell`

### D — Hypothesis value

0

Hypothesis value, returned as 0.

## Examples

### Repeated Measures Analysis of Variance

Load the sample data.

```
load fisheriris
```

The column vector `species` consists of iris flowers of three different species: `setosa`, `versicolor`, `virginica`. The double matrix `meas` consists of four types of measurements on the flowers: the length and width of sepals and petals in centimeters, respectively.

Store the data in a table array.

```
t = table(species,meas(:,1),meas(:,2),meas(:,3),meas(:,4),...
'VariableNames',{'species','meas1','meas2','meas3','meas4'});
Meas = dataset([1 2 3 4]','VarNames',{'Measurements'});
```

Fit a repeated measures model, where the measurements are the responses and the species is the predictor variable.

```
rm = fitrm(t,'meas1-meas4~species','WithinDesign',Meas);
```

Perform repeated measures analysis of variance.

```
ranovatbl = ranova(rm)
```

```
ans =
```

|                          | SumSq  | DF  | MeanSq   | F      | pValue      |
|--------------------------|--------|-----|----------|--------|-------------|
| (Intercept):Measurements | 1656.3 | 3   | 552.09   | 6873.3 | 0           |
| species:Measurements     | 282.47 | 6   | 47.078   | 586.1  | 1.4271e-206 |
| Error(Measurements)      | 35.423 | 441 | 0.080324 |        |             |

There are four measurements, three types of species, and 150 observations. So, degrees of freedom for measurements is  $(4-1) = 3$ , for species-measurements interaction it is  $(4-1)*(3-1) = 6$ , and for error it is  $(150-4)*(3-1) = 441$ . `ranova` computes the last three  $p$ -values using Greenhouse-Geisser, Huynh-Feldt, and Lower bound corrections, respectively. You can check the compound symmetry (sphericity) assumption using the `mauchly` method, and display the epsilon corrections using the `epsilon` method.

### Longitudinal Data

Navigate to the folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load('longitudinalData')
```

The matrix  $Y$  contains response data for 16 individuals. The response is the blood level of a drug measured at five time points (time = 0, 2, 4, 6, and 8). Each row of  $Y$  corresponds to an individual, and each column corresponds to a time point. The first eight subjects are female, and the second eight subjects are male. This is simulated data.

Define a variable that stores gender information.

```
Gender = ['F' 'F' 'F' 'F' 'F' 'F' 'F' 'F' 'M' 'M' 'M' 'M' 'M' 'M' 'M'];
```

Store the data in a proper table array format to do repeated measures analysis.

```
t = table(Gender, Y(:,1), Y(:,2), Y(:,3), Y(:,4), Y(:,5)), ...
 'VariableNames', {'Gender', 't0', 't2', 't4', 't6', 't8'});
```

Define the within-subjects variable.

```
Time = [0 2 4 6 8]';
```

Fit a repeated measures model, where the blood levels are the responses and gender is the predictor variable.

```
rm = fitrm(t, 't0-t8 ~ Gender', 'WithinDesign', Time);
```

Perform repeated measures analysis of variance.

```
ranovatbl = ranova(rm)
```

```
ranovatbl =
```

|                  | SumSq  | DF | MeanSq | F       | pValue     | pValueGG   |
|------------------|--------|----|--------|---------|------------|------------|
| (Intercept):Time | 881.7  | 4  | 220.43 | 37.539  | 3.0348e-15 | 4.7325e-09 |
| Gender:Time      | 17.65  | 4  | 4.4125 | 0.75146 | 0.56126    | 0.4877     |
| Error(Time)      | 328.83 | 56 | 5.872  |         |            |            |

There are 5 time points, 2 genders, and 16 observations. So, the degrees of freedom for time is  $(5-1) = 4$ , for gender-time interaction it is  $(5-1)*(2-1) = 4$ , and for error it is  $(16-2)*(5-1) = 56$ . The small  $p$ -value of  $2.6198e-05$  indicates that there is a significant effect of time on blood pressure. The  $p$ -value of 0.40063 indicates that there is no significant gender-time interaction.

### Specify the Within-Subjects Model

Load the sample data.

load `repeatedmeas`

The table `between` includes the between-subject variables `age`, `IQ`, `group`, `gender`, and eight repeated measures `y1` through `y8` as responses. The table `within` includes the within-subject variables `w1` and `w2`. This is simulated data.

Fit a repeated measures model, where the repeated measures `y1` through `y8` are the responses, and `age`, `IQ`, `group`, `gender`, and the group-gender interaction are the predictor variables. Also specify the within-subject design matrix.

```
rm = fitrm(between, 'y1-y8 ~ Group*Gender + Age + IQ', 'WithinDesign', within);
```

Perform repeated measures analysis of variance.

```
ranovatbl = anova(rm)
```

```
ranovatbl =
```

|                   | SumSq  | DF  | MeanSq | F       | pValue    | pValueGG |
|-------------------|--------|-----|--------|---------|-----------|----------|
| (Intercept):Time  | 6645.2 | 7   | 949.31 | 2.2689  | 0.031674  | 0.071235 |
| Age:Time          | 5824.3 | 7   | 832.05 | 1.9887  | 0.059978  | 0.10651  |
| IQ:Time           | 5188.3 | 7   | 741.18 | 1.7715  | 0.096749  | 0.14492  |
| Group:Time        | 15800  | 14  | 1128.6 | 2.6975  | 0.0014425 | 0.011884 |
| Gender:Time       | 4455.8 | 7   | 636.55 | 1.5214  | 0.16381   | 0.20533  |
| Group:Gender:Time | 4247.3 | 14  | 303.38 | 0.72511 | 0.74677   | 0.663    |
| Error(Time)       | 64433  | 154 | 418.39 |         |           |          |

Specify the model for the within-subject factors. Also display the matrices used in the hypothesis test.

```
[ranovatbl,A,C,D] = anova(rm, 'WithinModel', 'w1+w2')
```

```
ranovatbl =
```

|              | SumSq  | DF | MeanSq | F        | pValue    | pValueGG  |
|--------------|--------|----|--------|----------|-----------|-----------|

## Algorithms

`ranova` computes the regular  $p$ -value (in the `pValue` column of the `rmanova` table) using the  $F$ -statistic cumulative distribution function:

$p\text{-value} = 1 - \text{fcdf}(F, v_1, v_2)$ .

When the compound symmetry assumption is not satisfied, `ranova` uses a correction factor  $\epsilon$ , to compute the corrected  $p$ -values as follows:

$p\text{-value\_corrected} = 1 - \text{fcdf}(F, \epsilon^*v_1, \epsilon^*v_2)$ .

The `mauchly` method tests for sphericity (hence, compound symmetry) and `epsilon` method returns the epsilon adjustment values.

## raylcdf

Rayleigh cumulative distribution function

### Syntax

```
p = raylcdf(x,b)
p = raylcdf(x,b,'upper')
```

### Description

`p = raylcdf(x,b)` returns the Rayleigh cdf at each value in `x` using the corresponding scale parameter, `b`. `x` and `b` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input for `x` or `b` is expanded to a constant array with the same dimensions as the other input.

`p = raylcdf(x,b,'upper')` returns the complement of the Rayleigh cdf at each value in `x`, using an algorithm that more accurately computes the extreme upper tail probabilities.

The Rayleigh cdf is

$$y = F(x | b) = \int_0^x \frac{t}{b^2} e^{\left(\frac{-t^2}{2b^2}\right)} dt$$

### Examples

#### Compute and Plot Rayleigh Distribution cdf

Compute the cdf of a Rayleigh distribution with parameter `B = 1`.

```
x = 0:0.1:3;
p = raylcdf(x,1);
```

Plot the cdf.

```
figure;
plot(x,p)
```

# prob.RayleighDistribution class

**Package:** prob

**Superclasses:** prob.ToolboxFittableParametricDistribution

Rayleigh probability distribution object

## Description

`prob.RayleighDistribution` is an object consisting of parameters, a model description, and sample data for a normal probability distribution.

Create a probability distribution object with specified parameter values using `makedist`. Alternatively, fit a distribution to data using `fitdist` or the Distribution Fitting app.

## Construction

`pd = makedist('Rayleigh')` creates a Rayleigh probability distribution object using the default parameter values.

`pd = makedist('Rayleigh', 'b', b)` creates a Rayleigh probability distribution object using the specified parameter value.

## Input Arguments

**b** — Defining parameter

1 (default) | positive scalar value

Defining parameter for the Rayleigh distribution, specified as a positive scalar value.

Data Types: `single` | `double`

## Properties

**b** — Defining parameter

positive scalar value

Defining parameter for the Rayleigh distribution, stored as a positive scalar value.

Data Types: `single` | `double`

**DistributionName** — Probability distribution name

probability distribution name string

Probability distribution name, stored as a valid probability distribution name string. This property is read-only.

Data Types: `char`

**InputData** — Data used for distribution fitting

structure

Data used for distribution fitting, stored as a structure containing the following:

- **data**: Data vector used for distribution fitting.
- **cens**: Censoring vector, or empty if none.
- **freq**: Frequency vector, or empty if none.

This property is read-only.

Data Types: `struct`

**IsTruncated** — Logical flag for truncated distribution

0 | 1

Logical flag for truncated distribution, stored as a logical value. If `IsTruncated` equals 0, the distribution is not truncated. If `IsTruncated` equals 1, the distribution is truncated. This property is read-only.

Data Types: `logical`

**NumParameters** — Number of parameters

positive integer value

Number of parameters for the probability distribution, stored as a positive integer value. This property is read-only.

Data Types: `single` | `double`

**ParameterCovariance** — Covariance matrix of the parameter estimates

matrix of scalar values

Covariance matrix of the parameter estimates, stored as a  $p$ -by- $p$  matrix, where  $p$  is the number of parameters in the distribution. The  $(i,j)$  element is the covariance between

the estimates of the  $i$ th parameter and the  $j$ th parameter. The  $(i,i)$  element is the estimated variance of the  $i$ th parameter. If parameter  $i$  is fixed rather than estimated by fitting the distribution to data, then the  $(i,i)$  elements of the covariance matrix are 0. This property is read-only.

Data Types: `single` | `double`

### **ParameterDescription** — Distribution parameter descriptions

cell array of strings

Distribution parameter descriptions, stored as a cell array of strings. Each cell contains a short description of one distribution parameter. This property is read-only.

Data Types: `char`

### **ParameterIsFixed** — Logical flag for fixed parameters

array of logical values

Logical flag for fixed parameters, stored as an array of logical values. If 0, the corresponding parameter in the `ParameterNames` array is not fixed. If 1, the corresponding parameter in the `ParameterNames` array is fixed. This property is read-only.

Data Types: `logical`

### **ParameterNames** — Distribution parameter names

cell array of strings

Distribution parameter names, stored as a cell array of strings. This property is read-only.

Data Types: `char`

### **ParameterValues** — Distribution parameter values

vector of scalar values

Distribution parameter values, stored as a vector. This property is read-only.

Data Types: `single` | `double`

### **Truncation** — Truncation interval

vector of scalar values

Truncation interval for the probability distribution, stored as a vector containing the lower and upper truncation boundaries. This property is read-only.

Data Types: `single` | `double`

## Methods

## Definitions

### Rayleigh Distribution

The Rayleigh distribution is a special case of the Weibull distribution. It is often used in communication theory to model scattered signals that reach a receiver by multiple paths.

The Rayleigh distribution uses the following parameter.

| Parameter | Description        | Support |
|-----------|--------------------|---------|
| b         | Defining parameter | $b > 0$ |

The probability density function (pdf) is

$$f(x | b) = \frac{x}{b^2} \exp\left\{\frac{-x^2}{2b^2}\right\} ; \quad x \geq 0.$$

## Examples

### Create a Rayleigh Distribution Object Using Default Parameters

Create a Rayleigh distribution object using the default parameter values.

```
pd = makedist('Rayleigh')
```

```
pd =
```

```
RayleighDistribution
```

```
Rayleigh distribution
B = 1
```

### Create a Rayleigh Distribution Object Using Specified Parameters

Create a Rayleigh distribution object by specifying the parameter values.

```
pd = makedist('Rayleigh','b',3)
```

```
pd =
```

```
RayleighDistribution
```

```
Rayleigh distribution
B = 3
```

Compute the mean of the distribution.

```
m = mean(pd)
```

```
m =
```

```
3.7599
```

# raylfit

Rayleigh parameter estimates

## Syntax

```
raylfit(data,alpha)
[phat,pci] = raylfit(data,alpha)
```

## Description

`raylfit(data,alpha)` returns the maximum likelihood estimates of the parameter of the Rayleigh distribution given the data in the vector `data`.

`[phat,pci] = raylfit(data,alpha)` returns the maximum likelihood estimate and  $100(1 - \alpha)\%$  confidence interval given the data. The default value of the optional parameter `alpha` is 0.05, corresponding to 95% confidence intervals.

## More About

- “Rayleigh Distribution” on page B-129

## raylinv

Rayleigh inverse cumulative distribution function

### Syntax

```
X = raylinv(P,B)
```

### Description

`X = raylinv(P,B)` returns the inverse of the Rayleigh cumulative distribution function using the corresponding scale parameter, `B` at the corresponding probabilities in `P`. `P` and `B` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input for `P` or `B` is expanded to a constant array with the same dimensions as the other input.

### Examples

```
x = raylinv(0.9,1)
x =
 2.1460
```

### More About

- `icdf`
- “Rayleigh Distribution” on page B-129

### See Also

`raylcdf` | `raylpdf` | `raylrnd` | `raylstat`

# raylpdf

Rayleigh probability density function

## Syntax

```
Y = raylpdf(X,B)
```

## Description

`Y = raylpdf(X,B)` computes the Rayleigh pdf at each of the values in `X` using the corresponding scale parameter, `B`. `X` and `B` can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of `Y`. A scalar input for `X` or `B` is expanded to a constant array with the same dimensions as the other input.

The Rayleigh pdf is

$$y = f(x | b) = \frac{x}{b^2} e^{\left(\frac{-x^2}{2b^2}\right)}$$

## Examples

### Compute and Plot Rayleigh Distribution pdf

Compute the pdf of a Rayleigh distribution with parameter `B = 0.5`.

```
x = [0:0.01:2];
p = raylpdf(x,0.5);
```

Plot the pdf.

```
figure;
plot(x,p)
```

## More About

- “Rayleigh Distribution” on page B-129

pdf | raylcdf | raylinv | raylstat | raylfit | raylrnd

# raylrnd

Rayleigh random numbers

## Syntax

```
R = raylrnd(B)
R = raylrnd(B,v)
R = raylrnd(B,m,n)
```

## Description

`R = raylrnd(B)` returns a matrix of random numbers chosen from the Rayleigh distribution with scale parameter, **B**. **B** can be a vector, a matrix, or a multidimensional array. The size of **R** is the size of **B**.

`R = raylrnd(B,v)` returns a matrix of random numbers chosen from the Rayleigh distribution with parameter **B**, where **v** is a row vector. If **v** is a 1-by-2 vector, **R** is a matrix with **v(1)** rows and **v(2)** columns. If **v** is 1-by-*n*, **R** is an *n*-dimensional array.

`R = raylrnd(B,m,n)` returns a matrix of random numbers chosen from the Rayleigh distribution with parameter **B**, where scalars **m** and **n** are the row and column dimensions of **R**.

## Examples

```
r = raylrnd(1:5)
r =
 1.7986 0.8795 3.3473 8.9159 3.5182
```

## More About

- “Rayleigh Distribution” on page B-129

## See Also

random | raylpdf | raylcdf | raylinv | raylstat | raylfit

## raylstat

Rayleigh mean and variance

### Syntax

```
[M,V] = raylstat(B)
```

### Description

`[M,V] = raylstat(B)` returns the mean of and variance for the Rayleigh distribution with scale parameter `B`.

The mean of the Rayleigh distribution with parameter  $b$  is  $b\sqrt{\pi/2}$  and the variance is

$$\frac{4-\pi}{2}b^2$$

### Examples

```
[mn,v] = raylstat(1)
mn =
 1.2533
v =
 0.4292
```

### More About

- “Rayleigh Distribution” on page B-129

# rcoplot

Residual case order plot

## Syntax

```
rcoplot(r,rint)
```

## Description

`rcoplot(r,rint)` displays an errorbar plot of the confidence intervals on the residuals from a regression. The residuals appear in the plot in case order. Inputs `r` and `rint` are outputs from the `regress` function.

## Examples

The following plots residuals and prediction intervals from a regression of a linearly additive model to the data in `moore.mat`:

```
load moore
X = [ones(size(moore,1),1) moore(:,1:5)];
y = moore(:,6);
alpha = 0.05;
[betahat,Ibeta,res,Ires,stats] = regress(y,X,alpha);
rcoplot(res,Ires)
```

The interval around the first residual, shown in red, does not contain zero. This indicates that the residual is larger than expected in 95% of new observations, and suggests the data point is an outlier.

**See Also**  
regress

# refcurve

Add reference curve to plot

## Syntax

```
refcurve(p)
refcurve
hcurve = refcurve(...)
```

## Description

`refcurve(p)` adds a polynomial reference curve with coefficients `p` to the current axes. If `p` is a vector with `n+1` elements, the curve is:

$$y = p(1)*x^n + p(2)*x^{(n-1)} + \dots + p(n)*x + p(n+1)$$

`refcurve` with no input arguments adds a line along the  $x$  axis.

`hcurve = refcurve(...)` returns the handle `hcurve` to the curve.

## Examples

### Add Population and Fitted Mean Functions

Generate data with a polynomial trend.

```
p = [1 -2 -1 0];
t = 0:0.1:3;
rng default % For reproducibility
y = polyval(p,t) + 0.5*randn(size(t));
```

Plot data and add the population mean function using `refcurve`.

```
plot(t,y,'ro')
h = refcurve(p);
h.Color = 'r';
```

Also add the fitted mean function.

```
q = polyfit(t,y,3);
refcurve(q)
legend('Data', 'Population Mean', 'Fitted Mean', ...
 'Location', 'NW')
```

### Plot Trajectories of a Batted Baseball Using refcurve

Introduce the relevant physical constants.

```

M = 0.145; % Mass (kg)
R = 0.0366; % Radius (m)
A = pi*R^2; % Area (m^2)
rho = 1.2; % Density of air (kg/m^3)
C = 0.5; % Drag coefficient
D = rho*C*A/2; % Drag proportional to the square of the speed
g = 9.8; % Acceleration due to gravity (m/s^2)

```

Simulate the trajectory with drag proportional to the square of the speed, assuming constant acceleration in each time interval.

```
dt = 1e-2; % Simulation time interval (s)
r0 = [0 1]; % Initial position (m)
s0 = 50; % Initial speed (m/s)
alpha0 = 35; % Initial angle (deg)
v0 = s0*[cosd(alpha0) sind(alpha0)]; % Initial velocity (m/s)

r = r0;
v = v0;
trajectory = r0;
while r(2) > 0
 a = [0 -g] - (D/M)*norm(v)*v;
 v = v + a*dt;
 r = r + v*dt + (1/2)*a*(dt^2);
 trajectory = [trajectory;r];
end
```

Plot trajectory and use `refcurve` to add the drag-free parabolic trajectory (found analytically) to the plot of trajectory.

```
figure
plot(trajectory(:,1),trajectory(:,2),'m','LineWidth',2)
xlim([0,250])
h = refcurve([-g/(2*v0(1)^2),...
 (g*r0(1)/v0(1)^2) + (v0(2)/v0(1)),...
 (-g*r0(1)^2/(2*v0(1)^2) - (v0(2)*r0(1)/v0(1)) + r0(2)]);
h.Color = 'c';
h.LineWidth = 2;
axis equal
ylim([0,50])
grid on
xlabel('Distance (m)')
ylabel('Height (m)')
title('{\bf Baseball Trajectories}')
legend('With Drag','Without Drag')
```

**See Also**

refline | lsline | gline | polyfit

## refit

**Class:** GeneralizedLinearMixedModel

Refit generalized linear mixed-effects model

## Syntax

```
glmenew = refit(glme, ynew)
```

## Description

`glmenew = refit(glme, ynew)` returns a refitted generalized linear mixed-effects model, `glmenew`, based on the input model `glme`, using a new response vector, `ynew`.

## Tips

- You can use `refit` and `random` to conduct a simulated likelihood ratio test or parametric bootstrap.

## Input Arguments

**glme** — Generalized linear mixed-effects model

GeneralizedLinearMixedModel object

Generalized linear mixed-effects model, specified as a `GeneralizedLinearMixedModel` object. For properties and methods of this object, see `GeneralizedLinearMixedModel`.

**ynew** — New response vector

$n$ -by-1 vector of scalar values

New response vector, specified as an  $n$ -by-1 vector of scalar values, where  $n$  is the number of observations used to fit `glme`.

For an observation  $i$  with prior weights  $w_i^p$  and binomial size  $n_i$  (when applicable), the response values  $y_i$  contained in `ynew` can have the following values.

| Distribution    | Permitted Values                                                       | Notes                                      |
|-----------------|------------------------------------------------------------------------|--------------------------------------------|
| Binomial        | $\left\{0, \frac{1}{w_i^p n_i}, \frac{2}{w_i^p n_i}, \dots, 1\right\}$ | $w_i^p$ and $n_i$ are integer values $> 0$ |
| Poisson         | $\left\{0, \frac{1}{w_i^p}, \frac{2}{w_i^p}, \dots, 1\right\}$         | $w_i^p$ is an integer value $> 0$          |
| Gamma           | $(0, \infty)$                                                          | $w_i^p \geq 0$                             |
| InverseGaussian | $(0, \infty)$                                                          | $w_i^p \geq 0$                             |
| Normal          | $(-\infty, \infty)$                                                    | $w_i^p \geq 0$                             |

You can access the prior weights property  $w_i^p$  using dot notation.

```
glme.ObservationInfo.Weights
```

Data Types: `single` | `double`

## Output Arguments

### **glmenew** — Generalized linear mixed-effects model

GeneralizedLinearMixedModel object

Generalized linear mixed-effects model, returned as a `GeneralizedLinearMixedModel` object. `glmenew` is an updated version of the generalized linear mixed-effects model `glme`, refit to the values in the response vector `ynew`.

For properties and methods of this object, see `GeneralizedLinearMixedModel`.

## Examples

### Refit Model to New Response Vector

Navigate to the folder containing the sample data. Load the sample data.

```
cd(matlabroot)
```

```
cd('help/toolbox/stats/examples')
```

```
load mfr
```

This simulated data is from a manufacturing company that operates 50 factories across the world, with each factory running a batch process to create a finished product. The company wants to decrease the number of defects in each batch, so it developed a new manufacturing process. To test the effectiveness of the new process, the company selected 20 of its factories at random to participate in an experiment: Ten factories implemented the new process, while the other ten continued to run the old process. In each of the 20 factories, the company ran five batches (for a total of 100 batches) and recorded the following data:

- Flag to indicate whether the batch used the new process (**newprocess**)
- Processing time for each batch, in hours (**time**)
- Temperature of the batch, in degrees Celsius (**temp**)
- Categorical variable indicating the supplier (A, B, or C) of the chemical used in the batch (**supplier**)
- Number of defects in the batch (**defects**)

The data also includes **time\_dev** and **temp\_dev**, which represent the absolute deviation of time and temperature, respectively, from the process standard of 3 hours at 20 degrees Celsius.

Fit a generalized linear mixed-effects model using **newprocess**, **time\_dev**, **temp\_dev**, and **supplier** as fixed-effects predictors. Include a random-effects term for intercept grouped by **factory**, to account for quality differences that might exist due to factory-specific variations. The response variable **defects** has a Poisson distribution, and the appropriate link function for this model is log. Use the Laplace fit method to estimate the coefficients. Specify the dummy variable encoding as **'effects'**, so the dummy variable coefficients sum to 0.

The number of defects can be modeled using a Poisson distribution

$$defects_{ij} \sim \text{Poisson}(\mu_{ij})$$

This corresponds to the generalized linear mixed-effects model

$$\log(\mu_{ij}) = \beta_0 + \beta_1 \text{newprocess}_{ij} + \beta_2 \text{time\_dev}_{ij} + \beta_3 \text{temp\_dev}_{ij} + \beta_4 \text{supplier\_C}_{ij} + \beta_5 \text{supplier\_B}_{ij} +$$

where

- $defects_{ij}$  is the number of defects observed in the batch produced by factory  $i$  during batch  $j$ .
- $\mu_{ij}$  is the mean number of defects corresponding to factory  $i$  (where  $i = 1, 2, \dots, 20$ ) during batch  $j$  (where  $j = 1, 2, \dots, 5$ ).
- $newprocess_{ij}$ ,  $time\_dev_{ij}$ , and  $temp\_dev_{ij}$  are the measurements for each variable that correspond to factory  $i$  during batch  $j$ . For example,  $newprocess_{ij}$  indicates whether the batch produced by factory  $i$  during batch  $j$  used the new process.
- $supplier\_C_{ij}$  and  $supplier\_B_{ij}$  are dummy variables that use effects (sum-to-zero) coding to indicate whether company C or B, respectively, supplied the process chemicals for the batch produced by factory  $i$  during batch  $j$ .
- $b_i \sim N(0, \sigma_b^2)$  is a random-effects intercept for each factory  $i$  that accounts for factory-specific variation in quality.

```
glme = fitglme(mfr, 'defects ~ 1 + newprocess + time_dev + temp_dev + supplier + (1|factory)')
```

Use `random` to simulate a new response vector from the fitted model.

```
rng(0, 'twister'); % For reproducibility
ynew = random(glme);
```

Refit the model using the new response vector.

```
glme = refit(glme, ynew)
```

```
glme =
```

Generalized linear mixed-effects model fit by ML

# refline

Add reference line to plot

## Syntax

```
refline(m,b)
refline(coeffs)
refline
refline(ax, ___)
hline = refline(___)
```

## Description

`refline(m,b)` adds a reference line with slope `m` and intercept `b` to the current axes.

`refline(coeffs)`, where `coeffs` is a two-element coefficient vector, adds the line

$$y = coeffs(1)*x + coeffs(2)$$

to the figure.

`refline` with no input arguments is equivalent to `lsline`.

`refline(ax, ___)` adds a reference line to the plot in the axis specified by `ax`, using any of the previous syntaxes.

`hline = refline( ___ )` returns the handle `hline` to the line.

## Examples

### Add a Reference Line at the Mean

Generate sample data for independent variable `x` and a dependent variable `y`.

```
x = 1:10;
```

```
y = x + randn(1,10);
```

Create a scatter plot of  $x$  and  $y$  .

```
scatter(x,y,25,'b','*')
```

Superimpose a least-squares line on the scatter plot.

```
lsline
```

Add a reference line at the mean of the scatter and its least-squares line.

```
mu = mean(y);
hline = refline([0 mu]);
hline.Color = 'r';
```

The red line shows the reference line at the mean of data.

### Specify Axes for Least-Squares and Reference Lines

Define the x-variable and two different y-variables to use for the plots.

```
rng default % For reproducibility
x = 1:10;
y1 = x + randn(1,10);
y2 = 2*x + randn(1,10);
```

Define `ax1` as the top half of the figure, and `ax2` as the bottom half of the figure. Create the first scatter plot on the top axis using `y1`, and the second scatter plot on the bottom axis using `y2`.

```
figure
ax1 = subplot(2,1,1);
ax2 = subplot(2,1,2);

scatter(ax1,x,y1)
scatter(ax2,x,y2)
```

Superimpose a least-squares line on the top plot, and a reference line at the mean of the  $y_2$  values in the bottom plot.

```
lsline(ax1)

mu = mean(y2);
refline(ax2,[0 mu])
```

## regress

Multiple linear regression

### Syntax

```
b = regress(y,X)
[b,bint] = regress(y,X)
[b,bint,r] = regress(y,X)
[b,bint,r,rint] = regress(y,X)
[b,bint,r,rint,stats] = regress(y,X)
[...] = regress(y,X,alpha)
```

### Description

`b = regress(y,X)` returns a  $p$ -by-1 vector **b** of coefficient estimates for a multilinear regression of the responses in **y** on the predictors in **X**. **X** is an  $n$ -by- $p$  matrix of  $p$  predictors at each of  $n$  observations. **y** is an  $n$ -by-1 vector of observed responses.

`regress` treats NaNs in **X** or **y** as missing values, and ignores them.

If the columns of **X** are linearly dependent, `regress` obtains a basic solution by setting the maximum number of elements of **b** to zero.

`[b,bint] = regress(y,X)` returns a  $p$ -by-2 matrix **bint** of 95% confidence intervals for the coefficient estimates. The first column of **bint** contains lower confidence bounds for each of the  $p$  coefficient estimates; the second column contains upper confidence bounds.

If the columns of **X** are linearly dependent, `regress` returns zeros in elements of **bint** corresponding to the zero elements of **b**.

`[b,bint,r] = regress(y,X)` returns an  $n$ -by-1 vector **r** of residuals.

`[b,bint,r,rint] = regress(y,X)` returns an  $n$ -by-2 matrix **rint** of intervals that can be used to diagnose outliers. If the interval `rint(i,:)` for observation **i** does

not contain zero, the corresponding residual is larger than expected in 95% of new observations, suggesting an outlier.

In a linear model, observed values of  $y$  are random variables, and so are their residuals. Residuals have normal distributions with zero mean but with different variances at different values of the predictors. To put residuals on a comparable scale, they are “Studentized,” that is, they are divided by an estimate of their standard deviation that is independent of their value. Studentized residuals have  $t$  distributions with known degrees of freedom. The intervals returned in `rint` are shifts of the 95% confidence intervals of these  $t$  distributions, centered at the residuals.

`[b,bint,r,rint,stats] = regress(y,X)` returns a 1-by-4 vector `stats` that contains, in order, the  $R^2$  statistic, the  $F$  statistic and its  $p$  value, and an estimate of the error variance.

---

**Note:** When computing statistics,  $X$  should include a column of 1s so that the model contains a constant term. The  $F$  statistic and its  $p$  value are computed under this assumption, and they are not correct for models without a constant.

The  $F$  statistic is the test statistic of the F-test on the regression model, for a significant linear regression relationship between the response variable and the predictor variables.

The  $R^2$  statistic can be negative for models without a constant, indicating that the model is not appropriate for the data.

---

`[...] = regress(y,X,alpha)` uses a  $100*(1-alpha)\%$  confidence level to compute `bint` and `rint`.

## Examples

### Estimate Multiple Linear Regression Coefficients

This example shows how to estimate the coefficients of a multiple linear regression.

Load the sample data. Identify weight and horsepower as predictors, and mileage as the response.

```
load carsmall
```

```
x1 = Weight;
x2 = Horsepower; % Contains NaN data
y = MPG;
```

Compute the regression coefficients for a linear model with an interaction term.

```
X = [ones(size(x1)) x1 x2 x1.*x2];
b = regress(y,X) % Removes NaN data
```

```
b =

 60.7104
 -0.0102
 -0.1882
 0.0000
```

Plot the data and the model.

```
scatter3(x1,x2,y,'filled')
hold on
x1fit = min(x1):100:max(x1);
x2fit = min(x2):10:max(x2);
[X1FIT,X2FIT] = meshgrid(x1fit,x2fit);
YFIT = b(1) + b(2)*X1FIT + b(3)*X2FIT + b(4)*X1FIT.*X2FIT;
mesh(X1FIT,X2FIT,YFIT)
xlabel('Weight')
ylabel('Horsepower')
zlabel('MPG')
view(50,10)
```

# RegressionBaggedEnsemble class

**Superclasses:** RegressionEnsemble

Regression ensemble grown by resampling

## Description

RegressionBaggedEnsemble combines a set of trained weak learner models and data on which these learners were trained. It can predict ensemble response for new data by aggregating predictions from its weak learners.

## Construction

`ens = fitensemble(X,Y,'bag',nlearn,learners,'type','regression')` creates a bagged regression ensemble. For more information on the syntax, see the `fitensemble` function reference page.

## Properties

### CategoricalPredictors

List of categorical predictors. `CategoricalPredictors` is a numeric vector with indices from 1 to `p`, where `p` is the number of columns of `X`.

### CombineWeights

A string describing how the ensemble combines learner predictions.

### FitInfo

A numeric array of fit information. The `FitInfoDescription` property describes the content of this array.

### FitInfoDescription

String describing the meaning of the `FitInfo` array.

**FResample**

A numeric scalar between 0 and 1. `FResample` is the fraction of training data `fitensemble` resampled at random for every weak learner when constructing the ensemble.

**LearnerNames**

Cell array of strings with names of the weak learners in the ensemble. The name of each learner appears just once. For example, if you have an ensemble of 100 trees, `LearnerNames` is `{ 'Tree' }`.

**Method**

A string with the name of the algorithm `fitensemble` used for training the ensemble.

**ModelParameters**

Parameters used in training `ens`.

**NumObservations**

Numeric scalar containing the number of observations in the training data.

**NumTrained**

Number of trained learners in the ensemble, a positive scalar.

**PredictorNames**

A cell array of names for the predictor variables, in the order in which they appear in `X`.

**ReasonForTermination**

A string describing the reason `fitensemble` stopped adding weak learners to the ensemble.

**Regularization**

A structure containing the result of the `regularize` method. Use `Regularization` with `shrink` to lower resubstitution error and shrink the ensemble.

**Replace**

Boolean flag indicating if training data for weak learners in this ensemble were sampled with replacement. **Replace** is **true** for sampling with replacement, **false** otherwise.

**ResponseName**

A string with the name of the response variable Y.

**ResponseTransform**

Function handle for transforming scores, or string representing a built-in transformation function. 'none' means no transformation; equivalently, 'none' means  $@(x)x$ .

Add or change a **ResponseTransform** function using dot notation:

```
ens.ResponseTransform = @function
```

**Trained**

The trained learners, a cell array of compact regression models.

**TrainedWeights**

A numeric vector of weights the ensemble assigns to its learners. The ensemble computes predicted response by aggregating weighted predictions from its learners.

**UseObsForLearner**

A logical matrix of size N-by-NumTrained, where N is the number of rows (observations) in the training data X, and NumTrained is the number of trained weak learners. **UseObsForLearner(I,J)** is **true** if observation I was used for training learner J, and is **false** otherwise.

**W**

The scaled weights, a vector with length n, the number of rows in X. The sum of the elements of W is 1.

**X**

The matrix of predictor values that trained the ensemble. Each column of X represents one variable, and each row represents one observation.

**Y**

The numeric column vector with the same number of rows as *X* that trained the ensemble. Each entry in *Y* is the response to the data in the corresponding row of *X*.

**Methods**

|                         |                                         |

## Copy Semantics

Value. To learn how value classes affect copy operations, see “Copying Objects” in the MATLAB documentation.

## Examples

Create a bagged regression ensemble to predict the mileage of cars in the `carsmall` data set based on their engine displacement, horsepower, and weight:

```
load carsmall
X = [Displacement Horsepower Weight];
ens = fitensemble(X,MPG,'bag',100,'Tree',...
 'type','regression')

ens =

classreg.learning.regr.RegressionBaggedEnsemble:
 PredictorNames: {'x1' 'x2' 'x3'}
 CategoricalPredictors: []
 ResponseName: 'Y'
 ResponseTransform: 'none'
 NumObservations: 94
 NumTrained: 100
 Method: 'Bag'
 LearnerNames: {'Tree'}
 ReasonForTermination: [1x77 char]
 FitInfo: []
 FitInfoDescription: 'None'
 Regularization: []
 FResample: 1
```

```
 Replace: 1
UseObsForLearner: [94x100 logical]
```

Predict the mileage of a car whose characteristics are the average of those of the first 10 cars:

```
car10 = mean(X(1:10,:));
predict(ens,car10)
```

```
ans =
 14.6569
```

# RegressionEnsemble class

**Superclasses:** CompactRegressionEnsemble

Ensemble regression

## Description

RegressionEnsemble combines a set of trained weak learner models and data on which these learners were trained. It can predict ensemble response for new data by aggregating predictions from its weak learners.

## Construction

`ens = fitensemble(X,Y,method,nlearn,learners)` returns an ensemble model that can predict responses to data. The ensemble consists of models listed in `learners`. For more information on the syntax, see the `fitensemble` function reference page.

`ens = fitensemble(X,Y,method,nlearn,learners,Name,Value)` returns an ensemble model with additional options specified by one or more `Name,Value` pair arguments. For more information on the syntax, see the `fitensemble` function reference page.

## Properties

### CategoricalPredictors

List of categorical predictors. `CategoricalPredictors` is a numeric vector with indices from 1 to `p`, where `p` is the number of columns of `X`.

### CombineWeights

A string describing how the ensemble combines learner predictions.

### FitInfo

A numeric array of fit information. The `FitInfoDescription` property describes the content of this array.

**FitInfoDescription**

String describing the meaning of the `FitInfo` array.

**LearnerNames**

Cell array of strings with names of the weak learners in the ensemble. The name of each learner appears just once. For example, if you have an ensemble of 100 trees, `LearnerNames` is `{ 'Tree' }`.

**Method**

A string with the name of the algorithm `fitensemble` used for training the ensemble.

**ModelParameters**

Parameters used in training `ens`.

**NumObservations**

Numeric scalar containing the number of observations in the training data.

**NumTrained**

Number of trained learners in the ensemble, a positive scalar.

**PredictorNames**

A cell array of names for the predictor variables, in the order in which they appear in `X`.

**ReasonForTermination**

A string describing the reason `fitensemble` stopped adding weak learners to the ensemble.

**Regularization**

A structure containing the result of the `regularize` method. Use `Regularization` with `shrink` to lower resubstitution error and shrink the ensemble.

**ResponseName**

A string with the name of the response variable `Y`.

**ResponseTransform**

Function handle for transforming scores, or string representing a built-in transformation function. 'none' means no transformation; equivalently, 'none' means  $@(x)x$ .

Add or change a ResponseTransform function using dot notation:

```
ens.ResponseTransform = @function
```

**Trained**

The trained learners, a cell array of compact regression models.

**TrainedWeights**

A numeric vector of weights the ensemble assigns to its learners. The ensemble computes predicted response by aggregating weighted predictions from its learners.

**W**

The scaled weights, a vector with length  $n$ , the number of rows in  $X$ . The sum of the elements of  $W$  is 1.

**X**

The matrix of predictor values that trained the ensemble. Each column of  $X$  represents one variable, and each row represents one observation.

**Y**

The numeric column vector with the same number of rows as  $X$  that trained the ensemble. Each entry in  $Y$  is the response to the data in the corresponding row of  $X$ .

**Methods**

|          |                                             |
|----------|---------------------------------------------|
| compact  | Create compact regression ensemble          |
| crossval | Cross validate ensemble                     |

|              |                                                                 |
|--------------|-----------------------------------------------------------------|
| regularize   | Find weights to minimize resubstitution error plus penalty term |
| resubLoss    | Regression error by resubstitution                              |
| resubPredict | Predict response of ensemble by resubstitution                  |
| resume       | Resume training ensemble                                        |
| shrink       | Prune ensemble                                                  |

## Inherited Methods

|                     |                                               |
|---------------------|-----------------------------------------------|
| loss                | Regression error                              |
| predict             | Predict response of ensemble                  |
| predictorImportance | Estimates of predictor importance             |
| removeLearners      | Remove members of compact regression ensemble |

## Copy Semantics

Value. To learn how value classes affect copy operations, see “Copying Objects” in the MATLAB documentation.

## Examples

Create a boosted regression ensemble to predict the mileage of cars in the `carsmall` data set based on their weights and numbers of cylinders:

```
load carsmall
learner = templateTree('MinParent',20);
ens = fitensemble([Weight, Cylinders],MPG,...
 'LSBoost',100,learner,'PredictorNames',{ 'W', 'C'},...
 'categoricalpredictors',2)

ens =
classreg.learning.regr.RegistrationEnsemble:
 PredictorNames: {'W' 'C'}
 CategoricalPredictors: 2
 ResponseName: 'Response'
 ResponseTransform: 'none'
 NumObservations: 94
 NumTrained: 100
 Method: 'LSBoost'
 LearnerNames: {'Tree'}
 ReasonForTermination: [1x77 char]
 FitInfo: [100x1 double]
 FitInfoDescription: [2x83 char]
 Regularization: []
```

Predict the mileage of 4,000-pound cars with 4, 6, and 8 cylinders:

```
mileage4K = predict(ens,[4000 4; 4000 6; 4000 8])
```

```
mileage4K =
 20.0294
 19.4206
 15.5000
```

## RegressionPartitionedEnsemble class

**Superclasses:** RegressionPartitionedModel

Cross-validated regression ensemble

### Description

`RegressionPartitionedEnsemble` is a set of regression ensembles trained on cross-validated folds. Estimate the quality of classification by cross validation using one or more “kfold” methods: `kfoldfun`, `kfoldLoss`, or `kfoldPredict`. Every “kfold” method uses models trained on in-fold observations to predict response for out-of-fold observations. For example, suppose you cross validate using five folds. In this case, every training fold contains roughly 4/5 of the data and every test fold contains roughly 1/5 of the data. The first model stored in `Trained{1}` was trained on `X` and `Y` with the first 1/5 excluded, the second model stored in `Trained{2}` was trained on `X` and `Y` with the second 1/5 excluded, and so on. When you call `kfoldPredict`, it computes predictions for the first 1/5 of the data using the first model, for the second 1/5 of data using the second model and so on. In short, response for every observation is computed by `kfoldPredict` using the model trained without this observation.

### Construction

`cvens = crossval(ens)` creates a cross-validated ensemble from `ens`, a regression ensemble. For syntax details, see the `CROSSVAL` method reference page.

`cvens = fitensemble(X,Y,method,nlearn,learners,name,value)` creates a cross-validated ensemble when `name` is one of `'crossval'`, `'kfold'`, `'holdout'`, `'leaveout'`, or `'cvpartition'`. For syntax details, see the `fitensemble` function reference page.

### Input Arguments

**ens**

A regression ensemble constructed with `fitensemble`.

## Properties

### **CategoricalPredictors**

List of categorical predictors. `CategoricalPredictors` is a numeric vector with indices from 1 to `p`, where `p` is the number of columns of `X`.

### **CrossValidatedModel**

Name of the cross-validated model, a string.

### **Kfold**

Number of folds used in a cross-validated tree, a positive integer.

### **ModelParameters**

Object holding parameters of tree.

### **NumObservations**

Numeric scalar containing the number of observations in the training data.

### **NTrainedPerFold**

Vector of `Kfold` elements. Each entry contains the number of trained learners in this cross-validation fold.

### **Partition**

The partition of class `cvpartition` used in creating the cross-validated ensemble.

### **PredictorNames**

A cell array of names for the predictor variables, in the order in which they appear in `X`.

### **ResponseName**

Name of the response variable `Y`, a string.

### **ResponseTransform**

Function handle for transforming scores, or string representing a built-in transformation function. 'none' means no transformation; equivalently, 'none' means  $@(x)x$ .

Add or change a `ResponseTransform` function using dot notation:

```
ens.ResponseTransform = @function
```

### **Trainable**

Cell array of ensembles trained on cross-validation folds. Every ensemble is full, meaning it contains its training data and weights.

### **Trained**

Cell array of compact ensembles trained on cross-validation folds.

### **W**

The scaled weights, a vector with length `n`, the number of rows in `X`.

### **X**

A matrix of predictor values. Each column of `X` represents one variable, and each row represents one observation.

### **Y**

A numeric column vector with the same number of rows as `X`. Each entry in `Y` is the response to the data in the corresponding row of `X`.

## **Methods**

`kfoldLoss`

Cross-validation loss of partitioned regression ensemble

`resume`

Resume training ensemble

## **Inherited Methods**

`kfoldfun`

Cross validate function

|                           |                                                          |
|---------------------------|----------------------------------------------------------|
| <code>kfoldLoss</code>    | Cross-validation loss of partitioned regression model    |
| <code>kfoldPredict</code> | Predict response for observations not used for training. |

## Copy Semantics

Value. To learn how value classes affect copy operations, see “Copying Objects” in the MATLAB documentation.

## Examples

Construct a partitioned regression ensemble, and examine the cross-validation losses for the folds:

```
load carsmall
XX = [Cylinders Displacement Horsepower Weight];
YY = MPG;
rens = fitensemble(XX,YY,'LSBoost',100,'Tree');
cvrens = crossval(rens);
L = kfoldLoss(cvrens,'mode','individual')
```

```
L =
 42.4468
 12.3158
 65.9432
 39.0019
 30.5908
 16.6225
 17.3071
 46.1769
 8.0561
 12.9689
```

## See Also

RegressionPartitionedModel

## RegressionPartitionedModel class

Cross-validated regression model

### Description

`RegressionPartitionedModel` is a set of regression models trained on cross-validated folds. Estimate the quality of regression by cross validation using one or more “kfold” methods: `kfoldPredict`, `kfoldLoss`, and `kfoldfun`. Every “kfold” method uses models trained on in-fold observations to predict response for out-of-fold observations. For example, suppose you cross validate using five folds. In this case, every training fold contains roughly 4/5 of the data and every test fold contains roughly 1/5 of the data. The first model stored in `Trained{1}` was trained on `X` and `Y` with the first 1/5 excluded, the second model stored in `Trained{2}` was trained on `X` and `Y` with the second 1/5 excluded, and so on. When you call `kfoldPredict`, it computes predictions for the first 1/5 of the data using the first model, for the second 1/5 of data using the second model and so on. In short, response for every observation is computed by `kfoldPredict` using the model trained without this observation.

### Construction

`cvmodel = crossval(tree)` creates a cross-validated classification model from a regression tree. For syntax details, see the `crossval` method reference page.

`cvmodel = fitrtree(X,Y,Name,Value)` creates a cross-validated model when `name` is one of 'CrossVal', 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'. For syntax details, see the `fitrtree` function reference page.

### Input Arguments

#### **tree**

A regression tree constructed with `fitrtree`.

## Properties

### **CategoricalPredictors**

List of categorical predictors. `CategoricalPredictors` is a numeric vector with indices from 1 to  $p$ , where  $p$  is the number of columns of  $X$ .

### **CrossValidatedModel**

Name of the cross-validated model, a string.

### **Kfold**

Number of folds used in a cross-validated tree, a positive integer.

### **ModelParameters**

Object holding parameters of tree.

### **Partition**

The partition of class `cvpartition` used in the cross-validated model.

### **PredictorNames**

A cell array of names for the predictor variables, in the order in which they appear in  $X$ .

### **ResponseName**

Name of the response variable  $Y$ , a string.

### **ResponseTransform**

Function handle for transforming the raw response values (mean squared error). The function handle should accept a matrix of response values and return a matrix of the same size. The default string 'none' means  $@(x)x$ , or no transformation.

Add or change a `ResponseTransform` function using dot notation:

```
ctree.ResponseTransform = @function
```

### **Trained**

The trained learners, a cell array of compact regression models.

**W**

The scaled weights, a vector with length  $n$ , the number of rows in  $X$ .

**X**

A matrix of predictor values. Each column of  $X$  represents one variable, and each row represents one observation.

**Y**

A numeric column vector with the same number of rows as  $X$ . Each entry in  $Y$  is the response to the data in the corresponding row of  $X$ .

## Methods

`kfoldfun`

Cross validate function

`kfoldLoss`

Cross-validation loss of partitioned regression model

`kfoldPredict`

Predict response for observations not used for training.

## Copy Semantics

Value. To learn how value classes affect copy operations, see “Copying Objects” in the MATLAB documentation.

## Examples

### Evaluate Cross-Validation Error

Load the sample data. Create a variable  $X$  containing the `Horsepower` and `Weight` data.

```
load carsmall
```

```
X = [Horsepower Weight];
```

Construct a regression tree using the sample data.

```
tree = fitrtree(X,MPG);
```

Evaluate the cross-validation error of the `carsmall` data using `Horsepower` and `Weight` as predictor variables for mileage (`MPG`).

```
L = kfoldLoss(cvtree)
```

```
L =
```

```
26.4414
```

## RegressionTree class

**Superclasses:** CompactRegressionTree

Regression tree

### Description

A decision tree with binary splits for regression. An object of class `RegressionTree` can predict responses for new data with the `predict` method. The object contains the data used for training, so can compute resubstitution predictions.

### Construction

`tree = fitrtree(x,y)` returns a regression tree based on the input variables (also known as predictors, features, or attributes) `x` and output (response) `y`. `tree` is a binary tree where each branching node is split based on the values of a column of `x`.

`tree = fitrtree(x,y,Name,Value)` fits a tree with additional options specified by one or more `Name,Value` pair arguments.

### Input Arguments

**x**

A matrix of predictor values. Each column of `x` represents one variable, and each row represents one observation.

`fitrtree` considers NaN values in `x` as missing values. `fitrtree` does not use observations with all missing values for `x` the fit. `fitrtree` uses observations with some missing values for `x` to find splits on variables for which these observations have valid values.

**y**

A numeric column vector with the same number of rows as `x`. Each entry in `y` is the response to the data in the corresponding row of `x`.

`fitrtree` considers NaN values in `y` to be missing values. `fitrtree` does not use observations with missing values for `y` in the fit.

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`,`Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

#### 'CategoricalPredictors' — Categorical predictors list

numeric or logical vector | cell array of strings | character matrix | 'all'

Categorical predictors list, specified as the comma-separated pair consisting of 'CategoricalPredictors' and one of the following.

- A numeric vector with indices from 1 to `p`, where `p` is the number of columns of `x`.
- A logical vector of length `p`, where a `true` entry means that the corresponding column of `x` is a categorical variable.
- A cell array of strings, where each element in the array is the name of a predictor variable. The names must match entries in the `PredictorNames` property.
- A character matrix, where each row of the matrix is a name of a predictor variable. Pad the names with extra blanks so each row of the character matrix has the same length.
- 'all', meaning all predictors are categorical.

Data Types: `single` | `double` | `logical` | `char` | `cell`

#### 'CrossVal' — Cross-validation flag

'off' (default) | 'on'

Cross-validation flag, specified as the comma-separated pair consisting of 'CrossVal' and either 'on' or 'off'.

If 'on', `fitrtree` grows a cross-validated decision tree with 10 folds. You can override this cross-validation setting using one of the 'KFold', 'Holdout', 'Leaveout', or 'CVPartition' name-value pair arguments. Note that you can only use one of these four options ('KFold', 'Holdout', 'Leaveout', or 'CVPartition') at a time when creating a cross-validated tree.

Alternatively, cross-validate tree later using the `crossval` method.

Example: `'CrossVal', 'on'`

**'CVPartition' — Partition for cross-validation tree**

`cvpartition` object

Partition for cross-validated tree, specified as the comma-separated pair consisting of `'CVPartition'` and an object created using `cvpartition`.

Note that if you use `'CVPartition'`, you cannot use any of the `'KFold'`, `'Holdout'`, or `'Leaveout'` name-value pair arguments.

**'Holdout' — Fraction of data for holdout validation**

0 (default) | scalar value in the range `[0, 1]`

Fraction of data used for holdout validation, specified as the comma-separated pair consisting of `'Holdout'` and a scalar value in the range `[0, 1]`. Holdout validation tests the specified fraction of the data, and uses the rest of the data for training.

Note that if you use `'Holdout'`, you cannot use any of the `'CVPartition'`, `'KFold'`, or `'Leaveout'` name-value pair arguments.

Example: `'Holdout', 0.1`

Data Types: `single` | `double`

**'KFold' — Number of folds**

10 (default) | positive integer value

Number of folds to use in a cross-validated tree, specified as the comma-separated pair consisting of `'KFold'` and a positive integer value.

Note that if you use `'KFold'`, you cannot use any of the `'CVPartition'`, `'Holdout'`, or `'Leaveout'` name-value pair arguments.

Example: `'KFold', 8`

Data Types: `single` | `double`

**'Leaveout' — Leave-one-out cross-validation flag**

`'off'` (default) | `'on'`

Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of `'Leaveout'` and either `'on'` or `'off'`. Use leave-one-out cross validation by setting to `'on'`.

Note that if you use 'Leaveout', you cannot use any of the 'CVPartition', 'Holdout', or 'KFold' name-value pair arguments.

Example: 'Leaveout', 'on'

### **'MergeLeaves' — Leaf merge flag**

'on' (default) | 'off'

Leaf merge flag, specified as the comma-separated pair consisting of 'MergeLeaves' and 'on' or 'off'.

If MergeLeaves is 'on', then RegressionTree:

- Merges leaves that originate from the same parent node, and that yields a sum of risk values greater or equal to the risk associated with the parent node
- Estimates the optimal sequence of pruned subtrees, but does not prune the regression tree

Otherwise, RegressionTree does not merge leaves.

Example: 'MergeLeaves', 'off'

### **'MinLeafSize' — Minimum number of leaf node observations**

1 (default) | positive integer value

Minimum number of leaf node observations, specified as the comma-separated pair consisting of 'MinLeafSize' and a positive integer value. Each leaf has at least MinLeafSize observations per tree leaf. If you supply both MinParentSize and MinLeafSize, fitrtree uses the setting that gives larger leaves:  $\text{MinParentSize} = \max(\text{MinParentSize}, 2 * \text{MinLeafSize})$ .

Example: 'MinLeafSize', 3

Data Types: single | double

### **'MinParentSize' — Minimum number of branch node observations**

10 (default) | positive integer value

Minimum number of branch node observations, specified as the comma-separated pair consisting of 'MinParentSize' and a positive integer value. Each branch node in the tree has at least MinParentSize observations. If you supply both MinParentSize and MinLeafSize, fitrtree uses the setting that gives larger leaves:  $\text{MinParentSize} = \max(\text{MinParentSize}, 2 * \text{MinLeafSize})$ .

Example: `'MinParentSize',8`

Data Types: `single` | `double`

**'NumVariablesToSample' — Number of predictors for split**

`'all'` (default) | positive integer value

Number of predictors to select at random for each split, specified as the comma-separated pair consisting of `'NumVariablesToSample'` and a positive integer value. You can also specify `'all'` to use all available predictors.

Example: `'NumVariablesToSample',3`

Data Types: `single` | `double`

**'PredictorNames' — Predictor variable names**

`{'x1','x2',...}` (default) | cell array of strings

Predictor variable names, specified as the comma-separated pair consisting of `'PredictorNames'` and a cell array of strings containing the names for the predictor variables, in the order in which they appear in `x`.

Data Types: `cell`

**'Prune' — Flag to estimate optimal sequence of pruned subtrees**

`'on'` (default) | `'off'`

Flag to estimate the optimal sequence of pruned subtrees, specified as the comma-separated pair consisting of `'Prune'` and `'on'` or `'off'`.

If `Prune` is `'on'`, then `RegressionTree` grows the regression tree and estimates the optimal sequence of pruned subtrees, but does not prune the regression tree. Otherwise, `RegressionTree` grows the regression tree without estimating the optimal sequence of pruned subtrees.

To prune a trained regression tree, pass the regression tree to `prune`.

Example: `'Prune','off'`

**'PruneCriterion' — Pruning criterion**

`'error'` (default)

Pruning criterion, specified as the comma-separated pair consisting of `'PruneCriterion'` and `'error'`.

Example: 'PruneCriterion', 'error'

**'QuadraticErrorTolerance' — Quadratic error tolerance**

1e-6 (default) | positive scalar value

Quadratic error tolerance per node, specified as the comma-separated pair consisting of 'QuadraticErrorTolerance' and a positive scalar value. Splitting nodes stops when quadratic error per node drops below  $\text{QuadraticErrorTolerance} \times \text{QED}$ , where QED is the quadratic error for the entire data computed before the decision tree is grown.

Example: 'QuadraticErrorTolerance', 1e-4

**'ResponseName' — Response variable name**

'Y' (default) | string

Response variable name, specified as the comma-separated pair consisting of 'ResponseName' and a string containing the name of the response variable in y.

Example: 'ResponseName', 'Response'

Data Types: char

**'ResponseTransform' — Response transform function**

'none' (default) | function handle

Response transform function for transforming the raw response values, specified as the comma-separated pair consisting of 'ResponseTransform' and either a function handle or 'none'. The function handle should accept a matrix of response values and return a matrix of the same size. The default string 'none' means  $@(x) x$ , or no transformation.

Add or change a ResponseTransform function using dot notation:

```
tree.ResponseTransform = @function
```

Data Types: function\_handle

**'SplitCriterion' — Split criterion**

'MSE' (default)

Split criterion, specified as the comma-separated pair consisting of 'SplitCriterion' and 'MSE', meaning mean squared error.

Example: 'SplitCriterion', 'MSE'

**'Surrogate' — Surrogate decision splits flag**`'off' | 'on' | 'all' | positive integer value`

Surrogate decision splits flag, specified as the comma-separated pair consisting of 'Surrogate' and 'on', 'off', 'all', or a positive integer value.

- When 'on', `fitrtree` finds at most 10 surrogate splits at each branch node.
- When set to a positive integer value, `fitrtree` finds at most the specified number of surrogate splits at each branch node.
- When set to 'all', `fitrtree` finds all surrogate splits at each branch node. The 'all' setting can use much time and memory.

Use surrogate splits to improve the accuracy of predictions for data with missing values. The setting also enables you to compute measures of predictive association between predictors.

Example: 'Surrogate', 'on'

Data Types: `single` | `double`

**'Weights' — Observation weights**`ones(size(X,1),1) (default) | vector of scalar values`

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a vector of scalar values. The length of `Weights` is the number of rows in `x`.

Data Types: `single` | `double`

## Properties

**CategoricalPredictors**

List of categorical predictors, a numeric vector with indices from 1 to `p`, where `p` is the number of columns of `X`.

**CategoricalSplits**

An  $n$ -by-2 cell array, where  $n$  is the number of categorical splits in tree. Each row in `CategoricalSplits` gives left and right values for a categorical split. For each branch node with categorical split `j` based on a categorical predictor variable `z`, the left child is chosen if `z` is in `CategoricalSplits(j,1)` and the right child is chosen if `z` is in

`CategoricalSplits(j,2)`. The splits are in the same order as nodes of the tree. Nodes for these splits can be found by running `cuttype` and selecting 'categorical' cuts from top to bottom.

### **Children**

An  $n$ -by-2 array containing the numbers of the child nodes for each node in tree, where  $n$  is the number of nodes. Leaf nodes have child node 0.

### **CutCategories**

An  $n$ -by-2 cell array of the categories used at branches in tree, where  $n$  is the number of nodes. For each branch node  $i$  based on a categorical predictor variable  $x$ , the left child is chosen if  $x$  is among the categories listed in `CutCategories{i,1}`, and the right child is chosen if  $x$  is among those listed in `CutCategories{i,2}`. Both columns of `CutCategories` are empty for branch nodes based on continuous predictors and for leaf nodes.

`CutPoint` contains the cut points for 'continuous' cuts, and `CutCategories` contains the set of categories.

### **CutPoint**

An  $n$ -element vector of the values used as cut points in tree, where  $n$  is the number of nodes. For each branch node  $i$  based on a continuous predictor variable  $x$ , the left child is chosen if  $x < \text{CutPoint}(i)$  and the right child is chosen if  $x \geq \text{CutPoint}(i)$ . `CutPoint` is NaN for branch nodes based on categorical predictors and for leaf nodes.

### **CutType**

An  $n$ -element cell array indicating the type of cut at each node in tree, where  $n$  is the number of nodes. For each node  $i$ , `CutType{i}` is:

- 'continuous' — If the cut is defined in the form  $x < v$  for a variable  $x$  and cut point  $v$ .
- 'categorical' — If the cut is defined by whether a variable  $x$  takes a value in a set of categories.
- '' — If  $i$  is a leaf node.

`CutPoint` contains the cut points for 'continuous' cuts, and `CutCategories` contains the set of categories.

**CutPredictor**

An  $n$ -element cell array of the names of the variables used for branching in each node in tree, where  $n$  is the number of nodes. These variables are sometimes known as *cut variables*. For leaf nodes, `CutPredictor` contains an empty string.

`CutPoint` contains the cut points for 'continuous' cuts, and `CutCategories` contains the set of categories.

**IsBranchNode**

An  $n$ -element logical vector `ib` that is `true` for each branch node and `false` for each leaf node of tree.

**ModelParameters**

Object holding parameters of tree.

**NumObservations**

Number of observations in the training data, a numeric scalar. `NumObservations` can be less than the number of rows of input data  $X$  when there are missing values in  $X$  or response  $Y$ .

**NodeError**

An  $n$ -element vector `e` of the errors of the nodes in tree, where  $n$  is the number of nodes. `e(i)` is the misclassification probability for node  $i$ .

**NodeMean**

An  $n$ -element numeric array with mean values in each node of tree, where  $n$  is the number of nodes in the tree. Every element in `NodeMean` is the average of the true  $Y$  values over all observations in the node.

**NodeProbability**

An  $n$ -element vector `p` of the probabilities of the nodes in tree, where  $n$  is the number of nodes. The probability of a node is computed as the proportion of observations from the original data that satisfy the conditions for the node. This proportion is adjusted for any prior probabilities assigned to each class.

**NodeRisk**

An  $n$ -element vector of the risk of the nodes in the tree, where  $n$  is the number of nodes. The risk for each node is the node error weighted by the node probability.

**NodeSize**

An  $n$ -element vector `sizes` of the sizes of the nodes in tree, where  $n$  is the number of nodes. The size of a node is defined as the number of observations from the data used to create the tree that satisfy the conditions for the node.

**NumNodes**

The number of nodes  $n$  in tree.

**Parent**

An  $n$ -element vector `p` containing the number of the parent node for each node in tree, where  $n$  is the number of nodes. The parent of the root node is 0.

**PredictorNames**

A cell array of names for the predictor variables, in the order in which they appear in `X`.

**PruneAlpha**

Numeric vector with one element per pruning level. If the pruning level ranges from 0 to  $M$ , then `PruneAlpha` has  $M + 1$  elements sorted in ascending order. `PruneAlpha(1)` is for pruning level 0 (no pruning), `PruneAlpha(2)` is for pruning level 1, and so on.

**PruneList**

An  $n$ -element numeric vector with the pruning levels in each node of tree, where  $n$  is the number of nodes. The pruning levels range from 0 (no pruning) to  $M$ , where  $M$  is the distance between the deepest leaf and the root node.

**ResponseName**

Name of the response variable `Y`, a string.

**ResponseTransform**

Function handle for transforming the raw response values (mean squared error). The function handle should accept a matrix of response values and return a matrix of the same size. The default string 'none' means  $@(x)x$ , or no transformation.

Add or change a `ResponseTransform` function using dot notation:

```
tree.ResponseTransform = @function
```

### **SurrogateCutCategories**

An  $n$ -element cell array of the categories used for surrogate splits in tree, where  $n$  is the number of nodes in tree. For each node  $k$ , `SurrogateCutCategories{k}` is a cell array. The length of `SurrogateCutCategories{k}` is equal to the number of surrogate predictors found at this node. Every element of `SurrogateCutCategories{k}` is either an empty string for a continuous surrogate predictor, or is a two-element cell array with categories for a categorical surrogate predictor. The first element of this two-element cell array lists categories assigned to the left child by this surrogate split, and the second element of this two-element cell array lists categories assigned to the right child by this surrogate split. The order of the surrogate split variables at each node is matched to the order of variables in `SurrogateCutPredictor`. The optimal-split variable at this node does not appear. For nonbranch (leaf) nodes, `SurrogateCutCategories` contains an empty cell.

### **SurrogateCutFlip**

An  $n$ -element cell array of the numeric cut assignments used for surrogate splits in tree, where  $n$  is the number of nodes in tree. For each node  $k$ , `SurrogateCutFlip{k}` is a numeric vector. The length of `SurrogateCutFlip{k}` is equal to the number of surrogate predictors found at this node. Every element of `SurrogateCutFlip{k}` is either zero for a categorical surrogate predictor, or a numeric cut assignment for a continuous surrogate predictor. The numeric cut assignment can be either  $-1$  or  $+1$ . For every surrogate split with a numeric cut  $C$  based on a continuous predictor variable  $Z$ , the left child is chosen if  $Z < C$  and the cut assignment for this surrogate split is  $+1$ , or if  $Z \geq C$  and the cut assignment for this surrogate split is  $-1$ . Similarly, the right child is chosen if  $Z \geq C$  and the cut assignment for this surrogate split is  $+1$ , or if  $Z < C$  and the cut assignment for this surrogate split is  $-1$ . The order of the surrogate split variables at each node is matched to the order of variables in `SurrogateCutPredictor`. The optimal-split variable at this node does not appear. For nonbranch (leaf) nodes, `SurrogateCutFlip` contains an empty array.

### **SurrogateCutPoint**

An  $n$ -element cell array of the numeric values used for surrogate splits in tree, where  $n$  is the number of nodes in tree. For each node  $k$ , `SurrogateCutPoint{k}` is a numeric vector. The length of `SurrogateCutPoint{k}` is equal to the number of surrogate predictors found at this node. Every element of `SurrogateCutPoint{k}` is either

NaN for a categorical surrogate predictor, or a numeric cut for a continuous surrogate predictor. For every surrogate split with a numeric cut  $C$  based on a continuous predictor variable  $Z$ , the left child is chosen if  $Z < C$  and `SurrogateCutFlip` for this surrogate split is +1, or if  $Z \geq C$  and `SurrogateCutFlip` for this surrogate split is -1. Similarly, the right child is chosen if  $Z \geq C$  and `SurrogateCutFlip` for this surrogate split is +1, or if  $Z < C$  and `SurrogateCutFlip` for this surrogate split is -1. The order of the surrogate split variables at each node is matched to the order of variables returned by `SurrCutPredictor`. The optimal-split variable at this node does not appear. For nonbranch (leaf) nodes, `SurrogateCutPoint` contains an empty cell.

### **SurrogateCutType**

An  $n$ -element cell array indicating types of surrogate splits at each node in tree, where  $n$  is the number of nodes in tree. For each node  $k$ , `SurrogateCutType{k}` is a cell array with the types of the surrogate split variables at this node. The variables are sorted by the predictive measure of association with the optimal predictor in the descending order, and only variables with the positive predictive measure are included. The order of the surrogate split variables at each node is matched to the order of variables in `SurrogateCutPredictor`. The optimal-split variable at this node does not appear. For nonbranch (leaf) nodes, `SurrogateCutType` contains an empty cell. A surrogate split type can be either 'continuous' if the cut is defined in the form  $Z < V$  for a variable  $Z$  and cut point  $V$  or 'categorical' if the cut is defined by whether  $Z$  takes a value in a set of categories.

### **SurrogateCutPredictor**

An  $n$ -element cell array of the names of the variables used for surrogate splits in each node in tree, where  $n$  is the number of nodes in tree. Every element of `SurrogateCutPredictor` is a cell array with the names of the surrogate split variables at this node. The variables are sorted by the predictive measure of association with the optimal predictor in the descending order, and only variables with the positive predictive measure are included. The optimal-split variable at this node does not appear. For nonbranch (leaf) nodes, `SurrogateCutPredictor` contains an empty cell.

### **SurrogatePredictorAssociation**

An  $n$ -element cell array of the predictive measures of association for surrogate splits in tree, where  $n$  is the number of nodes in tree. For each node  $k$ , `SurrogatePredictorAssociation{k}` is a numeric vector. The length of `SurrogatePredictorAssociation{k}` is equal to the number of surrogate predictors found at this node. Every element of `SurrogatePredictorAssociation{k}` gives

the predictive measure of association between the optimal split and this surrogate split. The order of the surrogate split variables at each node is the order of variables in `SurrogateCutPredictor`. The optimal-split variable at this node does not appear. For nonbranch (leaf) nodes, `SurrogatePredictorAssociation` contains an empty cell.

## W

The scaled weights, a vector with length  $n$ , the number of rows in  $X$ .

## X

A matrix of predictor values. Each column of  $X$  represents one variable, and each row represents one observation.

## Y

A numeric column vector with the same number of rows as  $X$ . Each entry in  $Y$  is the response to the data in the corresponding row of  $X$ .

## Methods

|                           |                                         |

## Copy Semantics

Value. To learn how value classes affect copy operations, see “Copying Objects” in the MATLAB documentation.

## Examples

### Construct a Regression Tree

Load the sample data.

```
load carsmall;
```

Construct a regression tree using the sample data.

```
tree = fitrtree([Weight, Cylinders],MPG,...
 'categoricalpredictors',2,'MinParentSize',20,...
 'PredictorNames',{'W','C'})
```

```
tree =
```

```
RegressionTree
 PredictorNames: {'W' 'C'}
 ResponseName: 'Y'
 ResponseTransform: 'none'
 CategoricalPredictors: 2
 NumObservations: 94
```

Predict the mileage of 4,000-pound cars with 4, 6, and 8 cylinders.

```
mileage4K = predict(tree,[4000 4; 4000 6; 4000 8])
```

```
mileage4K =
```

# regstats

Regression diagnostics

## Syntax

```
regstats(y,X,model)
stats = regstats(...)
stats = regstats(y,X,model,whichstats)
```

## Description

`regstats(y,X,model)` performs a multilinear regression of the responses in `y` on the predictors in `X`. `X` is an  $n$ -by- $p$  matrix of  $p$  predictors at each of  $n$  observations. `y` is an  $n$ -by-1 vector of observed responses.

---

**Note:** By default, `regstats` adds a first column of 1s to `X`, corresponding to a constant term in the model. Do not enter a column of 1s directly into `X`.

---

The optional input `model` controls the regression model. By default, `regstats` uses a linear additive model with a constant term. `model` can be any one of the following strings:

- 'linear' — Constant and linear terms (the default)
- 'interaction' — Constant, linear, and interaction terms
- 'quadratic' — Constant, linear, interaction, and squared terms
- 'purequadratic' — Constant, linear, and squared terms

Alternatively, `model` can be a matrix of model terms accepted by the `x2fx` function. See `x2fx` for a description of this matrix and for a description of the order in which terms appear. You can use this matrix to specify other models including ones without a constant term.

With this syntax, the function displays a graphical user interface (GUI) with a list of diagnostic statistics, as shown in the following figure.

When you select check boxes corresponding to the statistics you want to compute and click **OK**, `regstats` returns the selected statistics to the MATLAB workspace. The names of the workspace variables are displayed on the right-hand side of the interface.

You can change the name of the workspace variable to any valid MATLAB variable name.

`stats = regstats(...)` creates the structure `stats`, whose fields contain all of the diagnostic statistics for the regression. This syntax does not open the GUI. The fields of `stats` are listed in the following table.

| Field      | Description                                          |
|------------|------------------------------------------------------|
| Q          | $Q$ from the $QR$ decomposition of the design matrix |
| R          | $R$ from the $QR$ decomposition of the design matrix |
| beta       | Regression coefficients                              |
| covb       | Covariance of regression coefficients                |

| standres   | Standardized residuals                               |
| studres    | Studentized residuals                                |
| dfbetas    | Scaled change in regression coefficients             |
| dffit      | Change in fitted values                              |
| dffits     | Scaled change in fitted values                       |
| covratio   | Change in covariance                                 |
| cookd      | Cook's distance                                      |
| tstat      | $t$ statistics and $p$ -values for coefficients      |
| fstat      | $F$ statistic and $p$ -value                         |
| dwstat     | Durbin-Watson statistic and $p$ -value               |

Note that the fields names of `stats` correspond to the names of the variables returned to the MATLAB workspace when you use the GUI. For example, `stats.beta` corresponds to the variable `beta` that is returned when you select **Coefficients** in the GUI and click **OK**.

`stats = regstats(y,X,model,whichstats)` returns only the statistics that you specify in `whichstats`. `whichstats` can be a single string such as `'leverage'` or a cell array of strings such as `{'leverage' 'standres' 'studres'}`. Set `whichstats` to `'all'` to return all of the statistics.

---

**Note:** The  $F$  statistic is computed under the assumption that the model contains a constant term. It is not correct for models without a constant. The  $R^2$  statistic can be negative for models without a constant, which indicates that the model is not appropriate for the data.

---

## Examples

Open the `regstats` GUI using data from `hald.mat`:

```
load hald
regstats(heat,ingredients,'linear');
```

Select **Fitted Values** and **Residuals** in the GUI:

Click **OK** to export the fitted values and residuals to the MATLAB workspace in variables named `yhat` and `r`, respectively.

You can create the same variables using the `stats` output, without opening the GUI:

```
whichstats = {'yhat','r'};
stats = regstats(heat,ingredients,'linear',whichstats);
yhat = stats.yhat;
r = stats.r;
```

## regularize

**Class:** RegressionEnsemble

Find weights to minimize resubstitution error plus penalty term

### Syntax

```
ens1 = regularize(ens)
ens1 = regularize(ens,Name,Value)
```

### Description

`ens1 = regularize(ens)` finds optimal weights for learners in `ens` by lasso regularization. `regularize` returns a regression ensemble identical to `ens`, but with a populated `Regularization` property.

`ens1 = regularize(ens,Name,Value)` computes optimal weights with additional options specified by one or more `Name,Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### Input Arguments

**ens**

A regression ensemble, created by `fitensemble`.

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**'lambda'**

Vector of nonnegative regularization parameter values for lasso. For the default setting of `lambda`, `regularize` calculates the smallest value `lambda_max` for which all optimal

weights for learners are 0. The default value of `lambda` is a vector including 0 and nine exponentially-spaced numbers from `lambda_max/1000` to `lambda_max`.

**Default:** `[0 logspace(log10(lambda_max/1000), log10(lambda_max), 9)]`

**'npass'**

Maximal number of passes for lasso optimization, a positive integer.

**Default:** 10

**'reltol'**

Relative tolerance on the regularized loss for lasso, a numeric positive scalar.

**Default:** 1e-3

**'verbose'**

Verbosity level, either 0 or 1. When set to 1, `regularize` displays more information as it runs.

**Default:** 0

## Output Arguments

**ens1**

A regression ensemble. Usually you set `ens1` to the same name as `ens`.

## Definitions

### Lasso

The lasso algorithm finds an optimal set of learner weights  $\alpha_t$  that minimize

$$\sum_{n=1}^N w_n \mathcal{G} \left( \left( \sum_{t=1}^T \alpha_t h_t(x_n) \right), y_n \right) + \lambda \sum_{t=1}^T |\alpha_t|.$$

Here

- $\lambda \geq 0$  is a parameter you provide, called the lasso parameter.
- $h_t$  is a weak learner in the ensemble trained on  $N$  observations with predictors  $x_n$ , responses  $y_n$ , and weights  $w_n$ .
- $g(f,y) = (f - y)^2$  is the squared error.

## Examples

Regularize an ensemble of bagged trees:

```
X = rand(2000,20);
Y = repmat(-1,2000,1);
Y(sum(X(:,1:5),2)>2.5) = 1;
bag = fitensemble(X,Y,'Bag',300,'Tree',...
 'type','regression');
bag = regularize(bag,'lambda',[0.001 0.1],'verbose',1);
```

`regularize` reports on its progress.

To see the resulting regularization structure:

```
bag.Regularization
ans =
 Method: 'Lasso'
 TrainedWeights: [300x2 double]
 Lambda: [1.0000e-003 0.1000]
 ResubstitutionMSE: [0.0616 0.0812]
 CombineWeights: @classreg.learning.combiner.WeightedSum
```

See how many learners in the regularized ensemble have positive weights (so would be included in a shrunken ensemble):

```
sum(bag.Regularization.TrainedWeights > 0)

ans =
 116 91
```

To shrink the ensemble using the weights from `Lambda = 0.1`:

```
cmp = shrink(bag,'weightcolumn',2)
```

```
cmp =

classreg.learning.regr.CompactRegressionEnsemble:
 PredictorNames: {1x20 cell}
 CategoricalPredictors: []
 ResponseName: 'Y'
 ResponseTransform: 'none'
 NumTrained: 91
```

There are 91 members in the regularized ensemble, which is less than 1/3 of the original 300.

## RegularizationValue property

**Class:** gmdistribution

Value of 'Regularize' parameter

### Description

The value of the parameter 'Regularize'.

---

**Note:** This property applies only to gmdistribution objects constructed with fitgmdist.

---

# relieff

Importance of attributes (predictors) using ReliefF algorithm

## Syntax

```
[RANKED,WEIGHT] = relieff(X,Y,K)
[RANKED,WEIGHT] = relieff(X,Y,K, 'PARAM1',val1, 'PARAM2',val2,...)
```

## Description

[RANKED,WEIGHT] = `relieff(X,Y,K)` computes ranks and weights of attributes (predictors) for input data matrix `X` and response vector `Y` using the ReliefF algorithm for classification or RReliefF for regression with `K` nearest neighbors. For classification, `relieff` uses `K` nearest neighbors per class. `RANKED` are indices of columns in `X` ordered by attribute importance, meaning `RANKED(1)` is the index of the most important predictor. `WEIGHT` are attribute weights ranging from -1 to 1 with large positive weights assigned to important attributes.

If `Y` is numeric, `relieff` by default performs RReliefF analysis for regression. If `Y` is categorical, logical, a character array, or a cell array of strings, `relieff` by default performs ReliefF analysis for classification.

Attribute ranks and weights computed by `relieff` usually depend on `K`. If you set `K` to 1, the estimates computed by `relieff` can be unreliable for noisy data. If you set `K` to a value comparable with the number of observations (rows) in `X`, `relieff` can fail to find important attributes. You can start with `K = 10` and investigate the stability and reliability of `relieff` ranks and weights for various values of `K`.

```
[RANKED,WEIGHT] = relieff(X,Y,K, 'PARAM1',val1, 'PARAM2',val2,...)
```

specifies optional parameter name/value pairs.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single

quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

**'method'**

Either 'regression' (default if Y is numeric) or 'classification' (default if Y is not numeric).

**'prior'**

Prior probabilities for each class, specified as a string ('empirical' or 'uniform') or as a vector (one value for each distinct group name) or as a structure S with two fields:

- S.group containing the group names as a categorical variable, character array, or cell array of strings
- S.prob containing a vector of corresponding probabilities

If the input value is 'empirical' (default), class probabilities are determined from class frequencies in Y. If the input value is 'uniform', all class probabilities are set equal.

**'updates'**

Number of observations to select at random for computing the weight of every attribute. By default all observations are used.

**'categoricalx'**

'on' or 'off', 'off' by default. If 'on', treat all predictors in X as categorical. If 'off', treat all predictors in X as numerical. You cannot mix numerical and categorical predictors.

**'sigma'**

Distance scaling factor. For observation  $i$ , influence on the attribute weight from its nearest neighbor  $j$  is multiplied by  $\exp((-rank(i,j)/sigma)^2)$ , where  $rank(i,j)$  is the position of  $j$  in the list of nearest neighbors of  $i$  sorted by distance in the ascending order. Default is Inf (all nearest neighbors have the same influence) for classification and 50 for regression.

## Examples

### Rank Predictors by Importance

Load the sample data.

```
load ionosphere;
```

Rank the predictors based on importance.

```
[ranked,weights] = relieff(X,Y,10);
```

Create a bar plot of predictor importance weights.

```
bar(weights(ranked));
xlabel('Predictor rank');
ylabel('Predictor importance weight');
```

### Determine the Important Predictors

Load the sample data.

```
load fisheriris
```

Find the important predictors.

```
[ranked,weight] = relieff(meas,species,10)
```

```
ranked =
```

```
4 3 1 2
```

weight =

0.1399    0.1226    0.3590    0.3754

The fourth predictor is the most important, and the second predictor is the least important.

## removeLearners

**Class:** CompactClassificationEnsemble

Remove members of compact classification ensemble

### Syntax

```
cens1 = removeLearners(cens, idx)
```

### Description

`cens1 = removeLearners(cens, idx)` creates a compact classification ensemble identical to `cens` only without the ensemble members in the `idx` vector.

### Tips

- Typically, set `cens1` equal to `cens` to retain just one ensemble.
- Removing learners reduces the memory used by the ensemble and speeds up its predictions.

### Input Arguments

#### **cens**

Compact classification ensemble, constructed with `compact`.

#### **idx**

Vector of positive integers with entries from 1 to `cens.NumTrained`, where `cens.NumTrained` is the number of members in `cens`. `cens1` contains all members of `cens` except those with indices in `idx`.

Typically, you set `idx = j:cens.NumTrained` for some positive integer `j`.

## Output Arguments

### **cens1**

Compact classification ensemble, identical to `cens` except `cens1` does not contain those members of `cens` with indices in `idx`.

## Examples

### **Remove Learners from an Ensemble**

Create a compact classification ensemble. Compact it further by removing members of the ensemble.

Create a compact classification ensemble for the `ionosphere` data.

```
load ionosphere
ens = fitensemble(X,Y, 'AdaBoostM1',100, 'Tree');
cens = compact(ens);
```

Remove the last 50 members of the ensemble.

```
idx = cens.NumTrained-49:cens.NumTrained;
cens1 = removeLearners(cens,idx);
```

- “Classification with Imbalanced Data” on page 16-75

### **See Also**

`CompactClassificationEnsemble`

## removeLearners

**Class:** CompactRegressionEnsemble

Remove members of compact regression ensemble

### Syntax

```
cens1 = removeLearners(cens, idx)
```

### Description

### Tips

- Typically, set `cens1` equal to `cens` to retain just one ensemble.
- Removing learners reduces the memory used by the ensemble and speeds up its predictions.

### Input Arguments

#### **cens**

Compact regression ensemble, constructed with `compact`.

#### **idx**

Vector of positive integers with entries from 1 to `cens.NumTrained`, where `cens.NumTrained` is the number of members in `cens`. `cens1` contains the members of `cens` except those with indices in `idx`.

Typically, you set `idx = j:cens.NumTrained` for some positive integer `j`.

## Output Arguments

### **cens1**

Compact regression ensemble, identical to `cens` except `cens1` does not contain members of `cens` with indices in `idx`.

## Examples

### **Remove Learners from an Ensemble**

Create a compact regression ensemble. Compact it further by removing members of the ensemble.

Create a compact regression ensemble for the `carsmall` data.

```
load carsmall
X = [Weight Cylinders];
ens = fitensemble(X,MPG,'LSBoost',100,'Tree','categorical',2);
cens = compact(ens);
```

Remove the last 50 members of the ensemble.

```
idx = cens.NumTrained-49:cens.NumTrained;
cens1 = removeLearners(cens,idx);
```

### **See Also**

`CompactRegressionEnsemble`

## removeTerms

**Class:** GeneralizedLinearModel

Remove terms from generalized linear model

### Syntax

```
mdl1 = removeTerms(mdl, terms)
```

### Description

`mdl1 = removeTerms(mdl, terms)` returns a linear model the same as `mdl` but with fewer terms.

### Input Arguments

#### **mdl**

Generalized linear model, as constructed by `fitglm` or `stepwiseglm`.

#### **terms**

Terms to remove from the `mdl` regression model. Specify as either a:

- Text string representing one or more terms to remove. For details, see “Wilkinson Notation” on page 21-3731.
- Row or rows in the terms matrix (see `modelspec` in `fitglm`). For example, if there are three variables A, B, and C:

```
[0 0 0] represents a constant term or intercept
[0 1 0] represents B; equivalently, A^0 * B^1 * C^0
[1 0 1] represents A*C
[2 0 0] represents A^2
[0 1 2] represents B*(C^2)
```

## Output Arguments

### mdl1

Generalized linear model, the same as `mdl` but without the terms given in `terms`. You can set `mdl1` equal to `mdl` to overwrite `mdl`.

## Definitions

### Wilkinson Notation

Wilkinson notation describes the factors present in models. The notation relates to factors present in models, not to the multipliers (coefficients) of those factors.

| Wilkinson Notation                      | Factors in Standard Notation |
|-----------------------------------------|------------------------------|
| 1                                       | Constant (intercept) term    |
| $A^k$ , where $k$ is a positive integer | $A, A^2, \dots, A^k$         |
| $A + B$                                 | $A, B$                       |
| $A*B$                                   | $A, B, A*B$                  |
| $A:B$                                   | $A*B$ only                   |
| $-B$                                    | Do not include $B$           |
| $A*B + C$                               | $A, B, C, A*B$               |
| $A + B + C + A:B$                       | $A, B, C, A*B$               |
| $A*B*C - A:B:C$                         | $A, B, C, A*B, A*C, B*C$     |
| $A*(B + C)$                             | $A, B, C, A*B, A*C$          |

Statistics Toolbox notation always includes a constant term unless you explicitly remove the term using `-1`.

For details, see Wilkinson and Rogers [1].

## Examples

### Remove a Term from a Generalized Linear Regression Model

This example makes a model using two predictors, then removes one.

Generate artificial data for the model, Poisson random numbers with two underlying predictors  $X(1)$  and  $X(2)$ .

```
rng('default') % for reproducibility
rndvars = randn(100,2);
X = [2+rndvars(:,1),rndvars(:,2)];
mu = exp(1 + X*[1;2]);
y = poissrnd(mu);
```

Create a generalized linear regression model of Poisson data.

```
mdl = fitglm(X,y,'y ~ x1 + x2','distr','poisson')
mdl =
```

```
Generalized Linear regression model:
log(y) ~ 1 + x1 + x2
Distribution = Poisson
```

Estimated Coefficients:

|             | Estimate | SE        | tStat  | pValue |
|-------------|----------|-----------|--------|--------|
| (Intercept) | 1.0405   | 0.022122  | 47.034 | 0      |
| x1          | 0.9968   | 0.003362  | 296.49 | 0      |
| x2          | 1.987    | 0.0063433 | 313.24 | 0      |

```
100 observations, 97 error degrees of freedom
Dispersion: 1
Chi^2-statistic vs. constant model: 2.95e+05, p-value = 0
```

Remove the second predictor from the model.

```
mdl1 = removeTerms(mdl,'x2')
mdl1 =
```

Generalized Linear regression model:

$\log(y) \sim 1 + x1$   
Distribution = Poisson

Estimated Coefficients:

|             | Estimate | SE        | tStat  | pValue |
|-------------|----------|-----------|--------|--------|
| (Intercept) | 2.7784   | 0.014043  | 197.85 | 0      |
| x1          | 1.1732   | 0.0033653 | 348.6  | 0      |

100 observations, 98 error degrees of freedom

Dispersion: 1

Chi<sup>2</sup>-statistic vs. constant model: 1.25e+05, p-value = 0

- “Plots to Understand Predictor Effects and How to Modify a Model” on page 10-30

## removeTerms

**Class:** LinearModel

Remove terms from linear model

### Syntax

```
mdl1 = removeTerms(mdl, terms)
```

### Description

`mdl1 = removeTerms(mdl, terms)` returns a linear model the same as `mdl` but with terms removed.

### Input Arguments

**mdl**

Linear model, as constructed by `fitlm` or `stepwiselm`.

**terms**

Terms to remove from the `mdl` regression model. Specify as either a:

- Text string representing one or more terms to remove. For details, see “Wilkinson Notation” on page 21-3735.
- Row or rows in the terms matrix (see `modelspec` in `fitlm`). For example, if there are three variables A, B, and C:

```
[0 0 0] represents a constant term or intercept
[0 1 0] represents B; equivalently, A^0 * B^1 * C^0
[1 0 1] represents A*C
[2 0 0] represents A^2
[0 1 2] represents B*(C^2)
```

## Output Arguments

### mdl1

Linear model, the same as `mdl` but with `terms` removed. You can set `mdl1` equal to `mdl` to overwrite `mdl`.

## Definitions

### Wilkinson Notation

Wilkinson notation describes the factors present in models. The notation relates to factors present in models, not to the multipliers (coefficients) of those factors.

| Wilkinson Notation                      | Factors in Standard Notation |
|-----------------------------------------|------------------------------|
| 1                                       | Constant (intercept) term    |
| $A^k$ , where $k$ is a positive integer | $A, A^2, \dots, A^k$         |
| $A + B$                                 | $A, B$                       |
| $A*B$                                   | $A, B, A*B$                  |
| $A:B$                                   | $A*B$ only                   |
| $-B$                                    | Do not include $B$           |
| $A*B + C$                               | $A, B, C, A*B$               |
| $A + B + C + A:B$                       | $A, B, C, A*B$               |
| $A*B*C - A:B:C$                         | $A, B, C, A*B, A*C, B*C$     |
| $A*(B + C)$                             | $A, B, C, A*B, A*C$          |

Statistics Toolbox notation always includes a constant term unless you explicitly remove the term using `-1`.

For details, see Wilkinson and Rogers [1].

## Examples

### Remove Terms from Model

Construct a default linear model of the Hald data. Remove terms with high  $p$ -values.

Load the data.

```
load hald
X = ingredients; % predictor variables
y = heat; % response
```

Fit a default linear model to the data.

```
mdl = fitlm(X,y)
```

```
mdl =
```

Linear regression model:

```
y ~ 1 + x1 + x2 + x3 + x4
```

Estimated Coefficients:

|             | Estimate | SE      | tStat    | pValue   |
|-------------|----------|---------|----------|----------|
| (Intercept) | 62.405   | 70.071  | 0.8906   | 0.39913  |
| x1          | 1.5511   | 0.74477 | 2.0827   | 0.070822 |
| x2          | 0.51017  | 0.72379 | 0.70486  | 0.5009   |
| x3          | 0.10191  | 0.75471 | 0.13503  | 0.89592  |
| x4          | -0.14406 | 0.70905 | -0.20317 | 0.84407  |

Number of observations: 13, Error degrees of freedom: 8

Root Mean Squared Error: 2.45

R-squared: 0.982, Adjusted R-Squared 0.974

F-statistic vs. constant model: 111, p-value = 4.76e-07

Remove the **x3** and **x4** terms because their  $p$ -values are so high.

```
terms = 'x3 + x4'; % terms to remove
mdl1 = removeTerms(mdl, terms)
```

```
mdl1 =
```

Linear regression model:

```
y ~ 1 + x1 + x2
```

Estimated Coefficients:

|             | Estimate | SE       | tStat  | pValue     |
|-------------|----------|----------|--------|------------|
| (Intercept) | 52.577   | 2.2862   | 22.998 | 5.4566e-10 |
| x1          | 1.4683   | 0.1213   | 12.105 | 2.6922e-07 |
| x2          | 0.66225  | 0.045855 | 14.442 | 5.029e-08  |

Number of observations: 13, Error degrees of freedom: 10

Root Mean Squared Error: 2.41

R-squared: 0.979, Adjusted R-Squared 0.974

F-statistic vs. constant model: 230, p-value = 4.41e-09

The new model has the same adjusted R-Squared value (0.974) as the previous model, meaning it is about as good a fit. All the terms in the new model have extremely low  $p$ -values.

- “Linear Regression” on page 9-11

## reorderlevels

Reorder levels of nominal or ordinal arrays

### Compatibility

The `nominal` and `ordinal` array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the MATLAB categorical data type instead.

### Syntax

```
B = reorderlevels(A,newlevels)
```

### Description

`B = reorderlevels(A,newlevels)` returns a `nominal` or `ordinal` array object the same as `A` but with levels in the new order specified by `newlevels`.

For ordinal arrays, the order of the levels has significance for relational operators, minimum and maximum, and for sorting.

### Examples

- “Reorder Category Levels” on page 2-11
- “Sort Ordinal Arrays” on page 2-40

### Input Arguments

#### **A** — Nominal or ordinal array

`nominal` array | `ordinal` array

Nominal or ordinal array, specified as a `nominal` or `ordinal` array object created using `nominal` or `ordinal`.

**newlevels** — New order of levels

cell array of strings | 2-D character matrix

New order of levels, specified as a cell array of strings or 2-D character matrix. `newlevels` must be a reordering of the labels returned by `getlabels`.

Data Types: char | cell

## Output Arguments

**B** — Nominal or ordinal array

nominal array | ordinal array

Nominal or ordinal array, returned as a `nominal` or `ordinal` array object.

## More About

- Using nominal Objects
- Using ordinal Objects

## See Also

addlevels | droplevels | getlabels | nominal | ordinal | reorderlevels

## repartition

**Class:** `cvpartition`

Repartition data for cross-validation

## Syntax

```
cnew = repartition(c)
```

## Description

`cnew = repartition(c)` constructs an object `cnew` of the `cvpartition` class defining a random partition of the same type as `c`, where `c` is also an object of the `cvpartition` class.

Repartitioning is useful for Monte-Carlo repetitions of cross-validation analyses. `repartition` is called by `crossval` when the `'mcreps'` parameter is specified.

## Examples

Partition and repartition 100 observations for 3-fold cross-validation:

```
c = cvpartition(100,'kfold',3)
c =
K-fold cross validation partition
 N: 100
NumTestSets: 3
 TrainSize: 67 66 67
 TestSize: 33 34 33

cnew = repartition(c)
cnew =
K-fold cross validation partition
 N: 100
NumTestSets: 3
 TrainSize: 67 66 67
 TestSize: 33 34 33
```

Check for equality of the test data in the first fold:

```
isequal(test(c,1),test(cnew,1))
ans =
 0
```

### **See Also**

cvpartition

## RepeatedMeasuresModel class

Repeated measures model class

### Description

A `RepeatedMeasuresModel` object represents a model fitted to data with multiple measurements per subject. The object comprises data, fitted coefficients, covariance parameters, design matrix, error degrees of freedom, and between- and within-subjects factor names for a repeated measures model. You can predict model responses using the `predict` method and generate random data at new design points using the `random` method.

### Construction

You can fit a repeated measures model using `fitrm(t,modelspec)`.

### Input Arguments

#### **t** — Input data

table

Input data, which includes the values of the response variables and the between-subject factors to use as predictors in the repeated measures model, specified as a table.

Data Types: table

#### **modelspec** — Formula for model specification

string of the form 'y1-yk ~ terms'

Formula for model specification, specified as a string of the form 'y1-yk ~ terms'. Specify the terms using Wilkinson notation. `fitrm` treats the variables used in model terms as categorical if they are categorical (nominal or ordinal), logical, char arrays, or a cell array of strings.

Example: 'y1-y4 ~ x1 + x2 \* x3'

## Properties

### **BetweenDesign** — Design for between-subject factors

table

Design for between-subject factors and values of repeated measures, stored as a table.

Data Types: table

### **BetweenModel** — Model for between-subjects factors

string

Model for between-subjects factors, stored as a string. This string is the text representation to the right of the tilde in the model specification you provide when fitting the repeated measures model using `fitrm`.

Data Types: char

### **BetweenFactorNames** — Names of variables used as between-subject factors

cell array of strings

Names of variables used as between-subject factors in the repeated measures model, `rm`, stored as a cell array of strings.

Data Types: cell

### **ResponseNames** — Names of variables used as response variables

cell array of strings

Names of variables used as response variables in the repeated measures model, `rm`, stored as a cell array of strings.

Data Types: cell

### **WithinDesign** — Values of within-subject factors

table

Values of the within-subject factors, stored as a table.

Data Types: table

### **WithinModel** — Model for within-subjects factors

string

Model for within-subjects factors, stored as a string.

Data Types: `char`

### **WithinFactorNames** — Names of within-subject factors

cell array of strings

Names of the within-subject factors, stored as a cell array of strings.

Data Types: `cell`

### **Coefficients** — Values of estimated coefficients

table

Values of the estimated coefficients for fitting the repeated measures as a function of the terms in the between-subjects model, stored as a table.

`fitrm` defines the coefficients for a categorical term using 'effects' coding, which means coefficients sum to 0. There is one coefficient for each level except the first. The implied coefficient for the first level is the sum of the other coefficients for the term.

You can display the coefficient values as a matrix rather than a table using `coef = r.Coefficients{:, :}`.

You can display marginal means for all levels using the `margmean` method.

Data Types: `table`

### **Covariance** — Estimated response covariances

table

Estimated response covariances, that is, covariance of the repeated measures, stored as a table. `fitrm` computes the covariances around the mean returned by the fitted repeated measures model `rm`.

You can display the covariance values as a matrix rather than a table using `coef = r.Covariance{:, :}`.

Data Types: `table`

### **DFE** — Error degrees of freedom

scalar value

Error degrees of freedom, stored as a scalar value. DFE is the number of observations minus the number of estimated coefficients in the between-subjects model.

Data Types: double

| plot        | Plot data with optional grouping                                  |
| plotprofile | Plot expected marginal means with optional grouping               |
| predict     | Compute predicted values given predictor values                   |
| random      | Generate new random response values given predictor values        |
| ranova      | Repeated measures analysis of variance                            |

## Definitions

### Wilkinson Notation

Wilkinson notation describes the factors present in models. It does not describe the multipliers (coefficients) of those factors.

Use these rules to specify the responses in modelspec.

| Wilkinson Notation | Description                            |
|--------------------|----------------------------------------|
| Y1, Y2, Y3         | Specific list of variables             |
| Y1-Y5              | All table variables from Y1 through Y5 |

Use these rules to specify terms in modelspec.

| Wilkinson Notation                      | Factors in Standard Notation            |
|-----------------------------------------|-----------------------------------------|
| 1                                       | Constant (intercept) term               |
| $X^k$ , where $k$ is a positive integer | $X, X^2, \dots, X^k$                    |
| $X1 + X2$                               | $X1, X2$                                |
| $X1 * X2$                               | $X1, X2, X1 * X2$                       |
| $X1 : X2$                               | $X1 * X2$ only                          |
| $-X2$                                   | Do not include $X2$                     |
| $X1 * X2 + X3$                          | $X1, X2, X3, X1 * X2$                   |
| $X1 + X2 + X3 + X1 : X2$                | $X1, X2, X3, X1 * X2$                   |
| $X1 * X2 * X3 - X1 : X2 : X3$           | $X1, X2, X3, X1 * X2, X1 * X3, X2 * X3$ |
| $X1 * (X2 + X3)$                        | $X1, X2, X3, X1 * X2, X1 * X3$          |

Statistics Toolbox notation always includes a constant term unless you explicitly remove the term using -1.

## Examples

### Fit a Repeated Measures Model

Load the sample data.

```
load fisheriris
```

The column vector, `species`, consists of iris flowers of three different species: *setosa*, *versicolor*, *virginica*. The double matrix `meas` consists of four types of measurements on the flowers: the length and width of sepals and petals in centimeters, respectively.

Store the data in a table array.

```
t = table(species,meas(:,1),meas(:,2),meas(:,3),meas(:,4),...
'VariableNames',{'species','meas1','meas2','meas3','meas4'});
Meas = table([1 2 3 4'],'VariableNames',{'Measurements'});
```

Fit a repeated measures model, where the measurements are the responses and the species is the predictor variable.

```
rm = fitrm(t,'meas1-meas4~species','WithinDesign',Meas)
```

```
rm =
```

```
RepeatedMeasuresModel with properties:
```

```
Between Subjects:
```

```
 BetweenDesign: [150x5 table]
```

```
 ResponseNames: {'meas1' 'meas2' 'meas3' 'meas4'}
```

```
 BetweenFactorNames: {'species'}
```

```
 BetweenModel: '1 + species'
```

```
Within Subjects:
```

```
 WithinDesign: [4x1 table]
```

```
 WithinFactorNames: {'Measurements'}
```

```
 WithinModel: 'separatemeans'
```

```
Estimates:
```

```
 Coefficients: [3x4 table]
```

```
 Covariance: [4x4 table]
```

Display the coefficients.

```
rm.Coefficients
```

```
ans =
```

```
meas1
```

```
meas2
```

```
meas3
```

```
meas4
```

```
(Intercept) 5.8433 3.0573 3.758 1.1993
species_setosa -0.83733 0.37067 -2.296 -0.95333
species_versicolor 0.092667 -0.28733 0.502 0.12667
```

`fitrm` uses the 'effects' contrasts, which means that the coefficients sum to 0. The `rm.DesignMatrix` has one column of 1s for the intercept, and two other columns `species_setosa` and `species_versicolor`, which are as follows:

$$\text{species\_setosa} = \begin{cases} 1, & \text{if } setosa \\ 0, & \text{if } versicolor \\ -1, & \text{if } virginica \end{cases} \quad \text{and} \quad \text{species\_versicolor} = \begin{cases} 0, & \text{if } setosa \\ 1, & \text{if } versicolor \\ -1, & \text{if } virginica \end{cases}$$

Display the covariance matrix.

```
rm.Covariance
```

```
ans =
```

|       | meas1    | meas2    | meas3    | meas4    |
|-------|----------|----------|----------|----------|
| meas1 | 0.26501  | 0.092721 | 0.16751  | 0.038401 |
| meas2 | 0.092721 | 0.11539  | 0.055244 | 0.03271  |
| meas3 | 0.16751  | 0.055244 | 0.18519  | 0.042665 |
| meas4 | 0.038401 | 0.03271  | 0.042665 | 0.041882 |

Display the error degrees of freedom.

```
rm.DFE
```

```
ans =
```

```
147
```

The error degrees of freedom is the number of observations minus the number of estimated coefficients in the between-subjects model, e.g.  $150 - 3 = 147$ .

- “Property Attributes”

## replacedata

**Class:** dataset

Replace dataset variables

### Compatibility

The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

### Syntax

```
B = replacedata(A,X)
B = replacedata(A,X,vars)
B = replacedata(A,fun)
B = replacedata(A,fun,vars)
```

### Description

`B = replacedata(A,X)` creates a dataset array `B` with the same variables as the dataset array `A`, but with the data for those variables replaced by the data in the array `X`. `replacedata` creates each variable in `B` using one or more columns from `X`, in order. `X` must have as many columns as the total number of columns in all of the variables in `A`, and as many rows as `A` has observations.

`B = replacedata(A,X,vars)` creates a dataset array `B` with the same variables as the dataset array `A`, but with the data for the variables specified in `vars` replaced by the data in the array `X`. The remaining variables in `B` are copies of the corresponding variables in `A`. `vars` is a positive integer, a vector of positive integers, a variable name, a cell array containing one or more variable names, or a logical vector. Each variable in `B` has as many columns as the corresponding variable in `A`. `X` must have as many columns as the total number of columns in all the variables specified in `vars`.

`B = replacedata(A,fun)` or `B = replacedata(A,fun,vars)` creates a dataset array `B` by applying the function `fun` to the values in `A`'s variables. `replacedata` first

horizontally concatenates **A**'s variables into a single array, then applies the function **fun**. The specified variables in **A** must have types and sizes compatible with the concatenation. **fun** is a function handle that accepts a single input array and returns an array with the same number of rows and columns as the input.

## Examples

```
data = dataset({rand(3,3), 'Var1', 'Var2', 'Var3'})
```

```
% Use ZSCORE to normalize each variable in a dataset array
% separately, by explicitly extracting and transforming the
% data, and then replacing it.
```

```
X = double(data);
X = zscore(X);
data = replacedata(data,X)
```

```
% Equivalently, provide a handle to ZSCORE.
```

```
data = replacedata(data,@zscore)
```

```
% Use ZSCORE to normalize each observation in a dataset
% array separately by creating an anonymous function.
```

```
data = replacedata(data,@(x) zscore(x,[],2))
```

## See Also

dataset

# replaceWithMissing

**Class:** dataset

Insert missing data indicators into a dataset array

## Compatibility

The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

## Syntax

```
ds2 = replaceWithMissing(ds,Name,Value)
```

## Description

`ds2 = replaceWithMissing(ds,Name,Value)` replaces specified values in a dataset array with standard missing data indicators using options specified by one or more `Name,Value` pair arguments. Use `replaceWithMissing` to specify:

- Which numeric missing value indicators to replace with `NaN`.
- Which string missing value indicators to replace with an empty string.
- Which categorical levels to replace with `<undefined>`.

## Input Arguments

**ds**

dataset array.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single

quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

### **'NumericValues'**

Vector of numeric values that `replaceWithMissing` replaces with NaN.

### **'CategoricalLevels'**

String or cell array of strings naming the categorical levels that `replaceWithMissing` replaces with `<undefined>`.

### **'Strings'**

String or cell array of strings containing the strings that `replaceWithMissing` replaces with the empty string, ''.

### **'DataVars'**

Specified set of variables in `ds` for which `replaceWithMissing` replaces values. You can specify a positive integer or vector of positive integers indicating the variable column numbers, a variable name or a cell array of variables names, or a logical vector indicating which variables to replace missing values in.

**Default:** All variables in `ds`.

## **Output Arguments**

### **ds2**

dataset array that has the specified missing value indicators, in the specified variables of `ds`, replaced with standard missing value indicators.

## **Examples**

### **Replace Nonstandard Missing Value Indicators**

Replace nonstandard missing value indicators with standard missing value indicators.

Replace numeric missing values coded 99 with NaN, and string missing values coded ' .' with the empty string.

```
ds = replaceWithMissing(ds, 'NumericValues', 99, 'Strings', ' .');
```

- “Clean Messy and Missing Data” on page 2-113

dataset | ismissing

### More About

- “Dataset Arrays” on page 2-132

## reset

**Class:** grandstream

Reset state

## Syntax

reset(q)

## Description

reset(q) resets the state of the quasi-random number stream q of the grandstream class back to its initial state, 1. Subsequent points drawn from the stream will be the same as those drawn from a new stream. The command is equivalent to `q.State = 1`.

## Examples

Use grandstream to construct a 3-D Halton stream, based on a point set that skips the first 1000 values and then retains every 101st point:

```
q = grandstream('halton',3,'Skip',1e3,'Leap',1e2)
q =
 Halton quasi-random stream in 3 dimensions
 Point set properties:
 Skip : 1000
 Leap : 100
 ScrambleMethod : none

nextIdx = q.State
nextIdx =
 1
```

Use grand to generate two samples of size four:

```
X1 = grand(q,4)
X1 =
 0.0928 0.3475 0.0051
```

```
 0.6958 0.2035 0.2371
 0.3013 0.8496 0.4307
 0.9087 0.5629 0.6166
nextIdx = q.State
nextIdx =
 5
```

```
X2 = grand(q,4)
X2 =
 0.2446 0.0238 0.8102
 0.5298 0.7540 0.0438
 0.3843 0.5112 0.2758
 0.8335 0.2245 0.4694
nextIdx = q.State
nextIdx =
 9
```

Use `reset` to reset the stream, then generate another sample:

```
reset(q)
nextIdx = q.State
nextIdx =
 1

X = grand(q,4)
X =
 0.0928 0.3475 0.0051
 0.6958 0.2035 0.2371
 0.3013 0.8496 0.4307
 0.9087 0.5629 0.6166
```

## See Also

`grandstream` | `grand`

# residuals

**Class:** `GeneralizedLinearMixedModel`

Residuals of fitted generalized linear mixed-effects model

## Syntax

```
r = residuals(glme)
r = residuals(glme, Name, Value)
```

## Description

`r = residuals(glme)` returns the raw conditional residuals from a fitted generalized linear mixed-effects model `glme`.

`r = residuals(glme, Name, Value)` returns the residuals using additional options specified by one or more `Name, Value` pair arguments. For example, you can specify to return Pearson residuals for the model.

## Input Arguments

**glme** — Generalized linear mixed-effects model

`GeneralizedLinearMixedModel` object

Generalized linear mixed-effects model, specified as a `GeneralizedLinearMixedModel` object. For properties and methods of this object, see `GeneralizedLinearMixedModel`.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

**'Conditional' — Indicator for conditional residuals**

true (default) | false

Indicator for conditional residuals, specified as the comma-separated pair consisting of 'Conditional' and one of the following.

|       |                                                                        |
|-------|------------------------------------------------------------------------|
| true  | Contributions from both fixed effects and random effects (conditional) |
| false | Contribution from only fixed effects (marginal)                        |

Conditional residuals include contributions from both fixed- and random-effects predictors. Marginal residuals include contribution from only fixed effects. To obtain marginal residual values, `residuals` computes the conditional mean of the response with the empirical Bayes predictor vector of random effects, `b`, set to 0.

Example: 'Conditional', false

**'ResidualType' — Residual type**

'raw' (default) | 'Pearson'

Residual type, specified as the comma-separated pair consisting of 'ResidualType' and one of the following.

| Residual Type | Conditional                                                                                            | Marginal                                                                                         |
|---------------|--------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------|
| 'raw'         | $r_{ci} = y_i - g^{-1}(x_i^T \hat{\beta} + z_i^T \hat{b})$                                             | $r_{mi} = y_i - g^{-1}(x_i^T \hat{\beta} + \delta_i)$                                            |
| 'Pearson'     | $r_{ci}^{pearson} = \frac{r_{ci}}{\sqrt{\frac{\hat{\sigma}^2}{w_i} v_i(\mu_i(\hat{\beta}, \hat{b}))}}$ | $r_{mi}^{pearson} = \frac{r_{mi}}{\sqrt{\frac{\hat{\sigma}^2}{w_i} v_i(\mu_i(\hat{\beta}, 0))}}$ |

In each of these equations:

- $y_i$  is the  $i$ th element of the  $n$ -by-1 response vector,  $y$ , where  $i = 1, \dots, n$ .
- $g^{-1}$  is the inverse link function for the model.
- $x_i^T$  is the  $i$ th row of the fixed-effects design matrix  $X$ .

- $z_i^T$  is the  $i$ th row of the random-effects design matrix  $Z$ .
- $\delta_i$  is the  $i$ th offset value.
- $\sigma^2$  is the dispersion parameter.
- $w_i$  is the  $i$ th observation weight.
- $v_i$  is the variance term for the  $i$ th observation.
- $\mu_i$  is the mean of the response for the  $i$ th observation.
- $\hat{\beta}$  and  $\hat{b}$  are estimated values of  $\beta$  and  $b$ .

Raw residuals from a generalized linear mixed-effects model have nonconstant variance. Pearson residuals are expected to have an approximately constant variance, and are generally used for analysis.

Example: 'ResidualType', 'Pearson'

## Output Arguments

### **r** — Residuals

$n$ -by-1 vector

Residuals of the fitted generalized linear mixed-effects model `glme` returned as an  $n$ -by-1 vector, where  $n$  is the number of observations.

## Examples

### Plot Residuals Versus Fitted Values

Navigate to the folder containing the sample data. Load the sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')

load mfr
```

This simulated data is from a manufacturing company that operates 50 factories across the world, with each factory running a batch process to create a finished product. The

company wants to decrease the number of defects in each batch, so it developed a new manufacturing process. To test the effectiveness of the new process, the company selected 20 of its factories at random to participate in an experiment: Ten factories implemented the new process, while the other ten continued to run the old process. In each of the 20 factories, the company ran five batches (for a total of 100 batches) and recorded the following data:

- Flag to indicate whether the batch used the new process (`newprocess`)
- Processing time for each batch, in hours (`time`)
- Temperature of the batch, in degrees Celsius (`temp`)
- Categorical variable indicating the supplier (A, B, or C) of the chemical used in the batch (`supplier`)
- Number of defects in the batch (`defects`)

The data also includes `time_dev` and `temp_dev`, which represent the absolute deviation of time and temperature, respectively, from the process standard of 3 hours at 20 degrees Celsius.

Fit a generalized linear mixed-effects model using `newprocess`, `time_dev`, `temp_dev`, and `supplier` as fixed-effects predictors. Include a random-effects term for intercept grouped by `factory`, to account for quality differences that might exist due to factory-specific variations. The response variable `defects` has a Poisson distribution, and the appropriate link function for this model is log. Use the Laplace fit method to estimate the coefficients.

The number of defects can be modeled using a Poisson distribution

$$defects_{ij} \sim \text{Poisson}(\mu_{ij})$$

This corresponds to the generalized linear mixed-effects model

$$\log(\mu_{ij}) = \beta_0 + \beta_1 newprocess_{ij} + \beta_2 time\_dev_{ij} + \beta_3 temp\_dev_{ij} + \beta_4 supplier\_C_{ij} + \beta_5 supplier\_B_{ij} +$$

where

- $defects_{ij}$  is the number of defects observed in the batch produced by factory  $i$  (where  $i = 1, 2, \dots, 20$ ) during batch  $j$  (where  $j = 1, 2, \dots, 5$ ).

- $\mu_{ij}$  is the mean number of defects corresponding to factory  $i$  during batch  $j$ .
- $supplier\_C_{ij}$  and  $supplier\_B_{ij}$  are dummy variables that indicate whether company C or B, respectively, supplied the process chemicals for the batch produced by factory  $i$  during batch  $j$ .
- $b_i \sim N(0, \sigma_b^2)$  is a random-effects intercept for each factory  $i$  that accounts for factory-specific variation in quality.

```
glme = fitglme(mfr, 'defects ~ 1 + newprocess + time_dev + temp_dev + supplier + (1|fact
```

Generate the conditional Pearson residuals and the conditional fitted values from the model.

```
r = residuals(glme, 'ResidualType', 'Pearson');
mufit = fitted(glme);
```

Display the first ten rows of the Pearson residuals.

```
r(1:10)
```

```
ans =
```

```
 0.4530
 0.4339
 0.3833
 -0.2653
 0.2811
 -0.0935
 -0.2984
 -0.2509
 1.5547
 -0.3027
```

Plot the Pearson residuals versus the fitted values, to check for signs of nonconstant variance among the residuals (heteroscedasticity).

```
figure
scatter(mufit,r)
title('Residuals versus Fitted Values')
xlabel('Fitted Values')
ylabel('Residuals')
```

The plot does not show a systematic dependence on the fitted values, so there are no signs of nonconstant variance among the residuals.

`GeneralizedLinearMixedModel` | `designMatrix` | `fitted` | `response`

# residuals

**Class:** LinearMixedModel

Residuals of fitted linear mixed-effects model

## Syntax

```
R = residuals(lme)
R = residuals(lme,Name,Value)
```

## Description

`R = residuals(lme)` returns the raw conditional residuals from a fitted linear mixed-effects model `lme`.

`R = residuals(lme,Name,Value)` returns the residuals from the linear mixed-effects model `lme` with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify Pearson or standardized residuals, or residuals with contributions from only fixed effects.

## Input Arguments

**lme** — Linear mixed-effects model

LinearMixedModel object

Linear mixed-effects model, returned as a LinearMixedModel object.

For properties and methods of this object, see LinearMixedModel.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single

quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

**'Conditional' — Indicator for conditional residuals**

True (default) | False

Indicator for conditional residuals, specified as the comma-separated pair consisting of 'Conditional' and one of the following.

- True Contribution from both fixed effects and random effects (conditional)
- False Contribution from only fixed effects (marginal)

Example: 'Conditional, 'False'

**'ResidualType' — Residual type**

'Raw' (default) | 'Pearson' | 'Standardized'

Residual type, specified by the comma-separated pair consisting of ResidualType and one of the following.

| Residual Type  | Conditional                                                            | Marginal                                                           |
|----------------|------------------------------------------------------------------------|--------------------------------------------------------------------|
| 'Raw'          | $r_i^C = [y - X\hat{\beta} - Z\hat{b}]_i$                              | $r_i^M = [y - X\hat{\beta}]_i$                                     |
| 'Pearson'      | $pr_i^C = \frac{r_i^C}{\sqrt{[\widehat{Var}_{y,b}(y - X\beta)]_{ii}}}$ | $pr_i^M = \frac{r_i^M}{\sqrt{[\widehat{Var}_y(y - X\beta)]_{ii}}}$ |
| 'Standardized' | $st_i^C = \frac{r_i^C}{\sqrt{[\widehat{Var}_y(r^C)]_{ii}}}$            | $st_i^M = \frac{r_i^M}{\sqrt{[\widehat{Var}_y(r^M)]_{ii}}}$        |

For more information on the conditional and marginal residuals and residual variances, see **Definitions** at the end of this page.

Example: 'ResidualType', 'Standardized'

## Output Arguments

### R — Residuals

*n*-by-1 vector

Residuals of the fitted linear mixed-effects model `lmer` returned as an *n*-by-1 vector, where *n* is the number of observations.

## Examples

### Plot Residuals vs. Fitted Values

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load weight
```

`weight` contains data from a longitudinal study, where 20 subjects are randomly assigned to 4 exercise programs, and their weight loss is recorded over six 2-week time periods. This is simulated data.

Store the data in a table. Define `Subject` and `Program` as categorical variables.

```
tbl = table(InitialWeight,Program,Subject,Week,y);
tbl.Subject = nominal(tbl.Subject);
tbl.Program = nominal(tbl.Program);
```

Fit a linear mixed-effects model where the initial weight, type of program, week, and the interaction between the week and type of program are the fixed effects. The intercept and week vary by subject.

```
lme = fitlme(tbl,'y ~ InitialWeight + Program*Week + (Week|Subject)');
```

Compute the fitted values and raw residuals.

```
F = fitted(lme);
R = residuals(lme);
```

Plot the residuals versus the fitted values.

```
plot(F,R,'bx')
xlabel('Fitted Values')
ylabel('Residuals')
```

Now, plot the residuals versus the fitted values, grouped by program.

```
figure();
```

```
gscatter(F,R,Program)
```

The residuals seem to behave similarly across levels of the program as expected.

### Compute Conditional and Marginal Pearson Residuals

Load the sample data.

```
load carbig
```

Store the variables for miles per gallon (MPG), acceleration, horsepower, cylinders, and model year in a table.

```
tbl = table(MPG,Acceleration,Horsepower,Cylinders,Model_Year);
```

Fit a linear mixed-effects model for miles per gallon (MPG), with fixed effects for acceleration, horsepower, and the cylinders, and potentially correlated random effects for intercept and acceleration grouped by model year.

```
lme = fitlme(tbl, 'MPG ~ Acceleration + Horsepower + Cylinders + (Acceleration|Model_Year)')
```

Compute the conditional Pearson residuals and display the first five residuals.

```
PR = residuals(lme, 'ResidualType', 'Pearson');
PR(1:5)
```

```
ans =
```

```
-0.0533
0.0652
0.3655
-0.0106
-0.3340
```

Compute the marginal Pearson residuals and display the first five residuals.

```
PRM = residuals(lme, 'ResidualType', 'Pearson', 'Conditional', false);
PRM(1:5)
```

```
ans =
```

```
-0.1250
0.0130
0.3242
-0.0861
-0.3006
```

### Examine Residuals

Load the sample data.

```
load carbig
```

Store the variables for miles per gallon (MPG), acceleration, horsepower, cylinders, and model year in a table.

```
tbl = table(MPG, Acceleration, Horsepower, Cylinders, Model_Year);
```

Fit a linear mixed-effects model for miles per gallon (MPG), with fixed effects for acceleration, horsepower, and the cylinders, and potentially correlated random effects for intercept and acceleration grouped by model year.

```
lme = fitlme(tbl, 'MPG ~ Acceleration + Horsepower + Cylinders + (Acceleration|Model_Year)')
```

Draw a histogram of the raw residuals with a normal fit.

```
r = residuals(lme);
histfit(r)
```

Normal distribution seems to be a good fit for the residuals.

Compute the conditional Pearson and standardized residuals and create box plots of all three types of residuals.

```
pr = residuals(lme, 'ResidualType', 'Pearson');
st = residuals(lme, 'ResidualType', 'Standardized');
```

```
X = [r pr st];
figure();
boxplot(X)
```

Red plus signs show the observations with residuals above or below  $q3 + 1.5(q3 - q1)$  and  $q1 - 1.5(q3 - q1)$ , where  $q1$  and  $q3$  are the 25th and 75th percentiles, respectively.

Find the observations with residuals that are 2.5 standard deviations above and below the mean.

```
find(r > nanmean(r) + 2.5*nanstd(r))
```

```
ans =
```

```

62
252
255
330
337
341
396

find(r < nanmean(r) - 2.5*nanstd(r))

ans =

119
324
375

```

## Definitions

### Conditional and Marginal Residuals

Conditional residuals include contributions from both fixed and random effects, whereas marginal residuals include contribution from only fixed effects.

Suppose the linear mixed-effects model `lme` has an  $n$ -by- $p$  fixed-effects design matrix  $X$  and an  $n$ -by- $q$  random-effects design matrix  $Z$ . Also, suppose the  $p$ -by-1 estimated fixed-effects vector is  $\hat{\beta}$ , and the  $q$ -by-1 estimated best linear unbiased predictor (BLUP) vector of random effects is  $\hat{b}$ . The fitted conditional response is

$$\hat{y}_{Cond} = X\hat{\beta} + Z\hat{b},$$

and the fitted marginal response is

$$\hat{y}_{Mar} = X\hat{\beta}.$$

`residuals` can return three types of residuals: raw, Pearson, and standardized. For any type, you can compute the conditional or the marginal residuals. For example, the conditional raw residual is

$$r_{Cond} = y - X\hat{\beta} - Z\hat{b},$$

and the marginal raw residual is

$$r_{Mar} = y - X\hat{\beta}.$$

For more information on other types of residuals, see the `ResidualType` name-value pair argument.

### **See Also**

`fitted` | `LinearMixedModel` | `plotResiduals` | `response`

## response

**Class:** GeneralizedLinearMixedModel

Response vector of generalized linear mixed-effects model

## Syntax

```
y = response(glme)
[y,binomialsized] = response(glme)
```

## Description

`y = response(glme)` returns the response vector `y` used to fit the generalized linear mixed effects model `glme`.

`[y,binomialsized] = response(glme)` also returns the binomial size associated with each element of `y` if the conditional distribution of response given the random effects is binomial.

## Input Arguments

**glme** — Generalized linear mixed-effects model

GeneralizedLinearMixedModel object

Generalized linear mixed-effects model, specified as a GeneralizedLinearMixedModel object. For properties and methods of this object, see GeneralizedLinearMixedModel.

## Output Arguments

**y** — Response values

$n$ -by-1 vector

Response values, specified as an  $n$ -by-1 vector, where  $n$  is the number of observations.

For an observation  $i$  with prior weights  $w_i^p$  and binomial size  $n_i$  (when applicable), the response values  $y_i$  can have the following values.

| Distribution    | Permitted Values                                                       | Notes                                      |
|-----------------|------------------------------------------------------------------------|--------------------------------------------|
| Binomial        | $\left\{0, \frac{1}{w_i^p n_i}, \frac{2}{w_i^p n_i}, \dots, 1\right\}$ | $w_i^p$ and $n_i$ are integer values $> 0$ |
| Poisson         | $\left\{0, \frac{1}{w_i^p}, \frac{2}{w_i^p}, \dots\right\}$            | $w_i^p$ is an integer value $> 0$          |
| Gamma           | $(0, \infty)$                                                          | $w_i^p \geq 0$                             |
| InverseGaussian | $(0, \infty)$                                                          | $w_i^p \geq 0$                             |
| normal          | $(-\infty, \infty)$                                                    | $w_i^p \geq 0$                             |

You can access the prior weights property  $w_i^p$  using dot notation. For example, to access the prior weights property for a model `glme`:

```
glme.ObservationInfo.Weights
```

### **binomialsize** — Binomial size

vector

Binomial size associated with each element of `y`, returned as an  $n$ -by-1 vector, where  $n$  is the number of observations. `response` only returns `binomialsize` if the conditional distribution of response given the random effects is binomial. `binomialsize` is empty for other distributions.

## Examples

### Plot Response Versus Fitted Values

Navigate to the folder containing the sample data. Load the sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

```
load mfr
```

This simulated data is from a manufacturing company that operates 50 factories across the world, with each factory running a batch process to create a finished product. The

company wants to decrease the number of defects in each batch, so it developed a new manufacturing process. To test the effectiveness of the new process, the company selected 20 of its factories at random to participate in an experiment: Ten factories implemented the new process, while the other ten continued to run the old process. In each of the 20 factories, the company ran five batches (for a total of 100 batches) and recorded the following data:

- Flag to indicate whether the batch used the new process (**newprocess**)
- Processing time for each batch, in hours (**time**)
- Temperature of the batch, in degrees Celsius (**temp**)
- Categorical variable indicating the supplier (A, B, or C) of the chemical used in the batch (**supplier**)
- Number of defects in the batch (**defects**)

The data also includes **time\_dev** and **temp\_dev**, which represent the absolute deviation of time and temperature, respectively, from the process standard of 3 hours at 20 degrees Celsius.

Fit a generalized linear mixed-effects model using **newprocess**, **time\_dev**, **temp\_dev**, and **supplier** as fixed-effects predictors. Include a random-effects term for intercept grouped by **factory**, to account for quality differences that might exist due to factory-specific variations. The response variable **defects** has a Poisson distribution, and the appropriate link function for this model is log. Use the Laplace fit method to estimate the coefficients. Specify the dummy variable encoding as '**effects**', so the dummy variable coefficients sum to 0.

The number of defects can be modeled using a Poisson distribution

$$defects_{ij} \sim \text{Poisson}(\mu_{ij})$$

This corresponds to the generalized linear mixed-effects model

$$\log(\mu_{ij}) = \beta_0 + \beta_1 \text{newprocess}_{ij} + \beta_2 \text{time\_dev}_{ij} + \beta_3 \text{temp\_dev}_{ij} + \beta_4 \text{supplier\_C}_{ij} + \beta_5 \text{supplier\_B}_{ij} +$$

where

- $defects_{ij}$  is the number of defects observed in the batch produced by factory  $i$  during batch  $j$ .

- $\mu_{ij}$  is the mean number of defects corresponding to factory  $i$  (where  $i = 1, 2, \dots, 20$ ) during batch  $j$  (where  $j = 1, 2, \dots, 5$ ).
- $newprocess_{ij}$ ,  $time\_dev_{ij}$ , and  $temp\_dev_{ij}$  are the measurements for each variable that correspond to factory  $i$  during batch  $j$ . For example,  $newprocess_{ij}$  indicates whether the batch produced by factory  $i$  during batch  $j$  used the new process.
- $supplier\_C_{ij}$  and  $supplier\_B_{ij}$  are dummy variables that use effects (sum-to-zero) coding to indicate whether company C or B, respectively, supplied the process chemicals for the batch produced by factory  $i$  during batch  $j$ .
- $b_i \sim N(0, \sigma_b^2)$  is a random-effects intercept for each factory  $i$  that accounts for factory-specific variation in quality.

```
glme = fitglme(mfr, 'defects ~ 1 + newprocess + time_dev + temp_dev + supplier + (1|fact
```

Extract the observed response values for the model, then use `fitted` to generate the fitted conditional mean values.

```
y = response(glme); % Observed response values
yfit = fitted(glme); % Fitted response values
```

Create a scatterplot of the observed response values versus fitted values. Add a reference line to improve the visualization.

```
figure
scatter(yfit,y)
xlim([0,12])
ylim([0,12])
refline(1,0)
title('Response versus Fitted Values')
xlabel('Fitted Values')
ylabel('Response')
```

The plot shows a positive correlation between the fitted values and the observed response values.

# resubEdge

**Class:** ClassificationDiscriminant

Classification edge by resubstitution

## Syntax

```
edge = resubEdge(obj)
```

## Description

`edge = resubEdge(obj)` returns the classification edge obtained by `obj` on its training data.

## Input Arguments

**obj**

Discriminant analysis classifier, produced using `fitcdiscr`.

## Output Arguments

**edge**

Classification edge obtained by resubstituting the training data into the calculation of `edge`.

## Definitions

### Edge

The *edge* is the weighted mean value of the classification *margin*. The weights are class prior probabilities. If you supply additional weights, those weights are normalized to

sum to the prior probabilities in the respective classes, and are then used to compute the weighted average.

## Margin

The classification *margin* is the difference between the classification *score* for the true class and maximal classification score for the false classes.

The classification margin is a column vector with the same number of rows as in the matrix X. A high value of margin indicates a more reliable prediction than a low value.

## Score

For discriminant analysis, the *score* of a classification is the posterior probability of the classification. For the definition of posterior probability in discriminant analysis, see “Posterior Probability” on page 15-7.

## Examples

### Estimate the Resubstitution Edge of Discriminant Analysis Classifiers

Estimate the quality of a discriminant analysis classifier for Fisher's iris data by resubstitution.

Load Fisher's iris data set.

```
load fisheriris
```

Train a discriminant analysis classifier.

```
Mdl = fitcdiscr(meas,species);
```

Compute the resubstitution edge.

```
redge = resubEdge(Mdl)
```

```
redge =
```

```
0.9454
```

resubMargin | ClassificationDiscriminant | fitcdiscr | edge

## **How To**

- “Discriminant Analysis” on page 15-3

## resubEdge

**Class:** ClassificationECOC

Classification edge for error-correcting output codes, multiclass models by resubstitution

### Syntax

```
e = resubEdge(Mdl)
e = resubEdge(Mdl,Name,Value)
```

### Description

`e = resubEdge(Mdl)` returns the classification edge (**e**) for the trained, error-correcting output codes (ECOC), multiclass model `Mdl` using the training data stored in `Mdl.X` and corresponding class labels stored in `Mdl.Y`.

`e = resubEdge(Mdl,Name,Value)` computes the resubstitution classification edge with additional options specified by one or more `Name,Value` pair arguments.

For example, specify a decoding scheme, binary learner loss function, or verbosity level.

### Input Arguments

**Mdl** — ECOC multiclass model

ClassificationECOC model

ECOC multiclass model, specified as a `ClassificationECOC` model returned by `fitcecoc`.

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**'BinaryLoss' — Binary learner loss function**

function handle | 'hamming' | 'linear' | 'exponential' | 'binodeviance' | 'hinge' | 'quadratic'

Binary learner loss function, specified as the comma-separated pair consisting of 'BinaryLoss' and a function handle or string.

- If the value is a string, then it must correspond to a built-in function. This table summarizes the built-in functions, where  $y_j$  is a class label for a particular binary learner (in the set  $\{-1,1,0\}$ ),  $s_j$  is the score for observation  $j$ , and  $g(y_j,s_j)$  is the binary loss formula.

| Value          | Description       | Score Domain       | $g(y_j,s_j)$                             |
|----------------|-------------------|--------------------|------------------------------------------|
| 'binodeviance' | Binomial deviance | $(-\infty,\infty)$ | $\log[1 + \exp(-2y_j s_j)] / [2\log(2)]$ |
| 'exponential'  | Exponential       | $(-\infty,\infty)$ | $\exp(-y_j s_j) / 2$                     |
| 'hamming'      | Hamming           | $\{-1,1\}$         | $[1 - \text{sign}(y_j s_j)] / 2$         |
| 'hinge'        | Hinge             | $(-\infty,\infty)$ | $\max(0, 1 - y_j s_j) / 2$               |
| 'linear'       | Linear            | $(-\infty,\infty)$ | $(1 - y_j s_j) / 2$                      |
| 'quadratic'    | Quadratic         | $[0,1]$            | $[1 - y_j(2s_j - 1)]^2 / 2$              |

The software normalizes the binary losses such that the loss is 0.5 when  $y_j = 0$ . Also, the software calculates the mean binary loss for each class.

- For a custom binary loss function, e.g., `customFunction`, specify its function handle 'BinaryLoss', @customFunction.

`customFunction` should have this form

```
bLoss = customFunction(M,s)
```

where:

- $M$  is the  $K$ -by- $L$  coding matrix stored in `Mdl.CodingMatrix`.
- $s$  is the 1-by- $L$  row vector of classification scores.
- `bLoss` is the classification loss. This scalar aggregates the binary losses for every learner in a particular class. For example, you can use the mean binary loss to aggregate the loss over the learners for each class.
- $K$  is the number of classes.

- $L$  is the number of binary learners.

For an example on passing a custom binary loss function, see “Predict Test-Sample Labels of ECOC Models Using Custom Binary Loss Function”.

This list describes the default values of `BinaryLoss`. If all binary learners are:

- SVMs, then `BinaryLoss` is `'hinge'`
- Ensembles trained by `AdaboostM1` or `GentleBoost`, then `BinaryLoss` is `'exponential'`
- Ensembles trained by `LogitBoost`, then `BinaryLoss` is `'binodeviance'`
- Predicting class posterior probabilities (i.e., set `'FitPosterior',1` in `fitcecoc`), then `BinaryLoss` is `'quadratic'`

Otherwise, the default `BinaryLoss` is `'hamming'`.

Example: `'BinaryLoss','binodeviance'`

Data Types: char | function\_handle

#### **'Decoding' — Decoding scheme**

`'lossweighted'` (default) | `'lossbased'`

Decoding scheme that aggregates the “binary losses”, specified as the comma-separated pair consisting of `'Decoding'` and `'lossweighted'` or `'lossbased'`.

Example: `'Decoding','lossbased'`

Data Types: char

#### **'Options' — Estimation options**

`[]` (default) | structure array returned by `statset`

Estimation options, specified as the comma-separated pair consisting of `'Options'` and a structure array returned by `statset`.

To invoke parallel computing:

- You need a Parallel Computing Toolbox license.
- Specify `'Options',statset('UseParallel',1)`.

#### **'Verbose' — Verbosity level**

0 (default) | 1

Verbosity level, specified as the comma-separated pair consisting of 'Verbose' and 0 or 1. **Verbose** controls the amount of diagnostic messages that the software displays in the Command Window.

If **Verbose** is 0, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: 'Verbose', 1

Data Types: single | double

## Output Arguments

**e** — Classification edge  
numeric scalar

Classification edge, returned as a scalar. **e** represents the (weighted) mean of the classification margins.

## Definitions

### Classification Edge

The *classification edge* is the weighted mean of the *classification margins*.

One way to choose among multiple classifiers, e.g., to perform feature selection, is to choose the classifier that yields the highest edge.

### Classification Margin

The *classification margins* are, for each observation, the difference between the negative loss for the positive class and maximal negative loss among the negative classes. If the margins are on the same scale, then they serve as a classification confidence measure, i.e., among multiple classifiers, those that yield larger margins are better “[4]”.

### Binary Loss

A *binary loss* is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Let:

- $m_{kj}$  be element  $(k,j)$  of the coding design matrix  $M$  (i.e., the code corresponding to class  $k$  of binary learner  $j$ )
- $s_j$  be the score of binary learner  $j$  for an observation
- $g$  be the binary loss function
- $\hat{k}$  be the predicted class for the observation

In *loss-based decoding* [3], the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j).$$

In *loss-weighted decoding* [3], the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \frac{\sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j)}{\sum_{j=1}^L |m_{kj}|}.$$

Allwein et al. [1] suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where  $y_j$  is a class label for a particular binary learner (in the set  $\{-1,1,0\}$ ),  $s_j$  is the score for observation  $j$ , and  $g(y_j, s_j)$ .

| Value          | Description       | Score Domain        | $g(y_j, s_j)$                            |
|----------------|-------------------|---------------------|------------------------------------------|
| 'binodeviance' | Binomial deviance | $(-\infty, \infty)$ | $\log[1 + \exp(-2y_j s_j)] / [2\log(2)]$ |
| 'exponential'  | Exponential       | $(-\infty, \infty)$ | $\exp(-y_j s_j) / 2$                     |
| 'hamming'      | Hamming           | $\{-1, 1\}$         | $[1 - \operatorname{sign}(y_j s_j)] / 2$ |

| Value       | Description | Score Domain        | $g(y_i, s_i)$             |
|-------------|-------------|---------------------|---------------------------|
| 'hinge'     | Hinge       | $(-\infty, \infty)$ | $\max(0, 1 - y_i s_i)/2$  |
| 'linear'    | Linear      | $(-\infty, \infty)$ | $(1 - y_i s_i)/2$         |
| 'quadratic' | Quadratic   | $[0, 1]$            | $[1 - y_i(2s_i - 1)]^2/2$ |

The software normalizes the binary losses such that the loss is 0.5 when  $y_j = 0$ , and aggregates using the average of the binary learners [1].

Do not confuse the binary loss with the overall classification loss (specified by the LossFun name-value pair argument of `predict` and `loss`), e.g., classification error, which measures how well an ECOC classifier performs as a whole.

## Examples

### Estimate the Resubstitution Edge of ECOC Models

Load Fisher's iris data set.

```
load fisheriris
X = meas;
Y = species;
```

Train an ECOC model using SVM binary classifiers. It is good practice to standardize the predictors and define the class order. Specify to standardize the predictors using an SVM template.

```
t = templateSVM('Standardize',1);
classOrder = unique(Y)
Mdl = fitcecoc(X,Y,'Learners',t,'ClassNames',classOrder);
```

```
classOrder =
 'setosa'
 'versicolor'
 'virginica'
```

`t` is an SVM template object. The software uses default values for empty options in `t` during training. `Mdl` is a `ClassificationECOC` model.

Estimate the resubstitution edge.

```
e = resubEdge(Mdl)
```

```
e =
```

```
0.4961
```

The mean of the training sample margins is 0.4961.

### Select ECOC Model Features by Comparing In-Sample Edges

The classifier edge measures the average of the classifier margins. One way to perform feature selection is to compare training sample edges from multiple models. Based solely on this criterion, the classifier with the highest edge is the best classifier.

Load Fisher's iris data set. Define two data sets:

- `fullX` contains all four predictors.
- `partX` contains the sepal measurements.

```
load fisheriris
X = meas;
fullX = X;
partX = X(:,1:2);
Y = species;
```

Train ECOC models using SVM binary learners for each predictor set. It is good practice to standardize the predictors and define the class order. Specify to standardize the predictors using an SVM template, and to compute posterior probabilities.

```
t = templateSVM('Standardize',1);
classOrder = unique(Y)
FullMdl = fitcecoc(fullX,Y,'Learners',t,'ClassNames',classOrder,...
 'FitPosterior',1);
PartMdl = fitcecoc(partX,Y,'Learners',t,'ClassNames',classOrder,...
 'FitPosterior',1);
```

```
classOrder =
```

```
'setosa'
'versicolor'
```

```
'virginica'
```

The default SVM score is distance from the decision boundary. If you specify to compute posterior probabilities, then the software uses posterior probabilities as scores.

Estimate the training sample edge for each classifier. The quadratic loss function operates on scores in the domain [0,1]. Specify to use quadratic loss when aggregating the binary learners for both models.

```
fullEdge = resubEdge(FullMdl, 'BinaryLoss', 'quadratic')
partEdge = resubEdge(PartMdl, 'BinaryLoss', 'quadratic')
```

```
fullEdge =
 0.9896
```

```
partEdge =
 0.5058
```

The edge for the classifier trained on the complete data set is greater, suggesting that the classifier trained using every predictor has a better in-sample fit.

- “Quick Start Parallel Computing for Statistics Toolbox” on page 20-2

## Tip

To compare margins or edges of several classifiers, use template objects to specify a common score transform function among the classifiers when you train them using `fitcecoc`.

# resubEdge

**Class:** ClassificationEnsemble

Classification edge by resubstitution

## Syntax

```
edge = resubEdge(ens)
edge = resubEdge(ens,Name,Value)
```

## Description

`edge = resubEdge(ens)` returns the classification edge obtained by `ens` on its training data.

`edge = resubEdge(ens,Name,Value)` calculates edge with additional options specified by one or more `Name,Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

## Input Arguments

### **ens**

A classification ensemble created with `fitensemble`.

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### **'learners'**

Indices of weak learners in the ensemble ranging from 1 to `NumTrained`. `resubEdge` uses only these learners for calculating edge.

**Default:** 1:NumTrained

**'mode'**

String representing the meaning of the output edge:

- 'ensemble' — edge is a scalar value, the loss for the entire ensemble.
- 'individual' — edge is a vector with one element per trained learner.
- 'cumulative' — edge is a vector in which element J is obtained by using learners 1:J from the input list of learners.

**Default:** 'ensemble'

## Output Arguments

**edge**

Classification edge obtained by ens by resubstituting the training data into the calculation of edge. Classification edge is classification margin averaged over the entire data. edge can be a scalar or vector, depending on the setting of the mode name-value pair.

## Definitions

### Edge

The *edge* is the weighted mean value of the classification margin. The weights are the class probabilities in ens.Prior.

### Margin

The classification *margin* is the difference between the classification *score* for the true class and maximal classification score for the false classes. Margin is a column vector with the same number of rows as in the matrix ens.X.

### Score (ensemble)

For ensembles, a classification *score* represents the confidence of a classification into a class. The higher the score, the higher the confidence.

Different ensemble algorithms have different definitions for their scores. Furthermore, the range of scores depends on ensemble type. For example:

- AdaBoostM1 scores range from  $-\infty$  to  $\infty$ .
- Bag scores range from 0 to 1.

## Examples

Find the resubstitution edge for an ensemble that classifies the Fisher iris data:

```
load fisheriris
ens = fitensemble(meas,species,'AdaBoostM2',100,'Tree');
edge = resubEdge(ens)

edge =
 3.2486
```

## See Also

## resubEdge

**Class:** ClassificationKNN

Edge of  $k$ -nearest neighbor classifier by resubstitution

## Syntax

`E = resubEdge(md1)`

## Description

`E = resubEdge(md1)` returns the classification edge for `md1` with the data used to train `md1` (see “Edge” on page 21-3797).

## Input Arguments

**md1 — Classifier model**

classifier model object

$k$ -nearest neighbor classifier model, returned as a classifier model object.

Note that using the 'CrossVal', 'KFold', 'Holdout', 'Leaveout', or 'CVPartition' options results in a model of class `ClassificationPartitionedModel`. You cannot use a partitioned tree for prediction, so this kind of tree does not have a `predict` method.

Otherwise, `md1` is of class `ClassificationKNN`, and you can use the `predict` method to make predictions.

## Output Arguments

**E**

Classification edge, a scalar that is the mean classification margin (see “Margin” on page 21-3797).

## Definitions

### Edge

The *edge* is the mean value of the classification *margin*.

### Margin

The classification *margin* is the difference between the classification *score* for the true class and maximal classification score for the false classes.

Margin is a column vector with the same number of rows as in the training data.

### Score

The *score* of a classification is the posterior probability of the classification. The posterior probability is the number of neighbors that have that classification, divided by the number of neighbors. For a more detailed definition that includes weights and prior probabilities, see “Posterior Probability” on page 21-3315.

## Examples

### Resubstitution Edge Calculation

Construct a  $k$ -nearest neighbor classifier for the Fisher iris data, where  $k = 5$ .

Load the data.

```
load fisheriris
X = meas;
Y = species;
```

Construct a classifier for 5-nearest neighbors.

```
mdl = fitcknn(X,Y,'NumNeighbors',5);
```

Examine the resubstitution edge of the classifier.

```
E = resubEdge(mdl)
```

E =

0.9253

- “Examine the Quality of a KNN Classifier” on page 16-29

# resubEdge

**Class:** ClassificationNaiveBayes

Classification edge for naive Bayes classifiers by resubstitution

## Syntax

```
e = resubEdge(Mdl)
```

## Description

`e = resubEdge(Mdl)` returns the resubstitution “classification edge” (**e**) for the naive Bayes classifier `Mdl` using the training data stored in `Mdl.X` and corresponding class labels stored in `Mdl.Y`.

## Input Arguments

**Mdl** — Fully trained naive Bayes classifier

ClassificationNaiveBayes model

A fully trained naive Bayes classifier, specified as a `ClassificationNaiveBayes` model trained by `fitcnb`.

## Output Arguments

**e** — Classification edge

scalar

“Classification edge”, returned as a scalar. If you passed in weights when training the classifier, then **e** is the weighted classification edge. The software normalizes the weights so that they sum to the prior probability of their respective class.

## Definitions

### Classification Edge

The *classification edge* is the weighted mean of the classification margins.

If you supply weights, then the software normalizes them to sum to the prior probability of their respective class. The software uses the normalized weights to compute the weighted mean.

One way to choose among multiple classifiers, e.g., to perform feature selection, is to choose the classifier that yields the highest edge.

### Classification Margins

The *classification margins* are, for each observation, the difference between the score for the true class and maximal score for the false classes. Provided that they are on the same scale, margins serve as a classification confidence measure, i.e., among multiple classifiers, those that yield larger margins are better “[2]”.

### Posterior Probability

The *posterior probability* is the probability that an observation belongs in a particular class, given the data.

For naive Bayes, the posterior probability that a classification is  $k$  for a given observation  $(x_1, \dots, x_p)$  is

$$\hat{P}(Y = k | x_1, \dots, x_p) = \frac{P(X_1, \dots, X_p | y = k) \pi(Y = k)}{P(X_1, \dots, X_p)},$$

where:

- $P(X_1, \dots, X_p | y = k)$  is the conditional joint density of the predictors given they are in class  $k$ . `Mdl.DistributionNames` stores the distribution names of the predictors.
- $\pi(Y = k)$  is the class prior probability distribution. `Mdl.Prior` stores the prior distribution.

- $P(X_1, \dots, X_P)$  is the joint density of the predictors. The classes are discrete, so

$$P(X_1, \dots, X_P) = \sum_{k=1}^K P(X_1, \dots, X_P | Y = k) \pi(Y = k).$$

## Prior Probability

The *prior probability* is the believed relative frequency that observations from a class occur in the population for each class.

## Score

The naive Bayes *score* is the class posterior probability given the observation.

## Examples

### Estimate the Resubstitution Edge of Naive Bayes Classifiers

Load Fisher's iris data set.

```
load fisheriris
X = meas; % Predictors
Y = species; % Response
rng(1);
```

Train a naive Bayes classifier. It is good practice to specify the class order. Assume that each predictor is conditionally, normally distributed given its label.

```
Mdl = fitcnb(X, Y, 'ClassNames', {'setosa', 'versicolor', 'virginica'});
```

Mdl is a trained `ClassificationNaiveBayes` classifier.

Estimate the resubstitution edge.

```
e = resubEdge(Mdl)
```

```
e =
```

0.8944

The mean of the training sample margins is approximately 0.9, which indicates that the classifier classifies in-sample observations with high confidence.

### Select Naive Bayes Classifier Features by Comparing In-Sample Edges

The classifier edge measures the average of the classifier margins. One way to perform feature selection is to compare training sample edges from multiple models. Based solely on this criterion, the classifier with the highest edge is the best classifier.

Load Fisher's iris data set. Define two data sets:

- `fullX` contains all predictors.
- `partX` contains the last two predictors.

```
load fisheriris
X = meas; % Predictors
Y = species; % Response
fullX = X;
partX = X(:,3:4);
```

Train naive Bayes classifiers for each predictor set.

```
FullMdl = fitcnb(fullX,Y);
PartMdl = fitcnb(partX,Y);
```

Estimate the training sample edge for each classifier.

```
fullEdge = resubEdge(FullMdl)
partEdge = resubEdge(PartMdl)
```

```
fullEdge =
```

```
0.8944
```

```
partEdge =
```

```
0.9169
```

The edge for the classifier trained on predictors 3 and 4 is greater, suggesting that the classifier trained using only those predictors has a better in-sample fit.

## resubEdge

**Class:** ClassificationSVM

Classification edge for support vector machine classifiers by resubstitution

### Syntax

```
e = resubEdge(SVMModel)
```

### Description

`e = resubEdge(SVMModel)` returns the resubstitution classification edge (**e**) for the support vector machine (SVM) classifier `SVMModel` using the training data stored in `SVMModel.X` and corresponding class labels stored in `SVMModel.Y`.

### Input Arguments

**SVMModel** — Full, trained SVM classifier

*ClassificationSVM classifier*

Full, trained SVM classifier, specified as a `ClassificationSVM` model trained using `fitcsvm`.

### Output Arguments

**e** — Classification edge

*scalar*

Classification edge, returned as a scalar. **e** represents the weighted mean of the classification margins.

## Definitions

### Edge

The *edge* is the weighted mean of the *classification margins*.

The weights are the prior class probabilities. If you supply weights, then the software normalizes them to sum to the prior probabilities in the respective classes. The software uses the renormalized weights to compute the weighted mean.

One way to choose among multiple classifiers, e.g., to perform feature selection, is to choose the classifier that yields the highest edge.

### Classification Margins

The *classification margins* are, for each observation, the difference between the score for the true class and maximal score for the false classes. Provided that they are on the same scale, margins serve as a classification confidence measure, i.e., among multiple classifiers, those that yield larger margins are better “[2]”.

### Score

The SVM *score* for classifying observation  $x$  is the signed distance from  $x$  to the decision boundary ranging from  $-\infty$  to  $+\infty$ . A positive score for a class indicates that  $x$  is predicted to be in that class, a negative score indicates otherwise.

The score is also the numerical, predicted response for  $x$ ,  $f(x)$ , computed by the trained SVM classification function

$$f(x) = \sum_{j=1}^n \alpha_j y_j G(x_j, x) + b,$$

where  $(\alpha_1, \dots, \alpha_n, b)$  are the estimated SVM parameters,  $G(x_j, x)$  is the dot product in the predictor space between  $x$  and the support vectors, and the sum includes the training set observations.

## Examples

### Estimate the Resubstitution Edge of SVM Classifiers

Load the `ionosphere` data set.

```
load ionosphere
```

Train an SVM classifier. It is good practice to standardize the predictors and define the class order.

```
SVMModel = fitcsvm(X,Y,'Standardize',true,'ClassNames',{'b','g'});
```

`SVMModel` is a trained `ClassificationSVM` classifier. 'b' is the negative class and 'g' is the positive class.

Estimate the resubstitution edge.

```
e = resubEdge(SVMModel)
```

```
e =
```

```
5.0998
```

The mean of the training sample margins is 5.0999.

### Select SVM Classifier Features by Comparing In-Sample Edges

The classifier edge measures the average of the classifier margins. One way to perform feature selection is to compare training sample edges from multiple models. Based solely on this criterion, the classifier with the highest edge is the best classifier.

Load the `ionosphere` data set. Define two data sets:

- `fullX` contains all predictors (except the removed column of 0s).
- `partX` contains the last 20 predictors.

```
load ionosphere
fullX = X;
partX = X(:,end-20:end);
```

Train SVM classifiers for each predictor set.

```
FullSVMModel = fitcsvm(fullX,Y);
PartSVMModel = fitcsvm(partX,Y);
```

Estimate the training sample edge for each classifier.

```
fullEdge = resubEdge(FullSVMModel)
partEdge = resubEdge(PartSVMModel)
```

```
fullEdge =
```

```
 3.3653
```

```
partEdge =
```

```
 2.0471
```

The edge for the classifier trained on the complete data set is greater, suggesting that the classifier trained using all of the predictors has a better in-sample fit.

## Algorithms

For binary classification, the software defines the margin for observation  $j$ ,  $m_j$ , as

$$m_j = 2y_j f(x_j),$$

where  $y_j \in \{-1, 1\}$ , and  $f(x_j)$  is the predicted score of observation  $j$  for the positive class. However, the literature commonly uses  $m_j = y_j f(x_j)$  to define the margin.

# resubEdge

**Class:** ClassificationTree

Classification edge by resubstitution

## Syntax

```
edge = resubEdge(tree)
```

## Description

`edge = resubEdge(tree)` returns the classification edge obtained by `tree` on its training data.

## Input Arguments

**tree**

A classification tree created using `fitctree`.

## Output Arguments

**edge**

Classification edge obtained by resubstituting the training data into the calculation of `edge`.

## Definitions

### Edge

The *edge* is the weighted mean value of the classification margin. The weights are the class probabilities in `tree.Prior`.

## Margin

The classification *margin* is the difference between the classification *score* for the true class and maximal classification score for the false classes. Margin is a column vector with the same number of rows as in the matrix  $X$ .

## Score (tree)

For trees, the *score* of a classification of a leaf node is the posterior probability of the classification at that node. The posterior probability of the classification at a node is the number of training sequences that lead to that node with the classification, divided by the number of training sequences that lead to that node.

For example, consider classifying a predictor  $X$  as true when  $X < 0.15$  or  $X > 0.95$ , and  $X$  is false otherwise.

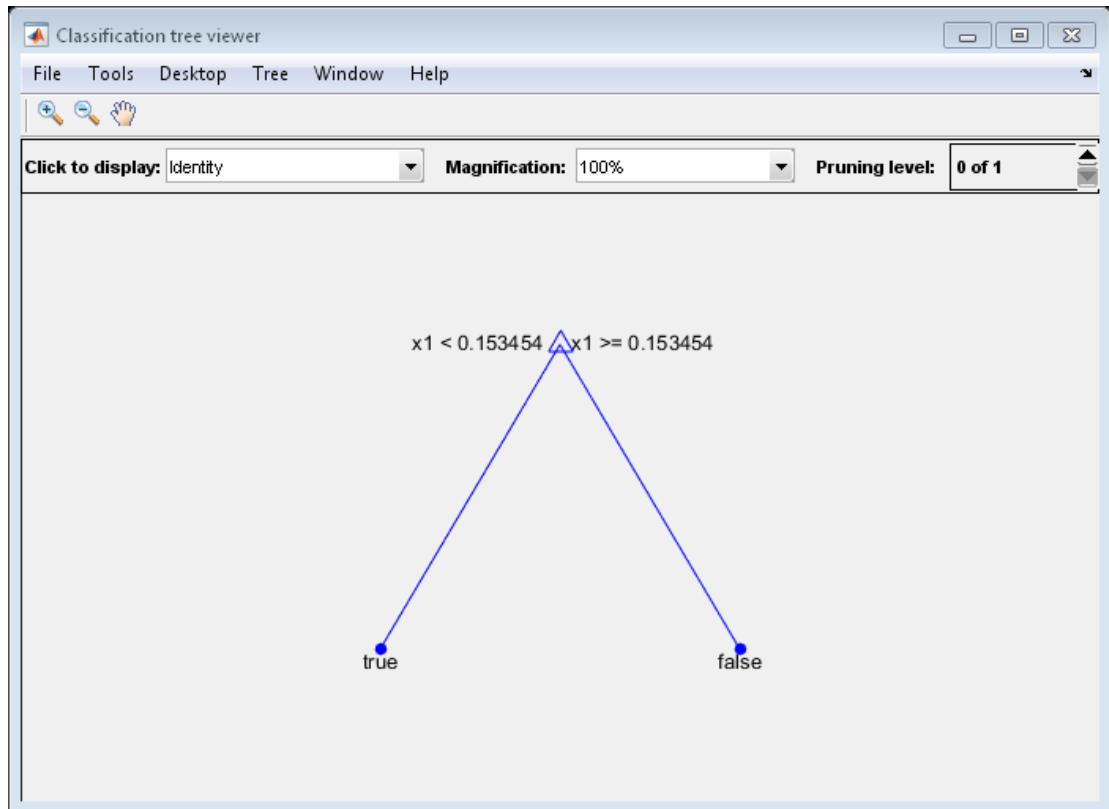

Generate 100 random points and classify them:

```
rng(0, 'twister') % for reproducibility
X = rand(100,1);
Y = (abs(X - .55) > .4);
tree = fitctree(X,Y);
view(tree, 'Mode', 'Graph')
```

Prune the tree:

```
tree1 = prune(tree, 'Level', 1);
view(tree1, 'Mode', 'Graph')
```

The pruned tree correctly classifies observations that are less than 0.15 as **true**. It also correctly classifies observations from .15 to .94 as **false**. However, it incorrectly classifies observations that are greater than .94 as **false**. Therefore, the score for observations that are greater than .15 should be about  $.05/.85=.06$  for **true**, and about  $.8/.85=.94$  for **false**.

Compute the prediction scores for the first 10 rows of X:

```
[~,score] = predict(tree1,X(1:10));
[score X(1:10,:)]
```

```
ans =
```

```
0.9059 0.0941 0.8147
```

|        |        |        |
|--------|--------|--------|
| 0.9059 | 0.0941 | 0.9058 |
| 0      | 1.0000 | 0.1270 |
| 0.9059 | 0.0941 | 0.9134 |
| 0.9059 | 0.0941 | 0.6324 |
| 0      | 1.0000 | 0.0975 |
| 0.9059 | 0.0941 | 0.2785 |
| 0.9059 | 0.0941 | 0.5469 |
| 0.9059 | 0.0941 | 0.9575 |
| 0.9059 | 0.0941 | 0.9649 |

Indeed, every value of  $X$  (the right-most column) that is less than 0.15 has associated scores (the left and center columns) of 0 and 1, while the other values of  $X$  have associated scores of 0.91 and 0.09. The difference (score 0.09 instead of the expected .06) is due to a statistical fluctuation: there are 8 observations in  $X$  in the range (.95, 1) instead of the expected 5 observations.

## Examples

Estimate the quality of a classification tree for the Fisher iris data by resubstitution.

```
load fisheriris
tree = fitctree(meas,species);
redge = resubEdge(tree)

redge =
 0.9384
```

## resubLoss

**Class:** ClassificationDiscriminant

Classification error by resubstitution

### Syntax

`L = resubLoss(obj)`

`L = resubLoss(obj,Name,Value)`

### Description

`L = resubLoss(obj)` returns the resubstitution loss, meaning the loss computed for the data that `fitcdiscr` used to create `obj`.

`L = resubLoss(obj,Name,Value)` returns loss statistics with additional options specified by one or more `Name,Value` pair arguments.

### Input Arguments

**obj**

Discriminant analysis classifier, produced using `fitcdiscr`.

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**'lossfun'**

Function handle or string representing a loss function. Built-in loss functions are:

- `'binodeviance'` — See “Loss Functions” on page 21-3815.

- 'classiferror' — Fraction of misclassified observations. See “Loss Functions” on page 21-3815.
- 'exponential' — See “Loss Functions” on page 21-3815.
- 'hinge' — See “Loss Functions” on page 21-3831.
- 'mincost' — Smallest misclassification cost as given by the obj.Cost matrix.

You can write your own loss function using the syntax described in “Loss Functions” on page 21-3815.

**Default:** 'mincost'

## Output Arguments

**L**

Classification error, a scalar. The meaning of the error depends on the values in `weights` and `lossfun`. See “Classification Error” on page 21-3815.

## Definitions

### Classification Error

The default classification error is the fraction of the training data  $X$  that `obj` misclassifies.

Weighted classification error is the sum of weight  $i$  times the Boolean value that is 1 when `obj` misclassifies the  $i$ th row of  $X$ , divided by the sum of the weights.

### Loss Functions

The built-in loss functions are:

- 'binodeviance' — For binary classification, assume the classes  $y_n$  are -1 and 1. With weight vector  $w$  normalized to have sum 1, and predictions of row  $n$  of data  $X$  as  $f(X_n)$ , the binomial deviance is

$$\sum w_n \log(1 + \exp(-2y_n f(X_n))).$$

- 'exponential' — With the same definitions as for 'binodeviance', the exponential loss is

$$\sum w_n \exp(-y_n f(X_n)).$$

- 'classiferror' — Predict the label with the largest posterior probability. The loss is then the fraction of misclassified observations.
- 'hinge' — Classification error measure that has the form

$$L = \frac{\sum_{j=1}^n w_j \max\{0, 1 - y_j' f(X_j)\}}{\sum_{j=1}^n w_j},$$

where:

- $w_j$  is weight  $j$ .
- For binary classification,  $y_j = 1$  for the positive class and  $-1$  for the negative class. For problems where the number of classes  $K > 3$ ,  $y_j$  is a vector of 0s, but with a 1 in the position corresponding to the true class, e.g., if the second observation is in the third class and  $K = 4$ , then  $y_2 = [0 \ 0 \ 1 \ 0]'$ .
- $f(X_j)$  is, for binary classification, the posterior probability or, for  $K > 3$ , a vector of posterior probabilities for each class given observation  $j$ .
- 'mincost' — Predict the label with the smallest expected misclassification cost, with expectation taken over the posterior probability, and cost as given by the **COST** property of the classifier (a matrix). The loss is then the true misclassification cost averaged over the observations.

To write your own loss function, create a function file in this form:

```
function loss = lossfun(C,S,W,COST)
```

- N is the number of rows of X.
- K is the number of classes in the classifier, represented in the **ClassNames** property.
- C is an N-by-K logical matrix, with one **true** per row for the true class. The index for each class is its position in the **ClassNames** property.

- **S** is an N-by-K numeric matrix. **S** is a matrix of posterior probabilities for classes with one row per observation, similar to the `posterior` output from `predict`.
- **W** is a numeric vector with N elements, the observation weights. If you pass **W**, the elements are normalized to sum to the prior probabilities in the respective classes.
- **COST** is a K-by-K numeric matrix of misclassification costs. For example, you can use `COST = ones(K) - eye(K)`, which means a cost of 0 for correct classification, and 1 for misclassification.
- The output `loss` should be a scalar.

Pass the function handle `@lossfun` as the value of the `LossFun` name-value pair.

## Posterior Probability

The posterior probability that a point  $z$  belongs to class  $j$  is the product of the prior probability and the multivariate normal density. The density function of the multivariate normal with mean  $\mu_j$  and covariance  $\Sigma_j$  at a point  $z$  is

$$P(x | k) = \frac{1}{(2\pi|\Sigma_k|)^{1/2}} \exp\left(-\frac{1}{2}(x - \mu_k)^T \Sigma_k^{-1}(x - \mu_k)\right),$$

where  $|\Sigma_k|$  is the determinant of  $\Sigma_k$ , and  $\Sigma_k^{-1}$  is the inverse matrix.

Let  $P(k)$  represent the prior probability of class  $k$ . Then the posterior probability that an observation  $x$  is of class  $k$  is

$$\hat{P}(k | x) = \frac{P(x | k)P(k)}{P(x)},$$

where  $P(x)$  is a normalization constant, the sum over  $k$  of  $P(x | k)P(k)$ .

## Prior Probability

The prior probability is one of three choices:

- 'uniform' — The prior probability of class  $k$  is one over the total number of classes.
- 'empirical' — The prior probability of class  $k$  is the number of training samples of class  $k$  divided by the total number of training samples.

- Custom — The prior probability of class `k` is the `k`th element of the `prior` vector. See `fitcdiscr`.

After creating a classifier `obj`, you can set the prior using dot notation:

```
obj.Prior = v;
```

where `v` is a vector of positive elements representing the frequency with which each element occurs. You do not need to retrain the classifier when you set a new prior.

## Cost

The matrix of expected costs per observation is defined in “Cost” on page 15-8.

## Examples

Compute the resubstituted classification error for the Fisher iris data:

```
load fisheriris
obj = fitcdiscr(meas,species);
L = resubLoss(obj)
```

```
L =
 0.0200
```

## How To

- “Discriminant Analysis” on page 15-3

# resubLoss

**Class:** ClassificationECOC

Classification loss for error-correcting output codes, multiclass models by resubstitution

## Syntax

```
L = resubLoss(Mdl)
L = resubLoss(Mdl,Name,Value)
```

## Description

`L = resubLoss(Mdl)` returns classification loss (L) for the trained, error-correcting output codes (ECOC), multiclass model `Mdl` using the training data stored in `Mdl.X` and corresponding class labels stored in `Mdl.Y`.

`L = resubLoss(Mdl,Name,Value)` returns the classification loss with additional options specified by one or more `Name,Value` pair arguments.

For example, specify the loss function, decoding scheme, or verbosity level.

## Input Arguments

**Mdl** — ECOC multiclass model

ClassificationECOC model

ECOC multiclass model, specified as a `ClassificationECOC` model returned by `fitcecoc`.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**'BinaryLoss' — Binary learner loss function**

function handle | 'hamming' | 'linear' | 'exponential' | 'binodeviance' | 'hinge' | 'quadratic'

Binary learner loss function, specified as the comma-separated pair consisting of 'BinaryLoss' and a function handle or string.

- If the value is a string, then it must correspond to a built-in function. This table summarizes the built-in functions, where  $y_j$  is a class label for a particular binary learner (in the set  $\{-1,1,0\}$ ),  $s_j$  is the score for observation  $j$ , and  $g(y_j,s_j)$  is the binary loss formula.

| Value          | Description       | Score Domain       | $g(y_j,s_j)$                             |
|----------------|-------------------|--------------------|------------------------------------------|
| 'binodeviance' | Binomial deviance | $(-\infty,\infty)$ | $\log[1 + \exp(-2y_j s_j)] / [2\log(2)]$ |
| 'exponential'  | Exponential       | $(-\infty,\infty)$ | $\exp(-y_j s_j) / 2$                     |
| 'hamming'      | Hamming           | $\{-1,1\}$         | $[1 - \text{sign}(y_j s_j)] / 2$         |
| 'hinge'        | Hinge             | $(-\infty,\infty)$ | $\max(0, 1 - y_j s_j) / 2$               |
| 'linear'       | Linear            | $(-\infty,\infty)$ | $(1 - y_j s_j) / 2$                      |
| 'quadratic'    | Quadratic         | $[0,1]$            | $[1 - y_j(2s_j - 1)]^2 / 2$              |

The software normalizes the binary losses such that the loss is 0.5 when  $y_j = 0$ . Also, the software calculates the mean binary loss for each class.

- For a custom binary loss function, e.g., `customFunction`, specify its function handle 'BinaryLoss',@`customFunction`.

`customFunction` should have this form

```
bLoss = customFunction(M,s)
```

where:

- $M$  is the  $K$ -by- $L$  coding matrix stored in `Mdl.CodingMatrix`.
- $s$  is the 1-by- $L$  row vector of classification scores.
- `bLoss` is the classification loss. This scalar aggregates the binary losses for every learner in a particular class. For example, you can use the mean binary loss to aggregate the loss over the learners for each class.
- $K$  is the number of classes.

- $L$  is the number of binary learners.

For an example on passing a custom binary loss function, see “Predict Test-Sample Labels of ECOC Models Using Custom Binary Loss Function”.

This list describes the default values of `BinaryLoss`. If all binary learners are:

- SVMs, then `BinaryLoss` is `'hinge'`
- Ensembles trained by `AdaboostM1` or `GentleBoost`, then `BinaryLoss` is `'exponential'`
- Ensembles trained by `LogitBoost`, then `BinaryLoss` is `'binodeviance'`
- Predicting class posterior probabilities (i.e., set `'FitPosterior', 1` in `fitcecoc`), then `BinaryLoss` is `'quadratic'`

Otherwise, the default `BinaryLoss` is `'hamming'`.

Example: `'BinaryLoss', 'binodeviance'`

Data Types: `char` | `function_handle`

#### **'Decoding' — Decoding scheme**

`'lossweighted'` (default) | `'lossbased'`

Decoding scheme that aggregates the “binary losses”, specified as the comma-separated pair consisting of `'Decoding'` and `'lossweighted'` or `'lossbased'`.

Example: `'Decoding', 'lossbased'`

Data Types: `char`

#### **'LossFun' — Loss function**

`'classiferror'` (default) | `function handle`

Loss function, specified as the comma-separated pair consisting of `'LossFun'` and a function handle or `'classiferror'`.

You can:

- Specify the built-in function `'classiferror'`, then the loss function is classification error, in other words, the proportion of misclassified observations.
- Specify your own function using function handle notation.

Suppose that  $n = \text{size}(X, 1)$  is the sample size and  $k$  is the number of classes. Your function must have the signature `lossvalue = lossfun(C,S,W,Cost)`, where:

- The output argument `lossvalue` is a scalar.
- You choose the function name (*lossfun*).
- `C` is an  $n$ -by- $k$  logical matrix with rows indicating to which class the corresponding observation belongs. The column order corresponds to the class order in `Mdl.ClassNames`.

Construct `C` by setting  $C(p, q) = 1$  if observation `p` is in class `q` for each row. Set all other elements of row `p` to 0.

- `S` is an  $n$ -by- $k$  numeric matrix of negated loss values for classes. Each row corresponds to an observation. The column order corresponds to the class order in `CVMDL.ClassNames`. `S` is similar to the output argument `negLoss` of `resubPredict`.
- `W` is an  $n$ -by-1 numeric vector of observation weights. If you pass `W`, the software normalizes its elements to sum to 1.
- `Cost` is a  $k$ -by- $k$  numeric matrix of misclassification costs. For example, `Cost = ones(K) - eye(K)` specifies a cost of 0 for correct classification, and 1 for misclassification.

Specify your function using `'LossFun', @lossfun`.

#### **'Options' — Estimation options**

`[]` (default) | structure array returned by `statset`

Estimation options, specified as the comma-separated pair consisting of `'Options'` and a structure array returned by `statset`.

To invoke parallel computing:

- You need a Parallel Computing Toolbox license.
- Specify `'Options', statset('UseParallel', 1)`.

#### **'Verbose' — Verbosity level**

0 (default) | 1

Verbosity level, specified as the comma-separated pair consisting of `'Verbose'` and 0 or 1. `Verbose` controls the amount of diagnostic messages that the software displays in the Command Window.

If `Verbose` is 0, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: 'Verbose', 1

Data Types: single | double

## Output Arguments

### L — Classification loss

scalar

Classification loss, returned as a scalar. L is a generalization or resubstitution quality measure. Its interpretation depends on the loss function and weighting scheme, but, in general, better classifiers yield smaller loss values.

## Definitions

### Classification Error

The *classification error* is a binary classification error measure that has the form

$$L = \frac{\sum_{j=1}^n w_j e_j}{\sum_{j=1}^n w_j},$$

where:

- $w_j$  is the weight for observation  $j$ . The software renormalizes the weights to sum to 1.
- $e_j = 1$  if the predicted class of observation  $j$  differs from its true class, and 0 otherwise.

In other words, it is the proportion of observations that the classifier misclassifies.

### Binary Loss

A *binary loss* is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Let:

- $m_{kj}$  be element  $(k,j)$  of the coding design matrix  $M$  (i.e., the code corresponding to class  $k$  of binary learner  $j$ )
- $s_j$  be the score of binary learner  $j$  for an observation
- $g$  be the binary loss function
- $\hat{k}$  be the predicted class for the observation

In *loss-based decoding* [3], the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j).$$

In *loss-weighted decoding* [3], the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \frac{\sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j)}{\sum_{j=1}^L |m_{kj}|}.$$

Allwein et al. [1] suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where  $y_j$  is a class label for a particular binary learner (in the set  $\{-1,1,0\}$ ),  $s_j$  is the score for observation  $j$ , and  $g(y_j, s_j)$ .

| Value          | Description       | Score Domain        | $g(y_j, s_j)$                            |
|----------------|-------------------|---------------------|------------------------------------------|
| 'binodeviance' | Binomial deviance | $(-\infty, \infty)$ | $\log[1 + \exp(-2y_j s_j)] / [2\log(2)]$ |
| 'exponential'  | Exponential       | $(-\infty, \infty)$ | $\exp(-y_j s_j) / 2$                     |
| 'hamming'      | Hamming           | $\{-1, 1\}$         | $[1 - \operatorname{sign}(y_j s_j)] / 2$ |

| Value       | Description | Score Domain        | $g(y_i, s_i)$             |
|-------------|-------------|---------------------|---------------------------|
| 'hinge'     | Hinge       | $(-\infty, \infty)$ | $\max(0, 1 - y_i s_i)/2$  |
| 'linear'    | Linear      | $(-\infty, \infty)$ | $(1 - y_i s_i)/2$         |
| 'quadratic' | Quadratic   | $[0, 1]$            | $[1 - y_i(2s_i - 1)]^2/2$ |

The software normalizes the binary losses such that the loss is 0.5 when  $y_j = 0$ , and aggregates using the average of the binary learners [1].

Do not confuse the binary loss with the overall classification loss (specified by the LossFun name-value pair argument of `predict` and `loss`), e.g., classification error, which measures how well an ECOC classifier performs as a whole.

## Examples

### Determine the Resubstitution Loss of ECOC Models

Load Fisher's iris data set.

```
load fisheriris
X = meas;
Y = species;
```

Train an ECOC model using SVM binary classifiers. It is good practice to standardize the predictors and define the class order. Specify to standardize the predictors using an SVM template.

```
t = templateSVM('Standardize',1);
classOrder = unique(Y)
Mdl = fitcecoc(X,Y,'Learners',t,'ClassNames',classOrder);
```

```
classOrder =
 'setosa'
 'versicolor'
 'virginica'
```

`t` is an SVM template object. The software uses default values for empty options in `t` during training. `Mdl` is a `ClassificationECOC` model.

Estimate the resubstitution loss (i.e., the in-sample classification error).

```
L = resubLoss(Mdl)
```

```
L =
```

```
 0.0267
```

The ECOC model misclassifies 2.67% of the training sample irises.

### Determine the ECOC Model Quality Using a Custom Resubstitution Loss

Suppose that it is interesting to know how well a model classifies a particular class. This example shows how to pass such a custom loss function to `resubLoss`.

Load Fisher's iris data set.

```
load fisheriris
X = meas;
Y = categorical(species);
n = numel(Y); % Sample size
classOrder = unique(Y) % Class order
K = numel(classOrder); % Number of classes
```

```
classOrder =

 setosa
 versicolor
 virginica
```

Train an ECOC model using SVM binary classifiers. It is good practice to standardize the predictors and define the class order. Specify to standardize the predictors using an SVM template.

```
t = templateSVM('Standardize',1);
Mdl = fitcecoc(X,Y,'Learners',t,'ClassNames',classOrder);
```

`t` is an SVM template object. The software uses default values for empty options in `t` during training. `Mdl` is a `ClassificationECOC` model.

Compute the negated losses for the training observations.

```
rng(1); % For reproducibility
[~,negLoss] = resubPredict(Mdl);
```

Create a function that takes the minimal loss for each observation, and then averages the minimal losses across all observations.

```
lossfun = @(C,S,~,~)mean(min(-negLoss,[],2));
```

Compute the custom loss for the training data.

```
resubLoss(Mdl, 'LossFun', lossfun)
```

```
ans =
```

```
0.0065
```

The average, minimal, binary loss in the training data is 0.0065.

# resubLoss

**Class:** ClassificationEnsemble

Classification error by resubstitution

## Syntax

`L = resubLoss(ens)`

`L = resubLoss(ens,Name,Value)`

## Description

`L = resubLoss(ens)` returns the resubstitution loss, meaning the loss computed for the data that `fitensemble` used to create `ens`.

`L = resubLoss(ens,Name,Value)` calculates loss with additional options specified by one or more `Name,Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

## Input Arguments

### **ens**

A classification ensemble created with `fitensemble`.

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### **'learners'**

Indices of weak learners in the ensemble ranging from 1 to `NumTrained`. `resubLoss` uses only these learners for calculating loss.

**Default:** 1:NumTrained

**'lossfun'**

Function handle or string representing a loss function. Built-in loss functions:

- 'binodeviance' — See “Loss Functions” on page 21-3831
- 'classiferror' — Fraction of misclassified data
- 'exponential' — See “Loss Functions” on page 21-3831
- 'hinge' — See “Loss Functions” on page 21-3831.
- 'mincost' — Smallest misclassification cost as given by the obj.Cost matrix. See “Loss Functions” on page 21-3831.

You can write your own loss function in the syntax described in “Loss Functions” on page 21-3831.

**Default:** 'classiferror'

**'mode'**

String representing the meaning of the output L:

- 'ensemble' — L is a scalar value, the loss for the entire ensemble.
- 'individual' — L is a vector with one element per trained learner.
- 'cumulative' — L is a vector in which element J is obtained by using learners 1:J from the input list of learners.

**Default:** 'ensemble'

## Output Arguments

**L**

Loss, by default the fraction of misclassified data. L can be a vector, and can mean different things, depending on the name-value pair settings.

## Definitions

### Classification Error

The default classification error is the fraction of the training data  $X$  that ens misclassifies.

Weighted classification error is the sum of weight  $i$  times the Boolean value that is 1 when tree misclassifies the  $i$ th row of  $X$ , divided by the sum of the weights.

### Loss Functions

The built-in loss functions are:

- 'binodeviance' — For binary classification, assume the classes  $y_n$  are -1 and 1. With weight vector  $w$  normalized to have sum 1, and predictions of row  $n$  of data  $X$  as  $f(X_n)$ , the binomial deviance is

$$\sum w_n \log(1 + \exp(-2y_n f(X_n))).$$

- 'classiferror' — Fraction of misclassified data, weighted by  $w$ .
- 'exponential' — With the same definitions as for 'binodeviance', the exponential loss is

$$\sum w_n \exp(-y_n f(X_n)).$$

- 'hinge' — Classification error measure that has the form

$$L = \frac{\sum_{j=1}^n w_j \max\{0, 1 - y_j' f(X_j)\}}{\sum_{j=1}^n w_j},$$

where:

- $w_j$  is weight  $j$ .

- For binary classification,  $y_j = 1$  for the positive class and  $-1$  for the negative class. For problems where the number of classes  $K > 3$ ,  $y_j$  is a vector of 0s, but with a 1 in the position corresponding to the true class, e.g., if the second observation is in the third class and  $K = 4$ , then  $y_2 = [0\ 0\ 1\ 0]'$ .
- $f(X_j)$  is, for binary classification, the posterior probability or, for  $K > 3$ , a vector of posterior probabilities for each class given observation  $j$ .
- 'mincost' — Predict the label with the smallest expected misclassification cost, with expectation taken over the posterior probability, and cost as given by the `Cost` property of the classifier (a matrix). The loss is then the true misclassification cost averaged over the observations.

To write your own loss function, create a function file of the form

```
function loss = lossfun(C,S,W,COST)
```

- `N` is the number of rows of `ens.X`.
- `K` is the number of classes in `ens`, represented in `ens.ClassNames`.
- `C` is an `N`-by-`K` logical matrix, with one `true` per row for the true class. The index for each class is its position in `tree.ClassNames`.
- `S` is an `N`-by-`K` numeric matrix. `S` is a matrix of posterior probabilities for classes with one row per observation, similar to the `score` output from `predict`.
- `W` is a numeric vector with `N` elements, the observation weights.
- `COST` is a `K`-by-`K` numeric matrix of misclassification costs. The default 'classiferror' gives a cost of 0 for correct classification, and 1 for misclassification.
- The output `loss` should be a scalar.

Pass the function handle `@lossfun` as the value of the `lossfun` name-value pair.

## Examples

Compute the resubstitution loss for a classification ensemble for the Fisher iris data:

```
load fisheriris
ens = fitensemble(meas,species,'AdaBoostM2',100,'Tree');
loss = resubLoss(ens)
```

```
loss =
 0.0333
```

### **See Also**

resubEdge | resubLoss | resubMargin | resubPredict

## resubLoss

**Class:** ClassificationKNN

Loss of  $k$ -nearest neighbor classifier by resubstitution

### Syntax

```
L = resubLoss(md1)
L = resubLoss(md1,Name,Value)
```

### Description

`L = resubLoss(md1)` returns the resubstitution loss, meaning the loss computed for the data that `fitcknn` used to create `md1`.

`L = resubLoss(md1,Name,Value)` returns loss statistics with additional options specified by one or more `Name,Value` pair arguments.

### Input Arguments

**md1** — Classifier model

classifier model object

$k$ -nearest neighbor classifier model, returned as a classifier model object.

Note that using the `'CrossVal'`, `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'` options results in a model of class `ClassificationPartitionedModel`. You cannot use a partitioned tree for prediction, so this kind of tree does not have a `predict` method.

Otherwise, `md1` is of class `ClassificationKNN`, and you can use the `predict` method to make predictions.

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single

quotes ( ' ' ). You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

### 'lossfun'

Function handle or string representing a loss function. Built-in loss functions are:

- 'binodeviance' — See “Loss Functions” on page 21-3836.
- 'classiferror' — Fraction of misclassified observations. See “Loss Functions” on page 21-3836.
- 'exponential' — See “Loss Functions” on page 21-3836.
- 'hinge' — See “Loss Functions” on page 21-3836.
- 'mincost' — Smallest misclassification cost as given by the mdl.Cost matrix.

You can write your own loss function using the syntax described in “Loss Functions” on page 21-3836.

**Default:** 'mincost'

## Output Arguments

### L

Classification error, a scalar. The meaning of the error depends on the values in `weights` and `lossfun`. See “Classification Error” on page 21-3835.

## Definitions

### Classification Error

The default classification error is the fraction of data X that mdl misclassifies, where Y represents the true classifications.

The weighted classification error is the sum of weight  $i$  times the Boolean value that is 1 when mdl misclassifies the  $i$ th row of X, divided by the sum of the weights.

## Loss Functions

The built-in loss functions are:

- 'binodeviance' — For binary classification, assume the classes  $y_n$  are -1 and 1. With weight vector  $w$  normalized to have sum 1, and predictions of row  $n$  of data  $X$  as  $f(X_n)$ , the binomial deviance is

$$\sum w_n \log(1 + \exp(-2y_n f(X_n))).$$

- 'exponential' — With the same definitions as for 'binodeviance', the exponential loss is

$$\sum w_n \exp(-y_n f(X_n)).$$

- 'classiferror' — Predict the label with the largest posterior probability. The loss is then the fraction of misclassified observations.
- 'hinge' — Classification error measure that has the form

$$L = \frac{\sum_{j=1}^n w_j \max\{0, 1 - y_j' f(X_j)\}}{\sum_{j=1}^n w_j},$$

where:

- $w_j$  is weight  $j$ .
- For binary classification,  $y_j = 1$  for the positive class and -1 for the negative class. For problems where the number of classes  $K > 3$ ,  $y_j$  is a vector of 0s, but with a 1 in the position corresponding to the true class, e.g., if the second observation is in the third class and  $K = 4$ , then  $y_2 = [0 \ 0 \ 1 \ 0]'$ .
- $f(X_j)$  is, for binary classification, the posterior probability or, for  $K > 3$ , a vector of posterior probabilities for each class given observation  $j$ .
- 'mincost' — Predict the label with the smallest expected misclassification cost, with expectation taken over the posterior probability, and cost as given by the **Cost**

property of the classifier (a matrix). The loss is then the true misclassification cost averaged over the observations.

To write your own loss function, create a function file in this form:

```
function loss = lossfun(C,S,W,COST)
```

- $N$  is the number of rows of  $X$ .
- $K$  is the number of classes in the classifier, represented in the `ClassNames` property.
- $C$  is an  $N$ -by- $K$  logical matrix, with one `true` per row for the true class. The index for each class is its position in the `ClassNames` property.
- $S$  is an  $N$ -by- $K$  numeric matrix.  $S$  is a matrix of posterior probabilities for classes with one row per observation, similar to the `posterior` output from `predict`.
- $W$  is a numeric vector with  $N$  elements, the observation weights. If you pass  $W$ , the elements are normalized to sum to the prior probabilities in the respective classes.
- $COST$  is a  $K$ -by- $K$  numeric matrix of misclassification costs. For example, you can use `COST = ones(K) - eye(K)`, which means a cost of 0 for correct classification, and 1 for misclassification.
- The output `loss` should be a scalar.

Pass the function handle `@lossfun` as the value of the `LossFun` name-value pair.

## True Misclassification Cost

There are two costs associated with KNN classification: the true misclassification cost per class, and the expected misclassification cost per observation.

You can set the true misclassification cost per class in the `Cost` name-value pair when you run `fitcknn`. `Cost(i,j)` is the cost of classifying an observation into class  $j$  if its true class is  $i$ . By default, `Cost(i,j)=1` if  $i \neq j$ , and `Cost(i,j)=0` if  $i=j$ . In other words, the cost is 0 for correct classification, and 1 for incorrect classification.

## Expected Cost

There are two costs associated with KNN classification: the true misclassification cost per class, and the expected misclassification cost per observation. The third output of `predict` is the expected misclassification cost per observation.

Suppose you have `Nobs` observations that you want to classify with a trained classifier `mdl`. Suppose you have `K` classes. You place the observations into a matrix `Xnew` with one observation per row. The command

```
[label,score,cost] = predict(mdl,Xnew)
```

returns, among other outputs, a `cost` matrix of size `Nobs`-by-`K`. Each row of the `cost` matrix contains the expected (average) cost of classifying the observation into each of the `K` classes. `cost(n,k)` is

$$\sum_{i=1}^K \hat{P}(i | X_{new}(n)) C(k | i),$$

where

- $K$  is the number of classes.
- $\hat{P}(i | X_{new}(n))$  is the posterior probability of class  $i$  for observation  $X_{new}(n)$ .
- $C(k | i)$  is the true misclassification cost of classifying an observation as  $k$  when its true class is  $i$ .

## Examples

### Loss Calculation

Construct a  $k$ -nearest neighbor classifier for the Fisher iris data, where  $k = 5$ .

Load the data.

```
load fisheriris
```

Construct a classifier for 5-nearest neighbors.

```
mdl = fitcknn(meas,species,'NumNeighbors',5);
```

Examine the resubstitution loss of the classifier.

```
L = resubLoss(mdl)
```

```
L =
```

0.0333

The classifier predicts incorrect classifications for 1/30 of its training data.

- “Examine the Quality of a KNN Classifier” on page 16-29
- “Predict Classification Based on a KNN Classifier” on page 16-30
- “Modify a KNN Classifier” on page 16-30

## resubLoss

**Class:** ClassificationNaiveBayes

Classification loss for naive Bayes classifiers by resubstitution

### Syntax

```
L = resubLoss(Mdl)
L = resubLoss(Mdl, Name, Value)
```

### Description

`L = resubLoss(Mdl)` returns the in-sample minimum misclassification cost loss (L), which is a scalar representing how well the trained naive Bayes classifier `Mdl` classifies the predictor data stored in `Mdl.X` as compared to the true class labels stored in `Mdl.Y`.

`L = resubLoss(Mdl, Name, Value)` returns the in-sample classification loss with additional options specified by one or more `Name, Value` pair arguments.

### Input Arguments

**Mdl** — Fully trained naive Bayes classifier

ClassificationNaiveBayes model

A fully trained naive Bayes classifier, specified as a `ClassificationNaiveBayes` model trained by `fitcnb`.

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

**'LossFun' — Loss function**

'classiferror' (default) | 'binodeviance' | 'exponential' | 'hinge' | function handle

Loss function, specified as the comma-separated pair consisting of 'LossFun' and a function handle or string.

- This table describes the built-in loss functions. Specify one using its corresponding string.

| String         | Loss Function                         |
|----------------|---------------------------------------|
| 'binodeviance' | “Binomial deviance”                   |
| 'classiferror' | “Classification error”                |
| 'exponential'  | “Exponential loss”                    |
| 'hinge'        | “Hinge loss”                          |
| 'mincost'      | “Minimum misclassification cost loss” |

- Specify your own function using function handle notation.

Suppose that  $n = \text{size}(X,1)$  is the sample size and  $k = \text{size}(\text{Mdl.ClassNames},1)$  is the number of classes. Your function must have the signature `lossvalue = lossfun(C,S,W,Cost)`, where:

- The output argument `lossvalue` is a scalar.
- You choose the function name (`lossfun`).
- `C` is an  $n$ -by- $k$  logical matrix with rows indicating to which class the corresponding observation belongs. The column order corresponds to the class order in `Mdl.ClassNames`.

Construct `C` by setting  $C(p,q) = 1$  if observation  $p$  is in class  $q$ , for each row. Set all other elements of row  $p$  to 0.

- `S` is an  $n$ -by- $k$  numeric matrix of classification scores. The column order corresponds to the class order in `Mdl.ClassNames`. `S` is a matrix of posterior probabilities, similar to the output of `predict`.
- `W` is an  $n$ -by-1 numeric vector of observation weights. If you pass `W`, the software normalizes the weights to sum to the prior probability of their respective class. If `Mdl` is a compact model, then you must also supply the weights using the 'Weights' name-value pair argument.

- `Cost` is a k-by-k numeric matrix of misclassification costs. For example, `Cost = ones(K) - eye(K)` specifies a cost of 0 for correct classification, and 1 for misclassification.

Specify your function using `'LossFun', @lossfun`.

## Output Arguments

### L — Classification loss

scalar

Classification loss, returned as a scalar. L is a generalization or resubstitution quality measure. Its interpretation depends on the loss function and weighting scheme, but, in general, better classifiers yield smaller loss values.

## Definitions

### Binomial Deviance

The *binomial deviance* (or *multinomial deviance* for number of classes  $K > 3$ ) is a classification error measure that has the form

$$L = \frac{\sum_{j=1}^n w_j \log(1 + \exp(-2y_j'f(X_j)))}{\sum_{j=1}^n w_j},$$

where:

- $w_j$  is weight  $j$ .
- For binary classification,  $y_j = 1$  for the positive class and  $-1$  for the negative class. For problems where the number of classes  $K > 3$ ,  $y_j$  is a vector of 0s, but with a 1 in the position corresponding to the true class, e.g., if the second observation is in the third class and  $K = 4$ , then  $y_2 = [0 \ 0 \ 1 \ 0]'$ .

- $f(X_j)$  is, for binary classification, the posterior probability or, for  $K > 3$ , a vector of posterior probabilities for each class given observation  $j$ .

The binomial deviance has connections to the maximization of the binomial likelihood function. For details on binomial deviance, see “[1]”.

## Classification Error

The *classification error* is a binary classification error measure that has the form

$$L = \frac{\sum_{j=1}^n w_j e_j}{\sum_{j=1}^n w_j},$$

where:

- $w_j$  is the weight for observation  $j$ . The software renormalizes the weights to sum to 1.
- $e_j = 1$  if the predicted class of observation  $j$  differs from its true class, and 0 otherwise.

In other words, it is the proportion of observations that the classifier misclassifies.

## Exponential Loss

*Exponential loss* is a classification error measure that is similar to binomial deviance, and has the form

$$L = \frac{\sum_{j=1}^n w_j \exp(-y_j' f(X_j))}{\sum_{j=1}^n w_j},$$

where:

- $w_j$  is weight  $j$ .

- For binary classification,  $y_j = 1$  for the positive class and  $-1$  for the negative class. For problems where the number of classes  $K > 3$ ,  $y_j$  is a vector of 0s, but with a 1 in the position corresponding to the true class, e.g., if the second observation is in the third class and  $K = 4$ , then  $y_2 = [0 \ 0 \ 1 \ 0]'$ .
- $f(X_j)$  is, for binary classification, the posterior probability or, for  $K > 3$ , a vector of posterior probabilities for each class given observation  $j$ .

## Hinge Loss

*Hinge loss* is a binary classification error measure that has the form

$$L = \frac{\sum_{j=1}^n w_j \max\{0, 1 - y_j' f(X_j)\}}{\sum_{j=1}^n w_j},$$

where:

- $w_j$  is weight  $j$ .
- For binary classification,  $y_j = 1$  for the positive class and  $-1$  for the negative class. For problems where the number of classes  $K > 3$ ,  $y_j$  is a vector of 0s, but with a 1 in the position corresponding to the true class, e.g., if the second observation is in the third class and  $K = 4$ , then  $y_2 = [0 \ 0 \ 1 \ 0]'$ .
- $f(X_j)$  is, for binary classification, the posterior probability or, for  $K > 3$ , a vector of posterior probabilities for each class given observation  $j$ .

Hinge loss linearly penalizes for misclassified observations, and is related to the support vector machine (SVM) objective function used for optimization. For more details on hinge loss, see “[1]”.

## Minimum Misclassification Cost Loss

The *minimum misclassification cost loss* is the weighted average of the minimum expected “misclassification costs” for each observation.

In other words, the minimum misclassification cost is

$$L = \frac{\sum_{j=1}^n w_j c_j}{\sum_j w_j},$$

where:

- $w_j$  is the weight of observation  $j$ .
- $c_j$  is the minimum of the expected misclassification costs for observation  $j$ .

## Misclassification Cost

A *misclassification cost* is the relative severity of a classifier labeling an observation into the wrong class.

There are two types of misclassification costs: true and expected. Let  $K$  be the number of classes.

- *True misclassification cost* — A  $K$ -by- $K$  matrix, where element  $(i,j)$  indicates the misclassification cost of predicting an observation into class  $j$  if its true class is  $i$ . The software stores the misclassification cost in the property `Mdl.Cost`, and used in computations. By default, `Mdl.Cost(i, j) = 1` if  $i \neq j$ , and `Mdl.Cost(i, j) = 0` if  $i = j$ . In other words, the cost is 0 for correct classification, and 1 for any incorrect classification.
- *Expected misclassification cost* — A  $K$ -dimensional vector, where element  $k$  is the weighted average misclassification cost of classifying an observation into class  $k$ , weighted by the class posterior probabilities. In other words,

$$c_k = \sum_{j=1}^K \hat{P}(Y = j | x_1, \dots, x_P) \text{Cost}_{jk}.$$

the software classifies observations to the class corresponding with the lowest expected misclassification cost.

## Posterior Probability

The *posterior probability* is the probability that an observation belongs in a particular class, given the data.

For naive Bayes, the posterior probability that a classification is  $k$  for a given observation  $(x_1, \dots, x_p)$  is

$$\hat{P}(Y = k | x_1, \dots, x_p) = \frac{P(X_1, \dots, X_p | y = k)\pi(Y = k)}{P(X_1, \dots, X_p)},$$

where:

- $P(X_1, \dots, X_p | y = k)$  is the conditional joint density of the predictors given they are in class  $k$ . `Mdl.DistributionNames` stores the distribution names of the predictors.
- $\pi(Y = k)$  is the class prior probability distribution. `Mdl.Prior` stores the prior distribution.
- $P(X_1, \dots, X_p)$  is the joint density of the predictors. The classes are discrete, so

$$P(X_1, \dots, X_p) = \sum_{k=1}^K P(X_1, \dots, X_p | y = k)\pi(Y = k).$$

## Prior Probability

The *prior probability* is the believed relative frequency that observations from a class occur in the population for each class.

## Examples

### Determine the Resubstitution Loss of Naive Bayes Classifiers

Load Fisher's iris data set.

```
load fisheriris
X = meas; % Predictors
Y = species; % Response
```

Train a naive Bayes classifier. It is good practice to specify the class order. Assume that each predictor is conditionally, normally distributed given its label.

```
Mdl = fitcnb(X,Y,'ClassNames',{ 'setosa', 'versicolor', 'virginica' });
```

Mdl is a trained `ClassificationNaiveBayes` classifier.

Estimate the default resubstitution loss, which is the in-sample minimum misclassification cost.

```
L = resubLoss(Mdl)
```

```
L =
```

```
0.0400
```

The average, in-sample cost of classification is 0.04.

### Determine Resubstitution Classification Error of Naive Bayes Classifiers

Load Fisher's iris data set.

```
load fisheriris
X = meas; % Predictors
Y = species; % Response
```

Train a naive Bayes classifier. It is good practice to specify the class order. Assume that each predictor is conditionally, normally distributed given its label.

```
Mdl = fitcnb(X,Y,'ClassNames',{ 'setosa', 'versicolor', 'virginica' });
```

Mdl is a trained `ClassificationNaiveBayes` classifier.

Estimate the in-sample proportion of misclassified observations.

```
L = resubLoss(Mdl,'LossFun','classiferror')
```

```
L =
```

```
0.0400
```

The naive Bayes classifier misclassifies 4% of the training observations.

# resubLoss

**Class:** ClassificationSVM

Classification loss for support vector machine classifiers by resubstitution

## Syntax

```
L = resubLoss(SVMModel)
L = resubLoss(SVMModel,Name,Value)
```

## Description

`L = resubLoss(SVMModel)` returns the classification loss by resubstitution (`L`), the in-sample classification loss, for the support vector machine (SVM) classifier `SVMModel` using the training data stored in `SVMModel.X` and corresponding class labels stored in `SVMModel.Y`.

`L = resubLoss(SVMModel,Name,Value)` returns the classification loss by resubstitution with additional options specified by one or more `Name,Value` pair arguments.

## Input Arguments

**SVMModel** — Full, trained SVM classifier

ClassificationSVM classifier

Full, trained SVM classifier, specified as a `ClassificationSVM` model trained using `fitcsvm`.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single

quotes ( ' ' ). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### 'LossFun' — Loss function

'ClassifError' (default) | 'binodeviance' | 'exponential' | 'hinge' | function handle

Loss function, specified as the comma-separated pair consisting of 'LossFun' and a function handle or string.

- The following lists available loss functions. Specify one using its corresponding string.

| Value          | Loss Function          |
|----------------|------------------------|
| 'binodeviance' | “Binomial deviance”    |
| 'classiferror' | “Classification error” |
| 'exponential'  | “Exponential loss”     |
| 'hinge'        | “Hinge loss”           |

- Specify your own function using function handle notation.

Suppose that  $n = \text{size}(X,1)$  is the sample size and  $k = \text{size}(SVMModel.ClassNames,1)$  is the number of classes. Your function must have the signature `lossvalue = lossfun(C,S,W,Cost)`, where:

- The output argument `lossvalue` is a scalar.
- You choose the function name (*lossfun*).
- `C` is an  $n$ -by- $k$  logical matrix with rows indicating which class the corresponding observation belongs. The column order corresponds to the class order in `SVMModel.ClassNames`.

Construct `C` by setting  $C(p,q) = 1$  if observation  $p$  is in class  $q$ , for each row. Set all other elements of row  $p$  to 0.

- `S` is an  $n$ -by- $k$  numeric matrix of classification scores. The column order corresponds to the class order in `SVMModel.ClassNames`. `S` is a matrix of classification scores, similar to the output of `predict`.
- `W` is an  $n$ -by-1 numeric vector of observation weights. If you pass `W`, the software normalizes them to sum to 1.

- `Cost` is a k-by-k numeric matrix of misclassification costs. For example, `Cost = ones(K) - eye(K)` specifies a cost of 0 for correct classification, and 1 for misclassification.

Specify your function using `'LossFun', @lossfun`.

## Output Arguments

### **L** — Classification loss

scalar

Classification loss, returned as a scalar. `L` is a generalization or resubstitution quality measure. Its interpretation depends on the loss function and weighting scheme, but, in general, better classifiers yield smaller loss values.

## Definitions

### Binomial Deviance

The binomial deviance is a binary classification error measure that has the form

$$L = \frac{\sum_{j=1}^n w_j \log\left(1 + \exp\left(-2y_j f(X_j)\right)\right)}{\sum_{j=1}^n w_j},$$

where:

- $w_j$  is weight  $j$ . The software renormalizes the weights to sum to 1.
- $y_j = \{-1, 1\}$ .
- $f(X_j)$  is the score for observation  $j$ .

The binomial deviance has connections to the maximization of the binomial likelihood function. For details on binomial deviance, see “[1]”.

## Classification Error

The *classification error* is a binary classification error measure that has the form

$$L = \frac{\sum_{j=1}^n w_j e_j}{\sum_{j=1}^n w_j},$$

where:

- $w_j$  is the weight for observation  $j$ . The software renormalizes the weights to sum to 1.
- $e_j = 1$  if the predicted class of observation  $j$  differs from its true class, and 0 otherwise.

In other words, it is the proportion of observations that the classifier misclassifies.

## Exponential Loss

A binary classification error measure that is similar to binomial deviance, and has the form

$$L = \frac{\sum_{j=1}^n w_j \exp(-y_j f(X_j))}{\sum_{j=1}^n w_j},$$

where:

- $w_j$  is weight  $j$ . The software renormalizes the weights to sum to 1.
- $y_j = \{-1, 1\}$ .
- $f(X_j)$  is the score for observation  $j$ .

## Hinge Loss

Hinge loss is a binary classification error measure that has the form

$$L = \frac{\sum_{j=1}^n w_j \max\{0, 1 - y_j f(X_j)\}}{\sum_{j=1}^n w_j},$$

where:

- $w_j$  is weight  $j$ . The software renormalizes the weights to sum to 1.
- $y_j = \{-1, 1\}$ .
- $f(X_j)$  is the score for observation  $j$ .

Hinge loss linearly penalizes for misclassified observations, and is related to the SVM objective function used for optimization. For more details on hinge loss, see “[1]”.

## Score

The SVM *score* for classifying observation  $x$  is the signed distance from  $x$  to the decision boundary ranging from  $-\infty$  to  $+\infty$ . A positive score for a class indicates that  $x$  is predicted to be in that class, a negative score indicates otherwise.

The score is also the numerical, predicted response for  $x$ ,  $f(x)$ , computed by the trained SVM classification function

$$f(x) = \sum_{j=1}^n \alpha_j y_j G(x_j, x) + b,$$

where  $(\alpha_1, \dots, \alpha_n, b)$  are the estimated SVM parameters,  $G(x_j, x)$  is the dot product in the predictor space between  $x$  and the support vectors, and the sum includes the training set observations.

## Examples

### Determine the Resubstitution Loss of SVM Classifiers

Load the ionosphere data set.

```
load ionosphere
```

Train an SVM classifier. It is good practice to standardize the data.

```
SVModel = fitcsvm(X,Y, 'ClassNames', {'b', 'g'}, 'Standardize', true);
```

SVModel is a trained ClassificationSVM classifier. The negative class is 'b' and the positive class is 'g'.

Estimate the resubstitution loss (i.e., the in-sample classification error).

```
L = resubLoss(SVModel)
```

```
L =
```

```
0.0570
```

The SVM classifier misclassifies 5.7% of the training sample radar returns.

### Determine the Resubstitution Hinge Loss of SVM Classifiers

Load the ionosphere data set.

```
load ionosphere
```

Train an SVM classifier. It is good practice to standardize the data.

```
SVModel = fitcsvm(X,Y, 'ClassNames', {'b', 'g'}, 'Standardize', true);
```

SVModel is a trained ClassificationSVM classifier. The negative class is 'b' and the positive class is 'g'.

Estimate the in-sample hinge loss.

```
L = resubLoss(SVModel, 'LossFun', 'Hinge')
```

L =

0.1603

The hinge loss is 0.1603. Classifiers with hinge losses close to 0 are desirable.

## resubLoss

**Class:** ClassificationTree

Classification error by resubstitution

### Syntax

```
L = resubLoss(tree)
L = resubLoss(tree,Name,Value)
L = resubLoss(tree,'Subtrees',subtreevector)
[L,se] = resubLoss(tree,'Subtrees',subtreevector)
[L,se,NLeaf] = resubLoss(tree,'Subtrees',subtreevector)
[L,se,NLeaf,bestlevel] = resubLoss(tree,'Subtrees',subtreevector)
[L,...] = resubLoss(tree,'Subtrees',subtreevector,Name,Value)
```

### Description

`L = resubLoss(tree)` returns the resubstitution loss, meaning the loss computed for the data that `fitctree` used to create `tree`.

`L = resubLoss(tree,Name,Value)` returns the loss with additional options specified by one or more `Name,Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`L = resubLoss(tree,'Subtrees',subtreevector)` returns a vector of classification errors for the trees in the pruning sequence `subtreevector`.

`[L,se] = resubLoss(tree,'Subtrees',subtreevector)` returns the vector of standard errors of the classification errors.

`[L,se,NLeaf] = resubLoss(tree,'Subtrees',subtreevector)` returns the vector of numbers of leaf nodes in the trees of the pruning sequence.

`[L,se,NLeaf,bestlevel] = resubLoss(tree,'Subtrees',subtreevector)` returns the best pruning level as defined in the `TreeSize` name-value pair. By default,

`bestlevel` is the pruning level that gives loss within one standard deviation of minimal loss.

`[L,...] = resubLoss(tree,'Subtrees',subtreevector,Name,Value)` returns loss statistics with additional options specified by one or more `Name,Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

## Input Arguments

### **tree**

A classification tree constructed by `fitctree`.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### **'LossFun'**

Function handle or string representing a loss function. Built-in loss functions:

- `'binodeviance'` — See “Loss Functions” on page 21-3859
- `'classiferror'` — Fraction of misclassified observations. See “Loss Functions” on page 21-3859.
- `'exponential'` — See “Loss Functions” on page 21-3859
- `'hinge'` — See “Loss Functions” on page 21-3859.
- `'mincost'` — Smallest misclassification cost as given by the tree. `Cost` matrix. See “Loss Functions” on page 21-3859.

You can write your own loss function in the syntax described in “Loss Functions” on page 21-3859.

**Default:** `'mincost'`

`Name,Value` arguments associated with pruning subtrees:

**'Subtrees'**

A vector with integer values from 0 (full unpruned tree) to the maximal pruning level `max(tree.PruneList)`.

**Default:** 0

**'TreeSize'**

One of the following strings:

- `'se'` — `loss` returns the highest pruning level with loss within one standard deviation of the minimum ( $L+se$ , where `L` and `se` relate to the smallest value in `Subtrees`).
- `'min'` — `loss` returns the element of `Subtrees` with smallest loss, usually the smallest element of `Subtrees`.

## Output Arguments

**L**

Classification error, a vector the length of `Subtrees`. The meaning of the error depends on the values in `Weights` and `LossFun`; see “Classification Error” on page 21-3859.

**se**

Standard error of loss, a vector the length of `Subtrees`.

**NLeaf**

Number of leaves (terminal nodes) in the pruned subtrees, a vector the length of `Subtrees`.

**bestlevel**

A scalar whose value depends on `TreeSize`:

- `TreeSize = 'se'` — `loss` returns the highest pruning level with loss within one standard deviation of the minimum ( $L+se$ , where `L` and `se` relate to the smallest value in `Subtrees`).
- `TreeSize = 'min'` — `loss` returns the element of `Subtrees` with smallest loss, usually the smallest element of `Subtrees`.

## Definitions

### Classification Error

The default classification error is the fraction of the training data  $X$  that tree misclassifies.

Weighted classification error is the sum of weight  $i$  times the Boolean value that is 1 when tree misclassifies the  $i$ th row of  $X$ , divided by the sum of the weights.

### Loss Functions

The built-in loss functions are:

- 'binodeviance' — For binary classification, assume the classes  $y_n$  are -1 and 1. With weight vector  $w$  normalized to have sum 1, and predictions of row  $n$  of data  $X$  as  $f(X_n)$ , the binomial deviance is

$$\sum w_n \log(1 + \exp(-2y_n f(X_n))).$$

- 'exponential' — With the same definitions as for 'binodeviance', the exponential loss is

$$\sum w_n \exp(-y_n f(X_n)).$$

- 'classiferror' — Predict the label with the largest posterior probability. The loss is then the fraction of misclassified observations.
- 'hinge' — Classification error measure that has the form

$$L = \frac{\sum_{j=1}^n w_j \max\{0, 1 - y_j' f(X_j)\}}{\sum_{j=1}^n w_j},$$

where:

- $w_j$  is weight  $j$ .

- For binary classification,  $y_j = 1$  for the positive class and  $-1$  for the negative class. For problems where the number of classes  $K > 3$ ,  $y_j$  is a vector of 0s, but with a 1 in the position corresponding to the true class, e.g., if the second observation is in the third class and  $K = 4$ , then  $y_2 = [0\ 0\ 1\ 0]'$ .
- $f(X_j)$  is, for binary classification, the posterior probability or, for  $K > 3$ , a vector of posterior probabilities for each class given observation  $j$ .
- 'mincost' — Predict the label with the smallest expected misclassification cost, with expectation taken over the posterior probability, and cost as given by the `COST` property of the classifier (a matrix). The loss is then the true misclassification cost averaged over the observations.

To write your own loss function, create a function file in this form:

```
function loss = lossfun(C,S,W,COST)
```

- `N` is the number of rows of `X`.
- `K` is the number of classes in the classifier, represented in the `ClassNames` property.
- `C` is an `N`-by-`K` logical matrix, with one `true` per row for the true class. The index for each class is its position in the `ClassNames` property.
- `S` is an `N`-by-`K` numeric matrix. `S` is a matrix of posterior probabilities for classes with one row per observation, similar to the `posterior` output from `predict`.
- `W` is a numeric vector with `N` elements, the observation weights. If you pass `W`, the elements are normalized to sum to the prior probabilities in the respective classes.
- `COST` is a `K`-by-`K` numeric matrix of misclassification costs. For example, you can use `COST = ones(K) - eye(K)`, which means a cost of `0` for correct classification, and `1` for misclassification.
- The output `loss` should be a scalar.

Pass the function handle `@lossfun` as the value of the `LossFun` name-value pair.

## True Misclassification Cost

There are two costs associated with classification: the true misclassification cost per class, and the expected misclassification cost per observation.

You can set the true misclassification cost per class in the `Cost` name-value pair when you create the classifier using the `fitctree` method. `Cost(i, j)` is the cost of

classifying an observation into class  $j$  if its true class is  $i$ . By default,  $\text{Cost}(i, j) = 1$  if  $i \neq j$ , and  $\text{Cost}(i, j) = 0$  if  $i = j$ . In other words, the cost is 0 for correct classification, and 1 for incorrect classification.

## Expected Misclassification Cost

There are two costs associated with classification: the true misclassification cost per class, and the expected misclassification cost per observation.

Suppose you have `Nobs` observations that you want to classify with a trained classifier. Suppose you have  $K$  classes. You place the observations into a matrix `Xnew` with one observation per row.

The expected cost matrix `CE` has size `Nobs`-by- $K$ . Each row of `CE` contains the expected (average) cost of classifying the observation into each of the  $K$  classes.  $\text{CE}(n, k)$  is

$$\sum_{i=1}^K \hat{P}(i | X_{\text{new}(n)}) C(k | i),$$

where

- $K$  is the number of classes.
- $\hat{P}(i | X_{\text{new}(n)})$  is the posterior probability of class  $i$  for observation  $X_{\text{new}(n)}$ .
- $C(k | i)$  is the true misclassification cost of classifying an observation as  $k$  when its true class is  $i$ .

## Examples

### Compute the Resubstituted Classification Error

Compute the resubstituted classification error for the `ionosphere` data.

```
load ionosphere
tree = fitctree(X,Y);
L = resubLoss(tree)
```

```
L =
```

0.0114

**See Also**

loss | resubMargin | resubPredict | resubEdge | fitctree

# resubLoss

**Class:** RegressionEnsemble

Regression error by resubstitution

## Syntax

```
L = resubLoss(ens)
L = resubLoss(ens,Name,Value)
```

## Description

`L = resubLoss(ens)` returns the resubstitution loss, meaning the mean squared error computed for the data that `fitensemble` used to create `ens`.

`L = resubLoss(ens,Name,Value)` calculates loss with additional options specified by one or more `Name,Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

## Input Arguments

### **ens**

A regression ensemble created with `fitensemble`.

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### **'learners'**

Indices of weak learners in the ensemble ranging from 1 to `NumTrained`. `resubLoss` uses only these learners for calculating loss.

**Default:** 1:NumTrained

**'lossfun'**

Function handle for loss function, or the string 'mse', meaning mean squared error. If you pass a function handle `fun`, `resubLoss` calls it as

```
FUN(Y,Yfit,W)
```

where `Y`, `Yfit`, and `W` are numeric vectors of the same length. `Y` is the observed response, `Yfit` is the predicted response, and `W` is the observation weights.

**Default:** 'mse'

**'mode'**

String representing the meaning of the output `L`:

- 'ensemble' — `L` is a scalar value, the loss for the entire ensemble.
- 'individual' — `L` is a vector with one element per trained learner.
- 'cumulative' — `L` is a vector in which element `J` is obtained by using learners `1:J` from the input list of learners.

**Default:** 'ensemble'

## Output Arguments

**L**

Loss, by default the mean squared error. `L` can be a vector, and can mean different things, depending on the name-value pair settings.

## Examples

Find the resubstitution predictions of mileage from the `carsmall` data based on horsepower and weight, and look at their mean square difference from the training data.

```
load carsmall
X = [Horsepower Weight];
```

```
ens = fitensemble(X,MPG,'LSBoost',100,'Tree');
MSE = resubLoss(ens)
```

```
MSE =
 6.4336
```

## See Also

resubPredict | loss | resubLoss

## resubLoss

**Class:** RegressionTree

Regression error by resubstitution

### Syntax

```
L = resubLoss(tree)
L = resubLoss(tree,Name,Value)
L = resubLoss(tree,'Subtrees',subtreevector)
[L,se] = resubLoss(tree,'Subtrees',subtreevector)
[L,se,NLeaf] = resubLoss(tree,'Subtrees',subtreevector)
[L,se,NLeaf,bestlevel] = resubLoss(tree,'Subtrees',subtreevector)
[L,...] = resubLoss(tree,'Subtrees',subtreevector,Name,Value)
```

### Description

`L = resubLoss(tree)` returns the resubstitution loss, meaning the loss computed for the data that `fitrtree` used to create `tree`.

`L = resubLoss(tree,Name,Value)` returns the loss with additional options specified by one or more `Name,Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`L = resubLoss(tree,'Subtrees',subtreevector)` returns a vector of mean squared errors for the trees in the pruning sequence `subtreevector`.

`[L,se] = resubLoss(tree,'Subtrees',subtreevector)` returns the vector of standard errors of the classification errors.

`[L,se,NLeaf] = resubLoss(tree,'Subtrees',subtreevector)` returns the vector of numbers of leaf nodes in the trees of the pruning sequence.

`[L,se,NLeaf,bestlevel] = resubLoss(tree,'Subtrees',subtreevector)` returns the best pruning level as defined in the `TreeSize` name-value pair. By default, `bestlevel` is the pruning level that gives loss within one standard deviation of minimal loss.

`[L,...] = resubLoss(tree,'Subtrees',subtreevector,Name,Value)`  
returns loss statistics with additional options specified by one or more Name,Value pair arguments. You can specify several name-value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

## Input Arguments

### **tree**

A regression tree constructed using `fitrtree`.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

### **'LossFun'**

Function handle, or the string 'mse' meaning mean squared error.

You can write your own loss function in the syntax described in “Loss Functions” on page 21-3868.

**Default:** 'mse'

Name,Value arguments associated with pruning subtrees:

### **'Subtrees'**

A vector with integer values from 0 (full unpruned tree) to the maximal pruning level `max(tree.PruneList)`.

**Default:** 0

### **'TreeSize'**

One of the following strings:

- `'se'` — `loss` returns the highest pruning level with loss within one standard deviation of the minimum ( $L + se$ , where `L` and `se` relate to the smallest value in `Subtrees`).
- `'min'` — `loss` returns the element of `Subtrees` with smallest loss, usually the smallest element of `Subtrees`.

## Output Arguments

### **L**

Mean squared error, a vector the length of `Subtrees`. The meaning of the error depends on the values in `Weights` and `LossFun`.

### **se**

Standard error of loss, a vector the length of `Subtrees`.

### **NLeaf**

Number of leaves (terminal nodes) in the pruned subtrees, a vector the length of `Subtrees`.

### **bestlevel**

A scalar whose value depends on `TreeSize`:

- `TreeSize = 'se'` — `loss` returns the highest pruning level with loss within one standard deviation of the minimum ( $L + se$ , where `L` and `se` relate to the smallest value in `Subtrees`).
- `TreeSize = 'min'` — `loss` returns the element of `Subtrees` with smallest loss, usually the smallest element of `Subtrees`.

## Definitions

### **Loss Functions**

The built-in loss function is `'mse'`, meaning mean squared error.

To write your own loss function, create a function file of the form

```
function loss = lossfun(Y,Yfit,W)
```

- `N` is the number of rows of `tree.X`.
- `Y` is an `N`-element vector representing the observed response.
- `Yfit` is an `N`-element vector representing the predicted responses.
- `W` is an `N`-element vector representing the observation weights.
- The output `loss` should be a scalar.

Pass the function handle `@lossfun` as the value of the `LossFun` name-value pair.

## Examples

Find the mean square error of a model of the `carsmall` data:

```
load carsmall
X = [Displacement Horsepower Weight];
tree = fitrtree(X,MPG);
resubLoss(tree)
```

```
ans =
 4.8952
```

## See Also

`resubPredict` | `loss` | `fitrtree`

## resubMargin

**Class:** ClassificationDiscriminant

Classification margins by resubstitution

### Syntax

```
M = resubMargin(obj)
```

### Description

`M = resubMargin(obj)` returns resubstitution classification margins for `obj`.

### Input Arguments

**obj**

Discriminant analysis classifier, produced using `fitcdiscr`.

### Output Arguments

**M**

Numeric column-vector of length `size(obj.X,1)` containing the classification margins.

### Definitions

#### Margin

The classification *margin* is the difference between the classification *score* for the true class and maximal classification score for the false classes.

The classification margin is a column vector with the same number of rows as in the matrix  $X$ . A high value of margin indicates a more reliable prediction than a low value.

## Score

For discriminant analysis, the *score* of a classification is the posterior probability of the classification. For the definition of posterior probability in discriminant analysis, see “Posterior Probability” on page 15-7.

## Examples

### Estimate Resubstitution Margins for Discriminant Analysis Classifiers

Find the margins for a discriminant analysis classifier for Fisher's iris data by resubstitution. Examine several entries.

Load Fisher's iris data set.

```
load fisheriris
```

Train a discriminant analysis classifier.

```
Mdl = fitcdiscr(meas,species);
```

Compute the resubstitution margins, and display several of them.

```
m = resubMargin(Mdl);
m(1:25:end)
```

```
ans =

 1.0000
 1.0000
 0.9998
 0.9998
 1.0000
 0.9946
```

## See Also

ClassificationDiscriminant | fitcdiscr | margin

## **How To**

- “Discriminant Analysis” on page 15-3

# resubMargin

**Class:** ClassificationECOC

Classification margins for error-correcting output codes, multiclass models by resubstitution

## Syntax

```
m = margin(Mdl)
m = margin(Mdl,Name,Value)
```

## Description

`m = margin(Mdl)` returns the classification margins (`m`) for the trained, error-correcting output codes (ECOC), multiclass model `Mdl` using the training data stored in `Mdl.X` and corresponding class labels stored in `Mdl.Y`.

`m = margin(Mdl,Name,Value)` returns the classification margins with additional options specified by one or more `Name,Value` pair arguments.

For example, specify a decoding scheme, binary learner loss function, or verbosity level.

## Input Arguments

**Mdl** — ECOC multiclass model  
ClassificationECOC model

ECOC multiclass model, specified as a `ClassificationECOC` model returned by `fitcecoc`.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**'BinaryLoss' — Binary learner loss function**

function handle | 'hamming' | 'linear' | 'exponential' | 'binodeviance' | 'hinge' | 'quadratic'

Binary learner loss function, specified as the comma-separated pair consisting of 'BinaryLoss' and a function handle or string.

- If the value is a string, then it must correspond to a built-in function. This table summarizes the built-in functions, where  $y_j$  is a class label for a particular binary learner (in the set  $\{-1,1,0\}$ ),  $s_j$  is the score for observation  $j$ , and  $g(y_j,s_j)$  is the binary loss formula.

| Value          | Description       | Score Domain       | $g(y_j,s_j)$                             |
|----------------|-------------------|--------------------|------------------------------------------|
| 'binodeviance' | Binomial deviance | $(-\infty,\infty)$ | $\log[1 + \exp(-2y_j s_j)] / [2\log(2)]$ |
| 'exponential'  | Exponential       | $(-\infty,\infty)$ | $\exp(-y_j s_j) / 2$                     |
| 'hamming'      | Hamming           | $\{-1,1\}$         | $[1 - \text{sign}(y_j s_j)] / 2$         |
| 'hinge'        | Hinge             | $(-\infty,\infty)$ | $\max(0, 1 - y_j s_j) / 2$               |
| 'linear'       | Linear            | $(-\infty,\infty)$ | $(1 - y_j s_j) / 2$                      |
| 'quadratic'    | Quadratic         | $[0,1]$            | $[1 - y_j(2s_j - 1)]^2 / 2$              |

The software normalizes the binary losses such that the loss is 0.5 when  $y_j = 0$ . Also, the software calculates the mean binary loss for each class.

- For a custom binary loss function, e.g., `customFunction`, specify its function handle 'BinaryLoss', @customFunction.

`customFunction` should have this form

```
bLoss = customFunction(M,s)
```

where:

- $M$  is the  $K$ -by- $L$  coding matrix stored in `Mdl.CodingMatrix`.
- $s$  is the 1-by- $L$  row vector of classification scores.
- `bLoss` is the classification loss. This scalar aggregates the binary losses for every learner in a particular class. For example, you can use the mean binary loss to aggregate the loss over the learners for each class.
- $K$  is the number of classes.

- $L$  is the number of binary learners.

For an example on passing a custom binary loss function, see “Predict Test-Sample Labels of ECOC Models Using Custom Binary Loss Function”.

This list describes the default values of `BinaryLoss`. If all binary learners are:

- SVMs, then `BinaryLoss` is `'hinge'`
- Ensembles trained by `AdaboostM1` or `GentleBoost`, then `BinaryLoss` is `'exponential'`
- Ensembles trained by `LogitBoost`, then `BinaryLoss` is `'binodeviance'`
- Predicting class posterior probabilities (i.e., set `'FitPosterior', 1` in `fitcecoc`), then `BinaryLoss` is `'quadratic'`

Otherwise, the default `BinaryLoss` is `'hamming'`.

Example: `'BinaryLoss', 'binodeviance'`

Data Types: `char` | `function_handle`

#### **'Decoding' — Decoding scheme**

`'lossweighted'` (default) | `'lossbased'`

Decoding scheme that aggregates the “binary losses”, specified as the comma-separated pair consisting of `'Decoding'` and `'lossweighted'` or `'lossbased'`.

Example: `'Decoding', 'lossbased'`

Data Types: `char`

#### **'Options' — Estimation options**

`[]` (default) | structure array returned by `statset`

Estimation options, specified as the comma-separated pair consisting of `'Options'` and a structure array returned by `statset`.

To invoke parallel computing:

- You need a Parallel Computing Toolbox license.
- Specify `'Options', statset('UseParallel', 1)`.

#### **'Verbose' — Verbosity level**

0 (default) | 1

Verbosity level, specified as the comma-separated pair consisting of 'Verbose' and 0 or 1. Verbose controls the amount of diagnostic messages that the software displays in the Command Window.

If Verbose is 0, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: 'Verbose', 1

Data Types: single | double

## Output Arguments

### **m** — Classification margins

numeric column vector

Classification margins, returned as a numeric column vector.

**m** has the same length as **Mdl.Y**. The software estimates each entry of **m** using the trained ECOC model **Mdl**, the corresponding row of **Mdl.X**, and the true class label **Mdl.Y**.

## Definitions

### Classification Margin

The *classification margins* are, for each observation, the difference between the negative loss for the positive class and maximal negative loss among the negative classes. If the margins are on the same scale, then they serve as a classification confidence measure, i.e., among multiple classifiers, those that yield larger margins are better “[4]”.

### Binary Loss

A *binary loss* is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Let:

- $m_{kj}$  be element  $(k,j)$  of the coding design matrix  $M$  (i.e., the code corresponding to class  $k$  of binary learner  $j$ )
- $s_j$  be the score of binary learner  $j$  for an observation
- $g$  be the binary loss function
- $\hat{k}$  be the predicted class for the observation

In *loss-based decoding* [3], the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j).$$

In *loss-weighted decoding* [3], the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \frac{\sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j)}{\sum_{j=1}^L |m_{kj}|}.$$

Allwein et al. [1] suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where  $y_j$  is a class label for a particular binary learner (in the set  $\{-1, 1, 0\}$ ),  $s_j$  is the score for observation  $j$ , and  $g(y_j, s_j)$ .

| Value          | Description       | Score Domain        | $g(y_j, s_j)$                            |
|----------------|-------------------|---------------------|------------------------------------------|
| 'binodeviance' | Binomial deviance | $(-\infty, \infty)$ | $\log[1 + \exp(-2y_j s_j)] / [2\log(2)]$ |
| 'exponential'  | Exponential       | $(-\infty, \infty)$ | $\exp(-y_j s_j) / 2$                     |

| 'quadratic' | Quadratic   | [0,1]        | $[1 - y_j(2s_j - 1)]^2/2$ |

The software normalizes the binary losses such that the loss is 0.5 when  $y_j = 0$ , and aggregates using the average of the binary learners [1].

Do not confuse the binary loss with the overall classification loss (specified by the LossFun name-value pair argument of `predict` and `loss`), e.g., classification error, which measures how well an ECOC classifier performs as a whole.

## Examples

### Estimate In-Sample Classification Margins of ECOC Models

Load Fisher's iris data set.

```
load fisheriris
X = meas;
Y = species;
```

Train an ECOC model using SVM binary classifiers. It is good practice to standardize the predictors and define the class order. Specify to standardize the predictors using an SVM template.

```
t = templateSVM('Standardize',1);
classOrder = unique(Y)
Mdl = fitcecoc(X,Y,'Learners',t,'ClassNames',classOrder);
```

```
classOrder =
 'setosa'
 'versicolor'
 'virginica'
```

`t` is an SVM template object. The software uses default values for empty options in `t` during training. `Mdl` is a `ClassificationECOC` model.

Estimate the in-sample classification margins. Display the distribution of the margins using a boxplot.

```
m = resubMargin(Mdl);

figure;
boxplot(m);
title 'In-Sample Margins'
```

An observation margin is the positive-class, negated loss minus the maximum negative-class, negated loss. Classifiers that yield relatively large margins are desirable.

### Select ECOC Model Features by Examining In-Sample Margins

The classifier margins measure, for each observation, the difference between the positive-class, negated loss score and the maximal negative-class, negated loss. One way to

perform feature selection is to compare in-sample margins from multiple models. Based solely on this criterion, the model with the highest margins is the best model.

Load Fisher's iris data set. Define two data sets:

- `fullX` contains all 4 predictors.
- `partX` contains the sepal measurements.

```
load fisheriris
X = meas;
fullX = X;
partX = X(:,1:2);
Y = species;
```

Train ECOC models using SVM binary learners for each predictor set. It is good practice to standardize the predictors and define the class order. Specify to standardize the predictors using an SVM template, and to compute posterior probabilities.

```
t = templateSVM('Standardize',1);
classOrder = unique(Y)
FullMdl = fitcecoc(fullX,Y,'Learners',t,'ClassNames',classOrder,...
 'FitPosterior',1);
PartMdl = fitcecoc(partX,Y,'Learners',t,'ClassNames',classOrder,...
 'FitPosterior',1);
```

```
classOrder =
 'setosa'
 'versicolor'
 'virginica'
```

Estimate the in-sample margins for each classifier. For each model, display the distribution of the margins using a boxplot.

```
fullMargins = resubMargin(FullMdl);
partMargins = resubMargin(PartMdl);

figure;
boxplot([fullMargins partMargins],'Labels',{'All Predictors','Two Predictors'});
title('Boxplots of In-Sample Margins')
```

The margin distribution of CMdl is situated higher, and with less variability than the margin distribution of PCMdl.

- “Quick Start Parallel Computing for Statistics Toolbox” on page 20-2

## Tip

To compare margins or edges of several classifiers, use template objects to specify a common score transform function among the classifiers when you train them using `fitcecoc`.

# resubMargin

**Class:** ClassificationEnsemble

Classification margins by resubstitution

## Syntax

```
margin = resubMargin(ens)
margin = resubMargin(ens,Name,Value)
```

## Description

`margin = resubMargin(ens)` returns the classification margin obtained by `ens` on its training data.

`margin = resubMargin(ens,Name,Value)` calculates margins with additional options specified by one or more `Name,Value` pair arguments.

## Input Arguments

### **ens**

A classification ensemble created with `fitensemble`.

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### **'learners'**

Indices of weak learners in the ensemble ranging from 1 to `NumTrained`. `resubMargin` uses only these learners for calculating margin.

Default: 1:NumTrained

## Output Arguments

### **margin**

A numeric column-vector of length `size(ens.X,1)` containing the classification margins.

## Definitions

### **Margin**

The classification *margin* is the difference between the classification *score* for the true class and maximal classification score for the false classes. Margin is a column vector with the same number of rows as in the matrix `ens.X`.

### **Score (ensemble)**

For ensembles, a classification *score* represents the confidence of a classification into a class. The higher the score, the higher the confidence.

Different ensemble algorithms have different definitions for their scores. Furthermore, the range of scores depends on ensemble type. For example:

- AdaBoostM1 scores range from  $-\infty$  to  $\infty$ .
- Bag scores range from 0 to 1.

## Examples

Find the resubstitution margins for an ensemble that classifies the Fisher iris data:

```
load fisheriris
ens = fitensemble(meas,species,'AdaBoostM2',100,'Tree');
margin = resubMargin(ens);
[min(margin) mean(margin) max(margin)]
```

```
ans =
 -0.5674 3.2486 4.6245
```

**See Also**

resubEdge | resubMargin | resubLoss | resubPredict

## resubMargin

**Class:** ClassificationKNN

Margin of  $k$ -nearest neighbor classifier by resubstitution

### Syntax

```
m = resubMargin mdl
```

### Description

`m = resubMargin(mdl)` returns the classification margins of the data used to train `mdl`. For the definition, see “Margin” on page 21-3887.

### Input Arguments

**mdl** — Classifier model

classifier model object

$k$ -nearest neighbor classifier model, returned as a classifier model object.

Note that using the 'CrossVal', 'Kfold', 'Holdout', 'Leaveout', or 'CVPartition' options results in a model of class `ClassificationPartitionedModel`. You cannot use a partitioned tree for prediction, so this kind of tree does not have a `predict` method.

Otherwise, `mdl` is of class `ClassificationKNN`, and you can use the `predict` method to make predictions.

### Output Arguments

**m**

A numeric column vector of length `size(mdl.X,1)`, where `mdl.X` is the training data for `mdl`. Each entry in `m` represents the margin for the corresponding row of `mdl.X` and (true class) `mdl.Y`.

## Definitions

### Margin

The classification *margin* is the difference between the classification *score* for the true class and maximal classification score for the false classes.

Margin is a column vector with the same number of rows as in the training data.

### Score

The *score* of a classification is the posterior probability of the classification. The posterior probability is the number of neighbors that have that classification, divided by the number of neighbors. For a more detailed definition that includes weights and prior probabilities, see “Posterior Probability” on page 21-3315.

## Examples

### Resubstitution Margin Calculation

Construct a  $k$ -nearest neighbor classifier for the Fisher iris data, where  $k = 5$ .

Load the data.

```
load fisheriris
X = meas;
Y = species;
```

Construct a classifier for 5-nearest neighbors.

```
mdl = fitcknn(X,Y,'NumNeighbors',5);
```

Examine some statistics of the resubstitution margin of the classifier.

```
m = resubMargin(mdl);
[max(m) min(m) mean(m)]
```

```
ans =
```

```
1.0000 -0.6000 0.9253
```

The mean margin is over 0.9, indicating fairly high classification accuracy for resubstitution. For more reliable assessment of model accuracy, consider cross validation, such as `kfoldLoss`.

- “Examine the Quality of a KNN Classifier” on page 16-29

# resubMargin

**Class:** ClassificationNaiveBayes

Classification margins for naive Bayes classifiers by resubstitution

## Syntax

```
m = resubMargin(Mdl)
```

## Description

`m = resubMargin(Mdl)` returns the resubstitution classification margins (`m`) for the naive Bayes classifier `Mdl` using the training data stored in `Mdl.X` and corresponding class labels stored in `Mdl.Y`.

## Input Arguments

**Mdl** — Fully trained naive Bayes classifier  
ClassificationNaiveBayes model

A fully trained naive Bayes classifier, specified as a `ClassificationNaiveBayes` model trained by `fitcnb`.

## Output Arguments

**m** — Classification margins  
numeric vector

Classification margins, returned as a numeric vector.

`m` has the same length equal to `size(Mdl.X,1)`. Each entry of `m` is the classification margin of the corresponding observation (row) of `Mdl.X` and element of `Mdl.Y`.

## Definitions

### Classification Edge

The *classification edge* is the weighted mean of the classification margins.

If you supply weights, then the software normalizes them to sum to the prior probability of their respective class. The software uses the normalized weights to compute the weighted mean.

One way to choose among multiple classifiers, e.g., to perform feature selection, is to choose the classifier that yields the highest edge.

### Classification Margin

The *classification margins* are, for each observation, the difference between the score for the true class and maximal score for the false classes. Provided that they are on the same scale, margins serve as a classification confidence measure, i.e., among multiple classifiers, those that yield larger margins are better “[2]”.

### Posterior Probability

The *posterior probability* is the probability that an observation belongs in a particular class, given the data.

For naive Bayes, the posterior probability that a classification is  $k$  for a given observation  $(x_1, \dots, x_p)$  is

$$\hat{P}(Y = k | x_1, \dots, x_p) = \frac{P(X_1, \dots, X_p | y = k) \pi(Y = k)}{P(X_1, \dots, X_p)},$$

where:

- $P(X_1, \dots, X_p | y = k)$  is the conditional joint density of the predictors given they are in class  $k$ . `Mdl.DistributionNames` stores the distribution names of the predictors.
- $\pi(Y = k)$  is the class prior probability distribution. `Mdl.Prior` stores the prior distribution.

- $P(X_1, \dots, X_P)$  is the joint density of the predictors. The classes are discrete, so

$$P(X_1, \dots, X_P) = \sum_{k=1}^K P(X_1, \dots, X_P | y = k) \pi(Y = k).$$

## Prior Probability

The *prior probability* is the believed relative frequency that observations from a class occur in the population for each class.

## Score

The naive Bayes *score* is the class posterior probability given the observation.

## Examples

### Estimate In-Sample Classification Margins of Naive Bayes Classifiers

Load Fisher's iris data set.

```
load fisheriris
X = meas; % Predictors
Y = species; % Response
```

Train a naive Bayes classifier. It is good practice to specify the class order. Assume that each predictor is conditionally, normally distributed given its label.

```
Mdl = fitcnb(X, Y, 'ClassNames', {'setosa', 'versicolor', 'virginica'});
```

Mdl is a `ClassificationNaiveBayes` classifier.

Estimate the in-sample classification margins. Display the distribution of the margins using a boxplot.

```
m = resubMargin(Mdl);

figure;
boxplot(m);
h = gca;
iqr = quantile(m, 0.75) - quantile(m, 0.25);
h.YLim = median(m) + iqr*[-4 4];
```

```
title 'Boxplot of the Margins';
```

An observation margin is the observed (true) class score minus the maximum false class score among all scores in the respective class. Classifiers that yield relatively large margins are desirable.

### Select Naive Bayes Classifier Features by Examining In-Sample Margins

The classifier margins measure, for each observation, the difference between the true class observed score and the maximal false class score for a particular class. One way to perform feature selection is to compare in-sample margins from multiple models. Based solely on this criterion, the model with the highest margins is the best model.

Load Fisher's iris data set. Define two data sets:

- `fullX` contains all predictors (except the removed column of 0s).
- `partX` contains the last 20 predictors.

```
load fisheriris
X = meas; % Predictors
Y = species; % Response
fullX = X;
partX = X(:,3:4);
```

Train naive Bayes classifiers for each predictor set.

```
FullMdl = fitcnb(fullX,Y);
PartMdl = fitcnb(partX,Y);
```

Estimate the in-sample margins for each classifier. Compute confidence intervals for each sample.

```
fullM = resubMargin(FullMdl);
partM = resubMargin(PartMdl);
n = size(X,1);
fullMCI = mean(fullM) + 2*[-std(fullM)/n std(fullM)/n]
partMCI = mean(partM) + 2*[-std(partM)/n std(partM)/n]
```

```
fullMCI =
 0.8898 0.8991
```

```
partMCI =
 0.9129 0.9209
```

The confidence intervals are tight, and mutually exclusive. The margin confidence interval of the classifier trained using just predictors 3 and 4 has higher values than that of the full model. Therefore, the model trained on two predictors has better in-sample performance.

# resubMargin

**Class:** ClassificationSVM

Classification margins for support vector machine classifiers by resubstitution

## Syntax

```
m = resubMargin(SVMModel)
```

## Description

`m = resubMargin(SVMModel)` returns the resubstitution “classification margins” (`m`) for the support vector machine (SVM) classifier `SVMModel` using the training data stored in `SVMModel.X` and corresponding class labels stored in `SVMModel.Y`.

## Input Arguments

**SVMModel** — Full, trained SVM classifier

ClassificationSVM classifier

Full, trained SVM classifier, specified as a `ClassificationSVM` model trained using `fitcsvm`.

## Output Arguments

**m** — Classification margins

numeric vector

Classification margins, returned as a numeric vector.

`m` has the same length as `Y`. The software estimates each entry of `m` using the trained SVM classifier `SVMModel`, the corresponding row of `X`, and the true class label `Y`.

## Definitions

### Margins

The *classification margins* are, for each observation, the difference between the score for the true class and maximal score for the false classes. Provided that they are on the same scale, margins serve as a classification confidence measure, i.e., among multiple classifiers, those that yield larger margins are better “[2]”.

### Edge

The *edge* is the weighted mean of the *classification margins*.

The weights are the prior class probabilities. If you supply weights, then the software normalizes them to sum to the prior probabilities in the respective classes. The software uses the renormalized weights to compute the weighted mean.

One way to choose among multiple classifiers, e.g., to perform feature selection, is to choose the classifier that yields the highest edge.

### Score

The SVM *score* for classifying observation  $x$  is the signed distance from  $x$  to the decision boundary ranging from  $-\infty$  to  $+\infty$ . A positive score for a class indicates that  $x$  is predicted to be in that class, a negative score indicates otherwise.

The score is also the numerical, predicted response for  $x$ ,  $f(x)$ , computed by the trained SVM classification function

$$f(x) = \sum_{j=1}^n \alpha_j y_j G(x_j, x) + b,$$

where  $(\alpha_1, \dots, \alpha_n, b)$  are the estimated SVM parameters,  $G(x_j, x)$  is the dot product in the predictor space between  $x$  and the support vectors, and the sum includes the training set observations.

## Examples

### Estimate In-Sample Classification Margins of SVM Classifiers

Load the ionosphere data set.

```
load ionosphere
```

Train an SVM classifier. It is good practice to specify the class order and standardize the data.

```
SVMModel = fitcsvm(X,Y, 'ClassNames', {'b', 'g'}, 'Standardize', true);
```

SVMModel is a ClassificationSVM classifier. The negative class is 'b' and the positive class is 'g'.

Estimate the in-sample classification margins.

```
m = resubMargin(SVMModel);
m(10:20)
```

```
ans =
```

```
 5.5622
 4.2918
 1.9993
 4.5520
 -1.4897
 3.2816
 4.0260
 4.5419
 16.4449
 2.0006
 23.3782
```

An observation margin is the observed (true) class score minus the maximum false class score among all scores in the respective class. Classifiers that yield relatively large margins are desirable.

### Select SVM Classifier Features by Examining In-Sample Margins

The classifier margins measure, for each observation, the difference between the true class observed score and the maximal false class score for a particular class. One way to

perform feature selection is to compare in-sample margins from multiple models. Based solely on this criterion, the model with the highest margins is the best model.

Load the `ionosphere` data set. Define two data sets:

- `fullX` contains all predictors (except the removed column of 0s).
- `partX` contains the last 20 predictors.

```
load ionosphere
fullX = X;
partX = X(:,end-20:end);
```

Train SVM classifiers for each predictor set.

```
FullSVMModel = fitcsvm(fullX,Y);
PartSVMModel = fitcsvm(partX,Y);
```

Estimate the in-sample margins for each classifier.

```
fullMargins = resubMargin(FullSVMModel);
partMargins = resubMargin(PartSVMModel);
n = size(X,1);
p = sum(fullMargins < partMargins)/n
```

```
p =
```

```
0.2222
```

Approximately 22% of the margins from the full model are less than those from the model with fewer predictors. This suggests that the model trained using all of the predictors is better.

## Algorithms

For binary classification, the software defines the margin for observation  $j$ ,  $m_j$ , as

$$m_j = 2y_j f(x_j),$$

where  $y_j \in \{-1,1\}$ , and  $f(x_j)$  is the predicted score of observation  $j$  for the positive class. However, the literature commonly uses  $m_j = y_j f(x_j)$  to define the margin.

## resubMargin

**Class:** ClassificationTree

Classification margins by resubstitution

### Syntax

```
M = resubMargin(tree)
```

### Description

`M = resubMargin(tree)` returns resubstitution classification margins for `tree`.

### Input Arguments

**tree**

A classification tree created by `fitctree`.

### Output Arguments

**M**

A numeric column-vector of length `size(tree.X,1)` containing the classification margins.

### Definitions

#### Margin

Classification *margin* is the difference between classification *score* for the true class and maximal classification score for the false classes. A high value of margin indicates a more reliable prediction than a low value.

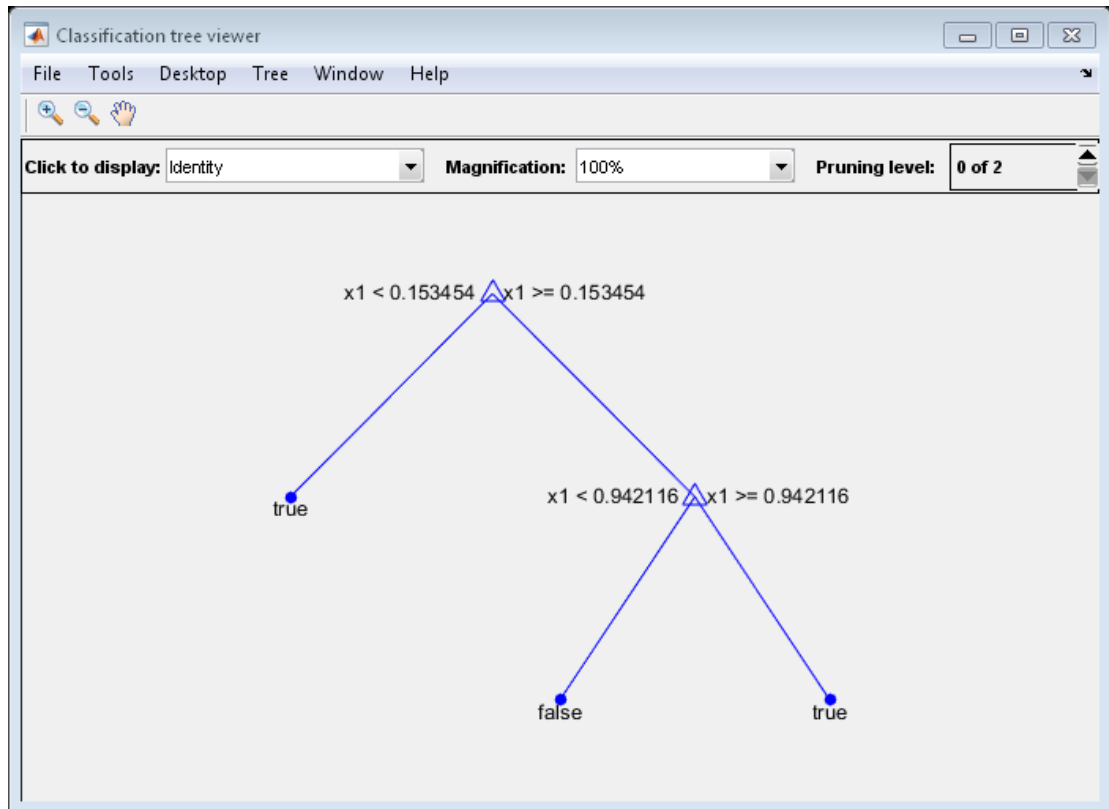

## Score (tree)

For trees, the *score* of a classification of a leaf node is the posterior probability of the classification at that node. The posterior probability of the classification at a node is the number of training sequences that lead to that node with the classification, divided by the number of training sequences that lead to that node.

For example, consider classifying a predictor  $X$  as true when  $X < 0.15$  or  $X > 0.95$ , and  $X$  is false otherwise.

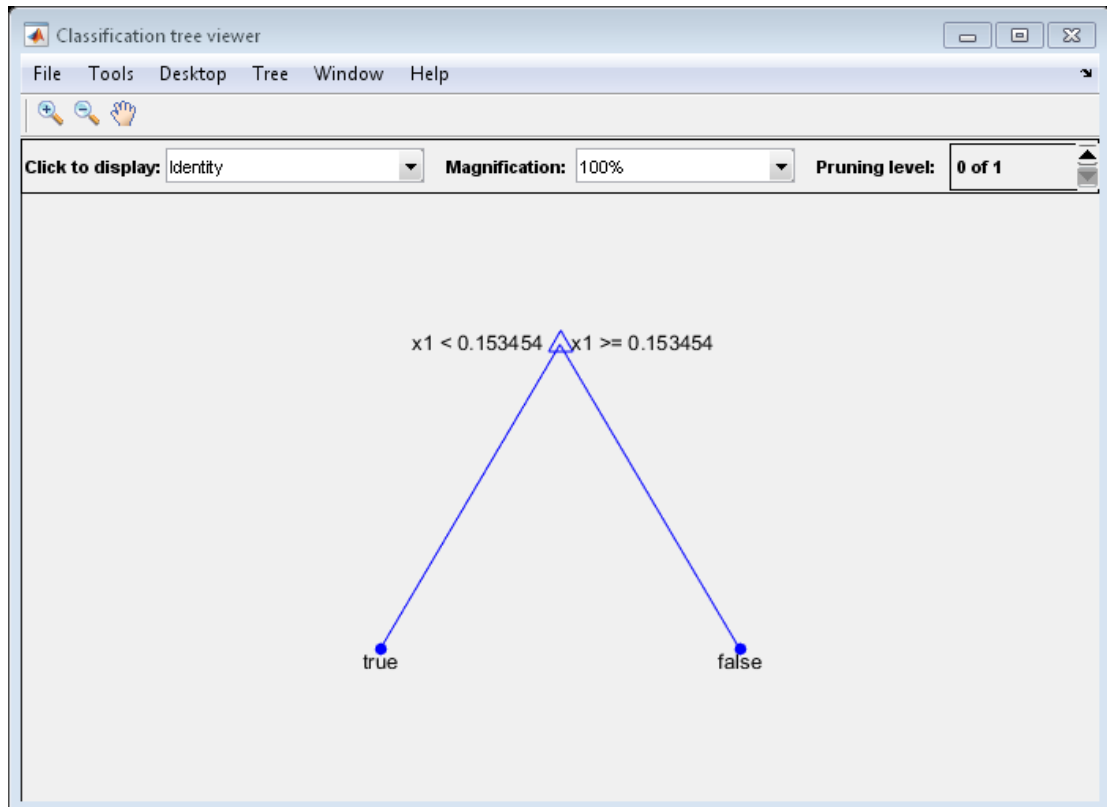

Generate 100 random points and classify them:

```
rng(0,'twister') % for reproducibility
X = rand(100,1);
Y = (abs(X - .55) > .4);
tree = fitctree(X,Y);
view(tree,'Mode','Graph')
```

Prune the tree:

```
tree1 = prune(tree, 'Level', 1);
view(tree1, 'Mode', 'Graph')
```

The pruned tree correctly classifies observations that are less than 0.15 as **true**. It also correctly classifies observations from .15 to .94 as **false**. However, it incorrectly classifies observations that are greater than .94 as **false**. Therefore, the score for observations that are greater than .15 should be about  $.05/.85=.06$  for **true**, and about  $.8/.85=.94$  for **false**.

Compute the prediction scores for the first 10 rows of X:

```
[~,score] = predict(tree1,X(1:10));
[score X(1:10,:)]
```

ans =

```
0.9059 0.0941 0.8147
```

```
0.9059 0.0941 0.9058
 0 1.0000 0.1270
0.9059 0.0941 0.9134
0.9059 0.0941 0.6324
 0 1.0000 0.0975
0.9059 0.0941 0.2785
0.9059 0.0941 0.5469
0.9059 0.0941 0.9575
0.9059 0.0941 0.9649
```

Indeed, every value of  $X$  (the right-most column) that is less than 0.15 has associated scores (the left and center columns) of 0 and 1, while the other values of  $X$  have associated scores of 0.91 and 0.09. The difference (score 0.09 instead of the expected .06) is due to a statistical fluctuation: there are 8 observations in  $X$  in the range (.95, 1) instead of the expected 5 observations.

## Examples

Find the margins for a classification tree for the Fisher iris data by resubstitution. Examine several entries:

```
load fisheriris
tree = fitctree(meas,species);
M = resubMargin(tree);
M(1:25:end)
```

```
ans =
 1.0000
 1.0000
 1.0000
 1.0000
 0.9565
 0.9565
```

## See Also

[margin](#) | [resubEdge](#) | [fitctree](#) | [resubLoss](#) | [resubPredict](#)

# resubPredict

**Class:** ClassificationDiscriminant

Predict resubstitution response of classifier

## Syntax

```
label = resubPredict(obj)
[label,posterior] = resubPredict(obj)
[label,posterior,cost] = resubPredict(obj)
```

## Description

`label = resubPredict(obj)` returns the labels `obj` predicts for the data `obj.X`. `label` is the predictions of `obj` on the data that `fitcdiscr` used to create `obj`.

`[label,posterior] = resubPredict(obj)` returns the posterior class probabilities for the predictions.

`[label,posterior,cost] = resubPredict(obj)` returns the predicted misclassification costs per class for the resubstituted data.

## Input Arguments

**obj**

Discriminant analysis classifier, produced using `fitcdiscr`.

## Output Arguments

**label**

Response `obj` predicts for the training data. `label` is the same data type as the training response data `obj.Y`. The predicted class labels are those with minimal expected misclassification cost; see “How the predict Method Classifies” on page 15-6.

**posterior**

N-by-K matrix of posterior probabilities for classes obj predicts, where N is the number of observations and K is the number of classes.

**cost**

N-by-K matrix of predicted misclassification costs. Each cost is the average misclassification cost with respect to the posterior probability.

## Definitions

### Posterior Probability

`posterior(i,k)` is the posterior probability of class `k` for observation `i`. For the mathematical definition, see “Posterior Probability” on page 15-7.

## Examples

Find the total number of misclassifications of the Fisher iris data for a discriminant analysis classifier:

```
load fisheriris
obj = fitcdiscr(meas,species);
Ypredict = resubPredict(obj); % the predictions
Ysame = strcmp(Ypredict,species); % true when ==
sum(~Ysame) % how many are different?
```

```
ans =
 3
```

### How To

- “Discriminant Analysis” on page 15-3

# resubPredict

**Class:** ClassificationECOC

Predict error-correcting output codes, multiclass model resubstitution responses

## Syntax

```
label = resubPredict(Mdl)
label = resubPredict(Mdl,Name,Value)
[label,NegLoss,PBScore] = resubPredict(___)
[label,NegLoss,PBScore,Posterior] = resubPredict(___)
```

## Description

`label = resubPredict(Mdl)` returns a vector of predicted class labels for the predictor data (stored in `Mdl.X`) based on the trained error-correcting output codes, multiclass model `Mdl`.

The software predicts the classification of an observation by assigning the observation to the class yielding the largest negated average binary loss (or, equivalently, the smallest average binary loss).

`label = resubPredict(Mdl,Name,Value)` returns predicted class labels with additional options specified by one or more `Name,Value` pair arguments.

For example, specify the posterior probability estimation method, decoding scheme, or verbosity level.

`[label,NegLoss,PBScore] = resubPredict( ___ )` additionally returns negated average binary loss per class (`NegLoss`) for observations, and positive-class scores (`PBScore`) for the observations classified by each binary learner.

`[label,NegLoss,PBScore,Posterior] = resubPredict( ___ )` additionally returns posterior class probability estimates for observations (`Posterior`).

To obtain posterior class probabilities, you must set `'FitPosterior',1` when training the ECOC model using `fitcecoc`. Otherwise, `resubPredict` throws an error.

## Input Arguments

### Mdl — ECOC multiclass model

ClassificationECOC model

ECOC multiclass model, specified as a `ClassificationECOC` model returned by `fitcecoc`.

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1`, `Value1`, ..., `NameN`, `ValueN`.

### 'BinaryLoss' — Binary learner loss function

function handle | 'hamming' | 'linear' | 'exponential' | 'binodeviance' | 'hinge' | 'quadratic'

Binary learner loss function, specified as the comma-separated pair consisting of 'BinaryLoss' and a function handle or string.

- If the value is a string, then it must correspond to a built-in function. This table summarizes the built-in functions, where  $y_j$  is a class label for a particular binary learner (in the set  $\{-1, 1, 0\}$ ),  $s_j$  is the score for observation  $j$ , and  $g(y_j, s_j)$  is the binary loss formula.

| Value          | Description       | Score Domain        | $g(y_j, s_j)$                            |
|----------------|-------------------|---------------------|------------------------------------------|
| 'binodeviance' | Binomial deviance | $(-\infty, \infty)$ | $\log[1 + \exp(-2y_j s_j)] / [2\log(2)]$ |
| 'exponential'  | Exponential       | $(-\infty, \infty)$ | $\exp(-y_j s_j) / 2$                     |
| 'hamming'      | Hamming           | $\{-1, 1\}$         | $[1 - \text{sign}(y_j s_j)] / 2$         |
| 'hinge'        | Hinge             | $(-\infty, \infty)$ | $\max(0, 1 - y_j s_j) / 2$               |
| 'linear'       | Linear            | $(-\infty, \infty)$ | $(1 - y_j s_j) / 2$                      |
| 'quadratic'    | Quadratic         | $[0, 1]$            | $[1 - y_j(2s_j - 1)]^2 / 2$              |

The software normalizes the binary losses such that the loss is 0.5 when  $y_j = 0$ . Also, the software calculates the mean binary loss for each class.

- For a custom binary loss function, e.g., `customFunction`, specify its function handle `'BinaryLoss',@customFunction`.

`customFunction` should have this form

```
bLoss = customFunction(M,s)
where:
```

- `M` is the  $K$ -by- $L$  coding matrix stored in `Mdl.CodingMatrix`.
- `s` is the 1-by- $L$  row vector of classification scores.
- `bLoss` is the classification loss. This scalar aggregates the binary losses for every learner in a particular class. For example, you can use the mean binary loss to aggregate the loss over the learners for each class.
- $K$  is the number of classes.
- $L$  is the number of binary learners.

For an example on passing a custom binary loss function, see “Predict Test-Sample Labels of ECOC Models Using Custom Binary Loss Function”.

This list describes the default values of `BinaryLoss`. If all binary learners are:

- SVMs, then `BinaryLoss` is `'hinge'`
- Ensembles trained by `AdaboostM1` or `GentleBoost`, then `BinaryLoss` is `'exponential'`
- Ensembles trained by `LogitBoost`, then `BinaryLoss` is `'binodeviance'`
- Predicting class posterior probabilities (i.e., set `'FitPosterior',1` in `fitcecoc`), then `BinaryLoss` is `'quadratic'`

Otherwise, the default `BinaryLoss` is `'hamming'`.

Example: `'BinaryLoss','binodeviance'`

Data Types: `char` | `function_handle`

#### **'Decoding' — Decoding scheme**

`'lossweighted'` (default) | `'lossbased'`

Decoding scheme that aggregates the “binary losses”, specified as the comma-separated pair consisting of 'Decoding' and 'lossweighted' or 'lossbased'.

Example: 'Decoding', 'lossbased'

Data Types: char

### **'NumKLInitializations' — Number of random initial values**

0 (default) | nonnegative integer

Number of random initial values for fitting posterior probabilities by Kullback-Leibler divergence minimization, specified as the comma-separated pair consisting of 'NumKLInitializations' and a nonnegative integer.

If you do not request the fourth output argument (Posterior) and set 'PosteriorMethod', 'kl' (the default), then the software ignores the value of NumKLInitializations.

For more details, see “Posterior Estimation Using Kullback-Leibler Divergence” on page 21-3340.

Example: 'NumKLInitializations',5

Data Types: single | double

### **'Options' — Estimation options**

[] (default) | structure array returned by `statset`

Estimation options, specified as the comma-separated pair consisting of 'Options' and a structure array returned by `statset`.

To invoke parallel computing:

- You need a Parallel Computing Toolbox license.
- Specify 'Options', `statset('UseParallel',1)`.

### **'PosteriorMethod' — Posterior probability estimation method**

'kl' (default) | 'qp'

Posterior probability estimation method, specified as the comma-separated pair consisting of 'PosteriorMethod' and 'kl' or 'qp'.

- If `PosteriorMethod` is 'kl', then the software estimates multiclass posterior probabilities by minimizing the Kullback-Leibler divergence between the predicted

and expected posterior probabilities returned by binary learners. For details, see “Posterior Estimation Using Kullback-Leibler Divergence”.

- If `PosteriorMethod` is `'qp'`, then the software estimates multiclass posterior probabilities by solving a least-squares problem using quadratic programming. You need an Optimization Toolbox license to use this option. For details, see “Posterior Estimation Using Quadratic Programming”.
- If you do not request the fourth output argument (`Posterior`), then the software ignores the value of `PosteriorMethod`.

Example: `'PosteriorMethod', 'qp'`

Data Types: `char`

### **'Verbose' — Verbosity level**

0 (default) | 1

Verbosity level, specified as the comma-separated pair consisting of `'Verbose'` and 0 or 1. `Verbose` controls the amount of diagnostic messages that the software displays in the Command Window.

If `Verbose` is 0, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: `'Verbose', 1`

Data Types: `single` | `double`

## **Output Arguments**

### **label1 — Predicted class labels**

categorical array | character array | logical vector | vector of numeric values | cell array of strings

Predicted class labels, returned as a categorical or character array, logical or numeric vector, or cell array of strings.

`label1` is the same data type as the `Mdl.ClassNames`, and has length equal to the number of rows of `Mdl.X`.

The software predicts the classification of an observation by assigning the observation to the class yielding the largest negated average binary loss (or, equivalently, the smallest average binary loss).

**NegLoss — Negated average binary losses**

numeric matrix

Negated, average binary losses, returned as a numeric matrix. `NegLoss` is an  $n$ -by- $K$  matrix, where  $n$  is the number of observations (`size(Mdl.X,1)`) and  $K$  is the number of unique classes (`size(Mdl.ClassNames,1)`).

**PBScore — Positive-class scores**

numeric matrix

Positive-class scores for each binary learner, returned as a numeric matrix. `PBScore` is an  $n$ -by- $L$  matrix, where  $n$  is the number of observations (`size(Mdl.X,1)`) and  $L$  is the number of binary learners (`size(Mdl.CodingMatrix,2)`).

**Posterior — Posterior class probabilities**

numeric matrix

Posterior class probabilities, returned as a numeric matrix. `Posterior` is an  $n$ -by- $K$  matrix, where  $n$  is the number of observations (`size(Mdl.X,1)`) and  $K$  is the number of unique classes (`size(Mdl.ClassNames,1)`).

You must set `'FitPosterior',1` when training the ECOC model using `fitcecoc` to request `Posterior`. Otherwise, the software throws an error.

## Definitions

### Binary Loss

A *binary loss* is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Let:

- $m_{kj}$  be element  $(k,j)$  of the coding design matrix  $M$  (i.e., the code corresponding to class  $k$  of binary learner  $j$ )
- $s_j$  be the score of binary learner  $j$  for an observation
- $g$  be the binary loss function
- $\hat{k}$  be the predicted class for the observation

In *loss-based decoding* [3], the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j).$$

In *loss-weighted decoding* [3], the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \frac{\sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j)}{\sum_{j=1}^L |m_{kj}|}.$$

Allwein et al. [1] suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where  $y_j$  is a class label for a particular binary learner (in the set  $\{-1, 1, 0\}$ ),  $s_j$  is the score for observation  $j$ , and  $g(y_j, s_j)$ .

| Value          | Description       | Score Domain        | $g(y_j, s_j)$                            |
|----------------|-------------------|---------------------|------------------------------------------|
| 'binodeviance' | Binomial deviance | $(-\infty, \infty)$ | $\log[1 + \exp(-2y_j s_j)] / [2\log(2)]$ |
| 'exponential'  | Exponential       | $(-\infty, \infty)$ | $\exp(-y_j s_j) / 2$                     |
| 'hamming'      | Hamming           | $\{-1, 1\}$         | $[1 - \operatorname{sign}(y_j s_j)] / 2$ |
| 'hinge'        | Hinge             | $(-\infty, \infty)$ | $\max(0, 1 - y_j s_j) / 2$               |
| 'linear'       | Linear            | $(-\infty, \infty)$ | $(1 - y_j s_j) / 2$                      |
| 'quadratic'    | Quadratic         | $[0, 1]$            | $[1 - y_j(2s_j - 1)]^2 / 2$              |

The software normalizes the binary losses such that the loss is 0.5 when  $y_j = 0$ , and aggregates using the average of the binary learners [1].

Do not confuse the binary loss with the overall classification loss (specified by the LossFun name-value pair argument of `predict` and `loss`), e.g., classification error, which measures how well an ECOC classifier performs as a whole.

## Examples

### Predict Labels of Training Data Using ECOC Models

Load Fisher's iris data set.

```
load fisheriris
X = meas;
Y = categorical(species);
n = numel(Y); % Sample size
classOrder = unique(Y);
```

Train an ECOC model using SVM binary classifiers. It is good practice to standardize the predictors and define the class order. Specify to standardize the predictors using an SVM template.

```
t = templateSVM('Standardize',1);
Mdl = fitcecoc(X,Y,'Learners',t,'ClassNames',classOrder);
```

`t` is an SVM template object. The software uses default values for empty options in `t` during training. `Mdl` is a `ClassificationECOC` model.

Predict the labels of the training data. Print a random subset of true and predicted labels.

```
labels = resubPredict(Mdl);
rng(1);
idx = randsample(n,10);
table(Y(idx),labels(idx),'VariableNames',{'TrueLabels','PredictedLabels'})
```

ans =

| TrueLabels | PredictedLabels |
|------------|-----------------|
| setosa     | setosa          |
| versicolor | versicolor      |
| virginica  | virginica       |
| setosa     | setosa          |
| versicolor | versicolor      |
| setosa     | setosa          |
| versicolor | versicolor      |
| versicolor | versicolor      |
| setosa     | setosa          |

```
setosa setosa
```

Mdl correctly labeled the observations with indices idx.

### Predict Resubstitution Labels of ECOC Models Using a Custom Binary Loss Function

Load Fisher's iris data set.

```
load fisheriris
X = meas;
Y = categorical(species);
n = numel(Y); % Sample size
classOrder = unique(Y); % Class order
K = numel(classOrder); % Number of classes
```

Train an ECOC model using SVM binary classifiers. It is good practice to standardize the predictors and define the class order. Specify to standardize the predictors using an SVM template.

```
t = templateSVM('Standardize',1);
Mdl = fitcecoc(X,Y,'Learners',t,'ClassNames',classOrder);
```

t is an SVM template object. The software uses default values for empty options in t during training. Mdl is a ClassificationECOC model.

SVM scores are signed distances from the observation to the decision boundary.

Therefore, the domain is  $(-\infty, \infty)$ . Create a custom binary loss function that:

- Maps the coding design matrix ( $M$ ) and positive-class classification scores ( $s$ ) for each learner to the binary loss for each observation
- Uses linear loss
- Aggregates the binary learner loss using the median

You can create a separate function for the binary loss function, and then save it on the MATLAB® path. Or, you can specify an anonymous binary loss function.

```
customBL = @(M,s)nanmedian(1 - bsxfun(@times,M,s),2)/2;
```

Predict resubstitution labels and estimate the median binary loss per class. Print the median negative binary losses per class for a random set of 10 observations.

```
[label,NegLoss] = resubPredict(Mdl,'BinaryLoss',customBL);
rng(1); % For reproducibility
```

```

idx = randsample(n,10);
classOrder
table(Y(idx),label(idx),NegLoss(idx,:), 'VariableNames',...
 {'TrueLabel', 'PredictedLabel', 'NegLoss'})

classOrder =

 setosa
versicolor
virginica

ans =

 TrueLabel PredictedLabel NegLoss
 _____ _____ _____

 setosa versicolor 0.12376 1.9575 -3.5812
versicolor versicolor -1.0171 0.62948 -1.1123
virginica virginica -1.9088 -0.21759 0.62641
setosa versicolor 0.43846 2.2448 -4.1833
versicolor versicolor -1.0735 0.3965 -0.82299
setosa versicolor 0.26658 2.201 -3.9675
versicolor versicolor -1.1237 0.69927 -1.0756
versicolor versicolor -1.2716 0.51847 -0.74687
setosa versicolor 0.35211 2.0683 -3.9204
setosa versicolor 0.23342 2.1892 -3.9226

```

The column order corresponds to the elements of `classOrder`. The software predicts the label based on the maximum negated loss. The results seem to indicate that the median of the linear losses might not perform as well as other losses.

### Estimate Posterior Probabilities Using ECOC Classifiers

Load Fisher's iris data set. Train the classifier using the petal dimensions as predictors.

```

load fisheriris
X = meas(:,3:4);
Y = species;
rng(1); % For reproducibility

```

Create an SVM template, and specify the Gaussian kernel. It is good practice to standardize the predictors.

```
t = templateSVM('Standardize',1,'KernelFunction','gaussian');
```

`t` is an SVM template. Most of its properties are empty. When the software trains the ECOC classifier, it sets the applicable properties to their default values.

Train the ECOC classifier using the SVM template. Transform classification scores to class posterior probabilities (which are returned by `predict` or `resubPredict`) using the 'FitPosterior' name-value pair argument. Display diagnostic messages during the training using the 'Verbose' name-value pair argument. It is good practice to specify the class order.

```
Mdl = fitcecoc(X,Y,'Learners',t,'FitPosterior',1,...
 'ClassNames',{'setosa','versicolor','virginica'},...
 'Verbose',2);
```

```
Training binary learner 1 (SVM) out of 3 with 50 negative and 50 positive observations
Negative class indices: 2
Positive class indices: 1
```

```
Fitting posterior probabilities for learner 1 (SVM).
Training binary learner 2 (SVM) out of 3 with 50 negative and 50 positive observations
Negative class indices: 3
Positive class indices: 1
```

```
Fitting posterior probabilities for learner 2 (SVM).
Training binary learner 3 (SVM) out of 3 with 50 negative and 50 positive observations
Negative class indices: 3
Positive class indices: 2
```

```
Fitting posterior probabilities for learner 3 (SVM).
```

`Mdl` is a `ClassificationECOC` model. The same SVM template applies to each binary learner, but you can adjust options for each binary learner by passing in a cell vector of templates.

Predict the in-sample labels and class posterior probabilities. Display diagnostic messages during the computation of labels and class posterior probabilities using the 'Verbose' name-value pair argument.

```
[label,~,~,Posterior] = resubPredict(Mdl,'Verbose',1);
Mdl.BinaryLoss
```

```
Predictions from all learners have been computed.
Loss for all observations has been computed.
```

```
Computing posterior probabilities...
```

```
ans =
```

```
quadratic
```

The software assigns an observation to the class that yields the smallest average binary loss. Since all binary learners are computing posterior probabilities, the binary loss function is `quadratic`.

Display a random set of results.

```
idx = randsample(size(X,1),10,1);
Mdl.ClassNames
table(Y(idx),label(idx),Posterior(idx,:),...
 'VariableNames',{ 'TrueLabel', 'PredLabel', 'Posterior' })
```

```
ans =
```

```
'setosa'
'versicolor'
'virginica'
```

```
ans =
```

| TrueLabel    | PredLabel    | Posterior  |            |            |
|--------------|--------------|------------|------------|------------|
| 'virginica'  | 'virginica'  | 0.0039321  | 0.0039869  | 0.99208    |
| 'virginica'  | 'virginica'  | 0.017067   | 0.018263   | 0.96467    |
| 'virginica'  | 'virginica'  | 0.014948   | 0.015856   | 0.9692     |
| 'versicolor' | 'versicolor' | 2.2197e-14 | 0.87317    | 0.12683    |
| 'setosa'     | 'setosa'     | 0.999      | 0.00025091 | 0.00074639 |
| 'versicolor' | 'virginica'  | 2.2195e-14 | 0.059429   | 0.94057    |
| 'versicolor' | 'versicolor' | 2.2194e-14 | 0.97001    | 0.029986   |
| 'setosa'     | 'setosa'     | 0.999      | 0.0002499  | 0.00074741 |
| 'versicolor' | 'versicolor' | 0.0085646  | 0.98259    | 0.008849   |
| 'setosa'     | 'setosa'     | 0.999      | 0.00025013 | 0.00074718 |

The columns of `Posterior` correspond to the class order of `Mdl.ClassNames`.

Define a grid of values in the observed predictor space. Predict the posterior probabilities for each instance in the grid.

```
xMax = max(X);
xMin = min(X);

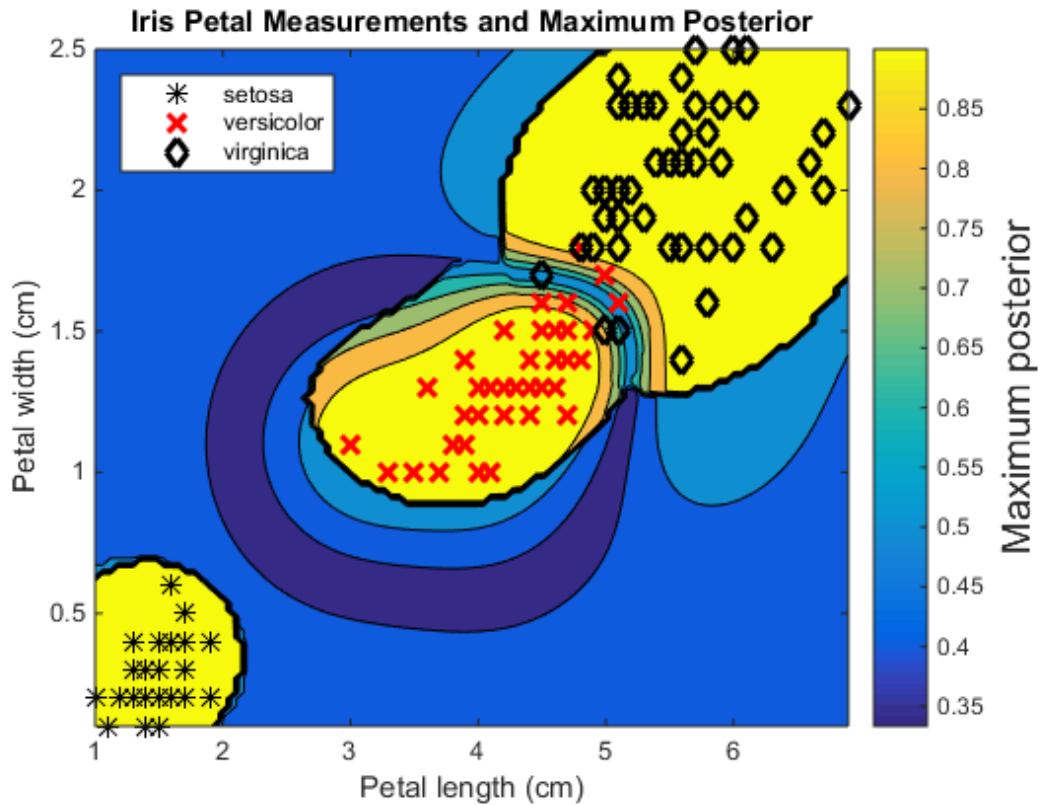

x1Pts = linspace(xMin(1),xMax(1));
x2Pts = linspace(xMin(2),xMax(2));
[x1Grid,x2Grid] = meshgrid(x1Pts,x2Pts);

[~,~,~,PosteriorRegion] = predict(Mdl,[x1Grid(:),x2Grid(:)]);
```

For each coordinate on the grid, plot the maximum class posterior probability among all classes.

```
figure;
contourf(x1Grid,x2Grid,...
 reshape(max(PosteriorRegion,[],2),size(x1Grid,1),size(x1Grid,2)));
h = colorbar;
h.YLabel.String = 'Maximum posterior';
h.YLabel.FontSize = 15;
hold on
gh = gscatter(X(:,1),X(:,2),Y,'krk','*xd',8);
gh(2).LineWidth = 2;
gh(3).LineWidth = 2;

title 'Iris Petal Measurements and Maximum Posterior';
xlabel 'Petal length (cm)';
ylabel 'Petal width (cm)';
axis tight
legend(gh,'Location','NorthWest')
hold off
```

### Estimate Posterior Probabilities Using Parallel Computing

Train an error-correcting output codes, multiclass model and estimate posterior probabilities using parallel computing.

Load the arrhythmia data set.

```
load arrhythmia
Y = categorical(Y);
tabulate(Y)
n = numel(Y);
K = numel(unique(Y));
```

| Value | Count | Percent |
|-------|-------|---------|
| 1     | 245   | 54.20%  |

|    |    |        |
|----|----|--------|
| 2  | 44 | 9.73%  |
| 3  | 15 | 3.32%  |
| 4  | 15 | 3.32%  |
| 5  | 13 | 2.88%  |
| 6  | 25 | 5.53%  |
| 7  | 3  | 0.66%  |
| 8  | 2  | 0.44%  |
| 9  | 9  | 1.99%  |
| 10 | 50 | 11.06% |
| 14 | 4  | 0.88%  |
| 15 | 5  | 1.11%  |
| 16 | 22 | 4.87%  |

Several classes are not represented in the data, and many other classes have low relative frequencies.

Specify an ensemble learning template that uses the GentleBoost method and 50 weak, classification tree learners.

```
t = templateEnsemble('GentleBoost',50,'Tree');
```

t is a template object. Most of the options are empty ([ ]). The software uses default values for all empty options during training.

Since there are many classes, specify a sparse random coding design.

```
rng(1); % For reproducibility
Coding = designecoc(K,'sparserandom');
```

Train an ECOC model using parallel computing. Specify to fit posterior probabilities.

```
pool = parpool; % Invokes workers
options = statset('UseParallel',1);
Mdl = fitcecoc(X,Y,'Learner',t,'Options',options,'Coding',Coding,...
'FitPosterior',1);
```

Starting parallel pool (parpool) using the 'local' profile ... connected to 4 workers.

Mdl is a ClassificationECOC model. You can access its properties using dot notation. The pool invokes four workers. The number of workers might vary among systems.

Estimate posterior probabilities, and display the posterior probability of being classified as not having arrhythmia (class 1) given the data.

```
[~,~,~,posterior] = resubPredict(Mdl);
```

```
idx = randsample(n,10,1);
table(idx,Y(idx),posterior(idx,1),...
 'VariableNames',{'ObservationIndex','TrueLabel','PosteriorNoArrhythmia'})
ans =
```

| ObservationIndex | TrueLabel | PosteriorNoArrhythmia |
|------------------|-----------|-----------------------|
| 79               | 1         | 0.91522               |
| 248              | 1         | 0.95376               |
| 398              | 10        | 0.032369              |
| 207              | 1         | 0.97965               |
| 340              | 1         | 0.93628               |
| 206              | 1         | 0.97795               |
| 345              | 10        | 0.015643              |
| 296              | 2         | 0.14796               |
| 391              | 1         | 0.96494               |
| 406              | 1         | 0.94867               |

- “Quick Start Parallel Computing for Statistics Toolbox” on page 20-2

## Algorithms

The software can estimate class posterior probabilities using quadratic programming or by minimizing the Kullback-Leibler divergence. For the following descriptions of the posterior estimation algorithms, let:

- $m_{kj}$  be the element  $(k,j)$  of the coding design matrix  $M$ .
- $I$  be the indicator function.
- $\hat{p}_k$  be the class posterior probability estimate for class  $k$  of an observation,  $k = 1, \dots, K$ .
- $r_j$  be the positive-class posterior probability for binary learner  $j$ . That is,  $r_j$  is the probability that binary learner  $j$  classifies an observation into the positive class, given the training data.

### Posterior Estimation Using Kullback-Leibler Divergence

By default, the software minimizes the Kullback-Leibler divergence to estimate class posterior probabilities. The Kullback-Leibler divergence between the expected and observed positive-class posterior probabilities is

$$\Delta(r, r) = \sum_{j=1}^L w_j \left[ r_j \log \frac{r_j}{r_j} + (1-r_j) \log \frac{1-r_j}{1-r_j} \right],$$

where  $w_j = \sum_{S_j} w_i^*$  is the weight for binary learner  $j$  with  $S_j$  the set of observation

indices that binary learner  $j$  is trained on and  $w_i^*$  is the weight of observation  $i$ . The software minimizes the divergence iteratively. The first step is to choose initial values  $\hat{p}_k^{(0)}$ ;  $k = 1, \dots, K$  for the class posterior probabilities.

- If you do not specify NumKLIterations, then the software uses both sets of deterministic initial values described next, and uses the one that minimizes  $\Delta$ .
- $\hat{p}_k^{(0)} = 1 / K$ ;  $k = 1, \dots, K$ .
- $\hat{p}_k^{(0)}$ ;  $k = 1, \dots, K$  is the solution of the system

$$M_{01} \hat{p}^{(0)} = r,$$

where  $M_{01}$  is  $M$  with all  $m_{kj} = -1$  replaced with 0, and  $r$  is a vector of positive-class posterior probabilities returned by the  $L$  binary learners [2]. The software uses `lsqnonneg` to solve the system.

- If you specify 'NumKLIterations',  $c$ , where  $c$  is a natural number, then the software does the following to choose  $\hat{p}_k^{(0)}$ ;  $k = 1, \dots, K$ , and uses the one that minimizes  $\Delta$ .
  - The software chooses both sets of deterministic initial values as described previously.
  - The software randomly generates  $c$  vectors of length  $K$  using `rand`, and then normalizes each vector to sum to 1.

At iteration  $t$ , the software:

- 1 Computes

$$\hat{r}_j^{(t)} = \frac{\sum_{k=1}^K \hat{p}_k^{(t)} I(m_{kj} = +1)}{\sum_{k=1}^K \hat{p}_k^{(t)} I(m_{kj} = +1 \cup m_{kj} = -1)}.$$

- 2 Estimates the next class posterior probability using

$$\hat{p}_k^{(t+1)} = \hat{p}_k^{(t)} \frac{\sum_{j=1}^L w_j [r_j I(m_{kj} = +1) + (1 - r_j) I(m_{kj} = -1)]}{\sum_{j=1}^L w_j [\hat{r}_j^{(t)} I(m_{kj} = +1) + (1 - \hat{r}_j^{(t)}) I(m_{kj} = -1)]}.$$

- 3 Normalizes  $\hat{p}_k^{(t+1)}$ ;  $k = 1, \dots, K$  so that they sum to 1.
- 4 Checks for convergence.

For more details, see [5] and [7].

## Posterior Estimation Using Quadratic Programming

Posterior probability estimation using quadratic programming requires an Optimization Toolbox license. To estimate posterior probabilities for an observation using this method, the software:

- 1 Estimates the positive-class posterior probabilities,  $r_j$ , for binary learners  $j = 1, \dots, L$ .
- 2 Using the relationship between  $r_j$  and  $\hat{p}_k$  [6], minimizes

$$\sum_{j=1}^L \left[ -r_j \sum_{k=1}^K \hat{p}_k I(m_{kj} = -1) + (1 - r_j) \sum_{k=1}^K \hat{p}_k I(m_{kj} = +1) \right]^2$$

with respect to  $\hat{p}_k$  and the restrictions

$$0 \leq \hat{p}_k \leq 1$$
$$\sum_k \hat{p}_k = 1.$$

The software performs minimization using `quadprog`.

# resubPredict

**Class:** ClassificationEnsemble

Predict ensemble response by resubstitution

## Syntax

```
label = resubPredict(ens)
[label, score] = resubPredict(ens)
[label, score] = resubPredict(ens, Name, Value)
```

## Description

`label = resubPredict(ens)` returns the labels `ens` predicts for the data `ens.X`. `label` is the predictions of `ens` on the data that `fitensemble` used to create `ens`.

`[label, score] = resubPredict(ens)` also returns scores for all classes.

`[label, score] = resubPredict(ens, Name, Value)` finds resubstitution predictions with additional options specified by one or more `Name, Value` pair arguments.

## Input Arguments

**ens**

A classification ensemble created with `fitensemble`.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

**'learners'**

Indices of weak learners in the ensemble ranging from 1 to NumTrained. `oobLoss` uses only these learners for calculating loss.

**Default:** 1:NumTrained

## Output Arguments

**label**

The response `ens` predicts for the training data. `label` is the same data type as the training response data `ens.Y`, and has the same number of entries as the number of rows in `ens.X`.

**score**

An N-by-K matrix, where N is the number of rows in `ens.X`, and K is the number of classes in `ens`. High score value indicates that an observation likely comes from this class.

## Definitions

### Score (ensemble)

For ensembles, a classification *score* represents the confidence of a classification into a class. The higher the score, the higher the confidence.

Different ensemble algorithms have different definitions for their scores. Furthermore, the range of scores depends on ensemble type. For example:

- AdaBoostM1 scores range from  $-\infty$  to  $\infty$ .
- Bag scores range from 0 to 1.

## Examples

Find the total number of misclassifications of the Fisher iris data for a classification ensemble:

```
load fisheriris
ens = fitensemble(meas,species,'AdaBoostM2',100,'Tree');
Ypredict = resubPredict(ens); % the predictions
Ysame = strcmp(Ypredict,species); % true when ==
sum(~Ysame) % how many are different?
```

```
ans =
 5
```

## See Also

## resubPredict

**Class:** ClassificationKNN

Predict resubstitution response of  $k$ -nearest neighbor classifier

### Syntax

```
label = resubPredict mdl
[label, score] = resubPredict mdl
[label, score, cost] = resubPredict mdl
```

### Description

`label = resubPredict(mdl)` returns the labels `mdl` predicts for the data `mdl.X`. `label` is the predictions of `mdl` on the data that `fitcknn` used to create `mdl`.

`[label, score] = resubPredict(mdl)` returns the posterior class probabilities for the predictions.

`[label, score, cost] = resubPredict(mdl)` returns the misclassification costs.

### Input Arguments

**mdl** — Classifier model

classifier model object

$k$ -nearest neighbor classifier model, returned as a classifier model object.

Note that using the 'CrossVal', 'KFold', 'Holdout', 'Leaveout', or 'CVPartition' options results in a model of class `ClassificationPartitionedModel`. You cannot use a partitioned tree for prediction, so this kind of tree does not have a `predict` method.

Otherwise, `mdl` is of class `ClassificationKNN`, and you can use the `predict` method to make predictions.

## Output Arguments

### label

Predicted class labels for the points in the training data  $X$ , a vector with length equal to the number of rows in the training data  $X$ . The label is the class with minimal expected cost (see “Expected Cost” on page 21-3932).

### score

Numeric matrix of size  $N$ -by- $K$ , where  $N$  is the number of observations (rows) in the training data  $X$ , and  $K$  is the number of classes (in `mdl.ClassNames`). `score(i, j)` is the posterior probability that row  $i$  of  $X$  is of class  $j$ . See “Posterior Probability” on page 21-3931.

### cost

Matrix of expected costs of size  $N$ -by- $K$ , where  $N$  is the number of observations (rows) in the training data  $X$ , and  $K$  is the number of classes (in `mdl.ClassNames`). `cost(i, j)` is the cost of classifying row  $i$  of  $X$  as class  $j$ . See “Expected Cost” on page 21-3932.

## Definitions

### Posterior Probability

For a vector (single query point)  $X$  and model `mdl`, let

- $K$  be the number of nearest neighbors used in prediction, `mdl.NumNeighbors`
- `nbd(mdl, X)` be the  $K$  nearest neighbors to  $X$  in `mdl.X`
- `Y(nbd)` be the classifications of the points in `nbd(mdl, X)`, namely `mdl.Y(nbd)`
- `W(nbd)` be the weights of the points in `nbd(mdl, X)`
- `prior` be the priors of the classes in `mdl.Y`

If there is a vector of prior probabilities, then the observation weights  $W$  are normalized by class to sum to the priors. This might involve a calculation for the point  $X$ , because weights can depend on the distance from  $X$  to the points in `mdl.X`.

The posterior probability  $p(j | X)$  is

$$p(j | \mathbf{X}) = \frac{\sum_{i \in \text{nb}d} W(i) \mathbf{1}_{Y(X(i)=j)}}{\sum_{i \in \text{nb}d} W(i)}.$$

Here  $\mathbf{1}_{Y(X(i)=j)}$  means 1 when `mdl.Y(i) = j`, and 0 otherwise.

## Expected Cost

There are two costs associated with KNN classification: the true misclassification cost per class, and the expected misclassification cost per observation. The third output of `predict` is the expected misclassification cost per observation.

Suppose you have `Nobs` observations that you want to classify with a trained classifier `mdl`. Suppose you have `K` classes. You place the observations into a matrix `X` with one observation per row. The command

```
[label,score,cost] = predict(mdl,X)
```

returns, among other outputs, a `cost` matrix of size `Nobs`-by-`K`. Each row of the `cost` matrix contains the expected (average) cost of classifying the observation into each of the `K` classes. `cost(n,k)` is

$$\sum_{i=1}^K \hat{P}(i | X(n)) C(k | i),$$

where

- $K$  is the number of classes.
- $\hat{P}(i | X(n))$  is the posterior probability of class  $i$  for observation  $X(n)$ .
- $C(k | i)$  is the true misclassification cost of classifying an observation as  $k$  when its true class is  $i$ .

## True Misclassification Cost

There are two costs associated with KNN classification: the true misclassification cost per class, and the expected misclassification cost per observation.

You can set the true misclassification cost per class in the `Cost` name-value pair when you run `fitcknn`. `Cost(i,j)` is the cost of classifying an observation into class `j` if its true class is `i`. By default, `Cost(i,j)=1` if `i~=j`, and `Cost(i,j)=0` if `i=j`. In other words, the cost is 0 for correct classification, and 1 for incorrect classification.

## Algorithms

If you specified to standardize the predictor data, that is, `mdl.Mu` and `mdl.Sigma` are not empty (`[]`), then `resubPredict` standardizes the predictor data before predicting labels.

## Examples

### Predict the Labels of the Training Data

Examine the quality of a classifier by its resubstitution predictions.

Load the data.

```
load fisheriris
X = meas;
Y = species;
```

Construct a classifier for 5-nearest neighbors.

```
mdl = fitcknn(X,Y,'NumNeighbors',5);
```

Generate the resubstitution predictions.

```
label = resubPredict(mdl);
```

Calculate the number of differences between the predictions `label` and the original data `Y`.

```
mydiff = not(strcmp(Y,label)); % mydiff(i) = 1 means they differ
sum(mydiff) % Number of differences
```

```
ans =
```

```
5
```

A values of 1 in `mydiff` indicates that the observed label differs from the corresponding predicted label. There are 5 misclassifications.

# resubPredict

**Class:** ClassificationNaiveBayes

Predict naive Bayes classifier resubstitution response

## Syntax

```
label = resubPredict(Mdl)
[label,Posterior,Cost] = predict(Mdl)
```

## Description

`label = resubPredict(Mdl)` returns a vector of predicted class labels (`label`) for the trained naive Bayes classifier `Mdl` using the predictor data `Mdl.X`.

`[label,Posterior,Cost] = predict(Mdl)` additionally returns posterior probabilities (`Posterior`) and predicted (expected) misclassification costs (`Cost`) corresponding to the observations (rows) in `Mdl.X`.

## Input Arguments

**Mdl** — Fully trained naive Bayes classifier

ClassificationNaiveBayes model

A fully trained naive Bayes classifier, specified as a `ClassificationNaiveBayes` model trained by `fitcnb`.

## Output Arguments

**label** — Predicted class labels

categorical vector | character array | logical vector | numeric vector | cell vector of strings

Predicted class labels, returned as a categorical vector, character array, logical or numeric vector, or cell vector of strings.

label:

- Is the same data type as the observed class labels (Y) that trained Mdl
- Has length equal to the number of rows of X
- Is the class yielding the lowest expected misclassification cost (Cost)

### **Posterior — Class posterior probabilities**

numeric matrix

Class posterior probabilities, returned as a numeric matrix. `Posterior` has rows equal to the number of rows of `Mdl.X` and columns equal to the number of distinct classes in the training data (`size(Mdl.ClassNames, 1)`).

`Posterior(j, k)` is the predicted posterior probability of class `k` (i.e., in class `Mdl.ClassNames(k)`) given the observation in row `j` of `Mdl.X`.

Data Types: double

### **Cost — Expected misclassification costs**

numeric matrix

Expected misclassification costs, returned as a numeric matrix. `Cost` has rows equal to the number of rows of `Mdl.X` and columns equal to the number of distinct classes in the training data (`size(Mdl.ClassNames, 1)`).

`Cost(j, k)` is the expected misclassification cost of the observation in row `j` of `Mdl.X` being predicted into class `k` (i.e., in class `Mdl.ClassNames(k)`).

## **Definitions**

### **Misclassification Cost**

A *misclassification cost* is the relative severity of a classifier labeling an observation into the wrong class.

There are two types of misclassification costs: true and expected. Let  $K$  be the number of classes.

- *True misclassification cost* — A  $K$ -by- $K$  matrix, where element  $(i,j)$  indicates the misclassification cost of predicting an observation into class  $j$  if its true class is  $i$ .

The software stores the misclassification cost in the property `Mdl.Cost`, and used in computations. By default, `Mdl.Cost(i, j) = 1` if  $i \neq j$ , and `Mdl.Cost(i, j) = 0` if  $i = j$ . In other words, the cost is 0 for correct classification, and 1 for any incorrect classification.

- *Expected misclassification cost* — A  $K$ -dimensional vector, where element  $k$  is the weighted average misclassification cost of classifying an observation into class  $k$ , weighted by the class posterior probabilities. In other words,

$$c_k = \sum_{j=1}^K \hat{P}(Y = j | x_1, \dots, x_P) \text{Cost}_{jk}.$$

the software classifies observations to the class corresponding with the lowest expected misclassification cost.

## Posterior Probability

The *posterior probability* is the probability that an observation belongs in a particular class, given the data.

For naive Bayes, the posterior probability that a classification is  $k$  for a given observation  $(x_1, \dots, x_P)$  is

$$\hat{P}(Y = k | x_1, \dots, x_P) = \frac{P(X_1, \dots, X_P | y = k) \pi(Y = k)}{P(X_1, \dots, X_P)},$$

where:

- $P(X_1, \dots, X_P | y = k)$  is the conditional joint density of the predictors given they are in class  $k$ . `Mdl.DistributionNames` stores the distribution names of the predictors.
- $\pi(Y = k)$  is the class prior probability distribution. `Mdl.Prior` stores the prior distribution.
- $P(X_1, \dots, X_P)$  is the joint density of the predictors. The classes are discrete, so

$$P(X_1, \dots, X_P) = \sum_{k=1}^K P(X_1, \dots, X_P | y = k) \pi(Y = k).$$

## Prior Probability

The *prior probability* is the believed relative frequency that observations from a class occur in the population for each class.

## Examples

### Label Training Sample Observations for Naive Bayes

Load Fisher's iris data set.

```
load fisheriris
X = meas; % Predictors
Y = species; % Response
```

Train a naive Bayes classifier. It is good practice to specify the class order. Assume that each predictor is conditionally, normally distributed given its label.

```
Mdl = fitcnb(X,Y,...
 'ClassNames',{'setosa','versicolor','virginica'});
```

Mdl is a `ClassificationNaiveBayes` classifier.

Predict the training sample labels. Display the results for the 10 observations.

```
label = resubPredict(Mdl);
rng(1); % For reproducibility
idx = randsample(size(X,1),10);
table(Y(idx),label(idx),'VariableNames',...
 {'TrueLabel','PredictedLabel'})
```

```
ans =
```

| TrueLabel    | PredictedLabel |
|--------------|----------------|
| 'setosa'     | 'setosa'       |
| 'versicolor' | 'versicolor'   |
| 'virginica'  | 'virginica'    |
| 'setosa'     | 'setosa'       |
| 'versicolor' | 'versicolor'   |
| 'setosa'     | 'setosa'       |

```
'versicolor' 'versicolor'
'versicolor' 'versicolor'
'setosa' 'setosa'
'setosa' 'setosa'
```

## Estimate In-Sample Posterior Probabilities of Naive Bayes Classifiers

Load Fisher's iris data set.

```
load fisheriris
X = meas; % Predictors
Y = species; % Response
```

Train a naive Bayes classifier. It is good practice to specify the class order. Assume that each predictor is conditionally, normally distributed given its label.

```
Mdl = fitcnb(X,Y,...
 'ClassNames',{'setosa','versicolor','virginica'});
```

Mdl is a `ClassificationNaiveBayes` classifier.

Estimate posterior probabilities and expected misclassification costs for the training data. Display the results for 10 observations.

```
[label,Posterior,MisclassCost] = resubPredict(Mdl);
rng(1); % For reproducibility
idx = randsample(size(X,1),10);
Mdl.ClassNames
table(Y(idx),label(idx),Posterior(idx,:), 'VariableNames',...
 {'TrueLabel','PredictedLabel','PosteriorProbability'})
MisclassCost(idx,:)
```

ans =

```
'setosa'
'versicolor'
'virginica'
```

ans =

| TrueLabel | PredictedLabel | PosteriorProbability |
|-----------|----------------|----------------------|
|-----------|----------------|----------------------|

---

|              |              |             |            |            |
|--------------|--------------|-------------|------------|------------|
| 'setosa'     | 'setosa'     | 1           | 3.8821e-16 | 5.5878e-24 |
| 'versicolor' | 'versicolor' | 1.2516e-54  | 1          | 4.5001e-06 |
| 'virginica'  | 'virginica'  | 5.5646e-188 | 0.00058232 | 0.99942    |
| 'setosa'     | 'setosa'     | 1           | 4.5352e-20 | 3.1301e-27 |
| 'versicolor' | 'versicolor' | 5.0002e-69  | 0.99989    | 0.00010716 |
| 'setosa'     | 'setosa'     | 1           | 2.9813e-18 | 2.1524e-25 |
| 'versicolor' | 'versicolor' | 4.6313e-60  | 0.99999    | 7.5413e-06 |
| 'versicolor' | 'versicolor' | 7.9205e-100 | 0.94293    | 0.057072   |
| 'setosa'     | 'setosa'     | 1           | 1.799e-19  | 6.0606e-27 |
| 'setosa'     | 'setosa'     | 1           | 1.5426e-17 | 1.2744e-24 |

ans =

|        |        |        |
|--------|--------|--------|
| 0.0000 | 1.0000 | 1.0000 |
| 1.0000 | 0.0000 | 1.0000 |
| 1.0000 | 0.9994 | 0.0006 |
| 0.0000 | 1.0000 | 1.0000 |
| 1.0000 | 0.0001 | 0.9999 |
| 0.0000 | 1.0000 | 1.0000 |
| 1.0000 | 0.0000 | 1.0000 |
| 1.0000 | 0.0571 | 0.9429 |
| 0.0000 | 1.0000 | 1.0000 |
| 0.0000 | 1.0000 | 1.0000 |

The order of the columns of `Posterior` and `MisclassCost` corresponds to the order of the classes in `Mdl.ClassNames`.

## resubPredict

**Class:** ClassificationSVM

Predict support vector machine classifier resubstitution responses

### Syntax

```
label = resubPredict(SVMModel)
[label,Score] = resubPredict(SVMModel)
```

### Description

`label = resubPredict(SVMModel)` returns a vector of predicted class labels (`label`) for the trained support vector machine (SVM) classifier `SVMModel` using the predictor data `SVMModel.X`.

`[label,Score] = resubPredict(SVMModel)` additionally returns class likelihood measures, that is, either scores or posterior probabilities.

### Input Arguments

**SVMModel** — Full, trained SVM classifier

ClassificationSVM classifier

Full, trained SVM classifier, specified as a `ClassificationSVM` model trained using `fitcsvm`.

### Output Arguments

**label** — Predicted class labels

categorical array | character array | logical vector | vector of numeric values | cell array of strings

Predicted class labels, returned as a categorical or character array, logical or numeric vector, or cell array of strings.

`label`:

- Is the same data type as the observed class labels (`SVMMODEL.Y`)
- Has length equal to the number of rows of `SVMMODEL.X`

For one-class learning, the elements of `label` are the one class represented in `SVMMODEL.Y`

### **Score — Predicted class scores or posterior probabilities**

numeric column vector | numeric matrix

Predicted class “scores” or “posterior probabilities”, returned as a numeric column vector or numeric matrix.

- For one-class learning, **Score** is a column vector with the same number of rows as `SVMMODEL.X`. The elements are the positive class scores for the corresponding observations. You cannot obtain posterior probabilities for one-class learning.
- For two-class learning, **Score** is a two column matrix with the same number of rows as `SVMMODEL.X`.
  - If you fit the optimal score-to-posterior probability transformation function using `fitPosterior` or `fitSVMPosterior`, then **Score** contains class posterior probabilities. That is, if the value of `SVMMODEL.ScoreTransform` is not `none`, then the elements of the first and second columns of **Score** are the negative class (`SVMMODEL.ClassNames{1}`) and positive class (`SVMMODEL.ClassNames{2}`) posterior probabilities for the corresponding observations, respectively.
  - Otherwise, the elements of the first column are the negative class scores and the elements of the second column are the positive class scores for the corresponding observations.

Data Types: `double` | `single`

## Definitions

### Score

The SVM *score* for classifying observation  $x$  is the signed distance from  $x$  to the decision boundary ranging from  $-\infty$  to  $+\infty$ . A positive score for a class indicates that  $x$  is predicted to be in that class, a negative score indicates otherwise.

The score is also the numerical, predicted response for  $x$ ,  $f(x)$ , computed by the trained SVM classification function

$$f(x) = \sum_{j=1}^n \alpha_j y_j G(x_j, x) + b,$$

where  $(\alpha_1, \dots, \alpha_n, b)$  are the estimated SVM parameters,  $G(x_j, x)$  is the dot product in the predictor space between  $x$  and the support vectors, and the sum includes the training set observations.

## Posterior Probability

The probability that an observation belongs in a particular class, given the data.

For SVM, the posterior probability is a function of the score,  $P(s)$ , that observation  $j$  is in class  $k = \{-1, 1\}$ .

- For separable classes, the posterior probability is the step function

$$P(s_j) = \begin{cases} 0; & s < \max_{y_k=-1} s_k \\ \pi; & \max_{y_k=-1} s_k \leq s_j \leq \min_{y_k=+1} s_k, \\ 1; & s_j > \min_{y_k=+1} s_k \end{cases}$$

where:

- $s_j$  is the score of observation  $j$ .
- $+1$  and  $-1$  denote the positive and negative classes, respectively.
- $\pi$  is the prior probability that an observation is in the positive class.
- For inseparable classes, the posterior probability is the sigmoid function

$$P(s_j) = \frac{1}{1 + \exp(As_j + B)},$$

where the parameters  $A$  and  $B$  are the slope and intercept parameters.

## Prior Probability

The *prior probability* is the believed relative frequency that observations from a class occur in the population for each class.

## Examples

### Label Training Sample Observations for SVM Classifiers Using resubPredict

Load the `ionosphere` data set.

```
load ionosphere
```

Train an SVM classifier. It is good practice to specify the class order and standardize the data.

```
SVMModel = fitcsvm(X,Y,'ClassNames',{'b','g'},'Standardize',true);
```

`SVMModel` is a `ClassificationSVM` classifier. The positive class is `'g'`.

Predict the training sample labels and scores. Display the results for the first 10 observations.

```
[label,score] = resubPredict(SVMModel);
table(Y(1:10),label(1:10),score(1:10,2),'VariableNames',...
 {'TrueLabel','PredictedLabel','Score'})
```

```
ans =
```

| TrueLabel | PredictedLabel | Score   |
|-----------|----------------|---------|
| 'g'       | 'g'            | 1.4861  |
| 'b'       | 'b'            | -1.0004 |
| 'g'       | 'g'            | 1.8685  |
| 'b'       | 'b'            | -2.6458 |
| 'g'       | 'g'            | 1.2805  |

```
'b' 'b' -1.4617
'g' 'g' 2.1672
'b' 'b' -5.7085
'g' 'g' 2.4797
'b' 'b' -2.7811
```

### Estimate In-Sample Posterior Probabilities of SVM Classifiers

Load the `ionosphere` data set.

```
load ionosphere
```

Train an SVM classifier. It is good practice to specify the class order and standardize the data.

```
SVMMModel = fitcsvm(X,Y,'ClassNames',{'b','g'},'Standardize',true);
```

`SVMMModel` is a `ClassificationSVM` classifier. The positive class is `'g'`.

Fit the optimal score-to-posterior-probability transformation function.

```
rng(1); % For reproducibility
ScoreSVMMModel = fitPosterior(SVMMModel)
```

```
ScoreSVMMModel =
```

```
ClassificationSVM
 PredictorNames: {1x34 cell}
 ResponseName: 'Y'
 ClassNames: {'b' 'g'}
 ScoreTransform: '@(S)sigmoid(S,-9.481802e-01,-1.218745e-01)'
```

NumObservations: 351

```
 Alpha: [90x1 double]
 Bias: -0.1343
KernelParameters: [1x1 struct]
 Mu: [1x34 double]
 Sigma: [1x34 double]
 BoxConstraints: [351x1 double]
 ConvergenceInfo: [1x1 struct]
 IsSupportVector: [351x1 logical]
 Solver: 'SMO'
```

Since the classes are inseparable, the score transformation function (`ScoreSVMModel.ScoreTransform`) is the sigmoid function.

Estimate scores and positive class posterior probabilities for the training data. Display the results for the first 10 observations.

```
[label,scores] = resubPredict(SVMModel);
[~,postProbs] = resubPredict(ScoreSVMModel);
table(Y(1:10),label(1:10),scores(1:10,2),postProbs(1:10,2), 'VariableNames',...
 {'TrueLabel', 'PredictedLabel', 'Score', 'PosteriorProbability'})
```

ans =

| TrueLabel | PredictedLabel | Score   | PosteriorProbability |
|-----------|----------------|---------|----------------------|
| 'g'       | 'g'            | 1.4861  | 0.82215              |
| 'b'       | 'b'            | -1.0004 | 0.30436              |
| 'g'       | 'g'            | 1.8685  | 0.86916              |
| 'b'       | 'b'            | -2.6458 | 0.084183             |
| 'g'       | 'g'            | 1.2805  | 0.79184              |
| 'b'       | 'b'            | -1.4617 | 0.22028              |
| 'g'       | 'g'            | 2.1672  | 0.89814              |
| 'b'       | 'b'            | -5.7085 | 0.0050122            |
| 'g'       | 'g'            | 2.4797  | 0.92223              |
| 'b'       | 'b'            | -2.7811 | 0.074805             |

## Algorithms

- By default, the software computes optimal posterior probabilities using Platt's method "[1]":
  - 1 Performing 10-fold cross validation
  - 2 Fitting the sigmoid function parameters to the scores returned from the cross validation
  - 3 Estimating the posterior probabilities by entering the cross-validation scores into the fitted sigmoid function
- The software incorporates prior probabilities in the SVM objective function during training.

- For SVM, `predict` classifies observations into the class yielding the largest score (i.e., the largest posterior probability). The software accounts for misclassification costs by applying the average-cost correction before training the classifier. That is, given the class prior vector  $P$ , misclassification cost matrix  $C$ , and observation weight vector  $w$ , the software defines a new vector of observation weights ( $W$ ) such that

$$W_j = w_j P_j \sum_{k=1}^K C_{jk}.$$

# resubPredict

**Class:** ClassificationTree

Predict resubstitution response of tree

## Syntax

```
label = resubPredict(tree)
[label,posterior] = resubPredict(tree)
[label,posterior,node] = resubPredict(tree)
[label,posterior,node,cnum] = resubPredict(tree)
[label,...] = resubPredict(tree,Name,Value)
```

## Description

`label = resubPredict(tree)` returns the labels `tree` predicts for the data `tree.X`. `label` is the predictions of `tree` on the data that `fitctree` used to create `tree`.

`[label,posterior] = resubPredict(tree)` returns the posterior class probabilities for the predictions.

`[label,posterior,node] = resubPredict(tree)` returns the node numbers of `tree` for the resubstituted data.

`[label,posterior,node,cnum] = resubPredict(tree)` returns the predicted class numbers for the predictions.

`[label,...] = resubPredict(tree,Name,Value)` returns resubstitution predictions with additional options specified by one or more `Name,Value` pair arguments.

## Input Arguments

### **tree**

A classification tree constructed by `fitctree`.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

### 'Subtrees'

A vector with integer values from 0 (full unpruned tree) to the maximal pruning level `max(tree.PruneList)`.

Subtrees must be in ascending order.

**Default:** 0

## Output Arguments

### **label**

The response tree predicts for the training data. `label` is the same data type as the training response data `tree.Y`.

If the `Subtrees` name-value argument contains  $m > 1$  entries, `label` has  $m$  columns, each of which represents the predictions of the corresponding subtree. Otherwise, `label` is a vector.

### **posterior**

Matrix or array of posterior probabilities for classes tree predicts.

If the `Subtrees` name-value argument is a scalar or is missing, `posterior` is an  $n$ -by- $k$  matrix, where  $n$  is the number of rows in the training data `tree.X`, and  $k$  is the number of classes.

If `Subtrees` contains  $m > 1$  entries, `posterior` is an  $n$ -by- $k$ -by- $m$  array, where the matrix for each  $m$  gives posterior probabilities for the corresponding subtree.

### **node**

The node numbers of `tree` where each data row resolves.

If the `Subtrees` name-value argument is a scalar or is missing, `node` is a numeric column vector with  $n$  rows, the same number of rows as `tree.X`.

If `Subtrees` contains  $m > 1$  entries, `node` is a  $n$ -by- $m$  matrix. Each column represents the node predictions of the corresponding subtree.

### **cnum**

The class numbers that tree predicts for the resubstituted data.

If the `Subtrees` name-value argument is a scalar or is missing, `cnum` is a numeric column vector with  $n$  rows, the same number of rows as `tree.X`.

If `Subtrees` contains  $m > 1$  entries, `cnum` is a  $n$ -by- $m$  matrix. Each column represents the class predictions of the corresponding subtree.

## Definitions

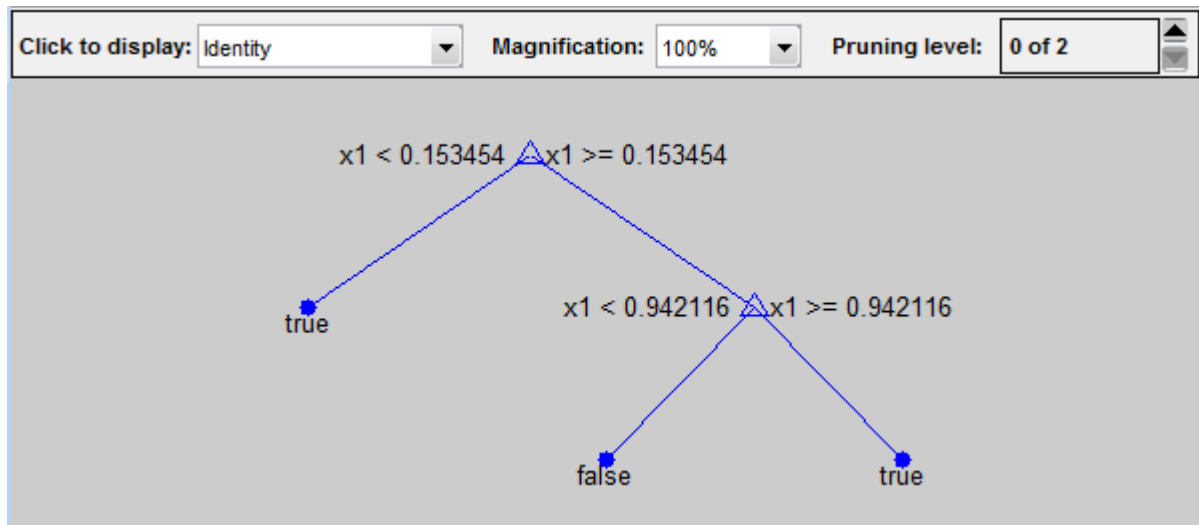

### Posterior Probability

The posterior probability of the classification at a node is the number of training sequences that lead to that node with this classification, divided by the number of training sequences that lead to that node.

For example, consider classifying a predictor `X` as `true` when `X < 0.15` or `X > 0.95`, and `X` is false otherwise.

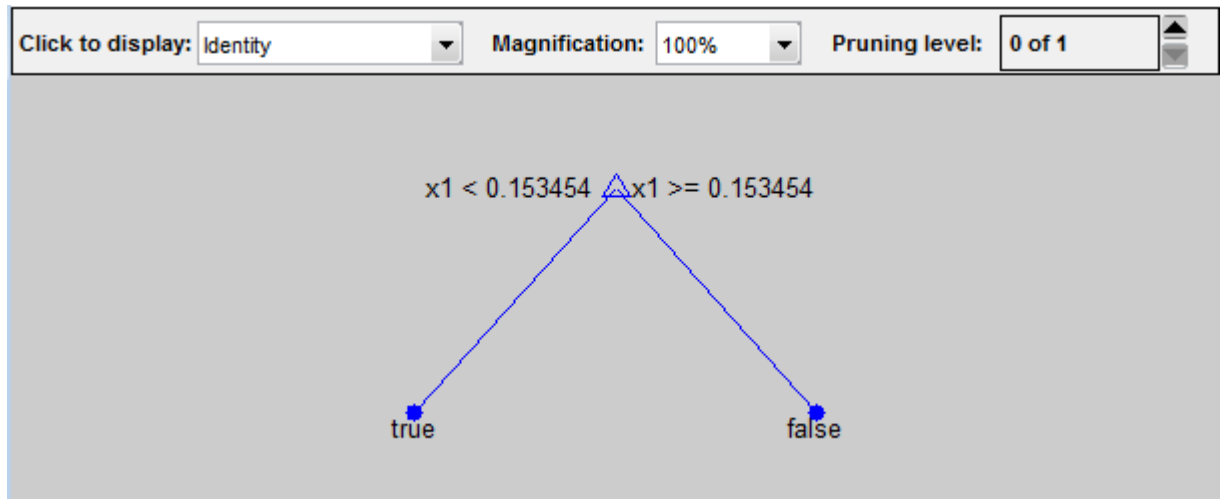

- 1 Generate 100 random points and classify them:

```
rng(0,'twister') % for reproducibility
X = rand(100,1);
Y = (abs(X - .55) > .4);
tree = fitctree(X,Y);
view(tree,'mode','graph')
```

2 Prune the tree:

```
tree1 = prune(tree,'level',1);
view(tree1,'mode','graph')
```

The pruned tree correctly classifies observations that are less than 0.15 as **true**. It also correctly classifies observations between .15 and .94 as **false**. However, it incorrectly classifies observations that are greater than .94 as **false**. Therefore the score for observations that are greater than .15 should be about  $.05/.85=.06$  for **true**, and about  $.8/.85=.94$  for **false**.

- 3** Compute the prediction scores for the first 10 rows of X:

```
[~,score] = predict(tree1,X(1:10));
[score X(1:10,:)]
```

```
ans =
 0.9405 0.0595 0.6555
 0.9405 0.0595 0.1712
 0.9405 0.0595 0.7060
 0 1.0000 0.0318
 0.9405 0.0595 0.2769
 0 1.0000 0.0462
 0 1.0000 0.0971
 0.9405 0.0595 0.8235
 0.9405 0.0595 0.6948
 0.9405 0.0595 0.3171
```

Indeed, every value of X (the rightmost column) that is less than 0.15 has associated scores (the left and center columns) of 0 and 1, while the other values of X have associated scores of 0.94 and 0.06.

## Examples

Find the total number of misclassifications of the Fisher iris data for a classification tree:

```
load fisheriris
tree = fitctree(meas,species);
Ypredict = resubPredict(tree); % the predictions
Ysame = strcmp(Ypredict,species); % true when ==
sum(~Ysame) % how many are different?
```

```
ans =
 3
```

## resubPredict

**Class:** RegressionEnsemble

Predict response of ensemble by resubstitution

### Syntax

```
Yfit = resubPredict(ens)
Yfit = resubPredict(ens,Name,Value)
```

### Description

`Yfit = resubPredict(ens)` returns the response `ens` predicts for the data `ens.X`. `Yfit` is the predictions of `ens` on the data that `fitensemble` used to create `ens`.

`Yfit = resubPredict(ens,Name,Value)` predicts responses with additional options specified by one or more `Name,Value` pair arguments.

### Input Arguments

#### **ens**

A regression ensemble created with `fitensemble`.

#### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

#### **'learners'**

Indices of weak learners in the ensemble ranging from 1 to `NumTrained`. `oobLoss` uses only these learners for calculating loss.

Default: 1:NumTrained

## Output Arguments

### Yfit

A vector of predicted responses to the training data, with `ens.X` elements.

## Examples

Find the resubstitution predictions of mileage from the `carsmall` data based on horsepower and weight, and look at their mean square difference from the training data.

```
load carsmall
X = [Horsepower Weight];
ens = fitensemble(X,MPG,'LSBoost',100,'Tree');
Yfit = resubPredict(ens);
MSE = mean((Yfit - ens.Y).^2)
```

```
MSE =
 6.4336
```

This is the same as the result of `resubLoss`:

```
resubLoss(ens)

ans =
 6.4336
```

## See Also

`resubLoss` | `predict` | `resubPredict`

## resubPredict

**Class:** RegressionTree

Predict resubstitution response of tree

### Syntax

```
Yfit = resubPredict(tree)
[Yfit,node] = resubPredict(tree)
[Yfit,node] = resubPredict(tree,Name,Value)
```

### Description

`Yfit = resubPredict(tree)` returns the responses `tree` predicts for the data `tree.X`. `Yfit` is the predictions of `tree` on the data that `fitrtree` used to create `tree`.

`[Yfit,node] = resubPredict(tree)` returns the node numbers of `tree` for the resubstituted data.

`[Yfit,node] = resubPredict(tree,Name,Value)` predicts with additional options specified by one or more `Name,Value` pair arguments.

### Input Arguments

#### **tree**

A regression tree constructed using `fitrtree`.

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### 'Subtrees'

A vector with integer values from 0 (full unpruned tree) to the maximal pruning level `max(tree.PruneList)`.

Subtrees must be in ascending order.

**Default:** 0

## Output Arguments

### Yfit

The response tree predicts for the training data.

If the `Subtrees` name-value argument is a scalar or is missing, `label` is the same data type as the training response data `tree.Y`.

If `Subtrees` contains  $m > 1$  entries, `label` has  $m$  columns, each of which represents the predictions of the corresponding subtree.

### node

The `tree` node numbers where `tree` sends each data row.

If the `Subtrees` name-value argument is a scalar or is missing, `node` is a numeric column vector with  $n$  rows, the same number of rows as `tree.X`.

If `Subtrees` contains  $m > 1$  entries, `node` is a  $n$ -by- $m$  matrix. Each column represents the node predictions of the corresponding subtree.

## Examples

Find the mean square error of a model of the `carsmall` data:

```
load carsmall
X = [Displacement Horsepower Weight];
tree = fitrtree(X,MPG);
Yfit = resubPredict(tree);
mean((Yfit - tree.Y).^2)
```

```
ans =
 4.8952
```

You can get the same answer using `resubLoss`:

```
resubLoss(tree)
```

```
ans =
 4.8952
```

### See Also

`resubLoss` | `predict` | `fitrtree`

## resume

**Class:** ClassificationEnsemble

Resume training ensemble

## Syntax

```
ens1 = resume(ens,nlearn)
ens1 = resume(ens,nlearn,Name,Value)
```

## Description

`ens1 = resume(ens,nlearn)` trains `ens` for `nlearn` more cycles. `resume` uses the same training options `fitensemble` used to create `ens`.

---

**Note:** You cannot `resume` training when `ens` is a `Subspace` ensemble created with `'AllPredictorCombinations'` number of learners.

---

`ens1 = resume(ens,nlearn,Name,Value)` trains `ens` with additional options specified by one or more `Name,Value` pair arguments.

## Input Arguments

### **ens**

A classification ensemble, created with `fitensemble`.

### **nlearn**

A positive integer, the number of cycles for additional training of `ens`.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single

quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

### **'nprint'**

Printout frequency, a positive integer scalar or 'off' (no printouts). Returns to the command line the number of weak learners trained so far. Useful when you train ensembles with many learners on large data sets.

**Default:** 'off'

## **Output Arguments**

### **ens1**

The classification ensemble ens, augmented with additional training.

## **Examples**

Train a classification ensemble for 10 cycles. Examine the resubstitution error. Then train for 10 more cycles and examine the new resubstitution error.

```
load ionosphere
ens = fitensemble(X,Y,'GentleBoost',10,'Tree');
L = resubLoss(ens)
```

```
L =
 0.0484
```

```
ens1 = resume(ens,10);
L = resubLoss(ens1)
```

```
L =
 0.0256
```

The new ensemble has much less resubstitution error than the original.

## **See Also**

fitensemble

## resume

**Class:** ClassificationPartitionedEnsemble

Resume training learners on cross-validation folds

## Syntax

```
ens1 = resume(ens,nlearn)
ens1 = resume(ens,nlearn,Name,Value)
```

## Description

`ens1 = resume(ens,nlearn)` trains `ens` in every fold for `nlearn` more cycles. `resume` uses the same training options `fitensemble` used to create `ens`.

`ens1 = resume(ens,nlearn,Name,Value)` trains `ens` with additional options specified by one or more `Name,Value` pair arguments.

## Input Arguments

### **ens**

A cross-validated classification ensemble. `ens` is the result of either:

- The `fitensemble` function with a cross-validation name-value pair. The names are 'crossval', 'kfold', 'holdout', 'leaveout', or 'cvpartition'.
- The `crossval` method applied to a classification ensemble.

### **nlearn**

A positive integer, the number of cycles for additional training of `ens`.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single

quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

### **'nprint'**

Printout frequency, a positive integer scalar or 'off' (no printouts). Returns to the command line the number of weak learners trained so far. Useful when you train ensembles with many learners on large data sets.

**Default:** 'off'

## **Output Arguments**

### **ens1**

The cross-validated classification ensemble ens, augmented with additional training.

## **Examples**

Train a partitioned classification ensemble for 10 cycles. Examine the error. Then train for 10 more cycles and examine the new error.

```
load ionosphere
cvens = fitensemble(X,Y,'GentleBoost',10,'Tree',...
 'crossval','on');
L = kfoldLoss(cvens)
```

```
L =
 0.0883
```

```
cvens = resume(cvens,10);
L = kfoldLoss(cvens)
```

```
L =
 0.0769
```

The ensemble has less cross-validation error after training for ten more cycles.

## **See Also**

## resume

**Class:** ClassificationSVM

Resume training support vector machine classifier

## Syntax

```
UpdatedSVMModel = resume(SVMModel,numIter)
UpdatedSVMModel = resume(SVMModel,numIter,Name,Value)
```

## Description

`UpdatedSVMModel = resume(SVMModel,numIter)` returns an updated support vector machine (SVM) classifier (`UpdatedSVMModel`) by training the support vector machine classifier `SVMModel` for `numIter` more iterations.

`resume` continues applying the training options that you set for `fitcsvm` to train `SVMModel`.

`UpdatedSVMModel = resume(SVMModel,numIter,Name,Value)` returns an updated support vector machine classifier (`UpdatedSVMModel`) with additional options specified by one or more `Name,Value` pair arguments.

## Tips

If optimization has not converged and the solver is 'SMO' or 'ISDA', then try to resume training the SVM classifier.

## Input Arguments

**SVMModel** — Full, trained SVM classifier

ClassificationSVM classifier

Full, trained SVM classifier, specified as a `ClassificationSVM` model trained using `fitcsvm`.

**numIter** — Number of iterations

Positive integer

Number of iterations to continue training the SVM classifier, specified as a positive integer.

Data Types: double

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

**'Verbose'** — Verbosity level

0 | 1 | 2

Verbosity level, specified as the comma-separated pair consisting of 'Verbose' and either 0, 1, or 2. Verbose controls the amount of optimization information that the software displays to the Command Window and is saved as a structure to SVMModel.ConvergenceInfo.History.

This table summarizes the available verbosity level options.

| Value | Description                                                                                                                                                                               |
|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0     | The software does not display or save convergence information.                                                                                                                            |
| 1     | The software displays diagnostic messages and saves convergence criteria every <i>numprint</i> iterations, where <i>numprint</i> is the value of the name-value pair argument 'NumPrint'. |
| 2     | The software displays diagnostic messages and saves convergence criteria at every iteration.                                                                                              |

By default, Verbose is the value that fitcsvm used to train SVMModel.

Example: 'Verbose',1

Data Types: double

### 'NumPrint' — Number of iterations between diagnostic message printouts

nonnegative integer

Number of iterations between diagnostic message printouts, specified as the comma-separated pair consisting of 'NumPrint' and a nonnegative integer.

If you set 'Verbose', 1 and 'NumPrint', *numprint*, then the software displays all optimization diagnostic messages from SMO and ISDA every *numprint* iterations to the Command Window.

By default, NumPrint is the value that `fitcsvm` used to train `SVMModel`.

Example: 'NumPrint', 500

Data Types: double

## Output Arguments

### UpdatedSVMModel1 — Updated SVM classifier

ClassificationSVM classifier

Updated SVM classifier, returned as a `ClassificationSVM` classifier.

## Examples

### Resume Training an SVM Classifier

If you trained an SVM classifier, and the solver failed to converge onto a solution, then you can resume training the classifier without having to restart the entire learning process.

Load the `ionosphere` data set.

```
load ionosphere
rng(1); % For reproducibility
```

Train an SVM classifier. For illustration, specify that the optimization routine uses at most 50 iterations.

```
SVMModel = fitcsvm(X,Y,'IterationLimit',50);
DidConverge = SVMModel.ConvergenceInfo.Converged
Reason = SVMModel.ConvergenceInfo.ReasonForConvergence
```

```
DidConverge =

 0
```

```
Reason =

NoConvergence
```

`DidConverge = 0` indicates that the optimization routine did not converge onto a solution. `Reason` states the reason why the routine did not converge. Therefore, `SVMModel` is a partially trained, SVM classifier.

Resume training the SVM classifier for another 1500 iterations.

```
UpdatedSVMModel = resume(SVMModel,1500);
DidConverge = UpdatedSVMModel.ConvergenceInfo.Converged
Reason = UpdatedSVMModel.ConvergenceInfo.ReasonForConvergence
```

```
DidConverge =

 1
```

```
Reason =

DeltaGradient
```

`DidConverge` indicates that the optimization routine converged onto a solution. `Reason` indicates that the gradient difference (`DeltaGradient`) reached its tolerance level (`DeltaGradientTolerance`). Therefore, `SVMModel` is a fully trained SVM classifier.

### Monitor Training of an SVM Classifier

Load the ionosphere data set.

```
load ionosphere
```

Train an SVM classifier. For illustration, specify that the optimization routine uses at most 100 iterations. Monitor the algorithm specifying that the software prints diagnostic information every 50 iterations.

```
SVMMModel = fitcsvm(X,Y, 'IterationLimit',100, 'Verbose',1, 'NumPrint',50);
```

| Iteration | Set    | Set Size | Feasibility Gap | Delta Gradient | KKT Violation |
|-----------|--------|----------|-----------------|----------------|---------------|
| 0         | active | 351      | 9.971591e-01    | 2.000000e+00   | 1.000000e+00  |
| 50        | active | 351      | 8.214794e-01    | 3.736929e+00   | 3.801461e+00  |

SVM optimization did not converge to the required tolerance.

The software prints an iterative display to the Command Window. The printout indicates that the optimization routine has not converged onto a solution.

Estimate the resubstitution loss of the partially trained SVM classifier.

```
partialLoss = resubLoss(SVMMModel)
```

```
partialLoss =
```

```
0.1054
```

The training sample misclassification error is approximately 11%.

Resume training the classifier for another 1500 iterations. Specify that the software print diagnostic information every 250 iterations.

```
UpdatedSVMMModel = resume(SVMMModel,1500, 'NumPrint',250)
```

| Iteration | Set    | Set Size | Feasibility Gap | Delta Gradient | KKT Violation |
|-----------|--------|----------|-----------------|----------------|---------------|
| 250       | active | 351      | 7.907170e-01    | 1.701201e+00   | 4.783394e+00  |

```
Exiting Active Set upon convergence due to DeltaGradient.
```

```
UpdatedSVMModel =

ClassificationSVM
 PredictorNames: {1x34 cell}
 ResponseName: 'Y'
 ClassNames: {'b' 'g'}
 ScoreTransform: 'none'
 NumObservations: 351
 Alpha: [103x1 double]
 Bias: -3.8828
 KernelParameters: [1x1 struct]
 BoxConstraints: [351x1 double]
 ConvergenceInfo: [1x1 struct]
 IsSupportVector: [351x1 logical]
 Solver: 'SMO'
```

The software resumes at iteration 1000, and uses the same verbosity level as you set when you trained the model using `fitcsvm`. The printout indicates that the algorithm converged. Therefore, `UpdatedSVMModel` is a fully trained `ClassificationSVM` classifier.

```
updatedLoss = resubLoss(UpdatedSVMModel)
```

```
updatedLoss =
```

```
0.0769
```

The training sample misclassification error of the fully trained classifier is approximately 8%.

## resume

**Class:** RegressionEnsemble

Resume training ensemble

## Syntax

```
ens1 = resume(ens,nlearn)
ens1 = resume(ens,nlearn,Name,Value)
```

## Description

`ens1 = resume(ens,nlearn)` trains `ens` for `nlearn` more cycles. `resume` uses the same training options `fitensemble` used to create `ens`.

`ens1 = resume(ens,nlearn,Name,Value)` trains `ens` with additional options specified by one or more `Name,Value` pair arguments.

## Input Arguments

### **ens**

A regression ensemble, created with `fitensemble`.

### **nlearn**

A positive integer, the number of cycles for additional training of `ens`.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**'nprint'**

Printout frequency, a positive integer scalar or 'off' (no printouts). Returns to the command line the number of weak learners trained so far. Useful when you train ensembles with many learners on large data sets.

**Default:** 'off'

## Output Arguments

**ens1**

The regression ensemble `ens`, augmented with additional training.

## Examples

Train a regression ensemble for 50 cycles. Examine the resubstitution error. Then train for 50 more cycles and examine the new resubstitution error.

```
load carsmall
X = [Displacement Horsepower Weight];
ens = fitensemble(X,MPG,'LSBoost',50,'Tree');
L = resubLoss(ens)
```

```
L =
 6.2681
```

```
ens = resume(ens,50);
L = resubLoss(ens)
```

```
L =
 4.3904
```

The new ensemble has much less resubstitution error than the original.

## See Also

`fitensemble`

## resume

**Class:** RegressionPartitionedEnsemble

Resume training ensemble

## Syntax

```
ens1 = resume(ens,nlearn)
ens1 = resume(ens,nlearn,Name,Value)
```

## Description

`ens1 = resume(ens,nlearn)` trains `ens` in every fold for `nlearn` more cycles. `resume` uses the same training options `fitensemble` used to create `ens`.

`ens1 = resume(ens,nlearn,Name,Value)` trains `ens` with additional options specified by one or more `Name,Value` pair arguments.

## Input Arguments

### **ens**

A cross-validated regression ensemble. `ens` is the result of either:

- The `fitensemble` function with a cross-validation name-value pair. The names are 'crossval', 'kfold', 'holdout', 'leaveout', or 'cvpartition'.
- The `crossval` method applied to a regression ensemble.

### **nlearn**

A positive integer, the number of cycles for additional training of `ens`.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single

quotes ( ' ' ). You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

### 'nprint'

Printout frequency, a positive integer scalar or 'off' (no printouts). Returns to the command line the number of weak learners trained so far. Useful when you train ensembles with many learners on large data sets.

**Default:** 'off'

## Output Arguments

### ens1

The cross-validated regression ensemble ens, augmented with additional training.

## Examples

Train a regression ensemble for 50 cycles, and cross validate it. Examine the cross-validation error. Then train for 50 more cycles and examine the new cross-validation error.

```
load carsmall
X = [Displacement Horsepower Weight];
ens = fitensemble(X,MPG,'LSBoost',50,'Tree');
cvens = crossval(ens);
L = kfoldLoss(cvens)
```

```
L =
 25.6573
```

```
cvens = resume(cvens,50);
L = kfoldLoss(cvens)
```

```
L =
 26.7563
```

The additional training did not improve the cross-validation error.

## prob.RicianDistribution class

**Package:** prob

**Superclasses:** prob.ToolboxFittableParametricDistribution

Rician probability distribution object

### Description

`prob.RicianDistribution` is an object consisting of parameters, a model description, and sample data for a Rician probability distribution.

Create a probability distribution object with specified parameter values using `makedist`. Alternatively, fit a distribution to data using `fitdist` or the Distribution Fitting app.

### Construction

`pd = makedist('Rician')` creates a Rician probability distribution object using the default parameter values.

`pd = makedist('Rician', 's', s, 'sigma', sigma)` creates a Rician probability distribution object using the specified parameter values.

### Input Arguments

**s — Noncentrality parameter**

1 (default) | nonnegative scalar value

Noncentrality parameter for the Rician distribution, specified as a nonnegative scalar value.

Data Types: `single` | `double`

**sigma — scale parameter**

1 (default) | positive scalar value

Scale parameter for the Rician distribution, specified as a positive scalar value.

Data Types: `single` | `double`

## Properties

### **s** — Noncentrality parameter

nonnegative scalar value

Noncentrality parameter of the Rician distribution, stored as a nonnegative scalar value.

Data Types: `single` | `double`

### **sigma** — scale parameter

positive scalar value

Scale parameter for the Rician distribution, stored as a positive scalar value.

Data Types: `single` | `double`

### **DistributionName** — Probability distribution name

probability distribution name string

Probability distribution name, stored as a valid probability distribution name string. This property is read-only.

Data Types: `char`

### **InputData** — Data used for distribution fitting

structure

Data used for distribution fitting, stored as a structure containing the following:

- **data**: Data vector used for distribution fitting.
- **cens**: Censoring vector, or empty if none.
- **freq**: Frequency vector, or empty if none.

This property is read-only.

Data Types: `struct`

### **IsTruncated** — Logical flag for truncated distribution

0 | 1

Logical flag for truncated distribution, stored as a logical value. If **IsTruncated** equals 0, the distribution is not truncated. If **IsTruncated** equals 1, the distribution is truncated. This property is read-only.

Data Types: `logical`

**NumParameters** — Number of parameters

positive integer value

Number of parameters for the probability distribution, stored as a positive integer value. This property is read-only.

Data Types: `single` | `double`

**ParameterCovariance** — Covariance matrix of the parameter estimates

matrix of scalar values

Covariance matrix of the parameter estimates, stored as a  $p$ -by- $p$  matrix, where  $p$  is the number of parameters in the distribution. The  $(i,j)$  element is the covariance between the estimates of the  $i$ th parameter and the  $j$ th parameter. The  $(i,i)$  element is the estimated variance of the  $i$ th parameter. If parameter  $i$  is fixed rather than estimated by fitting the distribution to data, then the  $(i,i)$  elements of the covariance matrix are 0. This property is read-only.

Data Types: `single` | `double`

**ParameterDescription** — Distribution parameter descriptions

cell array of strings

Distribution parameter descriptions, stored as a cell array of strings. Each cell contains a short description of one distribution parameter. This property is read-only.

Data Types: `char`

**ParameterIsFixed** — Logical flag for fixed parameters

array of logical values

Logical flag for fixed parameters, stored as an array of logical values. If 0, the corresponding parameter in the `ParameterNames` array is not fixed. If 1, the corresponding parameter in the `ParameterNames` array is fixed. This property is read-only.

Data Types: `logical`

**ParameterNames** — Distribution parameter names

cell array of strings

Distribution parameter names, stored as a cell array of strings. This property is read-only.

Data Types: char

### **ParameterValues** — Distribution parameter values

vector of scalar values

Distribution parameter values, stored as a vector. This property is read-only.

Data Types: single | double

### **Truncation** — Truncation interval

vector of scalar values

Truncation interval for the probability distribution, stored as a vector containing the lower and upper truncation boundaries. This property is read-only.

Data Types: single | double

|           |                                                                 |
|-----------|-----------------------------------------------------------------|
| truncate  | Truncate probability distribution object                        |
| mean      | Mean of probability distribution object                         |
| negloglik | Negative loglikelihood of probability distribution object       |
| paramci   | Confidence intervals for probability distribution parameters    |
| profilik  | Profile likelihood function for probability distribution object |
| std       | Standard deviation of probability distribution object           |
| var       | Variance of probability distribution object                     |

## Definitions

### Rician Distribution

The Rician distribution is used in communications theory to model scattered signals that reach a receiver using multiple paths.

The Rician distribution uses the following parameters.

| Name  | Description             | Support      |
|-------|-------------------------|--------------|
| s     | Noncentrality parameter | $s \geq 0$   |
| sigma | Scale parameter         | $\sigma > 0$ |

The probability density function (pdf) is

$$f(x | s, \sigma) = I_0 \left( \frac{xs}{\sigma^2} \right) \left( \frac{x}{\sigma^2} \right) \exp \left\{ -\frac{x^2 + s^2}{2\sigma^2} \right\} ; \quad x \geq 0 ,$$

where  $I_0$  is the zero-order modified Bessel function of the first kind.

## Examples

### Create a Rician Distribution Object Using Default Parameters

Create a Rician distribution object using the default parameter values.

```
pd = makedist('Rician')
```

```
pd =
```

```
RicianDistribution
```

```
Rician distribution
```

```
 s = 1
```

```
 sigma = 1
```

### Create a Rician Distribution Object Using Specified Parameters

Create a Rician distribution object by specifying the parameter values.

```
pd = makedist('Rician', 's', 0, 'sigma', 2)
```

```
pd =
```

```
RicianDistribution
```

```
Rician distribution
```

```
 s = 0
```

```
 sigma = 2
```

Compute the mean of the distribution.

```
m = mean(pd)
```

```
m =
```

2.5066

# ridge

Ridge regression

## Syntax

```
b = ridge(y,X,k)
b = ridge(y,X,k,scaled)
```

## Description

`b = ridge(y,X,k)` returns a vector **b** of coefficient estimates for a multilinear ridge regression of the responses in **y** on the predictors in **X**. **X** is an  $n$ -by- $p$  matrix of  $p$  predictors at each of  $n$  observations. **y** is an  $n$ -by-1 vector of observed responses. **k** is a vector of ridge parameters. If **k** has  $m$  elements, **b** is  $p$ -by- $m$ . By default, **b** is computed after centering and scaling the predictors to have mean 0 and standard deviation 1. The model does not include a constant term, and **X** should not contain a column of 1s.

`b = ridge(y,X,k,scaled)` uses the {0,1}-valued flag **scaled** to determine if the coefficient estimates in **b** are restored to the scale of the original data. `ridge(y,X,k,0)` performs this additional transformation. In this case, **b** contains  $p+1$  coefficients for each value of **k**, with the first row corresponding to a constant term in the model. `ridge(y,X,k,1)` is the same as `ridge(y,X,k)`. In this case, **b** contains  $p$  coefficients, without a coefficient for a constant term.

The relationship between `b0 = ridge(y,X,k,0)` and `b1 = ridge(y,X,k,1)` is given by

```
m = mean(X);
s = std(X,0,1)';
b1_scaled = b1./s;
b0 = [mean(y)-m*b1_scaled; b1_scaled]
```

This can be seen by replacing the  $x_i$  ( $i = 1, \dots, n$ ) in the multilinear model  $y = b_0^0 + b_1^0 x_1 + \dots + b_n^0 x_n$  with the  $z$ -scores  $z_i = (x_i - \mu_i)/\sigma_i$ , and replacing  $y$  with  $y - \mu_y$ .

In general, **b1** is more useful for producing plots in which the coefficients are to be displayed on the same scale, such as a *ridge trace* (a plot of the regression coefficients as a function of the ridge parameter). **b0** is more useful for making predictions.

Coefficient estimates for multiple linear regression models rely on the independence of the model terms. When terms are correlated and the columns of the design matrix  $X$  have an approximate linear dependence, the matrix  $(X^T X)^{-1}$  becomes close to singular. As a result, the least-squares estimate

$$\hat{\beta} = (X^T X)^{-1} X^T y$$

becomes highly sensitive to random errors in the observed response  $y$ , producing a large variance. This situation of *multicollinearity* can arise, for example, when data are collected without an experimental design.

*Ridge regression* addresses the problem by estimating regression coefficients using

$$\hat{\beta} = (X^T X + kI)^{-1} X^T y$$

where  $k$  is the *ridge parameter* and  $I$  is the identity matrix. Small positive values of  $k$  improve the conditioning of the problem and reduce the variance of the estimates. While biased, the reduced variance of ridge estimates often result in a smaller mean square error when compared to least-squares estimates.

## Examples

### Ridge Regression

Load the sample data.

```
load acetylene
```

`acetylene` has observations for the predictor variables `x1` , `x2` , `x3` , and the response variable `y` .

Plot the predictor variables against each other.

```
subplot(1,3,1)
plot(x1,x2, '.')
xlabel('x1'); ylabel('x2'); grid on; axis square
subplot(1,3,2)
```

```

plot(x1,x3,'. ')
xlabel('x1'); ylabel('x3'); grid on; axis square

subplot(1,3,3)
plot(x2,x3,'. ')
xlabel('x2'); ylabel('x3'); grid on; axis square

```

Note the correlation between  $x_1$  and the other two predictor variables.

Compute coefficient estimates for a multilinear model with interaction terms, for a range of ridge parameters using `ridge` and `x2fx`.

```

X = [x1 x2 x3];
D = x2fx(X, 'interaction');

```

```
D(:,1) = []; % No constant term
k = 0:1e-5:5e-3;
b = ridge(y,D,k);
```

Plot the ridge trace.

```
figure
plot(k,b,'LineWidth',2)
ylim([-100 100])
grid on
xlabel('Ridge Parameter')
ylabel('Standardized Coefficient')
title('{\bf Ridge Trace}')
legend('x1','x2','x3','x1x2','x1x3','x2x3')
```

The estimates stabilize to the right of the plot. Note that the coefficient of the  $x_2x_3$  interaction term changes sign at a value of the ridge parameter  $\approx 5 * 10^{-4}$ .

## risk

**Class:** classregtree

Node risks

## Syntax

```
r = risk(t)
r = risk(t,nodes)
```

## Description

`r = risk(t)` returns an  $n$ -element vector  $r$  of the risk of the nodes in the tree  $t$ , where  $n$  is the number of nodes. The risk  $r(i)$  for node  $i$  is the node error  $e(i)$  (computed by `nodeerr`) weighted by the node probability  $p(i)$  (computed by `nodeprob`).

`r = risk(t,nodes)` takes a vector `nodes` of node numbers and returns the risk values for the specified nodes.

## Examples

Create a classification tree for Fisher's iris data:

```
load fisheriris;

t = classregtree(meas,species,...
 'names',{'SL' 'SW' 'PL' 'PW'})

t =
Decision tree for classification
1 if PL<2.45 then node 2 elseif PL>=2.45 then node 3 else setosa
2 class = setosa
3 if PW<1.75 then node 4 elseif PW>=1.75 then node 5 else versicolor
4 if PL<4.95 then node 6 elseif PL>=4.95 then node 7 else versicolor
5 class = virginica
6 if PW<1.65 then node 8 elseif PW>=1.65 then node 9 else versicolor
7 class = virginica
8 class = versicolor
9 class = virginica

view(t)

# robustdemo

Interactive robust regression

## Syntax

```
robustdemo
robustdemo(x,y)
```

## Description

`robustdemo` shows the difference between ordinary least squares and robust regression for data with a single predictor. With no input arguments, `robustdemo` displays a scatter plot of a sample of roughly linear data with one outlier. The bottom of the figure displays equations of lines fitted to the data using ordinary least squares and robust methods, together with estimates of the root mean squared errors.

Use the right mouse button to click on a point and view its least-squares leverage and robust weight.

Use the left mouse button to click-and-drag a point. The displays will update.

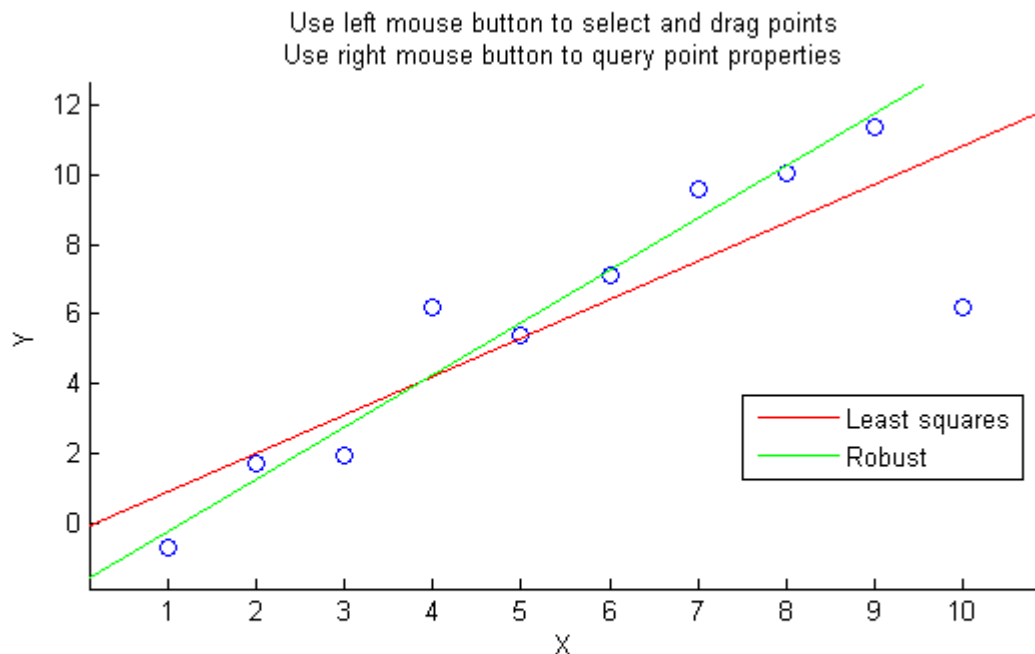

`robustdemo(x,y)` uses `x` and `y` data vectors you supply, in place of the sample data supplied with the function.

## Examples

The following steps show you how to use `robustdemo`.

- 1 **Start the example.** To begin using `robustdemo` with the built-in data, simply type the function name:

```
robustdemo
```

|                |                               |                     |
|----------------|-------------------------------|---------------------|
| Least squares: | $Y = -0.188327 + 1.10351 * X$ | RMS error = 2.21375 |
| Robust:        | $Y = -1.77278 + 1.50415 * X$  | RMS error = 1.43663 |

The resulting figure shows a scatter plot with two fitted lines. The red line is the fit using ordinary least-squares regression. The green line is the fit using robust regression. At the bottom of the figure are the equations for the fitted lines, together with the estimated root mean squared errors for each fit.

- View leverages and robust weights.** Right-click on any data point to see its least-squares leverage and robust weight:

|                |                               |                     |
|----------------|-------------------------------|---------------------|
| Least squares: | $Y = -0.188327 + 1.10351 * X$ | RMS error = 2.21375 |
| Robust:        | $Y = -1.77278 + 1.50415 * X$  | RMS error = 1.43663 |

In the built-in data, the right-most point has a relatively high leverage of 0.35. The point exerts a large influence on the least-squares fit, but its small robust weight shows that it is effectively excluded from the robust fit.

- 3 See how changes in the data affect the fits.** With the left mouse button, click and hold on any data point and drag it to a new location. When you release the mouse button, the displays update:

|                |                              |                     |
|----------------|------------------------------|---------------------|
| Least squares: | $Y = -1.0661 + 1.33785 * X$  | RMS error = 1.21477 |
| Robust:        | $Y = -1.18916 + 1.36459 * X$ | RMS error = 1.27697 |

Bringing the right-most data point closer to the least-squares line makes the two fitted lines nearly identical. The adjusted right-most data point has significant weight in the robust fit.

## See Also

robustfit | leverage

# robustfit

Robust regression

## Syntax

```
b = robustfit(X,y)
b = robustfit(X,y,wfun,tune)
b = robustfit(X,y,wfun,tune,const)
[b,stats] = robustfit(...)
```

## Description

`b = robustfit(X,y)` returns a  $(p + 1)$ -by-1 vector `b` of coefficient estimates for a robust multilinear regression of the responses in `y` on the predictors in `X`. `X` is an  $n$ -by- $p$  matrix of  $p$  predictors at each of  $n$  observations. `y` is an  $n$ -by-1 vector of observed responses. By default, the algorithm uses iteratively reweighted least squares with a bisquare weighting function.

---

**Note:** By default, `robustfit` adds a first column of 1s to `X`, corresponding to a constant term in the model. Do not enter a column of 1s directly into `X`. You can change the default behavior of `robustfit` using the input `const`, below.

---

`robustfit` treats NaNs in `X` or `y` as missing values, and removes them.

`b = robustfit(X,y,wfun,tune)` specifies a weighting function `wfun`. `tune` is a tuning constant that is divided into the residual vector before computing weights.

The weighting function `wfun` can be any one of the following strings:

| Weight Function         | Equation                                    | Default Tuning Constant |
|-------------------------|---------------------------------------------|-------------------------|
| 'andrews'               | $w = (\text{abs}(r) < \pi) .* \sin(r) ./ r$ | 1.339                   |
| 'bisquare'<br>(default) | $w = (\text{abs}(r) < 1) .* (1 - r.^2).^2$  | 4.685                   |

| Weight Function | Equation                                       | Default Tuning Constant |
|-----------------|------------------------------------------------|-------------------------|
| 'cauchy'        | $w = 1 ./ (1 + r.^2)$                          | 2.385                   |

| 'talwar'        | $w = 1 * (\text{abs}(r) < 1)$                  | 2.795                   |
| 'welsch'        | $w = \exp(-(r.^2))$                            | 2.985                   |

If `tune` is unspecified, the default value in the table is used. Default tuning constants give coefficient estimates that are approximately 95% as statistically efficient as the ordinary least-squares estimates, provided the response has a normal distribution with no outliers. Decreasing the tuning constant increases the downweight assigned to large residuals; increasing the tuning constant decreases the downweight assigned to large residuals.

The value  $r$  in the weight functions is

$$r = \text{resid} / (\text{tune} * s * \sqrt{1-h})$$

where `resid` is the vector of residuals from the previous iteration, `h` is the vector of leverage values from a least-squares fit, and `s` is an estimate of the standard deviation of the error term given by

$$s = \text{MAD} / 0.6745$$

Here `MAD` is the median absolute deviation of the residuals from their median. The constant 0.6745 makes the estimate unbiased for the normal distribution. If there are  $p$  columns in  $X$ , the smallest  $p$  absolute deviations are excluded when computing the median.

You can write your own weight function. The function must take a vector of scaled residuals as input and produce a vector of weights as output. In this case, `wfun` is specified using a function handle `@` (as in `@myfun`), and the input `tune` is required.

`b = robustfit(X,y,wfun,tune,const)` controls whether or not the model will include a constant term. `const` is 'on' to include the constant term (the default), or

'off' to omit it. When *const* is 'on', `robustfit` adds a first column of 1s to *X* and *b* becomes a  $(p + 1)$ -by-1 vector. When *const* is 'off', `robustfit` does not alter *X*, then *b* is a  $p$ -by-1 vector.

`[b,stats] = robustfit(...)` returns the structure *stats*, whose fields contain diagnostic statistics from the regression. The fields of *stats* are:

- `ols_s` — Sigma estimate (RMSE) from ordinary least squares
- `robust_s` — Robust estimate of sigma
- `mad_s` — Estimate of sigma computed using the median absolute deviation of the residuals from their median; used for scaling residuals during iterative fitting
- `s` — Final estimate of sigma, the larger of `robust_s` and a weighted average of `ols_s` and `robust_s`
- `resid` — Residual
- `rstud` — Studentized residual (see `regress` for more information)
- `se` — Standard error of coefficient estimates
- `covb` — Estimated covariance matrix for coefficient estimates
- `coeffcorr` — Estimated correlation of coefficient estimates
- `t` — Ratio of *b* to *se*
- `p` —  $p$ -values for *t*
- `w` — Vector of weights for robust fit
- `R` —  $R$  factor in  $QR$  decomposition of *X*
- `dfe` — Degrees of freedom for error
- `h` — Vector of leverage values for least-squares fit

The `robustfit` function estimates the variance-covariance matrix of the coefficient estimates using  $\text{inv}(X' * X) * \text{stats.s}^2$ . Standard errors and correlations are derived from this estimate.

## Examples

### Compare Robust and Least-Squares Regression

Generate data with the trend  $y = 10 - 2 * x$ , then change one value to simulate an outlier.

```
x = (1:10)';
rng default; % For reproducibility
y = 10 - 2*x + randn(10,1);
y(10) = 0;
```

Fit a straight line using ordinary least squares regression.

```
bls = regress(y,[ones(10,1) x])
```

```
bls =

 7.8518
 -1.3644
```

Now use robust regression to estimate a straight-line fit.

```
brob = robustfit(x,y)
```

```
brob =

 8.4504
 -1.5278
```

Create scatter plot of the data together with the fits.

```
scatter(x,y,'filled'); grid on; hold on
plot(x,bls(1)+bls(2)*x,'r','LineWidth',2);
plot(x,brob(1)+brob(2)*x,'g','LineWidth',2)
legend('Data','Ordinary Least Squares','Robust Regression')
```

The robust fit is less influenced by the outlier than the least-squares fit.

# rotatefactors

Rotate factor loadings

## Syntax

```
B = rotatefactors(A)
B = rotatefactors(A, 'Method', 'orthomax', 'Coeff', gamma)
B = rotatefactors(A, 'Method', 'procrustes', 'Target', target)
B = rotatefactors(A, 'Method', 'pattern', 'Target', target)
B = rotatefactors(A, 'Method', 'promax')
[B,T] = rotatefactors(A, ...)
```

## Description

`B = rotatefactors(A)` rotates the  $d$ -by- $m$  loadings matrix `A` to maximize the varimax criterion, and returns the result in `B`. Rows of `A` and `B` correspond to variables and columns correspond to factors, for example, the  $(i, j)$ th element of `A` is the coefficient for the  $i$ th variable on the  $j$ th factor. The matrix `A` usually contains principal component coefficients created with `pca` or `pcacov`, or factor loadings estimated with `factoran`.

`B = rotatefactors(A, 'Method', 'orthomax', 'Coeff', gamma)` rotates `A` to maximize the orthomax criterion with the coefficient `gamma`, i.e., `B` is the orthogonal rotation of `A` that maximizes

$$\text{sum}(D * \text{sum}(B.^4, 1) - \text{GAMMA} * \text{sum}(B.^2, 1).^2)$$

The default value of 1 for `gamma` corresponds to varimax rotation. Other possibilities include `gamma = 0`,  $m/2$ , and  $d(m - 1)/(d + m - 2)$ , corresponding to quartimax, equamax, and parsimax. You can also supply the strings `'varimax'`, `'quartimax'`, `'equamax'`, or `'parsimax'` for the `'method'` parameter and omit the `'Coeff'` parameter.

If `'Method'` is `'orthomax'`, `'varimax'`, `'quartimax'`, `'equamax'`, or `'parsimax'`, then additional parameters are

- `'Normalize'` — Flag indicating whether the loadings matrix should be row-normalized for rotation. If `'on'` (the default), rows of `A` are normalized prior to rotation to have unit Euclidean norm, and unnormalized after rotation. If `'off'`, the raw loadings are rotated and returned.

- `'Reltol'` — Relative convergence tolerance in the iterative algorithm used to find `T`. The default is `sqrt(eps)`.
- `'Maxit'` — Iteration limit in the iterative algorithm used to find `T`. The default is 250.

`B = rotatefactors(A, 'Method', 'procrustes', 'Target', target)` performs an oblique procrustes rotation of `A` to the  $d$ -by- $m$  target loadings matrix `target`.

`B = rotatefactors(A, 'Method', 'pattern', 'Target', target)` performs an oblique rotation of the loadings matrix `A` to the  $d$ -by- $m$  target pattern matrix `target`, and returns the result in `B`. `target` defines the "restricted" elements of `B`, i.e., elements of `B` corresponding to zero elements of `target` are constrained to have small magnitude, while elements of `B` corresponding to nonzero elements of `target` are allowed to take on any magnitude.

If `'Method'` is `'procrustes'` or `'pattern'`, an additional parameter is `'Type'`, the type of rotation. If `'Type'` is `'orthogonal'`, the rotation is orthogonal, and the factors remain uncorrelated. If `'Type'` is `'oblique'` (the default), the rotation is oblique, and the rotated factors might be correlated.

When `'Method'` is `'pattern'`, there are restrictions on `target`. If `A` has  $m$  columns, then for orthogonal rotation, the  $j$ th column of `target` must contain at least  $m - j$  zeros. For oblique rotation, each column of `target` must contain at least  $m - 1$  zeros.

`B = rotatefactors(A, 'Method', 'promax')` rotates `A` to maximize the promax criterion, equivalent to an oblique Procrustes rotation with a target created by an orthomax rotation. Use the four orthomax parameters to control the orthomax rotation used internally by promax.

An additional parameter for `'promax'` is `'Power'`, the exponent for creating promax target matrix. `'Power'` must be 1 or greater. The default is 4.

`[B, T] = rotatefactors(A, ...)` returns the rotation matrix `T` used to create `B`, that is, `B = A*T`. You can find the correlation matrix of the rotated factors by using `inv(T'*T)`. For orthogonal rotation, this is the identity matrix, while for oblique rotation, it has unit diagonal elements but nonzero off-diagonal elements.

## Examples

```
rng('default') % for reproducibility
```

```

X = randn(100,10);

% Default (normalized varimax) rotation:
% first three principal components.
LPC = pca(X);
[L1,T] = rotatefactors(LPC(:,1:3));

% Equamax rotation:
% first three principal components.
[L2,T] = rotatefactors(LPC(:,1:3),...
 'method','equamax');

% Promax rotation:
% first three factors.
LFA = factoran(X,3,'Rotate','none');
[L3,T] = rotatefactors(LFA(:,1:3),...
 'method','promax',...
 'power',2);

% Pattern rotation:
% first three factors.
Tgt = [1 1 1 1 1 0 1 0 1 1; ...
 0 0 0 1 1 1 0 0 0 0; ...
 1 0 0 1 0 1 1 1 1 0]';
[L4,T] = rotatefactors(LFA(:,1:3),...
 'method','pattern',...
 'target',Tgt);
inv(T'*T) % Correlation matrix of the rotated factors
ans =

 1.0000 -0.9593 -0.7098
 -0.9593 1.0000 0.5938
 -0.7098 0.5938 1.0000

# rowexch

Row exchange

## Syntax

```
dRE = rowexch(nfactors, nruns)
[dRE, X] = rowexch(nfactors, nruns)
[dRE, X] = rowexch(nfactors, nruns, model)
[dRE, X] = rowexch(..., param1, val1, param2, val2, ...)
```

## Description

`dRE = rowexch(nfactors, nruns)` uses a row-exchange algorithm to generate a  $D$ -optimal design `dRE` with `nruns` runs (the rows of `dRE`) for a linear additive model with `nfactors` factors (the columns of `dRE`). The model includes a constant term.

`[dRE, X] = rowexch(nfactors, nruns)` also returns the associated design matrix `X`, whose columns are the model terms evaluated at each treatment (row) of `dRE`.

`[dRE, X] = rowexch(nfactors, nruns, model)` uses the linear regression model specified in `model`. `model` is one of the following strings:

- 'linear' — Constant and linear terms. This is the default.
- 'interaction' — Constant, linear, and interaction terms
- 'quadratic' — Constant, linear, interaction, and squared terms
- 'purequadratic' — Constant, linear, and squared terms

The order of the columns of `X` for a full quadratic model with  $n$  terms is:

- 1 The constant term
- 2 The linear terms in order 1, 2, ...,  $n$
- 3 The interaction terms in order (1, 2), (1, 3), ..., (1,  $n$ ), (2, 3), ..., ( $n-1$ ,  $n$ )
- 4 The squared terms in order 1, 2, ...,  $n$

Other models use a subset of these terms, in the same order.

Alternatively, *model* can be a matrix specifying polynomial terms of arbitrary order. In this case, *model* should have one column for each factor and one row for each term in the model. The entries in any row of *model* are powers for the factors in the columns. For example, if a model has factors *X1*, *X2*, and *X3*, then a row `[0 1 2]` in *model* specifies the term  $(X1.^0) .* (X2.^1) .* (X3.^2)$ . A row of all zeros in *model* specifies a constant term, which can be omitted.

`[dRE,X] = rowexch(...,param1,val1,param2,val2,...)` specifies additional parameter/value pairs for the design. Valid parameters and their values are listed in the following table.

| Parameter     | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'bounds'      | Lower and upper bounds for each factor, specified as a 2-by-nfactors matrix. Alternatively, this value can be a cell array containing nfactors elements, each element specifying the vector of allowable values for the corresponding factor.                                                                                                                                                                                                                                                      |
| 'categorical' | Indices of categorical predictors.                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 'display'     | Either 'on' or 'off' to control display of the iteration counter. The default is 'on'.                                                                                                                                                                                                                                                                                                                                                                                                             |
| 'excluderun'  | Handle to a function that excludes undesirable runs. If the function is <i>f</i> , it must support the syntax $b = f(S)$ , where <i>S</i> is a matrix of treatments with nfactors columns and <i>b</i> is a vector of Boolean values with the same number of rows as <i>S</i> . <i>b</i> ( <i>i</i> ) is true if the <i>i</i> th row <i>S</i> should be excluded.                                                                                                                                  |
| 'init'        | Initial design as an nruns-by-nfactors matrix. The default is a randomly selected set of points.                                                                                                                                                                                                                                                                                                                                                                                                   |
| 'levels'      | Vector of number of levels for each factor.                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| 'maxiter'     | Maximum number of iterations. The default is 10.                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| options       | A structure that specifies whether to run in parallel, and specifies the random stream or streams. Create the options structure with <code>statset</code> . Option fields: <ul style="list-style-type: none"> <li><code>UseParallel</code> — Set to <code>true</code> to compute in parallel. Default is <code>false</code>.</li> <li><code>UseSubstreams</code> — Set to <code>true</code> to compute in parallel in a reproducible fashion. Default is <code>false</code>. To compute</li> </ul> |

| Parameter | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|           | <p>reproducibly, set <code>Streams</code> to a type allowing substreams: 'mlfg6331_64' or 'mrg32k3a'.</p> <ul style="list-style-type: none"> <li>• <code>Streams</code> — A <code>RandStream</code> object or cell array of such objects. If you do not specify <code>Streams</code>, <code>rowexch</code> uses the default stream or streams. If you choose to specify <code>Streams</code>, use a single object except in the case <ul style="list-style-type: none"> <li>• You have an open Parallel pool</li> <li>• <code>UseParallel</code> is true</li> <li>• <code>UseSubstreams</code> is false</li> </ul> </li> </ul> <p>In that case, use a cell array the same size as the Parallel pool.</p> |
| 'tries'   | Number of times to try to generate a design from a new starting point. The algorithm uses random points for each try, except possibly the first. The default is 1.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

## Examples

Suppose you want a design to estimate the parameters in the following three-factor, seven-term interaction model:

$$y = \beta_0 + \beta_1 x_1 + \beta_2 x_2 + \beta_3 x_3 + \beta_{12} x_1 x_2 + \beta_{13} x_1 x_3 + \beta_{23} x_2 x_3 + \varepsilon$$

Use `rowexch` to generate a  $D$ -optimal design with seven runs:

```

nfactors = 3;
nruns = 7;
[dRE,X] = rowexch(nfactors,nruns,'interaction','tries',10)
dRE =
 -1 -1 1
 1 -1 1
 1 -1 -1
 1 1 1
 -1 -1 -1
 -1 1 -1
 -1 1 1
X =

```

|   |    |    |    |    |    |    |
|---|----|----|----|----|----|----|
| 1 | -1 | -1 | 1  | 1  | -1 | -1 |
| 1 | 1  | -1 | 1  | -1 | 1  | -1 |
| 1 | 1  | -1 | -1 | -1 | -1 | 1  |
| 1 | 1  | 1  | 1  | 1  | 1  | 1  |
| 1 | -1 | -1 | -1 | 1  | 1  | 1  |
| 1 | -1 | 1  | -1 | -1 | 1  | -1 |
| 1 | -1 | 1  | 1  | -1 | -1 | 1  |

Columns of the design matrix  $X$  are the model terms evaluated at each row of the design dRE. The terms appear in order from left to right: constant term, linear terms (1, 2, 3), interaction terms (12, 13, 23). Use  $X$  to fit the model, as described in “Linear Regression” on page 9-11, to response data measured at the design points in dRE.

## More About

### Algorithms

Both `cordexch` and `rowexch` use iterative search algorithms. They operate by incrementally changing an initial design matrix  $X$  to increase  $D = |X^T X|$  at each step. In both algorithms, there is randomness built into the selection of the initial design and into the choice of the incremental changes. As a result, both algorithms may return locally, but not globally,  $D$ -optimal designs. Run each algorithm multiple times and select the best result for your final design. Both functions have a 'tries' parameter that automates this repetition and comparison.

At each step, the row-exchange algorithm exchanges an entire row of  $X$  with a row from a design matrix  $C$  evaluated at a candidate set of feasible treatments. The `rowexch` function automatically generates a  $C$  appropriate for a specified model, operating in two steps by calling the `candgen` and `candexch` functions in sequence. Provide your own  $C$  by calling `candexch` directly. In either case, if  $C$  is large, its static presence in memory can affect computation.

# rsmdemo

Interactive response surface demonstration

## Syntax

rsmdemo

## Description

rsmdemo opens a group of three graphical user interfaces for interactively investigating response surface methodology (RSM), nonlinear fitting, and the design of experiments.

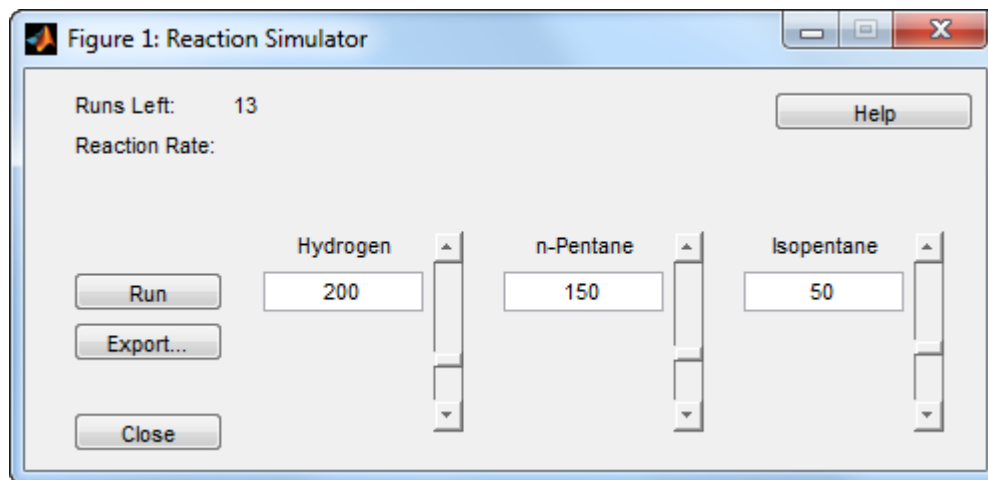

The interfaces allow you to collect and model data from a simulated chemical reaction. Experimental predictors are concentrations of three reactants (hydrogen, *n*-Pentane, and isopentane) and the response is the reaction rate. The reaction rate is simulated by a Hougen-Watson model (Bates and Watts, [2], pp. 271–272):

$$rate = \frac{\beta_1 x_2 - x_3 / \beta_5}{1 + \beta_2 x_1 + \beta_3 x_2 + \beta_4 x_3}$$

where *rate* is the reaction rate,  $x_1$ ,  $x_2$ , and  $x_3$  are the concentrations of hydrogen, *n*-pentane, and isopentane, respectively, and  $\beta_1, \beta_2, \dots, \beta_5$  are fixed parameters. Random errors are used to perturb the reaction rate for each combination of reactants.

Collect data using one of two methods:

- 1 Manually set reactant concentrations in the **Reaction Simulator** interface by editing the text boxes or by adjusting the associated sliders.

When you click **Run**, the concentrations and simulated reaction rate are recorded on the **Trial and Error Data** interface.

You are allowed up to 13 independent experimental runs for data collection.

- 2 Use a designed experiment to set reactant concentrations in the **Experimental Data** interface by clicking the **Do Experiment** button.

A 13-run  $D$ -optimal design for a full quadratic model is generated by the `cordexch` function, and the concentrations and simulated reaction rates are recorded on the same interface.

Once data is collected, scatter plots of reaction rates vs. individual predictors are generated by selecting one of the following from the **Plot** pop-up menu below the recorded data:

- **Hydrogen vs. Rate**
- **n-Pentane vs. Rate**
- **Isopentane vs. Rate**

Fit a response surface model to the data by clicking the **Analyze** button below the trial-and-error data or the **Response Surface** button below the experimental data. Both buttons load the data into the Response Surface Tool `rstool`. By default, trial-and-error data is fit with a linear additive model and experimental data is fit with a full quadratic model, but the models can be adjusted in the Response Surface Tool.

For experimental data, you have the additional option of fitting a Hougen-Watson model. Click the **Nonlinear Model** button to load the data and the model in `hougen` into the Nonlinear Fitting Tool `nlintool`.

# rstool

Interactive response surface modeling

## Syntax

```
rstool
rstool(X,Y,model)
rstool(x,y,model,alpha)
rstool(x,y,model,alpha,xname,yname)
```

## Description

rstool opens a graphical user interface for interactively investigating one-dimensional contours of multidimensional response surface models.

By default, the interface opens with the data from `hald.mat` and a fitted response surface with constant, linear, and interaction terms.

A sequence of plots is displayed, each showing a contour of the response surface against a single predictor, with all other predictors held fixed. `rstool` plots a 95% simultaneous confidence band for the fitted response surface as two red curves. Predictor values are displayed in the text boxes on the horizontal axis and are marked by vertical dashed blue lines in the plots. Predictor values are changed by editing the text boxes or by dragging the dashed blue lines. When you change the value of a predictor, all plots update to show the new point in predictor space.

The pop-up menu at the lower left of the interface allows you to choose among the following models:

- **Linear** — Constant and linear terms (the default)
- **Pure Quadratic** — Constant, linear, and squared terms
- **Interactions** — Constant, linear, and interaction terms
- **Full Quadratic** — Constant, linear, interaction, and squared terms

Click **Export** to open the following dialog box:

The dialog allows you to save information about the fit to MATLAB workspace variables with valid names.

`rstool(X, Y, model)` opens the interface with the predictor data in `X`, the response data in `Y`, and the fitted model `model`. Distinct predictor variables should appear in different columns of `X`. `Y` can be a vector, corresponding to a single response, or a matrix, with

columns corresponding to multiple responses.  $Y$  must have as many elements (or rows, if it is a matrix) as  $X$  has rows.

The optional input *model* can be any one of the following strings:

- 'linear' — Constant and linear terms (the default)
- 'purequadratic' — Constant, linear, and squared terms
- 'interaction' — Constant, linear, and interaction terms
- 'quadratic' — Constant, linear, interaction, and squared terms

To specify a polynomial model of arbitrary order, or a model without a constant term, use a matrix for *model* as described in `x2fx`.

`rstool(x,y,model,alpha)` uses  $100(1-\alpha)\%$  global confidence intervals for new observations in the plots.

`rstool(x,y,model,alpha,xname,yname)` labels the axes using the strings in *xname* and *yname*. To label each subplot differently, *xname* and *yname* can be cell arrays of strings.

## Examples

The following uses `rstool` to visualize a quadratic response surface model of the 3-D chemical reaction data in `reaction.mat`:

```
load reaction
alpha = 0.01; % Significance level
rstool(reactants,rate,'quadratic',alpha,xn,yn)
```

The `rstool` interface is used by `rsmdemo` to visualize the results of simulated experiments with data like that in `reaction.mat`. As described in “Response Surface Designs” on page 18-9, `rsmdemo` uses a response surface model to generate simulated data at combinations of predictors specified by either the user or by a designed experiment.

# runstest

Run test for randomness

## Syntax

```
h = runstest(x)
h = runstest(x,v)
h = runstest(x,'ud')
h = runstest(____,Name,Value)
[h,p,stats] = runstest(____)
```

## Description

`h = runstest(x)` returns a test decision for the null hypothesis that the values in the data vector `x` come in random order, against the alternative that they do not. The test is based on the number of runs of consecutive values above or below the mean of `x`. The result `h` is `1` if the test rejects the null hypothesis at the 5% significance level, or `0` otherwise.

`h = runstest(x,v)` returns a test decision based on the number of runs of consecutive values above or below the specified reference value `v`. Values exactly equal to `v` are discarded.

`h = runstest(x,'ud')` returns a test decision based on the number of runs up or down. Too few runs indicate a trend, while too many runs indicate an oscillation. Values exactly equal to the preceding value are discarded.

`h = runstest( ____,Name,Value)` returns a test decision using additional options specified by one or more name-value pair arguments. For example, you can change the significance level of the test, specify the algorithm used to calculate the  $p$ -value, or conduct a one-sided test.

`[h,p,stats] = runstest( ____ )` also returns the  $p$ -value of the test `p`, and a structure `stats` containing additional data about the test.

## Examples

### Test Data for Randomness Using Sample Median

Generate a vector of 40 random numbers from a standard normal distribution.

```
rng default; % for reproducibility
x = randn(40,1);
```

Test whether the values in `x` appear in random order, using the sample median as the reference value.

```
[h,p] = runstest(x,median(x))
```

```
h =
```

```
 0
```

```
p =
```

```
 0.8762
```

The returned value of `h = 0` indicates that `runstest` does not reject the null hypothesis that the values in `x` are in random order at the default 5% significance level.

## Input Arguments

### **x** — Data vector

vector of scalar values

Data vector, specified as a vector of scalar values. `runstest` treats NaN values in `x` as missing values, and ignores them.

Data Types: `single` | `double`

### **v** — Reference value

mean of `x` (default) | scalar value

Reference value, specified as a scalar value. If you specify a value for `v`, then `runstest` performs the hypothesis test based on the number of runs of consecutive values above or below `v`. `runstest` discards values exactly equal to `v`.

Data Types: `single` | `double`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`,`Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( `' '`). You can specify several name and value pair arguments in any order as `Name1`,`Value1`, ..., `NameN`,`ValueN`.

Example:

### 'Alpha' — Significance level

0.05 (default) | scalar value in the range (0,1)

Significance level of the hypothesis test, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the range (0,1).

Example: `'Alpha',0.01`

Data Types: `single` | `double`

### 'Method' — Method used to compute *p*-value

`'exact'` | `'approximate'`

Method used to compute *p*-value, specified as the comma-separated pair consisting of `'Method'` and either `'exact'` to use an exact algorithm, or `'approximate'` to use a normal approximation. The default is `'exact'` for runs above/below, and for runs up/down when the length of `x` is less than or equal to 50. If `runstest` tests for runs up/down and the length of `x` is greater than 50, then the default is `'approximate'`, and the `'exact'` method is not available.

Example: `'Method','approximate'`

### 'Tail' — Type of alternative hypothesis

`'both'` (default) | `'right'` | `'left'`

Type of alternative hypothesis, specified as the comma-separated pair consisting of `'Tail'` and one of the following.

`'both'`                      Two-tailed test (sequence is not random)

|         |                                                                                                      |
|---------|------------------------------------------------------------------------------------------------------|
| 'right' | Right-tailed test (like values separate for runs above/below, direction alternates for runs up/down) |
| 'left'  | Left-tailed test (like values cluster for runs above/below, values trend for runs up/down)           |

Example: 'Tail', 'right'

## Output Arguments

### **h** — Hypothesis test result

1 | 0

Hypothesis test result, returned as a logical value.

- If  $h = 1$ , then `runstest` rejects the null hypothesis at the Alpha significance level.
- If  $h = 0$ , then `runstest` fails to reject the null hypothesis at the Alpha significance level.

The result in `runstest` is based on the number of runs of consecutive values above or below the mean of  $x$ . Too few runs indicate a tendency for high and low values to cluster. Too many runs indicate a tendency for high and low values to alternate.

`runstest` uses a test statistic which is the difference between the number of runs and its mean, divided by its standard deviation. The test statistic is approximately normally distributed when the null hypothesis is true.

### **p** — *p*-value

scalar value in the range [0,1]

*p*-value of the test, returned as a scalar value in the range [0,1]. *p* is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. Small values of *p* cast doubt on the validity of the null hypothesis.

*p* is computed from either the test statistic or the exact distribution of the number of runs, depending on the value specified for the 'Method' name-value pair argument.

### **stats** — Test data

structure

Test data, returned as a structure with the following fields.

- `nruns` — The number of runs
- `n1` — The number of values above `v`
- `n0` — The number of values below `v`
- `z` — The test statistic

**See Also**

`signrank` | `signtest`

## SampleWithReplacement property

**Class:** TreeBagger

Flag to sample with replacement

### Description

The `SampleWithReplacement` property is a logical flag specifying if data are sampled for each decision tree with replacement. True if `TreeBagger` samples data with replacement and false otherwise. True by default.

# sampsizewr

Sample size and power of test

## Syntax

```
n = sampsizewr(testtype,p0,p1)
n = sampsizewr(testtype,p0,p1,power)
power = sampsizewr(testtype,p0,p1,[],n)
p1 = sampsizewr(testtype,p0,[],power,n)
[...] = sampsizewr(...,n,param1,val1,param2,val2,...)
```

## Description

`n = sampsizewr(testtype,p0,p1)` returns the sample size  $n$  required for a two-sided test of the specified type to have a power (probability of rejecting the null hypothesis when the alternative hypothesis is true) of 0.90 when the significance level (probability of rejecting the null hypothesis when the null hypothesis is true) is 0.05. `p0` specifies parameter values under the null hypothesis. `p1` specifies the single parameter value being tested under the alternative hypothesis.

The following values are available for `testtype`:

- 'z' —  $z$ -test for normally distributed data with known standard deviation. `p0` is a two-element vector [`mu0` `sigma0`] of the mean and standard deviation, respectively, under the null hypothesis. `p1` is the value of the mean under the alternative hypothesis.
- 't' —  $t$ -test for normally distributed data with unknown standard deviation. `p0` is a two-element vector [`mu0` `sigma0`] of the mean and standard deviation, respectively, under the null hypothesis. `p1` is the value of the mean under the alternative hypothesis.
- 'var' — Chi-square test of variance for normally distributed data. `p0` is the variance under the null hypothesis. `p1` is the variance under the alternative hypothesis.
- 'p' — Test of the  $p$  parameter (success probability) for a binomial distribution. `p0` is the value of  $p$  under the null hypothesis. `p1` is the value of  $p$  under the alternative hypothesis.

The 'p' test is a discrete test for which increasing the sample size does not always increase the power. For  $n$  values larger than 200, there may be values smaller than the returned  $n$  value that also produce the desired size and power.

`n = sampsizepwr(testtype, p0, p1, power)` returns the sample size  $n$  such that the power is `power` for the parameter value `p1`.

`power = sampsizepwr(testtype, p0, p1, [], n)` returns the power achieved for a sample size of  $n$  when the true parameter value is `p1`.

`p1 = sampsizepwr(testtype, p0, [], power, n)` returns the parameter value detectable with the specified sample size  $n$  and power `power`.

When computing `p1` for the 'p' test, if no alternative can be rejected for a given null hypothesis and significance level, the function displays a warning message and returns NaN.

`[...] = sampsizepwr(..., n, param1, val1, param2, val2, ...)` specifies one or more of the following name/value pairs:

- 'alpha' — Significance level of the test (default 0.05)
- 'tail' — The type of test is one of the following:
  - 'both' — Two-sided test for an alternative not equal to  $p_0$
  - 'right' — One-sided test for an alternative larger than  $p_0$
  - 'left' — One-sided test for an alternative smaller than  $p_0$

## Examples

### Mean for Given Sample Size and Power

Compute the mean closest to 100 that can be determined to be significantly different from 100 using a  $t$ -test with a sample size of 60 and a power of 0.8.

```
mu1 = sampsizepwr('t', [100 10], [], 0.8, 60)
```

```
mu1 =
```

```
103.6770
```

### Compute Sample Size for a Binomial Test

Compute the sample size  $n$  required to distinguish  $p = 0.26$  from  $p = 0.6$  with a binomial test.

```
napprox = sampsizepwr('p',0.2,0.26,0.6)
```

Warning: Values  $N > 200$  are approximate. Plotting the power as a function of  $N$  may reveal lower  $N$  values that have the required power.

```
napprox =
```

```
244
```

The result is approximate, so make a plot to see if any smaller  $n$  values also have the required power of 0.5.

```
nn = 1:250;
pwr = sampsizepwr('p',0.2,0.26,[],nn);
nexact = min(nn(pwr>=0.6))
```

```
nexact =
```

```
213
```

```
plot(nn,pwr,'b-',[napprox nexact],pwr([napprox nexact]),'ro');
grid on
```

# scatterhist

Scatter plot with marginal histograms

## Syntax

```
scatterhist(x,y)
scatterhist(x,y,Name,Value)
```

```
h = scatterhist(___)
```

## Description

`scatterhist(x,y)` creates a 2-D scatter plot of the data in vectors `x` and `y`, and puts a univariate histogram on the horizontal and vertical axes of the plot.

`scatterhist(x,y,Name,Value)` creates the plot using additional options specified by one or more name-value pair arguments. For example, you can specify a grouping variable or change the display options.

`h = scatterhist( ___ )` returns a vector of three axis handles for the scatter plot, the histogram along the horizontal axis, and the histogram along the vertical axis, respectively, using any of the input arguments in the previous syntaxes.

## Examples

### Create a Scatterhist Plot

Load the sample data. Create data vector `x` from the first column of the data matrix, which contains sepal length measurements from iris flowers. Create data vector `y` from the second column of the data matrix, which contains sepal width measurements from the same flowers.

```
load fisheriris.mat;
x = meas(:,1);
y = meas(:,2);
```

Create a scatter plot and two marginal histograms to visualize the relationship between sepal length and sepal width.

```
scatterhist(x,y)
```

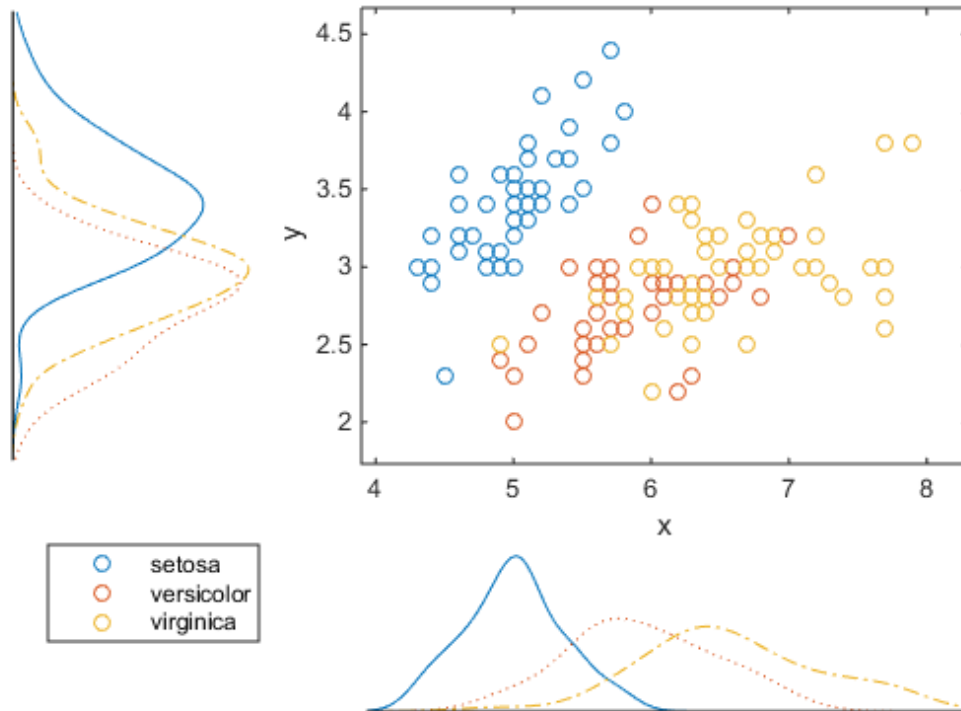

### Plot Grouped Data

Load the sample data. Create data vector `x` from the first column of the data matrix, which contains sepal length measurements from three species of iris flowers. Create data vector `y` from the second column of the data matrix, which contains sepal width measurements from the same flowers.

```
load fisheriris.mat;
x = meas(:,1);
y = meas(:,2);
```

Create a scatter plot and six kernel density plots to visualize the relationship between sepal length and sepal width, grouped by species.

```
scatterhist(x,y,'Group',species)
```

The plot shows that the relationship between sepal length and width varies depending on the flower species.

### Customize the Plot Display

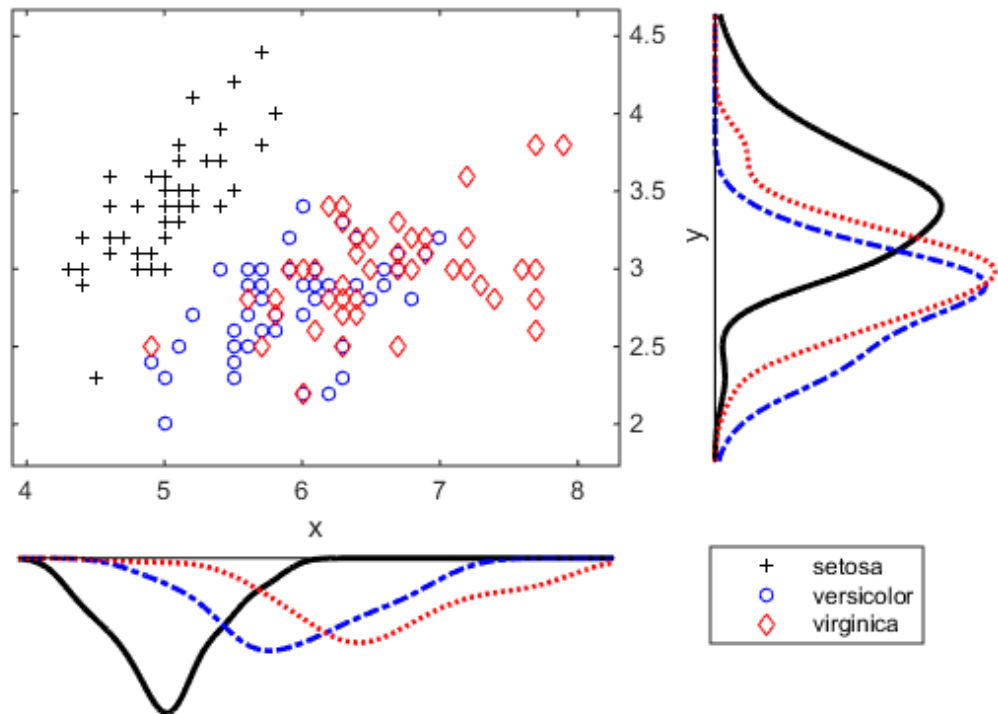

Load the sample data. Create data vector `x` from the first column of the data matrix, which contains sepal length measurements from three different species of iris flowers. Create data vector `y` from the second column of the data matrix, which contains sepal width measurements from the same flowers.

```
load fisheriris.mat;
x = meas(:,1);
```

```
y = meas(:,2);
```

Create a scatter plot and six kernel density plots to visualize the relationship between sepal length and sepal width as measured on three species of iris flowers, grouped by species. Customize the appearance of the plots.

```
scatterhist(x,y,'Group',species,'Location','SouthEast',...
'Direction','out','Color','kbr','LineStyle',{'-','-.'},...
'LineWidth',[2,2,2],'Marker','+od','MarkerSize',[4,5,6]);
```

### Customize Plots Using Axes Handles

Load the sample data. Create data vector `x` from the first column of the data matrix, which contains sepal length measurements from three species of iris flowers. Create

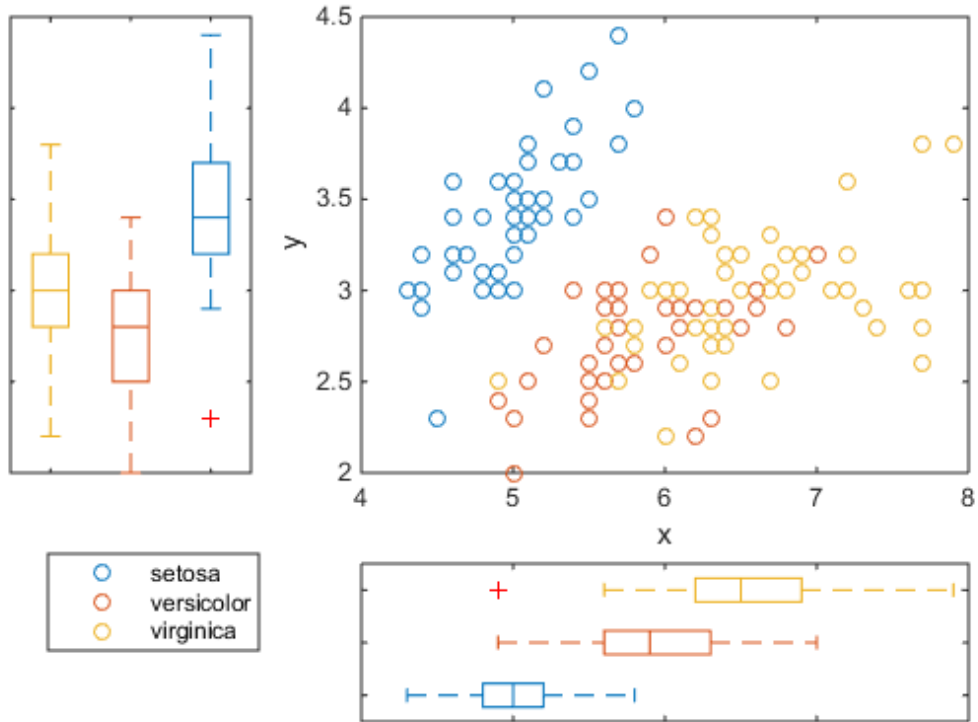

data vector `y` from the second column of the data matrix, which contains sepal width measurements from the same flowers.

```
load fisheriris.mat;
x = meas(:,1);
y = meas(:,2);
```

Use axis handles to replace the marginal histograms with box plots.

```
h = scatterhist(x,y,'Group',species);
hold on;
clr = get(h(1),'colororder');
boxplot(h(2),x,species,'orientation','horizontal',...
 'label',{' ',' ',' '},'color',clr);
boxplot(h(3),y,species,'orientation','horizontal',...
 'label',{' ',' ',' '},'color',clr);
set(h(2:3),'XTickLabel','');
view(h(3),[270,90]); % Rotate the Y plot
axis(h(1),'auto'); % Sync axes
hold off;
```

### Create a scatterhist Plot in a Specified Parent Container

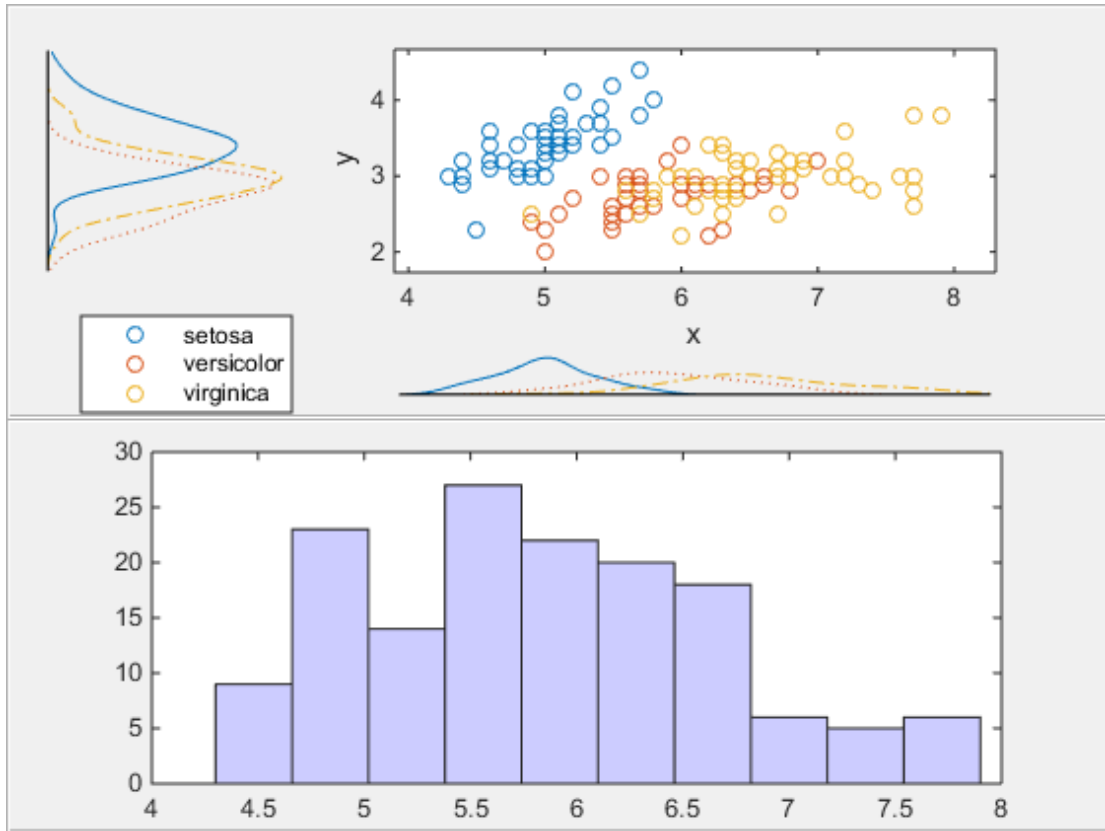

Load the sample data. Create data vector `x` from the first column of the data matrix, which contains sepal length measurements from iris flowers. Create data vector `y` from the second column of the data matrix, which contains sepal width measurements from the same flowers.

```
load fisheriris
x = meas(:,1);
y = meas(:,2);
```

Create a new figure and define two `uipanel` objects to divide the figure into two parts. In the upper half of the figure, plot the sample data using `scatterhist`. Include marginal

kernel density plots grouped by species. In the lower half of the figure, plot a histogram of the sepal length measurements contained in `x`.

```
figure
hp1 = uipanel('position',[0 .5 1 .5]);
hp2 = uipanel('position',[0 0 1 .5]);
scatterhist(x,y,'Group',species,'Parent',hp1);
axes('Parent',hp2);
hist(x);
```

## Input Arguments

### **x** — Sample data

vector

Sample data, specified as a vector. The data vectors `x` and `y` must be the same length.

If `x` or `y` contain NaN values, then `scatterhist`:

- Removes rows with NaN values in either `x` or `y` from both data vectors when generating the scatter plot

- Removes rows with NaN values only from the corresponding x or y data vector when generating the marginal histograms

Data Types: `single` | `double`

### **y** — Sample data

vector

Sample data, specified as a vector. The data vectors x and y must be the same length.

If x or y contain NaN values, then `scatterhist`:

- Removes rows with NaN values in either x or y from both data vectors when generating the scatter plot
- Removes rows with NaN values only from the corresponding x or y data vector when generating the marginal histograms

Data Types: `single` | `double`

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as Name1,Value1, . . . ,NameN,ValueN.

Example: `'Location','SouthEast','Direction','out'` specifies a plot with histograms located below and to the right of the scatter plot, with the bars directed away from the scatter plot.

### **'NBins'** — Number of bins for histograms

positive integer value | vector

Number of bins for histograms, specified as the comma-separated pair consisting of 'NBins' and a positive integer value greater than or equal to 2, or vector of two such values. If the number of bins is specified as a positive integer value, that value is the number of bins for both the x and y histograms. If the number of bins is specified by a vector, the first value is the number of bins for the x data, and the second value is the number of bins for the y data. By default, the number of bins is computed based on the sample standard deviation using Scott's rule.

Example: `'NBins', [5,7]`

Data Types: `single` | `double`

**'Location' — Location of marginal histograms**

`'SouthWest'` (default) | `'SouthEast'` | `'NorthEast'` | `'NorthWest'`

Location of the marginal histograms in the figure, specified as the comma-separated pair consisting of `'Location'` and one of the following.

`'SouthWest'` Plot the histograms below and to the left of the scatter plot.

`'SouthEast'` Plot the histograms below and to the right of the scatter plot.

`'NorthEast'` Plot the histograms above and to the right of the scatter plot.

`'NorthWest'` Plot the histograms above and to the left of the scatter plot.

Example: `'Location', 'SouthEast'`

**'Direction' — Direction of marginal histograms**

`'in'` (default) | `'out'`

Direction of the marginal histograms, specified as the comma-separated pair consisting of `'Direction'` and one of the following.

`'in'` Plot the histograms with the bars directed toward the scatter plot.

`'out'` Plot the histograms with the bars directed away from the scatter plot.

Example: `'Direction', 'out'`

**'Group' — Grouping variable**

categorical array | logical or numeric vector | cell array of strings

Grouping variable, specified as the comma-separated pair consisting of `'Group'` and a categorical array, logical or numeric vector, or cell array of strings. Each unique value in a grouping variable defines a group.

For example, if `Gender` is a cell array of strings with values `'Male'` and `'Female'`, you can use `Gender` as a grouping variable to plot your data by gender.

Multiple grouping variables can be used by specifying a cell array of grouping variable names. Observations are placed in the same group if they have common values of all specified grouping variables.

For example, if `Smoker` is a logical vector with values `0` for nonsmokers and `1` for smokers, then specifying the cell array `{Gender, Smoker}` divides observations into four groups: Male Smoker, Male Nonsmoker, Female Smoker, and Female Nonsmoker.

Example: `'Group', {Gender, Smoker}`

Data Types: `single | double | logical | cell | char`

### 'Kernel' — Grouped kernel density plot indicator

`'on' | 'off' | 'overlay'`

Grouped kernel density plot indicator, specified as the comma-separated pair consisting of `'Kernel'` and one of the following.

- `'on'` Display kernel density plots for each group. This is the default if a `Group` parameter is specified.
- `'off'` Display the overall marginal distribution as histograms. This is the default if a `Group` parameter is not specified.
- `'overlay'` Display the overall marginal distribution as kernel density plots overlaid onto histograms, similar to `histfit`.

Example: `'Kernel', 'overlay'`

### 'Bandwidth' — Bandwidth of kernel smoothing window

matrix

Bandwidth of kernel smoothing window, specified as the comma-separated pair consisting of `'Bandwidth'` and a matrix of size 2-by- $K$ , where  $K$  is the number of unique groups. The first row of the matrix gives the bandwidth of each group in  $x$ , and the second row gives the bandwidth of each group in  $y$ . By default, `scatterhist` finds the optimal bandwidth for estimating normal densities. Specifying a different bandwidth value changes the smoothing characteristics of the resulting kernel density plot. The value specified is a scaling factor for the normal distribution used to generate the kernel density plot.

Example: `'Bandwidth', [.5, .2, .1; .15, .25, .35]`

Data Types: `single | double`

**'Legend'** — Legend visibility indicator

'on' | 'off'

Legend visibility indicator, specified as the comma-separated pair consisting of 'Legend' and one of the following.

'on' Set legend visible. This is the default if a Group parameter is specified.

'off' Set legend invisible. This is the default if a Group parameter is not specified.

Example: 'Legend', 'on'

**'Parent'** — Parent container of the plot

uipanel container object | figure container object

Parent container for the plot, specified as a uipanel container object or figure container object. You can create panel container objects using uipanel or figure, respectively.

For example, if h1 is a panel container object, specify the parent container of the plot as follows.

Example: 'Parent', h1

**'LineStyle'** — Style of kernel density plot line

valid line style string | cell array of strings

Style of kernel density plot line, specified as the comma-separated pair consisting of 'LineStyle' and a valid line style string or a cell array of valid line style strings. See plot for valid line style strings. The default is a solid line. Use a cell array to specify different line styles for each group. When the total number of groups exceeds the number of specified values, scatterhist cycles through the specified values.

Example: 'LineStyle', {'-', ':', '-.'}

**'LineWidth'** — Width of kernel density plot line

0.5 (default) | nonnegative scalar value | vector

Width of kernel density plot line, specified as the comma-separated pair consisting of 'LineWidth' and a nonnegative scalar value or vector of nonnegative scalar values. The specified value is the size of the kernel density plot line measured in points. The default size is 0.5 points. Use a vector to specify different line widths for each group. When the

total number of groups is greater than the number of specified values, `scatterhist` cycles through the specified values.

Example: `'LineWidth', [0.5, 1, 2]`

Data Types: `single` | `double`

### **'Color' — Marker color for each scatter plot group**

valid color designation char | string of chars | matrix of RGB values

Marker color for each scatter plot group, specified as the comma-separated pair consisting of `'Color'` and a valid color designation character, a string of valid color designation characters, or a three-column matrix of RGB values in the range `[0,1]`. See `ColorSpec` for predefined colors and their RGB equivalents. If colors are specified using a matrix, each row of the matrix represents a group, and the three columns represent the R value, G value, and B value, respectively. When the total number of groups exceeds the number of specified colors, `scatterhist` cycles through the specified colors.

Example: `'Color', 'kcm'`

Example: `'Color', [.5, 0, 1; 0, .5, .5]`

Data Types: `single` | `double` | `char`

### **'Marker' — Marker symbol for each scatterplot group**

'o' (default) | valid marker symbol | string of valid marker symbols

Marker symbol for each scatter plot group, specified as the comma-separated pair consisting of `'Marker'` and a valid marker symbol or string of valid marker symbols. See `plot` for valid symbols. The default is `'o'`, a circle. When the total number of groups exceeds the number of specified symbols, `scatterhist` cycles through the specified symbols.

Example: `'Marker', '+do'`

### **'MarkerSize' — Marker size for each scatter plot group**

6 (default) | nonnegative scalar value | vector

Marker size for each scatter plot group, specified as the comma-separated pair consisting of `'MarkerSize'` and a nonnegative scalar value or a vector of nonnegative scalar values, measured in points. When the total number of groups exceeds the number of specified values, `scatterhist` cycles through the specified values.

Example: `'MarkerSize', 10`

Data Types: `single` | `double`

## Output Arguments

### **h** — Axes handles

vector

Axes handles for the three plots, returned as a vector. The vector contains the handles for the scatter plot, the histogram along the horizontal axis, and the histogram along the vertical axis, respectively.

# scramble

**Class:** grandset

Scramble quasi-random point set

## Syntax

```
ps = scramble(p, type)
ps = scramble(p, 'clear')
ps = scramble(p)
```

## Description

`ps = scramble(p, type)` returns a scrambled copy `ps` of the point set `p` of the `grandset` class, created using the scramble type specified in the string `type`. Point sets from different subclasses of `grandset` support different scramble types, as indicated in the following table.

| Subclass  | Scramble Types                                                                                                                                                                       |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| haltonset | 'RR2' — A permutation of the radical inverse coefficients derived by applying a reverse-radix operation to all of the possible coefficient values. The scramble is described in [1]. |
| sobolset  | 'MatousekAffineOwen' — A random linear scramble combined with a random digital shift. The scramble is described in [2].                                                              |

`ps = scramble(p, 'clear')` removes all scramble settings from `p` and returns the result in `ps`.

`ps = scramble(p)` removes all scramble settings from `p` and then adds them back in the order they were originally applied. This typically results in a different point set because of the randomness of the scrambling algorithms.

## Examples

Use `haltonset` to generate a 3-D Halton point set, skip the first 1000 values, and then retain every 101st point:

```
p = haltonset(3, 'Skip', 1e3, 'Leap', 1e2)
p =
 Halton point set in 3 dimensions (8.918019e+013 points)
 Properties:
 Skip : 1000
 Leap : 100
 ScrambleMethod : none
```

Use `scramble` to apply reverse-radix scrambling:

```
p = scramble(p, 'RR2')
p =
 Halton point set in 3 dimensions (8.918019e+013 points)
 Properties:
 Skip : 1000
 Leap : 100
 ScrambleMethod : RR2
```

Use `net` to generate the first four points:

```
X0 = net(p, 4)
X0 =
 0.0928 0.6950 0.0029
 0.6958 0.2958 0.8269
 0.3013 0.6497 0.4141
 0.9087 0.7883 0.2166
```

Use parenthesis indexing to generate every third point, up to the 11th point:

```
X = p(1:3:11, :)
X =
 0.0928 0.6950 0.0029
 0.9087 0.7883 0.2166
 0.3843 0.9840 0.9878
 0.6831 0.7357 0.7923
```

## ScrambleMethod property

**Class:** grandset

Settings that control scrambling

### Description

The `ScrambleMethod` property contains a structure that defines which scrambles to apply to the sequence. The structure consists of two fields:

- **Type:** A string containing the name of the scramble.
- **Options:** A cell array of parameter values for the scramble.

Different point sets support different scramble types as outlined in the help for each point set class. An error occurs if you set an invalid scramble type for a given point set.

The `ScrambleMethod` property also accepts an empty matrix as a value. This will clear all scrambling and set the property to contain a (0x0) structure.

The `scramble` method provides an alternative, easier way to set scrambles.

### Examples

Apply a random linear scramble combined with a random digital shift to a `sobolset` point set class:

```
P = sobolset(5);
P = scramble(P, 'MatousekAffineOwen');
P.ScrambleMethod
```

`sobolset` | `scramble`

## segment

**Class:** `piecewisedistribution`

Segments containing values

## Syntax

```
S = segment(obj,X,P)
```

## Description

`S = segment(obj,X,P)` returns an array `S` of integers indicating which segment of the piecewise distribution object `obj` contains each value of `X` or, alternatively, `P`. One of `X` and `P` must be empty (`[]`). If `X` is nonempty, `S` is determined by comparing `X` with the quantile boundary values defined for `obj`. If `P` is nonempty, `S` is determined by comparing `P` with the probability boundary values.

## Examples

Fit Pareto tails to a  $t$  distribution at cumulative probabilities 0.1 and 0.9:

```
t = trnd(3,100,1);
obj = paretotails(t,0.1,0.9);

pvals = 0:0.2:1;
s = segment(obj,[],pvals)
s =
 1 2 2 2 2 3
```

## sequentialfs

Sequential feature selection

### Syntax

```
inmodel = sequentialfs(fun,X,y)
inmodel = sequentialfs(fun,X,Y,Z,...)
[inmodel,history] = sequentialfs(fun,X,...)
[] = sequentialfs(...,param1,val1,param2,val2,...)
```

### Description

`inmodel = sequentialfs(fun,X,y)` selects a subset of features from the data matrix `X` that best predict the data in `y` by sequentially selecting features until there is no improvement in prediction. Rows of `X` correspond to observations; columns correspond to variables or features. `y` is a column vector of response values or class labels for each observation in `X`. `X` and `y` must have the same number of rows. `fun` is a function handle to a function that defines the criterion used to select features and to determine when to stop. The output `inmodel` is a logical vector indicating which features are finally chosen.

Starting from an empty feature set, `sequentialfs` creates candidate feature subsets by sequentially adding each of the features not yet selected. For each candidate feature subset, `sequentialfs` performs 10-fold cross-validation by repeatedly calling `fun` with different training subsets of `X` and `y`, `XTRAIN` and `ytrain`, and test subsets of `X` and `y`, `XTEST` and `ytest`, as follows:

```
criterion = fun(XTRAIN,ytrain,XTEST,ytest)
```

`XTRAIN` and `ytrain` contain the same subset of rows of `X` and `Y`, while `XTEST` and `ytest` contain the complementary subset of rows. `XTRAIN` and `XTEST` contain the data taken from the columns of `X` that correspond to the current candidate feature set.

Each time it is called, `fun` must return a scalar value `criterion`. Typically, `fun` uses `XTRAIN` and `ytrain` to train or fit a model, then predicts values for `XTEST` using that model, and finally returns some measure of distance, or *loss*, of those predicted values from `ytest`. In the cross-validation calculation for a given candidate feature

set, `sequentialfs` sums the values returned by `fun` and divides that sum by the total number of test observations. It then uses that mean value to evaluate each candidate feature subset.

Typical loss measures include sum of squared errors for regression models (`sequentialfs` computes the mean-squared error in this case), and the number of misclassified observations for classification models (`sequentialfs` computes the misclassification rate in this case).

---

**Note:** `sequentialfs` divides the sum of the values returned by `fun` across all test sets by the total number of test observations. Accordingly, `fun` should not divide its output value by the number of test observations.

---

After computing the mean `criterion` values for each candidate feature subset, `sequentialfs` chooses the candidate feature subset that minimizes the mean criterion value. This process continues until adding more features does not decrease the criterion.

`inmodel = sequentialfs(fun,X,Y,Z,...)` allows any number of input variables `X`, `Y`, `Z`, ... . `sequentialfs` chooses features (columns) only from `X`, but otherwise imposes no interpretation on `X`, `Y`, `Z`, ... . All data inputs, whether column vectors or matrices, must have the same number of rows. `sequentialfs` calls `fun` with training and test subsets of `X`, `Y`, `Z`, ... as follows:

```
criterion = fun(XTRAIN,YTRAIN,ZTRAIN,...,
 XTEST,YTEST,ZTEST,...)
```

`sequentialfs` creates `XTRAIN`, `YTRAIN`, `ZTRAIN`, ... , `XTEST`, `YTEST`, `ZTEST`, ... by selecting subsets of the rows of `X`, `Y`, `Z`, ... . `fun` must return a scalar value `criterion`, but may compute that value in any way. Elements of the logical vector `inmodel` correspond to columns of `X` and indicate which features are finally chosen.

`[inmodel,history] = sequentialfs(fun,X,...)` returns information on which feature is chosen at each step. `history` is a scalar structure with the following fields:

- `Crit` — A vector containing the criterion values computed at each step.
- `In` — A logical matrix in which row `i` indicates the features selected at step `i`.

`[] = sequentialfs(...,param1,val1,param2,val2,...)` specifies optional parameter name/value pairs from the following table.

| Parameter   | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

| 'nfeatures' | The number of features at which <code>sequentialfs</code> should stop. <code>inmodel</code> includes exactly this many features. The default value is empty, indicating that <code>sequentialfs</code> should stop when a local minimum of the criterion is found. A nonempty value overrides values of <code>MaxIter</code> and <code>TolFun</code> in <code>options</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| 'nullmodel' | A logical value, indicating whether or not the null model (containing no features from X) should be included in feature selection and in the <code>history</code> output. The default is <code>false</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 'options'   | Options structure for the iterative sequential search algorithm, as created by <code>statset</code> . <code>sequentialfs</code> uses the following <code>statset</code> parameters: <ul style="list-style-type: none"> <li>• <code>Display</code> — Amount of information displayed by the algorithm. The default is <code>'off'</code>.</li> <li>• <code>MaxIter</code> — Maximum number of iterations allowed. The default is <code>Inf</code>.</li> <li>• <code>TolFun</code> — Termination tolerance for the objective function value. The default is <code>1e-6</code> if <code>'direction'</code> is <code>'forward'</code>; <code>0</code> if <code>'direction'</code> is <code>'backward'</code>.</li> <li>• <code>TolTypeFun</code> — Use absolute or relative objective function tolerances. The default is <code>'rel'</code>.</li> <li>• <code>UseParallel</code> — Set to <code>true</code> to compute in parallel. Default is <code>false</code>.</li> <li>• <code>UseSubstreams</code> — Set to <code>true</code> to compute in parallel in a reproducible fashion. Default is <code>false</code>. To compute reproducibly, set <code>Streams</code> to a type allowing substreams: <code>'mlfg6331_64'</code> or <code>'mrg32k3a'</code>.</li> <li>• <code>Streams</code> — A <code>RandStream</code> object or cell array consisting of one such object. If you do not specify <code>Streams</code>, <code>sequentialfs</code> uses the default stream.</li> </ul> |

## Examples

Perform sequential feature selection for classification of noisy features:

```
load fisheriris;
X = randn(150,10);
X(:,[1 3 5 7])= meas;
y = species;

c = cvpartition(y,'k',10);
opts = statset('display','iter');
fun = @(XT,yT,Xt,yt)...
 (sum(~strcmp(yt,classify(Xt,XT,yT,'quadratic'))));

[fs,history] = sequentialfs(fun,X,y,'cv',c,'options',opts)
```

Start forward sequential feature selection:

```
Initial columns included: none
Columns that can not be included: none
Step 1, added column 7, criterion value 0.04
Step 2, added column 5, criterion value 0.0266667
Final columns included: 5 7
```

```
fs =
 0 0 0 0 1 0 1 0 0 0
history =
 In: [2x10 logical]
 Crit: [0.0400 0.0267]

history.In
ans =
 0 0 0 0 0 0 1 0 0 0
 0 0 0 0 1 0 1 0 0 0
```

## set

**Class:** dataset

Set and display properties

## Compatibility

The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

## Syntax

```
set(A)
set(A,PropertyName)
A = set(A,PropertyName,PropertyValue,...)
B = set(A,PropertyName,value)
```

## Description

`set(A)` displays all properties of the dataset array `A` and their possible values.

`set(A,PropertyName)` displays possible values for the property specified by the string `PropertyName`.

`A = set(A,PropertyName,PropertyValue,...)` sets property name/value pairs.

`B = set(A,PropertyName,value)` returns a dataset array `B` that is a copy of `A`, but with the property `'PropertyName'` set to the value `value`.

---

**Note:** Using `set(A,'PropertyName',value)` without assigning to a variable does not modify `A`'s properties. Use `A = set(A,'PropertyName',value)` to modify `A`.

---

## Examples

Create a dataset array from Fisher's iris data and add a description:

```
load fisheriris
NumObs = size(meas,1);
NameObs = strcat({'Obs'},num2str((1:NumObs)','%-d'));
iris = dataset({nominal(species),'species'},...
 {meas,'SL','SW','PL','PW'},...
 'ObsNames',NameObs);
iris = set(iris,'Description','Fisher''s Iris Data');
get(iris)
 Description: 'Fisher's Iris Data'
 Units: {}
 DimNames: {'Observations' 'Variables'}
 UserData: []
 ObsNames: {150x1 cell}
 VarNames: {'species' 'SL' 'SW' 'PL' 'PW'}
```

## See Also

## setDefaultYfit

**Class:** CompactTreeBagger

Set default value for predict

### Syntax

```
B = setDefaultYfit(B,Yfit)
```

### Description

`B = setDefaultYfit(B,Yfit)` sets the default prediction for ensemble `B` to `Yfit`. The default prediction must be a character variable for classification or a numeric scalar for regression. This setting controls what predicted value `CompactTreeBagger` returns when no prediction is possible, for example when the `predict` method needs to predict for an observation which has only false values in the matrix supplied through `'useifort'` argument.

### See Also

`predict` | `TreeBagger.DefaultYfit`

# setdiff

**Class:** dataset

Set difference for dataset array observations

## Compatibility

The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

## Syntax

```
C = setdiff(A,B)
C = setdiff(A,B,vars)
C = setxor(A,B,vars,setOrder)
[C,iA] = setxor(___)
```

## Description

`C = setdiff(A,B)` for dataset arrays `A` and `B` returns the set of observations that are in `A` but not `B`, with repetitions removed. The observations in the dataset array `C` are sorted.

`C = setdiff(A,B,vars)` returns the set of observations that are in `A` but not `B`, considering only the variables specified in `vars`, with repetitions removed. The observations in the dataset array `C` are sorted by these variables. The values for variables not specified in `vars` for each observation in `C` are taken from the corresponding observation in `A`. If there are multiple observations in `A` that correspond to an observation in `C`, those values are taken from the first occurrence.

`C = setxor(A,B,vars,setOrder)` returns the observations in `C` in the order specified by `setOrder`.

`[C,iA] = setxor( ___ )` also returns the index vector `iA` such that `C = A(iA,:)`. If there are repeated observations in `A`, then `setxor` returns the index of the first occurrence. You can use any of the previous input arguments.

## Input Arguments

### A, B

Input dataset arrays.

### vars

Cell array of strings containing variable names or a vector of integers containing variable column numbers, indicating the variables that `setdiff` considers.

Specify `vars` as `[]` to use its default value of all variables.

### setOrder

Flag indicating the sorting order for the observations in C. The possible values of `setOrder` are:

- |          |                                                                |
|----------|----------------------------------------------------------------|
| 'sorted' | Observations in C are in sorted order (default).               |
| 'stable' | Observations in C are in the same order that they appear in A. |

## Output Arguments

### C

Dataset array with the observations that are in A but not B, with repetitions removed. C is in sorted order (by default), or the order specified by `setOrder`.

### iA

Index vector, indicating the observations from A that are in C. The vector `iA` contains the index to the first occurrence of any repeated observations in A.

## Examples

### Set Difference of Two Dataset Arrays

Create a scalar structure array, and then convert it into two dataset arrays.

```
S(1,1).Name = 'CLARK';
S(1,1).Gender = 'M';
S(1,1).SystolicBP = 124;
S(1,1).DiastolicBP = 93;
```

```
S(2,1).Name = 'BROWN';
S(2,1).Gender = 'F';
S(2,1).SystolicBP = 122;
S(2,1).DiastolicBP = 80;
```

```
S(3,1).Name = 'MARTIN';
S(3,1).Gender = 'M';
S(3,1).SystolicBP = 130;
S(3,1).DiastolicBP = 92;
```

```
A = struct2dataset(S(1:2));
B = struct2dataset(S(2:3));
```

The intersection of A and B is the second observation, with last name BROWN.

Return the set difference of A and B.

```
[C,iA] = setdiff(A,B)
```

```
C =
```

| Name    | Gender | SystolicBP | DiastolicBP |
|---------|--------|------------|-------------|
| 'CLARK' | 'M'    | 124        | 93          |

```
iA =
```

```
1
```

The first observation in A is not present in B.

## setlabels

Assign labels to levels of nominal or ordinal arrays

### Compatibility

The `nominal` and `ordinal` array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the MATLAB categorical data type instead.

### Syntax

```
B = setlabels(A,labels)
B = setlabels(A,labels,levels)
```

### Description

`B = setlabels(A,labels)` returns a `nominal` or `ordinal` array object the same as `A` but with levels labeled in the order specified by `labels`.

`B = setlabels(A,labels,levels)` labels only the levels specified in `levels`.

### Examples

- “Change Category Labels” on page 2-9

### Input Arguments

#### **A** — Nominal or ordinal array

`nominal` array | `ordinal` array

Nominal or ordinal array, specified as a `nominal` or `ordinal` array object created using `nominal` or `ordinal`.

**labels** — Labels to assign

cell array of strings | 2-D character matrix

Labels to assign to levels, specified as a cell array of strings or 2-D character matrix.

Data Types: char | cell

**levels** — Levels to assign labels

cell array of strings | 2-D character matrix

Level to assign labels to, specified as a cell array of strings or 2-D character matrix.

Data Types: char | cell

## Output Arguments

**B** — Nominal or ordinal array

nominal array | ordinal array

Nominal or ordinal array, returned as a `nominal` or `ordinal` array object.

## More About

- Using nominal Objects
- Using ordinal Objects

## See Also

`getlabels` | `nominal` | `ordinal`

## setxor

**Class:** dataset

Set exclusive or for dataset array observations

## Compatibility

The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

## Syntax

```
C = setxor(A,B)
C = setxor(A,B,vars)
C = setxor(A,B,vars,setOrder)
[C,iA,iB] = setxor(___)
```

## Description

`C = setxor(A,B)` for `dataset` arrays `A` and `B` returns the set of observations that are not in the intersection of the two arrays, with repetitions removed. The observations in the dataset array `C` are sorted.

`C = setxor(A,B,vars)` returns the set of observations that are not in the intersection of the two arrays, considering only the variables specified in `vars`, with repetitions removed. The observations in the dataset array `C` are sorted by these variables. The values for variables not specified in `vars` for each observation in `C` are taken from the corresponding observation in `A` or `B`. If there are multiple observations in `A` or `B` that correspond to an observation in `C`, those values are taken from the first occurrence.

`C = setxor(A,B,vars,setOrder)` returns the observations in `C` in the order specified by `setOrder`.

`[C,iA,iB] = setxor( ___ )` also returns index vectors `iA` and `iB` such that `C` is a sorted combination of the values `A(iA,:)` and `B(iB,:)`. If there are repeated

observations in **A** or **B**, then `setxor` returns the index of the first occurrence. You can use any of the previous input arguments.

## Input Arguments

### **A, B**

Input dataset arrays.

### **vars**

Cell array of strings containing variable names or a vector of integers containing variable column numbers, indicating the variables in **A** and **B** that `setxor` considers.

Specify `vars` as `[]` to use its default value of all variables.

### **setOrder**

Flag indicating the sorting order for the observations in **C**. The possible values of `setOrder` are:

|          |                                                                                               |
|----------|-----------------------------------------------------------------------------------------------|
| 'sorted' | Observations in <b>C</b> are in sorted order (default).                                       |
| 'stable' | Observations in <b>C</b> are in the same order that they appear in <b>A</b> , then <b>B</b> . |

## Output Arguments

### **C**

Dataset array with the observations not in the intersection of **A** and **B**, with repetitions removed. **C** is in sorted order (by default), or the order specified by `setOrder`.

### **iA**

Index vector, indicating the observations from **A** that are in **C**. The vector `iA` contains the index to the first occurrence of any repeated observations in **A**.

**iB**

Index vector, indicating the observations from **B** that are in **C**. The vector **iB** contains the index to the first occurrence of any repeated observations in **B**.

## Examples

### Symmetric Difference of Two Dataset Arrays

Create a scalar structure array, and then convert it into two dataset arrays.

```
S(1,1).Name = 'CLARK';
S(1,1).Gender = 'M';
S(1,1).SystolicBP = 124;
S(1,1).DiastolicBP = 93;

S(2,1).Name = 'BROWN';
S(2,1).Gender = 'F';
S(2,1).SystolicBP = 122;
S(2,1).DiastolicBP = 80;

S(3,1).Name = 'MARTIN';
S(3,1).Gender = 'M';
S(3,1).SystolicBP = 130;
S(3,1).DiastolicBP = 92;

A = struct2dataset(S(1:2));
B = struct2dataset(S(2:3));
```

The intersection of **A** and **B** is the second observation, with last name **BROWN**.

Return the symmetric difference of **A** and **B**.

```
[C,iA,iB] = setxor(A,B);
C
```

```
C =
```

| Name     | Gender | SystolicBP | DiastolicBP |
|----------|--------|------------|-------------|
| 'CLARK'  | 'M'    | 124        | 93          |
| 'MARTIN' | 'M'    | 130        | 92          |

```
[iA iB]
```

```
ans =
```

```
 1 2
```

The symmetric difference contains the first observation from A, and the second observation from B.

### **More About**

- “Dataset Arrays” on page 2-132

## SharedCovariance property

**Class:** `gmdistribution`

`true` if all covariance matrices are restricted to be the same

### Description

Logical `true` if all the covariance matrices are restricted to be the same (pooled estimate); logical `false` otherwise.

# shrink

**Class:** RegressionEnsemble

Prune ensemble

## Syntax

```
cmp = shrink(ens)
cmp = shrink(ens,Name,Value)
```

## Description

`cmp = shrink(ens)` returns a compact shrunken version of `ens`, a regularized ensemble. `cmp` retains only learners with weights above a threshold.

`cmp = shrink(ens,Name,Value)` returns an ensemble with additional options specified by one or more `Name,Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

## Input Arguments

### `ens`

A regression ensemble created with `fitensemble`.

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### 'lambda'

Vector of nonnegative regularization parameter values for lasso. If `ens.Regularization` is nonempty (populate it with `regularize`), `shrink` regularizes

ens using lambda. If ens contains a `Regularization` structure, you cannot pass lambda.

**Default:** []

**'threshold'**

Lower cutoff on weights for weak learners, a numeric nonnegative scalar. `shrink` creates `cmp` from those learners with weights above `threshold`.

**Default:** 0

**'weightcolumn'**

Column index of `ens.Regularization.TrainedWeights`, a positive integer. `shrink` creates `cmp` with learner weights from this column.

**Default:** 1

## Output Arguments

**cmp**

A regression ensemble of class `CompactRegressionEnsemble`. Use `cmp` for making predictions exactly as you use `ens`, with the `predict` method.

`shrink` orders the members of `cmp` from largest to smallest.

## Examples

Shrink a 300-member bagged regression ensemble using 0.1 for the parameter `lambda`, and view the number of members of the resulting ensemble:

```
X = rand(2000,20);
Y = repmat(-1,2000,1);
Y(sum(X(:,1:5),2)>2.5) = 1;
bag = fitensemble(X,Y,'Bag',300,'Tree','type','regression');
cmp = shrink(bag,'lambda',0.1);
cmp.NumTrained
```

```
ans =
83
```

## See Also

`regularize` | `predict` | `cvshrink`

## Tutorials

## **Sigma property**

**Class:** gmdistribution

Input array of covariances

## **Description**

Input array of covariances **SIGMA**.

# signrank

Wilcoxon signed rank test

## Syntax

```
p = signrank(x)
p = signrank(x,y)
p = signrank(x,y,Name,Value)
[p,h] = signrank(___)
[p,h,stats] = signrank(___)

[___] = signrank(x,m)
[___] = signrank(x,m,Name,Value)
```

## Description

`p = signrank(x)` returns the  $p$ -value of a two-sided Wilcoxon signed rank test.

`signrank` tests the null hypothesis that data in the vector `x` come from a distribution whose median is zero at the 5% significance level. The test assumes that the data in `x` come from a continuous distribution symmetric about its median.

`p = signrank(x,y)` returns the  $p$ -value of a paired, two-sided test for the null hypothesis that  $x - y$  comes from a distribution with zero median.

`p = signrank(x,y,Name,Value)` returns the  $p$ -value for the sign test with additional options specified by one or more `Name,Value` pair arguments.

`[p,h] = signrank( ___ )` also returns a logical value indicating the test decision. `h = 1` indicates a rejection of the null hypothesis, and `h = 0` indicates a failure to reject the null hypothesis at the 5% significance level. You can use any of the input arguments in the previous syntaxes.

`[p,h,stats] = signrank( ___ )` also returns the structure `stats` with information about the test statistic.

[ \_\_\_ ] = `signrank(x,m)` returns any of the output arguments in the previous syntaxes for the null hypothesis that the data in `x` are observations from a distribution with median `m`.

[ \_\_\_ ] = `signrank(x,m,Name,Value)` returns any of the output arguments in the previous syntaxes for the signed rank test with additional options specified by one or more `Name,Value` pair arguments.

## Examples

### Test for Zero Median of a Single Population

Test the hypothesis of zero median.

Generate the sample data.

```
rng('default') % for reproducibility
x = randn(1,25) + 1.30;
```

Test the hypothesis that the data in `x` has zero median.

```
[p,h] = signrank(x)
```

```
p =
```

```
3.2229e-05
```

```
h =
```

```
1
```

At the default 5% significance level, the value `h = 1` indicates that the test rejects the null hypothesis of zero median.

### Test the Median of Differences of Paired Samples

Test the hypothesis of zero median for the difference between paired samples.

Generate the sample data.

```
rng('default') % for reproducibility
```

```
x = lognrnd(2, .25, 10, 1);
y = x + trnd(2, 10, 1);
```

Test the hypothesis that  $x - y$  has zero median.

```
[p,h] = signrank(x,y)
```

```
p =
 0.3223
```

```
h =
 0
```

The results indicate that the test fails to reject the null hypothesis of zero median in the difference at the default 5% significance level.

### Signed Rank Test for Large Samples

Conduct a -sided test on a large sample using approximation.

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load gradespaired
```

Test the null hypothesis that the median of the grade differences of students before and after participating in a tutoring program is 0 against the alternate that it is less than 0.

```
[p,h,stats] = signrank(gradespaired(:,1),...
 gradespaired(:,2), 'tail', 'left')
```

```
p =
 0.0047
```

```
h =
 1
```

```
stats =

 zval: -2.5982
 signedrank: 2.0175e+03
```

Because the sample size is greater than 15, `signrank` uses an approximate method to calculate the  $p$ -value and also returns the value of the  $z$ -statistic. The value `h = 1` indicates that the test rejects the null hypothesis that there is no difference between the grade medians at the 5% significance level. There is enough statistical evidence to conclude that the median grade before the tutoring program is less than the median grade after the tutoring program.

Repeat the test using the exact method.

```
[p,h,stats] = signrank(gradespaired(:,1),gradespaired(:,2),...
 'tail','left','method','exact')
```

```
p =

 0.0045
```

```
h =

 1
```

```
stats =

 signedrank: 2.0175e+03
```

The results obtained using the approximate method are consistent with the exact method.

### Two-Sided Test for the Median of a Single Population

Load the sample data.

```
load mileage
```

The data contains the mileages per gallon for three different types of cars in columns 1 to 3.

Test the hypothesis that the median mileage for the type of cars in the second column differs from 33.

```
[p,h,stats] = signrank(mileage(:,2),33)
```

```
p =
 0.0313
```

```
h =
 1
```

```
stats =
 signedrank: 21
```

At the 5% significance level, the results indicate that the median mileage for the second type of cars differs from 33. Note that `signrank` uses an exact method to calculate the  $p$ -value for small samples and does not return the  $z$ -statistic.

### Right-Sided Test for the Median of a Single Population

Use the name-value pair arguments in `signrank`.

Load the sample data.

```
load mileage
```

The data contains the mileage per gallon for three different types of cars in columns 1 to 3.

Test the hypothesis that the median mileage for the type of cars in the second row are larger than 33.

```
[p,h,stats] = signrank(mileage(:,2),33,'tail','right')
```

```
p =
 0.0156
```

```
h =
 1
```

```
stats =
 signedrank: 21
```

Repeat the same test at the 1% significance level using the approximate method.

```
[p,h,stats] = signrank(mileage(:,2),33,'tail','right',...
'alpha',0.01,'method','approximate')
```

```
p =
```

```
 0.0180
```

```
h =
```

```
 0
```

```
stats =
```

```
 zval: 2.0966
 signedrank: 21
```

This result,  $h = 0$ , indicates that the null hypothesis cannot be rejected at the 1% significance level.

## Input Arguments

### **x** — Sample data

vector

Sample data, specified as a vector.

Data Types: `single` | `double`

### **y** — Sample data

vector

Sample data, specified as a vector.  $y$  must be the same length as  $x$ .

Data Types: `single` | `double`

### **m** — Hypothesized value of the median

scalar

Hypothesized value of the median, specified as a scalar.

Example: `signrank(x,10)`

Data Types: `single` | `double`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of **Name**,**Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as **Name1**,**Value1**, . . . ,**NameN**,**ValueN**.

Example: 'alpha',0.01,'method','approximate','tail','right' specifies a right-tailed signed rank test with 1% significance level, which returns the approximate p-value.

### 'alpha' — Significance level

0.05 (default) | scalar value in the range 0 to 1

Significance level of the decision of a hypothesis test, specified as the comma-separated pair consisting of 'alpha' and a scalar value in the range 0 to 1. Significance level of **h** is  $100 * \text{alpha}\%$ .

Example: 'alpha',0.01

Data Types: double | single

### 'method' — Computation method of p

'exact' | 'approximate'

Computation method of **p**, specified as the comma-separated pair consisting of 'method' and one of the following.

|               |                                                                                                                                                                                                                                                   |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'exact'       | Exact computation of the <i>p</i> -value, <b>p</b> . Default value for 15 or fewer observations in <b>x</b> , <b>x - m</b> , or <b>x - y</b> when <b>method</b> is unspecified.                                                                   |
| 'approximate' | Normal approximation while computing the <i>p</i> -value, <b>p</b> . Default value for more than 15 observations in <b>x</b> , <b>x - m</b> , or <b>x - y</b> when 'method' is unspecified because the exact method can be slow on large samples. |

Example: 'method','exact'

Data Types: char

### 'tail' — Type of test

'both' (default) | 'right' | 'left'

Type of test, specified as the comma-separated pair consisting of 'tail' and one of the following:

|         |                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|---------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'both'  | Two-sided hypothesis test, which is the default test type. <ul style="list-style-type: none"> <li>For a one-sample test, the alternate hypothesis states that the data in <math>x</math> come from a continuous distribution with median different than 0 or <math>m</math>.</li> <li>For a two-sample test, the alternate hypothesis states that the data in <math>x - y</math> come from a distribution with median different than 0.</li> </ul> |
| 'right' | Right-tailed hypothesis test. <ul style="list-style-type: none"> <li>For a one-sample test, the alternate hypothesis states that the data in <math>x</math> come from a continuous distribution with median greater than 0 or <math>m</math>.</li> <li>For a two-sample test, the alternate hypothesis states the data in <math>x - y</math> come from a distribution with median greater than 0.</li> </ul>                                       |
| 'left'  | Left-tailed hypothesis test. <ul style="list-style-type: none"> <li>For a one-sample test, the alternate hypothesis states that the data in <math>x</math> come from a continuous distribution with median less than 0 or <math>m</math>.</li> <li>For a two-sample test, the alternate hypothesis states the data in <math>x - y</math> come from a distribution with median less than 0.</li> </ul>                                              |

Example: 'tail','left'

## Output Arguments

### **p** — *p*-value of the test

nonnegative scalar

*p*-value of the test, returned as a nonnegative scalar from 0 to 1. **p** is the probability of observing a test statistic as or more extreme than the observed value under the null hypothesis. `signrank` computes the two-sided *p*-value by doubling the most significant one-sided value.

### **h** — Result of the hypothesis test

1 | 0

Result of the hypothesis test, returned as a logical value.

- If  $h = 1$ , this indicates the rejection of the null hypothesis at the  $100 * \alpha\%$  significance level.

- If  $h = 0$ , this indicates a failure to reject the null hypothesis at the  $100 * \alpha\%$  significance level.

### **stats — Test statistics**

structure

Test statistics, returned as a structure. The test statistics stored in **stats** are:

- **signrank**: Value of the sign rank test statistic.
- **zval**: Value of the  $z$ -statistic (computed when 'method' is 'approximate').

## More About

### Wilcoxon Signed Rank Test

The Wilcoxon signed rank test is a nonparametric test for two populations when the observations are paired. In this case, the test statistic,  $W$ , is the sum of the ranks of positive differences between the observations in the two samples (that is,  $x - y$ ). When you use the test for one sample, then  $W$  is the sum of the ranks of positive differences between the observations and the hypothesized median value  $M_0$  (which is 0 when you use `signrank(x)` and  $m$  when you use `signrank(x, m)`).

### **z-Statistic**

For large samples, or when `method` is `approximate`, the `signrank` function calculates the  $p$ -value using the  $z$ -statistic, given by

$$z = \frac{(W - n(n+1)/4)}{\sqrt{\frac{n(n+1)(2n+1) - \text{tieadj}}{24}}},$$

where  $n$  is the sample size of the difference  $x - y$  or  $x - m$ . For the two-sample case, `signrank` uses `[tie_rank, tieadj] = tiedrank(abs(diffxy), 0, 0, epsdiff)` to obtain the tie adjustment value `tieadj`.

### Algorithms

`signrank` treats NaNs in  $x$  and  $y$  as missing values and ignores them.

For the two-sample case, `signrank` uses a tolerance based on the values `epsdiff = eps(x) + eps(y)`. The `signrank` function treats any pair of values with difference  $d(i) = x(i) - y(i)$  that differ by no more than the sum of their two `eps` values ( $\text{abs}(d(i)) < \text{epsdiff}(i)$ ) as ties.

# signtest

Sign test

## Syntax

```
p = signtest(x)
p = signtest(x,y)
p = signtest(x,y,Name,Value)
[p,h] = signtest(____)
[p,h,stats] = signtest(____)

[____] = signtest(x,m)
[____] = signtest(x,m,Name,Value)
```

## Description

`p = signtest(x)` returns the  $p$ -value for a two-sided sign test.

`signtest` tests the hypothesis that data in `x` has a continuous distribution with zero median against the alternative that the distribution does not have zero median at the 5% significance level.

`p = signtest(x,y)` returns the  $p$ -value of a two-sided sign test. Here, `signtest` tests for the hypothesis that the data in `x - y` has a distribution with zero median against the alternative that the distribution does not have zero median. Note that a hypothesis of zero median for `x - y` is not equivalent to a hypothesis of equal median for `x` and `y`.

`p = signtest(x,y,Name,Value)` returns the  $p$ -value for the sign test with additional options specified by one or more `Name,Value` pair arguments.

`[p,h] = signtest(____)` also returns a logical value indicating the test decision. The value `h = 1` indicates a rejection of the null hypothesis, and `h = 0` indicates a failure to reject the null hypothesis at the 5% significance level. You can use any of the input arguments in the previous syntaxes.

`[p,h,stats] = signtest(____)` also returns the structure `stats` containing information about the test statistic.

[ \_\_\_ ] = `signtest(x,m)` returns any of the output arguments in the previous syntaxes for the test whether the data in `x` are observations from a distribution with median `m` against the alternative that the median is different from `m`.

[ \_\_\_ ] = `signtest(x,m,Name,Value)` returns any of the output arguments in the previous syntaxes for the sign test with additional options specified by one or more `Name,Value` pair arguments.

## Examples

### Test for Zero Median of a Single Population

Test the hypothesis of zero median.

Generate the sample data.

```
rng('default') % for reproducibility
x = randn(1,25);
```

The sampling distribution of `x` is symmetric with zero median.

Test the null hypothesis that `x` comes from a distribution with a median different from zero median.

```
[p,h,stats] = signtest(x,0)
```

```
p =
 0.1078
```

```
h =
 0
```

```
stats =
 zval: NaN
 sign: 17
```

At the default 5% significance level, the result `h = 0` indicates that `signtest` fails to reject to the null hypothesis of zero median. `signtest` calculates the *p*-value using the exact method, hence it does not calculate `zval` and returns it as a NaN.

### Test for Zero Median for the Difference of Paired Samples

Test the hypothesis of zero median for the difference between paired samples.

Generate the sample data.

```
rng('default') % for reproducibility
before = lognrnd(2, .25, 10, 1);
after = before + (lognrnd(0, .5, 10, 1) - 1);
```

The sampling distribution of the difference between `before` and `after` is symmetric with zero median.

Test the null hypothesis that the difference of `before` and `after` has zero median.

```
[p,h] = signtest(before,after)
```

```
p =
```

```
0.7539
```

```
h =
```

```
0
```

At the default 5% significance level, the value `h = 0` indicates that `signtest` fails to reject to the null hypothesis of zero median in the difference.

### Medians of Paired Samples

Test the hypothesis of zero median for the difference between two paired samples using the exact and approximate methods.

Generate the sample data.

```
rng('default') % for reproducibility
x = lognrnd(2, .25, 15, 1);
y = x + trnd(2, 15, 1);
display([x y])
```

```
ans =
```

```
8.4521 7.8047
11.6869 11.4094
4.2009 5.1133
9.1664 12.1655
8.0020 10.0300
5.3285 6.0153
```

```
6.6300 5.1235
8.0499 8.6737
18.0763 19.2164
14.7665 15.3380
5.2726 8.4187
15.7798 16.2093
8.8583 8.5575
7.2735 7.4783
8.8347 7.8894
```

Test the hypothesis that  $x - y$  has zero median.

```
[p,h,stats] = signtest(x,y)
```

```
p =
```

```
0.3018
```

```
h =
```

```
0
```

```
stats =
```

```
zval: NaN
```

```
sign: 5
```

At the default 5% significance level, the value  $h = 0$  indicates that the test fails to reject the null hypothesis of zero median in the difference.

Repeat the test using the approximate method.

```
[p,h,stats] = signtest(x,y,'method','approximate')
```

```
p =
```

```
0.3017
```

```
h =
```

```
0
```

```
stats =
 zval: -1.0328
 sign: 5
```

The approximate  $p$ -value, which `signtest` obtains using the  $z$ -statistic, is really close to the exact  $p$ -value.

### Test for Large Samples

Perform a left-sided sign test for large samples.

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load gradespaired
```

Test the null hypothesis that the median of the grade differences before and after the tutoring program is 0 against the alternate that it is less than 0.

```
[p,h,stats] = signtest(gradespaired(:,1),gradespaired(:,2),...
 'tail','left')
```

```
p =
 0.0013
```

```
h =
 1
```

```
stats =
 zval: -3.0110
 sign: 37
```

Because the sample size is large (greater than 100), `signtest` uses an approximate method to calculate the  $p$ -value and also returns the value of the  $z$ -statistic. The test

rejects the null hypothesis that there is no difference between the grade medians at the 5% significance level.

### Test for Median of a Single Population

Test the hypothesis that the population median is different from a specified value.

Load the sample data.

```
load lawdata
```

The data set has 15 observations for variables `gpa` and `lsat`.

Test the hypothesis that the median `lsat` score is higher than 570.

```
[p,h,stats] = signtest(lsat,570,'tail','right')
```

```
p =
```

```
 0.0176
```

```
h =
```

```
 1
```

```
stats =
```

```
 zval: NaN
```

```
 sign: 12
```

Both the  $p$ -value, 0.0176, and  $h = 1$  indicate that at the 5% significance level the test concludes in favor of the alternate hypothesis.

## Input Arguments

### **x** — Sample data

vector

Sample data, specified as a vector.

Data Types: `single` | `double`

**y — Sample data**

vector

Sample data, specified as a vector. **y** must be the same length as **x**.

Data Types: `single` | `double`

**m — Hypothesized value of the median**

scalar

Hypothesized value of the median, specified as a scalar.

Example: `signtest(x,35)`

Data Types: `single` | `double`

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of **Name**,**Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as **Name1**,**Value1**, . . . ,**NameN**,**ValueN**.

Example: `'alpha',0.01,'method','approximate','tail','right'` specifies a right-tailed sign test with 1% significance level, which returns the approximate *p*-value.

**'alpha' — Significance level**

0.05 (default) | scalar value in the range 0 to 1

Significance level of the hypothesis test, specified as the comma-separated pair consisting of `'alpha'` and a scalar value in the range 0 to 1. The default value of `alpha` is 0.05. Significance level of *h* is  $100 * \alpha\%$ .

Example: `'alpha',0.01`

Data Types: `double` | `single`

**'method' — *p*-value computation method**

`'exact'` | `'approximate'`

*p*-value computation method, specified as the comma-separated pair consisting of `'method'` and one of the following:

|                      |                                                      |
|----------------------|------------------------------------------------------|
| <code>'exact'</code> | Exact computation of the <i>p</i> -value, <i>p</i> . |
|----------------------|------------------------------------------------------|

|               |                                                          |
|---------------|----------------------------------------------------------|
| 'approximate' | Normal approximation for computing the $p$ -value, $p$ . |
|---------------|----------------------------------------------------------|

The default computation method is 'exact', if there are fewer than 100 observations and 'approximate' if there are 100 observations or more.

Example: 'method', 'exact'

Data Types: char

### 'tail' — Type of test

'both' (default) | 'right' | 'left'

Type of test, specified as the comma-separated pair consisting of 'tail' and one of the following:

|         |                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|---------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'both'  | Two-sided hypothesis test, which is the default test type. <ul style="list-style-type: none"> <li>For a one-sample test, the alternate hypothesis states that the data in <math>x</math> come from a continuous distribution with median different than zero (or <math>m</math>).</li> <li>For a two-sample test, the alternate hypothesis states that the data in <math>x - y</math> come from a distribution with median different than zero.</li> </ul> |
| 'right' | Right-tailed hypothesis test. <ul style="list-style-type: none"> <li>For a one-sample test, the alternate hypothesis states that the data in <math>x</math> come from a continuous distribution with median greater than zero (or <math>m</math>).</li> <li>For a two-sample test, the alternate hypothesis states the data in <math>x - y</math> come from a distribution with median greater than zero.</li> </ul>                                       |
| 'left'  | Left-tailed hypothesis test. <ul style="list-style-type: none"> <li>For a one-sample test, the alternate hypothesis states that the data in <math>x</math> come from a continuous distribution with median less than zero (or <math>m</math>).</li> <li>For a two-sample test, the alternative hypothesis states the data in <math>x - y</math> come from a distribution with median less than zero.</li> </ul>                                            |

Example: 'tail', 'left'

## Output Arguments

**$p$**  —  $p$ -value of the test

nonnegative scalar

$p$ -value of the test, returned as a nonnegative scalar from 0 to 1.  $p$  is the probability of observing a test statistic as or more extreme than the observed value under the null hypothesis. `signtest` computes the two-sided  $p$ -value by doubling the most significant one-sided value.

### **h** — Result of the hypothesis test

1 | 0

Result of the hypothesis test, returned as a logical value.

- If  $h = 1$ , this indicates rejection of the null hypothesis at the  $100 * \alpha\%$  significance level.
- If  $h = 0$ , this indicates a failure to reject the null hypothesis at the  $100 * \alpha\%$  significance level.

### **stats** — Test statistics

structure

Test statistics, returned as a structure. The test statistics stored in `stats` are:

- `sign`: Value of the sign test statistic.
- `zval`: Value of the z-statistic (computed only for large samples).

## More About

### Sign Test

The sign test is a nonparametric test for the median of a population or median of the difference of two populations.

For example, for tests on a single population median:

- If the test is two-sided, then the test statistic,  $S$ , is the minimum of the number of observations that are smaller or larger than the hypothesized median value,  $M_0$ .
- If the test is right-sided, then  $S$  is the number of observations that are larger than the hypothesized median value  $M_0$ .
- If the test is left-sided, then  $S$  is the number of observations that are smaller than the hypothesized median value  $M_0$ .

### **z-Statistic**

For a large sample, `signtest` uses the  $z$ -statistic to approximate the  $p$ -value.

The `signtest` test statistic is the number of elements that are greater than 0 (for `signtest(x)` or `signtest(x-y)`), or  $m$  (for `signtest(x,m)`). Hence, the  $z$ -statistic of the sign test, with the continuity correction, is:

$$z = \frac{(S - E(S))}{\sqrt{V(S)}} = \frac{(S - (0.5)n - 0.5\text{sign}(npos - nneg))}{\sqrt{(0.5)(0.5)n}},$$

where  $npos$  and  $nneg$  are the number of positive and negative differences from the hypothesized median value, respectively.

### **Algorithms**

For a one-sample test, `signtest` omits values in  $x$  that are zero or NaN.

For a two-sample test, `signtest` omits values in  $x - y$  that are zero or NaN.

`ranksum` | `signrank` | `ttest` | `ztest`

# silhouette

Silhouette plot

## Syntax

```
silhouette(X,clust)
s = silhouette(X,clust)
[s,h] = silhouette(X,clust)
[...] = silhouette(X,clust,metric)
[...] = silhouette(X,clust,distfun,p1,p2,...)
```

## Description

`silhouette(X,clust)` plots cluster silhouettes for the  $n$ -by- $p$  data matrix  $X$ , with clusters defined by `clust`. Rows of  $X$  correspond to points, columns correspond to coordinates. `clust` can be a categorical variable, numeric vector, character matrix, or cell array of strings containing a cluster name for each point. `silhouette` treats NaNs or empty strings in `clust` as missing values, and ignores the corresponding rows of  $X$ . By default, `silhouette` uses the squared Euclidean distance between points in  $X$ .

`s = silhouette(X,clust)` returns the silhouette values in the  $n$ -by-1 vector `s`, but does not plot the cluster silhouettes.

`[s,h] = silhouette(X,clust)` plots the silhouettes, and returns the silhouette values in the  $n$ -by-1 vector `s`, and the figure handle in `h`.

`[...] = silhouette(X,clust,metric)` plots the silhouettes using the inter-point distance function specified in `metric`. Choices for `metric` are given in the following table.

| Metric        | Description                          |
|---------------|--------------------------------------|
| 'Euclidean'   | Euclidean distance                   |
| 'sqEuclidean' | Squared Euclidean distance (default) |
| 'cityblock'   | Sum of absolute differences          |

| Metric        | Description                                                                                                                                                                               |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'cosine'      | One minus the cosine of the included angle between points (treated as vectors)                                                                                                            |
| 'correlation' | One minus the sample correlation between points (treated as sequences of values)                                                                                                          |
| 'Hamming'     | Percentage of coordinates that differ                                                                                                                                                     |
| 'Jaccard'     | Percentage of nonzero coordinates that differ                                                                                                                                             |
| Vector        | A numeric distance matrix in upper triangular vector form, such as is created by <code>pdist</code> . <code>X</code> is not used in this case, and can safely be set to <code>[]</code> . |

For more information on each metric, see “Distance Metrics”.

`[...] = silhouette(X,clust,distfun,p1,p2,...)` accepts a function handle `distfun` to a metric of the form

```
d = distfun(X0,X,p1,p2,...)
```

where `X0` is a 1-by-`p` point, `X` is an `n`-by-`p` matrix of points, and `p1,p2,...` are optional additional arguments. The function `distfun` returns an `n`-by-1 vector `d` of distances between `X0` and each point (row) in `X`. The arguments `p1,p2,...` are passed directly to the function `distfun`.

## Examples

### Create Silhouette Plot

Create a silhouette plot from clustered data.

Generate random sample data.

```
rng('default'); % For reproducibility
X = [randn(10,2)+ones(10,2);randn(10,2)-ones(10,2)];
```

Cluster the data in `X` using `kmeans`.

```
cidx = kmeans(X,2);
```

Create a silhouette plot from the clustered data.

```
silhouette(X,cidx)
```

### Compute Silhouette Values

Compute the silhouette values from clustered data.

Generate random sample data.

```
rng('default'); % For reproducibility
X = [randn(10,2)+ones(10,2);randn(10,2)-ones(10,2)];
```

Use `kmeans` to cluster the data in `X` based on the sum of absolute differences in distance.

```
cidx = kmeans(X,2,'distance','cityblock');
```

Compute the silhouette values from the clustered data. Specify `metric` as `'cityblock'` to indicate that the `kmeans` clustering is based on the sum of absolute differences.

```
s = silhouette(X,cidx,'cityblock')
```

```
s =

## More About

### Silhouette Value

The silhouette value for each point is a measure of how similar that point is to points in its own cluster, when compared to points in other clusters. The silhouette value for the  $i$ th point,  $S_i$ , is defined as

$$S_i = (b_i - a_i) / \max(a_i, b_i)$$

where  $a_i$  is the average distance from the  $i$ th point to the other points in the same cluster as  $i$ , and  $b_i$  is the minimum average distance from the  $i$ th point to points in a different cluster, minimized over clusters.

The silhouette value ranges from -1 to +1. A high silhouette value indicates that  $i$  is well-matched to its own cluster, and poorly-matched to neighboring clusters. If most points have a high silhouette value, then the clustering solution is appropriate. If many points have a low or negative silhouette value, then the clustering solution may have either too many or too few clusters. The silhouette clustering evaluation criterion can be used with any distance metric.

## clustering.evaluation.SilhouetteEvaluation class

**Package:** clustering.evaluation

**Superclasses:** clustering.evaluation.ClusterCriterion

Silhouette criterion clustering evaluation object

### Description

`clustering.evaluation.SilhouetteEvaluation` is an object consisting of sample data, clustering data, and silhouette criterion values used to evaluate the optimal number of data clusters. Create a silhouette criterion clustering evaluation object using `evalclusters`.

### Construction

`eva = evalclusters(x,clust,'Silhouette')` creates a silhouette criterion clustering evaluation object.

`eva = evalclusters(x,clust,'Silhouette',Name,Value)` creates a silhouette criterion clustering evaluation object using additional options specified by one or more name-value pair arguments.

### Input Arguments

**x — Input data**

matrix

Input data, specified as an  $N$ -by- $P$  matrix.  $N$  is the number of observations, and  $P$  is the number of variables.

Data Types: `single` | `double`

**clust — Clustering algorithm**

'kmeans' | 'linkage' | 'gmdistribution' | matrix of clustering solutions | function handle

Clustering algorithm, specified as one of the following.

|                  |                                                                                                                                                                           |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'kmeans'         | Cluster the data in <code>x</code> using the <code>kmeans</code> clustering algorithm, with 'EmptyAction' set to 'singleton' and 'Replicates' set to 5.                   |
| 'linkage'        | Cluster the data in <code>x</code> using the <code>clusterdata</code> agglomerative clustering algorithm, with 'Linkage' set to 'ward'.                                   |
| 'gmdistribution' | Cluster the data in <code>x</code> using the <code>gmdistribution</code> Gaussian mixture distribution algorithm, with 'SharedCov' set to true and 'Replicates' set to 5. |

If `Criterion` is 'CalinskHarabasz', 'DaviesBouldin', or 'silhouette', you can specify a clustering algorithm using the `function_handle` (@) operator. The function must be of the form `C = clustfun(DATA,K)`, where `DATA` is the data to be clustered, and `K` is the number of clusters. The output of `clustfun` must be one of the following:

- A vector of integers representing the cluster index for each observation in `DATA`. There must be `K` unique values in this vector.
- A numeric  $n$ -by- $K$  matrix of score for  $n$  observations and  $K$  classes. In this case, the cluster index for each observation is determined by taking the largest score value in each row.

If `Criterion` is 'CalinskHarabasz', 'DaviesBouldin', or 'silhouette', you can also specify `clust` as a  $n$ -by- $K$  matrix containing the proposed clustering solutions.  $n$  is the number of observations in the sample data, and  $K$  is the number of proposed clustering solutions. Column  $j$  contains the cluster indices for each of the  $N$  points in the  $j$ th clustering solution.

### Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Example: 'KList',[1:5],'Distance','cityblock' specifies to test 1, 2, 3, 4, and 5 clusters using the sum of absolute differences distance measure.

### 'ClusterPriors' — Prior probabilities for each cluster

'empirical' (default) | 'equal'

Prior probabilities for each cluster, specified as the comma-separated pair consisting of 'ClusterPriors' and one of the following.

|             |                                                                                                                                                                                                                                                                                        |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'empirical' | Compute the overall silhouette value for the clustering solution by averaging the silhouette values for all points. Each cluster contributes to the overall silhouette value proportionally to its size.                                                                               |
| 'equal'     | Compute the overall silhouette value for the clustering solution by averaging the silhouette values for all points within each cluster, and then averaging those values across all clusters. Each cluster contributes equally to the overall silhouette value, regardless of its size. |

Example: 'ClusterPriors', 'empirical'

#### 'Distance' — Distance metric

'sqEuclidean' (default) | 'Euclidean' | 'cityblock' | vector | function | ...

Distance metric used for computing the criterion values, specified as the comma-separated pair consisting of 'Distance' and one of the following.

|               |                                                                                  |
|---------------|----------------------------------------------------------------------------------|
| 'sqEuclidean' | Squared Euclidean distance                                                       |
| 'Euclidean'   | Euclidean distance                                                               |
| 'cityblock'   | Sum of absolute differences                                                      |
| 'cosine'      | One minus the cosine of the included angle between points (treated as vectors)   |
| 'correlation' | One minus the sample correlation between points (treated as sequences of values) |
| 'Hamming'     | Percentage of coordinates that differ                                            |
| 'Jaccard'     | Percentage of nonzero coordinates that differ                                    |

For detailed information about each distance metric, see `pdist`.

You can also specify a function for the distance metric by using the `function_handle` (@) operator. The distance function must be of the form `d2 = distfun(XI, XJ)`, where `XI` is a 1-by- $n$  vector corresponding to a single row of the input matrix `X`, and `XJ` is an  $m_2$ -

by- $n$  matrix corresponding to multiple rows of  $X$ . `distfun` must return an  $m_2$ -by-1 vector of distances `d2`, whose  $k$ th element is the distance between  $XI$  and  $XJ(k, :)$ .

If `Criterion` is `'silhouette'`, you can also specify `Distance` as the output vector output created by the function `pdist`.

When `Clust` a string representing a built-in clustering algorithm, `evalclusters` uses the distance metric specified for `Distance` to cluster the data, except for the following:

- If `Clust` is `'linkage'`, and `Distance` is either `'sqEuclidean'` or `'Euclidean'`, then the clustering algorithm uses Euclidean distance and Ward linkage.
- If `Clust` is `'linkage'` and `Distance` is any other metric, then the clustering algorithm uses the specified distance metric and average linkage.

In all other cases, the distance metric specified for `Distance` must match the distance metric used in the clustering algorithm to obtain meaningful results.

Example: `'Distance', 'Euclidean'`

### **'KList' — List of number of clusters to evaluate**

vector

List of number of clusters to evaluate, specified as the comma-separated pair consisting of `'KList'` and a vector of positive integer values. You must specify `KList` when `clust` is a clustering algorithm name string or a function handle. When criterion is `'gap'`, `clust` must be a string or a function handle, and you must specify `KList`.

Example: `'KList', [1:6]`

## **Properties**

### **ClusteringFunction**

Clustering algorithm used to cluster the input data, stored as a valid clustering algorithm name string or function handle. If the clustering solutions are provided in the input, `ClusteringFunction` is empty.

### **ClusterPriors**

Prior probabilities for each cluster, stored as valid prior probability name string.

**ClusterSilhouettes**

Silhouette values corresponding to each proposed number of clusters in `InspectedK`, stored as a cell array of vectors.

**CriterionName**

Name of the criterion used for clustering evaluation, stored as a valid criterion name string.

**CriterionValues**

Criterion values corresponding to each proposed number of clusters in `InspectedK`, stored as a vector of numerical values.

**Distance**

Distance measure used for clustering data, stored as a valid distance measure name string.

**InspectedK**

List of the number of proposed clusters for which to compute criterion values, stored as a vector of positive integer values.

**Missing**

Logical flag for excluded data, stored as a column vector of logical values. If `Missing` equals `true`, then the corresponding value in the data matrix `X` is not used in the clustering solution.

**NumObservations**

Number of observations in the data matrix `X`, minus the number of missing (NaN) values in `X`, stored as a positive integer value.

**OptimalK**

Optimal number of clusters, stored as a positive integer value.

**OptimalY**

Optimal clustering solution corresponding to `OptimalK`, stored as a column vector of positive integer values. If the clustering solutions are provided in the input, `OptimalY` is empty.

**X**

Data used for clustering, stored as a matrix of numerical values.

## Methods

### Inherited Methods

|         |                                                    |
|---------|----------------------------------------------------|
| addK    | Evaluate additional numbers of clusters            |
| plot    | Plot clustering evaluation object criterion values |
| compact | Compact clustering evaluation object               |

## Definitions

### Silhouette Value

The silhouette value for each point is a measure of how similar that point is to points in its own cluster, when compared to points in other clusters. The silhouette value for the  $i$ th point,  $S_i$ , is defined as

$$S_i = (b_i - a_i) / \max(a_i, b_i)$$

where  $a_i$  is the average distance from the  $i$ th point to the other points in the same cluster as  $i$ , and  $b_i$  is the minimum average distance from the  $i$ th point to points in a different cluster, minimized over clusters.

The silhouette value ranges from -1 to +1. A high silhouette value indicates that  $i$  is well-matched to its own cluster, and poorly-matched to neighboring clusters. If most points have a high silhouette value, then the clustering solution is appropriate. If many points have a low or negative silhouette value, then the clustering solution may have

either too many or too few clusters. The silhouette clustering evaluation criterion can be used with any distance metric.

## Examples

### Evaluate the Clustering Solution Using Silhouette Criterion

Evaluate the optimal number of clusters using the silhouette clustering evaluation criterion.

Generate sample data containing random numbers from three multivariate distributions with different parameter values.

```
rng('default'); % For reproducibility
mu1 = [2 2];
sigma1 = [0.9 -0.0255; -0.0255 0.9];

mu2 = [5 5];
sigma2 = [0.5 0 ; 0 0.3];

mu3 = [-2, -2];
sigma3 = [1 0 ; 0 0.9];

N = 200;

X = [mvnrnd(mu1,sigma1,N);...
 mvnrnd(mu2,sigma2,N);...
 mvnrnd(mu3,sigma3,N)];
```

Evaluate the optimal number of clusters using the silhouette criterion. Cluster the data using `kmeans`.

```
E = evalclusters(X,'kmeans','silhouette','klist',[1:6])
```

```
E =
```

```
SilhouetteEvaluation with properties:
```

```
NumObservations: 600
 InspectedK: [1 2 3 4 5 6]
 CriterionValues: [NaN 0.8055 0.8551 0.7170 0.7376 0.6239]
 OptimalK: 3
```

The `OptimalK` value indicates that, based on the silhouette criterion, the optimal number of clusters is three.

Plot the silhouette criterion values for each number of clusters tested.

```
figure;
plot(E)
```

The plot shows that the highest silhouette value occurs at three clusters, suggesting that the optimal number of clusters is three.

Create a grouped scatter plot to visually examine the suggested clusters.

```
figure;
gscatter(X(:,1),X(:,2),E.OptimalY,'rbg','xod')
```

The plot shows three distinct clusters within the data: Cluster 1 is in the lower-left corner, cluster 2 is near the center of the plot, and cluster 3 is in the upper-right corner.

## More About

- “Class Attributes”
- “Property Attributes”

## single

**Class:** dataset

Convert dataset variables to single array

## Compatibility

The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

## Syntax

```
B = single(A)
B = single(A,vars)
```

## Description

`B = single(A)` returns the contents of the dataset `A`, converted to one single array. The classes of the variables in the dataset must support the conversion.

`B = single(A,vars)` returns the contents of the dataset variables specified by `vars`. `vars` is a positive integer, a vector of positive integers, a variable name, a cell array containing one or more variable names, or a logical vector.

## See Also

`dataset` | `double` | `replacedata`

## size

**Class:** dataset

Size of dataset array

## Compatibility

The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

## Syntax

```
D = SIZE(A)
[NOBS,NVARS] = SIZE(A)
[M1,M2,M3,...,MN] = SIZE(A)
M = size(A,dim)
```

## Description

`D = SIZE(A)` returns the two-element row vector `D = [NOBS,NVARS]` containing the number of observations and number of variables in the dataset `A`. A dataset array always has two dimensions.

`[NOBS,NVARS] = SIZE(A)` returns the numbers of observations and variables in the dataset `A` as separate output variables.

`[M1,M2,M3,...,MN] = SIZE(A)`, for `N > 2`, returns `M1 = NOBS`, `M2 = NVARS`, and `M3,...,MN = 1`.

`M = size(A,dim)` returns the length of the dimension specified by the scalar `dim`:

- `M = size(A,1)` returns `NOBS`
- `M = size(A,2)` returns `NVARS`
- `M = size(A,k)` returns 1 for `k > 2`

**See Also**

length | numel | ndims

## size

**Class:** grandset

Number of dimensions in matrix

## Syntax

```
d = size(p)
[m,n] = size(p)
m = size(p,dim)
```

## Description

`d = size(p)` returns the two-element row vector `d = [m,n]` containing the number of points in the point set and the number of dimensions the points are in, for the point set `p`. These correspond to the number of rows and columns in the matrix that would be produced by the expression `p(:, :)`.

`[m,n] = size(p)` returns the number of points and dimensions for `p` as separate output variables.

`m = size(p,dim)` returns the length of the dimension specified by the scalar `dim`. For example, `size(p,1)` returns the number of rows (points in the point set). If `dim` is greater than 2, `m` will be 1.

## Examples

The commands

```
P = sobolset(12);
d = size(P)
return
```

```
d = [9.0072e+015 12]
```

The command

```
[m,n] = size(P)
```

returns

```
m = 9.0072e+015
```

```
n = 12
```

The command

```
m2 = size(P, 2)
```

returns

```
m2 = 12
```

### **See Also**

`length` | `ndims` | `grandset`

# slicesample

Slice sampler

## Syntax

```
rnd = slicesample(initial,nsamples,'pdf',pdf)
rnd = slicesample(initial,nsamples,'logpdf',logpdf)
[rnd,neval] = slicesample(initial,...)
[rnd,neval] = slicesample(initial,...,Name,Value)
```

## Description

`rnd = slicesample(initial,nsamples,'pdf',pdf)` generates `nsamples` random samples using the slice sampling method (see “Algorithms” on page 21-4112). `pdf` gives the target probability density function (pdf). `initial` is a row vector or scalar containing the initial value of the random sample sequences.

`rnd = slicesample(initial,nsamples,'logpdf',logpdf)` generates samples using the logarithm of the pdf.

`[rnd,neval] = slicesample(initial,...)` returns the average number of function evaluations that occurred in the slice sampling.

`[rnd,neval] = slicesample(initial,...,Name,Value)` generates random samples with additional options specified by one or more `Name,Value` pair arguments.

## Input Arguments

### **initial**

Initial point, a scalar or row vector. Set `initial` so `pdf(initial)` is a strictly positive scalar. `length(initial)` is the number of dimensions of each sample.

### **nsamples**

Positive integer, the number of samples that `slicesample` generates.

**pdf**

Handle to a function that generates the probability density function, specified with @. pdf can be unnormalized, meaning it need not integrate to 1.

**logpdf**

Handle to a function that generates the logarithm of the probability density function, specified with @. logpdf can be the logarithm of an unnormalized pdf.

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1,Value1, . . . ,NameN,ValueN.

**'burnin'**

Nonnegative integer, the number of samples to generate and discard before generating the samples to return. The slice sampling algorithm is a Markov chain whose stationary distribution is proportional to that of the pdf argument. Set burnin to a high enough value that you believe the Markov chain approximately reaches stationarity after burnin samples.

**Default: 0****'thin'**

Positive integer, where slicesample discards every thin - 1 samples and returns the next. The slice sampling algorithm is a Markov chain, so the samples are serially correlated. To reduce the serial correlation, choose a larger value of thin.

**Default: 1****'width'**

Width of the interval around the current sample, a scalar or vector of positive values. slicesample begins with this interval and searches for an appropriate region containing the points of pdf that evaluate to a large enough value.

- If `width` is a scalar and the samples have multiple dimensions, `slicesample` uses `width` for each dimension.
- If `width` is a vector, it should have the same length as `initial`.

**Default:** 10

## Output Arguments

### `rnd`

`nsamples-by-length(initial)` matrix, where each row is one sample.

### `neval`

Scalar, the mean number of function evaluations per sample. `neval` includes the `burnin` and `thin` evaluations, not just the evaluations of samples returned in `rnd`. Therefore the total number of function evaluations is `neval*(nsamples*thin + burnin)`.

## Examples

### Generate Random Samples From a Multimodal Density

This example shows how to generate random samples from a multimodal density using `slicesample`.

Define a function proportional to a multimodal density.

```
rng default % For reproducibility
f = @(x) exp(-x.^2/2).*(1 + (sin(3*x)).^2).*...
 (1 + (cos(5*x)).^2));
area = integral(f,-5,5);
```

Generate 2000 samples from the density, using a burn-in period of 1000, and keeping one in five samples.

```
N = 2000;
x = slicesample(1,N,'pdf',f,'thin',5,'burnin',1000);
```

Plot a histogram of the sample.

```
[binheight,bincenter] = hist(x,50);
h = bar(bincenter,binheight,'hist');
h.FaceColor = [.8 .8 1];
```

Scale the density to have the same area as the histogram, and superimpose it on the histogram.

```
hold on
h = gca;
xd = h.XLim;
xgrid = linspace(xd(1),xd(2),1000);
binwidth = (bincenter(2)-bincenter(1));
y = (N*binwidth/area) * f(xgrid);
```

```
plot(xgrid,y,'r','LineWidth',2)
hold off
```

The samples seem to fit the theoretical distribution well, so the `burnin` value seems adequate.

## More About

### Tips

- There are no definitive suggestions for choosing appropriate values for `burnin`, `thin`, or `width`. Choose starting values of `burnin` and `thin`, and increase them, if

necessary, to give the requisite independence and marginal distributions. See Neal [1] for details of the effect of adjusting `width`.

### Algorithms

At each point in the sequence of random samples, `slicesample` selects the next point by “slicing” the density to form a neighborhood around the previous point where the density is above some value. Consequently, the sample points are not independent. Nearby points in the sequence tend to be closer together than they would be from a sample of independent values. For many purposes, the entire set of points can be used as a sample from the target distribution. However, when this type of serial correlation is a problem, the `burnin` and `thin` parameters can help reduce that correlation.

`slicesample` uses the slice sampling algorithm of Neal [1]. For numerical stability, it converts a `pdf` function into a `logpdf` function. The algorithm to resize the support region for each level, called “stepping-out” and “stepping-in,” was suggested by Neal.

# skewness

Skewness

## Syntax

```
y = skewness(X)
y = skewness(X,flag)
y = skewness(X,flag,dim)
```

## Description

`y = skewness(X)` returns the sample skewness of `X`. For vectors, `skewness(x)` is the skewness of the elements of `x`. For matrices, `skewness(X)` is a row vector containing the sample skewness of each column. For N-dimensional arrays, `skewness` operates along the first nonsingleton dimension of `X`.

`y = skewness(X,flag)` specifies whether to correct for bias (`flag = 0`) or not (`flag = 1`, the default). When `X` represents a sample from a population, the skewness of `X` is biased; that is, it will tend to differ from the population skewness by a systematic amount that depends on the size of the sample. You can set `flag = 0` to correct for this systematic bias.

`y = skewness(X,flag,dim)` takes the skewness along dimension `dim` of `X`.

`skewness` treats NaNs as missing values and removes them.

## Examples

```
X = randn([5 4])
X =
 1.1650 1.6961 -1.4462 -0.3600
 0.6268 0.0591 -0.7012 -0.1356
 0.0751 1.7971 1.2460 -1.3493
 0.3516 0.2641 -0.6390 -1.2704
 -0.6965 0.8717 0.5774 0.9846
```

```
y = skewness(X)
y =
 -0.2933 0.0482 0.2735 0.4641
```

## More About

### Algorithms

Skewness is a measure of the asymmetry of the data around the sample mean. If skewness is negative, the data are spread out more to the left of the mean than to the right. If skewness is positive, the data are spread out more to the right. The skewness of the normal distribution (or any perfectly symmetric distribution) is zero.

The skewness of a distribution is defined as

$$s = \frac{E(x - \mu)^3}{\sigma^3}$$

where  $\mu$  is the mean of  $x$ ,  $\sigma$  is the standard deviation of  $x$ , and  $E(t)$  represents the expected value of the quantity  $t$ . `skewness` computes a sample version of this population value.

When you set `flag` to 1, the following equation applies:

$$s_1 = \frac{\frac{1}{n} \sum_{i=1}^n (x_i - \bar{x})^3}{\left( \sqrt{\frac{1}{n} \sum_{i=1}^n (x_i - \bar{x})^2} \right)^3}$$

When you set `flag` to 0, the following equation applies:

$$s_0 = \frac{\sqrt{n(n-1)}}{n-2} s_1$$

This bias-corrected formula requires that  $X$  contain at least three elements.

## Skip property

**Class:** grandset

Number of initial points to omit from sequence

### Description

The `Skip` property of a point set contains a positive integer which specifies the number of initial points in the sequence to omit from the point set. The default `Skip` value is 0.

Initial points of a sequence sometimes exhibit undesirable properties, for example the first point is often  $(0, 0, 0, \dots)$  and this may "unbalance" the sequence since its counterpart,  $(1, 1, 1, \dots)$ , never appears. Another common reason is that initial points often exhibit correlations among different dimensions which disappear later in the sequence.

### Examples

Examine the difference between skipping and not skipping points:

```
% No skipping produces the standard Sobol sequence.
P = sobolset(5);
P(1:3,:)
```

```
% Skip the first point of the sequence. The point set now
% starts at the second point of the basic Sobol sequence.
P.Skip = 1;
P(1:3,:)
```

## How To

- “Quasi-Random Point Sets” on page 6-16

## sobolset

**Class:** sobolset

Construct Sobol quasi-random point set

### Syntax

```
p = sobolset(d)
p = sobolset(d,prop1,val1,prop2,val2,...)
```

### Description

`p = sobolset(d)` constructs a  $d$ -dimensional point set `p` of the `sobolset` class, with default property settings.

`p = sobolset(d,prop1,val1,prop2,val2,...)` specifies property name/value pairs used to construct `p`.

The object `p` returned by `sobolset` encapsulates properties of a specified quasi-random sequence. The point set is finite, with a length determined by the `Skip` and `Leap` properties and by limits on the size of point set indices (maximum value of  $2^{53}$ ). Values of the point set are not generated and stored in memory until you access `p` using `net` or parenthesis indexing.

### Examples

Generate a 3-D Sobol point set, skip the first 1000 values, and then retain every 101st point:

```
p = sobolset(3, 'Skip', 1e3, 'Leap', 1e2)
p =
 Sobol point set in 3 dimensions (8.918019e+013 points)
 Properties:
 Skip : 1000
 Leap : 100
 ScrambleMethod : none
 PointOrder : standard
```

Use `scramble` to apply a random linear scramble combined with a random digital shift:

```
p = scramble(p, 'MatousekAffineOwen')
p =
 Sobol point set in 3 dimensions (8.918019e+013 points)
 Properties:
 Skip : 1000
 Leap : 100
 ScrambleMethod : MatousekAffineOwen
 PointOrder : standard
```

Use `net` to generate the first four points:

```
X0 = net(p,4)
X0 =
 0.7601 0.5919 0.9529
 0.1795 0.0856 0.0491
 0.5488 0.0785 0.8483
 0.3882 0.8771 0.8755
```

Use parenthesis indexing to generate every third point, up to the 11th point:

```
X = p(1:3:11,:)
X =
 0.7601 0.5919 0.9529
 0.3882 0.8771 0.8755
 0.6905 0.4951 0.8464
 0.1955 0.5679 0.3192
```

## sortrows

**Class:** dataset

Sort rows of dataset array

## Compatibility

The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

## Syntax

```
B = sortrows(A)
B = sortrows(A,vars)
B = sortrows(A,'obsnames')
B = sortrows(A,vars,mode)
[B,idx] = sortrows(A)
```

## Description

`B = sortrows(A)` returns a copy of the dataset array `A`, with the observations sorted in ascending order by all of the variables in `A`. The observations in `B` are sorted first by the first variable, next by the second variable, and so on. Each variable in `A` must be a valid input to `sort`, or, if a variable has multiple columns, to the MATLAB `sortrows` function or to its own `sortrows` method.

`B = sortrows(A,vars)` sorts the observations in `A` by the variables specified by `vars`. `vars` is a positive integer, a vector of positive integers, variable names, a cell array containing one or more variable names, or a logical vector.

`B = sortrows(A,'obsnames')` sorts the observations in `A` by observation name.

`B = sortrows(A,vars,mode)` sorts in the direction specified by `mode`. When `mode` is the single string `'ascend'` (the default) or `'descend'`, `sortrows` sorts `A` by the

variables specified by `vars` in ascending or descending order, respectively. `mode` can also be a cell array containing the strings `'ascend'` or `'descend'`, to specify a different sorting direction for each variable in `vars`. Specify `[]` for `vars` to sort using all variables.

`[B,idx] = sortrows(A)` also returns an index vector `idx` such that `B = A(idx,:)`.

## Examples

Sort the data in `hospital.mat` by age and then by last name:

```
load hospital
hospital(1:5,1:3)
ans =
 LastName Sex Age
YPL-320 'SMITH' Male 38
GLI-532 'JOHNSON' Male 43
PNI-258 'WILLIAMS' Female 38
MIJ-579 'JONES' Female 40
XLK-030 'BROWN' Female 49
```

```
hospital = sortrows(hospital,{'Age','LastName'});
hospital(1:5,1:3)
ans =
```

```
 LastName Sex Age
REV-997 'ALEXANDER' Male 25
FZR-250 'HALL' Male 25
LIM-480 'HILL' Female 25
XUE-826 'JACKSON' Male 25
SCQ-914 'JAMES' Male 25
```

Sort the data in `hospital` by gender in ascending order, and age in descending order.

```
hospital = sortrows(hospital,{'Sex','Age'},{'ascend','descend'});
hospital(1:5,1:3)
ans =
```

```
 LastName Sex Age
XLK-030 'BROWN' Female 49
GGU-691 'HUGHES' Female 49
KKL-155 'ADAMS' Female 48
HQO-561 'BRYANT' Female 48
BKD-785 'CLARK' Female 48
```

```
hospital(end-4:end,1:3)
ans =
```

|         | LastName    | Sex  | Age |
|---------|-------------|------|-----|
| VNL-702 | 'MOORE'     | Male | 28  |
| REV-997 | 'ALEXANDER' | Male | 25  |
| FZR-250 | 'HALL'      | Male | 25  |
| XUE-826 | 'JACKSON'   | Male | 25  |
| SCQ-914 | 'JAMES'     | Male | 25  |

## squareform

Format distance matrix

### Syntax

```
Z = squareform(y)
y = squareform(Z)
Z = squareform(y, 'tovector')
Y = squareform(Z, 'tomatrix')
```

### Description

`Z = squareform(y)`, where `y` is a vector as created by the `pdist` function, converts `y` into a square, symmetric format `Z`, in which `Z(i, j)` denotes the distance between the `i`th and `j`th objects in the original data.

`y = squareform(Z)`, where `Z` is a square, symmetric matrix with zeros along the diagonal, creates a vector `y` containing the `Z` elements below the diagonal. `y` has the same format as the output from the `pdist` function.

`Z = squareform(y, 'tovector')` forces `squareform` to treat `y` as a vector.

`Y = squareform(Z, 'tomatrix')` forces `squareform` to treat `Z` as a matrix.

The last two formats are useful if the input has a single element, so that it is ambiguous whether the input is a vector or square matrix.

### Examples

```
y = 1:6
y =
 1 2 3 4 5 6

X = [0 1 2 3; 1 0 4 5; 2 4 0 6; 3 5 6 0]
X =
 0 1 2 3
```

```
1 0 4 5
2 4 0 6
3 5 6 0
```

Then `squareform(y) = X` and `squareform(X) = y`.

`pdist`

## stack

**Class:** dataset

Stack data from multiple variables into single variable

## Compatibility

The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

## Syntax

```
tall = stack(wide,datavars)
[tall,iwide] = stack(wide,datavars)
tall = stack(wide,datavars,Parameter,value)
```

## Description

`tall = stack(wide,datavars)` converts a wide-format dataset array into a tall-format array, by stacking multiple variables in `wide` into a single variable in `tall`. In general, `tall` contains fewer variables but more observations than `wide`.

`datavars` specifies a group of `m` data variables in `wide`. `stack` creates a single data variable in `tall` by interleaving their values, and if `wide` has `n` observations, then `tall` has `m`-by-`n` observations. In other words, `stack` takes the `m` data values from each observation in `wide` and stacks them up to create `m` observations in `tall`. `datavars` is a positive integer, a vector of positive integers, a variable name, a cell array containing one or more variable names, or a logical vector. `stack` also creates a grouping variable in `tall` to indicate which of the `m` data variables in `wide` each observation in `tall` corresponds to.

`stack` assigns values for the "per-variable properties (e.g., `Units` and `VarDescription`) for the new data variable in `tall` from the corresponding property values for the first variable listed in `datavars`.

`stack` copies the remaining variables from `wide` to `tall` without stacking, by replicating each of their values `m` times. These variables are typically grouping variables. Because their values are constant across each group of `m` observations in `tall`, they identify which observation in `wide` an observation in `tall` came from.

`[tall,iwide] = stack(wide,datavars)` returns an index vector `iwide` indicating the correspondence between observations in `tall` and those in `wide`. `stack` creates `tall(j,:)` using `wide(iwide(j),datavars)`.

For more information on grouping variables, see “Grouping Variables” on page 2-52.

## Input Arguments

`tall = stack(wide,datavars,Parameter,value)` uses the following parameter name/value pairs to control how `stack` converts variables in `wide` to variables in `tall`:

|                  |                                                                                                                                                                                                                                                                                                                                                 |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'ConstVars'      | Variables in <code>wide</code> to copy to <code>tall</code> without stacking. <code>ConstVars</code> is a positive integer, a vector of positive integers, a variable name, a cell array containing one or more variable names, or a logical vector. The default is all variables in <code>wide</code> not specified in <code>datavars</code> . |
| 'NewDataVarName' | A name for the data variable to be created in <code>tall</code> . The default is a concatenation of the names of the <code>m</code> variables that are stacked up.                                                                                                                                                                              |
| 'IndVarName'     | A name for the grouping variable to create in <code>tall</code> to indicate the source of each value in the new data variable. The default is based on the 'NewDataVarName' parameter.                                                                                                                                                          |

You can also specify multiple groups of data variables in `wide`, each of which becomes a variable in `tall`. All groups must contain the same number of variables. Use a cell array to contain multiple parameter values for `datavars`, and a cell array of strings to contain multiple 'NewDataVarName'.

## Examples

Convert a wide format data set to tall format, and then back to a different wide format:

```
load flu

% FLU has a 'Date' variable, and 10 variables for estimated
% influenza rates (in 9 different regions, estimated from
% Google searches, plus a nationwide estimate from the
% CDC). Combine those 10 variables into a "tall" array that
% has a single data variable, 'FluRate', and an indicator
% variable, 'Region', that says which region each estimate
% is from.
[flu2,iflu] = stack(flu, 2:11, 'NewDataVarName','FluRate', ...
 'IndVarName','Region')

% The second observation in FLU is for 10/16/2005. Find the
% observations in FLU2 that correspond to that date.
flu2(2,:)
flu2(iflu==2,:)

% Use the 'Date' variable from that tall array to split
% 'FluRate' into 52 separate variables, each containing the
% estimated influenza rates for each unique date. The new
% "wide" array has one observation for each region. In
% effect, this is the original array FLU "on its side".
dateNames = cellstr(datestr(flu.Date,'mmm_DD_YYYY'));
[flu3,iflu2] = unstack(flu2, 'FluRate', 'Date', ...
 'NewDataVarNames',dateNames)

% Since observations in FLU3 represent regions, IFLU2
% indicates the first occurrence in FLU2 of each region.
flu2(iflu2,:)
```

## How To

- “Grouping Variables” on page 2-52

## State property

**Class:** grandstream

Current state of the stream

### Description

The **State** property of a quasi-random stream contains the index into the associated point set of the next point to draw in the stream. Getting and resetting the **State** property allows you to return a stream to a previous state. The initial value of **State** is 1.

### Examples

```
Q = grandstream('sobol', 5);
s = Q.State;
u1 = grand(Q, 10)
Q.State = s;
u2 = grand(Q, 10) % contains exactly the same values as u1
```

### See Also

grand

## statget

Access values in statistics options structure

### Syntax

```
val = statget(options,param)
val = statget(options,param,default)
```

### Description

`val = statget(options,param)` returns the value of the parameter specified by the string `param` in the statistics options structure `options`. If the parameter is undefined in `options`, `statget` returns `[]`. You need to type only enough leading characters to define the parameter name uniquely. `statget` ignores case for parameter names. For available `options`, see `Inputs`.

`val = statget(options,param,default)` returns `default` if the specified parameter is undefined in the optimization options structure `options`.

## Input Arguments

### DerivStep

Relative difference used in finite difference derivative calculations. A positive scalar, or a vector of positive scalars the same size as the vector of parameters estimated by the Statistics Toolbox function using the options structure.

### Display

Amount of information displayed by the algorithm.

- `'off'` — Displays no information.
- `'final'` — Displays the final output.
- `'iter'` — Displays iterative output to the command window for some functions; otherwise displays the final output.

**FunValCheck**

Check for invalid values, such as NaN or Inf, from the objective function.

- 'off'
- 'on'

**GradObj**

Flags whether the objective function returns a gradient vector as a second output.

- 'off'
- 'on'

**Jacobian**

Flags whether the objective function returns a Jacobian as a second output.

- 'off'
- 'on'

**MaxFunEvals**

Maximum number of objective function evaluations allowed. Positive integer.

**MaxIter**

Maximum number of iterations allowed. Positive integer.

**OutputFcn**

The solver calls all output functions after each iteration.

- Function handle specified using @
- a cell array with function handles
- an empty array (default)

**Robust**

Invoke robust fitting option.

- 'off'

- 'on'

**RobustWgtFun**

A weight function for robust fitting. Valid only when `Robust` is 'on'. Can also be a function handle that accepts a normalized residual as input and returns the robust weights as output.

- 'bisquare'
- 'andrews'
- 'cauchy'
- 'fair'
- 'huber'
- 'logistic'
- 'talwar'
- 'welsch'

**Streams**

A single instance of the `RandStream` class, or a cell array of `RandStream` instances. The `Streams` option is accepted by some functions to govern what stream(s) to use in generating random numbers within the function. If 'UseSubstreams' is true, the `Streams` value must be a scalar, or must be empty. If 'UseParallel' is true and 'UseSubstreams' is false, then the `Streams` argument must either be empty, or its length must match the number of processors used in the computation: equal to the *parpool* size if a *parpool* is open, a scalar otherwise.

**TolBnd**

Parameter bound tolerance. Positive scalar.

**TolFun**

Termination tolerance for the objective function value. Positive scalar.

**TolTypeFun**

Use `TolFun` for absolute or relative objective function tolerances.

- 'abs'

- 'rel'

### **TolTypeX**

Use TolX for absolute or relative parameter tolerances.

- 'abs'
- 'rel'

### **TolX**

Termination tolerance for the parameters. Positive scalar.

### **Tune**

The tuning constant used in robust fitting to normalize the residuals before applying the weight function. The default value depends upon the weight function. This parameter is necessary if you specify the weight function as a function handle. Positive scalar.

### **UseParallel**

Flag indicating whether eligible functions should use capabilities of the Parallel Computing Toolbox (PCT), if the capabilities are available. That is, if the PCT is installed, and a PCT parpool is in effect. Valid values are `false` (the default), for serial computation, and `true`, for parallel computation.

### **UseSubstreams**

Flag indicating whether the random number generator in eligible functions should use `Substream` property of the `RandStream` class. `false` (default) or `true`. When `true`, high level iterations within the function will set the `Substream` property to the value of the iteration. This behavior helps to generate reproducible random number streams in parallel and/or serial mode computation.

### **WgtFun**

A weight function for robust fitting. Valid only when `Robust` is 'on'. Can also be a function handle that accepts a normalized residual as input and returns the robust weights as output.

- 'bisquare'
- 'andrews'

- 'cauchy'
- 'fair'
- 'huber'
- 'logistic'
- 'talwar'
- 'welsch'

## Examples

This statement returns the value of the `Display` statistics options parameter from the structure called `my_options`.

```
val = statget(my_options, 'Display')
```

Return the value of the `Display` statistics options parameter from the structure called `my_options` (as in the previous example). If the `Display` parameter is undefined, `statget` returns the value `'final'`.

```
optnew = statget(my_options, 'Display', 'final');
```

## See Also

`statset`

## statset

Create statistics options structure

### Syntax

```
statset
statset(statfun)
options = statset(...)
options = statset(fieldname1,val1,fieldname2,val2,...)
options = statset(oldopts,fieldname1,val1,fieldname2,val2,...)
options = statset(oldopts,newopts)
```

### Description

`statset` with no input arguments and no output arguments displays all fields of a statistics options structure and their possible values.

`statset(statfun)` displays fields and default values used by the Statistics Toolbox function `statfun`. Specify `statfun` using a string name or a function handle.

`options = statset(...)` creates a statistics options structure `options`. With no input arguments, all fields of the options structure are an empty array (`[]`). With a specified `statfun`, function-specific fields are default values and the remaining fields are `[]`. Function-specific fields set to `[]` indicate that the function is to use its default value for that parameter. For available options, see Inputs.

`options = statset(fieldname1,val1,fieldname2,val2,...)` creates an options structure in which the named fields have the specified values. Any unspecified values are `[]`. Use strings for field names. For fields that are string-valued, you must input the complete string for the value. If you provide an invalid string for a value, `statset` uses the default.

`options = statset(oldopts,fieldname1,val1,fieldname2,val2,...)` creates a copy of `oldopts` with the named parameters changed to the specified values.

`options = statset(oldopts,newopts)` combines an existing options structure, `oldopts`, with a new options structure, `newopts`. Any parameters in `newopts` with nonempty values overwrite corresponding parameters in `oldopts`.

## Input Arguments

### **DerivStep**

Relative difference used in finite difference derivative calculations. A positive scalar, or a vector of positive scalars the same size as the vector of parameters estimated by the Statistics Toolbox function using the options structure.

### **Display**

Amount of information displayed by the algorithm.

- 'off' — Displays no information.
- 'final' — Displays the final output.
- 'iter' — Displays iterative output to the command window for some functions; otherwise displays the final output.

### **FunValCheck**

Check for invalid values, such as NaN or Inf, from the objective function.

- 'off'
- 'on'

### **GradObj**

Flags whether the objective function returns a gradient vector as a second output.

- 'off'
- 'on'

### **Jacobian**

Flags whether the objective function returns a Jacobian as a second output.

- 'off'
- 'on'

### **MaxFunEvals**

Maximum number of objective function evaluations allowed. Positive integer.

### **MaxIter**

Maximum number of iterations allowed. Positive integer.

### **OutputFcn**

The solver calls all output functions after each iteration.

- Function handle specified using @
- a cell array with function handles
- an empty array (default)

### **Robust**

Invoke robust fitting option.

- 'off'
- 'on'

**Robust** will be removed in a future software release. Use **RobustWgtFun** for robust fitting.

### **RobustWgtFun**

Weight function for robust fitting. Can also be a function handle that accepts a normalized residual as input and returns the robust weights as output. If you use a function handle, give a **Tune** constant. See “Robust Options” on page 21-4142.

### **Streams**

A single instance of the **RandStream** class, or a cell array of **RandStream** instances. The **Streams** option is accepted by some functions to govern what stream(s) to use in generating random numbers within the function. If **'UseSubstreams'** is **true**, the **Streams** value must be a scalar, or must be empty. If **'UseParallel'** is **true** and **'UseSubstreams'** is **false**, then the **Streams** argument must either be empty, or its length must match the number of processors used in the computation: equal to the *parpool* size if a *parpool* is open, a scalar otherwise.

### **TolBnd**

Parameter bound tolerance. Positive scalar.

**TolFun**

Termination tolerance for the objective function value. Positive scalar.

**TolTypeFun**

Use `TolFun` for absolute or relative objective function tolerances.

- 'abs'
- 'rel'

**TolTypeX**

Use `TolX` for absolute or relative parameter tolerances.

- 'abs'
- 'rel'

**TolX**

Termination tolerance for the parameters. Positive scalar.

**Tune**

Tuning constant used in robust fitting to normalize the residuals before applying the weight function. The default value depends upon the weight function. This parameter is necessary if you specify the weight function as a function handle. Positive scalar. See “Robust Options” on page 21-4142.

**UseParallel**

Flag indicating whether eligible functions should use capabilities of the Parallel Computing Toolbox (PCT), if the capabilities are available. That is, if the PCT is installed, and a PCT parpool is in effect. Valid values are `false` (the default), for serial computation, and `true`, for parallel computation.

**UseSubstreams**

Flag indicating whether the random number generator in eligible functions should use `Substream` property of the `RandStream` class. `false` (default) or `true`. When `true`, high level iterations within the function will set the `Substream` property to the value of the iteration. This behavior helps to generate reproducible random number streams in parallel and/or serial mode computation.

## WgtFun

Weight function for robust fitting. Valid only when `Robust` is `'on'`. Can also be a function handle that accepts a normalized residual as input and returns the robust weights as output. See “Robust Options” on page 21-4142.

`WgtFun` will be removed in a future software release. Use `RobustWgtFun` instead.

## Examples

Suppose you want to change the default parameter values for the function `evfit`, which fits an extreme value distribution to data. The defaults parameter values are:

```
statset('evfit')
ans =
 Display: 'off'
 MaxFunEvals: []
 MaxIter: []
 TolBnd: []
 TolFun: []
 TolTypeFun: []
 TolX: 1.0000e-06
 TolTypeX: []
 GradObj: []
 Jacobian: []
 DerivStep: []
 FunValCheck: []
 Robust: []
 RobustWgtFun: []
 WgtFun: []
 Tune: []
 UseParallel: []
 UseSubstreams: []
 Streams: []
 OutputFcn: []
```

The only parameters that `evfit` uses are `Display` and `TolX`. To create an options structure with the value of `TolX` set to `1e-8`, enter:

```
options = statset('TolX',1e-8)
% Pass options to evfit:
mu = 1;
```

```
sigma = 1;
data = evrnd(mu,sigma,1,100);

paramhat = evfit(data,[],[],[],options)
```

## More About

### Robust Options

| Weight Function         | Equation                                    | Default Tuning Constant |
|-------------------------|---------------------------------------------|-------------------------|
| 'andrews'               | $w = (\text{abs}(r) < \pi) .* \sin(r) ./ r$ | 1.339                   |
| 'bisquare'<br>(default) | $w = (\text{abs}(r) < 1) .* (1 - r.^2).^2$  | 4.685                   |
| 'cauchy'                | $w = 1 ./ (1 + r.^2)$                       | 2.385                   |
| 'fair'                  | $w = 1 ./ (1 + \text{abs}(r))$              | 1.400                   |
| 'huber'                 | $w = 1 ./ \max(1, \text{abs}(r))$           | 1.345                   |
| 'logistic'              | $w = \tanh(r) ./ r$                         | 1.205                   |
| 'talwar'                | $w = 1 * (\text{abs}(r) < 1)$               | 2.795                   |
| 'welsch'                | $w = \exp(-(r.^2))$                         | 2.985                   |
| []                      | No robust fitting                           | —                       |

statget

## std

**Class:** prob.KernelDistribution

**Package:** prob

Standard deviation of probability distribution object

## Syntax

```
s = std(pd)
```

## Description

`s = std(pd)` returns the standard deviation `s` of the probability distribution `pd`.

## Input Arguments

**pd** — Probability distribution

probability distribution object

Probability distribution, specified as a probability distribution object. Fit a probability distribution object to data using `fitdist` or the Distribution Fitting app.

## Output Arguments

**s** — Standard deviation

nonnegative scalar value

Standard deviation of the probability distribution, returned as a nonnegative scalar value.

## Examples

### Standard Deviation of a Fitted Distribution

Load the sample data. Create a vector containing the first column of students' exam grade data.

```
load examgrades;
x = grades(:,1);
```

Create a probability distribution object by fitting a kernel distribution to the data.

```
pd = fitdist(x, 'Kernel')
```

```
pd =
```

```
KernelDistribution
```

```
Kernel = normal
Bandwidth = 3.61677
Support = unbounded
```

Compute the standard deviation of the fitted distribution.

```
s = std(pd)
```

```
s =
```

```
9.4069
```

## std

**Class:** ProbDistUnivParam

Return standard deviation of ProbDistUnivParam object

## Syntax

$S = \text{std}(PD)$

## Description

$S = \text{std}(PD)$  returns  $S$ , the standard deviation of the ProbDistUnivParam object  $PD$ .

## Input Arguments

$PD$                       An object of the class ProbDistUnivParam.

## Output Arguments

$S$                               The standard deviation of the ProbDistUnivParam object  $PD$ .

## See Also

std

## **std**

**Class:** `prob.ParametricTruncatableDistribution`

**Package:** `prob`

Standard deviation of probability distribution object

## **Syntax**

```
s = std(pd)
```

## **Description**

`s = std(pd)` returns the standard deviation `s` of the probability distribution `pd`.

## **Input Arguments**

**pd** — **Probability distribution**

probability distribution object

Probability distribution, specified as a probability distribution object. Create a probability distribution object with specified parameter values using `makedist`.

## **Output Arguments**

**s** — **Standard deviation**

nonnegative scalar value

Standard deviation of the probability distribution, returned as a nonnegative scalar value.

## **Examples**

### **Standard Deviation of a Triangular Distribution**

Create a triangular distribution object.

```
pd = makedist('Triangular', 'a', -3, 'b', 1, 'c', 3)
```

```
pd =
```

```
 TriangularDistribution
```

```
A = -3, B = 1, C = 3
```

Compute the standard deviation of the distribution.

```
s = std(pd)
```

```
s =
```

```
 1.2472
```

## See Also

makedist

## std

**Class:** prob.ToolboxFittableParametricDistribution

**Package:** prob

Standard deviation of probability distribution object

## Syntax

```
s = std(pd)
```

## Description

`s = std(pd)` returns the standard deviation `s` of the probability distribution `pd`.

## Input Arguments

**pd** — Probability distribution

probability distribution object

Probability distribution, specified as a probability distribution object. Create a probability distribution object with specified parameter values using `makedist`. Alternatively, create a probability distribution object by fitting it to data using `fitdist` or the Distribution Fitting app.

## Output Arguments

**s** — Standard deviation

nonnegative scalar value

Standard deviation of the probability distribution, returned as a nonnegative scalar value.

## Examples

### Standard Deviation of a Fitted Distribution

Load the sample data. Create a vector containing the first column of students' exam grade data.

```
load examgrades;
x = grades(:,1);
```

Fit a normal distribution object to the data.

```
pd = fitdist(x,'Normal')

pd =

NormalDistribution

Normal distribution
mu = 75.0083 [73.4321, 76.5846]
sigma = 8.7202 [7.7391, 9.98843]
```

Compute the standard deviation of the fitted distribution.

```
s = std(pd)

s =

8.7202
```

For a normal distribution, the standard deviation is equal to the parameter `sigma`.

### Standard Deviation of a Skewed Distribution

Create a Weibull probability distribution object

```
pd = makedist('Weibull','a',5,'b',2)

pd =

WeibullDistribution

Weibull distribution
A = 5
B = 2
```

Compute the standard deviation of the distribution.

```
s = std(pd)
```

```
s =
 2.3163
```

## step

**Class:** GeneralizedLinearModel

Improve generalized linear regression model by adding or removing terms

## Syntax

```
mdl1 = step(mdl)
mdl1 = step(mdl,Name,Value)
```

## Description

`mdl1 = step(mdl)` returns an improved generalized linear model based on `mdl`, with one predictor added or removed.

`mdl1 = step(mdl,Name,Value)` improves a generalized linear model with additional options specified by one or more `Name,Value` pair arguments.

## Tips

- Use `addTerms` or `removeTerms` to control exactly which terms enter or leave the model.

## Input Arguments

**mdl** — Generalized linear model

GeneralizedLinearModel object

Generalized linear model representing a least-squares fit of the link of the response to the data, returned as a `GeneralizedLinearModel` object.

For properties and methods of the generalized linear model object, `mdl`, see the `GeneralizedLinearModel` class page.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

### 'Criterion' — Criterion to add or remove terms

`'Deviance'` | `'sse'` | `'aic'` | `'bic'` | `'rsquared'` | `'adjrsquared'`

Criterion to add or remove terms, specified as the comma-separated pair consisting of `'Criterion'` and one of the following:

- `'Deviance'` — Default for `stepwiseglm`.  $p$ -value for  $F$  or chi-squared test of the change in the deviance by adding or removing the term.  $F$ -test is for testing a single model. Chi-squared test is for comparing two different models. This option is not valid for `stepwiselm`.
- `'sse'` — Default for `stepwiselm`.  $p$ -value for an  $F$ -test of the change in the sum of squared error by adding or removing the term.
- `'aic'` — Change in the value of Akaike information criterion (AIC).
- `'bic'` — Change in the value of Bayesian information criterion (BIC).
- `'rsquared'` — Increase in the value of  $R^2$ .
- `'adjrsquared'` — Increase in the value of adjusted  $R^2$ .

Example: `'Criterion', 'bic'`

### 'Lower' — Model specification describing terms that cannot be removed from model

`'constant'` (default)

Model specification describing terms that cannot be removed from the model, specified as the comma-separated pair consisting of `'Lower'` and one of the string options for `modelspec` naming the model.

Example: `'Lower', 'linear'`

### 'NSteps' — Number of steps to take

1 (default) | positive integer

Number of steps to take, specified as the comma-separated pair consisting of `'NSteps'` and a positive integer.

Data Types: `single` | `double`

### 'PEnter' — Improvement measure for adding term

scalar value

Improvement measure for adding a term, specified as the comma-separated pair consisting of 'PEnter' and a scalar value. The default values are below.

| Criterion     | Default value | Decision                                                                                                 |
|---------------|---------------|----------------------------------------------------------------------------------------------------------|
| 'Deviance'    | 0.05          | If the $p$ -value of $F$ or chi-squared statistic is smaller than PEnter, add the term to the model.     |
| 'SSE'         | 0.05          | If the SSE of the model is smaller than PEnter, add the term to the model.                               |
| 'AIC'         | 0             | If the change in the AIC of the model is smaller than PEnter, add the term to the model.                 |
| 'BIC'         | 0             | If the change in the BIC of the model is smaller than PEnter, add the term to the model.                 |
| 'Rsquared'    | 0.1           | If the increase in the R-squared of the model is larger than PEnter, add the term to the model.          |
| 'AdjRsquared' | 0             | If the increase in the adjusted R-squared of the model is larger than PEnter, add the term to the model. |

For more information on the criteria, see Criterion name-value pair argument.

Example: 'PEnter',0.075

### 'PRemove' — Improvement measure for removing term

scalar value

Improvement measure for removing a term, specified as the comma-separated pair consisting of 'PRemove' and a scalar value.

| Criterion     | Default value | Decision                                                                                                              |
|---------------|---------------|-----------------------------------------------------------------------------------------------------------------------|
| 'Deviance'    | 0.10          | If the $p$ -value of $F$ or chi-squared statistic is larger than PRemove, remove the term from the model.             |
| 'SSE'         | 0.10          | If the $p$ -value of the $F$ statistic is larger than PRemove, remove the term from the model.                        |
| 'AIC'         | 0.01          | If the change in the AIC of the model is larger than PRemove, remove the term from the model.                         |
| 'BIC'         | 0.01          | If the change in the BIC of the model is larger than PRemove, remove the term from the model.                         |
| 'Rsquared'    | 0.05          | If the increase in the R-squared value of the model is smaller than PRemove, remove the term from the model.          |
| 'AdjRsquared' | -0.05         | If the increase in the adjusted R-squared value of the model is smaller than PRemove, remove the term from the model. |

At each step, stepwise algorithm also checks whether any term is redundant (linearly dependent) with other terms in the current model. When any term is linearly dependent with other terms in the current model, it is removed, regardless of the criterion value.

For more information on the criteria, see Criterion name-value pair argument.

Example: 'PRemove', 0.05

**'Upper' — Model specification describing largest set of terms in fit**`'interaction' (default) | string`

Model specification describing the largest set of terms in the fit, specified as the comma-separated pair consisting of 'Upper' and one of the string options for `modelspec` naming the model.

Example: `'Upper', 'quadratic'`

**'Verbose' — Control for display of information**`1 (default) | 0 | 2`

Control for display of information, specified as the comma-separated pair consisting of 'Verbose' and one of the following:

- 0 — Suppress all display.
- 1 — Display the action taken at each step.
- 2 — Also display the actions evaluated at each step.

Example: `'Verbose', 2`

## Output Arguments

**mdl1**

Linear model, the same as `mdl` but with additional terms given in `terms`. You can set `mdl1` equal to `mdl` to overwrite `mdl`.

## Examples

**Add Predictors One at a Time**

Fit a Poisson regression model using random data and a single predictor, then step in other predictors.

Generate artificial data with 20 predictors, using three of the predictors for the responses.

```
rng('default') % for reproducibility
X = randn(100,20);
```

```
mu = exp(X(:, [5 10 15]) * [.4; .2; .3] + 1);
y = poissrnd(mu);
```

Construct a generalized linear model using  $X(:, 1)$  as the only predictor.

```
mdl = fitglm(X, y, ...
 'y ~ x1', 'Distribution', 'poisson')
```

```
mdl =
```

```
Generalized Linear regression model:
log(y) ~ 1 + x1
Distribution = Poisson
```

```
Estimated Coefficients:
```

|             | Estimate | SE       | tStat  | pValue     |
|-------------|----------|----------|--------|------------|
| (Intercept) | 1.1278   | 0.057487 | 19.618 | 1.0904e-85 |
| x1          | 0.061287 | 0.04848  | 1.2642 | 0.20617    |

```
100 observations, 98 error degrees of freedom
```

```
Dispersion: 1
```

```
Chi^2-statistic vs. constant model: 1.59, p-value = 0.208
```

Add a variable to the model using `step`.

```
mdl1 = step(mdl)
```

```
1. Adding x5, Deviance = 134.2976, Chi2Stat = 50.80176, PValue = 1.021821e-12
```

```
mdl1 =
```

```
Generalized Linear regression model:
log(y) ~ 1 + x1 + x5
Distribution = Poisson
```

```
Estimated Coefficients:
```

|             | Estimate | SE       | tStat   | pValue     |
|-------------|----------|----------|---------|------------|
| (Intercept) | 1.0418   | 0.062341 | 16.712  | 1.07e-62   |
| x1          | 0.018803 | 0.049916 | 0.37671 | 0.70639    |
| x5          | 0.47881  | 0.067875 | 7.0542  | 1.7357e-12 |

```
100 observations, 97 error degrees of freedom
```

```
Dispersion: 1
```

```
Chi^2-statistic vs. constant model: 52.4, p-value = 4.21e-12
```

Add another variable to the model using `step`.

```
mdl1 = step(mdl1)
```

```

## Algorithms

*Stepwise regression* is a systematic method for adding and removing terms from a linear or generalized linear model based on their statistical significance in explaining the response variable. The method begins with an initial model, specified using `modelspec`, and then compares the explanatory power of incrementally larger and smaller models.

MATLAB uses forward and backward stepwise regression to determine a final model. At each step, the method searches for terms to add to or remove from the model based on the value of the 'Criterion' argument. The default value of 'Criterion' is 'sse', and in this case, `stepwiselm` uses the  $p$ -value of an  $F$ -statistic to test models with and without a potential term at each step. If a term is not currently in the model, the null hypothesis is that the term would have a zero coefficient if added to the model. If there is sufficient evidence to reject the null hypothesis, the term is added to the model. Conversely, if a term is currently in the model, the null hypothesis is that the term has a zero coefficient. If there is insufficient evidence to reject the null hypothesis, the term is removed from the model.

Here is how stepwise proceeds when 'Criterion' is 'sse':

- 1 Fit the initial model.
- 2 If any terms not in the model have  $p$ -values less than an entrance tolerance (that is, if it is unlikely that they would have zero coefficient if added to the model), add the one with the smallest  $p$ -value and repeat this step; otherwise, go to step 3.
- 3 If any terms in the model have  $p$ -values greater than an exit tolerance (that is, the hypothesis of a zero coefficient can be rejected), remove the one with the largest  $p$ -value and go to step 2; otherwise, end.

The default for `stepwiseglm` is 'Deviance' and it follows a similar procedure for adding or removing terms.

There are several other criteria available, which you can specify using the 'Criterion' argument. You can use the change in the value of the Akaike information criterion, Bayesian information criterion, R-squared, adjusted R-squared as a criterion to add or remove terms.

Depending on the terms included in the initial model and the order in which terms are moved in and out, the method might build different models from the same set of potential terms. The method terminates when no single step improves the model. There is no guarantee, however, that a different initial model or a different sequence of steps will not lead to a better fit. In this sense, stepwise models are locally optimal, but might not be globally optimal.

## Alternatives

Use `stepwiseglm` to select a model from a starting model, continuing until no single step is beneficial.

Use `addTerms` or `removeTerms` to add or remove particular terms.

## step

**Class:** LinearModel

Improve linear regression model by adding or removing terms

## Syntax

```
mdl1 = step(mdl)
mdl1 = step(mdl,Name,Value)
```

## Description

`mdl1 = step(mdl)` returns an improved linear model based on `mdl`, with one predictor added or removed.

---

**Note:** You can use `step` only if `mdl.Robust = []`. This holds when you create `mdl` with `fitlm` having the `RobustOpts` name-value pair set to the default `'off'`.

---

`mdl1 = step(mdl,Name,Value)` improves a linear model with additional options specified by one or more `Name,Value` pair arguments.

## Input Arguments

**mdl**

Linear model, as constructed by `fitlm` or `stepwiselm`.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**'Criterion' — Criterion for selecting terms to add or remove**

'SSE' (default)

Criterion for selecting terms to add or remove, specified as the comma-separated pair consisting of 'Criterion' and one of the following.

| Criterion     | PEnter | PRemove | Compared Against               |
|---------------|--------|---------|--------------------------------|
| 'SSE'         | 0.05   | < 0.1   | $p$ -value for $F$ test        |
| 'AIC'         | 0      | < 0.01  | Change in AIC                  |
| 'BIC'         | 0      | < 0.01  | Change in BIC                  |
| 'Rsquared'    | 0.1    | > 0.05  | Increase in R-squared          |
| 'AdjRsquared' | 0      | > -0.05 | Increase in adjusted R-squared |

Example: 'Criterion', 'BIC'

**'Lower' — Model specification describing terms that cannot be removed from model**

'constant' (default)

Model specification describing terms that cannot be removed from the model, specified as the comma-separated pair consisting of 'Lower' and one of the string options for modelspec naming the model.

Example: 'Lower', 'linear'

**'NSteps' — Number of steps to take**

1 (default) | positive integer

Number of steps to take, specified as the comma-separated pair consisting of 'NSteps' and a positive integer.

Data Types: single | double

**'PEnter' — Improvement measure for adding term**

scalar value

Improvement measure for adding a term, specified as the comma-separated pair consisting of 'PEnter' and a scalar value. The default values are below.

| Criterion  | Default value | Decision                                                     |
|------------|---------------|--------------------------------------------------------------|
| 'Deviance' | 0.05          | If the $p$ -value of $F$ or chi-squared statistic is smaller |

| Criterion     | Default value | Decision                                                                                                               |
|---------------|---------------|------------------------------------------------------------------------------------------------------------------------|
|               |               | than <code>PEnter</code> , add the term to the model.                                                                  |
| 'SSE'         | 0.05          | If the SSE of the model is smaller than <code>PEnter</code> , add the term to the model.                               |
| 'AIC'         | 0             | If the change in the AIC of the model is smaller than <code>PEnter</code> , add the term to the model.                 |
| 'BIC'         | 0             | If the change in the BIC of the model is smaller than <code>PEnter</code> , add the term to the model.                 |
| 'Rsquared'    | 0.1           | If the increase in the R-squared of the model is larger than <code>PEnter</code> , add the term to the model.          |
| 'AdjRsquared' | 0             | If the increase in the adjusted R-squared of the model is larger than <code>PEnter</code> , add the term to the model. |

For more information on the criteria, see Criterion name-value pair argument.

Example: `'PEnter', 0.075`

### 'PRemove' — Improvement measure for removing term

scalar value

Improvement measure for removing a term, specified as the comma-separated pair consisting of `'PRemove'` and a scalar value.

| Criterion  | Default value | Decision                                                                                                                |
|------------|---------------|-------------------------------------------------------------------------------------------------------------------------|
| 'Deviance' | 0.10          | If the $p$ -value of $F$ or chi-squared statistic is larger than <code>PRemove</code> , remove the term from the model. |

| Criterion     | Default value | Decision                                                                                                                      |
|---------------|---------------|-------------------------------------------------------------------------------------------------------------------------------|
| 'SSE'         | 0.10          | If the $p$ -value of the F statistic is larger than <b>PRemove</b> , remove the term from the model.                          |
| 'AIC'         | 0.01          | If the change in the AIC of the model is larger than <b>PRemove</b> , remove the term from the model.                         |
| 'BIC'         | 0.01          | If the change in the BIC of the model is larger than <b>PRemove</b> , remove the term from the model.                         |
| 'Rsquared'    | 0.05          | If the increase in the R-squared value of the model is smaller than <b>PRemove</b> , remove the term from the model.          |
| 'AdjRsquared' | -0.05         | If the increase in the adjusted R-squared value of the model is smaller than <b>PRemove</b> , remove the term from the model. |

At each step, stepwise algorithm also checks whether any term is redundant (linearly dependent) with other terms in the current model. When any term is linearly dependent with other terms in the current model, it is removed, regardless of the criterion value.

For more information on the criteria, see Criterion name-value pair argument.

Example: 'PRemove', 0.05

### 'Upper' — Model specification describing largest set of terms in fit

'interaction' (default) | string

Model specification describing the largest set of terms in the fit, specified as the comma-separated pair consisting of 'Upper' and one of the string options for modelspec naming the model.

Example: 'Upper', 'quadratic'

**'Verbose' — Control for display of information**

1 (default) | 0 | 2

Control for display of information, specified as the comma-separated pair consisting of 'Verbose' and one of the following:

- 0 — Suppress all display.
- 1 — Display the action taken at each step.
- 2 — Also display the actions evaluated at each step.

Example: 'Verbose',2

## Output Arguments

**mdl1**

Linear model. Typically you set `mdl1` equal to `mdl`.

## Examples

**Modify a Linear Model**

Fit a linear model to car data. Use `step` to see if a quadratic model would help the fit quality.

Load `carsmall` data, and make a dataset from weight and model year predictors with MPG response.

```
load carsmall
ds = dataset(MPG,Weight);
ds.Year = ordinal(Model_Year);
```

Make a linear model of MPG as a function of Year and Weight.

```
mdl = fitlm(ds,'MPG ~ Year + Weight')
```

```
mdl =
```

```
Linear regression model:
MPG ~ 1 + Weight + Year
```

```
Estimated Coefficients:
 Estimate SE tStat pValue
```

|             |            |            |         |            |
|-------------|------------|------------|---------|------------|
| (Intercept) | 40.11      | 1.5418     | 26.016  | 1.2024e-43 |
| Weight      | -0.0066475 | 0.00042802 | -15.531 | 3.3639e-27 |
| Year_76     | 1.9291     | 0.74761    | 2.5804  | 0.011488   |
| Year_82     | 7.9093     | 0.84975    | 9.3078  | 7.8681e-15 |

Number of observations: 94, Error degrees of freedom: 90  
 Root Mean Squared Error: 2.92  
 R-squared: 0.873, Adjusted R-Squared 0.868  
 F-statistic vs. constant model: 206, p-value = 3.83e-40

Use `step` to adjust the model to potentially include full quadratic terms.

```
mdl1 = step(mdl, 'upper', 'quadratic')
```

```
1. Adding Weight^2, FStat = 9.9164, pValue = 0.0022303
```

```
mdl1 =
```

```
Linear regression model:
MPG ~ 1 + Weight + Year + Weight^2
```

```
Estimated Coefficients:
```

|             | Estimate   | SE         | tStat   | pValue     |
|-------------|------------|------------|---------|------------|
| (Intercept) | 54.206     | 4.7117     | 11.505  | 2.6648e-19 |
| Weight      | -0.016404  | 0.0031249  | -5.2493 | 1.0283e-06 |
| Year_76     | 2.0887     | 0.71491    | 2.9215  | 0.0044137  |
| Year_82     | 8.1864     | 0.81531    | 10.041  | 2.6364e-16 |
| Weight^2    | 1.5573e-06 | 4.9454e-07 | 3.149   | 0.0022303  |

Number of observations: 94, Error degrees of freedom: 89  
 Root Mean Squared Error: 2.78  
 R-squared: 0.885, Adjusted R-Squared 0.88  
 F-statistic vs. constant model: 172, p-value = 5.52e-41

## Algorithms

*Stepwise regression* is a systematic method for adding and removing terms from a linear or generalized linear model based on their statistical significance in explaining the response variable. The method begins with an initial model, specified using `modelspec`, and then compares the explanatory power of incrementally larger and smaller models.

MATLAB uses forward and backward stepwise regression to determine a final model. At each step, the method searches for terms to add to or remove from the model based on the value of the 'Criterion' argument. The default value of 'Criterion' is 'sse', and in this case, `stepwiselm` uses the  $p$ -value of an  $F$ -statistic to test models with and without a potential term at each step. If a term is not currently in the model, the null hypothesis is that the term would have a zero coefficient if added to the model. If

there is sufficient evidence to reject the null hypothesis, the term is added to the model. Conversely, if a term is currently in the model, the null hypothesis is that the term has a zero coefficient. If there is insufficient evidence to reject the null hypothesis, the term is removed from the model.

Here is how stepwise proceeds when 'Criterion' is 'sse':

- 1 Fit the initial model.
- 2 If any terms not in the model have  $p$ -values less than an entrance tolerance (that is, if it is unlikely that they would have zero coefficient if added to the model), add the one with the smallest  $p$ -value and repeat this step; otherwise, go to step 3.
- 3 If any terms in the model have  $p$ -values greater than an exit tolerance (that is, the hypothesis of a zero coefficient can be rejected), remove the one with the largest  $p$ -value and go to step 2; otherwise, end.

The default for `stepwiseglm` is 'Deviance' and it follows a similar procedure for adding or removing terms.

There are several other criteria available, which you can specify using the 'Criterion' argument. You can use the change in the value of the Akaike information criterion, Bayesian information criterion, R-squared, adjusted R-squared as a criterion to add or remove terms.

Depending on the terms included in the initial model and the order in which terms are moved in and out, the method might build different models from the same set of potential terms. The method terminates when no single step improves the model. There is no guarantee, however, that a different initial model or a different sequence of steps will not lead to a better fit. In this sense, stepwise models are locally optimal, but might not be globally optimal.

## Alternatives

Use `stepwiselm` to select a model from a starting model, continuing until no single step is beneficial.

Use `addTerms` or `removeTerms` to add or remove particular terms.

## **How To**

- “Linear Regression” on page 9-11

# stepwise

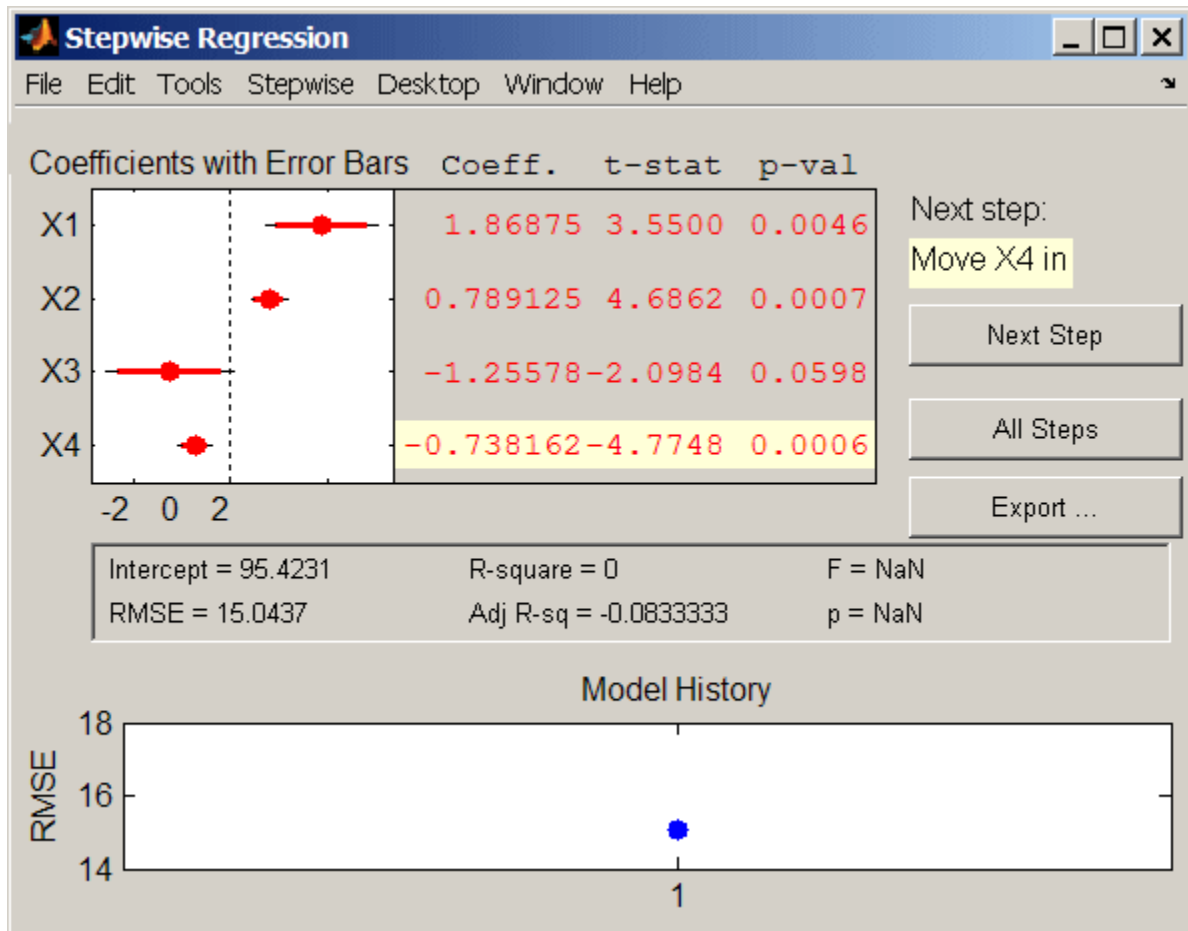

Interactive stepwise regression

## Syntax

```
stepwise
stepwise(X,y)
stepwise(X,y,inmodel,penter,premove)
```

## Description

`stepwise` uses the sample data in `hald.mat` to display a graphical user interface for performing stepwise regression of the response values in `heat` on the predictive terms in `ingredients`.

The upper left of the interface displays estimates of the coefficients for all potential terms, with horizontal bars indicating 90% (colored) and 95% (grey) confidence intervals. The red color indicates that, initially, the terms are not in the model. Values displayed in the table are those that would result if the terms were added to the model.

The middle portion of the interface displays summary statistics for the entire model. These statistics are updated with each step.

The lower portion of the interface, **Model History**, displays the RMSE for the model. The plot tracks the RMSE from step to step, so you can compare the optimality of

different models. Hover over the blue dots in the history to see which terms were in the model at a particular step. Click on a blue dot in the history to open a copy of the interface initialized with the terms in the model at that step.

Initial models, as well as entrance/exit tolerances for the  $p$ -values of  $F$ -statistics, are specified using additional input arguments to `stepwise`. Defaults are an initial model with no terms, an entrance tolerance of 0.05, and an exit tolerance of 0.10.

To center and scale the input data (compute  $z$ -scores) to improve conditioning of the underlying least-squares problem, select **Scale Inputs** from the **Stepwise** menu.

You proceed through a stepwise regression in one of two ways:

- 1 Click **Next Step** to select the recommended next step. The recommended next step either adds the most significant term or removes the least significant term. When the regression reaches a local minimum of RMSE, the recommended next step is “Move no terms.” You can perform all of the recommended steps at once by clicking **All Steps**.
- 2 Click a line in the plot or in the table to toggle the state of the corresponding term. Clicking a red line, corresponding to a term not currently in the model, adds the term to the model and changes the line to blue. Clicking a blue line, corresponding to a term currently in the model, removes the term from the model and changes the line to red.

To call `addedvarplot` and produce an added variable plot from the `stepwise` interface, select **Added Variable Plot** from the **Stepwise** menu. A list of terms is displayed. Select the term you want to add, and then click **OK**.

Click **Export** to display a dialog box that allows you to select information from the interface to save to the MATLAB workspace. Check the information you want to export and, optionally, change the names of the workspace variables to be created. Click **OK** to export the information.

`stepwise(X,y)` displays the interface using the  $p$  predictive terms in the  $n$ -by- $p$  matrix  $X$  and the response values in the  $n$ -by-1 vector  $y$ . Distinct predictive terms should appear in different columns of  $X$ .

---

**Note:** `stepwise` automatically includes a constant term in all models. Do not enter a column of 1s directly into  $X$ .

---

`stepwise` treats NaN values in either `X` or `y` as missing values, and ignores them.

`stepwise(X, y, inmodel, penter, premove)` additionally specifies the initial model (`inmodel`) and the entrance (`penter`) and exit (`premove`) tolerances for the  $p$ -values of  $F$ -statistics. `inmodel` is either a logical vector with length equal to the number of columns of `X`, or a vector of indices, with values ranging from 1 to the number of columns in `X`. The value of `penter` must be less than or equal to the value of `premove`.

## More About

### Algorithms

*Stepwise regression* is a systematic method for adding and removing terms from a multilinear model based on their statistical significance in a regression. The method begins with an initial model and then compares the explanatory power of incrementally larger and smaller models. At each step, the  $p$  value of an  $F$ -statistic is computed to test models with and without a potential term. If a term is not currently in the model, the null hypothesis is that the term would have a zero coefficient if added to the model. If there is sufficient evidence to reject the null hypothesis, the term is added to the model. Conversely, if a term is currently in the model, the null hypothesis is that the term has a zero coefficient. If there is insufficient evidence to reject the null hypothesis, the term is removed from the model. The method proceeds as follows:

- 1 Fit the initial model.
- 2 If any terms not in the model have  $p$ -values less than an entrance tolerance (that is, if it is unlikely that they would have zero coefficient if added to the model), add the one with the smallest  $p$  value and repeat this step; otherwise, go to step 3.
- 3 If any terms in the model have  $p$ -values greater than an exit tolerance (that is, if it is unlikely that the hypothesis of a zero coefficient can be rejected), remove the one with the largest  $p$  value and go to step 2; otherwise, end.

Depending on the terms included in the initial model and the order in which terms are moved in and out, the method may build different models from the same set of potential terms. The method terminates when no single step improves the model. There is no guarantee, however, that a different initial model or a different sequence of steps will not lead to a better fit. In this sense, stepwise models are locally optimal, but may not be globally optimal.

## GeneralizedLinearModel.stepwise

**Class:** GeneralizedLinearModel

Create generalized linear regression model by stepwise regression

### Compatibility

GeneralizedLinearModel.stepwise will be removed in a future release. Use `stepwiseglm` instead.

### Syntax

```
mdl = GeneralizedLinearModel.stepwise(tbl,modelspec)
mdl = GeneralizedLinearModel.stepwise(X,y,modelspec)
mdl = GeneralizedLinearModel.stepwise(...,modelspec,Name,Value)
```

### Description

`mdl = GeneralizedLinearModel.stepwise(tbl,modelspec)` creates a generalized linear model of a table or dataset array `tbl`, using stepwise regression to add or remove predictors. `modelspec` is the starting model for the stepwise procedure.

`mdl = GeneralizedLinearModel.stepwise(X,y,modelspec)` creates a generalized linear model of the responses `y` to a data matrix `X`, using stepwise regression to add or remove predictors.

`mdl = GeneralizedLinearModel.stepwise(...,modelspec,Name,Value)` creates a generalized linear model with additional options specified by one or more `Name,Value` pair arguments.

### Tips

- The generalized linear model `mdl` is a standard linear model unless you specify otherwise with the `Distribution` name-value pair.

- For other methods such as `devianceTest`, or properties of the `GeneralizedLinearModel` object, see `GeneralizedLinearModel`.

## Input Arguments

### **tbl** — Input data

table | dataset array

Input data, specified as a table or dataset array. When `modelspec` is a formula, it specifies the variables to be used as the predictors and response. Otherwise, if you do not specify the predictor and response variables, the last variable is the response variable and the others are the predictor variables by default.

Predictor variables can be numeric, or any grouping variable type, such as logical or categorical (see “Grouping Variables” on page 2-52). The response must be numeric or logical.

To set a different column as the response variable, use the `ResponseVar` name-value pair argument. To use a subset of the columns as predictors, use the `PredictorVars` name-value pair argument.

Data Types: `single` | `double` | `logical`

### **X** — Predictor variables

matrix

Predictor variables, specified as an  $n$ -by- $p$  matrix, where  $n$  is the number of observations and  $p$  is the number of predictor variables. Each column of `X` represents one variable, and each row represents one observation.

By default, there is a constant term in the model, unless you explicitly remove it, so do not include a column of 1s in `X`.

Data Types: `single` | `double` | `logical`

### **y** — Response variable

vector

Response variable, specified as an  $n$ -by-1 vector, where  $n$  is the number of observations. Each entry in `y` is the response for the corresponding row of `X`.

Data Types: `single` | `double`

### **modelspec** — Starting model

string specifying the model |  $t$ -by- $(p+1)$  terms matrix | string of the form ' $Y \sim \text{terms}$ '

Starting model for `stepwiseglm`, specified as one of the following:

- String specifying the type of model.

| String          | Model Type                                                                                                                                                                                                                                                                   |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'constant'      | Model contains only a constant (intercept) term.                                                                                                                                                                                                                             |
| 'linear'        | Model contains an intercept and linear terms for each predictor.                                                                                                                                                                                                             |
| 'interactions'  | Model contains an intercept, linear terms, and all products of pairs of distinct predictors (no squared terms).                                                                                                                                                              |
| 'purequadratic' | Model contains an intercept, linear terms, and squared terms.                                                                                                                                                                                                                |
| 'quadratic'     | Model contains an intercept, linear terms, interactions, and squared terms.                                                                                                                                                                                                  |
| 'polyijk'       | Model is a polynomial with all terms up to degree $i$ in the first predictor, degree $j$ in the second predictor, etc. Use numerals 0 through 9. For example, 'poly2111' has a constant plus all linear and product terms, and also contains terms with predictor 1 squared. |

- $t$ -by- $(p+1)$  matrix, namely terms matrix, specifying terms to include in model, where  $t$  is the number of terms and  $p$  is the number of predictor variables, and plus one is for the response variable.
- String representing a formula in the form ' $Y \sim \text{terms}$ ', where the `terms` are in “Wilkinson Notation” on page 21-4187.

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name,Value arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1, ..., NameN,ValueN`.

**'BinomialSize' — Number of trials for binomial distribution**

1 (default) | scalar value | vector

Number of trials for binomial distribution, that is the sample size, specified as the comma-separated pair consisting of a scalar value or a vector of the same length as the response. This is the parameter  $n$  for the fitted binomial distribution. **BinomialSize** applies only when the **Distribution** parameter is 'binomial'.

If **BinomialSize** is a scalar value, that means all observations have the same number of trials.

As an alternative to **BinomialSize**, you can specify the response as a two-column vector with counts in column 1 and **BinomialSize** in column 2.

Data Types: single | double

**'CategoricalVars' — Categorical variables**

cell array of strings | logical or numeric index vector

Categorical variables in the fit, specified as the comma-separated pair consisting of 'CategoricalVars' and either a cell array of strings of the names of the categorical variables in the table or dataset array **tbl**, or a logical or numeric index vector indicating which columns are categorical.

- If data is in a table or dataset array **tbl**, then the default is to treat all categorical or logical variables, character arrays, or cell arrays of strings as categorical variables.
- If data is in matrix **X**, then the default value of this name-value pair argument is an empty matrix **[]**. That is, no variable is categorical unless you specify it.

For example, you can specify the observations 2 and 3 out of 6 as categorical using either of the following examples.

Example: 'CategoricalVars',[2,3]

Example: 'CategoricalVars',logical([0 1 1 0 0 0])

Data Types: single | double | logical

**'Criterion' — Criterion to add or remove terms**

'Deviance' | 'sse' | 'aic' | 'bic' | 'rsquared' | 'adjrsquared'

Criterion to add or remove terms, specified as the comma-separated pair consisting of 'Criterion' and one of the following:

- `'Deviance'` — Default for `stepwiseglm`.  $p$ -value for  $F$  or chi-squared test of the change in the deviance by adding or removing the term.  $F$ -test is for testing a single model. Chi-squared test is for comparing two different models. This option is not valid for `stepwiselm`.
- `'sse'` — Default for `stepwiselm`.  $p$ -value for an  $F$ -test of the change in the sum of squared error by adding or removing the term.
- `'aic'` — Change in the value of Akaike information criterion (AIC).
- `'bic'` — Change in the value of Bayesian information criterion (BIC).
- `'rsquared'` — Increase in the value of  $R^2$ .
- `'adjrsquared'` — Increase in the value of adjusted  $R^2$ .

Example: `'Criterion','bic'`

**'DispersionFlag' — Indicator to compute dispersion parameter**

`false` for `'binomial'` and `'poisson'` distributions (default) | `true`

Indicator to compute dispersion parameter for `'binomial'` and `'poisson'` distributions, specified as the comma-separated pair consisting of `'DispersionFlag'` and one of the following.

|                    |                                                                   |
|--------------------|-------------------------------------------------------------------|
| <code>true</code>  | Estimate a dispersion parameter when computing standard errors    |
| <code>false</code> | Default. Use the theoretical value when computing standard errors |

The fitting function always estimates the dispersion for other distributions.

Example: `'DispersionFlag',true`

**'Distribution' — Distribution of the response variable**

`'normal'` (default) | `'binomial'` | `'poisson'` | `'gamma'` | `'inverse gaussian'`

Distribution of the response variable, specified as the comma-separated pair consisting of `'Distribution'` and one of the following.

|                         |                       |
|-------------------------|-----------------------|
| <code>'normal'</code>   | Normal distribution   |
| <code>'binomial'</code> | Binomial distribution |
| <code>'poisson'</code>  | Poisson distribution  |
| <code>'gamma'</code>    | Gamma distribution    |

'inverse gaussian' Inverse Gaussian distribution

Example: 'Distribution', 'gamma'

### 'Exclude' — Observations to exclude

logical or numeric index vector

Observations to exclude from the fit, specified as the comma-separated pair consisting of 'Exclude' and a logical or numeric index vector indicating which observations to exclude from the fit.

For example, you can exclude observations 2 and 3 out of 6 using either of the following examples.

Example: 'Exclude', [2,3]

Example: 'Exclude', logical([0 1 1 0 0 0])

Data Types: single | double | logical

### 'Intercept' — Indicator for constant term

true (default) | false

Indicator the for constant term (intercept) in the fit, specified as the comma-separated pair consisting of 'Intercept' and either true to include or false to remove the constant term from the model.

Use 'Intercept' only when specifying the model using a string, not a formula or matrix.

Example: 'Intercept', false

### 'Link' — Link function

The canonical link function (default) | scalar value | structure

Link function to use in place of the canonical link function, specified as the comma-separated pair consisting of 'Link' and one of the following.

| Link Function Name | Link Function                | Mean (Inverse) Function           |
|--------------------|------------------------------|-----------------------------------|
| 'identity'         | $f(\mu) = \mu$               | $\mu = Xb$                        |
| 'log'              | $f(\mu) = \log(\mu)$         | $\mu = \exp(Xb)$                  |
| 'logit'            | $f(\mu) = \log(\mu/(1-\mu))$ | $\mu = \exp(Xb) / (1 + \exp(Xb))$ |
| 'probit'           | $f(\mu) = \Phi^{-1}(\mu)$    | $\mu = \Phi(Xb)$                  |

| Link Function Name                                                                                                                                                                                                                                                                                                                                   | Link Function                   | Mean (Inverse) Function      |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------|------------------------------|
| 'comploglog'                                                                                                                                                                                                                                                                                                                                         | $f(\mu) = \log(-\log(1 - \mu))$ | $\mu = 1 - \exp(-\exp(Xb))$  |
| 'reciprocal'                                                                                                                                                                                                                                                                                                                                         | $f(\mu) = 1/\mu$                | $\mu = 1/(Xb)$               |
| p (a number)                                                                                                                                                                                                                                                                                                                                         | $f(\mu) = \mu^p$                | $\mu = Xb^{1/p}$             |
| S (a structure)<br>with three fields. Each field holds a function handle that accepts a vector of inputs and returns a vector of the same size:<br><br><ul style="list-style-type: none"> <li>• S.Link — The link function</li> <li>• S.Inverse — The inverse link function</li> <li>• S.Derivative — The derivative of the link function</li> </ul> | $f(\mu) = \text{S.Link}(\mu)$   | $\mu = \text{S.Inverse}(Xb)$ |

The link function defines the relationship  $f(\mu) = X^*b$  between the mean response  $\mu$  and the linear combination of predictors  $X^*b$ .

For more information on the canonical link functions, see [Definitions](#).

Example: 'Link', 'probit'

**'Lower'** — Model specification describing terms that cannot be removed from model  
'constant' (default)

Model specification describing terms that cannot be removed from the model, specified as the comma-separated pair consisting of 'Lower' and one of the string options for `modelspec` naming the model.

Example: 'Lower', 'linear'

**'Offset'** — Offset variable  
[] (default) | vector | string

Offset variable in the fit, specified as the comma-separated pair consisting of 'Offset' and a vector or name of a variable with the same length as the response.

`fitglm` and `stepwiseglm` use `Offset` as an additional predictor, with a coefficient value fixed at 1.0. In other words, the formula for fitting is  $\mu \sim \text{Offset} + (\text{terms involving real predictors})$

with the `Offset` predictor having coefficient 1.

For example, consider a Poisson regression model. Suppose the number of counts is known for theoretical reasons to be proportional to a predictor `A`. By using the log link function and by specifying `log(A)` as an offset, you can force the model to satisfy this theoretical constraint.

Data Types: `single` | `double` | `char`

### 'PEnter' — Improvement measure for adding term

scalar value

Improvement measure for adding a term, specified as the comma-separated pair consisting of 'PEnter' and a scalar value. The default values are below.

| Criterion  | Default value | Decision                                                                                                           |
|------------|---------------|--------------------------------------------------------------------------------------------------------------------|
| 'Deviance' | 0.05          | If the $p$ -value of $F$ or chi-squared statistic is smaller than <code>PEnter</code> , add the term to the model. |
| 'SSE'      | 0.05          | If the SSE of the model is smaller than <code>PEnter</code> , add the term to the model.                           |
| 'AIC'      | 0             | If the change in the AIC of the model is smaller than <code>PEnter</code> , add the term to the model.             |
| 'BIC'      | 0             | If the change in the BIC of the model is smaller than <code>PEnter</code> , add the term to the model.             |
| 'Rsquared' | 0.1           | If the increase in the R-squared of the model is larger than <code>PEnter</code> , add the term to the model.      |

| Criterion     | Default value | Decision                                                                                                               |
|---------------|---------------|------------------------------------------------------------------------------------------------------------------------|
| 'AdjRsquared' | 0             | If the increase in the adjusted R-squared of the model is larger than <code>PEnter</code> , add the term to the model. |

For more information on the criteria, see Criterion name-value pair argument.

Example: `'PEnter', 0.075`

### 'PredictorVars' — Predictor variables

cell array of strings | logical or numeric index vector

Predictor variables to use in the fit, specified as the comma-separated pair consisting of 'PredictorVars' and either a cell array of strings of the variable names in the table or dataset array `tbl`, or a logical or numeric index vector indicating which columns are predictor variables.

The strings should be among the names in `tbl`, or the names you specify using the 'VarNames' name-value pair argument.

The default is all variables in `X`, or all variables in `tbl` except for `ResponseVar`.

For example, you can specify the second and third variables as the predictor variables using either of the following examples.

Example: `'PredictorVars', [2,3]`

Example: `'PredictorVars', logical([0 1 1 0 0 0])`

Data Types: `single` | `double` | `logical` | `cell`

### 'PRemove' — Improvement measure for removing term

scalar value

Improvement measure for removing a term, specified as the comma-separated pair consisting of 'PRemove' and a scalar value.

| Criterion  | Default value | Decision                                                    |
|------------|---------------|-------------------------------------------------------------|
| 'Deviance' | 0.10          | If the $p$ -value of $F$ or chi-squared statistic is larger |

| Criterion     | Default value | Decision                                                                                                                      |
|---------------|---------------|-------------------------------------------------------------------------------------------------------------------------------|
|               |               | than <b>PRemove</b> , remove the term from the model.                                                                         |
| 'SSE'         | 0.10          | If the $p$ -value of the F statistic is larger than <b>PRemove</b> , remove the term from the model.                          |
| 'AIC'         | 0.01          | If the change in the AIC of the model is larger than <b>PRemove</b> , remove the term from the model.                         |
| 'BIC'         | 0.01          | If the change in the BIC of the model is larger than <b>PRemove</b> , remove the term from the model.                         |
| 'Rsquared'    | 0.05          | If the increase in the R-squared value of the model is smaller than <b>PRemove</b> , remove the term from the model.          |
| 'AdjRsquared' | -0.05         | If the increase in the adjusted R-squared value of the model is smaller than <b>PRemove</b> , remove the term from the model. |

At each step, stepwise algorithm also checks whether any term is redundant (linearly dependent) with other terms in the current model. When any term is linearly dependent with other terms in the current model, it is removed, regardless of the criterion value.

For more information on the criteria, see Criterion name-value pair argument.

Example: 'PRemove', 0.05

### 'ResponseVar' — Response variable

last column in `tbl` (default) | string for variable name | logical or numeric index vector

Response variable to use in the fit, specified as the comma-separated pair consisting of 'ResponseVar' and either a string of the variable name in the table or dataset

array `tbl`, or a logical or numeric index vector indicating which column is the response variable. You typically need to use `'ResponseVar'` when fitting a table or dataset array `tbl`.

For example, you can specify the fourth variable, say `yield`, as the response out of six variables, in one of the following ways.

Example: `'ResponseVar', 'yield'`

Example: `'ResponseVar', [4]`

Example: `'ResponseVar', logical([0 0 0 1 0 0])`

Data Types: `single` | `double` | `logical` | `char`

### **'Upper' — Model specification describing largest set of terms in fit**

`'interaction'` (default) | `string`

Model specification describing the largest set of terms in the fit, specified as the comma-separated pair consisting of `'Upper'` and one of the string options for `modelspec` naming the model.

Example: `'Upper', 'quadratic'`

### **'VarNames' — Names of variables in fit**

`{'x1', 'x2', ..., 'xn', 'y'}` (default) | `cell array of strings`

Names of variables in fit, specified as the comma-separated pair consisting of `'VarNames'` and a cell array of strings including the names for the columns of `X` first, and the name for the response variable `y` last.

`'VarNames'` is not applicable to variables in a table or dataset array, because those variables already have names.

For example, if in your data, horsepower, acceleration, and model year of the cars are the predictor variables, and miles per gallon (MPG) is the response variable, then you can name the variables as follows.

Example: `'VarNames', {'Horsepower', 'Acceleration', 'Model_Year', 'MPG'}`

Data Types: `cell`

### **'Weights' — Observation weights**

`ones(n, 1)` (default) | `n`-by-1 vector of nonnegative scalar values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and an  $n$ -by-1 vector of nonnegative scalar values, where  $n$  is the number of observations.

Data Types: single | double

## Output Arguments

### mdl — Generalized linear model

GeneralizedLinearModel object

Generalized linear model representing a least-squares fit of the link of the response to the data, returned as a GeneralizedLinearModel object.

For properties and methods of the generalized linear model object, mdl, see the GeneralizedLinearModel class page.

## Definitions

### Terms Matrix

A terms matrix is a  $t$ -by- $(p + 1)$  matrix specifying terms in a model, where  $t$  is the number of terms,  $p$  is the number of predictor variables, and plus one is for the response variable.

The value of  $T(i, j)$  is the exponent of variable  $j$  in term  $i$ . Suppose there are three predictor variables A, B, and C:

```
[0 0 0 0] % Constant term or intercept
[0 1 0 0] % B; equivalently, A^0 * B^1 * C^0
[1 0 1 0] % A*C
[2 0 0 0] % A^2
[0 1 2 0] % B*(C^2)
```

The 0 at the end of each term represents the response variable. In general,

- If you have the variables in a table or dataset array, then 0 must represent the response variable depending on the position of the response variable. The following example illustrates this.

Load the sample data and define the dataset array.

```
load hospital
ds = dataset(hospital.Sex,hospital.BloodPressure(:,1),hospital.Age,...
```

```
hospital.Smoker, 'VarNames', {'Sex', 'BloodPressure', 'Age', 'Smoker'});
```

Represent the linear model `'BloodPressure ~ 1 + Sex + Age + Smoker'` in a terms matrix. The response variable is in the second column of the dataset array, so there must be a column of 0s for the response variable in the second column of the terms matrix.

```
T = [0 0 0 0; 1 0 0 0; 0 0 1 0; 0 0 0 1]
```

```
T =
```

```

0 0 0 0
1 0 0 0
0 0 1 0
0 0 0 1
```

Redefine the dataset array.

```
ds = dataset(hospital.BloodPressure(:,1), hospital.Sex, hospital.Age, ...
hospital.Smoker, 'VarNames', {'BloodPressure', 'Sex', 'Age', 'Smoker'});
```

Now, the response variable is the first term in the dataset array. Specify the same linear model, `'BloodPressure ~ 1 + Sex + Age + Smoker'`, using a terms matrix.

```
T = [0 0 0 0; 0 1 0 0; 0 0 1 0; 0 0 0 1]
```

```
T =
```

```

0 0 0 0
0 1 0 0
0 0 1 0
0 0 0 1
```

- If you have the predictor and response variables in a matrix and column vector, then you must include 0 for the response variable at the end of each term. The following example illustrates this.

Load the sample data and define the matrix of predictors.

```
load carsmall
X = [Acceleration, Weight];
```

Specify the model `'MPG ~ Acceleration + Weight + Acceleration:Weight + Weight^2'` using a term matrix and fit the model to the data. This model includes

the main effect and two-way interaction terms for the variables, Acceleration and Weight, and a second-order term for the variable, Weight.

```
T = [0 0 0;1 0 0;0 1 0;1 1 0;0 2 0]
```

```
T =
```

```

0 0 0
1 0 0
0 1 0
1 1 0
0 2 0
```

Fit a linear model.

```
mdl = fitlm(X,MPG,T)
```

```
mdl =
```

```
Linear regression model:
```

```
y ~ 1 + x1*x2 + x2^2
```

```
Estimated Coefficients:
```

|             | Estimate    | SE         | tStat   | pValue     |
|-------------|-------------|------------|---------|------------|
| (Intercept) | 48.906      | 12.589     | 3.8847  | 0.00019665 |
| x1          | 0.54418     | 0.57125    | 0.95261 | 0.34337    |
| x2          | -0.012781   | 0.0060312  | -2.1192 | 0.036857   |
| x1:x2       | -0.00010892 | 0.00017925 | -0.6076 | 0.545      |
| x2^2        | 9.7518e-07  | 7.5389e-07 | 1.2935  | 0.19917    |

```
Number of observations: 94, Error degrees of freedom: 89
```

```
Root Mean Squared Error: 4.1
```

```
R-squared: 0.751, Adjusted R-Squared 0.739
```

```
F-statistic vs. constant model: 67, p-value = 4.99e-26
```

Only the intercept and x2 term, which correspond to the Weight variable, are significant at the 5% significance level.

Now, perform a stepwise regression with a constant model as the starting model and a linear model with interactions as the upper model.

```
T = [0 0 0;1 0 0;0 1 0;1 1 0];
mdl = stepwiselm(X,MPG,[0 0 0], 'upper', T)
```

```
1. Adding x2, FStat = 259.3087, pValue = 1.643351e-28
```

```
mdl =
```

```
Linear regression model:
y ~ 1 + x2
```

```
Estimated Coefficients:
```

|             | Estimate   | SE        | tStat   | pValue     |
|-------------|------------|-----------|---------|------------|
| (Intercept) | 49.238     | 1.6411    | 30.002  | 2.7015e-49 |
| x2          | -0.0086119 | 0.0005348 | -16.103 | 1.6434e-28 |

```
Number of observations: 94, Error degrees of freedom: 92
```

```
Root Mean Squared Error: 4.13
```

```
R-squared: 0.738, Adjusted R-Squared 0.735
```

```
F-statistic vs. constant model: 259, p-value = 1.64e-28
```

The results of the stepwise regression are consistent with the results of `fitlm` in the previous step.

## Formula

A formula for model specification is a string of the form ' $Y \sim terms$ '

where

- $Y$  is the response name.
- $terms$  contains
  - Variable names
  - $+$  means include the next variable
  - $-$  means do not include the next variable
  - $:$  defines an interaction, a product of terms
  - $*$  defines an interaction **and all lower-order terms**
  - $^$  raises the predictor to a power, exactly as in  $*$  repeated, so  $^$  includes lower order terms as well
  - $()$  groups terms

---

**Note:** Formulas include a constant (intercept) term by default. To exclude a constant term from the model, include  $-1$  in the formula.

---

For example,

' $Y \sim A + B + C$ ' means a three-variable linear model with intercept.

' $Y \sim A + B + C - 1$ ' is a three-variable linear model without intercept.

' $Y \sim A + B + C + B^2$ ' is a three-variable model with intercept and a  $B^2$  term.

' $Y \sim A + B^2 + C$ ' is the same as the previous example because  $B^2$  includes a  $B$  term.

' $Y \sim A + B + C + A:B$ ' includes an  $A*B$  term.

' $Y \sim A*B + C$ ' is the same as the previous example because  $A*B = A + B + A:B$ .

' $Y \sim A*B*C - A:B:C$ ' has all interactions among  $A$ ,  $B$ , and  $C$ , except the three-way interaction.

' $Y \sim A*(B + C + D)$ ' has all linear terms, plus products of  $A$  with each of the other variables.

## Wilkinson Notation

Wilkinson notation describes the factors present in models. The notation relates to factors present in models, not to the multipliers (coefficients) of those factors.

| Wilkinson Notation                      | Factors in Standard Notation |
|-----------------------------------------|------------------------------|
| 1                                       | Constant (intercept) term    |
| $A^k$ , where $k$ is a positive integer | $A, A^2, \dots, A^k$         |
| $A + B$                                 | $A, B$                       |
| $A*B$                                   | $A, B, A*B$                  |
| $A:B$                                   | $A*B$ only                   |
| $-B$                                    | Do not include $B$           |
| $A*B + C$                               | $A, B, C, A*B$               |
| $A + B + C + A:B$                       | $A, B, C, A*B$               |
| $A*B*C - A:B:C$                         | $A, B, C, A*B, A*C, B*C$     |
| $A*(B + C)$                             | $A, B, C, A*B, A*C$          |

Statistics Toolbox notation always includes a constant term unless you explicitly remove the term using  $-1$ .

## Canonical Link Function

The default link function for a generalized linear model is the *canonical link function*.

## Canonical Link Functions for Generalized Linear Models

| Distribution       | Link Function Name | Link Function                | Mean (Inverse) Function           |
|--------------------|--------------------|------------------------------|-----------------------------------|
| 'normal'           | 'identity'         | $f(\mu) = \mu$               | $\mu = Xb$                        |
| 'binomial'         | 'logit'            | $f(\mu) = \log(\mu/(1-\mu))$ | $\mu = \exp(Xb) / (1 + \exp(Xb))$ |
| 'poisson'          | 'log'              | $f(\mu) = \log(\mu)$         | $\mu = \exp(Xb)$                  |
| 'gamma'            | -1                 | $f(\mu) = 1/\mu$             | $\mu = 1/(Xb)$                    |
| 'inverse gaussian' | -2                 | $f(\mu) = 1/\mu^2$           | $\mu = (Xb)^{-1/2}$               |

## Examples

### Create a Generalized Linear Model Stepwise

Create response data using just three of 20 predictors, and create a generalized linear model stepwise to see if it uses just the correct predictors.

Create data with 20 predictors, and Poisson response using just three of the predictors, plus a constant.

```
rng('default') % for reproducibility
X = randn(100,20);
mu = exp(X(:, [5 10 15]) * [.4;.2;.3] + 1);
y = poissrnd(mu);
```

Fit a generalized linear model using the Poisson distribution.

```
mdl = stepwiseglm(X,y,...
 'constant', 'upper', 'linear', 'Distribution', 'poisson')
```

1. Adding x5, Deviance = 134.439, Chi2Stat = 52.24814, PValue = 4.891229e-13
2. Adding x15, Deviance = 106.285, Chi2Stat = 28.15393, PValue = 1.1204e-07
3. Adding x10, Deviance = 95.0207, Chi2Stat = 11.2644, PValue = 0.000790094

```
mdl =
```

```
Generalized Linear regression model:
log(y) ~ 1 + x5 + x10 + x15
Distribution = Poisson
```

```
Estimated Coefficients:
 Estimate SE tStat pValue
```

|             |         |          |        |            |
|-------------|---------|----------|--------|------------|
| (Intercept) | 1.0115  | 0.064275 | 15.737 | 8.4217e-56 |
| x5          | 0.39508 | 0.066665 | 5.9263 | 3.0977e-09 |
| x10         | 0.18863 | 0.05534  | 3.4085 | 0.0006532  |
| x15         | 0.29295 | 0.053269 | 5.4995 | 3.8089e-08 |

100 observations, 96 error degrees of freedom  
 Dispersion: 1  
 Chi^2-statistic vs. constant model: 91.7, p-value = 9.61e-20

- “Compare large and small stepwise models” on page 9-114

## Algorithms

*Stepwise regression* is a systematic method for adding and removing terms from a linear or generalized linear model based on their statistical significance in explaining the response variable. The method begins with an initial model, specified using `modelspec`, and then compares the explanatory power of incrementally larger and smaller models.

MATLAB uses forward and backward stepwise regression to determine a final model. At each step, the method searches for terms to add to or remove from the model based on the value of the `'Criterion'` argument. The default value of `'Criterion'` is `'sse'`, and in this case, `stepwiselm` uses the  $p$ -value of an  $F$ -statistic to test models with and without a potential term at each step. If a term is not currently in the model, the null hypothesis is that the term would have a zero coefficient if added to the model. If there is sufficient evidence to reject the null hypothesis, the term is added to the model. Conversely, if a term is currently in the model, the null hypothesis is that the term has a zero coefficient. If there is insufficient evidence to reject the null hypothesis, the term is removed from the model.

Here is how stepwise proceeds when `'Criterion'` is `'sse'`:

- 1 Fit the initial model.
- 2 If any terms not in the model have  $p$ -values less than an entrance tolerance (that is, if it is unlikely that they would have zero coefficient if added to the model), add the one with the smallest  $p$ -value and repeat this step; otherwise, go to step 3.
- 3 If any terms in the model have  $p$ -values greater than an exit tolerance (that is, the hypothesis of a zero coefficient can be rejected), remove the one with the largest  $p$ -value and go to step 2; otherwise, end.

The default for `stepwiseglm` is `'Deviance'` and it follows a similar procedure for adding or removing terms.

There are several other criteria available, which you can specify using the 'Criterion' argument. You can use the change in the value of the Akaike information criterion, Bayesian information criterion, R-squared, adjusted R-squared as a criterion to add or remove terms.

Depending on the terms included in the initial model and the order in which terms are moved in and out, the method might build different models from the same set of potential terms. The method terminates when no single step improves the model. There is no guarantee, however, that a different initial model or a different sequence of steps will not lead to a better fit. In this sense, stepwise models are locally optimal, but might not be globally optimal.

## Alternatives

You can also create a stepwise generalized linear model using `stepwiseglm`.

Use `fitglm` to create a model with a fixed specification. Use `step`, `addTerms`, or `removeTerms` to adjust a fitted model.

## More About

- “Generalized Linear Models” on page 10-12

# LinearModel.stepwise

**Class:** LinearModel

Create linear regression model by stepwise regression

## Compatibility

LinearModel.stepwise will be removed in a future release. Use `stepwiselm` instead.

## Syntax

```
mdl = LinearModel.stepwise(tbl,modelspec)
mdl = LinearModel.stepwise(X,y,modelspec)
mdl = LinearModel.stepwise(____,modelspec,Name,Value)
```

## Description

`mdl = LinearModel.stepwise(tbl,modelspec)` returns a linear model of a table or dataset array `tbl`, using stepwise regression to add or remove predictors. `modelspec` is the starting model for the stepwise procedure.

`mdl = LinearModel.stepwise(X,y,modelspec)` creates a linear model of the responses `y` to a data matrix `X`, using stepwise regression to add or remove predictors. `modelspec` is the starting model for the stepwise procedure.

`mdl = LinearModel.stepwise( ____,modelspec,Name,Value)` creates a linear model for any of the inputs in the previous syntaxes, with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify the categorical variables, the smallest or largest set of terms to use in the model, the maximum number of steps to take, or the criterion `LinearModel.stepwise` uses to add or remove terms.

## Tips

- You cannot use robust regression with stepwise regression. Check your data for outliers before using `LinearModel.stepwise`.
- For other methods or properties of the `LinearModel` object, see `LinearModel`.

## Input Arguments

### **tbl** — Input data

table | dataset array

Input data, specified as a table or dataset array. When `modelspec` is a `formula`, it specifies the variables to be used as the predictors and response. Otherwise, if you do not specify the predictor and response variables, the last variable is the response variable and the others are the predictor variables by default.

Predictor variables can be numeric, or any grouping variable type, such as logical or categorical (see “Grouping Variables” on page 2-52). The response must be numeric or logical.

To set a different column as the response variable, use the `ResponseVar` name-value pair argument. To use a subset of the columns as predictors, use the `PredictorVars` name-value pair argument.

Data Types: `single` | `double` | `logical`

### **X** — Predictor variables

matrix

Predictor variables, specified as an  $n$ -by- $p$  matrix, where  $n$  is the number of observations and  $p$  is the number of predictor variables. Each column of `X` represents one variable, and each row represents one observation.

By default, there is a constant term in the model, unless you explicitly remove it, so do not include a column of 1s in `X`.

Data Types: `single` | `double` | `logical`

### **y** — Response variable

vector

Response variable, specified as an  $n$ -by-1 vector, where  $n$  is the number of observations. Each entry in  $y$  is the response for the corresponding row of  $X$ .

Data Types: `single` | `double`

### **modelspec** — Starting model

string specifying the model |  $t$ -by- $(p+1)$  terms matrix | string of the form ' $Y \sim \text{terms}$ '

Starting model for the stepwise regression, specified as one of the following:

- String specifying the type of starting model.

| String          | Model Type                                                                                                                                                                                                                                                                   |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'constant'      | Model contains only a constant (intercept) term.                                                                                                                                                                                                                             |
| 'linear'        | Model contains an intercept and linear terms for each predictor.                                                                                                                                                                                                             |
| 'interactions'  | Model contains an intercept, linear terms, and all products of pairs of distinct predictors (no squared terms).                                                                                                                                                              |
| 'purequadratic' | Model contains an intercept, linear terms, and squared terms.                                                                                                                                                                                                                |
| 'quadratic'     | Model contains an intercept, linear terms, interactions, and squared terms.                                                                                                                                                                                                  |
| 'polyijk'       | Model is a polynomial with all terms up to degree $i$ in the first predictor, degree $j$ in the second predictor, etc. Use numerals 0 through 9. For example, 'poly2111' has a constant plus all linear and product terms, and also contains terms with predictor 1 squared. |

If you want to specify the smallest or largest set of terms in the model, use the Lower and Upper name-value pair arguments.

- $t$ -by- $(p+1)$  matrix, namely a terms matrix, specifying terms to include in model, where  $t$  is the number of terms and  $p$  is the number of predictor variables, and plus one is for the response variable.
- String representing a formula in the form ' $Y \sim \text{terms}$ ', where the `terms` are in “Wilkinson Notation” on page 21-4204.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

### 'CategoricalVars' — Categorical variables

cell array of strings | logical or numeric index vector

Categorical variables in the fit, specified as the comma-separated pair consisting of 'CategoricalVars' and either a cell array of strings of the names of the categorical variables in the table or dataset array `tbl`, or a logical or numeric index vector indicating which columns are categorical.

- If data is in a table or dataset array `tbl`, then the default is to treat all categorical or logical variables, character arrays, or cell arrays of strings as categorical variables.
- If data is in matrix `X`, then the default value of this name-value pair argument is an empty matrix `[]`. That is, no variable is categorical unless you specify it.

For example, you can specify the observations 2 and 3 out of 6 as categorical using either of the following examples.

Example: 'CategoricalVars', [2,3]

Example: 'CategoricalVars', logical([0 1 1 0 0 0])

Data Types: single | double | logical

### 'Criterion' — Criterion to add or remove terms

'Deviance' | 'sse' | 'aic' | 'bic' | 'rsquared' | 'adjrsquared'

Criterion to add or remove terms, specified as the comma-separated pair consisting of 'Criterion' and one of the following:

- 'Deviance' — Default for `stepwiseglm`.  $p$ -value for  $F$  or chi-squared test of the change in the deviance by adding or removing the term.  $F$ -test is for testing a single model. Chi-squared test is for comparing two different models. This option is not valid for `stepwiselm`.
- 'sse' — Default for `stepwiselm`.  $p$ -value for an  $F$ -test of the change in the sum of squared error by adding or removing the term.
- 'aic' — Change in the value of Akaike information criterion (AIC).

- `'bic'` — Change in the value of Bayesian information criterion (BIC).
- `'rsquared'` — Increase in the value of  $R^2$ .
- `'adjrsquared'` — Increase in the value of adjusted  $R^2$ .

Example: `'Criterion', 'bic'`

### **'Exclude' — Observations to exclude**

logical or numeric index vector

Observations to exclude from the fit, specified as the comma-separated pair consisting of `'Exclude'` and a logical or numeric index vector indicating which observations to exclude from the fit.

For example, you can exclude observations 2 and 3 out of 6 using either of the following examples.

Example: `'Exclude', [2,3]`

Example: `'Exclude', logical([0 1 1 0 0 0])`

Data Types: `single` | `double` | `logical`

### **'Intercept' — Indicator for constant term**

`true` (default) | `false`

Indicator the for constant term (intercept) in the fit, specified as the comma-separated pair consisting of `'Intercept'` and either `true` to include or `false` to remove the constant term from the model.

Use `'Intercept'` only when specifying the model using a string, not a formula or matrix.

Example: `'Intercept', false`

### **'Lower' — Model specification describing terms that cannot be removed from model**

`'constant'` (default)

Model specification describing terms that cannot be removed from the model, specified as the comma-separated pair consisting of `'Lower'` and one of the string options for `modelspec` naming the model.

Example: `'Lower', 'linear'`

**'NSteps' — Number of steps to take**

1 (default) | positive integer

Number of steps to take, specified as the comma-separated pair consisting of 'NSteps' and a positive integer.

Data Types: single | double

**'PEnter' — Improvement measure for adding term**

scalar value

Improvement measure for adding a term, specified as the comma-separated pair consisting of 'PEnter' and a scalar value. The default values are below.

| Criterion     | Default value | Decision                                                                                                 |
|---------------|---------------|----------------------------------------------------------------------------------------------------------|
| 'Deviance'    | 0.05          | If the $p$ -value of $F$ or chi-squared statistic is smaller than PEnter, add the term to the model.     |
| 'SSE'         | 0.05          | If the SSE of the model is smaller than PEnter, add the term to the model.                               |
| 'AIC'         | 0             | If the change in the AIC of the model is smaller than PEnter, add the term to the model.                 |
| 'BIC'         | 0             | If the change in the BIC of the model is smaller than PEnter, add the term to the model.                 |
| 'Rsquared'    | 0.1           | If the increase in the R-squared of the model is larger than PEnter, add the term to the model.          |
| 'AdjRsquared' | 0             | If the increase in the adjusted R-squared of the model is larger than PEnter, add the term to the model. |

For more information on the criteria, see Criterion name-value pair argument.

Example: 'PEnter',0.075

### 'PredictorVars' — Predictor variables

cell array of strings | logical or numeric index vector

Predictor variables to use in the fit, specified as the comma-separated pair consisting of 'PredictorVars' and either a cell array of strings of the variable names in the table or dataset array `tbl`, or a logical or numeric index vector indicating which columns are predictor variables.

The strings should be among the names in `tbl`, or the names you specify using the 'VarNames' name-value pair argument.

The default is all variables in `X`, or all variables in `tbl` except for `ResponseVar`.

For example, you can specify the second and third variables as the predictor variables using either of the following examples.

Example: 'PredictorVars',[2,3]

Example: 'PredictorVars',logical([0 1 1 0 0 0])

Data Types: single | double | logical | cell

### 'PRemove' — Improvement measure for removing term

scalar value

Improvement measure for removing a term, specified as the comma-separated pair consisting of 'PRemove' and a scalar value.

| Criterion  | Default value | Decision                                                                                                                |
|------------|---------------|-------------------------------------------------------------------------------------------------------------------------|
| 'Deviance' | 0.10          | If the $p$ -value of $F$ or chi-squared statistic is larger than <code>PRemove</code> , remove the term from the model. |
| 'SSE'      | 0.10          | If the $p$ -value of the $F$ statistic is larger than <code>PRemove</code> , remove the term from the model.            |
| 'AIC'      | 0.01          | If the change in the AIC of the model is larger than                                                                    |

| Criterion     | Default value | Decision                                                                                                                      |
|---------------|---------------|-------------------------------------------------------------------------------------------------------------------------------|
|               |               | <b>PRemove</b> , remove the term from the model.                                                                              |
| 'BIC'         | 0.01          | If the change in the BIC of the model is larger than <b>PRemove</b> , remove the term from the model.                         |
| 'Rsquared'    | 0.05          | If the increase in the R-squared value of the model is smaller than <b>PRemove</b> , remove the term from the model.          |
| 'AdjRsquared' | -0.05         | If the increase in the adjusted R-squared value of the model is smaller than <b>PRemove</b> , remove the term from the model. |

At each step, stepwise algorithm also checks whether any term is redundant (linearly dependent) with other terms in the current model. When any term is linearly dependent with other terms in the current model, it is removed, regardless of the criterion value.

For more information on the criteria, see Criterion name-value pair argument.

Example: 'PRemove', 0.05

### 'ResponseVar' — Response variable

last column in `tbl` (default) | string for variable name | logical or numeric index vector

Response variable to use in the fit, specified as the comma-separated pair consisting of 'ResponseVar' and either a string of the variable name in the table or dataset array `tbl`, or a logical or numeric index vector indicating which column is the response variable. You typically need to use 'ResponseVar' when fitting a table or dataset array `tbl`.

For example, you can specify the fourth variable, say `yield`, as the response out of six variables, in one of the following ways.

Example: 'ResponseVar', 'yield'

Example: 'ResponseVar', [4]

Example: `'ResponseVar',logical([0 0 0 1 0 0])`

Data Types: `single | double | logical | char`

### **'Upper' — Model specification describing largest set of terms in fit**

`'interaction'` (default) | `string`

Model specification describing the largest set of terms in the fit, specified as the comma-separated pair consisting of `'Upper'` and one of the string options for `modelspec` naming the model.

Example: `'Upper', 'quadratic'`

### **'VarNames' — Names of variables in fit**

`{'x1', 'x2', ..., 'xn', 'y'}` (default) | `cell array of strings`

Names of variables in fit, specified as the comma-separated pair consisting of `'VarNames'` and a cell array of strings including the names for the columns of `X` first, and the name for the response variable `y` last.

`'VarNames'` is not applicable to variables in a table or dataset array, because those variables already have names.

For example, if in your data, horsepower, acceleration, and model year of the cars are the predictor variables, and miles per gallon (MPG) is the response variable, then you can name the variables as follows.

Example: `'VarNames', {'Horsepower', 'Acceleration', 'Model_Year', 'MPG'}`

Data Types: `cell`

### **'Verbose' — Control for display of information**

`1` (default) | `0 | 2`

Control for display of information, specified as the comma-separated pair consisting of `'Verbose'` and one of the following:

- `0` — Suppress all display.
- `1` — Display the action taken at each step.
- `2` — Also display the actions evaluated at each step.

Example: `'Verbose', 2`

### **'Weights' — Observation weights**

`ones(n, 1)` (default) | `n`-by-1 vector of nonnegative scalar values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and an  $n$ -by-1 vector of nonnegative scalar values, where  $n$  is the number of observations.

Data Types: `single` | `double`

## Output Arguments

### **mdl** — Linear model

`LinearModel` object

Linear model representing a least-squares fit of the response to the data, returned as a `LinearModel` object.

For the properties and methods of the linear model object, `mdl`, see the `LinearModel` class page.

## Definitions

### Terms Matrix

A terms matrix is a  $t$ -by- $(p + 1)$  matrix specifying terms in a model, where  $t$  is the number of terms,  $p$  is the number of predictor variables, and plus one is for the response variable.

The value of  $T(i, j)$  is the exponent of variable  $j$  in term  $i$ . Suppose there are three predictor variables  $A$ ,  $B$ , and  $C$ :

```
[0 0 0 0] % Constant term or intercept
[0 1 0 0] % B; equivalently, A^0 * B^1 * C^0
[1 0 1 0] % A*C
[2 0 0 0] % A^2
[0 1 2 0] % B*(C^2)
```

The 0 at the end of each term represents the response variable. In general,

- If you have the variables in a table or dataset array, then 0 must represent the response variable depending on the position of the response variable. The following example illustrates this.

Load the sample data and define the dataset array.

```
load hospital
ds = dataset(hospital.Sex,hospital.BloodPressure(:,1),hospital.Age,...
```

```
hospital.Smoker, 'VarNames', {'Sex', 'BloodPressure', 'Age', 'Smoker'});
```

Represent the linear model 'BloodPressure ~ 1 + Sex + Age + Smoker' in a terms matrix. The response variable is in the second column of the dataset array, so there must be a column of 0s for the response variable in the second column of the terms matrix.

```
T = [0 0 0 0;1 0 0 0;0 0 1 0;0 0 0 1]
```

```
T =
```

```

0 0 0 0
1 0 0 0
0 0 1 0
0 0 0 1
```

Redefine the dataset array.

```
ds = dataset(hospital.BloodPressure(:,1),hospital.Sex,hospital.Age,...
hospital.Smoker, 'VarNames', {'BloodPressure', 'Sex', 'Age', 'Smoker'});
```

Now, the response variable is the first term in the dataset array. Specify the same linear model, 'BloodPressure ~ 1 + Sex + Age + Smoker', using a terms matrix.

```
T = [0 0 0 0;0 1 0 0;0 0 1 0;0 0 0 1]
```

```
T =
```

```

0 0 0 0
0 1 0 0
0 0 1 0
0 0 0 1
```

- If you have the predictor and response variables in a matrix and column vector, then you must include 0 for the response variable at the end of each term. The following example illustrates this.

Load the sample data and define the matrix of predictors.

```
load carsmall
X = [Acceleration,Weight];
```

Specify the model 'MPG ~ Acceleration + Weight + Acceleration:Weight + Weight^2' using a term matrix and fit the model to the data. This model includes

the main effect and two-way interaction terms for the variables, Acceleration and Weight, and a second-order term for the variable, Weight.

```
T = [0 0 0;1 0 0;0 1 0;1 1 0;0 2 0]
```

```
T =
```

```

0 0 0
1 0 0
0 1 0
1 1 0
0 2 0
```

Fit a linear model.

```
mdl = fitlm(X,MPG,T)
```

```
mdl =
```

```
Linear regression model:
```

```
y ~ 1 + x1*x2 + x2^2
```

```
Estimated Coefficients:
```

|             | Estimate    | SE         | tStat   | pValue     |
|-------------|-------------|------------|---------|------------|
| (Intercept) | 48.906      | 12.589     | 3.8847  | 0.00019665 |
| x1          | 0.54418     | 0.57125    | 0.95261 | 0.34337    |
| x2          | -0.012781   | 0.0060312  | -2.1192 | 0.036857   |
| x1:x2       | -0.00010892 | 0.00017925 | -0.6076 | 0.545      |
| x2^2        | 9.7518e-07  | 7.5389e-07 | 1.2935  | 0.19917    |

```
Number of observations: 94, Error degrees of freedom: 89
```

```
Root Mean Squared Error: 4.1
```

```
R-squared: 0.751, Adjusted R-Squared 0.739
```

```
F-statistic vs. constant model: 67, p-value = 4.99e-26
```

Only the intercept and x2 term, which correspond to the Weight variable, are significant at the 5% significance level.

Now, perform a stepwise regression with a constant model as the starting model and a linear model with interactions as the upper model.

```
T = [0 0 0;1 0 0;0 1 0;1 1 0];
mdl = stepwiselm(X,MPG,[0 0 0], 'upper', T)
```

```
1. Adding x2, FStat = 259.3087, pValue = 1.643351e-28
```

```
mdl =
```

```
Linear regression model:
 y ~ 1 + x2
```

```
Estimated Coefficients:
```

|             | Estimate   | SE        | tStat   | pValue     |
|-------------|------------|-----------|---------|------------|
| (Intercept) | 49.238     | 1.6411    | 30.002  | 2.7015e-49 |
| x2          | -0.0086119 | 0.0005348 | -16.103 | 1.6434e-28 |

```
Number of observations: 94, Error degrees of freedom: 92
```

```
Root Mean Squared Error: 4.13
```

```
R-squared: 0.738, Adjusted R-Squared 0.735
```

```
F-statistic vs. constant model: 259, p-value = 1.64e-28
```

The results of the stepwise regression are consistent with the results of `fitlm` in the previous step.

## Formula

A formula for model specification is a string of the form ' $Y \sim terms$ '

where

- $Y$  is the response name.
- $terms$  contains
  - Variable names
  - + means include the next variable
  - - means do not include the next variable
  - : defines an interaction, a product of terms
  - \* defines an interaction **and all lower-order terms**
  - ^ raises the predictor to a power, exactly as in \* repeated, so ^ includes lower order terms as well
  - ( ) groups terms

---

**Note:** Formulas include a constant (intercept) term by default. To exclude a constant term from the model, include -1 in the formula.

---

For example,

' $Y \sim A + B + C$ ' means a three-variable linear model with intercept.

' $Y \sim A + B + C - 1$ ' is a three-variable linear model without intercept.

' $Y \sim A + B + C + B^2$ ' is a three-variable model with intercept and a  $B^2$  term.

' $Y \sim A + B^2 + C$ ' is the same as the previous example because  $B^2$  includes a  $B$  term.

' $Y \sim A + B + C + A:B$ ' includes an  $A*B$  term.

' $Y \sim A*B + C$ ' is the same as the previous example because  $A*B = A + B + A:B$ .

' $Y \sim A*B*C - A:B:C$ ' has all interactions among  $A$ ,  $B$ , and  $C$ , except the three-way interaction.

' $Y \sim A*(B + C + D)$ ' has all linear terms, plus products of  $A$  with each of the other variables.

## Wilkinson Notation

Wilkinson notation describes the factors present in models. The notation relates to factors present in models, not to the multipliers (coefficients) of those factors.

| Wilkinson Notation                      | Factors in Standard Notation |
|-----------------------------------------|------------------------------|
| 1                                       | Constant (intercept) term    |
| $A^k$ , where $k$ is a positive integer | $A, A^2, \dots, A^k$         |
| $A + B$                                 | $A, B$                       |
| $A*B$                                   | $A, B, A*B$                  |
| $A:B$                                   | $A*B$ only                   |
| $-B$                                    | Do not include $B$           |
| $A*B + C$                               | $A, B, C, A*B$               |
| $A + B + C + A:B$                       | $A, B, C, A*B$               |
| $A*B*C - A:B:C$                         | $A, B, C, A*B, A*C, B*C$     |
| $A*(B + C)$                             | $A, B, C, A*B, A*C$          |

Statistics Toolbox notation always includes a constant term unless you explicitly remove the term using  $-1$ .

## Examples

### Linear Model from Stepwise Regression

Fit a linear model of the Hald data using stepwise regression.

Load the data.

```
load hald
```

Fit a linear model to the data.

```
mdl = LinearModel.stepwise(ingredients,heat,'PEnter',0.06)
```

1. Adding x4, FStat = 22.7985, pValue = 0.000576232
2. Adding x1, FStat = 108.2239, pValue = 1.105281e-06
3. Adding x2, FStat = 5.0259, pValue = 0.051687
4. Removing x4, FStat = 1.8633, pValue = 0.2054

```
mdl =
```

Linear regression model:

$$y \sim 1 + x1 + x2$$

Estimated Coefficients:

|             | Estimate | SE       | tStat  | pValue     |
|-------------|----------|----------|--------|------------|
| (Intercept) | 52.577   | 2.2862   | 22.998 | 5.4566e-10 |
| x1          | 1.4683   | 0.1213   | 12.105 | 2.6922e-07 |
| x2          | 0.66225  | 0.045855 | 14.442 | 5.029e-08  |

Number of observations: 13, Error degrees of freedom: 10

Root Mean Squared Error: 2.41

R-squared: 0.979, Adjusted R-Squared 0.974

F-statistic vs. constant model: 230, p-value = 4.41e-09

### Simultaneously Specify the Variables and Use Formula

Simultaneously identify response and predictor variables and specify the initial model using formula in stepwise regression.

Load sample data.

```
load hospital
```

Fit a linear model to the data.

```
mdl = LinearModel.stepwise(hospital, 'Weight~1+Smoker', ...
 'ResponseVar', 'Weight', 'PredictorVars', {'Sex', 'Age', 'Smoker'}, ...
 'CategoricalVar', {'Sex', 'Smoker'})
```

1. Adding Sex, FStat = 770.0158, pValue = 6.262758e-48
2. Removing Smoker, FStat = 0.21224, pValue = 0.64605

```
mdl =
```

```
Linear regression model:
 Weight ~ 1 + Sex
```

```
Estimated Coefficients:
```

|             | Estimate | SE     | tStat  | pValue      |
|-------------|----------|--------|--------|-------------|
| (Intercept) | 130.47   | 1.1995 | 108.77 | 5.2762e-104 |
| Sex_Male    | 50.06    | 1.7496 | 28.612 | 2.2464e-49  |

```
Number of observations: 100, Error degrees of freedom: 98
```

```
Root Mean Squared Error: 8.73
```

```
R-squared: 0.893, Adjusted R-Squared 0.892
```

```
F-statistic vs. constant model: 819, p-value = 2.25e-49
```

The weight of the patients do not seem to differ significantly according to age or the status of smoking, or interaction of these factors with gender. `LinearModel.stepwise` only includes `Sex` in the final linear model.

- “Compare large and small stepwise models” on page 9-114

## Algorithms

*Stepwise regression* is a systematic method for adding and removing terms from a linear or generalized linear model based on their statistical significance in explaining the response variable. The method begins with an initial model, specified using `modelspec`, and then compares the explanatory power of incrementally larger and smaller models.

MATLAB uses forward and backward stepwise regression to determine a final model. At each step, the method searches for terms to add to or remove from the model based on the value of the `'Criterion'` argument. The default value of `'Criterion'` is `'sse'`, and in this case, `stepwiselm` uses the  $p$ -value of an  $F$ -statistic to test models with and without a potential term at each step. If a term is not currently in the model, the

null hypothesis is that the term would have a zero coefficient if added to the model. If there is sufficient evidence to reject the null hypothesis, the term is added to the model. Conversely, if a term is currently in the model, the null hypothesis is that the term has a zero coefficient. If there is insufficient evidence to reject the null hypothesis, the term is removed from the model.

Here is how stepwise proceeds when 'Criterion' is 'sse':

- 1 Fit the initial model.
- 2 If any terms not in the model have  $p$ -values less than an entrance tolerance (that is, if it is unlikely that they would have zero coefficient if added to the model), add the one with the smallest  $p$ -value and repeat this step; otherwise, go to step 3.
- 3 If any terms in the model have  $p$ -values greater than an exit tolerance (that is, the hypothesis of a zero coefficient can be rejected), remove the one with the largest  $p$ -value and go to step 2; otherwise, end.

The default for `stepwiseglm` is 'Deviance' and it follows a similar procedure for adding or removing terms.

There are several other criteria available, which you can specify using the 'Criterion' argument. You can use the change in the value of the Akaike information criterion, Bayesian information criterion, R-squared, adjusted R-squared as a criterion to add or remove terms.

Depending on the terms included in the initial model and the order in which terms are moved in and out, the method might build different models from the same set of potential terms. The method terminates when no single step improves the model. There is no guarantee, however, that a different initial model or a different sequence of steps will not lead to a better fit. In this sense, stepwise models are locally optimal, but might not be globally optimal.

## References

- [1] Draper, N. R., and H. Smith. *Applied Regression Analysis*. Hoboken, NJ: Wiley-Interscience, pp. 307–312, 1998.

## Alternatives

You can also construct a stepwise linear model using `stepwiselm`.

You can construct a model using `fitlm`, then manually adjust the model using `step`, `addTerms`, or `removeTerms`. Use `fitlm` for robust regression. You cannot use robust regression and stepwise regression together.

`step` | `LinearModel` | `fitlm`

### How To

- “Linear Regression” on page 9-11
- “Stepwise Regression” on page 9-114

# stepwiseglm

Create generalized linear regression model by stepwise regression

## Syntax

```
mdl = stepwiseglm(tbl,modelspec)
mdl = stepwiseglm(X,y,modelspec)
mdl = stepwiseglm(...,modelspec,Name,Value)
```

## Description

`mdl = stepwiseglm(tbl,modelspec)` creates a generalized linear model of a table or dataset array `tbl`, using stepwise regression to add or remove predictors. `modelspec` is the starting model for the stepwise procedure.

`mdl = stepwiseglm(X,y,modelspec)` creates a generalized linear model of the responses `y` to a data matrix `X`, using stepwise regression to add or remove predictors.

`mdl = stepwiseglm(...,modelspec,Name,Value)` creates a generalized linear model with additional options specified by one or more `Name,Value` pair arguments.

## Examples

### Generalized Linear Model Using Stepwise Algorithm

Create response data using just three of 20 predictors, and create a generalized linear model using stepwise algorithm to see if it uses just the correct predictors.

Create data with 20 predictors, and Poisson response using just three of the predictors, plus a constant.

```
rng('default') % for reproducibility
X = randn(100,20);
mu = exp(X(:,[5 10 15]).* [.4;.2;.3] + 1);
y = poissrnd(mu);
```

Fit a generalized linear model using the Poisson distribution.

```
mdl = stepwiseglm(X,y,...
 'constant', 'upper', 'linear', 'Distribution', 'poisson')
```

```

```
Chi^2-statistic vs. constant model: 91.7, p-value = 9.61e-20
```

The starting model is the constant model. `stepwiseglm` by default uses deviance of the model as the criterion. It first adds `x5` into the model, as the  $p$ -value for the test statistic, deviance (the differences in the deviances of the two models), is less than the default threshold value 0.05. Then, it adds `x15` because given `x5` is in the model, when `x15` is added, the  $p$ -value for chi-squared test is smaller than 0.05. It then adds `x10` because given `x5` and `x15` are in the model, when `x10` is added, the  $p$ -value for the chi-square test statistic is again less than 0.05.

- “Compare large and small stepwise models” on page 9-114

## Input Arguments

### **tbl** — Input data

table | dataset array

Input data, specified as a table or dataset array. When `modelspec` is a `formula`, it specifies the variables to be used as the predictors and response. Otherwise, if you do not specify the predictor and response variables, the last variable is the response variable and the others are the predictor variables by default.

Predictor variables can be numeric, or any grouping variable type, such as logical or categorical (see “Grouping Variables” on page 2-52). The response must be numeric or logical.

To set a different column as the response variable, use the `ResponseVar` name-value pair argument. To use a subset of the columns as predictors, use the `PredictorVars` name-value pair argument.

Data Types: `single` | `double` | `logical`

### **X — Predictor variables**

matrix

Predictor variables, specified as an  $n$ -by- $p$  matrix, where  $n$  is the number of observations and  $p$  is the number of predictor variables. Each column of  $X$  represents one variable, and each row represents one observation.

By default, there is a constant term in the model, unless you explicitly remove it, so do not include a column of 1s in  $X$ .

Data Types: `single` | `double` | `logical`

### **y — Response variable**

vector

Response variable, specified as an  $n$ -by-1 vector, where  $n$  is the number of observations. Each entry in  $y$  is the response for the corresponding row of  $X$ .

Data Types: `single` | `double`

### **modelspec — Starting model**

string specifying the model |  $t$ -by- $(p+1)$  terms matrix | string of the form '`Y ~ terms`'

Starting model for `stepwiseglm`, specified as one of the following:

- String specifying the type of model.

| String          | Model Type                                                                                                      |
|-----------------|-----------------------------------------------------------------------------------------------------------------|
| 'constant'      | Model contains only a constant (intercept) term.                                                                |
| 'linear'        | Model contains an intercept and linear terms for each predictor.                                                |
| 'interactions'  | Model contains an intercept, linear terms, and all products of pairs of distinct predictors (no squared terms). |
| 'purequadratic' | Model contains an intercept, linear terms, and squared terms.                                                   |

| String      | Model Type                                                                                                                                                                                                                                                                             |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'quadratic' | Model contains an intercept, linear terms, interactions, and squared terms.                                                                                                                                                                                                            |
| 'polyijk'   | Model is a polynomial with all terms up to degree <i>i</i> in the first predictor, degree <i>j</i> in the second predictor, etc. Use numerals 0 through 9. For example, 'poly2111' has a constant plus all linear and product terms, and also contains terms with predictor 1 squared. |

- $t$ -by- $(p+1)$  matrix, namely terms matrix, specifying terms to include in model, where  $t$  is the number of terms and  $p$  is the number of predictor variables, and plus one is for the response variable.
- String representing a formula in the form `'Y ~ terms'`, where the `terms` are in “Wilkinson Notation” on page 21-4225.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example:

`'Criterion', 'aic', 'Distribution', 'poisson', 'Upper', 'interactions'` specifies Akaike Information Criterion as the criterion to add or remove variables to the model, Poisson distribution as the distribution of the response variable, and a model with all possible interactions as the largest model to consider as the fit.

### 'BinomialSize' — Number of trials for binomial distribution

1 (default) | scalar value | vector

Number of trials for binomial distribution, that is the sample size, specified as the comma-separated pair consisting of a scalar value or a vector of the same length as the response. This is the parameter  $n$  for the fitted binomial distribution. **BinomialSize** applies only when the **Distribution** parameter is 'binomial'.

If **BinomialSize** is a scalar value, that means all observations have the same number of trials.

As an alternative to `BinomialSize`, you can specify the response as a two-column vector with counts in column 1 and `BinomialSize` in column 2.

Data Types: `single` | `double`

### 'CategoricalVars' — Categorical variables

cell array of strings | logical or numeric index vector

Categorical variables in the fit, specified as the comma-separated pair consisting of `'CategoricalVars'` and either a cell array of strings of the names of the categorical variables in the table or dataset array `tbl`, or a logical or numeric index vector indicating which columns are categorical.

- If data is in a table or dataset array `tbl`, then the default is to treat all categorical or logical variables, character arrays, or cell arrays of strings as categorical variables.
- If data is in matrix `X`, then the default value of this name-value pair argument is an empty matrix `[]`. That is, no variable is categorical unless you specify it.

For example, you can specify the observations 2 and 3 out of 6 as categorical using either of the following examples.

Example: `'CategoricalVars',[2,3]`

Example: `'CategoricalVars',logical([0 1 1 0 0 0])`

Data Types: `single` | `double` | `logical`

### 'Criterion' — Criterion to add or remove terms

`'Deviance'` | `'sse'` | `'aic'` | `'bic'` | `'rsquared'` | `'adjrsquared'`

Criterion to add or remove terms, specified as the comma-separated pair consisting of `'Criterion'` and one of the following:

- `'Deviance'` — Default for `stepwiseglm`.  $p$ -value for  $F$  or chi-squared test of the change in the deviance by adding or removing the term.  $F$ -test is for testing a single model. Chi-squared test is for comparing two different models. This option is not valid for `stepwiselm`.
- `'sse'` — Default for `stepwiselm`.  $p$ -value for an  $F$ -test of the change in the sum of squared error by adding or removing the term.
- `'aic'` — Change in the value of Akaike information criterion (AIC).
- `'bic'` — Change in the value of Bayesian information criterion (BIC).
- `'rsquared'` — Increase in the value of  $R^2$ .

- `'adjrsquared'` — Increase in the value of adjusted  $R^2$ .

Example: `'Criterion', 'bic'`

**'DispersionFlag' — Indicator to compute dispersion parameter**

`false` for `'binomial'` and `'poisson'` distributions (default) | `true`

Indicator to compute dispersion parameter for `'binomial'` and `'poisson'` distributions, specified as the comma-separated pair consisting of `'DispersionFlag'` and one of the following.

|                    |                                                                   |
|--------------------|-------------------------------------------------------------------|
| <code>true</code>  | Estimate a dispersion parameter when computing standard errors    |
| <code>false</code> | Default. Use the theoretical value when computing standard errors |

The fitting function always estimates the dispersion for other distributions.

Example: `'DispersionFlag', true`

**'Distribution' — Distribution of the response variable**

`'normal'` (default) | `'binomial'` | `'poisson'` | `'gamma'` | `'inverse gaussian'`

Distribution of the response variable, specified as the comma-separated pair consisting of `'Distribution'` and one of the following.

|                                 |                               |
|---------------------------------|-------------------------------|
| <code>'normal'</code>           | Normal distribution           |
| <code>'binomial'</code>         | Binomial distribution         |
| <code>'poisson'</code>          | Poisson distribution          |
| <code>'gamma'</code>            | Gamma distribution            |
| <code>'inverse gaussian'</code> | Inverse Gaussian distribution |

Example: `'Distribution', 'gamma'`

**'Exclude' — Observations to exclude**

logical or numeric index vector

Observations to exclude from the fit, specified as the comma-separated pair consisting of `'Exclude'` and a logical or numeric index vector indicating which observations to exclude from the fit.

For example, you can exclude observations 2 and 3 out of 6 using either of the following examples.

Example: `'Exclude', [2,3]`

Example: `'Exclude', logical([0 1 1 0 0 0])`

Data Types: `single` | `double` | `logical`

### 'Intercept' — Indicator for constant term

`true` (default) | `false`

Indicator the for constant term (intercept) in the fit, specified as the comma-separated pair consisting of `'Intercept'` and either `true` to include or `false` to remove the constant term from the model.

Use `'Intercept'` only when specifying the model using a string, not a formula or matrix.

Example: `'Intercept', false`

### 'Link' — Link function

The canonical link function (default) | scalar value | structure

Link function to use in place of the canonical link function, specified as the comma-separated pair consisting of `'Link'` and one of the following.

| Link Function Name                                                                                          | Link Function                   | Mean (Inverse) Function           |
|-------------------------------------------------------------------------------------------------------------|---------------------------------|-----------------------------------|
| <code>'identity'</code>                                                                                     | $f(\mu) = \mu$                  | $\mu = Xb$                        |
| <code>'log'</code>                                                                                          | $f(\mu) = \log(\mu)$            | $\mu = \exp(Xb)$                  |
| <code>'logit'</code>                                                                                        | $f(\mu) = \log(\mu/(1-\mu))$    | $\mu = \exp(Xb) / (1 + \exp(Xb))$ |
| <code>'probit'</code>                                                                                       | $f(\mu) = \Phi^{-1}(\mu)$       | $\mu = \Phi(Xb)$                  |
| <code>'comprologlog'</code>                                                                                 | $f(\mu) = \log(-\log(1 - \mu))$ | $\mu = 1 - \exp(-\exp(Xb))$       |
| <code>'reciprocal'</code>                                                                                   | $f(\mu) = 1/\mu$                | $\mu = 1/(Xb)$                    |
| <code>p</code> (a number)                                                                                   | $f(\mu) = \mu^p$                | $\mu = Xb^{1/p}$                  |
| <code>S</code> (a structure) with three fields. Each field holds a function handle that accepts a vector of | $f(\mu) = S.Link(\mu)$          | $\mu = S.Inverse(Xb)$             |

| Link Function Name                                                                                                                                                                                                                                               | Link Function | Mean (Inverse) Function |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------|-------------------------|
| inputs and returns a vector of the same size: <ul style="list-style-type: none"> <li>• <b>S.Link</b> — The link function</li> <li>• <b>S.Inverse</b> — The inverse link function</li> <li>• <b>S.Derivative</b> — The derivative of the link function</li> </ul> |               |                         |

The link function defines the relationship  $f(\mu) = X*b$  between the mean response  $\mu$  and the linear combination of predictors  $X*b$ .

For more information on the canonical link functions, see [Definitions](#).

Example: 'Link', 'probit'

**'Lower'** — Model specification describing terms that cannot be removed from model  
'constant' (default)

Model specification describing terms that cannot be removed from the model, specified as the comma-separated pair consisting of 'Lower' and one of the string options for `modelspec` naming the model.

Example: 'Lower', 'linear'

**'Offset'** — Offset variable  
[] (default) | vector | string

Offset variable in the fit, specified as the comma-separated pair consisting of 'Offset' and a vector or name of a variable with the same length as the response.

`fitglm` and `stepwiseglm` use `Offset` as an additional predictor, with a coefficient value fixed at 1.0. In other words, the formula for fitting is  $\mu \sim \text{Offset} + (\text{terms involving real predictors})$

with the `Offset` predictor having coefficient 1.

For example, consider a Poisson regression model. Suppose the number of counts is known for theoretical reasons to be proportional to a predictor `A`. By using the log link

function and by specifying  $\log(A)$  as an offset, you can force the model to satisfy this theoretical constraint.

Data Types: `single` | `double` | `char`

### 'PEnter' — Improvement measure for adding term

scalar value

Improvement measure for adding a term, specified as the comma-separated pair consisting of 'PEnter' and a scalar value. The default values are below.

| Criterion     | Default value | Decision                                                                                                 |
|---------------|---------------|----------------------------------------------------------------------------------------------------------|
| 'Deviance'    | 0.05          | If the $p$ -value of $F$ or chi-squared statistic is smaller than PEnter, add the term to the model.     |
| 'SSE'         | 0.05          | If the SSE of the model is smaller than PEnter, add the term to the model.                               |
| 'AIC'         | 0             | If the change in the AIC of the model is smaller than PEnter, add the term to the model.                 |
| 'BIC'         | 0             | If the change in the BIC of the model is smaller than PEnter, add the term to the model.                 |
| 'Rsquared'    | 0.1           | If the increase in the R-squared of the model is larger than PEnter, add the term to the model.          |
| 'AdjRsquared' | 0             | If the increase in the adjusted R-squared of the model is larger than PEnter, add the term to the model. |

For more information on the criteria, see Criterion name-value pair argument.

Example: 'PEnter', 0.075

**'PredictorVars' — Predictor variables**

cell array of strings | logical or numeric index vector

Predictor variables to use in the fit, specified as the comma-separated pair consisting of 'PredictorVars' and either a cell array of strings of the variable names in the table or dataset array `tbl`, or a logical or numeric index vector indicating which columns are predictor variables.

The strings should be among the names in `tbl`, or the names you specify using the 'VarNames' name-value pair argument.

The default is all variables in  $X$ , or all variables in `tbl` except for `ResponseVar`.

For example, you can specify the second and third variables as the predictor variables using either of the following examples.

Example: `'PredictorVars',[2,3]`

Example: `'PredictorVars',logical([0 1 1 0 0 0])`

Data Types: `single` | `double` | `logical` | `cell`

**'PRemove' — Improvement measure for removing term**

scalar value

Improvement measure for removing a term, specified as the comma-separated pair consisting of 'PRemove' and a scalar value.

| Criterion  | Default value | Decision                                                                                                                |
|------------|---------------|-------------------------------------------------------------------------------------------------------------------------|
| 'Deviance' | 0.10          | If the $p$ -value of $F$ or chi-squared statistic is larger than <code>PRemove</code> , remove the term from the model. |
| 'SSE'      | 0.10          | If the $p$ -value of the $F$ statistic is larger than <code>PRemove</code> , remove the term from the model.            |
| 'AIC'      | 0.01          | If the change in the AIC of the model is larger than <code>PRemove</code> , remove the term from the model.             |

| Criterion     | Default value | Decision                                                                                                                      |
|---------------|---------------|-------------------------------------------------------------------------------------------------------------------------------|
| 'BIC'         | 0.01          | If the change in the BIC of the model is larger than <b>PRemove</b> , remove the term from the model.                         |
| 'Rsquared'    | 0.05          | If the increase in the R-squared value of the model is smaller than <b>PRemove</b> , remove the term from the model.          |
| 'AdjRsquared' | -0.05         | If the increase in the adjusted R-squared value of the model is smaller than <b>PRemove</b> , remove the term from the model. |

At each step, stepwise algorithm also checks whether any term is redundant (linearly dependent) with other terms in the current model. When any term is linearly dependent with other terms in the current model, it is removed, regardless of the criterion value.

For more information on the criteria, see Criterion name-value pair argument.

Example: 'PRemove',0.05

### 'ResponseVar' — Response variable

last column in `tbl` (default) | string for variable name | logical or numeric index vector

Response variable to use in the fit, specified as the comma-separated pair consisting of 'ResponseVar' and either a string of the variable name in the table or dataset array `tbl`, or a logical or numeric index vector indicating which column is the response variable. You typically need to use 'ResponseVar' when fitting a table or dataset array `tbl`.

For example, you can specify the fourth variable, say `yield`, as the response out of six variables, in one of the following ways.

Example: 'ResponseVar','yield'

Example: 'ResponseVar',[4]

Example: 'ResponseVar',logical([0 0 0 1 0 0])

Data Types: `single` | `double` | `logical` | `char`

**'Upper'** — Model specification describing largest set of terms in fit

`'interaction'` (default) | `string`

Model specification describing the largest set of terms in the fit, specified as the comma-separated pair consisting of `'Upper'` and one of the string options for `modelspec` naming the model.

Example: `'Upper', 'quadratic'`

**'VarNames'** — Names of variables in fit

`{'x1', 'x2', ..., 'xn', 'y'}` (default) | cell array of strings

Names of variables in fit, specified as the comma-separated pair consisting of `'VarNames'` and a cell array of strings including the names for the columns of  $X$  first, and the name for the response variable  $y$  last.

`'VarNames'` is not applicable to variables in a table or dataset array, because those variables already have names.

For example, if in your data, horsepower, acceleration, and model year of the cars are the predictor variables, and miles per gallon (MPG) is the response variable, then you can name the variables as follows.

Example: `'VarNames', {'Horsepower', 'Acceleration', 'Model_Year', 'MPG'}`

Data Types: `cell`

**'Weights'** — Observation weights

`ones(n, 1)` (default) |  $n$ -by-1 vector of nonnegative scalar values

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and an  $n$ -by-1 vector of nonnegative scalar values, where  $n$  is the number of observations.

Data Types: `single` | `double`

## Output Arguments

**mdl** — Generalized linear model

`GeneralizedLinearModel` object

Generalized linear model representing a least-squares fit of the link of the response to the data, returned as a `GeneralizedLinearModel` object.

For properties and methods of the generalized linear model object, `mdl`, see the `GeneralizedLinearModel` class page.

## Alternatives

Use `fitglm` to create a model with a fixed specification. Use `step`, `addTerms`, or `removeTerms` to adjust a fitted model.

## More About

### Terms Matrix

A terms matrix is a  $t$ -by- $(p + 1)$  matrix specifying terms in a model, where  $t$  is the number of terms,  $p$  is the number of predictor variables, and plus one is for the response variable.

The value of  $T(i, j)$  is the exponent of variable  $j$  in term  $i$ . Suppose there are three predictor variables  $A$ ,  $B$ , and  $C$ :

```
[0 0 0 0] % Constant term or intercept
[0 1 0 0] % B; equivalently, A^0 * B^1 * C^0
[1 0 1 0] % A*C
[2 0 0 0] % A^2
[0 1 2 0] % B*(C^2)
```

The 0 at the end of each term represents the response variable. In general,

- If you have the variables in a table or dataset array, then 0 must represent the response variable depending on the position of the response variable. The following example illustrates this.

Load the sample data and define the dataset array.

```
load hospital
ds = dataset(hospital.Sex,hospital.BloodPressure(:,1),hospital.Age,...
hospital.Smoker,'VarNames',{'Sex','BloodPressure','Age','Smoker'});
```

Represent the linear model `'BloodPressure ~ 1 + Sex + Age + Smoker'` in a terms matrix. The response variable is in the second column of the dataset array,

so there must be a column of 0s for the response variable in the second column of the terms matrix.

```
T = [0 0 0 0;1 0 0 0;0 0 1 0;0 0 0 1]
```

```
T =
```

```
 0 0 0 0
 1 0 0 0
 0 0 1 0
 0 0 0 1
```

Redefine the dataset array.

```
ds = dataset(hospital.BloodPressure(:,1),hospital.Sex,hospital.Age,...
hospital.Smoker, 'VarNames',{ 'BloodPressure', 'Sex', 'Age', 'Smoker' });
```

Now, the response variable is the first term in the dataset array. Specify the same linear model, 'BloodPressure ~ 1 + Sex + Age + Smoker', using a terms matrix.

```
T = [0 0 0 0;0 1 0 0;0 0 1 0;0 0 0 1]
```

```
T =
```

```
 0 0 0 0
 0 1 0 0
 0 0 1 0
 0 0 0 1
```

- If you have the predictor and response variables in a matrix and column vector, then you must include 0 for the response variable at the end of each term. The following example illustrates this.

Load the sample data and define the matrix of predictors.

```
load carsmall
X = [Acceleration,Weight];
```

Specify the model 'MPG ~ Acceleration + Weight + Acceleration:Weight + Weight^2' using a term matrix and fit the model to the data. This model includes the main effect and two-way interaction terms for the variables, Acceleration and Weight, and a second-order term for the variable, Weight.

```
T = [0 0 0;1 0 0;0 1 0;1 1 0;0 2 0]
```

T =

```

0 0 0
1 0 0
0 1 0
1 1 0
0 2 0

```

Fit a linear model.

```
mdl = fitlm(X,MPG,T)
```

mdl =

Linear regression model:

```
y ~ 1 + x1*x2 + x2^2
```

Estimated Coefficients:

|             | Estimate    | SE         | tStat   | pValue     |
|-------------|-------------|------------|---------|------------|
| (Intercept) | 48.906      | 12.589     | 3.8847  | 0.00019665 |
| x1          | 0.54418     | 0.57125    | 0.95261 | 0.34337    |
| x2          | -0.012781   | 0.0060312  | -2.1192 | 0.036857   |
| x1:x2       | -0.00010892 | 0.00017925 | -0.6076 | 0.545      |
| x2^2        | 9.7518e-07  | 7.5389e-07 | 1.2935  | 0.19917    |

Number of observations: 94, Error degrees of freedom: 89

Root Mean Squared Error: 4.1

R-squared: 0.751, Adjusted R-Squared 0.739

F-statistic vs. constant model: 67, p-value = 4.99e-26

Only the intercept and x2 term, which correspond to the **Weight** variable, are significant at the 5% significance level.

Now, perform a stepwise regression with a constant model as the starting model and a linear model with interactions as the upper model.

```
T = [0 0 0;1 0 0;0 1 0;1 1 0];
mdl = stepwiselm(X,MPG,[0 0 0], 'upper',T)
```

1. Adding x2, FStat = 259.3087, pValue = 1.643351e-28

mdl =

Linear regression model:

```
y ~ 1 + x2
```

Estimated Coefficients:

|             | Estimate   | SE        | tStat   | pValue     |
|-------------|------------|-----------|---------|------------|
| (Intercept) | 49.238     | 1.6411    | 30.002  | 2.7015e-49 |
| x2          | -0.0086119 | 0.0005348 | -16.103 | 1.6434e-28 |

Number of observations: 94, Error degrees of freedom: 92

Root Mean Squared Error: 4.13

R-squared: 0.738, Adjusted R-Squared 0.735

F-statistic vs. constant model: 259, p-value = 1.64e-28

The results of the stepwise regression are consistent with the results of `fitlm` in the previous step.

## Formula

A formula for model specification is a string of the form '*Y ~ terms*'

where

- *Y* is the response name.
- *terms* contains
  - Variable names
  - + means include the next variable
  - - means do not include the next variable
  - : defines an interaction, a product of terms
  - \* defines an interaction **and all lower-order terms**
  - ^ raises the predictor to a power, exactly as in \* repeated, so ^ includes lower order terms as well
  - () groups terms

---

**Note:** Formulas include a constant (intercept) term by default. To exclude a constant term from the model, include -1 in the formula.

---

For example,

'*Y ~ A + B + C*' means a three-variable linear model with intercept.

' $Y \sim A + B + C - 1$ ' is a three-variable linear model without intercept.  
 ' $Y \sim A + B + C + B^2$ ' is a three-variable model with intercept and a  $B^2$  term.  
 ' $Y \sim A + B^2 + C$ ' is the same as the previous example because  $B^2$  includes a  $B$  term.  
 ' $Y \sim A + B + C + A:B$ ' includes an  $A*B$  term.  
 ' $Y \sim A*B + C$ ' is the same as the previous example because  $A*B = A + B + A:B$ .  
 ' $Y \sim A*B*C - A:B:C$ ' has all interactions among  $A$ ,  $B$ , and  $C$ , except the three-way interaction.  
 ' $Y \sim A*(B + C + D)$ ' has all linear terms, plus products of  $A$  with each of the other variables.

### Wilkinson Notation

Wilkinson notation describes the factors present in models. The notation relates to factors present in models, not to the multipliers (coefficients) of those factors.

| Wilkinson Notation                      | Factors in Standard Notation |
|-----------------------------------------|------------------------------|
| 1                                       | Constant (intercept) term    |
| $A^k$ , where $k$ is a positive integer | $A, A^2, \dots, A^k$         |
| $A + B$                                 | $A, B$                       |
| $A*B$                                   | $A, B, A*B$                  |
| $A:B$                                   | $A*B$ only                   |
| $-B$                                    | Do not include $B$           |
| $A*B + C$                               | $A, B, C, A*B$               |
| $A + B + C + A:B$                       | $A, B, C, A*B$               |
| $A*B*C - A:B:C$                         | $A, B, C, A*B, A*C, B*C$     |
| $A*(B + C)$                             | $A, B, C, A*B, A*C$          |

Statistics Toolbox notation always includes a constant term unless you explicitly remove the term using  $-1$ .

### Canonical Function

The default link function for a generalized linear model is the *canonical link function*.

### Canonical Link Functions for Generalized Linear Models

| Distribution       | Link Function Name | Link Function                | Mean (Inverse) Function           |
|--------------------|--------------------|------------------------------|-----------------------------------|
| 'normal'           | 'identity'         | $f(\mu) = \mu$               | $\mu = Xb$                        |
| 'binomial'         | 'logit'            | $f(\mu) = \log(\mu/(1-\mu))$ | $\mu = \exp(Xb) / (1 + \exp(Xb))$ |
| 'poisson'          | 'log'              | $f(\mu) = \log(\mu)$         | $\mu = \exp(Xb)$                  |
| 'gamma'            | -1                 | $f(\mu) = 1/\mu$             | $\mu = 1/(Xb)$                    |
| 'inverse gaussian' | -2                 | $f(\mu) = 1/\mu^2$           | $\mu = (Xb)^{-1/2}$               |

### Tips

- The generalized linear model `mdl` is a standard linear model unless you specify otherwise with the **Distribution** name-value pair.
- For other methods such as `devianceTest`, or properties of the `GeneralizedLinearModel` object, see `GeneralizedLinearModel`.

### Algorithms

*Stepwise regression* is a systematic method for adding and removing terms from a linear or generalized linear model based on their statistical significance in explaining the response variable. The method begins with an initial model, specified using `modelspec`, and then compares the explanatory power of incrementally larger and smaller models.

MATLAB uses forward and backward stepwise regression to determine a final model. At each step, the method searches for terms to add to or remove from the model based on the value of the 'Criterion' argument. The default value of 'Criterion' is 'sse', and in this case, `stepwiselm` uses the  $p$ -value of an  $F$ -statistic to test models with and without a potential term at each step. If a term is not currently in the model, the null hypothesis is that the term would have a zero coefficient if added to the model. If there is sufficient evidence to reject the null hypothesis, the term is added to the model. Conversely, if a term is currently in the model, the null hypothesis is that the term has a zero coefficient. If there is insufficient evidence to reject the null hypothesis, the term is removed from the model.

Here is how stepwise proceeds when 'Criterion' is 'sse':

- 1 Fit the initial model.
- 2 If any terms not in the model have  $p$ -values less than an entrance tolerance (that is, if it is unlikely that they would have zero coefficient if added to the model), add the one with the smallest  $p$ -value and repeat this step; otherwise, go to step 3.

- 3 If any terms in the model have  $p$ -values greater than an exit tolerance (that is, the hypothesis of a zero coefficient can be rejected), remove the one with the largest  $p$ -value and go to step 2; otherwise, end.

The default for `stepwiseglm` is 'Deviance' and it follows a similar procedure for adding or removing terms.

There are several other criteria available, which you can specify using the 'Criterion' argument. You can use the change in the value of the Akaike information criterion, Bayesian information criterion, R-squared, adjusted R-squared as a criterion to add or remove terms.

Depending on the terms included in the initial model and the order in which terms are moved in and out, the method might build different models from the same set of potential terms. The method terminates when no single step improves the model. There is no guarantee, however, that a different initial model or a different sequence of steps will not lead to a better fit. In this sense, stepwise models are locally optimal, but might not be globally optimal.

`fitglm` | `GeneralizedLinearModel`

## stepwiselm

Create linear regression model using stepwise regression

### Syntax

```
mdl = stepwiselm(tbl,modelspec)
mdl = stepwiselm(X,y,modelspec)
mdl = stepwiselm(____,Name,Value)
```

### Description

`mdl = stepwiselm(tbl,modelspec)` returns a linear model for the variables in the table or dataset array `tbl` using stepwise regression to add or remove predictors. `stepwiselm` uses forward and backward stepwise regression to determine a final model. At each step, the function searches for terms to add to or remove from the model based on the value of the 'Criterion' argument. `modelspec` is the starting model for the stepwise procedure.

`mdl = stepwiselm(X,y,modelspec)` creates a linear model of the responses `y` to the predictor variables in the data matrix `X`, using stepwise regression to add or remove predictors. `modelspec` is the starting model for the stepwise procedure.

`mdl = stepwiselm( ____,Name,Value)` creates a linear model for any of the inputs in the previous syntaxes, with additional options specified by one or more Name,Value pair arguments.

For example, you can specify the categorical variables, the smallest or largest set of terms to use in the model, the maximum number of steps to take, or the criterion `stepwiselm` uses to add or remove terms.

### Examples

#### Linear Model Using Stepwise Regression

Load the sample data.

```
load hald
```

`hald` contains hardening data for 13 different concrete compositions. `heat` is the heat of hardening after 180 days. `ingredients` is the percentage of each different ingredient in the cement sample.

Fit a linear model to the data. Set the criterion value to enter the model as 0.06.

```
mdl = stepwiselm(ingredients,heat,'PEnter',0.06)
```

1. Adding x4, FStat = 22.7985, pValue = 0.000576232
2. Adding x1, FStat = 108.2239, pValue = 1.105281e-06
3. Adding x2, FStat = 5.0259, pValue = 0.051687
4. Removing x4, FStat = 1.8633, pValue = 0.2054

```
mdl =
```

Linear regression model:

$$y \sim 1 + x1 + x2$$

Estimated Coefficients:

|             | Estimate | SE       | tStat  | pValue     |
|-------------|----------|----------|--------|------------|
| (Intercept) | 52.577   | 2.2862   | 22.998 | 5.4566e-10 |
| x1          | 1.4683   | 0.1213   | 12.105 | 2.6922e-07 |
| x2          | 0.66225  | 0.045855 | 14.442 | 5.029e-08  |

Number of observations: 13, Error degrees of freedom: 10

Root Mean Squared Error: 2.41

R-squared: 0.979, Adjusted R-Squared 0.974

F-statistic vs. constant model: 230, p-value = 4.41e-09

By default, the starting model is the constant model. `stepwiselm` performs forward selection and `x4`, `x1`, and `x2`, respectively, as the corresponding  $p$ -values are less than the `PEnter` value of 0.06. `stepwiselm` later uses backward elimination and eliminates `x4` from the model. Because, given that `x2` is in the model, the  $p$ -value of `x4` is higher than the default value of `PRemove`, 0.1.

### Specify Model Using Formula and Specify Variables

Perform stepwise regression with variables in a dataset array. Specify the starting model using formula, and identify the response and predictor variables with optional arguments.

Load the sample data.

```
load hospital
```

The hospital dataset array includes the gender, age, weight, and smoking status of patients.

Fit a linear model with a starting model of a constant term and `Smoker` as the predictor variable. Specify the response variable, `Weight`, and categorical predictor variables, `Sex`, `Age`, and `Smoker`.

```
mdl = stepwiselm(hospital, 'Weight-1+Smoker', ...
'ResponseVar', 'Weight', 'PredictorVars', {'Sex', 'Age', 'Smoker'}, ...
'CategoricalVar', {'Sex', 'Smoker'})
```

```
1. Adding Sex, FStat = 770.0158, pValue = 6.262758e-48
2. Removing Smoker, FStat = 0.21224, pValue = 0.64605
```

```
mdl =
```

```
Linear regression model:
Weight ~ 1 + Sex
```

```
Estimated Coefficients:
```

|             | Estimate | SE     | tStat  | pValue      |
|-------------|----------|--------|--------|-------------|
| (Intercept) | 130.47   | 1.1995 | 108.77 | 5.2762e-104 |
| Sex_Male    | 50.06    | 1.7496 | 28.612 | 2.2464e-49  |

```
Number of observations: 100, Error degrees of freedom: 98
Root Mean Squared Error: 8.73
R-squared: 0.893, Adjusted R-Squared 0.892
F-statistic vs. constant model: 819, p-value = 2.25e-49
```

At each step, `stepwiselm` searches for terms to add and remove. At first step, stepwise algorithm adds `Sex` to the model with a  $p$ -value of  $6.26e-48$ . Then, removes `Smoker` from the model, since given `Sex` in the model, the variable `Smoker` becomes redundant. `stepwiselm` only includes `Sex` in the final linear model. The weight of the patients do not seem to differ significantly according to age or the status of smoking.

- “Compare large and small stepwise models” on page 9-114
- “Linear Regression” on page 9-11

## Input Arguments

### **tbl** — Input data

table | dataset array

Input data, specified as a table or dataset array. When `modelspec` is a `formula`, it specifies the variables to be used as the predictors and response. Otherwise, if you do not specify the predictor and response variables, the last variable is the response variable and the others are the predictor variables by default.

Predictor variables can be numeric, or any grouping variable type, such as logical or categorical (see “Grouping Variables” on page 2-52). The response must be numeric or logical.

To set a different column as the response variable, use the `ResponseVar` name-value pair argument. To use a subset of the columns as predictors, use the `PredictorVars` name-value pair argument.

Data Types: `single` | `double` | `logical`

### **X** — Predictor variables

matrix

Predictor variables, specified as an  $n$ -by- $p$  matrix, where  $n$  is the number of observations and  $p$  is the number of predictor variables. Each column of `X` represents one variable, and each row represents one observation.

By default, there is a constant term in the model, unless you explicitly remove it, so do not include a column of 1s in `X`.

Data Types: `single` | `double` | `logical`

### **y** — Response variable

vector

Response variable, specified as an  $n$ -by-1 vector, where  $n$  is the number of observations. Each entry in `y` is the response for the corresponding row of `X`.

Data Types: `single` | `double`

### **modelspec** — Starting model

string specifying the model |  $t$ -by- $(p+1)$  terms matrix | string of the form '`Y ~ terms`'

Starting model for the stepwise regression, specified as one of the following:

- String specifying the type of starting model.

| String          | Model Type                                                                                                                                                                                                                                                                   |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'constant'      | Model contains only a constant (intercept) term.                                                                                                                                                                                                                             |
| 'linear'        | Model contains an intercept and linear terms for each predictor.                                                                                                                                                                                                             |
| 'interactions'  | Model contains an intercept, linear terms, and all products of pairs of distinct predictors (no squared terms).                                                                                                                                                              |
| 'purequadratic' | Model contains an intercept, linear terms, and squared terms.                                                                                                                                                                                                                |
| 'quadratic'     | Model contains an intercept, linear terms, interactions, and squared terms.                                                                                                                                                                                                  |
| 'polyijk'       | Model is a polynomial with all terms up to degree $i$ in the first predictor, degree $j$ in the second predictor, etc. Use numerals 0 through 9. For example, 'poly2111' has a constant plus all linear and product terms, and also contains terms with predictor 1 squared. |

If you want to specify the smallest or largest set of terms in the model, use the Lower and Upper name-value pair arguments.

- $t$ -by- $(p+1)$  matrix, namely a terms matrix, specifying terms to include in model, where  $t$  is the number of terms and  $p$  is the number of predictor variables, and plus one is for the response variable.
- String representing a formula in the form `'Y ~ terms'`, where the `terms` are in “Wilkinson Notation” on page 21-4243.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

Example: `'Criterion','aic','Upper',interactions,'Verbose',1` instructs `stepwiselm` to use the Akaike information criterion, display the action it takes at each step, and include at most the interaction terms in the model.

### 'CategoricalVars' — Categorical variables

cell array of strings | logical or numeric index vector

Categorical variables in the fit, specified as the comma-separated pair consisting of `'CategoricalVars'` and either a cell array of strings of the names of the categorical variables in the table or dataset array `tbl`, or a logical or numeric index vector indicating which columns are categorical.

- If data is in a table or dataset array `tbl`, then the default is to treat all categorical or logical variables, character arrays, or cell arrays of strings as categorical variables.
- If data is in matrix `X`, then the default value of this name-value pair argument is an empty matrix `[]`. That is, no variable is categorical unless you specify it.

For example, you can specify the observations 2 and 3 out of 6 as categorical using either of the following examples.

Example: `'CategoricalVars',[2,3]`

Example: `'CategoricalVars',logical([0 1 1 0 0 0])`

Data Types: `single` | `double` | `logical`

### 'Criterion' — Criterion to add or remove terms

`'Deviance'` | `'sse'` | `'aic'` | `'bic'` | `'rsquared'` | `'adjrsquared'`

Criterion to add or remove terms, specified as the comma-separated pair consisting of `'Criterion'` and one of the following:

- `'Deviance'` — Default for `stepwiseglm`.  $p$ -value for  $F$  or chi-squared test of the change in the deviance by adding or removing the term.  $F$ -test is for testing a single model. Chi-squared test is for comparing two different models. This option is not valid for `stepwiselm`.
- `'sse'` — Default for `stepwiselm`.  $p$ -value for an  $F$ -test of the change in the sum of squared error by adding or removing the term.
- `'aic'` — Change in the value of Akaike information criterion (AIC).
- `'bic'` — Change in the value of Bayesian information criterion (BIC).
- `'rsquared'` — Increase in the value of  $R^2$ .

- `'adjrsquared'` — Increase in the value of adjusted  $R^2$ .

Example: `'Criterion', 'bic'`

### **'Exclude' — Observations to exclude**

logical or numeric index vector

Observations to exclude from the fit, specified as the comma-separated pair consisting of `'Exclude'` and a logical or numeric index vector indicating which observations to exclude from the fit.

For example, you can exclude observations 2 and 3 out of 6 using either of the following examples.

Example: `'Exclude', [2,3]`

Example: `'Exclude', logical([0 1 1 0 0 0])`

Data Types: `single` | `double` | `logical`

### **'Intercept' — Indicator for constant term**

`true` (default) | `false`

Indicator the for constant term (intercept) in the fit, specified as the comma-separated pair consisting of `'Intercept'` and either `true` to include or `false` to remove the constant term from the model.

Use `'Intercept'` only when specifying the model using a string, not a formula or matrix.

Example: `'Intercept', false`

### **'Lower' — Model specification describing terms that cannot be removed from model**

`'constant'` (default)

Model specification describing terms that cannot be removed from the model, specified as the comma-separated pair consisting of `'Lower'` and one of the string options for `modelspec` naming the model.

Example: `'Lower', 'linear'`

### **'NSteps' — Number of steps to take**

1 (default) | positive integer

Number of steps to take, specified as the comma-separated pair consisting of 'NSteps' and a positive integer.

Data Types: `single` | `double`

### 'PEnter' — Improvement measure for adding term

scalar value

Improvement measure for adding a term, specified as the comma-separated pair consisting of 'PEnter' and a scalar value. The default values are below.

| Criterion     | Default value | Decision                                                                                                         |
|---------------|---------------|------------------------------------------------------------------------------------------------------------------|
| 'Deviance'    | 0.05          | If the $p$ -value of $F$ or chi-squared statistic is smaller than <b>PEnter</b> , add the term to the model.     |
| 'SSE'         | 0.05          | If the SSE of the model is smaller than <b>PEnter</b> , add the term to the model.                               |
| 'AIC'         | 0             | If the change in the AIC of the model is smaller than <b>PEnter</b> , add the term to the model.                 |
| 'BIC'         | 0             | If the change in the BIC of the model is smaller than <b>PEnter</b> , add the term to the model.                 |
| 'Rsquared'    | 0.1           | If the increase in the R-squared of the model is larger than <b>PEnter</b> , add the term to the model.          |
| 'AdjRsquared' | 0             | If the increase in the adjusted R-squared of the model is larger than <b>PEnter</b> , add the term to the model. |

For more information on the criteria, see Criterion name-value pair argument.

Example: 'PEnter', 0.075

**'PredictorVars' — Predictor variables**

cell array of strings | logical or numeric index vector

Predictor variables to use in the fit, specified as the comma-separated pair consisting of **'PredictorVars'** and either a cell array of strings of the variable names in the table or dataset array **tbl**, or a logical or numeric index vector indicating which columns are predictor variables.

The strings should be among the names in **tbl**, or the names you specify using the **'VarNames'** name-value pair argument.

The default is all variables in **X**, or all variables in **tbl** except for **ResponseVar**.

For example, you can specify the second and third variables as the predictor variables using either of the following examples.

Example: `'PredictorVars',[2,3]`

Example: `'PredictorVars',logical([0 1 1 0 0 0])`

Data Types: `single` | `double` | `logical` | `cell`

**'PRemove' — Improvement measure for removing term**

scalar value

Improvement measure for removing a term, specified as the comma-separated pair consisting of **'PRemove'** and a scalar value.

| Criterion  | Default value | Decision                                                                                                          |
|------------|---------------|-------------------------------------------------------------------------------------------------------------------|
| 'Deviance' | 0.10          | If the $p$ -value of $F$ or chi-squared statistic is larger than <b>PRemove</b> , remove the term from the model. |
| 'SSE'      | 0.10          | If the $p$ -value of the $F$ statistic is larger than <b>PRemove</b> , remove the term from the model.            |
| 'AIC'      | 0.01          | If the change in the AIC of the model is larger than <b>PRemove</b> , remove the term from the model.             |

| Criterion     | Default value | Decision                                                                                                                      |
|---------------|---------------|-------------------------------------------------------------------------------------------------------------------------------|
| 'BIC'         | 0.01          | If the change in the BIC of the model is larger than <b>PRemove</b> , remove the term from the model.                         |
| 'Rsquared'    | 0.05          | If the increase in the R-squared value of the model is smaller than <b>PRemove</b> , remove the term from the model.          |
| 'AdjRsquared' | -0.05         | If the increase in the adjusted R-squared value of the model is smaller than <b>PRemove</b> , remove the term from the model. |

At each step, stepwise algorithm also checks whether any term is redundant (linearly dependent) with other terms in the current model. When any term is linearly dependent with other terms in the current model, it is removed, regardless of the criterion value.

For more information on the criteria, see Criterion name-value pair argument.

Example: 'PRemove',0.05

### 'ResponseVar' — Response variable

last column in `tbl` (default) | string for variable name | logical or numeric index vector

Response variable to use in the fit, specified as the comma-separated pair consisting of 'ResponseVar' and either a string of the variable name in the table or dataset array `tbl`, or a logical or numeric index vector indicating which column is the response variable. You typically need to use 'ResponseVar' when fitting a table or dataset array `tbl`.

For example, you can specify the fourth variable, say `yield`, as the response out of six variables, in one of the following ways.

Example: 'ResponseVar','yield'

Example: 'ResponseVar',[4]

Example: 'ResponseVar',logical([0 0 0 1 0 0])

Data Types: `single` | `double` | `logical` | `char`

**'Upper'** — Model specification describing largest set of terms in fit

`'interaction'` (default) | `string`

Model specification describing the largest set of terms in the fit, specified as the comma-separated pair consisting of `'Upper'` and one of the string options for `modelspec` naming the model.

Example: `'Upper', 'quadratic'`

**'VarNames'** — Names of variables in fit

`'x1', 'x2', ..., 'xn', 'y'` (default) | cell array of strings

Names of variables in fit, specified as the comma-separated pair consisting of `'VarNames'` and a cell array of strings including the names for the columns of `X` first, and the name for the response variable `y` last.

`'VarNames'` is not applicable to variables in a table or dataset array, because those variables already have names.

For example, if in your data, horsepower, acceleration, and model year of the cars are the predictor variables, and miles per gallon (MPG) is the response variable, then you can name the variables as follows.

Example: `'VarNames', {'Horsepower', 'Acceleration', 'Model_Year', 'MPG'}`

Data Types: `cell`

**'Verbose'** — Control for display of information

1 (default) | 0 | 2

Control for display of information, specified as the comma-separated pair consisting of `'Verbose'` and one of the following:

- 0 — Suppress all display.
- 1 — Display the action taken at each step.
- 2 — Also display the actions evaluated at each step.

Example: `'Verbose', 2`

**'Weights'** — Observation weights

`ones(n, 1)` (default) |  $n$ -by-1 vector of nonnegative scalar values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and an  $n$ -by-1 vector of nonnegative scalar values, where  $n$  is the number of observations.

Data Types: `single` | `double`

## Output Arguments

### **mdl** — Linear model

LinearModel object

Linear model representing a least-squares fit of the response to the data, returned as a LinearModel object.

For the properties and methods of the linear model object, `mdl`, see the LinearModel class page.

## Alternative Functionality

You can construct a model using `fitlm`, and then manually adjust the model using `step`, `addTerms`, or `removeTerms`.

## More About

### Terms Matrix

A terms matrix is a  $t$ -by- $(p + 1)$  matrix specifying terms in a model, where  $t$  is the number of terms,  $p$  is the number of predictor variables, and plus one is for the response variable.

The value of  $T(i, j)$  is the exponent of variable  $j$  in term  $i$ . Suppose there are three predictor variables  $A$ ,  $B$ , and  $C$ :

```
[0 0 0 0] % Constant term or intercept
[0 1 0 0] % B; equivalently, A^0 * B^1 * C^0
[1 0 1 0] % A*C
[2 0 0 0] % A^2
[0 1 2 0] % B*(C^2)
```

The 0 at the end of each term represents the response variable. In general,

- If you have the variables in a table or dataset array, then 0 must represent the response variable depending on the position of the response variable. The following example illustrates this.

Load the sample data and define the dataset array.

```
load hospital
ds = dataset(hospital.Sex,hospital.BloodPressure(:,1),hospital.Age,...
hospital.Smoker,'VarNames',{'Sex','BloodPressure','Age','Smoker'});
```

Represent the linear model 'BloodPressure ~ 1 + Sex + Age + Smoker' in a terms matrix. The response variable is in the second column of the dataset array, so there must be a column of 0s for the response variable in the second column of the terms matrix.

```
T = [0 0 0 0;1 0 0 0;0 0 1 0;0 0 0 1]
```

```
T =
```

```
0 0 0 0
1 0 0 0
0 0 1 0
0 0 0 1
```

Redefine the dataset array.

```
ds = dataset(hospital.BloodPressure(:,1),hospital.Sex,hospital.Age,...
hospital.Smoker,'VarNames',{'BloodPressure','Sex','Age','Smoker'});
```

Now, the response variable is the first term in the dataset array. Specify the same linear model, 'BloodPressure ~ 1 + Sex + Age + Smoker', using a terms matrix.

```
T = [0 0 0 0;0 1 0 0;0 0 1 0;0 0 0 1]
```

```
T =
```

```
0 0 0 0
0 1 0 0
0 0 1 0
0 0 0 1
```

- If you have the predictor and response variables in a matrix and column vector, then you must include 0 for the response variable at the end of each term. The following example illustrates this.

Load the sample data and define the matrix of predictors.

```
load carsmall
X = [Acceleration,Weight];
```

Specify the model 'MPG ~ Acceleration + Weight + Acceleration:Weight + Weight^2' using a term matrix and fit the model to the data. This model includes the main effect and two-way interaction terms for the variables, Acceleration and Weight, and a second-order term for the variable, Weight.

```
T = [0 0 0;1 0 0;0 1 0;1 1 0;0 2 0]
```

```
T =
```

```

0 0 0
1 0 0
0 1 0
1 1 0
0 2 0
```

Fit a linear model.

```
mdl = fitlm(X,MPG,T)
```

```
mdl =
```

```
Linear regression model:
```

```
y ~ 1 + x1*x2 + x2^2
```

```
Estimated Coefficients:
```

|             | Estimate    | SE         | tStat   | pValue     |
|-------------|-------------|------------|---------|------------|
| (Intercept) | 48.906      | 12.589     | 3.8847  | 0.00019665 |
| x1          | 0.54418     | 0.57125    | 0.95261 | 0.34337    |
| x2          | -0.012781   | 0.0060312  | -2.1192 | 0.036857   |
| x1:x2       | -0.00010892 | 0.00017925 | -0.6076 | 0.545      |
| x2^2        | 9.7518e-07  | 7.5389e-07 | 1.2935  | 0.19917    |

```
Number of observations: 94, Error degrees of freedom: 89
```

```
Root Mean Squared Error: 4.1
```

```
R-squared: 0.751, Adjusted R-Squared 0.739
```

F-statistic vs. constant model: 67, p-value = 4.99e-26

Only the intercept and x2 term, which correspond to the `Weight` variable, are significant at the 5% significance level.

Now, perform a stepwise regression with a constant model as the starting model and a linear model with interactions as the upper model.

```
T = [0 0 0;1 0 0;0 1 0;1 1 0];
mdl = stepwiselm(X,MPG,[0 0 0], 'upper',T)
```

1. Adding x2, FStat = 259.3087, pValue = 1.643351e-28

mdl =

Linear regression model:

$y \sim 1 + x2$

Estimated Coefficients:

|             | Estimate   | SE        | tStat   | pValue     |
|-------------|------------|-----------|---------|------------|
| (Intercept) | 49.238     | 1.6411    | 30.002  | 2.7015e-49 |
| x2          | -0.0086119 | 0.0005348 | -16.103 | 1.6434e-28 |

Number of observations: 94, Error degrees of freedom: 92

Root Mean Squared Error: 4.13

R-squared: 0.738, Adjusted R-Squared 0.735

F-statistic vs. constant model: 259, p-value = 1.64e-28

The results of the stepwise regression are consistent with the results of `fitlm` in the previous step.

## Formula

A formula for model specification is a string of the form ' $Y \sim terms$ '

where

- $Y$  is the response name.
- $terms$  contains
  - Variable names
  - $+$  means include the next variable
  - $-$  means do not include the next variable

- `:` defines an interaction, a product of terms
- `*` defines an interaction **and all lower-order terms**
- `^` raises the predictor to a power, exactly as in `*` repeated, so `^` includes lower order terms as well
- `()` groups terms

---

**Note:** Formulas include a constant (intercept) term by default. To exclude a constant term from the model, include `-1` in the formula.

---

For example,

' $Y \sim A + B + C$ ' means a three-variable linear model with intercept.

' $Y \sim A + B + C - 1$ ' is a three-variable linear model without intercept.

' $Y \sim A + B + C + B^2$ ' is a three-variable model with intercept and a  $B^2$  term.

' $Y \sim A + B^2 + C$ ' is the same as the previous example because  $B^2$  includes a  $B$  term.

' $Y \sim A + B + C + A:B$ ' includes an  $A*B$  term.

' $Y \sim A*B + C$ ' is the same as the previous example because  $A*B = A + B + A:B$ .

' $Y \sim A*B*C - A:B:C$ ' has all interactions among  $A$ ,  $B$ , and  $C$ , except the three-way interaction.

' $Y \sim A*(B + C + D)$ ' has all linear terms, plus products of  $A$  with each of the other variables.

### Wilkinson Notation

Wilkinson notation describes the factors present in models. The notation relates to factors present in models, not to the multipliers (coefficients) of those factors.

| Wilkinson Notation                      | Factors in Standard Notation |
|-----------------------------------------|------------------------------|
| 1                                       | Constant (intercept) term    |
| $A^k$ , where $k$ is a positive integer | $A, A^2, \dots, A^k$         |
| $A + B$                                 | $A, B$                       |
| $A*B$                                   | $A, B, A*B$                  |
| $A:B$                                   | $A*B$ only                   |
| $-B$                                    | Do not include $B$           |

| Wilkinson Notation | Factors in Standard Notation |
|--------------------|------------------------------|
| $A*B + C$          | A, B, C, A*B                 |
| $A + B + C + A:B$  | A, B, C, A*B                 |
| $A*B*C - A:B:C$    | A, B, C, A*B, A*C, B*C       |
| $A*(B + C)$        | A, B, C, A*B, A*C            |

Statistics Toolbox notation always includes a constant term unless you explicitly remove the term using `-1`.

### Tips

- You cannot use robust regression with stepwise regression. Check your data for outliers before using `stepwiselm`.
- For other methods such as `anova`, or properties of the `LinearModel` object, see `LinearModel`.

### Algorithms

*Stepwise regression* is a systematic method for adding and removing terms from a linear or generalized linear model based on their statistical significance in explaining the response variable. The method begins with an initial model, specified using `modelspec`, and then compares the explanatory power of incrementally larger and smaller models.

MATLAB uses forward and backward stepwise regression to determine a final model. At each step, the method searches for terms to add to or remove from the model based on the value of the `'Criterion'` argument. The default value of `'Criterion'` is `'sse'`, and in this case, `stepwiselm` uses the  $p$ -value of an  $F$ -statistic to test models with and without a potential term at each step. If a term is not currently in the model, the null hypothesis is that the term would have a zero coefficient if added to the model. If there is sufficient evidence to reject the null hypothesis, the term is added to the model. Conversely, if a term is currently in the model, the null hypothesis is that the term has a zero coefficient. If there is insufficient evidence to reject the null hypothesis, the term is removed from the model.

Here is how stepwise proceeds when `'Criterion'` is `'sse'`:

- 1 Fit the initial model.
- 2 If any terms not in the model have  $p$ -values less than an entrance tolerance (that is, if it is unlikely that they would have zero coefficient if added to the model), add the one with the smallest  $p$ -value and repeat this step; otherwise, go to step 3.

- 3 If any terms in the model have  $p$ -values greater than an exit tolerance (that is, the hypothesis of a zero coefficient can be rejected), remove the one with the largest  $p$ -value and go to step 2; otherwise, end.

The default for `stepwiselm` is 'Deviance' and it follows a similar procedure for adding or removing terms.

There are several other criteria available, which you can specify using the 'Criterion' argument. You can use the change in the value of the Akaike information criterion, Bayesian information criterion, R-squared, adjusted R-squared as a criterion to add or remove terms.

Depending on the terms included in the initial model and the order in which terms are moved in and out, the method might build different models from the same set of potential terms. The method terminates when no single step improves the model. There is no guarantee, however, that a different initial model or a different sequence of steps will not lead to a better fit. In this sense, stepwise models are locally optimal, but might not be globally optimal.

- “Stepwise Regression” on page 9-114

`fitlm` | `LinearModel` | `step`

## stepwisefit

Stepwise regression

### Syntax

```
b = stepwisefit(X,y)
[b,se,pval,inmodel,stats,nextstep,history] = stepwisefit(...)
[...] = stepwisefit(X,y,param1,val1,param2,val2,...)
```

### Description

`b = stepwisefit(X,y)` uses a stepwise method to perform a multilinear regression of the response values in the  $n$ -by-1 vector  $y$  on the  $p$  predictive terms in the  $n$ -by- $p$  matrix  $X$ . Distinct predictive terms should appear in different columns of  $X$ .

$b$  is a  $p$ -by-1 vector of estimated coefficients for all of the terms in  $X$ . The `stepwisefit` function calculates the coefficient estimate values in  $b$  as follows:

- If a term is not in the final model, then the corresponding coefficient estimate in  $b$  results from adding only that term to the predictors in the final model.
- If a term is in the final model, then the coefficient estimate in  $b$  for that term is a result of the final model, that is `stepwise` does not consider the terms it excluded from the model while computing these values.

---

**Note:** `stepwisefit` automatically includes a constant term in all models. Do not enter a column of 1s directly into  $X$ .

---

`stepwisefit` treats NaN values in either  $X$  or  $y$  as missing values, and ignores them.

`[b,se,pval,inmodel,stats,nextstep,history] = stepwisefit(...)` returns the following additional information:

- `se` — A vector of standard errors for  $b$
- `pval` — A vector of  $p$ -values for testing whether elements of  $b$  are 0

- `inmodel` — A logical vector, with length equal to the number of columns in  $X$ , specifying which terms are in the final model
- `stats` — A structure of additional statistics with the following fields. All statistics pertain to the final model except where noted.
  - `source` — The string 'stepwisefit'
  - `dfe` — Degrees of freedom for error
  - `df0` — Degrees of freedom for the regression
  - `SStotal` — Total sum of squares of the response
  - `SSresid` — Sum of squares of the residuals
  - `fstat` —  $F$ -statistic for testing the final model vs. no model (mean only)
  - `pval` —  $p$  value of the  $F$ -statistic
  - `rmse` — Root mean square error
  - `xr` — Residuals for predictors not in the final model, after removing the part of them explained by predictors in the model
  - `yr` — Residuals for the response using predictors in the final model
  - `B` — Coefficients for terms in final model, with values for a term not in the model set to the value that would be obtained by adding that term to the model
  - `SE` — Standard errors for coefficient estimates
  - `TSTAT` —  $t$  statistics for coefficient estimates
  - `PVAL` —  $p$ -values for coefficient estimates
  - `intercept` — Estimated intercept
  - `wasnan` — Indicates which rows in the data contained NaN values
- `nextstep` — The recommended next step—either the index of the next term to move in or out of the model, or 0 if no further steps are recommended
- `history` — Structure containing information on steps taken, with the following fields:
  - `B` — Matrix of regression coefficients, where each column is one step, and each row is one coefficient.
  - `rmse` — Root mean square errors for the model at each step.
  - `df0` — Degrees of freedom for the regression at each step.

- `in` — Logical array indicating which predictors are in the model at each step, where each row is one step, and each column is one predictor.

`[...] = stepwisefit(X,y,param1,val1,param2,val2,...)` specifies one or more of the name/value pairs described in the following table.

| Parameter | Value                                                                                                                                         |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| 'inmodel' | A logical vector specifying terms to include in the initial fit. The default is to specify no terms.                                          |
| 'penter'  | The maximum $p$ value for a term to be added. The default is 0.05.                                                                            |
| 'premove' | The minimum $p$ value for a term to be removed. The default is the maximum of the value of 'penter' and 0.10.                                 |
| 'display' | 'on' displays information about each step in the command window. This is the default.<br><br>'off' omits the display.                         |
| 'maxiter' | The maximum number of steps in the regression. The default is Inf.                                                                            |
| 'keep'    | A logical vector specifying terms to keep in their initial state. The default is to specify no terms.                                         |
| 'scale'   | 'on' centers and scales each column of $X$ (computes $z$ -scores) before fitting.<br><br>'off' does not scale the terms. This is the default. |

## Examples

Load the data in `hald.mat`, which contains observations of the heat of reaction of various cement mixtures:

```
load hald
whos
 Name Size Bytes Class Attributes
 Description 22x58 2552 char
 hald 13x5 520 double
 heat 13x1 104 double
 ingredients 13x4 416 double
```

The response (heat) depends on the quantities of the four predictors (the columns of ingredients).

Use `stepwisefit` to carry out the stepwise regression algorithm, beginning with no terms in the model and using entrance/exit tolerances of 0.05/0.10 on the  $p$ -values:

```
stepwisefit(ingredients,heat,...
 'penter',0.05,'premove',0.10);
Initial columns included: none
Step 1, added column 4, p=0.000576232
Step 2, added column 1, p=1.10528e-006
Final columns included: 1 4
 'Coeff' 'Std.Err.' 'Status' 'P'
 [1.4400] [0.1384] 'In' [1.1053e-006]
 [0.4161] [0.1856] 'Out' [0.0517]
 [-0.4100] [0.1992] 'Out' [0.0697]
 [-0.6140] [0.0486] 'In' [1.8149e-007]
```

`stepwisefit` automatically includes an intercept term in the model, so you do not add it explicitly to `ingredients` as you would for `regress`. For terms not in the model, coefficient estimates and their standard errors are those that result by adding the corresponding term to the final model.

The `inmodel` parameter is used to specify terms in an initial model:

```
initialModel = ...
 [false true false false]; % Force in 2nd term
stepwisefit(ingredients,heat,...
 'inmodel',initialModel,...
 'penter',.05,'premove',0.10);
Initial columns included: 2
Step 1, added column 1, p=2.69221e-007
Final columns included: 1 2
 'Coeff' 'Std.Err.' 'Status' 'P'
 [1.4683] [0.1213] 'In' [2.6922e-007]
 [0.6623] [0.0459] 'In' [5.0290e-008]
 [0.2500] [0.1847] 'Out' [0.2089]
 [-0.2365] [0.1733] 'Out' [0.2054]
```

The preceding two models, built from different initial models, use different subsets of the predictive terms. Terms 2 and 4, swapped in the two models, are highly correlated:

```
term2 = ingredients(:,2);
term4 = ingredients(:,4);
```

```
R = corrcoef(term2,term4)
R =
 1.0000 -0.9730
 -0.9730 1.0000
```

To compare the models, use the `stats` output of `stepwisefit`:

```
[betahat1,se1,pval1,inmodel1,stats1] = ...
 stepwisefit(ingredients,heat,...
 'penter',.05,'premove',0.10,...
 'display','off');
[betahat2,se2,pval2,inmodel2,stats2] = ...
 stepwisefit(ingredients,heat,...
 'inmodel',initialModel,...
 'penter',.05,'premove',0.10,...
 'display','off');

RMSE1 = stats1.rmse
RMSE1 =
 2.7343
RMSE2 = stats2.rmse
RMSE2 =
 2.4063
```

The second model has a lower Root Mean Square Error (RMSE).

## More About

### Algorithms

*Stepwise regression* is a systematic method for adding and removing terms from a multilinear model based on their statistical significance in a regression. The method begins with an initial model and then compares the explanatory power of incrementally larger and smaller models. At each step, the  $p$  value of an  $F$ -statistic is computed to test models with and without a potential term. If a term is not currently in the model, the null hypothesis is that the term would have a zero coefficient if added to the model. If there is sufficient evidence to reject the null hypothesis, the term is added to the model. Conversely, if a term is currently in the model, the null hypothesis is that the term has a zero coefficient. If there is insufficient evidence to reject the null hypothesis, the term is removed from the model. The method proceeds as follows:

- 1 Fit the initial model.

- 2 If any terms not in the model have  $p$ -values less than an entrance tolerance (that is, if it is unlikely that they would have zero coefficient if added to the model), add the one with the smallest  $p$  value and repeat this step; otherwise, go to step 3.
- 3 If any terms in the model have  $p$ -values greater than an exit tolerance (that is, if it is unlikely that the hypothesis of a zero coefficient can be rejected), remove the one with the largest  $p$  value and go to step 2; otherwise, end.

Depending on the terms included in the initial model and the order in which terms are moved in and out, the method may build different models from the same set of potential terms. The method terminates when no single step improves the model. There is no guarantee, however, that a different initial model or a different sequence of steps will not lead to a better fit. In this sense, stepwise models are locally optimal, but may not be globally optimal.

## **subsasgn**

**Class:** classregtree

Subscripted reference for `classregtree` object

### **Syntax**

### **Description**

Subscript assignment is not allowed for a `classregtree` object.

### **See Also**

`classregtree`

# subsasgn

**Class:** dataset

Subscripted assignment to dataset array

## Compatibility

The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

## Description

`A = subsasgn(A,S,B)` is called for the syntax `A(i,j)=B`, `A{ i , j }=B`, or `A.var=B` when `A` is a dataset array. `S` is a structure array with the fields:

|                   |                                                                     |
|-------------------|---------------------------------------------------------------------|
| <code>type</code> | String containing '()', '{}', or '.' specifying the subscript type. |
| <code>subs</code> | Cell array or string containing the actual subscripts.              |

`A(i,j) = B` assigns the contents of the dataset array `B` to a subset of the observations and variables in the dataset array `A`. `i` and `j` are one of the following types:

- positive integers
- vectors of positive integers
- observation/variable names
- cell arrays containing one or more observation/variable names
- logical vectors

The assignment does not use observation names, variable names, or any other properties of `B` to modify properties of `A`; however properties of `A` are extended with default values if the assignment expands the number of observations or variables in `A`. Elements of `B` are assigned into `A` by position, not by matching names.

`A{i, j} = B` assigns the value `B` into an element of the dataset array `A`. `i` and `J` are positive integers, or logical vectors. Cell indexing cannot assign into multiple dataset elements, that is, the subscripts `i` and `j` must each refer to only a single observation or variable. `B` is cast to the type of the target variable if necessary. If the dataset element already exists, `A{i, j}` may also be followed by further subscripting as supported by the variable.

For dataset variables that are cell arrays, assignments such as `A{1, 'CellVar'} = B` assign into the contents of the target dataset element in the same way that `{}`-indexing of an ordinary cell array does.

For dataset variables that are `n`-D arrays, i.e., each observation is a matrix or array, an assignment such as `A{1, 'ArrayVar'} = B` assigns into the second and following dimensions of the target dataset element, i.e., the assignment adds a leading singleton dimension to `B` to account for the observation dimension of the dataset variable.

`A.var = B` or `A.(varname) = B` assigns `B` to a dataset variable. `var` is a variable name literal, or `varname` is a character variable containing a variable name. If the dataset variable already exists, the assignment completely replaces that variable. To assign into an element of the variable, `A.var` or `A.(varname)` may be followed by further subscripting as supported by the variable. In particular, `A.var(obsnames, ...)` = `B` and `A.var{obsnames, ...} = B` (when supported by `var`) provide assignment into a dataset variable using observation names.

`A.properties.propertyname = P` assigns to a dataset property. `propertyname` is one of the following:

- 'ObsNames'
- 'VarNames'
- 'Description'
- 'Units'
- 'DimNames'
- 'UserData'
- 'VarDescription'

To assign into an element of the property, `A.properties.propertyname` may also be followed by further subscripting as supported by the property.

You cannot assign multiple values into dataset variables or properties using assignments such as `[A.CellVar{1:2}] = B`, `[A.StructVar(1:2).field] = B`,

or `[A.Properties.ObsNames{1:2}] = B`. Use multiple assignments of the form `A.CellVar{1} = B` instead.

Similarly, if a dataset variable is a cell array with multiple columns or is an n-D cell array, then the contents of that variable for a single observation consists of multiple cells, and you cannot assign to all of them using the syntax `A{1, 'CellVar'} = B`. Use multiple assignments of the form `[A.CellVar{1,1}] = B` instead.

## subsref

**Class:** classregtree

Subscripted reference for `classregtree` object

## Syntax

`B = subsref(T,S)`

## Description

`B = subsref(T,S)` is called for the syntax `T(X)` when `T` is a `classregtree` object. `S` is a structure array with the fields:

|                   |                                                                     |
|-------------------|---------------------------------------------------------------------|
| <code>type</code> | String containing '()', '{}', or '.' specifying the subscript type. |
| <code>subs</code> | Cell array or string containing the actual subscripts.              |

`[...] = T(...)` invokes the `eval` method for the tree `T`.

## See Also

`classregtree` | `eval`

# subsref

**Class:** dataset

Subscripted reference for dataset array

## Compatibility

The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

## Syntax

`B = subsref(A,S)`

## Description

`B = subsref(A,S)` is called for the syntax `A(i,j)`, `A{i,j}`, or `A.var` when `A` is a dataset array. `S` is a structure array with the fields:

|                   |                                                                                                                |
|-------------------|----------------------------------------------------------------------------------------------------------------|
| <code>type</code> | String containing <code>'()' </code> , <code>'{}' </code> , or <code>'.'</code> specifying the subscript type. |
| <code>subs</code> | Cell array or string containing the actual subscripts.                                                         |

`B = A(i,j)` returns a dataset array that contains a subset of the observations and variables in the dataset array `A`. `i` and `j` are one of the following types:

- positive integers
- vectors of positive integers
- observation/variable names
- cell arrays containing one or more observation/variable names
- logical vectors

`B` contains the same property values as `A`, subsetted for observations or variables where appropriate.

`B = A{i, j}` returns an element of a dataset variable. `i` and `j` are positive integers, or logical vectors. Cell indexing cannot return multiple dataset elements, that is, the subscripts `i` and `j` must each refer to only a single observation or variable. `A{i, j}` may also be followed by further subscripting as supported by the variable.

For dataset variables that are cell arrays, expressions such as `A{1, 'CellVar'}` return the contents of the referenced dataset element in the same way that `{}`-indexing on an ordinary cell array does. If the dataset variable is a single column of cells, the contents of a single cell is returned. If the dataset variable has multiple columns or is n-D, multiple outputs containing the contents of multiple cells are returned.

For dataset variables that are n-D arrays, i.e., each observation is a matrix or an array, expressions such as `A{1, 'ArrayVar'}` return `A.ArrayVar(1, :, ...)` with the leading singleton dimension squeezed out.

`B = A.var` or `A.(varname)` returns a dataset variable. `var` is a variable name literal, or `varname` is a character variable containing a variable name. `A.var` or `A.(varname)` may also be followed by further subscripting as supported by the variable. In particular, `A.var(obsnames, ...)` and `A.var{obsnames, ...}` (when supported by `var`) provide subscripting into a dataset variable using observation names.

`P = A.Properties.propertyname` returns a dataset property. `propertyname` is one of the following:

- `'ObsNames'`
- `'VarNames'`
- `'Description'`
- `'Units'`
- `'DimNames'`
- `'UserData'`
- `'VarDescription'`

`A.properties.propertyname` may also be followed by further subscripting as supported by the property.

## Limitations

Subscripting expressions such as `A.CellVar{1:2}`, `A.StructVar(1:2).field`, or `A.Properties.ObsNames{1:2}` are valid, but result in `subsref` returning

multiple outputs in the form of a comma-separated list. If you explicitly assign to output arguments on the left-hand side of an assignment, for example, `[cellval1,cellval2] = A.CellVar{1:2}`, those variables will receive the corresponding values. However, if there are no output arguments, only the first output in the comma-separated list is returned.

Similarly, if a dataset variable is a cell array with multiple columns or is an n-D cell array, then subscripting expressions such as `A{1, 'CellVar'}` result in `subsref` returning the contents of multiple cells. You should explicitly assign to output arguments on the left-hand side of an assignment, for example, `[cellval1,cellval2] = A{1, 'CellVar'}`.

## subsref

**Class:** `gmdistribution`

Subscripted reference for Gaussian mixture distribution object

## Syntax

`B = subsref(T,S)`

## Description

`B = subsref(T,S)` is called for the syntax `T(X)` when `T` is a `gmdistribution` object. `S` is a structure array with the following fields:

|                   |                                                                     |
|-------------------|---------------------------------------------------------------------|
| <code>type</code> | String containing '()', '{}', or '.' specifying the subscript type. |
| <code>subs</code> | Cell array or string containing the actual subscripts.              |

## See Also

`gmdistribution`

## subsref

**Class:** NaiveBayes

Subscripted reference for NaiveBayes object

## Syntax

`b = subsref(nb,s)`

## Description

`b = subsref(nb,s)` is called for the syntax `nb(s)` when `nb` is a NaiveBayes object. `S` is a structure array with the fields:

|                   |                                                                     |
|-------------------|---------------------------------------------------------------------|
| <code>type</code> | string containing '()', '{}', or '.' specifying the subscript type. |
| <code>subs</code> | Cell array or string containing the actual subscripts.              |

## subsref

**Class:** grandset

Subscripted reference for grandset

## Syntax

```
x = p(i,j)
x = subsref(p,s)
```

## Description

`x = p(i,j)` returns a matrix that contains a subset of the points from the point set `p`. The indices in `i` select points from the set and the indices in `j` select columns from those points. `i` and `j` are vector of positive integers or logical vectors. A colon used as a subscript, as in `p(i,:)`, indicates the entire row (or column).

`x = subsref(p,s)` is called for the syntax `p(i)`, `p{i}`, or `p.i`. `s` is a structure array with the fields:

|                   |                                                                     |
|-------------------|---------------------------------------------------------------------|
| <code>type</code> | string containing '()', '{}', or '.' specifying the subscript type. |
| <code>subs</code> | Cell array or string containing the actual subscripts.              |

## Examples

| Command                        | Returns                            |
|--------------------------------|------------------------------------|
| <code>p = sobolset(5);</code>  | The fifth point                    |
| <code>x = p(1:10,:)</code>     | All columns of the first 10 points |
| <code>x = p(end,1)</code>      | The first column of the last point |
| <code>x = p([1,4,5], :)</code> | Points 1, 4, and 5                 |

## See Also

grandset

## summary

**Class:** dataset

Print summary of dataset array

## Compatibility

The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

## Syntax

```
summary(A)
s = summary(A)
```

## Description

`summary(A)` prints a summary of a dataset array and the variables that it contains.

`s = summary(A)` returns a scalar structure `s` that contains a summary of the dataset `A` and the variables that `A` contains. For more information on the fields in `s`, see [Outputs](#).

Summary information depends on the type of the variables in the data set:

- For numerical variables, `summary` computes a five-number summary of the data, giving the minimum, the first quartile, the median, the third quartile, and the maximum.
- For logical variables, `summary` counts the number of `true`s and `false`s in the data.
- For categorical variables, `summary` counts the number of data at each level.

## Output Arguments

The following list describes the fields in the structure `s`:

- **Description** — A character array containing the dataset description.
- **Variables** — A structure array with one element for each dataset variable in A. Each element has the following fields:
  - **Name** — A character string containing the name of the variable.
  - **Description** — A character string containing the variable's description.
  - **Units** — A character string containing the variable's units.
  - **Size** — A numeric vector containing the size of the variable.
  - **Class** — A character string containing the class of the variable.
  - **Data** — A scalar structure containing the following fields.

For numeric variables:

- **Probabilities** — A numeric vector containing the probabilities [0.0 .25 .50 .75 1.0] and NaN (if any are present in the corresponding dataset variable).
- **Quantiles** — A numeric vector containing the values that correspond to 'Probabilities' for the corresponding dataset variable, and a count of NaNs (if any are present).

For logical variables:

- **Values** — The logical vector [true false].
- **Counts** — A numeric vector of counts for each logical value.

For categorical variables:

- **Levels** — A cell array containing the labels for each level of the corresponding dataset variable.
- **Counts** — A numeric vector of counts for each level.

'Data' is empty if variable is not numeric, categorical, or logical. If a dataset variable has more than one column, then the corresponding 'Quantiles' or 'Counts' field is a matrix or an array.

## Examples

Summarize Fisher's iris data:

```

load fisheriris
species = nominal(species);
data = dataset(species,meas);
summary(data)
species: [150x1 nominal]
 setosa versicolor virginica
 50 50 50
meas: [150x4 double]
 min 4.3000 2 1 0.1000
 1st Q 5.1000 2.8000 1.6000 0.3000
 median 5.8000 3 4.3500 1.3000
 3rd Q 6.4000 3.3000 5.1000 1.8000
 max 7.9000 4.4000 6.9000 2.5000

```

Summarize the data in hospital.mat:

```

load hospital
summary(hospital)

```

Dataset array created from the data file hospital.dat.

The first column of the file ("id") is used for observation names. Other columns ("sex" and "smoke") have been converted from their original coded values into categorical and logical variables. Two sets of columns ("sys" and "dia", "trial1" through "trial4") have been combined into single variables with multivariate observations. Column headers have been replaced with more descriptive variable names. Units have been added where appropriate.

```

LastName: [100x1 cell string]

```

```

Sex: [100x1 nominal]
 Female Male
 53 47

```

```

Age: [100x1 double, Units = Yrs]

```

```

 min 1st Q median 3rd Q max
 25 32 39 44 50

```

```

Weight: [100x1 double, Units = Lbs]

```

```

 min 1st Q median 3rd Q max
 111 130.5000 142.5000 180.5000 202

```

```

# Support property

**Class:** ProbDist

Read-only structure containing information about support of ProbDist object

## Description

`Support` is a read-only property of the `ProbDist` class. `Support` is a structure containing information about the support of a `ProbDist` object. It includes the following fields:

- `range`
- `closedbound`
- `iscontinuous`

## Values

The values for the three fields in the structure are:

- `range` — A two-element vector `[L, U]`, such that all of the probability is contained from `L` to `U`.
- `closedbound` — A two-element logical vector indicating whether the corresponding range endpoint is included. Possible values for each endpoint are `1 (true)` or `0 (false)`.
- `iscontinuous` — A logical value indicates if the distribution takes values on the entire interval from `L` to `U` (`true`), or if it takes only integer values within this range (`false`). Possible values are `1 (true)` or `0 (false)`.

Use this information to view and compare information about the support of distributions.

## struct2dataset

Convert structure array to dataset array

### Compatibility

The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

### Syntax

```
ds = struct2dataset(S)
ds = struct2dataset(S,Name,Value)
```

### Description

`ds = struct2dataset(S)` converts a structure array to a dataset array.

`ds = struct2dataset(S,Name,Value)` performs the conversion using additional options specified by one or more `Name,Value` pair arguments.

### Examples

#### Convert Scalar Structure Array to Dataset Array

Convert a scalar structure array to a dataset array using the default options.

Create a structure array to convert.

```
S.Name = {'CLARK';'BROWN';'MARTIN'};
S.Gender = {'M';'F';'M'};
S.SystolicBP = [124;122;130];
S.DiastolicBP = [93;80;92];
```

S

S =

```

 Name: {3x1 cell}
 Gender: {3x1 cell}
 SystolicBP: [3x1 double]
 DiastolicBP: [3x1 double]

```

The scalar structure array has four fields, each with three rows.

Convert the structure array to a dataset array.

```
ds = struct2dataset(S)
```

ds =

| Name     | Gender | SystolicBP | DiastolicBP |
|----------|--------|------------|-------------|
| 'CLARK'  | 'M'    | 124        | 93          |
| 'BROWN'  | 'F'    | 122        | 80          |
| 'MARTIN' | 'M'    | 130        | 92          |

The structure field names in S become the variable names in the output dataset array. The size of ds is 3-by-4.

### Convert Nonscalar Structure Array to Dataset Array

Convert a nonscalar structure array to a dataset array, using one of the structure fields for observation names.

Create a nonscalar structure array to convert.

```

S(1,1).Name = 'CLARK';
S(1,1).Gender = 'M';
S(1,1).SystolicBP = 124;
S(1,1).DiastolicBP = 93;

```

```

S(2,1).Name = 'BROWN';
S(2,1).Gender = 'F';
S(2,1).SystolicBP = 122;
S(2,1).DiastolicBP = 80;

```

```

S(3,1).Name = 'MARTIN';
S(3,1).Gender = 'M';

```

```
S(3,1).SystolicBP = 130;
S(3,1).DiastolicBP = 92;
```

```
S
```

```
S =
```

```
3x1 struct array with fields:
 Name
 Gender
 SystolicBP
 DiastolicBP
```

This is a 3-by-1 structure array with 4 fields.

Convert the structure array to a dataset array, using the `Name` field for observation names.

```
ds = struct2dataset(S, 'ReadObsNames', 'Name')
```

```
ds =
```

|        | Gender | SystolicBP | DiastolicBP |
|--------|--------|------------|-------------|
| CLARK  | 'M'    | 124        | 93          |
| BROWN  | 'F'    | 122        | 80          |
| MARTIN | 'M'    | 130        | 92          |

The size of `ds` is 3-by-3 because the structure field `Name` is used for observation names, and not as a dataset array variable.

```
ds.Properties.DimNames
```

```
ans =
```

```
 'Name' 'Variables'
```

```
ds.Properties.ObsNames
```

```
ans =
```

```
 'CLARK'
 'BROWN'
 'MARTIN'
```

- “Create a Dataset Array from Workspace Variables” on page 2-63

- “Create a Dataset Array from a File” on page 2-69

## Input Arguments

### **S** — Input structure array

structure array

Input structure array to convert to a dataset array, specified as a scalar structure array with  $N$  fields, each with  $M$  rows, or a nonscalar  $M$ -by-1 structure array with  $N$  fields.

Data Types: `struct`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1`, `Value1`, ..., `NameN`, `ValueN`.

Example: `'ReadObsNames'`, `'myField'` specifies that the structure field, `myField`, contains observation names.

### **'ReadObsNames'** — Name of structure field containing observation names for dataset array

`false` (default) | string

Name of structure field containing observation names for the output dataset array, specified as the comma-separated pair consisting of `'ReadObsNames'` and a string containing a field name from the input structure array, `S`. When you specify a field name, `struct2dataset` uses that field to create observation names, and sets `ds.Properties.DimNames` equal to `{ReadObsNames, 'Variables'}`.

For example, to specify that observation names are in the structure field, `Names`, use

Example: `'ReadObsNames'`, `'Names'`

By default, or if `ReadObsNames` is equal to `false`, `struct2dataset` does not create observation names unless you specify names using the name-value pair argument `ObsNames`.

### **'ObsNames'** — Observation names for dataset array

cell array of strings

Observation names for the output dataset array, specified as the comma-separated pair consisting of 'ObsNames' and a cell array of strings containing observation names. The names do not need to be valid MATLAB identifiers, but they must be unique.

**'AsScalar' — Indicator for how to treat scalar structure**

false | true

Indicator for how to treat a scalar input structure array, specified as the comma-separated pair consisting of 'AsScalar' and either `true` or `false`. The default value is `true` if `S` is a scalar structure array, and `false` otherwise.

By default, `struct2dataset` converts a scalar structure array with  $N$  fields, each with  $M$  rows, into an  $M$ -by- $N$  dataset array.

If instead you set `AsScalar` equal to `false` for a scalar input structure array, then `struct2dataset` converts `S` to a dataset array with  $N$  observations.

## Output Arguments

**ds — Output dataset array**

dataset array

Output dataset array, returned by default with  $M$  observations and  $N$  variables.

- If `S` is a scalar structure array with  $N$  fields, each with  $M$  rows, then `ds` is an  $M$ -by- $N$  dataset array.
- If `S` is a nonscalar  $M$ -by-1 structure array with  $N$  fields, then `ds` is an  $M$ -by- $N$  dataset array.
- If `S` is a scalar structure array with  $N$  fields, each with  $M$  rows, and `AsScalar` is set equal to `false`, then `ds` is a dataset array with  $N$  observations.

# surfht

Interactive contour plot

## Syntax

```
surfht(Z)
surfht(x,y,Z)
```

## Description

`surfht(Z)` is an interactive contour plot of the matrix `Z` treating the values in `Z` as height above the plane. The  $x$ -values are the column indices of `Z` while the  $y$ -values are the row indices of `Z`.

`surfht(x,y,Z)` where `x` and `y` are vectors specify the  $x$  and  $y$ -axes on the contour plot. The length of `x` must match the number of columns in `Z`, and the length of `y` must match the number of rows in `Z`.

There are vertical and horizontal reference lines on the plot whose intersection defines the current  $x$  value and  $y$  value. You can drag these dotted white reference lines and watch the interpolated  $z$  value (at the top of the plot) update simultaneously. Alternatively, you can get a specific interpolated  $z$  value by typing the  $x$  value and  $y$  value into editable text fields on the  $x$ -axis and  $y$ -axis respectively.

## surrctcategories

**Class:** classregtree

Categories used for surrogate splits in decision tree

### Syntax

```
C = surrctcategories(T)
C = surrctcategories(T,J)
```

### Description

`C = surrctcategories(T)` returns an  $n$ -element cell array `C` of the categories used for surrogate splits in the decision tree `T`, where  $n$  is the number of nodes in the tree. For each node `K`, `C{K}` is a cell array. The length of `C{K}` is equal to the number of surrogate predictors found at this node. Every element of `C{K}` is either an empty string for a continuous surrogate predictor or a two-element cell array with categories for a categorical surrogate predictor. The first element of this two-element cell array lists categories assigned to the left child by this surrogate split and the second element of this two-element cell array lists categories assigned to the right child by this surrogate split. The order of the surrogate split variables at each node is matched to the order of variables returned by `surrctvar`. The optimal-split variable at this node is not included. For non-branch (leaf) nodes, `C` contains an empty cell.

`C = surrctcategories(T,J)` takes an array `J` of node numbers and returns the categories for the specified nodes.

# surrctflip

**Class:** classregtree

Numeric cutpoint assignments used for surrogate splits in decision tree

## Syntax

```
V = surrctflip(T)
V = surrctflip(T,J)
```

## Description

`V = surrctflip(T)` returns an  $n$ -element cell array  $V$  of the numeric cut assignments used for surrogate splits in the decision tree  $T$ , where  $n$  is the number of nodes in the tree. For each node  $K$ ,  $V\{K\}$  is a numeric vector. The length of  $V\{K\}$  is equal to the number of surrogate predictors found at this node. Every element of  $V\{K\}$  is either zero for a categorical surrogate predictor or a numeric cut assignment for a continuous surrogate predictor. The numeric cut assignment can be either  $-1$  or  $+1$ . For every surrogate split with a numeric cut  $C$  based on a continuous predictor variable  $Z$ , the left child is chosen if  $Z < C$  and the cut assignment for this surrogate split is  $+1$ , or if  $Z \geq C$  and the cut assignment for this surrogate split is  $-1$ . Similarly, the right child is chosen if  $Z \geq C$  and the cut assignment for this surrogate split is  $+1$ , or if  $Z < C$  and the cut assignment for this surrogate split is  $-1$ . The order of the surrogate split variables at each node is matched to the order of variables returned by `surrctvar`. The optimal-split variable at this node is not included. For non-branch (leaf) nodes,  $V$  contains an empty array.

`V = surrctflip(T,J)` takes an array  $J$  of node numbers and returns the cutpoint assignments for the specified nodes.

## surrucutpoint

**Class:** classregtree

Cutpoints used for surrogate splits in decision tree

### Syntax

```
V = surrucutpoint(T)
V = surrucutpoint(T,J)
```

### Description

`V = surrucutpoint(T)` returns an  $n$ -element cell array `V` of the numeric values used for surrogate splits in the decision tree `T`, where  $n$  is the number of nodes in the tree. For each node `K`, `V{K}` is a numeric vector. The length of `V{K}` is equal to the number of surrogate predictors found at this node. Every element of `V{K}` is either either `NaN` for a categorical surrogate predictor or a numeric cut for a continuous surrogate predictor. For every surrogate split with a numeric cut  $C$  based on a continuous predictor variable  $Z$ , the left child is chosen if  $Z < C$  and `surrucutflip` for this surrogate split is `-1`. Similarly, the right child is chosen if  $Z \geq C$  and `surrucutflip` for this surrogate split is `+1`, or if  $Z < C$  and `surrucutflip` for this surrogate split is `-1`. The order of the surrogate split variables at each node is matched to the order of variables returned by `surrucutvar`. The optimal-split variable at this node is not included. For non-branch (leaf) nodes, `V` contains an empty cell.

`V = surrucutpoint(T,J)` takes an array `J` of node numbers and returns the cutpoint assignments for the specified nodes.

## surrctype

**Class:** classregtree

Types of surrogate splits used at branches in decision tree

### Syntax

`C = surrctype(T)`  
`C = surrctype(T,J)`

### Description

`C = surrctype(T)` returns an  $n$ -element cell array `C` indicating types of surrogate splits at each node in the tree `T`, where  $n$  is the number of nodes in the tree. For each node  $K$ , `C{K}` is a cell array with the types of the surrogate split variables at this node. The variables are sorted by the predictive measure of association with the optimal predictor in the descending order, and only variables with the positive predictive measure are included. The order of the surrogate split variables at each node is matched to the order of variables returned by `surrctvar`. The optimal-split variable at this node is not included. For non-branch (leaf) nodes, `C` contains an empty cell. A surrogate split type can be either 'continuous' if the cut is defined in the form  $Z < V$  for a variable  $Z$  and cutpoint  $V$  or 'categorical' if the cut is defined by whether  $Z$  takes a value in a set of categories.

`C = surrctype(T,J)` takes an array `J` of node numbers and returns the cut types for the specified nodes.

### See Also

classregtree | cuttype | numnodes | surrctvar

## surrctvar

**Class:** classregtree

Variables used for surrogate splits in decision tree

### Syntax

```
V = surrctvar(T)
V = surrctvar(T,J)
[V,NUM] = surrctvar(...)
```

### Description

`V = surrctvar(T)` returns an  $n$ -element cell array `V` of the names of the variables used for surrogate splits in each node of the tree `T`, where  $n$  is the number of nodes in the tree. Every element of `V` is a cell array with the names of the surrogate split variables at this node. The variables are sorted by the predictive measure of association with the optimal predictor in the descending order, and only variables with the positive predictive measure are included. The optimal-split variable at this node is not included. For non-branch (leaf) nodes, `V` contains an empty cell.

`V = surrctvar(T,J)` takes an array `J` of node numbers and returns the cut types for the specified nodes.

`[V,NUM] = surrctvar(...)` also returns a cell array `NUM` with indices for each variable.

### See Also

classregtree | children | numnodes | cutvar

## surrvarassoc

**Class:** classregtree

Predictive measure of association for surrogate splits in decision tree

### Syntax

A = surrvarassoc(T)  
A = surrvarassoc(T,J)

### Description

A = surrvarassoc(T) returns an  $n$ -element cell array A of the predictive measures of association for surrogate splits in the decision tree T, where  $n$  is the number of nodes in the tree. For each node K, A{K} is a numeric vector. The length of A{K} is equal to the number of surrogate predictors found at this node. Every element of A{K} gives the predictive measure of association between the optimal split and this surrogate split. The order of the surrogate split variables at each node is matched to the order of variables returned by surrcutvar. The optimal-split variable at this node is not included. For non-branch (leaf) nodes, V contains an empty cell.

A = surrvarassoc(T,J) takes an array J of node numbers and returns the predictive measure of association for the specified nodes.

## svmclassify

Classify using support vector machine (SVM)

### Syntax

```
Group = svmclassify(SVMStruct, Sample)
Group = svmclassify(SVMStruct, Sample, 'Showplot', true)
```

### Description

`Group = svmclassify(SVMStruct, Sample)` classifies each row of the data in `Sample`, a matrix of data, using the information in a support vector machine classifier structure `SVMStruct`, created using the `svmtrain` function. Like the training data used to create `SVMStruct`, `Sample` is a matrix where each row corresponds to an observation or replicate, and each column corresponds to a feature or variable. Therefore, `Sample` must have the same number of columns as the training data. This is because the number of columns defines the number of features. `Group` indicates the group to which each row of `Sample` has been assigned.

`Group = svmclassify(SVMStruct, Sample, 'Showplot', true)` plots the `Sample` data in the figure created using the `Showplot` property with the `svmtrain` function. This plot appears only when the data is two-dimensional.

### Input Arguments

#### **SVMStruct**

Support vector machine classifier structure created using the `svmtrain` function.

#### **Sample**

A matrix where each row corresponds to an observation or replicate, and each column corresponds to a feature or variable. Therefore, `Sample` must have the same number of columns as the training data. This is because the number of columns defines the dimensionality of the data space.

## ShowPlot

Describes whether to display a plot of the classification. Displays only for 2-D problems. Follow with a Boolean argument: `true` to display the plot, `false` to give no display.

## Output Arguments

### Group

Column vector with the same number of rows as `Sample`. Each entry (row) in `Group` represents the class of the corresponding row of `Sample`.

## Examples

### Classify an Observation Using a Trained SVM Classifier.

Find a line separating the Fisher iris data on versicolor and virginica species, according to the petal length and petal width measurements. These two species are in rows 51 and higher of the data set, and the petal length and width are the third and fourth columns.

```
load fisheriris
xdata = meas(51:end,3:4);
group = species(51:end);
figure;
svmStruct = svmtrain(xdata,group,'ShowPlot',true);
```

Classify two new flowers, one with petal length 5 and petal width 2 and the other with petal length 4 and petal width 1.5.

```
Xnew = [5 2; 4 1.5];
species = svmclassify(svmStruct,Xnew,'ShowPlot',true)
hold on;
plot(Xnew(:,1),Xnew(:,2),'ro','MarkerSize',12);
hold off
```

```
species =
 'virginica'
 'versicolor'
```

## More About

### Algorithms

The `svmclassify` function uses results from `svmtrain` to classify vectors  $x$  according to the following equation:

$$c = \sum_i \alpha_i k(s_i, x) + b,$$

where  $s_i$  are the support vectors,  $a_i$  are the weights,  $b$  is the bias, and  $k$  is a kernel function. In the case of a linear kernel,  $k$  is the dot product. If  $c \geq 0$ , then  $x$  is classified as a member of the first group, otherwise it is classified as a member of the second group.

svmtrain

## svmtrain

Train support vector machine classifier

### Syntax

```
SVMStruct = svmtrain(Training,Group)
SVMStruct = svmtrain(Training,Group,Name,Value)
```

### Description

`SVMStruct = svmtrain(Training,Group)` returns a structure, `SVMStruct`, containing information about the trained support vector machine (SVM) classifier.

`SVMStruct = svmtrain(Training,Group,Name,Value)` returns a structure with additional options specified by one or more `Name,Value` pair arguments.

### Input Arguments

#### Training

Matrix of training data, where each row corresponds to an observation or replicate, and each column corresponds to a feature or variable. `svmtrain` treats NaNs or empty strings in `Training` as missing values and ignores the corresponding rows of `Group`.

#### Group

Grouping variable, which can be a categorical, numeric, or logical vector, a cell vector of strings, or a character matrix with each row representing a class label. Each element of `Group` specifies the group of the corresponding row of `Training`. `Group` should divide `Training` into two groups. `Group` has the same number of elements as there are rows in `Training`. `svmtrain` treats each NaN, empty string, or 'undefined' in `Group` as a missing value, and ignores the corresponding row of `Training`.

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single

quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

**'autoscale'**

Boolean specifying whether `svmtrain` automatically centers the data points at their mean, and scales them to have unit standard deviation, before training.

**Default:** true

**'boxconstraint'**

Value of the box constraint `C` for the soft margin. `C` can be a scalar, or a vector of the same length as the training data.

If `C` is a scalar, it is automatically rescaled by  $N / (2 * N1)$  for the data points of group one and by  $N / (2 * N2)$  for the data points of group two, where `N1` is the number of elements in group one, `N2` is the number of elements in group two, and  $N = N1 + N2$ . This rescaling is done to take into account unbalanced groups, that is cases where `N1` and `N2` have very different values.

If `C` is an array, then each array element is taken as a box constraint for the data point with the same index.

**Default:** 1

**'kernelcachelimit'**

Value that specifies the size of the kernel matrix cache for the SMO training method. The algorithm keeps a matrix with up to `kernelcachelimit × kernelcachelimit` double-precision, floating-point numbers in memory.

**Default:** 5000

**'kernel\_function'**

Kernel function `svmtrain` uses to map the training data into kernel space. The default kernel function is the dot product. The kernel function can be one of the following strings or a function handle:

- 'linear' — Linear kernel, meaning dot product.
- 'quadratic' — Quadratic kernel.
- 'polynomial' — Polynomial kernel (default order 3). Specify another order with the `polyorder` name-value pair.

- `'rbf'` — Gaussian Radial Basis Function kernel with a default scaling factor, `sigma`, of 1. Specify another value for `sigma` with the `rbf_sigma` name-value pair.
- `'mlp'` — Multilayer Perceptron kernel with default scale `[1 -1]`. Specify another scale with the `mlp_params` name-value pair.
- `@kfun` — Function handle to a kernel function. A kernel function must be of the form

```
function K = kfun(U, V)
```

The returned value, `K`, is a matrix of size `M-by-N`, where `U` and `V` have `M` and `N` rows respectively.

If `kfun` has extra parameters, include the extra parameters via an anonymous function. For example, suppose that your kernel function is:

```
function k = kfun(u,v,p1,p2)
k = tanh(p1*(u*v')+p2);
```

Set values for `p1` and `p2`, and then use an anonymous function:

```
@(u,v) kfun(u,v,p1,p2)
```

**Default:** `'linear'`

**'kktviolationlevel'**

Value that specifies the fraction of variables allowed to violate the Karush-Kuhn-Tucker (KKT) conditions for the SMO training method. Set any value in `[0,1]`. For example, if you set `kktviolationlevel` to `0.05`, then 5% of the variables are allowed to violate the KKT conditions.

---

**Tip** Set this option to a positive value to help the algorithm converge if it is fluctuating near a good solution.

---

For more information on KKT conditions, see Cristianini and Shawe-Taylor [4].

**Default:** `0`

**'method'**

Method used to find the separating hyperplane. Options are:

- `'QP'` — Quadratic programming (requires an Optimization Toolbox license). The classifier is a 2-norm soft-margin support vector machine. Give quadratic programming options with the `options` name-value pair, and create `options` with `optimset`.
- `'SMO'` — Sequential Minimal Optimization. Give SMO options with the `options` name-value pair, and create `options` with `statset`.
- `'LS'` — Least squares.

**Default:** SMO

### `'mlp_params'`

Parameters of the Multilayer Perceptron (`mlp`) kernel. The `mlp` kernel requires two parameters, `[P1 P2]`. The kernel  $K = \tanh(P1*U*V' + P2)$ , where  $P1 > 0$  and  $P2 < 0$ .

**Default:** `[1 -1]`

### `'options'`

Options structure for training.

- When you set `'method'` to `'SMO'` (default), create the `options` structure using `statset`. Options are:

|                      |                                                                                                                                                                                                                                                                                                                                                                             |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>Display</code> | String that specifies the level of information about the optimization iterations that is displayed as the algorithm runs. Choices are: <ul style="list-style-type: none"><li>• <code>off</code> (default) — Reports nothing.</li><li>• <code>iter</code> — Reports every 500 iterations.</li><li>• <code>final</code> — Reports only when the algorithm finishes.</li></ul> |
| <code>MaxIter</code> | Integer that specifies the maximum number of iterations of the main loop. If this limit is exceeded before the algorithm converges, then the algorithm stops and returns an error. Default is 15000.                                                                                                                                                                        |

The other name-value pairs that relate specifically to the `'SMO'` method are `kernelcachelimit`, `kktviolationlevel`, and `tolkkt`.

- When you set `method` to `'QP'`, create the options structure using `optimset`. For details of applicable option choices, see `quadprog` options. SVM uses a convex quadratic program, so you can choose the `'interior-point-convex'` `quadprog` algorithm. In limited testing, the `'interior-point-convex'` algorithm was the best `quadprog` option for `svmtrain`, in both speed and memory utilization.

**'polyorder'**

Order of the polynomial kernel.

**Default:** 3

**'rbf\_sigma'**

Scaling factor (sigma) in the radial basis function kernel.

**Default:** 1

**'showplot'**

Boolean indicating whether to plot the grouped data and separating line. Creates a plot only when the data has two columns (features).

**Default:** false

**'tolkkt'**

Value that specifies the tolerance with which the Karush-Kuhn-Tucker (KKT) conditions are checked for the SMO training method. For a definition of KKT conditions, see “Karush-Kuhn-Tucker (KKT) Conditions” on page 21-4293.

**Default:** 1e-3

## Output Arguments

**SVMStruct**

Structure containing information about the trained SVM classifier in the following fields:

- `SupportVectors` — Matrix of data points with each row corresponding to a support vector in the normalized data space. This matrix is a subset of the *Training* input data matrix, after normalization has been applied according to the `'AutoScale'` argument.

- **Alpha** — Vector of weights for the support vectors. The sign of the weight is positive for support vectors belonging to the first group, and negative for the second group.
- **Bias** — Intercept of the hyperplane that separates the two groups in the normalized data space (according to the 'AutoScale' argument).
- **KernelFunction** — Handle to the function that maps the training data into kernel space.
- **KernelFunctionArgs** — Cell array of any additional arguments required by the kernel function.
- **GroupNames** — Categorical, numeric, or logical vector, a cell vector of strings, or a character matrix with each row representing a class label. Specifies the group identifiers for the support vectors. It has the same number of elements as there are rows in **SupportVectors**. Each element specifies the group to which the corresponding row in **SupportVectors** belongs.
- **SupportVectorIndices** — Vector of indices that specify the rows in **Training**, the training data, that were selected as support vectors after the data was normalized, according to the **AutoScale** argument.
- **ScaleData** — Field containing normalization factors. When 'AutoScale' is set to **false**, it is empty. When **AutoScale** is set to **true**, it is a structure containing two fields:
  - **shift** — Row vector of values. Each value is the negative of the mean across an observation in *Training*, the training data.
  - **scaleFactor** — Row vector of values. Each value is 1 divided by the standard deviation of an observation in *Training*, the training data.

Both **svmtrain** and **svmclassify** apply the scaling in **ScaleData**.

- **FigureHandles** — Vector of figure handles created by **svmtrain** when using the 'Showplot' argument.

## Examples

### Train an SVM Classifier

Find a line separating the Fisher iris data on *versicolor* and *virginica* species, according to the petal length and petal width measurements. These two species are in rows 51 and higher of the data set, and the petal length and width are the third and fourth columns.

```
load fisheriris
xdata = meas(51:end,3:4);
group = species(51:end);
svmStruct = svmtrain(xdata,group,'ShowPlot',true);
```

## More About

### Karush-Kuhn-Tucker (KKT) Conditions

The Karush-Kuhn-Tucker (KKT) conditions are analogous to the condition that the gradient must be zero at a minimum, modified to take constraints into account. The difference is that the KKT conditions hold for constrained problems. The KKT conditions use the auxiliary Lagrangian function:

$$L(x, \lambda) = f(x) + \sum \lambda_{g,i} g_i(x) + \sum \lambda_{h,i} h_i(x).$$

Here  $f(x)$  is the objective function,  $g(x)$  is a vector of constraint functions  $g(x) \leq 0$ , and  $h(x)$  is a vector of constraint functions  $h(x) = 0$ . The vector  $\lambda$ , which is the concatenation of  $\lambda_g$  and  $\lambda_h$ , is the Lagrange multiplier vector. Its length is the total number of constraints.

The KKT conditions are:

$$\begin{aligned}\nabla_x L(x, \lambda) &= 0 \\ \lambda_{g,i} g_i(x) &= 0 \quad \forall i \\ g(x) &\leq 0 \\ h(x) &= 0 \\ \lambda_{g,i} &\geq 0.\end{aligned}$$

For more information, see Karush-Kuhn-Tucker conditions.

### Tips

- To classify new data, use the result of training, `SVMStruct`, with the `svmclassify` function.

### Algorithms

The `svmtrain` function uses an optimization method to identify support vectors  $s_i$ , weights  $a_i$ , and bias  $b$  that are used to classify vectors  $x$  according to the following equation:

$$c = \sum_i \alpha_i k(s_i, x) + b,$$

where  $k$  is a kernel function. In the case of a linear kernel,  $k$  is the dot product. If  $c \geq 0$ , then  $x$  is classified as a member of the first group, otherwise it is classified as a member of the second group.

### Memory Usage and Out of Memory Error

When you set 'Method' to 'QP', the `svmtrain` function operates on a data set containing  $N$  elements, and it creates an  $(N+1)$ -by- $(N+1)$  matrix to find the separating

hyperplane. This matrix needs at least  $8 * (n+1)^2$  bytes of contiguous memory. If this size of contiguous memory is not available, the software displays an “out of memory” error message.

When you set 'Method' to 'SMO' (default), memory consumption is controlled by the `kernelcachelimit` option. The SMO algorithm stores only a submatrix of the kernel matrix, limited by the size specified by the `kernelcachelimit` option. However, if the number of data points exceeds the size specified by the `kernelcachelimit` option, the SMO algorithm slows down because it has to recalculate the kernel matrix elements.

When using `svmtrain` on large data sets, and you run out of memory or the optimization step is very time consuming, try either of the following:

- Use a smaller number of samples and use cross-validation to test the performance of the classifier.
- Set 'Method' to 'SMO', and set the `kernelcachelimit` option as large as your system permits.
- “Support Vector Machines (SVM)” on page 16-161
- “Grouping Variables” on page 2-52

## table2dataset

Convert table to dataset array

### Compatibility

The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

### Syntax

```
ds = table2dataset(t)
```

### Description

`ds = table2dataset(t)` converts a table to a dataset array.

### Examples

#### Convert a Table to a Dataset Array

Load the sample data, which contains nutritional information for 77 cereals.

```
load cereal;
```

Create a table containing the calorie, protein, fat, and name data for the first five cereals. Label the variables.

```
Calories = Calories(1:5);
Protein = Protein(1:5);
Fat = Fat(1:5);
Name = Name(1:5);
```

```
cereal = table(Calories,Protein,Fat,'RowNames',Name)
```

```
cereal =
```

|                           | Calories | Protein | Fat |
|---------------------------|----------|---------|-----|
|                           | -----    | -----   | --- |
| 100% Bran                 | 70       | 4       | 1   |
| 100% Natural Bran         | 120      | 3       | 5   |
| All-Bran                  | 70       | 4       | 1   |
| All-Bran with Extra Fiber | 50       | 4       | 0   |
| Almond Delight            | 110      | 2       | 2   |

Convert the table to a dataset array.

```
ds = table2dataset(cereal)
```

```
ds =
```

|                           | Calories | Protein | Fat |
|---------------------------|----------|---------|-----|
| 100% Bran                 | 70       | 4       | 1   |
| 100% Natural Bran         | 120      | 3       | 5   |
| All-Bran                  | 70       | 4       | 1   |
| All-Bran with Extra Fiber | 50       | 4       | 0   |
| Almond Delight            | 110      | 2       | 2   |

## Input Arguments

### **t** — Input table

table

Input table to convert to a dataset array, specified as a table. Each variable in `t` becomes a variable in the output dataset array `ds`.

Example:

Data Types: table

## Output Arguments

### **ds** — Output dataset array

dataset array

Output dataset array, returned as a dataset array containing the variables from the input table `t`.

# tabulate

Frequency table

## Syntax

```
TABLE = tabulate(x)
tabulate(x)
```

## Description

`TABLE = tabulate(x)` creates a frequency table of data in vector `x`. Information in `TABLE` is arranged as follows:

- 1st column — The unique values of `x`
- 2nd column — The number of instances of each value
- 3rd column — The percentage of each value

If `x` is a numeric array, `TABLE` is a numeric matrix. If the elements of `x` are nonnegative integers, `TABLE` includes 0 counts for integers between 1 and `max(x)` that do not appear in `x`.

If `x` is a categorical variable, character array, or cell array of strings, `TABLE` is a cell array.

`tabulate(x)` with no output arguments displays the table in the command window.

## Examples

```
tabulate([1 2 4 4 3 4])
Value Count Percent
1 1 16.67%
2 1 16.67%
3 1 16.67%
4 3 50.00%
```

# tblread

Read tabular data from file

## Syntax

```
[data, varnames, casenames] = tblread
[data, varnames, casenames] = tblread(filename)
[data, varnames, casenames] = tblread(filename, delimiter)
```

## Description

[data, varnames, casenames] = tblread displays the File Open dialog box for interactive selection of a tabular data file. The file format has variable names in the first row, case names in the first column and data starting in the (2, 2) position. Outputs are:

- **data** — Numeric matrix with a value for each variable-case pair
- **varnames** — String matrix containing the variable names in the first row of the file
- **casenames** — String matrix containing the names of each case in the first column of the file

[data, varnames, casenames] = tblread(*filename*) allows command line specification of the name of a file in the current folder, or the complete path name of any file, using the string *filename*.

[data, varnames, casenames] = tblread(*filename*, *delimiter*) reads from the file using *delimiter* as the delimiting character. Accepted values for *delimiter* are:

- ' ' or 'space'
- '\t' or 'tab'
- ',' or 'comma'
- ';' or 'semi'
- '|' or 'bar'

The default value of *delimiter* is 'space'.

## Examples

```
[data,varnames,casenames] = tblread('sat.dat')
data =
 470 530
 520 480
```

```
varnames =
Male
Female
```

```
casenames =
Verbal
Quantitative
```

## See Also

`tblwrite` | `tdfread` | `caseread`

# tblwrite

Write tabular data to file

## Syntax

```
tblwrite(data, varnames, casenames)
tblwrite(data, varnames, casenames, filename)
tblwrite(data, varnames, casenames, filename, delimiter)
```

## Description

`tblwrite(data, varnames, casenames)` displays the **File Open** dialog box for interactive specification of the tabular data output file. The file format has variable names in the first row, case names in the first column and `data` starting in the (2,2) position.

`varnames` is a string matrix containing the variable names. `casenames` is a string matrix containing the names of each case in the first column. `data` is a numeric matrix with a value for each variable-case pair.

`tblwrite(data, varnames, casenames, filename)` specifies a file in the current folder, or the complete path name of any file in the string `filename`.

`tblwrite(data, varnames, casenames, filename, delimiter)` writes to the file using `delimiter` as the delimiting character. The following table lists the accepted character values for `delimiter` and their equivalent string values.

| Character | String  |
|-----------|---------|
| ' '       | 'space' |
| '\t'      | 'tab'   |
| ' , '     | 'comma' |
| ' ; '     | 'semi'  |
| '   '     | 'bar'   |

The default value of `delimiter` is 'space'.

## Examples

Continuing the example from `tblread`:

```
tblwrite(data, varnames, casenames, 'sattest.dat')
type sattest.dat
 Male Female
Verbal 470 530
Quantitative 520 480
```

## See Also

`casewrite` | `tblread`

# tcdf

Student's  $t$  cumulative distribution function

## Syntax

```
p = tcdf(x,nu)
p = tcdf(x,nu,'upper')
```

## Description

`p = tcdf(x,nu)` returns the cumulative distribution function (cdf) of the Student's  $t$  distribution at each of the values in `x` using the corresponding degrees of freedom in `nu`. `x` and `nu` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs.

`p = tcdf(x,nu,'upper')` returns the complement of the Student's  $t$  cdf at each value in `x`, using an algorithm that more accurately computes the extreme upper tail probabilities.

## Examples

### Compute Student's $t$ cdf

```
mu = 1; % Population mean
sigma = 2; % Population standard deviation
n = 100; % Sample size

rng default % For reproducibility
x = normrnd(mu,sigma,n,1); % Random sample from population

xbar = mean(x); % Sample mean
s = std(x); % Sample standard deviation
t = (xbar - mu)/(s/sqrt(n))
```

```
t =
 1.0589

p = 1-tcdf(t,n-1) % Probability of larger t-statistic

p =
 0.1461
```

This probability is the same as the  $p$  value returned by a  $t$  test of the null hypothesis that the sample comes from a normal population with mean  $\mu$

```
[h,ptest] = ttest(x,mu,0.05,'right')
```

```
h =
 0

ptest =
 0.1461
```

## More About

### Student's $t$ cdf

The cumulative distribution function (cdf) of Student's  $t$  distribution is

$$p = F(x | \nu) = \int_{-\infty}^x \frac{\Gamma\left(\frac{\nu+1}{2}\right)}{\Gamma\left(\frac{\nu}{2}\right)} \frac{1}{\sqrt{\nu\pi}} \frac{1}{\left(1 + \frac{t^2}{\nu}\right)^{\frac{\nu+1}{2}}} dt$$

where  $\nu$  is the degrees of freedom and  $\Gamma(\cdot)$  is the Gamma function. The result  $p$  is the probability that a single observation from the  $t$  distribution with  $\nu$  degrees of freedom will fall in the interval  $[-\infty, x]$ .

- “Student's  $t$  Distribution” on page B-133

### **See Also**

tpdf | tinvs | tstat | trnd | cdf

## tdfread

Read tab-delimited file

### Syntax

```
tdfread
tdfread(filename)
tdfread(filename,delimiter)
s = tdfread(filename,...)
```

### Description

`tdfread` displays the **File Open** dialog box for interactive selection of a data file, then reads data from the file. The file should have variable names separated by tabs in the first row, and data values separated by tabs in the remaining rows. `tdfread` creates variables in the workspace, one for each column of the file. The variable names are taken from the first row of the file. If a column of the file contains only numeric data in the second and following rows, `tdfread` creates a **double** variable. Otherwise, `tdfread` creates a **char** variable. After all values are imported, `tdfread` displays information about the imported values using the format of the `tdfread` command.

`tdfread(filename)` allows command line specification of the name of a file in the current folder, or the complete path name of any file, using the string *filename*.

`tdfread(filename,delimiter)` indicates that the character specified by *delimiter* separates columns in the file. Accepted values for *delimiter* are:

- ' ' or 'space'
- '\t' or 'tab'
- ',' or 'comma'
- ';' or 'semi'
- '|' or 'bar'

The default delimiter is 'tab'.

`s = tdfread(filename, ...)` returns a scalar structure `s` whose fields each contain a variable.

## Examples

The following displays the contents of the file `sat2.dat`:

```
type sat2.dat

Test,Gender,Score
Verbal,Male,470
Verbal,Female,530
Quantitative,Male,520
Quantitative,Female,480
```

The following creates the variables `Gender`, `Score`, and `Test` from the file `sat2.dat` and displays the contents of the MATLAB workspace:

```
tdfread('sat2.dat','')

Name Size Bytes Class Attributes
Gender 4x6 48 char
Score 4x1 32 double
Test 4x12 96 char
```

# ClassificationDiscriminant.template

**Class:** ClassificationDiscriminant

Discriminant analysis classifier template for ensemble (to be removed)

## Compatibility

ClassificationDiscriminant.template will be removed in a future release. Use templateDiscriminant instead.

## Syntax

```
t = ClassificationDiscriminant.template()
t = ClassificationDiscriminant.template(Name,Value)
```

## Description

t = ClassificationDiscriminant.template() returns a learner template suitable to use in the fitensemble function.

t = ClassificationDiscriminant.template(Name,Value) creates a template with additional options specified by one or more Name,Value pair arguments.

## Input Arguments

### Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

'Delta' — Linear coefficient threshold  
0 (default) | nonnegative scalar value

Linear coefficient threshold, specified as the comma-separated pair consisting of `'Delta'` and a nonnegative scalar value. If a coefficient of `obj` has magnitude smaller than `Delta`, `obj` sets this coefficient to 0, and you can eliminate the corresponding predictor from the model. Set `Delta` to a higher value to eliminate more predictors.

`Delta` must be 0 for quadratic discriminant models.

Data Types: `single` | `double`

**'DiscrimType' — Discriminant type**

`'linear'` (default) | `'quadratic'` | `'diagLinear'` | `'diagQuadratic'` | `'pseudoLinear'` | `'pseudoQuadratic'`

Discriminant type, specified as the comma-separated pair consisting of `'DiscrimType'` and one of the following:

- `'linear'`
- `'quadratic'`
- `'diagLinear'`
- `'diagQuadratic'`
- `'pseudoLinear'`
- `'pseudoQuadratic'`

Example: `'DiscrimType', 'quadratic'`

**'FillCoeffs' — Coeffs property flag**

`'on'` | `'off'`

`Coeffs` property flag, specified as the comma-separated pair consisting of `'FillCoeffs'` and `'on'` or `'off'`. Setting the flag to `'on'` populates the `Coeffs` property in the classifier object. This can be computationally intensive, especially when cross validating. The default is `'on'`, unless you specify a cross validation name-value pair, in which case the flag is set to `'off'` by default.

Example: `'FillCoeffs', 'off'`

**'Gamma' — Regularization parameter**

scalar value in the range `[0, 1]`

Parameter for regularizing the correlation matrix of predictors, specified as the comma-separated pair consisting of `'Gamma'` and a scalar value in the range `[0, 1]`.

- Linear discriminant — Scalar value in the range  $[0, 1]$ .
  - If you pass a value strictly between 0 and 1, `fitcdiscr` sets the discriminant type to `'Linear'`.
  - If you pass 0 for `Gamma` and `'Linear'` for `DiscrimType`, and if the correlation matrix is singular, `fitcdiscr` sets `Gamma` to the minimal value required for inverting the covariance matrix.
  - If you set `Gamma` to 1, `fitcdiscr` sets the discriminant type to `'DiagLinear'`.
- Quadratic discriminant — Either 0 or 1.
  - If you pass 0 for `Gamma` and `'Quadratic'` for `DiscrimType`, and if one of the classes has a singular covariance matrix, `fitcdiscr` errors.
  - If you set `Gamma` to 1, `fitcdiscr` sets the discriminant type to `'DiagQuadratic'`.
  - If you set `Gamma` to a value between 0 and 1 for a quadratic discriminant, `fitcdiscr` errors.

Example: `'Gamma', 1`

Data Types: `single` | `double`

### **'SaveMemory' — Flag to save covariance matrix**

`'off'` (default) | `'on'`

Flag to save covariance matrix, specified as the comma-separated pair consisting of `'SaveMemory'` and either `'on'` or `'off'`. If you specify `'on'`, then `fitcdiscr` does not store the full covariance matrix, but instead stores enough information to compute the matrix. The `predict` method computes the full covariance matrix for prediction, and does not store the matrix. If you specify `'off'`, then `fitcdiscr` computes and stores the full covariance matrix in `obj`.

Specify `SaveMemory` as `'on'` when the input matrix contains thousands of predictors.

Example: `'SaveMemory', 'on'`

## Output Arguments

### **t — Discriminant analysis classification template**

classification template object

Discriminant analysis classification template suitable to use in the `fitensemble` function, returned as a classification template object. In an ensemble, `t` specifies how to create the discriminant analysis classifier.

## Examples

### Discriminant Analysis Template for Nondefault Options

Create a nondefault discriminant analysis template for use in `fitensemble`.

Create a template for pseudolinear discriminant analysis.

```
t = ClassificationDiscriminant.template('discrimType','pseudoLinear')
t =
```

```
Fit template for classification Discriminant.
```

```
DiscrimType: 'pseudoLinear'
 Gamma: []
 Delta: []
FillCoeffs: []
SaveMemory: []
 Method: 'Discriminant'
 Type: 'classification'
```

You can use `t` for ensemble learning.

### See Also

`ClassificationDiscriminant` | `fitensemble` | `templateDiscriminant`

## ClassificationKNN.template

**Class:** ClassificationKNN

*k*-nearest neighbor classifier template for ensemble (to be removed)

### Compatibility

ClassificationKNN.template will be removed in a future release. Use templateKNN instead.

### Syntax

```
t = ClassificationKNN.template()
t = ClassificationKNN.template(Name,Value)
```

### Description

t = ClassificationKNN.template() returns a learner template suitable to use in the fitensemble function.

t = ClassificationKNN.template(Name,Value) creates a template with additional options specified by one or more Name,Value pair arguments.

### Input Arguments

#### Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

**'BreakTies'** — Tie-breaking algorithm

'smallest' (default) | 'nearest' | 'random'

Tie-breaking algorithm used by the `predict` method if multiple classes have the same smallest cost, specified as the comma-separated pair consisting of `'BreakTies'` and one of the following:

- `'smallest'` — Use the smallest index among tied groups.
- `'nearest'` — Use the class with the nearest neighbor among tied groups.
- `'random'` — Use a random tiebreaker among tied groups.

By default, ties occur when multiple classes have the same number of nearest points among the  $K$  nearest neighbors.

Example: `'BreakTies', 'nearest'`

### **'BucketSize' — Maximum data points in node**

50 (default) | positive integer value

Maximum number of data points in the leaf node of the  $kd$ -tree, specified as the comma-separated pair consisting of `'BucketSize'` and a positive integer value. This argument is meaningful only when `NSMethod` is `'kdtree'`.

Example: `'BucketSize', 40`

Data Types: `single` | `double`

### **'Cov' — Covariance matrix**

`nancov(X)` (default) | positive definite matrix of scalar values

Covariance matrix, specified as the comma-separated pair consisting of `'Cov'` and a positive definite matrix of scalar values representing the covariance matrix when computing the Mahalanobis distance. This argument is only valid when `'Distance'` is `'mahalanobis'`.

You cannot simultaneously specify `'Standardize'` and either of `'Scale'` or `'Cov'`.

Data Types: `single` | `double`

### **'Distance' — Distance metric**

valid distance metric string | function handle

Distance metric, specified as the comma-separated pair consisting of `'Distance'` and a valid distance metric string or function handle. The allowable strings depend on the `NSMethod` parameter, which you set in `fitcknn`, and which exists as a field in

`ModelParameters`. If you specify `CategoricalPredictors` as `'all'`, then the default distance metric is `'hamming'`. Otherwise, the default distance metric is `'euclidean'`.

| <b>NSMethod</b>         | <b>Distance Metric Names</b>                                                                                 |
|-------------------------|--------------------------------------------------------------------------------------------------------------|
| <code>exhaustive</code> | Any distance metric of <code>ExhaustiveSearcher</code>                                                       |
| <code>kdtree</code>     | <code>'cityblock'</code> , <code>'chebychev'</code> , <code>'euclidean'</code> , or <code>'minkowski'</code> |

For definitions, see “Distance Metrics”.

This table includes valid distance metrics of `ExhaustiveSearcher`.

| <b>Value</b>               | <b>Description</b>                                                                                                                                                                                                                                                                                                                                                                             |
|----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>'cityblock'</code>   | City block distance.                                                                                                                                                                                                                                                                                                                                                                           |
| <code>'chebychev'</code>   | Chebychev distance (maximum coordinate difference).                                                                                                                                                                                                                                                                                                                                            |
| <code>'correlation'</code> | One minus the sample linear correlation between observations (treated as sequences of values).                                                                                                                                                                                                                                                                                                 |
| <code>'cosine'</code>      | One minus the cosine of the included angle between observations (treated as vectors).                                                                                                                                                                                                                                                                                                          |
| <code>'euclidean'</code>   | Euclidean distance.                                                                                                                                                                                                                                                                                                                                                                            |
| <code>'hamming'</code>     | Hamming distance, percentage of coordinates that differ.                                                                                                                                                                                                                                                                                                                                       |
| <code>'jaccard'</code>     | One minus the Jaccard coefficient, the percentage of nonzero coordinates that differ.                                                                                                                                                                                                                                                                                                          |
| <code>'mahalanobis'</code> | Mahalanobis distance, computed using a positive definite covariance matrix <code>C</code> . The default value of <code>C</code> is the sample covariance matrix of <code>X</code> , as computed by <code>nancov(X)</code> . To specify a different value for <code>C</code> , use the <code>'Cov'</code> name-value pair argument.                                                             |
| <code>'minkowski'</code>   | Minkowski distance. The default exponent is 2. To specify a different exponent, use the <code>'Exponent'</code> name-value pair argument.                                                                                                                                                                                                                                                      |
| <code>'seuclidean'</code>  | Standardized Euclidean distance. Each coordinate difference between <code>X</code> and a query point is scaled, meaning divided by a scale value <code>S</code> . The default value of <code>S</code> is the standard deviation computed from <code>X</code> , <code>S = nanstd(X)</code> . To specify another value for <code>S</code> , use the <code>Scale</code> name-value pair argument. |

| Value            | Description                                                                                                                                                                                                                                                                                                                                                                                                                         |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'spearman'       | One minus the sample Spearman's rank correlation between observations (treated as sequences of values).                                                                                                                                                                                                                                                                                                                             |
| @ <i>distfun</i> | Distance function handle. <i>distfun</i> has the form<br><pre>function D2 = DISTFUN(ZI,ZJ) % calculation of distance ... where</pre> <ul style="list-style-type: none"> <li>• ZI is a 1-by-N vector containing one row of X or y.</li> <li>• ZJ is an M2-by-N matrix containing multiple rows of X or y.</li> <li>• D2 is an M2-by-1 vector of distances, and D2(k) is the distance between observations ZI and ZJ(J,:).</li> </ul> |

Example: 'Distance', 'minkowski'

Data Types: function\_handle

### 'DistanceWeight' – Distance weighting function

'equal' (default) | 'inverse' | 'squaredinverse' | function handle

Distance weighting function, specified as the comma-separated pair consisting of 'DistanceWeight' and either a function handle or one of the following strings specifying the distance weighting function.

| DistanceWeight   | Meaning                                                                                                                                                                                                          |
|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'equal'          | No weighting                                                                                                                                                                                                     |
| 'inverse'        | Weight is 1/distance                                                                                                                                                                                             |
| 'squaredinverse' | Weight is 1/distance <sup>2</sup>                                                                                                                                                                                |
| @ <i>fcn</i>     | <i>fcn</i> is a function that accepts a matrix of nonnegative distances, and returns a matrix the same size containing nonnegative distance weights. For example, 'squaredinverse' is equivalent to @(d)d.^(-2). |

Example: 'DistanceWeight', 'inverse'

Data Types: function\_handle

**'Exponent' — Minkowski distance exponent**

2 (default) | positive scalar value

Minkowski distance exponent, specified as the comma-separated pair consisting of `'Exponent'` and a positive scalar value. This argument is only valid when `'Distance'` is `'minkowski'`.

Example: `'Exponent',3`Data Types: `single` | `double`**'IncludeTies' — Tie inclusion flag**`false` (default) | `true`

Tie inclusion flag, specified as the comma-separated pair consisting of `'IncludeTies'` and a logical value indicating whether `predict` includes all the neighbors whose distance values are equal to the Kth smallest distance. If `IncludeTies` is `true`, `predict` includes all these neighbors. Otherwise, `predict` uses exactly K neighbors.

Example: `'IncludeTies',true`Data Types: `logical`**'NSMethod' — Nearest neighbor search method**`'kdtree'` | `'exhaustive'`

Nearest neighbor search method, specified as the comma-separated pair consisting of `'NSMethod'` and `'kdtree'` or `'exhaustive'`.

- `'kdtree'` — Create and use a *kd*-tree to find nearest neighbors. `'kdtree'` is valid when the distance metric is one of the following:
  - `'euclidean'`
  - `'cityblock'`
  - `'minkowski'`
  - `'chebyshev'`
- `'exhaustive'` — Use the exhaustive search algorithm. The distance values from all points in X to each point in y are computed to find nearest neighbors.

The default is `'kdtree'` when X has 10 or fewer columns, X is not sparse, and the distance metric is a `'kdtree'` type; otherwise, `'exhaustive'`.

Example: `'NSMethod','exhaustive'`

**'NumNeighbors' — Number of nearest neighbors to find**

1 (default) | positive integer value

Number of nearest neighbors in X to find for classifying each point when predicting, specified as the comma-separated pair consisting of 'NumNeighbors' and a positive integer value.

Example: 'NumNeighbors',3

Data Types: single | double

**'Scale' — Distance scale**

nanstd(X) (default) | vector of nonnegative scalar values

Distance scale, specified as the comma-separated pair consisting of 'Scale' and a vector containing nonnegative scalar values with length equal to the number of columns in X. Each coordinate difference between X and a query point is scaled by the corresponding element of Scale. This argument is only valid when 'Distance' is 'seuclidean'.

You cannot simultaneously specify 'Standardize' and either of 'Scale' or 'Cov'.

Data Types: single | double

## Output Arguments

**t — Classification template**

classification template object

$K$ -nearest neighbor classification template suitable to use in the `fitensemble` function. In an ensemble, `t` specifies how to create the KNN classifier.

## Examples

**KNN template for nondefault options**

Create a nondefault  $k$ -nearest neighbor template for use in `fitensemble`.

Create a template for 5-nearest neighbor search.

```
t = ClassificationKNN.template('NumNeighbors',5)
```

```
t =

Fit template for classification KNN.

 NumNeighbors: 5
 NSMethod: ''
 Distance: ''
 BucketSize: []
 IncludeTies: ''
DistanceWeight: []
 BreakTies: []
 Exponent: []
 Cov: []
 Scale: []
 Method: 'KNN'
 Type: 'classification'
```

You can use `t` for ensemble learning.

- “Random Subspace Classification” on page 16-115

`ClassificationKNN` | `fitensemble`

# ClassificationTree.template

**Class:** ClassificationTree

Create classification template (to be removed)

## Compatibility

ClassificationTree.template will be removed in a future release. Use templateTree instead.

## Syntax

```
t = ClassificationTree.template
t = ClassificationTree.template(Name,Value)
```

## Description

t = ClassificationTree.template returns a learner template suitable to use in the fitensemble function.

t = ClassificationTree.template(Name,Value) creates a template with additional options specified by one or more Name,Value pair arguments. You can specify several name-value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

## Input Arguments

### Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

**'AlgorithmForCategorical'**

Algorithm to find the best split on a categorical predictor for data with  $K = 3$  or more classes. The available algorithms are:

**'Exact'**

For a categorical predictor with  $C$  categories, consider all  $2^{C-1} - 1$  combinations.

**'PullLeft'**

Start with all  $C$  categories on the right branch. Consider moving each category to the left branch as it achieves the minimum impurity for the  $K$  classes among the remaining categories. Out of this sequence, choose the split that has the lowest impurity.

**'PCA'**

Compute a score for each category using the inner product between the first principal component of a weighted covariance matrix (of the centered class probability matrix) and the vector of class probabilities for that category. Sort the scores in ascending order, and consider all  $C - 1$  splits.

**'OVAbyClass'**

Start with all  $C$  categories on the right branch. For each class, order the categories based on their probability for that class. For the first class, consider moving each category to the left branch in order, recording the impurity criterion at each move. Repeat for the remaining classes. Out of this sequence, choose the split that has the minimum impurity.

**Default:** `ClassificationTree` selects the optimal subset of algorithms for each split using the known number of classes and levels of a categorical predictor. For two classes, `ClassificationTree` always performs the exact search.

**'MaxCat'**

`ClassificationTree` splits a categorical predictor using the exact search algorithm if the predictor has at most `MaxCat` levels in the split node. Otherwise, `ClassificationTree` finds the best categorical split using one of the inexact algorithms.

Specify `MaxCat` as a numeric nonnegative scalar value. Passing a small value can lead to long computation time and memory overload.

**Default:** 10

**'MergeLeaves'**

String that specifies whether to merge leaves after the tree is grown. Values are 'on' or 'off'.

When 'on', `ClassificationTree` merges leaves that originate from the same parent node, and that give a sum of risk values greater or equal to the risk associated with the parent node. When 'off', `ClassificationTree` does not merge leaves.

**Default:** 'off'

**'MinLeaf'**

Each leaf has at least `MinLeaf` observations per tree leaf. If you supply both `MinParent` and `MinLeaf`, `ClassificationTree` uses the setting that gives larger leaves:  $\text{MinParent} = \max(\text{MinParent}, 2 * \text{MinLeaf})$ .

**Default:** Half the number of training observations for boosting, 1 for bagging

**'MinParent'**

Each branch node in the tree has at least `MinParent` observations. If you supply both `MinParent` and `MinLeaf`, `ClassificationTree` uses the setting that gives larger leaves:  $\text{MinParent} = \max(\text{MinParent}, 2 * \text{MinLeaf})$ .

**Default:** Number of training observations for boosting, 2 for bagging

**'NVarToSample'**

Number of predictors to select at random for each split. Can be a positive integer or 'all', which means use all available predictors.

**Default:** 'all' for boosting, square root of number of predictors for bagging

**'Prune'**

When 'on', `ClassificationTree` grows the classification tree and computes the optimal sequence of pruned subtrees. When 'off' `ClassificationTree` grows the tree without pruning.

**Default:** 'off'

**'PruneCriterion'**

String with the pruning criterion, either 'error' or 'impurity'.

**Default:** 'error'

**'SplitCriterion'**

Criterion for choosing a split. One of 'gdi' (Gini's diversity index), 'twoing' for the twoing rule, or 'deviance' for maximum deviance reduction (also known as cross entropy).

**Default:** 'gdi'

**'Surrogate'**

String describing whether to find surrogate decision splits at each branch node. Specify as 'on', 'off', 'all', or a positive scalar value.

- When 'on', `ClassificationTree` finds at most 10 surrogate splits at each branch node.
- When set to a positive integer value, `ClassificationTree` finds at most the specified number of surrogate splits at each branch node.
- When set to 'all', `ClassificationTree` finds all surrogate splits at each branch node. The 'all' setting can use much time and memory.

Use surrogate splits to improve the accuracy of predictions for data with missing values. The setting also enables you to compute measures of predictive association between predictors.

**Default:** 'off'

## Output Arguments

**t**

Classification tree template suitable to use in the `fitensemble` function. In an ensemble, `t` specifies how to grow the classification trees.

## Examples

### Construct a Classification Template with Surrogate Splits

Create a classification template with surrogate splits, and train an ensemble for the Fisher iris model with the template.

```
t = ClassificationTree.template('surrogate','on');
load fisheriris
ens = fitensemble(meas,species,'AdaBoostM2',100,t);
```

## RegressionTree.template

**Class:** RegressionTree

Create regression template (to be removed)

### Compatibility

RegressionTree.template will be removed in a future release. Use templateTree instead.

### Syntax

```
t = RegressionTree.template
t = RegressionTree.template(Name, Value)
```

### Description

t = RegressionTree.template returns a learner template suitable to use in the fitensemble function.

t = RegressionTree.template(Name, Value) creates a template with additional options specified by one or more Name, Value pair arguments. You can specify several name-value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

### Input Arguments

#### Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

**'MergeLeaves'**

String that specifies whether to merge leaves after the tree is grown. Values are 'on' or 'off'.

When 'on', `RegressionTree` merges leaves that originate from the same parent node, and that give a sum of risk values greater or equal to the risk associated with the parent node. When 'off', `RegressionTree` does not merge leaves.

**Default:** 'off'

**'MinLeaf'**

Each leaf has at least `MinLeaf` observations per tree leaf. If you supply both `MinParent` and `MinLeaf`, `RegressionTree` uses the setting that gives larger leaves:  $\text{MinParent} = \max(\text{MinParent}, 2 * \text{MinLeaf})$ .

**Default:** Half the number of training observations for boosting, 5 for bagging

**'MinParent'**

Each branch node in the tree has at least `MinParent` observations. If you supply both `MinParent` and `MinLeaf`, `RegressionTree` uses the setting that gives larger leaves:  $\text{MinParent} = \max(\text{MinParent}, 2 * \text{MinLeaf})$ .

**Default:** Number of training observations for boosting, 10 for bagging

**'NVarToSample'**

Number of predictors to select at random for each split. Can be a positive integer or 'all', which means use all available predictors.

**Default:** 'all' for boosting, one third of the number of predictors for bagging

**'Prune'**

When 'on', `RegressionTree` grows the regression tree and computes the optimal sequence of pruned subtrees. When 'off' `RegressionTree` grows the tree without pruning.

**Default:** 'off'

**'Surrogate'**

String describing whether to find surrogate decision splits at each branch node. Specify as 'on', 'off', 'all', or a positive scalar value.

- When 'on', `RegressionTree` finds at most 10 surrogate splits at each branch node.
- When set to a positive integer value, `RegressionTree` finds at most the specified number of surrogate splits at each branch node.
- When set to 'all', `RegressionTree` finds all surrogate splits at each branch node. The 'all' setting can use much time and memory.

Use surrogate splits to improve the accuracy of predictions for data with missing values. The setting also enables you to compute measures of predictive association between predictors.

**Default:** 'off'

## Output Arguments

**t**

Regression tree template suitable to use in the `fitensemble` function. In an ensemble, `t` specifies how to grow the regression trees.

## Examples

Create a regression template with surrogate splits, and train an ensemble for the `carsmall` data with the template:

```
t = RegressionTree.template('surrogate','on');
load carsmall
X = [Acceleration Displacement Horsepower Weight];
ens = fitensemble(X,MPG,'LSBoost',100,t);
```

## See Also

`RegressionTree` | `fitrtree` | `fitensemble`

# templateDiscriminant

Discriminant analysis classifier template

## Syntax

```
t = templateDiscriminant()
t = templateDiscriminant(Name,Value)
```

## Description

`t = templateDiscriminant()` returns a discriminant analysis learner template suitable for training ensembles or error-correcting output code (ECOC) multiclass models.

If you specify a default template, then the software uses default values for all input arguments during training.

Specify `t` as a learner in `fitensemble` or `fitcecoc`.

`t = templateDiscriminant(Name,Value)` creates a template with additional options specified by one or more name-value pair arguments.

For example, you can specify the discriminant type or the regularization parameter.

If you display `t` in the Command Window, then all options appear empty (`[]`), except those that you specify using name-value pair arguments. During training, the software uses default values for empty options.

## Examples

### Create a Discriminant Analysis Template for Ensemble Learning

Create a nondefault discriminant analysis template for use in “fitensemble”.

Load Fisher's iris data set.

```
load fisheriris
```

Create a template for pseudolinear discriminant analysis.

```
t = templateDiscriminant('DiscrimType','pseudoLinear')
```

```
t =
```

Fit template for classification Discriminant.

```
DiscrimType: 'pseudoLinear'
Gamma: []
Delta: []
FillCoeffs: []
SaveMemory: []
Method: 'Discriminant'
Type: 'classification'
```

All properties of the template object are empty except for `DiscrimType`, `Method`, and `Type`. When trained on, the software fills in the empty properties with their respective default values.

Specify `t` as a weak learner for a classification ensemble.

```
Mdl = fitensemble(meas,species,'Subspace',100,t);
```

Display the in-sample (resubstitution) misclassification error.

```
L = resubLoss(Mdl)
```

```
L =
```

```
0.0400
```

## Input Arguments

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`,`Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single

quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'DiscrimType', 'pseudoLinear', 'SaveMemory', 'on'` specifies a template for pseudolinear discriminant analysis that does not store the full covariance matrix.

### 'Delta' — Linear coefficient threshold

0 (default) | nonnegative scalar value

Linear coefficient threshold, specified as the comma-separated pair consisting of `'Delta'` and a nonnegative scalar value. If a coefficient of `Obj` has magnitude smaller than `Delta`, `Obj` sets this coefficient to 0, and you can eliminate the corresponding predictor from the model. Set `Delta` to a higher value to eliminate more predictors.

`Delta` must be 0 for quadratic discriminant models.

Data Types: `single` | `double`

### 'DiscrimType' — Discriminant type

'linear' (default) | 'quadratic' | 'diagLinear' | 'diagQuadratic' | 'pseudoLinear' | 'pseudoQuadratic'

Discriminant type, specified as the comma-separated pair consisting of `'DiscrimType'` and one of the following:

- 'linear'
- 'quadratic'
- 'diagLinear'
- 'diagQuadratic'
- 'pseudoLinear'
- 'pseudoQuadratic'

Example: `'DiscrimType', 'quadratic'`

### 'FillCoeffs' — Coeffs property flag

'on' | 'off'

`Coeffs` property flag, specified as the comma-separated pair consisting of `'FillCoeffs'` and `'on'` or `'off'`. Setting the flag to `'on'` populates the `Coeffs` property in the classifier object. This can be computationally intensive, especially when

cross validating. The default is 'on', unless you specify a cross validation name-value pair, in which case the flag is set to 'off' by default.

Example: 'FillCoeffs', 'off'

### 'Gamma' — Regularization parameter

scalar value in the range [0,1]

Parameter for regularizing the correlation matrix of predictors, specified as the comma-separated pair consisting of 'Gamma' and a scalar value in the range [0,1].

- Linear discriminant — Scalar value in the range [0,1].
  - If you pass a value strictly between 0 and 1, `fitcdiscr` sets the discriminant type to 'Linear'.
  - If you pass 0 for Gamma and 'Linear' for `DiscrimType`, and if the correlation matrix is singular, `fitcdiscr` sets Gamma to the minimal value required for inverting the covariance matrix.
  - If you set Gamma to 1, `fitcdiscr` sets the discriminant type to 'DiagLinear'.
- Quadratic discriminant — Either 0 or 1.
  - If you pass 0 for Gamma and 'Quadratic' for `DiscrimType`, and if one of the classes has a singular covariance matrix, `fitcdiscr` errors.
  - If you set Gamma to 1, `fitcdiscr` sets the discriminant type to 'DiagQuadratic'.
  - If you set Gamma to a value between 0 and 1 for a quadratic discriminant, `fitcdiscr` errors.

Example: 'Gamma', 1

Data Types: single | double

### 'SaveMemory' — Flag to save covariance matrix

'off' (default) | 'on'

Flag to save covariance matrix, specified as the comma-separated pair consisting of 'SaveMemory' and either 'on' or 'off'. If you specify 'on', then `fitcdiscr` does not store the full covariance matrix, but instead stores enough information to compute the matrix. The `predict` method computes the full covariance matrix for prediction, and does not store the matrix. If you specify 'off', then `fitcdiscr` computes and stores the full covariance matrix in `obj`.

Specify `SaveMemory` as `'on'` when the input matrix contains thousands of predictors.

Example: `'SaveMemory', 'on'`

## Output Arguments

### **t** — Discriminant analysis classification template

template object

Discriminant analysis classification template suitable for training ensembles or error-correcting output code (ECOC) multiclass models, returned as a template object. Pass `t` to `fitensemble` or `fitcecoc` to specify how to create the discriminant analysis classifier for the ensemble or ECOC model, respectively.

If you display `t` to the Command Window, then all unspecified options appear empty (`[]`). However, the software replaces empty options with their corresponding default values during training.

### See Also

`ClassificationDiscriminant` | `fitcecoc` | `fitensemble` | `predict`

## templateEnsemble

Ensemble learning template

### Syntax

```
t = templateEnsemble(Method,NLearn,Learners)
t = templateNaiveBayes(Method,NLearn,Learners,Name,Value)
```

### Description

`t = templateEnsemble(Method,NLearn,Learners)` returns an ensemble learning template suitable for training error-correcting output code (ECOC) multiclass models, which uses the method `Method`, `NLearn` learning cycles, and the weak learners (`Learners`).

All other options of the template (`t`) specific to ensemble learning appear empty, but the software uses their corresponding default values during training.

Specify `t` as a binary learner, or one in a set of binary learners, in `fitcecoc` to train an ECOC multiclass classifier.

`t = templateNaiveBayes(Method,NLearn,Learners,Name,Value)` returns a template with additional options specified by one or more name-value pair arguments.

For example, you can specify the number of predictors in each random subspace learner, learning rate for shrinkage, or the target classification error for `RobustBoost`.

If you display `t` in the Command Window, then all options appear empty (`[]`), except those that you specify using name-value pair arguments. During training, the software uses default values for empty options.

### Input Arguments

#### Method

Case-insensitive string consisting of one of the following.

- For classification with two classes:
  - 'AdaBoostM1'
  - 'LogitBoost'
  - 'GentleBoost'
  - 'RobustBoost' (requires an Optimization Toolbox license)
  - 'LPBoost' (requires an Optimization Toolbox license)
  - 'TotalBoost' (requires an Optimization Toolbox license)
  - 'RUSBoost'
  - 'Subspace'
  - 'Bag'
- For classification with three or more classes:
  - 'AdaBoostM2'
  - 'LPBoost' (requires an Optimization Toolbox license)
  - 'TotalBoost' (requires an Optimization Toolbox license)
  - 'RUSBoost'
  - 'Subspace'
  - 'Bag'
- For regression:
  - 'LSBoost'
  - 'Bag'

'Bag' applies to all methods. So when you use 'Bag', indicate whether you want a classifier or regressor with the `type` name-value pair set to 'classification' or 'regression'.

### **NLearn**

Number of ensemble learning cycles, a positive integer (or the string 'AllPredictorCombinations', see the next paragraph). At every training cycle, `fitensemble` loops over all learner templates in `Learners` and trains one weak learner for every template. The total number of trained learners in `Ensemble` is `NLearn*numel(Learners)`.

If you set `Method` to `'Subspace'`, you can set `NLearn` to `'AllPredictorCombinations'`. With this setting, `fitensemble` constructs learners for all possible combinations of predictors taken `NPredToSample` at a time. This gives a total of `nchoosek(size(X,2),NPredToSample)` learners in the ensemble. You can use only one learner template for this setting.

`NLearn` for ensembles can vary from a few dozen to a few thousand. Usually, an ensemble with a good predictive power needs from a few hundred to a few thousand weak learners. You do not have to train an ensemble for that many cycles at once. You can start by growing a few dozen learners, inspect the ensemble performance and, if necessary, train more weak learners using the `resume` method of the ensemble.

### Learners

One of the following:

- A string with the name of a weak learner:
  - `'Discriminant'` (recommended for `'Subspace'`)
  - `'KNN'` (applies only to `'Subspace'`)
  - `'Tree'` (applies to all methods except `'Subspace'`)
- A single weak learner template you create with `templateTree`, `templateKNN`, or `templateDiscriminant`.
- A cell array of weak learner templates. Usually you should supply only one weak learner template.

Ensemble performance depends on the parameters of the weak learners, and you can get poor performance using weak learners with default parameters. Specify the parameters for the weak learners in the template.

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

## All Ensembles

### 'FResample'

Fraction of the training set to be selected by resampling for every weak learner. A numeric scalar from 0 through 1. This parameter has no effect unless you grow an ensemble by bagging or set 'Resample' to 'on'. The default setting is the one used most often for an ensemble grown by resampling.

**Default:** 1

### 'NPredToSample'

Number of predictors in each random subspace learner, a positive integer from 1 to the number of predictors.

**Default:** 1

### 'NPrint'

Printout frequency, a positive integer scalar. Set to 'Off' for no printout. Use this parameter to track how many weak learners have been trained so far. This is useful when you train ensembles with many learners on large data sets. If you use one of the cross-validation options, this parameter defines the printout frequency per number of cross-validation folds.

**Default:** 'Off'

### 'Replace'

'On' or 'Off'. If 'On', sample with replacement. If 'Off', sample without replacement. This parameter has no effect unless you grow an ensemble by bagging or set Resample to 'On'. If you set Resample to 'On' and Replace to 'Off', fitensemble samples training observations assuming uniform weights, and boosts by reweighting observations.

**Default:** 'On'

### 'Resample'

'On' or 'Off'. If 'On', grow an ensemble by resampling, with the resampling fraction given by FResample, and sampling with or without replacement given by Replace.

- Boosting — When 'Off', the boosting algorithm reweights observations at every learning iteration. When 'On', the algorithm samples training observations using updated weights as the multinomial sampling probabilities.
- Bagging — You can use only the default value of this parameter ('On').

**Default:** 'Off' for boosting, 'On' for bagging

## AdaBoostM1, AdaBoostM2, LogitBoost, GentleBoost, RUSBoost, and LSBoost:

### 'LearnRate'

Learning rate for shrinkage, a numeric scalar from 0 to 1. If you set the learning rate to less than 1, the ensemble requires more learning iterations but often achieves a better accuracy. 0.1 is a popular choice for an ensemble grown with shrinkage.

**Default:** 1

## RUSBoost

### 'RatioToSmallest'

Either a numeric scalar or vector with  $K$  elements when there are  $K$  classes. Every element of this vector is the sampling proportion for this class with respect to the class with fewest observations in  $Y$ . If you pass a scalar, the software uses this sampling proportion for all classes. For example, suppose you have class A with 100 observations and class B with 10 observations. If you pass [2 1] for 'RatioToSmallest', every learner in the ensemble is trained on 20 observations of class A and 10 observations of class B. If you pass 2 or [2 2], every learner is trained on 20 observations of class A and 20 observations of class B. If you specify class names by using the `ClassNames` name-value pair argument of the fitting function, then the software matches elements in the array of class names to elements in this vector.

**Default:** ones( $K$ , 1)

## LPBoost and TotalBoost

### 'MarginPrecision'

Margin precision, a numeric scalar between 0 and 1. `MarginPrecision` affects the number of boosting iterations required for conversion. Use a small value to grow an ensemble with many learners, and use a large value to grow an ensemble with few learners.

**Default:** 0.01

## RobustBoost

### 'RobustErrorGoal'

Target classification error for `RobustBoost`, a numeric scalar from 0 through 1. Usually there is an optimal range for this parameter for your training data. If you set the error goal too low or too high, `RobustBoost` can produce a model with poor classification accuracy.

**Default:** 0.1

### 'RobustMarginSigma'

Spread of the distribution of classification margins over the training set for `RobustBoost`, a numeric positive scalar. You should consult literature on `RobustBoost` before setting this parameter

**Default:** 0.1

### 'RobustMaxMargin'

Maximal classification margin for `RobustBoost` in the training set, a nonnegative numeric scalar. `RobustBoost` minimizes the number of observations in the training set with classification margins below `RobustMaxMargin`.

**Default:** 0

## Output Arguments

### **t** — Classification template for ensemble learning

classification template object

Classification template for ensemble learning suitable for training error-correcting output code (ECOC) multiclass models, returned as a template object. Pass **t** to `fitcecoc` to specify how to create the ensemble learning classifier for the ECOC model.

If you display **t** in the Command Window, then all, unspecified options appear empty (`[]`). However, the software replaces empty options with their corresponding default values during training.

## Examples

### Create an Ensemble Learning Template

Use `templateEnsemble` to specify an ensemble learning template. You must specify the ensemble method, the number of learning cycles, and the type of weak learners. For this example, specify the `AdaBoostM1` method, 100 learners, and classification tree weak learners.

```
t = templateEnsemble('AdaBoostM1',100,'tree')
```

```
t =
```

```
Fit template for classification AdaBoostM1.
```

```
 Type: 'classification'
 Method: 'AdaBoostM1'
LearnerTemplates: 'Tree'
 NLearn: 100
 LearnRate: []
```

All properties of the template object are empty except for `Method`, `Type`, `LearnerTemplates`, and `NLearn`. When trained on, the software fills in the empty properties with their respective default values. For example, the software fills the `LearnRate` property with 1.

`t` is a plan for an ensemble learner, and no computation takes place when you specify it. You can pass `t` to “`fitcecoc`” to specify ensemble binary learners for ECOC multiclass learning.

### Create an Ensemble Template for ECOC Multiclass Learning

Create an ensemble template for use in “`fitcecoc`”.

Load the arrhythmia data set.

```
load arrhythmia
tabulate(categorical(Y));
rng(1); % For reproducibility
```

| Value | Count | Percent |
|-------|-------|---------|
| 1     | 245   | 54.20%  |
| 2     | 44    | 9.73%   |
| 3     | 15    | 3.32%   |
| 4     | 15    | 3.32%   |
| 5     | 13    | 2.88%   |
| 6     | 25    | 5.53%   |
| 7     | 3     | 0.66%   |
| 8     | 2     | 0.44%   |
| 9     | 9     | 1.99%   |
| 10    | 50    | 11.06%  |
| 14    | 4     | 0.88%   |
| 15    | 5     | 1.11%   |
| 16    | 22    | 4.87%   |

Some classes have small relative frequencies in the data.

Create a template for a GentleBoost ensemble of classification trees, and specify to use a 100 learners and a shrinkage of 0.1. By default, boosting grows stumps (i.e., one node having a set of leaves). Since there are classes with small frequencies, the trees must be leafy enough to be sensitive to the minority classes. Specify the minimum number of leaf node observations to 3.

```
tTree = templateTree('MinLeaf',20);
t = templateEnsemble('AdaBoostM1',100,tTree,'LearnRate',0.1);
```

All properties of the template objects are empty except for `Method` and `Type`, and the corresponding properties of the name-value pair argument values in the function calls. When you pass `t` to the training function, the software fills in the empty properties with their respective default values.

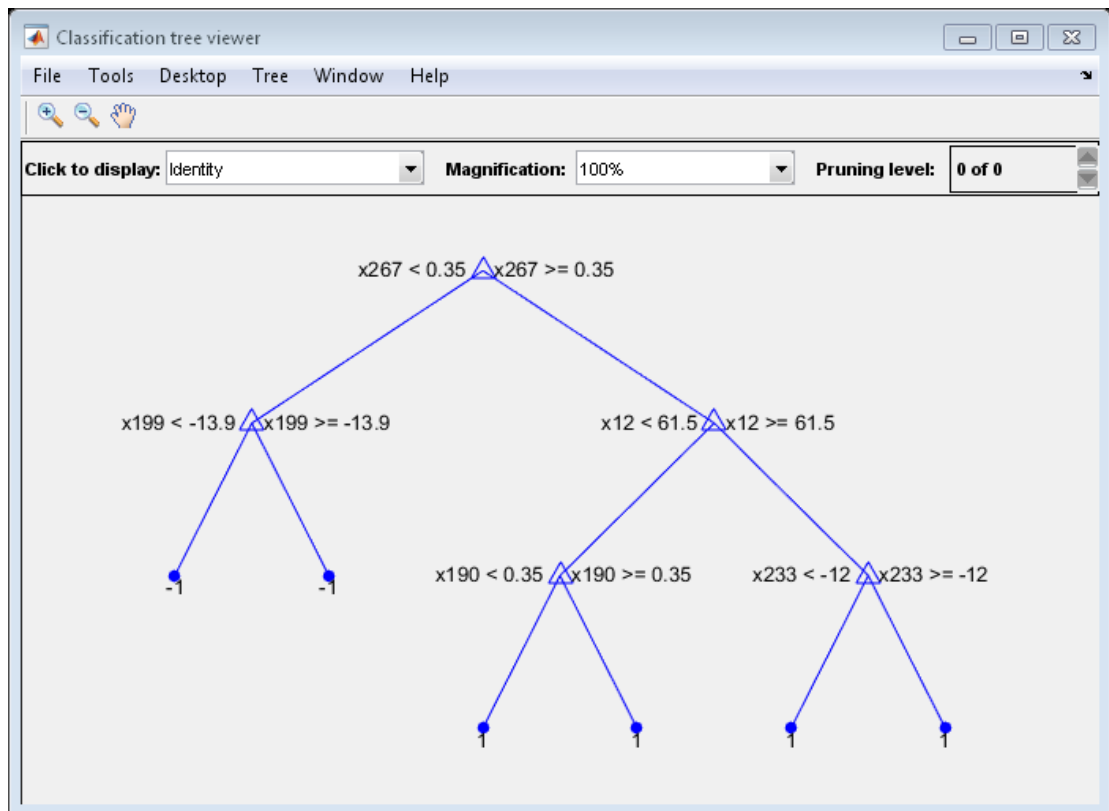

Specify `t` as a binary learner for an ECOC multiclass model. Train using the default one-versus-one coding design.

```
Mdl = fitcecoc(X,Y,'Learners',t);
```

- `Mdl` is a `ClassificationECOC` multiclass model.
- `Mdl.BinaryLearners` is a 78-by-1 cell array of `CompactClassificationEnsemble` models.
- `Mdl.BinaryLearners{j}.Trained` is a 100-by-1 cell array of `CompactClassificationTree` models, for  $j = 1, \dots, 78$ .

You can verify that one of the binary learners contains a weak learner that isn't a stump by using `view`.

```
view(Mdl.BinaryLearners{1}.Trained{1}, 'Mode', 'graph')
```

Display the in-sample (resubstitution) misclassification error.

```
L = resubLoss(Mdl, 'LossFun', 'classiferror')
```

```
L =
```

```
 0.0597
```

## More About

### Algorithms

By default, if you specify `Method` to be a boosting algorithm and `Learners` to be decision trees, then the software grows *stumps* (i.e., one root node connected to two terminal, leaf nodes). You can adjust this by specifying values for the `MinLeaf` or `MinParent` name-value pair arguments using `templateTree`.

### See Also

`ClassificationECOC` | `ClassificationEnsemble` | `fitcecoc` | `fitensemble` | `templateDiscriminant` | `templateKNN` | `templateTree`

## templateKNN

*k*-nearest neighbor classifier template

### Syntax

```
t = templateKNN()
t = templateKNN(Name, Value)
```

### Description

`t = templateKNN()` returns a *k*-nearest neighbor (KNN) learner template suitable for training ensembles or error-correcting output code (ECOC) multiclass models.

If you specify a default template, then the software uses default values for all input arguments during training.

Specify `t` as a learner in `fitensemble` or `fitcecoc`.

`t = templateKNN(Name, Value)` creates a template with additional options specified by one or more name-value pair arguments.

For example, you can specify the nearest neighbor search method, the number of nearest neighbors to find, or the distance metric.

If you display `t` in the Command Window, then all options appear empty (`[]`), except those that you specify using name-value pair arguments. During training, the software uses default values for empty options.

### Examples

#### Create a *k*-Nearest Neighbors Template for Ensemble

Create a nondefault *k*-nearest neighbor template for use in `fitensemble`.

Load Fisher's iris data set.

```
load fisheriris
```

Create a template for a 5-nearest neighbor search, and specify to standardize the predictors.

```
t = templateKNN('NumNeighbors',5,'Standardize',1)
```

```
t =
```

```
Fit template for classification KNN.
```

```

 NumNeighbors: 5
 NSMethod: ''
 Distance: ''
 BucketSize: ''
 IncludeTies: []
 DistanceWeight: []
 BreakTies: []
 Exponent: []
 Cov: []
 Scale: []
StandardizeData: 1
 Method: 'KNN'
 Type: 'classification'

```

All properties of the template object are empty except for `NumNeighbors`, `Method`, `StandardizeData`, and `Type`. When you specify `t` as a learner, the software fills in the empty properties with their respective default values.

Specify `t` as a weak learner for a classification ensemble.

```
Mdl = fitensemble(meas,species,'Subspace',100,t);
```

Display the in-sample (resubstitution) misclassification error.

```
L = resubLoss(Mdl)
```

```
L =
```

```
0.0600
```

### Create a $k$ -Nearest Neighbors Template for ECOC Multiclass Learning

Create a nondefault  $k$ -nearest neighbor template for use in `fitcecoc`.

Load Fisher's iris data set.

```
load fisheriris
```

Create a template for a 5-nearest neighbor search, and specify to standardize the predictors.

```
t = templateKNN('NumNeighbors',5,'Standardize',1)
```

```
t =
```

Fit template for classification KNN.

```
 NumNeighbors: 5
 NSMethod: ''
 Distance: ''
 BucketSize: ''
 IncludeTies: []
 DistanceWeight: []
 BreakTies: []
 Exponent: []
 Cov: []
 Scale: []
StandardizeData: 1
 Method: 'KNN'
 Type: 'classification'
```

All properties of the template object are empty except for `NumNeighbors`, `Method`, `StandardizeData`, and `Type`. When you specify `t` as a learner, the software fills in the empty properties with their respective default values.

Specify `t` as a binary learner for an ECOC multiclass model.

```
Mdl = fitcecoc(meas,species,'Learners',t);
```

By default, the software trains `Mdl` using the one-versus-one coding design.

Display the in-sample (resubstitution) misclassification error.

```
L = resubLoss(Mdl,'LossFun','classiferror')
```

```
L =
```

0.0467

- “Random Subspace Classification” on page 16-115

## Input Arguments

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'NumNeighbors', 4, 'Distance', 'minkowski'` specifies a 4-nearest neighbor classifier template using the Minkowski distance measure.

#### 'BreakTies' — Tie-breaking algorithm

`'smallest'` (default) | `'nearest'` | `'random'`

Tie-breaking algorithm used by the `predict` method if multiple classes have the same smallest cost, specified as the comma-separated pair consisting of `'BreakTies'` and one of the following:

- `'smallest'` — Use the smallest index among tied groups.
- `'nearest'` — Use the class with the nearest neighbor among tied groups.
- `'random'` — Use a random tiebreaker among tied groups.

By default, ties occur when multiple classes have the same number of nearest points among the `K` nearest neighbors.

Example: `'BreakTies', 'nearest'`

#### 'BucketSize' — Maximum data points in node

50 (default) | positive integer value

Maximum number of data points in the leaf node of the *kd*-tree, specified as the comma-separated pair consisting of `'BucketSize'` and a positive integer value. This argument is meaningful only when `NSMethod` is `'kdtree'`.

Example: 'BucketSize',40

Data Types: single | double

**'Cov' — Covariance matrix**

nancov(X) (default) | positive definite matrix of scalar values

Covariance matrix, specified as the comma-separated pair consisting of 'Cov' and a positive definite matrix of scalar values representing the covariance matrix when computing the Mahalanobis distance. This argument is only valid when 'Distance' is 'mahalanobis'.

You cannot simultaneously specify 'Standardize' and either of 'Scale' or 'Cov'.

Data Types: single | double

**'Distance' — Distance metric**

valid distance metric string | function handle

Distance metric, specified as the comma-separated pair consisting of 'Distance' and a valid distance metric string or function handle. The allowable strings depend on the NSMethod parameter, which you set in fitcknn, and which exists as a field in ModelParameters. If you specify CategoricalPredictors as 'all', then the default distance metric is 'hamming'. Otherwise, the default distance metric is 'euclidean'.

| NSMethod   | Distance Metric Names                                 |
|------------|-------------------------------------------------------|
| exhaustive | Any distance metric of ExhaustiveSearcher             |
| kdtree     | 'cityblock', 'chebychev', 'euclidean', or 'minkowski' |

For definitions, see “Distance Metrics”.

This table includes valid distance metrics of ExhaustiveSearcher.

| Value         | Description                                                                                    |
|---------------|------------------------------------------------------------------------------------------------|
| 'cityblock'   | City block distance.                                                                           |
| 'chebychev'   | Chebychev distance (maximum coordinate difference).                                            |
| 'correlation' | One minus the sample linear correlation between observations (treated as sequences of values). |
| 'cosine'      | One minus the cosine of the included angle between observations (treated as vectors).          |

| Value            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'euclidean'      | Euclidean distance.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 'hamming'        | Hamming distance, percentage of coordinates that differ.                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| 'jaccard'        | One minus the Jaccard coefficient, the percentage of nonzero coordinates that differ.                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 'mahalanobis'    | Mahalanobis distance, computed using a positive definite covariance matrix <b>C</b> . The default value of <b>C</b> is the sample covariance matrix of <b>X</b> , as computed by <code>nancov(X)</code> . To specify a different value for <b>C</b> , use the ' <b>Cov</b> ' name-value pair argument.                                                                                                                                                                                                    |
| 'minkowski'      | Minkowski distance. The default exponent is 2. To specify a different exponent, use the ' <b>Exponent</b> ' name-value pair argument.                                                                                                                                                                                                                                                                                                                                                                     |
| 'seuclidean'     | Standardized Euclidean distance. Each coordinate difference between <b>X</b> and a query point is scaled, meaning divided by a scale value <b>S</b> . The default value of <b>S</b> is the standard deviation computed from <b>X</b> , <code>S = nanstd(X)</code> . To specify another value for <b>S</b> , use the <b>Scale</b> name-value pair argument.                                                                                                                                                |
| 'spearman'       | One minus the sample Spearman's rank correlation between observations (treated as sequences of values).                                                                                                                                                                                                                                                                                                                                                                                                   |
| @ <i>distfun</i> | Distance function handle. <i>distfun</i> has the form<br><pre>function D2 = DISTFUN(ZI,ZJ) % calculation of distance ... where</pre> <ul style="list-style-type: none"> <li>• <b>ZI</b> is a 1-by-N vector containing one row of <b>X</b> or <b>y</b>.</li> <li>• <b>ZJ</b> is an M2-by-N matrix containing multiple rows of <b>X</b> or <b>y</b>.</li> <li>• <b>D2</b> is an M2-by-1 vector of distances, and <b>D2(k)</b> is the distance between observations <b>ZI</b> and <b>ZJ(J,:)</b>.</li> </ul> |

Example: 'Distance', 'minkowski'

Data Types: function\_handle

**'DistanceWeight' — Distance weighting function**

'equal' (default) | 'inverse' | 'squaredinverse' | function handle

Distance weighting function, specified as the comma-separated pair consisting of 'DistanceWeight' and either a function handle or one of the following strings specifying the distance weighting function.

| DistanceWeight   | Meaning                                                                                                                                                                                                          |
|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'equal'          | No weighting                                                                                                                                                                                                     |
| 'inverse'        | Weight is 1/distance                                                                                                                                                                                             |
| 'squaredinverse' | Weight is 1/distance <sup>2</sup>                                                                                                                                                                                |
| @fcn             | <i>fcn</i> is a function that accepts a matrix of nonnegative distances, and returns a matrix the same size containing nonnegative distance weights. For example, 'squaredinverse' is equivalent to @(d)d.^(-2). |

Example: 'DistanceWeight','inverse'

Data Types: function\_handle

**'Exponent' — Minkowski distance exponent**

2 (default) | positive scalar value

Minkowski distance exponent, specified as the comma-separated pair consisting of 'Exponent' and a positive scalar value. This argument is only valid when 'Distance' is 'minkowski'.

Example: 'Exponent',3

Data Types: single | double

**'IncludeTies' — Tie inclusion flag**

false (default) | true

Tie inclusion flag, specified as the comma-separated pair consisting of 'IncludeTies' and a logical value indicating whether `predict` includes all the neighbors whose distance values are equal to the Kth smallest distance. If `IncludeTies` is `true`, `predict` includes all these neighbors. Otherwise, `predict` uses exactly K neighbors.

Example: 'IncludeTies',true

Data Types: logical

**'NSMethod' — Nearest neighbor search method**`'kdtree' | 'exhaustive'`

Nearest neighbor search method, specified as the comma-separated pair consisting of `'NSMethod'` and `'kdtree'` or `'exhaustive'`.

- `'kdtree'` — Create and use a *kd*-tree to find nearest neighbors. `'kdtree'` is valid when the distance metric is one of the following:
  - `'euclidean'`
  - `'cityblock'`
  - `'minkowski'`
  - `'chebyshev'`
- `'exhaustive'` — Use the exhaustive search algorithm. The distance values from all points in X to each point in y are computed to find nearest neighbors.

The default is `'kdtree'` when X has 10 or fewer columns, X is not sparse, and the distance metric is a `'kdtree'` type; otherwise, `'exhaustive'`.

Example: `'NSMethod', 'exhaustive'`

**'NumNeighbors' — Number of nearest neighbors to find**`1 (default) | positive integer value`

Number of nearest neighbors in X to find for classifying each point when predicting, specified as the comma-separated pair consisting of `'NumNeighbors'` and a positive integer value.

Example: `'NumNeighbors', 3`

Data Types: `single | double`

**'Scale' — Distance scale**`nanstd(X) (default) | vector of nonnegative scalar values`

Distance scale, specified as the comma-separated pair consisting of `'Scale'` and a vector containing nonnegative scalar values with length equal to the number of columns in X. Each coordinate difference between X and a query point is scaled by the corresponding element of `Scale`. This argument is only valid when `'Distance'` is `'seuclidean'`.

You cannot simultaneously specify `'Standardize'` and either of `'Scale'` or `'Cov'`.

Data Types: `single | double`

**'Standardize' — Flag to standardize predictors**`false (default) | true`

Flag to standardize the predictors, specified as the comma-separated pair consisting of 'Standardize' and true (1) or false (0).

If you set 'Standardize', true, then the software centers and scales each column of the predictor data (X) by the column mean and standard deviation, respectively.

The software does not standardize categorical predictors, and throws an error if all predictors are categorical.

You cannot simultaneously specify 'Standardize', 1 and either of 'Scale' or 'Cov'.

It is good practice to standardize the predictor data.

Example: 'Standardize', true

Data Types: logical

## Output Arguments

**t — kNN classification template**`template object`

kNN classification template suitable for training ensembles or error-correcting output code (ECOC) multiclass models, returned as a template object. Pass t to `fitensemble` or `fitcecoc` to specify how to create the KNN classifier for the ensemble or ECOC model, respectively.

If you display t to the Command Window, then all, unspecified options appear empty ([ ]). However, the software replaces empty options with their corresponding default values during training.

**See Also**`ClassificationKNN | ExhaustiveSearcher | fitcecoc | fitensemble`

# templateNaiveBayes

Naive Bayes classifier template

## Syntax

```
t = templateNaiveBayes()
t = templateNaiveBayes(Name,Value)
```

## Description

`t = templateNaiveBayes()` returns a naive Bayes template suitable for training error-correcting output code (ECOC) multiclass models.

If you specify a default template, then the software uses default values for all input arguments during training.

Specify `t` as a learner in `fitcecoc`.

`t = templateNaiveBayes(Name,Value)` returns a template with additional options specified by one or more name-value pair arguments. All properties of `t` are empty, except those you specify using `Name,Value` pair arguments.

For example, you can specify distributions for the predictors.

If you display `t` in the Command Window, then all options appear empty (`[]`), except those that you specify using name-value pair arguments. During training, the software uses default values for empty options.

## Examples

### Create a Default Naive Bayes Template

Use `templateNaiveBayes` to specify a default naive Bayes template.

```
t = templateNaiveBayes()
```

```
t =

Fit template for classification NaiveBayes.

 DistributionNames: [1x0 double]
 Kernel: []
 Support: []
 Width: []
 Method: 'NaiveBayes'
 Type: 'classification'
```

All properties of the template object are empty except for `Method` and `Type`. When you pass `t` to the training function, the software fills in the empty properties with their respective default values. For example, the software fills the `DistributionNames` property with a 1-by-`D` cell array of strings with `'normal'` in each cell, where `D` is the number of predictors. For details on other default values, see “`fitcnb`”.

`t` is a plan for a naive Bayes learner, and no computation occurs when you specify it. You can pass `t` to “`fitcecoc`” to specify naive Bayes binary learners for ECOC multiclass learning.

### Create a Naive Bayes Template for ECOC Multiclass Learning

Create a nondefault naive Bayes template for use in “`fitcecoc`”.

Load Fisher's iris data set.

```
load fisheriris
```

Create a template for naive Bayes binary classifiers, and specify kernel distributions for all predictors.

```
t = templateNaiveBayes('DistributionNames','kernel')
```

```
t =

Fit template for classification NaiveBayes.

 DistributionNames: 'kernel'
 Kernel: []
 Support: []
 Width: []
 Method: 'NaiveBayes'
```

```
Type: 'classification'
```

All properties of the template object are empty except for `DistributionNames`, `Method`, and `Type`. When you pass `t` to the training function, the software fills in the empty properties with their respective default values.

Specify `t` as a binary learner for an ECOC multiclass model.

```
Mdl = fitcecoc(meas,species,'Learners',t);
```

By default, the software trains `Mdl` using the one-versus-one coding design.

Display the in-sample (resubstitution) misclassification error.

```
L = resubLoss(Mdl,'LossFun','classiferror')
```

```
L =
```

```
0.0333
```

## Input Arguments

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'DistributionNames','mn'` specifies to treat all predictors as token counts for a multinomial model.

#### 'DistributionNames' — Data distributions

```
'kernel' | 'mn' | 'mvmn' | 'normal' | cell array of strings
```

Data distributions `fitcnb` uses to model the data, specified as the comma-separated pair consisting of `'DistributionNames'` and a string or cell array of strings.

This table summarizes the available distributions.

| Value    | Description                                                                                                                                                                                                                                         |
|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'kernel' | Kernel smoothing density estimate.                                                                                                                                                                                                                  |
| 'mn'     | Multinomial distribution. If you specify <code>mn</code> , then all features are components of a multinomial distribution. Therefore, you cannot include <code>'mn'</code> as an element of a cell array of strings. For details, see “Algorithms”. |
| 'mvmn'   | Multivariate multinomial distribution. For details, see “Algorithms”.                                                                                                                                                                               |
| 'normal' | Normal (Gaussian) distribution.                                                                                                                                                                                                                     |

If you specify a string, then the software models all the features using that distribution. If you specify a 1-by- $P$  cell array of strings, then the software models feature  $j$  using the distribution in element  $j$  of the cell array.

By default, the software sets all predictors specified as categorical predictors (using the `CategoricalPredictors` name-value pair argument) to `'mvmn'`. Otherwise, the default distribution is `'normal'`.

You must specify that at least one predictor has distribution `'kernel'` to additionally specify `Kernel`, `Support`, or `Width`.

Example: `'Distribution','mn'`

Data Types: `cell` | `char`

### 'Kernel' — Kernel smoother type

`'normal'` (default) | `'box'` | `'epanechnikov'` | `'triangle'` | cell array of strings

Kernel smoother type, specified as the comma-separated pair consisting of `'Kernel'` and a string or cell array of strings.

This table summarizes the available options for setting the kernel smoothing density region. Let  $I\{u\}$  denote the indicator function.

| Value | Kernel        | Formula                     |
|-------|---------------|-----------------------------|
| 'box' | Box (uniform) | $f(x) = 0.5I\{ x  \leq 1\}$ |

| Value       | Kernel       | Formula                                      |
|-------------|--------------|----------------------------------------------|
| 'epanechni' | Epanechnikov | $f(x) = 0.75(1 - x^2)I\{ x  \leq 1\}$        |
| 'normal'    | Gaussian     | $f(x) = \frac{1}{\sqrt{2\pi}} \exp(-0.5x^2)$ |
| 'triangle'  | Triangular   | $f(x) = (1 -  x )I\{ x  \leq 1\}$            |

If you specify a 1-by- $P$  cell array, with each cell containing any value in the table, then the software trains the classifier using the kernel smoother type in cell  $j$  for feature  $j$  in  $X$ . The software ignores cells of `Kernel` not corresponding to a predictor whose distribution is `'kernel'`.

You must specify that at least one predictor has distribution `'kernel'` to additionally specify `Kernel`, `Support`, or `Width`.

Example: `'Kernel', {'epanechnikov', 'normal'}`

Data Types: `cell` | `char`

### 'Support' — Kernel smoothing density support

`'unbounded'` (default) | `'positive'` | cell array | numeric row vector

Kernel smoothing density support, specified as the comma-separated pair consisting of `'Support'` and `'positive'`, `'unbounded'`, a cell array, or a numeric row vector. The software applies the kernel smoothing density to the specified region.

This table summarizes the available options for setting the kernel smoothing density region.

| Value                     | Description                                                                                                                                             |
|---------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1-by-2 numeric row vector | For example, <code>[L,U]</code> , where <code>L</code> and <code>U</code> are the finite lower and upper bounds, respectively, for the density support. |
| 'positive'                | The density support is all positive real values.                                                                                                        |
| 'unbounded'               | The density support is all real values.                                                                                                                 |

If you specify a 1-by- $P$  cell array, with each cell containing any value in the table, then the software trains the classifier using the kernel support in cell  $j$  for feature  $j$  in  $X$ . The

software ignores cells of `Kernel` not corresponding to a predictor whose distribution is `'kernel'`.

You must specify that at least one predictor has distribution `'kernel'` to additionally specify `Kernel`, `Support`, or `Width`.

Example: `'KSSupport', {[ -10,20], 'unbounded' }`

Data Types: `cell | char | double`

### **'Width' — Kernel smoothing window width**

`matrix of numeric values | numeric column vector | numeric row vector | scalar`

Kernel smoothing window width, specified as the comma-separated pair consisting of `'Width'` and a matrix of numeric values, numeric column vector, numeric row vector, or scalar.

Suppose there are  $K$  class levels and  $P$  predictors. This table summarizes the available options for setting the kernel smoothing window width.

| Value                                 | Description                                                             |
|---------------------------------------|-------------------------------------------------------------------------|
| $K$ -by- $P$ matrix of numeric values | Element $(k,j)$ specifies the width for predictor $j$ in class $k$ .    |
| $K$ -by-1 numeric column vector       | Element $k$ specifies the width for all predictors in class $k$ .       |
| 1-by- $P$ numeric row vector          | Element $j$ specifies the width in all class levels for predictor $j$ . |
| scalar                                | Specifies the bandwidth for all features in all classes.                |

By default, the software selects a default width automatically for each combination of predictor and class by using a value that is optimal for a Gaussian distribution. If you specify `Width` and it contains NaNs, then the software selects widths for the elements containing NaNs.

You must specify that at least one predictor has distribution `'kernel'` to additionally specify `Kernel`, `Support`, or `Width`.

Example: `'Width', [NaN NaN]`

Data Types: `double | struct`

## Output Arguments

### **t** — Naive Bayes classification template

template object

Naive Bayes classification template suitable for training error-correcting output code (ECOC) multiclass models, returned as a template object. Pass **t** to `fitcecoc` to specify how to create the naive Bayes classifier for the ECOC model.

If you display **t** to the Command Window, then all, unspecified options appear empty (`[]`). However, the software replaces empty options with their corresponding default values during training.

## More About

### Naive Bayes

*Naive Bayes* is a classification algorithm that applies density estimation to the data.

The algorithm leverages Bayes theorem, and (naively) assumes that the predictors are conditionally independent, given the class. Though the assumption is usually violated in practice, naive Bayes classifiers tend to yield posterior distributions that are robust to biased class density estimates, particularly where the posterior is 0.5 (the decision boundary) “[1]”.

Naive Bayes classifiers assign observations to the most probable class (in other words, the *maximum a posteriori* decision rule). Explicitly, the algorithm:

- 1 Estimates the densities of the predictors within each class.
- 2 Models posterior probabilities according to Bayes rule. That is, for all  $k = 1, \dots, K$ ,

$$\hat{P}(Y = k | X_1, \dots, X_P) = \frac{\pi(Y = k) \prod_{j=1}^P P(X_j | Y = k)}{\sum_{k=1}^K \pi(Y = k) \prod_{j=1}^P P(X_j | Y = k)},$$

where:

- $Y$  is the random variable corresponding to the class index of an observation.
  - $X_1, \dots, X_P$  are the random predictors of an observation.
  - $\pi(Y = k)$  is the prior probability that a class index is  $k$ .
- 3 Classifies an observation by estimating the posterior probability for each class, and then assigns the observation to the class yielding the maximum posterior probability.

If the predictors compose a multinomial distribution, then the posterior probability  $\hat{P}(Y = k | X_1, \dots, X_P) \propto \pi(Y = k) P_{mn}(X_1, \dots, X_P | Y = k)$ , where  $P_{mn}(X_1, \dots, X_P | Y = k)$  is the probability mass function of a multinomial distribution.

### Algorithms

- If you specify 'Distribution', 'mn' when training Mdl using `fitcnb`, then the software fits a multinomial distribution using the “bag-of-tokens model”. The software stores the probability that token  $j$  appears in class  $k$  in the property `DistributionParameters{k,j}`. Using additive smoothing “[2]”, the estimated probability is

$$P(\text{token } j | \text{class } k) = \frac{1 + c_{j|k}}{P + c_k},$$

where:

- $c_{j|k} = n_k \frac{\sum_{i: y_i \in \text{class } k} x_{ij} w_i}{\sum_{i: y_i \in \text{class } k} w_i}$ ; which is the weighted number of occurrences of token  $j$  in class  $k$ .
- $n_k$  is the number of observations in class  $k$ .
- $w_i$  is the weight for observation  $i$ . The software normalizes weights within a class such that they sum to the prior probability for that class.

- $c_k = \sum_{j=1}^P c_{j|k}$ ; which is the total weighted number of occurrences of all tokens in class  $k$ .
- If you specify 'Distribution', 'mvmn' when training Mdl using `fitcnb`, then:
  - 1 For each predictor, the software collects a list of the unique levels, stores the sorted list in `CategoricalLevels`, and considers each level a bin. Each predictor/class combination is a separate, independent multinomial random variable.
  - 2 For predictor  $j$  in class  $k$ , the software counts instances of each categorical level using the list stored in `CategoricalLevels{j}`.
  - 3 The software stores the probability that predictor  $j$ , in class  $k$ , has level  $L$  in the property `DistributionParameters{k,j}`, for all levels in `CategoricalLevels{j}`. Using additive smoothing “[2]”, the estimated probability is

$$P(\text{predictor } j = L \mid \text{class } k) = \frac{1 + m_{j|k}(L)}{m_j + m_k},$$

where:

- $$m_{j|k}(L) = n_k \frac{\sum_{i: y_i \in \text{class } k} I\{x_{ij} = L\} w_i}{\sum_{i: y_i \in \text{class } k} w_i};$$
 which is the weighted number of

observations for which predictor  $j$  equals  $L$  in class  $k$ .

- $n_k$  is the number of observations in class  $k$ .
- $I\{x_{ij} = L\} = 1$  if  $x_{ij} = L$ , 0 otherwise.
- $w_i$  is the weight for observation  $i$ . The software normalizes weights within a class such that they sum to the prior probability for that class.
- $m_j$  is the number of distinct levels in predictor  $j$ .

- $m_k$  is the weighted number of observations in class  $k$ .

`ClassificationECOC` | `ClassificationNaiveBayes` | `fitcecoc` | `fitcnb`

# templateSVM

Support vector machine template

## Syntax

```
t = templateSVM()
t = templateSVM(Name,Value)
```

## Description

`t = templateSVM()` returns a support vector machine (SVM) learner template suitable for training error-correcting output code (ECOC) multiclass models.

If you specify a default template, then the software uses default values for all input arguments during training.

Specify `t` as a binary learner, or one in a set of binary learners, in `fitcecoc` to train an ECOC multiclass classifier.

`t = templateSVM(Name,Value)` creates a template with additional options specified by one or more name-value pair arguments.

For example, you can specify the box constraint, the kernel function, or whether to standardize the predictors.

If you display `t` in the Command Window, then all options appear empty (`[]`), except those that you specify using name-value pair arguments. During training, the software uses default values for empty options.

## Examples

### Create a Default Support Vector Machine Template

Use `templateSVM` to specify a default SVM template.

```
t = templateSVM()
```

```
t =

Fit template for classification SVM.

 Alpha: [0x1 double]
 BoxConstraint: []
 CacheSize: []
 CachingMethod: ''
DeltaGradientTolerance: []
 GapTolerance: []
 KKTolerance: []
 IterationLimit: []
 KernelFunction: ''
 KernelScale: []
 KernelOffset: []
KernelPolynomialOrder: []
 NumPrint: []
 Nu: []
 OutlierFraction: []
 ShrinkagePeriod: []
 Solver: ''
 StandardizeData: []
 VerbosityLevel: []
 Method: 'SVM'
 Type: 'classification'
```

All properties of the template object are empty except for `Method` and `Type`. When you pass `t` to the training function, the software fills in the empty properties with their respective default values. For example, the software fills the `KernelFunction` property with `'linear'`. For details on other default values, see “`fitsvm`”.

`t` is a plan for an SVM learner, and no computation occurs when you specify it. You can pass `t` to “`fitcecoc`” to specify SVM binary learners for ECOC multiclass learning. However, by default, `fitcecoc` uses default SVM binary learners.

### Create an SVM Template for ECOC Multiclass Learning

Create a nondefault SVM template for use in “`fitcecoc`”.

Load Fisher's iris data set.

```
load fisheriris
```

Create a template for SVM binary classifiers, and specify to use a Gaussian kernel function.

```
t = templateSVM('KernelFunction','gaussian')
```

```
t =
```

```
Fit template for classification SVM.
```

```

 Alpha: [0x1 double]
 BoxConstraint: []
 CacheSize: []
 CachingMethod: ''
DeltaGradientTolerance: []
 GapTolerance: []
 KKTolerance: []
 IterationLimit: []
 KernelFunction: 'gaussian'
 KernelScale: []
 KernelOffset: []
 KernelPolynomialOrder: []
 NumPrint: []
 Nu: []
 OutlierFraction: []
 ShrinkagePeriod: []
 Solver: ''
 StandardizeData: []
 VerbosityLevel: []
 Method: 'SVM'
 Type: 'classification'

```

All properties of the template object are empty except for **DistributionNames**, **Method**, and **Type**. When trained on, the software fills in the empty properties with their respective default values.

Specify **t** as a binary learner for an ECOC multiclass model.

```
Mdl = fitcecoc(meas,species,'Learners',t);
```

**Mdl** is a **ClassificationECOC** multiclass classifier. By default, the software trains **Mdl** using the one-versus-one coding design.

Display the in-sample (resubstitution) misclassification error.

```
L = resubLoss(Mdl, 'LossFun', 'classiferror')
```

```
L =
```

```
0.0200
```

## Input Arguments

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( `' '`). You can specify several name and value pair arguments in any order as `Name1`, `Value1`, ..., `NameN`, `ValueN`.

Example:

`'BoxConstraint', 0.1, 'KernelFunction', 'gaussian', 'Standardize', 1` specifies a box constraint of 0.1, to use the Gaussian (RBF) kernel, and to standardize the predictors.

#### **'BoxConstraint' — Box constraint**

1 (default) | positive scalar

Box constraint, specified as the comma-separated pair consisting of `'BoxConstraint'` and a positive scalar.

For one-class learning, the software always sets the box constraint to 1.

Example: `'BoxConstraint', 100`

Data Types: `double` | `single`

#### **'CacheSize' — Cache size**

1000 (default) | `'maximal'` | positive scalar

Cache size, specified as the comma-separated pair consisting of `'CacheSize'` and `'maximal'` or a positive scalar.

If `CacheSize` is `'maximal'`, then the software reserves enough disk space to hold the entire  $n$ -by- $n$  Gram matrix.

If `CacheSize` is a positive scalar, then the software reserves `CacheSize` megabytes of disk space for training the classifier.

Example: `'CacheSize', 'maximal'`

Data Types: `double | char | single`

### **'DeltaGradientTolerance' – Tolerance for gradient difference**

nonnegative scalar

Tolerance for the gradient difference between upper and lower violators obtained by Sequential Minimal Optimization (SMO) or Iterative Single Data Algorithm (ISDA), specified as the comma-separated pair consisting of `'DeltaGradientTolerance'` and a nonnegative scalar.

If `DeltaGradientTolerance` is 0, then the software does not use the tolerance for the gradient difference to check for optimization convergence.

The defaults are:

- `1e-3` if the solver is SMO (for example, you set `'Solver', 'SMO'`)
- `0` if the solver is ISDA (for example, you set `'Solver', 'ISDA'`)

Example: `'DeltaGapTolerance', 1e-2`

Data Types: `double | single`

### **'GapTolerance' – Feasibility gap tolerance**

0 (default) | nonnegative scalar

Feasibility gap tolerance obtained by SMO or ISDA, specified as the comma-separated pair consisting of `'GapTolerance'` and a nonnegative scalar.

If `GapTolerance` is 0, then the software does not use the feasibility gap tolerance to check for optimization convergence.

Example: `'GapTolerance', 1e-2`

Data Types: `double | single`

### **'IterationLimit' – Maximal number of numerical optimization iterations**

1e6 (default) | positive integer

Maximal number of numerical optimization iterations, specified as the comma-separated pair consisting of `'IterationLimit'` and a positive integer.

The software returns a trained classifier regardless of whether the optimization routine successfully converges.

Example: `'IterationLimit', 1e8`

Data Types: `double` | `single`

### 'KernelFunction' — Kernel function

string

Kernel function used to compute the Gram matrix, specified as the comma-separated pair consisting of 'KernelFunction' and a string.

This table summarizes the available options for setting a kernel function.

| Value               | Description                                                                                                                       | Formula                                           |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------|
| 'gaussian' or 'rbf' | Gaussian or Radial Basis Function (RBF) kernel, default for one-class learning                                                    | $G(x_1, x_2) = \exp\left(-\ x_1 - x_2\ ^2\right)$ |
| 'linear'            | Linear kernel, default for two-class learning                                                                                     | $G(x_1, x_2) = x_1'x_2$                           |
| 'polynomial'        | Polynomial kernel. Use 'PolynomialOrder', <code>polyOrder</code> to specify a polynomial kernel of order <code>polyOrder</code> . | $G(x_1, x_2) = (1 + x_1'x_2)^p$                   |

You can set your own kernel function, for example, `kernel`, by setting 'KernelFunction', 'kernel'. `kernel` must have the following form:

```
function G = kernel(U,V)
```

where:

- `U` is an  $m$ -by- $p$  matrix.
- `V` is an  $n$ -by- $p$  matrix.
- `G` is an  $m$ -by- $n$  Gram matrix of the rows of `U` and `V`.

And `kernel.m` must be on the MATLAB path.

It is good practice to avoid using generic names for kernel functions. For example, call a sigmoid kernel function 'mysigmoid' rather than 'sigmoid'.

Example: 'KernelFunction', 'gaussian'

Data Types: char

### 'KernelOffset' — Kernel offset parameter

nonnegative scalar

Kernel offset parameter, specified as the comma-separated pair consisting of 'KernelOffset' and a nonnegative scalar.

The software adds `KernelOffset` to each element of the Gram matrix.

The defaults are:

- 0 if the solver is SMO (for example, you set 'Solver', 'SMO')
- 0.1 if the solver is ISDA (for example, you set 'Solver', 'ISDA')

Example: 'KernelOffset', 0

Data Types: double | single

### 'KernelScale' — Kernel scale parameter

1 (default) | 'auto' | positive scalar

Kernel scale parameter, specified as the comma-separated pair consisting of 'KernelScale' and 'auto' or a positive scalar.

- If `KernelFunction` is 'gaussian' ('rbf'), 'linear', or 'polynomial', then the software divides all elements of the predictor matrix  $X$  by the value of `KernelScale`. Then, the software applies the appropriate kernel norm to compute the Gram matrix.
- If you specify 'auto', then the software uses a heuristic procedure to select the scale value. The heuristic procedure uses subsampling. Therefore, to reproduce results, set a random number seed using `rng` before training the classifier.
- If you specify `KernelScale` and your own kernel function, for example, `kernel`, using 'KernelFunction', 'kernel', then the software displays an error. You must apply scaling within `kernel`.

Example: 'KernelScale', 'auto'

Data Types: double | single | char

### 'KKTolerance' — Karush-Kuhn-Tucker complementarity conditions violation tolerance

nonnegative scalar

Karush-Kuhn-Tucker (KKT) complementarity conditions violation tolerance, specified as the comma-separated pair consisting of `'KKTolerance'` and a nonnegative scalar.

If `KKTolerance` is 0, then the software does not use the KKT complementarity conditions violation tolerance to check for optimization convergence.

The defaults are:

- 0 if the solver is SMO (for example, you set `'Solver', 'SMO'`)
- `1e-3` if the solver is ISDA (for example, you set `'Solver', 'ISDA'`)

Example: `'KKTolerance', 1e-2`

Data Types: `double` | `single`

### **'Nu' — # parameter for one-class learning**

0.5 (default) | positive scalar

$\nu$  parameter for one-class learning, specified as the comma-separated pair consisting of `'Nu'` and a positive scalar. `NU` must be greater than 0 and at most 1.

Set `NU` to control the tradeoff between ensuring most training examples are in the positive class and minimizing the weights in the score function.

Example: `'Nu', 0.25`

Data Types: `double` | `single`

### **'NumPrint' — Number of iterations between optimization diagnostic message output**

1000 (default) | nonnegative integer

Number of iterations between optimization diagnostic message output, specified as the comma-separated pair consisting of `'NumPrint'` and a nonnegative integer.

If you use `'Verbose', 1` and `'NumPrint', numprint`, then the software displays all optimization diagnostic messages from SMO and ISDA every `numprint` iterations in the Command Window.

Example: `'NumPrint', 500`

Data Types: `double` | `single`

### **'OutlierFraction' — Expected proportion of outliers in training data**

0 (default) | nonnegative scalar

Expected proportion of outliers in the training data, specified as the comma-separated pair consisting of 'OutlierFraction' and a nonnegative scalar. OutlierFraction must be at least 0 and less than 1.

If you set 'OutlierFraction', outlierfraction, where outlierfraction is a value greater than 0, then:

- For two-class learning, the software implements *robust learning*. In other words, the software attempts to remove  $100 \times \text{outlierfraction}\%$  of the observations when the optimization algorithm converges. The removed observations correspond to gradients that are large in magnitude.
- For one-class learning, the software finds an appropriate bias term such that outlierfraction of the observations in the training set have negative scores.

Example: 'OutlierFraction',0.01

Data Types: double | single

### 'PolynomialOrder' — Polynomial kernel function order

3 (default) | positive integer

Polynomial kernel function order, specified as the comma-separated pair consisting of 'PolynomialOrder' and a positive integer.

If you set 'PolynomialOrder' and KernelFunction is not 'polynomial', then the software displays an error.

Example: 'PolynomialOrder',2

Data Types: double | single

### 'ShrinkagePeriod' — Number of iterations between movement of observations from active to inactive set

0 (default) | nonnegative integer

Number of iterations between the movement of observations from the active to inactive set, specified as the comma-separated pair consisting of 'ShrinkagePeriod' and a nonnegative integer.

If you set 'ShrinkagePeriod',0, then the software does not shrink the active set.

Example: 'ShrinkagePeriod',1000

Data Types: double | single

**'Solver' — Optimization routine**`'ISDA' | 'L1QP' | 'SMO'`

Optimization routine, specified as a string.

This table summarizes the available optimization routine options.

| Value               | Description                                                                                                                                                |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>'ISDA'</code> | Iterative Single Data Algorithm                                                                                                                            |
| <code>'L1QP'</code> | Uses <code>quadprog</code> to implement <i>L1</i> soft-margin minimization by quadratic programming. This option requires an Optimization Toolbox license. |
| <code>'SMO'</code>  | Sequential Minimal Optimization                                                                                                                            |

The defaults are:

- `'ISDA'` if you set `'OutlierFraction'` to a positive value and for two-class learning
- `'SMO'` otherwise

Example: `'Solver', 'ISDA'`

Data Types: `char`

**'Standardize' — Flag to standardize predictors**`false (default) | true`

Flag to standardize the predictors, specified as the comma-separated pair consisting of `'Standardize'` and `true` (1) or `false` (0).

If you set `'Standardize', true`, then the software centers and scales each column of the predictor data (*X*) by the column mean and standard deviation, respectively. It is good practice to standardize the predictor data.

Example: `'Standardize', true`

Data Types: `logical`

**'Verbose' — Verbosity level**`0 (default) | 1 | 2`

Verbosity level, specified as the comma-separated pair consisting of 'Verbose' and either 0, 1, or 2. Verbose controls the amount of optimization information that the software displays in the Command Window and saves as a structure to `SVMModel.ConvergenceInfo.History`.

This table summarizes the available verbosity level options.

| Value | Description                                                                                                                                                                                           |
|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0     | The software does not display or save convergence information.                                                                                                                                        |
| 1     | The software displays diagnostic messages and saves convergence criteria every <code>numprint</code> iterations, where <code>numprint</code> is the value of the name-value pair argument 'NumPrint'. |
| 2     | The software displays diagnostic messages and saves convergence criteria at every iteration.                                                                                                          |

Example: 'Verbose', 1

Data Types: double | single

## Output Arguments

### **t** — SVM classification template

template object

SVM classification template suitable for training error-correcting output code (ECOC) multiclass models, returned as a template object. Pass `t` to `fitcecoc` to specify how to create the SVM classifier for the ECOC model.

If you display `t` to the Command Window, then all, unspecified options appear empty (`[]`). However, the software replaces empty options with their corresponding default values during training.

### See Also

ClassificationECOC | ClassificationSVM | fitcecoc | fitcsvm

## templateTree

Create decision tree template

### Syntax

```
t = templateTree
t = templateTree(Name,Value)
```

### Description

`t = templateTree` returns a default decision tree learner template suitable for training ensembles or error-correcting output code (ECOC) multiclass models. Specify `t` as a learner using:

- `fitensemble` for classification or regression
- `fitcecoc` for classification

If you specify a default decision tree template, then the software uses default values for all input arguments during training. It is good practice to specify the type of decision tree, e.g., for a classification tree template, specify `'Type', 'classification'`. If you specify the type of decision tree and display `t` in the Command Window, then all options except `Type` appear empty (`[]`).

`t = templateTree(Name,Value)` creates a template with additional options specified by one or more name-value pair arguments.

For example, you can specify the algorithm used to find the best split on a categorical predictor, the split criterion, or the number of predictors selected for each split.

If you display `t` in the Command Window, then all options appear empty (`[]`), except those that you specify using name-value pair arguments. During training, the software uses default values for empty options.

## Examples

### Create a Classification Template with Surrogate Splits

Create a decision tree template with surrogate splits, and use the template to train an ensemble using sample data.

Load Fisher's iris data set.

```
load fisheriris
```

Create a decision tree template with surrogate splits.

```
t = templateTree('Surrogate', 'on')
```

```
t =
```

```
Fit template for Tree.
 Surrogate: 'on'
```

All options of the template object are empty except for **Surrogate**. When you pass **t** to the training function, the software fills in the empty options with their respective default values.

Specify **t** as a weak learner for a classification ensemble.

```
Mdl = fitensemble(meas, species, 'AdaBoostM2', 100, t)
```

```
Mdl =
```

```
classreg.learning.classif.ClassificationEnsemble
 PredictorNames: {'x1' 'x2' 'x3' 'x4'}
 ResponseName: 'Y'
 ClassNames: {'setosa' 'versicolor' 'virginica'}
 ScoreTransform: 'none'
 NumObservations: 150
 NumTrained: 100
 Method: 'AdaBoostM2'
 LearnerNames: {'Tree'}
 ReasonForTermination: 'Terminated normally after completing the reques...'
 FitInfo: [100x1 double]
```

```
FitInfoDescription: {2x1 cell}
```

Display the in-sample (resubstitution) misclassification error.

```
L = resubLoss(Mdl)
```

```
L =
```

```
0.0333
```

### Train a Regression Ensemble

Use a trained, boosted regression tree ensemble to predict the fuel economy of a car. Choose the number of cylinders, volume displaced by the cylinders, horsepower, and weight as predictors.

Load the `carsmall` data set. Set the predictors to `X`.

```
load carsmall
X = [Cylinders,Displacement,Horsepower,Weight];
xnames = {'Cylinders','Displacement','Horsepower','Weight'};
```

Specify a regression tree template that uses surrogate splits to improve predictive accuracy in the presence of NaN values.

```
RegTreeTemp = templateTree('Surrogate','On');
```

Train the regression tree ensemble using `LSBoost` and 100 learning cycles.

```
RegTreeEns = fitensemble(X,MPG,'LSBoost',100,RegTreeTemp,...
 'PredictorNames',xnames);
```

`RegTreeEns` is a trained `RegressionEnsemble` regression ensemble.

Use the trained regression ensemble to predict the fuel economy for a four-cylinder car with a 200-cubic inch displacement, 150 horsepower, and weighing 3000 lbs.

```
predMPG = predict(RegTreeEns,[4 200 150 3000])
```

```
predMPG =
```

21.7781

The average fuel economy of a car with these specifications is 21.78 mpg.

## Input Arguments

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'Surrogate', 'on', 'NVarToSample', 'all'` specifies a template with surrogate splits, and uses all available predictors at each split.

## For Classification Trees and Regression Trees

### 'MergeLeaves' — Leaf merge flag

'off' (default) | 'on'

Leaf merge flag, specified as the comma-separated pair consisting of `'MergeLeaves'` and either `'on'` or `'off'`.

When `'on'`, the decision tree merges leaves that originate from the same parent node, and that provide a sum of risk values greater or equal to the risk associated with the parent node. When `'off'`, the decision tree does not merge leaves.

Example: `'MergeLeaves', 'on'`

### 'MinLeaf' — Minimum observations per leaf

positive integer value

Minimum observations per leaf, specified as the comma-separated pair consisting of `'MinLeaf'` and a positive integer value. Each leaf has at least `MinLeaf` observations per tree leaf. If you supply both `MinParent` and `MinLeaf`, the decision tree uses the setting that gives larger leaves: `MinParent = max(MinParent, 2*MinLeaf)`.

For boosting, the default is 1. For bagging, the default is 1 for classification or 5 for regression.

Example: `'MinLeaf', 2`

### **'MinParent' — Minimum observations per branch node**

positive integer value

Minimum observations per branch node, specified as the comma-separated pair consisting of `'MinParent'` and a positive integer value. Each branch node in the tree has at least `MinParent` observations. If you supply both `MinParent` and `MinLeaf`, the decision tree uses the setting that gives larger leaves: `MinParent = max(MinParent, 2*MinLeaf)`.

For boosting, the default is the number of training observations. For bagging, the default is 2 for classification, or 10 for regression.

Example: `'MinParent', 4`

### **'NVarToSample' — Number of predictors selected for each split**

positive integer value | `'all'`

Number of predictors selected for each split at random, specified as the comma-separated pair consisting of `'NVarToSample'` and a positive integer value. Alternatively, you can specify `'all'` to use all available predictors. The default for boosting is `'all'`. The default for bagging is the square root of the number of predictors for classification, or one third of predictors for regression.

Example: `'NVarToSample', 3`

### **'Prune' — Pruning flag**

`'off'` (default) | `'on'`

Pruning flag, specified as the comma-separated pair consisting of `'Prune'` and `'on'` or `'off'`. When `'on'`, `fitensemble` grows unpruned trees and computes the optimal sequence of pruned subtrees for each tree. When `'off'`, `fitensemble` grows the tree without pruning.

Example: `'Prune', 'on'`

### **'PruneCriterion' — Pruning criterion**

`'error'` | `'impurity'` | `'mse'`

Pruning criterion, specified as the comma-separated pair consisting of 'PruneCriterion' and a pruning criterion string valid for the tree type.

- For classification trees, you can specify 'error' (default) or 'impurity'.
- For regression, you can only specify 'mse' (default).

Example: 'PruneCriterion', 'impurity'

### 'SplitCriterion' — Split criterion

'gdi' | 'twoing' | 'deviance' | 'mse'

Split criterion, specified as the comma-separated pair consisting of 'SplitCriterion' and a split criterion string valid for the tree type.

- For classification trees:
  - 'gdi' for Gini's diversity index (default)
  - 'twoing' for the twoing rule
  - 'deviance' for maximum deviance reduction (also known as cross entropy)
- For regression trees:
  - 'mse' for mean squared error (default)

Example: 'SplitCriterion', 'deviance'

### 'Surrogate' — Surrogate decision splits

'off' (default) | 'on' | 'all' | positive integer value

Surrogate decision splits flag, specified as the comma-separated pair consisting of 'Surrogate' and one of 'off', 'on', 'all', or a positive integer value.

- When 'off', the decision tree does not find surrogate splits at the branch nodes.
- When 'on', the decision tree finds at most 10 surrogate splits at each branch node.
- When set to 'all', the decision tree finds all surrogate splits at each branch node. The 'all' setting can consume considerable time and memory.
- When set to a positive integer value, the decision tree finds at most the specified number of surrogate splits at each branch node.

Use surrogate splits to improve the accuracy of predictions for data with missing values. This setting also lets you compute measures of predictive association between predictors.

Example: 'Surrogate', 'on'

## For Classification Trees Only

**'AlgorithmForCategorical'** — Algorithm for best categorical predictor split  
'Exact' | 'PullLeft' | 'PCA' | 'OVAbyClass'

Algorithm to find the best split on a categorical predictor for data with  $C$  categories for data and  $K \geq 3$  classes, specified as the comma-separated pair consisting of 'AlgorithmForCategorical' and one of the following.

'Exact'

Consider all  $2^{C-1} - 1$  combinations.

'PullLeft'

Start with all  $C$  categories on the right branch. Consider moving each category to the left branch as it achieves the minimum impurity for the  $K$  classes among the remaining categories. From this sequence, choose the split that has the lowest impurity.

'PCA'

Compute a score for each category using the inner product between the first principal component of a weighted covariance matrix (of the centered class probability matrix) and the vector of class probabilities for that category. Sort the scores in ascending order, and consider all  $C - 1$  splits.

'OVAbyClass'

Start with all  $C$  categories on the right branch. For each class, order the categories based on their probability for that class. For the first class, consider moving each category to the left branch in order, recording the impurity criterion at each move. Repeat for the remaining classes. From this sequence, choose the split that has the minimum impurity.

`ClassificationTree` selects the optimal subset of algorithms for each split using the known number of classes and levels of a categorical predictor. For two classes, `ClassificationTree` always performs the exact search. Use the

'AlgorithmForCategorical' name-value pair argument to specify a particular algorithm.

Example: 'AlgorithmForCategorical', 'PCA'

**'MaxCat' — Maximum category levels in split node**

10 (default) | nonnegative scalar value

Maximum category levels in the split node, specified as the comma-separated pair consisting of 'MaxCat' and a nonnegative scalar value. `ClassificationTree` splits a categorical predictor using the exact search algorithm if the predictor has at most `MaxCat` levels in the split node. Otherwise, `ClassificationTree` finds the best categorical split using one of the inexact algorithms. Note that passing a small value can increase computation time and memory overload.

Example: 'MaxCat', 8

## For Regression Trees Only

**'QEToler' — Quadratic error tolerance**

1e-6 (default) | nonnegative scalar value

Quadratic error tolerance per node, specified as the comma —separated pair consisting of 'QEToler' and a nonnegative scalar value. `RegressionTree` stops splitting nodes when the quadratic error per node drops below  $QETolr * QED$ , where `QED` is the quadratic error for the entire data computed before the decision tree is grown.  $QED = NORM(Y - YBAR)$ , where `YBAR` is estimated as the average of the input array `Y`.

Example: 'QEToler', 1e-4

## Output Arguments

**t — Decision tree template for classification or regression**

template object

Decision tree template for classification or regression suitable for training ensembles or error-correcting output code (ECOC) multiclass models, returned as a template object. Pass `t` to `fitensemble` or `fitcecoc` to specify how to create the decision tree for the ensemble or ECOC model, respectively.

If you display `t` in the Command Window, then all unspecified options appear empty (`[]`). However, the software replaces empty options with their corresponding default values during training.

## test

**Class:** `classregtree`

Error rate

## Syntax

```
cost = test(t, 'resubstitution')
cost = test(t, 'test', X, y)
cost = test(t, 'crossvalidate', X, y)
[cost, secost, ntnodes, bestlevel] = test(...)
[...] = test(..., param1, val1, param2, val2, ...)
```

## Description

`cost = test(t, 'resubstitution')` computes the cost of the tree `t` using a resubstitution method. `t` is a decision tree as created by `classregtree`. The cost of the tree is the sum over all terminal nodes of the estimated probability of a node times the cost of a node. If `t` is a classification tree, the cost of a node is the sum of the misclassification costs of the observations in that node. If `t` is a regression tree, the cost of a node is the average squared error over the observations in that node. `cost` is a vector of cost values for each subtree in the optimal pruning sequence for `t`. The resubstitution cost is based on the same sample that was used to create the original tree, so it under estimates the likely cost of applying the tree to new data.

`cost = test(t, 'test', X, y)` uses the matrix of predictors `X` and the response vector `y` as a test sample, applies the decision tree `t` to that sample, and returns a vector `cost` of cost values computed for the test sample. `X` and `y` should not be the same as the learning sample, that is, the sample that was used to fit the tree `t`.

`cost = test(t, 'crossvalidate', X, y)` uses 10-fold cross-validation to compute the cost vector. `X` and `y` should be the learning sample, that is, the sample that was used to fit the tree `t`. The function partitions the sample into 10 subsamples, chosen randomly but with roughly equal size. For classification trees, the subsamples also have roughly the same class proportions. For each subsample, `test` fits a tree to the remaining data and uses it to predict the subsample. It pools the information from all subsamples to compute the cost for the whole sample.

`[cost,secost,ntnodes,bestlevel] = test(...)` also returns the vector `secost` containing the standard error of each `cost` value, the vector `ntnodes` containing the number of terminal nodes for each subtree, and the scalar `bestlevel` containing the estimated best level of pruning. A `bestlevel` of 0 means no pruning. The best level is the one that produces the smallest tree that is within one standard error of the minimum-cost subtree.

`[...] = test(...,param1,val1,param2,val2,...)` specifies optional parameter name/value pairs for methods other than 'resubstitution', chosen from the following:

- 'weights' — Observation weights.
- 'nsamples' — The number of cross-validation samples (default is 10).
- 'treesize' — Either 'se' (default) to choose the smallest tree whose cost is within one standard error of the minimum cost, or 'min' to choose the minimal cost tree.

## Examples

### Compute the Cost of a Decision Tree

Find the best tree for Fisher's iris data using cross-validation.

Grow a large tree:

```
load fisheriris;
t = classregtree(meas,species,...
 'names',{'SL' 'SW' 'PL' 'PW'},...
 'minparent',5)
view(t)
```

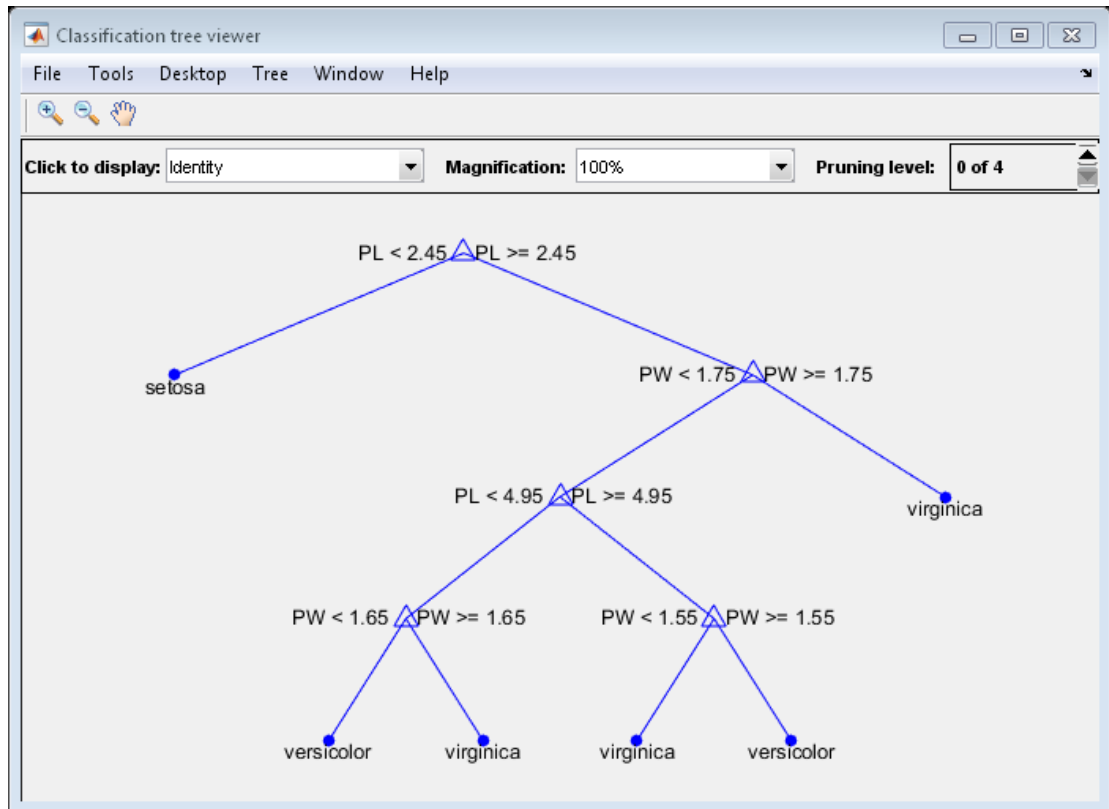

t =

```
Decision tree for classification
1 if PL<2.45 then node 2 elseif PL>=2.45 then node 3 else setosa
2 class = setosa
3 if PW<1.75 then node 4 elseif PW>=1.75 then node 5 else versicolor
4 if PL<4.95 then node 6 elseif PL>=4.95 then node 7 else versicolor
5 class = virginica
6 if PW<1.65 then node 8 elseif PW>=1.65 then node 9 else versicolor
7 if PW<1.55 then node 10 elseif PW>=1.55 then node 11 else virginica
```

```

8 class = versicolor
9 class = virginica
10 class = virginica
11 class = versicolor

```

Find the minimum-cost tree:

```

rng(1); % For reproducibility
[c,s,n,best] = test(t,'crossvalidate',meas,species);
tmin = prune(t,'level',best)
view(tmin)

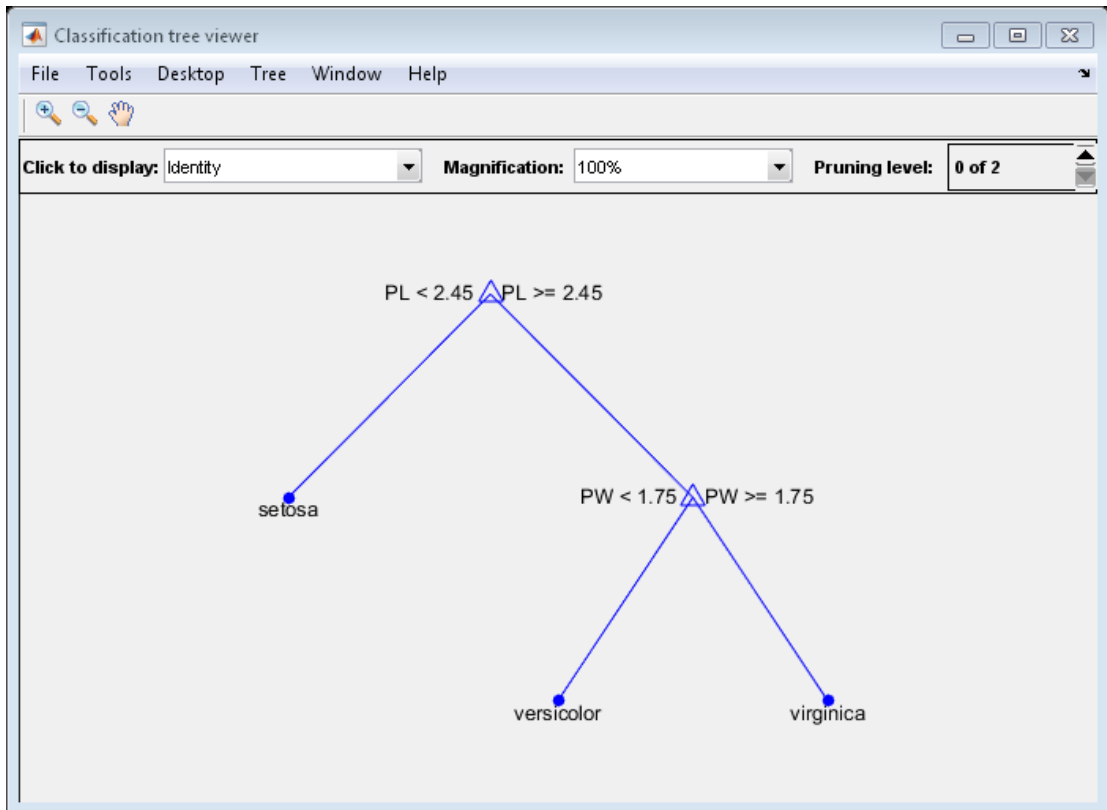

```

```
tmin =
```

```

Decision tree for classification
1 if PL<2.45 then node 2 elseif PL>=2.45 then node 3 else setosa
2 class = setosa
3 if PW<1.75 then node 4 elseif PW>=1.75 then node 5 else versicolor
4 class = versicolor
5 class = virginica

```

Plot the smallest tree within one standard error of the minimum cost tree:

```

[mincost,minloc] = min(c);
plot(n,c,'b-o',...
 n(best+1),c(best+1),'bs',...
 n,(mincost+s(minloc))*ones(size(n)),'k--')

```

```
xlabel('Tree size (number of terminal nodes)')
ylabel('Cost')
```

The solid line shows the estimated cost for each tree size, the dashed line marks one standard error above the minimum, and the square marks the smallest tree under the dashed line.

`classregtree` | `view` | `eval` | `prune`

## test

**Class:** cvpartition

Test indices for cross-validation

## Syntax

```
idx = test(c)
idx = test(c,i)
```

## Description

`idx = test(c)` returns the logical vector `idx` of test indices for an object `c` of the `cvpartition` class of type `'holdout'` or `'resubstitution'`.

If `c.Type` is `'holdout'`, `idx` specifies the observations in the test set.

If `c.Type` is `'resubstitution'`, `idx` specifies all observations.

`idx = test(c,i)` returns the logical vector `idx` of test indices for repetition `i` of an object `c` of the `cvpartition` class of type `'kfold'` or `'leaveout'`.

If `c.Type` is `'kfold'`, `idx` specifies the observations in the test set in fold `i`.

If `c.Type` is `'leaveout'`, `idx` specifies the observation left out at repetition `i`.

## Examples

Identify the test indices in the first fold of a partition of 10 observations for 3-fold cross-validation:

```
c = cvpartition(10,'kfold',3)
c =
K-fold cross validation partition
 N: 10
 NumTestSets: 3
```

```
 TrainSize: 7 6 7
 TestSize: 3 4 3

test(c,1)
ans =
 1
 1
 0
 0
 0
 0
 0
 0
 0
 1
 0
```

### See Also

`cvpartition` | `training`

## TestSize property

**Class:** cvpartition

Size of each test set

### Description

Value is a vector in partitions of type 'kfold' and 'leaveout'.

Value is a scalar in partitions of type 'holdout' and 'resubstitution'.

## tiedrank

Rank adjusted for ties

### Syntax

```
[R,TIEADJ] = tiedrank(X)
[R,TIEADJ] = tiedrank(X,1)
[R,TIEADJ] = tiedrank(X,0,1)
```

### Description

`[R,TIEADJ] = tiedrank(X)` computes the ranks of the values in the vector `X`. If any `X` values are tied, `tiedrank` computes their average rank. The return value `TIEADJ` is an adjustment for ties required by the nonparametric tests `signrank` and `ranksum`, and for the computation of Spearman's rank correlation.

`[R,TIEADJ] = tiedrank(X,1)` computes the ranks of the values in the vector `X`. `TIEADJ` is a vector of three adjustments for ties required in the computation of Kendall's tau. `tiedrank(X,0)` is the same as `tiedrank(X)`.

`[R,TIEADJ] = tiedrank(X,0,1)` computes the ranks from each end, so that the smallest and largest values get rank 1, the next smallest and largest get rank 2, etc. These ranks are used in the Ansari-Bradley test.

### Examples

Counting from smallest to largest, the two 20 values are 2nd and 3rd, so they both get rank 2.5 (average of 2 and 3):

```
tiedrank([10 20 30 40 20])
ans =
 1.0000 2.5000 4.0000 5.0000 2.5000
```

### See Also

`ansaribradley` | `ranksum` | `signrank` | `corr` | `partialcorr`

## tinv

Student's  $t$  inverse cumulative distribution function

### Syntax

`x = tinv(p,nu)`

### Description

`x = tinv(p,nu)` returns the inverse of Student's  $t$  cdf using the degrees of freedom in `nu` for the corresponding probabilities in `p`. `p` and `nu` can be vectors, matrices, or multidimensional arrays that are the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs. The values in `p` must lie on the interval  $[0\ 1]$ .

The  $t$  inverse function in terms of the  $t$  cdf is

$$x = F^{-1}(p | \nu) = \{x : F(x | \nu) = p\}$$

where

$$p = F(x | \nu) = \int_{-\infty}^x \frac{\Gamma\left(\frac{\nu+1}{2}\right)}{\Gamma\left(\frac{\nu}{2}\right)} \frac{1}{\sqrt{\nu\pi}} \frac{1}{\left(1 + \frac{t^2}{\nu}\right)^{\frac{\nu+1}{2}}} dt$$

The result,  $x$ , is the solution of the cdf integral with parameter  $\nu$ , where you supply the desired probability  $p$ .

## Examples

### Compute Student's $t$ icdf

What is the 99th percentile of the Student's  $t$  distribution for one to six degrees of freedom?

```
percentile = tinv(0.99,1:6)
```

```
percentile =
```

```
 31.8205 6.9646 4.5407 3.7469 3.3649 3.1427
```

# prob.tLocationScaleDistribution class

**Package:** prob

**Superclasses:** prob.ToolboxFittableParametricDistribution

*t* Location-Scale probability distribution object

## Description

prob.tLocationScaleDistribution is an object consisting of parameters, a model description, and sample data for a *t* location-scale probability distribution.

Create a probability distribution object with specified parameter values using `makedist`. Alternatively, fit a distribution to data using `fitdist` or the Distribution Fitting app.

## Construction

`pd = makedist('tLocationScale')` creates a *t* location-scale probability distribution object using the default parameter values.

`pd = makedist('tLocationScale', 'mu', mu, 'sigma', sigma, 'nu', nu)` creates a *t* location-scale probability distribution object using the specified parameter values.

## Input Arguments

**mu** — Location parameter

0 (default) | scalar value

Location parameter for the *t* location-scale distribution, specified as a scalar value.

Data Types: `single` | `double`

**sigma** — Scale parameter

1 (default) | positive scalar value

Scale parameter for the *t* location-scale distribution, specified as a positive scalar value.

Data Types: `single` | `double`

**nu** — Degrees of freedom

5 (default) | positive scalar value

Degrees of freedom for the  $t$  location-scale distribution, specified as a positive scalar value.

Data Types: `single` | `double`

## Properties

### **mu** — Location parameter

scalar value

Location parameter of the  $t$  location-scale distribution, stored as a scalar value.

Data Types: `single` | `double`

### **sigma** — Scale parameter

positive scalar value

Scale parameter of the  $t$  location-scale distribution, stored as a positive scalar value.

Data Types: `single` | `double`

### **nu** — Degrees of freedom

positive scalar value

Degrees of freedom of the  $t$  location-scale distribution, stored as a positive scalar value.

Data Types: `single` | `double`

### **DistributionName** — Probability distribution name

probability distribution name string

Probability distribution name, stored as a valid probability distribution name string. This property is read-only.

Data Types: `char`

### **InputData** — Data used for distribution fitting

structure

Data used for distribution fitting, stored as a structure containing the following:

- **data**: Data vector used for distribution fitting.
- **cens**: Censoring vector, or empty if none.

- **freq**: Frequency vector, or empty if none.

This property is read-only.

Data Types: struct

### **IsTruncated** — Logical flag for truncated distribution

0 | 1

Logical flag for truncated distribution, stored as a logical value. If **IsTruncated** equals 0, the distribution is not truncated. If **IsTruncated** equals 1, the distribution is truncated. This property is read-only.

Data Types: logical

### **NumParameters** — Number of parameters

positive integer value

Number of parameters for the probability distribution, stored as a positive integer value. This property is read-only.

Data Types: single | double

### **ParameterCovariance** — Covariance matrix of the parameter estimates

matrix of scalar values

Covariance matrix of the parameter estimates, stored as a  $p$ -by- $p$  matrix, where  $p$  is the number of parameters in the distribution. The  $(i,j)$  element is the covariance between the estimates of the  $i$ th parameter and the  $j$ th parameter. The  $(i,i)$  element is the estimated variance of the  $i$ th parameter. If parameter  $i$  is fixed rather than estimated by fitting the distribution to data, then the  $(i,i)$  elements of the covariance matrix are 0. This property is read-only.

Data Types: single | double

### **ParameterDescription** — Distribution parameter descriptions

cell array of strings

Distribution parameter descriptions, stored as a cell array of strings. Each cell contains a short description of one distribution parameter. This property is read-only.

Data Types: char

### **ParameterIsFixed** — Logical flag for fixed parameters

array of logical values

Logical flag for fixed parameters, stored as an array of logical values. If 0, the corresponding parameter in the `ParameterNames` array is not fixed. If 1, the corresponding parameter in the `ParameterNames` array is fixed. This property is read-only.

Data Types: `logical`

#### **ParameterNames** — Distribution parameter names

cell array of strings

Distribution parameter names, stored as a cell array of strings. This property is read-only.

Data Types: `char`

#### **ParameterValues** — Distribution parameter values

vector of scalar values

Distribution parameter values, stored as a vector. This property is read-only.

Data Types: `single` | `double`

#### **Truncation** — Truncation interval

vector of scalar values

Truncation interval for the probability distribution, stored as a vector containing the lower and upper truncation boundaries. This property is read-only.

Data Types: `single` | `double`

## Methods

### Inherited Methods

`cdf`

Cumulative distribution function of probability distribution object

`icdf`

Inverse cumulative distribution function of probability distribution object

|           |                                                                 |

## Definitions

### *t* Location-Scale Distribution

The *t* location-scale distribution is useful for modeling data distributions with heavier tails (more prone to outliers) than the normal distribution. It approaches the normal distribution as  $\nu$  approaches infinity, and smaller values of  $\nu$  yield heavier tails.

The *t* location-scale distribution uses the following parameters.

| Parameter | Description        | Support                  |
|-----------|--------------------|--------------------------|
| mu        | Location parameter | $-\infty < \mu < \infty$ |
| sigma     | Scale parameter    | $\sigma > 0$             |
| nu        | Shape parameter    | $\nu > 0$                |

The probability density function (pdf) is

$$f(x | \mu, \sigma, \nu) = \frac{\Gamma\left(\frac{\nu+1}{2}\right)}{\sigma\sqrt{\nu\pi}\Gamma\left(\frac{\nu}{2}\right)} \left[ \frac{\nu + \left(\frac{x-\mu}{\sigma}\right)^2}{\nu} \right]^{-\left(\frac{\nu+1}{2}\right)} ; \quad -\infty < x < \infty ,$$

where  $\Gamma(\cdot)$  is the Gamma function.

## Examples

### Create a *t* Location-Scale Distribution Object Using Default Parameters

Create a *t* location scale distribution object using the default parameter values.

```
pd = makedist('tLocationScale')
```

```
pd =
```

```
tLocationScaleDistribution

t Location-Scale distribution
 mu = 0
 sigma = 1
 nu = 5
```

### Create a *t* Location-Scale Distribution Object Using Specified Parameters

Create a *t* location-scale distribution object by specifying the parameter values.

```
pd = makedist('tLocationScale', 'mu', -2, 'sigma', 1, 'nu', 20)
```

```
pd =
```

```
tLocationScaleDistribution

t Location-Scale distribution
 mu = -2
 sigma = 1
 nu = 20
```

Compute the interquartile range of the distribution.

```
r = iqr(pd)
```

```
r =
```

```
1.3739
```

## prob.ToolboxFittableParametricDistribution class

**Package:** prob

**Superclasses:** prob.TruncatableDistribution

Toolbox-integrated fittable parametric probability distribution object

### Description

Create a probability distribution object with specified parameter values using `makedist`. Alternatively, fit a distribution to data using `fitdist` or the Distribution Fitting app.

### Methods

|                        |                                                                 |
|------------------------|-----------------------------------------------------------------|
| <code>mean</code>      | Mean of probability distribution object                         |
| <code>negloglik</code> | Negative loglikelihood of probability distribution object       |
| <code>paramci</code>   | Confidence intervals for probability distribution parameters    |
| <code>proflik</code>   | Profile likelihood function for probability distribution object |
| <code>std</code>       | Standard deviation of probability distribution object           |
| <code>var</code>       | Variance of probability distribution object                     |

### Inherited Methods

|                  |                                                                     |

## tpdf

Student's  $t$  probability density function

### Syntax

```
y = tpdf(x, nu)
```

### Description

`y = tpdf(x, nu)` returns the probability density function (pdf) of the Student's  $t$  distribution at each of the values in `x` using the corresponding degrees of freedom in `nu`. `x` and `nu` can be vectors, matrices, or multidimensional arrays that have the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs.

### Examples

#### Compute Student's $t$ pdf

The mode of the Student's  $t$  distribution is at  $x = 0$ . This example shows that the value of the function at the mode is an increasing function of the degrees of freedom.

```
tpdf(0,1:6)
```

```
ans =
```

```
0.3183 0.3536 0.3676 0.3750 0.3796 0.3827
```

The  $t$  distribution converges to the standard normal distribution as the degrees of freedom approaches infinity. How good is the approximation for  $\nu$  equal to 30?

```
difference = tpdf(-2.5:2.5,30) - normpdf(-2.5:2.5)
```

```
difference =
```

0.0035   -0.0006   -0.0042   -0.0042   -0.0006   0.0035

## More About

### Student's $t$ pdf

The probability density function (pdf) of the Student's  $t$  distribution is

$$y = f(x | \nu) = \frac{\Gamma\left(\frac{\nu+1}{2}\right)}{\Gamma\left(\frac{\nu}{2}\right)} \frac{1}{\sqrt{\nu\pi}} \frac{1}{\left(1 + \frac{x^2}{\nu}\right)^{\frac{\nu+1}{2}}}$$

where  $\nu$  is the degrees of freedom and  $\Gamma(\cdot)$  is the Gamma function. The result  $y$  is the probability of observing a particular value of  $x$  from a Student's  $t$  distribution with  $\nu$  degrees of freedom.

- “Student's  $t$  Distribution” on page B-133

## training

**Class:** cvpartition

Training indices for cross-validation

### Syntax

```
idx = training(c)
idx = training(c,i)
```

### Description

`idx = training(c)` returns the logical vector `idx` of training indices for an object `c` of the `cvpartition` class of type `'holdout'` or `'resubstitution'`.

If `c.Type` is `'holdout'`, `idx` specifies the observations in the training set.

If `c.Type` is `'resubstitution'`, `idx` specifies all observations.

`idx = training(c,i)` returns the logical vector `idx` of training indices for repetition `i` of an object `c` of the `cvpartition` class of type `'kfold'` or `'leaveout'`.

If `c.Type` is `'kfold'`, `idx` specifies the observations in the training set in fold `i`.

If `c.Type` is `'leaveout'`, `idx` specifies the observations left in at repetition `i`.

### Examples

Identify the training indices in the first fold of a partition of 10 observations for 3-fold cross-validation:

```
c = cvpartition(10,'kfold',3)
c =
K-fold cross validation partition
 N: 10
 NumTestSets: 3
```

---

```
 TrainSize: 7 6 7
 TestSize: 3 4 3

training(c,1)
ans =
 0
 0
 1
 1

## TrainSize property

**Class:** cvpartition

Size of each training set

### Description

Value is a vector in partitions of type 'kfold' and 'leaveout'.

Value is a scalar in partitions of type 'holdout' and 'resubstitution'.

### See Also

type

## TreeArgs property

**Class:** TreeBagger

Cell array of arguments for `fitctree` or `fitrtree`

### Description

The `TreeArgs` property is a cell array of arguments for `fitctree` or `fitrtree`. `TreeBagger` uses these arguments in growing new trees for the ensemble.

### See Also

`ClassificationTree` | `RegressionTree` | `TreeBagger` | `fitctree` | `fitrtree`

## TreeBagger class

Bootstrap aggregation for ensemble of decision trees

### Description

`TreeBagger` bags an ensemble of decision trees for either classification or regression. Bagging stands for bootstrap aggregation. Every tree in the ensemble is grown on an independently drawn bootstrap replica of input data. Observations not included in this replica are "out of bag" for this tree. To compute prediction of an ensemble of trees for unseen data, `TreeBagger` takes an average of predictions from individual trees. To estimate the prediction error of the bagged ensemble, you can compute predictions for each tree on its out-of-bag observations, average these predictions over the entire ensemble for each observation and then compare the predicted out-of-bag response with the true value at this observation.

`TreeBagger` relies on the `ClassificationTree` and `RegressionTree` functionality for growing individual trees. In particular, `ClassificationTree` and `RegressionTree` accepts the number of features selected at random for each decision split as an optional input argument.

The `compact` method returns an object of another class, `CompactTreeBagger`, with sufficient information to make predictions using new data. This information includes the tree ensemble, variable names, and class names (for classification). `CompactTreeBagger` requires less memory than `TreeBagger`, but only `TreeBagger` has methods for growing more trees for the ensemble. Once you grow an ensemble of trees using `TreeBagger` and no longer need access to the training data, you can opt to work with the compact version of the trained ensemble from then on.

### Construction

`.TreeBagger`

Create ensemble of bagged decision trees

## Methods

|                 |                                                  |
|-----------------|--------------------------------------------------|
| append          | Append new trees to ensemble                     |
| compact         | Compact ensemble of decision trees               |
| error           | Error (misclassification probability or MSE)     |
| fillProximities | Proximity matrix for training data               |
| growTrees       | Train additional trees and add to ensemble       |
| margin          | Classification margin                            |
| mdsProx         | Multidimensional scaling of proximity matrix     |
| meanMargin      | Mean classification margin                       |
| oobError        | Out-of-bag error                                 |
| oobMargin       | Out-of-bag margins                               |
| oobMeanMargin   | Out-of-bag mean margins                          |
| oobPredict      | Ensemble predictions for out-of-bag observations |
| predict         | Predict response                                 |

## Properties

### ClassNames

A cell array containing the class names for the response variable  $Y$ . This property is empty for regression trees.

### ComputeOOBPrediction

A logical flag specifying whether out-of-bag predictions for training observations should be computed. The default is `false`.

If this flag is true, the following properties are available:

- `OOBIndices`
- `OOBInstanceWeight`

If this flag is true, the following methods can be called:

- `oobError`
- `oobMargin`
- `oobMeanMargin`

See also `oobError`, `OOBIndices`, `OOBInstanceWeight`, `oobMargin`, `oobMeanMargin`.

### ComputeOOBVarImp

A logical flag specifying whether out-of-bag estimates of variable importance should be computed. The default is `false`. If this flag is `true`, then `ComputeOOBPrediction` is true as well.

If this flag is true, the following properties are available:

- `OOBPermutedVarDeltaError`
- `OOBPermutedVarDeltaMeanMargin`
- `OOBPermutedVarCountRaiseMargin`

### Cost

A matrix with misclassification costs. This property is empty for ensembles of regression trees.

### DefaultYfit

Default value returned by `predict` and `oobPredict`. The `DefaultYfit` property controls what predicted value is returned when no prediction is possible. For example, when `oobPredict` needs to predict for an observation that is in-bag for all trees in the ensemble.

- For classification, you can set this property to either `' '` or `'MostPopular'`. If you choose `'MostPopular'` (the default), the property value becomes the name of the most probably class in the training data. If you choose `' '`, the in-bag observations are excluded from computation of the out-of-bag error and margin.
- For regression, you can set this property to any numeric scalar. The default value is the mean of the response for the training data. If you set this property to `NaN`, the in-bag observations are excluded from computation of the out-of-bag error and margin.

### DeltaCritDecisionSplit

A numeric array of size 1-by-*Nvars* of changes in the split criterion summed over splits on each variable, averaged across the entire ensemble of grown trees.

See also `ClassificationTree.predictorImportance` and `RegressionTree.predictorImportance`.

### FBoot

Fraction of observations that are randomly selected with replacement for each bootstrap replica. The size of each replica is  $Nobs \times FBoot$ , where *Nobs* is the number of observations in the training set. The default value is 1.

### MergeLeaves

A logical flag specifying whether decision tree leaves with the same parent are merged for splits that do not decrease the total risk. The default value is `false`.

### Method

Method used by trees. The possible values are `'classification'` for classification ensembles, and `'regression'` for regression ensembles.

### MinLeaf

Minimum number of observations per tree leaf. By default, `MinLeaf` is 1 for classification and 5 for regression. For decision tree training, the `MinParent` value is set equal to  $2 * MinLeaf$ .

**NTrees**

Scalar value equal to the number of decision trees in the ensemble.

**NVarSplit**

A numeric array of size 1-by-*Nvars*, where every element gives a number of splits on this predictor summed over all trees.

**NVarToSample**

Number of predictor or feature variables to select at random for each decision split. By default, `NVarToSample` is equal to the square root of the total number of variables for classification, and one third of the total number of variables for regression.

**OOBIndices**

Logical array of size *Nobs*-by-*NTrees*, where *Nobs* is the number of observations in the training data and *NTrees* is the number of trees in the ensemble. A `true` value for the  $(i,j)$  element indicates that observation *i* is out-of-bag for tree *j*. In other words, observation *i* was not selected for the training data used to grow tree *j*.

**OOBInstanceWeight**

Numeric array of size *Nobs*-by-1 containing the number of trees used for computing the out-of-bag response for each observation. *Nobs* is the number of observations in the training data used to create the ensemble.

**OOBPermutedVarCountRaiseMargin**

A numeric array of size 1-by-*Nvars* containing a measure of variable importance for each predictor variable (feature). For any variable, the measure is the difference between the number of raised margins and the number of lowered margins if the values of that variable are permuted across the out-of-bag observations. This measure is computed for every tree, then averaged over the entire ensemble and divided by the standard deviation over the entire ensemble. This property is empty for regression trees.

**OOBPermutedVarDeltaError**

A numeric array of size 1-by-*Nvars* containing a measure of importance for each predictor variable (feature). For any variable, the measure is the increase in prediction error if the

values of that variable are permuted across the out-of-bag observations. This measure is computed for every tree, then averaged over the entire ensemble and divided by the standard deviation over the entire ensemble.

### **OOBPermutedVarDeltaMeanMargin**

A numeric array of size 1-by-*Nvars* containing a measure of importance for each predictor variable (feature). For any variable, the measure is the decrease in the classification margin if the values of that variable are permuted across the out-of-bag observations. This measure is computed for every tree, then averaged over the entire ensemble and divided by the standard deviation over the entire ensemble. This property is empty for regression trees.

### **OutlierMeasure**

A numeric array of size *Nobs*-by-1, where *Nobs* is the number of observations in the training data, containing outlier measures for each observation.

See also `CompactTreeBagger.OutlierMeasure`.

### **Prior**

A vector with prior probabilities for classes. This property is empty for ensembles of regression trees.

### **Proximity**

A numeric matrix of size *Nobs*-by-*Nobs*, where *Nobs* is the number of observations in the training data, containing measures of the proximity between observations. For any two observations, their proximity is defined as the fraction of trees for which these observations land on the same leaf. This is a symmetric matrix with 1s on the diagonal and off-diagonal elements ranging from 0 to 1.

See also `CompactTreeBagger.proximity`.

### **Prune**

The `Prune` property is true if decision trees are pruned and false if they are not. Pruning decision trees is not recommended for ensembles. The default value is false.

See also `ClassificationTree.prune` and `RegressionTree.prune`.

**SampleWithReplacement**

A logical flag specifying if data are sampled for each decision tree with replacement. True if `TreeBagger` samples data with replacement and false otherwise. True by default.

**TreeArgs**

Cell array of arguments for `fitctree` or `fitrtree`. These arguments are used by `TreeBagger` when growing new trees for the ensemble.

**Trees**

A cell array of size  $NTrees$ -by-1 containing the trees in the ensemble.

See also `NTrees`.

**VarAssoc**

A matrix of size  $Nvars$ -by- $Nvars$  with predictive measures of variable association, averaged across the entire ensemble of grown trees. If you grew the ensemble setting 'surrogate' to 'on', this matrix for each tree is filled with predictive measures of association averaged over the surrogate splits. If you grew the ensemble setting 'surrogate' to 'off' (default), `VarAssoc` is diagonal.

**VarNames**

A cell array containing the names of the predictor variables (features). `TreeBagger` takes these names from the optional 'names' parameter. The default names are 'x1', 'x2', etc.

**W**

Numeric vector of weights of length  $Nobs$ , where  $Nobs$  is the number of observations (rows) in the training data. `TreeBagger` uses these weights for growing every decision tree in the ensemble. The default `W` is `ones(Nobs, 1)`.

**X**

A numeric matrix of size  $Nobs$ -by- $Nvars$ , where  $Nobs$  is the number of observations (rows) and  $Nvars$  is the number of variables (columns) in the training data. This matrix contains the predictor (or feature) values.

## Y

An array of true class labels for classification, or response values for regression. Y can be a numeric column vector, a character matrix, or a cell array of strings.

## Copy Semantics

Value. To learn how this affects your use of the class, see “Comparing Handle and Value Classes” in the MATLAB Object-Oriented Programming documentation.

## How To

- “Ensemble Methods” on page 16-60
- “Classification Trees and Regression Trees” on page 16-33
- “Grouping Variables” on page 2-52

## TreeBagger

**Class:** TreeBagger

Create ensemble of bagged decision trees

### Syntax

```
B = TreeBagger(NTrees,X,Y)
```

```
B = TreeBagger(NTrees,X,Y,'param1',val1,'param2',val2,...)
```

### Description

`B = TreeBagger(NTrees,X,Y)` creates an ensemble `B` of `NTrees` decision trees for predicting response `Y` as a function of predictors `X`. By default `TreeBagger` builds an ensemble of classification trees. The function can build an ensemble of regression trees by setting the optional input argument `'method'` to `'regression'`.

`X` is a numeric matrix of training data. Each row represents an observation and each column represents a predictor or feature. `Y` is an array of true class labels for classification or numeric function values for regression. True class labels can be a numeric vector, character matrix, vector cell array of strings or categorical vector. `TreeBagger` converts labels to a cell array of strings for classification.

For more information on grouping variables, see “Grouping Variables” on page 2-52.

`B = TreeBagger(NTrees,X,Y,'param1',val1,'param2',val2,...)` specifies optional parameter name/value pairs:

- |                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>'FBoot'</code> | Fraction of input data to sample with replacement from the input data for growing each new tree. Default value is 1.                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>'Cost'</code>  | Square matrix <code>C</code> , where <code>C(i,j)</code> is the cost of classifying a point into class <code>j</code> if its true class is <code>i</code> . Alternatively, <code>COST</code> can be a structure <code>S</code> having two fields: <ul style="list-style-type: none"><li>• <code>S.ClassNames</code> containing the group names as a categorical variable, character array, or cell array of strings</li><li>• <code>S.ClassificationCosts</code> containing the cost matrix <code>C</code></li></ul> |

The default value is  $C(i, j) = 1$  if  $i \neq j$ , and  $C(i, j) = 0$  if  $i = j$ .

If `Cost` is highly skewed, then, for in-bag samples, the software oversamples unique observations from the class that has a large penalty. For smaller sample sizes, this might cause a very low relative frequency of out-of-bag observations from the class that has a large penalty. Therefore, the estimated out-of-bag error is highly variable, and might be difficult to interpret.

|                         |                                                                                                                                                                                                                                                                                                                                                  |
|-------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'SampleWithReplacement' | to sample with replacement or 'off' to sample without replacement. If you sample without replacement, you need to set 'FBoot' to a value less than one. Default is 'on'.                                                                                                                                                                         |
| 'OOBPred'               | 'on' to store info on what observations are out of bag for each tree. This info can be used by <code>oobPredict</code> to compute the predicted class probabilities for each tree in the ensemble. Default is 'off'.                                                                                                                             |
| 'OOBVarImp'             | 'on' to store out-of-bag estimates of feature importance in the ensemble. Default is 'off'. Specifying 'on' also sets the 'OOBPred' value to 'on'.                                                                                                                                                                                               |
| 'Method'                | Either 'classification' or 'regression'. Regression requires a numeric Y.                                                                                                                                                                                                                                                                        |
| 'NVarToSample'          | Number of variables to select at random for each decision split. Default is the square root of the number of variables for classification and one third of the number of variables for regression. Valid values are 'all' or a positive integer. Setting this argument to any valid value but 'all' invokes Breiman's 'random forest' algorithm. |
| 'NPrint'                | Number of training cycles (grown trees) after which <code>TreeBagger</code> displays a diagnostic message showing training progress. Default is no diagnostic messages.                                                                                                                                                                          |
| 'MinLeaf'               | Minimum number of observations per tree leaf. Default is 1 for classification and 5 for regression.                                                                                                                                                                                                                                              |

## 'Options'

A structure that specifies options that govern the computation when growing the ensemble of decision trees. One option requests that the computation of decision trees on multiple bootstrap replicates uses multiple processors, if the Parallel Computing Toolbox is available. Two options specify the random number streams to use in selecting bootstrap replicates. You can create this argument with a call to `statset`. You can retrieve values of the individual fields with a call to `statget`. Applicable `statset` parameters are:

- `'UseParallel'` — If `true` and if a `parpool` of the Parallel Computing Toolbox is open, compute decision trees drawn on separate bootstrap replicates in parallel. If the Parallel Computing Toolbox is not installed, or a `parpool` is not open, computation occurs in serial mode. Default is `false`, or serial computation.
- `'UseSubstreams'` — If `true` select each bootstrap replicate using a separate Substream of the random number generator (aka Stream). This option is available only with `RandStream` types that support Substreams: `'mlfg6331_64'` or `'mrg32k3a'`. Default is `false`, do not use a different Substream to compute each bootstrap replicate.
- `Streams` — A `RandStream` object or cell array of such objects. If you do not specify `Streams`, `TreeBagger` uses the default stream or streams. If you choose to specify `Streams`, use a single object except in the case
  - You have an open Parallel pool
  - `UseParallel` is `true`
  - `UseSubstreams` is `false`

In that case, use a cell array the same size as the Parallel pool.

**'Prior'**

Prior probabilities for each class. Specify as one of:

- A string:
  - **'Empirical'** determines class probabilities from class frequencies in  $Y$ . If you pass observation weights, they are used to compute the class probabilities. This is the default.
  - **'Uniform'** sets all class probabilities equal.
- A vector (one scalar value for each class)
- A structure **S** with two fields:
  - **S.ClassNames** containing the class names as a categorical variable, character array, or cell array of strings
  - **S.ClassProbs** containing a vector of corresponding probabilities

If you set values for both **Weights** and **Prior**, the weights are renormalized to add up to the value of the prior probability in the respective class.

If **Prior** is highly skewed, then, for in-bag samples, the software oversamples unique observations from the class that has a large prior probability. For smaller sample sizes, this might cause a very low relative frequency of out-of-bag observations from the class that has a large prior probability. Therefore, the estimated out-of-bag error is highly variable, and might be difficult to interpret.

'CategoricalPredictors', Categorical predictors list, specified as the comma-separated pair consisting of 'CategoricalPredictors' and one of the following.

- A numeric vector with indices from 1 to `p`, where `p` is the number of columns of `X`.
- A logical vector of length `p`, where a `true` entry means that the corresponding column of `X` is a categorical variable.
- A cell array of strings, where each element in the array is the name of a predictor variable. The names must match entries in `PredictorNames` values.
- A character matrix, where each row of the matrix is a name of a predictor variable. The names must match entries in `PredictorNames` values. Pad the names with extra blanks so each row of the character matrix has the same length.
- 'all', meaning all predictors are categorical.

In addition to the optional arguments above, this method accepts all optional `fitctree` and `fitrtree` arguments with the exception of 'minparent'. Refer to the documentation for `fitctree` and `fitrtree` for more detail.

## Examples

### Train a Bagged Ensemble of Classification Trees

Load Fisher's iris data set.

```
load fisheriris
```

Train a bagged ensemble of classification trees using the data and specifying 50 weak learners. Store which observations are out of bag for each tree.

```
rng(1); % For reproducibility
BaggedEnsemble = TreeBagger(50,meas,species,'OOBPred','On')
```

```
BaggedEnsemble =
```

```
TreeBagger
Ensemble with 50 bagged decision trees:
 Training X: [150x4]
 Training Y: [150x1]
 Method: classification
 Nvars: 4
 NVarToSample: 2
 MinLeaf: 1
 FBoot: 1
 SampleWithReplacement: 1
 ComputeOOBPrediction: 1
 ComputeOOBVarImp: 0
 Proximity: []
 ClassNames: 'setosa' 'versicolor' 'virginica'
```

`BaggedEnsemble` is a `TreeBagger` ensemble. `BaggedEnsemble.OOBIndices` stores the out-of-bag indices as a matrix of logical values.

Plot the out-of-bag error over the number of grown classification trees.

```
oobErrorBaggedEnsemble = oobError(BaggedEnsemble);
plot(oobErrorBaggedEnsemble)
xlabel 'Number of grown trees';
ylabel 'Out-of-bag classification error';
```

The out-of-bag error decreases with the number of grown trees.

To label out-of-bag observations, pass `BaggedEnsemble` to `oobPredict`.

## Algorithms

`TreeBagger` generates in-bag samples by oversampling classes with large misclassification costs and undersampling classes with small misclassification costs. Consequently, out-of-bag samples have fewer observations from classes with large misclassification costs and more observations from classes with small misclassification costs. If you train a classification ensemble using a small data set and a highly skewed

cost matrix, then the number of out-of-bag observations per class might be very low. Therefore, the estimated out-of-bag error might have a large variance and might be difficult to interpret. The same phenomenon can occur for classes with large prior probabilities.

## Tips

Avoid large estimated out-of-bag error variances by setting a more balanced misclassification cost matrix or a less skewed prior probability vector.

## How To

- “Ensemble Methods” on page 16-60
- “Grouping Variables” on page 2-52

## treedisp

Plot tree

---

**Note:** `treedisp` will be removed in a future release. Use `classregtree.view` instead.

---

### Syntax

```
treedisp(t)
treedisp(t,param1,va11,param2,va12,...)
```

### Description

---

**Note:** This function is superseded by the `view` method of the `classregtree` class and is maintained only for backwards compatibility. It accepts objects `t` created with the `classregtree` constructor.

---

`treedisp(t)` takes as input a decision tree `t` as computed by the `treefit` function, and displays it in a figure window. Each branch in the tree is labeled with its decision rule, and each terminal node is labeled with the predicted value for that node.

For each branch node, the left child node corresponds to the points that satisfy the condition, and the right child node corresponds to the points that do not satisfy the condition.

The **Click to display** pop-up menu at the top of the figure enables you to display more information about each node, as described in the following table.

| Menu Choice | Displays                                                                                    |
|-------------|---------------------------------------------------------------------------------------------|
| Identity    | The node number, whether the node is a branch or a leaf, and the rule that governs the node |

| Menu Choice     | Displays                                                           |
|-----------------|--------------------------------------------------------------------|
| Variable ranges | The range of each of the predictor variables for that node         |
| Node statistics | Descriptive statistics for the observations falling into this node |

After you select the type of information you want, click any node to display the information for that node.

The **Pruning level** button displays the number of levels that have been cut from the tree and the number of levels in the unpruned tree. For example, **1 of 6** indicates that the unpruned tree has six levels, and that one level has been cut from the tree. Use the spin button to change the pruning level.

`treedisp(t,param1,val1,param2,val2,...)` specifies optional parameter name-value pairs, listed in the following table.

| Parameter    | Value                                                                                                                                                            |
|--------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'names'      | A cell array of names for the predictor variables, in the order in which they appear in the X matrix from which the tree was created (see <code>treefit</code> ) |
| 'prunelevel' | Initial pruning level to display                                                                                                                                 |

## Examples

Create and graph classification tree for Fisher's iris data. The names in this example are abbreviations for the column contents (sepal length, sepal width, petal length, and petal width).

```
load fisheriris;
t = treefit(meas,species);
treedisp(t,'names',{'SL' 'SW' 'PL' 'PW'});
```

Click to display:  Magnification:  Pruning level:

# treefit

Fit tree

---

**Note:** `treefit` will be removed in a future release. Use `fitctree` or `fitrtree` instead.

---

## Syntax

```
t = treefit(X,y)
t = treefit(X,y,param1,val1,param2,val2,...)
```

## Description

`t = treefit(X,y)` creates a decision tree `t` for predicting response `y` as a function of predictors `X`. `X` is an `n`-by-`m` matrix of predictor values. `y` is either a vector of `n` response values (for regression), or a character array or cell array of strings containing `n` class names (for classification). Either way, `t` is a binary tree where each non-terminal node is split based on the values of a column of `X`.

`t = treefit(X,y,param1,val1,param2,val2,...)` specifies optional parameter name-value pairs. Valid parameter strings are:

The following table lists parameters available for all trees.

| Parameter  | Value                                                                                                                           |
|------------|---------------------------------------------------------------------------------------------------------------------------------|
| 'catidx'   | Vector of indices of the columns of <code>X</code> . <code>treefit</code> treats these columns as unordered categorical values. |
| 'method'   | Either 'classification' (default if <code>y</code> is text) or 'regression' (default if <code>y</code> is numeric).             |
| 'splitmin' | A number <code>n</code> such that impure nodes must have <code>n</code> or more observations to be split (default 10).          |

| Parameter | Value                                                                                                                  |
|-----------|------------------------------------------------------------------------------------------------------------------------|
| 'prune'   | 'on' (default) to compute the full tree and a sequence of pruned subtrees, or 'off' for the full tree without pruning. |

The following table lists parameters available for classification trees only.

| Parameter        | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'cost'           | p-by-p matrix <b>C</b> , where p is the number of distinct response values or class names in the input <b>y</b> . $C(i, j)$ is the cost of classifying a point into class <b>j</b> if its true class is <b>i</b> . (The default has $C(i, j)=1$ if $i \neq j$ , and $C(i, j)=0$ if $i=j$ .) <b>C</b> can also be a structure <b>S</b> with two fields: <b>S.group</b> containing the group names, and <b>S.cost</b> containing a matrix of cost values. |
| 'splitcriterion' | Criterion for choosing a split: either 'gdi' (default) for Gini's diversity index, 'twoing' for the twoing rule, or 'deviance' for maximum deviance reduction.                                                                                                                                                                                                                                                                                          |
| 'priorprob'      | Prior probabilities for each class, specified as a vector (one value for each distinct group name) or as a structure <b>S</b> with two fields: <b>S.group</b> containing the group names, and <b>S.prob</b> containing a vector of corresponding probabilities.                                                                                                                                                                                         |

## Examples

Create a classification tree for Fisher's iris data:

```
load fisheriris;
t = treefit(meas,species);
treedisp(t,'names',{'SL' 'SW' 'PL' 'PW'});
```

# treeprune

Prune tree

---

**Note:** treeprune will be removed in a future release. Use `classregtree.prune` instead.

---

## Syntax

```
t2 = treeprune(t1,'level',level)
t2 = treeprune(t1,'nodes',nodes)
t2 = treeprune(t1)
```

## Description

---

**Note:** This function is superseded by the `prune` method of the `classregtree` class and is maintained only for backwards compatibility. It accepts objects `t1` created with the `classregtree` constructor and returns objects `t2` in the `classregtree` class.

---

`t2 = treeprune(t1,'level',level)` takes a decision tree `t1` as created by the `treefit` function, and a pruning level, and returns the decision tree `t2` pruned to that level. Setting `level` to 0 means no pruning. Trees are pruned based on an optimal pruning scheme that first prunes branches giving less improvement in error cost.

`t2 = treeprune(t1,'nodes',nodes)` prunes the nodes listed in the `nodes` vector from the tree. Any `t1` branch nodes listed in `nodes` become leaf nodes in `t2`, unless their parent nodes are also pruned. The `treedisp` function can display the node numbers for any node you select.

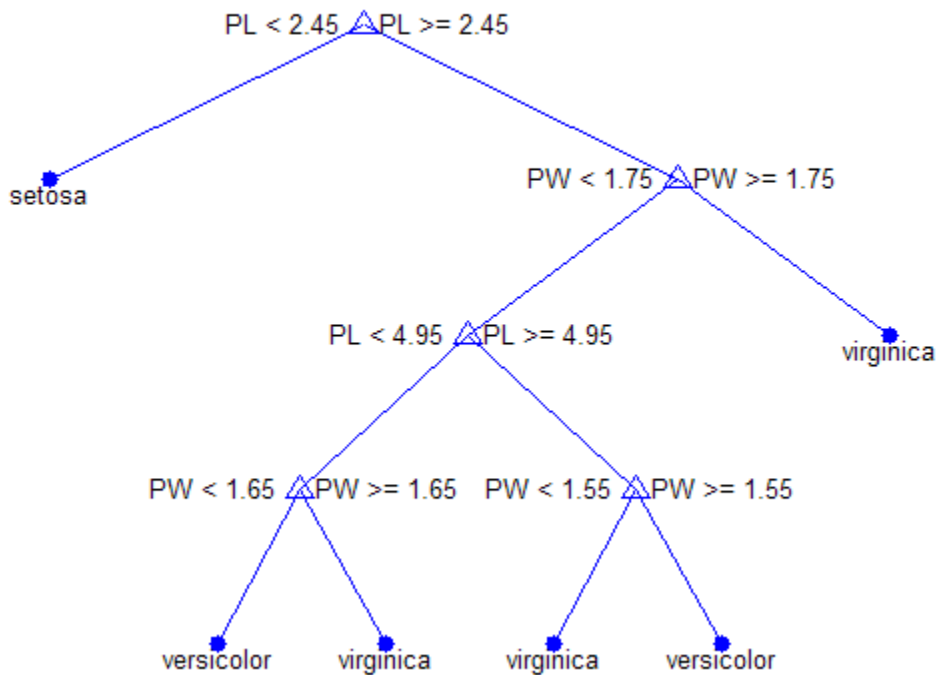

`t2 = treeprune(t1)` returns the decision tree `t2` that is the same as `t1`, but with the optimal pruning information added. This is useful only if you created `t1` by pruning another tree, or by using the `treefit` function with pruning set 'off'. If you plan to prune a tree multiple times, it is more efficient to create the optimal pruning sequence first.

Pruning is the process of reducing a tree by turning some branch nodes into leaf nodes, and removing the leaf nodes under the original branch.

## Examples

Display the full tree for Fisher's iris data, as well as the next largest tree from the optimal pruning sequence:

```
load fisheriris;
t1 = treefit(meas,species,'splitmin',5);
treedisp(t1,'names',{'SL' 'SW' 'PL' 'PW'});
```

```
t2 = treeprune(t1,'level',1);
```

```
treedisp(t2,'names',{'SL' 'SW' 'PL' 'PW'});
```

Click to display:  Magnification:  Pruning level:

## Trees property

**Class:** TreeBagger

Decision trees in ensemble

### Description

The `Trees` property is a cell array of size `NTrees-by-1` containing the trees in the ensemble.

### See Also

`NTrees`

## treetest

Error rate

### Syntax

```
cost = treetest(t, 'resubstitution')
cost = treetest(t, 'test', X, y)
cost = treetest(t, 'crossvalidate', X, y)
[cost, secost, ntnodes, bestlevel] = treetest(...)
[...] = treetest(..., param1, val1, param2, val2, ...)
```

---

**Note:** `treetest` will be removed in a future release. Use `classregtree.test` instead.

---

### Description

---

**Note:** This function is superseded by the `test` method of the `classregtree` class and is maintained only for backwards compatibility. It accepts objects `t` created with the `classregtree` constructor.

---

`cost = treetest(t, 'resubstitution')` computes the cost of the tree `t` using a resubstitution method. `t` is a decision tree as created by the `treefit` function. The cost of the tree is the sum over all terminal nodes of the estimated probability of that node times the node's cost. If `t` is a classification tree, the cost of a node is the sum of the misclassification costs of the observations in that node. If `t` is a regression tree, the cost of a node is the average squared error over the observations in that node. `cost` is a vector of cost values for each subtree in the optimal pruning sequence for `t`. The resubstitution cost is based on the same sample that was used to create the original tree, so it underestimates the likely cost of applying the tree to new data.

`cost = treetest(t, 'test', X, y)` uses the predictor matrix `X` and response `y` as a test sample, applies the decision tree `t` to that sample, and returns a vector `cost` of cost

values computed for the test sample.  $X$  and  $y$  should not be the same as the learning sample, which is the sample that was used to fit the tree  $t$ .

`cost = treetest(t, 'crossvalidate', X, y)` uses 10-fold cross-validation to compute the cost vector.  $X$  and  $y$  should be the learning sample, which is the sample that was used to fit the tree  $t$ . The function partitions the sample into 10 subsamples, chosen randomly but with roughly equal size. For classification trees, the subsamples also have roughly the same class proportions. For each subsample, `treetest` fits a tree to the remaining data and uses it to predict the subsample. It pools the information from all subsamples to compute the cost for the whole sample.

`[cost, secost, ntnodes, bestlevel] = treetest(...)` also returns the vector `secost` containing the standard error of each `cost` value, the vector `ntnodes` containing number of terminal nodes for each subtree, and the scalar `bestlevel` containing the estimated best level of pruning. `bestlevel = 0` means no pruning, i.e., the full unpruned tree. The best level is the one that produces the smallest tree that is within one standard error of the minimum-cost subtree.

`[...] = treetest(..., param1, val1, param2, val2, ...)` specifies optional parameter name-value pairs chosen from the following table.

| Parameter  | Value                                                                                                                                                    |
|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'nsamples' | The number of cross-validations samples (default is 10).                                                                                                 |
| 'treesize' | Either 'se' (default) to choose the smallest tree whose cost is within one standard error of the minimum cost, or 'min' to choose the minimal cost tree. |

## Examples

Find the best tree for Fisher's iris data using cross-validation. The solid line shows the estimated cost for each tree size, the dashed line marks one standard error above the minimum, and the square marks the smallest tree under the dashed line.

```
% Start with a large tree.
load fisheriris;
t = treefit(meas, species, 'splitmin', 5);

% Find the minimum-cost tree.
[c, s, n, best] = treetest(t, 'cross', meas, species);
```

```

tmin = treeprune(t,'level',best);

% Plot smallest tree within 1 std of minimum cost tree.
[mincost,minloc] = min(c);
plot(n,c,'b-o',...
 n(best+1),c(best+1),'bs',...
 n,(mincost+s(minloc))*ones(size(n)),'k--');
xlabel('Tree size (number of terminal nodes)')
ylabel('Cost')

```

# treeval

Predicted responses

---

**Note:** `treeval` will be removed in a future release. Use `predict` (`ClassificationTree`) or `predict` (`RegressionTree`) instead.

---

## Syntax

```
yfit = treeval(t,X)
yfit = treeval(t,X,subtrees)
[yfit,node] = treeval(...)
[yfit,node,cname] = treeval(...)
```

## Description

`yfit = treeval(t,X)` takes a classification or regression tree `t` as produced by the `treefit` function and a matrix `X` of predictor values, and produces a vector `yfit` of predicted response values. For a regression tree, `yfit(i)` is the fitted response value for a point having the predictor values `X(i,:)`. For a classification tree, `yfit(i)` is the class number into which the tree would assign the point with data `X(i,:)`. To convert the number into a class name, use the third output argument, `cname` (described below).

`yfit = treeval(t,X,subtrees)` takes an additional vector `subtrees` of pruning levels, with 0 representing the full, unpruned tree. `T` must include a pruning sequence as created by the `treefit` or `prunetree` function. If `subtree` has  $k$  elements and `X` has  $n$  rows, the output `yfit` is an  $n$ -by- $k$  matrix, with the  $j$ th column containing the fitted values produced by the `subtrees(j)` subtree. `subtrees` must be sorted in ascending order.

`[yfit,node] = treeval(...)` also returns an array `node` of the same size as `yfit` containing the node number assigned to each row of `X`. The `treedisp` function can display the node numbers for any node you select.

[yfit,node,cname] = treeval(...) is valid only for classification trees. It returns a cell array cname containing the predicted class names.

## Examples

Find the predicted classifications for Fisher's iris data:

```
load fisheriris;
t = treefit(meas,species); % Create decision tree
sfit = treeval(t,meas); % Find assigned class numbers
sfit = t.classname(sfit); % Get class names
mean(strcmp(sfit,species)) % Proportion in correct class
ans =
 0.9800
```

# prob.TriangularDistribution class

**Package:** prob

**Superclasses:** prob.ParametricTruncatableDistribution

Triangular probability distribution object

## Description

`prob.TriangularDistribution` is an object consisting of parameters and a model description for a triangular probability distribution. Create a probability distribution object with specified parameters using `makedist`.

## Construction

`pd = makedist('Triangular')` creates a triangular probability distribution object using the default parameter values.

`pd = makedist('Triangular', 'a', a, 'b', b, 'c', c)` creates a triangular distribution object using the specified parameter values.

## Input Arguments

### **a** — Lower limit

0 (default) | scalar value

Lower limit for the triangular distribution, specified as a scalar value.

Data Types: `single` | `double`

### **b** — Peak location

0.5 (default) | scalar value

Peak location for the triangular distribution, specified as a scalar value greater than or equal to `a`.

Data Types: `single` | `double`

**c — Upper limit**

1 (default) | scalar value

Upper limit for the triangular distribution, specified as a scalar value greater than or equal to **b**.

Data Types: `single` | `double`

## Properties

**a — Lower limit**

scalar value

Lower limit for the triangular distribution, stored as a scalar value.

Data Types: `single` | `double`

**b — Peak location**

scalar value

Location of the peak for the triangular distribution, stored as a scalar value greater than or equal to **a**.

Data Types: `single` | `double`

**c — Upper limit**

scalar value

Upper limit for the triangular distribution, stored as a scalar value greater than or equal to **b**.

Data Types: `single` | `double`

**DistributionName — Probability distribution name**

probability distribution name string

Probability distribution name, stored as a valid probability distribution name string. This property is read-only.

Data Types: `char`

**IsTruncated — Logical flag for truncated distribution**

0 | 1

Logical flag for truncated distribution, stored as a logical value. If `IsTruncated` equals 0, the distribution is not truncated. If `IsTruncated` equals 1, the distribution is truncated. This property is read-only.

Data Types: `logical`

### **NumParameters** — Number of parameters

positive integer value

Number of parameters for the probability distribution, stored as a positive integer value. This property is read-only.

Data Types: `single` | `double`

### **ParameterDescription** — Distribution parameter descriptions

cell array of strings

Distribution parameter descriptions, stored as a cell array of strings. Each cell contains a short description of one distribution parameter. This property is read-only.

Data Types: `char`

### **ParameterNames** — Distribution parameter names

cell array of strings

Distribution parameter names, stored as a cell array of strings. This property is read-only.

Data Types: `char`

### **ParameterValues** — Distribution parameter values

vector of scalar values

Distribution parameter values, stored as a vector. This property is read-only.

Data Types: `single` | `double`

### **Truncation** — Truncation interval

vector of scalar values

Truncation interval for the probability distribution, stored as a vector containing the lower and upper truncation boundaries. This property is read-only.

Data Types: `single` | `double`

## Methods

| <code>std</code>      | Standard deviation of probability distribution object                       |
| <code>var</code>      | Variance of probability distribution object                                 |

## Definitions

### Triangular Distribution

The triangular distribution is frequently used in simulations when limited sample data is available. The lower and upper limits represent the smallest and largest values, and the location of the peak represents an estimate of the mode.

The triangular distribution uses the following parameters.

| Parameter | Description   | Support           |
|-----------|---------------|-------------------|
| a         | Lower limit   | $a \leq b$        |
| b         | Peak location | $a \leq b \leq c$ |
| c         | Upper limit   | $c \geq b$        |

The probability density function (pdf) is

$$f(x | a, b, c) = \begin{cases} \frac{2(x-a)}{(c-a)(b-a)} & ; a \leq x \leq b \\ \frac{2(c-x)}{(c-a)(c-b)} & ; b < x \leq c \\ 0 & ; x < a, x > c \end{cases} .$$

and

$$f(x | a, b, c) = \frac{2(c-x)}{(c-a)(c-b)} ; b < x \leq c .$$

The value of the pdf is 0 when  $x < a$  or  $x > c$ .

## Examples

### Create a Triangular Distribution Object Using Default Parameters

Create a triangular distribution object using the default parameter values.

```
pd = makedist('Triangular')
```

```
pd =
```

```
TriangularDistribution
```

```
A = 0, B = 0.5, C = 1
```

### Create a Triangular Distribution Object Using Specified Parameters

Create a triangular distribution object by specifying parameter values.

```
pd = makedist('Triangular', 'a', -2, 'b', 1, 'c', 5)
```

```
pd =
```

```
TriangularDistribution
```

```
A = -2, B = 1, C = 5
```

Compute the mean of the distribution.

```
m = mean(pd)
```

```
m =
```

```
1.3333
```

# trimmean

Mean excluding outliers

## Syntax

```
m = trimmean(X,percent)
trimmean(X,percent,dim)
m = trimmean(X,percent,flag)
m = trimmean(x,percent,flag,dim)
```

## Description

`m = trimmean(X,percent)` calculates the trimmed mean of the values in `X`. For a vector input, `m` is the mean of `X`, excluding the highest and lowest `k` data values, where  $k = n * (\text{percent} / 100) / 2$  and where `n` is the number of values in `X`. For a matrix input, `m` is a row vector containing the trimmed mean of each column of `X`. For `n`-D arrays, `trimmean` operates along the first non-singleton dimension. `percent` is a scalar between 0 and 100.

`trimmean(X,percent,dim)` takes the trimmed mean along dimension `dim` of `X`.

`m = trimmean(X,percent,flag)` controls how to trim when `k` is not an integer. `flag` can be chosen from the following:

|          |                                                                                                                                                                                                                                      |
|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'round'  | Round <code>k</code> to the nearest integer (round to a smaller integer if <code>k</code> is a half integer). This is the default.                                                                                                   |
| 'floor'  | Round <code>k</code> down to the next smaller integer.                                                                                                                                                                               |
| 'weight' | If $k = i + f$ where <code>i</code> is the integer part and <code>f</code> is the fraction, compute a weighted mean with weight $(1 - f)$ for the $(i + 1)$ th and $(n - i)$ th values, and full weight for the values between them. |

`m = trimmean(x,percent,flag,dim)` takes the trimmed mean along dimension `dim` of `x`.

## Examples

### Efficiency of the Trimmed Mean

Generate a 100-by-100 matrix of random numbers from the standard normal distribution. This represents 100 samples, each containing 100 data points.

```
rng default; % For reproducibility
x = normrnd(0,1,100,100);
```

Compute the sample mean and the 10% trimmed mean for each column of the data matrix.

```
m = mean(x);
trim = trimmean(x,10);
```

Compute the efficiency of the 10% trimmed mean relative to the sample mean for the data.

```
sm = std(m);
strim = std(trim);
efficiency = (sm/strim).^2
```

```
efficiency =
 0.9663
```

### Trimmed Mean for Distributions with Outliers

Generate random data from the  $t$  location-scale distribution, which tends to have outliers.

```
rng default; % For reproducibility
x = trnd(1,40,1);
```

Visualize the distribution using a normal probability plot.

```
probplot(x)
```

Although the distribution is symmetric around zero, there are several outliers which will affect the mean. The trimmed mean is closer to zero, which is more representative of the data.

```
mean = mean(x)
tmean = trimmean(x,25)
```

```
mean =
```

```
2.7991
```

```
tmean =
```

0.8797

## More About

### Tips

The trimmed mean is a robust estimate of the location of a sample. If there are outliers in the data, the trimmed mean is a more representative estimate of the center of the body of the data than the mean. However, if the data is all from the same probability distribution, then the trimmed mean is less efficient than the sample mean as an estimator of the location of the data.

# trnd

Student's  $t$  random numbers

## Syntax

```
r = trnd(nu)
r = trnd(nu,m,n,...)
r = trnd(nu,[m,n,...])
```

## Description

`r = trnd(nu)` generates random numbers from Student's  $t$  distribution with `nu` degrees of freedom. `nu` can be a vector, a matrix, or a multidimensional array. The size of `r` is equal to the size of `nu`.

`r = trnd(nu,m,n,...)` or `r = trnd(nu,[m,n,...])` generates an `m`-by-`n`-by-... array. The `nu` parameter can be a scalar or an array of the same size as `r`.

## Examples

### Generate Student's $t$ Distribution Random Numbers

```
r1 = trnd(ones(1,6))
```

```
r1 =
```

```
 0.2108 7.8450 -11.0511 0.4134 4.3293 -0.8323
```

```
r2 = trnd(1:6,[1 6])
```

```
r2 =
```

```
 8.9290 -0.1908 0.3496 -0.7658 1.3234 -1.2808
```

```
r3 = trnd(3,2,6)
```

```
r3 =
```

```
 1.3157 0.7010 0.1591 -1.3840 4.1354 0.2442

# truncate

**Class:** prob.TruncatableDistribution

**Package:** prob

Truncate probability distribution object

## Syntax

```
t = truncate(pd, lower, upper)
```

## Description

`t = truncate(pd, lower, upper)` returns a probability distribution `t`, which is the probability distribution `pd` truncated to the specified interval with lower limit, `lower`, and upper limit, `upper`.

## Input Arguments

### **pd** — Probability distribution

probability distribution object

Probability distribution, specified as a probability distribution object. Create a probability distribution object with specified parameter values using `makedist`. Alternatively, for fittable distributions, create a probability distribution object by fitting it to data using `fitdist` or the Distribution Fitting app.

### **lower** — Lower truncation limit

scalar value

Lower truncation limit, specified as a scalar value.

Data Types: `single` | `double`

### **upper** — Upper truncation limit

scalar value

Upper truncation limit, specified as a scalar value.

Data Types: `single` | `double`

## Output Arguments

### **t** — Truncated distribution

probability distribution object

Truncated distribution, returned as a probability distribution object. The pdf of `t` is 0 outside the truncation interval. Inside the truncation interval, the pdf of `t` is equal to the pdf of `pd`, but divided by the probability assigned to that interval by `pd`.

## Examples

### Truncate a Probability Distribution

Create a standard normal probability distribution object.

```
pd = makedist('Normal')
```

```
pd =
```

```
NormalDistribution
```

```
Normal distribution
```

```
mu = 0
```

```
sigma = 1
```

Truncate the distribution to have a lower limit of -2 and an upper limit of 2.

```
t = truncate(pd,-2,2)
```

```
t =
```

```
NormalDistribution
```

```
Normal distribution
```

```
mu = 0
```

```
sigma = 1
```

Truncated to the interval  $[-2, 2]$

Plot the pdf of the original and truncated distributions for a visual comparison.

```
x = -3:.1:3;
figure;
plot(x,pdf(pd,x),'Color','red','LineWidth',2)
hold on;
plot(x,pdf(t,x),'Color','blue','LineWidth',2)
hold off;
```

### Generate Random Numbers from a Truncated Distribution

Create a standard normal probability distribution object.

```
pd = makedist('Normal')
```

```
pd =
```

```
NormalDistribution
```

```
Normal distribution
```

```
mu = 0
```

```
sigma = 1
```

Truncate the distribution by restricting it to positive values. Set the lower limit to 0 and the upper limit to infinity.

```
t = truncate(pd,0,inf)
```

```
t =
```

```
NormalDistribution
```

```
Normal distribution
```

```
mu = 0
```

```
sigma = 1
```

```
Truncated to the interval [0, Inf]
```

Generate random numbers from the truncated distribution and visualize with a histogram.

```
r = random(t,10000,1);
```

```
hist(r,100)
```

### See Also

[dfittool](#) | [fitdist](#) | [makedist](#)

## tstat

Student's  $t$  mean and variance

## Syntax

```
[m,v] = tstat(nu)
```

## Description

`[m,v] = tstat(nu)` returns the mean of and variance for Student's  $t$  distribution using the degrees of freedom in `nu`. `nu` can a vectors, matrix, or multidimensional array. The returned values for `m` and `v` are the same size as `nu`.

## Examples

### Compute Student's $t$ Mean and Variance

Compute the mean and variance for Student's  $t$  distributions with degrees of freedom `nu` equal to 1 through 30.

```
nu = reshape(1:30,6,5);
[m,v] = tstat(nu)
```

`m =`

```
NaN 0 0 0 0
0 0 0 0 0
0 0 0 0 0
0 0 0 0 0
0 0 0 0 0
0 0 0 0 0
```

`v =`

```
NaN 1.4000 1.1818 1.1176 1.0870
```

|        |        |        |        |        |
|--------|--------|--------|--------|--------|
| NaN    | 1.3333 | 1.1667 | 1.1111 | 1.0833 |
| 3.0000 | 1.2857 | 1.1538 | 1.1053 | 1.0800 |
| 2.0000 | 1.2500 | 1.1429 | 1.1000 | 1.0769 |
| 1.6667 | 1.2222 | 1.1333 | 1.0952 | 1.0741 |
| 1.5000 | 1.2000 | 1.1250 | 1.0909 | 1.0714 |

Note that the variance does not exist for one and two degrees of freedom.

## More About

### Student's $t$ Mean and Variance

The mean of the Student's  $t$  distribution is

$$\text{mean} = 0$$

for degrees of freedom  $\nu$  greater than 1. If  $\nu$  equals 1, then the mean is undefined.

The variance of the Student's  $t$  distribution is

$$\text{var} = \frac{\nu}{\nu - 2}$$

for degrees of freedom  $\nu$  greater than 2. If  $\nu$  is less than or equal to 2, then the variance is undefined.

- “Student's  $t$  Distribution” on page B-133

### See Also

tpdf | tcdf | tinvs | trnd

## ttest

One-sample and paired-sample *t*-test

### Syntax

```
h = ttest(x)
```

```
h = ttest(x,y)
```

```
h = ttest(x,y,Name,Value)
```

```
h = ttest(x,m)
```

```
h = ttest(x,m,Name,Value)
```

```
[h,p] = ttest(___)
```

```
[h,p,ci,stats] = ttest(___)
```

### Description

`h = ttest(x)` returns a test decision for the null hypothesis that the data in `x` comes from a normal distribution with mean equal to zero and unknown variance, using the one-sample *t*-test. The alternative hypothesis is that the population distribution does not have a mean equal to zero. The result `h` is 1 if the test rejects the null hypothesis at the 5% significance level, and 0 otherwise.

`h = ttest(x,y)` returns a test decision for the null hypothesis that the data in `x - y` comes from a normal distribution with mean equal to zero and unknown variance, using the paired-sample *t*-test.

`h = ttest(x,y,Name,Value)` returns a test decision for the paired-sample *t*-test with additional options specified by one or more name-value pair arguments. For example, you can change the significance level or conduct a one-sided test.

`h = ttest(x,m)` returns a test decision for the null hypothesis that the data in `x` comes from a normal distribution with mean `m` and unknown variance. The alternative hypothesis is that the mean is not `m`.

`h = ttest(x,m,Name,Value)` returns a test decision for the one-sample  $t$ -test with additional options specified by one or more name-value pair arguments. For example, you can change the significance level or conduct a one-sided test.

`[h,p] = ttest(____)` also returns the  $p$ -value,  $p$ , of the test, using any of the input arguments from the previous syntax groups.

`[h,p,ci,stats] = ttest(____)` also returns the confidence interval  $ci$  for the mean of  $x$ , or of  $x - y$  for the paired  $t$ -test, and the structure  $stats$  containing information about the test statistic.

## Examples

### Test for a Mean Equal to Zero

Load the sample data. Create a vector containing the third column of the stock returns data.

```
load stockreturns;
x = stocks(:,3);
```

Test the null hypothesis that the sample data comes from a population with mean equal to zero.

```
[h,p,ci,stats] = ttest(x)
```

```
h =
 1
```

```
p =

 0.0106
```

```
ci =
 -0.7357
 -0.0997
```

```
stats =
 tstat: -2.6065
 df: 99
 sd: 1.6027
```

The returned value  $h = 1$  indicates that `ttest` rejects the null hypothesis at the 5% significance level.

### Test Hypothesis at a Different Significance Level

Load the sample data. Create a vector containing the third column of the stock returns data.

```
load stockreturns;
x = stocks(:,3);
```

Test the null hypothesis that the sample data are from a population with mean equal to zero at the 1% significance level.

```
h = ttest(x,0,'Alpha',0.01)
```

```
h =
 0
```

The returned value  $h = 0$  indicates that `ttest` does not reject the null hypothesis at the 1% significance level.

### Paired-Sample *t*-Test

Load the sample data. Create vectors containing the first and second columns of the data matrix to represent students' grades on two exams.

```
load examgrades;
x = grades(:,1);
y = grades(:,2);
```

Test the null hypothesis that the pairwise difference between data vectors `x` and `y` has a mean equal to zero.

```
[h,p] = ttest(x,y)
```

```
h =
 0
```

```
p =
 0.9805
```

The returned value of  $h = 0$  indicates that `ttest` does not reject the null hypothesis at the default 5% significance level.

### Paired-Sample *t*-Test at a Different Significance Level

Load the sample data. Create vectors containing the first and second columns of the data matrix to represent students' grades on two exams.

```
load examgrades;
x = grades(:,1);
y = grades(:,2);
```

Test the null hypothesis that the pairwise difference between data vectors  $x$  and  $y$  has a mean equal to zero at the 1% significance level.

```
[h,p] = ttest(x,y,'Alpha',0.01)
```

```
h =
 0
```

```
p =
 0.9805
```

The returned value of  $h = 0$  indicates that `ttest` does not reject the null hypothesis at the 1% significance level.

### Test for a Hypothesized Mean

Load the sample data. Create a vector containing the first column of the students' exam grades data.

```
load examgrades;
x = grades(:,1);
```

Test the null hypothesis that sample data comes from a distribution with mean  $m = 75$ .

```
h = ttest(x,75)
```

```
h =
 0
```

The returned value of `h = 0` indicates that `ttest` does not reject the null hypothesis at the 5% significance level.

### One-Sided Hypothesis Test

Load the sample data. Create a vector containing the first column of the students' exam grades data.

```
load examgrades;
x = grades(:,1);
```

Test the null hypothesis that the data comes from a population with mean equal to 65, against the alternative that the mean is greater than 65.

```
h = ttest(x,65,'Tail','right')

h =
 1
```

The returned value of `h = 1` indicates that `ttest` rejects the null hypothesis at the 5% significance level, in favor of the alternate hypothesis that the data comes from a population with a mean greater than 65.

## Input Arguments

### **x** — Sample data

vector | matrix | multidimensional array

Sample data, specified as a vector, matrix, or multidimensional array. `ttest` performs a separate *t*-test along each column and returns a vector of results. If `y` sample data is specified, `x` and `y` must be the same size.

Data Types: `single` | `double`

### **y** — Sample data

vector | matrix | multidimensional array

Sample data, specified as a vector, matrix, or multidimensional array. If `y` sample data is specified, `x` and `y` must be the same size.

Data Types: `single` | `double`

**m — Hypothesized population mean**

0 (default) | scalar value

Hypothesized population mean, specified as a scalar value.

Data Types: single | double

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`,`Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1`,`Value1`, . . . ,`NameN`,`ValueN`.

Example: `'Tail','right','Alpha',0.01` conducts a right-tailed hypothesis test at the 1% significance level.

**'Alpha' — Significance level**

0.05 (default) | scalar value in the range (0,1)

Significance level of the hypothesis test, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the range (0,1).

Example: `'Alpha',0.01`

Data Types: single | double

**'Dim' — Dimension**

first nonsingleton dimension (default) | positive integer value

Dimension of the input matrix along which to test the means, specified as the comma-separated pair consisting of `'Dim'` and a positive integer value. For example, specifying `'Dim',1` tests the column means, while `'Dim',2` tests the row means.

Example: `'Dim',2`

Data Types: single | double

**'Tail' — Type of alternative hypothesis**

'both' (default) | 'right' | 'left'

Type of alternative hypothesis to evaluate, specified as the comma-separated pair consisting of `'Tail'` and one of the following.

|                      |                                                                                |
|----------------------|--------------------------------------------------------------------------------|
| <code>'both'</code>  | Test the alternative hypothesis that the population mean is not $m$ .          |
| <code>'right'</code> | Test the alternative hypothesis that the population mean is greater than $m$ . |
| <code>'left'</code>  | Test the alternative hypothesis that the population mean is less than $m$ .    |

Example: `'Tail', 'right'`

## Output Arguments

### **h** — Hypothesis test result

1 | 0

Hypothesis test result, returned as a logical value.

- If  $h = 1$ , this indicates the rejection of the null hypothesis at the Alpha significance level.
- If  $h = 0$ , this indicates a failure to reject the null hypothesis at the Alpha significance level.

### **p** — *p*-value

scalar value in the range [0,1]

*p*-value of the test, returned as a scalar value in the range [0,1]. *p* is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. Small values of *p* cast doubt on the validity of the null hypothesis.

### **ci** — Confidence interval

vector

Confidence interval for the true population mean, returned as a two-element vector containing the lower and upper boundaries of the  $100 \times (1 - \text{Alpha})\%$  confidence interval.

### **stats** — Test statistics

structure

Test statistics, returned as a structure containing the following:

- `tstat` — Value of the test statistic.
- `df` — Degrees of freedom of the test.

- `sd` — Estimated population standard deviation. For a paired  $t$ -test, this is the standard deviation of  $x - y$ .

## More About

### One-Sample $t$ -Test

The one-sample  $t$ -test is a parametric test of the location parameter when the population standard deviation is unknown.

The test statistic is

$$t = \frac{\bar{x} - \mu}{s / \sqrt{n}},$$

where  $\bar{x}$  is the sample mean,  $\mu$  is the hypothesized population mean,  $s$  is the sample standard deviation, and  $n$  is the sample size. Under the null hypothesis, the test statistic has Student's  $t$  distribution with  $n - 1$  degrees of freedom.

### Multidimensional Array

A multidimensional array has more than two dimensions. For example, if  $x$  is a 1-by-3-by-4 array, then  $x$  is a three-dimensional array.

### First Nonsingleton Dimension

The first nonsingleton dimension is the first dimension of an array whose size is not equal to 1. For example, if  $x$  is a 1-by-2-by-3-by-4 array, then the second dimension is the first nonsingleton dimension of  $x$ .

## See Also

`ttest2` | `ztest`

## ttest2

Two-sample *t*-test

### Syntax

```
h = ttest2(x,y)
h = ttest2(x,y,Name,Value)
[h,p] = ttest2(____)
[h,p,ci,stats] = ttest2(____)
```

### Description

`h = ttest2(x,y)` returns a test decision for the null hypothesis that the data in vectors `x` and `y` comes from independent random samples from normal distributions with equal means and equal but unknown variances, using the two-sample *t*-test. The alternative hypothesis is that the data in `x` and `y` comes from populations with unequal means. The result `h` is 1 if the test rejects the null hypothesis at the 5% significance level, and 0 otherwise.

`h = ttest2(x,y,Name,Value)` returns a test decision for the two-sample *t*-test with additional options specified by one or more name-value pair arguments. For example, you can change the significance level or conduct the test without assuming equal variances.

`[h,p] = ttest2(____)` also returns the *p*-value, `p`, of the test, using any of the input arguments in the previous syntaxes.

`[h,p,ci,stats] = ttest2(____)` also returns the confidence interval on the difference of the population means, `ci`, and the structure `stats` containing information about the test statistic.

### Examples

#### Test for Equal Means

Load the data set. Create vectors containing the first and second columns of the data matrix to represent students' grades on two exams.

```
load examgrades;
x = grades(:,1);
y = grades(:,2);
```

Test the null hypothesis that the two data samples are from populations with equal means.

```
[h,p,ci,stats] = ttest2(x,y)
```

```
h =
 0
```

```
p =
 0.9867
```

```
ci =
 -1.9438
 1.9771
```

```
stats =
 tstat: 0.0167
 df: 238
 sd: 7.7084
```

The returned value of  $h = 0$  indicates that `ttest2` does not reject the null hypothesis at the default 5% significance level.

### Test for Equal Means Without Assuming Equal Variances

Load the data set. Create vectors containing the first and second columns of the data matrix to represent students' grades on two exams.

```
load examgrades;
x = grades(:,1);
y = grades(:,2);
```

Test the null hypothesis that the two data vectors are from populations with equal means, without assuming that the populations also have equal variances.

```
[h,p] = ttest2(x,y,'Vartype','unequal')
```

```
h =
 0
```

```
p =
```

0.9867

The returned value of `h = 0` indicates that `ttest2` does not reject the null hypothesis at the default 5% significance level even if equal variances are not assumed.

## Input Arguments

### **x** — Sample data

vector | matrix | multidimensional array

Sample data, specified as a vector, matrix, or multidimensional array. `ttest2` treats NaN values as missing data and ignores them.

- If `x` and `y` are specified as vectors, they do not need to be the same length.
- If `x` and `y` are specified as matrices, they must have the same number of columns. `ttest2` performs a separate *t*-test along each column and returns a vector of results.
- If `x` and `y` are specified as multidimensional arrays, they must have the same size along all but the first nonsingleton dimension.

Data Types: `single` | `double`

### **y** — Sample data

vector | matrix | multidimensional array

Sample data, specified as a vector, matrix, or multidimensional array. `ttest2` treats NaN values as missing data and ignores them.

- If `x` and `y` are specified as vectors, they do not need to be the same length.
- If `x` and `y` are specified as matrices, they must have the same number of columns. `ttest2` performs a separate *t*-test along each column and returns a vector of results.
- If `x` and `y` are specified as multidimensional arrays, they must have the same size along all but the first nonsingleton dimension. `ttest2` works along the first nonsingleton dimension.

Data Types: `single` | `double`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside `single`

quotes ( ' '). You can specify several name and value pair arguments in any order as Name1,Value1, ...,NameN,ValueN.

Example: 'Tail','right','Alpha',0.01,'Vartype','unequal' specifies a right-tailed test at the 1% significance level, and does not assume that x and y have equal population variances.

### 'Alpha' — Significance level

0.05 (default) | scalar value in the range (0,1)

Significance level of the hypothesis test, specified as the comma-separated pair consisting of 'Alpha' and a scalar value in the range (0,1).

Example: 'Alpha',0.01

Data Types: single | double

### 'Dim' — Dimension

first nonsingleton dimension (default) | positive integer value

Dimension of the input matrix along which to test the means, specified as the comma-separated pair consisting of 'Dim' and a positive integer value. For example, specifying 'Dim',1 tests the column means, while 'Dim',2 tests the row means.

Example: 'Dim',2

Data Types: single | double

### 'Tail' — Type of alternative hypothesis

'both' (default) | 'right' | 'left'

Type of alternative hypothesis to evaluate, specified as the comma-separated pair consisting of 'Tail' and one of the following.

|         |                                                                                                         |
|---------|---------------------------------------------------------------------------------------------------------|
| 'both'  | Test the alternative hypothesis that the population means are not equal.                                |
| 'right' | Test the alternative hypothesis that the population mean of x is greater than the population mean of y. |
| 'left'  | Test the alternative hypothesis that the population mean of x is less than the population mean of y.    |

Example: 'Tail','right'

**'Vartype' — Variance type**`'equal'` (default) | `'unequal'`

Variance type, specified as the comma-separated pair consisting of `'Vartype'` and one of the following.

`'equal'` Conduct test using the assumption that  $x$  and  $y$  are from normal distributions with unknown but equal variances.

`'unequal'` Conduct test using the assumption that  $x$  and  $y$  are from normal distributions with unknown and unequal variances. This is called the Behrens-Fisher problem. `ttest2` uses Satterthwaite's approximation for the effective degrees of freedom.

`Vartype` must be a single string, even when  $x$  is a matrix or a multidimensional array.

Example: `'Vartype', 'unequal'`

## Output Arguments

**`h` — Hypothesis test result**`1` | `0`

Hypothesis test result, returned as a logical value.

- If  $h = 1$ , this indicates the rejection of the null hypothesis at the Alpha significance level.
- If  $h = 0$ , this indicates a failure to reject the null hypothesis at the Alpha significance level.

**`p` —  $p$ -value**scalar value in the range  $[0,1]$ 

$p$ -value of the test, returned as a scalar value in the range  $[0,1]$ .  $p$  is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. Small values of  $p$  cast doubt on the validity of the null hypothesis.

**`ci` — Confidence interval**

vector

Confidence interval for the difference in population means of  $x$  and  $y$ , returned as a two-element vector containing the lower and upper boundaries of the  $100 \times (1 - \text{Alpha})\%$  confidence interval.

### **stats — Test statistics**

structure

Test statistics for the two-sample  $t$ -test, returned as a structure containing the following:

- **tstat** — Value of the test statistic.
- **df** — Degrees of freedom of the test.
- **sd** — Pooled estimate of the population standard deviation (for the equal variance case) or a vector containing the unpooled estimates of the population standard deviations (for the unequal variance case).

## More About

### Two-Sample $t$ -test

The two-sample  $t$ -test is a parametric test that compares the location parameter of two independent data samples.

The test statistic is

$$t = \frac{\bar{x} - \bar{y}}{\sqrt{\frac{s_x^2}{n} + \frac{s_y^2}{m}}},$$

where  $\bar{x}$  and  $\bar{y}$  are the sample means,  $s_x$  and  $s_y$  are the sample standard deviations, and  $n$  and  $m$  are the sample sizes.

In the case where it is assumed that the two data samples are from populations with equal variances, the test statistic under the null hypothesis has Student's  $t$  distribution with  $n + m - 2$  degrees of freedom, and the sample standard deviations are replaced by the pooled standard deviation

$$s = \sqrt{\frac{(n-1)s_x^2 + (m-1)s_y^2}{n+m-2}}.$$

In the case where it is not assumed that the two data samples are from populations with equal variances, the test statistic under the null hypothesis has an approximate Student's *t* distribution with a number of degrees of freedom given by Satterthwaite's approximation. This test is sometimes called Welch's *t*-test.

**Multidimensional Array**

A multidimensional array has more than two dimensions. For example, if *x* is a 1-by-3-by-4 array, then *x* is a three-dimensional array.

**First Nonsingleton Dimension**

The first nonsingleton dimension is the first dimension of an array whose size is not equal to 1. For example, if *x* is a 1-by-2-by-3-by-4 array, then the second dimension is the first nonsingleton dimension of *x*.

# type

**Class:** classregtree

Tree type

## Syntax

```
ttype = type(t)
```

## Description

`ttype = type(t)` returns the type of the tree `t`. `ttype` is 'regression' for regression trees and 'classification' for classification trees.

## Examples

Create a classification tree for Fisher's iris data:

```
load fisheriris;

t = classregtree(meas,species,...
 'names',{'SL' 'SW' 'PL' 'PW'})
t =
Decision tree for classification
1 if PL<2.45 then node 2 elseif PL>=2.45 then node 3 else setosa
2 class = setosa
3 if PW<1.75 then node 4 elseif PW>=1.75 then node 5 else versicolor
4 if PL<4.95 then node 6 elseif PL>=4.95 then node 7 else versicolor
5 class = virginica
6 if PW<1.65 then node 8 elseif PW>=1.65 then node 9 else versicolor
7 class = virginica
8 class = versicolor
9 class = virginica

view(t)
```

Click to display:  Magnification:  Pruning level:

```
ttype = type(t)
ttype =
classification
```

## Type property

**Class:** cvpartition

Type of partition

## Description

The type of validation partition. It is 'kfold', 'holdout', 'leaveout', or 'resubstitution'.

## See Also

trainsize

## Type property

**Class:** grandset

Name of sequence on which point set P is based

## Description

P.Type returns a string that contains the name of the sequence on which the point set P is based, for example 'Sobol'. You cannot change the Type property for a point set.

# prob.UniformDistribution class

**Package:** prob

**Superclasses:** prob.ParametricTruncatableDistribution

Uniform probability distribution object

## Description

`prob.UniformDistribution` is an object consisting of parameters and a model description for a uniform probability distribution. Create a probability distribution object with specified parameters using `makedist`.

## Construction

`pd = makedist('Uniform')` creates a uniform probability distribution object using the default parameter values.

`pd = makedist('Uniform', 'Lower', lower, 'Upper', upper)` creates a uniform distribution object using the specified parameter values.

## Input Arguments

**lower** — Lower parameter

0 (default) | scalar value

Lower limit for the uniform distribution, specified as a scalar value.

Data Types: `single` | `double`

**upper** — Upper parameter

1 (default) | scalar value

Upper parameter for the uniform distribution, specified as a scalar value greater than `lower`.

Data Types: `single` | `double`

## Properties

### **lower** — Lower parameter

scalar value

Lower parameter for the uniform distribution, stored as a scalar value.

Data Types: `single` | `double`

### **upper** — Upper parameter

scalar value

Upper parameter for the uniform distribution, stored as a scalar value greater than `lower`.

Data Types: `single` | `double`

### **DistributionName** — Probability distribution name

probability distribution name string

Probability distribution name, stored as a valid probability distribution name string. This property is read-only.

Data Types: `char`

### **IsTruncated** — Logical flag for truncated distribution

0 | 1

Logical flag for truncated distribution, stored as a logical value. If `IsTruncated` equals 0, the distribution is not truncated. If `IsTruncated` equals 1, the distribution is truncated. This property is read-only.

Data Types: `logical`

### **NumParameters** — Number of parameters

positive integer value

Number of parameters for the probability distribution, stored as a positive integer value. This property is read-only.

Data Types: `single` | `double`

### **ParameterDescription** — Distribution parameter descriptions

cell array of strings

Distribution parameter descriptions, stored as a cell array of strings. Each cell contains a short description of one distribution parameter. This property is read-only.

Data Types: char

#### **ParameterNames** — Distribution parameter names

cell array of strings

Distribution parameter names, stored as a cell array of strings. This property is read-only.

Data Types: char

#### **ParameterValues** — Distribution parameter values

vector of scalar values

Distribution parameter values, stored as a vector. This property is read-only.

Data Types: single | double

#### **Truncation** — Truncation interval

vector of scalar values

Truncation interval for the probability distribution, stored as a vector containing the lower and upper truncation boundaries. This property is read-only.

Data Types: single | double

## Methods

### Inherited Methods

cdf

Cumulative distribution function of probability distribution object

icdf

Inverse cumulative distribution function of probability distribution object

iqr

Interquartile range of probability distribution object

|          |                                                                 |
|----------|-----------------------------------------------------------------|
| median   | Median of probability distribution object                       |
| pdf      | Probability density function of probability distribution object |
| random   | Generate random numbers from probability distribution object    |
| truncate | Truncate probability distribution object                        |
| mean     | Mean of probability distribution object                         |
| std      | Standard deviation of probability distribution object           |
| var      | Variance of probability distribution object                     |

## Definitions

### Uniform Distribution

The uniform distribution has a constant probability density function between its two parameters, lower (the minimum) and upper (the maximum). This distribution is appropriate for representing round-off errors in values tabulated to a particular number of decimal places.

The uniform distribution uses the following parameters.

| Parameter | Description     | Support                                 |
|-----------|-----------------|-----------------------------------------|
| lower     | Lower parameter | $-\infty < \text{lower} < \text{upper}$ |
| upper     | Upper parameter | $\text{lower} < \text{upper} < \infty$  |

The probability density function (pdf) is

$$f(x | lower, upper) = \begin{cases} \frac{1}{upper - lower} & ; \text{ lower} \leq x \leq \text{upper} \\ 0 & ; \text{ otherwise} \end{cases} .$$

and 0 otherwise.

## Examples

### Create a Uniform Distribution Object Using Default Parameters

Create a uniform distribution object using the default parameter values.

```
pd = makedist('Uniform')
```

```
pd =
```

```
UniformDistribution
```

```
Uniform distribution
```

```
Lower = 0
```

```
Upper = 1
```

### Create a Uniform Distribution Object Using Specified Parameters

Create a uniform distribution object by specifying parameter values.

```
pd = makedist('Uniform', 'Lower', -4, 'Upper', 2)
```

```
pd =
```

```
UniformDistribution
```

```
Uniform distribution
```

```
Lower = -4
```

```
Upper = 2
```

Compute the interquartile range of the distribution

```
r = iqr(pd)
```

```
r =
```

3

# union

**Class:** dataset

Set union for dataset array observations

## Compatibility

The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

## Syntax

```
C = union(A,B)
C = union(A,B,vars)
C = union(A,B,vars,setOrder)
[C,iA,iB] = union(___)
```

## Description

`C = union(A,B)` for `dataset` arrays `A` and `B` returns the combined set of observations from the two arrays, with repetitions removed. The observations in the `dataset` array `C` are sorted.

`C = union(A,B,vars)` returns the combined set of observations from the two arrays, with repetitions of unique combinations of the variables specified in `vars` removed. The observations in the `dataset` array `C` are sorted by those variables.

The values for variables not specified in `vars` for each observation in `C` are taken from the corresponding observation in `A` or `B`, or from `A` if there are common observations in both `A` and `B`. If there are multiple observations in `A` or `B` that correspond to an observation in `C`, those values are taken from the first occurrence.

`C = union(A,B,vars,setOrder)` returns the observations in `C` in the order specified by `setOrder`.

`[C, iA, iB] = union( ___ )` also returns index vectors `iA` and `iB` such that `C` is a sorted combination of the values `A(iA, :)` and `B(iB, :)`. If there are common observations in `A` and `B`, then `union` returns only the index from `A`, in `iA`. If there are repeated observations in `A` or `B`, then the index of the first occurrence is returned. You can use any of the previous input arguments.

## Input Arguments

### **A, B**

Input dataset arrays.

### **vars**

Cell array of strings containing variable names or a vector of integers containing variable column numbers, indicating the variables for which `union` removes repetitions of unique combinations of the variables.

Specify `vars` as `[]` to use its default value of all variables.

### **setOrder**

Flag indicating the sorting order for the observations in `C`. The possible values of `setOrder` are:

|          |                                                                                                                 |
|----------|-----------------------------------------------------------------------------------------------------------------|
| 'sorted' | Observations in <code>C</code> are in sorted order (default).                                                   |
| 'stable' | Observations in <code>C</code> are in the same order that they appear in <code>A</code> , then <code>B</code> . |

## Output Arguments

### **C**

Dataset array with the combined observations of `A` and `B`, with repetitions removed. `C` is in sorted order (by default), or the order specified by `setOrder`.

### **iA**

Index vector, indicating the observations in `A` that contribute to the union. `iA` contains the index to the first occurrence of any repeated observations in `A`.

**iB**

Index vector, indicating the observations in **B** that contribute to the union. If there are common observations in **A** and **B**, then `union` returns only the index from **A**, in `iA`. `iB` contains the index to the first occurrence of any repeated observations in **B**.

## Examples

### Union of Two Dataset Arrays

Navigate to the folder containing sample data, and load sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')

A = dataset('XLSFile','hospitalSmall.xlsx');
B = dataset('XLSFile','hospitalSmall.xlsx','Sheet',2);
[length(A) length(B)]
```

```
ans =
 14 8
```

The first dataset array, **A**, has 14 observations. The second dataset array, **B**, has 8 observations.

Return the union.

```
C = union(A,B);
length(C)
```

```
ans =
 21
```

The union of the two dataset arrays has 21 observations, indicating that there was one observation replicated in **A** and **B**.

## **More About**

- “Dataset Arrays” on page 2-132

# unique

**Class:** dataset

Unique observations in dataset array

## Compatibility

The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

---

**Note:** The behavior of `dataset.unique` is consistent with the MATLAB function `unique`. For a demonstration of using the `'legacy'` flag to preserve the behavior from R2012b and prior in your existing code, see the documentation for `unique`.

---

## Syntax

```
C = unique(A)
[C,ia,ic] = unique(A)
C = unique(A,vars)
[C,ia,ic] = unique(A,vars)
[...] = unique(A,vars,occurrence)
[...] = unique(...,'R2012a')
[...] = unique(...,'legacy')
[...] = unique(A,vars,setOrder)
```

## Description

`C = unique(A)` returns a copy of the dataset `A` that contains only the sorted unique observations. `A` must contain only variables whose class has a `unique` method, including:

- numeric

- character
- logical
- categorical
- cell arrays of strings

For a variable with multiple columns, its class's `unique` method must support the 'rows' flag.

`[C,ia,ic] = unique(A)` also returns index vectors `ia` and `ic` such that `C = A(ia,:)` and `A = C(ic,:)`.

`C = unique(A,vars)` returns a dataset that contains only one observation for each unique combination of values for the variables in `A` specified in `vars`. `vars` is a positive integer, a vector of positive integers, a variable name, a cell array containing one or more variable names, or a logical vector. `C` includes all variables from `A`. The values in `C` for the variables not specified in `vars` are taken from the last occurrence among observations in `A` with each unique combination of values for the variables specified in `vars`.

`[C,ia,ic] = unique(A,vars)` also returns index vectors `ia` and `ic` such that `C = A(ia,:)` and `A(:,vars) = C(ic,vars)`.

`[...] = unique(A,vars,occurrence)` specifies which index is returned in `ia` in the case of repeated observations in `A`. The default value is `occurrence='last'`, which returns the index of the last occurrence of each repeated observation in `A`. `occurrence='first'` returns the index of the first occurrence of each repeated observation in `A`. The values in `C` for variables not specified in `vars` are taken from the observations `A(ia,:)`. Specify `vars` as `[]` to use the default value of all variables.

`[...] = unique(...,'R2012a')` adopts the future behavior of `unique`. You can specify the flag as the final argument with any previous syntax that accepts `A`, `vars`, or `occurrence`.

`[...] = unique(...,'legacy')` preserves the current behavior of `unique`. You can specify the flag as the final argument with any previous syntax that accepts `A`, `vars`, or `occurrence`.

`[...] = unique(A,vars,setOrder)` returns the observations of `C` in a specific order. `setOrder='sorted'` returns the values of `C` in sorted order. `setOrder='stable'` returns the values of `C` in the same order as `A`. If there are repeated observations in `A`, then `ia` returns the index of the first occurrence of each repeated observation. Specify `vars` as `[]` to use the default value of all variables.

## **See Also**

dataset | set | subsasgn

## Units property

**Class:** dataset

Units of variables in data set

## Compatibility

The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

## Description

A cell array of strings giving the units of the variables in the data set. This property may be empty, but if not empty, the number of strings must equal the number of variables. Any individual string may be empty for a variable that does not have units defined. The default is an empty cell array.

# unidcdf

Discrete uniform cumulative distribution function

## Syntax

```
p = unidcdf(x,N)
p = unidcdf(x,N,'upper')
```

## Description

`p = unidcdf(x,N)` returns the discrete uniform cdf at each value in `x` using the corresponding maximum observable value in `N`. `x` and `N` can be vectors, matrices, or multidimensional arrays that have the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs. The maximum observable values in `N` must be positive integers.

`p = unidcdf(x,N,'upper')` returns the complement of the discrete uniform cdf at each value in `x`, using an algorithm that more accurately computes the extreme upper tail probabilities.

The discrete uniform cdf is

$$p = F(x | N) = \frac{\text{floor}(x)}{N} I_{(1,\dots,N)}(x)$$

The result,  $p$ , is the probability that a single observation from the discrete uniform distribution with maximum  $N$  will be a positive integer less than or equal to  $x$ . The values  $x$  do not need to be integers.

## Examples

### Compute Discrete Uniform Distribution cdf

What is the probability of drawing a number 20 or less from a hat with the numbers from 1 to 50 inside?

```
probability = unidcdf(20,50)
```

```
probability =
 0.4000
```

`cdf` | `unidpdf` | `unidinv` | `unidstat` | `unidrnd` | `mle`

# unidinv

Discrete uniform inverse cumulative distribution function

## Syntax

```
X = unidinv(P,N)
```

## Description

`X = unidinv(P,N)` returns the smallest positive integer `X` such that the discrete uniform cdf evaluated at `X` is equal to or exceeds `P`. You can think of `P` as the probability of drawing a number as large as `X` out of a hat with the numbers 1 through `N` inside.

`P` and `N` can be vectors, matrices, or multidimensional arrays that have the same size, which is also the size of `X`. A scalar input for `N` or `P` is expanded to a constant array with the same dimensions as the other input. The values in `P` must lie on the interval `[0 1]` and the values in `N` must be positive integers.

## Examples

```
x = unidinv(0.7,20)
x =
 14
```

```
y = unidinv(0.7 + eps,20)
y =
 15
```

A small change in the first parameter produces a large jump in output. The cdf and its inverse are both step functions. The example shows what happens at a step.

`icdf` | `unidcdf` | `unidpdf` | `unidstat` | `unidrnd`

# unidpdf

Discrete uniform probability density function

## Syntax

`Y = unidpdf(X,N)`

## Description

`Y = unidpdf(X,N)` computes the discrete uniform pdf at each of the values in `X` using the corresponding maximum observable value in `N`. `X` and `N` can be vectors, matrices, or multidimensional arrays that have the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs. The parameters in `N` must be positive integers.

The discrete uniform pdf is

$$y = f(x | N) = \frac{1}{N} I_{(1, \dots, N)}(x)$$

You can think of  $y$  as the probability of observing any one number between 1 and  $n$ .

## Examples

For fixed  $n$ , the uniform discrete pdf is a constant.

```
y = unidpdf(1:6,10)
y =
 0.1000 0.1000 0.1000 0.1000 0.1000 0.1000
```

Now fix  $x$ , and vary  $n$ .

```
likelihood = unidpdf(5,4:9)
likelihood =
 0 0.2000 0.1667 0.1429 0.1250 0.1111
```

# unidrnd

Discrete uniform random numbers

## Syntax

```
R = unidrnd(N)
R = unidrnd(N,m,n,...)
R = unidrnd(N,[m,n,...])
```

## Description

`R = unidrnd(N)` generates random numbers for the discrete uniform distribution with maximum `N`. The parameters in `N` must be positive integers. `N` can be a vector, a matrix, or a multidimensional array. The size of `R` is the size of `N`. The discrete uniform distribution arises from experiments equivalent to drawing a number from one to `N` out of a hat.

`R = unidrnd(N,m,n,...)` or `R = unidrnd(N,[m,n,...])` generates an `m`-by-`n`-by-... array. The `N` parameter can be a scalar or an array of the same size as `R`.

## Examples

In the Massachusetts lottery, a player chooses a four-digit number. Generate random numbers for Monday through Saturday.

```
numbers = unidrnd(10000,1,6)-1
numbers =
 4564 185 8214 4447 6154 7919
```

## unidstat

Discrete uniform mean and variance

### Syntax

```
[M,V] = unidstat(N)
```

### Description

`[M,V] = unidstat(N)` returns the mean and variance of the discrete uniform distribution with minimum value 1 and maximum value  $N$ .

The mean of the discrete uniform distribution with parameter  $N$  is  $(N + 1)/2$ . The variance is  $(N^2 - 1)/12$ .

### Examples

```
[m,v] = unidstat(1:6)
m =
 1.0000 1.5000 2.0000 2.5000 3.0000 3.5000
v =
 0 0.2500 0.6667 1.2500 2.0000 2.9167
```

# unifcdf

Continuous uniform cumulative distribution function

## Syntax

```
p = unifcdf(x,a,b)
p = unifcdf(x,a,b,'upper')
```

## Description

`p = unifcdf(x,a,b)` returns the uniform cdf at each value in `x` using the corresponding lower endpoint (minimum), `a` and upper endpoint (maximum), `b`. `x`, `a`, and `b` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant matrix with the same dimensions as the other inputs.

`p = unifcdf(x,a,b,'upper')` returns the complement of the uniform cdf at each value in `x`, using an algorithm that more accurately computes the extreme upper tail probabilities.

The uniform cdf is

$$p = F(x | a,b) = \frac{x-a}{b-a} I_{[a,b]}(x)$$

The standard uniform distribution has `a = 0` and `b = 1`.

## Examples

### Compute Uniform Distribution cdf

What is the probability that an observation from a standard uniform distribution will be less than 0.75?

```
probability = unifcdf(0.75)
```

```
probability =
 0.7500
```

What is the probability that an observation from a uniform distribution with  $a = -1$  and  $b = 1$  will be less than 0.75?

```
probability = unifcdf(0.75,-1,1)
```

```
probability =
 0.8750
```

# unifinv

Continuous uniform inverse cumulative distribution function

## Syntax

```
X = unifinv(P,A,B)
```

## Description

`X = unifinv(P,A,B)` computes the inverse of the uniform cdf with parameters `A` and `B` (the minimum and maximum values, respectively) at the corresponding probabilities in `P`. `P`, `A`, and `B` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs.

The inverse of the uniform cdf is

$$x = F^{-1}(p | a, b) = a + p(a - b)I_{[0,1]}(p)$$

The standard uniform distribution has `A = 0` and `B = 1`.

## Examples

What is the median of the standard uniform distribution?

```
median_value = unifinv(0.5)
median_value =
 0.5000
```

What is the 99th percentile of the uniform distribution between -1 and 1?

```
percentile = unifinv(0.99, -1, 1)
percentile =
 0.9800
```

## **More About**

## **See Also**

`icdf` | `unifcdf` | `unifpdf` | `unifstat` | `unifit` | `unifrnd`

# unifit

Continuous uniform parameter estimates

## Syntax

```
[ahat,bhat] = unifit(data)
[ahat,bhat,ACI,BCI] = unifit(data)
[ahat,bhat,ACI,BCI] = unifit(data,alpha)
```

## Description

`[ahat,bhat] = unifit(data)` returns the maximum likelihood estimates (MLEs) of the parameters of the uniform distribution given the data in `data`.

`[ahat,bhat,ACI,BCI] = unifit(data)` also returns 95% confidence intervals, `ACI` and `BCI`, which are matrices with two rows. The first row contains the lower bound of the interval for each column of the matrix `data`. The second row contains the upper bound of the interval.

`[ahat,bhat,ACI,BCI] = unifit(data,alpha)` enables you to control of the confidence level `alpha`. For example, if `alpha = 0.01` then `ACI` and `BCI` are 99% confidence intervals.

## Examples

```
r = unifrnd(10,12,100,2);
[ahat,bhat,aci,bci] = unifit(r)
ahat =
 10.0154 10.0060
bhat =
 11.9989 11.9743
aci =
 9.9551 9.9461
 10.0154 10.0060
bci =
 11.9989 11.9743
```

12.0592 12.0341

# unifpdf

Continuous uniform probability density function

## Syntax

`Y = unifpdf(X,A,B)`

## Description

`Y = unifpdf(X,A,B)` computes the continuous uniform pdf at each of the values in `X` using the corresponding lower endpoint (minimum), `A` and upper endpoint (maximum), `B`. `X`, `A`, and `B` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs. The parameters in `B` must be greater than those in `A`.

The continuous uniform distribution pdf is

$$y = f(x | a, b) = \frac{1}{b - a} I_{[a, b]}(x)$$

The standard uniform distribution has `A = 0` and `B = 1`.

## Examples

For fixed `a` and `b`, the uniform pdf is constant.

```
x = 0.1:0.1:0.6;
y = unifpdf(x)
y =
 1 1 1 1 1 1
```

What if `x` is not between `a` and `b`?

```
y = unifpdf(-1,0,1)
y =
 0
```

## **More About**

- “Uniform Distribution (Continuous)” on page B-150

## **See Also**

pdf | unifcdf | unifinv | unifstat | unifit | unifrnd

# unifrnd

Continuous uniform random numbers

## Syntax

```
R = unifrnd(A,B)
R = unifrnd(A,B,m,n,...)
R = unifrnd(A,B,[m,n,...])
```

## Description

`R = unifrnd(A,B)` returns an array `R` of random numbers generated from the continuous uniform distributions with lower and upper endpoints specified by `A` and `B`, respectively. If `A` and `B` are arrays, `R(i,j)` is generated from the distribution specified by the corresponding elements of `A` and `B`. If either `A` or `B` is a scalar, it is expanded to the size of the other input.

`R = unifrnd(A,B,m,n,...)` or `R = unifrnd(A,B,[m,n,...])` returns an `m`-by-`n`-by-... array. If `A` and `B` are scalars, all elements of `R` are generated from the same distribution. If either `A` or `B` is an array, they must be `m`-by-`n`-by-... .

## Examples

Generate one random number each from the continuous uniform distributions on the intervals (0,1), (0,2), ..., (0,5):

```
a = 0; b = 1:5;
r1 = unifrnd(a,b)
r1 =
 0.8147 1.8116 0.3810 3.6535 3.1618
```

Generate five random numbers each from the same distributions:

```
B = repmat(b,5,1);
R = unifrnd(a,B)
R =
```

```
0.0975 0.3152 0.4257 2.6230 3.7887
0.2785 1.9412 1.2653 0.1428 3.7157
0.5469 1.9143 2.7472 3.3965 1.9611
0.9575 0.9708 2.3766 3.7360 3.2774
0.9649 1.6006 2.8785 2.7149 0.8559
```

Generate five random numbers from the continuous uniform distribution on (0,2):

```
r2 = unifrnd(a,b(2),1,5)
r2 =
 1.4121 0.0637 0.5538 0.0923 0.1943
```

# unifstat

Continuous uniform mean and variance

## Syntax

```
[M,V] = unifstat(A,B)
```

## Description

`[M,V] = unifstat(A,B)` returns the mean of and variance for the continuous uniform distribution using the corresponding lower endpoint (minimum), `A` and upper endpoint (maximum), `B`. Vector or matrix inputs for `A` and `B` must have the same size, which is also the size of `M` and `V`. A scalar input for `A` or `B` is expanded to a constant matrix with the same dimensions as the other input.

The mean of the continuous uniform distribution with parameters  $a$  and  $b$  is  $(a + b)/2$ , and the variance is  $(a - b)^2/12$ .

## Examples

```
a = 1:6;
b = 2.*a;
[m,v] = unifstat(a,b)
m =
 1.5000 3.0000 4.5000 6.0000 7.5000 9.0000
v =
 0.0833 0.3333 0.7500 1.3333 2.0833 3.0000
```

## unstack

**Class:** dataset

Unstack data from single variable into multiple variables

### Compatibility

The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

### Syntax

```
wide = unstack(tall,datavar,indvar)
[wide,itall] = unstack(tall,datavar,indvar)
wide = unstack(tall,datavar,indvar,'Parameter',value)
```

### Description

`wide = unstack(tall,datavar,indvar)` converts a dataset array `tall` to an equivalent dataset array `wide` that is in wide format, by unstacking a single variable in `tall` into multiple variables in `wide`. In general `wide` contains more variables, but fewer observations, than `tall`.

`datavar` specifies the data variable in `tall` to unstack. `indvar` specifies an indicator variable in `tall` that determines which variable in `wide` each value in `datavar` is unstacked into. `unstack` treats the remaining variables in `tall` as grouping variables. Each unique combination of their values defines a group of observations in `tall` that will be unstacked into a single observation in `wide`.

`unstack` creates `m` data variables in `wide`, where `m` is the number of group levels in `indvar`. The values in `indvar` indicate which of those `m` variables receive which values from `datavar`. The `j`-th data variable in `wide` contains the values from `datavar` that correspond to observations whose `indvar` value was the `j`-th of the `m` possible levels.

Elements of those  $m$  variables for which no corresponding data value in `tall` exists contain a default value.

`datavar` is a positive integer, a variable name, or a logical vector containing a single true value. `indvar` is a positive integer, a variable name, or a logical vector containing a single true value.

`[wide, itall] = unstack(tall, datavar, indvar)` returns an index vector `itall` indicating the correspondence between observations in `wide` and those in `tall`. For each observation in `wide`, `itall` contains the index of the first in the corresponding group of observations in `tall`.

For more information on grouping variables, see “Grouping Variables” on page 2-52.

## Input Arguments

`wide = unstack(tall, datavar, indvar, 'Parameter', value)` uses the following parameter name/value pairs to control how `unstack` converts variables in `tall` to variables in `wide`:

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'GroupVars '       | Grouping variables in <code>tall</code> that define groups of observations. <code>groupvars</code> is a positive integer, a vector of positive integers, a variable name, a cell array containing one or more variable names, or a logical vector. The default is all variables in <code>tall</code> not listed in <code>datavar</code> or <code>indvar</code> .                                                                                                                                                                                                                                                                                                         |
| 'NewDataVarNames ' | A cell array of strings containing names for the data variables <code>unstack</code> should create in <code>wide</code> . Default is the group names of the grouping variable specified in <code>indvar</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| 'AggregationFun '  | A function handle that accepts a subset of values from <code>datavar</code> and returns a single value. <code>stack</code> applies this function to observations from the same group that have the same value of <code>indvar</code> . The function must aggregate the data values into a single value, and in such cases it is not possible to recover <code>tall</code> from <code>wide</code> using <code>stack</code> . The default is <code>@sum</code> for numeric data variables. For non-numeric variables, there is no default, and you must specify 'AggregationFun ' if multiple observations in the same group have the same values of <code>indvar</code> . |

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'ConstVars' | Variables in <code>tall</code> to copy to <code>wide</code> without unstacking. The values for these variables in <code>wide</code> are taken from the first observation in each group in <code>tall</code> , so these variables should typically be constant within each group. <code>ConstVars</code> is a positive integer, a vector of positive integers, a variable name, a cell array containing one or more variable names, or a logical vector. The default is no variables. |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

You can also specify more than one data variable in `tall`, each of which becomes a set of `m` variables in `wide`. In this case, specify `datavar` as a vector of positive integers, a cell array containing variable names, or a logical vector. You may specify only one variable with `indvar`. The names of each set of data variables in `wide` are the name of the corresponding data variable in `tall` concatenated with the names specified in `'NewDataVarNames'`. The function specified in `'AggregationFun'` must return a value with a single row.

## Examples

Convert a "wide format" data set to "tall format", and then back to a different "wide format":

```
load flu

% FLU has a 'Date' variable, and 10 variables for estimated
% influenza rates (in 9 different regions, estimated from
% Google searches, plus a nationwide estimate from the
% CDC). Combine those 10 variables into a "tall" array that
% has a single data variable, 'FluRate', and an indicator
% variable, 'Region', that says which region each estimate
% is from.
[flu2,iflu] = stack(flu, 2:11, 'NewDataVarName','FluRate', ...
 'IndVarName','Region')

% The second observation in FLU is for 10/16/2005. Find the
% observations in FLU2 that correspond to that date.
flu2(2,:)
flu2(iflu==2,:)

% Use the 'Date' variable from that tall array to split
% 'FluRate' into 52 separate variables, each containing the
% estimated influenza rates for each unique date. The new
```

```
% "wide" array has one observation for each region. In
% effect, this is the original array FLU "on its side".
dateNames = cellstr(datestr(flu.Date,'mmm_DD_YYYY'));
[flu3,iflu2] = unstack(flu2, 'FluRate', 'Date', ...
 'NewDataVarNames',dateNames)

% Since observations in FLU3 represent regions, IFLU2
% indicates the first occurrence in FLU2 of each region.
flu2(iflu2,:)
```

- “Grouping Variables” on page 2-52

## upperparams

**Class:** paretotails

Upper Pareto tails parameters

### Syntax

```
params = upperparams(obj)
```

### Description

`params = upperparams(obj)` returns the 2-element vector `params` of shape and scale parameters, respectively, of the upper tail of the Pareto tails object `obj`. `upperparams` does not return a location parameter.

### Examples

Fit Pareto tails to a  $t$  distribution at cumulative probabilities 0.1 and 0.9:

```
t = trnd(3,100,1);
obj = paretotails(t,0.1,0.9);
```

```
lowerparams(obj)
ans =
 -0.1901 1.1898
upperparams(obj)
ans =
 0.3646 0.5103
```

### See Also

# UserData property

**Class:** dataset

Variable containing additional information associated with data set

## Compatibility

The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

## Description

Any variable containing additional information to be associated with the data set. The default is an empty array.

## **var**

**Class:** prob.KernelDistribution

**Package:** prob

Variance of probability distribution object

## **Syntax**

`v = var(pd)`

## **Description**

`v = var(pd)` returns the variance `v` of the probability distribution `pd`.

## **Input Arguments**

**pd** — **Probability distribution**

probability distribution object

Probability distribution, specified as a probability distribution object. Fit a probability distribution object to data using `fitdist` or the Distribution Fitting app.

## **Output Arguments**

**v** — **Variance**

nonnegative scalar value

Variance of the probability distribution, returned as a nonnegative scalar value.

## **Examples**

### **Variance of a Fitted Distribution**

Load the sample data. Create a vector containing the first column of students' exam grade data.

```
load examgrades;
x = grades(:,1);
```

Fit a kernel distribution object to the data.

```
pd = fitdist(x, 'Kernel')
```

```
pd =
```

```
KernelDistribution
```

```
Kernel = normal
Bandwidth = 3.61677
Support = unbounded
```

Compute the variance of the fitted distribution.

```
v = var(pd)
```

```
v =
```

```
88.4893
```

## See Also

[dfittool](#) | [fitdist](#)

## var

**Class:** ProbDistUnivParam

Return variance of ProbDistUnivParam object

## Syntax

$V = \text{var}(PD)$

## Description

$V = \text{var}(PD)$  returns  $V$ , the variance of the ProbDistUnivParam object  $PD$ .

## Input Arguments

$PD$  An object of the class ProbDistUnivParam.

## Output Arguments

$V$  The variance of the ProbDistUnivParam object  $PD$ .

## See Also

var

## var

**Class:** prob.ParametricTruncatableDistribution

**Package:** prob

Variance of probability distribution object

## Syntax

```
v = var(pd)
```

## Description

`v = var(pd)` returns the variance `v` of the probability distribution `pd`.

## Input Arguments

**pd — Probability distribution**

probability distribution object

Probability distribution, specified as a probability distribution object. Create a probability distribution object with specified parameter values using `makedist`.

## Output Arguments

**v — Variance**

nonnegative scalar value

Variance of the probability distribution, returned as a nonnegative scalar value.

## Examples

### Variance of a Triangular Distribution

Create a triangular distribution object.

```
pd = makedist('Triangular', 'a', -3, 'b', 1, 'c', 3)
```

```
pd =
```

```
 TriangularDistribution
```

```
A = -3, B = 1, C = 3
```

Compute the variance of the distribution.

```
v = var(pd)
```

```
v =
```

```
 1.5556
```

### See Also

makedist

## var

**Class:** prob.ToolboxFittableParametricDistribution

**Package:** prob

Variance of probability distribution object

## Syntax

`v = var(pd)`

## Description

`v = var(pd)` returns the variance `v` of the probability distribution `pd`.

## Input Arguments

**pd** — Probability distribution

probability distribution object

Probability distribution, specified as a probability distribution object. Create a probability distribution object with specified parameter values using `makedist`. Alternatively, create a probability distribution object by fitting it to data using `fitdist` or the Distribution Fitting app.

## Output Arguments

**v** — Variance

nonnegative scalar value

Variance of the probability distribution, returned as a nonnegative scalar value.

## Examples

### Variance of a Fitted Distribution

Load the sample data. Create a vector containing the first column of students' exam grade data.

```
load examgrades;
x = grades(:,1);
```

Fit a normal distribution object to the data.

```
pd = fitdist(x,'Normal')

pd =

NormalDistribution

Normal distribution
 mu = 75.0083 [73.4321, 76.5846]
 sigma = 8.7202 [7.7391, 9.98843]
```

Compute the variance of the fitted distribution.

```
v = var(pd)

v =

 76.0419
```

For a normal distribution, the variance is equal to the square of the parameter `sigma`.

### Variance of a Skewed Distribution

Create a Weibull probability distribution object.

```
pd = makedist('Weibull','a',5,'b',2)

pd =

WeibullDistribution

Weibull distribution
 A = 5
 B = 2
```

Compute the variance of the distribution.

```
v = var(pd)
```

```
v =
 5.3650
```

### **See Also**

## VarDescription property

**Class:** dataset

Cell array of strings giving descriptions of variables in data set

## Compatibility

The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

## Description

A cell array of strings giving the descriptions of the variables in the data set. This property may be empty, but if not empty, the number of strings must equal the number of variables. Any individual string may be empty for a variable that does not have a description defined. The default is an empty cell array.

# varimportance

**Class:** classregtree

Compute embedded estimates of input feature importance

## Syntax

```
imp = varimportance(t)
```

## Description

`imp = varimportance(t)` computes estimates of input feature importance for tree `t` by summing changes in the risk due to splits on every feature. The returned vector `imp` has one element for each input variable in the data used to train this tree. At each node, the risk is estimated as node impurity if impurity was used to split nodes and node error otherwise. This risk is weighted by the node probability. Variable importance associated with this split is computed as the difference between the risk for the parent node and the total risk for the two children.

## See Also

`risk`

## VarNames property

**Class:** dataset

Cell array giving names of variables in data set

## Compatibility

The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

## Description

A cell array of nonempty, distinct strings giving the names of the variables in the data set. The number of strings must equal the number of variables. The default is the cell array of string names for the variables used to create the data set.

## VarNames property

**Class:** TreeBagger

Variable names

### Description

The `VarNames` property is a cell array containing the names of the predictor variables (features). `TreeBagger` takes these names from the optional `'names'` parameter. The default names are `'x1'`, `'x2'`, etc.

## vartest

Chi-square variance test

### Syntax

```
h = vartest(x,v)
h = vartest(x,v,Name,Value)
[h,p] = vartest(___)
[h,p,ci,stats] = vartest(___)
```

### Description

`h = vartest(x,v)` returns a test decision for the null hypothesis that the data in vector `x` comes from a normal distribution with variance `v`, using the chi-square variance test. The alternative hypothesis is that `x` comes from a normal distribution with a different variance. The result `h` is 1 if the test rejects the null hypothesis at the 5% significance level, and 0 otherwise.

`h = vartest(x,v,Name,Value)` performs the chi-square variance test with additional options specified by one or more name-value pair arguments. For example, you can change the significance level or conduct a one-sided test.

`[h,p] = vartest( ___ )` also returns the  $p$ -value of the test, `p`, using any of the input arguments in the previous syntaxes.

`[h,p,ci,stats] = vartest( ___ )` also returns the confidence interval for the true variance, `ci`, and the structure `stats` containing information about the test statistic.

### Examples

#### Test for a Specified Variance

Load the sample data. Create a vector containing the first column of the students' exam grades matrix.

```
load examgrades;
x = grades(:,1);
```

Test the null hypothesis that the data comes from a distribution with a variance of 25.

```
[h,p,ci,stats] = vartest(x,25)
```

```
h =
 1
```

```
p =
 0
```

```
ci =
 59.8936
 99.7688
```

```
stats =
 chisqstat: 361.9597
 df: 119
```

The returned value `h = 1` indicates that `vartest` rejects the null hypothesis at the default 5% significance level. `ci` shows the lower and upper boundaries of the 95% confidence interval for the true variance, and suggests that the true variance is greater than 25.

### One-Sided Hypothesis Test

Load the sample data. Create a vector containing the first column of the students' exam grades matrix.

```
load examgrades;
x = grades(:,1);
```

Test the null hypothesis that the data comes from a distribution with a variance of 25, against the alternative hypothesis that the variance is greater than 25.

```
[h,p] = vartest(x,25, 'Tail', 'right')
```

```
h =
 1
```

```
p =
 2.4269e-26
```

The returned value of  $h = 1$  indicates that `vartest` rejects the null hypothesis at the default 5% significance level, in favor of the alternative hypothesis that the variance is greater than 25.

## Input Arguments

### **x** — Sample data

vector | matrix | multidimensional array

Sample data, specified as a vector, matrix, or multidimensional array. For matrices, `vartest` performs separate tests along each column of `x`, and returns a row vector of results. For multidimensional arrays, `vartest` works along the first nonsingleton dimension of `x`.

Data Types: `single` | `double`

### **v** — Hypothesized variance

nonnegative scalar value

Hypothesized variance, specified as a nonnegative scalar value.

Data Types: `single` | `double`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Tail','right','Alpha',0.01` specifies a right-tailed hypothesis test at the 1% significance level.

### **'Alpha'** — Significance level

0.05 (default) | scalar value in the range (0,1)

Significance level of the hypothesis test, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the range (0,1).

Example: `'Alpha',0.01`

Data Types: `single` | `double`

**'Dim' — Dimension**

first nonsingleton dimension (default) | positive integer value

Dimension of the input matrix to test along, specified as the comma-separated pair consisting of 'Dim' and a positive integer value. For example, specifying 'Dim',1 tests the data in each column for equality to the hypothesized variance, while 'Dim',2 tests the data in each row.

Example: 'Dim',2

Data Types: single | double

**'Tail' — Type of alternative hypothesis**

'both' (default) | 'right' | 'left'

Type of alternative hypothesis to evaluate, specified as the comma-separated pair consisting of 'Tail' and one of the following.

|         |                                                                                    |
|---------|------------------------------------------------------------------------------------|
| 'both'  | Test the alternative hypothesis that the population variance is not $v$ .          |
| 'right' | Test the alternative hypothesis that the population variance is greater than $v$ . |
| 'left'  | Test the alternative hypothesis that the population variance is less than $v$ .    |

Example: 'Tail','right'

## Output Arguments

**h — Hypothesis test result**

1 | 0

Hypothesis test result, returned as a logical value.

- If  $h = 1$ , this indicates the rejection of the null hypothesis at the Alpha significance level.
- If  $h = 0$ , this indicates a failure to reject the null hypothesis at the Alpha significance level.

**p — p-value**

scalar value in the range [0,1]

*p*-value of the test, returned as a scalar value in the range [0,1]. *p* is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. Small values of *p* cast doubt on the validity of the null hypothesis.

### **ci** — Confidence interval

vector

Confidence interval for the true variance, returned as a two-element vector containing the lower and upper boundaries of the  $100 \times (1 - \text{Alpha})\%$  confidence interval.

### **stats** — Test statistics

structure

Test statistics for the chi-square variance test, returned as a structure containing:

- `chisqstat` — Value of the test statistic.
- `df` — Degrees of freedom of the test.

## More About

### Chi-Square Variance Test

The chi-square variance test is used to test if the variance of a population is equal to a hypothesized value.

The test statistic is

$$T = (n - 1) \left( \frac{s}{\sigma_0} \right)^2,$$

where *n* is the sample size, *s* is the sample standard deviation, and  $\sigma_0$  is the hypothesized standard deviation. The denominator is the ratio of the sample standard deviation to the hypothesized standard deviation. The further this ratio deviates from 1, the more likely you are to reject the null hypothesis. The test statistic *T* has a chi-square distribution with *n* – 1 degrees of freedom under the null hypothesis.

### Multidimensional Array

A multidimensional array has more than two dimensions. For example, if **x** is a 1-by-3-by-4 array, then **x** is a three-dimensional array.

**First Nonsingleton Dimension**

The first nonsingleton dimension is the first dimension of an array whose size is not equal to 1. For example, if `x` is a 1-by-2-by-3-by-4 array, then the second dimension is the first nonsingleton dimension of `x`.

**See Also**

`vartest2` | `vartestn`

## vartest2

Two-sample  $F$ -test for equal variances

### Syntax

```
h = vartest2(x,y)
h = vartest2(x,y,Name,Value)
[h,p] = vartest2(___)
[h,p,ci,stats] = vartest2(___)
```

### Description

`h = vartest2(x,y)` returns a test decision for the null hypothesis that the data in vectors `x` and `y` comes from normal distributions with the same variance, using the two-sample  $F$ -test. The alternative hypothesis is that they come from normal distributions with different variances. The result `h` is 1 if the test rejects the null hypothesis at the 5% significance level, and 0 otherwise.

`h = vartest2(x,y,Name,Value)` returns a test decision for the two-sample  $F$ -test with additional options specified by one or more name-value pair arguments. For example, you can change the significance level or conduct a one-sided test.

`[h,p] = vartest2( ___ )` also returns the  $p$ -value of the test, `p`, using any of the input arguments in the previous syntaxes.

`[h,p,ci,stats] = vartest2( ___ )` also returns the confidence interval for the true variance ratio, `ci`, and the structure `stats` containing information about the test statistic.

## Examples

### Test for Equal Variances

Load the sample data. Create vectors containing the first and second columns of the data matrix to represent students' grades on two exams.

```
load examgrades;
x = grades(:,1);
```

```
y = grades(:,2);
```

Test the null hypothesis that the data in `x` and `y` comes from distributions with the same variance.

```
[h,p,ci,stats] = vartest2(x,y)
```

```
h =
 1
```

```
p =
 0.0019
```

```
ci =
 1.2383
 2.5494
```

```
stats =
 fstat: 1.7768
 df1: 119
 df2: 119
```

The returned result `h = 1` indicates that `vartest2` rejects the null hypothesis at the default 5% significance level. `ci` contains the lower and upper boundaries of the 95% confidence interval for the true variance ratio. `stats` contains the value of the test statistic for the  $F$ -test and the numerator and denominator degrees of freedom.

### One-Sided Hypothesis Test

Load the sample data. Create vectors containing the first and second columns of the data matrix to represent students' grades on two exams.

```
load examgrades;
x = grades(:,1);
y = grades(:,2);
```

Test the null hypothesis that the data in `x` and `y` comes from distributions with the same variance, against the alternative that the population variance of `x` is greater than that of `y`.

```
vartest2(x,y,'Tail','right')
```

```
h =
 1
```

```
p =
```

9.4364e-04

The returned result `h = 1` indicates that `vartest2` rejects the null hypothesis at the default 5% significance level, in favor of the alternative hypothesis that the population variance of `x` is greater than that of `y`.

## Input Arguments

### **x** — Sample data

vector | matrix | multidimensional array

Sample data, specified as a vector, matrix, or multidimensional array.

- If `x` and `y` are vectors, they do not need to be the same length.
- If `x` and `y` are matrices, they must have the same number of columns, but do not need to have the same number of rows. `vartest2` performs separate tests along each column and returns a vector of the results.
- If `x` and `y` are multidimensional arrays, they must have the same number of dimensions, and the same size along all but the first nonsingleton dimension.

Data Types: `single` | `double`

### **y** — Sample data

vector | matrix | multidimensional array

Sample data, specified as a vector, matrix, or multidimensional array.

- If `x` and `y` are vectors, they do not need to be the same length.
- If `x` and `y` are matrices, they must have the same number of columns, but do not need to have the same number of rows. `vartest2` performs separate tests along each column and returns a vector of the results.
- If `x` and `y` are multidimensional arrays, they must have the same number of dimensions, and the same size along all but the first nonsingleton dimension.

Data Types: `single` | `double`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single

quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Tail','right','Alpha',0.01` specifies a right-tailed hypothesis test at the 1% significance level.

#### **'Alpha' — Significance level**

0.05 (default) | scalar value in the range (0,1)

Significance level of the hypothesis test, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the range (0,1).

Example: `'Alpha',0.01`

Data Types: `single` | `double`

#### **'Dim' — Dimension**

first nonsingleton dimension (default) | positive integer value

Dimension of the input matrix to test along, specified as the comma-separated pair consisting of `'Dim'` and a positive integer value. For example, specifying `'Dim',1` tests the data in each column for variance equality, while `'Dim',2` tests the data in each row.

Example: `'Dim',2`

Data Types: `single` | `double`

#### **'Tail' — Type of alternative hypothesis**

`'both'` (default) | `'right'` | `'left'`

Type of alternative hypothesis to evaluate using the  $F$ -test, specified as the comma-separated pair consisting of `'Tail'` and one of the following.

|                      |                                                                                              |
|----------------------|----------------------------------------------------------------------------------------------|
| <code>'both'</code>  | Test the alternative hypothesis that the population variances are not equal.                 |
| <code>'right'</code> | Test the alternative hypothesis that the population variance of x is greater than that of y. |
| <code>'left'</code>  | Test the alternative hypothesis that the population variance of x is less than that of y.    |

Example: `'Tail','right'`

## Output Arguments

### **h** — Hypothesis test result

1 | 0

Hypothesis test result, returned as a logical value.

- If  $h = 1$ , this indicates the rejection of the null hypothesis at the Alpha significance level.
- If  $h = 0$ , this indicates a failure to reject the null hypothesis at the Alpha significance level.

### **p** — *p*-value

scalar value in the range [0,1]

*p*-value of the test, returned as a scalar value in the range [0,1]. *p* is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. Small values of *p* cast doubt on the validity of the null hypothesis.

### **ci** — Confidence interval

vector

Confidence interval for the true ratio of the population variances, returned as a two-element vector containing the lower and upper boundaries of the  $100 \times (1 - \text{Alpha})\%$  confidence interval.

### **stats** — Test statistics

structure

Test statistics for the hypothesis test, returned as a structure containing:

- `fstat` — Value of the test statistic.
- `df1` — Numerator degrees of freedom of the test.
- `df2` — Denominator degrees of freedom of the test.

## More About

### Two-Sample *F*-Test

The two-sample *F*-test is used to test if the variances of two populations are equal.

The test statistic is

$$F = \frac{s_1^2}{s_2^2},$$

where  $s_1$  and  $s_2$  are the sample standard deviations. The test statistic is a ratio of the two sample variances. The further this ratio deviates from 1, the more likely you are to reject the null hypothesis. Under the null hypothesis, the test statistic  $F$  has a  $F$ -distribution with numerator degrees of freedom equal to  $N_1 - 1$  and denominator degrees of freedom equal to  $N_2 - 1$ , where  $N_1$  and  $N_2$  are the sample sizes of the two data sets.

### **Multidimensional Array**

A multidimensional array has more than two dimensions. For example, if  $x$  is a 1-by-3-by-4 array, then  $x$  is a three-dimensional array.

### **First Nonsingleton Dimension**

The first nonsingleton dimension is the first dimension of an array whose size is not equal to 1. For example, if  $x$  is a 1-by-2-by-3-by-4 array, then the second dimension is the first nonsingleton dimension of  $x$ .

### **See Also**

vartest | vartestn

## **vartestn**

Multiple-sample tests for equal variances

### **Syntax**

```
vartestn(x)
vartestn(x,Name,Value)

vartestn(x,group)
vartestn(x,group,Name,Value)

p = vartestn(___)
[p,stats] = vartestn(___)
```

### **Description**

`vartestn(x)` returns a summary table of statistics and a box plot for a Bartlett test of the null hypothesis that the columns of data vector `x` come from normal distributions with the same variance. The alternative hypothesis is that not all columns of data have the same variance.

`vartestn(x,Name,Value)` returns a summary table of statistics and a box plot for a test of unequal variances with additional options specified by one or more name-value pair arguments. For example, you can specify a different type of hypothesis test or change the display settings for the test results.

`vartestn(x,group)` returns a summary table of statistics and a box plot for a Bartlett test of the null hypothesis that the data in each categorical group comes from normal distributions with the same variance. The alternative hypothesis is that not all groups have the same variance.

`vartestn(x,group,Name,Value)` returns a summary table of statistics and a box plot for a test of unequal variances with additional options specified by one or more name-value pair arguments. For example, you can specify a different type of hypothesis test or change the display settings for the test results.

`p = vartestn( ___ )` also returns the  $p$ -value of the test,  $p$ , using any of the input arguments in the previous syntaxes.

`[p,stats] = vartestn( ___ )` also returns the structure `stats` containing information about the test statistic.

## Examples

### Test Data for Equal Variances

Load the sample data.

```
load examgrades;
```

Test the null hypothesis that the variances are equal across the five columns of data in the students' exam grades matrix, `grades`.

```
vartestn(grades)
```

| Group Summary Table  |         |         |         |
|----------------------|---------|---------|---------|
| Group                | Count   | Mean    | Std Dev |
| 1                    | 120     | 75.0083 | 8.7202  |
| 2                    | 120     | 74.9917 | 6.54204 |
| 3                    | 120     | 74.9917 | 7.43091 |
| 4                    | 120     | 75.0333 | 8.60128 |
| 5                    | 120     | 74.9917 | 5.25884 |
| Pooled               | 600     | 75.0033 | 7.42558 |
| Bartlett's statistic | 38.7332 |         |         |
| Degrees of freedom   | 4       |         |         |
| p-value              | 0       |         |         |

The low  $p$ -value,  $p = 0$ , indicates that `vartestn` rejects the null hypothesis that the variances are equal across all five columns, in favor of the alternative hypothesis that at least one column has a different variance.

### Test Grouped Data for Equal Variances

Load the sample data.

```
load carsmall;
```

Test the null hypothesis that the variances in miles per gallon (MPG) are equal across different model years.

```
vartestn(MPG,Model_Year)
```

**Group Summary Table**

| Group                | Count   | Mean    | Std Dev |
|----------------------|---------|---------|---------|
| 70                   | 29      | 17.6897 | 5.33923 |
| 76                   | 34      | 21.5735 | 5.8893  |
| 82                   | 31      | 31.7097 | 5.39255 |
| Pooled               | 94      | 23.7181 | 5.562   |
| Bartlett's statistic | 0.36619 |         |         |
| Degrees of freedom   | 2       |         |         |
| p-value              | 0.83269 |         |         |

The high  $p$ -value,  $p = 0.83269$ , indicates that `vartestn` does not reject the null hypothesis that the variances in miles per gallon (MPG) are equal across different model years.

### Test for Equal Variances Using Levene's Test

Load the sample data.

```
load carsmall;
```

Use Levene's test to test the null hypothesis that the variances in miles per gallon (MPG) are equal across different model years.

```
p = vartestn(MPG,Model_Year, 'TestType', 'LeveneAbsolute')
```

p =

0.6320

| Group Summary Table           |         |         |         |
|-------------------------------|---------|---------|---------|
| Group                         | Count   | Mean    | Std Dev |
| 70                            | 29      | 17.6897 | 5.33923 |
| 76                            | 34      | 21.5735 | 5.8893  |
| 82                            | 31      | 31.7097 | 5.39255 |
| Pooled                        | 94      | 23.7181 | 5.562   |
| Levene's statistic (absolute) | 0.46126 |         |         |
| Degrees of freedom            | 2, 91   |         |         |
| p-value                       | 0.63195 |         |         |

The high  $p$ -value,  $p = 0.63195$ , indicates that `vartestn` does not reject the null hypothesis that the variances in miles per gallon (MPG) are equal across different model years.

### Test for Equal Variances Using the Brown-Forsythe Test

Load the sample data.

```
load examgrades;
```

Test the null hypothesis that the variances are equal across the five columns of data in the students' exam grades matrix, `grades`, using the Brown-Forsythe test. Suppress the display of the summary table of statistics and the box plot.

```
[p,stats] = vartestn(grades, 'TestType', 'BrownForsythe', 'Display', 'off')

p =

 1.3121e-06

stats =

 fstat: 8.4160
 df: [4 595]
```

The small  $p$ -value,  $p = 1.3121e-06$ , indicates that `vartestn` rejects the null hypothesis that the variances are equal across all five columns, in favor of the alternative hypothesis that at least one column has a different variance.

## Input Arguments

### **x** — Sample data

matrix | vector

Sample data, specified as a matrix or vector. If a grouping variable group is specified, `x` must be a vector. If a grouping variable is not specified, `x` must be a matrix. In either case, `vartestn` treats NaN values as missing values and ignores them.

Data Types: `single` | `double`

### **group** — Grouping variable

categorical array | logical or numeric vector | cell array of strings

Grouping variable, specified as a categorical array, logical or numeric vector, or cell array of strings with one row for each element of `x`. Each unique value in a grouping variable defines a group.

For example, if `Gender` is a cell array of strings with values `'Male'` and `'Female'`, you can use `Gender` as a grouping variable to test your data by gender.

Example: `Gender`

Data Types: `single` | `double` | `logical` | `cell` | `char`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( `' '` ). You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `'TestType', 'BrownForsythe', 'Display', 'off'` specifies a Brown-Forsythe test and omits the plot of the results.

### 'Display' — Display settings for test results

`'on'` (default) | `'off'`

Display settings for test results, specified as the comma-separated pair consisting of `'Display'` and one of the following.

`'on'`                    Display a box plot and table of summary statistics.

`'off'`                    Do not display a box plot and table of summary statistics.

Example: `'display', 'off'`

### 'TestType' — Type of hypothesis test

`'Bartlett'` (default) | `'LeveneQuadratic'` | `'LeveneAbsolute'` |  
`'BrownForsythe'` | `'OBrien'`

Type of hypothesis test to perform, specified as the comma-separated pair consisting of `'TestType'` and one of the following.

`'Bartlett'`                    Bartlett's test.

`'LeveneQuadratic'`            Levene's test computed by performing ANOVA on the squared deviations of the data values from their group means.

`'LeveneAbsolute'`            Levene's test computed by performing ANOVA on the absolute deviations of the data values from their group means.

`'BrownForsythe'`            Brown-Forsythe test computed by performing ANOVA on the absolute deviations of the data values from the group medians.

`'OBrien'`                    O'Brien's modification of Levene's test with  $W = 0.5$ .

Example: `'TestType', 'OBrien'`

## Output Arguments

### **p** — *p*-value

scalar value in the range [0,1]

*p*-value of the test, returned as a scalar value in the range [0,1]. *p* is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. Small values of *p* cast doubt on the validity of the null hypothesis.

### **stats** — Test statistics

structure

Test statistics for the hypothesis test, returned as a structure containing:

- **chistat**: Value of the test statistic.
- **df**: Degrees of freedom of the test.

## More About

### **Bartlett's Test**

Bartlett's test is used to test whether multiple data samples have equal variances, against the alternative that at least two of the data samples do not have equal variances.

The test statistic is

$$T = \frac{(N - k) \ln s_p^2 - \sum_{i=1}^k (N_i - 1) \ln s_i^2}{1 + (1 / (3(k - 1))) \left( \left( \sum_{i=1}^k 1 / (N_i - 1) \right) - 1 / (N - k) \right)},$$

where  $s_i^2$  is the variance of the *i*th group, *N* is the total sample size, *N<sub>i</sub>* is the sample size of the *i*th group, *k* is the number of groups, and  $s_p^2$  is the pooled variance. The pooled variance is defined as

$$s_p^2 = \sum_{i=1}^k (N_i - 1) s_i^2 / (N - k).$$

The test statistic has a chi-square distribution with  $k - 1$  degrees of freedom under the null hypothesis.

Bartlett's test is sensitive to departures from normality. If your data comes from a nonnormal distribution, Levene's test could provide a more accurate result.

### Levene, Brown-Forsythe, and O'Brien Tests

The Levene, Brown-Forsythe, and O'Brien tests are used to test if multiple data samples have equal variances, against the alternative that at least two of the data samples do not have equal variances.

The test statistic is

$$W = \frac{(N - k) \sum_{i=1}^k N_i (\bar{Z}_{i.} - \bar{Z}_{..})^2}{(k - 1) \sum_{i=1}^k \sum_{j=1}^{N_i} (Z_{ij} - \bar{Z}_{i.})^2},$$

where  $N_i$  is the sample size of the  $i$ th group, and  $k$  is the number of groups. Depending on the type of test specified with the `TestType` name-value pair arguments,  $Z_{ij}$  can have one of four definitions:

- If you specify `LeveneAbsolute`, `vartestn` uses  $Z_{ij} = |Y_{ij} - \bar{Y}_{i.}|$ , where  $\bar{Y}_{i.}$  is the mean of the  $i$ th subgroup.
- If you specify `LeveneQuadratic`, `vartestn` uses  $Z_{ij}^2 = (Y_{ij} - \bar{Y}_{i.})^2$ , where  $\bar{Y}_{i.}$  is the mean of the  $i$ th subgroup.
- If you specify `BrownForsythe`, `vartestn` uses  $Z_{ij} = |Y_{ij} - \tilde{Y}_{i.}|$ , where  $\tilde{Y}_{i.}$  is the median of the  $i$ th subgroup.
- If you specify `OBrien`, `vartestn` uses

$$Z_{ij} = \frac{(0.5 + n_i - 2)n_i (y_{ij} - \bar{y}_i)^2 - 0.5(n_i - 1)\sigma_i^2}{(n_i - 1)(n_i - 2)},$$

where  $n_i$  is the size of the  $i$ th group,  $\sigma_i^2$  is its sample variance.

In all cases, the test statistic has an  $F$ -distribution with  $k - 1$  numerator degrees of freedom, and  $N - k$  denominator degrees of freedom.

The Levene, Brown-Forsythe, and O'Brien tests are less sensitive to departures from normality than Bartlett's test, so they are useful alternatives if you suspect the samples come from nonnormal distributions.

## vertcat

**Class:** dataset

Vertical concatenation for dataset arrays

## Compatibility

The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

## Syntax

```
ds = vertcat(ds1, ds2, ...)
```

## Description

`ds = vertcat(ds1, ds2, ...)` vertically concatenates the dataset arrays `ds1`, `ds2`, ... . Observation names, when present, must be unique across datasets. `vertcat` fills in default observation names for the output when some of the inputs have names and some do not.

Variable names for all dataset arrays must be identical except for order. `vertcat` concatenates by matching variable names. `vertcat` assigns values for the "per-variable" properties (e.g., `Units` and `VarDescription`) in `ds` from the corresponding property values in `ds1`.

## See Also

`cat` | `horzcat`

# view

**Class:** `classregtree`

Plot tree

## Syntax

```
view(t)
view(t,param1,va11,param2,va12,...)
```

## Description

`view(t)` displays the decision tree `t` as computed by `classregtree` in a figure window. Each branch in the tree is labeled with its decision rule, and each terminal node is labeled with the predicted value for that node. Click any node to get more information about it. The information displayed is specified by the **Click to display** pop-up menu at the top of the figure.

`view(t,param1,va11,param2,va12,...)` specifies optional parameter name/value pairs:

- `'names'` — A cell array of names for the predictor variables, in the order in which they appear in the matrix `X` from which the tree was created. (See `classregtree`.)
- `'prunelevel'` — Initial pruning level to display.

For each branch node, the left child node corresponds to the points that satisfy the condition, and the right child node corresponds to the points that do not satisfy the condition.

## Examples

Create a classification tree for Fisher's iris data:

```
load fisheriris;
```

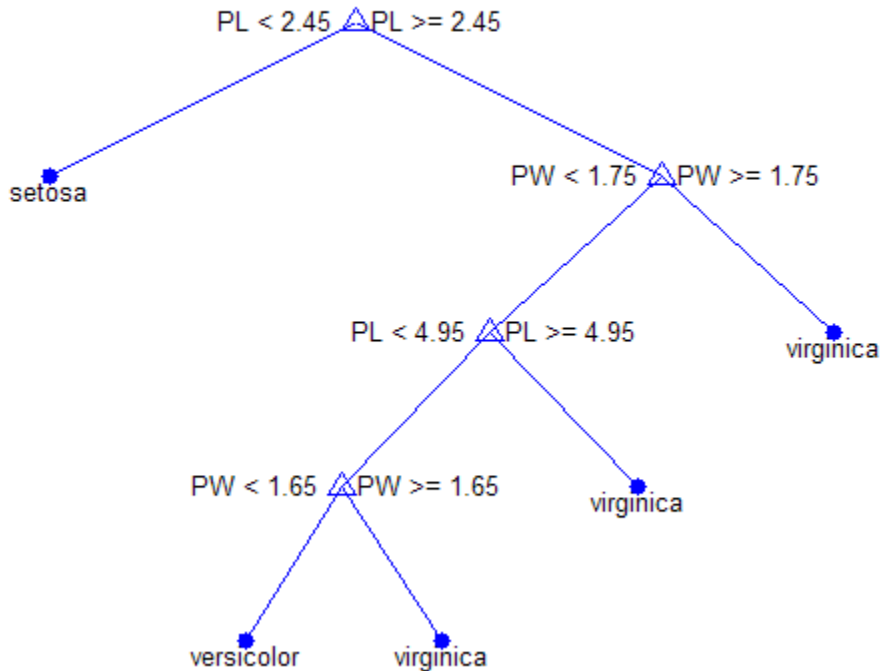

```

t = classregtree(meas,species,...
 'names',{'SL' 'SW' 'PL' 'PW'})
t =
Decision tree for classification
1 if PL<2.45 then node 2 elseif PL>=2.45 then node 3 else setosa
2 class = setosa
3 if PW<1.75 then node 4 elseif PW>=1.75 then node 5 else versicolor
4 if PL<4.95 then node 6 elseif PL>=4.95 then node 7 else versicolor
5 class = virginica
6 if PW<1.65 then node 8 elseif PW>=1.65 then node 9 else versicolor
7 class = virginica
8 class = versicolor
9 class = virginica

view(t)

```

Click to display:  Magnification:  Pruning level:

---

## compact

**Class:** clustering.evaluation.ClusterCriterion

**Package:** clustering.evaluation

Compact clustering evaluation object

## Syntax

```
c = compact(eva)
```

## Description

`c = compact(eva)` returns a compact clustering evaluation object, which contains a subset of information about the clustering solution in `eva`. Compacting a clustering evaluation object reduces the memory requirements of the object, which is useful when clustering a large data set.

## Input Arguments

**eva** — Clustering evaluation data

clustering evaluation object

Clustering evaluation data, specified as a clustering evaluation object. Create a clustering evaluation object using `evalclusters`.

## Output Arguments

**c** — Compact clustering evaluation object

clustering evaluation object

Compact clustering evaluation object, returned as a clustering evaluation object. The compact object includes the clustering evaluation results. In the compact object, the properties for the input data `X`, optimal clustering solution `OptimalY`, and the list of excluded data `Missing` are empty.

## Examples

### Create a Compact Clustering Evaluation Object

Create a compact clustering evaluation object from a full clustering evaluation object.

Load the sample data.

```
load fisheriris;
```

The data contains length and width measurements from the sepals and petals of three species of iris flowers.

Create a clustering evaluation object. Cluster the data using `kmeans`, and evaluate the optimal number of clusters using the gap criterion.

```
rng('default'); % For reproducibility
eva = evalclusters(meas,'kmeans','Gap','KList',[1:6])
```

```
eva =
```

```
GapEvaluation with properties:
```

```
NumObservations: 150
 InspectedK: [1 2 3 4 5 6]
CriterionValues: [0.0747 0.5906 0.8737 1.0055 1.0466 0.9848]
 OptimalK: 4
```

Create a compact clustering evaluation object from `eva`.

```
c = compact(eva)
```

```
c =
```

```
GapEvaluation with properties:
```

```
NumObservations: 150
 InspectedK: [1 2 3 4 5 6]
CriterionValues: [0.0747 0.5906 0.8737 1.0055 1.0466 0.9848]
 OptimalK: 4
```

The displayed output of the compact object `c` is the same as the original object `eva`, but some properties not shown in the display are different. For example, in the compact object, the properties `x`, `OptimalY`, and `Missing` are empty.

Display the optimal clustering solution `OptimalY` for `c`.

```
c.OptimalY
```

```
ans =
```

```
 []
```

### **See Also**

`evalclusters`

## view

**Class:** CompactClassificationTree

View tree

## Syntax

```
view(tree)
view(tree,Name,Value)
```

## Description

`view(tree)` returns a text description of `tree`, a decision tree.

`view(tree,Name,Value)` describes `tree` with additional options specified by one or more `Name,Value` pair arguments.

## Input Arguments

### **tree**

A classification tree or compact classification tree created by `fitctree` or `compact`.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### **'Mode'**

String describing the display of `tree`, either `'graph'` or `'text'`. `'graph'` opens a user interface displaying `tree`, and containing controls for querying the tree. `'text'` sends output to the Command Window describing `tree`.

**Default:** `'text'`

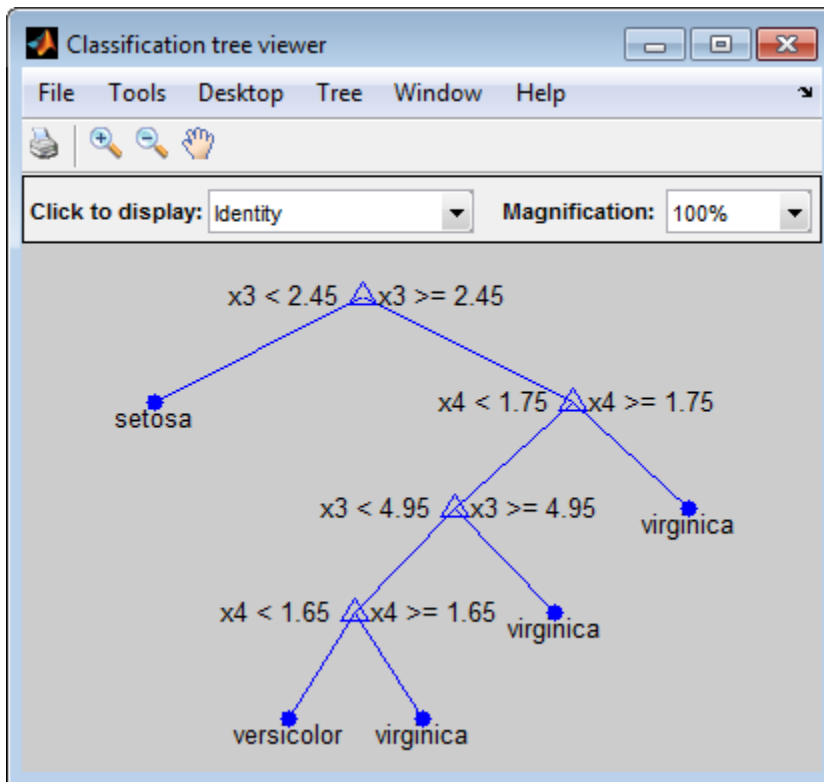

## Examples

View the classification tree for Fisher's iris model in both textual and graphical displays:

```
load fisheriris
tree = fitctree(meas,species);
view(tree)
```

```
Decision tree for classification
1 if x3<2.45 then node 2 elseif x3>=2.45 then node 3 else setosa
2 class = setosa
3 if x4<1.75 then node 4 elseif x4>=1.75 then node 5 else versicolor
4 if x3<4.95 then node 6 elseif x3>=4.95 then node 7 else versicolor
5 class = virginica
6 if x4<1.65 then node 8 elseif x4>=1.65 then node 9 else versicolor
7 class = virginica
8 class = versicolor
9 class = virginica
```

```
view(tree,'Mode','graph')
```

## **See Also**

`ClassificationTree` | `fitctree`

## view

**Class:** CompactRegressionTree

View tree

## Syntax

```
view(tree)
view(tree,Name,Value)
```

## Description

`view(tree)` returns a text description of `tree`, a decision tree.

`view(tree,Name,Value)` describes `tree` with additional options specified by one or more `Name,Value` pair arguments.

## Input Arguments

### **tree**

A regression tree or compact regression tree created by `fitrtree` or `compact`.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### **'Mode'**

String describing the display of `tree`, either `'graph'` or `'text'`. `'graph'` opens a GUI displaying `tree`, and containing controls for querying the tree. `'text'` sends output to the Command Window describing `tree`.

**Default:** `'text'`

## Examples

View a regression tree for the `carsmall` data in both textual and graphical displays:

```
load carsmall
tree = fitrtree([Weight, Cylinders],MPG,...
 'categoricalpredictors',2,'MinParent',20,...
 'PredictorNames',{'W','C'});
view(tree)

Decision tree for regression
 1 if W<3085.5 then node 2 elseif W>=3085.5 then node 3 else 23.7181
 2 if W<2371 then node 4 elseif W>=2371 then node 5 else 28.7931
 3 if C=8 then node 6 elseif C in {4 6} then node 7 else 15.5417
 4 if W<2162 then node 8 elseif W>=2162 then node 9 else 32.0741
 5 if C=6 then node 10 elseif C=4 then node 11 else 25.9355
 6 if W<4381 then node 12 elseif W>=4381 then node 13 else 14.2963
 7 fit = 19.2778
 8 fit = 33.3056

## wblcdf

Weibull cumulative distribution function

### Syntax

```
p = wblcdf(x,a,b)
[p,plo,pup] = wblcdf(x,a,b,pcov,alpha)
[p,plo,pup] = wblcdf(____, 'upper')
```

### Description

`p = wblcdf(x,a,b)` returns the cdf of the Weibull distribution with scale parameter `a` and shape parameter `b`, at each value in `x`. `x`, `a`, and `b` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array of the same size as the other inputs. The default values for `a` and `b` are both 1. The parameters `a` and `b` must be positive.

`[p,plo,pup] = wblcdf(x,a,b,pcov,alpha)` returns confidence bounds for `p` when the input parameters `a` and `b` are estimates. `pcov` is the 2-by-2 covariance matrix of the estimated parameters. `alpha` has a default value of 0.05, and specifies  $100(1 - \text{alpha})\%$  confidence bounds. `plo` and `pup` are arrays of the same size as `p` containing the lower and upper confidence bounds.

`[p,plo,pup] = wblcdf( ____, 'upper' )` returns the complement of the Weibull cdf for each value in `x`, using an algorithm that more accurately computes the extreme upper tail probabilities. You can use `'upper'` with any of the previous syntaxes.

The function `wblcdf` computes confidence bounds for `p` using a normal approximation to the distribution of the estimate

$$\hat{b}(\log x - \log \hat{a})$$

and then transforms those bounds to the scale of the output `p`. The computed bounds give approximately the desired confidence level when you estimate `mu`, `sigma`, and `pcov` from large samples, but in smaller samples other methods of computing the confidence bounds might be more accurate.

The Weibull cdf is

$$p = F(x | a, b) = \int_0^x b a^{-b} t^{b-1} e^{-\left(\frac{t}{a}\right)^b} dt = 1 - e^{-\left(\frac{x}{a}\right)^b} I_{(0, \infty)}(x)$$

## Examples

### Weibull Distribution cdf

What is the probability that a value from a Weibull distribution with parameters  $a = 0.15$  and  $b = 0.8$  is less than 0.5?

```
probability = wblcdf(0.5, 0.15, 0.8)
```

```
probability =
0.9272
```

How sensitive is this result to small changes in the parameters?

```
[A, B] = meshgrid(0.1:0.05:0.2, 0.2:0.05:0.3);
probability = wblcdf(0.5, A, B)
```

```
probability =
0.7484 0.7198 0.6991
0.7758 0.7411 0.7156
0.8022 0.7619 0.7319
```

## wblfit

Weibull parameter estimates

### Syntax

```
parmhat = wblfit(data)
[parmhat,parmci] = wblfit(data)
[parmhat,parmci] = wblfit(data,alpha)
[...] = wblfit(data,alpha,censoring)
[...] = wblfit(data,alpha,censoring,freq)
[...] = wblfit(...,options)
```

### Description

`parmhat = wblfit(data)` returns the maximum likelihood estimates, `parmhat`, of the parameters of the Weibull distribution given the values in the vector `data`, which must be positive. `parmhat` is a two-element row vector: `parmhat(1)` estimates the Weibull parameter  $a$ , and `parmhat(2)` estimates the Weibull parameter  $b$ , in the pdf

$$y = f(x | a, b) = ba^{-b} x^{b-1} e^{-\left(\frac{x}{a}\right)^b} I_{(0, \infty)}(x)$$

`[parmhat,parmci] = wblfit(data)` returns 95% confidence intervals for the estimates of  $a$  and  $b$  in the 2-by-2 matrix `parmci`. The first row contains the lower bounds of the confidence intervals for the parameters, and the second row contains the upper bounds of the confidence intervals.

`[[parmhat,parmci] = wblfit(data,alpha)` returns  $100(1 - \text{alpha})\%$  confidence intervals for the parameter estimates.

`[...] = wblfit(data,alpha,censoring)` accepts a Boolean vector, `censoring`, of the same size as `data`, which is 1 for observations that are right-censored and 0 for observations that are observed exactly.

`[...] = wblfit(data,alpha,censoring,freq)` accepts a frequency vector, `freq`, of the same size as `data`. The vector `freq` typically contains integer frequencies for the

corresponding elements in `data`, but can contain any non-negative values. Pass in `[]` for `alpha`, `censoring`, or `freq` to use their default values.

`[...] = wblfit(...,options)` accepts a structure, `options`, that specifies control parameters for the iterative algorithm the function uses to compute maximum likelihood estimates. The Weibull fit function accepts an `options` structure that can be created using the function `statset`. Enter `statset ('wblfit')` to see the names and default values of the parameters that `lognfit` accepts in the `options` structure. See the reference page for `statset` for more information about these options.

## Examples

```
data = wblrnd(0.5,0.8,100,1);
[parmhat, parmci] = wblfit(data)
parmhat =
 0.5861 0.8567
parmci =
 0.4606 0.7360
 0.7459 0.9973
```

## wblinv

Weibull inverse cumulative distribution function

### Syntax

```
X = wblinv(P,A,B)
[X,XLO,XUP] = wblinv(P,A,B,PCOV,alpha)
```

### Description

`X = wblinv(P,A,B)` returns the inverse cumulative distribution function (cdf) for a Weibull distribution with scale parameter `A` and shape parameter `B`, evaluated at the values in `P`. `P`, `A`, and `B` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array of the same size as the other inputs. The default values for `A` and `B` are both 1.

`[X,XLO,XUP] = wblinv(P,A,B,PCOV,alpha)` returns confidence bounds for `X` when the input parameters `A` and `B` are estimates. `PCOV` is a 2-by-2 matrix containing the covariance matrix of the estimated parameters. `alpha` has a default value of 0.05, and specifies 100(1 - `alpha`)% confidence bounds. `XLO` and `XUP` are arrays of the same size as `X` containing the lower and upper confidence bounds.

The function `wblinv` computes confidence bounds for `X` using a normal approximation to the distribution of the estimate

$$\log a + \frac{\log q}{b}$$

where  $q$  is the  $P$ th quantile from a Weibull distribution with scale and shape parameters both equal to 1. The computed bounds give approximately the desired confidence level when you estimate `mu`, `sigma`, and `PCOV` from large samples, but in smaller samples other methods of computing the confidence bounds might be more accurate.

The inverse of the Weibull cdf is

$$x = F^{-1}(p | a, b) = -a \left[ \ln(1 - p) \right]^{1/b} I_{[0,1]}(p)$$

## Examples

The lifetimes (in hours) of a batch of light bulbs has a Weibull distribution with parameters  $a = 200$  and  $b = 6$ .

Find the median lifetime of the bulbs:

```
life = wblinv(0.5, 200, 6)
life =
 188.1486
```

Generate 100 random values from this distribution, and estimate the 90th percentile (with confidence bounds) from the random sample

```
x = wblrnd(200,6,100,1);
p = wblfit(x)
[nlogl,pcov] = wbllike(p,x)
[q90,q90lo,q90up] = wblinv(0.9,p(1),p(2),pcov)
p =
```

```
 204.8918 6.3920
```

```
nlogl =
```

```
 496.8915
```

```
pcov =
```

```
 11.3392 0.5233
 0.5233 0.2573
```

```
q90 =
```

```
 233.4489
```

```
q90lo =
```

```
 226.0092
```

q90up =

241.1335

## **More About**

## **See Also**

icdf | wblcdf | wblpdf | wblstat | wblfit | wbllike | wblrnd

# wbllike

Weibull negative log-likelihood

## Syntax

```
nlogL = wbllike(params,data)
[logL,AVAR] = wbllike(params,data)
[...] = wbllike(params,data,censoring)
[...] = wbllike(params,data,censoring,freq)
```

## Description

`nlogL = wbllike(params,data)` returns the Weibull log-likelihood. `params(1)` is the scale parameter, `A`, and `params(2)` is the shape parameter, `B`.

`[logL,AVAR] = wbllike(params,data)` also returns `AVAR`, which is the asymptotic variance-covariance matrix of the parameter estimates if the values in `params` are the maximum likelihood estimates. `AVAR` is the inverse of Fisher's information matrix. The diagonal elements of `AVAR` are the asymptotic variances of their respective parameters.

`[...] = wbllike(params,data,censoring)` accepts a Boolean vector, `censoring`, of the same size as `data`, which is 1 for observations that are right-censored and 0 for observations that are observed exactly.

`[...] = wbllike(params,data,censoring,freq)` accepts a frequency vector, `freq`, of the same size as `data`. `freq` typically contains integer frequencies for the corresponding elements in `data`, but can contain any nonnegative values. Pass in `[]` for `censoring` to use its default value.

The Weibull negative log-likelihood for uncensored data is

$$(-\log L) = -\log \prod_{i=1} f(a,b | x_i) = -\sum_{i=1}^n \log f(a,b | x_i)$$

where  $f$  is the Weibull pdf.

wbllike is a utility function for maximum likelihood estimation.

## Examples

This example continues the example from `wblfit`.

```
r = wblrnd(0.5,0.8,100,1);
[logL, AVAR] = wbllike(wblfit(r),r)
logL =
 47.3349
AVAR =
 0.0048 0.0014
 0.0014 0.0040
```

# wblpdf

Weibull probability density function

## Syntax

`Y = wblpdf(X,A,B)`

## Description

`Y = wblpdf(X,A,B)` computes the Weibull pdf at each of the values in `X` using the corresponding scale parameter, `A` and shape parameter, `B`. `X`, `A`, and `B` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array of the same size as the other inputs. The parameters in `A` and `B` must be positive.

The Weibull pdf is

$$f(x | a, b) = \frac{b}{a} \left( \frac{x}{a} \right)^{b-1} e^{-(x/a)^b}.$$

Some references refer to the Weibull distribution with a single parameter. This corresponds to `wblpdf` with `A = 1`.

## Examples

The exponential distribution is a special case of the Weibull distribution.

```
lambda = 1:6;
y = wblpdf(0.1:0.1:0.6,lambda,1)
y =
 0.9048 0.4524 0.3016 0.2262 0.1810 0.1508

y1 = exppdf(0.1:0.1:0.6,lambda)
y1 =
 0.9048 0.4524 0.3016 0.2262 0.1810 0.1508
```

# wblplot

Weibull probability plot

## Syntax

```
wblplot(X)
h = wblplot(X)
```

## Description

`wblplot(X)` displays a Weibull probability plot of the data in `X`. If `X` is a matrix, `wblplot` displays a plot for each column.

`h = wblplot(X)` returns handles to the plotted lines.

The purpose of a Weibull probability plot is to graphically assess whether the data in `X` could come from a Weibull distribution. If the data are Weibull the plot will be linear. Other distribution types might introduce curvature in the plot. `wblplot` uses midpoint probability plotting positions. Use `probplot` when the data included censored observations.

## Examples

### Create a Weibull Probability Plot

Generate a vector `r` containing 50 random numbers from a Weibull distribution with parameters `A = 1.2` and `B = 1.5`.

```
rng default; % For reproducibility
r = wblrnd(1.2,1.5,50,1);
```

Create a Weibull probability plot to visually determine if the data comes from a Weibull distribution.

```
figure;
```

```
wblplot(r)
```

The plot indicates that the data likely comes from a Weibull distribution.

## wblrnd

Weibull random numbers

### Syntax

```
R = wblrnd(A,B)
R = wblrnd(A,B,m,n,...)
R = wblrnd(A,B,[m,n,...])
```

### Description

`R = wblrnd(A,B)` generates random numbers for the Weibull distribution with scale parameter, `A` and shape parameter, `B`. The input arguments `A` and `B` can be either scalars or matrices. `A` and `B`, can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array of the same size as the other input.

`R = wblrnd(A,B,m,n,...)` or `R = wblrnd(A,B,[m,n,...])` generates an `m`-by-`n`-by-... array. The `A`, `B` parameters can each be scalars or arrays of the same size as `R`.

Devroye [1] refers to the Weibull distribution with a single parameter; this is `wblrnd` with `A = 1`.

### Examples

```
n1 = wblrnd(0.5:0.5:2,0.5:0.5:2)
n1 =
 0.0178 0.0860 2.5216 0.9124
```

```
n2 = wblrnd(1/2,1/2,[1 6])
n2 =
 0.0046 1.7214 2.2108 0.0367 0.0531 0.0917
```

## wblstat

Weibull mean and variance

### Syntax

```
[M,V] = wblstat(A,B)
```

### Description

`[M,V] = wblstat(A,B)` returns the mean of and variance for the Weibull distribution with scale parameter, **A** and shape parameter, **B**. Vector or matrix inputs for **A** and **B** must have the same size, which is also the size of **M** and **V**. A scalar input for **A** or **B** is expanded to a constant matrix with the same dimensions as the other input.

The mean of the Weibull distribution with parameters  $a$  and  $b$  is

$$a \left[ \Gamma(1+b^{-1}) \right]$$

and the variance is

$$a^2 \left[ \Gamma(1+2b^{-1}) - \Gamma(1+b^{-1})^2 \right]$$

### Examples

```
[m,v] = wblstat(1:4,1:4)
m =
 1.0000 1.7725 2.6789 3.6256
v =
 1.0000 0.8584 0.9480 1.0346

wblstat(0.5,0.7)
ans =
 0.6329
```

## prob.WeibullDistribution class

**Package:** prob

**Superclasses:** prob.ToolboxFittableParametricDistribution

Weibull probability distribution object

### Description

`prob.WeibullDistribution` is an object consisting of parameters, a model description, and sample data for a Weibull probability distribution.

Create a probability distribution object with specified parameter values using `makedist`. Alternatively, fit a distribution to data using `fitdist` or the Distribution Fitting app.

### Construction

`pd = makedist('Weibull')` creates a Weibull probability distribution object using the default parameter values.

`pd = makedist('Weibull', 'a', a, 'b', b)` creates a Weibull probability distribution object using the specified parameter values.

### Input Arguments

#### **a** — Scale parameter

1 (default) | positive scalar value

Scale parameter of the Weibull distribution, specified as a positive scalar value.

Data Types: `single` | `double`

#### **b** — Shape parameter

1 (default) | positive scalar value

Shape parameter of the Weibull distribution, specified as a positive scalar value.

Data Types: `single` | `double`

## Properties

### **a** — Scale parameter

positive scalar value

Scale parameter of the Weibull distribution, stored as a positive scalar value.

Data Types: `single` | `double`

### **b** — Shape parameter

positive scalar value

Shape parameter of the Weibull distribution, stored as a positive scalar value.

Data Types: `single` | `double`

### **DistributionName** — Probability distribution name

probability distribution name string

Probability distribution name, stored as a valid probability distribution name string. This property is read-only.

Data Types: `char`

### **InputData** — Data used for distribution fitting

structure

Data used for distribution fitting, stored as a structure containing the following:

- **data**: Data vector used for distribution fitting.
- **cens**: Censoring vector, or empty if none.
- **freq**: Frequency vector, or empty if none.

This property is read-only.

Data Types: `struct`

### **IsTruncated** — Logical flag for truncated distribution

0 | 1

Logical flag for truncated distribution, stored as a logical value. If `IsTruncated` equals 0, the distribution is not truncated. If `IsTruncated` equals 1, the distribution is truncated. This property is read-only.

Data Types: `logical`

**NumParameters** — Number of parameters

positive integer value

Number of parameters for the probability distribution, stored as a positive integer value. This property is read-only.

Data Types: single | double

**ParameterCovariance** — Covariance matrix of the parameter estimates

matrix of scalar values

Covariance matrix of the parameter estimates, stored as a  $p$ -by- $p$  matrix, where  $p$  is the number of parameters in the distribution. The  $(i, j)$  element is the covariance between the estimates of the  $i$ th parameter and the  $j$ th parameter. The  $(i, i)$  element is the estimated variance of the  $i$ th parameter. If parameter  $i$  is fixed rather than estimated by fitting the distribution to data, then the  $(i, i)$  elements of the covariance matrix are 0. This property is read-only.

Data Types: single | double

**ParameterDescription** — Distribution parameter descriptions

cell array of strings

Distribution parameter descriptions, stored as a cell array of strings. Each cell contains a short description of one distribution parameter. This property is read-only.

Data Types: char

**ParameterIsFixed** — Logical flag for fixed parameters

array of logical values

Logical flag for fixed parameters, stored as an array of logical values. If 0, the corresponding parameter in the `ParameterNames` array is not fixed. If 1, the corresponding parameter in the `ParameterNames` array is fixed. This property is read-only.

Data Types: logical

**ParameterNames** — Distribution parameter names

cell array of strings

Distribution parameter names, stored as a cell array of strings. This property is read-only.

Data Types: char

**ParameterValues — Distribution parameter values**

vector of scalar values

Distribution parameter values, stored as a vector. This property is read-only.

Data Types: `single` | `double`

**Truncation — Truncation interval**

vector of scalar values

Truncation interval for the probability distribution, stored as a vector containing the lower and upper truncation boundaries. This property is read-only.

Data Types: `single` | `double`

## Methods

## Definitions

### Weibull Distribution

The Weibull distribution is used in reliability and lifetime modeling, and to model the breaking strength of materials.

The Weibull distribution uses the following parameters.

| Parameter | Description     | Support |
|-----------|-----------------|---------|
| a         | Scale parameter | $a > 0$ |
| b         | Shape parameter | $b > 0$ |

The probability density function (pdf) is

$$f(x | a, b) = \frac{b}{a} \left(\frac{x}{a}\right)^{b-1} \exp\left\{-\left(\frac{x}{a}\right)^b\right\} ; x \geq 0 .$$

## Examples

### Create a Weibull Distribution Object Using Default Parameters

Create a Weibull distribution object using the default parameter values.

```
pd = makedist('Weibull')
```

```
pd =
```

```
WeibullDistribution
```

```
Weibull distribution
```

```
A = 1
```

```
B = 1
```

### Create a Weibull Distribution Object Using Specified Parameter Values

Create a Weibull distribution object by specifying the parameter values.

```
pd = makedist('Weibull','a',2,'b',5)
```

```
pd =
```

```
WeibullDistribution
```

```
Weibull distribution
```

```
A = 2
```

```
B = 5
```

Compute the mean of the distribution.

```
m = mean(pd)
```

```
m =
```

```
1.8363
```

# wishrnd

Wishart random numbers

## Syntax

```
W = wishrnd(Sigma,df)
W = wishrnd(Sigma,df,D)
[W,D] = wishrnd(Sigma,df)
```

## Description

`W = wishrnd(Sigma,df)` generates a random matrix `W` having the Wishart distribution with covariance matrix `Sigma` and with `df` degrees of freedom. The inverse of `W` has the Inverse Wishart distribution with parameters `Tau = inv(Sigma)` and `df` degrees of freedom.

`W = wishrnd(Sigma,df,D)` expects `D` to be the Cholesky factor of `Sigma`. If you call `wishrnd` multiple times using the same value of `Sigma`, it's more efficient to supply `D` instead of computing it each time.

`[W,D] = wishrnd(Sigma,df)` returns `D` so you can provide it as input in future calls to `wishrnd`.

This function defines the parameter `Sigma` so that the mean of the output matrix is `Sigma*df`

## More About

`iwishrnd`

## X property

**Class:** TreeBagger

X data used to create ensemble

### Description

The X property is a numeric matrix of size **Nobs**-by-**Nvars**, where **Nobs** is the number of observations (rows) and **Nvars** is the number of variables (columns) in the training data. This matrix contains the predictor (or feature) values.

# xptread

Create table from data stored in SAS XPORT format file

## Syntax

```
data = xptread
data = xptread(filename)
[data,missing] = xptread(filename)
xptread(..., 'ReadObsNames', true)
```

## Description

`data = xptread` displays a dialog box for selecting a file, then reads data from the file into a table. The file must be in the SAS XPORT format.

`data = xptread(filename)` retrieves data from a SAS XPORT format file `filename`. The XPORT format allows for 28 missing data types, represented in the file by an upper case letter, '.' or '\_'. `xptread` converts all missing data to NaN values in `data`. However, if you need the specific missing types then you can recover this information by specifying a second output.

`[data,missing] = xptread(filename)` returns a nominal array, `missing`, of the same size as `data` containing the missing data type information from the `xport` format file. The entries are undefined for values that are not present and are one of '.', '\_', 'A', ..., 'Z' for missing values.

`xptread(..., 'ReadObsNames', true)` treats the first variable in the file as observation names. The default value is false.

`xptread` only supports single data sets per file. `xptread` does not support compressed files.

## Examples

### Read In SAS XPORT Data

Read in SAS XPORT format data.

```
data = xptread('sample.xpt');
```

### **See Also**

table

## x2fx

Convert predictor matrix to design matrix

### Syntax

```
D = x2fx(X,model)
D = x2fx(X,model,categ)
D = x2fx(X,model,categ,catlevels)
```

### Description

`D = x2fx(X,model)` converts a matrix of predictors `X` to a design matrix `D` for regression analysis. Distinct predictor variables should appear in different columns of `X`.

The optional input `model` controls the regression model. By default, `x2fx` returns the design matrix for a linear additive model with a constant term. `model` is one of the following strings:

- 'linear' — Constant and linear terms. This is the default.
- 'interaction' — Constant, linear, and interaction terms
- 'quadratic' — Constant, linear, interaction, and squared terms
- 'purequadratic' — Constant, linear, and squared terms

If `X` has  $n$  columns, the order of the columns of `D` for a full quadratic model is:

- 1 The constant term
- 2 The linear terms (the columns of `X`, in order 1, 2, ...,  $n$ )
- 3 The interaction terms (pairwise products of the columns of `X`, in order (1, 2), (1, 3), ..., (1,  $n$ ), (2, 3), ..., ( $n-1$ ,  $n$ ))
- 4 The squared terms (in order 1, 2, ...,  $n$ )

Other models use a subset of these terms, in the same order.

Alternatively, `model` can be a matrix specifying polynomial terms of arbitrary order. In this case, `model` should have one column for each column in `X` and one row for each term in the model. The entries in any row of `model` are powers for the corresponding columns of `X`. For example, if `X` has columns `X1`, `X2`, and `X3`, then a row `[0 1 2]` in

*model* specifies the term  $(X1.^0) \cdot (X2.^1) \cdot (X3.^2)$ . A row of all zeros in *model* specifies a constant term, which can be omitted.

$D = x2fx(X, model, categ)$  treats columns with numbers listed in the vector *categ* as categorical variables. Terms involving categorical variables produce dummy variable columns in *D*. Dummy variables are computed under the assumption that possible categorical levels are completely enumerated by the unique values that appear in the corresponding column of *X*.

$D = x2fx(X, model, categ, catlevels)$  accepts a vector *catlevels* the same length as *categ*, specifying the number of levels in each categorical variable. In this case, values in the corresponding column of *X* must be integers in the range from 1 to the specified number of levels. Not all of the levels need to appear in *X*.

## Examples

### Example 1

The following converts 2 predictors *X1* and *X2* (the columns of *X*) into a design matrix for a full quadratic model with terms constant, *X1*, *X2*,  $X1 \cdot X2$ ,  $X1.^2$ , and  $X2.^2$ .

```
X = [1 10
 2 20
 3 10
 4 20
 5 15
 6 15];
```

```
D = x2fx(X, 'quadratic')
```

```
D =
 1 1 10 10 1 100
 1 2 20 40 4 400
 1 3 10 30 9 100
 1 4 20 80 16 400
 1 5 15 75 25 225
 1 6 15 90 36 225
```

### Example 2

The following converts 2 predictors *X1* and *X2* (the columns of *X*) into a design matrix for a quadratic model with terms constant, *X1*, *X2*,  $X1 \cdot X2$ , and  $X1.^2$ .

```
X = [1 10
 2 20
 3 10
 4 20
 5 15
 6 15];
model = [0 0
 1 0
 0 1
 1 1
 2 0];
```

```
D = x2fx(X,model)
```

```
D =
 1 1 10 10 1
 1 2 20 40 4
 1 3 10 30 9
 1 4 20 80 16
 1 5 15 75 25
 1 6 15 90 36
```

## **Y property**

**Class:** TreeBagger

Y data used to create ensemble

### **Description**

The Y property is an array of true class labels for classification, or response values for regression. Y can be a numeric column vector, a character matrix, or a cell array of strings.

## zscore

Standardized  $z$ -scores

### Syntax

```
Z = zscore(X)
Z = zscore(X, flag)
Z = zscore(X, flag, dim)
[Z, mu, sigma] = zscore(___)
```

### Description

`Z = zscore(X)` returns the  $z$ -score for each element of  $X$  such that columns of  $X$  are centered to have mean 0 and scaled to have standard deviation 1.  $Z$  is the same size as  $X$ .

- If  $X$  is a vector, then  $Z$  is a vector of  $z$ -scores.
- If  $X$  is a matrix, then  $Z$  is a matrix of the same size as  $X$ , and each column of  $Z$  has mean 0 and standard deviation 1.
- For multidimensional arrays,  $z$ -scores in  $Z$  are computed along the first nonsingleton dimension of  $X$ .

`Z = zscore(X, flag)` scales  $X$  using the standard deviation indicated by `flag`.

- If `flag` is 0 (default), then `zscore` scales  $X$  using the sample standard deviation, with  $n - 1$  in the denominator of the standard deviation formula. `zscore(X, 0)` is the same as `zscore(X)`.
- If `flag` is 1, then `zscore` scales  $X$  using the population standard deviation, with  $n$  in the denominator of standard deviation formula.

`Z = zscore(X, flag, dim)` standardizes  $X$  along dimension `dim`. For example, for a matrix  $X$ , if `dim = 1`, then `zscore` uses the means and standard deviations along the columns of  $X$ , if `dim = 2`, then `zscore` uses the means and standard deviations along the rows of  $X$ .

`[Z, mu, sigma] = zscore( ___ )` also returns the means and standard deviations used for centering and scaling, `mu` and `sigma`, respectively. You can use any of the input arguments in the previous syntaxes.

## Examples

### Z-Scores of Two Data Vectors

Compute and plot the  $z$ -scores of two data vectors, and then compare the results.

Load the sample data.

```
load('lawdata.mat')
```

Two variables load into the workspace: `gpa` and `lsat`.

Plot both variables on the same axes.

```
plot([gpa,lsat])
legend('gpa','lsat','Location','East')
```

It is difficult to compare these two measures because they are on a very different scale.

Plot the z-scores of `gpa` and `lsat` on the same axes.

```
Zgpa = zscore(gpa);
Zlsat = zscore(lsat);
plot([Zgpa, Zlsat])
legend('gpa z-scores', 'lsat z-scores', 'Location', 'Northeast')
```

Now, you can see the relative performance of individuals with respect to both their `gpa` and `lsat` results. For example, the third individual's `gpa` and `lsat` results are both one standard deviation below the sample mean. The eleventh individual's `gpa` is around the sample mean but has an `lsat` score almost 1.25 standard deviations above the sample average.

Check the mean and standard deviation of the z-scores you created.

```
mean([Zgpa,Zlsat])
```

```
ans =
```

```
1.0e-14 *
```

```

 -0.1088 0.0357

std([Zgpa,Zlsat])
ans =
 1 1

```

By definition, *z*-scores of *gpa* and *lsat* have mean 0 and standard deviation 1.

### Z-Scores for a Population vs. Sample

Load the sample data.

```
load('lawdata.mat')
```

Two variables load into the workspace: *gpa* and *lsat*.

Compute the *z*-scores of *gpa* using the population formula for standard deviation.

```
Z1 = zscore(gpa,1); % population formula
Z0 = zscore(gpa,0); % sample formula
disp([Z1 Z0])

```

```

1.2554 1.2128
0.8728 0.8432
-1.2100 -1.1690
-0.2749 -0.2656
1.4679 1.4181
-0.1049 -0.1013
-0.4024 -0.3888
1.4254 1.3771
1.1279 1.0896
0.1502 0.1451
0.1077 0.1040
-1.5076 -1.4565
-1.4226 -1.3743
-0.9125 -0.8815
-0.5724 -0.5530

```

For a sample from a population, the population standard deviation formula with  $n$  in the denominator corresponds to the maximum likelihood estimate of the population standard

deviation, and might be biased. The sample standard deviation formula, on the other hand, is the unbiased estimator of the population standard deviation for a sample.

### **Z-Scores of a Data Matrix**

Compute *z*-scores using the mean and standard deviation computed along the columns or rows of a data matrix.

Load the sample data.

```
load('flu.mat')
```

The dataset array `flu` is loaded in the workspace. `flu` has 52 observations on 11 variables. The first variable contains dates (in weeks). The other variables contain the flu estimates for different regions in the U.S.

Convert the dataset array to a data matrix.

```
flu2 = double(flu(:,2:end));
```

The new data matrix, `flu2`, is a 52-by-10 double data matrix. The rows correspond to the weeks and the columns correspond to the U.S. regions in the data set array `flu`.

Standardize the flu estimate for each region (the *columns* of `flu2`).

```
Z1 = zscore(flu2,[],1);
```

You can see the *z*-scores in the variable editor by double-clicking on the matrix `Z1` created in the workspace.

Standardize the flu estimate for each week (the *rows* of `flu2`).

```
Z2 = zscore(flu2,[],2);
```

### **Z-Scores, Mean, and Standard Deviation**

Return the mean and standard deviation used to compute the *z*-scores.

Load the sample data.

```
load('lawdata.mat')
```

Two variables load into the workspace: `gpa` and `lsat`.

Return the  $z$ -scores, mean, and standard deviation of `gpa`.

```
[Z,gpamean,gpastdev] = zscore(gpa)
```

```
Z =
```

```

```

```
gpamean =
```

```
 3.0947
```

```
gpastdev =
```

```
 0.2435
```

## Input Arguments

### **X** — Input data

vector | matrix | multidimensional array

Input data, specified as a vector, matrix, or multidimensional array.

Data Types: `double` | `single`

### **flag** — Indicator for the standard deviation

0 (default) | 1

Indicator for the standard deviation used to compute the  $z$ -scores, specified as 0 or 1.

- If `flag` is 0 (default), then `zscore` scales `X` using the sample standard deviation. `zscore(X,0)` is the same as `zscore(X)`.
- If `flag` is 1, then `zscore` scales `X` using the population standard deviation.

**dim — Dimension**

1 (default) | positive integer

Dimension along which to calculate the  $z$ -scores of `X`, specified as a positive integer. For example, for a matrix `X`, if `dim = 1`, then `zscore` uses the means and standard deviations along the columns of `X`, if `dim = 2`, then `zscore` uses the means and standard deviations along the rows of `X`.

## Output Arguments

**Z — z-scores**

vector | matrix | multidimensional array

$z$ -scores, returned as a vector, matrix, or multidimensional array. A vector of  $z$ -scores has mean 0 and variance 1.

- If `X` is a vector, then `Z` is a vector of  $z$ -scores.
- If `X` is an array, then `ZSCORE` is an array, with each column or row standardized to have mean 0 and variance 1 (depending on `dim`). If `dim` is not specified, `zscore` standardizes along the first nonsingleton dimension of `X`.

**mu — Mean**

scalar | vector

Mean of `X` used to compute the  $z$ -scores, returned as a scalar or vector.

- If `X` is a vector, then `mu` is a scalar.
- If `X` is a matrix, then `mu` is a row vector if `zscore` calculates the means along the columns of `X` (`dim = 1`), and a column vector if `zscore` calculates the means along the rows of `X` (`dim = 2`).

**sigma — Standard deviation**

scalar | vector

Standard deviation of `X` used to compute the  $z$ -scores, returned as a scalar or vector.

- If  $X$  is a vector, then `sigma` is a scalar.
- If  $X$  is a matrix, then `sigma` is a row vector if `zscore` calculates the standard deviations along the columns of  $X$  (`dim = 1`), and a column vector if `zscore` calculates the standard deviations along the rows of  $X$  (`dim = 2`).

## More About

### Z-Score

For a random variable  $X$  with mean  $\mu$  and standard deviation  $\sigma$ , the  $z$ -score of a value  $x$  is

$$z = \frac{(x - \mu)}{\sigma}.$$

For sample data with mean  $\bar{X}$  and standard deviation  $S$ , the  $z$ -score of a data point  $x$  is

$$z = \frac{(x - \bar{X})}{S}.$$

$z$ -scores measure the distance of a data point from the mean in terms of the standard deviation. This is also called *standardization* of data. The standardized data set has mean 0 and standard deviation 1, and retains the shape properties of the original data set (same skewness and kurtosis).

You can use  $z$ -scores to put data on the same scale before further analysis. This lets you to compare two or more data sets with different units.

### Multidimensional Array

A *multidimensional array* is an array with more than two dimensions. For example, if  $X$  is a 1-by-3-by-4 array, then  $X$  is a three-dimensional array.

### First Nonsingleton Dimension

A *first nonsingleton dimension* is the first dimension of an array whose size is not equal to 1. For example, if  $X$  is a 1-by-2-by-3-by-4 array, then the second dimension is the first nonsingleton dimension of  $X$ .

### Sample Standard Deviation

The *sample standard deviation*,  $S$ , is given by

$$S = \sqrt{\frac{\sum_{i=1}^n (x_i - \bar{X})^2}{n - 1}}.$$

$S$  is the square root of an unbiased estimator of the variance of the population from which  $X$  is drawn, as long as  $X$  consists of independent, identically distributed samples.

Notice that the denominator in this variance formula is  $n - 1$ .

### Population Standard Deviation

If the data is the entire population of values, then you can use the *population standard deviation*,

$$\sigma = \sqrt{\frac{\sum_{i=1}^n (x_i - \mu)^2}{n}}.$$

If  $X$  is a random sample from a population, then  $\mu$  is estimated by the sample mean, and  $\sigma$  is the biased maximum likelihood estimator of the population standard deviation.

Notice that the denominator in this variance formula is  $n$ .

### Algorithms

`zscore` returns NaNs for any sample containing NaNs.

`zscore` returns 0s for any sample that is constant (all values are the same). For example, if  $X$  is a vector of the same numeric value, then  $Z$  is a vector of 0s. If  $X$  is a matrix with a column of consisting of the same value, then that column of  $Z$  consists of 0s.

## ztest

z-test

### Syntax

```
h = ztest(x,m,sigma)
h= ztest(x,m,sigma,Name,Value)
[h,p] = ztest(____)
[h,p,ci,zval] = ztest(____)
```

### Description

`h = ztest(x,m,sigma)` returns a test decision for the null hypothesis that the data in the vector `x` comes from a normal distribution with mean `m` and a standard deviation `sigma`, using the *z*-test. The alternative hypothesis is that the mean is not `m`. The result `h` is 1 if the test rejects the null hypothesis at the 5% significance level, and 0 otherwise.

`h= ztest(x,m,sigma,Name,Value)` returns a test decision for the *z*-test with additional options specified by one or more name-value pair arguments. For example, you can change the significance level or conduct a one-sided test.

`[h,p] = ztest(____)` also returns the *p*-value of the test, using any of the input arguments from previous syntaxes.

`[h,p,ci,zval] = ztest(____)` also returns the confidence interval of the population mean, `ci`, and the value of the test statistic, `zval`.

### Examples

#### Test for a Hypothesized Mean

Load the sample data. Create a vector containing the first column of the students' exam grades data.

```
load examgrades;
```

```
x = grades(:,1);
```

Test the null hypothesis that the data comes from a normal distribution with mean  $m = 75$  and standard deviation  $\sigma = 10$ .

```
[h,p,ci,zval] = ztest(x,75,10)
```

```
h =
 0
```

```
p =
 0.9927
```

```
ci =
 73.2191
 76.7975
```

```
zval =
 0.0091
```

The returned value of  $h = 0$  indicates that `ztest` does not reject the null hypothesis at the default 5% significance level.

### One-Sided Hypothesis Test

Load the sample data. Create a vector containing the first column of the students' exam grades data.

```
load examgrades;
x = grades(:,1);
```

Test the null hypothesis that the data comes from a normal distribution with mean  $m = 65$  and standard deviation  $\sigma = 10$ , against the alternative that the mean is greater than 65.

```
[h,p] = ztest(x,65,10,'Tail','right')
```

```
h =
 1
```

```
p =
 2.8596e-28
```

The returned value of `h = 1` indicates that `ztest` rejects the null hypothesis at the default 5% significance level, in favor of the alternative hypothesis that the population mean is greater than 65.

## Input Arguments

### **x** — Sample data

vector | matrix | multidimensional array

Sample data, specified as a vector, matrix, or multidimensional array.

- If `x` is specified as a vector, `ztest` returns a single value for each output argument.
- If `x` is specified as a matrix, `ztest` performs a separate *z*-test along each column of `x` and returns a vector of results.
- If `x` is specified as a multidimensional array, `ztest` works along the first nonsingleton dimension of `x`.

In all cases, `ztest` treats NaN values as missing data and ignores them.

Data Types: `single` | `double`

### **m** — Hypothesized mean

scalar value

Hypothesized mean, specified as a scalar value.

Data Types: `single` | `double`

### **sigma** — Population standard deviation

scalar value

Population standard deviation, specified as a scalar value.

Data Types: `single` | `double`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single

quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'Tail', 'right', 'Alpha', 0.01` specifies a right-tailed hypothesis test at the 1% significance level.

#### **'Alpha' — Significance level**

0.05 (default) | scalar value in the range (0,1)

Significance level of the hypothesis test, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the range (0,1).

Example: `'Alpha', 0.01`

Data Types: `single` | `double`

#### **'Dim' — Dimension**

first nonsingleton dimension (default) | positive integer value

Dimension of the input matrix along which to test the means, specified as the comma-separated pair consisting of `'Dim'` and a positive integer value. For example, specifying `'Dim', 1` tests the column means, while `'Dim', 2` tests the row means.

Example: `'Dim', 2`

Data Types: `single` | `double`

#### **'Tail' — Type of alternative hypothesis**

`'both'` (default) | `'right'` | `'left'`

Type of alternative hypothesis to evaluate, specified as the comma-separated pair consisting of `'Tail'` and one of the following.

|                      |                                                                                |
|----------------------|--------------------------------------------------------------------------------|
| <code>'both'</code>  | Test the alternative hypothesis that the population mean is not equal to $m$ . |
| <code>'right'</code> | Test the alternative hypothesis that the population mean is greater than $m$ . |
| <code>'left'</code>  | Test the alternative hypothesis that the population mean is less than $m$ .    |

Example: `'Tail', 'right'`

## Output Arguments

### **h** — Hypothesis test result

1 | 0

Hypothesis test result, returned as a logical value.

- If  $h = 1$ , this indicates the rejection of the null hypothesis at the Alpha significance level.
- If  $h = 0$ , this indicates a failure to reject the null hypothesis at the Alpha significance level.

### **p** — *p*-value

scalar value in the range [0,1]

*p*-value of the test, returned as a scalar value in the range [0,1]. *p* is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. Small values of *p* cast doubt on the validity of the null hypothesis.

### **ci** — Confidence interval

vector

Confidence interval for the true population mean, returned as a two-element vector containing the lower and upper boundaries of the  $100 \times (1 - \text{Alpha})\%$  confidence interval.

### **zval** — Test statistic

nonnegative scalar value

Test statistic, returned as a nonnegative scalar value.

## More About

### **z-Test**

The *z*-test is a parametric hypothesis test used to determine whether a sample data set comes from a population with a particular mean. The test assumes the sample data comes from a population with a normal distribution and a known standard deviation.

The test statistic is

$$z = \frac{\bar{x} - \mu}{\sigma / \sqrt{n}},$$

where  $\bar{x}$  is the sample mean,  $\mu$  is the population mean,  $\sigma$  is the population standard deviation, and  $n$  is the sample size. Under the null hypothesis, the test statistic has a standard normal distribution.

### **Multidimensional Array**

A multidimensional array has more than two dimensions. For example, if  $x$  is a 1-by-3-by-4 array, then  $x$  is a three-dimensional array.

### **First Nonsingleton Dimension**

The first nonsingleton dimension is the first dimension of an array whose size is not equal to 1. For example, if  $x$  is a 1-by-2-by-3-by-4 array, then the second dimension is the first nonsingleton dimension of  $x$ .

# Sample Data Sets

---

Statistics Toolbox software includes the sample data sets in the following table.

To load a data set into the MATLAB workspace, type:

```
load filename
```

where *filename* is one of the files listed in the table.

Data sets contain individual data variables, description variables with references, and dataset arrays encapsulating the data set and its description, as appropriate.

| File           | Description of Data Set                                                                                                                                               |
|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| acetylene.mat  | Chemical reaction data with correlated predictors                                                                                                                     |
| arrhythmia.mat | Cardiac arrhythmia data from the UCI machine learning repository                                                                                                      |
| carbig.mat     | Measurements of cars, 1970–1982                                                                                                                                       |
| carsmall.mat   | Subset of <code>carbig.mat</code> . Measurements of cars, 1970, 1976, 1982                                                                                            |
| cereal.mat     | Breakfast cereal ingredients                                                                                                                                          |
| cities.mat     | Quality of life ratings for U.S. metropolitan areas                                                                                                                   |

## Bernoulli Distribution

**In this section...**

“Overview” on page B-2

“Parameters” on page B-2

“Probability Mass Function” on page B-2

“Descriptive Statistics” on page B-2

“Relationship to Other Distributions” on page B-3

### Overview

The Bernoulli distribution is a discrete probability distribution with the only two possible values for the random variable. Each instance of an event with a Bernoulli distribution is called a Bernoulli trial.

### Parameters

The Bernoulli distribution uses the following parameter.

| Parameter | Description            | Support           |
|-----------|------------------------|-------------------|
| $p$       | Probability of success | $0 \leq p \leq 1$ |

### Probability Mass Function

The probability mass function (pmf) is

$$f(x | p) = \begin{cases} 1 - p & , \quad x = 0, \\ p & , \quad x = 1. \end{cases}$$

### Descriptive Statistics

The mean is

$$\text{mean} = p.$$

The variance is

$$\text{var} = p(1 - p).$$

## Relationship to Other Distributions

The Bernoulli distribution is a special case of the binomial distribution, with the number of trials  $n = 1$ . The geometric distribution models the number of Bernoulli trials before the first success (or first failure).

## Beta Distribution

**In this section...**

“Definition” on page B-4

“Background” on page B-4

“Parameters” on page B-5

“Example” on page B-6

### Definition

The beta pdf is

$$y = f(x | a, b) = \frac{1}{B(a, b)} x^{a-1} (1-x)^{b-1} I_{(0,1)}(x)$$

where  $B(\cdot)$  is the Beta function. The indicator function  $I_{(0,1)}(x)$  ensures that only values of  $x$  in the range  $(0, 1)$  have nonzero probability.

### Background

The beta distribution describes a family of curves that are unique in that they are nonzero only on the interval  $(0, 1)$ . A more general version of the function assigns parameters to the endpoints of the interval.

The beta cdf is the same as the incomplete beta function.

The beta distribution has a functional relationship with the  $t$  distribution. If  $Y$  is an observation from Student's  $t$  distribution with  $\nu$  degrees of freedom, then the following transformation generates  $X$ , which is beta distributed.

$$X = \frac{1}{2} + \frac{1}{2} \frac{Y}{\sqrt{\nu + Y^2}}$$

$$\text{If } Y \sim t(\nu), \text{ then } X \sim \beta\left(\frac{\nu}{2}, \frac{\nu}{2}\right)$$

This relationship is used to compute values of the  $t$  cdf and inverse function as well as generating  $t$  distributed random numbers.

## Parameters

Suppose you are collecting data that has hard lower and upper bounds of zero and one respectively. Parameter estimation is the process of determining the parameters of the beta distribution that fit this data best in some sense.

One popular criterion of goodness is to maximize the likelihood function. The likelihood has the same form as the beta pdf. But for the pdf, the parameters are known constants and the variable is  $x$ . The likelihood function reverses the roles of the variables. Here, the sample values (the  $x$ 's) are already observed. So they are the fixed constants. The variables are the unknown parameters. Maximum likelihood estimation (MLE) involves calculating the values of the parameters that give the highest likelihood given the particular set of data.

The function `betafit` returns the MLEs and confidence intervals for the parameters of the beta distribution. Here is an example using random numbers from the beta distribution with  $a = 5$  and  $b = 0.2$ .

```
rng default % For reproducibility
r = betarnd(5,0.2,100,1);
[phat, pci] = betafit(r)
```

```
phat =
```

```
 7.4911 0.2135
```

```
pci =
```

```
 5.0861 0.1744
 11.0334 0.2614
```

The MLE for parameter  $a$  is 7.4911, compared to the true value of 5. The 95% confidence interval for  $a$  goes from 2.8051 to 6.2610, which does not include the true value. While this is an unlikely result, it does sometimes happen when estimating distribution parameters.

Similarly the MLE for parameter  $b$  is 0.2135, compared to the true value of 0.2. The 95% confidence interval for  $b$  goes from 0.1771 to 0.2832, which does include the true value. In this made-up example you know the “true value.” In experimentation you do not.

## Example

The shape of the beta distribution is quite variable depending on the values of the parameters, as illustrated by the plot below.

```
X = 0:.01:1;
y1 = betapdf(X,0.75,0.75);
y2 = betapdf(X,1,1);
y3 = betapdf(X,4,4);

figure
plot(X,y1,'Color','r','LineWidth',2)
hold on
plot(X,y2,'LineStyle','-','Color','b','LineWidth',2)
plot(X,y3,'LineStyle',':','Color','g','LineWidth',2)
legend({'a = b = 0.75','a = b = 1','a = b = 4'},'Location','NorthEast');
hold off
```

The constant pdf (the flat line) shows that the standard uniform distribution is a special case of the beta distribution, which occurs when  $a = b = 1$ .

# Binomial Distribution

**In this section...**

“Overview” on page B-8

“Parameters” on page B-8

“Probability Density Function” on page B-8

“Descriptive Statistics” on page B-9

“Relationship to Other Distributions” on page B-9

“Example” on page B-9

## Overview

The binomial distribution models the total number of successes in repeated trials from an infinite population under the following conditions:

- Only two outcomes are possible on each of  $n$  trials.
- The probability of success for each trial is constant.
- All trials are independent of each other.

## Parameters

The binomial distribution uses the following parameters.

| Parameter | Description            | Support           |
|-----------|------------------------|-------------------|
| $N$       | Number of trials       | positive integer  |
| $p$       | Probability of success | $0 \leq p \leq 1$ |

## Probability Density Function

The probability density function (pdf) is

$$f(x | n, p) = \binom{n}{x} p^x (1-p)^{n-x} \quad ; \quad x = 0, 1, 2, \dots, n,$$

where  $x$  is the number of successes in  $n$  trials of a Bernoulli process with probability of success  $p$ .

## Descriptive Statistics

The mean is

$$\text{mean} = np.$$

The variance is

$$\text{var} = np(1-p).$$

## Relationship to Other Distributions

The binomial distribution is a generalization of the Bernoulli distribution, allowing for a number of trials  $n$  greater than 1. The binomial distribution generalizes to the multinomial distribution when there are more than two possible outcomes for each trial.

## Example

Suppose you are collecting data from a widget manufacturing process, and you record the number of widgets within specification in each batch of 100. You might be interested in the probability that an individual widget is within specification. Parameter estimation is the process of determining the parameter,  $p$ , of the binomial distribution that fits this data best in some sense.

One popular criterion of goodness is to maximize the likelihood function. The likelihood has the same form as the binomial pdf above. But for the pdf, the parameters ( $n$  and  $p$ ) are known constants and the variable is  $x$ . The likelihood function reverses the roles of the variables. Here, the sample values (the  $x$ 's) are already observed. So they are the fixed constants. The variables are the unknown parameters. MLE involves calculating the value of  $p$  that give the highest likelihood given the particular set of data.

The function `binofit` returns the MLEs and confidence intervals for the parameters of the binomial distribution. Here is an example using random numbers from the binomial distribution with  $n = 100$  and  $p = 0.9$ .

```
rng default; % for reproducibility
r = binornd(100,0.9)
[phat, pci] = binofit(r,100)
```

```
r =
```

```
85
```

```
phat =
```

```
0.8500
```

```
pci =
```

```
0.7647 0.9135
```

The MLE for parameter  $p$  is 0.8800, compared to the true value of 0.9. The 95% confidence interval for  $p$  goes from 0.7998 to 0.9364, which includes the true value. In this made-up example you know the “true value” of  $p$ . In experimentation you do not.

The following commands generate a plot of the binomial pdf for  $n = 10$  and  $p = 1/2$ .

```
x = 0:10;
y = binopdf(x,10,0.5);
plot(x,y, '+')
```

## Birnbaum-Saunders Distribution

**In this section...**

“Definition” on page B-12

“Background” on page B-12

“Parameters” on page B-13

### Definition

The Birnbaum-Saunders distribution has the density function

$$\frac{1}{\sqrt{2\pi}} \exp \left\{ - \frac{\left( \sqrt{x/\beta} - \sqrt{\beta/x} \right)^2}{2\gamma^2} \right\} \left( \frac{\sqrt{x/\beta} + \sqrt{\beta/x}}{2\gamma x} \right)$$

with scale parameter  $\beta > 0$  and shape parameter  $\gamma > 0$ , for  $x > 0$ .

If  $x$  has a Birnbaum-Saunders distribution with parameters  $\beta$  and  $\gamma$ , then

$$\frac{\left( \sqrt{x/\beta} - \sqrt{\beta/x} \right)}{\gamma}$$

has a standard normal distribution.

### Background

The Birnbaum-Saunders distribution was originally proposed as a lifetime model for materials subject to cyclic patterns of stress and strain, where the ultimate failure of the material comes from the growth of a prominent flaw. In materials science, Miner's Rule suggests that the damage occurring after  $n$  cycles, at a stress level with an expected lifetime of  $N$  cycles, is proportional to  $n / N$ . Whenever Miner's Rule applies, the Birnbaum-Saunders model is a reasonable choice for a lifetime distribution model.

## **Parameters**

To estimate distribution parameters, use `mle` or the Distribution Fitting app.

## Burr Type XII Distribution

**In this section...**

“Definition” on page B-14

“Background” on page B-15

“Parameters” on page B-16

“Fit a Burr Distribution and Draw the cdf” on page B-17

“Compare Lognormal and Burr pdfs” on page B-19

“Burr pdf for Various Parameters” on page B-21

“Survival and Hazard Functions of Burr Distribution” on page B-23

“Divergence of Parameter Estimates” on page B-25

### Definition

The Burr type XII distribution is a three-parameter family of distributions on the positive real line. The cumulative distribution function (cdf) of the Burr distribution is

$$F(x | \alpha, c, k) = 1 - \frac{1}{\left(1 + \left(\frac{x}{\alpha}\right)^c\right)^k}, \quad x > 0, \alpha > 0, c > 0, k > 0,$$

where  $c$  and  $k$  are the shape parameters and  $\alpha$  is the scale parameter. The probability density function (pdf) is

$$f(x | \alpha, c, k) = \frac{\frac{kc}{\alpha} \left(\frac{x}{\alpha}\right)^{c-1}}{\left(1 + \left(\frac{x}{\alpha}\right)^c\right)^{k+1}}, \quad x > 0, \alpha > 0, c > 0, k > 0.$$

The density of the Burr type XII distribution is L-shaped if  $c \leq 1$  and unimodal, otherwise.

## Background

Burr distribution was first discussed by Burr (1942) as a two-parameter family. An additional scale parameter was introduced by Tadikamalla (1980). It is a very flexible distribution family that can express a wide range of distribution shapes. The Burr distribution includes, overlaps, or has as a limiting case, many commonly used distributions such as gamma, lognormal, loglogistic, bell-shaped, and J-shaped beta distributions (but not U-shaped). Some compound distributions also correspond to the Burr distribution. For example, compounding a Weibull distribution with a gamma distribution for its scale parameter results in a Burr distribution. Similarly, compounding an exponential distribution with a gamma distribution for its rate parameter,  $1/\mu$ , also yields a Burr distribution. The Burr distribution also has two asymptotic limiting cases: Weibull and Pareto Type I.

The Burr distribution can fit a wide range of empirical data. Different values of its parameters cover a broad set of skewness and kurtosis. Hence, it is used in various fields such as finance, hydrology, and reliability to model a variety of data types. Examples of data modeled by the Burr distribution are household income, crop prices, insurance risk, travel time, flood levels, and failure data.

The survival and hazard functions of Burr type XII distribution are, respectively,

$$S(x | \alpha, c, k) = \frac{1}{\left[1 + \left(\frac{x}{\alpha}\right)^c\right]^k}$$

and

$$h(x | \alpha, c, k) = \frac{\frac{kc}{\alpha} \left(\frac{x}{\alpha}\right)^{c-1}}{1 + \left(\frac{x}{\alpha}\right)^c}.$$

If  $c > 1$ , the hazard function  $h(x)$  is non-monotonic with a mode at  $x = \alpha(c - 1)^{1/c}$ .

## Parameters

The three-parameter Burr distribution is defined by its scale parameter  $\alpha$  and shape parameters  $c$  and  $k$ . You can estimate the parameters using `mle` or `fitdist`. Both functions support censored data for Burr distribution.

Generate sample data from a Burr distribution with scale parameter 0.5 and shape parameters 2 and 5.

```
rng('default')
R = random('burr',0.5,2,5,1000,1);
```

Estimate the parameters and the confidence intervals.

```
[phat,pci] = mle(R,'distribution','burr')
```

```
phat =
```

```
 0.4154 2.1217 4.0550
```

```
pci =
```

```
 0.2985 1.9560 2.4079
 0.5782 2.3014 6.8288
```

The default 95% confidence intervals for the parameters include the true parameter values.

The three-parameter Burr distribution converges asymptotically to one of the two limiting forms as its parameters diverge:

- If  $k \rightarrow 0$ ,  $c \rightarrow \infty$ ,  $ck = \lambda$ , then the Burr distribution reduces to a two-parameter Pareto distribution with the cdf

$$F_P = 1 - \left(\frac{x}{\alpha}\right)^{-\lambda}, \quad x \geq \alpha.$$

- If  $k \rightarrow \infty$ ,  $\alpha \rightarrow \infty$ ,  $\alpha/k^{1/c} = \theta$ , then the Burr distribution reduces to a two-parameter Weibull distribution with the cdf

$$F_W(x | c, \theta) = 1 - \exp\left[-\left(\frac{x}{\theta}\right)^c\right].$$

If `mle` or `fitdist` detects such divergence, it returns an error message, but informs you of the limiting distribution and corresponding parameter estimates for that distribution.

## Fit a Burr Distribution and Draw the cdf

This example shows how to fit a Burr distribution to data, draw the cdf, and construct a histogram with a Burr distribution fit.

1. Load the sample data.

```
load('arrhythmia.mat')
```

The fifth column in `X` contains a measurement obtained from electrocardiograms, called QRS duration.

2. Fit a Burr distribution to the QRS duration data, and get the parameter estimates.

```
PD = fitdist(X(:,5), 'burr');
```

`PD` has the maximum likelihood estimates of the Burr distribution parameters in the property `Param`. The estimates are  $\alpha = 80.4515$ ,  $c = 18.9251$ ,  $k = 0.4492$ .

3. Plot the cdf of the QRS duration data.

```
QRScdf=cdf('burr', sortrows(X(:,5)), 80.4515, 18.9251, 0.4492);
plot(sortrows(X(:,5)), QRScdf)
xlabel('QRS Duration')
```

**cdf of QRS duration data**

4. Draw the histogram of QRS duration data with 15 bins and the pdf of the Burr distribution fit.

```
histfit(X(:,5),15,'burr')
xlabel('QRS Duration')
```

**Histogram of QRS data with a Burr distribution fit**

## Compare Lognormal and Burr pdfs

This example shows how to compare the lognormal pdf to the Burr pdf using income data generated from a lognormal distribution.

1. Generate the income data.

```
rng('default') % for reproducibility
y = random('logn', log(25000), 0.65, 500, 1);
```

2. Fit a Burr distribution.

```
pd = fitdist(y, 'burr');
```

3. Plot both the Burr and lognormal pdfs of income data on the same axis.

```
p = pdf('burr', sortrows(y), 26007, 2.6374, 1.0966);
p2 = pdf('logn', sortrows(y), log(25000), 0.65);
plot(sortrows(y), p, 'g', sortrows(y), p2, 'r', 'LineWidth', 2)
legend('burr', 'lognormal')
```

**Burr and Lognormal pdfs fitted to income data**

### Burr pdf for Various Parameters

This example shows how to create a variety of shapes for probability density functions of the Burr distribution.

```
X = 0:0.01:5;
c = [0.5 0.95 2 5];
k = [0.5 0.75 2 5];
alpha = [0.5 1 2 5];
colors = ['b'; 'g'; 'r'; 'k']
```

```
figure
for i = 1:1:4
pdf1(i,:) = pdf('burr',X,1,c(i),0.5);
pdf2(i,:) = pdf('burr',X,1,2,k(i));
pdf3(i,:) = pdf('burr',X,alpha(i),2,0.5);

axC = subplot(3,1,1);
pC(i) = plot(X,pdf1(i,:),colors(i),'LineWidth',2);
title('Effect of c, \alpha = 1, k = 0.5'),xlabel('x')
hold on

axK = subplot(3,1,2);
pK(i) = plot(X,pdf2(i,:),colors(i),'LineWidth',2);
title('Effect of k, \alpha = 1, c = 2'),xlabel('x')
hold on

axAlpha = subplot(3,1,3);
pAlpha(i) = plot(X,pdf3(i,:),colors(i),'LineWidth',2);
title('Effect of \alpha, c = 2, k = 0.5'),xlabel('x')
hold on
end

set(axC,'XLim',[0 3],'YLim',[0 1.2]);
set(axK,'XLim',[0 3],'YLim',[0 2.1]);
set(axAlpha,'XLim',[0 5],'YLim',[0 1]);

legend(axC,'c=0.5','c=0.95','c=2','c=5');
legend(axK,'k=0.5','k=0.75','k=2','k=5');
legend(axAlpha,'\alpha=0.5','\alpha=1','\alpha=2','\alpha=5');
```

This figure illustrates how the shape and scale of the Burr distribution changes for different values of its parameters.

## Survival and Hazard Functions of Burr Distribution

This example shows how to find and plot the survival and hazard functions for a sample coming from a Burr distribution.

1. Generate the data.

```
X = 0:0.015:2.5;
```

2. Evaluate the pdf and cdf of data in X.

```
Xpdf = pdf('burr',X,0.2,5,0.5);
Xcdf = cdf('burr',X,0.2,5,0.5);
```

3. Evaluate and plot the survival function of data in X.

```
S = 1.-Xcdf; % survival function
plot(X,S,'LineWidth',2)
xlabel('x')
```

**Survival function**

4. Evaluate and plot the hazard function of data in X.

```
H = Xpdf./S; % hazard function
plot(X,H,'r','LineWidth',2)
xlabel('x')
```

**Hazard function**

## Divergence of Parameter Estimates

This example shows how to interpret the display when the parameter estimates diverge when fitting a Burr distribution to input data.

1. Generate sample data from the Weibull distribution with parameters 0.5 and 2.

```
rng('default') % for reproducibility
X = wblrnd(0.5,2,100,1);
```

2. Fit a Burr distribution.

```
PD = fitdist(X,'burr');
```

```
Error using addburr>burrfit (line 566)
The data are not fit by a Burr distribution with finite
parameters. The maximum likelihood fit is provided by the
k->Inf, alpha->Inf limiting form of the Burr distribution: a
Weibull distribution with the parameters below.
 a (scale): 0.476817
 b (shape): 1.96219
```

```
Error in fitdata (line 24)
 p = F(x, fixedparams{:}, 0.05, opts{:});
```

```
Error in ProbDistUnivParam.fit (line 94)
pd = fitdata(pd, spec, x, cens, freq, fixedparams, options);
```

```
Error in fitdist (line 124)
 pd =
 ProbDistUnivParam.fit(x, distname, 'cens', cens, 'freq', freq, args{:});
```

The error message tells you that the Weibull family seems to fit the data better and gives you the parameter estimates from a Weibull fit. You can use those estimates directly. If you need covariance estimates for the parameters or other information about the fit, you can refit a Weibull distribution to the data.

3. Fit a Weibull distribution to the data and find the confidence intervals for the parameter estimates.

```
PD = fitdist(X,'weibull');
paramci(PD)
```

```
ans =
```

```
 0.4291 1.6821
 0.5298 2.2890
```

These are the 95% confidence intervals of the parameter estimates for the Weibull distribution fit.

- “Parameters” on page B-28
- “Probability Density Function” on page B-28
- “Cumulative Distribution Function” on page B-29
- “Descriptive Statistics” on page B-29
- “Relationship to Other Distributions” on page B-29
- “Examples” on page B-29

## Overview

The chi-square distribution is commonly used in hypothesis testing, particularly the chi-squared test for goodness of fit.

## Parameters

The chi-square distribution uses the following parameter.

| Parameter | Description        | Support                              |
|-----------|--------------------|--------------------------------------|
| $\nu$     | Degrees of freedom | $\nu$ is a nonnegative integer value |

## Probability Density Function

The probability density function (pdf) is

$$y = f(x | \nu) = \frac{x^{(\nu-2)/2} e^{-x/2}}{2^{\nu/2} \Gamma(\nu/2)}$$

where  $\Gamma(\cdot)$  is the Gamma function,  $\nu$  is the degrees of freedom, and  $x \geq 0$ .

## Cumulative Distribution Function

The cumulative distribution function (cdf) is

$$p = F(x | \nu) = \int_0^x \frac{t^{(\nu-2)/2} e^{-t/2}}{2^{\nu/2} \Gamma(\nu/2)} dt$$

where  $\Gamma(\cdot)$  is the Gamma function,  $\nu$  is the degrees of freedom, and  $x \geq 0$ .

## Descriptive Statistics

The mean is  $\nu$ .

The variance is  $2\nu$ .

## Relationship to Other Distributions

The  $\chi^2$  distribution is a special case of the gamma distribution where  $b = 2$  in the equation for gamma distribution below.

$$y = f(x | a, b) = \frac{1}{b^a \Gamma(a)} x^{a-1} e^{-\frac{x}{b}}$$

The  $\chi^2$  distribution gets special attention because of its importance in normal sampling theory. If a set of  $n$  observations is normally distributed with variance  $\sigma^2$ , and  $s^2$  is the sample standard deviation, then

$$\frac{(n-1)s^2}{\sigma^2} \sim \chi^2(n-1)$$

This relationship is used to calculate confidence intervals for the estimate of the normal parameter  $\sigma^2$  in the function `normfit`.

## Examples

### Compute Chi-Square Distribution pdf

Compute the pdf of a chi-square distribution with 4 degrees of freedom.

```
x = 0:0.2:15;
y = chi2pdf(x,4);
```

Plot the pdf.

```
figure;
plot(x,y)
```

The chi-square distribution is skewed to the right, especially for few degrees of freedom.

## Copulas

See “Copulas: Generate Correlated Samples” on page 5-122.

## Custom Distributions

User-defined custom distributions, created using files and function handles, are supported by the Statistics Toolbox functions `pdf`, `cdf`, `icdf`, and `mle`, and the Statistics Toolbox Distribution Fitting app.

# Exponential Distribution

**In this section...**

“Definition” on page B-33

“Background” on page B-33

“Parameters” on page B-33

“Examples” on page B-34

## Definition

The exponential pdf is

$$y = f(x | \mu) = \frac{1}{\mu} e^{-\frac{x}{\mu}}$$

## Background

Like the chi-square distribution, the exponential distribution is a special case of the gamma distribution (obtained by setting  $\alpha = 1$ )

$$y = f(x | a, b) = \frac{1}{b^a \Gamma(a)} x^{a-1} e^{-\frac{x}{b}}$$

where  $\Gamma(\cdot)$  is the Gamma function.

The exponential distribution is special because of its utility in modeling events that occur randomly over time. The main application area is in studies of lifetimes.

## Parameters

Suppose you are stress testing light bulbs and collecting data on their lifetimes. You assume that these lifetimes follow an exponential distribution. You want to know how long you can expect the average light bulb to last. Parameter estimation is the process of determining the parameters of the exponential distribution that fit this data best in some sense.

One popular criterion of goodness is to maximize the likelihood function. The likelihood has the same form as the exponential pdf above. But for the pdf, the parameters are known constants and the variable is  $x$ . The likelihood function reverses the roles of the variables. Here, the sample values (the  $x$ 's) are already observed. So they are the fixed constants. The variables are the unknown parameters. MLE involves calculating the values of the parameters that give the highest likelihood given the particular set of data.

The function `expfit` returns the MLEs and confidence intervals for the parameters of the exponential distribution. Here is an example using random numbers from the exponential distribution with  $\mu = 700$ .

```
lifetimes = exprnd(700,100,1);
[muhat, mucu] = expfit(lifetimes)
```

```
muhat =

 672.8207
```

```
mucu =

 547.4338
 810.9437
```

The MLE for parameter  $\mu$  is 672, compared to the true value of 700. The 95% confidence interval for  $\mu$  goes from 547 to 811, which includes the true value.

In the life tests you do not know the true value of  $\mu$  so it is nice to have a confidence interval on the parameter to give a range of likely values.

## Examples

### Exponentially Distributed Lifetime Data

For exponentially distributed lifetimes, the probability that an item will survive an extra unit of time is independent of the current age of the item. The example shows a specific case of this special property.

```
l = 10:10:60;
lpd = l+0.1;
deltap = (expcdf(lpd,50) - expcdf(l,50)) ./ (1 - expcdf(l,50))

deltap =
 0.0020 0.0020 0.0020 0.0020 0.0020 0.0020
```

**Compute the Exponential Distribution pdf**

Compute the pdf of an exponential distribution with parameter  $\mu = 2$ .

```
x = 0:0.1:10;
y = exppdf(x,2);
```

Plot the pdf.

```
figure;
plot(x,y)
```

## Extreme Value Distribution

| In this section...        |
|---------------------------|
| “Definition” on page B-36 |
| “Background” on page B-36 |
| “Parameters” on page B-38 |
| “Examples” on page B-39   |

### Definition

The probability density function for the extreme value distribution with location parameter  $\mu$  and scale parameter  $\sigma$  is

$$y = f(x | \mu, \sigma) = \sigma^{-1} \exp\left(\frac{x - \mu}{\sigma}\right) \exp\left(-\exp\left(\frac{x - \mu}{\sigma}\right)\right)$$

This form of the probability density function is suitable for modeling the minimum value. To model the maximum value, use the negative of the original values.

If  $T$  has a Weibull distribution with parameters  $a$  and  $b$ , then  $\log T$  has an extreme value distribution with parameters  $\mu = \log a$  and  $\sigma = 1/b$ .

### Background

Extreme value distributions are often used to model the smallest or largest value among a large set of independent, identically distributed random values representing measurements or observations. The extreme value distribution is appropriate for modeling the smallest value from a distribution whose tails decay exponentially fast, for example, the normal distribution. It can also model the largest value from a distribution, such as the normal or exponential distributions, by using the negative of the original values.

For example, the following fits an extreme value distribution to minimum values taken over 1000 sets of 500 observations from a normal distribution.

```
rng default; % For reproducibility
```

```

xMinima = min(randn(1000,500), [], 2);
paramEstsMinima = evfit(xMinima);
y = linspace(-5,-1.5,1001);
hist(xMinima,-4.75:.25:-1.75);
p = evpdf(y,paramEstsMinima(1),paramEstsMinima(2));
line(y,.25*length(xMinima)*p,'color','r')

```

The following fits an extreme value distribution to the maximum values in each set of observations.

```

rng default; % For reproducibility
xMaxima = max(randn(1000,500), [], 2);
paramEstsMaxima = evfit(-xMaxima);
y = linspace(1.5,5,1001);

```

```
hist(xMaxima,1.75:.25:4.75);
p = evpdf(-y,paramEstsMaxima(1),paramEstsMaxima(2));
line(y,.25*length(xMaxima)*p, 'color', 'r')
```

Although the extreme value distribution is most often used as a model for extreme values, you can also use it as a model for other types of continuous data. For example, extreme value distributions are closely related to the Weibull distribution. If  $T$  has a Weibull distribution, then  $\log(T)$  has a type 1 extreme value distribution.

## Parameters

The function `evfit` returns the maximum likelihood estimates (MLEs) and confidence intervals for the parameters of the extreme value distribution. The following example

shows how to fit some sample data using `evfit`, including estimates of the mean and variance from the fitted distribution.

Suppose you want to model the size of the smallest washer in each batch of 1000 from a manufacturing process. If you believe that the sizes are independent within and between each batch, you can fit an extreme value distribution to measurements of the minimum diameter from a series of eight experimental batches. The following code returns the MLEs of the distribution parameters as `parmhat` and the confidence intervals as the columns of `parmci`.

```
x = [19.774 20.141 19.44 20.511 21.377 19.003 19.66 18.83];
[parmhat, parmci] = evfit(x)

parmhat =
 20.2506 0.8223

parmci =
 19.644 0.49861
 20.857 1.3562
```

You can find mean and variance of the extreme value distribution with these parameters using the function `evstat`.

```
[meanfit, varfit] = evstat(parmhat(1),parmhat(2))

meanfit =
 19.776

varfit =
 1.1123
```

## Examples

### Compute the Extreme Value Distribution pdf

Compute the pdf of an extreme value distribution.

```
t = [-5:.01:2];
y = evpdf(t);
```

Plot the pdf.

```
figure;
```

```
plot(t,y)
```

The extreme value distribution is skewed to the left, and its general shape remains the same for all parameter values. The location parameter,  $\mu$ , shifts the distribution along the real line, and the scale parameter,  $\sigma$ , expands or contracts the distribution.

The following plots the probability function for different combinations of  $\mu$  and  $\sigma$ .

```
x = -15:.01:5;
plot(x,evpdf(x,2,1), '- ', ...
 x,evpdf(x,0,2), ': ', ...
 x,evpdf(x,-2,4), '-. ');
legend({'mu = 2, sigma = 1', ...
 'mu = 0, sigma = 2', ...
```

```
'mu = -2, sigma = 4'}, ...
'Location', 'NW')
xlabel('x')
ylabel('f(x|mu,sigma)')
```

## F Distribution

### In this section...

“Definition” on page B-42

“Background” on page B-42

“Examples” on page B-42

### Definition

The pdf for the  $F$  distribution is

$$y = f(x | v_1, v_2) = \frac{\Gamma\left[\frac{(v_1 + v_2)}{2}\right]}{\Gamma\left(\frac{v_1}{2}\right)\Gamma\left(\frac{v_2}{2}\right)} \left(\frac{v_1}{v_2}\right)^{\frac{v_1}{2}} \frac{x^{\frac{v_1-2}{2}}}{\left[1 + \left(\frac{v_1}{v_2}\right)x\right]^{\frac{v_1+v_2}{2}}}$$

where  $\Gamma(\cdot)$  is the Gamma function.

### Background

The  $F$  distribution has a natural relationship with the chi-square distribution. If  $\chi_1$  and  $\chi_2$  are both chi-square with  $v_1$  and  $v_2$  degrees of freedom respectively, then the statistic  $F$  below is  $F$ -distributed.

$$F(v_1, v_2) = \frac{\chi_1 / v_1}{\chi_2 / v_2}$$

The two parameters,  $v_1$  and  $v_2$ , are the numerator and denominator degrees of freedom. That is,  $v_1$  and  $v_2$  are the number of independent pieces of information used to calculate  $\chi_1$  and  $\chi_2$ , respectively.

### Examples

#### Compute the $F$ Distribution pdf

Compute the pdf of an  $F$  distribution with 5 numerator degrees of freedom and 3 denominator degrees of freedom.

```
x = 0:0.01:10;
y = fpdf(x,5,3);
```

Plot the pdf.

```
figure;
plot(x,y)
```

The plot shows that the  $F$  distribution exists on positive real numbers and is skewed to the right.

## Gamma Distribution

**In this section...**

“Definition” on page B-44

“Background” on page B-44

“Parameters” on page B-44

“Examples” on page B-45

### Definition

The gamma pdf is

$$y = f(x | a, b) = \frac{1}{b^a \Gamma(a)} x^{a-1} e^{-\frac{x}{b}}$$

where  $\Gamma(\cdot)$  is the Gamma function.

### Background

The gamma distribution models sums of exponentially distributed random variables.

The gamma distribution family is based on two parameters. The chi-square and exponential distributions, which are children of the gamma distribution, are one-parameter distributions that fix one of the two gamma parameters.

The gamma distribution has the following relationship with the incomplete Gamma function.

$$f(x | a, b) = \text{gammainc}\left(\frac{x}{b}, a\right)$$

When  $a$  is large, the gamma distribution closely approximates a normal distribution with the advantage that the gamma distribution has density only for positive real numbers.

### Parameters

Suppose you are stress testing computer memory chips and collecting data on their lifetimes. You assume that these lifetimes follow a gamma distribution. You want to

know how long you can expect the average computer memory chip to last. Parameter estimation is the process of determining the parameters of the gamma distribution that fit this data best in some sense.

One popular criterion of goodness is to maximize the likelihood function. The likelihood has the same form as the gamma pdf above. But for the pdf, the parameters are known constants and the variable is  $x$ . The likelihood function reverses the roles of the variables. Here, the sample values (the  $x$ 's) are already observed. So they are the fixed constants. The variables are the unknown parameters. MLE involves calculating the values of the parameters that give the highest likelihood given the particular set of data.

The function `gamfit` returns the MLEs and confidence intervals for the parameters of the gamma distribution. Here is an example using random numbers from the gamma distribution with  $a = 10$  and  $b = 5$ .

```
lifetimes = gamrnd(10,5,100,1);
[phat, pci] = gamfit(lifetimes)
```

```
phat =
```

```
 10.9821 4.7258
```

```
pci =
```

```
 7.4001 3.1543
 14.5640 6.2974
```

Note `phat(1) =  $\hat{a}$`  and `phat(2) =  $\hat{b}$` . The MLE for parameter  $a$  is 10.98, compared to the true value of 10. The 95% confidence interval for  $a$  goes from 7.4 to 14.6, which includes the true value.

Similarly the MLE for parameter  $b$  is 4.7, compared to the true value of 5. The 95% confidence interval for  $b$  goes from 3.2 to 6.3, which also includes the true value.

In the life tests you do not know the true value of  $a$  and  $b$  so it is nice to have a confidence interval on the parameters to give a range of likely values.

## Examples

### Compute the Gamma Distribution pdf

Compute the pdf of a gamma distribution with parameters  $A = 100$  and  $B = 10$ . For comparison, also compute the pdf of a normal distribution with parameters  $\mu = 1000$  and  $\sigma = 100$ .

```
x = gaminv((0.005:0.01:0.995),100,10);
y = gampdf(x,100,10);
y1 = normpdf(x,1000,100);
```

Plot the pdfs of the gamma distribution and the normal distribution on the same figure.

```
figure;
plot(x,y,'-.',x,y1,'-.-')
```

## Gaussian Distribution

See “Normal Distribution” on page B-119.

## Gaussian Mixture Distributions

See the discussion of the `gmdistribution` class in “Gaussian Mixture Models” on page 5-113.

## Generalized Extreme Value Distribution

### In this section...

“Definition” on page B-49

“Background” on page B-49

“Parameters” on page B-50

“Examples” on page B-51

### Definition

The probability density function for the generalized extreme value distribution with location parameter  $\mu$ , scale parameter  $\sigma$ , and shape parameter  $k \neq 0$  is

$$y = f(x | k, \mu, \sigma) = \left(\frac{1}{\sigma}\right) \exp\left(-\left(1 + k \frac{(x - \mu)}{\sigma}\right)^{-\frac{1}{k}}\right) \left(1 + k \frac{(x - \mu)}{\sigma}\right)^{-1 - \frac{1}{k}}$$

for

$$1 + k \frac{(x - \mu)}{\sigma} > 0$$

$k > 0$  corresponds to the Type II case, while  $k < 0$  corresponds to the Type III case. For  $k = 0$ , corresponding to the Type I case, the density is

$$y = f(x | 0, \mu, \sigma) = \left(\frac{1}{\sigma}\right) \exp\left(-\exp\left(-\frac{(x - \mu)}{\sigma}\right) - \frac{(x - \mu)}{\sigma}\right)$$

### Background

Like the extreme value distribution, the generalized extreme value distribution is often used to model the smallest or largest value among a large set of independent, identically distributed random values representing measurements or observations. For example, you might have batches of 1000 washers from a manufacturing process. If you record the size of the largest washer in each batch, the data are known as block maxima (or minima if you record the smallest). You can use the generalized extreme value distribution as a model for those block maxima.

The generalized extreme value combines three simpler distributions into a single form, allowing a continuous range of possible shapes that includes all three of the simpler distributions. You can use any one of those distributions to model a particular dataset of block maxima. The generalized extreme value distribution allows you to “let the data decide” which distribution is appropriate.

The three cases covered by the generalized extreme value distribution are often referred to as the Types I, II, and III. Each type corresponds to the limiting distribution of block maxima from a different class of underlying distributions. Distributions whose tails decrease exponentially, such as the normal, lead to the Type I. Distributions whose tails decrease as a polynomial, such as Student's  $t$ , lead to the Type II. Distributions whose tails are finite, such as the beta, lead to the Type III.

Types I, II, and III are sometimes also referred to as the Gumbel, Frechet, and Weibull types, though this terminology can be slightly confusing. The Type I (Gumbel) and Type III (Weibull) cases actually correspond to the mirror images of the usual Gumbel and Weibull distributions, for example, as computed by the functions `evcdf` and `evfit`, or `wblcdf` and `wblfit`, respectively. Finally, the Type II (Frechet) case is equivalent to taking the reciprocal of values from a standard Weibull distribution.

## Parameters

If you generate 250 blocks of 1000 random values drawn from Student's  $t$  distribution with 5 degrees of freedom, and take their maxima, you can fit a generalized extreme value distribution to those maxima.

```
blocksize = 1000;
nblocks = 250;
rng default % For reproducibility
t = trnd(5,blocksize,nblocks);
x = max(t); % 250 column maxima
paramEsts = gevfit(x)
```

```
paramEsts =
 0.1185 1.4530 5.8929
```

Notice that the shape parameter estimate (the first element) is positive, which is what you would expect based on block maxima from a Student's  $t$  distribution.

```
hist(x,2:20);
```

```
h = findobj(gca,'Type','patch');
h.FaceColor = [.8 .8 1];
xgrid = linspace(2,20,1000);
line(xgrid,nblocks*...
 gevpdf(xgrid,paramEsts(1),paramEsts(2),paramEsts(3)));
```

## Examples

### Compute the Generalized Extreme Value Distribution pdf

Generate examples of probability density functions for the three basic forms of the generalized extreme value distribution.

```
x = linspace(-3,6,1000);
```

```
y1 = gevpdf(x, -.5, 1, 0);
y2 = gevpdf(x, 0, 1, 0);
y3 = gevpdf(x, .5, 1, 0);
plot(x, y1, '-', x, y2, '--', x, y3, ':')
legend({'K < 0, Type III' 'K = 0, Type I' 'K > 0, Type II'})
```

Notice that for  $k = 0$ , the distribution has zero probability density for  $x$  such that  $x < -\sigma/k + \mu$ .

For  $k = 0$ , the distribution has zero probability density for  $x > -\sigma/k + \mu$ .

For  $k = 0$ , there is no upper or lower bound.

**Compute the Generalized Extreme Value Distribution pdf**

Generate examples of probability density functions for the three basic forms of the generalized extreme value distribution.

```
x = linspace(-3,6,1000);
y1 = gevpdf(x,-.5,1,0);
y2 = gevpdf(x,0,1,0);
y3 = gevpdf(x,.5,1,0);
plot(x,y1,'-', x,y2,'--', x,y3,':')
legend({'K < 0, Type III' 'K = 0, Type I' 'K > 0, Type II'})
```

Notice that for  $k = 0$ , the distribution has zero probability density for  $x$  such that  $x < -\sigma/k + \mu$ .

For  $k = 0$ , the distribution has zero probability density for  $x > -\sigma/k + \mu$ .

For  $k = 0$ , there is no upper or lower bound.

# Generalized Pareto Distribution

## In this section...

“Definition” on page B-55

“Background” on page B-55

“Parameters” on page B-56

“Examples” on page B-57

## Definition

The probability density function for the generalized Pareto distribution with shape parameter  $k \neq 0$ , scale parameter  $\sigma$ , and threshold parameter  $\theta$ , is

$$y = f(x | k, \sigma, \theta) = \left( \frac{1}{\sigma} \right) \left( 1 + k \frac{(x - \theta)}{\sigma} \right)^{-1 - \frac{1}{k}}$$

for  $\theta < x$ , when  $k > 0$ , or for  $\theta < x < \theta - \sigma/k$  when  $k < 0$ .

For  $k = 0$ , the density is

$$y = f(x | 0, \sigma, \theta) = \left( \frac{1}{\sigma} \right) e^{-\frac{(x - \theta)}{\sigma}}$$

for  $\theta < x$ .

If  $k = 0$  and  $\theta = 0$ , the generalized Pareto distribution is equivalent to the exponential distribution. If  $k > 0$  and  $\theta = \sigma/k$ , the generalized Pareto distribution is equivalent to the Pareto distribution.

## Background

Like the exponential distribution, the generalized Pareto distribution is often used to model the tails of another distribution. For example, you might have washers from a manufacturing process. If random influences in the process lead to differences in the sizes of the washers, a standard probability distribution, such as the normal, could be used to model those sizes. However, while the normal distribution might be a good model

near its mode, it might not be a good fit to real data in the tails and a more complex model might be needed to describe the full range of the data. On the other hand, only recording the sizes of washers larger (or smaller) than a certain threshold means you can fit a separate model to those tail data, which are known as *exceedences*. You can use the generalized Pareto distribution in this way, to provide a good fit to extremes of complicated data.

The generalized Pareto distribution allows a continuous range of possible shapes that includes both the exponential and Pareto distributions as special cases. You can use either of those distributions to model a particular dataset of exceedences. The generalized Pareto distribution allows you to “let the data decide” which distribution is appropriate.

The generalized Pareto distribution has three basic forms, each corresponding to a limiting distribution of exceedence data from a different class of underlying distributions.

- Distributions whose tails decrease exponentially, such as the normal, lead to a generalized Pareto shape parameter of zero.
- Distributions whose tails decrease as a polynomial, such as Student's *t*, lead to a positive shape parameter.
- Distributions whose tails are finite, such as the beta, lead to a negative shape parameter.

The generalized Pareto distribution is used in the tails of distribution fit objects of the `paretotails` class.

## Parameters

If you generate a large number of random values from a Student's *t* distribution with 5 degrees of freedom, and then discard everything less than 2, you can fit a generalized Pareto distribution to those exceedences.

```
rng default % For reproducibility
t = trnd(5,5000,1);
y = t(t > 2) - 2;
paramEsts = gpfity
```

```
paramEsts =
 0.1445 0.7225
```

Notice that the shape parameter estimate (the first element) is positive, which is what you would expect based on exceedences from a Student's  $t$  distribution.

```
hist(y+2,2.25:.5:11.75);
h = findobj(gca,'Type','patch');
h.FaceColor = [.8 .8 1];
xgrid = linspace(2,12,1000);
line(xgrid,.5*length(y)*...
 gppdf(xgrid,paramEsts(1),paramEsts(2),2));
```

## Examples

### Compute Generalized Pareto Distribution pdf

Compute the pdf of three generalized Pareto distributions. The first has shape parameter  $k = -0.25$ , the second has  $k = 0$ , and the third has  $k = 1$ .

```
x = linspace(0,10,1000);
y1 = gppdf(x,-.25,1,0);
y2 = gppdf(x,0,1,0);
y3 = gppdf(x,1,1,0);
```

Plot the three pdfs on the same figure.

```
figure;
plot(x,y1,'-', x,y2,'--', x,y3,':');
legend({'K < 0' 'K = 0' 'K > 0'});
```

# Geometric Distribution

## In this section...

“Overview” on page B-59

“Parameters” on page B-59

“Probability Distribution Function” on page B-59

“Cumulative Distribution Function” on page B-62

“Mean and Variance” on page B-64

“Example” on page B-65

## Overview

The geometric distribution models the number of failures before one success in a series of independent trials, where each trial results in either success or failure, and the probability of success in any individual trial is constant. For example, if you toss a coin, the geometric distribution models the number of tails observed before getting a heads. The geometric distribution is discrete, existing only on the nonnegative integers.

## Parameters

The geometric distribution uses the following parameter.

| Parameter         | Description            |
|-------------------|------------------------|
| $0 \leq p \leq 1$ | Probability of success |

## Probability Distribution Function

### Definition

The probability distribution function (pdf) of the geometric distribution is

$$y = f(x | p) = p(1 - p)^x \quad ; \quad x = 0, 1, 2, \dots,$$

where  $p$  is the probability of success, and  $x$  is the number of failures before the first success. The result  $y$  is the probability of observing exactly  $x$  trials before a success, when the probability of success in any given trial is  $p$ . For discrete distributions, the probability distribution function is also known as the probability mass function (pmf).

### Plot

This plot shows how changing the value of the probability parameter  $p$  alters the shape of the pdf. Use `geopdf` to compute the pdf for values at  $x$  equals 1 through 10, for three different values of  $p$ . Then plot all three pdfs on the same figure for a visual comparison.

```
x = [1:10];
y1 = geopdf(x,0.1); % For p = 0.1
y2 = geopdf(x,0.25); % For p = 0.25
y3 = geopdf(x,0.75); % For p = 0.75

figure;
plot(x,y1,'kd')
hold on
plot(x,y2,'ro')
plot(x,y3,'b+')
legend({'p = 0.1','p = 0.25','p = 0.75'})
hold off
```

In this plot, the value of  $y$  is the probability of observing exactly  $x$  trials before a success. When the probability of success  $p$  is large,  $y$  decreases rapidly as  $x$  increases, and the probability of observing a large number of failures before a success quickly becomes small. But when the probability of success  $p$  is small,  $y$  decreases slowly as  $x$  increases. The probability of observing a large number of failures before a success still decreases as the number of trials increases, but at a much slower rate.

### Random Number Generation

A random number generated from a geometric distribution represents the number of failures observed before a success in a single experiment, given the probability of success  $p$  for each independent trial. Use `geornd` to generate random numbers from the

geometric distribution. For example, the following generates a random number from a geometric distribution with probability of success  $p$  equal to 0.1.

```
p = 0.1;
r = geornd(p)
```

```
r =

 1
```

The returned random number represents the number of failures observed before a success in a series of independent trials.

### Relationship to Other Distributions

The geometric distribution is a special case of the negative binomial distribution, with the specified number of successes parameter  $r$  equal to 1.

## Cumulative Distribution Function

### Definition

The cumulative distribution function (cdf) of the geometric distribution is

$$y = F(x | p) = 1 - (1 - p)^{x+1}; x = 0, 1, 2, \dots,$$

where  $p$  is the probability of success, and  $x$  is the number of failures before the first success. The result  $y$  is the probability of observing up to  $x$  trials before a success, when the probability of success in any given trial is  $p$ .

### Plot

This plot shows how changing the value of the parameter  $p$  alters the shape of the cdf. Use `geocdf` to compute the cdf values at  $x$  equals 1 through 10, for three different values of  $p$ . Then plot all three cdfs on the same figure for a visual comparison.

```
x = [1:10];
y1 = geocdf(x,0.1); % For p = 0.1
y2 = geocdf(x,0.25); % For p = 0.25
```

```

y3 = geocdf(x,0.75); % For p = 0.75

figure;
plot(x,y1,'kd')
hold on
plot(x,y2,'ro')
plot(x,y3,'b+')
legend({'p = 0.1','p = 0.25','p = 0.75'})
hold off

```

In this plot, the value of  $y$  is the probability of observing up to  $x$  trials before a success. When the probability of success  $p$  is large,  $y$  increases rapidly as  $x$  increases. The probability of observing a success quickly becomes very high, even for a small number of trials. But when the probability of success  $p$  is small,  $y$  increases slowly as  $x$  increases.

The probability of observing a success still increases as the number of trials increases, but at a much slower rate.

### Inverse cdf

The inverse cdf of a geometric distribution determines the value of  $x$  that corresponds to a probability  $y$  of observing  $x$  successes in a row in independent trials. Use `geoinv` to compute the inverse cdf of the geometric distribution. For example, the following returns the smallest possible integer  $x$  such that the geometric cdf  $y$  evaluated at  $x$  is greater than or equal to 0.1, when the probability of success for each independent trial  $p$  is 0.03.

```
y = 0.1;
p = 0.03;
x = geoinv(y,p)
```

```
x =
```

```
3
```

### Mean and Variance

The mean of the geometric distribution is

$$\text{mean} = \frac{1-p}{p},$$

and the variance of the geometric distribution is

$$\text{var} = \frac{1-p}{p^2},$$

where  $p$  is the probability of success.

Use `geostat` to compute the mean and variance of a geometric distribution. For example, the following computes the mean  $m$  and variance  $v$  of a geometric distribution with probability parameter  $p$  equal to 0.25.

```
p = 0.25;
```

```
[m,v] = geostat(p)
```

```
m =
```

```
3
```

```
v =
```

```
12
```

## Example

### Compute Geometric Distribution Probabilities

Suppose the probability of a five-year-old car battery not starting in cold weather is 0.03. What is the probability of the car starting for 25 consecutive days during a long cold snap?

Model the scenario using a geometric distribution. In this case, the "failure" event is the car starting, and the "success" event is the car not starting. We want to determine the probability of observing 25 failures (the car starting) without observing a single success (the car not starting). The probability of success for each trial (the car not starting in any single attempt) is  $P = 0.03$ .

To solve, first compute the cumulative distribution function (cdf) for  $x = 25$  trials. This returns the probability of observing success (the car not starting) in up to 25 trials. Then subtract this result from 1 to determine the probability of *not* observing success in up to 25 trials - in other words, the probability that the car starts at every one of the 25 attempts.

```
pstart = 1 - geocdf(25,0.03)
```

```
pstart =
```

```
0.4530
```

The returned result `pstart = 0.4530` is the probability that the car will start every day for 25 days in a row during a cold snap.

This plot of the cdf for this scenario shows that, as the number of trials ( $x$ ) increases, the probability of success ( $y$ ) also increases. In the context of this example, it means that the more times you attempt to start the car, the greater the probability that it does not start on at least one of those occasions.

```
figure;
x = 0:25;
y = geocdf(x,0.03);
stairs(x,y)
```

# Hypergeometric Distribution

**In this section...**

“Definition” on page B-67

“Background” on page B-67

“Examples” on page B-68

## Definition

The hypergeometric pdf is

$$y = f(x | M, K, n) = \frac{\binom{K}{x} \binom{M-K}{n-x}}{\binom{M}{n}}$$

## Background

The hypergeometric distribution models the total number of successes in a fixed-size sample drawn without replacement from a finite population.

The distribution is discrete, existing only for nonnegative integers less than the number of samples or the number of possible successes, whichever is greater. The hypergeometric distribution differs from the binomial only in that the population is finite and the sampling from the population is without replacement.

The hypergeometric distribution has three parameters that have direct physical interpretations.

- $M$  is the size of the population.
- $K$  is the number of items with the desired characteristic in the population.
- $n$  is the number of samples drawn.

Sampling “without replacement” means that once a particular sample is chosen, it is removed from the relevant population for all subsequent selections.

## Examples

### Compute and Plot Hypergeometric Distribution CDF

This example shows how to compute and plot the cdf of a hypergeometric distribution.

Compute the cdf of a hypergeometric distribution that draws 20 samples from a group of 1000 items, when the group contains 50 items of the desired type.

```
x = 0:10;
y = hygecdf(x, 1000, 50, 20);
```

Plot the cdf.

```
stairs(x,y)
```

The x-axis of the plot shows the number of items drawn that are of the desired type. The y-axis shows the corresponding cdf values.

## Inverse Gaussian Distribution

| In this section...        |
|---------------------------|
| “Definition” on page B-70 |
| “Background” on page B-70 |
| “Parameters” on page B-70 |

### Definition

The inverse Gaussian distribution has the density function

$$\sqrt{\frac{\lambda}{2\pi x^3}} \exp\left\{-\frac{\lambda}{2\mu^2 x}(x-\mu)^2\right\}$$

### Background

Also known as the Wald distribution, the inverse Gaussian is used to model nonnegative positively skewed data. The distribution originated in the theory of Brownian motion, but has been used to model diverse phenomena. Inverse Gaussian distributions have many similarities to standard Gaussian (normal) distributions, which lead to applications in inferential statistics.

### Parameters

To estimate distribution parameters, use `mle` or the Distribution Fitting app.

# Inverse Wishart Distribution

## Definition

The probability density function of the  $d$ -dimensional Inverse Wishart distribution is given by

$$y = f(X, \Sigma, \nu) = \frac{|T|^{(\nu/2)} e^{\left(-\frac{1}{2}\text{trace}(TX^{-1})\right)}}{2^{(\nu d)/2} \pi^{(d(d-1))/4} |X|^{(\nu+d+1)/2} \Gamma(\nu/2) \dots \Gamma(\nu - (d-1))/2},$$

where  $X$  and  $T$  are  $d$ -by- $d$  symmetric positive definite matrices, and  $\nu$  is a scalar greater than or equal to  $d$ . While it is possible to define the Inverse Wishart for singular  $T$ , the density cannot be written as above.

If a random matrix has a Wishart distribution with parameters  $T^{-1}$  and  $\nu$ , then the inverse of that random matrix has an inverse Wishart distribution with parameters  $T$  and  $\nu$ . The mean of the distribution is given by

$$\frac{1}{\nu - d - 1} T$$

where  $d$  is the number of rows and columns in  $T$ .

Only random matrix generation is supported for the inverse Wishart, including both singular and nonsingular  $T$ .

## Background

The inverse Wishart distribution is based on the Wishart distribution. In Bayesian statistics it is used as the conjugate prior for the covariance matrix of a multivariate normal distribution.

## Example

Notice that the sampling variability is quite large when the degrees of freedom is small.

```
Tau = [1 .5; .5 2];
df = 10; S1 = iwishrnd(Tau,df)*(df-2-1)
```

```
S1 =
 1.7959 0.64107
 0.64107 1.5496
```

```
df = 1000; S2 = iwishrnd(Tau,df)*(df-2-1)
```

```
S2 =
 0.9842 0.50158
 0.50158 2.1682
```

## Kernel Distribution

| In this section...                       |
|------------------------------------------|
| “Overview” on page B-74                  |
| “Kernel Density Estimator” on page B-74  |
| “Kernel Smoothing Function” on page B-74 |
| “Bandwidth” on page B-80                 |

### Overview

A kernel distribution is a nonparametric representation of the probability density function (pdf) of a random variable. You can use a kernel distribution when a parametric distribution cannot properly describe the data, or when you want to avoid making assumptions about the distribution of the data. This distribution is defined by a smoothing function and a bandwidth value that controls the smoothness of the resulting density curve.

### Kernel Density Estimator

The kernel density estimator is the estimated probability density function (pdf) of the random variable. Its formula is given by the equation

$$\hat{f}_h(x) = \frac{1}{nh} \sum_{i=1}^n K\left(\frac{x - x_i}{h}\right) ; \quad -\infty < x < \infty,$$

where  $n$  is the sample size,  $K(\cdot)$  is the kernel smoothing function,  $h$  is the bandwidth.

### Kernel Smoothing Function

The kernel smoothing function defines the shape of the curve used to generate the pdf. Similar to a histogram, the kernel distribution builds a function to represent the probability distribution using the sample data. But unlike a histogram, which places the values into discrete bins, a kernel distribution sums the component smoothing functions for each data value to produce a smooth, continuous probability curve. The following plots show a visual comparison of a histogram and a kernel distribution generated from the same sample data.

A histogram represents the probability distribution by establishing bins and placing each data value in the appropriate bin.

```
SixMPG = [13;15;23;29;32;34];
figure;
hist(SixMPG)
```

Because of this bin count approach, the histogram produces a discrete probability density function. This might be unsuitable for certain applications, such as generating random numbers from a fitted distribution.

Alternatively, the kernel distribution builds the pdf by creating an individual probability density curve for each data value, then summing the smooth curves. This approach creates one smooth, continuous probability density function for the data set.

```
figure;
pdSix = fitdist(SixMPG,'Kernel','BandWidth',4);
x = 0:.1:45;
ySix = pdf(pdSix,x);
plot(x,ySix,'k-','LineWidth',2);

% Plot each individual pdf and scale its appearance on the plot
hold on;
for i=1:6
 pd = makedist('Normal','mu',SixMPG(i),'sigma',4);
 y = pdf(pd,x);
 y = y/6;
 plot(x,y,'b:');
end
hold off;
```

The smaller dashed curves are the probability distributions for each value in the sample data, scaled to fit the plot. The larger solid curve is the overall kernel distribution of the SixMPG data. The kernel smoothing function refers to the shape of those smaller component curves, which have a normal distribution in this example.

You can choose one of several options for the kernel smoothing function. This plot shows the shapes of the available smoothing functions.

Set plot specifications

```
hname = {'normal' 'epanechnikov' 'box' 'triangle'};
colors = {'r' 'b' 'g' 'm'};
lines = {'-', '-.', '--', ':'};

% Generate a sample of each kernel smoothing function and plot
data = [0];
figure;
for j=1:4
 pd = fitdist(data, 'kernel', 'Kernel', hname{j});
 x = -3:.1:3;
 y = pdf(pd, x);
 plot(x, y, 'Color', colors{j}, 'LineStyle', lines{j});
 hold on;
end
legend(hname{:});
hold off;
```

To understand the effect of different kernel smoothing functions on the shape of the resulting pdf estimate, compare plots of the mileage data (MPG) from `carbig.mat` using each available kernel function.

```
load carbig;
% Set plot specifications
hname = {'normal' 'epanechnikov' 'box' 'triangle'};
colors = {'r' 'b' 'g' 'm'};
lines = {'-' '---' '---' ':'};

% Generate kernel distribution objects and plot
figure;
for j=1:4
 pd = fitdist(MPG,'kernel','Kernel',hname{j});
```

```
x = -10:1:60;
y = pdf(pd,x);
plot(x,y, 'Color',colors{j},'LineStyle',lines{j});
hold on;
end
legend(hname{:});
hold off;
```

Each density curve uses the same input data, but applies a different kernel smoothing function to generate the pdf. The density estimates are roughly comparable, but the shape of each curve varies slightly. For example, the box kernel produces a density curve that is less smooth than the others.

## Bandwidth

The choice of bandwidth value controls the smoothness of the resulting probability density curve. This plot shows the density estimate for the same MPG data, using a normal kernel smoothing function with three different bandwidths.

Create kernel distribution objects

```
pd1 = fitdist(MPG,'kernel');
pd2 = fitdist(MPG,'kernel','BandWidth',1);
pd3 = fitdist(MPG,'kernel','BandWidth',5);

% Compute each pdf
x = -10:1:60;
y1 = pdf(pd1,x);
y2 = pdf(pd2,x);
y3 = pdf(pd3,x);

% Plot each pdf
plot(x,y1,'Color','r','LineStyle','-');
hold on;
plot(x,y2,'Color','k','LineStyle',':');
plot(x,y3,'Color','b','LineStyle','--');
legend({'BandWidth = Default','BandWidth = 1','BandWidth = 5'});
hold off;
```

The default bandwidth, which is theoretically optimal for estimating densities for the normal distribution, produces a reasonably smooth curve. Specifying a smaller bandwidth produces a very rough curve, but reveals that there might be two major peaks in the data. Specifying a larger bandwidth produces a curve nearly identical to the kernel function, and is so smooth that it obscures potentially important features of the data.

## Logistic Distribution

### In this section...

“Overview” on page B-83

“Parameters” on page B-83

“Probability Density Function” on page B-83

“Relationship to Other Distributions” on page B-83

### Overview

The logistic distribution is used for growth models and in logistic regression. It has longer tails and a higher kurtosis than the normal distribution.

### Parameters

The logistic distribution uses the following parameters.

| Parameter | Description     | Support                  |
|-----------|-----------------|--------------------------|
| mu        | Mean            | $-\infty < \mu < \infty$ |
| sigma     | Scale parameter | $\sigma \geq 0$          |

### Probability Density Function

The probability density function (pdf) is

$$f(x | \mu, \sigma) = \frac{\exp\left\{\frac{x - \mu}{\sigma}\right\}}{\sigma \left(1 + \exp\left\{\frac{x - \mu}{\sigma}\right\}\right)^2} ; \quad -\infty < x < \infty.$$

### Relationship to Other Distributions

The loglogistic distribution is closely related to the logistic distribution. If  $x$  is distributed loglogistically with parameters  $\mu$  and  $\sigma$ , then  $\log(x)$  is distributed logistically with mean and standard deviation.

## Loglogistic Distribution

**In this section...**

“Overview” on page B-84

“Parameters” on page B-84

“Probability Density Function” on page B-84

“Relationship to Other Distributions” on page B-85

### Overview

The loglogistic distribution is a probability distribution whose logarithm has a logistic distribution. This distribution is often used in survival analysis to model events that experience an initial rate increase, followed by a rate decrease. It is also known as the Fisk distribution in economics applications.

### Parameters

The loglogistic distribution uses the following parameters.

| Parameter | Description         | Support      |
|-----------|---------------------|--------------|
| mu        | Log mean            | $\mu > 0$    |
| sigma     | Log scale parameter | $\sigma > 0$ |

### Probability Density Function

The probability density function (pdf) is

$$f(x | \mu, \sigma) = \frac{1}{\sigma} \frac{1}{x} \frac{e^z}{(1+e^z)^2} \quad ; \quad x \geq 0,$$

where  $z = \frac{\log(x) - \mu}{\sigma}$ .

## Relationship to Other Distributions

The loglogistic distribution is closely related to the logistic distribution. If  $x$  is distributed loglogistically with parameters  $\mu$  and  $\sigma$ , then  $\log(x)$  is distributed logistically with mean and standard deviation. The relationship is similar to that between the lognormal and normal distribution.

# Lognormal Distribution

| In this section...                                 |
|----------------------------------------------------|
| “Overview” on page B-86                            |

| “Probability Density Function” on page B-86        |
| “Descriptive Statistics” on page B-87              |
| “Relationship to Other Distributions” on page B-87 |
| “Examples” on page B-87                            |

## Overview

The lognormal distribution is a probability distribution whose logarithm has a normal distribution. It is sometimes called the Galton distribution. The lognormal distribution is applicable when the quantity of interest must be positive, since  $\log(x)$  exists only when  $x$  is positive.

## Parameters

The lognormal distribution uses the following parameters.

| Parameter | Description            | Support                  |
|-----------|------------------------|--------------------------|
| mu        | Log mean               | $-\infty < \mu < \infty$ |
| sigma     | Log standard deviation | $\sigma \geq 0$          |

## Probability Density Function

The probability density function (pdf) of the lognormal distribution is

$$f(x | \mu, \sigma) = \frac{1}{x\sigma\sqrt{2\pi}} \exp\left\{-\frac{(\ln x - \mu)^2}{2\sigma^2}\right\} ; \quad x > 0.$$

## Descriptive Statistics

The mean is

$$\text{mean} = \exp\left(\mu + \frac{\sigma^2}{2}\right).$$

The variance is

$$\text{var} = \exp(2\mu + \sigma^2)\left(\exp(\sigma^2) - 1\right).$$

You can compute these descriptive statistics using the `lognstat` function.

## Relationship to Other Distributions

The lognormal distribution is closely related to the normal distribution. If  $x$  is distributed lognormally with parameters  $\mu$  and  $\sigma$ , then  $\log(x)$  is distributed normally with mean  $\mu$  and standard deviation  $\sigma$ . The lognormal distribution is applicable when the quantity of interest must be positive, since  $\log(x)$  exists only when  $x$  is positive.

## Examples

### Compute the Lognormal Distribution pdf

Suppose the income of a family of four in the United States follows a lognormal distribution with `mu = log(20,000)` and `sigma = 1`. Compute and plot the income density.

```
x = (10:1000:125010)';
y = lognpdf(x,log(20000),1.0);

figure;
plot(x,y)
h = gca;
h.XTick = [0 30000 60000 90000 120000];
h.XTickLabel = {'0', '$30,000', '$60,000', ...
 '$90,000', '$120,000'};
```

# Multinomial Distribution

## In this section...

“Overview” on page B-89

“Parameter” on page B-89

“Probability Density Function” on page B-89

“Descriptive Statistics” on page B-90

“Relationship to Other Distributions” on page B-90

## Overview

Multinomial distribution models the probability of each combination of successes in a series of independent trials. Use this distribution when there are more than two possible mutually exclusive outcomes for each trial, and each outcome has a fixed probability of success.

## Parameter

Multinomial distribution uses the following parameter.

| Parameter     | Description           | Constraints                                                                               |
|---------------|-----------------------|-------------------------------------------------------------------------------------------|
| probabilities | Outcome probabilities | $0 \leq \text{probabilities}(i) \leq 1; \sum_{\text{all}(i)} \text{probabilities}(i) = 1$ |

## Probability Density Function

The multinomial pdf is

$$f(x | n, p) = \frac{n!}{x_1! \dots x_k!} p_1^{x_1} \dots p_k^{x_k},$$

where  $k$  is the number of possible mutually exclusive outcomes for each trial, and  $n$  is the total number of trials. The vector  $x = (x_1 \dots x_k)$  is the number of observations of each  $k$  outcome, and contains nonnegative integer components that sum to  $n$ . The vector  $p$

$= (p_1 \dots p_k)$  is the fixed probability of each  $k$  outcome, and contains nonnegative scalar components that sum to 1.

## Descriptive Statistics

The expected number of observations of outcome  $i$  in  $n$  trials is

$$E\{x_i\} = np_i,$$

where  $p_i$  is the fixed probability of outcome  $i$ .

The variance is of outcome  $i$  is

$$\text{var}(x_i) = np_i(1 - p_i).$$

The covariance of outcomes  $i$  and  $j$  is

$$\text{cov}(x_i, x_j) = -np_i p_j, \quad i \neq j.$$

## Relationship to Other Distributions

The multinomial distribution is a generalization of the binomial distribution. While the binomial distribution gives the probability of the number of “successes” in  $n$  independent trials of a two-outcome process, the multinomial distribution gives the probability of each combination of outcomes in  $n$  independent trials of a  $k$ -outcome process. The probability of each outcome in any one trial is given by the fixed probabilities  $p_1, \dots, p_k$ .

## **Multivariate Gaussian Distribution**

See “Multivariate Normal Distribution” on page B-92.

## Multivariate Normal Distribution

**In this section...**

“Definition” on page B-92

“Background” on page B-92

“Examples” on page B-93

### Definition

The probability density function of the  $d$ -dimensional multivariate normal distribution is given by

$$y = f(x, \mu, \Sigma) = \frac{1}{\sqrt{|\Sigma|} (2\pi)^d} e^{-\frac{1}{2}(x-\mu)' \Sigma^{-1}(x-\mu)}$$

where  $x$  and  $\mu$  are 1-by- $d$  vectors and  $\Sigma$  is a  $d$ -by- $d$  symmetric positive definite matrix. While it is possible to define the multivariate normal for singular  $\Sigma$ , the density cannot be written as above. Only random vector generation is supported for the singular case. Note that while most textbooks define the multivariate normal with  $x$  and  $\mu$  oriented as column vectors, for the purposes of data analysis software, it is more convenient to orient them as row vectors, and Statistics Toolbox software uses that orientation.

### Background

The multivariate normal distribution is a generalization of the univariate normal to two or more variables. It is a distribution for random vectors of correlated variables, each element of which has a univariate normal distribution. In the simplest case, there is no correlation among variables, and elements of the vectors are independent univariate normal random variables.

The multivariate normal distribution is parameterized with a mean vector,  $\mu$ , and a covariance matrix,  $\Sigma$ . These are analogous to the mean  $\mu$  and variance  $\sigma^2$  parameters of a univariate normal distribution. The diagonal elements of  $\Sigma$  contain the variances for each variable, while the off-diagonal elements of  $\Sigma$  contain the covariances between variables.

The multivariate normal distribution is often used as a model for multivariate data, primarily because it is one of the few multivariate distributions that is tractable to work with.

## Examples

### Compute the Multivariate Normal pdf

Compute and plot the pdf of a multivariate normal distribution.

```
mu = [0 0];
Sigma = [.25 .3; .3 1];
x1 = -3:.2:3; x2 = -3:.2:3;
[X1,X2] = meshgrid(x1,x2);
F = mvnpdf([X1(:) X2(:)],mu,Sigma);
F = reshape(F,length(x2),length(x1));
surf(x1,x2,F);
caxis([min(F(:))-.5*range(F(:)),max(F(:))]);
axis([-3 3 -3 3 0 .4])
xlabel('x1'); ylabel('x2'); zlabel('Probability Density');
```

### Compute the Multivariate Normal cdf

Compute and plot the cdf of a multivariate normal distribution with parameters  $\mu = [1 \ -1]$  and  $\text{SIGMA} = \begin{bmatrix} .9 & .4 \\ .4 & .3 \end{bmatrix}$ .

```
mu = [1 -1];
SIGMA = [.9 .4; .4 .3];
figure;
[X1,X2] = meshgrid(linspace(-1,3,25)',linspace(-3,1,25)');
X = [X1(:) X2(:)];
p = mvncdf(X,mu,SIGMA);
surf(X1,X2,reshape(p,25,25));
```

### Compute Cumulative Probabilities Over Regions

Since the bivariate normal distribution is defined on the plane, you can also compute cumulative probabilities over rectangular regions.

Compute the probability contained within the unit square, and create a contour plot of the results.

```
mu = [0 0];
Sigma = [.25 .3; .3 1];
x1 = -3:.2:3; x2 = -3:.2:3;
[X1,X2] = meshgrid(x1,x2);
F = mvnpdf([X1(:) X2(:)],mu,Sigma);
F = reshape(F,length(x2),length(x1));
```

```
mvncdf([0 0],[1 1],mu,Sigma);
contour(x1,x2,F,[.0001 .001 .01 .05:.1:.95 .99 .999 .9999]);
xlabel('x'); ylabel('y');
line([0 0 1 1 0],[1 0 0 1 1],'linestyle','--','color','k');
```

Computing a multivariate cumulative probability requires significantly more work than computing a univariate probability. By default, the `mvncdf` function computes values to less than full machine precision, and returns an estimate of the error as an optional second output.

```
[F,err] = mvncdf([0 0],[1 1],mu,Sigma)
```

F =

0.2097

err =

1.0000e-08

## Multivariate $t$ Distribution

**In this section...**

“Definition” on page B-98

“Background” on page B-98

“Example” on page B-99

### Definition

The probability density function of the  $d$ -dimensional multivariate Student's  $t$  distribution is given by

$$f(x, \Sigma, \nu) = \frac{1}{|\Sigma|^{1/2}} \frac{1}{\sqrt{(\nu\pi)^d}} \frac{\Gamma((\nu + d) / 2)}{\Gamma(\nu / 2)} \left( 1 + \frac{x' \Sigma^{-1} x}{\nu} \right)^{-(\nu+d)/2} .$$

where  $x$  is a 1-by- $d$  vector,  $\Sigma$  is a  $d$ -by- $d$  symmetric, positive definite matrix, and  $\nu$  is a positive scalar. While it is possible to define the multivariate Student's  $t$  for singular  $\Sigma$ , the density cannot be written as above. For the singular case, only random number generation is supported. Note that while most textbooks define the multivariate Student's  $t$  with  $x$  oriented as a column vector, for the purposes of data analysis software, it is more convenient to orient  $x$  as a row vector, and Statistics Toolbox software uses that orientation.

### Background

The multivariate Student's  $t$  distribution is a generalization of the univariate Student's  $t$  to two or more variables. It is a distribution for random vectors of correlated variables, each element of which has a univariate Student's  $t$  distribution. In the same way as the univariate Student's  $t$  distribution can be constructed by dividing a standard univariate normal random variable by the square root of a univariate chi-square random variable, the multivariate Student's  $t$  distribution can be constructed by dividing a multivariate normal random vector having zero mean and unit variances by a univariate chi-square random variable.

The multivariate Student's  $t$  distribution is parameterized with a correlation matrix,  $\Sigma$ , and a positive scalar degrees of freedom parameter,  $\nu$ .  $\nu$  is analogous to the degrees of freedom parameter of a univariate Student's  $t$  distribution. The off-diagonal elements of  $\Sigma$  contain the correlations between variables. Note that when  $\Sigma$  is the identity matrix, variables are uncorrelated; however, they are not independent.

The multivariate Student's  $t$  distribution is often used as a substitute for the multivariate normal distribution in situations where it is known that the marginal distributions of the individual variables have fatter tails than the normal.

## Example

### Plot PDF and CDF of Multivariate $t$ -Distribution

Plot the pdf of a bivariate Student's  $t$  distribution. You can use this distribution for a higher number of dimensions as well, although visualization is not easy.

```
Rho = [1 .6; .6 1];
nu = 5;
x1 = -3:.2:3; x2 = -3:.2:3;
[X1,X2] = meshgrid(x1,x2);
F = mvtpdf([X1(:) X2(:)],Rho,nu);
F = reshape(F,length(x2),length(x1));
surf(x1,x2,F);
caxis([min(F(:))-.5*range(F(:)),max(F(:))]);
axis([-3 3 -3 3 0 .2])
xlabel('x1'); ylabel('x2'); zlabel('Probability Density');
```

Plot the cdf of a bivariate Student's  $t$  distribution.

```
F = mvtcdf([X1(:) X2(:)],Rho,nu);
F = reshape(F,length(x2),length(x1));
surf(x1,x2,F);
caxis([min(F(:))-0.5*range(F(:)),max(F(:))]);
axis([-3 3 -3 3 0 1])
xlabel('x1'); ylabel('x2'); zlabel('Cumulative Probability');
```

Since the bivariate Student's  $t$  distribution is defined on the plane, you can also compute cumulative probabilities over rectangular regions. For example, this contour plot illustrates the computation that follows, of the probability contained within the unit square shown in the figure.

```
contour(x1,x2,F,[.0001 .001 .01 .05:.1:.95 .99 .999 .9999]);
xlabel('x'); ylabel('y');
line([0 0 1 1 0],[1 0 0 1 1],'linestyle','--','color','k');
```

Compute the value of the probability contained within the unit square.

```
F = mvtcdf([0 0],[1 1],Rho,nu)
```

```
F =
```

```
0.1401
```

Computing a multivariate cumulative probability requires significantly more work than computing a univariate probability. By default, the `mvtcdf` function computes values to less than full machine precision and returns an estimate of the error, as an optional second output.

```
[F,err] = mvtcdf([0 0],[1 1],Rho,nu)
```

```
F =
```

```
0.1401
```

```
err =
```

```
1.0000e-08
```

# Nakagami Distribution

**In this section...**

“Definition” on page B-104

“Background” on page B-104

“Parameters” on page B-104

## Definition

The Nakagami distribution has the density function

$$2\left(\frac{\mu}{\omega}\right)^{\mu} \frac{1}{\Gamma(\mu)} x^{(2\mu-1)} e^{-\frac{\mu}{\omega}x^2}$$

with shape parameter  $\mu$  and scale parameter  $\omega > 0$ , for  $x > 0$ . If  $x$  has a Nakagami distribution with parameters  $\mu$  and  $\omega$ , then  $x^2$  has a gamma distribution with shape parameter  $\mu$  and scale parameter  $\omega/\mu$ .

## Background

In communications theory, Nakagami distributions, Rician distributions, and Rayleigh distributions are used to model scattered signals that reach a receiver by multiple paths. Depending on the density of the scatter, the signal will display different fading characteristics. Rayleigh and Nakagami distributions are used to model dense scatters, while Rician distributions model fading with a stronger line-of-sight. Nakagami distributions can be reduced to Rayleigh distributions, but give more control over the extent of the fading.

## Parameters

To estimate distribution parameters, use `mle` or the Distribution Fitting app.

# Negative Binomial Distribution

## In this section...

“Definition” on page B-105

“Background” on page B-105

“Parameters” on page B-106

“Example” on page B-108

## Definition

When the  $r$  parameter is an integer, the negative binomial pdf is

$$y = f(x | r, p) = \binom{r+x-1}{x} p^r q^x I_{(0,1,\dots)}(x)$$

where  $q = 1 - p$ . When  $r$  is not an integer, the binomial coefficient in the definition of the pdf is replaced by the equivalent expression

$$\frac{\Gamma(r+x)}{\Gamma(r)\Gamma(x+1)}$$

## Background

In its simplest form (when  $r$  is an integer), the negative binomial distribution models the number of failures  $x$  before a specified number of successes is reached in a series of independent, identical trials. Its parameters are the probability of success in a single trial,  $p$ , and the number of successes,  $r$ . A special case of the negative binomial distribution, when  $r = 1$ , is the geometric distribution, which models the number of failures before the first success.

More generally,  $r$  can take on non-integer values. This form of the negative binomial distribution has no interpretation in terms of repeated trials, but, like the Poisson distribution, it is useful in modeling count data. The negative binomial distribution is more general than the Poisson distribution because it has a variance that is greater than its mean, making it suitable for count data that do not meet the assumptions of

the Poisson distribution. In the limit, as  $r$  increases to infinity, the negative binomial distribution approaches the Poisson distribution.

## Parameters

Suppose you are collecting data on the number of auto accidents on a busy highway, and would like to be able to model the number of accidents per day. Because these are count data, and because there are a very large number of cars and a small probability of an accident for any specific car, you might think to use the Poisson distribution. However, the probability of having an accident is likely to vary from day to day as the weather and amount of traffic change, and so the assumptions needed for the Poisson distribution are not met. In particular, the variance of this type of count data sometimes exceeds the mean by a large amount. The data below exhibit this effect: most days have few or no accidents, and a few days have a large number.

```
accident = [2 3 4 2 3 1 12 8 14 31 23 1 10 7 0];
m = mean(accident)
v = var(accident)
```

```
m =
```

```
8.0667
```

```
v =
```

```
79.3524
```

The negative binomial distribution is more general than the Poisson, and is often suitable for count data when the Poisson is not. The function `nbinfit` returns the maximum likelihood estimates (MLEs) and confidence intervals for the parameters of the negative binomial distribution. Here are the results from fitting the `accident` data:

```
[phat,pci] = nbinfit(accident)
```

```
phat =
```

```
1.0060 0.1109
```

```
pci =
```

```
0.2152 0.0171
1.7968 0.2046
```

It is difficult to give a physical interpretation in this case to the individual parameters. However, the estimated parameters can be used in a model for the number of daily accidents. For example, a plot of the estimated cumulative probability function shows that while there is an estimated 10% chance of no accidents on a given day, there is also about a 10% chance that there will be 20 or more accidents.

```
plot(0:50,nbincdf(0:50,phat(1),phat(2)), '-');
xlabel('Accidents per Day')
ylabel('Cumulative Probability')
```

## Example

### Compute and Plot Negative Binomial Distribution PDF

Compute and plot the pdf using four different values for the parameter  $r$ , the desired number of successes:  $.1$ ,  $1$ ,  $3$ , and  $6$ . In each case, the probability of success  $p$  is  $.5$ .

```
x = 0:10;
plot(x,nbinpdf(x,.1,.5),'s-', ...
 x,nbinpdf(x,1,.5),'o-', ...
 x,nbinpdf(x,3,.5),'d-', ...
 x,nbinpdf(x,6,.5),'^-',);
legend({'r = .1' 'r = 1' 'r = 3' 'r = 6'})
xlabel('x')
ylabel('f(x|r,p)')
```

The plot shows that the negative binomial distribution can take on a variety of shapes, ranging from very skewed to nearly symmetric, depending on the value of  $r$ .

## Noncentral Chi-Square Distribution

**In this section...**

“Definition” on page B-110

“Background” on page B-110

“Examples” on page B-111

### Definition

There are many equivalent formulas for the noncentral chi-square distribution function. One formulation uses a modified Bessel function of the first kind. Another uses the generalized Laguerre polynomials. The cumulative distribution function is computed using a weighted sum of  $\chi^2$  probabilities with the weights equal to the probabilities of a Poisson distribution. The Poisson parameter is one-half of the noncentrality parameter of the noncentral chi-square

$$F(x | \nu, \delta) = \sum_{j=0}^{\infty} \left( \frac{\left(\frac{1}{2}\delta\right)^j}{j!} e^{-\frac{\delta}{2}} \right) \Pr \left[ \chi_{\nu+2j}^2 \leq x \right]$$

where  $\delta$  is the noncentrality parameter.

### Background

The  $\chi^2$  distribution is actually a simple special case of the noncentral chi-square distribution. One way to generate random numbers with a  $\chi^2$  distribution (with  $\nu$  degrees of freedom) is to sum the squares of  $\nu$  standard normal random numbers (mean equal to zero.)

What if the normally distributed quantities have a mean other than zero? The sum of squares of these numbers yields the noncentral chi-square distribution. The noncentral chi-square distribution requires two parameters: the degrees of freedom and the noncentrality parameter. The noncentrality parameter is the sum of the squared means of the normally distributed quantities.

The noncentral chi-square has scientific application in thermodynamics and signal processing. The literature in these areas may refer to it as the “Rician Distribution” on page B-132 or generalized “Rayleigh Distribution” on page B-129.

## Examples

### Compute Noncentral Chi-Square Distribution pdf

Compute the pdf of a noncentral chi-square distribution with degrees of freedom  $V = 4$  and noncentrality parameter  $\text{DELTA} = 2$ . For comparison, also compute the pdf of a chi-square distribution with the same degrees of freedom.

```
x = (0:0.1:10)';
ncx2 = ncx2pdf(x,4,2);
chi2 = chi2pdf(x,4);
```

Plot the pdf of the noncentral chi-square distribution on the same figure as the pdf of the chi-square distribution.

```
figure;
plot(x,ncx2,'b-','LineWidth',2)
hold on
plot(x,chi2,'g--','LineWidth',2)
legend('ncx2','chi2')
```

## Noncentral F Distribution

### In this section...

“Definition” on page B-113

“Background” on page B-113

“Examples” on page B-113

### Definition

Similar to the noncentral  $\chi^2$  distribution, the toolbox calculates noncentral  $F$  distribution probabilities as a weighted sum of incomplete beta functions using Poisson probabilities as the weights.

$$F(x | v_1, v_2, \delta) = \sum_{j=0}^{\infty} \left( \frac{\left(\frac{1}{2}\delta\right)^j}{j!} e^{-\frac{\delta}{2}} \right) I\left(\frac{v_1 \cdot x}{v_2 + v_1 \cdot x} \mid \frac{v_1}{2} + j, \frac{v_2}{2}\right)$$

$I(x | a, b)$  is the incomplete beta function with parameters  $a$  and  $b$ , and  $\delta$  is the noncentrality parameter.

### Background

As with the  $\chi^2$  distribution, the  $F$  distribution is a special case of the noncentral  $F$  distribution. The  $F$  distribution is the result of taking the ratio of  $\chi^2$  random variables each divided by its degrees of freedom.

If the numerator of the ratio is a noncentral chi-square random variable divided by its degrees of freedom, the resulting distribution is the noncentral  $F$  distribution.

The main application of the noncentral  $F$  distribution is to calculate the power of a hypothesis test relative to a particular alternative.

### Examples

#### Compute Noncentral $F$ Distribution pdf

Compute the pdf of a noncentral  $F$  distribution with degrees of freedom  $NU1 = 5$  and  $NU2 = 20$ , and noncentrality parameter  $DELTA = 10$ . For comparison, also compute the pdf of an  $F$  distribution with the same degrees of freedom.

```
x = (0.01:0.1:10.01)';
p1 = ncfpdf(x,5,20,10);
p = fpdf(x,5,20);
```

Plot the pdf of the noncentral  $F$  distribution and the pdf of the  $F$  distribution on the same figure.

```
figure;
plot(x,p1,'b-','LineWidth',2)
hold on
plot(x,p,'g--','LineWidth',2)
legend('Noncentral F','F distribution')
```

## Noncentral $t$ Distribution

**In this section...**

“Definition” on page B-116

“Background” on page B-116

“Examples” on page B-117

### Definition

The most general representation of the noncentral  $t$  distribution is quite complicated. Johnson and Kotz [60] give a formula for the probability that a noncentral  $t$  variate falls in the range  $[-u, u]$ .

$$P(-u < x < u | \nu, \delta) = \sum_{j=0}^{\infty} \left( \frac{\left(\frac{1}{2}\delta^2\right)^j}{j!} e^{-\frac{\delta^2}{2}} \right) I\left(\frac{u^2}{\nu + u^2} \middle| \frac{1}{2} + j, \frac{\nu}{2}\right)$$

$I(x | \nu, \delta)$  is the incomplete beta function with parameters  $\nu$  and  $\delta$ .  $\delta$  is the noncentrality parameter, and  $\nu$  is the number of degrees of freedom.

### Background

The noncentral  $t$  distribution is a generalization of Student's  $t$  distribution.

Student's  $t$  distribution with  $n - 1$  degrees of freedom models the  $t$ -statistic

$$t = \frac{\bar{x} - \mu}{s / \sqrt{n}}$$

where  $\bar{x}$  is the sample mean and  $s$  is the sample standard deviation of a random sample of size  $n$  from a normal population with mean  $\mu$ . If the population mean is actually  $\mu_0$ , then the  $t$ -statistic has a noncentral  $t$  distribution with noncentrality parameter

$$\delta = \frac{\mu_0 - \mu}{\sigma / \sqrt{n}}$$

The noncentrality parameter is the normalized difference between  $\mu_0$  and  $\mu$ .

The noncentral  $t$  distribution gives the probability that a  $t$  test will correctly reject a false null hypothesis of mean  $\mu$  when the population mean is actually  $\mu_0$ ; that is, it gives the power of the  $t$  test. The power increases as the difference  $\mu_0 - \mu$  increases, and also as the sample size  $n$  increases.

## Examples

### Compute Noncentral $t$ Distribution pdf

Compute the pdf of a noncentral  $t$  distribution with degrees of freedom  $V = 10$  and noncentrality parameter  $\text{DELTA} = 1$ . For comparison, also compute the pdf of a  $t$  distribution with the same degrees of freedom.

```
x = (-5:0.1:5)';
nct = nctpdf(x,10,1);
t = tpdf(x,10);
```

Plot the pdf of the noncentral  $t$  distribution and the pdf of the  $t$  distribution on the same figure.

```
plot(x,nct,'b-', 'LineWidth',2)
hold on
plot(x,t,'g--', 'LineWidth',2)
legend('nct','t')
```

# Normal Distribution

**In this section...**

“Definition” on page B-119

“Background” on page B-119

“Parameters” on page B-119

“Examples” on page B-121

## Definition

The normal pdf is

$$y = f(x | \mu, \sigma) = \frac{1}{\sigma \sqrt{2\pi}} e^{-\frac{(x-\mu)^2}{2\sigma^2}}$$

## Background

The normal distribution is a two-parameter family of curves. The first parameter,  $\mu$ , is the mean. The second,  $\sigma$ , is the standard deviation. The standard normal distribution (written  $\Phi(x)$ ) sets  $\mu$  to 0 and  $\sigma$  to 1.

$\Phi(x)$  is functionally related to the error function, *erf*.

$$\text{erf}(x) = 2\Phi(x\sqrt{2}) - 1$$

The first use of the normal distribution was as a continuous approximation to the binomial.

The usual justification for using the normal distribution for modeling is the Central Limit Theorem, which states (roughly) that the sum of independent samples from any distribution with finite mean and variance converges to the normal distribution as the sample size goes to infinity.

## Parameters

To use statistical parameters such as mean and standard deviation reliably, you need to have a good estimator for them. The maximum likelihood estimates (MLEs) provide

one such estimator. However, an MLE might be biased, which means that its expected value of the parameter might not equal the parameter being estimated. For example, an MLE is biased for estimating the variance of a normal distribution. An unbiased estimator that is commonly used to estimate the parameters of the normal distribution is the *minimum variance unbiased estimator (MVUE)*. The MVUE has the minimum variance of all unbiased estimators of a parameter.

The MVUEs of parameters  $\mu$  and  $\sigma^2$  for the normal distribution are the sample mean and variance. The sample mean is also the MLE for  $\mu$ . The following are two common formulas for the variance.

$$s^2 = \frac{1}{n} \sum_{i=1}^n (x_i - \bar{x})^2$$

$$s^2 = \frac{1}{n-1} \sum_{i=1}^n (x_i - \bar{x})^2$$

where

$$\bar{x} = \sum_{i=1}^n \frac{x_i}{n}$$

Equation 1 is the maximum likelihood estimator for  $\sigma^2$ , and equation 2 is the MVUE.

As an example, suppose you want to estimate the mean,  $\mu$ , and the variance,  $\sigma^2$ , of the heights of all fourth grade children in the United States. The function `normfit` returns the MVUE for  $\mu$ , the square root of the MVUE for  $\sigma^2$ , and confidence intervals for  $\mu$  and  $\sigma^2$ . Here is a playful example modeling the heights in inches of a randomly chosen fourth grade class.

```
rng default; % For reproducibility
height = normrnd(50,2,30,1); % Simulate heights
[mu,s,muci,sci] = normfit(height)
```

```
mu =
```

```
51.1038

s =

 2.6001

muci =

 50.1329
 52.0747

sci =

 2.0707
 3.4954
```

Note that  $s^2$  is the MVUE of the variance.

```
s^2

ans =

 6.7605
```

## Examples

### Compute the Normal Distribution pdf

Compute the pdf of a standard normal distribution, with parameters  $\mu = 0$  and  $\sigma = 1$ .

```
x = [-3:.1:3];
norm = normpdf(x,0,1);
```

Plot the pdf.

```
figure;
plot(x,norm)
```

# Piecewise Linear Distribution

| In this section...                                  |
|-----------------------------------------------------|
| “Overview” on page B-125                            |
| “Parameters” on page B-125                          |
| “Cumulative Distribution Function” on page B-125    |
| “Relationship to Other Distributions” on page B-125 |

## Overview

The piecewise linear distribution creates a nonparametric representation of the cumulative distribution function (cdf) by linearly connecting the known cdf values from the sample data.

## Parameters

The piecewise linear distribution uses the following parameters.

| Parameter | Description                                               |
|-----------|-----------------------------------------------------------|
| $x$       | Vector of $x$ values at which the cdf changes slope       |
| $F_x$     | Vector of cdf values that correspond to each value in $x$ |

## Cumulative Distribution Function

The piecewise linear distribution constructs a continuous cumulative distribution function (cdf) by connecting the empirical cdf values such that the cdf increases linearly between  $x(j)$  and  $x(j + 1)$ .

## Relationship to Other Distributions

The piecewise linear distribution is a continuous version of the discrete empirical cumulative distribution function (ecdf).

## Poisson Distribution

| In this section...         |
|----------------------------|
| “Definition” on page B-126 |
| “Background” on page B-126 |
| “Parameters” on page B-127 |
| “Examples” on page B-127   |

### Definition

The Poisson pdf is

$$f(x | \lambda) = \frac{\lambda^x}{x!} e^{-\lambda}; x = 0, 1, 2, \dots, \infty.$$

### Background

The Poisson distribution is appropriate for applications that involve counting the number of times a random event occurs in a given amount of time, distance, area, etc. Sample applications that involve Poisson distributions include the number of Geiger counter clicks per second, the number of people walking into a store in an hour, and the number of flaws per 1000 feet of video tape.

The Poisson distribution is a one-parameter discrete distribution that takes nonnegative integer values. The parameter,  $\lambda$ , is both the mean and the variance of the distribution. Thus, as the size of the numbers in a particular sample of Poisson random numbers gets larger, so does the variability of the numbers.

The Poisson distribution is the limiting case of a binomial distribution where  $N$  approaches infinity and  $p$  goes to zero while  $Np = \lambda$ .

The Poisson and exponential distributions are related. If the number of counts follows the Poisson distribution, then the interval between individual counts follows the exponential distribution.

## Parameters

The MLE and the MVUE of the Poisson parameter,  $\lambda$ , is the sample mean. The sum of independent Poisson random variables is also Poisson distributed with the parameter equal to the sum of the individual parameters. This is used to calculate confidence intervals  $\lambda$ . As  $\lambda$  gets large the Poisson distribution can be approximated by a normal distribution with  $\mu = \lambda$  and  $\sigma^2 = \lambda$ . This approximation is used to calculate confidence intervals for values of  $\lambda$  greater than 100.

## Examples

### Compute and Plot Poisson Distribution PDF

Compute and plot the pdf of a Poisson distribution with parameter `lambda = 5`.

```
x = 0:15;
y = poisspdf(x,5);
plot(x,y, '+')
```

# Rayleigh Distribution

**In this section...**

“Definition” on page B-129

“Background” on page B-129

“Parameters” on page B-129

“Examples” on page B-130

## Definition

The Rayleigh pdf is

$$y = f(x | b) = \frac{x}{b^2} e^{\left(\frac{-x^2}{2b^2}\right)}$$

## Background

The Rayleigh distribution is a special case of the Weibull distribution. If  $A$  and  $B$  are the parameters of the Weibull distribution, then the Rayleigh distribution with parameter  $b$  is equivalent to the Weibull distribution with parameters  $A = \sqrt{2}b$  and  $B = 2$ .

If the component velocities of a particle in the  $x$  and  $y$  directions are two independent normal random variables with zero means and equal variances, then the distance the particle travels per unit time is distributed Rayleigh.

In communications theory, Nakagami distributions, Rician distributions, and Rayleigh distributions are used to model scattered signals that reach a receiver by multiple paths. Depending on the density of the scatter, the signal will display different fading characteristics. Rayleigh and Nakagami distributions are used to model dense scatters, while Rician distributions model fading with a stronger line-of-sight. Nakagami distributions can be reduced to Rayleigh distributions, but give more control over the extent of the fading.

## Parameters

The `raylf` function returns the MLE of the Rayleigh parameter. This estimate is

$$b = \sqrt{\frac{1}{2n} \sum_{i=1}^n x_i^2}$$

## Examples

### Compute and Plot Rayleigh Distribution pdf

Compute the pdf of a Rayleigh distribution with parameter  $B = 0.5$ .

```
x = [0:0.01:2];
p = raylpdf(x,0.5);
```

Plot the pdf.

```
figure;
plot(x,p)
```

## Rician Distribution

**In this section...**

“Definition” on page B-132

“Background” on page B-132

“Parameters” on page B-132

### Definition

The Rician distribution has the density function

$$I_0\left(\frac{xs}{\sigma^2}\right)\frac{x}{\sigma^2}e^{-\left(\frac{x^2+s^2}{2\sigma^2}\right)}$$

with noncentrality parameter  $s \geq 0$  and scale parameter  $\sigma > 0$ , for  $x > 0$ .  $I_0$  is the zero-order modified Bessel function of the first kind. If  $x$  has a Rician distribution with parameters  $s$  and  $\sigma$ , then  $(x/\sigma)^2$  has a noncentral chi-square distribution with two degrees of freedom and noncentrality parameter  $(s/\sigma)^2$ .

### Background

In communications theory, Nakagami distributions, Rician distributions, and Rayleigh distributions are used to model scattered signals that reach a receiver by multiple paths. Depending on the density of the scatter, the signal will display different fading characteristics. Rayleigh and Nakagami distributions are used to model dense scatters, while Rician distributions model fading with a stronger line-of-sight. Nakagami distributions can be reduced to Rayleigh distributions, but give more control over the extent of the fading.

### Parameters

To estimate distribution parameters, use `mle` or the Distribution Fitting app.

# Student's *t* Distribution

## In this section...

“Overview” on page B-133

“Parameters” on page B-133

“Probability Density Function” on page B-133

“Cumulative Distribution Function” on page B-136

“Mean and Variance” on page B-138

“Example” on page B-139

## Overview

The Student's *t* distribution is a family of curves depending on a single parameter  $\nu$  (the degrees of freedom).

## Parameters

The Student's *t* distribution uses the following parameter.

| Parameter              | Description        |
|------------------------|--------------------|
| $\nu = 1, 2, 3, \dots$ | Degrees of freedom |

## Probability Density Function

### Definition

The probability density function (pdf) of the Student's *t* distribution is

$$y = f(x | \nu) = \frac{\Gamma\left(\frac{\nu+1}{2}\right)}{\Gamma\left(\frac{\nu}{2}\right)} \frac{1}{\sqrt{\nu\pi}} \frac{1}{\left(1 + \frac{x^2}{\nu}\right)^{\frac{\nu+1}{2}}}$$

where  $\nu$  is the degrees of freedom and  $\Gamma(\cdot)$  is the Gamma function. The result  $y$  is the probability of observing a particular value of  $x$  from a Student's  $t$  distribution with  $\nu$  degrees of freedom.

### Plot

This plot shows how changing the value of the degrees of freedom parameter  $\nu$  alters the shape of the pdf. Use `tpdf` to compute the pdf for values  $x$  equals 0 through 10, for three different values of  $\nu$ . Then plot all three pdfs on the same figure for a visual comparison.

```
x = [0:.1:10];
y1 = tpdf(x,5); % For nu = 5
y2 = tpdf(x,25); % For nu = 25
y3 = tpdf(x,50); % For nu = 50

figure;
plot(x,y1,'Color','black','LineStyle','-')
hold on
plot(x,y2,'Color','red','LineStyle','-')
plot(x,y3,'Color','blue','LineStyle','-')
legend({'nu = 5','nu = 25','nu = 50'})
hold off
```

### Random Number Generation

Use `trnd` to generate random numbers from the Student's  $t$  distribution. For example, the following generates a random number from a Student's  $t$  distribution with degrees of freedom  $\nu$  equal to 10.

```
nu = 10;
r = trnd(nu)
```

```
r =
```

```
1.0585
```

### Relationship to Other Distributions

As the degrees of freedom  $\nu$  goes to infinity, the  $t$  distribution approaches the standard normal distribution.

If  $x$  is a random sample of size  $n$  from a normal distribution with mean  $\mu$ , then the statistic

$$t = \frac{\bar{x} - \mu}{s / \sqrt{n}}$$

where  $\bar{x}$  is the sample mean and  $s$  is the sample standard deviation, has Student's  $t$  distribution with  $n - 1$  degrees of freedom.

The Cauchy distribution is a Student's  $t$  distribution with degrees of freedom  $\nu$  equal to 1. The Cauchy distribution has an undefined mean and variance.

### Cumulative Distribution Function

#### Definition

The cumulative distribution function (cdf) of Student's  $t$  distribution is

$$p = F(x | \nu) = \int_{-\infty}^x \frac{\Gamma\left(\frac{\nu+1}{2}\right)}{\Gamma\left(\frac{\nu}{2}\right)} \frac{1}{\sqrt{\nu\pi}} \frac{1}{\left(1 + \frac{t^2}{\nu}\right)^{\frac{\nu+1}{2}}} dt$$

where  $\nu$  is the degrees of freedom and  $\Gamma(\cdot)$  is the Gamma function. The result  $p$  is the probability that a single observation from the  $t$  distribution with  $\nu$  degrees of freedom will fall in the interval  $[-\infty, x]$ .

#### Plot

This plot shows how changing the value of the parameter  $\nu$  alters the shape of the cdf. Use `tcdf` to compute the cdf for values  $x$  equals 0 through 10, for three different values of  $\nu$ . Then plot all three cdfs on the same figure for a visual comparison.

```
x = [0:.1:10];
y1 = tcdf(x,5); % For nu = 5
```

```
y2 = tcdf(x,25); % For nu = 25
y3 = tcdf(x,50); % For nu = 50

figure;
plot(x,y1,'Color','black','LineStyle','-')
hold on
plot(x,y2,'Color','red','LineStyle','-')
plot(x,y3,'Color','blue','LineStyle','-')
legend({'nu = 5','nu = 25','nu = 50'})
hold off
```

### Inverse cdf

Use `tinvcdf` to compute the inverse cdf of the Student's  $t$  distribution.

```
p = .95;
nu = 50;
x = tinv(p,nu)
```

```
x =
```

```
1.6759
```

## Mean and Variance

The mean of the Student's *t* distribution is

$$\text{mean} = 0$$

for degrees of freedom  $\nu$  greater than 1. If  $\nu$  equals 1, then the mean is undefined.

The variance of the Student's *t* distribution is

$$\text{var} = \frac{\nu}{\nu - 2}$$

for degrees of freedom  $\nu$  greater than 2. If  $\nu$  is less than or equal to 2, then the variance is undefined.

Use `tstat` to compute the mean and variance of a Student's *t* distribution. For example, the following computes the mean and variance of a Student's *t* distribution with degrees of freedom  $\nu$  equal to 10.

```
nu = 10;
[m,v] = tstat(nu)
```

```
m =
```

```
0
```

```
v =
 1.2500
```

## Example

### Compare Student's $t$ and Normal Distribution pdfs

Compute the pdf for a Student's  $t$  distribution with parameter  $\nu = 5$ , and for a standard normal distribution.

```
x = -5:0.1:5;
y = tpdf(x,5);
z = normpdf(x,0,1);
```

Plot the Student's  $t$  and standard normal pdfs on the same figure. The standard normal pdf (dashed line) has shorter tails than the Student's  $t$  pdf (solid line).

```
figure;
plot(x,y,'-',x,z,'-.-')
```

## t Location-Scale Distribution

### In this section...

“Overview” on page B-141

“Parameters” on page B-141

“Probability Density Function” on page B-141

“Cumulative Distribution Function” on page B-142

“Descriptive Statistics” on page B-142

“Relationship to Other Distributions” on page B-143

### Overview

The  $t$  location-scale distribution is useful for modeling data distributions with heavier tails (more prone to outliers) than the normal distribution. It approaches the normal distribution as  $\nu$  approaches infinity, and smaller values of  $\nu$  yield heavier tails.

### Parameters

The  $t$  location-scale distribution uses the following parameters.

| Parameter | Description        | Support                  |
|-----------|--------------------|--------------------------|
| $\mu$     | Location parameter | $-\infty < \mu < \infty$ |
| $\sigma$  | Scale parameter    | $\sigma > 0$             |
| $\nu$     | Shape parameter    | $\nu > 0$                |

To estimate distribution parameters, use `mle`. Alternatively, fit a `prob.tLocationScaleDistribution` object to data using `fitdist` or the Distribution Fitting app, `disttool`.

### Probability Density Function

The probability density function (pdf) of the  $t$  location-scale distribution is

$$\frac{\Gamma\left(\frac{\nu+1}{2}\right)}{\sigma\sqrt{\nu\pi}\Gamma\left(\frac{\nu}{2}\right)} \left[ \frac{\nu + \left(\frac{x-\mu}{\sigma}\right)^2}{\nu} \right]^{-\left(\frac{\nu+1}{2}\right)}$$

where  $\Gamma(\cdot)$  is the gamma function,  $\mu$  is the location parameter,  $\sigma$  is the scale parameter, and  $\nu$  is the shape parameter.

To compute the probability density function, use `pdf`. Alternatively, you can create a `prob.tLocationScaleDistribution` object using `fitdist` or `makedist`, then use the `pdf` method to work with the object.

## Cumulative Distribution Function

To compute the probability density function, use `cdf`. Alternatively, you can create a `prob.tLocationScaleDistribution` object using `fitdist` or `makedist`, then use the `cdf` method to work with the object.

## Descriptive Statistics

The mean of the  $t$  location-scale distribution is

$$\text{mean} = \mu ,$$

where  $\mu$  is the location parameter. The mean is only defined for shape parameter values  $\nu > 1$ . For other values of  $\nu$ , the mean is undefined.

The variance of the  $t$  location-scale distribution is

$$\text{var} = \sigma^2 \frac{\nu}{\nu - 2} ,$$

where  $\mu$  is the location parameter and  $\nu$  is the shape parameter. The variance is only defined for values of  $\nu > 2$ . For other values of  $\nu$ , the variance is undefined.

To compute the mean and variance, create a `prob.tLocationScaleDistribution` object using `fitdist` or `makedist`. You can also use the Distribution Fitting app, `disttool`.

## Relationship to Other Distributions

If  $x$  has a  $t$  location-scale distribution, with parameters  $\mu$ ,  $\sigma$ , and  $\nu$ , then

$$\frac{x - \mu}{\sigma}$$

has a Student's  $t$  distribution with  $\nu$  degrees of freedom.

# Triangular Distribution

**In this section...**

“Overview” on page B-144

“Parameters” on page B-144

“Probability Density Function” on page B-145

“Cumulative Distribution Function” on page B-146

“Descriptive Statistics” on page B-148

## Overview

The triangular distribution provides a simplistic representation of the probability distribution when limited sample data is available. Its parameters are the minimum, maximum, and mode of the data. Common applications include business and economic simulations, project management planning, natural phenomena modeling, and audio dithering.

## Parameters

The triangular distribution uses the following parameters.

| Parameter | Description   | Constraints       |
|-----------|---------------|-------------------|
| $a$       | Lower limit   | $a \leq b$        |
| $b$       | Peak location | $a \leq b \leq c$ |
| $c$       | Upper limit   | $c \geq b$        |

## Parameter Estimation

Typically, you estimate triangular distribution parameters using subjectively reasonable values based on the sample data. You can estimate the lower and upper limit parameters  $a$  and  $c$  using the minimum and maximum values of the sample data, respectively. You can estimate the peak location parameter  $b$  using the sample mean, median, mode, or any other subjectively reasonable estimate of the population mode.

## Probability Density Function

The probability density function (pdf) of the triangular distribution is

$$f(x|a,b,c) = \begin{cases} \frac{2(x-a)}{(c-a)(b-a)} & ; a \leq x \leq b \\ \frac{2(c-x)}{(c-a)(c-b)} & ; b < x \leq c \\ 0 & ; x < a, x > c \end{cases} .$$

This plot shows how changing the value of the parameters  $a$ ,  $b$ , and  $c$  alters the shape of the pdf.

```
% Create four distribution objects with different parameters
pd1 = makedist('Triangular');
pd2 = makedist('Triangular','a',-1,'b',0,'c',1);
pd3 = makedist('Triangular','a',-.5,'b',0,'c',1);
pd4 = makedist('Triangular','a',0,'b',0,'c',1);

% Compute the pdfs
x = -2:.01:2;
pdf1 = pdf(pd1,x);
pdf2 = pdf(pd2,x);
pdf3 = pdf(pd3,x);
pdf4 = pdf(pd4,x);

% Plot the pdfs
figure;
plot(x,pdf1,'r','LineWidth',2)
hold on;
plot(x,pdf2,'k','LineWidth',2);
plot(x,pdf3,'b-.','LineWidth',2);
plot(x,pdf4,'g--','LineWidth',2);
legend({'a = 0, b = 0.5, c = 1','a = -1, b = 0, c = 1',...
 'a = -0.5, b = 0, c = 1','a = 0, b = 0, c = 1'},'Location','NW');
hold off;
```

As the distance between  $a$  and  $c$  increases, the density at any particular value within the distribution boundaries decreases. Because the density function integrates to 1, the height of the pdf plot decreases as its width increases. The location of the peak parameter  $b$  determines whether the pdf skews right or left, or if it is symmetrical.

## Cumulative Distribution Function

The cumulative distribution function (cdf) of the triangular distribution is

$$F(x|a,b,c) = \begin{cases} 0 & , x < a \\ \frac{(x-a)^2}{(c-a)(b-a)} & , a \leq x \leq b \\ 1 - \frac{(c-x)^2}{(c-a)(c-b)} & , b < x \leq c \\ 1 & , x > c \end{cases} .$$

This plot shows how changing the value of the parameters  $a$ ,  $b$ , and  $c$  alters the shape of the cdf.

```
% Create four distribution objects with different parameters
pd1 = makedist('Triangular');
pd2 = makedist('Triangular','a',-1,'b',0,'c',1);
pd3 = makedist('Triangular','a',-.5,'b',0,'c',1);
pd4 = makedist('Triangular','a',0,'b',0,'c',1);

% Compute the cdfs
x = -1.2:.01:1.2;
cdf1 = cdf(pd1,x);
cdf2 = cdf(pd2,x);
cdf3 = cdf(pd3,x);
cdf4 = cdf(pd4,x);

% Plot the cdfs
figure;
plot(x,cdf1,'r','LineWidth',2)
xlim([-1.2 1.2]);
ylim([0 1.1]);hold on;
plot(x,cdf2,'k:','LineWidth',2);
plot(x,cdf3,'b-.','LineWidth',2);
plot(x,cdf4,'g-','LineWidth',2);
legend({'a = 0, b = 0.5, c = 1','a = -1, b = 0, c = 1',...
'a = -0.5, b = 0, c = 1','a = 0, b = 0, c = 1'},'Location','NW');
hold off;
```

## Descriptive Statistics

The mean and variance of the triangular distribution are related to the parameters  $a$ ,  $b$ , and  $c$ .

The mean is

$$\text{mean} = \left( \frac{a + b + c}{3} \right).$$

The variance is

$$\text{var} = \left( \frac{a^2 + b^2 + c^2 - ab - ac - bc}{18} \right).$$

## Uniform Distribution (Continuous)

### In this section...

“Overview” on page B-150

“Parameters” on page B-150

“Probability Density Function” on page B-150

“Cumulative Distribution Function” on page B-152

“Descriptive Statistics” on page B-154

“Relationship to Other Distributions” on page B-155

### Overview

The uniform distribution (also called the rectangular distribution) is notable because it has a constant probability distribution function (pdf) between its two bounding parameters. It is appropriate for representing the distribution of round-off errors in values tabulated to a particular number of decimal places, and is used in random number generating techniques such as the inversion method.

### Parameters

The uniform distribution uses the following parameters.

| Parameter | Description | Constraints                                 |
|-----------|-------------|---------------------------------------------|
| lower     | Lower limit | $-\infty < \textit{lower} < \textit{upper}$ |
| upper     | Upper limit | $\textit{lower} < \textit{upper} < \infty$  |

### Parameter Estimation

The maximum likelihood estimator (MLE) for *lower* is the sample minimum. The MLE for *upper* is the sample maximum.

### Probability Density Function

The probability density function (pdf) of the continuous uniform distribution is

$$f(x | lower, upper) = \begin{cases} \left( \frac{1}{upper - lower} \right) & ; \text{ lower} \leq x \leq \text{upper} \\ 0 & ; \text{ otherwise} \end{cases} .$$

The pdf is constant between *lower* and *upper*.

This plot illustrates how changing the value of the parameters *lower* and *upper* affects the shape of the pdf.

```
% Create three distribution objects with different parameters
pd1 = makedist('Uniform');
pd2 = makedist('Uniform','lower',-2,'upper',2);
pd3 = makedist('Uniform','lower',-2,'upper',1);

% Compute the pdfs
x = -3:.01:3;
pdf1 = pdf(pd1,x);
pdf2 = pdf(pd2,x);
pdf3 = pdf(pd3,x);

% Plot the pdfs
figure;
stairs(x,pdf1,'r','LineWidth',2);
hold on;
stairs(x,pdf2,'k:','LineWidth',2);
stairs(x,pdf3,'b-.','LineWidth',2);
ylim([0 1.1]);
legend({'lower = 0, upper = 1','lower = -2, upper = 2',...
'lower = -2, upper = 1'},'Location','NW');
hold off;
```

As the distance between *lower* and *upper* increases, the density at any particular value within the distribution boundaries decreases. Because the density function integrates to 1, the height of the pdf plot decreases as its width increases.

### Cumulative Distribution Function

The cumulative distribution function (cdf) of the continuous uniform distribution is

$$F(x | lower, upper) = \begin{cases} 0 & ; \quad x < lower \\ \frac{x - lower}{upper - lower} & ; \quad lower \leq x < upper . \\ 1 & ; \quad x \geq upper \end{cases}$$

This plot illustrates how changing the value of the parameters *lower* and *upper* affects the shape of the cdf.

```
% Create three distribution objects with different parameters
pd1 = makedist('Uniform');
pd2 = makedist('Uniform','lower',-2,'upper',2);
pd3 = makedist('Uniform','lower',-2,'upper',1);

% Compute the cdfs
x = -3:.01:3;
cdf1 = cdf(pd1,x);
cdf2 = cdf(pd2,x);
cdf3 = cdf(pd3,x);

% Plot the cdfs
figure;
plot(x,cdf1,'r','LineWidth',2);
hold on;
plot(x,cdf2,'k','LineWidth',2);
plot(x,cdf3,'b-.','LineWidth',2);
ylim([0 1.1]);
legend({'lower = 0, upper = 1','lower = -2, upper = 2',...
 'lower = -2, upper = 1'},'Location','NW');
hold off;
```

## Descriptive Statistics

The mean and variance of the continuous uniform distribution are related to the parameters *lower* and *upper*.

The mean is

$$\text{mean} = \frac{1}{2}(\text{lower} + \text{upper}) .$$

The variance is

$$\text{var} = \frac{1}{12}(\text{upper} - \text{lower})^2 .$$

## Relationship to Other Distributions

The standard uniform distribution ( $\text{lower} = 0$  and  $\text{upper} = 1$ ) is a special case of the beta distribution obtained by setting the beta distribution parameters  $\mathbf{a} = 1$  and  $\mathbf{b} = 1$ .

The inversion method uses the continuous standard uniform distribution to generate random numbers for any other continuous distribution. The inversion method relies on the principle that continuous cumulative distribution functions (cdfs) range uniformly over the open interval (0,1). If  $u$  is a uniform random number on (0,1), then  $x = F^{-1}(u)$  generates a random number  $x$  from any continuous distribution with the specified cdf  $F$ .

## Uniform Distribution (Discrete)

| In this section...         |
|----------------------------|
| “Definition” on page B-156 |
| “Background” on page B-156 |
| “Examples” on page B-156   |

### Definition

The discrete uniform pdf is

$$y = f(x | N) = \frac{1}{N} I_{(1, \dots, N)}(x)$$

### Background

The discrete uniform distribution is a simple distribution that puts equal weight on the integers from one to  $N$ .

### Examples

#### Plot a Discrete Uniform Distribution cdf

As for all discrete distributions, the cdf is a step function. The plot shows the discrete uniform cdf for  $N = 10$ .

```
x = 0:10;
y = unidcdf(x,10);
figure;
stairs(x,y)
h = gca;
h.XLim = [0 11];
```

### Generate Discrete Uniform Random Numbers

Pick a random sample of 10 from a list of 553 items.

```
rng default; % for reproducibility
numbers = unidrnd(553,1,10)
```

numbers =

```
451 501 71 506 350 54 155 303 530 534
```

## Weibull Distribution

| In this section...         |
|----------------------------|
| “Definition” on page B-158 |
| “Background” on page B-158 |
| “Parameters” on page B-159 |
| “Example” on page B-159    |

### Definition

The Weibull pdf is positive only for positive values of  $x$ , and is zero otherwise. For strictly positive values of the shape parameter  $b$  and scale parameter  $a$ , the density is

$$f(x | a, b) = \frac{b}{a} \left( \frac{x}{a} \right)^{b-1} e^{-(x/a)^b}.$$

### Background

Waloddi Weibull offered the distribution that bears his name as an appropriate analytical tool for modeling the breaking strength of materials. Current usage also includes reliability and lifetime modeling. The Weibull distribution is more flexible than the exponential for these purposes.

To see why, consider the hazard rate function (instantaneous failure rate). If  $f(t)$  and  $F(t)$  are the pdf and cdf of a distribution, then the hazard rate is

$$h(t) = \frac{f(t)}{1 - F(t)}$$

Substituting the pdf and cdf of the exponential distribution for  $f(t)$  and  $F(t)$  above yields a constant. The example below shows that the hazard rate for the Weibull distribution can vary.

## Parameters

Suppose you want to model the tensile strength of a thin filament using the Weibull distribution. The function `wblfit` gives maximum likelihood estimates and confidence intervals for the Weibull parameters.

```
rng('default'); % For reproducibility
strength = wblrnd(0.5,2,100,1); % Simulated strengths
[p,ci] = wblfit(strength)
```

p =

```
 0.4768 1.9622
```

ci =

```
 0.4291 1.6821
 0.5298 2.2890
```

The default 95% confidence interval for each parameter contains the true value.

## Example

The exponential distribution has a constant hazard function, which is not generally the case for the Weibull distribution. The plot shows the hazard function for exponential (dashed line) and Weibull (solid line) distributions having the same mean life. The Weibull hazard rate here increases with age (a reasonable assumption).

```
t = 0:0.1:4.5;
h1 = exppdf(t,0.6267) ./ (1-expcdf(t,0.6267));
h2 = wblpdf(t,2,2) ./ (1-wblcdf(t,2,2));
plot(t,h1,'--',t,h2,'-')
```

## Wishart Distribution

### In this section...

“Definition” on page B-161

“Background” on page B-161

“Example” on page B-162

“See Also” on page B-162

### Definition

The probability density function of the  $d$ -dimensional Wishart distribution is given by

$$y = f(X, \Sigma, \nu) = \frac{|X|^{(\nu-d-1)/2} e^{\left(-\frac{1}{2}\text{trace}(\Sigma^{-1}X)\right)}}{2^{(\nu d)/2} \pi^{(d(d-1))/4} |\Sigma|^{\nu/2} \Gamma(\nu/2) \dots \Gamma(\nu-(d-1))/2}$$

where  $X$  and  $\Sigma$  are  $d$ -by- $d$  symmetric positive definite matrices, and  $\nu$  is a scalar greater than  $d - 1$ . While it is possible to define the Wishart for singular  $\Sigma$ , the density cannot be written as above.

Only random matrix generation is supported for the Wishart distribution, including both singular and nonsingular  $\Sigma$ .

### Background

The Wishart distribution is a generalization of the univariate chi-square distribution to two or more variables. It is a distribution for symmetric positive semidefinite matrices, typically covariance matrices, the diagonal elements of which are each chi-square random variables. In the same way as the chi-square distribution can be constructed by summing the squares of independent, identically distributed, zero-mean univariate normal random variables, the Wishart distribution can be constructed by summing the inner products of independent, identically distributed, zero-mean multivariate normal random vectors.

The Wishart distribution is parameterized with a symmetric, positive semidefinite matrix,  $\Sigma$ , and a positive scalar degrees of freedom parameter,  $\nu$ .  $\nu$  is analogous to the

degrees of freedom parameter of a univariate chi-square distribution, and  $\Sigma_v$  is the mean of the distribution.

The Wishart distribution is often used as a model for the distribution of the sample covariance matrix for multivariate normal random data, after scaling by the sample size.

## Example

If  $x$  is a bivariate normal random vector with mean zero and covariance matrix

$$\Sigma = \begin{pmatrix} 1 & .5 \\ .5 & 2 \end{pmatrix}$$

then you can use the Wishart distribution to generate a sample covariance matrix without explicitly generating  $x$  itself. Notice how the sampling variability is quite large when the degrees of freedom is small.

```
Sigma = [1 .5; .5 2];
df = 10; S1 = wishrnd(Sigma,df)/df
```

```
S1 =
 1.7959 0.64107
 0.64107 1.5496
```

```
df = 1000; S2 = wishrnd(Sigma,df)/df
```

```
S2 =
 0.9842 0.50158
 0.50158 2.1682
```
